[Traduit par la revue]

Introduction

The macrocyclic polyether 18-crown-6 readily forms complexes with hydrates of strong acids (pK_a of the acid $< pK_a$ of H_3O^+ at −1.7), which exist as hydronium salts. In 1972, Izatt *et al.* (1) reported the formation of 1:1 complexes between *cis-syn-cis*-dicyclohexano-18-crown-6 and $H_3O^+ClO_4^-$ or $H_3O^+PF_6^-$. These stable complexes were characterized by elemental analysis and infrared spectroscopy. In recent years, it has been shown that 18-crown-6 and derivatives are good complexing agents for the hydronium ion, and complexes have been obtained with several strong acids (2–9). X-ray diffraction studies have shown that the H_3O^+ ion in the adduct is anchored at the center of the macrocyclic cavity by three OH---O hydrogen bonds (5–9). One aim of these X-ray studies was the determination of the geometry (planar or pyramidal) of the hydronium ion, i.e., the position of the central oxygen relative to the plane of the three attached hydrogen atoms. Several structures lend strong support for the pyramidal H_3O^+ but two have been interpreted in terms of planar H_3O^+. Recently, Reinhoudt and co-workers (9) reported that 2-sulfo-1,3-xylyl crown ethers are good receptor molecules not only for H_3O^+ but also for higher hydrated species, $H_3O^+(H_2O)_n$ where n = 1, 2.

In the present study we report the preparation and characterization of new complexes of 18-crown-6 with hydronium ions derived from transition metal (Mn and Zn) chlorides and hydrochloric acid.

Experimental

Preparation of the complexes (general procedure)

The transition metal chloride (2 mmol) is dissolved in tetrahydrofuran (25 mL) and concentrated hydrochloric acid (2 mL). This solution is added to a solution of 18-crown-6 (2 mmol) in tetrahydrofuran (15 mL). The complex crystallizes immediately at room temperature. The solid complex is filtered and dried under vacuum. The complex is recrystallized in tetrahydrofuran and dried under vacuum until a constant melting point is obtained. Physical data pertaining to the individual complexes are given below.

*$[(H_3O^+ \cdot 18\text{-crown-}6)_2(ZnCl_4^{2-})]$ **1***

Yield: 90%; mp 142–143°C (colorless). IR (Nujol): 2950, 2180, 1685, 1350, 1285, 1245, 1140, 1090, 960, 935, 830, 805 cm^{-1}. ^1H NMR (CD_2Cl_2) δ: 3.74 (24H, s, crown), 10.57 (3H, br s, H_3O^+). ^{13}C NMR (CD_2Cl_2) δ: 70.34. Anal. calcd. for $C_{24}H_{54}O_{14}ZnCl_4$: C 37.25, H 7.03, Zn 8.45, Cl 18.33; found: C 37.63, H 7.22, Zn 8.32, Cl 18.41.

*$[(H_3O^+ \cdot 18\text{-crown-}6)_2(MnCl_4^{2-})]$ **2***

Yield: 84%; mp 135–137°C (colorless). IR (Nujol): 2950, 2180, 1670, 1350, 1290, 1245, 1140, 1090, 960, 935, 830, 805 cm^{-1}. ^1H NMR: useless because of extreme line broadening. ^{13}C NMR

(CD_2Cl_2) δ: 72.07. Anal. calcd. for $C_{24}H_{54}O_{14}MnCl_4$: C 37.76, H 7.13, Mn 7.20, Cl 18.58; found: C 37.44, H 7.15, Mn 6.76, Cl 18.80.

The NMR spectra were taken on a Varian XL-200 multinuclear spectrometer. The infrared spectra, obtained from Nujol mulls contained between Irtran-2 (ZnS) windows, were recorded on a Beckman-4250 spectrometer. The microanalyses were performed by Dr. C. Daessle, Organic Microanalysis, Montreal, or by ourselves on a Carlo Erba Strumentazione-1106 elemental analyser.

Crystallographic characterization of the $[(H_3O^+ \cdot 18\text{-crown-}6)_2(MCl_4^{2-})]$ complexes

Single crystals suitable for X-ray diffraction analysis were obtained after a slow recrystallization of the complex in tetrahydrofuran. The unit cell dimensions were computed from the angular settings of 25 well-centered reflections in the range $40 \leq 2\theta \leq 50°$ (Zn) or $18 \leq 2\theta \leq 22°$ (Mn). The final parameters and other crystal data of interest are presented in Table 1. The data collection for the Zn complex was done over 4 octants, by the ω scan technique, with graphite monochromatized copper radiation. The intensities of six standard reflections were monitored every hour. The largest fluctuation of the intensities of the standard reflections was 3.5%, revealing a slight decomposition of the crystal under radiation. The averaging (R averaging = 0.08) of the 7182 measured reflections to the $2/m$ Laue symmetry yielded 3587 reflections of which 1817 were considered observed ($I/\sigma(I) \geq 3.0$). In the data reduction,[2] all the reflections were placed on a common scale, thus taking care of the small decay of the crystal. The final σ was computed as $\sigma = [\sigma_1^2 + \sigma_2^2]^{1/2}$. In this relation σ_1 and σ_2 are the individual σ's associated with the intensities of the reflections being averaged. Lorentz, polarization, and absorption corrections (10 × 10 × 10 grid, extreme values of the transmission factor: 0.23–0.52) were applied to the data.

In the case of the Mn complex, the intensities of only two octants were measured by the ω scan technique using graphite monochromatized molybdenum radiation. The intensities of seven reference reflections were evaluated every hour. They did not fluctuate by more than 4.9% over the duration of the data collection. Of the 3314 measured reflections only 728 were retained for the structure determination ($I/\sigma(I) \geq 3.0$). The reflections were placed on a common scale to compensate for the decomposition of the crystal. Lorentz and polarization corrections were applied, but due to the small value of the absorption coefficient for the Mo radiation the data were not corrected for absorption. The small proportion of observed reflections is attributed to the disorder present in the structure.

Both structures were solved using the Patterson method combined with difference Fourier syntheses (SHELX). The (MCl_4^{2-}) anions are located on a crystallographic twofold axis of rotation. The crown ether molecule and H_3O^+ are disordered over two sites. Initially the refinement of the crown ether was conducted with a constrained model. In this model, the C—C and C—O distances were allowed to vary within ±0.05 Å from the corresponding quantities as found in other 18C6 macrocycles (8, 19, 20). This was relaxed in the last refinement cycles. The occupancy factor, which was also refined, converged to a 50/50 occupation for the Zn complex. The refinements, based on F's, minimized the quantity $\Sigma w \Delta F^2$ using the block-diagonal approximation. All non-hydrogen atoms were refined anisotropically. The H-atom coordinates were calculated at idealized positions, (d_{C-H} = 0.95 Å, B_{iso} = 15.0 Å^2 (crown), B_{iso} = 12.0 Å^2 (H_3O^+)), riding on the atom to which they are bonded. The H atoms of the hydronium ion were placed at 0.85 Å from OW along the OW...O line and were not refined. The procedure was very much the same in the case of the Mn complex. However, since the number of observed reflections was small the refinement was always constrained. The refinement converged to a situation where the crown ether is also disordered over two orientations but with a 60/40 occupancy. The refinements were concluded when the indicators given in Table 2 reached their minimum values.[3] In both cases, the weights used in the least-squares refinement were derived from the counting statistics. The scattering curves for the non-hydrogen atoms were taken from ref. 13 and those for the H-atoms from ref. 14.

Results and discussion

Hydronium ion – crown ether complexes are prepared in 80–90% yield by mixing the transition metal chloride, aqueous hydrochloric acid, and 18-crown-6 in tetrahydrofuran. The

[2]The programs used here are modifications of NRC-2, data reduction; NRC-3, absorption correction; NRC-10, bond distances and angles; FORDAP, Fourier and Patterson maps (A. Zalkin); SHELX, program for structure determination; and ORTEP, stereodrawings (10–12).

[3]Tables of the bond distances, angles, and torsion angles of the 18-crown-6 molecules, of the anisotropic thermal parameters, the calculated H-atom coordinates, and the structure factor amplitudes may be purchased from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

Tables of bond distances and angles and of the calculated H-atom coordinates have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, Lensfield Road, Cambridge CBE 1EW, U.K.

complexes are stable solids with sharp melting points. The stoichiometry of the compounds was determined by elemental analysis (hydrogen, carbon, chlorine) and by atomic absorption spectroscopy (zinc, manganese). The analyses are in agreement with the stoichiometry defined by eqs. [1] and with that observed in the X-ray determinations.

[1] $2(18\text{–crown–}6) + 2H_2O + 2HCl + MCl_2 \rightarrow$

M = Zn, **1**
M = Mn, **2**
$(18\text{–crown–}6 \cdot H_3O^+)_2 \cdot MCl_4^{2-}$

Spectroscopy

The infrared spectra are clearly indicative of the presence of the H_3O^+ ion in both complexes. The bands are readily assigned by comparison to literature (15, 16) values for hydronium salts: 2780–3250 cm^{-1} (ν_1, symmetric stretching), 2500–3100 cm^{-1} (ν_3 asymmetric stretching), 1480–1705 cm^{-1} (ν_4, asymmetric bending), and 1050–1180 cm^{-1} (ν_2, symmetric bending). The stretching modes of H_3O^+ (ν_1, ν_3) are responsible for the strong and broad band at ~2950 cm^{-1}, which overlaps with the sharper maximum arising from the C–H stretching of the crown in the 2925 cm^{-1} region. The exact position of the ν_2 mode is difficult to determine as it occurs in a region of strong absorption by the C—O stretching of the crown ether. However, the first harmonic of ν_2 is always present at ~2190 cm^{-1}. The asymmetric bending mode (ν_4) gives a characteristic band at ~1650 cm^{-1}. Infrared spectra also indicate some departure from the D_{3d} symmetry for the crown. IR spectra of symmetric complexes such as $M^+ \cdot 18\text{-crown-}6 \cdot Br^-$ contain two singlets in the 800–1000 cm^{-1} region: CH_2 rocking at 960 cm^{-1} and C–C stretching at 835 cm^{-1} (17, 18). The crown is distorted to a lower symmetry and two doublets are observed at ~805,830 and ~930,960 cm^{-1} in the spectra of hydronium complexes **1** and **2**. This distortion of the ring is confirmed by the X-ray diffraction study.

The ^{1}H NMR signal of the crown ether protons in complex **1** is shifted downfield (3.74 ppm) compared to free 18-crown-6 (3.60 ppm) in the same solvent (CD_2Cl_2) and a new signal characteristic of the hydronium ion protons appears in the 10–11 ppm range. The chemical shift for the hydronium ion protons is concentration-dependent. The ^{1}H NMR spectrum of complex **2** shows extreme line broadening and chemical shifts cannot be evaluated. In ^{13}C NMR, the chemical shift of the crown carbons in the zinc and manganese adducts (70.34 and 72.07 ppm) are close to the shift of the free crown carbons in the same solvent (70.67 ppm).

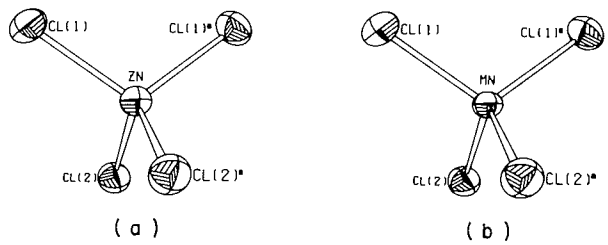

FIG. 1. Views and atomic numbering of the individual anions. (a) $ZnCl_4^{2-}$; (b) $MnCl_4^{2-}$.

Crystal structure

The unit cell dimensions, the space group (Table 1), and the refinement confirm that the two compounds are isostructural. The atomic numbering adopted for the anions and for the crown ether are shown in Figs. 1 and 2 respectively. Those figures also show the structural units with their thermal ellipsoids at the end of the refinement. The bond distances and angles calculated from the final atomic coordinates (Tables 3 and 4) are compared in Tables 5 and 6 for the anions and the 18-crown-6 molecules respectively. The structural units (18-crown-6, H_3O^+, MCl_4^{2-}) that are the constituents of the complexes are shown in their relative environment by the stereopair of Fig. 4.

The 18-crown-6 macrocycle

In both complexes the crown ether macrocycles are disordered over two orientations. It was thought that the space group might be $P2/c$ rather than $C2/c$. Then there would be two independent molecules per asymmetric unit rather than two molecules related by centering. This possibility has been

explored in the case of the Zn complex. However, upon refinement and Fourier difference syntheses, it was found that the disorder remained. Thus the space group is $C2/c$ and there are indeed two disordered molecules in the asymmetric unit. The only difference between the Zn and Mn complexes is that the two molecules are in equal proportion for the former and 60/40 for the latter.

The disorder of the crown ether molecules, which is responsible for the small number of observed reflections, is detrimental to the obtention of accurate bond distances and angles in this part of the structure. With this in mind, the bond distances and angles of the two molecules in the two complexes are within the ranges reported for the 18-crown-6 macrocycles (8, 19, 20). There are, however, some large fluctuations in the bond distances, bond angles, and in the torsion angles. For the Zn complex the conformation of molecule A is $(ttg)_6$, the *t* torsion angle (*t* = *trans*) has values in the range 170–179° while the values of the *g* torsion angle (*g* = *gauche*) vary between 14 and 44°. In the second molecule B of the Zn complex, the conformation is more regular, $(ttg)_5ttc$. Here *t* is in the range 170–180°, while *g* varies from 51 to 72° and *c* has the value of 12°.

In the case of the Mn complex, for which fewer reflections were observed, one notes the same disparities. In molecule A the fluctuations of the non-*trans* torsion angles are in the range 9–69°, while molecule B has the nearly perfect $(ttg)_6$ conformation. It is not possible to establish with certainty whether these differences are real or are effects associated with the disorder. This latter possibility is the most likely.

The hydronium cation

Each H_3O^+ ion forms three hydrogen bonds to the oxygen atoms of the 18-crown-6 molecule (see Figs. 2 and 3). The

TABLE 5. Comparison of the bond distances (Å) and angles (deg) in the $ZnCl_4^{2-}$ and $MnCl_4^{2-}$ anions

Bond	Distances (esd's), Å	Bonds	Angles (esd's), deg
$ZnCl_4^{2-}$			
Zn—Cl(1)	2.264(2)	Cl(1)—Zn—Cl(2)	107.2(1)
Zn—Cl(2)	2.275(2)	Cl(1)—Zn—Cl(1)*	109.1(1)
		Cl(1)—Zn—Cl(2)*	111.7(1)
		Cl(2)—Zn—Cl(2)*	110.0(1)
$MnCl_4^{2-}$			
Mn—Cl(1)	2.353(5)	Cl(1)—Mn—Cl(2)	106.7(2)
Mn—Cl(2)	2.370(5)	Cl(1)—Mn—Cl(1)*	109.4(2)
		Cl(1)—Mn—Cl(2)*	112.0(2)
		Cl(2)—Mn—Cl(2)*	110.0(2)

*$-x, y, \frac{1}{2} - z$.

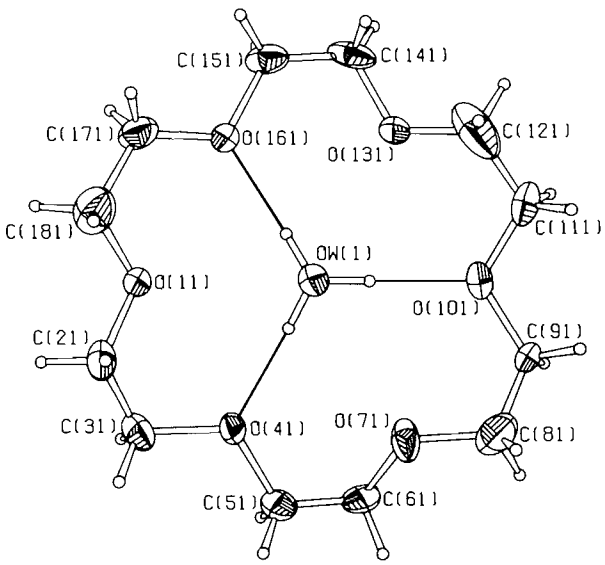

FIG. 2. Numbering scheme adopted for the 18-crown-6·H_3O^+ cation.

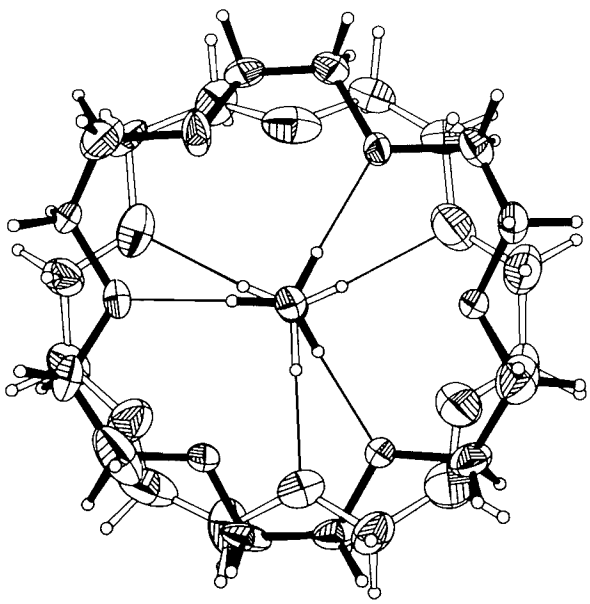

FIG. 3. View of the two overimposed orientations of the 18-crown-6·H_3O^+ cations found in the $ZnCl_4^{2-}$ complex. Darkened bonds are used to distinguish one of the two disordered cations. The disorder in the $MnCl_4^{2-}$ complex is similar.

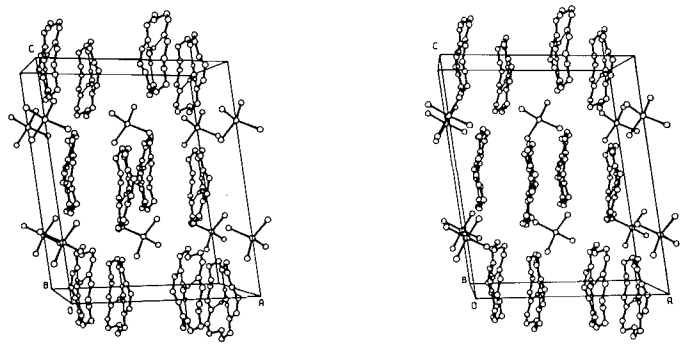

FIG. 4. Stereoview of the unit cell content of the (18-crown-6·H_3O)$_2$(MCl_4) complex. For clarity, only one orientation of the crown ether is shown and its hydrogen atoms have been omitted.

O(hydronium)...O(crown) distances are in the range 2.603(9)–2.710(11) Å (Zn complex) and 2.66(3)–2.99(5) Å for the Mn complex. The H_3O^+ ion in the Zn complex is more strongly bonded to the macrocycle than in the Mn analog. Although the H atoms were not located on Fourier difference syntheses, the position of the OW atoms above the plane of the three oxygen atoms of the 18-crown-6 molecule is clearly indicative of a pyramidal geometry. Thus, in the Zn complex, the water molecules are at 0.333(7) and −0.194(7) Å from the plane formed by the three oxygen atoms of the corresponding disordered crown ether molecules. These distances are −0.45(2) and 0.88(2) Å respectively in the Mn complex.

The MCl_4^{2-} anion, M = Zn, Mn

As indicated earlier, the MCl_4^{2-} anions occupy a crystallographic twofold axis of symmetry. Each anion is tetrahedral. The Cl—M—Cl angles vary between 107.2(1) and 111.7(1)° and between 106.7(2) and 112.0(2)° for the Zn and Mn complexes respectively. The M—Cl bond distances average 2.270 and 2.361 Å for the Zn and Mn complexes respectively. Such distances are in good agreement with values reported for other Zn and Mn complexes. For example, in pyridinium tetrachloromanganate(II), the four Mn—Cl distances are in the range 2.350(4)–2.376(4) Å (21) while the four Zn—Cl distances vary between 2.263(2) and 2.273(2) in monomethylammonium tetrachlorozincate(II) (22) and between 2.241(2) and 2.272(2) in 1,3-propanediammonium tetrachlorozincate(II) (23).

Packing of the structural units

There are only two structurally distinct units, the MCl_4^{2-}

anion and the $H_3O^+\cdot$18-crown-6 cation, the hydronium anion and the crown ether being hydrogen-bonded together. As may be clearly appreciated in Fig. 4, the structure consists of alternating layers of MCl_4^{2-} anions and $H_3O^+\cdot$8-crown-6 cations. The MCl_4^{2-} units are in planes parallel to *ab*, at $c/4$ and $3c/4$. The mean plane of the 18-crown-6 macrocycle is parallel to the *bc* plane of the unit cell. These molecules form layers, also parallel to *ab*, at $c = 0, 1/2, 1$, etc. Thus the macrocycles are perpendicular to the layer. There are no short contacts between atoms in consecutive layers. The packing of the structural units in the Zn and Mn complexes is comparable to that observed in $(18\text{-crown-6}\cdot H_3O^+)_2(Pd_2Cl_6^{2-})$ (8).

A spiro-annulation approach to the zizaane sesquiterpenes

D. Jean Burnell[1] and Yong-Jin Wu

Department of Chemistry, Memorial University of Newfoundland, St. John's, Nfld., Canada A1B 3X7

Received December 20, 1989

D. Jean Burnell and Yong-Jin Wu. Can. J. Chem. **68**, 804 (1990).

4,4-Dimethyl-2-oxabicyclo[3.2.1]octan-3-one (**10**), obtained in two steps from norcamphor, was converted to 3-(1,1-dimethyl-2-oxopropyl)cyclopentanone (**14**), then selectively ketalized. The ketal function underwent Lewis acid catalysed spiro-annulation with 1,2-bis)trimethylsiloxy)cyclobutene (**4**) yielding 7-(1,1-dimethyl-2-oxopropyl)spiro[4.4]nonane-1,4-dione (**21**), and intramolecular titanium-induced ketone–ketone coupling and oxidation afforded (±)-isokhusimone (**3**) in an overall yield of 35% from norcamphor. In an alternative approach, the ethylene ketal of methyl 2-methyl-2-(3-oxocyclopentyl)propanoate (**27**) was prepared from **10**. Spiro-annulation proceeded in good yield, but subsequent titanium-induced ketone–ester coupling failed to provide the desired tricyclic product, 7,7-dimethyltricyclo[6.2.1.0^{1,5}]undecane-2,6-dione (**30**).

Key words: annulation, carbonyl coupling, isokhusimone, terpene.

D. Jean Burnell et Yong-Jin Wu. Can. J. Chem. **68**, 804 (1990).

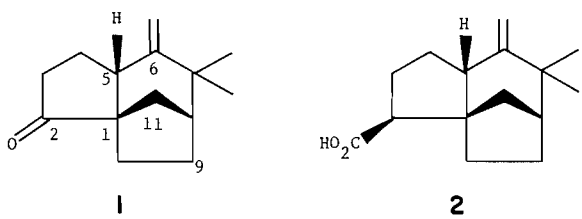
Le 4,4-diméthyl-2-oxabicyclo[3.2.1]octane-3-one (**10**), que l'on obtient en deux étapes à partir du norcamphre, peut être transformée en 3-(1,1-diméthyl-2-oxopropyl)cyclopentanone (**14**) dont on forme ensuite le cétal. Avec le 1,2-bis(triméthylsiloxy)cyclobutène (**4**), cette fonction subit une spiro-annelation, catalysée par les acides de Lewis, qui conduit à la 7-(1,1-diméthyl-2-oxopropyl)spiro[4.4]nonane-1,4-dione (**21**) et éventuellement, par un couplage cétone–cétone intramoléculaire induit par le titane et une oxydation, à la (±)-isokhusimone (**3**) avec un rendement global de 35% à partir du norcamphre. Dans une approche alternative, on a préparé le cétal éthylénique du 2-méthyl-2-(3-oxocyclopentyl)propanoate de méthyle (**27**) à partir du composé **10**. Sa spiro-annellation s'est produite avec un bon rendement; toutefois, le couplage subséquent cétone–ester, induit par le titane, n'a pas fourni le produit tricyclique désiré, soit la 7,7-diméthyltricyclo[6.2.1.0^{1,5}]undécane-2,6-dione (**30**).

Mots clés : annelation, couplage carbonyl, khusimone, terpène.

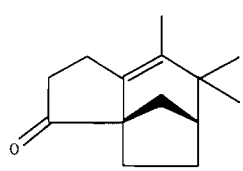
[Traduit par la revue]

Introduction

Vetiver oil is a rich source of sesquiterpenoids including many with a tricyclo[6.2.1.0^{1,5}]undecane ring system, characteristic of a group of sesquiterpenes termed the zizaanes. These include the fragrant norsesquiterpenoid (−)-khusimone (**1**) (1). Khusimone is a natural insect repellent (2), which, nevertheless, has been used as a flavoring material (3). Maurer produced **1** by degradation of natural zizanoic acid (**2**), and he showed that **1** isomerizes to isokhusimone (**3**) on treatment with warm



1 **2**



3

formic acid (3). The first total synthesis of (racemic) khusimone (**1**) was by Büchi *et al.* (4). Their route proceeded via **3** by rearrangement of the minor product of an intramolecular Diels–Alder reaction. Other syntheses of racemic and of (−)-khusimone have involved as key steps a photochemical [2 + 2] cycloaddition (5), the intramolecular magnesium–ene reaction (6), and an intermolecular Diels–Alder reaction (7). Furthermore, Liu and Chan (5) have converted **1** into zizanoic acid (**2**) and its C-2 epimer.[2] In this paper we describe an efficient, alternative strategy for the synthesis of isokhusimone (**3**) and hence, in a formal sense, of the zizaane sesquiterpenes.[3]

Results and discussion

Retrosynthetic scission of the six-membered ring of the zizaane skeleton leads to a system with spiro-linked five-membered rings, of which one could be a symmetrical, 1,3-cyclopentanedione moiety. *C*-Alkylation of cyclic β-diketones can be a poor reaction (10), but Kuwajima and co-workers (11) demonstrated that the Lewis acid catalysed reaction of a dimethyl, a diethyl, or a dibenzyl ketal (but not a ketone) with 1,2-bis(tri-

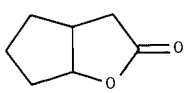
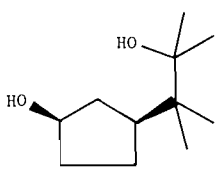
methylsiloxy)cyclobutene (**4**) followed by rearrangement of the resulting cyclobutanone **5** with trifluoroacetic acid (TFA) can give a 2,2-disubstituted 1,3-cyclopentanedione **6** in a reasonable yield.[4] Thus, our plan was to obtain an appropriately functionalized cyclopentanone, to ketalize it, to spiro-annulate using **4**, and lastly to cyclize the six-membered ring.

The first cyclopentanone moiety was derived from norcamphor. Baeyer–Villiger oxidation with *m*-chloroperoxybenzoic acid at room temperature gave lactone **7** in a yield of 86% following vacuum distillation. An older preparation (using peroxyacetic acid) advocated strongly acidic conditions for the formation of **7** (14). We found that a strongly acidic medium gave mainly **8**. Methylation of the lithium enolate of **7** with one equivalent of iodomethane provided **9**, and a second methylation to give **10** followed cleanly. Base hydrolysis of the lactone yielded the solid hydroxy-acid **11** almost quantitatively and, without purification, this could be treated with 15 equivalents of methyl lithium, then quenched with 20 equivalents of chlorotrimethylsilane, after the method of Rubottom and Kim (15). Aqueous work-up afforded mainly the desired hydroxy-ketone **12** (in a yield of 85% from the lactone **10**) and only a little (6%) of the diol **13**.[5] Direct conversion of the lactone **10** to the



8



13

hydroxy-ketone **12** with methylmagnesium chloride in HMPA (17) proved to be of much lower yield than the two-step procedure via the acid. Oxidation of **12** with pyridinium chlorochromate (PCC) yielded the diketone **14**.

Diketals were formed easily from **14**. Consequently, we were unable to monoketalize the ring ketone of **14** selectively as a dimethyl or diethyl ketal, and formation of the monoketal with ethylene glycol produced both **15***a* and **16***a* under a variety of conditions. Nevertheless, the reaction of **14** with 2,2-dimethylpropanediol catalysed by pyridinium *p*-toluenesulfonate (PPTS) under carefully controlled conditions yielded, after chromatography, 89% of the monoketal **15***b* and only 4% of the diketal **16***b*. The methylene signals of the 1,3-dioxane rings in the 300 MHz ^{1}H nmr spectrum of the diketal **16***b* appeared as a four-proton singlet at δ 3.45 ppm flanked by two two-proton doublets. The spectrum of the monoketal **15***b* showed only the singlet at δ 3.45 ppm, which was consistent with conformational mobility of the dioxane ring. As expected, the side-chain dioxane of **16***b* was predominantly in one conformation, its axial and equatorial methylene protons giving rise to the two doublets.

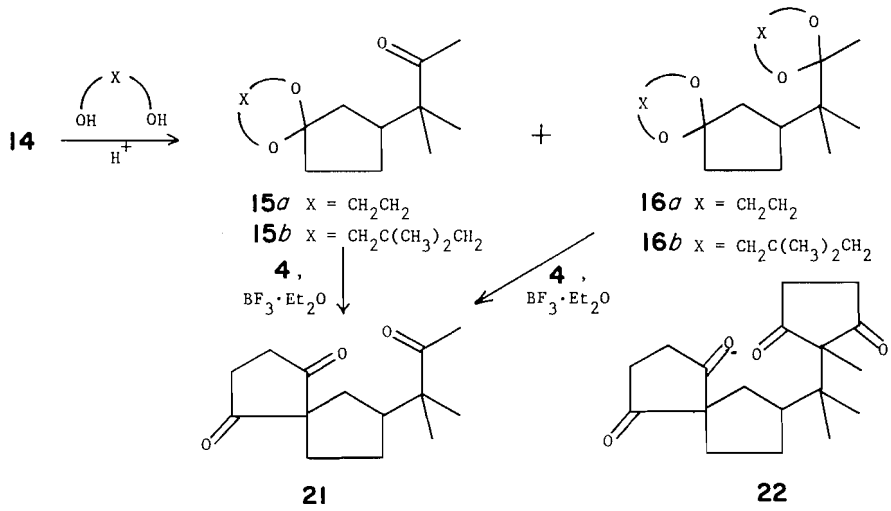
Kuwajima and co-workers (11) had used neither a 1,3-dioxolane nor a 1,3-dioxane with **4** in a geminal acylation reaction leading to a spiro-annulated product. Regarding a related reaction leading to a keto-ester, they commented that unlike the dimethyl, diethyl, and dibenzyl ketals the (cyclic) trimethylene ketal of 4-methyl-3-cyclohexen-1-one "posed considerable problems." Therefore, we were apprehensive about trying the spiro-annulation reaction with **15***a*/*b* or **16***a*/*b*. First we chose to examine the reactions of **4** with simpler cyclic ketals, and we wondered if conditions might be found that might effect the acid-catalysed rearrangement (**5** → **6**) in the same operation. Cyclic ketals of both types reacted with **4**. Furthermore, in the presence of a much larger excess of BF_3 etherate than in the Kuwajima procedure, 1,3-cyclopentanediones (**17**–**20**) were obtained *directly*, obviating the isolation of the cyclobutanones **5** and their treatment with TFA, and our yields of the 2,2-disubstituted 1,3-cyclopentanediones were generally higher than by the original two-step procedure. (Unsubstituted 1,3-cyclopentanedione was not produced from either 5,5-dimethyl-1,3-dioxane or *s*-trioxane, even after the addition of TFA.)

The monoketal **15***b* was treated with three equivalents of **4** and 15 equivalents of BF_3 etherate at −78°C. We were gratified that the gc–ms of the crude product indicated only one component. After column chromatography to remove a trace amount of some stubborn colored material, we were left with an 86% yield of a pure compound that was clearly the desired triketone **21**. (The ^{13}C nmr spectrum of this product showed signals at δ 213.0, 215.3, and 215.7 ppm for three ketone carbonyls, and the ^{1}H nmr spectrum included a complex four-proton multiplet around δ 2.778 ppm for the adjacent methylenes of the 1,3-cyclopentanedione moiety.) The same triketone could also be obtained from the diketals. We expected steric hindrance to render the side-chain ketal in **16***a* and **16***b* less reactive than the other ketal. Indeed, the diketal **16***a* with **4** gave, after aqueous

[4]Other syntheses employing this reaction are given in refs. 12 and 13.

[5]In contrast, without the chlorotrimethylsilane quench, following the procedure of House and Bare (16), we obtained 22% of **13**, 37% of **14**, and 31% recovered **12**.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.



work-up, a good yield of the desired triketone **21**, a little **14** (by hydrolysis), and none of the tetraketone **22**. Reaction of **16***b* with **4** provided **21**, but the product was accompanied by an equal amount of the hydrolysis product **14**, and one small-scale reaction with **16***b* produced a small amount of a compound tentatively identified as the tetraketone **22**. Thus, the reaction of the monoketal **15***b* presented a route to **21** that was marginally cleaner than via either diketal.

McMurry (18) has reported many intramolecular carbonyl coupling reactions involving low-valent titanium, but for our synthesis it was necessary to effect an intramolecular coupling of two ketones while suppressing the reduction and intermolecular coupling of a third ketone. This required considerable experimentation. One of our first attempts followed McMurry's "representative procedure" with $TiCl_3$ and the Zn–Cu couple (19). Chromatography of the product provided only 8% isokhusimone (**3**) along with 29% of a 1:1 mixture of the epimeric alcohols **23***a* and **23***b*, 28% recovered triketone **21**, and a significant amount of very nonpolar, heterogeneous material. The ^{13}C nmr spectrum of this material displayed many signals in the region of δ 140 ppm, which suggested a mixture of the overreduced and intermolecularly coupled hydrocarbons, **24**, and molecules with gross structure **25**. Similar results were obtained with $TiCl_3$ and other reducing agents: $LiAlH_4$, potassium metal, or Zn–Ag (20). However, when the triketone **21** was added *very slowly* by syringe pump to the slurry produced by $TiCl_3$ and freshly prepared Zn–Cu couple in a relatively large volume of boiling DME, the product we obtained repeatably was over 50% **3** with another (approximately) 20% of the alcohols **23***a*/*b* and very little hydrocarbon.

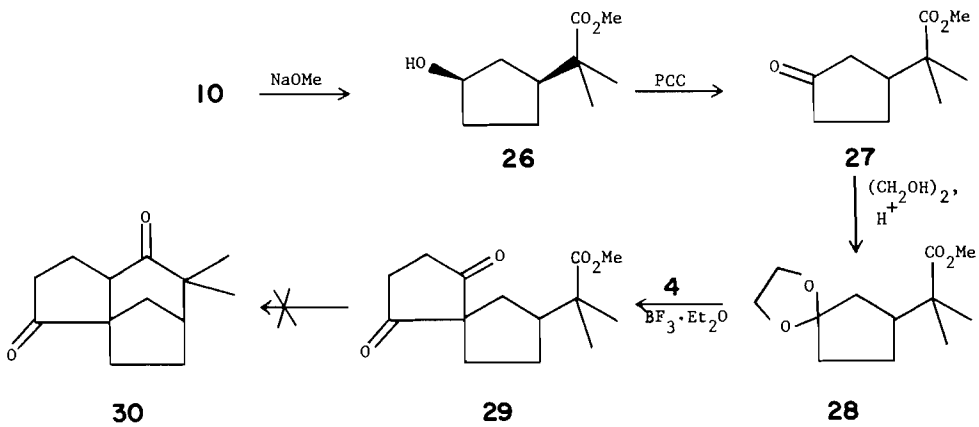
Oxidation of **23***a*/*b* to **3** with PCC was essentially quantitative,[6] so it was more efficient to oxidize the mixture of reaction products without separation of **3** from **23***a*/*b*. Our best yield of **3** over the two steps from **21** was 78%, and overall our yield of isokhusimone (**3**) was 35% from norcamphor. The ir, ^{1}H nmr, and mass spectra of our product were completely in accord with spectra of isokhusimone kindly provided by Professor G. Büchi. Büchi's group (4) has converted isokhusimone (**3**) to khusimone (**1**) in two steps, and Liu and Chan (5) have derived **2** and its epimer from **1** in a straightforward fashion.

As a sideline to our synthesis of **3**, we attempted a variation on our approach to the tricyclic skeleton that involved intramolecular carbonyl-coupling of a ketone with an ester (18). Methanolysis of the dimethyl-lactone **10** gave the methyl ester **26**, which in turn was oxidized with PCC to the keto-ester **27** and ketalized with ethylene glycol to give the ketal **28** in a yield of 83% from **10**. Addition of **28** to a solution of three equivalents of **4** and 15 equivalents of BF_3 etherate at −78°C provided the spiro-annulated compound **29** in a yield of 80% after chromatography. However, all our attempts to modify McMurry's con-



ditions to effect ketone–ester coupling to a tricyclic product **30** resulted in complex mixtures of many unidentified products and significant amounts of recovered **29**.

Although this second approach was ultimately unsuccessful, both routes demonstrated the synthetic utility of spiro-annulation with **4**, particularly via the simple one-pot procedure described here. Indeed, our first route was a considerable improvement over others for the construction of the zizaane system in its racemic form, and it should be amenable to chiral syntheses of zizaane sesquiterpenoids by starting from readily available (+)- or (−)-norcamphor (21).

Experimental

Melting points were determined on a Fisher–Johns apparatus and are uncorrected. Infrared (ir) spectra were recorded on a Perkin Elmer 283 spectrophotometer. Nuclear magnetic resonance (nmr) spectra were obtained in $CDCl_3$ solution, unless otherwise noted, on a General Electric GE 300-NB (300 MHz) instrument; chemical shifts were measured relative to internal standards: tetramethylsilane for ^{1}H and $CDCl_3$ (δ 77.0 ppm) for ^{13}C. Multiplicities are described by standard abbreviations. The nmr assignments were aided by APT, COSY, and HET-CORR 2-D spectra. Except where noted, both the low and the

[6]Reduction of **3** back to the alcohol with sodium borohydride resulted in the formation of *only one* of the epimeric alcohols. Molecular models suggest that formation of **23***b* might be favored because of somewhat less steric hindrance to the approach of the reducing agent from the face *syn* to the methano bridge.

high resolution mass spectral (ms) data were obtained on a V.G. Micromass 7070HS instrument. A Hewlett–Packard system (model 5890 gas chromatograph coupled to a model 5970 mass selective detector) equipped with a Hewlett–Packard 12.5-m fused silica capillary column with cross-linked dimethylsilicone as the liquid phase was used for gc–ms analyses. Microanalyses were by the Canadian Microanalytical Service Ltd., New Westminster, B.C. All reactions were run under an atmosphere of dry N_2. Solvents and reagents were purified by distillation; tetrahydrofuran (THF) and dimethoxyethane (DME) were distilled from sodium. "Ether" refers to diethyl ether. Silica gel (230–400 mesh) was used for flash column chromatography.

2-Oxabicyclo[3.2.1]octan-3-one (7)

Norcamphor (6.00 g, 52.5 mmol) and 85% *m*-chloroperoxybenzoic acid (14.10 g, 69.4 mmol) were stirred in $CHCl_3$ for 2 days at room temperature. The solution was washed with 10% NaOH (×5) and H_2O (×4), dried ($MgSO_4$), and concentrated. Vacuum distillation of the residue provided pure lactone **7** (5.70 g, 86%); ir (film) ν_{max}: 1730 cm^{-1}; ^1H nmr δ: 1.62–2.05 (5H, mm), 2.171 (1H, dt, J = 2.3, 9.5 Hz), 2.491 (1H, dt, J = 1.9, 18.4 Hz), 2.554 (1H, br d, J = 4.6 Hz), 2.727 (1H, ddd, J = 1.8, 5.0, 18.4 Hz), and 4.866 (1H, br s); ^{13}C nmr δ (attached H's): 28.5 (2), 31.1 (1), 31.8 (2), 35.0 (2), 39.9 (2), 80.4 (1), and 170.2 (0); ms from gc–ms m/z (%): 126 (5.5, M^+), 98 (14), 97 (11), 83 (39), 82 (66), 69 (42), 67 (99), 55 (48), 54 (51), 42 (54), and 41 (100). Exact mass calcd. for $C_7H_{10}O_2$: 126.0680; found: 126.0677.

2-Oxabicyclo[3.3.0]octan-3-one (8)[7]

Repeating the above on a small scale, but with the addition of concentrated H_2SO_4, gave a dark solution that was mainly **8** (98% by gc–ms analysis) with a small amount of **7**. For **8**: ir (film) ν_{max}: 1765 cm^{-1}; ^1H nmr δ: 1.50–2.08 (6H, mm), 2.290 (1H, dd, J = 1.6, 17.1 Hz), 2.78–2.94 (2H, mm), and 5.008 (1H, t, J = 5.1 Hz); ^{13}C nmr δ (attached H's): 23.2 (2), 33.3 (2), 33.4 (2), 35.9 (2, C-3), 37.7 (1), 86.2 (1), and 178.6 (0); ms from gc–ms m/z (%): 126 (6, M^+), 98 (31), 97 (29), 83 (17), 82 (12), 80 (22), 67 (100), 55 (56), 54 (54), and 41 (79).

4,4-Dimethyl-2-oxabicyclo[3.2.1]octan-3-one (10)

Lactone **7** (938 mg, 7.44 mmol) in dry THF was added slowly to 2.0 equivalents of LDA in THF at −78°C. The solution was stirred for 1 h before a solution of CH_3I (3.17 g, 22.3 mmol) and HMPA (22) (2.59 mL, 14.9 mmol) in THF was added over 10 min. The mixture was allowed to warm to −40°C, and was stirred for 1 h. The reaction was quenched with saturated NH_4Cl and extracted with ether (×4). The combined organic layers were washed with saturated NaCl (×2), dried ($MgSO_4$), and concentrated to provide the crude monomethyl-lactone **9**: ir (film) ν_{max}: 1720 cm^{-1}; ^1H nmr δ: 1.326 (3H, d, J = 7.5 Hz), 1.55 (1H, m), 1.71 (1H, m), 1.83–2.15 (4H, mm), 2.267 (1H, br t), 2.524 (1H, tq, J = 1.2, 7.5 Hz), and 4.817 (1H, br s); ^{13}C nmr δ: 18.9, 29.5, 31.9, 32.0, 38.3, 45.2, 80.7, and 174.4; ms m/z (%): 140 (4, M^+), 112 (4), 111 (3), 97 (50), 96 (21), 83 (26), 81 (56), 68 (30), 67 (67), 56 (33), and 55 (100). Exact mass calcd. for $C_8H_{12}O_2$: 140.0836; found: 140.0833. Repetition of this procedure with **9** as the starting material gave the crude dimethyl-lactone **10**. Chromatography (4% acetone in petroleum ether) yielded pure **10** (936 mg, 82% from **7**): mp 64–65°C; ir (Nujol) ν_{max}: 1740 cm^{-1}; ^1H nmr δ: 1.247 (3H, s), 1.328 (3H, s), 1.55–1.78 (2H, m), 1.90–2.10 (3H, mm), 2.110 (1H, t, J = 5.5 Hz, methine), 2.269 (1H, br d, J = 13.0 Hz), and 4.772 (1H, br s, methine); ^{13}C nmr δ (attached H's): 24.0 (2), 24.4 (3), 28.4 (3), 31.2 (2), 33.5 (2), 43.1 (0), 43.4 (1), 80.5 (1), and 177.1 (0); ms from gc–ms m/z (%): 154 (2, M^+), 111 (14), 110 (16), 95 (20), 69 (100), 67 (68), and 41 (75). Anal. calcd. for $C_9H_{14}O_2$: C 70.10, H 9.15; found: C 69.87, H 9.01.

cis-*2-(3-Hydroxycyclopentyl)-2-methylpropanoic acid (11)*

A solution of the dimethyl-lactone **10** (261 mg, 1.69 mmol) in ethanol, to which 10 mL of 10% KOH was added, was heated at reflux for 15 h. Once the solution had cooled, H_2O and 5% HCl were added until pH 4.5. Extraction with EtOAc (×5) followed by washing with saturated NaCl (×2), drying ($MgSO_4$) of the organic layer, and evaporation of the solvent yielded **11** as a colorless solid (289 mg, 99%): mp 105–106°C; ir (film) ν_{max}: 3600–2500 (very br) and 1700 cm^{-1}; ^1H nmr (CD_3SOCD_3) δ: 1.026 (3H, s), 1.035 (3H, s), 1.16 (1H, m), 1.35–1.48 (3H, m), 1.61 (1H, m), 1.80 (1H, m), 2.03 (1H, m), 4.01 (1H, m), 4.45 (1H, O*H*), and 12.01 (1H, CO_2H); ^{13}C nmr (CD_3SOCD_3) δ: 22.4, 22.5, 24.4, 34.9, 36.8, 43.1, 45.3, 71.3, and 178.8; ms m/z (%): no M^+, 155 (0.9), 154 (0.8), 128 (2), 111 (9), 109 (22), 88 (90), 69 (67), 67 (100), and 41 (68). Anal. calcd. for $C_9H_{16}O_3$: C 62.77, H 9.36; found: C 62.30, H 9.24.

cis-*3-(3-Hydroxycyclopentyl)-3-methyl-2-butanone (12)*

To an ice-bath-cooled solution of **11** (4.661 g, 27.06 mmol) in THF was added 228 mL (319 mmol) of 1.4 M CH_3Li in hexanes. The solution was stirred for 47 h, then at ice-bath temperature $(CH_3)_3SiCl$ (75 mL) was added all at once (solution became cloudy), followed by 5% HCl (solution cleared again). After stirring for 0.5 h, the mixture was extracted with ether (×3), and the combined organic layers were washed with H_2O, saturated $NaHCO_3$, and saturated NaCl. The solution was dried ($MgSO_4$) and concentrated. Chromatography (5% acetone in petroleum ether) yielded the hydroxy-ketone **12** (3.936 g, 85%) and a very small amount of the diol **13**. For **12**: ir (film) ν_{max}: 3420 (br) and 1700 cm^{-1}; ^1H nmr δ: 1.111 (3H, s), 1.119 (3H, s), 1.22–2.02 (6H, mm), 2.131 (3H, s), 2.168 (1H, apparent quintet, J = 8.7 Hz, methine), 2.45 (1H, v br, O*H*), and 4.265 (1H, apparent quintet, J = 4.8 Hz); ^{13}C nmr δ (attached H's): 21.8 (3), 22.0 (3), 24.8 (2), 25.6 (3), 35.4 (2), 36.8 (2), 45.0 (1), 49.3 (0), 73.1 (1), and 214.1 (0); ms m/z (%): 170 (0.4, M^+), 152 (3), 127 (14), 109 (100), 86 (44), 67 (78), 55 (35), and 43 (82). Exact mass calcd. for $C_{10}H_{18}O_2$: 170.1307; found: 170.1294; and calcd. for $C_{10}H_{16}O$ ($M^+ - H_2O$): 152.1201; found: 152.1213. For cis-*3-(2-hydroxy-1,1,2-trimethylpropane)-1-cyclopentanol* (**13**): ir (film) ν_{max}: 3380 (br), 1470, and 1380 cm^{-1}; ^1H nmr (OH signals first removed by exchange) δ: 0.880 (3H, s), 0.893 (3H, s), 1.191 (6H, s), 1.383 (1H, m), 1.45–1.76 (4H, mm), 1.94–2.11 (2H, mm), and 4.220 (1H, m); ^{13}C nmr δ (attached H's): 19.7 (3), 20.4 (3), 26.2 (3), 26.5 (2), 34.8 (2), 38.9 (2), 41.3 (0), 43.8 (1), 72.7 (1), and 76.2 (0); ms from gc–ms m/z (%): no M^+, 153 (2), 150 (4), 135 (9), 110 (20), 109 (24), 84 (60), 83 (91), 69 (78), 67 (77), 59 (59), 55 (93), 43 (55), and 41 (100).

3-(1,1-Dimethyl-2-oxopropyl)cyclopentanone (14)

A solution of the hydroxy-ketone **12** (3.6642 g, 21.52 mmol) in CH_2Cl_2 (30 mL) was added to PCC (23) (6.97 g, 32.3 mmol) in CH_2Cl_2. The solution was stirred at room temperature for 26 h. Filtration through a Florisil pad removed a black precipitate. Five volumes of anhydrous ether were passed through the pad, and concentration of the combined organic solutions provided the diketone **14** (3.5937 g, 99%): ir (film) ν_{max}: 1740 and 1700 cm^{-1}; ^1H nmr δ: 1.144 (3H, s), 1.167 (3H, s), 1.54–2.40 (6H, mm), 2.175 (3H, s), and 2.537 (1H, m, methine); ^{13}C nmr δ (attached H's): 21.1 (3), 21.5 (3), 24.0 (2), 25.5 (2), 38.6 (2), 40.0 (2), 43.4 (1), 48.7 (0), 212.6 (0), and 218.0 (0); ms m/z (%): 168 (0.5, M^+), 140 (18), 125 (19), 97 (16), 86 (57), 83 (55), 82 (18), 69 (44), 55 (100), 43 (74), and 41 (47). Exact mass calcd. for $C_{10}H_{16}O_2$: 168.1149; found: 168.1149.

Ketalization of 14 with ethylene glycol: 15a and 16a

A solution of the diketone **14** (37.5 mg, 0.223 mmol), ethylene glycol (13.7 μL, 0.25 mmol), and a very small amount of *p*-toluenesulfonic acid (*p*-TSA) in benzene was heated under reflux for 8 h with a Barrett water-separator filled with 4 Å molecular sieves. The cooled solution was washed with saturated $NaHCO_3$ and saturated NaCl. The aqueous layers were reextracted with ether (×4). The combined organic extracts were dried ($MgSO_4$) and concentrated. Column chromatography (4% acetone in petroleum ether) of the residue provided 15.0 mg of starting ketone and 22.2 mg (49%) of the monoketal **15***a*: ^1H nmr δ: 1.072 (3H, s), 1.083 (3H, s), 1.35–1.95 (6H, mm), 2.128 (3H, s), 2.363 (1H, m), and 3.84–394 (4H, mm); ms from gc–ms m/z (%): no M^+, 169 (2, $M^+ - COCH_3$), 141 (6), 127 (100), 99 (31), 86 (17), 83 (19), 55 (38), 43 (40), and 41 (28). In a similar reaction a benzene solution of **14** was heated overnight in the presence of a large excess of ethylene glycol and a catalytic amount of PPTS.

[7]We thank Mr. Paul F. Walsh for performing this experiment.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

The product consisted of **15***a* and the diketal **16***a* (1:2, respectively, by gc–ms). For **16***a*: ir (film) ν_{max}: 2975, 2880, 1475, 1370, and 1330 cm^{-1}; ^1H nmr δ: 0.876 (3H, s), 0.912 (3H, s), 1.235 (3H, s), 1.41–1.56 (1H, m), 1.62–1.94 (5H, mm), 2.09–2.22 (1H, m, methine), and 3.83–3.97 (8H, mm); ^{13}C nmr δ (attached H's): 19.2 (3), 19.4 (3), 20.1 (3), 25.9 (2), 35.8 (2), 38.9 (2), 42.9 (0), 43.3 (1), 64.0 (2), 64.1 (2), 64.5 (2), 64.6 (2), 114.3 (0), and 117.4 (0); ms from gc–ms *m/z* (%): no M^+, 241 (3.5), 141 (2), 127 (40), 99 (19), 87 (100), 55 (14), and 43 (32).

*Ketalization of **14** with 2,2-dimethyl-1,3-propanediol: **15**b and **16**b*

A solution of the diketone **14** (435.3 mg, 2.587 mmol), 2,2-dimethyl-1,3-propanediol (700 mg, 6.72 mmol), and PPTS (approximately 120 mg) in benzene was heated under reflux for 40 min. After cooling, ether was added to the solution, which was washed with saturated $NaHCO_3$, H_2O, and saturated NaCl, then dried ($MgSO_4$). Evaporation of the solvent under reduced pressure followed by chromatography (8% acetone in petroleum ether) provided 577.0 mg (88%) of the monoketal **15***b* and 37.6 mg (4%) of the diketal **16***b*. For **15***b*: ir (film) ν_{max}: 1710 and 1120 cm^{-1}; ^1H nmr δ: 0.948 (3H, s), 0.965 (3H, s), 1.067 (3H, s), 1.078 (3H, s), 1.3–1.7 (3H, mm), 1.80–2.03 (3H, mm), 2.128 (3H, s), 2.340 (1H, m, methine), and 3.455 (4H, m); ^{13}C nmr δ (attached H's): 21.1 (2C, 3), 22.3 (3), 22.4 (3), 24.5 (2), 25.3 (3), 30.0 (0), 34.8 (2), 36.1 (2), 43.6 (1), 49.1 (0), 71.7 (2), 72.0 (2), 108.3 (0), and 213.4 (0); ms *m/z* (%): no M^+, 239 (0.4, $M^+ - CH_3$), 211 (2, $M^+ - COCH_3$), 183 (2), 169 (94), 141 (18), 128 (14), 83 (100), 69 (86), 55 (64), 43 (52), and 41 (56). Anal. calcd. for $C_{15}H_{26}O_3$: 70.83, H 10.30; found: C 70.86, H 10.20. Similarly, heating a benzene solution of **14** (81.4 mg, 0.484 mmol) and a catalytic amount of PPTS with a large excess of the diol for 19 h yielded, after chromatography, 20.1 mg (16%) of the monoketal **15***b* and 129.4 mg (79%) of the diketal **16***b*: ir (film) ν_{max}: 2945, 2865, 1470, and 1120 cm^{-1}; ^1H nmr δ: 0.704 (3H, s), 0.917 (6H, s), 0.937 (3H, s), 0.981 (3H, s), 1.143 (3H, s), 1.314 (3H, s), 1.460 (1H, m), 1.53–1.78 (3H, m), 1.981 (1H, dd, J = 8.9, 10.5 Hz), 2.112 (1H, dd, J = 7.4, 13.4 Hz), 2.273 (1H, m, methine), 3.298 (1H, d, J = 11.5 Hz), 3.469 (4H, s), and 3.652 (2H, d, J = 11.5 Hz); ^{13}C nmr δ (attached H's): 11.8 (3), 18.9 (3), 19.7 (3), 22.38 (2C, 3), 22.42 (3), 23.3 (3), 26.4 (2), 29.7 (0), 30.0 (0), 34.2 (2), 38.8 (2), 42.3 (1), 43.6 (0), 69.9 (2C, 2), 71.6 (2), 71.9 (2), 102.4 (0), and 108.7 (0); ms *m/z* (%): no M^+, 325 (0.6), 205 (3), 169 (10), 141 (5), 129 (7), 115 (18), 88 (10), 86 (63), 84 (100), 69 (24), 56 (46), 47 (22), and 41 (44).

*Typical procedure for reaction of 1,2-bis(trimethylsiloxy)cyclobutene (**4**) with a ketal: 2-ethyl-2-methylcyclopentane-1,3-dione (**18**)*

Compound **4** was prepared by the method of Bloomfield and Nelke (24). A solution of 2-ethyl-2-methyl-1,3-dioxolane (280.5 mg, 2.42 mmol) in CH_2Cl_2 was stirred at −78°C as freshly distilled BF_3 etherate (2.98 mL, 24.2 mmol) was added, followed over a period of 5 min by a solution of **4** (1.61 mL, 6.05 mmol) in CH_2Cl_2. The mixture was allowed to attain room temperature while stirring overnight. The solution was washed with H_2O, saturated $NaHCO_3$, and saturated NaCl. The aqueous layers were reextracted with CH_2Cl_2 (×3), then the combined organic extracts were dried ($MgSO_4$) and concentrated to provide a yellow oil that showed only one component on gc–ms. The oil was chromatographed to yield colorless **18** (309.3 mg, 91.5%): ir (film) ν_{max}: 1750 (shoulder) and 1720 cm^{-1}; ^1H nmr δ: 0.808 (3H, t, J = 7.4 Hz), 1.095 (3H, s), 1.668 (2H, q, J = 7.4 Hz), and 2.785 (4H, s); ^{13}C nmr δ (attached H's): 8.7 (3), 17.8 (3), 28.6 (2), 35.0 (2), 56.9 (0), and 216.4 (0); ms *m/z* (%): 140 (51, M^+), 125 (92), 97 (31), 84 (12), 83 (13), 69 (100), 56 (36), 55 (29), and 41 (83). Exact mass calcd. for $C_8H_{12}O_2$: 140.0837; found: 140.0843.

Similarly, the 5,5-dimethyl-1,3-dioxane derived from acetone gave **17** (crude product 92.6% by gc–ms, 68% after chromatography): ir (film) ν_{max}: 1725 cm^{-1}; ^1H nmr δ: 1.153 (6H, s) and 2.810 (4H, s); ^{13}C nmr δ (attached H's): 20.2 (3), 34.5 (2), 52.6 (0), and 216.3 (0); ms *m/z* (%): 126 (54, M^+), 111 (19), 83 (18), 70 (100), 56 (23), 55 (21), and 42 (83). Exact mass calcd. for $C_7H_{10}O_2$: 126.0680; found: 126.0678.

The 1,3-dioxolane and the 5,5-dimethyl-1,3-dioxane derived from cyclohexanone gave **19** (96% and 98%, respectively, crystallized from EtOAc): mp 60–61°C (lit.(11) mp 61–62°C); ir (film) ν_{max}: 1755 (weak) and 1720 cm^{-1}; ^1H nmr δ: 1.4–1.7 (10H, mm) and 2.677 (4H, s); ^{13}C nmr δ (attached H's): 20.4 (2), 24.9 (2), 29.2 (2), 34.3 (2), 55.9 (0), and 215.8 (0); ms *m/z* (%): 166 (100, M^+), 137 (25), 124 (32), 112 (61), 111 (46), 85 (46), 81 (37), 67 (74), and 56 (44). Exact mass calcd. for $C_{10}H_{14}O_2$: 166.0993; found: 166.0985.

The 1,3-dioxolane derived from norcamphor gave **20** (82%, crystallized from ether): mp 108–109°C (lit. (11) mp 109.5–110.5°C); ir (film) ν_{max}: 1760 (weak) and 1715 cm^{-1}; ^1H nmr δ: 1.18–1.57 (6H, mm), 1.76–1.89 (2H, mm), 2.372 (1H, br t, bridgehead H), 2.480 (1H, br d, bridgehead H), and 2.51–3.07 (4H, mm); ^{13}C nmr δ (attached H's): 24.5 (2), 28.0 (2), 32.9 (2), 34.4 (2), 35.3 (2), 37.0 (1), 37.2 (2), 48.9 (1), 66.6 (0), 213.1 (0), and 213.4 (0); ms *m/z* (%): 178 (19, M^+), 149 (46), 112 (100), 93 (15), 79 (13), 67 (19), 66 (12), and 65 (13). Exact mass calcd. for $C_{11}H_{14}O_2$: 178.0993; found: 178.1002.

*7-(1,1-Dimethyl-2-oxopropyl)spiro[4.4]nonane-1,4-dione (**21**)*

*From the monoketal **15**b*

A solution of **15***b* (611.0 mg, 2.402 mmol) in CH_2Cl_2 was cooled to −78°C. Freshly distilled BF_3 etherate (4.44 mL, 36.1 mmol) was added followed, dropwise, by a solution of **4** (1.60 mL, 6.05 mmol) in CH_2Cl_2. The mixture was stirred overnight, over which time the solution was allowed to attain room temperature. The black solution was washed with H_2O, saturated $NaHCO_3$, and saturated NaCl. The aqueous layers were reextracted with CH_2Cl_2 (×3), and the combined organic extracts were dried ($MgSO_4$). Concentration of the solvent left a yellow oil (716.5 mg) that was chromatographed (5% acetone in petroleum ether) to provide pure **21** (491.2 mg, 87%): ir (film) ν_{max}: 1760 (shoulder), 1725, and 1705 cm^{-1}; ^1H nmr δ: 1.100 (3H, s), 1.136 (3H, s), 1.44–1.96 (6H, mm), 2.141 (3H, s), 2.491 (1H, m, methine), and 2.778 (4H, m); ^{13}C nmr δ (attached H's): 21.2 (3), 21.6 (3), 25.3 (3), 27.6 (2), 34.1 (2), 34.7 (2), 34.9 (2), 35.2 (2), 46.7 (1), 48.9 (0), 62.3 (0), 213.0 (0), 215.3 (0), and 215.7 (0); ms from gc–ms *m/z* (%): 236 (0.1, M^+), 221 (0.4), 193 (96), 176 (12), 175 (15), 151 (66), 137 (17), 133 (25), 125 (30), 111 (29), 109 (22), 86 (56), 55 (30), 43 (100), and 41 (56). Exact mass calcd. for $C_{12}H_{17}O_2$ ($M^+ - COCH_3$): 193.1227; found: 193.1215.

*From the diketal **16**a*

A CH_2Cl_2 solution of the diketal **16***a* (91.9 mg, 0.359 mmol) was treated as above with BF_3 etherate (0.89 mL, 7.2 mmol) and **4** (0.58 mL, 2.2 mmol). The gc–ms analysis of the crude product showed **21** as the almost exclusive component along with ca. 3% **14**. Chromatography (5% acetone in petroleum ether) provided 72.9 mg (86%) of pure **21**.

*From the diketal **16**b*

A CH_2Cl_2 solution of the diketal **16***b* (129.4 mg, 0.380 mmol) was treated as above with BF_3 etherate (0.94 mL, 7.6 mmol) and **4** (0.61 mL, 2.3 mmol). The gc–ms analysis of the crude product showed a mixture of mainly **21** and **14** (1 : 1). Chromatography provided 42.3 mg (47%) of pure **21** and 27.6 mg (43%) of recovered **14**. The following is the mass spectrum of a compound tentatively identified as **22** from the gc–ms of the crude product of one very small-scale reaction of **16***b* with **4**: *m/z* (%): 304 (2, M^+), 239 (5), 221 (2), 219 (2), 207 (24), 153 (25, complete side chain), 137 (23), 123 (100), 81 (33), 79 (24), 73 (15), 69 (18), 55 (18), and 41 (26).

*Intramolecular titanium-induced ketone–ketone coupling in **21**: isokhusimone (**3**)*

Zn–Cu couple was made by the procedure of McMurry *et al.* (19). The couple (556 mg, 8.56 mmol) was added to $TiCl_3$ (516 mg, 3.35 mmol) in 150 mL of dry DME, and this was heated under reflux for 4 h. A solution of the triketone **21** (96.6 mg, 0.409 mmol) in DME (20 mL) was added to the hot slurry over a period of 50.5 h using a syringe pump, then the reaction mixture was heated for another 84 h. After cooling, the solution was passed through a pad of Florisil. The residue from concentration of the solvent was chromatographed (2% acetone in petroleum ether) to afford, in order of elution, isokhusimone (**3**) (47.4 mg, 57%), a 1:1 mixture of the epimeric alcohols **23***a* and **23***b* (17.8 mg, 21%), and 8.1 mg of recovered triketone **21**. For **3**: ir (film) ν_{max}:

For personal use only.

1740 and 1675 (weak) cm^{-1}; ^1H nmr δ: 1.020 (3H, s), 1.039 (3H, s), 1.534 (3H, s), 1.64–1.88 (7H, mm), 2.025 (1H, m, methine), and 2.28–2.71 (3H, mm); ^{13}C nmr δ (attached H's): 12.2 (3), 23.1 (2), 24.7 (2), 25.1 (3), 28.2 (3), 35.7 (2), 38.0 (2), 38.3 (2), 40.5 (0), 48.6 (1), 55.9 (0), 130.6 (0), 136.3 (0), and 222.6 (0); ms *m/z* (%): 204 (15, M^+), 189 (36), 161 (23), 133 (30), 119 (100), 105 (12), 91 (22), 77 (15), and 41 (29). Exact mass calcd. for $C_{14}H_{20}O$: 204.1513; found: 204.1531. For **23***a* (tentative assignment of relative stereochemistry at C-2): ^1H nmr (from the spectrum of the mixture of epimers) δ: 0.990 (3H, s), 1.037 (3H, s), 1.479 (3H, s), and 4.031 (1H, m); ^{13}C nmr (from the spectrum of the mixture of epimers) δ: 13.4, 25.0, 25.1, 25.8, 32.6, 33.3, 36.6, 40.4, 47.7, 56.3, 79.7, 128.9, and 139.5; ms nearly identical with **23***b*. For **23***b*: see below. Oxidation of **23***a*/*b* with PCC yielded **3** essentially quantitatively.

Reduction of **3**

Isokhusimone (38.2 mg, 0.187 mmol) was dissolved in methanol (8 mL) and cooled in an ice-bath as $NaBH_4$ was added in small portions. Thin-layer chromatography indicated a complete reaction within 30 min. Some H_2O was added and much of the methanol was removed by evaporation under reduced pressure. The product was extracted into ether, which was washed with saturated NaCl, dried ($MgSO_4$), and concentrated. Although the crude oily residue (39.1 mg) was homogeneous by tlc and gc–ms, column chromatography (10% acetone in petroleum ether) was used to remove some yellow color. This afforded the alcohol tentatively assigned as epimer **23***b* as a colorless powder, mp 102–103°C; ir (film) ν_{max}: 3370 (very br) cm^{-1}; ^1H nmr δ: 0.989 (3H, s), 1.006 (3H, s), 1.20–2.35 (mm), 1.421 (3H, s), and 4.002 (1H, dd, J = 6.0, 11.2 Hz); ^{13}C nmr δ (attached H's): 12.5 (3), 24.1 (2C, 2), 24.9 (3), 28.3 (3), 28.4 (2), 32.1 (2), 36.2 (2), 40.4 (0), 47.2 (1), 53.0 (0), 76.3 (1), 129.7 (0), and 138.8 (0); ms from gc–ms *m/z* (%): 206 (29, M^+), 191 (75), 173 (10), 163 (24), 145 (48), 119 (100), 105 (17), and 91 (25). Exact mass calcd. for $C_{13}H_{19}O$ ($M^+ - CH_3$): 191.1435; found: 191.1435.

Methyl cis*-2-(3-hydroxycyclopentyl)-2-methylpropanoate (***26***)*

Sodium (800 mg) was added to dry methanol (160 mL) followed by **10** (1.1665 g, 7.564 mmol), and the solution was heated at reflux for 22 h. Much of the solvent was removed by evaporation under reduced pressure, then H_2O was added followed by concentrated HCl to pH 4.5. This was extracted with EtOAc (×4). The organic solution was washed with saturated $NaHCO_3$ and saturated NaCl, dried ($MgSO_4$), and concentrated to give a yellow oil (1.5048 g) containing mainly **26** and a little **10**. Only a small portion was purified; for **26**: ir (film) ν_{max}: 3430 (br) and 1730 cm^{-1}; ^1H nmr δ: 1.170 (3H, s), 1.175 (3H, s), 1.376 (1H, m), 1.55–1.77 (3H, mm), 1.95–2.20 (2H, mm), 2.21 (1H, v br, O*H*), 3.660 (3H, s), and 4.258 (1H, m); ^{13}C nmr δ (attached H's): 23.0 (3), 23.2 (3), 24.9 (2), 35.4 (2), 37.0 (2), 44.1 (0), 46.3 (1), 51.6 (3), 73.1 (1), and 178.3 (0); ms *m/z* (%): no M^+, 169 (0.4), 155 (1.3), 111 (11), 110 (10), 109 (63), 102 (100), 87 (20), 83 (16), 69 (92), 67 (87), 55 (31), and 41 (68).

*Methyl 2-methyl-2-(3-oxocyclopentyl)propanoate (***27***)*

A CH_2Cl_2 solution of the crude **26** from the above reaction was stirred overnight in the presence of PCC (2.45 g, 11.37 mmol). The mixture was filtered through a Florisil pad, which was washed with ether (×4), and the combined organic solutions were concentrated to give a colorless liquid (1.239 g). A small portion was purified; for **27**: ir (film) ν_{max}: 1740 and 1730 cm^{-1}; ^1H nmr δ: 1.205 (3H, s), 1.214 (3H, s), 1.646 (1H, m), 1.98–2.53 (6H, mm), and 3.687 (3H, s); ^{13}C nmr δ (attached H's): 22.5 (3), 22.6 (3), 24.4 (2), 38.8 (2), 40.4 (2), 43.7 (0), 45.0 (1), 51.8 (3), 177.2 (0), and 218.2 (0); ms *m/z* (%): 184 (1, M^+), 156 (3), 125 (17), 102 (100), 87 (14), 83 (57), 82 (19), 70 (13), 69 (28), 55 (65), and 41 (36). Anal. calcd. for $C_{10}H_{16}O_3$: C 65.18, H 8.76; found: C 65.03, H 8.80.

*7-(1-Carbomethoxy-1-methylethyl)-1,4-dioxaspiro[4.4]nonane (***28***)*

To benzene solution of the crude **27** from the above reaction was added ethylene glycol (4.3 mL, 75.8 mmol) and a small amount of *p*-TSA. The mixture was heated under reflux with a Barrett water separator for 21 h. The solution was washed with saturated $NaHCO_3$, H_2O, and saturated NaCl. The aqueous layers were reextracted with ether (×2), and the combined organic extracts were dried ($MgSO_4$) and concentrated to give a yellow oil (1.5405 g). Chromatography (2% acetone in petroleum ether) of this material provided pure **28** (1.2429 g, 72% from **10**): ir (film) ν_{max}: 1730 and 1130 cm^{-1}; ^1H nmr δ: 1.141 (3H, s), 1.144 (3H, s), 1.40–1.91 (6H, mm), 2.313 (1H, m, methine), 3.653 (3H, s), and 3.890 (4H, m); ^{13}C nmr δ (attached H's): 22.2 (3), 22.4 (3), 24.7 (2), 35.7 (2), 37.4 (2), 43.7 (0), 45.1 (1), 51.4 (3), 63.9 (2), 64.0 (2), 117.2 (0), and 117.5 (0); ms *m/z* (%): no M^+, 199 (1), 169 (9), 127 (100), 99 (78), 83 (22), 55 (30), and 41 (18). Anal. calcd. for $C_{12}H_{20}O_4$: C 63.14, H 8.83; found: C 63.42, H 8.82.

*7-(1-Carbomethoxy-1-methylethyl)spiro[4.4]nonane-1,4-dione (***29***)*

A solution of **28** (52.2 mg, 0.229 mmol) in CH_2Cl_2 was cooled to −78°C and BF_3 etherate (0.43 mL, 3.45 mmol) was added, followed dropwise by a CH_2Cl_2 solution of **4** (0.25 mL, approximately 0.92 mmol). The mixture was stirred for 28 h during which time the reaction was allowed to attain room temperature. The solution was washed with H_2O, saturated $NaHCO_3$, and saturated NaCl, then dried ($MgSO_4$) and concentrated. The residue was chromatographed to provide pure **29** (46.1 mg, 80%): mp 32–33°C; ir (film) ν_{max}: 1715 (br) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.174 (3H, s), 1.182 (3H, s), 1.53–1.95 (6H, mm), 2.435 (1H, m, methine), 2.777 (4H, br s), and 3.668 (3H, s); ^1H nmr (C_6D_6) δ: 1.123 (6H, s), 1.55–1.80 (6H, s), 2.050 (4H, br s), 2.444 (1H, m), and 3.381 (3H, s); ^{13}C nmr ($CDCl_3$) δ (attached H's): 22.7 (3), 22.9 (3), 27.8 (2), 34.1 (2), 34.6 (2), 34.8 (2), 35.2 (2), 43.5 (0), 48.2 (1), 51.6 (3), 62.4 (0), 177 (0), 215.3 (0), and 215.6 (0); ^{13}C nmr (C_6D_6) δ: 23.0, 23.4, 28.2, 34.6 (2C), 34.7, 35.4, 43.8, 48.9, 51.3, 62.3, 176.9, 214.3, and 214.5; ms *m/z* (%): 252 (0.4, M^+), 250 (1), 193 (10), 191 (10), 190 (15), 151 (16), 150 (22), 149 (36), 102 (100), 87 (16), 55 (15), and 41 (26). Anal. calcd. for $C_{14}H_{20}O_4$: C 66.65, H 7.99; found: 66.62, H 7.99.

Attempted intramolecular titanium-induced ketone–ester coupling in **29**

Reaction media based on $TiCl_3$/Zn–Cu couple (19) and on $TiCl_3$/$LiAlH_4$ (25) gave complex mixtures along with significant amounts of recovered starting material. (Oxidation of the crude product with PCC did not appear to lead to a simpler mixture.)

Acknowledgements

We thank Dr. C. R. Jablonski and Messrs. A. Earle and R. Sammynaiken for 300 MHz nmr spectra, and Dr. B. Gregory and Miss M. Baggs for mass spectra. We are grateful to Drs. Ž. Stojanac and A. G. Fallis for helpful discussions, and we thank Professor G. Büchi for spectra of authentic isokhusimone. The Natural Sciences and Engineering Research Council of Canada and the Memorial University of Newfoundland provided financial support for this work.

Received December 13, 1989

GRAEME KELLY, C. J. WILLSHER, F. WILKINSON, J. C. NETTO-FERREIRA, A. OLEA, D. WEIR, L. J. JOHNSTON, and J. C. SCAIANO. Can. J. Chem. **68**, 812 (1990).

Diphenylmethyl radicals have been generated by 266 nm laser excitation of 1,1,3,3-tetraphenylacetone adsorbed on silica gel and included in NaX and Silicalite zeolites and have been studied using diffuse reflectance laser flash photolysis techniques. The spectrum for the radical shows λ_{max} at ~335 nm in all three supports and is similar to that in solution. The radicals decay over time scales that vary from hundreds of nanoseconds to minutes and there are indications that some radicals may be decaying on shorter time scales than we can monitor. The efficiency of oxygen quenching increases in going from Silicalite to NaX to silica gel, consistent with the greater accessibility of oxygen to silica gel pores as compared to the narrow channels in Silicalite. Laser dose and ketone loading effects were also examined for the various supports. Potential applications of a kinetic treatment of the data based on dispersive reaction kinetics are also discussed as a means of dealing with the problem of decay kinetics that occur over a wide range of time scales.

Key words: zeolites, kinetics, diphenylmethyl radicals, laser photolysis.

On a produit des radicaux diphénylméthyles en excitant, à l'aide d'un laser opérant à 266 nm, de la 1,1,3,3-tétraphénylacétone adsorbée sur du gel de silice ou incluse dans des zéolithes de NaX et de Silicalite et on les a étudiés en faisant appel aux techniques de photolyse «flash» à l'aide de laser à réflectance diffuse. Le spectre du radical présente un λ_{max} à environ 335 nm dans chacun des trois supports et il est semblable à celui observé en solution. Les radicaux se décomposent à des vitesses qui varient de quelques centièmes de nanosecondes à des minutes; certaines indications nous laissent croire que certains radicaux pourraient se décomposer à des vitesses plus rapides que celles que l'on peut mesurer. L'efficacité du piégeage par l'oxygène augmente lorsqu'on passe de la Silicalite au NaX au gel de silice; cet ordre est en accord avec la plus grande disponibilité de l'oxygène sur les pores du gel de silice par comparaison avec les canaux étroits qui existent sur la Silicalite. Pour divers supports, on a aussi examiné les effets de la dose du laser ainsi que de la quantité de cétone utilisée. On discute aussi des applications potentielles d'un traitement cinétique des données basé sur la cinétique de réactions dispersives comme moyen de résoudre le problème de la cinétique de décompositions qui se produisent à des vitesses très différentes.

Mots clés : zéolithes, cinétique, radicaux diphénylméthyles, photolyse de laser.

[Traduit par la revue]

There is considerable current interest in the study of photochemical reactions on solid supports (1–3). In many cases it has been demonstrated that adsorption on solids such as silica and alumina and inclusion in zeolites can often modify the normal solution photochemistry of a given species. In particular, a variety of benzyl radical pairs have been used to examine the effects of zeolites and silicas on the pathways available to organic molecules adsorbed on the various surfaces (1, 2, 4). These studies have investigated the effects of the additives, temperature, and modifications of the silica or zeolite properties upon the observed chemistry of the radicals. In several cases, novel reactions have been observed as a result of the restrictions imposed upon radical pairs or biradicals by their environment within the zeolite (1).

Recent developments in diffuse reflectance laser flash photolysis have made it possible to study transients in a variety of opaque samples (5–10). For example, there are several reports of time-resolved investigations of triplet states of organic molecules adsorbed on or included in solids (5, 6, 11–13), as well as a recent study of radical cations on surfaces (14). These have demonstrated that restrictions on the mobility may often enhance the transient lifetimes with respect to those observed in solution, and have provided evidence for multiple absorption and inclusion sites. We report herein the first example of the application of diffuse reflectance laser photolysis to the study of radicals in opaque samples. Diphenylmethyl radicals supported on silica gel and NaX and Silicalite zeolites have been examined using both diffuse reflectance transient techniques and product studies.

Experimental

Silica gel (Aldrich, Davisil grade 633, 60 Å), NaX (BDH), and Silicalite (Union Carbide) were heated at 500°C for ~12 h before use. 1,1,3,3-Tetraphenylacetone (TPA) was synthesized according to a previously described modification (15) of a literature procedure (16) and purified by either recrystallization or chromatography.

Sample preparation

Samples of tetraphenylacetone on silica gel and NaX were prepared by stirring solutions of the ketone in hexane with the support (~2 mL solvent/g solid) for 2 h and then slowly removing the solvent on a rotary evaporator. The material was then vacuum dried at room temperature for at least 2 h. Silicalite samples were prepared by stirring the solid with isooctane solutions of the ketone for 12 h, filtering the sample, and washing the solid twice with 2 mL isooctane. The solid was then vacuum dried. The amount of ketone remaining in the isooctane was determined by gas chromatography in order to calculate

the sample loading. It should be noted that in earlier work we observed some problems with color formation during sample preparation for certain batches of Silicalite (17). However, this was not a problem for any of the samples used in the present experiments.

Diffuse reflectance laser flash photolysis

The frequency quadrupled line (266 nm) from a Lumonics HY400 Nd/Yag laser was used for the transient experiments. The experimental setup for diffuse reflectance laser flash photolysis was the same as that which has been described except for the use of the laser indicated above and an IBM-PC compatible computer for experiment control and data acquisition (8). The samples were contained in 3×7 mm^2 quartz cells and were deaerated by passing a stream of nitrogen or oxygen through the cell.

The kinetic analysis is based on the fraction of reflected light absorbed by the intermediate ($\Delta J/J_0$) where J_0 is the signal before laser excitation and ΔJ is the difference between J_0 and J_t, the signal at time t after excitation. Laser dose experiments (see later) show that increasing the laser intensity leads to an increase in the intensity of the transient absorption, demonstrating that a saturated plug of totally converted ground state to transient is not produced and, therefore, a Kubelka–Munk treatment is not appropriate (18).

Product studies

The samples were prepared as outlined above using 8:2 isooctane/dichloromethane, and removing the solvent on a rotary evaporator. The samples for the nitrogen vs. oxygen effects were evacuated at room temperature on a vacuum line (0.01 Torr; 1 Torr = 133.3 Pa) and then placed under a positive pressure of nitrogen or oxygen and sealed. In the case of a sample equilibrated with $H_2{}^{18}O$, a sample of silica gel was dried as usual and then stored under nitrogen in a dry box. The sample (2 g) was placed in a round-bottom flask, which was attached to a second flask containing 1 g $H_2{}^{18}O$, and the entire system was evacuated and closed. After 24 h all the water had been adsorbed by the silica and the ketone was adsorbed as usual, except that the entire procedure was done in a dry box and the solvent was removed using an Air-Cadet pump.

The samples were irradiated using 300-nm Rayonet lamps and were rotated constantly during the irradiation to provide for adequate sample mixing. After irradiation each sample was extracted in a Soxhlet apparatus for ~12 h using benzene as solvent. This was found to be the best solvent for quantitatively removing ketone from the support. The extract was concentrated and analyzed by GC (Perkin Elmer 8320 gas chromatograph; DB-1 on fused silica capillary column; 15 m × 0.242 mm) using biphenyl as an internal standard and solutions of TPA, benzophenone, and 1,1,2,2-tetraphenylethane for calibration purposes.

Results and discussion

The α-cleavage of 1,1,3,3-tetraphenylacetone (reaction [1]) was used as a source of diphenylmethyl radicals in our experiments. The production of the second diphenylmethyl radical via decarbonylation of the initial diphenylacetyl radical occurs rapidly ($k = 1.3 \times 10^8$ s^{-1} (19)) and reaction [1] is thus an efficient and practically instantaneous source of two diphenylmethyl radicals per ketone molecule (15).

[1] $Ph_2CHC(O)CHPh_2 \rightarrow Ph_2CH\dot{C}O + Ph_2\dot{C}H \rightarrow 2Ph_2\dot{C}H$

The three solid supports used in these experiments differ considerably in their properties. Silica gel is a porous solid with, in our case, an average pore size of 60 Å and a surface area of 480 m^2/g. Silicalite has a channel system consisting of near-circular zigzag channels (diameter of 5.4 Å), cross-linked by elliptical straight channels with a cross-section of 5.75 × 5.15 Å (20). Both silica gel and Silicalite contain primarily silicon and oxygen although the latter is hydrophobic whereas in the former the surface is rich in SiOH groups and has a large amount of physically adsorbed water. The structure of the aluminosilicate NaX zeolite is composed of a three-dimensional network of relatively large cavities or supercages (~12 Å) connected by 7–8 Å pores or channels (21). The Si/Al ratio of approximately 1.5 results in a large proportion of exchangeable cations (in our case Na) and a strongly hydrophilic zeolite. It should be noted that TPA can easily fit within the pore structure of silica gel and the channel system of NaX. However, the relatively small channels of Silicalite result in adsorption of TPA only on the external surface, although the diphenylmethyl radicals may migrate into the channels. For all three supports the external surface is a small fraction of the internal pore or channel surfaces. Ground-state spectra for tetraphenylacetone on the three solids were similar to that in methanol and showed a clearly defined n,π^* band at ~300 nm, which was only slightly broader than that in solution.

The transient experiments for diphenylmethyl radicals on each of the solid supports are discussed separately below. In each case the radicals were generated by 266 nm pulsed laser irradiation of TPA contained at 1–3% (w/w) on the various supports. Unless otherwise stated, all experiments were carried out under a nitrogen atmosphere.

Silica gel

Figure 1 illustrates two time-resolved diffuse reflectance traces obtained from a sample of TPA (1% w/w) on silica gel under nitrogen. The acquisition conditions for these two traces differ only in the time scale monitored, i.e., 0.1 and 1.6 μs per point (tpp) for decay traces of 250 points. It is apparent that the first half-life, as obtained from $\Delta J/J_0$, is much shorter than the second half-life, which is shorter than the third half-life, etc. Also, when the acquisition rate is decreased and the values are averaged over a much longer time, very rapid information may be lost, yielding an artificially low initial value of $\Delta J/J_0$. Thus, the first half-life measured for trace A for this particular tpp is 2.2 μs while both the initial value of $\Delta J/J_0$ and the first half-life measured from trace B change. Trace B gives a half-life of 7 μs (tpp = 1.6 μs). Even longer lifetimes can be obtained if the starting point of the calculation is delayed in time. Throughout the entire time range monitored the transient spectra retain the characteristic features of the diphenylmethyl radicals expected from the photocleavage of TPA, with $\lambda_{max} \sim 330$ nm and no significant absorptions above 400 nm.[3] Figure 2 (bottom) shows a spectrum obtained at 5 μs following the laser pulse for a 5% sample.

It is rather remarkable that, after the laser experiment, the steady-state diffuse reflectance spectrum of samples exposed to a few tens to a hundred laser shots also reveals the presence of diphenylmethyl radicals. This is illustrated in Fig. 3, which shows difference spectra obtained at various times following the laser exposure; these clearly reveal the presence of the same intermediate produced in the transient experiment, i.e., $Ph_2\dot{C}H$. The half-life under these conditions was approximately 30 min (see insert in Fig. 3), although all indications are that with improved spectral sensitivity and longer recording times, even longer values could be obtained. Even the limited data of Fig. 3 indicate that the long-time data show positive deviations. Similar results were observed for other plots of the same type for the other supports employed in our work. It should be noted that while both Figs. 2 and 3 show difference spectra, the parameter

[3]The absence of absorptions in this region rules out the possible involvement of species such as benzophenone triplets, which show $\lambda_{max} \sim 530$ nm (28).

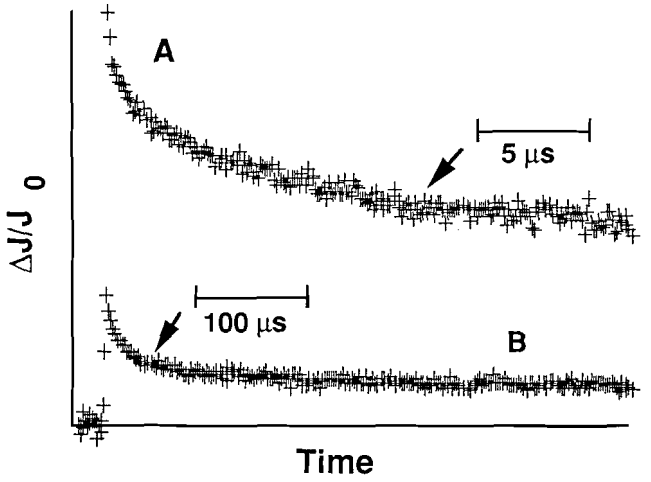

FIG. 1. Transient decay traces monitored at 340 nm on two time scales following 266 nm excitation of a 1% sample of TPA on silica gel.

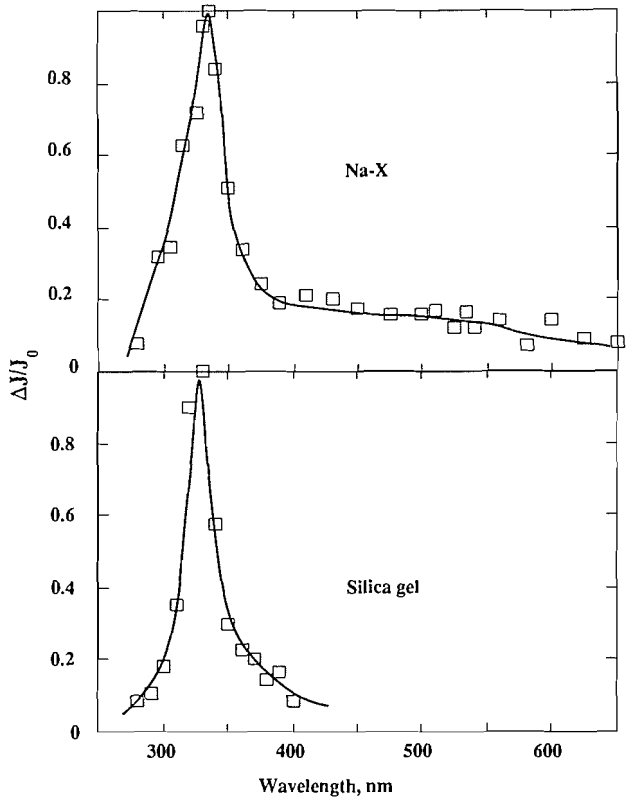

FIG. 2. Transient spectra for diphenylmethyl radicals produced by 266 nm excitation of samples of 5% TPA on NaX (top) and 3% TPA on silica gel. Spectra were recorded 5 and 2 μs after the laser for the silica gel and NaX spectra, respectively.

is not strictly the same for the transient and steady-state spectra. The former reflect spectral differences after and before laser excitation. For the latter (i.e., the steady-state measurements) the difference was calculated between the spectrum at a given time, and at a time arbitrarily defined as "infinite" time. For example, this measurement for Fig. 3 was taken 270 min after the end of the laser irradiation. The two types of measurement would be equivalent if the laser experiment did not induce permanent absorption changes in the spectral region of interest; while this is not strictly the case for any of the supports used, the changes are sufficiently small that the approximation does not invalidate our conclusions.

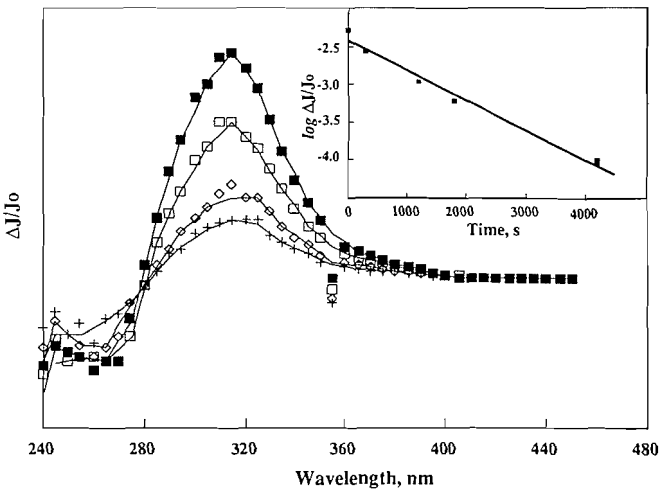

FIG. 3. Difference spectra measured using a UV spectrometer 0 (■), 300 (□), 1200 (◇), and 1800 (+) s after exposure of a 3% TPA on silica gel sample to ~100 laser shots. Insert: plot of log $(\Delta J/J_0)$ as a function of time for the same sample.

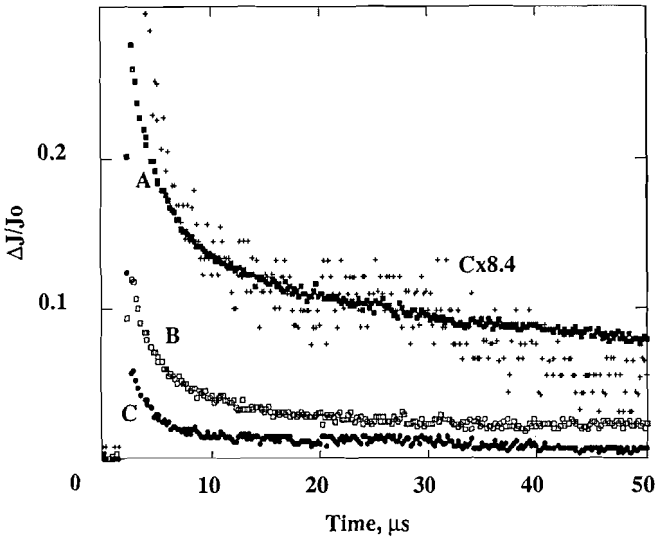

FIG. 4. Transient decay traces monitored at 340 nm following 266 nm excitation of 1% TPA on silica gel using 100% (A,■), 37% (B,□), and 11% (C, • and +) of the full laser intensity.

Studies of the dose dependence of the absorption signals and their decay kinetics were carried out by varying the laser intensity by a factor of ~8. Figure 4 shows representative traces recorded at a tpp of 200 ns for a 1% sample of TPA on silica gel deaerated with nitrogen. Two features of the data are worth noting: the changes in the decay kinetics are minor in comparison with the extensive changes in excitation dose, and the initial absorbance does not fully reflect the changes in laser intensity. The insensitivity of the decay kinetics to the laser intensity indicates that the complex behaviour observed is dominated by pseudo-first-order processes in the time domain examined. However, the fact that the total signal does not fully reflect the laser dose suggests that rapid geminate processes may take place at shorter time scales. It is also possible that light absorption by $Ph_2\dot{C}H$ radicals produced during the early part of the laser pulse also contributes to the attenuation effect mentioned above due to a UV screening effect.

The transient decay traces such as that shown in Fig. 1A can frequently be fitted with a biexponential expression; however,

such a treatment is probably of little significance (*vide infra*) and should be regarded simply as a convenient form of analysis that may only be useful in some cases (e.g., when comparing the effects of scavengers within a selected time scale). The results in Figs. 1 and 3 demonstrate that the time domain selected for monitoring plays a key role in determining the observed dynamics. In experiments similar to those in Fig. 1, we recorded half-lives of 0.8 ms and 0.2 s for tpps of 0.9 μs and 100 μs, respectively. The initial signals on the longer time scale were typically about 10% of those recorded in the traces measured at 50–100 ns tpp. This clearly indicates that ~80% of the radicals decay during the first millisecond.

Studies of surface coverage illustrate some of the interesting features of radical decay on surfaces. For example, a comparison of 1 and 3% w/w samples of TPA on a tpp of 0.1 μs show that the initial absorbance is only about 25% higher for the higher coverage. The decay kinetics are similar for the two samples over a range of time scales (0.1–1.0 μs tpp) and in both cases the amount of residual absorption is the same within experimental error. It is possible that at the higher coverage there may be a higher proportion of fast decay processes, which are not observable on our shortest time scale and which tend to deplete a higher fraction of the initial radical concentration for the 3% sample.

Oxygen has a dramatic effect on the transient decay traces for diphenylmethyl radical on silica gel. The initial optical absorption decreases between 20 and 50% with respect to that observed under nitrogen for both short (tpp = 50 ns) and intermediate (tpp = 5 μs) time scales. The effect on the dynamics of radical decay is even more dramatic. Figure 5 shows decay traces under oxygen and nitrogen; these were recorded on time scales that differ by approximately a factor of three in order to adequately capture the two decay processes. Under oxygen the decay fits reasonably a monoexponential process with a lifetime of 280 ns, although there is some residual absorption (~20%). This residual and the fact that some radicals persist for very long times (*vide supra*) suggest the presence of a limited number of highly protected sites. In addition, the variations in amplitude in the presence of nitrogen, air, and oxygen suggest that even faster processes than those monitored for tpp < 20 ns may account for some of the loss of signal in the presence of oxygen. Note, for example, that the amplitude is higher under nitrogen despite the longer acquisition times.

Our results also indicate that sequential two-photon processes may play a role in the very early phenomena observed upon laser excitation. Specifically, in the 530 nm region we detect a short-lived emission that is readily characterized as due to excited $Ph_2\dot{C}H$ produced by photoexcitation of $Ph_2\dot{C}H$ formed during the early part of the laser pulse. The lifetimes for this emission ranged from 130 to 170 ns in various samples, corresponding to about one half the lifetime in homogeneous solution (236 ns in methanol) (15). Figure 6 illustrates a typical decay trace and the emission spectrum obtained for a sample containing 5% w/w TPA. The excited radicals probably represent only a small fraction of the radicals present; in solution the decay of excited diphenylmethyl radicals occurs without chemical change. It is not clear if their fate is the same on silica surfaces.

NaX zeolite

In some respects the data obtained for diphenylmethyl radicals in this zeolite are similar to those observed on silica gel. The transient produced upon excitation of TPA on NaX may be readily identified as the diphenylmethyl radical on the basis of its spectrum (Fig. 2). Just as in the case of silica gel, there are no absorption maxima above 400 nm. However, the decay of the radicals occurs less rapidly than on silica gel. For example, Fig. 7 shows decay traces monitored on both 0.1 and 2 μs tpp for a 1% w/w sample; the trace on the longer time scale still shows extensive residual absorption even after 500 μs. When this residual is compared to the maximum signal obtained on the shorter time scale, one can estimate that the residual accounts

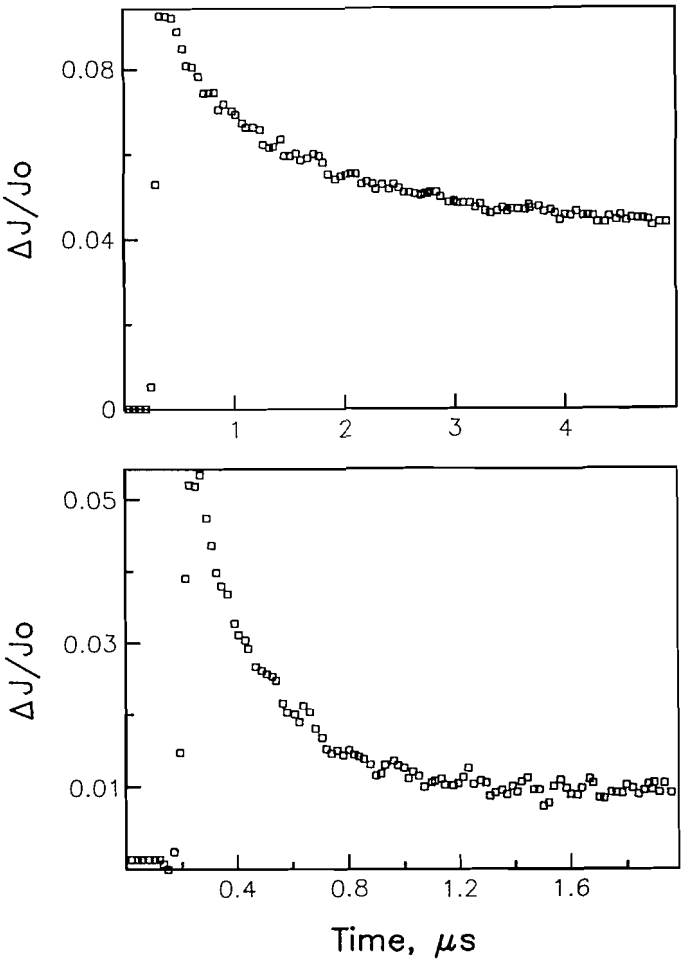

FIG. 5. Transient decay traces monitored at 340 nm for a 3% sample of TPA on silica gel in the presence of nitrogen (top) and oxygen (bottom).

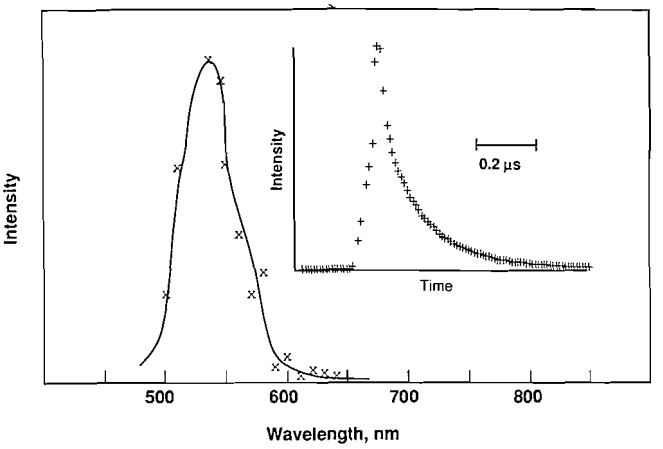

FIG. 6. Emission spectrum for the diphenylmethyl radical obtained by 266 nm excitation of 5% TPA on silica gel. Insert: emission decay trace monitored at 530 nm for the same sample.

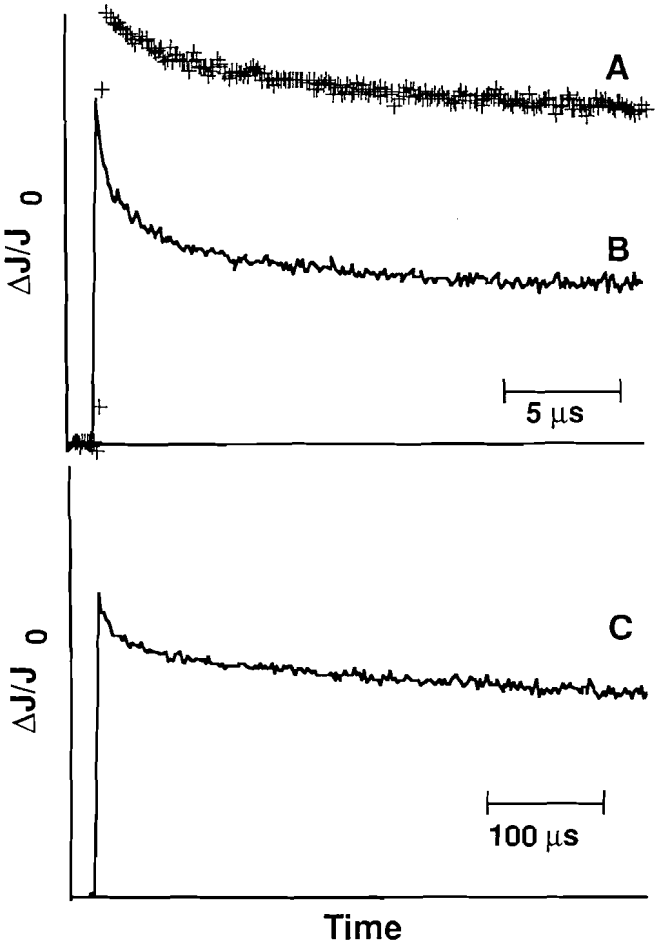

FIG. 7. Transient decay traces monitored at 340 nm following 266 nm excitation of 1% TPA on NaX in the presence of nitrogen (A, C) and oxygen (B). The vertical scale is the same for all three traces.

for 40% of the original signal, i.e., ~3% times that obtained on silica gel. The somewhat higher initial signals for the NaX samples and the slower decays suggest that in this case there are probably fewer radicals decaying on shorter time scales than those we can conveniently monitor.

Ground-state diffuse reflectance studies similar to those already described for silica gel show that the residual absorption also corresponds to the diphenylmethyl radical. These experiments lead to lifetimes of over 30 min, which may be compared to the fact that transient decay traces such as those in the insert of Fig. 6 show that a significant fraction of the initial radicals decay in ~20 μs. This corresponds to a range of time scales of over seven orders of magnitude. As far as we can tell, any time scale within this range will show that a significant fraction of the remaining radicals will decay over the time frame monitored.

The reactivity towards oxygen is considerably lower for diphenylmethyl radicals on NaX as compared to silica gel. Figure 7 shows decay traces recorded on a tpp of 0.1 μs for a sample of 1% TPA on NaX in the presence of nitrogen and oxygen. In the presence of oxygen approximately half of the detectable radicals decay within ~4 μs and the observed decrease in the maximum signal indicates that there are some which decay even more rapidly. Qualitatively similar results are observed for a 3% w/w sample. Despite the fact that some of the radicals react reasonably efficiently with oxygen, the residual absorption indicates that there are others which are very well protected from the quencher. This is further confirmed by

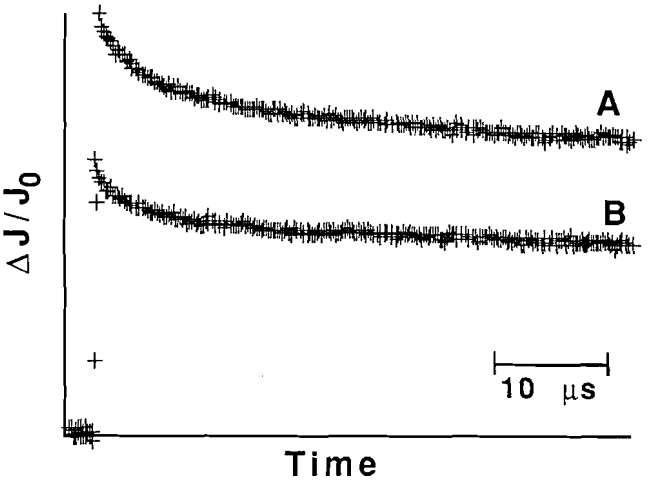

FIG. 8. Transient decay traces monitored at 340 nm following 266 nm excitation of 3% TPA (A) and 1% TPA (B) on NaX.

examining the radical decay under oxygen on longer time scales (1–2 μs tpp). In this case the amount of residual absorption is decreased to approximately one third of what it was under nitrogen but the decay kinetics for the two are very similar. These results suggest that there is a very wide variation in the accessibility of the radicals to oxygen for the NaX samples.

Changes in the load of TPA (1% vs. 3% w/w) show a more pronounced enhancement in the initial signals for the higher load than do those on silica gel. For example, for samples under nitrogen at a tpp of 0.2 μs the ratio of initial signals was ~1.7 for the high/low load. This may be a reflection of the fact that the radicals are longer lived on NaX and there is, therefore, a smaller fraction of radicals that decay on shorter time scales than we can monitor. There may also be contributions due to differences in the light penetration depth for the various supports. As shown in Fig. 8, the two samples showed very similar decay kinetics. The residual absorption was larger for the higher load, although the residuals accounted for similar fractions of the initial signals for both samples.

The effect of laser power on the signals was examined for a 1% w/w sample under nitrogen. Attenuation of the laser by a factor of eight decreased the signal intensity to 34% of its initial value as measured on a tpp of 0.2 μs and there was essentially no change in the decay kinetics or the relative amounts of residual absorption. Very similar results were also obtained on a longer time scale (2 μs tpp).

Silicalite

The transient spectrum for TPA on Silicalite agrees well with that expected for diphenylmethyl radical. In general, the radicals decayed considerably more rapidly on Silicalite than on NaX and there was less residual absorption. This is illustrated in the decay trace for a 3% w/w sample on 0.1 μs tpp shown in Fig. 9. In this system approximately 80% of the radicals decayed within 10–15 μs and the traces gave reasonable fits to a monoexponential decay.

Ground-state diffuse reflectance experiments similar to those described for both silica gel and NaX samples were attempted for Silicalite samples. Although there were certainly changes in the ground-state spectra recorded at increasing delays after the laser irradiation, these were not sufficiently large or reproducible to allow us to positively conclude that we were looking at long-lived diphenylmethyl radicals. The problems with this particular system arise partly from the fact that the lower absorption for these samples results in lower initial radical

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12

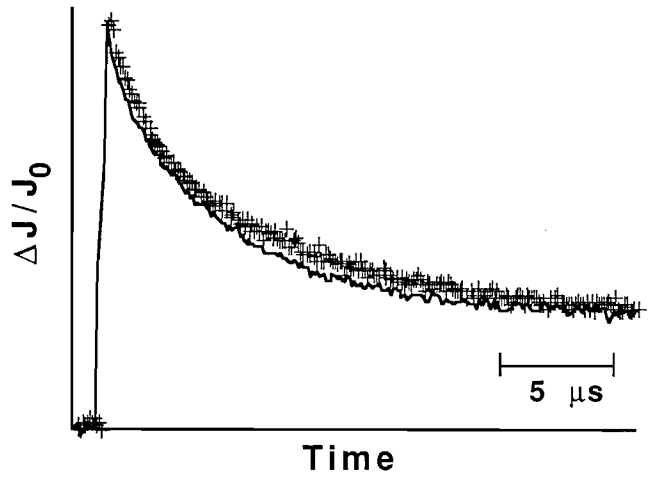

FIG. 9. Transient decay traces monitored at 340 nm following 266 nm excitation of 3% TPA on Silicalite in the presence of nitrogen (+) and oxygen (−).

concentrations and partly from the more rapid deterioration of the samples at high laser doses.

Loading effects were also examined for Silicalite samples. The ratio of initial signals on a tpp of 0.1 μs was ~2.5 for 2.5%/0.6% samples. However, the decay kinetics were identical for the two samples. Similarly, there was very little effect of oxygen on the decay of the radicals on a tpp of 0.1 μs (Fig. 9), although for some samples there were small changes in the amounts of initial signals. These results are in sharp contrast to the oxygen effects on silica gel where very efficient quenching was observed, and suggest that the diphenylmethyl radicals move into the Silicalite channels where they are well protected from oxygen.

Attenuation of the laser dose leads to results similar to those already discussed for silica gel and NaX. That is, there was no change in the decay of the radicals and the maximum signal decreased to 38% of its initial value for an eightfold decrease in laser dose.

Product studies

Laser excitation (266 nm) of TPA on silica gel gave 1,1,2,2-tetraphenylethane as the main product along with trace amounts of benzophenone. The high yield of the radical dimer is the anticipated result based on the solution behavior of diphenylmethyl radicals. To carry out experiments at higher conversions under relatively simple irradiation conditions, we carried out a series of lamp irradiations for TPA on all three supports. To our surprise, the products extracted from a photolysed sample on silica gel showed approximately equal amounts of benzophenone and tetraphenylethane, whereas on NaX the benzophenone accounted for only 20–30% of the isolated products.[4] In contrast, photolysis of TPA on Silicalite yielded very little benzophenone.

Several experiments were carried out to test for the involvement of water and oxygen in the production of benzophenone in the lamp irradiations. Firstly, matched samples of TPA (1%) on each of the three supports were degassed and then had either nitrogen or oxygen added. The product mixtures extracted after irradiation showed similar amounts of benzophenone and tetraphenylethane for the two samples under nitrogen and oxygen for each of the supports. Secondly, a sample of the ketone on silica gel was prepared using silica gel that had been dried and then stored under dry conditions. The sample was then equilibrated with water-^{18}O as described in the experimental section and irradiated. Based on GC/MS analysis of the extracted products, there was no evidence for the incorporation of ^{18}O in the recovered benzophenone. These experiments indicate that neither oxygen or water present in the sample during the photolysis is responsible for the isolation of benzophenone from the irradiated samples. At this point the only other possibilities which come to mind are the incorporation of oxygen from the surface itself or during the extraction procedure. The former seems very unlikely; the latter possibility would require the presence of a stable intermediate, which reacts during the extraction procedure but is not sensitive to water or oxygen present during the photolysis. Additional experiments are obviously necessary to identify the source of this unexpected formation of benzophenone. However, the products in the laser irradiation give us confidence that this unusual reaction of diphenylmethyl radicals is of minor importance under the conditions of our transient experiments.

Conclusions and suggestions for improved kinetic analysis

The above results demonstrate that diphenylmethyl radicals may be readily generated on silica gel, and on the zeolites NaX and Silicalite. Table 1 summarizes the data obtained for the three supports under a variety of conditions of loading, degassing, and laser intensity. The diphenylmethyl radicals show a very wide range of lifetimes on all three supports, as evidenced by the fact that one can obtain lifetimes of anywhere from several microseconds to minutes. Furthermore, for some of the samples there are probably radicals that are decaying on shorter time scales than we can monitor. These results suggest that there are a wide range of possible sites or environments for the radicals. It should be noted that these may reflect largely the distribution of the radicals with respect to each other and the starting ketone rather than particular surface sites on which the radicals are particularly stable. For the surface loadings that have been examined in these experiments, we do not see any evidence for preferential filling of particular sites at low loadings. Neither do we see attenuation effects that can be attributed to the dominance of second-order components in the decay of the radicals. A lengthening of the transient lifetimes would have been expected if radical–radical coupling involving diffusion of both partners was determining the transient lifetime. However, we note that the product studies indicate that the radical dimer accounts for most of the products for the laser irradiations. It is likely that a large fraction of the radicals decay very rapidly via dimerization and are invisible in our transient experiments.

Our results for the three supports indicate that diphenylmethyl radicals have substantially longer lifetimes on NaX than on silica gel or Silicalite. Even more striking differences are observed between the three supports in the oxygen quenching experiments. The radicals are very well protected from oxygen within the channel structure of Silicalite but are rapidly quenched by oxygen on silica gel. This is consistent with the much larger pores in the silica gel structure, which should allow ready access of oxygen to most of the available surface area. The intermediate size of the cages and channels in NaX results in behavior that is intermediate between that of silica gel and Silicalite.

It is clear from the preceding discussion that at the present time we lack a good model that would allow us to interpret the kinetic behavior of free radicals on nonreactive surfaces.

[4]We emphasize that benzophenone is an important product *only* under lamp irradiation. Under laser excitation only traces of benzophenone are detected.

TABLE 1. Summary of results

Effect	Silica gel	NaX	Silicalite
Absorption sites	Surface/pores (60 Å)	Cavities ca. 12 Å Channels ca. 8 Å	Surface for TPA, surface + channels for radicals
Initial (100 ns) signal ($\Delta J/J_0$)	High	Highest	Low
Decay fraction 0.2 μs ⇒ 100 μs	~85%	≤50%	>80%
Long-lived radicals (minutes) detected	Yes	Yes	Possibly
Decrease of laser dose of 8:1	Load 1%; tpp 0.2 μs	Load 1%; tpp 0.2 μs	Load 0.6%; tpp 0.2 μs
on ($\Delta J/J_0$)	1:0.2	1:0.34	1:0.38
on kinetics	Minor	Minor	Minor
Reduce load by 3			
on ($\Delta J/J_0$)	1.3:1	1.7:1	2.5:1
on kinetics	Similar	Very similar	Identical
Oxygen effect			
on ($\Delta J/J_0$)	20–50% decrease	<20%	Small decrease
on kinetics	1st order with τ of 280 ns and 20% residual	50% decay in 4 μs, the rest well protected; decay complex	no effect for tpp 0.1 μs, decay as under nitrogen
Excited radical detected?	Yes		

First- and second-order kinetic analyses, as well as various combinations of these, fail to provide a good versatile model suitable for the interpretation of data obtained over a wide range of time scales. This situation is neither new, nor specific to free radicals; for example, in the case of xanthone triplets on Silicalite (13), we obtained traces on time scales differing by a factor of 1000, which in spite of this look remarkably similar. While the simple approach of earlier sections is useful in comparing specific effects (oxygen, loading, laser dose), it cannot offer a detailed understanding of the system. Quite clearly, our data emphasize the need for a better model.

In the last few years dispersive kinetic analysis has provided a solid basis for understanding some complex kinetic problems in solid systems (22–27), notably, the decay kinetics of methyl radicals in methanol glasses (23–27). This analysis assumes a distribution of rate constants for decay; detailed models are available for a Gaussian distribution of exponential decays. This analysis leads to the conclusion that a plot of (signal) vs. log (time) should give a smooth sigmoid curve, from which it is possible to determine the *most probable rate constant* (at the peak of the distribution) as well as the width of the distribution; the former is obtained directly from the inflection point of the plot mentioned above. While keeping in mind the mechanistic differences between our system and that for which the model was developed, we tried a similar representation. This is illustrated in Fig. 10 for TPA on silica gel under nitrogen (top) and TPA on NaX (bottom) in the absence and presence of oxygen.[5] A polynomial fit of these curves indicates inflection

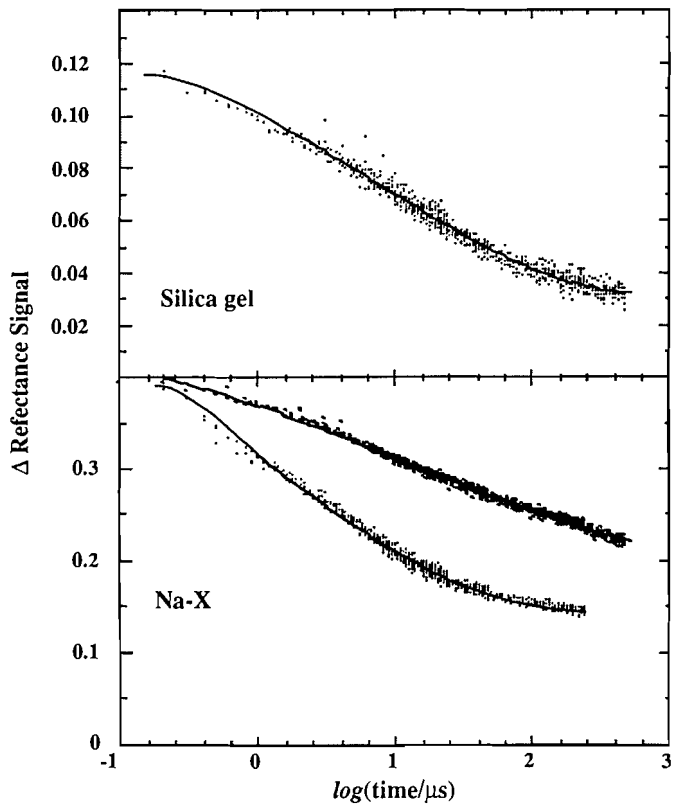

FIG. 10. Decay of diphenylmethyl radicals on silica gel under nitrogen (top) and in NaX under nitrogen (bottom, upper trace) and oxygen (bottom, lower trace), plotted following the format employed for dispersive kinetics analysis (see text). Four or five traces on different time scales were combined in each case by normalizing in the time range where they overlap.

[5]To obtain the data in Fig. 10 it is necessary to combine traces obtained in different, but overlapping, time scales. To do this the traces were normalized in the overlap region, since variations of the laser dose from shot to shot tend to cause some vertical displacements. This normalization required multipliers in the 0.86–1.26 range.

points at 7.3, 10.5, and 0.97 μs for silica gel (N_2), NaX (N_2), and NaX (O_2), respectively. Clearly, oxygen reduces dramatically the most probable value of the lifetime; in addition, the corresponding curve shows a clear break after the first 60% of the decay is complete. This suggests that under oxygen there are at least two distributions of lifetimes, indicating that some radicals are better protected than others.

In summary, it would appear that a model based on dispersive kinetics can probably be adapted to the understanding of radical self-reactions on solid supports. At this point, three advances are needed before a proper quantitative analysis can be performed: (i) an adequate mathematical model; (ii) an improvement in the time resolution of the experiment, so that the early part of the decay can be monitored in more detail; and (iii) temperature dependence capabilities in the diffuse reflectance measurements. These problems are currently being addressed.

Computer simulation studies of the solvation of oligosaccharides

HELMUT BEIERBECK[1] AND RAYMOND U. LEMIEUX[2]
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received August 30, 1989

HELMUT BEIERBECK and RAYMOND U. LEMIEUX. Can. J. Chem. **68**, 820 (1990).

Computer simulations of the hydration of the tetrasaccharide αLFuc(1→2)βDGal(1→3)[αLFuc(1→4)]βDGlcNAc-OMe and one of its deoxy derivatives were carried out as a first step toward an understanding of the role of water in the recognition of oligosaccharides by proteins. The model consisted of one solute molecule in one of its low-energy conformations, surrounded by 250 water molecules. The solute–water and water–water interaction energies were evaluated with Clementi's potentials. Ensemble states for the derivation of average properties were generated by Monte Carlo methods. As expected, the strength of interaction between water and the amphiphilic solute was found to be considerably greater at hydrophilic than at hydrophobic sites. Furthermore, the average distance between the solvation shell and the solute surface was about 1 Å greater near hydrophobic than around hydrophilic groups. There is also a definitive alignment of the water dipole around the hydroxyl groups of the saccharide, which is not evident over the hydrophobic regions. Finally, in a parallel investigation the tetrasaccharides were solvated by adding water to the solute at sites of minimum energy of association, in order to explore less-CPU-time-consuming alternatives to Monte Carlo simulations. While the patterns of interaction energies, distances, and dipole orientations were found to be similar to Monte Carlo results, the time savings were not as significant as hoped.

Key words: Monte Carlo simulations, numerical solvation studies, solvation simulations of oligosaccharides, molecular recognition, carbohydrate solvation.

HELMUT BEIERBECK et RAYMOND U. LEMIEUX. Can. J. Chem. **68**, 820 (1990).

Comme première étape vers une compréhension du rôle de l'eau dans la reconnaissance des oligosaccharides par les protéines, on a effectué des simulations par ordinateurs de l'hydratation du tétrasaccharide αLFuc(1→2)βDGal(1→3)[αLFuc(1→4)]βDGlcNAc-OMe ainsi que celle d'un de ses dérivés désoxylés. Le modèle comporte une molécule de soluté, dans l'une de ses conformations de basse énergie et entourée par 250 molécules d'eau. Utilisant des potentiels de Clementi, on a évalué les énergies d'interaction soluté–eau et eau–eau. On a fait appel à des méthodes de Monte Carlo pour générer les états d'ensemble nécessaires pour dériver les propriétés moyennes. Comme on pouvait s'y attendre, on a trouvé que la force de l'interaction entre l'eau et les solutés amphiliques est beaucoup plus importante aux sites hydrophiles plutôt qu'aux sites hydrophobes. De plus, la distance moyenne entre la couche de solvatation et la surface du soluté est environ 1 Å plus grande près des groupes hydrophobes qu'autour des groupes hydrophiles. Il existe aussi un alignement certain du dipôle de l'eau autour des groupements hydroxyles du saccharide; on n'observe pas ce phénomène dans les régions hydrophobes. Enfin, dans le cadre d'une étude parallèle destinée à évaluer des méthodes de calcul alternatives demandant moins de temps de CPU que les simulations de Monte Carlo, on a solvaté des tétrasaccharides par l'addition d'eau au soluté à des sites d'énergie minimale d'association. Alors que les résultats pour les énergies d'interactions, les distances et les orientations dipolaires sont très semblables à celles obtenues à l'aide de simulations de Monte Carlo, le temps de calcul qui est sauvé n'est pas aussi important qu'on l'avait espéré.

Mots clés : simulations de Monte Carlo, études numériques de solvatation, solvatation simulations des oligosaccharides, reconnaissance moléculaire, solvatation du hydrate de carbone.

[Traduit par la revue]

Introduction

The formation in aqueous solution of a complex between an oligosaccharide and a protein is expected to be enthalpy driven as the result of an energetically favorable exchange in molecular partnerships. The changes in intermolecular polar and nonpolar interactions occur not only between the complementary surfaces presented by the oligosaccharide and the protein, but also between the solute surfaces and the solvation shell. Therefore the driving force for molecular association cannot be properly understood without a consideration of the role played by water.

To better appreciate the energetics of molecular recognition we initiated computer simulations of intermolecular interactions, particularly interactions with the solvation shell. We chose for these solvation studies the tetrasaccharide αLFuc (1→2)βDGal(1→3)[αLFuc(1→4)]βDGlcNAc-OMe, or Le^b-OMe (Fig. 1), a carbohydrate related to the determinant of the human Lewis b blood group. Le^b-OMe is one of a number of oligosaccharides whose recognition by lectins and antibodies we have studied (1–8). It is conformationally well defined in aqueous solution and strongly bound ($\Delta G^\circ = -6.3$ kcal/mol at 305 K) by GS4, the readily accessible fourth lectin derived from the African plant *Griffonia simplicifolia*. We were able to identify the key functionalities of Le^b-OMe from the relative potencies of its derivatives, and to propose models for its recognition by the protein receptors. The conclusions from the immunological work on the Le^b-OMe–GS4 system are supported by the strong binding between GS4 and the Y-tetrasaccharide, another human blood group determinant which differs from Le^b-OMe only by the interchange of the substituents at C-3a and C-4a. In aqueous solution these two oligosaccharides have precisely those surface features in common that, according to the immunological data, are recognized by GS4. Another reason for the choice of Le^b-OMe in the computer simulations was the successful crystallization of complexes of Le^b-OMe and derivatives with GS4 (9). The crystal structure of the Le^b-OMe–GS4 complex has recently been established to 2.8 Å resolution (10).

The main approach to the computer analysis of Le^b-OMe solvation consisted of Monte Carlo simulations and ensemble averaging. However, in a second series of calculations low-energy solvation clusters were generated by adding water molecules to the emerging shell at geometries of minimum energy. This was done mainly to see whether information comparable to Monte Carlo results could be obtained at lower

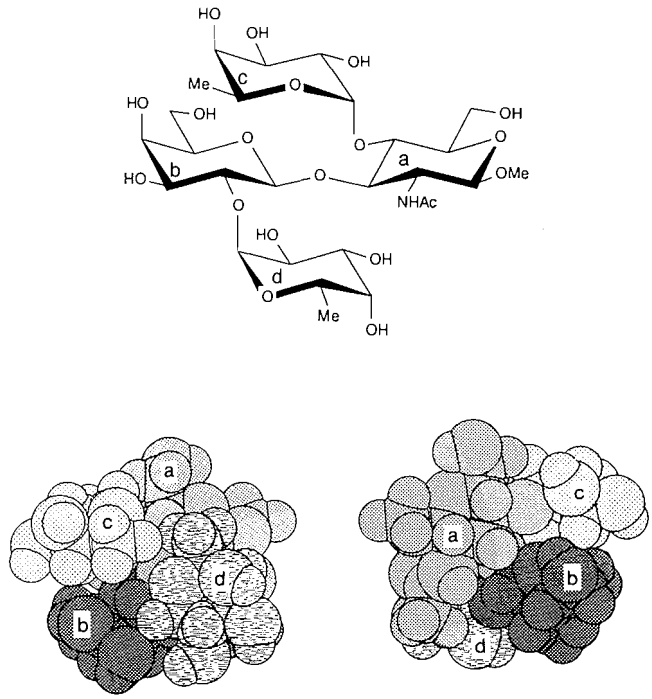

FIG. 1. Structure of the Le^b-OMe tetrasaccharide related to the human Lewis-b blood group determinant, and views of opposite sides of a CPK model of Le^b-OMe.

computing costs. In all cases Clementi's additive potentials for solute–water (11, 12) and water–water (13) interactions were used.

The work described here represents the first stage in an investigation aimed at an appreciation of the differential changes in enthalpy that occur in the binding of Le^b-OMe and its derivatives by GS4.

Methods

The Le^b-OMe coordinates were generated in the usual way from X-ray data for the monosaccharides (14), using the torsion angles about the intersugar glycosidic bonds for the predominant conformation, as determined by ^{1}H NMR interunit deshielding effects and nuclear Overhauser enhancements (8). This same conformation also proved to be an energy minimum in hard sphere *exo*-anomeric (HSEA) calculations (15) and was found to be compatible with the electron density map determined by X-ray diffraction (10). The glycosidic C—O—C valency angles were set to 117° (14).

ϕ^H	ψ^H
H—C-1b—O—C-3a = 55°	C-1b—O—C-3a—H = 10°
H—C-1c—O—C-4a = 55°	C-1c—O—C-4a—H = 25°
H—C-1d—O—C-2b = 45°	C-1d—O—C-2b—H = 15°

Free rotation about all ten hydroxyl groups of Le^b-OMe would give rise to 3^{10} staggered conformations. Based on our immunological results the hydroxyl group orientations on the CPK model shown in Fig. 1 are considered the most likely arrangement in the GS4–Le^b-OMe complex. This will therefore be the reference conformation throughout this presentation, although other Le^b-OMe conformers were also used in the solvation simulations. The bond lengths, 0.9572 Å, and valency angle, 104.5°, for the water molecule were taken from the paper by Benedict *et al.* (16).

The energy of interaction between atom i of the organic solute and atom j of water was calculated with Clementi's three-term expression (11, 12):

$$[1] \quad E_{ij} = -A_{ij}/r_{ij}^6 + B_{ij}/r_{ij}^{12} + C_{ij}q_iq_j/r_{ij}$$

where r_{ij} is the internuclear distance, q_i and q_j are effective nuclear charges, and A_{ij}, B_{ij}, and C_{ij} are constants (see Tables V and VII in ref. 12). There are two sets of constants A, B, and C for every class of solute atoms, i.e., every substitution pattern, one for the interaction with water oxygen atoms and one for hydrogen. The q_i and q_j are the average class charges computed by Fraga (17) from Clementi's quantum-mechanically obtained effective nuclear charges for amino acids (11) and DNA bases (12). These class charges were scaled (17) according to eq. [2]:

$$[2] \quad q_i^{\text{corr}} = q_i\,(1 + cq_i/|q_i|)$$

where

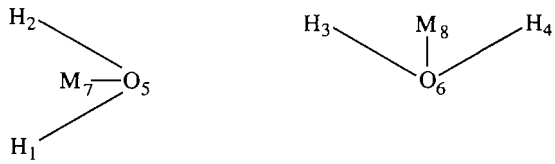
$$c = (q^m - \sum_i q_i)/\sum_i |q_i|$$

in order to arrive at the correct (neutral) molecular charge for Le^b-OMe, $q^m = 0$. The water charges were $q^H = 0.3321$ and $q^O = -0.6642$ esu (18). The average and corrected charges are shown in Table 1, and the class assignments are given in Table 2.

The energy of interaction between two water molecules was calculated with Clementi's expression (13):

$$\begin{aligned}[3] \quad E_{WW} = {} & q^2[(1/r_{13} + 1/r_{23} + 1/r_{14} + 1/r_{24}) + 4/r_{78} \\ & -2(1/r_{18} + 1/r_{28} + 1/r_{37} + 1/r_{47})] + a_1\exp(-b_1r_{56}) \\ & + a_2[\exp(-b_2r_{13}) + \exp(-b_2r_{14}) + \exp(-b_2r_{23}) \\ & \qquad + \exp(-b_2r_{24})] \\ & + a_3[\exp(-b_3r_{16}) + \exp(-b_3r_{26}) + \exp(-b_3r_{35}) \\ & \qquad + \exp(-b_3r_{45})] \\ & - a_4[\exp(-b_4r_{16}) + \exp(-b_4r_{26}) + \exp(-b_4r_{35}) \\ & \qquad + \exp(-b_4r_{45})].\end{aligned}$$

where q^2, a_1–a_4, and b_1–b_4 are constants (see Table VIII, column ϵ_{inter} in ref. 13), the r_{ij} are distances between H, O, and M, and M is a point along the C_{2v} axis of water, 0.26765 Å from oxygen.



The charges and coefficients for eq. [1] are the result of quantum-mechanical calculations for amino acids and DNA bases. While the assignment for most of the Le^b-OMe atoms presented no problem, no parameters were available for the anomeric carbons. These atoms were therefore assigned to class 18, together with all other oxygenated carbons (Table 2), which is undoubtedly the most questionable of all class assignments. For example, the effective nuclear charges for the anomeric carbons in DNA fragments were calculated to be 0.13–0.14 esu (19), i.e., considerably more positive than 0.008, the net charge for class 18.

Low-energy solvation shells were constructed by adding one water molecule at a time to the growing cluster, at a geometry of minimum energy, i.e., a hydrogen-bonding site. A set of r^2

random water coordinates (probe locations) was generated, restricted only by the requirement that the oxygen atoms lay on a sphere of radius $r + 3$ from the center of mass of the solute. The radius r was initially the largest distance of any atom from the solute center and was subsequently replaced by the largest distance of any water oxygen atom from the center. A water molecule, the probe, was then placed at each probe location in turn, and that probe was rotated and translated until a probe geometry of minimum energy was reached. The search for the energy minima was carried out by the method of steepest descent (20). When all probe locations were optimized, one of the minima was occupied and that probe geometry was replaced in the probe coordinate set by new random coordinates. If r increased, a corresponding number of new random coordinates was added to the set of probe locations, and the next search cycle was started. Occupation of the geometry of lowest energy resulted in poor coverage, since existing water molecules were solvated in preference to hydrophobic regions of the solute to form clusters of water molecules, as shown in Fig. 2a. A uniform coverage was achieved by picking that geometry instead, which put the water oxygen atom closest to the center of Le^b-OMe, as shown in Fig. 2b. The addition of 250 water molecules gave reasonable coverage of Le^b-OMe (about three water layers, see Fig. 3a) at acceptable computing costs (about one hour on a Cyber 205 computer).

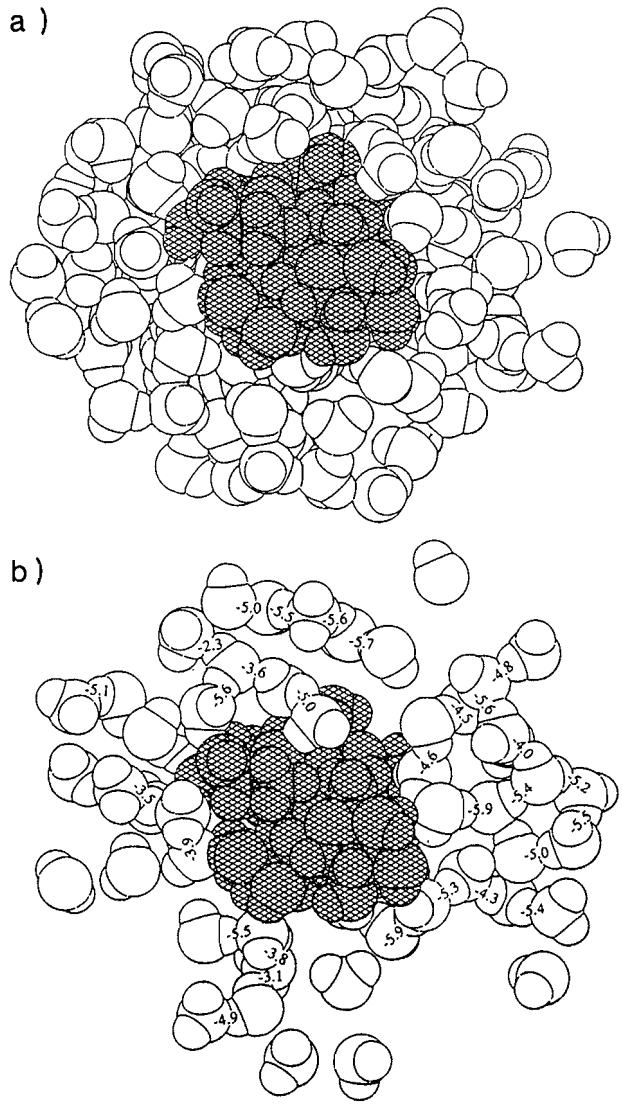

FIG. 3. Cuts through the hydration shell of Fig. 2b. (a) All water molecules in front of the plane through the center of mass of Le^b-OMe were removed to show the thickness of the solvation shell. The Monte Carlo simulations (21, 22) were carried out on solvation clusters consisting of one solute molecule and 250 water molecules, enclosed in a sphere, at unit density and 300 K. The procedure was started either from the low-energy cluster or by randomly adding water molecules to the solute in the spherical enclosure, subject to the constraint that no two atoms approach each other more closely than 90% of the sum of the van der Waals radii. The solute was kept immobile and the water molecules were moved in cycles; in each cycle every water molecule was moved once, in a random sequence. Each move consisted of random translations along, and random rotations about, all three axes by maximally ±0.1 Å and ±0.1 radians, respectively. A move was accepted, i.e., the old water coordinates were replaced, if $\exp(-\Delta E/RT)$ exceeded a random number between 0 and 1, and if the molecule did not penetrate the restraining sphere. If the simulation started from a low-energy cluster, in which case some water molecules usually penetrated the containing sphere, an acceptable move had to fulfil the additional condition that any exterior atom move closer to the sphere. These conditions resulted in the acceptance of about 80% of all moves. The ensemble properties of interest were updated after every move, using either the properties of the new configuration or, if the move was rejected, by using again the old configuration.

Typical Monte Carlo simulations consisted of 500 equilibration and 3000 sampling cycles, i.e., 3000 × 250 different cluster geometries, and required about two hours of Cyber 205 CPU time. Interaction energies between solute atoms and the solvation shell, radial distribution functions for water oxygen, and orientational water correlation functions were calculated.

The radial distribution and orientational correlation functions (23) for water were generated as follows. The space around each solute atom was divided by concentric spheres into intervals of 0.1 Å thickness. Furthermore, a water molecule was considered to be near a given solute atom only if its oxygen atom fell inside a cone of 45° containing the van der Waals sphere of that solute atom and with the cone apex either (X—*H*) on the bond axis or (R—*O*—R′) on the bisector of the valency angle. The radial distribution functions were then constructed by determining the average numbers of water oxygen atoms at the various 0.1 Å intervals from the solute atom. The orientational correlation functions were derived by calculating the average values, for

each 0.1 Å interval, of the cosines of the angles between the C_{2v} axes of the water molecules and the vectors pointing from the solute atoms to the oxygen atoms of the water molecules.

All programs were written in FORTRAN 77, and the calculations were carried out on the Cyber 205 computer at the University of Calgary.[3]

Results and discussion

The stepwise buildup of a solvation shell by energy minimization was mainly undertaken to see if information comparable to Monte Carlo results could be obtained at significantly lower computing costs. This comparison was one of the reasons for enclosing the solvation cluster in a sphere during the Monte Carlo simulation, rather than using a box with periodic boundary conditions (21, 22). The main reason for choosing a spherical enclosure was the need to eventually apply the procedure to the receptor–Le^b-OMe complex, where periodic boundary conditions are inapplicable. The solvation of Le^b-OMe was, in fact, repeated with the usual boundary conditions and found to give essentially the same interaction energies, water–solute distances, and average water orientations near the solute surface.

The addition of 250 water molecules to Le^b-OMe at geometries of minimum energy resulted in a uniform solvation shell, which provided a complete coverage of the solute (Fig. 2b). As the cut solvent shell in Fig. 3a shows, the cluster consists of about three water layers. The hydrogen-bonding network is evident in a slice through the solvation shell (Fig. 3b). Only those water molecules are shown whose oxygen nuclei are within ±0.5 Å of a plane through the center of mass of Le^b-OMe. Some of the energies of hydrogen bonding within the cross section are indicated in the figure. The bonding energies to water molecules outside this slice are of the same magnitude. Solute–solvent interaction energies, radial distribution functions, and orientational correlation functions for low-energy and

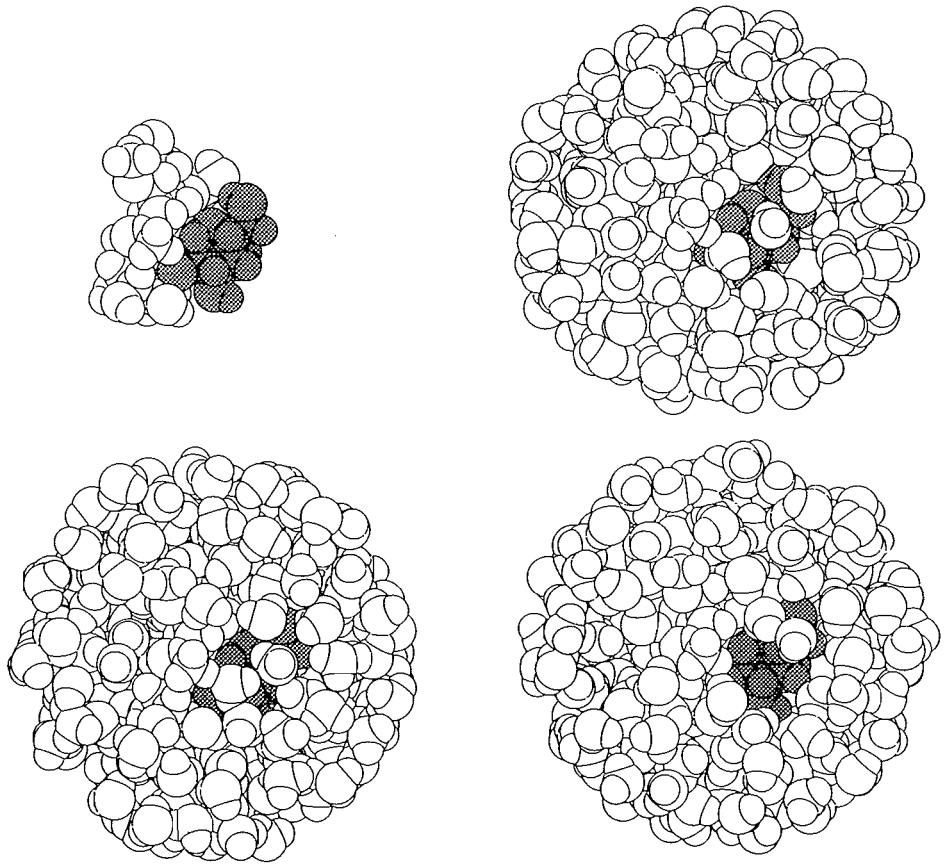

FIG. 6. CPK models of Le^b-OMe and the solvation cluster after 1000 (top right), 2000 (bottom left), and 3000 Monte Carlo sampling cycles, cut to show the extent of hydration of the hydrophobic region of the galactose. H-1b, H-3b, and H-5b are in the plane of the paper, and water molecules entirely in front of a plane 3 Å from these hydrogen nuclei are removed.

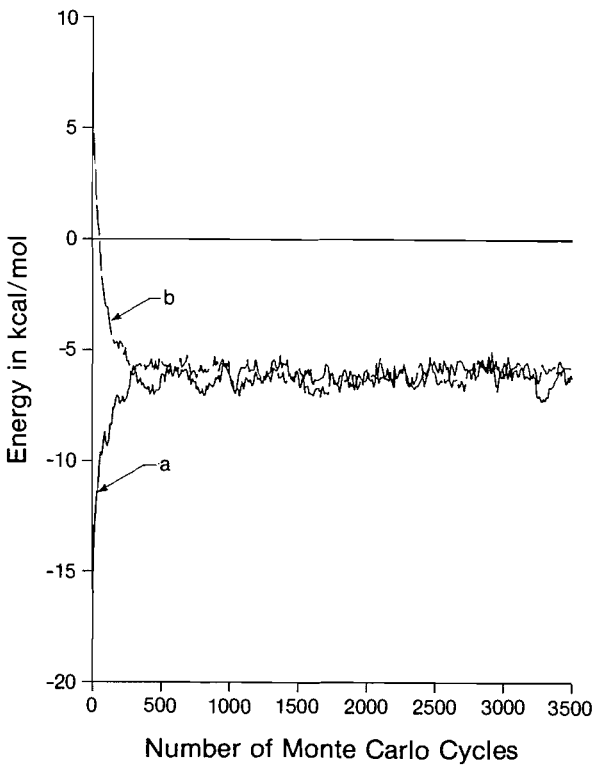

FIG. 7. Convergence of the average energy of interaction between a water molecule and the rest of the Le^b-OMe solvation cluster to the ensemble average, starting from (a) low-energy and (b) random configurations, respectively.

Monte Carlo clusters are compared in Figs. 4 and 5. Figure 4 shows CPK models of Le^b-OMe in which negative energies of interaction between individual solute atoms and the complete solvation shell are identified by dark shading, and positive interaction energies are indicated by light shading. These patterns map out the hydrophilic and hydrophobic surface areas of Le^b-OMe and, as a comparison of Figs. 4a and 4b shows, the distribution of attractive and repulsive interactions is quite similar for the low-energy cluster and the Monte Carlo averages.

Figure 5 shows radial distribution functions (RDFs) and orientational correlation functions (OCFs) for the low-energy (5a) and Monte Carlo (5b) solvation clusters of Le^b-OMe. The hydrophilic and hydrophobic RDFs and OCFs for the low-energy cluster are averages for all O-H and C-H protons in Le^b-OMe, respectively, whereas the corresponding functions for the Monte Carlo cluster are additionally averaged over all sampled states of the solvation shell. In the case of the low-energy cluster, the functions for the hydrophilic protons show sharp peaks at the hydrogen bonding distance (ca. 1.7–1.8 Å), with indistinct features at distances corresponding to second and higher solvation shells. The water molecules are tightly held by the hydroxyl groups of Le^b-OMe and are aligned such that oxygen points toward the solute and the hydrogens into water. The average hydrogen-bonding distances and angles are H...O ~1.98 Å and ∠ O—H... ~157°, from neutron diffraction data for crystalline hydrates (24). The first maximum of the RDF for the hydrophobic hydrogens is not nearly as well defined. The interactions are weaker and often repulsive (Fig. 4), and consequently there is no strongly preferred internuclear distance or water dipole orientation.

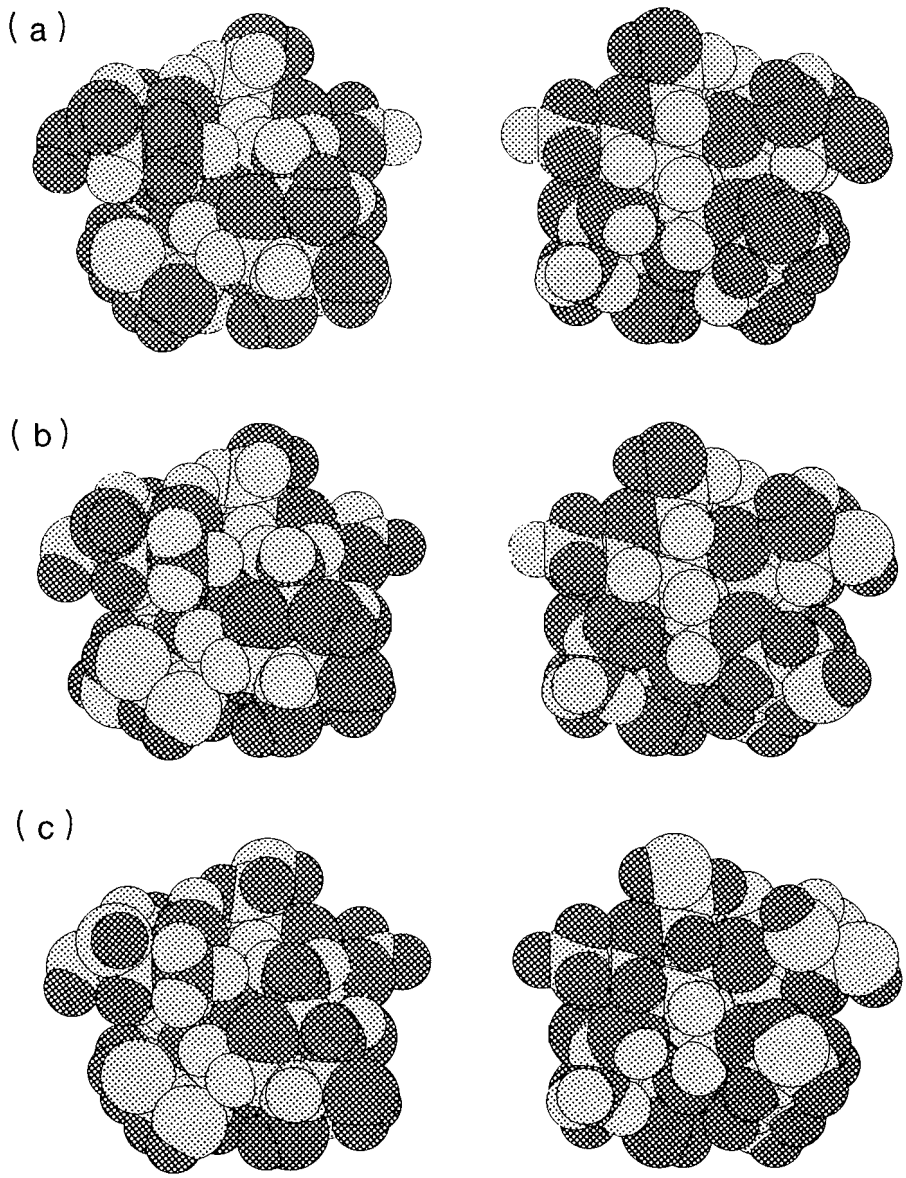

FIG. 8. Energies of interaction between solute atoms and the solvation shell. Atoms with negative interaction energies are darker. (a) Le^b-OMe, differing from the reference conformation in Fig. 1 by rotation about the C-4d—O-4d bond. (b) Le^b-OMe after rotation about bonds C-5b—C-6b and C-6b—O-6b. (c) 4d-Deoxy-Le^b-OMe in the Le^b-OMe reference conformation of Fig. 1.

The RDFs and OCFs from the Monte Carlo simulation show the same trends. For hydrophilic hydrogens the optimal hydrogen-bond length is again the preferred solute–solvent distance, with strongly aligned water dipoles. Near hydrophobic hydrogens, on the other hand, the distance and orientation of the first solvation shell are much less critical. On average, water is about 1 Å further from hydrophobic surface areas than from hydrophilic groups.

That there are voids between the solvation shell and the hydrophobic regions of Le^b-OMe may also be demonstrated by stripping away the solvation shell. For example, if after 1000, 2000, and 3000 Monte Carlo sampling cycles the solvation shell was cut 3 Å from the plane defined by H1b, H3b, and H5b, these three hydrogens were all visible to varying degrees (Fig. 6).

While the results from the low-energy solvation clusters agree satisfactorily with the Monte Carlo simulations, the savings in computing cost were not as significant as hoped, and the stepwise addition of water at minimum energy was abandoned. The low-energy cluster served, however, as a useful test for the convergence of the Monte Carlo simulation to equilibrium (Fig. 7).

Figure 8 shows the patterns of attractive (dark shading) and repulsive (light shading) energies of interaction between solute atoms and the solvation shell, for two slightly different conformers and the 4d-deoxy derivative of Le^b-OMe. The only qualitative change of significance occurs at C-4d of 4d-deoxy-Le^b-OMe, which now falls into a different atomic class. The changes in interaction energies with water on bond rotation are quantitative and essentially restricted to the hydroxyl group closest to the site of conformational change. On rotation about C-4d—O-4d the energy of interaction with the solvation shell increases for O-4d and decreases for HO-4d, without significantly altering the radial distribution functions or orientational correlation function for that hydroxyl group. On rotation about C-5b—C-6b and C-6b—O-6b the same quantitative shift is observed at the hydroxyl group on C-6b.

In summary, the solvation of a tetrasaccharide was computer simulated in two ways, first by building a hydration cluster by water addition at sites of minimum energy, and then by Monte Carlo determinations of ensemble averages over time. The static and dynamic procedures generated essentially the same picture of the distribution and extent of hydrophilic and hydrophobic surface areas. Both methods also showed that there is a strong alignment of the water dipoles around hydrogen-bonding substituents on the oligosaccharide. Finally, the solvation shell was found to be on average about 1 Å further from the lipophilic than from the hydrophilic surface portions, regardless of the orientations of the H—O bonds of Le^b-OMe. This finding supports the earlier expectation (25) that an important contribution to the driving force for complexation is the filling of these voids through the association of complementary surfaces, and, indeed, was the main reason for initiating these studies. Consequently, similar studies of the solvation of the receptor on the protein are planned, once the X-ray structure determination of the GS4—Le^b-OMe complex is completed at the highest resolution that can be achieved. Together these results should afford a much improved appreciation of the role of water in the recognition of oligosaccharides by proteins.

Acknowledgments

This research was supported by an operational grant for research to R.U.L. by the Natural Sciences and Engineering Research Council of Canada (A170). We thank the Supercomputer Allocation Committee of the University of Alberta for generous access to the Cyber 205 computer at the University of Calgary. We are deeply grateful for the opportunity thus granted to explore this approach to the understanding of molecular recognition. We also wish to acknowledge helpful discussions with Professor S. Fraga.

Synthesis of glycan fragments of glycoproteins using peracetylated *N*-allyloxycarbonyl-β-D-glucosamine and 1,6-anhydro-β-D-mannopyranose derivatives

DOMINIQUE LAFONT,[1] PAUL BOULLANGER, JOSEPH BANOUB,[2] AND GERARD DESCOTES

Laboratoire de chimie organique 2, Université Claude Bernard, Lyon 1 (Centre national de la recherche scientifique, Unité de recherche associée n° 463), École superieure de chimie industrielle de Lyon, 43, Bd. du 11 Novembre 1918 – 69622, Villeurbanne CEDEX, France

Received November 24, 1989

DOMINIQUE LAFONT, PAUL BOULLANGER, JOSEPH BANOUB, and GERARD DESCOTES. Can. J. Chem. **68**, 828 (1990).

The disaccharides β-D-GlcNAOC-(1→2)-D-Man, β-D-GlcNAOC-(1→4)-D-Man, the trisaccharide β-D-GlcNAOC-(1→2)-[β-D-GlcNAOC-(1→4)]-D-Man, and the tetrasaccharide β-D-GlcNAOC-(1→2)-[β-D-GlcNAOC-(1→3)]-[β-D-GlcNAOC-(1→4)]-D-Man have been synthesized in their peracetylated form, using the Lewis acid catalyzed condensations of 1,3,4,6-tetra-*O*-acetyl-2-*N*-allyloxycarbonylamino-2-deoxy-β-D-glucopyranose **1** with properly substituted 1,6-anhydro-β-D-mannopyranose derivatives. The anhydro glycosylation products obtained were then easily transformed into the $^4C_1$ peracetylated derivatives by acetolysis. The *N*-allyloxycarbonyl groups could be converted into *N*-acetyl groups in the presence of Pd(0) complexes, followed by reacetylation of the free amino function in high yields.

Key words: *N*-allyloxycarbonyl, glycosylation, glucosamine, glycan fragments.

DOMINIQUE LAFONT, PAUL BOULLANGER, JOSEPH BANOUB et GERARD DESCOTES. Can. J. Chem. **68**, 828 (1990).

Les disaccharides β-D-GlcNAOC-(1→2)-D-Man, β-D-GlcNAOC-(1→4)-D-Man, le trisaccharide β-D-GlcNAOC-(1→2)-[β-D-GlcNAOC-(1→4)]-D-Man et le tétrasaccharide β-D-GlcNAOC-(1→2)-[β-D-GlcNAOC-(1→3)]-[β-D-GlcNAOC-(1→4)]-D-Man ont été synthétisés sous forme acétylée, en condensant, en présence d'un acide de Lewis, le tétra-*O*-acétyl-1,3,4,6-*N*-allyloxycarbonylamino-2-désoxy-2-β-D-glucopyranose **1** avec des dérivés de l'anhydro-1,6-β-D-mannopyranose convenablement protégés. Les produits de glycosylation de type anhydro ont ensuite été transformés, par acétolyse, en composés peracétylés de configuration $^4C_1$. Le passage du groupe protecteur *N*-allyloxycarbonyle au groupe *N*-acétyle a été réalisé par coupure en présence de complexes du Pd(0), suivie d'une réacétylation de la fonction amine libre avec des rendements élevés.

Mots clés : *N*-allyloxycarbonyl, glycosylation, glucosamine, glycan fragments.

Introduction

The chemistry and biochemistry of glycoproteins have acquired a tremendous importance during the past decade (1–3). The glycan chains of glycoproteins have highly complex structures and are abundant at the cell surfaces. Because of these characteristics, they are assumed to play a key role in recognition phenomena and in immunochemical events.

Amongst *N*-glycoproteins, the immunologically important *N*-acetyl-lactosaminic type (1) is composed of a pentasaccharide inner core formed of a trisaccharide of mannose attached by a β-glycosidic linkage to a di-*N*-acetylchitobiose-asparagine-*N*-glycoside. The two terminal non-reducing mannose residues of the pentasaccharide inner core are substituted by a variable number of residues of *N*-acetyl-lactosamine [β-D-Gal-(1→4)-D-GlcNAc]. The linkages between the *N*-acetyl glucosamine and these mannose residues constitute the branched points of the antenna structure.

Previous work in our laboratories (4) established the efficiency of the *N*-allyloxycarbonyl derivatives of D-glucosamine as potent promoters of 1,2-*trans*-glycosylation. Using the *N*-allyloxycarbonyl approach, a variety of disaccharides and immunologically important heptopyranose-disaccharides were synthesized in a stereospecific and regioselective manner. The *N*-allyloxycarbonyl protective group was easily removed with Pd(0) complexes, thus affording the free amino group, which could then be smoothly acetylated.

To broaden the scope of applications of the *N*-allyloxycarbonyl procedure and before attempting to extend this method to the lactosamine-type structures, we devoted our efforts towards the glycosylation of the different positions of D-mannose in order to obtain the different di-, tri-, and tetrasaccharides containing one, two, or three glucosaminyl residues respectively.

We describe in this paper the stereocontrolled syntheses of the fragments β-D-GlcNAc-(1→2)-Man, β-D-GlcNAc-(1→4)-Man, β-D-GlcNAc-(1→2)-[β-D-GlcNAc-(1→4)]-Man, and related precursor oligosaccharides, in their peracetylated forms. These syntheses were realised by the trimethylsilyl triflate glycosylation of the suitably protected 1,6-anhydro-β-D-mannopyranose glycosyl acceptor with 1,3,4,6-tetra-*O*-acetyl-2-*N*-allyloxycarbonylamino-2-deoxy-β-D-glucopyranose as glycosyl donor (4).

Results and discussion

The syntheses of fragments related to compounds **3**, **9**, and **15** have already been reported (5–8) in the literature, using the *N*-phthaloyl derivatives of D-glucosamine or D-lactosamine as donors and various mannopyranosides as acceptors. To our knowledge there have been only a few examples of glycosylations involving 1,6-anhydro-β-D-mannopyranoses as acceptors (8–11). Therefore, because of the bidentate simultaneous protection of the very reactive OH-1 and OH-6 positions, and the ease of opening the anhydro-ring structure, the 1,6-anhydro-β-D-mannopyranoses were chosen as acceptors in this work.

1,6-Anhydro-2,3-*O*-isopropylidene-β-D-mannopyranose **2** (12) was prepared by the Zemplen deacetylation of 2,3,4-tri-*O*-acetyl-1,6-anhydro-β-D-mannopyranose (12, 13) followed by acetalization. Condensation of 1,3,4,6-tetra-*O*-acetyl-2-*N*-allyloxycarbonylamino-2-deoxy-β-D-glucopyranose **1** (4) with one equivalent of the acceptor **2**, promoted by trimethylsilyl trifluoromethanesulfonate (1 equiv.) at low temperature, afforded

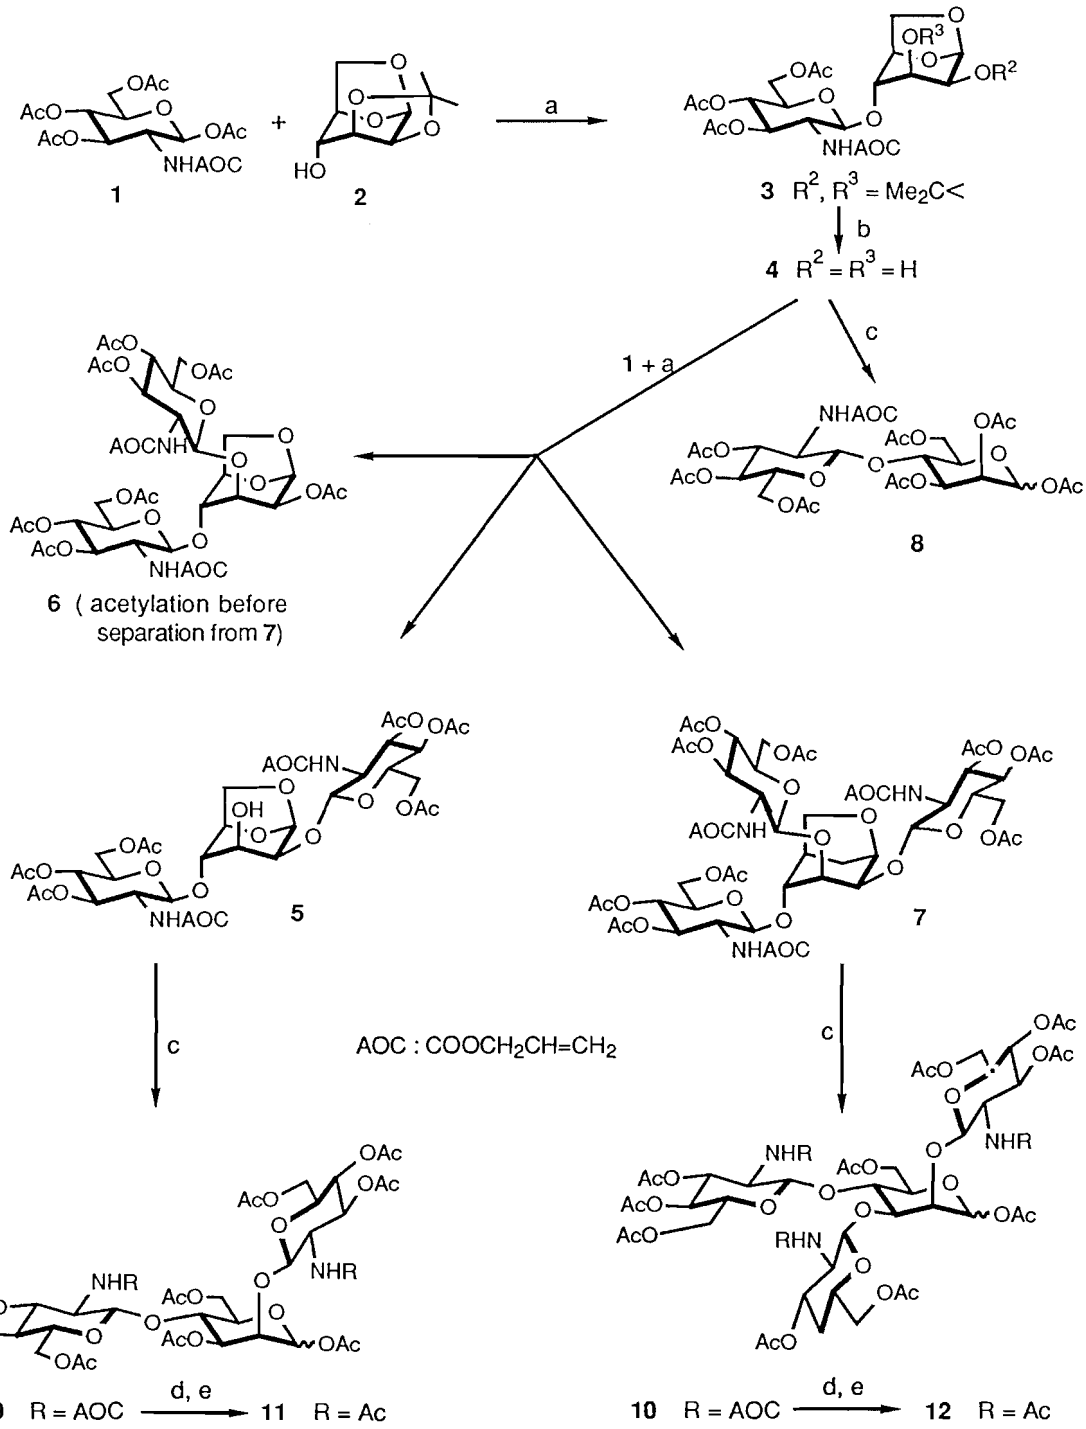

SCHEME 1

the expected β-linked disaccharide in 77% yield. The disaccharide **3** was easily converted into the diol **4** (85%) followed by treatment with 10% trifluoroacetic acid in acetic anhydride to afford an α/β (3:1) mixture of 1,2,3,6-tetra-*O*-acetyl-4-*O*-(3,4,6-tri-*O*-acetyl-2-*N*-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-D-mannopyranose **8** in 91% yield (Scheme 1). The β configurations of the glucosidic linkages were ascertained by ^1H and ^{13}C nmr (Table 1).

Disaccharide **4** was in turn glycosylated with one equivalent of the donor **1**; the trisaccharide **5** was obtained in a 36% yield together with other compounds, which, after acetylation, were separated and identified as the trisaccharide **6** (6%) and the tetrasaccharide **7** (37%). When two equivalents of the donor and the Lewis acid were used, the yields were brought respectively to 17, 4, and 63%. From these results, it can be mentioned that an increase in nucleophilicity of OH-3 is observed when OH-2 has been glycosylated, despite the higher steric hindrance created. Such an observation has already been indicated in the

[e]Spectrum recorded in $CDCl_3$.

glycosylation of 4,6-diols of the *gluco* and *manno* series, using the same glycosylation procedure (14). The precise sites of glycosylation in compounds **5** and **6** were determined by two-dimensional heteronuclear (^1H–^{13}C) shift correlation. In compound **5**, the connectivity between H-2 (δ 3.69 ppm) and C-2 (δ 76.71 ppm) was clearly established. Furthermore, an important upfield chemical shift of C-2 (+9.5 ppm from **4** to **5**) was observed, while in compound **6** the H-2 chemical shift (δ 4.66 ppm) was characteristic of an acetylated OH-2 position of the anhydro ring. The β-glucosidic linkages were also confirmed by both ^1H and ^{13}C nmr.

The openings of the anhydro ring in compounds **5** and **7** were realized to afford respectively **9α** (71%) – **9β** (27%) and **10α** (77%) – **10β** (18%). The deprotection of the *N*-allyloxycarbonyl group for compounds **9α** and **10α** was realized as already reported (4), with catalytic amounts of tetrakis(triphenylphosphine) palladium in the presence of an excess of dimethyl malonate as allyl acceptor. The free amino groups were then reacetylated respectively to afford compounds **11** and **12** with overall yields of 86 and 84%. The ^1H and ^{13}C nmr spectra of these products were in complete agreement with the assigned structures.

An alternative route to the trisaccharide **9** is the stereoselective glycosylation of a OH-4 protected 1,6-anhydro-β-D-mannopyranose. In this route, compound **2** was reacted with trichloroethylchloroformate (15) to afford compound **13** in 90% yield. After hydrolysis of the 2,3-isopropylidene protective group from **13**, the compound **14** obtained was glycosylated with one equivalent of the glycosyl donor **1**, as already described for the disaccharide **4**. Two disaccharides (**15** and **16**) and one trisaccharide (**17**) were separated from the reaction mixtures in the respective yields of 56, 10, and 16%. The regioselectivity of this reaction was due to a lack of reactivity of the C-3 position and could be attributed to the deactivating effect of the strongly electronegative trichloroethoxycarbonyl protective group on OH-4 (Scheme 2).

The regio- and stereochemistry of glycosylation at the anomeric centers of disaccharides **15** and **16** were determined by ^1H and ^{13}C nmr. The chemical resonances of glycosylated carbon atoms were shifted upfield from their values in the diol

14 (respectively 8.9 and 10.0 ppm for C-2 in **15** and C-3 in **16**) while the non-glycosylated positions remained unchanged. The 1,2-*trans*-glycosylation was confirmed by the ^{13}C-1 chemical shifts (Table 1) and ^{1}H-1 chemical shifts (5.11 and 4.92 ppm in **15** and **16** respectively) and J_{12} coupling constants (8.5 Hz in **15** and **16**).

The trichloroethoxycarbonyl protective group in compound **15** was then removed by treatment with a Zn/Cu couple in acetic acid (16) to afford compound **18** recovered in 93% yield. The anhydro ring of diol **18** was then opened with 10% trifluoroacetic acid in acetic anhydride to afford disaccharide **20** (95% yield) as an anomeric mixture (α/β, 7:1). The ^{1}H and ^{13}C nmr spectra of compound **20** were in complete agreement with the expected structure and, moreover, confirmed the structure of compound **15**.

The same treatment as previously described was applied to trisaccharide **17**, which afforded compound **21** (83% overall yield) as an anomeric mixture (α/β, 9:1).

On the other hand, the free OH-3 group of disaccharide **15** was acetylated, and the compound obtained was deprotected

by treatment with a Zn/Cu couple to afford disaccharide **22** containing the free OH-4 group, which in turn was glycosylated with donor **1** (under the usual conditions) to give the trisaccharide **23** in 69% yield. The structure of compound **23** was assigned by ^1H and ^{13}C nmr and confirmed by acetylation of the already obtained trisaccharide **5**, which yielded to the same derivative.

Conclusion

The strategy of the syntheses presented in this paper for the preparation of the various glycan fragments broadens the scope of applications of the methods previously reported (17).

The 1,6-anhydro-β-D-mannopyranose intermediates, structurally protected on OH-1 and OH-6, are good acceptors for the Lewis acid catalyzed glycosylation reactions, allowing several protective group variations and subsequent possibilities of opening the anhydro ring for further elongation.

The *N*-allyloxycarbonyl glycosylation procedure allowed the preparation of different glycan fragments in high yields and high stereoselectivities on all of the mannose positions, depending on the structure of the selected glycosyl acceptor. It is worthwhile to mention that the steric hindrance in a polysubstituted mannose oligosaccharide does not seem to represent a limitation to this method. As can be judged from the results presented in this paper, the yields of glycosylation are quite comparable with those previously reported in the literature for similar derivatives. For example, van Boom and co-workers (8) reported the coupling of 1,3,4,6-tetra-*O*-acetyl-2-deoxy-2-phthalimido-β-D-glucopyranose with 1,6-anhydro-2,3-*O*-(4-methoxybenzylidene)-β-D-mannopyranose in 71% yield (to be compared with the glycosylation of **2** on OH-4 in 77% yield). Glycosylation on OH-2 of $^4C_1$ mannose acceptors with stoichiometric amounts of D-glucosaminyl donors are usually realized in 65–75% yield (see for examples refs. 5, 7, 18, and 19), which is of the same order as the results described in this paper (the synthesis of **15** + **17** from **14** represents a 72% yield of glycosylation on OH-2).

Beside the glycosylation yields, the most important improvement of the *N*-allyloxycarbonyl approach lies in the high chemioselectivity and the very smooth conditions required for the cleavage of the amino protective group. Most of the functionalities are stable in presence of Pd(0) complexes and the use of *O*- and *N*-allyloxycarbonyl protective groups has been well documented in the fields of carbohydrates (20), nucleotides (21), and peptides (22).

Experimental

Melting points were determined on a Büchi apparatus and were uncorrected. Optical rotations were measured on a Perkin–Elmer 241 polarimeter in a 1-dm cell. The ^1H and ^{13}C nmr spectra were recorded on a Bruker AM 300 spectrometer working respectively at 300 and 75.5 MHz with tetramethylsilane as internal reference; interpretations are tentative since no distinction was made between the different glucosamine moieties in oligosaccharides; all the spectra contain additional signals corresponding to the acetyl protons. Elemental analyses were realized by the "Laboratoire Central d'Analyses du CNRS" (Solaize, France). Silica gel columns were realized on silica gel Amicon (230–400 mesh). Dry alcohol-free dichloromethane was obtained by washing with water, drying over calcium chloride, distillation on phosphorus pentoxide, and storage over 4 Å molecular sieves before use in the glycosylation steps.

4-O-(3,4,6-Tri-O-acetyl-2-N-allylcarbonylamino-2-deoxy-β-D-glucopyranosyl)-1,6-anhydro-2,3-O-isopropylidene-β-D-mannopyranose (3)

1,3,4,6-Tetra-*O*-acetyl-2-*N*-allyloxycarbonylamino-2-deoxy-β-D-glucopyranose **1** (4) (0.906 g, 2.10 mmol) and the alcohol **2** (0.404 g, 2.0 mmol) (12) were dissolved in dichloromethane (30 mL). The mixture was flushed with dry nitrogen while cooling to −30°C. Trimethylsilyl triflate (382 μL, 2.10 mmol) was then introduced through a syringe and the mixture stirred at −30°C for 16 h. The reaction was then quenched with triethylamine (620 μL, 4.5 mmol), the mixture allowed to reach 0°C, and then poured into a cold, dilute aqueous solution of sodium carbonate. The aqueous layer was extracted with dichloromethane (3 × 30 mL); the organic phase was washed with water (5 mL), dried over calcium chloride, and evaporated to afford a mixture, which was chromatographed on silica gel (eluent: ethyl acetate/hexane, 3:1). The title compound was recovered as a white crystalline material (77%); mp 184–185°C (ethanol); $[\alpha]_D^{20}$ −18.5° (*c* 1.5, $CHCl_3$); ^1H nmr (CD_3COCD_3) δ: 6.61 (d, 1H, $J_{2',NH}$ = 8.3 Hz, N*H*), 5.91 (m, 1H, -C*H*=CH_2), 5.32 (dd, 1H, $J_{2',3'}$ = 9.7 Hz, $J_{3',4'}$ = 9.8 Hz, H-3'), 5.26 (m, 1H, 0.5 × C*H*$_2$=CH-), 5.22 (d, 1H, $J_{1,2}$ = 2.9 Hz, H-1), 5.16–5.12 (m, 2H, H-1', 0.5 × C*H*$_2$=CH-), 5.00 (dd, 1H, $J_{4',5'}$ = 9.6 Hz, H-4'), 4.64 (m, 1H, $J_{4,5}$ = 1.5 Hz, $J_{5,6a}$ = 1.2 Hz, $J_{5,6b}$ = 6.3 Hz, H-5), 4.60–4.56 (m, 2H, allyl C*H*$_2$), 4.28 (m, 1H, H-3), 4.27 (dd, 1H, $J_{5',6'a}$ = 5.2 Hz, $J_{6'a,6'b}$ = 12.0 Hz, H-6'a), 4.11 (dd, 1H, $J_{5',6'b}$ = 2.4 Hz, H-6'b), 4.10 (m, 1H, H-4), 3.96 (dd, 1H, $J_{2,3}$ = 6.2 Hz, H-2), 3.88 (dd, 1H, $J_{6a,6b}$ = 7.2 Hz, H-6a), 3.87 (m, 1H, H-5'), 3.64 (dd, 1H, H-6b), 3.63 (m, 1H, H-2'), 1.46, 1.28 (2s, 6H, C*H*$_3$ isopropylidene). Anal. calcd. for $C_{25}H_{35}NO_{14}$ (Mol. Wt. 573.54): C 52.35, H 6.15, N 2.44; found: C 52.29, H 5.95, N 2.42.

4-O-(3,4,6-Tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-1,6-anhydro-β-D-mannopyranose (4)

Compound **3** (0.860 g, 1.5 mmol) was heated for 0.7 h at 100°C in 40% aqueous acetic acid (25 mL). The solution was then evaporated to dryness and the syrup redissolved in and reevaporated from toluene to provide a solid, which was recrystallized from ethanol (75%). Column chromatography of the mother liquor (eluent: ethyl acetate/acetone, 7:1) gave an additional amount of compound **4** (0.080 g, 10%); mp 179–180°C (ethanol); $[\alpha]_D^{20}$ −43.1° (*c* 1.0, $CHCl_3$); ^1H nmr (CD_3COCD_3) δ: 6.54 (d, 1H, $J_{2',NH}$ = 8.2 Hz, N*H*), 5.91 (m, 1H, -C*H*=CH_2), 5.30 (dd, 1H, $J_{2',3'}$ = 10.2 Hz, $J_{3',4'}$ = 9.4 Hz, H-3'), 5.26 and 5.14 (m, 2H, C*H*$_2$=CH-), 5.19 (br s, 1H, $J_{1,2}$ = 2.0 Hz, H-1), 5.06 (d, 1H, $J_{1',2'}$ = 8.3 Hz, H-1'), 4.98 (dd, 1H, $J_{4',5'}$ = 10.0 Hz, H-4'), 4.57 (m, 1H, $J_{3,5}$ = $J_{4,5}$ = 1.5 Hz, $J_{5,6a}$ = 0.9 Hz, $J_{5,6b}$ = 6.0 Hz, H-5), 4.51 (m, 2H, allyl C*H*$_2$), 4.29 (dd, 1H, $J_{5',6'a}$ = 5.2 Hz, $J_{6'a,6'b}$ = 12.2 Hz, H-6'a), 4.14 (dd, 1H, $J_{6a,6b}$ = 7.0 Hz, H-6a), 4.13–4.12 (m, 2H, OH), 4.07 (dd, 1H, $J_{5',6'b}$ = 2.5 Hz, H-6'b), 4.04 (m, 1H, H-3), 3.95 (dd, 1H, $J_{3,4}$ = 1.5 Hz, H-4), 3.86 (m, 1H, H-5'), 3.63 (m, 1H, H-2'), 3.59 (dd, 1H, H-6b), 3.55 (m, 1H, $J_{2,3}$ = 5.3 Hz, $J_{2,OH}$ = 8.0 Hz, H-2). Anal. calcd. for $C_{22}H_{31}NO_{14}$ (Mol. Wt. 533.48): C 49.53, H 5.86, N 2.63; found: C 49.54, H 5.99, N 2.53.

Glycosylation of compound 4

Disaccharide **4** (0.468 g, 0.88 mmol) was glycosylated with the donor **1** (0.380 g, 0.88 mmol) and trimethylsilyl triflate (320 μL, 1.76 mmol) for 24 h under the same conditions and work-up procedure as described for compound **3**. The recovered mixture was purified by column chromatography on silica gel (eluent: ethyl acetate). The first fraction (0.280 g) was acetylated (pyridine, 2 mL/acetic anhydride, 1 mL/DMAP, catalytic) for 4 h at 0°C and, after the usual work-up, chromatographed again (eluent: dichloromethane/acetone, 3:1) to afford compounds **6** (6%) and **7** (37%). The second fraction from the first chromatographic separation was compound **5**, recovered directly as a crystalline material (36%).

2,4-Di-O-(3,4,6-tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-1,6-anhydro-β-D-mannopyranose (5)

White crystalline material: mp 208–210°C (ethanol); $[\alpha]_D^{20}$ −21.5° (*c* 1.0, $CHCl_3$); ^1H nmr (CD_3COCD_3) δ: 6.56 (d, 2H, N*H*), 5.90 (m, 2H, C*H*=CH_2), 5.30 (br s, 1H, $J_{1,2}$ = 1.6 Hz, H-1), 5.29–5.28 (m, 2H, H-3', H-3"), 5.26 and 5.13 (m, 4H, C*H*$_2$=CH-), 5.03 (d, 2H, $J_{1',2'}$ = $J_{1",2"}$ = 8.5 Hz, H-1', H-1"), 5.00 (dd, 1H, $J_{3',4'}$ = $J_{4',5'}$ = 9.5 Hz, H-4'), 4.99 (dd, 1H, $J_{3",4"}$ = $J_{4",5"}$ = 9.5 Hz, H-4"), 4.60 (m, 1H, $J_{3,5}$ = $J_{4,5}$ = 1.5 Hz, $J_{5,6a}$ = 1.0 Hz, $J_{5,6b}$ = 6.0 Hz,

2,3,4-Tri-O-(3,4,6-tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-1,6-anhydro-β-D-mannopyranose (7)

White crystalline material; mp 107–109°C (ether/hexane); $[\alpha]_D^{20}$ −22.3° (*c* 1.0, $CHCl_3$). Anal. calcd. for $C_{54}H_{73}N_3O_{32}$ (Mol. Wt. 1276.15): C 50.82, H 5.77, N 4.20; found: C 50.87, H 5.93, N 3.93.

1,2,3,6-Tetra-O-acetyl-4-O-(3,4,6-tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-α-D-mannopyranose (8α)

Trifluoroacetic acid (0.6 mL) was added to a cold solution of compound **4** (0.267 g, 0.5 mmol) in acetic anhydride (6 mL) with stirring. After 4 h, the solution was evaporated to dryness and the syrup redissolved in and reevaporated twice from toluene. Column chromatography (eluent: ethyl acetate/hexane, 3:1) afforded an anomeric mixture (91%) of **8α** and **8β** (3:1); the pure α anomer was obtained after four successive recrystallizations in ethanol; mp 192°C (ethanol); $[\alpha]_D^{20}$ +42.0° (*c* 1.0, $CHCl_3$); ^{1}H nmr (CD_3COCD_3) δ: 6.53 (d, 1H, *J* = 9.0 Hz, N*H*), 5.97 (d, 1H, $J_{1,2}$ = 1.8 Hz, H-1), 5.92 (m, 1H, -C*H*=CH_2), 5.30 (dd, 1H, $J_{2,3}$ = 3.6 Hz, $J_{3,4}$ = 9.6 Hz, H-3), 5.29 (m, 1H, H-3'), 5.24 and 5.15 (m, 2H, CH_2=CH-), 5.20 (dd, 1H, H-2), 4.98 (dd, 1H, $J_{3',4'}$ = 9.5 Hz, $J_{4',5'}$ = 10.0 Hz, H-4'), 4.95 (d, 1H, $J_{1',2'}$ = 8.5 Hz, H-1'), 4.56–4.43 (m, 2H, allyl CH_2), 4.39 (dd, 1H, $J_{5,6a}$ = 1.5 Hz, $J_{6a,6b}$ = 12.1 Hz, H-6a), 4.30 (dd, 1H, $J_{5',6'a}$ = 4.9 Hz, $J_{6'a,6'b}$ = 12.2 Hz, H-6'a), 4.19 (dd, 1H, H-4), 4.17 (dd, 1H, $J_{5,6b}$ = 4.9 Hz, H-6b), 4.06 (m, 1H, H-5), 4.02 (dd, 1H, $J_{5',6'b}$ = 2.2 Hz, H-6'b), 3.87 (m, 1H, H-5'), 3.59 (m, 1H, H-2'). Anal. calcd. for $C_{30}H_{41}NO_{19}$ (Mol. Wt. 719.64): C 50.07, H 5.74, N 1.95; found: C 49.98, H 5.83, N 1.91.

For compound **8β**: 6.00 (d, 1H, $J_{1,2}$ = 0.8 Hz, H-1), 5.44 (dd, 1H, $J_{2,3}$ = 3.5 Hz, H-2).

1,3,6-Tri-O-acetyl-2,4-di-O-(3,4,6-tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-α-D-mannopyranose (9α)

The same treatment and work-up procedure as in the case of compound **4** were applied to compound **5** (0.230 g, 0.254 mmol). The recovered cristalline material was purified by column chromatography (eluent: ethyl acetate/hexane, 3:1). The α anomer was eluted first (0.195 g, 71%). White crystalline material; mp 184–185°C (2-propanol); $[\alpha]_D^{20}$ +2.8° (*c* 1.0, $CHCl_3$); ^{1}H nmr (CD_3COCD_3) δ: 6.63 and 6.52 (2d, 2H, *J* = 9.6 Hz, N*H*), 6.00 (d, 1H, $J_{1,2}$ = 1.7 Hz, H-1), 5.89 (m, 2H, -C*H*=CH_2), 5.28–5.09 (m, 6H, CH_2=CH-, H-3', H-3''), 5.07 (dd, 1H, $J_{2,3}$ = 3.7 Hz, $J_{3,4}$ = 9.7 Hz, H-3), 5.00 (dd, 1H, $J_{3',4'}$ = $J_{4',5'}$ = 9.7 Hz, H-4'), 4.97 (dd, 1H, $J_{3'',4''}$ = $J_{4'',5''}$ = 9.7 Hz, H-4''), 4.95 (d, 1H, $J_{1',2'}$ = 8.5 Hz, H-1'), 4.80 (d, 1H, $J_{1'',2''}$ = 8.5 Hz, H-1''), 4.60–4.25 (m, 7H, allyl CH_2, H-6a, H-6'a, H-6''a), 4.21 (dd, 1H, H-2), 4.12 (dd, 1H, $J_{4,5}$ = 9.6 Hz, H-4), 4.07–3.80 (m, 6H, H-5, H-5', H-5'', H-6b, H-6'b, H-6''b), 3.76 (m, 1H, $J_{2',3'}$ = 10.2 Hz, H-2'), 3.64 (m, 1H, $J_{2'',3''}$ = 10.5 Hz, H-2''). Anal. calcd. for $C_{44}H_{60}N_2O_{27}$ (Mol. Wt. 1048.93): C 50.38, H 5.77, N 2.67; found: C 50.26, H 5.73, N 2.58.

Compound **9β** (27%) was obtained as a mixture with **9α** and had the following ^{1}H nmr characteristics: 5.84 (br s, 1H, H-1), 4.85 (d, 1H, $J_{1',2'}$ = 8.5 Hz, H-1').

1,6-Di-O-acetyl-2,3,4-tri-O-(3,4,6-tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-α-D-mannopyranose (10α)

The same treatment and work-up procedure as in the case of compounds **4** and **5** were applied to compound **7** (0.180 g, 0.14 mmol). The recovered crystalline material was purified by column chromatography (eluent: ethyl acetate). The α anomer was eluted first (0.151 g, 77%). Syrup; $[\alpha]_D^{20}$ −10.8° (*c* 1.0, $CHCl_3$); ^{1}H nmr (CD_3COCD_3) δ: 6.09 (d, 1H, $J_{1,2}$ = 2.2 Hz, H-1). Anal. calcd. for $C_{58}H_{79}N_3O_{35}$ (Mol. Wt. 1378.23): C 50.54, H 5.78, N 3.05; found: C 50.17, H 5.89, N 2.93.

Compound **10β** had $[\alpha]_D^{20}$ +27.0° (*c* 1.0, $CHCl_3$); ^{1}H nmr (CD_3COCD_3) δ: 5.71 (d, 1H, $J_{1,2}$ = 0.8 Hz, H-1).

1,3,6-Tri-O-acetyl-2,4-di-O-(2-acetamido-3,4,6-tri-O-acetyl-2-deoxy-β-D-glucopyranosyl)-α-D-mannopyranose (11)

Palladium bis(dibenzylidene acetone) (0.014 g, 0.024 mmol) was reacted with triphenylphosphine (0.035 g, 0.134 mmol) in dry, oxygen-free oxolane (2 mL) at room temperature for 10 min. Compound **9α** (0.240 g, 0.228 mmol) dissolved in oxygen-free oxolane (5 mL) and dimethylmalonate (0.42 mL, 4.9 mmol) was then added to the above solution and the mixture was stirred for 24 h at room temperature. After concentration to 1 mL, the mixture was applied to the top of a small silica gel column and eluted first with ethyl acetate, to remove the triphenylphosphine by-products, and then with ethyl acetate/methanol (2:1), to recover the expected amino-free derivative, which was acetylated overnight and extracted as usual. After column chromatography (eluent: ethyl acetate/acetone, 4:1), the pure compound **11** (86%) was recovered as a white foam; $[\alpha]_D^{20}$ −17.9° (*c* 1.0, $CHCl_3$); ^{1}H nmr ($CDCl_3$) δ: 6.81 and 6.65 (2d, 2H, *J* = 7.2 and 8.7 Hz, N*H*), 6.02 (br s, 1H, H-1), 5.31–5.07 (m, 5H, H-3, H-3', H-3'', H-4', H-4''), 4.62 (d, 1H, $J_{1',2'}$ = 8.0 Hz, H-1'), 4.58 (d, 1H, $J_{1'',2''}$ = 8.2 Hz, H-1''), 4.40–3.70 (m, 13H, H-2, H-2', H-2'', H-4, H-5, H-5', H-5'', H-6a, H-6'a, H-6''a, H-6b, H-6'b, H-6''b). Anal. calcd. for $C_{40}H_{56}N_2O_{25}$ (Mol. Wt. 964.86): C 49.79, H 5.85, N 2.90; found: C 49.32, H 5.91, N 2.69.

1,6-Di-O-acetyl-2,3,4-tri-O-(2-acetamido-3,4,6-tri-O-acetyl-2-deoxy-β-D-glucopyranosyl)-α-D-mannopyranose (12)

The same treatment and work-up procedure as described for compound **9α** were applied to compound **10α**. The recovered material was purified by column chromatography (eluent: ethyl acetate/methanol, 8:1) to afford compound **12** (84%) as a white foam; $[\alpha]_D^{20}$ −10.8° (*c* 1.0, $CHCl_3$); ^{1}H nmr (CD_3COCD_3) δ: 7.39 and 7.26 (2d, 2H, *J* = 9.4 and 9.6 Hz, N*H*), 6.70 (m, 1H, N*H*), 6.02 (d, 1H, $J_{1,2}$ = 3.4 Hz, H-1), 5.27, 5.17, 5.14 (3t, 3H, *J* = 9.8 and 9.9 Hz, H-3', H-3'', H-3'''), 5.03, 5.02, 5.02 (3t, 3H, H-4', H-4'', H-4'''), 4.94 (d, 1H, 5.17, $J_{1',2'}$ = 8.5 Hz, H-1'), 4.91 (d, 2H, *J* = 8.6 Hz, H-1'', H-1'''), 4.60–3.88 (m, 18H, H-2, H-2', H-2'', H-2''', H-3, H-4, H-5, H-5', H-5'', H-5''', H-6a, H-6'a, H-6''a, H-6'''a, H-6b, H-6'b, H-6''b, H-6'''b). Anal. calcd. for $C_{52}H_{73}N_3O_{32}$ (Mol. Wt. 1252.13): C 49.87, H 5.88, N 3.36; found: C 49.46, H 5.63, N 3.01.

1,6-Anhydro-2,3-O-isopropylidene-4-O-(2,2,2-trichloroethoxycarbonyl)-β-D-mannopyranose (13)

Trichloroethylchloroformate (0.76 mL, 5.5 mmol) was added dropwise to a cold (−5°C) solution of compound **2** (1.010 g, 5.0 mmol) in dry pyridine (20 mL). The mixture was stirred overnight and the solvent then evaporated under vacuum. The mixture obtained was redissolved in and reevaporated from toluene (2 × 10 mL) and chromatographed on silica gel (eluent: ethyl acetate/hexane, 1:3) to afford compound **13** as a white crystalline material (90%); mp 142–

*Glycosylation of compound **14***

Compound **14** (0.608 g, 1.8 mmol) was glycosylated with the donor **1** (0.777 g, 1.8 mmol) and trimethylsilyl triflate (327 μL, 1.8 mmol) for 24 h under the same conditions and work-up procedure as described for the synthesis of compound **3**. The recovered mixture crystallized spontaneously and was recrystallized twice from ethanol to afford the pure disaccharide **15** (53%). The mother liquor was concentrated and chromatographed on silica gel (eluent: dichloromethane/acetone, 6:1). The disaccharide **16** (10%) was first eluted, the trisaccharide **17** (16%) and remaining **15** (3%) were then obtained by further elution.

*2-*O*-(3,4,6-Tri-*O*-acetyl-2-*N*-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-1,6-anhydro-4-*O*-(2,2,2-trichloroethoxycarbonyl)-β-D-mannopyranose (**15**)*

White crystalline material; mp 178°C (ethanol); $[\alpha]_D^{20}$ −44.0° (*c* 1.0, $CHCl_3$); ^1H nmr (CD_3COCD_3) δ: 6.57 (d, 1H, $J_{2',NH}$ = 7.5 Hz, N*H*), 5.92 (m, 1H, -C*H*=CH_2), 5.40 (br s, 1H, H-1), 5.33 (m, 2H, 0.5 × CH_2=CH-, H-3′), 5.18–5.13 (m, 1H, 0.5 × CH_2=CH-), 5.11 (d, 1H, $J_{1',2'}$ = 8.5 Hz, H-1′), 5.00 (dd, 1H, $J_{3',4'} = J_{4',5'}$ = 9.7 Hz, H-4′), 4.96 (m, 2H, CH_2CCl_3), 4.83 (br s, 1H, H-4), 4.71 (m, 1H, H-5), 4.58–4.47 (m, 2H, allyl CH_2), 4.29 (dd, 1H, $J_{5,6a}$ = 1.0 Hz, $J_{6a,6b}$ = 7.2 Hz, H-6a), 4.24 (dd, 1H, $J_{5',6'a}$ = 5.8 Hz, $J_{6'a,6'b}$ = 12.2 Hz, H-6′a), 4.16 (m, 1H, H-3), 4.13 (dd, 1H, $J_{5',6'b}$ = 2.6 Hz, H-6′b), 3.95 (m, 1H, H-5′), 3.82 (dd, 1H, $J_{2,3}$ = 5.1 Hz, $J_{1,2}$ = 1.9 Hz, H-2), 3.72 (m, 1H, H-2′), 3.71 (dd, 1H, $J_{5,6b}$ = 6.2 Hz, H-6b), 3.56 (s, 1H, O*H*). *1,3,4,6-Tetra-*O*-acetyl-2-*O*-(3,4,6-tri-*O*-acetyl-2-*N*-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-α-D-mannopyranose (**20α**)*

Compound **18** (0.243 g, 0.455 mmol) was treated as in the case of compound **4**, affording **8**. The recovered α/β mixture (7:1) was purified by column chromatography (eluent: ethyl acetate/hexane, 3:1). The pure α derivative (72%) was recovered first as a white crystalline material; a second fraction contained an unseparated α/β mixture (1:1, 23%); mp 149–150°C (2-propanol); $[\alpha]_D^{20}$ −2.8° (*c* 1.0, CH_2Cl_2); ^1H nmr (CD_3COCD_3) δ: 6.64 (d, 1H, $J_{2',NH}$ = 9.3 Hz, N*H*), 6.07 (d, 1H, $J_{1,2}$ = 1.9 Hz, H-1), 5.89 (m, 1H, -C*H*=CH_2), 5.37–5.12 (m, 4H, H-3′, H-4, CH_2=CH-), 5.06 (dd, 1H, $J_{2,3}$ = 2.5 Hz, $J_{3,4}$ = 10.4 Hz, H-3), 5.01 (dd, 1H, $J_{3',4'} = J_{4',5'}$ = 9.7 Hz, H-4′), 4.89 (d, 1H, $J_{1',2'}$ = 8.5 Hz, H-1′), 4.56–4.47 (m, 2H, allyl CH_2), 4.30 (dd, 1H, H-2), 4.26 (dd, 1H, $J_{5',6'a}$ = 5.4 Hz, $J_{6'a,6'b}$ = 11.8 Hz, H-6′a), 4.15–3.98 (m, 4H, H-5, H-6a, H-6b, H-6′b), 3.82 (m, 1H, $J_{5',6'b}$ = 2.3 Hz, H-5′), 3.74 (m, 1H, $J_{2',3'}$ = 10.1 Hz, H-2′).

Anal. calcd. for $C_{30}H_{41}NO_{19}$ (Mol. Wt. 719.64): C 50.07, H 5.74, N 1.95; found: C 49.80, H 5.83, N 1.94.

Compound **20**β was characterized by an anomeric proton at 5.88 (d, 1H, $J_{1,2}$ = 0.8 Hz, H-1).

1,4,6-Tri-O-acetyl-2,3-di-O-(3,4,6-tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-D-mannopyranose (21)

This derivative was prepared as compound **8** from compound **4**, to afford, after chromatographic purification (eluent: ethyl acetate), an anomeric mixture (87%, α/β, 9:1) that was difficult to separate; ^{1}H nmr (CD_3COCD_3) δ: 6.73, 6.18 (2m, 2H, N*H*), 6.13 (d, 0.9H, $J_{1,2}$ = 2.7 Hz, H-1α), 6.08, 5.92 (2m, 2H, -C*H*=CH_2), 5.83 (d, 0.1H, $J_{1,2}$ = 0.8 Hz, H-1β). Anal. calcd. for $C_{44}H_{60}N_2O_{27}$ (Mol. Wt. 1048.94): C 50.38, H 5.77, N 2.67; found: C 50.37, H 5.89, N 2.52.

3-O-Acetyl-2-O-(3,4,6-tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-1,6-anhydro-β-D-mannopyranose (22)

The disaccharide **15** (0.690 g, 0.974 mmol) was acetylated as usual and then treated with the Zn/Cu couple as already described for the synthesis of compound **18**. After column chromatography (eluent: ethyl acetate/acetone, 7:1), **22** was recovered as a white foam (91%); $[\alpha]_D^{20}$ −44.7° (*c* 1.0, $CHCl_3$); ^{1}H nmr (CD_3COCD_3) δ: 6.54 (d, 1H, $J_{2',NH}$ = 8.6 Hz, N*H*), 5.94 (m, 1H, -C*H*=CH_2), 5.30 (m, 1H, 0.5 × CH_2=CH-), 5.25 (dd, 1H, $J_{2',3'} = J_{3',4'}$ = 9.7 Hz, H-3′), 5.20 (m, 1H, $J_{2,3}$ = 5.6 Hz, $J_{3,4}$ = 1.5 Hz, H-3), 5.17 (m, 1H, 0.5 × CH_2=CH-), 4.98 (dd, 1H, $J_{4',5'}$ = 10.0 Hz, H-4′), 4.96 (d, 1H, $J_{1',2'}$ = 8.5 Hz, H-1′), 4.64 (d, 1H, *J* = 6.0 Hz, O*H*), 4.60–4.49 (m, 3H, H-5, allyl CH_2), 4.23 (dd, 1H, $J_{5',6'a}$ = 4.6 Hz, $J_{6'a,6'b}$ = 12.2 Hz, H-6′a), 4.11 (dd, 1H, $J_{5,6a}$ = 1.0 Hz, $J_{6a,6b}$ = 7.1 Hz, H-6a), 4.02 (dd, 1H, $J_{5',6'b}$ = 2.2 Hz, H-6′b), 3.99 (dd, 1H, H-2), 3.86 (m, 1H, H-5′), 3.75 (m, 1H, $J_{4,5}$ = 1.5 Hz, H-4), 3.69 (dd, 1H, $J_{5,6b}$ = 6.0 Hz, H-6b), 3.65 (m, 1H, H-2′). Anal. calcd. for $C_{24}H_{33}NO_{15}$ (Mol. Wt. 575.51): C 50.08, H 5.78, N 2.43; found: C 50.10, H 5.74, N 2.53.

3-O-Acetyl-2,4-di-O-(3,4,6-tri-O-acetyl-2-N-allyloxycarbonylamino-2-deoxy-β-D-glucopyranosyl)-1,6-anhydro-β-D-mannopyranose (23)

The disaccharide **22** (0.460 g, 0.80 mmol) was glycosylated as usual with the donor **1** (0.360 g, 0.83 mmol) and trimethylsilyl triflate (0.218 mL, 1.2 mmol). After the usual work-up procedure and column chromatography (eluent: ethyl acetate), compound **23** was obtained as a white crystalline material (68%); mp 216°C (ether); $[\alpha]_D^{20}$ −4.5° (*c* 1.0, $CHCl_3$); ^{1}H nmr (CD_3COCD_3) δ: 6.51 (2m, 2H, N*H*), 5.97–5.87 (m, 2H, C*H*=CH_2), 5.51 (m, 1H, H-3), 5.37 (br s, 1H, H-1), 5.31–5.13 (m, 6H, CH_2=CH-, H-3′, H-3″), 5.03 (d, 1H, $J_{1',2'}$ = 8.0 Hz, H-1′), 5.02 (dd, 1H, $J_{3',4'}$ = 9.8 Hz, $J_{4',5'}$ = 10.0 Hz, H-4′), 4.98 (dd, 1H, $J_{3'',4''}$ = 9.5 Hz, $J_{4'',5''}$ = 10.0 Hz, H-4″), 4.95 (d, 1H, $J_{1'',2''}$ = 8.0 Hz, H-1″), 4.58–4.52 (m, 5H, allyl CH_2, H-5), 4.28–4.26 (m, 2H, H-6′a, H-6″a), 4.18 (dd, 1H, $J_{5',6'b}$ = 2.5 Hz, $J_{6'a,6'b}$ = 12.2 Hz, H-6′b), 4.08 (dd, 1H, $J_{5,6a}$ = 1.0 Hz, $J_{6a,6b}$ = 7.2 Hz, H-6a), 3.99 (dd, 1H, $J_{5'',6''b}$ = 2.1 Hz, $J_{6''a,6''b}$ = 12.2 Hz, H-6″b), 3.89–3.81 (m, 4H, H-2, H-4, H-5′, H-5″), 3.69 (dd, 1H, $J_{5,6b}$ = 6.0 Hz, H-6b), 3.65 (m, 1H, H-2′), 3.62 (m, 1H, H-2″). Anal. calcd. for $C_{40}H_{54}N_2O_{24}$ (Mol. Wt. 946.85): C 50.74, H 5.75, N 2.96; found: C 50.94, H 5.86, N 2.98.

The three-dimensional structure of the antiviral agent 5-methoxymethyl-2′-deoxycytidine (MMdCyd) was deduced by X-ray crystallographic analysis. MMdCyd crystallized in space group $P2_1$ with $a = 7.9255(6)$ Å; $b = 16.1505(15)$ Å, $c = 10.1861(5)$ Å, $\beta = 103.801(5)°$, and $Z = 4$ (2 molecules per asymmetric unit); $R = 0.044$ ($R_w = 0.046$) for 2560 observed reflections with net $I > 3\sigma(I)$. The furanose ring adopts the C(3′)-*exo* envelope conformation ($_3E$) in molecule A and the C(2′)-*endo* envelope conformation (^2E) in molecule B. In the sugar ring of both crystallographically independent molecules A and B, the side chain at C(5′) has the g^+ conformation. This appears to be a preferred geometry required for antiherpes activity in 2′-deoxyribonucleosides. The glycosyl linkage is *anti* with $\chi = 213.7°$ for the A molecule and 222.2° for the B molecule. With respect to this *anti* conformation, the methoxy group at C(5) in molecules A and B exhibits different conformations; it is on the same side of the pyrimidine plane as the deoxyribofuranose ring oxygen (O4′) in molecule B and on the opposite side in molecule A.

Key words: antiherpes agent, conformation, 5-methoxymethyl-2′-deoxycytidine, crystal structure.

ZONGCHAO JIA, GUY TOURIGNY, LOUIS T. J. DELBAERE, ALLAN L. STUART et SAGAR V. GUPTA. Can. J. Chem. **68**, 836 (1990).

On a déduit la structure tridimensionnelle de l'agent antiviral, 5-méthoxyméthyl-2′-désoxycytidine (MMdCyd), d'une analyse par diffraction des rayons-X. Le MMdCyd crystallise dans le groupe d'espace $P2_1$, avec $a = 7{,}9255(6)$, $b = 16{,}1505(15)$ et $c = 10{,}1861(5)$ Å, $\beta = 1030{,}801(5)°$ et $Z = 2$ (2 molécules par unité asymétrique); $R = 0{,}044$ ($R_w = 0{,}046$) pour 2560 réflexions observées avec $I > 3\sigma(I)$. Le cycle furanose adopte la conformation enveloppe C(3′)-*exo* ($_3E$) dans la molécule A et la conformation enveloppe C(2′)-*endo* (^2E) dans la molécule B. Dans le sucre cyclique de chacune des molécules A et B qui sont indépendantes d'un point de vue cristallographique, la chaîne latérale en C(5′) possède une conformation g^+. Cette conformation semble possédée la géométrie préférée pour détenir une activité antiherpès dans les 2′-désoxyribonucléosides. La liaison glycosyle est *anti* avec $\chi = 213{,}7°$ pour la molécule A et 222,2° pour la molécule B. Par rapport à cette conformation *anti*, les groupements méthoxyles présents dans les positions C(5) des molécules A et B présentent des conformations différentes; ils se trouvent sur le même côté du plan pyrimidine sous la forme de l'oxygène O4′ du cycle du désoxyribofuranose de la molécule B et sur des côtés opposés dans la molécule A.

Mots clés : agent antiherpès, conformation, 5-méthoxyméthyl-2′-désoxycytidine, structure cristalline.

[Traduit par la revue]

Introduction

The discovery of 5-substituted-2′-deoxyuridines with selective activity against Herpes simplex virus was a major development in the area of viral chemotherapy (for reviews see refs. 1–3). The basis for selective antiherpes activity of 5-alkyl-2′-deoxyuridines is primarily due to the specific interaction with two virus-induced enzymes, the deoxythymidine-deoxycytidine (dThd/dCyd) kinase (viral-K) and the DNA polymerase. Cleavage of the *N*-glycosidic bond of many of these 5-substituted-2′-deoxyuridines by nucleoside phosphorylases rapidly leads to loss of biological activity (4–6). Thymidine phosphorylase (EC 2.4.2.4) is specific for the 2′-deoxyribosyl moiety of the nucleosides whereas uridine phosphorylase (EC 2.4.2.3) has broader substrate specificity (7–10). One possible approach to overcome this limitation is to use deoxycytidine analogs. The rationale for this hypothesis is (i) dCyd analogs are not substrates for thymidine and (or) uridine phosphorylase and (ii) in HSV-infected cells, dCyd analogs will be metabolized primarily by the virus-induced dCyd kinase – deoxycytidylate kinase pathway. Our findings on the biological activity of (*E*)-5-(2-bromovinyl)-2′-deoxycytidine (BrVdCyd) and 5-methoxymethyl-2′-deoxycytidine (MMdCyd) are consistent with the proposed hypothesis. When deamination is prevented, BrVdCyd and MMdCyd are potent and selective inhibitors of HSV replication (11, 12).[2] MMdCyd is selectively phosphorylated by the viral-K and the substrate specificity is related to the chain length of the substituent at the C(5) position of the pyrimidine ring. MMdCyd triphosphate is utilized preferentially by HSV-induced DNA polymerase and is also a potent inhibitor of viral DNA polymerase (11).[3]

As a part of our program to determine the steric conformation required for the substrate specificity towards viral-K and mammalian phosphorylases (15–19), we have determined the crystal structure of MMdCyd and the results are discussed in this paper. Impetus for continuing these investigations is that understanding molecular conformation requirements for biological activity would aid in the design of better drugs for the treatment of viral infections.

*MMdCyd, molecule A.
†MMdCyd, molecule B.

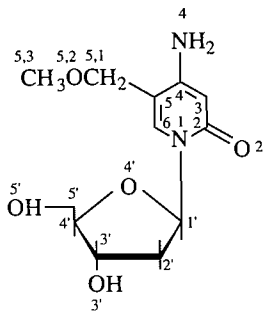

FIG. 1. Structure and atomic numbering of MMdCyd.

Results and discussion

The synthesis of MMdCyd **5** was accomplished from MMdUrd (1) in four steps. Protection of the 3′- and 5′-OH groups by acetylation was followed by conversion to the 4-triazolyl derivative which was treated with a saturated solution of ammonia in dioxane. Deacetylation with methanolic ammonia gave the desired product, **5**, in 44% yield. The structural formula with atomic numbering for MMdCyd is shown in Fig. 1.

X-Ray analysis

The bond lengths and angles determined for MMdCyd are given in Tables 1 and 2 respectively. The stereoscopic view of the molecules A and B of MMdCyd are shown in Fig. 2. The two crystallographically independent molecules are very similar to each other. Bond lengths and angles for MMdCyd molecules are similar to those reported for 5-methoxymethyl-2′-deoxyuridine (MMdUrd) and are in the range reported for 2′-deoxycytidine nucleosides (15, 20–25). Selected torsion angles for molecules A and B of MMdCyd compared to the corresponding angles in MMdUrd are shown in Table 3. The conformation of the glycosidic bond is *anti* with the torsion angle O(4′)-C(1′)-N(1)-C(2), χ, having values of 213.7° and 222.2° for molecules A and B, respectively. These values are lower than the χ value of MMdUrd (233.3°) but are in the range reported for cytidine and deoxycytidine nucleosides (200–222°). The exocyclic 5′CH_2OH side chain has the g^+ conformation in both molecules A and B of MMdCyd and also in MMdUrd; this seems to be a preferred conformation for antiherpes activity in 2′-deoxyribonucleosides. The g^+ conformation is the most common found in cytidine and deoxycytidine compounds. However, it is interesting to note that 5-methyl-2′-deoxycytidine displays the t conformation (21).

In addition to the slightly different conformation of the deoxyribofuranose ring, the orientation of the methoxymethyl group at C(5) of the cytosine moiety is different in molecules A and B of MMdCyd. With respect to the *anti* conformation of the glycosidic bond, the C(5) substituent is on the same side of the pyrimidine ring plane as O(4′) in molecule B and on the opposite side in molecule A as demonstrated by torsion angles, C(6)—C(5)—C(5,1)—O(5,2), 129.5(4)°(A), −115.8(4)°(B) (Fig. 2.). It is interesting to note that for HMdUrd, the only other case where different steric orientation of the C(5) substituent has previously been reported, the two possible orientations were attributed to disorder, with little difference in energy between them (26). In the case of MMdCyd, the two different orientations of the C(5) substituent are not the result of statistic disorder but are probably due to packing forces in the unit cell.

The deoxyribose ring has an envelope conformation in both molecules A and B of MMdCyd. The conformations and the corresponding displacements from the mean plane through the other four ring atoms are as follows: C(3′)-*exo* ($_3E$), 0.49 Å (planar within 0.04 Å) for molecule A and C(2′)-*endo* (^2E), 0.52 Å (planar within 0.05 Å) for molecule B. The values calculated for the two pseudo-rotational parameters of the furanose ring torsion angles in terms of the two degrees of freedom for ring puckering (27) are phase angles P = 185.5° and 174.5° and puckering amplitude τ_m = 32.3° and 36.3° for

molecules A and B, respectively. The values calculated for the two pseudorotational parameters for MMdUrd were $P = 159.3°$ and $\tau_m = 39.6°$. These results indicate that the deoxyribose moiety in both molecules A and B of MMdCyd has a typical *S* conformation. Most deoxycytidine derivatives have either ^2E or $_3E$ puckering of the sugar ring.

The crystal structure has several intermolecular hydrogen bonds, which are summarized in Table 4.

Experimental

Chemistry

5-Methoxymethyl-3',5'-di-O-acetyl-2'-deoxyuridine, 2

Acetic anhydride (22 mL, 240 mmol) was added to a solution of 5-methoxymethyl-2'-deoxyuridine, **1**, (5.00 g, 18.4 mmol) in 75 mL of anhydrous pyridine and the solution was stirred at room temperature for 18 h. The reaction mixture, concentrated to 25 mL, was added slowly to 250 mL of cold water. The aqueous solution was extracted with $CHCl_3$ and the organic layer was washed with 0.1 M HCl, 5% $NaHCO_3$, and H_2O. Residual pyridine was removed by coevaporation with toluene. The solution was dried and the solvent was removed on a rotary evaporator. Recrystallization from ethyl acetate – petroleum ether gave *5-methoxymethyl-3',5'-di-O-acetyl-2'-deoxyuridine*, **2**, (6.0 g, 70%), mp 110–112°C; UV (MeOH), λ_{max}: 264 nm (ϵ, 9300), λ_{min}: 232 nm (ϵ, 2100); ^{1}H NMR (DMSO-d_6), δ: 11.46 (s, 1, 3-NH), 7.61 (s, 1, 6-H), 6.17 (m, 1, 1'-H), 5.18 (m, 1, 3'-H), 4.22 (m, 2, 5'-H, 5''-H), 4.18 (m, 1, 4'-H), 4.06 (s, 2, 5-CH_2O), 3.24 (s, 5-OCH_3), 2.35 (m, 2, 2'-H, 2''-H), 2.06 (s, 6, CH_3COO). Anal. calcd. for $C_{15}H_{20}N_2O_8$: C 50.56, H 5.66, N 7.86; found: C 50.86, H 5.63, N 7.60.

5-Methoxymethyl-3',5'-di-O-acetyl-2'-deoxycytidine, 4

1,2,4-Triazole (11.2 g, 162 mmol), redistilled $POCl_3$ (3.4 mL, 36 mmol), and triethylamine (22 mL, 160 mmol) were added dropwise

with stirring to 49 mL of acetonitrile at 4°C. **2** (2.14 g, 6.05 mmol), dissolved in 24 mL of acetonitrile, was added to the suspension and the mixture was stirred at room temperature for 1.5 h. The solvent was evaporated and the residue was dissolved in $CHCl_3$, washed with saturated $NaHCO_3$, then with water, and dried over $MgSO_4$. TLC on silica gel G with EtOAc indicated one UV sensitive spot (R_f 0.29). The ratio of the UV absorption maxima in MeOH, λ250: λ322, was 1.45. The crude 4-triazolyl-5-methoxymethyl-3′,5′-di-*O*-acetyl-2′-deoxyuridine, **3**, was dissolved in 50 mL of dried, peroxide-free 1,4-dioxane. The solution was chilled, saturated with ammonia, and stored in a Wheaton pressure bottle at room temperature for 18 h. The solvent was evaporated and the gummy residue was eluted with 90:10 $CHCl_3$–MeOH on a silica gel column (2.7 cm × 100 cm). Recrystallization from EtOAc gave *5-methoxymethyl-3′,5′-di-*O*-acetyl-2′-deoxycytidine*, **4** (1.81 g, 84%), mp 124–125°C; UV (0.1 M HCl), λ_{max}: 283 nm (ε, 11 800), λ_{min}: 244 nm (ε, 1600); UV (0.1 M NaOH), λ_{max}: 274 nm (ε, 7800), λ_{min}: 252 nm (ε, 5500); ^{1}H NMR (DMSO-d_6), δ: 7.61 (s, 1, 6-H), 7.46, 6.75 (broad peaks, 4-NH_2), 6.18 (m, 1′-H), 5.17 (m, 1, 3′-H), 4.23 (m, 2, 5′-H, 5″-H), 4.16 (m, 1, 4′-H), 4.11 (s, 2, 5-CH_2O), 3.22 (s, 3, OCH_3), 2.29 (m, 2, 2′-H, 2″-H), 2.06 (s, 3, CH_3COO), 2.04 (s, 3, CH_3COO). Anal. calcd. for $C_{15}H_{21}N_3O_7$: C 50.70, H 5.96, N 11.83; found: C 50.65, H 5.58, N 11.64.

5-Methoxymethyl-2′-deoxycytidine, 5

The diacetyl (**4**, 4.80 g, 13.5 mmol) was dissolved in 240 mL of MeOH, cooled to 4°C, saturated with ammonia, and stored at room temperature for 4 h. Removal of solvent gave *5-methoxymethyl-2′-deoxycytidine*, **5**, as a white amorphous solid, which was recrystallized from MeOH–EtOAc (2.7 g, 74%), mp 171–172°C; UV (0.1 M HCl), λ_{max}: 284 nm (ε, 12 500), λ_{min}: 244 nm (ε, 1300); UV (0.1 M NaOH), λ_{max}: 274 nm (ε, 8300), λ_{min}: 252 nm (ε, 5500); ^{1}H NMR (DMSO-d_6), δ: 7.85 (s, 1, 6-H), 7.35, 6.62 (broad peaks, 4-NH_2), 6.13 (m, 1, 1′-H), 5.17 (d, 1, 3′-OH), 4.98 (t, 1, 5′-OH), 4.20 (m, 1, 3′-H), 4.10, 4.07 (pair d, 2, 5-CH_2O), 3.75 (m, 1, 4′-H), 3.56 (m, 2, 5′-H, 5″-H), 3.20 (s, 3, OCH_3), 2.12 (m, 2″-H), 1.94 (m, 1, 2′-H). Anal. calcd. for $C_{11}H_{17}N_3O_5$: C 48.70, H 6.32, N 15.49; found: C 48.84, H 6.11, N 15.44.

X-ray crystallography

Suitable crystals were obtained from a solution of MMdCyd in ethyl ether – methanol. The colorless crystal of MMdCyd, empirical formula $C_{11}H_{17}N_3O_5$, size 0.60 × 0.28 × 0.19 mm, has the space group $P2_1$ with a = 7.9255(6) Å, b = 16.1505(15) Å, c = 10.1861(5) Å, β = 103.801(5)°, V = 1266.19 Å^3, Z = 4 (2 molecules per asymmetric unit), μ = 1.31 cm^{-1}, calculated density = 1.44 g cm^{-3} (density was not determined). The estimated standard deviations of the unit cell dimensions represent the values obtained after least-squares refinement using 25 reflections with $25.52 < \theta < 38.53°$; these esd's are smaller than usually quoted because the diffractometer had the long detector arm configuration (368 mm from crystal to detector) with a helium-filled tube located between the crystal and the detector. The diffractometer room is maintained at 14 ± 1°C. Quantitative data collection was done on an Enraf–Nonius CAD4F diffractometer with an ω/2θ scan and Ni-filtered copper radiation (λ = 1.5418 Å). Three standard reflections were checked every 10 000 s for intensity variations and every 200 reflections for orientation. There was no significant decay of the crystal over the entire data collection. A total of 2950 reflections were collected out to $\theta = 75°$, $-9 \le h \le 9$, $0 \le k \le 20$, $0 \le l \le 12$; of 2682 unique reflections, 2560 had net $I > 3\sigma(I)$. No absorption or extinction corrections were applied. Merging R based on intensities was 2.16% for 397 replicate reflections. X-ray data were processed and the structure was solved by direct methods using XTAL 2.4 (28).

All non-hydrogen atoms were found on the E map and H atoms were located by using a difference Fourier map. Finally, refinement was carried out by full-matrix least-squares refinement of positions and anisotropic temperature factors for non-H atoms; hydrogen atom parameters were not refined (with U_{iso} assigned as U_{equiv} of the attached atom).

The anisotropic refinement for non-hydrogen atoms converged to an R index[4] of 0.044. R_w was 0.046 and S was 2.955 for 2560 observed reflections. A total of 342 parameters were refined and structure factor amplitudes were used in least-squares refinement. Final $(\Delta/\sigma)_{ave}$ = 0.032, $(\Delta/\sigma)_{max}$ = 0.23. Δρ in the final difference map were +0.26 and −0.28 e Å^{-3}. Atomic scattering factors were from International tables for X-ray crystallography (1974) (13). The final coordinates of non-hydrogen atoms are given in Table 5.[5] All calculations were performed on a VAX8650 computer at the University of Saskatchewan.

[4] $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$
$R_w = [\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2]^{1/2}$
$S = [\Sigma w\Delta F^2/(m - n)]^{1/2}$

[5] Tables of structure amplitudes, thermal parameters, and H-atom coordinates may be purchased from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

The table of H-atom coordinates has also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, UK.

Acknowledgements

This research was funded by grants from the Medical Research Council. We thank Mr. Ted Mazurek, Plant Biotechnology Institute, for the NMR spectra, Mr. Ken Toms, Department of Chemistry, for the CHN analyses, and Dr. L. Prasad, Department of Biochemistry, for valuable suggestions. Mr. Z. Jia is the recipient of a Graduate Scholarship from the University of Saskatchewan.

THIERRY AUBERT, MICHEL FARNIER et ROGER GUILARD. Can. J. Chem. **68**, 842 (1990).

Des isoindoline-ones-1 *N*-substituées et des isoquinoléines 3-acylées ont été synthétisées en une étape par condensation de l'*ortho*-phtalaldéhyde sur divers iminophosphoranes. Trois types de schémas réactionnels sont proposés, en fonction de la nature de l'iminophosphorane et des conditions opératoires. Tous les composés obtenus ont été pleinement caractérisés, en particulier par spectroscopie de résonance magnétique nucléaire mono- et bi-dimensionnelle.

Mots clés : isoindolones, isoquinoléines, iminophosphoranes.

THIERRY AUBERT, MICHEL FARNIER, and ROGER GUILARD. Can. J. Chem. **68**, 842 (1990).

The condensation of various iminophosphoranes with *o*-phthalaldehyde led directly to *N*-substituted isoindoline-1-ones and 3-acylisoquinolines. Three different mechanisms, depending on the nature of the iminophosphorane and reaction conditions, are proposed. All the compounds have been fully characterized, particularly by one- and two-dimensional nuclear magnetic resonance spectroscopy.

Key words: isoindolones, isoquinolines, iminophosphoranes.

Introduction

Les iminophosphoranes, obtenus généralement par action d'un azide sur un composé trisubstitué du phosphore selon la réaction de Staudinger (pour une revue, voir réf. 1), sont connus pour réagir avec la plupart des composés monocarbonylés selon la réaction d'aza-Wittig 1 (2–6).

En revanche, la réactivité d'iminophosphoranes vis-à-vis de composés dicarbonylés n'a jusqu'alors pas été explorée systématiquement. Ainsi, mis à part quelques réactions de condensation où l'une des deux fonctions du dérivé dicarbonylé n'a qu'un rôle secondaire et reste inchangée après réaction (7, 8), seules sont décrites dans la littérature dès condensations de composés dicarbonylés avec des bis-iminophosphoranes (9, 10). Ce type de réaction ne fait donc pas apparaître une réactivité nouvelle puisque chacune des fonctions iminophosphoranes réagit selon le schéma 1. En revanche, Garcia *et al.* (11) a signalé récemment la condensation de monoiminophosphoranes avec l'anhydride phtalique qui conduit directement à des phtalimides. Ceci permettait d'envisager une réaction de cyclisation analogue au départ d'autres composés dicarbonylés.

Dans le cadre des travaux réalisés au laboratoire sur l'intérêt des iminophosphoranes en synthèse hétérocyclique (12, 13), nous avons donc entrepris l'étude de la réactivité de synthons porteurs d'une seule fonction iminophosphorane vis à vis de divers composés dicarbonylés. Dans une communication préliminaire (14), nous avons décrit les résultats obtenus lors de la condensation sur l'*ortho*-phtalaldéhyde (OPTA) d'iminophosphoranes comportant un groupe méthylène en α d'une fonction cétone. Afin de proposer un schéma réactionnel général en fonction de la nature du synthon mis en jeu et des conditions opératoires, l'OPTA a été opposé à une série beaucoup plus large d'iminophosphoranes et nous reportons dans ce mémoire l'ensemble de nos résultats.

Résultats et discussion

Comme la réaction de Staudinger (1) est quantitative, nous avons réalisé toutes les condensations au départ des azides en générant *in situ* les iminophosphoranes correspondants. Outre la rapidité de la méthode, ce procédé présente l'avantage de ne pas avoir à isoler les iminophosphoranes, composés souvent sensibles aux traces d'humidité ou susceptibles de réactions d'autocondensation (15). Ainsi l'addition à température ambiante d'une solution d'iminophosphorane dans le dichlorométhane à une solution d'OPTA dans le même solvant conduit, avec les rendements indiqués dans le tableau 1, à un mélange des isoindolones **1** et **2** ou uniquement aux isoquinoléines **3** selon la nature de l'iminophosphorane (schéma 1). Dans le premier cas, les isoindolones **1** sont obtenues majoritairement quand l'OPTA et l'iminophosphorane sont utilisés dans les proportions stoechiométriques. Les proportions peuvent être inversées en opérant avec un excès d'OPTA. À titre d'exemple, en utilisant 1,5 moles d'OPTA par mole d'iminophosphorane Ph-NPPh$_3$, nous avons isolé les isoindolones **1***a* et **2***a* avec des rendements respectifs de 10 et 44%. Contrairement à nos prévisions, en opérant avec un plus large excès d'OPTA (2 équiv.), le

SCHÉMA 2

rendement en **2***a* est sensiblement le même. De plus, il est alors difficile d'isoler l'isoindolone **1***a* en raison de la présence d'OPTA qui n'a pas réagi car ces deux composés sont de polarité voisine. D'autre part, lorsqu'on inverse l'addition de réactifs (OPTA en défaut), le rendement en isoindolone **2***a* diminue (10%) comme attendu, mais le rendement en **1***a* reste voisin de 20%. Par ailleurs, sauf dans le cas où deux équivalents d'OPTA sont mis en jeu, ce réactif est consommé entièrement lors de la formation des isoindolones. Le bilan (isoindolone **1** + isoindolone **2**) fait donc apparaître une perte de masse de 35–70% selon les cas. Cette donnée expérimentale résulte pour l'essentiel de la grande polarité des iminophosphoranes et des dérivés qui peuvent éventuellement se former lors de la réaction. En effet, l'iminophosphorane inaltéré ou les intermédiaires iminiques ne peuvent pas être séparés de l'oxyde de triphénylphosphine lui-même très polaire.

Le mécanisme que nous proposons pour expliquer la formation des isoindolones **1** est représenté sur le schéma 2. Après élimination d'oxyde de triphénylphosphine, une attaque nucléophile de l'atome d'azote sur la deuxième fonction aldéhyde suivie d'une migration d'un ion hydrure conduit aux isoindolones **1**. Il faut souligner que des migrations d'ions hydrure sur des carbones de type iminique ont déjà été proposées par plusieurs auteurs (16, 17) et en particulier quelques exemples

SCHÉMA 3

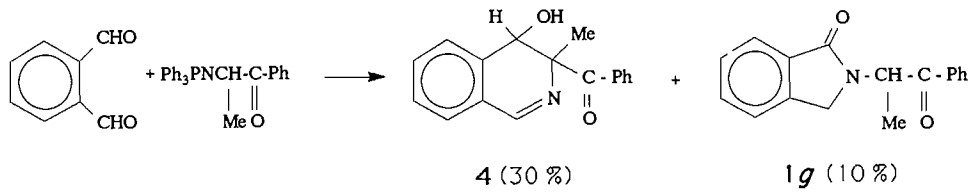

SCHÉMA 4

de migration 1–3 ont été signalés pour des systèmes cycliques à cinq chaînons (17–19). De plus, l'hypothèse d'une intervention d'un intermédiaire iminique est fortement supportée par l'obtention, au départ des iminophosphoranes cétoniques $RCOCH_2NPPh_3$, de systèmes cycliques présentant le motif iminique.

La formation des isoindolones **2** implique de plus la condensation d'une deuxième molécule d'OPTA qui s'effectue probablement sur l'intermédiaire (C) (schéma 2) selon un mécanisme que nous n'avons pas élucidé. En effet, il est peu probable que cette condensation intervienne au niveau des intermédiaires (A) ou (B) car l'élimination d'oxyde de triphénylphosphine et la formation de la liaison C—N par attaque nucléophile de l'atome d'azote sont a priori des réactions plus rapides. Enfin, et de manière inattendue, nous n'avons pas observé la formation de l'isoindolone **2***a* par chauffage à reflux prolongé de l'isoindolone **1***a* et de l'OPTA en excès (2 équiv.) dans le dichlorométhane.

Dans le cas de la formation des isoquinoléïnes **3**, en raison de l'équilibre céto-énolique représenté sur le schéma 3, la cyclisation conduit à un système hydroxylé à six chaînons qui subit ensuite une réaction de déshydratation. Nous avons mis en évidence l'intervention d'un dérivé hydroxylé comme entité intermédiaire en opérant au départ d'un iminophosphorane porteur d'un seul hydrogène méthylénique (schéma 4). Nous avons alors obtenu majoritairement l'isoquinoléine **4**, l'étape finale du mécanisme décrit dans le schéma 3 étant bloquée. Conjointement au dérivé **4**, nous avons également isolé une faible proportion de l'isoindolone **1***g*. Dans ce cas, il y a donc compétition entre les deux centres nucléophiles, l'atome de carbone α-énolique et l'atome d'azote iminique. Celle-ci résulte vraisemblablement de la présence du groupe méthyle qui induit une diminution de la mobilité de l'atome d'hydrogène méthylénique et défavorise donc la forme énolique.

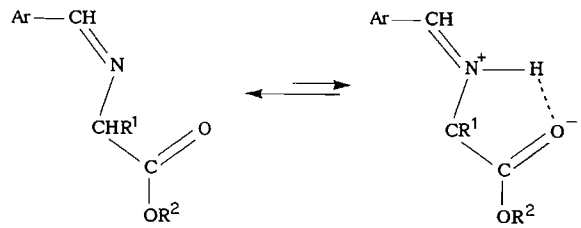

SCHÉMA 5

Ajoutons que la condensation sur l'OPTA de l'iminophosphorane $EtO_2CCH_2NPPh_3$ a conduit uniquement aux isoindolones **1***e* et **2***e* bien que cet iminophosphorane présente également un groupe méthylène en α d'une fonction carbonyle. Ce résultat est en bon accord avec le mécanisme proposé pour les iminophosphoranes cétoniques (schéma 3). En effet, les équilibres céto-énoliques n'interviennent que rarement dans le cas des fonctions ester et la cyclisation en isoquinoléines n'est donc pas favorisée pour l'iminophosphorane $EtO_2CCH_2NPPh_3$. Grigg *et al.* (20) a cependant montré récemment que des imines comportant une fonction ester en α de l'atome d'azote sont en équilibre avec une forme dipolaire grâce à l'existence d'une liaison hydrogène intramoléculaire selon le schéma 5. Or, après la condensation de l'iminophosphorane $EtO_2CCH_2NPPh_3$ sur l'une des fonctions aldéhydes de l'OPTA, un équilibre de ce type était envisageable. La présence d'un carbanion en α de l'atome d'azote suggérait alors la possibilité d'orientation de la cyclisation vers la formation d'une isoquinoléine. Pour vérifier cette hypothèse, nous avons opéré à basse température (−20°C) de manière à favoriser la forme pour laquelle interviendrait une liaison hydrogène : nous avons alors isolé l'isoquinoléine **3***e* (**3**, R = OEt) attendue mais le produit de cyclisation majoritaire reste cependant l'isoindolone **1***e*.

En résumé, le schéma 6 représente les trois types de méca-

SCHÉMA 6

nisme que nous avons proposés pour expliquer la cyclisation en isoindolones et en isoquinoléines, en fonction de la nature de l'iminophosphorane et des conditions opératoires. Nous pensons que la condensation d'iminophosphoranes sur des composés dicarbonylés est une nouvelle voie de synthèse très prometteuse d'hétérocycles azotés puisque, comme nous l'avons montré en utilisant l'OPTA, la cyclisation peut s'effectuer en une seule étape à partir d'azides organiques très aisément accessibles. Ainsi, à l'exception des isoindolones de type **1**, notre méthode se révèle supérieure, quant aux rendements, à celles décrites dans la littérature. En effet, dans le cas des isoindolones de type **2** qui n'ont été signalées antérieurement que par DoMinh *et al.* (21), l'isoindolone **2***a* a été obtenue par cet auteur avec un rendement de 39% en produit brut alors que dans les mêmes conditions de stoechiométrie, nous avons isolé la même isoindolone avec un rendement de 44% après recristallisation. Enfin, les quatre synthèses d'isoquinoléines acylées en position 3 reportées dans la littérature comportent de nombreuses étapes et la préparation préalable d'isoquinoléines substituées en position 3 par un reste de type halogène (22, 23), méthyle (24) ou carboxylate d'éthyle (25). Enfin les multiples possibilités synthétiques au départ des cétones rendent notre méthode particulièrement intéressante pour accéder à la famille des isoquinoléines substituées en position 3, composés qui ont été étudiés en tant qu'inhibiteurs d'enzymes (26), intermédiaires de synthèse (27), ou modèles biologiques (25). Ajoutons également que certains métabolites fongiques appartiennent à cette classe d'hétérocycles (28).

Étude structurale

Les isoindolones **1***a,b*, **2***a* et isoquinoléines **3***a,d,e*, décrites dans la littérature, ont été identifiées en comparant leurs caractéristiques physicochimiques à celles déjà reportées ou à celles des composés de la même série (voir partie expérimentale). La structure des nouvelles isoindolones **1***c–g*, **2***b–e* et isoquinoléines **3***b,c* a été établie en particulier par analyse des spectres de rmn protonique dont les caractéristiques sont rassemblées dans les tableaux 2, 3 et 4. Il faut noter que l'isoindolone **1***e* a déjà été signalée, mais seulement sous forme de mélange et donc sans précision sur ses caractéristiques (voir partie expérimentale).

L'attribution des signaux singulets correspondants aux méthylènes intra- et extracycliques des isoindolones **1***c–f* a été effectuée sans ambiguïté par enregistrement des spectres COSY LR (Long Range) pour **1***c*, **1***e* et **1***f* et par comparaison avec **1***c* pour **1***d*. À titre d'exemple, le spectre COSY LR de l'isoindolone **1***c* présente deux taches de corrélation entre le singulet le plus déblindé et les signaux des protons thiophéniques $H_{3'}$ (^4J) et $H_{4'}$ (^5J) respectivement, ce qui permet d'attribuer ce singulet au méthylène extracyclique. De même, le singulet le plus blindé présente deux taches de corrélation avec deux des multiplets correspondant aux protons H_4–H_6.

Concernant la série des isoindolones **2**, seul le composé **2***a* (R = Ph) a été décrit par DoMinh *et al.* (21). Celui-ci n'a cependant fourni aucune preuve formelle pour confirmer la structure proposée et en particulier éliminer une structure de type isoquinoléine. Les deux structures (I) et (II) (schéma 7) étaient en effet envisageables d'après les données spectroscopiques et nous avons cherché à confirmer, par voie chimique, la structure des composés **2** obtenus. Pour cela, nous avons réalisé successivement, au départ du dérivé **2***a* (schéma 8), une réaction de déshydratation dans l'acide acétique et une réaction d'ozonolyse dans le dichlorométhane du dérivé **5** obtenu. Nous avons ainsi isolé le phtalimide **6**, identifié par comparaison avec un échantillon de référence, ce qui permet de proposer une structure de type isoindolone pour le produit de déshydratation **5**. À l'exception du singulet à 5,59 ppm correspondant au méthylène en position 3', les signaux du spectre de rmn protonique unidimensionnel du dérivé **5** se situent de manière inattendue entre 6 et 8,4 ppm. Nous avons donc confirmé la structure proposée par l'enregistrement du spectre COSY de ce composé (figures 1 et 2). En supposant que le signal le plus déblindé correspond au proton H_7, comme c'est le cas dans toute la série des isoindolones **1** et **2**, on peut attribuer aisément les trois signaux qui sont corrélés à H_7 aux protons du cycle A. Par suite, le deuxième système de quatre signaux corrélés correspond au cycle B. Enfin, le dernier système de trois signaux corrélés est attribué au cycle C (figure 2). Ainsi, bien que le mécanisme de la réaction de déshydratation conduisant au produit **5** soit encore mal compris, l'obtention d'une isoindolone permet sans ambiguïté d'écarter l'hypothèse d'une structure de type isoquinoléine (II) pour les composés **2**.

L'examen des spectres de rmn protonique des isoindolones **2**, dont les caractéristiques sont rassemblées dans le tableau 4, montre qu'il se forme toujours un mélange de deux diastéréoisomères dont les proportions relatives dépendent de la nature du

(II)

SCHÉMA 7

reste lié à l'atome d'azote. La comparaison des déplacements chimiques des protons de l'isoindolone **2***a* reportés par DoMinh *et al.* (21) et nous-mêmes tend à indiquer qu'il s'agit du même diastéréoisomère (majoritaire). Toutefois, nous proposons une attribution différente de celle de cet auteur pour les signaux situés à 5,78 et 6,11 ppm. En effet, le signal à 6,11 ppm apparaît sous forme de doublet, inchangé après deutériation, et ne peut donc être attribué qu'au proton H_3 et non $H_{1'}$. Le signal à 5,78 ppm est quant à lui attribuable à $H_{1'}$ et non à $H_{3'}$, puisqu'il apparaît sous forme de pseudo-triplet par couplage avec H_3 et $H_{3'}$ avec des valeurs de constante de couplage voisines.

Enfin, les signaux des protons H_1 et H_4 des isoquinoléines **3** résonnent sous forme de multiplets en raison de la présence de couplages ^4J et ^5J de l'ordre de 0,8–1 Hz. Leur attribution a été réalisée par comparaison des valeurs des glissements chimiques avec les valeurs données dans la littérature pour des isoquinoléines non substituées en position 1,3 et 4 (29) ou pour des thiénopyridines (30, 31), dont l'attribution des signaux du cycle azoté est non ambigüe.

Partie expérimentale

Les points de fusion ont été déterminés sur un banc de Kofler et ne sont pas corrigés. Les spectres ir ont été enregistrés sur un spectrophotomètre Perkin Elmer 580 B à partir de dispersions à 1% dans l'iodure de césium ou le bromure de potassium. Les spectres de masse ont été obtenus sur appareil Finnigan 3300 (70 eV, 0,4 mA). Les spectres de rmn ont été relevés à 400 MHz sur un appareil Bruker WM 400 du CEREMA («Centre de Résonance Magnétique» de l'Université de Bourgogne). Les valeurs de δ sont exprimées en ppm, le tétraméthylsilane étant pris comme référence (s : singulet, d : doublet, dd : double doublet, t : triplet, q : quadruplet, m : multiplet). Les analyses ont été effectuées par le Laboratoire central de microanalyses du C.N.R.S.

Matériel de départ

Les azides ont été préparés par les méthodes citées en référence : PhN_3 (32), Ph- et Th-CH_2N_3 (33), $RCOCH_2N_3$ (R = Me ou EtO) (34), $PhCOCHRN_3$ (R = H ou Me) (35), $ThCOCH_2N_3$ (36).

*Méthode générale de synthèse des isoindolones **1** et **2***

À une solution d'azide (0,01 mol) dans le dichlorométhane anhydre (ou le benzène dans le cas de l'azidoacétate d'éthyle) (10 mL), est ajoutée à température ambiante et goutte à goutte une solution de triphénylphosphine (2,62 g, 0,01 mol) dans 20 mL du même solvant. À la fin de l'addition, l'agitation est maintenue 2–4 h à température

*Méthode générale de synthèse des isoquinoléines **3***

À une solution d'azidocétone (2,5 mmol) dans 50 mL de dichlorométhane anhydre est ajoutée à 0°C et goutte à goutte une solution de triphénylphosphine (0,66 g, 2,5 mmol) dans le même solvant. La solution est maintenue à 0°C jusqu'à disparition des produits de départ (suivie en chromatographie sur couches minces) puis ajoutée à la même température, à une solution d'*ortho*-phtalaldéhyde (0,34 g, 2,5 mmol) dans 20 mL de dichlorométhane anhydre. À la fin de l'addition, la solution est maintenue 30 min à 0°C et on laisse ensuite remonter la température lentement jusqu'à l'ambiante. Après évaporation du solvant, élution du résidu sur gel de silice par le mélange dichlorométhane–acétone (40 : 1) et recristallisation on isole les isoquinoléines **3**.

*Phényl isoquinolyl-3 cétone (**3**c)* : Rdt 30% (0,17 g); F = 82°C (éther éthylique – hexane) (litt. (22) F = 79–81°C).

*Thiényl-2 isoquinolyl-3 cétone (**3**b)* : Rdt 35% (0,21 g); F = 124°C (éther éthylique – hexane); ir ν_{max} (KBr) : 1641 (CO), 1614, 1498, 1404 cm^{-1}; sm m/z : 239 (M^+, 25), 211 (100), 128 (16), 128 (16), 111 (67). Anal. calc. pour $C_{14}H_9NOS$: C 70,27, H 3,79, N 5,85, S 13,40; tr. : C 70,49, H 3,69, N 5,81, S 13,43.

*Thiényl-3 isoquinolyl-3 cétone (**3**c)* : Rdt 30% (0,18 g); F = 89–90°C (éther éthylique – hexane); ir ν_{max} (KBr) : 1661 (CO), 1618, 1508, 1391 cm^{-1}; sm m/z : 239 (M^+, 56), 211 (60), 210 (53), 128 (23), 111 (100). Anal. calc. pour $C_{14}H_9NOS$: C 70,27, H 3,79, N 5,85, S 13,40; tr. : C 69,95, H 3,74, N 5,88, S 13,30.

*Méthyl isoquinolyl-3 cétone (**3**d)* : Rdt 30% (0,13 g); F = 90–92°C (éther éthylique – hexane) (litt. (40) F = 92–92,8°C).

Condensation de l'iminophosphorane dérivé de l'azide $PhCOCH(Me)N_3$ sur l'OPTA

Le mode opératoire décrit pour la synthèse des isoquinoléines **3** conduit, après chromatographie sur gel de silice par le mélange dichlorométhane–acétone (40 : 1), à l'isoindolone **1***g* et à l'isoquinoléine **4**.

*(Méthyl-1 phénacyl)-2 isoindoline one-1 (**1**g)* : Rdt 10% (0,53 g); F = 80–82°C (éther éthylique – hexane); ir ν_{max} (KBr) : 1690 (CO extracyclique), 1678 (CO intracyclique), 1220, 740 cm^{-1}; sm m/z : 265 (M^+, 1), 174 (7), 160 (100), 132 (8), 119 (4), 105 (5), 91 (14), 77 (10). Anal. calc. pour $C_{17}H_{15}NO_2$: C 76,96, H 5,70, N 5,28; tr. : C 76,83, H 5,71, N 5,06.

*Benzoyl-3 hydroxy-4 méthyl-3 dihydro-3,4 isoquinoléine (**4**)* : Rdt 30% (1,59 g); F = 137–138°C (éther éthylique – hexane); ir ν_{max} (KBr) : 3132 (OH), 1680 (CO), 1672 (CN) cm^{-1}; rmn ^1H (DMSO-d_6) δ : 1,12 (3H, s, CH_3), 4,79 (1H, d, J = 5,23 Hz, singulet après deutériation, C*H*OH), 5,74 (1H, d, J = 5,23 Hz, s'échange avec D_2O, OH), 7,43–7,61 (7H, m, ArH), 7,86 (2H, m, $H_{2'}$ et $H_{6'}$), 8,49 (1H, s, H_1) ppm; sm m/z : 265 (M^+, 3), 248 (27), 143 (60), 118 (38), 105 (100), 77 (51). Anal. calc. pour $C_{17}H_{15}NO_2$: C 76,96, H 5,70, N 5,28; tr. : C 76,74, H 5,56, N 5,10.

Condensation à basse température de l'iminophosphorane dérivé de l'azidoacétate d'éthyle sur l'OPTA

À une solution de l'azidoacétate d'éthyle (2,58 g, 20 mmol) dans le dichlorométhane anhydre (25 mL) est ajoutée à température ambiante et goutte à goutte une solution de triphénylphosphine (5,24 g, 20 mmol) dans 60 mL du même solvant. À la fin de l'addition, l'agitation est maintenue 4 h à température ambiante puis la solution est refroidie à −20°C et ajoutée, à cette température et goutte à goutte, à une solution d'*ortho*-phtalaldéhyde dans le dichlorométhane anhydre (200 mL). À la fin de l'addition, on laisse la température revenir très progressivement à l'ambiante puis on maintient l'agitation à cette température pendant 3 h. Après évaporation du solvant et élution du résidu sur gel de silice par le mélange dichlorométhane–acétone (50 : 1), on isole l'isoindolone **1***e* et l'isoquinoléine **3***e*.

*Ethoxycarbonyl-2 isoindoline one-1 (**1**e)* : Rdt 30% (1,31 g).

*Ethoxycarbonyl-3 isoquinoléine (**3**e)* : Rdt 6% (0,24 g); identifiée par spectroscopie rmn (voir tableau 4).

*(Dihydro-1,3 isobenzofurannylidène-1)-3 phényl-2 isoindoline one-1 (**5**)*

Une solution de l'isoindolone (**2***a*) (0,86 g, 2,5 mmol) dans 100 mL

d'acide acétique est chauffée à reflux pendant 10 min. La solution est diluée à l'eau et extraite au dichlorométhane. Les phases organiques sont lavées par une solution de bicarbonate de sodium, puis à l'eau jusqu'à neutralité. Après séchage des phases organiques sur sulfate de magnésium, évaporation du solvant et élution du résidu sur gel de silice par le mélange dichlorométhane–acétone (25 : 1), on isole 0,28 g d'isoindolone **5**; Rdt 35%; F = 230°C (acétone–eau); ir ν_{max} (KBr) : 1688 (CO), 1628, 1334, 1144 cm^{-1}; rmn ^1H ($CDCl_3$) δ : 5,59 (2H, s, $(CH_2)_{3'}$), 6,04 (1H, m, $H_{7'}$), 6,84 (1H, m, $H_{6'}$), 7,20 (1H, m, $H_{5'}$), 7,27–7,32 (2H, m, $H_{4'}$ et $H_{4''}$), 7,39–7,46 (3H, m, $H_{3''}$, $H_{5''}$ et H_5), 7,50 (2H, m, $H_{2''}$ et $H_{6''}$), 7,65 (1H, m, H_6), 7,96 (1H, m, H_4), 8,37 (1H, m, H_7); sm m/z : 325 (M^+, 100), 296 (57), 268 (54), 165 (19). Anal. calc. pour $C_{22}H_{15}NO_2$: C 81,22, H 4,64, N 4,31; tr. : C 81,11, H 4,66, N 4,17.

Ozonolyse du dérivé **5**

Une solution de l'isoindolone **5** (32,5 mg, 0,1 mmol) dans le dichlorométhane (40 mL) est soumise au passage d'un courant d'ozone (O_3 + O_2) à température ambiante pendant 1 h. L'excès d'ozone est éliminé par un courant d'azote puis on ajoute au milieu réactionnel 1 mL d'une solution d'hydrogénosulfite de sodium (d = 1,32). La phase organique est lavée à l'eau puis séchée sur sulfate de magnésium. Après évaporation du solvant, on isole 19 mg de phtalimide **6**; Rdt 87%; F = 208°C (dichlorométhane); identifiée par comparaison avec un échantillon de référence.

Cycloaddition reactions of dichlorodithionitronium hexafluoroarsenate(V) with alkynes and alkenes; the preparation and X-ray crystal structure of 1,3-dichloro-1,3,2-dithiazolidinium hexafluoroarsenate(V)

SIMON PARSONS, JACK PASSMORE,[1] MELBOURNE J. SCHRIVER, AND PETER S. WHITE[1]
Department of Chemistry, University of New Brunswick, Fredericton, N.B., Canada E3B 6E2

Received September 18, 1989

SIMON PARSONS, JACK PASSMORE, MELBOURNE J. SCHRIVER, and PETER S. WHITE. Can. J. Chem. **68**, 852 (1990).

The dichlorodithionitronium cation, $ClSNSCl^+$, undergoes symmetry-allowed, concerted, cycloaddition reactions with alkynes and alkenes in liquid sulphur dioxide. With ethyne and propyne it gives corresponding 1,3,2-dithiazolium salts in quantitative yield. Cycloaddition with alkenes yields (hitherto unknown) 1,3-dichloro-1,3,2-dithiazolidinium cations. The reactions are sensitive to substituents, and only the cycloaddition with ethene occurs quantitatively on a preparative scale. Cycloadditions with propyne and *E*- and *Z*-2-butene have been observed in solution. The preparation, characterization, and X-ray crystal structure of the product of the reaction of $ClSNSCl^+$ with ethene, 1,3-dichloro-1,3,2-dithiazolidinium hexafluoroarsenate(V), are reported. Crystals of 1,3-dichloro-1,3,2-dithiazolidinium hexafluoroarsenate(V) are monoclinic, of space group $P2_1/c$, $a = 6.3161(6)$ Å, $b = 17.1724(23)$ Å, $c = 19.1558(18)$ Å, and $\beta = 98.143(8)°$; $Z = 4$ and $R = 0.061$. The 1,3-dichloro-1,3,2-dithiazolidinium cation consists of a five-membered $\overline{CSNSC}^+$ ring, axially substituted at the sulphurs by chlorine (average bond lengths: S—N 1.603(8) Å, S—Cl 2.025(4) Å, S—C 1.822(10) Å, and C—C 1.504(13) Å). Two crystallographically unique cations are linked by weak S..N contacts into pseudo-dimers. These data are used, together with structural comparisons with related SNS-containing cations and the sulphoxides and the ^{14}N chemical shift, to show that the bonding in the SNS region of the cation is best represented by the valence canonicals $\rangle S^+—N^-—S^+\langle$ and $\rangle S{=}N—S^+\langle$, such that the sulphur and nitrogen atoms respectively carry absolute positive and negative charges. This picture is also supported by the fluoride contacts to the cation from the AsF_6^- anion, which are exclusively to sulphur. Nuclear magnetic resonance data were consistent with the retention of the solid state structure of $H_2\overline{C(Cl)N(Cl)CH_2}^+$ in solution.

Key words: sulphur-nitrogen chloride, sulphur-nitrogen cations, 1,3-dichloro-1,3,2-dithiazolidinium, cycloaddition reactions, X-ray crystallography.

SIMON PARSONS, JACK PASSMORE, MELBOURNE J. SCHRIVER et PETER S. WHITE. Can. J. Chem. **68**, 852 (1990).

Dans le bioxyde de soufre, le cation dichlorodithionitronium, $ClSNSCl^+$, réagit avec les alcynes et les alcènes pour donner des produits de cycloadditions concertées permises par la symétrie. Avec l'éthyne et le propyne, il y a formation des sels 1,3,2-dithiazolium correspondants, avec des rendements quantitatifs. Les cycloadditions avec les alcènes conduisent aux cations 1,3-dichloro-1,3,2-dithiazolidinium inconnus jusqu'à maintenant. Les réactions sont très sensibles à la présence de substituants et seule la cycloaddition avec l'éthène se produit d'une façon quantitative sur une base préparative. En solution, on a observé des cycloadditions avec le propyne et les *E*- et *Z*-but-2-ènes. On rapporte la préparation, la caractérisation ainsi que la détermination de la structure cristalline du produit de la réaction du $ClSNSCl^+$ avec l'éthène, l'hexafluoroarsénate du 1,3-dichloro-1,3,2-dithiazolidinium. Les cristaux de l'hexafluoroarsénate du 1,3-dichloro-1,3,2-dithiazolidinium sont monocliniques, groupe d'espace $P2_1/c$ avec $a = 6{,}3161(6)$, $b = 17{,}1724(23)$ et $c = 19{,}1558(18)$ Å, $\beta = 98{,}143(8)°$, $Z = 4$ et $R = 0{,}061$. Le cation 1,3-dichloro-1,3,2-dithiazolidinium comporte un cycle $\overline{CSNSC}^+$ dont les soufres sont substitués par des chlores axiaux (longueurs moyennes des liaisons : S—N, 1,603(8) Å; S—Cl, 2,025(4) Å; S—C, 1,822(10) Å et C—C, 1,504(13) Å). Deux cations qui sont distincts d'un point de vue cristallographique sont liés par de faibles contacts S..N pour former des pseudo-dimères. On a comparé ces données ainsi que les valeurs des déplacements chimiques en RMN du ^{14}N avec celles obtenues pour des structures de sulfoxydes et de cations apparentés contenant du SNS et on en conclut que la meilleure façon de représenter les liaisons dans la région du cation est d'utiliser les valences canoniques $\rangle S^+—N^-—S^+\langle$ et $\rangle S{=}N—S^+\langle$; de cette façon, les atomes de soufre et de carbone portent respectivement des charges absolues positive et négative. Cette représentation est en accord avec les contacts des ions fluorures avec le cation de l'anion AsF_6^- qui se font uniquement avec le soufre. Les données de la RMN sont aussi en accord avec le fait que la structure du cation $H_2\overline{C(Cl)N(Cl)CH_2}^+$ à l'état solide est maintenue en solution.

Mots clés : chlorure de soufre et d'azote, cations de soufre et d'azote, 1,3-dichloro-1,3,2-dithiazolidinium, réactions de cycloaddition, cristallographie à l'aide de rayons-X.

[Traduit par la revue]

Introduction

The cycloaddition reactions of sulphur-nitrogen compounds have been the subject of recent interest (1). S_4N_4 undergoes cycloaddition reactions only with some strained alkenes (2). In contrast, SNS^+ undergoes a series of general, symmetry-allowed, quantitative cycloadditions with a variety of unsaturated species (3, 4). Not only do the symmetries of the frontier orbitals of SNS^+ match those of many unsaturated species, but its cationic charge lowers its molecular orbital energies relative to those in neutral sulphur-nitrogen compounds, and thermodynamically and kinetically facilitates reverse electron demand cycloadditions (4). This is illustrated in Fig. 1.

The π-manifold of SNS^+ contains two perpendicular 3 centre/4 electron π bonds (Fig. 1). We have recently shown that the 1:1 cycloadduct of SNS^+ and ethene, $\overline{CH_2SNSCH_2}^+$, which contains a similar 3 centre/4 electron π bond in one plane

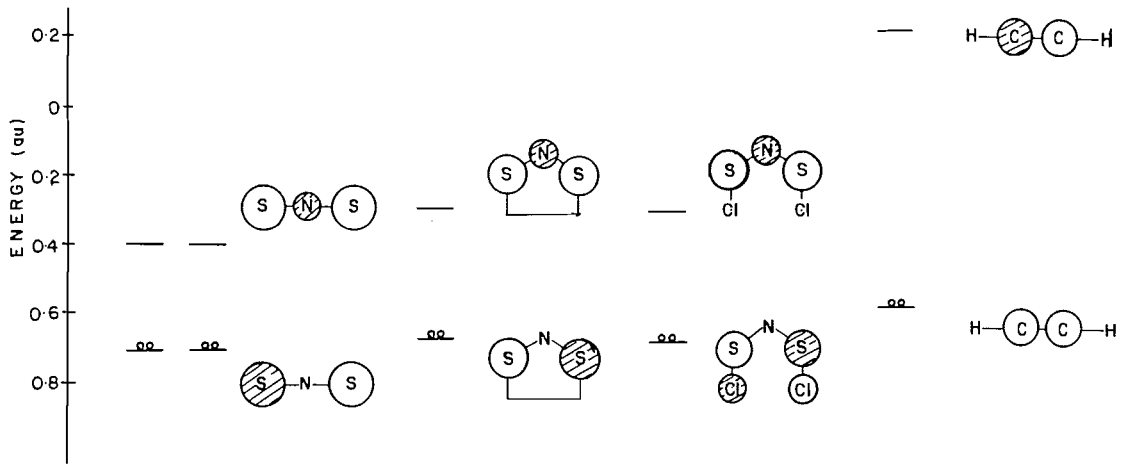

FIG. 1. The frontier molecular orbital energies of SNS^+, $\overline{CH_2SNSCH_2}^+$, $ClSNSCl^+$, and ethyne. Calculated by CNDO/2. Geometries: $ClSNSCl^+$ experimental (27); SNS^+ experimental for AsF_6^- salt corrected for thermal effects (31); $\overline{CH_2SNSCH_2}^+$ extrapolated from the observed structure of **5** (4): bond lengths: S—N 1.65 Å, S—C 1.81 Å, C—C 1.51 Å, C—H 1.0 Å; bond angles at: N 112°, S 102°, C 112°).

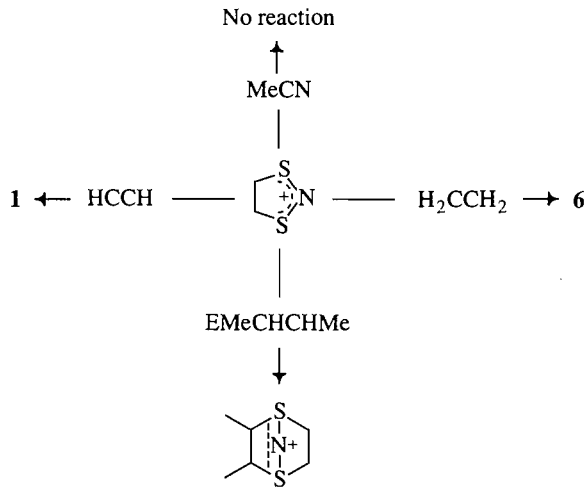

SCHEME 1. Reactions of $\overline{CH_2SNSCH_2}^+$ (all as the AsF_6^- salt in SO_2 solvent (4, 5)).

(Fig. 1), undergoes cycloadditions analogous to those of SNS^+ (Scheme 1) (4, 5). The allowedness of these reactions is enhanced by the positive charge on $\overline{CH_2SNSCH_2}^+$, although it is less reactive than SNS^+ (for example, it does not react with acetonitrile).

We predicted that any $XSNSX^+$ fragment with similar frontier molecular orbitals would undergo similar cycloaddition reactions with unsaturated centres. In this paper we describe experiments carried out to confirm this hypothesis with $ClSNSCl^+$, and the synthesis and characterization of the first 1,3-dichloro-1,3,2-dithiazolidinium salt, prepared by the reaction of $ClSNSClAsF_6$ and ethene. A preliminary abstract of this work has been published (6*a*).

Various $ClSNSCl^+$ salts have been prepared in good yield (6*b*; see also ref. 12), but apart from a recent report of its quantitative reduction to SNS^+ (6*c*), very little is known of its chemistry. In this paper we describe a systematic investigation of its cycloaddition chemistry, and compare its reactivity with that of SNS^+ and $\overline{CH_2SNSCH_2}^+$.

Experimental

Apparatus, techniques, and chemicals, unless specified, have been described (7–11). $ClSNSClAsF_6$ was prepared as in ref. 12. Ethyne, ethene (Canadian Liquid Air), propene, *E*-2-butene (Matheson), *Z*-2-butene (Aldrich), perfluoroethene (Columbia), perfluoro-2-butyne (PCR), propyne (Farchan), and triphenyl antimony (Lancaster Synthesis) were used as received.

All nmr spectra were recorded on a Varian Associates XL-200 spectrometer and accumulated in 4K (^{14}N), 16K (^1H), or 32K (^{13}C and ^{19}F) of memory, and obtained unlocked at room temperature. ^1H spectra were run at 200 MHz in 32–200 scans with a spectral width of 2.6 kHz (0.3 Hz/data point, acquisition time 2.991 s, pulse width 6.1 μs). ^{19}F spectra were obtained at 188.15 MHz in 100–200 scans with a spectral width of 56.5 kHz (3.8 Hz/data point, acquisition time 0.266 s, pulse width 4 μs). ^{13}C spectra were run at 50.29 MHz with a spectral width of 15.0 kHz (1 Hz/data point, acquisition time 1.001 s, pulse width 4 μs) with broad band "waltz" decoupling. ^{14}N spectra were run at 14.45 MHz in 2000–10000 scans with a spectral width of 15.0 kHz (10.2 Hz/data point, acquisition time 0.098 s, pulse width 38 μs). The pulse widths quoted correspond to tip angles of 90° (^{14}N), 60° (^1H), 30° (^{19}F), and 22.5° (^{13}C). Samples for ^1H and ^{19}F nmr spectroscopy were contained in sealed thick-walled 5-mm precision nmr tubes, and those for ^{13}C and ^{14}N nmr in thick-walled 10-mm (or occasionally 16-mm for ^{14}N) nmr tubes fitted with J. Young "O Ringette" type valves. Spectra were referenced externally to a solution of TMS and Freon-11 in SO_2 (^1H and ^{19}F), TMS in SO_2 (^{13}C), or neat nitromethane (^{14}N).

Reaction of $ClSNSClAsF_6$ with unsaturated bonds

SO_2 (0.842 g, 13.14 mmol) and ethyne (0.004 g, 0.14 mmol) were successively condensed onto $ClSNSClAsF_6$ (0.048 g, 0.14 mmol) in a 5-mm nmr tube, which was then flame sealed. The mixture was kept at −196°C until the ^1H nmr was acquired. This showed only a singlet at 11.0 ppm ($\overline{HCSNSCH}^+$, **1***a* (5)). The results of this and other experiments, performed according to a similar procedure, are given in Table 1.

Reaction of substituted alkenes (propene, *E* and *Z* but-2-enes) with $ClSNSCl^+$ according to this procedure led to the formation of mixtures containing mostly RCH(Cl)CHR(Cl) and $\overline{RCHSNSCHR}^+$ (R = Me or H). In an attempt to obtain clean cycloaddition, experiments were carried out in which solutions of alkenes were poured directly onto solid $ClSNSClAsF_6$. The results are shown in Table 2. Experiments in which solutions of alkenes and $ClSNSClAsF_6$ were mixed gave essentially the same results as those carried out in nmr tubes.

The preparation of $HCSNSCHAsF_6$ by the reaction of $ClSNSClAsF_6$ with ethyne

The ^{14}N nmr spectrum of a yellow solution of $ClSNSClAsF_6$ (0.338 g, 1.00 mmol) in SO_2 (3.70 g) in a 16-mm nmr tube showed only one resonance at 19 ppm ($\Delta\nu$ = 450 Hz) due to $ClSNSCl^+$ (13).

[a]Experiments carried out in 5-mm nmr tube according to procedure described in text.
[b]A less concentrated solution was used here. More concentrated solutions led to a less well resolved multiplet.
[c]See Table 2 for comparison.
[d]Procedure as described in text, and in addition the sample was heated to 70°C for 14 h before recording nmr spectrum.

HCCH (0.086 g, 3.30 mmol, 2.3-fold excess with respect to eq. [2] (see below)) was added, giving a clear yellow solution that became colourless after 20 h, and one resonance in the ^{14}N nmr spectrum at −5 ppm ($\Delta\nu$ = 350 Hz), **1***a* (13). The volatile products contained SO_2, SO_2Cl_2, HCCH, and H(Cl)CC(Cl)H (ir). The white-brown solid product was $\overline{HCSNSCH}AsF_6$ (ir) (0.283 g, 0.97 mmol, 97% yield) (3).

Synthesis of $\overline{CH_2(SCl)N(SCl)CH_2}AsF_6$ (2)

SO_2 (8.140 g) and ethene (0.160 g, 5.72 mmol) were condensed onto $ClSNSClAsF_6$ (1.936 g, 5.73 mmol) in a two-bulbed vessel incorporating a sintered glass frit. The solution turned from bright yellow to pale yellow within a minute of thawing, but the reaction mixture was stirred at room temperature for 20 min to ensure complete reaction. The volatiles (SO_2, ir) were removed, leaving pure **2** (2.087 g, 5.71 mmol, 99% yield, according to eq. [1]).

[a] Solution of alkene poured onto solid $ClSNSClAsF_6$; procedure described in text.

[b] $MeCH(SCl)N(SCl)CH_2^+$ can exist in either diastereomeric form **3***a* or **3***b*. **3***b* is expected to be more abundant because this isomer will experience less steric hindrance between the methyl group and the chlorines than **3***a*. The assignment of individual resonances was made using 2D-COSY ^{1}H nmr and confirmed using a series of low power ^{1}H decoupling experiments. The ^{13}C spectrum of a 0.6 M solution prepared by pouring $MeCHCH_2$ (0.063 g, 1.50 mmol) in SO_2 (3.432 g) onto solid $ClSNSClAsF_6$ (0.527 g, 1.56 mmol) showed resonances at 78.7, 73.3, 68.6, 66.0, 18.6, and 13.0 ppm (**3***a*,*b*); 67.1, 62.4, and 15.7 ppm ($MeCHSNSCH_2^+$); and 57.7, 50.5, and 22.3 ppm ($MeCHClCH_2Cl$).

[c] ^{13}C spectrum of a solution prepared by pouring *E*-MeCHCHMe (0.044 g, 0.78 mmol) in SO_2 (3.883 g) onto solid $ClSNSClAsF_6$ (0.305 g, 0.902 mmol): 82.1, 76.1, 12.1, and 11.4 ppm (*anti*-$MeCH(SCl)N(SCl)CH_2^+$); 74.1 and 14.2 ppm ($MeCHSNSCH_2^+$); 62.0 and 21.1 ppm ($MeCHClCH_2Cl$); and 70.4, 58.6, 17.3, and 9.9 ppm (unassigned).

[d] The connectivities implied by these assignments were deduced from a 2D-COSY ^{1}H nmr experiment. This also showed that the broad resonance at 4.9 ppm was linked to another broad resonance beneath the two doublets at 2.2 ppm. This accounts for the anomalously large integration of this set of resonances.

[e] ^{13}C spectrum of a solution prepared by pouring *Z*-MeCHCHMe (0.052 g, 0.93 mmol) in SO_2 (2.146 g) onto $ClSNSClAsF_6$ (0.330 g, 0.98 mmol): 80.8, 71.6, 12.7, and 10.5 ppm (*syn*-$MeCH(SCl)N(SCl)CH_2^+$; two isomers, *exo* and *endo*); 70.8 and 8.4 ppm (*syn*-$MeCHSNSCHMe^+$); 62.5 and 21.1 ppm (MeCHClCHClMe); and 67.6, 67.3, 65.6, 13.4, and 13.0 (unassigned).

[f] *syn*-$MeCH(SCl)N(SCl)CHMe^+$ can exist in *exo* and *endo* forms. By similar reasoning to that given in footnote *b*, the *endo* form is likely to be more abundant. The connectivities implied by these assignments were confirmed by a series of low power decoupling experiments.

between KBr plates): 3027 (m), 3002 (m, ν(CH)), 1417 (m), 1402 (m, $\beta(CH_2)$), 1149, 1101 (mw, $\nu_{asym}(S_2N)$), 906 (s, $\beta(CH_2)$), 738 (s), 690 (vs, $\nu_3(AsF_6^+)$), 659 (sh), 651 (sh), 617 (m), 551 (mw), 521 (s, ν_{asym}(S-Cl)), 476 (s), 455 (s, ν_{sym}(S-Cl)), 396 (s, $\nu_4(AsF_6^-)$) cm^{-1}. A copy of the spectrum has been deposited.[2] The ^1H nmr spectrum: AA′BB′ pattern about 5.3 ppm (Fig. 2) (due to **2**). An additional peak at 4.9 ppm (ca. 3% of total integrated intensity) was observed in solutions of isolated **2** redissolved in SO_2. This is due to $H_2\overline{CSNSCH_2}^+$ arising from dechlorination of **2**; ^{13}C nmr: δ = 62.5 ppm. A much weaker resonance at 55.2 ppm was also observed and assigned to the dechlorinated product (5); ^{14}N nmr: δ = −243 ppm ($\Delta\nu$ = 415 Hz). Anal. calcd. for $C_2H_4S_2NCl_2AsF_6$: S 17.52, N 3.83, Cl 19.37, C 6.56, H 1.10%; found: S 17.78, N 3.91, Cl 19.54, C 6.79, H 1.13%.

Dechlorination of 2

The appearance of the resonances at 4.9 ppm (^1H) and 55.2 ppm (^{13}C) in the nmr spectra of isolated **2** redissolved in SO_2 indicated that it is unstable with respect to dechlorination. Solutions of **2** prepared *in situ* in SO_2 only showed slight dechlorination (2%) after standing at room temperature for over four hours (^1H nmr). In the presence of a large excess of chlorine the ^1H nmr of a solution of **2** in SO_2 showed only a broadish singlet at 5.2 ppm ($\Delta\nu$ = 9 Hz).

Dechlorination of **2** becomes quantitative in the presence of a stronger chlorine acceptor. The ^1H nmr of a mixture of **2** (0.047 g, 0.13 mmol) and $SbPh_3$ (0.044 g, 0.14 mmol) in SO_2 exhibited resonances only at 8.3 ppm, 7.7 ppm ($SbPh_3Cl_2$), and 4.9 ppm ($H_2\overline{CSNSCH_2}^+$).

Single crystal X-ray diffraction study

Crystals of **2** (0.148 g) suitable for X-ray crystallography were grown from a mixture of SO_2 (3.419 g) and Freon-11 (1.938 g) by slow evaporation of the solvent over 12 h, and mounted under dry nitrogen in rigorously dried Pyrex capillaries as described elsewhere (14).

After a preliminary photographic investigation a suitable crystal was mounted on an Enraf–Nonius CAD4 diffractometer equipped with graphite monochromated Mo Kα radiation and under the control of the NRCCAD (15) program system. Full details of the data collection and other crystallographic information are given in Table 3.

The structure was solved by direct methods. After refinement with isotropic thermal parameters and empirical absorption correction was applied using the DIFABS routine (16). In the final cycles of least-squares refinement all non-hydrogen atoms were permitted to refine with anisotropic thermal parameters. Hydrogen atoms were placed at calculated positions (with C—H bond length 0.96 Å) and assigned isotropic thermal parameters based on the carbon atom to which they are attached. Scattering factors were taken from ref. 17 and corrected for anomalous dispersion. Final atomic coordinates are given in Table 4.[2] All computations were performed using the PC version of the NRCVAX suite of programs (18).

Discussion

Concerted, symmetry-allowed cycloaddition reactions of $ClSNSCl^+$ are observed in dilute solution for a number of

TABLE 3. Crystal data for $\overline{CH_2(SCl)N(SCl)CH_2}AsF_6$ (**2**)

System	Monoclinic
Space group	$P2_1/c$
a (Å)	6.3161(6)
b (Å)	17.1724(23)
c (Å)	19.1558(18)
β (°)	98.143(8)
V (Å^3)	2056.7
Z	4
Crystal size (mm)	0.52 × 0.33 × 0.15
μ (mm^{-1})	4.26
D_{calc} (mg m^{-3})	2.36
$F(000)$	1408
Diffractometer	Nonius CAD4
Scan type	θ–2θ
Scan width (deg 2θ corrected for dispersion)	1.8
Scan speed (deg 2θ min^{-1})	2
$2\theta_{max}$	50
Number of standards per interval per hour	3
Number of measured reflections	7214
Number of observed reflections ($I > 2.5\sigma(I)$)	2662
Number of unique reflections	3607
Octants collected	$\pm h, \pm k, l$, with h(max) = 7, k(max) = 19, l(max) = 22
λ – Mo K_α (Å)	0.70930
Temperature (K)	293
Relative transmission factors	0.70–1.73
Weighing scheme	$w = 1/(\sigma(F) + 0.001F^2)$
R (= $\Sigma\|\Delta F\|/\Sigma\|F\|$) observed data	0.061
all data	0.089
R (= $\Sigma w\|\Delta F\|^2/\Sigma wF_o^2$) observed data	0.078
all data	0.085
Number of refined parameters	257
Final difference synthesis maximum (e/Å^3)	1.23
Final difference synthesis minimum (e/Å^3)	−0.99

non-electrophilic alkenes and alkynes. A summary of results is given in Scheme 2. The cycloaddition reactions are less general than those of SNS^+, and more resemble those of $\overline{CH_2SNSCH_2}^+$ (see Scheme 1 and below) (4). The higher reactivity of SNS^+ relative to $ClSNSCl^+$ is likely a kinetic effect, arising in part from the smaller energy differences between its LUMO and the HOMOs of alkenes and alkynes (see Fig. 1) (19).

The reaction of $ClSNSCl^+$ with ethyne on a preparative scale gave **1***a* quantitatively, and it is likely that this reaction is a general preparative route to a variety of derivatives of **1**. In contrast, only ethene gave the corresponding dichloro cycloadduct (**2**) in high yield on a preparative scale.

Reactions with alkynes

$ClSNSClAsF_6$ was reacted with HCCH, MeCCH, and CF_3CCCF_3. Cycloaddition with chlorine elimination occurred in the case of ethyne and propyne (eq. [2]), but no reaction was observed with CF_3CCCF_3, even in the presence of an excess of alkyne with heating to 70°C for 14 h.

[2] $HCCH + ClSNSClAsF_6 \rightarrow \overline{HCSNSCH}AsF_6 + Cl_2$

The reactions were followed by ^1H or ^{19}F nmr, and the nmr results were confirmed on a prepative scale in the reaction with ethyne.

The cycloaddition of alkynes with the $ClSNSCl^+$ cation likely proceeds via an intermediate of type **4**, which then loses Cl_2 under the driving force of the aromaticity of the final product (here **1***a* and *b*), and the formation of SO_2Cl_2:

[3] $Cl_2 + SO_2 \rightarrow SO_2Cl_2$

Although these heterocycles can also be obtained by the reaction of SNS^+ or $\overline{CH_2SNSCH_2}^+$ with an alkyne (3), their synthesis from more readily available $ClSNSCl^+$ salts potentially represents a more convenient route.

MeCN did not react with $ClSNSCl^+$, in contrast to its facile cycloaddition with SNS^+. This is consistent with the known reluctance of nitriles to behave as dienophiles (20): for example, Diels–Alder cycloaddition to a nitrilic function often requires very high temperatures or even gas phase conditions.

The reaction of SNS^+ with CF_3CCCF_3 is slower than with alkyl analogues (5), and it is not surprising that it does not react at all with $ClSNSCl^+$. CF_3CCCF_3 is a poorer electron donor than R_HCCR_H, and would therefore be expected to be less reactive towards acceptors. In addition, SNS^+ is a better acceptor than $ClSNSCl^+$, by virtue of its lower energy LUMO (see Fig. 1). This observation is an illustration of the general requirement that components of cycloaddition reactions have "complimentary electronic character" (20).

Reactions with alkenes

$ClSNSClAsF_6$ was reacted with ethene, propene, *E*- and *Z*-2-butene, and perfluoroethene in SO_2 at room temperature (Scheme 2). The predicted cycloaddition was observed in solution to some extent in all cases except the last. These findings constitute the first observation of 1,3-dichloro-1,3,2-dithiazolidinium cations, which are potentially useful prepara-

tive intermediates because they contain synthetically versatile S—Cl bonds.

^1H and ^{13}C nuclear magnetic resonance were used to characterize the products of these reactions. $ClSNSCl^+$ reacts quantitatively with ethene to give **2**, the 200-MHz ^1H nmr spectrum of which shows an AA′BB′ resonance that is consistent with **2** containing a CH_2CH_2 moiety with no plane of symmetry through the carbon atoms, as also shown by X-ray diffraction (see below), which confirms that the structure in solution is the same as in the solid state. The ^1H nmr spectra of reaction mixtures involving substituted alkenes were complicated by second-order effects and the overlap of peaks. However, selective low power decoupling and ^1H-COSY experiments largely enabled these spectra to be completely assigned, although small amounts (5%) of unidentified species were present in the reactions with *E* and *Z* butenes.

The nature of the products obtained in these reactions depended on experimental conditions. Strict 1:1 stoichiometry was necessary because dechlorination occurred in the presence of excess alkene. Reaction of substituted alkenes with $ClSNSCl^+$ in nmr tubes led to the formation of mixtures. The highest yields of cycloadducts with substituted alkenes were observed when a solution of the alkene was poured onto solid $ClSNSClAsF_6$, and reaction mixtures were 0.2–0.3 M in the reactants. Under these conditions the cycloaddition of $ClSNSCl^+$ with propene proceeded quantitatively, but those with *E* and *Z* butenes only in 56 and 70% yields respectively (as calculated from nmr integrations).

All the cycloadditions with alkenes were observed in solution by nmr on a small scale, but only the ethene cycloadduct was isolated and fully characterized. The only substituted species to be obtained pure in solution (**3***a*,*b*) gave an involatile reddish oil on removal of the solvent. Given these findings, it is unlikely that the procedures described here will constitute viable general syntheses of 1,3-dichloro-1,3,2-dithiazolidinium salts. (N.B. Reaction of $\overline{CH_2SNSCH_2}AsF_6$ with Cl_2 leads to a mixture of products not including **2** (5).)

The side products of the reactions of substituted alkenes with $ClSNSCl^+$ were usually chlorinated alkene and $R\overline{CHSNSCHR}^+$. It is likely that these arise via two alternative routes, one mediated by SO_2:

[4] $R\overline{CH(SCl)N(SCl)CHR}^+ + SO_2 \rightarrow R\overline{CHSNSCHR}^+ + SO_2Cl_2$

[5] $RCH{=}CHR + SO_2Cl_2 \rightarrow RCH(Cl)CH(Cl)R + SO_2$

and another by alkene:

[6] $R\overline{CH(SCl)N(SCl)CHR}^+ + RCH{=}CHR \rightarrow R\overline{CHSNSCHR}^+ + RCH(Cl)CH(Cl)R$

The sensitivity to substituents of the cycloadditions of alkenes with $ClSNSCl^+$ is seen to a limited extent in their related cycloadditions with SNS^+. Although *E*- and *Z*-2-butene cycloadd cleanly to SNS^+, the fully substituted alkene 2,3-dimethyl-2-butene (Me_2CCMe_2) produces a variety of products, which have so far not been identified. It is possible that these effects are a result of steric factors.

F_2CCF_2, a very poor electron donor, did not react with $ClSNSCl^+$. Neither have we observed it to react with SNS^+ (5).

The preparation of **2**

The symmetry-allowed cycloaddition of ethene and $ClSNSCl^+$ proceeds quantitatively according to eq. [1] to produce **2**, the first example of a 1,3-dichloro-1,3,2-dichlorodithiazolidinium salt. Figure 1 illustrates the dominant frontier orbital interactions.

Although **2** is unstable with respect to dechlorination in sulphur dioxide, the process is slow, and the product is obtained pure provided reaction times are kept short. The dechlorination reaction:

[7] $\mathbf{2} \rightarrow H_2\overline{CSNSCH_2}AsF_6 + Cl_2$

is likely displaced to the right by the formation of SO_2Cl_2 (eq. [3]).

Addition of excess chlorine to a solution of **2** in SO_2 inhibits dechlorination, but also causes the collapse of the AA′BB′ multiplet to a broadish singlet at 5.2 ppm ($\Delta\nu$ = 9 Hz), conceivably due to rapid chlorine exchange causing equilibration of the A and B protons.

Dechlorination of **2** becomes quantitative in the presence of a stronger chlorine acceptor. **2** reacts with $SbPh_3$ according to eq. [8]:

[8] $\mathbf{2} + SbPh_3 \rightarrow H_2\overline{CSNSCH_2}AsF_6 + SbPh_3Cl_2$

Acetonitrile dissolves $ClSNSClAsF_6$ without reaction, and it was hoped that dechlorination would be lessened in this solvent.

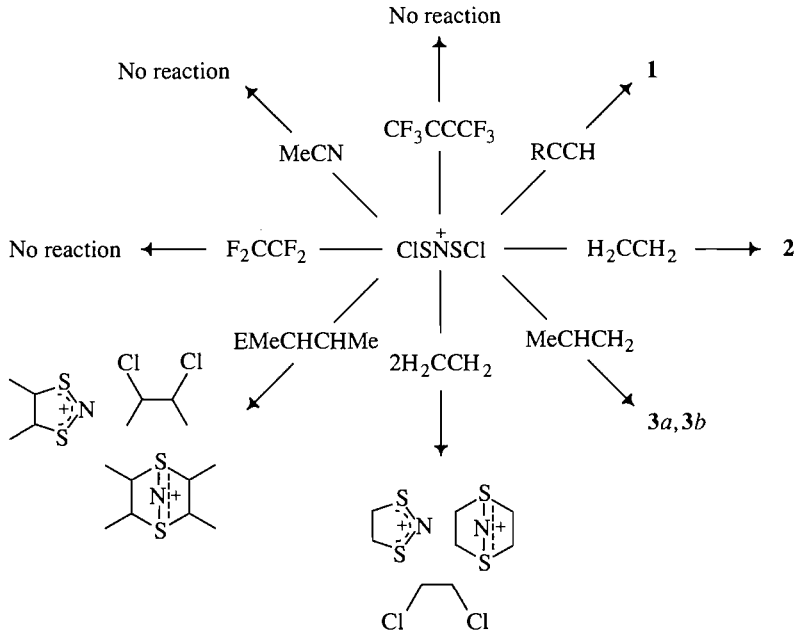

SCHEME 2. Reactions of $ClSNSCl^+$ (all as the AsF_6^- salt in SO_2).

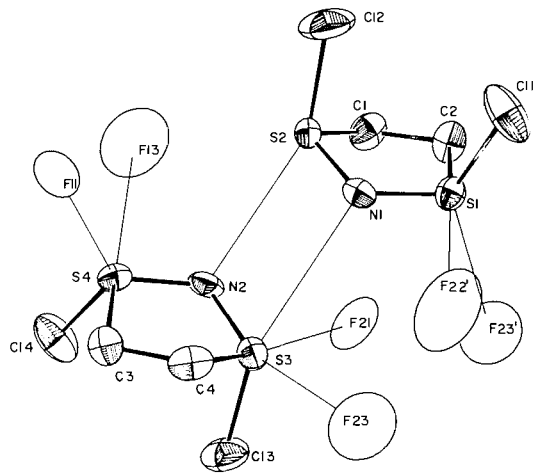

FIG. 3. The two crystallographically different cations in $\overline{CH_2(SCl)N(SCl)CH_2}AsF_6$ (**2**), showing fluorine contacts to the rings.

However, the ^1H nmr spectra of reactions of alkenes with $ClSNSClAsF_6$ in CD_3CN showed complex mixtures of products, which included the same dechlorinated sulphur-nitrogen heterocycles as observed in the reactions carried out in SO_2.

The X-ray crystal structure of **2**

2 consists of discrete $\overline{CH_2(SCl)N(SCl)CH_2}^+$ cations and AsF_6^- anions, which are packed in the unit cell in alternate layers.[3] Two structurally identical (see below), but crystallographically distinct, $\overline{CH_2(SCl)N(SCl)CH_2}$ cations are observed, with weak cation–cation and cation–anion contacts (Fig. 3). Bond distances and angles are presented in Tables 5 and 6. The two crystallographically different heterocyclic cations both have half-chair conformations (Fig. 3), with torsional S—C—C—S angles of 24.8° along C1—C2 and 29.9° along C3—C4,

[3]A stereoview of the unit cell of **2** has also been deposited (see footnote 2).

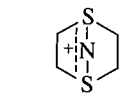
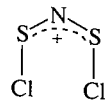
2.025 Å, S—C 1.822 Å, and C—C 1.504 Å) may be used to calculate average bond orders (S—N 1.6, S—Cl 1.0, S—C 1.0, C—C 1.1).[4] These imply that π bonding (of $p\pi$–$d\pi$ type according to one model described in ref. 23) is only significant in the SNS region.

The cations are loosely associated as head-to-head pseudo-dimers with contacts between S2—N2 and S3—N1 just below the sum of the van der Waals radii of N and S (Table 5, Fig. 3) (24). Equivalent bond distances and angles in the two cations

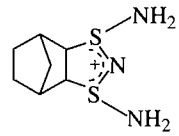
[4]For SN bonds in which the N possesses a nonparticipating lone pair, bond order (bo) is related to length (22*a*) (Å) by the equation: $bo(NS) = 0.429 + 6.850d(NS) - 3.825d(NS)^2$. For other systems: $D_n = D_1 - 0.71 \log(bo)$, where D_1 is the length of a formal single bond (22*b*).



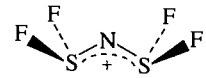
6



7



8



9

10*a*

10*b*

are not significantly different. Cation–fluorine contacts are exclusively to sulphur, and weak (averaging 5% less than the sum of the van der Waals radii of S and F (3.27 Å)). Fluorine contacts are on average weaker to those sulphurs (S2 and S3) contacted by nitrogen, with no fluorine contacts to S2[5] (which has the stronger N contact). The sulphur atoms adopt pseudo-octahedral or -trigonal bipyramidal geometries in the second coordination sphere (see Table 6): AX_3Y_2E (S1, S3, S4) or AX_3YE (S2) (26).

Table 7 compares the average bond distances observed in **2** with those in the related systems **6** (4), **7** (27), **8** (28), and **9** (12). The S—N bond length in **2** is shorter than that in **6**, and this is consistent with the formal replacement of Cl in **2** by the less electronegative hydrocarbon fragment in **6**. Conversely, replacement of Cl and CH_2 in **2** with more electronegative fluorine (**9**) results in a shorter S—N distance.

Similar effects are observed in the sulphoxides (**10***a* and **10***b* are isoelectronic, cf. ref. 29). In fact, the ratio of the SO distances in F_2SO and Me_2SO (0.953) (30) is essentially the same as the ratio of the SN distances in **9** and **5** (0.949). The charge on the S and O atoms in sulphoxides and the S and N atoms in $\rangle SNS\langle$ species reflect, to a first approximation, the relative lengths of the SO and SN bonds (ref. 22*b*, Chap. 9). The larger the charge, the longer the corresponding bond. The trend in SN bond length in the series **6**, **2**, and **9** relates to the contribution of the forms $\rangle S^+—N^-—S^+\langle$ and $\rangle S{=}N—S^+\langle$, both being significant in bonding in **2**.

The average bond angle at nitrogen in **2** is 115.3°. Banister *et al.* (32) have shown that in cationic SNS moieties the S—N bond length (pm) is related to the SNS bond angle (°) by the equation:

$$[9] \quad d(SN) = 187.03 - 0.2263\angle N$$

A sulphur–nitrogen distance of 1.603 Å corresponds to an ideal bond angle of 118°, which is in reasonable agreement with that observed and implies that ring strain does not affect the ring

[5]Nyburg (25) has shown that the van der Waals radii of atoms are generally not spherical, but spheroidal, with the longest effective radii being perpendicular to bond vectors. This will very likely increase the significance of S..N contacts, and decrease the importance of most S..F contacts. Nyburg's treatment, however, is limited to S(II) bonded to carbon in R_2CS compounds, and is not quantitatively applicable in this form to this cation, which contains tricoordinate S(IV) bonded to Cl and N.

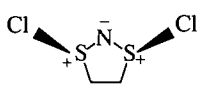
TABLE 7. Comparison of the geometry of $\overline{CH_2(SCl)N(SCl)CH_2}^+$ with similar species

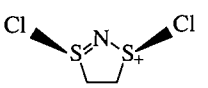
Cation	Average d(SN) (Å)	Average d(SCl) (Å)	∠SNS (°)	∠NSCl (°)
$H_2C(SCl)N(SCl)CH_2^+$ (**2**)	1.603(8)	2.025(4)	115.3(5)	108.4(4)
$ClSNSCl^+$ (**7**)	1.528(2)	1.992(1)	151.0(2)	110.7(1)
$S_2N(C_2H_4)_2^+$ (**5**)	1.634(4)		102.4(2)	
$C_7H_{14}SN_3S_2^+$ (**8**)	1.622(2)		115.9(2)	
$F_2SNSF_2^+$ (**9**)	1.551(10)		121.1(6)	

angles in this system. The bond angles around the sulphur atoms in **2** (NSCl 108.4°, NSC 99.7°, CSCl 99.9°) show them to be pseudo-tetrahedral (AX_3E) in the first coordination sphere. This too implies that the sulphur atoms carry significant positive charge (cf. isoelectronic tri-coordinate phosphorus(III) compounds). The NSCl angle in **2** (108.4°) is greater than the CSCl angle (99.9°), contrary to predictions based purely on atomic electronegativity arguments, but consistent with the π contribution to the SN bond (24). The presence of cation–cation S..N contacts implies that the nitrogen atom of one cation is at least as effective an electron donor towards another cation as the AsF_6^- anion. This is consistent with a negative charge of some absolute fractional value residing on the nitrogen atom. A similar situation is observed in the Sb(III) fluorocations, in which fluoroantimony(III) cations are better donors than the SbF_6^- counteranions, leading to cationic polymers (33).

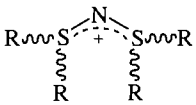
It is clear from the data presented that in **2** significant absolute positive and negative charges reside on the sulphur and nitrogen atoms respectively. Valence canonical **11** therefore contributes significantly to bonding in **2**. This is supported by the ^{14}N nmr chemical shift (−243 ppm), which suggests a strongly shielded nitrogen atom, the cation–anion contacts being only to sulphur and the head-to-head alignment of the cations in the unit cell. However, the empirical S—N bond order of 1.6 (see above) implies that canonical form **12** must also contribute to overall bonding, and therefore **2** is best represented as a resonance hybrid of **11** and **12**.



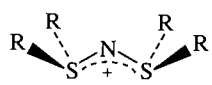
11



12



13



14

2 is a member of the series of cations $R^1R^2SNSR^3R^{4+}$, **13**, the geometries of which depend on whether they are a-, mono-, or bi-cyclic. The acyclic members **9** (12) and **14** (34, R = Me) have the same geometry as $(PF_2)_2N$ in $P_3N_3F_6$ (35). It is not geometrically possible for the monocyclic cations to adopt this conformation, and **2** and **15** have sulphur substituents (Cl and NH_2 respectively) in the 1,3-diaxial positions, and the more sterically demanding lone pair in the equatorial position. The nitrogen atoms in **2** and **15** are slightly displaced from the plane containing the two sulphur atoms and the mid-point of the C—C bond (by 0.3 Å in the case of **2**). In the bicyclic cation **6** (4) the nitrogen lies in the middle of the two C_2S_2 planes, significantly displaced from both.

The average As—F distance (1.676(8) Å) in the independent AsF_6^- anions is shorter than that observed in an ionic AsF_6^- salt (1.69 Å) (36). This reflects the fact that cation–anion contacts are weak in this structure, in part because of the presence of cation–cation interactions. In addition, the average As—F bond length is longer (1.686 Å) when the fluorines are involved in contacts to the cation than when they are not (1.659 Å) (see Table 5).

Réaction du fluoroborate de 2-benzoyl-1,2-dihydro isoquinaldonitrile avec les esters α,β-éthyléniques. II. Cas des esters oléfiniques *gem*-disubstitués. Stéréochimie des produits de condensation–réarrangement, dérivés du 4,5-dihydro-3*H*-pyrrole

GÉRARD SCHMITT, BOUBKER NASSER, NGUYEN DINH AN, BERNARD LAUDE et MAXIME ROCHE. Can. J. Chem. **68**, 863 (1990).

La réaction du fluoroborate d'un composé de Reissert avec divers esters α,β-éthyléniques *gem*-disubstitués est effectuée en présence de triéthylamine. La structure des produits de condensation–réarrangement **8** confirme un mécanisme suggéré par d'autres auteurs. Les paramètres de résonance magnétique nucléaire protonique de ces composés permettent de déterminer leur stéréochimie et de mettre en évidence un phénomène d'isomérisation pour deux d'entre eux.

Mots clés : fluoroborate d'un compose de Reissert, cycloaddition [4 + 2], stéréochimie.

GÉRARD SCHMITT, BOUBKER NASSER, NGUYEN DINH AN, BERNARD LAUDE, and MAXIME ROCHE. Can. J. Chem. **68**, 863 (1990).

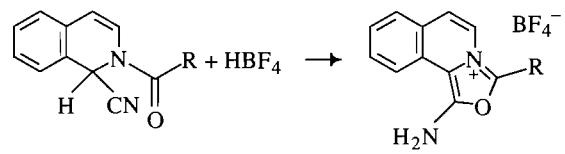
The previously suggested mechanism of the condensation–rearrangement reaction of a Reissert compound hydrofluoroborate salt with reactive olefins was reexamined in the case of methyl methacrylate, itaconate, citraconate, and mesaconate. Addition of triethylamine to the reaction medium leads to the isolation of a presumed intermediate **8**. Spectrometric (proton magnetic resonance) data of the compounds **8** allow us to specify their stereochemistry and in two cases to point out an isomerization equilibrium.

Key words : Reissert compound fluoroborate salt, [4 + 2] cycloaddition, stereochemistry.

Introduction

Des études antérieures (1, 2) de solutions de fluoroborates de 2-acyl-1,2-dihydroisoquinaldonitriles (composés de Reissert **1**) ont mis en évidence l'existence d'un équilibre entre diverses structures, l'espèce **2** étant généralement majoritaire (figure 1).

Dans un précédent article (3) nous avons décrit la compétition entre les réactions de cycloaddition dipolaire-1,3 et de cycloaddition de Diels–Alder du fluoroborate d'un composé de Reissert **1** (R = Ph) avec trois dipolarophiles-diénophiles : les esters acrylique, fumarique et maléïque. Cette compétition intervient en présence de triéthylamine dans le mélange réactionnel. Dans les mêmes conditions, mais avec d'autres esters éthyléniques dont la double liaison est plus encombrée, nous n'avons pas observé la formation d'un cycloadduit [3+2], mais seulement une cycloaddition de type Diels–Alder, faisant intervenir l'espèce **2** (R = Ph). C'était d'ailleurs la seule réaction décrite par McEwen *et al.* (4, 5) avec toutes les oléfines mises en oeuvre. Ces auteurs rendent compte de la structure du produit **7** obtenu en suggérant le mécanisme réactionnel représenté sur la figure 2 (partie gauche) : dans le mélange initial, l'entité majeure **2** est un hétérodiène et la séquence débute par une cycloaddition de Diels–Alder. Si l'oléfine est monosubstituée à chaque extrêmité de la double liaison (R^2 = H), le cycloadduit **4** évolue ensuite vers le composé **7** totalement aromatisé. Dans tous les travaux décrits jusqu'à présent, hormis notre note préliminaire (6), aucun intermédiaire n'a été isolé ou décrit. Cette évolution qui implique, à partir de l'intermédiaire **6**, la perte d'un proton (R^2 = H) sur le sommet 3 du cycle pyrrolinique et une déshydratation acido-catalysée par HBF_4, peut être empêchée si le sommet 3 du cycle est disubstitué et si le milieu réactionnel n'est pas suffisamment acide. C'est ce que nous avons observé en mettant en oeuvre quatre esters α,β-éthyléniques *gem*-disubstitués en présence de triéthylamine.



1 **2**

FIGURE 1

Résultats

À partir des diénophiles **3***a–d*, en présence de triéthylamine, nous avons isolé les produits de structure **8** dérivés du 2-(1-isoquinoléïnyl)-5-hydroxy-5-phényl-4,5-dihydro-3*H*-pyrrole (partie droite de la figure 2). Si les rendements sont convenables pour **8***a* et **8***b*, ils diminuent considérablement pour **8***c* et **8***d* par suite des contraintes stériques. Les réactions de cycloaddition conduites sur ces mêmes diénophiles sans adjonction de triéthylamine donnent directement les 3*H*-pyrroles **9** et le traitement des composés **8** à l'ébullition dans l'éthanol, acidifié par l'acide sulfurique, conduit quantitativement aux mêmes produits **9**.

Ces résultats apportent déjà un argument en faveur de la régiospécificité de la réaction de cycloaddition initiale. Le seul produit **8** obtenu ne peut donner une réaction de déshydratation que si hydrogène et hydroxyle sont situés sur deux atomes de carbone vicinaux et c'est le même sens de cycloaddition de Diels–Alder que celui observé dans le cas de l'acrylate d'éthyle (**7**, $R^1 = CO_2Et$, R^3 = H) et déjà décrit par McEwen *et al.* (5).

Les transformations chimiques représentées dans la figure 3 confirment les structures **8** et **9** et par suite la régiochimie de la réaction. Ainsi le produit **9***a* (issu du méthacrylate de méthyle) saponifié et décarboxylé donne un produit **7***a*. Ce même produit a pu être obtenu en plusieurs étapes à partir du composé **9***c* issu du mésaconate et du citraconate de méthyle et également à partir du composé **9***b* provenant de l'itaconate de méthyle.

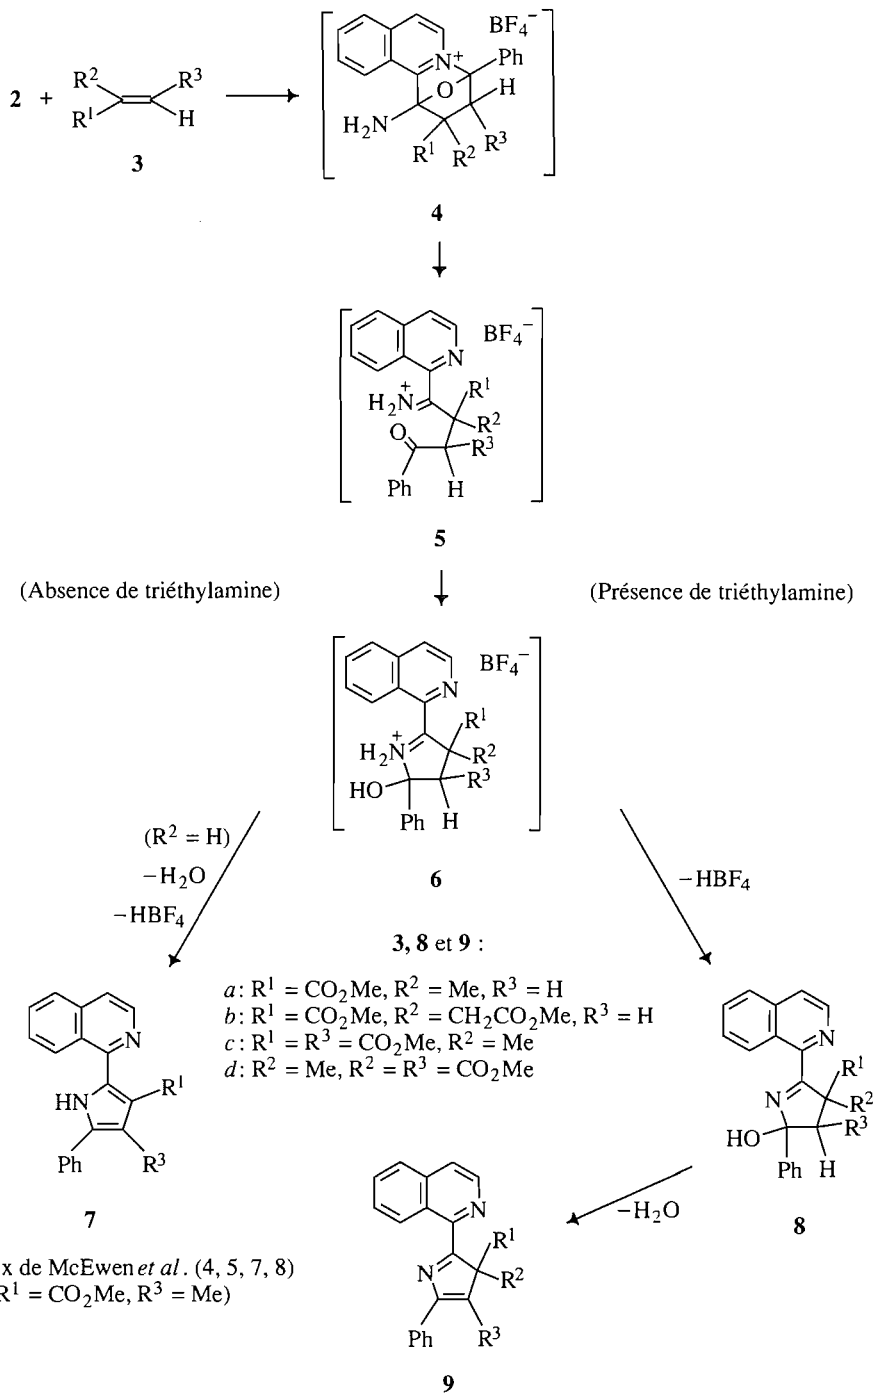

FIGURE 2

Pour confirmer cette régiochimie, nous avons fait réagir le fluoroborate **2** avec le crotonate de méthyle en l'absence de triéthylamine. La réaction conduit alors au produit **7***e* sans qu'il soit possible d'isoler un intermédiaire. La saponification suivie d'une décarboxylation du produit **7***e* conduit au composé **7***f* qui diffère du composé **7***a* par la position du groupe méthyle qui se trouve en 3 dans le produit **7***a* et en 4 dans l'isomère **7***f* (figure 4).

L'ensemble de ces réactions confirme sans ambiguïté l'hypothèse mécanistique suggérée par Evanguelidou et McEwen (8) pour expliquer la formation des composés **7** à partir d'un cycloadduit de type Diels–Alder (non isolé), obtenu par action du fluoroborate d'un composé de Reissert **1** sur une oléfine. L'addition de triéthylamine au milieu réactionnel nous a permis d'obtenir, dans certains cas, le précurseur de **7** qui n'avait jamais été isolé. Les résultats d'analyse et les paramètres spectroscopiques sont en bon accord avec la structure proposée pour les composés **7**, **8** et **9**.

Ces paramètres spectroscopiques nous ont d'ailleurs permis de mener une étude de la stéréochimie des composés **8**.

Étude spectrométrique de la stéréochimie des composés 8

Puisque la séquence réactionnelle débute par une cycloaddition de Diels–Alder, la stéréochimie relative autour de la liaison

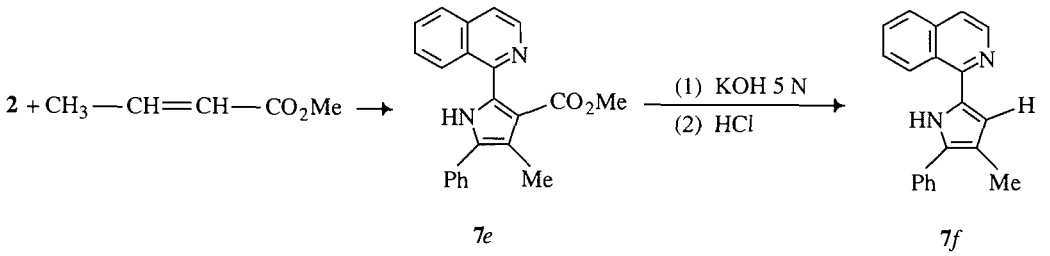

FIGURE 4

C3—C4 reste celle des oléfines de départ et le seul problème à résoudre est celui de la disposition des groupes phényle et hydroxyle situés sur le carbone 5, par rapport à la disposition des groupements R^1, R^2, H et R^3 fixés sur les sommets 3 et 4 (figure 5).

Les spectres des produits uniques **8***c* et **8***d* obtenus à partir du mésaconate et du citraconate de méthyle sont les plus aisés à analyser. Le tableau 1 rassemble leurs paramètres spectrométriques. L'existence d'une bande assez fine vers 3410–3420 cm^{-1}, dont la position ne varie pas avec la concentration d'une solution dans CCl_4 rend compte de l'existence d'une liaison hydrogène intramoléculaire entre le groupe OH en position 5 et le groupe méthoxycarbonyle en position 4. Ceci est confirmé par l'existence d'une bande νCO = 1690 cm^{-1} (**8***d*) et 1700 cm^{-1} (**8***c*) dont la fréquence est abaissée par liaison hydrogène et par la valeur élevée du déplacement chimique du proton du

FIGURE 5

groupe hydroxyle (δ = 6,20 ppm et 6,57 ppm). Une telle disposition *cis* pour deux groupes OH et ester situés sur deux carbones vicinaux au cours d'une addition nucléophile intramoléculaire conduisant à un cycle pentagonal a déjà été décrite par d'auteurs (9, 10).

Cette stéréochimie est confirmée par le relatif blindage du groupe méthyle en position 3 dans le cas du composé **8***d* (δ = 1,72 ppm), blindage dû à l'effet du phényle-5 en *cis* par rapport à ce méthyle, alors que le groupe méthyle en 3 qui, dans le produit **8***c*, ne subit pas l'effet de ce phényle présente un déplacement chimique de 2,02 ppm.

Les produits **8** issus du méthacrylate et de l'itaconate de méthyle présentent un centre de chiralité de moins que ceux discutés plus haut. On peut toutefois encore envisager l'existence de deux diastéréoisomères **8** et **8**′ selon la disposition relative des substituants sur les sommets 3 et 5. Le spectre de rmn ^1H d'une solution du **8***a* préparée extemporanément dans le benzène hexadeutéré permet de relever un ensemble de signaux dont les paramètres sont rassemblés dans le tableau 2.

La valeur du déplacement chimique du groupe méthyle en 3 (δ = 2,08 ppm) est proche de celle observée pour le groupe méthyle du produit **8***c* issu du mésaconate (δ = 2,02 ppm) et permet d'envisager une disposition *trans* pour les groupes méthyle en 3 et phényle en 5 (structure **8***a*). Mais cette solution, laissée à température ambiante pendant plusieurs heures, donne alors un spectre de rmn protonique où apparaissent des signaux supplémentaires. Ces nouvelles transitions sont également répertoriées dans le tableau 2 pour le produit **8**′*a*. Nous rejetons l'hypothèse de l'existence de deux conformères, puisque ces deux ensembles de signaux apparaissant rapidement par chauffage, persistent après retour à température ordinaire. Il s'agit donc des deux isomères **8***a* et **8**′*a*. Cette isomérisation peut s'expliquer par une réaction d'ouverture–fermeture de l'« hémiaminoacétal » **8** en solution qui conduit aux deux isomères **8** et **8**′. Cette hypothèse est confortée par le fait que le produit **8***a* mis en solution dans $CDCl_3$ présente immédiatement un spectre de rmn ^1H comportant les signaux des deux isomères. Cette rapidité d'isomérisation peut s'expliquer par une catalyse dûe à la légère acidité résiduelle du chloroforme deutéré. Le deuxième isomère **8**′*a*, comportant les deux groupes phényle en 5 et méthyle en 3 dans une disposition *cis*, présente une

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

déplacement chimique plus faible pour le groupe méthyle mais aussi pour le proton $R^3 = H^a$ qui est soumis à l'influence simultanée des blindages par les groupes méthyle et phényle.

Le produit **8***b* issu du l'itaconate a un comportement analogue à celui du composé **8***a*. Une solution dans C_6D_6 fraîchement préparée conduit à un spectre de rmn ^1H comportant uniquement les signaux de l'isomère **8***b*. Avec le temps, les signaux de l'autre isomère **8′***b* apparaissent. Ces paramètres sont rassemblés dans le tableau 3.

Il n'est pas impossible que la réaction de cyclisation par addition nucléophile intramoléculaire lors du passage de l'intermédiaire **5** au composé **8** conduise au mélange de deux isomères **8** et **8′**, mais par cristallisation nous n'avons jamais réussi à isoler que l'isomère **8** même à partir d'une solution contenant les deux produits **8** et **8′**.

Le phénomène d'isomérisation n'apparaît pas dans le cas des composés **8***c* et **8***d* issus du mésaconate et du citraconate et nous pensons que ceci s'explique parce qu'ils sont plus stables que leurs éventuels isomères **8′**. Cette plus grande stabilité est dûe à la fois à une moindre interaction stérique dans le cas d'une disposition *trans* des groupes phényle en 5 et méthoxycarbonyle en 4 et par l'existence d'une liaison hydrogène intramoléculaire entre les groupes hydroxyle en 5 et méthoxycarbonyle en 4. L'absence de ce dernier groupe en 4 dans le cas des composés **8***a* et **8***b* rend possible une isomérisation partielle en composés **8′**.

Conclusion

La réaction du fluoroborate de 2-benzoyl-1,2-dihydroisoquinaldonitrile **1** (R = Ph) effectuée en présence de triéthylamine sur les esters éthyléniques étudiés dans le présent travail permet de confirmer le mécanisme envisagé par McEwen puisque nous avons réussi à isoler les intermédiaires supposés de structure **8**.

L'étude stéréochimique de ces derniers nous a permis de montrer que certains d'entre eux pouvaient s'épimériser par une réaction d'ouverture–fermeture et ce phénomène conforte l'existence de l'intermédiaire ouvert de structure **5**.

Partie expérimentale

Les points de fusion déterminés sur banc Kofler ne sont pas corrigés. Les spectres d'absorption ir ont été obtenus avec un spectrophotomètre Beckman IR 33, les produits étant pastillés dans KBr. Les spectres de rmn protonique ont été obtenus avec un spectromètre Bruker AC 200, les échantillons étant dissous dans C_6D_6 ou $CDCl_3$ avec le tétraméthylsilane comme référence interne. Les chromatographies sur colonne ouverte ont été effectuées avec la silice Merck (70–230 mesh) comme support. Les microanalyses ont été assurées par le Service d'Analyses du CNRS à Vernaison. Le fluoroborate de 2-benzoyl-1,2-dihydro isoquinaldonitrile **2** (R = Ph) est obtenu selon le mode opératoire de McEwen *et al.* (4). Les esters **3** sont des produits du commerce exceptés **3***c* et **3***d* qui ont été préparés par réaction du méthanol avec les chlorures d'acide correspondants.

1. Condensations en présence de triéthylamine

Mode opératoire général : À une solution de 3 g de fluoroborate **2** (R = Ph) dans 25 mL de DMF, on ajoute 3 mL d'ester **3**. Le mélange est refroidi à 0°C au bain de glace et on additionne lentement et sous agitation magnétique une solution de 2 mL de triéthylamine dans 15 mL de DMF (l'addition dure environ une demi-heure). Après 4 h d'agitation à 0°C, on verse le mélange réactionnel dans 200 mL d'eau froide. L'huile qui se sépare est extraite à l'éther. La solution éthérée est lavée à l'eau, séchée et concentrée. L'huile résiduelle est alors soit reprise par l'éthanol (**8***a*, **8***b*), soit chromatographiée (**8***c*, **8***d*).

*2-(1-Isoquinoléïnyl)-3-méthyl-5-hydroxy-5-phényl-4,5-dihydro-3*H*-pyrrole-3-carboxylate de méthyle* **8***a* : F = 146°C (éthanol), Rdt : 50%. Anal. calc. pour $C_{22}H_{20}N_2O_3$: C 73,31; H 5,59; N 7,77; trouvé : C 73,52; H 5,32; N 7,63.

*2-(1-Isoquinoléïnyl)-3-méthoxycarbonylméthyl-5-hydroxy-5-phényl-4,5-dihydro-3*H*-pyrrole-3-carboxylate de méthyle* **8***b* : F = 140°C (éthanol), Rdt : 42%. Anal. calc. pour $C_{24}H_{22}N_2O_5$: C 68,88; H 5,30; N 6,69; trouvé : C 68,72; H 5,47; N 6,80.

2-(1-Isoquinoléïnyl)-3-*méthyl-5-hydroxy-5-phényl-4,5-dihydro-*3H*-pyrrole*-trans*-3,4-dicarboxylate de diméthyle* **8***c* : la chromatographie du brut réactionnel (éluant $CHCl_3$) permet de séparer d'abord l'excès d'ester et de composé de Reissert **1** (R = Ph). Elle livre ensuite le produit **8***c*, F = 138,5°C (éthanol), Rdt : 18%. Anal. calc. pour $C_{24}H_{22}N_2O_5$: C 68,88; H 5,30; N 6,69; trouvé : C 69,03; H 5,18; N 6,48.

*2(1-Isoquinoléïnyl)-3-méthyl-5-hydroxy-5-phényl-4,5-dihydro-3*H*-pyrrole*-cis*-3,4-dicarboxylate de diméthyle* **8***d* : la chromatographie du brut réactionnel (éluant $CHCl_3$) livre le produit **8***d* après élution des excès d'ester de départ et de composé de Reissert **1** (R = Ph), F = 160°C (éthanol), Rdt : 12%. Anal. calc. pour $C_{24}H_{22}N_2O_5$: C 68,88; H 5,30; N 6,69; trouvé : C 68,67; H 5,42; N 6,57.

Les paramètres spectrométriques de ces composés ont été donnés en partie théorique.

II. Condensations effectuées sans addition de triéthylamine

1. *2-(1-Isoquinoléïnyl)-3-méthyl-5-phényl-3*H*-pyrrole-3,4-dicarboxylate de diméthyle* **9***c* à partir du mésaconate ou du citraconate de méthyle.

Une solution de 3 g de fluoroborate et 3 mL de citraconate ou de mésaconate de méthyle dans 50 mL de DMF est abandonnée 48 h à température ambiante puis 12 h à l'étuve à 60°C. On verse alors dans l'eau. L'huile ainsi formée est extraite à l'éther et cette solution lavée 4 fois à l'eau. Après séchage et évaporation du solvant, le résidu est repris à l'éthanol et filtré. Le solide est recristallisé dans l'éthanol. F = 110°C, Rdt : 58%; ir : ν(C=O) = 1710, 1730 cm^{-1}; rmn ^1H ($CDCl_3$) : δ = 1,75 ppm (s, 3H, CH_3 en -3); δ = 3,50 ppm (s, 3H, OCH_3); δ = 3,70 ppm (s, 3H, OCH_3); δ = 7,00–9,00 ppm (m, 11H arom.). Anal. calc. pour $C_{24}H_{20}N_2O_4$: C 71,98; H 5,03; N 6,99; trouvé : C 72,13; H 4,97; N 6,82.

2. *2-(1-Isoquinoléïnyl)-4-méthyl-5-phényl pyrrole-3-carboxylate de méthyle* **7***e* à partir du crotonate de méthyle.

Une solution de 3 g de fluoroborate et 4 mL de crotonate de méthyle dans 20 mL de DMF est abandonnée 24 h à température ambiante. On dissout le tout dans 150 cm^3 d'éther et lave 3 fois avec une solution aqueuse saturée de chlorure de sodium. La phase éthérée est séchée puis évaporée. Le résidu violet est trituré avec de l'éthanol et le solide obtenu est recristallisé dans l'éthanol. F = 216°C, Rdt = 68%; ir : ν(C=O) = 1700 cm^{-1}, ν(NH) = 3060 cm^{-1}; rmn ^1H ($CDCl_3$) : δ = 2,5 ppm (s, 3H, CH_3 en -4); δ = 3,80 ppm (s, 3H, OCH_3); δ = 12,10 ppm (s, NH); δ = 7,00–9,30 ppm (m, 11H arom.). Anal. calc. pour $C_{22}H_{18}N_2O_2$: C 77,17; H 5,30; N 8,18; trouvé : C 76,92; H 5,47; N 7,97.

III. Deshydratation des composés 8

Mode opératoire général : Chaque composé **8** (10 mmol) est dissout dans 30 mL d'éthanol additionnés de 4 gouttes d'acide sulfurique concentré. Le mélange est ensuite porté à reflux durant 1 h puis versé dans l'eau froide. Le précipité est filtré, lavé et recristallisé. Les rendements sont quantitatifs. Les composés **8***c* et **8***d* conduisent au produit **9***c*.

*2-(1-Isoquinoleïnyl)-3-méthyl-5-phényl-3*H*-pyrrole-3-carboxylate de méthyle* **9***a* obtenu à partir du composé **8***a*, F = 139°C (recristallisé de CH_3COOH); ir : ν(=O) = 1690 cm^{-1}; rmn ^1H ($CDCl_3$) : δ = 1,80 ppm (s, 3H, CH_3 en -3); δ = 3,60 ppm (s, 3H, OCH_3); δ = 6,60 ppm (s, 1H, H-4); δ = 7,00–9,60 ppm (m, 11H arom.). Anal. calc. pour $C_{22}H_{18}N_2O_2$: C 77,17; H 5,30; N 8,18; trouvé : C 77,26; H 5,18; N 8,32.

*2-(1-Isoquinoleïnyl)-3-méthoxycarbonylméthyl-2-phényl-3*H*-pyrrole-3-carboxylate de méthyle* **9***b*, F = 144°C (éthanol); ir : ν(C=O) = 1690 cm^{-1}; rmn ^1H ($CDCl_3$) : δ = 2,90 ppm (d, 1H) et δ = 3,50 ppm (d, 1H); J = 15 Hz -CH_2- CO_2Me; δ = 3,50 ppm (s, 3H, OCH_3); δ = 7,00 ppm (s, 1H, H-4); δ = 7,05–9,60 ppm (m, 11H arom.). Anal. calc. pour $C_{24}H_{20}N_2O_4$: C71,98; H 5,03; N 6,99; trouvé : C 72,07; H 5,12; N 6,77.

IV. Réactions de saponification et decarboxylation des esters **9**

1. Saponification par la potasse méthanolique 2 N

Mode opératoire général : 5 mmol de chaque ester étudié sont dissoutes dans 20 mL de potasse méthanolique 2 N. On porte à ébullition durant 2 h. On verse alors dans l'eau froide et neutralise par action de HCl 2 N. Le précipité qui se forme est extrait à l'éther, lavé, séché et le solvant évaporé. Le résidu est repris par un solvant de cristallisation.

2-(1-Isoquinoléïnyl)-3-méthyl-5-phényl pyrrole **7***a* à partir du composé **9***a*, F = 203°C (isopropanol), Rdt : 95%; ir : ν(NH) = 3100 cm^{-1}; rmn ^1H ($CDCl_3$) : δ = 2,25 ppm (s, 3H, CH_3 en -3); δ = 6,60 ppm (s, 1H, H-4); δ = 7,10–9,10 ppm (m, 11H arom.); δ = 9,90 ppm (s, 1H, NH). Anal. calc. pour $C_{20}H_{16}N_2$: C 84,47; H 5,67; N 9,85; trouvé : C 84,62; H 5,54; N 10,05.

Acide 2-(1-isoquinoléïnyl)-5-phényl pyrrole-3-acétique **7***b* à partir du composé **9***b*, F = 250°C (du *n*-propanol), Rdt : 70%; ir : ν(C═O) = 1700 cm^{-1}, ν(OH) et (νNH) bande élargie entre 2600 et 3400 cm^{-1}; rmn ^1H ($CDCl_3$) : δ = 3,70 ppm (s, 2H, CH_2-COOH); δ = 6,70 ppm (s, 1H, H-4); δ = 7,10–9,10 ppm (m, 11H arom.); δ = 9,20 ppm (s, 1H, OH); δ = 11,80 ppm (s, 1H, NH). Anal. calc. pour $C_{21}H_{16}N_2O_2$: C 76,80; H 4,91; N 8,53; trouvé : C 76,67; H 5,07; N 8,75.

2-(1-Isoquinoléïnyl)-3-méthyl-5-phényl pyrrole-4-carboxylate de méthyle **7***c* à partir du composé **9***c*, F = 194°C de l'éthanol, Rdt : 44%; ir : ν(C═O) = 1680 cm^{-1}, ν(NH) = 3060 cm^{-1}; rmn ^1H ($CDCl_3$) : δ = 2,20 ppm (s, 3H, CH_3 en -3); δ = 3,80 ppm (s, 3H, OCH_3); δ = 7,10–9,20 ppm (m, 11H arom.); δ = 12,30 ppm (s, 1H, NH). Anal. calc. pour $C_{22}H_{18}N_2O_2$: C 77,17; H 5,30; N 8,18; trouvé : C 77,32; H 5,17; N 8,02.

2. Saponification par la potasse méthanolique 5 N

Le mode opératoire est le même que le précédent excepté que l'on utilise de la potasse 5 N au lieu de 2 N.

(a) Obtention du produit **7***a* (déjà décrit) à partir du composé **9***c*, Rdt : 81%.

(b) *2-(1-Isoquinoléïnyl)-4-méthyl-5-phényl pyrrole* **7***f* à partir de **7***e*, F = 137°C (éthanol), Rdt = 49%; ir : ν(NH) = 3100 cm^{-1}; rmn ^1H ($CDCl_3$) : δ = 2,30 ppm (s, 3H, CH_3 en -4); δ = 6,90 ppm (s, 1H, H-3); δ = 7,10–9,30 ppm (m, 11H arom.); δ = 10,20 ppm (s, 1H, NH). Anal. calc. pour $C_{20}H_{16}N_2$: C 84,47; H 5,67; N 9,85; trouvé : C 84,28; H 5,79; N 10,02.

3. Produit **7**a *par décarboxylation du composé* **7**b

De l'acide **7***b* (1 g) et 0,1 g de cuivre en poudre sont chauffés à reflux 4 h dans 30 cm^3 de quinoléine. Le mélange est refroidi, versé dans l'eau et acidifié. On extrait à l'éther, sèche la solution et évapore le solvant. Le résidu très noir est filtré sur colonne de silice en éluant par du chloroforme. On récupère une très faible quantité de produit jaune, identifié au produit **7***a* (ir, rmn ^1H et point de fusion de mélange).

HILARY A. JENKINS, STEPHEN J. LOEB, DAVID G. DICK and DOUGLAS W. STEPHAN. Can. J. Chem. **68**, 869 (1990).

The reaction of $Li[Fe(CO)_4(PCy_2)]$ with *trans*-$PtCl(H)(PEt_3)_2$ results in the formation of the hydride complex $(CO)_3Fe(\mu\text{-}H)(\mu\text{-}PCy_2)Pt(PEt_3)_2$, **1.** This heterobimetallic, phosphido-bridged complex reacts with one equivalent of $HBF_4 \cdot Et_2O$ to give the complex $[(CO)_3Fe(\mu\text{-}H)_2(\mu\text{-}PCy_2)Pt(PEt_3)_2][BF_4]$, **2,** which contains two bridging hydride ligands. This species is isolated and fully characterized by $^{31}P\{^1H\}$ and ^1H NMR and infrared spectroscopy. In contrast, **1** reacts with one equivalent of HCl·DMA (DMA = dimethylacetamide) to give the complex $(CO)_3ClFe(\mu\text{-}PCy_2)Pt(PEt_3)_2$, **3.** This species is the result of oxidative addition of HCl with subsequent reductive elimination of H_2(g). This complex is fully characterized by $^{31}P\{^1H\}$ and ^1H NMR, infrared spectroscopy and an X-ray crystal structure determination. **3** crystallizes in the space group $P\bar{1}$ with $a = 10.037(4)$ Å, $b = 10.644(3)$ Å, $c = 17.137(9)$ Å, $\alpha = 102.80(3)°$, $\beta = 76.74(3)°$, $\gamma = 103.99(3)°$, $V = 1702(1)$ Å^3, and $Z = 2$. The structure was refined to $R = 2.54\%$ and $R_w = 2.73\%$ for 4056 reflections with $F_o^2 > 3\sigma(F_o^2)$.

Key words: heterobimetallic, hydride, phosphide, protonation.

HILARY A. JENKINS, STEPHEN J. LOEB, DAVID G. DICK et DOUGLAS W. STEPHAN. Can. J. Chem. **68**, 869 (1990).

La réaction du $Li[Fe(CO)_4(PCy_2)]$ avec le *trans*-$PtCl(H)(PEt_3)_2$ conduit à la formation de l'hydrure complexe $(CO)_3Fe(\mu\text{-}H)(\mu\text{-}PCy_2)Pt(PEt_3)_2$, **1.** Ce complexe hétérobimétallique comportant une pont phosphido réagit avec un équivalent de $HBF_4 \cdot Et_2O$ pour fournir le complexe $[(CO)_3Fe(\mu\text{-}H)_2(\mu\text{-}PCy_2)Pt(PEt_3)_2][BF_4]$, **2** qui contient deux ligands hydrures agissant comme ponts. On a isolé cette espèce et on l'a caractérisée complètement par rmn du $^{31}P\{^1H\}$ et du ^1H ainsi que par spectroscopie infrarouge. Par opposition, le composé **1** réagit avec un équivalent de HCl·DMA (DMA = diméthylacétamide) pour donner le complexe $(CO)_3ClFe(\mu\text{-}PCy_2)Pt(PEt_3)_2$, **3.** Cette espèce est le résultat d'une addition oxydante du HCl avec une élimination réductrice subséquente de H_2(g). On a caractérisé complètement ce complexe par rmn du $^{31}P(^1H)$ et du ^1H, par spectroscopie infrarouge ainsi que par une détermination de sa structure par diffraction des rayons-X. Le composé **3** cristallise dans le groupe d'espace $P\bar{1}$ avec $a = 10{,}037(4)$, $b = 10{,}644(3)$ et $c = 17{,}137(9)$ Å, $\alpha = 102{,}80(3)$, $\beta = 76{,}74(3)$ et $\gamma = 103{,}99(3)°$, $V = 1702(1)$ Å^3, et $Z = 2$; on a affiné la structure jusqu'à des valeurs respectives de $R = 0{,}0254$ et $R_w = 0{,}0273$ pour 4056 réflexions avec $F_o^2 > 3\sigma(F_o^2)$.

Mots clés : hétérobimétallique, hydrure, phosphure, protonation.

[Traduit par la revue]

Introduction

The protonation of transition metal hydride complexes is a fundamental process in organometallic and catalytic chemistry. In general, the reactions of transition metal hydrido complexes with protonic acids can be divided into three types (1): (*i*) strong acids with weakly coordinating conjugate bases which form salts of the dihydride complex, (*ii*) weak acids with strongly coordinating conjugate bases which form oxidative addition products, and (*iii*) strong acids with non-coordinating conjugate bases which form salts of the molecular hydrogen (η^2-H_2) complex. These reactions are often followed by the rapid evolution of H_2(g) via a reductive elimination reaction or direct labilization of an η^2-H_2 ligand. The analogous reactions of a heterobimetallic hydrido complex are complicated by the fact that protonation may occur at either of the two metal sites or at the metal—metal bond if one exists (2). It is thus of interest to investigate the protonation reactions of heterobimetallic hydride complexes to determine the basic reactivity differences between these and monometallic species. To this end, we describe herein a comparison of the reactivity of the phosphido-bridged complex $(CO)_3Fe(\mu\text{-}H)(\mu\text{-}PCy_2)Pt(PEt_3)_2$, **1,** with the protonic acids HCl and HBF_4.

Experimental section

General

$Fe(CO)_4(PCy_2H)$, *trans*-$PtCl(H)(PEt_3)_2$, and DMA·HCl (DMA = dimethylacetamide) were prepared by the literature methods (3–5). $Fe_2(CO)_9$, PCy_2H (Strem), K_2PtCl_4, PEt_3, $HBF_4 \cdot Et_2O$ (Aldrich) were purchased and used as received. THF (tetrahydrofuran), toluene, and *n*-hexane were dried by distillation from Na–benzophenone ketyl under N_2. All other solvents were dried on molecular sieves and degassed prior to use. All reactions were conducted under an atmosphere of dry N_2 using standard Schlenk techniques.

$^{31}P\{^1H\}$ and ^1H NMR spectra were recorded at 121.5 and 300.1 MHz, respectively, on a Bruker AM300 spectrometer using deuterated solvents as lock. Phosphorus chemical shifts were measured relative to external H_3PO_4 with positive shifts downfield. Infrared spectra were recorded on a Perkin-Elmer 781 grating spectrometer. Elemental analyses were performed by Canadian Microanalytical Services Ltd., New Westminster, British Columbia.

Preparation of $(CO)_3Fe(\mu\text{-}H)(\mu\text{-}PCy_2)Pt(PEt_3)_2$, 1

n-Butyllithium (1.27 mL, 2.03 mmol of 1.6 M solution in hexanes) was added dropwise via syringe to a brown solution of $Fe(CO)_4(PCy_2H)$ (0.742 g, 2.03 mmol) in THF (10 mL). This solution was stirred for 30 min and then added dropwise, over 20 min, to a solution of *trans*-$PtCl(H)(PEt_3)_2$ (0.948 g, 2.03 mmol) in THF (15 mL). The resulting orange–red solution was stirred at room temperature for 18 h, and the solvent removed *in vacuo*. The orange residue was extracted with acetone (5 × 10 mL), the volume reduced to 15 mL, and the solution cooled to −20°C for 18 h. This yielded orange microcrystals of

1; yield 1.56 g (71%). Infrared: ν(CO) (CH_2Cl_2) 1945 (s), 1862 (s), 1851 (s). *Anal.* calcd. for $C_{27}H_{53}FeO_3P_3Pt$: C 42.13, H, 6.96; found: C 42.96, H 6.55.

Preparation of [(CO)$_3$Fe(μ-H)$_2$(μ-PCy$_2$)Pt(PEt$_3$)$_2$][BF$_4$], 2

1 (0.254 g, 0.330 mmol) was dissolved in CH_2Cl_2 (5 mL) and $HBF_4 \cdot Et_2O$ (0.18 mL) added via microsyringe. The orange–red solution immediately turned a very pale yellow colour. The solution was filtered to remove a small amount of white solid and diethylether (3 mL) added. The resulting solution was cooled to −20°C for 15 h to give colourless microcrystals of **2**; yield 0.218 g (77%). Infrared: ν(CO) (CH_2Cl_2) 1998 (m), 1862 (m, br). *Anal.* calcd. for $C_{27}H_{94}BF_4FeO_3P_3Pt$: C 37.82, H, 6.36; found: C 37.33, H 6.18.

Preparation of (CO)$_3$ClFe(μ-PCy$_2$)Pt(PEt$_3$)$_2$, 3

1 (0.288 g, 0.374 mmol) was dissolved in CH_2Cl_2 (5 mL) and HCl·DMA (0.048 g, 0.390 mmol) added with stirring. The solution slowly changed colour from orange-red to orange-brown over 30 min. The solution was stirred for a further 12 h, the solvent removed *in vacuo*, and the brownish residue taken up in acetone (10 mL). Cooling to −20°C for 48 h yielded orange-brown crystals of **3** suitable for X-ray diffraction studies. A second crop of solid product was obtained by reduction of the solution volume to 5 mL and further cooling for 24 h. This gave a total of 0.198 g of **3**; (66%). Infrared: ν(CO) (CH_2Cl_2) 2009 (m), 1938 (s,br). *Anal.* calcd. for $C_{27}H_{92}ClFeO_3P_3Pt$: C 40.33, H, 6.53; found: C 39.77, H 6.44.

X-ray crystallographic analysis of (CO)$_3$ClFe(μ-PCy$_2$)Pt(PEt$_3$)$_2$, 3

Orange-brown crystals of **3** were grown from acetone at −20°C. Diffraction experiments were performed on a four-circle Syntex $P2_1$ diffractometer with graphite monochromatized MoKα radiation. The initial orientation matrix was obtained from 15 machine-centered reflections selected from rotation photographs. Partial rotation photographs around each axis were consistent with a triclinic crystal system. Ultimately, 40 high-angle reflections ($22° < 2\theta < 25°$) were used to obtain the final lattice parameters and orientation matrix. Machine parameters, crystal data, and data collection parameters are summarized in Table 1. Intensity data ($\pm h$, $\pm k$, $+l$) were collected in two shells ($4.5° < 2\theta < 40°$, $40° < 2\theta < 45°$) and three standard reflections were recorded every 197 reflections. The intensities of these standard reflections showed an 8% decay in intensity over the duration of the data collection. Therefore, a decay correction was applied to the data. The data were processed using the SHELX-76 program package on the computing facilities at the University of Windsor. A total of 4682 reflections were collected and 4056 unique reflections with $F_o^2 > 3\sigma(F_o^2)$ were used in the refinement. An empirical absorption correction (μ = 45.71 cm^{-1}) was applied to the data based on three ψ-scans.

The Pt atom position was determined using the Patterson method, ($P\bar{1}$), and the remaining non-hydrogen atoms located from successive difference Fourier map calculations. Refinement was carried out using full-matrix least-squares techniques on F minimizing the function $\Sigma w(|F_o| - F_c|)^2$, where $w = 4F_o^2/\sigma^2(F_o^2)$ and F_o and F_c are the observed and calculated structure factors. Atomic scattering factors (6) and anomalous dispersion (7, 8) terms were taken from the usual sources. The space group $P\bar{1}$ was confirmed by a successful structure solution and refinement. In the final cycles of refinement, all the non-hydrogen atoms were assigned anisotropic thermal parameters. Fixed H atom contributions were included with C—H bond distances of 0.95 Å and thermal parameters equal to 1.1 times the isotropoic thermal parameters of the bonded C atoms. No H atoms were refined, but all values were updated as refinement continued. This resulted in $R = \Sigma||F_o| - |F_c||/\Sigma|F_o| = 2.54\%$ and $R_w = (\Sigma w(|F_o| - |F_o|)^2/\Sigma wF_o^2)^{1/2} = 2.73\%$ at final convergence.

The Δ/σ values for any parameter in the final cycles were less than 0.002. A final difference Fourier map calculation showed no peaks of chemical significance; the largest was 1.30 electrons /Å^3 and associated with the Pt atom. Selected bond distances and angles are summarized in Table 2 and atomic positional parameters in Table 3. Anisotropic thermal parameters (Table S-1), hydrogen atom parame-

Results

Synthesis and reactions

The complex $(CO)_3Fe(\mu\text{-}H)(\mu\text{-}PCy_2)Pt(PEt_3)_2$, **1**, containing both a bridging dicyclohexylphosphido group and a bridging hydride ligand, can be easily prepared by the bridge-assisted synthetic method (3, 9–11). This involves the nucleophilic displacement of chloride from *trans*-$PtCl(H)(PEt_3)_2$ by the phosphido group of $Li[Fe(CO)_4(PCy_2)]$ in THF. The $^{31}P\{^1H\}$ NMR shows a downfield resonance (δ 220.6 (ddt)) due to the bridging PCy_2 ligand coupled to two different PEt_3 groups ($^2J_{PP}$ (μ-*trans*) = 205.7 Hz and $^2J_{PP}$ (μ-*cis*) = 12.7 Hz) and the ^{195}Pt centre ($^1J_{PtP}$ = 1822 Hz).[3] The two PEt_3 ligands are both coordinated to the Pt atom and are designated as being either *trans* (δ 10.4 (ddt); $^1J_{PtP}$ = 3596 Hz) or *cis* (δ 10.3 (ddt); $^2J_{PP}$ (*cis–trans*) = 18.2 Hz; $^1J_{PtP}$ = 2348 Hz) to the μ-PCy_2 group. The ^{1}H NMR exhibits a single downfield resonance (Fig. 1) indicative of the hydride ligand (δ − 12.25 (dddt)) coupled to the μ-PCy_2 ligand ($^2J_{PH}(\mu)$ = 17.7 Hz), the PEt_3 ligands ($^2J_{PH}$ = 30.9 Hz and $^2J_{PH}$ = 76.5 Hz), and the Pt centre ($^1J_{PtH}$ = 511.7 Hz). The bridging nature of the hydride ligand is indicated by the relatively small value of $^1J_{PtH}$ (2, 12–16). The infrared spectrum (CH_2Cl_2) shows three ν(CO) absorptions at 1945 (s), 1862 (s), and 1851 (s) cm^{-1} confirming the presence of three terminal CO groups bonded to Fe. The spectroscopic and X-ray characterization of this complex were recently communicated in the literature and our spectroscopic data agree well with those reported (12).

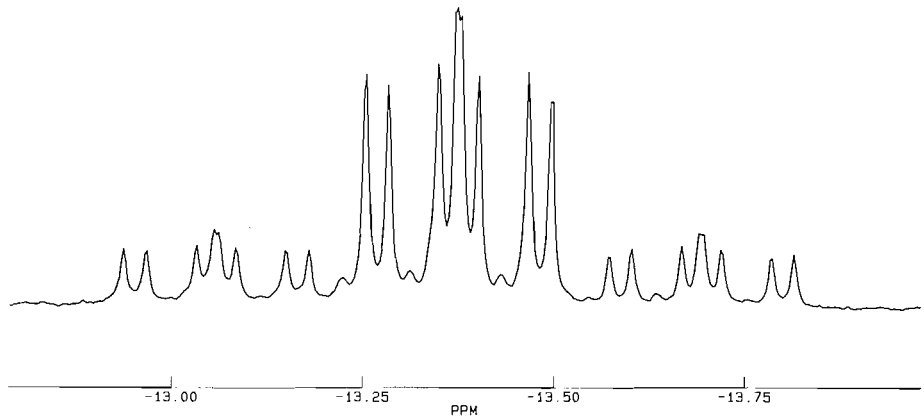

FIG. 2. The ^1H NMR spectrum of $[(CO)_3Fe(\mu\text{-}H)_2(\mu\text{-}PCy_2)Pt(PEt_3)_2][BF_4]$, **2**, at 300 K, showing the hydride resonances only.

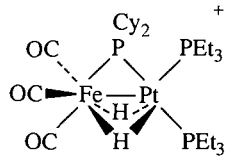
The addition of one equivalent of $HBF_4 \cdot Et_2O$ to **1** results in the rapid protonation of this species to give a single product as evidenced by $^{31}P\{^1H\}$ and ^1H NMR monitoring. This compound is identified as the dihydride complex $[(CO)_3Fe(\mu\text{-}H)_2(\mu\text{-}PCy_2)Pt(PEt_3)_2][BF_4]$, **2**. The $^{31}P\{^1H\}$ NMR spectrum shows the same pattern as **1** with resonances due to the μ-PCy_2 group (δ 222.6) and the two PEt_3 ligands (δ 12.3 (*cis*); 9.0 (*trans*)). The phosphorus–phosphorus coupling constants ($^2J_{PP}$ (μ-*trans*) = 217.0 Hz, $^2J_{PP}$ (μ-*cis*) < 3 Hz, and $^2J_{PP}$ (*cis-trans*) = 21.1 Hz) indicate no major change has occurred in the relative geometry of these ligands. However, the platinum–phosphorus coupling constant for the μ-PCy_2 group ($^1J_{PtP}$ (μ) = 1290 Hz) is reduced considerably. These results suggest that protonation has occurred at the bridging site and this is supported by the ^1H NMR spectrum of **2** which is very different from **1** (Fig. 2). There is a single resonance in the hydride region (δ −13.38), which integrates as two protons, establishing the equivalence of the two hydride ligands. The coupling constants ($^2J_{PH}(\mu)$ = 9.0 Hz, $^2J_{PH}$(*trans*) = 35.7 Hz, $^2J_{PH}$(*cis*) = 28.5 Hz and $^1J_{PtH}$ = 190.9 Hz) reflect the change in geometry from a singly bridging hydride to a doubly bridging hydride complex. The infrared spectrum (CH_2Cl_2) of **2** shows ν(CO) absorptions at 1998(m) and 1973 (s,br).



2

The reaction of **1** with HCl, as the DMA adduct, also results in the relatively rapid production of only one complex, **3**, as shown by the $^{31}P\{^1H\}$ NMR spectrum of the reaction solution. This species also displays the same type of $^{31}P\{^1H\}$ NMR resonance pattern as **1**, but with significant chemical shift differences. Upon conversion of **1** to **3**, the resonance due to μ-PCy_2, bridging the FePt bond, shifts to higher field (δ 183.8) while the resonances due to the PEt_3 groups shift to lower field (δ(*trans*) 16.5; (*cis*) 20.5). This infers that the basic geometry of the phosphorus ligands has remained the same, but some change in the structural or electronic nature of the coordination sphere has occurred. This notion is supported by the infrared spectrum (CH_2Cl_2) of **3** which shows two ν(CO) absorptions at 2009 (m), and 1938 (s, br): a significant blue shift compared to **1**. The major difference however, is that the ^1H NMR spectrum

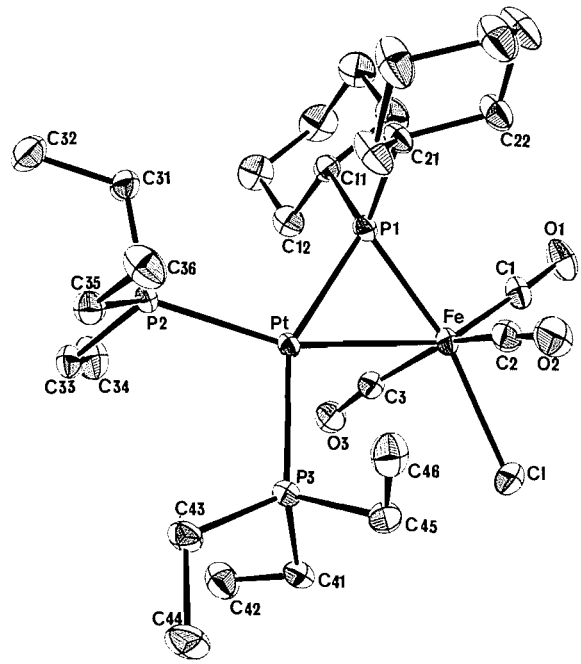


FIG. 3. Perspective ORTEP drawing of $(CO)_3ClFe(\mu\text{-}PCy_2)Pt(PEt_3)_2$, **3**, showing the numbering scheme. The numbering of cyclohexyl ring carbon atoms starts at the atom bound to phosphorus: 20% thermal ellipsoids are shown.

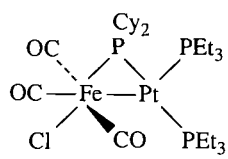
shows no evidence of a resonance due to a hydride ligand. It was therefore assumed that **3** was the product of oxidative addition of HCl to **1** followed by reductive elimination of H_2 and incorporation of the conjugate base, the chloride ligand, into the coordination sphere. The identification of **3** as $(CO)_3ClFe(\mu\text{-}PCy_2)Pt(PEt_3)_2$ required an X-ray crystallographic study which verified the presence of a terminal chloride ligand bound to the Fe centre.



3

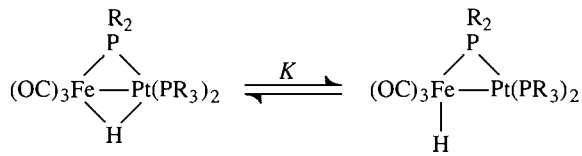
The closest intermolecular nonbonded contact is 2.3 Å between H25A and H46B. Complete listings of the interatomic bond distances and angles can be found in Tables 2 and S-3.

The geometry at the Fe centre is distorted octahedral with bonds to the μ-PCy_2 group, the chloride ligand, three CO groups, and the Pt atom. The chloride ligand is *trans* to the μ-PCy_2 group with a CL—Fe—P1 angle of 167.1(1)°. The three CO groups and the Pt atom are in a distorted square plane such that the angles within the plane are 100.1(3)° (C1—Fe—C2), 104.0(3)° (C1—Fe—C3), 93.0(2)° (Pt—Fe—C2), and 70.4(2)° (Pt—Fe—C3). The major distortion from octahedral geometry at Fe is due to the geometric restrictions imposed by a μ-PCy_2 ligand bridging a metal–metal bond. This causes the Pt atom to be pulled out of the square plane towards P1 and results in a Pt—Fe—P1 angle of 54.6(1)° and a Pt—Fe—CL angle of 112.4(1)°. The geometry at the Pt centre is best described as severely distorted square planar with P1 *trans* to P3 and P2 *trans* to Fe with angles of 150.0(1)° and 157.0(1)°, respectively. Again, the square plane is distorted in order to allow for the bridging phosphido ligand and the presence of a metal–metal bond. We therefore observe a small Fe—Pt—P1 angle (52.0(1)°) offset by increases in the other *cis* angles to give P1—Pt—P2 (107.0(1)°), P2—Pt—P3 (102.3(1)°), and Fe—Pt—P3 (99.9(1)°). The Fe—Pt bond distance of 2.675(1)Å is consistent with a single bond between these centres. This compares well to the value of 2.698(2) Å found for $(CO)_3(H)Fe(\mu\text{-}PPh_2)Pt(PPh_3)_2$ but is significantly shorter than that measured for **1**; 2.800(4) Å (12).

Discussion

In a preliminary report on complex **1** and some related FePt hydride complexes, Powell *et al.* demonstrated that these types of molecules may undergo an equilibration between bridging and terminal hydride coordination modes (12).



For **1**, the equilibrium was shifted completely to the bridging hydride and the X-ray crystal structure was determined. The observed geometries at the two metal atoms suggested that this complex is best described as having Fe(0) and Pt(II) centres.

The geometry of **3** is very different from that observed for **1**. The presence of an anionic chloride ligand at Fe, a shorter FePt bond distance (2.675(1) Å for **3** compared to 2.800(4) Å for **1**) and the distorted octahedral geometry at Fe are the major differences. This geometry is also what was observed by Powell *et al.* for the FePt hydride complex $(CO)_3HFe(\mu\text{-}PPh_2)Pt(PPh_3)_2$, except that for **3** the chloride ligand is *trans* to the μ-PCy_2 group while the hydride ligand for $(CO)_3HFe(\mu\text{-}PPh_2)Pt(PPh_3)_2$ is *trans* to a carbonyl group with the FeH bond perpendicular to the Fe(μ-PPh_2)Pt plane (12). The pseudo-octahedral geometry at Fe and the considerable blue shift of the ν(CO) absorptions are consistent with the formulation of **3** as a complex which now contains Fe(II) and Pt(0) centres. The downfield shift in the ^{31}P resonance due to the μ-PR_2 group and the upfield shift in the ^{31}P resonances of the Pt bound PR_3 groups may also be an indication of the reduction to Pt(0). However, this may simply be indicative of structural changes at the Fe(μ-PCy_2)Pt bridging fragment, since Carty has shown that ^{31}P NMR shifts in μ-PR_2 complexes can be very dependent on the nature of the M—M bonding, the M—M separation and the M—P—M angle (17).

A number of bonding descriptions are possible for **2**, but the lack of structural data makes a detailed discussion difficult. Observations of a small blue shift in the infrared ν(CO) absorptions and a very pale colour are not inconsistent with the

For personal use only.

description of **2** as an Fe(II)—Pt(II) complex. This is also consistent with the idea that these protonation reactions involve oxidation addition to the Fe(0)—Pt(II) complex **1** to give Fe(II)—Pt(II) species such as **2**, which can be stabilized in the presence of a non-coordinating anion (BF_4^-). This would then be followed by hydride transfer and reductive elimination of H_2 from the Pt(II) centre to give an Fe(II)—Pt(0) complex such as **3**.

In conclusion, we observed that the heterobimetallic FePt complex **1** reacted with protic acids HCl and HBF_4 in a way that was reminiscent of monometallic species (1). When the conjugate base was a non-coordinating anion (BF_4^-) the dihydride complex **2** was stabilized. However, when the conjugate base could occupy a coordination site (Cl^-) reductive elimination of H_2 was favoured. Thus the resulting product and the ease of H_2 reductive elimination was dependent on the ability of the conjugate base to act as a coordinating anion to the transition metal. The major difference between these FePt complexes and simple monometallic species is the ability of the heterobimetallic complexes to transfer ligands or electrons between metal centres as part of the overall reaction scheme. This may result in an intramolecular redox isomerization between bridging and terminal hydride modes (12) or changes in individual metal oxidation states in the stepwise oxidative addition, reductive elimination sequence, as was observed in the conversion of **1** to **3**. This cooperativity between metal centres is therefore an important factor in the protonation of heterobimetallic hydride complexes.

Received September 15, 1989

C. T. YIM and D. F. R. GILSON. Can. J. Chem. **68**, 875 (1990).

The orientational order parameters of benzonitrile and *o*-, *m*-, and *p*-dicyanobenzene, monobromo- and *p*-dibromobenzene, and *p*-benzoquinone, dissolved in two nematic solvents, 1132 and EBBA, have been measured as functions of temperature, and used to determine the potential energy parameters for each solute–solvent pair. These parameters have been correlated with a short-range interaction based upon a shape and size function of the solute molecule and a long-range contribution due to the interaction between the solute molecular quadrupole moment and the average electric field gradient.

Key words: nematic liquid crystals, orientational ordering of solutes.

C. T. YIM et D. F. R. GILSON. Can. J. Chem. **68**, 875 (1990).

On a mesuré les paramètres d'ordre d'orientation du benzonitrile, des *o*-, *m*- et *p*-dicyanobenzènes, des monobromo- et *p*-dibromobenzènes ainsi que de la benzoquinone dissous dans deux solvants nématiques, le 1132 et l'EBBA, en fonction de la température et on a utilisé ces données pour déterminer les paramètres d'énergie potentielle pour chacune des paires soluté–solvant. On a établi une corrélation entre ces paramètres et une interaction à courte distance évaluée en se basant sur une fonction de la forme et de la grosseur des molécules de solutés ainsi que sur a contribution à longue distance qui serait due à l'interaction entre le moment quadripolaire moléculaire du soluté et le gradient moyen du champ électrique.

Mots clés : cristaix liquides nématiques, ordre orientationnel des solutés.

[Traduit par la revue]

Introduction

When solutes are dissolved in nematic liquid crystal solvents, the interaction between solute and solvent molecules results in an orientational ordering of the solute. An understanding of solvent–solute interactions in these anisotropic systems is desirable in view of their importance, for instance, as analogues of biological membranes and in various technological applications. Recently, the orientational behaviour of mono- and dichlorobenzenes in two nematic solvents, EBBA (a Schiff-base) and 1132 (a mixed phenylcyclohexylcyanide solvent), was studied as a function of temperature and of concentration (1, 2). The results showed that chlorobenzene molecules were more highly oriented in 1132 than in EBBA. This difference was attributed to a change in sign of the electric field gradient in the two solvents and the resulting effect upon the interaction between the molecular quadrupole moment of the solute and the average electric field gradient from the solvent. The importance of this interaction in determining the solute orientation was first demonstrated in studies of D_2 and HD dissolved in nematic solvents by Burnell and co-workers (3–6), who also showed that a mixture of the two solvents in which the field gradient is zero could be used to eliminate the long-range interaction and limit the potential to a short-range interaction. This latter contribution was interpreted using a Hooke's law force constant for the displacement of the solvent molecules with the molecular circumference of the solute defining this displacement (6). Diehl and co-workers (7) have studied a series of eleven chlorobenzenes and interpreted the orientation using a bond interaction model. They concluded that a molecular shape function must be included and adopted the force constant – molecular circumference model. In our earlier studies on chlorobenzene and the dichlorobenzenes dissolved in EBBA and 1132 (1, 2), the short range term was shown to depend on the shape and size of the solute molecule, and, to further probe the solute–solvent interaction in these two solvent systems, we have extended our investigation to include other substituted benzenes. In particular, the cyano-derivatives were chosen, as this substituent group is common to the phenylcyanocyclohexyl class of liquid crystals, and *p*-benzoquinone, which is often a component part of dye molecules used as guests in display devices.

The solute orientation parameters are entirely determined by the orientation-dependent part of the intermolecular interaction potential. Since all the molecules studied in the present work possess at least C_{2v} symmetry, a two-parameter function is required to describe the orientation potential $U(\Theta, \Phi)$:

$$[1] \qquad U(\Theta, \Phi) = -AS^{(1)}(\cos^2\Theta + B\sin^2\Theta\cos 2\Phi)$$

where Θ and Φ are the polar and azimuthal angles, and $S^{(1)}$ is the solvent order parameter. The solvent molecules are assumed to be rigid cylinders. For the solute molecules, the three-axis is taken to be the long molecular axis, and the two-axis to be perpendicular to the ring plane, as shown in Fig. 1. The parameter A corresponds to a potential energy difference between two solute orientations when axis-3 is parallel and perpendicular to the liquid crystal director, while (AB) represents the difference between orientations with axis-1 and axis-2 parallel to the director. The parameters A and (AB) are divided into a long-range contribution, due to the field gradient – molecular quadrupole moment interaction, and a size–shape dependent short-range term. Thus, $A = A_{LR} + A_{SR}$, and $(AB) = (AB)_{LR} + (AB)_{SR}$.

For the short-range term, we employ a function of the type commonly used to describe anisotropic properties, in this case based on molecular dimensions:

$$[2] \qquad A_{SR} = A_L(L_3 - (1/2)(L_1 + L_2)) = A_L A[\mathrm{vdW}]$$

$$[3] \qquad (AB)_{SR} = (1/2)A_L(L_1 - L_2)$$

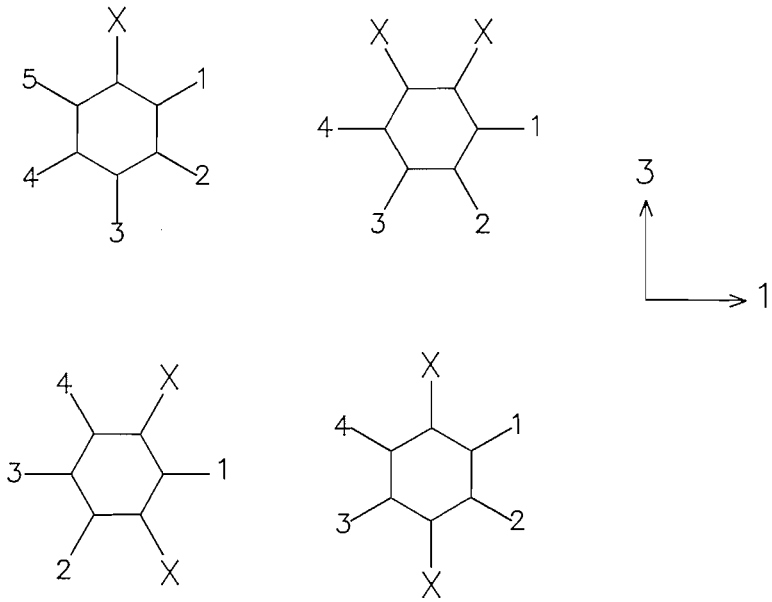

FIG. 1. Coordinate system and atomic labelling for mono- and disubstituted benzenes.

[4] $B_{SR} = (L_1 - L_2)/(2L_3 - L_1 - L_2) = B[\text{vdW}]$

where L_i is the molecular dimension, including the van der Waals radii, along the ith axis, and A_L is a constant which is assumed to depend only on the properties of the solvent. The long-range terms, A_{LR} and $(AB)_{LR}$, are given by similar functions based, in this case, upon the molecular quadrupole moments:

[5] $A_{LR} = (1/2)(Q_{33} - (1/2)(Q_{11} + Q_{22}))F_{ZZ}^0$

[6] $(AB)_{LR} = (1/4)(Q_{11} - Q_{22})F_{ZZ}^0$

where Q_{ii} are the components of the molecular quadrupole moment tensor, and $F_{ZZ}^0 = F_{ZZ}/S^{(1)}$, with F_{ZZ} being the average electric field gradient along the liquid crystal director as the z-axis. For both the short- and long-range interactions, the B parameters should depend only on the solute properties.

In analyzing the orientational potential function, the A_L value for each solvent can be obtained from our earlier studies (1, 2, 8), and, for the molecules studied in the present work, the molecular quadrupole moments will be treated as unknown parameters to be fitted. In eqs. [2]–[6], it is assumed that A_L is constant and that the electric field gradient is invariant over all the local environments that a solute molecule might prefer, so that the potential can be factorized into solvent-dependent and solute-dependent terms. This type of factorization is usually considered valid for dispersion forces (9, 10), but has also been suggested for repulsion forces (11).

Experimental

Spectra were recorded on either Varian XL-200 or XL-300 spectrometers and the solute order parameters were determined by analyzing the proton nmr spectra to give the direct dipole–dipole coupling constants. The molecular geometry was optimized by fitting to the dipolar coupling constants obtained from the room temperature spectra, and the same geometry was used for analyzing the spectra recorded at other temperatures. The solutes were obtained from commercial sources. Bromobenzene, *p*-dibromobenzene, *p*-dicyanobenzene, and benzoquinone were purified before use. The remaining chemicals were of high purity grade and used without further purification. Dilute solutions were used, with concentrations between 0.6 and 1.8 mol%.

Results and discussion

The calculated proton–proton distance ratios are given in Table 1, where they are compared with values reported in the literature. There were no significant differences between the present results and the previously published data, and minor differences can be attributed to the use of different nematic solvents. Corrections for the effects of molecular vibrations were not included in the analysis.

The values of experimental parameters A and B at each temperature were calculated by computer fits to the experimentally determined order parameters, S_{33} and $(S_{11} - S_{22})$, via the following equations:

[7] $$S_{33} = (3/2Z)(\int\int \cos^2\Theta \exp\{-U(\Theta, \Phi)/kT\} \sin\Theta \, d\Theta \, d\Phi) - 1/2$$

[8] $$(S_{11} - S_{22}) = (3/2Z) \int\int (\sin^2\Theta \cos 2\Phi \exp\{-U(\Theta, \Phi)/kT\} \sin\Theta \, d\Theta \, d\Phi)$$

where

$$Z = \int\int \exp\{-U(\Theta, \Phi)/kT\} \sin\Theta \, d\Theta \, d\Phi$$

The order parameters of the pure solvents were taken from the literature (refs. 12, 13 and our unpublished results for EBBA), and the computation of A and B used the reduced temperature dependence, since the solvent order parameter is a function of reduced temperature only, and is independent of the solute and its concentration (14). The parameter A should include the variation of the molar volume with temperature and its effect on the intermolecular forces, but, in the study of the chlorobenzenes (1, 2), it was found that including this volume dependence neither led to a significant improvement in the fit, nor had a marked effect on the relative magnitudes of the parameters A for the two solvent systems. Since the available data do not permit us to take full account of the small temperature effect on the energy parameters, only the averaged values of A and B were

used, and these are listed in Table 2 for each of the systems studied. The values of B showed a small variation with temperature, with rms deviations from the mean value ranging from 1.3 to 9.3%. The largest value was for *p*-dibromobenzene in EBBA. It has been suggested that the temperature dependence of B can be attributed to the neglect of higher rank terms in the order potential, or to the biaxiality of the solvent molecules (9, 10). The short- and long-range interactions in the ordering potential may have different temperature coefficients (15), which could also contribute to the observed temperature dependence of B.

The average field gradient, F_{ZZ}, decreases with increasing temperature, and it seems reasonable to assume that it is proportional to the solvent order parameter, $S^{(1)}$. This assumption can be avoided if the data are compared at the same reduced temperatures used by Burnell and co-workers (16) to measure the field gradients, which would limit the fit to only two temperatures. In the study on dichlorobenzenes (2), it was shown that the conclusions were unchanged. The average electric field gradient in the host solvent is also assumed to be independent of the size of the solute molecule. Therefore, F_{ZZ}^0 in eqs. [5] and [6] can be taken to be constant for a given solvent. Based on the reported data on the two solvents (16), the F_{ZZ}^0 values were found to be 2.41×10^{18} and -2.62×10^{18} V m^{-2} for 1132 and EBBA, respectively. The direct calculation of A_{LR} and $(AB)_{LR}$, using eqs. [5] and [6], requires values for the molecular quadrupole moments, which, unfortunately, are not available for the compounds studied here. However, since A_L is a constant for a given solvent, the ratio $(A_L)^{1132}/(A_L)^{EBBA}$ is independent of the solute and the long-range interaction can be written as

$$[9] \qquad A_{LR}{}^{1132} = (A^{1132} - wA^{EBBA})/(1-wx)$$

where $w = A_L{}^{1132}/A_L{}^{EBBA}$, and the x is the ratio of the electric field gradients, $F_{ZZ}{}^{0,EBBA}/F_{ZZ}{}^{0,1132}$. Similar equations can be obtained for $A_{LR}{}^{EBBA}$ and the $(AB)_{LR}$ terms. The value of w can be derived in the cases where the molecular quadrupole moments of the solute molecules are known, and, using the results for benzene, trichlorobenzene, and tribromobenzene (8), an average value of 1.13 was obtained. The short-range contributions A_{SR} and $(AB)_{SR}$ can then be obtained by subtracting the corresponding long-range term from the experimental values. The values of A_{LR}, $(AB)_{LR}$, A_{SR}, and $(AB)_{SR}$ calculated in this way are listed in Table 2. The same short-range contributions can also be calculated directly by using eqs. [2]–[4], with the molecular dimensions and van der Waals radii (17). The required A_L values in the two solvents, 1132 and EBBA, are taken to be 3.40 and 3.02×10^{-11} J m^{-1} molecule^{-1}, respectively, from the dependence of A_{SR} on A[vdW], obtained from the results on benzene, tribromobenzene, and five chlorobenzenes (1, 2, 8). The A[vdW] values were calculated using eq. [2] and the values of $A_L A$[vdW] and B[vdW] were then combined with the long-range contributions, listed in Table 2, to yield A^{calc} $(=A_L A[\text{vdW}] + A_{LR})$, $(AB)^{calc}$ $(=A_L A[\text{vdW}]B[\text{vdW}] + (AB)_{LR})$, and B^{calc}, Table 3. These values were then used to calculate the order parameters S_{33} and S_{22}. The results are compared with the experimental values in Fig. 2 for the four cyanobenzenes. The average percent rms errors between the calculated and observed order parameters for each solvent–solute pair are also given in Table 3. It can be seen that, for the substituted benzenes in either solvent, an orientation potential based on the proposed short-and long-range interactions yields order parameters in reasonable agreement with the experimental values, the worst case being a total disagreement of 15% summed over all the experimental points.

The molecular quadrupole moments, which, by necessity, have become fitted parameters, are listed in Table 4. For all molecules described in these studies, except *p*-benzoquinone, the contribution of A_{LR} is less than 20% and, therefore, a 50% variation in the term $(Q_{33} - (Q_{11} + Q_{22})/2)$ would not change A^{cal} by more than 10%. On the other hand, $(AB)^{cal}$ would be more strongly affected by the uncertainty in the term $(Q_{11} - Q_{22})$. Therefore the values of the individual tensor components may not be very significant.

In our analysis of orientational potentials we have shown that the short-range interaction in solvent 1132 is stronger by about 10%, as reflected in the corresponding A_L values. However, the average orientation along the long molecular axis, S_{33}, under similar conditions, also depends upon the contributions from the long-range interactions. To illustrate this, the order parameters at room temperature for benzene, benzoquinone, and other mono- and disubstituted compounds are given in Table 5. The interaction between the electric field gradient and the molecular quadrupole moment makes its most important contribution not

through the term A_{LR}, but through $(AB)_{LR}$, which has a positive value in 1132 but a negative value in EBBA for all the biaxial solutes studied so far (1, 2, 8). This explains the experimental result that higher B values, and, correspondingly, a larger difference in the order parameters along the molecular axes 1 and 2, i.e. $(S_{11} - S_{22})$, are always observed for 1132 and, therefore, the ring plane (see Fig. 1) is much better oriented along the liquid crystal director in this solvent than in EBBA. This may be an important factor in the choice of solvent when the anisotropic property of interest is more associated with the ring structure than with a particular substitution group, or vice versa (18).

Liquid crystal display devices may incorporate a pleochroic dye as a solute in order to improve the contrast properties of the display, or to add colours. Apart from the photochemical stability, absorption wavelength, etc., the "guest" molecule must have a high dichroic ratio, since the contrast between the on-and-off states of the display depends upon the difference between the absorption of light polarized parallel and perpendicular to the liquid crystal director. Two different types of guest molecule can be considered, either a long cylindrical

shape (approximately) or a planar molecule, and two different electronic transitions, $\pi \rightarrow \pi^*$ or $n \rightarrow \pi^*$. Ideally, the transition moment should lie along, or very close to, the axis of highest orientation, but, for molecules with less than C_{2v} symmetry, the direction of the transition moment and the axis of principal orientation are not necessarily coincident.

The term A represents the difference in potential energy between orientations with the long molecular axis parallel and perpendicular to the liquid crystal axis, and, in order to achieve the highest orientation along this axis, A_{SR} and A_{LR} should be large. This requires that L_3 should be much greater than $(L_1 + L_2)$, that Q_{33} should be large and have the same sign as

the electric field gradient, and that either Q_{11} or Q_{22} should have the opposite sign. (AB) describes the potential energy difference between the alignment of axis-1 and axis-2 parallel to the liquid crystal director and in planar molecules, this term should be large in order to orient the plane of the molecule (rather than the longest axis) parallel to the liquid crystal axis. In this case L_1 should be greater than L_2, which is normal for planar aromatics, since L_2 is always the shortest dimension and is approximately constant at the thickness of the ring. To maximize the long-range term in the potential, Q_{11} should have the same sign as F_{zz} and be greater than Q_{22}. The component of the quadrupole moment perpendicular to the ring, Q_{22}, is usually negative, while Q_{11} is positive, and, therefore, $(Q_{11} - Q_{22})$ is always positive. In a solvent with a field gradient of opposite sign, as in EBBA, the $(AB)_{LR}$ term would have a negative sign resulting in a diminished orientational potential.

In designing suitable guest molecules it is unfortunate that the molecular quadrupole moment data are not easily available. It is clear, however, that the choice of solvent is important since the orientation of the molecular plane can, in some cases, be enhanced at the expense of the longer molecular axis by choosing a solvent with an electric field gradient of opposite sign to the A_{LR} parameter, leading to improved contrast for displays based on $n \rightarrow \pi^*$ transitions.

DOUGLAS L. HUIZENGA and HOWARD H. PATTERSON. Can. J. Chem. **68**, 881 (1990).

The reaction of Cr(III) with chelate-forming carboxylate ligands can be monitored at the low ligand concentrations typical of natural waters by chemiluminescence analysis of unreacted Cr(III). This technique is utilized here for the measurement of Cr(III) reaction kinetics with oxalate, salicylate, and humic acid over a wider ligand concentration range than previously reported. Variation of the pH and ligand concentrations allowd the determination of rates of reaction by three pathways with different pH dependencies. The magnitude of rate constants of these pathways for Cr(III) with inorganic (Cl^-, SCN^-) and carboxylate ligands gives insight into the reaction pathways for the environmentally important ligand humic acid.

Key words: Cr(III), oxalate, salicylate, humic acid.

DOUGLAS L. HUIZENGA et HOWARD H. PATTERSON. Can. J. Chem. **68**, 881 (1990).

Faisant appel à des analyses de chimiluminescence du Cr(III) qui n'a pas réagi, on peut suivre l'évolution de la réaction du Cr(III) avec des ligands carboxylates pouvant former des chélates à de faibles concentrations de ligand types de celles qui existent dans les eaux naturelles. On a utilisé cette technique pour la mesure de cinétriques de réactions du Cr(III) avec les acides oxalique, salicylique et humique, sur des écarts de concentration beaucoup plus grands que ceux rapportés antérieurement. En faisant varier le pH et les concentrations de ligand, on a pu déterminer que, suivant le pH, il existe trois voies réactionnelles différentes. L'amplitude des constantes de vitesse des réactions du Cr(III) avec des ligands inorganiques (Cl^-, SCN^-) et carboxyliques permet de comprendre les voies réactionnelles du ligand, acide humique, qui est important d'un point de vue environnemental.

Mot clés : Cr(III), oxalate, salicylate, acide humique.

[Traduit par la revue]

Introduction

Knowledge of both the rate of conversion of aquated Cr(III) to bound forms and the ultimate equilibrium speciation of Cr(III) are important in predicting its biogeochemical behavior in natural waters. In general, the reaction kinetics of Cr(III) are dominated by the slow exchange of water molecules from the inner coordination sphere. The rates of reaction of Cr(III) with inorganic ligands such as Cl^- and SCN^- have been extensively studied either directly or indirectly by combination of aquation rate and equilibrium measurements and the results have been systematically compared (1). In contrast, the rates of reaction of Cr(III) with carboxylate ligands and humic materials have been little studied. The few studies available for carboxylate ligands have been conducted under acid conditions and at high ligand concentrations (2).

The rates of reaction of Cr(III) with carboxylate ligands at the low concentrations typical of dissolved organic matter in natural waters (about 10^{-5} M) have not been reported. At such low concentrations, the rate of reaction should become dependent upon the ligand concentration. We have used chemiluminescence analysis to monitor rates of reaction of Cr(III) with the carboxylate ligands oxalate, salicylate, and humic acid over a wide range of ligand concentrations (10^{-2} to 10^{-5} M). The technique involves the oxidation of luminol by hydrogen peroxide in the presence of unbound Cr(III) to yield a product which luminesces (3). The intensity of luminescence is proportional to the unreacted Cr(III) concentration. Because of its high sensitivity, chemiluminescence analysis is well suited to kinetic studies of Cr(III) reacting with carboxylate and humic ligands at low concentrations.

Methods

Monitoring of Cr(III) reaction rates was performed by the technique of chemiluminescence analysis as described in Huizenga and Patterson (3). Reagent grade chemicals were used for this work except for the humic acid. The water was distilled and passed through an organic absorbent followed by a mixed bed chelating resin. The ionic strength of test solutions was maintained at 0.10 by mixing of 0.1 M KNO_3 with 0.1 ionic strength ligand stock solutions. The 0.1 M KNO_3 medium was acidified to pH 3.5 by addition of nitric acid and purged with nitrogen prior to preparation of samples in order to remove traces of carbon dioxide.

The salicylate stock solution was prepared by neutralization of salicylic acid with KOH. The solution was adjusted to pH 4 and purged with nitrogen. The oxalate stock was prepared from $Na_2C_2O_4$ to be 0.0333 M. The humic acid stock solution was prepared from the sodium salt of humic acid (Aldrich) at 20 g/L. Samples prepared with humic acid were adjusted to pH 3.5 and purged with nitrogen prior to adjustment to the test pH. The chromium(III) stock solution was prepared from $Cr(NO_3)_3 \cdot 9H_2O$ to give 0.01 M Cr(III). Nitric acid (0.01 M) was added to the Cr(III) stock to suppress formation of polymeric species.

A temperature of 25.0°C was maintained with a circulating water bath for all reactions and pH measurements. The measurement of pH was performed with a combination pH electrode and digital pH meter. Dilute NBS pH buffers were prepared according to Bates (4). The electrodes were standardized several times a day with a single buffer, the 0.05 molal phthalate buffer (pH_{NBS} = 4.008 at 25.0°C). Care was taken to prevent transfer of phthalate into sample solutions. Periodically a second buffer was used, the 1:3.5 phosphate buffer (pH_{NBS} = 7.413 at 25.0°C). Titrations of standardized 0.1 M HNO_3 into 0.1 M KNO_3 were performed in order to calibrate the electrodes in terms of hydrogen ion concentration. Comparison of these two hydrogen ion scales yielded the relationship:

$$[1] \quad -\log [H^+] = pH_{NBS} - 0.114$$

This relationship is dependent upon the specific electrodes used for the measurements. All results are reported here on the hydrogen ion

concentration scale. Conversion between the hydrogen ion concentration and NBS activity scales can be made with the above relationship.

Reactions were initiated by addition of Cr(III) solution into the reaction medium containing ligand to give 10^{-6} M Cr(III). The reacting solutions were maintained at 25.0°C and pH measurements were performed just after the Cr(III) addition and after the final analysis of the sample. The pH was continuously monitored during rapid reactions (high pH reactions). A single standard for the chemiluminescence measurements was prepared just prior to use to be 10^{-6} M Cr(III) in 0.1 M KNO_3 acidified with 1.6×10^{-4} M KNO_3. The standard was run after every four to five samples. Rapid reactions were followed continuously with the standard run before and after the reaction. Rapid reactions were run in 500 mL polyethylene bottles and inserted into a jacketed beaker temperature controlled by a circulating water bath. Slower reactions were run in 250 mL polyethylene bottles which were suspended in the thermostated water bath between measurements.

The ionic strength was maintained at 0.10 M and the temperature at 25.0°C for the reaction of chromium with the various ligands. Only data with the degree of reaction less than 50% were used for the calculation of the pseudo-first order rate constants for oxalate and salicylate reactions. The pseudo-first order rate constants were calculated from the slope of the plot of log [unreacted Cr(III)] versus time.

Results and discussion

Rate of reaction of Cr(III) with oxalate

The pseudo-first order rate constants for reaction of 10^{-6} M Cr(III) with oxalate at concentrations between 4×10^{-5} and 1×10^{-2} M were determined over the pH range 3.5 to 7. The rate of disappearance of unreacted Cr(III) in terms of the pseudo-first order rate constant, k_{obs}, is given by:

$$[2] \quad \text{Rate} = k_{obs}[\text{unreacted Cr(III)}]$$

The observed pseudo-first order rate constant varies with pH and oxalate concentration (see Fig. 1). At low oxalate concentration and a fixed pH, the k_{obs} is proportional to the ligand concentration, so second order kinetics are observed. At low pH and high oxalate concentration, the k_{obs} approaches a limiting value, indicating limiting first order kinetics. At high pH and oxalate concentrations up to 0.01 M, limiting kinetics are not observed. At low pH, the slope of log k_{obs} against pH for any given oxalate concentrations approaches one. This indicates the importance of a reaction path through an activated complex containing a hydroxide ion.

The rate of disappearance of total Cr(III) by pathways with different hydrogen ion dependencies under conditions where second order kinetics are observed is given by:

$$[3] \quad \text{Rate} = (k_0 + k_1[H^+]^{-1} + k_2[H^+]^{-2})[Cr^{3+}][L]$$

where L represents the fully dissociated ligand, the k_n values represent the reaction rate constants for the various reaction pathways. The term in parentheses is the observed second-order rate constant, k, and the three terms describe its pH variation for the following reactions in which outer-sphere complexes react to give inner-sphere complexes:

$$[4a] \quad Cr(H_2O)_6,L \xrightarrow{k_0} Cr(H_2O)_5L + H_2O$$

$$[4b] \quad Cr(OH)(H_2O)_5,L \xrightarrow{k_1} Cr(OH)(H_2O)_4L + H_2O$$

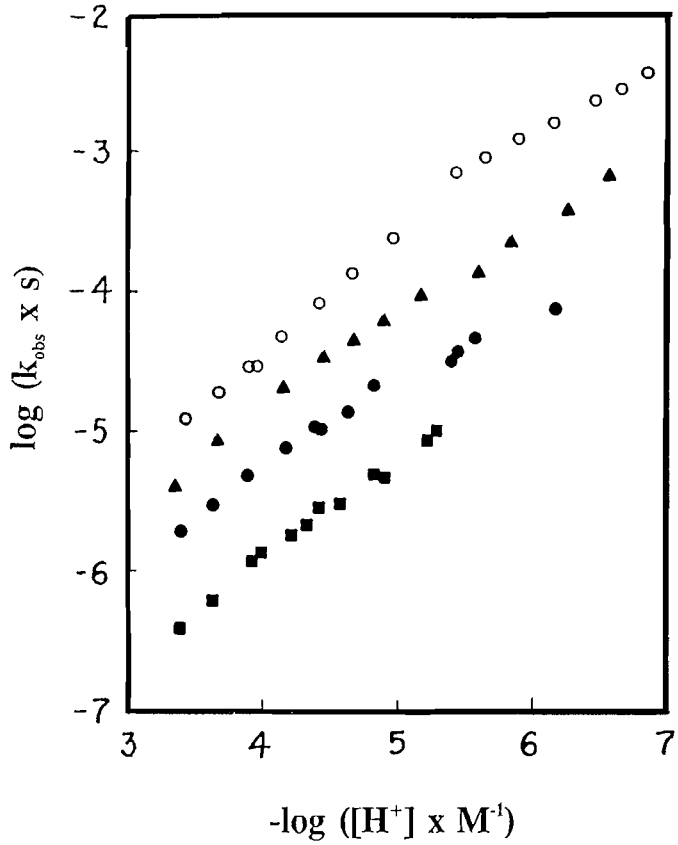

FIG. 1. Variation in the log of the observed pseudo-first order rate constant k_{obs} with pH for the reaction of 10^{-6} M Cr(III) with varying concentrations of oxalate: ■ 4×10^{-5} M oxalate; ● 1.7×10^{-4} M oxalate; ▲ 10^{-3} M oxalate; and ○ 10^{-2} M oxalate.

$$[4c] \quad Cr(OH)_2(H_2O)_4,L \xrightarrow{k_2} Cr(OH)_2(H_2O)_3L + H_2O$$

The inner-sphere complexes shown would be the initial reaction products. Addition of the ligand into the inner-sphere will render the Cr(III) more labile toward further reaction to form multi-ligand species. The observed pseudo-first order rate constant, k_{obs}, can be converted into the second order rate constant, k, as follows:

$$[5] \quad k = k_{obs}(1 + \beta_1^*[H^+]^{-1} + \beta_2^*[H^+]^{-2})/[L]$$

where the stability constants β_1^* and β_2^* describe the hydrolysis equilibria of Cr(III) and are defined in Table 1.

The second-order rate constant, k, was calculated from eq. [5] for the rate data obtained at low oxalate concentrations (see Fig. 2). The concentration of the fully dissociated oxalate was used for the ligand concentration. The value used for the second acid dissociation constant of oxalate for these calculations is listed in Table 1. Toward pH 7 the slope of the curve was two indicating that the predominant reaction has an activated complex containing two hydroxide ions. At pH 4.2 the slope was one, indicating reaction predominantly by a pathway with an activated complex that contains one hydroxide ion. The slope of the line at pH 3.5 was less than one, indicating the presence of an acid independent pathway. These data were modeled with the following equation:

$$[6] \quad k = k_0 + k_1[H^+]^{-1} + k_2[H^+]^{-2}$$

and the results are reported in Table 2.

Rate of reaction of Cr(III) with salicylate

The pseudo-first order rate constants for the reaction of 10^{-6} M Cr(III) with salicylate was measured at concentrations of 5×10^{-4} to 1×10^{-2} over the pH range 3.5 to 7. All other experimental conditions were the same as for the oxalate reactions. The variation in the observed pseudo-first order rate constant is qualitatively similar to that observed for oxalate. For a given pH and ligand concentration, however, the rate of reaction is higher for oxalate than for salicylate, especially at lower ligand concentrations. The variation in the second order rate constant k with pH is shown in Fig. 3. The data were modeled and the resulting k_i values reported in Table 2.

Limiting behavior for reaction of Cr(III)

At higher concentrations of oxalate and salicylate, the rate of reaction of Cr(III) with a ligand approaches a limiting rate. There are two general models for describing this limiting behavior. In the first model, formation of an outer-sphere complex between Cr(III) and the ligand precedes the reaction to give the inner-sphere complex. In this case, the limiting behavior would result from nearly total association of the Cr(III) with ligand and movement of the ligand into the inner-sphere upon loss of a water molecule from the inner-sphere. The second model assumes that one water molecule has been lost from the inner-coordination sphere of the Cr(III) and that water and ligand molecules compete for the open inner-sphere position. With this model, as the concentration of ligand is increased, a concentration will be reached where the ligand out competes water molecules for the vacancy in the inner-sphere and the maximum rate of reaction will be obtained. The two models are generally experimentally indistinguishable and lead to the same functional relationship (5):

$$[7] \quad k_{obs}^{-1} = a[L]^{-1} + b$$

where [L] represents the concentration of fully dissociated ligand. The mechanistic significance of the constants a and b differ for the two models. For a fixed pH, the fraction of the ligand that is not protonated is constant and the total ligand concentration may be substituted without altering the form of the equation.

The oxalate data were plotted to examine the limiting behavior of the reaction between Cr(III) and oxalate for two fixed pH values (Fig. 4). The relationship is not linear; the highest concentration data point (lowest [salicylate]$^{-1}$) at both pHs falls below the line fitting the rest of the data. This more

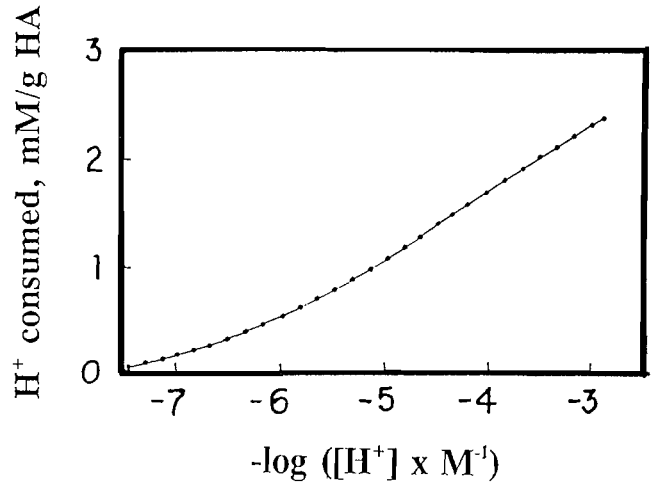

FIG. 6. Consumption of protons during acid titration of 240 mg/L humic acid. The solid line represents the modified Henderson-Hasselbach model of the data.

complicated relationship could be due to association between Cr(III) ion and more than one oxalate molecule at the same time.

A similar examination of the salicylate data for the simple limiting model does show a linear relationship (Fig. 5). The stronger electrostatic interaction between oxalate and Cr(III) may lead to more complicated limiting behavior near 0.01 M oxalate where oxalate makes up a significant portion of the total ionic strength of the test solutions. It is possible that salicylate would show the same type of behavior at higher concentrations (>0.01 M), especially considering that the final limiting rates for the two ligands are expected to be the same (6).

Rates of reaction of Cr(III) with humic acid

The pseudo-first order rate constant for reaction of Cr(III) with humic acid was determined for concentrations of 1, 5, and 25 mg/L humic acid in 0.1 M KNO_3 over the pH range 3.5 to 7. Because of non-linearity of plots of log [Cr(III)] versus time for the reaction of Cr(III) with humic acid, initial reaction rates were utilized. We have previously shown that the non-linearity is not related to the relative concentrations of different reaction sites on the humic acid (3). However, the non-linear first order behavior could be accounted for by the simultaneous formation of chelated and non-chelated bound Cr(III). Non-chelated bound Cr(III) gives the same response with the chemiluminescence technique as unbound Cr(III) (3). The initial rate method will provide the best estimate of the rate of reaction of Cr(III) with humic acid to form chelated complexes.

The observed first-order rate constant varies with humic acid concentration and pH. The k_{obs} at a fixed pH is proportional to the concentration of humic acid. No tendency toward limiting first-order kinetics is observed for humic acid concentrations up to 25 mg/L.

In order to compare the reaction rate data for humic acid with that observed for oxalate and salicylate, the protonation behavior of the humic acid must be known. The acid titration curve of 240 mg/L humic acid in 0.1 M KNO_3 is shown in Fig. 6. The data can be modeled with the modified Henderson–Hasselbach equation:

$$[8] \quad pH = pK_a + n \log ([A]/[HA])$$

Simple acid dissociation has an n value of 1 in this equation. Because of its polymeric nature and chemical differences in the functional group environments, humic acid generally shows n

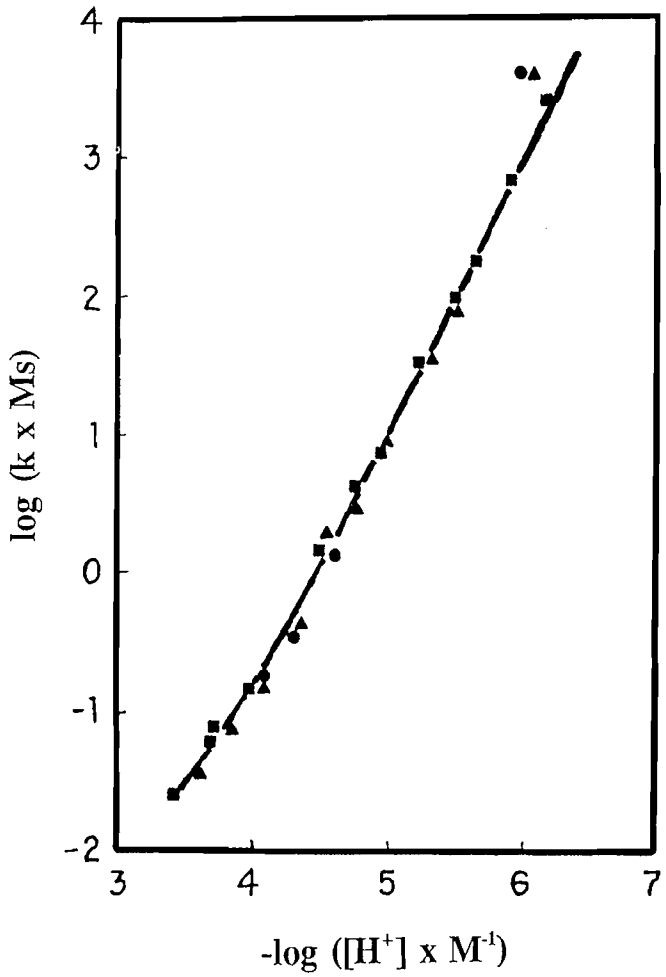

FIG. 7. Variation in the log of the second order rate constant k with pH for the reaction of Cr(III) with humic acid: ● 1 mg/L humic acid; ▲ 5 mg/L humic acid; and ■ 25 mg/L humic acid.

values of about 2.5. Non-linear least-squares modeling of the titration data yielded $pK_a = 4.30 \pm 0.02$ (standard error), $n = 3.22 \pm 0.03$, and 3.71 ± 0.03 millimolar carboxylate/(g humic acid).

The protonation model (eq. 6) was used to calculate the concentration of dissociated carboxylic functional groups as a function of pH. The rate data for reaction of Cr(III) with humic acid were plotted as the calculated second-order rate constant against pH (see Fig. 7). These data were then modeled with eq. [6] and the k_i values for the different pathways are presented in Table 2. The slope of the curve near pH 3.5 is not less than one as was observed for oxalate and salicylate. Consequently, the pathway which is zero order in $[H^+]$ does not appear to be important in the experimental pH range and has been omitted from the model.

The second-order rate constant for humic acid is similar to that for oxalate at low pH values; the k_1 of the humic acid is similar to the k_1 for oxalate. At higher pH where an inverse second order dependency on hydrogen ion is observed, the k_2 for humic acid is much greater than that of either oxalate or salicylate. Calculation of the second order rate constant for humic acid simply on the basis of its dissociated carboxylate functional groups does not adequately describe its reactivity with Cr(III).

The absence of limiting first-order kinetics for the reaction of Cr(III) with humic acid is due to the low concentration of functional groups. At the highest concentration of humic acid studied, 25 mg/L, the total concentration of carboxylate groups is only 9×10^{-5} M. Oxalate and salicylate both show simple second-order kinetics at such low concentrations.

Comparison of reaction rates for carboxylate and inorganic ligands

The nature of the reaction of Cr(III) with carboxylate ligands differs greatly from that with simple inorganic ligands. Carboxylate ligands show limiting first-order behavior while the inorganic ligands do not. The electrostatic interactions that would lead to formation of outer-sphere ion pairs for both types of ligands should be approximately the same. Comparison of k_1 values for Cr(III) with two inorganic ligands of the same charge type, CL^- and SCN^-, shows large differences for the various reaction pathways. The k_0 values for the inorganic ligands are 3 to 5 orders of magnitude lower than for salicylate. The k_1 values for the inorganic ligands are 2 to 3 orders of magnitude lower than for salicylate. The k_2 values, however, are similar. The differences in the kinetic behavior between the two types of ligands decreases as the number of hydroxide ions in the activated complex increases. This correlates with a decrease in electrostatic interaction between the ligand and the chromium species.

The two simple carboxylate ligands differ from each other due to charge differences. For all three pathways, oxalate (charge −2) reacts almost one order of magnitude faster than salicylate (charge −1).

Conclusion

The carboxylate ligands, oxalate, salicylate, and humic acid, showed second-order rate laws at low ligand concentrations ($<10^{-3}$ M). These data can be used to predict the rate of conversion of Cr(III) to chelate bound forms under environmental conditions. Conversion of Cr(III) to bound forms may affect its biogeochemical behavior in natural waters. The initial product formed with a single ligand per metal ion will likely react further with other ligands as the system moves toward equilibrium.

A better synthetic route to β-carboxyaspartic acid (Asa) was achieved through condensation of sodium dibenzyl malonate and benzyl 2-bromoacetate as an alternative to two steps in the method of Koch *et al.* Catalytic hydrogenation at 5 atm pressure in a shaken stainless steel vessel removed protecting carbobenzyloxy groups. Asa was purified on a cation exchange column. An extract of *E. coli* was found to catalyse the decarboxylation of Asa in a doubly coupled assay designed to be specific for produced aspartic acid. Evidence for enzymatic decarboxylation includes complete loss of activity on boiling and progressive loss of activity on repeated freeze–thawing of the extract.

Key words: decarboxylation, β-carboxyaspartic acid, Asa decarboxylase.

On a développé une meilleure méthode de synthèse de l'acide β-carboxyaspartique (Asa) qui fait appel à une condensation du sel de sodium du malonate de dibenzyle avec le 2-bromoacétate de benzyle, à la place de deux étapes de la méthode de Koch et ses collaborateurs. Pour éliminer les groupements protecteurs carbobenzyloxy, on a effectué une hydrogénation catalytique, à une pression de 5 atmosphères, dans des contenants en acier inoxydable qui étaient agités. On a purifié l'Asa par un échange cationique sur colonne. Lors d'essais doublement couplés effectués dans le but spécifique d'évaluer l'acide aspartique produit, on a trouvé qu'un extrait d'*E. coli* catalyse la décarboxylation de l'Asa. Parmi les données suggérant l'existence du décarboxylation enzymatique, on doit mentionner la perte totale d'activité qui est observée lorsqu'on fait bouillir l'extrait ainsi que la perte progressive de son activité lorsqu'on le soumet d'une façon répétée à des congélations suivies de périodes de réchauffement.

Mots clés : décarboxylation, l'acide β-carboxyaspartique, Asa-décarboxylase.

Introduction

Discovery of the carboxylated amino acids, aminomalonic acid (Ama),[2] γ-carboxyglutamic acid (Gla), and Asa in various tissues including atherosclerotic plaque (1), osteocalcin (2), and *E. coli* ribosomal proteins (3) has generated considerable interest in their synthesis and properties. Several methods for racemic Asa (3–5) and one for D-β-Asa (6) have been reported. All prescribe millimolar quantities, with suggestions for scaling up offered in one procedure (4).

Carboxylations of the amino acids are thought to take place post-translationally and, in the case of Gla, a Vitamin K-dependent carboxylase has been characterized (7). The kinetics of thermal decarboxylation of the three synthetically prepared carboxy amino acids have been compared (8). Enzymes catalysing the decarboxylation of Ama have been described (9, 10). We wish to report the demonstration of Asa decarboxylase activity in an extract of *E. coli*.

Experimental

Asa was prepared essentially by the scaled-up method of Koch *et al.* (4) with the following modifications. The first two steps involving the nucleophilic substitution of sodium diethylmalonate with methyl chloroacetate to produce 1,1,2-tris(carbomethoxy)ethane followed by transesterification to 1,1,2-tris(carbobenzyloxy)ethane were replaced by a single reaction. The consideration of equimolar amounts of sodium dibenzyl malonate and benzyl 2-bromoacetate result in a larger yield (84% overall) of product.

$$BnO_2CCH_2Br + NaCH(CO_2Bn)_2 \rightarrow BnO_2CCH_2CH(CO_2Bn)_2 + NaBr$$

In a typical experiment 1.65 g of Na was added in small pieces to 20.36 g of dibenzyl malonate in 163 mL of dry methanol at 0°C and stirred for 1 h. After addition of 16.41 g of benzyl 2-bromoacetate, stirring was continued at room temperature overnight. Following rotary evaporation of the methanol an orange oil was obtained; this oil was placed in a separatory funnel with 100 mL of ether, 200 mL of deionized water, and 7.5 mL of 6 M HCl. After extraction and separation of the ether layer the water layer was back-extracted twice with 100-mL portions of ether. The ether layers were combined, dried over anhydrous $MgSO_4$, and rotary evaporated. The residue was a light yellow oil weighing 25.98 g.

The catalytic hydrogenation of the azide, tribenzyl 1-azidoethane-1,2,2-tricarboxylate, to reduce the protective carbobenzyloxy groups to toluene and yield Asa was carried out by placing 0.70 g of azide, 0.35 g of $PdCl_2$, and 150 mL of dry methanol in a stainless steel vessel (inner diameter 54 mm, height 78 mm), purging, then pressurizing to 5 atm with H_2 (1 atm = 101.3 kPa). After shaking mechanically for 48 h the reaction mixture was filtered and rotary evaporated. Three additions of benzene were followed by rotary evaporation to remove traces of toluene. The yellow solid remaining was washed five times with ether, then dissolved in 4 mL of deionized water, pH 7.0. A small amount of insoluble material was removed by centrifugation at 10 000 g for 15 min. The supernatant was passed through a 5-cm column of Amberlite IRC-50 cation exchange resin. After freeze-drying of the clear eluate, there remained 0.112 g of a white crystalline powder (yield 43%), which was shown to be chromatographically pure and was identified as Asa monohydrate by NMR, IR, and MS.

For the enzyme assay an *E. coli* extract was prepared by suspending late log phase cells harvested from 30 mL of nutrient broth in 5 mL of H_2O. After ultrasonic disruption at 5°C, cellular debris was removed centrifugally. Commercial preparations of GOT (1667 units/mL) and MDH (10 000 units/mL) were dialysed against deionized water and diluted to working solutions with a 0.1 M potassium phosphate

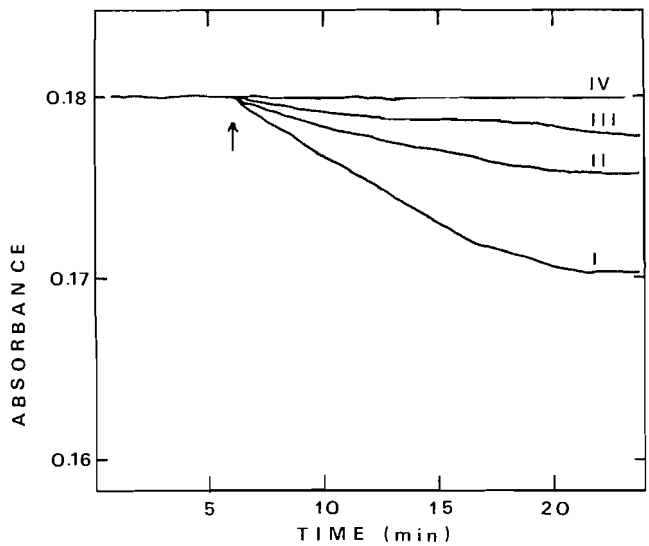

FIG. 2. Effect of freeze-thawing on Asa decarboxylase activity. (I) Complete assay mixture. (II), (III), (IV) Subsequent freezings and thawings of extract. (↑) Point of addition of extract.

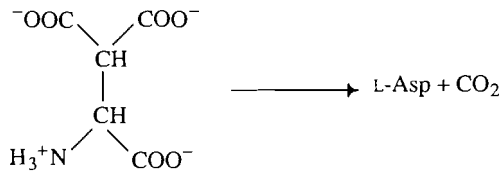
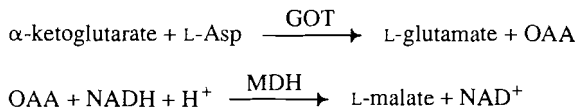
buffer solution, pH 7.6, containing 1 mg bovine serum albumin per mL.

The assay mixture was as follows: 0.1 mL 10^{-2} M α-ketoglutarate, 0.1 mL 1/10 diluted GOT, 0.1 mL 5/1000 diluted MDH, 0.1 mL 10^{-3} M NADH, 0.3 mL 0.1 M potassium phosphate buffer pH 7.6, 1.6 mL H_2O, 0.1 mL 10^{-2} M Asa, and 0.1 mL *E. coli* extract.

Results

The assay procedure is a doubly coupled one, with the first appearance of L-aspartic acid (L-Asp) being scavenged by the glutamate–oxalacetate transaminase (GOT) reaction, using a suitable excess of α-ketoglutarate and GOT. The oxalacetate (OAA) produced is coupled to the malate dehydrogenase (MDH) reaction. The disappearance of coenzyme NADH is followed spectrophotometrically at 340 nm, and is a direct measure of the rate-limiting decarboxylase step:





Evidence for enzymatic decarboxylation of Asa is shown in Fig. 1. When GOT is left out of the assay mixture no absorbance decrease is observed, suggesting the effective absence of any interfering levels of dehydrogenases. MDH is known to be highly specific for OAA, making the doubly coupled assay a true indicator of Asa decarboxylation. Boiling the *E. coli* extract for 5 min results in a total loss of enzyme activity. Further evidence of enzyme character (Fig. 2) is the progressive loss of activity due to repeated freezing and thawing of the extract.

Intrinsic gramicidin fluorescence lifetimes in bilayer lipid membranes and in vesicles

JOSE-MIGUEL CAMALEÑO-DELGADO, XIAO KANG ZHAO, AND JANOS H. FENDLER[1]

Département de chimie, Université de Montréal, C.P. 6128, succursale A, Montréal (Québec), Canada H3C 3J7

Received October 28, 1989

JOSE-MIGUEL CAMALEÑO-DELGADO, XIAO KANG ZHAO, and JANOS H. FENDLER. Can. J. Chem. **68**, 888 (1990).

Intrinsic Gramicidin A′ tryptophan steady-state fluorescence anisotropies and fluorescence lifetimes have been determined in bilayer lipid membranes (BLMs) prepared from glyceryl monooleate (GMO). In GMO BLMs, fluorescence anisotropy, the r value, was found to be 0.05 ± 0.02. Decays of Gramicidin A′ fluorescence intensities were fitted to the sum of three exponentials (τ_1, τ_2, and τ_3) and appropriate pre-exponentials (A_1, A_2, and A_3). These values allowed for the assessment of average fluorescence lifetimes, $\langle\tau\rangle$. These values related to those determined in vesicles prepared from dipalmitoylphosphatidylcholine (DPPC), dioleoylphosphatidylcholine (DOPC), distearoylphosphatidylcholine (DSPC), and diphytanoylphosphatidylcholine (DPhPC). In BLMs, $\langle\tau\rangle$ = 1.9 ns, 3.6 ns, and 2.3 ns were determined for vertically, horizontally, and unpolarized average fluorescence lifetimes, respectively. Increasing the applied potential across the BLM from 0 to 80 mV increased $\langle\tau\rangle$ from 2.2 ns to 4.9 ns and τ_1 from 0.43 ± 0.05 to 0.73 ± 0.06 ns, as well as the contributions and lifetimes of the longer lived fluorescence (A_2 and A_3, τ_2 and τ_3). The emission maximum of Gramicidin A′ (334 nm in DPPC) and the absence of quenching by iodide ions indicated complete incorporation of the polypeptide into vesicles. The r values were of the order of 0.10 in vesicles prepared from DPPC and DSPC, both in the absence and in the presence of added 1.2×10^{-4} M CsCl. In vesicles prepared from DOPC and DPhPC, r values increased to 0.13 and 0.14 in water and to 0.15 and 0.20 in 1.2×10^{-4} M CsCl, respectively. At 25.0°C, the temperature of the measurements, DPPC and DSPC are in their "solid" states, but DOPC and DPhPC are in their "liquid" states. $\langle\tau\rangle$ values for Gramicidin A′ in vesicles prepared from DPPC, DOPC, and DSPC were all in the 3.0 ± 0.3 ns range. In DPhPC vesicles, $\langle\tau\rangle$ = 2.2 ns was determined. Time-dependent anisotropies became observable in DOPC and DPhPC vesicles, particularly in the presence of 1.2×10^{-4} M CsCl.

Key words: gramicidin, fluorescence lifetimes, vesicles, bilayer lipid membranes, time-dependent anisotropies.

JOSE-MIGUEL CAMALEÑO-DELGADO, XIAO KANG ZHAO et JANOS H. FENDLER. Can. J. Chem. **68**, 888 (1990).

On a déterminé les anisotropies intrinsèques de fluorescence et les temps de vie de fluorescence de l'état stationnaire de la Gramicidine A′ et du tryptophane dans des membranes lipidiques en bicouches (MLB) préparées à partir de monooléate de glycéryle (MOG). On a trouvé que dans des MLB de MOG, l'anisotropie de fluorescence, la valeur r, est égale à 0,05 ± 0,02. On a ajusté les intensités de la dégénérescence de la fluorescence de la Gramicidine A′ avec la somme des trois exponentielles (τ_1, τ_2 et τ_3) et des pré-exponentielles appropriées (A_1, A_2 et A_3). On a utilisé ces valeurs pour évaluer les temps de vie moyens de la fluorescence $\langle\tau\rangle$. Il existe une corrélation entre ces valeurs et celles déterminées dans des vésicules préparées à partir de dipalmitoylphosphatidylcholine (DPPC), de dioléoylphosphatidylcholine (DOPC), de distéaroylphosphatidylcholine (DSPC) et de diphytanoylphosphatidylcholine (DPhPC). Dans les MLB, on a déterminé des valeurs de $\langle\tau\rangle$ de 1,9, 3,6 et 2,3 ns respectivement pour les temps de vie moyens verticaux, horizontaux ainsi que non polarisés. Une augmentation du potentiel appliqué sur les MLB de 0 à 80 mV provoque une augmentation de la valeur de $\langle\tau\rangle$ de 2,2 à 4,9 ns et de la valeur de τ_1 de 0,43 ± 0,05 à 0,73 ± 0,06 ns ainsi que des augmentations des contributions et des temps de vie de la fluorescence (A_2 et A_3, τ et τ_3). L'émission maximale de la Gramicidine A′ (334 nm dans le DPPC) ainsi que l'absence de piégeage par les ions iodures indique que le polypeptide est complètement incorporé dans les vésicules. Les valeurs de r sont de l'ordre de 0,10 dans les vésicules préparées à l'aide de DPPC et de DSPC soit en l'absence ou en présence de CsCl ajouté à la concentration de $1,2 \times 10^{-4}$ M. Dans les vésicules préparées à l'aide de DOPC et de DPhPC, les valeurs de r augmentent respectivement jusqu'à 0,13 et 0,14 dans l'eau et jusqu'à 0,15 et 0,20 dans une solution à $1,2 \times 10^{-4}$ M de CsCl. À 25,0°C, la température à laquelle les mesures ont été faites, les DPPC et DSPC sont dans leur état «solide» alors que les DOPC et DPhPC sont dans leur état liquide. Toutes les valeurs de $\langle\tau\rangle$ pour la Gramicidine A′ dans des vésicules préparées à l'aide de DPPC, de DOPC et de DSPC sont dans l'ordre de 3,0 ± 0,3 ns. Dans les vésicules de DPhPC, on a établi la valeur de $\langle\tau\rangle$ à 2,2 ns. Avec les vésicules de DOPC et de DPhPC, on a commencé à observer des anisotropies variant en fonction du temps, particulièrement en présence d'une solution à $1,2 \times 10^{-4}$ M de CsCl.

Mots clés : gramicidine, temps de vie de fluorescence, vésicules, membranes lipidiques en bicouches, anisotropies variant en fonction du temps.

[Traduit par la revue]

Introduction

The importance of transmembrane ion transport and the comparative simplicity of gramicidin have prompted extensive investigations of this channel-forming ionophore (1–4). The primary structure of Gramicidin A has been determined to be HCO-Val[1]-Gly[2]-Ala[3]-D-Leu[4]-Ala[5]-D-Val[6]-L-Val[7]-D-Val[8]-L-Trp[9]-D-Leu[10]-L-Trp[11]-D-Leu[12]-L-Trp[13]-D-Leu[14]-L-Trp[15]-$NHCH_2CH_2OH$ (5). The membrane channel, a left-handed, 26 Å long, β helix with 6.3 residues per turn, is formed from two gramicidins that are linked together at their amino terminals (6). This organization exposes the hydrophobic parts to the membrane while the carbonyl moieties of the peptide form an internal pore of about 4 Å diameter, which can accommodate monovalent cations. The four tryptophans, located close to the entry and exit ports of the channel, have been shown to play an essential role in ion transport (7–11).

Gramicidin conformation and association are dynamic and media-dependent (12, 13). In ethanol, several conformers coexist with the antiparallel β double helix dimer being predominant. In dimethyl sulfoxide, monomers prevail. In anhydrous lipids, X-ray crystallography established that gramicidin forms a cylindrical, intertwined, antiparallel double helix (14, 15). Introduction of gramicidin into phospholipid dispersion results not only in head-to-head (amino terminal to

amino terminal) dimer formation, but also in a concomitant reorganization of the bilayer structure (16, 17). The dynamics of this reorganization have been monitored by examining the deuterium magnetic resonance of gramicidin, deuterated in its tryptophan residues, in different phospholipid dispersions (18). In 1-palmitoyl-*sn*-glycero-3-phosphocholine/gramicidin = 4:1 dispersion, the peptide was found to be rigid in the fluid lipid over a large temperature range. Conversely, in 1,2-dioleoyl-*sn*-glycero-3-phosphocholine or 1,2-dimyristoyl-*sn*-glycero-3-phosphocholine dispersions, gramicidin was mobile above, but rigid below, the phase transition of the lipid (18). Clearly, different membrane models elicit different behavior in a less-than-straightforward way.

Similar conclusions were drawn from observing gramicidin tryptophan rotational amplitudes by phase modulation fluorometry in different phospholipid dispersions (19). To the best of our knowledge, there are only two additional reports on tryptophan fluorescence measurements on lipid-aggregate-incorporated gramicidin. Steady-state (20) and time-resolved (21) intrinsic gramicidin fluorescence were measured in lysolipid dispersions. The data obtained were fitted to three exponentials with decay times in the 6–8 ns, 1.8–3.0 ns, and 0.3–0.8 ns ranges (21). The low emission efficiency of tryptophan has to date precluded intrinsic fluorescence measurements of the tiny amounts of gramicidin present in a bilayer lipid membrane (BLM). Measurements of extrinsic dansyl fluorescence simultaneously with ion conductances have provided, of course, an early and crucial substantiation for dimeric (dansyl) gramicidin as the active channel in BLMs (22–24).

Our ability to observe intrinsic gramicidin fluorescence lifetimes in GMO BLMs is the most significant result of the present work. Fluorescence lifetime parameters have been shown to be substantially affected by the angle of observation and by the application of a potential across the BLM.

Intrinsic fluorescence lifetime parameters of gramicidin tryptophans have also been determined in unilamellar dipalmitoylphosphatidylcholine (DPPC), dioleoylphosphatidylcholine (DOPC), diphytanoylphosphatidylcholine (DPhPC), and distearoylphosphatidylcholine (DSPC) surfactant vesicles. Addition of KI or CsCl as quenchers did not affect the fluorescence lifetime parameters in vesicles at a constant gramicidin concentration. Steady-state and time-dependent gramicidin fluorescence anisotropies have also been determined in vesicles prepared from DPPC, DSPC, DOPC, and DPPC in the absence and in the presence of CsCl.

Materials and methods

Gramicidin A′ is a mixture of Gramicidin A/Gramicidin B/Gramicidin C = 80:5:15. These gramicidins are identical in all respects, with the exception that Trp^{11} in Gramicidin A (see structure in the Introduction) is replaced by Tyr^{11} or Phe^{11} in Gramicidin B or Gramicidin C, respectively (22–25). Some measurements were carried out on authentic Gramicidin A. Emission spectra and lifetimes (see Tables 4 and 5) determined on this sample were identical, within the experimental error, with those obtained on the commercial sample. DPPC (Sigma), DOPC (Sigma), DPhPC (Sigma), DSPC (Sigma), GMO (Nucheck), NaOH, and HCl (Baker analyzed reagents) were used as received. No fluorescences of the solvents were detected by single photon counting. Decane, chloroform, or ethanol (Aldrich spectroscopic grade) were used, therefore, as received. Water was purified with a Millipore Milli-Q system provided with a 0.4 μm Millistack filter at the outlet.

Vesicles were prepared by dispersing the appropriate lipid (0.5–5.0 mg/mL) in water, or in aqueous 10 mM Tris HCl buffer at pH 7.5, by sonication for 15 min at 70°C using the microtip of a Braunsonic 1510 sonicator. Ethanolic solutions of Gramicidin A′ were added to vesicles to yield the appropriate gramicidin/lipid ratios. Gramicidin-containing vesicles were incubated at 70°C for 9 h prior to the removal of titanium particles by centrifugation (26). These preparations gave predominantly unilamellar unidispersed vesicles of 600–800 Å in diameter (27).

BLMs were formed on a Teflon pinhole separating two aqueous, electrically isolated compartments. A thin (100–150 μm) Teflon film containing a 0.10 cm diameter hole was sandwiched between two triangular pathlength quartz cells by silicon rubber adhesive. The hypotenuse faces of the two cells, in contact with the Teflon film, contained 0.6 cm × 1.5 cm windows through which the 0.1 cm diameter hole and some surrounding area of the Teflon film remained exposed. The cells were filled with 4 mL of water or 2 M KCl solutions at ambient temperature. The BLMs were made by brushing a small amount of the BLM-forming solution (4×10^{-4} M Gramicidin A′ in hexadecane) on the 0.1 cm diameter hole. Thinning of the initially formed thick film to a black bilayer lipid membrane was monitored by observing the reflected light from a 200-W mercury–xenon lamp through a microscope and by capacitance measurements (28, 29). The accuracy of capacitance measurements was found to be within 1.0%. GMO BLMs typically lasted for 4–6 h, after which time they broke. This lack of long-term stability did not allow extensive gramicidin incubation into the BLMs. Electrical measurements indicated, however, the presence of well-functioning channels prior to commencing the fluorescence lifetime measurements. Fluorescence measurements were limited to the bilayer (i.e., excluding the Plateau–Gibbs borders) by focusing the laser to a 0.05 cm diameter spot in the middle of the BLM.

Excitation of gramicidin at 280 nm has been shown to result in channel inactivation (30–32). Conductance measurements subsequent to the accumulation of lifetime data indicated conductances identical to those measured prior to fluorescence measurements. Under our experimental conditions (294 nm excitation by nanojoule/pulse laser energies), therefore, gramicidin does not suffer appreciable photodamage.

Absorption spectra were taken on a Hewlett–Packard 8450 diode-array spectrophotometer.

Fluorescence lifetimes were determined on a time-correlated, single-photon counting system, which uses a synchronously pumped, cavity-dumped, Rhodamine 6G dye laser (Spectra-Physics 375) pumped by a mode-locked argon ion laser (Spectra-Physics 2020) as an excitation source. Vertical polarization of the excitation is assured by a Glan air space prism. The laser beam is attenuated by suitable neutral density filters to ensure that the fluorescence count rate is always less than 1% of the cavity-dumper frequency (generally 819 kHz). For ultraviolet operation, the dye laser beam is frequency doubled by using a temperature-tuned, ammonium dihydrogen arsenate crystal (Inrad) and is rotated to vertical polarization by a Babinet–Soliel compensator (Karl Lambrecht). Single fluorescence photons are detected by a Hamamatsu 1564 microchannel plate photomultiplier tube (MCPPMT). The quartz collection optics are matched to those of the 0.25-m Jarrel–Ash monochromator that is used for wavelength resolution. The output of the MCPPMT is amplified by a Hewlett–Packard 8447 F preamplifier power amplifier and conditioned by one of the four channels of a Tennelec TC 455 quad constant fraction discriminator (CFD) whose output serves as the start signal for an Ortec 457 biased, time-to-pulse-height converter (TAC). The stop signal comes from a TIED 56 photodiode, which monitors the output of the dye laser and is conditioned by another section of the CFD. This signal is delayed (Ortec 425) such that the signal appears on the screen of a Tracor Northern 7200/4NP multichannel analyzer. The 1024-point histogram is accumulated to at least 10 000 counts at its maximum and is transferred to a Zenith ZW118 microcomputer, which is equipped with 768K memory and an 8087 coprocessor. The time per channel of the TAC–MCA combination was calibrated by slightly detuning the cavity dumper to allow two consecutive pulses to be dumped. The known spacing between the pulses was used as the time standard for ranges where both pulses appear on the MCA screen. For the shorter time ranges, a previously measured length of cable was inserted and used

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

as the standard. The instrument response function of the system, measured by using a dilute scattering solution (either non-dairy coffee creamer or Ludox), was found to be 130 ps full-width at half-maximum and 250 ps full-width at tenth-maximum and is independent of wavelength. The decays were analyzed in terms of sums of exponentials:

$$[1] \quad I(t) = \sum_i A_i e^{-t/\tau_i}$$

where τ_i's are the fluorescence lifetimes and A_i's measure the contribution of the different lifetimes to the total fluorescence decay. The fluorescence parameters were determined from

$$[2] \quad S(t) = I(t)_r I(t) = \int_0^t I_r(t')I(t - t')dt$$

where $S(t)$ is the convolution of the fluorescence due to the sample measured, $I(t)$, and the instrument response, $I_r(t)$. Decays were analyzed by a reiterative, nonlinear least-squares routine using the Marquardt algorithm (33). In this procedure, the weighted sum of squared residuals, WSSR, is minimized according to

$$[3] \quad \text{WSSR} = \sum_{k=1}^{n} w_k[S(t_k) - S_c(t_k)]^2$$

where $S_c(t)$ is the calculated fit of $S(t)$, w_k is the weight factor of the data points $S(t_k)$, and n is the total number of data points. Goodness of an individual fit was judged by the magnitude of the reduced χ^2 and the randomness of the weighted residuals. Each method also employs a time-shift parameter that is minimized in the fitting routines. In our case, this time-shift parameter arises from the long-term stability of the electronics rather than from any wavelength dependence of the detector. This small but measurable shift is rarely greater than 30 ps and seems to arise from small, ambient temperature changes. We do not correct for background signal (dark noise) since it never exceeds 5×10^{-4} counts per second per channel. The procedure involves the measurement of the instrument response function by detection of the excitation pulse scattered from a dilute colloidal solution. One then measures the fluorescent intensity of the sample at the selected wavelength and polarization(s). Next one calculates the intensity on the basis of the instrument response function and an assumed photophysical model using initial parameter guesses. The weighted square differences between the experimental and calculated intensities are minimized with respect to the parameters until convergence is attained. Any combination of the parameters may be held constant while the others vary, though most often all parameters are allowed to vary freely. Lack of any instrumental artifact was demonstrated by reproducing the published fluorescence lifetimes of *N*-acetyltryptophan in water (2.82 ± 0.04 ns) using a single exponential decay function (34).

Steady-state fluorescence anisotropies were determined by integrating the total emission intensities recorded on the MCA by sequentially placing HNB polaroid polarizers (Polaroid Corporation, Cambridge, Massachusetts) vertically and horizontally into the emission signal generated in the excitation of the samples by vertically polarized laser pulses (*vide supra*). The steady-state anisotropy, r, of the fluorescence signal was measured at 340 nm as

$$[4] \quad r = \frac{I_{VV} - GI_{VH}}{I_{VV} + 2GI_{VH}}$$

where I_{VV} and I_{VH} are the vertical (parallel to vertical excitation, 90°) and horizontal (vertical to vertical excitation, 0°) components of the emitted light when excited by vertically polarized light. The factor G corrects for emission monochromator polarization effects and is equal to I_{HH}/I_{HV} (where I_{HH} and I_{HV} are the horizontal and vertical components of emission from horizontally polarized exciting light). The value of G at 340 nm was determined to be 0.80. Correction for light scattering by the vesicles was made by subtracting the emission signal due to vesicles that did not contain gramicidin. This correction was found to be negligible.

BLM resistances and capacitances were measured by an RLC Digibridge (model 1689 M, Genrad).

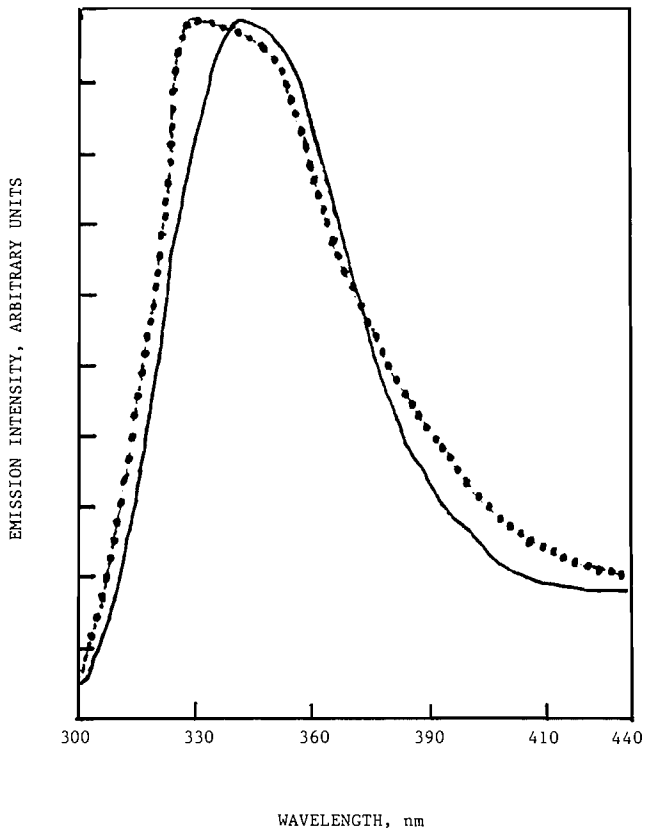

FIG. 1. Normalized emission spectra of Gramicidin A′ in DPPC vesicles (solid line) and in GMO BLMs (dotted line). λ_{ex} = 294 nm. Spectra were taken by the time-correlated single-photon counting system using the MCA to record emission intensities at different wavelengths.

Results and discussion

Gramicidin A′ in bilayer lipid membranes

Intrinsic gramicidin fluorescence spectra, anisotropy, and lifetimes have been determined in a 50 Å thick BLM in the present work. Introduction of Gramicidin A′ into the BLM-forming solution ensures its incorporation into the bilayer in the form of functioning channels. The observed emission spectra of Gramicidin A′ in GMO BLMs (Fig. 1), as well as conductivity measurements, substantiate this interpretation. It should be pointed out, however, that the GMO BLM is fluid (T_{PT} = 16°C) at the temperature of the measurements. GMO, hexadecane, and gramicidin molecules are distributed between the bilayer and the surrounding Plateau–Gibbs border, which serves as a reservoir. While thermodynamically the fluidity should favor dimeric channel formation, this process is kinetically controlled. Under the experimental conditions, a considerably greater number of dimeric channels are likely to prevail in vesicles than in BLMs.

Gramicidin A′ steady-state fluorescence anisotropy, the r value, in GMO BLMs (0.050 ± 0.02; Table 1) is somewhat higher than that in alcohols (ca. 0.03), indicating the decreased rotational freedom of the tryptophan moieties in the bilayers. Tryptophans at the 9th, 11th, 13th, and 15th positions in gramicidin are located at the outside turns of the left-hand helices and are thus exposed to relatively hydrophobic environments (35). The r values for Gramicidin A′ in DPPC and DSPC vesicles (ca. 0.1, Table 1) are similar to those reported for lysolecithin dispersions (0.1; ref. 20) and are unaffected by

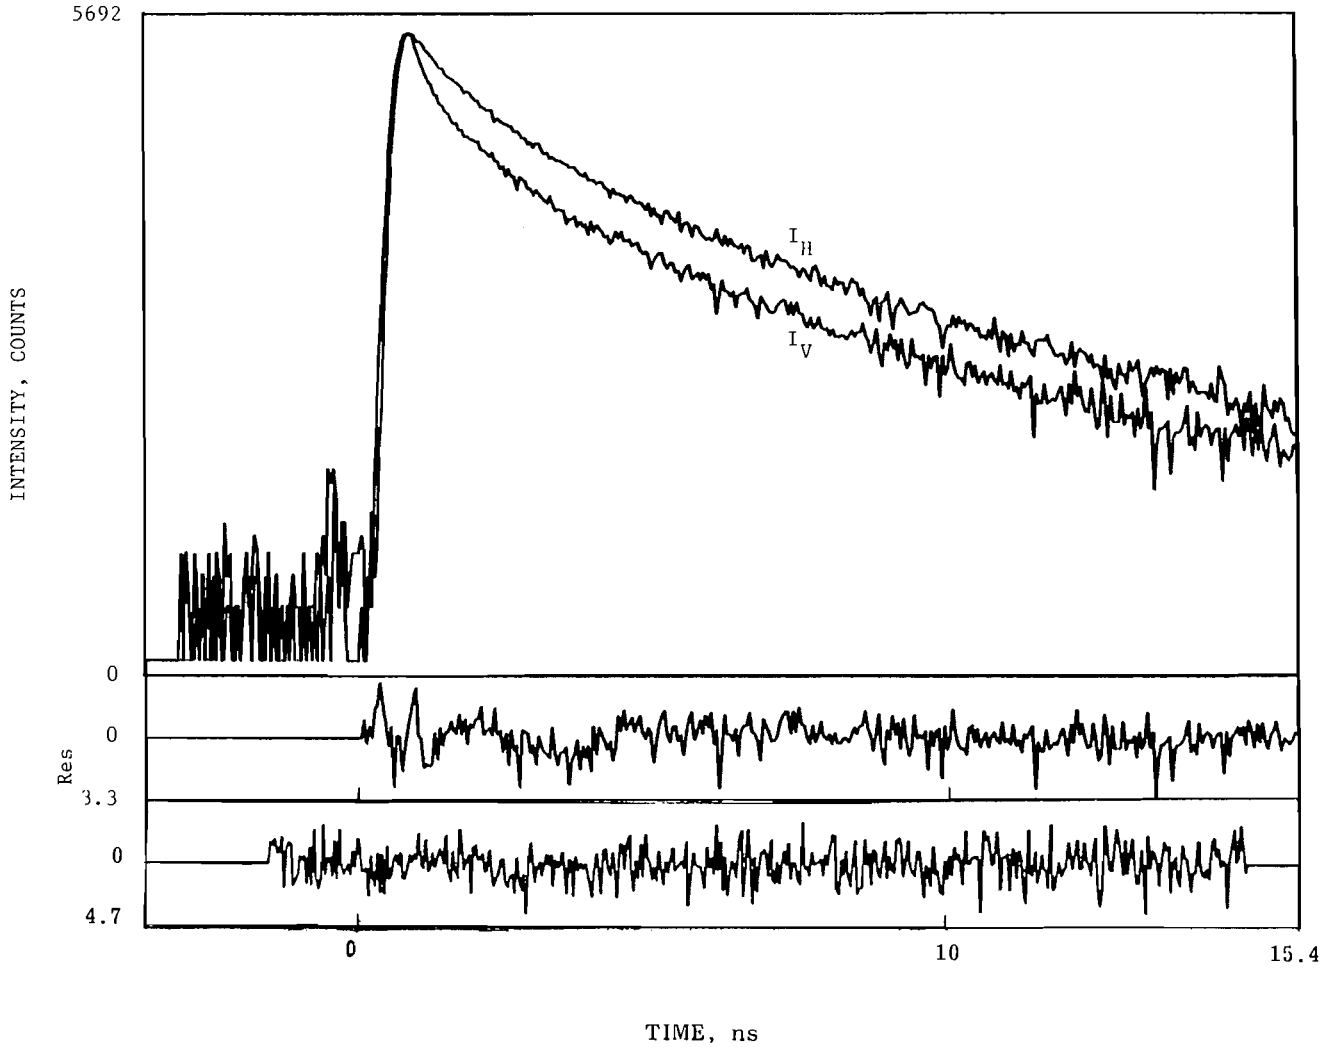

FIG. 2. Fluorescence decay of Gramicidin A′ in GMO BLMs. GMO BLMs were prepared by brushing a hexadecane solution of Gramicidin A′ across the Teflon pinhole separating the two compartments. Gramicidin A′/lipid ratios were kept at 1:50. λ_{ex} = 294 nm (vertically polarized), λ_{em} = 340 nm. V = vertical (90°) and H = horizontal (0°) observation of the emission. The solid lines are the best fits of the experimental data fitted to three exponential decays. Weighted sums of squared residuals are below the curves.

TABLE 1. Steady-state fluorescence polarization of Gramicidin A′ in vesicles and BLMS[a]

Vesicle	Solvent	T_{PT}, °C	Anisotropy, r^b
GMO BLM	2.0 M KCl	16	0.050±0.02
DPPC	H_2O	41	0.109±0.012
DPPC	1.2×10^{-4} M CsCl		0.097±0.015
DPPC[c]	H_2O		0.118±0.010
DPPC	1.2×10^{-4} M CsCl		0.107±0.012
DSPC	H_2O	55	0.094±0.005
DSPC	1.2×10^{-4} M CsCl		0.089±0.02
DOPC	H_2O	−22	0.132±0.09
DOPC	1.2×10^{-4} M CsCl		0.153±0.03
DPhPC	H_2O	<15	0.140±0.08
DPhPC	1.2×10^{-4} M CsCl		0.199±0.05

[a]All r values were measured at 25°C and represent the mean of four determinations, with the exception of GMO BLMs. Vesicles were prepared by sonication (0.5 mg lipid/1.0 mL H_2O). Gramicidin A′/lipid ratios were kept at 1:50, unless stated otherwise. λ_{ex} = 294 nm, λ_{em} = 340 nm.
[b]See eq. [4] and Materials and methods for details.
[c]Gramicidin A′/lipid = 1:1000.

the addition of 1.2×10^{-4} M CsCl (Table 1). Gramicidin fluorescence anisotropy in GMO BLMs was found to be considerably smaller than that in vesicles (Table 1). Although GMO is fluid at the temperature of the experiment, insufficient incubation precluded extensive dimer formation. Apparently, it is the hindered rotation of dimeric channels rather than the tryptophan moieties that determines gramicidin anisotropies.

Typical Gramicidin A′ intensity decays in GMO BLMs, observed at 0° and 90°, are shown in Fig. 2. Attempts to fit the intensity to one and two exponential decays gave poor results (long time convergence of the iterations, $\chi^2 > 3$, and non-random fits of the residuals). Good fits were obtained, however, in terms of three exponential decays. Sums of the three exponentials provide, of course, a better fit for intensity decays than the simpler one or two exponentials. This has been observed for tryptophan decays in proteins (36, 37). The three exponential fluorescence decays of gramicidin in lysolecithin dispersions have been attributed to three different sets of tryptophans in the polypeptide ionophore (21). The short (ca. 0.3 ns) lifetime component was suggested to originate in

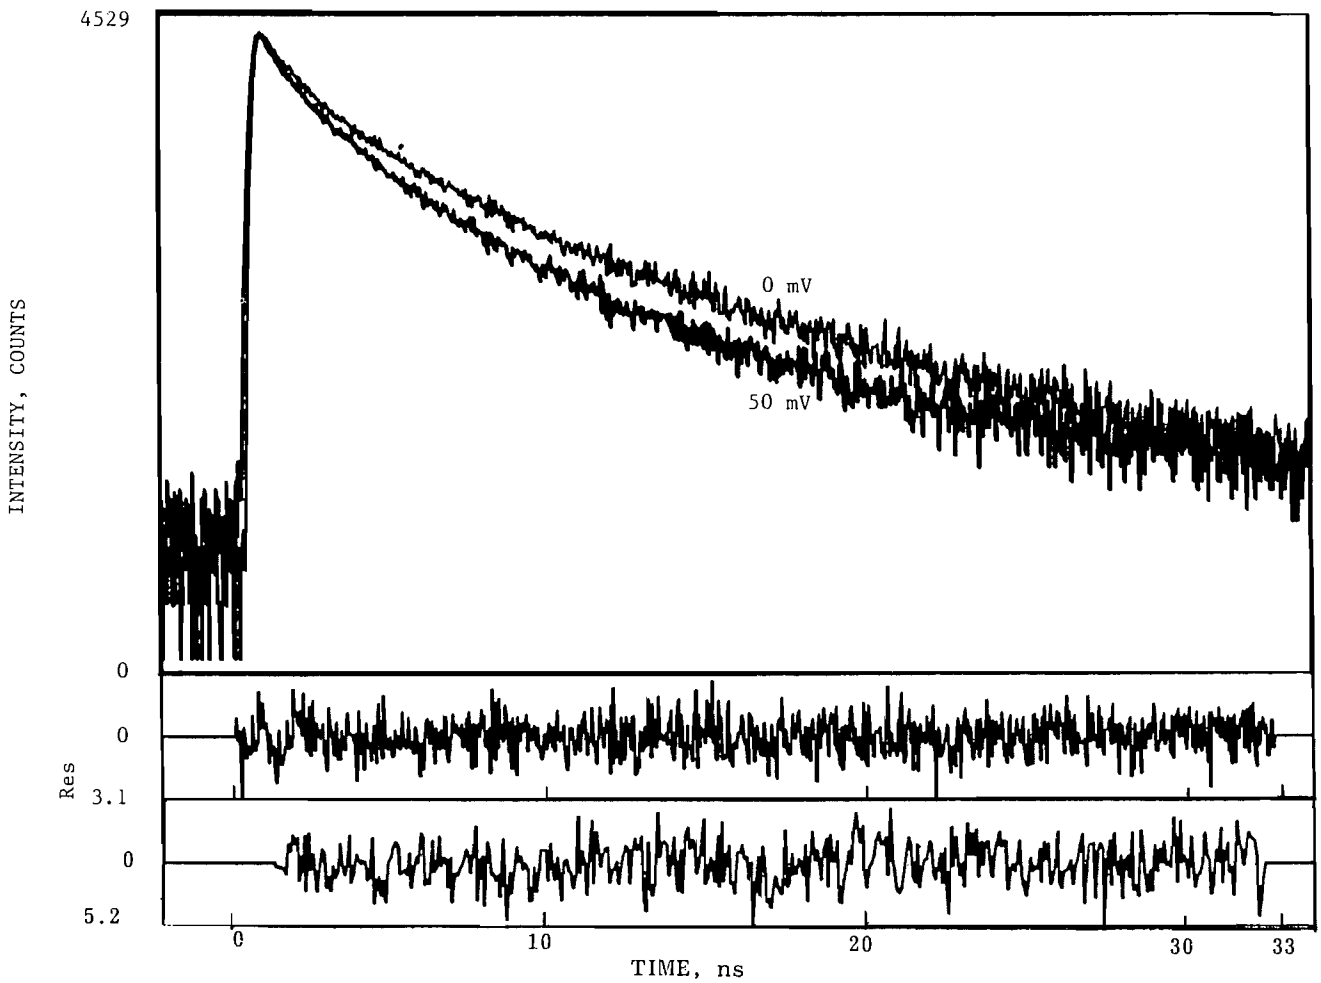

FIG. 3. Fluorescence decay of Gramicidin A′ in GMO BLMs in the absence and in the presence of 50-mV transmembrane potential. GMO BLMs were prepared by brushing a hexadecane solution of Gramicidin A′ across the Teflon pinhole separating the two compartments. Gramicidin A′/lipid ratios were kept at 1:50. λ_{ex} = 294 nm (vertically polarized), λ_{em} = 340 nm (no polarizer). The solid lines are the best fits of the experimental data fitted to three exponential decays. Weighted sums of squared residuals are below the curves.

exciton interactions between the indole groups in neighboring tryptophan moieties, 9 and 15. The long (6–8 ns) lifetime component was ascribed to tryptophans that are "deeply buried" in the bilayer, 11 and 13, while the medium lifetime was attributed to tryptophans that are located close to the membrane surface, 13 and 15. Although appealing, these assignments are likely to be gross oversimplifications since the A values determined in the present work in a variety of different vesicles do not correspond to the ratios of the different tryptophans in gramicidin. Different fluorescence decay components could also be ascribed to different gramicidins (monomers, dimers, and higher aggregates), different conformations of gramicidin channels, or indeed to different conformation states of the tryptophan. Even though no unambiguous assignment can be given to the three-component gramicidin decays, fluorescence lifetimes of the different systems can be fruitfully compared. The determined gramicidin fluorescence lifetimes (τ_1, τ_2, and τ_3 values), mean lifetimes ($\langle\tau\rangle$ values), pre-exponentials (A_1,

[a]Decay parameters were measured at 25°C and represent the means of five (DPPC and DOPC) and four (DSPC and DPhPC) determinations. Vesicles were prepared by sonication (0.5 mg/1.0 mL H_2O). Gramicidin A′/lipid ratios were kept at 1:50. λ_{ex} = 294 nm, λ_{em} = 340 nm. Fluorescence intensities were observed at the magic angle (54.9°).
[b]Average lifetimes were calculated as $\langle\tau\rangle = \sum_i A_i\tau_i^2/\sum_i A_i\tau_i$.
[c]Using an authentic Gramicidin A sample.
[d]Data interpolated for the published (21) figure to 24 h incubation time and λ_{em} = 340 nm. LL = lysolecithin dispersion.
[e]Taken from ref. 19. DMPC = dimyristoylphosphatidylcholine. EggPC = egg phosphatidylcholine.

A_2, and A_3 values), and χ^2 in GMO BLMs are collected in Table 2. There are marked differences between the behavior of the ionophore in BLMs and vesicles. Thus, the average Gramicidin A′ fluorescence lifetimes (determined without polarizers) in GMO BLMs (ca. 2.0 ns) are shorter than those found in vesicles (ca. 3.0 ns, Table 4). There are more pronounced differences in A and τ values. In particular, A_1 values are greater and A_3 values are smaller in BLMs than in vesicles. Differences between GMO and the lipids used for vesicle preparations, as well as the presence of hexadecane molecules and the Plateau–Gibbs border in the BLM, are responsible for the observed fluorescences in these two matrices. The complexity of the system does not warrant, however, more detailed interpretation. Pronounced differences between horizontal and vertical Gramicidin A′ fluorescence decays in GMO BLMs (Fig. 2 and Table 2) underscore the disparate behavior of the two bilayer systems. The average lifetime of the vertically observed Gramicidin A′ fluorescence (1.9 ns) is shorter than that observed horizontally (3.6 ns), while the $\langle\tau\rangle$ value in the absence of polarization (i.e., at magic angle) falls between these two extremes (2.3 ns). The A_3 value is markedly higher and the A_1 value is somewhat smaller for horizontally than for vertically observed Gramicidin A′ fluorescence in GMO BLMs.

Effects of potential applied across GMO BLMs on the fluorescence decay are illustrated in Fig. 3 and the data are collected in Table 3. Increasing the applied potential increased the average Gramicidin A′ fluorescence lifetimes (τ_1, τ_2, and τ_3) and the contributions of the longer lived fluorescences (A_2 and A_3) at the expense of the short component (A_1). This paralleled the observed increase of conductance with increasing transmembrane potential. The significant increase of τ_1 with increasing transmembrane potential (from 0.43 ns at 0 mV to 0.74 ns at 80 mV applied potential, Table 3) suggests the increased importance of stacking interaction. Increasing the transmembrane potential is likely to decrease the thickness of the solvent therein. This, in turn, may lead to increased gramicidin dimerization. Increasing the gramicidin dimer population results in decreased mobilities and, hence, in increased fluorescence lifetimes. It is interesting to note that applying a transmembrane potential across the GMO BLM has the same effect as changing the angle of observation of gramicidin fluorescence from 0° to 90°.

Gramicidin A′ in vesicles

Steady-state emission spectra, fluorescence quenching, and anisotropy measurements have been used to establish the incorporation of Gramicidin A′ into vesicles prepared from DPPC, DSPC, DOPC, and DPhPC. Addition of iodide ions in Gramicidin A′-containing vesicle solutions did not result in fluorescence quenching. Since iodide ions cannot penetrate into bilayers, their inability to quench gramicidin fluorescence has been taken as evidence for the incorporation of this polypeptide into the vesicle matrix (19). The shift of the gramicidin emission maximum to a wavelength shorter than 340 nm was used as an additional criterion for gramicidin incorporation into apolar medium of vesicles (21). Fluorescence spectra of Gramicidin A′ in all vesicles used in the present work had emission maxima

[a]Decay parameters were measured at 25°C. Vesicles were prepared by sonication (0.5 mg lipid/1.0 mL H_2O). Gramicidin A′/lipid ratios were kept at 1:50. λ_{ex} = 294 nm, λ_{em} = 340 nm.
[b]V = vertical (90°) and H = horizontal (0°).
[c]Average lifetimes were calculated as $\langle\tau\rangle = \sum_i A_i\tau_i^2/\sum_i A_i\tau_i$.

below 340 nm. As an example, the emission spectrum of Gramicidin A′ in DPPC vesicles is shown in Fig. 1.

Gramicidin A′ steady-state fluorescence anisotropy, r values, in DPPC, DSPC, DOPC, and DPhPC vesicles in the absence and in the presence of added 1.2×10^{-4} M CsCl are collected in Table 1. Rotation of the tryptophans in DPPC was not affected by diluting the gramicidin. The r values, within the experimental error, remained the same for 1:50 and 1:1000 gramicidin/lipid ratios. These ratios correspond to having 25 and 1 gramicidin channels per vesicle, respectively. Phase transition temperatures of DPPC and DSPC (Table 1) are higher than the temperature of fluorescence measurements (25°C). Thus, Gramicidin A′ is spanning "solid" phases of vesicles prepared from DPPC and DSPC and the presence of ions in the channels is unlikely to influence the mobility of tryptophans. Since DOPC and DPhPC have low temperature phase transitions (Table 1), gramicidin anisotropies were determined in the fluid phases of vesicles prepared from these lipids. Addition of CsCl resulted in marked increases in the anisotropy and, hence, in appreciable decreases in tryptophan mobilities. This is attributed to shifting the gramicidin monomer ↔ gramicidin dimer equilibrium in favor of the latter (38, 39).

Typical Gramicidin A′ intensity decays, observed at 0° and 90°, in the absence and in the presence of added 1.2×10^{-4} M CsCl in vesicles prepared from DPPC, DSPC, DOPC, and DPhPC are shown in Fig. 4. Fluorescence decay components were not influenced by the sample used (Gramicidin A′, which is a mixture of Gramicidin A/Gramicidin B/Gramicidin C = 80:5:15) since identical lifetimes were obtained on using an authentic sample of Gramicidin A (see Tables 4 and 5).

Values of $\langle\tau\rangle$ for Gramicidin A′ in vesicles prepared from DPPC, DOPC, and DSPC are all in the 3.0 ± 0.3 ns range (Table 4). The average gramicidin fluorescence lifetimes in vesicles prepared from DOPC (2.5 ns), DMPC (3.5 ns), and EggPC (2.4 ns) reported previously by Scarlata (19) agree with values obtained in DPPC, DOPC, and DSPC vesicles in the present work (Table 4). Gramicidin in lysolecithin dispersions has a similar $\langle\tau\rangle$ value (3.4 ns; ref. 21). There is a notable deviation: the average gramicidin fluorescence lifetime in DPhPC vesicles is much shorter ($\langle\tau\rangle$ = 2.2 ns) than those determined in other vesicles in the present work (Table 4). Decrease in the average gramicidin fluorescence lifetime cannot be ascribed to the fluidity of DPhPC since DOPC is also fluid, but DPPC and DSPC are solid at the temperature of the experiments.

Conclusion

Advantage has been taken, in the present work, of intrinsic gramicidin fluorescence to obtain information on the behavior of this ionophore in GMO BLMs and vesicles. Although the emission spectrum of gramicidin in GMO BLMs was quite similar to that in vesicles, considerable differences were found in steady-state anisotropies and fluorescence lifetime parameters. In general, in BLMs, gramicidin anisotropy values were lower and fluorescence lifetimes were shorter than those in vesicles. The necessity of treating fluorescence lifetimes in terms of three exponential decays did not allow unambiguous assignments or warrant undue mechanistic interpretation. Nevertheless, the observed increase in the average gramicidin fluorescence lifetimes, paralleling the increased contribution of

the longer lived components with increasing applied potential across the GMO BLM, is highly significant and is likely to be the consequence of increased gramicidin dimerization.

Acknowledgments

Support of this work by a grant from the Natural Sciences and Engineering Research Council (NSERC) is gratefully acknowledged. We also express our sincere appreciation to Dr. Ranieri Rolandi for providing an authentic Gramicidin A sample.

YVAN GUINDON, YVES GIRARD, SYLVIE BERTHIAUME, VIDA GORYS, RENÉ LEMIEUX, and CHRISTIANE YOAKIM. Can. J. Chem. **68**, 897 (1990).

Dimethylboron bromide or diphenylboron bromide can be used in combination with borane to achieve the regiocontrolled conversion of benzylidene acetals to their corresponding hydroxy benzyl ethers with moderate to high yields.

Key words: dimethylboron bromide, diphenylboron bromide, reductive opening, benzylidene, acetals.

YVAN GUINDON, YVES GIRARD, SYLVIE BERTHIAUME, VIDA GORYS, RENÉ LEMIEUX et CHRISTIANE YOAKIM. Can. J. Chem. **68**, 897 (1990).

Le bromure de diméthylbore ou le bromure de diphénylbore peuvent être utilisés en présence de complexe borane–THF pour transformer de façon régiosélective un acétal de type benzylidène en un dérivé diol mono benzylé avec de bons à excellents rendements.

Mots clés : bromure de diméthylbore, bromure de diphénylbore, ouverture réductive, benzylidène, acétals.

Introduction

We have recently included benzylidene acetals in an ongoing study to better understand the reactivity and chemoselectivity (1) of dialkyl and diaryl boron halides. Moreover, during the course of this work, it was found that the application of these boron reagents to benzylidene acetals incorporating 1,3-dioxolane or 1,3-dioxane systems (2) offers, after a two-step sequence, a means of selective protection of the secondary hydroxyl in the presence of a primary hydroxyl group in 1,2- and 1,3-diol systems. This two-step sequence would involve initial protection of the primary and secondary hydroxyls as a benzylidene acetal, followed by Lewis acid induced reductive cleavage of the acetal to give the protected secondary alcohol.

The rearrangement of benzylidene acetals has been well documented. For instance, Hanessian and Pleassas (3), as well as Hullar and Siskin (4), have independently reported the cleavage of *O*-benzylidene protected sugars with *N*-bromosuccinimide (NBS) to afford the corresponding bromo benzoates. A modification of this reaction employing NBS and photochemical initiation was used by Binkley *et al.* (5) to give the corresponding hydroxy benzoates, which can also be produced via oxidative cleavage of benzylidene acetals with ozone (6).

Reductive ring cleavage of benzylidene acetals can be achieved using different reducing reagents under acidic conditions. For example, reagents such as sodium cyanoborohydride combined with acetic acid or trifluoroacetic acid (7), lithium aluminum hydride with aluminum chloride (8) or diisobutylaluminum hydride (9), and sodium cyanoborohydride with hydrogen chloride (10) have been utilized. Although some of these reactions have proven useful, those that employ strong reducing agents are restricted in their use, particularly in the presence of sensitive functionalities. Moreover, in some cases, protection of the less substituted alcohol occurs preferentially when an unsymmetrical benzylidene acetal is cleaved (10).

We would like to report herein the tandem use of dimethyl (or diphenyl) boron bromide and borane for the regiocontrolled conversion of benzylidene acetals to their corresponding hydroxy benzyl ethers. The scope and limitations of this method will also be discussed.

SCHEME 1

Results and discussion

Reactivity of benzylidene acetals to Me_2BBr

Our preliminary work showed that various acetals and ketals react with dimethylboron bromide at −78°C to afford within 1 h the corresponding α-bromo ethers, which serve as useful intermediates for the synthesis of thioglycosides, cyanomethyl ethers, and hemithioacetals (11). Under these conditions, for example, the acetonide **1** (Scheme 1) afforded the diol **2** in 86% yield. However, treatment of the benzylidene acetal **3** under similar conditions gave only starting material. The apparent lack of reactivity of the benzylidene acetal in the latter case was rather surprising in light of our previous results. It was possible that the benzylidene acetal had indeed reacted with Me_2BBr to give the intermediate bromo ether **4**, which subsequently recyclized to give the starting material **3** after hydrolysis of the borinate ester and intramolecular displacement of bromide. To test this hypothesis, a nucleophile was added after treatment with Me_2BBr in an attempt to trap the presumed ring-opened intermediate. Indeed treatment of **3** at −78°C with Me_2BBr followed by the addition of 3 equivalents of thiophenol in the presence of triethylamine gave the corresponding hydroxy *O*,*S*-acetal **5** in 85% yield.

The reaction of a number of polyfunctional benzylidene acetals incorporating substituted 1,3-dioxolane or 1,3-dioxane systems illustrates the scope of this process. As shown in

4	**6**	BH_3•THF[e]	**8**	96
5	 **9**	PhSH[c]	 **10**	92
6	**9**	BH_3•THF[e]	 **11**	75
7	 **12**	PhSH[c]	 **13**	70
8	**12**	BH_3•THF[e]	 **14**	91

[a] *All reactions were carried out at a concentration of 0.2M in CH_2Cl_2 using 0.1 equiv of Et_3N and 2.2 equiv of Me_2BBr at -78°C for 45 min.*

[b] *Yields of isolated products.*

[c] *PhSH (3.0 equiv) and Et_3N (3.5 equiv) were added and the reaction mixture was stirred at -78°C for 1 h.*

[d] *DIBAL or Super Hydride (2.0 equiv) was added and the reaction mixture was stirred at -78°C for 1 h.*

[e] *BH_3•THF (2.0 equiv) was added at -78°C and the reaction mixture was warmed to -20°C for 1 h.*

Table 1, both five- and six-membered analogs were converted to the corresponding monoprotectd diols in excellent yields. Notably, methyl ethers **6** and **12** and methyl ester **9** are stable under the reaction conditions. To generate a monobenzylated diol as the product of benzylidene ring cleavage, a hydride source was used as the nucleophile. Both Super-Hydride (entry 2) and diisobutylaluminum hydride (entry 3) were found to react rapidly with the intermediate arising from **6** at −78°C to give **8** in good yields. Borane–tetrahydrofuran (BH_3·THF) complex reacted cleanly (entries 4, 6, 8), although it was necessary to warm the reaction mixture to −20°C. The advantage of these latter conditions is the chemoselective conversion of a benzylidene acetal to a monobenzylated diol in the presence of an ester.

Reductive cleavage of unsymmetrical benzylidene acetals

To investigate the regioselectivity of the reductive cleavage of benzylidene acetals upon reaction with Me_2BBr/borane,

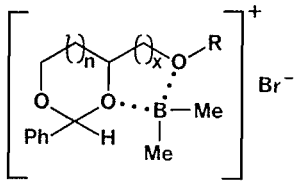
unsymmetrically substituted acetals were used. As shown in Table 2, it is possible to generate predominately the primary alcohol **A** rather than the secondary alcohol **B**. This regioselectivity is attributed to the preferential complexation of the less hindered oxygen with the boron reagent, followed by reductive ring cleavage to give the secondary alcohol protected as a benzyl ether. It is noteworthy that greater regioselectivity for the primary alcohol **A** is observed for the *trans*-disubstituted dioxolane (entry 1) than for the corresponding *cis*-disubstituted dioxolane (entry 2). For the *trans* isomer the complexation of the boron reagent to the oxygen corresponding to the secondary alcohol would be less favoured owing to the steric congestion of a substituent on both α and β faces.

Such regioselectivity might also be enhanced by the use of bulkier ligands on the boron reagent. Indeed, this hypothesis was confirmed by the use of diphenylboron bromide, which exhibited a greater preference for the formation of **A** over **B** (entries 3 and 6 compared with 2 and 5, respectively).

The regioselectivity may be altered by the presence of neighboring functionalities capable of coordinating with the boron halide, a similar effect observed in the boron bromide mediated ring opening of tetrahydrofuran systems (1*b*). For example, in the presence of a methyl ether (as in **17**) proximal to the reactive acetal it is possible to form a bidentate complex (see Scheme 2),[3] which would favor the formation of the secondary alcohol **B** more than the analogous systems in which functionalities capable of chelation are absent. Poorer regioselectivity was observed in those examples (entries 4 and 5) where anchimeric participation competes with steric factors.

[3]As suggested by one referee, complexation of the borane to the exocyclic methoxy group could explain the loss in regiocontrol based on the principal of least chemical distance argument (i.e., monodentate vs. bidentate explanation). It is reasonable to suggest, based on our previous results, that an ester could replace the ether functionality as a coordinating species (1*b*).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.



SCHEME 2

Such bidentate complexation is destabilized by the use of the bulkier diphenylboron bromide reagent, thus improving selectivity for **A**, as illustrated by the comparison between entries 5 and 6.

Although more complex, the 1,3-dioxane benzylidene acetal derivatives of methyl pyranosides (see Table 3), upon treatment with boron bromides, were found to rearrange in the same fashion as the simpler acetal system described above. That is, complexation of the boron bromide reagent with the least hindered oxygen of the acetal is followed by ring cleavage and formation of the putative acyclic bromo acetal intermediate, which is subsequently trapped in excellent yields with nucleophiles such as thiolate (entry 1). The results obtained for the simpler unsymmetrical benzylidene acetals (as above) would lead one to predict that the regioselectivity arising from the coordination of the boron bromide to the *O*-6 of the pyranoside would increase as bulkier boron reagents are used (i.e., dimethylboron bromide < diphenylboron bromide = 9-borobicyclo[3.3.1]nonanyl bromide (9-BBN-Br)). Indeed, when dimethylboron bromide was reacted with **19** (entry 1) and the reaction was quenched with thiophenol, the primary alcohol **20** was obtained as the major isomer in a 4:1 ratio. In contrast, the use of the bulkier diphenylboron and 9-BBN bromides (entries 2 and 3, respectively) gave **20** as the sole product detected.

High regioselectivity was observed as well when BH_3·THF complex served as the trapping agent (entry 4). The reagent combination of dialkylboron bromide/BH_3·THF offers a significant advantage over reagents such as $LiAlH_4$–$AlCl_3$ (12), the use of which requires the presence of a large protective group such as a benzyl ether at *O*-3 in order to obtain practical yields of the primary alcohol. In other words, it is necessary to increase the steric factor at *O*-3 to decrease the coordination of *O*-4 with $AlCl_3$ prior to ring cleavage and hydride delivery by $LiAlH_4$. However, when diphenyl boron bromide/BH_3·THF was used, a methyl ether at *O*-3 sufficed to afford exclusively the 4-*O*-benzyl ether **22** in excellent yield. Moreover, a comparison of entries 4 and 5 demonstrates that the regioselectivity in favor of the primary alcohol is unaffected by the anomeric configuration.

A potential limitation of the described protocol for cleavage of the benzylidene acetals is the necessity to work with protected hydroxyl groups in order to avoid the hydrolysis of the boron halides to Brønsted acids, which could affect the product ratio (13). It has been reported that the treatment of benzylidene acetal pyranosides with such acids leads to the formation of 6-*O*-benzyl derivatives, the regioselectivity of which has been attributed to the relative acidities of *O*-4 versus *O*-6 (7, 10). A more plausible explanation might be the existence of an equilibrium between the primary (*O*-6) and secondary (*O*-4) oxonium species (or corresponding halo ethers) arising from the parent acetal and the faster rate of hydride delivery to the former species. Another limitation of the described reductive cleavage employing the tandem addition of dialkyl (diaryl) boron bromide – borane reagents is the reactivity of these Lewis acids with other functionalities (14) besides benzylidene acetals. For example, we have reported the Me_2BBr-induced endocyclic and exocyclic carbon–oxygen bond cleavage at the glycosidic centers of carbohydrate derivatives (14*b*). Since the anomeric centres of the 2-deoxy series were found to be particularly reactive with dimethylboron bromides, it is not surprising that a complex mixture was obtained when the 2-deoxy benzylidene acetal **25** was subjected to the tandem addition of dimethylboron bromide and thiophenol (entry 6 of Table 3).

Conclusion

Dimethylboron and diphenylboron bromides are versatile reagents for the cleavage of benzylidene acetals under mild conditions. Under such conditions, these boron-based Lewis acids exhibit good chemoselectivity and therefore predictable reactivity. Bromo ether – borinate esters resulting from the ring cleavage can be quenched with thiophenol to yield hydroxy *O*,*S*-acetals, or can be reduced with different hydride sources to give monobenzylated diols. The regioselectivity of these reactions can be predicted on the basis of steric and anchimeric considerations.

Experimental

General

Infrared (ir) spectra were recorded on a Perkin–Elmer model 681 or 781 spectrophotometer. Proton nuclear magnetic resonance (^{1}H nmr) spectra were recorded on a Bruker AM250 or a Bruker AC200, using in all instances tetramethylsilane as a reference. Mass spectrometric measurements were performed by Morgan Schaffer, Montreal, Quebec, using a Hitachi Perkin–Elmer RMV-6D mass spectrometer. Elemental analyses were performed by Guelph Chemical Laboratories Ltd., Guelph, Ontario. Flash chromatography was accomplished using 230–400 mesh silica gel (E. Merck).

All reactions were carried out under inert atmosphere of nitrogen. Glassware and syringes were dried in an oven (120°C) prior to use. Chlorinated solvents as well as triethylamine were distilled from CaH_2 and stored over 4 Å molecular sieves.

Dimethylboron bromide was purchased from the Alfa Division of Ventron Corp. or from Aldrich Chemical Co. or prepared from tetrabutyltin and boron tribromide (1*d*). Diphenylboron bromide was purchased from Alfa. Solutions of these reagents were prepared in dry CH_2Cl_2 (1.5–2.0 M) and could be stored at −5°C for several months without noticeable decomposition. Solutions of β-bromo-9-BBN in CH_2Cl_2 were used as purchased (Aldrich Chemical Co.). Starting materials were obtained from Aldrich Chemical Co. or prepared under standard conditions (2).

Representative procedure A for the rearrangement of benzylidene acetals using thiophenol as nucleophile. Preparation of O,S-*acetal* **7**

To a cold (−78°C), stirred solution of the benzylidene **6** (76 mg, 0.32 mmol) in 1.5 mL of dry CH_2Cl_2 were added successively Et_3N (9 μL, 0.064 mmol) and a solution of Me_2BBr (2.1 M, 335 μL) in CH_2Cl_2. The reaction mixture was stirred at −78°C for 45 min and then treated with Et_3N (1.12 mmol) and a solution of thiophenol in CH_2Cl_2 (1 M, 960 μL). After 1 h at −78°C the mixture was cannulated into a saturated aqueous solution of $NaHCO_3$ (5 mL). Ether (20 mL) was then added. The layers were separated and the organic layer was successively washed with saturated aqueous $NaHCO_3$, water, and brine, and dried over anhydrous $MgSO_4$. Removal of solvent and purification by flash chromatography gave the hydroxy compound **7** in 88% yield: ir (neat): 3450 (OH) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 2.70 (br s, 1H, OH, D_2O exchangeable), 3.35 (s, 3H, OCH_3), 3.36 (s, 3H, OCH_3), 3.40–3.70 (m, 5H, $2CH_2OMe$, CHO), 4.87 (m, 1H, CHOH), 6.10 (2s, 1H, CHAr), 7.20–7.55 (m, 10H, 2Ar). Mass spectrum, *m/e*: 239 (M^+ − SPh). Anal. calcd. for $C_{19}H_{24}O_4S$: C 65.43, H 6.94, S 9.20; found: C 65.43, H 6.68, S 9.38.

Representative procedure B for the formation of benzyl ethers using Super Hydride or diisobutylaluminium hydride. The preparation of benzyl ether 8

To a cold (−78°C) solution of benzylidene **6** (1.0 mmol) in 3.8 mL of dry CH_2Cl_2, under nitrogen, were added successively Et_3N (0.2 mmol) and a solution of Me_2BBr (2.1 M, 2.2 mmol). After 45 min at −78°C the reaction mixture was treated with Super Hydride or DIBAL-H (2.0 equiv.) and stirred at −78°C for 1 h. Saturated aqueous $NaHCO_3$ (10 mL) and Et_2O (40 mL) were then added. The organic layer was washed with H_2O, then with brine, and dried over anhydrous $MgSO_4$. Concentration and purification by flash chromatography gave pure benzyl ether **8** in 62 and 80% yield respectively; ir (neat): 3425 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 2.60 (br s, 1H, OH, D_2O exchangeable), 3.35 (s, 3H, OCH_3), 3.36 (s, 3H, OCH_3), 3.40–3.70 (m, 5H, $2CH_2OMe$, CHOBn), 4.60, 4.80 (2d, 2H, CH_2Ar), 4.87 (m, 1H, CHOH), 7.20–7.40 (m, 5H, Ar). Mass spectrum, *m/e*: 240 (M^+). Anal. calcd. for $C_{13}H_{20}O_4$: C 64.98, H 8.39; found: C 64.89, H 8.30.

Representative procedure C for the formation of benzyl ethers using BH_3·THF. The preparation of benzyl ether 8

Following the same procedure as described in B with the exception that BH_3·THF complex (2.0 equiv.) was added (instead of Super Hydride or DIBAL-H) at −78°C and the reaction mixture was allowed to warm to −20°C for 1 h. The solution was then diluted with Et_2O (40 mL) and H_2O (10 mL) and treated as described above to afford benzyl ether **8** in 96% yield.

Compound 5 was obtained as a diastereoisomeric mixture using procedure A: ir (neat): 3470 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.10–1.95 (m, 10H), 2.25, 2.50 (2s, 1H, OH), 3.30–3.40, 3.50–3.65 (2m, 2H, 2CHO), 7.20–7.55 (m, 10H, 2Ar). Mass spectrum, *m/e*: 219 (M^+ −

SPh). Anal. calcd. for $C_{20}H_{24}O_2S$: C 73.13, H 7.36, S 9.76; found: C 72.89, H 7.55, S 9.70.

Compound ***10*** was obtained as a diastereoisomeric mixture using procedure A: ir (neat): 3500 (OH), 1700 (CO) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.10 (d, 1H, OH), 3.65, 3.66, 3.72, 3.79 (4s, 6H, $2CO_2Me$), 4.30, 5.15 (2d, 1H, CHO), 4.65 (dd, 1H, CHOH), 6.03, 6.21 (2s, 1H, CH-Ar), 7.25–7.50 (m, 10H, 2Ar). Mass spectrum, *m/e*: 267 (M^+ − SPh).

Compound ***11*** was obtained as an oil using procedure C; ^1H nmr ($CDCl_3$) δ: 3.46 (dd, 1H, OH), 3.66, 3.84 (2s, 6H, $2CO_2Me$), 4.33, 4.60 (2d, 2H, 2CHO), 4.42, 4.87 (2d, 2H, CH_2-Ar), 7.25–7.36 (m, 5H, Ar). Mass spectrum, *m/e*: 269 (M^+ + 1). Anal. calcd. for $C_{13}H_{16}O_6$: C 58.20, H 6.01; found: C 58.41, H 6.07.

Compound ***13*** was obtained as a diastereoisomeric mixture using procedure A; ir (neat): 3450 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 2.80 (br s, 1H, OH), 3.29 (s, 6H, $2OCH_3$), 3.40, 3.41 (2s, 4H, $2CH_2OMe$), 3.65–3.70 (m, 2H, CH_2OH), 3.45–3.47, 3.82–3.86 (2m, 2H, CH_2O), 5.42, 5.75 (2s, 1H, CH-Ar), 7.20–7.50 (m, 10H, 2Ar). Mass spectrum, *m/e*: 253 (M^+ − SPh). Anal. calcd. for $C_{20}H_{26}O_4S$: C 66.27, H 7.23, S 8.85; found: C 66.55, H 6.90, S 8.95.

Compound ***14*** was obtained as an oil using procedure C; ir (neat): 3425 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 2.90 (br s, OH, D_2O exchangeable), 3.32 (s, 6H, 2OMe), 3.44 (s, 4H, $2CH_2OMe$), 3.50 (s, 2H, CH_2OBn), 3.71 (s, 2H, CH_2OH), 4.50 (s, 2H, CH_2-Ar), 7.27–7.38 (m, 5H, Ar). Mass spectrum, *m/e*: 254 (M^+). Anal. calcd. for $C_{14}H_{22}O_4$: C 66.12, H 8.72; found: C 66.09, H 8.60.

Compound ***15A*** was obtained as an oil using procedure C; ir (neat): 3430 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.90 (t, 3H, CH_3), 1.20–1.60 (m, 10H, $5CH_2$), 2.00 (t, 1H, OH, D_2O exchangeable), 3.45–3.75 (m, 3H, CH_2OH, CHOBn), 4.65 (2d, 2H, CH_2-Ar), 7.30–7.45 (m, 5H, Ar). Anal. calcd. for $C_{15}H_{24}O_2$: C 76.23, H 10.23; found: C 76.16, H 10.10.

Compound ***15B*** was obtained as an oil using procedure C; ir (neat): 3400 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 0.88 (t, 3H, CH_3), 1.18–1.50 (m, 10H, $5CH_2$), 2.35 (d, 1H, OH, D_2O exchangeable), 3.28–3.35, 3.48–3.55 (2m, 2H, CH_2OBn), 3.75–3.90 (m, 1H, CHOH), 4.58 (s, 2H, CH_2-Ar), 7.30–7.45 (m, 5H, Ar). Mass spectrum, *m/e*: 236 (M^+). Anal. calcd. for $C_{15}H_{24}O_2$: C 76.23, H 10.23; found: C 76.16, H 10.10.

Compound ***17A + 17B*** was obtained as an oil using procedure C; ir: 3430 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.35 (s, 3H, OCH_3), 3.50–3.70 (m, 5H, CH_2OMe, CHO, CH_2O), 4.54 (s, 2H, CH_2-Ar, **17B**); 4.55 (2d, CH_2-Ar, **17A**), 7.25–7.40 (m, 5H, Ar). Mass spectrum, *m/e*: 196 (M^+).

Compound ***18A*** was obtained as an oil using procedure C; ir (neat): 3450 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.75–2.00 (m, 2H, CH_2), 2.20 (br s, 1H, OH, D_2O exchangeable), 3.35 (s, 3H, OCH_3), 3.42–3.52 (m, 2H, CH_2OMe), 3.53–3.78 (m, 3H, CH_2OH, CHOBn), 4.60 (s, 2H, CH_2-Ar), 7.30–7.43 (m, 5H, Ar). Mass spectrum, *m/e*: 179 (M^+ − OMe). Anal. calcd. for $C_{12}H_{18}O_3$: C 68.55, H 8.63; found: C 68.15, H 8.59.

Compound ***18B*** was obtained as an oil using procedure C; ir (neat): 3500 (OH) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.65–1.80 (m, 2H, CH_2), 2.05 (br s, OH, D_2O exchangeable), 3.35 (s, 3H, OCH_3), 3.20–3.40 (m, 2H, CH_2OMe), 3.70 (t, 2H, CH_2OBn), 3.93–4.05 (m, 1H, CHOH), 4.56 (s, 2H, CH_2-Ar), 7.28–7.40 (m, 5H, Ar). Mass spectrum, *m/e*: 179 (M^+ − OMe). Anal. calcd. for $C_{12}H_{18}O_3$: C 68.55, H 8.63; found: C 68.15, H 8.59.

Compound ***20*** was obtained as a diastereoisomeric mixture using procedure A; ^1H nmr ($CDCl_3$) δ: 3.10–3.25 (m, 1H, H-2), 3.28, 3.38, 3.45 (3s, 9H, OMe), 4.75, 4.85 (2d, 1H, H-1), 6.18, 6.42 (2s, 1H, CH-Ar), 7.19–7.57 (m, 10H, 2Ar). Mass spectrum, *m/e*: 419 (M^+ − 1). Anal. calcd. for $C_{22}H_{28}O_6S$: C 62.83, H 6.71, S 7.62; found: C 62.25, H 6.95, S 7.18.

Compound ***21*** was obtained as a diastereoisomeric mixture using procedure A; ^1H nmr ($CDCl_3$) δ: 1.56, 2.40 (2 br s, 1H, OH), 3.10–3.37 (m, 1H, H-2), 3.39, 3.49, 3.63 (3s, 9H, 3OMe), 3.40–3.55 (m, 2H, H-3, H-5), 3.70–3.85 (m, 2H, H-6), 4.02–4.20 (m, 1H, H-4); 4.78–4.85 (m, 1H, H-1), 5.86–6.18 (2s, 1H, CH-Ar), 7.15–7.55 (m, 10H, 2Ar). Mass spectrum, *m/e*: 419 (M^+ − 1). Anal. calcd. for $C_{22}H_{28}O_6S$: C 62.83, H 6.71, S 7.62; found: C 62.15, H 6.98, S 7.14.

Compound ***22*** was obtained using procedure C; ^1H nmr ($CDCl_3$) δ: 1.45 (br s, 1H, OH), 3.22 (dd, 1H, H-2), 3.41 (s, 3H, OMe), 3.48 (m, 1H, H-4), 3.55 (s, 3H, OMe), 3.68 (s, 3H, OMe), 3.55–3.70 (m, 2H, H-3, H-5), 3.72–3.85 (m, 2H, H-6), 4.65, 4.90 (2d, 2H, CH_2-Ar), 4.84 (d, 1H, H-1), 7.30–7.43 (m, 5H, Ar). Mass spectrum, *m/e*: 312 (M^+). Anal. calcd. for $C_{16}H_{24}O_6$: C 61.52, H 7.74; found: C 61.20, H 7.62.

Compound ***24*** was obtained using procedure C; ^1H nmr ($CDCl_3$) δ: 1.85 (t, 1H, OH); 3.00 (dd, 1H, H-2), 3.27–3.54 (m, 3H, H-3, H-4, H-5), 3.55, 3.59, 3.65 (3s, 9H, OMe), 3.60–3.90 (m, 2H, H-6), 4.22 (d, 1H, H-1), 4.64, 4.86 (2d, 2H, CH_2-Ar), 7.30–7.40 (m, 5H, Ar). Mass spectrum, *m/e*: 312 (M^+). Anal. calcd. for $C_{16}H_{24}O_6$: C 61.52, H 7.74; found: C 61.44, H 7.70.

A novel electrochemical method of benzoylating aminoalcohols **2** by use of methyl benzoates **1** at room temperature was developed. 2-Aminoethanols **2** ($n = 0$, $R^3 = H$) and 3-aminopropanols **2** ($n = 1$, $R^3 = H$) gave the corresponding benzamides **4**, as a result of electrochemical transesterification followed by *O,N*-actyl migration. In contrast, *o*- and *m*-aminobenzylalcohols (**7***a* and **7***b*) and *trans*-4-(aminomethyl)cyclohexanemethanol (**8***a*) afforded the corresponding benzoic esters, since their acyl migration is hindered. A local anesthetic, procaine, was prepared by using this electrochemical reaction. A mechanism for electrochemical transesterification, which involves a formation of alcoholate anion by a one-electron reduction of alcohol, is presented.

Key words: amides, aminoalcohols, benzoylation, electrochemical, esters.

KENJI ARAI, SHOHEI TAMURA, TATSUYA MASUMIZU, KEN-ICHI KAWAI SHOICHI NAKAJIMA et AKIRA UEDA. Can. J. Chem. **68**, 903 (1990).

On a mis au point une nouvelle méthode électrochimique permettant de benzoyler des aminoalcools de type **2** à l'aide de benzoates de méthyle de type **1**, à la température ambiante. Les 2-aminoéthanols **2** ($n = 0$, $R^3 = H$) et 3-aminopropanols **2** ($n = 1$, $R^3 = H$) fournissent les benzamides **4** correspondants qui sont le résultat d'une transestérification électrochimique suivie d'une migration acyle-*N,O*. Par opposition, les *o*- et *m*-aminobenzylalcools (**7***a* et **7***b*) ainsi que le *trans*-4-(aminométhyl)cyclohexaneméthanol (**8***a*) conduisent aux esters benzoïques correspondants parce que, dans ces cas, la migration acyle est empêchée. Faisant appel à cette réaction électrochimique, on a préparé un anesthésique local, la procaïne. On propose un mécanisme pour la transestérification électrochimique; celui-ci implique la formation de l'anion alcoolate par la réduction de l'alcool par un électron.

Mots clés : amides, aminoalcools, benzoylation, électrochimique, esters.

Introduction

The principal advantage of electrochemical reactions lies in the fact that they do not require thermal energy to overcome activation barriers, and hence are applicable to thermally sensitive compounds. We recently (1) published a versatile electrochemical procedure for the transesterification of phenylacetic, cinnamic, and phenylglyoxylic esters in acetonitrile on a glassy carbon electrode. This method of transesterification does not require high temperature nor specific reagents such as metal alcoholate (2), aluminum oxide (3), sulfuric acid (4), *p*-toluenesulfonic acid (5), and so on. As a continuation of this work, we report an electrochemical method for either *N*- or *O*-benzoylation of aminoalcohols **2**, by methyl benzoates **1**, on a Pt electrode. All the electrochemical reactions (Scheme 1 or Table 1) proceeded smoothly at room temperature merely by passing electric current under the conditions specified below. In contrast, it was shown that even after heating the contents of each cathodic solution at the boiling point of the solvent for 3 h, no reaction products were formed. An earlier preparation of aminoalkyl benzoates was by reaction of benzoyl chloride with aminoalcohols either by heating for 4–24 h, or by leaving at room temperature for 5 days (6). In the present method, we can use such mild reagents as esters, in place of acid chlorides.

Method, results, and discussion

The electrochemical reaction of aminoalcohols **2** with methyl benzoates **1***a–f* was performed in the cathodic compartment of a divided cell on Pt electrodes at a controlled potential of either −1.2 or −1.7 V vs. SCE. As shown in entry 3 or 6 of Table 1, electrolysis at the potential −1.2 V vs. SCE of **1***a* in the presence of **2***a* ($n = 0$, $R^1 = Me$, $R^2 = R^3 = H$) or **2***a* ($n = 1$, $R^1 = R^2 = R^3 = H$) provided the corresponding benzamide **4***a* in 49 and 73% yield, but at the more negative potential of −1.7 V vs. SCE, the yields were better (86 and 92%) (entries 4 and 7). Alteration of the molar ratio (aminoalcohol to benzoate) from 1.5 to 5.0 led to an improvement of the amide yields: 32% (entry 2) to 86% (entry 4); 36% (entry 5) to 92% (entry 7). Thus all other reactions were carried out at the potential −1.7 V vs. SCE and the molar ratio five, as shown in Table 1.

Interestingly, although 2-aminoethanol (**2**; $n = 0$, $R^1 = R^2 = R^3 = H$) reacted with methyl benzoate **1***a* affording amide **4***a* ($n = 0$, $R^1 = R^2 = H$) in 73% yield (entry 1), 2-methoxyethylamine, whose hydroxyl group is protected, did not react with **1***a*. This fact suggests that the electrochemical reaction is not actually an amidation but a transesterification, which is followed non-electrochemically by *O,N*-acyl migration (7) to give an amide as the product. This hypothesis was clearly substantiated by monitoring the product distribution in the catholyte solution during the course of the electrolytic reaction of **1***a* with 3-aminopropanol (**2**; $n = 1$, $R^1 = R^2 = R^3 = H$) (see

[a]Electrolyses were carried out in the cathodic compartment of a divided cell with Pt electrodes (4 cm^2), by passing 1.2 F/mol (on the basis of benzoate) of electricity into the acetonitrile solution containing 0.15 M TEAP.
[b]Based on isolated products.

Fig. 1). The amount of substrate **1***a* (○) decreases as the amount of the intermediate ester **3***a* (n = 1, R^1 = R^2 = R^3 = H) increases (quantitized as its acetate **5**, △). Further, the amount of this intermediate decreases with increase in the amount of the product amide **4***a* (n = 1, R^1 = R^2 = H) (quantitized as its acetate **6**, ●). At the end of the electrolysis (1.2 F/mol of benzoate), the product is totally changed into the amide.[3]

[3]It can be considered from Fig. 1 that the necessary amount of current passed would be ca. 0.25 F/mol. Since this value is less than one, it is likely that the methanolate anion liberated by the reaction deprotonates the aminoalcohol to furnish the aminoalkyl anion for further reaction. The current efficiency, on the basis of pathway B of Scheme 2, thus reaches about 400%.

Furthermore, the electrolyic reaction of **1***a* was tried with *o*- and *m*-aminobenzyl alcohols (**7***a* and **7***b*), whose ester intermediates are not expected to rearrange due to the low nucleophilicity of the amino group (it is attached directly to the benzene nucleus), and also with *trans*-4-(aminomethyl)cyclohexanemethanol **8***a*, whose intermediate ester is unlikely to rearrange due to steric

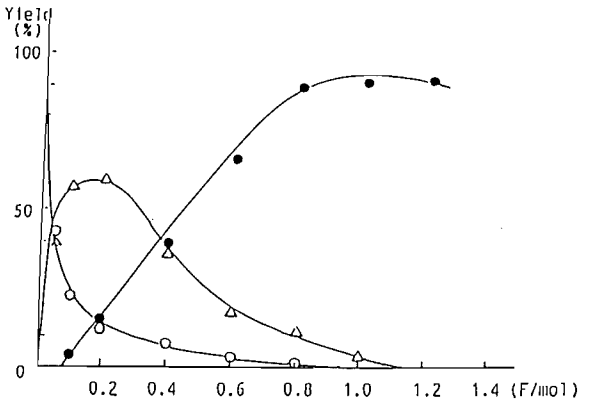

FIG. 1. plots of product distribution of the cathodic reaction of **1***a* and **2** (n = 1, $R^1 = R^2 = R^3$ = H) with electricity passed (F/mol). ○: **1***a*. △: 3-Acetylaminopropyl benzoate (*N*-acetate **5** of **3***a*: n = 1, $R^1 = R^2 = R^3$ = H). ●: 3-Benzoylaminopropyl acetate (*O*-acetate **6** of **4***a*: n = 1, $R^1 = R^2 = R^3$ = H). NOTE: Percent yield was calculated on the basis of the acetylated products.

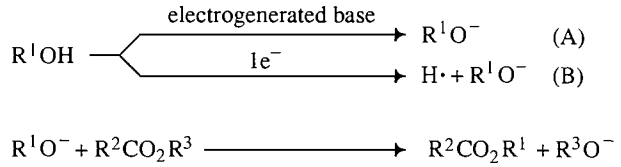
hindrance. As expected, we obtained the transesterification product **7***d* or, after treatment with Ac_2O-pyridine, the acetylated transesterification products (**7***c* and **8***c*) exclusively, but not the amides nor the acetylated amides.

As an example of the application of this electrochemical reaction, the widely used local anesthetic procaine (**3***f*; n = 0, $R^1 = R^2$ = H, R^3 = Et) was prepared from methyl *p*-aminobenzoate **1***f* and *N,N*-diethylaminoethanol (**2**; n = 0, $R^1 = R^2$ = H, R^3 = Et) as shown in entry 13 of Table 1. We can anticipate that this electrochemical method will find wide application not only for benzoylation but for other acylations on various amino-alcohols.

The mechanistic aspects of this electrochemical transesterification were examined as follows. When benzyl alcohol was mixed and stirred for 30 min at room temperature with a pre-electrolyzed (−1.7 V vs. SCE, 0.5 F/mol of ester) solution of a mixture of methyl cinnamate and tetraethylammonium perchlorate (TEAP) in acetonitrile, no transesterification product was formed. In contrast, when methyl cinnamate was stirred similarly with the pre-electrolyzed acetonitrile solution of a mixture of benzyl alcohol and TEAP, the transesterification occurred in fairly good yield (71%). In a similar way, methyl phenylglyoxylate was prepared in 66% yield by mixing (−)-menthyl phenylglyoxylate with the pre-electrolyzed acetonitrile solution of methanol and TEAP. Thus it is certain that the intermediary active species produced by the cathodic reduction at the Pt electrode does not come from the esters but from the alcohol, solvent, or supporting electrolyte. It is very likely that an alcoholate anion is formed in the cathodic compartment and serves as an initiator for this electrochemical transesterification (see below).

The formation of an alcoholate anion by cathodic reduction has previously been suggested (8). In particular, Islam *et al.* (8*b*)[4] recently indicated that their electrochemical transesterification, conducted not on Pt but on a mercury electrode, was a base-catalyzed reaction (pathway A of Scheme 2). Their reaction mixture contained the oxalic ester, which is known to electro-reduce particularly easily to give an anion radical as an electrogenerated base (8*b*), but our mixture does not contain such an easily electro-reducible ester, as demonstrated by the

[4]This paper followed our first communication on electrochemical transesterification (1).



SCHEME 2

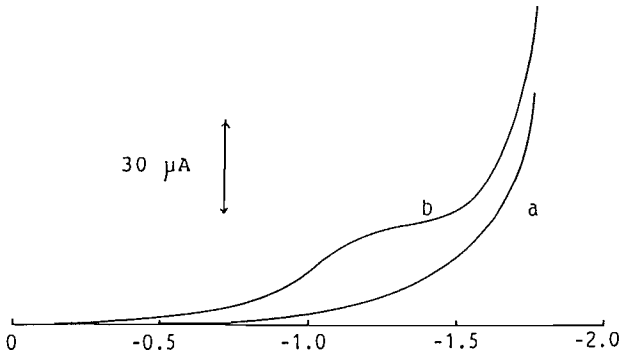


FIG. 2. Linear sweep voltammograms of (a) methanol and (b) 1-amino-2-propanol on platinum electode substrate, ca. 2 mM; acetonitrile-0.3 M TEAP; scan rate, 50 mV/s^{-1}.

pre-electrolysis experiments described above.[5] In addition, we used Pt, as electrode of low hydrogen overvoltage, instead of mercury, and it is probable that the alcoholate anion, the initiator of this reaction, was formed by direct cathodic reduction as shown in pathway B of Scheme 2. Supporting this speculation, the linear voltammograms of methanol and 1-amino-2-propanol (see Fig. 2) showed curves bending upward slightly at the potential near −1.0 V, and steeply at −1.7 V vs. SCE. Furthermore, hydrogen evolution is clearly observed in this potential range. This postulation is also applicable to the reaction of Shono *et al.* (8*a*), who prepared ether from aliphatic alcohol and alkyl chloride by cathodic reaction, since their reaction was conducted on a Pt electrode.[6] It is possible that this electrochemical reaction is supported by the tetraalkylammonium ion as the counter cation to the alcoholate anion (9).

Experimental

EI-MS spectra were measured on a JEOL JMS-D 300 spectrometer. IR spectra were taken with a Hitachi model 215 grating spectrophotometer. ^1H NMR spectra were obtained on a JEOL JNM FX-100 spectrometer at 99.60 MHz, using tetramethylsilane as an internal standard. High-pressure liquid chromatography (HPLC) was performed with a Jasco 880-PU apparatus equipped with a Soma S-310A model II ultraviolet (UV) detector (Soma Kogaku Co., Ltd.), and a Senshu Pak. ODS-1251-S No. 3331 (Senshu Kagaku Co., Ltd.) (4.8 × 250 mm).

Electrolysis apparatus

Electrolyses were conducted by use of a Hokuto Denko HA-105 potentio-galvanostat connected with a Hokuto Denko HF-201 coulom-

[5]Voltammetric work showed no occurrence of the reduction of methyl benzoate at −1.7 V vs. SCE.

[6]Partial translation, referring to tabulated results in ref. 8*a*: "As shown in Table 1, not only primary or secondary alcohols, but also tertiary alcohol(s) (run 6) or diols (run 7, 8) afford the corresponding ether in good yield. From this result, we consider that the alcoholate anion, probably generated electrochemically, has a higher reactivity than the same anion non-electrochemically produced."

eter. An ordinary H-type cell divided into two compartments with a glass frit, equipped with Pt plate (4 cm^2) electrodes and a saturated calomel electrode as a reference, was used. The temperature of the catholyte solution was kept at 23 ± 2°C by external cooling with water and stirring by use of a magnetic stirrer.

Reagents

The aminoalcohols **7***a*, **7***b*, **8***a* were prepared by reduction of the corresponding esters with $LiAlH_4$ (10). Acetonitrile was dried by distillation from P_2O_5, then CaH_2. Benzyl alcohol was dried by distillation from $LiAlH_4$. Commercially available anhydrous methanol with water content not exceeding 0.05% (Wako Junyaku Kogyo Co., Ltd.) was used. Other materials used were commercially available reagents dried over P_2O_5.

*General procedure for the electrochemical benzoylation of aminoalcohols (**2**, **7**a, **7**b, and **8**a)*

The benzoylation was carried out by passing 1.2 F/mol of electricity (based on the consumption of the benzoate) under potential control (at −1.7 V vs. SCE unless otherwise designated) through the anhydrous acetonitrile solution (20 mL) containing benzoate **1** (2 mmol), aminoalcohol **2**, **7***a*, **7***b*, or **8***a* (10 mmol except when designated otherwise), and tetraethylammonium perchlorate (TEAP) (3 mmol). After the electrolysis, the solvent was removed *in vacuo*. The product amide **4** or alcoholysis product procaine (**3***f*; $n = 0$, $R^1 = R^2 = H$, $R^3 = Et$), **7***d* or **8***b*, as well as any recovered benzoate, were separated either by chromatography on silica gel (procaine, **4**, **7***d*) or by chromatography on silica gel after acetylation by treatment with Ac_2O-pyridine (**7***c*, **8***c*). The solvent compositions for the elutions as follows: $CHCl_3$ – EtOH (25:1) for **4**; CH_2Cl_2–hexane (5:1) for procaine and **7***b*; benzene–acetone (25:1) for **7***c*; benzene–acetonitrile–$CHCl_3$ (1:0.5:2) for **8***c*.

The procaine prepared by this procedure was identified by mixture melting point and comparison of the IR spectrum with that for the commercially available authentic sample. The products **4***a* ($n = 0$, $R^1 = R^2 = H$), **4***a* ($n = 0$, $R^1 = Me$, $R^2 = H$), **4***a* ($n = 1$, $R^1 = H$, $R^2 = Me$), **4***b–e*, and **7***c* obtained by this procedure were identified by mixture melting point and by the comparison of the spectral data listed below with those for each authentic sample, synthesized from the corresponding aminoalcohols either by reaction with benzoyl chloride and NaOH at room temperature (**4***a*; $n = 0$, $R^1 = Me$, $R^2 = H$, and **4***a*; $n = 1$, $R^1 = H$, $R^2 = Me$), by refluxing for 3 h with each benzoate (**4***b–e* and **4***a*; $n = 0$, $R^1 = R^2 = H$) (11), or by the method of Raiford *et al.* (**7***c*) (12), respectively. The product **4***a* ($n = 1$, $R^1 = R^2 = H$), which is an oil, was identified by comparing the spectral data with those for the sample synthesized by the reaction with benzoyl chloride and NaOH at room temperature. The product **7***d* was identified by comparing the mp and the spectral data with those described in literature (13).

The yields of procaine and **4** are listed in Table 1. The yields of **7***c*, **7***d*, and **8***c* were 52, 54, and 65% respectively.

The physical properties and spectral data of the electrolysis products **4**, **7***c*, **7***d*, and **8***c* are as follows.

Anal. calcd. for $C_{17}H_{23}NO_3$: C 70.56, H 8.01, N 4.84; found: C 70.42, H 8.20, N 4.82.

*Analysis of product distribution (Fig. 1) of 3-acetylaminopropyl benzoate **5** and 3-benzoylaminopropyl acetate **6** during the course of electrolysis*

All the conditions for the electrolysis are the same as those described above for the preparative scale experiments. After passing each faraday of electricity (at −1.7 V vs. SCE), 1.0 mL each of catholyte and anolyte was removed and combined. The resulting solution was mixed with Ac_2O–pyridine (1:1, 2 mL) and stirred overnight at room temperature. Then the mixture was treated with ice-water, extracted with $CHCl_3$, dried over Na_2SO_4, and the $CHCl_3$ was removed *in vacuo*. The residual substance was dissolved in MeOH (50 mL) and used for separation and quantitation of **5** and **6** as well as the recovered **1***a*, by HPLC with the solvent AcOH–MeOH–H_2O (1:500:500).

The physical and spectral data of the products obtained are as follows.

*3-Acetylaminopropyl benzoate (**5**)*

Colorless prisms, mp 59–60°C. IR (KBr, cm^{-1}): 1720 (ester), 1635 (amide). ^1H NMR ($CDCl_3$, δ): 1.98 (2H, m, C-CH_2-C), 1.98 (3H, s, COMe), 3.39 (2H, q, $J = 6$ Hz, NCH_2), 4.41 (2H, t, $J = 6$ Hz, OCH_2), 5.84 (1H, br, NH), 7.35–8.08 (5H, m, Ar). MS *m/z*: 221 (M^+). Anal. calcd. for $C_{12}H_{15}NO_3$: C 65.14, H 6.83, N 6.33; found: C 65.03, H 6.93, N 6.31.

*3-Benzoylaminopropyl acetate (**6**)*

Colorless needles, mp 55–57°C. IR (KBr, cm^{-1}): 1720 (ester), 1630 (amide). ^1H NMR ($CDCl_3$, δ): 1.98 (2H, m, C-CH_2-C), 2.08 (3H, s, COMe), 3.51 (2H, q, $J = 6$ Hz, NCH_2), 4.23 (2H, t, $J = 6$ Hz, OCH_2), 6.60 (1H, br, NH), 7.40–7.84 (5H, m, Ar). MS *m/z*: 221 (M^+). Anal. calcd. for $C_{12}H_{15}NO_3$: C 65.14, H 6.83, N 6.33; found: C 65.11, H 6.93, N 6.32.

Reaction of methyl cinnamate (or (−)-menthyl phenylglyoxylate) with the pre-electrolyzed solution of benzylalcohol (or methanol)

An anhydrous solution of benzyl alcohol (or methanol) (80 mmol),

TEAP (4 mmol), and acetonitrile (70 ml) was electrolysed at −1.7 V vs. SCE until 2 mF of electricity was passed. The catholyte was then mixed with methyl cinnamate (or (−)-menthyl phenylglyoxylate, 4 mmol) and stirred for 30 min at room temperature. The residue, obtained after evaporation of solvent at room temperature *in vacuo*, washing with water, and drying, was purified by column chromatography on silica gel with benzene–hexane (1:5), affording pure benzyl cinnamate in 71% yield (or methyl phenylglyoxylate, 66% yield). Each product was identified by comparison of the thin-layer chromatography, MS, and IR spectra with those of authentic samples.

When benzyl alcohol (or (−)-menthol) was stirred with the pre-electrolyzed anhydrous acetonitrile solution of methyl cinnamate (or methyl phenylglyoxylate) and TEAP, no reaction occurred.

Linear sweep voltammetry

Linear sweep voltammograms of methanol and 1-amino-2-propanol were obtained in acetonitrile solution containing TEAP as supporting electrolyte. A three-electrode system consisting of a Pt indicator electrode (0.38 mm^2), a Pt counter electrode, and a saturated calomel electrode was used. To protect the solution from moisture, a compartment (a glass tube of 15 mm. diameter with one sharp end outlet) of 0.3 M acetonitrile solution of TEAP was placed between the catholyte and the KCl agar salt bridge. Measurements were made at 22°C with a substrate concentration of ca. 2 mM and with a scanning rate of 50 mV s^{-1}. The concentration of supporting electrolute was 0.3 M.

Synthesis, electronic spectroscopy, and evaluation of photoconducting oligomers with pendant bichromophores. Part 1. Influence of donor–acceptor orbital overlap on aggregate emission and photoactivity

D. GRAVEL,[1] S. GAUTHIER, F. BRISSE,[1] S. RAYMOND, M. D'AMBOISE, P. MESSIER, B. ZELENT, AND G. DUROCHER[1]

Département de chimie, Université de Montréal, C.P. 6128, Succ. A, Montréal (Québec), Canada H3C 3J7

Received June 12, 1989[2]

D. GRAVEL, S. GAUTHIER, F. BRISSE, S. RAYMOND, M. D'AMBOISE, P. MESSIER, B. ZELENT, and G. DUROCHER. Can. J. Chem. **68**, 908 (1990).

The synthesis, electronic spectroscopy, and photoactivity of two polysebacate oligomers with pendant donor–acceptor bichromophores of the alkylcarbazole–dinitrofluorene type ($\mathbf{P_1}$) and the alkylcarbazole–trinitrofluorenone carboxylic acid ester type ($\mathbf{P_2}$) are reported. The crystal structure of the basic acceptor chromophore $\mathbf{A_2}$ and donor–acceptor bichromophore $\mathbf{B_2}$ of oligomer $\mathbf{P_2}$ are also reported. In bichromophore $\mathbf{B_2}$, the amount of overlap is evaluated at 50% while the distance between the donor and the acceptor is 3.42 Å. It is shown that while no ground state intramolecular charge-transfer interaction takes place in the bichromophore $\mathbf{B_1}$ of oligomer $\mathbf{P_1}$ itself (in solution or the solid state), aggregates (acceptor–acceptor) are present in 3MP and in the solid state. The spectrum of oligomer $\mathbf{P_1}$ in low temperature 3MP matrices indicates a small aggregation effect while aggregate fluorescence of bichromophore $\mathbf{B_1}$ and oligomer $\mathbf{P_1}$ is observed in the solid state. Absorption spectra show that bichromophores $\mathbf{B_2}$ and $\mathbf{B_{2a}}$ and oligomer $\mathbf{P_2}$ give rise to charge-transfer bands with maxima at around 550 and 450 nm in CH_3CN and 590 and 470 nm in the solid state. The fluorescence and the phosphorescence of the carbazolyl chromophore and the phosphorescence of the 2,4,7-trinitro-9-fluorenone chromophore are quenched for $\mathbf{B_2}$, $\mathbf{B_{2a}}$, and $\mathbf{P_2}$ in EPA but a structureless emission is observed between 500 and 680 nm in the solid state that can be assigned to aggregate fluorescence. The negative values of ΔG_{ET} indicate that intramolecular electron transfer in bichromophores $\mathbf{B_1}$, $\mathbf{B_2}$, and $\mathbf{B_{2a}}$ should be highly probable on thermodynamic grounds if optimal orbital overlap is available. The spectroscopic properties of the bichromophoric compounds studied are discussed on the basis of conformational effects. The photoactivity evaluation of oligomers $\mathbf{P_1}$ and $\mathbf{P_2}$ shows that $\mathbf{P_2}$ is more photoactive than $\mathbf{P_1}$ due, mainly, to better orbital overlap between the donor and the acceptor moieties in oligomer $\mathbf{P_2}$ as compared to oligomer $\mathbf{P_1}$. Furthermore, a comparison of $\mathbf{P_1}$ and $\mathbf{P_2}$ to a standard PVK–TNF system reveals that the latter is much more photoactive due, again, mainly to better orbital overlap. Finally, the relative efficiencies of these systems as hole or electron conductors is discussed.

Key words: photoconducting polymers, donor–acceptor bichromophores, bichromophores, substituted carbazoles, polynitrofluorene derivatives.

D. GRAVEL, S. GAUTHIER, F. BRISSE, S. RAYMOND, M. D'AMBOISE, P. MESSIER, B. ZELENT et G. DUROCHER. Can. J. Chem. **68**, 908 (1990).

On a réalisé la synthèse et on a examiné les spectres électroniques ainsi que la photoactivité de deux oligomères polysébacates portant des bichromophores donneur–accepteur de type alkylcarbazole-dinitrofluorène ($\mathbf{P_1}$) et de type alkylcarbazole–ester de l'acide trinitrofluorénonecarboxylique ($\mathbf{P_2}$). On a aussi déterminé la structure cristalline du chromophore accepteur de base $\mathbf{A_2}$ ainsi que celle du bichromophore donneur–accepteur $\mathbf{B_2}$. Dans le bichromophore $\mathbf{B_2}$, on a évalué que le recouvrement est d'environ 50% alors que la distance entre le donneur et l'accepteur est de 3,42 Å. On démontre que, même s'il ne se produit pas d'interaction intramoléculaire de transfert de charge dans l'état fondamental du bichromophore $\mathbf{B_1}$ de l'oligomère $\mathbf{P_1}$ lui-même (tant en solution qu'à l'état solide), il existe des agrégats (accepteur–accepteur) dans le 3MP ainsi qu'à l'état solide. Les spectres de l'oligomère $\mathbf{P_1}$ obtenus à basse température dans des matrices de 3MP suggèrent la présence d'un faible effet d'agrégation alors que, à l'état solide, on observe de la fluorescence d'agrégats du bichromophore $\mathbf{B_1}$ et de l'oligomère $\mathbf{P_1}$. Les spectres d'absorption des bichromophores $\mathbf{B_2}$, $\mathbf{B_{2a}}$ et de l'oligomère $\mathbf{P_2}$ donnent lieu à des bandes de transfert de charge avec des maxima autour de 550 et de 450 nm dans le CH_3CN et de 590 et 470 nm à l'état solide. La fluorescence et la phosphorescence du chromophore carbazolyle et la phosphorescence du chromophore 2,4,7-trinitrofluorèn-9-one des composés $\mathbf{B_2}$, $\mathbf{B_{2a}}$ et $\mathbf{P_2}$ dans l'EPA sont piégées; toutefois, à l'état solide, on n'observe qu'une émission sans structure entre 500 et 680 nm et on l'attribue à de la fluorescence d'agrégats. Les valeurs négatives de ΔG_{ET} indiquent que, sur une base thermodynamique, le transfert intramoléculaire d'électrons dans les bichromophores $\mathbf{B_1}$, $\mathbf{B_2}$ et $\mathbf{B_{2a}}$ devrait être très probable si le recouvrement des orbitales est optimal. On utilise des arguments basés sur les effets conformationnels pour discuter des propriétés spectroscopiques des composés bichromophoriques étudiés. L'évaluation de la photoactivité des oligomères $\mathbf{P_1}$ et $\mathbf{P_2}$ permet de démontrer que $\mathbf{P_2}$ est plus photoréactif que $\mathbf{P_1}$ principalement à cause d'un meilleur recouvrement d'orbitales entre les portions donneur et accepteur de l'oligomère $\mathbf{P_2}$ par opposition à ce qui existe dans l'oligomère $\mathbf{P_1}$. De plus, une comparaison de $\mathbf{P_1}$ et de $\mathbf{P_2}$ avec le système standard PVK–TNF révèle que ce dernier est beaucoup plus photoréactif principalement à cause d'un meilleur recouvrement d'orbitales. Enfin, on discute des efficacités relatives de ces systèmes comme conducteurs de trous ou d'électrons.

Mots clés: polymères photoconducteurs, bichromophores donneur–accepteur, bichromophores, carbazoles substitués, dérivés polynitrofluorènes.

[Traduit par la revue]

Introduction

The continued widespread interest in the synthesis, evaluation, and physical characterization of organic based photoconducting polymers attests to their importance both from the economic and academic point of view (1). On the one hand, the industrial competitiveness of the electrophotographic and reprographic industry relies on the development of new, better performing, and cheaper photoactive materials and, on the other, the fundamental description of the morphology and intimate mechanism of action of these systems remains an area of great scientific challenge.

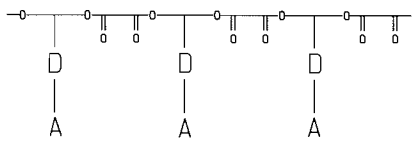

FIG. 1. Polyester with pendant D–A bichromophores.

One system that continues to attract much attention is the carbazole based family of polymers (2, 3) where charge is generated by an organic acceptor chromophore or an inorganic acceptor. This, no doubt, is a result of the fact that poly-*N*-vinylcarbazole (PVK) molecularly doped with 2,4,7-trinitrofluorenone (TNF) had yielded the best performing system in the early days (4). Although this performance has today been superseded by new industrial materials, the interest around the carbazole system remains high because of the wealth of information accumulated in the literature and the opportunity it may provide for the rational design and optimization of high performance organic based photoactive polymers.

Our approach to the study of this basic system has been to generate polyesters bearing carbazole based donor–acceptor bichromophores as pendant groups (Fig. 1). These should yield information on the influence, on the photoactivity of these polymers, of the relative distance between D–A pairs, of the relative distance between the donor and the acceptor chromophores, of the free energy changes in electron transfer, and of the eventual formation of chromophore aggregates, ground state charge transfer complexes, excimers, or exciplexes. The main difference between this system and the well-studied molecularly doped PVK is the possibility of varying the interbichromophore distance along the chain and of better controlling the distance between donors and acceptors, which was impossible, by design, in the doped PVK systems where phase separation between dopant and polymer could occur.

In earlier papers, we reported on the synthesis, crystal structure, and absorption spectroscopy of a carbazole–dinitrofluorene bichromophore (5) and on the intramolecular photoprocesses of the same bichromophore and a polysebacate containing it as pendant bichromophore (6). In the present paper, we report on the synthesis and a comparison of the electronic spectroscopy and photoactivity of two polysebacate oligomers with pendant D–A bichromophores where the nature (electron affinity) of the acceptor is varied.

Results and discussion

1. Synthesis of the D-A oligomers, the model chromophores, and bichromophores

For the sake of simplicity, the key substrates referred to in this study are identified as oligomers $\mathbf{P_1}$ and $\mathbf{P_2}$, the model acceptors $\mathbf{A_1}$ and $\mathbf{A_2}$, the model donors $\mathbf{D_1}$ and $\mathbf{D_2}$, and the model bichromophores $\mathbf{B_1}$, $\mathbf{B_2}$, and $\mathbf{B_{2a}}$. Scheme 1 outlines first the synthesis of the D–A oligomer $\mathbf{P_1}$ starting from *N*-benzylcarbazole (**1**). Formylation of the starting material **1** under the usual conditions yields 92% of the desired *N*-benzylcarbazole-3-carboxaldehyde (**2**), which is condensed with diethyl malonate under Knoevenagel conditions to give 90% of the expected malonylidene derivative **3**. Although the next operation pertains to three different reductions, namely reduction of the conjugated double bond, reduction of the malonyl moiety, and reductive cleavage of the *N*-benzyl group, it has unfortunately not been possible to carry out the three stages of reduction in one single step with good yield. In a first stage, catalytic reduction of the olefin is achieved in quantitative yield to give the malonate derivative **4**, which in turn is reduced with LAH to the corresponding 1,3-diol **5** in an 89% yield; then, reductive debenzylation is carried out in the presence of sodium in liquid ammonia to give a mixture of the desired debenzylated compound **6** contaminated with some overreduced material. Treatment of the crude product for 3 h with 10% palladium over charcoal in refluxing 1,3,5-trimethylbenzene, however, affords the desired 1,3-diol **6** in a 68% yield or better, depending on the reaction scale. In preparation for the attachment of the acceptor chromophore, diol **6** is first protected in the form of an acetonide acetal **7** in 83% yield; coupling to the 9-(3-bromopropyl)-9-methyl-2,7-dinitrofluorenyl acceptor chromophore **8** then takes place in the presence of sodium hydride in THF, in the presence of HMPA, and the desired diol monomer **9** is obtained directly by acid hydrolysis of the reaction mixture. An overall yield of 77% is obtained for the two steps. The final reaction in the sequence is the preparation of the oligomer by condensation of diol **9** with sebacoyl chloride in the presence of triethylamine. The desired D–A oligomer $\mathbf{P_1}$ is obtained as a low molecular weight orange solid in a 93% yield, after precipation from hexanes. On the other hand, the synthesis of model $\mathbf{D_2}$, which is patterned on the same scheme following the sequence: **10**, **11**, **12**, **13**, $\mathbf{D_2}$, will not be discussed here and the reader is referred to the experimental section for details.

Scheme 2 outlines the synthesis of D–A oligomer $\mathbf{P_2}$ along with those of models $\mathbf{A_2}$, $\mathbf{B_2}$, and $\mathbf{B_{2a}}$. The first sequence leading to model $\mathbf{B_2}$ and oligomer $\mathbf{P_2}$ is based on compound **7** from the previous scheme. In a first step, the β-hydroxethyl spacer group is introduced on the carbazole derivative **7** by reaction with ethylene oxide in the presence of powdered KOH in anhydrous butanone. The desired intermediate **14** is obtained in a 68% yield along with a small amount of the double condensation product, i.e., the *N*-β-hydroxyethyloxyethyl derivative **14***a* (see Experimental). Precursor **14** is then attached to the acceptor chromophore by reaction with the trinitrofluorenonecarboxylic acid chloride **15** in the presence of triethylamine to yield the bichromophoric monomer model $\mathbf{B_2}$ in a 97% yield. Finally, the bichromophore monomer is liberated in 83% yield by 10%HCl in THF and the resulting diol **16** oligomerized by reaction with sebacoyl chloride at 170–180°C. The desired oligomer $\mathbf{P_2}$ is obtained in a 45% yield as a low molecular weight grey solid. Again, as in the previous case, the synthesis of model $\mathbf{B_{2a}}$, which is patterned on the same scheme following the sequence: **17**, **18**, $\mathbf{B_{2a}}$, will not be discussed here and the reader is referred to the experimental section for details.

2. Crystallographic investigation of the acceptor chromophore A_2 and the bichromophore B_2

The atomic numbering for the description of the acceptor chromophore and the donor–acceptor bichromophore, whose crystal structures have been established, is shown in Fig. 2.

2.1. Acceptor A_2

The bond distances and angles of the two independent molecules in the unit cell have been deposited.[3] Corresponding values are in good agreement with one another. The point of

[3]Atomic coordinates, anisotropic thermal parameters, bond distances and angles (12 pages), and tables of observed and calculated structure factors (48 pages) may be purchased from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

Tables of atomic coordinates, bond lengths, and bond angles have also been deposited with the Cambridge Crystallographic Data Centre. They may be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, U.K.

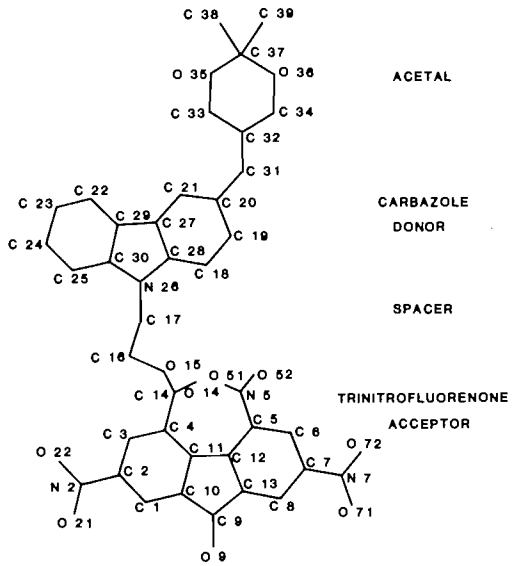

FIG. 2. Atomic numbering for $\mathbf{B_2}$.

TABLE 1. Dihedral angles of the carboxylate or the nitro groups with respect to the fluorenone mean plane

		Dihedral angle (deg)			
		Nitro at		Carboxylate at	
		C(2)	C(7)	C(5)	C(4)
Trinitrofluorenone $\mathbf{A_2}$	a	1.4	6.5	39.6	30.6
	b	2.1	1.1	35.7	37.1
Bichromophore $\mathbf{B_2}$		8.1	5.8	37.0	44.8

interest, however, lies with the nitro groups. As one may appreciate from the data of Table 1, the carboxylate group and each nitro group are planar but none is coplanar with the fluorenone ring system. The tilt of some of the nitro groups with respect to the fluorenone system is in the range of 2°–8°. However, the carboxylate group at C(4) and the nitro group at C(5) are inclined by as much as 35° with respect to the fluorenone mean plane. This of course is to minimize the interactions between oxygen atoms of the two neighbouring groups. It is worth noting that in this arrangement, although strongly tilted, the NO_2 and CO_2 groups remain nearly parallel to one another.

2.2. Bichromophore B_2

The bichromophore molecule is represented by the stereopair in Fig. 3. The bond distances and angles of the fluorenyl moiety of the bichromophore $\mathbf{B_2}$ compare very well with the corresponding quantities in the trinitrofluorenone molecule $\mathbf{A_2}$. All the effects described for the latter are observed here as well. The geometrical characteristics of the carbazole part have been deposited.

2.3 Flatness of the fluorenyl ring system

This is a major concern when studying the potentiality of a close approach between fluorenyl groups. In a systematic survey of fluorene and substituted fluorene ring systems Raymond (7) has recognized three types of distortions of such systems. A V-type distortion occurs when the outer atoms of the six-membered rings deviate on the same side of the fluorenyl mean plane. When the deviation from the same mean plane is positive on one side and negative on the other, this is referred to as an S-type distortion. The third distortion is of the propeller-type. This type of deviation from "planarity", as observed here for both molecules within the asymmetric unit, is to be associated with substitution at both C(4) and C(5). Here, the two bulky nitro and carboxylate groups cannot remain in the fluorenyl plane and tend to move apart from one another. This repulsion also affects atoms C(4) and C(5), which are thus displaced in opposite directions.

The intracyclic angles at the NO_2-substituted carbons, C(2), C(5), and C(7), are systematically larger than 120°. The average angle has a value of 122.0° and the spread between extreme values is only 1.4°. The corresponding bond angle and spread are 118.6° and 0.5° at the carboxylate-substituted C(4) atom. However, more importantly, it is the values of the exocyclic bond angles that are the most revealing. The 12 exocyclic bond angles at C(2) and C(7) are nearly all equal; they average 118.8° with a spread of 1.1°. In the case of the C(5) atom, also NO_2 substituted, three of the angles average 115.4° (spread 1.7°) while the other three average 122.6° (spread 0.7°). At C(4), the carboxylate-substituted atom, the dissymmetry is just as marked, since the two exocyclic angles have values of 114.3(5)° and 126.7(5)°. Thus the proximity of substituents causes major deviations from planarity of the fluorenyl ring system and its substituents.

2.4 The conformation of the spacer and molecular packing

The conformation of the spacer in the bichromophore $\mathbf{B_2}$ is given by the sequence of torsion angles in Table 2. From C(4) to N(26), the torsion angles of interest are successively *trans* and *gauche*. Bearing in mind that the carboxylate group is tilted by about 45° away from the trinitrofluorenone mean plane, this puts the two planar groups of the same bichromophore molecule parallel to one another. These are the carbazole (a) and trinitrofluorenone (b) groups in Fig. 4a. The amount of overlap is evaluated at 50% while the distance between the donor and the acceptor is 3.42 Å (Fig. 4b). All the acceptor and donor moieties are parallel to one another and nearly equidistant. There is no contact between semi-heavy atoms shorter than 3.4 Å.

There are two crystallographically distinct molecules of trinitrofluorenone $\mathbf{A_2}$ in a unit cell, molecules (a) and (b). The dihedral angle between these two planar molecules, (a) and (b), is 50°. However, each molecule is in turn centrosymmetrically related to another one, respectively (a′) and (b′). Because of the centers of symmetry, the overlaps are of the head-to-tail type. The amount of overlap and the interplanar distance are 60% and 3.34 Å for the (a,a′) pair and 65% and 3.47 Å for the (b,b′) pair. The disposition of the molecules in the crystal may be visualized in the projections of Fig. 5.

3. Spectroscopic properties of the D–A oligomers as compared to those of the bichromophores

3.1. Absorption spectra of P_1 and B_1

The electronic absorption spectra of bichromophore $\mathbf{B_1}$ and polysebacate $\mathbf{P_1}$, containing $\mathbf{B_1}$ as a pendant bichromophore in 3MP, EPA, and acetonitrile solutions at room temperature, are presented in Fig. 6. As can be seen in the figure, the second and third electronic transitions in the absorption spectra of the oligomer $\mathbf{P_1}$ as compared to the spectra of the bichromophoric molecule $\mathbf{B_1}$ are shifted to lower energies. Such a shift in the spectra is due to the substituent effect at position 3 of the carbazolyl chromophore in $\mathbf{P_1}$ since the second and third bands in the spectra of the bichromophore have been assigned to the carbazole moiety (5). This substitutional effect also explains the

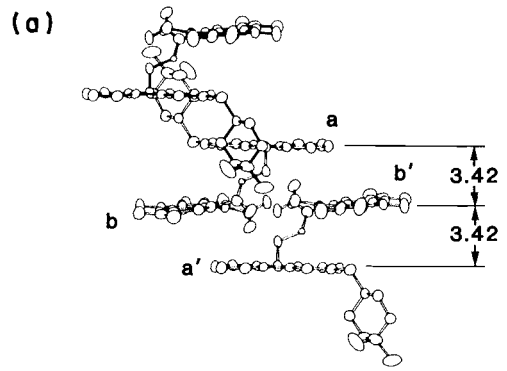

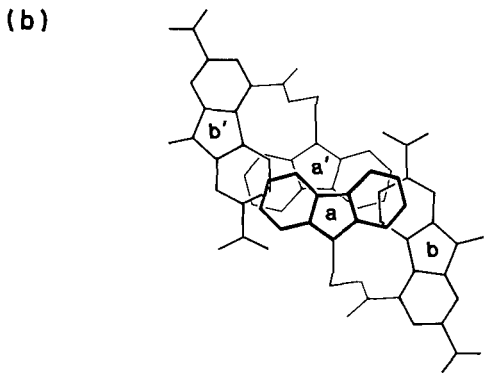

FIG. 4. (a) Side view of the packing of the bichromophore $\mathbf{B_2}$ in the unit cell. (b) Overlap of the various units of the bichromophore $\mathbf{B_2}$. The primed and unprimed molecules are centrosymmetrically related.

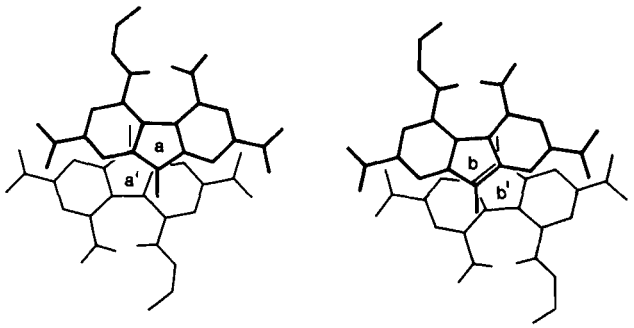

FIG. 5. The two kinds of overlap between molecules (a) and (b) of trinitrofluorenone $\mathbf{A_2}$. The primed and unprimed molecules are centrosymmetrically related.

observed shifts between the absorption spectra of $\mathbf{P_1}$ and $\mathbf{B_1}$ in the solid state (see Table 3 and Fig. 7). Figure 6 clearly shows that no ground state intramolecular charge-transfer interaction exists between the carbazolyl chromophore as the electron donor and the 2,7-dinitrifluorene chromophore as the electron acceptor in the oligomer $\mathbf{P_1}$, as already shown (5, 6). On the other hand, the absorption spectra presented in Fig. 6 also show that no aggregation takes place between two 2,7-dinitrofluorene chromophores in polar solutions at these concentrations.

In 3MP, even at 10^{-6} M, the aggregate is present (band at 365 nm). For the bichromophoric molecule $\mathbf{B_1}$ in 3MP such absorption, assigned as the absorption of the aggregates (acceptor–acceptor interactions), appears and increases in intensity (5) when the temperature of the solution decreases from 296 to 148 K. The aggregation effect observed in 3MP strongly depends on the concentration of $\mathbf{B_1}$ in the solution, and at low temperature is clearly detectable even in the concentration range of 10^{-6}–10^{-5} M. Since the edge-to-edge distance between the bichromophoric segments in the stretched conformation of oligomer $\mathbf{P_1}$ is 23.75 Å (according to Dreiding models), the observed aggregation effect for $\mathbf{P_1}$ in 3MP would be due to the interchain chromophore–chromophore interactions rather than intrachain interactions only if the oligomer adopts the rigid rod structure in 3 MP. But the very fact that the aggregates appear at much lower concentrations in the oligomer than in the bichromophore (Fig. 6) tends to show that the former rather

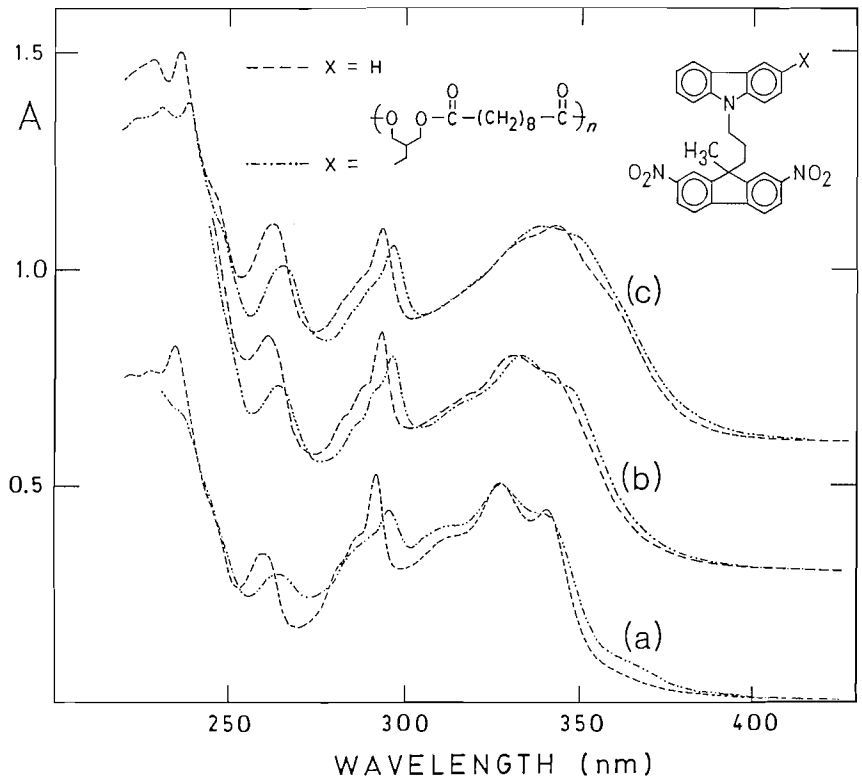

FIG. 6. Electronic absorption spectra of polysebacate $\mathbf{P_1}$ (–··–··–) (a) in 3MP ($C = 1 \times 10^{-6}$ M, $l = 5$ cm, $A \times 15$), (b) in EPA ($C \approx 5 \times 10^{-5}$ M, $l = 1$ cm, $A \times 1.5$), and (c) in acetonitrile ($C = 4.3 \times 10^{-5}$ M, $l = 1$ cm, $A \times 2.0$) as compared to the absorption spectra of bichromophore $\mathbf{B_1}$ (––––) (a) in 3MP ($C = 3.8 \times 10^{-6}$ M, $L = 5$ cm, $A \times 10$), (b) in EPA ($C = 1 \times 10^{-5}$ M $l = 1$ cm, $A \times 1.8$), and (c) in acetonitrile ($C = 1 \times 10^{-5}$ M, $l = 1$ cm, $A \times 2$). All spectra have been measured at 296 K.

adopts a flexible random coil in 3MP, giving rise to intrachain interactions between two 2,7-dinitrofluorene moieties in different segments. Since 3MP is a poor solvent for the bichromophore, it will surely tend to make the macromolecular coil contract below the normal value expected in better solvents. This might explain quite well the fact that at the lowest concentration available, in order to see something in the absorption spectra of the oligomer (10^{-7} M), the "aggregation band" is always present (there is not much difference between the 10^{-6} or 10^{-7} M spectra) because, obviously, the isolated random coils in 3MP are always present.

On the other hand one can see in Fig. 7 that the aggregation effect for $\mathbf{B_1}$ and $\mathbf{P_1}$ in the solid state is about the same. The solid state absorption spectra of $\mathbf{P_1}$ and $\mathbf{B_1}$, with the characteristic new absorption band at 370 nm assigned to aggregates (5), are similar.

Apart from the substituent effect already discussed, Fig. 6 also shows the solvent effect on the absorption spectra of the bichromophoric molecule $\mathbf{B_1}$ and the oligomer $\mathbf{P_1}$. This normal spectral shift, which increases with the solvent polarity, is due to the solute–solvent dipole–dipole interactions in which the 2,7-dinitrofluorene and the carbazolyl chromophores in $\mathbf{B_1}$ and $\mathbf{P_1}$ are involved (see Table 3). The long-wavelength absorption bands of $\mathbf{P_1}$ and $\mathbf{B_1}$ are modified and strongly shifted to lower energy when the temperature of the solution decreases from 296 to 77 K (Fig. 8). This is mainly due to the changes in the absorption spectrum of the 2,7-dinitrofluorene chromophore. For instance, the $^1L_b \leftarrow {}^1A$ transition in model $\mathbf{D_2}$ in EPA going from room temperature to 77 K decreases in energy only by 160 cm^{-1} (see Table 3). But the absorption band of acceptor model $\mathbf{A_1}$ clearly shifts to lower energy by 860 cm^{-1} at 77K.

Figure 8 also shows the phosphorescence excitation spectrum of $\mathbf{A_1}$ and the absorption spectrum of $\mathbf{P_1}$ in EPA at 77 K. These spectra are all identical to the $\mathbf{A_1}$ absorption spectra at 77 K in the region of the first electronic transition, indicating that the phosphorescence of $\mathbf{A_1}$ and the absorption of the oligomer in this electronic region of the spectrum are due to the free $\mathbf{A_1}$ chromophore.

3.2 Luminescence properties of B_1 and P_1

The fluoresence and phosphorescence emissions of the carbazole molecule in EPA solution are well known to have a good quantum yield (8–11). Nevertheless, the electronic excitation of the carbazolyl chromophore ($\lambda_{exc} = 295$ nm) in $\mathbf{B_1}$ in EPA solution does not lead to the appearance of any fluorescence at room temperature or fluorescence and phosphorescence at 77 K. This indicates that the singlet state of the carbazolyl chromophore in $\mathbf{B_1}$ is completely quenched by the 2,7-dinitrofluorene moiety. On the other hand, no fluorescence emission has been detected at room temperature ($\lambda_{exc} = 345$ nm) or at 77 K ($\lambda_{exc} = 362$ nm) for the 2,7-dinitrofluorene chromophore in $\mathbf{B_1}$ or in $\mathbf{A_1}$. But molecule $\mathbf{A_1}$ is characterized by a phosphorescence emission in the range 490–650 nm in EPA at 77 K. This phosphorescence remains unchanged in the bichromophoric molecule (6) $\mathbf{B_1}$ ($\phi_p = 0.06$). The same luminescence properties as described for the bichromophoric molecule $\mathbf{B_1}$ in EPA solution have also been observed for the oligomer $\mathbf{P_1}$ ($\phi_p = 0.06$).

The phosphorescence spectra of $\mathbf{A_1}$ and $\mathbf{B_1}$ in a nonpolar solvent like 3MP at the concentration of 1×10^{-6} M (Fig. 9) are the same as in EPA solutions (spectrum 1). It is well known that the phosphorescence spectra are not much affected by the polarity of the solvent. On the other hand the emission spectrum of $\mathbf{B_1}$ in 3MP changes drastically when the concentration increases from 1×10^{-6} to 5×10^{-6} M (curves 1–4). The phosphorescence of the 2,7-dinitrofluorene monochromophore

in $\mathbf{B_1}$ decreases in intensity while a new broad structureless emission, at $\lambda_{max} = 575$ nm, increases in intensity. The limit of these changes can be visualized in the emission spectrum of $\mathbf{B_1}$ in the solid state (curve 5), which is the same at room temperature and at 77 K. This new emission can be assigned to aggregate fluorescence of $\mathbf{B_1}$ in 3MP. Such a conclusion is supported by the absorption spectroscopy of $\mathbf{B_1}$ in 3MP (Fig. 6) as previously reported (5) and in the solid state (Fig. 7) for both $\mathbf{B_1}$ and $\mathbf{P_1}$. Secondly, this new emission is short lived compared to the long-lived phosphorescence emission of $\mathbf{B_1}$ ($\tau_p = 0.12$ s) (6). Moreover, the emission excitation spectrum ($\lambda_{em} = 575$ nm) of the oligomer in the solid state at room temperature perfectly superimposes over the corresponding absorption spectrum in Fig. 7. The phosphorescence spectra of the polysebacate $\mathbf{P_1}$ in a 3MP clear glassy solution (77 K) (saturated solution: $C < 1 \times 10^{-6}$ M) (Fig. 9, curve 8) indicate a small aggregation in the solution even at this very low concentration since the ratio I_{540}/I_{500} increases in the oligomer spectrum (curve 8 vs. 7). The spectra (curve 5) in the solid state can also be shifted depending upon the film thicknesses. Indeed, the solid state fluorescence spectrum of $\mathbf{P_1}$ has the same shape as the spectrum of $\mathbf{B_1}$ (curves 6 and 5) but, as stated above, the bichromophore aggregate spectrum gives rise to different maxima depending upon the thickness of the film used.

3.3 Absorption and luminescence properties of B_2, B_{2a}, and P_2

2,4,7-Trinitro-9-fluorenone (TNF) is known as a strong organic electron acceptor that forms charge transfer (CT) complexes with various carbazolyl donor molecules (12–14). These CT complexes can be characterized by new asymmetric absorption bands in the visible region of the spectrum. The asymmetry of these new CT bands is due to the presence of two electronic CT transitions involving two closely lying higher occupied molecular π-orbitals of the carbazolyl chromophore

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12

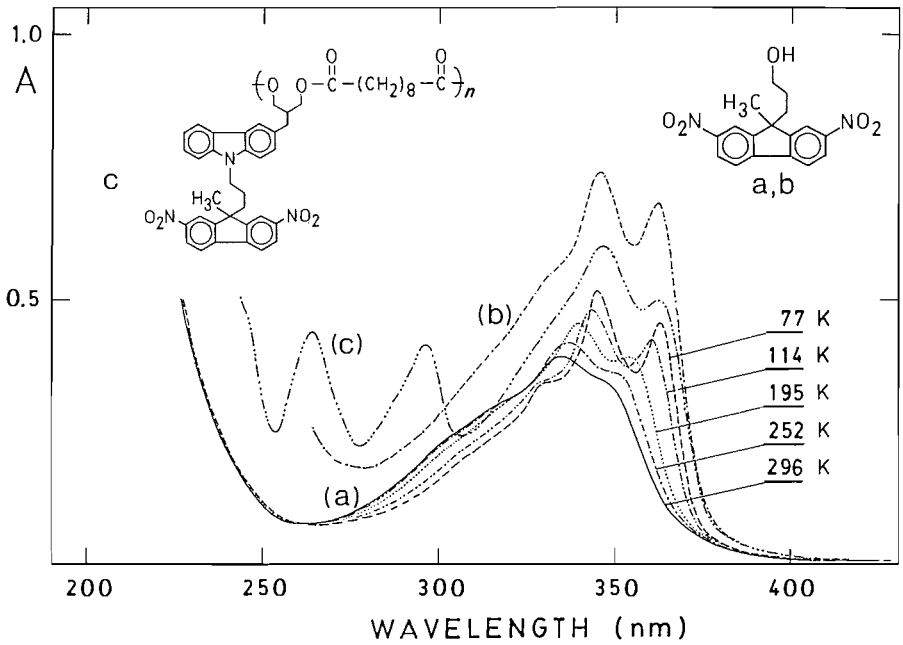

FIG. 8. (a) Changes in the absorption spectrum of acceptor model $\mathbf{A_1}$ ($C = 1 \times 10^{-5}$ M, $l = 1.3$ cm) in EPA solution when temperature decreases and (b) phosphorescence excitation spectrum of $\mathbf{A_1}$ in EPA at 77 K ($C = 1 \times 10^{-5}$ M) at $\lambda_{em} = 499$ nm as compared to (c) the absorption spectrum of polysebacate $\mathbf{P_1}$ ($C = 1 \times 10^{-6}$ M, $l = 1.3$ cm, $A \times 8$) in EPA at 77 K.

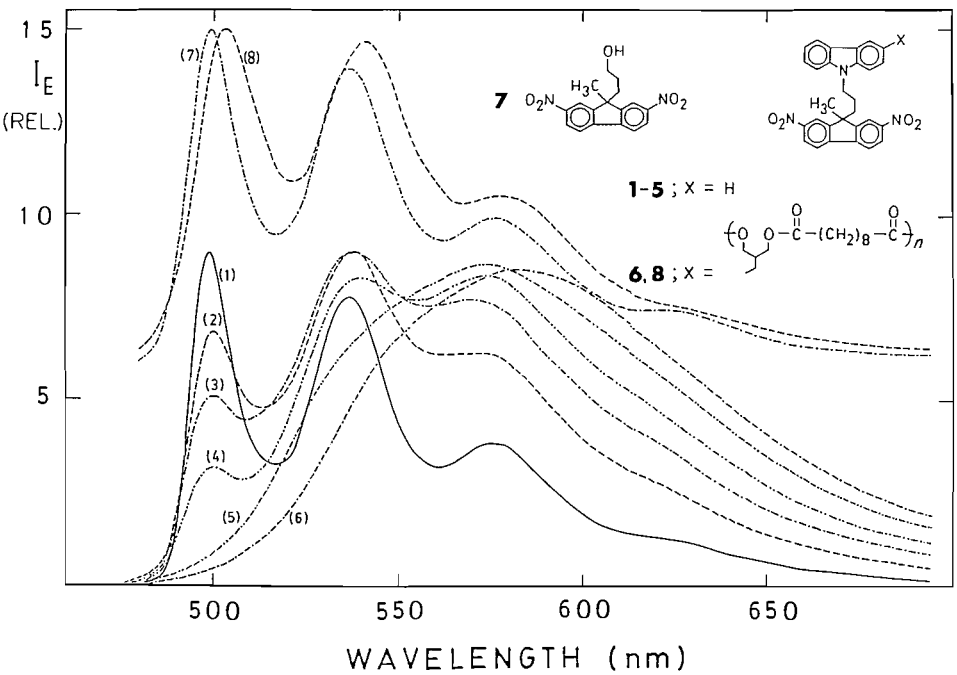

FIG. 9. Changes in the phosphorescence spectrum of bichromophore $\mathbf{B_1}$ in 3MP when concentration increases: (1) 1×10^{-6} M; (2) 1.66×10^{-6} M; (3) 2×10^{-6} M; and (4) 5×10^{-6} M; along with the solid state fluorescence spectra of (5) $\mathbf{B_1}$ and (6) polysebacate $\mathbf{P_1}$. Curves (7) and (8) refer to phosphorescence spectra of acceptor model $\mathbf{A_1}$ (1×10^{-6} M) and $\mathbf{P_1}$ (saturated solution) in 3MP at 77 K ($\lambda_{exc} = 360$ nm).

and the lowest vacant π-orbital of TNF. For *N*-ethylcarbazole ($\mathbf{D_1}$) the first two ionization potentials taken from the photoelectron spectra are $IP_1 = 7.41$ eV and $IP_2 = 7.96$ eV (15). In the absorption spectra of the TNF-D_1 system, the CT bands are at $\lambda_1 = 557$ nm and $\lambda_2 = 429$ nm in CH_2Cl_2 (14) and at $\lambda_1 = 550$ nm and $\lambda_2 = 470$ nm in tetrahydrofuran (14). These CT interactions are also observed in the bichromophoric compounds $\mathbf{B_2}$, $\mathbf{B_{2a}}$ and the polysebacate $\mathbf{P_2}$ dissolved in CH_3CN even if they are much weaker than in the intermolecular systems. Figure 10 shows the long-wavelength absorption bands of the electronic absorption spectra $\mathbf{B_2}$, $\mathbf{B_{2a}}$, and $\mathbf{P_2}$ along with the spectrum of the model electron-acceptor molecule $\mathbf{A_2}$ in an acetonitrile solution. These spectra indicate that $\mathbf{B_2}$, $\mathbf{B_{2a}}$, and $\mathbf{P_2}$ possess similar CT absorption bands with maxima at around 550 nm and 450 nm. $\mathbf{B_2}$ and $\mathbf{B_{2a}}$ show the same CT bands in the solid state. In these transparent films the CT electronic absorption spectra (Fig. 11) are shifted to lower energy and the corresponding maxima are at 590 nm and 470 nm respectively. Similar CT interactions in the

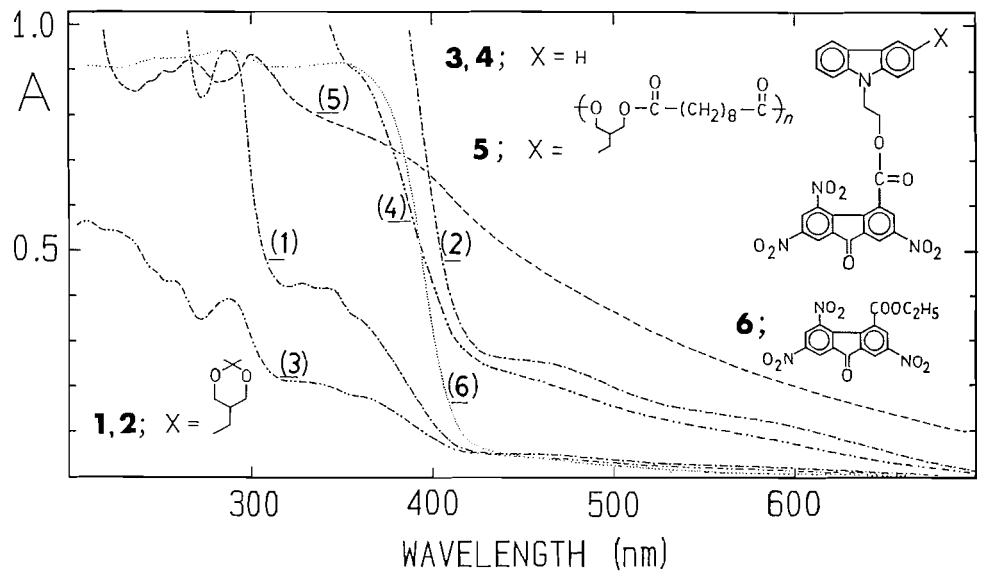

FIG. 11. Solid state electronic absorption spectra of $\mathbf{B_2}$: (1) at A and (2) at $A \times 5$; $\mathbf{B_{2a}}$: (3) at $A \times 2$ and (4) at $A \times 10$; as well as $\mathbf{P_2}$: (5) at $A \times 10$ and $\mathbf{A_2}$: (6) at $A \times 2$.

solid state would also be expected for the polysebacate $\mathbf{P_2}$ but it seems that the CT bands of $\mathbf{P_2}$ are hidden due to light scattering by the oligomer samples.

These absorption spectra (Figs. 10 and 11) strongly suggest the existence of molecular orbital overlap between the donor (carbazolyl) and the acceptor (2,4,7-trinitro-9-fluorenonyl) chromophores in the ground electronic states of the bichromophoric units in acetonitrile and also in the solid state. It is worth noting that these CT bands were never observed in the $\mathbf{B_1}$ and $\mathbf{P_1}$ electronic absorption spectra in acetonitrile or in the solid state.

Similarly as in $\mathbf{B_1}$ and $\mathbf{P_1}$, the fluorescence and the phosphorescence of the carbazolyl chromophore when excited are not observed in the bichromophoric compounds $\mathbf{B_2}$ and $\mathbf{B_{2a}}$ or in the polysebacate $\mathbf{P_2}$ in EPA or acetonitrile solutions. This indicates the strong intramolecular quenching effect of the singlet excited electronic state of the carbazolyl chromophore by the 2,4,7-trinitro-9-fluorenone chromophore. Considering the electron affinity of $\mathbf{A_2}$ as well as the singlet and the triplet energy levels of $\mathbf{A_2}$, which are of lower energy than the singlet and the triplet energy levels of $\mathbf{D_1}$ (see Table 4), we can expect two photoprocesses as quenching mechanisms in the bichromophoric systems when the donor is excited: the electron and (or) the energy transfer. However, this discussion would be irrelevant to the photoactivity experiment, where visible light is used and can only excite the acceptor moiety of the bichromophore. In such cases, no fluorescence of the 2,4,7-trinitro-9-fluorenone chromophore in $\mathbf{A_2}$ or in $\mathbf{B_2}$, $\mathbf{B_{2a}}$, and $\mathbf{P_2}$ has been observed. A weak phosphorescence emission of $\mathbf{A_2}$ in EPA at 77 K was detected with a quantum yield of 0.005. But this phosphorescence emission is completely quenched in $\mathbf{B_2}$, $\mathbf{B_{2a}}$, and $\mathbf{P_2}$. This quenching effect of the excited triplet state of the 2,4,7-trinitro-9-fluorenone chromophore might only be due to

the intramolecular electron transfer process in the singlet or in the triplet states of the acceptor moiety. Furthermore, $\mathbf{A_2}$ as well as $\mathbf{B_2}$, $\mathbf{B_{2a}}$, and $\mathbf{P_2}$ in the solid state also show very low structureless emissions between 500 nm and 680 nm with λ_{max} = 590 nm at λ_{exc} = 370 nm. Such emissions, which are about of the same intensity at room temperature and at 77 K, can be assigned as fluorescence from aggregates of the acceptor moieties. But these emissions are much lower (by a factor of about ten) for $\mathbf{B_2}$, $\mathbf{B_{2a}}$, and $\mathbf{P_2}$ than those for $\mathbf{B_1}$ and $\mathbf{P_1}$ (Fig. 9). This shows that the overlap between two acceptor moieties is much weaker in $\mathbf{B_2}$, $\mathbf{B_{2a}}$, and $\mathbf{P_2}$.

The above spectroscopic results on the polysebacates $\mathbf{P_1}$ and $\mathbf{P_2}$ clearly show that the spectroscopic properties in solution of the oligomers in the ground and in the excited electronic states are rather similar to those of the corresponding bichromophoric molecules $\mathbf{B_1}$, $\mathbf{B_2}$, or $\mathbf{B_{2a}}$. On the other hand it has been shown that, in the solid state, the oligomers and the bichromophores show some spectral properties that are assigned to aggregate formation between the acceptor moieties. This is another example where the effect of phase on the oligomer spectroscopy is important (17).

4. Electron transfer in the bichromophoric donor–acceptor system

The electrochemical measurements of the half-wave potentials of the oxidation of $\mathbf{D_1}$ and $\mathbf{D_2}$ and the reduction of $\mathbf{A_1}$ and $\mathbf{A_2}$ molecules in the ground electronic states, along with their lowest singlet and triplet excitation energy considering acetonitrile as a solvent, are presented in Table 4. These data were used to obtain the ΔG_{ET} values for the $\mathbf{D_1A_1}$, $\mathbf{D_2A_2}$, and $\mathbf{D_1A_2}$ system pairs from the Rehm–Weller equation (6, 18, 20) (see Table 5). As can be seen in the table the free-energy changes for the photoinduced electron transfer in all systems considered would be negative for perfect overlapping between the donor and the acceptors. In such donor–acceptor molecular systems, the electron transfer can then be represented by the following equation when the acceptor moiety alone is excited in its first electronic singlet and (or) triplet state:

$$\mathbf{D} + {}^{1,3}\mathbf{A}^* \rightarrow \mathbf{D}^{\cdot +} + \mathbf{A}^{\cdot -} \quad (\Delta G_{ET} < 0)$$

Table 5 also shows that the ΔG_{ET} values for the $\mathbf{D_2A_2}$ and $\mathbf{D_1A_2}$ systems are about the same and they are ~0.7 eV more negative than the corresponding ΔG_{ET} values for the $\mathbf{D_1A_1}$ system. Such a difference in the ΔG_{ET} is mainly due to the higher EA value of the $\mathbf{A_2}$ molecule as compared to that of the $\mathbf{A_1}$ molecule (see Table 4). The effect of intermolecular distances on the ΔG_{ET} values plays a minor role. The negative values of ΔG_{ET} in Table 5 indicate that intramolecular electron transfer in the bichromophoric compounds $\mathbf{B_1}$, $\mathbf{B_2}$, and $\mathbf{B_{2a}}$, which correspond to the $\mathbf{D_1A_1}$, $\mathbf{D_2D_2}$, and $\mathbf{D_1A_2}$ systems, is highly probable on the basis of thermodynamic grounds alone (19). When the acceptor chromophore is excited in its singlet state, the electron transfer photoprocess can then compete with the intersystem crossing process ($S_1 \rightsquigarrow T_1$) which is strongly allowed by the nitro substituents in the fluorene chromophore (21).

5. Conformational effect in B_1 and B_2

We previously reported (6) that, for the bichromophoric compound $\mathbf{B_1}$ in EPA solution, no intramolecular charge transfer or electron transfer interactions exist in the ground or in the excited electronic states even if $\Delta G_{ET} < 0$. $\mathbf{B_1}$ also behaves the same way in acetonitrile solutions. This might be explained by steric and conformational effects since the sp^3-hybridized carbon-9 in the fluorene chromophore is connected to the nitrogen atom in the carbazolyl chromophore through the propylene bridge, which prevents appropriate overlap of the chromophores (5).

Because of the sp^3-hybridization of the fluorene carbon-9, the sandwich conformation of the two chromophores in $\mathbf{B_1}$ (vertical distance of ~3.75 Å estimated from Dreiding models) should be unstable. We have shown (5) from crystalline structure that such a conformation of the bichromophoric molecule can easily change to the low-energy conformation with a center-to-center donor–acceptor distance of 6.1 Å with no ring orbital overlap.

The same sandwich conformation between the two carbazolyl chromophores in 1,3-bis(carbazolyl)-propane (22–26) is the low energy conformation with a distance of 2.5 Å between the chromophores (according to Dreiding models). The propylene bridge between the two *N*-carbazolyl groups in the 1,3-bis-(carbazolyl)propane creates convenient conditions for intramolecular charge-transfer interactions when one of the chromophores of the molecule is in the excited electronic state. For 1,3-bis(carbazolyl)propane, the low-energy sandwich excimers have been detected through the well-known structureless emission band at 420 nm. Such sandwich excimers can be formed directly or by reorientation of the high-energy excimers (λ_{max} = 375 nm) in which only one pair of phenyl rings from the two carbazolyl chromophores overlaps.

For the 1,3-bis(*N*-carbazolyl)propane molecule, the excimer emissions have been observed even if the carbazolyl chromophore is a poorer electron acceptor than 2,7-dinitrofluorene. Considering the sandwich conformation between the two chromophores in the bichromophoric molecule $\mathbf{B_1}$ as the proper conformation for intramolecular CT or ET interactions, this would mean that in the low energy conformation the center-to-center distance (6.1 Å in the crystal), along with the restricted mutual orientation between the chromophores, does not allow any electron transfer to take place.

The conformational effect of the chromophores in the bichromophoric molecule $\mathbf{B_2}$ is quite different than that in $\mathbf{B_1}$. The four-atom UV-transparent spacer in $\mathbf{B_2}$ connects the carbazolyl chromophore with the trinitrofluorenone chromophore at position 5 of the fluorenone aromatic ring. Such a connection between the chromophores in $\mathbf{B_2}$ allows for the existence of numerous conformers for the bichromophore. The highest available center-to-center chromophore–chromophore distance in a linear conformer of $\mathbf{B_2}$ is 9.4 Å. On the other hand, for the sandwich conformer of $\mathbf{B_2}$, assuming 100% of donor–acceptor molecular orbital overlap, the vertical distance between the chromophores would be 2.7 Å. These two conformers of $\mathbf{B_2}$, even sterically highly probable, seem to be the limiting cases in the spatial arrangements of the chromophores in the molecule. Indeed, from crystallographic studies of the solid state of $\mathbf{B_2}$, the lowest energy conformer of the bichromophoric molecule possesses about 50% of molecular orbital overlap between the donor and the acceptor chromophores separated by 3.42 Å. The center-to-center chromophore–chromophore distance in $\mathbf{B_2}$ has been measured as 5.75 Å.

From the crystallographic data alone, it is clear that the low energy conformer of $\mathbf{B_2}$ allows for intramolecular CT interactions between the chromophores. This is evidenced by the weak ground state CT electronic transitions observed in $\mathbf{B_2}$ in the solid state as well as in acetonitrile solutions. The acetal substituent at position 3 of the carbazolyl chromophore in $\mathbf{B_2}$ seems to play a minor role in the mutual orientation of the chromophores since the electronic absorption spectra of $\mathbf{B_{2a}}$ in the solid state and in acetonitrile solutions are similar to those for $\mathbf{B_2}$. Two other spectroscopic results might also be correlated to the conformational effect in the bichromophoric systems studied, and these are the phosphorescence quantum yields and the fluorescence spectra of the aggregates. As far as the phosphorescence quantum yield is concerned, it is the same for $\mathbf{B_1}$ and $\mathbf{A_1}$, whereas the phosphorescence of $\mathbf{A_2}$ is completely quenched in $\mathbf{B_2}$ or $\mathbf{B_{2a}}$ when exciting in the acceptor moiety alone. Since the energy transfer is forbidden from the acceptor to the donor, the electron transfer from the donor D to the excited singlet or triplet

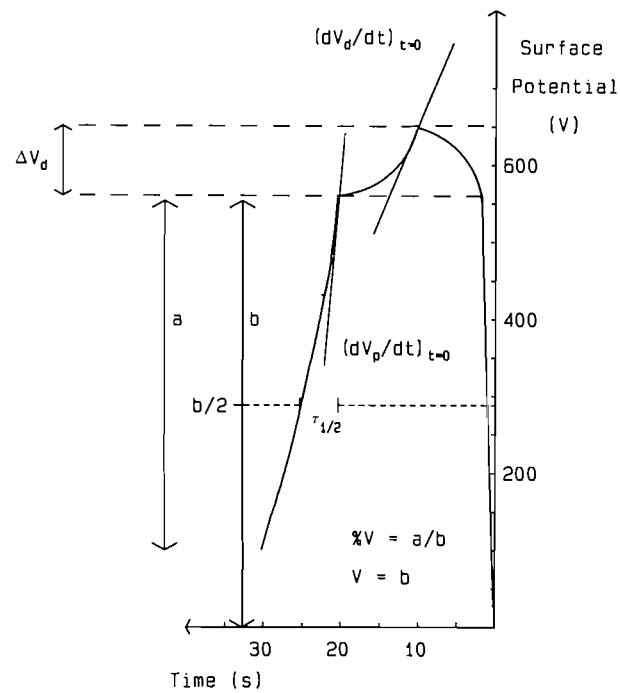

FIG. 12. Typical xerographic pattern and important quantities derivable from it.

of the acceptor A appears to be the only mechanism responsible for the phosphorescence quenching in $\mathbf{B_2}$ and $\mathbf{B_{2a}}$. On the other hand the fluorescence spectra of the aggregates in $\mathbf{B_1}$ are much stronger than in $\mathbf{B_2}$ or $\mathbf{B_{2a}}$, probably because the acceptor moiety in $\mathbf{B_1}$ is entirely free to interact with the other acceptors on other bichromophore units since practically no CT interactions (no orbital overlap) can occur between the donor and the acceptor in the same unit. All these spectroscopic results can be explained by the conformational effect discussed above.

6. Evaluation of photoactivity

The photoactivity of oligomers $\mathbf{P_1}$ and $\mathbf{P_2}$ was evaluated by

[d]Molar ratio 1:1.

the xerographic technique using a static charge analyzer (27). This apparatus allows the measurement of the surface potential decay as a function of time. The surface charge, either positive or negative, which is applied to the surface by a corona, is allowed to decay in the dark and its rate recorded; then, illumination with visible light gives rise to photosensitized decay, which is also recorded.

Since photoactivity is related to photoconductivity, which is a function of carrier generation efficiency and carrier mobility (27), it follows that, although the present xerographic evaluation of oligomers $\mathbf{P_1}$ and $\mathbf{P_2}$ cannot provide any separate information on the number of charge carriers and their mobility, an analysis of the shape of the xerographic decay curves and other quantities derived with respect to the other physical measurements already described above, and a comparison with an appropriate sample of the classic PVK–TNF system, should provide useful information that may be used in the design or optimization of future photoactive materials in this series.

Figure 12 represents a typical xerographic pattern, which can be analyzed in terms of its charge decay profile. The important quantities derivable are defined as follows:

$(dV_d/dt)_{t=0}$: the initial rate of surface potential decay in the dark.

$(dV_p/dt)_{t=0}$: the initial rate of surface potential decay under irradiation, after a period of dark decay.

$\tau_{1/2}$: the time required to reduce the initial surface potential to half its value.

$\%V$: the percentage of surface potential neutralized upon illumination for a time t.

ΔV_d: the surface potential lost (in volts) by dark decay after a time t.

A priori, favorable conditions for a good photoconductor are (a) a high initial surface potential, (b) a slow dark decay, (c) a fast initial rate of photosensitized decay, (d) a small $\tau_{1/2}$ value, (e) a short tailing of the decay curve, and (f) a large percentage of neutralized surface potential after illumination.

Evaluation of the first oligomer $\mathbf{P_1}$ reveals (Table 6) that, although it has excellent film forming properties and takes up negative charge very well, the material is nevertheless a very poor photoconductor relative to the standard PVK–TNF system. Indeed, for equivalent electric field charging ($d_{p2} \cdot V_{p1} = d_{p1} \cdot V_{p2}$, where d = film thickness), it has an initial rate of photosensitized surface potential decay 220 times slower than that of the reference (entries 1 and 7), a long half-life of the surface potential (≫ 10 s versus 0.25 s), and an almost negligibly small percentage (2.9%) of neutralized surface potential after illumination. As expected, maximum charging of the film (entry 2) improves performance markedly but, nevertheless, the material remains a relatively poor performer.

The main explanation for this behavior derives directly from the spectroscopic study, which showed an absence of charge transfer interaction in the pendant bichromophores of the oligomer $\mathbf{P_1}$ in the ground state. This then leaves only the long-wavelength absorption of the dinitrofluorenyl group, which tails in the visible, to serve as the only absorbing chromophore for the photosensitizing source used in the xerographic technique. These results are corroborated by the X-ray and spectroscopic study, which showed that in the single crystal and the aggregates of the oligomer, close interaction takes place between the acceptor chromophores but not between the donor and acceptor chromophores, most probably because of the sp^3 hybridized carbon at C-9 of the dinitrofluorenyl spacer and the three-carbon chain, which prevents good overlap between the donor and the acceptor. This morphology could perhaps be favorable to good electron mobility but not to electron transfer required for charge generation, in spite of the fact that the estimated ΔG_{ET} is less than zero for this donor–acceptor pair in close contact.

Evaluation of the second oligomer $\mathbf{P_2}$ reveals (Table 6) that the material is superior to $\mathbf{P_1}$ (compare, as above, entries 1 and 3) but still not a good photoconductor relative to PVK–TNF (see below). On the other hand, when the oligomeric film $\mathbf{P_2}$ is charged to its maximum, one again observes an enhanced performance (compare entries 3 and 5) but, relative to the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

standard PVK–TNF system, oligomer $\mathbf{P_2}$ remains a relatively poor photoconductor (compare entries 3 and 7). If the comparison was made at maximum charging (entries 5 and 7), it is evident that oligomer $\mathbf{P_2}$ would compare more favorably because of its greater electric field capacity. Comments regarding the general difference between $\mathbf{P_1}$, $\mathbf{P_2}$, and the PVK–TNF system will be deferred until the end of the present discussion.

In view of the above considerations it is concluded that the photoactivity results observed for oligomers $\mathbf{P_1}$ and $\mathbf{P_2}$ are largely explainable on the basis of the spectroscopic and X-ray crystallographic results reported herein. Indeed, the marked enhancement of photoactivity of oligomer $\mathbf{P_2}$ over $\mathbf{P_1}$ is most logically attributable to the charge transfer complex formation between the donor and acceptor chromophores observed in $\mathbf{P_2}$, which absorb in the visible. Also, the measured photoactivity correlates well with the observed complete quenching of the phosphorescence of the acceptor chromophore in $\mathbf{P_2}$ by an electron transfer mechanism (since energy transfer is not possible in this case), which generates the charge carriers for photoconduction. Finally, although the experiments performed do not give direct information on the nature of the charge carrier(s) and its (their) mobility, it is interesting to note that the structureless emission observed for $\mathbf{P_1}$ and $\mathbf{P_2}$ is due to aggregate fluorescence of the acceptor moieties, as could be anticipated from the X-ray data, which suggests the possibility that these oligomers could function preferentially as electron rather than hole conductors because of the propensity of the acceptor groups to associate and therefore favor the electron hopping process. This effect has been discussed previously (28, 29) and it appears that the formation of large aggregates is detrimental to good mobility because of phase separation, which causes deep traps at the amorphous–crystalline interface (30) and, of course, reduces the concentration of potential sites for charge migration.

An experimental test of the possibility that $\mathbf{P_1}$ and $\mathbf{P_2}$ may function better as electron rather than hole conductors is to compare the photoactivity characteristics of the systems upon positive charging of the films with those observed for negative charging (31) (see Table 6). It is apparent from the table that for equivalent electric field charging there is no significant difference in the case of oligomer $\mathbf{P_1}$ (entries 1 and 8). However, if the comparison was made at maximum charging (entries 2 and 9), positive charging gives a lower photoactivity, which is certainly attributable to the lower electric field capacity under positive polarity. In the case of oligomer $\mathbf{P_2}$, positive charging gives values approximately 10–20% lower for the initial rate of surface potential decay under irradition and percentage of surface potential neutralized (entries 3 and 10 or 4 and 11). The fact that $\mathbf{P_1}$ shows no difference depending on the sign of the surface charge, whereas $\mathbf{P_2}$ shows a slight decrease upon positive charging, suggests that oligomer $\mathbf{P_2}$ may, in fact, be a slightly better electron than hole conductor, not because of the propensity of its acceptor groups to associate as aggregates as in $\mathbf{P_1}$ (which shows no voltage polarity effect) but because of the formation of charge-transfer complexes (with the donor chromophores), which prevents their aggregation as crystallites as remarked by Loufty and Ong (29). This, in turn, should keep them relately free to participate in the hopping process for electron transport, whereas the donor chromophores, which are bound to both an acceptor and the backbone of the oligomer and which participate, in many cases, in charge transfer complexing, should be relatively more hindered in their donor–donor interactions for hole transport. It is important to recall here that, at least for PVK–TNF, hole transport appears to involve only noncomplexed carbazole groups, whereas electron transport occurs via both free and complexed TNF molecules (1*a*).

Finally, examination of the standard PVK–TNF system under negative and positive charging shows that photoactivity is lower, as seen by the initial rate of surface potential decay under irradiation, for positive charging than for negative charging (entries 6 and 12). As in the case of oligomer $\mathbf{P_2}$, this value is approximately 20% lower for positive charging. This phenomenon has been discussed by Pearson (1*a*) and appears to be due to the fact that "electron transport involves the LUMO orbitals of the acceptor chromophores which are more spatially delocalized than the bonding orbitals involved in hole transport in PVK and therefore can tolerate larger separation/perturbations without impacting the local electron transfer reactions". On the other hand, "hole transport is dependent on the overlap between the HOMO orbitals of the donor chromophores and all the results from the vinylcarbazole polymers and copolymers plus the PVK–TNF systems indicate that this overlap is very sensitive to perturbation, either morphological or from other chemical species, e.g. comonomers, end groups, dopants". As indicated above, hole transport appears to involve only noncomplexed carbazole groups whereas electron transport occurs via both free and complexed TNF molecules.

Now that the standard PVK–TNF system has been compared under negative and positive charging and pertinent literature discussion has been recalled, a comment regarding the great difference between the photoactivity of oligomers $\mathbf{P_1}$ and $\mathbf{P_2}$ and that of PVK–TNF would be in order. A priori, it would appear that four major factors could be at the origin of the difference observed: (1) a greater absorbance in the visible because of better donor–acceptor overlap due to the freedom of the acceptor chromophore, which would lead to more efficient charge-carrier generation; (2) a greater concentration of chromophores versus polymer backbone (one chromophore unit every third backbone atom in PVK compared to one chromophore unit every 16 backbone atoms in $\mathbf{P_2}$ or $\mathbf{P_1}$), which translates into a 95% chromophore loading for PVK–TNF compared to 78% for $\mathbf{P_2}$ and 75% for $\mathbf{P_1}$, and which should affect charge mobility through the bulk and also possibly charge-carrier generation; (3) a greater freedom of both chromophores to interact with chromophores of the same nature in the charge transport process; and (4) a greater charge mobility due to the much larger molecular weight of PVK, which means fewer chain ends that can act as traps. Although all of these factors most certainly contribute to various extents to the observed difference, a comparison of the absorption constants α (cm^{-1}) at 450 nm, where only the D,A charge transfer complexes absorb, reveals for films of the $\mathbf{P_2}$ oligomer and the 1:1 PVK–TNF system reported in the literature (32) that the absorption constant for the latter is about 10–20% greater than that for $\mathbf{P_2}$. This in itself should certainly make the first factor mentioned above the major contributor to the observed difference.

Further systematic work is in progress to better probe these and other new oligoesters with pendant donor–acceptor bichromophores, and will be reported in due course.

Experimental

Synthetic investigation

Melting points were determined on a Büchi apparatus and are uncorrected. Infrared spectra were taken in KBr pellets (unless otherwise specified) on a Perkin–Elmer apparatus, model 710-B or 783, using the 1601 cm^{-1} band of polystyrene as reference. High resolution mass spectra (EI) were recorded on an AEI MS-902 apparatus. The ^1H

NMR spectra were determined in deuterochloroform ($CDCl_3$) (unless otherwise indicated) using a Bruker WH-90 (90 MHz) spectrometer; the chemical shifts are expressed in ppm, downfield from tetramethylsilane (TMS), used as internal standard. The symbols s, d, dd, t, q, and m were respectively used for singlet, doublet, doublet of doublets, triplet, quartet, and multiplet. Number-average molecular weights, $\bar{M}_n$, and weight-average molecular weights, $\bar{M}_p$, were determined by GPC on a Waters model 510 apparatus using three Ultrastyragel columns in series, THF as eluant, and a Waters 410 differential refractometer; the calibration curve used was that of polystyrene. Glass temperatures (T_g) were measured on a Perkin– Elmer model DSC-4 apparatus equipped with a System 4 thermal analyser from Perkin–Elmer. Thin-layer chromatography (TLC) analyses were done on Merck, 0.2 mm, silica gel 60 F_{254} aluminum sheets and were visualized with UV light. Flash column chromatography was carried out on Merck 60 silica gel, 230–400 mesh. Microanalytical data were obtained from Guelph Chemical Laboratories Ltd., Guelph, Ont.

X-Ray investigation

Acceptor A_2

Crystals of the acceptor $\mathbf{A_2}$ were obtained from dichloromethane–methanol. They are tabular yellow-orange crystals. The unit-cell dimensions, given in Table 7 with other crystallographic data of interest, were obtained by least-squares fit to the angular settings of 25 well-centered reflections in the range $40 \leq 2\theta \leq 50°$. Intensity data were collected on a Nonius CAD4 diffractometer using copper (λCuK$\bar{\alpha}$ = 1.54178 Å), graphite-monochromatized radiation. The $\omega/2\theta$ scan mode was used with a scan range calculated by $\Delta\omega = (1.00 + 0.14 \tan\theta)°$. The intensities of seven reference reflections were monitored every hour while the orientation of the crystal was verified every 100 measurements, and readjustment was made when needed. The details of the data collections are placed in Table 7. Data reduction, i.e., scaling and Lorentz and polarization corrections, was performed, but no absorption correction was applied since the crystal is small and the absorption coefficient has a low value.

Bichromophore B_2

Crystals of the bichromophore $\mathbf{B_2}$ obtained from an acetonitrile solution are dark red. They are in the shape of very thin platelets. The unit-cell dimensions were obtained by least squares from angular data measured in the range $40 \leq 2\theta \leq 50°$. These and other crystal data are presented in Table 7. The data collection and reduction were obtained as for the acceptor $\mathbf{A_2}$. The bichromophore $\mathbf{B_2}$ crystallized with a molecule of solvent. Because of this, the data collection was done at 143 K. The structures were solved by direct methods using the multi-solution program MULTAN80 (33).

For the acceptor $\mathbf{A_2}$ the E-map computed for the set of phases corresponding to the highest figure of merit revealed all the non-hydrogen atoms. In the case of the bichromophore $\mathbf{B_2}$, it turned out that the crystal contains one molecule of acetonitrile, the crystallization solvent, for every molecule of bichromophore $\mathbf{B_2}$. This was only revealed near the end of the structure determination. The atomic coordinates and the anisotropic temperature of the non-hydrogen atoms were refined by least squares using the block-diagonal approximation (SHELX program (34)). For the acceptor $\mathbf{A_2}$ the coordinates and the isotropic temperature factors of the H atoms were refined except for those on C(16) and C(17), which were kept at a fixed position and given a U_{iso} value 0.125. In the case of the bichromophore $\mathbf{B_2}$, the coordinates of the solvent molecule were not refined. All the H atoms except those on C(38) and C(39) were refined.

The quantity minimized was $\Sigma w\Delta F^2$, where each reflection was assigned a weight $w = 1/\sigma^2(F_o)$. The final agreement indices[4] were $R_w = 0.047$ and $S = 2.052$ for the acceptor $\mathbf{A_2}$ and $R_w = 0.071$ and $S = 2.904$ for the bichromophore $\mathbf{B_2}$. The average and largest para-

[4] $R_w = [\Sigma w\Delta F^2/\Sigma wF_0]^{1/2}$; $S = [\Sigma w\Delta F^2/(m - n)]^{1/2}$.

For personal use only.

meter shifts of the atomic coordinates and temperature factors were 0.04, 0.33, and 0.03, 0.09 for the acceptor $\mathbf{A_2}$ and the bichromophore $\mathbf{B_2}$ respectively. The final difference Fourier syntheses showed no significant residual electron density, the extreme fluctuations being in the range ± 0.25 e $Å^{-3}$ (acceptor $\mathbf{A_2}$) – ± 0.36 e $Å^{-3}$ (bichromophore $\mathbf{B_2}$). The X-ray scattering factors were taken from ref. 35 for O, N, and C atoms and from ref. 36 for H atoms.

Spectroscopic investigation

Materials

N-Ethylcarbazole ($\mathbf{D_1}$), γ-hydroxypropylmethyldinitrofluorene $\mathbf{A_1}$, and bichromophore $\mathbf{B_1}$ were synthesized and purified as described previously (5). Donor model $\mathbf{D_2}$, acceptor model $\mathbf{A_2}$, bichromophores $\mathbf{B_2}$ and $\mathbf{B_{2a}}$, and polysebacates $\mathbf{P_1}$ and $\mathbf{P_2}$ were synthesized, purified, and characterized as reported herein.

Acetonitrile, 99%, spectrophotometric grade, was obtained from Aldrich Chemical Co. and was distilled before use. 3-Methylpentane (3MP), pure grade (99%) from Phillips Petroleum Co., was further purified as described previously (5). Isopentane, of pure grade quality from Phillips Petroleum Co., and ethyl ether are analyzed reagents from Baker and were purified in the same way as 3MP. Ethanol was purified by refluxing with concentrated sulfuric acid (4 mL H_2SO_4/1000 mL solvent) for 24 h and then distilled twice before use. The EPA solvent mixture was made from ethyl ether, isopentane, and ethanol in the volume ratio 5:5:2 respectively.

Apparatus

The absorption spectra were recorded by means of a Cary-17 spectrophotometer and a PU 8800 UV/VIS spectrophotomer (Phillips) using 1.0, 1.3, and 5 cm quartz cells. Quartz plates were used to measure the absorption spectra of solids. The low temperature Dewar, including a 1.3 cm quartz cell, was designed and built in our laboratory. Liquid nitrogen and also a mixture of propionitrile–*n*-butyronitrile (1.1 v/v) cooled by liquid nitrogen were used to stabilize the temperature in the range 296–77 K for the solutions studied. The temperatures of the solutions and the solvent were measured in the cell with a calibrated copper–constantan thermocouple with an accuracy of ±0.5 K.

Phosphorescence spectra along with phosphorescence excitation spectra were recorded on a Spex Fluorolog fluorometer model 1902 using a cylindrical Dewar assembly.

Relative fluorescence and phosphorescence quantum yields were measured and calculated by means of the Spex Fluorolog – Nova 3/12 minicomputer couple system using a FORTRAN program called SURFREND. Carbazole (**17**) was used as the fluorescence quantum yield standard. To check the system, the fluorescence quantum yields of carbazole (**17**) and *N*-ethylcarbazole ($\mathbf{D_1}$) in ethanol glasses were reproduced (8).

Electrochemical investigation

Electrochemical measurements were made using an EG&G Princeton Applied Research model 264 polarographic analyzer/stripping voltammeter. Linear sweep voltammograms (LSV) were recorded on a 7005 B *X–Y* recorder (Hewlett–Packard); the current varied between 1 and 50 μA. Voltage sweep rate was 5 mV/s. Oxidations were measured using a platinum disk electrode rotated at 20 rpm. Reduction potentials were measured using a dropping mercury working electrode (EG&P PARC model 303 static mercury drop electrode assembly); droptime was 0.5 s. LSV and polarograms were measured in the differential pulse mode; pulse amplitude was 20–50 mV. Potentials were measured against an Ag/AgCl reference electrode; a platinum wire was used as auxiliary electrode. Tetraethylammonium perchlorate (TEAP) (0.05 M) in acetonitrile was the supporting electrolyte. Solutions of the electron donor (10^{-4} M) to which the supporting electrolyte had been added were deaerated using dry nitrogen gas; purge time was 4 min. A nitrogen blanket was maintained above the solutions during electrometric measurements.

Photoactivity investigation

Photoconducting films were prepared by the following method. Under reduced light, the polymer was weighed in a brown bottle and appropriate solvent was added (dichloromethane for polymer $\mathbf{P_1}$ and dioxane for polymer $\mathbf{P_2}$). The solution contained 15% by weight of the solids for polymer $\mathbf{P_1}$ and 10% by weight for polymer $\mathbf{P_2}$. The solution was stirred overnight, then manually cast over an aluminum sheet (3-1/3 in. × 8 in., Western DP plates, brush grained) with a multiple-clearance film applicator (2 in. × 2 in.). The film obtained was dried in air overnight in the dark and in an oven at 125°C for 20 min and punched to give disks (diameter of 1 in.). The thickness of the film was measured with a coating thickness tester (Dermitron D-9).

Film photoactivity was evaluated by using a static charge analyzer (Monroe no. 276A), which has a tungsten lamp (GE no. 1076) as light source. Xerographic patterns were obtained and the quantities $(dV_d/dt)_{t=0}$, $(dV_p/dt)_{t=0}$, $\tau½$, $\%V$, and ΔV_d derived from them (Table 6).

N-*Benzylcarbazole-3-carboxaldehyde (2) (ref. 37)*

In a preliminary step, the imidoyl halide is prepared by treating, under argon and at 0°C, *N*,*N*-dimethylformamide (1.50 g, 0.0205 mol) with phosphorus oxychloride (4.0 mL, 0.043 mol) and stirring for 1 h. The mixture is then heated on an oil bath at 45°C and treated, over a 1 h period, with *N*-benzylcarbazole (**1**) (38) (5.00 g, 0.0194 mol); towards the end of the addition, the reaction mixture, which becomes solid, is heated at 95–100°C overnight.

The reaction mixture is treated with 10 mL of water, then transferred to a beaker and the volume increased to approximately 100 mL with water. The mixture is stirred overnight at about 40°C. The precipitate is filtered, washed generously with water, and dried in air to give 5.9 g of crude product. Recrystallization from 95% ethanol yields the desired formyl derivative **2** (5.08 g, 92%) in the form of a slightly beige solid; R_f 0.66 (30% ethyl acetate – 70% hexane); mp 131.5–132.5°C; IR:710, 740, 810, 1130, 1330, 1590, 1680, 2725, and 2800 cm^{-1}; NMR δ: 5.28 (s, 2H), 6.94–7.39 (m, 9H), 7.83 (dd, 1H), 8.04 (dd, 1H), 8.46 (d, 1H), and 9.96 (s, 1H). Exact mass calcd. for $C_{20}H_{15}NO$: 285.1153; found: 285.1158.

*Ethyl 2-carbethoxy-3-(*N*-benzyl-3-carbazolyl)propenoate (3)*

A solution of *N*-benzylcarbazole-3-carboxaldehyde (**2**) (4.28 g, 0.0150 mol), diethyl malonate (2.40 g, 0.0150 mol), acetic acid (0.30 mL), and piperidine (0.09 mL) in 10 mL anhydrous benzene is heated to reflux for 20 h in a Dean-Stark apparatus where the water separator tube is filled with benzene and 3Å molecular sieves.

The mixture is cooled and transferred to a separatory funnel with 30 mL of benzene. The organic phase is washed twice with 40 mL of saturated aqueous sodium bicarbonate solution, twice with 40 mL of brine, and then dried over magnesium sulfate. Evaporation of the solvent *in vacuo* gives a crude solid. Recrystallization in 95% ethanol yields a yellow solid (5.79 g, 90%); R_f 0.64 (30% ethyl acetate – 70% hexane); mp 126.5–127.5°C; IR: 810, 1150, 1160, 1180, 1210, 1230, 1260, 1480, 1500, 1600, 1620, and 1720 cm^{-1}; NMR δ: 1.34 (t, 6H), 4.32 (q, 2H), 4.41 (q, 2H), 5.50 (s, 2H), 7.12–7.61 (m, 10H), 7.93 (s, 1H), 8.08 (dd, 1H), and 8.26 (d, 1H). Exact mass calcd. for $C_{27}H_{25}NO_4$: 427.1783; found: 427.1777.

*Ethyl 2-carbethoxy-3-(*N*-benzyl-3-carbazolyl)propionate (4)*

A suspension of ethyl 2-carbethoxy-3-(*N*-benzyl-3-carbazolyl) propenoate (**3**) (5.50 g, 0.0129 mol) and 10% palladium on charcoal (280 mg) in ethyl acetate (75 mL) is stirred overnight while hydrogen is bubbled gently through the solution. Argon is then bubbled through the solution to displace the remaining hydrogen and the suspension is filtered over Celite. The precipitate is washed generously with ethyl acetate and the solvent evaporated *in vacuo* to yield a white solid (5.60 g, quantitative yield); R_f 0.58 (30% ethyl acetate – 70% hexane); mp 58–60°C; IR: 1150, 1220, 1290, and 1730 cm^{-1}; NMR δ: 1.18 (t, 6H), 3.40 (d, 2H) 3.66–3.83 (m, 1H), 4.15 (q, 4H), 5.47 (s, 2H), 7.03–7.43 (m, 10H), 7.96 (s, 1H), and 8.08 (d, 1H). Exact mass calcd. for $C_{27}H_{27}NO_4$: 429.1940; found: 429.1887.

*2-Hydroxymethyl-3-(*N*-benzyl-3-carbazolyl)propanol (5)*

Under inert atmosphere, a suspension of lithium aluminum hydride (0.76 g, 0.020 mol) in anhydrous THF (10 mL) is prepared and cooled to 0°C. The latter is treated at 0°C, over a period of 30 min, with a solution of ethyl 2-carbethoxy-3-(*N*-benzyl-3-carbazolyl) propionate (**4**) (4.29 g, 0.0100 mol) in dry THF (12 mL) and the reaction mixture

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

heated to reflux for 3 h. The mixture is cooled to 0°C and treated dropwise in sequence with cooled distilled water (0.75 mL), 10% aqueous sodium hydroxide (0.75 mL), and distilled water (2.25 mL). The salts are filtered over fritted glass and the solids washed repeatedly with THF. The combined organic solutions are dried over anhydrous sodium sulfate, filtered, and evaporated *in vacuo*. The residue obtained is recrystallized from 95% ethanol–ether to yield a white solid (3.08 g, 89%); R_f 0.52 (ethyl acetate); mp 121.5–122°C; IR: 740. 1040, 1330, 1450, 1460, 1490, and 3300 cm^{-1}; NMR δ: 2.14 (m, 1H), 2.34 (br s, 2H), 2.78 (d, 2H), 3.75 (br d, 4H), 5.47 (s, 2H), 7.05–7.43 (m, 10H), 7.92 (s, 1H), and 8.09 (d, 1H). Exact mass calcd. for $C_{23}H_{23}NO_2$: 345.1729; found: 345.1740.

*2-Hydroxymethyl-3-(3-carbazolyl)propanol (**6**)*

Under inert atmosphere, a solution of 2-hydroxymethyl-3-(*N*-benzyl-3-carbazolyl) propanol (**5**) (0.450 g, 0.00130 mol) is prepared in dry THF (7 mL) and added at −78°C to distilled liquid ammonia (25 mL) contained in a three-necked flask equipped with a Dry Ice – acetone condenser. The mixture is treated with tiny, hexane-rinsed, pieces of metallic sodium (0.120 g, 0.0052 mol) and the cooling bath removed to accelerate the discharge of the blue color. After 15 min, the reaction mixture is again cooled to −78°C and again treated with metallic sodium (0.060 mg, 0.0026 mol); once again the cooling bath is removed and, after 2 h, TLC analysis shows that the reaction is complete. After an additional hour, the mixture is cooled to −78°C and treated with ammonium chloride. The ammonia is allowed to evaporate overnight, the residual mixture treated with distilled water (20 mL), and most of the THF contained in the mixture evaporated *in vacuo*. The remaining reaction mixture is saturated with sodium chloride and extracted with ethyl acetate (3 × 25 mL). The organic phase is dried over anhydrous magnesium sulfate, filtered, and evaporated *in vacuo* to yield a yellowish solid (0.315 g), which is a mixture of the desired debenzylated carbazole derivative **6** and some debenzylated material where the carbazole ring system is partially reduced.

To minimize loss of material, the crude product (0.315 g) is treated for 3 h under inert atmosphere with 10% palladium on charcoal (60 mg) in 0.6 mL of anhydrous refluxing 1,3,5-trimethylbenzene. The catalyst is filtered on Celite and washed generously with THF. The organic phase is evaporated *in vacuo* and the residue (0.288 g) recrystallized from ethanol–water to yield a white solid (0.225 g, 68%) (yields are generally higher on larger scales); R_f 0.43 (ethyl acetate); mp 147–149°C; IR: 750, 1030, 1240, 1450, 1470, 3350, and 3400 cm^{-1}; NMR (acetone-d_6) δ: 2.02 (m, 1H, visible only in CD_3OD), 2.81 (d, 2H), 3.67 (d, 4H), 7.05–7.55 (m, 5H), 7.96 (s, 1H), 8.09 (d, 1H), and 10.22 (m, 1H). Exact mass calcd. for $C_{16}H_{17}NO_2$: 255.1259; found: 255.1216.

*5-(3-Carbazolylmethyl)-2,2-dimethyl-1,3-dioxane (**7**)*

A mixture of 2-hydroxymethyl-3-(3-carbazolyl) propanol (**6**) (0.201 g, 0.787 mmol), *p*-toluenesulfonic acid monohydrate (19 mg, 0.10 mmol), 3 Å (a dozen granules) molecular sieves, and Spectrograde acetone (10 mL) is prepared and stirred under inert atmosphere for 24 h. Triethylamine (3 drops) is added and the mixture stirred for an additional hour. The reaction mixture is filtered over Celite and the solvent evaporated *in vacuo*. Flash chromatography (20% ethyl acetate – 80% hexane; for large scale preparation, a solvent gradient of dichloromethane to 10% ethyl acetate – 90% dichloromethane is used) of the crude product gives a white solid (0.194 g, 83%); R_f 0.22 (20% ethyl acetate – 80% hexane); mp 135.5–136.5°C; IR: 750, 810, 830, 1070, 1130, 1150, 1200, 1250, 1260, 1380, 1390, and 3400 cm^{-1}; NMR δ: 1.43 and 1.48 (2s, 6H), 2.16 (m,1H), 2.77 (d, 2H), 3.58–4.00 (m, 4H), 7.12–7.42 (m, 5H), 7.85 (s, 1H), and 8.04 (d, 1H). Exact mass calcd. for $C_{19}H_{21}NO_2$: 295.1572; found: 295.1547.

*Bichromophore **9***

Under inert atmosphere, freshly washed (pentane) 60% sodium hydride (0.500 g, 0.0125 mol) is treated with a solution of 5-(3-carbazolylmethyl)-2,2-dimethyl-1,3-dioxane (**7**) (1.22 g, 0.00413 mol) in dry THF (25 mL). Vigorous liberation of hydrogen takes place at first, then the mixture is stirred for 15 min and heated to reflux for 30 min. The pink solution is cooled to room temperature and treated over a 30 min period with a solution of 9-(3-bromopropyl)-9-methyl-2,7-dinitrofluorene (**8**) (1.70 g, 0.00435 mol) in dry THF (25 mL). The reaction mixture, which goes from pink to green to brown during the addition, is treated with a solution of HMPA (0.70 mL, 0.0038 mol) in dry THF (15 mL) and left stirring for 20 h. A solution of cold 3.3% hydrochloric acid (45 mL) is carefully added and the mixture stirred for 1.5 h, after which time it is neutralized with 10% aqueous sodium bicarbonate and stirred again for 1 h. Evaporation *in vacuo* of the THF leaves an aqueous mixture, which is diluted with 50 mL distilled water and extracted with dichloromethane (3 × 100 mL). The organic phase is washed with brine (2 × 200 mL), dried over anhydrous magnesium sulfate, and evaporated *in vacuo*, to yield a crude product (2.9 g), which is flash chromatographed (solvent gradient: dichloromethane to 3% methanol – 97% dichloromethane) to yield a yellow solid (1.79 g, 77%); R_f 0.34 (ethyl acetate); mp 118–122°C; IR: 740, 1020, 1340, 1470, 1480, 1520, and 3400 cm^{-1}; NMR δ: 1.10–1.34 (m, 2H), 1.46 (s, 3H), 2.04–2.32 (m, 5H), 2.79 (d, 2H), 3.72–3.92 (m, 4H), 4.06 (t, 2H), 6.85–7.40 (m, 5H), and 7.80–8.30 (m, 8H). Exact mass calcd. for $C_{33}H_{31}N_3O_6$: 565.2212; found: 565.2189. Anal. calcd. for $C_{33}H_{31}N_3O_6$: C 70.08, H 5.52, N 7.43; found: C 69.76, H 5.42, N 7.40.

Oligomer P_1

A solution of bichromophore **9** (1.00 g, 0.00177 mol) in dry 1,2-dichloroethane (5.0 mL) and dry triethylamine (0.50 mL, 0.0036 mol) is treated, at 0°C under inert atmosphere and over a 45 min period, with a cooled solution of sebacoyl chloride (0.43 g, 0.0018 mol) in dry 1,2-dichloroethane (7.0 mL). The ice bath is removed and the reaction mixture stirred for 90 min, after which time it is taken up in 1,2-dichloroethane (approximately 20 mL) and washed with distilled water (20 mL). The organic phase is dried over anhydrous magnesium sulfate and concentrated *in vacuo* to approximately one half its volume, after which it is precipitated by dropwise addition, over a 1 h period, to a large volume of hexanes (200 mL). The precipitated oligomer is then stirred overnight in the solvent mixture and the latter decanted. The oligomer is taken up in 1,2-dichloroethane and placed in a round-bottom flask where the solvent is evaporated *in vacuo* to yield an orange solid (1.20 g, 93%); $\overline{M}_n$ 4964; $\overline{M}_w$ 13584; $\overline{DP}_w$ 18.6; T_m 99°C; T_g 85.5°C; IR: 740, 1170, 1350, 1520, 1730, 2850, and 2925 cm^{-1}; NMR δ: 1.20 (m, 2H), 1.30 and 1.40 (2s, 8H), 1.44 (s, 3H), 1.62 (m, 4H), 1.90–2.65 (m, t, 7H), 2.85 (d, 2H), 4.09 (d, deformed, 6H), 6.87–7.37 (m, 5H), and 7.76–8.26 (m, 8H). Anal. calcd. for $C_{43}H_{45}N_3O_8$: C 70.57, H 6.20, N 5.74; found: C 70.12, H 6.52, N 5.50.

*Ethyl-2-carbethoxy-3-(N-ethylcarbazolyl)propenoate (**11**)*

The title compound **11** is prepared by the same method as described for compound **3**. The following amounts were used: *N*-ethylcarbazole-3-carboxaldehyde (**10**) (6.70 g, 0.0300 mol) (obtained from Aldrich Chemical Co. and recrystallized in 95% ethanol), diethyl malonate (4.81 g, 0.0300 mol), acetic acid (0.60 mL), and piperidine (0.18 mL) in 8 mL of anhydrous benzene. Recrystallization in 95% ethanol yields a yellow solid (9.35 g, 85%); R_f 0.37 (30% ethyl acetate – 70% hexane); mp 98–99°C; IR: 820, 1130, 1170, 1180, 1220, 1240, 1260, 1480, 1600, 1620, and 1720 cm^{-1}; NMR δ: 1.35 (t, 6H), 1.39 (t, 3H), 4.29 (q, 2H), 4.32 (q, 2H), 4.43 (q, 2H), 7.15–7.63 (m, 5H), 7.93 (s, 1H), 8.03 (d, 1H), and 8.20 (d, 1H). Exact mass calcd. for $C_{22}H_{23}NO_4$: 365.1627; found: 365.1634.

*Ethyl-2-carbethoxy-3-(N-ethyl-3-carbazolyl)propionate (**12**)*

The title compound (**12**) is prepared by the same method as described for compound **4**. The following amounts were used: ethyl 2-carbethoxy-3-(*N*-ethyl-3-carbazolyl)propenoate (**11**) (9.00 g, 0.0246 mol) and 10% palladium on charcoal (450 mg) in 100 mL of ethyl acetate. Evaporation of solvent yields a white solid (9.10 g, quantitative yield; R_f 0.46 (30% ethyl acetate – 70% hexane); mp 47–49°C; IR: 1150, 1230, and 1740 cm^{-1}; NMR δ: 1.19 (t, 6H), 1.39 (t, 3H), 3.42 (d, 2H), 3.67–3.84 (m, 1H), 4.16 (q, 4H), 4.32 (q, 2H), 7.05–7.55 (m, 5H), 7.93 (s, 1H), and 8.06 (d, 1H). Exact mass calcd. for $C_{22}H_{25}NO_4$: 367.1783; found: 367.1887.

2-Hydroxymethyl-3-(N-ethyl-3-carbazolyl)propanol (13)

The title compound (**13**) is prepared by the same method as described for compound **5**. After destruction of the excess of hydride, the salts are filtered over fritted glass and the solids washed once with THF. The organic phase is evaporated *in vacuo* and the residue recrystallized from ethanol–water to yield a white solid (2.47 g, 87%); R_f 0.28 (ethyl acetate); mp 117.5–119°C; IR: 750, 1040, 1240, 1480, 1490, and 3300 cm^{-1}; NMR δ: 1.42 (t, 3H), 2.24 (m, 3H), 2.80 (d, 2H), 3.61–3.96 (m, 4H), 4.34 (q, 2H), 7.11–7.48 (m, 5H), 7.90 (s, 1H), and 8.07 (d, 1H). Exact mass calcd. for $C_{18}H_{21}NO_2$: 283.1572; found: 283.1572.

5-(N-Ethyl-3-carbazolylmethyl)-2,2-dimethyl-1,3-dioxane (D_2)

The title compound $\mathbf{D_2}$ is prepared by the same method as described for compound **7** using 2-hydroxymethyl-3-(*N*-ethyl-3-carbazolyl)propanol (**13**) as starting material. Flash chromatography (25% ethyl acetate – 75% hexane) of the crude product yields a white solid (0.512 g, 90%); R_f 0.33 (25% ethyl acetate – 75% hexane); mp 77.5–80.5°C; IR ($CHCl_3$): 1070, 1150, 1200, 1230, 1370, 1380, 1470, and 1490 cm^{-1}; NMR δ: 1.20 (t, 3H), 1.42 and 1.47 (2s, 6H), 2.23 (m, 1H), 2.78 (d, 2H), 3.57–3.99 (m, 4H), 4.32 (q, 2H), 7.13–7.45 (m, 5H), 7.87 (s, 1H), and 8.07 (d, 1H). Exact mass calcd. for $C_{21}H_{25}NO_2$: 323.1885; found: 323.1879.

5-(N-β-Hydroxyethyl-3-carbazolylmethyl)-2,2-dimethyl-1,3-dioxane (14)

At 0°C, a solution of 5-(3-carbazolylmethyl)-2,2-dimethyl-1,3-dioxane (**7**) (3.63 g, 0.0123 mol) and potassium hydroxide powder (0.69 g, 0.0123 mol) in 8.0 mL anhydrous butanone is treated with cold ethylene oxide (0.62 mL, 0.0123 mol). The reaction mixture is stirred for 15 min, heated at 55°C for 3 h, then treated again with potassium hydroxide powder (0.070 g, 0.0012 mol) and cold ethylene oxide (0.05 mL, 0.001 mol) and stirred at the same temperature for 1 h. The red solution is cooled, treated with water (10 mL), and evaporated *in vacuo*. The aqueous phase is extracted with ether (6 × 15 mL). The organic phase is washed with brine (2 × 35 mL), dried over sodium sulfate, and evaporated *in vacuo*. The crude oil is flash chromatographed (solvent gradient: 60% ethyl acetate – 40% hexane to ethyl acetate) to yield the starting material (0.54 g, 15%), the desired product (compound **14**) as a white solid (2.84 g, 68%), and a yellowish oil (0.51 g, 11%) (identified as 5-(*N*-β-hydroxyethyloxyethyl-3-carbazolylmethyl)-2,2-dimethyl-1,3-dioxane (**14***a*)). (a) Compound **14**: R_f 0.39 (60% ethyl acetate – 40% hexane); mp 49–51°C; IR: 745, 825, 1070, 1200, 1470, 1490, and 3440 cm^{-1}; NMR δ: 1.35–1.41 (2s, 6H), 2.08 (m, 1H), 2.31 (s, 1H), 2.70 (d, 2H), 3.57–3.91 (m, 6H), 4.29 (t, 2H), 7.11–7.40 (m, 5H), 7.81 (s, 1H), and 8.01 (d, 1H). Exact mass calcd. for $C_{21}H_{25}NO_3$: 339.1834; found: 339.1823. (b) Compound **14***a*: R_f 0.24 (60% ethyl acetate – 40% hexane); IR (film): 730, 745, 825, 1075, 1130, 1200, 1470, 1490, and 3440 cm^{-1}; NMR δ: 1.42 and 1.48 (2s, 6H), 1.61 (s, 1H), 2.17 (m, 1H), 2.78 (d, 2H), 3.43–3.93 (m, 10H), 4.49 (t, 2H), 7.12–7.65 (m, 5H), 7.87 (s, 1H), and 8.06 (d, 1H). Exact mass calcd. for $C_{23}H_{29}NO_4$: 383.2097; found: 383.1996.

2,5,7-Trinitrofluorenonecarboxylic acid chloride (15)

A solution of 2,5,7-trinitrofluorenonecarboxylic acid (39) (2.70 g, 0.00752 mol) in 35 mL thionyl chloride is heated to reflux overnight. The black solution is distilled *in vacuo* and the crude solid obtained recrystallized from toluene, then dried in an Abder–Alden apparatus (P_2O_5, 5×10^{-2} Torr (1 Torr = 133.3 Pa), water) to yield a yellow solid (2.52 g, 89%); mp 193.5–196°C; IR: 690, 730, 760, 790, 835, 1345, 1535, 1590, 1615, and 1740 cm^{-1}; NMR (acetone-d_6) δ: 8.84 (d, 2H), 9.04 (d, 1H), and 9.11 (d, 1H).

Bichromophore B_2

Under inert atmosphere, a suspension of 5-(3-carbazolylmethyl)-2,2-dimethyl-1,3-dioxane (**7**) (0.90 g, 0.00265 mol) and 2,5,7-trinitrofluorenonecarboxylic acid chloride (**15**) (1.05 g, 0.00278 mol) in anhydrous dichloromethane (25 mL) is prepared and cooled to 0°C. The latter is treated at 0°C, over a 10 min period, with anhydrous triethylamine (0.41 mL, 0.00295 mol). The red-brown solution is stirred and allowed to warm up to room temperature over a period of 2.5 h, during which time a brown solid precipitates. The reaction mixture is then transferred to a separatory funnel with 40 mL of saturated aqueous sodium bicarbonate solution, extracted once, decanted, and concentrated *in vacuo*. The resulting suspension is filtered and the crude solid washed with water and dried in air to yield a brown solid (1.75 g, 97%). A sample is recrystallized from acetonitrile; R_f 0.59 (15% ethyl acetate – 85% dichloromethane); mp 256–257°C; IR: 1070, 1090, 1155, 1175, 1200, 1280, 1345, 1545, and 1740 cm^{-1}; NMR (benzene-d_6) δ: 1.45 and 1.47 (2s, 6H), 2.00 (m, 1H), 2.61 (d, 2H), 3.43–3.87 (m, 6H), 4.30 (t, 2H), 6.89–7.27 (m, 5H), 7.71 (s, 1H), 7.78 (d, 1H), 7.84 (br s, 1H), 7.94 (d, 1H), 8.07 (d, 1H), and 8.13 (d, 1H). Exact mass calcd. for $C_{35}H_{28}N_4O_{11}$: 680.1754; found: 680.1574. Anal. calcd. for $C_{37}H_{31}N_5O_{11}$: C 61.58, H 4.33, N 9.70; found: C 61.51, H 4.42, N 9.51.

Bichromophore 16

A solution of bichromophore $\mathbf{B_2}$ (1.75 g, 0.00257 mol) in 45 mL of 2:1 (v/v) THF – 10% HCl solution is heated to reflux for 15 min and cooled to room temperature. The THF is evaporated *in vacuo* and the resulting suspension filtered; the brown solid is then washed with water, dried in air, and stirred with Spectrograde methanol (60 mL) for 3 days. The suspension is filtered and the crude solid washed with methanol and dried in air to yield a brown solid (1.37 g, 83%); R_f 0.33 (ethyl acetate); mp 236.5–237.5°C; IR: 1025, 1345, 1470, 1540, 1595, 1620, 1740, and 3430 cm^{-1}; NMR (DMSO-d_6) δ: 1.78 (m, 1H), 2.66 (d, 2H), 3.40 (d, 4H), 4.40 (t, 2H), 4.65 (br s, 4H), and 6.97–7.94 (m, 11H). Anal. calcd. for $C_{32}H_{24}N_4O_{11}$: C 60.00, H 3.78, N 8.75; found: C 60.44, H 4.27, N 9.28.

Oligomer P_2

Under inert atmosphere, bichromophore **16** (0.213 g, 0.333 mmol) and sebacoyl chloride (0.081 g, 0.34 mmol) are heated gradually on an oil bath to 180°C for 90 min. Then the reaction mixture is evacuated to 0.01 Torr for 2 h, cooled to room temperature, treated once more with sebacoyl chloride (0.020 g, 0.084 mmol), heated to 170°C for 1 h, and again cooled to room temperature. The crude oligomer is dissolved in dioxane (5 mL) and the resulting solution filtered over cotton wool and precipitated by dropwise addition to a large volume of methanol (100 mL). The purified oligomer, isolated by centrifugation, is then dried in air to yield a grey solid (0.120 g, 45%); $\overline{M}_n$ 2934; $\overline{M}_w$ 6150; $\overline{DP}_w$ 7.6; T_m 78°C; T_g 54.5°C; IR: 1090, 1155, 1175, 1345, 1470, 1540, 1545, 1595, 1615, and 1740 cm^{-1}; NMR (pyridine-d_5) δ: 1.28 (br s, 8H), 1.71 (m, 4H), 2.45 (br t, 5H), 3.05 (m, 2H), 4.41 (br d, 4H), 4.76 (m, 2H), 4.91 (m, 2H), 7.0–7.6 (m, 5H), 8.06 (br s, 2H), and 8.45–8.95 (m, 4H). Anal. calcd. for $C_{42}H_{38}N_4O_{13}$: C 62.53, H 4.75, N 6.94; found: C 62.49, H 5.00, N 6.51.

Bichromophore B_{2a}

The title compound $\mathbf{B_{2a}}$ is prepared by the same method as described for bichromophore $\mathbf{B_2}$. The following amounts were used: *N*-β-hydroxyethylcarbazole (40) (**18**) (0.317 g, 0.00150 mol) and 2,5,7-trinitrofluorenonecarboxylic acid chloride (**15**) (0.595 g, 0.00158 mol) in anhydrous dichloromethane (25 mL) and anhydrous triethylamine (0.83 mL, 0.0060 mol). The crude solid obtained is recrystallized from dimethyl sulfoxide to yield a black solid (0.400 g, 48%); R_f 0.02 (15% ethyl acetate – 85% dichloromethane); mp 310°C; IR: 725, 740, 755, 1090, 1150, 1280, 1310, 1340, 1460, 1485, 1535, 1595, 1620, and 1740 cm^{-1}; NMR (DMSO-d_6) δ: 4.65 (br s, 4H) and 6.99–7.99 (m, 12H).

Ethyl 2,5,7-trinitrofluorenonecarboxylate (A_2)

Under inert atmosphere, a solution of 2,5,7-trinitrofluorenonecarboxylic acid chloride (**15**) (0.190 g, 0.500 mol) in 4.0 mL anhydrous ethanol is heated to reflux for 1 h. After dissolution of the starting material, the desired product precipitates. The suspension is cooled and filtered. The crude solid is washed with cold ethanol, dried in air, then taken up in 85% dichloromethane – 15% benzene, filtered over silica gel, and recrystallized from dichloromethane–methanol to yield a yellow solid (0.130 g, 69%); R_f 0.25 (20% ethyl acetate – 80% hexane); mp 157.5–159°C; IR: 710, 740, 835, 1090, 1185, 1235, 1290, 1315, 1345, 1545, 1595, 1620, 1720, and 1740 cm^{-1}; NMR δ: 1.47 (t, 3H), 4.46 (q, 2H), 8.76 (d, 1H), 8.82 (d, 1H), 8.87 (d, 1H), and 8.96 (d, 1H). Exact mass calcd. for $C_{16}H_9N_3O_9$: 387.0339; found: 387.0345.

Received October 27, 1989

AMALIA RODRIGUEZ, FRANCISCO SÁNCHEZ BURGOS, JOHN BURGESS, and CARMEN CARMONA. Can. J. Chem. **68**, 926 (1990).

The reactions between hexacyanoferrate(II)–peroxodisulphate, hexacyanoferrate(III)–sulphite, hexacyanoferrate(III)–iodide and peroxodisulphate–iodide have been studied in methanol–water mixtures at different methanol concentrations. The results have been analyzed using different approaches, namely electrostatic theory, the $\delta\mu^{\theta}$ initial state – transition state analysis, the decomposition of free energy of activation into enthalpic and entropic terms and, finally, correlation between reactivity and the Grunwald–Winstein parameter, Y. The four reactions show similar behaviour and a correlation between reactivity and the charge of the reactants apparently does not exist. The effect of solvent polarity on the encounter formation processes seems to be an important factor in determining reactivity. However, the influence of solvent on electron transfer process within the encounter complexes cannot be discarded.

Key words: Solvent effects, kinetics, methanol, activation parameters, thermodynamic functions of transfer.

AMALIA RODRIGUEZ, FRANCISCO SÁNCHEZ BURGOS, JOHN BURGESS et CARMEN CARMONA. Can. J. Chem. **68**, 926 (1990).

Opérant à diverses concentrations de méthanol, dans des mélanges de méthanol-eau, on a étudié les réactions entre les ions hexacyanoferrate(II) et peroxodisulfate, hexacyanoferrate(III) et sulfite, hexacyanoferrate(III) et iodure et peroxodisulfate et iodure. On a analysé les résultats à l'aide de diverses approches, soit la théorie électrostatique, l'analyse de l'état initial $\delta\mu^{\theta}$ et de l'état de transition, la décomposition de l'énergie libre d'activation en termes enthalpique et entropique et finalement la corrélation entre la réactivité et le paramètre Y de Grunwald–Winstein. Les quatre réactions présentent des corportements semblables, mais il ne semble pas exister de corrélation entre la réactivité et la charge des réactifs. Il semble que la réactivité soit fortement influencée par l'effet de la polarité du solvant sur les processus de formation des rencontres. Toutefois, on ne peut pas éliminer l'influence du solvant sur le processus de transfert d'électron à l'intérieur des complexes de rencontre.

Mots clés : effets de solvant, cinétique, méthanol, paramètres d'activation, fonctions thermodynamiques de transfert.

[Traduit par la revue]

Introduction

Over the years different approaches have been used to examine solvent effects on reaction rates. Rate constants may be correlated with a physical parameter characteristic of the solvent or with an empirical parameter (1, 2). Recently this type of analysis has been extended to multiple linear correlations to assess the relative importance of the different variables (3, 4). Also, the solvent effect on log k or $\Delta G^{\neq}$ can be dissected into contributions from the initial state and the transition state using the thermodynamic functions of transfer (5–7). This study allows an analysis of the importance of the solvation changes of both states on reactivity. Finally, the variation of the enthalpy and entropy of activation with solvent composition has been utilized to discuss the influence of solvent structure on reactivity (8, 9).

Although the above methods have been used extensively in discussions on solvent effects, they are not usually utilized simultaneously. For this reason and because of our interest on the influence of medium effects on reaction rates (9–13), we were interested in analyzing reactivity trends in binary aqueous mixtures using the above methods simultaneously. To start with, methanol–water mixtures have been chosen. Also for purposes of comparison and to make the study more general, we have selected four reactions: iodide–peroxodisulphate, iodide–hexacyanoferrate(III), sulphite–hexacyanoferrate(III), and peroxodisulphate–hexacyanoferrate(II) reactions. The choice has been made because firstly there is already some information on medium effects on these reactions (9–15) and secondly they are reactions between anions of different charges. As a result the influence of changing the charge of the reactants can also be analyzed.

Experimental

Reagents

All reagents were AnalaR grade chemicals. The water used had a resistivity $> 6\ M\Omega\ cm^{-1}$. Sodium hexacyanoferrate(III) was obtained by passing potassium hexacyanoferrate(III) through a mixed bed cation-exchange column "Lawatit S 100 (cationic)".

The pH of the sulphite solutions was maintained at a value of nine and these solutions were always titrated before used.

Kinetic data

Kinetic runs were carried out in 1-cm silica cells in the thermostated cell compartment of a Perkin-Elmer 554 spectrophotometer. The temperature in the cell was fixed at 20.0, 25.0, 30.0, 35.0, and 40.0 ± 0.1°C. Mixtures water–methanol were prepared by weight. The dielectric constant data at 25.0°C are from ref. 16. In each case the cosolvent was found to be inert in relation to the reactants and products. The solution also contained K_2H_2edta to prevent catalysis of any metal ions that might be present as impurities ($[K_2H_2edta] = 5 \times 10^{-4}$ mol dm^{-3}). Duplicate and triplicate runs were made under all the experimental conditions. The rate constant error was estimated to be less than 2%.

The activation energy was obtained in water + methanol mixtures prepared to have the same dielectric constant at 25.0°C.

The reaction between sulphite and hexacyanoferrate(III) ions was made in solutions containing an excess of sulphite ions by following the change in absorbance at 420 nm at fixed time intervals (at this

wavelength only hexacyanoferrate(III) absorbs). The concentrations of reactants were $[Na_3Fe(CN)_6] = 1 \times 10^{-3}$ mol dm^{-3} and $[Na_2SO_3] = 1 \times 10^{-2}$ mol dm^{-3}, respectively. The rate constants were evaluated by Guggenheim's method (17).

The peroxodisulphate–hexacyanoferrate(II) reaction was carried out in solutions containing an excess of hexacyanoferrate(II) ions by following the change in absorbance at 420 nm. The concentrations of reactants were $[K_4Fe(CN)_6] = 3 \times 10^{-2}$ and $[K_2S_2O_8] = 7.5 \times 10^{-4}$ mol dm^{-3}, respectively. The rate constants were evaluated from linear plots of the function $-\ln(A_\infty - A_t)$ versus time. A_∞ and A_t are the absorbances at equilibrium time and time t, respectively.

The reaction between hexacyanoferrate(III) and iodide ions was followed by monitoring the changes in absorbance at 400 nm at fixed time intervals. At this wavelength both hexacyanoferrate(III) and tri-iodide ions absorb. Thus, under these conditions, relation [1] is maintained where A is the total absorbance of the solutions,

$$[1] \quad A = \epsilon(a - x) + \epsilon'(x/2)$$

ϵ and ϵ' are the molar absorption coefficients of hexacyanoferrate(III) and tri-iodide ions respectively, a is the initial concentration of hexacyanoferrate(III), and $(a - x)$ its concentration at the time of measurement. The concentrations of reactants were $[KI] = 4 \times 10^{-1}$ mol dm^{-3} and $[K_3Fe(CN)_6] = 8 \times 10^{-4}$ mol dm^{-3}.

Solubilities

The values of the standard transfer chemical potentials were calculated from solubilities, at 298.2 K, in water and in water–methanol mixtures, respectively. The solubilities were determined after achieving an equilibrium between the solid phase and its solution. Due to sulphite instability, we have made the assumption that the general trends on solubilities of this ion and sulphate ion should be kept. Thus, solubilities of the sulphate ion instead of the sulphite ion have been measured. The concentrations of the salts in different methanol–water mixtures and in water were estimated iodometrically ($(K_2S_2O_8)$ (18)), turbidimetrically ((K_2SO_4) (19)), and spectrophotometrically (for $K_4Fe(CN)_6$ $\epsilon = 1810$ at 270 nm (20), for Ph_4AsI $\epsilon = 3200$ at 266 nm, for $Co(NH_3)_6Fe(CN)_6$ $\epsilon = 1030$ at 420 nm (21)). The solubilities of $Co(NH_3)_6Pi_3$, KPi, KPh_4B, and Ph_4AsPi were also measured. The preparation and characterization of these compounds was made using literature sources (22–25).

Results

The values of the rate constants for the four reactions at different methanol concentrations and different temperatures are recorded in Table 1. The only comparable literature values (i.e. those obtained at the same ionic strength) are in parentheses in this table. As can be seen, the general pattern of rate constants for all reactions is remarkably similar: there is a decrease in k values with increasing methanol concentration. At this point, it should be noted that because of experimental requirements, the four reactions have been studied at different ionic strengths. Since ionic strength increase gives rise to a rate constant increase for reactions between ions of the same sign, if we wish to compare the results of the four reactions, the k values should be corrected. Thus we will examine the results after extracting a standard allowance for the long-range Debye–Hückel interactions (26) according to:

$$[2] \quad \log k = \log k_0' + 2\frac{1.814 \times 10^6}{(DT)^{3/2}} Z_A Z_B \frac{I^{1/2}}{1 + I^{1/2}}$$

where k is the actual rate constant, D is the macroscopic dielectric constant and the other symbols have their usual meaning. The values of k_0' have been tabulated in Table 2 as $\delta\Delta G^{\neq}_{I=0}$ where

$$\delta\Delta G^{\neq}_{I=0} = \Delta G^{\neq}_{I=0}(\text{methanol–water}) - \Delta G^{\neq}_{I=0}(\text{water})$$

The activation parameters obtained from the k_0' values at different temperatures are plotted against organic solvent mole fraction in Figs. 1–4.

The solubilities for all reactants in water and in methanol–water mixtures are recorded in Table 3. Our data look reasonable in relation to published solubilities in water of KPi

$(2.42 \times 10^{-2} - 1.97 \times 10^{-2}$ mol dm$^{-3})$ (22, 24, 27), KPh_4B $(1.72 \times 10^{-4} - 3.00 \times 10^{-4}$ mol dm$^{-3})$ (22, 24, 27), and $K_2S_2O_8$ $(1.92 \times 10^{-1}$ mol dm$^{-3})$ (18).

The standard transfer chemical potentials for all the salts were calculated using eq. [2]

$$[2] \quad \delta_m\mu^\theta(\text{salt}) = nRT \ln \frac{s(\text{w})\gamma_\pm(\text{w})}{s(\text{x})\gamma_\pm(\text{x})}$$

where s(w) and s(x) are the solubilities in water and in the solvent mixtures, respectively. Usually, $\delta_m\mu^\theta$(salt) values are calculated on the assumption that the ratio of the mean activity coefficients in water and in the aqueous solvent mixtures is in all cases a unity (28, 29). However, we have calculated these ratios by means of eq. [3] and their values have been considered in eq. [2]

$$[3] \quad \log \gamma_\pm = 1.826 \times 10^6 (DT)^{-3/2} \frac{Z_+ Z_- I^{1/2}}{1 + I^{1/2}}$$

Although the absolute values of $\delta_m\mu^\theta$(salt) differ from those obtained assuming $\gamma_\pm(\text{w})/\gamma_\pm(\text{x})$ ca. 1, the trends observed on changing solvent composition are completely similar.

The estimation of transfer chemical potentials for ions has been made using the extrathermodynamic assumption $\delta_m\mu^\theta(Ph_4As^+) = \delta_m\mu^\theta(BPh_4^-)$ (30, 31). Finally, with the individual values, the transfer functions of the initial states for the four reactions in every methanol composition have been obtained. Also from the kinetic data, the values for the transition states have been calculated. These values together with $\delta\Delta G^{\neq}_{I=0}$ values are plotted against solvent composition in Fig. 5 for the peroxodisulphate–iodide rection.

Discussion

As expected, the general trends of k'_0 on changing methanol composition are the same as those observed before the ionic strength correction. There is always a decrease of reactivity on decreasing the macroscopic dielectric constant of the medium. Although this decrease of reactivity is in agreement with the electrostatic theory predictions (32), the results of the present experiments cannot be unequivocally explained by application of this theory. The $\delta\Delta G^{\neq}_{I=0}$ vs. D^{-1} dependence is nonlinear in all cases. As an example, $\delta\Delta G^{\neq}_{I=0}$ vs. D^{-1} has been plotted for the hexacyanoferrate(III)–sulphite reaction in Fig. 6.

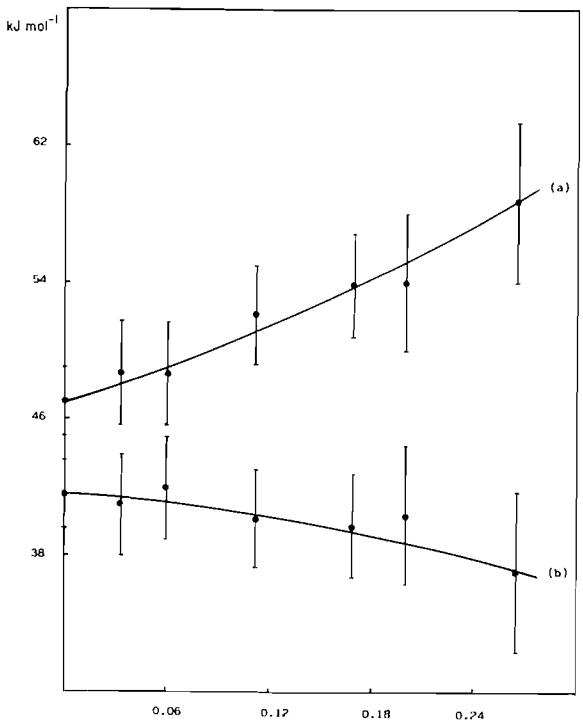

FIG. 3. Plot of (*a*) $\Delta H^{\neq}_{I=0}$ and (*b*) $-T\Delta S^{\neq}_{I=0}$ vs. mole fraction of methanol at 298.2 K for the reaction betweeen sulphite and hexacyanoferrate(III) ions.

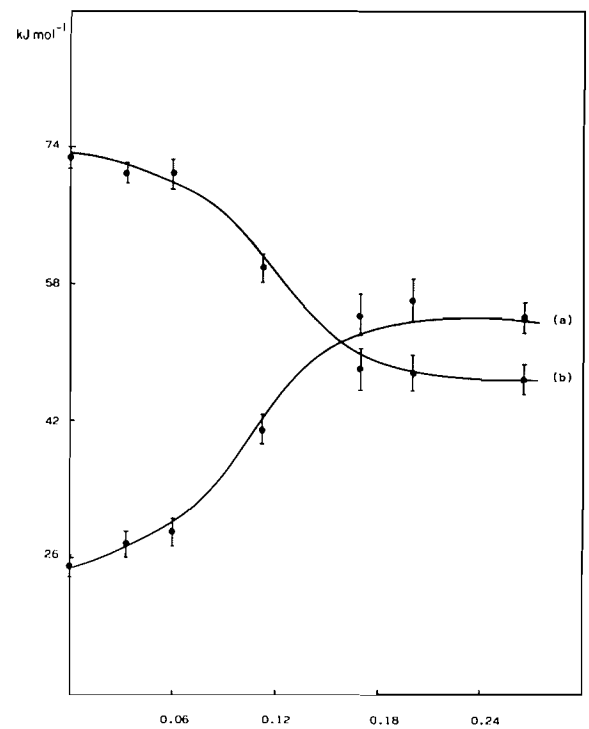

FIG. 4. Plot of (*a*) $\Delta H^{\neq}_{I=0}$ and (*b*) $-T\Delta S^{\neq}_{I=0}$ vs. mole fraction of methanol at 298.2 K for the reaction between iodide and hexacyanoferrate(III) ions.

The nonlinearity of $\delta\Delta G^{\neq}_{I=0}$ vs. D^{-1} plots has sometimes been associated with the differential effect of solvent structure between the initial and transition states (8). This effect is not necessarily apparent in $\delta\Delta G^{\neq}_{I=0}$ behaviour, but it could be evident in the changes of $\delta\Delta H^{\neq}_{I=0}$ and $\delta\Delta S^{\neq}_{I=0}$ with organic solvent composition (8). In spite of the fact that methanol, when mixed with water, does not produce very pronounced extrema in the variation of physical properties with solvent composition (33), which have been imputed to structural effects, the changes of $\delta\Delta H^{\neq}_{I=0}$ and $\delta\Delta S^{\neq}_{I=0}$ on changing solvent composition have been analyzed. As can be seen in Figs. 1–4 a smooth and monotonic variation of these parameters is always observed except for the iodide–hexacyanoferrate(III) reaction. However, even in this case no clear extrema are observed.

Figures 1–4 also show that although $\delta\Delta G^{\neq}_{I=0}$ always increases with methanol concentration, this increase is sometimes due to the dominance of the entropic term and sometimes due to the dominance of the enthalpic term. There is even a changeover in the dominant parameter for the iodide–hexacyanoferrate(III) reaction. These effects cannot be related to charge increase in the transition state but rather to the characteristics of the substrates and reactions.

On the other hand, the variation in the thermodynamic parameters of activation as a function of methanol composition is composed of initial and transition state contributions. In order to separate them, $\delta_m\mu^\theta$ of transfer from water to the binary mixtures has been determined for all the solutes studied in the present work. The initial state – transition state analysis for peroxodisulphate–iodide reaction in the methanol–water mixtures is shown in Fig. 5. The destabilization of the initial state reflects a marked destabilization of both reactants on increasing methanol content.

A perusal of Fig. 5 shows that great changes of transfer chemical potentials of the initial and transition states give rise to minor variations of $\delta\Delta G^{\neq}_{I=0}$, with methanol composition. In all cases, the small increase in $\delta\Delta G^{\neq}_{I=0}$ with increasing mole fraction of methanol is due to a somewhat more pronounced

destabilization of the transition state in comparison with the destabilization of the initial state. This behaviour is in agreement with the charge increase upon transferring the substrates into the transition states. In fact, $\delta\mu^{\theta}_{TS}$ decreases linearly on increasing the polarity of the media as measured by the

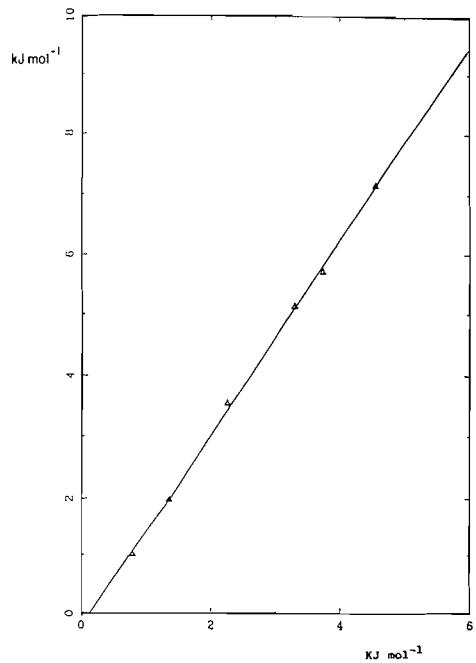

FIG. 7. Plot of $\delta\Delta G^{\neq}_{I=0}$ for peroxodisulphate–iodide reaction vs. $\delta\Delta G^{\neq}_{I=0}$ for sulphite–hexacyanoferrate(III) reaction in methanol–water mixtures at 298.2 K.

Grunwald–Winstein parameter (34), $\delta y = y_{H_2O} - y_{MetOH-water}$. Moreover, the negative slopes of these plots decrease as the charge of the transition states increases.

On the other hand, if $\delta\Delta G^{\neq}_{I=0}$ for one of the reactions is plotted against $\delta\Delta G^{\neq}_{I=0}$ for another, good linear correlations are observed. As an example, $\delta\Delta G^{\neq}_{I=0}$ values for sulphite–hexacyanoferrate(III) reaction have been plotted against $\delta\Delta G^{\neq}_{I=0}$ for iodide–peroxodisulphate reaction in Fig. 7. The existence of such linear plots is noteworthy, taking into account that the reactions have been carried out in the presence of different cations at different concentrations. Therefore, under the present conditions, specific cation effects do not seem to be important. At this point, it is apparent that whatever the solvent properties important in determining reactivity are, they are similar for all reactions studied in the present work. Thus, if log k'_0 for one reaction is linearly related to log k'_0 for another, the existence of a solvent parameter that could be linearly related to both sets of log k'_0 values could be suggested (35). As $\delta\mu^{\theta}_{TS}$ values vary linearly with δY parameter, we have tried to correlate $\delta\Delta G^{\neq}_{I=0}$ with the same solvent parameter. These plots are depicted in

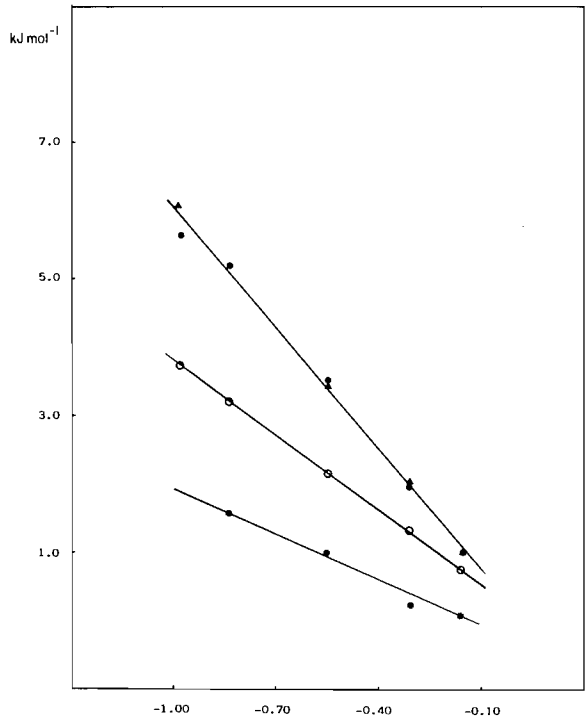

FIG. 8. Plots of Gibbs free energies of activation $\delta\Delta G^{\neq}_{I=0}$ vs. the Grunwald–Winstein parameter δY at 298.2 K. (△)hexacyanoferrate(III)–iodide reaction; (●) hexacyanoferrate(III)–sulphite reaction; (○) peroxodisulphate–iodide reaction; (*) peroxodisulphate–hexacyanoferrate(II) reaction.

Fig. 8 for all reactions. As can be seen in this figure linear correlations are always observed; there is no relation between the slopes of the plots and the charge of the reactants. However, these relations should not be expected because free energy activation parameter is composed of initial and transition state contributions.

The observed linearity between $\delta\Delta G^{\neq}_{I=0}$ and δY parameter suggests a plausible explanation of the experimental results. As is known (36), the rate constant for a bimolecular electron transfer reaction can be expressed as a product of an equilibrium constant for the formation of the precursor complex and the first order rate constant for electron tranfer within the precursor complex. The diffusing together of the similarly charged reactants to form the precursor complex will be favoured on increasing polarity of the media (37), while the energy required to reorganize the solvent decreases as the polarity decreases (37). Finally, the standard free energy change for the overall reactions can make a positive or negative contribution depending on the reactants. Thus it appears that the formation of the precursor complex is, if not the only, an important factor on determining reactivity for the reactions studied. However, it should be realized that if the formation of the precursor complexes was the dominant factor, the correlation of $\delta\Delta G^{\neq}_{I=0}$ against δY should have the same slopes in different solvent systems. Therefore the study of these reactions in mixtures of water with organic solvents, different from methanol, could help in the analysis of the relative importance of other terms; for example, the reorganization free energy of the solvent. Further work is in progress on this theme.

An electrostatic approach to negatively charged substrate reactions with hydroxide ion in cationic CTAB micelles

C. DOLCET AND E. RODENAS[1]

Departamento de Química Física, Universidad de Alcalá, Alcalá de Henares, Madrid, Spain

Received August 1, 1989[2]

C. DOLCET and E. RODENAS. Can. J. Chem. **68**, 932 (1990).

An electrostatic treatment is presented to explain the experimental kinetic data we obtained for the basic hydrolysis of the negatively charged substrates acetylsalicylic acid and 3-acetoxy-2-naphthoic acid. This treatment, based on the non-linearized Poisson–Boltzmann equation, considers specific interactions between the counterions and the micellar surface and explains the displacement of these substrates from the micellar to the aqueous phase through bromide counterion addition.

Key words: electrostatic approach, cationic CTAB micelles.

C. DOLCET et E. RODENAS. Can. J. Chem. **68**, 932 (1990).

On présente un traitement électrostatique qui permet d'expliquer les données cinétiques expérimentales que nous avons obtenues lors de l'hydrolyse basique de substrats chargés d'une façon négative et obtenus à partir des acides acétylsalicylique et 3-acétoxy-2-naphtoïque. Ce traitement, qui est basé sur une équation de Poisson–Boltzmann non-linéarisée, considère les interactions spécifiques entre les contre-ions et la surface micellaire et il explique le déplacement de ces substrats de la phase micellaire vers la phase aqueuse par le biais de l'addition du brome comme contre-ion.

Mots clés : traitement électrostatique, cationique CTAB micelles.

Introduction

In earlier papers we have reported our results in the basic hydrolysis of some aromatic esters in cationic micelles (CTAB, CTACl, CTAOH), hexadecyltrimethilammonium bromide, chloride, and hydroxide respectively (1, 2). These results were accounted for with the pseudophase ion-exchange (3, 4) and the mass-action models (5). To explain the results for negatively charged substrates like acetylsalicylic acid (2-acetoxybenzoic acid) and 3-acetoxy-2-naphthoic acid the micellar counterion effect had to be taken into account. For reactions in CTAB micelles the addition of an additional Br^- counterion to the CTAB micelles displaces these substrates from the micellar to the aqueous phase (6). The opposite effect has been found with positively charged substrates for which Br^- counterion addition produces a sharp increase in substrate to micelle binding (7–9). It is also known that the pseudophase ion-exchange model fails at high reactive ion concentrations according to some experimental evidence in literature (10) so that it becomes necessary to consider an increase in the fraction of neutralized micellar head groups (11, 12) or to consider an additional reaction pathway in which the reactive ion in the aqueous phase reacts with the micelle bound substrate (13).

From all of this evidence, it becomes necessary to develop a new theoretical treatment. For these negatively charged substrates, in an early paper, we assumed that the substrate distribution between aqueous and micellar phases was the same as that for ions in solution as did other authors in literature (14). This treatment neglects the micellar surface potential and is not able to explain our kinetic results (15).

In trying to fit all our kinetic results we developed an electrostatic treatment that treats the ion distribution around micelles by the Poisson–Boltzmann non-linearized equation (NLPB). The Poisson–Boltzmann ion distribution around micelles has been successfully used to explain the thermodynamic behavior of ionic colloids with monovalent ions (16, 17) although it fails to describe the distribution of multivalent ions adequately (18). This treatment explains kinetic results in reactive-ion counterion micelles (19).

In the case of CTAB micelles, the bromide ion distribution around micelles according to the Poisson–Boltzmann equation does not explain the experimental value for the fraction of neutralized micellar head groups. To explain this value it is necessary to consider specific interactions between the Br^- ion and the micellar surface. Some authors in the literature consider the amount of bromide ions specifically adsorbed to be independent of surface potential (20, 21) but this treatment does not fit our kinetic data either.

We have developed a new approach which relates the number of ions that is adsorbed depending on the micellar surface potential. This treatment explains the basic hydrolysis kinetic results for positively charged substrates such as crystal violet (22). In this paper we discuss the validity of this approach to explain kinetic data for the basic hydrolysis of negatively charged substrates such as acetylsalicylic acid and 3-acetoxy-2-naphthoic acid. The experimental data have been reported in earlier papers (1, 2, 6).

Theoretical description of this electrostatic approach

According to the non-linearized Poisson–Boltzmann equation the ion distribution around CTAB micelles can be obtained on the basis of the cell model. Under our experimental conditions, CTAB micelles and cells are considered spherical (23), and the ions are distributed in the region $r_m < r < r_c$ according to the non-linearized Poisson–Boltzmann equation which, for spherical symmetry and if only monovalent ions are present in solution, is expressed as

$$[1] \quad \epsilon_r\epsilon_0(1/r^2)\mathrm{d}/\mathrm{d}r(r^2\mathrm{d}\phi/\mathrm{d}r) = -F\{c_{+0}\exp(-e\phi/kT) - c_{-0}\exp(e\phi/kT)\}$$

Here r_m is the micelle radius, r_c the cell radius, ϵ_r the relative permittivity assumed to be constant in the cell with a value of 78.54, ϵ_0 the vacuum permittivity, T the absolute temperature, k the Boltzmann constant, ϕ the electrostatic potential, e the electron charge, and c_{+0} and c_{-0} are the concentrations

(mol m^{-3}) of positive and negative ions, respectively, at a point on the solution where $\phi = 0$.

The parameters c_{+0} and c_{-0} are related to the total number of positive and negative ions in the cell, n_+ and n_-, by the normalization conditions

$$[2] \quad n_+ = c_{+0}N_A\int_{r_m}^{r_c} \exp(-e\phi/kT)(4\pi r^2)dr$$

$$[3] \quad n_- = c_{-0}N_A\int_{r_m}^{r_c} \exp(e\phi/kT)(4\pi r^2)dr$$

where N_A is Avogadro's number.

Equation [1] can be solved with the fourth order Runge–Kutta method using the boundary conditions

$$[4] \quad \phi(r = r_c) = 0$$

$$[5] \quad (d\phi/dr)_{(r=r_c)} = \phi'(r = r_c) = 0$$

and with the electroneutrality condition

$$[6] \quad (d\phi/dr)_{(r=r_m)} = \phi'(r = r_m) = -\sigma/\epsilon_0\epsilon_r$$

where σ is micellar surface charge per m^2.

Solution of the Poisson–Boltzmann equation gives the average concentration of bromide ions in a layer of thickness Δr around the micelle. The fraction of micellar head groups neutralized with statistically distributed bromide ions that can be considered part of the micellar aggregate is expressed as

$$[7] \quad m_{BrNCA} = (N_A/N)\int_{r_m}^{r_m+\Delta r} c_{-0}\exp(e\phi_0/kT)4\pi r^2dr$$

where N is the micellar aggregation number and ϕ_0 is the micellar surface potential.

The values of β, $\beta = m_{BrNCA}$, obtained from eq. [7] do not agree with experiments (22). For CTAB micelles, β values have been determined by different methods such as emf (24) and conductivity (25, 26); β is essentially independent of surfactant concentration (27) ($\beta = 0.8$), although some experimental evidence shows a slight increase with surfactant concentration and with added salt (28). To explain the β values for CTAB micelles in solution, we assume that the Br^- ion specifically adsorbs on charged surfaces, in agreement with experimental evidence. The number of ions specifically adsorbed, [Br^-_{CA}], depends on surface charge, solvent, environment, etc. (29). For this study we have considered the following equilibrium accounting for Br^- ion contact adsorption according to Butler–Volmer

$$Br^-_{NCA} + Dn \underset{\overleftarrow{k}}{\overrightarrow{k}} Br^-_{CA}$$

with an equilibrium condition given by

$$[8] \quad \frac{m_{BrCA}}{[Br^-_{NCA}](1 - m_{BrCA})} = K_{BrCA}\exp(e\phi_0/kT)$$

where [Br^-_{NCA}] is the non-specifically adsorbed bromide ion concentration, m_{BrCA} the fraction of micellar surface neutralized by the specifically adsorbed bromide ions, $(1 - m_{BrCA})$ represents the fraction of free micellar surface, and K_{BrCA} is the bromide ion specific adsorption constant.

We solved eq. [1] using an iterative method with the fourth order Runge–Kutta method, starting from chosen initial values of ϕ_0, c_{+0}, and c_{-0} and optimizing to a complete solution using the boundary conditions (4, 5) and normalization conditions (2, 3) and then checked the calculated results using eq. [6] where $\sigma = Ne(1 - m_{BrCA})/4\pi r_m^2$. The numerical values for the integral in eqs. [2] and [3] were obtained by Simpson's rules.

In this case, the total fraction of neutralized micellar head groups is given by

$$[9] \quad \beta = m_{BrCA} + m_{BrNCA}$$

where m_{BrNCA} is given by eq. [7].

As reported (22), a K_{BrCA} value of 30 M^{-1} best explains the observed value of β for CTAB.

Since the experimental results in this paper were obtained with an added quantity of acetonitrile in the reaction mixture, we have considered the additional ionization of CTAB micelles produced by acetonitrile. According to the results of our conductivity measurements, the fraction of neutralized micellar head groups is 0.74 independent of surfactant concentration (30). The bromide ion specific adsorption constant, K_{BrCA} in eq. [8] that best fits this result is 25 M^{-1} which means that the added acetonitrile slightly decreases the bromide ion specific adsorption on to the CTA^+ micelles.

The acetonitrile in the concentration used also produces a slight decrease in the micellar aggregation number (31). The micellar aggregation numbers used in the calculations were determined by fluorescence quenching measurements (31–33) with pyrene as probe and cetylpiridinium chloride as static quencher (34). Our experimental results, given in Table 2, are smaller than the CTAB aggregation numbers reported (35). Acetonitrile does not affect the peak intensity ratio I_1/I_{III} in the pyrene spectra, which means that acetonitrile does not appreciably affect the dielectric constant micellar surface (31).

Hydroxide ions can be considered non-specifically adsorbed on the micellar surface and once the Poisson–Boltzmann equation has been solved, the average concentration of bromide and hydroxide ions in a layer of thickness Δr can be calculated by eq. [10].

$$[10] \quad m_{OH} + m_{BrNCA} = (N_A/N)\int_{r_m}^{r_m+\Delta r} c_{-0}\exp(e\phi_0/kT)4\pi r^2dr$$

m_{OH} and m_{BrNCA} are the fraction of micellar head groups neutralized with hydroxide and bromide ions statistically distributed in the layer $r_m + \Delta r$.

The total fraction of micellar head groups neutralized is given by

$$[11] \quad \beta = m_{OH} + m_{BrCA} + m_{BrNCA}$$

and m_{OH}

$$[12] \quad m_{OH} = \frac{(m_{BrNCA} + m_{OH})[OH^-]}{[Br^-_{NCA}] + [OH^-]}$$

At the total concentration of hydroxide ions used in this study the fraction of micellar head groups neutralized with statistically distributed bromide and hydroxide ions (given by eq. [10]) cannot be neglected relative to m_{BrCA}, the fraction of neutralized micellar head groups with specifically adsorbed bromide ion, given by eq. [8], as one can see from Table 1. We therefore improved our calculation using the following equilibrium condition to give the amount of bromide ion specifically adsorbed

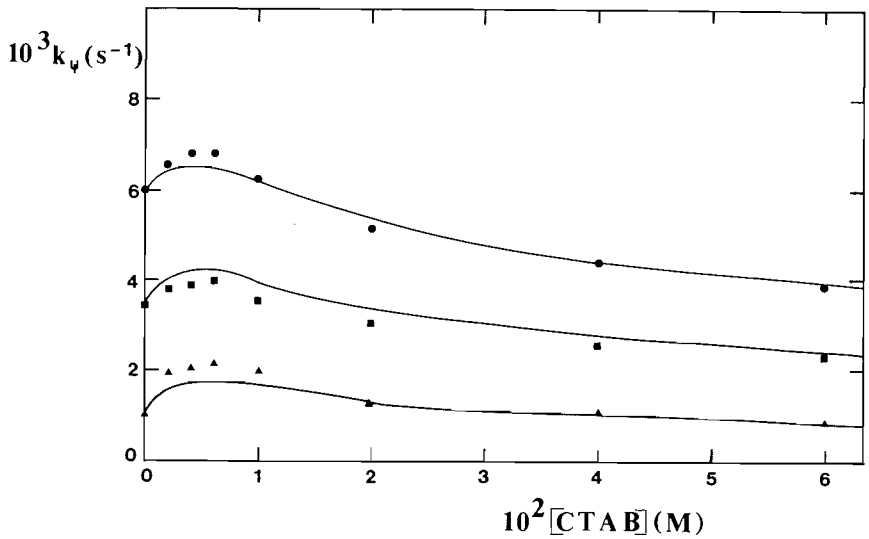

FIG. 1. Pseudo-first order rate constant for the basic hydrolysis of acetylsalicylic acid in CTAB micelles at different surfactant and ion concentrations. Solid lines are the calculated values (▲ [NaOH] = 0.010 M; ■ [NaOH] = 0.030 M; ● [NaOH] = 0.050 M).

$$[13]\quad \frac{m_{BrCA}}{[Br^-_{NCA}](1 - m_{BrCA} - m_{BrNCA} - m_{OH})} = K_{BrCA} \exp(e\phi_0/kT)$$

In the iterative calculation method used to solve the Poisson–Boltzmann equation, initial values were assigned ($m_{OH} + m_{BrNCA}$), c_{-0}, and c_{+0}, which were then optimized until a satisfactory solution of the equation was obtained.

In the calculation, cells have been considered spherical with a radius, r_c, given by

$$[14]\quad 4\pi r_c^3/3 = N/10^3 N_A([D] - \text{cmc})$$

where [D] is the surfactant concentration and cmc is the critical micelle concentration with added salt, calculated using the empirical equation (36)

$$[15]\quad \log \text{cmc} = -3.7671 - 0.2133 \log (c_m + [NaOH] + [KBr])$$

c_m is the critical micellar concentration for simple CTAB micelles, $c_m = 9 \times 10^{-4}$ M.

The Stern layer thickness has been assumed to be constant, $\Delta r = 4$ Å as we used in ref. 22. The micellar radius, r_m, has been calculated from Tanford's expression (37)

$$[16]\quad (4/3)\pi r_m^3 = N(27.4 + 26.9 n_c)$$

where $n_c = 15$ for CTAB, so that the volume of micellar phase per mol of micellized surfactant, $\bar{V}$, is constant with a surfactant concentration, the value is 0.259 L mol^{-1}.

Above the cmc, the substrate distributes between the aqueous and micellar phases. The binding of these negatively charged substrates to cationic micelles has been described by assuming an ideal behavior of the micellar pseudophase. In this way the electrochemical substrate potential in the micellar and aqueous phases would be equal at equilibrium:

$$[17]\quad \mu^0_{SM} + RT \ln [\overline{S_M}] + z_s F \phi_M = \mu^0_{SW} + RT \ln [\overline{S_W}] + z_S F \phi_W$$

Here μ^0_{SM} and μ^0_{SW} denote the substrate standard chemical potential in the micellar and in the aqueous phase, respectively, and $[\overline{S_M}]$ and $[\overline{S_W}]$ are the effective substrate concentrations in the micellar and the aqueous phases. These quantities are related to the analytical concentrations by

$$[18]\quad [\overline{S_M}] = \frac{[S_M]}{[Dn]\bar{V}} \qquad [\overline{S_W}] = \frac{[S_W]}{1 - [Dn]\bar{V}}$$

under our experimental conditions $1 - [Dn]\bar{V} \simeq 1$.

The substrate partition coefficient, P_S, between both phases is given by

$$[19]\quad P_S = \frac{[\overline{S_M}]}{[\overline{S_W}]} = P^0_S \exp\{-ez_S(\phi_M - \phi_W)/kT\}$$

where $P^0_S = \exp(\mu^0_{SW} - \mu^0_{SM})/RT$ and $(\phi_M - \phi_W)$ denotes the electrostatic attractive potential that contributes to the binding of these negatively charged substrates to cationic micelles.

The partition coefficient P_S is related to the substrate to micelle binding constant, K_S, by $P_S = K_S/\bar{V}$ as

$$[20]\quad K_S = \frac{[S_M]}{[S_W][Dn]}$$

This electrostatic approach shows that substrate binding to cationic micelles increases with micellar surface potential.

The reaction rate defined in terms of effective concentration in the micellar and the aqueous phase is given by

$$[21]\quad v = k_m[\overline{S_M}][\overline{OH^-_M}][Dn]\bar{V} + k_W[\overline{S_W}][\overline{OH^-_W}](1 - [Dn]\bar{V})$$

where $\bar{V}$ is the micellar phase molar volume, k_m is the second order rate constant for the reaction in the micellar phase. The pseudo-first order rate constant is easily deduced in terms of the substrate partition coefficient as

$$[22]\quad k_\psi = \frac{k_W[OH^-] + (k_m P_S - k_W) m_{OH}[Dn]}{1 + P_S[Dn]\bar{V}}$$

Results and discussion

The pseudo-first order rate constant for the basic hydrolysis of acetylsalicylic acid and 3-acetoxy-2-naphthoic acid at different hydroxide ion and surfactant concentrations are represented by

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12

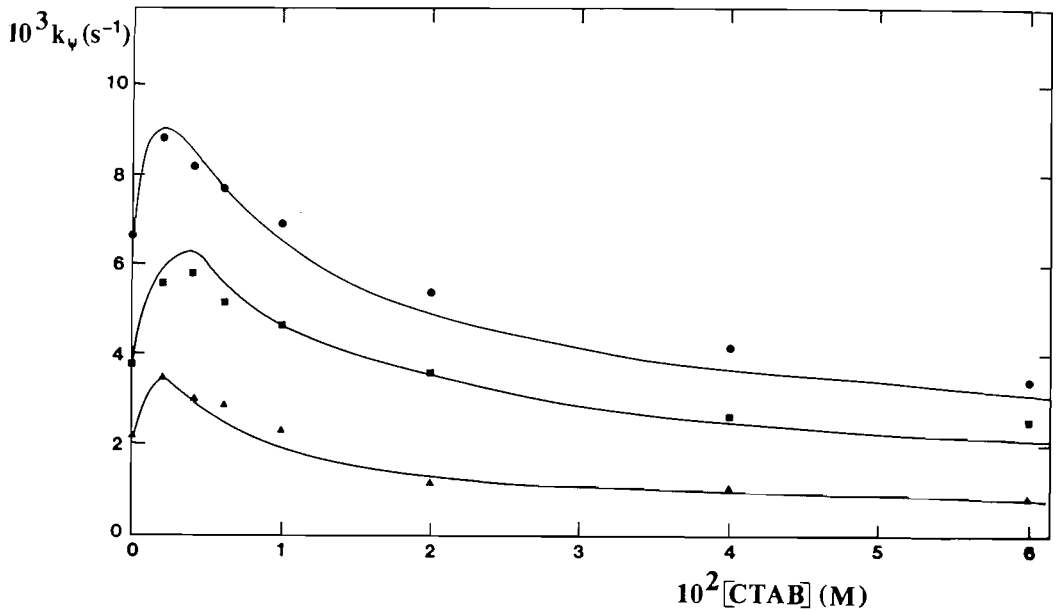

FIG. 2. Pseudo-first order rate constant for the basic hydrolysis of 3-acetoxy-2-naphthoic acid in CTAB micelles at different surfactant and ion concentrations (see legend of Fig. 1).

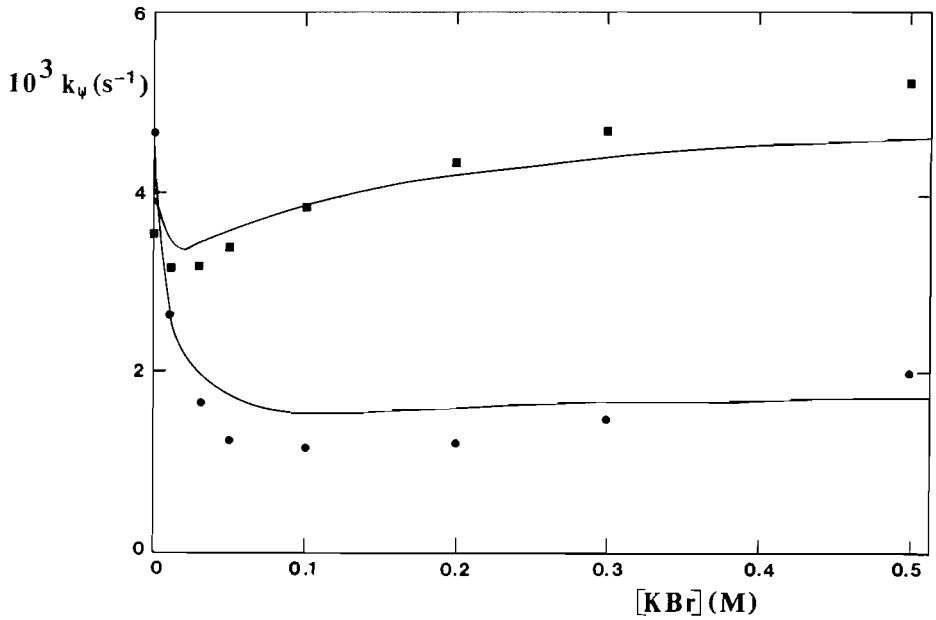

FIG. 3. Pseudo-first order rate constant for the basic hydrolysis of acetylsalicylic acid (■) and 3-acetoxy-2-naphthoic acid (●) in CTAB micelles at different KBr concentrations for [D] = 0.010 M and [NaOH] = 0.030 M. Solid lines are the calculated values.

dots in Figs. 1 and 2 from refs. 1 and 2. The effect of an additional amount of KBr is shown in Fig. 3 from ref. 6. These results have been obtained using acetonitrile substrate stock solution. The amount of acetonitrile in the reaction mixture is 3% as previously reported (1, 2, 6).

Second order rate constants of both substrate for the reaction in water are 0.124 M^{-1} s^{-1} and 0.160 M^{-1} s^{-1} for acetylsalicylic acid and 3-acetoxy-2-naphthoic acid, respectively. These second order rate constants are strongly affected for by the following empirical variations according to the results given in ref. 6.

$$[23] \quad \log k_W = (-0.896 + 0.5581[KBr] - 0.6229[KBr]^2)$$

$$[24] \quad \log k_W = (-0.799 + 0.3556[KBr] - 0.3296[KBr]^2)$$

The kinetic results in micelles have been explained with the pseudophase ion-exchange model by considering a displacement of these negatively charged substrates from the micellar to the aqueous phase with Br^- ion addition (6).

To fit the experimental results, m_{OH} and $\phi_{4Å}$ have been calculated by the electrostatic treatment given before and P^0_S and k_m have been taken as adjustable parameters. The values that best fit these results are $P^0_S = 36.7$ and $k_m = 0.015\ M^{-1}\ s^{-1}$ for acetylsalicylic acid and $P^0_S = 1083.0$ and $k_m = 0.0155\ M^{-1}\ s^{-1}$ for 3-acetoxy-2-naphthoic acid. The pseudo-first order rate constant calculated is represented by the solid lines in Figs. 1, 2, and 3. The calculated values for ϕ_0, $\phi_{4Å}$, the fraction of neutralized micellar head groups with bromide ions specifically adsorbed (m_{BrCA}), the fraction of neutralized micellar head

groups with OH^- and Br^- ions non-specifically adsorbed (m_{OH} and m_{BrNCA}) and the total fraction of neutralized micellar head groups (β) are given in Table 2.

This calculation predicts that the micellar surface potential decreases with surfactant concentration and with the amount of additional KBr in solution, in agreement with our experimental results (6) and with results in the literature (38). The drop in the micellar surface potential is related to the decreased binding of these negatively charged substrates to the micelle according to eq. [19].

Second order rate constants for both substrate reactions in the micellar phase are nearly one hundred times smaller than the second order rate constant for the reaction in the aqueous phase. Clearly, micelles produce a strong inhibition effect on these reactions. The same effect is predicted by the pseudophase ion-exchange and mass-action models (1, 2, 6).

The P^0_S obtained for 3-acetoxy-2-naphthoic acid is higher than P^0_S for acetylsalicylic acid, as would be expected for a more hydrophobic substrate.

To compare these results with those obtained with the pseudophase ion-exchange kinetic model we have calculated values of substrate to micelle binding constant, K_S, given by eq. [20], and the exchange equilibrium constant given by equation

$$[25] \quad K^{OH}_{Br} = \frac{[OH^-_W][Br^-_M]}{[OH^-_M][Br^-_W]}$$

and predicted by this electrostatic treatment. The results are shown in Table 3.

As one can see this treatment predicts that the substrate-to-micelle binding constant given by eq. [20] decreases with surfactant concentration and hydroxide ion concentration in solution. The opposite effect is found for positively charged substrates (7–9, 11, 39, 40). The ion-exchange equilibrium constant from eq. [25] decreases with surfactant concentration and with the addition of KBr. This exchange equilibrium constant increases with the concentration of hydroxide ions in solution. However, the average value is much larger than the values, $K^{OH}_{Br} = 2$ and 5 obtained by using the ion-exchange equilibrium treatment for acetylsalicylic acid and 3-acetoxy-

For personal use only.

2-naphthoic acid, respectively. Note that some larger values are also reported in the literature (41).

We conclude that the non-linearized Poisson–Boltzmann equation, which treats the ion distribution around micelles, can explain our experimental results for reactions with negatively-charged substrates in cationic CTAB micelles. This treatment predicts the decrease in substrate binding to micelle with added ions, based on the decrease in the micellar surface potential. This effect can not be explained by the pseudophase ion-exchange model.

Considering the results we have obtained with this electrostatic treatment we have come to the conclusion that it explains our kinetic data for positively or negatively charged substrates such as crystal violet, acetylsalicylic acid, or 2-acetoxy-2-naphthoic acid, which are supposed to be solubilized near the micellar Stern layer. However, this treatment fails for very hydrophobic charged or neutral substrates like tris(4,7-diphenyl-1,10-phenantroline)Fe(II) ion or DDT, perhaps because they are solubilized within the micellar core and thereby changing the micellar structure. This agrees with our initial conclusion in ref. 42 but still needs experimental verification.

On the possibilities of π-ylides

RICHARD FRANCIS LANGLER[1] AND LAURA PRECEDO
Department of Chemistry, Florida Institute of Technology, Melbourne, FL 32901-6988, U.S.A.

Received November 24, 1989

RICHARD FRANCIS LANGLER and LAURA PRECEDO. Can. J. Chem. **68**, 939 (1990).

A systematic survey of substituted annulenes, using zeroth order Hückel theory, has uncovered a subclass of such structures which are predicted to have very substantial charge separation. An examination of selected structures by MNDO semi-empirical molecular orbital computations provided support for the Hückel descriptions. Such compounds may be of immediate interest to those pursuing synthetic or mechanistic problems which involve cycloaddition reactions.

Key words: π-ylides.

RICHARD FRANCIS LANGLER et LAURA PRECEDO. Can. J. Chem. **68**, 939 (1990).

Un examen systématique d'annulénes substitués, faisant appel à la théorie d'ordre zéro de Hückel, a permis de déceler des sous-classes de ces structures pour lesquelles on prédit qu'il existera de trés importantes séparations de charges. Des calculs semi-empiriques d'orbitales moléculaires MNDO effectués sur des structures choisies ont fourni un support pour les descriptions de Hückel. De tels composés peuvent présenter un intérét immédiat pour ceux qui examinent les problèmes de synthèse ou mécanistiques impliquant des réactions de cyclo-additions.

Mots clés : π-ylides.

[Traduit par la revue]

Introduction

Recently, our interest in Hückel theory (1) has prompted us to begin an examination of substituted even annulenes. We outline here our conclusions regarding those species for which fully π-bonded Lewis structures cannot be drawn,[2] e.g. **1**, **2***a*, and **3**.

In graph theoretical terms,[3] any hydrocarbon with a π system can be assigned a characteristic polynomial (2, 3) of the general form:

$$[1] \quad a_0x^j + a_1x^{j-1} + a_2x^{j-2} + \ldots\ldots + a_j = 0$$

The roots of the polynomial r_1, $r_2 \ldots . r_j$ are related to the eigenvalues of the Hückel eigenfunctions as shown in eq. [2].

$$[2] \quad E_i = \alpha + r_i\beta$$

The coefficients a_0, a_1, a_2 ..... a_j may be determined (in conjunction with the Sachs' formula (2, 3) by counting Sachs' graphs(s) containing the appropriate number of carbon atoms, e.g., j carbon atoms/graph (s_j) to determine a_j. For "diradical" substituted even annulenes, e.g. **1**, **2**, and **3**, no Sachs' graphs, s_j, can be drawn. Therefore a_j must be zero. All such "diradicals" must have a non-bonding molecular orbital ($E = \alpha$).

These systems can be subdivided (4) into alternant hydrocarbons **1** and non-alternant hydrocarbons **2***a* and **3**. For all even alternant hydrocarbons a_{j-1} must be zero. As is the case for **1**, all even alternant "diradicals"[4] must have a pair of non-bonding molecular orbitals (NBMO's) and are expected to be ground state triplets in accord with their simple Lewis structures. Consistent with that picture, each carbon in **1** has a Hückel π-electron population-derived partial charge of zero.

The following conclusions are most easily reached from even non-alternant "diradical" structures[4] in which one electron is endocyclic and the other is exocyclic as shown for **2***a* and **3**. For Lewis structures of that type, in which one or more of the ring carbons are involved in exocyclic π bonds e.g. **2***a*, it is not possible to draw any Sachs' graphs: s_{j-1}. Therefore, (*i*) a_{j-1} is zero, (*ii*) there is a second NBMO, and (*iii*) they too must be ground state triplets. Consistent with that picture, the ring in **2***a* only develops a small positive charge as shown in **2***b*. The total π-electron-based charge developed in the ring for **2***a*, **2***b* is substantially less than that of other non-alternant systems e.g. **4**.

For even non-alternant "diradical" structures[4] (one endocyclic and one exocyclic electron) which have no exocyclic π bonds, e.g., **3**, it is always possible to draw at least one Sachs' graph:[5] s_{j-1}.

Therefore, (*i*) a_{j-1} cannot be zero, (*ii*) there is only one NBMO, and (*iii*) *unlike* **1** *and* **2***a*, **3** *is expected to be a ground state singlet*.

Since **3** has a spin-pair of non-bonding electrons, why not write the Lewis structure with a lone pair as shown in **5***a*? We choose the charge separated structure **5***a* which has the aromatic cyclopropenyl ring.

Related arguments have permitted earlier workers to deduce that **5***a* and **7***a* have one NBMO each (5). Both earlier reports raise the question of ground state multiplicity for such compounds and both conclude that they are likely to be ground state singlets. Our next article will examine the question of ground state multiplicity for **5***a* and **7***a* using, *inter alia, ab initio* computations at the STO 3-21G level. Further discussion, here, will focus exclusively on singlet states.

The present report is a theoretical study of non-alternant structures like **3**, **5***a* with a view to the exploration of (*i*) the likelihood that such structures will be strongly polarized, (*ii*) the possibility that these structures may be accessible in the laboratory, and (*iii*) the synthetic potential structural analogues might have for the construction of carbocycles and heterocycles.

Method

Simple Hückel calculations, assuming the orthogonality of adjacent p orbitals, were carried out in the usual way (4).

Full molecular orbital computations were done using the

[1]Author to whom correspondence should be addressed. Present address: Department of Chemistry, Mount Allison University, Sackville, N.B., Canada E0A 3C0.

[2]The present report is limited to a consideration of structures which have two non-bonding electrons in their Lewis structures.

[3]Zeroth order Hückel theory and graph spectral theory are fully equivalent (2).

[4]Generalizations apply only to substituted monocycles.

[5]All Sachs' graphs s_{j-1} for such structures must contain the ring as a component.

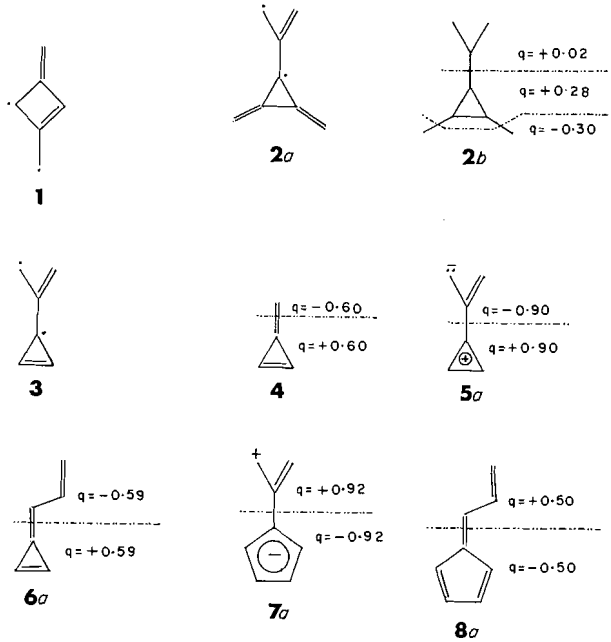

Fig. 1. Structures and partial group charges (q) derived from Hückel π-electron population numbers.

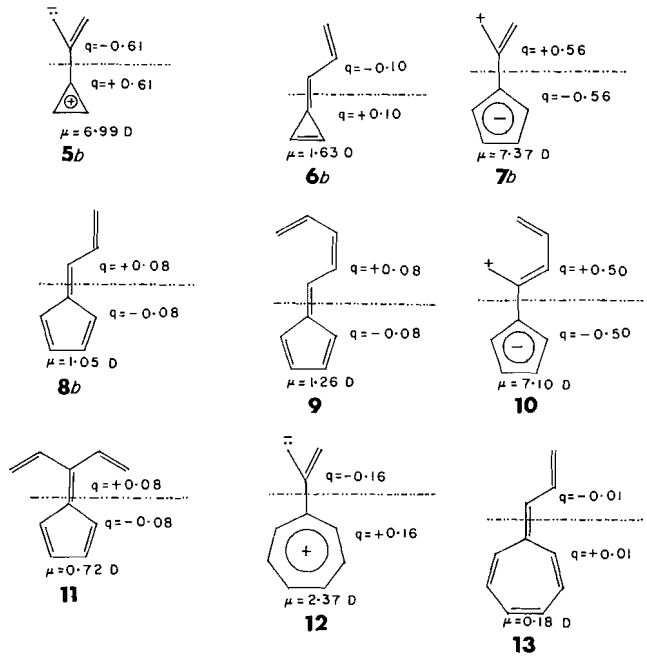

Fig. 2. Structures, MNDO calculated dipole moments (μ) and partial group charges (q) obtained from MNDO π-electron population numbers.

MNDO (Modified Neglect of Differential Overlap) semiempirical method (6).

The isopropyl substituted systems were constrained to have C_{2v} symmetry but were otherwise fully optimized. All other structures were fully optimized.

Results

Figure 1 presents the results of simple Hückel calculations on an assortment of non-alternant hydrocarbons. They ascribe very strongly polarized π systems to the representative "π-ylides" **5***a* and **7***a*. Their close structural relatives **4**, **6***a*, and **8***a* have more weakly polarized π systems at the Hückel level.

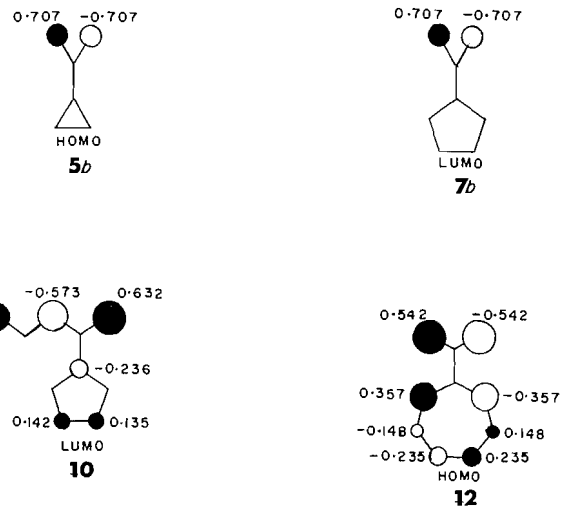

Fig. 3. MNDO frontier orbitals for "π-ylides."

Figure 2 presents the results of our MNDO computations on an assortment of "π-ylides" and some close structural relatives. The MNDO results suggest systematically weaker polarization for non-alternant hydrocarbons than do the Hückel results. However, the MNDO computations suggest a much more dramatic difference in the degree of polarization in the π systems of the "π-ylides" **5***b*, **7***b*, **10**, and **12** and their close structural relatives **6***b*, **8***b*, **9**, **11**, and **13**.

Furthermore, the calculated dipole moments are as much as an order of magnitude larger for the "π-ylides" than for their structural isomers. We note that the calculated dipole moments for **5***b*, **7***b*, and **10** (*ca.* 7 D) are comparable to the experimental gas phase dipole moment of LiBr (7. 27 D) (7).

Discussion

Our calculations, both simple Hückel and MNDO, fully support the strongly polarized π systems we first proposed for structures like **5***a* when we deduced that each had a single NBMO at the Hückel level. In each case, the side chain would be expected to have high reactivity while the aromatic ring would be expected to be relatively unreactive. In accord with these expectations, the appropriate MNDO frontier molecular orbital, i.e. that which corresponds to the Hückel NBMO, indicates significantly higher reactivity (8) in the side chain as shown in Fig. 3.

The chemistry expected for "π-ylides" with electron-rich side-chains may have much in common with that of conventional ylides. Those with electron-deficient side chains offer the novel possibility of *umpolung* ylide reactivity.

Cycloaddition reactions between appropriately selected "π-ylides" should be unusually facile since they may proceed through symmetry-allowed transition states which would enjoy very favorable coulombic interactions, e.g. reaction [3]. Reactions [3]–[5] illustrate potential applications of "π-ylides" to the construction of some carbocycles.

Attempts to develop "π-ylide" reagents for synthetic purposes must presuppose that such structures may be sufficiently stable to permit their preparation. The very substantial charge development in the rings of the "π-ylide" structures **5***a* and **7***a* compares favorably with the total charge in their annulene counterparts, the cyclopropenyl cation and the cyclopentadienyl anion. To obtain further support for the highly developed aromatic character of the "π-ylides," we have calculated the

[c]Selected annulenes are included for comparative purposes.

topological resonance energies[6] for the substitited annulenes shown in Figs. 1 and 2 (see Table 1). The topological resonance energies clearly indicate pronounced aromatic character for the "π-ylides" **5**, **7**, **10**, and **12**. Consequently, there is some reason to hope that such structures may be successfully prepared.

[3] 
5 **7**

[4] 
5

[5] 
7

The development of synthetic methodology using such reagents would be severely limited in scope if products had to contain pendant carbocyclic rings. It would be advantageous should such reagents be constructed with heterocyclic rings instead of carbocyclic rings. This would open up the possibility that the heterocyclic ring might be transformed into useful functionality after formation of the desired carbocycle. The design of such heterocycles would be facilitated by application of the rule of *topological charge stabilization* (9). Simply stated, one should introduce ring heteroatoms which best support the excess charge indicated by *Hückel calculations on the hydrocarbon system*.

The result might well be a reagent with satisfactory initial stability and a product amenable to removal of the polarizing ring. As an example, **7** might be replaced (in reaction [3]) by a nitrogen heterocycle which would be more amenable to hydrolysis. One could easily envision a sequence of the sort shown in reaction [6].

[6] 
We note that the foregoing discussion could be applied to the side chain of the "π-ylide." In the event that heteroatoms were incorporated into the side chain, the newly constructed ring in the product would be heterocyclic. Synthetic strategies based on π-ylides might well facilitate access to new heterocyclic systems.

Summary

A highly polar group of non-alternant hydrocarbons have been recognized viz: "π-ylides."

Both simple Hückel calculations and MNDO computations suggest a very high degree of charge separation in "π-ylide" structures.

Topological resonance energies indicate a pronounced aromatic character for "π-ylides," suggesting that these novel structures may be accessible in the laboratory.

"π-ylides" offer tantalizing potential for new synthetic methodology vis-à-vis the preparations of carbocycles and heterocycles.

Received September 12, 1989

DENNIS M. WHITFIELD, HENRIANNA PANG, JEREMY P. CARVER, and JIRI J. KREPINSKY. Can. J. Chem. **68**, 942 (1990).

As part of our studies of complex oligosaccharides, in particular their three-dimensional structure, we have synthesized the antigen I branchpoint penta- and tetrasaccharides. The unbranched trisaccharide **3***D* was also synthesized, and its derivative **3***B* served as the intermediate for the synthesis of higher oligosaccharides. NMR spectra of major intermediates as well as of the final oligosaccharides were completely assigned. Mass spectra of the synthetic intermediates and the final oligosaccharides were analyzed and compared with those of a similar group of oligosaccharides containing L-fucose, *N*-acetyl-D-glucosamine, and D-galactose. Certain observations were made that could be utilized in the interpretation of mass spectra for the structural determination of protected oligosaccharides during the synthesis.

Key words: oligosaccharide synthesis, I antigen, carbohydrate mass spectrometry, carbohydrate NMR spectrometry, Gal-GlcNAc oligomers.

DENNIS M. WHITFIELD, HENRIANNA PANG, JEREMY P. CARVER et JIRI J. KREPINSKY. Can. J. Chem. **68**, 942 (1990).

Dans le cadre de nos travaux sur les oligosaccharides complexes, en particulier en ce qui a trait à leur structure tridimensionnelle, on a synthétisé les penta- et tétra-saccharides des ramifications de l'antigène I. On a aussi synthétisé le trisaccharide linéaire **3***D* et on utilisé son dérivé **3***B* comme intermédiaire dans la synthèse d'oligosaccharides plus importants. On a attribué toutes les bandes des spectres RMN des intermédiaires principaux ainsi que des oligosaccharides finaux. On a analysé les spectres de masse des intermédiaires de synthèse ainsi que des oligosaccharides finaux et on les a comparés avec ceux d'un groupe similaire d'oligosaccharides contenant du L-fucose, de la *N*-acétyl-D-glucosamine et du D-galactose. On a fait certaines observations qui pourraient être utilisées durant les synthèses pour interpréter les spectres de masse et pour déterminer les structures d'oligosaccharides.

Mots clés : synthèse d'oligosaccharides, l'antigène I, spectrométrie de masse des hydrates de carbone, spectrométrie RMN des hydrates de carbone, oligomères Gal-GlcNAc.

[Traduit par la revue]

Introduction

Biological functions of the oligosaccharide moieties of glycoproteins depend on their three-dimensional structures, and of particular interest are the branching points, since these are areas of potential interactions between different chains (1). The more highly branched oligosaccharides have been consistently reported in both O-linked and N-linked oligosaccharides from glycoproteins obtained from tumour tissues and transformed or cancer cell lines (2). One such branching, resulting from the glycosylation of O-6 of the galactose residue of an "i" disaccharide fragment by another GlcNAc residue is responsible for the oncofetal differentiation from "i" to "I" structures (3). We have investigated by NMR spectroscopy and potential energy calculations the conformations of "minimal" structure of the "I" antigen class of compounds, GlcNAc(β1-3)[GlcNAc(β1-6)]-Galβ-, and in order to assess the influence of elongation of the oligosaccharide chains on the spatial arrangements of the chains, we have now synthesized tetra- and pentaoligosaccharides (the results of our conformational studies will be reported later).[4]

Synthesis

For our conformational analysis we required an NMR "silent" glycoside in order to avoid the overlap of OCH_n of an aglycon with ring hydrogens on the chemical shift scale and the ambiguity of anomerization (in the case of a free reducing sugar), and to reduce the number of relaxation pathways. Consequently, all our compounds are trideuteriomethyl glycosides.

Several groups have investigated methods for the formation of oligosaccharides at this branchpoint. Previously, Veyrières and co-workers prepared reducing oligosaccharides similar to **3***D* and **6***C* (5). They used an acid catalyzed oxazoline approach to prepare the GlcNAc(β1-3)Gal linkage in approximately 50% yield, and a similar yield is reported using silver promoted glycosylation with halides (6). These yields are comparable to those reported by Abbas and Matta (7) and Tejima and co-workers (8) for this linkage. Reports from both the Veyrières (6) and Ogawa (9) laboratories indicate yields in the 70–80% range using Lewis acid catalyzed glycosylation with fluorides or trichloroacetimidates. Enzymic synthesis also has been applied

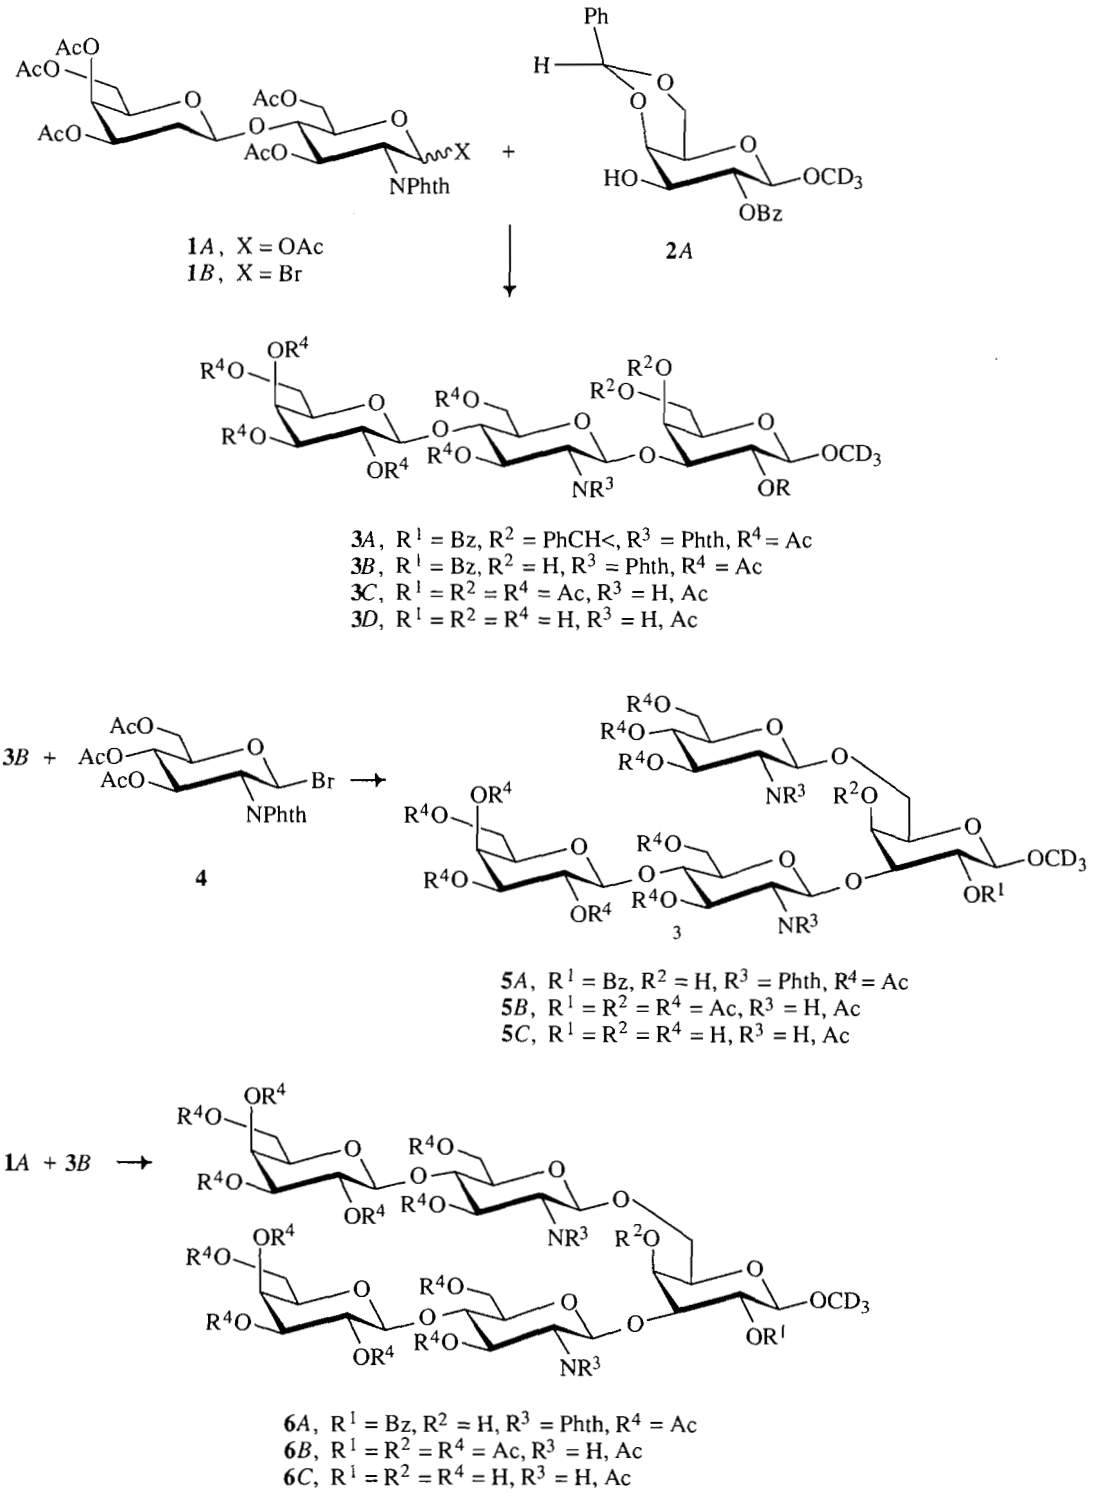

SCHEME 1

to syntheses of oligosaccharides in this area (10). The approach described in this communication utilizes the non-nucleophilic base 2,6-di-*tert*-butyl-4-methylpyridine (DTBMP) to provide easily reproducible 72% yields. This base (DTBMP) was crucial to success of the silver triflate coupling, as the more often used bases such as sym-collidine (11) produced intractable mixtures from which only traces of the desired product **3***A* could be isolated after extensive purification by HPLC (16).

The lactosamine unit protected as **1***A* was transformed into the bromide **1***B* (11) with which the galactosyl derivative **2***A* (8, 12) was glycosylated to give the protected trisaccharide **3***A* (previously the chloride (13) had also been used as a glycosylating agent). Both bromides **1***B* and **4** have been used for syntheses of larger oligosaccharides; e.g., refs. 9 and 11. The compound **3***A* was first subjected to hydrogenolysis to remove the benzylidine protection at the galactose, yielding **3***B* (it

should be noted that an attempted removal with acetic acid led to splitting off of the complete galactose unit). Hydrazinolysis with hydrazine hydrate in ethanol effected the removal of the phthalimido protection in good yield and after acetylation gave **3***C*. Peracetylated oligosaccharides are usually more suitable for purification by chromatography than completely deprotected compounds; consequently **3***C* was subjected to chromatography and the acetyls were then removed by KCN-catalyzed methanolysis to give **3***D*. Potassium cyanide was superior to sodium methoxide (Zemplen reagent) in this situation since the latter afforded partially decomposed products only.

Protected tetrasaccharide **5***A* and pentasaccharide **6***A* were prepared by taking advantage of the differential reactivity in **3***B* of the primary (O*H*; δ = 2.945 ppm, dd, J = 7.8 and 5.6 Hz) and the secondary (O*H*; δ = 3.269 ppm, broad singlet) hydroxyls (cf. Table 1). After glycosylation only the secondary hydroxyls at δ = 2.863 ppm in **5***A* (cf. Table 2) and at δ = 2.866 ppm in **6***A* (cf. Table 3) were present in the spectra of the respective compounds.

Thus, glycosylation of **3***B* with the bromide **4**, using silver zeolite promoter (13), gave tetrasaccharide **5***A*, which was subjected to hydrazinolysis to remove both phthalimido protecting groups and the benzoyl group. Acetyls were lost during the hydrazinolysis as well. Complete reacetylation yielded **5***B*, from which *O*-acetyl groups were removed smoothly during KCN-catalyzed methanolysis to give the desired oligosaccharide **5***C*.

Protected pentasaccharide **6***A* was again prepared from the intermediate **3***B* using the bromide **1***B*. As in the case of the protected tetrasaccharide **5***A*, the hydroxyl on C-6 was substantially more reactive than the hydroxy group on C-4 and the pentasaccharide derivative **6***A* was obtained exclusively. Depro-

tection of **6*A*** by hydrazinolysis and KCN-catalyzed methanolysis subsequently gave **6*B*** and **6*C***.

NMR spectrometry

The ^{1}H NMR data of the synthetic intermediates are listed in the tables: the trisaccharide, Table 1, tetrasaccharide, Table 2, and pentasaccharide, Table 3. In most cases it was possible to assign also ^{1}H resonances by conventional decoupling and (or) ^{1}H–^{1}H COSY techniques. All coupling constants and chemical shifts are based on peak separations. Overlapping resonances are marked with the same superscript numbers. All spectra are consistent with the proposed structures. The ^{13}C and ^{1}H resonances of the unprotected oligosaccharides were assigned through heteronuclear ^{1}H–^{13}C COSY (cf. Tables 4 and 5).

The only ambiguity is in the assignment of the terminal galactose residues of the pentasaccharide derivatives. The appropriate connectivities were readily established within the respective arms, but which arm (6 or 3) remained ambiguous. The proposed assignments are based on a comparison with tetrasaccharides **5*A*–5*C*** where the terminal galactose is definitively on the 3 arm.

Several of these compounds contain a single benzoate group. Since its aromatic (*o, m, p*) resonances are very distinct, they provided a reliable marker allowing the assessment of the purity of individual preparations. All ^{1}H and ^{13}C phthalimido resonances were broad, and in the cases where these resonances overlapped with other aromatic resonances, their presence could only be ascertained by integration values. Fortunately, characteristic fragments for the phthalimido group were found in the mass spectra of the same samples (cf. below).

One surprising observation was made in connection with the upfield shift of the GlcNAcβ1,6 H-5 proton in compounds **5*A*** (3.006) and **6*A*** (2.823). The origin of this effect is not immediately apparent but it is suggestive of a juxtaposition of this hydrogen and an aromatic ring (such as the phthalimide).

Mass spectrometry

Fast atom bombardment mass spectrometry (FAB/MS) in positive ion mode was utilized to confirm the structures of the target substances and synthetic intermediates. In addition, a number of compounds previously synthesized in this laboratory (12, 16) (cf. formulae listed in Table 6) were also investigated by FAB/MS. We have often noted that, particularly in the case of more complicated protected oligosaccharides, it is difficult to interpret unequivocally their unidimensional NMR spectra because of the complexity and overlapping of their signals. In some such cases mass spectrometry can give a quick and definitive proof of the presence of certain structural elements

in the molecule, in addition to the molecular mass of the compounds.

The mass spectra of the compounds investigated can be exemplified by that of compounds **6***A*, **6***C*, **8***A*, and **8***B* (shown in Figs. 1 and 2). Other mass spectrometric data are listed in Table 7. Relatively weak $[M+H]^+$ ions and $[M+Na]^+$ and $[M+NH_4]^+$ ions are observed in all the spectra. In compounds containing several benzyl and sometimes benzylidine protecting groups, $[M-H]^+$ ions become more dominant than $[M+H]^+$ ions; cf. for example, the more abundant m/z 804 $[M-H]^+$ ion than m/z 806 $[M+H]^+$ ion in Fig. 2a. Completely deprotected oligosaccharides usually display the $[M+H]^+$ ion with fair intensity: often it is one of the most abundant ions in the spectrum (with the exception of ions at very low m/z).

Fragmentation in the FAB mass spectra of peracetylated and permethylated oligosaccharides (4, 14, 17) occurs at the glycosidic bonds between the anomeric carbon and the charge-carrying oxygen (fragmentation pathway (a)). This fragmentation pathway gives rise to a series of fragment ions, for example, m/z 331, 706, and 1677 of compound **6***A* (Fig. 1a). The cleavage of the aglycon (loss of OCD_3 or OC_3D_7), however, is difficult in deprotected larger oligosaccharides and they consequently display very few $[M-OCD_3]^+$ or $[M-OC_3D_7]^+$ ions.

Gal- |-O-GN- |-O-Gal-| -O-Agl

(a)

In unprotected oligosaccharides (**14**, **3***D*, **5***C*, **6***C*), *N*-acetyllactosamine consistently gives rise to an abundant ion (m/z 366, fragmentation pathway (a), Fig. 1b). Terminal 2-acetamido-2-deoxyhexose (such as *N*-acetylglucosamine) gives rise to an ion at m/z 204 (**13***C*).

After the initial loss of the aglycon moiety through fragmentation pathway (a), further cleavage between the anomeric carbon and the oxygen, accompanied by hydrogen transfer to the oxygen and charge retention at the "reducing" end of the oligosaccharides, gives rise to m/z 972 in compound **6***A* (Fig. 1a), m/z 351 in compound **8***B* (Fig. 2b), and m/z 355 in compound **8***A* (Fig. 2a; cf. formula **15**, Table 6). The ion **15** (m/z 355, Table 6) indicates the presence of 2-*O*-benzoyl-4,6-*O*-benzylidene hexose in the molecule (e.g., monosaccharides **2***A* or **2***C*, or oligosaccharides **3***A*, **8***A*, **10**α, **10**β**A**). Transfer of

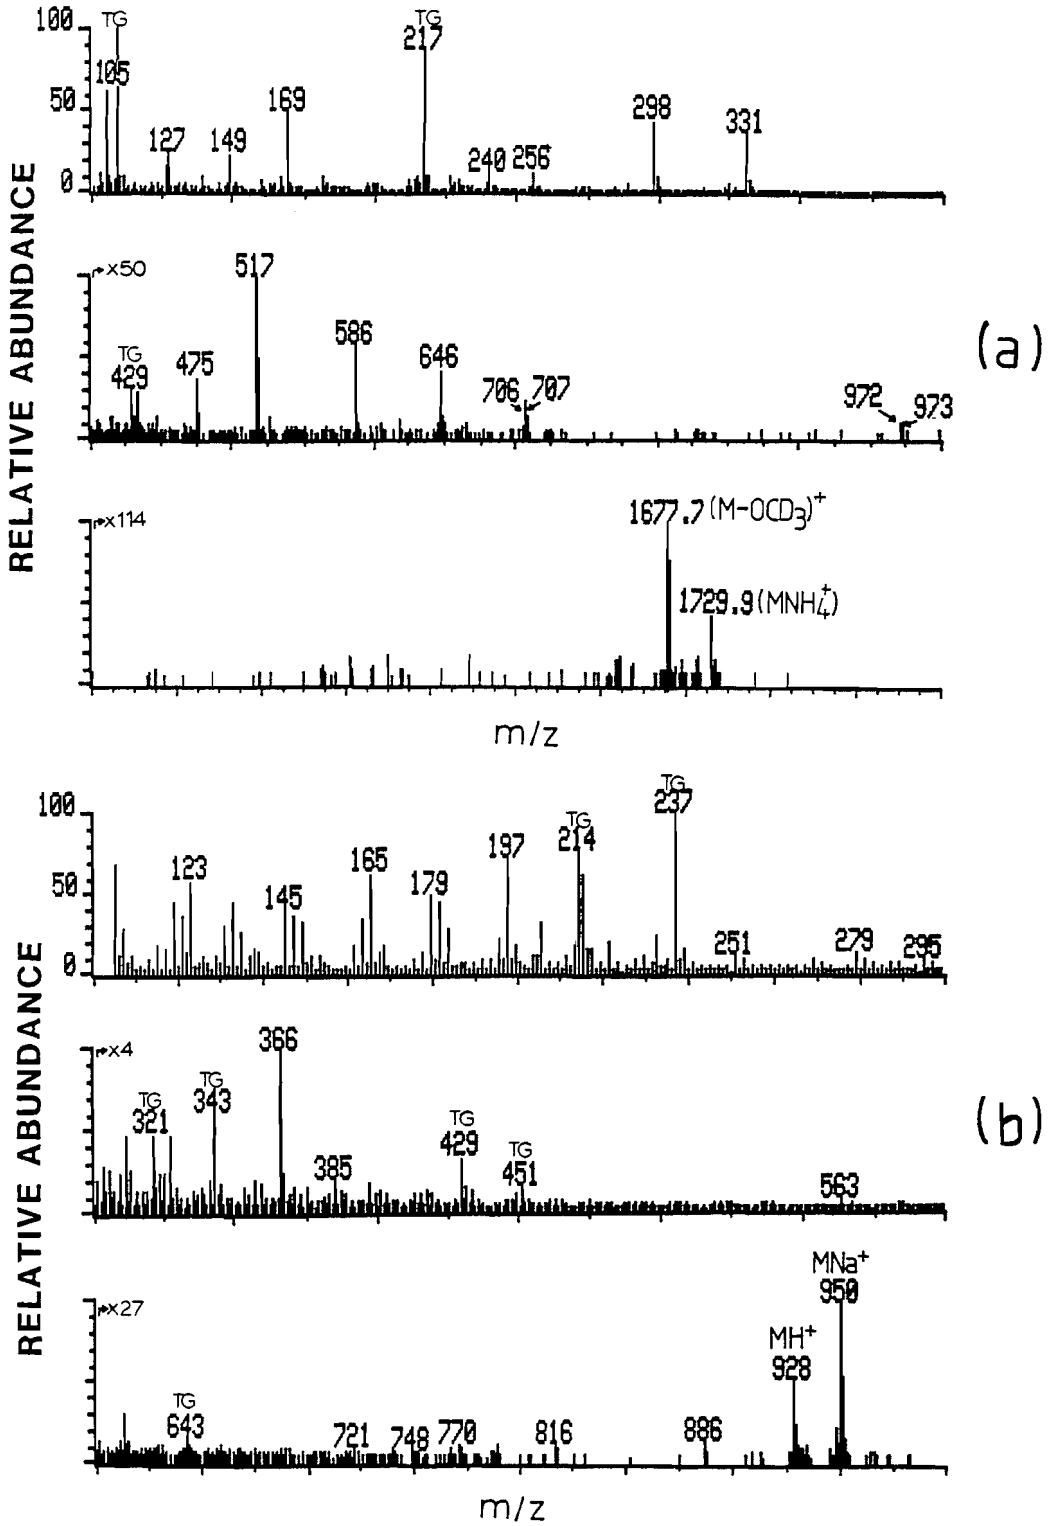

FIG. 1. FAB mass spectra of (a) compound **6***A*, and (b) compound **6***C*. TG indicates ions originating from thioglycerol matrix.

groups other than hydrogen, such as benzyl or acetyl, to the oxygen has occasionally been observed.

Certain protecting groups also can be identified. For instance, benzoyls give rise to an ion at m/z 105 in every compound studied (**7***A*–**7***C*, **8***A*, **8***B*; cf. spectra of **8***A* and **8***B*, Fig. 2). Benzyl groups can be identified through the loss of 90 mass units (benzyl group and hydrogen transfer). The phthalimido group used frequently for the protection of the NH_2 functionality reveals itself by the presence of an ion at m/z 418 (2-deoxy-2-phthalimido-3,4,6-tri-*O*-acetylhexose, at a non-reducing terminus), which subsequently loses two acetyl groups to give an abundant m/z 298 ion. The m/z 298 ion is also formed from an internal unit bearing an *N*-phthalimido group (**3***A*, **3***B*, **9***A*, **10**α, **10**β*A*, **10**β*B*, **11***A*, **13***A*).

As an example of a quick analysis utilizing the above principles, the mass spectrum of **6***A* (Fig. 1) reveals the presence of benzoyl (m/z 105), peracetylated *N*-phthalimido-lactosamine (m/z 706, 331, 298), and the remaining portion of the molecule after the loss of one arm from $[M-OCD_3]^+$ at m/z 1677. The spectrum of **6***B* confirms that the phthalimido group

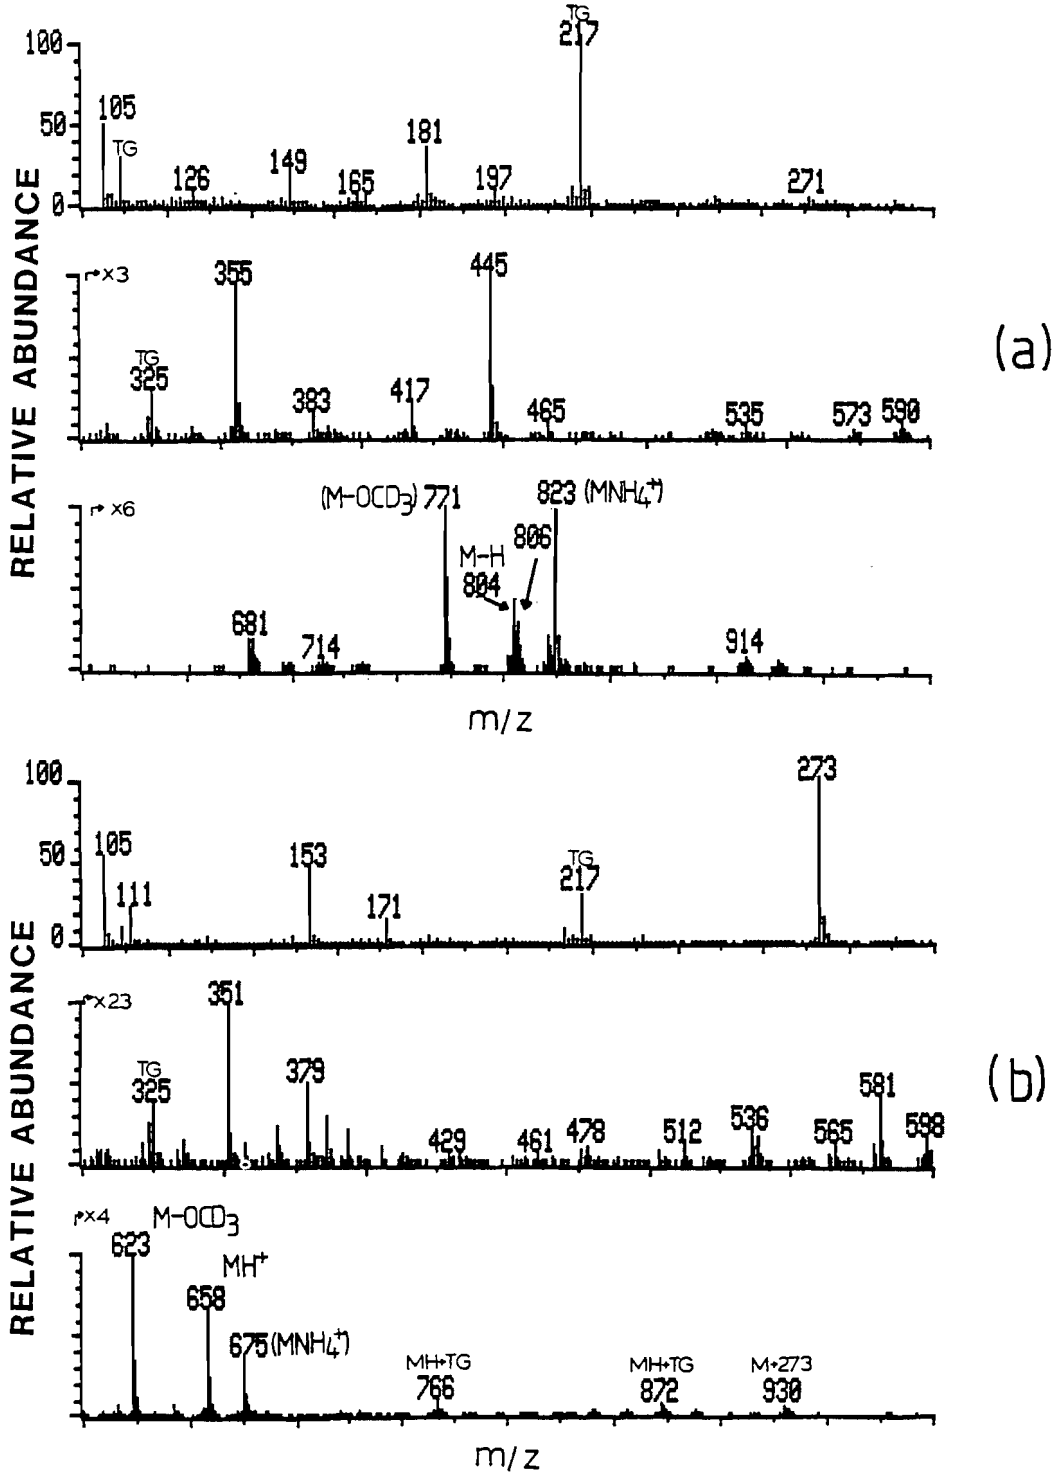

FIG. 2. FAB mass spectra of (a) compound **8***A*, and (b) compound **8***B*. TG indicates ions originating from thioglycerol matrix.

was completely replaced by *N*-acetyl (ions at m/z 618, 331; the other part of the molecule after the loss of one arm from $[M+H]^+$ gives rise to an ion at m/z 899).

Experimental

General methods

Melting points were determined on a Reichert Thermovar melting point apparatus and are uncorrected. Optical rotations were measured with a Perkin–Elmer polarimeter (model 243B) at 26 ± 1°C. Microanalyses were performed by the Micro Analytical Laboratory Ltd., Markham, Ontario. IR spectra were recorded on a Perkin–Elmer (model 1430) spectrometer using thin film on NaCl plates.

^{1}H NMR spectra were recoreded at 360.06 MHz with a Nicolet spectrometer at the NMR Spectroscopy Laboratory of the Carbohydrate Research Centre, University of Toronto. ^{13}C NMR spectra were recorded at 100.566 MHz with a Varian XL-400 spectrometer at the Chemistry Department, University of Toronto. Spectra were obtained at 19 ± 2°C either in $CDCl_3$ containing a trace of TMS (0 ppm, ^{1}H and ^{13}C) as the internal standard or in D_2O (99.98%, Aldrich) containing a trace of acetone (2.225 ppm relative to internal DSS, ^{1}H) as the internal standard. ^{13}C spectra in D_2O were referenced to external dioxane (67.4 ppm relative to TMS). Samples for NMR analyses in D_2O were passed through a Chelex 100 (Bio-Rad) ion-exchange resin in doubly distilled H_2O to remove paramagnetic impurities, lyophilized, and then lyophilized three times with D_2O. In the ^{1}H NMR tables, overlapping

resonances are marked with the same superscript numbers. Throughout the experimental section, ^{13}C NMR resonances whose resonances may be interchanged are marked with the same superscript numbers.

Fast Atom Bombardment mass spectras (FAB-MS) were recorded with a VG Analytical ZAB-SE mass spectrometer at the Mass Spectrometry Laboratory of the Carbohydrate Research Centre, University of Toronto. The samples in thioglycerol were bombarded by neutral xenon atoms (8 keV and 1 mA anode current) generated by Ion-Tech Saddle Field Ion Gun.

Thin-layer chromatography (TLC) was performed on silica gel $^{60}F_{254}$ (Merck) plastic plates and visualized by spraying with 50% sulfuric acid and (or) 1% orcinol acidic ferric chloride (15) and heating at 200°C. Silica gel (230–400 mesh; Toronto Research Chemicals) was used for flash chromatography. All starting materials were dried overnight under vacuum (10^{-3} Torr; 1 Torr = 133.3 Pa) prior to use and the solvents were distilled from appropriate drying agents. Solutions were concentrated at water aspirator pressure.

Trideuteriomethyl 2-O-*benzoyl-4,6-*O-*benzylidene-3-*O-*(2,3,4,6-tetra-*O-*acetyl-4-*O-β-D-*galactopyranosyl-3,6-di-*O-*acetyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl)-β-D-galactopyranoside (3*A*)*

The crude bromide **1***B* was prepared by saturating a mixture of dichloromethane (30 mL) and acetic anhydride (2 mL) with HBr gas at 5°C, adding acetate **1***A* (1.86 g; 2.4 mmol) as a solid, and rinsing the residue into the flask with dichloromethane (10 mL). HBr was bubbled through this mixture for 45 min and then the flask was tightly stoppered and the temperature allowed to rise for 1.5 h. Excess HBr was removed by flushing the flask with argon gas for 20 min. The remaining solvents were removed by evaporation on a rotary evaporator at high vacuum without heating. Dry dichloromethane (5 mL) and toluene (10 mL) were added to the residue and evaporated at high vacuum (twice), to remove residual acetic anhydride. The residue was dried under vacuum overnight, then dissolved in dry dichloromethane (15 mL) and added to a stirred mixture of alcohol **2***A* (0.46 g; 1.2 mmol), silver trifluoromethanesulphonate (0.6 g; 2.4 mmol), 2,6-di-*tert*-butyl-4-methylpyridine (0.48 g; 2.4 mmol), flame dried molecular sieves 3 Å (5 g), and dry dichloromethane (20 mL) at 0–5°C under an atmosphere of argon. The stirring was continued for 16 h and the temperature was allowed to rise to room temperature. The solids were removed by filtration through a Celite bed, washed with dichloromethane, and the combined filtrates evaporated to dryness. The residue was purified by flash chromatography on silica gel (ethyl acetate:toluene:hexane 60:30:10) to yield **3***A* as a mixture (1.1 g; 85:15; 72%) with an unidentified impurity. A small sample of this mixture was purified to homogeneity by preparative HPLC (μ Porasil, hexane:dichloromethane:ethyl acetate 40:20:40); mp 268–272°C; $[\alpha]_D$ +29.9° (*c* 0.68, $CHCl_3$); IR (neat): 1780 sh, 1750, 1725 (CO) cm^{-1}; ^{13}C NMR ($CDCl_3$) δ: 169.1–170.3 (6 × CH_3CO), 167.5 (br, CONCO), 167.3 (PhCO), 101.7[1] (Cl-Gal-β-OCD_3), 101.0[1] (Cl-Gal-β-1,4-), 100.8[1] ($PhCO_2$), 99.5 (Cl-Glc). Anal. calcd. for $C_{53}H_{54}D_3NO_{24}$ (1095.002): C 58.14, H 4.97, N 1.28; found: C 57.92, H 4.91, N 1.28.

Trideuteriomethyl 2-O-*benzoyl-3-*O-*(2,3,4,6-tetra-*O-*acetyl-4-*O-β-D-*galactopyranosyl-3,6-di-*O-*acetyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl)-β-D-galactopyranoside (3*B*)*

Compound **3***A* (1.0 g, 0.78 mmol), prepared as described above and without purification, was dissolved in acetic acid (40 mL) and hydrogenated at room temperature and atmospheric pressure for 16 h with Palladium black (Strem, 700 mg) as catalyst. The solids were removed by filtration through acetic acid wetted Celite, rinsed with 95% ethanol, and the solvents were evaporated at high vacuum. The residual acetic acid and water were removed by azeotropic distillation with toluene (2 × 50 mL). The residue was purified by flash chromatography on silica gel (isopropanol:dichloromethane 8:92) to yield pure **3***B* (0.68 g, 87%); mp 153–154°C; $[\alpha]_D$ +36.7° (*c* 1.8, $CHCl_3$); IR (neat):3250 (br OH), 1780 sh, 1750, 1725 (CO) cm^{-1}; ^{13}C NMR ($CDCl_3$) δ: 169.2–171.0 (6 × CH_3CO), 167.8 (br, CONCO), 164.7 (PhCO), 101.9[2] (Cl-Gal-β-OCD_3, $^2J_{C-H}$ 160), 101.1[2] (Cl-Gal-β-1,4-, $^2J_{C-H}$ 162), 98.5 (Cl-Glc, $^2J_{C-H}$ 160). Anal. calcd, for $C_{46}H_{50}D_3NO_{24}$ (1006.893): C 54.87, H 5.00, N 1.39; found: C 55.45, H 5.03, N 1.36

*Trideuteriomethyl 2,4,6-tri-*O-*acetyl-3-*O-*(2,3,4,6-tetra-*O-*acetyl-4-*O-β-D-*galactopyranosyl-2-acetamido-3,6-di-*O-*acetyl-2-deoxy-β-D-glucopyranosyl)-β-D-galactopyranoside (3*C*)*

Diol (**3***B*) (0.35 g, 0.35 mmol) was dissolved in ethanol (6 mL), hydrazine hydrate (Aldrich 85%, 3 mL) was added, and the mixture heated at 70°C for 30 min. The liquids were removed by evaporation at high vacuum and the residual water removed by coevaporation with toluene (2 × 25 mL). The residue was cooled in an ice bath under an atmosphere of argon, then dry pyridine (8 mL) and dry acetic anhydride (5 mL) were added. The stirring was continued for 60 h and the temperature allowed to rise to room temperature. The liquids were removed by evaporation at high vacuum followed by coevaporation with toluene (3 × 20 mL). The residue was purified by chromatography on silica gel (isopropanol:dichloromethane 6:94) to yield **3***C* (0.28 g, 85%); mp 124–127°C; $[\alpha]_D$ +7.8° (*c* 1.04, $CHCl_3$); IR (neat): 3365 br (OH), 1750 (COO), 1680, 1550 (CON) cm^{-1}. Anal. calcd. for $C_{39}H_{52}D_3NO_{25}$ (940.8315): C 49.79, H 5.57, N 1.49; found: C 50.10, H 5.61, N 1.53.

*Trideuteriomethyl 3-*O-*(2-acetamido-2-deoxy-4-*O-β-D-*galactopyranosyl-β-D-glucopyranosyl)-β-D-galactopyranoside (3*D*)*

Peracetate (**3***C*) (0.15 g, 0.16 mmol) was dissolved in methanol (6 mL) and KCN (70 mg) was added under argon; the mixture was left to stir for 16 h under an argon atmosphere. To this mixture was added methanol (10 mL), water (5 mL), and mixed bed resin Ag 501-X8 (5 g). After 30 min of stirring, the solids were removed by filtration, washed with methanol:water (1:1, 50 mL), and methanol (50 mL). The filtrate was concentrated at high vacuum and taken up in a small volume of water, filtered through a disposable millipore filter, and lyophilized to yield pure **3***D* (0.82 g, 91%); mp 181–186°C; $[\alpha]_D$ −8.3° (*c* 1.21,

$CH_3OH:H_2O$ 4:1); IR (neat): 3350 (br, OH, NH), 1665, 1550 (CON), cm^{-1}. Anal. calcd. for $C_{21}H_{34}D_3NO_{16}$ (562.4967): C 44.84, H 6.09, N 2.49; found: C 45.16, H 5.83, N 2.43.

Trideuteriomethyl 2-O-benzoyl-3-O-(2,3,4,6-tetra-O-acetyl-4-O-β-D-galactopyranosyl-3,6-di-O-acetyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl)-6-O-(3,4,6-tri-O-acetyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl)-β-D-galactopyranoside (5A)

Bromide **4** (Toronto Research Chemicals, 85 mg; 0.17 mmol) dissolved in dichloromethane (1 mL) was added to a stirred mixture of diol **3*B*** (115 mg; 0.11 mmol), silver zeolite 13X (2 g), and dichloromethane (6 mL) under an atmosphere of argon. The stirring was continued for 2.5 h and the solids removed by filtration through Celite and rinsed with dichloromethane. The filtrates were evaporated to dryness and the residue was purified by flash chromatography (silica gel, dichloromethane:isopropanol 25:1) to yield tetrasaccharide **5*A*** (112 mg; 69%; mp 170–173°C; $[\alpha]_D$ +32.7° (*c* 0.97, $CHCl_3$); IR (neat): 3400 (OH), 1780 sh, 1750, 1720 (CO) cm^{-1}; ^{13}C NMR ($CDCl_3$) δ: 169.4–170.8 (9 × CH_3CO), 167.5 (br, CONCO), 164.4 (PhCO), 101.4[3] (Cl-Gal-β-OCD_3), 101.3[3], (Cl-Gal-β-1,4-) 97.7[4], (Cl, 3-Glc), 97.6[4], (Cl, 6-Glc). Anal. calcd. for $C_{66}H_{69}D_3N_2O_{33}$ (1424.265): C 55.66, H 4.88, N 1.97; found: C 55.82, H 5.03, N 1.92.

Trideuteriomethyl 2,4-di-O-acetyl-3-O-(2,3,4,6-tetra-O-acetyl-4-O-β-D-galactopyranosyl-2-acetamido-3,6-di-O-acetyl-2-deoxy-β-D-glucopyranosyl)-6-O-(2-acetamido-3,4,6-tri-O-acetyl-2-deoxy-β-D-glucopyranosyl-β-D-galactopyranoside (5B)

Tetrasaccharide **5*A*** (112 mg; 0.079 mmol) was treated with the same procedure described for the peracetate **3*C***. The product was purified by flash chromatography (silica gel, isopropanol:dichloromethane 1:10) to yield **5*B*** (77 mg; 80%); mp 269–273°C; $[\alpha]_D$ −19.3° (*c* 0.23, $CHCl_3$); IR (neat): 3300 (br, NH), 1750 (COO), 1660, 1550 (CON) cm^{-1}; ^{13}C NMR ($CDCl_3$) δ: 169.0–171.2 (13 × CH_3CO), 101.7[5] (Cl-Gal-β-OCD_3, $^2J_{C-H}$ 160), 101.0[5] (Cl-Gal-β-1,4-, $^2J_{C-H}$ 160), 100.3[6] (Cl, 3-Glc; $^2J_{C-H}$ 160), 99.9[6] (Cl, 6-Glc, $^2J_{C-H}$ 160. Anal. calcd. for $C_{51}H_{69}D_3N_2O_{32}$ (1228.10): C 49.88, H 5.66, N 2.28; found: C 49.98, H 5.62, N 2.26

Trideuteriomethyl 3-O-(4-O-β-D-galactopyranosyl-2-acetamido-2-deoxy-β-D-glucopyranosyl)-6-O-(2-acetamido-2-deoxy-β-D-glucopyranosyl)-β-D-galactopyranoside (5C)

The acetyls of **5*B*** (20 mg; 0.016 mmol) were removed following the procedure used for compound **3*D*** to yield pure tetrasaccharide **5*C*** (8 mg; 65% (**5*C***)); mp 238–243°C; $[\alpha]_D$ −17.4° (*c* 0.47, $CH_3OH:H_2O$ 5:1); IR (neat): 3320 (br, OH, NH), 1650, 1550 (CON) cm^{-1}. Anal. calcd. for $C_{29}H_{47}D_3N_2O_{21}$ (765.6911): C 45.49, H 6.19, N 3.66; found: C 45.42, H 6.28, N 3.76.

Trideuteriomethyl 2-O-benzoyl-3,6-di-O-(2,3,4,6-tetra-O-acetyl-4-O-β-D-galactopyranosyl-3,6-di-O-acetyl-2-deoxy-2-phthalimido-β-D-glucopyranosyl-β-D-galactopyranoside (6A)

Compound **6*A*** was prepared as described for tetrasaccharide **5*A*** from diol **3*B*** (464 mg; 0.46 mmol) except that bromide **1*B*** generated from acetate **1*A*** (545 mg; 0.69 mmol), as described above, was used as the donor. The pentasaccharide **6*A*** was purified by flash chromatography (silica gel, dichloromethane:isopropanol 25:1) to yield pure **6*A*** (361 mg; 46%); mp 169–173°C; $[\alpha]_D$ +25.4 (*c* 1.7, $CHCl_3$); IR (neat): 3560 (OH), 1780 sh, 1750, 1720 (CO) cm^{-1}; ^{13}C NMR ($CDCl_3$) δ: 169.1–170.8 (12 × CH_3CO), 168, 167.5 (br, CONCO), 164.4 (PhCO), 101.4[7], (Cl-Gal-β-OCD_3, $^2J_{C-H}$ 160), 101.4[7] (Cl-Gal-β-1,4 (6), $^2J_{C-H}$ 160), 101.2[7] (Cl-Gal-β,4 (3), $^2J_{C-H}$ 160), 97.6[8] (Cl,3-Glc, $^2J_{C-H}$ 160), 97.3[8] (Cl,6-Glc, $^2J_{C-H}$ 160). Anal. calcd. for $C_{78}H_{85}D_3N_2O_{41}$ (1712.518); C 54.71, H 5.00, N 1.64; found: C 54.71, H 4.84, N 1.42.

Trideuteriomethyl 2,4-di-O-acetyl-3,6-di-O-(2,3,4,6-tetra-O-acetyl-4-O-β-D-galactopyranosyl-2-acetamido-3,6-di-O-acetyl-2-deoxy-β-D-glucopyranosyl)-β-D-galactopyranoside (6B)

Pentasaccharide **6*A*** (279 mg; 0.16 mmol) was treated with the same procedure described for the peracetate **3*C***. The product was purified by flash chromatography (silica gel, isopropanol:dichloromethane 1:10) to yield pure **6*B*** (173 mg; 70%); mp 135–142°C; $[\alpha]_D$ −3.5° (*c* 1.5, $CHCl_3$); IR (neat): 3340, 3220 (NH), 1750 (COO), 1660, 1545 (CON) cm^{-1}. Anal. calcd. for $C_{63}H_{85}D_3N_2O_{40}$ (1516. 354): C 49.90, H 5.65, N 1.85; found: C 50.06, H 5.62, N 1.83.

Trideuteriomethyl 3,6-di-O-(4-O-β-D-galactopyranosyl-2-acetamido-2-deoxy-β-D-glucopyranosyl)-β-D-galactopyranoside (6C)

The acetates of **6*B*** (112 mg; 0.074 mmol) were removed, following the procedure used for compound **3*D***, to yield pure pentasaccharide **6*C*** (50 mg; 73%); mp 204–207°C; $[\alpha]_D$ −7.67° (*c* 0.30, $CH_3OH:H_2O$ 1:1); IR (neat): 3300 (br, OH, NH), 1650, 1550 (CON) cm^{-1}. Anal. calcd. for $C_{35}H_{57}D_3N_2O_{26}$ (927.8331): C 45.31, H 6.19, N 3.02; found: C 45.41, H 6.18, N 2.92.

Received September 12, 1989

HO HUAT LEE, JOSE A. B. BAPTISTA, and JIRI J. KREPINSKY. Can. J. Chem. **68**, 953 (1990).

We describe a simple and efficient method for the preparation of the trisaccharide GlcNAc(β1-4)-[Fuc(α1-6)-]GlcNAc(β1-) (**1**) and of the protected form of GlcNAc(β1-4)-[Fuc(α1-6)-]GlcNAc(β1-Asn) (**2**). The key intermediate is benzyl 4,6-benzylidene chitobioside **5** giving the desired trisaccharide by *in situ* anomerization–glycosylation reaction with 2,3,4-tribenzylfucosyl bromide. The benzyl glycoside in the trisaccharide **6** has been replaced by acetate and then bromine; this glycosylating agent was used to prepare methyl and 8-methoxycarbonyloctyl glycosides as well as isothiocyanate **12**, in a series of reactions. The latter compound gave, on reaction with 1-benzyl *N*-benzyloxycarbonyl-L-asparate, compound **13** (a protected derivative of **2**), which should serve as a synthon for syntheses of glycopeptides.

Key words: glycopeptide, synthesis; oligosaccharide, synthesis; chitobiosides; fucosylated chitobiosides; *N*-linked oligosaccharides.

HO HUAT LEE, JOSE A. B. BAPTISTA et JIRI J. KREPINSKY. Can. J. Chem. **68**, 953 (1990).

On décrit une méthode simple et efficace de préparer le trisaccharide GlcNAc(β1-4)-[Fuc(α1-6)-]GlcNAc(β1-) (**1**) ainsi que la forme protégée du GlcNAc(β1-4)-[Fuc(α1-6)-]GlcNAc(β1-Asn) (**2**). L'intermédiaire clé est le 4,6-benzylidène chitobioside de benzyle (**5**) qui fournit le trisaccharide désiré grâce à une réaction d'anomérisation et de glycosylation *in situ* à l'aide du bromure de 2,3,4-tribenzylfucosyle. On a remplacé le glucoside de benzyle du trisaccharide **6** par l'acétate et finalement le bromure; dans une série de réactions, on a utilisé cet agent de glycosylation pour préparer les glucosides de méthyle ou de 8-méthoxycarbonyloctyle ainsi que l'isothiocyanate **12**. Ce dernier composé, par réaction avec le *N*-benzyloxycarbonyl-L-aspartate de benzyle, conduit au composé **13** (une forme protégée du composé **2**) qui devrait s'avérer être un synthon utile pour la synthèse de glycopeptides.

Mots clés: glucoside, synthèse; oligosaccharide, synthèse; chitobiosides; chitobiosides fucosylés; oligosaccharides liés à l'azote.

[Traduit par la revue]

As part of our studies of unusual carbohydrate epitopes appearing in neoplasia and cancer (cf. also ref. 1), we are investigating synthetic approaches to complex oligosaccharides and building blocks for syntheses of glycopeptides. The carbohydrate structures in an appropriate form are usually immunogenic and consequently can be used for the preparation of antibodies, which in turn can recognize the original carbohydrate structure. Suitably modified or as such, the antibodies can serve as diagnostic reagents. Glycosylasparagine derivatives also can be used for the construction of glycosylpeptides required as models for immunological and conformational studies. The very common trisaccharide GlcNAc(β1-4)-[Fuc(α1-6)-]GlcNAc(β1-) (**1**) occurs in the core portion of the structure of N-linked oligosaccharides in glycoproteins. The procedures that we previously described for syntheses of trisaccharide glycosides **10** and **11** were lengthy (1, 3). Consequently, we have attempted to synthesize **1** from peracetylated chitobiose (which can be obtained in quantity (2) by acetolysis of chitin). We also wanted to ascertain whether a bromide derived from **1** could be obtained without disturbing the linkage of L-fucose to one of the *N*-acetylglucosamines.[6] We anticipated that such a bromide could be utilized for a synthesis of the synthon GlcNAc(β1-4)-[Fuc(α1-6)-]GlcNAc(β1-Asn) (**2**), which could in turn be used for the preparation of glycopeptides by an extension of the peptide chain.

A major problem connected with the formation of such a synthetic intermediate is the acid lability of α-L-fucosides. To achieve glycosylation with a glycosylating agent based on fucose, fucose has to be protected by benzyl groups. Otherwise the glycosylating agent would not be sufficiently reactive (5). For instance, glycosylation of benzylidene chitobioside **5** with 2,3,4-triacetylfucosyl halogenides does not give any identifiable product. Benzyl protection on the other hand renders fucose sensitive to acid conditions. Therefore, to effect transformation of the 1-*O*-acetyl of trisaccharide **1** into a bromide for eventual use as a glycosylating agent, all hydroxy groups of **1** have to be protected as their acetyls. Thus it can be expected that the peracetylated bromide of **1** should be sufficiently stable to act as a glycosylating agent.

SCHEME 1

The formation of *N*-glycosidic linkages between glucose (6–8), 2-acetamido-2-deoxy glucose (or chitobiose) (9–13) or derivatives (16), and asparagine has been previously reported. Most often glycosylamides (4, 6–16) were used in reaction with 1-benzyl *N*-(benzyloxycarbonyl)-L-aspartate. However, in alternate approaches glycosylamines were reacted with *N*-(benzyloxycarbonyl)-L-aspartic anhydride (14), with 1-benzyl *N*-[2-(-triphenylphosphonio)ethoxycarbonyl]aspartate (15), or 1-*tert*-butyl *N*-allyloxycarbonylaspartate (4). The glycosylamines were prepared either by reduction of azides (4, 6–16, 20) or by reaction of reducing aldoses with ammonium hydrogen carbonate (19). These procedures are all relatively time-consum-

For personal use only.

ing, and thus our objective has been to reduce the complexity and shorten time requirements for the synthesis. Glycosylisothiocyanate (17) was successfully reacted with 1-benzyl *N*-benzyloxycarbonyl-L-aspartate (18), which served as precedent for our final coupling to give **13**.

Octaacetylchitobiose (**3***a*) obtained by acetolysis of chitin (2) can be transformed efficiently into either heptaacetylchitobiosyl chloride by treatment with anhydrous HCl or heptaacetylchitobiosyl bromide by treatment with titanium tetrabromide. Both of these halogenides yield benzyl glycosides on reaction with benzyl alcohol. The 4- and 6-hydroxy groups on the "nonreducing" terminal monosaccharide unit of this benzyl glycoside are protected as their benzylidene derivative, rendering the other 6-hydroxy group (residing on the "reducing" monosaccharide unit) as the only available primary hydroxyl for the reaction with 2,3,4-tri-*O*-benzyl-L-fucosyl bromide (1, 3). The secondary OH-3 groups do not react with the fucosyl residue to any appreciable extent under these conditions.

The protected trisaccharide **6**, made in just four steps, is then debenzylated and acetylated. The acetylated intermediates are suitable for chromatography, assuring that the starting material for the preparation of the bromide, by a reaction with titanium tetrabromide (21), is indeed pure. The bromide was then used without purification as the glycosylating synthon to prepare methyl glycoside **8** and 8-methoxycarbonyloctyl glycoside **10** by reaction with appropriate alcohols, and isothiocyanate **12** by reaction with potassium thiocyanate. The two former compounds were identical to samples synthesized previously by a substantially more tedious procedure (the acetyl protecting groups were smoothly removed using Zemplen's conditions) (1, 3). The isothiocyanate served as one of the starting materials for the simple and efficient synthesis of the protected derivative **13** of GlcNAc(β1-4)-[Fuc(α1-6)-]GlcNAc(β1-Asn). The anomericity of 2-acetamido-2-deoxy D-glucosides in both **12** and **13** is β, as can be seen from the diaxial coupling constants of H-1 and H-1′: J = 8.3 Hz (**12**), and 9.0 and 9.7 Hz (**13**), cf. Experimental. The synthetic design is portrayed in Scheme 1.

The choice of the isothiocyanate reaction for the introduction of the amino function into the anomeric position at the trisaccharide reducing end deserves a comment. Most importantly, it was chosen because of the mild reaction conditions required. An alternate pathway via glycosyl azides (22) (in this case the azide derived from **7** (R^1 = Ac, R^2 = N_3)) involves the reduction of the N_3 group to an amino group. The resulting amine (R^1 = Ac, R^2 = NH_2) is unstable because of the complex pattern of acetyl migrations to the amino group (cf. ref. 22). Considering the overall requirements of the azide route (cf. ref. 22 for an excellent discussion of the azide procedure), we believed that, although it gives moderate yields, the isothiocyanate approach is preferable since it is experimentally simple and easily reproducible.

After appropriate deprotection, compound **13** can be used in oligopeptide synthesis or, alternatively, the glycosylated asparagine can be obtained. The use of **13** and its variations in glycopeptide synthesis will be described in a future communication.

Experimental

General methods

Melting points were determined with a Reichert Thermovar melting point apparatus and are uncorrected. Optical rotations were measured with a Perkin–Elmer polarimeter (model 243B) at 26 ±1°C. Microanalyses were performed by the Microanalytical Laboratory Ltd., Markham, Ontario. ^{1}H NMR spectra were recorded at 360.06 MHz with a Nicolet spectrometer or at 500 MHz with a Bruker AM spectrometer at the NMR spectroscopy laboratory of the Carbohydrate Research Centre, University of Toronto. Spectra were obtained at 23 ±2°C; chemical shifts are cited in δ (ppm) scale relative to TMS (0 ppm) and coupling constants are reported in hertz (Hz). The IR spectra were recorded on a Perkin–Elmer (model 1430) spectrometer using thin film or NaCl plates. Fast Atom Bombardment mass spectra (FAB-MS) were performed with a VG Analytical ZAB-SE high-mass high-resolution mass spectrometer at the mass spectrometry laboratory of the Carbohydrate Research Centre, University of Toronto.

Thin-layer chromatography (TLC) was performed on silica gel $60F_{254}$ (Merck) plastic plates, which were developed using 30% sulfuric acid followed by heating at 150°C. Silica gel (230–400 mesh; Toronto Research Chemicals) was used for flash chromatography. All starting materials were dried under high vacuum over P_2O_5 or KOH overnight prior to use. Solvents were distilled under argon from appropriate drying agents onto anhydrous 3 Å molecular sieves and were transferred via syringe. Solvents were removed at reduced pressures using a rotary evaporator at temperatures not exceeding 40°C.

Benzyl 2-acetamido-4-O-(2′-acetamido-2′-deoxy-3′, 4′, 6′-tri-O-acetyl-β-D-glucopyranosyl)-2-deoxy-3,6-di-O-acetyl-β-D-glucopyranoside (3b)

Method A

To solid titanium(IV) bromide (12.2 g) stirring at 0°C was added a solution of chitobiosyl octaacetate (2) (3.00 g, 4.23 mmol) in dry dichloromethane (120 mL), followed by ethyl acetate (30 mL) (21). The resulting homogeneous reddish brown mixture was further stirred at room temperature for 6 h. It was diluted with dry dichloromethane (50 mL) and anhydrous sodium acetate (12 g) was added. After stirring for 15 min the reaction mixture was poured onto ice-water (100 mL) and the product was extracted into dichloromethane (300 mL), dried over $MgSO_4$, and evaporated and coevaporated with toluene (2 × 30 mL) to give a colourless solid residue (3.08 g). This was dissolved in dichloromethane (300 mL) and treated with benzyl alcohol (14.4 mL, 141 mmol) and *p*-toluenesulfonic acid monohydrate (160 mg, 0.85 mmol) at room temperature for 69 h. The reaction mixture was washed with ice-water (150 mL), dried over $MgSO_4$, and evaporated to dryness giving a light orange liquid residue. It was subjected to chromatography on a silica gel column ($CHCl_3$–acetone, 2:1), giving pure **3***b* (1.11 g, 36%) as a colourless solid, mp 277–280°C (dichloromethane–acetone); $[\alpha]_D$ −63.0° (*c* 0.60, $CHCl_3$); R_f 0.58 (threefold development in chloroform–acetone, 2:1); IR (neat); 3295 (NH), 3075 (aromatic CH), 1750 (COOR), and 1665 (CONH) cm^{-1}; ^{1}H NMR (δ): 7.32 (m, 5, $C_6H_5CH_2$), 6.02 (d, 1H, J = 9.0 Hz, N*H*′), 5.62 (d, 1H, J = 9.3 Hz, N*H*′), 5.18 (t, 1H, J= 9.3 Hz, H-3′), 5.04 (t, 2H, J = ca. 9.02 Hz, overlapping H-3 and H-4′), 4.86 and 4.57 (2d, 2H, J = 12.2 Hz, $C_6H_5CH_2$), 4.56 (d, 1H, J = 8.6 Hz, H-1′), 4.44 (d, 1H, J = 7.9 Hz, H-1), 4.09 (td, 1H, J = 9.3 and 7.9 Hz, H-2), 3.87 (br q, 1H, J = 9.0 Hz, H-2′), 3.74 (t, 1H, J = 8.6 Hz, H-4), 3.59–3.67 (m, 2H, H-5, H-5′), 2.16, 2.07, 2.03, 2.01, and 1.96 (5s, 21H, CH_3CO). Anal. calcd. for $C_{33}H_{44}N_2O_{16}$: C 54.69, H 6.12, N 3.87; found: C 54.60, H 6.23, N 3.72.

Method B

To a solution (14 mL) of acetic acid and acetic anhydride (1:1, v/v) saturated with anhydrous HCl at 0°C was added chitobiosyloctaacetate (1.1 g) and the reaction mixture was slowly stirred for 60 h at room temperature. Then the reaction mixture was diluted with ice-cold $CHCl_3$ (50 mL), ice was added, and the solution was washed successively with ice-cold water, saturated aqueous $NaHCO_3$, and water, dried over Na_2SO_4, and evaporated to dryness at temperatures <35°C. The residue was triturated with dry diethyl ether and recrystallized from chloroform–acetone mixture, giving a white crystalline chloride, mp 212–214°C, 420 mg (11, 23). The chloride (0.2 g) was dissolved in benzylalcohol (12 mL; dried over 4 Å molecular sieve), anhydrous Ag_2CO_3 (65 mg) and anhydrous $CaSO_4$ (680 mg) were added, and the mixture was slowly stirred for 48 h at room temperature. After filtering the reaction mixture through a bed of Celite that was subsequently washed with $CHCl_3$, the combined washings were evaporated to dryness *in vacuo*, and the residue was

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

subjected to chromatography on a silica gel column as described in Method A (cf. above).

Benzyl 2-acetamido-4-O-(2'-acetamido-4,6-O-benzylidene-2'-deoxy-β-D-glucopyranosyl)-2-deoxy-β-D-glucopyranoside (5)

Compound **3***b* (300 mg) in CH_3OH (25 mL) was stirred with 0.1 N sodium methoxide at room temperature for 4 h. Methanol was evaporated at <30°C, water (60 mL) was added to the residue, and the resulting solution was washed with diethyl ether (3×). The combined ether washings were washed with water, and all aqueous fractions were combined, neutralized with 1 M aqueous HCl, treated with mixed bed resin AG 501 X-8 for 45 min, filtered, and evaporated to dryness to give **4**. To a clear solution of compound **4** (537 mg, 1.04 mmol) and *p*-toluenesulfonic acid monohydrate (145 mg) in acetonitrile–DMF (1:4, 25 mL) was added benzaldehyde dimethyl acetal (0.50 mL) (24) and the reaction mixture was stirred in the dark at room temperature. After 22 h additional acetal (0.30 mL) was added and the reaction mixture was stirred for another 74 h. Triethylamine (1 mL) was added and the solution was stirred for 5 min, evaporated to dryness, and the light brown residue was taken up into DMF (1.5 mL) and applied to a silica gel column (chloroform–methanol, 10:1) to give compound **5** (457 mg, 73%) as a colourless solid; mp 287–290°C (chloroform–methanol; dec.); $[\alpha]_D$ −81.7° (*c* 0.59, MeOH–H_2O, 2:1); R_f 0.30 (chloroform–methanol, 8:1); ^1H NMR (δ): 7.20–8.00 (m, 10, H, C_6H_5), 5.60 (s, 1H, PhC*H*(-O)$_2$), 4.77 (d, 1H, *J* = 12.5 Hz, PhC*H*H), 4.59 (d, 1H, *J* = 7.6 Hz, H-1'), 4.51 (d, 1H, *J* = 12.5 Hz, PhCH*H*), 4.38 (d, 1H, *J* = 8.4 Hz, H-1), 1.84 and 1.81 (2s, 6H, CH_3CO). Anal. calcd. for $C_{30}H_{38}N_2O_{11}$: C 59.79, H 6.36, N 4.65; found: C 59.82, H 6.38, N 4.71.

Benzyl 2-acetamido-4-O-(2'-acetamido-4,6-O-benzylidene-2'-deoxy-β-D-glucopyranosyl)-2-deoxy-6-O-(2'',3'',4''-tri-O-benzyl-α-L-fucopyranosyl)-β-D-glucopyranoside (6)

Dry dichloromethane (9 mL) and powdered 4 Å molecular sieve (1.12 g) were added to a mixture of compound **5** (570 mg, 0.943 mmol) and tetraethylammonium bromide (1.12 g) in DMF (9 mL) and the resulting suspension was stirred for 0.5 h. Then a solution of 2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl bromide (0.562 g, 1.13 mmol) in dichloromethane (2 mL) was added. The residue of bromide in the flask was rinsed into the reaction vessel with additional dichloromethane (2 × 1 mL). To this reaction mixture, after being slowly stirred for 19 h, triethylamine (2 mL) was added and the mixture was stirred for an additional few minutes. The solids were filtered off and washed with dichloromethane (3 × 50 mL). The combined filtrate and washings were washed with water (2 × 50 mL) and the aqueous portions back-extracted with chloroform (2 × 30 mL). The combined organic extracts were dried over $MgSO_4$, then evaporated to dryness to give a light brown syrup (1.40 g), which was purified by chromatography on a silica gel column (ethyl acetate eluted nonpolar impurities, and chloroform–methanol, 20:1, eluted the required product) to yield compound **6** (474 mg, 49%) as a colorless solid, mp 256–260°C (dec.) (methanol – ethyl acetate); $[\alpha]_D$ −88.3° (*c* 0.53, $CHCl_3$); R_f 0.36 (chloroform–methanol, 10:1); ^1H NMR (δ): 7.20–7.60 (m, 25H, C_6H_5), 6.53 (d, 1H, *J* = 8.7 Hz, exchangeable with D_2O, N*H*), 5.47 (s, 1H, PhC*H*(-O$_2$), 5.46 (d, 1H, partly overlapped with the signal at 5.47, *J* approx. 6 Hz, exchangeable with D_2O, N*H*), 4.87 (d, 1H, *J* = 3.5 Hz, H-1''), 4.47 (d, 1H, *J* = 8.4 Hz, H-1'), 4.29 (d, 1H, *J* = 8.2 Hz, H-1), 4.15 (q, 1H, *J* = 6.5 Hz, H-5''), 2.02 and 1.80 (2s, 6H, CH_3CO), 1.17 (d, 3H, *J* = 6.5 Hz, H-6''). Anal. calcd. for $C_{57}H_{66}N_2O_{15}$: C 67.18, H 6.53, N 2.75; found: C 67.21, H 6.60, N 2.68.

2-Acetamido-4-O-(2'-acetamido-2'-deoxy-3',4'-6'-tri-O-acetyl-β-D-glucopyranosyl)-2-deoxy-1,3-di-O-acetyl-6-O-(2'',3'',4''-tri-O-acetyl-α-L-fucopyranosyl)-α-D-glucopyranose (7)

Compound **6** (97 mg, 0.095 mmol) in acetic acid – methanol (10 mL, 3:2) was hydrogenolysed on Pd–C (10%). After the reaction was completed (monitored by TLC), the catalyst was filtered off using a Celite bed, the bed was washed with methanol–water (1:1, 5 × 20 mL), and the combined filtrates were evaporated to dryness. The residue was treated with acetic anhydride (3 mL) and pyridine (3 mL) at room temperature. The white precipitate formed was brought into solution by warming up the reaction mixture to 40°C. The homogeneous mixture was then stirred at room temperature for 16 h. It was diluted with ethyl acetate (100 mL) and washed with cold (0°C) water (3 × 30 mL). The organic layer was dried over $MgSO_4$ and evaporated to give compound **7** as a colourless solid (67 mg, 78%), homogeneous by TLC (ethyl acetate – methanol, 9:1, R_f 0.47); mp 262–265°C (from ethyl acetate – hexane); $[\alpha]_D$ −25.1° (*c* 0.55, $CHCl_3$). ^1H NMR (δ): 6.11 (d, 1H, *J* = 3.9 Hz, H-1), 5.64 (d, 1H, *J* = 8.4 Hz, N*H*), 5.52 (d, 1H, *J* = 9.0 Hz, N*H*), 5.11 (d, 1H, *J* = 3.6 Hz, H-1''), 4.89 (d, 1H, *J* = 8.2 Hz, H-1'), 2.18, 2.17, 2.16, 2.09, 2.08, 2.02, 2.01, 2.00, 1.94, and 1.93 (10s, 30H, CH_3CO), 1.15, (d, 3H, *J* = 6.5 Hz, H-6''). Anal. calcd. for $C_{38}H_{54}N_2O_{23}$: C 50.33, H 6.00, N 3.09; found: C 50.52, H 6.12, N 3.15.

Methyl 2-acetamido-4-O-(2'-acetamido-2'-deoxy-β-D-glucopyranosyl)-2-deoxy-6-O-(α-L-fucopyranosyl)-α-D-glucopyranoside (9)

To solid titanium(IV) bromide (1.29 g) was added a solution of α-1-*O*-acetyl trisaccharide **7** (204 mg, 0.225 mmol) in dry dichloromethane (9 mL) stirring at 0°C, followed by addition of ethyl acetate (2.5 mL) (21). The resulting homogeneous reddish brown mixture was stirred at room temperature for 4.5 h. Then it was diluted with dry dichloromethane (10 mL), anhydrous sodium acetate (4 g) was added, and the mixture was stirred for 5 min, poured onto ice-water (50 mL), and the product extracted into dichloromethane (200 mL). It was then dried over $MgSO_4$, and evaporated and coevaporated with toluene (2 × 50 mL) to give a pure yellow solid (159 mg), which was treated with dry methanol (0.564 mL of 1 mmol per mL CH_2Cl_2 solution, 0.564 mmol) and *p*-toluenesulfonic acid monohydrate (4 mg, 0.019 mmol) in dichloromethane (2 mL) at room temperature for 18 h. It was diluted with dichloromethane (30 mL), poured into ice-water (20 mL), separated, dried over $MgSO_4$, and evaporated to give a pale yellow solid (129 mg), which was purified on a silica gel column ($CHCl_3$–acetone, 1:1), yielding peracetylated compound **8** (67 mg, 35%); R_f 0.47 (twofold development in $CHCl_3$–acetone, 1:1; identical with an authentic sample prepared by acetylation of compound **8** prepared by another method (3); ^1H NMR (δ): 5.74 (d, 1H, *J* = 8.3 Hz, exchangeable with D_2O, N*H*), 5.67 (d, 1H, *J* = 9.4 Hz, exchangeable with D_2O, N*H*), 5.09 (d, 1H, *J* = 3.6 Hz, H-1''), 4.93 (d, 1H, *J* = 8.3 Hz, H-1'), 4.41 (d, 1H, *J* = 7.6 Hz, H-1), 4.30 (br, 1, 1H, *J* approx. 6.8 Hz, H-5''), 3.45 (s, 3H, OCH_3), 2.18, 2.15, 2.07, 2.01, 2.00, 1.98, and 1.92 (7s, 27H, CH_3CO), 1.15 (d, 3H, *J* = 6.5 Hz, H-6'').

Compound **8** was dried and treated with 1% sodium methoxide (1 mL) in dry methanol (92 mL) at room temperature for 20 min. Then the reaction mixture was neutralized with acidic resin (0.5 mL), filtered, washed with MeOH–H_2O (1:1, 3 × 10 mL), and evaporated to give compound **9** (45 mg, 34%) as a colourless solid; mp 300–302°C (from ethanol–water); $[\alpha]_D$ −67.9° (*c* 0.67, H_2O) (lit. (3) mp 298–300°C (dec.); $[\alpha]_D$ −65.8° (*c* 0.53, H_2O). The ^1H NMR spectrum of **9** was identical with that of the authentic sample (3).

8-Methoxycarbonyloctyl 2-acetamido-4-O-(2'-acetamido-2'-deoxy-3',4'-6'-tri-O-acetyl-β-D-glucopyranosyl)-3-O-acetyl-2-deoxy-6-O-(2'',3'',4''-tri-O-acetyl-α-L-fucopyranosyl)-β-D-glucopyranoside (10)

To solid titanium(IV) bromide (0.79 g) was added a solution of α-1-*O*-acetyl trisaccharide **7** (124 mg, 0.137 mmol) in dry dichloromethane (4 mL) stirring at 0°C, followed by an addition of ethyl acetate (1 mL) (21). The reaction mixture was stirred at room temperature for 17 h. Then it was diluted with dry dichloromethane (15 mL), anhydrous sodium acetate (1.5 g) was added, and after stirring for 15 min it was shaken with ice-water (25 mL). The product was then extracted into dichloromethane (70 mL), dried over $MgSO_4$, and the solvents were evaporated and coevaporated with toluene (100 mL) to give pale yellow solid bromide (96 mg). It was treated with 8-methoxycarbonyl-octanol (25) (400 mg, 2.12 mmol) and *p*-toluenesulfonic acid (3 mg) in dichloromethane (2 mL) at room temperature for 26 h. The reaction mixture was then diluted with dichloromethane (70 mL) and poured into ice-water (20 mL). The usual work-up gave a crude product, which after chromatography on a silica gel column (ethyl acetate) yielded pure

10 (38 mg, 27%); $[\alpha]_D$ −68.5° (*c* 0.99, $CHCl_3$) (lit. (1) $[\alpha]_D$ −69.2° (*c* 1.0, $CHCl_3$)); R_f and ^1H NMR were identical with those of an authentic sample (1).

*8-Methoxycarbonyloctyl 2-acetamido-4-*O*-(2′-acetamido-2′-deoxy-β-*D*-glucopyranosyl)-2-deoxy-6-*O*-α-fucopyranosyl-p-*D*-glycopyranoside (**11**)*

Zemplen deacetylation of **10** (52 mg, 0.050 mmol) in dry methanol (2 mL) was done as described previously (1), using 1% sodium methoxide (1 mL) and neutralizing acidic resin (0.5 mL). The trisaccharide **11** (37 mg, 100%) was obtained as a colourless solid, mp 282–286°C (aqueous ethanol); $[\alpha]_D$ −60.6° (*c* 0.31, 50% aqueous ethanol); (lit. (1) mp 283–286°C; $[\alpha]_D$ −63.5° (*c* 0.42, 50% aqueous ethanol). The ^1H NMR was identical with that of the authentic sample (1).

*2-Acetamido-4-*O*-(2′-acetamido-2′-deoxy-3′,4′-6′-tri-*O*-acetyl-β-*D*-glucopyranosyl)-3-*O*-acetyl-2-deoxy-6-*O*-(2″,3″,4″-tri-*O*-acetyl-α-*L*-fucopyranosyl)-β-*D*-glucopyranosyl isothiocyanate (**12**)*

Trisaccharide **7** (308 mg, 0.340 mmol) was treated with titanium(IV) bromide (1.68 g) in dichloromethane (15 mL) and ethyl acetate (4 mL) as described for compound **10**. The reaction mixture was diluted after 4.5 h with dry dichloromethane (50 mL) and after the usual work-up (using anhydrous sodium acetate (5 g), ice-water (100 mL), dichloromethane (220 mL), and toluene (2 × 50 mL)) a pale yellow solid bromide (229 mg) was obtained. It was treated (26) with potassium thiocyanate (0.5 g) and *p*-toluenesulfonic acid monohydrate (50 mg) in acetonitrile (10 mL) at 70°C (bath temperature) for 15 min. Then the reaction mixture was cooled, diluted with dichloromethane (100 mL), washed with water (50 mL), and the organic layer was dried over $MgSO_4$ and evaporated to give a light yellow solid (220 mg). By chromatography on a silica gel column using chloroform–acetone, 37:13 (followed by solvent ratio 2:1), pure **12** (161 mg, 53%) was obtained as a colourless solid; mp 155–157°C (ethyl acetane – hexane); $[\alpha]_D$ −74.2° (*c* 0.67, $CHCl_3$); R_f 0.34 (twofold development in chloroform–acetone, 2:1); IR (neat). 3320 (NH), 2022(-NCS), 1750 (COOR), 1670 (CONH) cm^{-1}; ^1H NMR (δ): 6.03 (br, d, 1H *J* = 8.6 Hz, exchangeable with D_2O, N*H*), 5.81 (d, 1H, *J* = 7.9 Hz exchangeable with D_2O, N*H*′), 5.39 (dd, 1H, *J* = 10.8 and 3.2 Hz, H-3″), 5.32 (br d, 1H, *J* = 3.2 Hz, H-4″), 5.18 (dd, 1H, *J* = 10.8 and 3.6 Hz, H-2″), 5.09 (d, 1H, *J* = 3.6 Hz, H-1″), 5.06 (d, 1H, *J* = 8.3 Hz, H-1), 4.92 (d, 1H, *J* = 8.3 Hz, H-1′), 4.27 (br q, 1H, *J* = 6.5 Hz, H-5″), 3.57 (m, 1H, became dd after exchange with D_2O, *J* = 10.4 and 8.3 Hz, H-2′), 2.18, 2.16, 2.10, 2.08, 2.02, 2.01, and 1.92 (7s, 27H, C*H*$_3$CO), 1.17 (d, 3H, *J* = 6.5 Hz, H-6″). Anal. calcd. for $C_{37}H_{51}N_3SO_{21}$: C 49.06, H 5.68, N 4.64, S 3.54; found: C 49.26, H 5.56, N 4.81, S 3.62.

*2-Acetamido-4-*O*-(2′-acetamido-2′-deoxy-3′,4′-6′-tri-*O*-acetyl-β-*D*-glucopyranosyl)-3-*O*-acetyl-2-deoxy-6-*O*-(2″,3″,4″-tri-*O*-acetyl-α-*L*-fucopyranosyl)-1-*N*-[1-benzyl *N*-(benzyloxy)carbonyl-*L*-aspart-4-oyl]-β-*D*-glucopyranosylamine (**13**)*

A mixture of isothiocyanate **12** (114 mg, 0.126 mmol), 1-benzyl *N*-(benzyloxy)carbonyl-L-aspartate (134 mg, 0.378 mmol), and triethylamine (0.03, 0.192 mmol) in dry toluene (2.5 mL) was stirred (18) at room temperature for 71 h. Then it was diluted with chloroform (70 mL), and the chloroform solution was washed successively with cold (0°C) aqueous sodium bicarbonate (20 mL) and water (20 mL). The chloroform solution was dried over $MgSO_4$ and evaporated to give a pale yellow syrup (185 mg), which after chromatography on a silica gel column (chloroform–acetone, 37:13) yielded pure **13** (49 mg, 32%) as a colourless solid, mp 185°C (with sintering at 128°C; recrystallized from hexane – methanol); $[\alpha]_D$ −43.7° (*c* 0.51, $CHCl_3$); R_f 0.35 (fivefold development in $CHCl_3$–acetone, 37:13); IR (neat):3360 (NH), 3062 and 3036 (aromatic C—H), 1750 (COOR), 1678 (CONH) cm^{-1}; ^1H NMR (δ): 7.30 (m, 10H, $C_6H_5CH_2$), 5.50 (t, 1H, *J* = 9.7 Hz, H-3′), 5.36 (dd, 1H, *J* = 10.8 and 3.2 Hz, H-3″), 5.29 (br d, 1H, *J* = 3.0 Hz, H-4″), 5.21 (d, 1H, *J* approx. 9.0 Hz, H-1′), 5.06 (d, 1H, *J* = 3.6 Hz, H-1″), 5.01 (t, 1H, *J* = 9.7 Hz, H-4′), 4.73 (br t, 1H, *J* approx. 8.6 Hz; became d after exchange with D_2O, *J* = 9.7 Hz, H-1) 4.64 (m, 1H, became t after exchange with D_2O, *J* = 3.6 Hz, H-2 (asparagine)), 4.29 (br q, 1H, *J* = 6.5 Hz, H-5″), 4.02 (br q, 1H, became t after exchange with D_2O, *J* = 10.0 Hz, H-2), 3.90 (t, 1H, *J* = 9.4 Hz, H-4), 3.54 (br d, 1H, *J* = 9.4 Hz, H-5), 3.20 (m, 1H, became br t after exchange with D_2O, *J* approx. 9.3 Hz, H-2′), 2.85 (dd, 1H, *J* = 16.2 and 4.0 Hz, H-3 (asparagine)), 2.68 (dd, 1H, *J* = 16.2 and 4.0 Hz, H-3) (asparagine)), 2.15, 2.13, 2.05, 2.00, 1.99, 1.91, and 1.86 (7s, 27H, C*H*$_3$CO), 1.03 (d, 3H, *J* = 6.5 Hz, H-6″). Anal. calcd. for $C_{55}H_{70}N_4O_{26}$: C 54.91, H 5.87, N 4.66; found: C 54.72, H 5.71, N 4.83.

Received August 20, 1989

VICENTA LOPEZ, JAVIER CATALAN, ROSA M^A CLARAMUNT, CONCEPCION LOPEZ, EDUARDO CAYON, and JOSE ELGUERO. Can. J. Chem. **68**, 958 (1990).

The comparison between thermodynamic pK_a values and oxidation potentials of the pentacyanoferrate(II) complexes of a series of azoles shows the existence of two parallel lines: one for pyrazoles and another one for benzazoles. Using the equation corresponding to the second one, the pK_a value of 1-methylbenzotriazole (2.49) can be estimated from the $E_{1/2}$ value of its complex.

Key words: azole basicity, oxidation potentials, pyrazoles, benzotriazoles.

VICENTA LOPEZ, JAVIER CATALAN, ROSA M^A CLARAMUNT, CONCEPCION LOPEZ, EDUARDO CAYON et JOSE ELGUERO. Can. J. Chem. **68**, 958 (1990).

La comparaison entre les pK_a thermodynamiques d'une série d'azoles et les potentiels d'oxydation de leurs complexes avec l'anion pentacyanoferrate(II) montre l'existence de deux relations linéaires, une pour les pyrazoles et l'autre pour les benzazoles. La seconde permet d'estimer le pK_a du méthyl-1 benzotriazole (2,49) à partir de la valeur de $E_{1/2}$ de son complexe.

Mots clés : basicité des azoles, potentiels d'oxydation, pyrazoles, benzotriazoles.

Introduction

Our interest in the acid–base properties of azoles (1) prompted us to study Brisset and Ilimby's method (2) of indirect determination of the basicity of pyrazoles and indazoles. This method has the advantage that it can be used to determine the pK_a of very weak bases. Since $E_{1/2}$ is constant for a wide range of pH values, it is possible to determine the pK_a value without reaching the pH zone corresponding to the pK_a. Following previous studies on pyridines, these authors determined the oxidation potentials $E_{1/2}$ (in mV) of the pentacyanoferrate(II) complexes of five pyrazoles (pyrazole itself, 3(5)-methylpyrazole, 3,5-dimethylpyrazole, 4-chloropyrazole, and 1-methylpyrazole) and of indazole, and postulated the existence of a linear relationship between $E_{1/2}$ and the corresponding pK_a (proton gain) of the free ligands:

[1] $$E_{1/2} = 309.43 - 41.65\, p\mathrm{K_a} \qquad n = 6,\ r^2 = 0.98$$

With this equation and the experimental $E_{1/2}$ values of other pyrazoles and indazoles they predicted the pK_a of the following compounds: 1-acetylpyrazole (2.99, reported in ref. 1), 4-nitroindazole (0.25, reported in ref. 1), 5-nitroindazole (−0.04), 6-nitroindazole (0.49), 7-nitroindazole (−1.00, reported in ref. 1), and 5,6-dinitroindazole (−0.90, reported in ref. 1). The values for 5- and 6-nitroindazoles were not reported in ref. 1 since we had previously determined (3) their thermodynamic pK_a's (−0.96 and −0.97, respectively).

Due to the discrepancies involving the last two compounds, we decided to test the method of Brisset and Ilimby (2) using a larger and better-balanced set of azoles.

TABLE 1. Half-wave potentials (mV) of the complexes and pK_a values (proton gain) of the azole ligand

No.	Ligand	E^a1/2	pK_a^b
1	Pyrazole	192 R	2.48
2	3(5)-Methyl	152 R	3.27
3	3,5-Dimethyl	136 R	4.06
4	1,3,5-Trimethyl	160.5 QR	3.74
5	4-Phenyl	203.5 QR	1.64
6	3,5-Diphenyl	198.5 NR	1.75
7	4-Bromo	240 R	0.63
8	1-Nitro	180.5 NR	−4.15
9	3(5)-Nitro	332.5 NR	−4.66
10	4-Nitro	301 R	−2.0
11	3,5-Dimethyl-4-nitro	263 NR	−0.45
12	1,2,4-Triazole	233.5 QR	2.45
13	Benzimidazole	140 QR	5.56
14	2-Methyl	127.5 QR	6.19
15	1-Ethyl-2-methyl	128 QR	6.30
16	Indazole	265.5 QR	1.04
17	5-Nitro	317.5 NR	−0.96
18	6-Nitro	323.5 QR	−0.97
19	Benzotriazole	243.5 QR	1.6
20	1-Methyl	226 R	[c]

[a] R: reversible, QR: quasi-reversible, NR: not reversible.
[b] All values from ref. 1 save that of compound **15** taken from ref. 5.
[c] Unknown.

Experimental

All the compounds are commercially available or were prepared by conventional methods (4). The complexes were prepared *in situ* by dissolving solid $Na_3Fe(CN)_5NH_3$ (2) and the corresponding azole or benzazole in a ratio close to 1:10 in a 0.5 M electrolytic solution of $NaClO_4$. The pH was varied by small additions of strong acid ($HClO_4$) or base (NaOH). The electrochemical method used was identical to that described by Brisset and Ilimby (2).

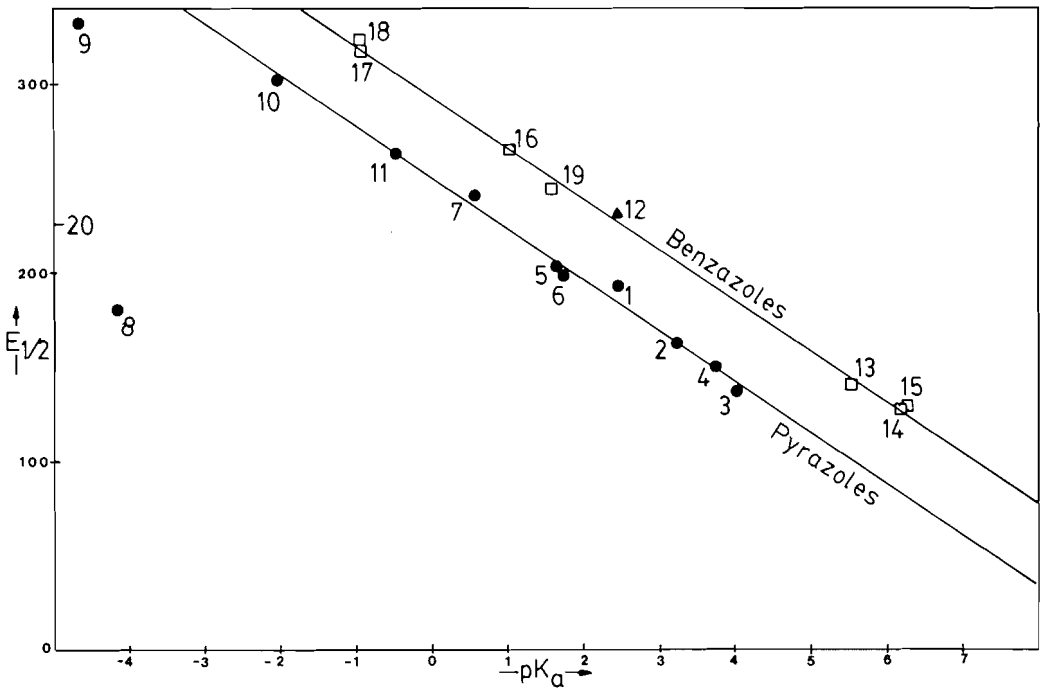

FIG. 1. Representation of the half-wave potentials vs. the pK_a's. Pyrazoles (●); benzazoles (□); 1,2,4-triazole (▲).

Results and discussion

Table 1 contains the $E_{1/2}$ values determined here together with the thermodynamic pK_a values; the corresponding bi-dimensional plot is that represented in Fig. 1.

The following conclusions can be drawn:

(i) Two *parallel* lines are observed, pyrazoles having a special behaviour as in other studies dealing with their basicity or acidity (6, 7).

(ii) *All* benzazoles have been included in the linear regression, which yields eq. [2].

[2] $E_{1/2} = 292.7 - 26.8\,p\mathrm{K_a}$ $\quad n = 7,\ r^2 = 0.998$

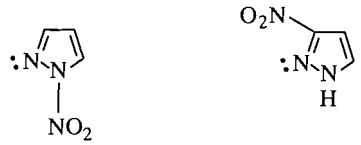
(iii) Nitropyrazoles **8** and **9** have been excluded from the regression leading to eq. [3].

[3] $E_{1/2} = 250.2 - 26.8\,p\mathrm{K_a}$ $\quad n = 9,\ r^2 = 0.98$

(iv) 1,2,4-Triazole **12** is near the line for the benzazoles. From eq. [2']

[2'] $p\mathrm{K_a} = 10.9 - 0.037\ \mathrm{E_{1/2}}$

and from the $E_{1/2}$ value of 1-methylbenzotriazole **20**, its pK_a can be estimated (2.49). The pyrazoles that behave abnormally, **8** and **9**, both have a nitro group near the basic center:



8

9

This situation could interfere with the complex formation.

The fact that the value of the slope in eq. [1] is twice those of eqs. [2] and [3] results from the fact that it was calculated using points belonging to both lines, pyrazoles **1**, **2**, **3**, and 4-chloropyrazole, and benzazoles, indazole **16**. With our values for compounds **1**, **2**, **3**, and **16**, the following equation is found: $E_{1/2} = 306.6 - 44.3\ p\mathrm{K_a}$, $n = 4$, $r^2 = 0.98$, which is close to eq. [1].

It is not possible to use the $E_{1/2}$ values of ref. 2 and our equations [2] and [3] to calculate the pK_a of the compounds studied by Brisset and Ilimby, since for common derivatives the $E_{1/2}$ values differ. However, with their $E_{1/2}$ value for 4-chloropyrazole (225), eq. [3] yields pK_a = 0.88, which is much closer to the thermodynamic value (0.59 (1)) than the value calculated with eq. [1] (1.86 (2)).

ROBERT CHÊNEVERT, MARTIN LÉTOURNEAU, and SONIA THIBOUTOT. Can. J. Chem. **68**, 960 (1990).

Methyl *N*-acetyl phenylserinates (**1**, **2**), methyl *N*-acetyl nitrophenylserinates (**3**, **4**), and methyl *N*-benzoyl threoninates (**5**, **6**) were resolved conveniently into the enantiomers with high optical purities by enzymatic hydrolysis in the presence of α-chymotrypsin, subtilisin, or bromelain. The *threo* and *erythro* forms were treated separately and the latter form was usually more reactive. Chymotrypsin and subtilisin are highly specific for the enantiomer having the same configuration on carbon-2 (*S*) as the natural standard amino acids. In contrast, bromelain shows the reverse specificity on phenylserine derivatives. This is a notable exception to the usual *S*-stereospecificity pattern of proteases.

Key words: enzymatic hydrolysis, resolution of amino acids.

ROBERT CHÊNEVERT, MARTIN LÉTOURNEAU et SONIA THIBOUTOT. Can. J. Chem. **68**, 960 (1990).

Nous décrivons la résolution des *N*-acétyl phénylsérinates de méthyle (**1**, **2**), des *N*-acétyl *p*-nitrophénylsérinates de méthyle (**3**, **4**) et des *N*-benzoyl thréoninates de méthyle (**5**, **6**) par hydrolyse enzymatique en présence de l'α-chymotrypsine, de la subtilisine ou de la bromélaine. Les formes *thréo* et *erythro* ont été traitées séparément et la forme *érythro* est habituellement plus réactive. La chymotrypsine et la substilisine sont spécifiques pour l'énantiomère ayant la même configuration (*S*) que les acides aminés standards. Au contraire, la bromélaine montre une stéréospécificité inverse sur les dérivés de la phénylsérine. Il s'agit d'une exception notable à la stéréospécificité usuelle des protéases.

Mots clés : hydrolyse enzymatique, résolution des acides aminés.

Introduction

Hydrolytic enzymes are useful catalysts in asymmetric synthesis (1, 2). In recent years, several hydrolases have been used for the resolution of racemates (3–6) or the enantiotopic group differentiation in meso compounds (7–10). Hydrolases have proved particularly useful for the resolution of amino acids (11–13). Past studies on the enzymatic resolution of amino acids have been confined mostly to substrates with only one asymmetric center. We report here a study on the enzymatic resolution of β-hydroxy-α-amino acids by the action of proteases on their *N*-acyl methyl esters (14). These compounds exist in four stereoisomeric forms and enzymes can exhibit diastereoselectivity as well as enantioselectivity. β-Hydroxy-α-amino acids are frequently encountered as part structures of many biologically active compounds (11). *S*-Threonine is an essential amino acid. Derivatives of phenylserine are intermediates in the synthesis of natural compounds such as chloramphenicol (15), resolving reagents (16), chiral auxiliaries, and precursors to chiral 2-oxazolines (17).

Results and discussion

Methyl β-hydroxyl-*N*-acylamino esters **1**–**6** were obtained in their pure (±)-*threo* and (±)-*erythro* forms by literature methods. Methyl esters were selected because proteases usually show a higher rate of hydrolysis and a better enantioselectivity when the alcohol component of the ester is a methyl or a small group. Acylation of the amino group was necessary to meet the requirements of endopeptidases used in this study. The benzoyl group was preferred over the more usual acetyl group in the case of threonine because these derivatives are easier to purify and the corresponding *N*-benzoyl amino acids are easier to extract from the aqueous medium after the hydrolysis.

Preparative-scale (2–6 mmol) enzyme-catalyzed hydrolyses were performed in buffered aqueous solutions at pH 7–8. The enzymatic reaction was indicated by the decrease of pH, which was maintained at its initial value by the addition of a dilute sodium hydroxide solution. The reactions were monitored by the consumption of base and terminated when 50% of the ester was hydrolyzed. The unreacted esters were recovered from the reaction mixtures by extraction with ethyl acetate at pH 8. The product acids that are present in the aqueous phase as sodium salts were isolated by acidification to pH 2 and extraction with ethyl acetate. Samples of the acids were converted to their methyl esters before determining their optical purity. Enantiomeric excess (ee) values were determined by ^{1}H nmr analysis using tris[3-(heptafluoropropylhydroxymethylene)-*d*-camphorato]europium(III) as a chiral shift reagent. In every case, well-resolved signals were obtained for the ester methyl protons. Absolute configurations were assigned by chemical hydrolyses of the *N*-acylamino acids obtained from the enzymatic reactions and comparison with the optical rotation signs reported in the literature for these free amino acids. The results are summarized in Table 1.

Subtilisin exhibits wide substrate specificity and catalyzes the hydrolyses of all esters **1**–**6** with very high enantioselectivity. Chymotrypsin is also highly enantioselective but its substrate specificity is somewhat narrower and *threo-p*-nitrophenylserinate **3** is not a substrate. Both enzymes that are serine proteases catalyze the hydrolysis of the enantiomer having the same configuration on carbon-2 (*S*) as the natural standard amino acids.

Bromelain, a sulfhydryl protease, has a much narrower substrate specificity and only phenylserines **1** and **2** are hydrolyzed by this enzyme. The enantioselectivity is low for the *threo* form but very high for the *erythro* form. It is noteworthy that bromelain has the opposite enantioselectivity to chymotrypsin and subtilisin. Bromelain selectively hydrolyzes compounds with the *R* configuration on carbon-2. This is a notable exception to the usual *S*-stereoselectivity pattern of proteases.

Based on the time required to hydrolyze 50% of the racemic mixture under the same experimental conditions, the *erythro*

[b]The ee values were determined by ^{1}H nmr (200 MHz) using the chiral shift reagent Eu(hfc)$_3$; the accuracy of this method is ±2%.

forms are more reactive than the *threo* forms for phenylserine and *p*-nitrophenylserine. In the threonine series, the difference of reactivity between the *threo* and *erythro* forms is small in favor of the *threo* form. Chymotrypsin is highly enantioselective and diastereoselective for *p*-nitrophenylserines. Similarly, Shiba and co-workers reported the enantio- and diastereoselective hydrolysis of β-hydroxyornithine by acylase (18). Esterase (pig liver), acetylesterase, and lipase (porcine pancreatic) are not active on compounds **1–6**. Also, these compounds are not substrates for other sulfhydryl proteases like papain, chymopapain, and ficin.

In previous studies (11–13), the resolutions of *RS*-threonine and *RS-allo*-threonine were achieved via asymmetric hydrolytic action of acylase on their *N*-chloroacetyl derivatives. Threonine has also been resolved by papain-catalyzed amidation of its *N*-capryloyl derivative with aniline. Acylase I and carboxypeptidase A were found ineffective toward either *N*-acetyl or *N*-chloroacetyl derivatives of β-phenylserines. However (±)-*threo* and (±)-*erythro* phenylserines have been resolved as the reactive *N*-trifluoroacetyl derivatives by carboxypeptidase.

The stereospecificity exhibited by chymotrypsin towards compounds **1–6** can be rationalized in terms of Cohen's active-site model (12). Figure 1 shows schematic representations of the binding of the good substrate *N*-acetyl-*S*-phenylalanine methyl ester (a), and *erythro* isomers of compounds **1–6** (b). The *ar*-site is a hydrophobic pocket large enough to accommodate aromatic or aliphatic groups. The *am*-site binds *N*-acyl groups by means of hydrogen bonding. The nucleophilic attack occurs at the *n*-site where the ester group is bonded. The hydrogen on carbon-2 fits into the volume restricted *h*-site. The stereochemical consequence of this topography is that only amino acids with the 2*S* configuration are hydrolyzed rapidly. This is what we observed with substrates **1–6**. For the preferred *erythro* stereoisomers, the 3*R*-OH group must occupy the position at the junction of *ar* and *h* sites (equivalent to the H_S position of the *N*-acetyl-*S*-phenylalanine methyl ester.

Subtilisin and chymotrypsin are both serine protease. They have a similar active site and often have the same stereoselectivity. However the substrate specificity of subtilisin is broader than that of chymotrypsin (12). Data in Table 1 confirm this statement.

Bromelain, a thiol protease, has not been exploited so far for resolution. Papain is the best documented member of the group and available data show that its enantioselectivity is not wholly predictable. Although an *S*-enantioselectivity is usual, several examples of reactions for which the *R* enantiomers are substrates have been reported (12).

Our results constitute a valuable alternative to the enzymatic resolution of threonines and phenylserines and provide the first enzymatic resolution of *p*-nitrophenylserines.

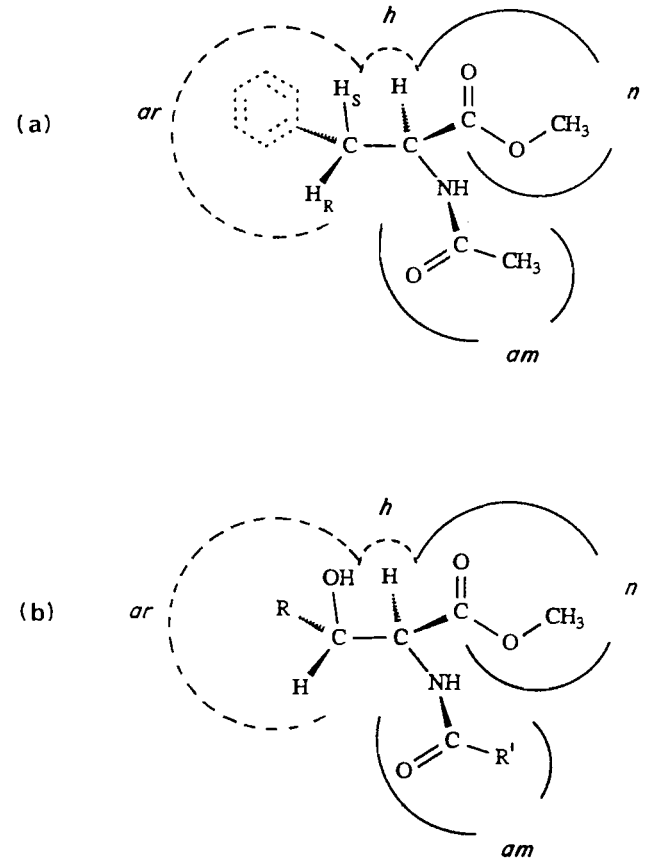

FIG. 1. The active site of α-chymotrypsin according to Cohen's model. (a) The binding of the good specific substrate *N*-acetyl-*S*-phenylalanine methyl ester, and (b) binding of *erythro* isomers of compounds **1–6**.

Experimental

Melting points were determined on a Thomas–Hoover capillary apparatus and are uncorrected. IR spectra were recorded on a Beckman 4250 spectrometer. NMR spectra were recorded on a Varian XL-200 multinuclear instrument. Optical rotations were measured with a Jasco DIP-360 digital polarimeter. α-Chymotrypsin (EC 3.4.21.1, type II), subtilisin (EC 3.4.21.14, Carlsberg, protease type VIII), and bromelain (EC 3.4.22.4) were purchased from Sigma.

Methyl (±)-threo-N-*acetyl-β-phenylserinate (1)*

Acetic anhydride (2.6 mL, 27 mmol) was added dropwise to a cold solution (5°C) of commercially available methyl (±)-*threo* β-phenylserinate hydrochloride (2.09 g, 9 mmol) and sodium acetate (2.96 g, 36 mmol) in 45 mL of water. The reaction mixture was stirred overnight at room temperature. The product was collected by filtration and recrystallized from water. Yield 87%; mp 182–183°C (lit. (19) mp 174–180°C); IR (KBr): 3410, 3205, 1750, 1540, 1305, 1220, 1150, 1100, 1070, 725 cm^{-1}; ^1H NMR (DMSO) δ: 1.76 (3H, s), 3.59 (3H, s), 4.53 (1H, dd, $J_1 = 7$ H, $J_2 = 3$ Hz), 5.08 (1H, dd, $J_1 = 3$ Hz, $J_2 = 5$ Hz), 5.83 (1H, d, $J = 5$ Hz), 7.29 (5H, m), 8.12 (1H, d, $J = 7$ Hz).

Methyl (±)-erythro-N-*acetyl-β-phenylserinate (2)*

Methyl (±)-*erythro*-β-phenylserinate was first prepared from methyl benzoylacetate (20) and then *N*-acetylated as described for the *threo* isomer. Yield 83%; mp 118–119°C (lit. (21) mp 120–122°C); IR (KBr): 3400, 3320, 1720, 1670, 1540, 1305, 1240, 1200, 1060, 730 cm^{-1}; ^1H NMR (DMSO) δ: 1.70 (3H, s), 3.59 (3H, s), 4.47 (1H, d, $J = 7$ Hz), 4.69 (1H, d, $J = 7$ Hz), 5.82 (1H, d, $J = 3$ Hz), 7.31 (5H, m), 8.26 (1H, d, $J = 8$ Hz).

Methyl (±)-threo-N-*acetyl*-p-*nitrophenylserinate (3)*

Methyl (±)-*threo-p*-nitrophenylserinate was first obtained by condensation of *p*-nitrobenzaldehyde with methyl glycinate according to the procedure of Ehrhart *et al.* (15) and then *N*-acetylated. The product was recrystallized in water/methanol. Yield 97%; mp 195–197°C (lit. (21) mp 198–200°C); IR (KBr): 3360, 3500–3100, 1745, 1650, 1520, 1340, 1215 cm^{-1}. ^1H NMR (DMSO) δ: 1.74 (3H, s), 3.65 (3H, s), 4.73 (1H, dd, $J_1 = 3.5$ Hz, $J_2 = 9$ Hz), 5.29 (1H, dd, $J_1 = 3.5$ Hz, $J_2 = 5$ Hz), 6.21 (1H, d, $J = 5$ Hz), 7.70 (2H, d, $J = 9$ Hz), 8.16 (2H, d, $J = 9$ Hz), 8.27 (1H, d, $J = 9$ Hz).

Methyl (±)-erythro-N-*acetyl*-p-*nitrophenylserinate (4)*

This compound was prepared according to the procedure of Bergmann *et al.* (22). Yield 91%; mp 179–181°C (lit. (21) mp 181–184°C); IR (KBr): 3300, 1735, 1635, 1500, 1330, 1200 cm^{-1}. ^1H NMR δ: 1.73 (3H, s), 3.59 (3H, s), 4.52 (1H, dd, $J_1 = J_2 = 8.5$ Hz), 4.85 (1H, dd, $J_1 = 8.5$ Hz, $J_2 = 7$ Hz), 6.14 (1H, d, $J = 7$ Hz), 7.62 (2H, d, $J = 8.5$ Hz), 8.18 (2H, d, $J = 8.5$ Hz), 8.43 (1H, d, $J = 8.5$ Hz).

Methyl N-*benzoyl (±)-threoninate (5)*

Commercially available (±)-threonine methyl ester hydrochloride (11.5 g, 68 mmol) was dissolved in 100 mL of water/dioxane (2:1). Benzoyl chloride (6.20 mL, 68 mmol) was added dropwise over a period of 1 h. The pH of the solution was maintained at 8.5–9.0 by addition of 4 M aqueous NaOH and the temperature was kept below 30°C. Dioxane was removed under reduced pressure and the aqueous phase was extracted with ethyl acetate. The organic phase was dried ($MgSO_4$) and evaporated under vacuum to give an oil that crystallized on standing. The crude product was recrystallized from chloroform. Yield 64%; mp 94–95.5°C (lit. (23) mp 92–94°C); IR (KBr): 3415, 3320, 1745, 1640, 1520, 1260, 1110, 1020, 780, 710 cm^{-1}; ^1H NMR (DMSO) δ: 1.16 (3H, d, $J = 4$ Hz), 3.65 (3H, s), 4.18 (1H, m), 4.51 (1H, dd, $J_1 = 5$ Hz, $J_2 = 2$ Hz), 4.95 (1H, d, $J = 4$ Hz), 7.52 (3H, m), 7.88 (2H, dd, $J_o = 5$ Hz, $J_m = 1$ Hz), 8.20 (1H, d, $J = 5$ Hz).

Methyl N-*benzoyl (±)*-allo-*threoninate (6)*

Prepared by esterification and benzoylation of commercial (±)-*allo*-threonine. Yield 57%; mp 95–96°C (lit. (24) mp 110–111°C); IR (KBr): 3415, 3320, 1745, 1640, 1520, 1260, 1110, 1020, 710 cm^{-1}; ^1H NMR (DMSO) δ: 1.25 (3H, d, $J = 4$ Hz), 3.72 (1H, m), 3.83 (3H, s), 4.31 (1H, m) 4.89 (1H, dd, $J_1 = 4$ Hz, $J_2 = 2$ Hz), 7.19 (1H, d, $J = 4$ Hz), 7.49 (3H, m), 7.82 (2H, dd, $J_o = 4$ Hz, $J_m = 0.5$ Hz).

Enzyme-catalyzed hydrolyses of methyl β-hydroxy-N-*acyl-α-amino-esters. General procedure*

The ester (2 mmol) was suspended in a buffered aqueous solution (50 mL) at room temperature. The enzyme was added and the pH of the solution was maintained at its initial value by addition of 0.1 M aqueous NaOH. The reaction was stopped at the 50%-of-hydrolysis point (reaction times are reported in Table 1). The reaction mixture was first extracted at initial pH with ethyl acetate (3 × 250 mL) to remove the unchanged ester. The aqueous mixture was then acidified to pH 2.0 with cold 2 M aqueous HCl and was extracted with ethyl acetate (3 × 250 mL) again to remove the product acid. Organic extracts were dried ($MgSO_4$) and evaporated under vacuum. Details pertaining to each enzyme are the following. α-Chymotrypsin: enzyme (20 mg, 800 units), solvent (phosphate buffer, pH 7.70). Subtilisin: enzyme (60 mg, 800 units), solvent (phosphate buffer, pH 7.70). Bromelain: enzyme (1300 mg, 800 units), solvent (phosphate buffer, pH 6.00), catalytically essential sulfhydryl groups of the enzyme were activated by cysteine (200 mg).

Properties of recovered esters

The physical and spectral properties of recovered esters were identical with those reported above, except for the magnitudes of their rotations. The $[\alpha]_D^{25}$ values observed for recovered esters were as follows:

Substrate **1**: (2*R*, 3*S*), [α] = −27.6° (*c* 2.0, acetic acid).
Substrate **2**: (2*R*, 3*R*), [α] = −62.8° (*c* 2.0, acetic acid); (2*S*, 3*S*), [α] = +62.6° (*c* 2, acetic acid).
Substrate **3**: (2*R*, 3*S*), [α] = −36.6° (*c* 1.0, methanol).
Substrate **4**: (2*R*, 3*R*), [α] = −48.0° (*c* 1.0, methanol).
Substrate **5**: (2*R*, 3*S*), [α] = −22.8° (*c* 1.0, ethanol).
Substrate **6**: (2*R*, 3*R*), [α] = −5.8° (*c* 1.0, methanol).

Properties of acid products

threo-N-*Acetyl-β-phenylserine*: mp 163–164°C. IR (KBr): 3505, 3320, 3080, 3025, 2980, 1695, 1615, 1555, 1495, 1365, 1250, 1115, 1040, 760, 695 cm^{-1}. ^1H NMR (DMSO) δ: 1.74 (3H, s), 4.46 (1H, dd, J_1 = 5 Hz, J_2 = 1 Hz), 5.12 (1H, d, J = 1 Hz), 5.80 (2H, m), 7.35 (5H, m), 7.97 (1H, d, J = 5 Hz). [α] for the 2*S*,3*R* isomer, +29.7° (*c* 2.0, acetic acid).

erythro-N-*Acetyl-β-phenylserine:* mp 177–178°C. IR (KBr): 3540, 3320, 3080, 3025, 2980, 1695, 1615, 1555, 1495, 1365, 1250, 1115, 1040, 760, 695 cm^{-1}. ^1H NMR (DMSO) δ: 1.7 (3H, s), 4.42 (1H, dd, J_1 = 5 Hz, J_2 = 8 Hz), 4.69 (1H, d, J = 8 Hz), 7.34 (5H, m), 8.11 (1H, d, J = 5 Hz). [α] for the 2*S*,3*S* isomer, +64.9° (*c* 2.0, acetic acid); 2*S*,3*S* isomer, −63.9° (*c* 2.0, acetic acid).

threo-N-*Acetyl*-p-*nitrophenylserine:* mp 160–172°C. IR (KBr): 3585, 3400, 3090, 3035, 2985, 1710, 1660, 1610, 1550, 1530, 1500, 1345, 1250, 1190, 1140, 1065, 855, 710 cm^{-1}. ^1H NMR (DMSO) δ: 1.79 (3H, s), 4.75 (1H, dd, J_1 = 5 Hz, J_2 = 1 Hz), 5.41 (1H, d, J = 1 Hz), 7.76 (2H, d, J = 4 Hz), 7.84 (1H, d, J = 5 Hz), 8.18 (2H, d, J = 4 Hz). [α] for the 2*S*,3*R* isomer, +27.4 (*c* 1.0, methanol).

erythro-N-*Acetyl*-p-*nitrophenylserine*: mp 147–148°C. IR (KBr): 3440, 3380, 3090, 3030, 2985, 1705, 1660, 1610, 1550, 1530, 1500, 1345, 1250, 1190, 1140, 1065, 855, 710 cm^{-1}. ^1H NMR (DMSO) δ: 1.76 (3H, s), 4.50 (1H, dd, J_1 = 5 Hz, J_2 = 4 Hz), 4.88 (1H, d, J = 4 Hz), 7.66 (2H, d, J = 4 Hz), 8.22 (2H, d, J = 4 Hz), 8.28 (1H, d, J = 5 Hz). [α] for the 2*S*,3*S* isomer, +65.2° (*c* 1.0, methanol).

threo-N-*Benzoyl-threonine*: mp 137–138°C. IR (KBr): 3405, 3106, 3015, 2975, 1760, 1700, 1530, 1340, 1210, 1110, 710 cm^{-1}. ^1H NMR (DMSO) δ: 1.13 (3H, d, J = 6 Hz), 4.19 (1H, m), 4.44 (1H, dd, J_1 = 4 Hz, J_2 = 2 Hz), 4.51 (1H, m), 7.52 (3H, m), 7.87 (2H, dd, J_1 = 5 Hz, J_2 = 1 Hz), 8.05 (1H, d, J = 4 Hz), 12.32 (1H, m). [α] for the 2*S*,3*R* isomer, +33.4° (*c* 1.0, methanol).

erythro-N-*Benzoyl-threonine*: mp 132–133°C. IR (KBr): 3425, 3200, 3015, 2975, 1765, 1705, 1530, 1340, 1210, 1110, 1095, 710 cm^{-1}. ^1H NMR (DMSO) δ: 1.21 (3H, d, J = 6 Hz), 4.06 (1H, m), 4.39 (1H, dd, J_1 = 8 Hz, J_2 = 4 Hz), 7.52 (3H, m) 7.87 (2H, dd, J_1 = 6 Hz, J_2 = 1 Hz), 8.38 (1H, d, J = 8 Hz), 12.14 (1H, m). [α] for the 2*S*,3*S* isomer, +23.9° (*c* 1.0, methanol).

Absolute configuration

For substrates **1** and **2**, absolute configurations were assigned by chemical hydrolyses of the *N*-acylamino acids obtained from the enzymatic reactions and comparison with the optical rotation signs reported in the literature for these free amino acids. 2*S*,3*R*, [α] = −29.2 (*c* 0.5, H_2O) (lit. (25) α = −31.1° (*c* 1.0, H_2O)); 2*S*,3*S*, [α] = +7.9° (*c* 0.5, H_2O) (lit. (25) [α] = +8.2° (*c* 1.0, H_2O)). For substrates **3–6**, absolute configurations were assigned by comparison of optical rotation signs of recovered esters or acid products, or both, with signs reported in the literature for these compounds.

Substrate **3**: 2*R*,3*S* ester, [α] = −36.6° (*c* 1.0, methanol) (lit. (26) [α] = −37.6° (*c* 1, methanol)). 2*S*,3*R* acid, [α] = +27.4° (*c* 1.0 methanol) (lit. (26) [α] = +27.4° (*c* 1.0, methanol)).

Substrate **4**: 2*R*,3*R* ester, [α] = −40.6° (*c* 4.0, methanol) (lit. (26) [α] = −40.0° (*c* 4.0, methanol)).

Substrate **5**: 2*R*,3*S* recovered ester, [α] = −22.3° (*c* 1.0, ethanol) (lit. (23) [α] = −22.0 (*c* 6.0, ethanol)).

Substrate **6**: 2*S*,3*S* acid, [α] = +22.9° (*c* 0.5, methanol) (lit. (24) [α] = +23.7° (*c* 1.0, methanol)).

New total synthesis of phenanthrene alkaloids

JUAN C. ESTÉVEZ, M. CARMEN VILLAVERDE, RAMÓN J. ESTÉVEZ, JULIO A. SEIJAS, AND LUIS CASTEDO[1]

Departamento de Química Orgánica, Facultad de Química y Sección de Alcaloides del C.S.I.C., Universidad de Santiago de Compostela, Spain

Received October 4, 1989

JUAN C. ESTÉVEZ, M. CARMEN VILLAVERDE, RAMÓN J. ESTÉVEZ, JULIO A. SEIJAS, and LUIS CASTEDO. Can J. Chem. **68**, 964 (1990).

We describe a new synthesis of phenanthrene alkaloids based on the photocyclization of stilbene compounds prepared by a simple, efficient new method. It allows the preparation of phenanthrene compounds with a primary amine group in their side chain.

Key words: alkaloid, phenanthrene, stilbene, photocyclization.

JUAN C. ESTÉVEZ, M. CARMEN VILLAVERDE, RAMÓN J. ESTÉVEZ, JULIO A. SEIJAS et LUIS CASTEDO. Can. J. Chem. **68**, 964 (1990).

On décrit une nouvelle méthode de synthèse d'alcaloïdes dérivés du phénanthrène qui est basée sur une photocyclisation de composés du stilbène qui ont été préparés par une nouvelle méthode simple et efficace. Cette nouvelle méthode permet de préparer des composés du phénanthrène qui contiennent des groupements amines sur leur chaîne latérale.

Mots clés : alcaloïdes, phénanthrène, stilbène, photocyclisation.

Introduction

The phenanthrene alkaloids are a minor group of isoquinoline bases biogenetically related to the aporphines, from which they can be obtained by degradative procedures (1). The first total synthesis of a member of this family of natural compounds involved the photochemical electrocyclization of a stilbene compound (2) prepared by mixed dicarbonyl coupling of aldehydes with low valent titanium (3). We now wish to describe the total synthesis of the phenanthrene alkaloids secoglaucine **9***a*, *N*-methylsecoglaucine **9***b*, and atherosperminine **9***c* using a modified approach that seems to be a suitable alternative to the titanium method when the aldehydes required fr coupling are not easily available. This modified method, which requires the preparation of the stilbene compounds from type-**1** ketoacids, constitutes yet another example of the usefulness of these ketoacids in the synthesis of isoquinoline alkaloids (4).

Results and discussion

As indicated in Scheme 1, when ketoacid **1***a* (obtained by self-condensation of 3,4-dimethoxyphenylacetic acid) was treated with $NaBH_4$ in methanol and the resulting mixture acidified and then heated gently, the lactone **2***a* was obtained in almost quantitative yield. Subsequent treatment of this lactone with methanol saturated with hydrogen chloride gave, also in high yield, the *E* isomer of the stilbene compound **3***a* as indicated by the ^1H nmr spectrum.

Photochemical irradiation of compound **3***a* for 3 h with a 450-W Hanovia medium-pressure mercury lamp equipped with a Pyrex filter gave, in moderate yield, the phenanthrene ester **5***a*, which was transformed in good yield into the corresponding amide **6***a* by treatment with aqueous ammonia. Alternatively, the phenanthreneacetamide **6***a* was also prepared, in lower yield, by photocyclization of the stilbene compound **4***a* previously obtained by treatment of **3***a* with aqueous ammonia.

Finally, LAH reduction of amide **6***a* afforded the desired phenanthreneamine **7***a*, which was then transformed into the phenanthrene alkaloids **9***a* and **9***b* as follows (Scheme 2). Treatment of **7***a* with ethyl chloroformate furnished the phenanthrene urethane **8***a*, which was converted into its *N*-methyl analogue **8***b*. Basic hydrolysis of the *N*-carbethoxy group yielded the phenanthrene alkaloid secoglaucine **9***a*. Alternatively, compound **8***b* was easily transformed into the phenanthrene alkaloid *N*-methylsecoglaucine **9***b* by treatment with LAH.

A parallel synthetic approach allowed atherosperminine **9***c* to be obtained from the ketoacid **1***c* via the lactone **2***b*. Ketoacid **1***c* itself could not be prepared in the same way as **1***a* because it has different substituents in the aromatic rings. Instead, it was prepared by Friedel–Crafts acylation of methyl 3,4-dimethoxyphenylacetate (5) with phenylacetyl chloride and subsequent hydrolysis of the ester group.

The approach to phenanthrene alkaloids described here allows the preparation of phenanthrene alkaloid analogues with a primary amine group in the side chain.

Experimental

Melting points were determined on a Kofler Thermogeräte apparatus and are uncorrected. Infrared spectra were determined in potassium bromide on a Perkin Elmer 1420 spectrophotometer. Ultraviolet spectra were recorded in ethanol on a Pye Unicam SP-1700 spectrophotometer. The nuclear magnetic resonance spectra were determined on a Bruker WM-250 apparatus in deuteriochloroform solution containing tetramethylsilane as the internal standard. Mass spectra were obtained on a Kratos MS 50 TC mass spectrometer. Elemental analyses were performed at Instituto de Química Orgánica General del C.S.I.C. (Madrid). Photolyses were carried out with medium-pressure mercury vapor arc lamps (Hanovia, 450 W) using Pyrex-filtered light and cooling by water. Thin-layer chromatography (tlc) was performed using Merck GF-254 type 60 silica gel and methylene chloride – methanol mixtures as eluent; the tlc spots were visualized with ultraviolet light or iodine vapour. Column chromatography was carried out using Merck type 9385 silica gel. Solvents were purified as in ref. 6.

*Methyl 2-phenylacetyl-4,5-dimethoxyphenylacetate (**1**b)*

A mixture of commercial phenylacetic acid (1.5 g, 11 mmol) and thionyl chloride (5 mL, 70 mmol) was refluxed under a dry atmosphere (calcium chloride tube) for 1 h. The excess thionyl chloride was evaporated *in vacuo* and the residue was dissolved in dry methylene chloride (3 mL). This solution was added dropwise to a stirred suspension of aluminium trichloride (1.74 g, 13 mmol) in dry methylene chloride (4 mL). To this mixture, cooled at 0°C in an ice/water bath, a solution of methyl 3,4-dimethoxyphenylacetate (1.89

g, 9 mmol) in dry methylene chloride (3 mL) was added dropwise over 15 min. The mixture was stirred for 2 h at room temperature and was then added to an ice/concentrated hydrochloric acid solution. The mixture was extracted with dichloromethane (3 × 50 mL) and the organic layers were washed with saturated sodium bicarbonate solution followed by water, dried with anhydrous sodium sulphate, and concentrated *in vacuo* to give 2.6 g (88% yield) of white crystals, mp 119°C (MeOH); ir (ν,cm^{-1}): 1735, 1670, 1600, 1270; nmr (δ): 3.68 (s, 3H, -$COOCH_3$), 3.86 (s, 3H, Ar-OCH_3), 3.88 (s, 2H, -CH_2-COO), 3.92 (s, 3H, Ar-OCH_3), 4.22 (s, 2H, -CH_2-CO), 6.71 (s, 1H, Ar-H), 7.26–7.32 (m, 5H, 5 × Ar-H), 7.38 (s, 1H, Ar-H); ms (*m/z*): 237 (25), 235 (18), 210 (21), 209 (100), 181 (14), 179 (21), 178 (12), 169 (16), 151 (49), 150 (26). Anal. calcd. for $C_{19}H_{20}O_5$: c 69.51, H 6.10; found: C 69.45, H 6.08.

*2-Phenylacetyl-4,5-dimethoxphenylacetic acid (**1**c)*

A mixture of methyl 2-phenylacetyl-4,5-dimethoxyphenylacetate (**1***b*) (3 g, 9.1 mmol) and a 5:1 solution of dioxane/20% aqueous sulphuric acid (30 mL) was refluxed for 2 h. The mixture was concentrated *in vacuo* and then diluted in water and extracted with dichloromethane (3 × 25 mL). The organic layers were washed with water, dried with anhydrous sodium sulphate, and evaporated *in vacuo* to afford **1***c* (2.28 g, 79% yield), mp 164–165°C (MeOH); nmr (δ): 3.79 (s, 2H, -CH_2-COO), 3.87 (s, 3H, Ar-OCH_3), 3.92 (s, 3H, Ar-OCH_3), 4.26 (s, 2H, -CH_2-CO), 6.80 (s, 1H, Ar-H), 7.22–7.33 (m, 5H, 5 × Ar-H), 7.35 (s, 1H, Ar-H); ms (*m/z*): 195 (17), 92 (15), 91 (100), 89 (10).

*1-Benzyl-6,7-dimethoxy-3-isocromanone (**2**b)*

To a stirred solution of **1***c* (2 g, 6.4 mmol) in 200 mL of methanol, sodium borohydride (2.3 g, 60.1 mmol) was added in small portions for 3 h. Then 300 mL of water was added and the solution acidified to pH 3 with 20% hydrochloric acid, and heated at 60°C for 30 min with stirring. The organic solvent was evaporated off, and the remaining aqueous solution was extracted with dichloromethane. Work-up provided **2***b*, 1.8 g (95% yield), mp 109–111°C (MeOH); ir (ν, cm^{-1}): 1740, 1610, 1515; nmr (δ): 2.83 and 3.36 (AB, *J* = 19.7 Hz, 2H, -CH_2-CO), 3.21 (m, 2H, -CH_2-CO), 3.76 (s, 3H, Ar-OCH_3), 3.84 (s, 3H, Ar-OCH_3) 5.59 (t, *J* = 5.6 Hz, 1H, -CH-O), 6.44 (s, 1H, Ar-H), 6.49 (s, 1H, Ar-H) 6.96 (m, 2H, 2 × Ar-H), 7.21 (m, 3H, 3 × Ar-H); ms (*m/z*): 298 (M^+, 2), 207 (44), 179 (100), 151 (20). Anal. calcd. for $C_{18}H_{18}O_4$: C 72.48, H 6.04; found: C 72.62, H 6.09.

*Methyl (E)-4,5-dimethoxy-2-(3′,4′-dimethoxystyryl)phenylacetate (**3**a)*

A mixture of 1-(3′,4′-dimethoxybenzyl)-6,7-dimethoxy-3-isocromanone (**2***a*) (7) (1 g, 2.8 mmol) and 50 mL of methanol saturated with hydrogen chloride was refluxed for 5 h. Work-up supplied 1 g (96% yield) of **3***a*, mp 121–122°C (MeOH); uv (λ,nm): 224, 295(sh), 332; ir (ν, cm^{-1}): 1735, 1600, 1515; nmr (δ): 3.68 (s, 3H, -$COOCH_3$), 3.72 (s, 2H, -CH_2-CO), 3.89 (s, 6H, 2 × Ar-OCH_3), 3.94 (s, 6H, 2 × Ar-OCH_3), 6.75 (s, 1H, Ar-H), 6.85 (d, *J* = 15.9 Hz, 1H, CH=C), 6.86 (d, *J* = 8.5 Hz, 1H, Ar-H), 7.05 (s, 1H, Ar-H), 7.06 (d, *J* = 8.5 Hz, 1H, Ar-H), 7.11 (s, 1H, Ar-H), 7.17 (d, *J* = 15.9 Hz, 1H, -C=CH-); ms (*m/z*): 372 (M^+, 100), 357 (15), 313 (16), 297 (11), 284 (10), 282 (18). Anal. calcd. for $C_{21}H_{24}O_6$: C 67.74, H 6.45; found: C 67.55, H 6.72.

*Methyl (E)-2-styryl-4,5-dimethoxyphenylacetate (**3**b)*

Compound **3***b* was obtained in 94% yield from **2***b* using the same procedure as above; mp 78–80°C (MeOH); uv (λ, nm): 215, 230, 296 (sh), 308, 326; ir(ν, cm^{-1}): 1735, 1600, 1515; nmr (δ): 3.69 (s, 3H, -$COOCH_3$), 3.73 (s, 2H, -CH_2-CO), 3.91 (s, 3H, Ar-OCH_3), 3.95 (s, 3H, Ar-OCH_3), 6.76 (s, 1H, Ar-H), 6.91 (d, *J* = 16.0 Hz, 1H, -CH=C), 7.13 (s, 1H, Ar-H), 7.20–7.60 (m, 6H, 5 × Ar-H and -C=CH-); ms (*m/z*): 312 (M^+, 100), 253 (41), 222 (33), 221 (27).

*(E)-4,5-Dimethoxy-2-(3′,4′-dimethoxystyryl)phenylacetamide (**4**a)*

A mixture of methyl (*E*)-4,5-dimethoxy-2(3′, 4′-dimethoxystyryl)-phenylacetate (**3***a*) (1 g, 2.7 mmol), methanol (100 mL), and concentrated aqueous ammonia solution (100 mL) was stirred at room temperature for 48 h. Work-up provided (*E*)-4,5-dimethoxy-2(3′,4′-dimethoxystyryl)phenylacetamide (**4***a*) (0.92 g, 96% yield), mp 149–150°C (MeOH); ir (ν, cm^{-1}): 3325, 1665, 1600, 1515; nmr (δ): 3.69 (s, 2H, -CH_2-CO), 3.90 (s, 6H, 2 × Ar-OCH_3), 3.94 (s, 3H, Ar-OCH_3), 3.95 (s, 3H, Ar-OCH_3), 5.45 (bs, 1H, -NH_2), 5.75 (bs, 1H, -NH_2), 6.73 (s, 1H, Ar-H), 6.85 (d, *J* = 8.3 Hz, 1H, Ar-H), 6.88 (d, *J* = 16.0 Hz, 1H, -CH=C-), 7.05 (s, 1H, Ar-H), 7.05 (d, *J* = 8.3 Hz, 1H, Ar-H), 7.05 (d, *J* = 16.0 Hz, 1H, -C=CH-), 7.15 (s, 1H, Ar-H); ms (*m/z*): 357 (M^+, 100); hrms: 357.1566 (M^+, 100); calcd. for $C_{20}H_{23}NO_5$: 357.1576.

*(E)-4,5-Dimethoxy-2-styrylphenylacetamide (**4**b)*

Compound **4***b* was prepared in 90% yield from methyl (*E*)-2-styryl-4,5-dimethoxyphenylacetate (**3***b*) by the same procedure as above; mp 198–199°C (MeOH); ir (ν, cm^{-1}): 3410, 1660, 1605, 1520; nmr (δ): 3.69 (s, 2H, -CH_2-CO), 3.90 (s, 3H, Ar-OCH_3), 3.96 (s, 3H, Ar-OCH_3), 5.43 (bs, 1H, NH_2), 5.63 (bs, 1H, NH_2), 6.74 (s, 1H, Ar-H), 6.93 (d, *J* = 16.0 Hz, 1H, -CH=C-), 7.15–7.55 (m, 7H, 6 × Ar-H and -C=CH-); ms (*m/z*): 297 (M^+, 96), 253 (100), 222 (70), 207 (36).

*Methyl (3,4,6,7-tetramethoxy-1-phenanthryl)acetate (**5**a)*

A stirred mixture of stilbene **3***a* (200 mg, 0.54 mmol), 200 mL of ethyl ether, and a catalytic amount of iodine (12 mg, 0.03 mmol) was oxygenated by passing air for 15 min and was then irradiated at room temperature for 3 h. The ether solution was washed with saturated sodium thiosulphate and water, dried with anhydrous sodium sulphate, and evaporated *in vacuo* to give a mixture that was separated by preparative tlc (methylene chloride) to afford methyl (3,4,6,7-tetramethoxy-1-phenanthryl)acetate (**5***a*) (107 mg, 54% yield), mp 145–146°C (MeOH); ir (ν, cm^{-1}): 1740, 1600, 1520; nmr (δ): 3.70 (s, 3H,

-$COOCH_3$), 3.94 (s, 3H, Ar-OCH_3), 4.04 (s, 6H, 2 × Ar-OCH_3), 4.07 (s, 5H, Ar-OCH_3 and -CH_2-CO), 7.20 (s, 1H, Ar-H), 7.23 (s,1H, Ar-H), 7.56 and 7.69 (AB, J = 9.1 Hz, 2H, -CH=CH-), 9.27 (s, 1H, Ar-H); ms (m/z): 370 (M^+, 100), 355 (42), 311 (39). Anal. calcd. for $C_{21}H_{22}O_6$: C 68.11, H 5.95; found: C 67.75, H 6.12.

*Methyl (3,4-dimethoxy-1-phenanthryl)acetate (**5**b)*

Photochemical irradiation of **3***b* (168 mg, 0.54 mmol) in the same conditions as above gave compound **5***b* (58 mg, 35% yield), mp 125–126°C (MeOH); ir (ν, cm^{-1}): 1735, 1595, 1270; nmr (δ): 3.70 (s, 3H, -$COOCH_3$), 3.93 (s, 3H, Ar-OCH_3), 4.04 (s, 3H, Ar-OCH_3), 4.09 (s, 2H, -CH_2-CO), 7.28 (s, 1H, Ar-H), 7.50–7.70 (m, 2H, Ar-H), 7.63 and 7.78 (AB, J = 9.2 Hz, 2H, -CH=CH-), 7.84 (m, 1H, Ar-H), 9.65 (d, J = 8.5 Hz, 1H, Ar-H); ms (m/z): 310 (M^+, 100), 295 (35), 267 (22), 251 (82), 235 (64), 225 (26), 208 (44), 207 (35). Anal. calcd. for $C_{19}H_{18}O_4$: C 73.55, H 5.81; found: C 73.39, H 6.02.

*3,4,6,7-Tetramethoxy-1-phenanthrylacetamide (**6**a)*

Procedure a

Photochemical irradiation of styrene **4***a* (193 mg, 0.54 mmol) following the same procedure as above gave 3,4,6,7-tetramethoxy-1-phenanthrylacetamide (**6***a*) (77 mg, 40% yield), mp 162–163°C (MeOH); ir (ν, cm^{-1}): 3430, 1670, 1600, 1520; nmr (δ): 3.96 (s, 3H, Ar-OCH_3), 4.05 (s, 8H, 2 × Ar-OCH_3 and -CH_2-CO-), 4.08 (s, 3H, Ar-OCH_3), 5.34 (bs, 1H, -NH_2), 5.43 (bs, 1H, -NH_2), 7.23 (s, 1H, Ar-H), 7.25 (s, 1H, Ar-H), 7.59 and 7.67 (AB, J = 9.1 Hz, 2H, -CH=CH-), 9.27 (s, 1H, Ar-H); ms (m/z): 355 (M^+, 16), 312 (16), 311 (18), 208 (18), 193 (33), 181 (55), 165 (42), 69 (100). Anal. calcd. for $C_{20}H_{21}NO_5$: C 67.61, H 5.92, N 3.94; found: C 67.21, H 6.09, N 3.61.

Procedure b

A mixture of methyl (3,4,6,7-tetramethoxy-1-phenanthryl)acetate (**5***a*) (250 mg, 0.67 mmol), methanol (50 mL), and a concentrated aqueous ammonia solution (50 mL) was stirred at room temperature for 24 h. Work-up provided a mixture that was separated by preparative tlc (Cl_2CH_2/methanol 95:5) to afford phenanthrylamide **6***a* (167 mg, 70% yield), which was crystallized from methanol.

*3,4-Dimethoxy-1-phenanthrylacetamide (**6**b)*

Procedure a

Photochemical irradiation of **4***b* (160 mg, 0.54 mmol) using the general procedure gave compound **6***b* (47.6 mg, 30% yield), mp 147–148°C (MeOH); ir (ν, cm^{-1}): 3360, 1660, 1595, 1270; nmr (δ): 3.95 (s, 3H, Ar-OCH_3), 4.04 (bs, 5H, Ar-OCH_3 and -CH_2-CO), 5.34 (bs, 1H, -NH_2), 5.56 (bs, 1H, -NH_2), 7.25 (s, 1H, Ar-H), 7.61 (m, 2H, 2 × Ar-H), 7.64 and 7.74 (AB, J = 9.1 Hz, 2H, -CH=CH-), 7.85 (m, 1H, Ar-H), 9.65 (d, J = 8.5 Hz,1H, Ar-H); ms (m/z): 295 (M^+, 74), 252 (19), 251 (100), 237 (19), 165 (20).

Procedure b

Compound **6***b* was prepared in 65% yield from **5***b* by the procedure described above.

*2-(3′,4′,6′,7′-Tetramethoxy-1′-phenanthryl)ethylamine (**7**a)*

A solution of 3,4,6,7-tetramethoxy-1-phenanthrylacetamide (**6***a*) (250 mg, 0.7 mmol) in dry THF (20 mL) was added dropwise to a vigorously stirred suspension of LAH (100 mg) in dry THF (25 mL). The mixture was refluxed for 5 h and was then left at room temperature overnight. A 15% aqueous solution of sodium hydroxide (4 mL) was added dropwise, followed by water (12 mL); the suspension was filtered and the THF of the filtrate evaporated off *in vacuo*. The residue was extracted with methylene chloride (3 × 25 mL) and the combined organic extracts treated with a 10% aqueous solution of hydrochloric acid (3 × 25 mL); the aqueous extracts were basified with a 10% aqueous solution of sodium hydroxide and extracted with methylene chloride (3 × 25 mL). The extracts were dried with anhydrous sodium sulphate and concentrated *in vacuo* to afford crude amine **7***a* as an oil that was used without further purification; nmr (δ): 3.12 (t, J = 6.0 Hz, 2H, -CH_2-), 3.24 (t, J = 6.0 Hz, 2H, -CH_2-), 3.92 (s, 3H, Ar-OCH_3), 4.03 (s, 3H, Ar-OCH_3), 4.04 (s, 3H, Ar-OCH_3), 4.07 (s, 3H, Ar-OCH_3), 7.19 (s, 1H, Ar-H), 7.20 (s, 1H, Ar-H), 7.53 and 7.77 (AB, J = 9.1 Hz, 2H, -CH=CH-), 9.28 (s, 1H, Ar-H); ms (m/z): 341 (M^+, 43), 312 (72), 311 (100), 297 (22).

*2-(3′,4′-Dimethoxy-1′-phenanthryl)ethylamine (**7**b)*

Amide **6***b* (200 mg, 0.68 mmol) was treated as above to afford compound **7***b* as an oil that was used without further purification; nmr (δ): 3.15 (t, J = 6.3 Hz, 2H, -CH_2-), 3.30 (t, J = 6.3 Hz, 2H, -CH_2-), 3.92 (s, 3H, Ar-OCH_3), 4.03 (s, 3H, Ar-OCH_3), 7.24 (s, 1H, Ar-H), 7.50–7.70 (m, 3H, 2 × Ar-H and -CH=C-), 7.82 (m, 1H, Ar-H), 7.86 (d, J = 9.2 Hz, 1H, -C=CH-), 9.65 (d, J = 8.3 Hz, 1H, Ar-H); ms (m/z): 281 (M^+, 36), 252 (90), 251 (100), 237 (23).

N-*Carbethoxy-2-(3′,4′,6′,7′-tetramethoxy-1′-phenanthryl)ethylamine (**8**a)*

A solution of crude 2-(3′,4′,6′,7′-tetramethoxy-1′-phenanthryl)-ethylamine (**7***a)* (225 mg) in methylene chloride (10 mL) was treated with an excess of ethyl chloroformate (1 mL) and stirred at room temperature for 30 min. Then water (10 mL) was added and the organic layers separated, dried with anhydrous sodium sulphate, and concentrated. The residue was purified by preparative tlc to afford 218 mg (75% from **6***a*) of urethane **8***a*; ir (ν, cm^{-1}): 1370, 1715, 1520; nmr (δ): 1.26 (t, J = 7.1 Hz, 3H, -CH_2-*CH_3*), 3.30 (t, J = 7.6 Hz, 2H, -CH_2-), 3.57 (m, 2H, -CH_2-), 3.93 (s, 3H, Ar-OCH_3), 4.03 (s, 3H, Ar-OCH_3), 4.05 (s, 3H, Ar-OCH_3), 4.07 (s, 3H, Ar-OCH_3), 4.15 (q, J = 7.1 Hz, 2H, -O-*CH_2*-CH_3) 4.75 (bs, 1H, -NH-), 7.16 (s, 1H, Ar-H), 7.21 (s,1H, Ar-H), 7.56 and 7.81 (AB, J = 9.1 Hz, 2H, -CH=CH-), 9.28 (s, 1H, Ar-H); ms (m/z): 413 (M^+, 45), 367 (23), 311 (100), 297 (14), 265 (13).

N-*Carbethoxy-2-(3′,4′-dimethoxy-1′-phenanthryl)ethylamine (**8**c)*

Crude amine **7***b* (160 mg) was treated as above to afford 168 mg (70% from **6***b*) of *N*-carbethoxyamine **8***c*, nmr (δ): 0.88 (t, J = 7.3 Hz, 3H, -CH_2-*CH_3*), 3.32 (t, J = 7.1 Hz, 2H, -CH_2-), 3.55 (m, 2H, -CH_2-), 3.93 (s, 3H, Ar-OCH_3), 4.03 (s, 3H, Ar-OCH_3), 4.16 (q, J = 7.3 Hz, 2H, -O-*CH_2*-CH_3), 7.20 (s, 1H, Ar-H), 7.50–7.70 (m, 3H, 3 × Ar-H), 7.80–8.00 (m, 2H, 2 × Ar-H), 9.67 (d, J = 7.7 Hz, 1H, Ar-H); ms (m/z): 353 (M^+, 50), 251 (100).

N-*Carbethoxy*-N-*methyl-2-(3′,4′,6′,7′-tetramethoxy-1′-phenanthryl)-ethylamine (**8**b)*

A solution of urethane **8***a* (200 mg, 0.48 mmol) in dry THF (5 mL) was added dropwise to a stirred mixture of sodium hydride (100 mg) in dry THF (5 mL). This suspension was stirred at room temperature for 30 min, then an excess of methyl iodide (1 mL) was added and the mixture stirred at room temperature for 2 h. Water (25 mL) was added and the THF was eliminated *in vacuo*. The aqueous mixture was extracted with methylene chloride, dried with anhydrous sodium sulphate, and concentrated *in vacuo* to give quantitatively the urethane **8***b*, mp 110–111°C (EtOH): ir (ν, cm^{-1}): 1690, 1590, 1480, 1200, 1110; nmr (δ): 1.22–1.32 (m, 3H, -CH_2-*CH_3*), 2.85 and 2.95 (2s, 3H, -N-CH_3), 3.24–3.38 (m, 2H -CH_2-), 3.55–3.65 (m, 2H, -CH_2-), 3.92 (s, 3H, Ar-OCH_3), 4.03 (s, 3H, Ar-OCH_3), 4.04 (s, 3H, Ar-OCH_3), 4.07 (s, 3H, Ar-OCH_3), 4.04–4.10 (m, 2H, -O-*CH_2*-CH_3), 7.11 and 7.19 (2s, 1H, Ar-H), 7.21 (s, 1H, Ar-H), 7.56 (d, J = 8.9 Hz, 1H, -CH=C-), 7.84 and 7.90 (2d, J = 9.2 Hz, 1H, -C=CH-), 9.28 (s, 1H, Ar-H); ms (m/z): 427 (M^+, 35), 311 (100), 116 (28), 44 (93). Anal. calcd. for $C_{24}H_{29}NO_6$: C 67.43, H 6.83, N 3.28; found: C 67.90, H 7.10, N 3.60.

N-*Carbethoxy*-N-*methyl-2-(3′,4′-dimethoxy-1′phenanthryl)-ethylamine (**8**d)*

Starting with **8***c* (100 mg, 0.28 mmol), the same procedure as above gave compound **8***d* in quantitative yield; ir (ν, cm^{-1}): 1700, 1590, 1510, 1200; nmr (δ): 1.25–1.29 (m, 3H, -CH_2-*CH_3*), 2.84 and 2.95 (2s, 3H, N-CH_3), 3.25–3.40 (m, 2H, -CH_2-N), 3.54 (m, 2H, Ar-CH_2), 3.91 (s, 3H, Ar-OCH_3), 4.03 (s, 3H, Ar-OCH_3), 4.01–4.13 (m, 2H, -O-*CH_2*-CH_3), 7.16–7.36 (m, 2H, Ar-H), 7.55–7.66 (m, 2H, Ar-H), 7.83–8.01 (m, 2H, Ar-H), 9.67 (m,1H, Ar-H); ms (m/z): 367 (M^+, 30), 251 (80), 44 (100).

*Secoglaucine (**9**a)*

A mixture of potassium hydroxide (2 g) and absolute ethanol (10

mL) was refluxed under argon until total dissolution. This solution, under an argon atmosphere, was added to 100 mg (0.23 mmol) of urethane **8***b* and the mixture refluxed for 15 h. Then a solution of citric acid (2 g) in water (15 mL) was added dropwise and the mixture stirred at room temperature for 15 min. The ethanol was evaporated and the residue extracted with methylene chloride; work-up provided 62 mg (75%) of secoglaucine **9***a*, which was identified by direct comparison with an authentical sample (8).

N-*Methyl secoglaucine (***9**b*)*

A solution of urethane **8***b* (100 mg, 0.23 mmol) in dry THF (5 mL) was added dropwise to a stirred suspension of LAH (50 mg, 1.31 mmol) and $AlCl_3$ (100 mg, 0.75 mmol) in dry THF (10 mL). This mixture was refluxed for 1.5 h and then water (1 mL), 10% aqueous sodium hydroxide solution (1 mL), and water (4 mL) were successively added dropwise. The mixture was filtered, the THF evaporated off, and the residue extracted with methylene chloride (3 × 25 mL). The mixed organic extracts were treated with 10% hydrochloric acid (3 × 25 mL). The combined aqueous extracts were brought to pH 9 with 10% aqueous sodium hydroxide solution and then extracted again with methylene chloride (3 × 25 mL), dried with anhydrous sodium sulphate, and concentrated *in vacuo* to give 61 mg (70%) of *N*-methylsecoglaucine **9***b*, which was compared with an authentic sample (9).

*Atherosperminine (***9**c*)*

Urethane **8***d* (100 mg, 0.27 mmol) was transformed into atherosperminine (**9***c*) (57 mg, 68%) by the same procedure as above. Compound **9***c* was compared with an authentic sample (2).

Received August 9, 1988[3]

MOHAMMED MUNEER, PRASHANT V. KAMAT, and MANAPURATHU V. GEORGE. Can. J. Chem. **68**, 969 (1990).

The results of our studies on potassium-induced transformations of some selected nitrogen heterocycles are presented. The substrates under investigation include 2,3-diphenylindole (**1***a*), 2,3-diphenyl-1-methylindole (**1***b*), 1,2,3-triphenylindole (**1***c*), 2,3,4,5-tetraphenylpyrrole (**5***a*), 1,2,3,5-tetraphenylpyrrole (**5***b*), 1-benzyl-2,3,5-triphenylpyrrole (**5***c*), 2,4,5-triphenyloxazole (**15***a*), 4,5-diphenyl-2-methyloxazole (**15***b*), 2,4-diphenyl-5-methyloxazole (**15***c*), and 2,4,5-triphenylimidazole (**19**). Treatment of **1***a* with potassium in THF gave 9*H*-dibenzo[*a*,*c*]carbazole (**3***a*), whereas **1***c* gave a mixture of 9-phenyl-9*H*-dibenzo-[*a*,*c*]carbazole (**3***c*) and 2,3-diphenylindole (**1***a*). Under identical conditions, **1***b* gave only the cleavage product **1***a*. In contrast, when the reactions of **1***a*,*c* were carried out with potassium in THF saturated with oxygen, and with potassium superoxide in benzene containing 18-crown-6, a mixture of 2-benzamidobenzophenone (**4***a*), the carbazoles **3***a*,*c*, and **1***a* was formed. Although no product was isolated on treatment of **5***a* with potassium in THF, the reaction of **5***a* with potassium in THF saturated with oxygen gave a mixture of tetraphenylpyrazine (**7***a*), the benzoylaminostilbene **8***a*, the lactam **12***a*, benzamide (**11***a*), and benzoic acid (**14**). Similar results were obtained in the reaction of **5***a* with potassium superoxide. The reaction of N-substituted pyrroles such as **5***b*,*c* with potassium gave the NH pyrrole **9***b* in each case, whereas the reaction of **5***b*,*c* with potassium in THF, saturated with oxygen, gave a mixture of **9***b*, the butanone **10***b*, the 1,4-dione **13***b*, the lactam **12***b*, the amides **11***a*–*c*, and benzoic acid (**14**). Attempted reactions of **5***b*,*c* with potassium superoxide did not give any isolable product; most of the starting material could be recovered unchanged in each case. A mixture of *N*-(1,2-diphenylethyl)benzamide (**18***a*) and benzoic acid (**14**) was formed in the reaction of the oxazole **15***a* with potassium, whereas **15***b*,*c*, under analogous conditions, gave the *N*-vinylamides **17***b*,*c* and benzoic acid (**14**). In contrast, treatment of the imidazole **19** with potassium in THF did not give any product; however, when the reaction of **19** was carried out with potassium in THF saturated with oxygen, and with potassium superoxide, dibenzamide (**21**) was isolated, in each case.

Radical ions have been invoked as intermediates in the transformation of the different substrates to the observed products. Cyclic voltammetric studies have been carried out to measure the reduction potentials of these radical anion intermediates. These radical anions have also been generated by pulse radiolysis in methanol, and their absorption spectra recorded.

Key words: nitrogen heterocycles, radical ions, potassium-induced transformations, pulse radiolysis, cyclic voltammetry.

MOHAMMED MUNEER, PRASHANT V. KAMAT, et MANAPURATHU V. GEORGE. Can. J. Chem. **68**, 969 (1990).

On rapporte les résultats obtenus lors de notre étude sur les réactions du potassium avec quelques hétérocycles azotés choisis. On a étudié le 2,3-diphénylindole (**1***a*), le 2,3-diphényl-1-méthylindole (**1***b*), le 1,2,3-triphénylindole (**1***c*), le 2,3,4,5-tétraphénylpyrrole (**5***a*), le 1,2,3,5-tétraphénylpyrrole (**5***b*), le 1-benzyl-2,3,5-triphénylpyrrole (**5***c*), le 2,4,5-triphényl-oxazole (**15***a*), le 4,5-diphényl-2-méthyloxazole (**15***b*), le 2,4-diphényl-5-méthyloxazole (**15***c*) et le 2,4,5-triphénylimidazole (**19**). La réaction du produit **1***a* avec le potassium dans le THF donne le 9*H*-dibenzo[*a*,*c*]carbazole (**3***a*), tandis que le **1***c* conduit à un mélange de 9-phényl-9*H*-dibenzo[*a*,*c*]carbazole (**3***c*) et de 2,3-diphénylindole (**1***a*). Dans des conditions semblables, le produit **1***b* ne donne que le produit de clivage **1***a*. Par ailleurs, lorsqu'on a soumis les produits **1***a* et **1***c* à l'action du potassium dans du THF saturé avec de l'oxygène ou à l'action du superoxyde de potasium dans du benzéne contenant de l'éther 18-couronne-6, on isole un mélange formé de 2-benzamidobenzophénone (**4***a*), des carbazoles **3***a* et **3***c* et du composé **1***a*. Même si la réaction du composé **5***a* avec le potassium dans le THF ne permet pas d'isoler de produit, la réaction du produit **5***a* avec du potassium dans du THF saturé d'oxygène fournit un mélange de tétraphénylpyrazine (**7***a*), de benzoylaminostilbène (**8***a*), de lactame **12***a*, de benzamide **11***a* et d'acide benzoïque (**14**). On a obtenu des résultats semblables lors de la réaction du composé **5***a* avec le superoxyde de potassium. La réaction de pyrroles N-substitués, comme les produits **5***b et* **5***c*, avec du potassium dans le THF saturé d'oxygène fournit un mélange formé du composés **9***b*, de la butanone **10***b*, de la 1,4-dione **13***b*, de la lactame **12***b*, des amides **11***a*–*c* et de l'acide benzoïque (**14**). Lorsqu'on a essayé de faire réagir les composés **5***b* et **5***c* avec du superoxyde de potassium, aucun produit n'a pu être isolé; dans chaque cas, on a récupéré pratiquement tout le produit de départ. La réaction de l'oxazole **15***a* avec du potassium fournit un mélange de *N*-(1,2-diphényléthyl)benzamide (**18***a*) et d'acide benzoïque (**14**); mis dans les mêmes conditions, les produits **15***b* et **15***c* fournissent les *N*-vinylamides (**17***b* et **17***c*) et de l'acide benzoïque (**14**). Par ailleurs, la réaction de l'imidazole **19** avec du potassium dans le THF ne fournit aucun produit; toutefois, lorsqu'on traite le

composé **19** soit avec du potassium dans le THF saturé d'oxygène soit avec du superoxyde de potassium, on isole dans chaque cas du dibenzamide (**21**).

Pour expliquer la formation des divers produits observés, on suggère l'existence d'intérmédiaires de types ions radicaux. On a réalisé des études de voltamétrie cyclique pour mesurer les potentiels de réduction de ces intermédiaires anions radicalaires. On a aussi généré ces anions radicaux en faisant intervenir des radiations pulsées dans le méthanol et on a enregistré leurs spectres d'absorption.

Mots clés: hétérocycles azotés, ions radicaux, réactions du potassium avec hétérocycles, radiations pulsées, voltamétrie cyclique.

Introduction

Very few examples of the reaction of nitrogen heterocycles with alkali metals are reported in the literature (1–5). It has been reported that pyrrole is not reduced by potassium in liquid ammonia, whereas indoles are reduced to the corresponding dihydroindoles, on treatment with sodium in ammonia (2). However, when indole is reduced by a large excess of lithium and methanol, a mixture of 4,7-dihydroindole and 4,5,6,7-tetrahydroindole, in equal amounts, is reported to be formed (3). Subsequent studies by Remers *et al.* (4) have shown that ring selectivity in the reduction of indoles and quinolines by sodium in liquid ammonia could be controlled, depending on whether or not the reduction is carried out in the presence of methanol. The sodium–ethanol reduction of 2,4,5-triphenyloxazole has been reported to give *N*-(2-oxy-1,2-diphenylethyl)-benzylamine, whereas the reduction of 4,5-diphenyl-2-methyloxazole gives *N*-(1,2-diphenylethyl)acetamide (5).

In a recent study (6), we showed that several Δ^2-oxazoline-5-ones react with potassium in THF to give a variety of products, arising through radical anion and dianion intermediates. The object of the present investigation has been to examine the reactions of some selected heterocyclic substrates such as indoles, pyrroles, oxazoles, and imidazoles with potassium in THF, to study the nature of the products formed in these reactions.

Results and discussion

In the present studies, we have examined the reactions of 2,3-diphenylindole (**1***a*), 2,3-diphenyl-1-methylindole (**1***b*), 1,2,3-triphenylindole (**1***c*), 2,3,4,5-tetraphenylpyrrole (**5***a*), 1,2,3,5-tetraphenylpyrrole (**5***b*), and 1-benzyl-2,3,5-triphenylpyrrole (**5***c*) with potassium in THF. In addition, the reactions of a few oxazoles such as 2,4,5-triphenyloxazole (**15***a*), 4,5-diphenyl-2-methyloxazole (**15***b*), and 2,4-diphenyl-5-methyloxazole (**15***c*) and an imidazole such as 2,4,5-triphenylimidazole (**19**) with potassium have been examined. The reaction of **1***a* with potassium in THF, for example, gave 9*H*-dibenzo[*a*,*c*]carbazole (**3***a*, 49%), whereas **1***c*, under analogous conditions, gave a mixture of 9-phenyl-9*H*-dibenzo[*a*,*c*]carbazole (**3***c*, 20%) and 2,3-diphenylindole (**1***a*, 19%). The reaction of **1***b* with potassium gave **1***a* (68%) as the only isolable product. In contrast, the reactions of **1***a*,*c* with potassium in THF saturated with oxygen, and with potassium superoxide, gave a mixture of 2-benzamidobenzophenone (**4***a*, 20–34%), the carbazoles **3***a*,*c* (10–13%), and 2,3-diphenylindole (**1***a*, 7–9%), in each case.

The formation of the different products in the reaction of **1***a–c* with potassium in THF may involve the radical anion intermediates **2***a–c*, which can undergo subsequent transformations (Scheme 1). The radical anion intermediates **2***a–c*, for example, can undergo a radical type of cyclization to give the corresponding dihydrocarbazoles and ultimately the carbazoles **3***a*,*c*, under the work-up conditions. The formation of **1***a* from both **1***b* and **1***c*, on the other hand, may be through the cleavage reactions of the corresponding radical anion intermediates **2***b* and **2***c*, respectively. The different oxygenated products and ring cleavage products formed when the reactions were carried out under oxygen saturation, and also in presence of potassium superoxide, may arise through complex reaction pathways. It may be mentioned, in this connection, that ring cleavage products such as **4***a* have been observed in the reaction of several indole derivatives with potassium superoxide, and dioxetane intermediates have been invoked in these reactions (7).

An attempted reaction of a pyrrole such as 2,3,4,5-tetraphenylpyrrole (**5***a*) with potassium in THF did not give any product; most of the starting material could be recovered unchanged. However, when the reaction of **5***a* was carried out with potassium in THF saturated with oxygen, a mixture of tetraphenylpyrazine (**7***a*, 13%), α-benzoylamino-α′-benzoylstilbene (**8***a*), 2,3,4,4-tetraphenyl-2-pyrrolin-5-one (**12***a*, 19%), benzamide (**11***a*, 15%), benzoic acid (**14**, 10%), and some unchanged starting material (**5***a*, 30%) was obtained (Scheme 2). The reaction of the N-substituted pyrroles **5***b*,*c* with potassium gave the pyrrole **9***b* (30–33%) in each case, whereas the reaction of **5***b*,*c* with potassium in THF saturated with oxygen gave a mixture of **9***b* (7–8%), 1,3,4-triphenylbutan-1-one (**10***b*, 12–14%), 1,2,4-triphenylbutan-1,4-dione (**13***b*, 11–13%), 2,4,4-triphenyl-2-pyrrolin-5-one (**12***b*, 10–12%), the amides **11***a–c* (9–17%), and benzoic acid (**14**, 14–15%).

The reaction of an oxazole such as 2,4,5-triphenyloxazole (**15***a*) with potassium in THF gave a mixture of *N*-(1,2-diphenylethyl)benzamide (**18***a*, 27%) and benzoic acid (**14**, 5%), whereas the oxazoles **15***b*,*c*, under analogous conditions, gave a mixture of the *N*-vinylamides **17***b*,*c* (30–37%) and benzoic acid (**14**, 4%) (Scheme 3). In contrast, the reaction of the imidazole **19** under similar conditions did not give any product; however, treatment of **19** with potassium in THF saturated with oxygen gave dibenzamide (**21**, 21%) as the only isolable product.

The formation of the different products in the reactions of **5***a–c*, **15***a–c*, and **19** with potassium in THF may involve the initially formed radical anion intermediates **6***a–c*, **16***a–c*, and **20**, respectively, which can undergo further transformations.

To examine whether any of the oxygenated products formed in the reaction of **1***a–c*, **5***a–c*, **15***a–c*, and **19** with potassium in THF arises through the involvement of superoxide in these reactions, we have carried out the reaction of these substrates with potassium superoxide in benzene containing 18-crown-6. It is interesting to note that the products formed in most of these cases closely resemble those formed in the reaction of these substrates with potassium in THF, saturated with oxygen. In the case of the N-substituted pyrroles **5***b–c*, however, the reaction with potassium superoxide did not give any product under our conditions and it is likely that, in these cases, the radical anion intermediates **6***b*,*c* are not formed through electron transfer from potassium superoxide. The fact that oxygenated products were observed in the case of **5***a*, on the other hand, would suggest that potassium superoxide may be abstracting the NH

proton from **5***a* to give initially the corresponding anionic species, which may then undergo further transformations to give the observed products.

The structures of all the products formed in the reaction of **1***a–c*, **5***a–c*, **15***a–c*, and **19** with potassium were established on the basis of analytical results, spectral data, and comparison with authentic samples, wherever possible.

Cyclic voltammetric studies

In earlier studies (6, 8–10), we highlighted the importance of electrochemical investigations in the generation and characterization of radical anions, the primary intermediates involved in the reaction of several unsaturated organic substrates with potassium in THF. In the present study, we have generated electrochemically the radical anions of **1***a–c*, **5***a–c*, **15***a–c*, and **19**, the substrates under investigation, and the reduction potentials are summarized in Table 1. The substrates **1***a–c*, **5***a–c*, and **19** exhibited irreversible reduction peaks with the reduction potentials in the region of −1.88 to −2.6 V versus SSCE. Because of the irreversible nature of the reduction peaks, it was not possible to elaborate further the electrochemical investigations of these compounds. The substrates **15***a–c* underwent reversible reduction with half-peak potentials in the range of −2.21 to −2.46 V versus SSCE.

Pulse radiolysis studies

As reported earlier (6, 9–13), the radical anions of unsaturated organic compounds can be generated through their reaction with solvated electron (e^-_{sol}) in polar solvents such as methanol under pulse radiolytic conditions. In the present investigation, the radical anions of **1***a–c*, **5***a–c*, **15***a–c*, and **19** were generated in methanol. These radical anions were characterized by strong absorption maxima in the region of 300–500 nm (Table 1). The lifetimes of these radical anions in methanol varied from 2 to 275 μs. It is evident from Table 1 that these radical anions are formed from their appropriate precurcors through the reaction with solvated electrons under diffusion controlled rates.

Experimental

All melting points are uncorrected and were determined on a Mel-Temp apparatus. The petroleum ether used was the fraction with bp 60–80°C. THF used was dried over sodium and was distilled before use. Gold Label (Aldrich) acetonitrile was used for cyclic voltammetric studies and spectral grade methanol (Fisher Scientific) was used for pulse radiolysis.

Starting materials

2,3-Diphenylindole (**1***a*) (14), mp 123–124°C; 2,3-diphenyl-1-methylindole (**1***b*) (14), mp 129–130°C; 1,2,3-triphenylindole (**1***c*) (15), mp 186–187°C; 2,3,4,5-tetraphenylpyrrole (**5***a*) (16), mp 212–213°C; 1,2,3,5-tetraphenylpyrrole (**5***b*) (17), mp 199–200°C; 1-benzyl-2,3,5-triphenylpyrrole (**5***c*), (17), mp 166–167°C; 2,4,5-triphenyloxazole (**15***a*) (18), mp 116–117°C; 4,5-diphenyl-2-methyloxazole (**15***b*) (18), bp 210–212°C (18 Torr; 1 Torr = 133.3 Pa); 2,4-diphenyl-5-methyloxazole (**15***c*) (19), mp 74–75°C; and 2,4,5-triphenylimidazole (**19**) (18, 20), mp 274–275°C, were prepared by reported procedures.

Reaction of **1**a–c, **5**a–c, **15**a–c, *and* **19** *with potassium in THF under nitrogen and oxygen*

A general procedure was to shake the appropriate substrate with finely cut potassium metal in THF under nitrogen, for several hours in a stoppered Schlenk tube. A few clean, broken glass pieces were added to the mixture to ensure a fresh surface of the metal throughout the reaction. The reaction mixture underwent pronounced color changes, in each case, indicative of the formation of radical anion intermediates. On completion of the reaction, the mixture was drained into moist THF (10 mL) to destroy any unchanged potassium and the solvent was removed under reduced pressure. The residual solid was treated with water (10 mL) and extracted with methylene chloride. The aqueous layer was acidified with dilute hydrochloric acid and worked up in the usual manner to give acidic products, which were purified by recrystallization from suitable solvents. Work-up of the organic layer by removal of the solvent under vacuum and fractional crystallization from suitable solvents or chromatography over neutral alumina gave the non-acidic products, which were further purified by recrystallization from suitable solvents.

In cases where the reactions were carried out under oxygen saturation, the same experimental procedure was adopted in each case, except that the starting substrates were shaken initially with potassium in THF for several hours, under oxygen saturation.

The details of reaction conditions and products are shown in Table 2.

Reaction of **1**a–c, **5**a–c, **15**a–c, *and* **19** *with potassium superoxide*

A general procedure was to stir the appropriate substrate (2 mmol) with potassium superoxide (4 mmol) and 18-crown-6 (2 mmol) in

benzene (100 mL) for 24 h. On completion of the reaction, the mixture was treated with water (20 mL) and extracted with an aqueous solution of sodium chloride. The organic layer was dried over sodium sulfate and the solvent was removed under vacuum. The residual solid was chromatographed over neutral alumina and recrystallized from suitable solvents to give the non-acidic products. The aqueous layer, on acidification with dilute hydrochloric acid, gave the acidic products, which were purified by recrystallization from suitable solvents.

The details of reaction conditions and products are indicated in Table 3.

Cyclic voltammetry

Measurements were made with a Princeton Applied Research (PAR) model 173 potentiostat/galvanostat, a PAR model 175 universal programmer, and a Kipp and Zonen X–Y recorder. Experiments were performed in a standard three-compartment cell, equipped with a Pt-disc working electrode, a Pt-wire counter electrode, and a saturated sodium chloride – calomel electrode (SSCE). Cyclic voltammograms were recorded in deaerated acetonitrile containing 0.1 M tetrabutylammonium perchlorate (TBAP).

Pulse radiolysis

The pulse radiolysis experiments were carried out using a computer controlled apparatus (21) and the irradiation was carried out with 5-ns electron pulses from the Notre Dame 7 MeV ARCO LP-7 linear accelerator, using a dose rate of $\sim 2 \times 10^{16}$ eV/g per pulse. The solutions (0.2–0.5 mM) of the substrates were taken in graduated 250-mL cylindrical reservoirs and deaerated by bubbling nitrogen for at least 30 min prior to irradiation. Nitrogen bubbling was continued in the reservoir from which the solution was allowed to flow continuously through the cell (1 cm pathlength). The rate constants for the reactions with solvated electrons (e^-_{sol}) were determined from the kinetic analysis of the enhanced rate of decay of e^-_{sol} in the presence of the substrate or from the growth rate of the radical anion.

COMMUNICATION

Biomimetic ion transport: on the mechanism of ion transport by an artificial ion channel mimic

THOMAS M. FYLES,[1] TONY D. JAMES, AND KATHARINE C. KAYE
Department of Chemistry, University of Victoria, Victoria, B.C., Canada V8W 2Y2

Received December 4, 1989

THOMAS M. FYLES, TONY D. JAMES, and KATHARINE C. KAYE. Can. J. Chem. **68**, 976 (1990).

The influx of cations into vesicles mediated by a synthetic transporter is coupled to proton efflux and may be quantified by a pH-stat technique. The dependence of the transport upon cation type and concentration, upon transporter concentration, and upon temperature has been examined. The synthetic transporter is closely similar to the natural channel forming compound gramicidin, and significantly different from the carrier valinomycin, with respect to the variables examined.

Key words: ion transport, vesicle membrane, channel, gramicidin, transport mechanism.

THOMAS M. FYLES, TONY D. JAMES et KATHARINE C. KAYE. Can. J. Chem. **68**, 976 (1990).

On a couplé l'influx de cations dans des vésicules qui est assisté par un transporteur de synthèse avec un efflux de proton et on l'a quantifié à l'aide d'une technique de pH. On a examiné la relation qui existe entre le transport et le type et la concentration du cation, la concentration du transporteur et la température. Par rapport aux variables qui ont été examinées, le transporteur de synthèse est très semblable à la gramicidine, le composé naturel formant des canaux, mais il diffère de la valinomycine.

Mots clés : transport ionique, membranes vésiculaires, canaux, gramicidine, mécanismes de transport.

[Traduit par la revue]

Introduction

Biomimetic model systems of ion transport processes seek to illuminate the fundamental features of natural transport systems (1). Two main molecular mechanisms can be discerned: transport mediated by carriers, and transport mediated by pores or channels. Recent emphasis from synthesis has been on the former (2), despite the fact that the latter mechanism appears to be more general among natural systems (3). A few notable exceptions are the synthetic channels of Tabushi *et al.* and Nolte and co-workers (4*a*)[2] and systems involving amphiphile association for the creation of pores (5). We recently reported the synthesis and ion transport activity of a type of ion channel designed to mimic channels such as gramicidin (6). An example is sketched in Fig. 1. The speculative structure illustrated served initially as a guide to target selection and synthesis. This report addresses the question of the implied mechanism embedded in the design: does the mimic transport cations by a channel mechanism?

The transport of cations across vesicle bilayer membranes was determined by a pH-stat method (7).[3] Vesicles were prepared and purified in a choline sulfate/Bis-Tris buffer at pH 6.60, diluted in unbuffered choline sulfate, and brought to pH 7.5 with choline base. Addition of the proton carrier FCCP and the transporter has little effect on the slow rate of proton efflux due to the collapse of the pH gradient. Upon addition of metal ion, a trans-membrane cation gradient is established, which collapses via electroneutral cation/proton antiport (7). The proton efflux can then be determined by addition of choline base to maintain the external pH. Proton efflux occurs rapidly, but decreases in a monotonic fashion to a steady-state rate equal to the slow efflux of the background in the absence of transporter. Addition of Triton X100 provokes complete vesicle lysis and releases any remaining internal buffer. Figure 2 illustrates the experimental result provoked by the transporter, at a concentration of 7×10^{-10} M (about 1 per vesicle), for variation in the metal ion added.

The principal feature of all experiments is that the synthetic transporter fails to empty all the vesicles. By electron microscopy,[3] the vesicle preparations are predominantly unilamellar (LUV, 125 nm diameter) but contain some larger multilamellar structures (MLV), accounting for 10–15% of the entrapped proton titer. Gary-Bobo and co-workers (7) previously noted that carriers such as valinomycin can empty the LUV fraction irrespective of the amount of carrier added, but that channel forming compounds (gramicidin, amphotericin) exhibit a concentration-dependent plateau, lower than the total LUV fraction. The results given in Fig. 2 for the synthetic transporter are

[1]Author to whom correspondence may be addressed.

[2]Non-functional channels have also been described (4*b*).

[3]Egg phosphatidyl choline, cholesterol, and phosphatidic acid (8:1:1) in ether was mixed with 0.2 M Bis-Tris/sulfate buffer (pH 6.60) containing 0.054 M D-mannitol. The mixture was sonicated, the organic solvent removed at reduced pressure, and the vesicle solution diluted with more buffer solution and successively filtered through 3- and 0.4 μm cellulose acetate filters. The sized vesicles were isolated by chromatography on Sephadex G10 (10 mL) using 0.11 M choline sulfate containing 0.093 M D-mannitol as eluent and then aged for 16 h at ambient temperature. The lipid content was determined (11); 3.3 mg/mL was a typical value. The pH-stat method described in the text utilized 0.00491 M choline base in 0.35 M D-mannitol as titrant. A vesicle sample (0.5 mL, 2.4 μmol lipid) was diluted with 3.5 mL of the choline sulfate/ D-mannitol solution and brought to pH 7.5 (about 1 mL of titrant added). FCCP (carbonyl cyanide (4-trifluoromethoxy) phenyl hydrazone, 80 pmol) followed by the transporter (**6***b* of ref. 6, prepared and purified as previously, 3.4 pmol) were added as solutions in methanol. Transport was initiated by addition of metal sulfates. The electron microscopy samples were prepared by dipping Formvar-coated copper grids into the vesicle solution, air drying, and staining with phosphotungstic acid at pH 7.2. A Phillips EM360 transmission electron microscope was used. Controls establish the following: no transport without the addition of transporter, no effect of methanol alone, no detergent effect of the transporter on the vesicles, and vesicles are intact at the end of the pH-stat experiment.

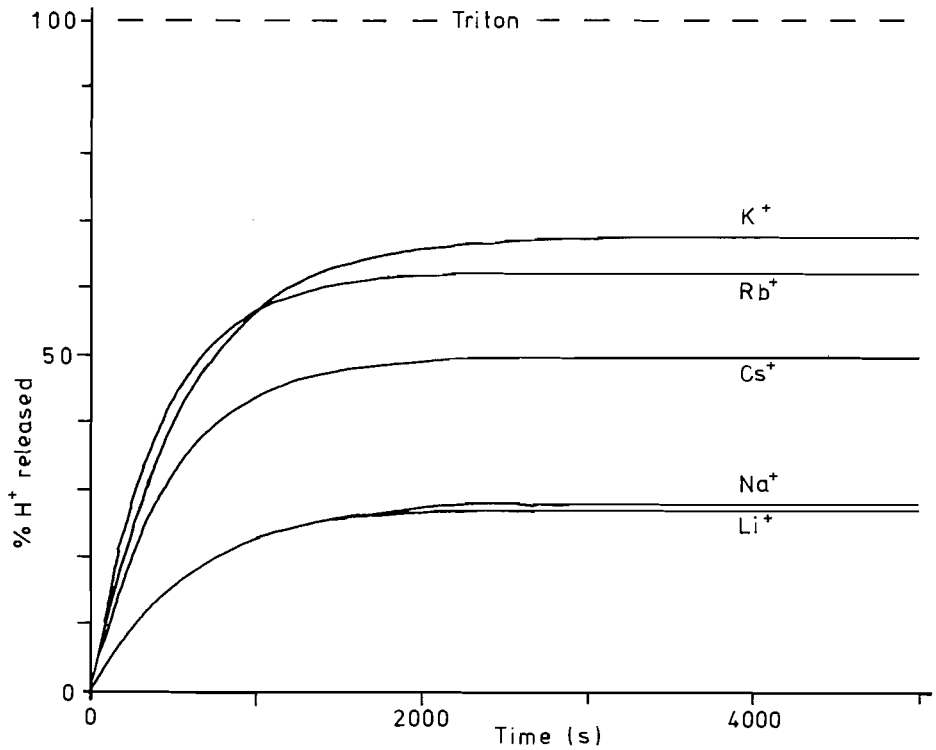

FIG. 2. Extent of proton efflux as a function of time, expressed as the percentage of the total entrapped titer released by Triton X100 lysis. See Table 1 for conditions, data of entries 5–8 and 11.

gramicidin is 32 ± 8 kJ/mol, while for the carrier valinomycin the value is 43 ± 16 kJ/mol. The extent of transport is not temperature dependent in the latter two cases.

Taken together, the available data are most consistent with the synthetic transporter acting via a channel mechanism: the observation of the plateau behaviour, the inability of the transporter to move between vesicles, the low kinetic order in transported cation, and the temperature dependence and activation energy all argue for this view. The unit order in transporter, the observation of a saturable process, and the observation of ion selectivity are consistent with either a carrier or a channel mechanism. The selectivity of the gramicidin pore can be directly determined under conditions where the anion symport (or cation antiport) is not rate limiting (10). The use of FCCP is intended to achieve this condition (7), thus the selectivities determined here could also derive from a channel mechanism. In total, the synthetic transporter is more similar to a known channel-forming compound, gramicidin, than to a known carrier such as valinomycin. The sketch of Fig. 1 thus represents a likely mode of action of this synthetic channel in a bilayer.

Conformational analysis of key disaccharide components of *Brucella* A and M antigens[1]

THOMAS PETERS,[2] JEAN-ROBERT BRISSON, AND DAVID R. BUNDLE
Division of Biological Sciences, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received December 19, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

THOMAS PETERS, JEAN-ROBERT BRISSON, and DAVID R. BUNDLE. Can. J. Chem. **68**, 979 (1990).

The synthetic α1,2 and α1,3 disaccharide methyl glycosides of 4-amino-4,6-dideoxy-D-mannose **1–6** that constitute key structural elements of *Brucella* A and M antigens were analyzed by ^1H and ^{13}C nuclear magnetic resonance spectroscopy. A detailed conformational analysis was performed for the *N*-acetylated derivatives **1** and **4** as well as for the amino derivatives **2** and **5**. Potential energy calculations using the GESA program established the global minima for the disaccharides **1**, **2**, **4**, and **5**, and mapped the energy surface as a function of the glycosidic torsion angles ϕ and ψ. Ensemble averaged nuclear Overhauser enhancements, weighted according to the Boltzmann distribution function, were derived for each of the four disaccharides. This procedure improved the fit between experimentally and theoretically derived nOe values, when compared to interpretations based on a single conformer model. The *Brucella* A and M antigens are homopolymers of 4-formamido-4,6-dideoxy-D-mannose and, as *N*-formyl groups (saccharides **3**, **6**, and **8**) are essential for the binding of these antigens to their respective antibodies, amide conformation was analyzed by examination of the vicinal proton–proton and proton–carbon coupling constants of the model monosaccharide **8**. The conformational properties of the model compounds **1–8** were used to model the *Brucella* A and M polysaccharide antigens.

Key words: conformational analysis, disaccharide conformation, nuclear Overhauser measurements, molecular modeling, *Brucella* antigen.

THOMAS PETERS, JEAN-ROBERT BRISSON et DAVID R. BUNDLE. Can. J. Chem. **68**, 979 (1990).

Faisant appel à la spectroscopie en résonance magnétique nucléaire du ^1H et du ^{13}C, on a analysé les α1,2 et α1,3 disaccharide glucosides de méthyle (**1–6**) du 4-amino-4,6-didésoxy-D-mannose qui constituent les éléments clés de la structure des antigènes de la *Brucella* A et M. On a réalisé une analyse conformationnelle détaillée des dérivés *N*-acétylés **1** et **4** ainsi que des dérivés aminés **2** et **5**. Des calculs d'énergie potentielle effectués à l'aide du programme GESA ont permis d'établir les minima globaux des disaccharides **1**, **2**, **4** et **5** ainsi qu'une carte de l'énergie superficielle en fonction des angles de torsion ϕ et ψ de la liaison glycosidique. Pour chacun des quatre disaccharides, on a déterminé les valeurs moyennes de nOe des ensembles, pondérés à l'aide d'une fonction de distribution de Boltzmann. Cette procédure a permis d'améliorer la corrélation entre les valeurs expérimentales des nOe et les valeurs calculées d'une façon théorique à l'aide d'un modèle conformère unique. Les antigènes de la *Brucella* A et M sont des homopolymères du 4-formamido-4,6-didésoxy-D-mannose dont les groupements *N*-formyles (saccharides **3**, **6** et **8**) sont essentiels pour la liaison de ces antigènes avec leurs anticorps respectifs; on a donc analysé la conformation de l'amide grâce à un examen des constantes de couplage proton–proton et proton–carbone vicinaux du monosaccharide modèle, **8**. On a utilisé les propriétés conformationnelles des composés modèles **1–8** pour déduire un modèle des polysaccharides des antigènes de la *Brucella* A et M.

Mots clés: analyse conformationnelle, conformation du disaccharide, mesures de nOe, modèle moléculaire, antigène de la *Brucella*.

[Traduit par la revue]

Introduction

Brucella polysaccharide antigens are homopolymers of the rare sugar 4,6-dideoxy-4-formamido-D-mannopyranose (D-Rha4NFo). The A polysaccharide is α1,2 linked and hence may be regarded as having a monomeric repeating unit (1, 2), while the M antigen has a pentameric repeating sequence due to the replacement of one α1,2 linkage in every five by an α1,3 linkage (2, 3).

A antigen: [→2)-α-D-Rha4NFo-(1-]

M antigen: [→2)-α-D-Rha4NFo-(1→2)-α-D-Rha4NFo-(1→2)-α-D-Rha4NFo-(1→2)-α-D-Rha4NFo-(1→3)-α-D-Rha4NFo-(1-]

Monoclonal antibodies that bind these antigens have been crystallized in the form of Fab fragments and as complexes with a synthetic pentasaccharide (4). One of these crystal structures has been solved at 2.7 Å resolution (4), and separate work on binding site modeling based upon sequence homology with solved structures has also yielded a model of the protein site (5).

In order that the bound ligand may be realistically modeled in the combining site it is desirable to understand the conformational properties of short oligomeric di-, tri-, tetra-, and pentasaccharide sequences of the *Brucella* antigens, which have also been used to immunochemically map the binding site (6). To accomplish this, key α1,2- and α1,3-linked disaccharides in the form of acetamido-deoxy derivatives **1** and **4**, amino-deoxy derivatives **2** and **5**, and deoxy-formamido derivatives **3** and **6** were synthesized in addition to tri-, tetra-, and pentasaccharides (7–9). The structural variation at the 4-amino group was considered to be a necessity in the conformational analysis of antigen fragments because 4,6-dideoxy-4-formamido-D-mannose exists in solution as both *E* and *Z* isomers (2, 10, 11), a complication that prevents a practical analysis of conformation at the level of trisaccharide or higher homologues. Consequently, *N*-acetyl derivatives **1** and **4** as well as the amino derivatives **2** and **5** were synthesized together with the *N*-acetylated and *N*-formylated monosaccharides **7** and **8** so that a detailed conformational analysis by nmr spectroscopy could be performed on the basic element of the antigen structure.

In this paper we describe the detailed conformational analysis of the disaccharides **1**, **2**, **4**, and **5** by nmr spectroscopy and

potential energy calculations. The approach adopted utilized the HSEA force field (12, 13) to map the energy surface defined by the glycosidic torsion angles, but rather than rely upon a single-state model to interpret the nmr data (12–19), the method of Cummings and Carver (20, 21) was used to predict ensemble averaged nOe values. Finally, a three-dimensional model for the *Brucella* A and M polysaccharide chains is proposed by combining the results of the potential energy calculations with vicinal proton–proton and proton–carbon coupling constant data for the *N*-formylated monosaccharide **8**, data that defines the orientation of the *N*-formyl group.

Results

Calculations

Potential energy calculations were performed using the GESA program (17).[3] This program embodies the rigid body HSEA (Hard Sphere Exo Anomeric) approach of Lemieux (11, 12), which assumes that van der Waals interactions and the *exo*-anomeric (23) effect are the main forces determining conformational equilibria of carbohydrates in aqueous solution. Treatment of hydroxyl group orientation is deliberately avoided by omitting hydrogen atoms attached to oxygen. The torsional degrees of freedom defining a certain conformation ϕ^H (H1—C1—O1—CX) and ψ^H (C1—O1—CX—HX) at the glycosidic linkages and the torsional angle ω (O5—C5—C6—O6) describing the orientation of the hydroxymethyl group (not used here) are minimized simultaneously using the Davidon–Fletcher–Powell algorithm (24) from a chosen set of starting angles. The initial parameter settings may be varied to ensure that the global minimum is reached. Consequently, it is important to know the shape of the energy surface prior to minimization. For the disaccharides to be discussed, this surface is a function of only two variable angles and Fig. 1 shows the energy surfaces of the *N*-acetyl derivatives of the α1,2- and α1,3-linked disaccharide methyl glycosides **1** and **4**. These two surfaces are very similar despite the difference of linkage position. For both linkages the global minima are found to exhibit ϕ and ψ angles between $-40°$ and $-50°$ and between $-10°$ and $-20°$ respectively. The shapes of the energy surfaces indicate that not only the ψ but also the ϕ angle exhibits flexibility, although the latter in general is more restricted because of the *exo*-anomeric effect (23). Varying ϕ and ψ to positive values yields local minima about 16 kJ above the respective global minima for the two disaccharides (Fig. 1). The global and local minima have been refined for the disaccharides **1**–**6** and are summarized in Table 1.

These results suggest that in solution the disaccharides can sample a relatively wide range of energetically accessible ϕ,ψ values and cannot be adequately represented by a single fixed conformer. In this study we use nOe's to probe conformational behaviour. Calculation of nOe's based upon a multi-state model requires averaging over all energetically accessible conformational microstates (cf. Fig. 1). If the internal motion responsible for the interconversion of different conformational microstates is slow relative to the overall molecular tumbling, and the correlation time τ_i for the internal motion is greater than the molecular tumbling time τ_c, two cases (a and b) can be distinguished (20, 25).[4] If the internal motion is faster than the overall molecular tumbling, cases c and d have to be considered.

(a) $T_1 \ll \tau_i$: interconversion of conformers is very slow and each single conformer can separately reach a steady state during the nOe experiment. The average nOe's are simply calculated by weighting the nOe's for the different conformers using the Boltzmann distribution function.

(b) $\tau_c < \tau_i < T_1$: fast interconversion of conformers takes place and ensemble averaged nOe's, denoted ⟨nOe⟩, are calculated by first weighting the r^{-6} term for the different conformers, again using the Boltzmann distribution function, then taking the average giving rise to ensemble averaged values, denoted $\langle r^{-6}\rangle$. The relaxation matrix constructed from these $\langle r^{-6}\rangle$ values is finally used to calculate the ⟨nOe's⟩.

(c) $\tau_i < \tau_c$: under these conditions it can be shown that the effective nOe is determined by $\langle r^{-3}\rangle^2$ (26, 27).

(d) the C-6 methyl groups of 4-amino-4,6-dideoxy-D-mannose undergo fast internal rotation, which is also taken into account for the calculation of ⟨nOe's⟩ from the ensemble average relaxation matrix (for details see the experimental section).

Case b has been applied to conformational equilibria at glycosidic linkages (20) and thus one treatment here considers ⟨nOe's⟩ calculated on the basis of $\langle r^{-6}\rangle$ values. On the other hand, molecular dynamics calculations for peptides and proteins reveal internal motions to occur on the picosecond time scale, and for this reason a second approach calculates nOe's on the basis of $\langle r^{-3}\rangle^2$ values. The results of these calculations will be discussed together with the experimentally determined values (Table 5).

Nuclear magnetic resonance spectroscopic experiments

A complete assignment of the ^1H and ^{13}C nmr signals of all disaccharides was achieved by applying standard homonuclear,

[3]Also, B. Meyer. Manuscript in preparation.

[4]After submission of this manuscript two papers by Lipkind *et al.* (22) appeared, which deal with ensemble averaged nOe, but use an algorithm that assumes slow exchange of conformers on the nmr time scale (case a, this manuscript). It is important to emphasize that interconversion occurs on a fast time scale (case b, above).

COSY (28), and heteronuclear shift correlated experiments (29). In the case of the *N*-formylated saccharides **3**, **6**, and **8**, spectral interpretation is complicated by the E/Z isomerism of the *N*-formyl groups (2, 10, 11). The two isomeric forms of each *N*-formyl group interconvert slowly on the nmr time scale thus giving rise to 2^n different isomers for an oligosaccharide consisting of n monosaccharide residues. Therefore, each proton in the disaccharides **3** and **6** should theoretically split into four different signals corresponding to $2^n = 4$ isomers. As might be expected, this splitting cannot be observed for each proton even at 500 MHz, a field strength at which most protons are affected only by the orientation of the *N*-formyl group within the same monosaccharide residue. Protons directly attached to the carbonyl carbon of the *N*-formyl groups give eight separate lines between δ 8.0 and 8.3 ppm confirming the presence of four equilibrating isomers. Integration of these signals reveals a $Z{:}E$ ratio of 3.5:1 in deuterium oxide. The most pronounced effect of the rotational isomerism is found for the protons attached to C-4. When the *N*-formyl group adopts the E orientation the chemical shift of H-4 is found at high field around δ 3.4 ppm, whilst in the Z form eclipsing of H-4 by the carbonyl group results in substantial deshielding that moves the resonance to roughly δ 3.9 ppm. The same complications arise for ^{13}C nmr spectra. Again inspection of chemical shift differences caused by E/Z isomerism of the *N*-formyl groups reveals that their orientation has only a minor influence on the chemical shifts of the adjacent sugar ring. Only for the α1,3-linked disaccharide **6** are the signals for the two carbon atoms, C-3′ and C-5′, split into the theoretical four lines (Table 3). Major differences occur in the chemical shifts of the carbon atoms C4, C4′ and the carbonyl carbons. Those signals arising from the E isomers are shifted downfield several ppm. Additionally, the adjacent carbon atoms C5 and C5′ show small upfield shifts in the range of 0.5 ppm. The resonances of the carbon atoms involved in the glycosidic linkage are unaffected by the E/Z isomerism. All ^1H and ^{13}C nmr data (chemical shifts and coupling constants) are summarized in Tables 2 and 3.

Isotropic reorientation with correlation times in the extreme narrowing limit, $\tau_c \simeq 10^{-10}$ s, allows a simplified protocol for the calculation of nOe's or proton spin lattice relaxation times from geometry parameters, provided longitudinal relaxation is dominated by dipole–dipole interactions. Similar ^{13}C T_1 values for the pyranose ring carbon atoms provided supporting evidence for isotropic tumbling of the disaccharides **1** and **4**, although fluctuations in the T_1's of carbon atoms involved in the glycosidic linkage suggested the emergence of a preferred axis of motion (Table 4). The same T_1 measurements also revealed internal motion about the C5—C6 bond, since NT_1 values (N = number of protons attached to a particular carbon) are not constant when T_1's of C-6 atoms are compared with those of the ring carbon atoms. It is clear that an adequate model, such as the three-state jump model (30), must take internal motion for the methyl group rotation about the C5—C6 bonds into account when nOe's are calculated (cf. experimental section, calculations).

Steady-state, one-dimensional nOe difference experiments were performed for the *N*-acetylated disaccharides **1** and **4**, and the amino derivatives **2** and **5**. The quantitative data were compared with the nOe predicted by calculation of ensemble averaged values as well as those predicted by the global minimum conformation (Table 5). Selective irradiation of single resonances (31, 32) and, hence, quantitative nOe measurements could only be accomplished in those instances where anomeric or other ring protons were well resolved and free of overlap. Those experiments which allowed precise quantitation are compared with theoretical predictions (Table 5). One of these experiments performed on disaccharide **1** is representative

of the quality of these measurements (Fig. 2). For the *N*-formylated disaccharides **3** and **6** selective irradiation was not possible because of severe overlap of the signals belonging to the different isomers. Thus NOESY spectra (33) were recorded to qualitatively detect nOe's (data not presented). Those results are in good agreement with the one-dimensional nOe data for disaccharides **1**, **2**, **4**, and **5**.

Discussion

Conformational analysis of glycosidic linkages

Measurement of experiment nOe's for biomolecules represents one of the most important tools by which their solution tertiary structure may be elucidated. In the case of proteins nOe values can provide sufficient conformational constraints to define a unique solution structure (34). With few exceptions comparable nOe experiments performed on oligosaccharides fail to deliver enough distance or torsional constraints to define a unique solution conformation. It has been proposed recently that the hydroxyl functions can be used as so-called "long range sensors" to obtain additional conformational constraints (35) but this method requires nOe experiments to be performed in dimethyl sulfoxide. The problem remains that under physio-

logical conditions in aqueous solutions the conformational behaviour of oligosaccharides cannot be assessed solely on the basis of nOe experiments. Thus additional nmr experimental data such as ^1H chemical shifts (14) or ^{13}C chemical shifts (36) have to be invoked in the discussion of carbohydrate solution conformation. Most often, inferences of tertiary structure from these data have been based upon further correlations with potential energy calculations, and a large body of literature has accumulated on this topic (12–19).

Flexibility about glycosidic linkages poses an additional problem for conformational analysis (20, 21). In general, and in particular for the disaccharides under investigation, the energy minima as a function of the torsional angles ϕ and ψ at the glycosidic linkages are seen to be rather shallow and even exhibit local minima (Fig. 1). In the following discussion experimentally derived nOe's are compared with data calculated on the basis of models that take into account motional averaging according to methods described by Cumming and Carver (20, 21) or Kessler *et al.* and Torda *et al.* (26, 27). Data calculated for the global and local minima are presented as well. The results of this comparison are summarized in Table 5 (details of the computational procedures are described in the experimental section). Two points are immediately obvious:

1. The nOe values calculated for the local minima cannot account for the observed data.
2. The single-state model based only on the calculated global minima predicts reasonable nOe values but in four cases the relative order of magnitude of the observed nOe's is opposite to that calculated.

The nOe experiments carried out on compounds **1**, **2**, and **5** lead to the following observations:

Irradiation of H-1′ (**5**) causes an interglycosidic nOe to H-3 that is more than twice as large as the intra-residue nOe experienced by H-2′, the opposite magnitude to that predicted by the single-state model. For the same compound irradiation of H-2 produces a similar result, a larger nOe to H-3 than to H-5′, opposite to the relative ordering predicted by the global minimum conformation. When compounds **1** and **2** were used for nOe measurements, irradiation of H-1′ in either compound **1** or **2** produced an inter-glycosidic nOe to H-2 that is observed to be larger than the intra-glycosidic nOe of H-2′. None of these results is consistent with or predicted by the calculations based upon the global minimum conformer.

The fit between experimentally available data and theoretical values can be significantly improved by calculating ensemble averaged nOe's as described in the experimental section. It is seen (Table 5) that where incorrect relative ordering of the nOe magnitude is predicted by the single-state model, the statistical mechanical model (20, 21) based upon averaging either r^{-6} or r^{-3} terms predicts the correct order or at least significantly improves the situation, as exemplified by the irradiation of H-2 in disaccharide **5**: the nOe calculated for H-1 shows good agreement with the observed value, and nOe's for H-3 and H-5′ now converge toward the experimental values, although the

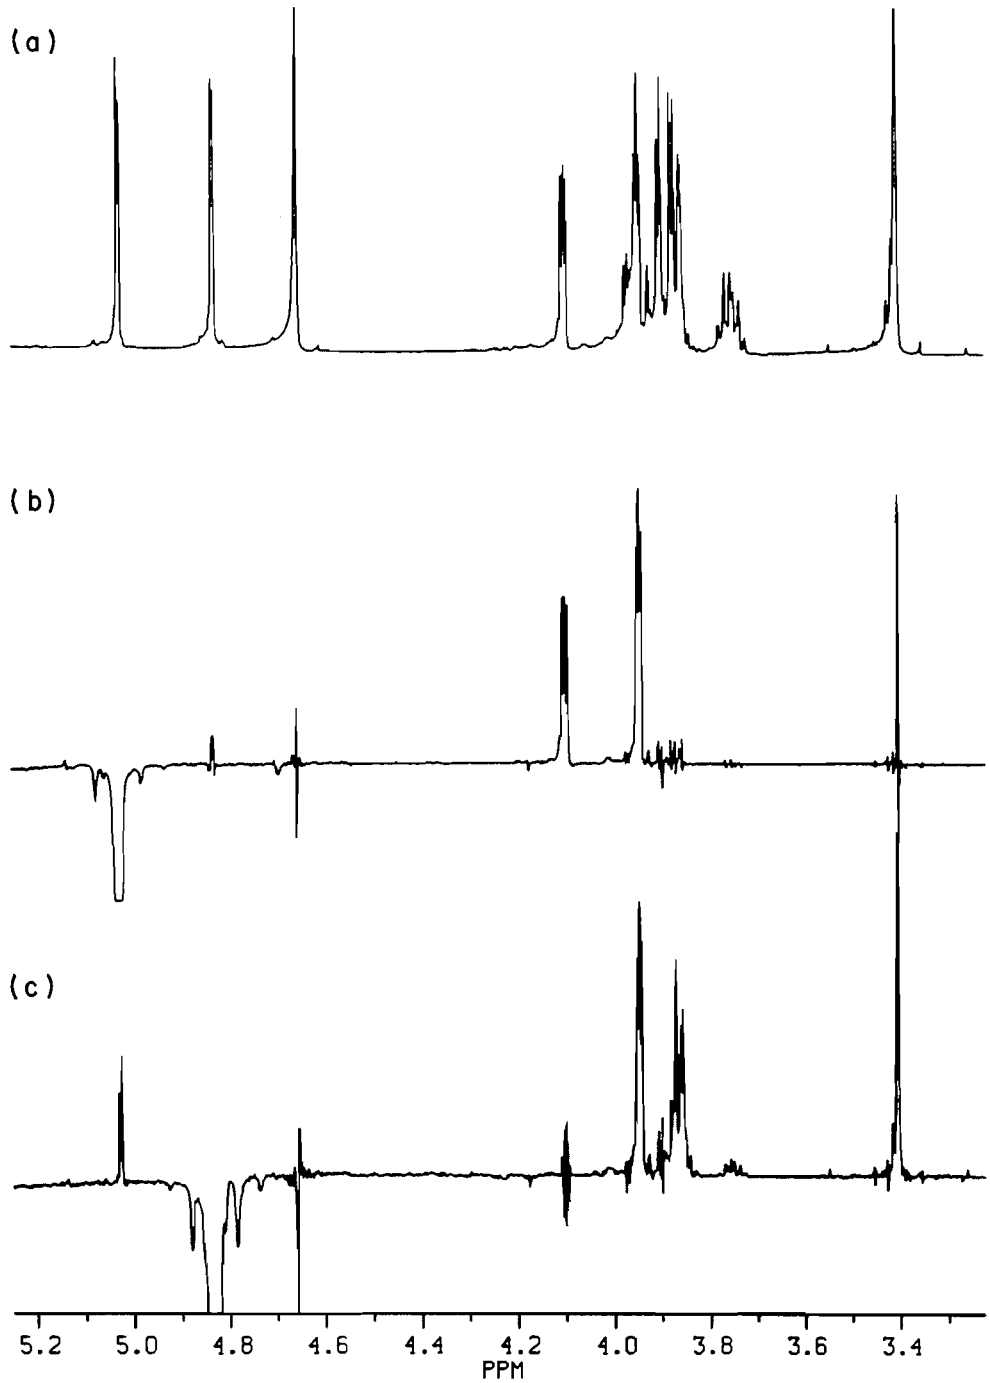

FIG. 2. The nOe difference spectra for disaccharide **1**; (a) reference spectrum; (b) irradiation of H-1′; (c) irradiation of H-1.

nOe for H-5′ remains larger than that at H-3. This might indicate that the calculated energy surface is too crude to allow the prediction of nOe's that are generally sensitive to conformational preferences.

As pointed out above, for the *N*-formylated disaccharides **3** and **6** only qualitative nOe data from NOESY experiments are available. These values are consistent with the results discussed above and there is no indication that the *N*-formyl groups alter the glycosidic linkage conformation.

To evaluate the effect of glycosylation on the ^{1}H chemical shifts, Table 2 also contains the ^{1}H chemical shifts of the monosaccharide building blocks **7** and **8**. A comparison of the chemical shift data of the disaccharides carrying the *N*-formyl and the *N*-acetyl group with the corresponding monosaccharides reveals several points of interest and these should be compared with the short H····O distances. Major changes in chemical shifts are observed for the protons H-1′ and H-2′ of disaccharide **1**; H-1′ is 0.30 ppm downfield shifted in comparison to H-1 in the monosaccharide compound **7**. This is explained by a close proximity of H-1′ to O-3 across the glycosidic linkage (for the minimum energy molecule a H-1····O-3 distance of about 2.6 Å is calculated). A downfield shift of 0.19 ppm for H-2′ due to the formation of the glycosidic linkage cannot readily be explained by the single-state conformer in terms of short H-2′ to oxygen distances. The local minimum provides a short distance between H-2′ and O-3 (2.7 Å), indicating the necessity

[d] ⟨nOe⟩ = ensemble average $\langle r^{-3}\rangle^2$ nOe's.

for motional averaging. Equivalent observations can be made for the *N*-formylated disaccharide **3**. For the α1,3-linked disaccharides **4** and **6** no such large shift differences can be observed. The most interesting but not the largest shift is observed for H-2′, which is upfield shifted by 0.10 ppm. This effect is found to be even more pronounced in the naturally occurring M polysaccharide (2) and can be explained by the relative orientation of H-2′ towards the *N*-acetyl or the *N*-formyl group in the reducing unit. The molecular model for the global minimum conformation, which is shown in Fig. 3, indicates that H-2′ is in a region of the anisotropy cone of the amide carbonyl where shielding is caused. Another significant shift is that of H-1′ in **4** which is shifted 0.22 ppm downfield compared to monosaccharide **7**. The same is observed for the corresponding *N*-formylated derivative **6**. In this case the shift must be due to a close proximity to the *N*-acetyl group in the case of **4** and to the *N*-formyl group in the case of **6**.

The ^{13}C nmr chemical shift data also reveal several points of interest. It is known that the chemical shift of the anomeric carbon atom as well as the aglyconic carbon atom can be used to qualitatively access the glycosidic linkage conformation (36). Inspection of the chemical shifts of the anomeric carbons of the disaccharides **1** and **6** (Table 3) indicates that neither the *E*/*Z* isomerism nor the nature of the substituent at the nitrogen atom greatly influences the glycosidic linkage conformation. This is in agreement with the results of the HSEA calculations, which predict that the conformations of the glycosidic linkage are closely related for compounds **1**–**6**.

Conformation of the N*-formyl groups*

The carbonyl carbon – nitrogen bond in methyl 4,6-dideoxy-4-formamido-α-D-mannopyranoside **8** exhibits considerable double bond character, in accordance with the energy barrier to rotation of ca. 87 kJ/mol measured by dynamic nmr studies in dimethyl sulfoxide (11). Interconversion between isomers *Z* (**8***a*) and *E* (**8***c*) is slow on the nmr chemical shift time scale, with a half-life for each isomer of ~30 s (11). Proton–proton as well as heteronuclear vicinal coupling constants, $^3J_{CH}$, were used to determine the conformation of the *N*-formyl group in monosaccharide **8** and to exclude other possible isomers **8***b* and **8***d* (11).

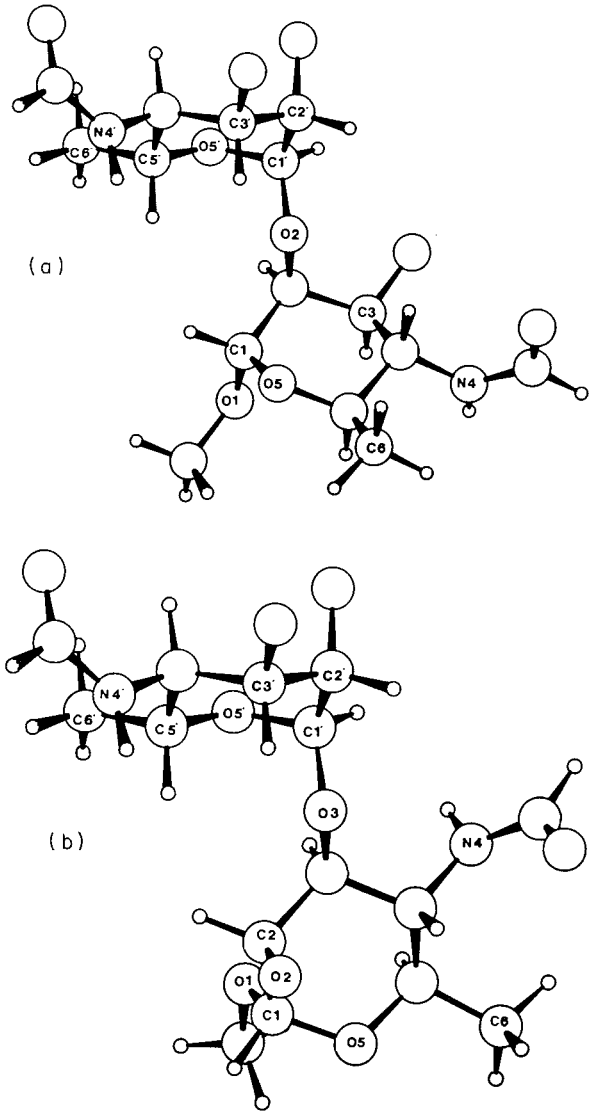

FIG. 3. Molecular models for the global minimum energy conformations of the disaccharides **3** and **6**; (a) global minimum for **3**, α-D-Rha4NFo-(1→2)-α-D-Rha4NFo-1-OMe; (b) global minimum for **6**, α-D-Rha4NFo-(1→3)-α-D-Rha4NFo-1-OMe.

Amide coupling constants measured for **8** in water were 10.0 Hz for both *Z* and *E* isomers, which is in agreement with the usual in-plane, anti-periplanar arrangement for the fragment H—N—C—H. Vicinal coupling constants observed for the *Z* isomer (^3J = 2.2 Hz, *HCONH*; $^3J_{C,H}$ = 2.6 Hz, *CONCH*) could be interpreted as suggesting an orientation for the *N*-formyl fragment in which a hydrogen bond is formed between CO and HO-3. A similar hydrogen bond was suggested by other authors (10) on the basis of ^{13}C T_1 data for *N*-formyl neuraminic acid. However, attempts to titrate this putative hydrogen bond with monosaccharide **8** dissolved in dimethyl sulfoxide as done for sucrose (37) were unsucccessful. In fact it is unnecessary to assume a hydrogen bond to explain these coupling constants, nor does it require a "W" arrangement between the formyl proton and H-4 in the *Z* conformer to explain the long-range coupling between these two protons. The long-range coupling can be understood as an allylic type coupling and the vicinal coupling constants are governed by the amount of double bond character of the carbonyl carbon – nitrogen bond, a feature which invalidates the Karplus relationship. In support of this interpretation a comparison with values for the model compounds *N*-cyclohexylformamide and *N*-formanilide clearly indicates that electronic factors satisfactorily explain the observed vicinal coupling constants (*N*-cyclohexylformamide, *Z* isomer: ^3J = 2.1 Hz, *HCONH*; ^3J = 2.8 Hz (*Z*), *CONCH*; formanilide, *Z* isomer: ^3J = 2.1 Hz *HCONH*). In these cases no hydrogen bond is possible.

It is concluded that the *N*-formyl groups in both the *Z* and *E* isomers have an "in-plane arrangement" of all bonds, with the NH bond antiperiplanar to the C4—H4 bond. No evidence was found in the nmr measurements performed on methyl 4,6-dideoxy-4-formamido-α-D-mannopyranoside **8** that would support the existence in water of the two isomers **8***b* or **8***d*, one of which, **8***d*, was postulated to exist in DMSO solution (11).

Conclusions

Advances in the molecular modeling of the conformational behaviour of biomolecules in solution have increased due to progress in fields such as nmr spectroscopy and computer technology. A relatively simple, computationally fast and inexpensive method, HSEA potential energy calculations (12–19), has been remarkably successful for carbohydrates, a class of molecules that have not responded well to generalized force fields, such as MM2, without additional parameterization (38). Recent improvement to the HSEA method includes explicit treatment of populated conformational states other than the global minimum (20, 21). This motional averaging has been shown to be of practical importance for the calculation of nOe's and T_1's. In the present paper we applied this approach to a series of disaccharide molecules that represent the key elements of *Brucella* A and M antigens. The comparison of observed nOe's with values calculated on the basis of the "classical" single-state model and the more realistic statistical mechanical model indicates that ensemble average values provide an improved fit with the experimental data. This fit depends on the quality of the calculated energy surface and it may be expected that in the future more sophisticated energy calculations can be performed on even faster computers to model more accurately such energy surfaces and, possibly even more importantly, the contribution and influence of solvent water. For the present, the described approach appears to provide agreement with experimental data better than or as good as the more sophisticated MM2 (38), MNDO (39), or PCILO calculations (40), because incorporation of motional averaging with these models becomes demanding in terms of computational time and costs. The calculation of ensemble averaged nOe's represents a more realistic treatment of oligosaccharide conformational properties, which is supported by the improved fit between experimental and calculated nmr parameters for those compounds studied here and elsewhere (20, 21), but the general validation of this approach by examination of a wider range of oligosaccharides is highly desirable.

The models for the α1,2- and the α1,3-linked disaccharides **3** and **6** can be best represented by depicting the global minimum energy conformations for an impression of the proximities between atoms in the molecules (Fig. 3). This should be used in combination with the energy surfaces for these linkages (Fig. 1) to appreciate the degree of oligosaccharide mobility. One major finding of this work concerns the relative orientation of the *N*-acyl substituents in the two disaccharide types. Whereas these groups are at an angle of 144° in the α1,2-linked disaccharides **1** and **3**, they are disposed almost at a right angle in the case of the α1,3-linked disaccharides **4** and **6**. This has

important consequences for the conformation of the polysaccharide incorporating these features. When glycosidic torsion angles close to those of the minimum energy conformation are adopted, a helical structure results that contains five α1,2-linked residues per turn of the *Brucella* A polysaccharide. This is consistent with immunochemical findings that monoclonal antibodies specific for the A antigen require a pentasaccharide fragment for optimum binding (6), and with molecular modeling studies of the binding of the antigenic determinant in the combining site, which suggests that residues one and five of a pentasaccharide effectively interact with amino acid residues at either end of the combining site (5). The occurrence of an α1,3 linkage at every fifth residue in the *Brucella* M polysaccharide alters the direction of chain propagation, resulting in a much wider helix. The surface topology of this antigen cannot interact with the complementary surfaces of antibodies that bind the A antigen, even though the M polysaccharide also has a pentasaccharide repeating unit. Other antibodies that require only an α1,2-linked tetrasaccharide to fill the binding site are able to bind either the A or M antigens with equal affinity (6).

Experimental

Computational methods

Calculation of the global minima was performed using the GESA (17, 22) program. The torsional angles at the glycosidic linkages and the C5—C6 axes are defined as follows, ϕ^H = H1—C1—O1—CX, ψ^H = C1—O1—CX—HX, and ω = O5—C5—C6—O6, where X is the aglyconic linkage site. Clockwise rotations are always positive (14).

Energy surfaces for the disaccharides **1**, **2**, **4**, and **5** were calculated covering a φ/ψ range from −90° to +90° in 5° steps thus giving rise to 36^2 conformational microstates. On the basis of these energies, ensemble average values for the r^{-6} (r = distance between two protons) were calculated, which are denoted as $\langle r^{-6}\rangle$: r^{-6} values for each microstate j are weighted according to the Boltzmann distribution function and subsequently these values are summed over the whole conformational space,

$$[1] \quad \langle r^{-6}\rangle = \sum_j P_j r_j^{-6}$$

where r = distance between any two protons, j = index of the microstate, P = relative population (probability) of the jth microstate.

The relative population is given by expression [2]

$$[2] \quad P_j = e^{(-\Delta E_j/RT)} \Big/ \left[\sum_j e^{(-\Delta E_j/RT)}\right]$$

where ΔE_j = the energy difference between the microstate j and the global minimum, R = gas constant, and T = temperature (in the calculations, 310 K); values greater than 20 kcal above the global minimum were not considered.

From $\langle r^{-6}\rangle$ values an ensemble average cross relaxation matrix $\langle R\rangle$ was constructed, eq. [3]. This matrix was subsequently used to calculate ensemble average nOe's, ⟨nOe⟩;

$$[3] \quad \langle R\rangle = \sum_j P_j R_j$$

with j and P defined as above.

In the same way $\langle r^{-3}\rangle$ values are obtained, which then can be used to construct an ensemble average relaxation matrix $\langle R\rangle$ from the $\langle r^{-3}\rangle^2$ values.

The internal motions of *C*-methyl groups were treated according to Heatley *et al.* (41) and Brisson and Carver (15), who based their calculations on expressions given by Rowan *et al.* (42). For the calculation of the relaxation matrix $\langle R\rangle$, the overall molecular correlation time τ_c and the internal correlation time τ_i for the methyl group reorientation have to be known, which may be calculated from the ^{13}C T_1 data (Table 4) using eq. [4] (10, 43, 44):

$$[4] \quad \tau = r^6/(N\gamma_H^2\gamma_C^2 h^2 T_1)$$

where $\tau = \tau_c$ or $\tau = (\tau_c^{-1} + \tau_i^{-1})^{-1}$ for a methyl group, r = C—H bond distance (1.10 Å), N = number of protons attached to the particular carbon atom, γ_H, γ_C = gyromagnetic ratio for ^1H and ^{13}C respectively, T_1 = spin-lattice relaxation time of the particular carbon atom. Utilising eq. [4], the measured ^{13}C T_1 values (Table 4) give a mean value of 2.3×10^{-11} s for τ_i and 0.9×10^{-10} s for τ_c.

For steady-state conditions the ensemble average nOe's, ⟨nOe's⟩, can be calculated by solving the series of simultaneous eqs. [5] given by Heatley *et al.* (41):

$$[5] \quad \sum_{j\neq k} \langle R_{ij}\rangle\langle \mathrm{nOe}(j,k)\rangle = \langle R_{ik}\rangle (i \neq k)$$

where $\langle R_{ij}\rangle$, $\langle R_{ik}\rangle$ = elements of the ensemble average cross relaxation matrix $\langle R\rangle$, ⟨nOe(j, k)⟩ = ensemble average nuclear Overhauser enhancement factor of proton j upon irradiation of proton k. Single-state nOe's are calculated using the same series of eqs. [5] but instead utilize a single-state relaxation matrix.

The Fortran listing of the GESA program and subroutines that have been specifically written or modified from the original GESA program (22) to accomplish the task of ensemble averaging and nOe calculation will be deposited with the journal, and copies of the programs will be supplied on request to the authors. Coordinates for the minimum energy molecules will also be supplied.

Nuclear magnetic resonance experiments

The model compounds **1–8** were of synthetic origin (7–9). Samples were dissolved in 0.5 mL D_2O (99.996 at.% D, Aldrich) after repeated lyophilization from D_2O (99.96 at.% D, Aldrich). The samples were not degassed and were prepared at concentrations of 20–30 mM for ^1H nmr and 50–100 mM for ^{13}C nmr measurements. Acetone was used as internal reference (^1H δ 2.225 ppm, ^{13}C δ 30.50 ppm).

^1H and ^{13}C nmr spectroscopy

The nmr experiments were performed at 37°C, unless stated otherwise, using Bruker AM500 and AM200 spectrometers. Coupling constants for the exchangeable amide protons in monosaccharide **8** were measured in 98% H_2O/2% D_2O solution at 500 MHz. Suppression of the water signal was achieved by presaturation of the H_2O resonance. Spectral width and size of the data sets were chosen to give digital resolutions of 0.2 Hz/pt in the case of the ^1H nmr spectra. The coupling constants reported are first-order values.

Amide coupling constants

Compound **8** dissolved in 98% H_2O/2% D_2O solution gave the following three-bond coupling constants. Heteronuclear couplings were measured for the ^{13}C label *N*-formyl derivative that was prepared in separate work (Peters and Bundle, unpublished work).

Z isomer: ^3J = 10.0 Hz, N*H*C*H*; ^3J = 2.2 Hz, *H*CON*H*; $^3J_{C,H}$ = 2.6 Hz, CONC*H*

E isomer: ^3J = 10.0 Hz, N*H*C*H*; ^3J = 11.8 Hz, *H*CON*H*; $^3J_{C,H}$ = 5.5 Hz, CONC*H*

Solutions of *N*-cyclohexylformamide and formanilide in deuteriochloroform were used to measure both homonuclear and heteronuclear coupling constants.

N-cyclohexylformamide:

Z isomer: ^3J = 2.1 Hz, *H*CON*H*; $^3J_{C,H}$ = 2.8 Hz, CONC*H*

E isomer: ^3J = 12.0 Hz, *H*CON*H*; $^3J_{C,H}$ = 5.6 Hz, CONC*H*

Formanilide:

Z isomer: ^3J = 2.1 Hz, *H*CON*H*

E isomer: ^3J = 11.3 Hz, *H*CON*H*

Nuclear Overhauser enhancement difference spectroscopy

The nOe experiments were performed in the difference mode (31). Steady-state experiments were performed with irradiation times and relaxation delays that were at least five times the largest T_1 values in the sample. Saturation of signals was accomplished by single line irradiation (32).

^{13}C T_1 measurements

^{13}C spin-lattice relaxation times were measured by the fast inversion–recovery method (45, 46) utilizing a composite 180° pulse (47). Calculation of T_1 values was achieved by employing an exponential three-parameter fit with standard Bruker software.

Two-dimensional nmr spectroscopy

Phase sensitive COSY experiments (28) used 512 increments in $t1$ and 2K data points in $t2$. The data matrix was multiplied by sine bell window functions and Fourier transformed to a 2K × 2K spectral matrix. H/C heteronuclear shift correlation experiments were performed with decoupling in both frequency dimensions (29). Carbon spectra, 256 experiments each collected over 4K data points, were recorded, and the data matrix was multiplied in both dimensions by $\pi/4$ shifted sine bell squared window functions, followed by Fourier transformation to give a power spectrum.

Acknowledgements

We wish to thank Professor H. Rüterjans, Institute of Biophysics, University of Frankfurt, for access to a Bruker AM500 that was used for water suppression experiments. The final stages of the modification of the GESA program were facilitated by NATO research grant RG 85/0021 to D.R.B., together with access to the computer facilities of the Carlsberg Laboratory, Copenhagen, kindly made available by Professor Klaus Bock.

Received October 30, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

YUFEI GUO and M. A. WHITEHEAD. Can. J. Chem. **68**, 989 (1990).

The self-interaction-corrected generalized exchange local-spin-density functional theory (LSD-GX-SIC) with Gopinathan, Whitehead, and Bogdanovic (GWB) Fermi-hole exchange parameters is used to calculate the ionization potentials of the multiply charged ions for the elements C, Al, Cl, Ar, Ca, Fe, and Br. The effect of the correlation correction on the ionization potentials is considered. The calculated ionization potentials are compared with Hartree–Fock, recent Xα, and experiment. The correlation correction is important in the calculations. The results in the LSD-GX-SIC theory with GWB Fermi-hole exchange parameters and the Vosko, Wilk, and Nusair correlation correction are in excellent agreement with experiment. The LSD-GX-SIC theory can predict unknown ionization potentials for the multiply charged ions with acceptable computational time, since there is no need to optimize the exchange parameters.

Key words: ionization potentials, multiply charged ions, density functional theory.

YUFEI GUO et M. A. WHITEHEAD. Can. J. Chem. **68**, 989 (1990).

Pour calculer les potentials d'ionisation des ions à charges multiples du C, du Al, du Cl, du Ar, du Ca, du Fe et du Br, on a utilisé la théorie fonctionnelle de la densité locale de spin, avec échange généralisé et correction par auto-interaction (LSD-GX-SIC) ainsi que des paramètres d'échange des trous de Fermi de Gopinathan, Whitehead et Bogdanovic (GWB). On a considéré l'effet de la correction de corrélation sur les potentials d'ionisation. On a comparé les potentials d'ionisation avec ceux de Hartree–Fock, avec de récents Xα et avec des données expérimentales. La correction de la corrélation est importante dans les calculs. Les résultats obtenus à l'aide de la théorie LSD-GX-SIC et les paramètres GWB d'échange de trous de Fermi et la correction de corrélation de Vosko, Wilk et Nusair sont en excellent accord avec les résultats expérimentaux. Puisqu'il n'y a pas besoin d'optimiser les paramètres d'échange, la théorie LSD-GX-SIC peut prédire les potentials d'ionisation inconnus d'ions portant de multiples charges en ne requérant que des temps de calcul acceptables.

Mots clés : potentials d'ionisation, ions à charges multiples, théorie fonctionnelle de la densité.

[Traduit par la revue]

Introduction

Investigation of ionization potentials for multiply charged ions has attracted attention (1, 2) because of the interest in these ionization potentials for interpreting stellar spectra. Other properties of multiply charged ions, e.g., ionization cross section, have also attracted some attention (3, 4) experimentally. Theoretical calculations for them might be interesting.

Few publications dealing with the ionization potentials of ions using the local-spin-density functional (LSD) theory (5) can be found in the literature, even for the multiply charged ions (2), although the LSD theory has been widely used in the calculations for atoms, molecules, and the solid state. The reason might be that the values of the exchange parameters, e.g., α in the Xα theory (6) and *a* in the Ξ*a* theory (7), have been missing in the literature for ions. Also it is time consuming to search for the optimal exchange parameters for all multiply charged ions of all atoms in the periodic table.

In 1987, Gáspár and Nagy (2) published the ionization potentials for some multiply charged ions evaluated by means of the Xα method in which the value of α was self-consistently determined by the electron charge density; their results are comparable with those from the Hartree–Fock method and agree with experiment. The advantage in Gáspár and Nagy's Xα method is that the exchange parameter α can be optimized in each iteration according to the electron density during the self-consistent field process, unlike the traditional Xα method in which α was determined by fitting the total Xα energy to the Hartree–Fock total energy, or by fitting the total energy to satisfy the virial theorem.

The generalized exchange local-spin-density functional (LSD-GX) theory derived by Manoli (8) and Manoli and Whitehead (9) is somewhat analogous to Gáspár and Nagy's Xα method in determining the optimal exchange parameters for atoms and ions. However, obtaining the exchange parameters is much easier and simpler in the LSD-GX theory than in Gáspár and Nagy's Xα method. The exchange parameters in the LSD-GX theory are fixed once the Fermi-hole shape is chosen (5, 9–11). Therefore one set of parameters applies for all atoms and ions. In addition, the LSD-GX theory with self-interaction correction (LSD-GX-SIC) and correlation correction has proved successful in calculating atomic properties, especially the first ionization potentials and electron affinities of atoms (12–15), and in predicting the negative-ion structure of the alkaline-earth elements and noble gases (16, 17).

The present paper tests the reliability of the LSD-GX theory in predicting ionization potentials of multiply charged ions. If it works, it can be used to calculate the ionization potentials for the multiply charged ions that have not been experimentally measured. The LSD-GX theory is much easier to use than Hartree–Fock theory because the local exchange potential is used in the LSD-GX theory, and is even easier to use than Xα theory because there is a unique set of parameters for all atoms once the Fermi hole is selected.

Therefore the LSD-GX-SIC theory is used to calculate the ionization potentials of multiply charged ions for C, Al, Ca, Fe, and Br, to compare the results with those from Xα calculations,

and for Cl and Ar, which are interesting to chemists and astrophysicists. The effect on the ionization potential of the correlation correction proposed by Vosko *et al.* (18) is considered.

Method

Details of the LSD-GX theory were given by Manoli (8), and Manoli and Whitehead (9); a short summary is provided.

The one-electron Schrödinger equation, in Rydberg atomic units is

$$[1] \qquad [\hat{f} + V_c(\mathbf{r}) + V_{X_j}^{GX}(\mathbf{r})]u_j(\mathbf{r}) = \varepsilon_j u_j(\mathbf{r})$$

where the kinetic and nuclear attraction energy operator is

$$[2] \qquad \hat{f} = -\nabla^2 - \frac{2Z}{r}$$

and $V_c(\mathbf{r})$ and $V_{X_j}^{GX}(\mathbf{r})$ are the Coulomb and generalized statistical exchange potentials, respectively,

$$[3] \qquad V_c(\mathbf{r}) = \int n(\mathbf{r}')(2/|\mathbf{r}-\mathbf{r}'|)d\mathbf{r}'$$

and

$$[4] \qquad V_{X_j}^{GX}(\mathbf{r}) = -\frac{9}{2}c\,\alpha^{\lim}\left\{\sum_i^s [n_s(\mathbf{r}) + B_2\, n_i(\mathbf{r})]^{-2/3}\, n_i(\mathbf{r}) - \frac{2}{3}\sum_i^s [n_s(\mathbf{r}) + B_1 n_i(\mathbf{r})][n_s(\mathbf{r}) + B_2 n_i(\mathbf{r})]^{-5/3}\, n_i(\mathbf{r}) + [n_s(\mathbf{r}) + 2B_1 n_j(\mathbf{r})][n_s(\mathbf{r}) + B_2 n_j(\mathbf{r})]^{-2/3} - \frac{2}{3}B_2[n_s(\mathbf{r}) + B_1 n_j(\mathbf{r})][n_s(\mathbf{r}) + B_2 n_j(\mathbf{r})]^{-5/3}\, n_j(\mathbf{r})\right\}$$

where $n(\mathbf{r})$ is the total density of the electrons, $n_s(\mathbf{r})$ the total density of electrons with spin s, and $n_i(\mathbf{r})$ the ith electron density; c is a constant equal to $(3/4\pi)^{1/3}$. The exchange parameters B_1, B_2, and $\alpha^{\lim}$ are constants depending on the Fermi-hole shape. Several Fermi holes can be found in the literature (5, 9–11). The parameters B_1, B_2 and $\alpha^{\lim}$ for these Fermi holes have been given by Manoli and Whitehead (9).

Because the self-interactions in the Coulomb and exchange terms do not cancel exactly in the LSD theory, the statistical total energy in the LSD-GX theory (9) differs from that in Hartree–Fock theory in which this cancellation is exact. Perdew and Zunger (19) proposed a self-interaction correction (SIC) by explicity removing the Coulomb self-interaction and the approximate exchange self-interaction. For atomic systems (neutral), this self-interaction correction approach leads to a potential that exhibits the correct asymptotic $1/r$ behaviour. If the SIC is used in the LSD-GX theory, eq. [1] becomes

$$[5] \qquad [\hat{f} + V_{c_j}(\mathbf{r}) + V_{X_j}^{GX}(\mathbf{r}) + V_{s_j}(\mathbf{r})u_j(\mathbf{r}) = \varepsilon_j u_j(\mathbf{r})$$

where $V_{c_j}(\mathbf{r})$ is the pure Coulomb potential without self-interaction and $V_{s_j}(\mathbf{r})$ is the self-exchange potential for electron j,

$$[6] \qquad V_{c_j}(\mathbf{r}) = \int [n(\mathbf{r}') - n_j(\mathbf{r}')](2/|\mathbf{r}-\mathbf{r}'|)d\mathbf{r}'$$

and

$$V_{s_j}(\mathbf{r}) = 6\,c\,\alpha^{SI} n_j^{1/3}(\mathbf{r})$$

Using the Perdew and Zunger procedure, it is easy to relate exchange parameters α^{SI} and $\alpha^{\lim}$(20, 21).

The statistical total energy of an atom or ion in the LSD-GX-SIC theory can be written as

$$[7] \qquad E_{tot} = \sum_i f_i \langle u_i(\mathbf{r})|f|u_i(\mathbf{r})\rangle + \sum_{i>j} f_i f_j \langle u_i(\mathbf{r})u_j(\mathbf{r}') \parallel u_i(\mathbf{r})u_j(\mathbf{r}')\rangle + \frac{1}{2}\sum_i f_i \langle u_i(\mathbf{r})|U_{+_i}^{GX\text{-}SIC}(\mathbf{r})|u_i(\mathbf{r})\rangle + \frac{1}{2}\sum_i f_i \langle u_i(\mathbf{r})|U_{-_i}^{GX\text{-}SIC}(\mathbf{r})|u_i(\mathbf{r})\rangle$$

where f_i is the occupation number of orbital i. The energy density functional of the generalized exchange with self-exchange interaction correction, per electron, is

$$[8] \qquad U_{s_i}^{GX\text{-}SIC}(\mathbf{r}) = -9c\,\alpha^{\lim}\{n_s(\mathbf{r}) + B_1 n_i(\mathbf{r}\}\{n_s(\mathbf{r}) + B_2 n_i(\mathbf{r})\}^{-2/3} + 9c\,\alpha^{SI}\, n_i^{1/3}(\mathbf{r})$$

The statistical exchange approximation is treated in the LSD-

particle of the homogeneous electron gas with partial densities $n_+(\mathbf{r})$ and $n_-(\mathbf{r})$ for spin-up and spin-down electrons. In eq. [9], the correlation self-interaction is included. If a self-interaction correction of the correlation (SICC) is introduced into E_c by using the definition of Stoll, Pavlidou, and Preuss (24), expression [9] becomes

$$[10] \quad E_c = \int [n_+(\mathbf{r}) + n_-(\mathbf{r})]\, \varepsilon_c(n_+(\mathbf{r}), n_-(\mathbf{r}))\, d\mathbf{r} - \int n_+(\mathbf{r})\, \varepsilon_c(n_+(\mathbf{r}), 0)\, d\mathbf{r} - \int n_-(\mathbf{r})\, \varepsilon_c(0, n_-(\mathbf{r}))\, d\mathbf{r}$$

The explicit expression for $\varepsilon_c(n_+, n_-)$ is given by Vosko, Wilk, and Nusair (18).

Consequently, the ionization potential for the k^{th} ion, including the SIC contribution and the SICC correction, is

$$[11] \quad I^k = [E_{\text{tot}}(f_k - 1) - E_{\text{tot}}(f_k)] + [E_c(f_k - 1) - E_c(f_k)]$$

The first term in eq. [11] is the contribution of the kinetic, Coulomb, and exchange energies, and the second term is the correlation energy. The energies E_{tot} and E_c are obtained from separate self-consistent wavefunctions of the k^{th} and $(k+1)^{\text{th}}$ ions.

Results and discussion

The one-electron Schrödinger equation, [5], combined with eq. [2], [4], and [6] is solved numerically (9). As is usual in LSD calculations, the electron densities, $n_i(\mathbf{r})$, were spherically averaged before calculating the potential and the total energy for atoms. This "central-field" approximation is perhaps most severe for the $2p$ orbital, which makes a sizable contribution to the total self-interaction correction. However, according to Perdew and Zunger (19), the self-Coulomb energy for a hydrogenic $2p$ orbital (with $m_l = 0$) is only 4% larger than it would be for the spherically averaged density.

Of the four Fermi-hole shapes in the literature (5, 9–11), the statistical total energies of atoms (atomic number $Z \leq 36$) in the LSD-GX-SIC theory with the exchange parameters of Gopinathan, Whitehead, and Bogdanovic's Fermi-hole shape (GWB) are in excellent agreement with the total energies in the Hartree–Fock theory (25). The percentage differences between the statistical total energies and Hartree–Fock energies for all these atoms are less than 0.08. Furthermore, the differences decrease with increasing atomic number. Thus the LSD-GX-SIC theory with GWB should give the best ionization potentials.

The ionization potential is (i) approximately the negative of

the one-electron eigenvalue in the LSD-GX-SIC theory under the frozen orbital approximation (26), and equals (ii) the negative of the one-electron eigenvalue generated by removing a half-electron from the corresponding orbital to infinity in the LSD-GX theory (Slater transition state theory (27)). Finally, the ionization potential is (iii) the difference between two statistical total energies, one for the k^{th} ion and another for the $(k+1)^{th}$ ion obtained by two separated self-consistent field (SCF) calculations. Although (i) and (ii) are computationally easier than (iii), there is not much difference in the computational time, when all the ionization potentials of the successive multiply charged ions for an atom are needed. The orbital relaxation in the ionization process is neglected totally in (i) and partly in (ii), but is included completely in (iii). Therefore the ionization potentials of the multiply charged ions are calculated by (iii).

The LSD-GX-SIC theory with GWB Fermi-hole parameters was used to calculate the wavefunctions of some neutral atoms (atomic numbers 6, 13, 17, 18, 20, 26, and 35) together with the wavefunctions of the corresponding multiply charged ions. These numerical wavefunctions were then used to calculate the corresponding statistical total energies (eq. [7]) and VWN correlation energies (eq. [10]) for the atoms and ions. The VWN correlation potential (28) has not been treated self-consistently, because it is not important in calculating ionization potentials (13–15, 29), although it is essential in predicting electron affinities for the alkaline-earth elements, noble gases, and actinides (16, 17, 30). The ionization potentials were obtained from the differences of the statistical total energies, which included the VWN correlation energies for the k^{th} and $(k+1)^{th}$ ions (eq. [11]). Results in Tables 1–7 are compared to the Hartree-Fock results (25) and with experiment (31–33).

Relaxation lowers the total energy but decreases as the number of the electrons increases. The Hartree–Fock results in columns 4 and 5 of Tables 1–6 show the ionization potentials of the multiply charged ions without relaxation to be usually larger. In addition, correlation lowers the total energy but increases as the number of electrons increases and, therefore, the correlation correction increases the ionization potential; all the values in column 3 are larger than those in column 2.

The Coulomb correlation correction plays an important role in the first ionization potentials, and electron affinities (13, 14, 16), because the contribution of the correlation correction to the electron affinity is comparable to that of the kinetic, Coulomb, and exchange interaction energies. Comparing the results of the LSD-GX-SIC theory with GWB Fermi-hole parameters and the VWN correlation correction in column 3 of Tables 1–7 with those excluding VWN in column 2 shows that the correlation energy correction also plays a role in the ionization potentials of the multiply charged ions.

In Tables 1, 2, and 5–7, the recent calculations of the multiply charged ions obtained by using a Slater transition state calculation in the Xα method with the theoretically determined parameter α(2) are also presented. The data show that the results in LSD-GX-SIC theory with GWB Fermi-hole parameters and transition state of the Xα theory with the theoretically determined parameter α are comparable with the results from Hartree–Fock theory. But ionization potentials of the multiply charged ions in LSD-GX-SIC theory with GWB Fermi-hole parameters and correlation corrections are much better than all others. Their agreement with experiment is excellent.

The deviation of each calculated ionization potential, Tables 1–7, from the experimental value is expressed as a percentage. These percentages are averaged for all multiply charged ions of the same element to give the average percentage deviation from the experiment. The last lines in Tables 1–7 list the average percentage deviations for the theories discussed in this work, the relaxed and the unrelaxed Hartree–Fock, and the recent Xα transition state results. The results using LSD-GX-SIC theory with GWB Fermi-hole parameters and VWN correlation correction are the best. The average percentage deviations for all these elements in this theory are less than 1.5%. Furthermore, the percentage deviation for each value is around one.

One might expect to calculate the ionization potentials of the multiply charged ions by using the traditional Xα theory with the corresponding optimal α values of the neutral atoms. To compare the LSD-GX-SIC results with those in the traditional Xα theory, the relaxed Xα calculations for the ionization potentials of these multiply charges ions were carried out using Schwarz's α values(34) for neutral atoms and the corresponding α values of the atoms that are of the same electrons as the multiply charged ions. The results (not listed here because of the limited length of the paper) are much worse, in the agreement with experiment, than those in Hartree–Fock and LSD-GX-SIC theories. The averge percentage deviations are around 3.5.

Conclusion

The ionization potentials of multiply charged ions calculated by means of the difference between two statistical total energies in the LSD-GX-SIC theory with GWB Fermi-hole exchange parameters are comparable with those in Hartree–Fock theory. The LSD-GX-SIC theory is much easier and cheaper to use than Hartree–Fock theory. The correlation energy correction of the electrons with different spin is important, so that the LSD-GX-SIC theory with GWB Fermi-hole exchange parameters and with VWN correlation correction gives excellent ionization potentials for the multiply charged ions, in agreement with experiment. One can expect that the quasi-relativistic (35, 36) LSD-GX-SIC theory with GWB and VWN should give very

For personal use only.

good ionization potentials of the multiply charged ions for the high-Z elements, even for the actinides, with acceptable computational time, because there is no need to search for optimal exchange parameters for each atom or ion. Based on the excellent agreement between the calculated and experimental values, the LSD-GX-SIC theory with GWB exchange parameters and VWN correlation correction can be used to predict ionization potentials of multiply charged ions that are unknown experimentally.

Acknowledgments

Dr. Perlin by his vision, humour, gentleness, kindness, and openness has always appreciated and encouraged research in fields other than his own. The authors also wish to thank Mr. M. Wrinn for interesting discussions. The research was supported by the Natural Sciences and Engineering Research Council of Canada.

Received August 31, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

TED SCHAEFER, RUDY SEBASTIAN, HUA YAN LI, and TINH QUACH. Can. J. Chem. **68**, 996 (1990).

Analyses of the ^{1}H nuclear magnetic resonance spectra of 3-methoxybenzaldehyde in CS_2/C_6D_{12} and in acetone-d_6 solutions at 300 K yield the values of stereospecific long-range spin–spin coupling constants for the aldehydic and methyl protons. These coupling constants are used to deduce the conformational bias for both substituents. The conformers in which the carbonyl group lies *trans* to the methoxy group have a population P_t, which is $0.63(2)P_c$ for the CS_2/C_6D_{12} solution, P_c being the population of the conformers in which the carbonyl group lies *cis* to the methoxy substituent; in acetone-d_6 solution, $P_t = 0.80(2)P_c$. Both of these numbers are substantially larger than that deduced from nuclear Overhauser enhancements for a $CDCl_3$ solution. If P_t is the fractional population of the conformers in which the methoxy is oriented *trans* to the aldehyde substituent, then $P_t = 0.53(1)P_c$ in CS_2/C_6D_{12} and $P_t = 0.67(1)P_c$ in acetone-d_6, both numbers again being rather larger than that deduced from polarization experiments. STO-3G and 4-21G MO computations of the conformer stabilities agree qualitatively with the relative stabilities of the four planar conformers. Extrapolation of the populational data in solution yields vapor phase estimates midway between the two theoretical estimates. Limits can be placed on the fractional population of each of the conformers in the vapor and in the solutions. The relative stabilities of the free conformers can be rationalized in terms of electrostatics and of preferences of the carbonyl and methoxy groups for certain orientations with respect to the ring C—C bonds of highest double bond character.

Key words: 3-methoxybenzaldehyde, NMR; 3-methoxybenzaldehyde, conformations for solutions and vapor; 3-methoxybenzaldehyde, MO calculations.

Une analyse des spectres RMN du ^{1}H du 3-méthoxybenzaldéhyde mesurés à 300 K, en solutions dans le CS_2/C_6D_{12} ainsi que dans l'acétone-d_6, fournit les valeurs des constantes de couplage spin–spin à longue distance qui sont spécifiques aux protons de l'aldéhyde et des méthyles. On a utilisé ces constantes de couplage pour déduire les tendances conformationnelles des deux substituants. Pour la solution dans le CS_2/C_6D_{12}, la population P_t des conformères dans lesquels le groupement carbonyle se trouve en position *trans* par rapport au groupement méthoxy est égale à $0,63(2)P_c$ et P_c correspond à la population des conformères dans lesquels le groupement carbonyle est *cis* par rapport au groupement méthoxy; pour la solution dans l'acétone-d_6, $P_t = 0,80(2)P_c$. Ces deux valeurs sont beaucoup plus élevées que celles obtenues en faisant appel à des mesures de rehaussement de l'effet Overhauser pour des solutions dans le $CDCl_3$. Si la valeur P_t est égale à la fraction de la population des conformères dans lesquels le groupement méthoxy est orienté *trans* par rapport au substituant aldéhydique, alors $P_t = 0,53(1)P_c$ pour la solution dans le CS_2/C_6D_{12} et $P_t = 0,67(1)P_c$ pour la solution dans l'acétone-d_6 et ces deux valeurs sont encore une fois plus élevées que celles obtenues à partir d'expériences de polarisation. Des calculs d'OM aux niveaux STO-3G et 4-21G conduisent à des stabilités des conformères qui correspondent qualitativement avec les stabilités relatives des quatre conformères plans. Une extrapolation des données relatives aux populations en solution fournit une évaluation des valeurs en phase gazeuse qui est intermédiaire entre les deux évaluations théoriques. On peut placer des limites sur les fractions de population de chacun des conformères en phase vapeur et en solutions. On peut rationaliser les stabilités relatives des conformères libres en fonction de facteurs électrostatiques et des préférences des groupements carbonyle et méthoxy pour certaines orientations par rapport aux liaisons C—C du cycle dont le caractère de double liaison est le plus élevé.

Mots clés : 3-méthoxybenzaldéhyde, RMN; 3-méthoxybenzaldéhyde, conformations en phase vapeur et en solutions; 3-méthoxybenzaldéhyde, calculs d'OM.

[Traduit par la revue]

Introduction

In the vapor phase, low-resolution microwave spectroscopy provides evidence for the existence of three of the four possible planar conformers of 3-methoxybenzaldehyde (1). The spectrum of **1** is not seen but, noting the broadness and weakness of the spectra of **2–4**, the probable low dipole moment of **1** may account for its apparent absence. The relative populations of the conformers are difficult to extract from these spectra (1).

In solution, the barriers to rotation about the C_{sp^2}—C_{sp^2} and C_{sp^2}—O bonds for the aldehyde (2) and methoxy (3) groups are large enough to allow a discussion of the conformational behaviour of 3-methoxybenzaldehyde at ambient temperatures in terms of the planar conformers, **1–4**. In acetone-d_6 solution (4), ^5J(H-5,CHO) is 0.375(13) Hz; as a stereospecific spin–spin coupling constant, it indicates the population of **1** + **2**

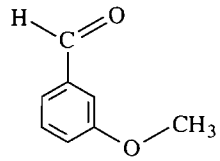
relative to that of **3** + **4**, although this population was not deduced. Decoupling experiments show that the methoxy protons are coupled to H-2 and H-4 but the coupling constants are not resolved (4). On the basis of PCILO computations (4), it is suggested that electrostatic interactions between *meta* substituents make an important contribution to the relative stability of the conformers of 2,5-dimethoxybenzaldehyde and, by inference, of 3-methoxybenzaldehyde. In other words, the roughly antiparallel electric dipoles in **1** presumably favour this conformation. No populations are deduced (4).

An alternative interpretation of the conformational preferences of the aldehyde and methoxy groups in aromatic systems (5–7) is that the former is preferentially arranged so that the carbonyl lies *trans* to the *ortho* position of highest double bond character, as in **5** (valence-bond picture), or of highest



5

π-electron density (molecular orbital picture); the latter, however, prefers to lie *cis* to the bond of the highest double character, as in vinyl ether. It is not clear to us whether it is the methoxy group or the aldehyde group which causes the lower energy of the resonance form indicated in **5**. In any event, the nuclear Overhauser effect for the protons *ortho* to the aldehyde functionality (irradiation of the aldehyde proton peaks) is interpreted to mean that $K = (P_1 + P_2)/(P_3 + P_4)$ is roughly 1.8 for $CDCl_3$ or benzene-d_6 solutions (7). There exist (6, 8) various complications in the interpretation of these polarization experiments. Nevertheless, from measurements of the polarizations (enhancements) and of spin-lattice relaxation times of ^{13}C and ^1H nuclei of 3-methoxyacetophenone in $CDCl_3$ solutions (6), it is concluded that the acetyl group displays the same conformational behaviour as the aldehyde group in 3-methoxybenzaldehyde and, furthermore, that the methoxy group has $K = (P_1 + P_4)/(P_2 + P_4)$ as 2.2. In other words, the methoxy group is strongly oriented towards the aldehyde site.

Now, both $^5J(H,CHO)$ and $^5J(H,OCH_3)$ are stereospecific (9–17). Thus, ^5J(H-5,CHO) in **1** and **2** are expected to vanish (9, 12), whereas they will be as large as 0.9 Hz in **3** and **4**. Again, ^5J(H-4,OCH_3) in **2** and **3** will be near −0.3 Hz but negligible in **1** and **4**; corresponding statements (13–17) hold for ^5J(H-2,OCH_3). $^5J(H,OCH_3)$ is a proximate coupling (14) and, as such, is sizeable only when the methoxy protons lie very near the ring proton. Therefore, a precise analysis of the ^1H NMR spectrum of 3-methoxybenzaldehyde should yield precise values of ^5J(H-5,CHO) and $^5J(H,OCH_3)$, from which $K = (P_1 + P_2)/(P_3 + P_4)$ and $K = (P_1 + P_4)/(P_2 + P_3)$, respectively, can be deduced for solutions. Molecular orbital calculations may give an indication of the conformational behaviour of the free molecule, including relative populations of each of **1**–**4**. Such measurements and calculations are reported below.

Experimental

Solutions of 3-methoxybenzaldehyde in CS_2/C_6D_{12} and in acetone-d_6 (see Table 1) were transferred to 5 mm od NMR sample tubes, were degassed by the freeze–pump–thaw procedure, and were then flame-sealed under vacuum. ^1H NMR spectra were acquired at a probe temperature of 300 K on a Bruker AM300 spectrometer under conditions previously described (18). A wide sweepwidth survey spectrum was obtained in order to reference the spectrum with respect to TMS, and to obtain the locations of the aromatic and side-chain regions. Each region was examined in detail, with sweepwidth and data region adjusted to give acquisition times of approximately 40 s. Four to 16 scans were acquired. Zero filling to twice the original data region was done before transforming the FIDs using a small amount of Gaussian multiplication. Linewidths at half height were approximately 0.04 Hz after this resolution enhancement. Because of the many long-range coupling constants between the four ring protons and the four on the side chains, spectra were obtained by decoupling, successively, the aldehydic proton and then the methoxy protons. The ensuing spectra, corresponding to seven and five spin 1/2 systems, were amenable to reasonably precise analyses.

Molecular orbital computations utilized the computer program GAUSSIAN 86 (19). The geometry optimization procedures contained the constraint that the carbon and hydrogen atoms of the aromatic nucleus remain in a plane; all other bond angles and lengths were allowed to change.

Results and discussion

The ^1H NMR spectra were analyzed with the computer program NUMARIT (20), as modified by R. Sebastian in this laboratory. The spectral parameters of 3-methoxybenzaldehyde appear in Table 1. The decoupling procedures during spectral acquisition caused Bloch–Siegert shifts, apparent in Table 1. For the CS_2/C_6D_{12} solvent mixture, the existence of large correlations (footnotes to Table 1) between certain coupling constants within the ring, and between them and some chemical shifts, causes a relatively large imprecision in these parameters. Fortunately, those long-range coupling constants of immediate interest to the following discussion do not suffer from such imprecision. Figure 1 shows the ^1H NMR spectrum of H-2 in CS_2 solution.

The conformational behaviour of the aldehydic group

In benzaldehyde, $^5J(H,CHO)$ is 0.431(2) Hz for a CS_2/C_6D_{12} solution and is 0.430(1) Hz for an acetone-d_6 solution (21). The available evidence (9–12) on benzaldehyde derivatives implies that $^5J(H,CHO)$ vanishes in **1** and **2**, thereby implying that $^5J(H,CHO)$ is 0.861(4) in **3** and **4**; the methoxy group is distant from the coupling path for this σ electron coupling (21) and will therefore minimally perturb the magnitude of the coupling constant.

Accordingly, because $^5J(H,CHO)$ is 0.332(6) Hz in CS_2/C_6D_{12} solution and is 0.382(4) Hz in acetone-d_6, $K(CHO) = (P_3 + P_4)/(P_1 + P_2) = 0.332(6)/(0.861(4) - 0.332(6)) = 0.63(2)$ for the former and is $0.382(4)/(0.861(4) - 0.382(4)) = 0.80(2)$ for the latter solution at 300 K. The nuclear Overhauser enhancements measured for $CDCl_3$ and (or) C_6D_6 solutions of 3-methoxybenzaldehyde (7) imply a K(CHO) of 0.56 (temperature not stated). It is unlikely that the *meta* substituent perturbs $^5J(H,CHO)$ enough to reduce the value of K(CHO) to 0.56. Thus, for 4-fluorobenzaldehyde in acetone-d_6 solution, in which the substituent is now rather closer to the coupling path, $^5J(H,CHO)$ is 0.439(1) Hz (unpublished work in this laboratory). If this number were to apply, then K(CHO) would become 0.77(2) for 3-methoxybenzaldehyde in acetone-d_6 solution.

The present results show that the conformational bias of the aldehydic group in 3-methoxybenzaldehyde is solvent dependent.

Conformational behaviour of the methoxy group

Precise analyses of the ^1H NMR spectra of anisole yield $^5J(H,OCH_3)$ as −0.152(0) and −0.155(0) Hz in CS_2/C_6D_{12}

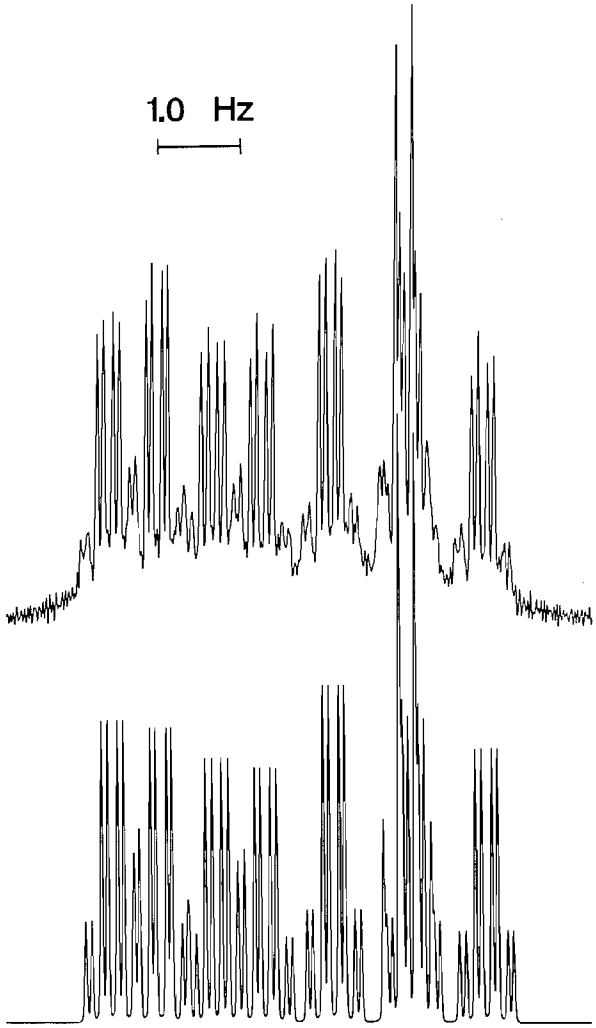

FIG. 1. The ^{1}H NMR spectrum of H-2 in 3-methoxybenzaldehyde, as a dilute solution in CS_2/C_6D_{12}/TMS (Table 1), is displayed. The linewidth at half-height is about 0.04 Hz and the small splittings (quartets of doublets) are very near 0.07 Hz in magnitude. The theoretical spectrum uses the coupling constants in Table 1, but the chemical shifts lie midway between those given in Table 1. Bloch–Siegert shifts, caused by the decoupling fields, render the true chemical shifts in the fully coupled spectrum somewhat uncertain; this uncertainty probably accounts for the quite small incongruence between the measured and theoretical spectra above.

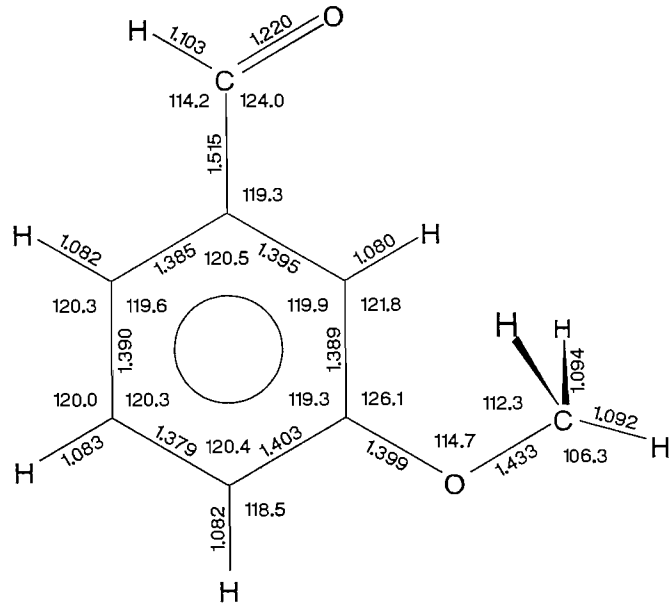

FIG. 2. The STO-3G MO structure of 3-methoxybenzaldehyde is shown for the planar conformer, **1**, which is most stable. Bond angles are in degrees and lengths in angstrom units. The bond lengths within the benzene moiety show some degree of alternation, of some interest to literature interpretations of the conformational bias of the substituents (see text), but appear to be controlled by the orientation of the methoxy group (see Figs. 3–5).

and acetone-d_6 solutions, respectively (16). The evidence is again (13–17) that ^5J(H,OCH$_3$) is vanishingly small if the methoxy group lies *trans* to the *ortho* C—H bond containing the coupled proton. If so, then ^5J(H,OCH$_3$) is -0.304 and -0.310 Hz for the CS_2/C_6D_{12} and acetone-d_6 solutions when the methoxy group lies *cis* to the *ortho* C—H bond. The sums of ^5J(H-2,OCH$_3$) and ^5J(H-4,OCH$_3$) in Table 1 are $-0.298(2)$ Hz for the CS_2 solution and $-0.301(2)$ Hz for the acetone-d_6 solution. It appears that the perturbation of this coupling interaction by the aldehyde substituent is rather small.

Based on this appearance, it follows that $K(OCH_3) = (P_2 + P_3)/(P_1 + P_4) = 0.103(1)/0.195(1) = 0.53(1)$ for the nonpolar solvent and is $0.121(1)/0.180(1) = 0.67(1)$ for the acetone-d_6 solution. For a 0.1M solution of 3-methoxyacetophenone in $CDCl_3$ (temperature not given) the nuclear Overhauser enhancements yield a $K(OCH_3)$ of 0.45 if they are corrected for the spin-lattice relaxation times and for the correlation times of the protons *ortho* to the methoxy group. Without these corrections, $K(OCH_3)$ would be 0.53. Again, the long-range coupling constants imply a lower conformational bias for the methoxy group than do the combined polarization and relaxation measurements. The spin coupling data also yield a solvent dependence of $K(OCH_3)$, the equilibrium constant being nearer unity for the polar solvent.

Of course, both types of measurements give the conformational bias, relative to the other substituent, of each substituent individually. They cannot give the populations of each of **1**–**4**. At this juncture, molecular orbital computations become of some value.

STO-3G MO computations

Previous experience with minimal basis set calculations on benzaldehyde (22, 23) shows that the torsional potential for the exocyclic C—C bond is better reproduced than with split-valence bases, even those containing polarization functions. For anisole, a 6-31G* basis yields a potential for torsion about the C_{sp^2}—O bond very similar to that obtained from the minimal basis, STO-3G (24, 25). It appears, therefore, that computations of the conformational properties of 3-methoxybenzaldehyde with the minimal basis set may well be sensible.

Table 2 displays the computed energies of the four planar conformers, as well as their dipole moments. The most stable conformer is computed to be **1**, in which the group dipole moments are arranged in such a way as to lead to a small dipole moment and lending some support to the electrostatic arguments (4) discussed above. Figure 2 displays the STO-3G structure of **1** and, judging by the C—C bond lengths within the ring, some apparent support exists for the importance (7) of valence-bond structure **5**, as also discussed in the introduction. However, the alternation in bond lengths is not striking and, in Figs. 3–5, showing the computed geometries of the other conformers, it appears that the bond lengths in the benzene nucleus are

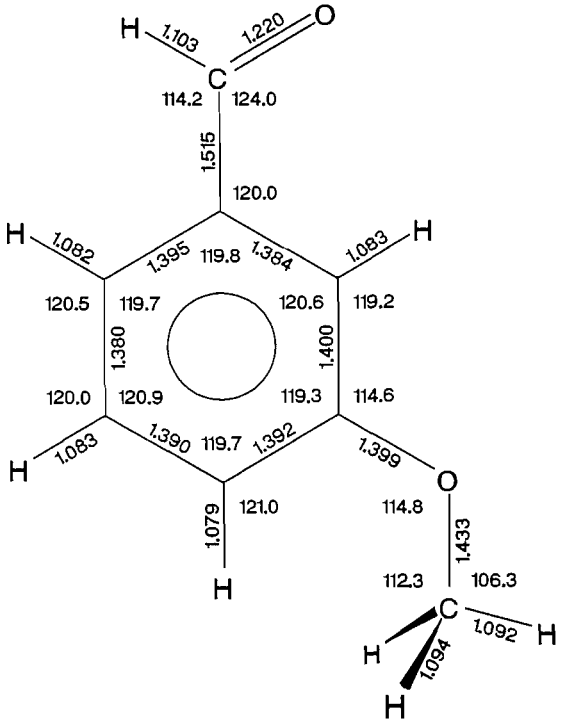

FIG. 3. Comparison of this STO-3G structure of 3-methoxybenzaldehyde with that in Fig. 2 implies that the orientation of the methoxy group determines the bond length variations within the ring.

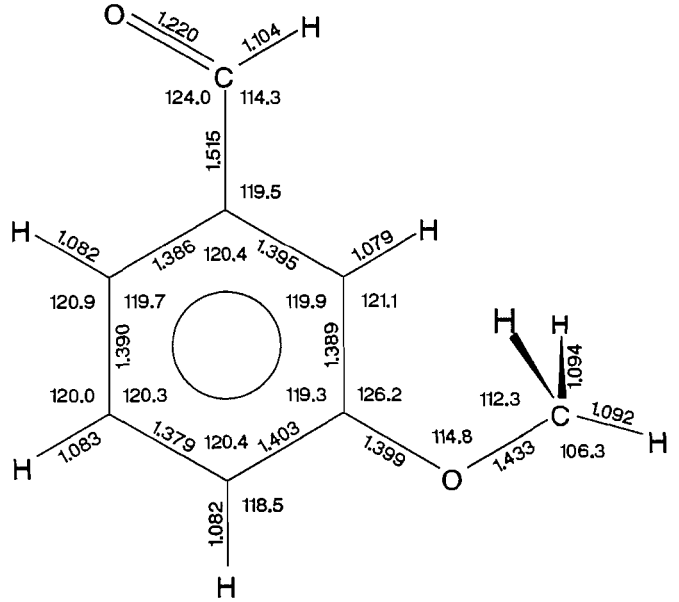

FIG. 4. Comparison of this STO-3G structure with that in Fig. 2 implies that the orientation of the aldehyde substituent does not change the computed bond lengths within the benzene moiety.

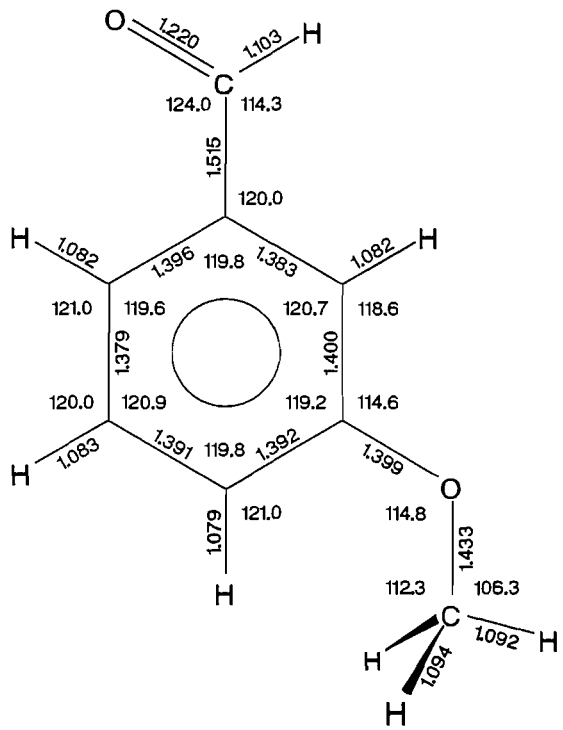

FIG. 5. Again, comparison of this STO-3G structure with that in Fig. 3 bears out the independence of the ring geometry on the aldehyde orientation.

determined by the conformation of the methoxy group and not by that of the aldehyde substituent. At this level of MO theory, therefore, a combined interpretation of the stability of **1** postulates that electrostatic interactions determine the preponderance of **1**. This, in turn, leads to the apparent preference of the methoxy group for that *ortho* ring C—C bond of larger double character and, thereby, also to the apparent preference of the C=O bond to lie *trans* to a similar C—C bond of the ring. The flaw in this description is that, while the STO-3G dipole moment of anisole is within 5% of the experimental value (26), the computed dipole moment of benzaldehyde, at 1.92 D (22), is much less than the experimental value of 2.96 D (27). Clearly, the charge redistribution[2] caused by the aldehydic substituent is incorrectly given by the minimal basis set (it does *not* follow that conformational energies and internal rotational barriers are badly estimated (28)).

Suppose that 1.0 D is added to each of the computed dipole moments of **1**–**4**; this seems reasonable in that, for example, the dipole moment of **1** becomes 1.73_5 D, as compared to 1.74 D assumed on the basis of group moments in a study (27) of the dipole moment of 3-methoxybenzaldehyde. Such an adjustment of the dipole moments in Table 2, combined with the STO-3G MO populations, yields a computed dipole moment of 2.98 D at 300 K. The experimental value, in benzene solution, is 2.94 D at 298 K. This agreement is coincidental, of course.

Thus (Table 2), the populations of **1**–**4** must alter in passing from CS_2 to acetone-d_6 solution, according to the long-range coupling constants. No doubt coincidentally, the values of K(CHO) and $K(OCH_3)$ obtained from the coupling constants in acetone-d_6 solution agree rather closely with those computed for the free molecule from the minimal basis set. In fact, the populations given by the latter at 300 K, combined with the coupling constants expected for each of the conformers (see above) yield ^5J(H,CHO) as 0.386 Hz (the measured value in acetone-d_6 is 0.382(4) Hz) and $^5J(\text{H-2,OCH}_3)$ and $^5J(\text{H-4,OCH}_3)$ as −0.174 and −0.126 Hz, respectively (the measured values are −0.180(1) and −0.121(1) Hz), reflecting the difference of 0.05 between the STO-3G and experimental $K(OCH_3)$ values in Table 2. These comparisons, taken with the clear solvent dependence of the populational distribution,

[2]The computed dipole moment depends on the way in which overlap populations are divided among the atoms in question, the standard Mulliken population analysis being used in this paper.

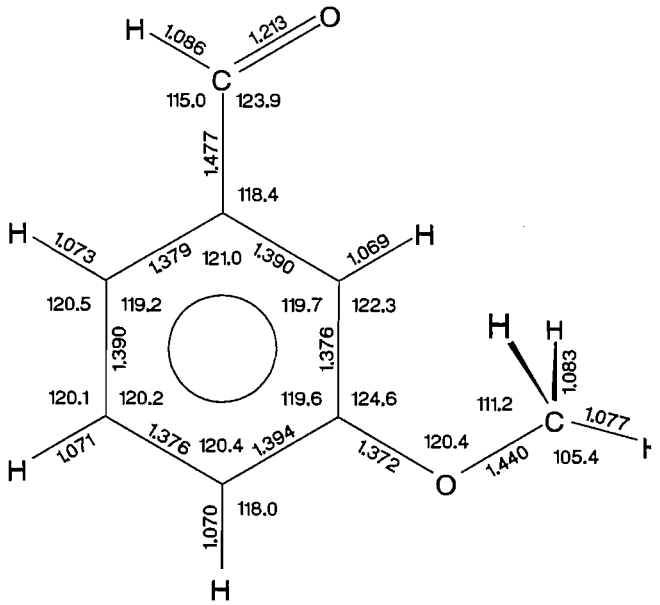

FIG. 6. The 4-21G structure of the most stable conformer of 3-methoxybenzaldehyde is displayed. The bond lengths are rather smaller than those from the minimal basis (Fig. 2). The carbonyl bond and the methoxy group are situated *trans* and *cis*, respectively, to the shorter of the two possible C—C bonds in the ring (see the text for a discussion).

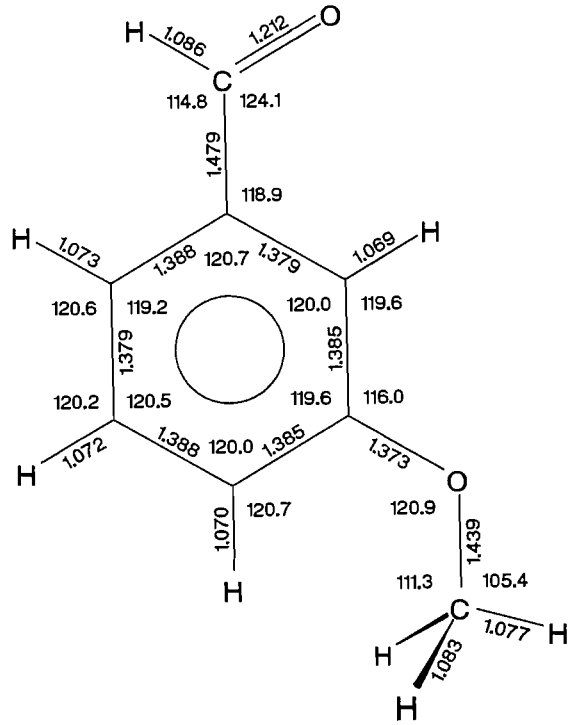

FIG. 7. The 4-21G structure of conformer **2**, the least stable, of 3-methoxybenzaldehyde is shown. The C=O bond is now *trans* to the longer of the two neighbouring C—C bonds and both C—C bonds next to the methoxy group have the same length. In addition, the group dipoles now repel one another (27). The three unfavorable interactions rationalize the instability of this conformer.

demonstrate that the STO-3G MO populations for the free molecule are probably incorrect.

4-21 G MO computations

From unpublished calculations in this laboratory, using various split-valence bases and including polarization functions, it appears that the 4-21G basis, with a dipole moment of 3.37D for benzaldehyde, comes closest to experiment. Accordingly, 4-21G MO computations were performed for the planar conformers, **1**–**4**. The relative energies and dipole moments of the four planar forms are found in Table 2. Comparison of the dipole moments with those from STO-3G computations (note discussion above) and from group moments suggests that the dipole moment of **1** may indeed be very near 1.7 D; the dipole moments of the other conformers are not reproduced by the 4-21G basis, judging by those deduced from group moments in Table 2.

Furthermore, the relative energies of the various conformers, as given by the two bases, agree that $P_1 >> P_3 + P_4 + P_2$ at 300 K (Table 2) but imply strikingly different values for the values of P_1–P_4 and, of course, for K(CHO) and $K(OCH_3)$. Consequently, a semiempirical approach, outlined in the next section, is adopted.

Prior to that, however, note that the 4-21G structures of **1**–**4**, as given in Figs. 6–9, tend to bear out the relative C—C bond lengths in the ring obtained with the minimal basis set. Again, the relative bond lengths appear to be controlled by the orientation of the methoxy group. The methoxy group lies *cis* to the shorter C—C bond (in **2** the two C—C bonds are equal in length), but the C=O bond does not always lie *trans* to the shorter of the two C—C bonds in the ring. In fact, the two structures in which the C=O bond is *trans* to the longer of the two C—C bonds, **2** and **4**, also have the highest computed energies. Furthermore, **2** is of higher energy than **4** and has equal C—C bonds next to the methoxy substituent. In this sense, the relative stabilities of **2**–**4** can be understood in terms of the valence-bond approach (5, 6), given that **1** is the most stable because of electrostatic attraction between the group dipoles (4).

Extrapolation from solution data

An estimate of K(CHO) and $K(OCH_3)$ can be had from a plot of ln K versus $(\epsilon - 1)/(2\epsilon + 1)$ and extrapolation to a value of unity for the dielectric constant, ϵ, of the solution. This approach is based on the reaction field model (30), noting (31, 32) that this model yields free energy differences between conformers (examine eq. 13.18 and p. 562 of ref. 30). Various corrections ignored in such a plot, and the uncertainties in the actual dielectric constants of the CS_2 and acetone-d_6 solutions in Table 1, at first imply that large errors could be involved even within the assumptions of the model. Yet, because of the logarithm and because of the relatively large difference in the dielectric functions for the two solutions, the error in extrapolation is rather small.

The extrapolation yields K(CHO) and $K(OCH_3)$ as 0.46_5 and 0.39(1) in the vapor at 300 K, very nearly midway between the two theoretical estimates (Table 2). From the expressions for K(CHO) and $K(OCH_3)$, together with the normalization condition for the four fractional populations, sums and differences of populations can be had and are presented in Table 2. It follows that the fractional population of **1**, P_1, is greater than 0.40(2) and less than 0.68(2) in the vapor phase. It also follows that $P_4 - P_2 = 0.03_5$. Suppose that $P_1 = 0.54(4)$, the mean of the limiting values; then $P_2 = 0.14(4)$, $P_3 = 0.14(4)$, and $P_4 = 0.18(4)$. Qualitatively, but by no means quantitatively, one has agreement with the theoretical estimates of the *relative* proportions of the conformers in the vapor.

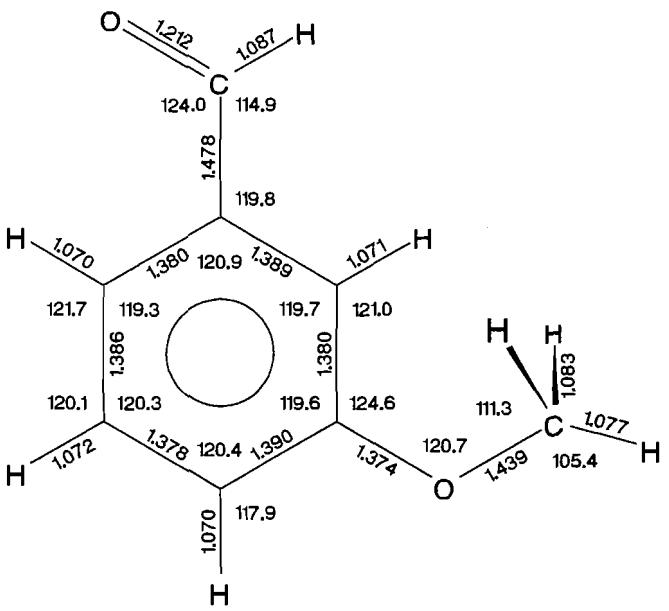

FIG. 8. The 4-21G structure of conformer **4** is displayed. The C=O bond is again *trans* to the longer of the ring C—C bonds but the methoxy group lies *cis* to the shorter of the two C—C bonds. Qualitatively, as discussed in the text, it is therefore sensible that this conformer is somewhat more stable than **2** (Fig. 7).

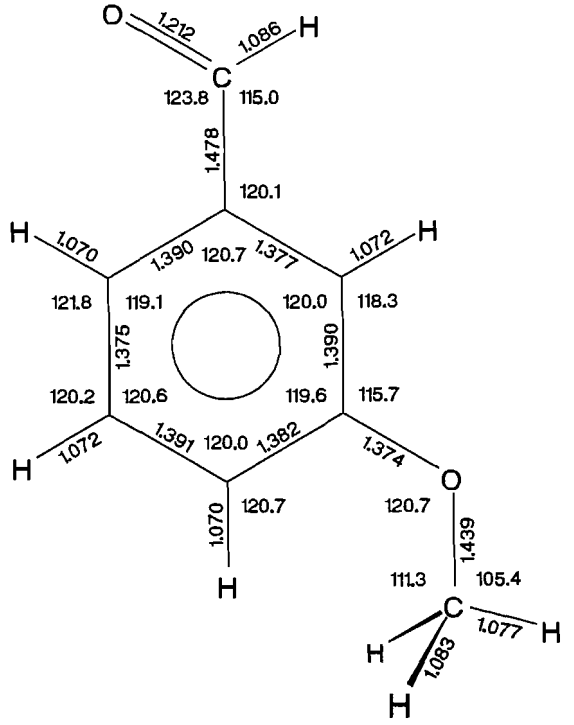

FIG. 9. The 4-21G structure of conformer **3** has the C=O bond *trans* to the shorter C—C in the ring and the methoxy group *cis* to such a bond. Presumably this conformer is of higher energy than **1** because in the latter the group dipoles are roughly antiparallel.

In the solutions, $P_4 - P_2$ remains at 0.04(1) and P_1 apparently decreases, as is sensible for the conformer with the lowest dipole moment. In the CS_2 solvent mixture, take P_1 as 0.44(4), again the means of its limits. Then P_2 is 0.18(4), P_3 is 0.17(4), and P_4 0.21(4). In the acetone-d_6 solution, the mean of the limits for P_1 is 0.37(4).

Of course, if a stereospecific coupling constant involving nuclei within the two substituents were to exist, then the individual populations could be derived. The existence of such a coupling constant, for instance, that over six bonds between the aldehydic proton and the ^{13}C nucleus in the methoxy group, is rather unlikely. Thus, ^5J(H,CHO) in planar benzaldehyde is apparently a pure σ electron coupling interaction because in 3,5-dimethylbenzaldehyde (21) there is no evidence for a finite coupling constant $^6J(H,CH_3)$, involving the aldehydic and methyl protons. It happens (33) that CNDO/2 FPT (34) computations of ^5J(H,CHO) reproduce its magnitude and stereospecificity. Therefore such computations (35) were done for **1**–**4** employing the 4-21 G geometries. $^6J(CHO,OCH_3)$ was computed as less than 0.01 Hz for **1**, **3**, and **4** and as only 0.06 Hz for **2**, implying that this parameter cannot be used as a measure of the population of one of these conformers. $^5J(CHO,OCH_3)$ was calculated as 0.11 Hz for **2** and **3** and as <0.01 Hz for **1** and **4**, again suggesting that an individual population is unavailable from this coupling constant.

Internal rotational barriers

The STO-3G energies were also computed for conformations in which one substituent lay in-plane while the other rotated about the exocyclic bond in steps of 15°. These results are not presented here in detail, but are available from the authors.

Rotation of the aldehyde group by 90° for conformer **1** raises the energy by 24.64 kJ/mol, whereas it costs 23.24 kJ/mol to do so for **4**. These numbers are very similar to the 24.28 kJ/mol computed with the same basis set for benzaldehyde (23) and that measured as 22.7 ± 1.4 kJ/mol from vibronic fluorescence spectra (29). A substantial substituent effect on the C_{sp^2}—C_{sp^2} barrier is not apparent.

Again, rotation about the C_{sp^2}—O bond by 90° in **1** is calculated to raise the energy by 8.25 kJ/mol but, while the aldehydic rotational potential is predominantly twofold, both for 3-methoxybenzaldehyde and benzaldehyde, that for the methoxy group is now rather complex. In fact, for rotation in conformer **1**, the 13 energies in ϕ, the angle of twist about the C_{sp^2}—O bond, are fit by eq. [1], the standard error in

$$[1]\quad V(\phi)/\text{kJ mol}^{-1} = 1.98\sin^2(\phi/2) + 7.43\sin^2\phi - 0.06\sin^2(3\phi/2) + 2.48\sin^2 2\phi - 0.15\sin^2 3\phi - 0.29\sin^2 4\phi$$

the coefficients being 0.10 kJ/mol. Thus, there are significant twofold, in $\sin^2\phi$, and fourfold, in $\sin^2 2\phi$, components. A very similar equation holds for rotation in ϕ for **4**. For anisole, the minimal basis set gives the twofold and fourfold components as 5.6(4) and 2.1(4) kJ/mol, respectively (24). It appears that the aldehyde substituent has increased the twofold component by 1.8(5) kJ/mol in 3-methoxybenzaldehyde, whereas in 4-methoxybenzaldehyde this increase is calculated as 1.7(9) kJ/mol (24). The usual explanation for the latter molecule is that the aldehyde group accepts π electron density from the methoxy group, thereby increasing the double-bond character of the C_{sp^2}—O bond and hence the twofold component of the ϕ barrier. The barrier in the gas phase of anisole itself has not been determined.

AND
ALISTAIR M. STEPHEN AND NEIL RAVENSCROFT
Department of Chemistry, University of Cape Town, Rondebosch 7700, Republic of South Africa

Received November 6, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

ALEXANDER J. CHARLSON, ALISTAIR M. STEPHEN, and NEIL RAVENSCROFT. Can. J. Chem. **68**, 1004 (1990).

Carboxyl groups in *Acacia saligna* (syn. *cyanophylla*) gum were reduced by reacting the gum propionate with diborane. Acetolysis of the reduced gum afforded a mixture of oligosaccharide acetates. After de-*O*-acetylation, 3-*O*-(α-D-galactopyranosyl)-L-arabinose, 3-*O*-(β-D-galactopyranosyl)-D-galactose, and 4-*O*-(α-L-rhamnopyranosyl)-D-glucose were isolated from the mixture.

Key words: acetolysis, *Acacia* gums.

ALEXANDER J. CHARLSON, ALISTAIR M. STEPHEN et NEIL RAVENSCROFT. Can. J. Chem. **68**, 1004 (1990).

On a réduit les groupements carboxyles de gommes de l'*Acacia saligna* (syn. *cyanophylla*) en soumettant le propionate de la gomme à l'action du diborane. Une acétolyse de la gomme réduite fournit un mélange d'acétates d'oligosaccharides. Après une de-*O*-acétylation du mélange, on a pu isoler du 3-*O*-(α-D-galactopyranosyl)-L-arabinose, du 3-*O*-(β-D-galactopyranosyl)-D-galactose et 4-*O*-(α-L-rhamnopyranosyl)-D-glucose.

Mots clés : acétolyse, gommes de l'*Acacia*.

[Traduit par la revue]

Introduction

We reported (1) that *A. saligna* (syn. *cyanophylla*) gum yielded D-galactose, L-arabinose, L-rhamnose, and D-glucuronic acid on acid hydrolysis. It was known that these monosaccharides were also produced on acid hydrolysis of *A. senegal* gum (gum arabic) (2), *A. mollissima* (now *mearnsii*) gum (3), and *A. pycnantha* gum (4). The proportions of the monomers were different in each of the four polysaccharides, as shown subsequently for *Acacia* gums in general, notably by Anderson and his co-workers (5, 6). Glucuronic acid often occurs as its 4-methyl ether (7). Since the molar ratio of L-rhamnose to D-glucuronic acid was nearly unity for *A. saligna* gum, for *A. mollissima* (now *mearnsii*) gum, and for gum arabic, we postulated (1) that L-rhamnose may be glycosidically linked to D-glucuronic acid in the three gums. Smith and Montgomery had also suggested (8) that L-rhamnose might be glycosidically linked to D-glucuronic acid in gum arabic. Aspinall *et al.* (9, 10) isolated 4-*O*-(α-L-rhamnopyramosyl)-D-glucose from the de-*O*-acetylated mixture produced on acetolysis of reduced gum arabic. This result provided definite evidence that some of the L-rhamnose residues are glycosidically linked to D-glucuronic acid in gum arabic. On the basis of more recent investigations of gum arabic structure employing base degradation of methylated gums, Aspinall and Rosell reported (11) that all the L-rhamnose residues are linked to D-glucuronic acid, and such linkages have been demonstrated in a similar manner for other *Acacia* gums (12).

In this investigation the reduced *A. saligna* gum was prepared by reacting the gum propionate with diborane, and acetolysis was performed on the *O*-acetylated reduced gum. The product from the acetolysis was de-*O*-acetylated and the oligosaccharide mixture produced was fractionated using cellulose column chromatography. Crystalline samples of 3-*O*-(β-D-galactopyranosyl)-D-galactose and 3-*O*-(α-D-galactopyranosyl)-L-arabinose were obtained, and shown to be identical with authentic material. Smith reported (2) that 3-*O*-(α-D-galactopyranosyl)-L-arabinose was present in the autohydrolysis mixture from gum arabic, and we found (1) that the same disaccharide was cleaved in a similar manner from *A. saligna* gum; the disaccharide (obtained from *Watsonia* corm-sacs, ref. 13) has been fully characterized by nmr spectroscopy using COSY, HETCOR, and APT to assign all ^1H and ^{13}C signals for the α and β forms in D_2O solution (14). Hirst and Perlin (4) obtained 3-*O*-(β-D-galactopyranosyl)-D-galactose using graded acid hydrolysis of *A. pycnantha* gum.

In addition to the two crystalline disaccharides, a syrupy disaccharide consisting of rhamnose and glucose was isolated. The results from lead tetraacetate and periodate oxidations suggested that rhamnose was joined to glucose by a 1→4 linkage. Aspinall *et al.* (9, 10) described similar experiments. Further evidence for the 1→4 linkage was obtained by examination of the methanolysis products from the methylated disaccharide using gas–liquid chromatography. The specific rotation of the disaccharide, $[\alpha]_D$ −5°, is close to the value, $[\alpha]_D$ −6°, recorded by Aspinall *et al.* (9, 10). Recently, Fügedi (16) reported $[\alpha]_D$ −10.5° for synthetic 4-*O*-(α-L-rhamnopyranosyl)-D-glucose. The nmr characteristics of this disaccharide produced from *A. saligna* gum have been described (17), a combination of the ^1H spectrum (at 200 MHz), the COSY experiment, the ^{13}C spectrum (at 50.3 MHz), HETCOR, and long-range HETCOR leading to a complete assignment of the proton and carbon signals and a listing of glycosylation shifts relative to α-Glc-OH, β-Glc-OH, and α-RhapOMe. The solvent was D_2O. Anomeric signals were assigned for α-Rhap ($\delta_{H\text{-}1}$ 4.85 ppm; δ_{C-1} 101.46), for α-Glc-OH (δ_{H-1} 5.21, J 3.5 Hz; δ_{C-1} 92.42), and for β-Glcp-OH (δ_{H-1} 4.62, J 8 Hz; δ_{C-1} 96.37). The H-5 (δ 4.01) and H-6 (δ 1.28) resonances established the α-Rha configuration in the disaccharide, supporting a deduction made on the basis of $[\alpha]_D$, found and calculated from Hudson's rules (18). The site of glucosylation at O-4 of Glc was deduced from positive glycosylation shifts (ppm) for H-4 (+0.25α, +0.24β) and C-4 (+7.4α, +7.2β) and the negative shifts for C-3 (−1.8α, −1.0β) and C-5 (−1.2α, −1.8β). The ^{13}C data were in conformity with the absolute configurations of Rha and Glc as L and D respectively (19).

Long-range HETCOR (setting of $^3J_{C,H} = 6$ Hz) established connectivities as follows: (i) H-1 and C-5 of α-Glc; (ii) H-5 and C-3 of α-Rhap; (iii) H-1 with C-3 and C-5 of α-Rhap; and, importantly, (iv) H-1 of α-Rha with C-4 of Glc (across the glycosidic bond).

The isolation of 4-*O*-(α-L-rhamnopyranosyl)-D-glucose provides definite evidence that some of the rhamnose residues are glycosidically linked to glucuronic acid in *A. saligna* gum. Our postulate that rhamnose may be glycosidically linked to glucuronic acid in three different *Acacia* gums (1) has been shown in this way to be correct for gum arabic and *A. saligna* gum. Lindberg and co-workers reported (20) that rhamnose is glycosidically linked to glucuronic acid in a bacterial polysaccharide. Since then it has been demonstrated that rhamnose is linked to glucuronic acid in several bacterial polysaccharides (21–25). In all these cases the linkages are 1→4. The fact that this identical structural feature occurs in a number of different bacterial polysaccharides and also in *Acacia* gums is of interest. It is possible that the biosynthesis of *Acacia* gums involves a step where rhamnose is transferred from bacterial nucleotide diphosphate rhamnose to the plant polysaccharide utilizing a bacterial glycosyl transferase.

Experimental

Unless otherwise stated, concentration of solutions was carried out at 40°C/20 Torr (1 Torr = 133.3 Pa), melting points are uncorrected, and specific rotations were measured in aqueous solution. Paper chromatography was performed on Whatman No. 1 filter papers with the following solvent systems (V/V): (A) ethyl acetate – acetic acid – formic acid – water (18:3:1:4); (B) ethyl acetate – pyridine–water (10:4:3); (C) 2-butanone – acetic acid – water, saturated with boric acid (9:1:1). The nmr spectra were determined on a Varian VXR-200 instrument, the sample being D-exchanged thrice before analysis.

Carboxyl reduced A. saligna *gum acid*

Crude *A. saligna* gum was precipitated once from slightly acid solution with ethanol. *Acacia saligna* gum acid was then precipitated from aqueous solution with ethanol. The gum acid (11.5 g), equivalent mass 750 and $[\alpha]_D$ −23° (*c* 1.0), was acetylated with acetic anhydride and pyridine in formamide according to the method of Carson and Maclay (26) to yield 15.6 g of the acetate $[\alpha]_D$ −41° (*c* 1.0, chloroform). An attempt was made to reduce the gum acetate (15 g) in 1,2-dimethoxyethane (300 mL) with boron trifluoride – ether complex (6 g) and sodium borohydride (7.1 g) by the *in situ* method (27) as described by Aspinall *et al.* (9, 10). The yield of the partially reduced product was 9.8 g: a sample of this material in water was deionized with Amberlite IR-120 (H^+) and Amberlite IR-4B (OH^-), then deionized again with IR-120 (H^+) and freeze-dried. An acid equivalent mass of 1570, obtained on the freeze-dried product, corresponds to 52% reduction of carboxyl groups. The gum acid (31 g) was reacted with propionic anhydride and pyridine (26) to yield 43 g of the propionate $[\alpha]_D$ −43° (*c* 2, chloroform). The gum propionate (21 g) was reduced with diborane using the *in situ* method to yield 11.5 g of carboxyl-reduced *A. saligna* gum $[\alpha]_D$ −13° (*c* 1.1) A sample was deionized and freeze-dried as described above: the product had an acid equivalent mass of 4500 corresponding to 83% reduction. In a second preparation the propionate (21 g) was reduced with diborane to yield reduced *A. saligna* gum (11.4 g) $[\alpha]_D$ −20° (*c* 0.96); acid equivalent mass 4000 or 81% reduction. Galactose, arabinose, rhamnose, and glucose were detected on a paper chromatogram run in solvent (B) after acid hydrolysis of the reduced gum. The spot on paper corresponding to the aldobiouronic acid was very faint.

Acetolysis of acetylated reduced A. saligna *gum*

The reduced gum (12 g) was converted (26) into the acetate (16.2 g) $[\alpha]_D$ −19° (*c* 1.3, chloroform). The acetate (14 g) was added with stirring to a solution of concentrated sulphuric acid (4.5 mL) in acetic anhydride (150 mL) at 0°C. Stirring was continued 0.5 h at 0°C and then 4 h at ambient temperature. After standing at room temperature overnight, the reaction mixture was decomposed with ice water and the acetates produced were extracted with chloroform (5 × 100 mL). The chloroform extract was washed successively with water, sodium hydrogen carbonate solution, and water, and then dried over anhydrous sodium sulphate. Removal of the chloroform in vacuum left a viscous syrup (17.5 g); this was de-*O*-acetylated at 3°C in 0.2 M sodium methoxide (100 mL). After acidifying with a few drops of acetic acid and distilling off the methanol, the residue was dissolved in water, deionized, and concentrated to a syrup (8.1 g). The syrup was fractionated on a cellulose column (40 × 6.4 cm) by eluting with half-saturated aqueous butanol, then three-quarter-saturated aqueous butanol, and finally acetone. Earlier fractions contained monosaccharides (rhamnose, arabinose, galactose, and glucose) and some material with chromatographic mobility faster than rhamnose (possibly saccharides that had not been completely deacetylated). Later five oligosaccharide fractions were collected. Fraction 2 (a mixture of fractions 1 and 3) and fraction 4 (a mixture of fractions 3 and 5) were not investigated further.

Fraction 1: 4-O-*(α-L-rhamnopyranosyl)-D-glucose*

The syrup (0.73 g) had $[\alpha]_D$ −5° (*c* 2.0): chromatographic mobilities were R_{gal} 0.82 in solvent (A) and R_{gal} 1.0 in solvent (B), and the material afforded glucose and rhamnose on acid hydrolysis (paper chromatographic identification using solvent (B)). Lead tetraacetate oxidation of the syrup (12 mg) was carried out for 2.5 h in 98% acetic acid at room temperature (15). Excess lead tetraacetate was destroyed and lead (II) ions were precipitated by addition of oxalic acid in acetic acid. Hydrolysis of the oxidation product afforded rhamnose and erythrose (paper chromatographic identification using solvent (C)). Periodate oxidation and formation of a formaldehyde dimedone derivative was performed according to Reeves (28). The syrup (15 mg) yielded the dimedone derivative (11 mg), mp 172–174°C; after recrystallization from aqueous methanol it had mp 187–188°C undepressed on admixture with an authentic sample. Methylation of the syrup (145 mg) was conducted in dimethyl sulphoxide (10 mL) with potassium tertiary butoxide (370 mg) and methyl iodide (1 mL) by the method of Hakomori (29). After methanolysis of this material, peaks having the retention times of the methyl glycosides of 2,3,4-tri-*O*-methylrhamnose and 2,3,6-tri-*O*-methylglucose were detected using gas–liquid chromatography.

Fraction 3: 3-O-*(α-D-galactopyranosyl)-L-arabinose*

The syrup (0.42 g) showed mobilities on paper identical to an authentic sample of 3-*O*-(α-D-galactopyranosyl)-L-arabinose using solvent (A) and solvent (B), and on acid hydrolysis afforded galactose and arabinose (paper chromatographic identification using solvent (B)). A solution of the syrup in methanol deposited crystals, $[\alpha]_D$ +197° (*c* 1.0), and mp and mixture mp 156°C after seeding with the authentic disaccharide.

Fraction 5: 3-O-*(β-D-galactopyranosyl)-D-galactose*

A solution of the syrup (0.24 g) in methanol slowly deposited crystals, $[\alpha]_D$ +60° (*c* 0.4), which on hydrolysis gave only galactose (identified on paper using solvent (B)). The crystals were shown to be 3-*O*-(β-D-galactopyranosyl)-D-galactose, by comparison with the authentic disaccharide using paper chromatography, by mp and mixture mp 161°C, and by production of galactose and lyxose (paper chromatography using solvent (B)) on hydrolysis of the lead tetraacetate oxidation product (15).

The structures and reactions of stannylene acetals from carbohydrate-derived *trans*-diols. Part I. In the absence of added nucleophiles

T. Bruce Grindley and Rasiah Thangarasa
Department of Chemistry, Dalhousie University, Halifax, N.S., Canada B3H 4J3

Received September 12, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

T. Bruce Grindley and Rasiah Thangarasa. Can. J. Chem. **68**, 1007 (1990).

Di-*n*-butylstannylene acetals of benzyl 4,6-*O*-benzylidene-α- and -β-D-glucopyranoside and galactopyranoside have been prepared and studied in solution by ^{1}H, ^{13}C, and ^{119}Sn nuclear magnetic resonance spectroscopy. The species present in solution have been identified from the ^{119}Sn nmr spectral data, by comparison of the ^{13}C nmr chemical shifts of the stannylene acetals and their precursor diols and also by analysis of the products of reactions performed without added nucleophiles. The orientations of the two substituents on the carbons in the pyranose ring attached to the carbons in the stannylene ring determine the structures adopted by the stannylene acetal in solution. If one substituent is axial and the other equatorial, the stannylene acetal exists as a single symmetrical dimer in which the two oxygen atoms in the two 1,3,2-dioxastannolane rings adjacent to the axial substituents are dicoordinate. A stannylene acetal with two adjacent equatorial substituents exists as a non-interconverting mixture of dimers; one with two adjacent axial substituents is present as a rapidly interconverting mixture of dimers, trimers, and tetramers. Benzoylation and benzylation of the latter two types of stannylene acetals have been performed and have been shown to be only slightly regioselective in contrast to the known highly regioselective reactions of the first type. Only when single dimers are present are regiospecific or highly regioselective reactions obtained. The causes of the variation in the species present and of the reaction regioselectivity for different stannylene acetals are discussed.

Key words: stannylene acetals, 1,3,2-dioxastannolanes, ^{119}Sn NMR spectroscopy, regioselective reactions, carbohydrates.

T. Bruce Grindley et Rasiah Thangarasa. Can. J. Chem. **68**, 1007 (1990).

On a préparé les di-*n*-butylstannylène acétals des 4,6-*O*-benzylidène-α- et -β-glucopyranosides et galactopyranosides de benzyle et on les a étudiés, en solution, en faisant appel à la résonance magnétique nucléaire du ^{1}H, du ^{13}C et du ^{119}Sn. On a identifié les espèces présentes en solution à partir des données de la rmn du ^{119}Sn, par comparaison des déplacements chimiques en rmn du ^{13}C des stannylène acétals et des diols qui leur ont donné naissance ainsi que par une analyse des produits des réactions réalisées en l'absence de nucléophiles. Les orientations des deux substituants attachés aux carbones du cycle pyranosique qui font partie du cycle stannylène déterminent les structures adoptées par le stannylène acétal en solution. Si l'un des substituants est axial alors que l'autre est équatorial, le stannylène acétal existe sous la forme d'un dimère symétrique unique dans lequel les deux atomes d'oxygène des deux cycles 1,3,2-dioxastannolanes adjacents aux substituants axiaux sont doublement coordonnés. Un stannylène acétal comportant deux substituants équatoriaux adjacents existe sous la forme d'un mélange de dimères qui ne se convertissent pas l'un dans l'autre; l'un des deux substituants axiaux adjacents est présent sous la forme d'un mélange de dimères, de trimères et de tétramères qui se convertissent les uns dans les autres. On a effectué la benzoylation et la benzylation des deux derniers types de stannylène acétals et on a montré que ces réactions ne sont que légèrement régiosélectives; ce comportement diffère grandement des réactions hautement régiosélectives observées avec le premier type. On n'obtient des réactions régiospécifiques ou hautement régiosélectives qu'avec des dimères isolés. On discute des causes qui affectent la variation dans les espèces présentes et la régiosélectivité des réactions des divers stannylène acétals.

Mots clés : stannylène acétals, 1,3,2-dioxastannolanes, spectroscopie RMN du ^{119}Sn, réactions régiosélectives, hydrates de carbone.

[Traduit par la revue]

Introduction

A continuing goal of synthetic organic chemists, particularly those working with carbohydrates, has been to develop reactions that occur at only one of two or more hydroxyl groups in similar environments. Dialkylstannylene acetals are easily formed from diols and serve as intermediates in reactions that have shown considerable promise towards achieving this goal. Since their initial use by Moffat and co-workers and by David (1), di-*n*-butylstannylene acetals derived from many different carbohydrates have been observed to react with several types of electrophiles to give predominantly monosubstitution products (2). Alkylation, esterification, and oxidation of stannylene acetals are the most common reactions and the monosubstitution products are often obtained in a regiospecific or highly regioselective manner (2). Sometimes, even enzyme-like selectivity has been achieved, where one hydroxyl group of many reacts (3). In addition, stannylene acetals react much faster with electrophiles than do free diols (2). However, the stannylene acetals of many carbohydrate diols do not undergo regioselective reactions (2) and neither the types of structures of substrates for which selective reactions can be anticipated, nor the cause of the selectivity, have been fully defined. The marked effects of additional nucleophiles on the rates (4) and regioselectivity (5) of reactions with di-*n*-butylstannylene acetals will be analysed later (6).

A number of suggestions have been made as to the causes of both the regioselectivity and of the rate enhancement (2). Evidence will be presented here that supports the idea that the regioselectivity obtained in a reaction is related to the particular oligomeric structure or structures assumed by the stannylene acetal in solution (7). In the solid state, the simplest stannylene acetal, 2,2-di-*n*-butyl-1,3,2-dioxastannolane, exists as an infinite ribbon polymer (8). Of the two carbohydrate stannylene acetals whose X-ray structures have been determined, one exists as a dimer (9) while the other is a pentamer (10). We have shown that di-*n*-butylstannylene acetals derived from simple symmetrical primary or secondary diols exist in solution in nonpolar solvents as complex mixtures containing dimers, trimers, tetramers, pentamers, and possibly higher oligomers. The composition of the mixture present is extremely tempera-

For personal use only.

ture and concentration dependent, with dimers being minor constituents at −50°C but becoming increasingly favoured as the temperature is increased from 0 to 100°C (11).

We now report a study of the ^1H, ^{13}C, and ^{119}Sn nmr spectra of a series of di-*n*-butylstannylene acetals derived from carbohydrates that contained isolated *trans*-1,2-diols on pyranose rings with the four possible combinations of different stereochemistries at the adjacent centres. Some reactions have been performed on those stannylene derivatives for which there were insufficient data about reaction selectivity. The aims of the study are to define the solution structures, to relate them to reactivity and selectivity, and to identify the causes of the selectivity in the absence of added nucleophiles.

Results

The compounds examined were the 2,2-di-*n*-butylstannylene derivatives (**1***b*–**5***b*, respectively) of methyl 4,6-*O*-benzylidene-α-D-glucopyranoside (**1***a*), benzyl 4,6-*O*-benzylidene-α- and -β-D-glucopyranoside (**2***a* and **3***a*, respectively), and benzyl 4,6-*O*-benzylidene-β- and -α-D-galactopyranoside (**4***a* and **5***a*, respectively). Carbohydrates **1***a*–**4***a* were made by standard methods. **5***a* was prepared by the method used to make **2***a* (12). The di-*n*-butylstannylene derivatives were prepared by refluxing the diols with di-*n*-butyltin oxide in benzene for 12 h with azeotropic distillation of water.

The best method currently available for identifying the nature of the tin species present in solution is ^{119}Sn nmr spectroscopy. The ^{119}Sn nmr chemical shift is closely related to the coordination status of the tin atom; in 2,2-di-*n*-butyl-1,3,2-dioxastannolanes and related acyclic tin derivatives, tetracoordinate, pentacoordinate, and hexacoordinate tin nuclei absorb in the ranges −20 to −40 ppm, −100 to −170 ppm, and −230 to −300 ppm, respectively, relative to tetramethyl tin (11, 14, 15).[1]

The ^{119}Sn nmr chemical shifts observed are listed in Table 1. As has been previously noted, two of the compounds (**1***b* and **4***b* in chloroform-*d* (7, 9) and **1***b* in toluene-d_8 (16)) gave spectra containing a single sharp line in the region of the spectrum where pentacoordinate tin is expected to absorb, consistent with a dimeric structure. In each monomer unit in a dimer, one oxygen atom is dicoordinate, while the other is tricoordinate. A particular dimer structure will be named here by using the number of the two tricoordinate oxygen atoms, illustrated for compound **3***b* in Fig. 1. For the compounds studied, three dimers are possible, the 2,2, the 2,3, and the 3,3 dimers. An X-ray crystal structure determination showed that **1***b* is present in the solid state as a 3,3 dimer (9).

To confirm that the same structure is present in solution as in the solid state for **1***b*, the ^{119}Sn and ^{13}C solid state nmr spectra have been recorded. The chemical shifts observed are listed in Tables 1 and 2. The solid-state spectra of both nuclei contained two sets of equal intensity lines with values of the chemical shifts close to those observed in solution. In the X-ray crystal structure, the two halves of the dimer had slightly different geometries (9) and these differences presumably account for the line doubling. The ^{119}Sn nmr chemical shift values observed for **3***b* (see later) demonstrate that different dimer structures give different ^{119}Sn nmr chemical shifts and considerable differences would also be expected in the ^{13}C nmr spectra if a different dimer was present in solution. Hence, it can be concluded that **1***b* is present in solution predominantly as a 3,3 dimer.

Tables 2 and 3 contain the ^{13}C and ^1H nmr chemical shifts of the di-*n*-butylstannylene acetals and their percursors, and the differences between them. In all cases, assignments were made initially for the ^1H nmr spectra by single frequency homonuclear decoupling, then for the ^{13}C nmr spectra by correlation with the ^1H nmr spectra through single frequency heteronuclear decoupling or by 2-D correlation experiments. The ^{13}C nmr spectrum of only one stannylene acetal, **1***b*, had been examined previously and the assignments for C-2 and C-3 considered less likely (16) were found to be correct.

Compound **2***b*, the benzyl analog of the methyl glycoside **1***b*, has almost the same ^{13}C nmr chemical shifts as **1***b*. The ^1H nmr chemical shifts of the skeletal protons, except for H-1, are also very similar. In addition, the pattern of differences between the ^1H and ^{13}C nmr chemical shifts of **1***b* and **1***a* and of **2***b* and **2***a* are similar. Thus, **2***b* is present as the same 3,3 dimer as **1***b* in solution. The ^{119}Sn nmr spectra of both **1***b* and **2***b* in chloroform-*d* contain a single sharp line from −55 to +55°C, consistent with the 3,3 dimer being the predominant species present over this temperature range.

An outline of the reactions performed on di-*n*-butylstannylene derivatives of carbohydrates containing *trans*-diols on pyranose rings is given in Table 4. As for **1***b*, **2***b* reacts almost exclusively at O-2. Comparison of the ^{13}C nmr chemical shifts of the stannylene derivatives **1***b* and **2***b* with those of their precursor diols (Table 2) shows that the signals of the C-2's, the carbons bearing the reactive oxygens, are shifted downfield by 4.3 and 4.4 ppm, respectively, on stannylene acetal formation. The signals of the C-1's are also shifted downfield, by 2.6 and 3.3 ppm, but changes in shifts of the other carbons are small.

The ^{119}Sn nmr spectra of solutions of **3***b* in chloroform-*d* (0.25 M), benzene-d_6 (0.10 M), or toluene-d_8 (0.19 M) are more complex (Fig. 1). Each contains one major signal, plus two smaller identical intensity signals, all close together in the pentacoordinate tin region of the spectrum. Thus, only dimers are present. Spectra recorded over a temperature range of −60 to +50°C in chloroform-*d* or −60 to +100°C in toluene-d_8 all contain the same three signals with about the same intensities, although the relative chemical shifts vary considerably. The benzal proton region of the ^1H nmr spectrum in chloroform-*d*

of peaks expected for a monomer in the spectra of all nuclei indicates that the major species present is a symmetrical dimer. For **1***b*, **2***b*, and **4***b* (*vide infra*), comparison of the ^{13}C nmr chemical shifts of the carbons involved in stannylene acetal formation in the spectra of the stannylene acetals with those from their precursors allowed assignment of the carbon bearing the dicoordinate oxygen atom from its markedly larger chemical shift change. The signals for both C-2 and C-3 had larger chemical shifts in the spectra of the major species of **3***b* than in those of **3***a* (by 3.5 and 2.9 ppm in chloroform-*d* and 3.6 and 3.2 ppm in toluene-d_8, respectively). Thus, the structure of the major dimer cannot be determined from these shift differences. Also present in the ^1H and ^{119}Sn nmr spectra of **3***b* were two other sets of signals having identical intensities under all conditions. The equality of the intensities indicates that these lines are caused by a single species, the nonsymmetrical 2,3 dimer. The observation of some very minor signals suggests that the third dimer is present to a very limited extent. Integration of the ^{119}Sn nmr signals allowed evaluation of the relative proportions of the major and minor dimers; at 26°C, these were 57:38, 75:25, and 72:28 for solutions in chloroform-*d* (0.25 M), in toluene-d_8 (0.19 M), and in benzene-d_6 (0.10 M), respectively.

Reactions with electrophiles performed on **7**, the methyl analogue of **3***b*, gave mixtures of products with selectivity that varied with the reaction type and conditions (21). Benzylation of **3***b* was performed in benzene with added tetra-*n*-butylammonium bromide at reflux. The structures of the benzyl derivatives (**3***c* and **3***d*) were assigned by analysis of the ^1H nmr spectra of their acetates; the key observation was the size of the coupling constants for the most downfield signal of a skeletal proton. $J_{1,2}$ is noticeably smaller than $J_{2,3}$ or $J_{3,4}$. Benzoylation was performed in benzene without added base. The structures of the benzoates were assigned directly from their ^1H nmr spectra.

13

Benzylation gave more of the 3-*O*-benzyl derivative (55:21) but benzoylation yielded more of the 2-*O*-benzoate (53:37). All reactions with **7** except for benzoylation gave about a 2:1 to 3:1 preference for reaction at O-3 (21). Benzoylation here and in ref. 21 was conducted at room temperature in the absence of additional nucleophiles whereas the other reactions were conducted in the presence of added nucleophiles often at elevated temperatures. The products of benzoylation are, therefore, most likely to be related to the structures of the major species present in solution in the solvent alone. We conclude that the major symmetrical dimer present for **3***b* and **7** is the 3,3 dimer.

As previously noted (7), the ^{119}Sn nmr spectrum of **4***b* in chloroform-*d* contains a single sharp line at temperatures ranging from −55 to +50°C, consistent with a single symmetrical dimer. The ^{1}H and ^{13}C nmr spectra contain a single set of lines, indicating that the dimer present is symmetrical. The downfield shift (4.2 ppm) observed for C-3 on conversion of **4***a* to **4***b* indicates that the dimer present is the 2,2 dimer. In agreement with this conclusion, **4***b* reacts almost exclusively at O-3 (Table 4).

Confirmation of the structures of the dimers present in chloroform-*d* for **2***b* and **4***b* can be obtained by consideration of the differences in the chemical shifts of the methylene protons in the benzyl groups when the ^{1}H nmr spectra of the diols are compared with those of the stannylene acetals (Table 3). In the assignment of these signals, it was assumed that there was no reversal of chemical shift order for the signals from the benzyl groups on stannylene acetal formation. For **2***b*, where O-2 is dicoordinate, the large substituents attached to tin are held away from the benzyl group and the chemical shift changes observed are small. For **4***b*, the major dimer has O-2 tricoordinate. The two *n*-butyl groups are close to the glycosidic benzyls and presumably influence the mixtures of conformations present. Large changes in chemical shift are observed when the chemical shifts of the benzyl protons of **4***b* are compared with those of **4***a*. For **3***b*, the differences in chemical shift differences (ΔΔδ 0.20) were much smaller than for **4***b* (ΔΔδ 0.59), but were larger than for **2***b* (ΔΔδ 0.04). This result is in agreement with the evidence presented earlier that the major dimer for **3***b* was the 3,3 dimer.

The spectra of solutions of **4***b* in toluene-d_8 were rather complicated and very temperature dependent (see Fig. 2). At all temperatures, the ^{119}Sn nmr spectra contained one main signal (at −136.0 ppm at −40°C), presumably that of the 2,2 dimer. At −40°C and below, the ^{119}Sn nmr spectrum contained eight other signals including three in the hexacoordinate region of the spectrum, at −248.0, −294.7, and at −298.9 ppm. If signals for hexacoordinate tin are observed, higher oligomers than the dimer must be present. The most likely species are trimers and

tetramers (11). There are four possible trimer structures, none of which have any symmetry, and ten possible tetramer structures, of which four have C_2 symmetry. We believe that two trimers, one tetramer, and possibly the 2,3 dimer are also present. The two trimers, termed A and B, were assigned as trimers on the basis of the chemical shifts of the high field signals and of changes in intensities with temperature. In the spectra of a number of di-*n*-butylstannylene acetals derived from ethylene glycol and simple di-secondary diols, the chemical shifts of hexacoordinate tin signals of trimers were 15–20 ppm more negative than those of tetramers, falling in the range of −280 to −295 ppm (11). In spectra recorded at −60°C, the signal assigned to the tetramer, at −251.4 ppm, was about the same size as the other two signals arising from hexacoordinate tin; at −40°C, it was much smaller than the other two; by −20°C, the signal had almost disappeared and it was not present in spectra recorded at 0°C and above. Lower temperatures favour higher oligomers (11, 15). Similarly, the signals assigned to trimers were larger in comparison to those assigned to dimers at low temperatures than they were at higher temperatures; the ratios of mole fractions of dimers to trimers changed from 0.51 to 1.5 to 6.8 at −60, −20, and 30°C, respectively. The ^{119}Sn nmr spectra of trimers should contain three signals, two in the pentacoordinate region. Two signals at −294.7 and −119.6 ppm with identical intensities are assigned to trimer A. A second set of two signals at −298.9 and −121.3 ppm with intensities identical to each other but lower than those assigned to trimer A is assigned to trimer B. A signal at −132.2 ppm had an intensity about equal to the sum of the intensities at −294.7 and −298.9 ppm or −119.6 and −121.3 ppm and probably was due to a coincidence of the third signal of both trimers.

The trimer structures are named here from the numbers of the positions of the bonded tricoordinate oxygen atoms in the sequence present in the structure. The four possibilities are the 2,3,2,2, 2,2,3,3, 2,3,2,3, and 3,3,2,3 trimers, shown in Fig. 3. We believe that the two trimers present are the 2,2,3,3 and the 2,3,2,3 structures, for reasons that will be discussed later.

At 50°C and above, the only sharp signal visible to the high frequency side of the main signal was a small signal with a chemical shift of −132.9 ppm at 70°C. At low temperatures, a slight shoulder was observed on the high frequency side of the main peak at chemical shifts close to this value. This signal may have been caused by the 2,3 dimer; if it was, and if it is assumed that the nonsymmetrical 2,3 dimer gave rise to a second signal coincident with the main signal, the 2,3 dimer contributed about 12% of the mixture present at these temperatures.

The line widths and intensities of the remaining two signals, at −140.3 and +151.6 ppm, were much less sensitive to changes in temperature. They were therefore assigned to an impurity or impurities arising from reaction of **4***b* with a slight amount of water present in the system. Compounds with similar chemical shifts were obtained when model compounds were exposed to water (11).

There was considerable evidence in these spectra of **4***b* in toluene-d_8 that exchange processes were becoming more rapid as the temperature increased. The signals assigned to hexacoordinate tin in trimers were very broad at 30°C and were too broad to be observed at higher temperatures. The two highest frequency trimer signals broadened and merged at 0°C and continued to broaden as the temperature increased so that at 70°C they formed part of the shoulder on the envelope of the main dimer peak. The other trimer peak also broadened so that it

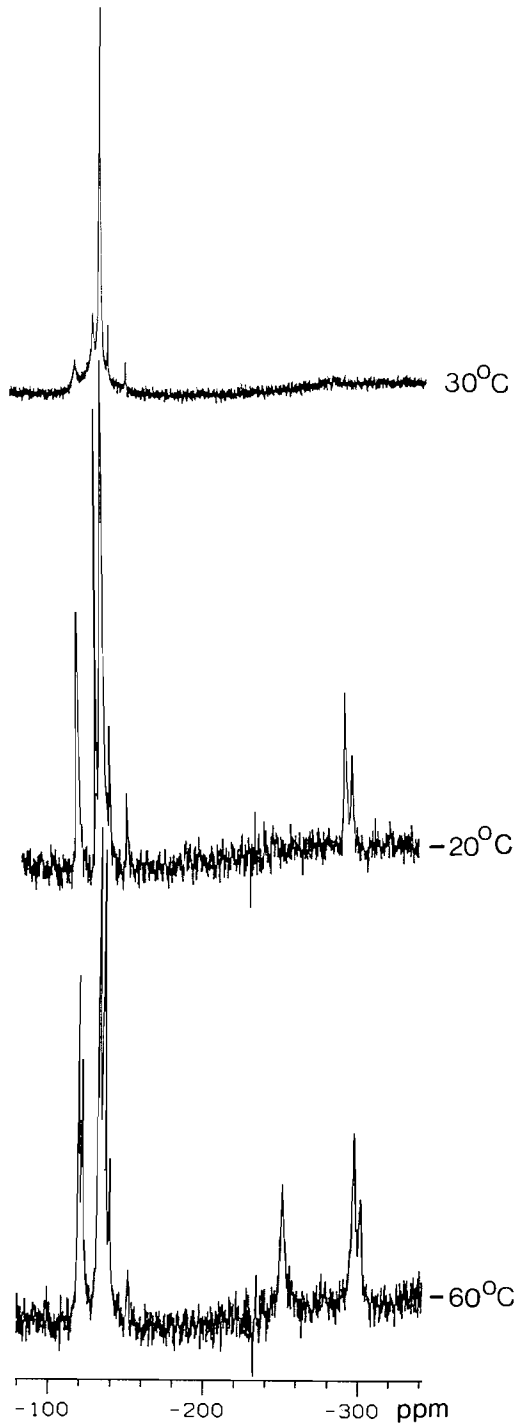

FIG. 2. 134.6 MHz ^{119}Sn nmr spectra of a 0.19 M solution of compound **4***b* in toluene-d_8 at various temperatures.

was part of the shoulder of the main peak by 50°C. The minor peak tentatively assigned to the 2,3 dimer broadened as the temperature was raised but was still distinct at the highest temperature recorded, 90°C. The peaks assigned to hydrolysis products were much sharper than the other two peaks at 70 and 90°C.

The nmr spectra of compound **5***b* are very different. At room temperature, the ^{119}Sn nmr spectrum of **5***b* in chloroform-*d* contains a number of very broad lines that sharpen as the temperature is lowered. At −55°C, there are two intense lines plus three lines of about half their intensity between −119 and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

−127 ppm, plus two lines of about half the intensity of the most intense lines at −255.0 and −262.6 ppm. The latter two lines are from hexacoordinate tin. In addition, there were low intensity lines between −138 and −144 ppm and between −233 and −243 ppm. It is probable that the more intense hexacoordinate tin signals arise from trimers and the very weak penta- and hexa-coordinate signals come from tetramers. Trimers and (or) tetramers alone could not account for all of the signals observed. One or more dimers must be present and cause at least part of the most intense signals.

The behaviour of the ^{13}C nmr spectra of **5***b* is also complex. At 50°C in chloroform-*d*, the spectrum contains the number of lines anticipated for a monomeric structure but all lines are broad. As the temperature is lowered the lines broaden, split, then sharpen to give very complex patterns. For instance, the signal for C-5 divides into at least two major peaks, plus two peaks of about half the intensity of the major peaks. The coalescence point for the two major peaks for C-5 was about 28°C, giving a rough estimate of $\Delta G^{\ddagger}$ of 14.7 kcal mol^{-1}.

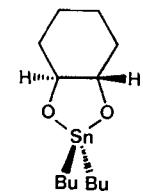
No reactions had previously been performed for **5***b*. Benzylation and benzoylation were performed here. The structures of the benzyl derivatives were assigned by analysis of the ^1H nmr spectra. In each case, the spectra of the dry crystalline sample in dry chloroform-*d* contained a sharp one-hydrogen doublet near 2 ppm due to the OH proton, which could be assigned by decoupling experiments. Analysis of the remainder of the spectra, confirmed by decoupling experiments, yielded the positions of the benzyl groups. The 2-*O*-benzyl derivative (**5***e*) was a known compound (24). Benzoylation was performed in benzene in the presence and absence of triethylamine. Structures of products were determined as for the benzyl derivatives. Little selectivity was observed in these reactions (see Table 4). These results are in contrast to the excellent selectivity claimed for tosylation of **10**, the methyl analog of **5***b* (17).

Discussion

Structures of species present in solution

The spectral results described above have allowed assignment of the species present in solution. Compounds **1***b* and **2***b* are present as single species, the 3,3 dimers. In chloroform-*d*, **4***b* is also present as a single dimer, but now a different one, the 2,2 dimer. Although solutions of **4***b* in toluene-d_8 are more complex, the 2,2 dimer was the major species present at temperatures above −50°C and constituted more than 80% of the species present on a molar basis at 30°C and above, for a 0.19 M solution. Presumably, the more dilute solutions used for reactions would contain even more of the 2,2 dimer and less of the trimers, as was observed for model compounds (11). **3***b* exists as a mixture of dimers in all solvents; the 3,3 dimer, to a lesser extent the 2,3 dimer, and perhaps a small amount of the 2,2 dimer are present. Interconversion of these species is slow on the nmr time-scale, at 50°C in chloroform-*d* and at 100°C in toluene-d_8. **5***b* exists as a rapidly interconverting mixture of dimers and trimers at room temperature.

Steric factors are clearly most important in determining which species is present in solution for a particular stannylene acetal. The compound without adjacent axial substituents (**3***b*) exists as a mixture of dimers; those with one adjacent axial oxygen (**1***b*, **2***b*, and **4***b*) exist in chloroform-*d* as single dimers, the ones with the tricoordinate oxygens not adjacent to the axial groups; two adjacent axial substituents (**5***b*) make all possible dimers less stable. Evidently an adjacent axial substituent destabilizes the dimer that has the closest oxygen atom of the stannylene acetal tricoordinate. Examination of models and of the available crystal structures (9, 10) indicates that the largest destabilizing interaction in a dimer with a tricoordinate oxygen adjacent to an axial substituent is between the axial group and one of the butyl groups on pentacoordinate tin. The interaction between an equatorial substituent and the other butyl group is much less destabilizing. In the crystal structure of **1***b*, the two substituents on the two O-4's in the dimer are each almost equally distant from their adjacent pair of butyl groups; the distances from each of the two O-4's to the closest two α-methylene carbons of the butyl groups calculated from the crystal coordinates (9) are 3.40 and 3.37 Å and 3.65 and 3.48 Å.



14

The behaviour of **3***b* and that of the di-*n*-butylstannylene acetal derived from (*S*,*S*)-1,2-cyclohexanediol (**14**) provide an instructive contrast. Neither compound has axial substituents on carbons adjacent to those bearing the stannylene acetal. In chloroform solutions, **3***b* contains at least two dimers that do not interconvert on the nmr time-scale even at the highest temperature studied, 100°C, and there is no evidence of higher oligomers at any temperature. Compound **14** is present at room temperature as a complex, rapidly interconverting mixture containing dimers, trimers, tetramers, and, to a small extent, pentamers (11). For **14**, interconversion becomes slow on the nmr time-scale only when the temperature is below −30°C. The positions of the complex equilibria are highly dependent on temperature and, to a lesser extent, dependent on concentration. For a 0.43 M solution, the mole fraction of dimer present is 0.15 at −73°C but 0.75 at 27°C. The routes available for equilibration of oligomers were shown to be the reversible association of dimer molecules to tetramers, of dimer and trimer molecules to pentamers, of trimer molecules to hexamers, and of dimer and tetramer molecules to hexamers (11). **3***b* interconverts much more slowly because trimers and still higher oligomers are sterically disfavoured.

The relatively lower stability of higher oligomers for stannylene acetals from carbohydrates with *trans*-diequatorial-1,2-diols probably arises from interactions between alternate monomer units in the higher oligomer, for instance, between the terminal units of a trimer. The distorted octahedral arrangement about a hexacoordinate tin atom in a higher oligomer holds the two four-membered Sn_2O_2 rings attached to that tin atom close to coplanar, and the three attached 1,3,2-dioxastannolane rings are also close to coplanar. Hence, the alternate carbohydrate rings are nearly coplanar, but the shortest distance between coordinated oxygen atoms on these rings is about 4.8 Å due to the two long Sn--O bonds (2.50 Å) and the large O--Sn--O angle (142–151°) (8, 10). The distance between alternate rings is slightly increased because the bonds from the coordinated oxygens to the rings are inclined slightly away from each other. However, the ends of the two rings decrease the separation by about 2.5 Å so that the distance between C-1 on one ring and C-4 on the other is in the order of 2–4 Å. Therefore, equatorial substituents on those two carbons, particularly large substituents, will cause severe nonbonded interactions between

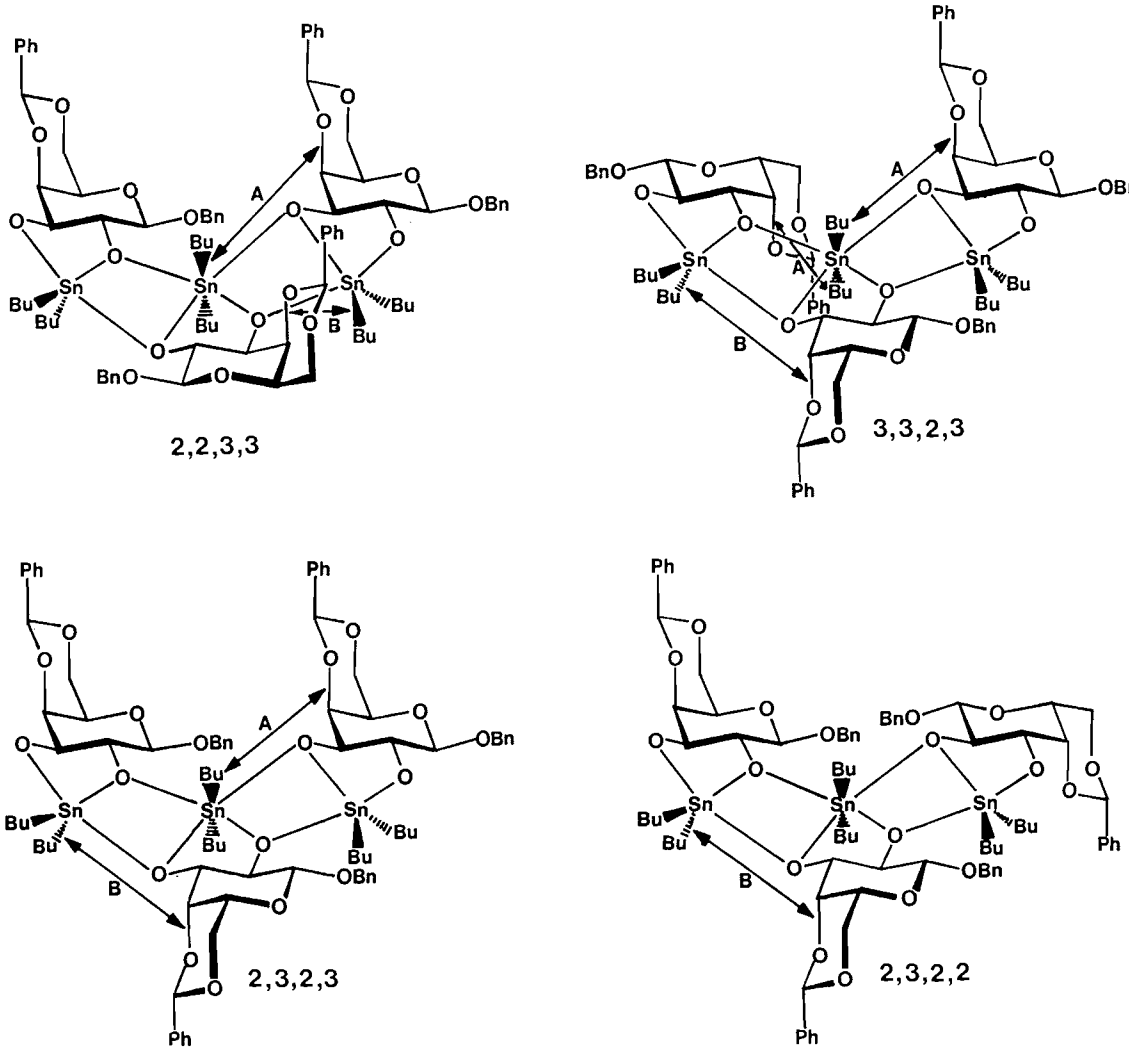


FIG. 3. Possible trimer structures for compound **4***b*. Steric interactions between axial substituents and butyl groups on hexacoordinate and pentacoordinate tin are indicated by arrows labelled by the letters A and B, respectively.

alternate monomer units in the higher oligomers. A single large rigid equatorial substituent, like a 4,6-*O*-benzylidene ring with a length of about 8 Å, as in **1***b* or **2***b*, is quite sufficient to inhibit higher oligomer formation. The equatorial *O*-benzyl group, as in **4***b*, is less effective. In chloroform-*d* no higher oligomers were observed, but in toluene-d_8 the signals of higher oligomers were prominent, particularly at low temperatures. Presumably, in higher oligomers of **4***b*, the rotamer about the C1—O1 bond favoured by the *exo*-anomeric effect and the rotamers about the O1—CH_2 bond that take the phenyl group away from the stannylene side of the molecule are populated. The formation of higher oligomers for **3***b* is very unfavourable. Interconversion of dimers for **3***b*, which occurs via higher oligomers for **14**, is observed to be very slow, in agreement with the conclusion drawn above and earlier (11) that the normal lowest energy mechanism for interconversion of dimers involves higher oligomers. Consideration of the formation and cleavage of various higher oligomers shows that oligomers with odd numbers of monomer units must be involved to interconvert 3,3 dimers and 2,3 dimers. **5***b*, with axial substituents at both C-1 and C-4, avoids the severe interannular steric interactions in the higher oligomers. Hence, it is present as trimers and tetramers as well as dimers, and the various species interconvert rapidly at room temperature.

The slight preferences for **3***b* to assume a 3,3 dimer rather than a 2,3 dimer are calculated to be 0.24 and 0.65 kcal mol^{-1} in chloroform-*d* and toluene-d_8, respectively, at 299 K. If it is assumed that this difference reflects the difference in energy for O-3 rather than O-2 to be tricoordinate, the relative stability of the 2,2 dimer can be calculated. Evaluation of the equilibrium constants indicates that the 2,2 dimer should be present at 21% and 8% levels in chloroform-*d* and toluene-d_8, respectively. No signals assignable to the 2,2 dimer were observed in toluene-d_8. In chloroform-*d*, it may have been present at the 5% level. Obviously, the 2,2 dimer is less stable than was anticipated on the basis of the relative stabilities of the 3,3 and 2,3 dimers. The small difference in stability between the 3,3 and 2,3 dimers may simply be due to the effects associated with the greater freedom of movement of the glycosidic benzyl group than the almost identically sized but sterically restricted 4,6-*O*-benzylidene group.

The considerations discussed above can be used to assign the structures of the trimers present in toluene-d_8 solutions of **4***b*. The four possible structures and the destabilizing interactions contained in each are illustrated in Fig. 3. The 2,3,2,2 structure can be ruled out because it has two equatorial *O*-benzyl groups opposing each other from the inside ends of the two terminal units of the trimer. Support for this contention can be drawn

For personal use only.

from the equilibrium mixture present for **3***b*; no trimers were observed although its 2,3,2,2 trimer would be destabilized only by this interaction. The 3,3,2,3 trimer has no interactions between equatorial substituents on the terminal units but has the maximum number of intermonomer interactions between axial *O*-4 benzylidene groups and butyl groups on tin atoms: two interactions involving butyl groups on a hexacoordinate tin atom (A type) and one involving a butyl group on a pentacoordinate tin atom (B type). The 2,2,3,3 and 2,3,2,3 trimers should have similar stabilities because each has two different intermonomer interactions (types A and B). These two isomers should also have similar chemical shifts because they differ only by changing the bonding order of the central unit. Because two dimers of similar stabilities having small chemical shift differences between each of the pairs of tin signals were observed, it is considered most likely that the species present are these two latter structures.

The presence of higher oligomers in solutions of **4***b* in toluene-d_8 in contrast to their absence in chloroform-*d* can be ascribed to the lower polarity of the former solvent. Less polar solvents should favour association of the relatively polar stannylene acetals. Similar results have been observed for other carbohydrate-derived stannylene acetals.[1]

The cause of the selectivity and the reaction mechanism

David *et al.* suggested that the structure of the dimer present determines the product obtained in these reactions (7). For the first time, the exact structures present in solution have been determined here. For some compounds, the products obtained are directly related to the nature of the major species present. When a stannylene acetal exists predominantly as a single dimer (**1***b*, **2***b*, **4***b*), reaction normally occurs at the dicoordinate oxygen although products of attack at the other oxygen are sometimes observed. These other products are only found when the reaction is conducted in the presence of added nucleophiles or polar solvents at higher than room temperature.

Compound **3***b* contains a mixture of the 3,3 dimer (major) and the 2,3 dimer (minor). The amounts of the two dimers present determine the extent to which the individual oxygen atoms are dicoordinate. For a 0.2 M solution in benzene-d_6 at 26°C, 86% of the O-2's in the two types of dimer are dicoordinate. Benzoylation of **3***b* in benzene at room temperature in the absence of additional nucleophiles yields a mixture of products containing more of the 2-benzoate (53:37) but the product composition does not match the amount of dicoordinate oxygen. Additional factors need to be considered. Possibly the different dicoordinate oxygen atoms have different reactivities. Another explanation could be that the chloride released from benzoyl chloride affects the product composition, as do added nucleophiles. In the presence of added nucleophiles, a preference for addition at O-3 is observed.

Compound **5***b* is present as a complex, rapidly interconverting mixture and little selectivity is obtained. The tosylation of the methyl analogue **7** reported by Munavu and Szmant (17) is anomalous in this regard.

The cause of the enhanced reactivity towards electrophiles of the oxygens in stannylene acetals has been the subject of considerable discussion (2). One suggestion was that electron density was transferred from the electropositive tin atom to the dicoordinate oxygen, making it more nucleophilic. If considerable electron density had been transferred to the dicoordinate oxygen, upfield chemical shifts would be observed for the attached carbon. Similarly, Lewis structures of these species suggest that the tricoordinate oxygen is electron deficient and a significant downfield shift for the attached carbon is anticipated. For instance, protonation or methylation of ethereal or alcoholic oxygens results in downfield shifts of 10–19 ppm for α-carbons (25). Comparison of the ^{13}C nmr shifts of starting diols and stannylene acetals (Table 3) demonstrates that the chemical shift of the carbon that becomes attached to the dicoordinate oxygen moves downfield by 3–5 ppm, while the carbon that becomes attached to the tricoordinate oxygen moves downfield by 1–3 ppm, similar to the effects observed for most of the other carbons in the diols. The magnitudes and directions of these changes in shift are similar to the values observed when normal acetals are formed (26). Surprisingly, the observed chemical shift changes are not consistent with significant transfers of electron density to or from oxygen on formation of the stannylene acetal. Similar results were obtained when the effects of complexation with tin (27) were compared with the effects of protonation (28) on ^1H and ^{13}C nmr chemical shifts of pyridines.

A possible explanation for the rate enhancement observed for the stannylene acetals is that significant electron transfer towards the dicoordinate oxygen only occurs in the transition state for reaction, when there is greatly increased electron demand.

Of the literature studies, the results of oxidation of the 2,3-*O*-dibutylstannylene acetals of methyl 3′,4′-*O*-isopropylidene-α- and -β-lactoside are contrary to the general trend observed for simple glucose derivatives **1***b*, **2***b*, **3***b*, and **7** (Table 4), since the α-derivative (**6**) gives a mixture while the β-derivative (**8**) gives one product (20). However, these particular glucose derivatives (**6** and **8**) have a very large equatorial substituent on O-4, a 3,4-*O*-isopropylidene-β-D-galactose unit. Presumably the butyl groups on tin in the 3,3 dimer are sufficiently close to this large group for this particular dimer to be sterically destabilized. Thus compound **6** probably exists as a rapidly interconverting mixture of species, like compound **5***b*, while **8** is present as a single species, like **1***b* and **2***b*. Oxidation of stannylene acetals with bromine is the reaction most likely to give products with structures directly related to the species present in solution because the reaction occurs instantaneously.

The oxidation of the dibutylstannylene acetal of methyl 2-*O*-methyl-6-*O*-triphenylmethyl-α-D-glucopyranoside (**9**) gives a single product, in accord with the results on **6** and **8** (18). Here the stannylene acetal oxygen atoms are flanked by two equatorial groups, as for **3***b*, but one is much larger, a triphenylmethoxymethyl group, as compared with a methoxy group. Thus the dimer having the dicoordinate oxygen atom close to the large group, the 3,3 dimer, should be favoured, and reaction should take place at position 4, as observed. The benzoylation reaction on **9** did not give results in accord with this suggestion but the long time required for the reaction to go to completion, 48 h, may allow the inherently greater reactivity of position 3 (18) to influence the results.

The results obtained on compounds **6**, **8**, and **9** indicate that the proper choice of groups on centres adjacent to diol units used to form stannylene acetals may allow direction of electrophiles to one of the two diol oxygens.

The results of benzylation of the dibutylstannylene acetal of 1,2:5,6-*O*-cyclohexylidene-*myo*-inositol (**13**) (23) also appear to be contrary to the predictions made here because the two oxygen atoms in the acetal are equatorial and flanked by equatorial and axial groups if the inositol ring is present in a

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

chair conformation. However, the vicinal coupling constants in the ^{1}H nmr spectrum of **13** (23) show that it is not present in a chair conformation, making predictions unreliable. The results of benzylation of compound **12** (23) are similar to those with similar adjacent stereochemistry, **3***b* and **7**, as expected.

Conclusions

The regioselectivity of reactions of dibutylstannylene acetals derived from *trans*-1,2-diols on six-membered rings with electrophiles in the absence of added nucleophiles is determined by the structure of the dimer and (or) oligomers present in solution. In a dimer, two of the oxygen atoms are dicoordinate and two are tricoordinate. If only a single dimer is present, reaction occurs on the two dicoordinate oxygen atoms. The structures of the dimers or oligomers formed are determined by the stereochemistry of the substituents on carbons adjacent to the diol oxygens. Axial substituents destabilize species that have the adjacent oxygen atom tricoordinate, probably because of repulsive steric interactions between the axial substituent and one of the butyl groups on tin. As a result, compounds with one adjacent substituent axial and the other equatorial exist mainly as single dimers and give virtually regiospecific reactions on the oxygen atom adjacent to the axial substituent. Compounds having other stereochemistries for adjacent substituents do not give highly regioselective reactions and exist as mixtures of dimers and (or) higher oligomers.

Experimental

Melting points were determined using a Fisher–Johns melting point apparatus and are uncorrected. Rotations were measured with a Perkin–Elmer model 141 polarimeter. Elemental analyses were performed by Canadian Microanalytical Service Ltd., Vancouver, B.C. Thin-layer chromatography (tlc) was performed on 0.20 mm thick Merck silica gel 60F-254 aluminum sheets cut to be approximately 7 cm long. Components were located by spraying with 2% ceric sulfate in 2 N sulfuric acid and heating on a hot plate for a few minutes at 150°C. Column chromatography was performed on 60–200 mesh silica gel. The ^{1}H, ^{13}C, and ^{119}Sn nmr spectra at 361.04, 90.79, and 134.62 MHz respectively were recorded on a Nicolet NT-360 NB spectrometer. The ^{119}Sn nmr spectra were recorded with gated broad-band decoupling on only during acquisition and pulse intervals of 0.85–3 s. The short pulse intervals were used because ^{119}Sn atoms in dialkyldialkoxytin compounds, where the tin atom is pentacoordinate or hexacoordinate, have T_1 values in the 10–200 ms range (29). Under these conditions, signal intensity will be directly related to the amount of ^{119}Sn present. The ^{119}Sn nmr chemical shifts were referenced to external tetramethyltin. The ^{1}H nmr spectra at 60 MHz and ^{13}C nmr spectra at 20 MHz were measured on Varian EM-360L and Varian CFT-20 spectrometers respectively. Solutions for ^{1}H and ^{13}C nmr spectra were prepared in chloroform-*d* with tetramethylsilane (TMS) as internal reference, unless stated otherwise. Chemical shifts are reported in ppm downfield from TMS. The ^{1}H nmr spectra were analysed on a first-order basis. The appearance of ^{13}C nmr signals in off-resonance decoupled or in coupled spectra are indicated in the experimental using the designations s, d, t, and q. Solid-state ^{13}C and ^{119}Sn nmr spectra were recorded on a Bruker MSL 200 nmr spectrometer at 50.32 and 74.54 MHz respectively. In the work-up of reactions, the final organic solutions were dried with anhydrous magnesium sulfate, then filtered. Acetylation reactions were performed by stirring the compound in dried pyridine and acetic anhydride at room temperature. Pyridine was dried by distilling from barium oxide after refluxing for 4 h, and it was maintained over anhydrous calcium sulfate. The term "pet ether" refers to petroleum ether 30–60°C.

Methyl 4,6-*O*-benzylidene-α-D-glucopyranoside (**1***a*) (30), benzyl 4,6-*O*-benzylidene-α-D-glucopyranoside (**2***a*) (12), benzyl 4,6-*O*-benzylidene-β-D-glucopyranoside (**3***a*) (31), and benzyl 4,6-*O*-benzylidene-β-D-galactopyranoside (**4***a*) (32) were prepared by standard methods and had physical constants in agreement with literature values. For most ^{13}C chemical shifts, see Table 2. The other values are δ: **1***a*, 137.1, 129.1, 128.2, 126.3 (Ph C); **1***b*, 136.9, 128.3, 129.4, 126.4 (Ph C), 27.0, 26.8 (β- and γ-Bu C), 23.5, 22.0 (α-Bu C), 13.6, 13.4 (δ-Bu C); **1***b* (solid state), 138.8, 138.5, 131.7, 131.3, 129.4, 128.9, 127.4 (Ph C), 28.5, 27.9, 27.0, 25.7 (β- and γ-Bu C), 23.1, 22.2 (α-Bu C), 15.9, 15.3, 14.3, 13.9 (δ-Bu C); **2***b*, 27.2, 27.0, 26.9, 26.7 (β- and γ-Bu C), 23.6, 21.9 (α-Bu C), 13.7, 13.6 (δ-Bu C); **3***b*, 27.2, 26.9, 26.7 (β- and γ-Bu C), 23.7, 22.1 (α-Bu C), 13.6, 13.5 (δ-Bu C), lower intensity signals, 23.8, 23.7, 13.7, 13.5; **4***a*, 137.4, 137.0, 129.2, 128.5, 128.2, 128.0, 126.4 (Ph C); **4***b* (chloroform-*d*), 138.0, 136.5, 128.7, 128.4, 128.3, 128.1, 127.8 (Ph C), 27.2, 27.0, 26.7 (β- and γ-Bu C), 23.7 ($^1J_{Sn,C}$ 586, 612 Hz), 22.6 ($^1J_{Sn,C}$ 580, 603 Hz) (α-Bu C), 13.7, 13.6 (δ-Bu C).

Sample preparation for nuclear magnetic resonance

Most solutions for ^{119}Sn nmr spectroscopy were prepared by refluxing equimolar amounts of the diol and di-*n*-butyltin oxide for 12 h in benzene in an apparatus for the azeotropic removal of water. The clear solutions in benzene were attached to a vacuum system, then concentrated to a solid. Previously dried and degassed nmr solvents, stored under vacuum over molecular sieves, were distilled under vacuum onto the solid. The resulting solutions were transferred through a sintered glass frit under vacuum to the nmr tube, which was then sealed. A few samples were prepared under argon but not sealed.

*Benzyl 4,6-O-benzylidene-α-D-galactopyranoside (**5**a)*

A solution of D-galactose (100 g) and *p*-toluenesulfonic acid (5 g) in benzyl alcohol (188 mL) was kept at 70–80°C for 3 days, cooled, and then poured into an excess of ether. The ether solution was stirred for 15 min and stored overnight at room temperature. The supernatant was decanted from a syrupy residue that contained both benzyl pyranosides. A mixture of this residue and zinc chloride (62.5 g) in benzaldehyde (188 mL) was stirred vigorously at room temperature for 3 h, then poured into a mixture of water (375 mL) and pet ether (375 mL). The solution was stirred for 30 min. The oily product was separated using a separatory funnel, then dissolved in the minimum volume of hot ethanol (containing ammonia). The ethanolic solution was poured into excess water. The oily product was again separated, then fractionated into α and β anomers by column chromatography on silica gel using 4:1 chloroform–THF as eluent (R_f's 0.42, 0.24). The title compound (**5***a*) was recrystallized from ethanol as fine needles, mp 109–110°C, $[\alpha]_D^{22.5}$ +109.4° (*c* 1.2, chloroform) (lit. (33) mp 108–109°C, $[\alpha]_D^{20}$ +117°); ^{1}H nmr δ: 3.60 (1H, br s, H-5), 3.92 (2H, m, H-2 and H-3), 3.98 (1H, dd, $J_{6,6'}$ = 12.53 Hz, $J_{5,6}$ = 1.49 Hz, H-6), 4.17 (1H, m, H-4), 4.18 (1H, dd, $J_{5,6'}$ = 1.27 Hz, H-6'), 4.60 and 4.72 (2H, 2d, J = 11.92 Hz, $PhCH_2$), 5.11 (1H, d, $J_{1,2}$ = 1.91 Hz, H-1), 5.50 (1H, s, benzal H), 7.26–7.50 (10H, m, Ph H), ^{13}C nmr δ: 63.0 (d, C-5), 69.1 (dd, C-6), 69.4, 69.5 (2 d, C-2 and C-3), 70.0 (t, $PhCH_2$), 76.0 (d, C-4), 98.7 (d, C-1), 101.0 (d, benzal C), 126.0–137.5 (Ph C).

General procedure for preparation of di-n-butylstannylene derivatives of monosaccharides

An equimolar mixture of monosaccharide and di-*n*-butyltin oxide in benzene was refluxed 12 h in an apparatus equipped for the azeotropic removal of water. Evaporation of solvent under reduced pressure gave the crude stannylene derivative, which was used for acylation and alkylation reactions without further purification.

*Benzylation of **3**a*

To a solution of stannylene derivative of **3***a* (1 mmol) in benzene (25 mL) was added powdered molecular sieves (type 4A, 1 g), tetra-*n*-butylammonium iodide (0.37 g, 1 mmol), and benzyl bromide (520 μL, 4.4 mmol). The mixture was refluxed for 24 h, then cooled and filtered. The filtrate was diluted with dichloromethane (50 mL). The resulting solution was washed with a 1 M sodium thiosulfate solution (20 mL) and with water (2 × 20 mL), then dried and concentrated. The syrup was dissolved in chloroform and filtered through a short column of silica gel to give a mixture of **3***c* and

For personal use only.

3*d* (340 mg). The major component was benzyl 3-*O*-benzyl-4,6-*O*-benzylidene-β-D-glucopyranoside (**3***d*); ^{1}H nmr δ: 2.43 (1H, d, $J_{H,H}$ = 1.96 Hz, HO-2), 3.40–3.48 (1H, m, H-5), 3.6 (1H, dd, H-2), 4.38 (1H, dd, H-6$_{eq}$), 4.50 (1H, d, $J_{1,2}$ = 7.45 Hz, H-1), 4.63–5.00 (CH_2Ph), 5.58 (1H, s, benzal H), 7.25–7.50 (m, Ph); ^{13}C nmr δ: 66.6 (d, C-5), 68.8 (dd, C-6), 71.4 (t, $PhCH_2$-O C-1), 74.4 (d, C-2), 74.6 (t, $PhCH_2$-O C-3), 80.3 (d, C-4), 81.4 (d, C-3), 101.3 (d, benzal C), 102.3 (d, C-1). The minor component was benzyl 2-*O*-benzyl-4,6-*O*-benzylidene-β-D-glucopyranoside (**3***c*); ^{1}H nmr δ: 2.48 (1H, d, J = 2.0 Hz, HO-3), 3.40–3.48 (1H, m, H-5), 4.63–5.00 (CH_2Ph), 4.65 (1H, d, H-1), 5.53 (1H, s, benzal H); ^{13}C nmr δ: 66.2 (d, C-5), 68.8 (dd, C-6), 71.6 (t, $PhCH_2$-O C-1), 73.3 (d, C-3), 74.9 (t, $PhCH_2$-O C-2), 80.5 (d, C-4), 81.9 (d, C-2), 101.8 (d, benzal C), 102.8 (d, C-1). The mixture was acetylated and the components in the mixture of the acetates were identified by assignment of signals of skeletal protons with shifts greater than 5 ppm by means of single frequency homonuclear decoupling experiments starting with the doublet of H-1 from the major isomer. The major isomer was benzyl 2-*O*-acetyl-3-*O*-benzyl-4,6-*O*-benzylidene-β-D-glucopyranoside (**3***f*); ^{1}H nmr δ: 1.95 (3H, s, $COCH_3$), 3.43 (1H, dt, H-5), 3.69 (1H, t, J = 9.10 Hz, H-3), 3.801 (1H, t, J = 9.4 Hz, H-4), 3.83 (1H, t, J = 10.3 Hz, H-6$_{ax}$), 4.38 (1H, dd, $J_{6eq,6ax}$ = 10.46 Hz, $J_{5,6eq}$ = 4.96 Hz, H-6$_{eq}$), 4.52 (1H, d, $J_{1,2}$ = 7.94 Hz, H-1), 4.589, 4.879 (2H, 2d, J = 12.35 Hz, CH_2Ph), 4.659, 4.864 (2H, 2d, J = 12.12 Hz, CH_2Ph), 5.10 (1H, dd, $J_{1,2}$ = 7.98 Hz, $J_{2,3}$ = 9.00 Hz, H-2), 5.58 (1H, s, benzal H), 7.30–7.50 (m, Ph H). The minor isomer was benzyl 3-*O*-acetyl-2-*O*-benzyl-4,6-*O*-benzylidene-β-D-glucopyranoside (**3***e*); ^{1}H nmr δ: 2.08 (3H, s, $COCH_3$), 3.494 (1H, dd, $J_{1,2}$ = 7.79 Hz, $J_{2,3}$ = 9.14 Hz, H-2), 3.50 (1H, m, H-5), 3.595 (1H, t, J = 9.5 Hz, H-4), 3.785 (1H, t, J = 10.1 Hz, H-6$_{ax}$), 4.64, 4.66, 4.86, 4.96 (4H, 4d, J = 11.8, 12.3 Hz, 2 CH_2Ph), 4.72 (1H, d, $J_{1,2}$ = 7.7 Hz, H-1), 5.31 (1H, t, J = 9.3 Hz, H-3), 5.46 (1H, s, benzal H), 7.30–7.50 (15H, m, Ph H).

The ratios of **3***c* to **3***d* obtained from the peak heights of H-1 in the spectra of the mixture and of the acetylated mixture were 28:72. Thus, the overall yields for **3***c* and **3***d* were 21 and 55% respectively.

Benzoylation of **3**a

A solution of benzoyl chloride (130 μL, 1.1 mmol) in benzene (25 mL) was added dropwise over 30 min to a vigorously stirred mixture of **3***b* (1 mmol) and powdered molecular sieves (type 4A, 1 g) in benzene (50 mL). After being stirred for 2 h, the mixture was filtered. The filtrate was diluted with dichloromethane (100 mL) and the solution was washed with water (2 × 25 mL), dried, and concentrated. The resulting solid was separated by column chromatography on silica gel using chloroform–hexane – ethyl acetate (6:3:1) as eluent. The first fraction (102 mg, 22%) was recrystallized from ethyl acetate and pet ether to give fine needles of benzyl 3-*O*-benzoyl-4,6-*O*-benzylidene-β-D-glucopyranoside (**3***g*); mp 168–169°C, $[\alpha]_D^{25}$ −105.5° (*c* 0.77, chloroform) (lit. (13) mp 167–169°C, $[\alpha]_D$ −103.5°); ^{1}H nmr δ: 2.62 (1H, d, $J_{2,OH}$ = 3.14 Hz, OH-2), 3.60 (1H, dt, $J_{4,5}$ = $J_{5,6ax}$ = 9.5 Hz, $J_{5,6eq}$ = 4.82 Hz, H-5), 3.80 (1H, ddd, $J_{1,2}$ = 7.68 Hz, $J_{2,3}$ = 9.7 Hz, H-2), 3.84 (1H, t, $J_{3,4}$ = $J_{4,5}$ = 9.6 Hz, H-4), 3.86 (1H, t, H-6$_{ax}$), 4.42 (1H, dd, $J_{6eq,6ax}$ = 10.51 Hz, H-6$_{eq}$), 4.65 (1H, d, H-1), 4.69, 4.97 (2H, 2d, J = 11.65 Hz, $PhCH_2$), 5.48 (1H, t, $J_{3,4}$ = $J_{2,3}$ = 9.7 Hz, H-3), 5.54 (1H, s, benzal H), 7.20–8.10 (15H, m, Ph H); ^{13}C nmr δ: 66.6 (C-5), 68.7 (C-6), 71.6 (CH_2Ph), 73.6 (C-2), 74.2 (C-3), 78.6 (C-4), 101.5 (C-7), 102.5 (C-1), 126.1–136.8 (Ph C), 166.4 (C=O). A mixed fraction (152 mg) was followed by another solid (164 mg, 35%), which was recrystallized from the same solvent mixture to give fine needles of benzyl 2-*O*-benzoyl-4,6-*O*-benzylidene-β-D-glucopyranoside (**3***h*); mp 154–155.5°C; $[\alpha]_D^{25}$ −78.6° (*c* 0.91, chloroform) (lit. (13) mp 154–156°C; $[\alpha]_D$ −96.4° (*c* 0.44, chloroform)); ^{1}H nmr δ: 2.72 (1H, d, $J_{3,OH}$ = 3.14 Hz, OH-3), 3.51 (1H, dt, $J_{5,6eq}$ = 4.89 Hz, $J_{4,5}$ = $J_{5,6ax}$ = 9.8 Hz, H-5), 3.70 (1H, t, $J_{3,4}$ = $J_{4,5}$ = 9.2 Hz, H-4), 3.86 (1H, t, $J_{5,6ax}$ = $J_{6eq,6ax}$ = 10.4 Hz, H-6$_{ax}$), 4.01 (1H, dt, $J_{2,3}$ = $J_{3,4}$ = 9.2 Hz, H-3), 4.42 (1H, dd, H-6$_{eq}$), 4.65, 4.88 (2H, 2d, J = 12.52 Hz, $PhCH_2$), 4.71 (1H, d, $J_{1,2}$ = 7.91 Hz, H-1), 5.26 (1H, dd, $J_{2,3}$ = 9.17 Hz, H-2), 5.58 (1H, s, benzal H), 7.20–8.02 (15H, m, Ph H); ^{13}C nmr δ: 66.2 (C-5), 68.6 (C-6), 70.6 (CH_2Ph), 72.5 (C-3), 74.8 (C-2), 80.9 (C-4), 99.7 (C-1), 101.9 (C-7), 126.3–136.9 (Ph C), 165.9 (C=O). The mixed fraction consisted of **3***h* and **3***g* in the ratio of 23:27 as measured by ^{1}H nmr peak heights, giving overall yields of **3***h* and **3***g* of 53 and 37%, respectively.

Benzylation of **5**a

To a solution of stannylene derivative of **5***a* (0.5 mmol) in benzene (20 mL) was added powdered molecular sieves (type 4A, 0.5 g), tetra-*n*-butylammonium bromide (161 mg, 0.5 mmol), and benzyl bromide (65 μL, 0.55 mmol). The mixture was refluxed for 48 h, then cooled and filtered. The filtrate was diluted with dichloromethane (50 mL) and the solution was washed with water (2 × 20 mL), dried, and concentrated to a syrup that was separated by column chromatography on silica gel using 9:1 chloroform – ethyl acetate as eluent. The first fraction, a solid (80 mg, 36%), was crystallized from ethyl acetate and pet ether to give fine needles containing benzyl 3-*O*-benzyl-4,6-*O*-benzylidene-α-D-galactopyranoside (**5***f*) and one equivalent of water of crystallization; mp 134–136°C, $[\alpha]_D^{22.5}$ +128.3° (*c* 0.71, chloroform); ^{1}H nmr δ: 1.580 (2H, s, H_2O of crystallization), 2.194 (1H, d, $J_{2,OH}$ = 7.05 Hz, OH), 3.59 (1H, br s, H-5), 3.842 (1H, dd, $J_{2,3}$ = 10.01 Hz, $J_{3,4}$ = 3.40 Hz, H-3), 3.976 (1H, dd, $J_{5,6}$ = 1.64 Hz, $J_{6,6'}$ = 12.55 Hz, H-6), 4.188 (1H, dd, $J_{5,6'}$ = 1.49 Hz, H-6′), 4.21 (1H, narrow m, H-4), 4.24 (1H, ddd, H-2), 4.75 (2H, s, $PhCH_2$-O C-3), 4.74 and 4.66 (2H, 2d, $J_{H,H}$ = 11.97 Hz, $PhCH_2$-O C-1), 5.20 (1H, d, $J_{1,2}$ = 3.79 Hz, H-1), 5.45 (1H, s, benzal H), 7.27–7.93 (15H, m, Ph H). Anal. calcd. for $C_{27}H_{28}O_6 \cdot H_2O$: C 69.51, H 6.48; found: C 69.52, H 6.45. A mixed fraction (75 mg) was followed by a solid (50 mg, 22%), which was also recrystallized from ethyl acetate and petroleum ether to give fine needles of benzyl 2-*O*-benzyl-4,6-*O*-benzylidene-α-D-galactopyranoside (**5***e*); mp 131.5–133.5°C, $[\alpha]_D^{22.5}$ +88.7° (*c* 0.62, chloroform) (lit. (24) mp 131.5–133°C, $[\alpha]_D$ +103°); ^{1}H nmr δ: 2.422 (1H, d, $J_{3,OH}$ = 7.43 Hz, OH), 3.69 (1H, br s, H-5), 3.85 (1H, dd, $J_{1,2}$ = 3.47 Hz, $J_{2,3}$ = 9.95 Hz, H-2), 4.03 (1H, dd, $J_{6,6'}$ = 12.55 Hz, $J_{5,6}$ = 1.62 Hz, H-6), 4.20 (1H, dd, $J_{5,6'}$ = 1.19 Hz, H-6$_{eq}$), 4.22 (1H, ddd, H-3), 4.30 (1H, br d, $J_{3,4}$ = 3.7 Hz, H-4), 4.552, 4.575, 4.694, 4.694 (4H, 4d, J = 11.26, 11.52 Hz, 2 CH_2Ph), 5.06 (1H, d, $J_{1,2}$ = 3.42 Hz, H-1), 5.56 (1H, s, benzal H), 7.09–7.52 (15H, m, Ph H). Anal. calcd. for $C_{27}H_{28}O_6$: C 72.31, H 6.29; found: C 72.07, H 6.29.

The mixed fraction consisted of **5***e* and **5***f* in the ratio of 3:2 as measured by ^{1}H nmr spectroscopy. Thus, the overall yields for **5***e* and **5***f* were 43 and 49%.

Benzoylation of **5**a

5*b* (1 mmol) was benzoylated exactly as for **3***b*. The resulting syrup was separated by column chromatography on silica gel using chloroform – ethyl acetate (99:1) as eluent. The first fraction, a solid (84 mg, 18%), was recrystallized from ethyl acetate and pet ether to give fine colorless needles of benzyl 3-*O*-benzoyl-4,6-*O*-benzylidene-α-D-galactopyranoside (**5***h*); mp 148–149°C, $[\alpha]_D^{25}$ +218.9° (*c* 1.14, chloroform); ^{1}H nmr δ: 2.02 (1H, d, $J_{2,OH}$ = 10.71 Hz, OH-2), 3.77 (1H, br s, H-5), 4.04 (1H, dd, $J_{5,6}$ = 1.34 Hz, $J_{6,6'}$ = 10.50 Hz, H-6), 4.24 (1H, dd, $J_{5,6'}$ = 1.30 Hz, H-6′), 4.35 (1H, dt, $J_{1,2}$ = 3.75 Hz, $J_{2,3}$ = $J_{2,OH}$ = 10.7 Hz, H-2), 4.49 (1H, d, $J_{3,4}$ = 3.39 Hz, H-4), 4.66, 4.80 (2H, 2d, J = 11.79 Hz, $PhCH_2$), 5.24 (1H, d, H-1), 5.43 (1H, dd, H-3), 5.52 (1H, s, benzal H), 7.25–8.08 (15H, m, Ph H). Anal. calcd. for $C_{27}H_{26}O_7$: C 70.12, H 5.67; found: C 70.10, H 5.51. A mixed fraction (234 mg) was followed by a syrup (75 mg, 16%), which was crystallized from the same solvent mixture to give fine colorless needles of benzyl 2-*O*-benzoyl-4,6-*O*-benzylidene-α-D-galactopyranoside (**5***g*); mp 118–119°C; $[\alpha]_D^{25}$ +144.6° (*c* 0.88, chloroform); ^{1}H nmr δ: 2.43 (1H, d, $J_{3,OH}$ = 10.43 Hz, OH-3), 3.82 (1H, br s, H-5), 4.08 (1H, dd, $J_{5,6}$ = 1.60 Hz, $J_{6,6'}$ = 12.51 Hz, H-6), 4.29 (1H, dd, $J_{5,6'}$ = 1.00 Hz, H-6′), 4.36 (1H, br s, H-4), 4.38 (1H, m, H-3), 4.62, 4.76 (2H, 2d, J = 12.38 Hz, $PhCH_2$), 5.30 (1H, d, $J_{1,2}$ = 3.53 Hz, H-1), 5.40 (1H, dd, $J_{2,3}$ = 9.82 Hz, H-2), 5.59 (1H, s, benzal H), 7.23–8.09 (15H, m, Ph H). Anal. calcd. for $C_{27}H_{26}O_7$: C 70.12, H 5.67; found: C 69.99, H 5.67. The mixed

fraction consisted of **5***g* and **5***h* in the ratio of 11:14 as measured from the average of several ^{1}H nmr peak heights, to give overall yields of **5***g* and **5***h* of 38 and 46%, respectively.

A reaction conducted exactly as above, but with 1,2-dimethoxyethane as solvent and with triethylamine (154 μL, 1 mmol) present, gave a mixture of **5***g* and **5***h* in the ratio of 51:49 as measured from ^{1}H nmr peak heights from a sample of the crude product.

Acknowledgements

We thank Drs. R. Wasylishen and M. McKinnon for recording the solid-state nmr spectra and Dr. N. Burford for help with preparing nmr samples under vacuum. We are grateful to the Atlantic Research Laboratories of NRC for use of their polarimeter. The financial support of the Natural Sciences and Engineering Research Council of Canada is gratefully acknowledged.

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

MARTIN B. HOCKING and GORDON W. BUSHNELL. Can. J. Chem. **68**, 1020 (1990).

Preparations of a 7-phosphanorbornene, from the reaction of 1,2,5-triphenylphosphole-1-oxide with inhibited acrylonitrile in benzene, were repeated under various conditions to determine if one, or more than one, stereoisomer was formed. Adduct formation failed to occur when the reaction was attempted in ethanol, or when the precursor 1,2,5-triphenylphosphole was substituted for the phosphole oxide. Elemental analysis and spectroscopic measurements confirmed that a 1:1 adduct had been obtained, and an X-ray structure determination of the ethanol complex established that this was 5-cyano-1,4,7-triphenyl-7-phosphabicyclo[2.2.1]hept-2-ene-7-oxide, **3***a*. Details of the ^{1}H, ^{13}C, and ^{31}P NMR assignments, of potential value in the structural assignment of other similar adducts, are related to previous results. The results of a brief mass spectrometric analysis of the changes in the thermal fragmentation pattern of the adduct with temperature are discussed in relation to the synthetic reaction.

Key words: phosphole adduct, phosphanorbornene, phosphabicycloheptene, acrylonitrile.

MARTIN B. HOCKING et GORDON W. BUSHNELL. Can. J. Chem. **68**, 1020 (1990).

Dans le but de déterminer s'il se forme un ou plusieurs stéréoisomères, on a fait varier les conditions expérimentales utilisées lors de préparations d'un 7-phosphanorbornène par réaction du 1,2,5-triphénylphosphole-1-oxyde avec de l'acrylonitrile inhibé, dans le benzène. Il n'y a pas de formation d'adduit lorsqu'on essaye de réaliser la réaction dans l'éthanol ou lorsqu'on essaye de substituer l'oxyde par le 1,2,5-triphénylphosphole. Des analyses élémentaires et des données spectroscopiques ont permis de confirmer qu'un adduit 1:1 est obtenu et la diffraction des rayons-X du complexe avec l'éthanol a permis d'établir sa structure, le 5-cyano-1,4,7-triphényl-7-phosphabicyclo[2.2.1]hept-2-ène-7-oxyde, **3***a*. On a établi une corrélation entre les attributions détaillées de ses spectres RMN du ^{1}H, du ^{13}C et du ^{31}P et ceux obtenus antérieurement; ces données peuvent s'avérer utiles pour déterminer les structures d'adduits semblables. On a déterminé la variation des patrons de fragmentation des spectres de masse de l'adduit en fonction de la température; on discute de ces variations en relation avec la réaction de synthèse.

Mots clés : adduit de phosphole, phosphanorbornène, phosphabicycloheptène, acrylonitrile.

[Traduit par la revue]

Introduction

1,2,5-Triphenylphosphole-1-oxide was known to form a 1:1 adduct with acrylonitrile from elemental analysis data (1), and subsequent NMR studies enabled an assignment of its stereochemistry (2). As part of a current, more comprehensive study of the behaviour of the phosphole ring under Diels–Alder reaction conditions, this preparation was repeated several times to provide further samples for more detailed study. Careful work-ups, followed by an X-ray crystal structure determination, were used to confirm the original adduct ratio and the previously assigned stereochemistry (2), and to determine whether a single or several stereoisomers were formed. Stereochemical details of the adduct were found to be in accord with those predictable from Woodward–Hoffman theory. Finally, it was anticipated that application of unequivocally determined proton, phosphorus, and carbon NMR parameters for this adduct would be valuable aids to the establishment of the structure and stereochemistry of other adducts in the series.

Experimental

Melting points were determined on an Electrothermal model A/FBM/AJB apparatus using a calibrated thermometer, and are uncorrected. Infrared spectra were recorded on a Perkin Elmer 1320 instrument using Nujol mulls between sodium chloride plates. Chemical ionization mass spectra were obtained from a Finnigan model 3300 quadrupole GC/MS system. Electron impact spectra were obtained using the Finnigan, using an LKB 9000 instrument equipped with a Varian data processing unit, and for the accurate mass determinations a Kratos (AEI) MS 50 instrument operated in 10 000 resolution mode, in all cases using a heated solid inlet probe. Ion source conditions for all electron impact spectra were as follows: energy, 70 eV; temperature, 290°C; current, 60 mA.

*Preparation of 1,2,5-triphenylphosphole **1**, and its 1-oxide **2***

The phosphole was prepared by heating (*E,E*)-1,4-diphenyl-1,3-butadiene with dichlorophenylphosphine at 215°C using the original procedure (3). The crude product was recrystallized from chloroform, mp 186–188°C (lit. (3) mp 186.5–187.5°C). ^{31}P NMR ($CDCl_3$): proton decoupled, +3.28 ppm (lit. (4) +3 ppm); coupled, an apparent quintet, low to high field: peak number, relative intensity, (separation, Hz, to next peak) 1, 1.0, (9.1); 2, 3.2, (9.2); 3, 4.5, (9.1); 4, 3.1, (9.8); 5. 0.95.

The phosphole oxide **2** was obtained from a solution of 1,2,5-triphenylphosphole (15.00 g; 48.0 mmol) dissolved in 1.3 L of a warm 1.7:1 (by volume) mixture of ethyl acetate and ethanol, by oxidation with 13 mL (114 mmol) of 30% aqueous hydrogen peroxide. Concentration and cooling gave two crops of yellow prisms (9.94 g; 63%). Recrystallization from ethyl acetate gave material that melted at 239–240°C (lit. (1, 3) mp 237.5–238°C).

*Preparation of phosphole oxide – acrylonitrile adduct, **3***

1,2,5-Triphenylphoshole-1-oxide (1.40 g, 4.26 mmol) was dissolved in hot benzene (100 mL) that had just been azeotropically dried. Acrylonitrile (BDH, 3.0 mL, 45 mmol) was then added, with retention of the *p*-methoxyphenol (50 ppm) inhibitor, and then boiled under reflux, protected from atmospheric moisture, for 6 h. The benzene was then evaporated from the now pale yellow solution under reduced pressure using a 50°C water bath, and the residual amorphous pale

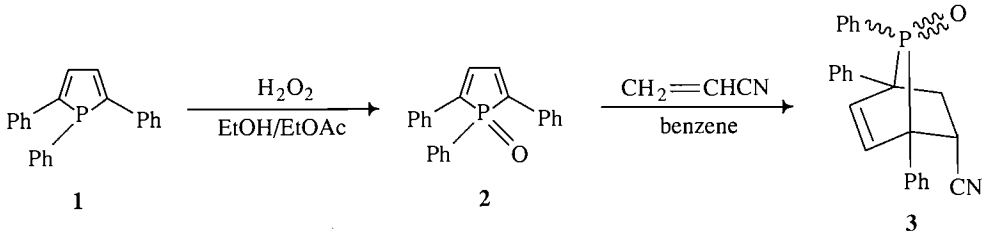
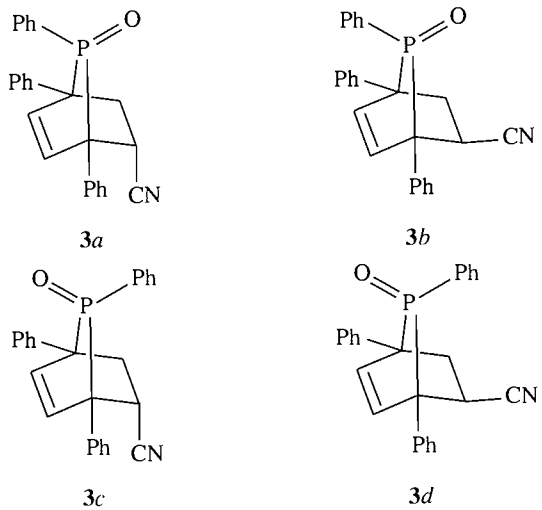


SCHEME 1



yellow powder (1.45 g) recrystallized twice from 100% ethanol. Colourless prisms of pure 5-cyano-1,4,7-triphenyl-7-phosphabicyclo [2.2.1]hept-2-ene-7-oxide, **3**, 0.80 g, mp 183–186°C (lit. (1) mp 180°C; (2) mp 174.6–176.6°C) were obtained. Anal. calcd. for $C_{25}H_{20}NOP$: C 78.73, H 5.29, N 3.67, P 8.12; found: C 78.96, H 5.43, N 3.55, P 7.65. Accurate mass determination calcd. for $C_{25}H_{20}NOP$: 381.1282; found: 381.1277. A second crop of a further 0.23 g was also obtained; purified yield on phosphole oxide, 63%. Crystals of this pure material were used for the spectroscopic data below and the NMR experiments.

Spectroscopic details: IR (Nujol mull); 2245s (CN), 1450m (P—Ph), 1190s (P=O), 760s, 700s (C—Ph arom.), 750m, 690m (P—Ph arom.) cm^{-1}; NMR, see Tables 1–3. Low resolution electron impact ms, probe temperature 63°C: no molecular ion, m/z (relative intensity): 328(3), 327(2), 259(2), 258(21), 257(100), 256(10), 255(3), 254(2), 251(2), 242(1), 241(1), 240(1). Lower masses >3% of base: 215(3), 202(4), 180(5), 179(3), 153(2), 152(3), 128(3), 115(4), 102(3), 91(17), 77(6.5), 51(3). Low resolution methane chemical ionization ms, probe temperature 250°C: $M+1$, 382 (100); $M+29$, 410 (15); $M+41$, 422 (6), established molecular weight as 381.

Selected accurate mass data, Kratos (AE) MS 50, inlet probe temperature 150°C; measured mass found, fragment formula, mass deviation from calculated (millimass units): 381.1277, $C_{25}H_{20}NOP$, (−0.5), parent ion; 328.1010, $C_{22}H_{17}OP$, (−0.7), phosphole oxide **2**; 257.1204, $C_{19}H_{15}N$, (0.0), parent ion less PhPO; 256.1120, $C_{19}H_{14}N$, (−0.7), parent ion less PhPO(H); 251.0664, $C_{16}H_{12}OP$, (3.9), acrylonitrile plus phenyl loss; 230.1094, $C_{18}H_{14}$, (−0.2), terphenyl; 180.0822, $C_{13}H_{10}N$, (0.8), PhPO plus phenyl loss; 124.0043, C_6H_5OP, (−3.5), PhPO bridge; 91.0550, C_7H_7, (0.2), tropylium; 77.0406, C_6H_5, (1.5), phenyl.

Crystals for X-ray diffraction measurements were successfully obtained from a hot filtered solution of 250 mg of pure adduct in 5 mL of 100% ethanol diluted with a further 3 mL of ethanol at ambient temperature. Slow initial solvent evaporation plus use of a seed crystal eventually yielded suitable crystals.

X-ray structure

The colourless crystal of compound **3** gave a well-defined optical extinction between crossed polars. It was mounted on the a-axis in a Lindemann tube and subjected to Weissenberg and precision photography using CuK_α radiation. The compound was found to be monoclinic, space group $P2_1/c$ (No. 14), and approximate unit cell dimensions were established. The crystal was then transferred to a Picker 4-circle diffractometer automated with a PDP 11/10 computer and, using Zr filtered MoK_α radiation ($\lambda = 0.71069$ Å), the cell and matrix were refined using 20 2θ measurements in the range 20–44°, each measured in both the positive and negative directions. The crystal data are given in Table 4. Intensity measurements were made in the 2θ range 2–50° from $hkl = -12,0,0-+12,23,12$. The scanning was in 200 steps of 0.01° in 2θ counting for 0.5 s per step with background counting for 50 s at each end of the scan. Three standard reflections 4,0,0; 0,12,0; and 0,0,4 were measured before each batch of 50 reflections. 4037 reflections were measured. The measurements were corrected for absorption using a numerical integration method (5) and a Gaussian grid of 16 × 8 × 8 points. The crystal shape was defined by the following crystal face indices and perpendicular distances to the origin in mm: ±(100), 0.4795; ±(010), 0.1748; ±(001), 0.2944. The transmission range was 0.471–0.637. The intensities were corrected for Lorentz and polarisation effects, and reflections for which $I < 2.5\,\sigma(I)$ were omitted from the subsequent refinement. 2415 reflections were retained using this criterion. The SHELX-76 set of programs were used to solve and refine the structure. The phase problem yielded to direct methods. The structure was completed by successive Fourier maps, and was refined by least squares minimizing $\Sigma w\Delta^2$ where $\Delta = \| F_o| - |F_c \|$ and $w = 1/(\sigma^2(F) + 0.001\ F^2)$. The f-curves used were those built into the SHELX program, and anomalous dispersion corrections were done. All atoms, including H, were found. During the final stages of refinement, six of the H atoms were put in calculated positions at a C—H separation of 1.02 Å. The refinement converged with a maximum shift/esd (non-H) of 0.06. The final difference map had a maximum of 0.43 e $Å^{-3}$ and a minimum of 0.12 e $Å^{-3}$, and indicated that nothing had been missed. The final residuals were $R = 0.0695$, $R_w = 0.0839$, for 360 parameters and 2415 independent observations. Supplementary tables S1–S4, including observed and calculated structure factors, have been deposited.[3]

NMR data

Preliminary 60 MHz proton magnetic resonance spectra were recorded from deuteriochloroform solutions using tetramethylsilane as reference, on a JEOL JNM-PMX 60 spectrometer. Detailed interpretation was from proton NMR spectra obtained on a Bruker WM 250 (250 MHz) spectrometer, and from proton, phosphorus, and carbon NMR spectra obtained on a Varian VXR-400 (at 400, 161.92, and 100.59 MHz, respectively) spectrometer. Tetramethylsilane (TMS) or solvent deuterium was used for the lock signal on the high frequency spectrometers. Proton and carbon shifts are referenced to internal

[a]Assignments determined by olefinic shift, correct matches of multiplicity and coupling constants, and two-stage NOE experiments (see Discussion).
[b]Assignments based on shift, multiplicity, decoupling experiments, and similar phosphorus couplings.
[c]Assignments based on NOE experiments to H(5x) and H(6x).
[d]Assignments tentatively based on influence of P coupling on apparent multiplicity.

TABLE 2. 161.92 MHz coupled phosphorus NMR data for nitrile adduct **3***a* in deuteriochloroform at room temperature[a]

Assignment	|J| (Hz)	P, H Torsion angle, (degrees)[b]
P,H(2)	11.1	144(2)
P,H(3)	9.6	144(3)
P,H(5x)	0.7	77(4)
P,H(6n)	24.5	160(3)
P,H(6x)	1.6	73(2)

[a]Proton-decoupled shift was +75.47 ppm (lit.(2), +75.5 ppm) from 85% phosphoric acid. Superimposed on the proton-coupled, apparent quintet was a fine structure of about 1 Hz presumably arising from couplings to H(5x) and H(6x) (see Table 1, and Discussion).
[b]Torsion angles were calculated from respective carbon, hydrogen, and phosphorus atomic coordinates. Estimated error (one standard deviation) given in parentheses.

TMS. Phosphorus shifts are referenced to external 85% phosphoric acid, positive values being downfield from the reference. Assignments were determined from decoupling experiments, measurement of nuclear Overhauser effects, connectivity experiments, and homonuclear and hetero-correlated 2D-*J* resolved experiments confirmed where necessary with the use of computer simulations.

Homonuclear 2D-*J* resolved experiments on protons were carried out at 399.95 MHz, spectral width 5000 Hz, 2D spectral width 50.0 Hz, acquisition time 0.41 s, pulse width 90°, first pulse 180°, FT size 4K × 256 using pseudo echo weighting and double precision acquisition. The proton–carbon heterocorrelated 2D-*J* resolved experiment was run at 100.6 MHz in the carbon domain, using sweep width 11376.6 Hz, acquisition time 0.090 s, with a delay of 1.500 s (recycle time 1.59 s) for 2048 data points, 128 transients per spectrum with decoupling during detection for C spectra; and in the proton domain using 4599.8 Hz sweep width for 256 experiments, again processed with a pseudo weighting function in both domains.

Results and discussion

Synthetic background

An isolated yield of 63% of a single stereoisomer of the phosphabicycloheptene was obtained from a 4 mmolar preparation, suggested by the relatively easy purification with high recovery, and a sharp melting point of the purified adduct. When the scale was raised to 50 mmolar the yield of purified product was raised to 82% (both based on starting phosphole oxide).

If the phosphole **1** was substituted for the phosphole oxide **2**, otherwise using the same conditions, the starting phosphole was recovered unchanged (6). Similarly, if the benzene solvent used in the reported preparation was replaced by ethanol under otherwise the same conditions, no reaction was obtained (6). This evidence strongly suggests that a polar transition state is involved in the cycloaddition.

The infrared spectrum established that nitrile, phosphoryl, and monosubstituted aromatic chromophores were all still present in the product, and combustion analysis confirmed that it was a 1:1 adduct.

Stereochemical predictions

The stereochemistry of the anticipated product of the Diels–Alder reaction of 1,2,5-triphenylphosphole-1-oxide with acrylonitrile can be predicted, based on the principles of Woodward and Hoffman (ref. 7, Fig. 1). Electron withdrawal as a consequence of the charged, zwitterionic resonance form

P^+—O^- of the phosphoryl group in the phosphole makes it probable that the LUMO of the phosphole would be the most likely to react. Likewise the electron-withdrawing effect of the nitrile on acrylonitrile makes it likely that the HOMO of this dienophile would be the form involved in an electrocyclic reaction. A LUMO plus HOMO concerted $4\pi + 2\pi$ electrocyclic reaction is thermally allowed, to obtain conservation of orbital symmetry.

Frontier orbital considerations, however, do not permit a clear prediction of product stereochemistry without further information. Consideration of the Alder rule, which dictates that the transition state that maximizes the accumulation of unsaturation will lead to the preferred product (Fig. 1a), would predict formation of the *endo* adduct. On the other hand, the opposite orientation of the nitrile confers a strongly stabilizing interaction with the phosphoryl oxygen favouring a transition state that would lead to the formation of the *exo* adduct (Fig. 1b). The *exo* transition state would also dictate phosphoryl orientation over the saturated, nitrile side rather than over the

olefinic, phosphole side of the adduct. Secondary orbital interactions in the *endo* transition state would also favour this as a likely outcome for phosphoryl orientation. In the absence of any more quantitative information to support the favouring of one transition state over the other it is not possible to unequivocally predict an *endo* or *exo* result for this process. However, this analysis does predict that the phosphoryl group would be expected to be oriented in the direction of the newly reacting dienophile in either case.

X-ray structure

The X-ray crystal structure determination of the 1:1 ethanol complex served to unequivocally establish the *endo* orientation of the nitrile group and that the orientations of the phosphoryl group and P-phenyl were over the newly formed saturated carbon–carbon bond of the original acrylonitrile and the olefinic bond of the adduct, respectively (Fig. 2, Tables 5–8). Thus, structure **3***a* was known for the adduct prior to the NMR analysis, which permitted a number of assignments that would otherwise have been difficult or inconclusive. Oxygen–oxygen atom spacing in the ethanol complex was 2.715 Å, midway between the normal 2.4–3.0 range and good evidence of an H-bonded interaction.

The olefinic bond of the adduct at 1.333(6) Å is 0.016 Å shorter than the 1.349 Å average of the two olefinic bonds of the non-oxidized precursor phosphole, **1**. The single bonds adjacent to the olefinic bond in the adduct have an average length of 1.506(6) Å, 0.066 Å longer than the 1.440 Å of the comparable C—C bond in the phosphole. These bond length differences are all in the correct direction to suggest some small degree of electron delocalization in the phosphole as compared to the necessarily fully localized bonds in the adduct. However, this change is also evidently partly the consequence of the presence of tetracovalent phosphoryl phosphorus in the adduct as compared to the trivalent phosphorus in the non-oxidized phosphole, from an examination of the close agreement of the C—C single bond distance of the adduct with the former (Table 9).

In the adduct, the phosphorus–carbon bridgehead bond length average, 1.867(5) Å, and the phosphorus to phenyl carbon bond length of 1.811(5) Å, both come close to the 1.822

The symmetry positions are for the second atom. They are defined: 1 = x,y,z; $z = -x$, 0.5 + y, 0.5 − Z. A negative symmetry position denotes inversion. The translations (T) are applied finally.

Å average given for all P—C bond distances in the phosphole (8) and to the equivalent 1.831(5) Å P—C bond in triphenylphosphine (11). The 1.810(3) and 1.796(3) Å bond lengths seen for the bonds to ring carbon and to phenyl carbon in 1,2,3,4,5-pentaphenylphosphole-1-oxide (9) are each somewhat shorter than the analogous bonds in the adduct, possibly because of some delocalization in the phosphole oxide.

Ring bonds for the saturated, non-bridgehead carbons are near the expected tetrahedral angles at 107.4 (4) and 107.4 (3)°. However, the bridged ring distorts the ring bonds to carbon from the olefinic carbons from normal sp^2 angles to bond angles of 113.2(4)° for C(2) and 112.6(4)° for C(3). This bridged ring distortion even more severely strains the angle at phosphorus, which has a value of only 84.3(2)° in the adduct as compared to a near tetrahedral angle of 107.2° in triphenylphosphine oxide (Table 10). Mean plane calculations show that the plane including phosphorus and the two bridgehead carbons is nearly evenly displaced between the olefin and the saturated sides of the carbocyclic ring with an angle to the olefin side of 125.9(5)° and 117.2(5)°, respectively (15). The dihedral angle of the 6-membered carbocyclic ring is 116.9(5)°, with bond angles of 106.0(4)° and 106.7(4)° at the carbons on the intersection of the planes.

Proton NMR

Preliminary proton spectra were obtained at 60 and 90 MHz followed by 250 and 400 MHz results, which assisted differentiation of shifts from coupling constants in the more complex multiplets. Analysis of spectra at different frequencies was particularly valuable in this system because of the prevalent variable dihedral angles, which affected through-bond coupling of protons and carbon to phosphorus (Table 1). Together with the X-ray data, these enabled assignment of many previously unreported shifts and coupling constants.

At high NMR frequencies the resonances due to the olefinic protons, H(2) and H(3), could be readily differentiated from the mass of aromatic multiplets. There is a slightly smaller coupling to phosphorus for H(2) than for H(3), 9.6 versus 11.1 Hz. Other factors than torsion angle must be operating to produce this coupling difference since the torsion angles calculated from the X-ray atomic coordinates were an identical 144° (Table 2).

Two-stage nuclear Overhauser effect (NOE) experiments were conducted to enable unequivocal assignment of the olefinic protons. Irradiation at $\delta = 3.5$ and 4.3 ppm enhanced the 7.5 and 7.6 ppm aromatic doublets, which established that these resonances originated from the *ortho* protons of the phenyls at C(1) and C(4), respectively. Irradiation at 7.5 and 7.6 ppm enhanced the multiplets at 7.03 and 6.92 ppm respec-

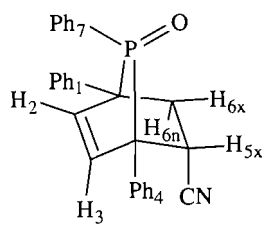
tively, which established in turn that these resonances arose from H(2) and H(3), in accord with the previous assignment (2). The *ortho* aromatic proton assignments that this procedure established are listed for the first time.

The *exo* orientation of aliphatic H(5) decreases the phosphorus coupling to an almost negligible 0.7 Hz, in keeping with its torsion angle of 77(4)° and not previously determined. This is part of the evidence used to assign the *exo* H(6x), since this coupling to phosphorus is also a small 1.6 Hz, relative to H(6n), which has a relatively large coupling of 24.5 Hz. This assignment of shifts and coupling constants is also confirmed by the geminal coupling constant for the methylenes of 12.3 Hz, which is close in absolute value to the methine, eclipsed methylene proton coupling of 10.0 Hz. Both the geminal and the eclipsed proton couplings are much larger than the methine, staggered methylene proton coupling value of 4.4 Hz.



3*a*, for NMR assignments

Phosphorus NMR

The 161.92 MHz decoupled ^{31}P NMR of nitrile adduct **3***a* in deuteriochloroform at room temperature gave a single sharp peak at +75.47 ppm from 85% phosphoric acid, in agreement with the previously determined value of +75.5 ppm (2). This

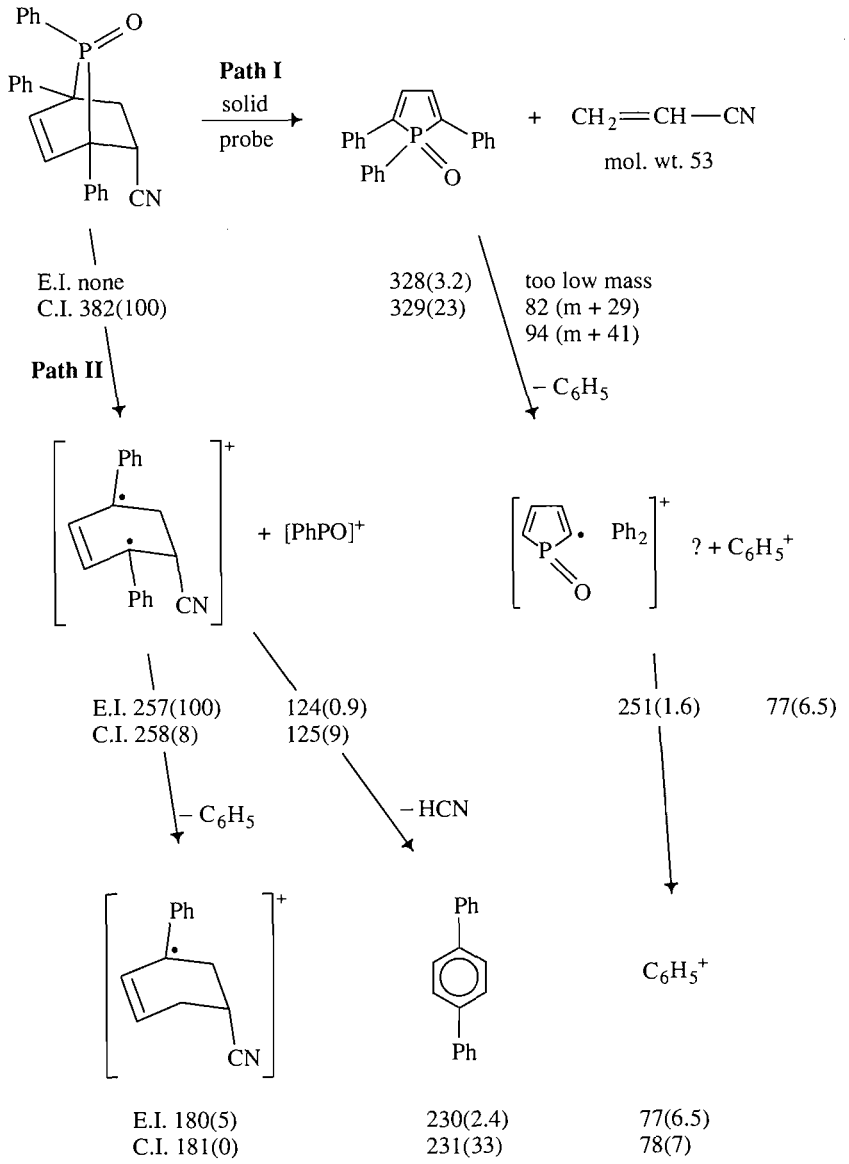

FIG. 3. Thermal decomposition pathways of adduct **3***a*.

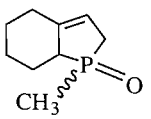
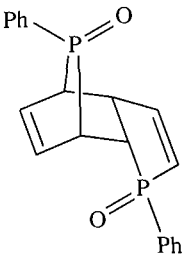
value also compares quite closely to the +70.5 ppm (*trans*) and +77.1 ppm (*cis*) phosphorus shifts recorded by Quin and Symmes (20) for an analogous hexahydrophosphoindole oxide **4**. Proton-decoupled phosphorus shifts for the 1,2,5-triphenylphosphole-1-oxide **2**, and for its precursor phosphole **1** in the same solvent, were found to be +40.69 and +3.28 ppm respectively, the latter quite close to the experimental value previously recorded by Waite and Tebby of +3 ppm (4). These are both significantly downfield of the adduct **3***a*. Apparently the change in the electronic structure of the adduct is the key feature reflected in the strong downfield shift change since alternative aryl substitution patterns or heteroatom insertion as represented by 3,5-diphenyl-1-phenoxyphosphole-1-oxide still gave a phosphorus shift of only +46.6 ppm (21).



4



5

The proton-coupled phosphorus spectrum of the nitrile adduct gave an apparent broad quintet, specified low to high field as follows: peak number, relative intensity, (spacing, Hz, to next) 1. 1.0, (10.2); 2. 1.7, (11.5); 3. 1.9, (11.5); 4. 1.8, (9.0); 5. 1.2 Superimposed on this "quintet" was a fine structure of about 1Hz. The quintet evidently arose from four overlapping doublets, because of the close coincidence of the large phosphorus to H(6n) coupling of 24.5 Hz, to the sum of the couplings of the two olefinic protons, H(2) 9.6 and H(3) 11.1 Hz (Table 2). In agreement with this assignment are the measured experimental multiplet width at half height of 49.5 Hz as compared to a calculated requirement of 47.5 Hz, the relative intensities of 1.0:1.7:1.9:1.8:1.2, as compared to a required 1:2:2:2:1, and the full confirmation of phosphorus couplings from proton and 2D-*J* resolved spectra, with simulations of these. Evidently the approximately 1Hz couplings to H(5x) and H(6x) are the consequence of the operation of a Karplus-type relationship with the near 80° torsion angles between the bonds

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

involved. The large 24.5 Hz coupling is observed for the 160(3)° torsion angle, near 180° when it would be expected to be at a maximum.

The coupled phosphorus NMR for the trivalent phosphorus in the phosphole precursor **1** also gave an apparent quintet, although much better resolved. From the closer match of the relative intensity pattern to the 1:4:6:4:1 pattern expected for a true quintet, this appeared to be a likely interpretation, and from a comparison with the proton couplings it is probable that this coupling is to the four chemically equivalent *ortho* hydrogens of the two phenyl groups bonded to carbon.

The immediate precursor of the adduct, the phosphole oxide **2**, gave a well-resolved proton-coupled phosphorus spectrum of a triplet of triplets with intensity ratios of 1:2:1:2:4:2:1:2:1 in complete agreement with theory. Couplings of 37.3 Hz to the olefinic protons on the phosphole ring and 12.3 Hz to the *ortho* phenyl protons on phosphorus were confirmed from proton spectra at 400 MHz where the olefinic resonances could be clearly differentiated, and from low frequency spectra.

Carbon-13 NMR

Assignment of ^{13}C NMR shift data, using the numbering given on the X-ray structure, was based on information obtained from normal, proton-decoupled ^{13}C and coupled ^{13}C spectra as well as heteronuclear 2D-*J* resolved NMR experiments to obtain $^{13}C-^{1}H$ connectivity, and hence shift information (Table 3). Carbon–^{1}H coupling constants were also assignable with confidence from this information. Quaternary carbons were determined by DEPT experiments. Shifts and coupling constants of the bridgehead carbons of the nitrile adduct, δ's 55.99 and 58.44 ($J_{C,P}$'s 63.1 and 66.0 Hz), are in good agreement with those measured for the phosphorus bridge in the analogous phosphole dimer **5**, δ's 41.9 and 44 ($J_{C,P}$'s 61.7 and 62.9 Hz) (23).

Mass spectrometry

It was not possible to detect a molecular ion from low resolution electron impact mass spectrometry, but from a base peak at m/z 257 it is likely that loss of the PhPO bridge unit (mass 124), either as a concerted process or in stages, represents the major fragmentation path. An m/z of 381 was established for the adduct using low resolution chemical ionization (CI) mass spectrometry from a base peak at 382 ($M + 1$) plus $M + 29$ and $M + 41$ peaks. More interesting though, under these milder ionization conditions, was the observance of a peak at m/z of 329 ($M + 1$) of intensity nearly 70% of base, which corresponds to the molar mass (M) of the phosphole oxide **2**. Since the ratio of these peak intensities varied with the temperature of the direct heated probe used for sample entry to the spectrometer, this result prompted a series of adduct thermal fragmentation studies.

Thermal decomposition pathways

Two dominant routes for the thermal fragmentation of adduct **3***a* were detected by electron impact (EI) mass spectrometry. By EI the reverse Diels–Alder process (Path I, Fig. 3) was always dominant over loss of the PhPO bridge (Path II, Fig. 3). However, the ratio of these processes changed from about 100:5, Path I to Path II, at a solid ms probe temperature of 63°C, to about 100:40 at 200°C. In a separate EI test with the precursor phosphole oxide **2** the base peak was the molecular ion at m/z 328, and carried 20% of the total ion current (22). This test established the reliability of using the 328 mass ion as a measure of the proportion of adduct **3***a* that thermally fragmented via the reverse Diels–Alder path. The phenyl phosphoryl (PhPO) moiety of Path II presumably left primarily as a neutral fragment from the observed low intensity of the m/z 124 ion.

Accurate mass determinations confirmed the elemental composition of all the molecular fragments of Fig. 3 (see Experimental) and enabled likely structures to be assigned. They also verified, from the presence of only a 0.2% abundance ion at 124.0043 m/z (for $PhPO^+$) as the only ion below mass 251 to contain C,H,O, and P, that very little fragmentation of the ionized phosphole oxide **2** occurs. Since chemical ionization (CI) mass spectrometry enabled observation of $M + 1$, $M + 29$, and $M + 41$ peaks for all major fragments ions, CI established that the major ions observed via EI mass spectrometry were ionized, thermally induced fragments of the initial adduct **3***a*, and were not formed from subsequent ion fragmentation reactions.

Acknowldegements

The authors thank O. Mamer of the Biomedical Mass Spectrometry Unit, McGill University, for the LKB-9000 mass spectrum. R. A. Jacobson, Iowa State University, is thanked for a copy of the atomic coordinates from the X-ray structure determination of 1,2,5-triphenylphosphole, from which mean plane calculations were performed for comparison purposes

Structure of the L1 and L6 core oligosaccharide epitopes of *Neisseria meningitidis*[1]

JOSE L. DI FABIO,[2] FRANCIS MICHON,[2] JEAN-ROBERT BRISSON, AND HAROLD J. JENNINGS[3]
Division of Biological Sciences, National Research Council of Canada, Ottawa, Ont., Canada K1A 0R6

Received November 23, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

JOSE L. DI FABIO, FRANCIS MICHON, JEAN-ROBERT BRISSON, and HAROLD J. JENNINGS. Can. J. Chem. **68**, 1029 (1990).

The core oligosaccharides obtained from the lipopolysaccharides of *Neisseria meningitidis* serotypes 1 and 6 were isolated by mild acid hydrolysis, and their structures elucidated by combined chemical, biochemical, and physical techniques. Use was made of 500 MHz ^{1}H nuclear magnetic resonance measurements in both one-dimensional and two-dimensional modes as well as of nuclear Overhauser enhancement experiments. To assist in the structural assignments, the purified oligosaccharides were also degraded by chemical and enzymatic procedures to smaller fragments. The L1 oligosaccharide is a biantennary partially *O*-acetylated heptasaccharide in which the larger antenna terminates in a α-D-Gal*p* 1→4β-D-Gal*p* 1→4β-D-Glc*p* unit, whereas the smallest disaccharide antenna carries phosphorylethanolamine groups at *O*-3 of its heptosyl moiety. The L6 oligosaccharide is also a biantennary partially *O*-acetylated heptasaccharide but, unlike the L1 core, is terminated by a β-D-Glc*p*NAc1→3β-D-Gal*p* 1→4β-D-Glc*p* unit in its larger antenna. The heptosyl moiety in the small disaccharide antenna bears a phosphorylethanolamine group at *O*-7, unlike *O*-3 for the L1 determinant.

Key words: lipopolysaccharides, *Neisseria meningitidis*, oligosaccharide epitopes, structure, NMR spectroscopy.

JOSE L. DI FABIO, FRANCIS MICHON, JEAN-ROBERT BRISSON et HAROLD J. JENNINGS. Can. J. Chem. **68**, 1029 (1990).

On a procédé à une hydrolyse douce en milieu acide pour isoler les oligosaccharides de base des lipopolysaccharides du *Neisseria meningitidis* des sérotypes 1 et 6; on a aussi élucidé leurs structures en combinant des techniques chimiques, biochimiques et physiques. On a utilisé la résonance magnétique nucléaire du ^{1}H dans les modes mono- et bi-dimensionnels ainsi que des expériences d'effet Overhauser nucléaire. Afin de faciliter les attributions de structure, on a aussi utilisé des méthodes chimiques ainsi qu'enzymatiques pour dégrader les oligosaccharides en fragments plus petits. L'oligosaccharide L1, un heptasaccharide partiellement *O*-acétylé, portant deux antennes, dans lequel l'antenne la plus importante est une unité α-D-Gal*p* 1→4β-D-Gal*p* 1→4β-D-Glc*p* alors que la plus petite antenne est un disaccharide portant des groupements phosphoryléthanolamine en position *O*-3 de sa portion heptosyle. L'oligosaccharide L6 est aussi un heptasaccharide partiellement *O*-acétylé portant deux antennes; toutefois, par opposition au produit L1, il se termine avec antenne portant une unité β-D-Glc*p*NAc1→3β-D-Gal*p* 1→4β-D-Glc*p*. La portion heptosyle du disaccharide de la petite antenne porte un groupement phosphoryléthanolamine qui se trouve en position *O*-7 plutôt qu'en *O*-3 comme dans le déterminant L1.

Mots clés : lipopolysaccharides, *Neisseria meningitidis*, épitopes d'oligosaccharide, structure, spectroscopie RMN.

Introduction

The meningococcal lipopolysaccharides (LPS) have been implicated in the immune response to natural infection (1) and at least 11 serotypes (L1–L11) have been identified (2, 3). There is no apparent correlation between meningococcal serogroup, designated by meningococci having a common capsular polysaccharide, and LPS serotype, except that the L10 and L11 serotypes are exclusively associated with serogroup A organisms (4). The LPS serotype epitopes are located in the glycose moieties of the LPS (5), the latter having been identified as low molecular weight oligosaccharides of the R-type (6, 7). By injecting rabbits with protein conjugates of the above oligosaccharides it has also been demonstrated (5) that they contain bactericidal epitopes. Structural studies (7, 8) on the largest of the oligosaccharides obtained from some individual meningococcal serotypes have identified regions of structural similarity and structural difference in them that are probably responsible for both the serotype specificity and cross reactivity exhibited by meningococci (3, 5).

However, the above structural studies did not address the phenomenon of heterogeneity among the LPS oligosaccharides associated with individual meningococcal serotypes (9, 10), which is probably the basis of even further immunologic diversity. This heterogeneity is generated either by structurally similar oligosaccharides having phosphoethanolamine groups in differing locations (8) or by glycose deletions from the oligosaccharides (11). These phenomena were first hypothesized to explain the molecular size heterogeneity exhibited by the LPS of individual meningococcal serotypes when run in SDS gels (12, 13), and this heterogeneity has since been established by column chromatographic procedures on the isolated oligosaccharides (8, 14). It was also hypothesized that the oligosaccharides obtained from each meningococcal serotype would be structurally related, the smaller being biological precursors of the larger. This latter hypothesis has also been recently confirmed by the isolation and structural determination of three different sized but structurally related oligosaccharides from the meningococcal L5 serotype (11). This paper describes the structural determination of the oligosaccharides of the L1 and L6 serotypes, both of which exhibit heterogeneity, which is due only to *O*-acetyl substituents. *O*-Acetyl substituents have been previously reported (11) in the oligosaccharides of the L5 serotype.

Experimental

Materials

Group B *Neisseria meningitidis* strain M992 (serotype L6) and group C *Neisseria meningitidis* strain 126E (serotype L1) were grown in *Neisseria* chemically defined medium (General Biochemical Inc., Chagrin Falls, Ohio) as described previously (7), as has also isolation of the LPS.

Analytical methods

Quantitative colorimetric methods used were the phenol – sulfuric acid assay for neutral glycoses (15), the periodate – thiobarbituric acid

[1]This is NRCC No. 31386 and was presented at the Xth International Symposium on Glycoconjugates, Jerusalem, Israel, September 10–15, 1989.

[2]Supported by IAF Biochem. International Inc., Laval, Quebec.

[3]Author to whom correspondence may be addressed.

assay for 3-deoxy-octulosonate (16), and the method of Chen for phosphate (17).

Glycoses were determined essentially as previously described (6); following hydrolysis, deamination, and conversion into alditol acetates, the sugars were identified and quantified by glc. Methylation analyses were performed by the method of Hakomori (18), the products purified with C_{18} Sep-Pak cartridges (Waters Associates). Methylated products were hydrolyzed with 0.5 N H_2SO_4 in 95% acetic acid for 18 h at 80°C and, following a twofold dilution with water, samples were hydrolyzed for an additional 5 h at 80°C (19). The individual methylated components were identified and quantified by glc–ms after conversion into alditol acetates. The absolute configuration of the glycoses was established by capillary glc of their silylated (−)-2-butyl glycosides according to the method of Leontein *et al.* (20).

Gel filtrations were done at room temperature on columns (1.6 × 90 cm) of Bio-Gel P4 (Bio-Rad Laboratories, minus 400 mesh) using pyridinium acetate buffer (0.02 M, pH 5.4). Individual fractions were monitored using a Waters R 403 differential refractometer.

Instrumental methods

Gas–liquid chromatography (glc) was performed on a Hewlett–Packard 5830A instrument equipped with a flame ionization detector and a model 3380A electronic integrator. The following conditions were used with a capillary column (0.32 mm × 25 m) of 007 bonded-phase, fused silica OV-17 (Quadrex Corp.). Program A for alditol acetates: from 180°C to 240°C at 4°C/min, and program B for methylated alditol acetates: from 200°C to 240°C at 1°C/min. Combined gas–liquid chromatography – mass spectrometry (glc–ms) was carried out on a Hewlett–Packard 5985B instrument using the above capillary column and employing programs A and B as described above and an ionization potential of 70 eV.

The ^{1}H nmr spectra were recorded at 500 MHz at 300 and 343 K with a Bruker AM500 spectrometer, in the pulsed Fourier transform mode. The chemical shifts (δ) are quoted relative to internal acetone (0.1%, v/v); δ = 2.225 ppm downfield from sodium 4,4-dimethyl-4-silapentane-1-sulfonate (DSS). Proton homonuclear shift-correlated 2D nmr experiments COSY (21) and relayed COSY (22) were performed using the standard pulse sequences provided by Bruker (DISB87). Quadrature detection in both dimensions was employed. The initial (t_1,t_2) matrices of 256 × 1024 data points provided 1.6 Hz/point digital resolution in the second domain. Resolution enhancement in both dimensions was done by the unshifted sine bell window function prior to Fourier transformation. Magnitude spectra symmetrized about the diagonal were used to represent data. The nuclear Overhauser enhancement (nOe) experiments were performed in the difference mode with sequential irradiation of each line in a multiplet (23, 24). Total irradiation time per multiplet was 1 s.

Isolation of oligosaccharides

The core oligosaccharides were obtained by heating the LPS (10 mg/mL) in 1% acetic acid for 2 h at 100°C. The insoluble lipid A was eliminated from the hydrolysis mixture by centrifugation at 10 000 rpm. The cores were then purified by gel filtration on Bio-Gel P4 using pyridinium acetate buffer as eluant. A main oligosaccharide fraction was identified for each individual serotype L1 and L6 LPS. A portion of the core oligosaccharide was de-*O*-acetylated in 0.1 N NH_4OH at room temperature for 16 h and purified by gel filtration on Bio-Gel P4. Dephosphorylation of the core fractions was performed with 48% aqueous HF at 4°C for 72 h. After removal of HF under vacuum, over NaOH pellets, the purification was done by gel filtration on Bio-Gel P4.

Enzymatic deglycosylations

Treatment with α-galactosidase: oligosaccharide (5–15 mg) was dissolved in 0.1 M potassium phosphate buffer pH 6.5 (0.5–1.0 mL), and to this solution was added 5 U of α-galactosidase (Boehringer Mannheim GmBH) (EC 3.2.1.22) from green coffee beans. A few drops of toluene were added to the solution and incubation was carried out at 37°C for 48 h.

Treatment with β-*N*-acetylglucosaminidase: oligosaccharide (10–15 mg) was dissolved in 0.05 M sodium citrate buffer, pH 4.5 (0.5–1.0 mL), and to this solution was added 2 U of β-*N*-acetylglucosaminidase (Sigma Laboratories) from *Aspergillus niger* (EC 3.2.1.30). A few drops of toluene were added and incubation was carried out at 37°C for 48 h.

Digestion products were purified by gel filtration on Bio-Gel P4 using conditions described above and thereafter analyzed by methylation and ^{1}H nmr.

Results

Structure of the L1 core oligosaccharide

The L1 oligosaccharide was obtained by mild 1% acetic acid hydrolysis with subsequent elution of the hydrolyzate from a Bio-Gel P4 column. The column afforded a single fraction, which eluted from the column as a broad peak. Sugar analysis of the fraction indicated that it was composed of D-galactose, D-glucose, 2-acetamido-2-deoxy-D-glucose, L-*glycero*-D-*manno*heptose, and 3-deoxy-D-*manno*-octulosonic acid (KDO) in the ratios 2:1:1:2:1. In addition it contained one mole of phosphorus and one mole of ethanolamine, suggesting the presence of one mole of phosphoethanolamine. Examination of this fraction by ^{1}H nmr indicated that it was heterogeneous, as reflected by the complexity of the anomeric region of its spectrum between δ 5.50 and 4.30. The spectrum also suggested that *O*-acetyl groups (signal at δ 2.19), which were present in the molar ratio of ≈0.4, were a contributing factor to this heterogeneity. This was confirmed when removal of *O*-acetyl by mild base produced pure **1**, which eluted as a narrow peak (K_{av} 0.49) from a Bio-Gel P4 column and which did not exhibit the complexity of anomeric signals associated with the ^{1}H nmr spectrum of its precursor. The ^{1}H nmr spectrum of **1** (Table 2) was still in agreement with the sugar analysis, i.e., six signals in the anomeric region integrating for six protons indicating that **1** contained at least six sugar residues. Four of these anomeric signals at δ 5.516, 5.163, 5.075, and 4.951 with small vicinal coupling constant values ($^3J_{1,2}$ = 1–3 Hz) were assigned to residues with α-anomeric configuration; the last two at δ 4.554 and 4.538 having large vicinal coupling constants ($^3J_{1,2}$ = 7–8 Hz) were assigned the β-anomeric configuration. In addition, the spectrum had one signal at δ 2.050 associated with one *N*-acetyl group, indicating that the 2-amino-2-deoxy-D-glucosyl units are *N*-acetylated.

The ^{13}C nmr of **1** is complex, but it exhibited intense signals at δ 103.70, 103.07, 101.59, 101.09, 100.39, and 100.05 associated with six anomeric carbon atoms. A less intense signal at δ 96.6 could be associated with C-2 of one of the anomeric forms of the reducing KDO. A doublet at δ 40.95 ($^3J_{C,P}$ = 8.0 Hz) is characteristic of a phosphoethanolamine substituent (7), in agreement with the composition analysis described above. Other signals at δ 54.82, 38.41, and 23.09 are assigned to the carbons linked to acetamido groups, to C-3 of the reducing KDO, and to the methyl of the *N*-acetyl groups, respectively.

Methylation analysis of **1** (Table 1) indicated that it contained terminal non-reducing galactose and 2-acetamido-2-deoxy-glucose residues, one galactose, and one glucose linked at *O*-4; both heptoses were branch points, one of them substituted at *O*-3 and *O*-4 and the other at *O*-2 and *O*-3. KDO was linked at *O*-5 (Table 1), as it is in the L3 and L5 oligosaccharide (7, 11). When **1** was dephosphorylated with aqueous HF to afford **2**, its methylation analysis (Table 1) indicated that the 4,6,7-trimethyl-heptopyranosyl residue present in the methylation analysis of **1** was now replaced by a 3,4,6,7-tetramethyl-heptopyranosyl residue, indicating that the phosphoethanolamine groups were located at *O*-3 of the *O*-2 linked heptose

[a]Measured at 300 K and 500 MHz, assignments made from data obtained by homonuclear 2D shift-correlated (H,H) COSY and two-step relayed COSY.

residue. Thus, this would indicate that a phosphoethanolamine group located at position *O*-3 of a L,D-heptose is very labile under the hydrolysis conditions used for permethylated **1**.

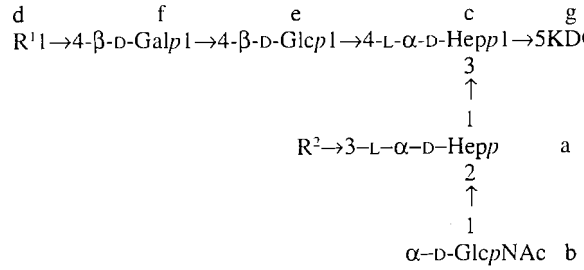
To obtain evidence for the sequence of the sugar residues in the L1 core, **2** was treated with α-galactosidase and, following purification by gel filtration on Bio-Gel P4, the product of hydrolysis was identified as **3** following methylation (Table 1) and ^{1}H nmr analysis (Table 2). The disappearance of a 2,3,6-trimethyl-galactopyranosyl residue (*O*-4 linked), in the methylation analysis of **3** with respect to that of **2**, indicated that a terminal α-D-galactopyranosyl residue had been removed from the oligosaccharide by the enzyme and that this residue was previously linked to *O*-4 of another galactopyranosyl unit. Thus, the sequence α-D-Gal*p*1→4Gal was ascertained. This evidence was supported by ^{1}H nmr data obtained from **3** (Table 2), where the anomeric signal (H-1d) at δ 4.951 present in **2** was no longer present in the spectrum of **3**.

TABLE 4. Nuclear Overhauser enhancements for dephosphorylated L1 core oligosaccharide **2**

	Observed nOe	
Saturated signal[a]	Intra-residue	Inter-residue
1-a	2-a	3-c
1-b	2-b	2-a
1-c	2-c	NA
1-d	2-d	4-f
1-e	2-e,3-e,5-e	4-c
1-f	2-f,3-f,4-f,5-f	4-e

[a]Letters a–f refer to residues a–f as depicted in Fig. 1. NA: not assigned.

The complete sequence and anomeric configurations of the individual residues of dephosphorylated L1 core (**2**) were ascertained from ^{1}H nmr (nOe) data. First, the chemical shifts of some of the protons associated with the individual residues of **2** were assigned by 2D (H,H) COSY using one-step (21) and two-step relayed coherent transfer (22) (Table 3). Following assignments, the individual anomeric signals of each of the residues a, b, c, d, e, and f in **2** (Fig. 1) were selectively irradiated, and the observed nOe's are listed in Table 4. Irradiation of H-1a gave enhancements on both vicinal H-2a and on H-3c, which indicated that the L-*glycero*-D-*manno*-heptopyranosyl residue **2**a is in the α-D-*manno* configuration since no enhancements are observed on its own H-3a and H-5a, and is also linked to *O*-3 of the branch L-*glycero*-D-*manno*-heptopyranosyl residue **2**c. Irradiation of H-1b gave enhancements on vicinal H-2b as well as on H-2a, indicating that the 2-acetamido-2-deoxy-D-glucopyranosyl residue **2**b is in the α-D-*gluco* configuration and in addition is linked to *O*-2 of the L-*glycero*-α-D-*manno*-heptopyranosyl residue a. When H-1c was irradiated, enhancement was observed for H-2c but not for H-3c or H-5c, indicating that the branch L-*glycero*-D-*manno*-heptopyranosyl residue c is in the α-D-*manno* configuration; other not-assigned resonances, which could belong to the *O*-5 linked KDO residue g, were enhanced. Irradiation of H-1d gave clear enhancements on both H-2d and H-4f, indicating that the D-galactopyranosyl residue is in the α-D-*galacto* configuration and is linked to *O*-4 of the adjacent galactosyl residue **2**f. Irradiation of H-1e gave enhancements on H-2, H-3, and H-5 of the same residue as well as on H-4 of the branch L-*glycero*-D-*manno*-heptopyranosyl residue (**2**c), indicating that the D-glucopyranosyl residue **2**e has the β-D-*gluco* configuration and furthermore is linked to *O*-4 of residue **2**c. At this point, the following sequences (i) β-D-Glc*p*1→4[α-D-Glc*p*NAc1→2-α-LD-Hep*p*1→3]-α-LD-Hep*p*1→5KDO and also (ii) α-D-Gal*p*1→4-β-D-Gal*p*1→ can be written. How (i) and (ii) are linked together can be decided from enhancements observed following irradiation of H-1f. In effect, besides expected nOe's for H-2, H-3, H-4, and H-5 of the β-galactosyl residue **2**f, enhancement was also observed for H-4 of the β-D-glucopyranosyl residue e, indicating that **2**f was linked to *O*-4 of **2**e.



1 R^1 = α-D-Gal*p*; R^2 = PEA
2 R^1 = α-D-Gal*p*; R^2 = H
3 $R^1 = R^2$ = H

FIG. 1. Structure of the *O*-deacetylated L1 core oligosaccharide and derived products.

TABLE 5. Methylation analysis of oligosaccharides derived from the L6 lipopolysaccharide cores

Methylated sugars[b]	Molar ratios[a] 4	5	6
2,3,4,6-Me_4 Gal	—	—	1.00
2,3,6-Me_3 Glc	1.00	1.00	1.05
2,4,6-Me_3 Gal	0.95	1.00	—
3,4,6,7-Me_4 Hep	—	0.80	0.85
3,4,6-Me_3 GlcNMeAc	1.75	1.75	0.80
2,6,7-Me_3 Hep	0.90	0.90	0.85
3,4,6-Me_3 Hep[c]	0.65	—	—

[a]4: de-*O*-acetylated core; 5: de-*O*-acetylated and dephosphorylated core; 6: de-*O*-acetylated, dephosphorylated, and β-*N*-acetylglucosaminidase treated core.
[b]KDO was detected in **4** as its 1,2,4,6,7,8-hexamethyl-3-deoxy-5-OAc derivative as described in Jennings *et al.* (6).
[c]Obtained after methylation and treatment with 48% HF.

Thus the disaccharide sequence (ii) is linked to the pentasaccharide (i) via *O*-4 of residue **2**e, and the final sequence for the L1 oligosaccharide (**1**) is therefore as reported in Fig. 1. It is a phosphorylated core as opposed to the L5 determinant (11), the phosphoethanolamine groups being located at *O*-3 of the L-*glycero*-D-*manno*-heptopyranosyl moiety (**2**a).

Structure of the L6 core oligosaccharide

The L6 oligosaccharide was obtained as described for L1 by mild hydrolysis of the serotype L6 LPS and gel filtration on Bio-Gel P4. It afforded a single fraction that eluted as a broad peak. Sugar analysis of this fraction indicated that it contained D-galactose, D-glucose, 2-acetamido-2-deoxy-D-glucose, L-*glycero*-D-*manno*-heptose, and KDO in the ratios of 1:1:2:2:1. In addition, it contained one mole of phosphoethanolamine. Examination of this fraction by ^{1}H nmr indicated that it had extensive microheterogeneity as reflected by the complexity of the anomeric region of its spectrum between δ 5.50 and 4.30 and also by the presence of three signals at δ 2.18, 2.12, and 2.10 associated with multiple *O*-acetyl groups. Upon mild treatment of the above fraction with base, the generated de-*O*-acetylated product referred to as **4** eluted as a very narrow peak (K_{av} 0.47) on Bio-Gel P4. The ^{1}H nmr analysis of **4** showed in its spectrum absence of *O*-acetyl signals, indicating complete *O*-deacetylation. The anomeric region (Table 6) with five signals integrating for six anomeric protons indicated that **4** contained at least six sugar residues. Two of these signals at δ 5.645 (1H), 5.077 (2H)

FIG. 2. Structure of the *O*-deacetylated L6 core oligosaccharide and derived products.

with small vicinal coupling constants ($^3J_{1,2}$ = 1–3 Hz) were assigned to residues with α-anomeric configuration; the other three at δ 4.700 (1H), 4.555 (1H), and 4.470 (1H) having large coupling constant values ($^3J_{1,2}$ = 7–8 Hz) were assigned the β-anomeric configuration. In addition, the spectrum had one signal at δ 2.050 integrating for six protons associated with two *N*-acetyl groups.

Methylation analysis of **4** (Table 5) indicated that it contained two terminal non-reducing 2-acetamido-2-deoxy-glucose residues, glucose linked through *O*-4, galactose linked at *O*-3, KDO linked at *O*-5, and one heptose branch point substituted at *O*-3 and *O*-4. No other heptose was detected, suggesting that this residue was phosphorylated. Indeed, when permethylated **4** was treated with aqueous HF and then subjected to acid hydrolysis and glc–ms analysis, a 3,4,6-trimethyl heptose appeared in the methylation analysis, indicating that the missing heptose was also a branch point substituted at *O*-2 and *O*-7. Thus the phosphoethanolamine substituent must be located at either *O*-2 or *O*-7 of this sugar residue. To conclusively decide, **4** was treated with aqueous HF to afford **5**. Methylation analysis of **5** (Table 5) gave the same methylated products found in that of **4** except for the appearance of a 3,4,6,7-tetramethyl heptose and disappearance of the 3,4,6-trimethyl heptose, indicating that this heptose residue is *O*-2 linked and therefore carries the phosphoethanolamine groups at *O*-7 in the native core. The chemical shifts associated with the anomeric protons of **5** are not significantly different from those associated with phosphorylated **4** except for the anomeric proton (H1-a).

As for the L1 core, the sequence of the sugar residues of L6 had to be established. Firstly, dephosphorylated **5** was treated

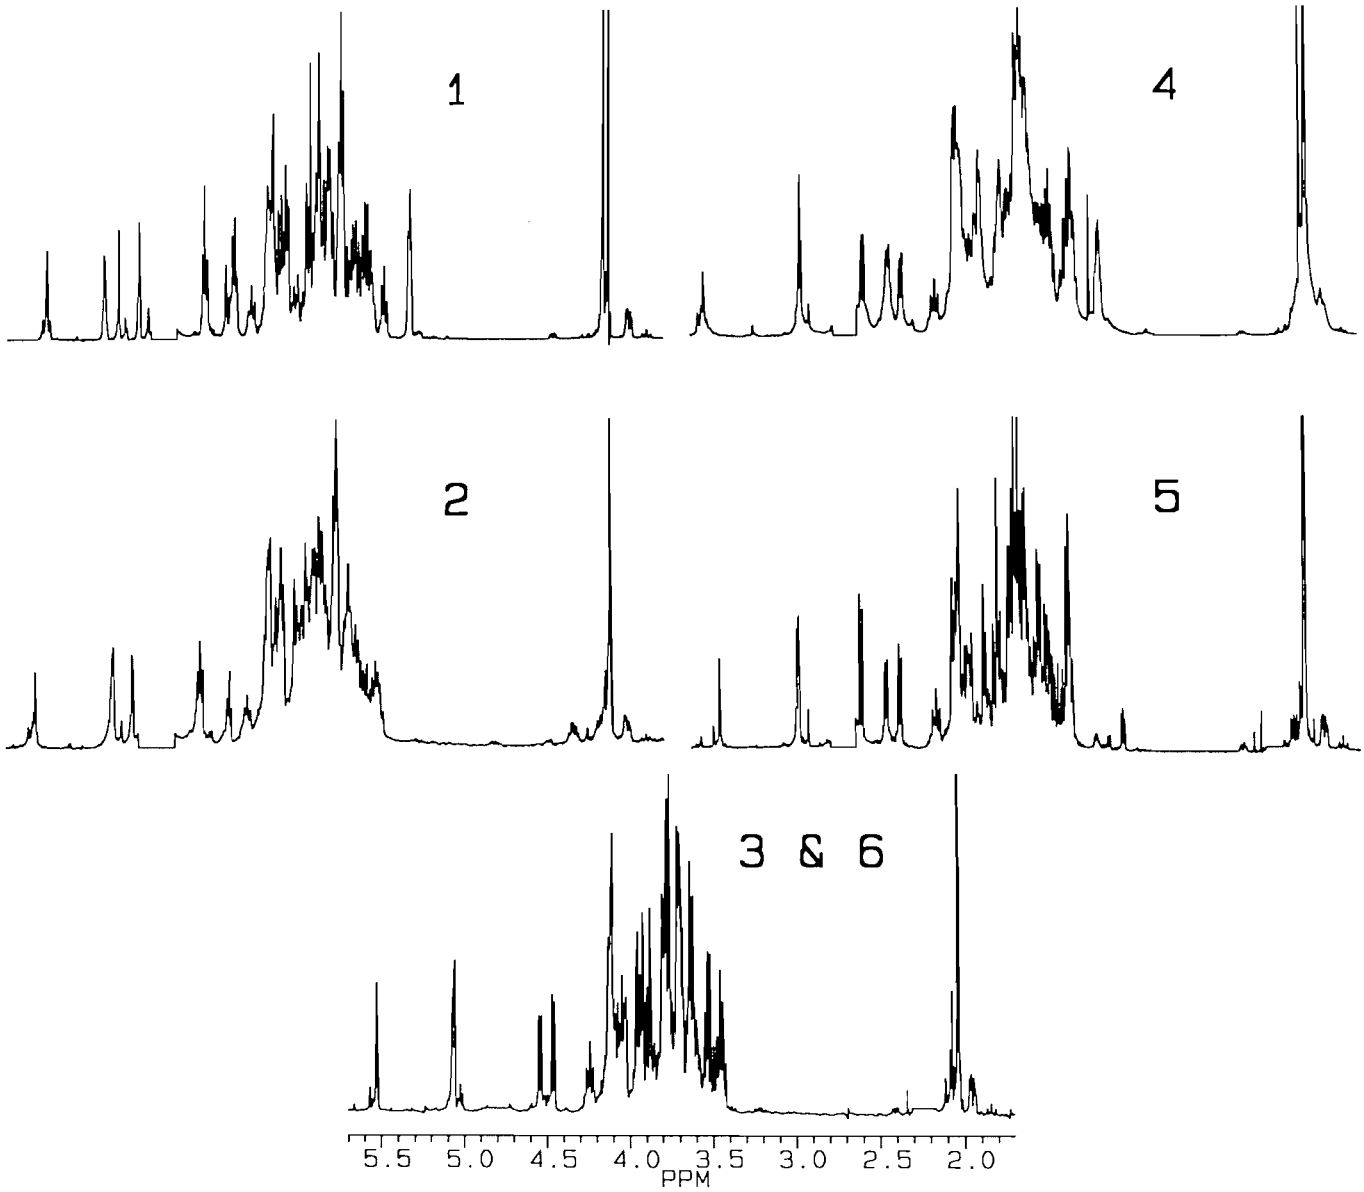

FIG. 3. The ^{1}H nmr spectra (500 MHz, 300 K) of *O*-deacetylated L1 (**1**) and L6 (**4**) core oligosaccharides, their respective derived dephosphorylated products (**2** and **5**), and their respective products following treatment with glycosidases (**3** and **6**). The chemical shift scale shown applies to all spectra in the figure.

with β-*N*-acetylglucosaminidase from *Aspergillus niger*. The digestion products were purified by gel filtration on Bio-Gel P4, and a major oligosaccharide product **6** was identified by methylation and ^{1}H nmr analysis. By comparison with the methylation analysis of **5**, that of **6** has an additional 2,3,4,6-tetramethyl galactopyranosyl residue corresponding to the 2,4,6-trimethyl galactopyranosyl residue present in the methylation of **5**. In addition, one of the two 2,3,4,6-tetramethyl-2-acetamido-2-deoxy-glucopyranosyl residues is missing, indicating the enzyme had removed the terminal 2-acetamido-2-deoxy-β-D-glucopyranosyl residue (**5**d) from **5** and that **5**d was linked to *O*-3 of the adjacent galactopyranosyl residue **5**f (Fig. 2).

Interestingly, the methylation analysis of **6** yielded the same methylated components and in the same ratios as were found for the dephosphorylated and degalactosylated L1 core (**3**), suggesting identical structure for **3** and **6**. Indeed, this was confirmed upon examination of the ^{1}H nmr spectrum of **6** (Table 6 and Fig. 3), which is identical to that of **3** (Table 2 and Fig. 3). Therefore we can conclusively say that **3** and **6** are identical and that the structure of the *O*-deacetylated L6 core is as reported in Fig. 2. It is also a phosphorylated core, with the phosphoethanolamine groups located at *O*-7 (instead of *O*-3 for L1) of the L-*glycero*-D-*manno*-heptopyranosyl residue (**4**a), and its glycose sequence is identical to that of the L1 core except for the fact that L6 has a non-reducing terminal 2-acetamido-2-deoxy-β-D-glucopyranosyl linked to *O*-3 of an adjacent β-D-galactopyranosyl residue (Fig. 2), whereas L1 has a non-reducing terminal α-D-galactopyranosyl residue linked to *O*-4 of the same adjacent β-D-galactopyranosyl residue (Fig. 1).

Both the L1 and L6 oligosaccharides contain *O*-acetyl groups previously identified as substituents of the L5 serotype oligosaccharides (11). The sharpening of the peaks in the elution profiles (Bio-Gel P4) of both the *O*-deacetylated L1 (**1**) and L6 (**4**), when compared to those of peaks in the elution profiles (Bio-Gel P4) of the original oligosaccharides, would suggest

that the heterogeneity exhibited in the latter, unlike that exhibited by the L5 oligosaccharides (11), is due only to the presence of *O*-acetyl substituents. However, it cannot be stated with certainty that this heterogeneity also extends to the LPS-associated oligosaccharide epitopes, because it is a distinct possibility that *O*-acetyl groups could be partially removed under the mild hydrolytic conditions used to obtain the oligosaccharides from the LPS.

Enantiospecific synthesis of (6*R*, 7*S*)-diastereoisomer of asperlin

TONY K. M. SHING[1] AND MAHMOUD ALOUI
Department of Chemistry, The Victoria University of Manchester, Manchester M13 9PL, U.K.

Received November 14, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

TONY K. M. SHING and MAHMOUD ALOUI. Can. J. Chem. **68**, 1035 (1990).

An unambiguous synthesis of the (6*R*,7*S*)-diastereoisomer of asperlin from D-glucose involving a tandem epoxide formation/intramolecular Wadsworth–Emmons–Horner olefination has established the absolute configuration of the oxirane moiety in natural asperlin as (6*S*,7*R*).

Key words: asperlin, synthesis; Wadsworth–Emmons–Horner olefination; epoxide formation.

TONY K. M. SHING et MAHMOUD ALOUI. Can. J. Chem. **68**, 1035 (1990).

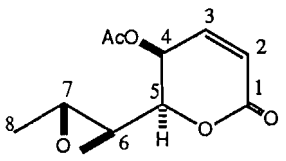
Grâce à une synthèse non ambiguë du diastéréoisomère (6*R*,7*S*) de l'asperline, à partir du D-glucose et faisant appel à un tandem de réactions impliquant la formation d'un époxyde et une oléfination intramoléculaire de Wadsworth–Emmons–Horner, on a pu établir que la configuration absolue de la portion oxirane de l'asperline naturelle est (6*S*,7*R*).

Mots clés : asperline, synthèse; oléfination Wadsworth–Emmons–Horner; formation d'un époxyde.

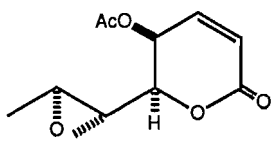
[Traduit par la revue]

Introduction

Asperlin, a fungal metabolite isolated (1) from cultures of *Aspergillus nidulans*, has been shown (2) to exhibit antibiotic and antitumour activity. Earlier nmr spectroscopic (3, 4) and synthetic studies (4, 5) of asperlin have demonstrated that the 4,5-substituents[2] of the lactone ring had the L-*threo* configuration and the exocyclic epoxypropyl moiety was *trans*; the absolute stereochemisty of the oxirane remained unsolved. These data have reduced the possible constitutions of asperlin to absolute configuration **1** or its 6,7-diastereoisomer **2.** Recently,



1



2

spin-lattice relaxation and nuclear Overhauser enhancement experiments were used to assign the (6*R*,7*S*)-diastereoisomer **2** to asperlin (6). However, a very recent synthesis (7) of D-asperlin indicated that natural asperlin was the (6*S*,7*R*)-diastereoisomer, i.e., **1.** This paper describes an unambiguous synthesis of **2**, which is diastereoisomeric to asperlin, thereby confirming by exclusion that the absolute configuration of the natural material is **1**. A preliminary account of this work has appeared (8).

Results and discussion

The strategy for the enantiospecific fabrication of **2**, illustrated in Scheme 1, involves a tandem oxirane formation/intramolecular Wadsworth–Emmons–Horner (9) olefination (this would guarantee the *Z*-geometry of the double bond) of the lactol **3**, which is readily derived from D-glucose.

3-*O*-Benzyl-1,2:5,6-di-*O*-isopropylidene-D-glucose **4** (10), readily affordable from D-glucose in two steps, was converted into the epoxy-lactone **2** in eight steps with an overall yield of 14%. Thus selective hydrolysis of the terminal isopropylidene group in **4** followed by esterification of the resultant diol with methanesulphonyl chloride as described previously (11) gave the dimethanesulphonate **5** in 73% overall yield. The primary methanesulphonate in **5** was displaced with lithium aluminium hydride (LAH) to provide the deoxy derivative **6** (91%), which then was debenzylated by palladium hydroxide catalysed hydrogenolysis to give the alcohol **7** in 94% yield. Esterification of **7** with dimethylphosphonoacetic acid in the presence of dicyclohexylcarbodiimide (DCCI) afforded the phosphonate **8** in 92% yield. Acetolysis of **8** with acetic anhydride mediated by boron trifluoride etherate gave smoothly the diacetate **9** (a mixture of anomers) in 97% yield. The anomeric acetoxy group in **9** was selectively (12) hydrolyzed ($SnCl_4$/MeCN followed by aqueous $HCONMe_2$) to the lactol **3** in 52% yield. The β-D-configuration of the anomeric hydroxy group in **3** was evident from the nmr spectrum ($J_{1,2} \approx 0.0$Hz). Transformation of the base labile **3** into the target epoxy-lactone **2** proved eventful. After considerable experimentation, treatment of **3** with mild base (13) (LiCl, 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU)) gratifyingly produced the desired pyrone **2** in 47% yield. The epoxy-lactone **2** had mp 55–57°C, $[\alpha]_D$ +172° (*c* 1, EtOH), R_f 0.45 (silica gel tlc, diethyl ether), and spectroscopic data (mass, ir, ^{1}H nmr) similar to those of an authentic sample of asperlin. Since natural asperlin had mp 71–73°C, $[\alpha]_D$ +345° (*c* 0.5, EtOH) (1), R_f 0.50 (diethyl ether), **2** must be its diastereoisomer. The absolute configuration **1** is therefore assigned to asperlin.

Experimental

Melting points were recorded on a Kofler block. ^{1}H nuclear magnetic resonance (nmr) spectra were recorded on a Varian SC300 spectrometer at 300 MHz using deuteriochloroform as solvent unless otherwise stated. Mass spectra were recorded on a Kratos MS25 instrument. Infrared (ir) spectra were recorded on a Perkin–Elmer FT-IR 1710 spectrometer with samples as thin films; selected absorptions are reported in wave numbers (cm^{-1}). Optical rotations were measured on an AA-100 polarimeter using acetone as solvent unless otherwise stated. Thin-layer chromatography (tlc) was performed on glass plates precoated with Merck silica $60F_{254}$, and compounds were visualized with a spray of 5% v/v sulphuric acid in ethanol and subsequent heating. Tetrahydrofuran (THF) was distilled from sodium and benzophenone under dry nitrogen. Dichloromethane and acetonitrile were distilled from P_2O_5.

3-O-Benzyl-6-deoxy-1,2-O-isopropylidene-5-O-methanesulphonyl-α-D-glucofuranose **6**

To a stirred solution of the dimesylate **5** (11) (3.12 g, 6.69 mmol) in dry THF (95 mL) was added LAH (0.509 g, 13.39 mmol). The resultant solution was then heated at reflux under argon for 5 h. The reaction was quenched cautiously with water (3 mL), followed by the addition of aqueous ammonium chloride (15 mL), and extracted into chloroform (3 × 50 mL). The combined extracts were washed with water and aqueous ammonium chloride, dried (NA_2SO_4), and filtered. The filtrate was concentrated and the residue was chromatographed (ethyl acetate – hexane (1:2 v/v)) to give the 6-deoxy derivative **6** (2.25 g, 91%) as a colourless syrup that crystallized slowly. Recrystallization from diethyl ether – light petroleum (bp 40–60°C) afforded white crystals, mp 82–84°C; $[\alpha]_D^{20}$ −25.3° (*c* 4.4); R_f 0.50 (tlc, ethyl acetate – hexane (4:1 v/v)); ^{1}H nmr δ: 1.30 and 1.49 (2s, 6H, 2Me), 1.55 (d, 3H, $J_{6,5}$ 6.4 Hz, Me-6), 2.92 (s, 3H, CH_3SO_2), 4.05 (d, 1H, $J_{3,4}$ 2.9 Hz, H-3), 4.15 (d, 1H, $J_{4,5}$ 8.0 Hz, H-4), 4.61 (obscured by $PhCH_2$, 1H, H-2), 4.60 and 4.64 (2d, 2H J_{gem} 11.2 Hz, $PhCH_2$), 5.14 (m, 1H, H-5), 5.89 (d, 1H, $J_{1,2}$ 4.0 Hz, H-1), 7.35 (br s, 5H, pH); ms *m/z* (CI, NH_3): 390 (92%, MNH_4^+). Anal. calcd. for $C_{17}H_{24}O_7S$: C 54.8, H 6.5, S 8.6; found: C54.4, H 6.6, S 8.8.

6-Deoxy-1,2-O-isopropylidene-5-O-methanesulphonyl-α-D-glucofuranose **7**

A solution of **6** (3.03 g, 8.1 mmol) in ethanol (40 mL) was hydrogenated over $Pd(OH)_2$ (1.2 g) at room temperature and atmospheric pressure for 15 h. The catalyst was removed by filtration and the filtrate concentrated to give the alcohol **7** (2.18 g, 94%) as a white solid, which was recrystallized from diethyl ether–light petroleum (bp 40 – 60°C), mp 56–58°C; $[\alpha]_D^{20}$ −22.0° (*c* 2.9); R_f 0.24 (tlc, ethyl acetate – hexane (1:1 v/v)); ir: 3500 (OH); ^{1}H nmr δ: 1.30 and 1.49 (2s, 6H, 2Me), 155 (d, 3H, $J_{6,5}$ 6.5 Hz, Me-6), 3.07 (s, 3H, CH_3SO_2), 3.10 (d, 1H, $J_{OH,3}$ 4.2 Hz, OH-3), 4.02 (dd, 1H, $J_{4,3}$ 2.2, $J_{4,5}$ 9 Hz, H-4), 4.29 (dd, 1H, H-3), 4.55 (d, 1H, $J_{2,1}$ 3.7 Hz, H-2), 4.97 (dq, 1H, H-5), 5.89 (d, 1H, H-1); ms *m/z* (CI, NH_3): 300 (100%, MNH_4^+). Anal. calcd. for $C_{10}H_{18}O_6S$: C 42.5, H 6.4, S 11.3; found: C 42.5, H 6.4, S 11.4.

6-Deoxy-3-O-dimethylphosphonoacetyl-1,2-O-isopropylidene-5-O-methanesulphonyl-α-D-glucofuranose **8**

Dicyclohexylcarbodiimide (3.60 g, 17.4 mmol) was added in one portion to a stirred solution of the alcohol **7** (3.07 g, 10.88 mmol) and dimethylphosphonoacetic acid (2.2 g, 13.06 mmol) in dry dichloromethane (60 mL) at 0°C. After 2 h, the reaction was quenched with ethanol (5 mL) and acetic acid (1 mL), and filtered. The filtrate was concentrated and the residue chromatographed (ethyl acetate) to give **8** (4.31 g, 92%) as a colourless syrup; $[\alpha]_D^{20}$ −8.3° (*c* 3.4); R_f 0.18 (tlc, ethyl acetate); ir: 1747 (ester C=O); ^{1}H nmr δ: 1.23 and 1.48 (2s, 6H, 2Me), 1.54 (d, 3H, $J_{6,5}$ 6.5 Hz, Me-6), 2.97 (s, 3H, CH_3SO_2), 3.02 (dd, 1H, $^2J_{PH'}$ 21.0, J_{gem} 15.0 Hz, PCH'), 3.12 (dd, 1H, $^2J_{PH}$ 21.0 Hz, PCH), 3.76 and 3.80 (2d, 6H, $^3J_{PH}$ 11.5 Hz, 2 MeO), 4.17 (dd, 1H, $J_{4,3}$ 2.8, $J_{4,5}$ 8.6 Hz, H-4), 4.52 (d, 1H, $J_{2,1}$ 3.5 Hz, H-2), 4.96 (dq, 1H, H-5), 5.32 (d, 1H, H-3), 5.89 (d, 1H, H-1); ms *m/z* (CI, NH_3): 433 (57%, MH^+). Exact mass calcd. for $C_{14}H_{26}O_{11}PS$ (MH^+): 433.0931; found: 433.0933.

1,2-Di-O-acetyl-6-deoxy-3-O-dimethylphosphonoacetyl-5-O-methanesulphonyl-D-glucofuranose **9**

The acetonide **8** (5.7 g, 13.2 mmol) was dissolved in acetic anhydride (40 mL) and $BF_3 \cdot OEt_2$ (4 mL, 32.5 mmol) was introduced at 0°C with stirring. After 1 h, the reaction mixture was quenched with ice-water and extracted into ethyl acetate (3 × 120 mL). The combined extracts were washed successively with brine (2 × 80 mL), aqueous $NaHCO_3$ (2 × 70 mL), and brine (2 × 70 mL), dried (Na_2SO_4), and filtered. The filtrate was concentrated and the residue chromatographed to give **9** (6.1 g, 97%) as a pale yellow syrup; $[\alpha]_D^{22}$ +17.4° (*c* 9.3 ethanol); R_f 0.39 (tlc, chloroform–methanol (9:1 v/v)); ir: 1751 (ester C=O); ^{1}H nmr δ: inter alia 6.05 (s, 0.4H, αH-1), 6.40 (d, 0.6H, $J_{1,2}$ 4.4 Hz, βH-1); ms *m/z* (CI, NH_3): 494 (43% MNH_4^+). Exact mass calcd. for $C_{15}H_{21}NO_{13}PS$ (MH_4^+): 494.10951; found: 494.11429.

2-O-Acetyl-6-deoxy-3-O-dimethylphosphonoacetyl-5-O-methanesulphonyl-β-D-glucofuranose **3**

Stannic chloride (0.869 mL, 7.41 mmol) was added to a solution of the diacetate **9** (1.17 g, 2.47 mmol) in acetonitrile (15 mL) with stirring at 0°C. After 2 h at room temperature, the reaction mixture was treated with acetonitrile (5 mL) containing water (4 M) and $HCONMe_2$ (0.4 M). After a further 20 h, the reaction was quenched with aqueous $NaHCO_3$ (3 mL) and extracted with chloroform (40 mL). The extract was dried (Na_2SO_4), filtered, and the filtrate concentrated. The residue was chromatographed to give the lactol **3** (0.407 g, 55% based on recovered starting material (0.35 g)) as a colourless syrup; $[\alpha]_D^{20}$ +13.26° (*c* 1.9); R_f 0.25 (tlc, chloroform–methanol (9:1 v/v)); ir: 3450 (OH), 1747 (ester C=O); ^{1}H nmr δ: 1.58 (d, 3H, $J_{6,5}$ 6.2 Hz, Me-6), 2.93 (s, 3H, CH_3SO_2), 3.24 (dd, 1H, $^2J_{PH'}$ 21.0, J_{gem} 14.5 Hz, PCH'), 3.32 (dd, 1H, $^2J_{PH}$ 21.0 Hz, PCH), 3.82 (d, 6H, $^3J_{PH}$ 11.5 Hz, 2 MeO), 4.12 (dd, 1H, $J_{4,3}$ 3.5, $J_{4,5}$ 8.7 Hz, H-4), 5.02 (s, 1H, H-1), 5.11 (dq, 1H, H-5), 5.21 (s, 1H, H-2), 5.28 (d, 1H, H-3); ms *m/z* (CI,

Thermal fragmentation analysis of neutral polysaccharides and the presence of 1,6-anhydrooligosaccharides

R. J. HELLEUR AND P. JACKMAN

Department of Chemistry, Memorial University of Newfoundland, St. John's, Nfld., Canada A1B 3X7

Received December 7, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

R. J. HELLEUR and P. JACKMAN. Can. J. Chem. **68**, 1038 (1990).

Small quantities of pyrolysates were obtained from micro-scale off-line pyrolysis of the neutral polysaccharides: cellulose, amylose, laminaran, nigeran, and a mannan from ivory nut. The pyrolytic fragments were analyzed by desorption chemical ionization – mass spectrometry, trimethylsilyl derivatization – capillary gas chromatography (– ammonia chemical ionization mass spectrometry) and benzoyl derivatization – high pressure liquid chromatography. Intact 1,6-anhydrohexosemonosaccharide, and -disaccharide fragments were identified as major products. By using off-line analytical pyrolysis information on saccharide composition can be obtained from the formation of anhydromonosaccharide products while linkage information is obtainable from distinctive anhydrodisaccharide products.

Key words: pyrolysis, polysaccharides, 1,6-anhydrooligosaccharides, desorption chemical ionization, mass spectrometry, gas chromatography, high pressure liquid chromatography.

R. J. HELLEUR et P. JACKMAN. Can. J. Chem. **68**, 1038 (1990).

La pyrolyse périphérique à l'échelle microscopique de polysaccharides neutres, comme la cellulose, l'amylose, la laminarane, le nigerane et un mannane tiré de la noix d'ivoire, permet d'isoler de faibles quantités de produits de pyrolyse. On a analysé les fragments de la pyrolyse en faisant appel à la spectroscopie de masse par désorption et ionisation chimique, par chromatographie capillaire en phase gazeuse après formation de dérivés triméthylsilyles (spectroscopie de masse par ionisation chimique à l'aide de l'ammoniac) et par chromatographie liquide à haute performance sur des dérivés benzoyles. Les produits majeurs sont des fragments de 1,6-anhydrohexosemonosaccharides et -disaccharides. Faisant appel à la pyrolyse analytique et en se basant sur la nature des anhydro-monosaccharides, on peut obtenir de l'information sur la composition des saccharides alors que la nature des anhydro-disaccharides fournit de l'information sur la nature des liaisons qui les relient.

Mots clés: pyrolyse, polysaccharides, 1,6-anhydrooligosaccharides, désorption et ionization chimique, spectroscopie de masse, chromatographie en phase gazense, chromatographie liquide à haute performance.

Introduction

Structural elucidation of polysaccharides has been a particularly formidable biochemical problem to which solid sample analyses such as fast atom bombardment mass spectrometry has begun to make important contributions. To date, most of the work has been in the structural confirmation of saccharides resolved by gas chromatography. The importance of the structural identification problem is such that a more extensive and diverse contribution by other methods of analysis such as analytical pyrolysis (more appropriately called thermal fragmentation analysis) should be expected.

Numerous studies involving rapid pyrolysis of carbohydrates have shown that anhydrosugars are primary products (1–4). Rapid removal of pyrolysis products from the heated zone is important and this can be accomplished either by vacuum conditions or with the aid of a carrier gas flow. Recently, Helleur *et al.* (5–7) have used the thermal formation of anhydrosugars as a means of developing a new and rapid, solid sample technique of polysaccharide analysis. A heterolytic mechanism has been proposed for the glycosidic bond cleavage which involves a nucleophilic displacement of the glycosidic group by one of the ring hydroxyl groups to form an anhydrosugar (8). Another mechanism proposed by Essig *et al.* (9) suggests that anhydrosugar products from polysaccharides arise by a pyrolytic scission of glycosidic linkages to generate a resonance-stabilized glycose cation, which then adds an oxygen-nucleophile from within the same glycose cation to generate the anhydrosugar.

Pyrolysis in combination with gas chromatography (py-g.c.) has been used successfully in the identification of the saccharide composition of oligosaccharides and polysaccharides (6) and of more complex heterosaccharides (7). Each saccharide residue (e.g., gluco, arabino) produces its characteristic anhydrosugar (i.e., 1,6-anhydroglucopyranose, 1,4-anhydroarabinopyranose) which are then separated and identified using a polar phase – capillary gas chromatography column.

Past studies have reported or speculated on the existence of anhydrooligosaccharides in the pyrolytic sirups obtained from cellulose pyrolysis (10, 11). Recently, Radlein *et al.* (12) have identified cellobiosan, or, 4-O-(β-D-glucopyranosyl)-1,6-anhydro-β-D-glucopyranose, as the major anhydrodisaccharide product from rapid cellulose pyrolysis using a large fluid bed unit. the observation of intact anhydrooligomers of pyrolysis has also been claimed by Helleur *et al.* (13) and by others (14, 15) using the technique of pyrolysis – direct chemical ionization – mass spectrometry. In the present study, the optimization of "off-line" pyrolysis and the isolation and characterization of intact anhydrooligosaccharides is reported as a novel means of generating oligomer fragments from which linkage information can be obtained.

Experimental

Materials

Amylose, cellulose, laminaran, nigeran, sodium hydride, DMSO, methyl iodide, benzoic anhydride, 1,6-anhydro-β-D-glucopyranose, and 4-dimethylaminopyridine were purchased from Sigma Chemicals. HPLC Spectro-grade acetonitrile was obtained from Canlab. Silyl-grade pyridine and Tri-Sil Z were from Pierce Chemicals. Sephadex LH 20 was obtained from Pharmacia Fine Chemicals while Sep-Pak

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

C-18 cartridges were purchased from Waters. The mannan gum of ivory nut was a gift from Dr. G. Hay, Queen's University. 1,6-Anhydromannopyranose was a gift of Dr. A. S. Perlin, McGill University. Cellobiosan, maltosan, and 4-*O*-(6-*O*-β-D-galactopyranosyl-β-D-galactopyranosyl)-1,6-anhydro-β-D-glucopyranose were kindly donated by Dr. Taku Chiba, Nagoya City University.

Benzoylation

The samples (0.01–0.2 mg) were benzoylated by a procedure similar to that of Daniel *et al.* (16) using a dry pyridine solution (1.5 mL) containing 10% (w/v) benzoic anhydride and 5% (w/v) 4-dimethylaminopyridine. Reaction product mixtures were purified by chromatography using Sep-Pak C-18 cartridges.

Methylation

Dried pyrolysate oils were dissolved in DMSO (0.2 mL) under a nitrogen atmosphere and methylated with methyl sulfinyl anion and methyl iodide according to Hakomori's procedure (17). The methylated products were isolated from methylating agents by passage through a small column of Sephadex LH-20 suspended in chloroform followed by elution with the same solvent. Eluting fractions at 1 mL intervals were tested by TLC for products and, later, the fractions were combined and the chloroform evaporated off. The products were fully methylated as determined by IR.

Trimethylsilylation

Trimethylsilyl (TMS) derivatives were prepared using Tri-Sil Z reagent (*N*-trimethylsilylimidazole in dry pyridine) (TMS derivatization procedure as given in ref. 18). Samples were heated in 0.5 mL Reacti-Vials at 90°C for 20 min. In some cases the reaction mixture was diluted with water and the TMS-derivatized products were isolated by extraction with hexane.

Off-line pyrolysis

The off-line pyrolysis apparatus, illustrated in Fig. 1, was constructed using the water condenser part of a micro-sublimator (Kontes Glassware, $24/25 joint, #306500-000) and a Ace-Thred thermometer adapter (Aldrich Chemicals, $24/40 joint, #Z17,501-3). The adapter was modified by the addition of a gas purge side arm. The end of the condenser was drawn out to a fine tip so as to fit just inside the pyrolysis tube (about 0.25 cm from the pyrolysis zone).

The polysaccharide (50–200 μg) was placed between two porous plugs of silanized quartz wool in the quartz tube. The tube was positioned inside the coil of a Pyroprobe 1/4 inch probe (Chemical Data Systems) as shown in Fig. 1. The nitrogen flow of 5 mL/min and a vacuum of 2 mm Hg was normally applied during pyrolysis. Pyrolysis was usually carried out at 600°C for 10 s. The condensed pyrolysate was washed off with small amounts of the solvent used during derivatization.

Chromatographic methods

Gas chromatography was performed using a Varian 3700 gas chromatograph equipped with a flame ionization detector. A non-polar fused silica capillary column (J&W Scientific, DB-5, 1.0 μm thickness, 30 m × 0.322 mm id) operated at a colum flow rate of 2.5 mL of He/min and a split ratio of 10:1 was used for high resolution separation of TMS derivatives. Temperature program settings were as follows: initial temperature, 120°C, hold 2 min; increase 5°C/min until 270°C, hold for 15 min. The injection port and detector were heated at 280°C. TMS derivatives were also analyzed using an on-column injector (J&W Scientific) and a non-polar capillary column (J&W DB-5, 1.0 μm thickness, 10 m × 0.25 mm id) with a column flow rate of 2 mL He/min. Temperature program settings were initial temperature, 80°C, hold 2 min; increase 8°C/min until 340°C, hold 10 min. The detector was heated at 350°C. One μL samples were injected in each case.

High pressure liquid chromatography (HPLC) of benzoylated derivatives were analyzed using a Varian 5000 HPLC equipped with a Varian Model UV-10, variable wavelength UV detector. The detector wavelength was set at 230 nm. Reversed phase chromatography was performed on a 5 μm Sperisorb ODS-2, 250 × 4.6 mm column

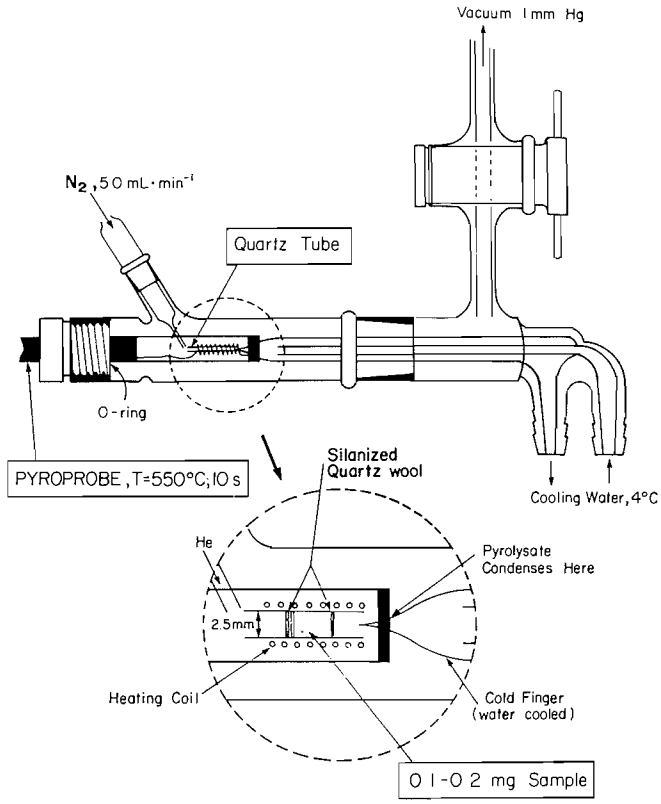

FIG. 1. Off-line pyroprobe pyrolysis apparatus.

(Alltech), sample loop 10 μL. Gradient elution from 65% CH_3CN/35% H_2O to 100% CH_3CN in 20 min, at a flow rate of 1 mL/min, was used.

Gas chromatography – mass spectrometry

The conditions of chromatography were identical to those used for high resolution separation, i.e., 30 m column, but with a reduced column flow rate. The column outlet was led directly into the ion source of a VG 7070HS double focusing mass spectrometer equipped with a DS 2035 data system. Mass spectrometric detection was carried out under chemical ionization conditions using ammonia as reagent gas and with a combinaion EI-CI source in the CI mode (CI slit). The ammonia gas was admitted into the ion source until the pressure above the diffusion pump was 6×10^{-5} mbar. The electron impact ionization energy was set at 100 eV, the source temperature at 140°C and the column inlet temperature at 270°C. The resulting ion abundance ratio of adducts of ammonia, m/z 18 and 35 were observed to be approximately 5 to 1.

Desorption chemical ionization – mass spectrometry

Mass spectra were acquired with a VG analytical ZAB-EQ hybrid instrument fitted with a VG 11-250J data system. Samples were evaporated onto a DCI platinum filament probe and inserted into a combination EI-CI source in the CI mode (CI slit). The source was operated at 160°C. Ammonia gas was admitted into the source until the pressure above the diffusion pump was 7×10^{-5} mbar. Electrons with 100 eV energy were used to ionize the ammonia reagent gas. A reasonably high ammonia gas pressure was obtained in this source where the ion abundance ratios of the ammonia adducts m/z 18, 35, and 52 were measured at 2:8:5. The samples were desorbed by heating the platinum filament for approximately 120 s, the final temperature of the filament being close to 350°C. The mass spectra were time-integrated.

Results and discussion

"Off-line" pyrolysis conditions

The important considerations in the design of the pyrolysis apparatus, as shown in Fig. 1, were that it should bear the

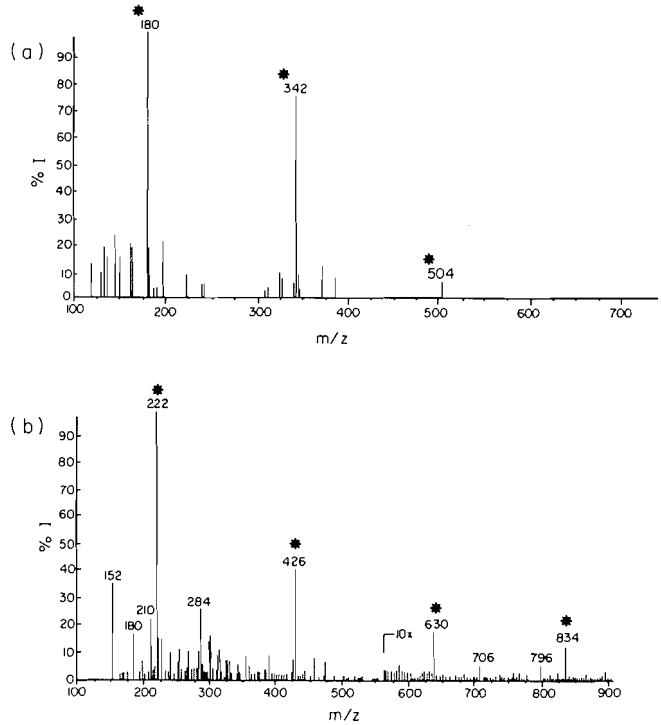

FIG. 2. Desorption ammonia chemical ionization – mass spectra of (*a*) underivatized amylose pyrolysate and (*b*) permethylated derivative of amylose pyrolysate.

following features: of simple construction, using commercially available parts; afford a means for observing the pyrolysis; and use of the CDS pyroprobe, an ultra-rapid pyrolysis unit widely used in research. Three major parameters were found to affect the generation and isolation of anhydrosugars: the pyrolysis temperature, the vacuum, and the location of the cold finger. Conditions were optimized to obtain the lowest anhydro monomer-to-dimer ratio using amylose (100 μg) as the standard. A pyrolysis temperature of 600°C was selected. It was found that temperatures outside the range 600 ± 100°C resulted in change in product distribution and poor reproducibility. A temperature of 600°C was found to be suitable for many other polysaccharides studied. The heat transfer from the heating coil to the quartz tube was retarded if the pressure was much less than 1 mm Hg. The positioning of the cold finger condensor was important because if it were too close to the pyrolysis tube partial blockage of the flow of gases occurred, whereas if it were too far from the tube higher molecular weight products were not trapped and the ratio of dimeric products to monomeric decreased.

Once the pyrolysis conditions were set up replicate analyses of amylose showed only small variations (approximately 10%) in reproducibility of the anhydro monomer-to-dimer ratio. Average yields of total anhydrosugars ranged from 10 to 20%. A study of yields among the glucans having different linkage and anomeric configuration was not carried out with off-line pyrolysis but preliminary studies using py–g.c. indicate a substantial difference in anhydro glucose yields among three different glucan samples (samples had been washed free of trace metals before pyrolysis).

Desorption ammonia chemical ionization mass spectra isolated pyrolysates

Preliminary evidence of the presence of oligomeric products in the condensate from our "off-line" pyrolysis was obtained by direct probe mass spectrometry. The mass spectrum of the underivatized mixture of pyrolysis products of amylose (Fig. 2*a*) shows important pseudo-molecular ions, i.e., m/z 180, 342, and 504. These fragment ions most likely correspond to the ammonium adducts of an anhydrohexose, an anhydrohexose disaccharide, and an anhydrohexose trisaccharide, respectively. The ammoniated anhydrooligosaccharide ion series can be described as $[(162)_n + 18]$ in which "n" represents the number of saccharide units and 18 represents the NH_4^+-adduct. Additional information pertaining to the structure of the anhydrosaccharides was obtained by the mass spectrum (Fig. 2*b*) of the per-*O*-methylate pyrolysate of amylose. The spectrum reveals ions corresponding to the ammonia ion adducts of the per-*O*-methylated anhydrooligosaccharides. This homologous series of per-*O*-methylated products can be described as $[(204)_n + 18]$ in which n represents the number of methylated saccharide units.

High temperature gas chromatographic analysis of TMS derivatives and identification of anhydrosugar products

Sample analysis by on-column injection short-column gas chromatography coupled with high temperature programming insures, first, that labile compounds do not degrade when injected, and, second, that high mass products such as a TMS anhydrotrimer compound will elute from the chromatographic column. The chromatogram of the TMS derivatives of an amylose pyrolysate is given in Fig. 3. The frontal peaks correspond to large amounts of remaining TMS reagent and decomposition products. (It was found that no loss of product was observed if the TMS reaction mixture was extracted with hexane.) Two large chromatographic peaks are observed, peak A and peak B, the retention times which corresponds to those of the standards 1,6-anhydro-2,3,4-tri-*O*-(trimethylsilyl)β-D-glucopyranose and 4-*O*-(2,3,4,6-tetra-*O*-(trimethylsilyl)α-D-glucopyranosyl)-1,6-anhydro-2,3-di-*O*-(trimethylsilyl)-βD-glucopyranose, respectively. Confirmation of the molar mass of these anhydrosugars was obtained by gas chromatography – ammonia chemical ionization mass spectrometry. Their ammonia chemical ionization mass spectra are shown in Fig. 3. Note that extensive fragmentation is observed even under ammonia chemical ionization conditions. Parent ions of carbohydrates are usually not observed unless very soft ionization is used.

No TMS anhydrotrimer product was observed in the chromatogram even though an anhydrotrimer ion was observed by desorption – mass spectrometry as shown above. The TMS derivative of our anhydrotrisaccharide standard eluted with a retention time of 33.1 min.

Separation of benzoylated derivatives of amylose pyrolysate by HPLC

The technique of HPLC was used in this study to obtain chromatographic evidence of an anhydrotrisaccharide product and to be able, in future studies, to isolate small quantities of fractionated products for structural characterization. The HPLC chromatogram of the benzoylated products of an amylose pyrolysate, Fig. 4, shows a large solvent and reagent peak along with a number of small molecular weight products of pyrolysis. There are also three later-eluting peaks whose elution times are 12.9, 20.5, and 23.7 min. Under the conditions employed the benzoylated derivatives of 1,6-anhydro-β-D-glucopyranose and 4-*O*-(α-D-glucopyranosyl)-β-D-glucopyranose standards had retention times of 12.9 and 20.5 min. The compound eluting at 23.7 has not been identified.

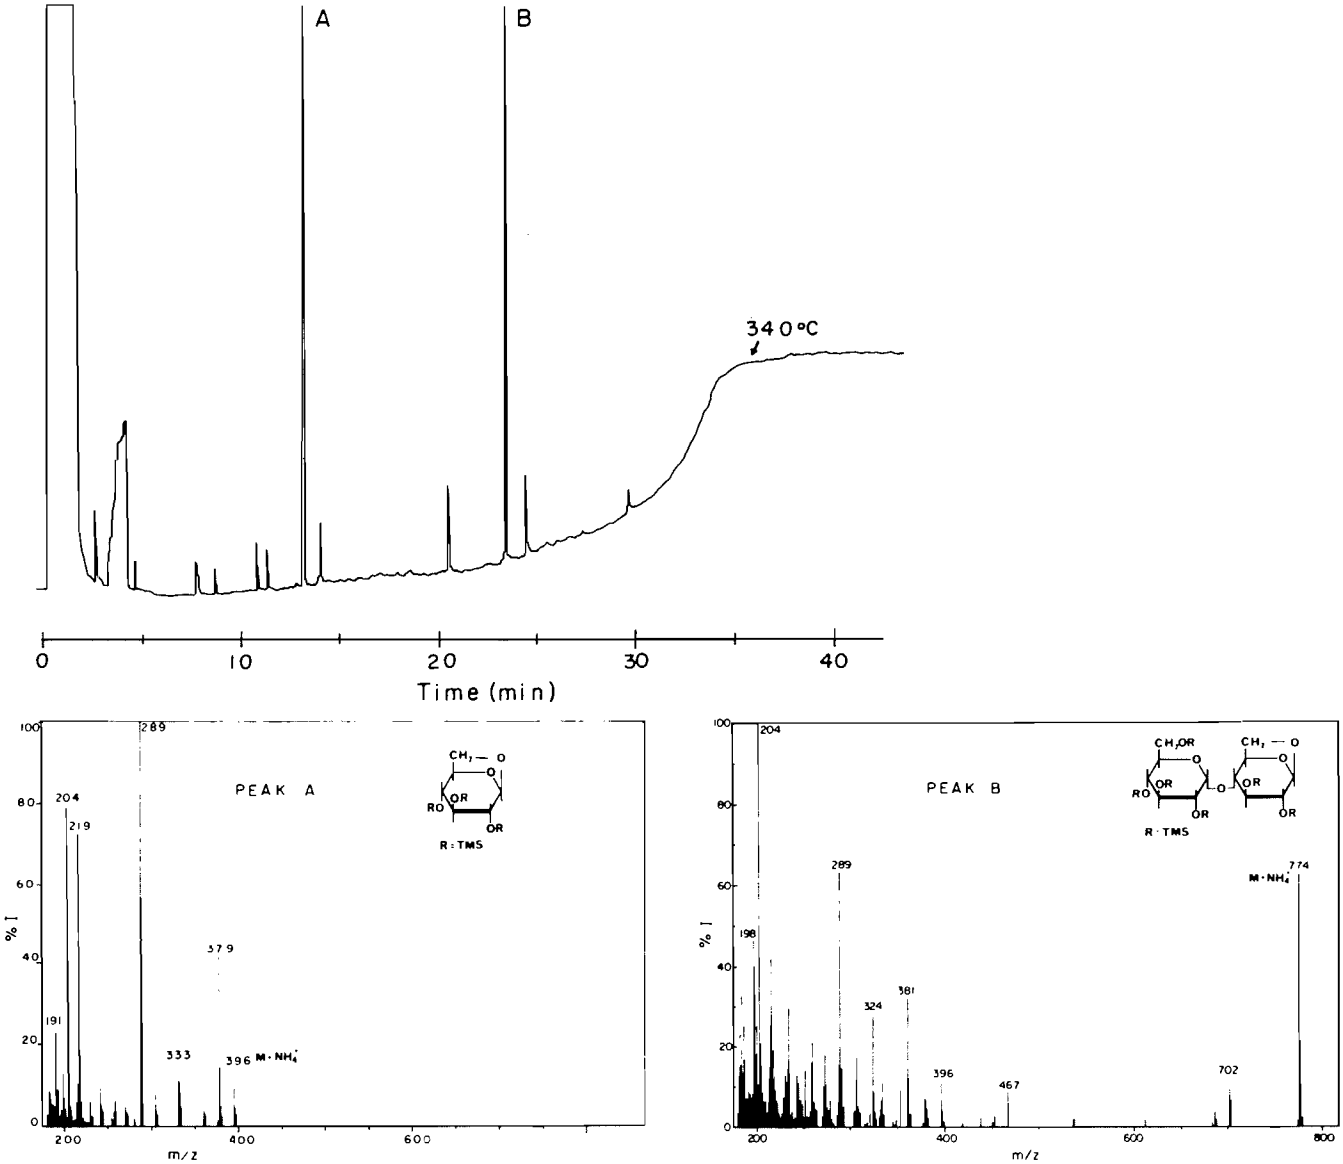

FIG. 3. On-column injected – short column – gas chromatogram of TMS derivative of amylose pyrolysate and ammonia chemical ionization mass spectra representing those of the compounds of peak A and Peak B whose spectra closely resemble the standards, 1,6-anhydro-2,3,4-tri-*O*-(trimethylsilyl)-β-D-glucopyranose and 4-*O*-(2,3,4,6-tetra-*O*-(trimethylsilyl)-α-D-glucopyranosyl)-1,6-anhydro-2,3-di-*O*-(trimethylsilyl)-β-D-glucopyranose, respectively.

Structural analysis of polysaccharides by off-line pyrolysis – TMS derivatization – high resolution g.c.

One of the objectives of this study is to develop a rapid analysis for polysaccharides to obtain both saccharide and structural information. Five different polysaccharides were analyzed: four glucans, i.e., amylose (-α-D-(1→4)-linked), cellulose (-β-D-(1 → 4)-), laminaran (-β-D-(1→3)-), and nigeran (alternating -α-D-(1→4)- and -α-D(1→3)-linked), and, a ivory nut mannan. Current evidence (19) indicates that ivory nut mannans are principally linear β-D-(1→4)-linked D-mannans. The gas chromatograms of all five TMS-pyrolysate samples are given in Fig. 5. The identity of the minor peaks, which are not labelled, has not been confirmed. Based on previous pyrolysis work (20) and comparison with the retention times of other standards, the minor peaks eluted before the M-labelled one have been tentatively assigned to 5-(hydroxymethyl)-2-furaldehyde, and 1,5-anhydro-4-deoxyD-*glycero*-hex-1-en-3-ulose. The minor peaks in the high mass region, around the

Identity (* = tentative) of labelled peaks: *peak M1*, 15.4 min, 1,6-anhydro-2,3,4-tri-*O*-(trimethylsilyl)-β-D-glucopyranose; *peak M2*, 14.2 min, 1,6-anhydro-2,3,4-tri-*O*-(trimethylsilyl)-β-D-mannopyranose; *peak D1*, 33.8 min, 4-*O*-(2,3,4,6-tetra-*O*-(trimethylsilyl)-β-D-glucopyranosyl)-1,6-anhydro-2,3-di-*O*-(trimethylsilyl)-β-D-glucopyranose; *peak D2*, 33.4 min, 4-*O*-(2,3,4,6-tetra-*O*-(trimethylsilyl)-α-D-glucopyranosyl)-1,6-anhydro-2,3-di-*O*-(trimethylsilyl)-β-D-glucopyranose; *peak D3*, 32.7 min, 3-*O*-(2,3,4,6-tetra-*O*-(trimethylsilyl)-β-D-glucopyranosyl)-1,6-anhydro-2,3-di-*O*-(trimethylsilyl)-β-D-glucopyranose*; *peak D4*, 32.8 min, 3-*O*-(2,3,4,6-tetra-*O*-(trimethylsilyl)-α-D-glucopyranosyl)-1,6-anhydro-2,3-di-*O*-(trimethylsilyl)-β-D-glucopyranose*; *peak D5*, 34.7 min, 4-*O*-(2,3,4,6-tetra-*O*-(trimethylsilyl)-β-D-mannopyranosyl)-1,6-anhydro-2,3-di-*O*-(trimethylsilyl-β-D-mannopyranose*.

retention time of the D-labelled peaks, are believed to be various anhydrodisaccharides having different glucosidic linkages as the result of polymerization of levoglucosan in the melt and re-pyrolysis (21, 22). It is noteworthy that laminaran (Fig. 5*c*), by giving the highest amount of levoglucosan, generated a large number of minor anhydrodisaccharide products.

Each polysaccharide sample produced major quantities of anhydromonomeric and -dimeric fragments characteristic of their saccharide composition and structural linkage. A remarkable feature of these products is that each has its distinctive retention time as listed in the legend of Fig. 5.

In summary, this study has described a relatively simple pyrolysis apparatus for the isolation of intact 1,6-anhydrooligosaccharides from thermal fragmentation of neutral polysaccharides. With TMS derivatization followed by g.c. analysis, information on saccharide composition can be obtained from anhydromonosaccharide products while linkage information can be obtained from distinctive anhydrodisaccharide products. Future studies will be conducted to obtain higher mass fragments and HPLC will be used more extensively. In addition to neutral saccharides, analysis of thermal fragments from uronic acid- and amino-containing polysaccharides will improve our understanding of the complex pyrolysis mechanisms of these important polymeric units.

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

DONALD A. POWELL, WILLIAM S. YORK, HERMAN VAN HALBEEK, JOSEPH T. ETSE, ALEXANDER I. GRAY, and PETER G. WATERMAN. Can. J. Chem. **68**, 1044 (1990).

The structure of Mezzettiaside 3, a highly acylated trisaccharide obtained from the stem bark of *Mezzettia leptopoda*, was determined by a combination of double-quantum-filtered $\{^1H,^1H\}$ correlation spectroscopy, two-dimensional homonuclear Hartmann–Hahn, and ^1H-detected $\{^1H,^{13}C\}$ one-bond and multiple-bond shift correlation nuclear magnetic resonance experiments, in conjunction with fast-atom-bombardment mass spectrometry. Mezzettiaside 3 was found to be the α-(*n*-octyl)glycoside of 3,4-di-*O*-acetyl-L-rhamnopyranosyl-α(1→3)-2,4-di-*O*-acetyl-L-rhamnopyranosyl-α(1→3)-4-*O*-hexanoyl-L-rhamnopyranose. The heteronuclear multiple-bond correlation NMR technique proved to be invaluable in establishing the location of the *O*-acyl groups in this complex carbohydrate.

Key words: oligosaccharide, HMBC, HMQC, HOHAHA, FAB-MS.

DONALD A. POWELL, WILLIAM S. YORK, HERMAN VAN HALBEEK, JOSEPH T. ETSE, ALEXANDER I. GRAY et PETER G. WATERMAN. Can. J. Chem. **68**, 1044 (1990).

La structure du Mezzettiaside 3, un trisaccharide très acylé, obtenu à partir de l'écorce du tronc de *Mezzettia leptopoda*, a été elucidée en faisant appel à la spectrométrie de masse par bombardement avec des atomes rapides (SM-FAB) en combinaison avec les methodes de résonance magnétique nucléaire (RMN) suivantes : spectroscopie de corrélation $\{^1H,^1H\}$ doublement filtré d'un point de vue quantique, spectroscopie Hartmann-Hahn homonucléaire bidimensionelle et spectroscopie de corrélation des déplacements $\{^1H,^{13}C\}$ par liaisons simples et multiples avec détection de ^1H. On a trouvé que la Mezzettiaside 3 est l'α-(*n*-octyl)glycoside du 3,4-di-*O*-acétyl-L-rhamnopyranosyl-α(1→3)-2,4-di-*O*-acétyl-L-rhamnopyranosyl-α(1→3)-4-*O*-hexanoyl-L-rhamnopyranose. La technique de corrélation hétéronucléaire des liaisons multiples par RMN s'est avérée très utile pour déterminer la position des groupements *O*-acylés de ce carbohydrate complexe.

Mots clés : oligosaccharide, HMBC, HMQC, HOHAHA, FAB-MS.

Introduction

Mezzettiaside 3 (ML-3) is the third of seven oligorhamnosides whose isolation and purification from the stem bark of *Mezzettia leptopoda* Oliv. *ex* King (*Annonaceae*) has been described (1). Here we report the characterization of the primary structure of ML-3 by utilizing results from three different techniques: (i) gas chromatography (GC) of *S*(+)-2-butylglycosides generated from ML-3; (ii) fast-atom-bombardment mass spectrometry (FAB-MS) of the native ML-3, of deuterio-acetylated ML-3, and of de-acylated ML-3; and (iii) a combination of one-dimensional (1-D) and two-dimensional (2-D) NMR spectroscopy, including homonuclear Hartmann–Hahn (HOHAHA) spectroscopy, and heteronuclear multiple quantum coherence (HMQC and HMBC) experiments.

Experimental

Isolation and purification of Mezzettiaside 3 (ML-3)

Highly acylated oligorhamnosides were isolated (1) in a mixture from the stem bark of *Mezzettia leptopoda* by extraction with petroleum ether (bp 60–80°C). Seven components were separated by silica gel chromatography utilizing stepwise elution with toluene, toluene containing 10–40% ethyl acetate, and finally with pure methanol. The third fraction, designated ML-3, eluted with toluene containing 15% ethyl acetate, in a yield of 0.1% (w/w of powdered stem bark). Further purification of ML-3 was performed by circular preparative thin-layer chromatography on silica gel using chloroform/methanol (95:5, v/v). The optical rotation $[\alpha]_D$ of ML-3 was −49° (*c* 0.38, chloroform, 20°C) (1).

Butanolysis and gas chromatography

For glycosyl composition analysis, ML-3 was subjected to butanolysis followed by trimethylsilylation and gas chromatography. The chemicals used in this analysis were acetyl chloride and L-rhamnose (purchased from Sigma), *S*(+)-2-butanol and *R*/*S*(−/+)-2-butanol (from Aldrich), and Trisil (from Pierce). The *S*(+)- and *R*(−)-2-butylglycosides of L-rhamnose, and the *S*(+)-2-butylglycosides from ML-3 were prepared according to the butanolysis method of Gerwig *et al.* (2, 3). Gas chromatography of these derivatives was performed on a Hewlett Packard 5890 instrument with a Supelco SP2330 capillary column (30 m × 0.25 mm i.d.). Cochromatography of the ML-3

derived butylglycosides with the appropriate standards, namely, *S*(+)-2-butyl-L-rhamnoside and *R*(−)-2-butyl-L-rhamnoside (which behaves the same on the column as its enantiomer *S*(+)-2-butyl-D-rhamnoside) was applied for identification of the ML-3 glycosyl residues.

Fast-atom-bombardment mass spectrometry

FAB mass spectra were recorded on a VG Analytical ZAB-SE mass spectrometer (4). ML-3 samples (5 μg/μL methanol) were prepared in several ways for different FAB-MS experiments. Approximately 1 mg of ML-3 was deuterio-acetylated as described by Dell and Tiller (5). Also, 0.5 mg of ML-3 was de-acylated in 0.4 mL methanol with 0.1 mL of 0.5 M NaOH at 30°C. After 16 h, water (0.3 mL) was added and the solution was desalted over a Dowex-50 cation exchange column at 4°C and dried with filtered air.

FAB mass spectra of the native ML-3 and its de-acylated derivative were recorded in the negative-ion mode using an aminoglycerol matrix (4). The FAB mass spectrum of deuterio-acetylated ML-3 was recorded in the positive-ion mode using a thioglycerol matrix. Sodium acetate was added to the deuterio-acetylated derivative to give a strong parent ion (6).

NMR spectroscopy

NMR experiments were performed on a Bruker AM-500 instrument interfaced with an Aspect 3000 computer using the DISR88 software package. The ML-3 sample (20 mg) was dissolved in 0.4 mL of benzene-d_6/methanol-d_4 (Aldrich) (4:1, v/v), in a 5-mm Wilmad 535-PP NMR tube. ^{1}H and ^{13}C chemical shifts are expressed in ppm downfield from internal tetramethylsilane (TMS, Aldrich). 1-D nuclear Overhauser effect (NOE) difference experiments were performed by the selective presaturation method of Wagner and Wüthrich (7).

A double-quantum-filtered {^{1}H,^{1}H} COSY spectrum was recorded in the phase-sensitive mode, with quadrature detection in t_1 according to the TPPI method (8, 9). The spectral width was 2500 Hz, and the relaxation delay 4.5 s; 512 FIDs each having 1k data points were acquired with a t_1 increment of 200 μs. Unshifted sine bell window functions were used in processing the data both in the t_1 and t_2 dimensions. The data matrix was expanded to a 2k × 2k data file before Fourier transformation, giving rise to a digital resolution in F2 of 2.441 Hz/pt.

2-D HOHAHA spectroscopy was performed in the phase-sensitive mode (TPPI) using the MLEV-17 sequence for mixing (10–13). The spectral width was 2500 Hz; 512 experiments of 48 scans and 2k data points each (relaxation delay 1 s; t_1 increment 200 μs; mixing time 100 ms) were acquired. The total time for data collection of the HOHAHA experiment was 11.5 h. For processing, a sine bell window shifted by $\pi/10$ was applied in both dimensions, followed by expansion of the data matrix to 2k × 2k data points and transformation. The resulting digital resolution in F2 was 2.441 Hz/pt.

Heteronuclear 2-D *J*-resolved NMR spectroscopy was carried out using the spin–flip method (14). The spectral width was 31 250 Hz in F2 and 556 Hz in F1. 128 experiments of 96 scans each were acquired in 8k data points (relaxation delay 3 s; t_1 increment 900 μs). After applying a 10 Hz Gaussian linebroadening in the t_2 dimension only, the data matrix was expanded to a 16k × 512 w file (F2 digital resolution: 3.81 Hz/pt; F1 digital resolution: 2.17 Hz/pt) and then transformed.

The ^{1}H-detected {^{1}H,^{13}C} shift correlation experiments utilized a 5-mm broadband probe with reversed geometry. The decoupler transmitter was used for ^{1}H pulses (reverse mode) and the sample was not spun.

^{1}H-Detected heteronuclear multiple quantum coherence (HMQC) experiments were performed according to Bax and co-workers (12, 15), preceded by a BIRD pulse to suppress ^{1}H resonances not coupled to ^{13}C (12, 16) and with GARP1 ^{13}C decoupling during ^{1}H data acquisition (17). The spectral width in the ^{1}H dimension was 2500 Hz and in the ^{13}C dimension 12 500 Hz; 250 experiments of 200 scans each (relaxation delay 1 s; t_1 increment 400 μs; delay after BIRD pulse 300 ms) were acquired in 1k data points each; the total time for data collection in the HMQC experiment conducted under these conditions was 18.5 h. An unshifted sine bell window function was applied in the t_2 dimension and a Gaussian window (line broadening 100 Hz) in the t_1 dimension; then the data matrix was expanded to 1k × 512w before Fourier transformation. The resulting digital resolutions were 4.883 Hz/pt in F2 (^{1}H) and 24.415 Hz/pt in F1 (^{13}C dimension).

Heteronuclear multiple bond correlation (HMBC) spectroscopy was performed according to Bax and co-workers (11, 12, 18). The spectral width in the ^{1}H dimension was 2500 Hz, and in the ^{13}C dimension 25 000 Hz; 200 FIDs of 192 scans in 2k data points each (relaxation delay 1 s; t_1 increment 200 μs) were collected during a total time of 17 h. An unshifted sine bell window function was applied in the t_2 dimension, and a Gaussian window (line broadening 100 Hz) in the t_1 dimension. The data matrix was then expanded to 2k × 512w and transformed. The final resolution in F2 was 2.441 Hz/pt, in F1 48.82 Hz/pt.

Results

Composition and sequence analysis by GC and FAB-MS

The glycosyl composition of ML-3, including the absolute configuration of the constituent monosaccharide residues, was determined by butanolysis followed by gas chromatography of the TMS derivatives of the butylglycosides. GC of the *S*(+)-2-butylglycosides generated from ML-3 showed exclusively *S*(+)-2-butyl-L-rhamnoside; therefore, ML-3 was found to consist of L-rhamnose residues.

Negative-ion FAB-MS of native ML-3 gave a molecular ion $[M-H]^-$ at *m/z* 833 but the intensity of fragment ion peaks was weak. To enhance fragment ion information, the free hydroxyl groups in ML-3 were deuterio-acetylated. Use of acetic acid-d_3 in the derivatization procedure allowed the endogenous *O*-acetyl groups to be distinguished from those introduced chemically (5). From the $[M+Na]^+$ ion (*m/z* 947) and the fragment ions (*m/z* 795, 506, and 276) observed in the positive-ion FAB mass spectrum of the deuterio-acetylated sample (see Fig. 1a), ML-3 was deduced to be the octyl glycoside of a linear trirhamnoside which has a number of endogenous acyl substituents, as follows. Comparison of *m/z* 947 for the $[M+Na]^+$ peak of the deuterio-acetylated ML-3 and *m/z* 833 for $[M-H]^-$ of native ML-3 (see above) indicates that only two deuterio-acetyl (Ac*) groups were introduced chemically. One of these occurs at the non-reducing-end Rha residue denoted Rha-C, as was inferred from the *m/z* value of fragment ion 276 $[Rha(Ac^*)Ac_2]^+$; the other one is at Rha-A, since a type A fragment ion (5, 6) was observed at *m/z* 795 $[Rha_3(Ac^*)_2Ac_4R]^+$, while another type A fragment at *m/z* 506 $[Rha_2(Ac^*)Ac_4]^+$ indicates that Rha-B does not become deuterio-acetylated. From the mass of the fragment ion at *m/z* 795 it was determined that R is a hexanoyl group. The aglycone R′ of ML-3 was deduced to be an octyl group, by virtue of the mass of OR′ being 129, i.e., the difference between M and the A fragment at *m/z* 795. This implies that the Rha residue at the non-reducing end (Rha-C) has two endogenous *O*-acetyl groups attached; the adjacent residue Rha-B also has two endogenous *O*-acetyl groups, and the third residue, Rha-A at the potentially reducing end, has an *O*-hexanoyl substituent and an *O*-octyl aglycone.

To confirm the nature of the aglycone, an aliquot of ML-3 was de-acylated. Under the mild alkali conditions used to remove the *O*-acyl groups, the base-stable glycoside was not cleaved. The FAB mass spectrum of de-acylated ML-3 recorded in the negative-ion mode (see Fig. 1b) showed the $[M-H]^-$ ion at *m/z* 567 that represents $[Rha_3$-*O*-octyl$]^-$; this interpretation is supported by the presence of ions at *m/z* 421 and 275 that arise by consecutive losses of rhamnosyl residues from the nonreducing end. Each of these fragment ions still contains the octyl aglycone.

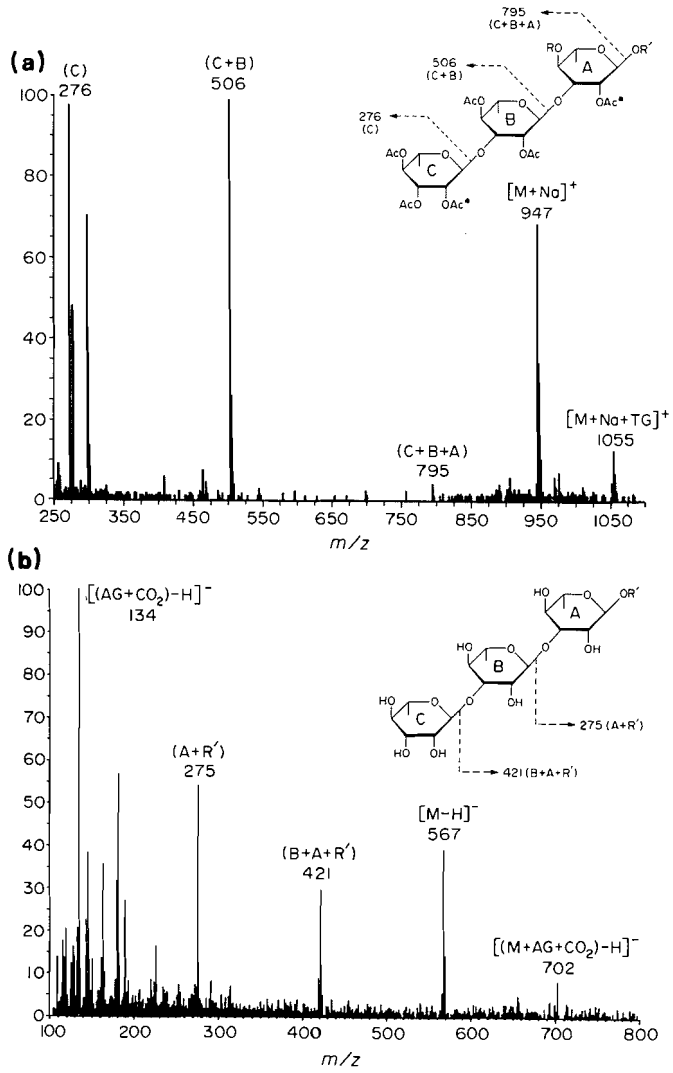

FIG. 1. (a) FAB mass spectrum of deuterio-acetylated ML-3 in the positive-ion mode; (b) FAB mass spectrum of deacylated ML-3 in the negative-ion mode. Insets illustrate the observed fragmentation patterns; R = $CO(CH_2)_4CH_3$; R′ = $-(CH_2)_7CH_3$; Ac* = trideuterioacetyl group. In spectrum (a), a matrix adduct ion $[M+Na+TG]^+$ is observed at m/z 1055, where TG stands for thioglycerol. In spectrum (b), a characteristic matrix ion $[AG+CO_2-H]^-$ occurs at m/z 134; it is formed when the aminoglycerol (AG) matrix is exposed to CO_2 (W.S. York; unpublished observations). This process also gives rise to an adduct ion at m/z 702 $[(M+AG+CO_2)-H]^-$.

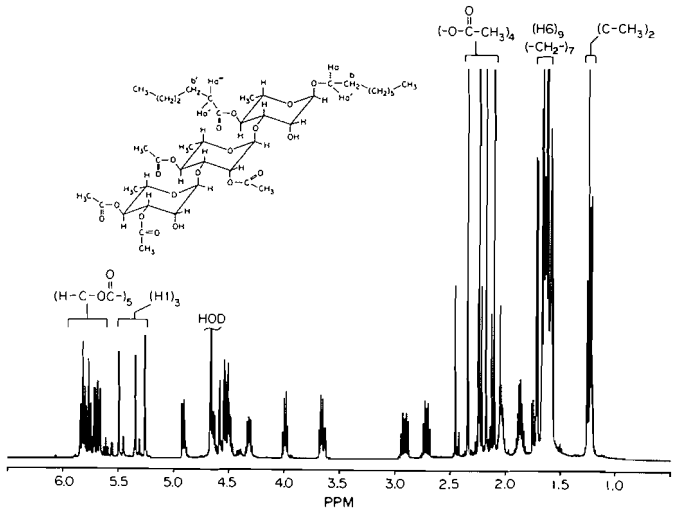

FIG. 2. 500-MHz ^1H NMR spectrum of ML-3 at 27°C in benzene-d_6/methanol-d_4 (4:1, v/v) with an inset of its structure. $(H1)_3$ refers to the anomeric protons of the three Rha residues and HOD refers to residual water in the solvent. Between δ 5.65 and 5.85 ppm, five non-anomeric rhamnosyl ring proton resonances are observed, indicating the presence of five acyl substituents in ML-3. In the upfield region of the spectrum, four acetyl methyl singlets are observed between δ 2.1 and 2.4 ppm; seven methylene multiplets and the doublets of three Rha C6 methyl groups are overlapping at δ ≈ 1.6 ppm, whereas two aliphatic methyl groups show intertwined triplets at δ ≈ 1.25 ppm. Chemical shifts are referenced to TMS.

Determination of glycosyl linkage positions and configurations, and locations of appended groups by NMR

To complete the determination of the primary structure of ML-3, various 1-D and 2-D, ^1H and ^{13}C NMR spectra of the compound were recorded. Their assignments allowed the determination of the linkage positions between the L-rhamnose residues and the positions of attachment of the acetyl and hexanoyl groups.

The ^1H NMR spectrum of ML-3 (Fig. 2) was virtually completely assigned by the combination of double-quantum-filtered (DQF) COSY (Fig. 3a) and 2-D HOHAHA experiments (Fig. 3b). The ^1H chemical shifts and coupling constants are listed in Table 1; in the methylene proton region ($1.55 < \delta < 1.68$) severe signal overlap prevented more detailed assignments. The three resonances observed at δ 5.49, 5.34, and 5.25 ppm were assigned to the anomeric protons by virtue of their being doublets. The signals, at this point, were designated H1X, H1Y, and H1Z, respectively, since the identity of the spin systems to which each belonged, i.e., Rha-A, -B, or -C, was yet to be determined. Downfield of the anomeric proton signals, between δ 5.85 and 5.65 ppm, a group of five non-anomeric ring proton signals was found, reflecting the presence of five acyl substituents. Other signals of interest, at δ 3.99, 3.66, 2.91, and 2.71 ppm, are due to methylene protons that are adjacent to the glycosidic oxygen in the aglycone or the carbonyl group in the hexanoyl substituent (denoted as Ha, Ha′, Ha″, and Ha‴, respectively, in the inset of Fig. 2). In addition, there are four acetyl singlets (at δ 2.34, 2.24, 2.18, and 2.10 ppm) and three methyl doublets arising from the H6 protons of the rhamnosyl residues (at δ 1.71, 1.66, and 1.62 ppm). The DQF-COSY experiment allowed the sequential assignment of several resonances for each rhamnosyl ring system, starting from the anomeric resonances. This is illustrated for Rha-Y (later identified as Rha-B; see below) in Fig. 3a. Not all of the Rha proton resonances could successfully be assigned from the COSY spectrum, since some of the crosspeaks were overlapping, e.g., those for proton pairs H4X/H5X and H3Z/H4Z. To complete the assignments, a 2-D HOHAHA spectrum was recorded (Fig. 3b). From this experiment, subspectra were obtained for each isolated spin system, in this case rhamnosyl residue (see Fig. 3b). All of the Rha proton resonances were assigned by the combination of HOHAHA and COSY results (see Table 1), except for the H4X and H4Z protons. The latter two signals, although resolved in the 1-D spectrum by 0.004 ppm (2 Hz) (Fig. 2), were not discernible in the 2-D (COSY and HOHAHA) spectra, because of the limitations in digital resolution (2.441 Hz/pt). In addition to the Rha proton signals, some key resonances for protons in the octyl aglycone (Ha, Ha′, and Hb) and hexanoyl group (Ha″, Ha‴, and Hb′) spin systems were identified (see Table 1). However, since the protons across the

[b]First-order data.

[c]For designations Rha A–C, for numbering of H atoms in the rhamnosyl rings, and for lettering of the H atoms in the substituent groups, see the structure of ML-3. R′ = octyl aglycone (at A1); R = hexanoyl (at A4); Ac = acetyl (at B2, B4, C3 and C4). The number of equivalent protons is given in parentheses.

[d]The triplets of H4A and H4C are resolved in the resolution-enhanced 1-D spectrum (see the ^{1}H projection in Fig. 4B), but not in the 2-D COSY and HOHAHA experiments (see Fig. 3). The lack of resolution in the 2-D {^{1}H,^{1}H} spectra prevented conclusive assignment of these signals by NMR alone. The combination of the FAB-MS and HMBC results enabled us to assign the signal at δ 5.824 ppm to H4A (see text and Fig. 4B).

[e]Individual chemical shifts and coupling constants could not be deduced for any signal within this range.

[f]Assignments of these signals are inconclusive with respect to the location of the acetyl groups, essentially due to lack of resolution of the corresponding carbonyl signals in the ^{13}C spectrum (see Fig. 4B).

glycosidic linkages are four bonds apart and therefore do not show any scalar coupling, no correlations between individual spin systems are observed in COSY or HOHAHA spectra; in other words, no sequence information was obtained from these experiments.

To establish the sequence of the three rhamnosyl spin systems X, Y, and Z (i.e., to determine how they match residues A, B, and C) and to determine the glycosyl linkage positions, a series of 1-D NOE experiments was carried out. The NOE difference spectrum upon presaturation of the H1Z at δ 5.25 ppm showed an NOE across the glycosidic linkage to Ha and Ha′ (at 3.99 and 3.66 ppm) of the aglycone and thereby identified spin system Z as Rha-A. The NOE difference spectrum obtained upon presaturation of the H1Y resonance at 5.34 ppm showed an interglycosidic NOE to H3Z (identified as H3A) at 4.51 ppm. This established spin system Y as being Rha-B, and also indicated the linkage between Rha-B and Rha-A to be (1→3). The interglycosidic NOE from H1X at 5.49 ppm to H3B (i.e., H3Y) at 4.91 ppm confirmed that spin system X is Rha-C, and indicated the linkage between Rha-C and Rha-B to be (1→3).

Presaturation of each of the H1 resonances showed, in addition to the aforementioned interresidue NOE, only one intraresidue NOE, namely, to H2. It is interesting to note the absence of intraresidue NOEs between the H1 atoms and the (axial) H3 and H5 atoms within the same residue. This implies that each H1 is in equatorial orientation, which strongly suggests the α configuration for both L-Rha*p*-(1→3)-L-Rha*p* linkages.

To determine conclusively the anomeric configuration of the glycosyl linkages, a 2-D J_{CH}-resolved experiment was performed. From the completely resolved multiplets for the three anomeric ^{13}C atoms, at δ 102.0, 100.4, and 99.8 ppm, all three of the $^1J_{C1H1}$ coupling constants were found to be >169 Hz. Such values for $^1J_{C1H1}$ establish the α configuration for each L-Rha*p*-(1→3)-L-Rha*p* linkage (19, 20). In addition, long-

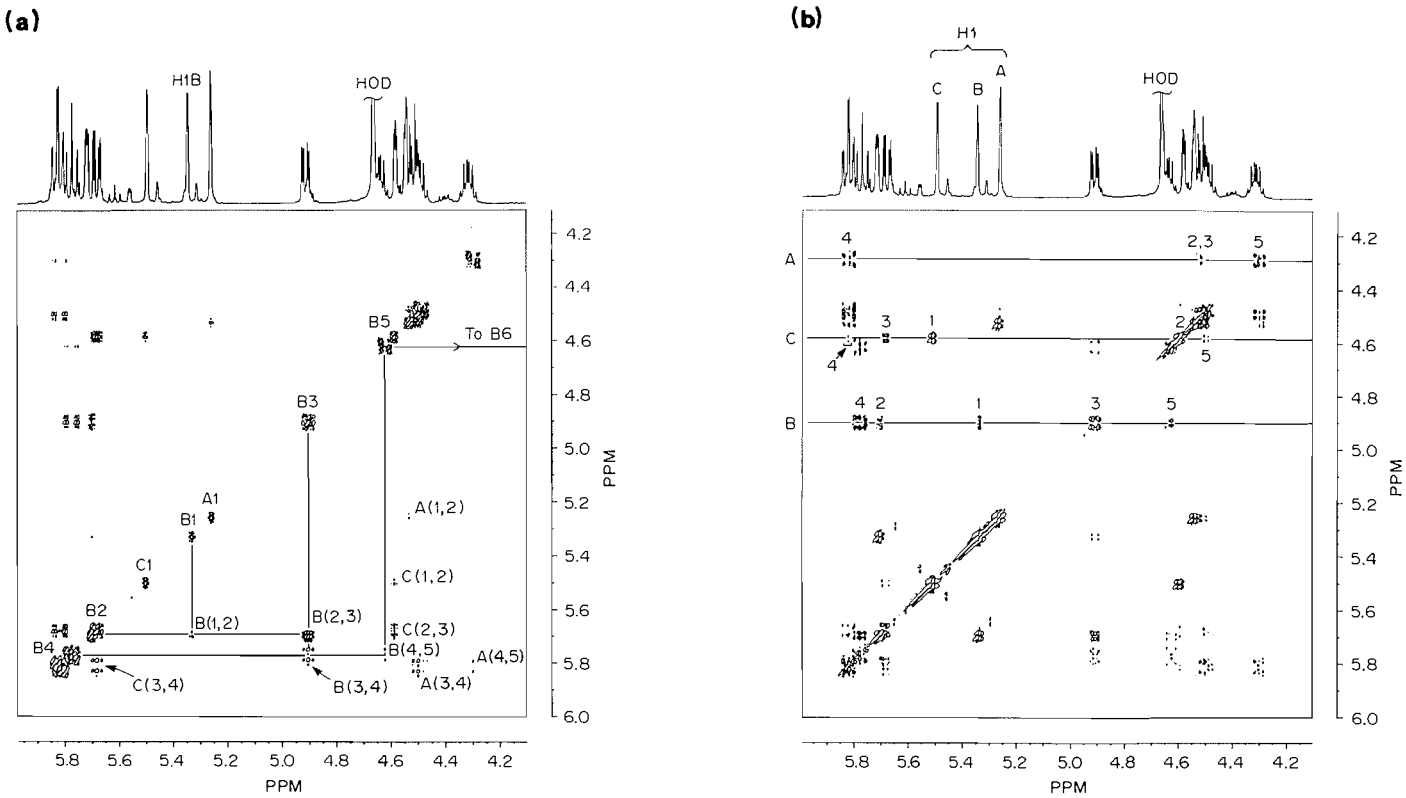

FIG. 3. Two-dimensional $\{^1H,^1H\}$ correlation NMR spectra of ML-3, recorded at 27°C in benzene-d_6/methanol-d_4 (4:1, v/v). (a) Expanded region of phase-sensitive DQF-COSY spectrum with high resolution 1-D projection. Selected region shows intraring crosspeaks for H1–H5 of each ring. Tracing of the *J*-connectivity trail is indicated for Rha-B residue. (b) Expanded region of HOHAHA spectrum with high resolution 1-D projection. Selected region shows each intraring H1–H5 subspectrum; those in the F2 cross sections through H5A, H3B, and H2C on the diagonal are indicated. Note that the H4A and H4C crosspeaks show no apparent difference in their chemical shifts (see Results).

range ($^2J_{CH}$ and (or) $^3J_{CH}$) couplings of 7–8 Hz were seen for the Rha-B and Rha-C anomeric carbons. The ^{13}C chemical shifts and the one-bond and long-range coupling constants observed are listed in Table 2.

To locate the positions of the substituents, i.e., the four acetyl groups and the hexanoyl group, the pertinent resonances in the ^{13}C spectrum were assigned. By utilizing the assignments from the ^1H spectrum (see above), this was accomplished via a ^1H-detected $\{^1H,^{13}C\}$ one-bond correlation experiment (HMQC). As suggested by Bax and Subramanian (16) for molecules in the extreme narrowing limit, such as ML-3, a BIRD pulse was used to suppress signals arising from protons linked to ^{12}C. The GARP1 composite pulse sequence was used for ^{13}C decoupling during ^1H data acquisition. Almost all carbon signals between 10 and 110 ppm were assigned from this experiment. Unfortunately, due to limited resolution in the ^{13}C domain, three of the four acetyl methyl carbon signals (two carbons at δ 20.11 and one carbon at 20.02 ppm) did not have well-resolved cross peaks in the HMQC experiment, thus preventing their definitive assignments. Only two other methyl carbon resonances were identified in the ^{13}C spectrum, namely, at δ 14.28 and δ 14.08 ppm (their proton multiplicity was verified by a 1-D DEPT experiment (21)). This implies that the alkyl chains in the hexanoyl (R) and octyl (R′) groups are both linear since only one terminal CH_3 group per chain occurs.

With the ^{13}C assignments summarized in Table 2, the locations of the various substituents were established by means of a ^1H-detected multiple-bond correlation (HMBC) spectrum optimized for long-range couplings ($^2J_{CH}$ and $^3J_{CH} \approx 7$ Hz). The results of this experiment first of all enabled us to assign the carbonyl carbon signals via $^2J_{CH}$ crosspeaks between the hexanoyl ester carbonyl (δ 173.5 ppm) and each of the atoms Ha″ (δ 2.91 ppm) and Ha‴ (δ 2.71 ppm) on one hand, and between the acetyl methyl protons (δ 2.34, 2.24, 2.18, and 2.10 ppm) and the acetyl carbonyls (δ 170.7 ppm) on the other (not shown in Fig. 4). The interglycosidic $^3J_{CH}$ crosspeaks between H1C and C3B, and also between H1B and C3A (Fig. 4a), confirmed the positions of the linkages to be (1→3), as suggested by the 1-D NOE experiments. The acetyl carbonyl resonances showed $^3J_{CH}$ connectivities to the ring protons H2B, H3C, H4B, and either H4C or H4A (Fig. 4b), thus indicating that the acetyl groups are attached to C2B, C3C, C4B, and either C4C or C4A. The connectivity of the hexanoyl carbonyl signal to either H4A or H4C indicated that this acyl group is attached to either C4A or C4C. The ambiguity is due to the inconclusive ^1H NMR assignments of H4A and H4C mentioned previously. However, the FAB-MS studies had already located the hexanoyl group on Rha-A (see above). Therefore, the combination of the results from NMR and mass spectral analyses identifies C4A as the location of the hexanoyl group, leaving C4C as the site of attachment for the fourth acetyl group.

In conclusion, the primary structure of ML-3 was determined to be

{3,4-OAc$_2$-L-Rha*p*}-α(1→3)-{2,4-OAc$_2$-L-Rha*p*}-
α(1→3)-{4-O-*n*-hexanoyl-L-Rha*p*}-α(1→*n*-octyl)

Ac C=O	—	170.70[h]	170.67[h]				

[a]Measured at 27°C in benzene-d_6/methanol-d_4 (4:1, v/v).

[b]One-bond $^{13}C-^1H$ coupling constants. The two- and three-bond (long-range) $^{13}C-^1H$ coupling constants, as measured via heteronuclear *J*-resolved spectroscopy, are given in parentheses.

[c]For designations Rha A–C, for numbering of carbon atoms in the rhamnosyl rings, and for lettering of the carbon atoms in the substituent groups, see the structure of ML-3 (Table 1). R′ = octyl aglycone (at A1); R = hexanoyl (at A4); Ac = acetyl (at B2, B4, C3 and C4).

[d]These values were measured both via heteronuclear *J*-resolved spectroscopy and via a 1-D ^1H-coupled ^{13}C spectrum with high digital resolution.

[e]Assignments of these signals are inconclusive with respect to number of the carbon atom in the chain, or even with respect to the octyl or the hexanoyl chain, because of lack of resolution of the corresponding CH_2 signals in the ^1H spectrum. Tentative assignments are based on ^{13}C chemical shifts for 1-octanol and hexanoate (27).

[f]Assignments may be interchanged.

[g]Assignments may be interchanged.

[h]Assignments may be interchanged.

Discussion

The primary structure elucidation of the highly acylated trisaccharide ML-3 required the application of a combination of techniques, among which FAB-MS and NMR spectroscopy were the most powerful. Given that ML-3 consists of L-Rha residues, as determined by GC analysis of *S*(+)-2-butylglycosides, FAB-MS revealed the size of the compound, the size of each of the appended groups, and their distribution to the residue level. Thus, it was deduced from the FAB-MS results that ML-3 is a trisaccharide with sequence C–B–A, with two *O*-acetyl groups attached to each of the Rha residues B and C, and an *O*-hexanoyl acyl and an octyl aglycone group to Rha-A. The mass spectra did not contain information on the positions and configurations of the glycosyl linkages, on the precise location of the appended groups on the Rha rings, or on the branching pattern of the hexanoyl and octyl groups. However, NMR spectroscopy did yield each of these structural parameters. To accomplish this, the virtually complete assignment of the ^1H and ^{13}C spectra of ML-3 was necessary.

Since L-Rha*p* occurs in the $^1C_4$ conformation, with H2 in equatorial orientation, neither the H1 and C1 chemical shifts nor the coupling constants $^3J_{H1H2}$ were useful in determining the configuration of the linkages (19, 20, 22). Evidence for the α configurations was obtained from the $^1J_{C1H1}$ values; this was consistent with the absence of intraresidue H1–H3 and H1–H5 NOEs.

Once the ^1H and ^{13}C spectra of ML-3 had been assigned, by the combination of COSY, HOHAHA, and HMQC experiments, the key experiment to determine the linkage positions and the positions of the attached acyl groups was the HMBC experiment. Long-range, $^3J_{CH}$ couplings between anomeric protons and substituted carbon atoms across the glycosidic linkages allowed the linkage positions to be determined as (1→3), whereas the $^3J_{CH}$ couplings between the acyl carbonyl carbons and the Rha ring protons permitted the localization of the acyl groups at C3C, C4C, C2B, C4B, and C4A. In the particular case of ML-3, because of the ambiguity in the assignment of H4A and H4C from the COSY and HOHAHA spectra, the determination of the exact position of the hexanoyl group required the combination of the FAB-MS results (indicating that it was linked to Rha-A), and the NMR HMBC results (indicating its attachment to either C4C or C4A). Once the structure of ML-3 had been elucidated, the unequivocal assignment of the proton signals at δ 5.824 ppm and δ 5.820 ppm to H4A and H4C, respectively, could be made (see Table 1 and Fig. 4b).

It is noteworthy that the results of 1-D NOE difference spectroscopy suggested that the two Rha→Rha linkages in ML-3 were (1→3); however, care must be taken in assigning linkage positions based solely on NOE data as several instances are documented where the strongest interresidue NOE upon saturation of the anomeric proton did not arise from the proton at the linkage position of the adjacent residue (22–24).

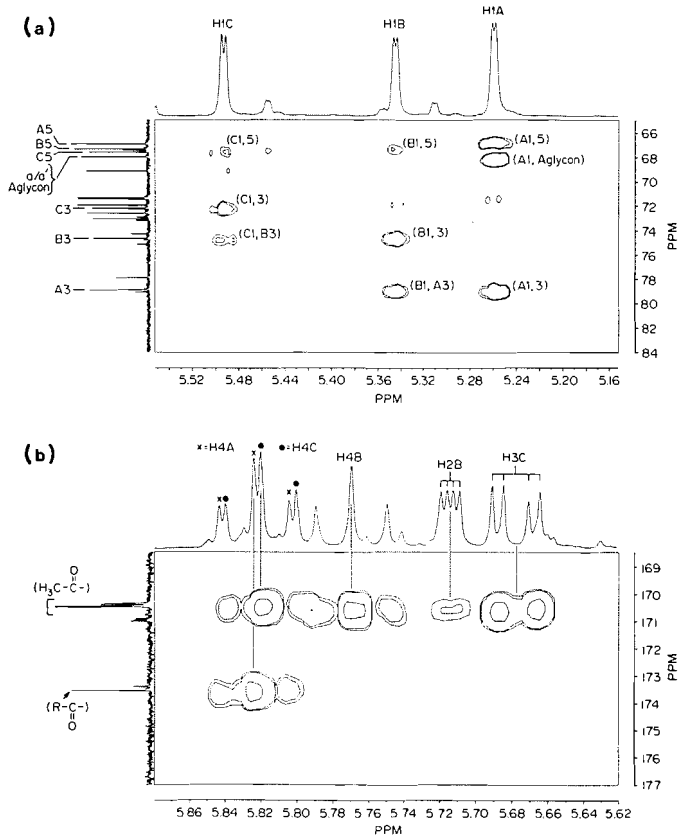

FIG. 4. ^{1}H-Detected heteronuclear multiple-bond correlation (HMBC) spectrum of ML-3 with high resolution 1-D ^{1}H and ^{13}C projections. (a) Expanded region showing the connectivities of the anomeric protons across the glycosidic linkages, as well as intraring connectivities. (b) Expanded region showing the connectivities of the ^{13}C carbonyl signals with the downfield rhamnosyl ring proton signals. Note that H4A and H4C are nearly coresonant in the high resolution ^{1}H projection. The carbonyl signal at 173.54 ppm was assigned to the hexanoyl group by virtue of its $^2J_{CH}$ correlation to Ha″ and Ha‴ in the HMBC spectrum (not shown).

The characterization of Mezzettiaside 3 (ML-3) is an elegant illustration of the combination of FAB-MS and NMR spectroscopy to structural analysis of complex carbohydrates (compare, e.g., refs. 25 and 26). To the best of our knowledge, this study represents the first example of the complete characterization, by these techniques, of a carbohydrate that is so highly acylated, including the exact identification of the nature and location of its acyl substituents.

Received December 14, 1989

This paper is dedicated to Professor Arthur Perlin on the occasion of his 67th birthday

SAUL WOLFE, B. MARIO PINTO, VIKRAM VARMA, and RONALD Y. N. LEUNG. Can. J. Chem. **68**, 1051 (1990).

The magnitude of a one-bond C–H coupling constant depends upon the chemical environment of the hydrogen atom and, especially, upon its stereochemical relationship to vicinal lone electron pairs. However, a lone electron pair is not essential for the observation of a stereoelectronic effect, since even cyclohexane exhibits different axial and equatorial C–H coupling constants. We propose the name "Perlin Effect" to describe such observations. An analysis of the extensive experimental data regarding the Perlin Effect reveals that, in cyclohexane and in six-membered rings having one or more heteroatoms of the first row attached to the carbon of interest, $^1J_{C-H}$ is always larger for an equatorial hydrogen than for an axial hydrogen. The magnitude of the Perlin Effect is reduced when the carbon carrying the hydrogen of interest is attached to first row and second row atoms or heteroatoms, and it reverses when the carbon atom carries two heteroatoms from below the first row.

The existence of the Perlin Effect in nuclear magnetic resonance spectra is reminiscent of an infrared effect known as the Bohlmann bands, whose origin has previously been explained by quantitative perturbational molecular orbital (PMO) theory in terms of the effects of lone electron pairs upon the lengths and strengths and, therefore, the chemical reactivities of vicinal C—H bonds. Since the magnitude of a one-bond C–H coupling constant is expected to vary inversely with bond length, the origins of the Perlin Effect and of the Bohlmann bands would seem to be the same, i.e., the longer (weaker) C—H bond has the smaller one-bond coupling constant. This expectation has now been confirmed: for 25 molecules, representing a total of 35 different kinds of C—H bonds, the bond lengths, stretching force constants, and charge distributions have been determined from fully optimized 6-31G* molecular orbital calculations. In nine of ten cases for which experimental data exist for pairs of diastereomeric or diastereotopic hydrogens, the shorter C—H bond of the pair has the larger coupling constant; in the tenth case, the experimental difference is only 1–2 Hz. Moreover, a global analysis of the data in terms of the equation $J = A + Bq_Cq_H + C/r$, where J is an experimental coupling constant, q is a total atomic charge, and r is a C—H bond length, correlates 23 different types of C—H bonds linearly with a correlation coefficient of 0.915. The C parameter is the leading term of the correlation. Among the systems studied theoretically are eight molecules of the type CH_3CHXY (Y = OH, SH; X = F, Cl, OH, SH), which are representative of systems containing both endocyclic and exocyclic first row and second row anomeric effects. The exocyclic effect is found to be very similar for first row and second row substituents, but the endocyclic effect is larger for the first row substituent. Both findings agree with experimental data in solution. Finally, quantitative PMO analysis has been employed to analyse the origins of the different C—H bond lengths in the various molecules of the study.

Key words: anomeric effect, PMO analysis, NMR, stereochemistry, molecular orbital calculations.

SAUL WOLFE, B. MARIO PINTO, VIKRAM VARMA et RONALD Y. N. LEUNG. Can. J. Chem. **68**, 1051 (1990).

L'amplitude de la constante de couplage d'un C–H à travers une liaison dépend de l'environnement chimique de l'atome d'hydrogène et spécialement de sa relation stéréochimique avec les paires d'électrons non partagées vicinales. Toutefois, la présence d'une paire d'électrons non partagée n'est pas essentielle pour observer un effet stéréoélectronique puisque même le cyclohexane présente des contantes de couplage différentes pour les C–H axiaux et équatoriaux. On propose d'appeler de telles observations l'«effet Perlin». Une analyse d'un large ensemble de données expérimentales relatives à l'effet Perlin révèle que, dans le cyclohexane et dans les cycles à six chaînons dans lesquels un ou plusieurs hétéroatomes de la première rangée sont attachés au carbone examiné, la valeur de $^1J_{C-H}$ est toujours plus grande pour un hydrogène équatorial que pour un hydrogène axial. L'amplitude de l'effet Perlin est réduite lorsque le carbone qui porte l'hydrogène examiné est attaché à des atomes ou des hétéroatomes des deux premières rangées et elle est inversée lorsque l'atome de carbone porte deux hétéroatomes des rangées autres que la première.

L'existence de l'effet Perlin dans les spectres de résonance magnétique nucléaire rappelle les bandes de Bohlmann observées dans les spectres infra-rouges dont les origines ont été expliquées antérieurement, en se basant sur la théorie des orbitales moléculaires perturbationnelles quantitatives (OMP), en fonction d'effets de paires d'électrons non partagées sur les longueurs et sur les forces et, donc, sur les réactivités chimiques des liaisons C—H vicinales. Puisqu'on peut s'attendre à ce que l'amplitude d'une constante de couplage d'une liaison C—H varie d'une façon inverse de la longueur de la liaison, il peut apparaître que les origines de l'effet Perlin et des bandes de Bohlmann sont les mêmes, à savoir que la liaison C—H la plus longue (la plus faible) possède la constante de couplage la plus faible. Cette attente est confirmée : utilisant des calculs d'orbitales moléculaires 6-31G* complètement optimisés, on a déterminé les longueurs de liaison, les constantes de force d'élongation et les distributions de charge pour 25 molécules représentant un total de 35 sortes différentes de liaisons C—H. Dans neuf des dix cas pour lesquels il existe des données expérimentales pour des paires diastéréomères ou diastéréotopes d'hydrogènes, la liaison C—H la plus courte de la paire est associée à la constante de couplage la plus grande; dans le dixième cas, la différence expérimentale n'est que de 1–2 Hz. De plus, un analyse globale des données en fonction de l'équation $J = A + Bq_Cq_M + C/r$, dans laquelle J est une constante de couplage expérimentale, q est une charge atomique totale et r est une longueur de liaison C—H, permet d'établir une corrélation

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

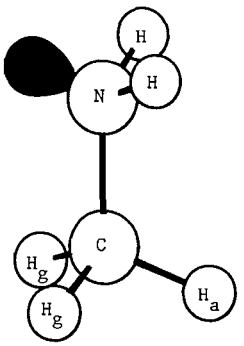
linéaire de 23 types différents de liaisons C—H avec un coefficient de corrélation de 0,915. Le paramètre *C* est le terme principal de la corrélation. Les systèmes étudiés d'une façon théorique comprennent huit molécules du type CH_3CHXY (Y = OH, SH; X = F, Cl, OH, SH) qui sont représentatives des systèmes donnant lieu à des effets anomériques endocycliques ainsi qu'exocycliques avec des éléments des deux premières rangées. On a trouvé que l'effet exocyclique est très semblable pour les substituants issus des deux premières rangées; toutefois, l'effet endocyclique est plus important avec les substituants de la première rangée. Ces deux observations sont en accord avec les données expérimentales obtenues en solution. Enfin, on a utilisé une analyse OMP quantitative pour analyser les origines des longueurs des diverses liaisons C—H contenues dans les diverses molécules examinées dans ce travail.

Mots clés : effet anomérique, analyse OMP, RMN, stéréochimie, calculs d'orbitales moléculaires.

[Traduit par la revue]

Introduction

The methyl hydrogens of methylamine (**1**) are diasterotopic. One, H_a, is antiperiplanar to the nitrogen lone pair; the other two, H_g, are *gauche* to the lone pair. The diastereotopic relationship is reflected in structural, spectroscopic, and chemical differences between C—H_a and C—H_g; C—H_a is longer (1) and weaker (2), and a 6–7 kcal/mol difference in the bond dissociation energies has been estimated (3).

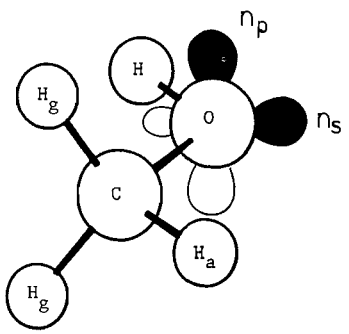


1

These stereoelectronic effects are also encountered in more complex amines when at least one α-hydrogen is antiperiplanar to the nitrogen lone pair (4). Their existence was discovered by Bohlmann (5), in studies of infrared stretching frequencies of quinolizidine alkaloids, and the presence or absence of "Bohlmann bands" in infrared spectra is commonly employed in the assignment of configuration and (or) conformation. Methylamine itself also exhibits Bohlmann bands (2).

The rate constants for the reactions of *tert*-butoxyl and *tert*-butylhydroperoxyl radicals and the benzophenone triplet with amines have been determined (6). There is a pronounced preference for attack upon a C—H bond that is eclipsed with the axis of the nitrogen lone pair.

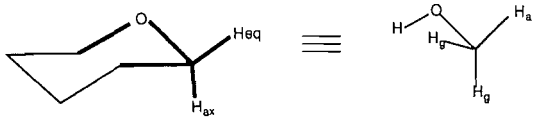
Methanol (**2**), like methylamine, contains diastereotopic methyl hydrogens. One, H_a, is antiperiplanar to the O—H *bond*; the other two, H_g, are *gauche* to this bond. Unlike methylamine, methanol contains two *energetically nonequivalent* lone pairs



2

(7). One, n_p, is derived mainly from the 2*p* atomic orbital of oxygen that is perpendicular to the H—O—C plane; the other, n_s, is a hybrid orbital containing contributions from the 2*p* atomic orbital of oxygen that lies in the H—O—C plane, and from the 1*s* atomic orbital of hydrogen and 2*s* or 2*p* atomic orbitals of carbon (8). The experimental energy difference between n_p and n_s is 35.5 kcal/mol (7).

Methanol, like methylamine, exhibits Bohlmann bands in its infrared spectrum (9). In this case, it is H_g that is longer (10) and weaker (2), and a 5 kcal/mol difference in bond dissociation energies has been estimated (3). When the skeleton of methanol is incorporated into a 6-membered ring (e.g., **3**), it can be seen



3

that H_g becomes H_{ax} and H_a becomes H_{eq}. All known examples of radical abstraction adjacent to the ether oxygens of such cyclic structures exhibit a kinetic preference for H_{ax} (11).

Clearly the Bohlmann band phenomenon and the relative radical reactivities of diastereotopic hydrogens α to nitrogen or α to oxygen can be traced to the differences in the C—H bond lengths and bond strengths associated with these hydrogens.

It seems natural to seek an interpretation of these differences in terms of "lone pair" effects. The problem, however, is that the lone pair of methylamine and the energetically nonequivalent lone pairs of methanol are not localized entities as depicted in **1** and **2**, but are major contributors to specific molecular orbitals that are delocalized over the molecules. In methylamine, the HOMO is mainly the nitrogen "lone pair", delocalized over all three of the methyl hydrogens (12). In methanol, the HOMO is mainly n_p, delocalized over H_g but not H_a (12); the subjacent orbital is mainly n_s, delocalized over all three methyl hydrogens.

These delocalization effects can be understood in terms of the symmetry properties of atomic orbitals and the concept of orbital interactions (13). Just as the Hückel molceular orbitals of butadiene can be seen to consist of in-phase and out-of-phase combinations of the Hückel molecular orbitals of two ethylene fragments (14), the molecular orbitals of methylamine can be written in terms of symmetry-allowed linear combinations of the orbitals of CH_3 and NH_2 fragments (15). Likewise, the molecular orbitals of methanol can be written in terms of symmetry-allowed linear combinations of the orbitals of CH_3 and OH fragments. Structure **4** depicts the linear combinations (orbital interactions) that lead to the frontier molecular orbitals of methylamine. The HOMO results from the out-of-phase combination of n_{NH_2} with π_{CH_3} and the in-phase combination of n_{NH_2} with $\pi^*_{CH_3}$ (16). The n–π interaction is two-orbital four-

For personal use only.

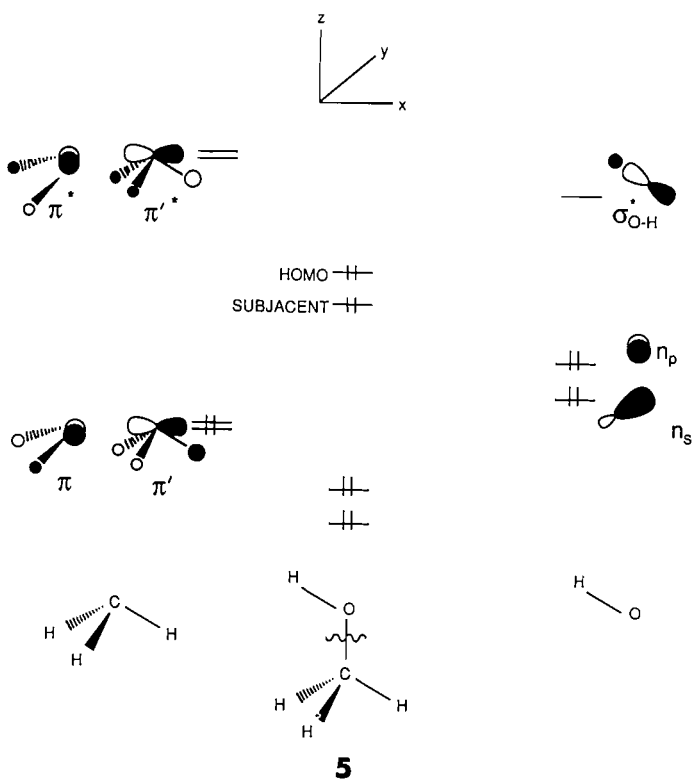
4

electrons in nature, and is destabilizing. The n–π^* interaction is two-orbital two-electrons in nature, and is stabilizing; a consequence of this latter interaction is a partial population of the π^* orbital. Since all three C—H regions of this orbital are antibonding, the result of the "charge transfer" is a weakening of all three C—H bonds. However, in the coordinate system shown in **4**, the *yz*-plane is a nodal plane. Therefore, in both π and π^*, the *s*-atomic orbital coefficient at H_a is twice that of H_g. This causes *the C—H_a bond to be weakened preferentially*. This preferential weakening is the origin of all of the stereoelectronic effects in amines discussed earlier.

The corresponding treatment of methanol (**5**) is slightly more complicated, because orbital interactions associated with both n_p and n_s should be taken into account. The left-hand side of **5** shows the degenerate π and π^* methyl group orbitals; the right-hand side shows n_p, n_s, and also σ^*_{O-H}, which has a symmetry-allowed interaction with π'. The centre of **5** shows the approximate positions of the occupied frontier molecular orbitals of the molecule. The HOMO is mainly n_p, but now contains contributions from π and π^*; the subjacent orbital is mainly n_s, but now contains contributions from π', $\pi^{*\prime}$, and σ^*_{O-H} (13).

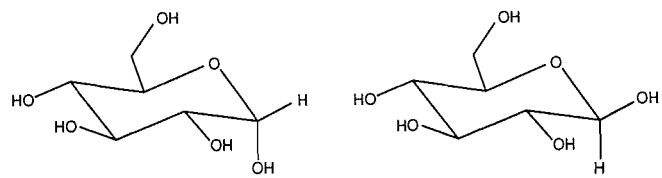


5

Symmetry-allowed charge transfer is possible (a) between n_p and π^*, (b) between n_s and $\pi^{*\prime}$, and (c) between π' and σ^*_{O-H}. Interaction (a) leads to a weakening of C—H_g, because H_a lies in the *xz*-nodal plane and its atomic orbital coefficient is zero in both π and π^*; interactions (b) and (c) lead to a preferential weakening of C—H_a, because the H_a atomic orbital coefficient is larger than that of H_g in both π' and $\pi^{*\prime}$. Since the magnitude of a stabilizing orbital interaction (and of charge transfer) is inversely proportional to the energy difference between the donor and acceptor orbitals (15, 16), interaction (a) is expected to dominate, *causing C—H_g of methanol to be weaker than C—H_a*. This preferential weakening is the origin of the stereoelectronic effects in ethers discussed earlier.

The Perlin Effect

In 1969, Perlin and Casu discovered that there is an approximately 10 Hz difference in $^1J_{C-H}$ coupling constants at the anomeric centres of anomeric pairs of glycosides (17). In the case of D-glucose (**6**), the α anomer, which contains an equatorial hydrogen at C1, had the larger coupling constant. As we have seen, an equatorial C1—H bond in a pyranose ring is shorter and stronger than an axial C1—H bond. Since the Fermi contact term makes the principal contribution to coupling between directly bonded nuclei (18), it is not surprising that the magnitude of the coupling should vary inversely with the C—H bond length.



6*a* **6***b*

The original observations of Perlin and Casu were rapidly extended by Perlin and his co-workers, and subsequently by many others (19). It seems proper to honour Professor Perlin at this time with the proposal that stereoelectronic effects upon one-bond C—H coupling constants be termed "Perlin Effects".

Table 1 summarizes some of the extensive experimental information related to the Perlin Effect (19) in cyclic and acyclic structures RCHXY. Even a cursory study of these data suggests that ΔJ for epimeric pairs of compounds is largest when both X and Y are atoms of the first row, somewhat smaller when one of X or Y is an atom below the first row, *and reverses* when both X and Y are atoms below the first row.

The factors that determine the magnitudes of one-bond C–H coupling constants have been the subject of much discussion (18, 20). The earliest work (20*a*, *b*) was greatly influenced by the finding that the trend of increasing coupling constant in the series C_2H_6, C_2H_4, C_2H_2 correlated linearly with the extent of *sp* hybridization on the carbon atom. This approach has been

criticized (20*c*, *d*) because of problems with the specification of the hybridization at carbon in systems more complex than the simple hydrocarbons. Although the problem would seem to be even more severe when the different hybridizations at carbon in a pair of stereoisomers have to be explained, in principle, molecular orbital theory (21) contains the required information in the bond order matrix element between the carbon 2*s* and hydrogen 1*s* orbitals, $P_{s_C s_H}$. The coupling constant is expected to be proportional to the square of this quantity. This approach forms the basis of the many semi-empirical (INDO, CNDO) calculations of $^1J_{C-H}$ (18), which give qualitatively reasonable results. Unfortunately, INDO and CNDO are not reliable for calculations of stereoelectronic effects on $^1J_{C-H}$, because the different bond lengths of diastereotopic hydrogens are not reproduced reliably by such methods.

Other correlations dealing with hybridization have been proposed, in which a leading term is the inverse of S^2_{CH}, the square of the overlap integral between the carbon hybrid and the hydrogen 1*s* orbital (20*e*).

Both *P* and S^2 depend upon bond length. Since, as we have seen, the consequences of the different bond lengths (bond strengths) of diastereotopic hydrogens are well established, and the origins of these trends can be explained, the principal initial objective of the present work was to determine, for pairs of epimers, whether the magnitude of $^1J_{C-H}$ varies inversely with the C—H bond length. As will be seen, this trend has been found to exist, *regardless of the nature of X and Y*. In the second phase of the work, we were, therefore, encouraged to seek an additional property, which varies as X and Y are varied, that would allow all of the compounds of the study to be included in a single correlation. As will be seen, the suggested property is $q_C q_H$, the product of the charges on carbon and hydrogen. Finally, using the appropriate modification of the orbital interaction diagram **5**, we are able to suggest an explanation for the reversal in $^1J_{C-H}$ (and in C—H bond lengths) when X and Y are atoms below the first row.

Methods

Bond lengths are taken from fully optimized geometries computed at the 6-31G* level (22), using GAUSSIAN 86 (23). Several of the systems were also examined at lower (3-21G, 3-21G* (24)) and higher (6-31+G* (25), 6-31++G* (26)) computational levels to check that 6-31G* is the appropriate basis set for the computation of C—H bond lengths. A one-point FORCE calculation was performed following optimization of each structure, to obtain diagonal stretching force constants. Total atomic charges were taken from the Mulliken population analysis (27). Quantitative PMO analyses were performed by the method of Whangbo, Schlegel, and Wolfe (16). Since this procedure is not yet available in GAUSSIAN 86, but has been incorporated into MONSTERGAUSS (28), the calculations were performed by Dr. M. R. Peterson at the University of Toronto, whose assistance is greatly appreciated. Initial study of the quantitative PMO data revealed very extensive charge transfer involving d-type functions, because of the use of the 6-31G* basis set. Therefore, to simplify the orbital analysis, this was performed at STO-3G. As will be seen, this strategy appears to identify the principal differences between first and second row X and Y.

Results and discussion

Data base

Figure 1 summarizes the C—H bond lengths (Å), C–H stretching force constants (in parentheses; units are mdyn/Å), and the total atomic charges on carbon and on hydrogen in the 6-31G* optimized structures of 22 molecules examined theoretically in the present work. Ethane, ethylene, and acetylene were also calculated.[1] The experimental value of $^1J_{C-H}$, shown beside each structure, is taken from the appropriate entry of Table 1. Except for the imines (entries 1–4) the calculations refer to model structures containing the C—H bond(s) of interest. For example, entry 5, methanediol in the conformation shown, is the model for a 1,3-dioxane ring in the chair conformation; entry 7 is the model for an α-D-glycopyranosyl fluoride; entry 8 is the model of a β-D-glycopyranosyl fluoride, etc.

To simulate more closely the cyclic structures from which the experimental data are taken, wherever appropriate a methyl group was attached to the carbon atom bearing the hydrogen of interest, and included in the complete geometry optimization. In the case of entries 7–16, this allows an updating of the theoretical anomeric effects of pyranosyl-X (X = F, Cl, OH, SH) and thiopyranosyl-X (X = OH) (29). The *exo*-anomeric effect (30) was taken into account for X = OH, SH, as can be seen upon inspection of these entries. In the case of entry 17, gauche butane, the model predicts that the axial C—H bond of cyclohexane is longer and weaker than the equatorial C—H bond; this is consistent with the 3-21G (31), 4-21G (32), and 4-31G (33) optimized structures of this molecule. In the calculations of Wiberg *et al.* (33), the axial and equatorial C—H bond lengths of cyclohexane are 1.088 and 1.086 Å, respectively. Our values for gauche butane are 1.0883 and 1.0874; the effect of the added methyl group can be seen in the structure found for propane (entry 18), in which the bond lengths are 1.0865 Å ("axial") and 1.0857 Å ("equatorial").

Several entries (1, 2, 5, 6, 17–22) contain diastereotopic C—H bonds, leading to a theoretical data base of 35 C—H bonds (including ethane, ethylene, and acetylene) for inclusion in a global analysis. However, experimental data appropriate to entires 2 and 19–22 are not available, leading to an experimental data base of 23 $^1J_{C-H}$ values.

The longer C—H bond has the lower one-bond C–H coupling constant

Of the ten pairs of diastereomers or molecules containing pairs of diastereotopic C—H bonds, in only one (entries 15 and 16) does the isomer having the longer C—H bond exhibit the larger $^1J_{C-H}$. In this pair, corresponding to the α and β anomers of a thiopyranoside, the isomer having the equatorial C—H bond has the larger coupling constant, *and also the longer bond*. It is noteworthy that this pair exhibits the smallest experimental difference in $^1J_{C-H}$, 1–2 Hz.

It is also noteworthy that the relative axial and equatorial C—H bond lengths of entries 15 and 16 are paralleled only in the 1,3-dithiane analog (entry 6), i.e., these are the only anomeric type systems in which *the equatorial C—H bond is longer than the axial C—H bond*. In the case of entry 6, however, the reversal of the usual trend in the bond lengths is accompanied by a reversal of the usual trend in the coupling constants, and *the shorter bond is characterized by the larger* $^1J_{C-H}$.

We conclude that the observations of Bailey *et al.* (19*e*) regarding the reversal of the relative magnitudes of the coupling constants at C2 in dioxanes and dithianes are not anomalous. The anomaly resides instead in the reversal of the relative magnitudes of *the bond lengths*. This point will be examined in a later section, but it is already clear that the Perlin Effect, like the Bohlmann band phenomenon, originates in the lengths and strengths of C—H bonds. It should therefore be possible to

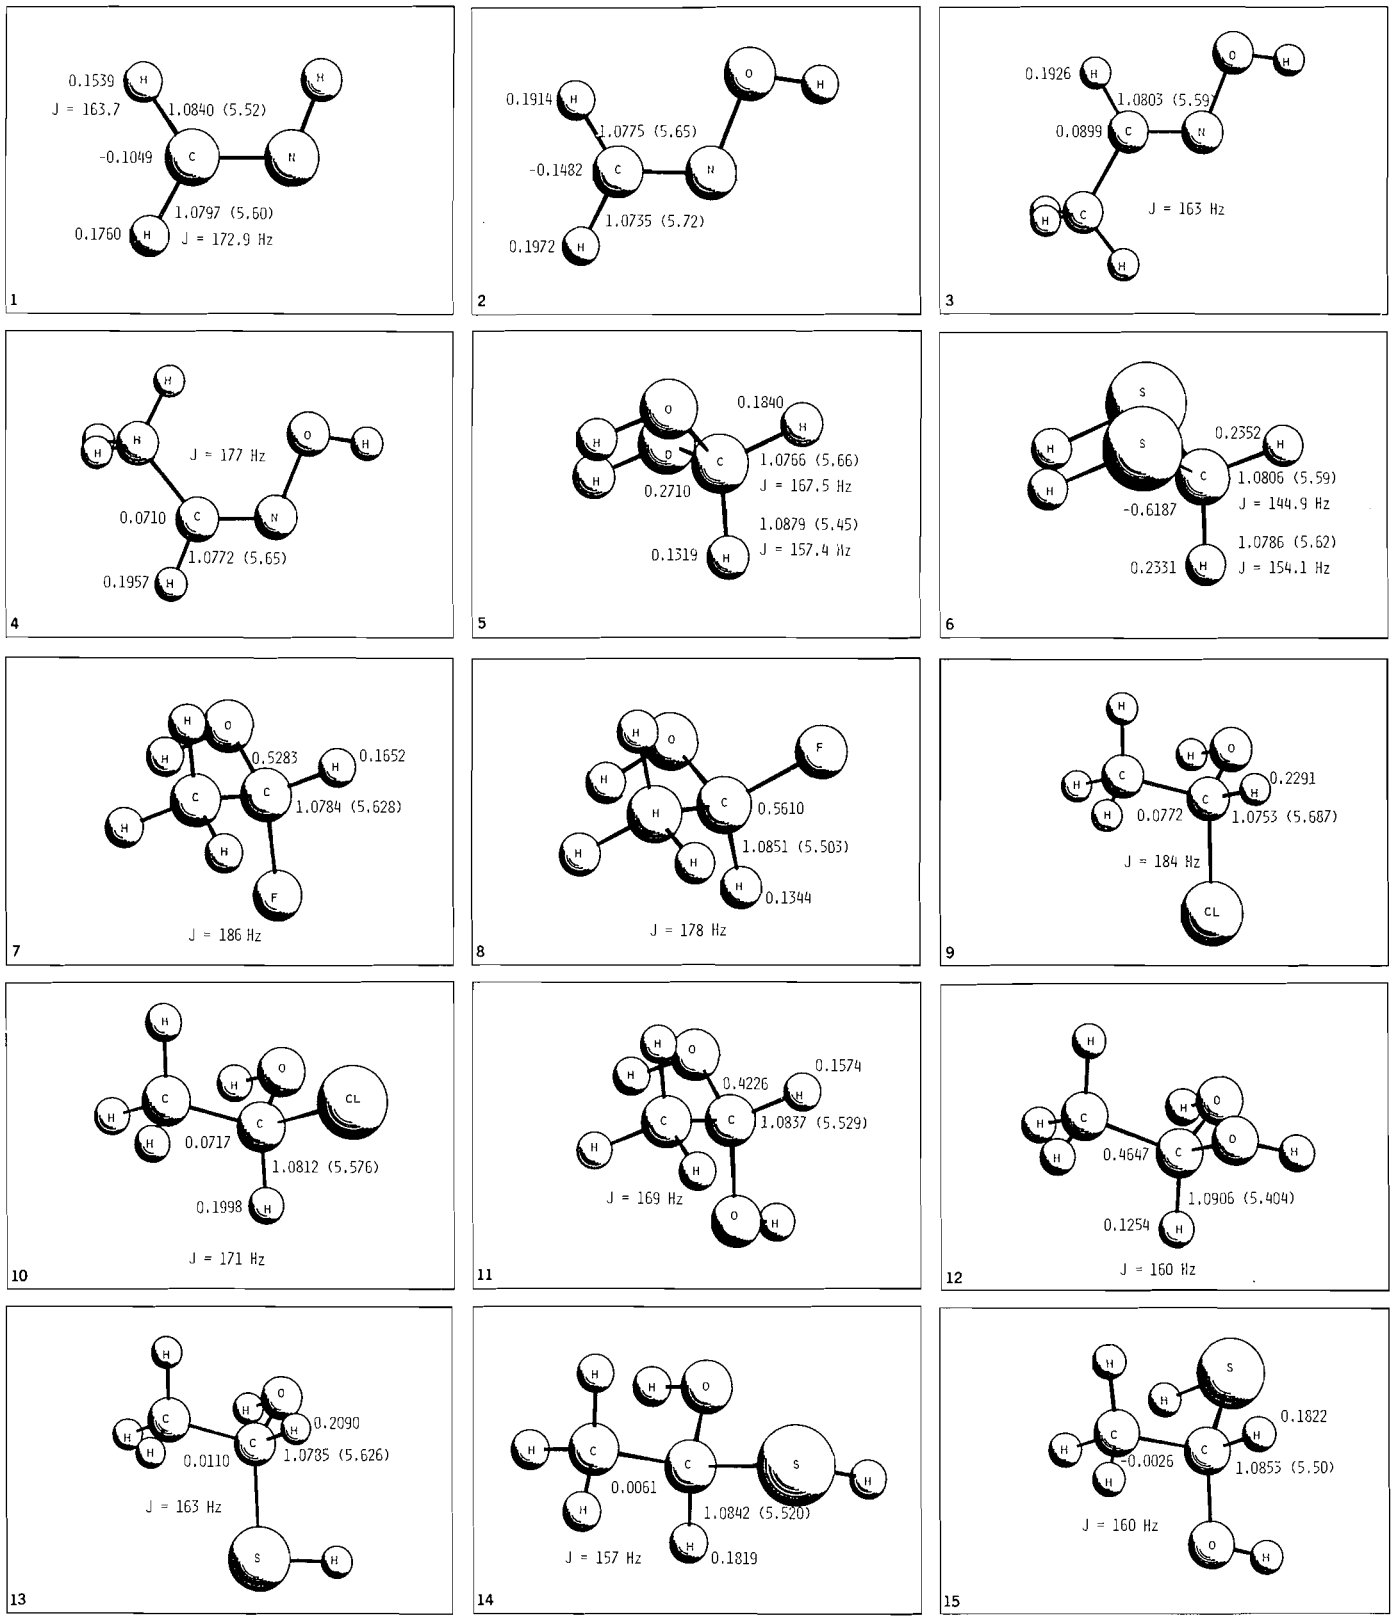

FIG. 1. Structures of the molecules computed in the present work. Entry numbers are at the lower left.

analyze the Perlin Effects in different classes of compounds in the manner described in the Introduction.

Propane, gauche butane, and cyclohexane

As noted above, propane (entry 18 of Fig. 1) exhibits the same trend in its "axial" and "equatorial" C—H bond lengths as gauche butane (entry 17) and cyclohexane. In the latter case Cieplak has suggested (34) that the longer and weaker (3*b*) axial C—H bond is the result of σ,σ^* hyperconjugation between antiperiplanar CH bonds. An examination of the 6-31G* HOMO of propane suggests a slightly different explanation of the effect. This HOMO is found to be π-type, resembling allyl. The orbital

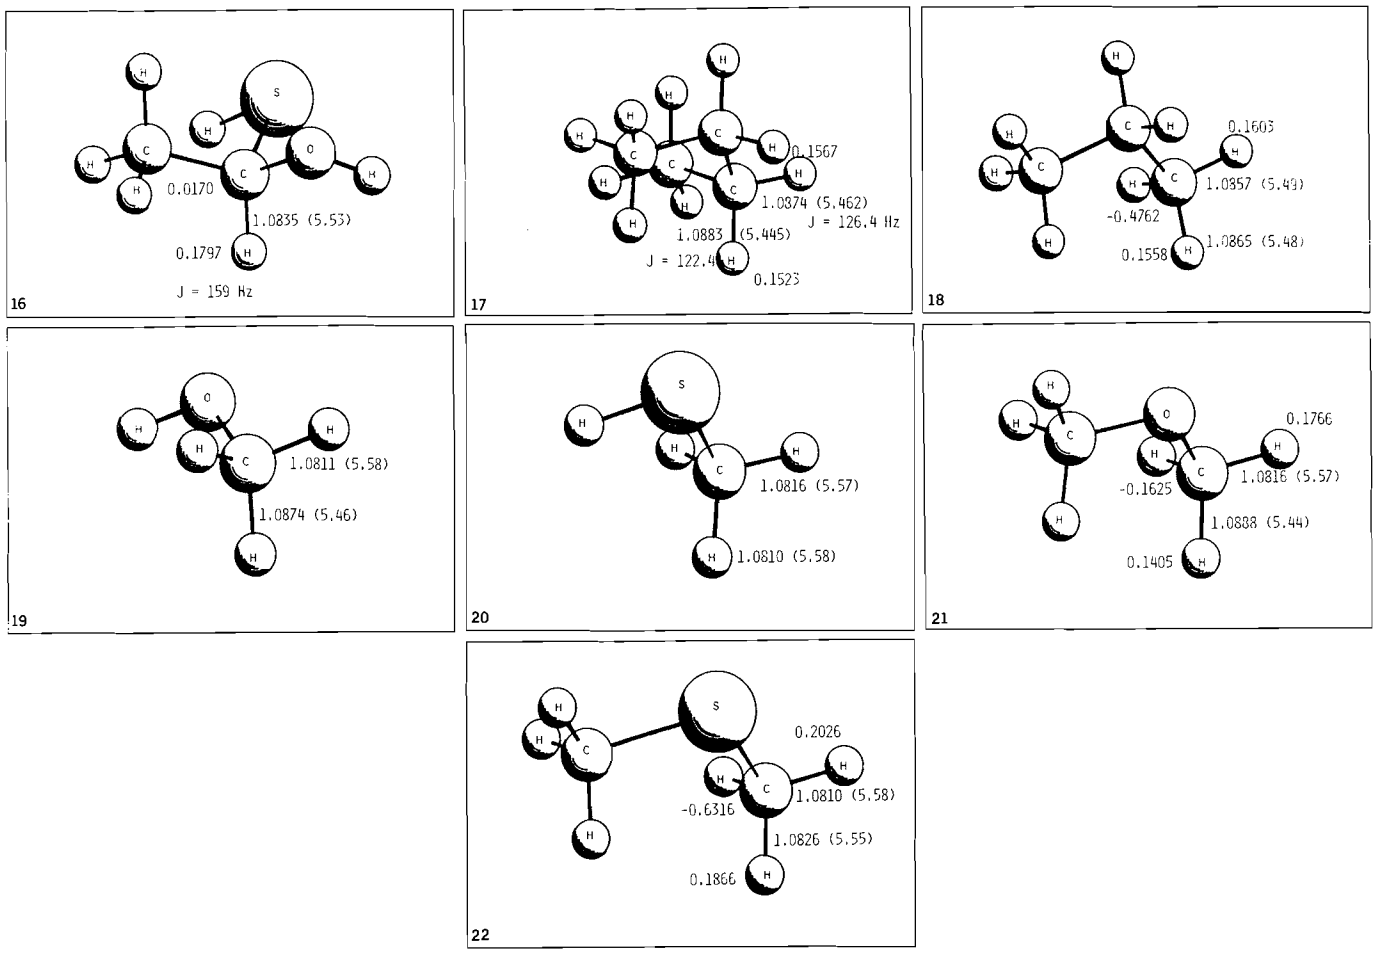

FIG. 1 (*concluded*)

interaction analysis of propane, based on the fragmentation $CH_3\cdots CH_2CH_3$, will therefore resemble the orbital interaction analysis of methanol, based on the fragmentation $CH_3\cdots OH$ (see **5**). The counterpart of n_p of methanol is the out-of-phase combination of π_{CH_2} and π_{CH_3} of the CH_2CH_3 moiety. As in **5**, charge transfer from this highest occupied fragment orbital of CH_2CH_3 to $\pi^*_{CH_3}$ weakens the methyl C—H bonds *gauche* to C—C. The quantitative PMO analysis reveals that this direction of charge transfer dominates over the alternative, i.e., π_{CH_3} to $\pi^*_{CH_2CH_3}$, which will also weaken the *gauche* C—H bonds of the methyl group.

Methanol and methanethiol

Inspection of entries 19 and 20 of Fig. 1 reveals that, at the 6-31G* level, *there is a reversal in the relative bond lengths of the "axial" and "equatorial" hydrogens*. The n_p,π^* interaction that accounts for the relative strengths and lengths of the C—H bonds of methanol (see **5**) must, in methanethiol, be overcome by an interaction that leads to preferential weakening of the C—H bond antiperiplanar to S—H. This interaction must be one of (b) or (c), discussed earlier in the qualitative analysis of methanol.

Figure 2 shows the orbital energies found in the quantitative PMO analyses of methanol and methanethiol. Preferential weakening of a C—H bond antiperiplanar to X—H can be caused by the combined effects of the (n_s,π^*_2), and (π_2,σ^*_{XH}) interactions outweighing the (n_p,π^*_1) interaction. It will be noted that the nonbonding n_p and n_s orbitals of sulfur lie higher, and the antibonding σ^*_{SH} orbital lies lower than the corresponding orbitals of oxygen. This is a well-known first row – second row effect (35). Neglecting overlap, charge transfer from the n_s orbital of sulfur is, therefore, greater than from the n_s orbital of oxygen but, of course, so is charge transfer from n_p of sulfur, which operates in the opposite direction. This argument leads to the conclusion that the first row – second row difference in the C—H bond length trends in methanol and methanethiol can be attributed to the effect of the lower lying σ^*_{SH} acceptor orbital. For the data shown in Fig. 2, this lies 102 kcal/mol lower than σ^*_{OH}, the corresponding acceptor orbital in methanol. In the language employed by Cieplak (34), this would correspond to $(\sigma_{CH},\sigma^*_{SH})$ hyperconjugation as the origin of the reversal.

Dimethyl ether and dimethyl sulfide

These are entries 21 and 22 of Fig. 1. With the 6-31G* basis set, attachment of the methyl group causes both C—H bond lengths of the ether to lengthen slightly. In the sulfide, the "equatorial" C—H bond shortens slightly and the "axial" C—H bond lengthens slightly, so that the trend in the bond lengths is the same in both compounds. On the other hand, the data from the PMO analysis, shown in Fig. 3, suggest that the small effect in the opposite direction seen in methanethiol should have been slightly enhanced in the sulfide, because the energy difference between the σ^*_{S-Me} and σ^*_{O-Me} acceptor orbitals is now 114 kcal/mol. The difference between CH_3OH/CH_3SH and CH_3OCH_3/CH_3SCH_3 may be too small to be found by the theoretical methods employed here. It might be noted that, in the work of McKean (*3b*), $\Delta\Delta D^\circ_{298}$, the difference in the bond dissociation energies of the diastereotopic hydrogens of metha-

nol compared to that of methanethiol, is 5.1 kcal/mol, and for dimethyl ether and dimethyl sulfide $\Delta\Delta D^{\circ}_{298}$ is 5.8 kcal/mol.

Methanediol and methanedithiol

These are entries 5 and 6 of Fig. 1. Both 1,3-dioxane and 1,3-dithiane exhibit axial–equatorial differences in $^1J_{C-H}$ of 10 Hz, but in opposite directions. The "axial"–"equatorial" C—H bond lengths also show opposite trends. Relevant data from the quantitative PMO analysis are found in Fig. 4. Not shown are the π_{CH_2} donor orbitals of the two molecules. The magnitudes of

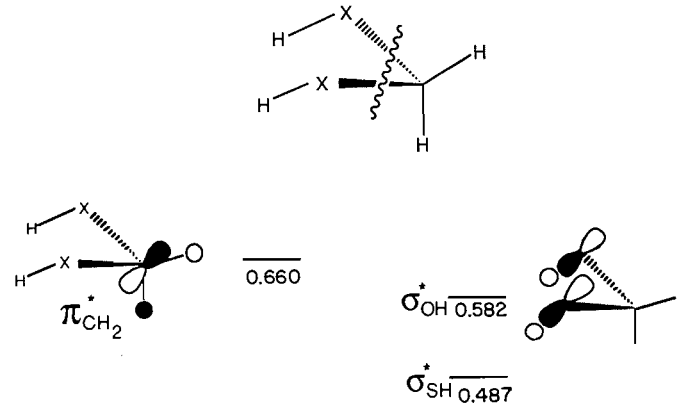

FIG. 4. Quantitative PMO analyses of methanediol and methanedithiol, showing the positions of the acceptor orbitals for the fragmentation $CH_2\cdots(XH)_2$.

the atomic orbital coefficients of the "axial" and "equatorial" C2 hydrogens are different in these donor orbitals; in the oxygen compound, the "axial" hydrogen has the larger coefficient but, in the sulfur compound, the "equatorial" hydrogen has the larger coefficient. The same differences in atomic orbital coefficients are found in the $\pi^*_{CH_2}$ acceptor orbitals. Thus, a (π,σ^*_{S-H}) charge transfer will weaken the equatorial C2—H bond preferentially, but a (π,σ^*_{O-H}) charge transfer will weaken the axial C2—H bond preferentially. The same trends will result from charge transfer in the opposite direction, i.e., (σ_{S-H},π^*) or (σ_{O-H},π^*). Interestingly, the magnitudes of charge transfer computed at STO-3G suggest that the former effect dominates in the oxygen compound, and the latter effect dominates in the sulfur compound. Using the language of Cieplak (34), the reversal in the C—H bond lengths can be said to be the result of $\sigma_{S-H},\sigma^*_{C-H}$ hyperconjugation. It will be noted that the direction of the hyperconjugation is the reverse of that found in methanethiol.

The "anomeric effects" in CH_3CHXY molecules

We define the "anomeric stabilization" in the molecules of the present study as the energy difference between the *gauche* and *anti* conformations, e.g., entries 7 versus 8 of Fig. 1, or the energy difference between the *gauche,gauche* and *anti,gauche* conformations, e.g., entries 11 versus 12. An alternative definition has been proposed by Schleyer *et al.* (35), in terms of the stabilization energies derived from the isodesmic reaction $XCH_2Y + CH_4 \rightarrow CH_3X + CH_3Y$ (36). The latter studies, carried out mainly at the 3-21G* level, suggest that the stabilization is greater than 10 kcal/mol for all combinations of first row X and Y (X,Y = F, OH, NH_2), but insignificant for all combinations of the second row substituents X,Y = Cl, SH, PH_2. However, significant anomeric interactions involving second row elements have been observed experimentally (19*i*, and references cited therein; also, unpublished results by Juaristi *et al.*).[2]

Tables 2 and 3 summarize the theoretical anomeric effects calculated for the relevant molecules of the present study, i.e., entries 7–16 of Fig. 1. Entries 7–14 refer to systems containing an endocyclic oxygen and an exocyclic X at the anomeric centre; entries 15 and 16 refer to molecules containing an endocyclic

[2]A more recent reexamination of $CH_2(SH)_2$ at a higher level of computation (MP4SDTQ/6-31G*//6-31G*)[3] now indicates that this system has greater stabilization than had been thought (35, 37).

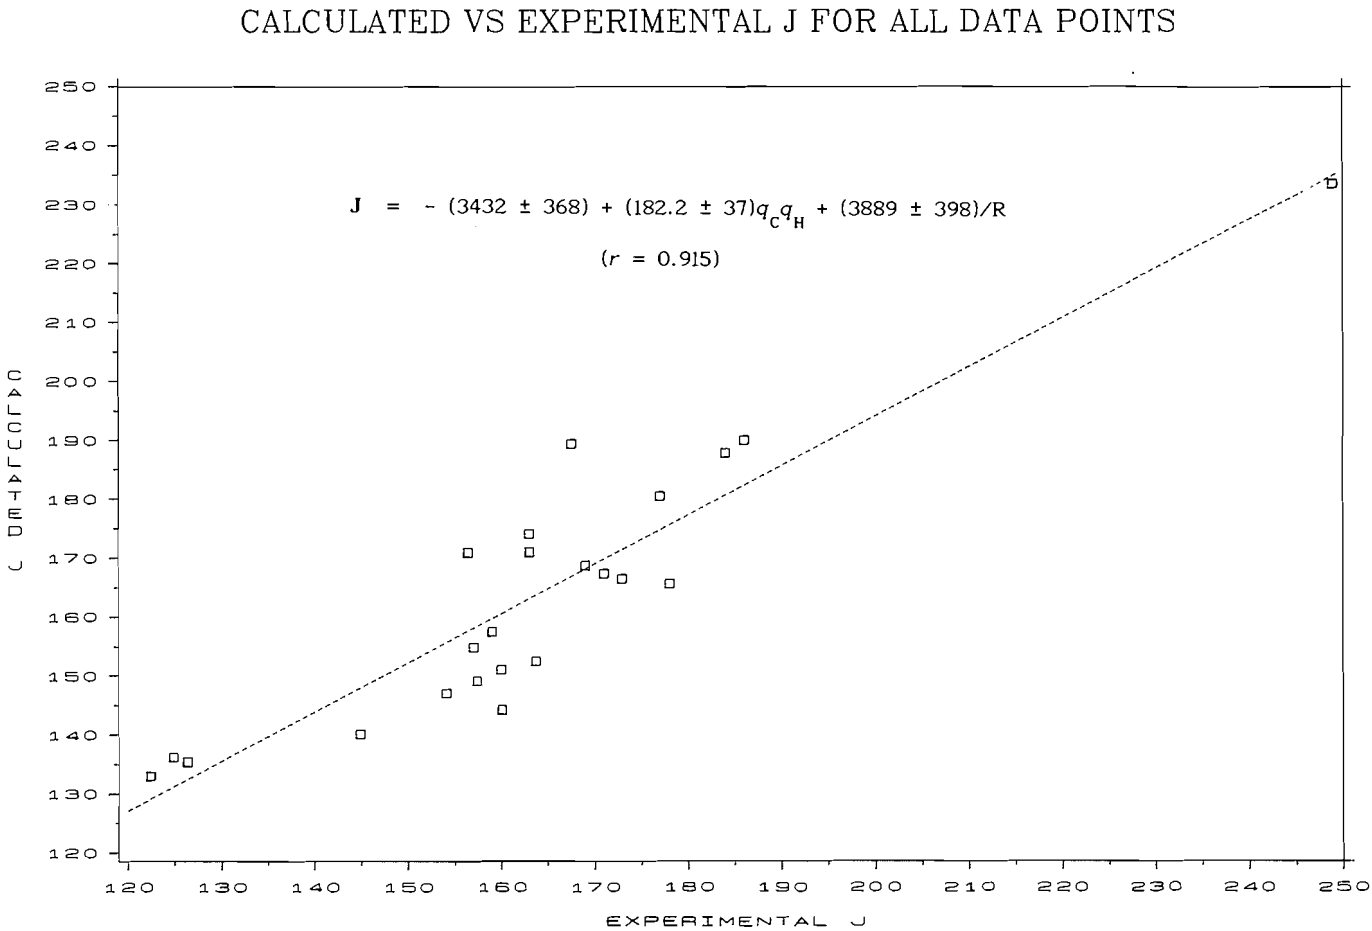

FIG. 6. Same as Fig. 5, for the set of data summarized in Table 4.

sulfur and an exocyclic hydroxyl group at the anomeric centre. The relative energies are given in kcal/mol. The tables include the calculated C—X and C—Y bond lengths, and the Y—C—X and Y—C—C bond angles in the two isomers. As expected from the geometrical consequences of the anomeric effect (29, 38), in all cases the C—Y bond is shorter, the C—X bond is longer, and the Y—C—X angle is larger in the "axial" isomers.

Interestingly, for "pyranosyl"-X, there is very little difference between the computed gas phase "anomeric effects" of first row and second row X. A value of 1.35 kcal/mol has been estimated for the anomeric effect in 2-MeS-tetrahydropyran, from the reported $\Delta G°$ value (0.35 in CCl_4 (39)), and the A value of MeS (1.0 kcal/mol (40)). A corresponding value of 1.29 kcal/mol in $CFCl_3/CDCl_3$ solvent can be estimated for 2-MeO-tetrahydropyran from the thermodynamic data for this compound and methoxycyclohexane (41). However, taking into account the conformational free energies for the axial–equatorial equilibria in 2-Me-tetrahydropyran (2.86 kcal/mol (42)) and methylcyclohexane (1.74 kcal/mol (43)) leads to experimental free energy anomeric effects of 1.67 and 1.99 kcal/mol, respectively, in 2-MeO- and 2-MeS-tetrahydropyran.

On the other hand, for a common X, there is an approximately 1 kcal/mol difference in the theoretical gas phase "anomeric effects" of "pyranosyl"-X and "thiapyranosyl"-X. Based on the available data (41–44) and the axial–equatorial equilibrium in 2-Me-tetrahydrothiapyran (1.40 kcal/mol (45)), we estimate experimental free energy anomeric effects of 3.07 and 2.19 kcal/mol, respectively, in 2-Cl-tetrahydropyran and 2-Cl-tetrahydrothiapyran.

Global analysis of the relationship between C—H bond lengths and one-bond coupling constants

As we have seen, for every diastereomeric or diastereotopic pair of C—H bonds, there is an inverse relationship between the C—H bond length and the magnitude of $^1J_{C-H}$. This is consistent with the simple notion that an interaction between two directly bonded atoms, in this case Fermi contact, will vary inversely with the distance between these atoms. Not surprisingly, however, when the 20 experimental C—H coupling constants listed in Fig. 1 are plotted against $1/R_{CH}$, the inverse of the C—H bond length, no statistically significant global correlation can be seen. Because of the different electronegativities of X and Y, the charges on the central carbon and on hydrogen vary throughout the series. One way to take these into account might involve a correlation such as $J = A + Bq_Cq_H + C/R$, where the q's are the total atomic charges on carbon and hydrogen, from the Mulliken population analysis. Figure 5 shows the result thus obtained for ethane, ethylene, and acetylene; in this case, taking the "electronegativity" contribution into account leads to a perfect correlation (r = 1.000). The inverse bond length term makes the dominant contribution to the correlation.

Accordingly, using the data of Table 4, a regression analysis of the type just described was performed on the 20 C—H bonds of the present study, to which ethane, ethylene, and acetylene were added. The result is shown in Fig. 6. As seen, the standard errors of the parameters of the equation are ca. 10%, and the correlation coefficient r = 0.915. Although an improved correlation might be achieved by taking additional geometrical and electronic effects into account, this is unlikely to alter our principal conclusions, namely, (1) the length of the C—H bond

is the dominant factor that determines the magnitude of $^1J_{C-H}$; (2) the two quantities are inversely related; (3) the Perlin Effect is the NMR counterpart of the Bohlmann bands.

Implications and predictions

The calculations on entry 6 of Fig. 1 predict that the relative reactivities towards radical abstraction of the C2-equatorial and C2-axial hydrogens of a 1,3-dithiane will be the opposite of that observed in a 1,3-dioxane (11). This prediction is currently under experimental investigation, but it is important to note that the analysis of the Perlin Effect presented herein would have allowed this prediction on the basis of the experimental $^1J_{C-H}$ coupling constants. Since a reversal of the relative magnitudes of the coupling constants at C2 is also observed in the third row analog 1,3-diselenane (19*k*, and unpublished results by Pinto *et al.*), this system is expected to resemble a 1,3-dithiane in the relative radical reactivities of its C2 hydrogens.

Received December 11, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

UDAY B. GOKHALE, OLE HINDSGAUL, and MONICA M. PALCIC. Can. J. Chem. **68**, 1063 (1990).

Chemical syntheses are reported for GDP-fucose (**5**), GDP-3-deoxy-fucose (**6**), and GDP-arabinose (**7**), the demethyl analog of **5**. All three sugar nucleotides were found to act as donor substrates for an α(1→4) fucosyltransferase isolated from human milk when βDGal(1→3)βDGlcNAc-O(CH_2)$_8$COOMe (**1**) was used as the acceptor. The rate of transfer of sugar residues to **1** was measured using a coupled spectrophotometric assay and was found to be 100% (**5**), 2.3% (**6**), and 5.9% (**7**). The product Le^a-active oligosaccharide analogs were identified by both an enzyme-linked immunosorbent assay (ELISA) and by ^1H NMR spectroscopy.

Key words: glycosyltransferase, oligosaccharide synthesis, sugar-nucleotide analog, ELISA assay, fucosyltransferase.

UDAY B. GOKHALE, OLE HINDSGAUL et MONICA M. PALCIC. Can. J. Chem. **68**, 1063 (1990).

On a réalisé la synthèse du GDP-fucose (**5**), du GDP-3-désoxy-fuxose (**6**) et du GDP-arabinose (**7**), l'analogue déméthylé du produit **5**. On a trouvé que, lorsque le βDGal(1→3)βDGlcNAc-O(CH_2)$_8$COOMe (**1**) est utilisé comme accepteur, ces trois nucléotides de sucre peuvent agir comme des substrats donneurs pour une α(1→4) fucosyltransférase isolée du lait humain. Utilisant une méthode spectrophotométrique couplée, on a mesuré les vitesses de transfert des résidus de sucre vers le produit **1** et on a trouvé que ces vitesses sont respectivement de 100% (**5**), de 2,3% (**6**) et de 5,9% (**7**). Faisant appel à la RMN du ^1H et à une méthode d'immunosorbance liée à un enzyme, on a identifié les analogues d'oligosaccharides actifs vis-à-vis de Le^a.

Mots clés : glycosyltransférase, synthèse d'oligosaccharides, analogue des nucléotides de sucre, méthode d'immunosorbance liée à un enzyme, fucosyltransférase.

Introduction

The use of enzyme assisted oligosaccharide synthesis is gaining wide popularity since it allows the rapid and specific homologation of relatively small, readily chemically synthesized mono- and disaccharides into larger and more complex structures (1). This homologation is most frequently accomplished using specific glycosyltransferases that transfer sugars from the appropriate sugar-nucleotide donors, all of which are commercially available, to suitable oligosaccharide acceptors. Accessibility to the required mammalian glycosyltransferases, most of which must still be isolated from natural sources, has been the single major impediment to the general applicability of this combined chemical–enzymatic approach to oligosaccharide synthesis. The availability of the required enzymes is, however, rapidly increasing as three of these enzymes are now commercially available and at least six have recently been cloned (2).

Analogs of the naturally occurring oligosaccharides, particularly deoxygenated oligosaccharides, are invaluable probes in studies on the molecular recognition of complex carbohydrates by protein combining sites (3, 4). The effect of specifically deoxygenating individual hydroxyl groups of oligosaccharide ligands, for example, provides direct evidence for the involvement of those hydroxyl groups in hydrogen bonding with the protein. While the utility of oligosaccharide analogs is generally recognized, the difficulty of preparing the required structures by multistep chemical synthesis remains a major obstacle to their broad use in the study of carbohydrate binding by antibodies, lectins, enzymes, and other receptors.

In anticipation of a wider availability of glycosyltransferases as "routine reagents" for the combined chemical–enzymatic synthesis of oligosaccharides, we have begun an evaluation of the scope of these enzymes in the production of oligosaccharide analogs. We present here an investigation using a readily isolated Lewis blood-group associated α(1→4) fucosyltransferase, a glycosyltransferase that has previously been used in the combined chemical–enzymatic synthesis of oligosaccharides terminating in the Lewis-a (Le^a) blood-group determinant (5). The Lewis fucosyltransferase (Le-Fuc-T), which has also recently been cloned (2), transfers an L-fucopyranosyl residue from guanosine-5′-diphospho-fucose (GDP-fucose, **5**) to the 4-hydroxyl group of oligosaccharides terminating in the Type 1 sequence βDGal(1→3)βDGlcNAc-OR (**1**), to produce the Le^a-active terminus βDGal(1→3)[αLFuc(1→4)]βDGlcNAc-OR (**2**) (5). This reaction has been kinetically characterized in vitro where R in the synthetic oligosaccharides **1** and **2** was the 8-methoxycarbonyloctyl aglycone (5). We report here a simple chemical synthesis of the parent GDP-fucose (**5**), as well as the preparation of GDP-3-deoxy-L-fucose (**6**, GDP-3-deoxy-β-L-*xylo*-hexose, GDP-colitose) and GDP-D-arabinose (**7**, GDP-β-D-*arabino*-pentose), its 5-demethyl analog. Both of these analogs were found to be sufficiently reactive as donors to allow the production of the Le^a-active trisaccharide analogs **3** and **4**. Formation of **3** and **4** could be detected in an enzyme-linked immunosorbent assay (ELISA) using a monoclonal anti-Le^a antibody that had previously been shown to recognize these modified structures (6, 7). The initial rates of transfer of fucose analogs was further

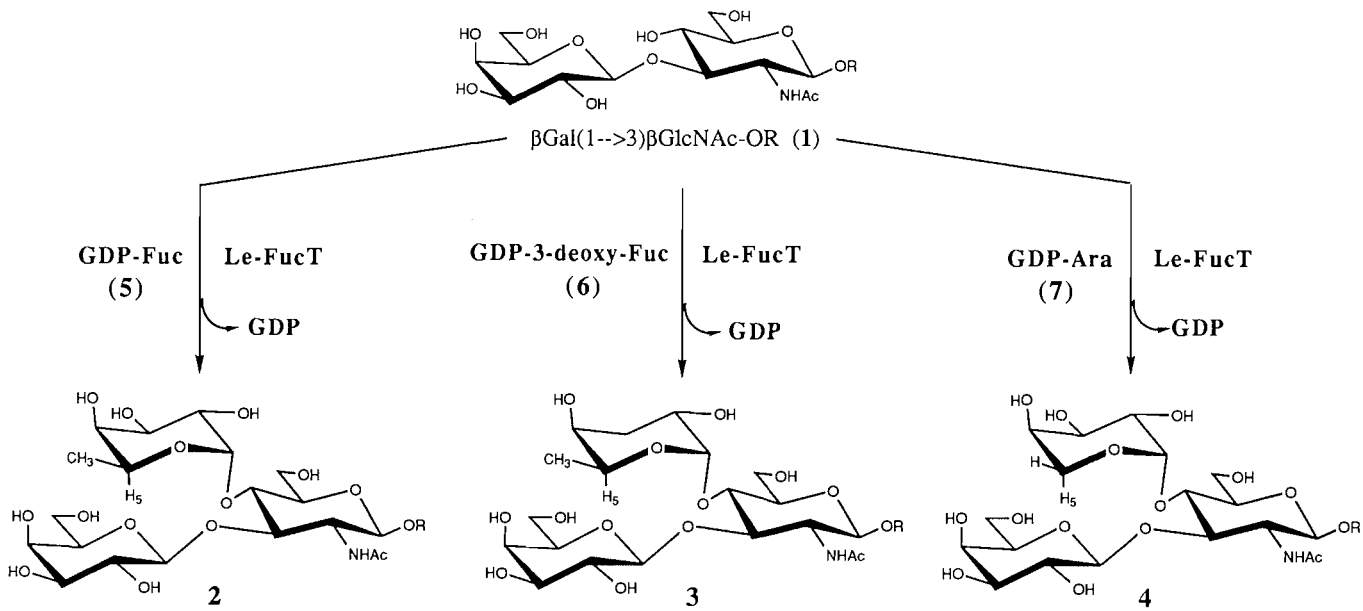
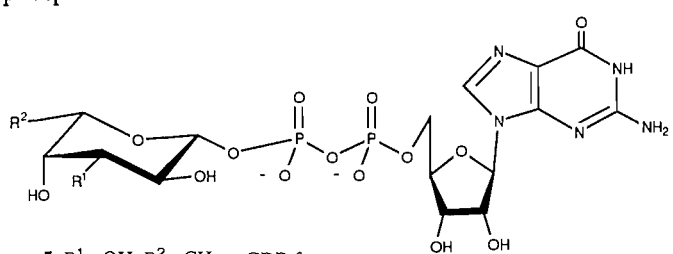


SCHEME 1

estimated using a novel spectrophotometric coupled enzyme assay. The structures of the enzymatically produced trisaccharides **2–4** were verified by ^{1}H NMR spectroscopy.

Chemical synthesis of GDP-fucose (5) and its analogs 6 and 7

Previous chemical syntheses of GDP-fucose required the stereospecific hydrolysis of acetobromofucose (**8**) to produce the β-reducing sugar **9** as the kinetic product (8). Compound **9** was then purified by fractional crystallization and phosphorylated using the highly reactive *o*-phenylene phosphorochloridate under conditions where isomerization to the more stable α-anomer **10** was minimized. Deprotection over three steps then provided the β-phosphate **14**, which could be converted to **5** (8). We found it very difficult to reproducibly obtain even 20% yields of **14** using this procedure. Since it was furthermore not assured that the required analogs of β-L-fucopyranose could be isolated by fractional crystallization of their glycosyl-bromide hydrolysis products, we elected instead to develop a simpler and potentially more general synthesis of β-pyranosyl phosphates.



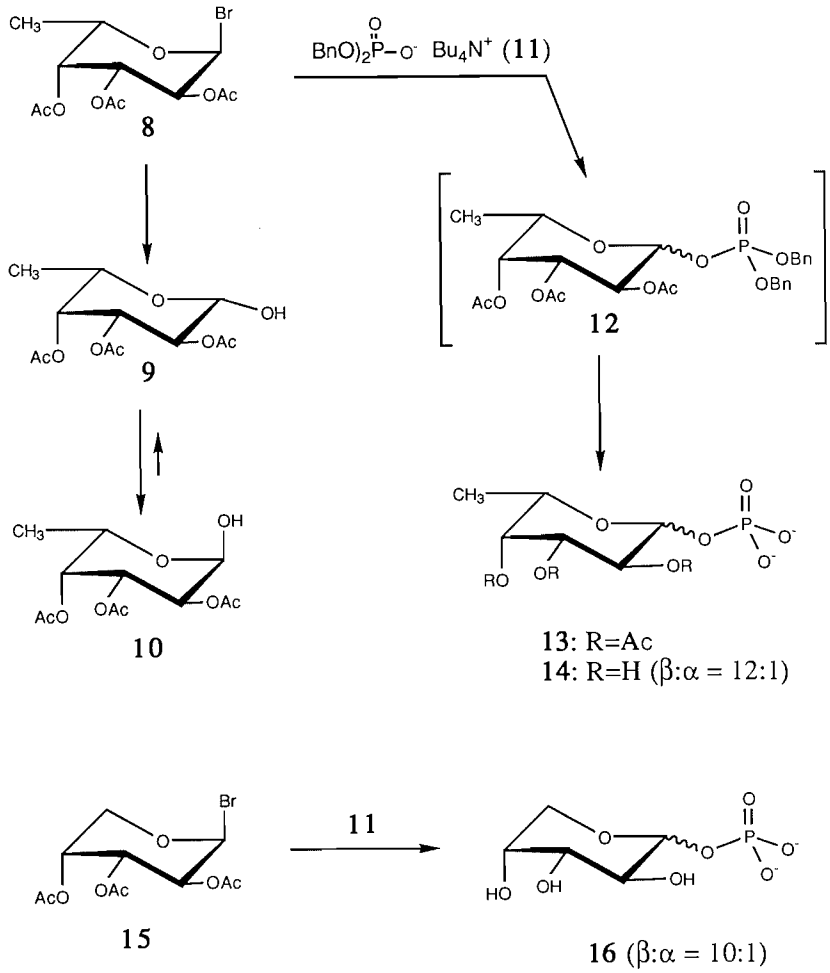
5: R^1= OH, R^2= CH_3, GDP-fucose
6: R^1= H, R^2= CH_3, GDP-3-deoxy-fucose
7: R^1= OH, R^2=H, GDP-arabinose

Reaction of **8** with tetra-*n*-butylammonium dibenzylphosphate (**11**) in DMF was found to proceed within 5 min at room temperature to produce a labile β-linked phosphotriester **12**. Compound **12** could be partially purified by rapid (< 10 min) chromatography on silica gel. The β-anomer of **12** proved to be unstable to extended contact with the silica gel and was completely destroyed by contact times as short as 2 h. Hydrogenolysis of the benzyl protecting groups in **12** gave the stable glycosyl phosphate **13**, which was treated with aqueous NaOH to provide **14**. Compound **14** was reproducibly obtained in 50% yield from **8** following ion-exchange chromatography and desalting. The ^{1}H NMR of **14** showed it to be a β/α mixture in the ratio 12:1. Similar reaction of 2,3,4-tri-*O*-acetyl-α-D-arabinopyranosyl bromide (**15**) gave phosphate **16** (β/α = 10:1) in 47% overall yield.

The synthesis of 3,6-dideoxy-L-*xylo*-hexopyranosyl phosphate (**27**) required several steps. Reaction of benzyl β-L-fucopyranoside (**17**) with dimethoxypropane gave acetal **18**, which was benzolated to provide **19** (60% from **17**). Removal of the isopropylidene group in **19** gave diol **20**, which was selectively 3-*O*-phenylthionocarbonylated (9) to provide **21** (68%). Reduction of **21** (Bu_3SnH, 51%) furnished the 3-deoxy derivative **22**, which was *O*-acetylated to give **23** (80%). Hydrogenolysis of the benzyl aglycon in **23** then gave the reducing sugar **24** (98%). Reaction of **24** with oxalyl bromide/DMF gave the unstable α-bromide **25**, which was immediately treated with **11**, followed by hydrogenation and saponification, to provide **26** (β/α = 5.4:1, 14%). The low yield of **26** is attributed at least partially to side reactions of the dideoxyglycosyl bromide **25**. Phosphates **14, 16**, and **26** were prepared at least four times following the above procedures and the isolated yields varied by less than 10%.

Two procedures were examined for conversion of **14, 16**, and **26** to the required GDP derivatives **5–7.** In our hands, coupling of these phosphates using either GMP-morpholidate (**27**) (8) or the phosphinothioic anhydride **28** (8) gave similar yields, which varied from experiment to experiment but always remained in the range of 25–50%. Similar observations were made in connection with a recent synthesis of CDP-quinovose (10). Representative procedures are reported in the experimental section. The product GDP derivatives could be purified by chromatography on Dowex anion-exchange resins using a LiCl gradient elution, which separated the faster eluting α-anomers. After desalting by passage through Bio-Gel P-2, the β-linked sugar nucleotides were isolated as their sodium salts following ion exchange. We wish to *explicitly* point out that the GDP derivatives **5–7** are unstable to either mildly acidic conditions

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.



or even in neutral solution of high ionic strength. For example, attempted removal of water from a frozen aqueous LiCl solution of GDP-fucose by lyophilization resulted in its complete destruction, to produce fucose and GDP. The analogs **6** and **7** are expected to be even less stable.

Enzymatic synthesis of trisaccharides 2–4

The Le-FucT from human milk has previously been shown to transfer fucosyl residues from GDP-fucose to the Type 1 disaccharide acceptor βDGal(1→3)βDGlcNAc-O(CH_2)$_8$$COOCH_3$ (**1**) to yield the Le^a-active trisaccharide **2** (5). Compound **2** had earlier been prepared by total chemical synthesis (11). It was considered important to establish early in this investigation whether the GDP-fucose analogs **6** and **7** would also be utilized by the Le-FucT. All of the quantitative fucosyltransferase assays published to date involve the measurement of the rate of transfer of radiolabelled (^3H or ^{14}C) fucose from radiolabelled GDP-fucose to acceptor oligosaccharides (12). Since the chemically synthesized GDP-fucose analogs described here were not radiolabelled, alternate fucosyltransferase assays had to be devised.

We recently described an enzyme-linked immunosorbent assay (ELISA) for the Le-FucT that utilizes a monoclonal antibody, directed against **2**, to detect the conversion of **1** to **2** using unlabelled GDP-fucose, when these are immobilized on microtiter plates as their bovine serum albumin (BSA) conjugates (6). The combining site of the antibody used in these studies, clone CF4-C4, has been thoroughly probed by Lemieux *et al.* (7) using chemically synthesized derivatives of the Le^a-trisaccharide **2** as the methyl glycoside (R = Me). These studies showed that CF4-C4 not only bound to the Le^a trisaccharide (**2**), *but also* to the corresponding chemically synthesized 3-deoxy-fucose and arabinose analogs. Incubation of microtiter plates coated with the BSA-conjugate of acceptor **1** with the purified human milk Le-FucT in the presence of the GDP-fucose analogs **6** and **7** did indeed produce an immobilized product that was recognized by CF4-C4 as evidenced by the ELISA. No attempt was made to quantitate the rate of production of Le^a-active trisaccharides in these solid-phase reactions but this evidence for the utilization of **6** and **7** by the enzyme was nevertheless considered unequivocal.

A concentrated solution of the affinity-purified Le-FucT was prepared and added to acceptor **1** and to each of **5–7**. The initial rate of glycosylation of **1**, using **5–7** as the donors, was estimated by monitoring the reaction spectrophotometrically using a coupled-enzyme assay previously applied to the detection of galactosyltransferase activity (13) and described here for the first time for a fucosyltransferase. Since the glycosylation of **1** would result in the formation of one equivalent of GDP in all 3 cases (see Scheme 1), the rate of formation of GDP in these reaction mixtures would reflect the rate of glycosylation. This rate could be estimated by coupling the GDP formation to NADH oxidation employing pyruvate kinase and lactate dehydrogenase. Reaction progess could therefore be monitored spectrophotometrically by observing the decrease in absorbance at 340 nm. Incubation of the Le-FucT with acceptor **1** and GDP donors **5–7** in the presence of the enzyme coupling system thus gave the initial reaction rates listed in Table 1. These data

TABLE 1. Comparisons of GDP-fucose (**5**), GDP-3-deoxy-fucose (**6**), and GDP-arabinose (**7**) as donor substrates for the Lewis α(1→4) fucosyltransferase using βGal(1→3)βGlcNAc-O(CH_2)$_8$COOMe as the acceptor

Donor	ΔA_{340}(min)[a]	Relative rate (ΔA_{340})
GDP-fucose (**5**)	−0.064	100
GDP-3-deoxy-fucose (**6**)	−0.0015	2.3
GDP-arabinose (**7**)	−0.0038	5.9

[a]Rates are expressed as decrease in absorbance/0.87 mL for 11 milliunits of enzyme; details are given in the experimental section. The background in these experiments (i.e., the change in absorbance in the absence of acceptor **1**) was 0.0023 and has been subtracted from the values listed.

provide an estimate of the relative rate of transfer of glycosyl residues from the GDP-fucose analogs to be 100% (**5**), 2.3% (**6**), and 5.9% (**7**).

The data obtained using the above spectrophotometric assay (Table 1), coupled with a positive product identification by antibody CF44-C4 in the ELISA, provided strong evidence that trisaccharides **2–4** had been produced by the enzyme. It was nevertheless considered essential to provide definitive structural proof for the products formed in these enzymatic syntheses and the reactions were therefore carried out on a scale that would permit product characterization by ^{1}H NMR. The product of the reaction of **1** and GDP-fucose (**5**), catalyzed by the Le-FucT, has previously been characterized by ^{1}H NMR spectroscopy and shown to be identical with the Le^a-trisaccharide **2** prepared by total chemical synthesis (11). The characteristically deshielded signal for H-5 of the fucosyl residue in **2** (δ = 4.874 ppm) (5, 11) is considered diagnostic for βDGal(1→3)βDGlcNAc structures that have been α-fucosylated at the 4-position of the GlcNAc residue. This unusual deshielding has been attributed (11, 14) to the van der Waals contact of H-5 to both the ring and aglyconic oxygens of the βDGal residue in **2** as a result of its rigid solution conformation. Trisaccharides **3** and **4** would be expected to adopt solution conformations similar to that of **2** and the signals for H-5 (axial) in these structures would therefore be predicted to be correspondingly deshielded. Incubations designed to provide products in quantities sufficient for detection by ^{1}H NMR spectroscopy were therefore carried out. The extent of conversion of **1** to the Le^a -analogs **2–4** was estimated by integration of the appropriate proton resonances to be 100, 30, and 65%, respectively. The Le^a trisaccharide analogs **3** and **4** were not purified away from unreacted **1** since their structures could be deduced from the ^{1}H NMR spectra of the crude reaction mixtures (Fig. 1). As expected, the signal for H-5 in the 3-deoxy Le^a analog **3** was characteristically deshielded and resonated at 4.79 ppm where it was partially obscured by the residual DOH

For personal use only.

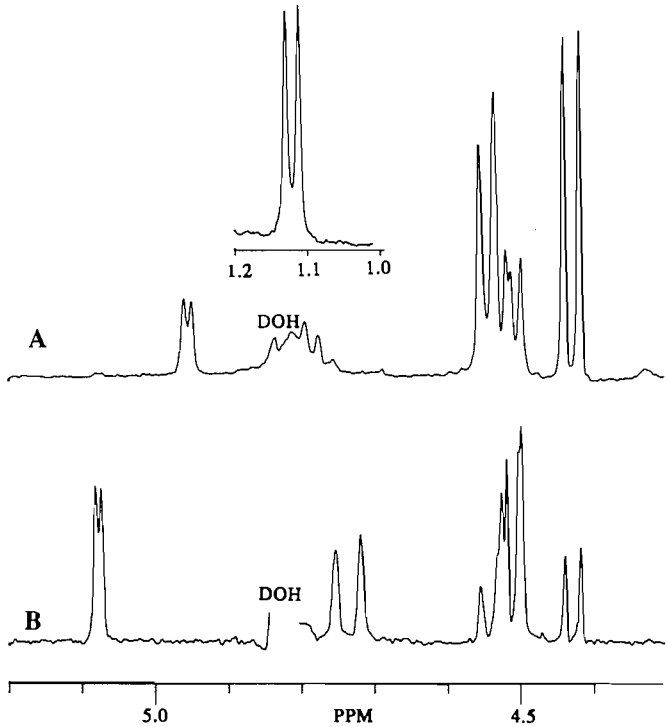

FIG. 1. Partial 360-MHz ^{1}H NMR spectra of the crude reaction products obtained on glycosylation of disaccharide **1** using GDP-3-deoxy-fucose **6** (A) and GDP-arabinose **7** (B) in D_2O. The spectral artifacts appearing near δ 4.82 ppm result from suppression of the residual DOH signal by presaturation.

signal (Fig. 1A). Irradiation at 4.79 ppm collapsed the methyl group doublet appearing at 1.120 ppm (inset, Fig. 1A) to a singlet, thereby confirming the signal assignments. The signal from the H-5 (axial) proton in the arabino-Le^a analog **4** was similarly deshielded (Fig. 1B), appearing at 4.736 ppm (J_{gem} = −12.5 Hz). The signals for the anomeric protons of the α-linked glycosyl residues in **3** and **4** are seen at 4.955 and 5.078 ppm, respectively, with vicinal coupling constants near 3 Hz. Both the ELISA and spectrophotometric assays are therefore concluded to be reliable assays for monitoring the synthesis of the Le^a-related structures described in this study.

In summary, straightforward syntheses of GDP-fucose and two of its analogs have been described. All three GDP-fucose derivatives were found to act as donors for an Le-FucT, as assayed by both ELISA and spectrophotometric methods, and the structures of the products were confirmed by ^{1}H NMR spectroscopy. The objective of this study was to demonstrate that glycosyltransferases could be used to synthesize analogs of the structures that they assemble in nature and thereby provide an attractive alternative to laborious total chemical syntheses for the provision of such oligosaccharide analogs. It remains to be determined whether other fucosyltransferases will also utilize the GDP-fucose analogs described here, thereby expanding the scope of the enzyme-assisted synthesis of oligosaccharide analogs. These studies with both fucosyltransferases and *N*-acetylglucosaminyltransferases (21) are currently in progress.

Experimental

General procedures

All solvents and reagents used were reagent grade, and in cases where further purification was required, standard procedures (15) were followed. All solid reactants for glycosylation and for moisture sensitive reactions were dried overnight over phosphorus pentoxide in high vacuum prior to use. Solution transfers where anhydrous conditions were required were done under dry nitrogen or argon using hypodermic syringes. Molecular sieves were purchased from BDH chemicals.

Thin-layer chromatograms (TLC) were performed on precoated silica gel 60-F254 plates (E. Merck, Darmstadt) and visualized by quenching of fluorescence and (or) by charring after spraying with 5% sulfuric acid in ethanol. For "silica gel chromatography" 40–63 μm (400–230 mesh) silica gel 60 (E. Merck No. 9385) and distilled solvents were used, and the ratio of silica gel to compound was in the range 50:1–100:1. Water was evaporated under the vacuum of an oil pump using a rotary evaporator equipped with a condenser containing acetone and Dry Ice. Organic solvents were removed on a rotary evaporator under the vacuum of a water aspirator with bath temperatures of 40°C or lower. For gel filtration, Bio-Gel P-2 (200–400 mesh) (Bio-Rad Laboratories, Richmond, California, U.S.A.) was used. Elemental analyses were performed by the Analytical Service Laboratory of the Chemistry Department. Proton nuclear magnetic resonance (^{1}H NMR) spectra were recorded at either 300 or 360 MHz (Bruker AM-300 or WM-360) with tetramethylsilane (δ 0 in $CDCl_3$) or acetone (δ 2.225 in D_2O) or TSP-d4 (δ 0 in D_2O) or acetonitrile (δ 2.049 in D_2O) as the internal standard at ambient temperature. Carbon-13 nuclear magnetic resonance (^{13}C NMR) spectra were recorded at 75 mHz (Bruker AM-300) with either external tetramethylsilane (δ 0 in $CDCl_3$) or external 1,4-dioxane (δ 67.4 in D_2O) as the reference standard. Phosphorus-31 nuclear magnetic resonance (^{31}P NMR) spectra were recorded at 161.97 MHz (Bruker AM-300) with external H_3PO_4 (85%) (δ 0 in D_2O) as the reference standard. The chemical shifts at lower field, relative to external H_3PO_4, are expressed as positive numbers while those at higher field are expressed as negative numbers. For some compounds, consideration of the water of hydration was necessary in order to obtain a match between the combustion analysis results and the expected elemental composition. Optical rotations were determined on a Perkin–Elmer 241 polarimeter in a 1 dm cell at ambient temperature (23 +/− 1°C). The melting points are uncorrected. High performance liquid chromatography (HPLC) was performed on a Waters Delta Prep 3000 preparative chromatography system.

Chemical synthesis

*Benzyl 2-O-benzoyl-3,4-di-O-isopropylidene-β-L-fucopyranoside (**19**)*

To a clear solution of **17** (16) (5.32 g, 20.9 mmol) in dichloromethane (80 mL) containing *p*-toluenesulfonic acid (50 mg) was added 2,2-dimethoxypropane (7.7 mL, 3 equiv.). The resulting solution was protected from moisture and stirred at 23°C for 6 h. Evaporation of the solvent gave **18** as a brown oil (R_f 0.68, ethyl acetate:hexane:EtOH, 10:10:1), which was dissolved in dichloromethane (15 mL) containing *N*,*N*-dimethylaminopyridine (100 mg). To this solution were then added pyridine (5 mL, 60 mmol) and benzoyl chloride (6.1 mL, 2.5 equiv.). After stirring for 10 h the solvent was evaporated and the residue was partitioned between dichloromethane (40 mL) and water (20 mL). The organic layer was successively washed with saturated $NaHCO_3$ (20 mL), water (20 mL), dried ($MgSO_4$) and evaporated. Purification of the residue by silica gel chromatography (ethyl acetate:hexane, 1:1) gave **19** (R_f 0.50) as a crystalline solid (4.96 g, 60% for two steps); mp 100–103°C; $[\alpha]_D$ −6.2° (*c* 0.28, $CHCl_3$); R_f 0.64 (toluene:ether, 2:1); ^{1}H NMR ($CDCl_3$) δ: 7.120–8.060 (arom, 10H), 5.306 (dd, 1H, $J_{1,2}$ = 8.5 Hz, $J_{2,3}$ = 7.5 Hz, H-2), 4.873 and 4.635 (2 × d, 2H, J_{gem} = 12.0 Hz, $C_6H_5CH_2$), 4.458 (d, 1H, H-1), 4.251 (dd, 1H, $J_{3,4}$ = 5.0 Hz, H-3), 4.058 (dd, 1H, $J_{4,5}$ = 2.0 Hz, H-4), 3.894 (dq, 1H, $J_{5,6}$ = 6.5 Hz, H-5), 1.646 and 1.357 (2 × s, 6H, isopropylidene methyls), 1.498 (d, 3H, H-6); ^{13}C NMR ($CDCl_3$ δ: 110.5 (quaternary carbon of isopropylidene), 28.1, 26.6 (isopropylidene methyls. Anal. calcd. for $C_{23}H_{26}O_6$: C 69.33, H 6.58; found: C 69.27, H 6.77.

*Benzyl 2-O-benzoyl-β-L-fucopyranoside (**20**)*

A solution of **19** (4.96 g, 12.45 mmol) in 60% aqueous AcOH (160 mL) was stirred for 2 h at 60°C. The solvent was evaporated and the residue was coevaporated with toluene (3 × 50 mL) to afford the

title compound as a colourless solid (4.34 mg, 97%); mp 151–152°C; $[\alpha]_D$ +64° (*c* 0.2, $CHCl_3$); R_f 0.20 (ethyl acetate:hexane, 1:1); ^1H NMR ($CDCl_3$ D_2O exchanged) δ: 7.12–8.06 (arom, 10H), 5.238 (dd, 1H, $J_{1,2}$ = 8.0 Hz, $J_{2,3}$ = 8.9 Hz, H-2). Anal. calcd. for $C_{20}H_{22}O_6$: C 67.03, H 6.19; found: C 66.47, H 6.18.

Benzyl 2-O-benzoyl-3-O-phenoxythionocarbonyl-β-L-fucopyranoside (21)

To a stirred solution of **20** (1.09 g, 2.98 mmol) in dichloromethane (50 mL) at −78°C were added pyridine (1 mL) and phenoxychlorothionocarbonate (9) (0.48 mL, 1.2 equiv.). Stirring of the reaction mixture at −10°C for 0.5 h resulted in a slow formation of the title compound (R_f 0.6, ethyl acetate:hexane, 1:1) at the expense of the starting material **20** (R_f 0.2). Finally, stirring at 0°C for 0.5 h resulted in a >95% conversion of **20** into the desired compound. The reaction mixture was partitioned between dichloromethane (40 mL) and cold water (20 mL). The organic layer was then dried ($MgSO_4$) and concentrated to a thick brown syrup. For the isolation of the product, a silica column (3 × 20 cm) was prepared in ethyl acetate:hexane (1:1) solvent mixture. The syrup was adsorbed on to the silica column and the material was eluted quickly (silica contact time, 10 min) with the same solvent mixture to provide the product. Evaporation of the appropriate fractions left **21** as a pale brown solid (960 mg, 68%); mp 145–146°C; $[\alpha]_D$ +27.8° (*c* 0.21, dichloromethane), R_f 0.6 (ethyl acetate: hexane, 1:1); ^1H NMR ($CDCl_3$) δ: 8.037–6.854 (arom, 15H), 5.741 (dd, $J_{1,2}$ = 7.5 Hz, $J_{2,3}$ = 10.0 Hz, H-2), 5.646 (dd, $J_{3,4}$ = 3.0 Hz, H-3), 4.911 (d, 1H, J_{gem} = 13.0 Hz, C_6H_5CHH), 4.676 (d, 1H, C_6H_5CHH), 4.657 (d, 1H, H-1), 4.187 (ddd, $J_{4,5}$ = 1.0 Hz, $J_{4,OH}$ = 7.0 Hz, H-4), 3.807 (dq, 1H, H-5), 2.309 (d, 1H, 4-OH), 1.446 (d, 3H, $J_{5,6}$ = 6.5 Hz, H-6). Anal. calcd. for $C_{27}H_{26}O_7S \cdot H_2O$: C 63.30, H 5.51, S 6.26; found: C 64.64, H 5.31, S 6.88.

Benzyl 2-O-benzoyl-3,6-dideoxy-β-L-xylohexopyranoside (22)

Compound **21** (960 mg, 1.94 mmol) was subjected to the radical deoxygenation exactly as described by Robins and Wilson (9). Evaporation of the solvent left a residue, which was dissolved in acetonitrile and extracted with hexane until the smell of tin residues was absent. Evaporation of the acetonitrile afforded a syrup (R_f 0.45, ethyl acetate:hexane, 1:1), which solidified under vacuum. The resulting solid was purified by silica gel chromatography (ethyl acetate:hexane, 2:3) to provide the title compound as colourless needles (340 mg, 51%); mp 128°C; $[\alpha]_D$ +98° (*c* 0.93, dichloromethane); ^1H NMR ($CDCl_3$) δ: 8.10–7.20 (arom, 10H), 5.292 (ddd, 1H, H-2), 4.619 (d, 1H, $J_{1,2}$ = 7.5 Hz), 3.746 (m, 2H, H-4 and H-5), 2.523 (ddd, 1H, J_{gem} = 13.0 Hz, $J_{2,3eq}$ = 5.0 Hz, $J_{3eq,4}$ = 3.0 Hz, H-3eq), 2.269 (d, 1H, $J_{4,OH}$ = 8.0 Hz, HO-4), 1.736 (ddd, $J_{2,3ax}$ = 12.0 Hz, $J_{3ax,4}$ = 3.0 Hz, H-3ax), 1.343 (d, 3H, $J_{5,6}$ = 6.5 Hz, H-6). Anal. calcd. for $C_{20}H_{22}O_5$: C 70.16, H 6.48; found: C 69.74, H 6.33.

Benzyl 4-O-acetyl-2-O-benzoyl-3,6-dideoxy-β-L-xylohexopyranoside (23)

Compound **22** (1.45 g, 4.24 mmol) was dissolved in pyridine (20 mL) and acetic anhydride (10 mL). After 24 h at room temperature, the reaction mixture was poured onto crushed ice and water (50 mL). The resulting sticky solid was taken up in dichloromethane (40 mL). The organic layer was washed with water (20 mL) and saturated $NaHCO_3$ (2 × 30 mL). Drying ($MgSO_4$) and evaporation of the solvent left a syrup, which was purified by silica gel chromatography in ethyl acetate: hexane (1:2) to afford the title compound as a colourless solid (1.3 g, 80%); mp 68°C; $[\alpha]_D$ +89° (*c* 0.36, dichloromethane); ^1H NMR ($CDCl_3$) δ: 7.83–7.18 (arom, 10H), 5.276 (ddd, 1H, H-2), 5.066 (m, 1H, H-4), 4.656 (d, 1H, $J_{1,2}$ = 8.0 Hz, H-1), 3.822 (dq, 1H, $J_{4,5}$ = 1.0 Hz, $J_{5,6}$ = 6.5 Hz, H-5), 2.475 (ddd, 1H, J_{gem} = 13.0 Hz, $J_{2,3eq}$ = 5.0 Hz, $J_{3eq,4}$ = 3.0 Hz, H-3eq), 2.177 (s, 3H, OAc), 1.800 (ddd, $J_{2,3ax}$ = 12.0 Hz, $J_{3ax,4}$ = 3.0 Hz, H-3ax), 1.267 (d, 3H, H-6). Anal. calcd. for $C_{22}H_{24}O_6$: C 68.73, H 6.29; found: C 68.79, H 6.27.

4-O-Acetyl-2-O-benzoyl-3,6-dideoxy-L-xylohexopyranose (24)

Compound **23** (930 mg, 2.42 mmol) was dissolved in ethanol (20 mL) containing Pd/C (5%, 650 mg) and stirred under H_2 (1 atm (= 101.3 kPa), for 24 h. The catalyst was filtered and washed with ethanol (2 × 40 mL). The combined filtrate was evaporated to dryness to afford the syrupy title compound as an α/β (1:1) mixture (710 mg, 98%); $[\alpha]_D$ −1.6° (*c* 1.4, methanol, 24 h); ^1H NMR ($CDCl_3$) δ: 5.519 (dd, $J_{1,2}$ = $J_{1,OH}$ = 3.0 Hz, H-1: α anomer), 4.793 (dd, $J_{1,2}$ = $J_{1,OH}$ = 8.0 Hz, H-1: β anomer). Anal. calcd. for $C_{15}H_{18}O_6 \cdot H_2O$: C 57.69, H 6.46; found: C 57.33, H 5.73.

4-O-Acetyl-2-O-benzoyl-3,6-dideoxy-α-L-xylopyranosyl bromide (25)

Compound **24** (568 mg, 1.9 mmol) was dissolved in dichloromethane (10 mL) containing DMF (2 mL) and the resulting solution was stirred at −10°C. Oxalyl bromide (1.5 equiv.) was then added at the same temperature. Stirring at 23°C for 1 h resulted in near-complete conversion of **24** into the title compound (R_f 0.78, ethyl acetate: hexane, 1:1), along with products of lower mobility, presumably hydrolysis products. This solution was used directly in the preparation of glycosyl phosphate **26** without any work-up.

Tetra-n-butylammonium dibenzyl phosphate (11)

(Procedure for the preparation of 16.2 mmol of **11**)

A suspension of dibenzyl hydrogen phosphate (4.37 g, 15.7 mmol) in water (50 mL) was stirred at room temperature. Tetra-*n*-butylammonium hydroxide (approx. 40% aq. w/w, 8.42 g) was added dropwise to the suspension to obtain a clear solution. At this stage some undissolved solid must remain to indicate that the reaction was not too basic. Filtration through Whatman filter paper gave a clear filtrate (pH 8–9). To this was added dibenzyl hydrogen phosphate in small portions until the pH decreased to 7. The resulting clear solution was lyophilized to afford **11** as a colourless syrup.

L-Fucose-1-phosphate (14)

To a clear solution of fucosyl bromide **8** (freshly prepared (8) from 1.2 g, 3.6 mmol of L-fucose tetraacetate) in dry DMF (3 mL) was added **11** (6 equiv.) in dry DMF (4 mL) to yield a pale yellow solution. After 10 min at 23°C the reaction mixture was partitioned between dichloromethane (30 mL) and cold water (10 mL). The organic layer was washed once more with cold water (10 mL), dried ($MgSO_4$), and evaporated to a syrup. A silica gel column (2.5 × 20 cm) packed in dichloromethane:ethyl acetate (1:1) was prepared and the syrup was placed on top of it. Rapid elution (10 min) using the same solvent afforded a material with R_f 0.80, presumably the intermediate triester (**12**). This material was concentrated to afford a syrup that was not characterized but was stirred in ethanol (40 mL) containing aqueous $NaHCO_3$ (1 N, 10 mL) and Pd/C (5%, 300 mg) under an atmosphere of hydrogen. After 2 h at room temperature, the material with R_f 0.8 (dichloromethane:ethyl acetate, 1:1) and which was UV absorbing had disappeared to give a baseline carbohydrate material. The solids were removed by filtration and the filtrate was concentrated to a syrup, which was partitioned between dichloromethane (20 mL) and water (20 mL). The aqueous layer was separated and aqueous NaOH (1 M, 20 mL) was added. After 0.5 h at 23°C the pH was carefully adjusted to 7 with cold AcOH (1 N). The resulting solution was diluted to about 200 mL with water and slowly adsorbed onto a resin bed of Dowex 2 (2.5 × 10 cm, Cl^-). The column was washed with water (100 mL) and then developed with a linear gradient (8) of LiCl. The mixing chamber contained 250 mL of water and the reservoir contained 250 mL of 0.45 M LiCl. The column was run at 23°C at a flow rate of about 120 mL/h and fractions (4 mL) were collected automatically. The eluate was monitored for the presence of acid-labile phosphate (H_2SO_4 spraying was used for the detection of the *carbohydrate material* and ammonium molybdate spray was used to detect the *phosphate*) (17). The appropriate fractions containing L-fucose-1-phosphates were pooled and lyophilized to provide a white solid. This solid was then transferred to screw-cap centrifuge tubes and shaken (exothermic!) with diethyl ether:95% ethanol, 2:1. Centrifugation of the resulting suspension afforded clear supernatants, which were discarded. The residues were extracted several times with the same solvent system (the presence of

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

Cl^- ions in the supernatants could be detected with aqueous $AgNO_3$). After all the LiCl had been extracted by this procedure, residual solids were dried over P_2O_5 and the L-fucose-1-phosphate content was assessed by ^1H NMR using trimethylsilyl propionate as the internal standard (**14**, 1.8 mmol, 50%, eq./ax.ratio = 12.5:1). The ^1H and ^{13}C NMR spectral characteristics of **14** were in accord with those in the literature (8). ^1H NMR (D_2O) δ: 4.830 (dd, $J_{1,2} = J_{1,P} = 8.0$ Hz, H-1), 3.8190 (dq, H-5), 3.759 (dd, $J_{3,4} = 3.5$ Hz, $J_{4,5} = 1.0$ Hz, H-4), 3.700 (dd, $J_{2,3} = 10.0$ Hz, H-3), 3.501 (dd, H-2), 1.253 (d, $J_{5,6} = 6.5$ Hz); ^{31}P NMR (D_2O) δ: −0.86 (s). This dilithium salt was dissolved in water and passed through a bed of Dowex 50-X8 (NEt_3H^+) resin. The water was then evaporated to afford the monotriethyl ammonium salt, which was dried over P_2O_5 prior to its use in the pyrophosphate coupling reaction for the synthesis of GDP-fucose (**5**).

D-Arabinose-1-phosphate (16)

Freshly prepared (18) crystalline 2,3,4-tri-*O*-acetyl-β-D-arabinopyranosyl bromide (**15**, 1.0 g, 2.9 mmol, δ ($CDCl_3$): 6.710 (d, $J_{1,2} = 3.7$ Hz, H-1)) was treated with **11** (6 equiv.) in dry DMF (7 mL). After 10 min at 23°C, all of the bromosugar (R_f 0.7, ethyl acetate:hexane, 1:1) had been converted into slower moving UV-absorbing phosphotriester (R_f 0.30, (major), 0.32 (minor)). The reaction mixture was partitioned between dichloromethane (40 mL) and cold water (20 mL). The organic layer was dried ($MgSO_4$) and evaporated to a syrup, which was purified by rapid elution through a silica gel column (2 × 20 cm, ethyl acetate:hexane, 3:2) to yield a material with R_f 0.30 (ethyl acetate:hexane, 1:1). The sample was then processed as described for the preparation of **14** to provide **16** as the dilithium salt (1.35 mmol, 47%, eq. (α)/ax. (β) = 10.7:1); $[\alpha]_D$ −31.9° (*c* 0.14, H_2O) (lit. (18) −39.1°); ^1H NMR (D_2O) δ: 5.456 (dd, $J_{1,2} = 3.6$ Hz, $J_{1,P} = 7.0$ Hz, H-1: axial (β)anomer), 4.800 (dd, $J_{1,2} = J_{1,P} = 7.5$ Hz, H-1:equatorial (α) anomer), 3.973–3.636 (m, H-3, H-4, H-5s), 3.586 (dd, H2, $J_{2,3} = 9.0$ Hz); ^{13}C NMR (D_2O) δ: 97.69 (d, $J_{C,1P} = 4.2$ Hz, C-1), 72.26 (C-3), 72.01 (d, $J_{C\text{-}2,P} = 5.8$ Hz, C-2), 68.19 (C-4), 66.15 (C-5).

3,6-Dideoxy-L-xylohexopyranose-1-phosphate (3-deoxy-L-fucose phosphate (26)

The bromosugar **25** (from 1.9 mmol of **24**) was treated with **11** (6 equiv.) in dry DMF (10 mL). Stirring at room temperature for 4 h resulted in a reaction mixture that, on TLC examination, showed the presence of a new spot (presumably the phosphotriester, R_f 0.47, ethyl acetate:hexane, 1:1). A spot corresponding to the bromosugar (**25**) still persisted. The reaction was terminated at this stage by partitioning the mixture between dichloromethane (40 mL) and water (20 mL). The organic layer was dried ($MgSO_4$) and evaporated to a syrup, which was purified by rapid passage through a short silica gel column (2 × 20 cm, ethyl acetate:hexane, 13:10). The fractions containing material with R_f 0.47 (ethyl acetate:hexane, 1:1) were pooled and concentrated to a syrup, which was then dissolved in ethanol (40 mL) containing aqueous $NaHCO_3$ (1 N, 20 mL) and Pd/C (5%, 1.2 g). Hydrogenation, saponification, and ion-exchange chromatography (as described for the preparation of **14**) afforded the title compound as the dilithium salt (0.266 mmol, 14%, eq. (α)/ax.(β) ratio = 5.4:1); ^1H NMR (D_2O, β anomer) δ: 4.833 (dd, $J_{1,2} = J_{1,P} = 7.5$ Hz, H-1), 3.863 (dq, $J_{4,5} = 1$ Hz, $J_{5,6} = 6.5$ Hz, H-5), 3.484 (m, H-4), 3.690 (ddd, H-2), 2.190 (ddd, $J_{gem} = 13.0$ Hz, $J_{2,3eq} = 5.0$ Hz, $J_{3eq,4} = 4.0$ Hz, H-3eq), 1.737 (ddd, $J_{2,3ax} = 12.0$ Hz, $J_{3ax,4} = 3.0$ Hz, H-3ax), 1.223 (d, H-6); ^{13}C NMR (D_2O) δ: 100.17 (d, $J_{C\text{-}1,P} = 3.5$ Hz, C-1), 75.23, 69.02 (C-5, C-4), 67.74 (d, $J_{C\text{-}2,P} = 3.5$ Hz, C-2), 37.37 (C-3), 16.53 (C-6); ^{31}P NMR (D_2O) δ: +2.5.

Guanosine 5′-(β-L-fucopyranosyl)-diphosphate (GDP-fucose, 5)

L-Fucose-1-phosphate **14** (triethylammonium salt, 0.89 mmol) and guanosine-5′-monophosphate morpholidate **27** (8) (800 mg, 1.2 equiv.) were combined in dry pyridine (10 mL). The heterogenous reaction was stirred at 23°C for 4 days. Evaporation of the solvent gave a syrup, which was diluted to 200 mL volume with water. It was then slowly passed through Dowex 2-X8 (2.5 × 30 cm, Cl^-). The column was washed with water (300 mL) and then eluted with a linear gradient of LiCl. The mixing vessel contained 1800 mL water. The reservoir contained 1800 mL of 0.8 M LiCl in water. The column was operated at 23°C at a flow rate of 3 mL/min and 15-mL fractions were collected and monitored at 262 nm. GDP-fucose eluted at 0.52 M and these fractions were pooled and concentrated (23°C) to a 5 mL volume and passed through a Bio-Gel P2 column (2 × 60 cm) in 10% EtOH in water. Fractions containing the product were pooled, concentrated to 5 mL, and repassed through the column until chloride ion could no longer be detected in the eluate. Four columns were required. The material obtained after this desalting was dissolved in water (10 mL) and passed through a column of AG-50 (Na^+, 1 × 20 cm). Lyophilization of the resulting solution furnished GDP-fucose as a white fluffy solid (155 mg, 27%); $[\alpha]_D$ −34° (*c* 0.18, H_2O); R_f 0.54 (NH_4OH:*i*PrOH:H_2O, 3:5:2), 0.76 (*i*PrOH:NH_4OAc 0.3 M, 1:1); ^1H NMR (D_2O) δ: 8.125 (s, 1H, H-8 base), 5.950 (d, 1H, $J_{1,2} = 6$ Hz H-1 ribose), 4.928 (dd, 1H, $J_{1,2} = J_{1,P} = 8.0$ Hz, H-1 fucose), 4.80 (H-2 ribose), 4.545 (m, 1H, H-3 ribose), 4.360 (m, 1H, H-4 ribose), 4.220 (m, 2H, H-5 ribose), 3.780 (q, 1H, H-5 fucose), 3.720 (dd, 1H, $J_{4,5} = 1.0$ Hz, H-4 fucose), 3.668 (dd, 1H, $J_{3,4} = 4.0$ Hz, $J_{2,3} = 10.0$ Hz, H-3 fucose), 3.565 (dd, 1H, H-2, fucose), 3.565 (dd, 1H, H-2, fucose), 1.225 (d, $J_{5,6} = 6.5$ Hz, H-6, fucose); ^{13}C NMR (D_2O) δ: 159.85 (C-6 base), 154.8 (C-2 base), 152.69 (C-4 base), 117.13 (C-5 base), 99.23 (d, $J_{C\text{-}1,P} = 5.7$ Hz, C-1 fucose), 57.60 (C-1 ribose), 84.68 (d, $J_{C\text{-}4,P} = 9.1$ Hz, C-4 ribose), 73.32 (C-3 fucose), 74.35, 72.25, 72.00, 71.84 (C-2, C-3, C-4, C-5, fucose; $J_{C\text{-}2,P}$ = approx. 8 Hz, GDP-3-deoxy-fucose), 71.32 (C-3 ribose), 66.18 (d, $J_{C\text{-}5,P} = 5.7$ Hz, C-5 ribose), 16.24 (C-6 fucose); ^{31}P NMR (D_2O) δ: −10.8 (d, $J_{P,P} = 20.8$ Hz, P attached to guanosine), −12.7 (d, P attached to fucose).

Guanosine 5′-(3,6-dideoxy-β-L-xylohexopyranosyl)-diphosphate (GDP-3-deoxy-fucose, 6)

The 3-deoxy-L-fucose-1-phosphate (mono triethylammonium salt, 0.2 mmol) and the phosphinothioc anhydride (8, 19) **28** (tetra-*n*-butylammonium salt, monohydrate, 211 mg, 0.29 mmol) were dried over P_2O_5. Dry pyridine (10 mL) was then added and evaporated *in vacuo*. This process was repeated three times using dry pyridine (10 mL). Dry pyridine (5 mL), followed by dry AgOAc (195 mg, 5.9 equiv.), was then added to the flask and the contents were vigorously stirred at 23°C, protected from light and moisture.

After 20 h at 23°C, H_2O (0.5 mL) was added to hydrolyze any unreacted **28**. After an additional 0.5 h the contents were transferred to screw-capped centrifuge tubes and a slow stream of H_2S was bubbled through the mixture for 5 min to precipate silver sulfide. Centrifugations afforded clear supernatants, which were removed. The residues were extracted with pyridine:water, 1:1. The combined supernatants were evaporated *in vacuo* to a syrup, which was partitioned between water (30 mL) and diethyl ether (30 mL). The aqueous layer was separated, diluted to 100 mL with water, and then adsorbed slowly onto a column of Dowex 1-X2 (2.5 × 15 cm, Cl^-). The column was washed with water (200 mL) and then eluted with a linear gradient of LiCl. The mixing vessel contained 200 mL water. The reservoir contained 200 mL of 0.8 M LiCl in water. The column was operated at 23°C at a rate of 0.5 mL/min. Fractions (4.5 mL) were collected and monitored by UV absorption at 262 nm. The desired nucleotide eluted near the end of the gradient in fractions 75–89 and these were desalted on Bio-Gel P-2 as described for the preparation of **5**. After conversion to the sodium form by passage through AG-50(Na^+) resin (1 × 10 cm), the product was lyophilized to furnish **6** as a white fluffy solid (58.6 mg, 47%); $[\alpha]_D$ −10.0° (*c* 0.12, H_2O); ^1H NMR (D_2O) δ: 8.100 (s, 1H, H-8 base), 5.999 (d, 1H, $J_{1,2} = 6.0$ Hz, H-1 ribose), 4.999 (dd, 1H, $J_{1,2} = J_{1,P} = 8.0$ Hz, H-1 fucose), 4.789 (m, 1H, H-2 ribose), 4.523 (m, 1H, H-3 ribose), 4.336 (m, 1H, H-4 ribose), 4.200 (m, 2H, H-5,5 ribose), 3.819–3.643 (m, 3H, H-2, H-4, H-5, fucose), 2.186 (ddd, 1H, $J_{gem} = 13.0$ Hz, $J_{2,3eq} = 5.0$ Hz, $J_{3eq,4} = 4.0$ Hz, H-3eq fucose), 1.689 (ddd, 1H, $J_{2,3ax} = 12.0$ Hz, $J_{3ax,4} = 3.0$ Hz, H-3ax fucose), 1.166 (d, 3H, $J_{5,6} = 6.5$ Hz, H-6 fucose methyl); ^{13}C NMR (D_2O) δ: 159.80 (C-6 base), 154.76 (C-2 base), 152.66 (C-4 base), 138.52 (C-8 base), 117.13 (C-5 base), 101.19 (d, $^2J_{C\text{-}1,P} = 6.0$ Hz, C-1 fucose), 87.65 (C-1 ribose), 84.64 (d, $J_{C\text{-}4,P} = 9.1$ Hz, C-4 ribose), 75.58 (C-2 ribose),

For personal use only.

74.36 and 68.82 (C-4 and C-5 fucose), 71.29 (C-3 ribose), 66.62 (d, $J_{C\text{-}2,P}$ = 8.3 Hz, C-2 fucose), 66.10 (d, $J_{C\text{-}5,P} \leq 6$ Hz, C-5 ribose), 37.16 (C-3 fucose), 16.45 (C-6 fucose); ^{31}P NMR (D_2O) δ: −10.8 (d, $J_{P,P}$ = 20.9 Hz, P attached to guanosine), −12.7 (d, P attached to fucose).

Guanosine 5′-(α-D-arabinopyranosyl)-diphosphate (GDP-arabinose, 7)

The D-arabinosyl-1-phosphate **16** (triethylammonium salt, 0.83 mmol), **28** (900 mg, 1.5 equiv.), and AgOAc (550 mg, 4 equiv.) were engaged in the pyrophosphate coupling reaction as described for the preparation of **6**. The contents were vigorously stirred at 23°C, protected from moisture.

After 10 h at 23°C, H_2O (0.5 mL) was added to hydrolyze any unreacted **28**. After 0.5 h the contents were transferred to screw-capped centrifuge tubes and a slow stream of H_2S was bubbled (5 min) to precipitate silver sulfide. Centrifugations afforded clear supernatants, which were removed. The residues were extracted with pyridine:water, 1:1. The combined supernatants were evaporated *in vacuo* to a syrup, which was partitioned between water (30 mL) and diethyl ether (30 mL). The aqueous layer was separated, diluted to 100 mL with water, and then adsorbed slowly onto a column of Dowex 1-X2 (2.5 × 30 cm, Cl^-). The column was washed with water (200 mL) and then eluted with a linear gradient of LiCl. The mixing vessel contained 1700 mL water. The reservoir contained 1700 mL of 0.8 M LiCl in water. Fractions (28 mL) were collected at a flow rate of 0.5 mL/min and monitored by UV absorption at 262 nm. The sugar nucleotide eluted at 0.45 M LiCl. The product was desalted, lyophilized, and converted to the sodium form, as described for **6**, to provide **7** as a white solid (145 mg, 28%); $[\alpha]_D$ −39° (*c* 0.6, H_2O); R_f 0.53 (NH_4OH:*i*PrOH: H_2O, 3:5:2), ^{1}H NMR (D_2O) δ: 7.925 (s, 1H, H-8 base), 5.736 (d, 1H, $J_{1,2}$ = 6.0 Hz, H-1 ribose), 4.723 (dd, $J_{1,2} = J_{1,P}$ = 7.5 Hz, H-1 arabinose), 4.583 (m, 1H, H-2 ribose), 4.349 (m, 1H, H-3 ribose), 4.173 (m, 1H, H-4 ribose), 4.033 (m, 1H, H-5, 5′ ribose), 3.790–3.707 (m, 2H), and 3.559–3.419 (m, 3H, H-2, 3, 4, 5, 5′, arabinose); ^{13}C NMR (D_2O) δ: 159.56 (C-6 base), 154.62 (C-2 base), 152.42 (C-4 base), 138.22 (C-8 base), 116.89 (C-5 base), 99.45 (d, $^2J_{C\text{-}1,P}$ = 5.8 Hz, C-1 arabinose), 87.67 (C-1 ribose), 84.46 (d, $^3J_{C\text{-}4,P}$ = 9.2 Hz, C-4 ribose), 74.66 (d, C-2, ribose), 72.69 (C-3 arabinose), 71.17 (d, $^3J_{C\text{-}2,P}$ = 8.2 Hz, C-2 arabinose), 71.17 (C-3 ribose), 68.79 (C-4 arabinose), 67.25 (C-5 arabinose), 66.10 (d, $J_{C\text{-}5,P}$ = 5.6 Hz, C-5 ribose); ^{31}P NMR (D_2O) δ: −10.4 (d, $J_{P,P}$ = 20.8 Hz, P attached to guanosine), −12.3 (d, attached to fucose).

ELISA assays

ELISA assays were carried out in triplicate with minor modifications of a previously described method (6). Microtiter plates coated with synthetic BSA-glycoconjugate of **1** (6) were incubated with 25 μunits of affinity-purified Lewis fucosyltransferase (**5**), and 50 μM GDP-fucose (**5**) or 50 μM analog **6** or **7** in 110 μL of 50 mM sodium cacodylate buffer pH 6.5 containing 5 mM $MnCl_2$. After reaction at ambient temperature for 15 h, solutions were removed from the microtiter plates by aspiration, and the wells washed with 200 μL H_2O and 200 μL phosphate-buffered saline containing 0.05% Tween 20 (PBST) (6). Antibody CF4-C4 (0.78 μg/mL in 100 μL PBST with 1% bovine serum albumin) was added to each well and the plate was kept at ambient temperature for 2 h. This solution was aspirated, the wells were washed, incubated with alkaline phosphatase conjugated IgG, washed, and incubated with *p*-nitrophenyl phosphate solution (6). The formation of *p*-nitrophenoxide was monitored at 405 nm. The absorbance in the control wells containing enzyme without nucleotide donor was 0.10 after 40 min and 0.26 after 80 min. The absorbance in wells containing only nucleotide donor without enzyme was 0.08 after 40 min and 0.18 after 80 min. With both fucosyltransferase and sugar nucleotide the absorbances at 40 min were 1.01 (**5**), 0.38 (**6**), and 0.29 (**7**). For 80-min readings, values of 1.86 (**5**), 0.80 (**6**), and 0.67 (**7**) were obtained.

Spectrophotometric assay for fucosyltransferase activity

Fucosyltransferase activity was estimated spectrophotometrically using a modification (20) of a method described for galactosyltransferase (13). Plastic cuvettes containing 1.4 mM **6** or **7**, 0.9 mM phosphoenolpyruvate, 0.45 mM NADH, 50 mM KCl, 5 mM $MnCl_2$, 50 units of pyruvate kinase, 50 units of lactate dehydrogenase, and 11 milliunits of purified Lewis α(1→4) fucosyltransferase (6) in 0.77 mL sodium cacodylate buffer pH 6.5 were equilibrated to 37°C in a Beckman DU-8 spectrophotometer. Background rates (0.0023 ΔOD/min) were estimated by monitoring the decrease in absorbance at 340 nm. Reaction was initiated by the addition of 590 μg **1** in 100 μL water, and the initial rate of GDP formation estimated using a millimolar extinction of 6.2 mM^{-1} cm^{-1} for NADH absorbance. After 8 h reaction at 37°C, an additional 750 μg of **6** or **7** was added to the mixtures. After 30 h reaction, samples were diluted to 10 mL with water and applied to reverse-phase C-18 cartridges, which were washed with 30 mL water. Products **3** and **4** were eluted in 15 mL methanol, evaporated to dryness, redissolved in water (5 mL), filtered through 0.22 μm Millex-GV filters, and lyophilized. The relative intensities of the characteristic ^{1}H NMR signals for unreacted **1** and the products **3** and **4** showed the extent of trisaccharide formation to be 30 and 65%, respectively. These yields are in good agreement with those extrapolated from the relative initial rates estimated spectrophotometrically (Table 1). The products were not isolated but the following ^{1}H NMR parameters could be determined on the mixtures. Trisaccharide **3**: δ 4.955 (d, H-1″, $J_{1'',2''}$ = 3.5 Hz), 4.79 (obscured by DO*H*, H-5″), 4.523 and 4.508 (each d, *J* = 7.8 Hz, H-1 and H-1′), 3.687 (OCH_3), 2.391 (CH_2COO), 2.034 ($COCH_3$), and 1.120 (d, *J* = 6.5 Hz, H-6″). Trisaccharide **4**: δ 5.078 (d, H-1″, $J_{1'',2''}$ = 2.9 Hz), 4.736 (d, $J_{5''a,5''e}$ = 12.5 Hz, H-5″a), 4.513 and 4.508 (each d, *J* = 7.5 Hz, H-1 and H-1′), 3.687(OCH_3), 2.389 (CH_2COO), and 2.033 (COCH3). Compound **5** was assayed similarly with 3 milliunits of fucosyltransferase, in a total volume of 1.2 mL. In this case, reaction was complete after 12 h at 37°C, as judged by ^{1}H NMR. The initial rates listed in Table 1 are corrected to account for the difference in fucosyltransferase concentration and volume.

A novel method of inversion for a class of matrices: application to calculation of two-component plasma viscosities in a magnetic field

BYUNG CHAN EU[1]

Department of Chemistry, McGill University, 801 Sherbrooke Street West, Montreal, P.Q., Canada H3A 2K6

Received October 24, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

BYUNG CHAN EU. Can. J. Chem. **68**, 1072 (1990).

To calculate transport coefficients for a plasma in a magnetic field in a linear approximation it is necessary to invert matrices of fairly high dimensions. In this paper we present a novel method of inverting matrices involved in such problems. The method requires a solution of an inhomogeneous matrix integral equation in the Neumann series and a resummation of the series obtained. It involves inversions of lower order matrices, which can be achieved easily. We then apply the method to calculate viscosities of a two-component plasma subject to a homogeneous magnetic field. The structure of the viscosity matrix (tensor) calculated thereby is shown to be the same as that of a neutral system with an axial symmetry; namely, it can be decomposed into a scalar, a 2×2 matrix, and a 3×3 matrix. The method developed here can be applied to calculate other transport coefficients of the two-component plasma.

Key words: mathematical method, viscosity, plasmas, transport coefficients, kinetic theory.

BYUNG CHAN EU. Can. J. Chem. **68**, 1072 (1990).

Lorsqu'on veut calculer les coefficients de transport d'un plasma dans un champ magnétique à l'aide d'une approximation linéaire, il est nécessaire d'inverser des matrices de dimensions hautes. Dans ce travail, on présente une nouvelle méthode pour inverser les matrices impliquées dans des tels problèmes. La méthode fait appel à une solution d'une équation intégrale matricielle inhomogène à l'aide de séries de Neumann et à une resommation des séries obtenues. Elle implique des inversions de matrices d'ordres moins élevés que l'on peut réaliser facilement. On a alors appliqué la méthode pour calculer les viscosités d'un plasma à deux composantes soumis à un champ magnétique homogène. On a démontré que la structure de la matrice de viscosité (tenseur) calculée ainsi est la même que celle d'un système neutre possédant une symétrie axiale, à savoir que l'on peut la décomposer en une matrice scalaire, une matrice 2×2 et une matrice 3×3. La méthode que l'on a développée ici peut être appliquée pour le calcul d'autres coefficients de transport de plasmas à deux composantes.

Mots clés : méthode mathématique, viscosité, plasmas, coefficients de transport, théorie cinétique.

[Traduit par la revue]

I. Introduction

Transport processes in plasmas subject to an external magnetic field are of considerable interest technologically (1–3) and also from the basic kinetic theory viewpoint (4–6) since they provide a good model for theoretical studies in kinetic theory and irreversible thermodynamics. The theoretical result presented in this article is an outcome of our efforts to develop kinetic theory methods (6) to handle dilute plasmas subject to steep thermodynamic gradients or a strong external magnetic field; these kinds of conditions call for special techniques that the conventional Chapman–Enskog method of solution for the Boltzmann equation fails to provide. The constitutive equations taken for shear stresses in this article are derived from the Boltzmann equation for a two-component plasma by using the modified moment method (7). This is a method that is proven to be applicable in the regime where the Chapman–Enskog method is inadequate.

If a fluid is a plasma or a paramagnetic substance that interacts with an external magnetic field, then the system is no longer isotropic and as a consequence the viscosity is not scalar. If the system has an axial symmetry around the external magnetic field, there are five independent phenomenological coefficients (8), i.e., viscosities. To demonstrate this feature, we will assume a two-component plasma subject to a homogeneous magnetic field applied in a direction, say, the x direction of the Cartesian coordinate system. These assumptions simplify the analysis. We would like to find such viscosities in terms of molecular parameters and the magnetic field strength. To that end we need to solve 12 coupled algebraic equations for shear stresses; these equations are in principle possible to solve, but their solutions are very cumbersome to obtain unless a numerical method is used. The aim of this paper is twofold: We would like to present a method to handle the aforementioned problem with much reduced algebraic labor, and then apply the method to calculate the viscosity formulas for a two-component plasma in terms of inverses of one-, two-, and three-dimensional matrices. The viscosity matrix thus calculated has the same structure as for a single component anisotropic system. The method used here can be applied to other problems involving a class of matrices similar to the one appearing in the present problem.

The present paper is organized as follows: In Sect. II constitutive equations are presented for shear stresses under the assumption that there is no heat flow in the system. The constitutive equations naturally define the problem in question, since it is now necessary to invert the relation between the shear stresses and the shear rate tensors. In Sect. III the matrix inversion method is developed to solve the problem and in Sect. IV various shear viscosities are given in terms of inverse matrices of one-, two-, and three-dimensional matrices.

II. Constitutive equations for shear stresses

It is convenient to define various symbols appearing in the constitutive equations before the latter are presented. The vector potential $\boldsymbol{A}$ of magnetic field $\boldsymbol{B}$ is defined by the relation

$$[1] \qquad \boldsymbol{B} = \nabla \times \boldsymbol{A}$$

We will find it convenient to work with an antisymmetric tensor $\vec{\omega}_A$ associated with the vector potential $\boldsymbol{A}$

[1]Also at the Department of Physics, McGill University.

[2] $\overleftrightarrow{\omega}_A = \nabla A - (\nabla A)^t$

and the commutator of $\overleftrightarrow{\omega}_A$ with the traceless symmetric stress tensor $\overleftrightarrow{\Pi}$:

[3] $[\overleftrightarrow{\Pi},\overleftrightarrow{\omega}_A] = \overleftrightarrow{\Pi}\cdot\overleftrightarrow{\omega}_A - \overleftrightarrow{\omega}_A\cdot\overleftrightarrow{\Pi}$

These tensors generally have six components, which will be assigned a numerical subscript in the following manner:

$$a \equiv (1,2,3,4,5,6) \Leftrightarrow b \equiv (xx,yy,zz,yz,zx,xy)$$

Thus, for example, component xx is assigned subscript 1, component yz is assigned subscript 4, etc. Under this convention we denote various tensor components by the symbols below:

[4] $$\Pi_a^{(i)} = \Pi_{ib} \qquad (a = 1,2,3;\ b = xx,yy,zz \text{ or } 1,2,3)$$
$$\Pi_a^{(i)} = 2\Pi_{ib} \qquad (a = 4,5,6;\ b = yz,zx,xy \text{ or } 4,5,6)$$

For example,

$$\Pi_1^{(i)} = \Pi_{ixx}, \qquad \Pi_4^{(i)} = 2\Pi_{iyz}, \text{ etc.}$$

where index i refers to the species. In the case of a two-component plasma the index i runs over 1 and 2. The same subscript convention holds for the antisymmetric tensor $\overleftrightarrow{\omega}_A$ and the rate-of-strain (shear rate) tensor $\overleftrightarrow{\gamma} = -[\nabla u + (\nabla u)^t]/2 + \overleftrightarrow{U}\nabla\cdot u/3$ where u is the fluid velocity and $\overleftrightarrow{U}$ is the unit second rank tensor. We also define the following symbols:

[5] $$\Omega_a^{(i)} = (Z_i/2cp_ik_BT)g\omega_{Ab} \qquad (a = 4,5,6;\ b = yz,zx,xy \text{ or } 4,5,6)$$

[6] $$g = (m_r/2k_BT)^{1/2}/n^2d^2$$

where $Z_i = e_i/m_i$, e_i = charge on species i, m_r = reduced mass, n = number density, d = mean size parameter of the particles, c = speed of light, p_i = pressure of component i, T = temperature, and k_B = Boltzmann constant. The factor $Z_i\omega_{Ab}/c$ appearing in $\Omega_a^{(i)}$ is the cyclotron (Larmor) frequency of charged particle i precessing around the external magnetic field.

The constitutive equations for stress tensor $\overleftrightarrow{\Pi}_i$ can be shown to be given by the equation (7b)

[7] $$-2p_i\overleftrightarrow{\gamma} + [\overleftrightarrow{\Pi}_i,\overleftrightarrow{\omega}_A]Z_i/c - (2p_ik_BT/g)\sum_{j=1}^{2}\theta R_{ij}\overleftrightarrow{\Pi}_j = 0, \qquad (i = 1,2)$$

where θ is a parameter defined such that

$$\theta = \begin{cases} 1 \text{ for diagonal components of tensor } \overleftrightarrow{\Pi}_i \\ 2 \text{ for off-diagonal components of tensor } \overleftrightarrow{\Pi}_i \end{cases}$$

This parameter may be absorbed into R_{ij}, but it is made explicit in deference to the kinetic theory result from which eq. [7] is derived. The coefficients R_{ij} may be given in terms of bracket integrals in the Boltzmann kinetic theory, but in this paper will be regarded as phenomenological coefficients since their statistical representation is not our concern here. By using the subscript convention, eq. [4], adopted in this paper we can cast eq. [7] in matrix form

[8] $$\mathcal{M}\Pi = -(g/k_BT)\gamma$$

where

[9a] $$\Pi = (\Pi_1^{(1)},\ldots,\Pi_6^{(1)},\Pi_1^{(2)},\ldots,\Pi_6^{(2)}) \equiv (\Pi^{(1)},\Pi^{(2)})$$

[9b] $$\gamma = (\gamma_1,\ldots,\gamma_6,\gamma_1,\ldots,\gamma_6) \equiv (\hat{\gamma},\hat{\gamma})$$

[10] $$\mathcal{M} = \begin{bmatrix} \boldsymbol{M}^{(11)} & \boldsymbol{M}^{(12)} \\ \boldsymbol{M}^{(21)} & \boldsymbol{M}^{(22)} \end{bmatrix}$$

[11] $$\boldsymbol{M}^{(ij)} = \begin{bmatrix} R_{ij} & 0 & 0 & 0 & -\delta_{ij}\Omega_5^{(j)} & \delta_{ij}\Omega_6^{(j)} \\ 0 & R_{ij} & 0 & \delta_{ij}\Omega_4^{(j)} & 0 & -\delta_{ij}\Omega_6^{(j)} \\ 0 & 0 & R_{ij} & -\delta_{ij}\Omega_4^{(j)} & \delta_{ij}\Omega_5^{(j)} & 0 \\ 0 & -\delta_{ij}\Omega_4^{(j)} & \delta_{ij}\Omega_4^{(j)} & R_{ij} & -\tfrac{1}{2}\delta_{ij}\Omega_6^{(j)} & \tfrac{1}{2}\delta_{ij}\Omega_5^{(j)} \\ \delta_{ij}\Omega_5^{(j)} & 0 & -\delta_{ij}\Omega_5^{(j)} & \tfrac{1}{2}\delta_{ij}\Omega_6^{(j)} & R_{ij} & -\tfrac{1}{2}\delta_{ij}\Omega_4^{(j)} \\ -\delta_{ij}\Omega_6^{(j)} & \delta_{ij}\Omega_6^{(j)} & 0 & -\tfrac{1}{2}\delta_{ij}\Omega_5^{(j)} & \tfrac{1}{2}\delta_{ij}\Omega_4^{(j)} & R_{ij} \end{bmatrix}$$

with $i,j = 1,2$. Here δ_{ij} are Kronecker's deltas. Since $\Omega_a^{(j)}$ all vanish except for $\Omega_4^{(j)}$ in the case of a magnetic field parallel to the x axis, we in fact obtain $\boldsymbol{M}^{(ij)}$ in the form

[12] $$\boldsymbol{M}^{(ij)} = \begin{bmatrix} R_{ij} & 0 & 0 & 0 & 0 & 0 \\ 0 & R_{ij} & 0 & \delta_{ij}\Omega_4^{(j)} & 0 & 0 \\ 0 & 0 & R_{ij} & -\delta_{ij}\Omega_4^{(j)} & 0 & 0 \\ 0 & -\delta_{ij}\Omega_4^{(j)} & \delta_{ij}\Omega_4^{(j)} & R_{ij} & 0 & 0 \\ 0 & 0 & 0 & 0 & R_{ij} & -\tfrac{1}{2}\delta_{ij}\Omega_4^{(j)} \\ 0 & 0 & 0 & 0 & \tfrac{1}{2}\delta_{ij}\Omega_4^{(j)} & R_{ij} \end{bmatrix}$$

The phenomenological matrix $\boldsymbol{R}$ is symmetric: $R_{ij} = R_{ji}$ in accordance with the Onsager reciprocity relation (8). Therefore, $\boldsymbol{M}^{(ij)}$ is symmetric in the following sense:

[13] $$\boldsymbol{M}^{(ij)}(\overleftrightarrow{\omega}_A) = \boldsymbol{M}^{(ji)}(-\overleftrightarrow{\omega}_A)$$

in accordance with the Onsager reciprocal theorem (8) for the case of an external magnetic field.

Inverting matrix $\mathcal{M}$, we obtain from eq. [8] the equation for Π

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

[14] $\Pi = -2\eta\gamma$

which defines the viscosity tensor

[15] $\eta = (g/2k_BT)\mathcal{M}^{-1}$

Our aim here is to find $\mathcal{M}^{-1}$ in terms of R_{ij} and $\Omega_a^{(i)}$. Note that the matrix $\mathcal{M}$ is 12×12. Before discussing the inversion of $\mathcal{M}$ it is useful to note that

[16] $$M^{(ii)-1} = \beta\begin{bmatrix} \bar{\eta}_1^{(i)} & 0 & 0 & 0 & 0 & 0 \\ 0 & \bar{\eta}_2^{(i)} & (\bar{\eta}_1^{(i)} - \bar{\eta}_2^{(i)}) & -\bar{\eta}_4^{(i)} & 0 & 0 \\ 0 & -(\bar{\eta}_1^{(i)} - \bar{\eta}_2^{(i)}) & \bar{\eta}_2^{(i)} & \bar{\eta}_4^{(i)} & 0 & 0 \\ 0 & \bar{\eta}_4^{(i)} & -\bar{\eta}_4^{(i)} & (2\bar{\eta}_2^{(i)} - \bar{\eta}_1^{(i)}) & 0 & 0 \\ 0 & 0 & 0 & 0 & \bar{\eta}_3^{(i)} & \bar{\eta}_5^{(i)} \\ 0 & 0 & 0 & 0 & -\bar{\eta}_5^{(i)} & \bar{\eta}_3^{(i)} \end{bmatrix}$$

where

$$\beta = (2k_BT/g)$$

[17] $\tau_i = (g/2p_ik_BT)R_{ii}^{-1}$

[18] $\Omega_i = \Omega_4^{(i)}(2p_ik_BT/g) = (Z_i/c)\omega_{Ayz} = (Z_i/c)B_x$

[19] $\bar{\eta}_1^{(i)} = p_i\tau_i$

[20] $\bar{\eta}_2^{(i)} = p_i\tau_i[1 + (\tau_i\Omega_i)^2]/[1 + 2(\tau_i\Omega_i)^2]$

[21] $\bar{\eta}_3^{(i)} = p_i\tau_i/[1 + \frac{1}{4}(\tau_i\Omega_i)^2]$

[22] $\bar{\eta}_4^{(i)} = p_i\tau_i\tau_i\Omega_i/[1 + 2(\tau_i\Omega_i)^2]$

[23] $\bar{\eta}_5^{(i)} = \frac{1}{2}p_i\tau_i\tau_i\Omega_i/[1 + \frac{1}{4}(\tau_i\Omega_i)^2]$

These formulas eventually give the magnetic field dependence for viscosities; in fact, there are five viscosities in the case of a system consisting of species i only. Note that in the limit of $\tau_i\Omega_i \to 0$, that is, as the magnetic field vanishes, the inverse matrix $M^{(ii)-1}$ tends to a diagonal matrix and

[24] $\bar{\eta}_1^{(i)} = \bar{\eta}_2^{(i)} = \bar{\eta}_3^{(i)}, \quad \bar{\eta}_4^{(i)} = \bar{\eta}_5^{(i)} = 0$

In this limit we obtain a diagonal viscosity tensor

[25] $$\eta = \begin{bmatrix} p_1\tau_1\boldsymbol{I} & \mathbf{0} \\ \mathbf{0} & p_2\tau_2\boldsymbol{I} \end{bmatrix} \qquad (\boldsymbol{I} = \text{unit matrix})$$

if the off-diagonal matrices $M^{(12)}$ and $M^{(21)}$ are neglected. This neglect of the off-diagonal matrices is equivalent to the assumption that the transport processes of the two components are not coupled with each other. It must be emphasized that this assumption is not made in this work except for the approximate equation [40] below.

III. A novel method for inverting $\mathcal{M}$

Although it is in principle possible to invert the matrix $\mathcal{M}$, which is 12×12, it is rather cumbersome in practice to invert it without resorting to a numerical method. We present a new method of inverting a class of matrices to which the matrix $\mathcal{M}$ belongs. This method requires inversions of 6×6 block-diagonal matrices, which are much simpler than the inversion of a 12×12 matrix, and it eventually reduces the problem to inversions of two- and three-dimensional matrices. To illustrate the method we write

[26] $\mathcal{M} = \mathcal{M}_0 + \mathcal{M}_1$

where

$$\mathcal{M}_0 = \begin{bmatrix} M^{(11)} & \mathbf{0} \\ \mathbf{0} & M^{(22)} \end{bmatrix}$$

[27]

$$\mathcal{M}_1 = R_{12}\begin{bmatrix} \mathbf{0} & \mathbf{I} \\ \mathbf{I} & \mathbf{0} \end{bmatrix}$$

$\boldsymbol{I}$ being the unit matrix of dimension 6. Note that R_{12} plays the role of coupling constant in this problem. Then the inverse $\mathcal{M}^{-1}$ of the matrix $\mathcal{M}$ may be formally written in the form

[28] $\mathcal{M}^{-1} = \mathcal{M}_0^{-1} - \mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}^{-1}$

This is easy to obtain by using the matrix identity

$$\boldsymbol{A}^{-1} - \boldsymbol{B}^{-1} = -\boldsymbol{B}^{-1}(\boldsymbol{A} - \boldsymbol{B})\boldsymbol{A}^{-1}$$

Written in the form of eq. [28], the inverse $\mathcal{M}^{-1}$ obeys a linear integral equation similar to the Lippmann–Schwinger equation in quantum scattering theory (9), and the latter may be solved by iteration. The result of iteration is the Neumann series

[29] $$\mathcal{M}^{-1} = \mathcal{M}_0^{-1} - \mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}_0^{-1} + \mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}_0^{-1} - \ldots$$

This series converges provided that $\|\mathcal{M}_0^{-1}\mathcal{M}_1\| < 1$, and thus is exact. However, it is not very useful for computing $\mathcal{M}^{-1}$ in its present form. Fortunately, this Neumann series is amenable to a block-by-block resummation, and since such resummations involve only lower order matrices as will be shown, the labor of inversion is very much reduced, making it possible to obtain the matrix elements easily.

Since

$$\mathcal{M}_0^{-1} = \begin{bmatrix} M^{(11)-1} & \mathbf{0} \\ \mathbf{0} & M^{(22)-1} \end{bmatrix}$$

and

$$\mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}_0^{-1} = R_{12}\begin{bmatrix} \mathbf{0} & M^{(11)-1}M^{(22)-1} \\ M^{(22)-1}M^{(11)-1} & \mathbf{0} \end{bmatrix}$$

$$\mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}_0^{-1}\mathcal{M}_1\mathcal{M}_0^{-1} = R_{12}^2\begin{bmatrix} M^{(11)-1}M^{(22)-1}M^{(11)-1} & \mathbf{0} \\ \mathbf{0} & M^{(22)-1}M^{(11)-1}M^{(22)-1} \end{bmatrix}$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

etc., so that, if we put $\boldsymbol{L} \equiv \boldsymbol{M}^{(11)-1}$ and $\boldsymbol{L}' \equiv \boldsymbol{M}^{(22)-1}$, we obtain

$$\boldsymbol{\mathcal{M}}^{-1} = \begin{bmatrix} \boldsymbol{L}(1 + R_{12}^2\boldsymbol{L}'\boldsymbol{L} + R_{12}^4\boldsymbol{L}'\boldsymbol{L}\boldsymbol{L}'\boldsymbol{L} + \ldots) & -R_{12}\boldsymbol{L}\boldsymbol{L}'(1 + R_{12}^2\boldsymbol{L}\boldsymbol{L}' + \ldots) \\ -R_{12}\boldsymbol{L}'\boldsymbol{L}(1 + R_{12}^2\boldsymbol{L}'\boldsymbol{L} + \ldots) & \boldsymbol{L}'(1 + R_{12}^2\boldsymbol{L}\boldsymbol{L}' + R_{12}^4\boldsymbol{L}\boldsymbol{L}'\boldsymbol{L}\boldsymbol{L}' + \ldots) \end{bmatrix}$$

Therefore the iterative series for $\boldsymbol{\mathcal{M}}^{-1}$ may be resummed block by block to yield the following form:

[30] $$\boldsymbol{\mathcal{M}}^{-1} = \begin{bmatrix} \boldsymbol{W}_{11} & \boldsymbol{W}_{12} \\ \boldsymbol{W}_{21} & \boldsymbol{W}_{22} \end{bmatrix}$$

where the submatrices are given by

[31]
$$\begin{aligned} \boldsymbol{W}_{11} &= \boldsymbol{M}^{(11)-1}[1 - R_{12}^2(\boldsymbol{M}^{(11)}\boldsymbol{M}^{(22)})^{-1}]^{-1} \\ \boldsymbol{W}_{22} &= \boldsymbol{M}^{(22)-1}[1 - R_{12}^2(\boldsymbol{M}^{(22)}\boldsymbol{M}^{(11)})^{-1}]^{-1} \\ \boldsymbol{W}_{12} &= -R_{12}(\boldsymbol{M}^{(22)}\boldsymbol{M}^{(11)})^{-1}[1 - R_{12}^2(\boldsymbol{M}^{(22)}\boldsymbol{M}^{(11)})^{-1}]^{-1} \\ \boldsymbol{W}_{21} &= -R_{12}(\boldsymbol{M}^{(11)}\boldsymbol{M}^{(22)})^{-1}[1 - R_{12}^2(\boldsymbol{M}^{(11)}\boldsymbol{M}^{(22)})^{-1}]^{-1} \end{aligned}$$

Equations [30] and [31] represent the result of the inversion method we set out to describe. This result holds for the class of matrices given in eq. [27]. It is important to recognize that although eq. [29] is basically a perturbation series the final results presented in eqs. [30] and [31] above are not, since the perturbation series in eq. [30] has been resummed block by block. The matrices in eq. [31] are exact.

IV. Viscosities of a binary plasma in a magnetic field

As is clear from eq. [31], since each submatrix in eq. [30] is 6×6 and the inverses of $\boldsymbol{M}^{(11)}$ and $\boldsymbol{M}^{(22)}$ are block-diagonal, it is rather simple to compute explicitly the elements of the inverse matrix $\boldsymbol{\mathcal{M}}^{-1}$. If we write $\boldsymbol{M}^{(ii)-1}$ in the form

[32] $$\boldsymbol{M}^{(ii)-1} = \beta \begin{bmatrix} \boldsymbol{V}_{1i} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{V}_{2i} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{V}_{3i} \end{bmatrix}$$

where

[33a] $$\boldsymbol{V}_{1i} = \bar{\eta}_1^{(i)}$$

[33b] $$\boldsymbol{V}_{2i} = \begin{bmatrix} \bar{\eta}_2^{(i)} & (\bar{\eta}_1^{(i)} - \bar{\eta}_2^{(i)}) & -\bar{\eta}_4^{(i)} \\ -(\bar{\eta}_1^{(i)} - \bar{\eta}_2^{(i)}) & \bar{\eta}_2^{(i)} & \bar{\eta}_4^{(i)} \\ \bar{\eta}_4^{(i)} & -\bar{\eta}_4^{(i)} & (2\bar{\eta}_2^{(i)} - \bar{\eta}_1^{(i)}) \end{bmatrix}$$

[33c] $$\boldsymbol{V}_{3i} = \begin{bmatrix} \bar{\eta}_3^{(i)} & \bar{\eta}_5^{(i)} \\ -\bar{\eta}_5^{(i)} & \bar{\eta}_3^{(i)} \end{bmatrix}$$

then with the definition

$$\alpha = (2R_{12}k_BT/g)^2$$

the submatrices $\boldsymbol{W}_{ij}$ $(i,j = 1,2)$ can be written as

[34a] $$\begin{aligned} \boldsymbol{W}_{11} &= \beta \begin{bmatrix} \boldsymbol{V}_{11}(1-\alpha\boldsymbol{V}_{12}\boldsymbol{V}_{11})^{-1} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{V}_{21}(1-\alpha\boldsymbol{V}_{22}\boldsymbol{V}_{21})^{-1} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{V}_{31}(1-\alpha\boldsymbol{V}_{32}\boldsymbol{V}_{31})^{-1} \end{bmatrix} \\ &\equiv \beta\boldsymbol{H}_1 \end{aligned}$$

[34b] $$\begin{aligned} \boldsymbol{W}_{22} &= \beta \begin{bmatrix} \boldsymbol{V}_{12}(1-\alpha\boldsymbol{V}_{11}\boldsymbol{V}_{12})^{-1} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{V}_{22}(1-\alpha\boldsymbol{V}_{21}\boldsymbol{V}_{22})^{-1} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{V}_{32}(1-\alpha\boldsymbol{V}_{31}\boldsymbol{V}_{32})^{-1} \end{bmatrix} \\ &\equiv \beta\boldsymbol{H}_2 \end{aligned}$$

[34c] $$\begin{aligned} \boldsymbol{W}_{12} &= (\alpha/R_{12}) \begin{bmatrix} \boldsymbol{V}_{11}\boldsymbol{V}_{12}(1-\alpha\boldsymbol{V}_{11}\boldsymbol{V}_{12})^{-1} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{V}_{21}\boldsymbol{V}_{22}(1-\alpha\boldsymbol{V}_{21}\boldsymbol{V}_{22})^{-1} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{V}_{31}\boldsymbol{V}_{32}(1-\alpha\boldsymbol{V}_{31}\boldsymbol{V}_{32})^{-1} \end{bmatrix} \\ &\equiv (\alpha/R_{12})\boldsymbol{H}_3 \end{aligned}$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

$$[34d]\quad \boldsymbol{W_{21}} = (\alpha/R_{12})\begin{bmatrix} V_{12}V_{11}(1-\alpha V_{12}V_{11})^{-1} & 0 & 0 \\ 0 & V_{22}V_{21}(1-\alpha V_{22}V_{21})^{-1} & 0 \\ 0 & 0 & V_{32}V_{31}(1-\alpha V_{32}V_{31})^{-1} \end{bmatrix} \equiv (\alpha/R_{12})\boldsymbol{H_4}$$

Here the first elements on the diagonals are one-dimensional, the second are three-dimensional, and the third are two-dimensional. Therefore the matrix $\boldsymbol{W}$ is a tri-block diagonal with one-, three-, and two-dimensional matrices on the main diagonals of the four submatrices. Note that these submatrices have exactly the same structure as the matrices $\boldsymbol{M}^{(ii)-1}$, $i = 1,2$; see eq. [16].

Since $\boldsymbol{\Pi} = -2\boldsymbol{\eta\gamma}$, we find

$$[35a]\quad \boldsymbol{\Pi}^{(1)} = -2(\boldsymbol{\eta}_{11} + \boldsymbol{\eta}_{12})\hat{\boldsymbol{\gamma}}$$

$$[35b]\quad \boldsymbol{\Pi}^{(2)} = -2(\boldsymbol{\eta}_{21} + \boldsymbol{\eta}_{22})\hat{\boldsymbol{\gamma}}$$

where

$$[36]\quad \boldsymbol{\eta}_{ij} = (R_{12}/\alpha)^{1/2}\boldsymbol{W}_{ij}$$

In view of the fact that the stresses on different charged species are not measured separately in practice, it is necessary to add the stresses together and obtain the total shear stress

$$[37]\quad \boldsymbol{\Pi}_t = \boldsymbol{\Pi}^{(1)} + \boldsymbol{\Pi}^{(2)} = -2(\boldsymbol{\eta}_{11} + \boldsymbol{\eta}_{22} + \boldsymbol{\eta}_{21} + \boldsymbol{\eta}_{12})\hat{\boldsymbol{\gamma}} = -2\boldsymbol{\eta}_t\hat{\boldsymbol{\gamma}}$$

Since $\boldsymbol{\eta}_{ij}$ have the same structure as eq. [16], so does the viscosity matrix $\boldsymbol{\eta}_t$. We note that

$$[38]\quad \boldsymbol{\eta}_t = (\boldsymbol{H_1} + \boldsymbol{H_2}) + (\alpha/R_{12})^{1/2}(\boldsymbol{H_3} + \boldsymbol{H_4})$$

This is clearly a block-diagonal matrix with a structure the same as eq. [16]. That is,

$$[39]\quad \boldsymbol{\eta}_t = \begin{bmatrix} \eta_{11} & 0 & 0 & 0 & 0 & 0 \\ 0 & \eta_{22} & \eta_{23} & \eta_{24} & 0 & 0 \\ 0 & \eta_{32} & \eta_{33} & \eta_{34} & 0 & 0 \\ 0 & \eta_{42} & \eta_{43} & \eta_{44} & 0 & 0 \\ 0 & 0 & 0 & 0 & \eta_{55} & \eta_{56} \\ 0 & 0 & 0 & 0 & \eta_{65} & \eta_{66} \end{bmatrix}$$

where the matrix elements are defined by eqs. [34], [36], and [38]. The total viscosity can be easily calculated from these formulas, although the exact expressions for the components can be quite complicated. To the approximation neglecting the terms of $O(\alpha)$ or $O(R_{12})$ $\boldsymbol{\eta}_t$ is given by the formula

$$[40]\quad \boldsymbol{\eta}_t \approx \boldsymbol{H_1}(\alpha = 0) + \boldsymbol{H_2}(\alpha = 0) = (\boldsymbol{M}^{(11)-1} + \boldsymbol{M}^{(22)-1})/\beta$$

In this approximation matrices $\boldsymbol{W_{12}}$ and $\boldsymbol{W_{21}}$ in eq. [30] are neglected and the viscosity is then given by the sum of those for independent charged species 1 and 2:

$$\eta_{11} \approx \bar{\eta}_1^{(1)} + \bar{\eta}_1^{(2)}$$

$$\eta_{22} = \eta_{33} \approx \bar{\eta}_2^{(1)} + \bar{\eta}_2^{(2)}$$

$$\eta_{23} = \eta_{32} \approx \bar{\eta}_1^{(1)} + \bar{\eta}_1^{(2)} - (\bar{\eta}_2^{(1)} + \bar{\eta}_2^{(2)})$$

$$\eta_{24} = -\eta_{42} \approx -(\bar{\eta}_4^{(1)} + \bar{\eta}_4^{(2)})$$

$$\eta_{34} = -\eta_{43} \approx \bar{\eta}_4^{(1)} + \bar{\eta}_4^{(2)}$$

$$\eta_{44} \approx 2(\bar{\eta}_2^{(1)} + \bar{\eta}_2^{(2)}) - (\bar{\eta}_1^{(1)} + \bar{\eta}_1^{(2)})$$

$$\eta_{55} = \eta_{66} \approx \bar{\eta}_3^{(1)} + \bar{\eta}_3^{(2)}$$

$$\eta_{56} = -\eta_{65} \approx \bar{\eta}_5^{(1)} + \bar{\eta}_5^{(2)}$$

where $\bar{\eta}_k^{(i)}$ are defined in eqs. [19]–[23]. Inclusion of off-diagonal submatrices $\boldsymbol{W}_{12}$ and $\boldsymbol{W}_{21}$ is straightforward but results in complicated formulas. The next order approximation would be

$$[41]\quad \boldsymbol{\eta}_t \approx \boldsymbol{H_1}(\alpha = 0) + \boldsymbol{H_2}(\alpha = 0) + (\alpha/R_{12})^{1/2}[\boldsymbol{H_3}(\alpha = 0) + \boldsymbol{H_4}(\alpha = 0)]$$

where $\boldsymbol{H_3}(\alpha = 0)$ and $\boldsymbol{H_4}(\alpha = 0)$ can be easily computed from eqs. [34*c*] and [34*d*]. In this approximation the coupling is taken into account to $O(R_{12}^{1/2})$. It must be noted that the second term in eq. [41] is proportional to $R_{12}^{1/2}$, which differs from the perturbation theory prediction of R_{12} for the factor. This qualitative difference originates from the resummation performed in eq. [30] to obtain the exact result, eq. [31], in the present method.

The excess heat capacity, C_p^E, has been measured through the concentration range at 25°C for cyclohexane + $Si(OR)_4$ where R = methyl (Me), ethyl (Et), propyl (Pr), and butyl (Bu). C_p^E is negative and concave upward for the last three oxysilanes. For R = Me C_p^E has a region of zero curvature, which, on reducing T to 2°C, becomes concave downward, i.e., its concentration dependence becomes *W*-shaped. C_p^E has also been obtained at 15°C for $Si(OMe)_4$ mixed with the following hydrocarbons of increasing molecular size: cyclooctane, *cis*-decalin, dicyclohexyl, n-hexadecane, 2,2,4,4,6,8,8-heptamethylnonane, 2,6,10,14-tetramethylpentadecane, and 2,6,10,15,19,23-heptamethyltetracosane (at 25°C). All C_p^E values for these systems present a *W*-shape, which, with increasing hydrocarbon size becomes increasingly pronounced and moves to lower hydrocarbon concentration. C_p^E behaviour correlates with degrees of non-randomness in the systems as quantified by the concentration–concentration correlation function S_{cc} which is predicted using the Flory–Huggins theory with a group-interaction model and assuming interaction between molecular surfaces. Differences between C_p^E for n-C_{16} and highly branched C_{16} isomer, 2,2,4,4,6,8,8-heptamethylnonane, are attributed to liquid state orientational order and higher molecular surface/volume ratio for the normal isomer.

Key words: excess heat capacity, W-shape, non-randomness, hydrocarbons, tetraalkylsiloxanes.

LINA ANDREOLI-BALL et DONALD PATTERSON. Can. J. Chem. **68**, 1077 (1990).

Opérant à 25°C et à des concentrations couvrant l'ensemble des possibilités, on a mesuré la capacité calorifique en excès, C_p^E, du système cyclohexane + $Si(OR)_4$ dans lequel R = méthyle (Me), éthyle (Et), propyle (Pr) et butyle (Bu). Pour les trois derniers oxysilanes, la valeur de C_p^E est négative et concave vers le haut; par ailleurs, lorsque R = Me, la valeur de C_p^E possède une région dont la courbure est nulle et qui, lorsqu'on réduit la température à 2°C, devient concave vers le bas, c'est'à-dire que sa dépendance sur la concentration prend la forme d'un *W*. On a aussi obtenu la valeur de C_p^E à 15°C pour le $Si(OMe)_4$ mélangé avec les hydrocarbures suivants, de grosseurs moléculaires croissantes: cyclooctane, cis-décaline, dicyclohexyle, n-hexadécane, 2,2,4,4,6,8,8-heptaméthylnonane, 2,6,10,14-tétraméthylpentadécane et 2,6,10,15,19,23-heptaméthyltétracosane (à 25°C). Les C_p^E de tous ces systèmes présentent une forme en W qui, par augmentation de la grosseur de l'hydrocarbure, devient plus prononcée et qui se déplace vers les concentrations plus faibles d'hydrocarbure. Il existe une corrélation entre le comportement du C_p^E et le manque de hasard des systèmes, tel que quantifié par la fonction de corrélation concentration–concentration S_{cc} qui est prédite lorsqu'on utilise la théorie de Flory–Huggins de concert avec un modèle d'interaction de groupe et en faisant l'hypothèse qu'il existe des interactions entre les surfaces moléculaires. La différence qui est observée entre les valeurs de C_p^E des hydrocarbures en C_{16} normal et hautement ramifié, 2,2,4,4,6,8,8-heptaméthylnonane, est attribuée à un ordre d'orientation de l'état liquide et à un rapport surface moléculaire/volume qui est plus grand pour l'isomère normal.

Mots clés : capacité calorifique d'excès, dépendance en W sur la concentration, solution non-aléatoire, hydrocarbures, tetraalkylsiloxanes.

[Traduit par la revue]

Introduction

An unusual *W*-shape concentration dependence of the excess heat capacity, C_p^E, of a non-electrolyte mixture has been found (1) and extensively studied (2) by Grolier and collaborators (examples in Fig. 3). The *W*-shape is considered (3) to arise from a combination of a negative C_p^E of normal parabolic shape with a positive contribution manifesting itself toward the middle of the concentration range. The second contribution is due to non-randomness in solution where molecular antipathy between the components causes the equimolar H^E and G^E values to exceed, respectively, ~1200 and ~800 J mol^{-1}. Non-randomness may be better quantified through (4, 5) the concentration –concentration correlation function, S_{cc} or the concentration fluctuations:

$$[1] \quad S_{cc} = N\langle\overline{\Delta x^2}\rangle = [\partial^2(G/RT)/\partial x^2]^{-1}$$

Rayleigh light scattering gives values of S_{cc} through

$$[2] \quad S_{cc} = x_1 x_2 R_c / R_{id}$$

where R_c is the concentration fluctuation Rayleigh ratio and R_{id} is its ideal value obtainable through calculation. A correlation has been found to exist between S_{cc} and the magnitude of the *W*-shape, a value of 0.7 in S_{cc} being suggested as the threshold for the occurrence of the *W*-shape, rather than the normal parabolic, C_p^E. S_{cc} is also obtainable from the concentration dependence of G^E for the system and a simple Flory–Huggins expression (4, 5) for G and G^E relates S_{cc} to molecular size of the components and their interaction. It predicts that S_{cc} and hence the *W*-shaped C_p^E should be enhanced by reduction of T and increase of molecular size of the components.

The excess thermodynamic quantities, e.g., H^E and V^E have been extensively studied (6) at 25°C for cyclohexane mixed with a series of tetraalkoxysilanes $Si(OR)_4$ where R is varied from methyl (Me) to butyl (Bu). Excess enthalpies (7) and excess free energies (8) are also available when R = 2-ethylbutyl (br–Hex). With increase of alkyl chain size, i.e., with decreasing exposure of the oxygen atom to the cyclohexane component, the equimolar H^E values decrease rapidly as Me 1351, Et 716, Pr 371, Bu 343, and 2-ethylbutyl 167 J mol^{-1}. H^E per volume decreases even more dramatically through the series, by a factor of 10. Furthermore, light scattering measurements at 25°C have been made (9) on cyclohexane + $Si(OMe)_4$ giving R_c values which, through eq. [2] give S_{cc} with a maximum value of 0.75

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

at $x_1 \sim 0.45$. Integration of R_c through the concentration range gave G^E with an equimolar value of 817 J mol^{-1}. Thus values of the quantities H^E, G^E, and S_{cc} for cyclohexane + Si(OMe)$_4$ all fall near the threshold for appearance of the *W*-shape while other Si(OR)$_4$ give H^E below threshold. It was therefore of interest to obtain C_p^E for the cyclohexane + Si(OR)$_4$ series and to test Flory–Huggins S_{cc} predictions by varying T and by mixing Si(OMe)$_4$ with hydrocarbons larger than cyclohexane. These were taken to be three cycloalkanes, cyclooctane, *cis*-decalin, and dicyclohexyl, and three branched alkanes, 2,2,4,4,6,8,8-heptamethylnonane (br–C_{16}), a branched C_{19}, 2,6,10,14-tetramethylpentadecane (pristane), and a branched C_{30}, 2,6,10,15,19,23-hexamethyltetracosane (squalane). n-C_{16} was also used for comparison with the isomer, br-C_{16}.

Flory–Huggins treatment of S_{cc}

Reference 6 showed that the excess quantities for the c-C_6 + Si(OR)$_4$ systems could be treated using a model (10) based on a Flory–Huggins (FH) combinatorial term and interactions between surfaces of groups in the component molecules. Using this model, the following expression is found for S_{cc}:

$$[3] \quad S_{cc}^{-1} = (x_1x_2)^{-1} + \left(\frac{r_1 - r_2}{x_1r_1 + x_2r_2}\right)^2 - \frac{2\,q_1^2q_2^2\,\frac{g_{12}}{RT}}{(x_1q_1 + x_2q_2)^3}$$

In the equation which is analogous to eq. [21] of ref. 4. r_i and q_i are numbers of segments in the component molecules which are proportional to, respectively, molecular volume and surface area, normalized by the volume and surface area of the methane molecule. g_{12} is the average interaction free energy per segment of the components analogous to $z\Delta w_{12}$ in the regular solution theory. In eq. [3], the three terms on the right hand side are, respectively, ideal, non-ideal combinatorial and interactional. The first two terms decrease S_{cc}, i.e., randomizing, while the third term increases non-randomness. It indicates that S_{cc} and *W*-shape character are enhanced by lowering T and by increasing the molecular surface area of either component, i.e. q_1 or q_2. Furthermore, it is clearly largest at low concentration of the component having the larger value of q, hence presumably larger molecular size.

Quantitative application of eq. [3] requires q values for the components mostly taken from refs. 6 and 10 where they were derived using Bondi group surface contributions (11). Ratios of r values may be obtained as the ratios V_2^*/V_1^* of hard-core volumes for the components obtained in the usual way from the thermal expansion coefficients and molar volumes. g_{12} is related to α_o, the fraction of molecular surface of an Si(OR)$_4$ molecule which is of oxygen character using the general eq. [80] of ref. 10 or, more specifically, eq. [7] of ref. 12. For the cycloalkanes + Si(OR)$_4$ we have

$$[4] \quad g_{12} = g_{oa}\alpha_o^2 - (g_{ac} + g_{oa} - g_{oc})\alpha_o + g_{ac}$$

Values of α_o are found in Table 1 of ref. 6, related to the surface areas of the oxygen atom and of the Si(OR)$_4$ molecule by $\alpha_o = q_0/q_1$. The g_{ij} are parameters for interaction between oxygen (o), aliphatic (a), and cyclohexyl (c) surfaces of the molecules. g_{ac}/RT is given in Table 1 of ref. 10 to be 0.0512 at 25°C and following ref. 6 we tentatively assume $g_{oa} = g_{oc}$. On the other hand, for the alkanes + Si(OR)$_4$, we have

$$[5] \quad g_{12} = g_{oa}\alpha_o^2$$

The only undetermined parameter in eqs. [4] and [5] is therefore g_{oa} which must be fitted to experiment. One possibility is to fit to G^E for c-C_6 + Si(OMe)$_4$ or to the corresponding value of S_{cc}, i.e. 0.75. When this is done, eqs. [3] and [4] predict that S_{cc} will have attained infinite values at 57 and 87°C for the pristane and squalane + Si(OMe)$_4$ systems. In fact, the UCST for these systems are much lower, that for the squalane system being measured to be 17°C. This incorrect prediction prompted an alternative procedure to obtain g_{oa}, i.e. fitting so that $S_{cc} \rightarrow \infty$ at 17°C for the squalane system. Using an equimolar H^E value of (6) 1571 J mol^{-1} for cyclohexane + Si(OMe)$_4$ to give the temperature dependence of g_{oa}, and the temperature dependence of g_{ac} from ref. 10, we have for cycloalkanes + Si(OR)$_4$,

$$[6] \quad g_{12}/RT = (3620T^{-1} - 6.29)\alpha_o^2 + (45.7T^{-1} - 0.102)(1 - \alpha_o)$$

and for alkanes + Si(OR)$_4$

$$[7] \quad g_{12}/RT = (3620T^{-1} - 6.29)\alpha_o^2$$

Experimental

Excess heat capacities were obtained using the Picker flow microcalorimeter and methods found in the literature (13, 14). The components were from Aldrich Chemical Co. and of 99% stated purity. The instrument measures the difference $\Delta C_p/V$ in volumetric heat capacity between liquid A in the working cell and liquid B in the reference cell. However, as in previous work (5) with systems with large values of H^E a "boundary effect" leads to a different $\Delta C_p/V$ value. If liquids A and B are interchanged then the "correct" value is the average of the two. Data in ref. 13 allow an estimate of the error incurred. Correspondingly, C_p^E depends on $\Delta C_p/V$ values between successive solutions (14). the C_p^E given here are based on average $\Delta C_p/V$ found through interchanging the two solutions, except in the case of squalane + Si(OMe)$_4$ where measurements in one direction were difficult due to the high viscosity of squalane. We estimate the accuracy of C_p^E to be ±0.03 J K^{-1} mol^{-1} toward the middle of the concentration range, and perhaps ±0.1 J K^{-1} mol^{-1} for the squalane system.

Results and discussion

Cyclohexane systems

The lower part of Fig. 1 shows S_{cc} values at 25°C for the series of cyclohexane + Si(OR)$_4$ systems with R from Me to br-Hex calculated using eq. [3] with eq. [6] for g_{12}/RT and with values of α_o, q, and r for the components from Table 1 of ref. 6. The upper part of Fig. 1 shows C_p^E values at 25°C for the same series of systems. C_p^E for all systems are negative with minima at high cyclohexane mole fraction reflecting the difference in molecular size of the components. However, for c-C_6 + Si(OMe)$_4$ the curvature of C_p^E is much less, suggesting an incipient *W*-shape at $x_1 \sim 0.6$ where the non-randomness indicator S_{cc} reaches its maximum. The special character of the c-C_6 + Si(OMe)$_4$ system is consistent with the S_{cc} values, S_{cc} being larger for this system than for others. Nevertheless, the calculated S_{cc} value of ~0.5 is lower than the threshold value of 0.7 found previously. This low value is due to fitting the theory by requiring $\partial^2(G/RT)/\partial x^2 = 0$ at the Upper Critical Solution Temperature or UCST for squalane + Si(OMe)$_4$. In fact, it is not surprising that a mean-field theory ignoring non-randomness does not give a good value of this curvature for the cyclohexane system far from its UCST. As the temperature rises above the UCST, the rate of increase of $\partial^2(G/RT)/\partial x^2$ away from zero is too large in a mean-field theory. This corresponds to $\partial^2H^E/\partial x^2$ remaining finite at the UCST instead of falling to zero as found (15) experimentally and theoretically, the classical critical exponent γ having a value of 1 instead of 1.24.

In Fig. 1, in order of increasingly negative C_p^E at the minima, the systems are Me < Pr < ET < Bu < br-Hex, the Pr system

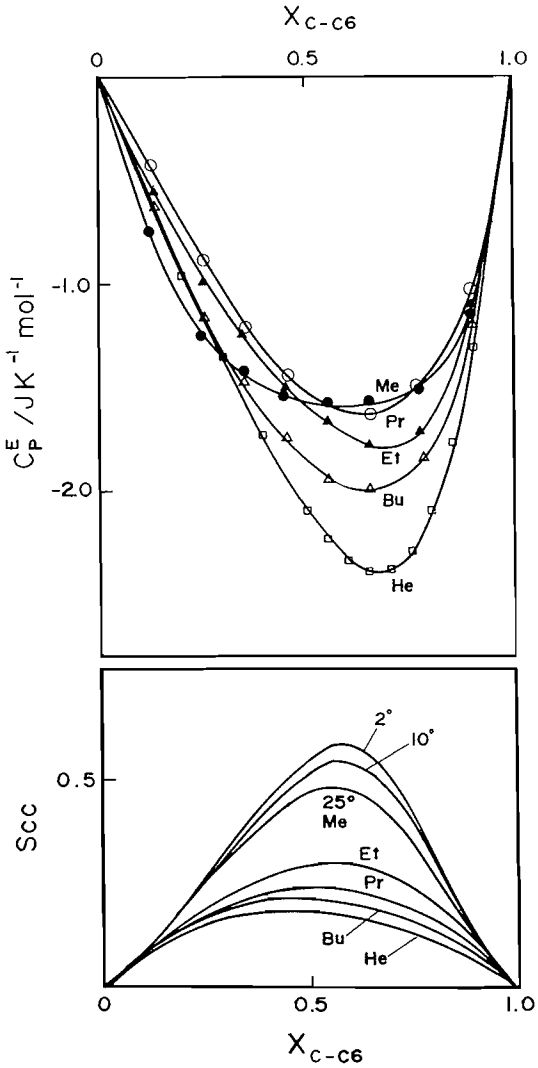

FIG. 1. (Upper part) C_p^E at 25°C for cyclohexane + Si(OR)$_4$, R = Me, Et, Pr, Bu, and branched-hexyl (at 30°C from $H^E(T)$ data (7)), against cyclohexane mole function. (Lower part) S_{cc} at 25°C for the same systems at 25°C and for cyclohexane + Me at 10 and 2°C.

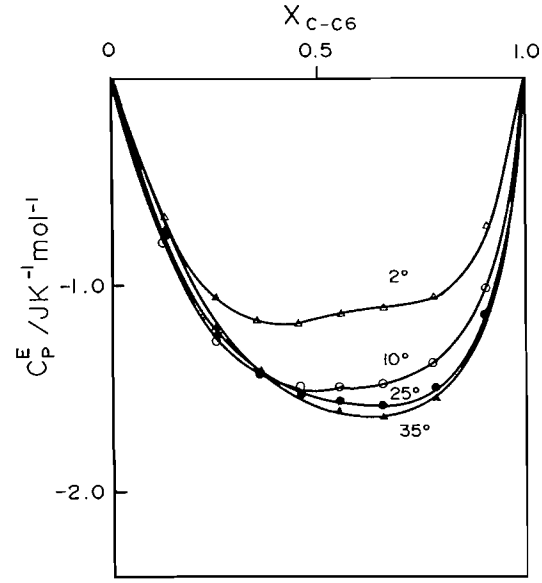

FIG. 2. C_p^E for cyclohexane + Si(OMe)$_4$ at various temperatures (for 2°C see text).

appearing out of place. We can only suggest tentatively that this anomaly may be due to an interplay of the positive non-randomness contribution with the two negative contributions which explain the overall negative sign of C_p^E. These are due to (*1*) destruction on mixing of polar order in the pure alkoxysilanes arising from dipole moments (6) which range from 1.83 D for Me to 1.61 D for Bu. This relatively important effect should increase with decreasing alkoxy group size which exposes the dipole and increases polar order, (*2*) free volume effects which should increase in magnitude as the alkoxy group becomes larger. We suggest that in the absence of the non-randomness contribution the polar effect would dictate the order of systems to be Pr < Et < Me as seen at low cyclohexane concentration and that non-randomness in the Me system at $x_1 \sim 0.6$ changes the order to Me < Pr < Et. The Bu and br-Hex positions are perhaps due to the increas higher temperature, 35°C. In the case of 2°C which lies below the melting point of pure cyclohexane at 6°C, the apparent molar heat capacity ϕ_c could be obtained for Si(OMe)$_4$ as a function of x_1 up to $x_1 = 0.95$. The curve was then extrapolated to $x_1 = 1$. Data at 10 and 25°C show that ϕ_c in the $0.95 < x_1 < 1.0$ region is a smooth extrapolation of data at lower x_1. Thus, C_p^U of the supercooled cyclohexane at 2°C was obtained and C_p^E calculated. Figure 2 shows the results and indeed at 2°C the *W*-shape is more apparent while at 35°C the curvature of C_p^E has increased. Figure 1 shows S_{cc} values for this system at 10 and 2°C calculated using eq. [6] for g_{12}/RT at those temperatures and eq. [3] for S_{cc}. There is clearly an increase of non-randomness with decrease of temperature with a maximum at $x_1 \sim 0.6$, an observation that is consistent with the C_p^E data.

The effect of temperature was also investigated for cyclohexane + Et, Pr, and Bu by measuring C_p^E at 10°C and using $H^E(T)$ data (7) for br-Hex. The effect of temperature is small, barely outside experimental error, with a maximum at $x_1 = 0.65$ where the magnitudes of dC_p^E/dT are $\sim 10^{-2}$ J K^{-2} mol^{-1} but the signs of the quantity vary as follows: Et −, Pr +, Bu ~0 and br-Hex +. C_p^E for Et may reflect some non-randomness while C_p^E for the other alkoxysilanes may be dominated by the dipolar term which undoubtedly would give $dC_p^E/dT > 0$.

Other hydrocarbon systems

Figure 3 shows C_p^E for Me mixed with a series of cycloalkanes of increasing molecular size: cyclooctane, *cis*-decalin, and dicyclohexyl and with a series of branched alkanes, br-C_{16}, pristane, and squalane. The temperature for all systems except squalane was 15°C. The squalane + Me system phase separates at a UCST of 17°C and the C_p^E measurements were made at 25°C. In Fig. 3, the *W*-shape is strongly enhanced with increase of the size of the hydrocarbon whether cycloalkane or branched alkane, finally reaching a strong positive peak with a value of ~4 J K^{-1} mol^{-1} for squalane + Si(OMe)$_4$. Correspondingly, as expected from the non-randomness concept, the central maximum or region of negative curvature moves to lower hydrocarbon concentration, finally to $x_1 \sim 0.15$ for the squalane system. Figure 3 also shows C_p^E for the largest cyclic, dicyclohexyl mixed with the next tetraalkylsilane, Et. The pronounced *W*-shape has now disappeared leaving only a flat region at $x_1 \sim 0.55$.

Figure 4 gives S_{cc} for the same systems and it is clear that there is at least a qualitative similarity between the evolution of S_{cc} and C_p^E with increasing molecular size of the hydrocarbons

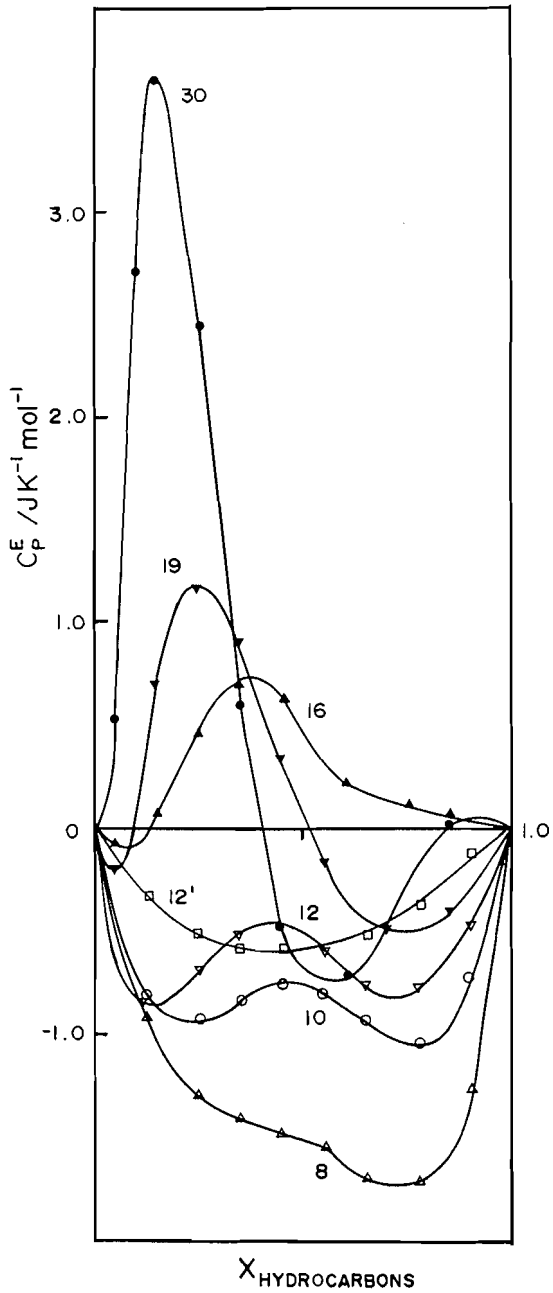

FIG. 3. C_p^E at 15°C for the following hydrocarbons, designated by their carbon numbers + $Si(OMe)_4$: cyclooctane, *cis*-decalin, dicyclohexyl, heptamethylnonane, tetramethylpentadecane (pristane), and hexamethyltetracosane (squalane, at 25°C). 12′ indicates dicyclohexyl + $Si(OEt)_4$.

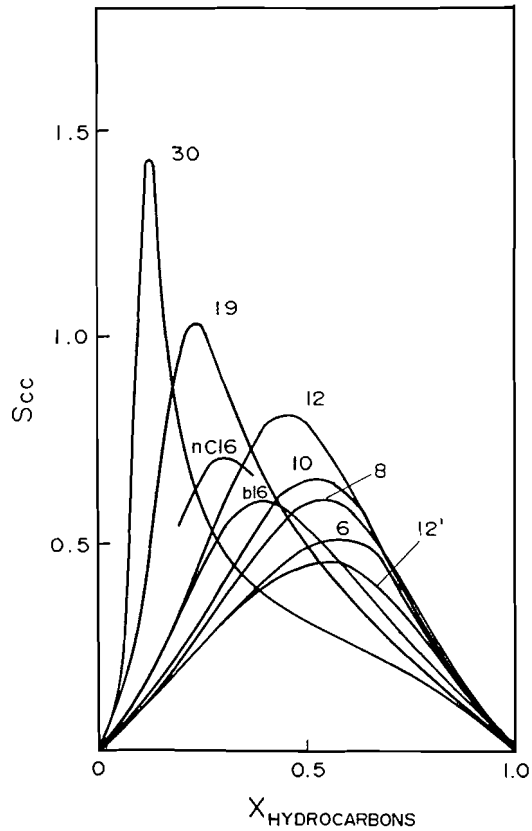

FIG. 4. S_{cc} at 15°C for the systems of Fig. 3, i.e., hydrocarbons, designated by their carbon numbers, + $Si(OMe)_4$: The squalane + $Si(OMe)_4$ system is at 25°C and 12′ indicates the dicyclohexyl + $Si(OEt)_4$ system. N16 and b16 indicate n-C_{16} (at 25°C) and br-C_{16} (at 15°C) + $Si(OMe)_4$.

mixed with $Si(OMe)_4$. The S_{cc} for dicyclohexyl + $Si(OEt)_4$ is small, similar to S_{cc} for cyclohexane + $Si(OMe)_4$ at 25°C, and consistent with the presence of only an incipient *W*-shape for this system. In general, the consistency between S_{cc} in Fig. 4 and C_p^E in Fig. 3 confirms the non-randomness origin for the *W*-shape.

The S_{cc} values were calculated using eqs. [3] and [6] for the cyclic hydrocarbons. All these cycloalkanes are of similar chemical character as suggested by the very small values of H^E, from 0 to 20 J mol^{-1} for a number of their mixtures (17). Equations [3] and [7] were used for the branched alkanes. Equation [3] requires molecular surface areas or q_1 values. Consistent with refs. 6 and 10 these may be computed using Bondi surface area contributions for CH and CH_2 groups (Table 14.16) and surface decrements (Table 14.17) required by intramolecular crowding which decreases the surface area in the cyclics. *cis*-Decalin is found to have a q_1 value smaller than for cyclooctane in spite of its substantially larger volume. This anomaly arises from the *cis*-decalin molecule being given a particularly large surface area decrement due to its "folded" shape. Corresponding to this, the maximum S_{cc} value for *cis*-decalin calculated through eq. [3] will be less than that for cylcooctane. In contrast to this prediction, the *cis*-decalin *W*-shape in Fig. 3 is in fact pronounced and that for cyclooctane hardly apparent. We therefore believe that the *cis*-decalin decrement is overestimated, and have turned to an alternative method of q_1 estimation from core volume V^* values assuming the cyclohexane, cyclooctane, and *cis*-decalin molecules to be spheres. Dicyclohexyl and br-C_{16} were assumed to be right cylinders with radii equal to, respectively, that of cyclohexane, 3.22 Å, and that of the polyisobutylene chain, 3.48 Å. This procedure to find the molecular surface of br-C_{16} has been used earlier (18). In each case, the q value was reduced by an almost trivial factor of 1.042 in order to bring the cyclohexane q_1 value into coincidence with that from Bondi given in ref. 6. The final values of q_1 are cyclooctane 3.07, *cis*-decalin 3.42, dicyclohexyl 4.49, and br-C_{16} 6.04. Bondi contributions were used, however, for the lightly branched pristane and squalane molecules, leading to q values of, respectively, 7.98 and 14.48. Figure 4 shows that S_{cc} and non-randomness in the br-C_{16} + $Si(OMe)_4$ system is less than for dicyclohexyl + $Si(OMe)_4$, predicting a less pronounced *W*-shape for C_p^E. This is not borne

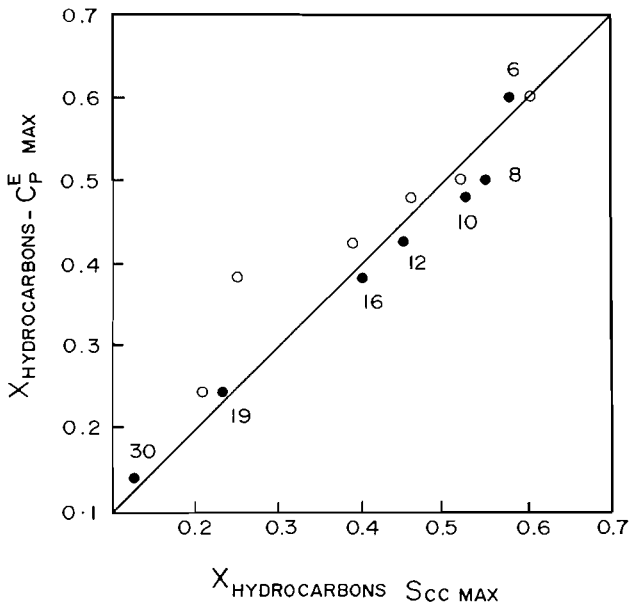

FIG. 5. Hydrocarbon mole fraction for maximum in C_p^E W-shape against mole fraction for maximum of predicted S_{cc}. Full points from eq. [3], i.e. using q; open points from eq. [3] setting $q = r$, i.e. molecular surfaces replaced by volumes in interactional term. Only the br-C_{16} isomer is shown.

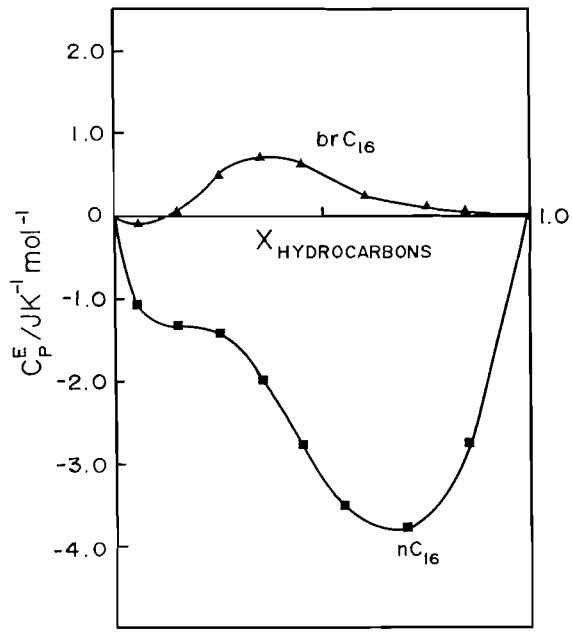

FIG. 6. C_p^E for n-C_{16} + Si(OMe)$_4$ (at 25°C) compared with C_p^E for br-C_{16} + Si(OMe)$_4$ (at 15°C).

out in the experimental results in Fig. 3 where the maximum of C_p^E is clearly much higher than for dicylcohexyl. However, it should be noted that it is difficult to assess the size of the non-randomness contribution in the br-C_{16} case relative to dicyclohexyl since, unlike the curves for other systems, C_p^E is positive throughout the concentration range, the normal random C_p^E apparently being positive instead of negative.

Figure 5 shows a plot of the hydrocarbon concentration at which C_p^E reaches a maximum or has maximum negative curvature against the concentration of maximum S_{cc}. An excellent correlation appears which becomes less good when q is replaced by r, i.e. using the original Flory–Huggins expression with molecular volumes in the interaction term, eq. [21] of ref. 4. Thus the maximum C_p^E for br-C_{16} occurs at a concentration which corresponds to the low surface/volume ratio of this compact molecule which is reflected in the q value but not the r value. As a test, C_p^E has been obtained for n-C_{16} + Si(OMe)$_4$.

The C_p^E results, as shown in Fig. 6, are strikingly different from those with the branched isomer, br-C_{16} which, for comparison, are repeated in Fig. 6. First, C_p^E is now negative at all concentrations, and, second, the mole fraction of C_{16} where the W-shape is most prominent has shifted to a lower value. The negative C_p^E is clearly due to the presence of orientational order or correlations of molecular orientation in the pure n-C_{16}, but not present in the pure br-C_{16}. This order is destroyed on mixing with the second component leading (19) to a negative "random" contribution to C_p^E. The size of this contribution in Fig. 6 makes it difficult to evaluate the "non-random" contribution, but it seems clear that its maximum value will occur at a lower C_{16} concentration than in the case of br-C_{16}. This is in accord with S_{cc} which is shown in Fig. 4 (at 25°C) and which is shifted with respect to br-C_{16}. Consistent with the extended molecular shape of n-C_{16} the Bondi group contribution method has been used to calculate the q parameter. This gives $q = 7.98$ for n-C_{16} comparing with the smaller value of 6.04 found for the more compact isomer, br-C_{16}. The increased surface area of n-C_{16} increases the interactional term in eq. [3] for S_{cc}, increasing S_{cc} and displacing its maximum to lower hydrocarbon concentration. The q parameters in eq. [3] may again be replaced by r, corresponding to the simple Flory–Huggins theory. However, the r values reflecting molar volumes are almost identical for normal and branched C_{16} as are the calculated S_{cc} values. We believe therefore that the displacement of the W-shape C_p^E found for n-C_{16} provides evidence for molecular interaction taking place between surfaces as provided for in the solution thermodynamics of ref. 10.

The LHRH anti-sense peptide (Ser[1]-Arg[2]-Ala[3]-Gln[4]-Ser[5]-Ile[6]-Gly[7]-Pro[8]-Val[9]-Leu[10]) and the inversed sequence, the LHRH inversed anti-sense peptide, have been studied by ^1H and ^{13}C NMR in one and two dimensions. The spectroscopic evidence, obtained in CD_3OH/H_2O (60/40) solution at pH 3.6, indicates that the first four amino acids of the anti-sense peptide form one complete 3_{10}-helical turn followed by an extended conformation for the rest of the peptide. On the time-averaged NMR scale the molecules in the 3_{10}-helical conformation are in fast exchange with the molecules that are extended throughout (major conformer). The reversed anti-sense peptide exhibits less discernible features. It appears likely that a small percentage of the molecules form a β-turn in the C-terminal four residues. Another β-turn might be located in the Val[2]-Ile[5] fragment. Both turns occur in very minor concentrations only, and therefore it is impossible to define what kind of β-turns are present.

Key words: LHRH anti-sense, inversed anti-sense, conformation, NMR.

ALBIN OTTER, PAUL G. SCOTT, JOHN M. STEWART et GEORGE KOTOVYCH. Can. J. Chem. **68**, 1083 (1990).

Faisant appel à la rmn du ^1H et du ^{13}C en une et en deux dimensions, on a étudié le peptide LHRH anti-sens (Ser[1]-Arg[2]-Ala[3]-Gln[4]-Ser[5]-Ile[6]-Gly[7]-Pro[8]-Val[9]-Leu[10]) ainsi que la séquence inversée, le peptide LHRH anti-sens inversé. Les données spectroscopiques, obtenues en solution dans le CD_3OH/H_2O (60/40), à un Ph de 3,6, indiquent que les quatre premiers acides aminés du peptide anti-sens forment une hélice 3_{10} complète alors que le reste de la molécule existe dans une conformation allongée. A l'échelle de temps de la rmn, les molécules de la conformation hélicoïdale 3_{10} s'échangent rapidement avec les molécules qui sont dans la conformation complètement allongée (conformère principal). Les caractéristiques du peptide anti-sens inversé sont moins bien définies. Il semble probable que les quatre résidues du terminal C donnent lieu à une faible proportion de molécules possédant une hélice β. Il est possible qu'une autre hélice β puisse exister dans le fragment Val[2]-Ile[5]. Les concentrations de ces deux hélices sont très faibles et il est donc impossible de définir quels sont les types d'hélice β qui sont présents.

Mots clés : LHRH anti-sens, anti-sens inversé, conformation, rmn.

[Traduit par la revue]

Introduction

The luteinizing hormone releasing hormone (LHRH) is a decapeptide that has been studied in detail by various techniques, including nuclear magnetic resonance (NMR) (1). The complementary decapeptide, Ser[1]-Arg[2]-Ala[3]-Gln[4]-Ser[5]-Ile[6]-Gly[7]-Pro[8]-Val[9]-Leu[10] (LHRH anti-sense peptide), specified by the RNA sequence complementary to the mRNA for human LHRH (2), was prepared as described in ref. 3. This sequence results from the fact that in cells, the sequence of amino acids along peptide chains is determined by the sequence of triplet nucleotides along genes coding for the proteins. It has been suggested that the LHRH and its anti-sense peptide may be interacting (3). Furthermore, antibodies directed against a peptide complementary to a particular hormone also bind to that hormone's receptor binding site (4). Since such interactions are almost certainly conformation-dependent, we studied the LHRH anti-sense peptide by ^1H and ^{13}C NMR. Included in our study is the conformational analysis of the LHRH reversed anti-sense peptide with the sequence Leu[1]-Val[2]-Pro[3]-Gly[4]-Ile[5]-Ser[6]-Gln[7]-Ala[8]-Arg[9]-Ser[10]. This decapeptide has been studied to find out to what extent the conformation is changed by a simple reversal of the orignal sequence. Our efforts are to be seen in light of ongoing interest in the formation and stabilization of secondary structures in small linear peptides (5–7). The results are based on several one and two-dimensional NMR techniques (8) for both proton and ^{13}C.

Materials and methods

The two decapeptides were synthesized and purified according to standard procedures (9). The NMR samples were prepared by dissolving 5 mg each of the solid materials in 0.2 mL H_2O/D_2O (1:1). The pH was adjusted to 3.6 (meter readings without adjustment for deuterium) by adding small aliquots of 0.2 N NaOH. CD_3OH (0.3 mL) (Merck, Sharp and Dohme, MD-67, 99.9% D) was added, the samples were bubbled with argon for approximately 15 min and then sealed. The final concentrations were 8 mM for both decapeptides.

The NMR experiments were essentially the same for both peptides under investigation and were carried out on Bruker AM 600 and AM 400 NMR spectrometers at ambient (295 ± 1° K) temperature. The temperature coefficients of the amide protons were calculated by comparing spectra recording at 286, 290, and 294° K. Data collection and

data processing were controlled by an Aspect 3000 computer using 1987 DISMR software. Chemical shifts were measured relative to CD_3OH at 3.30 ppm (^1H) and 49.0 ppm (^{13}C), respectively.

The 600 MHz one-dimensional proton spectra were recorded with a sweep width of 6400 Hz and 16K (zero-filled to 32K) data points. A total of 168 scans were accumulated and the spectra were resolution enhanced by means of a Gaussian multiplication (line-broadening factor −5 Hz). The solvent signals originating from H_2O and OH of CD_3OH at ca. 4.72 ppm and the undeuterated fraction of CD_3OH at 3.30 ppm were both presaturated during a 2.4 s relaxation delay. The frequency of the decoupler was switched every 0.2 s between the two solvent peaks and the water signal was presaturated twice as long as the methyl group to account for the difference in intensity of the two signals. The possibility of saturation transfer to the amide protons was carefully monitored. With the exception of NH(Arg^2) no loss of intensity was observed. The experimental conditions at 400 MHz were essentially the same as at 600 MHz except for a shorter sweep width and, accordingly, a reduced number of data points.

The ^{13}C spectra were recorded at 100.6 MHz (AM 400) using the DEPT (distortionless enhancement by polarization transfer) pulse sequence (10). The sweep width was 20 kHz divided into 32K (zero-filled to 64K) data points. To obtain a very good S/N ratio more than 40 000 scans were acquired. The total relaxation delay including the acquisition time was 1.8 s and the evolution time for the polarization transfer was 8.3 ms. The final ^1H detection pulse was 135°, resulting in positive signals for CH and CH_3 groups and negative signals for CH_2. Proton broadband decoupling was achieved by a WALTZ (11) composite pulse train. The FID was multiplied by a Gaussian function (line broadening factor −3.0 Hz, Gaussian multiplication factor 0.075) providing good resolution without too much loss in signal-to-noise. This procedure proved to be superior to the more commonly used exponential multiplication.

The parameters of the various two-dimensional NMR techniques are summarized in Table 1. The COSY (12), ROESY (13, 14), and the $^{13}C/^1H$ correlation experiments using DEPT for the polarization transfer (15) were carried out in the phase-sensitive mode using TPPI (time-proportional phase increments) (16), hence the denomination "PH" in Table 1.

Solvent suppression in the COSY and ROESY experiments was achieved as outlined for the one-dimensional spectra. In addition, continuous irradiation was applied at all times aside from the data acquisition (18). The ROESY spectra suffered somewhat from baseline distortions around intense diagonal peaks. This problem could be eliminated in both dimensions by fitting a polynomial function of fifth degree to the baseline (Bruker ABS baseline correction). Due to the non-negligible offset dependence of the ROE cross-peaks (19) it is often difficult to observe ROE interactions at the edge of the spectrum, such as between amide protons, irrespective of the internuclear distance involved. Therefore, the ROESY experiment was also recorded with the transmitter placed in the middle of the NH absorption range (approximately 8.3 ppm). The spin-lock conditions were achieved by a series of hard pulses of small flip angle (20) with a spin-locking time of 150 ms (at 600 MHz) and 125 ms (at 400 MHz, transmitter in the low-field region), respectively. The spin-locking field strength was 5.7 kHz at 600 MHz and 4.0 kHz at 400 MHz.

The samples for circular dichroism spectroscopy were prepared in water or in water/methanol (40/60) and spectra were recorded in a 0.0994 cm pathlength cell at ambient temperature in a Jasco J-20A spectropolarimeter that had been previousy calibrated with *d*-10-camphorsulfonic acid (21). Samples were 0.3 mg/mL for recordings in the range 245 nm to 205 nm and 0.1 mg/mL for recordings between 205 nm and 195 nm. The 32 scans under each set of conditions were averaged and combined to cover the full wavelength range.

TABLE 1. Experimental parameters in the two-dimensional NMR experiments[a,b]

Parameters	Value		
	COSYPH	ROESYPH[c]	XHDEPTPH
Sweep width F2 (Hz)	6410	6410	5500
Sweep width F1 (Hz)	3205	3205	400[d]
Matrix size (F1 × F2) before zero-filling	512 × 4K	512 × 4K	30 × 4K[d]
Matrix size (F1 × F2) after zero-filling	1K × 8K	1K × 4K	128 × 4K
Evolution time			
initial value (μs)	1	1	1
increment (μs)	78	78	312
Number of scans (dummy scans)	16(2)	32(2)	1464(2)
Acquisition time (s)	0.32	0.32	0.37
Relaxation delay (s)	1.80	1.80	1.45
Other delays (ms)	—	150[e]	4.17[f]
Window functions for 2D FT (F1/F2)[g]	S/S	S/S	E/E
Shifts of window functions in fractions of π (F1/F2)	6/8	3/4	5/5[h]

[a]Abbreviations of the techniques are explained in the text.
[b]The parameter sets, referred to the ^1H work at 600 MHz, were the same for both decapeptides. The concentration was 8 mM at pH 3.6 in CD_3OH/H_2O (60/40, v/v) in both cases. The temperature was ambient (295 ± 1K).
[c]The ROESY experiment was performed twice with different transmitter frequencies (see Materials and Methods).
[d]Due to the low concentration of the samples only a limited number of t_1-increments was feasible. Therefore, the sweep width in the proton domain was reduced and soft pulses (90°(^1H) pulse = 600 μs) with an approximate excitation range of 400 Hz were applied (17).
[e]Spin locking time, average field strength 5.6 kHz.
[f]$(2J_{^{13}C-^1H})^{-1}$.
[g]S: sine bell; E: exponential function.
[h]Line broadening factors.

Results and discussion

The spectral analysis of both decapeptides is based on the results of two-dimensional, phase-sensitive NMR experiments such as COSY (16), ROESY (13, 14), and $^{13}C/^1H$ shift correlation (15). Since most amino acids are unique in the sequence under study, assignments are fairly straightforward. The "fingerprint" region of the contour plots of the LHRH anti-sense peptide are shown in Fig. 1, those of the inversed anti-sense peptide in Fig. 2. The ROESY experiments depicted in these figures have been recorded with the transmitter approximately in the middle of the entire spectral range (ca. 4.8 ppm). It is noteworthy that all ROESY spectra obtained in this study were basically free from often reported artifacts (14, 19, 20, 22) which can be identified by their phase relative to the diagonal peaks. Only the ABM spin systems of the Serine moieties showed some, albeit not detrimental, Hartmann-Hahn magnetization transfer. This observation is quite typical for strongly coupled protons absorbing in a narrow range (23). The proton NMR assignments are summarized in Tables 2 and 3 together with the NH—H_α coupling constants and the NH temperature coefficients obtained from spectra recorded at 286, 290, and 294° K.

The NMR data (NH—H_α coupling constants, ROE distance constraints, amide temperature coefficients) provide the necessary information to estimate the torsion angles ϕ, Ψ, and ω (24) of the peptide backbone. Due to conformational averaging,

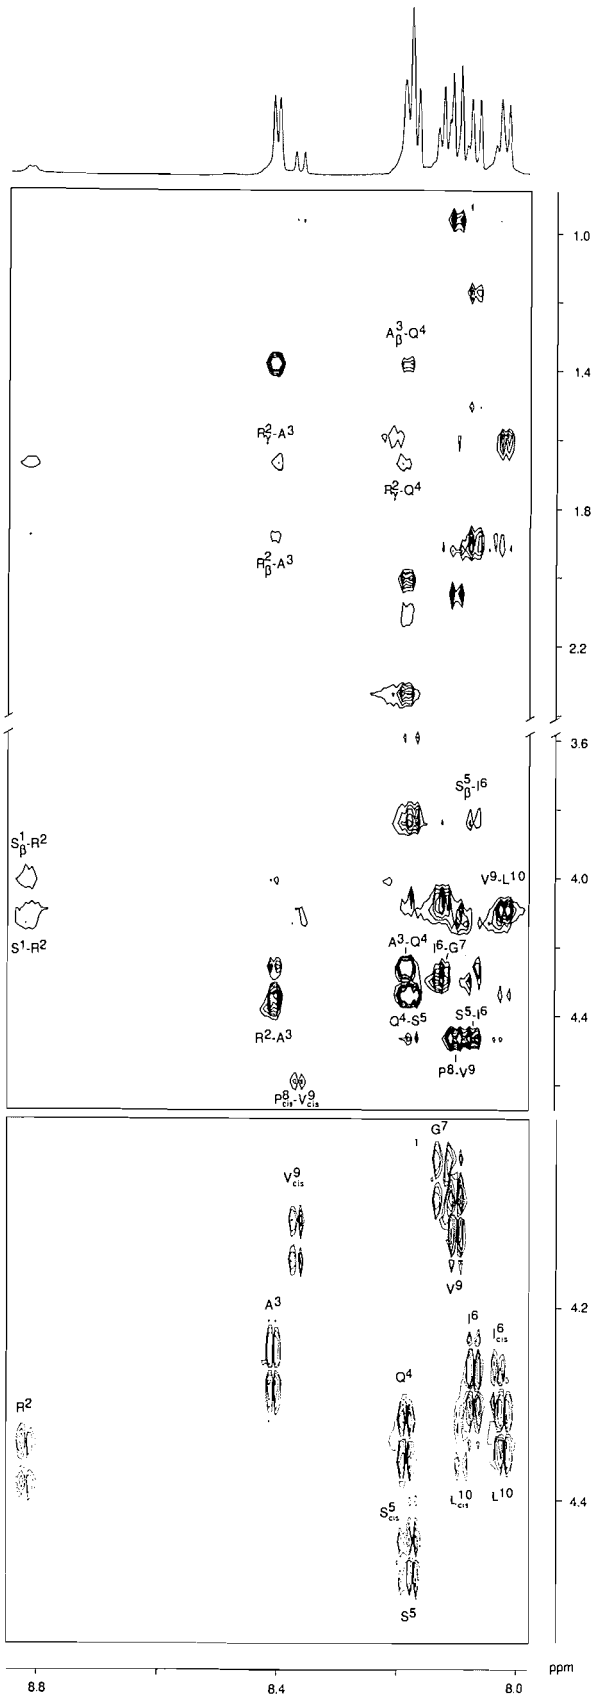

FIG. 1. 600 MHz two-dimensional contour plot of a phase-sensitive COSY (bottom) and phase-sensitive ROESY (top) experiment of the LHRH anti-sense peptide recorded at ambient temperature in CD_3OH/H_2O (60/40). The concentration was 8 mM, the pH 3.60. Positive and negative contours are plotted without distinction. In the ROESY spectrum the contours are equidistant and of opposite sign with respect to the diagonal. The ROE cross-peaks are labeled only when of sequential nature. The first number refers to $H_\alpha(i)$, the second to NH(i + 1) unless otherwise indicated.

which is always present in peptides of this size, the measured effects are the weighted average over two or more conformations making a numerically precise interpretation of, for example, the coupling constants impossible. Nevertheless, certain characteristics of the NMR parameters are diagnostic for the detection of non-extended conformers (5, 25). (*i*) Small NH—H_α coupling constants of one or more residues, (*ii*) NH(i)—NH(i + 1) nuclear Overhauser effect(s) due to short interproton distance(s), and (*iii*) reduced temperature coefficient of one or more of the amide protons. In addition, some of the amide protons might be shifted considerably to lower field (7, 26). This low-field shift together with a reduced NH temperature coefficient is clearly indicative of the formation of a hydrogen bond, whereas the coupling constants and the NOEs reflect altered torsion angles ϕ and Ψ. Depending on what kind of non-extended secondary structure is present and to what extent it coexists with different types of extended conformers, the magnitude of the effects might be small and therefore easily overlooked.

The ^{13}C assignments, based on $^{13}C/^1H$ shift correlation experiments, are listed in Table 4 for both peptides and the DEPT spectrum of the anti-sense peptide is depicted in Fig. 3.

Conformation of the LHRH anti-sense peptide

A review of the NMR data summarized in Table 2 reveals that this decapeptide is a typical representative of short linear peptides with *some* secondary structure. Most of the coupling constants and temperature coefficients as well as the ROEs (Fig. 4) are indicative of an extended conformation. However, the small NH—H_α coupling constants measured in Arg^2 and Ala^3 together with a reduced NH temperature coefficient of Gln^4 clearly show that the N-terminal end is not completely extended. This conclusion is further corroborated by the observation of weak NH(i)—NH(i + 1) ROEs between the residues Arg^2/Ala^3 and Ala^3/Gln^4 (only visible in cross-sections of the two-dimensional ROESY spectrum, not shown) and to a lesser extent by $H_\beta(i)$—NH(i + 1) ROEs (see Fig. 4). Moreover, the low-field shift and broad appearance of the NH(Arg^2) strongly suggests that C=O(Ser^1) takes part in a hydrogen bond (7, 26). In view of all these data, we conclude that the first four residues of the LHRH anti-sense peptide (Ser^1-Arg^2-Ala^3-Gln^4) form a 3_{10}-helical turn (25) stabilized by a C=O(Ser^1)—NH(Gln^4) hydrogen bond, followed by an extended conformation for the remaining residues 5 to 10. The magnitude of the effects discussed above and the observation of ROEs which are only consistent with an extended conformation, for example $H_\alpha(i)$—NH(i + 1) and the complementary $H_\alpha(i)$—$H_{\delta\delta'}(i + 1)$ throughout the peptide chain, entail that only a minor fraction of the molecules adopts the partially helical structure whereas the majority is extended throughout. Because of rapid interchange of the conformers on the NMR time scale, it is not possible to assess the relative populations of the molecules in the two conformations in a numerically precise way. Nevertheless, in comparison to values typically found in fully extended peptides, the reduced coupling constants and the NH(Gln^4) temperature coefficient indicate a time-averaged conformational ratio of approximately 3:1 (fully extended vs. 3_{10}-helical) as the upper limit for the 3_{10}-helical population.

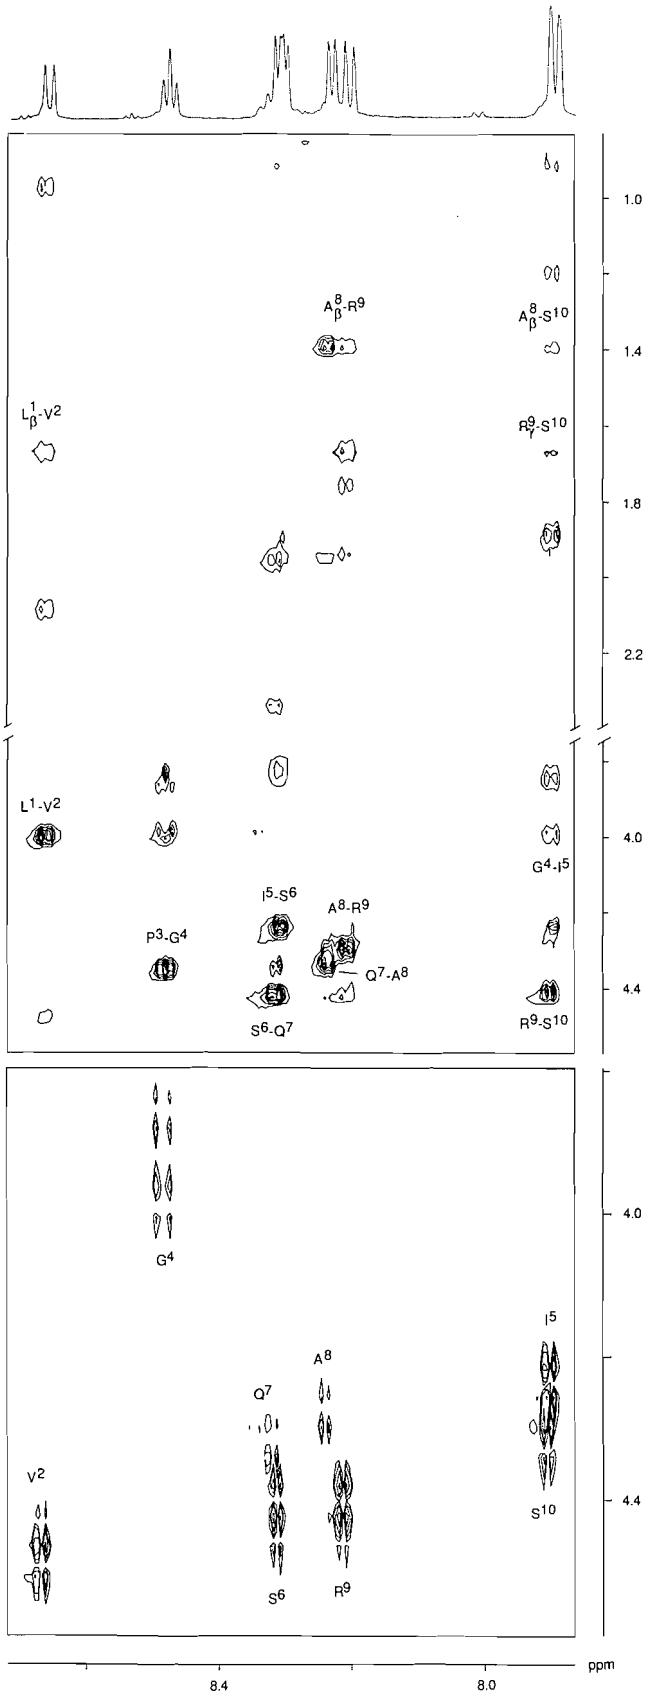

FIG. 2. The same data set as outlined in Fig. 1 recorded from the LHRH inversed anti-sense peptide. The conditions were equivalent to those reported in Fig. 1.

The observation of two ^{13}C resonance lines for most C_α-resonances (Fig. 3) is not conformation-related but due to an H/D isotope effect (27, 28). The ratio of 62:38 reflects the relative proportion of protons and deuterons in the mixed solvent. In the same, but completely deuterated solvent mixture, all C_α-resonances appear as single lines.

Having identified the first four residues to form a non-linear secondary structure, other conformations than the 3_{10}-helical turn have to be considered as well. In particular, the possibility of a β-turn has to be studied. Of the classical β-turn types, the type I turn is two to three times more common than the type II, while the mirror images (types I′ and II′) are very rare (29). The main difference in terms of NMR observables between a 3_{10}-helical turn and a type I β-turn is the observation of two consecutive small NH—H_α coupling constants in the former one whereas in the latter a small coupling constant is followed by a fairly large one (25). Using torsion angles of "ideal" turns (3_{10}: $\phi_2 = -60°$, $\Psi_2 = -26°$, $\phi_3 = -60°$, $\Psi_3 = -26°$, type I β-turn: $\phi_2 = -60°$, $\Psi_2 = -30°$, $\phi_3 = -90°$, $\Psi_3 = 0°$) and the well-known Karplus equation (30) with Karplus constants found in BPTI (basic pancreatic trypsin inhibitor) (31), the corresponding J-values are 4.2 Hz twice (3_{10}) and 4.2, 8.0 Hz (βI). The coupling constant data recorded for the LHRH anti-sense peptide (Table 2) are clearly not consistent with a type I β-turn structure and hence the conclusions as outlined before.

The weighted average distance between two consecutive amide protons in the Ser^1-Gln^4 region is approximately 3.9 Å for an estimated 3:1 ratio of extended versus 3_{10} conformation, instead of 2.6 Å as found in an ideal 3_{10}-helical turn. This result, based on molecular modeling (32) of the 3_{10} and fully extended conformation, explains why the NH—NH ROEs are of very weak nature, since the maximum obtainable nuclear Overhauser effect is reduced by ca. 90% relative to an ideal, 100% populated 3_{10}-helix.

As can be expected in view of the Gly^7-Pro^8 subunit, the peptide bond angles ω are not uniformly *trans* (ω = 180°). Evidence for *cis*/*trans* isomerism (33, 34) about the Gly^7-Pro^8 peptide bond is found in the ^{13}C as well as in the proton spectra. The *cis* isomer is present to the extent of 25% which is very close to the ratio found recently in another Gly-Pro case (26). Besides the doubling of ^1H resonances close to the isomerization site, a $H_\alpha(Gly^7)$—$H_\alpha(Pro^8)$ ROE was observed which is very diagnostic for the existence of a *cis* isomer. The chemical shifts related to the minor isomer are included in Tables 2 and 4 (footnote *d*).

The circular dichroism spectra of the LHRH anti-sense peptide (Fig. 5) show increased negative ellipticity around 215–230 nm in the presence of methanol, suggesting that a conformational change is induced by this organic cosolvent. These spectra do not lend themselves to quantitative analysis but visual comparison with reference spectra for peptides (35) and proteins (36) suggests that a small proportion of ordered secondary structure is present in 60% methanol. The dominant conformer, however, is a random coil.

Conformation of the inversed anti-sense peptide

The spectroscopic data are listed in Table 3 (^1H) and Table 4 (^{13}C) and the ^1H spectra are shown in Fig. 2. An overview of the proton data shows clearly that, in comparison to the previously studied anti-sense peptide, there are less discernible characteristics leading to the conclusion that a large majority of the peptide adopts an extended conformation. The only indications in the ^1H domain for possibly some non-linear conformation are the somewhat reduced temperature coefficients of NH(Ile^5) and NH(Ser^{10}) and the Ala^8 coupling constant of 6.0 Hz. However,

Leu^{10}	8.02 (8.09)	4.33 (4.35)	1.59	1.61 — (1.60)	H_δ: 0.90 $H_{\delta'}$: 0.86	8.2 (8.0)	6.4 (6.4)

[a]Chemical shifts in ppm relative to the undeuterated fraction of the CD_3OH methyl group (3.30 ppm downfield from TMS).
[b]Coupling constants in Hz.
[c]The effect of temperature change on the chemical shifts of the NH protons is measured in ppb/K.
[d]The spectra were measured at 8 mM concentration in CD_3OH/H_2O (60/40), pH 3.60. The temperature was 295 K.
[e]Pairs of protons x (x = β, γ, δ) could not be assigned stereospecifically. In an arbitrary manner, the larger chemical shift was assigned to proton x, the smaller one to x′.
[f]The hydroxyl protons of the two Ser moieties were observed at lower temperature (260 K): 7.25 and 6.75 ppm (not individually assigned).
[g]Values in brackets refer to the *cis* isomer (*cis* Gly^7-Pro^8 peptide bond), which is present to the extent of 25%. Entries into the table are only made where the minor isomer peak could be assigned without ambiguity.

[a]Chemical shifts in ppm relative to CD_3OH at 49.0 ppm downfield from TMS.

[b]The spectra of both peptides were measured at 8 mM concentration in CD_3OH/H_2O (60/40), pH 3.60. The temperature was 295 K.

[c]Most α-carbons and C_β (Ala) were observed as two lines at a ratio of 62:38 (anti-sense) and 75:25 (reversed anti-sense), respectively. The reason for this effect is discussed in the text. Only the chemical shifts of the main signals are listed.

[d]The Gly^7—Pro^8 peptide bond consists of 75% *trans* and 25% *cis* isomer. The chemical shifts of the *cis* isomer are $C_\beta(I^6)$: 37.71, $C_\alpha(Gly^7)$: 42.32, $C_\alpha(Pro^8)$: 60.51, $C_\beta(Pro^8)$: 33.12, $C_\gamma(Pro^8)$: 25.68, $C_\alpha(Val^9)$: 60.51, $C_\beta(Val^9)$: 31.11, $C_{\gamma'}(Val^9)$: 18.95, $C_{\delta'}(Leu^{10})$: 21.75.

[e]The Val^2-Pro^3 peptide bond is predominantly *trans* (~94%). Due to the low population of the *cis* isomer only very few signals can be observed and assigned unambiguously: $C_{\delta'}(Leu^1)$: 21.95, $C_\gamma(Val^2)$: 19.10, $C_{\gamma'}(Val^2)$: 18.55, $C_\delta(Ile^5)$: 11.40.

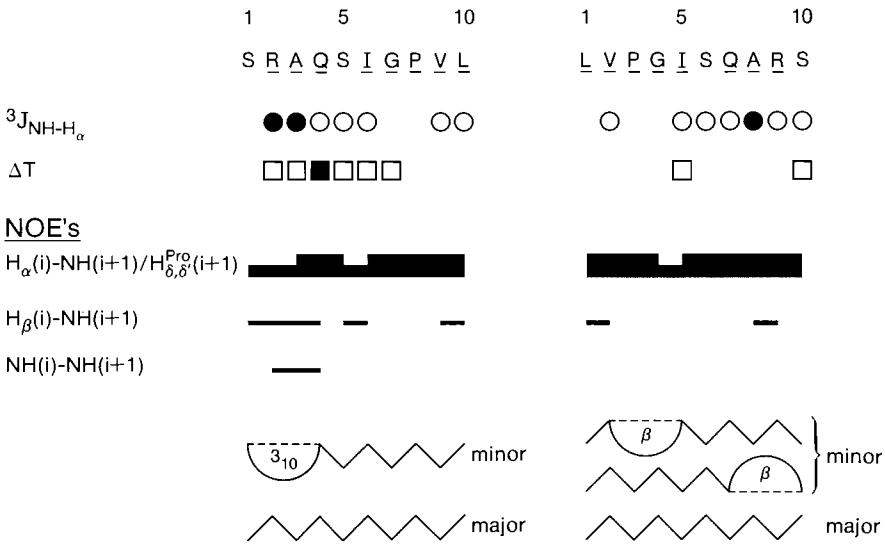

FIG. 4. A summary of NMR data obtained from the two peptides under study. The amino acid sequences are shown for the LHRH anti-sense peptide (left) and its reversed sequence, the LHRH inversed anti-sense peptide (right). Unique amino acids are underlined. The ^3J coupling constants (NH—H_α) are represented by the following symbols: filled circles for values ≤6.0 Hz, open circles for J above 6.0 Hz but below 9.0 Hz. A filled square stands for a NH temperature coefficient of 3.5 ppb/K, open squares are used for values between 4 and 5 ppb/K (left) and 5.5 ppb/K on the right. The ROEs are indicated by bars, the height of which depicts the strength of the effects separated into strong, medium and weak. The secondary structure is depicted schematically at the bottom together with an estimation of the relative population. β-turns and 3_{10}-helical turns are shown by half circles and dashed lines representing NH(i + 3)—C═O(i) hydrogen bonds. An extended chain is drawn as a zig-zag line.

all these effects are small and do not permit very firm conclusions. The absence of any measurable NH—NH ROEs further aggravates the situation. Based on the proton data, we exclude the possibility of a single non-linear conformation in coexistence with an extended conformer. Nevertheless, the presence of two minor conformers in rapid exchange with the molecules in an extended form appears to be a possible explanation. First, the combination of the reduced NH(Ser^{10}) temperature coefficient with the small NH—H_α(Ala^8) coupling constant suggests that a small amount (5 to 10%) of a β-turn could be present in the C-terminal part of the molecule. The sequence Gln-Ala-Arg-Ser shows an above average occurrence in type I β-turn form (29) which can be considered as further evidence although not as proof for our conclusion. It should be emphasized that our data do not permit defining what kind of β-turn is present but a type I β-turn in small proportion certainly does not violate our data set. Second, an additional turn could be located in the Val^2-Pro^3-Gly^4-Ile^5 part of the molecule with NH(Ile^5) taking part in a hydrogen bond and hence the somewhat reduced temperature dependence of its amide proton. Again, not more than 5 to 10% of the molecules are expected to adopt this conformation. In this sequence, the potentially small coupling constant of the second amino acid can, of course, not be observed, since this is a proline moiety. Therefore, our conclusion has to be considered

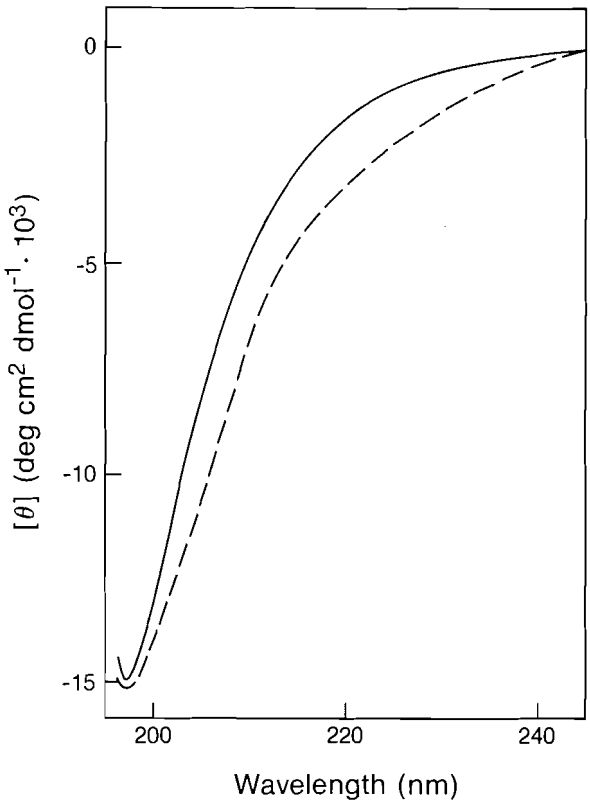

FIG. 5. Circular dichroism spectra of the LHRH anti-sense peptide in water (—) and in water/methanol (40/60) (---).

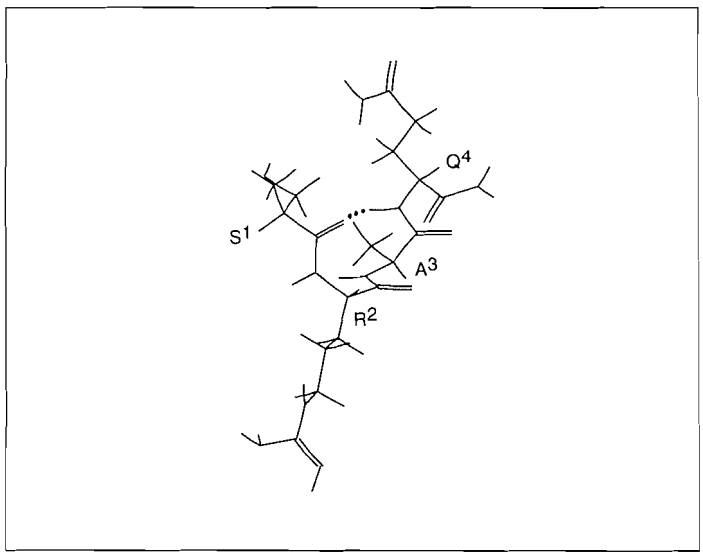

FIG. 6. A molecular model of the first four amino acids of the LHRH anti-sense peptide, forming one 3_{10}-helical turn stabilized by a hydrogen bond (dotted line) between NH(Gln^4) and C=O(Ser^1). The model depicted does not represent the only conformation of all the molecules, and it has been drawn by using torsion angles as described in the text.

somewhat speculative, but again, a statistical analysis (29) shows a high occurrence of a β-turn (type II in this case) in the tetrapeptide under question. It is noteworthy that the results of our attempt to understand an only partly conclusive data set coincide with the statistically clearly highest occurrence of β-turns anywhere in the decapeptide (29). The two possible β-turns do not necessarily have to coexist in the same molecules simultaneously. In view of the NMR evidence, showing that only a very minor percentage of the conformers are non-extended, we refrained from recording circular dichroism spectra of the reversed anti-sense peptide.

A final remark is directed towards the aforementioned *cis/trans* isomerism. Not surprisingly, this effect is much smaller compared to the anti-sense peptide. The Val^2-Pro^3 peptide bond exhibits a *cis*-isomer content of only 6%. The drastic decline from 25% in the Gly-Pro case demonstrates that in the absence of any additional stabilizing effects such as charge interactions (37) the *cis* isomer is rare when bulky amino acids precede proline. Due to the low percentage of *cis* isomer only few resonances were observed. They are included in Tables 3 and 4 (footnote *e*).

Conclusion

The ^{1}H and ^{13}C spectra of the LHRH anti-sense peptide as well as the LHRH inversed anti-sense peptide were analyzed by various two-dimensional NMR techniques in CD_3OH/H_2O (60/40) solutions. A summary of the spectroscopic data obtained from both decapeptides is presented in Fig. 4. There is very strong evidence that the N-terminal end of the anti-sense peptide forms one complete 3_{10}-helical turn stabilized by a NH(Gln^4)/C=O(Ser^1) hydrogen bond, followed by an extended conformation for the rest of the peptide. These conclusions are based on proton NMR results such as NH—NH ROEs (Ser^1/Arg^2 and Arg^2/Ala^3), reduced NH—H_α coupling constants (Arg^2, Ala^3), a low-field shift of NH(Arg^2) and a reduced temperature coefficient of NH(Gln^4). However, the magnitudes of these effects demonstrate clearly that on the time-averaged NMR scale the molecules with the 3_{10}-helical turn are in fast exchange with molecules that are extended throughout and hence the ratio between the two conformers can only be estimated. In comparison to linear peptides that are fully extended, we conclude that the 3_{10}-helix conformation is only present to a maximum of 25% of the time. Figure 6 depicts the first four amino acids of the anti-sense peptide in a 3_{10}-helical conformation. This was produced by molecular modeling (32) using torsion angles of an ideal 3_{10}-helical turn, followed by energy minimization (32) and checking for consistency with the NMR data set. The torsion angles used in Fig. 6 are (in the order Ser, Arg, Ala, Gln): ϕ = —, −72°, −50°, −71°; Ψ = 142°, −33°, −43°, 138°; ω = 173°, 174°, 177°, —; χ_1 = −63°, +63°, —, 180°, remaining χ's 180°. The distance O(Ser^1)—N(Gln^4) is 3.1 Å which is well within the 3.5 Å considered as the upper limit for hydrogen bonds.

The conformational data of the LHRH anti-sense peptide resemble those of LHRH (ref. 4 and references therein) in the sense that both peptides exist in solution as mixtures of several conformers in fast exchange. On the other hand, and not surprisingly in view of the different peptide sequences, the non-extended features are quite different.

The data obtained from the LHRH inversed anti-sense peptide are less conclusive. It appears likely that a small percentage of the molecules form a β-turn (probably type I) located in the C-terminal end. Another β-turn (possibly type II) could be located in the Val^2-Ile^5 fragment. In view of the somewhat incomplete evidence, we refrain from presenting a molecular model of the LHRH inversed anti-sense peptide. While both decapeptides exist in predominantly extended conformations, the minor, non-extended conformers are significantly different from each other both in terms of their nature and their percentage.

Received November 22, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

KATHLEEN M. SEMPLE, NATSUKO CYR, PHILLIP M. FEDORAK, and DONALD W. S. WESTLAKE. Can. J. Chem. **68**, 1092 (1990).

Asphaltenes from Cold Lake oil were separated into fractions by size exclusion chromatography to study the molecular size dependence of chemical structural characteristics. Each fraction was analyzed by proton NMR and UV–visible spectroscopy and by elemental analyses for C, H, N, S, Ni, and V. The results indicated that the nature of the average chemical structures in Cold Lake asphaltenes were not uniform throughout the total range of molecular sizes but varied significantly; some changed gradually and some changed quite abruptly. Especially in the very low molecular-weight fraction, the size of aromatic moieties seems to be much smaller, the contents of both aromatic carbon and aromatic hydrogen are higher, the C/H ratio is higher, and the porphyrin and vanadium concentrations are much higher than in heavier fractions.

Key words: Cold Lake asphaltenes, size fractionation, vanadium, proton NMR, porphyrin, chemical structural analysis.

KATHLEEN M. SEMPLE, NATSUKO CYR, PHILLIP M. FEDORAK, et DONALD W. S. WESTLAKE. Can. J. Chem. **68**, 1092 (1990).

Dans le but d'étudier la relation entre les caractéristiques chimiques et la grosseur des molécules et faisant appel à la chromatographie par perméation, on a séparé des asphaltènes provenant de l'huile de Cold Lake en plusieurs fractions. Chaque fraction a été analysée par run du ^1H, par spectroscopie UV–visible et par analyse élémentaire du C, H, N, S, Ni et V. Les résultats indiquent que les structures chimiques moyennes des asphaltènes provenant de l'huile de Cold Lake n'ont pas une nature uniforme et que les structures varient beaucoup en fonction des grosseurs des molécules; quelques-unes varient graduellement alors que d'autres changent brusquement. Dans la fraction de très bas poids moléculaire, on note en particulier que la grosseur des portions aromatiques est beaucoup plus petite, que les quantités de carbones et d'hydrogènes aromatiques sont plus élevées, que le rapport C/H est plus élevé et que les concentrations de porphyrine et de vanadium sont beaucoup plus élevées que dans les fractions de poids moléculaires plus élevées.

Mots clés : asphaltene de Cold Lake, fraction par taille, vanadium, RMP, porphyrin, analyse chimique structurale.

Introduction

Asphaltenes, the pentane-insoluble fraction of oil, consist of very high molecular-weight compounds of both aromatic and aliphatic nature (1). They are rich in heteroatoms (N, S, O) and metals (2, 3). There have been a number of studies which indicated that asphaltenes consist of condensed polynuclear aromatic rings bearing alkyl side chains (4–6) aggregated to different degrees through stacking of large aromatic sheets (5–8).

For a given oil, the asphaltene fraction is generally thought to consist of structurally similar molecules varying mainly in molecular weight (6, 9). However, there is evidence that the chemical charcateristics and "average" molecular structures may vary considerably with their sizes. For example, heavy metals are not uniformly distributed in asphaltenes (10) with vanadium concentrations being higher in lower molecular-weight fractions (11, 12). Similarly, petroporphyins (3, 11, 12) were found to be most abundant in low-molecular weight fractions. In addition, Ignasiak *et al.* (13) observed that the very high molecular-weight fraction of Athabasca asphaltenes was more prone to forming methylene chloride-insoluble polymers on heating than the low molecular-weight fractions which even seem to act as inhibitor of polymerization. These differences in chemical reactivity suggested that some molecular size fractions of asphaltenes may be more susceptible to enzymatic or microbial attack than other fractions.

Microorganisms have been shown to associate with bitumens. For example, Wyndham and Costerton (14) observed bacterial colonization of bitumen particles suspended in the Athabasca river and reported that these isolates reduced the maltene content of bitumen but were unable to grow on the asphaltene fraction. In addition, bacterial rods have been observed in freeze-fractured samples of Athabasca bitumen examined by transmission electron microscopy (15).

Although there have been numerous reports demonstrating that microorganisms can degrade *n*-alkanes, isoprenoids (16), aromatic hydrocarbons (17), and sulfur heterocycles (18), there is no chemical or physical evidence that microorganism can modify asphaltenes. The data reported in this paper are the results of the separation (by gel permeation chromatography) and chemical and physical characterization of various size fractions of Cold Lake asphaltenes which will be used in biotransformation studies. The analyses focus on variations in C/H ratio, aromatic characteristics, and the distributions of petroporphyrins, vanadium, and nickel among the fractions. Where possible, the results of our work with the Cold Lake

asphaltenes were compared to those obtained from Athabasca asphaltenes that had been fractionated using the same GPC method.

Experimental

Preparation of asphaltenes

Cold Lake bitumen (i.e. asphalt-like hydrocarbons found in oil sands) is an oil (API gravity of 11) with approximately 15% asphaltene content. It was recovered by steam injection by ESSO Resources and provided through the Alberta Research Council sample bank. Asphaltenes were prepared from fresh Cold Lake bitumen using *n*-pentane precipitation. Oil was dissolved overnight in one volume of toluene (19), thereby decreasing viscosity. Water and solids were sedimented by centrifugation (15 min in an IEC Clinical Centrifuge). The layer of oil/toluene was removed and the asphaltenes were precipitated by adding 40 volumes of *n*-pentane (pentane:toluene:oil = 40:1:1) and stirring at room temperature for 2 h. Asphaltenes were collected by vacuum filtration through a 10–15 μm scintered glass funnel. They were washed repeatedly with pentane. Asphaltenes were redissolved in a minimum amount of toluene and precipitated with 40 volumes of pentane and collected by filtration. This procedure was repeated three more times to remove any occluded resins and aromatics (20). Asphaltenes isolated in this manner were stored under a nitrogen atmosphere to minimize oxidation.

Fractionation of asphaltenes

Fractionation of asphaltenes was done using the gel permeation chromatography (GPC) method used by Ignasiak *et al.* (13). All solvents were reagent grade and used as provided by the manufacturer (Mallinckordt). Asphaltenes were fractionated on 2.5 × 100 cm Biobeads S-X1 columns using chloroform as eluent. Fraction collection was started when the first color was eluted (average void volume = 110 mL). Five major fractions (designated 1 to 5) corresponding to the fractions obtained by Ignasiak *et al.* (13) were collected (see Table 1). Fraction 5 was comprised of the last 170 mL collected from the GPC column. This volume was collected in five subfractions designated 5-1 to 5-5 (see Table 2). These subfractions were either characterized separately or pooled to give fraction 5. The solvent was removed using a rotary evaporator, then the samples were transferred in methylene chloride to preweighted vials and the solvent was evaporated overnight at room temperature. The samples were weighed and stored under a nitrogen atmosphere with Teflon-lined caps. The disappearance of solvent in samples was confirmed during NMR analyses.

Analytical GPC

The fractions from the Biobeads S-X1 columns were analyzed by GPC using three 30 cm × 7.8 mm i.d. Waters μ-Styragel columns (1000, 500, and 100 Å) in series with methylene chloride as eluent (21). The instrument used was a Milton-Roy HPLC system with a UV detector at 254 nm. Asphaltenes were dissolved in methylene chloride to a concentration of 5 mg/mL. The injection volume was 20 μL and the solvent flow rate was 1.5 mL/min. The relationship between the elution time and the apparent molecular weight was calibrated using monodispersed polystyrene standards (Perkin-Elmer) and toluene. The elution time of the peak mode for an asphaltene fraction was compared to the calibration curve and this value was taken as the apparent molecular weight.

TABLE 2. Yields and apparent molecular weights of Cold Lake asphaltenes in subfractions of fraction 5

Fraction	Eluted volume (mL)[a]	Solid yield (wt%)[b]	MW peak maxima[c]
5-1	30	6	1 200
5-2	30	3	700
5-3	30	2	450
5-4	30	1	200
5-5	50	0.5	100

[c]Based on polystyrene standards.

Nuclear magnetic resonance (NMR)

Proton NMR spectra were measured on a Bruker WP-80 spectrometer at 80 MHz in $CDCl_3$ solutions using TMS as internal standard. Each spectrum was integrated to determine the relative abundance of different types of protons in the sample.

Cross polarization/magic angle spinning (CP/MAS) C-13 NMR spectra of solid samples were recorded on a Bruker CXP-200 spectrometer operating at 50.3 MHz. The contact time was 1 ms, the recycle delay was 1 s, and the proton 90 degree pulse width was 6 μs (22). Cylindrical $A1_20_3$ rotors were used in a Doty Scientific probe and samples were spun at ~4.5 kHz. The apparent aromaticity, f_a, was calculated assuming that spinning sidebands on both sides of aromatic carbons were of equal size.

Electron spin resonance (ESR)

Electron spin resonance measurements were done on a Bruker ESR model ER-200 SRC spectrometer. Details of the experimental conditions and the method of calculation of spin numbers have been described elsewhere (23).

Ultraviolet–visible spectrophotometry and calculation of porphyrin concentration

A Pye-Unicam 8740 spectrophotometer was used to obtain UV–visible scans (200 to 600 nm) of asphaltene fractions dissolved in methylene chloride. The presence of petroporphyrins was detected by the prominent absorbance peak at ~410 nm (Soret peak) and a weaker absorbance at 573 nm (α peak) (24). Semi-quantitative analysis of porphyrins in asphaltenes was done in the concentration ranges where

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

the relationship between the absorption and the concentration was linear. Peak heights were measured using the baseline extrapolated from the minimum on each side of the peak (25, 26). For samples which showed a slight shoulder at 590 nm, the baseline for the 573 nm peak was measured back to 600 nm (27, 28). Peak heights were converted to absorbance values and the absorbance per mg of the original sample was calculated. The amount of porphyrin (μmol/g) in each fraction was estimated using the previously reported values for the molar extinction coefficients for pure and petroporphyrins in chloroform. Molar extinction coefficient $\epsilon = 45.0 \times 10^4$ was used for calculations at 410 nm (28, 29). Various molar extinction coefficients ranging from 2.15 to 3.7×10^4 (3, 28–33) were used for the peak at 573 nm. The concentration, in parts per million (μg/g) was estimated using an approximated molecular weight for porphyrins of 600 (vanadium octaethylporphyrin (30)).

Elemental analysis

Elemental analysis for C, H, and N was done in duplicate or quadruplicate at the microanalytical laboratory of the Chemistry Department, University of Alberta using a Perkin-Elmer 240B CHN analyzer. The Schoeniger combustion method was used for sulfur analysis (34).

Nickel and vanadium analyses were done on an Inductively Coupled Plasma (ICP) simultaneous spectrometer (Model 34000, Applied Research Laboratory). Samples of asphaltene fractions were dissolved in 10 mL xylene/mineral oil mixture.

Method of calculation

To obtain information on the molecular composition of the asphaltenes in each fraction, the total signal intensity from each NMR spectrum was taken as 100 and each spectrum was divided into four chemical shift regions, as is often done (5, 6, 35, 36): H1, methyl protons at the end of aliphatic chains (0.2–1.0 ppm); H2, methylene protons on aliphatetic chains (1.0–2.1 ppm); Ha, α protons to aromatic carbon (2.1–5.0 ppm); and Har, aromatic protons (7.0–9.0 ppm).

Chemical shift values separating regions were chosen at the minima of the spectra so that the errors in integrals are minimized. Naphthenic protons may appear in the region 1.5–2.1 ppm but this region was combined with the other types of methylene and methyne protons since there was no spectral minimum to separate this region.

For every 100 hydrogens detected by proton NMR, the following values were calculated to determine similarities and differences in chemical structures among asphaltene fractions. Figure 1 illustrates the different types of H atoms and C atoms considered in those calculations.

(i) Average number of aliphatic chains and their length

If we assume that all the aliphatic chains were composed of methylene groups (35) and these were longer than two-carbon length, the number of aliphatic chains ending with methyl groups can be calculated from the number of end methyl protons, H1 (0.2–1.0 ppm):

[1] The number of end methyl groups = H1/3

There should be an equal number of α carbons for each end methyl group. Therefore, the excess α carbons must belong to aliphatic chains not ending with methyl groups. These aliphatic chains would connect aromatic carbons or acyclic rings attached to aromatic rings. Heteroatoms, such as O or S, may be included in these aliphatic chains.

The number of α carbons can be obtained from Ha divided by 2, because of the assumption that only methylene groups were present:

[2] The number of α carbons = Ha/2

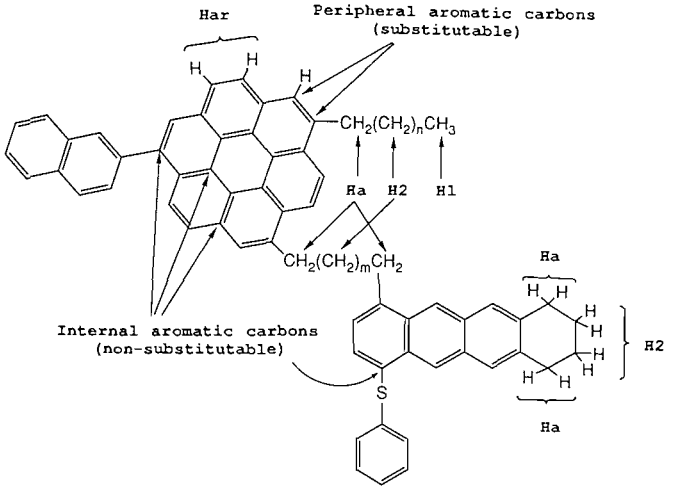

FIG. 1. Illustration of the types of hydrogen and carbon atoms considered for NMR analysis.

Because two methylene carbons are involved in connecting aromatic carbons, the number of such aliphatic chains is

[3] The number of chains connecting aromatic carbons
$= (1/2) \times [(Ha/2) - (H1/3)]$

The total number of aliphatic chains are the sum of [1] and [3]:

[4] The total aliphatic chains $= (1/2) \times (Ha/2 + H1/3)$

The average number of middle methylene carbons in the aliphatic chains can be calculated by dividing the total number of methylene carbons, H2/2, by the number of chains:

[5] The number of CH_2 in a chain $= (H2/2)/[(1/2) \times (Ha/2 + H1/3)]$

(ii) Average degree of alkyl substitution in aromatic rings

Assuming that no heteroatoms were directly bonded to aromatic carbons, but only methylene carbons were bonded to aromatic carbons, the total peripheral aromatic carbons can be obtained from the sum of the number of aromatic hydrogens, Har, and the number of α carbons, Ha:

[6] The peripheral aromatic carbons = Har + Ha/2

The degree of substitution on peripheral aromatic carbons can be obtained from the ratio of the total number of α carbons to the number of peripheral aromatic carbons calculated in [6]:

[7] The degree of substitution in peripheral aromatic carbons
$= (Ha/2)/(Ha/2 + Har)$

(iii) The total number of substitutable carbons

Although the number of quarternary carbons (other than methylene substituted aromatic carbons) was not obtainable from the analysis of the proton NMR, the total number of substitutable carbons can be calculated from the sum of the total end methyl carbons (H1/3), the total methylene carbons (H2/2), the total α carbons (Ha2/2), and the total peripheral aromatic carbon (Ha/2 + Har):

[8] The total number of substitutable carbons
$= H1/3 + H2/2 + Ha + Har$

(iv) Carbon aromaticity

The carbon aromaticity values based on proton NMR are the ratios of the peripheral aromatic carbons in [6] to the total

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

number of substitutable carbons in [8]. Types of carbons not included in this calculation are the inner aromatic carbons in condensed aromatic rings, those aromatic carbons directly connecting two aromatic moieties (such as found in biphenyl), aromatic carbons directly bonded to heteroatoms and quarternary aliphatic carbons.

The number of carbons for every 100 hydrogens calculated from the results of elemental analysis is larger than that obtained by eq. [8] because non-substitutable carbons are not included in the latter. The difference between those two numbers should be the number of non-substitutable carbons (see Fig. 1). If we assume that all the non-substitutable carbons are aromatic, the "true" carbon aromaticity can be calculated by adding this difference to the number of peripheral aromatic carbons in [6] and dividing by the total number of carbons:

[9] The "true" carbon aromaticity

$$= (D + \mathrm{Ha}/2 + \mathrm{Har})/(C/100\mathrm{H})$$

where $D = C/100\mathrm{H} - (\mathrm{H1}/3 + \mathrm{H2}/2 + \mathrm{Ha} + \mathrm{Har})$ and $C/100\mathrm{H}$ is the number of carbon for 100 hydrogen obtained from the elemental analysis.

Results and discussion

Yields and characteristics of fractionated Cold Lake asphaltenes

The volumes of chloroform solutions collected after the Biobeads S-X1 column separation and the yields of solid asphaltenes are shown in Tables 1 and 2. Figure 2 shows the analyses of these fractions by analytical GPC chromatography used to assign the apparent molecular weights. Although polymer molecular weight standards are known to have limited applications (11, 37–39), polystyrene molecular weight standards were chosen for use with the analytical GPC method because of simplicity and the need for apparent molecular weight markers in subsequent biotransformation studies.

The possible effect of adsorption of asphaltenes on the GPC columns was previously investigated by adding a polar solvent, methanol, to the eluent (40). This did not decrease the retention volume of the asphaltene indicating that there was no significant adsorption effect during the size separation process. Based on the results of 12 fractionations of the Cold Lake asphaltenes on Biobeads S-X1, 103 ± 3% of the asphaltenes applied to the column were recovered.

Table 1 also shows the elemental analyses of each of the major fractions of the Cold Lake asphaltenes. According to the result of the Duncan's multiple range test (41), there were no differences among the $C/100\mathrm{H}$ ratios of fractions 1 to 4, but this ratio was significantly higher in fraction 5 ($P < 0.05$). Similarly, there were no differences among the sulfur contents of fractions 1 to 4, but the sulfur content of fraction 5 was significantly lower than those in the other fractions.

The preparative-scale column chromatography procedure used in this study was the same as used in earlier work with Athabasca asphaltenes (13). The results of these two studies are summarized in Table 3. The yields of each fraction were somewhat different and these may be due to the differences in the nature of the asphaltenes in the two oils, in the method of asphaltenes preparation or in the void volumes of the chromatography columns. However, in both studies, the first two fractions contained approximately half of the asphaltenes. For each fraction, the value of $C/100\mathrm{H}$ of the Cold Lake asphaltenes is higher than that of the Athabasca asphaltenes suggesting that the former has a higher degree of aromaticity.

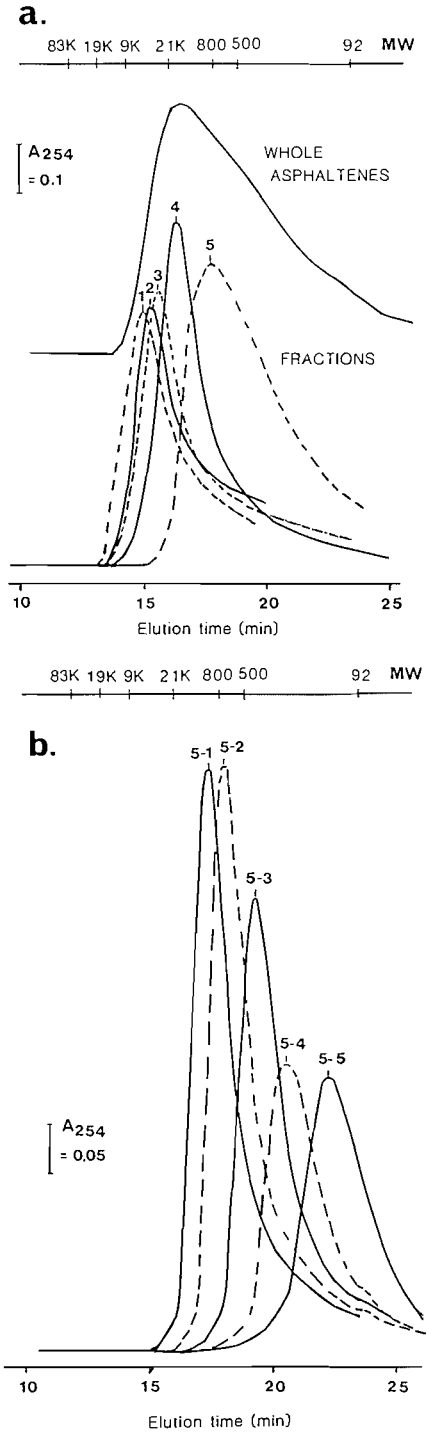

FIG. 2. Analytical gel permeation chromatograms of (*a*) the five major fractions and (*b*) the subfractions of fraction 5. For each fraction and subfraction, a solution of ~5 mg/mL was prepared and a 20 μL portion of these was analyzed. The areas under the curve do not reflect the fraction yields. The elution times of various polystyrene MW standards and toluene (MW = 92) are shown above the chromatograms.

NMR analyses

Proton NMR spectra have been used to character bitumes and their fractions (6, 36, 42–44). A stack plot of the proton NMR spectra is shown in Fig. 3. The general appearance of the spectra for fractions 1 to 4 was very similar. The spectrum of fraction 5 showed a much higher proportion of aromatic protons (Har) as well as of α protons (Ha) than those of other fractions. This may

[a]Calculated from data given by Ignasiak *et al.* (13).
[b]Calculated from data given by Cyr *et al.* (39).

be due to the presence of more peripheral aromatic carbons in low molecular-weight fractions than in high molecular-weight fractions. The spectra of the major fractions (Fig. 3a) showed no detectable signals between 4 and 6 ppm, the region which is characteristic of olefin protons. Nor were there detectable signals between 8.5 and 9.0 ppm where protons on condensed aromatic rings normally appear. Signals in this latter region became more apparent in the low molecular-weight subfractions of fraction 5 (Fig. 3b).

The integrated values of the various designated regions are shown in Table 4 as percent of the total intensity. Similarly, the proportion of aromatic protons measured in the various fractions of Athabasca asphaltenes (13) are also summarized in Table 4. For both asphaltene samples, the proportions of aromatic protons increased as the molecular weight of the fractions decreased. The lowest molecular-weight subfractions of the Cold Lake asphaltenes (5-4 and 5-5) had the highest proportion of aromatic hydrogen atoms. The proportions of aromatic hydrogen atoms in each major fraction of Cold Lake asphaltenes were higher than the corresponding fractions of the Athabasca asphaltenes. These results are consistent with the predicted higher aromaticity of the former asphaltenes based on the C/100H ratios.

The data in Table 5 summarizes the estimates of the average molecular composition in fractions of Cold Lake asphaltenes. Based on the NMR data it is seen that as the molecular weight decreases there is a decreasing trend in the number of aliphatic chains ending with methyl groups and an increasing trend in those connecting aromatic carbons. The average number of CH_2 groups in aliphatic chains seems to be fairly constant over the whole molecular-weight range with a slight tendency to decrease in the subfractions of fraction 5. The average aliphatic chain lengths are somewhat different from those of Athabasca asphaltenes which were determined from C-13 NMR spectra (45). The fractionated Athabasca asphaltenes had larger variations in chain lengths ranging from 7 to 12 carbon atoms (including α carbons and end methyl carbons). Results of ruthenium(VIII) catalyzed oxidation of Athabasca asphaltenes also had indicated the methylene chain length distribution to range between 4 and 13 (46, 47). The discrepancy could be attributed to the assumptions made for calculations based on NMR spectra.

From Table 5, the degree of substitution on peripheral aromatic carbons decreased as the molecular weights decreased and the C (substitutable) to H ratio increased with decreasing molecular weight. The carbon aromaticity, calculated using

only substitutable aromatic carbons, increased as the molecular weight decreased. The value for fraction 5 (44%) is much higher than those of the other fractions. This does not necessarily mean that the number of aromatic carbons in low molecular-weight fractions is larger. High molecular-weight fractions may contain more non-substitutable aromatic carbons such as condensed aromatic rings and/or biphenyl type of structures which contain very few aromatic protons.

The "true" carbon aromaticities (from [9]) as well as the apparent carbon aromaticities, f_a, obtained by solid-state CP/MAS NMR spectra are shown in Table 5. Because the apparent aromaticity values vary with spectral conditions such as contact time (22), they are not absolute measures. Nonetheless, the f_a value for fraction 5 is much larger than those for other fractions where the variation is small. This trend agrees well with the calculated aromaticity values.

Petroporphyrin, V, and Ni contents

Ultraviolet–visible analysis directly detected the presence of petroporphyrins in all fractions of Cold Lake asphaltenes without extraction. The total porphyrin content of each fraction, estimated from the prominent absorbance peak at ~410 nm (Soret peak), is shown in Table 6. Although it was preferable to use the absorbance at 573 nm (α peak) for quantitative analysis

of porphyrins because high background can flatten the Soret peak at 410 nm (38), this weaker peak was not measurable in fractions with very low porphyrin content (fractions 1 to 4). However, for fraction 5 and its subfractions, the 573 nm peak was easily measured over a series of dilutions. The porphyrin concentrations determined using the absorbance readings at 410 nm ($\epsilon = 45 \times 10^4$) and at 573 nm (average $\epsilon = 2.5 \times 10^4$) were in close agreement. The ratio of the two extinction coefficients at 410 nm and at 573 nm is 18:1. From the measurements, the average ratio of the absorbance readings at 410 nm and at 573 nm (A_{410}:A_{573}) was also found to be approximately 18:1. Therefore, the petroporphyrin content of the various fractions of Cold Lake asphaltenes was determined from the absorbance at 410 nm (Table 6). Approximately 80% of all the petroporphyrins detected were contained in fraction 5. Other studies (3, 11, 12, 38, 39, 48) using extracted petroporphyrin fractions have also reported that vanadium petroporphyrins occurred in a narrow, low molecular-weight band corresponding to the 800 molecuar weight polystyrene standard. The fact that low porphyrin concentrations were found in the high molecular-weight fractions suggests that porphyrins are not involved in geothermal chemical reactions such as polymerization or aromatization. Although the distribution of porphyrin structures was concentrated in fraction 5, they were minor components in these fractions. For example, the actual concentration of petroporphyrins was only about 2% (by weight) in subfraction 5-4, which contained the largest proportion (29%) of petroporphyrins (Table 6).

Vanadium and nickel were the main metallic elements found in bitumen (49, 50). Their contents in each of the fractions are listed in Table 7. Nickel was distributed fairly evenly through all fractions, except in the two lightest fractions where the concentration was approximately double of others. The vanadium concentration in fraction 5 was twice as high as that in the heavier fractions. By ESR measurements, only paramagnetic vanadium cations (V(II) and V(IV)) were detected. The order of magnitude found by ESR was the same as the amount detected by ICP. Therefore, the results suggest that most of V in asphaltenes exist in paramagnetic forms such as VO^{2+}.

[c]ND, not detected.

The vanadium content seemed to vary together with the porphyrin concentrations. Because petroporphyrins are known to be associated with vanadium (49, 50), the percent of vanadium associated with petroporphyrins have been estimated assuming all porphyrins were vanadium complexes. The data are also shown in Table 7. In the fraction with the highest porphyrin concentration, fraction 5-4, about 58% of vanadium was found to be associated with porphyrins. Smaller portions were associated in the heavier fractions. Non-porphyrin metal (V and Ni) complexes seem to be distributed over the whole range of molecular weights and constitute a majority of the metal containing compounds. These results agree with studies

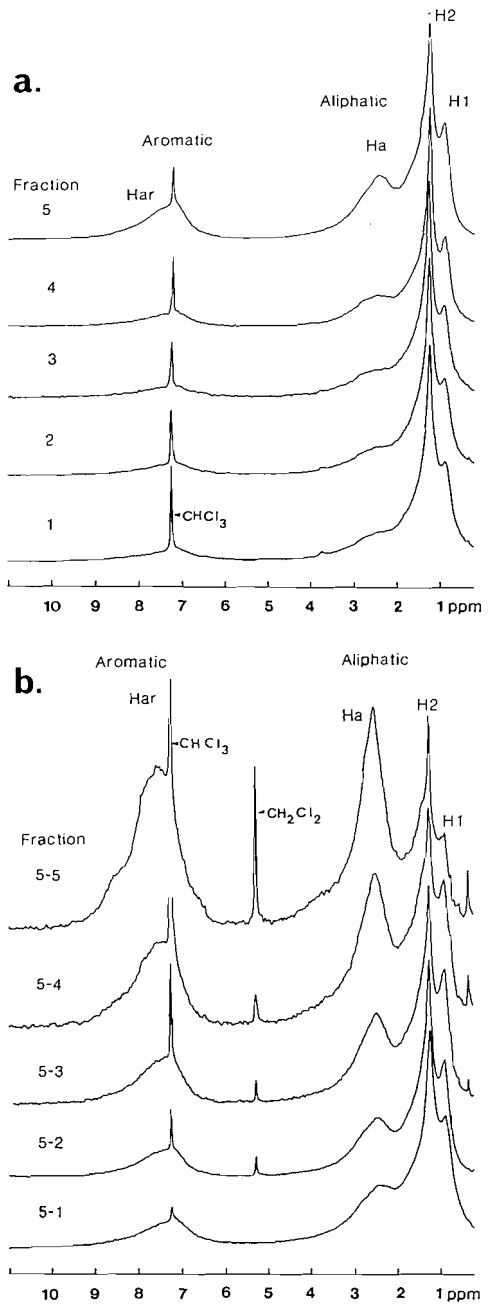

FIG. 3. Proton NMR spectra of (*a*) the five major asphaltene fractions and (*b*) the five subfractions of fraction 5. Designations for aromatic and aliphatic protons are shown: Har = aromatic protons; H1 = methyl protons at the end of aliphatic chains; H2 = methylene protons; Ha = protons α to aromatic carbons. on the size distribution and characterization of porphyrin and non-porphyrin metal complexes in asphaltenes from Athabasca and Cold Lake bitumen (51, 52) and other oils (11, 12, 38, 39, 48, 49, 51–55).

In summary, the nature of the average chemical structures is not uniform in asphaltenes throughout their molecular weight range. The very low molecular-weight fractions have very different chemical characteristics from heavy fractions. From the estimated number of inner non-substitutable carbons, the size of aromatic moieties decreased with the molecular weight except for fraction 5, where the size abruptly increases. The $C/100H$ ratio for fraction 5 was higher than the other fractions indicating fewer protons in the low molecular-weight fractions. Inspite of this, the degree of substitution on available aromatic carbons decreased with decreasing molecular weight. This implies the presence of fewer aliphatic carbons and agrees with the high aromaticity in low molecular-weight fractions. In addition, the porphyrin-type structure and vanadium were not uniform throughout the fractions. Based on these analyses, the various fractions of Cold Lake asphaltenes have different chemical moieties. These will likely have different susceptibilities to enzymatic or microbiol attack.

Copper(I) chloride catalyzed cross-dehydrocoupling reactions between silanes and ethynyl compounds. A new method for the copolymerization of silanes and alkynes

HUA QIN LIU AND JOHN F. HARROD
Chemistry Department, McGill University, Montreal, P.Q., Canada H3A 2K6

Received November 27, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

HUA QIN LIU and JOHN F. HARROD. Can. J. Chem. **68**, 1100 (1990).

In the presence of an amine, copper(I) chloride is an effective catalyst for the cross-dehycrocoupling of silanes with alkynes. The reactions proceed at useful rates above 100°C, but rates drop dramatically on going from 1° to 2° to 3° organosilanes. Primary silanes, $RSiH_3$ (R = Ph, *n*-hexyl), react in a stepwise fashion with phenylacetylene to give the products $RSiH_{3-x}(CCPh)_x$ ($x = 1-3$), each of which has been isolated and characterized. The secondary silanes $RR'SiH_2$ (R = R′ = Ph; R = Ph, R′ = Me; R = *n*-Bu, R′ = Me) also give mono- and diphenylethynyl products. The dehydrocoupling reaction has been applied to the synthesis of new polymers containing both acetylene units and silicon atoms in the backbone. 1,3-Diethynylbenzene gives polymers of relatively high molecular weight ($\overline{M}_w \approx 10^4-10^5$) with phenylsilane and phenylmethylsilane, but reactions of phenylmethyldiethynylsilane are too slow to give anything beyond low molecular weight oligomers.

Key words: organosilanes, alkynes, dehydrocoupling, copper(I) chloride, polymers, catalysis.

HUA QIN LIU et JOHN F. HARROD. Can. J. Chem. **68**, 1100 (1990).

En présence d'une amine, le chlorure de cuivre(I) est un catalyseur efficace pour le déhydro-couplage croisé des silanes avec les alcynes. Les réactions se produisent à des vitesses raisonnables lorsqu'on opère au-dessus de 100°C; toutefois, les vitesses diminuent d'une façon dramatique lorsqu'on passe des organosilanes 1° aux 2° et aux 3°. La réaction des silanes primaires, $RSiH_3$ (R = Ph, *n*-hexyle), avec le phénylacétylène se produit par étape pour donner les produits $RSiH_{3-x}(CCPh)_x$ ($x = 1-3$); chacun de ces produits a été isolé et caractérisé. Les silanes secondaires $RR'SiH_2$ (R = R′ = Ph; R = Ph, R′ = Me; R = *n*Bu, R′ = Me) donnent aussi des produits mono- et di-phényléthynyles. On a appliqué la réaction de déhydro-couplage à la synthèse de nouveaux polymères dont la chaîne fondamentale contient à la fois des unités acétylènes et des atomes de silicium. Avec le phénylsilane et le phénylméthylsilane, le 1,3-diéthynylbenzène fournit des polymères de poids moléculaires relativement élevés ($\overline{M}_w \approx 10^4-10^5$); toutefois, les réactions du phénylméthyldiéthynylsilane sont tellement lentes que les seuls produits isolés sont des oligomères de bas poids moléculaires.

Mots clés : organosilanes, alcynes, déhydro-couplage, chlorure de cuivre(I), polymères, catalyse.

[Traduit par la revue]

Introduction

The unusual electronic properties of polyenes, polyynes, and polysilanes have attracted a great deal of attention in recent years (1, 2). A number of workers have drawn attention to the similarity that exists between the delocalized π-bonding systems of the carbon chains in polyenes and the delocalized σ-bonding systems of the silicon chains in polysilanes (3). It is obvious that mixed chains of unsaturated carbons and of silicons are of a similar interest. However, synthetic routes to such chains are presently very limited.

In this paper, we present the results of a preliminary study of a promising new methodology for the production of copolymers of silanes and acetylenic compounds based on dehydrogenative coupling. Primary silanes have already been polymerized by catalytic dehydrocoupling with some success (4). The initial experiments in the present work were performed in an attempt to use hydrosilylation of acetylenic groups as a means of cross-linking low molecular weight polysilanes bearing Si—H groups on the backbone. Since attempts using the conventional group 8, 9, and 10 catalysts, such as complexes of platinum or rhodium (5), were all unsuccessful we turned to the catalyst developed by Bluestein (6) for the hydrosilylation of acrylonitrile and its derivatives. To our surprise, this copper(I) chloride/amine catalyst led to the highly selective cross-dehydrocoupling of the reactants, with no evidence of hydrosilation.

To our knowledge there is only one case in the literature of such a reaction occurring cleanly and in high yield (7). In this case, the coupling was achieved with an iodine-modified chloroplatinic acid catalyst and, despite the normally high catalytic activity of platinum towards hydrosilation, the reaction is highly selective for dehydrocoupling at room temperatures. In two other cases, dehydrocoupling in low yield was found to accompany hydrosilation (8) and hydrogen transfer (9) reactions. In addition, acetylenes have been successfully coupled by copper(I) catalyzed oxidative coupling (10), but there was no evidence that the coupling can be carried out in the absence of oxygen.

We describe herein some coupling experiments using di- and trifunctional silanes with monofunctional acetylenes, followed by some studies on the formation of polymers using di- and trifunctional silanes with difunctional acetylenes.

Results and discussion

Cross-dehydrocoupling reactions between silanes and phenylacetylene

Copper(I) chloride is an active catalyst for the dehydrocoupling reaction between phenylsilane (PS) and phenylacetylene (PA). In the presence of CuCl and N,N,N′,N′-tetramethylethylenediamine (TMED), or tributylamine, PS and PA react cleanly and rapidly under inert atmosphere, at temperatures around 100°C, to give the cross-dehydrocoupling products: $PhSiH_2CCPh$, **1**, $PhSiH(CCPh)_2$, **2**, and $PhSi(CCPh)_3$, **3**, depending on the initial ratio of the two monomers, and on the reaction time (eqs.[1]–[3]).

[1] $PhSiH_3 + PhCCH \rightarrow PhSiH_2(CCPh) + H_2$ **1**

[2] $PhSiH_2(CCPh) + PhCCH \rightarrow PhSiH(CCPh)_2 + H_2$ **2**

[3] $PhSiH(CCPh)_2 + PhCCH \rightarrow PhSi(CCPh)_3 + H_2$ **3**

TABLE 1. Dehydrocoupling reaction of phenylsilane and phenylacetylene under different reaction conditions

$[PhSiH_3]$ (M)	[PhCCH] (M)	[CuCl][a] (M)	T (°C)	t (h)	Conversion[b] (mol%)	Composition of products (mol%) 1	2	3
4	4	0.27	100	18	60	67	33	0
2.8	5.6	0.19	100	18	70	4	61	35
1.8	5.4	1	90	3.5	80	0	0	100

[a]CuCl:TMED molar ratio is 1:1.1.
[b]Conversion based on phenylsilane.

The reaction leads to the successive formation of **1, 2**, and **3** when carried out with an excess of phenylacetylene. The conversion of **2** to **3** requires much longer reaction times than the two first additions, but in the presence of high concentrations of catalyst and a sufficient amount of phenylacetylene, this reaction can be pushed essentially to completion (see Table 1).

Traces of styrene and 1,4-diphenylbutenyne (*cis* and *trans*), formed by Straus reaction (11), were detected in the reaction products. No trace of homocoupling product was found and the catalyst was found to be completely ineffective for the dehydrocoupling of the silane alone. The hydrogen evolved from the reaction was identified by ^1H NMR at 4.6 ppm in $CDCl_3$. The structures of compounds **1, 2**, and **3** were confirmed by ^1H and ^{13}C NMR and $^1H/^{13}C$ heterocoupling NMR, mass spectroscopy, and, for compounds **1** and **2**, elemental analysis. These data are summarized in Table 7 and in the experimental section.

The presence of amine is essential for the catalytic activity of CuCl but, on the basis of a comparison of tributylamine and TMED (Table 2), it appears that the nature of the amine has little effect on the reaction rate or the final products.

The influence of temperature on the reaction rate is large. At a 1:1 molar ratio of phenylsilane:phenylacetylene and a 15:1 ratio of monomer:CuCl, the rate of reaction was negligible at room temperature. The initial rate of consumption of phenylsilane increased from 7.3×10^{-5} M s^{-1} at 57°C to 1.1×10^{-3} M s^{-1} at 110°C, a factor of ca. 15 for the increase of ca. 50°C, or an Arrhenius coefficient of ca. 57 kJ/mol.

The initial rate of reaction increases with increasing catalyst concentration, but not in simple proportion. For example, increasing the CuCl concentration by a factor of 6 (from 0.047 to 0.27 M) increased the initial reaction rate by a factor of 10 (from 1.1×10^{-4} to 1.1×10^{-3} M s^{-1}).

A number of other silanes were studied to evaluate their reactivity with phenylacetylene. Diphenylsilane (DPS), phenylmethylsilane (PMS), and *n*-hexylsilane react with phenylacetylene in the same manner as phenylsilane to give mono-, di-, and (for *n*-hexylsilane) triphenylethynyl products. Some typical results for these reactions are summarized in Table 3.

The structures of the coupling products were assigned on the basis of their mass, ^1H, and ^{13}C NMR spectra. The MS results and the ^{13}C NMR chemical shifts of the phenylethynyl products are given in Table 8.

A study of the rates of coupling for different silanes indicates that the reactivity of the silanes decreases in the following order (Table 4):

$$PhSiH_3 >> n\text{-}C_6H_{13}SiH_3 > Ph_2SiH_2 > PhMeSiH_2$$

Although a number of possible mechanisms can be invoked on the basis of the foregoing results, one based on the initial formation of the cuprous acetylide seems most likely to us. It is well known that terminal alkynes react with CuCl to form acetylides (12, 13), thus:

TABLE 2. The influence of the amine on the rate of reaction of phenylsilane with phenylacetylene ($PhSiH_3$:PhCCH = 1:1)

$[PhSiH_3]_0$ (M)	[TMED] (M)	$[Bu_3N]$ (M)	[CuCl] (M)	$V_i \times 10^4$ (M s^{-1})
4	0.29	0	0.27	5.7
3.7	0.16	0.41	0.24	4.4
3.8	0	0.49	0.25	4.2

[4] RCC—H + CuCl → RCC—Cu + HCl

This reaction has been widely applied in organic synthesis (13). Hence, it is very likely that the first step of the dehydrocoupling involves such a reaction. In the second, rate-determining step, the cuprous acetylide probably reacts with the silane to form phenylethynyl substituted product and copper(I) hydride, thus:

[5] PhCC—Cu + $R^1R^2R^3$Si—H → PhCCSi$R^1R^2R^3$ + CuH

The catalytic cycle would then be completed by reaction of CuH with another phenylacetylene molecule to regenerate the cuprous phenylacetylide and evolve hydrogen, as shown in eq. [6].

[6] CuH + PhCC—H → PhCC—Cu + H_2

Reaction [5] most likely takes place through a four-center intermediate (eq.[7]), similar to that proposed for the "heterolytic" activation of H_2 by copper(I) complexes (14). In such a process, the nucleophilic acetylide displaces a hydride from the Si to the Cu. Thus, the more electrophilic the Si, the more easily the reaction will proceed. Lucovsky (15) and Sahn *et al.* (16) found that the infrared stretching frequency for Si–H in a series of silanes was proportional to the sum of the electronegativities of the substituents. Application of this correlation to the silanes used in the phenylacetylene dehydrocoupling experiments (see IR frequencies in Table 5) leads to the following ordering in terms of increasing electronegativity sum for the substituents

[7] 
$$PhMeSiH_2 \cong Ph_2SiH_2 < n\text{-}C_6H_{13}SiH_3 < PhSiH_3$$

This sequence corresponds to the observed rate sequence. However, the small range of the IR frequencies renders the correlation rather tenuous and it is almost certainly the case that steric effects also play a role in determining the reactivity of the silane. The relatively modest differences in rate for the

production of the mono-, di-, and triethynyl products from primary silanes (see Table 1) strongly suggest that the greater electron-withdrawing power of the ethynyl group compensates for its greater size relative to the H atom. On the other hand, the lower electronegativity and larger steric requirements of alkyl groups are in accord with the low activity of dialkylsilanes and the extremely low reactivity of trialkylsilanes.

Dehydrocoupling polymerization of PS and PMS with m-*diethynylbenzene (DEB) and phenylmethyldiethynylsilane (PMDS)*

m-Diethynylbenzene reacts with phenylsilane in the same manner as phenylacetylene and leads to the formation of polymers. Depending on the molar ratio between the monomers and cuprous chloride, the reaction temperature, and the reaction time, the reaction products may be low molecular weight oligomers or relatively high molecular weight polymers. The evolution of the various SiH_n groups in the course of a dehydrocoupling reaction of DEB and phenylsilene in a typical reaction is given in Table 6.

These data show that the reaction proceeds in two stages. The first is a coupling reaction between the initial reactants to form a new cross-coupled monomer, **4**:

[8] $PhSiH_3 + HC{\equiv}C$–C$_6$H$_4$–$C{\equiv}CH \longrightarrow$

$H_2Si(Ph)C{\equiv}CC_6H_4C{\equiv}CH + H_2$

4

For personal use only.

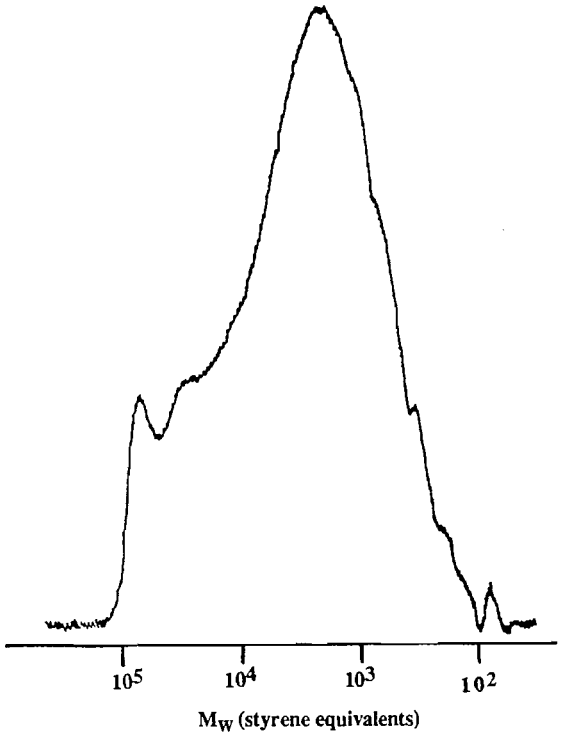

FIG. 1. Gel permeation chromatogram of a phenylsilane/DEB polymer.

In the second stage, this cross-coupled species reacts with either the small amounts of initial monomers remaining, or with other cross-coupled monomers to give higher oligomers, e.g.,

[9] $2\ H(SiHPhC{\equiv}CC_6H_4C{\equiv}C)_n\ H \rightarrow$

$$H(SiHPhC{\equiv}CC_6H_4C{\equiv}C)_{2n}\ H + H_2$$

At a molar ratio of monomer:CuCl of ca. 13:1, very high reaction temperatures are required to yield high molecular weight material. However, such reaction conditions are likely to induce cross-linking reactions. For example, after reacting at 100°C for 41 h, the degree of polymerization (DP) of the product is only about 4 for the conditions listed in Table 6. The same reaction performed at 90°C for 20 h, followed by a further 20 h at 120°C, gives a much higher molecular weight product with a DP ranging from 30 up to about 500 (see Fig. 1). These polymers remain soluble in common organic solvents.

Analysis of the polymers by ^1H NMR confirmed the presence of the tertiary Si-H at 5.2 ppm, the secondary Si-H at 4.75 ppm, and the ethynyl hydrogen at 3.1 ppm. The presence of C≡C was also confirmed by ^{13}C NMR (107.2 and 86.6 ppm.). The presence of these functional groups was also detected by infrared spectroscopy, ($\nu_{Si\text{-}H}$ at 2156 cm^{-1}, $\nu_{C{\equiv}C\text{—}H}$ at 3295 cm^{-1}, $\nu_{Si\text{—}H}$ at 473 and 492 cm^{-1}).

The high polydispersity of the high molecular weight material is most likely due to side reactions of the triple bonds, leading to branching and cross-linking. Increasing the ratio of CuCl:monomers from 1:14 to 1:4 results in the formation of insoluble polymer after 20 h at 90°C. Using a secondary silane such as phenylmethylsilane eliminates the cross-linking problem but the reaction rate is much slower and it is more difficult to achieve high molecular weight, even at very high catalyst concentrations. For a molar ratio of CuCl:monomer of 1:3 and at 100°C for 3 days, a polymer of $\overline{M}_w$ = 18 000 was obtained. It should be noted that, given the level of purity of the monomers

and the existence of side reactions, higher molecular weights than those observed would not be expected.

The cross-coupling of phenylsilane with phenylmethyldiethynylsilane also requires more forcing reaction conditions, because of the lower reactivity of the acetylene. For example, with a molar ratio of CuCl:monomer of 1:14 at 115°C for 22 h, most of the product consisted of the dimer **5**, by ^1H NMR analysis.

$$H_2Si(Ph)C{\equiv}CSi(PhMe)C{\equiv}CH$$

5

The highest molecular weight product obtained after 9 h at 130°C was only tetramer. Higher molecular weight material was formed by using CuCl equimolar with the two reactants. The $\overline{M}_w$, by GPC analysis, was 8000 (see Fig. 2). The freshly prepared polymer is soluble in common organic solvents but becomes insoluble after several days even under inert atmosphere. As would be expected from the reactivity patterns described above, cross-coupling of phenylmethylsilane with PMDES is extremely slow. For a molar ratio of CuCl:monomer of 1:2 after 18 h at 110°C, the reaction only leads to oligomers with $\overline{M}_w$ 1500, by GPC analysis.

Conclusion

The surprising reactivities of mono- and disubstituted silanes

with acetylenic monomers by cross-dehydrocoupling opens up an attractive new route to the synthesis of new simple and polymeric compounds containing both Si atoms and C≡C bonds in the same molecule. Such compounds could be useful in organic synthesis, or as novel electronic materials. The first generation of catalysts leaves much to be desired in terms of activity and it is hoped that they can be improved upon in the future. Although more work needs to be done to increase the molecular weights of the polymers, the simplicity and the effectiveness of the catalytic system together with the highly functionalized nature of the polymers already make this reaction very attractive in terms of practical application.

Experimental

Phenylsilane, phenylmethylsilane, diphenylsilane, and *n*-hexylsilane were prepared using a previously described method (17). Phenylacetylene, TMED, and tributylamine (Aldrich Chemical Co.) were distilled once immediately prior to use. CuCl (Anachemia) was used as received. *m*-Diethynylbenzene, kindly furnished by Dr. A. S. Hay of this department, was distilled, trap-to-trap, under vacuum immediately prior to use. Phenylmethyldiethynylsilane was synthesized according to the literature (18).

^1H NMR spectra were recorded on a Varian XL-200FT spectrometer and ^{13}C NMR spectra on a Varian XL-300FT spectrometer. The assignments of the chemical shifts of the dehydrocoupling products were made using 2D NMR methods (COSY and $^1H/^{13}C$ HETECOR).

Mass spectra were measured on a Dupont 21-492B spectrometer at a potential of 70 eV, and on a ZAB-HS mass spectrometer using FAB with an atomic energy of 8 kV at 1 mA.

The molecular weights of polymers were measured on a Varian 5000 gel permeation chromatograph, equipped with a Waters Ultrastyragel 1000 Å column at 35°C, and with tetrahydrofuran as solvent. Polystyrene standards were used for calibration.

Infrared spectra were measured on an Analect AQS-18 FTIR spectrometer.

Synthesis of $PhSiH_2(CCPh)$ and $PhSiH(CCPh)_2$

Reactions were carried out in carefully dried standard glassware under nitrogen. The following is a typical reaction. A mixture of phenylsilane (1.7 mL; 13.6 mmol), phenylacetylene (1.5 mL; 13.6 mmol), TMED (0.14 mL; 1.1 mmol), and CuCl (90 mg; 0.9 mmol) was

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

heated at 100°C with stirring for 18 h. Initially, the reaction proceeded rapidly with visible evolution of hydrogen. After a few hours, gas evolution was no longer evident. On completion of the reaction, the product was triturated with a few millilitres of toluene and the catalyst was removed by filtration. Removal of the toluene under vacuum gave 1.95 g of crude product. Vacuum distillation (100°C, 10^{-3} Torr; 1 Torr = 133.3 Pa), gave 1.12 g of **1**. (Anal. calcd. for $C_{14}H_{12}Si$: C 80.71, H 5.81, Si 13.48; found: C 80.41, H 5.61, Si 13.39). The residue (0.83 g) was shown by ^1H NMR to be **2** (>95%). The viscous yellow oil was further purified by distillation under vacuum (160°C, 10^{-3} Torr). (Anal. calcd. for $C_{22}H_{16}Si$: C 85.67, H 5.23, Si 9.10; found: C 85.74, H 5.28, Si 8.98).

The molecular weights of compounds **1**, **2** and **3** were confirmed by the observation of molecular ions in their mass spectra at 208, 308, and 408 respectively. The ^{13}C NMR chemical shifts of these compounds are listed in Table 7.

The coupling reactions of phenylacetylene with phenylmethylsilane, diphenylsilane, and *n*-hexylsilane were performed using essentially the same procedure. The results of these reactions are summarized in Table 3. The ^{13}C NMR data for the products are listed in Table 8.

Polymerization reactions

The polymerization reactions were carried out using the same techniques described in the previous section. The following specific example provides a general picture of the methodology.

Reaction of phenylsilane with m*-diethynylbenzene*

Oxygen-free phenylsilane (1.0 mL; 8 mmol), DEB (1.0 mL; 8 mmol), TMED (0.10 mL; 0.067 mmol), and CuCl (60 mg; 0.6 mmol) were introduced into a stirred nitrogen-filled reactor. The mixture was heated to 110°C and the colour changed from yellow to red and then to dark green. After 20 h, the initially mobile mixture had become very viscous. The product was dissolved in a few millilitres of toluene and the catalyst was removed by filtration. The solvent was removed under vacuum and the polymer was dried under high vacuum. Yield: 0.94 g; 80%.

The experimental conditions for the other polymerization reactions are given in Table 9.

^{13}C magnetic resonance studies. 142.[1] The fate of highly substituted acyclic ketones in strong base: β-enolization, Haller–Bauer cleavage, and an alkyl to aryl acyl shift

RAINER A. DYLLICK-BRENZINGER, VIJAY PATEL,[2] MOLLIN B. RAMPERSAD, J. B. STOTHERS, AND SHIRLEY E. THOMAS

Department of Chemistry, The University of Western Ontario, London, Ont., Canada N6A 5B7

Received December 1, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

RAINER A. DYLLICK-BRENZINGER, VIJAY PATEL, MOLLIN B. RAMPERSAD, J. B. STOTHERS, and SHIRLEY E. THOMAS. Can. J. Chem. **68**, 1106 (1990).

Di-*tert*-butyl ketone (**2***a*), 5,5,7,7-tetramethyl-6-undecanone (**2***b*), and 2,4-dimethyl-2,4-diphenyl-3-pentanone (**2***d*) have been found to undergo slow rearrangement by β-proton abstraction from the α-methyl groups upon treatment with *t*-BuO$^-$/*t*-BuOH/≥185°C. This is in contrast to the absence of such rearrangement in cyclic systems. It is the only significant process observed for **2***a* and **2***b*, whereas with **2***d* and its monomethyl analog **22** Haller–Bauer type cleavage and an unprecedented 1,3-acyl shift from sp^3 to sp^2 carbon accompany the β-enolate rearrangement. The rates of $^1H/^2H$ exchange of the methyl protons in **2***a*, *b* were found to be similar to those reported for a variety of cyclic systems but this exchange does not occur in **2***d*, where only aryl proton exchange was observed.

Key words: β-enolization, acyclic ketones, acyl shift.

RAINER A. DYLLICK-BRENZINGER, VIJAY PATEL, MOLLIN B. RAMPERSAD, J. B. STOTHERS et SHIRLEY E. THOMAS. Can. J. Chem. **68**, 1106 (1990).

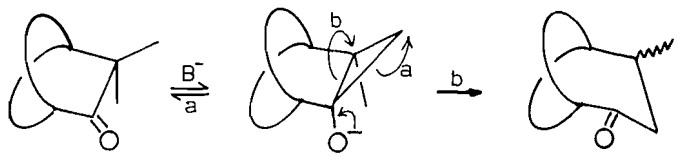
On a trouvé que, si on soumet la di-*tert*-butyl-cétone (**2***a*), la 5,5,7,7-tétraméthyl-undécan-6-one (**2***b*) ainsi que la 2,4-diméthyl-1,4-diphényl-pentan-3-one (**2***d*) à un traitement par le *tert*-BuO$^-$/*tert*-BuOH/≥185°C, il se produit une transposition lente impliquant un enlèvement du proton-β des groupements méthyles en α. Ce résultat est en opposition avec le fait que l'on n'observe pas de telles transpositions dans les systèmes cycliques. Cette transportation est le seul processus qui est observé à partir des composés **2***a* et **2***b* alors que, avec le produit **2***d* ainsi que son analogue monométhylé **22**, on observe un clivage de Haller–Bauer et un déplacement acyle-1,3 sans précédent du carbone sp^3 vers le carbone sp^2 qui accompagne la transposition de l'énolate β. On a trouvé que les taux d'échange $^1H/^2H$ des protons des groupements méthyles des composés **2***a* et **2***b* sont semblables à ceux rapportés antérieurement pour une variété de systèmes cycliques; toutefois, cet échange ne se produit pas avec le produit **2***d* alors que l'on n'observe que l'échange des protons aromatiques.

Mots clés : β-énolisation, cétones acycliques, déplacement acyle.

[Traduit par la revue]

Introduction

Over the past several years since the original discovery of the homoenolization process (1), the rearrangements of many cyclic monoketones have been found to occur through proton abstraction from carbons remote from the carbonyl group (2), generally from β-methylene carbons via β-enolates but with a few examples of γ-enolization leading to rearrangement (3). In most cases α-enolization was precluded as a competitive process, through α-methyl substitution or structurally with an α-proton at a bridgehead such that only an anti-Bredt α-enolate could be formed. Generally the investigations of these processes of remote proton abstraction have included examination of $^1H/^2H$ exchange to establish the regio- and stereoselectivity of proton abstraction. Invariably, exchange has been found to occur at the α-methyl sites but no ring-expanded products have been observed corresponding to those expected through ketonization of the putative cyclopropoxide intermediate **1**, i.e., cleavage *b* in Scheme 1. Evidence has been presented (4) in support of cyclopropoxide species as reasonable intermediates for α-methyl exchange in cyclic systems, and one example of rearrangement through an α-methyl carbon in a bicyclic diketone has been described (5). In contrast to the cyclic systems, however, some acyclic monoketones do undergo skeletal isomerization through β-enolizable methyl groups as was first observed with di-*tert*-butyl ketone and 5,5,7,7-tetramethylundecan-6-one (6). While this rearrangement is a very slow process for these aliphatic systems, a marked increase in the rate of rearrangement was observed for 2,4-dimethyl-2,4-diphenyl-3-pentanone (7). In addition, products from the competitive rearrangement involving an acyl shift from alkyl to aryl carbon were found, together with significant amounts of acidic components arising from Haller–Bauer type cleavage. While the results of these studies have been described in preliminary form, we wish to present the full details of our examination of these and some closely related ketones.



1

SCHEME 1

Results and discussion

Homoenolization experiments

(*a*) *Saturated ketones*

As the first model compound for our examination of acyclic ketones, commercially available di-*tert*-butyl ketone (**2***a*) was selected and dried over 4Å molecular sieves. Following our usual procedures (8), **2***a* was dissolved in anhydrous *t*-BuO$^-$/*t*-BuOH to provide a solution 0.2 M in **2***a* and 0.7 M in base. Aliquots of this solution were transferred to glass tubes under nitrogen, sealed under vacuum, and heated at 195°C for various times. The products were recovered by extraction with pentane

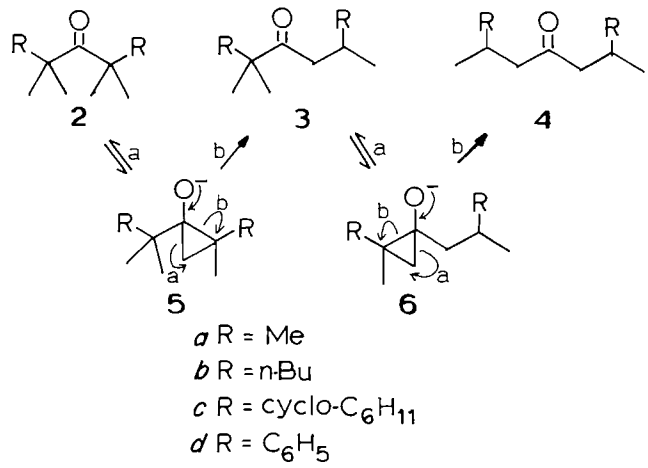
[b]Neutral products recovered in >90% yields.
[c]Total atoms ^{2}H/molecule by mass spectrometry.

(>90% yields) and analyzed by gas–liquid chromatography (glc) to reveal the presence of small amounts of a new component, in addition to the starting material, slowly increasing with increased reaction times (Table 1). After 75 h at 195°C, the new compound constituted 12% of the product and the amount doubled after 225 h; the data in Table 1 indicate that the pseudo first-order rate constant for rearrangement is $\sim 5 \times 10^{-7}$ s^{-1}. Longer reaction times gave only slightly greater amounts (26%, 350 h), as expected, since it has been shown that slow dehydration of *tert*-butyl alcohol occurs at elevated temperatures, leading to deterioration of the basic medium over reaction times >100 h (9), and some of the base is destroyed by reaction with the glass. In evidence of this, the product mixture, obtained after 200 h containing 22% of the new component, was treated with fresh base and found to contain 36% of the new ketone after 90 h at 195°C. Samples of the new ketone (1720 cm^{-1}, δ_C 215.3) were isolated by preparative glc and found to be identical to 2,2,5-trimethyl-3-hexanone (**3***a*) by ir and ^{1}H and ^{13}Cmr spectra. Samples of **3***a* in *t*-BuO$^-$/*t*-BuOH were heated at 195°C for up to 200 h and, in each case, **3***a* was recovered as the sole product in good yield (>80). Two samples were heated for >500 h; the recovered product contained very small amounts (<1%, by glc) of a second component having the same retention time as that of 2,6-dimethyl-4-heptanone (**4***a*) on three different glc columns. Two other tubes were heated at 210°C for 14 days and the neutral products also contained ~1% of the minor component, which was shown to be **4***a* by gc–ms.

The isomerization of **2***a* → **3***a* must involve proton abstraction leading to an intermediate β-enolate **5***a*, or its equivalent, which can suffer cleavage in two ways: path *a*, to regenerate **2***a*, or through cleavage of the original C-2, -3 bond, path *b*, to form **3***a*. Since no **2***a* was detected in the product obtained by the treatment of **3***a* with base, the cleavage of **5***a* → **3***a* is unidirectional. Trace quantities of **4***a* indicated that β-enolate **6***a* is generated, presumably reversibly, from **3***a*. Evidence confirming the sequence **2***a* ⇌ **5***a* → **3***a* ⇌ **6***a* → **4***a* was provided by the examination of ^{1}H/^{2}H exchange of the *tert*-butyl hydrogens in each of **2***a* and **3***a* under these strongly basic conditions. While **4** could undergo condensation, no such products were detected. Exchange in **2***a* was observed at 230°C in *t*-BuO$^-$/*t*-BuOD several years ago but no quantitative data were provided and the product mixture was not examined (10*a*).

Upon treatment of **2***a*, with anhydrous *t*-BuOD as solvent, the recovered samples of **2***a*-d_x were analyzed by mass



spectrometry to determine the extent of ^{2}H incorporation as a function of time. From the ^{2}H content in samples heated for 25, 50, 100, 125, and 150 h (Table 1), the rate constant for ^{2}H exchange was found to be $\sim 35 \times 10^{-7}$ s^{-1}, or approximately 7 times the rate of rearrangement. Clearly, the formation of **5***a* from **2***a* is reversible. Similar experiments with **3***a* for 25, 50, and 75 h revealed that slow exchange of the *tert*-butyl hydrogens (Table 1) accompanies rapid exchange of the α-methylene hydrogens, showing that the formation of **6***a* from **3***a* is also reversible. For each **3***a*-d_x sample, the ^{2}H content was determined by mass spectrometry and the proportions at the two sites of exchange were measured by integration of the ^{2}Hmr spectra. The rapid equilibration of the deuterium pool through α-exchange, however, may render the observed rate for β-exchange, $\sim 45 \times 10^{-7}$ s^{-1}, as a lower limit. In any event, β-exchange in **3***a* is twice as fast as that in **2***a*, on a per hydrogen basis, perhaps because of reduced steric strain, from nonbonded interactions, in **6***a* relative to that in **5***a*.

The second system chosen for examination was 5,5,7,7-tetramethylundecan-6-one (**2***b*) which, in principle, could undergo rearrangement through β-enolizable methyl groups and (or) the β-, or more remote, methylene sites. Ketone **2***b* was prepared by repeated methylation of the commerically available parent ketone with MeI/$NaNH_2$/Et_2O and then subjected to the usual homoenolization conditions. A glc analysis of the neutral product, isolated by pentane extraction, (>90% yields), revealed the presence of slowly increasing amounts (Table 1) of one new ketone (1710 cm^{-1}, δ_C 215.3), which was found to be isomeric with **2***b* by precise mass measurement. Samples for characterization were readily obtained by preparative glc. The ^{13}Cmr spectrum of the new ketone contained signals (δ_C, $CDCl_3$) for five methyl carbons, two of which are equivalent, at 14.0, 14.1, 20.0, and 24.3 (2), seven methylene, one methine, and a quaternary carbon, in addition to the carbonyl carbon signal. Clearly one methyl carbon has become a methylene carbon and the ^{13}C data accord well with those expected for **3***b*. An authentic sample of **3***b* was synthesized independently. Treatment of *N-tert*-butyl isobutyraldehyde imine, prepared according to House *et al.* (11), with *n*-butyllithium followed by the addition of *n*-butyl bromide gave *N-tert*-butyl 2,2-dimethylhexanal imine **7**. Hydrolysis of **7** afforded 2,2-dimethylhexanal (**8**), which was reacted immediately with propane-1,3-dithiol, as described by Seebach (12), to provide dithiane **9** (Scheme 2) in 75% yield. After lithiation of **9** with butyllithium, reaction with 1-bromo-2-methylhexane (**10**) gave dithiane **11** in 76% yield. Bromide **10** was prepared from the corresponding alcohol,

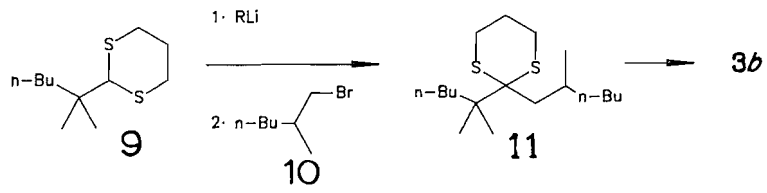
For personal use only.



SCHEME 2

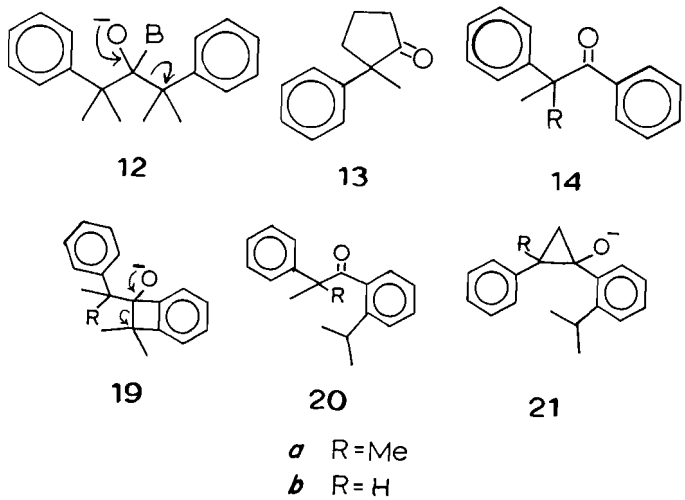
obtained from allyl alcohol in 77% yield by the method of Crandall and Clark (13), through reaction of its tosylate with sodium bromide in DMSO. Hydrolysis of **11** gave ketone **3*b***, in 67% yield, which was identical by ir, ms, and ^{1}H and ^{13}Cmr spectra with the rearrangement product from **2*b***. Treatment of **3*b*** with *t*-BuO$^-$/*t*-BuOH at 195°C for as long as 300 h led simply to the recovery of starting material in good yield (>80%) with no evidence of the presence of any isomeric ketone. Thus, **3*b*** is formed irreversibly from β-enolate **5*b***, or its equivalent. We found no evidence of a second β-enolate rearrangement leading to **4*b***.

As in the di-*tert*-butyl ketone system, experiments in deuterated media were carried out with **2*b*** and **3*b*** separately. Samples of **2*b*-d_x** isolated after 75 and 200 h in *t*-BuO$^-$/*t*-BuOD at 195°C contained 0.25 and 0.48 atoms ^{2}H/molecule, respectively, by mass spectrometry and each gave rise to an ^{2}Hmr spectrum containing a single peak corresponding to that expected for the α-methyl deuterons. Upon the addition of increasing amounts of Eu(fod)$_3$, this signal exhibited the same shifts as those found for the α-methyl protons in the ^{1}Hmr spectrum. Thus, ^{2}H exchange occurred only at the α-methyl carbons with no evidence of proton abstraction from the methylene carbons. For the analogous test with **3*b***, samples were first treated with MeO$^-$/MeOD by refluxing overnight to provide [7,7-$^2H_2$]-**3*b***, 1.96 atoms ^{2}H/molecule, which was heated at 195°C for 150 and 300 h in *t*-BuO$^-$/*t*-BuOD. After isolation of these **3*b*-d_x** samples, the α-deuterons were back-exchanged with MeO$^-$/MeOH before mass spectrometric analysis, which indicated incorporations of 0.67 and 0.88 atoms ^{2}H/molecule. The ^{13}C and ^{2}Hmr spectra of these samples showed that exchange occurred only at the α-methyl sites and from these data for **2*b*** and **3*b*** approximate rate constants for exchange at the α-methyl sites are 10 and 20 × 10^{-7} s^{-1}, respectively. Thus, the results for these two acyclic systems **2*a*** and **2*b*** are similar, although the β-exchange processes are somewhat slower for the latter case. It is interesting that proton abstraction from the β-methylene sites was not observed for either **2*b*** or **3*b***. From the exchange rates, β-enolate formation at the methyl carbons is faster for the less hindered ketones **3*a, b***, presumably reflecting differences in strain energy in the β-enolates **5*a, b*** vs. **6*a, b***, as noted earlier.

One other ketone, 2,4-dimethyl-2,4-dicyclohexylpentan-3-one (**2*c***), was also examined but even after heating with *t*-BuO$^-$/*t*-BuOH for >200 h at temperatures up to 210°C there was no evidence of rearrangement and **2*c*** was recovered in 85–90% yields. Perhaps steric crowding precludes the formation of the requisite β-enolate **5*c*** (R = cyclo-C_6H_{11}) that could lead to rearrangement.

(b) α-Phenyl ketones

From the results for **2*a*** and **2*b*** it was apparent that proton abstraction from the α-methyl carbons proceeds at rates comparable to those found for this process at β-methylene sites in several polycyclic ketones (2), but the competition between the modes of cleavage as denoted by *a* and *b* for **5** is strongly biased toward path *a*. The presence of a suitable substituent R in **5**, however, could serve to stabilize the incipient carbanion formed via path *b* to favour generation of the chain-extended isomer **3**. To examine this possibility, we selected 2,4-dimethyl-2,4-diphenyl-3-pentanone (**2*d***) as a model system, although it was realized that cleavage of the Haller–Bauer type through an intermediate species **12** could become a major competitive reaction. For example, ketones **13** and **14** (R = ethyl, dimethylallyl, benzyl) undergo this cleavage exclusively upon treatment with *t*-BuO$^-$/*t*-BuOH (14, 15). However, the more hindered carbonyl group in **2*d*** could render the rearrangement process more likely, since "ideally, the site of Haller–Bauer cleavage should not be subjected to any element of serious steric compression" (15). Also, cleavage *b* in **5*d*** leads to a benzylic carbanion. Thus, one could anticipate a closer competition between the two cleavages of **5*d*** than in the **5*a, b*** systems and this proved to be the case. Earlier investigations had shown that the *tert*-butyl esters formed in the Haller–Bauer cleavage (see **12**) do not survive under the conditions employed and the corresponding carboxylic acids are isolated.



Treatment of **2*d*** with *t*-BuO$^-$/*t*-BuOH at 185°C following our usual methods with a slightly modified isolation procedure gave a neutral fraction containing, by glc analysis, four principal components with small amounts (<2%) of minor materials. These neutral products were isolated by pentane extraction after dilution of the reaction mixture with water and the addition of concentrated NH_4Cl solution to avoid the formation of emulsions. The aqueous layer was then acidified to pH ~1 before extraction with ether to isolate the acidic product. The glc analyses of the acidic fractions after methylation with CH_2N_2 revealed the presence of three esters in relative amounts that varied with reaction time. Several preliminary experiments were carried out using an oven that was subsequently found to have poor thermal stability over the long reaction times employed. Thus, although their reproducibility was poor, these experiments gave a qualitative picture of the sequence of

appearance of the various products and provided samples of each component for identification. Reproducible results were obtained from a series of runs in which the tubes were immersed in an oil-bath at 185 ± 1°C. The combined neutral and acidic fractions isolated typically represented >90% yields in each run. Samples of each component could be obtained by preparative glc or by chromatography on silica. Their structures were readily deduced from their ir and nmr spectra and the identity of each was confirmed by independent synthesis.

In the neutral fractions recovered from reactions for up to 136 h, the major component was easily shown to be the initial ketone **2***d* accompanied by three new components, which were found to be ketonic (ir, ^{13}Cmr) and isomeric with **2***d* by precise mass measurement. The first new ketone to appear in the neutral product exhibited carbonyl absorption at 1710 cm^{-1} with δ_C 211.0. The ^{13}Cmr spectrum contained signals for three methyl (21.4, 24.8, 25.1), one methylene (46.1), one methine (34.9), and a quaternary carbon (52.1) in the high field region. These data are clearly compatible with structure **3***d* and this was confirmed by its synthesis. The reaction of 2-methyl-2-phenylpropanal with 2-phenylpropyl magnesium bromide gave 2-methyl-2,5-diphenyl-3-hexanol, which was oxidized to **3***d*. The relative amount of **3***d* in the neutral fraction was found to increase slowly over ca. 100 h and then decrease in the product isolated after longer reaction times.

The second new ketone (1720 cm^{-1}), initially appearing more slowly than **3***d*, became the major component in the neutral fractions isolated after reaction times >200 h. Its ^{13}C spectrum contained three, equally intense, absorptions for methyl, methylene, and methine carbons in the sp^3 region. While a single methyl signal was found (δ_C 21.9), the methylene and methine absorptions each consisted of a pair of closely spaced signals at δ_C 51.7, 51.9 and 35.2, 35.3, respectively. In addition to two carbonyl peaks, δ_C 208.8, 208.7, signals for phenyl carbons were found at 126.2, 126.8 (2), 128.5 (2), and 146.2. In contrast to the equivalence of the methyl carbons, the methyl protons gave rise to a pair of equally intense doublets at δ 1.17 and 1.21 with J = 7 Hz for each. The ^{1}H spectrum also contained a broad singlet, δ 7.20 (10 H), a broadened "sextet" centred at δ 3.30, and a multiplet at 2.6; these two multiplets exhibited a 1:2 intensity ratio with the total equal to that of the methyl absorptions. These data are consistent with those expected for **4***d* as a 1:1 mixture of diastereomers.

Small amounts of the same mixture were obtained from a four-step preparative sequence analogous to that employed for the synthesis of **3***b*. Reaction of lithio 2-(2-phenylpropyl)-1,3-dithiane with β-bromocumene followed by hydrolysis gave **4***d* in low yield. In both cases, **4***d* was isolated as an oil but attempts to crystallize the mixture from MeOH at −70°C afforded colourless crystals, mp 40–45°C. The nmr spectra of the crystalline material indicated that the proportion of diastereomers changed to ca. 2:1, since the lower field methyl doublet (δ 1.21) and the higher field methine (δ_C 35.2) and methylene (δ_C 51.7) signals were twice as intense as their counterparts at δ 1.17 and δ_C 35.3, 51.9, respectively.

The third new ketone (1690 cm^{-1}, δC 205.3), which was the minor component in the neutral product from reactions of up to 136 h, gave rise to absorptions for three methyl (δ_C 22.1, 24.2_0, 24.2_4), one methylene (51.4), and two methine carbons (29.3, 35.8) in the high field region of its ^{13}Cmr spectrum. In the ^{1}H spectrum, a pair of overlapping methyl doublets, δ 1.13, 1.16, each with J = 6.5 Hz, and a septet, δ 3.10, J = 6.5 Hz, readily revealed the presence of an isopropyl group. The remaining methyl protons gave rise to a doublet, δ 1.33, J = 6.9 Hz, due to coupling with a methine proton at δ 3.47 appearing as a broadened sextet, which upon irradiation of the 1.33 ppm doublet collapsed to a four-line pattern representing the X part of an ABX pattern. The methylene protons gave rise to the AB portion of this pattern: δ_A 3.08, δ_B 3.19, J_{AB} = 16.4 Hz, J_{AX} = 7.8 Hz, J_{BX} = 6.5 Hz. Although the aryl proton absorption, 7.1–7.4 (m, 9H) was not particularly informative, seven protonated aryl carbon signals were resolved, two of which were twice as intense as the other five: δC 125.3, 126.3, 126.5, 126,8, 126.9 (2), 128.5 (2), 130.7; these signals were accom-

panied by three peaks for fully substituted sp^2 carbon: δ_C 139.5, 146.2, 147.4. These data led to its tentative identification as 1-*o*-cumyl-3-phenyl-1-butanone **15** and this was confirmed by subsequent experiments described later.

The two major components of the acidic fractions were expected to be the methyl esters of 2-methyl-2-phenylpropionic acid (**16**) and 3-phenylbutyric acid (**17**) through Haller–Bauer cleavage of **2***d* and **3***d* as a result of addition at the carbonyl carbon by the alkoxide base, the collapse of which generates the benzylic cumyl anion as the leaving group (see **12**). The structures of these esters were confirmed, after isolation by preparative glc, by comparison with authentic samples obtained by methylation of the commercially available carboxylic acids. The third ester in the acidic fraction was shown to be isomeric with them by precise mass measurement. Its nmr spectra clearly showed the presence of an isopropyl group δ 1.24 (d, J = 7 Hz, 6H), δ_C 24.0; δ 3.73, (septet, J = 7 Hz, 1 H), δ_C 29.6, a methoxyl group (δ 3.86, δ_C 51.8) together with four equally intense protonated carbon signals (δ_C 125.5, 126.2, 129.9, 131.8), signals for two fully substituted carbons (130.0, 149.7), and a carboxyl carbon (168.7). The aryl protons gave rise to three multiplets centred at δ 7.20 (m, 1H), 7.40 (m, 2H), 7.75 (bd, J ~ 8 Hz, 1H). These data served to identify this ester as methyl 2-isopropylbenzoate and its properties were found to be identical to those of an authentic sample prepared from **18** using 2-isopropylacetophenone via the haloform reaction and methylation with CH_2N_2/Et_2O.

For the initial experiments, the compositions of the acidic fractions were assessed by glc analysis of the mixtures after methylation. In subsequent runs, these data were obtained from the ^{13}C spectra of the acid mixtures and by glc analysis after silylation (16) of the mixtures. The compositions of the neutral fractions were determined by ^{13}Cmr and glc analysis.

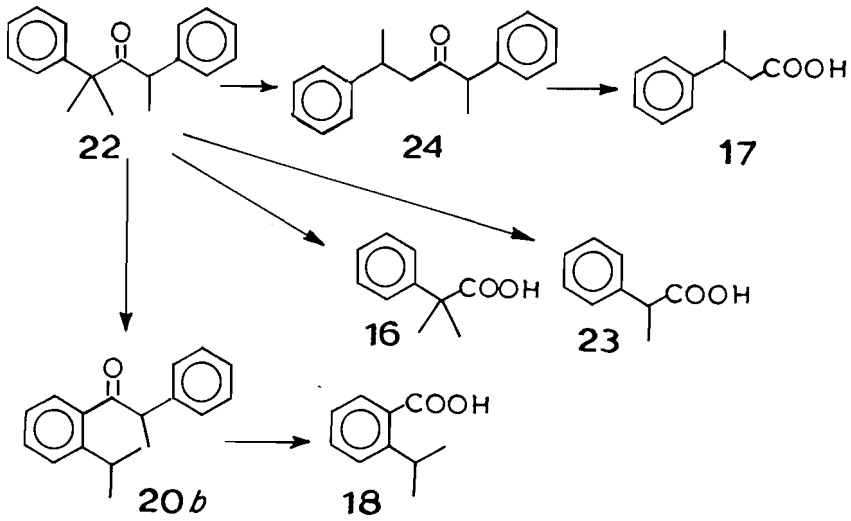
From the distribution of the various components in the neutral and acidic fractions (Table 2), it was apparent that skeletal rearrangement through β-enolization at the methyl groups does indeed compete with Haller–Bauer cleavage, in contrast to the situation found earlier for the less hindered ketones **13** and **14** (14, 15). In addition, a third process was discovered leading to the formation of **15**. The sequence **2***d* → **3***d* → **4***d* is readily explicable in terms of the β-enolate intermediates, **5***d* and **6** *d*, respectively, as in the saturated acyclic examples. However, the formation of **6***d* is a much more favoured process for the α-phenyl system, even though it competes with α-enolization.

Experiments with **2***d* in *t*-BuO$^-$/*t*-BuOD showed that ^{2}H exchange involved only the aryl protons since only aryl ^{2}H absorption was evident in the ^{2}Hmr spectra of the recovered **2***d*–d_x samples; none was detected at the methyl sites. Deuterium assays by mass spectrometry showed incorporations of 3.5 and 5.3 atoms ^{2}H/molecule after 16 and 88 h, respectively. Thus, the cleavage of β-enolate **5***d* proceeds exclusively through path *b*, in contrast to the results for the saturated acyclic systems. The regiospecificity of the cleavage of **5***d* is presumably governed by the fact that the incipient tertiary anion formed by this cleavage is benzylic. Similarly, one could anticipate that the formation of **6***d* would lead to the generation of **4***d* preferentially, which is entirely consistent with the observation that **4***d* is the major neutral component in the product isolated after long reaction times.

The relative ease of aryl exchange is not unexpected since aryl protons are more acidic than alkyl protons (10*b*). Proton abstraction would be expected to occur at each position on the aryl rings (17) and the formation of an *ortho*-phenyl anion could lead to the cyclobutoxide, or γ-enolate, **19***a*. Analogous species have been generated in a few saturated polycyclic systems under comparable conditions (18). Ketonization of **19***a* to the benzylic anion will lead to **20***a* and this should be a favoured route. Upon its formation, **20***a* can undergo rearrangement through one of the β-enolizable methyl groups to form **15**, i.e., via **21***a*, or suffer Haller–Bauer cleavage to produce 2-isopropylbenzoic acid. This sequence clearly accounts for the presence of these unusual products from the homoenolization of **2***d*. However, no material having structure **20***a* had been isolated. Consequently ketone **20***a* was synthesized and its behaviour upon treatment with *t*-BuO$^-$/*t*-BuOH examined.

Benzyl magnesium bromide was reacted with 2-isopropylbenzonitrile to give 2-isopropylphenyl benzyl ketone in 70% yield. Methylation with LDA/MeI/THF afforded the α-methyl derivative **20***b*, which in a second methylation cycle gave the desired α,α-dimethyl derivative **20***a*. The glc retention time of **20***a* was found to be very slightly shorter than that for **2***d* under the conditions employed for the analysis of the neutral products and the presence of a small amount of **20***a* could have escaped detection. In any event, it was found that **20***a* reacts relatively rapidly under the homoenolization conditions employed to produce a mixture of **15** and **18**, the latter isolated after methylation with CH_2N_2/Et_2O. The half-life for the disappearance of **20***a* was ca. 8 h at 185°C; the results for a series of experiments are summarized in Table 3. These results show that Haller–Bauer cleavage of **20***a* is somewhat faster than the β-enolate rearrangement to **15**. Careful examination of the nmr spectra of the **20***a* samples recovered from these runs failed to reveal the presence of any **2***d*, indicating that **19***a* → **20***a* is not reversible

From these results, the fate of **2***d* upon treatment with *t*-BuO$^-$/*t*-BuOH can be summarized as in Scheme 3.



SCHEME 4

[a]>90% recovery.
[b]Proportions of **15** and **20***a* determined by glc with an SE-30 column.

From the observation that β-enolization at the α-methyl groups in **3***d* competes favourably with α-enolization to generate **4***d* , it was of interest to compare the behaviour of 2-methyl-2,4-diphenyl-3-pentanone (**22**) with that of its fully methylated analog **2***d*. From a series of experiments in which **22** was heated at 185°C in *t*-BuO$^-$/*t*-BuOH for varying periods, the methylated acidic product was found to contain four esters, three of which were found to arise from **16, 17**, and **18**. The fourth ester, the major component in the acidic product from relatively short runs, was expected to be methyl 2-phenylpropionate arising from Haller–Bauer cleavage of **22**. This was confirmed by comparison with an authentic sample prepared from the commercially available carboxylic acid. The neutral fractions contained two new components in addition to decreasing amounts of **22**. The expected *o*-isopropyl derivative **20***b* was readily identified since an authentic sample was available from the preparative sequence employed to obtain **20***a*. The major neutral component in the products from the longer runs appeared to be a 1:1 mixture of diastereomers as anticipated for 2,5-diphenyl-3-hexanone (**24**), the ketone which would arise through β-enolization at one of the *gem*-dimethyl carbons in **22**. An authentic sample of **24** was obtained by a method analogous to that employed for the preparation of **3***b*. Lithiation of the dithiane formed from 2-phenylpropanal and 1,3-propanedithiol followed by reaction with β-bromocumene and hydrolysis gave in low yield the same 1:1 mixture of diastereomers **24** together with other unidentified material. An attempted alternative sequence utilizing the reaction of 2-phenylpropanal with the Grignard reagent from β-bromocumene, followed by oxidation, gave a different mixture of diastereomers **24** in low yield. The ^{13}Cmr spectrum indicated this mixture to be enriched in one of the two forms. The distribution of components in the neutral and acidic fractions after various reaction times was assessed by glc analysis; these results are collected in Table 4. The fate of **22** upon treatment with *t*-BuO$^-$/*t*-BuOH is summarized in Scheme 4.

(*c*) *Summary*

The data for the acyclic saturated ketones **2***a, b* show that proton abstraction from the α-methyl sites proceeds at rates comparable to those found for the corresponding sites in a variety of cyclic ketones (2). In contrast to the cyclic systems, however, the acyclic ketones rearrange slowly to **3***a, b*, showing that cleavage of the intermediate **5***a, b*, or equivalent species, leads to both primary (path *a*) and tertiary (path *b*) incipient carbanions. In the cyclic systems, only the former pathway has been observed. We suggest that the relative stabilities of **2***a, b* vs. **3***a, b* may be responsible. The carbonyl stretching frequencies differ by ca. 30 cm^{-1}, indicating a significant difference in the C—C(O)—C bond angle, which may destabilize **2***a, b* by a few kcal/mol. A similar difference has been shown to give 100% regioselectivity in the homoketonization of 2-acetoxydeltacyclane (19) for which the two possible modes of cleavage involve secondary carbanionic sites. We suggest that the difference in the stabilities of **2***a, b* and **3***a, b* alters the regioselectivity of the cleavage of **5***a, b* rendering the "unexpected" mode *b* competitive with regeneration of the initial ketone. Introduction of the α-phenyl groups in **2***d* renders cleavage of **5***d* regiospecific since no ^{1}H/^{2}H exchange was observed at the methyl carbons in **2***d*. Cleavage of **5***d* to generate a benzylic carbanionic site (path *b*) leading to **3***d* is clearly dominant, although Haller–Bauer type cleavage to acidic product becomes significant. Presumably, steric hindrance to carbonyl addition by *t*-BuO$^-$ in **2***d* renders β-enolate rearrangement more favourable energetically in contrast to the exclusive cleavage found for the less hindered **13** and **14**. If Haller–Bauer cleavage could be suppressed, there is some promise that β-enolization could be useful for chain extension and, perhaps, ring expansion in α-aryl substituted cyclic systems. Studies directed along these lines are currently in progress.

Experimental

Boiling points and melting points are uncorrected Gas–liquid chromatography was carried out on Varian 920, 3300, and 3700 instruments using columns of SE-30, DEGS, Carbowax 4000 or 20M on Chromosorb W, as indicated. Thin-layer chromatography was done on Kieselgel 60 F_{254} plates unless otherwise indicated. Tetrahydrofuran and ether were dried over sodium and freshly distilled before use. Undecan-6-one, 1,3-diphenyl-2-propanone, 2-phenylpropanol, β-bromocumene, ketones **2***a*, **3***a*, **4***a*, and the carboxylic acids **16**, **17**, and **23** were available commercially. The preparations of the remaining compounds are described below.

Infrared spectra were recorded with a Beckman 4250 instrument and mass spectra were obtained on a Varian MAT-311A system, at 70 eV (direct inlet). The ^{1}H and ^{13}Cmr spectra of each of the compounds were obtained to confirm their identities and those spectra were recorded with Varian XL-100, -200, or -300 spectrometers. Carbon, hydrogen, and sulfur analyses were performed by Chemalytics Inc., Tempe, Arizona.

*5,5,7-Trimethyl- and 5,5,7,7-tetramethylundecan-6-one (23*b)

To a stirred suspension of freshly powdered anhydrous sodium amide (13.7 g) in 1 L of anhydrous ether under a nitrogen atmosphere was added a solution of 6-undecanone (10 g) in 80 mL of dry ether. The mixture was stirred vigorously for 3 h under gentle reflux and then freshly distilled methyl iodide (84 g) in 80 mL of dry ether was added slowly. The mixture was stirred for 24 h at room temperature. After hydrolysis of excess $NaNH_2$ by the addition of water, the crude product was isolated by ether extraction and found to contain three components by glc analysis (10% Carbowax 4000), none of which corresponded to the starting ketone. The total product was recycled through the methylation procedure and after the third cycle a single product, isolated by preparative glc, exhibited properties consistent with those expected for 5,5,7-trimethylundecan-6-one; ir (liquid film): 1700 cm^{-1}; ^{1}Hmr ($CDCL_3$)δ: 0.88 (t, $J \sim 7$ Hz, 6H), 1.01 (d, $J \sim 6.5$ Hz, 3H), 1.11 (s, 3H), 1.12 (s, 3H), 2.95 (m, 1H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 14.0 (2), 18.1, 24.06, 24.12; CH_2, 22.9, 23.4, 27.0, 29.7, 34.0, 39.2; CH, 39.6; quat C, 48.0; C=O, 219.3.

A fourth cycle, during which the reaction mixture was refluxed for 22 h after the addition of the methyl iodide solution, gave a new ketone (13.4 g), essentially pure by glc analysis. Distillation under reduced pressure furnished pure **2***b*, bp 128–130°C/15 Torr (1 Torr = 133.3 Pa); ir (liq. film): 1675 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 0.98 (t, $J \sim 6.5$ Hz, 6H), 1.23 (s, 12H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 14.0, 26.3(2); CH_2, 23.4, 27.2, 41.6; quat C, 49.4; C=O, 218.2. Anal. calcd. for $C_{15}H_{30}O$: C 79.57, H 13.36; found: C 79.43, H 13.64.

*5,5,8-Trimethyl-6-dodecanone (3*b)

(*i*) N-tert-*Butyl-2,2-dimethylhexanal imine (7)*

A solution of *N-tert*-butyl isobutyraldehyde imine (16.2 g, 0.127 mol), prepared according to House *et al.* (11), in dry tetrahydrofuran (70 mL) was cooled to −20°C and a solution of butyllithium (65 g, 2 M in hexane) was added. The mixture, which turned yellow almost immediately, was allowed to warm to 0°C and this temperature was maintained as *n*-butyl bromide (26 g, 0.18 mol) was added slowly. After 30 min, saturated sodium chloride solution (300 mL) was added. The aqueous layer was extracted with ether and the extracts added to the organic layer, which was then dried over anhydrous $MgSO_4$. After removal of the solvent under reduced pressure, the residue was distilled to furnish a fraction (17.2 g) boiling in the range 85–95°C/70–100 Torr, containing two components in a 4:1 ratio. The major product, isolated by preparative glc (20% SE-30), slowly crystallized on standing and was the desired imine **7** (57% yield); mp 104–105°C; ir (mull); 2990, 2960, 2890, 1675, 1470, 1370, 1230 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 0.95 (s, 6H), 1.08 (s, 9H), 7.23 (s, 1H, -CH=N); ^{13}Cmr ($CDCl_3$)δ: CH_3, 14.1, 25.0(2), 29.8(3); CH_2, 23.6, 26.7, 40,6; CH, 164.3; C, 38.5, 56.0; ms: 183 (M^+). The minor product was not identified.

(*ii*) *Dithiane* **9**

Imine **7** (14.2 g, 0.08 mol) was dissolved in hexane (50 mL) and 20% aqueous acetic acid (130 mL) was added. After 15 min, sufficient NaCl was added to saturate the aqueous layer and the product isolated by repeated extraction with pentane. After evaporation of the solvent, the extracts furnished essentially pure 2,2-dimethylhexanal (**8**) (4.7 g, 47% yield); ^{1}Hmr ($CDCl_4$)δ: 1.03 (s, 6H), 9.33 (s, 1H, CHO); ^{13}Cmr ($CDCl_3$)δ: CH_3, 14.0, 21.4(2); CH_2, 23.6, 26.7, 37.3; CHO, 205.1; quat C, 45.7.

Aldehyde **8** (1.6 g) was dissolved in chloroform (40 mL) and propane-1,3-dithiol (1.3 mL) was added at room temperature (12). After stirring for 1 h, the solution was cooled to 0°C and BF_3/Et_2O (0.5 mL) was added. After standing overnight at 6°C, a small amount of water had separated. The $CHCl_3$ layer was extracted three times with cold 7% aqueous potassium hydroxide solution and once with water before drying over K_2CO_3. The residual oil obtained after evaporation of the solvent under reduced pressure was distilled to furnish **9** (2 g, 75% yield), bp 93°C/0.55 Torr; ^{1}Hmr ($CDCl_3$)δ: 0.9 (t, $J \sim 7$ Hz, 3H), 1.06 (s, 6H), 3.93 (s, 1H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 14.1, 25.4(2); CH_2, 23.4, 25.9, 26.2, 31.4(2), 40.2; CH, 60.9; quat C, 38.0. Anal. calcd. for $C_{11}H_{22}S_2$: C 60.48, H 10.15, S 29.36; found: C 60.70, H 10.30, S 29.70. Exact mass calcd. for $C_{11}H_{22}S_2$: 218.1163; found: 218.1165.

(*iii*) *Dithiane* ***11***

A solution of 2-methylhexan-1-ol (5.0 g), prepared from allyl alcohol in 77% yield as described by Crandall and Clark (13), in dry pyridine (40 mL) was cooled to 0°C and tosyl chloride (24 g) was added with stirring. After stirring for 30 min, the reaction mixture was stored at 0°C overnight before the addition of ice-cold water (70 mL). The product was extracted with Et_2O (3 × 50 mL) and the combined extracts washed with cold 10% aqueous HCl, 10% $NaHCO_3$ solution, and water before drying over $MgSO_4$. Removal of the solvent gave a slightly yellow oil (10.2 g, 88%) containing a single component by tlc. This oil was dissolved in DMSO (40 mL), and NaBr (10 g, was added with swirling. After 5 days, the crude product was isolated by ether extraction and purified by distillation to give 1-bromo-2-methylhexane (**10**) (6 g, 88% yield) boiling at 105–106°C/100 Torr; ^{13}Cmr ($CDCl_3$)δ: CH_3, 14.0, 18.8; CH_2, 22.8, 29.1, 34.6, 41.6; CH, 35.3.

Dithiane **9** (3.3 g) was dissolved in dry tetrahydrofuran (20 mL) under an argon atmosphere. After cooling to −30°C, *n*-butyllithium (7 mL, 2 M in hexane) was added. The colorless solution became

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

deep red and then developed a yellow tinge. The temperature was maintained at −15°C for 18 h and then raised to 0°C. After **10** (2.7 g) was added, the yellow colour slowly faded. The mixture was kept at 6°C for 2 days before the reaction was quenched by pouring the mixture into water. The crude product (4.4 g) was isolated by pentane extraction. Distillation under reduced pressure yielded dithiane **9** (1.1 g) and dithiane **11** (2.4 g, 76% yield based on reacted **9**), bp 138°C/0.05 Torr; ir (liquid film): 2925, 2873, 1470, 1459, 1418, 1383 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 0.90 (t, $J \sim 6$ Hz, 3H), 0.92 (t, $J \sim 6$ Hz, 3H), 1.05 (d, $J \sim 7$ Hz, 3H), 1.12 (s, 6H), 2.83 (bt, $J \sim 6$ Hz, 4H). Anal. calcd. for $C_{18}H_{36}S_2$: C 68.28, H 11.46, S 20.25; found: C 67.99, H 11.21, S 20.70. Exact mass calcd. for $C_{18}H_{36}S_2$: 316.2258; found: 316.2252.

(*iv*) *Ketone* **3***b*

A solution of dithiane **11** (2.4 g) in 90% aqueous methanol (50 mL) containing mercuric oxide (2.4 g and mercuric chloride (5.1 g) was heated under reflux with stirring for 3 h. After cooling, the reaction mixture was filtered and diluted with water (250 mL) before ether extraction. The combined extracts were washed with concentrated ammonium chloride solution. After drying, the solvent was evaporated to furnish essentially pure **3***b* as an oil (1.15 g, 67% yield). Bulb-to-bulb distillation at 100°C/0.05 Torr furnished an analytical sample; ir ($CHCl_3$): 1710 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 0.88 (t, $J \sim 6$ Hz, 6H), 0.86 (d, $J \sim 6$ Hz, 3H), 1.08 (s, 6H), 2.35 (dd, 2H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 14.0, 14.1, 20.0, 24.3(2); CH_2, 22.9, 23.4, 26.9, 29.3, 36.7, 39.7, 44.3; CH, 28.4; quat C 47.5; C=O, 215.4. Anal. calcd. for $C_{15}H_{30}O$: C 79.58, H 13.36; found: 79.32, H 13.29, Exact mass calcd. for $C_{15}H_3O$: 226.2289; found: 226.2290.

*2-Methyl-2,4-diphenyl- and 2,4-dimethyl-2,4-diphenyl-3-pentanone (**22**, **2**d)*

With the methylation procedure described above for 6-undecanone, 1,3-diphenyl-2-propanone gave, after three cycles, the tetramethyl derivative **2***d* in 60% yield after crystallization from EtOH, mp 111–112°C (lit.(20) mp 110–115°C (dec.)); ir ($CHCl_3$): 1690 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.26 (s, 12H), 7.1 (bs, 10H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 27.8; aryl CH, 125.8(2), 126.4, 128.3(2); quat C, 52.9, 144.3; C=O, 213.0. Anal. calcd. for $C_{19}H_{22}O$: C 85.66, H 8.32; found: C 85.52, H 8.41. Exact mass calcd. for $C_{19}H_{22}O$: 266.1671; found: 266.1673.

A single methylation cycle furnished a mixture of di- and trimethyl derivatives from which, through repeated recrystallizations from ethanol, the trimethyl ketone **22** could be isolated in ca. 50% yield, mp 56–57°C; ir ($CHCl_3$): 1708 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.28 (d, $J \sim 6.5$ Hz, 3H), 1.39 (s, 3H), 1.51 (s, 3H), 3.82 (q, $J \sim 6.5$ Hz, 1H), 7.5 (m, 10H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 21.8, 24.4, 25.6; CH, 47.4; quat C, 53.2; C=O, 213.2; aryl CH, 126.5(3), 126.9, 127.5(2), 128.3(2), 128.6(2); aryl C, 141.7, 143.0. Exact mass calcd. for $C_{18}H_{20}O$: 252.1514; found: 252.1518.

*2,4-Dimethyl-2,4-dicyclohexylpentan-3-one (**2**c)*

Hydrogenation of **2***d* (1.5 g) in glacial acetic acid (30 mL) and perchloric acid (20 mL) over PtO_2 at 380 kPa for 100 h furnished ketone **2***c* as a low melting solid (1.4 g, 88% yield). After recrystallization from methanol, **2***c* had mp 49–50°C; ir ($CHCl_3$): 1675 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.12 (s, 6H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 22.8; CH_2, 26.8, 27.2(2), 28.1(2); CH, 45.1; quat C, 52.8; C=O, 218.1. Anal. calcd. for $C_{19}H_{34}O$: C 81.94, H 12.32, found: C 81.68, H 12.62. Exact mass calcd. for $C_{19}H_{34}O$: 278.2610; found: 278.2612.

*2-Methyl-2,5-diphenyl-3-hexanone (**3**d)*

A solution of β-bromocumene (1.9 g) in anhydrous Et_2O (20 mL) containing Mg turnings (0.23 g) was treated with 2 drops of 1,2-dibromoethane before refluxing under argon for 1.5 h. After cooling to −70°C, the reaction mixture was treated with 2-methyl-2-phenylpropanal (1.4 g), which had been prepared as described by Schaffner and co-workers (21) with the Doering oxidation step (22). After warming to room temperature, ether extraction of the reaction mixture gave a crude product that, by glc analysis, contained a major component (~75%) accompanied by two minor components. This product was treated with Jones' reagent (23) until the colour persisted. The aqueous layer was separated, extracted with Et_2O, and the combined extracts dried before evaporation of the solvent. The crude product (0.5 g) was found to contain **3***d*, 2-methyl-2-phenylpropionic acid, and some unidentified material by tlc. A sample of **3***d* separated by tlc was identified by glc (SE-30) and its physical properties were identical to those found for **3***d* from the homoenolization experiments with **2***d*: ir (CCl_4): 3100, 3075, 3040, 2970, 2940, 1710, 1590 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.08 (d, $J \sim 7$ Hz, 3H), 1.33 (s, 3H), 1.46 (s, 3H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 21.4, 24.8, 25.1; CH_2, 46.1; CH, 34.9; quat C, 52.1; C=O, 211.0; aryl CH, 126.6(3), 126.7, 126.8(2), 128.2(2), 128.6(2); quat C, 143.5, 146.4. Exact mass calcd. for $C_{19}H_{22}O$: 266.1671; found: 266.1668.

*2,6-Diphenyl-4-heptanone (**4**d)*

Following a sequence analogous to that employed to generate **3***b*, this preparation required 2-(2-phenylpropyl)-1,3-dithiane, which was obtained (12) from metallated 1,3-dithiane (1.2 g) upon reaction with β-bromocumene (2 g) near 0°C for 15 h. The dithiane was isolated by pentane extraction (1.2 g, 50%) and distilled under reduced pressure, bp 130°C/0.01 Torr; ^{1}Hmr ($CDCl_3$)δ: 1.23 (d, $J \sim 7$ Hz, 3H), 2.95 (m, 1H), 3.56 (t, $J \sim 7$ Hz, 1H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 22.3; CH_2, 26.0, 29.8, 30.1, 36.2; CH, 43.6, 45.1; aryl CH, 126.2, 127.0(2), 128.4(2); quat C, 145.7. Exact mass calcd. for $C_{13}H_{18}S_2$: 238.0852; found: 238.0858.

Metallation of this dithiane followed by reaction with β-bromocumene and hydrolysis as described above for **3***b* gave a mixture of products containing small amounts of **4***d* as revealed by glc analysis and comparison with samples obtained in the homoenolization experiments with **2***d*. Material isolated from homoenolization of **2***d* as a 1:1 mixture of diastereomers had the following properties: ir (CCl_4): 3150, 2820, 2650, 1720, 1495, 1450 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.17 (d, $J \sim 7$ Hz, 3H), 1.21 (d, $J \sim 7$ Hz, 3H), 2.35–2.80 (m, 4H), 3.1–3.5 (m, 2H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 21.9; CH_2, 51.7, 51.8; CH, 35.2, 35.3; aryl CH, 126.2, 126.8(2), 128.5(2); quat C, 146.2; C=O, 208.5, 208.6. Exact mass calcd. for $C_{19}H_{22}O$: 266.1671; found: 266.1668.

Attempted recrystallization from methanol at −70°C gave a mixture, mp 40–45°C, which was significantly enriched in one of the diastereomeric forms and for which the 1.21 ppm doublet was enhanced in the ^{1}H spectrum while the higher field methylene and methine signals were the more intense in the ^{13}C spectrum.

Methyl 2-isopropylbenzoate

With vigorous stirring, 2-isopropylacetophenone (0.80 g) was added to a mixture of NaOH (4 g) and Br_2 (1.2 g) in ice-water (10 mL) while the temperature was maintained near 0°C with a cold brine bath. After 1 h, the reaction mixture was allowed to warm to room temperature and stirring was continued overnight. After thorough ether extraction, the aqueous phase was treated with $Na_2S_2O_5$ (0.5 g in 10 mL of H_2O) and then acidified with concentrated HCl solution. Ether extraction of the acidic aqueous phase afforded 2-isopropylbenzoic acid (0.70 g, 85% yield), mp 60–62°C; ^{13}Cmr ($CDCl_3$)δ: CH_3, 24.0(2): CH, 29.4; aryl CH, 125.6, 126.5, 131.0, 132.8; aryl C, 128.4, 151.0; C=O, 174.5.

Treatment of an ethereal solution of the acid (0.65 g) with excess CH_2N_2/Et_2O gave methytl 2-isopropylbenzoate (0.67 g, 95% yield); ir (CCl_4): 1728 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.26 (d, $J = 7$ Hz, 6H), 3.74 (septet, $J = 7$ Hz, 1H), 3.87 (s, 3H), 7.1–7.8 (m, 4H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 24.0(2); CH, 29.6; CH_3O, 51.8; aryl CH, 125.5, 126.2, 129.9, 131.8; aryl C, 130.0, 149.7; C=O, 168.7. Exact mass calcd. for $C_{11}H_{14}O_2$: 178.0994; found: 178.0995.

*Methyl esters of **16**, **17**, and **23***

Treatment of the corresponding carboxylic acids, which were commercially available, with excess CH_2N_2/Et_2O afforded authentic samples of the esters. (a) Methyl 2-methyl-2-phenylpropionate (**16**): ir (CCl_4): 1730 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.52 (s, 6H), 3.43 (s, 3H), 7.1 (bs, 5H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 26.5; C, 46.5; CH_3O, 51.8; aryl CH, 125.6(2), 126.7, 128.4(2); aryl C, 144.8; C=O, 176.8. (b) Methyl 3-phenylbutyrate (**17**): ir (CCl_4): 1728 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.27 (d, $J = 7.5$ Hz, 3H), 2.45 (m, 1H), 2.60 (m, 1H), 3.30 (m, 1H), 3.57 (s, 3H) 7.15 (bs, 5H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 21.8; CH, 36.5; CH_2, 42.7; CH_3O, 51.3; aryl CH, 126.4, 126.7(2), 128.5(2); aryl C, 145.8; C=O, 172.6. (c) Methyl 2-phenylpropionate (**23**): ir (CCl_4): 1735 cm^{-1};

^{1}Hmr ($CDCl_3$)δ: 1.50 (d, J = 7 Hz, 3H), 3.67 (s, 3H), 3.71 (q, J = 7 Hz, 1H), 7.33 (bs, 5H).

Benzyl phenyl ketones ***20***a, b

Following the standard Sandmeyer procedure, 2-isopropylbenzonitrile was prepared from 2-isopropylaniline in 38% yield, bp 100–101°C/5 Torr; ir (CCl_4); 2230 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.05 (d, $J \sim 7$ Hz, 6H), 3.33 (septet, $J \sim 7$ Hz, 1H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 23.1; CH, 32.5; aryl CH, 126.1, 126.6, 132.9, 133.2; quat C, 111.8, 152.2; CN, 118.0. Exact mass calcd. for $C_{10}H_{11}N$: 145.0891; found: 145.0895.

To a cooled solution (0°C) of benzylmagnesium bromide in anhydrous ether (300 mL), prepared from benzyl bromide (10.5 g) and magnesium turnings (2.2 g), was slowly added 2-isopropylbenzonitrile (10.5 g) in dry ether (15 mL). The reaction mixture was heated under gentle reflux for 20 h and then the reaction was quenched by adding concentrated HCl (50 mL) in water (150 mL). This mixture was heated on a steam bath for 1 h and, after cooling, the product was extracted with ether. After drying the extracts over anhydrous sodium sulfate and removal of the solvent, the residue was distilled under reduced pressure to yield 2-isopropylphenyl benzyl ketone in 70% yield (11.8 g); bp 130°C/1 Torr; ir ($CHCl_3$): 1695 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.10 (d, $J \sim$ 7 Hz, 6H), 3.20 (septet, $J \sim 7$ Hz, 1H), 4.03 (s, 2H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 24.1; CH_2, 49.7; CH, 29.4; C=O, 202.6; aryl CH, 125.2, 126.3, 126.8, 126.9, 128.5(2), 129.6(2), 130.7; quat C, 134.2, 138.8, 147.6. Exact mass calcd. for $C_{17}H_{18}O$: 238.1358: found: 238.1356.

A solution of lithium diisopropylamide (LDA) was prepared in a flame-dried flask under nitrogen by the dropwise addition of *n*-butyllithium (17.5 mL, 1.6 M in hexane) to a cooled solution of diisopropylamine (2.8 g, 0.028 mol) in freshly distilled tetrahydrofuran. After stirring the resulting solution of LDA at 0°C for 15 min, a solution of 2-isopropylphenyl benzyl ketone (6 g, 0.025 mol) in 10 mL of THF was added dropwise and the reaction mixture stirred for 15 min. To this solution methyl iodide (7.1 g, 0.05 mol) was added slowly and the temperature allowed to rise to ambient. After stirring for 5 h, 100 mL of water was added and the product isolated by ether extraction (2 × 75 mL). After drying and evaporating the solvent, the residue was crystallized from methanol to furnish the monomethyl derivative **20***b* (4.2 g, 67% yield); mp 65–67°C; ir ($CHCl_3$): 1692 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 0.88 (d, $J \sim$ 7 Hz, 3H), 1.20 (d, $J \sim 7$ Hz, 3H), 1.55 (d, $J \sim 7$ Hz, 3H), 2.93 (septet, $J \sim 7$ Hz, 1H), 4.35 (q, $J \sim 7$ Hz, 1H), 7.05–7.35 (m, 9H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 17.8, 23.8, 24.5; CH, 29.8, 52.1; C=O, 205.8; aryl CH, 125.1, 126.4(2), 127.0, 128.2(2), 128.7(2), 130.3; quat C, 139.6, 139.8, 147.4. Exact mass calcd. for $C_{18}H_{20}O$: 252.1514; found: 252.1517.

The above procedure using **20***b* as starting material with a twofold excess of LDA and a fivefold excess of methyl iodide furnished **20***a* in 60% yield, mp 33–34°C; ir ($CHCl_3$); 1685 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.18 (d, $J \sim 7$ Hz, 6H), 1.38 (s, 6H), 2.76 (septet, $J \sim 7$ Hz, 1H), ^{13}Cmr ($CDCl_3$)δ: CH_3, 24.4, 26.2; CH, 31.0; quat C, 52.1; C=O, 209.9; aryl CH, 124.5, 125.3, 125.9, 126.4(2), 127.0, 128.6(2), 129.2; quat C, 139.2, 143.2, 146.3. Exact mass calcd. for $C_{19}H_{22}O$: 266.1671; found: 266.1670.

*2,5-Diphenyl-3-hexanone (****24****)*

Following the procedures described for the preparation of dithiane **9** above, 2-(1-phenylethyl)-1,3-dithiane was prepared in 80% yield from 2-phenylpropanal; bp 115°C/0.05 Torr; ^{1}Hmr ($CDCl_3$)δ: 1.42 (d, J = 7 Hz, 3H), 1.7–2.1 (m, 2H), 2.5–2.8 (m, 4H), 3.03 (m, 1H), 4.16 (d, $J \sim 7$ Hz, 1H), 7.15 (bs, 5H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 18.5; CH_2, 25.6, 30.3, 30.7, CH, 44.6, 54.6: aryl CH: 126.7, 127.5(2), 128.0(2); aryl C, 142.8. Exact mass calcd. for $C_{12}H_{16}S_2$: 224.0693; found: 224.0690.

Lithiation of this dithiane in the usual way followed by the addition of β-bromocumene gave a mixture of products, which was hydrolyzed to furnish a 1:1 mixture of the diastereomers of **24** in low yield after tlc separation. This sample was identical to that isolated from the homoenolization of **22**; ir (CCl_4): 1720 cm^{-1}; ^{1}Hmr ($CDCl_3$)δ: 1.08 (d, J = 7 Hz, 3H), 1.18 (d, J = 7 Hz, 3H), 1.29 (d, J = 7 Hz, 3H), 1.31 ((d, J = 7 Hz, 3H), 2.4–2.9 (m, 4H), 3.1–3.45 (m, 2H), 3.52 (q, J = 7 Hz, 1H), 3.67 (q, J = 7 Hz, 1H), 7.0–7.4 (m, 20H); ^{13}Cmr ($CDCl_3$)δ: CH_3, 17.2(2), 21.5, 21.8; CH_2, 49.1, 49.5; CH, 35.1, 35.4, 53.5(2); aryl CH, 128.9(2), 128.8(2), 128.4(2), 128.3(2), 128.0(2), 127.8(2), 127.1, 127.0, 126.7(4), 126.2, 126.1; aryl C, 140.2, 140.3, 146.0, 146.1; C=CO, 207.5, 207.4. Exact mass calcd. for $C_{18}H_{20}O$: 252.1514; found: 252.1515.

An alternative synthesis of **24** was briefly examined but gave even poorer results than those just described. Following the procedure used to prepare **3***d*, β-bromocumene (2.0 g) was dissolved in dry Et_2O (20 mL) containing magnesium turnings (0.25 g), and 2 drops of 1,2-dibromoethane were added before refluxing for 1.5 h. After cooling to −70°C, 2-phenylpropanal (1.34 g) was added and the low temperature maintained for 1 h before allowing the mixture to warm to room temperature. The crude product was isolated by ether extraction and treated with Jones' reagent until the colour persisted. Preparative tlc of the product mixture isolated by ether extraction afforded a sample whose ^{13}Cmr spectrum indicated it to be a 3:1 mixture of the diastereomers of **24**.

Homoenolization experiments

The general procedure for these experiments has been described in detail previously (8) and was employed for the examinations of **2***a, b, c* and **3***a, b*. The nature of the products obtained from the reactions of **2***d*, **3***d*, **20***a*, and **22**, however, necessitated modification of the isolation procedures. The contents of the individual reaction tubes were poured into 20 volumes of water and some concentrated ammonium chloride solution added before extraction of the neutral fraction with pentane. The aqueous layer was then acidified to pH ~1 with either dilute H_2SO_4 or HCl solution and the acidic products extracted with ether. In the initial experiments after drying over $MgSO_4$, the ether extract was concentrated and treated with diazomethane in ether to convert the acids to their methyl esters. In later runs, the acid fraction was silylated (16) for analysis. The product compositions were determined by glc analysis using DEGS or Carbowax 4000 columns for **2***a, b* and **3***a, b* while SE-30 columns were most suitable for the products from the reactions of **2***d*, **3***d*, **20***a*, and **22**. In the latter experiments it was found that chromatography over silica gel before glc analysis removed small amounts of polymeric material from the neutral fractions, thereby improving the assessment of their composition. Preparative glc furnished samples of the various components in these mixtures for identification and characterization.

In the experiments involving **2***d*, recrystallization of the neutral fraction permitted separation of ~70% of the starting material from the product. Subsequent column chromatography on silica impregnated with 10% silver nitrate using pentane:ether (3:1) as eluent gave **2***d* as the first fraction, a mixture of **3***d* and **15** as the second fraction, and **4***d* essentially pure as the third fraction. Pure **3***d* could be isolated by repeated chromatography of the second fraction on $AgNO_3$-impregnated silica tlc plates.

To examine the $^1H/^2H$ exchange processes involving the α-methyl sites in **2***a, b, d* and **3***a, b*, these ketones were heated with *tert*-butyl alcohol-*o*-*d*, (99% deuterated, D_2O content <250 μg/mL) as solvent; the results of these experiments are described in the text.

The lectin IV of *Griffonia simplicifolia* (GS4) specifically binds the terminal tetrasaccharide unit of the Lewis b human blood group determinant (Le^b). The single crystal X-ray analysis of the complex with Le^b-OMe has demonstrated that the binding site on the lectin is a shallow depression with a negatively charged aspartate side chain at the bottom of the cavity. In addition to this aspartate, a serine and an asparagine side chain provide the polar groups that hydrogen bond to the three hydroxyl groups of Le^b, which has been termed the key polar grouping for complex formation. A notable characteristic of the binding site is that five aromatic amino acid side chains (one Phe, two Tyr, and two Trp residues) surround these polar interactions and make van der Waals contacts with the tetrasaccharide. Thus, as predicted from previous solution binding studies, extensive nonpolar interactions are involved, which contribute importantly both to the specificity of the reaction and the stability of the noncovalent complex that is formed. These results represent the first structural example of the molecular recognition of a human blood group determinant by the receptor site of a protein. Extensive sequence homology exists between GS4 and the concanavalin A (Con A), pea, and favin lectins. The main hydrophilic groups of the carbohydrate-binding site of GS4 and Con A are aspartate, asparagine, and serine residues; the homology suggests that the serine is replaced by asparagine in the case of the pea and favin lectins. It appears probable that these two latter lectins possess very similar, if not identical, specificities.

Key words: lectin, carbohydrate, molecular recognition, binding.

LOUIS T. J. DELBAERE, MARGARET VANDONSELAAR, LATA PRASAD, J. WILSON QUAIL, JOYCE R. PEARLSTONE, MICHAEL R. CARPENTER, LAWRENCE B. SMILLIE, PANDURANG V. NIKRAD, ULRIKE SPOHR et RAYMOND U. LEMIEUX. Can. J. Chem. **68**, 1116 (1990).

La lectine IV du *Griffonia simplicifolia* (GS4) se lie spécifiquement à l'unité tétrasaccharide terminale du déterminant du groupe sanguin humain Lewis b (Le^b). Une analyse par diffraction des rayons-X effectuée sur un cristal unique de son complexe avec le Le^b-OMe a permis de démontrer que le site de liaison de la lectine est une légère dépression au fond de laquelle on retrouve une chaîne latérale d'aspartate chargée négativement. En plus de cet aspartate, des chaînes latérales de sérine et d'asparagine fournissent des groupements polaires qui forment des points hydrogènes avec les trois groupements hydroxyles du Le^b; il s'agit du groupement polaire clé pour la formation de complexes. Le fait que cinq chaînes latérales formées d'acides aminés aromatiques entourent ces interactions dipolaires et qu'elles établissent des contacts de van der Waals avec le tétrasaccharide est une caractéristique notable de ce site de liaison. Tel que prédit à partir d'études antérieures de liaisons en solution, il existe donc de nombreuses interactions non-polaires qui apportent une contribution importante tant à la spécificité de la réaction qu'à la stabilité du complexe non-covalent qui se forme. Ces résultats correspondent au premier exemple de reconnaissance moléculaire d'un déterminant de groupe sanguin humain par le site récepteur d'une protéine. Il existe une homologie séquentielle importante entre le GS4, la concanavaline A (Con A) et les lectines de pois et de favine. Les groupements hydrophiles principaux du site de liaison de l'hydrate de carbone du GS4 et du Con A sont des résidus aspartate, asparagine et sérine; dans le cas des lectines de pois et de favine, l'homologie suggère de remplacer la sérine par l'asparagine. Il semble probable que ces deux dernières lectines possèdent des spécificités très semblables, sinon identiques.

Mots clés : lectine, hydrate de carbone, reconnaissance moléculaire, liaison.

[Traduit par la revue]

The process of molecular recognition is fundamental to an understanding of all living processes. A wide variety of proteins, such as enzymes and antibodies, function as receptors for the specific recognition and binding of distinct molecules. Lectins are proteins which are of widespread occurrence in tissues and which possess at least two sites (one per subunit) that are designed specifically to recognize and bind complex carbohydrate structures (1, 2). Lectins do not possess enzymic properties and are not products of an immune response. Their role in tissues appears diverse and is probably related to the organization and transport of biological macromolecules (1–3). This communication provides the first detailed X-ray analysis of a complex that involves the molecular recognition of a human blood group determinant. These results combined with the

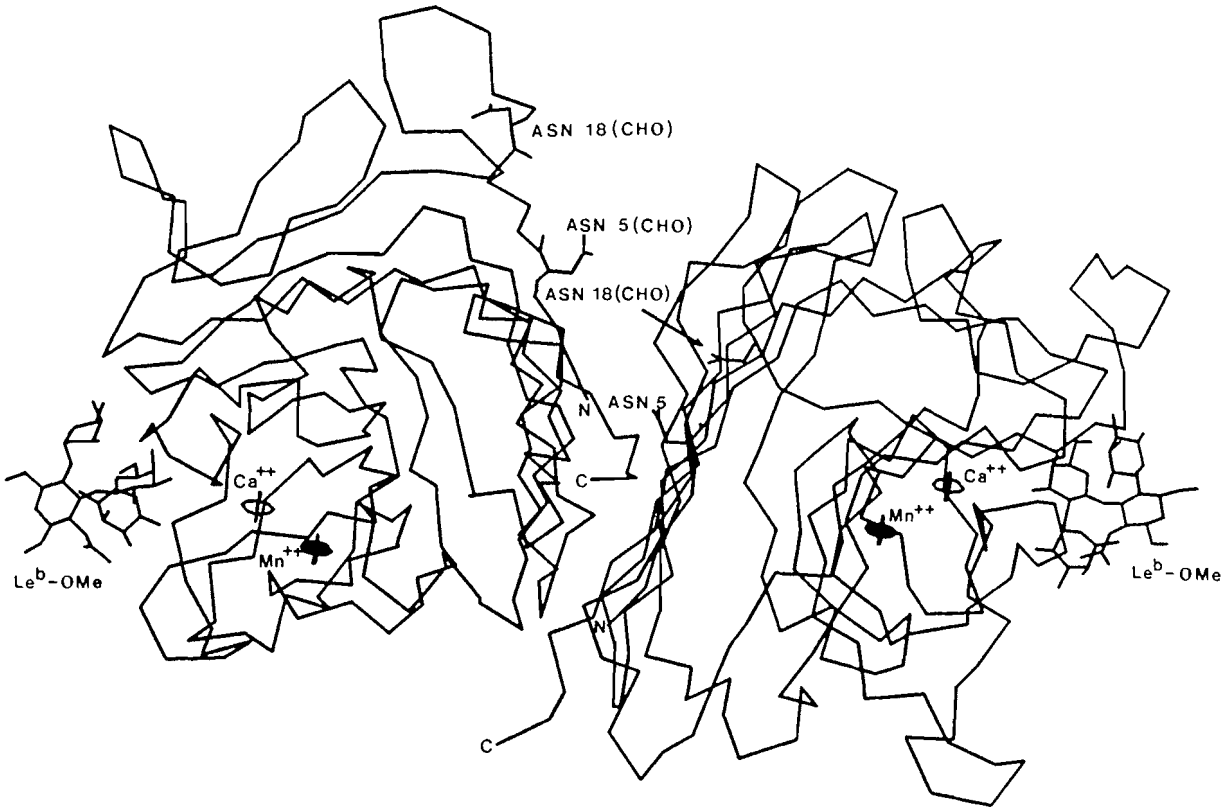

FIG. 1. The polypeptide chain folding of each subunit of the molecular dimer of GS4; only the α carbon atoms are illustrated. The binding sites of the Le^b-OMe are on opposite sides of the dimer. The N- and C-termini of each subunit are indicated. CHO refers to covalently attached oligosaccharide.

recently reported crystal structure for the concanavalin A (Con A) complex, Con A/α-D-Man-OMe (4), appear to provide insight toward an appreciation of the full specificities of the Con A, favin, and pea lectins.

Con A was the first lectin to have its crystal structure determined (5, 6). Furthermore, the preliminary description of the carbohydrate-binding site of a lectin corresponded to that of Con A (7, 8). Carver *et al.* (9) identified the four loops at the surface of this protein that form the combining site for α-D-Man-OMe; they also showed that a more stable complex is formed with α-D-Man(1 → 6)[α-D-Man(1 → 3)]D-Man than with the monosaccharide. The carbohydrate-binding site of favin was described in the structure of the favin/glucose complex (10). The crystal structure of native pea lectin (11) and the pea lectin/trimannose complex (12) have also been reported. The amino acid sequences of the leguminous lectins, Con A, favin, and pea lectin, have been published (13–15). Their specificities are reported to be related to mannose/glucose derived saccharides (1, 2). On the other hand the lectin IV of *Griffonia simplicifolia* (GS4) is known to bind specifically the surfaces held in common by the Lewis b (Le^b) and Y human blood group determinants (16, 17), which are the tetrasaccharide units α-L-Fuc(1→2)β-D-Gal(1→3)[α-L-Fuc(1→4)]β-DGlcNAc– and α-L-Fuc(1 → 2)β-D-Gal(1 → 4)[α-L-Fuc(1 → 3)β-D-GlcNAc–, respectively.

As displayed in Fig. 1, GS4 is a heterodimeric metalloglycoprotein and each subunit contains one Ca^{2+}, one Mn^{2+}, and one binding site for Le^b-OMe, the methyl glycoside of Le^b. There are two Lewis b tetrasaccharides bound per GS4 molecular heterodimer in the GS4/Le^b-OMe complex. The native GS4 and complexes of GS4 both with Le^b-OMe and a large variety of derivatives obtained by chemical alterations were reported to crystallize isomorphously in space group $P4_22_12$ (18). The crystal structure of the native GS4 was solved by the molecular replacement method (19) with the use of favin coordinates (10), pea lectin coordinates (11), and the aid of the amino acid sequence (20). The structure of the GS4/Le^b-OMe complex was also solved and least-squares refined (21, 22). Subsequent analysis showed that the true space group is $P4_2$ (23). Further refinement in space group $P4_2$ at 2.8 Å resolution gave an R index of 0.21 for 6844 reflections with $F > 4\sigma(F)$.[1] The crystal system is tetragonal with unit cell dimensions $a = 78.9$ Å, $c = 89.1$ Å with one molecular heterodimer in the asymmetric unit. Details of the crystallographic analysis are given elsewhere (23). The overall folding of the polypeptide chain of each subunit is presented in Fig. 1. Each subunit has two major antiparallel β-sheets, one six-stranded and the other seven-stranded, which are similar to those that occur in the subunits of Con A (4–6), pea (11), and favin (10) lectins. Both subunits of GS4 contain 243 amino acid residues, which are identical except for five residues where heterogeneity was observed (20). It has been demonstrated by chemical analysis that one subunit has a covalently linked oligosaccharide at Asn 5 and Asn 18 whereas the second subunit of the molecular heterodimer has N-linked carbohydrate only at Asn 18 (20) (see Fig. 1). The association of the monomers of GS4 is different from that occurring in the Con A (4–6), pea (11), and favin (10) lectins,

[1]The coordinates of the α carbon atoms for the two subunits of GS4 are available and may be purchased from the Directory of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

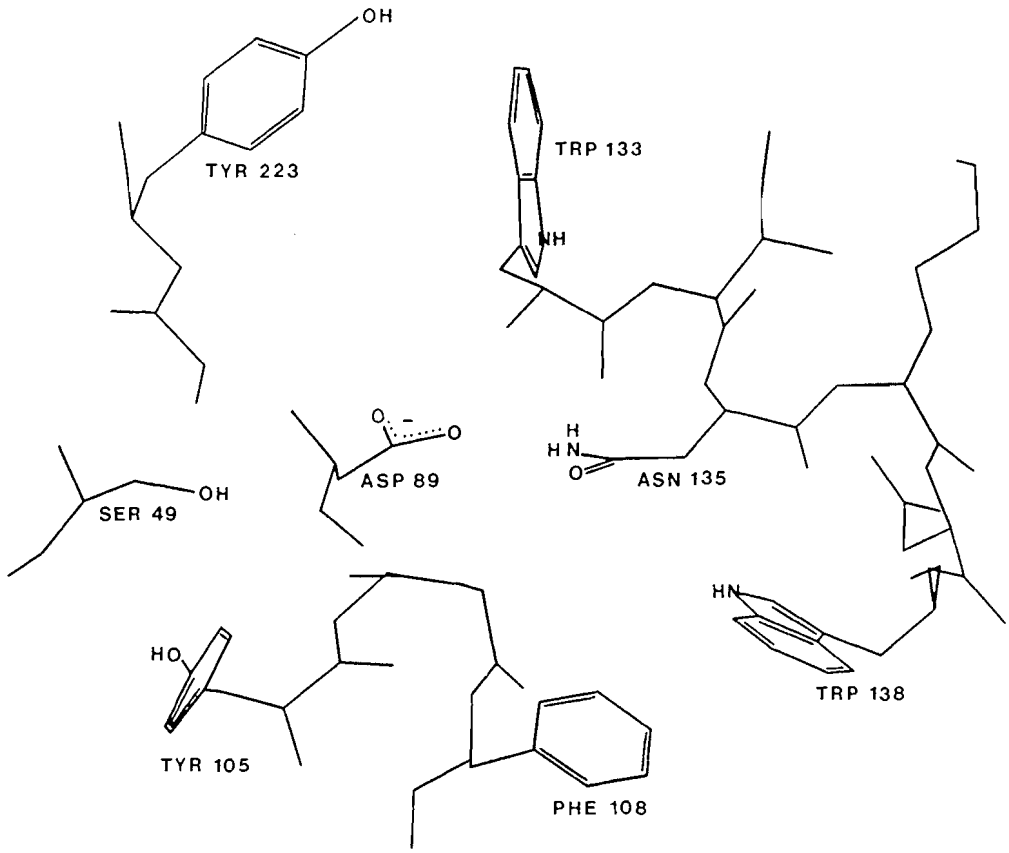

FIG. 2. Amino acid residues of GS4 that are present in the combining site for Le^b-OMe. This view is from the direction of the tetrasaccharide towards the protein. Selected non-carbon atoms are illustrated. It is expected that, at higher resolution, immobilized water molecules will be found to be present.

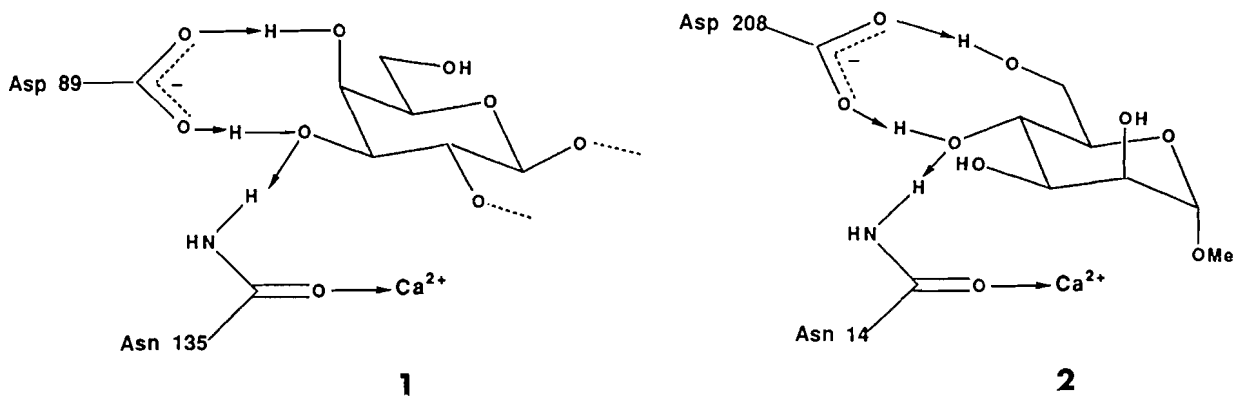

FIG. 3. Comparison of a key polar interaction for the binding of the β-D-Gal unit of the Le^b-OMe tetrasaccharide by GS4 (**1**) with that (**2**) for the binding of α-D-Man-OMe by Con A (4). In both cases the positive calcium ion cooperates with the negative carboxylate group in enhancing the charge delocalization for the strengthening of the intervening hydrogen bonds.

possibly due to the involvement of a portion of the covalently linked oligosaccharides in the interactions between the subunits of GS4. The ligands for the Ca^{2+} and Mn^{2+} cations are analogous to those reported for Con A (6, 24), pea (11), and favin (10) lectins. The Le^b-OMe noncovalent binding sites are located on opposite sides of the GS4 dimer (see Fig. 1) and the electron density is in accord with the expectation (17) that the Le^b-OMe molecule is bound in the same conformation in which it exists in aqueous solution (25).

The disposition of the amino acid residues of GS4 that bind Le^b-OMe is presented in Fig. 2. Three hydrophilic amino acid residues are directly involved in the binding. Two of these residues were found to have unusual features in that Asp 89 is involved in the *cis*-peptide linkage between Ala 88 and Asp 89 and the carbonyl group of the Asn 135 side chain is coordinated to the Ca^{2+} ion. However, since our preliminary communication of this work (26), an essentially analogous situation (see Fig. 3) has been found (4) to exist for the binding of methyl α-D-mannopyranoside by Con A. A particularly striking characteristic of the other amino acid residues that form the combining

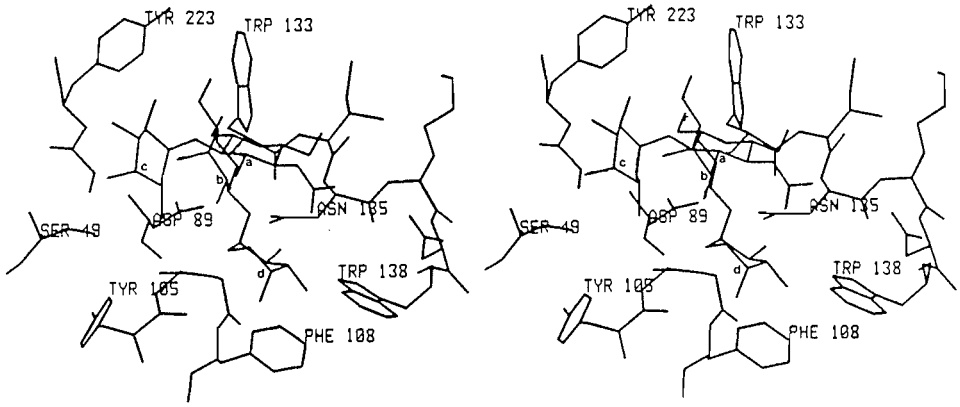

FIG. 4. Stereo illustration of the Le^b-OMe bound in the receptor site of GS4. The Asp 89 side chain is at the bottom of this cavity. This view is approximately the same as that in Fig. 2. The monosaccharide units of Le^b-OMe are denoted as follows: a, β-D-GlcNAc; b, β-D-Gal; c, α-L-Fuc(1 → 4); d, α-L-Fuc(1 → 2).

‡With α-D-Man-OMe (4).

§Both are reported to possess affinities for mannose/glucose. For the pea lectin the sequence number is one less, except for entry‖ where the sequence number is greater by five.

‖In the case of the pea lectin, alanine 221 replaces threonine 216.

site of GS4, except for the diglycine bridge between Tyr 105 and Phe 108, is that all of these have aromatic side chains that reside near the periphery of the complex. The amino acid side chains, which provide the key polar interaction, are toward the bottom of the shallow combining site.

Figure 4 shows a stereo drawing of the Le^b tetrasaccharide as it is bound in the complex with GS4. The GlcNAc-OMe group is not involved in any direct interactions with amino acid residues of GS4; this finding is in agreement with extensive inhibition (17) and thermodynamic studies of the binding of Le^b-OMe and several Le^b-OMe analogs (27). As was to be expected both from the cross-reaction with the Y tetrasaccharide and from the results obtained on probing the combining site with modified Le^b-OMe structures (17), the polar amino acid side chains hydrogen bond to the HO-3 and HO-4 groups of the β-D-Gal unit and to the HO-4 group of the α-L-Fuc(1 → 4) unit. An additional polar interaction involves the HO-2 group of the α-L-Fuc(1 → 2) unit. These polar interactions are surrounded by the five aromatic amino acids that make several van der Waals contacts with three of the four monosaccharide residues of Le^b-OMe.

The interactions between the Le^b-OMe tetrasaccharide and amino acid residues of GS4 are presented in Table 1. A further polar interaction, which has the hydroxyl group of Ser 49 hydrogen bonded to Tyr 105, was identified. The hydroxyl group of Ser 49 serves as proton acceptor from HO-4 of the α-L-Fuc(1 → 4) unit. As indicated, several interactions appear to be lipophilic in character (17). The 2.8 Å resolution structure appears to have Tyr 223 in lipophilic interaction with the β-D-Gal unit and with its hydroxyl group in contact with the aqueous phase.

As mentioned above, GS4 was found to possess extensive sequence homology with the Con A, favin, and pea lectins. A detailed comparison and alignment of the amino acid sequences

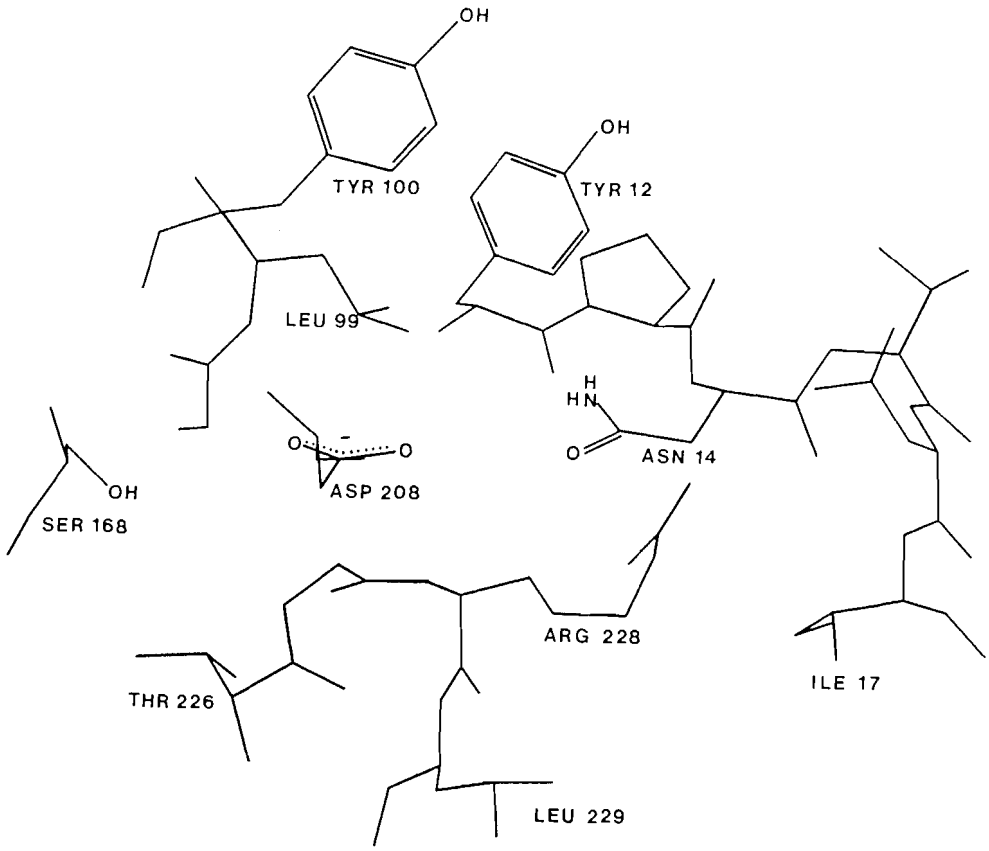

FIG. 5. The combining site in Con A as recently proposed (4) and extended to the regions that are homologous with the combining site of GS4. Selected non-carbon atoms are illustrated. This combining site should be compared with that of GS4 as shown in Figs. 2 and 4.

of GS4 with related lectins is underway. Also, the key polar interaction between GS4 and Le^b-OMe was found to be very similar to that between Con A and α-D-Man-OMe (Fig. 3). Indeed, in addition to Asp 89 and Asn 135 of GS4 being in sequence positions corresponding to Asp 208 and Asn 14 of Con A, Ser 49 of GS4 is equivalent to Ser 168 in Con A. Thus, it can be expected that the expression of the full specificity for Con A will prove to involve Ser 168 in a hydrogen bonding interaction with an appropriate oligosaccharide. Indeed, it is truly remarkable that the same tripeptide unit, namely, Ala-Asp-Gly, is found not only in all four lectins presented in Table 1, but also in seven other lectins listed in the recent review by Franz (2). Furthermore, Rini *et al.* (28) have found that Asp 81 of the pea lectin is involved in the binding of α-D-Man(1 → 3)[α-D-Man(1 → 6)]α-D-Man-OMe and Becker and Reeke (29) have reported the participation of Asp 82 in the binding of glucose by the favin lectin. Also, not only do the asparagine units that participate in the key polar interactions for the GS4 and Con A lectins correspond in sequence, but asparagine residues are found at the same sequence positions both in the favin and pea lectins (see Table 1) and in the lectins mentioned above and reviewed by Franz (2). For the favin and pea lectins, the adjacent amino acid residues are identical but this is not so for the corresponding asparagines of the GS4 and Con A lectins. These changes in structural features produce different topographies and are therefore expected to affect specificity of binding. In view of its widespread occurrence, the cooperation of anionic carboxylate and cationic Ca^{2+} for the strengthening of hydrogen-bonded networks may be a general binding property of lectins that contain Ca^{2+}. Furthermore, the region involving the combining site of these homologous lectins appears to contain an identical structural motif, which is responsible for binding oligosaccharides; this moiety consists of (i) the Ca^{2+} and Mn^{2+} cations with appropriate ligands, (ii) an Asn side chain that has the carbonyl group coordinated to the Ca^{2+} ion and the $-NH_2$ unit available for hydrogen bonding, (iii) a conserved tripeptide unit, Ala-Asp-Gly, which has a *cis*-peptide linkage between the Ala and Asp residues with the Asp side chain at the bottom of the depression and available for interaction with oligosaccharide.

Examination of Fig. 5 shows that the combining site that is proposed for the Con A lectin (the coordinates of Con A were obtained from the Protein Data Bank (30)) has several amino acid units with spatial dispositions very similar to those in the combining site of the GS4 lectin. However, these are mainly different types in that Trp 133, Trp 138, Phe 108, and Tyr 105 of the GS4 lectin are replaced by Tyr 12, Ile 17, Leu 229, and Thr 226 in the Con A lectin. Clearly, therefore, lipophilic interactions play a major role in determining the specificity of lectin affinities for oligosaccharides. In this regard, it is noteworthy that Tyr 223 in GS4 and Tyr 100 in Con A appear similarly disposed in space. These occur in sequences Gly-Tyr 223 and Gly-Leu-Tyr 100. In Fig. 5 the leucine 99 unit projects its side chain into the corresponding region of the GS4 combining site that accepts the α-L-Fuc(1 → 4) unit, see Fig. 4, and therefore the presence of Leu 99 must be an important reason that the Con A lectin does not bind Le^b-OMe. The peptide units of the favin and pea lectins, which fall into the sequence homology for the GS4 lectin, are so similar in primary structure (see Table 1) as to suggest that these two lectins have identical specificities.

Of major importance is the discovery arising from this study that the structural features of the GS4/Le^b-OMe complex are in good general accord with the kind of expectations that were

For personal use only.

based on the results of a systematic probing of the combining site using structurally slightly altered modifications of the Le^b-OMe tetrasaccharide (17, 27). Most noteworthy in this regard is the confirmation of the presence of an extensive contribution to the formation of the complex by lipophilic interactions. In fact, probing experiments have indicated that similarly extensive nonpolar interactions are present in the complexes between oligosaccharides and all the lectins and monoclonal antibodies that have been studied to date (31–36). Lemieux (37) has suggested that the stabilities of these complexes are importantly related to the exchange of interactions with water of amphiphilic regions of both the oligosaccharides and the combining site, with the interactions with water after the complex is formed. It was considered that the exchanges of polar interactions are mainly concerned with the provision of high fidelity to the specificity of the complexation. These notions were not previously expected for the association of such highly hydrophilic substances, like oligosaccharides, with proteins and may have a bearing on molecular recognition in general. It is anticipated that the X-ray structures of the wide array of isomorphous crystals (18) that have been obtained for complexes of GS4 with analogs of Le^b-OMe, and for which the thermodynamic parameters for their formation are known (38), will shed more light on this important matter, which is directly related to the role played by water.

Received November 15, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

ABDUL RASHID, WILLIAM MACKIE, IAN J. COLQUHOUN, and DORIANO LAMBA. Can. J. Chem. **68**, 1122 (1990).

The syntheses of the methyl α-D-galactopyranoside 2-, 3-, 4-, and 6-sulphates (**11**, **12**, **16**, and **21** respectively) have been achieved using trimethylamine – sulphur trioxide as the sulphating agent. The procedure used is high yielding and requires shorter reaction times than reported previously. Each compound was obtained in a crystalline form as the potassium salt. Improved syntheses are described of the 3,4-isopropylidene acetal **2** of the methyl α-D-galactopyranoside and methyl 2-*O*-acetyl 4,6-*O*-benzylidene α-D-galactopyranoside **8**, which are starting materials in the preparation of the 2- and 3-sulphates (**11** and **12** respectively). An efficient route has been devised for the synthesis of methyl 2,3,6-tri-*O*-acetyl-α-D-galactopyranoside **14** using a base-catalysed transesterification (C4-OH → C6-OH).

Key words: synthesis, methyl α-D-galactopyranoside, monosulphates.

ABDUL RASHID, WILLIAM MACKIE, IAN J. COLQUHOUN et DORIANO LAMBA. Can. J. Chem. **68**, 1122 (1990).

Utilisant le complexe triméthylamine – trioxyde de soufre comme agent sulfatant, on a réalisé la synthèse des α-D-galactopyranoside de méthyle 2-, 3-, 4- et 6-sulfates (**11**, **12**, **16**, et **21** respectivement). La méthode utilisée fournit d'excellents rendements et requiert des temps de réaction qui sont beaucoup plus courts que ceux utilisés antérieurement. On a obtenu les sels de potassium de chacun des composés sous une forme cristalline. On décrit des synthèses améliorées de l'acétal 3,4-isopropylidénique **2** de l'α-D-galactopyranoside de méthyle ainsi que du 2-*O*-actéyl-4,6-*O*-benzylidène-α-D-galactopyranoside de méthyle (**8**) qui sont des produits de départ pour la préparation des 2- et 3-sulfates (respectivement **11** et **12**). On a aussi mis au point une voie efficace pour la synthèse du 2,3,6-tri-*O*-acétyl-α-D-galactopyranoside de méthyle (**14**) qui fait appel à une transestérification catalysée par les bases (C4-OH → C6-OH).

Mots clés : synthèse, α-D-galactopyranoside de méthyle, monosulfates.

[Traduit par la revue]

Introduction

Sulphated carbohydrates are widely distributed in plants and animals. In animals, they occur in the glycosaminoglycans (chondroitins, keratan and dermatan sulphates) of the extracellular matrix of tissues such as cartilage, ligament, skin, cornea, and synovial fluid, in heparin which has anti-coagulant and anti-lipaemic properties, in brain and nerve tissue as sulphated cerebrosides (1, 2). In plants, they occur in the intercellular and cell wall region polysaccharides of brown and red algae (fucoidan, carrageenan) (3).

Of particular interest to us are the carrageenans. Structurally, these polysaccharides are based on an alternating sequence of α-(1 → 3)- and β-(1 → 4)-linked D-galactosyl residues, although the individual carrageenan samples differ according to the location of sulphate and the degree of sulphation as well as the occurrence of 3,6-anhydro-D-galactose residues (4).

Carrageenans are widely employed in the food industry as gelling agents due to their ability to form thermoreversible gels (5). It has been suggested that double-helical polysaccharide chains are involved in gel formation (6, 7) and there is evidence that cations associated with sulphate groups play an important role in the mechanism of gelation (8, 9). However, the exact function of the counterion is not well understood and it has been suggested that nonspecific competition by cations for water may also be important in promoting the interactions amongst polysaccharide chains that lead to the formation of a gel network, as well as specific conformational transitions of the polysaccharide chains (10–12).

Results from detailed structural studies on the polysaccharides are complex (13, 14). In consequence, we have endeavoured to explore the use of low molecular weight model compounds for obtaining reliable stereochemical data (15, 16). For example, X-ray crystallographic studies can provide information on hydrogen bonding and cation coordination that may be useful for modelling the polymer chains. High resolution ^{1}H and ^{13}C nmr, in both the solution and the solid state, may provide complementary information relevant to the biopolymer structure.

Suitable model compounds that could provide interesting stereochemical data on the polysaccharide chains of carrageenans are the methyl glycosides of galactose monosulphates. At the outset of our investigation, the only example of a definitive synthesis of such compounds was that of 4-(barium sulphate) of methyl α-D-galactopyranoside reported by Harris and Turvey (17). The compound was obtained in a modest yield from reaction of pyridine – sulphur trioxide with 2,3,6-tri-*O*-benzoyl-α-D-galactopyranoside. During the course of the present investigation, Vliegenthart and co-workers (18) reported the syntheses of sodium methyl α-D-galactopyranoside 2- and 3-sulphates, essentially using a similar sulphation procedure to the one employed by Harris and Turvey.

We now present the results of our own novel approach to the synthesis of potassium methyl α-D-galactopyranoside 2-, 3-, 4-

and 6-sulphates (**11**, **12**, **16**, and **21** respectively), using trimethylamine – sulphur trioxide as the sulphating agent. This sulphating agent has advantages over others in that the reaction times are shorter, the work-up is simple, and the product yields are high.

Results and discussion

For the synthesis of methyl α-D-galactopyranoside 2-sulphate **11**, the required intermediate, 3,4-*O*-isopropylidene-α-D-galactopyranoside **2**, was prepared by isopropylidenation of methyl α-D-galactopyranoside using a modification of the Liptak method (19). This procedure gave no significant amounts of the unwanted isomer **3**. Compound **2** was converted to the 6-*O*-trityl derivative **4** in the standard manner. Sulphation of **4** with trimethylamine – sulphur trioxide in dimethylformamide at 50–60°C for 30 min yielded **5**, which after removal of the protecting groups furnished **11** in 88% yield.

In the synthesis of methyl α-D-galactopyranoside 3-sulphate **12**, the intermediate methyl 2-*O*-acetyl-4,6-*O*-benzylidene-α-D-galactopyranoside **8** was obtained using the regioselective acetylation of methyl 4,6-*O*-benzylidene-α-D-galactopyranoside **6** via the stannylene intermediate **7** (20). Sulphation of **8** with trimethylamine – sulphur trioxide gave the protected sulphate **10**, which after deprotection gave **12** in 82% yield.

The intermediate methyl 2,3,4-tri-*O*-acetyl-6-*O*-trityl-α-D-galactopyranoside **13** was synthesized according to published procedure (23). Detritylation of **13** with a solution of chloroform saturated with hydrogen chloride gas at 0°C, followed by quenching the reaction with saturated aqueous sodium bicarbonate, led exclusively to the formation of methyl 2,3,6-tri-*O*-acetyl-α-D-galactopyranoside **14**. This C4 → C6 base-catalysed transesterification is well documented in the glucose series (21, 22). However, in the galactose series, attempts to prepare 1,2,3,6-tetra-*O*-acetyl-D-galactose from the corresponding 1,2,3,4-tetra-*O*-acetyl compound by acetyl migration in dilute alkali have led to complex mixtures of products (21). It is probable that the reaction time in alkali is critical and should be as short as possible.

Methyl α-D-galactopyranoside 4-sulphate **16** was obtained in an 86% yield from sulphation of **14** followed by subsequent removal of the acetyl groups with methanolic sodium methoxide.

In the synthesis of methyl α-D-galactopyranoside 6-sulphate **21**, it was appropriate to use the already available intermediate **13** to prepare the compound methyl 2,3,4-tri-*O*-acetyl-α-D-galactopyranoside **17** as described in the literature (23). Thus, to our surprise, detritylation of **13** with hydrogen chloride – chloroform at 0°C as before, followed by quenching the reaction with water, led to a mixture of 2,3,6-tri-*O*-acetyl **14** as the major product with **17** as a minor component. This result was in contrast to the published report (23) in which compound **17** was claimed to be the exclusive product, although no spectral data on the product are reported.

To overcome the problem of acetyl migration, it was decided to employ benzoyl as protecting groups since these are less prone to migration. Thus methyl 2,3,4-tri-*O*-benzoyl-α-D-galactopyranoside **19** was prepared from the corresponding 2,3,4-tri-*O*-benzoyl-6-*O*-trityl-α-D-galactopyranoside **18** by treatment with aqueous acetic acid. Sulphation of **19** with trimethylamine – sulphur trioxide followed by benzoyl deprotection using methanolic sodium methoxide furnished the 6-sulphate **21** in 88% yield.[2]

[2]Some preparations contained compound **16** as a minor impurity presumably arising as a result of benzoyl migration.

The sulphates **11**, **12**, **16**, and **21** were readily isolated as either the sodium or the potassium salts, each of which was usually crystalline.

The structures of the four sulphated monosaccharide potassium salts **11**, **12**, **16**, and **21** were confirmed by ^{13}C and ^1H nmr spectroscopy (Tables 1–3). The spectroscopic data are in general agreement with those published earlier (18) for the sodium salts of these compounds. In particular, protons α to the sulphate group are found to be deshielded by 0.4–0.7 ppm in comparison with corresponding protons in methyl α-D-galactopyranoside. The presence of a sulphate group causes an increase in the ^{13}C chemical shift of 6–8 ppm for the α carbons and a decrease of 1–2 ppm for the β carbons. Knowledge of these typical changes will be of value in interpreting the nmr spectra of sulphated oligo- and polysaccharides.

Experimental

Methyl α-D-galactopyranoside was purchased from Sigma Chemical Company and the trimethylamine – sulphur trioxide complex was obtained from Aldrich Chemical Company. Melting points were determined in capillary tubes with a Stuart melting point apparatus and are uncorrected. Optical rotations were measured at 22°C with a Thorn type 243 automatic polarimeter using a 0.1 dm cell. Elemental analyses were performed by the analytical service of the Department of Chemistry, University of Leeds.

The purity of the products was determined by tlc on silica gel 60 (Merck) with detection by charring with 5% sulphuric acid in ethanol. Column chromatography was performed on silica gel 60 (Merck, 70–230 mesh) and fractions were monitored by tlc. Unless otherwise indicated, the solvent systems used for chromatography were (v/v): A, 5:1 ethyl acetate – methanol; B, 1:1 ethyl acetate – petroleum ether (bp 60–80°C); C, 6:1 ethyl acetate – acetone; D, 4:1 ethyl acetate – methanol; E, 3:2 ethyl acetate – methanol; F, 2:1 ethyl acetate – methanol; G, ethyl acetate; H, 1:1 ethyl acetate – methanol; J, 2:3 ethyl acetate – petroleum ether (bp 60–80°C). Organic solvents were generally dried with anhydrous magnesium sulphate.

The nmr spectra were recorded at 25°C either on a Bruker AM-200 spectrometer at NMR Service, Area della Ricerca di Roma, C.N.R., Roma, or on a Jeol GX-400 spectrometer at the AFRC Laboratory, Norwich. ^1H chemical shifts were expressed in ppm relative to TMS using either TMS itself ($CDCl_3$ solutions) or acetone (δ 2.225 ppm, D_2O and CD_3OD solutions) as internal references. ^{13}C chemical shifts were also expressed relative to TMS using dioxan (δ 67.4 ppm, D_2O solutions) or solvent peaks ($CDCl_3$ 77.0 ppm, CD_3OD 49.0 ppm) as internal references.

Methyl 3,4-O-isopropylidene-α-D-galactopyranoside **2**

To a suspension of dry methyl-α-D-galactopyranoside **1** (5.72 g, 0.03 mol) in dry 2,2-dimethoxypropane (150 mL) was added *p*-toluenesulphonic acid monohydrate (0.3 g, 1.6 mmol). The reaction was stirred at room temperature for 48 h (the solid gradually dissolved) after which water (10 mL) was added. After 1 h (tlc showed a single product R_f 0.5, solvent A), the solvents were evaporated *in vacuo* and the residue chromatographed on silica (solvent C) to yield the product as a white solid. This solid was dissolved in acetone and precipitated with hexane to afford a crystalline product (6.2 g, 91%), mp 98–100°C (lit. (24) mp 97–98°C); $[\alpha]_D$ +147° (*c* 1, chloroform); ^1H nmr data (D_2O) δ: 4.75 (d, 1H, $J_{1,2}$ 3.7 Hz, H-1), 4.35 (dd, 1H, $J_{3,4}$ 5.4 Hz, $J_{4,5}$ 2.2 Hz, H-4), 4.19 (dd, 1H, $J_{2,3}$ 8.0 Hz, $J_{3,4}$ 5.4 Hz, H-3), 4.11 (ddd, 1H, $J_{4,5}$ 2.2 Hz, $J_{5,6}$ 4.3 Hz, $J_{5,6'}$ 7.9 Hz, H-5), 3.82 (dd, 1H, $J_{5,6}$ 4.3 Hz, $J_{6,6'}$ −11.8 Hz, H-6), 3.76 (dd, 1H, $J_{5,6'}$ 7.9 Hz, $J_{6,6'}$ −11.8 Hz, H-6′), 3.71 (dd, 1H, $J_{1,2}$ 3.7 Hz, $J_{2,3}$ 8.0 Hz, H-2), 3.38 (s, 3H, OMe), 1.47 (s, 3H, Me), 1.333 (s, 3H, Me).

Methyl 3,4-O-isopropylidene-6-O-trityl-α-D-galactopyranoside **4**

A solution of **2** (3.5 g, 15 mmol) and chlorotriphenylmethane (4.2 g, 15.1 mmol) in dry pyridine (50 mL) was kept at room temperature for 48 h, and then poured into ice-water (500 mL). The solvent was decanted from the sticky solid, and the solid was washed several times with water and finally taken up in acetone. Evaporation of the acetone under reduced pressure and chromatography of the residue (silica, solvent B) gave the product as a colourless foam, R_f 0.5 (5 g, 70%), mp 61–64°C (lit. (18) mp 60–61°C); $[\alpha]_D$ +49° (*c* 1, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.50–7.22 (m, 15H, Tr), 4.74 (d, 1H, $J_{1,2}$ 4.0 Hz, H-1), 4.21 (dd, 1H, $J_{3,4}$ 5.8 Hz, $J_{4,5}$ 1.9 Hz, H-4), 4.17 (dd, 1H, $J_{2,3}$ 10.3 Hz, $J_{3,4}$ 5.8 Hz, H-3), 4.01 (dt, 1H, $J_{4,5}$ 1.9 Hz, $J_{5,6}$ 6.3 Hz, $J_{5,6'}$ 6.3 Hz, H-5), 3.78 (ddd, 1H $J_{1,2}$ 4.0 Hz, $J_{2,OH}$ 6.5 Hz, $J_{2,3}$ 10.3 Hz, H-2), 3.46 (s, 3H, OMe), 3.45 (dd, 1H, $J_{5,6}$ 6.3 Hz, $J_{6,6'}$ −9.5 Hz, H-6), 3.36 (dd, 1H, $J_{5,6'}$ 6.3 Hz, $J_{6,6'}$ −9.5 Hz, H-6′), 2.24 (d, 1H, $J_{2,OH}$ 6.5 Hz, OH), 1.44 (s, 3H, Me), 1.33 (s, 3H, Me).

Methyl 3,4-O-isopropylidene-6-O-trityl-α-D-galactopyranoside 2-(potassium sulphate) **5**

To a solution of methyl 3,4-*O*-isopropylidene-6-*O*-trityl-α-D-galactopyranoside **4** (3.36 g, 7 mmol) in dry dimethylformamide (50 mL) was added trimethylamine – sulphur trioxide (2.1 g, 15 mmol), and the

reaction mixture heated with stirring at 50–60°C for 30 min (tlc then shows reaction to be complete, R_f 0.4, solvent D). After cooling, water (50 mL) was added to the reaction and the solution kept at room temperature for a further 30 min, the pH adjusted to neutrality by the addition of aqueous potassium bicarbonate, and the solvents removed under reduced pressure. The residue was taken up in methanol (50 mL), the solution filtered, and the filtrate evaporated to dryness. The residue was purified by chromatography on silica (solvent D) to afford the product as an amorphous solid (3.8 g, 90%). Recrystallized from isopropanol, mp 155–158°C (dec.); $[\alpha]_D$ +54° (*c* 1, methanol); ^{1}H nmr data (D_2O/acetone-d_6) δ: 7.25–7.65 (m, 15H, Tr), 5.14 (d, 1H, $J_{1,2}$ 3.2 Hz, H-1), 4.35 (dd, 1H, $J_{1,2}$ 3.2 Hz, $J_{2,3}$ 8.3 Hz, H-2), 4.34 (dd, 1H, $J_{3,4}$ 5.0 Hz, $J_{4,5}$ 3.2 Hz, H-4), 4.19 (dd, 1H, $J_{2,3}$ 8.3 Hz, $J_{3,4}$ 5.0 Hz, H-3), 4.15 (ddd, 1H, $J_{4,5}$ 3.2 Hz, $J_{5,6}$ 4.2 Hz, $J_{5,6'}$ 8.1 Hz, H-5), 3.30 (dd, 1H, $J_{5,6}$ 4.2 Hz, $J_{6,6'}$ −11.8 Hz, H-6), 3.38 (dd, 1H, $J_{5,6'}$ 8.1 Hz, $J_{6,6'}$ −11.8 Hz, H-6'), 3.41 (s, 3H, OMe), 1.46 (s, 3H, Me), 1.31 (s, 3H, Me); ^{13}C nmr δ: 145.50, 129.92, 128.90, 128.24 (Ph_3C), 109.90 (Me_2C), 99.84 (C-1), 75.61, 75.52, 75.33 (C-2/3/4, Ph_3C), 68.01 (C-5), 64.54 (C-6), 56.03 (OMe), 30.50 and 29.81 (Me_2C). Anal. calcd. for $C_{29}H_{31}KO_9S \cdot 2H_2O$: C 55.23, H 5.55, S 5.07; found: C 54.94, H 5.20, S 4.68.

Methyl α-D-galactopyranoside 2-(potassium sulphate) ***11***

Compound **5** (3.5 g, 5.8 mmol) was dissolved in a mixture of absolute ethanol (15 mL) – 50% acetic acid (15 mL), and the solution heated under reflux for 4 h (tlc then shows formation of a new product, R_f 0.5, solvent E). After cooling the reaction, the solvent was removed under reduced pressure, the residue coevaporated from ethanol, redissolved in ethanol (20 mL), and the solution neutralized with saturated aqueous potassium bicarbonate. The solvent was evaporated, the residue taken up in methanol, the solution filtered, and the filtrate evaporated to dryness. Chromatography of the residue (silica, solvent F) gave the product as a colourless solid which was crystallized from absolute ethanol (1.5 g, 88%), mp 185–190°C (dec.); $[\alpha]_D$ +100° (*c* 1, water). For the ^{13}C and ^{1}H nmr data, see Tables 1–3. Anal. calcd. for $C_7H_{13}KO_9S \cdot 3H_2O$: C 23.59, H 5.30, S 8.98; found: C 22.62, H 4.70, S 8.75.

*Methyl 4,6-benzylidene-2-*O*-acetyl-α-D-galactopyranoside* ***8***

A mixture of methyl 4,6-benzylidene-α-D-galactopyranoside **6** (2.82 g, 10 mmol) and dibutyltin oxide (2.48 g, 10 mmol) in dry methanol (100 mL) was heated under reflux for 2 h (the solution becomes clear) and then cooled. Evaporation of the solvent under reduced pressure gave a white solid **7**. This was dissolved in dry dioxan (50 mL), and to the solution was added triethylamine (2 mL, 15 mmol), followed by acetyl chloride (1 mL, 15 mmol) at 5°C. The reaction was allowed to warm to room temperature, stirred overnight, quenched with water (10 mL), and the solvents evaporated under reduced pressure. The residue was taken up in ethyl acetate (200 mL), washed with water (twice), dried, and the solvent evaporated to leave the crude product, R_f 0.6, solvent G. This was purified by chromatography on silica, first eluting with a mixture of ethyl acetate – petroleum ether 1:1 (200 mL), which is discarded, and then with ethyl acetate, to give the product as a white crystalline solid, which was crystallized from ethanol (2.5 g, 78%), mp 170–175°C (lit. (25) mp 168–174°C); $[\alpha]_D$ +140° (*c* 1, chloroform); H nmr data ($CDCl_3$) δ: 5.20 (dd, 1H, $J_{1,2}$ 3.6 Hz, $J_{2,3}$ 9.5 Hz, H-2), 4.88 (d, 1H, $J_{1,2}$ 3.6 Hz, H-1), 3.39 (s, 3H, OMe), 2.15 (s, 3H, OAc).

*Methyl 4,6-*O*-benzylidene-2-*O*-acetyl-α-D-galactopyranoside 3-(sodium sulphate)* ***10***

A mixture of 4,6-benzylidene-2-*O*-acetyl-α-D-galactopyranoside **8** (1.2 g, 4 mmol) and trimethylamine – sulphur trioxide complex (1.3 g, 10 mmol) in dry dimethylformamide (25 mL) was heated at 50–60°C for 30 min with stirring. Water (50 mL) was then added to the reaction mixture, and after 1 h the reaction was neutralized with aqueous sodium bicarbonate solution and the solvents evaporated under reduced pressure. The residue was dissolved in more water, the pH again adjusted to neutrality by adding aqueous sodium bicarbonate, and the solvents evaporated. The residue was dissolved in methanol (50 mL), the solution filtered, and the filtrate evaporated to dryness. Chromatography of the residue on silica (solvent D) afforded the product as an amorphous solid (1.5 g, 90%), R_f 0.5, recrystallized from ethanol, mp 160–165°C (dec); $[\alpha]_D$ +118° (*c* 1, methanol); H nmr data (D_2O) δ: 7.38–7.56 (m, 5H, aromatic), 5.70 (s, 1H, H-benz.), 4.93 (d,1H, $J_{1,2}$ 3.7 Hz, H-1), 4.69 (dd, 1H, $J_{3,4}$ 3.4 Hz, $J_{4,5}$ 4.6 Hz, H-4), 4.59 (dd, 1H, $J_{2,3}$ 10.2 Hz, $J_{3,4}$ 3.4 Hz, H-3), 4.18 (m, 2H, H6H6'), 4.04 (dd, 1H, $J_{1,2}$ 3.7 Hz, $J_{2,3}$ 10.2 Hz, H-2), 3.91 (m, 1H, H-5), 3.41 (s, 3H, OMe), 1.85 (s, 3H. OAc); ^{13}C nmr δ: 182.12 (MeCO), 152.74, 130.68, 129.51, 127.22 (PhC), 102.09 (C-1), 100.77 (PhC), 76.60, 75.40, 69.68, 66.70 (C-2/3/4/5), 63.45 (C-6), 58.18 (OMe), 24.63 (MeCO). Anal. calcd. for $C_{16}H_{19}NaO_{10}S \cdot 2H_2O$: C 41.55, H 4.97, S 6.92; found: C 41.88, H 4.90, S 6.35.

Methyl α-D-galactopyranoside 3-(potassium sulphate) ***12***

A solution of **10** (1.4 g) in 60% aqueous acetic acid (20 mL) was heated under reflux for 30 min. The cooled solution was evaporated to dryness, the residue taken up in dry methanol (20 mL) and treated with 1 M sodium methoxide in methanol solution (5 mL). After 30 min, the reaction mixture was acidified with Dowex-50 (H^+), the resin filtered, and the filtrate neutralized with aqueous potassium bicarbonate and evaporated to dryness. The residue was chromatographed on silica, first washing through with ethyl acetate – methanol 2:1, and then with ethyl acetate – methanol 1:1 to elute the required product as a white solid, R_f 0.5, solvent E; crystallized from dichloromethane and methanol (0.8 g, 82%), mp 180–185°C (dec.); $[\alpha]_D$ +126° (*c* 0.7, water). For the ^{13}C and ^{1}H nmr data, see Tables 1–3. Anal. calcd. for $C_7H_{13}KO_9S \cdot 2H_2O$: C 24.06, H 4.88, S 9.19; found: C 23.45, H 4.30, S 8.70.

*Methyl 2,3,4-tri-*O*-acetyl-6-*O*-trityl-α-D-galactopyranoside* ***13***

A solution of methyl α-D-galactopyranoside **1** (dried by heating at 110°C *in vacuo*) (5.72 g, 0.03 mol) and chlorotriphenylmethane (8.6 g, 0.031 mol) in dry pyridine (100 mL) was stirred at room temperature for 4 days (tlc then shows formation of product, R_f 0.4, solvent D). Acetic anhydride (10 ml, 0.2 mol) was added and the reaction allowed to proceed for a further 12 h. The contents were then poured into ice-water (500 mL), the product filtered, washed with absolute ethanol, and dried. Crystallization from ethanol gave the product as a white solid (12.5 g, 76%), mp 170–173°C (lit. (23) mp 167–169°C); $[\alpha]_D$ +60° (*c* 1, chloroform); ^{1}H nmr data ($CDCl_3$) δ: 7.20–7.41 (m, 15H, Tr), 5.53 (dd, 1H, $J_{3,5}$ 3.3 Hz, $J_{4,5}$ 1.2 Hz, H-4), 5.35 (dd, 1H, $J_{2,3}$ 10.7 Hz, $J_{3,4}$ 3.3 Hz, H-3), 5.08 (dd, 1H, $J_{1,2}$ 3.7 Hz, $J_{2,3}$ 10.7 Hz, H-2), 4.93 (d, 1H, $J_{1,2}$ 3.7 Hz, H-1), 4.04 (ddd, 1H, $J_{4,5}$ 1.2 Hz, $J_{5,6}$ 6.1 Hz, $J_{5,6'}$ 7.3 Hz, H-5), 3.39 (s, 1H, OMe), 3.31 (dd, 1H, $J_{5,6}$ 6.1 Hz, $J_{6,6'}$ −9.4 Hz, H-6), 3.05 (dd, 1H, $J_{5,6'}$ 7.3 Hz, $J_{6,6'}$ −9.4 Hz, H-6'), 2.07 (s, 3H, OAc), 1.97 (s, 3H, OAc), 1.90 (s, 3H, OAc).

*Methyl 2,3,6-tri-*O*-acetyl-α-D-galactopyranoside* ***14***

Compound **13** (5 g) was treated with a solution of chloroform saturated with hydrogen chloride gas at 0°C. After 10 min (tlc indicated reaction to be complete) the contents of the reaction were poured into a saturated aqueous sodium bicarbonate solution (50 mL). The organic layer was rapidly separated, dried, and evaporated to dryness. Chromatography of the residue on silica (solvent B) yielded the product as a syrup (2.5 g, 88%); $[\alpha]_D$ +150° (*c* 1, chloroform); ^{1}H nmr data ($CDCl_3$) δ: 5.25 (d, 1H, $J_{1,2}$ 3.6 Hz, H-1), 5.23 (dd, 1H, $J_{2,3}$ 10.6 Hz, $J_{3,4}$ 3.2 Hz, H-3), 4.97 (dd, 1H, $J_{3,4}$ 3.2 Hz, $J_{4,5}$ 1.0 Hz, H-4), 4.35 (dd, $J_{5,6}$ 6.0 Hz, $J_{6,6'}$ −11.0 Hz, H-6), 4.21 (dd, 1H, $J_{5,6'}$ 7.4 Hz, $J_{6,6'}$ −11.0 Hz, H-6'), 4.12 (dd, 1H, $J_{1,2}$ 3.6 Hz, $J_{2,3}$ 10.6 Hz, H-2), 4.04 (ddd, 1H, $J_{4,5}$ 1.0 Hz, $J_{5,6}$ 6.0 Hz, $J_{5,6'}$ 7.4 Hz, H-5), 3.39 (s, 4H, OMe, OH), 2.09 (s, 3H, OAc), 2.07 (s, 6H, 2OAc); ^{13}C nmr δ: 170.83, 170.37, 170.03 ($3CH_3CO$), 97.03 (C-1), 69.96 (C-4), 68.0 (C-3), 67.58, 67.41 (C-2/5), 62.86 (C-6), 55.14 (OMe), 20.79, 20.72, 20.67 ($3CH_3CO$). Methyl α-D-*galactopyranoside 4-(potassium sulphate)* **16**

Compound **15** (2.5 g) was dissolved in dry methanol (50 mL) and to the solution added methanolic 0.1 M sodium methoxide (10 mL) at room temperature. After 1 h, the reaction was complete as shown by tlc (solvent E), R_f 0.4. The solution was acidified with Amberlite IRC-50 (H^+), the resin filtered, and the filtrate neutralized with saturated aqueous potassium bicarbonate and concentrated to dryness. The residue was chromatographed on silica, eluting with ethyl acetate – methanol 2:1 to afford the product as a white solid (2.0 g, 86%), crystallized from aqueous isopropanol, mp 200–205°C (dec.); $[\alpha]_D$ +103° (*c* 1, water). For the ^{13}C and ^{1}H nmr data, see Tables 1–3. Anal. calcd. for $C_7H_{13}KO_9S\cdot 2H_2O$: C 24.06, H 4.88, S 9.19; found: C 23.20, H 4.40, S 8.50.

*Methyl 2,3,4-tri-*O*-benzoyl-*α*-D-galactopyranoside* **19**

Dry methyl α-D-galactopyranoside (5.72 g, 0.03 mol) and trityl chloride (8.6 g, 0.031 mol) in anhydrous pyridine (100 mL) were stirred together at room temperature for 24 h. Benzoyl chloride (17 mL, 0.15 mol) was then added dropwise with cooling and the reaction allowed to continue for a further 20 h after which the contents were poured into ice-water (1000 mL). The syrupy precipitate was dissolved in ethyl acetate (200 mL) and then washed with 0.1 M HCl, saturated aqueous sodium bicarbonate, water, dried, and concentrated to a syrup. Methyl 2,3,4-tri-*O*-benzoyl-6-*O*-trityl-α-D-galactopyranoside **18** was obtained as a white solid (19 g, 86%), R_f 0.8 (solvent J); ^{1}H nmr data ($CDCl_3$) δ: 8.06–7.12 (m, 1H, 3PhCO, Tr), 6.01 (dd, 1H, $J_{3,4}$ 3.3 Hz, $J_{4,5}$ 0.9 Hz, H-4), 5.96 (dd, 1H, $J_{2,3}$ 10.3 Hz, $J_{3,4}$ 3.3 Hz, H-3), 5.54 (dd, 1H, $J_{1,2}$ 3.6 Hz, $J_{2,3}$ 10.3 Hz, H-2), 5.23 (d, 1H, $J_{1,2}$ 3.6 Hz, H-1), 4.27 (dt, 1H, $J_{4,5}$ 0.9 Hz, $J_{5,6}$ 7.0 Hz, $J_{5,6'}$ 7.0 Hz, H-5), 3.68 (dd, 1H, $J_{5,6}$ 7.0 Hz, $J_{6,6'}$ −14.0 Hz, H-6), 3.43 (s, 3H, OMe), 3.27 (dd, 1H, $J_{5,6'}$ 7.0 Hz, $J_{6,6'}$ −14.0 Hz, H-6′); ^{13}C nmr δ: 166.05, 165.53, 165.30 ($3C_6H_5CO$), 129.88–126.96 ($3C_6H_5CO$, Tr), 97.42 (C-1), 86.95 (Ph_3C), 69.60 (C-4), 69.27 (C-3), 68.43 (C-5), 67.83 (C-2), 61.54 (C-6), 55.52 (OMe).

Compound **18** (10 g) was dissolved in 80% aqueous acetic acid (100 mL) and the solution heated under reflux for 2 h, cooled, and concentrated to a syrup. The product **19** was purified by column chromatography on silica (solvent J) and obtained as an amorphorus solid (6 g, 91%), R_f 0.4; ^{1}H nmr data ($CDCl_3$) δ: 7.96–7.13 (m, 15H, 3PhCO), 6.00 (dd, 1H, $J_{3,4}$ 3.2 Hz, $J_{4,5}$ 0.5 Hz, H-4), 5.95 (dd, 1H, $J_{2,3}$ 10.5 Hz, $J_{3,4}$ 3.2 Hz, H-3), 5.54 (dd, 1H, $J_{1,2}$ 3.5 Hz, $J_{2,3}$ 10.5 Hz, H-2), 5.23 (d, 1H, $J_{1,2}$ 3.5 Hz, H-1), 4.65 (dt, 1H, $J_{4,5}$ 0.5 Hz, $J_{5,6}$ 7.0 Hz, $J_{5,6'}$ 7.0 Hz, H-5), 3.69 (dd, 1H, $J_{5,6}$ 7.0 Hz, $J_{6,6'}$ −11.0 Hz, H-6), 3.43 (s, 3H, OMe), 3.28 (dd, 1H, $J_{5,6'}$ 7.0 Hz, $J_{6,6'}$ −11.0 Hz, H-6′); ^{13}C nmr δ: 166.06, 165.53, 165.30 ($3C_6H_5CO$), 129.79–128.33 ($3C_6H_5CO$), 97.42 (C-1), 69.28 (C-3/4), 68.43, 67.83 (C-2/5), 61.55 (C-6), 55.53 (OMe).

*Methyl 2,3,4-tri-*O*-benzoyl-*α*-D-galactopyranoside 6-(sodium sulphate)* **20**

To a solution of methyl 2,3,4-tri-*O*-benzoyl-α-D-galactopyranoside **19** (2.5 g, 5 mmol) in dry dimethylformamide (50 mL) was added trimethylamine – sulphur trioxide (1.4 g, 10 mmol) and the reaction mixture heated with stirring at 50–60°C for 30 min, after which tlc (solvent D) revealed a main product having R_f 0.7. Water (50 mL) was then added to the cooled reaction mixture and, after a further 30 min, the pH of the reaction was adjusted to neutrality by the addition of aqueous sodium bicarbonate solution, and the solvents were evaporated under reduced pressure. The residue was taken up in methanol (50 mL), the solution filtered, and the filtrate evaporated to dryness. The residual solid was washed with ether, dried, and crystallized from ethanol to afford the product as a white solid (2.7 g, 90%), mp 165–170°C (dec.); $[\alpha]_D$ +44° (*c* 1, methanol); ^{1}H nmr data (CD_3OD) δ: 8.07–7.21 (m, 15H, $3C_6H_5CO$), 5.97 (dd, 1H, $J_{3,4}$ 3.3 Hz, $J_{4,5}$ 1.2 Hz, H-4), 5.90 (dd, 1H, $J_{2,3}$ 10.6 Hz, $J_{3,4}$ 3.3 Hz, H-3), 5.67 (dd, 1H, $J_{1,2}$ 3.3 Hz, $J_{2,3}$ 10.6 Hz, H-2), 5.27 (d, 1H, $J_{1,2}$ 3.3 Hz, H-1), 5.65 (dt, 1H $J_{4,5}$ 1.2 Hz, $J_{5,6}$ 6.7 Hz, $J_{5,6'}$ 6.7 Hz, H-5), 4.16 (dd, 1H, $J_{5,6}$ 6.7 Hz, $J_{6,6'}$ −11.0 Hz, H-6), 4.15 (dd, 1H, $J_{5,6'}$ 6.7 Hz, $J_{6,6'}$ −11.0 Hz, H-6′), 3.53 (s, 3H, OMe); ^{13}C nmr δ: 134.73, 134.61, 134.42 ($3C_6H_5CO$), 131.02–129.22 ($3C_6H_5CO$), 98.94 (C-1), 70.84 (C-4), 70.56 (C-3), 68.60 (C-2), 66.96 (C-6), 56.14 (OMe). Anal. calcd. for $C_{28}H_{25}NaO_{12}S$; C 55.26, H 4.11, S 5.26; found: C 54.95, H 4.15, S 5.05

Methyl α-D-*galactopyranoside 6-(potassium sulphate)* **21**

A solution of **18** (2.5 g) in dry methanol (30 mL) was treated with methanolic 0.5 M sodium methoxide (3 mL) at room temperature. After 1 h the reaction was complete as shown by tlc (solvent E), R_f 0.5. The solution was acidified with Amberlite IRC-50 (H^+), the resin filtered, and the filtrate neutralized with saturated aqueous potassium bicarbonate and concentrated to dryness. The residue was chromatographed on silica, eluting with ethyl acetate – methanol 1:1 to afford the product as a white solid, crystallized from isopropanol and methanol (1.05 g, 88%), mp 210–215°C (dec); $[\alpha]_D$ +77° (*c* 1, water). For the ^{13}C and ^{1}H nmr data, see Tables 1–3. Anal. calcd. for $C_7H_{13}KO_9S\cdot 3H_2O$: C 23.59, H 5.33, S 8.98; found: C 22.90, H 4.65, S 9.20.

Received, December 8, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday[2]

R. GLASER, A. MICHEL, and M. DROUIN. Can. J. Chem. **68**, 1128 (1990).

The solid-state structure of nefopam methiodide, a quaternary ammonium salt of nefopam hydrochloride (a non-narcotic analgesic drug), has been determined by single crystal X-ray diffraction analysis. Nefopam methiodide gives crystals belonging to the monoclinic $P2_1/c$ space group and, at 298 K, a = 10.001(1), b = 9.928(1), c = 17.598(1) Å, β = 94.41(1)°, V = 1742.2(2) Å^3, Z = 4, $R(F)$ = 0.086, and $R_w(F)$ = 0.108. Due to disorder, the boat (flattened chair) and twist-chair (flattened chair) conformations of the 2,5-benzoxazocine eight-membered ring were both observed in the crystal with 55:45 occupancy, respectively. Positional disorder was also observed for the iodide counterion, which showed occupancies of 81:9.5:9.5.

Key words: nefopam, analgesic, X-ray crystallography, conformation.

R. GLASER, A. MICHEL et M. DROUIN. Can. J. Chem. **68**, 1128 (1990).

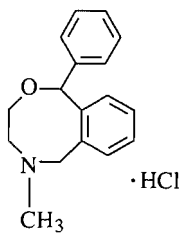
Faisant appel à la diffraction des rayons-X sur un cristal unique, on a déterminé la structure du méthiodure de néfopam, un sel d'ammonium quaternaire obtenu à partir du chlorhydrate de néfopam (un analgésique non-narcotique). Le méthiodure de néfopam donne des cristaux monocliniques qui appartiennent au groupe d'espace $P2_1/c$, avec a = 10.001(1), b = 9.928(1) et c = 17.598(1) Å, β = 94.41(1), V = 1742.2 Å^3, Z = 4, $R(F)$ = 0.086 et $R_w(F)$ = 0.108. À cause du désordre, les conformations bateau (chaise aplatie) et chaise croisée (chaise aplatie) du cycle à huit chaînons de la 2,5-benzoxazocine existent toutes les deux dans le cristal; les quantités relatives sont 45:55. On a aussi observé du désordre de positions pour le contre-ion iodure; les quantités relatives sont 81 : 9,5 : 9,5.

Mot clés : néfopam, analgésique, diffraction des rayons-X, conformation.

[Traduit par la revue]

Introduction

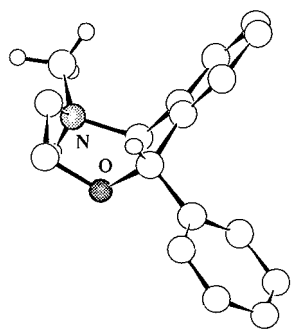
Nefopam hydrochloride (5-methyl-1-phenyl-3,4,5,6-tetrahydro-1*H*-2,5-benzoxazocine hydrochloride, **1**) is a non-narcotic



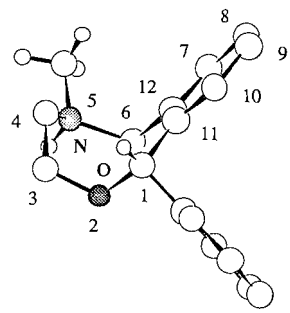
1

analgesic drug (1, 2). It has an equatorial *N*-methyl group orientation (**e**) in the crystalline state for both the racemic modification and for the chiral crystal (3, 4). The molecules in both types of crystal have similar geometries ((1*R*,5*R*)/(1*S*,5*S*) and (1*S*,5*S*) configuration, respectively (3)) in which the octagonal ring is twisted into the boat (flattened chair) conformation (4), **1e**. This is similar to the important boat-chair conformation having C_s symmetry observed for cyclooctane (5, 6).[3] In structure **1e**, the phenyl ring resides in a relatively sterically unhindered *exo*-type ring position *trans* to the methyl (3, 4).

Recently, ^{1}H and ^{13}C NMR evidence has been presented showing that acidic aqueous solutions (pH 1 or pD 1) of crystalline equatorial *N*-methyl racemic nefopam hydrochloride

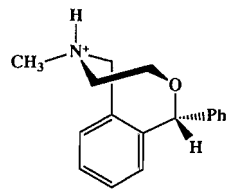


(+)-**1e**

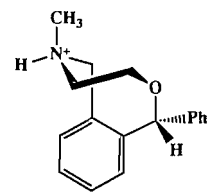


(±)-**1e**

(±)-**1e** show two slow exchange limit (SEL) $^+$NHCH$_3$ (or $^+$NDCH$_3$) diastereomeric species **1a,e** (ca. 1:1) differing in the stereochemistry of the *N*-methyl group (3, 8). The same two *N*-protonated diastereomeric species (**1a,e** ratio ca. 3:2) also exist in dichloromethane or chloroform solutions of crystalline (±)-**1e** or (+)-**1e**·H$_2$O (3, 8). A prototropic shift/nitrogen



1e



1a

inversion mechanism interconverts the two diastereomeric species in either aqueous medium or in the chlorinated organic solvent (3, 8).

While the boat (flattened chair) has been shown to be the

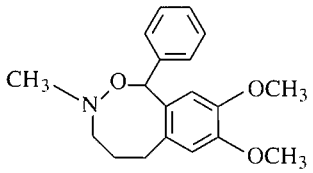
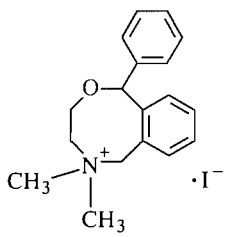
conformation for both solution species (3, 8), other benzoxazocine conformations are known, e.g., the twist-chair (flattened chair) has been found for the X-ray crystallographically determined structure of free base (±)-8,9-dimethoxy-3-methyl-1-phenyl-3,4,5,6-tetrahydro-1*H*-2,3-benzoxazocine (9), **2**. In the case of nefopam hydrochloride **1**, molecular mechanics has also shown this conformation to be comparable in energy to that of the boat (flattened chair) (4).



2

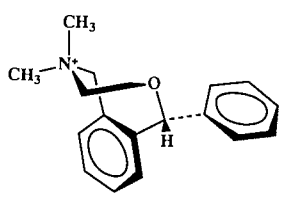
Some of the ^{1}H NMR resonances for the equatorial *N*-methyl epimer **1e** were observed to be broadened (the diastereotopic C(6) methylenic-*H*, in particular) (3, 8). This necessitated lowering the probe temperature to 233 K in order to sharpen them up (3, 8). However, no new resonances were readily apparent in the low temperature spectrum, and thus the boat (flattened chair) conformation **1e** was proposed as the major species in equilibrium with a *hidden partner* (8). This was in contradistinction to the line-shapes for the axial *N*-methyl **1a** species, since all the resonances for this epimer were found to be sharp in the ambient temperature ^{1}H NMR spectrum (8).

The ^{1}H and ^{13}C NMR spectral parameters of the nefopam methiodide quaternary ammonium salt **3** have recently been

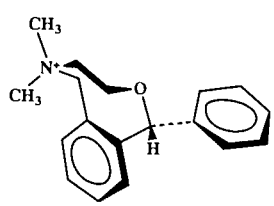


3

reported (10). Using trideuteriomethyl iodide, two isotopomeric **3**-d_3 diastereomers were produced as kinetic products of the quaternization (ca. 20% excess of equatorial *N*-CD_3 product was noted) (10). At ambient probe temperature, all the resonances were found to be ca. 3 times broader at half-height relative to that measured for an internal standard (10). The observation of this phenomenon suggested that conformational heterogeneity was also apparent for the quaternary salt (10). The time-averaged vicinal coupling constants and difference NOE experiments were readily interpreted as showing a preponderance of the boat (flattened chair) conformation species **4** within the equilibrium mixture solution (10). Based upon the earlier molecular mechanics studies (4), the second species was assigned as the putative twist-chair (flattened chair) conformation **5** (10). This paper reports the single-crystal X-ray diffraction analysis of the quaternary ammonium salt **3**, and the observation of both benzoxazocine conformations **4** and **5** in the disordered crystal.



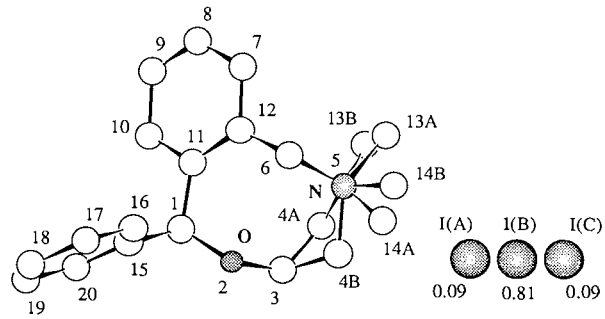
4



5

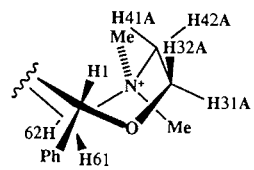
Results and discussion

Crystals of (±)-nefopam methiodide **3** belonging to the monoclinic space group $P2_1/c$ were obtained by vapour diffusion of acetone into an absolute ethanol solution of the salt. The crystal data are provided in Table 1. Due to disorder in the crystal, the boat (flattened chair) and twist-chair (flattened chair) conformations of the 2,5-benzoxazocine eight-membered ring were both observed in the solid state with 55:45 occupancy, respectively. Positional disorder was also observed for the iodide counterion, which showed occupancies of 9.5:81:9.5.

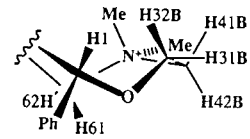


6

The atomic parameters *x*, *y*, and *z* for the boat (flattened chair) conformer (molecule **3A**), and the twist-chair (flattened chair) (molecule **3B**) conformer are listed in Table 2. The numbering scheme for the skeleton is provided in structure **6**, while that for the aliphatic protons is depicted in structure **7** (molecule **3A**) and in structure **8** (molecule **3B**). Intramolecular distances and



7



8

angles are given in Table 3, and selected torsion angles are presented in Table 4. Tables of thermal parameters, hydrogen atom coordinates, and structure factors have been deposited.[4]

Perusal of the octagonal-ring torsion angles in Table 4 shows that the **3A** boat (flattened chair) conformation is very similar to that found for both (±)-**1e** and (+)-**1e**·H_2O (4) (see **3A** versus (+)-**1e** and (±)-**1e** for a pictorial comparison).

[4]Hydrogen atom fractional coordinates, isotropic thermal parameters (B_{iso}), and corresponding occupancy factors for (±)-nefopam methiodide (**3**); anisotropic thermal parameters (×100) for non-hydrogen atoms with esd's in parentheses; and tables of observed and calculated structure factors have been deposited and may be purchased from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

Tables of isotropic thermal parameters and hydrogen atom coordinates have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from the Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, U.K.

3A

The *gauche* (synclinal) conformation oxydimethyleneamino fragment occupies the "boat" region of the boat (flattened chair) ring in **3A**. The staggered boat region of this conformation is similar to that found for the cyclooctane boat-chair (refs. 5, 6, and footnote 3) conformation, but differs in that the "chair" region of the cycle is distorted such that O(2) moves close to the nearly planar region denoted by C(1), C(6), C(11), and C(12) (and other benzo-ring atoms). This flattening of the chair region markedly reduces transannular nonbonded interactions in the benzoxazocine ring (e.g., that between H(1) and H(41A) in structure **7**). For instance, the internuclear distance between H(1) and the *endo*-oriented H(41A) is 2.26 Å in the MMX88 (11) molecular mechanics model of boat-chair cyclooctane **9**, versus 2.96 Å in a model of **3A** based on hydrogens geometrically placed on the X-ray crystallographically determined heavy-atom skeleton (C—H bond distance set at 1.08 Å). The latter value is similar to the 2.76 and 3.10 Å H(1)···H(41A) distances in crystalline (±)-**1e** and (+)-**1e**·H_2O, respectively (4). Flattening of the chair region by "pushing" C(11) "up" into the C(1,6,12) plane in **9** should result in a compensating torque around the C(1)—C(11) bond, thereby moving H(1ax) "down" and farther away from *endo*-H(41A).

Placement of a nonprotonated atom (oxygen) at the junction between the boat and chair regions in **1–3** also lessens the very severe transannular nonbonded interaction found in the parent hydrocarbon. This involves cyclooctane *endo*-oriented methylene protons ligated to carbons corresponding to O(2) and C(6). In addition, benzoxazocine-O(2) occupancy at the above-mentioned "junction" removed unfavorable torsional interactions found in

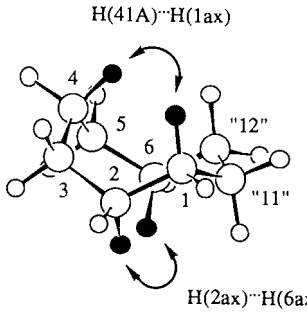
[e]For (+)-**1e** and (±)-**1e**, atoms no. 4, 13, and 14 are C(4, 13, 14); in **3A** they are C(4A, 13A, 14A); and in **3B** they are C(4B, 13B, 14B).
[f]Not applicable.

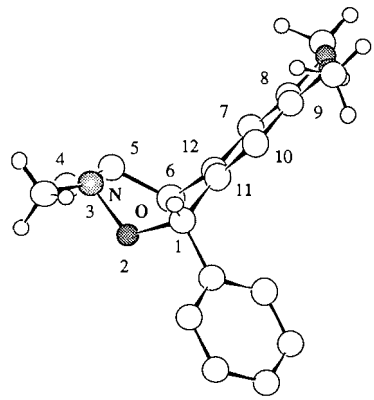
boat-chair cyclooctane **9** (20.8° H(1eq)—C(1)—C(2)—H(2eq) torsion angle from the MMX88 (11) model). The sp^2 hybridization for benzoxazocine-C(12) removed this interaction on the other side. The MMX88 calculated model for boat-chair **9** has octagonal-ring torsion angles that are very similar to those found by low temperature single-crystal X-ray diffraction analysis of a cyclooctane-thiourea adduct.[3]



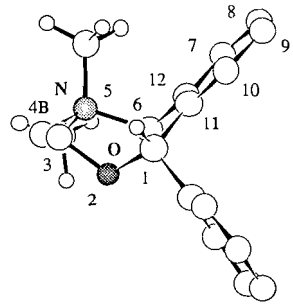
9

Inspection of the octagonal-ring torsion angles in Table 4 also shows that the twist-chair (flattened chair) conformation of **3B** is very similar to that found for **2** (9) (see **3B** versus **2** for a pictorial comparison). In addition, the pitch (or twist) of the phenyl ring around the C(1)—C_{ipso} bond in **3A** (and in **3B**) was found to be very similar to that in (±)-**1e**, while that for twist-chair (flattened chair) **2** was similar to that in (+)-**1e**.

Some of the Table 3 bond lengths involving atoms N(5), C(3, 4A/B, 13A/B, 14A/B) appear longer or shorter than expected (e.g., N—C(13A) is particularly long: 1.61(3) Å, while C(4A)—C(3) and C(4B)—C(3) are particularly short: 1.38(3) and 1.37(6) Å, respectively). The skeletal disorder concerning these very same atoms probably lies at the root of the problem.



2



3B

While the disorder then does present a problem, one must remember that the X-ray diffraction analysis was undertaken to study the molecular conformational geometry of the quaternary ammonium salt. When viewed in this light, it was indeed fortuitous that the skeletal disorder occurred, since it provided two different views of the molecule. The presence of two conformational types, and the assignment of their molecular geometries, is clear and undisputable, in spite of the fact that disorder in the crystal resulted in non-optimal final $R(F)$ and $R_w(F)$ values. The relatively large values of $R(F)$ and $R_w(F)$ are explained by the model for the iodine atom refinement, combined with the occurrence of a disordered structure. The existence of three iodine subsites accounts for anisotropic vibrations into a non-harmonic potential well. The validity of the model used is corroborated by interatomic distances of C(4A)···I(A) = 3.40(3) Å, C(4B)···I(A) = 3.26(5) Å, and C(7)···I(C) = 3.28(2) Å (where I(C) is symmetry related). Such values for close contacts are in accordance with the van der

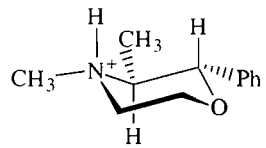
Waals radii deduced by Nyburg and Faerman (12), who determined the effective nonbonding shapes of halogen atoms from crystal data. Furthermore, the attractive van der Waals forces associated with such short distances can account for the anharmonicity. ORTEP drawings showing ellipsoids of thermal motion for atoms in **3A** and **3B** are depicted in Figs. 1 and 2, respectively.

Comparison of solution-state vs. solid-state conformational preferences for nefopam HCl/MeI

Molecule **3B** provides the first direct observation of a non-boat (flattened chair) conformation for the benzoxazocine skeleton of nefopam. As noted above, line-broadening of ^{1}H resonances for **1e** (and particularly for **3**) showed the existence of a rapid conformational equilibrium in CD_2Cl_2 solution (3, 8). Determination of the appropriate vicinal coupling constants for the -NCH_2CH_2O- fragment together with the use of Lambert's *R*-factor method (13) enabled the estimation of the time-averaged O(2)—C(3)—C(4)—N(5) dihedral angle (3, 8). Lambert's *R*-factor stands for a *ratio* of vicinal coupling constants ($R = (J_{aa} + J_{ee})/(J_{ae} = J_{ea})$) (12). In this method, the electronegative and orientation effects of X,Y-substituents in the -XCH_2CH_2Y- fragment are canceled by using a ratio of coupling constants (12). Thus, the O(2)—C(3)—C(4)—N(5) dihedral angles for the axial and equatorial *N*-methyl **1a,e** diastereomers in CD_2Cl_2 solution were estimated to be 53 ± 2° and 58 ± 2°, respectively (3, 8). These compared quite favorably with the X-ray crystallographically determined value of 57.7(2)° for (±)-**1e**, and the molecular mechanics determined 59.5° and 53.6° values for boat (flattened chair) **1e** and **1a**, respectively (4). Since the O(2)—C(3)—C(4)—N(5) dihedral angle is ca. 80 ± 3° for the twist-chair (flattened chair) conformation of **1** (molecular mechanics (4)), the experimentally determined values clearly point to a solution-state preference for the boat (flattened chair) geometry.

Nuclear Overhauser effect (difference-NOE) experiments were also consistent with boat (flattened chair) conformational preferences for **1e,a** in solution (8). Yet, line-broadening does show that another conformation is present for **1e**, albeit in minor amounts (3, 8). The equatorial *N*-methyl diastereomer of phendimetrazine mesylate **10** was used as a model for non-time-



10

averaged vicinal coupling constants in the *gauche* arrangement for the **1e** -NCH_2CH_2O- fragment (14). The study confirmed the time-averaged nature of the vicinal coupling constant values for the **1e** fragment (14).

As noted above, line-broadening for solutions of **3** appeared to be even more pronounced than that found for **1e** (10). Again, Lambert's method allows us to estimate a ca. 54° value for the O(2)—C(3)—C(4)—N(5) dihedral angle (10). The 48(1)° and −62(2)° values found for the (1*S*) enantiomer of solid-state (±)-**3A** and (±)-**3B**, respectively, show that the solution-state time-averaged value is consistent with a boat (flattened chair) preference for **3** in solution. The 55:45 **3A:3B** occupancy shows that only a slight conformational preference was found for **3** in the crystal. However, it remains to be proven whether the conformational disorder is dynamic or static.

The solid-state CP-MAS ^{13}C NMR spectrum of crystalline **3** was recorded in order to search for externally diastereotopic resonances from the two diastereomeric conformations. Only four of the six aliphatic ^{13}C resonances were found in the solid-state spectrum. A fairly sharp δ 85.33 C(1) signal was observed from the crystalline sample, but the C(3, 6) resonances are evidently overlapped at δ 66.97 (width at half-height ca. 3.1 times that for C(1)). Two *N*-methyl carbon resonances were observed at δ 54.46 and 50.17. Their assignment was confirmed by a dipolar dephasing experiment based on less efficient solid-state relaxation for methyl carbons (vis-à-vis methylene and methine carbons). After a suitable delay period was introduced prior to FID acquisition, *N*-CH_3 and $C_{quaternary}$ magnetization was still noted in the spectrum. While two species were not directly observed in the solid-state spectrum, the absence of a clearly defined signal from C(4) is consistent with the disorder for that atom. In comparison, time-averaged fast exchange limit resonances from all six aliphatic carbons were clearly assigned in the solution-state ^{13}C NMR (CD_2Cl_2) spectrum of **3** (δ 86.51 C(1), 65.61 C(3), 58.20 C(4), 68.09 C(6), 53.20 C(13), and 51.12 C(14)) (10). The δ 53.20 and 51.12 signals were assigned to internally diastereotopic equatorial and axial *N*-methyl carbons, respectively, via ^{1}H homonuc-

lear NOE experiments and an XHCORR $^{13}C/^{1}H$ correlation spectrum (10).

Studies are currently underway to force the nefopam benzoxazocine ring into structures having new stable conformations. Preliminary results have shown that appropriate derivatization of nefopam can afford compounds having predominantly the new twist-chair (flattened chair) conformation.[5]

Experimental

Nefopam methiodide was prepared by reaction of methyl iodide with nefopam free base in methanol. Nefopam hydrochloride was a gift of Mr. David Donnell of 3M Riker (United Kingdom). Dissolution in absolute ethanol followed by vapor diffusion of acetone yielded clear, colorless, crystalline prisms, belonging to the monoclinic system $P2_1/c$; melting point 253–256°C (dec.) (uncorrected).

Intensity data were collected at 298 K on an Enraf–Nonius CAD-4 automatic diffractometer. Table 1 provides crystallographic and data collection details. The NRCVAX programs (16) were used for centering, indexing, and data collection. The unit cell dimensions were obtained by a least-squares fit of 24 centered reflections in the range of $40° \leq 2\theta \leq 50°$. Reflections were measured with a constant scan speed of 2°/min. During data collection, the intensities of two standard reflections were monitored after every 60 min. No decay was observed.

The structure was solved by the application of direct methods and refined by least squares using the NRCVAX program (16). Unitary weights were used. Since the minimum and maximum transmission factors were respectively 0.13(1) and 0.23(1), an empirical absorption correction was applied. An isotropic extinction coefficient was included in the refinement (17) to account for secondary extinction effects (18); its value was 1.40(9). Atomic scattering factors stored in the NRCVAX program were those of Cromer and Waber (19). Hydrogen atomic positions were geometrically placed at 1.08 Å; they were assigned isotropic thermal parameters of their respective attached atoms but were not refined. Iodine subsites I(A) and I(C) and carbon (C(4A), C(4B), C(13A), C(13B), C(14A), and C(14B)) positions were refined isotropically and all other non-H atoms anisotropically. At convergence the final discrepancy indices on F were $R(F) = 0.086$ and $R_w(F) = 0.108$ for the 2690 reflections with $I_{net} \geq 2.5\sigma(I_{net})$ and 205 variables.[6] The residual positive and negative electron densities in the final map were 1.14 e/Å ($x,y,z = 0.4343, 0.7670, 0.3873$) near iodine subsite I(A) and −1.50 e/Å ($x,y,z = 0.6485, 0.7469, 0.3900$) near iodine subsites I(B) and I(C). The maximum shift/σ was 0.114. The occupancy factors for iodine subsites I(A), I(B), and I(C) and carbon atoms C(4A/B), C(13A/B), and C(14A/B) were refined. Upon convergence, the relative occupation for molecules A:B was found to be 55:45, while the relative occupation for I(A):I(B):I(C) was found to be 9.5:81:9.5.

The minimized energy geometry of the molecular mechanics calculated model compounds was determined by the MMX88 program (11), performed on a Micro VAX-II computer under Micro VMS V4.5. MMX88 is an enhanced version of Allinger's MM2 program (20) with MMP1 π-subroutines (21) incorporated for localized π-electron systems. Ball and stick structures were drawn with the BALL AND STICK 2.2 program (7). The ORTEP drawings were produced showing a 50% probability level for the ellipsoids of thermal motion.

Solid-state ^{13}C NMR (25.13 MHz) spectra were recorded on a Chemagnetics M100 solid-state Fourier transform spectrometer operating in the CP-MAS mode. Hexamethylbenzene (17.35 ppm CH_3) was used as an external secondary reference. An evolution delay period of 25 μs was used in the dipolar dephasing experiment (15).

[5]R. Glaser, J. Blumenfeld, K. Maartmann-Moe, and S. Geresh. Unpublished results.

[6]The final discrepancy index $R(F)$ is defined as $R(F) = (\Sigma_i||F_{obs}|_i - |F_{calc}|_i|)/(\Sigma_i|F_{obs}|_i)$; the weighted value R_w is defined as $R_w(F) = \mathrm{SQRT}[(\Sigma_i\{w_i(|F_{obs}|_i - |F_{calc}|_i|)\}^2)/(\Sigma_i\{w_i(|F_{obs}|_i)\}^2)]$, and the particular weighting factor w_i used is given in Table 1.

Acknowledgments

Gratitude is expressed to the Israel Center for Psychobiology, Charles E. Smith Family Foundation, for a research grant extended to R.G. Thanks are given to Dr. Fred Morin (McGill University) for recording the solid-state CP-MAS NMR spectra.

BRIAN R. HARKNESS and DEREK G. GRAY. Can. J. Chem. **68**, 1135 (1990).

A series of novel specifically substituted 6-*O*-trityl-2,3-*O*-alkyl cellulose derivatives have been prepared by the reaction of triphenylmethyl (trityl) cellulose in DMSO with powdered sodium hydroxide and an alkyl iodide (iodohexane, iodopentane, and iodobutane). These derivatives form lyotropic chiral nematic mesophases that exhibit both left- and right-handed twists. The dilute solution circular dichroism due to the phenyl chromophores along the chain does not correlate with the twist sense of the tertiary structures. However, a striking difference in the optical activity of the phenyl chromophores was observed in mesophases with the opposite twist sense. This may reflect some molecular factor responsible for the change in the macroscopic twist sense, or it may be due to the chirality of the helicoidal tertiary structure of the mesophase.

Key words: cellulose, trityl, mesophase, cholesteric, chiroptical.

BRIAN R. HARKNESS et DEREK G. GRAY. Can. J. Chem. **68**, 1135 (1990).

En faisant réagir de la triphénylméthyl (trityl) cellulose avec de l'hydroxyde de sodium et des iodures d'alkyles (iodohexane, iodopentane et iodobutane) en solution dans le DMSO, on a préparé une série de nouvelles 6-*O*-trityl-2,3-*O*-alkyl celluloses spécifiquement substituées. Ces dérivés forment des mésophases nématiques chirales lyotropes qui présentent des déviations vers la gauche ainsi que vers la droite. Des solutions diluées présentent un dichroïsme circulaire qui est dû aux chromophores phényles de la chaîne; il n'y a pas de corrélation entre ces spectres et le sens de rotation des structures tertiaires. Toutefois, les mésophases de sens de rotation opposés présentent des différences remarquables dans l'activité optique des chromophores phényles. Cette différence pourrait être le reflet de facteurs moléculaires responsables pour le changement dans le sens macroscopique de rotation ou bien elle pourrait être due à la chiralité de la structure hélicoïdale tertiaire de la mésophase.

Mots clés : cellulose, trityl, mésophase, cholestérique, chiroptique.

[Traduit par la revue]

Introduction

Many cellulose derivatives form lyotropic chiral nematic (cholesteric) liquid crystalline phases that exhibit reflection bands at specific wavelengths in the visible region due to the selective reflection of one component of circularly polarized light by the supramolecular helicoidal structure. The handedness of the reflected component depends on the twist sense of the helicoidal structure. Cellulose derivatives have been found to form both right-handed (1) and left-handed (2) chiral nematic structures. In some cases a chiral nematic inversion or change in twist sense may occur as the result of a chemical modification of the polymer (3, 4), a change in the solvent (2, 5), or a change in the temperature of the mesophase (6).

6-*O*-Triphenylmethyl-2,3-*O*-benzyl cellulose (TBzC) (7) and 6-*O*-triphenylmethyl-2,3-*O*-pentyl cellulose (TPeC) (8) form lyotropic liquid crystalline phases that exhibit chiral nematic reflection colours. In both of these cases the chiral nematic structure has a right-handed twist sense. Circular dichroism (CD) spectra of these polymers in dilute solution show peaks that correspond to the phenyl chromophores along the chain. These signals are the result of the perturbation of the phenyl electronic transitions by the chiral cellulose backbone. The signs and magnitudes of the phenyl CD bands were found to change markedly as the polymer concentration was increased above the critical concentration for liquid crystal formation. Although the formation of a liquid crystalline phase influences the apparent CD signals for the phenyl chromophores, it is not known whether a change in the twist sense of the chiral nematic structure influences this chiroptical activity.

In a continuation of our study of the chiroptical properties of triphenylmethyl (trityl) cellulose derivatives, we have prepared several new cellulose-based polymers with trityl groups at position six of the anhydroglucose units and alkyl groups at positions two and three. We find that this family of polymers forms both left-handed and right-handed lyotropic chiral nematic liquid crystalline phases. This observation has presented a unique opportunity to probe the relationship between the chiral nematic twist sense and the chiroptical activity of the phenyl chromophores in dilute solution and in the liquid crystalline state.

Experimental

Materials

Trityl cellulose was prepared by the reaction of regenerated cellulose (regenerated from cellulose acetate: Kodak; viscosity (ASTM-A) 27 ± 10) with triphenylmethyl chloride in pyridine according to the method of Hearon *et al.* (9). Trityl cellulose was alkylated according to a procedure similar to that described by Isogai *et al.* (10). Approximately 7–10 g of trityl cellulose was added to 300 mL of dry DMSO and allowed to dissolve. The clear solution was degassed with nitrogen for about 30 min. To the stirring solution was added 12 molar equivalents of sodium hydroxide per mole of polymeric hydroxyl groups (9 molar equivalents of base for the preparation of THeC1). The sodium hydroxide was pulverized with a mortar and pestle, or with a domestic coffee grinder prior to use. One hour following the addition of the sodium hydroxide, 12 molar equivalents of an alkyl iodide (iodobutane, iodopentane, or iodohexane) were added dropwise over 3 h (9 molar equivalents of iodohexane for the preparation of THeC1). The solution was stirred at 50°C for 18 h, then poured into 700 mL of methanol. The precipitate was filtered and dried under vacuum. The product was further purified by reprecipitation from tetrahydrofuran into methanol. A water wash of the filtered precipitate completed the purification process. The final yields of the polymers were greater than 85%.

General analysis

^{1}H NMR spectra were recorded with a Varian XL300 spectrometer at a frequency of 300 MHz. The spectra were recorded in chloroform-d_1 with tetramethylsilane as the internal reference. A small quantity of D_2O was added to the NMR solutions. The degrees of substitution of the 6-*O*-trityl-2,3-*O*-alkyl cellulose derivatives were determined by

integrating the ^{1}H NMR signals (which are proportional to the number of protons) and comparing the intensity of the side-group proton signals to the intensity of the signals from the cellulose backbone protons.

Infrared spectra of thin polymer films cast from chloroform were recorded with an Analect AQS-18 FTIR spectrometer. The mass average molar masses, $\overline{M}_w$, were measured in tetrahydrofuran with a Chromatix KMX6 long-angle laser light scattering photometer. Measurements of the Rayleigh factors for each solution were made at a scattering angle of 6–7°. The values for the specific refractive index increment dn/dc were measured with a Brice–Phoenix differential refractometer.

Solution properties

Concentrated solutions were prepared by placing approximately 0.15 g of the polymer into small vials and adding spectrograde chloroform or tetrahydrofuran to the polymer until an isotropic solution formed. The solvent was allowed to evaporate slowly over several days until the desired concentration had been reached. The vials were then weighed to determine the polymer concentration. The polymer solutions were quickly removed from the vials and placed as a thin layer between glass plates. The plates were sealed with epoxy to minimize solvent evaporation. The samples for UV–CD measurements were prepared as thin films (~0.1 mm) between quartz plates. During sample preparation some solvent evaporation occurred and therefore the actual polymer concentrations may be somewhat higher than the recorded value.

The dilute solution measurements were made on solutions of TPeC1 and THeC2 dissolved in spectrograde THF or chloroform, placed into 1.0 and 0.1 cm quartz solution cells at ambient temperature.

Circular reflectivity and circular dichroism spectra were recorded with a Jasco J-500 spectropolarimeter. Absorbance spectra were recorded with a Pye Unicam SP-150 UV–visible spectrometer equipped with a Mettler hot stage that heated the sample at a rate of 1 deg/min.

Results and discussion

Synthesis and characterization

The polymers 6-*O*-trityl-2,3-*O*-butyl cellulose (TBuC), 6-*O*-trityl-2,3-*O*-pentyl cellulose (TPeC), and 6-*O*-trityl-2,3-*O*-hexyl cellulose (THeC) were synthesized from trityl cellulose using a procedure similar to that described by Isogai *et al.* (10). These workers found that cellulosic hydroxyl groups can be alkylated by reacting cellulose, dissolved in a SO_2–DEA–DMSO solvent system, with sodium hydroxide and an appropriate alkyl iodide. A modification of these conditions has been successful in preparing 6-*O*-trityl-2,3-*O*-benzyl cellulose from trityl cellulose dissolved in DMSO (7). Unfortunately, this procedure was not as effective in promoting high degrees of substitution for the longer chain alkyl derivatives. As shown in Table 1, approximately one alkyl group substituted per anhydroglucose unit for both TBuC1 and TPeC1. The alkylating procedure was improved by grinding the sodium hydroxide into a very fine powder with the aid of a domestic coffee grinder. This modification resulted in much higher degrees of substitution, as shown for the polymers TBuC2, TPeC2, and THeC2. This improvement is likely due to the higher reactive surface area of the powdered sodium hydroxide as compared to the more granular form obtained upon hand grinding.[2] The lower DS for THeC1 resulted from the use of 9 rather than 12 molar equivalents of sodium hydroxide and iodohexane.

Figure 1 shows the 300 MHz ^{1}H NMR spectrum for TPeC2. The group of signals between 0.5 and 1.7 ppm can be assigned to most of the pentyl group protons. The signals between 2 and 5 ppm can be assigned to the cellulose backbone protons as well as to the pentyl protons adjacent to the ether linkage. The signals between 6.7 and 8 ppm are assigned to the trityl protons, and the sharp peak at 4.7 ppm is due to HOD present in the solution.

[2]T. Kondo. Personal communication.

TABLE 1. Degrees of substitution and molecular weights for a series of trityl-alkyl cellulose derivatives

Polymer	DS trityl	DS alkyl	Total DS	$\overline{M}_w$ (g/mol)
TBuC1	1.06	1.08	2.14	70 000
TPeC1	1.06	0.87	1.93	189 000
THeC1	1.06	1.21	2.27	166 000
TBuC2	1.03	1.74	2.77	166 000
TPeC2	1.03	1.82	2.85	144 000
THeC2	1.03	1.92	2.95	158 000

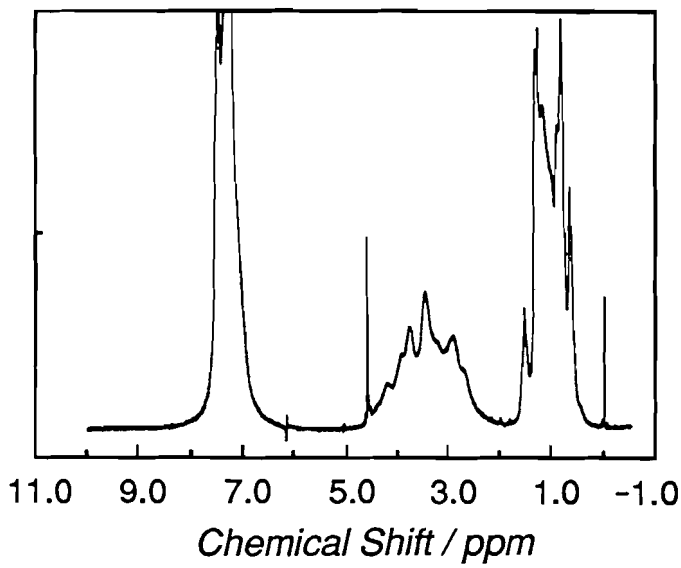

FIG. 1. 300 MHz ^{1}H NMR spectrum of TPeC2.

The NMR results were supported by the FTIR spectra, which showed only very small hydroxyl stretching bands for the polymers with high degrees of substitution. These results indicate that the described procedure is an effective method for alkylating trityl cellulose.

The mass average molar masses, $\overline{M}_w$, for these polymers are listed in Table 1.

Chiroptical properties

Concentrated solutions of the polymers in tetrahydrofuran and chloroform form liquid crystalline phases displaying anisotropy and microscopic textures when observed as thin layers under a polarizing microscope. Several of these mesophases exhibit chiral nematic reflection colours when dissolved in a particular solvent at a specific polymer concentration. The chiroptical properties of one of these polymers, 6-*O*-trityl-2,3-*O*-pentyl cellulose (TPeC1), has already been discussed in a previous paper (8). This polymer was found to form a right-handed chiral nematic structure when dissolved in tetrahydrofuran or chloroform. The reflection band wavelength was found to increase with an increase in temperature and decrease with an increase in the polymer concentration.

The 6-*O*-trityl-2,3-*O*-alkyl cellulose derivatives listed in Table 1 were found to form liquid crystalline phases above polymer concentrations of approximately 36 ± 4 mass percent polymer in tetrahydrofuran and 26 ± 4 mass percent polymer in chloroform.

The optical properties of the liquid crystalline solutions were strongly influenced by the chemical differences between the polymers. Several of these mesophases exhibited chiral nematic

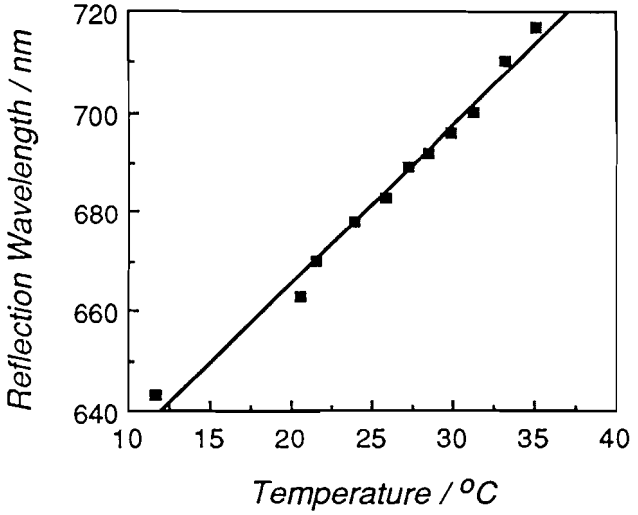

FIG. 3. Reflection wavelength as a function of temperature for a THeC2/THF mesophase at a concentration of 66 mass percent polymer.

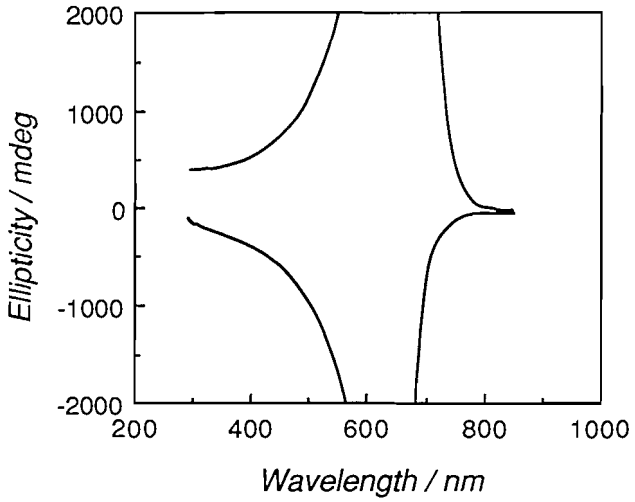

FIG. 4. Apparent circular dichroism spectra for the mesophases THeC2/THF (positive band) and TPeC1/THF (negative band) at concentrations of 66 and 46 mass percent polymer respectively.

reflection colours in tetrahydrofuran or chloroform, whereas others did not. Figure 2 shows the apparent absorbance spectra for mesophases of TPeC1 (solid line) and THeC2 (dashed line) in tetrahydrofuran at concentrations of 51 mass percent polymer and 66 mass percent polymer respectively. The reflection band for the THeC2 mesophase is much broader than the band for the TPeC1 mesophase. This indicates a higher degree of order and more perfect alignment of the chiral nematic axis in the less viscous TPeC1/THF mesophase.

The pitch, P, of the chiral nematic structure is determined from the wavelength of maximum reflectivity, λ_0, according to the relationship $\lambda_0 = \bar{n}P$, where $\bar{n}$ is the average refractive index of the mesophase (12). Due to the volatility of tetrahydrofuran and chloroform, $\bar{n}$ could not be measured accurately and, as a result, only the values of the reflection wavelengths are quoted in this report. The reflection wavelength for the THeC2/THF mesophase increases with an increase in temperature. As shown in Fig. 3, the increase in the reflection wavelength is almost linear with respect to temperature, with a value of 3.2 nm/deg C for $d(\bar{n}P)/dT$. The TPeC1/$CHCl_3$ mesophase exhibits a reflection band that is more sensitive to temperature (8), with a value of 7.2 nm/deg C for $d(\bar{n}P)/dT$.

The reflection wavelength as a function of temperature has also been measured for the mesophases TBzC/$CHBr_3$, TPeC1/$CHCl_3$, THeC2/THF, and TBuC1/$CHCl_3$ and in all of these cases the pitch increased with an increase in the temperature. This is the usual behavior for most cellulose derivatives although some show a decrease in the wavelength with increasing temperature (13), and a reversal of temperature dependence can occur in the two-phase region (14).

The reflection wavelengths for the mesophases TBzC/$CHBr_3$, TPeC1/$CHCl_3$, THeC2/THF, and TBuC1/$CHCl_3$ decrease with an increase in the polymer concentration. Again, this is the usual type of behavior although there have been reports of cellulose derivatives that show an increase in pitch as the polymer concentration is increased (13, 15). A change in the twist sense with a change in polymer concentration has been reported for the mesophase cellulose dicarbanilate/pyridine (13).

The circular reflectivity spectra for the mesophases THeC2/THF and TPeC1/THF, at concentrations of 66 and 46 mass percent polymer respectively, are shown in Fig. 4. The reflection for the TPeC1/THF mesophase shows negative ellipticity indicating that the right-handed component of the circularly polarized light is selectively reflected. The mesophase TPeC1/THF therefore has a right-handed chiral nematic structure. The reflection band for the THeC2/THF mesophase shows positive ellipticity, indicating that the left-handed circularly polarized component is selectively reflected. The mesophase THeC2/THF therefore has a left-handed chiral nematic structure. Table 2 lists the twist sense of the chiral nematic structures for the polymers in Table 1 that exhibit reflection colours in the visible region. The twist sense of the mesophases formed from TBzC (7) are also included in this list.

The difference in the handedness of the mesophases THeC2/THF and TPeC1/THF is another example of a change in the chiral nematic twist sense brought about by a change in the nature of the side groups attached to the cellulose backbone. It has been reported that a change in the handedness of cellulose acetate mesophases occurs when the unsubstituted hydroxyl groups on the polymer are trifluoroacetylated (3). Ethyl cellulose also shows a change in the twist sense when the remaining hydroxyl groups are acetylated (4) or ethylated (16). The twist sense of hydroxypropyl cellulose changes from right-handed to

L-H: Forms a left-handed mesophase.

?: Handedness not determined due to absence of visible reflection band.

left-handed upon attachment of acetoacetoxy groups to the polymer (17).

The results discussed above clearly indicate that derivatives of trityl cellulose are capable of forming both left- and right-handed chiral nematic mesophases depending on the nature of the side groups at positions two and three of the anhydroglucose units. It is not clear how the substitution of achiral groups onto the cellulose backbone affects the chirality of the chiral nematic mesophases formed by these derivatives. There have been several theoretical explanations for the observations of chiral nematic inversions in poly(γ-benzyl-L-glutamate)(PBLG) liquid crystals that occur with changes in solvent and temperature (18–21). A change in the optical activity of the polymer molecules can result in a change in the chiral nematic twist sense, although this is not a necessary condition for inversion. It has been shown (7, 8) that the phenyl chromophores of trityl cellulose derivatives show optically active electronic transitions in the ultraviolent region of the CD spectrum. This allows an examination of the chiroptical activity of these chromophores in the mesophase and in dilute solution.

The formation of a liquid crystalline phase from dilute solution can change the sign and magnitude of the optical activity observed from the trityl chromophores attached to the cellulose backbone of TPeC1 (8) and TBzC (7). However, it was not known what effect a change in the chiral nematic twist sense would have on this chiroptical activity since these derivatives formed only right-handed chiral nematic structures. It has been observed for lyotropic mesophases of poly(γ-benzyl-L-glutamate)(PBLG) (22), and thermotropic mesophases of poly(γ-benzyl L-glutamate-*co*-γ-dodecyl L-glutamates) (23), that the CD for the phenyl side groups changes sign when a change in the chiral nematic twist sense occurs. The CD spectrum for the phenyl transitions in mesophases of THeC2 (solid line) and TPeC1 (dashed line) in tetrahydrofuran at concentrations of 42 and 49 mass percent polymer, respectively, are shown in Fig. 5. It is apparent that the CD signals from the phenyl chromophores in the left-handed mesophase, THeC2, give a signal that is opposite in sign to the signal from the phenyl chromophores in a right-handed mesophase, TPeC1. It has been observed that all of the trityl cellulose derivatives that form right-handed chiral

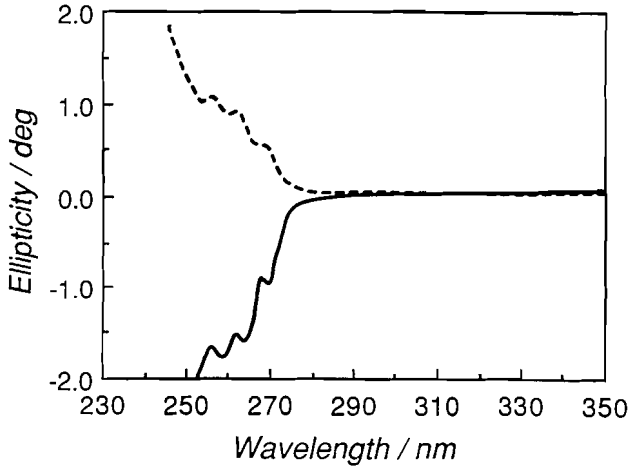

FIG. 5. CD spectra for THeC2/THF (solid line) and TPeC1/THF (dashed line) mesophases at concentrations of 42 and 49 mass percent polymer respectively.

nematic structures also show positive CD signals from the phenyl chromophores when in the mesomorphic state. The mesophase THeC2/THF has a left-handed chiral nematic structure and negative CD signals from the phenyl chromophores. These results suggest that the twist sense of mesophases formed by trityl cellulose derivatives correlates with the sign of the CD bands that arise from the phenyl chromophores in the mesophase.

Interestingly, it was observed that the phenyl CD bands for the THeC2/$CHCl_3$ mesophase were positive, like those observed in the right-handed mesophases. This suggests that there may be a solvent dependent change in the chiral nematic twist sense from left-handed in tetrahydrofuran to right-handed in chloroform. Unfortunately, the THeC2/$CHCl_3$ mesophase did not exhibit chiral nematic reflection colours in the lyotropic state, but reflection colours observed from thin films of THeC2, cast from chloroform, indicate that the frozen-in chiral nematic structure has a right-handed twist sense. This does not prove conclusively that the mesophase of THeC2/$CHCl_3$ is right-handed as it has been reported that the sign of CD peaks from chiral nematic reflection bands in cast films can be sensitive to residual linear orientation (24). If linear effects are present, then a rotation of the sample in the incident beam would be expected to alter the sign and magnitude of the reflection band. Rotation of the film sample by 90° in a direction orthogonal to the incident beam did not result in a change in the sign of the circular reflectivity band, and only a small change in the magnitude of the signal was observed. These results strongly indicate that there is in fact a solvent-dependent twist sense for mesophases of THeC2, which may be related to a difference in the conformation of this polymer in the two solvents.

In dilute solution, trityl cellulose derivatives show circular dichroism as a result of the chiral interaction between the phenyl chromophores and the cellulose backbone. If a change in polymer conformation is responsible for the change in twist sense, then this may be reflected in the dilute solution optical activity from the phenyl chromophores of THeC2 and TPeC1 in THF.

Figure 6 shows the dilute solution CD spectra for TPeC1 (solid line) and THeC2 (dashed line) in tetrahydrofuran. There are two phenyl electronic transitions that give rise to the CD bands in the region 210–280 nm. The ^1L_b transition exhibits negative ellipticity and characteristic fine structure with a maximum around 261 nm. The ^1L_a transition with its maximum

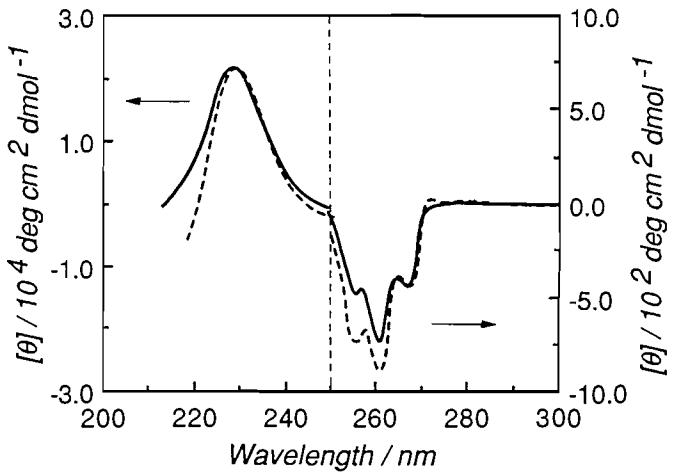

FIG. 6. Dilute solution CD spectra for TPeC1 (solid line) and THeC2 (dashed line) in tetrahydrofuran.

around 228 nm shows positive ellipticity. A comparison of the two spectra reveals that there are no changes in the signs of the CD bands, with the bands showing almost identical molar ellipticities. The similarity between the two spectra does not indicate a difference in the conformation of the trityl chromophores relative to the cellulose backbone for the two polymers. This result does not preclude the possibility that there are conformational differences in other regions of the polymer, such as the glycosidic linkage, that are responsible for the difference in the chirality of the liquid crystalline helicoidal structures. Since there does not appear to be a helical contribution to the dilute solution optical activity, as evidenced by the absence of exciton splitting of the bands, it is difficult to determine whether there is a difference in the conformation of the glycosidic linkages.

It is apparent from Fig. 6 that the dilute solution optical activity does not provide a basis for predicting the twist sense of the chiral nematic phases formed from THeC2 and TPeC1 in THF. The dilute solution CD spectra of THeC2 in chloroform and THF were identical, giving no indication of why the chiral nematic twist sense of this polymer is solvent dependent. It can be concluded that the difference in chiral nematic twist sense does not appear to be the result of a conformational change in the trityl group, although it is possible that the difference may be the result of other conformational changes in the polymer that are not reflected in the optical activity of the phenyl chromophores.

It was noted earlier that the formation of a chiral nematic mesophase from trityl-alkyl cellulose derivatives can alter dramatically the sign and magnitude of the CD signals from the phenyl chromophores. This is evident when comparing the dilute solution spectra in Fig. 6 with the spectra obtained in the mesophase (Fig. 5). The changes in the spectra due to mesophase formation may result from a tertiary helicoidal arrangement of chromophores enforced by the chiral nematic structure (11). Alternatively, the change in the sign and magnitude of the CD signal may be an artifact that results when CD measurements are made on a sample that is also linearly dichroic and linearly and circularly birefringent (25).

Conclusion

Several new specifically substituted trityl-alkyl cellulose derivatives with high degrees of alkyl substitution have been prepared by reacting trityl cellulose, dissolved in DMSO, with powdered sodium hydroxide and an alkyl iodide. These cellulose derivatives form chiral nematic mesophases with a right- or left-handed twist sense depending on the nature of the side-group substitution and the solvent. Dilute solution optical activity from the trityl group phenyl chromophores did not change when different alkyl groups were attached to the trityl cellulose backbone. Differences in the optical activity of the phenyl groups were observed in mesophases with opposite twist sense. Whether this indicates a molecular factor responsible for the twist sense of the mesophase or simply reflects the chirality of the chiral nematic phase is not yet clear.

Di-D-fructose 2′,1:2,1′-dianhydrides form complexes with metal cations if the two anomeric carbon atoms have the same configuration. Such anomers have the central 1,4-dioxane ring in a flexible form; complex formation involves O-1, O-1′, O-3, and O-3′, as confirmed by the X-ray crystal structure of the strontium complex of the β,β-dipyranose anomer. The α,β-anomers, and dianhydrides containing only furanose rings, do not form such complexes.
Key words: difructose dianhydrides, complex formation with cations, crystal structure of complex, chromatographic separation on ion-exchange resins.

STEPHEN JOHN ANGYAL, DONALD CHADWICK CRAIG, JACQUES DEFAYE et ANDRÉE GADELLE. Can. J. Chem. **68**, 1140 (1990).

Les 2′,1:2,1′-dianhydrides du di-D-fructose forment des complexes avec les cations métalliques si les deux atomes de carbone anomériques possèdent la même configuration. Dans de tels anomères, le cycle 1,4-dioxane central existe dans une conformation flexible; comme il a été établie par diffraction des rayons-X sur le complexe de strontium de l'anomère β,β-dipyranose, la formation de complexe implique les atomes O-1, O-1′, O-3 et O-3′. Les anomères α,β ainsi que les dianhydrides ne contenant que des cycles furanoses ne forment pas de tels complexes.
Mots clés : dianhydrides du difructose, formation de complexes avec les cations, structure cristalline du complexe, séparation par chromatographie sur des résines échangeuses d'ions.

[Traduit par la revue]

Introduction

The reaction of D-fructose or inulin with strong aqueous acids or with anhydrous hydrogen fluoride yields a mixture of difructose dianhydrides of which nine diastereomers have been isolated and characterized (2–5). To separate them, chromatographic methods are employed; five of the anhydrides have been separated from each other by reverse-phase high-performance liquid chromatography (HPLC) (6). It seemed desirable to ascertain whether chromatography on cation-exchange resins in the calcium form (7) would be suitable for their separation. In principle, this method does not seem to offer much promise because fructosides do not form strong complexes with cations (8): fructofuranosides do not complex, α-fructopyranosides form only very weak complexes at O-4–O-5, and β-fructopyranosides weak ones at O-4–O-5 and O-2–O-3. However, complexing involving hydroxyl groups of both fructose moieties may be favourable (9); in fact, it was found that one isomer, di-β-D-fructopyranose 2′,1:2,1′-dianhydride (**1**), complexes quite strongly. In this paper we describe the structure of this complex.

Results and discussion

Six of the dianhydrides have the 2′,1:2,1′ structure, that is, the anomeric carbon atom of each fructose moiety is linked to O-1 of the other one. (We shall use abbreviated names for them, for example, αF,βP for α-D-fructofuranose β-D-fructopyranose dianhydride.) The complexing ability of these six di-D-fructose 2′,1:2,1′-dianhydrides was compared by running them on TLC plates of cation-exchange resins in the calcium form (8). The R_f values are shown in Table 1. The same order was found for the retention times of these anhydrides on a "Sugar PAK 1" (Waters) HPLC column (an ion-exchange column in the Ca^{2+} form) (Table 1), confirming again that the HPLC separation on such a column is due to complex formation with the cation (9). It appears that all but the first two anhydrides could be separated from each other on a preparative ion-exchange column (7).

TABLE 1. TLC mobilities (R_f) and HPLC retention times (min) of di-fructose and di-sorbose 2′,1:2,1′-dianhydrides

Dianhydrides	R_f	Retention times (min)
αF,βF D-fructose	0.87	3.8
βF,βF D-fructose	0.86	3.8
αF,βP D-fructose	0.83	4.5
αP,βP D-fructose	0.78	4.8
βF,βP D-fructose	0.76	
βP,βP D-fructose	0.55	7.9
αP,βP L-sorbose	0.85	
αP,αP L-sorbose	0.70	7.7
αP,αP DL-sorbose		4.1

Table 1 shows that anhydrides with only furanose rings do not form complexes; those with one or two pyranose rings complex weakly; but one anhydride, the βP,βP isomer (**1**), complexes well, being strongly retained on the TLC plate and on the HPLC column. This strong complexing must be due to the involvement of oxygen atoms from both fructose moieties; its occurrence with just one isomer must be due to conformational factors.

In all of these anhydrides, the two fructose moieties are connected by a 1,4-dioxane ring. When C-2 and C-2′ have differing configurations, the dioxane ring, in its chair form, has

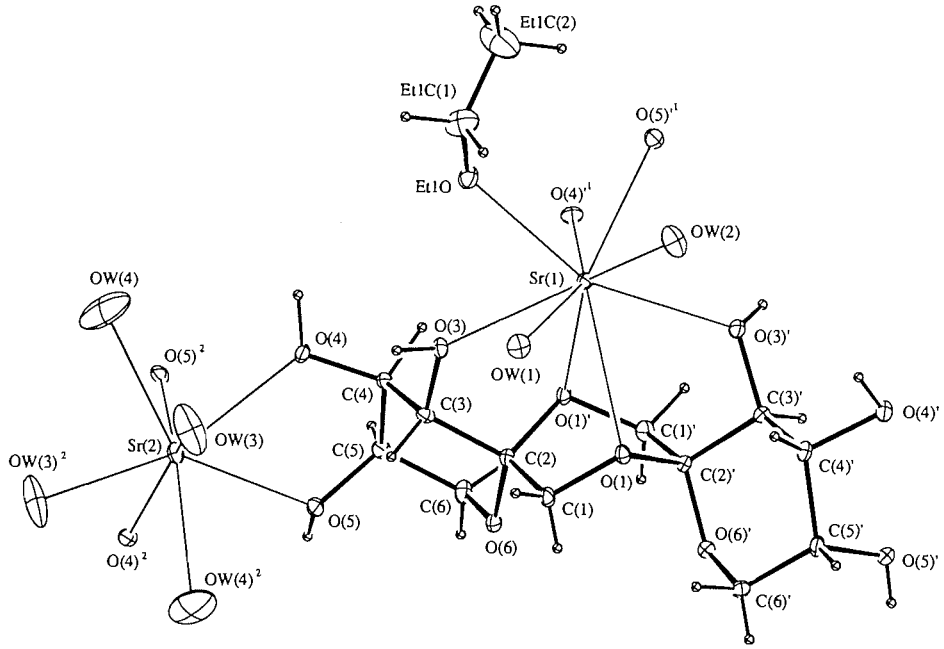

FIG. 1. ORTEP plot of the strontium complex of di-β-D-fructopyranose 2′,1:2,1′-dianhydride, showing the atomic numbering scheme. The coordination of O(4)′ and O(5)′ to another strontium ion is not shown.

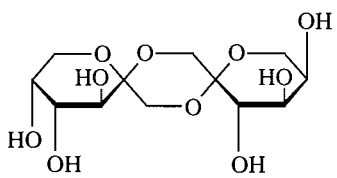
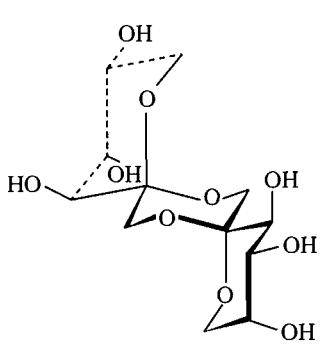
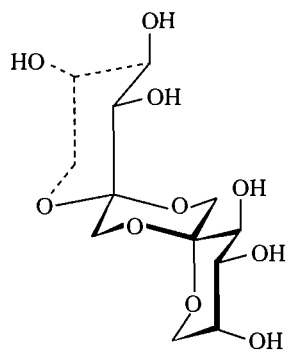
O-6 and O-6′ in axial disposition and C-3 and C-3′ in equatorial positions; a stable arrangement. An example is the αP,βP isomer (**2**), the conformation of which has been determined by X-ray crystallography (2). However, if the configurations of C-2 and C-2′ are the same, the dioxane ring in its chair form would have an axial carbon and an equatorial oxygen atom attached to it: an unfavourable arrangement. This is the case with the βP,βP isomer (**3**). Pedersen and co-workers (10) have shown that, in the crystal as well as in solution, this compound is found with the dioxane ring in a boat form, not only owing to the anomeric effect related to the 1,4-dioxane ring but also to the exo-anomeric effect related to the fructose moieties.



1



2



3

When the dioxane ring is in a chair form it is not possible for both of its oxygen atoms to be coordinated to the same cation. This is, however, possible in the skew or boat forms; moreover, both O-3 and O-3′ can be close to both ring oxygen atoms. It was therefore postulated that the complex formation of **1** is tetradentate and involves O-1, O-1′, O-3, and O-3′. In the βF,βP isomer, O-3 of the furanose ring cannot come close to O-1, although the dioxane ring must be in a flexible form here too; hence only tridentate complexing is possible, which is weaker (R_f 0.76). In the difuranose (βF,βF), both O-3 and O-3′ are unfavourably located for complex formation; hence complex formation is negligible.

Similar considerations apply to the di-L-sorbose dianhydrides (11). In the αP,αP isomer, the two anomeric centres have the same configuration; the compound differs from the βP,βP isomer of di-D-fructose dianhydride (**1**) only in the configuration of C-5 and C-5′. It complexes well with calcium ions, the R_f value being 0.70, only slightly higher than that of **1**. The difference is accounted for by the lack of *cis* hydroxyl groups on C-4 and C-5. By contrast, the αP,βP isomer of L-sorbose has R_f 0.85, indicating the absence of complex formation. Similarly, the mixed anhydride α-D-sorbopyranose α-L-sorbopyranose dianhydride (10) has two anomeric centres of differing configuration (α-D and α-L) and does not form a complex. It is so insoluble in water that it is not detected on the TLC plate but it emerges from the HPLC column after 4.1 min, compared with 7.7 min for the α-D, α-D isomer. The mixed anhydride β-D-fructopyranose α-L-sorbopyranose 2′,1:2,1′-dianhydride[3] has two anomeric centres of the same configuration (β-D and α-L); it also complexes well (R_f 0.65).

To prove the suggested location of the complexing site, we investigated the shifts caused by lanthanide ions in the ^{1}H NMR spectra (12). Addition of europium salts caused a small upfield shift of all of the signals in the spectrum of the βP,βP isomer; however, praseodymium salts shifted only the signal of H 3,3′

upfield, the other signals moving only slightly. The correlation between lanthanide-induced shifts and structure has only been studied (12) for tridentate complexes. The interpretation in case of tetradentate complexing is uncertain; all that can be safely concluded is that O-3 and O-3′ are involved in complex formation.

To establish the nature of complex formation, an X-ray crystal analysis of a complex was carried out. Suitable crystals were obtained of a complex of the βP,βP isomer with strontium chloride containing three strontium cations for two anhydride molecules. The structure is discussed in the next section. Two strontium ions were found to be coordinated, indeed, to O-1, O-1′, O-3, and O-3′ of the dianhydride, making it very probable that the same coordination would occur in solution too. The third strontium ion is coordinated only to O-4 and O-5 of two molecules; such bidentate complexing is, by past experience (9), not likely to persist in solution to any extent.

There are three known D-fructose dianhydrides that have, not the 2′,1:2,1′-, but the 2′,1:2,3′- structure. In these, there are no hydroxyl groups suitably placed for tetradentate complexing even when the 1,4-dioxane ring is in a flexible form, and they do not form complexes with cations: β-D-fructofuranose β-D-fructopyranose 2′,1:2,3′-dianhydride (2) and α-D-fructofuranose β-D-fructofuranose 2′,1:2,3′-dianhydride (4) both have R_f values of 0.85.

Crystal structure

The crystals investigated contain 1.5 strontium and 3 chloride ions for each anhydride molecule, and include water and ethanol of crystallization. Figure 1 shows a view of the complex with the

atomic numbering scheme.[4] The positional coordinates of the atoms (other than hydrogen) are shown in Table 2, bond distances in Table 3, selected bond angles in Table 4, and selected torsional angles in Table 5. The crystal structure is complex and shows several interesting features. Every oxygen atom of the anhydride is coordinated to a cation, except O-6 and O-6′. There are two different locations for the three strontium ions. Two are in ninefold coordination to O-1, O-1′, O-3, and O-3′ of one anhydride, O-4′ and O-5′ of another anhydride molecule, two water molecules, and one ethanol molecule. The third strontium cation, which lies on a crystallographic twofold axis, is in eightfold coordination: it bridges two anhydrides, being attached only to O-4 and O-5 of the two anhydrides, in addition to four water molecules. The coordination polyhedra are of irregular shapes. The Sr—O-1 and Sr—O-1′ distances are longer than the average Sr—O distances; these two oxygen atoms are bonded to two carbon atoms each and hence appear to form weaker coordination bonds than the others.

The conformation of the dianhydride in the strontium complex is remarkably similar to that of the uncomplexed βP,βP isomer of which the structure has been determined (10) but not yet published;[5] however, Dr. Pedersen kindly sent us his results. The 1,4-dioxane ring is also in the $^{O,O}B$ boat form; O-3 and O-3′ are in positions where they can coordiante to Sr^{2+} ions with the usual Sr—O distance. That is, the site for fourfold coordination is present in the molecule in its preponderant conformation and no change of conformation occurs when the complex is formed.

Experimental

α-D-Fructofuranose β-D-fructofuranose 2′,1:2,3′-dianhydride was a gift from Dr. Takao Uchiyama; the other dianhydrides were prepared as described (2, 3, 11). TLC was carried out on ion-exchange plates (Polygram Ionex-25 SA, from Macherey–Nagel GmbH, 5160 Düren, Germany) at ambient temperature (8), HPLC on a Sugar PAK 1 column (Waters) at 93°C. NMR spectra were recorded with a Bruker AM-500 spectrometer.

Lanthanide-induced shifts

^{1}H NMR data for β-D-fructopyranose β-D-fructopyranose 2′,1:2,1′-dianhydride: δ (D_2O): 3.80 (m, $J_{4,5}$ 3.5, $J_{5,6eq}$ 1.2, $J_{5,6ax}$ 2.0 Hz, H-5), 3.78 (d), $J_{1,1'}$ −12.5 Hz, H-1), 3.76 (dd, $J_{6eq,6ax}$ −12.5 Hz, H-6_{eq}), 3.72 (dd, $J_{3,4}$ 10.0 Hz, H-4), 3.52 (dd, H-6_{ax}), 3.51 (d, H-3), 3.47 (d, H-1′). The data shown for this isomer in ref. 2 are, erroneously, those for the αP,βP isomer. Addition of 0.01 equiv. of $PrCl_3$ caused the following induced shifts: H-1, −0.03; H-1′, −0.05; H-3, −0.21; H-4, −0.02; H-5, −0.01; H-6, 0.02; H-6′, −0.02.

Preparation of the crystalline strontium complex

The βP,βP isomer readily forms crystalline 1:1 complexes with

[4]Tables of atomic parameters with standard deviations, interatomic distances, interatomic angles, and rotational angles may be purchased from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

Tables of atomic parameters, interatomic distances and angles have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, U.K.

[5]NOTE ADDED IN PROOF: Described by J. A. Kanters, A. Schouten, J. Kroon, M. Mathloutli, J. H. van der Maas, and B. Lutz. Acta Crystallogr. Sect. C: Cryst. Struct. Commun. **C45**, 1934 (1989).

$CaCl_2$, $SrCl_2$, $BaCl_2$, or $LaCl_3$ when ethanol is added in small aliquots to a concentrated aqueous solution of an equimolecular mixture of the salt and the dianhydride; for example, Anal. calcd. for $C_{12}H_{20}O_{10}\cdot CaCl_2\cdot 2H_2O$: C 30.38, H 5.06, Ca 9.07, Cl 14.98; found: C 30.46, 30.35; H 5.35, 5.59, Ca 8.05, 8.13; Cl 15.36, 15.08. These 1:1 complexes form very thin long needles, unsuitable for X-ray crystal analysis.

When a large excess of $SrCl_2$ was used, the thin needles appeared readily but, on standing in solution, gradually changed into stout prisms. When this change was complete, the crystals were collected: they proved to be 2:3 complexes, suitable for X-ray analysis.

Crystal data

$C_{12}H_{20}O_{10}\cdot(SrCl_2)_{1.5}\cdot(H_2O)_5\cdot(C_2H_5OH)_{1.5}$ $M = 721.3$

Orthorhombic, space group $P2_12_12$, $a = 13.132(2)$, $b = 25.757(5)$, $c = 8.596(1)$ Å, $V = 2907.6(8)$ Å^3, $D_c = 1.65$ g cm^{-3}, $Z = 4$, $\mu_{Mo} = 30.20$ cm^{-1}. Crystal size 0.17 × 0.16 × 0.21 mm, $2\theta_{max} = 50°$, maximum and minimum transmission factors 0.55 and 0.66. The number of reflections was 2303 considered observed out of 2912 unique data. Final residuals R, R_w were 0.036, 0.048. Changing enantiomers resulted in R, R_w of 0.070, 0.094, so the original assignment seems correct.

Structure determination

Reflection data were measured with an Enraf–Nonius CAD-4 diffractometer in $\theta/2\theta$ scan mode using graphite monochromatized molybdenum radiation (λ 0.7107 Å). Data were corrected for absorption. Reflections with $I > 3\sigma(I)$ were considered observed. The structure was determined by direct phasing and Fourier methods. Hydrogen atoms for the carbohydrate moiety were located in a difference Fourier, positions for those of the coordinated ethanol were calculated, and all were assigned thermal parameters equal to those of the atom to which bonded. Hydrogen atoms were not located for the water molecules and the second ethanol, which was disordered about a 2-fold axis. Positional and anisotropic thermal parameters for the non-hydrogen atoms were refined using full-matrix least squares. Reflection weights used were $1/\sigma^2(F_o)$, with $\sigma(F_o)$ being derived from $\sigma(I_o) = [\sigma^2(I_o) + (0.04I_o)^2]^{1/2}$. The weighted residual is defined as $R_w = (\Sigma w\Delta^2/\Sigma wF_o^2)^{1/2}$. Atomic scattering factors and anomalous dispersion parameters were from International tables for X-ray crystallography (13). Structure solution was by MULTAN 80 (14) and refinement used BLOCKLS, a local version of ORFLS (15). ORTEP-II (16) running on a Macintosh IIcx was used for the structural diagram, and an IBM 3090 computer was used for the calculations.

Two-dimensional POMMIE carbon–proton chemical shift correlated ^{13}C NMR spectrum editing

BRUCE COXON

Center for Analytical Chemistry, National Institute of Standards and Technology, Gaithersburg, MD 20899, U.S.A.

Received December 11, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

BRUCE COXON. Can. J. Chem. **68**, 1145 (1990).

Two pulse sequences are described for acquisition of two-dimensional, carbon–proton chemical shift correlated ^{13}C NMR spectra by the "phase oscillations to maximize editing technique". One of these sequences provides two-dimensional, carbon–proton chemical shift correlated spectra in which the ^1H–^1H coupling constants are present in the ^1H chemical shift dimension, whereas the other sequence includes a bilinear rotation decoupling unit that removes the vicinal ^1H–^1H couplings in this dimension. Extensions of these techniques to generation of two-dimensional, carbon–proton chemical shift correlated CH, CH_2, and CH_3 ^{13}C NMR subspectra from linear combinations of three two-dimensional data sets are described. Decreased residual signals in the edited 2D subspectra have been achieved by Pascal programs that include six floating point coefficients, and a method for their calibration is discussed. Results are reported for troleandomycin (**1**).

Key words: ^{13}C nuclear magnetic resonance, carbon–proton chemical shift correlation, DEPT, Pascal programs, POMMIE, two-dimensional NMR spectrum editing, troleandomycin.

BRUCE COXON. Can. J. Chem. **68**, 1145 (1990).

On décrit deux séquences de pulsation qui permettent de faire l'acquisition de spectres RMN bidimensionnels du ^{13}C, avec corrélation des déplacements chimiques carbone–proton, par la «technique des oscillations de phase dans le but de maximiser l'édition». Une de ces séquences fournit des spectres bidimensionnels avec corrélation des déplacements chimiques carbone–proton dans laquelle les constantes de couplage ^1H–^1H sont présentes dans la dimension du déplacement chimique du ^1H; l'autre séquence comporte une unité de découplage bilinéaire de la rotation qui élimine les couplages vicinaux ^1H–^1H de cette dimension. On décrit des extensions de ces techniques qui permettent, à partir de combinaisons linéaires de trois données en deux dimensions, de générer des sous-spectres RMN bidimensionnels du ^{13}C des CH, des CH_2 et des CH_3, avec corrélation des déplacements chimiques carbone–hydrogène. On a diminué les signaux résiduels dans les sous-spectres 2D édités en faisant appel à des programmes en Pascal comportant six coefficients à point flottant; on discute d'une méthode pour leur calibration. On rapporte les résultats obtenus avec la troléandomycine (**1**).

Mots clés : résonance magnétique nucléaire du ^{13}C, corrélation des déplacements chimiques carbone–proton, DEPT, programme en Pascal, POMMIE, édition de spectres RMN bidimensionnels, troléandomycine.

Introduction

Polarization transfer techniques have made a significant contribution to the analytical power of nuclear magnetic resonance (NMR) methods. Many one-dimensional (1D) and two-dimensional (2D) NMR methods are based on these techniques, as are several procedures for NMR spectrum editing, which may be defined as the selective display of the resonances of individual molecular features. The **D**istortionless **E**nhancement by **P**olarization **T**ransfer (DEPT) technique (1, 2) has played a major role in the development of heteronuclear NMR spectrum editing or structure selective methods, and both 1D (1, 2) and 2D (3–6) implementations of these methods have been described.

A number of practical advantages have been claimed for an alternative polarization transfer technique, namely, the **P**hase **O**scillations to **MaxiMI**ze **E**diting (POMMIE) method (7, 8), which in its 1D form is similar to DEPT, except that the polarization transfer pulse (θ) in the latter method is supplanted by a pair of successive 90° pulses that are arranged to have a variable phase difference ϕ. The intensities of ^{13}C NMR signals acquired by the POMMIE technique (7, 8) have the same theoretical dependences on the phase shift ϕ as do the corresponding DEPT intensities on the pulse flip angle θ (1, 2). These dependences are $CH = k \sin x$, $CH_2 = k \sin 2x$, and $CH_3 = 3k (\sin x + \sin 3x)/4$, where $k = \gamma_H/\gamma_C$, and $x = \phi$ or θ.

2D heteronuclear, chemical shift correlation NMR (9, 10) has proved to be one of the more useful techniques for the structural analysis of organic and inorganic materials (11). This paper describes the use of two pulse sequences for 2D POMMIE, chemical shift correlated spectrum editing as alternative processes for simplifying interpretation of the shift correlated spectrum. Refinement of the 2D editing computations has been realized by introducing six floating point coefficients into the linear combinations of data that are used to compute the subspectra. The methods have been tested on the macrocyclic antibiotic, troleandomycin (**1**, the tri-*O*-acetyl derivative of oleandomycin (12)).

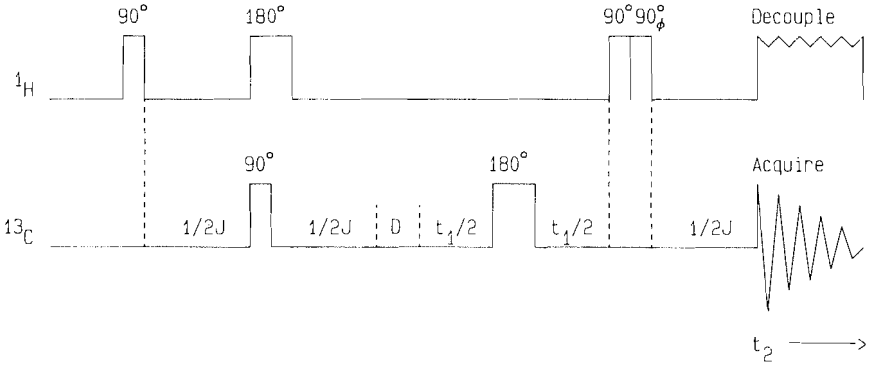

FIG. 1. Pulse sequence for 2D POMMIE, carbon–proton chemical shift correlated, ^{13}C NMR spectroscopy. J is an average value of the coupling constant between directly bonded proton and carbon nuclei, D is a delay equal to the width of the ^1H 180° pulse, and ϕ is the RF phase difference of the adjoining ^1H 90° pulses. Phase programs are listed in Table 1.

Experimental

Materials

A 0.2 mol L^{-1} solution of troleandomycin (**1**) in 1:1 v/v chloroform-*d*:dimethylsulfoxide-d_6 was used.

Measurement of ^{13}C NMR spectra

^{13}C NMR spectra were recorded at 100.6 MHz and at 300 K, by use of the Bruker[1] DISR88 program (version 880101.0) with a Bruker Instruments model WM-400 spectrometer that was equipped with a 5 mm dual frequency carbon–proton probe, digital frequency generation, a process controller, and an Aspect 3000 data system with array processor. The pulse power of the proton decoupler at 400 MHz was increased by means of a Henry Radio selective power amplifier, which afforded a gain of 10.5 db once the output was filtered through four parallel pairs of crossed diodes and a 400 MHz bandpass filter. In this manner, the ^1H 90° pulse width was decreased to 8.1 μs. The ^{13}C 90° pulse width was 9.3 μs. The transmitter and decoupler offsets were set to the centers of the respective frequency ranges for **1**. The ^{13}C chemical shifts are referenced to internal tetramethylsilane.

2D POMMIE, carbon–proton chemical shift correlated, ^{13}C NMR spectra with ^1H–^1H coupling in the F_1 dimension were acquired by use of the pulse sequence 90°(H)–1/2J–180°(H)90°(C)–1/2J–D–t_1/2–180°(C)–t_1/2–90°(H)90°(H,ϕ)–1/2J–acquire ^{13}C, decouple ^1H (sequence A, see Fig. 1) with the phase programs shown in Table 1.

The corresponding 2D POMMIE, carbon–proton chemical shift correlated spectra with vicinal ^1H–^1H decoupling in the F_1 dimension (13) were obtained by means of the sequence 90°(H)–t_1/2–90°(H)–1/2J–180°(H)90°(C,x)240°(C,y)90°(C,x)–1/2J–90°(H)–t_1/2–1/2J–180°(H)90°(C)–1/2J–90°(H)90°(H,ϕ)180°(C)–1/2J–acquire ^{13}C, de couple ^1H (sequence B, see Fig. 2), in conjunction with the phase programs in Table 1.

Phase comparability for data sets acquired by using ϕ = 45°, 90°, and 135° (angle set a) was ensured by the somewhat empirical procedure of adjusting the relative lengths of the contiguous 90°(H) and 90°(H,ϕ) pulses; i.e., the first of these pulses was lengthened by 1.2 μs, whereas the second pulse 90°(H,ϕ) was shortened by 1.2 μs. These adjustments are slightly larger than those (+1.0 and −1.0 μs) required for matching with the phase propagation delay of 2.0 μs that is defined by hardware delay lines in the Bruker process controller. The data acquisition conditions included the use of 4096 (t_2) × 128 (t_1) point data sets, zero-filled to 256 points in the t_1 dimension, two dummy scans with 64 scans per spectrum for all values of ϕ, spectral widths of 1.8 and 10.4 kHz in the F_1 and F_2 dimensions, respectively, and WALTZ-16 composite pulse ^1H decoupling (14) in the F_2 dimension. An average delay 1/2J(CH) = 3.52 ms was used, together with a pulse recycle time of 2.2 s.

[1]Certain commercial equipment, instruments, or materials are identified in this paper to specify adequately the experimental procedure. Such identification does not imply recommendation by the National Institute of Standards and Technology, nor does it imply that the materials or equipment are necessarily the best available for the purpose.

Data processing

2D POMMIE, carbon–proton chemical shift correlated, ^{13}C NMR subspectra were computed from the following algorithm:

$$\text{(Scheme A)}\quad CH_2 = \text{Data(45)} - a\cdot\text{Data(135)} - b\cdot\text{Data(90)}$$
$$CH_3 = \text{Data (45)} + c\cdot\text{Data(135)} - d\cdot\text{Data(90)}$$
$$CH = \text{Data(90)} - e\cdot CH_2 - f\cdot CH_3$$

where Data(45), Data(90), and Data(135) are the 2D data sets that were acquired by use of the sampling angles ϕ = 45°, 90°, and 135°, respectively, and a–f are six floating point coefficients. Both dimensions of the time–domain data were subjected to sine-bell squared apodization, with a window shift of $\pi/2$.

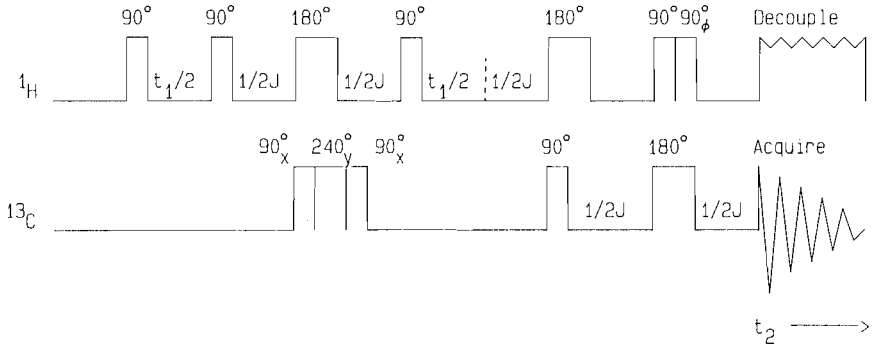

FIG. 2. Pulse sequence for 2D POMMIE, carbon–proton chemical shift correlated, ^{13}C NMR spectroscopy with BIRD ^{1}H–^{1}H decoupling. Definitions of parameters are the same as for Fig. 1. Phase programs are shown in Table 1.

Calibration of the six floating point coefficients

After the three complete 2D POMMIE, chemical shift correlated data sets had been acquired (usually overnight), a separate 1D calibration run was performed in which only the first row of each data matrix was collected (Bruker NE = 1). However, an increased number of scans (e.g., 1024 instead of 64) was done to increase the signal:noise ratio in the calibration spectra. The calculations in scheme A were then implemented consecutively in 1D dual display mode, and the values of the constants a–f were optimized by successive interactive knob adjustments to give good editing and residue reduction of the appropriate signals. For pulse sequence A, typical values of the coefficients were $a = 0.73$, $b = 0.33$, $c = 1.19$, $d = 1.55$, $e = -0.21$, and $f = 0.01$, and for sequence B, $a = 0.74$, $b = 0.37$, $c = 1.23$, $d = 1.59$, $e = -0.19$, and $f = 0.03$. These values may be compared with the ideal values $a = 1$, $b = 0$, $c = 1$, $d = 1.414$, $e = 0$, and $f = 0$.

Pascal program for 2D NMR spectrum editing

Earlier Pascal programs (6, 15) that had been written in fixed point format for 2D DEPT and 2D POMMIE J(CH)-resolved ^{13}C NMR spectrum editing were modified to include (a) keyboard entry of six floating point coefficients at program start, (b) floating point arithmetic on the six coefficients, (c) the 2D data matrix dimensions (size of free induction decay × number of spectra acquired) are read automatically from the data file and printed for inspection, and (d) the results of the floating point computations are converted to fixed point format before storage to the hard disk. A listing of this Pascal program (FPT6SIRE) is available on request. The compile-time option :H (an instruction to use the firmware floating point package) in the Bruker PASCOM program (version 880808.0) was used to speed the editing computations in floating point mode.

Results and discussion

The original version of the 1D DEPT method (1) required the acquisition of three heteronuclear NMR spectra, by use of a different value of the polarization transfer pulse flip angle (θ) for each. Angle set a ($\theta = 45°$, 90°, and 135°) has often been used for 1D DEPT spectrum editing, although use of the modified set $\theta = 30°$, 90°, and 150° (angle set b) is computationally advantageous for 2D DEPT NMR spectrum editing (4–6).

In previous work (15), a pulse sequence for 2D POMMIE J(CH)-resolved ^{13}C NMR was used to explore three methods for the automated acquisition of data for 2D spectrum editing and, when compared with the 2D DEPT J(CH)-resolved spectrum editing technique (6), the 2D POMMIE version was found to have the particular advantage that the programming of additional delays (3) into the sequence was not necessary in order to ensure equalization of the phases of the data sets (15). For these techniques (6, 15), angle set b was used for either θ or ϕ, because it allows the 2D J(CH)-resolved ^{13}C NMR subspectra to be computed from the simple 1:1 data combinations:

(Scheme B) CH = Data(90)

CH_2 = Data(30) − Data(150)

CH_3 = Data(30) + Data(150) − Data(90)

which were programmed in Pascal, in rapid fixed point arithmetic (for example, a computation time of 1.33 min for processing of three 4096 × 64 point data sets, with optimized array addressing). By contrast, use of the more traditional angle set a requires that at least one floating point coefficient be used in the linear combinations (1).

Attempts to perform 2D POMMIE, carbon–proton chemical shift correlated, ^{13}C NMR spectrum editing by using pulse sequences A and B, in conjunction with angle set b and computation scheme B, have revealed many cases where the residues in the 2D edited subspectra are unexpectedly large, despite the use of a probehead with good RF homogeneity (16). For molecules of biological interest, it is often difficult to obtain aesthetically pleasing 2D DEPT or 2D POMMIE, carbon–proton chemical shift correlated CH_2 subspectra. This difficulty appears to be largely due to the unique properties of methylene groups. In biomolecules, these groups often contain nonequivalent protons that split the CH_2 correlation cross peak into two to five or more components (sometimes an AB quartet with an extra central line), which tend to exaggerate the *relative* intensities of CH and CH_3 residues in the CH_2 subspectra by a factor of two to five, or more. Longer spin–spin relaxation times (T_2) for typical CH_3 carbon nuclei may also contribute to this effect, and if there are F_1 ridges in the spectra, then these artifacts are relatively emphasized, too.

In practice, the accuracy of 1D and 2D POMMIE spectrum editing experiments may be influenced (16) by several effects, including (a) lateral displacements of the ^{13}C intensity – phase shift (ϕ) dependence curves caused by the use of insufficient decoupler pulse power, (b) amplitude mismatch in the two sampling angle quadrants, $0° < \phi < 90°$, $90° < \phi < 180°$, and (c) signal phase mismatch in the two quadrants. Because of these limitations, the present experiments have been conducted at high decoupler pulse power (110 W). Although phase matching of all types of signals obtained in the two sampling angle (ϕ) quadrants has been achieved by adjustment of the relative lengths of the adjacent 90°(H) and 90°(H, ϕ) pulses (see Figs. 1 and 2 and the Experimental), this technique did not provide an amplitude match in the two ϕ quadrants. Therefore, this match has been improved by optimization of the six coefficients in computation scheme A. The use of spectrum editing computations with up to six or more floating point coefficients is now more feasible than before, because of improvements in Pascal programs and compilers.

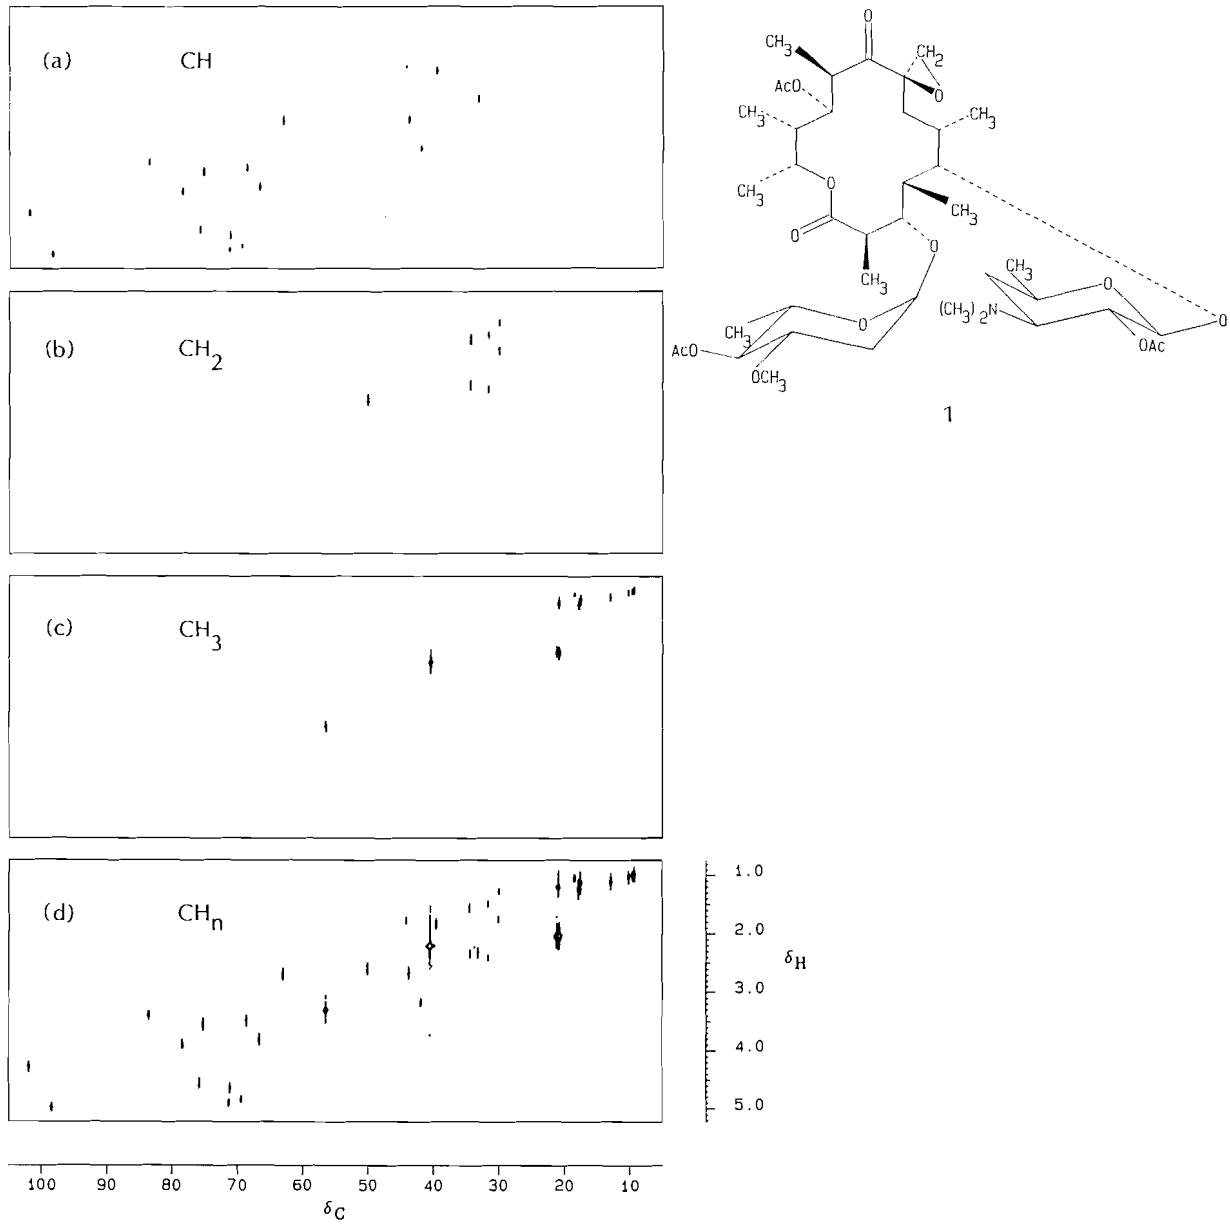

FIG. 3. Contour plots of the 2D POMMIE, carbon–proton chemical shift correlated, ^{13}C NMR spectra of troleandomycin (**1**, 0.2 mol L^{-1} in 1:1 v/v chloroform-*d*:dimethylsulfoxide-d_6). The CH, CH_2, and CH_3 subspectra in (a)–(c) were obtained from editing computations with six floating point coefficients (see scheme A), on raw data acquired by means of the sampling phase shifts $\phi = 45°$, 90°, and 135°. The unedited CH_n spectrum in (d) is the data from $\phi = 135°$.

In other work (16) on carbohydrate derivatives at low decoupler pulse power (10 W), alternative strategies for 2D POMMIE NMR spectrum editing have been tested, particularly adjustment of the sampling angle ϕ to values other than those of angle sets a or b, in order to achieve equalization of the amplitudes of certain specific resonances measured in the two quadrants of ϕ. For example, in studies of the 2D POMMIE, *J*(CH)-resolved ^{13}C NMR spectrum editing of a mixture of seven methyl glycopyranosides, the sampling angle set $\phi = 40°/96°/152°$ was used, and the three raw data matrices were processed in linear combinations with *two* floating point coefficients (16). However, the methods discussed in the present paper represent an optimized and refined technique in which high decoupler pulse power is used to force the ^{13}C intensity – sampling angle ϕ dependence curves to approach theoretical behavior, which allows use of the symmetrically related angles $\phi = 45°$ and 135° (or 30° and 150°).

In the present work, sampling angle set a was favored over angle set b, because the theoretical methylene carbon intensity function $CH_2 = k \sin 2\phi$ has amplitude maxima (without regard to algebraic sign) at $\phi = 45°$ and 135°. Extraction of the maximum methylene carbon amplitudes from the experiment tends to counteract any weakness in the methylene cross peaks caused by spin coupling between nonequivalent methylene protons. At $\phi = 30°$ and 150°, the theoretical CH_2 intensities are only 87% of those at $\phi = 45°$ and 135°. Linear combinations of the three data matrices with six floating point coefficients are then used to correct any remaining amplitude discrepancies in resonances measured in the two ϕ quadrants.

Computation scheme A includes "on the fly" reduction of

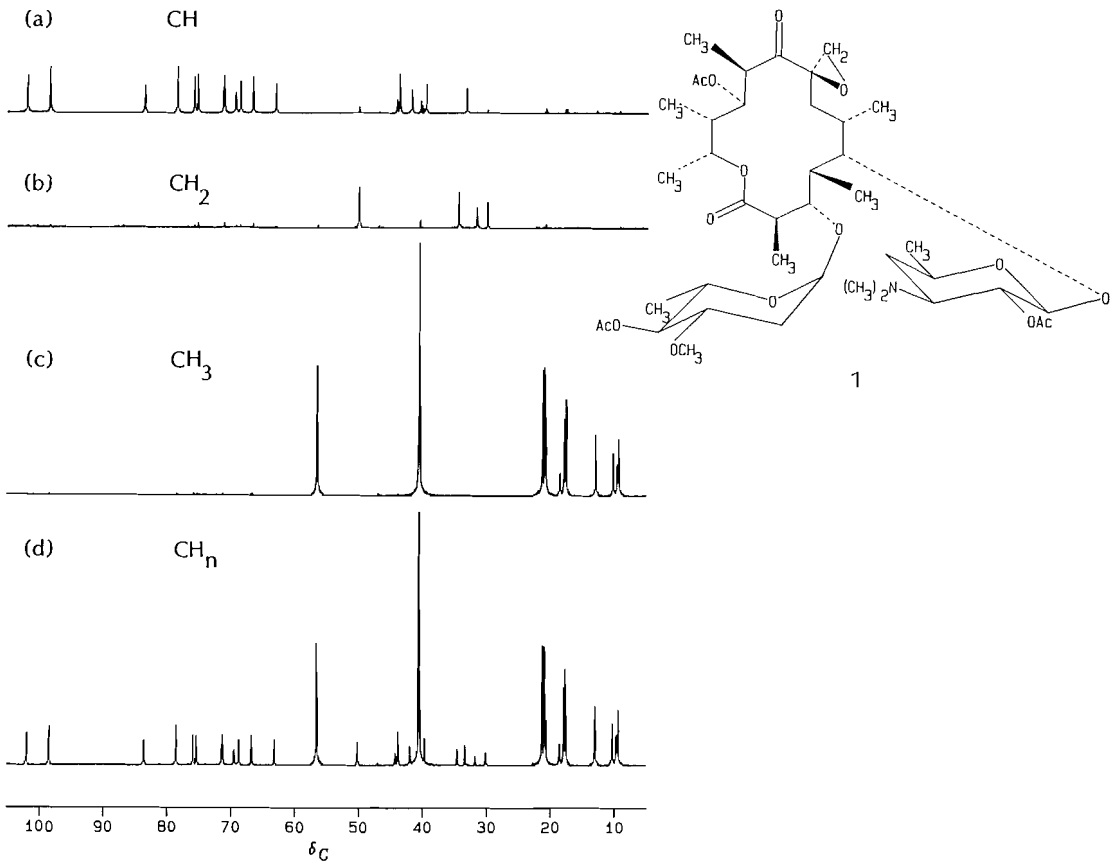

FIG. 4. F_2 projections of the 2D POMMIE, carbon–proton chemical shift correlated, ^{13}C NMR spectra of troleandomycin (**1**) shown in Fig. 3.

CH_2 and CH_3 residues in the CH 2D subspectrum by subtraction from Data(90) of small fractions *e* and *f*, respectively, of the CH_2 and CH_3 subspectra that have just been computed. These subtractions are performed while the corresponding 4096 point segments of Data(90) and the CH_2 and CH_3 subspectra are still in memory, thus minimizing disk access time. With a compile-time instruction to use the resident firmware floating point package, the current Pascal program with six floating point coefficients requires approximately 1 h (on the Bruker Aspect 3000 computer) to process three 4096 × 128 point data matrices, a time that is reasonably short for practical use. Without the firmware floating point package, the program computation times are a factor of 3.8 longer.

The complete 2D POMMIE, carbon–proton chemical shift correlated, ^{13}C NMR spectrum of a solution of troleandomycin is shown in Fig. 3d, a spectrum that was acquired by using pulse sequence A with $\phi = 135°$. Figures 3a–3c display the CH, CH_2, and CH_3 subspectra that were computed from the three raw data matrices (Data(45), Data(90), and Data(135)) by use of six floating point coefficients in scheme A. In Fig. 3b, three out of four of the methylene carbon signals appear as unresolved AB quartets. The separate CH_2 subspectrum supports the interpretation that each pair of cross peaks that have the same ^{13}C chemical shift but different proton chemical shifts is associated with the same methylene carbon nucleus, and not with carbon nuclei of other types that are accidentally equivalent in the carbon dimension.

An indication of the efficiency of the 2D spectrum editing is given by the F_2 projections of the 2D POMMIE, carbon–proton chemical shift correlated spectra shown in Fig. 4. The complete projection spectrum that was measured by use of $\phi = 135°$ is shown in Fig. 4d, in which the strong intensities of the methyl carbon signals are noteworthy. Nevertheless, the methyl residues in the CH and CH_2 subspectra (Fig. 4a and 4b, respectively) are effectively suppressed by the editing computation with six floating point coefficients.

The application of pulse sequence B and computation scheme A to troleandomycin gave a similar set of edited correlation subspectra and corresponding F_2 projections, except that the CH cross peaks were distinctly narrowed by the **BI**linear **R**otation **D**ecoupling (BIRD) unit in sequence B. The BIRD subsequence removes the vicinal $^1H-^1H$ couplings in the F_1 dimension (13), but not the geminal $^1H-^1H$ couplings in the methylene groups. Another difference in the results from the sequences performed with and without BIRD decoupling was that the latter technique produced an extra line in the center of the methylene AB quartet at lowest field (δ_C 34.38), thus further diluting the effective intensity of the methylene carbon correlation cross peaks. The origin and variability of these methylene correlation artifacts (5) has recently been discussed (17). They are thought to arise because the BIRD pulse sequence transfers some spin coherence between nonequivalent methylene protons, and a theoretical analysis has suggested that the artifacts may or may not be observed for particular methylene carbon atoms, because of a cyclic dependence on the chemical shift separation of the methylene protons (17).

Pascal programs based on scheme A may also be used for suppression of the residual signals in the edited subspectra

obtained by selective 2D DEPT carbon–proton chemical shift correlation (4, 5), and the 2D DEPT *J*(CH)-resolved (6) and 2D POMMIE *J*(CH)-resolved (15) methods.

Introduction

The plant hormone abscisic acid (ABA, **1**) is widely distributed in higher plants and is involved in the regulation of many developmental phases and stress responses including germination, dormancy, transpiration, and abscission (1). Many structural analogs of ABA have been synthesized for establishing structure–activity relationships and for developing practical plant growth regulators (2).

The natural hormone has the (S)-(+) configuration (Fig. 1) and is active in bioassays involving growth inhibition, germination inhibition, and reduction of transpiration by stomatal closure, when applied exogenously to plants (3, 4). The unnatural (*R*)-(−) enantiomer is as active as natural ABA in germination and growth inhibition, but is inactive in stomatal closure (3, 4). The metabolism of the two antipodes proceeds at different rates in plant cells, and is thought to lead to different products (5).

One of the goals of our research program is to develop ABA-like compounds that will enhance the hardiness of crop plants toward extreme climatic conditions such as cold and drought (6). Of a number of compounds tested in collaboration with other research groups, we find that racemic ABA and the known (7) analog racemic dihydroabscisic acid, (±)-**2**, are active in inducing cold tolerance in a brome grass tissue culture assay (8). Furthermore, both (±)-ABA and (±)-**2** have antitranspirant activity in Douglas fir seedlings that have been subjected to water stress.[3]

Another ABA analog (±)-4(*Z*)-(4α,5β)-4-hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone, (±)-**3**, which has an acetylenic group in the side chain (9), has recently been demonstrated to promote the germination of barley and stimulate the appearance of the enzyme α-

amylase.[4] To better understand the mechanisms by which these compounds function as growth regulators and their metabolism in plants, we have undertaken the synthesis and biological testing of both the (+) and (−) enantiomers of optically pure ABA analogs.

The literature has several reports on the synthesis of optically active ABA-like compounds and carotenoids (10–14). Some of these preparations involve the use of expensive resolving agents and tedious resolution procedures. This paper reports an efficient and inexpensive synthesis of the (−)-(4*R*,5*R*) isomer of dihydroabscisic acid (**2**),[5] the (+)-(4*S*,5*S*) enantiomer (**4**), and the (−)-(4*S*,5*R*) epimer (**5**). The acetylenic analog (−)-4(*Z*)-(4*S*,5*R*)-4-hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (**3**), as well as the corresponding (+)-(4*R*,5*S*) enantiomer (**6**) and the (−)-(4*R*,5*R*) epimer (**7**) have also been obtained (Fig. 1).

Results and discussion

Similar to the procedure of Mayer and co-workers (12, 13), our synthesis started with (−)-(6*R*)-2,2,6-trimethylcyclohexan-1,4-dione (**9**), which was readily prepared by the fermentation of oxoisophorone (**8**) with bakers' yeast according to the method of Leuenberger *et al.* (15) (Scheme 1). Regioselective reduction of diketone **9** was achieved with lithium tri-*sec*-butylborohydride (L-Selectride^R) (16). The thermodynamically less stable *trans* ketol (−)-(4*R*,6*R*)-4-hydroxy-2,2,6-trimethylcyclohexanone (**10**) was obtained as the major product. Some *cis* ketol of low optical purity, i.e., a mixture of compounds **11** and **12**, was also isolated, indicating that some epimerization of the methyl group at C6 had occurred.

For the synthesis of ABA analogs **2**, **3**, **5**, and **7**, which have the (5*R*) configuration (see Fig. 1), the *trans* ketol **10** was first protected as the *tert*-butyldimethylsilyl ether **13** (Scheme 1). The ^{1}H nuclear magnetic resonance (nmr) spectrum of **13** showed an apparent quintet at 4.08 ppm (J = 3.2 Hz) for the CHOSi proton. The observed coupling is consistent with the pattern expected for an equatorial proton, which usually has axial–equatorial and equatorial–equatorial coupling constants of 2–6 Hz. A doublet of doublets of quartets at 3.16 ppm with J = 13.2, 5.3, and 6.4 Hz was observed for the C*H*CH$_3$ proton, and the coupling constant of 13.2 Hz was indicative of a proton in the axial position. These nmr data demonstrated that conformation **13***a* with the silyl ether group in the axial position and an equatorial methyl group at C6 was preferred over **13***b*, which has strong 1,3-diaxial interaction between the methyl groups at C2 and C6 (see Scheme 1). The desired side chain containing an acetylenic group required for compounds **3** and **7** was then introduced by treating **13** with the dianion generated between (*Z*)-3-methylpent-2-en-4-yn-1-ol and two equivalents of *n*-butyllithium. A mixture of two addition products in an 8:1 ratio as determined by gas chromatographic (gc) analysis (DB1701 column) was obtained. The major product (retention time 20.05 min) was assigned the structure **14** with the (1*S*,6*R*) configuration, which was most likely formed by the well-documented preferential axial attack of cyclohexanone **13***a* by the acetylide anion (7, 9, 10, 12–14, 17). The minor product (retention time 19.77 min) was tentatively assigned as the (1*R*,6*R*) isomer **15**. The stereochemistry of compounds **14** and **15** was differentiated by studying the nuclear Overhauser enhancement (nOe) in the ^{1}H nmr spectra of their derivatives (see below). The (1*R*,6*S*) isomer **31** (see Scheme 4), which could be distinguished from **14** and **15** by gc analysis (retention time 19.11 min), was absent from the product mixture, therefore indicating that epimerization at the C6 position of the starting material **13** did not occur prior to the addition reaction.

The mixture of **14** and **15** was acetylated and then desilated to give compounds **16** and **17**, which could be separated by flash column chromatography followed by preparative thin-layer chromatography (tlc). Compounds **16** and **17** were separately oxidized and hydrolyzed to give the desired ABA analog (−)-4(*Z*)-(4*S*,5*R*)-4-hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (**3**) (10) and the (−)-(4*R*,5*R*) epimer (**7**), respectively.

At this point in the synthesis, the optical purity of the acetylenic analog **3** obtained was examined by treating it with (−)-(2*R*,3*R*)-2,3-butanediol to form the ketal **18** (Scheme 2) (10, 18). Analysis of **18** by gc on a DB1701 column showed only one component with retention time of 18.57 min, whereas the diastereomeric ketal **19** prepared in the same fashion from the (+)-(4*R*,5*S*) enantiomer **6** (see below) had a longer retention time of 18.76 min. Furthermore, both the ^{1}H and ^{13}C nmr spectra of ketal **18** demonstrated that it was a single compound, with signals distinctly different from those of the diastereomeric ketal **19** (see Experimental). Ketalization of the racemic acetylenic analog (±)-**3** (9) under the same conditions afforded a product with gc and nmr data that are consistent with a 1:1 mixture of compounds **18** and **19**.

To continue with the synthesis of (−)-(4*R*,5*R*)-dihydroabscisic acid (**2**), the carbonyl group in compound **3** was protected as the ketal to form **20** (Scheme 3). Reduction of **20** with sodium bis(2-methoxyethoxy)aluminium hydride (Redal^R) (19) gave compound **21** with the desired pentadienol side chain. After deketalization by acid-catalyzed hydrolysis to give **22**, the allylic alcohol was oxidized with manganese(IV) oxide to the aldehyde **23**. Further oxidation of **23** using a mixture of manganese(IV) oxide, sodium cyanide, acetic acid, and methanol (20) gave (−)-(4*R*,5*R*)-methyl dihydroabscisate (**24**), which was readily hydrolyzed to the desired ABA analog (−)-(4*R*,5*R*)-dihydroabscisic acid (**2**).

The conversion of compound **7** to (−)-(4*S*,5*R*)-dihydroabscisic acid (**5**) followed the same sequence of reactions (see Scheme 3). To confirm the stereochemistry at C4 of this series of compounds, an nOe experiment was performed with ketals **21** and **26**. When the C1′ olefinic proton doublet at 5.94 ppm in the ^{1}H nmr spectrum of ketal **21** was irradiated, an nOe of approximately 5% was observed for the multiplet at 1.34–1.42 ppm assigned to the two axial protons at C7 and C11. Likewise, an nOe of about 7% was observed for the doublet at 5.94 ppm when the multiplet at 1.34–1.42 was irradiated. On the other hand, no significant nOe was observed for the corresponding olefinic and axial proton signals when the ^{1}H nmr spectrum of ketal **26** was recorded under the same experimental conditions. These results support the assignment of epimeric structures **21** and **26** to the two ketals. The dienol group in compound **21** is in the axial position, with the olefinic proton at C1′ of the side chain in close proximity to the axial protons at C7 and C11 of the cyclohexane ring. The isomer **26** has an

[4]R. Hill, Department of Plant Science, University of Manitoba, personal communication.

[5]For the convenience of discussion, the same numbering system will be adopted for dihydroabscisic acid (**2**) and compound **3** in this paper (see Fig. 1). In the literature, the racemic form of structure **2** is also known as 2′,3′-dihydroabscisic acid (ref. 7) and [1α,1(2*Z*,4*E*),6β]-5-(1-hydroxy-2,2,6-trimethyl-4-oxocyclohexyl)-3-methyl-2,4-pentadienoic acid (Chem. Abstr. **96**, 1321F (1982); CAS registry no. 81749-10-2).

equatorial dienol side chain and the olefinic protons are too far away from the protons at C7 and C11 for nOe to be observed.

Our attention was next turned to the synthesis of ABA analogs **4** and **6**, both of which possess the (5*S*) configuration. The starting material required was (+)-(4*R*,6*S*)-4-hydroxy-2,2,6-trimethylcyclohexanone (**11**), which was readily obtained from the epimerization of ketol **10** under basic conditions (15). The conversion of **11** to the (+)-(4*R*,5*S*) acetylenic ABA analog **6** and to (+)-(4*S*,5*S*)-dihydroabscisic acid (**4**) followed a sequence of reactions similar to that employed in the synthesis of the (−) isomers (see Scheme 4). It is worth noting that, unlike the conversion of silyl ether **13** to a mixture of compounds **14** and **15** (see above), only one addition product **31** was obtained in the reaction between silyl ether **30** and the dianion of (*Z*)-3-methylpent-2-en-4-yn-1-ol.

As in the synthesis of (−) enantiomer **3**, the optical purity of the (+) acetylenic analog **6** obtained was established by converting it to a single ketal **19**, which could be differentiated from the diastereomeric ketal **18**, obtained from **3**, by gc and nmr analyses (see above and Scheme 2).

The ester (−)-(4*R*,5*R*)-methyl dihydroabscisate (**24**) and its (+)-(4*S*,5*S*) enantiomer (**37**) were found to be resolvable on the Chiracel OD chiral high performance liquid chromatography (hplc) column using 10% isopropanol and 90% hexane as the eluent at a flow rate of 1.0 mL min^{-1} (21, 22). Compound **24** had a retention time of 10.7 min, whereas its enantiomer **37** had a shorter retention time of 8.7 min under these conditions. Both the ester **24** and its enantiomer **37** obtained in our synthesis were found to be 100% optically pure by this method of analysis.

Furthermore, the optical purity of our synthetic (−)-(4*R*,5*R*)-dihydroabscisic acid (**2**) and its enantiomer (+)-(4*S*,5*S*)-dihydroabscisic acid (**4**) was confirmed by recording the ^{1}H nmr spectra of their sodium salts in D_2O with γ-cyclodextrin as the chiral complexing agent (23, 24). Under these conditions, the

spectra of mixtures of **2** and **4** showed doubling of the two vinyl proton doublets at 6.2 ppm and 7.3 ppm, as well as the doublet at 2.6 ppm due to the axial proton at C2, as two diastereomeric complexes were formed between cyclodextrin and the salts of compounds **2** and **4**. Doubling of signals was not observed when spectra of the synthetic samples of **2** and **4** were separately recorded under the same conditions.

An attempt was made to synthesize the (−) analogs **2** and **3** from (−)-(6*R*)-2,2,6-trimethylcyclohexan-1,4-dione (**9**) by a more direct route depicted in Scheme 5. Initial attempts to protect the less hindered ketone group in **9** by ketalization with ethylene glycol and *p*-toluenesulfonic acid as catalyst (25) resulted in loss of optical activity and a mixture of mono- and diketals. More success was met when treatment of **9** with 1.1 equivalent of 2,2-dimethyl-1,3-propanediol and a catalytic amount of pyridinium *p*-tosylate proceeded in 100% regioselectivity to give the monoketal **38**, which was optically active. The ^{1}H nmr spectrum of **38** did not show any doubling of the signals when γ-cyclodextrin was added as the chiral complexing agent (see above). Under the same conditions, two sets of doublet of doublets at about 2.3–2.6 ppm were observed for the equatorial proton at C7 of the racemate (±)-**38**, which was prepared from (±)-**9** (25). Since doubling of the C7 proton signals could be detected in the spectrum of a 4:1 mixture of **38** and its racemate, the monoketal **38** was estimated to be at least 90% optically pure. The acetylenic analog **3** and the (−)-dihydroabscisic acid **2** were prepared from **38** by the route shown in Scheme 5 and were found to be approximately 85% optically pure using the different methods described above.

The optically active ABA analogs obtained are being subjected to various biological tests involving germination and induction of cold hardiness. The (−)-(4*S*,5*R*) acetylenic analog **3** has been found to be more potent than its racemic counterpart in stimulating the release of α-amylase in the germination of barley.[6] The metabolism of the optically active analogs in plants is currently under investigation. Details of these studies will be reported elsewhere.

Experimental

General

Melting points (mp) are uncorrected and were recorded on an Ernst Leitz Wetzlar hot-stage melting point apparatus. Gas chromatographic (gc) separations were carried out with a Varian 3700 instrument equipped with a DB-1701 or a DB-5 capillary column (J and W Scientific, 30 m) and a flame ionization detector. Helium at a flow rate of about 2.5 cm min^{-1} was used as the carrier gas. High performance liquid chromatographic (hplc) analyses were carried out with an instrument consisting of a Spectra-Physics SP8700 solvent delivery

system and a Spectroflow 773 variable wavelength absorbance detector (Kratos Analytical Instrument). Infrared (ir) spectra were recorded on a Perkin–Elmer 257 grating infrared spectrophotometer using $CHCl_3$ as solvent and matching NaCl cavity cells (0.2 mm). Proton nuclear magnetic resonance (^{1}H nmr, 360 MHz) spectra and carbon-13 (^{13}C nmr, 90.55 MHz) spectra were recorded on a Bruker AM-360-WB spectrometer with $CDCl_3$ as solvent. The 90 MHz ^{1}H nmr spectra were recorded on a Perkin–Elmer EM390 nmr spectrometer. ^{1}H chemical shifts (δ) and coupling constants (J) are reported as if they are first order. The abbreviations ax and eq are used to indicate axial and equatorial protons, respectively. Low resolution mass spectra were obtained by using a DB-5 column (60 m) in a Finnigan–Mat 4000 E instrument with an Incos 2300 data system in the electron impact (eims) or chemical ionization (cims) mode. Mass spectral data are reported in mass to charge units (m/z) with the relative intensities as percentages of the base peak given in parentheses. High resolution mass spectra (hrms) were recorded in the electron impact mode using a VG70-250SEQ instrument with a Digital PDP 11/73 data system. Unless otherwise stated, all spectroscopic analyses were performed on intermediates and products that were at least 95% pure by gc analysis. Elemental analyses (Anal.) were performed by the Microanalytical Laboratory of the Department of Chemistry at the University of Alberta.

Flash column chromatography was performed using E. Merck silica gel 60 (230–400 mesh). E. Merck precoated glass plates of silica gel 60 F254 (0.25 or 1.0 mm) were used in preparative thin-layer chromatography (tlc). E. Merck silica gel 60 F254 plates (0.2 mm) with aluminium sheet backing were used in analytical tlc. Ultraviolet active materials were detected under an ultraviolet (uv) lamp. The plates were then dipped into a solution of phosphomolybdic acid and slowly heated on a hot plate to visualize the spots. Preparative tlc was also performed on the Chromatotron (Harrison Research) with circular glass plates precoated with silica gel F254 (1, 2, or 4 mm), where the radial flow of eluent and sample were centrifugally accelerated.

The solvent tetrahydrofuran (THF) was dried by distillation from sodium and benzophenone. *N,N*-Dimethyl formamide (DMF) was dried by distillation from calcium hydride and was stored over molecular sieves.

*(−)-(6R)-2,2,6-Trimethylcyclohexan-1,4-dione (**9**)*

Compound **9** was prepared according to the procedure reported by Leuenberger *et al.* (15). Active dry yeast (Fleischmann's Quick Rise, 12 g) suspended in warm distilled water (450 mL, 45°C) was added to a solution of sucrose (BDH, 25 g) in distilled water (500 mL). The resulting mixture was stirred at room temperature for 30 min. Oxoisophorone (**8**) (Fluka, 10.0 g, 0.065 mol) was then added, followed by distilled water (50 mL) and anti-foaming agent (Antifoam C Emulsion, Sigma, 4 drops). A gentle stream of air was bubbled through the mixture while it was stirred at room temperature for 9 days and, starting on the 5th day, extra portions of yeast (5 g) and sucrose (10 g) were added daily. The fermentation was terminated after 9 days by filtering the mixture through a bed of Celite^R by suction. The filtrate was extracted with CH_2Cl_2 (3 × 150 mL). The organic extract was dried over anhydrous Na_2SO_4 and concentrated to give yellowish oily crystals (8.5 g), which were recrystallized from ether-hexane (1:1) to give diketone **9** as colorless needles (4.4 g, 44%); mp 93–94°C (lit. (15) mp 91–92°C); $[\alpha]_D$ −269.2° (*c* 0.98, CH_3OH) (lit. (15) $[\alpha]_D$ −270° (*c* 0.4, CH_3OH)); ir: 1720 cm^{-1}; ^{1}H nmr (90 MHz) δ: 1.05 (d, J = 6 Hz, 3H, $CHCH_3$), 1.02 and 1.10 (2s, 6H, $2CH_3$), 2.3–4.4 (m, 5H, CH_2 and CH).

*(−)-(4R,6R)-4-Hydroxy-2,2,6-trimethylcyclohexanone (**10**)*

A solution of (−)-(6*R*)-2,2,6-trimethyl-1,4-cyclohexandione (**9**) (2.0 g, 13 mmol) in dry THF (50 mL) was stirred under argon and cooled to −65°C with a Dry Ice – acetone bath. Lithium tri-*sec*-butylborohydride (L-Selectride^R, Aldrich, 1 M in THF, 15 mL, 15 mmol) was added slowly such that the temperature of the reaction mixture did not rise above −60°C. Thirty minutes after the addition of L-Selectride^R was completed, the reaction mixture was poured, with stirring, into an ice-cold mixture of saturated NaCl (100 mL) and 1 M HCl (20 mL). The organic and aqueous layers were separated and the aqueous layer was extracted with CH_2Cl_2. The combined THF and CH_2Cl_2 layers were washed with H_2O, saturated $NaHCO_3$, and H_2O. Then most of the solvent was removed by evaporation. The residue was dissolved in hexane (30 mL) and cooled in an ice-water bath. A mixture of 30% H_2O_2 and water was added. After 2 h of stirring the aqueous and hexane layers were separated. The aqueous layer was extracted with CH_2Cl_2. The hexane and CH_2Cl_2 layers were combined, washed successively with H_2O, saturated $NaHSO_3$, H_2O, saturated $NaHCO_3$, H_2O, and dried over anhydrous Na_2SO_4. Evaporation of solvent gave a pale yellow liquid (2.3 g), which on purification by flash chromatography (75% ether + 25% hexane) gave *trans* ketol **10** as a colorless oil (1.2 g, 60%), tlc R_f 0.4 (75% ether + 25% hexane). The product, **10**, crystallized on storage at −10°C and was recrystallized from ether–hexane to give colorless needles, mp 45.0–47.5°C (lit. (15) mp 49.5–50.5°C); $[\alpha]_D$ −108.9° (*c* 1.06, CH_3OH) (lit. (15) $[\alpha]_D$ −113.9° (*c* 0.8, CH_3OH)); ir: 3460, 1700 cm^{-1}; ^{1}H nmr δ: 1.01 (d, J = 6.9 Hz, 3H, $CHCH_3$), 1.02 (s, 3H, CH_3), 1.33 (s, 3H, CH_3), 1.66 (ddd, J = 13.9, 13.9, 3.4 Hz, 1H, H-5_{ax}), 1.77 (dd, J = 14.5, 3.8 Hz, 1H, H-3_{ax}), 1.96 (ddd, J = 14.5, 3.8, 3.2 Hz, 1H, H-3_{eq}), 2.10 (dddd, J =

For personal use only.

13.9, 5.6, 4.4, 3.2 Hz, 1H, H-5_{eq}), 3.14 (m, 1H, H-6_{ax}), 4.2 (quintet or dddd, J = 3.5 Hz, 1H, H-4_{eq}); eims m/z: 156 (M^+, 10), 138 (8), 88 (41), 83 (89), 56 (100).

A more polar product was also isolated as a colorless oil from the flash column. It was identified as the partially racemized *cis* ketol (i.e., a mixture of **11** and **12**) (0.52 g, 26%), tlc R_f 0.3; $[\alpha]_D$ −65.7° (*c* 1.02, CH_3OH) (lit. (15) (−)-*cis*-ketol **12**, $[\alpha]_D$ −104.2° (*c* 0.8, CH_3OH); mp 51.5–52.5°C). The spectral data of the product were identical to those described below for *cis* ketol **11**.

(−)-(4R,6R)-4-tert-Butyldimethylsiloxy-2,2,6-trimethylcyclohexanone (13)

A mixture of *trans* ketol **10** (115 mg, 0.73 mmol), *tert*-butyldimethylsilyl chloride (Aldrich, 202 mg, 1.27 mmol), imidazole (100 mg, 1.47 mmol), and dry DMF (3 mL) was stirred at room temperature under an argon atmosphere for 1.5 h. Then water was added and the mixture was extracted with ether (3×). The ether extract was washed with saturated NaCl and dried over anhydrous Na_2SO_4. Evaporation of solvent gave a colorless oil (325 mg), which was distilled using the Kugelrohr apparatus. After some forerun that was discarded, the desired silyl ether **13** was collected as a colorless oil at 150–180°C, 9–10 Torr (1 Torr = 133.3 Pa) (156 mg, 80%). The product solidified on storage at −10°C to form colorless crystals, mp 29.5–31.5°C; $[\alpha]_D$ −65.1° (*c* 1.06, CH_3OH); ir: 1710 cm^{-1}; ^1H nmr δ: 0.06 and 0.07 (2s, 6H, CH_3SiCH_3), 0.89 (s, 9H, $3CH_3$), 0.98 (s, 3H, CH_3), 0.98 (d, J = 6.4 Hz, 3H, $CHCH_3$), 1.32 (s, 3H, CH_3), 1.57 (ddd, J = 13.4, 13.2, 2.7 Hz, H-5_{ax}), 1.65 (dd, J = 14.2, 3.4 Hz, 1H, H-3_{ax}), 1.88 (ddd, J = 14.2, 3.3, 3.2 Hz, 1H, H-3_{eq}), 1.99 (dddd, J = 13.4, 5.3, 3.3, 3.2 Hz, 1H, H-5_{eq}), 3.16 (ddq, J = 13.2, 5.3, 6.4 Hz, 1H, H-6_{eq}), 4.08 (quintet or dddd, J = 3.2 Hz, 1H, H-4_{eq}); eims m/z: 255 (M^+ − 15, 1), 213 (60), 171 (78), 121 (43), 75 (100). Exact Mass (hrms) calcd. for $C_{15}H_{30}O_2Si$: 270.2015; found: 270.2015.

(−)-1(Z)-(1S,4R,6R)- and (−)-1(Z)-(1R,4R,6R)-1-(5-Acetoxy-3-methylpent-3-en-1-ynyl)-2,2,6-trimethylcyclohexan-1,4-diol (16 and 17)

A solution of *Z*-3-methylpent-2-en-4-yn-1-ol (Fluka, 1.60 g, 16.7 mmol) in dry THF (20 mL) under an argon atmosphere was cooled to about −60°C in a Dry Ice – acetone bath. *n*-Butyllithium (Aldrich, 1.6 M in hexane, 19 mL, 30.4 mmol) was added dropwise with stirring. After all the *n*-butyllithium had been added the reaction mixture, which was orange in color, was allowed to warm up to −5°C over 30 min. Then it was again cooled to −60°C and a solution of silyl ether **13** (2.7 g, 10 mmol) in dry THF (20 mL) was added dropwise. After the addition had been completed the reaction mixture was allowed to warm to 0°C over 90 min before it was poured into water and extracted with ether (3×). The combined organic extracts were washed with saturated NaCl (2×) and dried over anhydrous Na_2SO_4. Evaporation of solvent gave a yellow oil (4.5 g) as the crude product. Purification of the product by flash column chromatography (75% ether + 25% hexane as eluent) followed by distillation (Kugelrohr, 180–200°C, 0.03 Torr) gave a mixture of compounds **14** and **15** as a yellow oil (2.82 g, 76% yield), gc retention times (DB1701 column, 70–240°C at 10°C min^{-1}) 20.05 min and 19.77 min, ratio of peak areas about 8:1, respectively.

The mixture of compounds **14** and **15** (2.82 g, 7.6 mmol) was dissolved in pyridine (15 mL). A mixture of acetic anhydride (2.35 g, 23.0 mmol) and pyridine (5 mL) was added, followed by 4-dimethylaminopyridine (Aldrich, 32 mg, 0.26 mmol). The reaction mixture was stirred at room temperature for 1 h, poured into water, and extracted with hexane (3×). The combined organic extract was washed with saturated NaCl and dried over anhydrous Na_2SO_4. Removal of solvent gave a mixture of acetates as a pale yellow oil (3.72 g), which was desilated without purification to give compounds **16** and **17** by the procedure below. Gas chromatographic analysis of the crude acetate mixture (DB1701 column, 70–240°C at 10°C min^{-1}) showed two components in the ratio of 8:1 (retention times 20.26 min and 20.12 min, respectively).

The crude acetates obtained in the above procedure were stirred with glacial acetic acid (30 mL) and H_2O (10 mL), and the mixture was heated to 70°C under argon for 20 h. After cooling to room temperature, the reaction mixture was diluted with water and extracted with $CHCl_3$ (3×). The organic extract was washed with H_2O, then with saturated $NaHCO_3$, and dried over anhydrous Na_2SO_4. Evaporation of solvent gave a yellow oil (2.98 g) as the crude product. Separation by flash column chromatography (75% ether + 25% hexane) followed by preparative tlc (same eluent) gave compounds **16** (1.26 g, 56% overall yield) and **17** (0.15 g, 7% overall yield).

Compound **16**, colorless oil; gc (DB5 column, 70–240°C at 10°C min^{-1}) retention time 18.37 min; tlc (90% ether + 10% hexane) R_f about 0.30; $[\alpha]_D$ −18.4° (*c* 1.02, CH_3OH); ir: 3610, 3400, 1735 cm^{-1}; ^1H nmr δ: 1.05 (d, J = 6.6 Hz, $CHCH_3$), 1.08 and 1.22 (2s, 6H, $2CH_3$), 1.55–1.75 (m, 4H, $2CH_2$), 1.89 (m, 3H, vinyl CH_3), 2.03 (s, 3H, CH_3COO), 2.34 (m, 1H, $CHCH_3$), 4.02 (m, 1H, CHOH), 4.71 (dd, J = 7.0, 1.0 Hz, 2H, CH_2O), 5.77 (ddq, J = 7.0, 7.0, 1.5 Hz, 1H, =CH); ^{13}C nmr δ: 16.05, 20.88, 23.08, 23.28, and 27.39 ($5CH_3$), 38.77 (C2), 31.92, 40.12 and 44.47 (CH_2 and CH), 62.80 and 67.55 (CH_2O and CHOH), 79.01 (COH), 84.89 and 95.33 (2 acetylenic C), 123.52 (=C), 130.03 (=CH), 170.83 (C=O); eims m/z: 234 (M^+ − 60, 6), 178 (28), 148 (100).

Compound **17**, colorless oil; gc (DB5 column, 70–240°C at 10°C min^{-1}) retention time 18.50 min; tlc (90% ether + 10% hexane) R_f about 0.35; $[\alpha]_D$ −28.3° (*c* 0.92, CH_3OH); ir: 3630, 3500, 1735 cm^{-1}; ^1H nmr δ: 1.05 (s, 3H, CH_3), 1.06 (d, J = 5.2 Hz, 3H, $CHCH_3$), 1.27 (s, 3H, CH_3), 1.43 (ddd, J = 14.6, 2.5, 2.5 Hz, 1H, H-3_{eq}), 1.52 (dddd, J = 14.3, 3.9, 2.5, 2.5 Hz, 1H, H-5_{eq}), 1.68 (ddd, J = 14.3, 12.6, 3.3 Hz, 1H, H-5_{ax}), 1.76 (dd, J = 14.6, 3.5 Hz, 1H, H-3_{ax}), 1.89 (m, 3H, vinyl CH_3), 2.03 (s, 3H, CH_3COO), 2.33 (m, 1H, $CHCH_3$), 4.07 (m, 1H, CHOH), 4.72 (dd, J = 7.0, 1.0 Hz, 2H, CH_2O), 5.76 (ddq, J = 7.0, 7.0, 1.5 Hz, 1H, =CH); ^{13}C nmr δ: 16.81, 20.91, 23.21, 26.78, and 27.13 ($5CH_3$), 38.17 (C2), 30.77, 35.75, and 40.29 ($2CH_2$ and CH), 62.79 and 67.04 (CH_2O and CHOH), 76.53 (COH), 83.52 and 97.37 (2 acetylenic C), 123.62 (=C), 129.99 (=CH), 170.86 (C=O); eims m/z: 234 (M^+ − 60, 3), 178 (10), 148 (100).

(−)-4(Z)-(4S,5R)-4-Hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (3)

To a solution of compound **16** (1.21 g, 4.1 mmol) in CH_2Cl_2 (50 mL) was added pyridinium dichromate (Aldrich, 5.0 g, 13.3 mmol). The mixture was stirred at room temperature for 5 h before it was filtered through a short column of Florisil^R. The residue and Florisil^R were rinsed with ether and CH_2Cl_2 and the rinsing was combined with the filtrate. Evaporation of solvent gave a pale yellow oil (1.35 g), which was purified by flash chromatography (75% ether + 25% hexane) to give a keto-acetate as colorless crystals (1.02 g, 84%). A small sample of the product was recrystallized twice from ether–hexane to give colorless needles, mp 120.0–122.0°C ((±)-keto-acetate mp 104–106°C); $[\alpha]_D$ −22.9° (*c* 0.99, CH_3OH); ir: 1720 cm^{-1}; ^1H nmr δ: 0.98 (s, 3H, CH_3), 1.14 (m, 3H, $CHCH_3$), 1.20 (s, 3H, CH_3), 1.92 (d, J = 1.4 Hz, 3H, vinyl CH_3), 2.03 (s, 3H, CH_3COO), 2.10 (dd, J = 14.3, 1.5 Hz, 1H, H-2_{eq}), 2.31 (m, 4H, $CHCH_3$, CH_2 at C6 and OH), 2.65 (d, J = 14.3 Hz, 1H, H-2_{ax}), 4.74 (dd, J = 7.1, 0.9 Hz, 2H, CH_2O), 5.84 (ddq, J = 7.1, 7.1, 1.5 Hz, 1H, =CH); eims m/z: 292 (M^+, about 2), 232 (18), 176 (45), 148 (54), 120 (31), 106 (100). Exact Mass (hrms) calcd. for $C_{17}H_{24}O_4$: 292.1675; found: 292.1650. Anal. calcd. for $C_{17}H_{24}O_4$: C 69.82, H 8.28%; found: C 69.50, H 8.32%.

The keto-acetate (1.0 g, 3.4 mmol) was hydrolyzed by stirring with 5 M NaOH (1 mL) and methanol (30 mL) at room temperature for 1 h. The solution was then concentrated, and the residue was diluted with H_2O and extracted with ether. The organic extract was washed with H_2O and dried over anhydrous Na_2SO_4. Evaporation of solvent gave a yellow oil (0.86 g), which after purification by flash column chromatography (75% ether + 25% hexane) gave the desired compound **3** as colorless crystals (0.74 g, 87%). A small sample of the product was recrystallized from ether–hexane to give colorless plates, mp 97–98°C ((±)-**3** mp 92–98°C, lit. (9) (±)-**3** was an oil); $[\alpha]_D$ −25.8° (*c* 0.93, CH_3OH); ir: 3400, 1710 cm^{-1}; ^1H nmr δ: 0.98 (s, 3H, CH_3), 1.14 (m, 3H, $CHCH_3$), 1.20 (s, 3H, CH_3), 1.91 (m, 3H, vinyl

The keto-acetate (90 mg, 0.3 mmol) was hydrolyzed by treating with 5 M KOH (5 drops) and methanol (10 mL) as described above to give compound **7** as a colorless oil (69 mg, 92%) that would not crystallize ((±)-**7** crystallized on storage at −10°C to give colorless crystals, mp 72.5–79.5°C); $[\alpha]_D$ −16.4° (*c* 0.62, CH_3OH); ir: 3630, 1710 cm^{-1}; ^{1}H nmr δ: 1.03 (s, 3H, CH_3), 1.17 (d, J = 6.4 Hz, 3H, CHCH_3), 1.19 (s, 3H, CH_3), 1.88 (m, 3H, vinyl CH_3), 1.96 (dd, J = 13.8, 2.3 Hz, 1H, H-2_{eq}), 2.16 (ddd, J = 13.3, 3.4, 2.3 Hz, 1H, H-6_{eq}), 2.32 (m, 1H, C*H*CH_3), 2.39 (ddd, J = 13.3, 12.8, 0.8 Hz, 1H, H-6_{ax}), 2.72 (ddd, J = 13.8, 0.8, 0.8 Hz, 1H, H-2_{ax}), 4.29 (dd, J = 6.8, 1.0 Hz, 2H, CH_2OH), 5.88 (ddq, J = 6.8, 6.8, 1.5 Hz, 1H, =CH); ^{13}C nmr δ: 16.76, 23.13, 24.98, and 25.41 (4q, $4CH_3$), 37.64 (d, CH), 43.06 (s, C3), 44.25, 49.48, and 61.27 (3t, $3CH_2$), 75.25 (s, COH), 84.47 and 94.85 (2s, 2 acetylenic C), 120.26 (s, =C), 136.08 (d, =CH), 210.86 (s, C=O); ms m/z: 250 (M^+, very weak), 232 (5), 179 (23), 165 (66), 106 (100). Exact Mass (hrms) calcd. for $C_{15}H_{22}O_3$: 250.1569; found: 250.1570.

(−)-8(Z)-(2R,3R,8S,9R)-8-(5-Hydroxy-3-methylpent-3-en-1-ynyl)-2,3,7,7,9-pentamethyl-1,4-dioxaspiro[4,5]decan-8-ol (18)

A mixture of (−)-4(*Z*)-(4*S*,5*R*)-4-hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (**3**) (7.8 mg, 0.03 mmol), (−)-(2*R*,3*R*)-butanediol (Aldrich, 23.6 mg, 0.26 mmol), pyridinium *p*-tosylate (Aldrich, 3.7 mg, 0.01 mmol), and benzene (4 mL) was heated to reflux under a Dean–Stark separator for 15 h (10, 18). The reaction mixture was then allowed to cool to room temperature, washed with saturated Na_2CO_3 and water, and dried over anhydrous Na_2SO_4. Evaporation of solvent gave a colorless oil (10 mg), which was purified on the Chromatotron (1 mm silica gel plate, 75% ether + 25% hexane) to give ketal **18** as a colorless oil (6.8 mg, 70%), gc retention time (DB1701 column, 70–240°C at 10°C min^{-1}) 18.57 min; $[\alpha]_D$ −30.0° (*c* 0.6, CH_3OH); ir: 3620 cm^{-1}; ^{1}H nmr δ: 1.04 (d, J = 6.5 Hz, 3H, CHCH_3 at C9), 1.08 and 1.11 (2s, 3H each, $2CH_3$), 1.18 and 1.22 (2d, J = 6.0 Hz, 3H each, CHCH_3 at C2 and C3), 1.70 (m, 2H, H-10), 1.52 (dd, J = 14.1, 2.6 Hz, 1H, H-6_{eq}), 1.76 (d, J = 14.1 Hz, 1H, H-6_{ax}), 1.86 (q, J = 1.1 Hz, 3H, vinyl CH_3), 2.22 (m, 1H, C*H*CH_3 at C9), 3.50 and 3.60 (2dq, J = 8.3, 6.0 Hz, 1H each, C*H*CH_3 at C2 and C3), 4.28 (dd, J = 6.7, 0.9 Hz, 2H, CH_2OH), 5.84 (ddq, J = 6.7, 6.7, 1.5 Hz, 1H, =CH); ^{13}C nmr δ: 16.17, 16.88, 17.10, 21.27, 23.27, and 27.38 (6q, $6CH_3$), 34.63 (d, C9), 39.84 (s, C7), 43.80 and 46.57 (2t, C6 and C10), 61.31 (t, CH_2OH), 77.37 and 78.27 (2d, C2 and C3), 78.47 (s, C8), 85.48 and 94.09 (2s, 2 acetylenic C), 107.15 (s, C5), 120.47 (s, =C), 135.73 (d, =CH); cims (isobutane) m/z: 321 (M^+ + 1, very weak), 305. Exact Mass (hrms) calcd. for $C_{19}H_{30}O_4$: 322.2144; found: 322.2135.

(−)-(9Z)-(9S,10R)-9-(5-Hydroxy-3-methylpent-3-en-1-ynyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (20)

A mixture of (−)-4(*Z*)-(4*S*,5*R*)-4-hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (**3**) (620 mg, 2.49 mmol), 2,2-dimethyl-1,3-propanediol (Aldrich, 460 mg, 4.4 mmol), pyridinium *p*-tosylate (Aldrich, 19 mg, 0.07 mmol), and benzene (18 mL) was heated to reflux under a Dean–Stark separator for 4 h. The reaction mixture was then allowed to cool to room temperature, and washed with saturated Na_2CO_3, saturated NaCl, and water. After drying over anhydrous Na_2SO_4 and evaporation of solvent, a yellow oil was obtained as the crude product (1 g). Purification by flash column chromatography (75% ether + 25% hexane) gave the desired ketal **20** as a pale yellow oil (750 mg, 90%); $[\alpha]_D$ −29.4° (*c* 1.02, CH_3OH); ir: 3610, 3440, 1110, and 1090 cm^{-1}; ^{1}H nmr δ: 0.83, 1.04, 1.05, 1.06, 1.09, and 1.11 (15H, $5CH_3$), 1.53–1.61 (m, 2H, 2 axial H at C7 and C11), 1.84 (m, 3H, vinyl CH_3), 1.98 (ddd, J = 13.8, 3.4, 3.4 Hz, 1H, H-11_{eq}), 2.18 (m, 1H, CH), 2.51 (dd, J = 14.3, 3.2 Hz, 1H, H-7_{eq}), 3.36 and 3.38 (2dd, J = 11.3, 1.9 Hz, 2H, 2 equatorial H at C2 and C4), 3.55 (d, J = 11.3 Hz, 2H, 2 axial H at C2 and C4), 4.29 (br s, 2H, CH_2OH), 5.50 (ddq, J = 6.7, 6.7, 1.5 Hz, 1H, =CH); eims (trimethylsilyl ether) m/z: 408 (M^+ of trimethylsilyl ether), 155 (100). Exact Mass (hrms) (trimethylsilyl ether) calcd. for $C_{23}H_{40}O_4Si$: 408.2696; found: 408.2718.

(−)-9(1E,3Z)-(9R,10R)-9-(5-Hydroxy-3-methyl-1,3-pentadienyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (21)

A solution of (−)-(9*Z*)-(9*S*,10*R*)-9-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (**20**) (730 mg, 2.2 mmol) in dry THF (50 mL) was stirred under an argon atmosphere and cooled with an ice-water bath. Sodium bis(2-methoxyethoxy)aluminium hydride (Redal^R, Aldrich, 3.4 M in toluene, 1.3 mL, 4.4 mmol) was added dropwise. Some frothing occurred as the Redal^R was added. The reaction mixture was stirred at 0°C until the frothing subsided. Then another portion of Redal^R (0.7 mL, 2.2 mmol) was added. After 1.5 h of stirring at 0°C followed by 1 h at room temperature, the reaction was worked up by pouring into H_2O and extracting with ether (3×). The combined organic extracts were washed with saturated NaCl and dried over anhydrous Na_2SO_4. Evaporation of solvent gave a colorless oil (about 1 g) as the crude product, which was usually hydrolyzed by the procedure described below to give compound **22** without purification. A small amount of the crude product was purified on the Chromatotron (75% ether + 25% hexane) to give the desired ketal **21** as a colorless oil; $[\alpha]_D$ −64.4° (*c* 1.02, CH_3OH); ir: 3600, 1600, 1100, 975, 910 cm^{-1}; ^{1}H nmr δ: 0.76, 0.78, 0.85, 1.05, and 1.12 (4s, 1d, 15H, $5CH_3$), 1.34–1.42 (m, 2H, 2 axial H at C7 and C11), 1.85 (d, J = 0.9 Hz, 3H, vinyl CH_3), 1.97 (ddd, J = 14.0, 3.5, 3.5 Hz, 1H, H-11_{eq}), 2.16 (m, 1H, CH), 2.29 (dd, J = 14.6, 3.2 Hz, 1H, H-7_{eq}), 3.40 (m, 2H, 2 equatorial H at C2 and C4), 3.57 and 3.58 (2d, J = 11.2, 11.4 Hz, respectively, 2H, 2 axial H at C2 and C4), 4.31 (d, J = 6.9 Hz, 2H, CH_2OH), 5.54 (t, J = 7 Hz, 1H, =CH), 5.94 (d, J = 15.6 Hz, 1H, =CH), 6.68 (d, J = 15.6 Hz, 1H, =CH).

(−)-4(1E,3Z)-(4R,5R)-4-Hydroxy-4-(5-hydroxy-3-methyl-1,3-pentadienyl)-3,3,5-trimethylcyclohexanone (22)

The crude ketal **21** obtained in the above procedure was hydrolyzed by stirring with 1 M HCl (5 drops) and acetone (50 mL) at room temperature for 2 h. After concentration of the acetone solution, saturated $NaHCO_3$ was added and the mixture was extracted with ether. The organic layer was dried with anhydrous Na_2SO_4 and concentrated to give a yellow oil as the crude product. Flash column chromatography using 90% ether + 10% hexane as eluent gave the desired compound **22** as a colorless oil (338 mg, 60%) that would not crystallize ((±)-**22** crystallized on standing at room temperature and was recrystallized from ether–hexane to give colorless crystals, mp 128°C (sharp));

*(−)-4(1*E*,3*Z*)-(4*R*,5*R*)-4-Hydroxy-4-(3-methyl-5-oxo-1,3-pentadienyl)-3,3,5-trimethylcyclohexanone (**23**)*[7]

To a solution of compound **22** (300 mg, 1.2 mmol) in acetone (30 mL) was added manganese oxide (2.08 g, 24 mmol). The mixture was stirred at room temperature under a drying tube for 1 h before the manganese oxide was removed by filtration. The solid residue was rinsed with acetone and the rinsing was combined with the filtrate. Evaporation of acetone gave the crude aldehyde **23**, which was usually oxidized to ester **24** (see below) without purification.

A small amount of aldehyde **23** was purified by preparative tlc (90% ether + 10% hexane) followed by recrystallization from ether–hexane to give colorless crystals, mp 106.0–108.5°C; $[\alpha]_D$ −64.5° (*c* 0.38, CH_3OH); ir: 3550, 1715, and 1665 cm^{-1}; ^1H nmr δ: 0.89 (d, *J* = 6.4 Hz, 3H, $CHCH_3$), 0.93 and 1.04 (2s, 6H, $2CH_3$), 2.11 (d, *J* = 1.1 Hz, 3H, vinyl CH_3), 2.15–2.42 (m, CH_2 at C6 and $CHCH_3$), 2.17 (dd, *J* = 14.9, 2.5 Hz, H-2_{eq}), 2.48 (d, *J* = 14.9 Hz, 1H, H-2_{ax}), 5.90 (d, *J* = 7.7 Hz, 1H, =CH), 6.49 and 7.50 (2d, *J* = 15.4 Hz, 2H, 2 =CH), 10.21 (d, *J* = 8.0 Hz, 1H, HC=O). Exact Mass (hrms) calcd. for $C_{15}H_{22}O_3$: 250.1569; found: 250.1575.

*(−)-(4*R*,5*R*)-Methyl dihydroabscisate (**24**)*[8]

Crude aldehyde **23** (about 1.2 mmol) obtained from the above procedure was dissolved in methanol (30 mL). Manganese oxide (1.79 g, 20 mmol), sodium cyanide (87 mg, 1.7 mmol), and glacial acetic acid (0.10 g, 1.6 mmol) were added. The mixture was stirred at room temperature for 5 h before it was filtered through Celite^R. The manganese oxide residue and Celite was rinsed with methanol and the rinsing was combined with the filtrate. The combined rinsing and filtrate was then concentrated, and the residue was partitioned between ether and H_2O. The ether layer was separated, dried over anhydrous Na_2SO_4, and concentrated to give a yellow oil (283 mg) as crude product. Purification on the Chromatotron (4 mm silica gel plate, 90% ether + 10% hexane) gave (−)-(4*R*,5*R*)-methyl dihydroabscisate (**24**) as colorless crystals (199 mg, 70% overall yield). Part of the product was recrystallized from ether–hexane to give colorless needles, mp 117.0–119.5°C; $[\alpha]_D$ −62.7°C (*c* 0.90, CH_3OH); hplc (Chiracel OD column (20, 21), 0.46 cm × 25 cm, 10% isopropanol + 90% hexane at 1.0 mL min^{-1}) retention time 10.7 min; ir: 3600, 1710 cm^{-1}; ^1H nmr δ: 0.88 (d, *J* = 6.3 Hz, 3H, $CHCH_3$), 0.92 and 1.04 (2s, 6H, $2CH_3$), 2.03 (d, *J* = 1.2 Hz, 3H, vinyl CH_3), 2.15 (dd, *J* = 16.0, 15.0 Hz, H-6_{ax}), 2.15 (dd, *J* = 15.0, 2.5 Hz, H-2_{eq}), 2.30–2.40 (m, 2H, $CHCH_3$ and H-6_{eq}), 2.46 (d, *J* = 14.9 Hz, 1H, H-2_{ax}), 3.69 (s, 3H, OCH_3), 5.74 (s, 1H, =CH), 6.46 (d, *J* = 16.0 Hz, 1H, =CH), 7.91 (dd, *J* = 16.0, 0.6 Hz, 1H, =CH); ^{13}C nmr δ: 16.00, 21.28, 22.87, and 25.25 (4q, $4CH_3$), 37.40 (d, CH), 41.71 (s, C3), 47.10 (t, CH_2), 51.10 (q, CH_3O), 52.92 (t, CH_2), 78.14 (s, COH), 117.62, 129.41, and 135.15 (3d, 3=CH), 149.41 (s, =C), 166.51 (s, OC=O), 209.12 (s, C=O); eims *m/z*: 280 (M^+, 2), 192 (35), 164 (23), 123 (100). Exact Mass (hrms) calcd. for $C_{16}H_{24}O_4$: 280.1675; found: 280.1664. Anal. calcd. for $C_{16}H_{24}O_4$: C 68.53, H 8.63%; found: C 68.67, H 8.74%.

*(−)-(4*R*,5*R*)-Dihydroabscisic acid (**2**)*[9]

A mixture of (−)-(4*R*,5*R*)-methyl dihydroabscisate (**24**) (166 mg, 0.6 mmol), 2 M KOH (6 mL), and methanol (3 mL) was stirred at room temperature for 4 h. Most of the methanol was then evaporated. The residue was diluted with H_2O, extracted with ether, and the ether extract was discarded. The aqueous layer was acidified with 1 M HCl and then extracted with $CHCl_3$. The $CHCl_3$ layer gave, after drying over anhydrous Na_2SO_4 and evaporation of solvent, (−)-(4*R*,5*R*)-dihydroabscisic acid (**2**) as white crystals (118 mg, 78%). Part of the product was recrystallized from $CHCl_3$–hexane to give white crystals, mp 177–184°C (lit. (7) (±)-**2** mp 193.5°C); $[\alpha]_D$ −65.2° (*c* 0.66, CH_3OH); ir: 2800–3200, 1715, 1690 cm^{-1}; ^1H nmr δ: 0.89 (d, *J* = 6.4 Hz, $CHCH_3$), 0.93 and 1.06 (2s, 6H, $2CH_3$), 2.08 (s, 3H, vinyl CH_3), 2.14–2.43 (m, 4H, $CHCH_3$, CH_2 at C6 and H-2_{eq}), 2.47 (d, *J* = 14.9 Hz, 1H, H-2_{ax}), 5.77 (br s, 1H, =CH), 6.50 and 7.88 (2d, *J* = 16.0 Hz, 2H, 2 =CH); eims (trimethylsilyl ether) *m/z*: 338 (M^+, 2), 192 (30), 73 (100). Exact Mass (hrms) (trimethylsilyl ether) calcd. for $C_{18}H_{30}O_4Si$: 338.1913; found: 338.1921. Anal. calcd. for $C_{15}H_{22}O_4$: C 67.63, H 8.33%; found: C 67.21, H 8.30%.

*(−)-(9*Z*)-(9*R*,10*R*)-9-(5-Hydroxy-3-methylpent-3-en-1-ynyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (**25**)*

(−)-4(*Z*)-(4*R*,5*R*)-4-Hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (**7**) (130 mg, 0.52 mmol) was treated with a mixture of 2,2-dimethyl-1,3-propanediol (160 mg, 1.53 mmol), pyridinium *p*-tosylate (9 mg, 0.04 mmol), and benzene (4 mL) according to the procedure described above for the conversion of compound **3** to ketal **20**. The desired ketal **25** was obtained as a pale yellow oil (149 mg, 89%); $[\alpha]_D$ −27.8° (*c* 1.2, CH_3OH); ir: 3610, 3440, 1110, and 1090 cm^{-1}; ^1H nmr δ: 0.84 (s), 1.04 (s), 1.08 (s), 1.09 (d, *J* = 6.8 Hz), and 1.16 (s) (15H, $5CH_3$), 1.52 (d, *J* = 14.1 Hz, 1H, H-7_{ax}), 1.58 (dd, *J* = 13.4, 13.2 Hz, 1H, H-11_{ax}), 1.83 (ddd, *J* = 13.4, 3.7, 2.9 Hz, 1H, H-11_{eq}), 1.87 (m, *J* = 1 Hz, 3H, vinyl CH_3), 2.11 (dd, *J* = 14.1, 2.8 Hz, 1H, H-7_{eq}), 2.13–2.22 (m, 1H, $CHCH_3$), 3.35–3.41 (m, 2H, 2 equatorial H at C2 and C4), 3.58 and 3.54 (2d, *J* = 11.9 and 12.6 Hz, respectively, 2H, 2 axial H at C2 and C4), 4.29 (d, *J* = 6.7 Hz, 2H, CH_2OH), 5.84 (ddq, *J* = 6.7, 6.7, 1.5 Hz, 1H, =CH). Exact Mass (hrms) (M^+ − 18 peak) calcd. for $C_{20}H_{30}O_3$: 318.2195; found: 318.2188.

*(−)-9(1*E*,3*Z*)-(9*S*,10*R*)-9-(5-Hydroxy-3-methyl-1,3-pentadienyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (**26**)*

(−)-(9*Z*)-(9*R*,10*R*)-9-(5-Hydroxy-3-methylpent-3-en-1-ynyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (**25**) (149 mg, 0.44 mmol) was reduced with sodium bis(2-methoxyethoxy)aluminium hydride (Redal^R, Aldrich, 3.4 M in toluene, 0.8 mL, 2.48 mmol) by the procedure described above for the preparation of compound **21**. The crude product **26** obtained was usually hydrolyzed by the procedure described below to give compound **27** without purification. A small amount of the crude product was purified on the Chromatotron (75% ether + 25% hexane) to give the desired ketal **26** as a colorless oil; ir: 3600, 1600, 1100, 975, 910 cm^{-1}; ^1H nmr δ: 0.76 (d, *J* = 6.9 Hz), 0.83 (s), 0.84 (s), 1.02 (s), and 1.06 (s) (15H, $5CH_3$), 1.57 (d, *J* = 14.1 Hz, 1H, H-7_{ax}), 1.59 (dd, *J* = 13.0, 12.7, 1H, H-11_{ax}), 1.84 (ddd, *J* = 12.7, 3.6, 2.7 Hz, 1H, H-11_{eq}), 1.85 (d, *J* = 0.9 Hz, 3H, vinyl CH_3), 2.08 (dd, *J* = 14.1, 2.7 Hz, 1H, H-7_{eq}), 2.16 (ddq, *J* = 13.0, 3.6, 6.8 Hz, 1H, $CHCH_3$), 3.30–3.50 (m, 2H, 2 equatorial H at C2 and C4), 3.56 and 3.60 (2d, *J* = 11.7, 11.5 Hz, respectively, 2H, 2 axial H at C2 and C4), 4.30 (d, *J* = 7.0 Hz, 2H, CH_2OH), 5.54 (dd, *J* = 7.0, 6.8 Hz, 1H, =CH), 5.70 (d, *J* = 15.8 Hz, 1H, =CH), 6.60 (d, *J* = 15.8 Hz, 1H, =CH).

[7]Alternatively, this compound can also be named as (−)-1(2*Z*,4*E*)-(1*R*,6*R*)-5-(1-hydroxy-2,2,6-trimethyl-4-oxocyclohexyl)-3-methyl-2,4-pentadienal.

[8]This compound can also be named as (−)-1(2*Z*,4*E*)-(1*R*,6*R*)-5-(1-hydroxy-2,2,6-trimethyl-4-oxocyclohexyl)-3-methyl-2,4-pentadienoic acid, methyl ester, or (−)-4(1*E*,3*Z*)-(4*R*,5*R*)-4-(4-carbomethoxy-3-methyl-1,3-butadienyl)-4-hydroxy-3,3,5-trimethylcyclohexanone.

[9]This compound can also be named as (−)-1(2*Z*,4*E*)-(1*R*,6*R*)-5-(1-hydroxy-2,2,6-trimethyl-4-oxocyclohexyl)-3-methyl-2,4-pentadienoic acid, or (−)-4(1*E*,3*Z*)-(4*R*,5*R*)-4-(4-carboxy-3-methyl-1,3-butadienyl)-4-hydroxy-3,3,5-trimethylcyclohexanone. See footnote 5.

(−)-4-(1E,3Z)-(4S,5R)-4-Hydroxy-4-(5-hydroxy-3-methyl-1,3-pentadienyl)-3,3,5-trimethylcyclohexanone (27)

The crude ketal **26** obtained in the above procedure was hydrolyzed by stirring with 1 M HCl (4 drops) and acetone (5 mL) at room temperature for 1 h. Working up in the manner previously described followed by purification on the Chromatotron (4 mm silica gel plate, 90% ether + 10% hexane) gave the desired compound **27** as a colorless oil (33 mg, 30% overall yield); $[\alpha]_D$ −18.3° (*c* 1.1, CH_3OH); ir: 3620, 1700 cm^{-1}; ^1H nmr δ: 0.86 (d, *J* = 6.5 Hz, $CHCH_3$), 0.88 and 0.93 (2s, 6H, CH_3), 1.86 (d, *J* = 1.1 Hz, 3H, vinyl CH_3), 1.90 (dd, *J* = 13.6, 2.2 Hz, 1H, H-2_{eq}), 2.18 (ddd, *J* = 13.5, 4.3, 2.2 Hz, 1H, H-6_{eq}), 2.23–2.33 (m, 1H, $CHCH_3$), 2.41 (t, *J* = 13.5 Hz, 1H, H-6_{ax}), 2.82 (d, *J* = 13.6 Hz, H-2_{ax}), 4.31 (m, 2H, CH_2OH), 5.59 (dd, *J* = 7.0, 6.3 Hz, 1H, =CH), 5.73 (d, *J* = 15.7 Hz, 1H, =CH), 6.69 (d, *J* = 15.7 Hz, 1H, =CH); ^{13}C nmr δ: 16.03, 20.72, 24.51, and 24.59 (4q, $4CH_3$), 36.83 (d, CH), 42.85 (s, C3), 45.11, 51.46, and 58.34 (3t, $3CH_2$), 77.78 (s, COH), 126.70, 128.28, and 134.02 (3d, 3 =CH), 134.51 (s, =C), 211.45 (s, C=O). Exact Mass (hrms) calcd. for $C_{15}H_{24}O_3$: 252.1725; found: 252.1708.

(−)-4(1E,3Z)-(4S,5R)-4-Hydroxy-4-(5-oxo-3-methyl-1,3-pentadienyl)-3,3,5-trimethylcyclohexanone (28)

Compound **27** (30 mg, 0.11 mmol) was oxidized with manganese oxide (420 mg, 4.8 mmol) to give aldehyde **28** by the procedure previously described (see the preparation of compound **23**). The crude aldehyde **28** was usually oxidized to ester **29** (see below) without purification.

A small amount of aldehyde **28** was purified by preparative tlc (90% ether + 10% hexane) to give a colorless oil; $[\alpha]_D$ −39.5° (*c* 0.77, CH_3OH); ir: 3610, 3450, 1700, and 1665 cm^{-1}; ^1H nmr δ: 0.89 (d, *J* = 6.4 Hz, 3H, $CHCH_3$), 0.96 (s, 6H, $2CH_3$), 1.93 (dd, *J* = 13.6, 2.2 Hz, H-2_{eq}), 2.08 (d, *J* = 1.1 Hz, 3H, vinyl CH_3), 2.20–2.46 (m, CH_2 at C6 and $CHCH_3$), 2.84 (d, *J* = 13.6 Hz, 1H, H-2_{ax}), 5.90 (d, *J* = 7.8 Hz, 1H, =CH), 6.16 (dd, *J* = 15.47, 0.4 Hz, 1H, =CH), 7.40 (d, *J* = 15.7 Hz, 1H, =CH), 10.20 (d, *J* = 7.8 Hz, 1H, HC=O).

(−)-(4S,5R)-Methyl dihydroabscisate (29)

Crude aldehyde **28** (about 0.11 mmol) obtained from the above procedure was reacted with a mixture of methanol (5 mL), manganese oxide (310 mg, 3.56 mmol), sodium cyanide (35 mg, 0.71 mmol), and glacial acetic acid (35 mg, 0.58 mmol) (see preparation of ester **24**). The desired product (−)-(4*S*,5*R*)-methyl dihydroabscisate (**29**) was obtained as colorless crystals (21 mg, 70% overall yield). Part of the product was recrystallized from ether–hexane at 0°C to give colorless plates, mp 105–108°C; $[\alpha]_D$ −40.6° (*c* 1.03, CH_3OH); ir: 1700 cm^{-1}; ^1H nmr δ: 0.87 (d, *J* = 6.5 Hz, 3H, $CHCH_3$), 0.94 and 0.96 (2s, 6H, $2CH_3$), 1.91 (dd, *J* = 13.6, 2.2 Hz, 1H, H-2_{eq}), 2.01 (d, *J* = 1.2 Hz, 3H, vinyl CH_3), 2.20 (ddd, *J* = 13.6, 4.2, 2.2 Hz, H-6_{eq}), 2.33 (m, 1H, $CHCH_3$), 2.44 (dd, *J* = 13.6, 13.0 Hz, 1H, H-6_{ax}), 2.86 (d, *J* = 13.6 Hz, 1H, H-2_{ax}), 3.70 (s, 3H, OCH_3), 5.72 (s, 1H, =CH), 6.09 (d, *J* = 15.9 Hz, 1H, =CH), 7.81 (d, *J* = 15.9 Hz, 1H, =CH); eims *m/z*: 280 (M^+, 4), 192 (43), 164 (24), 123 (100). Exact Mass (hrms) calcd. for $C_{16}H_{24}O_4$: 280.1675; found: 280.1649.

(−)-(4S,5R)-Dihydroabscisic acid (5)

(−)-(4*S*,5*R*)-Methyl dihydroabscisate (**29**) (15 mg, 0.05 mmol) was hydrolyzed with 2 M KOH (3 mL) and methanol (3 mL) as previously described to give (−)-(4*S*,5*R*)-dihydroabscisic acid (**5**) as a colorless oil (13 mg, 90%); $[\alpha]_D$ −34.5° (*c* 0.89, CH_3OH); ir: 2800–3500, 1680 cm^{-1}; ^1H nmr δ: 0.88 (d, *J* = 6.4 Hz, $CHCH_3$), 0.95 and 0.96 (2s, 6H, $2CH_3$), 1.91 (dd, *J* = 13.6, 2.1 Hz, 1H, H-2_{eq}), 2.04 (d, *J* = 1.2 Hz, 3H, vinyl CH_3), 2.21 (ddd, *J* = 13.4, 4.1, 2.1 Hz, H-6_{eq}), 2.35 (m, 1H, $CHCH_3$), 2.44 (dd, *J* = 13.4, 12.7 Hz, 1H, H-6_{ax}), 2.86 (d, *J* = 13.6 Hz, 1H, H-2_{ax}), 5.75 (s, 1H, =CH), 6.14 and 7.79 (2d, *J* = 16.1 Hz, 2H, 2=CH); ^{13}C nmr δ: 16.05, 21.48, 24.58, and 24.63 ($4CH_3$), 43.00 (C3), 36.67, 45.03, and 51.42 (CH and $2CH_2$), 78.00 (COH), 151.77, 140.60, 127.72, and 116.99 (4 =C), 170.63 (COOH), 211.26 (C=O); eims *m/z*: 266 (M^+, about 2), 248 (5), 192 (29), 164 (67), 123 (100). Exact Mass (hrms) calcd. for $C_{15}H_{22}O_4$: 266.1518; found: 266.1519.

(+)-(4R,6S)-4-Hydroxy-2,2,6-trimethylcyclohexanone (11)

A mixture of (−)-(4*R*,6*R*)-4-hydroxy-2,2,6-trimethylcyclohexanone (**10**) (300 mg, 0.19 mmol), 5 M NaOH (1 mL), and ethanol (10 mL) was heated to 85°C for 24 h under an argon atmosphere. Then most of the ethanol was removed by evaporation. The residue was dissolved in ether, and the solution was washed with water. After drying over anhydrous Na_2SO_4 and evaporation of the solvent, a pale yellow oil (255 mg) was obtained. Purification by flash chromatography (75% ether + 25% hexane) gave unreacted *trans* ketol **10** (46 mg); $[\alpha]_D$ −102.3° (*c* 0.92, CH_3OH), followed by the desired *cis* ketol **11** as a colorless oil (195 mg, 73% based on starting material consumed). The product **11** solidified on storage at −10°C and was recrystallized from ether–hexane to give colorless needles, mp 48.0–50.0°C (lit. (15) mp 52–53°C); $[\alpha]_D$ +95.0° (*c* 0.88, CH_3OH) (lit. (15) $[\alpha]_D$ +107.4° (*c* 0.8, CH_3OH)); ^1H nmr δ: 0.96 (d, *J* = 6.5 Hz, 3H, $CHCH_3$), 1.00 and 1.14 (2s, 3H each, $2CH_3$), 1.35 (ddd, *J* = 12.4, 12.4, 11.3 Hz, 1H, H-5_{ax}), 1.53 (dd, *J* = 12.2, 11.5 Hz, 1H, H-3_{ax}), 2.00 (ddd, *J* = 12.2, 4.2, 3.5 Hz, H-3_{eq}), 2.22 (m, 1H, H-5_{eq}), 2.67 (m, 1H, H-6_{ax}), 4.25 (tt, *J* = 11.3, 4.3 Hz, 1H, H-4_{ax}); eims *m/z*: 156 (M^+, 10), 138 (8), 83 (66), 74 (50), 69 (60), 57 (100).

(+)-(4R,6S)-4-tert-Butyldimethylsiloxy-2,2,6-trimethylcyclohexanone (30)

The *cis* ketol **11** (66 mg, 0.42 mmol) was treated with a mixture of *tert*-butyldimethylsilyl chloride (130 mg, 0.86 mmol), imidazole (73 mg, 1.07 mmol), and dry DMF (2 mL) by the procedure described above for the conversion of *trans* ketol **10** to silyl ether **13**. After working up and purification by distillation (Kugelrohr, 150–180°C, 8–10 Torr), the desired silyl ether **30** was obtained as a colorless oil (111 mg, 99%); $[\alpha]_D$ +58.0° (*c* 0.98, CH_3OH); ir: 1710 cm^{-1}; ^1H nmr δ: 0.07 (s, 6H, CH_3SiCH_3), 0.87 (s, 9H, $3CH_3$), 0.98 (d, *J* = 6.5 Hz, 3H, $CHCH_3$), 1.03 and 1.17 (2s, 3H each, $2CH_3$), 1.43 (ddd, *J* = 13.6, 12.8, 11.0 Hz, 1H, H-5_{ax}), 1.58 (dd, *J* = 13.1, 11.1 Hz, 1H, H-3_{ax}), 1.89 (ddd, *J* = 13.1, 4.3, 3.5 Hz, 1H, H-3_{eq}), 2.11 (m, 1H, H-5_{eq}), 2.68 (ddq, *J* = 12.8, 6.5, 6.5 Hz, 1H, H-6_{ax}), 4.24 (tt, *J* = 11.0, 4.4 Hz, 1H, H-4_{ax}); cims (isobutane) *m/z*: 271 (M^+ + 1). Exact Mass (hrms) calcd. for $C_{15}H_{30}O_2Si$: 270.2015; found: 270.2004.

(+)-1(Z)-(1R,4R,6S)-4-tert-Butyldimethylsiloxy-1-(5-hydroxy-3-methylpent-3-en-1-ynyl)-2,2,6-trimethylcyclohexanol (31)

Silyl ether **30** (5.7 g, 21 mmol) was treated with *Z*-3-methylpent-2-en-4-yn-1-ol (3.0 g, 32 mmol) and *n*-butyllithium (1.6 M in hexane, 40 mL, 63 mmol) by the procedure described for the conversion of silyl ether **13** to compounds **14** and **15**. The desired product **31** was obtained as a colorless oil (4.9 g, 64%), which solidified on storage at 0°C to give colorless crystals, gc (DB1701 column, 70–240°C at 10°C min^{-1}) retention time 19.11 min; mp 89–94°C; $[\alpha]_D$ +19.1° (*c* 0.82, CH_3OH); ir: 3620 cm^{-1}; ^1H nmr δ: 0.03 (s, 6H, CH_3SiCH_3), 0.86 (s, 9H, $3CH_3$), 1.01 (s, 3H, CH_3), 1.05 (d, *J* = 6.5 Hz, 3H, $CHCH_3$), 1.11 (s, 3H, CH_3), 1.40, 1.55, and 1.73 (3m, $2CH_2$), 1.89 (d, *J* = 1.0 Hz, 3H, vinyl CH_3), 1.92–2.00 (m, 1H, $CHCH_3$), 3.83 (tt, *J* = 10.8, 5.2 Hz, 1H, CHOSi), 4.32 (m, 2H, CH_2OH), 5.86 (ddd, *J* = 6.7, 6.7, 1.5 Hz, 1H, =CH); cims (isobutane) *m/z*: 367 (M^+ + 1), 349.

(+)-1(Z)-(1R,4R,6S)-1-(5-Acetoxy-3-methylpent-3-en-1-ynyl)-2,2,6-trimethylcyclohexan-1,4-diol (32)

Compound **31** (2.5 g, 6.9 mmol) was reacted with acetic anhydride (2.5 g, 18.6 mmol), pyridine (25 mL), and 4-dimethylaminopyridine (32 mg, 0.2 mmol) by the procedure previously described for the acetylation of compounds **14** and **15**. A small amount of the crude acetate obtained was purified on the Chromatotron (1 mm silica gel plate, 50% ether + 50% hexane) to give a colorless oil, gc (DB1701 column, 70–240°C at 10°C min^{-1}) retention time 19.37 min; $[\alpha]_D$ +17.6° (*c* 1.07, CH_3OH); ir: 3610, 3500, 1735 cm^{-1}; ^1H nmr δ: 0.03 (s, 6H, CH_3SiCH_3), 0.86 (s, 9H, $3CH_3$), 1.01 (s, 3H, CH_3), 1.05 (d, *J* = 6.5 Hz, 3H, $CHCH_3$), 1.11 (s, 3H, CH_3), 1.37, 1.56, and 1.73 (3m, $2CH_2$), 1.90 (d, *J* = 1.3 Hz, 3H, vinyl CH_3), 1.96 (m, 1H, $CHCH_3$), 2.03 (s, 3H, CH_3C=O), 3.84 (tt, *J* = 11.0, 5.0 Hz, 1H, CHOSi), 4.74 (dd, *J* = 7.1, 0.9 Hz, CH_2O), 5.79 (dd, *J* = 7.1, 7.1, 1.5 Hz, 1H, =CH); eims *m/z*: 348 (M^+ − 60); cims (isobutane) *m/z*: 409 (M^+ + 1), 349.

For personal use only.

The crude acetate was desilated by heating (80°C) with glacial acetic acid (30 mL) and water (10 mL) to give, after work-up and purification, the desired product **32** as a colorless oil (1.46 g, 73% overall yield); $[\alpha]_D$ +23.8° (*c* 0.4, CH_3OH); ir: 3610, 1735 cm^{-1}; ^1H nmr δ: 1.03 (s, 3H, CH_3), 1.06 (d, *J* = 6.5 Hz, 3H, $CHCH_3$), 1.12 (s, 3H, CH_3), 1.37 and 1.57 (2m, H-3_{ax} and CH_2 at C5), 1.70 (ddd, *J* = 12.7, 4.6, 2.3 Hz, 1H, H-3_{eq}), 1.91 (d, *J* = 1.3 Hz, vinyl CH_3), 2.00 (m, 1H, $CHCH_3$), 2.04 (s, 3H, $CH_3C{=}O$), 3.84 (m, 1H, $CHOH$), 4.77 (d, *J* = 7.3 Hz, CH_2O), 5.70 (ddd, *J* = 7.1, 7.1, 1.5 Hz, 1H, =CH); ^{13}C nmr δ: 16.43, 20.73, 20.95, 23.17, and 26.96 ($5CH_3$), 39.92 (C2), 35.86, 41.76, and 46.38 (CH and $2CH_2$), 62.89 and 66.10 (CHOH and CH_2O), 78.31 (COH), 85.43 and 95.17 (2 acetylenic C), 123.68 (=C), 129.96 (=CH), 171.04 (C=O); eims *m/z*: 294 (M^+, very weak), 234 (10), 148 (100).

(+)-4(Z)-(4R,5S)-4-Hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (6)

Compound **32** (1.44 g, 4.9 mmol) was oxidized with pyridinium dichromate (6.07 g, 16.1 mmol) in CH_2Cl_2 (30 mL) as previously described (see preparation of compound **3**). A keto-acetate was obtained as colorless needles (0.94 g, 70%), mp 118.0–120.0°C; $[\alpha]_D$ +20.5° (*c* 0.58, CH_3OH); ir, ^1H and ^{13}C nmr identical with those of the (−) enantiomer.

The keto-acetate (0.94 g, 3.2 mmol) was hydrolyzed by stirring with 5 M NaOH (1 mL) and methanol (25 mL) at room temperature for 1 h. After work-up and purification, the desired product (+)-4(*Z*)-(4*R*,5*S*)-4-hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (**6**) was obtained as colorless crystals (0.80 g, 100%), mp 96.5–98.0°C; $[\alpha]_D$ +22.3° (*c* 0.53, CH_3OH); ir, ^1H and ^{13}C nmr identical with those of the (−)-(4*S*,5*R*) enantiomer **3**.

8(Z)-(2R,3R,8R,9S)-8-(5-Hydroxy-3-methylpent-3-en-1-ynyl)-2,3,7,7,9-pentamethyl-1,4-dioxaspiro[4,5]decan-8-ol (19)

(+)-4(*Z*)-(4*R*,5*S*)-4-Hydroxy-4-(5-hydroxy-3-methylpent-3-en-1-ynyl)-3,3,5-trimethylcyclohexanone (**6**) (5.3 mg, 0.02 mmol) was treated with a mixture of (−)-(2*R*,3*R*)-butanediol (12 mg, 0.13 mmol), pyridinium *p*-tosylate (2 mg, 0.008 mmol), and benzene (4 mL) according to the procedure described above for the conversion of compound **3** to ketal **18**. After work-up and purification, ketal **19** was obtained as a colorless oil (2 mg, 30%), gc retention time (DB1701 column, 70–240°C at 10°C min^{-1}) 18.76 min; ^1H nmr δ: 1.05 (d, *J* = 6.6 Hz, 3H, $CHCH_3$ at C9), 1.10 and 1.12 (2s, 3H each, $2CH_3$), 1.19 and 1.21 (2d, *J* = 5.7 Hz, 6H, $CHCH_3$ at C2 and C3), 1.54–1.71 and 1.83 (2m, H-6 and H-10), 1.86 (d, *J* = 1.2 Hz, 3H, vinyl CH_3), 2.22 (m, 1H, $CHCH_3$ at C9), 3.58 (m, 2H, $CHCH_3$ at C2 and C3), 4.30 (br s, 2H, CH_2OH), 5.84 (ddq, *J* = 6.7, 6.7, 1.5 Hz, 1H, =CH); ^{13}C nmr δ: 16.17, 16.88, 17.10, 21.27, 23.27, and 27.38 (6q, $6CH_3$), 34.98 (d, C9), 39.58 (s, C7), 43.97 and 47.90 (2t, C6 and C10), 61.31 (t, CH_2OH), 77.37 and 78.27 (2d, C2 and C3), 78.47 (s, C8), 85.48 and 94.09 (2s, 2 acetylenic C), 107.27 (s, C5), 120.47 (s, =C), 135.73 (d, =CH).

(+)-(9Z)-(9R,10S)-9-(5-Hydroxy-3-methylpent-3-en-1-ynyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (33)

Compound **6** was ketalized to give **33**; $[\alpha]_D$ +27.1° (*c* 0.90, CH_3OH), by the procedure described above for the preparation of the (−) enantiomer **20**.

(+)-9(1E,3Z)-(9S,10S)-9-(5-Hydroxy-3-methyl-1,3-pentadienyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (34)

Compound **34** was obtained by reducing compound **33** with Redal^R (see preparation of compound **21**) and was hydrolyzed to give compound **35** (see below) without purification.

(+)-4(1E,3Z)-(4S,5S)-4-Hydroxy-4-(5-hydroxy-3-methyl-1,3-pentadienyl)-3,3,5-trimethylcyclohexanone (35)

Compound **34** was hydrolyzed with 1 M HCl and acetone as previously described to give the desired product **35**; $[\alpha]_D$ +42.6° (*c* 1.03, CH_3OH).

(+)-4(1E,3Z)-(4S,5S)-4-Hydroxy-4-(5-oxo-3-methyl-1,3-pentadienyl)-3,3,5-trimethylcyclohexanone (36)

Aldehyde **36** was prepared by the oxidation of compound **35** with manganese oxide (see conversion of compound **22** to **23**), and was further oxidized to (+)-(4*S*,5*S*)-methyl dihydroabscisate (**37**) without purification.

(+)-(4S,5S)-Methyl dihydroabscisate (37)

Aldehyde **36** was reacted with MnO_2, NaCN, methanol, and glacial acetic acid according to the procedure previously described to give (+)-(4*S*,5*S*)-methyl dihydroabscisate (**37**) as colorless needles, mp 117.5–118.5°C; $[\alpha]_D$ +65.7° (*c* 0.9, CH_3OH); hplc (Chiracel OD column, 10% isopropanol + 90% hexane at 1.0 mL min^{-1}) retention time 8.7 min.

(+)-(4S,5S)-Dihydroabscisic acid

(+)-(4*S*,5*S*)-Methyl dihydroabscisate (**37**) was hydrolyzed with 2 M KOH and methanol to give (+)-(4*S*,5*S*)-dihydroabscisic acid (**4**) as colorless crystals, mp 173–180°C; $[\alpha]_D$ +63.5° (*c* 1.17, CH_3OH).

(−)-(10R)-3,3,8,8,10-Pentamethyl-1,5-dioxaspiro[5,5]undecan-9-one (38)

A mixture of (−)-(6*R*)-2,2,6-trimethyl-1,4-cyclohexandione (**9**) (924 mg, 6.0 mmol), 2,2-dimethyl-1,3-propanediol (791 mg, 7.6 mmol), pyridinium *p*-tosylate (34 mg, 0.13 mmol), and benzene (15 mL) was heated to reflux under a Dean–Stark water separator for 4 h. The reaction mixture was allowed to cool to room temperature before it was washed with H_2O, and dried over anhydrous Na_2SO_4. Evaporation of solvent gave a pale yellow oil (1.43 g) as the crude product, which was distilled using the Kugelrohr apparatus (80–100°C, 0.03 Torr) to give pure ketal **38** as a colorless oil (1.31 g, 91%); $[\alpha]_D$ +87.7° (*c* 1.10, CH_3OH); ir: 1710 cm^{-1}; ^1H nmr δ: 0.85 (s, 3H, CH_3), 0.91 (d, *J* = 6.6 Hz, 3H, $CHCH_3$), 0.97 (s, 6H, $2CH_3$), 1.16 (s, 3H, CH_3), 1.56 (dd, *J* = 13.5, 13.5 Hz, H-11_{ax}), 1.58 (d, *J* = 14.2 Hz, H-7_{ax}), 2.38 (ddd, *J* = 13.5, 5.3, 3.8 Hz, 1H, H-11_{eq}), 2.47 (dd, *J* = 14.2, 3.8 Hz, 1H, H-7_{eq}), 2.85 (m, 1H, $CHCH_3$), 3.41 and 3.48 (2dd, *J* = 11.4, 1.6 Hz, 2H, 2 equatorial H at C2 and C4), 3.53 and 3.61 (2d, *J* = 11.4 Hz, 2H, 2 axial H at C2 and C4); ms *m/z*: 240 (M^+, 0.58), 141 (27), 155 (98), 83 (27), 69 (100).

(−)-(9Z)-(9S,10R)-9-(5-Hydroxy-3-methylpent-3-en-1-ynyl)-3,3,8,8,10-pentamethyl-1,5-dioxaspiro[5,5]undecan-9-ol (20)

Ketal **38** (1.31 g, 5.5 mmol) was reacted with *Z*-3-methylpent-2-en-4-yn-1-ol (0.65 g, 6.7 mmol) and *n*-butyllithium (1.6 M in hexane, 8 mL, 12.8 mmol) in dry THF by the procedure described for the preparation of compounds **14** and **15** (see above). The crude product obtained (yellow oil, 2.6 g) was purified by flash column chromatography (75% ether + 25% hexane) followed by distillation using the Kugelrohr apparatus (about 250°C, 0.06 Torr) to give compound **20** as a colorless oil (1.40 g, 77%); $[\alpha]_D$ −30.0° (*c* 1.05, CH_3OH); ir and ^1H nmr identical to those reported above for compound **20**.

Hydrolysis of compound 20

To a solution of ketal **20** (200 mg, 0.6 mmol) in acetone (5 mL) was added 1 M HCl (2 drops). The mixture was stirred at room temperature for 1.5 h before saturated $NaHCO_3$ was added to neutralize the acid. Most of the solvent was then evaporated. The residue was dissolved in ether and washed with saturated NaCl. The ether layer was separated and dried over anhydrous Na_2SO_4. Evaporation of ether gave a colorless oil (145 mg), which was purified on the Chromatotron (2 mm silica gel plate, 75% ether + 25% hexane) to give compound **3** as colorless crystals (123 mg, 80%), mp 85–93°C. A small sample of the product was recrystallized from ether–hexane to give colorless plates, mp 92–98°C; $[\alpha]_D$ −25.0° (*c* 0.68, CH_3OH); ir, ^1H and ^{13}C nmr identical to those reported above for compound **3**.

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

BÉLANGER-GARIÉPY, FRANÇOIS BRISSE, PIERRE D. HARVEY, DENIS F. R. GILSON, and IAN S. BUTLER. Can. J. Chem. **68**, 1163 (1990).

The crystal structure of adamantanecarboxylic acid, tricyclo[3.3.1.1^{3,7}] decan-1-carboxylic acid $C_{10}H_{15}COOH$, has been determined by X-ray diffraction at two temperatures, 173 and 280 K. At both temperatures, the unit cells are triclinic, space group $P\bar{1}$, and each contains two molecules. At 173 K, a = 6.452(3), b = 6.681(2), c = 11.510(3) Å, α = 80.84(2)°, β = 87.22(3)°, γ = 74.11(3)°; V = 471.10 Å^3, D_x = 1.271 g cm^{-3}, μ(CuKα) = 6.46 cm^{-1}. The structure was solved by direct-methods. The least-squares refinement, based on 1347 observed reflections converged to R = 0.0485 and R_w = 0.0415. At 280 K, a = 6.503(2), b = 6.849(2), c = 11.620(4) Å, α = 77.11(2)°, β = 85.77(2)°, γ = 76.34(2)°; V = 490.11 Å^3, D_x = 1.221 g cm^{-3}, μ(CuKα) = 6.21 cm^{-1}, R = 0.0874, and R_w = 0.0512 for 828 observed reflections. The low-temperature form is ordered while at room temperature the molecule is disordered. In the structure of the high-temperature phase, the adamantyl group takes two distinct orientations, in a 60:40 proportion, at about 14° from one another. The carboxylic group also has two orientations differing by about 170°. The geometry of the adamantane skeleton is not affected by the presence of the carboxylic group. The molecules form centrosymmetric dimers through hydrogen bonds of the O—H---O type. The O---O distances range between 2.616(11) and 2.752(15) Å. The order-disorder transition is interpreted using the Guthrie–McCullough approach.

Key words: adamantanecarboxylic acid, order–disorder transition, crystal structure.

BÉLANGER-GARIÉPY, FRANÇOIS BRISSE, PIERRE D. HARVEY, DENIS F. R. GILSON, et IAN S. BUTLER. Can. J. Chem. **68**, 1163 (1990).

On a déterminé la structure cristalline de l'acide adamantanecarboxylique, l'acide tricyclo[3.3.1.1^{3,7}] décane-1-carboxylique, $C_{10}H_{15}COOH$, par diffraction des rayons-X à deux températures, soit 173 et 280 K. Aux deux températures, les mailles élémentaires appartiennent au groupe d'espace $P\bar{1}$ et chacune contient deux molécules. A 173 K, a = 6,452(3), b = 6,681(2), et c = 11,510(3) Å, α = 80,84(2), β = 87,22(3),et γ = 74,11(3)°; V = 471,10 Å^3, D_x = 1,271 g cm^{-3}, μ(CuKα) = 6,46 cm^{-1}. On a détermine la structure par méthodes directes et on l'a affinée par la méthode des moindres carrés jusqu'à des valeurs respectives de R = 0,0485 et R_w = 0,0415 pour 1347 réflexions observées. A 280 K, a = 6,503(2), b = 6,849(2) et c = 11,620(4) Å, α = 77,11(2), β = 85,77(2) et γ = 76,34(2)°, V = 490,11 Å^3, D_x = 1,221 g cm^{-3}, μ(CuKα) = 6,21 cm^{-1}, R = 0,0874 et R_w = 0,0512 pour 828 réflexions observées. La forme qui existe à basse température est ordonnée alors que, à la température ambiante, la molécule est désordonnée. Dans la structure de la molécule telle qu'elle existe à haute température, le groupe adamantyle adopte deux orientations distinctes, qui existent dans des proportions de 60:40 et qui diffèrent par 14°. Le groupe carboxylique a aussi deux orientations différentes, à 170° l'une de l'autre. La géométrie du squelette adamantane n'est pas affectée par la présence du groupement carboxylique. Les molécules forment des dimères centrosymétriques par le biais de ponts hydrogènes du type O—H---O. Les distances O---O varient de 2,616(11) à 2,752(15) Å. On interprète la transition ordre–désordre en fonction de l'approche de Guthrie–McCullough.

Mots clés : acide adamantanecarboxylique, transition ordre–désordre, structure cristalline.

[Traduit par la revue]

Introduction

The cage hydrocarbon adamantane is a well-known example of a solid that undergoes an order–disorder transition (1), occurring in this case at 208 K (2). Substitution does not necessarily prevent the occurrence of such transitions, even when a strongly interacting group, such as a hydrogen bonding substituent, is present (3–7). In 1-hydroxyadamantane, the transition temperature is 353 K (6). In the 2-hydroxy-compound, there are two phase transitions, at 318 and 382 K, respectively (7). Thus, both compounds have their transitions moved to much higher temperatures. In *dl*-camphor the melting temperature is 451 K, and there are transitions at 204 and 350 K, with the major disordering occurring at the lower temperature (8). If the keto-group is reduced to the alcohol, to give *dl*-borneol, the major transition shifts to 346 K and the melting point to 487 K (9). Based on these, and other cases, it is apparent that the principal effect of the hydroxyl substituent is to raise the transition and melting temperatures, but not to prevent the occurrence of a disordered high-temperature phase.

In contrast, the transition in 1-adamantanamyne hydrochloride (10) occurs at 124 K, with an entropy change of 2.51 J K^{-1} mol^{-1}, and in the 1-carboxylic acid derivative (11) at 251 K with an entropy change of 8.96 J K^{-1} mol^{-1}. In both of these compounds, the entropy changes are too small for complete order–disorder transitions. In the case of the amine hydrochloride salt, the crystal structure determination of the high temperature phase confirmed the presence of an ordered phase (12).

The carboxylic acid compound seemed to be an excellent candidate for the determination of the crystal structures both above and below the phase transition temperature. The IR and Raman spectra showed only small changes at the phase transition (11) and the absence of large factor group splittings indicated that the site symmetry must be similar in the two phases, which is consistent with the relatively low transition

entropy. The lack of coincidence between vibrational frequencies in the IR and Raman spectra suggested that a centrosymmetric structure occurs. This was supported by the local frequencies of the carboxylic acid group, which showed that dimers exist. In this paper, the X-ray structures of 1-adamantyl carboxylic acid at 173 and 280 K are presented.

Experimental

The low temperature form

The crystal selected for X-ray structure analysis was a platelet bounded by {001}, {101}, {010} whose dimensions were 0.02 × 0.15 × 0.36 mm. The unit cell dimensions were obtained from 25 well-centered reflections in the range $40° \leq 2\theta \leq 60°$. The X-ray data were measured on a Nonius CAD-4 diffractometer using graphite-monochromatized CuKα radiation, λ(CuKα) = 1.54178 Å, and equipped with a modified Nonius low-temperature attachment. The intensities were collected by the ω–2θ scan technique with a scan width defined by $\Delta\omega = (1.00 + 0.14 \tan\theta)°$, within the sphere of reflection limited by $2\theta_{max} = 140.0°$ and $-7 \leq h \leq 7$, $-7 \leq k \leq 8$, $-14 \leq l \leq 14$. The orientation of the crystal was monitored every 100 measurements while the intensities were checked every hour using seven standard reflections. The largest intensity fluctuation during the measurement of 3515 reflections was 1.9%. After averaging of the equivalent reflections (R of averaging 0.045), 1347 reflections, $I \geq 1.96\sigma(I)$, were retained for structure determination and refinement. No absorption correction was applied as the absorption coefficient for the copper radiation is small.

The structure was solved by direct-methods (MULTAN 80).[2] A full-matrix weighted least-squares refinement was conducted, based on F's using isotropic then anisotropic temperature factors for all non-hydrogen atoms. All the H-atoms were found on a difference Fourier synthesis. They were included in the refinement with isotropic temperature factors. The function minimized was $\Sigma w(|F_o| - |F_c|)^2$. Convergence of the refinement was attained when $R = 0.0485$, $R_w = 0.0415$, and $S = 2.092$ for 183 refined parameters.[3] The weights were derived from the counting statistics, $w = 1/\sigma^2(F)$. The maximum and the average values of (Δ/σ) were 0.004 and 0.000, respectively. The residual electron density fluctuations on final difference Fourier synthesis were +0.25 and −0.23 e Å^{-3}.

The room temperature form

Another crystal was used for the room temperature data collection. The dimensions of the crystal were 0.03 × 0.08 × 0.18 mm. The unit cell dimensions were obtained from 25 well-centred reflections in the range $40° \leq 2\theta \leq 60°$. The intensity data were collected in the same conditions as for the low-temperature form up to $2\theta_{max} = 140.0°$. In this case, the intensities of the reference reflections decreased by about 20% over the duration of the data collection. This was attributed to the slow sublimation of the compound at this temperature. After averaging of the equivalent reflections of the 3616 measured reflections, only 831 with $I \geq 1.96\sigma(I)$ were considered observed (66%).

The stucture was solved by direct-methods using SHELX. At first, atoms O(1), O(2), C(0), C(1) of the carboxylic group were clearly visible while another six peaks, attached to C(1), suggested that the adamantyl ring system could be disordered over two or more sites. A succession of structure factor calculations and difference Fourier syntheses revealed most of the other non-hydrogen atoms. Then, in another difference Fourier synthesis, it was recognized that the carboxylic group was also disordered. Thus, it was concluded that the adamantanecarboxylic acid at 280 K was disordered in two orientations with only C(I) being common to both individuals. Assuming equally populated orientations, set **A** and set **B**, the space group could then be $P1$ rather than $P\bar{1}$. Solution of the structure in the $P1$ space group (without averaging the reflections) did not bring about any improvement. Thus, the $P1$ space group was retained. All atoms were refined isotropically with C—C distances constrained to 1.54 Å and occupancy factors of 0.50. At convergence, the thermal parameters associated with molecule **A** were found to by systematically lower than those for molecule **B**. Therefore, a few more refinement cycles were performed with fixed B values, this time adjusting the occupancy factors. This refinement indicated that the occupancy factor for molecule **A** was 0.60 and 0.40 for molecule **B**. Accordingly, fixed

[b] Atom C(1) is common to both molecules **2A** and **2B**.

[2] The programs used here are modified versions of NRC-2, data reduction, NRC-10, bond distances and angles and NRC-22, mean planes; MULTRAN80, multisolution program; SHELX, program for structure determination and ORTEP, stereodrawings (13–16).

[3] $R = \Sigma \| F_o| - |F_c| \| / \Sigma |F_o|$, $R_w = [\Sigma w(|F_o| - |F_c|)^2 / \Sigma w |F_o|^2]^{1/2}$. $S = [\Sigma w(|F_o| - |F_c|)^2/(m - n)]^{1/2}$.

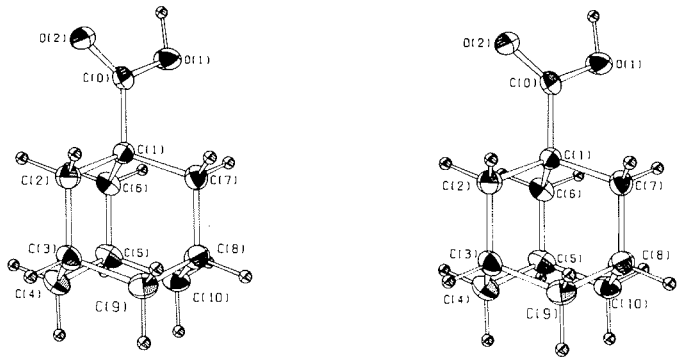

FIG. 1. Stereopair showing the structure of adamantanecarboxylic acid, the low temperature form, with atomic numbering. The ellipsoids correspond to 50% probability, except for hydrogens, which are shown as spheres of arbitrary size.

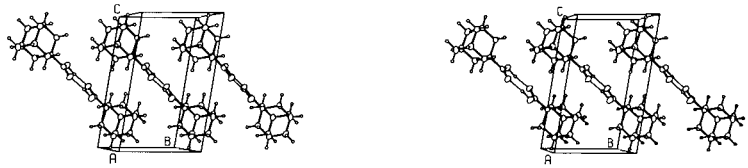

FIG. 2. Packing of the low temperature form of adamantanecarboxylic acid. Atoms are represented by spheres of arbitrary size. Hydrogens, except H(OH), are omitted for clarity.

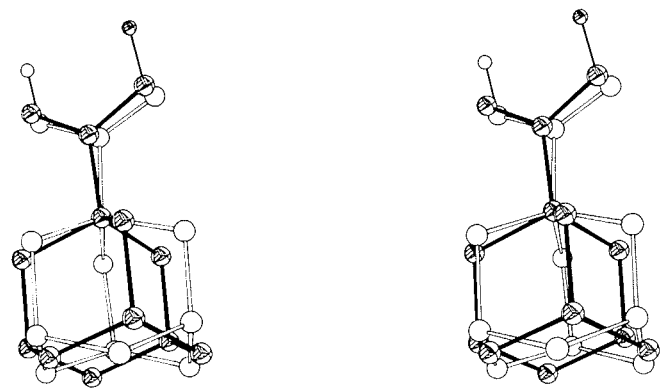

FIG. 3. Stereopair showing the two disordered molecules of adamantanecarboxylic acid in the high temperature phase. In order to differentiate the two molecules, the bonds of molecule **2B** (occupancy factor = 0.40) were blackened while their ellipsoids are not hatched. All the atoms are shown as spheres of arbitrary size.

normalized values of 0.60 and 0.40 were set for molecules **A** and **B** respectively. At this time, the constraints were removed and a full-matrix weighted least-squares refinement, based on F's was performed. All the H-atoms were fixed at idealized positions (C—H = 1.08 Å, isotropic U = 0.06 Å^2). At this stage, a difference Fourier synthesis showed peaks of 0.3 e Å^{-3} at reasonable positions for the hydrogen atoms of the carboxylic groups. The positions of these H-atoms and their isotropic temperature factors were refined. The function minimized was $\Sigma w(|F_c| - |F_o|)$.[2] In the last refinement cycles, three reflections (−1 0 1, 1 1 2, and 0 2 3) were given zero weight as they were clearly suffering from extinction. At convergence, the final agreement indices were R = 0.0874 and R_w = 0.0512 with weights derived from the counting statistics $w = 1/\sigma^2(F)$, while S = 2.068 for 235 refined parameters. The maximum and the average values of (Δ/σ) are 0.27 and 0.02, respectively. A final difference Fourier synthesis was essentially featureless, with general background between −0.24 to 0.26 e Å^{-3}.

The scattering curves for the nonhydrogen atoms were taken from Cromer and Mann (17) and those the H-atoms from Stewart, Davidson, and Simpson (18).

Results and discussion

The final atomic coordinates and the equivalent U_{eq} of the adamantanecarboxylic acid are presented in Table 1[4] for the low-temperature phase (molecule **1**), and in Table 2 for the high-temperature phase (molecules **2A** and **2B**). The atomic numbering adopted is given on the stereoview of the molecule **1** shown in Fig. 1. The packing of molecule **1** of the low-temperature phase is shown in Fig. 2. The molecular structure of the high-temperature phase (molecule **2**) is represented as stereopairs in Figs. 3 and 4. The bond distances, angles, and torsion angles of interest are compared in Table 3.

[4]Tables of atomic positions for hydrogen atoms, least-squares planes, anisotropic temperature factors and structure factor tables of the X-ray determinations of the low and the high tempertaure forms of the adamantanecarboxylic acid have been deposited and may be purchased from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K1A 0S2.

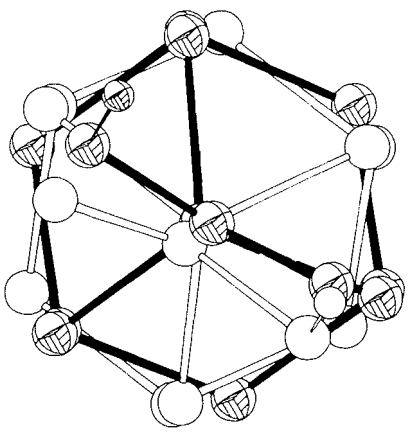

FIG. 4. View down the C(0)—C(1) bond of the room temperature form. The bonds of molecule **2B** are blackened.

The adamantane ring system

The C—C bonds of the low temperature phase of the adamantane ring system range from 1.527(4) to 1.548(3) Å, with a mean value of 1.534 Å, which is close to the expected value of 1.544 Å for C(sp^3)—C(sp^3) bond in diamond or 1.542 Å in adamantane-1,3,5,7-tetracarboxylic acid (21) whose structure is closely related to that of diamond. In the room-temperature phase, more distortions are observed. The C—C bonds in the adamantyl group **2A** or **2B** range from 1.453(16) to 1.602(16) Å, but the average value is 1.528 Å. The low-temperature distances are, on the average, nearly identical to those reported by Donohue and Goodman for adamantane itself (19), or in the theoretical calculations of Gleicher and Schleyer (20). In our structure at 173 K, the C—C—C bond angles range from 108.4(2) to 111.3(2)°, with a mean value of 109.5°, which is the expected tetrahedral angle. At 280 K, the C—C—C bond angles are not as well defined, since they take values in a larger range, from 103.1(9) to 116.0(11)°, but have a mean value of 109.5°. There are no significant differences in either the bond distances or angles when this molecule is compared to adamantane or its derivatives (19, 21).

The adamantane skeleton consists of four fused cyclohexane rings, the torsion angles for each of these rings are compared in Table 3. These angles suggest that each ring has a nearly perfect chair conformation. The overall mean torsion angles of 59.9° for molecule **1**, 59.2 and 59.8° respectively for molecule **2A** and **2B** is very close to the expected value of 60° for a perfectly staggered chair conformation with tetrahedral bond angles. All these values agree well with the corresponding quantities in some related compounds such as 1-adamantanol (24), or adamantanamine hydrochloride (12). The adamantane cage is quite rigid and its geometry is not affected by substitution and crystal packing forces.

The C(1)—C(0) bond with value of 1.511(3) Å for molecule **1** (at 173 K) agrees well with the value 1.523(1) Å reported for adamantane-1,3,5,7-tetracarboxylic acid (21) or the value of 1.522(17) Å in 2-aminoadamantane-2-carboxylic acid hydrobromide (22) and the values of 1.523(4) and 1.513(4) Å in bicyclo[2.2.2]octane-1,4-dicarboxylic acid (23). At 280 K, the two C(1)—C(0) distances with values of 1.540(12) and 1.480(14) Å show the effect of the disorder.

The bond distances and angles in the carboxylic group are normal when compared to the corresponding quantities in adamantane-1,3,5,7-tetracarboxylic acid (21) or in bicyclo[2.2.2]octane-1,4-dicarboxylic acid (23). The carboxylic group of atoms, [C(0),C(1),O(1),O(2)], is planar at low temperature and at room temperature.

The *syn*-planar arrangement Cβ—Cα—C = O is adopted for the carboxylic group. The torsion angle O(2)—C(0)—C(1)—C(2) has a value of −2.7(3)° for molecule **1**. This torsion angle is

TABLE 4. Distances (Å) and angles (deg) involving hydrogen bonds in adamantanecarboxylic acid at 173 and 280 K

	Distance			Angle
O—H---O	O—H	H---O	O---O	O—H—O
At 173 K, molecule **1**				
O(i)—H(O1)---O(2)[a]	1.00(3)	1.65(3)	2.642(2)	171(3)
At 280 K, molecule **2A**				
O(1)—H(O1)---O(2)[a]	1.05(2)	1.79(2)	2.616(11)	132(2)
Molecule **2B**				
O(1)—H(O1)---O(2)[a]	0.99(2)	1.79(2)	2.752(15)	165(2)

[a] $1-x, -1-y, 1-z$.

7.6(12)° and −12.9(15)°, respectively for molecule **2A** and molecule **2B**. This syn-planar conformation of the Cβ—Cα—C = O group is generally observed in saturated carboxylic acids (25). The deviation observed here from the *syn*-planar arrangement is small compared to that reported for adamantane-1,3,5,7-tetracarboxylic acid (21) where it takes the value of 17.0(2)° and the value of about 30° in the case of bicyclo[2.2.2] octane-1,4-dicarboxylic acid (23).

Molecular disorder

As mentioned in the Experimental section, at 280 K, the molecule of adamantancarboxylic acid is present in the crystal with two distinct orientations in a 60:40 ratio. The disorder observed can be described in terms of rotation of the adamantyl group and another rotation of the carboxylic group. No major change in site of factor group symmetry occurs when going from the high-temperature phase to the low-temperature phase. In the room temperature form, molecule **2B** is almost unchanged in position from the low temperature structure, and molecules **2A** and **2B** deviate from one another by a rotation around the pseudo-threefold axis by about 14°. Similarly, the carboxylic group of **2A** is at 168.4° of the corresponding group in **2B**. This situation may be more clearly appreciated in Fig. 4.

The adamantyl group has an almost threefold symmetry. It also has three non-crystallographic mirror planes, plane *1* [C(1),C(7),C(8),C(4)], plane *2* [C(1),C(6),C(5),C(9)], plane *3* [C(1),C(2),C(3),C(10)]. The dihedral angles between these planes is close to 120° for **1** and for **2A** and **2B**. Plane *3* is nearly coplanar with the carboxylic group in molecules **1**, **2A** and **2B**. The dihedral angle between the carboxylic group of atoms and plane *3* is only 3.2, 8.3, and 11.1° respectively for **1**, **2A**, and **2B**.

The structure is stabilized by strong hydrogen bonds. Apart from these hydrogen bonds, there are no other short contacts. The hydrogen bond distances and angles are compared in Table 4. The projection of the molecules **2A** and **2B** down C(1)—C(0) bond shows the C—O bond directions to be skewed with respect to the bonds covalently linked to C(1). The molecules are interconnected to form the cyclic hydrogen-bonded dimer which is the most commonly observed motif in the solid state (25). The middle of each hydrogen-bonded dimer lines on a crystallographic center of symmetry and this arrangement persists through the phase transition.

Interpretation of the entropy of transition in compounds of this type has often been based upon the Guthrie–McCullough equation, $S = R \ln (N_1/N_2)$, where N_1 and N_2 are the numbers of distinguishable positions in the two different phases (26). However, the entire entropy change should not be attributed to this configurational contribution, since the contribution due to any volume change is neglected. In the case of adamantyl carboxylic acid, the entropy change is, according to the Guthrie–McCullough approach, equivalent to $R \ln 3$. In adamantanamine hydrochloride, the entropy of transition is 2.51 J K^{-1} mol^{-1} (10). If we attribute the entropy of transition to the volume term and assume that the coefficients of thermal expansion and of compression are similar in adamantane carboxylic acid and in the amine salt, and that the molar volume changes at the transition are the same, then the configurational contribution to the entropy change in adamantyl carboxylic acid is reduced to 6.46 J K^{-1} mol^{-1}, or $R \ln 2.2$. This is in reasonable agreement with the observation reported here that there are two distinguishable molecules in the unit cell.

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

T. H. CHAN, K. R. GUERTIN, C. V. C. PRASAD, A. W. THOMAS, G. M. STRUNZ, and A. SALONIUS. Can. J. Chem. **68**, 1170 (1990).

Several compounds, each possessing a polyoxygenated decalin structure, were synthesized and tested for antifeedant activities against the spruce budworm, *Choristoneura fumiferana*. Definite biological activity was observed for some of these compounds. A structure–activity relationship was discussed on the basis of these results.

Key words: decalin, synthesis, antifeedant, spruce budworm.

T. H. CHAN, K. R. GUERTIN, C. V. C. PRASAD, A. W. THOMAS, G. M. STRUNZ et A. SALONIUS. Can. J. Chem. **68**, 1170 (1990).

On a synthétisé plusieurs composés, possédant chacun une structure décalinique polyoxygénée, et on a vérifié leur activité contre la tordeuse des bourgeons de l'épinette, *Choristoneura fumiferana*. Quelques-uns de ces composés présentent une activité biologique non ambiguë. Sur la base de ces résultats, on discute d'une relation structure–activité.

Mots clés : décaline, synthèse, tordeuse des bourgeons de l'épinette.

Introduction

The spruce budworm, *Choristoneura fumiferana*, is an insect pest that inflicts huge damage to the forest resource in eastern North America. In eastern Canada, the larvae of the budworm begin to feed on the buds or the newly opened shoots of the host tree in mid-May, and consume the greatest amount of foliage during their sixth instar in late June. A strategy that has been considered for pest control is to employ antifeedants to interfere with the feeding behaviour of insects. The approach may offer advantages over conventional methods of pest control since antifeedant could protect current year foliage while leading indirectly to budworm mortality without being generally toxic (2).

In screening programs, a number of natural products have been found to have antifeedant activity, e.g., azadirachtin (**1**) (3), clerodin (**2**) (4), and Nic-1 (**3**) (5). For the spruce budworm (6), an active compound, specionin (**4**), has been isolated from the leaves of *Catalpa speciosa* Warder (Bignoniaceae) (7). The chemical synthesis of specionin has recently been reported (8).

Because of the complexity of the structures of the known antifeedants (**1–4**), chemical synthesis of any of these compounds is considered a major challenge and not likely to be used in any large-scale application. A more practical approach is to prepare simpler analogs of these compounds. However, there has been relatively little study of structure–activity relationship with respect to antifeedant activity (9). There is therefore no guiding principle for the design of these simpler analogs.

Although their carbon skeletons or presumed biogenetic origin may differ widely, most insect antifeedants discovered so far share a common feature, namely, they are polyoxygenated molecules. Synthetic compounds **5**, **6**, and **7**, which have partial structures in common with azadirachtin (10) and clerodin (11), were found to exhibit antifeedant activities. In the case of the spruce budworm, we previously found that the iridoid derivative **8** has moderate but definite antifeeding activity (1).

In this paper, we report on the synthesis of a number of oxygenated decalins and examine them as potential antifeedants against spruce budworm. These compounds, though only remotely resembling clerodin (**2**), azadirachtin (**1**), and Nic-1 (**3**) in structure, provide a rigid framework to explore the structure–activity relationship.

Chemical synthesis

Recently, we described a new annelation reaction based on tandem Michael–Claisen condensation of the siloxydiene **9** with α,β-unsaturated ketones (12). The reaction has been used to construct the 9-methyldecalin and the hydrindan (13) systems, and in the syntheses of some sesquiterpenes (14). Since both clerodin (**2**) and azadirachtin (**1**) as well as many terpenoid natural products are disubstituted at the C-4 (steroid numbering) position, we decided to examine the use of the annelation reaction for the synthesis of polyoxygenated decalin compounds with similar dimethyl substituents.

Reaction of the siloxydiene **9** with the enone **10** promoted by titanium tetrachloride provided the Michael adduct as a mixture of *E* and *Z* isomers, **11***a* and **11***b* (*E*/*Z* = 4.0:1) respectively. Claisen cyclization of the major adduct **11***a* could be achieved under basic conditions by treatment with potassium *tert*-butoxide to give the decalone **12** in good yield. Alternatively, the *E*/*Z* mixture of **11** could be cyclized to the decalone **12** by treatment with lithium thiophenoxide as previously reported (12) (Scheme 1).

Methylation of **12** with K_2CO_3/CH_3I in acetonitrile gave a mixture of *C*- and *O*-methylated products, **13**, **14**, and **15**, in 35, 28, and 28% yields respectively. The *O*-methyl compound **15** could readily be distinguished from the two isomeric *C*-methyl compounds, **13** and **14**, on the basis of their spectroscopic data.

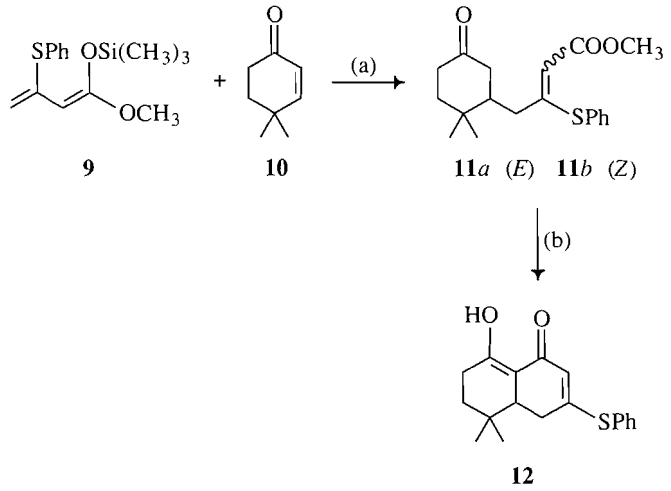
The assignment of the *trans* stereochemistry to compound **14** is based on chemical correlation according to Scheme 2. Compound **14** was thioketalized to **16** with ethanedithiol. Replacement of the thiophenyl group in **16** by a methoxy group was accomplished by reflux in sodium methoxide/methanol to give **17**. Raney nickel reduction of **17** gave the known compound **18** with *trans* ring junction stereochemistry (15). Reduction of **18** with lithium aluminum hydride followed by acid hydrolysis gave the known compound **19** as reported (15).



(a) $TiCl_4$, CH_2Cl_2, -78°C, 2.5 h, 57%; (b) KOt-Bu, THF, room temp., 1 h, 70%

SCHEME 1

With the stereochemistry of **14** thus firmly established, compound **13** must then have the *cis* ring junction stereochemistry.

The preferred formation of the *cis* compound **13** over the *trans* isomer **14** in the methylation of **12** under basic conditions is somewhat unexpected. We previously found that in the methylation of the parent decalone **20** with methyl iodide, using either KO-*t*-Bu or Bu_4NOH as the base, the *trans* isomer **21** was formed preferentially over the *cis* isomer **22** in a ratio of 9:4 (12). We therefore examined the methylation of the decalone **12** in greater detail under a variety of conditions. The selectivity as well as the yields of each reaction are given in Table 1. In all cases, the *cis* isomer **13** was formed preferentially, with stereoselectivity ranging from a low of 1.1:1 to a high of 7:1. The selectivity may be attributed to the steric hindrance of the C-4 axial methyl group in anion **23** to the approaching electrophile in forming **14**. When the counterion M^+ is larger (Cs^+, K^+, or Bu_4N^+) and less coordinating to the anion, or the solvent more polar (CH_3CN), relatively more of the *trans* compound **14** is formed because, in the transition state, the

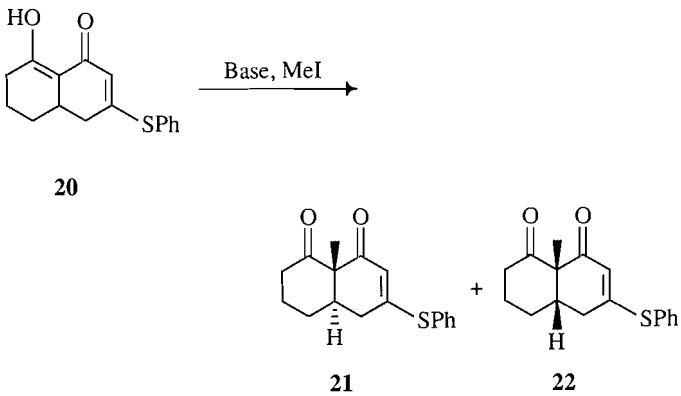
SCHEME 2

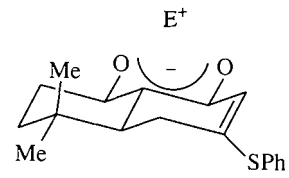
electrophile is farther away and is less subject to steric effect. Also, the degree of *O*-methylation seems to be significant when the M^+ is larger and less coordinating than Li^+.

The *O*-methyl isomer **15** can of course be recycled back to the starting decalone **12** by hydrolysis of the enol ether. Alternatively, it was deprotonated by lithium hexamethyldisilazide (LHMDS) to the anion **24**. Methylation of **24** with methyl iodide gave the *O*,*C*-dimethyl compound **25**, which was not isolated but hydrolysed to give a mixture of **13** and **14** in a ratio of 4:1. This two-step route therefore also offers an efficient way to prepare **13** selectively. This sequence of annelation–alkylation may well be useful for the synthesis of drimanic sesquiterpenes, especially for compounds such as sicannin (**26**) (16) where the stereochemistry of the ring junction is *cis*.

Reduction of **13** with $NaBH_4/CH_3OH$ or $LiAlH(O\text{-}t\text{-}Bu)_3$/THF gave the alcohol **27** stereoselectively in quantitative yield (Scheme 4). The stereochemistry of the hydroxy group in **27** was assigned on the basis of ^1H nmr. The methine hydrogen at 3.15 ppm showed both large (11 Hz) and small (5 Hz) coupling constants expected of an axial hydrogen. Protection of the hydroxy group of **27** was achieved with *tert*-butyldimethylsilyl triflate/2,6-lutidine to give the TBDMS ether **28**. Refluxing in sodium methoxide/methanol converted **28** to the methoxy compound **29**. Similar conditions converted **27** to the corresponding alcohol **30**, albeit in poor yield.

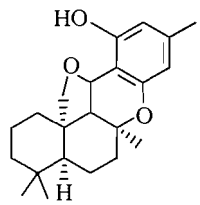
On the other hand, reduction of the *trans* isomer **14** with





23

$NaBH_4$ (Scheme 5) led to the diol **31***a* and the epimeric alcohol **31***b* (as a mixture of stereoisomers). The relative proportion of the two compounds obviously depended on the amount of reducing agent used. The assignment of stereochemistry of the two hydroxy groups in **31***a* is based on ^1H nmr as well as on the presumed axial attack of the hydride from the less hindered side. Acetylation of **31***a* with acetic anhydride/pyridine gave the diacetate **32** as the major product.



Sicannin **26**

Biological assay

Two sets of biological assays were conducted on ten of the synthetic compounds as well as on three simple commercially available ketoesters (**33**, **34**, **35**) for comparison purposes. Each bioassay involved feeding laboratory-colony spruce budworm larvae on artificial diet (17) containing 0.2% (wet weight) of the test compounds. In the assay, newly emerged 2nd-instar larvae were reared individually at 26°C, 17 h photoperiod, 50 replicates per test compound. At the point at which approximately 50% of the controls had reached the final (6th) instar, the larvae were sacrificed and their development stage determined. The mean development stage (instar) of larvae on each treatment diet was determined (mean instar in Tables 2 and 3) as well as the proportion of 6th instars. Because the data

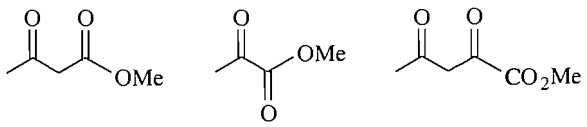
SCHEME 5

are clearly nonparametric, the rank transformation approach (18) was used for the purposes of statistical analysis. In each set of biological assays, all the observations (i.e., the instar of each of the 350 larvae in set 1, 400 in set 2) were ranked from the largest to the smallest, with average ranks assigned in cases of ties. The compounds were then listed in descending order according to their mean rank values (Tables 2 and 3). A one-way analysis of variance applied to the rank values allowed us to test nonparametrically for intercompound differences (19, 20). Significant differences were detected between the compounds in the first set of biological assays (Table 2) and a Tukey-type multiple comparison test, using rank sums instead of means, was performed to locate the differences (19, 20). Compounds followed by the same letter were not significantly different ($P > 0.05$) in their effect on the development rate of budworm larvae. No significant difference was found between the compounds in the second set of biological assays (Table 3).

The biological assay showed that the development of larvae



33 34 35

reared from second instar on test diets was significantly retarded by compounds **14**, **21**, **28**, and **13**, but not by the other compounds. The levels of activity of these compounds are comparable to that of compound **8** reported previously (1).

Several conclusions can be drawn from the structure–activity relationship observed so far. The absence of activity in the acyclic compounds (**33**, **34**, **35**) and the monocyclic compound **11** suggests that the two oxygen functions have to be fixed in their relative positions. The nature of the oxygen function is of critical importance, with the hydroxy group generally giving the inactive compounds. Comparing compounds **28** and **29**, electronic effect on the carbonyl group may be a factor in influencing activity. On the other hand, comparing compounds **14** and **21**, the *gem*-dimethyl group appears to have little influence at all.

Conclusion

The observation of definite biological activity in this series of easily accessible synthetic compounds gives hope that much more active compounds can be designed. On the basis of the structure of azadirachtin and clerodin, our next step in this structure–activity study will be to replace the angular methyl group in **21** by an oxygenated methyl group.[3]

Experimental

Melting points were determined on a Gallenkamp block and are uncorrected. The ^{1}H nmr spectra were taken on Varian XL-300 and XL-200 instruments and the data are reported in ppm relative to the $CHCl_3$ reference line with the multiplicity, coupling constants, and number of protons given in parentheses. The ir spectra were recorded on an Analect AQS-18 FT-IR instrument. Electron impact (EI) mass spectra were recorded at 70 eV on either a Dupont 21-492B or Kratos MS25RFA instrument and are reported as *m/z* (relative intensity %). Ammonia chemical ionization (CI) mass spectra were recorded on a Hewlett–Packard 5980A instrument. Column chromatography was performed on Merck silica gel 60 (230–400 mesh). All glassware was predried in an oven at approximately 200°C before using.

*Methyl 3-phenylthio-4-(3'-oxo-6',6'-dimethylcyclohexyl)-but-2-enoate (**11**a, **11**b)*

To a stirred solution of 4,4-dimethyl-2-cyclohexen-1-one (0.50 g; 0.53 mL; 4.02 mmol) and the siloxydiene **9** (1.80 g; 6.43 mmol; 1.6 equiv.) in dry methylene chloride (20 mL) under argon at −78°C was added titanium tetrachloride (0.49 mL; 4.42 mmol; 1.1 equiv.) dropwise. After 2 h 15 min the mixture was allowed to warm to room temperature, then poured into aqueous sodium bicarbonate and extracted twice with 20-mL portions of methylene chloride. The combined extracts were dried (Na_2SO_4) and concentrated to give 1.84 g of yellow semisolid residue. Flash chromatography on silica gel (eluent: 25% ethyl acetate/hexane) provided the *E* (mp 146–148°C) and *Z* (mp 134–136°C) isomers of **11** in a ratio of 4:1 in 57% yield.

The *E* isomer **11***a* had ir ($CHCl_3$, cm^{-1}): 3013, 2965, 1709, 1697, 1599, 1341, 1176; ^{1}H nmr ($CDCl_3$, ppm): 7.42–7.58 (m, 5H), 5.28 (s, 1H), 3.58 (s, 3H), 3.42–1.48 (m, 9H), 1.12 (s, 3H), 1.08 (s, 3H); ms: 332 ($M^{+\cdot}$, 39), 301 (16), 219 (26), 176 (29), 134 (29), 55 (100). Exact mass calcd. for $C_{19}H_{24}O_3S$: 332.145; found: 332.148.

The *Z* isomer **11***b* had ir ($CHCl_3$, cm^{-1}): 3013, 2965, 1707, 1581, 1436, 1177; ^{1}H nmr ($CDCl_3$, ppm): 7.67–7.10 (m, 5H), 5.82 (s, 1H), 3.77 (s, 3H), 2.87–1.23 (m, 9H), 0.73 (s, 3H), 0.40 (s, 3H); ms: 332 ($M^{+\cdot}$, 56), 300 (16), 258 (39), 223 (41), 205 (60), 149 (49), 110 (60), 28 (100). Exact mass calcd. for $C_{19}H_{24}O_3S$: 332.145; found: 332.141.

*3-Phenylthio-5,6,4a,8a-tetrahydro-5,5-dimethyl-(4*H,7H*)napthalen-1,8-dione (**12**)*

To a stirred solution of the *E* adduct **11***a* (3.99 g; 12.0 mmol) in dry THF (60 mL) under argon at 0°C was added potassium *tert*-butoxide (2.05 g; 18.3 mmol; 1.5 equiv.). The mixture was then allowed to warm to room temperature. After 1 h, the solvent was removed *in vacuo* and the residue taken into methylene chloride (50 mL) and washed with 10 mL of saturated NH_4Cl solution. The extract was dried (Na_2SO_4) and concentrated to give a crude yellow crystalline material. Flash chromatography on silica gel (eluent: 20% ethyl acetate/hexane) provided the dione **12** in 70% yield as a bright canary-yellow-colored solid, mp 124–126°C. **12** had ir ($CHCl_3$, cm^{-1}): 2934, 1617, 1594, 1558, 1270, 1249; ^{1}H nmr ($CDCl_3$, ppm): 7.50–7.40 (m, 5H), 5.41 (s, 1H), 2.73–2.13 (m, 5H), 1.65–1.47 (m, 2H), 1.04 (s, 3H), 0.88 (s, 3H), 15.15 (s, 1H); ms: 300 ($M^{+\cdot}$, 78), 298 (100), 283 (37), 255 (35), 244 (60), 191 (50), 135 (96), 110 (52). Exact mass calcd. for $C_{18}H_{20}O_2S$: 300.118; found: 300.121.

*Representative methylation of the decalone (**12**)*

To a stirred solution of the dione **12** (100 mg; 0.33 mmol) and dried potassium carbonate (69 mg; 0.50 mmol; 1.5 equiv.) in dry acetonitrile (5.0 mL) under argon at room temperature was added methyl iodide (0.21 mL; 3.33 mmol; 10.0 equiv.). The reaction flask was then fitted with a condenser and warmed to reflux. After 26 h at this temperature, the mixture was allowed to cool down to room temperature. The solvent was removed *in vacuo* and the residue taken into 20 mL of methylene chloride and washed with 10 mL of water. The aqueous phase was further extracted with 10 mL of methylene chloride. The combined organic phases were dried (Na_2SO_4) and concentrated to give a crude yellow residue. Flash chromatography on silica gel (eluent: 30% ethyl acetate/hexane) provided the *cis* compound **13** (mp 116–117°C) and the *trans* compound **14** (mp 132–134°C) in a ratio of 1.2:1 in 63% yield. Further elution of the column with 80% ethyl acetate/hexane afforded the *O*-methyl product **15** in 28% yield.

cis-**13** had ir ($CHCl_3$, cm^{-1}): 2966, 1717, 1646, 1591, 1230, 1097; ^{1}H nmr ($CDCl_3$, ppm): 7.44–7.56 (m, 5H), 5.44 (d, J = 2.2 Hz, 1H), 2.89 (ddd, J = 2.2, 6.3, 19 Hz, 1H), 2.57 (d, J = 19 Hz, 1H), 2.29 (dt, J = 3.5, 14 Hz, 1H), 2.06 (d, J = 6.3 Hz, 1H), 2.50–2.70 (m, 1H), 1.52–1.83 (m, 2H), 1.36 (s, 3H), 1.02 (s, 6H); ms: 314 ($M^{+\cdot}$, 9), 217 (17), 176 (63), 148 (39), 110 (32), 85 (24), 77 (56), 67 (100). Exact mass calcd. for $C_{19}H_{22}O_2S$: 314.134; found: 314.135.

trans-**14** had ir (B)r, cm^{-1}): 2950, 1718, 1648, 1590, 1250; ^{1}H nmr ($CDCl_3$, ppm): 7.40–7.55 (m, 5H), 5.35 (d, J = 1.8 Hz, 1H), 2.70 (ddd, J = 1.8, 12.2, 17.7 Hz, 1H), 2.40–2.63 (m, 4H), 1.58–1.90 (m, 2H), 1.41 (s, 3H), 1.11 (s, 3H), 1.09 (s, 3H); ms: 314 ($M^{+\cdot}$, 8), 258 (3), 217 (7), 200 (9), 176 (78), 148 (70), 110 (41), 85 (47), 77 (70), 67 (100), 39 (68).

15 had ^{1}H nmr ($CDCl_3$, ppm): 7.34–7.58 (m, 5H), 5.44 (d, J = 1.6 Hz, 1H), 3.73 (s, 3H), 2.12–2.65 (m, 5H), 1.58 (s, 3H), 1.22–1.56 (m, 2H), 0.88 (s, 3H).

trans-*6'-Phenylthio-3',4',4a',8a'-tetrahydro-4',4',8a'-trimethyl-spiro[1,3-dithiolane-2,1'(2'*H*)-naphthalen]-8'(5'*H*)-one (**16**)*

To a stirred solution of the dione **14** (1.26 g; 4.0 mmol) in 70 mL of benzene was added a catalytic amount of *p*-toluenesulfonic acid and 1,2-ethanedithiol (1.0 mL; 12.0 mmol). The mixture was then refluxed (Dean–Stark) and the reaction followed by tlc (eluent: 20% ethyl acetate/hexane). At the end of the reaction the mixture was diluted with 50 mL of ether and washed with 10% sodium bicarbonate solution. The solvent was evaporated *in vacuo* and the compound purified by column chromatography (eluent: 20% ethyl acetate/hexane) to give **16** in almost quantitative yield. **16** had ^{1}H nmr ($CDCl_3$, ppm): 7.43 (s, 5H), 5.32 (s, 1H), 3.00–3.80 (m, 4H), 1.43–2.73 (m, 7H), 1.38 (s, 3H), 0.93 (s, 6H); ms: 390 (6), 331 (28), 298 (40), 283 (20), 255 (18), 244 (24), 229 (29), 191 (25), 176 (29), 155 (19), 135 (46),

131 (46), 118 (33), 110 (57), 107 (33), 77 (28), 55 (39), 41 (45), 28 (100). Exact mass calcd. for $C_{21}H_{26}OS_3$: 390.115; found: 390.111.

trans-*6'-Methoxy-3',4',4a',8a'-tetrahydro-4',4',8a'-trimethyl-spiro-[1,3-dithiolane-2,1'(2'H)-naphthalen]-8'(5'H)-one (17)*

To a well-stirred solution of **16** (0.78 g; 2.0 mmol) in dry methanol (40 mL) under nitrogen was added sodium methoxide (0.55 g; 10.0 mmol) and the mixture refluxed for 24 h. The solvent was removed *in vacuo* and the residue extracted with 100 mL of ether. The ether layer was washed with 10 mL of water and then dried (Na_2SO_4). The solvent was removed *in vacuo* and the crude product purified by column chromatography (eluent: 30% ethyl acetate/hexane) to give **17** in 60% yield. The starting compound **16** was also recovered in 30% yield. **17** had ^{1}H nmr ($CDCl_3$, ppm): 5.13 (s, 1H), 3.30 (s, 3H), 3.10–3.80 (m, 4H), 1.50–2.53 (m, 7H), 1.20 (s, 3H), 0.98 (s, 3H), 0.95 (s, 3H); ms: 312 (44), 253 (53), 155 (68), 139 (42), 131 (100), 122 (20), 118 (47), 98 (38), 69 (48), 55 (45). Exact mass calcd. for $C_{16}H_{24}O_2S_2$: 312.122; found: 312.125.

trans-*3-Methoxy-5,6,4a,8a,7,8-hexahydro-5,5,8a-trimethyl-(4H)-naphthalen-1-one (18)*

To a stirred solution of **17** (0.62 g; 2.0 mmol) in 50 mL of ethanol was added 3.0 g of Raney nickel and the mixture was stirred for 6 h. At this point the reaction mixture was refluxed for another 6 h, the catalyst removed by filtration, and the solvent removed *in vacuo*. The crude product was purified by column chromatography (eluent: 20% ethyl acetate/hexane). The product was then crystallized from hexane to give **18**, mp 55–57°C, in 85% yield. The spectral properties of **18** are identical in all respects to the reported values (15). **18** had ^{1}H nmr ($CDCl_3$, ppm): 5.18 (s, 1H), 3.78 (s, 3H), 1.18–2.55 (m, 9H), 1.08 (s, 3H), 0.98 (s, 3H), 0.93 (s, 3H); ms: 222 (37), 207 (23), 151 (17), 139 (32), 109 (24), 98 (100), 68 (35), 41 (26), 28 (47). Exact mass calcd. for $C_{14}H_{22}O_2$: 222.162; found: 222.160.

trans-*5,6,4a,8a,7,8-Hexahydro-5,5,8a-trimethyl-(4H)naphthalen-3-one (19)*

To a stirred solution of **18** (111 mg; 0.5 mmol) in 40 mL of dry ether under nitrogen was added lithium aluminum hydride (19 mg; 2.0 mmol). After 30 min, once again LAH (19 mg; 2.0 mmol) was added and the solution refluxed for 1 h. Then, the excess LAH was destroyed by adding 2.0 mL of ethyl acetate. The mixture was diluted with 50 mL of ether, washed with 10% aqueous HCl, and then dried (Na_2SO_4). The solvent was removed *in vacuo* and the crude product treated with 20% HCl/methanol and stirred for 6 h. The solvent was removed again and the crude product extracted with ether. The ether extracts were washed with 10 mL of saturated sodium chloride solution and then dried (Na_2SO_4). The crude product was chromatographed (eluent: 15% ethyl acetate/hexane) to give **19** in 74% yield. The spectral properties were identical in all respects to the reported values (15). **19** had ^{1}H nmr ($CDCl_3$, ppm): 6.65 (d, J = 10 Hz, 1H), 5.67 (d, J = 10 Hz, 1H), 1.10–2.60 (m, 9H), 1.10 (s, 3H), 0.92 (s, 3H), 0.88 (s, 3H); ms: 192 (49), 177 (22), 151 (29), 150 (87), 135 (55), 121 (44), 109 (52), 79 (30), 69 (97), 55 (47), 41 (52), 28 (100). Exact mass calcd. for $C_{13}H_{20}O$: 192.151; found: 192.150.

cis-*3-Phenylthio-5,6,4a,8a,7,8-hexahydro-5,5,8a-trimethyl-(4H,7H)-naphthalen-1-one (27)*

To a stirring solution of the dione **13** (0.51 g; 1.62 mmol) in dry methanol (25 mL) under argon at 0°C was added sodium borohydride (0.080 g; 2.10 mmol; 1.3 mol equiv.). The mixture was then stirred for 6 h at which time water (2.0 mL) was added and the mixture allowed to warm to room temperature. The solvent was then removed *in vacuo* and the residue taken into 30 mL of methylene chloride and washed with 10 mL of water. The extract was dried ($MgSO_4$) and concentrated *in vacuo* to give **27** as a white solid in 100% yield. This material appeared to be quite pure by tlc (one spot) and ^{1}H nmr. The product could be further purified by recrystallization from absolute ethanol as white needles, mp 180–182°C. **27** had ir ($CHCl_3$, cm^{-1}): 3460, 3005, 2961, 1629, 1593, 1139, 1026; ^{1}H nmr ($CDCl_3$, ppm): 7.42–7.53 (m, 5H), 5.35 (d, J = 2.8 Hz, 1H), 4.81 (d, J = 10.6 Hz, exch. D_2O, 1H), 3.16 (ddd, J = 11.6, 10.6, 4.6 Hz, 1H), 2.92 (ddd, J = 19.1, 4.6, 2.8 Hz, 1H), 2.50 (dd, J = 19.1, 1 Hz, 1H), 1.21–1.89 (m, 5H), 1.47 (s, 3H), 0.96 (s, 3H), 0.77 (s, 3H); ms: 316 ($M^{+\cdot}$, 10), 217 (100), 176 (54), 148 (54), 139 (71), 108 (80), 67 (67), 43 (91), 39 (85). Exact mass calcd. for $C_{19}H_{24}O_2S$: 316.150; found: 316.144.

cis-*3-Phenylthio-5,6,4a,8a,7,8-hexahydro-5,5,8a-trimethyl-(4H)-naphthalen-8α(tert-butyldimethylsiloxy)-1-one (28)*

To a stirred solution of the hydroxydecalone **27** (0.32 g; 1.01 mmol) and 2,6-lutidine (0.30 mL; 0.27 g; 2.53 mmol; 2.5 equiv.) in dry methylene chloride (1.0 mL) under argon at room temperature was added *tert*-butyldimethylsilyl trifluoromethanesulfonate (0.35 mL; 0.40 g; 1.52 mmol; 1.5 equiv.) dropwise. After 5 h, the mixture was diluted with 20 mL of methylene chloride and washed with 10 mL of 10% sodium carbonate solution. The aqueous layer was further extracted with 10 mL of methylene chloride. The combined extracts were dried ($MgSO_4$) and concentrated *in vacuo* to give a crude oily liquid. Flash chromatography on silica gel (eluent: 5% ethyl acetate/hexane) afforded **28** in 77% yield as fine white crystals, mp 64–67°C. **28** had ir (Nujol, cm^{-1}): 1646, 1606, 1289, 1250, 1073, 1042; ^{1}H nmr ($CDCl_3$, ppm): 7.38–7.54 (m, 5H), 5.38 (d, J = 1.4 Hz, 1H), 2.81–3.00 (bm, 1H), 2.42 (dd, J = 17.0, 5.2 Hz, 1H), 1.72–1.90 (m, 3H), 1.49–1.67 (m, 1H), 1.28 (s, 3H), 1.19 (s, 3H), 0.98 (s, 3H), 0.84 (s, 9H), 0.01 (s, 3H), −0.12 (s, 3H); ms: 415 ($M^{+\cdot}$ − 15, 3), 373 (100), 249 (38), 217 (35), 75 (58), 57 (21), 41 (37). Exact mass calcd. for $C_{25}H_{39}O_2SSi$ (CI, NH_3, $M^{+\cdot}$ + 1): 431.244; found: 431.244.

cis-*3-Methoxy-5,6,4a,8a,7,8-hexahydro-5,5,8a-trimethyl-(4H)naphthalen-8α(tert-butyldimethylsiloxy)-1-one (29)*

To a stirred solution of sodium methoxide (1.74 mmol; prepared by dropwise addition of 10.0 mL of methanol to 41.8 mg of sodium hydride) in dry methanol under argon at room temperature was added **28** (150 mg; 0.38 mmol). The reaction flask was then fitted with a condenser and warmed to reflux. After 5 days, the mixture was allowed to cool and the solvent was removed *in vacuo*. The residue was taken into 20 mL of methylene chloride and washed with 10 mL of water. The organic layer was dried ($MgSO_4$) and concentrated *in vacuo*. The crude product was subjected to flash chromatography on silica gel (eluent: 8% ethyl acetate/hexane) to give 101.4 mg (83%) of **29** as fine waxy crystals, mp 68–70°C. **29** had ir ($CHCl_3$, cm^{-1}): 2929, 2856, 1627, 1381, 1079, 841; ^{1}H nmr ($CDCl_3$, ppm): 5.36 (d, J = 0.8 Hz, 1H), 3.82 (bm, 1H), 3.64 (s, 3H), 2.78 (m, 1H), 2.28 (dd, J = 17.8, 5.7 Hz, 1H), 1.50–1.90 (m, 5H), 1.31 (s, 3H), 1.13 (s, 3H), 0.95 (s, 3H), 0.79 (s, 9H), 0.02 (s, 3H), −0.08 (s, 3H); ms: 337 ($M^{+\cdot}$ − 15, 6), 297 (23), 296 (43), 295 (100), 171 (40), 139 (35), 101 (24), 89 (46), 75 (43), 73 (45), 41 (40). Exact mass calcd. for $C_{20}H_{37}O_3Si$ (CI, NH_3, $M^{+\cdot}$ + 1): 353.251; found: 353.251.

cis-*3-Methoxy-5,6,4a,8a,7,8-hexahydro-5,5,8a-trimethyl-(4H)naphthalen-8α-hydroxy-1-one (30)*

For compound **27**: This reaction (and work-up) was carried out as indicated above for **29** on a 100 mg (0.32 mmol) scale using 10.0 equivalents of sodium methoxide in 5.0 mL of methanol. The reaction required 4 days to reach completion. The crude residue after work-up was chromatographed (eluent: 25% ethyl acetate/hexane), providing **30** in 33% yield. **30** had ir ($CHCl_3$, cm^{-1}): 3420, 1620, 1237, 1179, 1155, 1076; ^{1}H nmr ($CDCl_3$, ppm): 5.22 (d, J = 1.8 Hz, 1H), 5.12 (d, J = 10.8 Hz, exch. D_2O, 1H), 3.69 (s, 3H), 3.17 (ddd, J = 11.0, 10.8, 5.3 Hz, 1H), 2.77 (ddd, J = 19.1, 6.8, 1.8 Hz, 1H), 2.36 (d, J = 19.1 Hz, 1H), 1.59–1.90 (m, 3H), 1.23–1.50 (m, 2H), 1.46 (s, 3H), 0.91 (s, 3H), 0.70 (s, 3H); ms: 238 ($M^{+\cdot}$, 2), 220 (8), 205 (5), 139 (100), 122 (46), 107 (70), 98 (88), 69 (57), 55 (36), 41 (34), 39 (29). Exact mass calcd. for $C_{14}H_{23}O_3$ (CI, NH_3, $M^{+\cdot}$ + 1): 239.165; found: 239.165.

trans-*3-Phenylthio-5,6,4a,8a,7,8-hexahydro-5,5,8a-trimethyl-naphthalen-8β-hydroxy-1β(1H,4H)-ol (31a)*

To a stirred solution of the *trans*-decalone **14** (250 mg; 0.796 mmol) in dry methanol (10.0 mL) under argon at 0°C was added sodium borohydride (39.1 mg; 1.03 mmol; 1.3 mol equiv.) in one portion. After 18 h of stirring at this temperature, water (1.0 mL) was added

Received December 8, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

T. H. CHAN, A. ALI, J. F. BRITTEN, A. W. THOMAS, G. M. STRUNZ, and A. SALONIUS. Can. J. Chem. **68**, 1178 (1990).

The crystal structure of 1,2-dibenzoyl-1-*tert*-butylhydrazine (**1**), a nonsteroidal ecdysone agonist, has been established by direct methods and refined to a final *R* value of 0.038 for 2502 observed reflections. The crystals belong to the monoclinic system, $a = 10.5114(7)$, $b = 31.557(3)$, $c = 11.1578(8)$ Å, $\beta = 113.210(6)°$, and the space group is $P2_1/n$. The N—N bond in **1** was found to adopt a *gauche* conformation with a dihedral angle of −71.8° or −58.1°. The two amide functions adopt different planar conformations. The compound is found to have a potent effect on the development of spruce budworm (*Choristoneura fumiferana*) larvae, causing early apolysis and subsequent mortality at 0.2–10 ppm concentration in artificial diet.

Key words: ecdysone, agonist, spruce budworm, 1,2-dibenzoyl-1-*tert*-butylhydrazine.

T. H. CHAN, A. ALI, J. F. BRITTEN, A. W. THOMAS, G. M. STRUNZ et A. SALONIUS. Can. J. Chem. **68**, 1178 (1990).

On a déterminé la structure cristalline de la 1,2-dibenzoyl-1-*tert*-butylhydrazine (**1**), un agoniste non-stéroïdal de l'ecdysone, à l'aide de méthodes directes et on l'a affinée jusqu'à une valeur finale de *R* de 0,038 pour 2502 réflexions observées. Les cristaux sont monocliniques, groupe d'espace $P2_1/n$, avec $a = 10{,}5114(7)$, $b = 31{,}557(3)$ et $c = 11{,}1578(8)$ Å et $\beta = 113{,}210(6)°$. On a trouvé que la liaison N—N du composé **1** adopte une conformation *gauche* avec un angle dièdre allant de −71,8 à −58,1°. Les deux fonctions amides adoptent des conformations planaires différentes. On a trouvé que le composé possède une activité importante vis-à-vis du développement de la larve de la tordeuse des bourgeons de l'épinette (*Choristoneura fumiferana*); à des concentrations allant de 0,2 à 10 ppm dans des diètes artificielles, il cause une apolyse précoce et une mortalité subséquente.

Mots clés : ecdysone, agoniste, tordeuse des bourgeons de l'épinette, 1,2-dibenzoyl-1-*tert*-butylhydrazine.

[Traduit par la revue]

Introduction

The spruce budworm, *Choristoneura fumiferana*, is an insect pest that causes considerable damage to the forest resource in eastern North America, threatening the wood supply from large areas of forest in eastern Canada. The damage is caused by the 2nd instar to the 6th instar larvae, which feed on the buds, newly opened shoots, and needles of the host tree from mid-May to late June. Efforts to control the spruce budworm up to now have relied on the spraying of insecticides.

Recently, we have examined some alternative approaches to the control of spruce budworm. One strategy that has been studied is to employ antifeedants to interfere with the feeding behaviour of insects (1, 2). Another line of attack is to intervene in the insect's development. The terpenoid juvenile hormone and the steroid ecdysone are known to regulate insect metamorphosis and development (3). While much research has been carried out with juvenile hormone mimics (4), compounds that only interfere with pupation do not appear to be the most useful control agents for insects that, like the spruce budworm, inflict their damage during the larval stages. On the other hand, relatively little attention has been focused on the interference of ecdysone functions as a mean of insect control. In 1988, 1,2-dibenzoyl-1-*tert*-butylhydrazine (**1**) was reported to mimic the action of 20-hydroxyecdysone (**2**) in competing for the same receptor sites (5). Furthermore, the compound was found to be extremely potent at promoting the onset of molting in larvae of the tobacco hornworm (*Manduca sexta*) (6). We have therefore investigated the effects of **1** on the spruce budworm.

[1]Author to whom correspondence may be addressed.

Biological assays

Compound **1** and its parent compound, 1,2-dibenzoylhydrazine (**3**), were synthesized by standard procedures. The compound was incorporated into artificial diet to give concentrations of 0.2, 1, 10, 100 ppm wet weight, and was offered to spruce budworm larvae from a laboratory colony. Diet subjected to the same solvent treatment but with no compound was used as a control. Full-strength artificial diet (7) was used for one set of assays beginning with 2nd instar larvae, whereas 40% diet (1 part diet:1.5 parts Alphacel) was used for another set beginning with 6th instar larvae.

Compound **1** caused early apolysis, seen as head-capsule

slippage, in 100% of the 2nd instar larvae at 10 ppm and 100 ppm, and all the larvae died before reaching the 3rd instar. At a concentration of 1 ppm, compound **1** had no effect on the development of 2nd instar larvae to 6th instars. No 6th instar survived to a pupa when fed 10 and 100 ppm of **1**. The no effect level for 6th instar larvae was 0.2 ppm.

In contrast, neither larval development from 2nd instar to 6th instar nor development of 6th instar larvae to pupae were affected by any concentration of **3** up to 100 ppm.

Crystal structure

The significant activity observed for **1** is encouraging in the context of the possible use of ecdysone agonists for control of the spruce budworm. From the chemistry point of view, a fundamental question is why **1** should behave as an ecdysone agonist (5, 6) when the two compounds, **1** and **2**, are structurally so different. Furthermore, any explanation will have to take into consideration the fact that **3**, the parent compound of **1**, fails to show significant activities in this and other bioassays (6). Molecular modelling, which has been used extensively in the field of drug design, may offer an understanding of the structure–activity relationship. A prerequisite of any meaningful molecular modelling calculation is the precise structure of an active compound obtained by X-ray structure determination. Towards this end, we have determined the crystal structure of **1**.

The title compound (**1**) was prepared by reacting *tert*-butylhydrazine with benzoyl chloride in aqueous sodium hydroxide solution. It was recrystallized from ethanol–water to give crystals with mp 174°C. A crystal approximately 0.20 × 0.20 × 0.20 mm was mounted on a glass fibre. The room temperature intensity data were collected using Cu $K_{\bar{\alpha}}$ radiation (λ = 1.54178 Å) on an Enraf–Nonius CAD4 diffractometer under NRCCAD (8) control with on-line profile fitting. Twenty seven reflections (70° < 2θ < 90°) were used for the cell determination. A θ/2θ collection of $\pm h$, $+k$, $+l$ set of reflections with $2\theta_{max}$ = 99.7° yielded 4529 measurements. The 400, 004, and −181 reflections were each measured after every 80 reflections and varied less than 0.7%. There were 3421 unique reflections, and 2502 with $I > 2.5\ \sigma_I$ were used for refinement. σ_I is given by (peak + m^2 background)$^{1/2}$, where m is the peak-to- background measurement time ratio.

Crystal data:

$C_{18}H_{20}N_2O_2$ MW 296.37 g mol^{-1}

Monoclinic, $P2_1/n$ (non-standard $P2_1/c$, no. 14), a = 10.5114(7) Å, b = 31.557(3) Å, c = 11.1578(8) Å, β = 113.210(6)°, V = 3401.6(4) Å^3 at 21°; Z = 8, ρ_c = 1.157 Mg m^{-3}, μ = 0.58 mm^{-1} (no absorption correction).

Data reduction, structure solution, and structure refinement were carried out using the NRCVAX (9) program system on a Silicon Graphics IRIS 3130. Direct methods (SOLVER (9)) revealed all non-hydrogen atoms for two independent molecules. Full-matrix least-squares refinement and a Fourier difference map revealed all hydrogen atoms. The final refinement, on 558 parameters (non-hydrogen atoms anisotropic) for 84 atoms, based on observed wF's, was weighted with $w = (\sigma_F^2 + 0.00001\ F^2)^{-1}$ and gave residuals R = 0.038, R_w = 0.027, and S = 2.06 where $R = \Sigma||F_o| - |F_c||/\Sigma F_o$, $R_w = [\Sigma(w(|F_o| - |F_c|)^2)/\Sigma(wF_o^2)]^{1/2}$, and $S = [\Sigma(w(|F_o| - |F_c|)^2)/(\text{number of reflections minus number of parameters})]^{1/2}$. The largest shift/error was 0.112 and the major features of the final difference map were a hole of −0.14 e/Å^3 and a peak of 0.12 e/Å^3. The secondary extinction coefficient refined to 1.57 (8).

fitting of the non-hydrogen atoms of A and B, performed with QUANTA[3] on the IRIS 3130 gave an rms displacement of 0.355 Å. Tables 2 and 3 illustrate the geometric similarities. In the discussion below, relevant comparisons are made.

The phenyl groups

The atoms of each of the two phenyl groups are coplanar. However, the two carbonyl groups to which they are bonded are not coplanar with the phenyl rings. The torsion angles defined by C(1)—C(6)—C(13)—O(1) and by C(7)—C(12)—C(14)—O(2) are −149.6(4)° (or −153.8(4)° for B) and 114.3(4)° (or 122.0(4)° for B) respectively, considerably different from the 180° (or 0°) expected. Furthermore, the relative orientation of the two phenyl rings is given by the dihedral angle of 66.3(2)° (or 60.8(2)° for B).

The tert*-butyl group*

The bond distances and angles in the *tert*-butyl group compare well with other *tert*-butyl groups in the literature (11). The bond distance in A of the N(2)—C(15) linkage, 1.506(4) Å

[3]The QUANTA progam is available from Polygen Corporation, 200 Fifth Ave., Waltham, MA 02254, U.S.A.

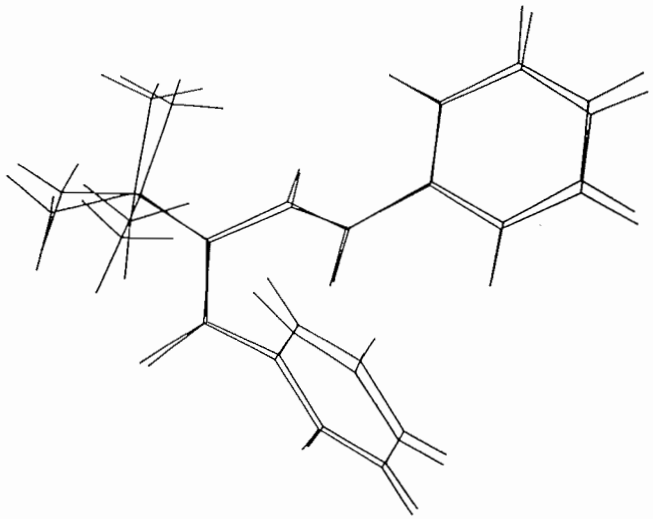

FIG. 2. Least-squares pairwise (non-hydrogen atoms) fitting of molecules A and B.

(1.507(4) Å for B), is within the expected range of 1.47 Å for the normal C—N single bond.

The hydrazine linkage

While the two amide functions adopt the expected planar structure, the amide bearing the N-H has the *s-cis* conformation (O(1)—C(13)—N(1)—N(2)) whereas the amide bearing the N-*tert*-butyl group has the *s-trans* conformation (O(2)—C(14)—N(2)—N(1)). Clearly, the steric size of the *tert*-butyl group causes the phenyl group to be directed away. For N(1), which bears the hydrogen, the nitrogen has an sp^2 hybridized structure with the bond angle for A of N(2)—N(1)—C(13) at 120.2(3)° (120.0(3)° for B). On the other hand, the other nitrogen, N(2), which bears the *tert*-butyl group, is distorted from the perfect trigonal structure, with N(1)—N(2)—C(14) = 116.7(3)°, N(1)—N(2)—C(15) = 117.6(2)°, and C(14)—N(2)—C(15) = 123.3(3)°(115.2(3)°, 116.8(2)°, and 123.0(3)° respectively for B). The N—N bond adopts a *gauche* conformation with a dihedral angle (ϕ) of −71.8° in A (−58.1° in B) for C(13)—N(1)—N(2)—C(14). Such a *gauche* effect has been observed for other hydrazine derivatives (12).

Packing

The crystal, which readily cleaves to give thin needles, shows hydrogen bonding only along the *a* direction, involving N(1) and O(2) atoms of alternating A and B molecules (see Table 2). van der Waals interactions are responsible for the three-dimensional stability.

Conclusions

The crystal structure of **1** reveals some interesting features. Possibly because of the steric effect of the *tert*-butyl group, the two amide functions in **1** adopt different conformations. Furthermore, in the *gauche* conformation of the hydrazine linkage, the carbonyl group of C(13) is away from the *tert*-butyl group. The two carbonyl oxygen atoms are therefore placed in positions relative to each other that would be expected to be different in diacylhydrazines not possessing the bulky *tert*-butyl group. Obviously, it remains to be seen whether this is the factor responsible for the structure–activity difference of **1** and **3**. In view of the potent biological effect of **1** on spruce budworm, further investigation in this area is clearly warranted.

Experimental

1,2-Dibenzoylhydrazine (**3**) was obtained commercially from Aldrich. 1,2-Dibenzoyl-1-*tert*-butylhydrazine (**1**) was synthesized according to the following procedure. Benzoyl chloride (1.12 g, 8 mmol) was added dropwise to a cooled (0°C) solution of *tert*-butylhydrazine hydrochloride (0.50 g, 4 mmol) in aqueous sodium hydroxide (0.30 g, 8 mmol) solution. White precipitate started to appear after 30 min. After 2 h, the white precipitate was filtered and recrystallized from ethanol and water (1:1) to give **1**, mp 174°C, in 78% yield. Compound **1** had IR ($CHCl_3$, cm^{-1}): 3073, 1698, 1610; ^1H NMR ($CDCl_3$, ppm): 1.60 (s, 9H), 7.49 (m, 10H).

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

J. L. WOLK, M. R. HAJNAL, S. HOZ, R. M. TARKKA, and E. BUNCEL. Can. J. Chem. **68**, 1182 (1990).

The S_N2 reaction of $H_2C{=}NO^-$ with CH_3Cl was investigated at the AM1, STO-3G, and 6-31 + G* levels. Three modes of approach of CH_3Cl to the oxygen of the nucleophile were examined: *syn* and *anti* to the lone pair on the nitrogen in the molecular plane, and an approach along the π system of the oximate anion. The AM1 method differed markedly from the two *ab initio* methods, both in the reactivity order of the three geometries as well as in the relative stabilities of the products. The reactivity order calculated at the STO-3G and the 6-31 + G* levels was *syn* > π > *anti* (AM1 order: *anti* > *syn* > π). Product stability order calculated by the two *ab initio* methods was *syn* > *anti* > π (AM1 order: *anti* > *syn* > π). Excellent agreement was obtained between percent bond elongations at the transition state predicted by the equation suggested by Shaik, Schlegel, and Wolfe, and the activation barriers calculated at the 6-31 + G* level. The relevance of the calculations with respect to the α-effect is also discussed.

Key words: oxygen lone pairs, aximate, S_N2, *ab initio*.

J. L. WOLK, M. R. HAJNAL, S. HOZ, R. M. TARKKA et E. BUNCEL. Can. J. Chem. **68**, 1182 (1990).

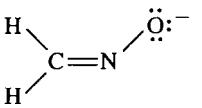
On a étudié la réaction S_N2 du $H_2C{=}NO^-$ avec le CH_3Cl aux niveaux AM1, STO-3G et 6-31 + G*. On a examiné trois modes d'approche du CH_3Cl et de l'oxygène du nucléophile : dans le plan moléculaire, *syn* et *anti* par rapport à la paire d'électrons non partagée de l'azote ainsi qu'une approche le long du système π de l'anion oximate. Il existe des différences importantes entre la méthode AM1 et les deux méthodes *ab initio*; elles se manifestent dans l'ordre de réactivité des trois géométries ainsi que dans les stabilités relatives des produits. L'ordre de réactivité, calculé aux niveaux STO-3G et 6-31 + G*, est *syn* > π > *anti* (avec AM1: *anti* > *syn* > π). La stabilité des produits, telle que calculée par les méthodes *ab initio*, est *syn* > *anti* > π (avec AM1: *anti* > *syn* > π). On a obtenu un excellent accord entre les pourcentages d'élongation des liaisons telles que prédites par l'équation suggérée par Shaik, Schlegel et Wolfe et les barrières à l'activitation calculées aux niveaux 6-31 + G*. On discute aussi de la relation entre ces calculs et l'effet α.

Mots clés : paire d'électrons non partagée de l'oxygène, oximate, S_N2, *ab initio*.

[Traduit par la revue]

Introduction

In simple alkoxides such as CH_3O^-, the three lone pairs on the oxygen atom, after rehybridization, have cylindrical symmetry (C_{3v}). Therefore, in S_N2 reactions, all the approach directions of the electrophile having the same angle with the C_3 symmetry axis are energetically equivalent. However, in oximate anions such as **1**, the three lone pairs are not equivalent because of the



1

asymmetric electronic environment. One lone pair is associated with the π system, one is located *syn* to the lone pair on the nitrogen, and one is located *anti* to it, as illustrated in Fig. 1.

Although the term ambident nucleophile (1) usually applies to a nucleophile having two separate reactive sites, this definition could be extended to the single site, i.e., the oxygen atom of the present system. In this case, it would apply to the distinct lone pairs or directions of approach to oxygen rather than to different atoms on the nucleophile.

The purpose of this work was therefore to compare the reactivity of **1** in the three modes of approach in an S_N2 reaction with CH_3Cl as a model electrophile. In addition, since the oximate anion is frequently used to explore the α-nucleophilicity phenomenon (2), we have also examined the compatibility of the relatively fast semi-empirical AM1 method for future structure–reactivity studies.

Methods

The AM1 calculations (3) were carried out on an IBM 3081 computer using the AMPAC program version 2.10. The STO-3G (4*a*) and 6-31 + G* (4*b*) calculations were performed on an IBM 3090 computer using Gaussian 86 (4*c*). The optimized geometries of the reactants, transition states, and products of eq. [1],

[1] $H_2C{=}NO^-\cdots CH_3Cl \rightarrow [H_2C{=}NO\cdots CH_3\cdots Cl]^{-\ddagger}$
$\rightarrow H_2C{=}NOCH_3\cdots Cl^-$

for all three modes of approach (*syn*, *anti*, and π), were calculated at all three levels. In all cases, the S_N2 collinear geometry of O···C···Cl was enforced. The π geometry was enforced by fixing the CNOC dihedral angle at 90°. Transition states were characterized by a single negative force constant associated with the asymmetric stretching frequency of O···C···Cl. Each 6-31 + G* transition state was further characterized by a frequency analysis. In all three cases (π, *syn*, and *anti*), one large (ca. 500 cm^{-1}) negative frequency associated with the reaction coordinate was obtained. In the case of the *syn* and *anti* geometries, this was accompanied by another much smaller (ca. 50 cm^{-1}) negative frequency, associated with out-of-plane bending of the nucleophile. It is thus clear that the reported transition states are located in the immediate vicinity of the stationary points, having practically the same energy.

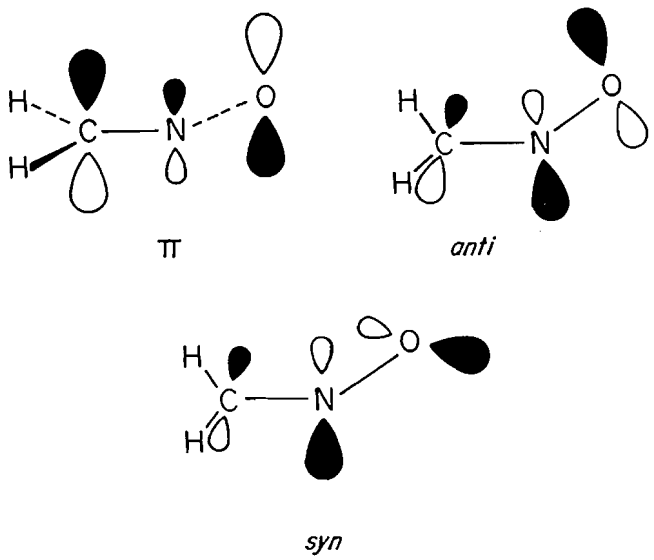

FIG. 1. Illustrations of the three molecular orbitals for oximate anion associated with the π, *anti*, and *syn* lone pairs, respectively. The HOMO is associated with the π oxygen lone pair, while the highest two subjacent occupied molecular orbitals are associated with the *syn* and *anti* oxygen lone pairs, respectively.

Results and discussion

Energies and geometries of ground states, transition states, and products

The energies of the various species at the three levels of calculation, together with the equilibrium and activation enthalpies, are given in Table 1. The geometries are given in Table 2. At the 6-31 + G* level, the reactant complex did not optimize in the *anti* geometry. While the CH_3Cl residue remained in the molecular plane during the optimization, the CON angle steadily increased. Scanning of the potential surface over a large range of CON angles revealed a shallow region between 130° and 160° in which the energy changes only by 0.7 kcal. The angle of 142° was hence arbitrarily assigned as the CON angle of the reactants. For the transition state and the products, the optimization procedure gave the local minima at the angles indicated in Table 2.

Examination of Table 1 reveals that the three levels of calculation give markedly different results for the kinetics and thermodynamics of the reactions. Assuming that the 6-31 + G* calculations are more reliable than the other two methods, the δH^0 values for the latter methods deviate equally from the 6-31 + G* values, though in opposite directions. The two *ab initio* methods predict the processes to be exothermic, whereas AM1 predicts the processes to be iso- or endothermic. More interesting is the relative order of stability of the products. While the two *ab initio* methods predict the stability order *syn* > *anti* > π, the AM1 order is *anti* > *syn* > π. The destabilization of the π-type product relative to the others in all three methods likely stems from disruption of allylic conjugation attendant to fixing the π lone pair as a covalent bond.

To ascertain whether the *syn–anti* stability order is affected by the chloride anion present in the products, the optimized geometries of the two methylformaldoximate conformers (**2**, R = CH_3) were calculated at the 6-31 + G* level.

The calculations showed that, in this system as well, the *syn* is more stable than *anti*, although by a larger margin (8.2 kcal/mol). A similar stability order was found for the parent

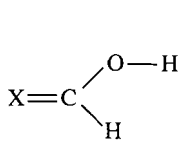
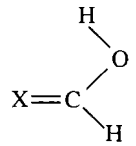
oxime (**2**, R = H) (for previous calculations see ref. 5). It is interesting to compare this stability order with that of the model system **3** in which the opposite stability order was found for X = CH_2 or O as compared to X = C(H)OH (6).



3 *syn*



3 *anti*

Several factors were considered to be the cause of this stability order for **3**, including electrostatic interactions, lone pair – lone pair interactions, hydrogen bonding, and nonbonded aromaticity (6). It seems, however, that in the oxime series, **2**, the most crucial factor is the lone pair – lone pair repulsion between the pairs on the oxygen and on the nitrogen. This destabilizing interaction becomes diminished when the lone pair on the oxygen is utilized for formation of the covalent bond.

Theoretical work by several groups (7) has shown that the protons in the *syn* and *anti* conformers of formic acid (**3**, X=O) are of different acidity. In other words, the two in-plane oxygen lone pairs differ in their basicity. This idea was used to draw important conclusions concerning the mechanism of enzymatic reactions catalyzed by proton transfer to a carboxylate residue (8), and more recently by Rebek and co-workers to design and prepare a new class of chelating agents in which the lone pair *syn* to the C=O function was utilized to ligate the metal cation (9).

TABLE 2 (*concluded*)

[a]Bond lengths in Å, angles in degrees.
[b]See text.

The results of the present study suggest, therefore, that in using the oximate function for chelation, the molecular system should be designed in such a way as to position the cation in the complex *syn* to the lone pair on nitrogen. Since the difference in the stability of the two isomers in formic acid is 4.5 kcal (7), whereas in the oxime system it is significantly larger (6.6 kcal), the geometrical requirements in the oxime seem to be more important than in the carboxylate system.

With respect to $\delta H^{\neq}$ values (Table 1), the three levels of calculation also give differing results. However, the STO-3G method gives values closer to 6-31 + G* than does AM1.

According to classical physical organic chemistry considerations, the reactivity order should be governed by product stability and (or) the energy of the HOMO. According to all three methods of calculation, the HOMO is associated with the π system. The MOs associated with the *syn* and *anti* lone pairs on oxygen are subjacent to the HOMO and in the plane of the molecule (Fig. 1). However, since the energies of the highest three occupied molecular orbitals are all contained within a range of 4 kcal (at the 6-31 + G* level), it is not surprising that $\delta H^{\neq}$ in the π approach is not the smallest (Table 1). A relatively higher barrier for this approach is expected on the basis of relative product stability. The importance of the latter factor is expected to be more dominant in late transition states. The relative *syn–anti* activity, in all methods, corresponds to product stability and is apparently governed as well by the lone pair – lone pair pair repulsion effect.

Relevance of the calculation to the α-effect phenomenon

The results of the calculations are also pertinent with respect to the α-effect, as was stated in the introduction. Oximate anion, as a representative α-nucleophile, possesses a lone pair of electrons on the atom adjacent to the nucleophilic center, and such nucleophiles have often been observed to show enhanced reactivity compared to normal nucleophiles of the same basicity (pK_a). Several factors have been advanced, the most common being ground-state destabilization, transition state stabilization, stabilization of α-nucleophilic products, solvation effects, and a variety of other causes including intramolecular hydrogen bonding, etc. (2).

These factors have been discussed in a number of articles and reviews (2), and it is not our purpose to analyze them at present. As we pointed out previously (2*b*), since the α-phenomenon is one of enhanced reactivity, the important point is that reaction of an α-nucleophile involves a decrease in the free energy of activation, and therefore, in principle, ground state destabilization and transition state stabilization could act in concerted fashion, resulting in the overall rate enhancement. However, we have already shown that ground state destabilization affects both nucleophilicity and basicity, and therefore cannot be the origin of the α-effect (2*i*). Therefore, the lone pair – lone pair interaction may enhance the relative reactivity of the *syn* lone pair

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 88.85.125.76 on 09/07/12
For personal use only.

compared to the other lone pairs, but the ground state destabilization it causes is not the foundation of the α-effect.

From the results we have obtained, it must be concluded that this study does not provide the key to the enigma of the α-effect, nor does it prove or disprove any of the existing theories. A more elaborate theoretical study would be needed for this purpose.

Transition state bond elongation model

We now address some of the geometrical features of the transition state as calculated at the 6-31 + G* level. Recently, Shaik, Schlegel, and Wolfe (10) reported an interesting relationship between the percent of elongation of the bonds of the central carbon atom to the nucleophile and the leaving group at the transition state of the S_N2 reactions ($Y^- + CH_3X \rightleftharpoons YCH_3 + X^-$). Percent bond elongation of the C—X bond is defined in eq. [2], and in a corresponding expression will apply to the C—Y bond.

$$[2] \quad \%\,CX = 100(d^{\ddagger}_{CX} - d^{\circ}_{CX}) \qquad (d = \text{bond length})$$

Using the data of some 30 S_N2 reactions calculated at the 4-31G level, they found a remarkable correlation between the percent bond elongation (%CX) and the activation barrier (eq. [3]).

$$[3] \quad \%CX = 0.76\,\delta H^{\ddagger} + 14$$

The data in Tables 1 and 2 allow an analysis of the present S_N2 reaction, $H_2C{=}NO^- + CH_3Cl \rightleftharpoons H_2C{=}NOCH_3 + Cl^-$, in both the forward and the reverse directions. It was found that for all three modes of approach, the percent C···O bond elongation at the transition state is 50 ± 1%, while for the C···Cl bond the elongation is 19 ± 1%. Using eq. [3] with the activation barriers in the forward and reverse directions to calculate the corresponding bond elongation at the transition state, we found that this equation predicts bond elongations with a very high degree of precision (±2% of our calculated 6-31 + G* values). This remarkable correlation with our data lends credence to the aforementioned equation, which is based on 4-31G data, showing it to be an effective tool in predicting transition state geometries from activation parameters in the gaseous phase.

Structural requirements for molecular recognition by the Neurokinin receptors

FRANÇOIS LEMAY, CHAKIB AMEZIANE HASSANI, AND ANDRÉ G. MICHEL[1]

Laboratoire de chimie structurale, Département de chimie, Université de Sherbrooke, Sherbrooke (Québec), Canada J1K 2R1

Received December 13, 1989

This paper is dedicated to Professor Arthur S. Perlin on the occasion of his 67th birthday

FRANÇOIS LEMAY, CHAKIB AMEZIANE HASSANI, and ANDRÉ G. MICHEL. Can. J. Chem. **68**, 1186 (1990).

Populations of lower energy conformers have been generated by conformational energy calculations, using empirical energy functions, for the C-terminal pentapeptide of Substance P (CH_3-CO-Phe-Phe-Gly-Leu-Met-NH_2), Neurokinins A and B (CH_3-CO-Phe-Val-Gly-Leu-Met-NH_2), and Eledoisin (CH_3-CO-Phe-Ile-Gly-Leu-Met-NH_2). The C-terminal sequences are greatly conserved in the Neurokinin and Tachychinin families of peptides and are mainly responsible for the molecular recognition. These sequences differ in the nature of the second residue. This substitution interferes with the recognition processes and modulates the specificities. A procedure based on a random generation of conformers, followed by energy minimizations, has been applied to produce the populations of conformers for the three pentapeptides. The conformational properties of the lower energy conformers have been analysed and compared with respect to the substitution of the second residue. Earlier nuclear magnetic resonance data as well as structure–activity relationship results have been interpreted in light of the proposed stable conformers. It is shown that the selectivity towards the NK3 receptor requires a structure with a restrained flexibility introduced at the second N-terminal residue. The selectivity towards the NK1 receptor is shown to be related to the presence of a constrained structure at the Gly residue. These structures suggest further chemical modifications be introduced in order to produce more selective and stable analogues.

Key words: peptide conformation, empirical energy, Neurokinin, molecular recognition.

FRANÇOIS LEMAY, CHAKIB AMEZIANE HASSANI et ANDRÉ G. MICHEL. Can. J. Chem. **68**, 1186 (1990).

Les populations des conformères les plus stables ont été générées par calculs conformationnels à l'aide de fonctions empiriques, pour les pentapeptides C-terminaux de la Substance P (CH_3-CO-Phe-Phe-Gly-Leu-Met-NH_2), des Neurokinines A et B (CH_3-CO-Phe-Val-Gly-Leu-Met-NH_2) ainsi que de l'Eledoisine (CH_3-CO-Phe-Ile-Gly-Leu-Met-NH_2). Ces séquences sont communes à ces familles de peptides et considérées comme responsable de la reconnaissance moléculaire par les récepteurs correspondants. Une procédure consistant à générer des structures aléatoires et ensuite à minimiser leurs énergies a été utilisée pour constituer les populations regroupant les conformères les plus stables pour les trois séquences considérées. Ces structures sont présentées et des résultats antérieurs obtenus par résonance magnétique nucléaire sont interprétés. Les hypothèses formulées à propos des relations structures–activités sont également reconsidérées à partir des résultats obtenus. Finalement, il est proposé que la sélectivité caractérisant le récepteur NK3 est reliée à la présence d'une rigidification conformationnelle au niveau du second résidu. En ce qui concerne le récepteur NK1, il est montré que des contraintes au niveau de résidu Gly sont de nature à augmenter la spécificité. Ces structures permettent de suggérer des modifications chimiques à effectuer sur ces peptides afin d'en augmenter la spécificité.

Mots clés : conformation de peptides, énergies empiriques, Neurokinine, reconnaissance moléculaire.

Introduction

In recent years, the important role played by endogenous peptides was demonstrated in various physiological mechanisms. Particularly, it was shown that Substance P may be the mediator of sensory stimuli, as well as the originator of the antidromic vasodilatation, increasing vascular permeability. Nevertheless, some years after the discovery of Substance P and its homologues in the families of Neurokinin and Tachykinin (Table 1) their structure–activity relationships remain undefined. Many biological studies have been done on these peptides to establish structural congruencies to account for their selectivities (1–9).

Physico-chemical studies like NMR (Nuclear Magnetic Resonance) (10–16) and CD (Circular Dichroïsm) experiments (17) as well as conformational analysis by molecular mechanics (18–22) have tried to establish their conformational properties. Divergent conclusions have been reached in many cases.

The NMR studies on Substance P and its fragments or analogues have postulated the formation of hydrogen bonds. It was suggested that a C-terminal carbonyl group might form an H-bond with the primary amide protons of Gln^5 and Gln^6 residues (11, 15). Another hypothesis was to involve the Phe^7 amide proton (12, 13). All these studies suggested a folded U-shape configuration for the C-terminal end (25). Nevertheless, other structure–activity relationship studies (7) and NMR investigations (16) postulated an extended structure for this part of the peptide.

Examining the results of theoretical calculations by empirical energy methods, it was obvious that the size of the problem, as well as the number of degrees of freedom, prevented a systematic search (20, 22). Consequently, the results presented did not give a complete picture of the conformational space accessible to these molecules. Generally these studies concentrated on frequently observed structures, rather than giving a description of the overall conformational behaviour of these peptides (31, 32).

From structure–activity relationship studies it was shown that the conformational study could be limited to the C-terminal hexapeptide, which retains a large portion of the activity (2). Moreover, the substitution of residue 6 in the hexapeptide SP(6–11) (23, 24) was shown to modulate the activity, but the C-terminal pentapeptide Phe-X-Gly-Leu-Met-NH_2 was common to all active peptides, with X = Phe (Tyr), Val, or Ile for Substance P, Neurokinin A/B, and Eledoisin, respectively.

These observations suggested that we concentrate the conformational analysis on the pentapeptides SP(7–11), NK(6–10), and EL(7–11) presented in Table 1, assuming that the spatial requirements for the recognition are included in those sequences. The size of the sequences allowed us to explore a significant part of the conformational space by empirical energy

TABLE 1. Amino acid sequences of Substance P, Neurokinin A and B, Eledoisin, and the pentapeptides SP(7–11), NK(6–10), EL(7–11)

Peptides	Code	Sequences
Neurokinins		
Substance P	SP	Arg^1-Pro^2-Lys^3-Pro^4-Gln^5-Gln^6-Phe^7-Phe^8-Gly^9-Leu^{10}-Met^{11}-NH_2
Neurokinin A	NKA	His^1-Lys^2-Thr^3-Asp^4-Ser^5-Phe^6-Val^7-Gly^8-Leu^9-Met^{10}-NH_2
Neurokinin B	NKB	Asp^1-Met^2-His^3-Asp^4-Phe^5-Phe^6-Val^7-Gly^8-Leu^9-Met^{10}-NH_2
Tachykinin		
Eledoisin	EL	$pGlu^1$-Pro^2-Ser^3-Lys^4-Asp^5-Ala^6-Phe^7-Ile^8-Gly^9-Leu^{10}-Met^{11}-NH_2
Pentapeptides		
Substance P(7–11)	SP(7–11)	Ac-Phe^7-Phe^8-Gly^9-Leu^{10}-Met^{11}-NH_2
Neurokinin A/B(6–10)	NK(6–10)	Ac-Phe^6-Val^7-Gly^8-Leu^9-Met^{10}-NH_2
Eledoisin(7–11)	EL(7–11)	Ac-Phe^7-Ile^8-Gly^9-Leu^{10}-Met^{11}-NH_2

calculations. Particularly, the influences of the nature of the residue in position 8 (7 for NK) could be related to the corresponding specificities towards receptors NK1, NK2, and NK3.[2] In light of the generated conformations, the NMR data as well as structure–activity relationships should be reconsidered.

Method

The investigation of the conformational space for the three pentapeptides SP(7–11), NK(6–10), and EL(7–11) shown in Table 1 was undertaken by empirical energy calculations using the system of programs PEPSEA (26). This system proceeds in three successive steps.

First, values are randomly generated for each variable dihedral angle selected in the sequence by the user. Then the conformational energy of the corresponding starting conformers is calculated using the ECEPP/2 force field (27). For the purpose of this application an *effective* dielectric constant of 2 was used (33). Using this value, the ECEPP force field was shown to reproduce CNDO/2 calculations on hydrogen bonding in peptidic molecules (33). Subsequently, the energies are minimized by the conjugated gradient techniques, varying the values of the predefined variable angles. The resulting sets of conformers are sorted and analyzed.

This procedure was applied to each of the three forementioned pentapeptides. The peptidic sequences were built from the standard fragments included in ECEPP/2 (27). The calculations included terminal groups CH_3CO- (Ac) and NH_2 at the N-terminal and C-terminal ends respectively. The 15 dihedral angles considered as variable for the generation and energy minimization processes were all ϕ, ψ, $\chi^{1,1}$ angles and $\chi^{2,1}$ for Leu. All other $\chi^{m,n}$ side-chain dihedral angles were set in the *trans* conformation, except for $\chi^{2,1} = 90°$ for the Phe residues. Sets of values were randomly generated for the 15 variable dihedral angles. The corresponding conformers were built for the three pentapeptides and their conformational energies minimized. This generation–minimization procedure was repeated as soon as duplicates frequently appeared, requiring 1000 runs. The three resultant populations of conformers were sorted by increasing values of the conformational energies.

For the 20 most stable conformers, the remaining interactions between side chains were eliminated by energy minimizations, varying all the dihedral angles simultaneously.
