
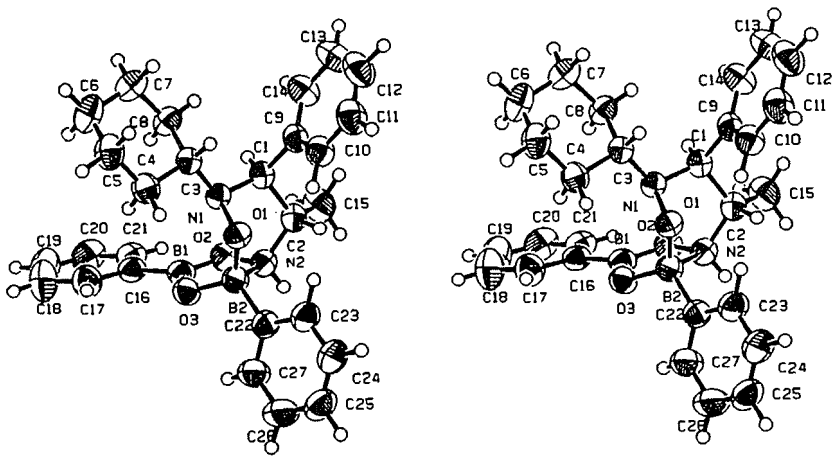

FIG 1. Stereoview of **5**; 50% probability thermal ellipsoids are shown for the nonhydrogen atoms.

TABLE 4. Intra-annular torsion angles (deg) with estimated standard deviations in parentheses

Atoms	Value (deg)
B(2)—O(1)—N(1)—C(1)	−91.4(1)
O(1)—N(1)—C(1)—C(2)	47.3(1)
N(1)—C(1)—C(2)—N(2)	21.5(1)
C(1)—C(2)—N(2)—B(2)	−54.7(1)
C(2)—N(2)—B(2)—O(1)	16.9(1)
N(2)—B(2)—O(1)—N(1)	50.2(1)
B(2)—N(2)—O(2)—B(1)	−6.1(1)
N(2)—O(2)—B(1)—O(3)	−5.2(1)
O(2)—B(1)—O(3)—B(2)	16.3(2)
B(1)—O(3)—B(2)—N(2)	−17.2(1)
O(3)—B(2)—N(2)—O(2)	13.9(1)

(sp^2)B—O—(sp^3)B segment in all cases reported to date, this distance ranging from 1.329 to 1.339 Å (3). The B—O π-bond order can be estimated as about 0.7 from a bond length versus π-bond order plot (11); this can be regarded as evidence for a considerable O—B pp(π) back-donation. Partial π-bond character can also be seen at the B(1)—O(2) bond, although it is of lesser magnitude in this portion of the ring. This is consistent with relative bond lengths observed for comparable B—O bonds in the BOBON rings of **7** (3), **8** (4), and the other structurally characterized BOBON rings (3). The approximate (or actual) planarity of these five-membered BOBON rings is consistent with the assumption of significant π-interactions.

The phenyl substituent at B(1) is nearly coplanar with the BOBON ring (dihedral angle between the normals to the mean planes = 5.6°), and the B(1)—C(16) bond length is exactly the same as the (sp^2)B—C(aryl) bond lengths in **7** (3) and **8** ($R^1 = R^2$ = Me, $R^3 = R^4$ = H) (4): 1.557 Å. The distance between B(2) and C(22) in **5** (1.593(2) Å), however, is longer than the (sp^3)B—C(aryl) distance in **7** (1.579 Å) (3). This corresponds to the short (1.706 Å) transannular N→B bond in **5** relative to that in **7** (1.756 Å), and is consistent with the previously noted observation (ref.3 and references therein) that, for a given set of ligand atoms, the sum of bond lengths about boron remains essentially constant. There is nearly no pyramidalization at B(1), the sum of bond angles at the trigonal planar boron centre being 359.8°. At N(1) the bond angle sum is 331.1°. The geometry at N(1) would allow a coordinative interaction with B(1), the non-bonding distance N(1)···B(1) of 2.855(2) Å being significantly shorter than the sum of van der Waals radii (~3.15 Å) and also shorter than the corresponding non-bonding distance of 2.972 Å in **7**. The bicyclic skeleton of **5** appears to be more compact than that of **7**, with both the transannular N—B bond and transannular non-bonding N···B contact shorter, possibly a result of reduced steric repulsion in **5**.

Unlike compound **8** ($R^1 = R^2$ = Me, $R^3 = R^4$ = H) (4) in which the $^+$N—H moiety forms an intermolecular hydrogen bond with a ring (B)O(C) oxygen atom, the $^+$N—H proton in **5** is *not* involved in any hydrogen bonding. This is presumably the result of steric blocking, both intramolecular and intermolecular, of the possible acceptor oxygen atoms by bulky phenyl and cyclohexyl groups. The crystal structure of **5** consists of molecules separated by normal van der Waals distances, the shortest intermolecular distance between non-hydrogen atoms being N(2)···C(21) = 3.313(2) Å.

Received October 22, 1991

WOLFGANG KLIEGEL, GOTTFRIED LUBKOWITZ, STEVEN J. RETTIG, and JAMES TROTTER. Can. J. Chem. **70**, 2033 (1992).

The 1,3-propanediamine derivatives *N,N'*-di-*tert*-butyl-*N,N'*-dihydroxy-1,3-propanediamine and *N,N'*-di-*tert*-butyl-*N,N'*-dihydroxy-1-phenyl-1,3-propanediamine have been prepared and reacted with oxybis(diphenylborane) to yield, respectively, the crystalline organoboron compounds *N,N'*-di-*tert*-butyl-*N,N'*-dihydroxypropane-1,3-diamine(*O-B*)-ethoxydiphenylborane, **5***a*, and N^1,N^2-di-*tert*-butyl-N^1,N^2-dihydroxy-1-phenylpropane-1,3-diamine(N^2-*O-B*)-hydroxydiphenylborane, **5***b*. Crystals of **5***a* are monoclinic, *C*2/*c*, a = 35.402(1), b = 9.212(2), c = 18.101(2) Å, β = 116.688(3)°, Z = 8, ρ_c = 1.079 g cm^{-3}, and crystals of **5***b* are monoclinic, $P2_1/c$, a = 12.899(4), b = 12.571(4), c = 17.412(3) Å, β = 90.02(2)°, Z = 4, ρ_c = 1.121 g cm^{-3}. The structures were solved by direct methods and were refined by full-matrix least-squares procedures to final R values of 0.047 and 0.041 for 2492 and 3334 reflections with $I \geq 3\sigma(I)$, respectively. Compounds **5***a* and **5***b* are open-chain hydroxylamine adducts of diphenylborinic acid and ethyl diphenylborinate, respectively. Both of these compounds are stabilized by a system of three intramolecular hydrogen bonds (O—H···O, N—H···O, and N—H···N). Bond lengths involving the tetrahedrally coordinated boron atoms are: (C)O—B = 1.457(3), (N)O—B = 1.558(3), and C—B = 1.613(4) and 1.615(4) Å for **5***a*; (H)O—B = 1.475(3), (N)O—B = 1.562(2), and C—B = 1.618(3) and 1.619(3) Å for **5***b*.

WOLFGANG KLIEGEL, GOTTFRIED LUBKOWITZ, STEVEN J. RETTIG et JAMES TROTTER. Can. J. Chem. **70**, 2033 (1992).

On a préparé les dérivés de la propane-1,3-diamine, *N,N'*-di-*tert*-butyl-*N,N'*-dihydroxypropane-1,3-diamine et la *N,N'*-di-*tert*-butyl-*N,N'*-dihydroxy-1-phényl-propane-1,3-diamine, et on les a fait réagir avec l'oxybis(diphénylborane) pour obtenir respectivement les composés organoborés, le *N,N'*-di-*tert*-butyl-*N,N'*-dihydroxypropane-1,3-diamine-(*O-B*)éthoxydiphénylborane, **5***a*, et le *N,N'*-di-*tert*-butyl-*N,N'*-dihydroxy-1-phényl-propane-1,3-diamine(N^2-*O-B*)hydroxydiphénylborane, **5***b*. Les cristaux du produit **5***a* sont monocliniques, *C*2/*c* avec a = 35,402(1), b = 9,212(2), et c = 18,101(2) Å, β = 116,688(3)°, Z = 8 et ρ_c = 1,079 g cm^{-3} alors que les cristaux du composé **5***b* sont monocliniques, $P2_1/c$ avec a = 12,899(4), b = 12,571(4) et c = 17,412(3) Å, β = 90,02(2)°, Z = 4 et ρ_c = 1,121 g cm^{-3}. On a résolu les structures par les méthodes directes et on les a affinées par la méthode des moindres carrés (matrice entière) jusqu'à des valeurs de R de 0,047 et 0,041 respectivement pour 2492 et 3334 réflexions avec $I \geq 3\sigma(I)$. Les composés **5***a* et **5***b* existent sous la forme des chaînes ouvertes d'adduits d'hydroxylamine sur respectivement l'acide diphénylborinique et le diphénylborinate d'éthyle. Ces deux composés sont stabilisés par un système de trois liaisons hydrogènes (O—H···O, N—H···O, et N—H···N). Les longueurs des liaisons impliquant les atomes de bore coordonnés d'une façon tétraédrique sont : (C)O—B = 1,457(3), (N)O—B = 1,558(3), et C—B = 1,613(4) et 1,615(4) Å pour le composé **5***a*; (H)O—B = 1,475(3), (N)O—B = 1,562(2), et C—B = 1,618(4) et 1,619(3) Å pour le composé **5***b*.

[Traduit par la rédaction]

Introduction

Our investigation of boron chelates of alkylene-bis-hydroxylamines led to the preparation of the 1,3-propanediamine derivatives **2** by reduction of the nitrone **1** (1) with either $NaBH_4$ or phenylmagnesium bromide. The 1,3-bis-hydroxylamines **2** (R = H or C_6H_5) were then reacted with oxybis(diphenylborane) in ethanolic solution in order to prepare the eight-membered diphenylboron chelates **3**. These compounds would be analogous to the seven-membered chelate **4** that is obtained under the same conditions from a 1,2-bis-hydroxylamine (2). The crystalline reaction products derived from **2***a* and **2***b* show the elemental analyses and ^{1}H nmr spectra of the expected derivatives plus 1 molar equivalent of ethanol in the case of **3***a*, and 1 molar equivalent of water in the case of **3***b*. These supposed "solvate" components could not be removed by recrystallization or by drying *in vacuo*. The nature of the bonding or association of the ethanol and water molecules, respectively, in these compounds cannot be ascertained from the infrared and ^{1}H nmr spectral data. In addition to the assumed solvate structures of both diphenylboron chelates (**3***a* · EtOH and **3***b* · H_2O) the 1:1 adducts, **2***a* · Ph_2BOEt and **2***b* · Ph_2BOH, had to be considered as isomeric structural alternatives. These adducts could arise from complex formation through the oxygen atom of one of the hydroxylamine groups of **2***a* leading to **5***a*, or of **2***b* leading to **5***b* or **5***b'*, respectively. Furthermore, the coordination of the hydroxylamine function via the nitrogen atom to boron, leading to the isomeric N→B coordinated complexes **6***a* and **6***b* or **6***b'*, had to be considered. This possibility has already been discussed for other adducts of hydroxylamines (3).

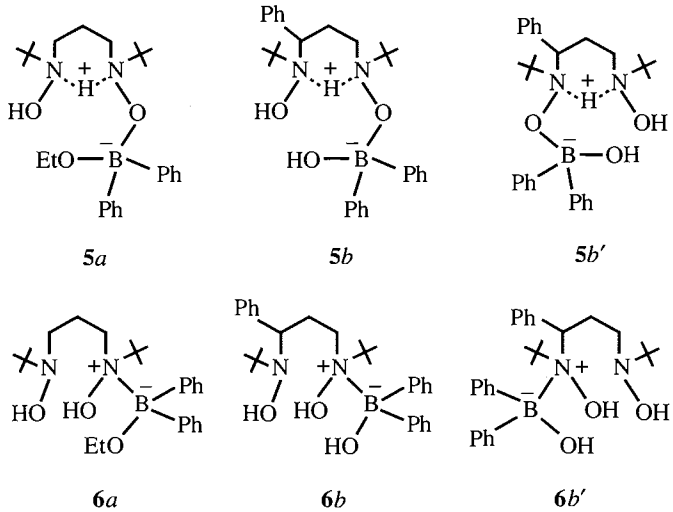
X-ray crystallographic analyses have been carried out for both compounds to distinguish between the three possible molecular structures in the solid state: the "solvate" (**3***a* · EtOH and **3***b* · H_2O), the O→B coordinated complex (**5***a* and **5***b* or **5***b*′), and the N→B coordinated complex (**6***a* and **6***b* or **6***b*′).



Experimental

N,N′-*Di*-tert-*butyl*-N,N′-*dihydroxy-1,3-propanediamine*, **2**a

N-tert-Butyl-3-[*tert*-butyl-(hydroxy)amino]propylidenamine-*N*-oxide, **1** (1), (1.08 g, 5 mmol) is dissolved in 60 mL of isopropanol and 10 mL of water. After addition of $NaBH_4$ (0.38 g, 10 mmol), the solution is refluxed for 2 h. Excess $NaBH_4$ is decomposed with tartaric acid, and the solution is adjusted to pH 9–10 using a solution of Na_2CO_3. Evaporation to a small volume induces crystallization of a colorless substance. Yield: 1.02 g (93%); mp 87–88°C (from petroleum ether, bp 30–75°C). Infrared (KBr): 3360 cm^{-1} (broad, O-H); ^1H nmr (90 MHz, $CDCl_3$/TMS) δ (ppm): 1.15 (s, 2 $(CH_3)_3C$), 1.70–1.99 (m, C-CH_2-C), 2.80 (t, J = 6 Hz, 2 CH_2N), 7.00 (s, very broad, exchangeable, 2 OH). Anal. calcd. for $C_{11}H_{26}N_2O_2$: C 60.51, H 12.00, N 12.83; found: C 60.57, H 12.19, N 12.83.

N,N′-*Di*-tert-*butyl*-N,N′-*dihydroxy-1-phenyl-1,3-propanediamine*, **2**b

N-tert-Butyl-3-[*tert*-butyl-(hydroxy)amino]propylidenamine-*N*-oxide, **1** (1), (2.16 g, 10 mmol) is dissolved in 100 mL of absolute ether and mixed, under vigorous stirring within 15 min, with a Grignard reagent prepared from bromobenzene (9.42 g, 60 mmol) and magnesium (1.46 g, 60 mmol) in 100 mL of absolute ether. After refluxing for 1 h the reaction mixture is hydrolyzed with water under cooling with ice, the precipitated magnesium hydroxide dissolved with 2 N HCl, and the acid solution neutralized with $NaHCO_3$. The ether layer is separated, and the aqueous solution extracted twice with 50 mL of ether. The combined ether solutions are dried with $MgSO_4$ and evaporated to a small volume. At −18°C a colorless substance crystallizes. Yield: 1.65 g (56%); mp 81°C (from ether). Infrared (KBr): 3380 cm^{-1} (broad, O-H); ^1H nmr (90 MHz, $CDCl_3$/TMS) δ (ppm): 0.97 (s, $(CH_3)_3C$), 1.18 (s, $(CH_3)_3C$), 1.49–3.23 (m, CH_2-CH_2N), 3.95 and 4.06 (d and d, N-C*H*-Ph), 6.20 (s, very broad, exchangeable, 2 OH), 7.13–7.28 (m, 3 aromatic H), 7.39–7.55 (m, 2 aromatic H). Anal. calcd. for $C_{17}H_{30}N_2O_2$: C 69.35, H 10.27, N 9.51; found: C 69.37, H 10.30, N 9.51.

N,N′-*Di*-tert-*butyl*-N,N′-*dihydroxypropane-1,3-diamine* (O-B) *ethoxydiphenylborane*, **5**a

2*a* (0.22 g, 1 mmol) is dissolved in 1 mL of absolute ethanol and mixed, stirring continuously, with a solution of oxybis(diphenylborane) (0.17 g, 0.5 mmol) in 0.5 mL of ethanol. The reaction mixture is cooled to −18°C for 24 h, and the precipitate is recrystallized from ethanol. Yield: 0.30 g (70%); mp 74°C (from ethanol). Infrared (KBr): 3570 (sharp, O-H/N-H), 3460 and 3210 cm^{-1} (broadened, O-H/N-H); ^1H nmr (DMSO-d_6/TMS) δ (ppm): 1.01 (s, 2 $(CH_3)_3C$), 1.09 (t, CH_3CH_2), 1.51–1.88 (m, C-CH_2-C), 2.42–2.65 (m, 2 CH_2N), 3.35–3.65 (m, CH_2CH_3), 4.25 and 6.92 (s and s, broad exchangeable, OH and NH), 7.09–7.72 (m, 2 C_6H_5). Anal. calcd. for $C_{25}H_{41}BN_2O_3$: C 70.09, H 9.65, B 2.52, N 6.54; found: C 69.89, H 9.68, B 2.57, N 6.40.

Crystals suitable for X-ray analysis were obtained by recrystallization from absolute ethanol.

N^1,N^2-*Di*-tert-*butyl*-N^1,N^2-*dihydroxy-1-phenylpropane-1,3-diamine* (N^2-O-B) *hydroxydiphenylborane*, **5**b

2*b* (0.59 g, 2 mmol) in 2 mL of ethanol and oxybis(diphenylborane) (0.35 g, 1 mmol) in 1 mL of ethanol are reacted as described above. Yield: 0.59 g (62%); mp 105–107°C (from benzene).[4] Infrared (KBr): 3650 (sharp, O-H/N-H), 3250 cm^{-1} (broadened, O-H/N-H); ^1H nmr (DMSO-d_6/TMS) δ (ppm): 0.90 (s, $(CH_3)_3C$), 1.00 (s, $(CH_3)_3C$), 1.68–1.88 and 2.06–2.24 (m and m, C-CH_2-C), 2.39–2.68 (m, CH_2N), 3.89–4.13 (m, N-C*H*-Ph), 7.12–7.79 (m, 3 C_6H_5, 2 OH, NH). Anal. calcd. for $C_{29}H_{41}BN_2O_3$: C 73.10, H 8.67, N 5.88; found: C 73.05, H 8.66, N 5.69.

[4]Recrystallization of **5***b* from ethanol yielded an unstable compound (mp 101–102°C, dec.) whose elemental analysis and ^1H nmr spectrum suggest the incorporation of 1 mol of ethanol, analogous to **5***a*.

[a]Temperature 294 K, Rigaku AFC6S diffractometer, Cu-K$_\alpha$ radiation (λ = 1.54178 Å), graphite monochromator, takeoff angle 6.0°, aperture 6.0 × 6.0 mm at a distance of 285 mm from the crystal, stationary background counts at each end of the scan (scan/background time ratio 2:1), $\sigma^2(F^2) = [S^2(C + 4B) + (0.03F^2)^2]/Lp^2$ (S = scan rate, C = scan count, B = normalized background count), function minimized $\Sigma w(|F_o|-|F_c|)^2$ where $w = 4F_o^2/\sigma^2(F_o^2)$, $R = \Sigma||F_o|-|F_c||/\Sigma|F_o|$, $R_w = (\Sigma w(|F_o|-|F_c|)^2/\Sigma w|F_o|^2)^{1/2}$ and gof = $[\Sigma w(|F_o|-|F_c|)^2/(m-n])^{1/2}$. Values given for R, R_w, and gof are based on those reflections with $I \geq 3\sigma(I)$.

Crystals suitable for X-ray analysis were obtained by recrystallization from absolute benzene.

X-ray crystallographic analyses of **5**a and **5**b

Crystallographic data for the two complexes appear in Table 1. The final unit-cell parameters were obtained by least squares on the setting angles for 25 reflections with 2θ = 55.0–78.5° for **5***a* and 45.5–64.5° for **5***b*. Although the β angle for compound **5***b* (90.02(2)°) suggests an orthorhombic unit cell, a check of the Laue symmetry clearly indicated monoclinic rather than orthorhombic symmetry. The intensities of three standard reflections, measured every 200 reflections throughout the data collections, showed linear decays of 15.0% for **5***a* and 6.9% for **5***b*. The data were processed,[5] and corrected for Lorentz and polarization effects, decay, and absorption (empirical, based on azimuthal scans for four reflections).

The structure analysis of **5***a* was initiated in the centrosymmetric space group $C2/c$ on the basis of E-statistics, this choice being confirmed by subsequent calculations. The structures were solved by direct methods, the coordinates of the non-hydrogen atoms being determined from E-maps or from subsequent difference Fourier syntheses. The non-hydrogen atoms were refined with anisotropic thermal parameters, OH and NH hydrogen atoms were refined with isotropic thermal parameters, and carbon-bound hydrogen atoms were fixed in idealized positions (C—H = 0.98 Å, B_H = 1.2 $B_{bonded\ atom}$). Neutral atom scattering factors and anomalous dispersion corrections for the non-hydrogen atoms were taken from the *International tables for X-ray crystallography* (4). Final atomic coordinates and equivalent isotropic thermal parameters, bond lengths, and bond angles appear in Tables 2–4, respectively. Hydrogen atom parameters, anisotropic thermal parameters, torsion angles, intermolecular contacts, and least-squares planes, and measured and calculated structure factor amplitudes for the both structures are available as supplementary material.[6]

[5]TEXSAN/TEXRAY structure analysis package which includes versions of the following: DIRDIF, direct methods for difference structures, by P. T. Beurskens; ORFLS, full-matrix least-squares, and ORFFE, function and errors, by W. R. Busing, K. O. Martin, and H. A. Levy; ORTEP II, illustrations, by C. K. Johnson.

[6]Supplementary material mentioned in the text may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0R6.

Tables of hydrogen atom parameters and inter- and intramolecular contacts involving hydrogen have also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 11 Union Road, Cambridge CB2 1EZ U.K.

Results and discussion

The X-ray analyses confirm the suggested constitutions **5a** and **5b**, respectively, for the crystalline adducts (see Fig. 1). In both compounds one of the hydroxylamine groups coordinates the borinic acid derivative via the oxygen atom. This results in a *B,N*-betainic complex structure similar to those reported for the related hydroxylamine-boron adducts **8** (5) and **9** (3). In compounds **8** and **9** the hydroxylamine-boron

(*O-B*) adducts are stabilized by hydrogen bonding involving the quaternized nitrogen atoms: intramolecular in **8**, and intermolecular (to form dimers) in **9**, at least in the solid state. In compounds **5***a* and **5***b*, stabilization is achieved by the formation of three intramolecular hydrogen bonds (cf. the general formula **7**) resulting in a basic skeletal structure that is geometrically similar in the two derivatives. The manifold intramolecular hydrogen bonding is a consequence of the polyfunctionality of this type of compound, containing five nucleophilic centres available for interaction with the acidic functions within the same molecule. The O—H···O hydrogen bonds are strongest in both compounds (O(2)—H···O(3), O—H = 1.07(5) and 0.92(3), H···O = 1.65(5) and 1.76(3), O···O = 2.703(3) and 2.674(2) Å, O—H···O = 167(4) and 170(2)°, respectively for **5***a* and **5***b*), the N—H···O interactions are of intermediate strength (N(1)—

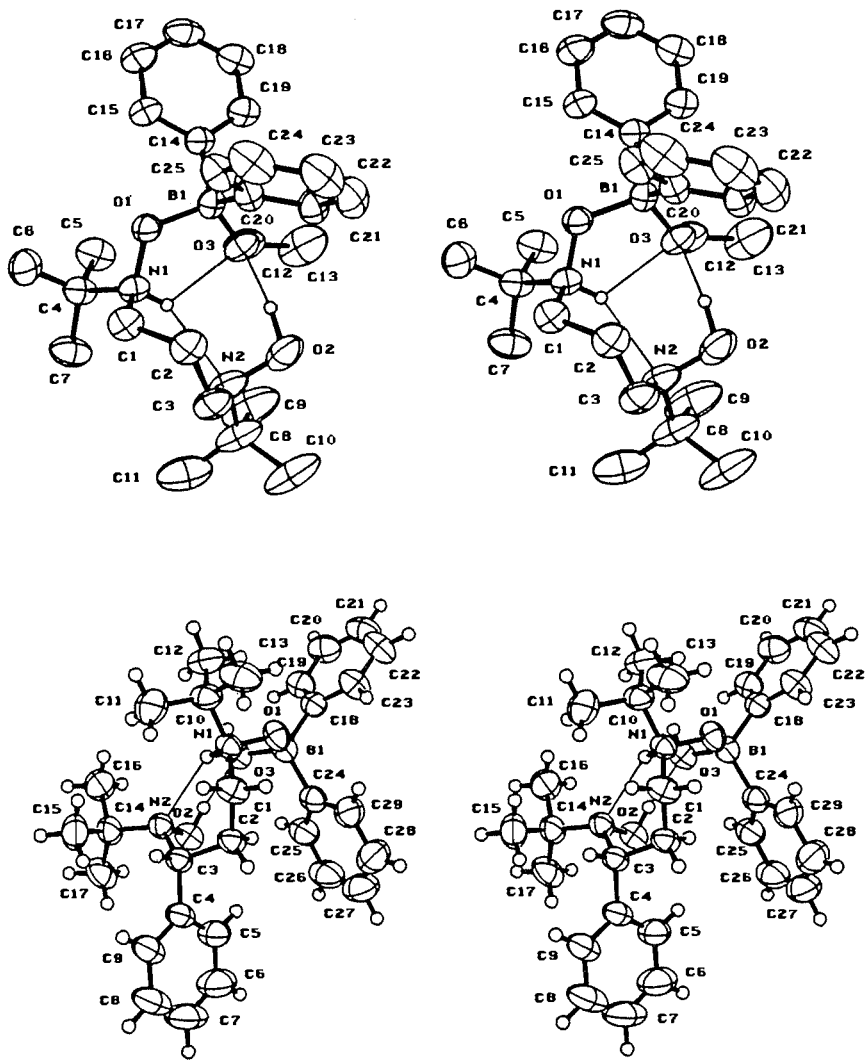

FIG. 1. Stereoviews of **5***a* (top) and **5***b* (bottom); 33% probability thermal ellipsoids are shown for the non-hydrogen atoms.

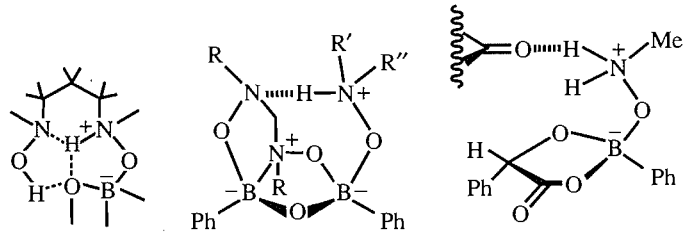
H···O(3), N—H = 0.93(2) and 0.97(2), H···O = 2.20(3) and 2.13(2), N···O = 2.752(3) and 2.702(2) Å, N—H···O = 117(2) and 116(2)°), while the N—H···N interactions are weakest (N(1)—H···N(2), N—H = 0.93(2) and 0.97(2), H···N = 2.29(3) and 2.30(2), N···N = 3.024(4) and 3.054(2) Å, N—H···N = 135(2) and 133(2)°). The intramolecular hydrogen-bonding system in each compound contains a bifurcation at the N(1)-positioned proton (H(2) in **5***a*, H(3) in **5***b*) that interacts simultaneously with both O(3) and N(2); the oxygen atom O(3) accepts two hydrogen atoms (H(1) and H(2) in **5***a*, H(1) and H(3) in **5***b*).



7 **8** **9**

The 1,3-diamine moieties of both molecules are cyclized by the hydrogen bridges to form six-membered proton chelates C(1)—N(1)—H···N(2)—C(3)—C(2). These rings have distorted "envelope"-like conformations with C(2) on the flap in both compounds. All of the *tert*-butyl groups in **5***a* and **5***b*, and the phenyl substituent in **5***b*, occupy (pseudo)equatorial positions, while the oxygen atoms O(1) and O(2) both occupy (pseudo)axial positions with respect to these proton chelate rings. Thus the two fused five-membered ring systems, also formed by hydrogen bonds (H···O—B—O—N and H···O···H—O—N), are connected (pseudo)axially to the six-membered ring system of the 1,3-diamine moiety in both compounds.

Bonds lengths are similar in the two derivatives **5***a* and **5***b* (see Table 3). A significant difference is noted for the B(1)—O(3) bond: in **5***a* this bond is 0.018(4) Å shorter than that in **5***b* reflecting the increased nucleophilicity of the EtO^- ligand in **5***a* relative to that of the HO^- ligand in **5***b*. This influence also manifests itself in the O(3)···H(1) distance, which is nearly 0.1 Å shorter in **5***a* than in **5***b*. Not surprisingly, the phenyl substituent at C(3) in compound **5***b* causes

lengthening of the adjacent bonds relative to those in **5***a*: C(3)—C(2) and C(3)—N(2) = 1.512(4) and 1.464(4) Å for **5***a*, 1.533(3) and 1.486(2) Å for **5***b*. In both of the compounds the N—O bonds at the quaternized nitrogen atom N(1) (1.401(3) and 1.407(2) Å) are about 0.05 Å shorter than those at the trivalent nitrogen N(2) (1.456(4) and 1.451(2) Å). Correspondingly, the N—C bonds at N(1) are about 0.04 Å longer than those at N(2) in both compounds. The geminal *B*-phenyl groups of both **5***a* and **5***b* show nearly equal B—C bond lengths, averaging 1.614 Å in the former and 1.619 Å in the latter. These B—C distances can be compared to the mean values of 1.624 Å in **4** (2), 1.600 Å in compounds of the type **8** (5), 1.589 Å in **9** (3), and similar values reported for other diphenylboron chelates (6–11). The (N)O—B distances (O(1)—B(1) = 1.558(3) and 1.562(2) Å for **5***a* and **5***b*, respectively) are longer than the corresponding bonds in other hydroxylamine(*O-B*)boron complexes such as **8** (average 1.509 Å) (5) or **9** (average 1.494 Å) (3), but resemble the O—B bond lengths in diphenylboron chelates of hydroxylamine derivatives like **4** (2) and other related compounds (6–11) having cyclic $^{+}$N—O—B^{-} betaine structures.

The tetracoordination at B(1) arising from the adduct formation causes, as expected, rehybridization of the trigonal planar (sp^2) boron atom in diphenylborinic acid (12) to a tetrahedral sp^3 boron atom in both the diphenylborinic ester complex **5***a* and the diphenylborinic acid complex **5***b*. Associated with this rehybridization is the usual lengthening of both the B—C and O—B bonds.

Reactions of *N*-formylmorpholine/$POCl_3$ with several unactivated olefins yield the corresponding α,β-unsaturated aldehydes. Norbornene affords with dimethylformamide/$POCl_3$ a product formed by a novel inverse-electron demand Diels–Alder reaction of an acyclic 2-azoniodiene. The structure of this product was confirmed by X-ray analysis. Crystals are monoclinic: a = 8.025(3), b = 11.670(3), c = 9.309(4) Å, β = 108.03(3)°, $P2_1$,Z = 2; the structure was refined to R = 0.044 for 1379 independent observed reflections.

ALAN R. KATRITZKY, IRINA V. SHCHERBAKOVA, ROBERT D. TACK et PETER J. STEEL. Can. J. Chem. **70**, 2040 (1992).

Les réactions du couple *N*-formylmorpholine/$POCl_3$ avec plusieurs oléfines inactives fournit les aldéhydes α,β-insaturés correspondants. Le norbornène qui réagit avec le couple diméthylformamide/$POCl_3$ par une nouvelle réaction de Diels–Alder comportant une demande inverse d'électrons fournit un 2-azoniodiène acyclique dont on a déterminé la structure par diffraction des rayons-X. Les cristaux sont monocliniques, groupe d'espace $P2_1$, avec a = 8,025(3), b = 11,670(3) et c = 9,309(4) Å, β = 108,03(3)° et Z = 2; on a affiné la structure jusqu'à une valeur de R = 0,044 pour 1379 réflexions indépendantes observées.

Introduction

Vilsmeier reagents have been used for the formylation of aromatic secondary and tertiary amines (1, 2), and applied in numerous synthetic transformations of carbonyl compounds to give β-chlorovinylaldehydes (3, 4) and derived cyanines (5, 6). Both vinyl ketones (7, 8) on the one hand and olefinic systems activated towards electrophilic attack (vinyl ethers (9), vinylamines (10), and vinyl halides (11)) on the other have all been thus employed. Terminal olefins and 1,1-disubstituted ethylenes can also be formylated; however, for these compounds further reactions often take place and the nature of the product depends on the environment of the vinyl or vinylidine group. Methylenecyclohexane consumed 2 mol of the Vilsmeier reagent to produce 1-dimethylamino-3-dimethylimmonio-2-[cyclohexen-1-yl]prop-1-ene, isolated as the perchlorate (12). 2-Methylenebornane underwent triformylation and subsequent transformation to furnish a formylpyridine derivative (12). Similarly, isobutene and 2-phenylpropene afford 2,7-naphthyridine-4-aldehyde and 4-phenylpyridine-3-aldehyde, respectively, each involving triformylation (13). However, in terminal olefins and 1,1-disubstituted ethylenes in which migration of the double bond to the adjacent position is blocked, Vilsmeier reactions favour monoformylation. Thus, camphene or 1,1,2,3,5,6-hexamethyl-4-methylene cyclohexa-2,5-diene (13) undergo monoformylation to α,β-unsaturated aldehydes. The monoformylation of steroids having an exocyclic methylene group (12, 14) is known. Monoformylation (40% yield) of a nonexocyclic methylene group in limonene along with isomerization to terpinolene (37% yield) was reported (15). Mono-, bi-, and tri-formylations of vinylcyclopropane derivatives have been intensively studied (16, 17). The present paper is concerned with a more general procedure for the preparation of α,β-unsaturated aldehydes by the monoformylation of unactivated olefins with an excess of the Vilsmeier reagent. We also describe an interesting example of a hetero Diels–Alder reaction of novel type under conditions of the Vilsmeier reaction: the course of the last transformation was supported by an X-ray analysis of the product.

Results and discussion

α,β-Unsaturated aldehydes are important in synthetic organic chemistry (18) and previous preparations include: (*i*) from ketones by one-carbon homologation procedures (19, 20); (*ii*) from methyl vinyl ethers by photooxidation (18); (*iii*) from aldehydes via organolithium derivatives (20, 22–24) or by oxidation via α-chloroaldimines (18); (*iv*) from α-bromoaldehydes via *N*,*N*-dimethylhydrazones (25) or piperidine enamines (26); (*v*) from α-lithiated allenic sulfides (27); and (*vi*) a single example (for 1-cyclohexenecarboxaldehyde) from a nitromethylolefin (28).

We now report that the Vilsmeier reagent *N*-formylmorpholine/phosphorus oxychloride, previously applied to the formylation of vinyl ketones (8), readily converts the unactivated olefines **1**, **3**, **4**, and **6** into the α,β-unsaturated aldehydes **2**, **5**, and **7** (Scheme 1). However, two alternative Vilsmeier reagents (dimethylformamide/phosphorus oxychloride or *N*-formylmethylaniline/phosphorus oxychloride) failed to effect these transformations, although they had earlier (12, 13) successfully monoformylated exocyclic methylene groups in hydrocarbons.

The present reactions were conducted in trichloroethyl-

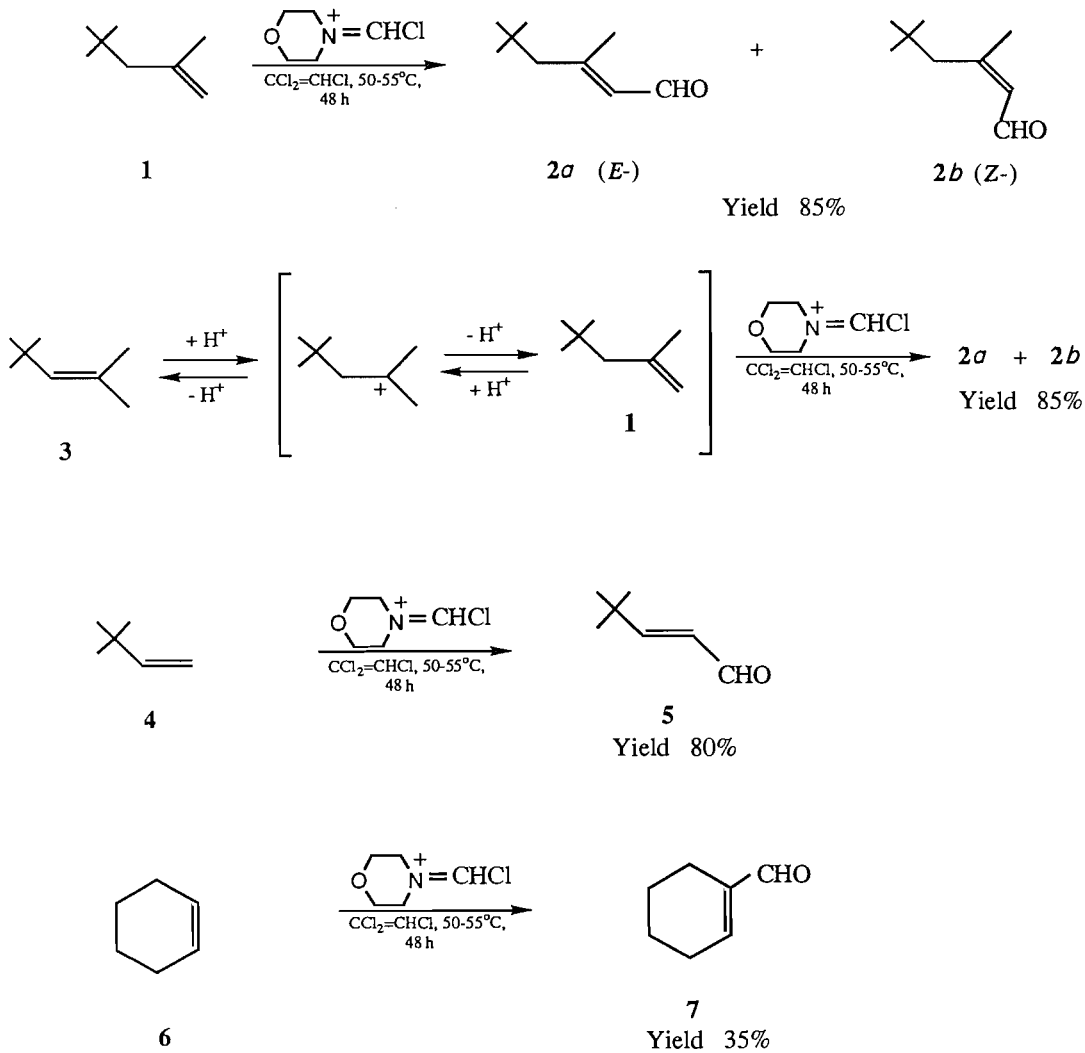

SCHEME 1

ene solution at 50°C for 48 h. Olefin, *N*-formylmorpholine, and $POCl_3$ were used in a molar ratio of 1:2.5:1.5, and the yields of aldehydes **2**, **5**, and **7** were 85, 80, and 35% respectively. When the reaction was carried out at 70–80°C for 24 hs, the yields of aldehydes **2** and **5** decreased somewhere to 60–70%, and cyclohexene gave a low yield of aldehyde **7** (15%). Interestingly, the use of stoichiometric amounts of 2,4,4-trimethylpent-1-ene (**1**), *N*-formylmorpholine, and $POCl_3$ in the absence of solvent at 80°C for 12 h yielded 55% of the corresponding aldehyde **2**.

The formylations of 2,4,4-trimethylpent-1-ene (**1**) and the -2-ene (**3**) both yield mixtures of the *E*-(**2***a*) and the *Z*-(**2***b*) isomers. The ^1H nmr integrals and the gc data show an approximate ratio of 2:1 for the isomers. The spectroscopic assignments are presented in Table 1. The preparation of 3,5,5-trimethyl-2-hexenal **2** as an unseparated mixture of *E*/*Z* isomers in a 7:3 ratio (^1H nmr data) has recently been reported (27). The isomerization of **3** to **1** is easily explained as shown in Scheme 1. Some traces of air moisture can initiate the proton formation. The similar isomerization was observed also for some vinylcyclopropane derivatives on conditions of the Vilsmeier reaction (17) and was explained by the tendency of a double bond to have less steric hindrance. The formylation of 3,3-dimethylbut-1-ene **4** yields only the *E* isomer **5** as is clearly indicated by the coupling constant for the vinyl protons (J = 16 Hz, Table 1). The chemical shifts of the proton and carbon signals in **7** (Table 1) clearly established the structure as 1-cyclohexene carboxaldehyde.

Norbornene **8** did not give the expected aldehyde (21, 29) under the conditions described above. We isolated an unstable colourless viscous oil that decomposed on keeping. The nmr spectra of this oil in $CDCl_3$, recorded immediately after isolation, showed signals for two aldehyde groups at δ 9.85 and 10.15 (^1H nmr) and at 198.50 and 199.15 (^{13}C nmr) and clearly indicated the presence of two bicyclo[2.2.1]heptyl residues. We failed to isolate any solid aldehyde derivative from this oil. Surprisingly, in contrast to its lack of reactivity with olefins **1**, **3**, **4**, and **6**, the use of DMF/$POCl_3$ as a formylating agent was effective for norbornene **8**. Treatment of the hydrolyzed reaction mixture with 70% perchloric acid yielded a stable colourless crystalline perchlorate (85% yield) of such low solubility that nmr spectra could not be obtained. The low resolution mass spectrum gave a molecular ion at m/z 244, and along with the elemental analysis data demonstrated the composition $C_{17}H_{26}N^+ClO_4^-$.

[a]The isomers have not been separated; the mixtures of **2***a* and **2***b* in a ratio of 2:1 were obtained from **1** and **3**.

Structure determination by X-ray crystallography revealed the spiro dimeric azinium salt **11** (Scheme 2 and Fig. 1). The proposed mechanism for the formation of **11** is shown in Scheme 2. The expected intermediate cation **9** is postulated to undergo a thermally allowed suprafacial [1,5]-hydrogen shift to give the isomeric cation **10** which then undergoes Diels–Alder reaction with more norbornene to give **11**. The X-ray structure determination demonstrates that the Diels–Alder reaction occurs in a diastereofacially selective manner on the *exo* face of both diene and dienophile. Diels–Alder reactions with inverse electron demand involving a 2-azoniobutadiene unit as part of a quaternary heteroaromatic ring (30, 31) or of *N*-arylimmonium ions (32) are well recognized, but we have not found any previous example in which the azoniobutadiene unit is acyclic.

The interaction of perchlorate **11** with aqueous alkali solution yields the hydroxide adduct **12** (Scheme 2) which is easily reconverted into **11** by treatment with 70% perchloric acid in ethanol solution. The structure **12** was established on the basis of elemental analysis and its ir spectrum (a hydroxyl band at 3350 cm^{-1}). The electron impact mass spectrum showed self-chemical ionization of the molecular ion to give the cation **11**, whereas the chemical ionization mass spectrum at high resolution gives the molecular ion of **12**. We failed to obtain the nmr spectra of **12** in DMSO-d_6, the only solvent which allows a sufficient concentration. It gives an unstable solution and the compound decomposed before a spectrum could be acquired.

Experimental

Apparatus, materials, and methods

Melting points were determined on a Thomas–Hoover capillary mp apparatus and are uncorrected. ^1H and ^{13}C nmr spectra were recorded on a Varian VXR 300 spectrometer (300 and 75 MHz,

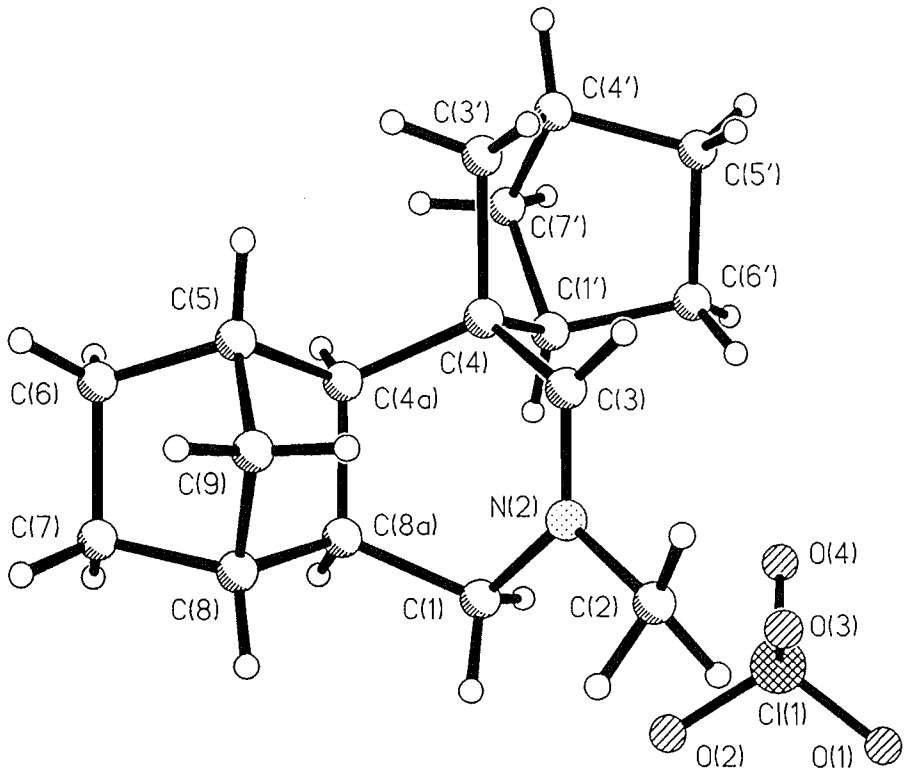

FIG. 1. Perspective view and atom labelling of the X-ray structure.

respectively), using $CDCl_3$ as solvent and tetramethylsilane as an internal reference. Infrared spectra were recorded as neat samples (unless otherwise stated) on a Perkin–Elmer 1600 series FTIR. Mass spectra were recorded on a Krafts AEI MS 30 spectrometer. Elemental analyses were performed on a Carbo Erba 1106 elemental analyser. Commercially available reagent grade solvents were dried over BDH-type 4A molecular sieves prior to use. Flash column chromatography was run over silica gel (EM Merck 60, 230–400 mesh).

X-ray crystallographic analysis

A colorless crystal with approximate dimensions 0.46 × 0.14 × 0.08 mm was cooled to approximately −100°C in a stream of cold nitrogen (controlled boil-off system) in a Nicolet R3/m four-circle diffractometer. Unit cell dimensions were determined by least-squares refinement of 25 accurately centred reflections (2θ = 13–33°). Crystal data are:

$C_{17}H_{26}ClNO_4$ fw = 343.8

Monoclinic, a = 8.025(3), b = 11.670(3), c = 9.309(4), β = 108.03(3), V = 829.0(5), Z = 2, ρ_c = 1.377 Mg m^{-3}, F(000) = 368, μ(Mo-Kα) = 2.47 cm^{-1}, space group $P2_1$.

Intensities were measured using graphite-monochromated Mo-Kα (λ = 0.7107 Å) radiation with ω–2θ scans to 2θ = 60° (±h, +k, +l). The intensities of three check reflections (210, 051, 005), measured every 100 reflections throughout the data collection, showed only small random fluctuations. The data were corrected for Lorentz and polarization effects but no correction for absorption was deemed necessary. Of the 2645 reflections measured, 2511 were unique (R_{int} = 0.020) and 1379 had intensities greater than three times their standard deviations.

The structure was solved[2] by direct methods and refined by full-

[2]All calculations, including the drawing of diagrams, were performed with SHELXTL PC™, Version 4.1 (1990), by G. M. Sheldrick and available from Siemens Analytical X-Ray Instruments Inc. The scattering factors used were those employed by SHELXTL PC™.

matrix least-squares procedures. All non-hydrogen atoms were refined with anisotropic displacement parameters and hydrogen atoms were included in calculated positions (C—H = 0.96 Å) with fixed isotropic parameters (the orientations of the methyl group hydrogens were based on difference map peaks). The function minimized was $\Sigma w(|F_o| - |F_c|)^2$, with $w = [\Sigma^2(F_o)+0.00005F_o^2]^{-1}$. The absolute configuration was deemed to be that which gave the better of two otherwise identical refinements. In the final cycles of refinement the maximum parameter shift corresponded to 0.005 σ. A final difference map showed no features >0.35 e^- Å^{-3}. Refinement converged[3] with $R = 0.044$, $wR = 0.036$ and $S = 1.41$ for the 1379 reflections with $I > 3\sigma(I)$.

The final positional and equivalent isotropic displacement parameters for the non-hydrogen atoms are given in Table 2. Bond lengths and angles are listed in Table 3. Anisotropic displacement parameters and tables of observed and calculated structure factors have been deposited.[4] The bonding geometries at N(2) and C(3) (Table 3) clearly locate the double bond between these two atoms. It is also noteworthy that the bonds to C(4) are somewhat elongated, which reflects the steric congestion about this spiro-center.

[3] $R = \Sigma(|F_o| - |F_c|)/\Sigma|F_o|$; $wR = \{\Sigma w(|F_o| - |F_c|)^2/\Sigma w(|F_o|)^2\}^{1/2}$; $S = \{\Sigma w(|F_o| - |F_c|)^2/n - m\}^{1/2}$.

[4] A complete set of tables may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2.

A table of hydrogen atom coordinates has also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2, 1EZ, U.K.

General procedure for preparation of α,β-unsaturated aldehydes

Freshly distilled phosphorus oxychloride (7.0 g, 45.8 mmol) was added to a stirred mixture of *N*-formylmorpholine (6.9 g, 60 mmol) and trichloroethylene (10 mL) over 5 min at 5°C. After stirring the resultant solution for 10 min at 20°C, the appropriate olefin (24 mmol) was added dropwise at 15–20°C. The mixture was then stirred at 50–55°C for 48 h and cooled. Methylene chloride (25 mL) was added, and the reaction mixture was brought to pH 7 with a solution of sodium carbonate (12.5 g, 0.12 M) in water (75 mL). The aqueous layer was extracted with methylene chloride (3 × 50 mL). The combined organic layers were washed with water (60 mL) and dried over $MgSO_4$. The solvent was removed under vacuum at room temperature and the residue distilled under vacuum or purified by flash column chromatography with ether as eluent. The spectroscopic data of aldehydes **2**, **5**, and **7** are presented in Table 1.

*4-Methyl-4-aziniumtricyclo[6.2.1.0^{2,7}]undec-4-ene-6-spiro-2′-bicyclo[2.2.1]heptane perchlorate (**11**)*

A solution of $POCl_3$ (4.5 mL, 50 mmol) in DMF (5 mL) was slowly added to DMF (10 mL) at 5°C. After stirring the resultant mixture for 5 min at 5°C, a solution of norbornene **8** (4.7 g, 50 mmol) in DMF (5 mL) was added dropwise at 15–20°C. The mixture was stirred at room temperature for 48 h and at 70–80°C for 2 h. The product was poured onto ice (150 g) and treated with 70% perchloric acid (5 mL). The colourless crystalline precipitate was filtered off, dried, and recrystallized from ethanol to give 7.30 g (85%) of **11**, mp 253°C. Anal. calcd. for $C_{17}H_{26}ClNO_4$: C 59.38, H 7.52, N 4.00; found: C 59.38, H 7.82, N 3.63.

*4-Methyl-4-aza-5-hydroxytricyclo[6.2.1.0^{2,7}]undecan-6-spiro-2′-bicyclo[2.2.1]heptane (**12**)*

A suspension of perchlorate **11** (0.34 g, 0.001 M) in 25% aqueous NaOH solution (10 mL) and ether (10 mL) was stirred for

Received August 26, 1991[3]

LUIS F. SALA, SANDRA R. SIGNORELLA, MARCELA RIZZOTTO, MARÍA I. FRASCAROLI, and FABIO GANDOLFO. Can. J. Chem. **70**, 2046 (1992).

The oxidation of L-rhamnose and D-mannose by Cr(VI) in perchloric acid follows the rate law:

$$-\frac{d[Cr(VI)]}{dt} = \frac{(k_0 + k_1 [h_0]^2) K [\text{aldose}] [Cr(VI)]}{1 + K [\text{aldose}]}$$

$K = 5.40$, $k_0 = 0.00138\ M^{-1}\ s^{-1}$, $k_1 = 6.71 \times 10^{-4}\ M^{-3}\ s^{-1}$ for D-mannose and $K = 2.63$, $k_0 = 2.51 \times 10^{-3}\ M^{-1}\ s^{-1}$, $k_1 = 2.74 \times 10^{-3}\ M^{-3}\ s^{-1}$ for L-rhamnose. This rate law corresponds to the reaction leading to the formation of L-1,4-rhamnonelactone and D-1,4-mannonelactone. No cleavage to carbon dioxide takes place when a 20-fold or higher excess of aldose over Cr(VI) is employed. Relative values of kinetic constants are interpreted in terms of primary hydroxyl group participation in the chromic ester formed in the first reaction step. The free radicals formed during the reaction react with Cr(VI) to yield Cr(V). Two signals ($g_{iso} = 1.977$ and $g_{iso} = 1.970$) ascribed to intermediate Cr(V) complexes were observed by electron paramagnetic resonance (epr) of 0.25–1 N $HClO_4$ solutions saturated with L-rhamnose and $Cr_2O_7^{2-}$. At higher pH (3–7), only the signal at $g = 1.977$ was detected. For D-mannose only one signal at $g = 1.978$ was observed over the whole range of $HClO_4$ concentrations.

LUIS F. SALA, SANDRA R. SIGNORELLA, MARCELA RIZZOTTO, MARÍA I. FRASCAROLI et FABIO GANDOLFO. Can. J. Chem. **70**, 2046 (1992).

L'oxydation du L-rhamnose et du D-mannose par le Cr(VI), dans l'acide perchlorique, suit l'équation de vitesse suivante :

$$-\frac{d[Cr(VI)]}{dt} = \frac{(k_0 + k_1 [h_0]^2) K [\text{aldose}] [Cr(VI)]}{1 + K [\text{aldose}]}$$

dans laquelle $K = 5{,}40$, $k_0 = 0{,}00138\ M^{-1}\ s^{-1}$, $k_1 = 6{,}71 \times 10^{-4}\ M^{-3}\ s^{-1}$ pour le D-mannose et $K = 2{,}63$, $k_0 = 2{,}51 \times 10^{-3}\ M^{-1}\ s^{-1}$, $k_1 = 2{,}74 \times 10^{-4}\ M^{-3}\ s^{-1}$ pour le L-rhamnose. Cette équation de vitesse correspond à la réaction conduisant à la formation de la L-1,4-rhamnonelactone et de la D-1,4-mannonelactone. Il ne se produit pas de clivage en dioxyde de carbone lorsque la quantité d'aldose utilisée dépasse de 20 fois ou plus la quantité de Cr(VI). On interprète les valeurs relatives des constantes cinétiques en fonction d'une participation du groupe hydroxyle primaire dans l'ester chromique qui se forme au cours de la première étape de la réaction. Les radicaux libres qui se forment au cours de la réaction réagissent avec le Cr(VI) pour former du Cr(V). On attribue deux signaux ($g_{iso} = 1{,}977$ et $g_{iso} = 1{,}970$) observés par resonance paramagnétique électronique (rpe) sur des solutions de 0,25 à 1 N de $HClO_4$ saturées en L-rhamnose et en $Cr_2O_7^{2-}$, aux complexes du Cr(V) intermédiaire. À des pH supérieurs (3–7), on n'a détecté que le signal à $g = 1{,}977$. Pour le D-mannose, on n'observe que le signal à $g = 1{,}978$ à toutes les concentrations de $HClO_4$.

[Traduit par la rédaction]

Introduction

Sugars are very attractive natural ligands for both toxic and essential metal ions. Besides acting simply as effective chelators (1), in many cases they are also reducing agents; e.g., for metal ions such as Ce(IV), V(V), Co(III), Fe(III) (refs. 2, 3, 4, 5 respectively), depending on the acidity of the medium. There is also an indication that some sugars, or their derivatives, may play an important role in the chemistry of chromium, specially in the environment (6–8), where Cr(VI) may present a serious hazard because of its mutagenic and carcinogenic activity. It has recently been reported that the major coordination sites involved in chromium binding in natural systems may be the hydroxyl (e.g., nucleic acids, polysaccharides) and thiol (in peptides and proteins) donors (9). They form stable esters or thioesters with chromate and stabilize Cr(V) intermediates after further interaction with biological reductants such as glutathione.

It was considered worthwhile to revise the degradative oxidation of aldoses by action of Cr(VI) (10–15) in order to determine: (*a*) the extension of ester chromate formation; (*b*) the detection of Cr(V) (not yet reported for the oxidation of aldoses); (*c*) the availability of the hydroxyl groups to bind Cr(VI).

We started by studying the degradative oxidation of two aldohexoses: L-rhamnose and D-mannose.

Experimental

L-Rhamnose and D-Mannose (Sigma pure) were used without further purification. Potassium dichromate (BDH reagent) was used for the kinetic runs, while the sodium salt (BDH reagent) was used for the products analysis, where the high concentrations cause precipitation of potassium perchlorate. Mixtures of sodium perchlorate (Aldrich puriss.) and perchloric acid (Merck reagent) were used to maintain a constant ionic strength of 2.0 M at different hydrogen ion concentrations. Stock solutions of perchloric acid were analyzed by titration employing standard analytical methods (16).

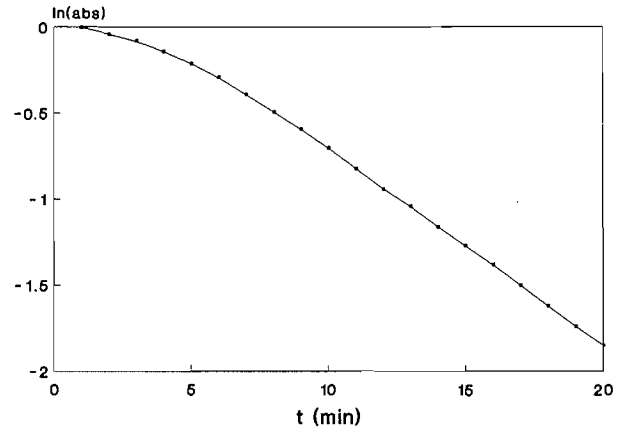

FIG. 1. Time dependence of ln(abs) at 350 nm. T = 33°C; [Cr(VI)] = 0.0008 M, [rhamnose] = 0.016 M, [$HClO_4$] = 1.75 M; I = 2.0 M.

Kinetics

Kinetic measurements were made at 350 nm by monitoring the absorbance changes on a Guilford Response II spectrophotometer with fully thermostated cell compartments. The concentration of Cr(VI) was kept constant at a 8×10^{-4} M, while the aldose concentrations were varied between 0.016 and 0.16 M (0.28 M in some cases), at a constant ionic strength of 2.0 M.

For both D-mannose and L-rhamnose, pseudo-first-order rate constants were calculated from the slopes of the linear part of the ln(abs) vs. time plots (Fig. 1). Rate constants obtained from multiple determinations were within ±5% of each other.

Products analysis

The stoichiometry of the chromic oxidation of L-rhamnose and D-mannose was determined by mixing chromic acid and aldose solutions to final concentrations of 0.112 M and 0.0158 M respectively, in 2 N $HClO_4$ at 80°C, during 2 days. After the reaction went to completion, yield of carbon dioxide per mole of aldose was determined as follows.

A slow stream of pure nitrogen was flushed through the reaction mixture to sweep the carbon dioxide formed into a barium hydroxide solution. The barium carbonate was filtered and the filtrate titrated against standard potassium hydrogen phthalate. The molar amount of barium hydroxide consumed and the barium carbonate weighed were always the same. On successive experiments carbon dioxide was also trapped in a sodium hydroxide solution of known titre and back-titrated, obtaining the same yield of carbon dioxide as by the previous method.

In this way, 4 moles of CO_2 were produced per mole of L-rhamnose and 6 moles of CO_2 per mole of D-mannose.

The amount of reacted Cr(VI) was determined spectrophotometrically. Six moles of Cr(VI) were consumed per mole of L-rhamnose, while 3 moles of D-mannose consumed 22 moles of Cr(VI).

From these experimental data, the stoichiometry for total oxidative degradation of L-rhamnose and D-mannose by Cr(VI) is:

$$[1] \quad C_6O_5H_{12} + 6Cr(VI) \rightarrow 4CO_2 + CH_3COOH + 6Cr(III)$$

$$[2] \quad 3C_6O_6H_{12} + 22Cr(VI) \rightarrow 18CO_2 + 22Cr(III)$$

Under conditions used in the kinetic measurements CO_2 was never detected. In excess of substrate (ratios of aldose over Cr(VI) from 20 to 200), qualitative identification of reaction products was carried out by paper chromatography. L-1,4-Rhamnonelactone and D-1,4-mannonelactone were identified against authentic samples, using *n*-butanol – acetic acid – water (4:1:5) as eluent. Paper chromatograms were visualized by two kinds of development reagents: a three-stage dip of silver nitrate, sodium hydroxide, and sodium thiosulfate (17) and *p*-anisidine reagent, specific for aldoses detection (18).

The EPR measurements

The epr spectra were recorded with a Bruker spectrometer model ER-200. g values were measured by refence to diphenylpicrylhydracyl (DPPH, g = 2.0036). Spectra were acquired at a frequency of ca. 9.8 GHz with a center field of 3550 G, a sweep width of 20–1000 G, and a variable modulation amplitude. The cavity and sample tube were kept at 25°C. 0.25–1 N $HClO_4$ solutions saturated with $Cr_2O_7^{2-}$ were used for Cr(V) detection. Under these experimental conditions the reaction went to completion in ca. 30 h, but Cr(V) could be followed during no longer than 30 min.

Results and discussion

Kinetic results

The observed rate constants were deduced from absorbance data obtained at 350 nm. The pseudo-first-order rate constants were calculated at various $[Cr(VI)]_0$ but at constant $[aldose]_0$, ionic strength (I = 2 N), and temperature. The rate was found to increase with increase in $[Cr(VI)]_0$. The values of k_{obs} $[Cr(VI)]_0/[Cr_2O_7^{2-}]$ at various $[Cr(VI)]_0$ were calculated at 35°C. The results (Table 1) indicate that the dimeric species, viz. $Cr_2O_7^{2-}$ is the effective oxidant. The equilibrium $HCrO_4^-/Cr_2O_7^{2-}$ (K = 76 (19)) was used to calculate $[Cr_2O_7^{2-}]$, neglecting the subsidiary equilibrium $HCrO_4^-/CrO_4^{2-}$ because of the high [$HClO_4$] employed. Table 2 summarizes values of k_{obs} for various concentrations of aldoses at fixed concentrations of perchloric acid. Plots of $1/k_{obs}$ vs. 1/[aldose], for both L-rhamnose and D-mannose, are given in Figs. 2 and 3. Effect of the aldose concentration on k_{obs} can be written as:

$$[3] \quad k_{obs} = \frac{kK\,[\text{aldose}]}{1 + K\,[\text{aldose}]}$$

Values of k and K for different perchloric acid concentrations are given in Table 3. It is observed that while K is clearly acidity independent over the whole range of hydrogen ion concentrations, k varies with acidity between 0.5 M and 2.0 M. Due to the high acidities employed in this study, the concentration of hydrogen ions was replaced by the acidity function h_0 (20). Plots of k vs. h_0^2 give straight lines with a positive intercept (Fig. 4) for both L-rhamnose and D-

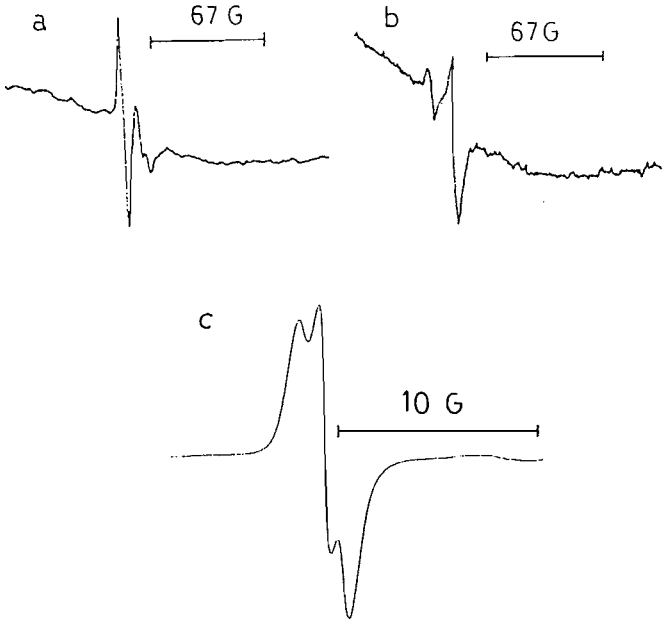

FIG. 5. The epr signal of a mixture of L-rhamnose and Cr(VI) (10:1 mole ratio) in $HClO_4$ (a) 0.25 N, 5 min after solution preparation; (b) 1 N, 3 min after mixing; and (c) 0.01 N, 3 h after solution preparation. T = 25°C.

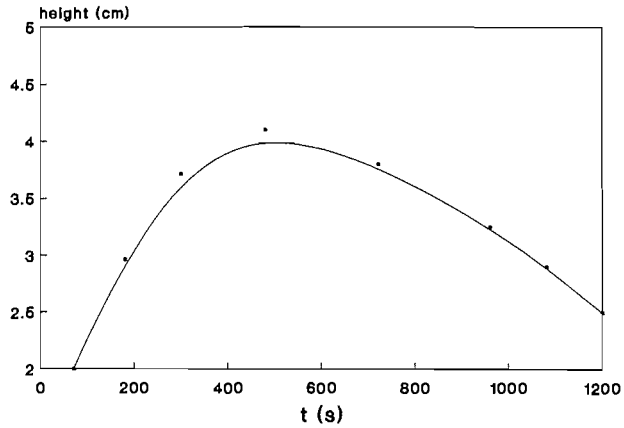

FIG. 6. Peak-to-peak heights of epr signal due to Cr(V) at g = 1.977 vs. time. $[HClO_4]$ = 0.25 N, [Cr(VI)] = 0.34 M, [rhamnose] = 0.77 M; T = 25°C.

observed does not necessarily mean that they are not present. All it means is that the sensivity of the instrumentation used was not sufficient to detect them, if they were present. Given the high concentrations of chromium that were required to detect the signals in other experiments, we believe that it is highly likely that Cr(V) signals are present in all of the experiments, but that they were not detected due to sensitivity problems of the measurements. When aldose and Cr(VI) saturated solutions were used, two different patterns of signals were observed for L-rhamnose–Cr(V) and D-mannose–Cr(V) complexes. Figure 5 shows the epr spectrum of an aqueous solution of Cr(VI) and rhamnose in 10:1 mole ratio in 0.25 N $HClO_4$. This spectrum was measured 5 min after solution preparation. The spectrum is dominated by a band at g_{iso} = 1.977, with its four weak ^{53}Cr (9.55% abundance, I = 3/2) hyperfine bands at 17.8 G spacing, and a superhyperfine (shf) splitting value of 0.90 G. The shf pattern clearly indicates that the Cr(V) ion coordinates to one sugar molecule via two hydroxyl oxygens and that the shf structure derives from the coupling with the two protons bound to the carbons. At this $[HClO_4]$ a minor band (g_{iso} = 1.970) is observed.

As the rhamnose:Cr(VI) ratio was decreased (10:1 to 1:1), the signal at g = 1.977 was always the major one. Both signals decayed with time, but the major band decayed faster than the band at g = 1.970.

Variation of the solution pH within the range 3–7 afforded the signal at g = 1.977, which remains during ca. 1 week. However, extra bands were not detected, even when different rhamnose:Cr(VI) mole ratios were used (Fig. 5).

In the range of 0.25–1 N $[HClO_4]$ the signal at g = 1.970 grew and became the dominant feature (Fig. 5).

These results show that interaction of L-rhamnose and Cr(VI) in perchloric acid solution produces at least two relatively long-lived Cr(V) species, characterized by their epr bands at g = 1.977 and g = 1.970, with the latter being strongly dependent upon $[HClO_4]$.

g_{iso} = 1.977 and A_{iso} = 17.8 are typical of five-coordinate oxochromate(V) complexes (21, 22) and the structure of this complex is most likely a square-pyramidal $[Cr{=}O]^{3+}$ species with the molecule of aldohexose bound in bidentate fashion through two *syn*-hydroxyl groups. Analysis of the signal at g = 1.970 is very difficult because of the low intensity of this signal and its badly resolved superhyperfine structure.

Figure 6 shows a typical growth and decay curve for peak-to-peak heights of the Cr(V) epr signal at g = 1.977 vs. time, obtained on a reacting solution. This signal grows and decays in a very short time (t_{max} = 8 min). This means that at high hydrogen ion concentrations the L-rhamnose/Cr(V) complex behaves like stationary stage that decomposes as it is formed.

An epr signal (g = 1.978) assigned to the Cr(V)–D-mannose complex has already been reported for the Cr(VI)/D-mannose reaction mixture at pH = 7.4 (23). We observed this signal in 0.25 N $HClO_4$ solution saturated with reactants, and, unlike L-rhamnose, no other signal was detected. This complex had been ascribed to Cr(V) coordinated to one sugar molecule via the two hydroxyl oxygens at C2 and C3. We propose a different structure for this species observed in the reaction of Cr(VI) with D-mannose. D-Mannose differs from L-rhamnose in the C6 hydroxyl group, so a different behavior in forming complexes with Cr(V) could be related to this structural difference. Examination of CPK models showed that, if the sugar is in the boat conformation, spatial disposition of hydroxyl groups on C1, C2, and C6 is appropriate to form a square-pyramidal $[Cr{=}O]^{3+}$ complex bound to the D-mannose, acting as tridentate ligand, and a water molecule in the fourth site of coordination. This structure seems to better reflect the formation of only one Cr(V) complex, such as proposed in Fig. 7, and it should be considered as a tentative hypothesis.

Mechanism

The observed deviation from first-order decay of ln(abs) at 350 nm at short times (Fig. 1) has already been observed in other systems where Cr(V) was detected (24). However,

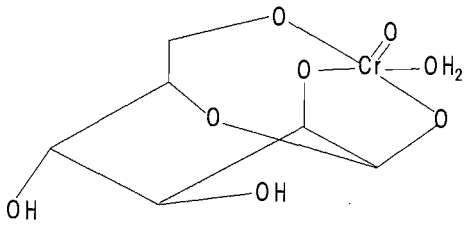

FIG. 7. Proposed structure for Cr(V)/mannose complex.

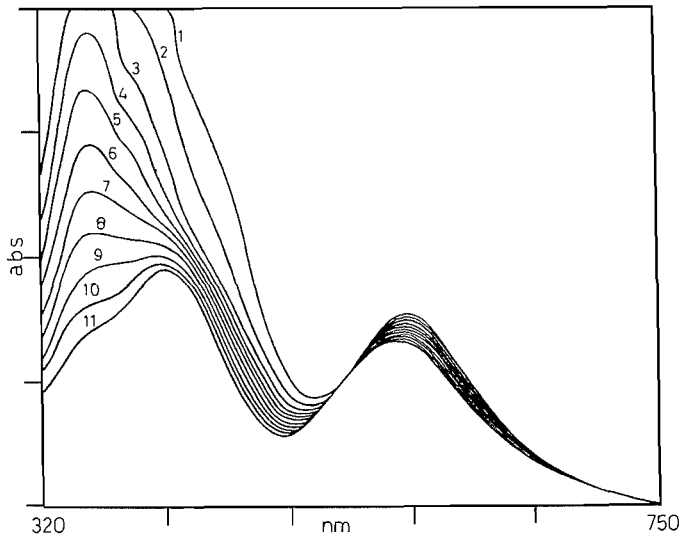

FIG. 8. Time evolution of UV/VIS spectrum of a mixture of D-mannose (0.18 M) and Cr(VI) (0.018 M). $[HClO_4]$ = 0.55 M; T = 30°C. Spectra 1–11 represent measurements taken over a period of ca. 70 min.

neither L-rhamnose nor D-mannose forms Cr(V) complexes stable enough to be detected under conditions used in the kinetic measurements. All attempts to observe Cr(V) at 750 nm were unsuccessful, even when saturated solutions were used. Besides, it was not possible to detect such a complex by epr measurements of dilute solutions of aldose/Cr(VI) mixtures. It might be observed by employing more sophisticated equipment. Only when aldose/Cr(VI) saturated solutions were mixed, could Cr(V) complexes be observed by epr. On the other hand, these Cr(V) complexes grow and decay in a very short time compared to Cr(VI) decay under the same reaction conditions. These results mean that the decomposition rate of Cr(V) has to be much larger than that of Cr(VI), and that Cr(V) concentration is not high enough to interfere significantly with the absorbances observed at 350 nm over a very short time, whereas k_{obs} values obtained from the linear part of the ln(abs) vs. time plot should not be further modified by Cr(V) absorbance.

Another suitable explanation for this initial deviation from linearity may be the formation of the chromic ester with aldose in a pre-equilibrium process. The maximum absorbance of these esters must not differ too much from that of chromic acid. The shoulder at 380 nm in the spectra obtained from wavelength scanning of aldose/Cr(VI) mixtures at different times may be attributed to the chromic ester (Fig. 8). Effect of the substrate concentration on the absorbance of Cr(VI) at 350 nm in the presence of either L-rhamnose or D-mannose in the kinetic studies supports this hypothesis.

From all experimental data, the following mechanism is deduced:

$$[6]\quad Cr_2O_7^{2-} + \text{aldose} \overset{K_1}{\rightleftharpoons} \underset{A}{[Cr_2O_7 - \text{aldose}]^-}$$

$$[7]\quad A \overset{k_2}{\rightarrow} Cr(IV) + RC_5O_5H_7 + HCrO_4^-$$

$$[8]\quad A + 2H^+ \overset{k_3}{\rightarrow} [AH_2]^+ \rightarrow Cr(IV) + RC_5O_5H_7 + HCrO_4^-$$

$$[9]\quad 2HCrO_4^- \rightleftharpoons Cr_2O_7^{2-} + H_2O$$

where R = CH_3 for L-rhamnose or R = CH_2OH for D-mannose.

The first step represents the formation of the rather stable anionic complex between Cr(VI) and the aldohexose (25). Possibly several linkage isomers might be formed by coordination of the sugar with Cr(VI) via any properly disposed hydroxyl group. In eq. [6] A (with the anomeric hydroxyl bound to Cr(VI)) has been chosen, since it should be the precursor of the lactone. This complex may decompose, directly to the products or may be doubly protonated to form a new complex in the slow step, which decomposes rapidly to the products. We propose that redox paths, involving either the anionic or the cationic complex, are two-electron steps, and Cr(IV) is formed with the lactone.

According to the proposed mechanism, the full rate law for the chromic acid oxidation of aldoses, under conditions studied in the kinetic measurements, can be written (eq. [10]):

$$[10]\quad -\frac{dCr(VI)}{dt} = (k_2 + k_3[H^+]^2)[A]$$
$$= (k_2 + k_3[H^+]^2) K_1 [\text{aldose}] [Cr_2O_7^{2-}]$$

Since

$$[11]\quad [Cr(VI)]_T = Cr_2O_7^{2-} + [A]$$
$$= [Cr_2O_7^{2-}]\{1 + K_1[\text{aldose}]\}$$

Replacing $[Cr_2O_7^{2-}]$ in eq. [10]

$$[12]\quad -\frac{dCr(VI)}{dt} = \frac{(k_2 + k_3[H^+]^2) K_1 [\text{aldose}]}{1 + K_1[\text{aldose}]} [Cr(VI)]_T$$

There are at least three possible explanations for the observed rate law:

1. $HCrO_4^-$ is the major Cr(VI) species in solution (which is inconsistent with other data).
2. The reactive complex is a monoester of dichromate instead of chromate.
3. The reactive intermediate is a diester of Cr(VI).

The experimental data are better fixed for possibility number two according to the proposed observed rate law. After the slow step, reactions [13], [14], and [15] may take place:

$$[13]\quad Cr(IV) + \text{aldose} \rightarrow Cr(III) + \text{aldose}^\bullet$$

$$[14]\quad \text{Aldose}^\bullet + Cr(VI) \rightarrow Cr(V) + \text{lactone}$$

$$[15]\quad Cr(V) + \text{aldose} \rightleftharpoons [\text{aldose} - Cr(V)] \rightarrow Cr(III) + \text{lactone}$$

Because under the conditions used in the kinetic measurements (20 to 200-fold ratio of aldohexose to Cr(VI)) the

TABLE 4. Effect of acrylonitrile on the yield of carbon dioxide. T = 70°C; [L-rhamnose] = 4×10^{-4} M; [Cr(VI)] = 6×10^{-3} M; [$HClO_4$] = 1 M; time = 24 h

Moles of acrylonitrile	—	0.2	0.5	0.9	1.7	2.0	2.3
Moles of CO_2/mole L-rhamnose	4.0	3.4	2.7	2.3	1.7	1.4	1.4

only product detected is the lactone, eqs. [6]–[9] and [13]–[15] represent the total reaction:

[16] $2H^+ + 3\text{aldose} + 2Cr(VI) \rightarrow 3\text{lactone} + 2Cr(III)$

However, when a 10-fold ratio of substrate to Cr(VI) was employed, the α-keto acid was observed by paper chromatography as a minor product, as well as the lactone (main product). Oxidation of the secondary hydroxyl group to ketone requires a two-electron step. Equations [17]–[20] are proposed to explain this reaction product:

[17] $\text{Lactone} + Cr(VI) \rightarrow Cr(IV) + RCOCOOH$

[18] $Cr(IV) + \text{lactone} \rightarrow Cr(III) + R'COOH^{\cdot}$

[19] $R'COOH^{\cdot} + Cr(VI) \rightarrow Cr(V) + RCOCOOH$

[20] $Cr(V) + \text{lactone} \rightarrow Cr(III) + RCOCOOH$

where lactone refers either to L-1,4-rhamnonelactone or D-1,4-mannonelactone; R = $C_4O_3H_9$ or $C_4O_4H_9$ and R′ = $C_5O_4H_{11}$ or $C_5O_5H_{11}$.

Test for free radicals

If the oxidation is carried out in the presence of acrylonitrile (free-radical scavenger) the formation of polymers indicates the presence of free-radical intermediates. We investigated the effect of the concentration of acrylonitrile on the yield of carbon dioxide in order to check if carbon dioxide formation involves the proposed free-radical steps. The blank experiments in absence of aldose or potassium dichromate did not show the formation of any precipitate. The yield of carbon dioxide is reduced in the presence of acrylonitrile and a limiting value is reached when the yield of CO_2 is reduced to one third of the stoichiometric amount (Table 4). These results fit well with a mechanism given by eqs. [6]–[9] and [13]–[24] for degradation of aldose to the lower carboxylic acid and eqs. [25]–[27] for total degradation of L-rhamnose in excess of Cr(VI).

[21] $RCOCOOH + Cr(VI) \rightarrow Cr(IV) + CO_2 + RCOOH$

[22] $Cr(IV) + RCOCOOH \rightarrow Cr(III) + RCOCOOH^{\cdot}$

[23] $RCOCOOH^{\cdot} + Cr(VI) \rightarrow Cr(V) + CO_2 + RCOOH$

[24] $Cr(V) + RCOCOOH \rightarrow Cr(III) + CO_2 + RCOOH$

[25] $3RCOOH + 4Cr(VI) \rightarrow 3CO_2 + 3R_1COOH + 4Cr(III)$

[26] $3R_1COOH + 4Cr(VI) \rightarrow 3CO_2 + 3R_2COOH + 4Cr(III)$

[27] $3R_2COOH + 4Cr(VI) \rightarrow 3CO_2 + 3R_3COOH + 4Cr(III)$

where R = $C_4O_3H_9$, R_1 = $C_3O_2H_7$, R_2 = C_2OH_5, and R_3 = CH_3.

Under these conditions, L-rhamnose undergoes a quantitative oxidation to CO_2 and acetic acid following the stoichiometry given in eq. [28]. When acrylonitrile is added, two thirds of the carbon dioxide, starting from the radical steps, is not produced.

[28] $3\,\text{Rhamnose} + 18Cr(VI) \rightarrow 12CO_2 + 3CH_3COOH + 18Cr(III)$

Thus, in the presence of a sufficient excess of free-radical scavenger to trap all $RCOOH^{\cdot}$ radicals, the yield of carbon dioxide should be reduced from 12 molecules to four molecules per three molecules of L-rhamnose.

These results may be extended to the total degradation of D-mannose.

Conclusions

From the previous results, it is evident that both D-mannose and L-rhamnose react in a similar fashion with Cr(VI) in perchloric acid. However, an important difference must be pointed out. The equilibrium constant K is twice as high for the D-mannose/Cr(VI) complex as for L-rhamnose, while the oxidation rate is faster for the L-rhamnose/Cr(VI) complex. This difference has to be related to a difference in structural features between these complexes. Additional work is in progress to determine the structure of such complexes exactly.

Since either glyceraldehyde (11, 26) or lower sugars without possibility of cyclic forms (15), under the same experimental conditions, do not show kinetic evidence of chromic-ester formation, we propose cyclic hemiacetal forms as the reactive forms for aldohexoses, where hydroxyl groups are better disposed to bind Cr(VI) (27). This is in agreement with the great stability observed for Cr(V)/aldohexose complexes at higher pH (23): oxidation rates of both aldose/Cr(VI) and aldose/ Cr(V) complexes (as can be deduced from epr measurements) are strongly pH dependent; so, at higher pH, oxidation is negligible and aldohexoses coordinate to Cr(VI) or Cr(V) without reducing them.

Finally, we are in a position to state that, when an excess of Cr(VI) over the sugar is used, further oxidation of the lactone formed in the first reaction stages occurs by abstraction of the *a*-H to yield the *a*-keto acid, preceding the decarboxylation process.

A quantitative study of the equilibria involved in the interaction of Cu(II) ion with D-glucoheptonic, D-gluconic, D-galactonic, D-ribonic, D-glucuronic, and D-galacturonic acids in aqueous medium has been carried out by means of potentiometric measurements of hydrogen ion concentrations at a constant temperature of 20°C and an ionic strength of 0.10 ($NaNO_3$). The equilibrium data were processed with the FORTRAN computer program BEST. It was found that Cu(II) interacts with D-aldonic acids to form 1:1, 2:2, and 1:2 (M/L) complexes. The copper(II) complexes with D-galacturonic and D-glucuronic acids are considerably weaker than those of D-aldonic acid. Possible structures of the complex species formed are discussed.

GRACIELA M. ESCANDAR et LUIS F. SALA. Can. J. Chem. **70**, 2053 (1992).

Faisant appel à des mesures potentiométriques de concentrations en ion hydrogène, à une température constante de 20°C et à une force ionique de 0,10 ($NaNO_3$), on a effectué une étude quantitative des équilibres impliqués dans l'interaction du Cu(II) avec les acides D-glucoheptonique, D-gluconique, D-galactonique, D-ribonique, D-glucoronique et D-galacturonique en milieu aqueux. On a examiné les données à l'aide du programme d'ordinateur BEST écrit en FORTRAN. On a trouvé que le Cu(II) interagit avec les acides D-aldoniques pour former des complexes 1 : 1, 2 : 2 et 1 : 2 (M/L). Les complexes du Cu(II) avec les acides D-galacturonique et D-glucuronique sont beaucoup plus faibles que ceux avec les acides D-aldoniques. On discute des structures possibles pour les espèces complexes qui se forment.

[Traduit par la rédaction]

Introduction

The aldonic and uronic acids (Scheme 1) play an important role in carbohydrate metabolism and they are components of many polysaccharides of biological importance. These sugars, characterized by a terminal carboxylate group, are able to bind both essential and toxic metal ions, forming soluble complexes (1). Uronic acids, present in plant cells, activate the solubilization of metal ions through complex formation, mobilizing them from poorly soluble salts (2). Besides, D-gluconic acid is used as sequestering agent for metal ions in medical, industrial, and agricultural areas (3). Recently, following a study of the chemical speciation of metal ions in aquatic environments, Haas made an investigation of sugar–metal complexes in seawater and their significance in marine processes (4).

The purpose of the present discussion, as part of a general program of analysis of metal–sugar acid chelates, is to define the quantitative interaction between these ligands and Cu(II) ion. A complete study of the cupric complexes formed by D-aldonic acid has not yet been made, and the results reported for D-alduronic acid by different authors are conflicting (5–8).

The computer program selected to process the data, allowed us to provide an accurate description of the aqueous coordination chemistry of Cu(II) for this series of saccharides. At the same time the stability constant values of the different species present in the systems under study were computed.

[1]Author to whom correspondence may be addressed.

Experimental section

Reagents

All the sugars were obtained commercially from Sigma Chemical Co. The lactones of the D-aldonic acids investigated were opened to the sodium salt in order to work with the carboxylate form. In the case of D-gluconic acid both the sodium salt and the 1,5 lactone were employed, obtaining the same results. The D-alduronic acids were purchased as D-galacturonic acid monohydrate and D-glucuronic acid free form. The purity of ligands was checked by pH titration. Stock solutions of $Cu(NO_3)_2$, Na(OH), and HNO_3 were prepared and standardized according to the method reported earlier (9).

Potentiometry

The procedures and apparatus used for potentiometric measurements were described previously in detail (10). Briefly, measurements were made at 20.0 ± 0.1°C and 0.10 M ($NaNO_3$) ionic strength. The pH meter was standardized by titrations of HNO_3 and acetic acid to read $-\log[H^+]$ rather than hydrogen ion activity. Concentrations of reactants in the experimental solutions were of the order of 2×10^{-3} M for each component. D-Aldonic acids were investigated at 1:1 and 1:2 (M/L) ratios. Because of the low stability of the cupric complexes with D-alduronic acids, potentiometric titrations were performed at a high ligand-to-metal ratio.

The lactones were dissolved in standard base and the lower end of the equilibrium curves developed from a back titration, by stepwise addition of standard acid.

Computations

Since the chelates studied are not completely formed at low pH, their stability constants were obtained directly by potentiometric measurements with the program BEST (11).

Results and discussion

The protonation constants of the ligands studied in this work are listed in Table 1.

Cu(II) – D-aldonic acid 1:1 systems

The Cu(II) – D-gluconic acid system was studied in strongly basic medium by Pecsok and Juvet, and two different species $Cu_2H_{-3}L_2^-$ and $Cu_2H_{-4}L_2^{2-}$ in less basic solution were proposed by these authors (14). Other D-aldonic acids have not been previously investigated with Cu(II).

The potentiometric behavior of D-gluconic, D-galactonic, and D-ribonic acids with Cu(II) was found to be similar. To explain the potentiometric results of these systems, it was necessary to introduce the macroscopic equilibria [1]–[4]:

[1] $Cu^{2+} + L^- = CuL^+$

[2] $CuL^+ = CuH_{-2}L^- + 2\,H^+$

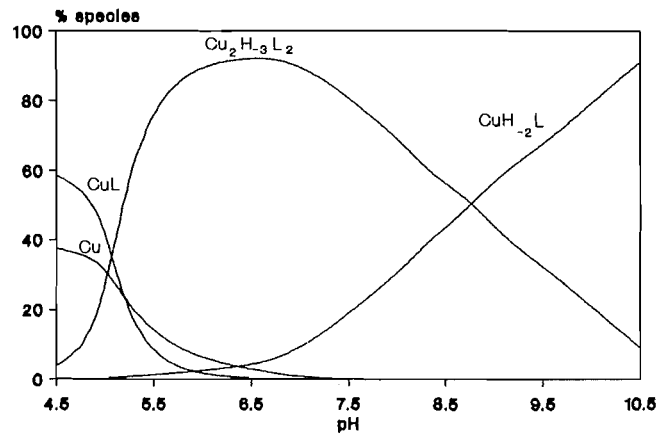

FIG. 1. Distribution of species as a function of p[H^+] in a 1:1 Cu(II)–D-gluconic acid system. Concentration of ligand and metal ion ≈ 2.00×10^{-3} M; μ = 0.10 ($NaNO_3$); t = 20.0°C

[3] $CuH_{-2}L^- = CuH_{-3}L^{2-} + H^+$

[4] $2\,Cu^{2+} + 2\,L^- = Cu_2H_{-3}L_2^- + 3\,H^+$

where the negative stoichiometric coefficient for H represents the protons displaced in the complex formation.

A comparison of the relative positions of the titration curves at different concentration levels of Cu(II) and ligand was employed as a qualitative indication of dimer forma-

[a]Calculated from the 1:2 (M/L) system.
( )See text.

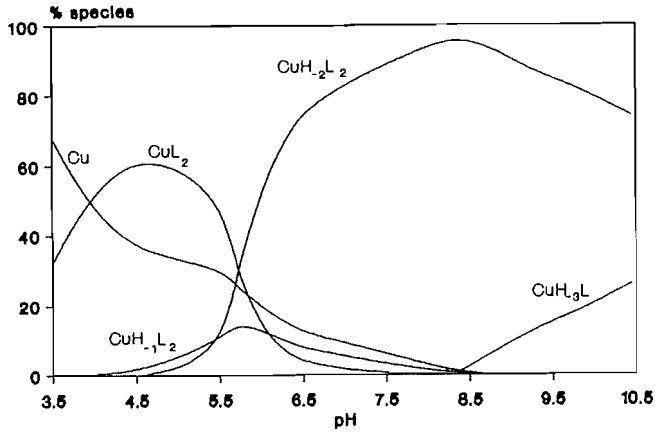

FIG. 2. Distribution of species as a function of p[H^+] in a 1:2 Cu(II)–D-ribonic acid system. Concentration of Cu(II) ≈ 2.00 × 10^{-3} M; μ = 0.10 ($NaNO_3$); t = 20.0°C.

tion (15). Polymeric copper(II) chelates have been reported previously (16). It was found that $CuH_{-1}L$ does not possess enough stability to be important relative to the strong tendency to form $CuH_{-2}L^-$. The dimer $Cu_2H_{-4}L_2^{-2}$ was not found in the systems investigated.

The species distribution – pH diagram in Fig. 1 points out the interplay of the above equilibria for the Cu(II) – D-gluconic acid (1:1) system. The stability constants are listed in Table 2. Since the presence of the more deprotonated $CuH_{-3}L^{2-}$ complex is found at high pH, where potentiometric measurements become less accurate, the last deprotonation constant values are reported within parentheses.

The titration curve for the Cu(II) – D-glucoheptonic acid (1:1) system showed precipitate formation above $a \approx 0.5$ (a : mol of NaOH added per mol of ligand or metal ion). Beyond $a \approx 2$ the insoluble species (probably the neutral $CuH_{-1}L^-$complex) dissolved to give a completely clear, green solution. The measurement of useful potentiometric data for a stability constant computation was not possible.

Cu(II) – D-aldonic acid (1:2) systems

Analysis of the equilibrium data for Cu(II) – D-aldonic acids (1:2) showed the formation of complexes with this ratio. Figure 2 shows the distribution diagram for the Cu(II) – D-ribonic acid (1:2) system.

It is interesting to point out the presence of the $CuH_{-3}L^{2-}$ 1:1 complex in very basic solutions in all the 1:2 systems. The dimer $Cu_2H_{-3}L_2^-$ complex is only detected in the D-gluconic acid system, over a wide range of pH. The corresponding equilibrium constants are shown in Table 2.

Cu(II) – D-alduronic acid systems

In recent years, the Cu(II) – D-uronic acid systems have been studied by different authors (5–8). Although the CuL^+ complex formation is generally accepted, the other species in equilibrium and the coordination centers with the metal ion are controversial (see Table 3).

The potentiometric curves of the Cu(II) – D-galacturonic acid (Fig. 3) and Cu(II) – D-glucuronic acid in a ratio 1:5 (M/L) show a first jump at a = 5 and another one at a = 6.8. Since precipitate formation occurs about a = 5.5 and equilibrium analysis in the presence of solid phase is difficult, constant computations were found necessary in each soluble region. The solid phase present in both systems is attributed to $Cu(OH)_2$ and prevents the evaluation of complex formation in alkaline medium.

The species formed in the D-galacturonic system at low pH are CuL^+ and $CuH_{-1}L$ and their stability constants are listed in Table 3. In our working conditions, the CuL^+ D-glucuronic acid complex was not found. The $CuH_{-1}L$ complex was detected at very low concentration just before precipitation occurred, therefore its stability constant value could not be determined. Cu(II) – D-alduronic acid 1:2 complexes were not found in the pH range investigated.

Conclusions

In the Cu(II) – D-aldonic acids (1:1) systems, the CuL^+ formation may be explained by the interaction of the Cu(II) with the carboxylate and α-hydroxyl groups (Scheme 2). The fact that the formation constant of this complex is more than

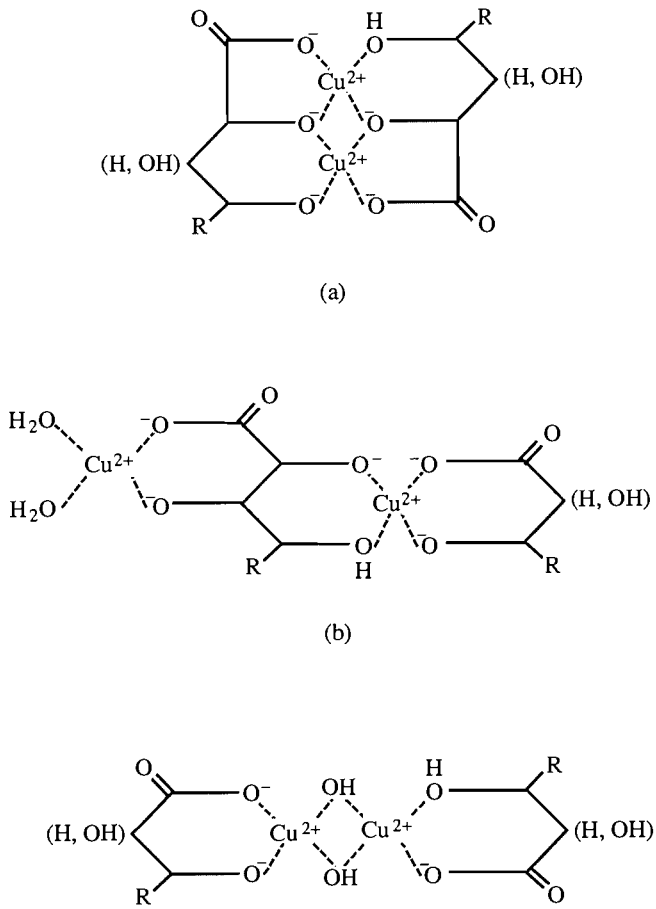

SCHEME 3

one log unit higher than the copper acetate complex (log K_{ML} = 1.83 at 25°C and μ = 0.1 M) (12) supports the conclusion that the α-hydroxyl group of the ligands interacts with the metal center. In addition, the magnitude of the D-hydroxypropanoic acid constant formation (log K_{ML} = 3.02 at 25°C and μ = 0) (12) compares more favorably to the D-aldonic acids. The subsequent deprotonation reactions in the 1:1 systems should be associated with the hydroxyl groups of the sugar chain with chelate ring formation. A large chelate effect should explain the high stability of the $CuH_{-3}L^{2-}$ complex, which is even detected in the 1:2 M/L systems. Examination of CPK models suggests different possibilities of binding with the metal center to form square-planar complexes. To get more rigorous structural information, spectroscopic studies should be made. The structure of the $Cu_2H_{-3}L_2^-$ dimer may be as proposed in Scheme 3. The coordinate bonding structures for the complexes involving two moles of ligand to copper ion could be represented by Scheme 4. The cupric-D-aldonic acid chelates are stable enough to avoid the precipitation of the hydroxide. By contrast, the D-alduronic complexes are considerably weaker than the former, and $Cu(OH)_2$ is separated in basic solution.

It is interesting to note that while some authors postulate

Cu(II) – D-galacturonic acid 1:2 complex formation, in the present work it was found necessary to introduce only two 1:1 Cu(II)-to-ligand species to bring the calculated and experimental p[H] values into line, at low pH.

The generally accepted bindings in the CuL^+ galacturonic acid complex involve the carboxylate group and the endocyclic sugar oxygen. The position of the proton liberated in the $CuH_{-1}L$ complex cannot be decided by potentiometric data. Studies of complex formation of various metal ions with alduronic acids have demonstrated that D-galacturonic acid complexes are more stable than D-glucuronic acid complexes (5). This fact suggests that the oxygen atom on C-4 is probably involved in the metal–ligand binding.

La réaction de 2-alcynoates d'alkyles fonctionnalisés (comme **13**–**19**) avec le (triméthylstannyl)(cyano)cuprate de lithium (**3**), dans deux ensembles de conditions expérimentales bien définies, fournit soit les (*Z*)- ou (*E*)-3-triméthylstannyl-2-alcènoates d'alkyles (comme **23**, **26**–**31** et **24**, **32**–**37**, respectivement) d'une façon à la fois efficace et stéréosélective.

[Traduit par la rédaction]

Introduction

We previously reported (1), *inter alia*, that reaction (tetrahydrofuran (THF), −78°C) of α,β-acetylenic esters **5** with lithium (phenylthio)(trimethylstannyl)cuprate (**1**) (2) in the presence of a proton source provides, highly stereoselectively, the corresponding alkyl (*E*)-3-trimethylstannyl-2-alkenoates **6** (eq. [1]). Furthermore, it was shown (1) that the stereoselective conversion of **5** into **6** could also be accomplished by use of the (trimethylstannyl)copper(I) reagents **2** (2) and **4** (2) (eq. [2]). Importantly, from a synthetic viewpoint, related investigations disclosed (1) that reaction of **5** with **1** under reaction conditions somewhat different than those given in eq. [1] provides, also highly stereoselectively, alkyl (*Z*)-3-trimethylstannyl-2-alkenoates **7** (eq. [3]). Thus, use of reagent **1**, along with selection of appropriate reaction conditions, allows one to control experimentally the stereochemical outcome of the overall addition of the elements of Me_3Sn–H across the triple bond of **5**. Interestingly, reagents **2** and **4** proved to be ineffective for the stereocontrolled transformation of **5** into **7**.

Recently, we required a number of new β-trimethylstannyl α,β-unsaturated esters of general formula **7**. Although reagent **1** had served quite well for the conversion of **5** into **7**, this method (eq. [3]) does have drawbacks. Phenylthiocopper(I) (PhSCu), which is used to prepare reagent **1** (2), is somewhat tedious to make (3). Furthermore, the latter preparation requires the use of thiophenol, a substance with a notably offensive odour. More importantly, PhSCu, like many copper(I) salts, is not particularly stable. Thus, the occasionally capricious nature of reactions employing the (phenylthio)cuprate **1** can nearly invariably be traced to the fact that PhSCu, after it has been stored for a period of time, no longer serves as a useful material for the preparation of synthetically effective cuprates.

Copper(I) cyanide is readily available, is a reasonably stable substance (CuCN is more stable than copper(II) cyanide (4)), and has been used extensively in organocuprate chemistry (5). Therefore, we have carried out a brief study to determine whether or not the lower order cuprate $[Me_3SnCuCN]Li$ (**3**), which is readily prepared by reaction of Me_3SnLi with CuCN in THF (2), would serve as an effective reagent, alternative to **1**, for the stereoselective conversion of **5** into **7**. The results derived from this study are presented below.

Results and discussion

(a) Preparation of the α,β-acetylenic esters 13–19

The structural formulas of the α,β-acetylenic esters **13**–**19** employed in this investigation are shown in Chart 1. Ethyl 2-pentynoate (**13**) is commercially available. Each of the remaining substances, except **16**, was prepared by treatment of the corresponding 1-alkyne (see **8**–**12**, Chart 1) with methyllithium in THF, followed by reaction of the resultant lithium acetylide with either ethyl or methyl chloroformate. Of the required 1-alkynes **8**–**12**, substances **11** and **12** are commercially available. Compounds **8** and **9** are readily de-

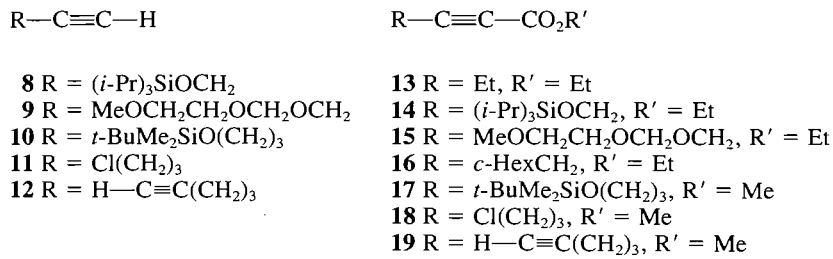

CHART 1

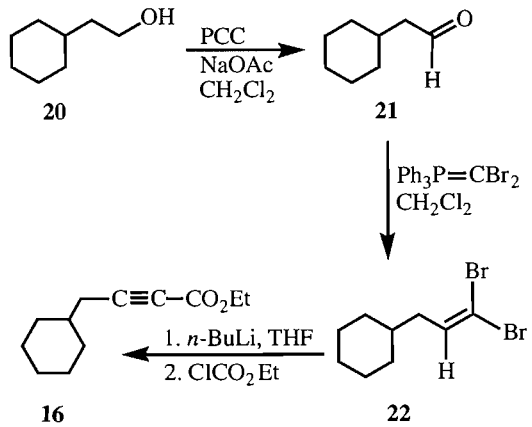
rived from 2-propyn-1-ol, while **10** is similarly prepared from 4-pentyn-1-ol. Details of these preparations are provided in the experimental section. In general, the reactions employed were straightforward and the yields were good to excellent.

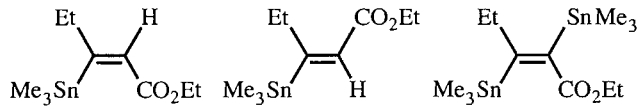
Ethyl 4-cyclohexyl-2-butynoate (**16**) was synthesized as shown in eq. [4]. Oxidation of the commercially available alcohol **20** with pyridinium chlorochromate (6), followed by reaction of the resultant aldehyde **21** with dibromomethylenetriphenylphosphorane in dichloromethane (7), gave the 1,1-dibromo-1-alkene **22**. Conversion of **22** into **16** was readily accomplished by means of a published method (7).



[4]

*(b) Conversion of the α,β-acetylenic esters **13–19** into the alkyl (Z)-3-trimethylstannyl-2-alkenoates **23** and **26–31***

The reaction of $[Me_3SnCuCN]Li$ (**3**) with ethyl 2-pentynoate (**13**) in THF was investigated under a variety of experimental conditions. It was found that when the reaction was carried out at −48°C for fairly short periods of time (≤1 h) and then was warmed to 0°C and subjected to work-up, the major (desired) product **23** was accompanied by minor (<10%) and significant (~20%) amounts of the geometric isomer **24** and ethyl (*E*)-2,3-bis(trimethylstannyl)-2-pentenoate (**25**),[2] respectively. However, further experimentation eventually revealed reaction conditions that effected a relatively clean conversion of **13** into **23**. Thus, reaction of **13** with approximately 1.1 equivalents of the cuprate **3** at −48°C for 2 h and then at 0°C for 2 h, followed by work-up, gave a product that consisted nearly entirely of **23**, accompanied by very minor amounts of **24** and **25**. Purification of this material by a combination of flash chromatography (9) on silica gel (which removed **24**) and distillation (**25** remained in the still-pot) provided the desired *Z* enoate **23** in 72% yield.



Subjection of the α,β-acetylenic esters **14–19** to reaction conditions very similar to those outlined above afforded the corresponding alkyl (*Z*)-3-trimethylstannyl-2-alkenoates **26–31** in very good yields. The results of these experiments are summarized in Table 1. In each case, the crude product contained minor amounts (<5%), of the corresponding (*E*)-3-trimethylstannyl-2-alkenoate and (*E*)-2,3-bis(trimethylstannyl)-2-alkenoate. The pure desired substances **26–31** could readily be obtained by subjection of the crude products to sequential flash chromatography and distillation.

As shown in Table 1, this procedure for the preparation of alkyl (*Z*)-3-trimethylstannyl-2-alkenoates can be accomplished successfully on substrates containing a variety of functional groups. Thus, silyl ethers (entries 2 and 5), acetals (entry 3), primary alkyl chlorides (entry 6), and terminal alkyne functions (entry 7) are stable to the reaction conditions.

*(c) Conversion of the α,β-acetylenic esters **13–19** into the alkyl (E)-3-trimethylstannyl-2-alkenoates **24** and **32–37***

For other ongoing research projects in our laboratory, we also required the α,β-unsaturated esters that are geometrically isomeric with the *Z* enoates listed in Table 1. Therefore, we carried out a short investigation to determine whether the cyanocuprate **3** could also be employed to effect the efficient, stereoselective conversion of α,β-acetylenic esters into alkyl (*E*)-3-trimethylstannyl-2-alkenoates.

Reaction (THF, −78°C, 4 h) of ethyl 2-pentynoate (**13**) with 1.3 equivalents of reagent **3** in the presence of 1.3 equivalents of ethanol provided a crude product that consisted of a mixture of the *E* and *Z* 2-pentenoates **24** and **23** in a ratio of ~97:3, respectively. Purification of this material by flash chromatography (9) and distillation provided pure **24** in 74% yield.

Reaction of the acetylenic esters **14–19** with the cuprate **3** under conditions similar to those described above produced the corresponding alkyl (*E*)-3-trimethylstannyl-2-alkenoates **32–37** in very good yields (see Table 2). The major, desired products were accompanied by small amounts (1–4%) of the *Z* isomers, but, in each case, the pure *E* isomer could

[2]For a previous report regarding the preparation of alkyl (*E*)-2,3-bis(trimethylstannyl)-2-alkenoates by reaction of α,β-acetylenic esters with $Me_3SnCu \cdot Me_2S$ (**4**), see ref. 8.

readily be obtained by subjection of the mixture to flash chromatography (9) and distillation.

Conclusion

This brief study has disclosed that the lower order cuprate reagent [$Me_3SnCuCN$]Li (**3**) can be used effectively for the synthetically useful, stereoselective conversion of α,β-acetylenic esters (e.g., **13**–**19**) into *either* alkyl (*Z*)-3-trimethylstannyl-2-alkenoates (e.g., **23**, **26**–**31**, respectively, Table 1) or alkyl *E*-3-trimethylstannyl-2-alkenoates (e.g., **24**, **32**–**37**, respectively, Table 2). The advantages of the procedures described herein over those reported earlier (1) are related to the nature of cuprate **3**. This reagent is conveniently prepared (2) from the stable copper(I) salt CuCN and, in terms of reaction efficacy, is significantly less capricious than other lower order (trimethylstannyl)cuprates such as [$Me_3SnCuSPh$]Li (**1**).

Experimental

General information

Distillation temperatures, which refer to short path (Kugelrohr) distillations, and melting points are uncorrected. Proton nuclear magnetic resonance (^1H nmr) spectra were recorded on $CDCl_3$ solutions. Signal positions (δ values) were measured relative to those of tetramethylsilane (δ = 0) or $CHCl_3$ (δ = 7.25). The tin–proton coupling constants (J_{Sn-H}) are given as an average of the ^{117}Sn and ^{119}Sn values. Carbon nuclear magnetic resonance (^{13}C nmr) spectra were taken on $CDCl_3$ solutions and the signal positions are given relative to that of $CDCl_3$ (δ = 77.0). Infrared (ir) spectra were obtained on liquid films (NaCl plates) employing a Perkin–Elmer model 1710 Fourier transform spectrophotometer with internal

calibration. For compounds containing the Me_3Sn moiety, high-resolution mass spectrometric measurements are based on ^{120}Sn and were made on the ($M^+ - Me$) peak. Flash chromatography (9) was carried out with 230–400 mesh silica gel (E. Merck). Gas–liquid chromatography (glc) was carried out on an instrument equipped with a flame-ionization detector and a 25 m × 0.32 mm fused silica column coated with cross-linked 5% phenylmethyl silicone. Thin-layer chromatography (tlc) was carried out with commercial, aluminum-backed silica gel plates.

Reagents and solvents were purified and dried using standard methods. Petroleum ether refers to a hydrocarbon mixture with bp 35–60°C. Copper(I) cyanide was purchased from Aldrich Chemical Co., Inc., and was used without further purification.

Aqueous NH_4Cl–NH_4OH (pH 8) refers to a solution prepared by addition of ~50 mL of aqueous NH_4OH (58%) to ~1 L of saturated aqueous NH_4Cl.

Note: All reactions were carried out under an atmosphere of argon in flame- or oven-dried glassware.

3-(Triisopropylsiloxy)propyne (8)

To a stirred solution of 2-propyn-1-ol (1.02 g, 18.2 mmol) in dry CH_2Cl_2 (30 mL) was added sequentially imidazole (1.86 g, 27.3 mmol) and triisopropylsilyl chloride (3.33 g, 17.3 mmol) and the resultant mixture was stirred at room temperature for 2 h. Aqueous NH_4Cl–NH_4OH (pH 8) (25 mL) was added and the mixture was extracted thoroughly with CH_2Cl_2. The combined extracts were washed with brine and then were dried ($MgSO_4$) and concentrated. Flash chromatography (35 g silica gel, hexanes) of the remaining material and distillation (45–47°C/0.15 Torr (1 Torr = 133.3 Pa)) of the acquired oil gave 2.75 g (75%, based on $(i\text{-Pr})_3SiCl$) of **8**, a colorless oil that displayed ir (neat): 3313, 2123, 1465, 1107 cm^{-1}; ^1H nmr (400 MHz) δ: 1.06 (d, 18H, J = 6.0 Hz), 1.10 (m, 3H), 2.46 (t, 1H, J = 2.0 Hz), 4.37 (d, 2H, J = 2.0 Hz); ^{13}C nmr (100.6 MHz) δ: 11.9, 17.8, 51.7, 72.5, 82.4. Anal. calcd. for $C_{12}H_{24}OSi$: C 67.86, H 11.39; found: C 67.86, H 11.43. Exact Mass calcd.: 212.1598; found: 212.1604.

3-[(2-Methoxyethoxy)methoxy] propyne (9)

To a cold (0°C), stirred solution of 2-propyn-1-ol (1.02 g, 18.2 mmol) and $(i\text{-Pr})_2NEt$ (3.53 g, 27.3 mmol) in dry CH_2Cl_2 (30 mL) was added, over a period of 1 min, 2.16 g (17.3 mmol) of $MeOCH_2CH_2OCH_2Cl$ and the resulting mixture was stirred at 0°C for 3.5 h. Hydrochloric acid (2 N, 15 mL) was added and the mixture was extracted with CH_2Cl_2 (3 × 20 mL). The combined extracts were washed with brine, dried ($MgSO_4$), and concentrated. Flash chromatography (50 g silica gel, 4:1 hexanes–Et_2O) of the remaining oil and distillation (65–68°C/10 Torr) of the liquid thus obtained gave 1.98 g (79%) of the alkyne **9**, a colorless oil that showed ir (neat): 3262, 2118, 1454, 1110 cm^{-1}; ^1H nmr (400 MHz) δ: 2.40 (t, 1H, J = 2.0 Hz), 3.38 (s, 3H), 3.54 (m, 2H), 3.70 (m, 2H), 4.22 (d, 2H, J = 2.0 Hz), 4.78 (s, 2H); ^{13}C nmr (100.6 MHz) δ: 54.1, 58.9, 67.1, 71.6, 74.2, 79.3, 93.8. Anal. calcd. for $C_7H_{12}O_3$: C 58.32, H 8.39; found: C 58.56, H 8.49. Exact Mass calcd. for $C_7H_{11}O_3$ (M^+ − H): 143.0704; found: 143.0700.

(5-tert-butyldimethylsiloxy)-1-pentyne (10)

A solution of 4-pentyn-1-ol (1.81 g, 21.5 mmol), *tert*-butyldimethylsilyl chloride (4.25 g, 28.2 mmol), and imidazole (3.70 g, 54.3 mmol) in dry *N*,*N*-dimethylformamide (10 mL) was stirred at room temperature for 16 h. Saturated aqueous $NaHCO_3$ and Et_2O (10 mL) were added and the mixture was extracted with Et_2O (3 × 20 mL). The combined extracts were washed with brine (2 × 60 mL), and then were dried ($MgSO_4$) and concentrated. Flash chromatography (150 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product and distillation (65–90°C/0.2 Torr) of the oil thus obtained afforded 4.04 g (95%) of the 1-pentyne **10**, a colorless liquid that exhibited ir (neat): 3315, 2121, 1109, 632 cm^{-1}; ^1H nmr (400 MHz) δ: 0.03 (s, 6H), 0.87 (s, 9H), 1.69 (quintet, 2H, J = 7.0 Hz), 1.89 (t, 1H, J = 2.5 Hz), 2.24 (dt, 2H, J = 2.5, 7.0 Hz), 3.67 (t, 2H, J = 7.0 Hz); ^{13}C nmr (50.3 MHz) δ: −5.4, 14.8, 18.2, 25.9, 31.5, 61.3, 68.2, 84.1. Anal. calcd. for $C_{11}H_{22}OSi$: C 66.60, H 11.18; found: C 66.80, H 11.30. Exact Mass calcd. for $C_7H_{13}OSi$ (M^+ − *t*-Bu): 141.0736; found: 141.0728.

Ethyl 4-(triisopropylsiloxy)-2-butynoate (14)

To a cold (−78°C), stirred solution of the 1-alkyne **8** (0.5 g, 2.36 mmol) in 15 mL of dry THF was added, dropwise, a solution of methyllithium (2.36 mmol) in Et_2O. After the solution had been stirred at −78°C for 15 min and at −20°C for 1 h, ethyl chloroformate (256 mg, 2.36 mmol) was added. The mixture was stirred at −20°C for 1 h and at room temperature for 1 h. Saturated aqueous $NaHCO_3$ (15 mL) was added and the mixture was extracted thoroughly with Et_2O. The combined extracts were washed twice with brine and then were dried ($MgSO_4$) and concentrated. Distillation (98–99°C/0.11 Torr) of the remaining oil yielded 512 mg (76%) of **14**, a colorless oil that exhibited ir (neat): 2241, 1718, 1465, 1258 cm^{-1}; ^1H nmr (400 MHz) δ: 1.04 (d, 18H, J = 6.0 Hz), 1.10 (m, 3H), 1.29 (t, 3H, J = 7.0 Hz), 4.20 (q, 2H, J = 7.0 Hz), 4.49 (s, 2H); ^{13}C nmr (100.6 MHz) δ: 11.9, 13.9, 17.7, 51.4, 61.9, 76.4, 85.7, 155.5. Anal. calcd. for $C_{15}H_{28}O_3Si$: C 63.33, H 9.92; found: C 63.34, H 9.84. Exact Mass calcd. for $C_{12}H_{21}O_3Si$ (M^+ − *i*-Pr): 241.1260; found: 241.1261.

Ethyl 4-[(2-methoxyethoxy)methoxy]-2-butynoate (15)

This substance was prepared via a procedure very similar to that described above. The quantities of reagents and solvents employed were as follows: starting material **9**, 0.5 g (3.47 mmol); THF, 15 mL; MeLi, 3.47 mmol; EtO_2CCl, 377 mg (3.47 mmol); saturated aqueous $NaHCO_3$, 15 mL. Distillation (85–87°C/0.11 Torr) of the crude product afforded 595 mg (79%) of **15**, a colorless oil that displayed ir (neat): 1718, 1450, 1254, 1045 cm^{-1}; ^1H nmr (400 MHz) δ: 1.30 (t, 3H, J = 7.5 Hz), 3.39 (s, 3H), 3.53 (m, 2H), 3.71 (m, 2H), 4.20 (q, 2H, J = 7.5 Hz), 4.34 (s, 2H), 4.77 (s, 2H); ^{13}C nmr (100.6 MHz) δ: 14.0, 54.0, 59.0, 62.1, 67.4, 71.6, 77.8, 83.0, 94.3, 153.1. Anal. calcd. for $C_{10}H_{16}O_5$: C 55.55, H 7.46; found: C 55.51, H 7.47. Exact Mass calcd.: 215.0920; found: 215.0918.

Methyl 6-(tert-butyldimethylsiloxy)-2-hexynoate (17)

A procedure similar to that given above was employed. The quantities of reagents and solvents used were as follows: substrate **10**, 3.59 g (18.1 mmol); THF, 36 mL; MeLi, 20.3 mmol; MeO_2CCl, 1.65 mL (21.4 mmol); saturated aqueous $NaHCO_3$, 25 mL. Distillation (80–100°C/0.2 Torr) of the crude product gave 3.82 g (82%) of **17**, a colorless oil that showed ir (neat): 2238, 1719, 1260, 1109, 1074 cm^{-1}; ^1H nmr (400 MHz) δ: 0.07 (s, 6H), 0.90 (s, 9H), 1.78 (quintet, 2H, J = 7.0 Hz), 2.44 (t, 2H, J = 7.0 Hz), 3.68 (t, 2H, J = 7.0 Hz), 3.75 (s, 3H); ^{13}C nmr (50.3 MHz) δ: −5.4, 15.2, 18.2, 25.9, 30.6, 52.5, 61.1, 72.9, 89.5, 154.2. Anal. calcd. for $C_{13}H_{24}O_3Si$: C 60.89, H 9.43; found: C 61.10, H 9.60. Exact Mass calcd. for $C_{12}H_{21}O_3Si$ (M^+ − Me): 241.1260; found: 241.1260.

Methyl 6-chloro-2-hexynoate (18)

A procedure similar to that described above was used. The quantities of reagents and solvents used were as follows: substrate **11**, 2.0 mL (18.9 mmol); THF, 40 mL; MeLi, 20.6 mmol; MeO_2CCl, 1.8 mL (23.3 mmol); saturated aqueous $NaHCO_3$, 80 mL. Flash chromatography (40 g silica gel, 9:1 petroleum ether – Et_2O) of the crude product, followed by distillation (50–70°C/0.6 Torr) of the acquired liquid, produced 2.45 g (81%) of **18**, a colorless oil that exhibited ir (neat): 2240, 1718, 1262 cm^{-1}; ^1H nmr (400 MHz) δ: 2.04 (quintet, 2H, J = 7.0 Hz), 2.55 (t, 2H, J = 7.0 Hz), 3.65 (t, 2H, J = 7.0 Hz), 3.78 (s, 3H); ^{13}C nmr (50.3 MHz) δ: 16.0, 30.2, 43.2, 52.3, 73.6, 87.4, 153.9. Anal. calcd. for $C_7H_9ClO_2$: C 52.35, H 5.65, Cl 22.08; found: C 52.42, H 5.72, Cl 21.90. Exact Mass calcd. for $C_7H_9{}^{35}ClO_2$: 160.0292; found: 160.0282.

Methyl 2,7-octadiynoate (19)[3]

This material was prepared via a procedure similar to that outlined above. The quantities of reagents and solvents used were as

[3]This experiment was carried out by Mr. Philip Coish. We are very grateful to Mr. Coish for a generous sample of compound **19**.

For personal use only.

follows: substrate **12**, 10.0 g (109 mmol); THF, 200 mL; MeLi, 109 mmol; MeO_2CCl (rapid addition!), 33.7 mL (436 mmol); saturated aqueous $NaHCO_3$, 150 mL. Distillation (80–100°C/0.3 Torr) of the crude product gave 13.2 g (81%) of **19**, a colorless oil that displayed ir (neat): 3292, 2239, 1714, 1435, 1264, 1078 cm^{-1}; ^1H nmr (400 MHz) δ: 1.78 (quintet, 2H, J = 7.0 Hz), 1.96 (t, 1H, J = 2.5 Hz), 2.32 (dt, 2H, J = 7.0, 2.5 Hz), 2.47 (t, 2H, J = 7.0 Hz), 3.73 (s, 3H); ^{13}C nmr (50.3 MHz) δ: 17.5, 17.6, 26.4, 52.5, 69.4, 73.4, 82.6, 88.4, 154.1. Anal. calcd. for $C_9H_{10}O_2$: C 71.98, H 6.71; found: C 71.72, H 6.78. Exact Mass calcd. for $C_9H_9O_2$ (M^+ − H): 149.0602; found: 149.0593.

1,1-Dibromo-3-cyclohexylpropene (22)

To a stirred mixture of pyridinium chlorochromate (33.7 g, 156 mmol) and sodium acetate (3.2 g, 39 mmol) in dry CH_2Cl_2 (200 mL) was added a solution of 2-cyclohexylethanol (**20**) (10.0 g, 78 mmol) in dry CH_2Cl_2 (300 mL). The mixture was stirred at room temperature for 2 h. Diethyl ether (400 mL) was added and the resultant mixture was filtered through a column of Florisil (6 cm diameter, 7.5 cm depth). The column was eluted with 1 L of Et_2O. Concentration of the combined eluant, followed by distillation (50–56°C/15 Torr) of the remaining liquid, gave 9.03 g (91%) of cyclohexylethanal (**21**), a colorless oil that exhibited ir (neat): 1725 cm^{-1}; ^{13}C nmr (75 MHz) δ: 25.9, 26.0, 33.0, 34.7, 41.7, 51.4, 203.1. Exact Mass calcd. for $C_8H_{14}O$: 125.0966; found: 125.0960.

To a solution of CBr_4 (18.71 g, 56.4 mmol) in dry CH_2Cl_2 (150 mL) was added slowly (at a rate such that the temperature of the reaction mixture remained below 50°C) a solution of triphenylphosphine (29.59 g, 112.8 mmol) in dry CH_2Cl_2 (150 mL). After the resultant mixture had been stirred for 5 min, a solution of the aldehyde **21** (3.55 g, 28.2 mmol) in dry CH_2Cl_2 (300 mL) was added over a period of 10 min and the mixture was then stirred at room temperature for an additional 30 min. Pentane (500 mL) was added and the resultant mixture was filtered through a column of Florisil (6 cm diameter, 7.5 cm depth). The column was washed with 1 L of pentane. The combined eluant was concentrated and the remaining oil was distilled (125–130°C/15 Torr) to provide 6.56 g (86%) of **22**, a colorless oil that displayed ir (neat): 1448, 785 cm^{-1}; ^1H nmr (400 MHz) δ: 0.90–1.05 (m, 2H), 1.10–1.30 (m, 3H), 1.35–1.50 (m, 1H), 1.55–1.90 (m, 5H), 2.05 (t, 2H, J = 7.0 Hz), 6.42 (t, 1H, J = 7.0 Hz); ^{13}C nmr (75 MHz) δ: 26.2, 26.3, 32.9, 37.2, 40.6, 88.7, 137.8. Anal. calcd. for $C_9H_{14}Br_2$: C 38.33, H 5.00; found: C 38.60, H 5.13. Exact Mass calcd.: 281.9443; found: 281.9440.

Ethyl 4-cyclohexyl-2-butynoate (16)

To a cold (−78°C), stirred solution of compound **22** (2.5 g, 8.9 mmol) in dry THF (115 mL) was added, dropwise, a solution of *n*-butyllithium (22.2 mmol) in hexanes. The mixture was stirred at −78°C for 1 h, at room temperature for 1 h, and then was recooled to −20°C. Ethyl chloroformate (1.06 g, 9.76 mmol) was added and the mixture was stirred at −20°C for 1 h and at room temperature for 1 h. Saturated aqueous $NaHCO_3$ (100 mL) was added and the mixture was extracted thoroughly with Et_2O. The combined extracts were washed with brine, dried ($MgSO_4$), and concentrated. Flash chromatography (75 g silica gel, 95:5 petroleum ether – Et_2O) of the crude product and distillation (90–96°C/12 Torr) of the acquired liquid provided 1.55 g (90%) of **16**, a colorless oil that showed ir (neat): 2232, 1713, 1249, 1076 cm^{-1}; ^1H nmr (400 MHz) δ: 0.97–1.08 (m, 2H), 1.12–1.30 (m, 2H), 1.32 (t, 3H, J = 7.0 Hz), 1.50–1.60 (m, 2H), 1.65–1.87 (m, 5H), 2.25 (d, 2H, J = 7.0 Hz), 4.24 (q, 2H, J = 7.0 Hz); ^{13}C nmr (100.6 MHz) δ: 14.1, 25.8, 25.9, 26.4, 32.7, 36.7, 61.8, 74.0, 88.6, 153.8. Anal. calcd. for $C_{12}H_{18}O_2$: C 74.22, H 9.35; found: C 74.40, H 9.41. Exact Mass calcd.: 194.1307; found: 194.1309.

Lithium (trimethylstannyl) (cyano)cuprate (3)

To a cold (−48°C), stirred solution of trimethylstannyllithium in dry THF (2) was added solid copper(I) cyanide (1 equiv.). The resultant mixture was stirred at −48°C for 20 min to produce a pale yellow solution of the cuprate **3**.

General procedure for the conversion of alkyl 2-alkynoates into alkyl (Z)-3-trimethylstannyl-2-alkenoates

To a cold (−48°C), stirred solution of [$Me_3SnCuCN$]Li (**3**) (1.01–1.09 equiv.) in dry THF was added, dropwise, a solution of the α,β-acetylenic ester (1 equiv.) in dry THF. The mixture was stirred at −48°C for 2 h and at 0°C for 2 h. Aqueous NH_4Cl–NH_4OH (pH 8) (one-half the volume of the total volume of the reaction mixture) was added, the mixture was opened to the atmosphere, was allowed to warm to room temperature, and then was stirred until the aqueous phase became deep blue. The organic phase was separated and the aqueous layer was extracted thoroughly with Et_2O. The combined organic phases were washed with brine, dried ($MgSO_4$), and concentrated. The crude product was purified by flash chromatography, followed by distillation.

The following substances were prepared via this general procedure.

Ethyl (Z)-3-trimethylstannyl-2-pentenoate (23)

The following amounts of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 4.38 mmol, in THF, 20 mL; substrate **13**, 507 mg (4.02 mmol), in THF, 4 mL. Flash chromatography (80 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product and distillation (54–84°C/0.6 Torr) of the acquired liquid afforded 843 mg (72%) of the (*Z*)-pentenoate **23**, a colorless oil that displayed ir (neat): 1703, 1601, 1201, 772 cm^{-1}; ^1H nmr (400 MHz) δ: 0.18 (s, 9H, $^2J_{Sn-H}$ = 55 Hz), 1.04 (t, 3H, J = 7.0 Hz), 1.29 (t, 3H, J = 7.0 Hz), 2.45 (qd, 2H, J = 7.0, 1.5 Hz, $^3J_{Sn-H}$ = 43 Hz), 4.18 (q, 2H, J = 7.0 Hz), 6.36 (t, 1H, J = 1.5 Hz, $^3J_{Sn-H}$ = 120 Hz); ^{13}C nmr (50.3 Hz) δ: −7.5, 13.6, 14.3, 32.9, 60.2, 126.9, 168.1, 177.1. Anal. calcd. for $C_{10}H_{20}O_2Sn$: C 41.28, H 6.93; found: C 41.47, H 7.09. Exact Mass calcd. for $C_9H_{17}O_2Sn$ (M^+ − Me): 277.0250; found: 277.0244.

Ethyl (Z)-4-(triisopropylsiloxy)-3-trimethylstannyl-2-butenoate (26)

The following quantities of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 0.37 mmol, in THF, 3 mL; substrate **14**, 100 mg (0.35 mmol), in THF, 0.5 mL. Flash chromatography (10 g silica gel, 97:3 hexanes–Et_2O) of the crude product, followed by distillation (100–104°C/0.11 Torr) of the acquired liquid, provided 120 mg (76%) of **26**, a colorless oil that exhibited ir (neat): 1702, 1609, 1465, 1299, 1191, 1044 cm^{-1}; ^1H nmr (400 MHz) δ: 0.18 (s, 9H, $^2J_{Sn-H}$ = 56 Hz), 1.05 (d, 18H, J = 6.0 Hz), 1.10 (m, 3H), 1.27 (t, 3H, J = 7.0 Hz), 4.15 (q, 2H, J = 7.0 Hz), 4.52 (d, 2H, J = 2.0 Hz, $^3J_{Sn-H}$ = 19 Hz), 6.72 (t, 1H, J = 2 Hz, $^3J_{Sn-H}$ = 114 Hz); ^{13}C nmr (100.6 MHz) δ: −7.9, 11.9, 14.2, 17.9, 60.3, 68.6, 124.6, 168.3, 171.6. Anal. calcd. for $C_{18}H_{38}O_3SiSn$: C 48.12, H 8.52; found: C 48.14, H 8.60. Exact Mass calcd. for $C_{17}H_{35}O_3SiSn$ (M^+ − Me): 435.1376; found: 435.1360.

Ethyl (Z)-4-[(2-methoxyethoxy)methoxy]-3-trimethylstannyl-2-butenoate (27)

The following amounts of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 0.49 mmol, in THF, 4 mL; substrate **15**, 100 mg (0.46 mmol), in THF, 0.5 mL. Flash chromatography (10 g silica gel, 85:15 hexanes–Et_2O) of the crude product and distillation (95–98°C/0.11 Torr) of the liquid thus obtained produced 127 mg (72%) of **27**, a colorless oil that displayed ir (neat): 1702, 1608, 1368, 1198 cm^{-1}; ^1H nmr (400 MHz) δ: 0.18 (s, 9H, $^2J_{Sn-H}$ = 56 Hz), 1.28 (t, 3H, J = 7.5 Hz), 3.37 (s, 3H), 3.52 (m, 2H), 3.71 (m, 2H), 4.17 (q, 2H, J = 7.5 Hz), 4.38 (d, 2H, J = 2.0 Hz, $^3J_{Sn-H}$ = 20 Hz), 4.75 (s, 2H), 6.63 (t, 1H, J = 2.0 Hz, $^3J_{Sn-H}$ = 112 Hz); ^{13}C nmr (100.6 MHz) δ: −7.7, 14.2, 58.9, 60.4, 66.9, 71.7, 72.4, 95.0, 125.8, 167.5, 168.7. Anal. calcd. for $C_{13}H_{26}O_5Sn$: C 40.98, H 6.88; found: C 41.20, H 7.01. Exact Mass calcd. for $C_{12}H_{23}O_5Sn$ (M^+ − Me): 367.0567; found: 367.0575.

Ethyl (Z)-4-cyclohexyl-3-trimethylstannyl-2-butenoate (28)

The following amounts of reagents and solvents were employed: [$Me_3SnCuCN$]Li (**3**), 0.54 mmol, in THF, 4.5 mL; substrate **16**, 100 mg (0.52 mmol), in THF, 1.0 mL. Flash chromatography (12 g silica gel, 97:3 hexanes–Et_2O) of the crude product and distillation (104–107°C/0.12 Torr) of the acquired liquid afforded 149 mg (81%) of **28**, a colorless oil that exhibited ir (neat): 1703, 1599, 1064 cm^{-1}; ^1H nmr (400 MHz) δ: 0.15 (s, 9H, $^2J_{Sn-H}$ = 55 Hz), 0.84 (m, 2H), 1.10–1.21 (m, 4H), 1.27 (t, 3H, J = 7.0 Hz), 1.30 (m, 1H), 1.63–1.70 (m, 4H), 2.28 (d, 2H, J = 6.0 Hz, $^3J_{Sn-H}$ = 54 Hz), 4.15 (q, 2H, J = 7.0 Hz), 6.25 (s, 1H, $^3J_{Sn-H}$ = 124 Hz); ^{13}C nmr (75 MHz) δ: −7.3, 14.3, 26.4, 26.5, 33.2, 37.5, 47.9, 60.3, 129.1, 167.8, 174.7. Anal. calcd. for $C_{15}H_{28}O_2Sn$: C 50.17, H 7.86; found: C 50.10, H 7.82. Exact Mass calcd. for $C_{14}H_{25}O_2Sn$ (M^+ − Me): 345.0877; found: 345.0871.

*Methyl (Z)-6-(*tert*-butyldimethylsiloxy)-3-trimethylstannyl-2-hexenoate (29)*

The following quantities of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 1.26 mmol, in THF, 6 mL; substrate **17**, 273 mg (1.20 mmol), in THF, 1.2 mL. Flash chromatography (20 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product and distillation (100–130°C/0.6 Torr) of the liquid thus obtained gave 397 mg (78%) of the product **29**, a colorless oil that solidified when cooled and exhibited mp 22–23°C; ir (neat): 1709, 1601, 1329, 1210, 1104, 837, 776 cm^{-1}; ^1H nmr (400 MHz) δ: 0.03 (s, 6H), 0.16 (s, 9H, $^2J_{Sn-H}$ = 55 Hz), 0.88 (s, 9H), 1.53–1.62 (m, 2H), 2.47 (dt, 2H, J = 1.0, 7.0 Hz, $^3J_{Sn-H}$ = 48 Hz), 3.59 (t, 2H, J = 6.0 Hz), 3.70 (s, 3H), 6.36 (t, 1H, J = 1.0 Hz, $^3J_{Sn-H}$ = 120 Hz); ^{13}C nmr (50.3 MHz) δ: −7.4, −5.3, 18.3, 25.9, 32.2, 36.4, 51.4, 62.3, 127.7, 168.3, 175.7. Anal. calcd. for $C_{16}H_{34}O_3SiSn$: C 45.51, H 8.12; found: C 45.80, H 8.21. Exact Mass calcd. for $C_{15}H_{31}O_3SiSn$ (M^+ − Me): 407.1065; found: 407.1071.

Methyl (Z)-6-chloro-3-trimethylstannyl-2-hexenoate (30)

The following amounts of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 2.28 mmol, in THF, 10 mL; substrate **18**, 351 mg (2.18 mmol), in THF, 2 mL. Flash chromatography (45 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product, followed by distillation (75–90°C/0.6 Torr) of the acquired liquid provided 565 mg (79%) of the chloro ester **30**, a colorless oil that exhibited ir (neat): 1708, 1601, 1213, 774 cm^{-1}; ^1H nmr (400 MHz) δ: 0.19 (s, 9H, $^2J_{Sn-H}$ = 55 Hz), 1.87 (quintet, 2H, J = 7.0 Hz), 2.59 (dt, 2H, J = 1.0, 7.0 Hz, $^3J_{Sn-H}$ = 47 Hz), 3.52 (t, 2H, J = 7.0 Hz), 3.73 (s, 3H), 6.40 (t, 1H, J = 1.0 Hz, $^3J_{Sn-H}$ = 116 Hz); ^{13}C nmr (50.3 MHz) δ: −7.4, 31.7, 36.9, 44.0, 51.6, 128.7, 168.1, 174.0. Anal. calcd. for $C_{10}H_{19}ClO_2Sn$: C 36.91, H 5.89, Cl 10.90; found: C 37.10, H 5.96, Cl 10.77. Exact Mass calcd. for $C_9H_{16}{}^{35}ClO_2Sn$ (M^+ − Me): 310.9862; found: 310.9862.

Methyl (Z)-3-trimethylstannyl-2-octen-7-ynoate (31)

The following amounts of reagents and solvents were employed: [$Me_3SnCuCN$]Li (**3**), 1.04 mmol, in THF, 5.5 mL; substrate **19**, 155 mg (1.03 mmol), in THF, 1.0 mL. Flash chromatography (20 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product and distillation (50–70°C/0.6 Torr) of the liquid thus obtained produced 254 mg (78%) of the alkyne ester **31**, a colorless oil that showed ir (neat): 3310, 2120, 1708, 1600, 1212, 774, 636 cm^{-1}; ^1H nmr (400 MHz) δ: 0.20 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 1.62 (quintet, 2H, J = 7.0 Hz), 1.98 (t, 1H, J = 2.5 Hz), 2.20 (dt, 2H, J = 2.5, 7.0 Hz), 2.55 (dt, 2H, J = 1.0, 7.0 Hz, $^3J_{Sn-H}$ = 48 Hz), 3.73 (s, 3H), 6.39 (t, 1H, J = 1.0 Hz, $^3J_{Sn-H}$ = 119 Hz); ^{13}C nmr (50.3 Hz) δ: −7.4, 17.9, 27.7, 38.7, 51.5, 68.9, 83.7, 128.3, 168.2, 174.8. Anal. calcd. for $C_{12}H_{20}O_2Sn$: C 45.76, H 6.40; found: C 46.03, H 6.49. Exact Mass calcd. for $C_{11}H_{17}O_2Sn$ (M^+ − Me): 301.0251; found: 301.0247.

*General procedure for the conversion of alkyl 2-alkynoates into alkyl (*E*)-3-trimethylstannyl-2-alkenoates*

To a cold (−78°C), stirred solution of [$Me_3SnCuCN$]Li (**3**) (1.30–1.50 equiv.) in dry THF was added dry ethanol (1.30–1.50 equiv., for ethyl ester substrates) or dry methanol (1.30–1.35 equiv., for methyl ester substrates). After 5 min, a solution of the α,β-acetylenic ester (1.0 equiv.) in dry THF was added dropwise over a period of about 2 min and the mixture was stirred at −78°C for 4 h. Aqueous NH_4Cl–NH_4OH (pH 8) (one-half the volume of the total volume of the reaction mixture) was added, the mixture was opened to the atmosphere, was allowed to warm to room temperature, and was stirred vigorously until the aqueous phase became deep blue. The phases were separated and the aqueous phase was extracted thoroughly with Et_2O. The combined organic extracts were washed with brine, dried ($MgSO_4$), and concentrated. The crude product was purified by flash chromatography and distillation.

The following substances were prepared by means of this general procedure.

*Ethyl (*E*)-3-trimethylstannyl-2-pentenoate (24)*

The following amounts of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 64.4 mmol, in THF, 200 mL; EtOH, 3.80 mL (64.7 mmol); substrate **13**, 6.25 g (49.5 mmol), in THF, 30 mL. Flash chromatography (250 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product and distillation (50–70°C/0.6 Torr) of the acquired liquid afforded 10.7 g (74%) of the ester **24**, a colorless oil that displayed ir (neat): 1718, 1598, 1179, 774 cm^{-1}; ^1H nmr (400 MHz) δ: 0.21 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.05 (t, 3H, J = 8.0 Hz), 1.29 (t, 3H, J = 7.0 Hz), 2.89 (qd, 2H, J = 8.0, 1.0 Hz, $^3J_{Sn-H}$ = 64 Hz), 4.16 (q, 2H, J = 7.0 Hz), 5.94 (t, 1H, J = 1.0 Hz, $^3J_{Sn-H}$ = 74 Hz); ^{13}C nmr (50.3 MHz) δ: −9.1, 14.1, 14.3, 27.9, 59.6, 126.9, 164.3, 174.5. Anal. calcd. for $C_{10}H_{20}O_2Sn$: C 41.28, H 6.93; found: C 41.08, H 6.87. Exact Mass calcd. for $C_9H_{17}O_2Sn$ (M^+ − Me): 277.0250; found: 277.0250.

*Ethyl (*E*)-4-(triisopropylsiloxy)-3-trimethylstannyl-2-butenoate (32)*

The following amounts of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 0.46 mmol, in THF, 3 mL; EtOH, 0.027 mL (0.46 mmol); substrate **14**, 100 mg (0.35 mmol), in THF, 0.5 mL. Flash chromatography (10 g silica gel, 97:3 hexanes–Et_2O) of the crude product and distillation (115–120°C/0.11 Torr) of the acquired liquid afforded 117 mg (74%) of the product **32**, a colorless oil that showed ir (neat): 1712, 1603, 1184, 1047 cm^{-1}; ^1H nmr (400 MHz) δ: 0.21 (s, 9H, $^2J_{Sn-H}$ = 57 Hz), 1.05 (d, 18H, J = 6.0 Hz), 1.12 (m, 3H), 1.27 (t, 3H, J = 7.0 Hz), 4.12 (q, 2H, J = 7.0 Hz), 4.95 (d, 2H, J = 2.5 Hz, $^3J_{Sn-H}$ = 30 Hz), 5.79 (t, 1H, J = 2.5 Hz, $^3J_{Sn-H}$ = 78 Hz); ^{13}C nmr (100.6 MHz) δ: −7.9, 11.9, 14.3, 18.0, 59.8, 67.2, 123.4, 161.8, 178.5. Anal. calcd. for $C_{18}H_{38}O_3SiSn$: C 48.12, H 8.52; found: C 48.23, H 8.58. Exact Mass calcd. for $C_{17}H_{35}O_3SiSn$ (M^+ − Me): 435.1376; found: 435.1374.

*Ethyl (*E*)-4-[(2-methoxyethoxy)methoxy]-3-trimethylstannyl-2-butenoate (33)*

The following quantities of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 0.60 mmol, in THF, 4 mL; EtOH, 0. 035 mL (0.60 mmol); substrate **15**, 100 mg (0.46 mmol), in THF, 0.5 mL. Flash chromatography (10 g silica gel, 3:1 hexanes–Et_2O) of the crude product and distillation (85–93°C/0.11 Torr) of the acquired liquid provided 122 mg (70%) of **33**, a colorless oil that displayed ir (neat): 1709, 1608, 1370, 1186 cm^{-1}; ^1H nmr (400 MHz) δ: 0.19 (s, 9H, $^2J_{Sn-H}$ = 56 Hz), 1.26 (t, 3H, J = 7.0 Hz), 3.37 (s, 3H), 3.53 (m, 2H), 3.65 (m, 2H), 4.13 (q, 2H, J = 7.0 Hz), 4.72 (s, 2H), 4.79 (d, 2H, J = 2.5 Hz, $^3J_{Sn-H}$ = 30 Hz), 5.92 (t, 1H, J = 2.5 Hz, $^3J_{Sn-H}$ = 73 Hz); ^{13}C nmr (100.6 MHz) δ: −8.1, 14.2, 59.0, 59.9, 66.9, 71.7, 72.1, 95.2, 124.5, 164.3, 173.6. Anal. calcd. for $C_{13}H_{26}O_5Sn$: C 40.98, H 6.88; found: C 41.23, H 7.01. Exact Mass calcd. for $C_{12}H_{23}O_5Sn$ (M^+ − Me): 367.0567; found: 367.0564.

*Ethyl (*E*)-4-cyclohexyl-3-trimethylstannyl-2-butenoate (34)*

The following quantities of reagents and solvents were employed: [$Me_3SnCuCN$]Li (**3**), 30.9 mmol, in THF, 320 mL; EtOH, 1.4 g (30.9 mmol); substrate **16**, 4.0 g (20.6 mmol), in THF,

10 mL. In this experiment, the reaction time was 7 h instead of 4 h. Flash chromatography (50 g silica gel, 97:3 petroleum ether – Et_2O) of the crude product, followed by distillation (100–110°C/0.12 Torr) of the acquired liquid, gave 5.98 g (81%) of the ester **34**, a colorless oil that showed ir (neat): 1718, 1598, 1177, 770 cm^{-1}; ^1H nmr (400 MHz) δ: 0.19 (s, 9H, $^2J_{Sn-H}$ = 56 Hz), 0.95–1.05 (m, 2H), 1.13–1.23 (m, 3H), 1.29 (t, 3H, J = 7.0 Hz), 1.32–1.40 (m, 1H), 1.60–1.75 (m, 5H), 2.83 (d, 2H, J = 8.0 Hz, $^3J_{Sn-H}$ = 61 Hz), 4.16 (q, 2H, J = 7.0 Hz), 6.03 (s, 1H, $^3J_{Sn-H}$ = 82 Hz); ^{13}C nmr (75 MHz) δ: −9.0, 14.3, 26.4 (3C), 33.2, 38.7, 41.9, 59.6, 128.4, 164.5, 172.4. Anal. calcd. for $C_{15}H_{28}O_2Sn$: C 50.17, H 7.86; found: C 50.40, H 7.88. Exact Mass calcd. for $C_{14}H_{25}O_2Sn$ (M^+ − Me): 345.0877; found: 345.0881.

Methyl (E)*-6-(*tert*-butyldimethylsiloxy)-3-trimethylstannyl-2-hexenoate (35)*

The following amounts of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 1.78 mmol, in THF, 9 mL; MeOH, 0.075 mL (1.85 mmol); substrate **17**, 312 mg (1.37 mmol), in THF, 1.4 mL. Flash chromatography (30 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product and distillation (110–130°C/0.6 Torr) of the acquired oil produced 446 mg (77%) of the ester **35**, a colorless oil that exhibited ir (neat): 1720, 1597, 1256, 1169, 1098, 836, 776 cm^{-1}; ^1H nmr (400 MHz) δ: 0.05 (s, 6H), 0.21 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 0.90 (s, 9H), 1.58–1.67 (m, 2H), 2.95 (br t, 2H, J = 8.0 Hz, $^3J_{Sn-H}$ = 62 Hz), 3.64 (t, 2H, J = 6.0 Hz), 3.69 (s, 3H), 5.98 (br s, 1H, $^3J_{Sn-H}$ = 73 Hz); ^{13}C nmr (50.3 MHz) δ: −9.1, −5.7, 18.3, 25.9, 31.5, 32.8, 50.8, 63.0, 127.2, 164.6, 173.3. Anal. calcd. for $C_{16}H_{34}O_3SiSn$: C 45.51, H 8.12; found: C 45.80, H 8.08. Exact Mass calcd. for $C_{15}H_{31}O_3SiSn$ (M^+ − Me): 407.1065; found: 407.1070.

Methyl (E)*-6-chloro-3-trimethylstannyl-2-hexenoate (36)*

The following amounts of reagents and solvents were employed: [$Me_3SnCuCN$]Li (**3**), 2.95 mmol, in THF, 15 mL; MeOH, 0.12 mL (2.96 mmol); substrate **18**, 364 mg (2.27 mmol), in THF, 2 mL. Flash chromatography (45 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product and distillation (70–90°C/0.6 Torr) of the liquid thus obtained provided 590 mg (80%) of the ester **36**, a colorless oil that exhibited ir (neat): 1718, 1598, 1176, 1152, 772 cm^{-1}; ^1H nmr (400 MHz) δ: 0.23 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 1.89 (quintet, 2H, J = 7.0 Hz), 3.01 (dt, 2H, J = 1.0, 7.0 Hz, $^3J_{Sn-H}$ = 60 Hz), 3.56 (t, 2H, J = 7.0 Hz), 3.70 (s, 3H), 6.02 (t, 1H, J = 1.0 Hz, $^3J_{Sn-H}$ = 71 Hz); ^{13}C nmr (50.3 MHz) δ: −9.2, 32.2, 32.5, 44.6, 50.9, 128.2, 164.4, 171.5. Anal. calcd. for $C_{10}H_{19}ClO_2Sn$: C 36.91, H 5.89, Cl 10.90; found: C 37.11, H 5.90, Cl 10.75. Exact Mass calcd. for $C_9H_{16}{}^{35}ClO_2Sn$ (M^+ − Me): 310.9862; found: 310.9860.

Methyl (E)*-3-trimethylstannyl-2-octen-7-ynoate (37)*

The following amounts of reagents and solvents were used: [$Me_3SnCuCN$]Li (**3**), 2.52 mmol, in THF, 12 mL; MeOH, 0.105 mL (2.59 mmol); substrate **19**, 293 mg (1.95 mmol), in THF, 2 mL. Flash chromatography (30 g silica gel, 200:3 petroleum ether – Et_2O) of the crude product and distillation (64–84°C/0.6 Torr) of the acquired liquid afforded 444 mg (72%) of the ester **37**, a colorless oil that displayed ir (neat): 3309, 2218, 1719, 1597, 1262, 1161, 774, 635 cm^{-1}; ^1H nmr (400 MHz) δ: 0.22 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 1.60–1.72 (m, 2H), 1.96 (t, 1H, J = 2.5 Hz), 2.23 (dt, 2H, J = 2.5, 8.0 Hz), 2.98 (dt, 2H, J = 1.0, 7.0 Hz, $^3J_{Sn-H}$ = 61 Hz), 3.70 (s, 3H), 6.00 (t, 1H, J = 1.0 Hz, $^3J_{Sn-H}$ = 73 Hz); ^{13}C nmr (100.6 MHz) δ: −9.1, 18.5, 28.4, 33.9, 50.9, 68.6, 84.1, 127.8, 164.5, 172.3. Anal. calcd. for $C_{12}H_{20}O_2Sn$: C 45.76, H 6.40; found: C 46.01, H 5.63. Exact Mass calcd. for $C_{11}H_{17}O_2Sn$ (M^+ − Me): 301.0251; found: 301.0253.

Thermal cyclizations of protonated poly-unsaturated aldehydes

GEORGE R. ELIA, RONALD F. CHILDS,[1] AND GARY S. SHAW
Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received November 22, 1991

GEORGE R. ELIA, RONALD F. CHILDS, and GARY S. SHAW. Can. J. Chem. **70**, 2065 (1992).

Protonated 2,4-hexadienal (**1H**) and 2,4,6-octatrienal (**2H**), prepared by protonation of the analogous aldehydes in FSO_3H, isomerized to give cyclized products **3H** and **4H** at 30°C and −20°C respectively. The rate constants for the cyclization of **1H** were measured in both FSO_3H and CF_3SO_3H. It was found that the rate constant for isomerization decreased when CF_3SO_3H was used as the reaction medium. It is suggested that the thermal cyclizations of **1H** and **2H** involve diprotonated species with protonation occurring on oxygen. **1H** and **2H** underwent photoisomerization at −78°C in FSO_3H to yield **5H** and **7H** respectively. It was found that **5H** underwent a cyclization reaction at −40°C to give **6H**, which subsequently rearranged to give **3H** at −10°C. However, **7H** was found to isomerize to **2H** at −50°C. The mechanisms of the thermal isomerization are discussed.

GEORGE R. ELIA, RONALD F. CHILDS et GARY S. SHAW. Can J. Chem **70**, 2065 (1992).

L'hexa-2,4-diènan (**1H**) et l'octa-2,4,6-triènal (**2H** protonés, préparés par protonation des aldéhydes correspondants par le FSO_3H, s'isomérisent pour donner les produits cycliques **3H** et **4H**, à 30°C et −20°C respectivement. On a mesuré les constantes de vitesse pour la cyclisation du produit **1H**, tant dans le FSO_3H que dans le CF_3SO_3H. On a trouvé que la constante de vitesse pour l'isomérisation diminue lorsqu'on utilise le CF_3SO_3H comme milieu réactionnel. Il est suggéré que les cyclisations thermiques des composés **1H** et **2H** impliquent des espèces diprotonées dans lesquelles la protonation se fait sur l'oxygène. Dans le FSO_3H, à −78°C, les composés **1H** et **2H** subissent des photo-isomèrisations qui conduisent respectivement aux composés **5H** et **7H**. On a trouvé que le composé **5H** subit une réaction de cyclisation à −40°C qui conduit au produit **6H** qui se transpose subséquemment pour donner le composé **3H** à −10°C. Toutefois, on a trouvé que, à −50°C, le composé **7H** s'isomérise en composé **2H**. On discute des mécanismes des isomérisations thermiques.

[Traduit par la rédaction]

The chemistry of polyenyl carbocations has been investigated extensively (1–3). The characteristic reaction of this important class of carbenium ions is ring closure of a pentadienyl fragment to form a substituted cyclopentenyl cation. This cyclization reaction has been shown to proceed via a stereoselective 4-π electron electrocyclic ring closure (4, 5). These reactions are generally facile, occurring, for example, at very low temperatures when the ions are generated as long-lived species in strong acid media.

There have been fewer studies reported on the chemistry on the hydroxy- or alkoxy-substituted polyenyl carbenium ions, despite the ease by which these ions can be prepared by the protonation of unsaturated carbonyl compounds and their derivatives (6). One important example is the cyclization of protonated cross-conjugated dienones to form protonated cyclopentenones, a reaction that forms the key step in what has become known as the Nazarov reaction (7). This cationic cyclization reaction parallels the cyclization reactions observed with the parent polyenyl cations referred to above (8). The Nazarov reaction is of synthetic importance as a route to cyclopentenones.

In contrast to the many examples of the thermal isomerization of protonated cross-conjugated dienones, no reports have appeared on the chemistry of the corresponding 1-hydroxy-pentadienyl or higher polyenyl cations. This is surprising given the ready availability of the corresponding unsaturated carbonyl compounds, the importance of this type of functionality in a variety of natural systems[2] and the potential use of cyclization reactions to prepare a variety of cyclopentenones (5). In this work we report on the protonation and isomerization of a variety of such systems.[3]

Results and discussion

The cations selected for study were **1H** and **2H**. These cations were prepared by the protonation of the corresponding carbonyl compounds, **1** and **2**. The ions were characterized by their low-temperature ^1H and ^{13}C NMR spectra, which were consistent with the assigned structures, Tables 1 and 2. The chemical shifts of the various proton resonances and coupling constants corresponded to those reported for the simpler enones (6, 11) and cyclic dienones (12). The *E* conformation about the formal double bonds was clearly shown by the characteristic 14.0 ± 0.4 Hz coupling constant observed between the two protons *trans* to each other on the bonds.

Detailed examination of the ^1H NMR spectra of these ions showed in each case that minor isomers were present. These isomers were shown to be the 4-*Z* isomer in the case of **1** and the 6-*Z* isomer in the case of **2**. In each case the $^1H/^1H$ coupling constant across the *Z* bond was found to be 11.1 ± 0.3 Hz; a value characteristic of a *Z* configuration in comparable cations (11). Both of these *Z* isomers were shown to be present in the neutral aldehydes prior to protonation, Table 3. As can be seen from the data in Table 3, in the case of **2** partial isomerization about the various C=C bonds to form the all-*E* isomer occurred on protonation and NMR characterization of the cation. The all-*E* isomer **2H** is expected to be the most thermodynamically stable conformer of this cation.

Rotational barriers about the formal C—C single bonds of cations comparable to **1H** and **2H** are expected to be low and,

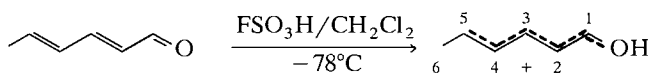
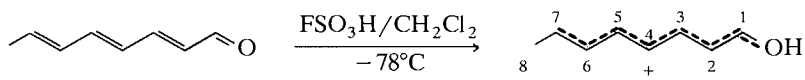
[c]Measured at −60°C.

as such, rotation about these bonds will be fast on the NMR time scale at temperatures above −100°C (13). The thermodynamically preferred conformations about the "single" bonds of **1H** and **2H** are also expected to be *E*. This was shown previously for 1-hydroxyallyl cations and conjugated iminium salts through low-temperature ^{13}C NMR studies (14). A crystallographic study of a dioxolynium cation corresponding to **1H** has shown it has an *E* configuration about each of the formal C—C and C=C bonds (15). Crystal structures of conjugated iminium salts have also shown the all-*E* conformation to be the present in the solid state (16, 17).



1 **1H**



2 **2H**

Thermal isomerizations

The 1-hydroxy cations **1H** and **2H** were stable in FSO_3H for several hours at −60°C. Thermal stability at higher temperatures was assessed using ^{1}H NMR and monitoring the resulting spectrum as the temperature was increased. The samples were maintained at each temperature for about 30 min while spectra were being acquired. From these spectra it was evident that **1H** isomerized to form a second species as the temperature was increased above 30°C. The cation **2H** was found to undergo a more facile reaction, with it forming another species at temperatures as low as −20°C. In both cases the isomerizations proceeded quantitatively.

The thermal products of **1H** and **2H** were identified as the protonated cyclopentenone, **3H**, and the cation, **4H**, respectively, on the basis of their ^{1}H NMR spectra, Table 1. In the case of the isomerization of **1H**, a key feature in the spectrum used in the identification of **3H** was the disappearance of all but one of the vinylic proton resonances. The presence of two methylene groups was evident from the two

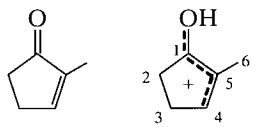
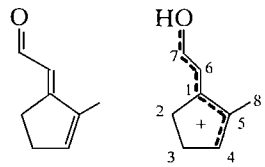
mutually coupled resonances appearing at 3.26 ppm and 3.34 ppm (18). Elucidation of the structure of **4H** proved to be a more difficult task than in the case of **3H**. The presence of the cyclopentene ring moiety was evidenced by ^{1}H NMR signals arising from two adjacent methylene groups as in the case of **3H**. The doublet at 9.25 ppm, characteristic of an aldehydic proton coupled to an adjacent vinyl proton, indicated that ring closure occurred between C3 and C7. An NOE experiment confirmed that the protonated carbonyl group was *trans* to the methyl group substituted on the cyclopentene ring.



3 **3H**



4 **4H**

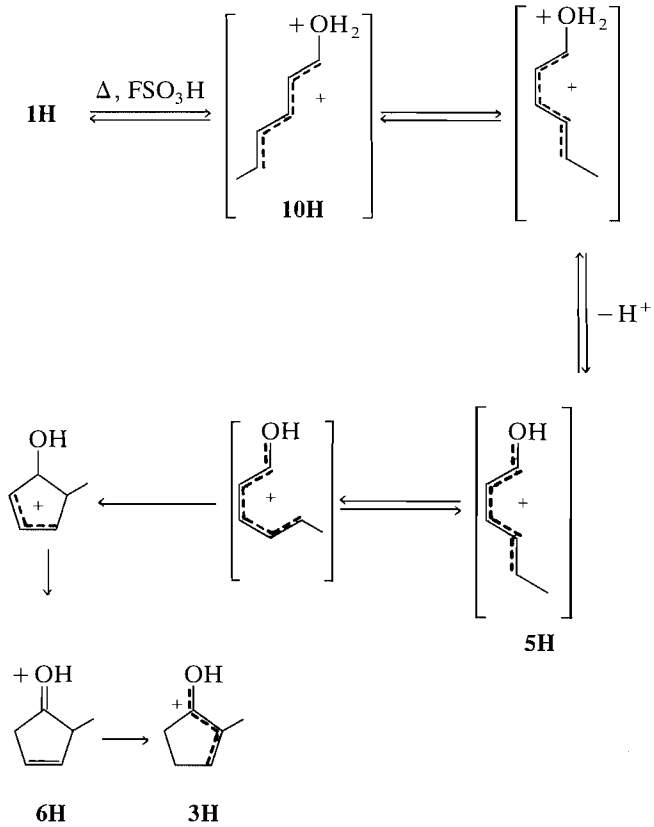
The acid solutions of **3H** and **4H** were neutralized in order to retrieve the cyclopentene derivatives **3** and **4**. This proved to be a facile task in the case of **3**, which was recovered and purified by gas chromatography. The identification of **3** was confirmed through an independent synthesis following the method of Ho and Liu (19). Protonation of 2-methyl-2-cyclopentenone in FSO_3H afforded a cation with the identical ^{1}H NMR spectrum to that of **3H** derived from the isomerization of **1H**.

Neutralization of an FSO_3H solution containing the cation **4H** led to the formation of a mixture of compounds. The major product was identified as 2-methyl-2-cyclopentylidene acetaldehyde by its ^{1}H NMR spectrum although isolation of a pure sample of this material proved to be difficult. The major product had an identical ^{1}H NMR spectrum to that described by Gilbert and Smith for **4** (20).

The overall steps in the isomerization of **1H** would most reasonably involve *E* to *Z* isomerization about both the C(1)—C(3) formal double and C(3)—C(4) single bonds of the starting cation, Scheme 1. The intermediary 2-*Z* isomer **5H** could then undergo cyclization and subsequent hydride shifts to give **3H**(21).

To test this suggested mechanism the 2-*Z* isomer **5H** was prepared by photoisomerization of **1H** (6, 11). An FSO_3H solution of **1H** (λ_{max} 338 nm (log ε = 4.1)) was irradiated at low temperature for about 6 h. A single isomer of the starting protonated aldehyde was formed (ca. 30% conversion), which was identified as **5H** on the basis of its ^{1}H NMR spectrum, Table 1. The spectrum of **5H** exhibited an 11.2 Hz coupling constant between the two protons attached to the C(2)C(3) partial double bond, clearly indicating the *Z* configuration of this bond. On continued irradiation beyond this point the ^{1}H NMR spectrum of the mixture of cations became more complex, suggesting the formation of other isomers such as the di-*Z* isomers. These cations were not identified.

The thermal isomerization of **5H** was examined by following the reactions by NMR. Heating a mixture of **1H** (70%) and **5H** (30%) to −40°C caused the latter isomer to isomerize to give **6H**. This new cation was identified as **6H** on the basis of its NMR spectrum, Table 1. On further heating the reaction mixture to −10°C, the cation **6H** was found to isomerize to give **3H**.



SCHEME 1

It is clear from these results that the isomerization could proceed via the formation of the thermodynamically less stable 2-*Z* isomer **5H**. Given the thermal lability of **5H** and its ring closure product **6H**, these isomers would not be detected at temperatures required for the isomerization of **1H**. The intermediacy of **6H** and its subsequent transformation to the thermodynamically most stable ion **3H** parallels the report of Olah *et al.* on the protonation of 3-cyclopentenone (18).

Further information on the mechanism of the thermal isomerization of **1H** was obtained by examining the reaction in media of different acidity. The rate constants for the isomerization of **1H** to the cyclopentenone cation **3H** were measured in both FSO_3H and CF_3SO_3H. The isomerizations followed first-order kinetics. The rate constants and activation parameters for the isomerizations are given in Table 4.

As can be seen from the data in Table 4, the isomerization of **1H** to **3H** is significantly faster in FSO_3H than in CF_3SO_3H. FSO_3H is a stronger acid than CF_3SO_3H(22). The faster rate of isomerization in the stronger acid medium suggests that the reaction is acid catalysed. The large negative entropy of activation (−42.5 cal K^{-1} mol^{-1} at 60°C) measured for the isomerization of **1H** to **3H** is fully consistent with protonation on oxygen to form a dication, Scheme 1. It is not clear whether it is a dication that undergoes ring closure or if a proton loss to form **5H** occurs prior to cycli-

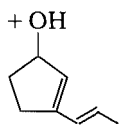
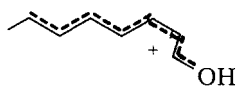
zation. Earlier work in this group has shown that the *Z* to *E* isomerizations of 3-aryl-1-methoxyallyl (23) and *N*-aryl-3-arylpropenylidene iminium salts (24) can involve protonation on the heteroatom to form a dication. There is growing evidence to suggest that comparable dications are involved in a range of other organic reactions (25).

The surprising feature of the isomerization of **2H** is the regioselectivity of the process. The other product that could have formed is **9H** (26); however, no such product could be detected in the NMR spectrum of the reaction mixture during the isomerization.

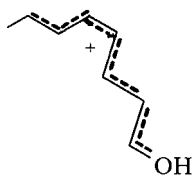
To examine this regioselectivity the 2-*Z* isomer of **2H** was prepared by irradiation. The cation **2H** exhibited a UV spectrum with a long-wavelength band at 425 nm (log ε = 4.0). Irradiation of an FSO_3H solution of **2H** at low temperature for about 6 h led to the formation of **7H** (45% conversion). The photoproduct was again identified as the corresponding 2-*Z* isomer **7H** on the basis of its ^1H NMR spectra, Table 1. On continued irradiation of the **2H/7H** mixture, the vinyl region in the ^1H NMR spectrum for both cations became complex suggesting the formation of the di-*Z* isomers. These cations were not identified.



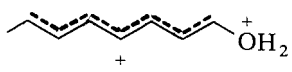
9H



7H



8H



11H

Warming the FSO_3H mixture of **7H** (45%) and **2H** (55%) to −50°C caused this ion to revert completely to **2H**. No cyclic products were formed under these conditions. The all-*Z* isomer **2H** was stable in the acid solution at −50°C and did not isomerize to **4H** until the solution was heated to −20°C. It is clear from these results that, while **7H** might well be thermally accessible from **2H** this isomer does not undergo a ring closure reaction.

The formation of **4H** from **2H** would seem to proceed via the 4-*Z* isomer **8H**. As **2H** is expected to be more basic than **1H**, isomerization about the formal C—C bonds of **2H** will again involve protonation on oxygen to form the dication **11H**. This dication can be considered to be a substituted heptatrienyl cation and should exhibit behaviour more typical of a trienyl cation than δ a protonated heptatrienal. Baird has shown by calculation that the barriers to rotation about the central partial double bonds of trienyl cations are lower than those of the terminal partial double bonds (13). As such it would be expected that **8H** could be produced preferentially in solutions of **2H** in FSO_3H. The lowest energy cyclization process available to **8H** is C(3)—C(7) bonding to eventually form **4H** rather than a C(1)—C(5) bonding reaction.

Experimental section

General

^1H NMR spectra were recorded on a Varian EM-390 or on a Bruker AM-500 spectrometer. The latter was used for all low-temperature studies and ^{13}C NMR spectra (125.78 MHz). UV spectra were recorded on a Hewlett Packard 8451A diode array spectrophotometer using FSO_3H as solvent. Centrifugal chromatography was carried out on silica (Merck Kieselgel $60PF_{254}$) coated plates (coating 2 or 4 mm) spinning in a Chromatotron model 7924T apparatus.

Materials

All solvents were available commercially and were purified by standard procedures. Compound **1** was also commercially available and distilled before use. Purity was checked using ^1H and ^{13}C NMR. FSO_3H and CF_3SO_3H were distilled twice under N_2 before use, and stored in sealed glass ampules.

2,4,6-Octatrienal (2)

A mixture of butenal (11.0 g, 0.16 mol). glacial acetic acid (1.5 mL, 0.025 mol), and piperidine (0.15 mL, 0.0015 mol) was heated over a steam bath for 10 min under an N_2 atmosphere and subsequently cooled in an ice bath. The entire contents of the flask were distilled under 0.05 Torr pressure (1 Torr = 133.3 Pa) and the fraction boiling at 65°C removed. A centrifugal chromatography separation using 10% ether/hexanes as solvent was carried out and the second band (R_F = 0.2) taken. The solvent was removed to give **2** as the major product with a small amount of *cis* isomers representing the minor products. ^1H NMR (CD_2Cl_2) δ: 1.80 (d, J = 7 Hz, CH_3, 3H), 6.05(m, H_2, H_7, 2H), 6.18 (dd, J = 11 Hz, 15 Hz, H_6, 1H), 6.33 (dd, J = 11 Hz, 15 Hz, H_4, 1H), 6.66 (dd, J = 11 Hz, 15 Hz, H_5 1H), 7.14 (dd, J = 11 Hz, 15 Hz, H_3, 1H), 9.46 (d, J = 8 Hz, H_1, 1H).

Preparation of cations

FSO_3H (1 mL) was cooled to −78°C and slowly added to a CD_2Cl_2 solution of the appropriate aldehyde (40–50 mg) also at

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

−78°C. CF_3SO_3H was cooled to −5°C and added in a similar manner.

Irradiations

All photoisomerizations were carried out using a photoreactor that consisted of 10 reactor lamps (Southern New England Ultraviolet Co., RPR 3000A or 3500A) arranged in a circle around a quartz Dewar. The samples were placed inside the Dewar and cooled using a FTS Systems Flexi-cooler refrigeration system and methanol. The photoisomerizations were monitored by ^{1}H NMR.

Rate measurements

The isomerization rates of protonated 2,4-hexadienal were determined by placing medium-walled NMR tubes containing the cation in a constant temperature bath. After a given time interval, the reaction was quenched by rapidly cooling the samples in an ice bath, and the reaction assayed by ^{1}H NMR at 20°C. Each spectrum was scanned twice and the extent of reaction determined by the average of integrations of methyl resonance of each species. In each rate determination some six to eight different points were taken, and first-order kinetics were observed. Each rate constant was determined in duplicate using independent samples.

A CAD study of isobaric $(CH_3)_3SiArH^+$ ions (ArH = benzene, toluene) formed by association and protonation

XIAOPING LI[1] AND JOHN A. STONE
Department of Chemistry, Queen's University, Kingston, Ont., Canada K763N6

Received February 11, 1992

XIAOPING LI and JOHN A. STONE. Can. J. Chem. **70**, 2070 (1992).

Collision-assisted dissociation has been used to compare the ions formed by (*a*) the addition of trimethylsilylium ($(CH_3)_3Si^+$) to benzene and toluene, and (*b*) the protonation of trimethylsilyl-substituted aromatics. The spectra of the isobaric ions are essentially identical at both high (8 keV) and low (<15 eV) collision energies. Proton transfer to trimethylamine is observed for all ions at centre of mass collision energies below 1.5 eV. The results show that the decomposing and reacting structures are the same for all these isobaric ions, whether formed by protonation or by addition of trimethylsilylium to aromatic, but they do not definitively resolve the question of the structure of their ground state, i.e., whether $(CH_3)_3Si$ is π or σ bonded.

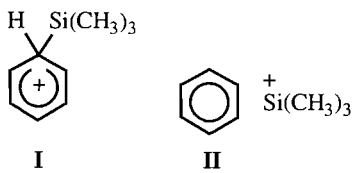
XIAOPING LI et JOHN A. STONE. Can. J. Chem. **70**, 2070 (1992).

On a utilisé une dissociation assistée par collision pour comparer les ions qui se forment par (*a*) l'addition du triméthylsilylium ($(CH_3)_3Si^+$) au benzène et au toluène et (*b*) la protonation de produits aromatiques substitués par des groupes triméthylsilyles. Les spectres des ions isobares sont pratiquement identiques aux énergies de collision tant élevées (8 keV) que basses (<15 eV). On a observé un transfert de proton vers la triméthylamine pour tous les ions au centre d'énergies de collision de masse inférieures à 1,5 eV. Les résultats montrent que les structures qui réagissent et qui se décomposent sont les mêmes pour tous ces ions isobares, qu'ils se forment par protonation ou par addition de triméthylsilylium à un produit aromatique; toutefois, ils ne permettent pas de résoudre d'une façon définitive la question de la structure de leur état fondamental, à savoir si le $(CH_3)_3Si$ est lié par des électrons δ ou π.

[Traduit par la rédaction]

Introduction

γ-Radiolysis of $CH_4/(CH_3)_4Si/ArH$ mixtures (ArH = aromatic = benzene, toluene, xylene) at pressures of around 1 atmosphere (1 atm = 101.3 kPa) leads to the formation of the silylated aromatics $(CH_3)_3SiAr$ (1, 2). The suggested mechanism has the σ-bonded structure **I** as an intermediate.



I **II**

For example, in the case of benzene the proposed mechanism involves initial formation of $(CH_3)_3Si^+$ by dissociative protonation of $(CH_3)_4Si$ followed by addition of $(CH_3)_3Si^+$ to benzene and subsequent deprotonation of the adduct by a base B.

[1] $CH_5^+ (C_2H_5^+) + (CH_3)_4Si \rightarrow CH_4 + CH_4(C_2H_4) + (CH_3)_3Si^+$

[2] $(CH_3)_3Si^+ + C_6H_6 \longrightarrow$  $+ BH^+$

The base employed was $(C_2H_5)_3N$ which has high Brønsted basicity but relatively low nucleophilicity. Preliminary experiments using ion cyclotron resonance spectroscopy showed that molecules with basic oxygen sites, such as cyclohexanone, which might be expected to deprotonate the suggested arenium ion, did not do so and only $(CH_3)_3Si^+$ transfer was observed (2).

[3] $(CH_3)_3SiArH^+ + C_6H_{10}O \rightarrow (CH_3)_3SiOC_6H_{10}^+ + ArH$

Earlier studies of the association of $(CH_3)_3Si^+$ with aromatics in a high-pressure mass spectrometer (HPMS) source (2–4.5 Torr; 1 Torr = 133.3 Pa) led to the suggestion that the observed stabilized $(CH_3)_3SiArH^+$ ions had the π-complex structure **II** rather than being σ-complexes (3). Later HPMS studies failed to find convincing evidence for arenium ion structures (4). Adducts were formed by the addition of either $(CH_3)_3Si^+$ or $(CH_3)_3C^+$ to perdeuterated benzene and toluene and $(C_2H_5)_3N$ was used as a deprotonating agent. The appearance of $(C_2H_5)_3ND^+$ was taken as evidence that deprotonation of an arenium ion had occurred according to reaction [2]. The disappearance of $(CH_3)_3CC_6D_6^+$, for example, was accompanied by an almost equal increase in $(C_2H_5)_3ND^+$, which characterizes $(CH_3)_3C^+$ adducts as arenium ions. Although the $(CH_3)_3Si^+$ adducts of perdeuterated aromatics disappeared as rapidly as did the analogous $(CH_3)_3C^+$ adducts in the presence of $(C_2H_5)_3N$, the accompanying formation of $(C_2H_5)_3ND^+$ was far less than expected; $(C_2H_5)_3NH^+$ was the major product. Therefore, although the results with the $(CH_3)_3C^+$ adducts show that HPMS is able to provide good evidence for the presence of arenium ions, the evidence obtained with the $(CH_3)_3Si^+$ adducts is inconclusive.

In this paper we report on a further investigation of the structures of the $(CH_3)_3SiArH^+$ complexes, this time using collision-assisted dissociation (CAD). In particular, a comparison is made of the CAD spectra of $(CH_3)_3SiArH^+$ ions formed by the addition of $(CH_3)_3Si^+$ to benzene and toluene and the isobaric ions formed by protonation of trimethylsilylbenzene and trimethylsilyltoluene. The evidence suggests that the isobaric $(CH_3)_3SiArH^+$ ions formed by the two dif-

ferent methods decompose from a common structure and that the ions probably do have the arenium ion structure **I**.

Experimental

All experiments were carried out using the ZAB-2FQ (BEQQ geometry) mass spectrometer located at the Ontario Regional Ion Centre at the University of Toronto. Two different ion sources were employed, the standard VG EI/CI source and a recently constructed high pressure source (HP) (5). The advantage of the latter is that since the electron-emitting filament is ~5 cm from the ion source block there is no heating of the block by the filament and temperatures as low as 300 K may be used. This aids in the formation of usable beams of ions that are susceptible to thermal decomposition. In addition, the HP source was operable at significantly higher pressures, 4 Torr vs. ~0.5 Torr.

Metastable spectra, due to the unimolecular decomposition of ions of unique m/z values in the second field free region between the magnetic and electrostatic sectors were obtained by scanning the electrostatic field at fixed acceleration voltage and magnet field (MIKES scan). Collisional-activated dissociations were carried out in the second field free region (high energy (HE)) or in the first of the two quadrupole mass filters, which was operated in the RF only mode (low energy (LE)). For HE studies the ion beam energy was usually 8 keV while for LE studies the energies of the decelerated ions ranged from 0.5 to 50 eV. Daughter ions from HE dissociations were analyzed using the electric sector and those from LE dissociations by using the second quadrupole analyzer. Helium was used as the collision gas at HE while both nitrogen and trimethylamine were used at LE. This latter collision gas adsorbs strongly on all surfaces and persisted for a considerable length of time in the system after its flow was turned off. The pressure reading of an ionization gauge well downstream was not a reliable measure of the pressure in the collision region. For example, changes in gauge reading did not correlate well with spectral changes and when N_2 was introduced as collision gas immediately after $(CH_3)_3N$ had been used, spectra at low beam energy (<6 eV) contained ions due to collisions with $(CH_3)_3N$. Multiple scans (10–100) were summed in a multichannel analyser to obtain each of the spectra presented in this paper. Pressure readings downstream from the collision cell were used as a rough guide to set up operating conditions for HE CAD studies but the main criterion to be met in obtaining the spectral data was a decrease in main-beam intensity of approximately 10–20%. With this attenuation the problem of multiple collisions was minimized. Of course identical parent ions should yield identical spectra under the same conditions whether they are in the single or multiple collision regime. A range of beam attenuations was used for CAD studies at low pressure to gain information on the observed ion–molecule reactions.

Trimethylsilylbenzene and trimethylsilyltoluene were obtained from PCR Laboratories Ltd. Tetramethylsilane (TMS), benzene-d_5, toluene-d_8, and toluene-α,α,α-d_3 were from Merck Sharpe and Dohme and all other chemicals were from the Aldrich Chemical Company Limited. All chemicals were used as received.

Results

The $(CH_3)_3Si^+$ adducts of benzene, benzene-d_6, toluene and toluene-α,α,α-d_3, and mesitylene were readily formed in both the HP source and the EI/CI source by addition of $(CH_3)_3Si^+$ to the aromatic via reactions [1] and [2]. Higher relative intensities of the adducts were obtained using the HP source because of more efficient third-body stabilization but the observed metastable and CAD spectra obtained were independent of the source employed. Ions of the same m/z values as the $(CH_3)_3Si^+$ adducts of benzene and toluene were also formed by protonation of $(CH_3)_3SiC_6H_5$ and p-$(CH_3)_3SiC_6H_4CH_3$. (Henceforth for convenience, such ions, no matter how formed, with elemental composition $(CH_3)_3$-SiArH$^+$ (ArH = aromatic) will be designated MH$^+$.) MH$^+$ formed by protonation was always of very low intensity even when the HP source was operated at 300 K and this was also the case if either the strong protonating reagent ion CH_5^+ was used or the much weaker i-$C_3H_7^+$ (PA(C_3H_6) = 180 kcal mol^{-1} (6)), generated in CH_4/C_3H_8 mixtures. The reason for the weak signal was that protonization by CH_5^+ can lead to extensive desilylation rather than protonation, while with i-$C_3H_7^+$ displacement of $(CH_3)_3Si^+$ competes with protonation (7). In addition there was always a significant M$^+$ peak (~60% the intensity of MH$^+$), which has a ^{29}Si isotopic component isobaric with MH$^+$. Presumably M$^+$ originated by direct electron impact ionization (8). The possibility was therefore present of metastable decomposition or collisional dissociation of M$^+$ interfering with studies of MH$^+$. M$^+$ was generated in the absence of MH$^+$ by electron impact on $(CH_3)_3SiC_6H_5$ and $(CH_3)_3SiC_6H_4CH_3$ in the EI/CI source at low pressure and the metastable and CAD spectra were recorded. A very intense [M − 15]$^+$ peak was the only metastable decomposition observed and this peak was also dominant in the HE CAD spectrum, constituting >80% total ion intensity.

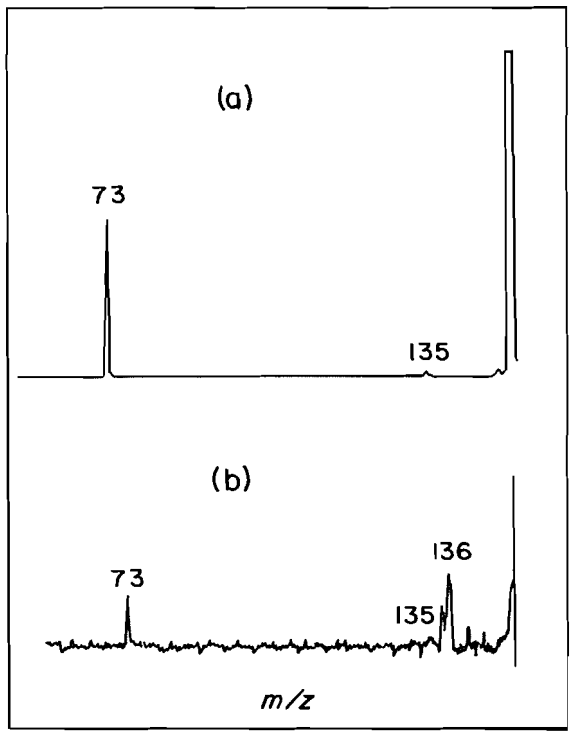

FIG. 1. The metastable spectra for m/z 151 formed by (*a*) the addition of $(CH_3)_3Si^+$ to C_6H_6, and (*b*) the protonation of $(CH_3)_3SiC_6H_5$. Main beam energy 8 keV.

Metastable (unimolecular) decompositions

The metastable decomposition spectra observed in the second field free region of MH$^+$ (ArH = C_6H_6) formed by the two different methods are compared in Fig. 1. The significant difference between the two spectra, apart from the obvious difference in intensity, is the pair of relatively large peaks attributed to loss of CH_3 (m/z 136) and CH_4 (m/z 135) from MH$^+$ formed by protonation. The peak at m/z 136 may be due, wholly or in part, to the unimolecular decomposition of the isobaric M$^+$ containing ^{29}Si, for which CH_3 loss constitutes the major, and very intense, metastable decom-

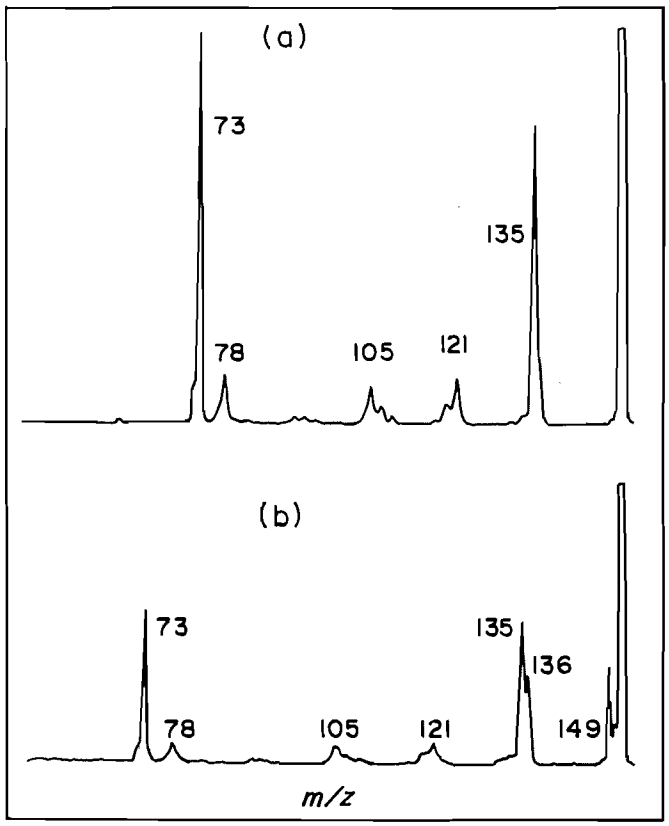

FIG. 2. The CAD spectra of m/z 151 formed by (*a*) the addition of $(CH_3)_3Si^+$ to C_6H_6, and (*b*) the protonation of $(CH_3)_3SiC_6H_5$. Main beam energy 8 keV, target gas He.

position. Loss of CH_4 occurs for all MH^+ but constitutes a greater fraction of the total for ions formed by protonation. This may be due to a slightly different energy content for these ions although most ions from the high-pressure source should be thermalized since the average ion suffers more than 10^4 collisions before exiting the source. The results for the metastable decomposition of MH^+ (ArH = $C_6H_5CH_3$), which are not shown, are similar to the results for MH^+ (ArH = C_6H_6) but the intensity of $[MH - 15]^+$ is only 5% of m/z 73 for the ion formed by protonation and only m/z 73 is observed for MH^+ formed by association.

The metastable spectra from decompositions subsequent to deceleration were observed at ion energies of 50 eV. The results confirm those described above, with loss of aromatic to yield $(CH_3)_3Si^+$ (m/z 73) being the major decomposition path. Peaks due to loss of CH_3 but only from protonated M, (mainly from ^{29}Si containing M^+?) and CH_4 are also observed.

CAD spectra

HE CAD spectra for MH^+ (ArH = C_6H_6) are shown in Fig. 2. The data from these figures are presented in Table 1, as are the data for MH^+ (ArH = $C_6H_5CH_3$). Also shown in the table are the assigned neutral losses. The assignments for MH^+ formed by association could be partially checked using C_6D_6 and $C_6D_5CD_3$. The loss of 16 mass units for the C_6H_6 adduct becomes 17 mass units with C_6D_6, i.e., the methane lost is composed of CH_3 from $(CH_3)_3Si$ and H from the aromatic ring. The CH_3 lost is entirely from the $(CH_3)_3Si$ group as is loss of C_2H_6 (ArH = C_6D_6) but loss of both masses 30 and 33 in almost equal proportions (C_2H_6 and $C_2H_3D_3$) is observed with $C_6D_5CD_3$. This interesting observation of an apparent combination of ring and silicon methyls was not pursued. Losses of masses 46, 44, and 42 from MH^+ (ArH = benzene) becomes losses of 47, 45, and 43 with C_6D_6. The lost neutrals are presumed not to contain silicon (for example 46 amu could be loss of $H_3{}^{28}SiCH_3$) since this implies significant rearrangement, which is not usually encountered in HE CAD.

LE CAD spectra of MH^+ were studied using either N_2 or $(CH_3)_3N$ as collision gas. With a beam energy of 50 eV there was no difference between the results obtained for any MH^+, loss of aromatic to give $(CH_3)_3Si^+$ being the only decomposition path. This path was the only one for N_2 CAD at all lower energies but at very low laboratory energies (<6 eV) other paths opened up with $(CH_3)_3N$. Figure 3 shows representative CAD spectra for MH^+ (ArH = C_6H_6) formed by both protonation of $(CH_3)_3SiC_6H_5$ and by addition of $(CH_3)_3Si^+$ to C_6H_6 with $(CH_3)_3N$ as collision gas. When C_6D_6 rather than C_6H_6 was complexed with $(CH_3)_3Si^+$ to form MH^+, the peaks at m/z 73 and 132 were unchanged and m/z 60 became 61. The major peaks are identified as $(CH_3)_3NH^+$ (m/z 60), $(CH_3)_3Si^+$ (m/z 73), and $(CH_3)_3SiN(CH_3)_3{}^+$ (m/z 132). The minor peak at m/z 119 is the proton-bound dimer $((CH_3)_3N)_2H^+$ but the identity of the small m/z 104 peak is not immediately evident. Although it is present in the two spectra of Fig. 3 it was absent when C_6D_6 was used instead of C_6H_6 in forming the complex with $(CH_3)_3Si^+$. This peak also appeared in the CAD spectrum of the toluene adduct and may be due to an impurity in the $(CH_3)_3N$. For all MH^+, a lowering of ion translational energy to ~0.5 eV resulted in the presence of essentially only two CAD ions, viz. m/z 60 and m/z 132, m/z 73 being of very low intensity.

The $(CH_3)_3Si^+$ adduct of 1,3,5-trimethylbenzene (mesitylene) was also examined in the same manner as those of benzene and toluene. The only metastable decomposition peak was due to loss of aromatic to give $(CH_3)_3Si^+$. The HE CAD spectrum was more intense than for the lower aromatics with large peaks for losses of CH_4, C_2H_6, and $(CH_3)_3Si^+$. An equally large peak at m/z 105 could be loss of $(CH_3)_4Si$. LE CAD with nitrogen as collision gas led only to m/z 73, i.e., loss of mesitylene. The same result occurred with $(CH_3)_3N$ as collision gas at centre of mass energies greater than 1 eV, but below this energy the $(CH_3)_3Si^+$ adduct of trimethylamine was formed. $(CH_3)_3NH^+$ was present but in a far diminished yield (<5% relative abundance) compared with those from the benzene and toluene adducts.

Discussion

Comparison of Figs. 2*a* and 2*b* and the data in Table 1 strongly suggests that the decomposing forms of MH^+ ions for ArH = benzene, whether formed by association or protonation, have the same structure. For ArH = toluene the relative intensities of CAD ions for MH^+ formed by the two methods are not as well matched as those for benzene but the intensity patterns are comparable. The contribution of metastable decomposition to each of the spectra was assessed by biasing the collision cell by 1 kV to separate CAD and metastable ions. Very small metastable contributions (<10% of the intensity of each peak) were observed for m/z 73 in all spectra. Metastable decomposition of MH^+ formed by protonation also showed a small contribution to the ion

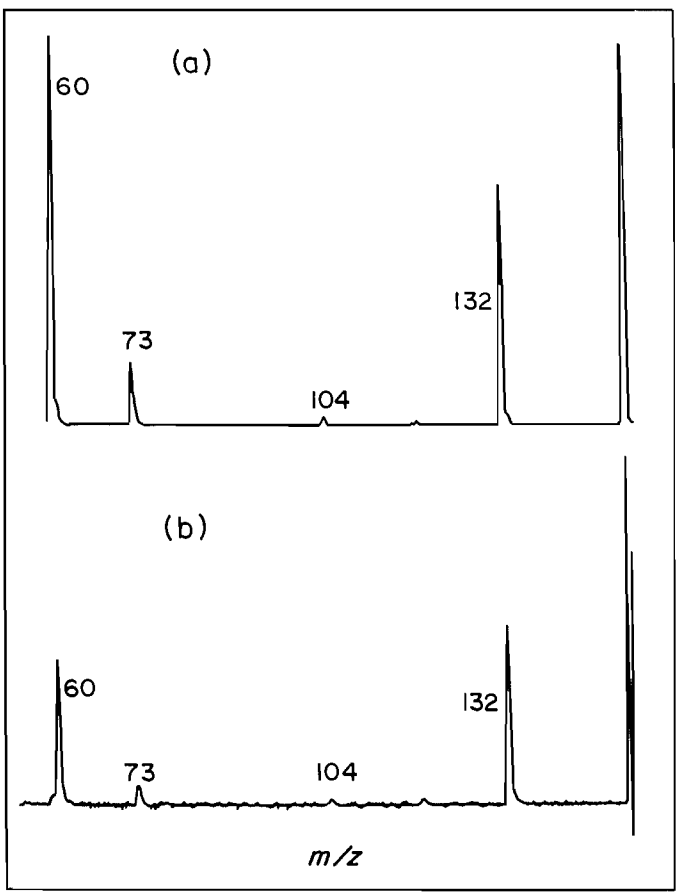

FIG. 3. The CAD spectra of m/z 151 formed by (*a*) the addition of $(CH_3)_3Si^+$ to C_6H_6, and (*b*) the protonation of $(CH_3)_3SiC_6H_5$. Main beam energy 1.5 eV, target gas $(CH_3)_3N$.

formed by loss of 15 amu, i.e., CH_3. The major CAD ion in all spectra is m/z 73 ($(CH_3)_3Si^+$) formed by loss of the aromatic molecule.

[4] $(CH_3)_3SiArH^+ \rightarrow (CH_3)_3Si^+ + ArH$

This is the expected ion if the dissociation is that of either a π or a σ complex since the positive charge will tend to remain with the fragment of lowest ionization energy ($IE(C_6H_6) = 9.25$ eV, IE ($(CH_3)_3Si$) ≈ 6.5 eV (9)). It is to be noted that a small peak corresponding to loss of $(CH_3)_3Si$ as neutral is also observed in all HE CAD spectra. The presence of this ion shows a minimum energy input in the collision process of $IE(C_6H_6) - IE((CH_3)_3Si) + D((CH_3)_3Si^+ - C_6H_6) = 3.76$ eV for $ArH = C_6H_6$. The observation of this ion requires activating collisions leading to excitation to upper electronic states of $(CH_3)_3SiArH^+$.

Most of the He CAD ions not discussed above arise from alkyl and alkene losses from the $(CH_3)_3Si$ group alone; losses of CH_3, C_2H_6, and C_3H_8 are particularly prominent. Of particular note is that loss of CH_4 becomes loss minimum energy input in the collision process of $IE(C_6H_6) - IE((CH_3)_3Si) + D((CH_3)_3Si^+ - C_6H_6) = 3.76$ eV for $ArH = C_6H_6$. The observation of this ion requires activating collisions leading to excitation to upper electronic states of $(CH_3)_3SiArH^+$.

Most of the He CAD ions not discussed above arise from alkyl and alkene losses from the $(CH_3)_3Si$ group alone; losses of CH_3, C_2H_6, and C_3H_8 are particularly prominent. Of particular note is that loss of CH_4 becomes loss of CH_3D for MH^+ formed by association of $(CH_3)_3Si^+$ with a perdeuterated aromatic. This methane loss results in the formation of the very stable $(CH_3)_2SiAr^+$ ion, which is the most intense ion in the electron impact mass spectra of $(CH_3)_3SiAr$ (Ar = C_6H_5, $CH_3C_6H_4$), demonstrating the greater stability of $(CH_3)_2SiAr^+$ compared with $(CH_3)_3Si^+$.

Figure 2*b* shows significant peaks due to loss of one and two mass units that are not present in Fig. 2*a*. We have no explanation for their presence and assume that they are not significant. These peaks were not observed in the LE CAD spectra of this same ion or indeed in any other spectrum. In particular, no such peaks were observed in the HE CAD spectrum of M^+.

The LE CAD spectra with N_2 or $(CH_3)_3N$ as collision gas with laboratory ion energies in the range 6–50 eV show only loss of aromatic for all MH^+. There are no competing dissociation paths. Dissociation under LE conditions is attrib-

utable to vibrational excitation of the ground electronic state (10). This is the reverse of the association, which occurs on the ground state electronic energy surface and for which the reversible association has been studied in a high-pressure mass spectrometer to yield $(CH_3)_3Si^+$–ArH binding energies of 23.9 ± 0.4 kcal mol^{-1} (ArH = C_6H_6) (11) and 28.4 ± 0.4 kcal mol^{-1} (ArH = $C_6H_5CH_3$) (4).

Ion–molecule reactions in addition to collisional dissociation occur between MH^+ and $(CH_3)_3N$ below 6 eV laboratory energy; for MH^+ (ArH = C_6H_6) this energy corresponds to a centre of mass energy of 2.8 eV. Proton transfer (reaction [5]) and displacement (reaction [6]) together with collisional dissociation (reaction [7]) are observed. The presence of a small amount of $((CH_3)_2N)_2H^+$ shows that multiple collisions are occurring. This ion is not significant (<1% total ion intensity) at nominal $(CH_3)_3N$ pressures less than 1×10^{-6} Torr.

[5] $(CH_3)_3SiC_6H_6^+ + (CH_3)_3N \rightarrow (CH_3)_3SiC_6H_5 + (CH_3)_3NH^+$

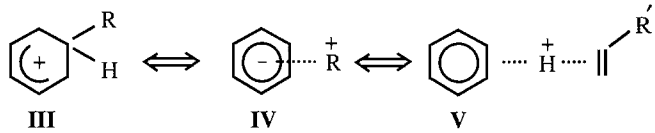
[6] $\rightarrow (CH_3)_3SiN(CH_3)_3^+ + C_6H_6$

[7] $\rightarrow (CH_3)_3Si^+ + C_6H_6 + (CH_3)_3N$

With decreasing energy the $(CH_3)_3Si^+$ peak decreases and is insignificant at a centre of mass energy ~0.14 eV. At this very low energy the relative rates of reactions [5] and [6] appear, within the aforementioned limitations of pressure measurement, to be independent of $(CH_3)_3N$ pressure below a pressure gauge reading of 9×10^{-7} Torr. From the relative peak heights $k_5/k_6 = 1.9 \pm 0.2$ for $(CH_3)_3N$ pressure readings from 1 to 9×10^{-7} Torr. Both reactions [5] and [6] are highly exothermic. The binding energies of $(CH_3)_3Si^+$ to C_6H_6 and $(CH_3)_3N$ are 24 (3) and >60 kcal mol^{-1} (11) respectively. If the proton affinity of $(CH_3)_3SiC_6H_5$ is taken to be roughly that of $(CH_3)_3CC_6H_5$ (193 kcal mol^{-1} (7)) then reaction [5] is exothermic by ~30 kcal mol^{-1}. The important conclusion to be drawn from these LE CAD studies is that they do not differentiate between MH^+ ions formed by the two methods, association and protonation.

The evidence cited in this paper strongly supports the idea that MH^+ has the same structure for a given aromatic whether it is formed by association of $(CH_3)_3Si^+$ with ArH or by protonation of $(CH_3)_3SiAr$. Kebarle and co-workers (12) verified the identity of the $(CH_3)_3C^+$ adduct of benzene and protonated *tert*-butyl benzene by showing the consistency of binding enthalpy with proton affinity. Such a thermochemical proof is not possible for the analogous silicon compounds discussed in this paper because of the lack of the required thermochemical data, namely the proton affinity and enthalpy of formation of $(CH_3)_3SiC_6H_5$. The uncertainties in any estimations of these values are such that no confidence could be placed in the conclusions drawn from their use.

The identity of the HE CAD spectra of protonated isopropyl-*n*-butyl benzene and the ion formed by the addition of the isopropylcarbenium ion to *n*-butyl benzene was taken by Holman and Gross as evidence not only that such reactions produce identical MH^+ species that collisionally decompose from identical structures but also that their ionization-threshold structures are the same (13). They argued that as the size of the alkyl group increases, its ability to accommodate carbenium ion character also increases. This ability also increases with branching in a given alkyl group, for example for butyl in the order *n*-butyl < *sec*-butyl < *tert*-butyl. This is also the order of stability of protonated butylbenzenes, the *n*-butyl and *sec*-butyl members of which, with suitable excitation, can isomerize to the more branched structures. Such an isomerization is presumed to occur via a π-complex and supporting evidence for this statement is the observation of hydrogen scrambling between the aromatic and alkyl hydrogens (13–15). This scrambling is envisaged to occur via the proton-bound structure **V** with the π-complex **IV** as a distinct intermediate on the potential energy surface.



III **IV** **V**

Structure **V** must be of relatively high energy for the $(CH_3)_3Si^+$ and $(CH_3)_3C^+$ adducts of benzene and toluene since no isotopic hydrogen scrambling between the ring and methyl hydrogens of $(CH_3)_3X$ is observed when the equilibrium association is studied using C_6D_6 or $C_6D_5CD_3$ (4). Presumably under the experimental conditions, the much higher proton affinities of $(CH_3)_2X{=}CH_2$ (PA($(CH_3)_2C{=}CH_2$) = 196 kcal mol^{-1} (6), PA($(CH_3)_2Si{=}CH_2$) = 228 kcal mol^{-1} (16)) than of benzene (PA = 181 kcal mol^{-1}) and toluene (190 kcal mol^{-1}) do not allow structures such as **V** to be accessible. A strong Brønsted base such as $(C_2H_5)_3N$ will proton transfer via **I** or **III** for silicon and carbon adducts respectively. A strong oxygen-containing nucleophile such as cyclohexanone but which has much weaker Brønsted basic properties than $(C_2H_5)_3N$ reacts via **II**, the very strong Si—O bond formed favouring a displacement reaction rather than proton transfer.

Little proton transfer is observed from the $(CH_3)_3Si^+$ adduct of 1,3,5-trimethylbenzene to $(C_2H_5)_3N$. This is in agreement with the observation that trimethylsilylation of mesitylene was not observed in the radiolysis of $(CH_3)_4Si/C_6H_3(CH_3)_3/(C_2H_5)_3N$ mixtures (2). The explanation of steric hindrance in the deprotonation step given for the radiolytic result is consistent with our observations. The enthalpy of binding of $(CH_3)_3Si^+$ to mesitylene is 7 kcal mol^{-1} greater than to benzene (3). The proton affinity of 2,4,6-trimethyl-1-trimethylsilylbenzene will be only slightly greater than the 201 kcal mol^{-1} of mesitylene. Reactions analogous to [5] and [6] will therefore still be highly exothermic with mesitylene and should be fast and competitive. The preponderance of the displacement reaction over the proton transfer reaction is indicative of significant steric hindrance in the latter reaction.

BRUCE J. ACKEN, DAVID E. GALLIS, JAMES A. WARSHAW, and DELANSON R. CRIST. Can. J. Chem. **70**, 2076 (1992).

The redox behavior of various *C*-substituted nitrones was investigated by cyclic voltammetry in acetonitrile. These included *C*-methoxynitrones (MeO)CR = N(O)*t*-Bu with R = C_6H_5(**1***a*), *p*-$MeOC_6H_4$ (**1***b*), *p*-$NO_2C_6H_4$ (**1***c*), and H (**1***d*) and nitrones YCH = N(O)*t*-Bu with Y = n-BuS (**2***a*), CN (**2***b*), and C_6H_5NH (**2***c*). All gave anodic peaks which can be identified as oxidations of the nitrone function. Controlled potential electrolysis of **1***a* at 1.05 V (SCE) showed that its oxidation was a one-electron process. Reduction of **1***a* occurs stepwise at −2.08 and at −2.47 V, the same potential for reduction of methyl *N-tert*-butylbenzimidate (MeO)CPh = N*t*-Bu. With electrochemical windows of ca. 3 V, all of the nitrones studied appear suitable for spin-trapping experiments.

BRUCE J. ACKEN, DAVID E. GALLIS, JAMES A. WARSHAW et DELANSON R. CRIST. Can. J. Chem. **70**, 2076 (1992).

Opérant dans l'acétonitrile et faisant appel à la voltampérométrie cyclique, on a étudié le comportement rédox de diverses nitrones *C*-substituées dont les *C*-méthyoxynitrones (MeO)CR = N(O)*t*-Bu dans lesquelles R = C_6H_5 (**1***a*), *p*-$MeOC_6H_4$ (**1***b*), *p*-$NO_2C_6H_4$ (**1***c*) et H (**1***d*) et les nitrones YCH = N(O)*t*-Bu dans lesquelles Y = *n*-BuS (**2***a*), CN (**2***b*) et C_6H_5NH (**2***c*). Tous ces produits donnent des pics anodiques que l'on peut identifier comme des oxydations de la fonction nitrone. Une électrolyse du composé **1***a* à un potentiel contrôlé de 1,05 V (SCE) montre que cette oxydation est un processus impliquant un électron. La réduction du composé **1***a* se produit par étapes à −2,08 et à −2,47 V, les mêmes potentiels que ceux observés lors de la réduction du N-*tert*-butylbenzimidate de méthyle (MeO)CPh = N*t*-Bu. Avec des plages électrochimiques d'environ 3 V, toutes les nitrones étudiées semblent appropriées pour des études de piégeage de spin.

[Traduit par la rédaction]

Most of the attention devoted to nitrone chemistry in recent years has concerned applications as synthetic intermediates (1) or as spin-trapping agents (2). In connection with spin-trapping applications Blount and co-workers (3) examined nitrone electrochemistry in aqueous and nonaqueous media in order to determine windows of inactivity suitable for electrochemical generation of free radicals. In acetonitrile most aldonitrones were oxidized at potentials greater than 1 V (vs. SCE) and reduced at ca. −2.0 V, a relatively wide window, in one-electron oxidation and two-electron reduction processes.

We now present electrochemical results on nitrones bearing RO, RS, R_2N, or CN at the α position. If the nitronyl function is considered analogous to a carbonyl group, these nitrones are related to esters, thio esters, ketonitriles, and amides, respectively. The effective spin-trapping ability of *C*-methoxy-*C*-aryl-*N-tert*-butylnitrones has previously been reported (4).

Results

Various *C*-methoxynitrones **1** and aldonitrones **2**(*a*–*c*) shown in Scheme 1 were prepared as previously described (5) and their electrochemistry studied by cyclic voltammetry. Also investigated as references were the well-known *C*-phenyl-*N-tert*-butylnitrone (PBN) **2***d*, imine **3***a*, and imidate **3***b*.

Cyclic voltammograms were taken in acetonitrile containing 0.1 M tetraethylammonium perchlorate, with oxidations at a platinum electrode (range ca. 2.5 to −1.8 V vs. SCE) and reductions at a hanging mercury drop electrode (HMDE) (range ca. 0.6 to −2.7 V vs. SCE).

C-Methoxynitrones

Nitrone **1***a* is irreversibly oxidized at 0.91 V at Pt (Fig. 1A). Controlled potential electrolysis showed that this oxidation released 1.06 electrons. Reduction of **1***a* is an irreversible two-step process with $E_{p(c)}$ = −2.08 and −2.47 V (Fig. 1B). The heights of the two reduction peaks in the cyclic voltammogram are essentially the same and the position of the second peak is the same as that for authentic benzimidate **3***b*.

To determine the substituent effect on the electrochemical characteristics of *C*-alkoxynitrones, cyclic voltammograms of **1***b* and **1***c* were also recorded and the data are summarized in Table 1. In the case of the nitro derivative there is an extra multi-step reduction at ca. −1.4 V corresponding (6) to a four-electron reduction of —NO_2 to —NHOH (Fig. 1C). Thus, the nitrone reduced at −2.04 V is *N*-hydroxylaminonitrone **5**, eq. [1], a similar conclusion reached for reduction of *C*-*p*-nitrophenyl-*N*-methylnitrone (7).

Electrochemical oxidation of **1***d* is similar to the other *C*-alkoxynitrones studied. It is oxidized in an irreversible one-step oxidation at 1.00 V (Fig. 1D). However, its reduction is quite different in that it undergoes a quasi-reversible one-step reduction at −1.96 V (Fig. 1E).

Other nitrones

C-n-Butylmercaptonitrone **2***a* undergoes a two-step irreversible oxidation at 1.17 and 1.77 V (Fig. 2A). There was no reduction of this compound prior to the solvent discharge. Sulfides are known to undergo two-electron oxidations to either the sulfoxide or a pseudo-dimer depending on the amount of water present (8). Since the peak at 1.17 V is approximately twice the size of the peak at 1.77 V and since aldonitrones are known to undergo one-electron oxidations in nonaqueous media (3), it is reasonable to assign the peak at 1.17 V to oxidation of the sulfide portion of the molecule and the peak at 1.77 V to nitrone oxidation.

SCHEME 1

C-Cyanonitrone **2***b* undergoes a one-step irreversible oxidation at 0.88 V (Fig. 2B) and a two-step irreversible reduction at −1.14 and −1.79 V (Fig. 2C). The extra reduction step at −1.14 V, as compared with aldonitrones **1***d* and PBN (see below), is in the region for reduction of CN by various processes (9–11). *C*-Anilinonitrone (**2***c*) undergoes a series of oxidations (Fig. 2D) at 0.63, 1.01, and 1.31 V and an irreversible two-step reduction at −2.06 and −2.66 V (Fig. 2E). Anilines are known (12) to be oxidized in two steps, each with two-electron, coupled anodic and cathodic peaks, so that the quasi-reversible oxidations at 0.63 and 1.31 V probably represent oxidation of the anilino group.

An aldonitrone, PBN (**2***d*), and two model compounds were also studied. PBN undergoes an irreversible one-electron oxidation at 1.34 V and a one-step, two-electron reduction at −2.28 V (Fig. 2F). Benzylidene-*tert*-butylamine (**3***a*) is irreversibly oxidized at 2.04 V and reduced irreversibly at −2.43 V. Methyl *N*-*tert*-butylbenzimidate (**3***b*) is irreversibly oxidized at 2.08 V and reduced at −2.46 V.

Discussion

C-Methoxynitrones

Nitrones **1**, **2***b*, and **2***d* all undergo an irreversible one-electron oxidation as reported for other nitrones in nonaqueous media (3). Oxidation of nitrones **2***a* and **2***c* involves prior oxidation of the *n*-butylmercapto and anilino groups, respectively. Attempts to characterize the product of oxidation of **1***a* were inconclusive. In the case of phenazine-*N*, *N*′-dioxide the radical cation produced dimerized (13).

The process for reduction of *C*-alkoxynitrone **1***a* shown

[2] 
1*a* **3***b* **4**

in eq. [2] is consistent with two reduction peaks of nearly the same heights, and thus involving the same number of electrons (14), and the fact that the second peak occurred at the same potential as that for authentic **3***b*.

The first step is analogous to reduction of *N*-phenylnitrones in aqueous acid (7, 15) and the second to reduction of imidates to aminals (16) and imines to amines (17). Unlike the present case, the double bond is reduced for PBN and other *N-tert*-butylnitrones in acetonitrile giving *N*-hydroxyamines (3) which are not reduced further (6).

Structural effects

Electron-withdrawing groups hindered oxidation of *C*-alkoxynitrones **1**, as shown by increasing $E_{p(a)}$ for the series **1***b*, **1***a*, and **1***c* (see Table 1). This is an expected result, since electron withdrawal from the nitrone function should make it more difficult to remove an electron, as reported for substituted pyridine *N*-oxides (18).

For reduction, the electron-donating *p*-MeO substituent retarded addition of electrons, since $E_{p(c)}$ is −2.26 V for **1***b* compared with −2.08 V for the unsubstituted phenyl **1***a*. The value of −2.04 V for the *p*-NO_2 derivative **1***c* is similar to that for *p*-MeO, since prior reduction of NO_2 gives a nitrone containing the electron-donating *p*-NHOH group on phenyl, eq. [1]. These results are in general agreement with the usual trend that substrates with electron-donating groups have more negative polarographic half-wave potentials (19), as reported specifically for *C*-aryl-*N*-methylnitrones (7).

Model compounds **2***d*, **3***a*, and **3***b* and alkoxynitrone **1***a* have peak potentials (Table 1) that give the following order[4] for ease of oxidation *and* reduction:

imidate < imine < aldonitrone < alkoxynitrone

Aromatic hydrocarbons exhibit the same behavior in that the one more easily oxidized is also more easily reduced (20).

Electrochemical windows

It has been shown (21) that nitrones can be used as spin traps in experiments using electrochemical generation of radicals. For this use, the range of electrochemical inactivity must first be known. For the nitrones in the present study, possible useful potentials would occur between the least positive $E_{p(a)}$ and least negative $E_{p(c)}$ listed in Table 1. A graphical representation of these resulting maximum electrochemical windows is shown in Fig. 3. Also included is *C*-phenyl-*N-tert*-butylnitrone **2***d* for comparison purposes.

The *C*-alkoxynitrones studied all have more narrow electrochemical windows than PBN. In the case of **1***c*, the win-

[4] $E_{p(a)}$ values for these compounds correlated with HOMO energies calculated by MNDO, but $E_{p(c)}$ did not show a relationship with LUMO energies (unpublished work).

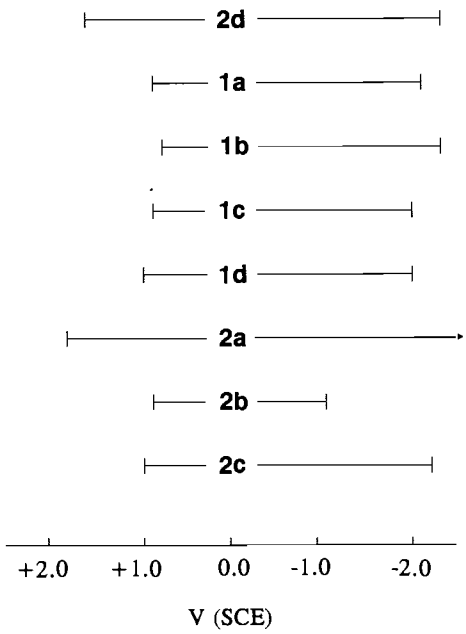

FIG. 3. Electrochemical windows of *C*-substituted nitrones. Limits are defined as the anodic and cathodic peak potentials of nitrone or other electroactive function (see text).

dow is narrowed considerably by reduction of the nitro group (6). Similarly, electrochemical reactions of the Y group in **2***a*, **2***b*, and **2***c* determine the width of the window, not the nitrone function itself. As is apparent from Fig. 3, however, all of the nitrones studied here would be suitable for electrochemical spin-trapping experiments. Most of these compounds have electrochemical windows of 3 V, the greatest being *C*-*n*-butylmercaptonitrone **2***a* which has a window of 3.95 V.

Experimental

Instrumentation

Nuclear magnetic resonance (NMR) spectra were obtained on a Bruker (Aspect 3000) 300 MHz spectrometer with absorptions given in ppm from internal tetramethylsilane. Cyclic voltammograms were obtained on an IBM Instruments EC/225 Voltammetric Analyzer. The working electrodes were either Pt (Bioanalytical Systems) or a HMDE (Metroh E-410). The reference electrode was a double junction, saturated calomel electrode (EG&G). Controlled potential electrolyses were done on a coulometer built by W. Craig, Georgetown University, with Pt gauze or a Hg pool as working electrodes.

Materials

All electrochemical studies were done in acetonitrile (Baker) that had been passed through alumina under Ar and stored over Molecular Sieves (Linde 4 A, previously heated at 400°C for 4 h). Nitrones **1** were prepared by alkylation of the hydroxamic acids with methyl triflate and deprotonation on silica gel/methanol as previously described (5). After evaporation of methanol at 0°C under N_2 the nitrone was taken up in 20 mL of acetonitrile containing 0.1 M Et_4NClO_4 to give a solution ca. 1 mM in nitrone. Nitrones **2***a*, **2***b*, and **2***c*, prepared from **1***d* as previously described (4), were purified by preparative thin-layer chromatography on 0.5 mm silica gel plates (CH_2Cl_2/MeOH 9:1). The nitrone band was scraped and eluted from silica with methanol. Solutions ca. 1 mM in nitrone in acetonitrile with 0.1 M Et_4NClO_4 were made as above. Imine **3***a* (22) and imidate **3***b* (23) were prepared as previously described and nitrone **2***d* was obtained from Kodak.

Cyclic voltammetry

Oxidations were done at a platinum electrode and reductions at a hanging mercury drop electrode (HMDE). In both cases the auxiliary electrode was platinum. All potentials are with respect to an aqueous saturated calomel electrode, separated from the sample solution by a double junction containing 0.1 M Et_4NClO_4 in acetonitrile. The reference electrode was standardized to the reduction of ferrocinium$^+$ to ferrocene, $E_{1/2}$ = 0.307 V in acetonitrile (0.2 M $LiClO_4$). Acetonitrile solutions of the species under study, 1–8 mM in substrate and 0.1 M in Et_4NClO_4, were degassed with Ar for 10–15 min prior to taking a voltammogram. The sweep rate was typically 50 mV/s and the current sensitivity 10 μA.

Cyclic voltammograms were run on similar solutions of methyl benzoate and *N*-*tert*-butylhydroxylamine, possible products of hydrolysis of **1***a*. The ester showed no oxidation prior to solvent discharge and an irreversible reduction with $E_{p(c)}$ = −2.42 V. The hydroxylamine was irreversibly oxidized with $E_{p(a)}$ = 0.59 V but showed no reduction prior to solvent discharge.

Controlled potential electrolysis of **1**a

For oxidation, a solution of 4 mg of **1***a* in 20 mL of acetonitrile 0.1 M in Et_4NClO_4 was degassed for 15 min with Ar. Exhaustive electrolysis was done at +1.05 V vs. SCE at a platinum gauze electrode. The auxiliary electrode was separated from the solution by a glass-fritted chamber containing acetonitrile 0.1 M in Et_4NClO_4. The solution was electrolyzed until the current–time curve reached a plateau. A solution containing only the supporting electrolyte was deoxygenated and electrolyzed. The difference in coulombs between these two currents, when converted to electrons, corresponds to a 1.06 electron oxidation. After removal of solvent at 0°C under a stream of N_2, the residue was taken up in $CDCl_3$. ^1H NMR showed only signals due to methyl benzoate δ ($CDCl_3$): 3.92 (s, 3H, OCH_3), 7.40–7.46 (m, 2H, ArH), 7.52–7.58 (m, 1H, ArH), 8.02–8.05 (m, 2H, ArH) and *N*-*tert*-butylhydroxylamine δ ($CDCl_3$): 1.13 (s, 9H, *N*-*t*-Bu).

For reduction, a solution of 3 mg of **1***a* was made as above. Exhaustive reduction was done at −2.20 V vs. SCE at a mercury pool electrode. The auxiliary electrode was separated from the solution by a glass-fritted chamber containing acetonitrile 0.1 M in

Et_4NClO_4. Electrolysis data indicated an apparent 8 electrons/mol nitrone, but this high value may be caused by reduction of the supporting electrolyte (24). After removal of solvent as described above, the residue was taken up in $CDCl_3$. ^1H NMR of the solution indicated a complex mixture containing a minor amount of methyl *N-tert*-butylbenzimidate δ ($CDCl_3$): 1.21 (s, 9H, *N-t*-Bu), 3.62 (s, 3H, OCH_3), 7.35 (s, 5H, ArH).

Reactions of hydriodic acid with aldonolactones and *n*-alkanolactones. Interconversions between lactones and iodocarboxylic acids

ZHENGCHUN LIU, ALESSANDRO GRANATA, XINHUA SHEN, AND ARTHUR S. PERLIN[1]
Department of Chemistry, McGill University, Montreal, Que., Canada H3A 2A7

Received February 18, 1992

ZHENGCHUN LIU, ALESSANDRO GRANATA, XINHUA SHEN, and ARTHUR S. PERLIN. Can. J. Chem. **70**, 2081 (1992).

Aldonolactones containing from four to eight carbon atoms, and lactones of the related monohydroxy-*n*-alkanoic acids, were subjected to reaction with 57% hydriodic acid at 125°C. As in the classical studies of Kiliani, the reduction of D-*glycero*-D-*ido*-heptono-1,4-lactone yielded mainly γ-heptanolactone. Analogously, the corresponding γ-alkanolactones were obtained as major products from the 1,4-lactones of the D-xylono-, D-allono-, and D-*erythro*-L-*talo*-octono configuration. Monoiodo-*n*-alkanoic acids were also formed in admixture with the lactones in all of these reactions. D-Erythrono-1,4-lactone was unique among the aldonolactones in that it led only to an acid, i.e., 3-iodo-*n*-butanoic acid. The latter was also the product of the non-reductive reaction of hydriodic acid with β-butyrolactone whereas, by contrast, γ-butyrolactone afforded 4-iodobutanoic acid. Among compounds in the five to eight carbon series, it was found that under conditions close to equilibrium the ratio of lactone to iodoacid decreased progressively with the length of the carbon chain; e.g., in the 4 h reactions of γ-valero-, γ-capro-, γ-heptano-, and γ-octanolactone, the ratios were 2.4, 1.2, 0.2, and 0.1, respectively. An accompanying characteristic of these reactions is a progression in the number of isomeric iodoacids formed. Whereas γ-valerolactone was accompanied by 4-iodopentanoic acid, there were two isomers (4- and 5-) of iodohexanoic acid, three monoiodo- (including 6-iodo-) heptanoic acids, and four (including 7-iodo-) octanoic acids. In all instances, the isomer substituted at the penultimate carbon was major. An interplay of several individual reactions, including ring-opening displacements, eliminations–additions, and rearrangements, as well as a probable influence of entropy changes on the lactone-acid equilibria, appear to account largely for these observations.

ZHENGCHUN LIU, ALESSANDRO GRANATA, XINHUA SHEN et ARTHUR S. PERLIN. Can. J. Chem. **70**, 2081 (1992).

On a soumis des aldonolactones contenant de quatre à huit atomes de carbone ainsi que les lactones des acides monohydroxy-*n*-alcanoïques apparentés à une réaction avec de l'acide periodique à 57%, à 125°C. Comme il a été observé dans les études classiques de Kiliani, la réduction de la D-*glycéro*-D-*ido*-heptono-1,4-lactone fournit principalement la γ-heptanolactone. De la même manière, on a obtenu les γ-alcanolactones comme produits principaux à partir des 1,4-lactones de configurations D-xylono, D-allono- et D-*érythro*-L-*talo*-octono. On observe aussi la formation des acides monoiodo-*n*-alcanoïques en mélange avec les lactones obtenues dans toutes ces réactions. La D-érythrono-1,4-lactone est unique parmi les aldonolactones puisqu'elle ne fournit qu'un acide, soit l'acide 3-iodo-*n*-butanoïque. Cet acide est aussi le produit de la réaction non-réductive de l'acide hydriodique avec la β-butyrolactone alors que, par contraste, la γ-butyrolactone fournit l'acide 4-iodobutanoïque. Parmi les composés de la série contenant de cinq à huit atomes de carbone, on a trouvé que, dans des conditions proches de celles de l'équilibre, le rapport entre la quantité lactone et celle d'acide iodé diminue progressivement avec une augmentation de la longueur de la chaîne carbonée; par exemple, dans les réactions de 4 h de γ-valéro-, γ-capro-, γ-heptano- et γ-octanolactone, les rapports sont respectivement de 2,4, 1,2, 0,2 et 0,1. Une autre caractéristique de ces réactions est une progression dans le nombre des acides iodés isomères qui se forment. Alors que la γ-valérolactone est accompagnée par de l'acide 4-iodopentanoïque, il se forme deux isomères (4- et 5-) de l'acide iodohexanoïque, trois acides monoiodo (incluant le 6-iodo-) heptanoïques et quatre acides monoiodo (y compris le 7-iodo-) octanoïques. Dans tous les cas, l'isomère substitué sur le pénultième atome de carbone est l'isomère principal. Il semble que l'interaction de plusieurs réactions individuelles, y compris des substitutions avec ouverture de cycle, des éliminations avec additions et des transpositions, ainsi que l'influence probable de changement entropique sur l'équilibre lactone/acide, soient largement responsables de ces observations.

Introduction

One of the early proofs that D-glucose is an *aldo*-hexose (**1**) is attributable to Kiliani (1), who converted the sugar via the cyanohydrin into a heptoglyconic acid (**2**), which on reduction (2) with hydriodic acid (HI), followed by zinc – hydrochloric acid, gave heptanoic acid (**3**). Only a low yield of **3** was obtained (3) from a crystalline γ-(1,4)-lactone form of **2**, i.e., **4**, whereas 60–70% of the product was γ-heptanolactone (**5**). Although this could imply that the lactone ring had remained intact, product **5** has been found subsequently[2] to be racemic, and hence the configuration at C-4 of **4** (and C-3 of **1**) is not retained in the process. This result, and a broader interest in the reactions of HI, led to the present examination of its chemistry as applied to a group of aldonolactones and also to the related lactones of monohydroxy-*n*-alkanoic acids (i.e., dihydro-2 (3*H*) furanone and several of its 5-alkyl derivatives).

Results and discussion

Compounds based on n-*butanoic acid*

Using reaction conditions similar to those in earlier studies (3), D-erythrono-1,4-lactone (**6**) was heated under reflux with 57% HI for 1 h. Extraction into methylene chloride afforded, on evaporation of solvent, a solid in 71% yield that, according to its ^1H and ^{13}C nmr spectra, consisted primarily of one compound (see Fig. 1*a* for the ^1H spectrum). Its mass spectrum indicated that the product was a monoiodobutanoic acid, and the fact that the methyl signal was a doublet (δ 2.0) and the H-3 multiplet was strongly deshielded (δ 4.4), verified that the structure is 3-iodobutanoic acid (**7**). Also consistent with the latter designation is the pair of doublet of doublets at δ ~ 3.1, attributable to diastereotopic H-2 and

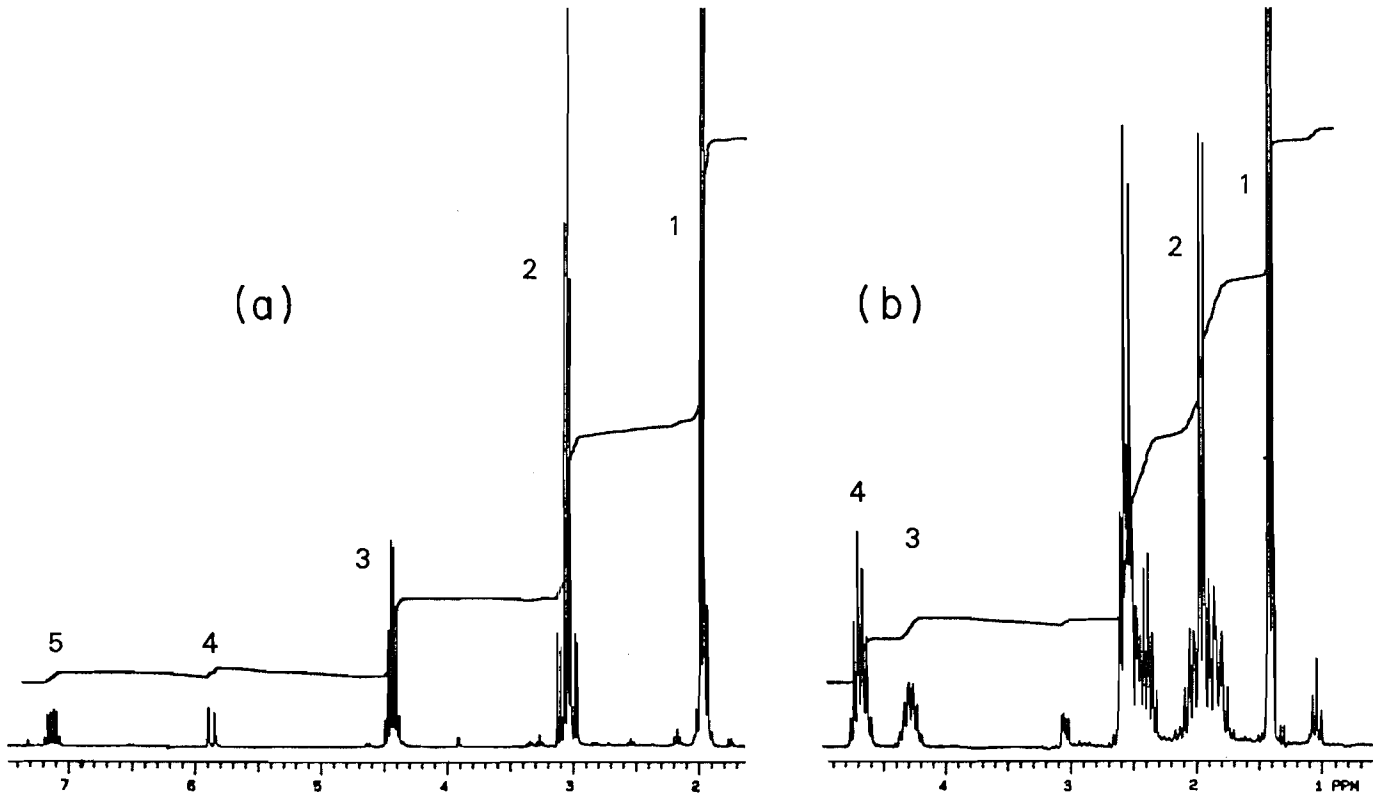

FIG. 1. The ^{1}H nmr spectra of the products (extracted into methylene chloride) from the reaction with 57% HI at 125°C of (*a*) D-erythrono-1,4-lactone (**6**) (1 h reaction); signals 1, 2, and 3 are those of CH_3, H-2,2′, and H-3, respectively, of 3-iodobutanoic acid (**7**), and signals 4 and 5 are those of H-3 and H-2, respectively, of *E*-2-butanoic acid (**12**), (*b*) γ-valerolactone (**14**) (4 h reaction); signals 1 and 4 are due to CH_3 and H-4, respectively, of **14** and signals 2 and 3 are those of CH_3 and H-4, respectively, of 4-iodopentanoic acid (**16**).

H-2′. (The two minor, downfield, signals are referred to later.)

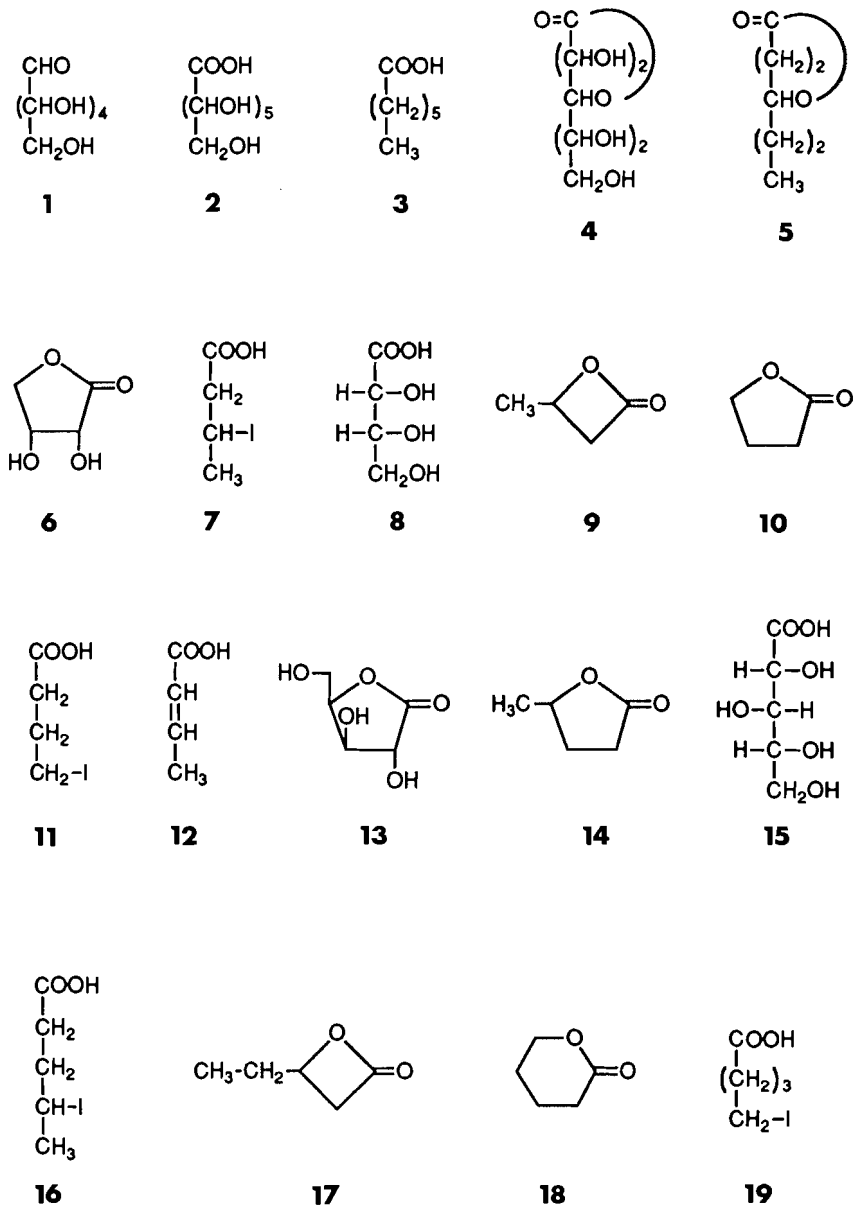
This inference that a four-carbon lactone may be unstable, e.g., relative to the seven-carbon homolog (**5**), received support from three other experiments. First, D-erythronic acid (**8**) gave virtually the same result as **6**, as shown by its ^{1}H nmr spectrum and mass spectral data. Although some isomerization to **6** in the HI solution was to be anticipated, little or no lactone was detected in the product. Second, a similar result, i.e., a 74% yield of **7** was obtained when the reflux period was extended to 4 h. Iodide **7** also was obtained, in 92% yield, from the 1 or 4 h reaction of β-butyrolactone (**9**) with HI. Third, complete ring opening was observed with γ-butyrolactone (**10**) although, in this instance, the product was found to be 4-iodobutanoic acid (**11**), on the basis of its ^{1}H nmr spectrum, ^{13}C nmr spectrum, and mass spectrum.

Formation of the 4-iodo product (**11**) is consistent with observations on macrocyclic ω-lactones, which showed (4, 5) that ring opening with HI affords the corresponding ω-iodocarboxylic acids. The fact that the β-lactone (**9**) was converted into the 3-iodide (**7**) appears (5, 6) to be an analogous example of a ring-opening displacement reaction. However, the formation of **7** from *erythro* derivatives **6** and **8** is clearly not accommodated by the same type of mechanism. Likely, such an intermediate as 2-butenoic acid (**12**) accounts for its formation. The occurrence of **12** as a minor reaction product is shown by the relatively weak signals in Fig. 1*a* at δ 7.15 and 5.90, which are coincident in chemical shift with resonances of the known *E* isomer of **12** (confirmed by introducing some *E* isomer into the solution used to obtain Fig. 1*a*). Electrophilic addition of HI to **12** would be expected (7) to lead regioselectively to the 3-iodide (**7**). Another indication of equilibration between these two species, was the presence (^{1}H nmr evidence) of a trace proportion of **12** in admixture with **7** obtained from β-butyrolactone (**9**), whereas none of it was detected in the reaction product (**11**) of γ-butyrolactone (**10**).

Compounds based on n*-pentanoic acid*

In this series, the lactone – iodocarboxylic acid equilibrium lies mainly in favor of the cyclic form, which contrasts strikingly with that of the four-carbon compounds.

The reaction of D-xylono-1,4-lactone (**13**) with HI for 4 h afforded an oil soluble in methylene chloride, which accounted for about a 70% yield of γ-valerolactone (**14**). That is, both the ^{1}H and ^{13}C nmr spectra of the crude product consisted primarily of signals superimposable on those of authentic **14**, although the presence of minor components, including olefinic ones, was evident as well. By analogy with the comparison of the *erythrono* homologues, when D-xylonic acid (**15**) was subjected to the same reaction for 4 h, its product was indistinguishable from that of **13**. The relative stability of the γ-lactone structure in this series was verified additionally by the finding that when pure γ-valerolactone was heated with HI for 4 h, 63% of it was recovered intact although, as the ^{1}H nmr spectrum (Fig. 1*b*) shows, it was accompanied by 26% of 4-iodopentanoic acid



(**16**). The ratio of **14** to **16** is given by the relative intensities of their H-4 signals (δ 4.7 and 4.3, respectively), both being located relatively far downfield due to deshielding by the ring O atom (of **14**) or the I atom (of **16**). Also each CH_3 signal is a doublet, attributable to the presence of only one vicinal ^1H, the signal at δ 1.95 reflecting the particularly strong deshielding effect (~0.9 ppm) of the neighboring I atom. (An analogous signal for CH_3 of **7** is the doublet at δ 1.95 in Fig. 1*a*.) Supporting evidence for the structure of **16** was given by ^{13}C nmr data, presented later, as well as by mass spectrometry (M = 228).

Virtually the same spectrum as represented by Fig. 1*b* was obtained from the product (95% yield) of the 4 h reaction of HI with β-valerolactone (**17**). This showed that **17** had been isomerized into γ-valerolactone (**14**) and, possibly (although see later), that ~25% of the latter had undergone a ring-opening displacement to give 4-iodo-*n*-pentanoic acid (**16**).

Consistent with the reaction of other ω-lactones with HI, δ-valerolactone (**18**) afforded 5-iodopentanoic acid (**19**) in 97% yield (at both 1 and 4 h).

Compounds based on hexa-, hepta-, and octanoic acid

In the reactions of HI with lactones (other than ω) having six, seven, or eight carbon atoms, the product ratios are progressively more in favor of the iodinated carboxylic acids as the number of carbons increases. In 4 h, both D-allono-1,4-lactone (**20**) and D-glucono-1,5-lactone (**21**) (see also ref. 2) were converted into 65–67% of γ-caprolactone (**22**), accompanied by about 20% of mixed iodohexanoic acids. (Lactone **22** was also a major product of the reaction of δ-caprolactone (**23**) with HI.) With a seven-carbon example, i.e., D-*glycero*-D-*ido*-heptanoic-1,4-lactone (**24** = **4**), the yield of γ-heptanolactone (**25**) in 1–4 h was about 60%, in agreement with the earlier results reported (3). A mixture of iodocarboxylic acids made up the remaining 30–34% of the product. The corresponding yields in the reaction of D-*erythrono*-L-*talo*-octono-1,4-lactone (**26**) with HI were 46% of

γ-octanolactone (**27**) and 35% of a mixture of iodocarboxylic acids.

Turning to the structurally related lactones of the monohydroxy-*n*-alkanoic acids, their reactions with HI show even more clearly the pronounced trend towards the iodoacid in the lactone–acid equilibrium. This is illustrated by ^{1}H nmr spectra of the reaction mixtures produced in 4 h from γ-caprolactone (**22**) and γ-octanolactone (**27**) (Figs. 2*a* and 2*b*, respectively). A comparison of the intensity of the lactone H-4 multiplet (δ 4.5) with that of the broad signal (δ ~4.2) attributable to a proton α to an iodine substituent, gives a lactone-to-iodocarboxylic acid ratio of 1.2 for **22**, and 0.11 for **27**; a ratio of 0.2 was found for γ-heptanolactone (**25**).

A relationship between the number of carbon atoms in the individual γ-lactones, and the percentage of those lactones remaining intact after reaction with HI for 1 h and 4 h, is depicted in Fig. 3. As most of the transformation into iodocarboxylic acid is seen to have taken place during the first period, the 4 h values must be close to equilibrium. Accordingly, the proportion of iodocarboxylic acid becomes progressively greater as the carbon chain is elongated from five to eight atoms.

Comparative data are included in Fig. 3 for the products of reduction of the aldonolactones at 4 h. When these isolated products, in turn, were subjected to reaction with fresh HI for 2 h, the percentage of lactone remaining decreased, and approached the values obtained for the alkanolactones.

*The formation of monoiodo-*n*-alkanoic acids*

Various isomeric iodo-*n*-alkanoic acids were recovered from the reaction of HI with either aldonolactones or aldonic acids, or with *n*-alkanoic lactones. As reported by others, when the lactone ring involved a primary carbon atom, the corresponding ω-iodo carboxylic acid was produced in high yield. Examples of this are described above for γ-butyrolactone and δ-valerolactone, and this also proved to be true for ε-caprolactone (**28**), which afforded 6-iodohexanoic acid (**29**). These correspond to a ring-opening displacement by iodide, as in an S_N2 type reaction. Although the conversion of β-butyrolactone into 3-iodo-*n*-butanoic acid

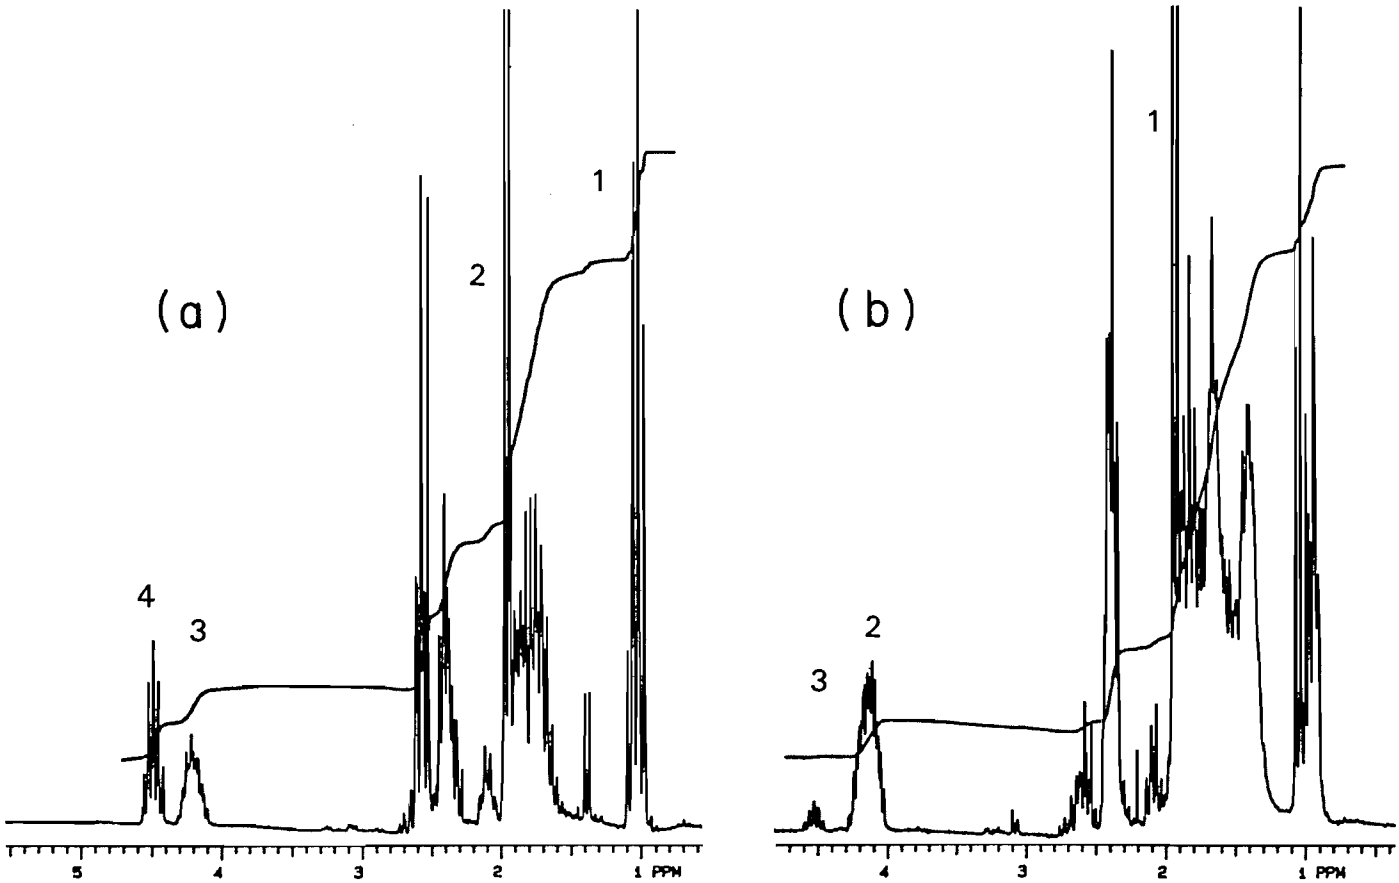

FIG. 2. The ^{1}H nmr spectra of the products (extracted into methylene chloride) from the 4 h reaction with 57% HI at 125°C of (*a*) γ-caprolactone (**22**); signals 1 and 4 are those of CH_3 and H-4, respectively of **22**, signal 2 is that of CH_3 of 5-iodohexanoic acid (**32**), and signal 3 is that of HC-I of the monoiodohexanoic acids, (*b*) γ-octanolactone (**27**); signal 1 is that of CH_3 of 7-iodooctanoic acid (**34**), signal 2 is that of HC-I of the monoiodooctanoic acids, and signal 3 is that of H-4 of **27**.

(**7**) may be accommodated in the same way, the latter was also the product of reduction of D-erythrono-1,4-lactone (as well as the acid form). Had γ-butyrolactone rather than 2-butenoic acid been an intermediate, then 4-iodo-*n*-butanoic acid should have been obtained instead.

With the presence of a fifth carbon atom in the substrate, i.e., D-xylono-1,4-lactone (**13**) (as well as the corresponding acid), the formation of an iodocarboxylic acid was now a minor event, as the preponderant product (71% in 4 h) was γ-valerolactone (**14**). When the latter was subjected to the HI reaction, it gave about 25% 4-iodopentanoic acid (**16**), in what appears to have been a ring-opening displacement. However, as seen with the D-*erythrono* homologues, the location of the iodine atom in the product is not necessarily the same as that of the lactone bridge initially. Another example of this is found in the fact that β-valerolactone (**17**) also yielded the 4-iodide (**16**) as well as γ-valerolactone (**14**) in a ratio of ~1:3. Both of these represent rearrangement products, the formation of which likely involved the 3-iodide (**30**) and perhaps an intermediate such as **31** (Scheme 1). This could account for the finding that both the iodine atom of **16** and the lactone bridge in **14** occur at a position different from that in **17**. Evidence that **30** was a transient product was obtained from ^{1}H and ^{13}C nmr spectra of the reaction components at 1 h, at which time no **17** remained and **30** was the major product. However, at 4 h the ^{1}H nmr spectrum was now essentially the same as that represented by Fig. 1*b*, showing that the final product consisted of a 2.5:1 mixture of **14** and **16**.

Analogous effects are observed in the six-carbon series: 5-iodohexanoic acid (**32**) was the major acid species produced from either D-allono-1,4-lactone (**20**) or γ-caprolactone (**22**), whereas the 4-iodo isomer constituted one third of the acid mixture. These then, are additional examples of a rearrangement accompanying the opening of the lactone ring, as is the fact that the same mixture of acids was obtained from D-glucono-1,5-lactone (**21**) and δ-caprolactone (**23**). The presence of **32** was apparent from its strong CH_3 doublet observable at δ 1.95 (Fig. 2*a*), comparable to that for the CH_3 group of **16** (Fig. 1*b*); supporting data from the ^{13}C nmr spectrum are given later.

The occurrence of isomers bearing an iodine atom at the carbon *adjacent* to the terminal methyl group is found even with the more extended *n*-alkyl chains of the 7- and 8-carbon compounds. Thus, the ^{1}H nmr spectra of the products from the aldoheptono-1,4-lactone (**24**) or γ-heptanolactone (**25**), and from the aldooctono-1,4-lactone (**26**) or γ-octanolactone (**27**) (see Fig. 2*b*), all contain a strong doublet at δ 1.95, diagnostic for the CH_3 group adjacent to the H-C-I group. This corresponds to the formation of 6-iodoheptanoic acid (**33**) and 7-iodooctanoic acid (**34**).

The absence of a 3-iodo-*n*-alkanoic acid, analogous to **7**,

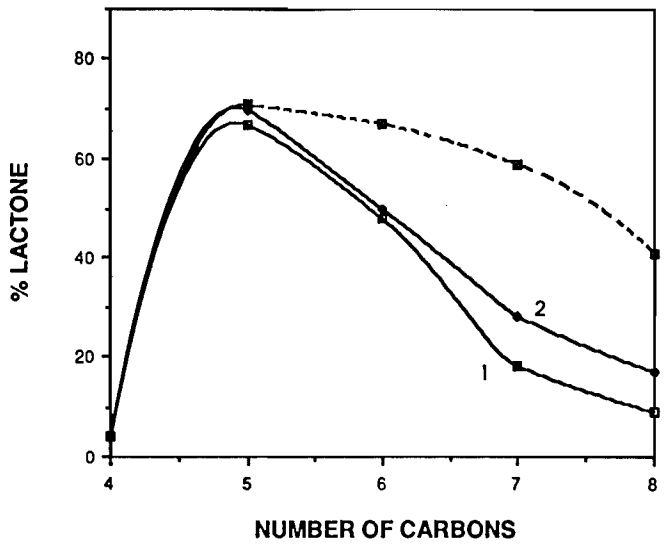

FIG. 3. (Solid lines) Percentages of the initial γ-*n*-alkanolactones, comprising from 4 to 8 carbon atoms, remaining after reaction with 57% HI at 125°C for 4 h (1) and 1 h (2). (Broken line) Comparative values for products of the HI reduction (4 h) of aldonolactones comprising from 4 to 8 carbon atoms. (Here, the joining of the points to form smooth curves is not intended to imply defined mathematical relationships between the parameters used but, rather, to highlight differences.)

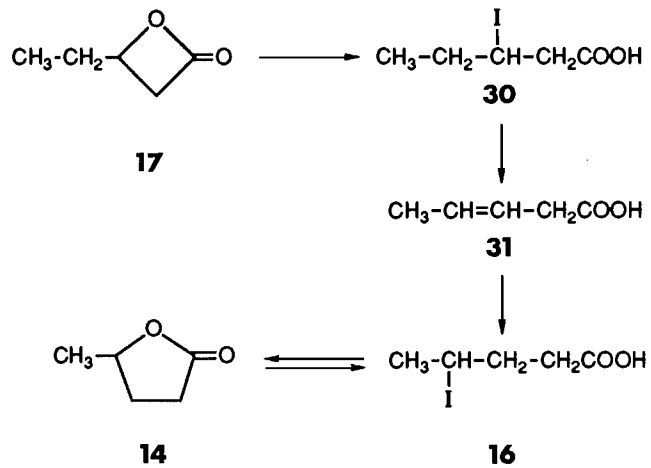

SCHEME 1

among the products from the 5 to 8-carbon aldonolactones is noteworthy in suggesting that electronic factors restrict the iodine atom to positions more remote from the carboxyl group. Whereas it is reasonable to find the iodine at position 4 of **16** in equilibrium with a γ-lactone (**14**), as in Scheme 1, migration of the iodine atom to C-5 would have required the intermediacy of the less stable, Δ-4,5 isomer of **31**, and also anti-Markovnikov addition of HI. The 5-iodocarboxylic acid (**19**) was accessible, nevertheless, through a direct displacement at C-5 of **18**, and hence was not accompanied by rearrangement products.

In the 6-carbon series, the formation of γ-caprolactone (**22**) from δ-lactones **21** and **23** finds precedence in many rearrangements of the δ- to the more stable γ-lactones (see, e.g., ref. 8). However, the occurrence of 5-iodohexanoic acid (**32**) among the products from the γ- as well as the δ-lactones is noteworthy. By analogy with Scheme 1, 4-iodohexanoic acid and 4-hexenoic acid could be feasible intermediates in the formation of **32**, and the fact that there was more of the latter present than of the 4-iodo isomer, may indicate the occurrence of competitive lactone-ring closure reactions in which an iodo substituent on C-4 is more frequently displaced than one on C-5.

More unexpected is the appearance of the 6-iodo- (**33**) and 7-iodo- (**34**) carboxylic acids as major species admixed with γ-heptanolactone (**25**) and γ-octanolactone (**27**), respectively, as well as among the products of the reaction of aldonolactones **24** and **26** with HI. That is, it is unclear why an iodine atom should appear at a location beyond C-4 or C-5, because those positions correspond to the more probable outcome of ring-opening and -closing displacement reactions envisaged for γ- and δ-lactones, respectively.

In all these instances, isomeric iodocarboxylic acids were present in minor proportions. Evidence for the co-occurrence of the minor isomers was most clearly afforded by ^{13}C nmr spectra (see later), based on the total number of resolved ^{13}C resonances and their relatively low intensities. The hexanoic acids were found to comprise a 2:1 mixture of the 5-iodo- (**32**) and 4-iodo isomers, whereas heptanoic and octanoic acid derivatives **33** and **34** were both accompanied by at least two, lesser, isomeric iodides. As would be expected, these minor products were characterized by relatively weak ^{13}C signals in the region δ 13.4–14.3 (and also ^{1}H signals at δ ~1.0), diagnostic for species in which the CH_3 group is more remote from the iodine atom than in **32**, **33**, or **34**. Most likely, therefore, they are 4- and 5-iodoheptanoic acids and 4-, 5-, and (or) 6-iodooctanoic acids.

It is worth noting that none of the parent, non-iodinated, *n*-alkanoic acids were detected among the reaction products. Although this appears to be at variance with the earlier reports (1–3) of such products as *n*-heptanoic acid (**3**), those studies involved an additional step in which the material isolated from the HI reaction was subjected to reduction with zinc/hydrochloric acid (1, 2) or catalytic hydrogenation (3), which would have displaced iodine atoms.

Overall, then, whereas only one secondary iodocarboxylic acid isomer is feasible in the 4-carbon (3-iodo, **7**) and 5-carbon (4-iodo, **16**) series, the higher homologues allow for isomeric secondary iodide structures. This helps to accommodate the formation of *two* 6-, *three* 7-, and *four* 8-carbon isomers. A related characteristic is the striking tendency for migration of the iodine atom toward the penultimate carbon of the carboxylic acid chain, which occurs to a lesser extent as the chain length increases. As to how far from the carboxyl group this tendency occurs remains to be determined, as well as if it also applies for the other halogens. Undoubtedly, the relatively severe conditions that these reactions with HI entail are conducive to extensive rearrangements, as well as to racemization and some decomposition of the aldonolactones.[3] Olefinic products, de-

[3]However, an example of a lactone that is relatively unaffected under these conditions is 3,3-dimethyl-2-hydroxy-γ-butyrolactone (pantolactone) (**35**). In contrast to the quantitative ring-opening reaction of γ-butyrolactone, two thirds of **35** was recovered after treatment for 1 h and 4 h. The product was the 4-iodoacid (**36**), which suggested that the *gem* dimethyl structure hindered not only the displacement at C-4, but also reduction of the hydroxyl group. Even more resistant was the "γ-butyrolactone" ring incorporated within norbornane derivative **37**.

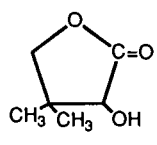
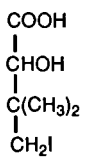
[a]Signals of lower intensity than those of **33**.
[b]Signals of lowest intensity.

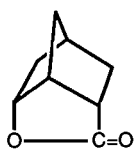
tected in some instances, may be involved as intermediates, although such other possibilities as rearrangements of transient carbocations (or, perhaps, free radicals) may be envisaged as well. The possibility that there are several competing reactions is strengthened by a different type of observation: when a specimen of δ-valerolactone (**23**) deuterated at C-5 (by deuteride reduction of the corresponding 5-ketoacid), was subjected to reaction with HI for 4 h, about 50% of the deuterium was exchanged (MS evidence).



35



36



37

Finally, the progressive decrease observed in the ratio of lactone to iodocarboxylic acid with lengthening of the carbon chain may reflect incremental increases in entropy associated with greater numbers of isomeric iodoacid species generated in the lactone–acid equilibria.

^{13}C nuclear magnetic resonance spectral data

This source of information was particularly helpful for the detection and identification of the iodocarboxylic acids. In many instances, the ^{13}C assignments were facilitated by use of the DEPT technique (9).

An iodine substituent introduces distinctive shielding characteristics, some of which have been recognized (10, 11) with other classes of compounds. For example, C-3 and C-4 of 4-iodo-*n*-butanoic acid (**11**) resonate *down*field (by 10 ppm) and *up*field (by 8 ppm), respectively of the corresponding nuclei of butanoic acid (Table 1). Similarly, these opposing effects are found for pentanoic acid and its 5-iodo derivative (**19**), as well as hexanoic acid and its 6-iodide (**29**).

Verification of the structure of 3-iodobutanoic acid (**7**) was provided by evidence (DEPT) that the signals at δ 17.3 and 29.0 (Table 1) are due to methine and methyl groups, respectively. Hence, the presence of an iodine atom at C-3 causes only a small increase in shielding, relative to the C-3 of butanoic acid, whereas the neighboring ^{13}C nuclei experience strong deshielding, by 12 ppm (C-2) and 15 ppm (C-4). In 4-iodopentanoic acid (**16**) the effect of the halogen atom is deshielding, not only for C-3 and C-5, but also for C-4.

Two secondary iodo isomers of hexanoic acid were recognized, in a ratio of ~2:1. The group of major signals was assigned to the 5-iodo isomer (**32**), because the appropriate methyl ^{13}C is strongly deshielded (relative to *n*-hexanoic acid), and hence is adjacent to the methine ^{13}C (C-5). By contrast, the chemical shift of the smaller methyl signal (δ 13.4) is consistent with a CH_3CH_2 structure, and that of the methine ^{13}C with the expectation that C-4 contains the substituent.

There are a total of 20 resolved signals in the spectrum of the product mixture obtained from γ-heptanolactone (**25**) (in addition to minor signals of the lactone), corresponding to three isomeric iodo-*n*-heptanoic acids in a ratio of about 1.5:1.0:0.5. Among the minor signals are two, at δ 13.5 and 13.0, which identifies their origin as $^{13}CH_3CH_2$ groups. However, as all of the major signals appear below δ 28, they must be due to the 6-iodo derivative (**33**), containing a CH_3CHI arrangement for which ^1H data have already been cited. As the individual resonances have not all been assigned, the chemical shifts are listed (Table 1) only according to sets for each isomer.

A similar assessment of the ^{13}C spectrum of the 8-carbon product mixture points to the co-occurrence of four isomeric iodocarboxylic acids. Aside from minor signals due

to γ-octanolactone (**27**), the spectrum contains 30 resolved resonances out of the 32 required, and their integral values correspond to an isomer ratio of roughly 2:1:1:1. Once again, the minor species were found to possess terminal CH_3CH_2 structures by virtue of their upfield $^{13}CH_3$ resonances, at δ 14.3, 14.2, and 13.4. By elimination, the major set of signals, all of which are found downfield of δ 24, is alloted to the 7-iodo isomer (**34**).

Experimental

Nuclear magnetic resonance spectra were recorded with a Varian XL-200, XL-300, or Gemini 200 spectrometer, operating at 200 MHz or 300 MHz for ^1H, and 50 MHz for ^{13}C. The solvent was $CDCl_3$, and chemical shifts are given with respect to the signal for internal Me_4Si (δ 0.0). Chemical ionization mass spectra were obtained with isobutane as the ionization reagent. Extracts of reaction mixtures were concentrated under diminished pressure at a bath temperature of 40°C. Hydriodic acid (57%) was obtained from Aldrich Chemical Co., as also were samples of β- and γ-butyrolactone, γ- and δ-valerolactone, γ-caprolactone, 5-ketohexanoic acid, ε-caprolactone, and γ-octanolactone. The aldonolactones were prepared by established procedures. Potassium D-erythronate and ammonium D-xylonate were obtained from Pfanstiehl Laboratories, Waukegan, Ill.

Representative of reactions of the lactones with HI are the following:

*Reaction of D-erythrono-1,4-lactone (**6**) with hydriodic acid*

A solution D-erythrono-1,4-lactone (0.60 g, 5.0 mmol) in hydriodic acid (57%, 5 mL) was heated under reflux at 125°C for 1 h. Saturated aqueous NaCl (10 mL) was added after cooling to room temperature and the mixture was extracted into dichloromethane (50 mL). The organic layer was washed successively with saturated aqueous $Na_2S_2O_3$ (10 mL) and saturated aqueous NaCl (3 × 10 mL), dried (anhydrous $MgSO_4$), and concentrated. The dark, solid, residue was recrystallized from dichloroethane – petroleum ether, affording yellow crystals (0.77g, 71%); mp 35–36°C; $[\alpha]_D$ +1.4 (4.6 *c*, $CHCl_3$). ^{13}C nmr data are given in Table 1. The ^1H nmr spectrum of the crude product extracted is shown in Fig. 1*a*; the introduction of authentic *E*-crotonic acid produced an increase in the relative intensities of the signals at σ 7.15 and 5.85. EI-mass spectrum: *m/z* 214 [M, 22.3%], *m/z* 127 [I, 25.0%], *m/z* 87 [(M − I), 100%].

*Reaction of D-allono-1,4-lactone (**20**) with HI*

A solution of the lactone (0.60 g, 3.3 mmol) in HI (57%, 5 mL) was heated under reflux for 4 h. After being cooled to room temperature the reaction mixture was processed as described for **6**. The dichloromethane extract afforded a reddish-brown oil (0.44 g, 88%), which, according to its ^1H and ^{13}C nmr spectra (see Fig. 1*b* and Table 1), consisted primarily of a mixture of γ-caprolactone (**22**) (67%), 5-iodohexanoic acid (**32**) (14%), and 4-iodohexanoic acid (7%). CI-mass spectrum: *m/z* [(M + H, iodoacid), 9.3%], *m/z* 115 [(M + H, lactone and (or) M iodoacid-I), 100%].

*Reaction of γ-octanolactone (**27**) with HI*

A solution of the lactone (0.60 g, 4.2 mmol) in HI (57%, 5 mL) was heated under reflux for 4 h, and the reaction mixture was processed as described for compound (**20**). The dichloromethane extract afforded a yellow oil (1.16 g, 98%), which, according to the ^1H and ^{13}C nmr spectra (see Fig. 2*b* and Table 1) consisted primarily of the lactone (**27**) (9%) and a mixture of monoiodooctanoic acids (89%). CI-mass spectrum: *m/z* 271 [(M + H, iodoacid), 12.2%], *m/z* 143 [(M + H, lactone and (or) M iodoacid-I), 100%].

*5-Iodo-*n*-pentanoic acid (**19**)*

Isolated, as above, from the reaction of δ-valerolactone (**18**) in 90% yield (1.2 g); yellow crystals, mp 59–60°C (lit. (5) mp 58°C); ^{13}C nmr data are given in Table 1.

CI-mass spectral data for iodoacids produced from aldonolactones and δ-caprolactone-5-^2H

D-Xylono-1,4-lactone: *m/z* 229 [(M + H), 15.7%]

D-Glucono-1,4-lactone: *m/z* 243 [(M + H), 4.6%]

D-*Glycero*-D-*ido*heptono-1,4-lactone: *m/z* 257 [(M + H), 2.5%]

D-*Erythro*-L-*talo*octono-1,4-lactone: *m/z* 271 [(M + H), 12.0%]

δ-Caprolactone-5-^2H: *m/z* 244 [(M + H, 6.1%)], 243 [(M − 50% ^2H + H), 61%], 116 [(M − HI), 93.6%], 115 [(M − 50% ^2H − HI), 100%].

Received January 2, 1992

TUAN Q. NGUYEN, FANQI QU, XIAOLING HUANG, and ALEXANDER F. JANZEN. Can. J. Chem. **70**, 2089 (1992).

Cationic complexes $PF_4(N\text{-}N)^+$, where N-N = 2,2′-bipyridine (bpy), 4-fluoro-2,2′-bipyridine (fbpy), and 1,10-phenanthroline (phen), were prepared in modest yield and identified by their A_2B_2 and A_2BC fluorine NMR spectra, which are similar to those of the isoelectronic $SiF_4(N\text{-}N)$ adducts. The ligands bpy, fbpy, and phen may be useful for monitoring reactions of HF and H_2O, or other fluorinated compounds, with glass apparatus because any liberated SiF_4 is then trapped as $SiF_4(N\text{-}N)$, which can be readily detected by NMR spectroscopy.

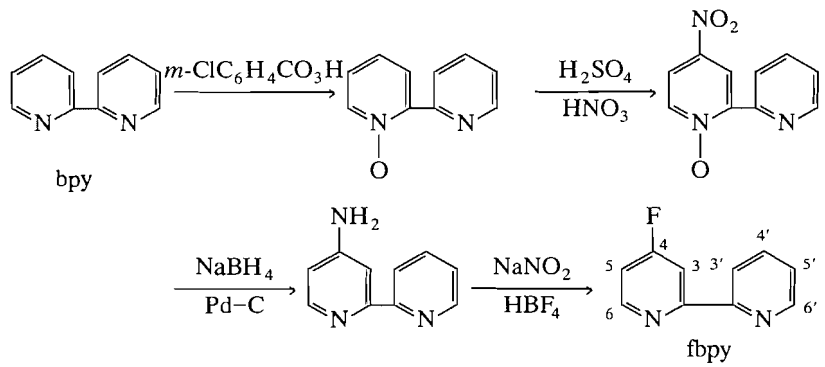
TUAN Q. NGUYEN, FANQI QU, XIAOLING HUANG et ALEXANDER F. JANZEN. Can. J. Chem. **70**, 2089 (1992).

On a préparé les complexes cationiques $PF_4(N\text{-}N)^+$, dans lesquels N-N = 2,2′-pyridine (bpy), 4-fluoro-2,2′-bipyridine (fbpy) et 1,10-phénanthroline (phen), avec de modestes rendements et on les a identifiés par leurs spectres RMN A_2B_2 et A_2BC du fluor qui sont semblables à ceux des adduits isoélectroniques $SiF_4(N\text{-}N)$. Dû au fait que tout SiF_4 libéré peut être piégé sous la forme de $SiF_4(N\text{-}N)$ que l'on peut facilement détecter par spectroscopie RMN, les ligands bpy, fbpy et phen peuvent être utiles pour suivre les réactions du HF, de l'eau ou d'autres composés fluorés avec les appareils de verre.

[Traduit par la rédaction]

Fluorophosphonium cations PF_4^+, RPF_3^+, $R_2PF_2^+$, R_3PF^+, and $PF_4(donor)_2^+$ are known (1), but a reported reaction between PF_5 and phenanthroline did not give the expected cation $PF_4(phen)^+$ (2), although $PCl_4(phen)^+$ is stable (2, 3). We have studied the reaction of PF_5 with bidentate ligands N-N, where N-N = 2,2′-bipyridine (bpy), 4-fluoro-2,2′-bipyridine (fbpy), and 1,10-phenanthroline (phen), in an attempt to identify the $PF_4(N\text{-}N)^+$ cation. During the course of this work it was observed that extraneous reactions with glass apparatus produced $SiF_4(N\text{-}N)$; its convenient detection by NMR provides a way of monitoring the reactions of fluorinated compounds with glassware.

The synthesis of 4-fluoro-2,2′-bipyridine (fbpy) was carried out in four stages and fbpy was characterized by means of mass spectrometry, ^{15}N (4), ^{19}F, ^{13}C, ^1H NMR, and by its reactions with iron and cobalt salts (4).



When the reaction of PF_5 with bidentate ligands bpy, fbpy, and phen was carried out in dichloromethane solution, using a glass vacuum line and a glass reaction tube with a PTFE insert, it was found that the cation $PF_4(N\text{-}N)^+$ was prepared in yields of 10–20%. The cations were identified

$$2PF_5 + N\text{-}N \xrightarrow[CH_2Cl_2]{-196 \text{ to } 25^\circ C} PF_4(N\text{-}N)^+PF_6^-$$

(10–20% yield) N-N = bpy, fbpy, phen

by ^{19}F NMR (Table 1) and showed an A_2B_2 spin system for $PF_4(bpy)^+$ and $PF_4(phen)^+$ and an A_2BC pattern for $PF_4(fbpy)^+$, consistent with an octahedral structure of the cation.

The isoelectronic adducts $SiF_4(N\text{-}N)$ were prepared in essentially quantitative yield and their NMR spectra are in agreement with the assignments for $PF_4(N\text{-}N)^+$ (Table 1).

$$SiF_4 + N\text{-}N \xrightarrow[CH_2Cl_2]{-196 \text{ to } 25^\circ C} SiF_4(N\text{-}N)$$

N-N = bpy, fbpy, phen

The crystal structure and the ^{19}F NMR and infrared spectra of $SiF_4(bpy)$ have been reported previously (5). Al-

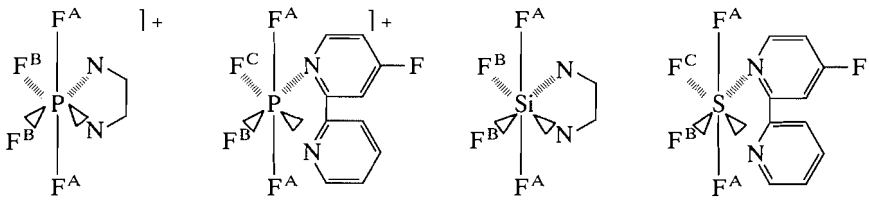
[b]^{29}Si NMR (DMSO): −176 ppm.
[c]^{29}Si NMR (DMSO): −176 ppm.

though the symmetry of the octahedral complexes allows a unique assignment of the F^A ligands, the assignment of F^B versus F^C in $PF_4(fbpy)^+$ and $SiF_4(fbpy)$ remains uncertain.

The reaction of SiF_4 with bpy, fbpy, and phen occurs on warming the reaction mixture from −196 to 25°C, and the mechanism of formation of $SiF_4(bpy)$ was described recently by the coordination model of reaction mechanisms (6) as a two-step pathway, P(4,2), in which the first step is viewed as a diffusion-controlled formation of a five-coordinate SiF_4–bpy adduct, followed by a rapid entropy-favoured five-center step to give the six-coordinate adduct $SiF_4(bpy)$, as illustrated in Scheme 1.



N-N = bpy, phen

N-N = bpy, phen

It is reasonable to propose a similar path for the formation of $PF_4(N\text{-}N)^+$, except that a fluorine ligand must be transferred, presumably via a fluorine-bridged intermediate, as shown in Scheme 2.

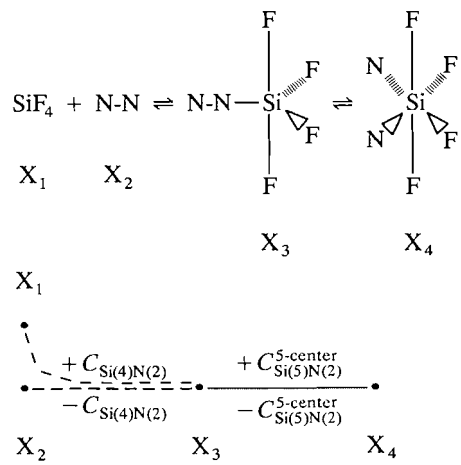
The formation of $PF_4(N\text{-}N)^+$ also occurs on warming the reaction mixture from −196 to 25°C but, as seen in Scheme 2, this reaction involves cleavage of a bridging P—F—P bond; however, such cleavage of bridging bonds in phosphorus fluorides is known to be a rapid process, even on the NMR time scale (7). Numerous other four- and five-coordinate metal halides react with bidentate ligands (8) in a manner entirely analogous to that proposed for SiF_4 and PF_5; consequently, pathways P(4,2) and P(8,4) may also be proposed for these reactions.

$$MX_4 + L\text{-}L \rightarrow X_4M(L\text{-}L)$$

$$2MX_5 + L\text{-}L \rightarrow X_4M(L\text{-}L)^+MX_6^-$$

^{31}P and ^{19}F NMR examination showed that the formation of $PF_4(N\text{-}N)^+$ was accompanied by the following products: $(N\text{-}NH)^+PF_6^-$, $F_2P(O)OH$, $FP(O)(OH)_2$, $P(O)(OH)_3$, $SiF_4(N\text{-}N)$, and BF_4^-, thus demonstrating that reaction with glass and moisture was the major reason for the low yield (10–20%) of formation of $PF_4(N\text{-}N)^+$. These reactions were carried out in Teflon-lined tubes; however, PF_5 was handled in a glass vacuum line and there was partial exposure to glass valves during the reaction. Once formed, the cation $PF_4(N\text{-}N)^+$ is stable in the reaction mixture.

No ligand exchange was observed when fbpy was added to $SiF_4(fbpy)$ nor when $SiF_4(fbpy)$ was added to $SiF_4(phen)$,



SCHEME 1. Proposed mechanism[3] of reaction of SiF_4 and N-N. Minimum set of CN: Si(4) Si(5) Si(6) N(2) N(3); pathway P(4,2).

nor was there line-broadening in the ^{19}F NMR spectrum of $SiF_4(N\text{-}N)$ or $PF_4(N\text{-}N)^+$ in DMSO solution if 1 equivalent of H_2O, CF_3COOH, or PhCOOH was added. Ligand

[3]Graph P(*X*,*C*) consists of a vertex set *X* of reactants, intermediates, and products, and an edge set *C* consisting of coordination number operators +C, −C, $+C^C$, and $-C^C$, which are drawn above the edges for forward steps and below for reverse steps; dashed lines refer to intermolecular steps and solid lines to intramolecular steps, as described previously (6).

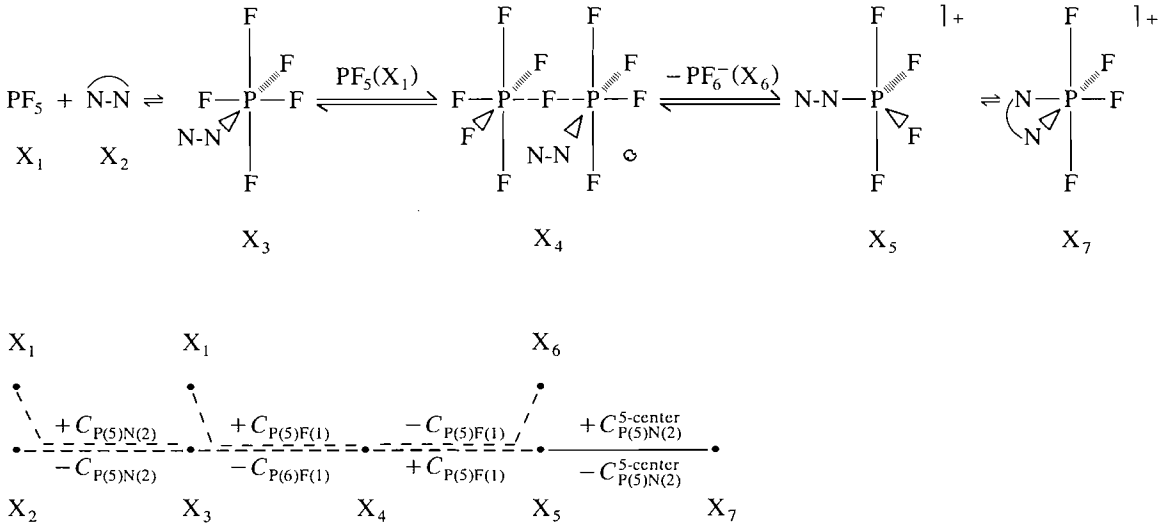
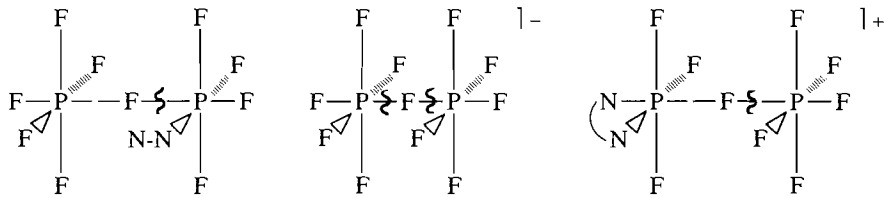


SCHEME 2. Proposed mechanism[3] of formation of $PF_4(N\text{-}N)^+PF_6^-$. N-N is bpy, fbpy, or phen; minimum set of CN: P(5) P(6) N(2) N(3) F(1) F(2); pathway P(8,4).

exchange did occur when excess PF_5 was added to $PF_4(N\text{-}N)^+PF_6^-$ in CH_2Cl_2 solution, but rapid fluorine exchange occurred only between anionic PF_6^- and PF_5, a known process (7), but not between cationic $PF_4(N\text{-}N)^+$ and PF_5, and this difference, as well as the fluorine transfer step of Scheme 2, may be attributed to the selective cleavage of bridging P—F—P bonds in the postulated intermediates, as shown below.

It was found that exchange between PF_6^- and excess PF_5 could be observed in CD_3CN, but not in DMSO solution, and this may be attributed to the relative stability of the PF_5 (solvent) adducts; dissociation of $PF_5(NCCD_3)$ gives free PF_5, however, the PF_5(DMSO) adduct is more stable and therefore PF_5 is not available for exchange with PF_6^-. Exchange between $PF_5(NCCH_3)$ and PF_6^- was also observed by Il'in and co-workers in their study of the interaction of PF_5 with phosphorus oxides (9). The NMR spectra of bpy and phen complexes, but not those of fbpy complexes, were therefore generally recorded in DMSO solution.



On adding DMSO to the reaction mixture containing $PF_4(fbpy)^+$, there was immediate loss of the fluorine substituent from the bound fbpy ligand and the appearance of a new A_2BC ^{19}F NMR spectrum assigned to $F_4P(Xbpy)^+$; furthermore, any SiF_4(fbpy) was also converted to SiF_4(Xbpy), but the identity of X was not established.

The fluorine chemical shift of free fbpy (−103.2 ppm) differs significantly from that of bound fbpy, e.g., SiF_4(fbpy) (−91.4 ppm) or $PF_4(fbpy)^+$ (−77.9 ppm), and it was possible to show in a qualitative way that adduct formation occurs in 3:1 mixtures of fbpy/$SbCl_5$ (−95 ppm), fbpy/$SnCl_4$ (−87.6 ppm), fbpy/SnI_4 (−87.8 ppm), and fbpy/SiI_4 (−94 ppm), all in acetone solution, and fbpy/$TeCl_4$ (−95 ppm) in $CH_3NO_2/CDCl_3$ solution, but the stoichiometry of the adducts was not investigated further.

Borosilicate glass, Lewis acids, and halogen-bridged intermediates

When alcohols and water are handled in Pyrex or quartz vessels, boron and silicon esters and their hydrolysis products are usually present (10); furthermore, hydrogen fluoride and water, even in minute amounts, also react with borosilicate glass to produce boron and silicon fluorides and removal of these impurities can stop ligand exchange or isomerization reactions of various fluorinated compounds (11).

In some previous NMR studies of ligand exchange, we attempted to identify trace amounts of glass-produced boron and silicon fluorides but, although BF_4^- can be readily detected by NMR because of the characteristic $^{11}BF_4^-/^{10}BF_4^-$ pattern, it is difficult to detect small amounts of silicon fluorides because these compounds can undergo a variety of fluorine exchange processes involving SiF_4, SiF_5^-, SiF_6^{2-}, $SiF_4(donor)_2$ and $SiF_5(donor)^-$(12, 13), which complicates the positive identification of silicon fluorides in solution.

It was therefore of interest to find in this study that during the reactions of PF_5 with bpy, fbpy, and phen, small amounts of SiF_4(bpy), SiF_4(fbpy), and SiF_4(phen), along with BF_4^-, were invariably present, although glass was the only source of silicon and boron in these reactions. These $SiF_4(N\text{-}N)$ complexes are all "rigid" on the NMR time scale,

For personal use only.

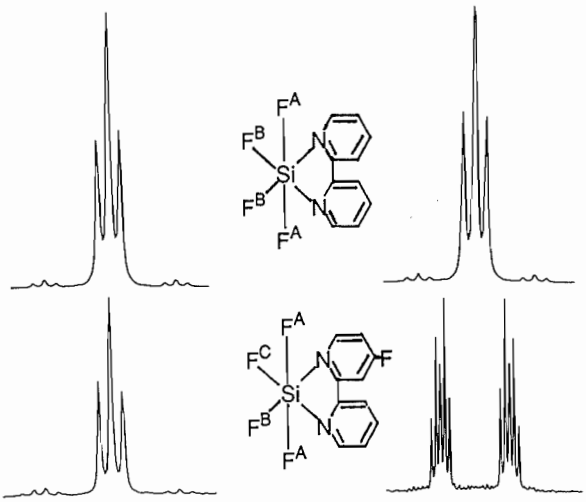

FIG. 1. The A_2B_2 ^{19}F NMR spectrum of SiF_4(bpy) (top) and the A_2BC spectrum of SiF_4(fbpy) (bottom) in DMSO-d_6 solution, recorded on a Bruker AM300 NMR spectrometer. Chemical shifts and coupling constants are given in Table 1.

and fluorine exchange does not interfere with identification by NMR. Therefore, in those reactions involving cleavage of element–halogen bonds, where Lewis acids and halogen-bridged intermediates are suspected (6, 11), but where glass may be the only source of silicon or boron Lewis acids, it may be possible to add small amounts of bidentate ligands such as bpy, fbpy, or phen to a reaction mixture and then use fluorine NMR to detect SiF_4(N-N), along with BF_4^-. Typical A_2B_2 and A_2BC fluorine NMR spectra of SiF_4(bpy) and SiF_4(fbpy) are shown in Fig. 1. For the detection and positive identification of small amounts of SiF_4 by this method, we have carried out parallel reactions using bpy and fbpy and then recorded each ^{19}F NMR spectrum in proton-coupled and proton-decoupled mode on a 300 MHz NMR spectrometer.

Experimental

General

The ^1H, ^{19}F, ^{13}C, ^{29}Si, and ^{31}P NMR spectra were recorded on a Bruker AM300 spectrometer using TMS, C_6F_6(−162.9 w.r.t. $CFCl_3$), and H_3PO_4 as references. High-resolution mass spectra were recorded on a VG7070E instrument.

The following compounds were prepared by literature methods and their NMR spectra were recorded and used to identify reaction products: PF_5(DMSO) (14), PF_5(pyridine) (15), and $PF_5(NCCH_3)$ (14). PF_5(pyridine-*N*-oxide) was prepared by condensing PF_5 (1.1 mmol) onto pyridine-*N*-oxide (1.1 mmol) in CH_2Cl_2 (2 mL) at −196°C and warming the mixture to room temperature. All volatile material was then removed and the remaining white solid identified by ^{19}F and ^{31}P NMR as PF_5(pyridine-*N*-oxide) (70% yield). $SiF_4(DMSO)_2$, prepared from SiF_4 and DMSO (13), gives a very broad ^{19}F NMR peak at about −135 ppm because of rapid fluorine exchange, but it can be detected by either lowering the temperature and thus reducing the line width, or by integrating the broad ^{19}F NMR spectrum in the region −130 to −140 ppm at ambient temperature. $F_2P(O)OH$, $FP(O)(OH)_2$, H_3PO_4, and PF_6^- were identified by ^{31}P and ^{19}F NMR.

4-Nitro-2,2′-bipyridine-N-oxide

2,2′-Bipyridine-*N*-oxide was obtained as an oil (2.6 g) from 2,2′-bipyridine (5.0 g) by the method of Sont and Alper (16). The oil was dissolved in concentrated sulphuric acid (15 mL). Fuming nitric acid (24 mL) in concentrated sulphuric acid (13 mL) was added during 10 min, and the mixture was refluxed for 2.5 h. The solution was poured onto ice (100 g) and neutralized, with cooling, to pH 8 by 38% NaOH. The light yellow precipitate was filtered and washed with water. Recrystallization from hot ethanol gave 4-nitro-2,2′-bipyridine-*N*-oxide (1.45 g, 21%), mp 180–181°C (lit. (17) mp 183–185°C); MS: 217 (M^+), 171 $(M - NO_2)^+$, 155 $(M - NO_2,O)^+$, 143 $(M - NO_2,CN)^+$.

4-Amino-2,2′-bipyridine

4-Nitro-2,2′-bipyridine-*N*-oxide (0.42 g, 1.9 mmol) in methanol (20 mL) was reduced with sodium borohydride (0.85 g, 23 mmol) in the presence of 5% palladium-on-carbon (150 mg) by the method of Neilson *et al.* (18). The solution was filtered, evaporated, extracted with ether, and dried over NaOH pellets. Ether was removed to give 4-amino-2,2′-bipyridine (282 mg, 85%), mp 115–116°C (lit. (17) mp 128–129°C); ^1H NMR ($CDCl_3$): H3 7.66, H5 6.54, H6 8.29, H3′ 8.34, H4′ 7.78, H5′ 7.27, H6′ 8.63; MS: 171 $(M)^+$, 170 $(M - H)^+$, 145 $(M - CN)^+$, 144 $(M - HCN)^+$, 143 $(M - H,HCN)^+$.

4-Fluoro-2,2′-bipyridine (fbpy)

Fluoroboric acid (12.0 g) was added gradually to 4-amino-2,2′-bipyridine (1.0 g), with cooling, and a solution of sodium nitrite (1.10 g) in 10 mL of cold water was added. The solution was then cooled in liquid nitrogen and the precipitate was filtered to give the diazonium salt. After drying, the diazonium salt was decomposed by heating and 20% aqueous sodium hydroxide was added until no more solid was formed.

The brown solid was then filtered, washed with cold water, and extracted with petroleum ether. Removal of solvent gave 4-fluoro-2,2′-bipyridine (fbpy) (0.53 g, 52%), light yellow solid, mp 83–85°C, ^1H NMR ($CDCl_3$): H3 8.17 ($^3J_{HF}$ = 10.4), H5 7.04 ($^3J_{HF}$ = 8.1), H6 8.64 ($^4J_{HF}$ = 8.5), H3′ 8.41, H4′ 7.83, H5′ 7.34, H6′ 8.68; ^{19}F NMR ($CDCl_3$): −103.2 ppm; (CD_3CN): −102.7 ppm; ^{13}C NMR (CD_2Cl_2): C2 159.7 ($^3J_{CF}$ = 7), C3 108.8 ($^2J_{CF}$ = 19.0), C4 169.7 ($^1J_{CF}$ = 261), C5 111.5 ($^2J_{CF}$ = 17), C6 151.5 ($^3J_{CF}$ = 7), C2′ 154.9 ($^4J_{CF}$ = 4), C3′ 121.3, C4′ 137.0, C5′ 124.3, C6′ 149.3; MS: 174 $(M)^+$, 173 $(M - H)^+$, 148 $(M - CN)^+$, 147 $(M - HCN)^+$, 146 $(M - H,HCN)^+$; Mol. Wt. (MS) calcd. for $C_{10}H_7FN_2$, *m/z*: 174.0593; found, *m/z*: 174.0594.

In aqueous sulphuric acid, the ^{19}F NMR peak of protonated fbpy shifts to −92.9 ppm.

Reaction of PF_5 with bpy, fbpy, and phen

PF_5 (3.3 g, 2.6 mmol) was handled in a standard glass vacuum line and condensed onto a solution of bpy (0.10 g, 0.64 mmol) in CH_2Cl_2 at −196°C in a glass reaction tube with a PTFE insert, and the mixture was slowly warmed to room temperature. After 1 h, the solvent was removed under vacuum and a pale yellow solid remained that was dissolved in DMSO-d_6 or CD_3CN and characterized as $PF_4(bpy)^+PF_6^-$ by ^{19}F NMR (Table 1). The reaction was carried out numerous times and the yield of product varied between 10 and 20%, with side products $(bpyH)^+PF_6^-$, $F_2P(O)OH$, $FP(O)(OH)_2$, $P(O)(OH)_3$, and SiF_4(bpy). A similar procedure was used for the preparation of $PF_4(fbpy)^+PF_6^-$ and $PF_4(phen)^+PF_6^-$, which were characterized by ^{19}F NMR (Table 1).

The complexes $PF_4(bpy)^+$ and $PF_4(phen)^+$ are stable in CH_2Cl_2, CH_3CN, and DMSO solution; $PF_4(fbpy)^+$ is also stable in CH_2Cl_2 and CH_3CN, but in DMSO solution the fluorine substituent in the bound fbpy ligand is lost and replaced by substituent X to give the cation $PF_4(Xbpy)^+$; however, X was not identified. $PF_4(Xbpy)^+$; A_2BC ^{19}F NMR (300 MHz; $(CD_3)_2SO$): −51.0 (F^A, J_{AB} = 60, J_{AC} = 62), −78.2 (F^B, J_{BC} = 61), −80.6 (F^C).

Reaction of SiF_4 with bpy, fbpy, and phen

Using standard procedures, SiF_4 (0.31 g, 3.0 mmol, Matheson) was condensed at −196°C onto a solution of bpy (0.28 g, 1.8 mmol)

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

in dried and redistilled CH_2Cl_2 in a reaction tube connected to a vacuum line. The mixture was warmed to room temperature and reaction occurred within 5 min. Removal of volatile material gave a white solid in quantitative yield identified as SiF_4(bpy) by ^{19}F and ^{29}Si NMR (Table 1).

A similar procedure was used for the preparation of SiF_4(fbpy) and SiF_4(phen) and their ^{19}F NMR data are found in Table 1. SiF_4(bpy), SiF_4(phen), and SiF_4(fbpy) are stable in CH_2Cl_2, CH_3CN, and DMSO solution; however, a slow conversion of SiF_4(fbpy) to SiF_4(Xbpy) occurs over a period of several weeks in DMSO solution, analogous to the conversion of $PF_4(fbpy)^+$ to $PF_4(fbpy)^+$ in DMSO described above. SiF_4(Xbpy); A_2BC ^{19}F NMR (300 MHz; $(CD_3)_2SO$): -119.4 (F^A, $J_{AB} = 14$, $J_{AC} = 14$), -142.5 (F^B, $J_{BC} = 28$), -143.5 (F^C).

Small amounts of SiF_4(N-N) and BF_4^- were always observed during the reactions of PF_5 and N-N although the only source of silicon and boron was the glass apparatus (see text).

Received October 28, 1991

JAMES P. KUTNEY, PHILIP J. GUNNING, ROBIN G. CLEWLEY, JOHN SOMERVILLE, and STEVEN J. RETTIG. Can. J. Chem. **70**, 2094 (1992).

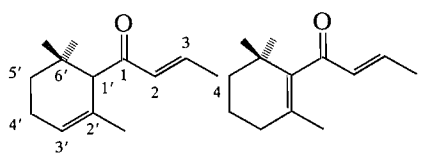
Thujone, a waste by-product of the Canadian forest industry, has been utilized as a starting material to develop a versatile synthetic route to the damascones (rose oil ketones) and related analogues. The synthetic sequence provides a route to β-cyclocitral (**45**), the latter having been previously converted to β-damascone (**2**). In addition, thujone-derived intermediates are converted to β-damascenone (**48**) and to intermediates that can be utilized for the preparation of damascone analogues. In conjunction with the above, an efficient route to safronitrile (**42**), β-cyclogeranonitrile (**43**), and β-cyclocitral (**45**) from 2,6-dimethylcyclohexanone has been developed. In summary, these studies afford an attractive versatile route to these important perfumery materials.

JAMES P. KUTNEY, PHILIP J. GUNNING, ROBIN G. CLEWLEY, JOHN SOMERVILLE et STEVEN J. RETTIG. Can. J. Chem. **70**, 2094 (1992).

On a utilisé le thuyone, un sous-produit de l'industrie forestière canadienne, comme produit de départ pour développer une voie de synthèse versatile conduisant aux damascones (cétones de l'huile de rose) et à des produits apparentés. La voie de synthèse conduit au β-cyclocitral (**45**) qui a été transformé antérieurement en β-damascone. De plus, des intermédiaires dérivés de la thuyone peuvent être transformés en β-damascénone (**48**) et en d'autres intermédiaires qui peuvent être utilisés pour la préparation d'analogues de la damascone. En relation avec les travaux mentionnés plus haut, on a aussi développé une voie efficace de synthèse du safronitrile (**42**), du β-cyclogéranonitrile (**43**) et du β-cyclocitral à partir de la 2,6-diméthylcyclohexanone. En bref, ces travaux ont permis de développer une voie versatile de synthèse de ces produits importants en parfumerie.

[Traduit par la rédaction]

The damascones or "rose oil ketones," as exemplified by α- and β-damascone (**1** and **2** respectively) are a family of natural products found as minor constituents in tea, tobacco, and in rose and geranium oils (2). Their importance as perfumery agents is well known (2) and the impracticality of their isolation from such natural sources, particularly rose oil, has stimulated interest in their laboratory syntheses. Major efforts by the group at Firmenich in Geneva, Switzerland, have provided commercial routes to these compounds (3–5) and other groups have also made substantial contributions to this field (6–13). In our program directed toward the use of thujone (**3**), a waste by-product of the Canadian forest industry, as a starting material for the syntheses of various natural products, biologically active and commercially important substances, we have directed our attention toward the development of a versatile route to the damascones and, in particular, to novel analogues of these compounds, the latter as potential perfumery agents. This publication presents results that satisfy these objectives.



1 **2**

The synthetic strategy for the synthesis of β-damascone (**2**) from thujone (**3**) is summarized in Scheme 1. Methylation of thujone would give a trimethylated bicyclo[3.1.0]cyclohexanone system (**4**) that could serve as a key intermediate. Two routes from this intermediate to the damascones are shown in Scheme 1. The first route, **4** → **5**, **6** → **2** involves attachment of the side chain present in the damascones either through a direct nucleophilic attack on the carbonyl group so as to attach the complete side chain, or by initial attack with a nucleophile, such as cyanide ion, followed by a chain extension. Cyclopropane ring-opening and isopropyl side-chain cleavage would lead to the damascones. The second route, **4** → **7** → **2**, involves cyclopropane ring-opening and isopropyl side-chain cleavage directly after methylation of thujone to obtain a cyclohexenone system to which the desired side chain could be attached. The strategy employed should allow the synthesis of damascone analogues with substitution at C2′, C3′, C4′, C5′, and C6′ positions of the "cyclohexane" part of the damascones, as well as numerous analogues in which the side chain is altered. Even the cyclopropane and isopropyl functionalities present in thujone could be retained for the synthesis of interesting analogues.

A large number of experiments concerning the best route to **4** were conducted. These involved studies with various bases (KOH, NaH, K-*tert*-butoxide) in different solvents (methanol, THF, *tert*-butanol) and iodomethane or dimethyl sulphate as alkylating agents. With KOH, in methanol, the only observed reaction was isomerization of the C-4 methyl group to afford an equilibrium mixture of (−)-isothujone (**3**, C-4 methyl in β-orientation) and (+)-thujone (**3**, C-4 methyl in α-orientation) in a ratio 2:3 respectively. The stronger base, NaH in THF and iodomethane as alkylating agent (3 equivalents of each), afforded a mixture of unreacted **3** (13%), the monomethylated product **8** (58%), and the dialkylated product **9** (14%) while replacement of NaH by potassium *tert*-butoxide (2.5 equivalents) afforded **8** (48%) and the fully alkylated ketone **10** (15%). In all cases, the re-

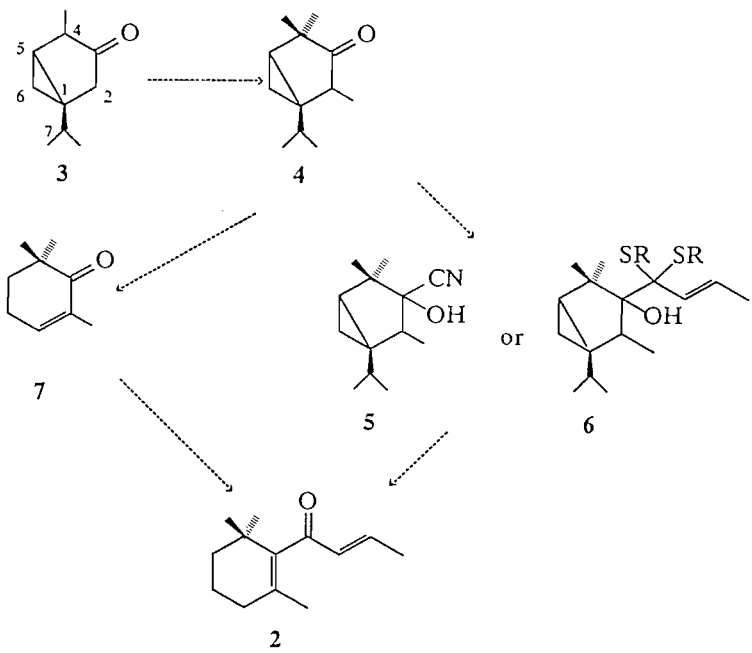
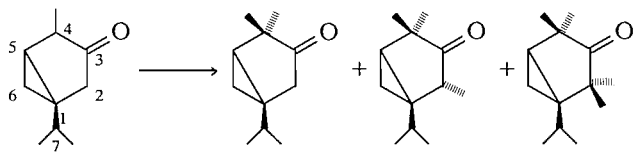
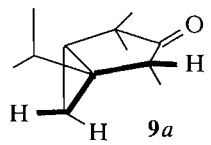


SCHEME 1. Synthetic strategy for synthesis of β-damascone (**2**) from thujone (**3**).

sulting reaction mixture was difficult to separate so a "one-step" alkylation process to provide the desired **9** (or its C-2 isomer) was clearly undesirable. Thus regiospecific monoalkylation of **3** at the C-4 position became the primary focus in the hope that **8** could be converted in higher overall yield to **9** in a subsequent reaction. Table 1 summarizes the



III



results obtained in studies directed to optimize yields of **8**. The high yields obtained (entries 2 and 3, Table 1) were encouraging and these conditions were employed in all subsequent studies. For purposes of compound characterization, **8** could be separated from **9** by repeated flash chromatography. Since it was expected that the rate of alkylation of **8** to **9** would be higher than **9** to undesired **10**, the mixture of **8** and **9**, as obtained in these studies, could be employed directly in the subsequent alkylation experiments.

The minor component **9**, which was eluted first from the column, showed a molecular ion peak at m/z = 180 in the mass spectrum. The ^{1}H NMR spectrum showed two singlets at δ 0.99 and 1.09 ppm, a doublet at δ 0.98 ppm and two overlapping doublets at δ 1.03 ppm each integrating for three protons, the three cyclopropane protons at high field, and the characteristic septet of the isopropyl group. A quartet of doublets at δ 2.80 ppm, assigned to the C-2 proton, was shown by decoupling to be coupled to one of the methyl doublets at δ 1.03 ppm and also to one of the cyclopropane protons by a W-coupling. Hence the C-2 methyl had to be *cis* to the cyclopropane ring (*endo* form or explicitly the *R* configuration)[3] to allow for a W-coupling of the C-2 proton with a C-6 proton (see **9***a*). Also the C-6 H_{exo} proton at δ 0.54 ppm could be assigned through this W-coupling.

The ^{1}H NMR spectrum of the monomethylated ketone **8** (M^+ at m/z = 166) clearly showed two methyl singlets at δ 1.12 and 1.03 ppm, and an AX system for the protons at C-2 (δ 2.09 and 2.66 ppm). The signal at δ 2.66 ppm has long-range coupling (J = 2.5 Hz) corresponding to a W-coupling with C-6-H_{exo} (δ 0.64 ppm), and so could be assigned as the *exo* C-2 proton.

Given the high yield of monomethylated thujone derivative **8**, a second methylation was required for the production of the desired dimethylated thujone **9**. Since the use of excess potassium tert-butoxide in the methylation of thujone gave rise to significant amounts of product **10**, as well as the desired products, it was decided to use lithium diisopropylamide as the base. Using 1 equivalent of lithium diisopropylamide in tetrahydrofuran in the reaction with **8**, and subsequent alkylation with iodomethane, gave a mixture, separable by spinning band distillation and column chromatography, that contained a predominance of two isomeric dimethylated compounds **9** (25%) and **11** (57%), with

[3]Previous workers (14) have used the term "pseudo-axial" and "pseudo-equatorial" for describing substituents on the thujone system. However, since the five-membered ring is very close to planarity, and so can be distorted by substituents into either a "boat" or "chair"-like conformation, these terms do seem very ambiguous. For this work the terms *exo* and *endo* have been used to describe substituents on the bicyclic system. The term *endo* is used when the substituent is closer to the longer of the two unsubstituted bridges (see **9***a*).

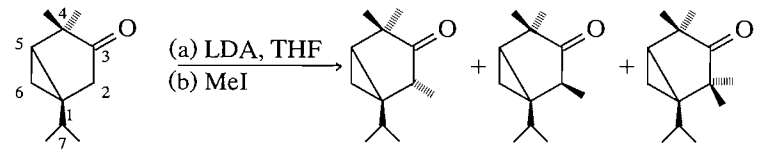
3	1.0	THF/'BuOH	1.0	81	13	86	—	

[a]Determined by GC analysis.

some starting material **8** (7%) and the fully methylated product **10** (6%). The overall yield of **9** and **11** from this reaction was 77%. It was found that after the methylation reaction had ceased, prolonging the reaction time resulted in an increase in the ratio of **9** to **11** with no change in the amount of **8** or **10**. It was believed that the diisopropylamine present was effecting an isomerization of **11** into **9**. Subsequently, the reaction mixture was treated with alcoholic potassium hydroxide to result in an almost complete isomerization of **11** to **9**. Since the methylation of the enolate generated from **8** is a kinetically controlled process, compounds **11** and **9** are both formed in the methylation of **8**. Approach of iodomethane can occur from either side of the enolate, with the *exo* face preferred (since the C-6-*endo* proton hinders attack from the *endo* face) giving rise to a predominance of **11** over **9**. However, ketone **9** is the more thermodynamically stable compound and thus becomes predominant on equilibration of the mixture. Both **10** and **11** were characterized from the usual spectroscopic data (see Experimental).



8 **9** **11** **10**

The isomerization of **11** to **9** was investigated. Treatment of either pure **11** or pure **9** with alcoholic potassium hydroxide, resulted in an identical mixture of **9**:**11** = 99:1. Treatment of a mixture of **8**, **9**, **11**, and **10** (**9**:**11** = 38:28) with thionyl chloride in methanol (a source of alcoholic hydrogen chloride) also resulted in isomerization of **11** to **9** (**9**:**11**) = 65:3). The isomerization of **11** to **9** would be expected, since in **11** the near-planarity of the cyclopentane ring forces an eclipsing relationship between the *exo* C-2 methyl group and the isopropyl group. On isomerization to **9**, the C-2 methyl group is *cis* to the cyclopropane ring, which is expected to be less sterically demanding than the isopropyl group.

The above detailed studies provided some understanding of the alkylation of thujone (**3**) to the ultimate desired product (**9** and (or) **11**) and allowed satisfactory yields of these compounds.

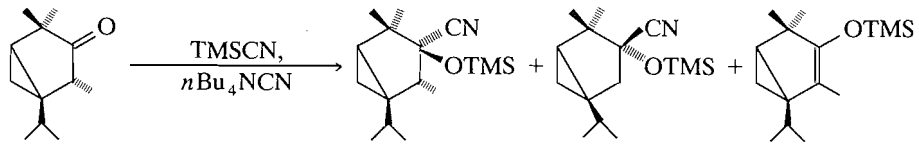
In summary, by the use of a two-step alkylation process, using initially potassium *tert*-butoxide and iodomethane to afford **8** as a major component, and without isolation, reaction with lithium diisopropylamide and iodomethane, followed by treatment of the latter mixture with potassium hydroxide, a 77% overall yield of **9** from **3** could be realized.

With the desired **9** in hand, the elaboration of the side chain, as required for the damascone series, and ring-opening of the cyclopropyl group was now considered. Preliminary investigations in our laboratory revealed that direct introduction of the four-carbon side chain, that is, the sequence, **4** → **7** → **2** or **4** → **6** → **2** (Scheme 1) would provide difficulties and the route, **4** → **5** → **2**, shown in Scheme 1 was pursued.

In considering the conversion of **9** (shown in general terms as **4** in Scheme 1) to the cyanohydrin **5**, it was deemed unnecessary to prepare a pure isomer of the two possible cyanohydrins since subsequent elimination of the hydroxyl function to generate the required double bond in **2** would not necessitate a specific stereochemistry in cyanohydrin **5**. For this purpose, studies involving direct addition of cyanide ion to **9** under a variety of conditions were pursued but no formation of **5** could be observed. However, the use of trimethylsilyl cyanide (15–17) (1.05 equivalents) with tetra-*n*-butylammonium cyanide (0.1 equivalent) as catalyst in the absence of solvent at 70–80°C did afford an essentially quantitative yield of the trimethylsilyl cyanides **12** and **13** in a ratio of 70:28 respectively (GC analysis). No attempt was made, either chemically or spectroscopically, to establish the configuration of each compound at this stage, though, following a literature search on the stereochemical outcome of this reaction, some conclusions as to the stereochemistry can be inferred. Evans *et al.* (18) established the stereochemical course of the trimethylsilyl cyanide addition to the relatively unhindered, but conformationally locked, 4-*tert*-butylcyclohexanone. Kinetically the cyanide ion preferentially attacks the carbonyl from its axial face. A thermodynamic equilibrium can be established in which the axial cyanide isomer also predominates. With the trimethylsilyl cyanohydrins from **9**, the isomer with the cyano group *endo* to the cyclopropane ring is likely to predominate in a thermodynamic equilibrium, since the periplanar interaction of the C-2

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

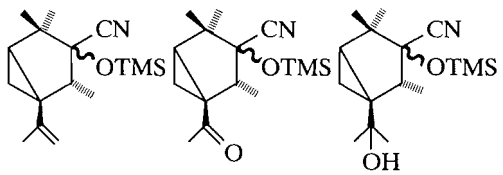
methyl and the nitrile would be less than the equivalent interaction of the C-2 methyl and the oxysilyl group. Since the use of tetra-*n*-butylammonium cyanide as a catalyst induces thermodynamic equilibrium (16), the major isomer is likely to be **12**.[4] Separation of the isomers for characterization proved difficult. As the trimethylsilyl group was intended to be eliminated at a later stage, there was no need to separate the isomers for the synthesis of the damascones.



9 **12** **13** **14**

Along with the above mixture of isomeric silyl cyanohydrins we obtained the silyl enol ether **14** as a very minor product (2% by GC). In larger scale reactions, **14** was separated from the silyl cyanohydrins. The generation of silyl enol ethers in the reaction of trimethylsilyl cyanide with ketones has been noted before (15).

With the desired introduction of the nitrile group in hand, attention was focussed on opening the cyclopropane ring to generate a six-membered ring system. The strategy employed here was based on an earlier observation in our laboratory (1) that ozonation of thujone-derived intermediates allows selective introduction of a hydroxyl group exclusively at the tertiary carbon atom of the isopropyl group, and the product thus formed can be elaborated to the desired system by successive treatment with mineral acid and tri-*n*-butyltin hydride. Application of this strategy of cyclopropane-opening/isopropyl cleavage to the present study was highly successful. Treatment of the mixture of silyl cyanohydrins **12/13** in ethyl acetate at 0°C with a stream of ozone for 8 h resulted in complete consumption of the starting material. The products, isolated as three separate mixtures of isomers, were the epimeric olefins **15/16** (1%), the epimeric ketones **17/18** (45%), and the epimeric alcohols **19/20** (21%). Attempts to separate the individual epimers

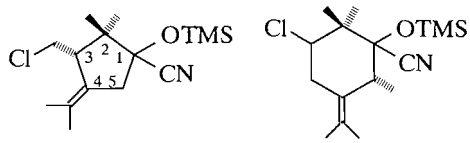


15/16 **17/18** **19/20**

from each of the mixtures by column chromatography for a detailed characterization resulted only in the enrichment of each isomer in the mixture. Pure compounds were not obtained in this study. The mixture of alcohols **19** and **20**, occurring as a white solid, consisted of a 66:34 mixture of the epimers similar to the ratio present in the starting material. The assumption is that the major product has the nitrile group *endo* to the cyclopropane ring. The ratio of isomers was determined by GC, and by integration in the ^{1}H NMR spectrum. Since mixtures greatly enriched in either of the alcohols could be obtained by chromatography, identification of the resonances in the ^{1}H NMR spectrum was possible.

The ketones **17** and **18**, obtained in 45% yield, occurred as an inseparable mixture (71:29) while the third mixture, obtained in 1% yield, was shown to be the alkenes **15** and **16**, present as a 60:40 mixture as determined by integration of the ^{1}H NMR resonances at δ 4.78 and 4.85 ppm corresponding to the terminal methylene protons.

Initial investigation of the ring-opening of the cyclopropane ring began with the alcohols **19** and **20**. Treatment of a mixture of the alcohols dissolved in dichloromethane with concentrated hydrochloric acid gave a mixture of three isomeric chlorides in 52% overall yield, of which **21** was the predominant compound (83% of the mixture). Repeated purification by column chromatography resulted in a pure sample of **21**. The mass spectrum showed it to be a chloride of formula $C_{16}H_{28}ClNOSi$. The ^{1}H NMR spectrum readily established **21** as the isolated product and not the alternative six-membered structure **22**.



21 **22**

On monitoring the reaction of **19** and **20** with hydrochloric acid by GC, it was found that an initial product was formed, which then decreased as the percentage of the chloride mixture containing **21** increased. By performing the same reaction at 0°C, the initial product could be obtained after careful work-up. The product was a highly unstable 60:40 mixture of the chlorides **23** and **24**, that rapidly decomposed to the alkenes **15** and **16**.

It was subsequently found that performing a sequence of reactions in which the chlorides were not purified led to significant increases in the yields. It was believed that the moderate yield of the chlorination step was due to the purification process.

The five-membered ring chloride **21** was not an unexpected product since, as noted earlier, studies in our laboratory (1) had provided a similar ring-opening reaction.

In parallel experiments, it was found that treatment of the mixture of chlorides (containing **21**) with tri-*n*-butyltin hydride afforded the alkenes **27** and **28** (83:17) in 69% yield. The ^{1}H nmr spectrum of **27** clearly showed that a rearrangement had occurred, since the methyl group doublet that would result from direct replacement of chlorine in **21** was absent.

[4]This argument assumes a near-planarity of the five-membered ring in the products **12** and **13**. It has been shown (19) that in 3-thujone (**3**) the five-membered ring is only slightly distorted from planarity.

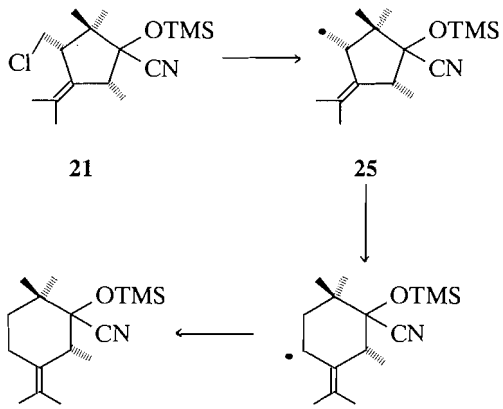
19/20 23/24 21

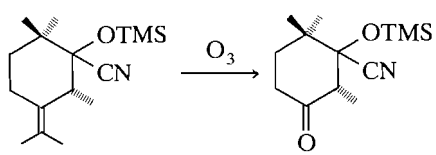
Such a radical rearrangement had been noted previously (1). Treatment of the chlorides with tri-*n*-butyltin hydride (20) leads to homolytic cleavage of the C—Cl bond to generate a free radical. Usually, this radical abstracts a hydrogen atom from the tin hydride to propagate the free-radical chain reaction. However, the radical can rearrange to a more stable radical before abstraction, as has apparently happened in this case (**21** → **25** → **26** → **27/28**). The primary radical **25** generated from **21** by tri-*n*-butyltin hydride may rearrange



21 25 27/28 26

to the secondary radical **26**. This secondary radical is then trapped by a hydrogen atom. Davies and co-workers (21) and Mariano and Bay (22) investigated cyclopropyl radical rearrangements in which either the primary or secondary radicals were obtained on ring-opening, depending on the conditions and the initial stereochemistry of the cyclopropyl radicals.

At this stage it was decided, since the alcohols **19/20** could be converted to the six-membered ring alkenes **27/28**, which on ozonolysis should be converted to the ketones **29/30**, that a study involving the conversion of the ketones **17/18** into the ketones **29/30** should also be investigated.



27/28 29/30

As discussed previously, the ketones **17** and **18** (71:29) were produced in 45% yield in the prolonged ozonation of **12** and **13**. Reduction with sodium borohydride gave, in 92% yield, a mixture of four isomeric alcohols **31**, **32**, **33**, and **34** (38:35:14:13 as shown by integration of the C-7 proton resonances in the ^{1}H nmr spectrum). It was not considered necessary to obtain pure alcohols for the subsequent reactions, since it was expected that eventually a common product would be obtained from all of the isomers. Analysis of the product ratios in relation to the composition of the starting material suggested that, for each ketone, the reducing reagent attacked both the *re* or *si* face at equal rates.

Reaction of this mixture of alcohols with hydrochloric acid resulted in the production of two chlorides **35** and **36** (63:37). (63:37). Traces of the five-membered ring chlorides were detected. Compounds **35** and **36** were clearly identified by the presence in the ^{1}H NMR spectrum of the signals corresponding to the cyclopropane protons, and the two signals at δ 3.75 and 4.11 ppm corresponding to the protons attached to the carbon atoms bearing chlorine. The simplification of the mixture from four isomers (for the alcohols) to two isomers (for the chlorides) was somewhat surprising, as was the retention of the cyclopropane functionality since, with the alcohols **19** and **20**, ring-opening to the five-membered ring chloride **21** occurred under the same conditions.

The formation of the chlorides **35** and **36** was of concern, since treatment with tri-*n*-butyltin hydride might result in the eventual retention of the cyclopropane functionality. Fortunately, on treatment with this reagent a rearrangement of the initial radical, formed by the homolytic cleavage of the C—Cl bond, resulted in an efficient conversion of the chloride into the alkenes **37** and **38** (**37**:**38** = 72:28) in 95% yield, possessing the desired six-membered ring. The two alkenes were epimeric about the silyl cyanohydrin functionality. Support for the structures of **37** and **38** was provided by the presence of the two vinylic protons at δ 5.20 and 5.41 ppm, and the absence of resonances corresponding to the cyclopropyl protons in the ^{1}H NMR spectrum. The stereochemistry about the double bond could not be determined from the regular proton spectrum. Since the stereochemistry was to be destroyed in the next step, further experiments to determine this stereochemistry were not undertaken.

Ozonolysis of the mixture **37** and **38** gave, in high yield (93%), the six-membered ring ketone, **29**, contaminated with 5% of the epimer **30** (further purification gave samples of **29** of 98.5% purity). This result was highly surprising. Obviously an epimerisation α to the carbonyl had occurred (Scheme 2). The isomer **29** must consist of a pair of enantiomers to account for the high yield of the reaction after starting with a mixture of diasteroisomers of 72:28 ratio. Although the product had $[\alpha]_D = -28$, it would be expected that **29** was not optically pure. Attempts at using a chiral shift reagent in the separation of the signals in the ^{1}H NMR spectrum were unsuccessful. The determination of the relative stereochemistry of **29** was based on ^{1}H NMR nOe difference experiments performed on **29**, reinforced by an

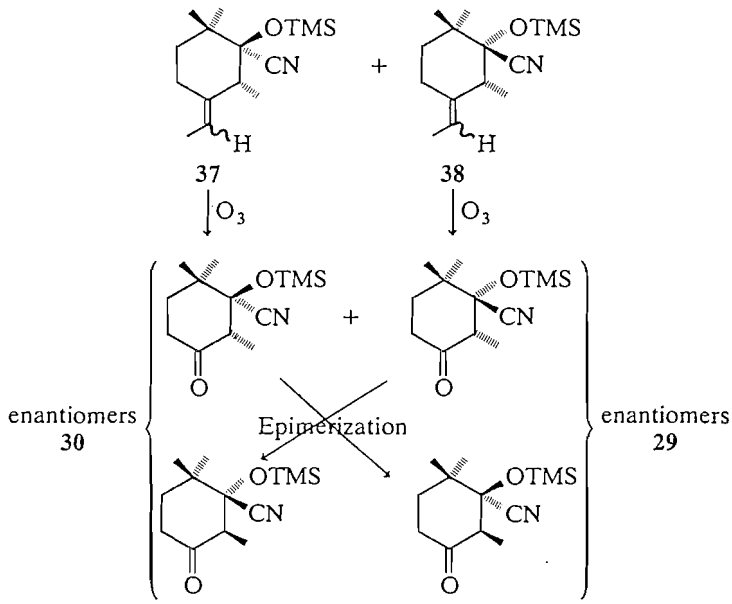
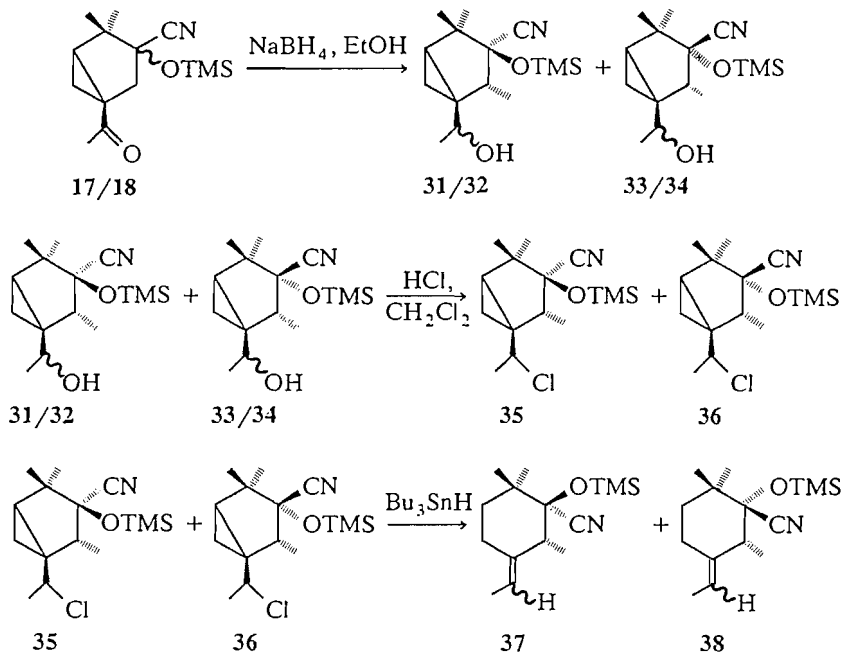


SCHEME 2. Conversion of isomeric trimethylsilyl cyanohydrins **37/38** into ketones **29/30**.



^{1}H NMR nOe difference experiment performed on a subsequent structure derived from **29** (see later).

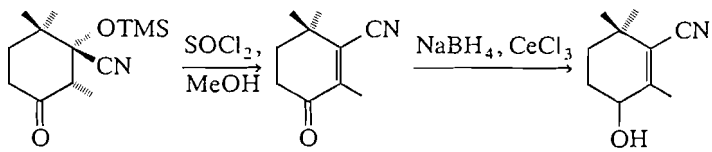
For preparative purposes, the above studies now afforded the opportunity to develop an efficient route from thujone (**3**), via **9**, to the desired ketones **29** (or **30**). It was clear that isolation of the various intermediates discussed above is not essential since on further reaction these various compounds will lead to the same end product along the sequence. Thus **9** is converted to the mixture of **12** and **13**, the latter is directly treated with ozone to afford a mixture of **15–20** that, without further separation, is reacted successively with sodium borohydride, hydrochloric acid, tri-*n*-butyltin hydride, and finally ozone. The latter mixture, on purification, provides ketones **29** and **30** in a ratio of 95:5 respectively and in 35% overall yield for this six-step process.

A further overall improvement of the above process was developed when it was noted that a crude reaction mixture resulting from the methylation of thujone, that is, conversion of **3** to **9** and **10**, discussed earlier, could be employed in the reaction with trimethylsilyl cyanide. The sterically hindered carbonyl group in **10** does not undergo conversion to the corresponding nitrile and **10** is consequently readily separated from **12** and **13**.

Having obtained ketone **29** via the rather efficient overall reaction sequence from thujone, elaboration of the side chain to afford a versatile route to the damascones and (or) novel

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

analogues thereof was now considered. Reduction of the nitrile function in **29** to the corresponding aldehyde by the classical reagent diisobutylaluminum hydride (23) was only moderately successful (41% yield) with reduction of nitrile and carbonyl functions as well as removal of the trimethylsilyl group occurring simultaneously. An alternative route involved treatment of **29** with thionyl chloride in methanol to afford an enone (**39**) and the latter, upon reduction with sodium borohydride in the presence of cerium III salts (24, 25) provided **40** in essentially quantitative yield. These reactions can be accomplished without isolation of intermediates and an overall 92% yield of **40** from **29** is achieved.

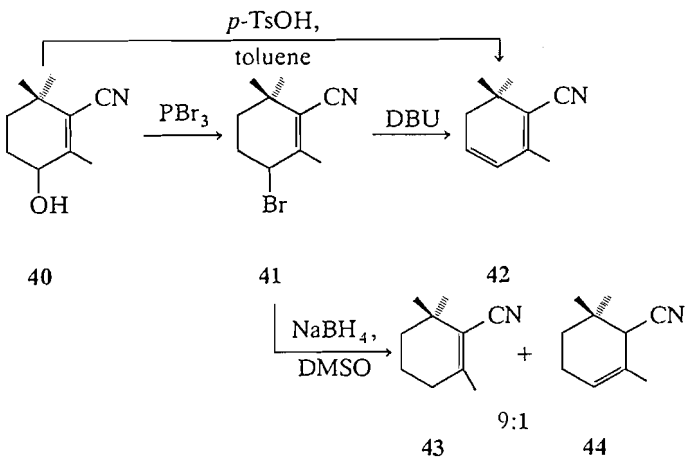


29 **39** **40**

Compound **40** was now envisaged to be a key intermediate in the production of β-damascenone. Elimination of the hydroxyl group to generate the unsaturated nitrile **42** would give access to the damascenones, whilst a reductive elimination would lead to the α,β-unsaturated nitrile **43**, which would give access to the damascone series.

Compound **40** was converted to the bromide **41** in 92% yield by treatment with phosphorus tribromide in petroleum ether at 0°C (molecular ion peaks at m/z = 229 and 227 in the mass spectrum). Reduction of the bromide, accomplished by sodium borohydride in dimethyl sulphoxide (26, 27) gave, in 95% yield, the α,β-unsaturated nitrile **43** and the non-conjugated nitrile **44**, as a 90:10 mixture.

The nitrile **43** has been reported previously in the literature (28, 29). Ohloff and co-workers (29) have mentioned that an equilibrium mixture of **43** and **44** contained 92% **44** and 8% **43**.



The conversion of **43** into β-cyclocitral (**45**) would constitute a formal synthesis of β-damascone (**2**) since **45** had been already converted to **2** (29, 30). For this purpose, our attention turned to the reduction of **43** with diisobutylaluminum hydride. While this research was in progress, Picard *et al.* (31) published results complementary to procedures we were employing. It was reported that the reduction of **43** by diisobutylaluminum hydride, with a work-up involving 5% sulphuric acid, gave the aldehyde, β-cyclocitral (**45**) in 70% yield. Repetition of this procedure with slight modifications (change in solvent and reaction time) afforded **45** in 90% yield after distillation. The presence of the unsaturated aldehyde functionality was shown by the absorbance at 1665 cm^{-1} in the infrared spectrum, and by the singlet at δ 10.11 ppm in the ^1H nmr spectrum. The facile oxidation of **45** to the corresponding acid required careful manipulation of the reaction mixture in order to obtain optimum yields of **45**. An alternative approach to **45** has also been published (32).

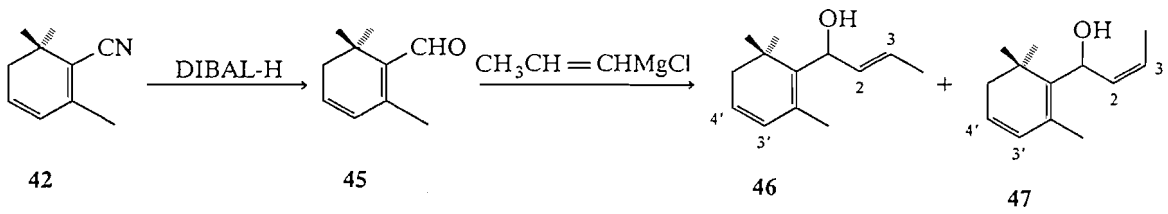
Having completed a formal synthesis of β-damascone, the production of β-damascenone was investigated. Treatment of **41** with 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) resulted in the formation of the diene **42** in 27% yield. The conjugated diene was characterized by the absorbances at 1640 and 1575 cm^{-1} in the infrared spectrum and by the maximum at 285 nm in the ultraviolet spectrum corresponding to the chromophore of the unsaturated nitrile. The synthesis of **42**, trivially named safronitrile, from the alcohol **40** by acid-catalyzed dehydration has been reported (28), though no yields or procedure were presented. It was found in our laboratory that treatment of **40** with *para*-toluenesulphonic acid (0.18 equivalent) in toluene, with azeotropic removal of water, resulted in dehydration to give the diene **42** in 75% yield.

Elongation of the side chain, utilizing **42** as starting material, was considered via the sequence, **42** → **45** → **46**/**47**. Reduction of **42** with diisobutylaluminum hydride afforded the expected aldehyde **45** (63% yield) and the latter was immediately subjected to reaction with 1-propenylmagnesium bromide to give a 1:1 mixture of the allylic alcohols **46** and **47**. The two alcohols are formed since the commercial supply of 1-bromopropene, used in the generation of the Grignard reagent, exists as a 1:1 mixture of geometric isomers. It was found that the *Z* isomer, **47**, was unstable to chromatography, possibly undergoing an acid-catalyzed rearrangement, while **46** was completely stable and could be isolated pure (43% overall yield) by chromatography of the mixture on silica gel. Assignments of stereochemistry at C-2 and C-3 were made based on conversion to subsequent structures and relating the configuration back through to **46** and **47**.

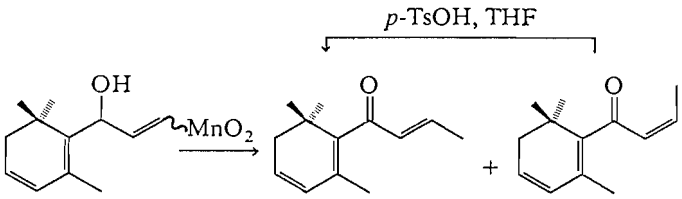
Mild oxidation of **46** with 20 equivalents of "active" manganese dioxide (33) gave quantitatively β-damascenone (**48**), which had spectral data consistent with the natural product.

Oxidation of the mixture of alcohols **46** and **47** (49:51) under the same conditions afforded a mixture of the ketones β-damascenone (**48**) and its *Z*-isomer (**49**) (49:51) in quan-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.



titative yield. β-Damascenone (**48**) showed the two olefinic protons of the side chain at δ 6.20 and 6.85 ppm with a coupling constant of 16 Hz. Ketone **49** showed the equivalent protons as a multiplet resonating at δ 6.20 ppm. The coupling constant indicated that the double bond has the *E* configuration in β-damascenone (**48**).



Separation of the mixture **48** and **49** was not required since it has been reported (34) that acid-catalyzed isomerization of **49** to **48** occurs. Treatment of the mixture with *para*-toluenesulphonic acid in tetrahydrofuran resulted in the production of pure β-damascenone (**48**) exclusively, in 76% yield after purification.

In summary, the total synthesis of **48** from thujone has been accomplished in 6% overall yield via the 15-step route outlined in Scheme 3. A majority of the intermediates noted need not be isolated, thereby increasing the efficiency of the overall process. Specifically the synthesis can be accomplished as a "several-pot" process: (*i*) **3** → → **9**; (*ii*) **9** → → **29/30**; (*iii*) **29/30** → **40**; (*iv*) **40** → → **42**; (*v*) **42** → **45**; (*vi*) **45** → → **48**.

As noted at the outset, it was the purpose of this investigation to develop a synthetic route to intermediates that could, in turn, allow the synthesis of novel damascone analogues that may reveal interesting perfumery or aroma properties. The intermediates **12/13**, **19/20**, and **27/28**, obtained in several steps from the readily available and inexpensive thujone, can, in conjunction with the chemistry developed herein, be utilized for this purpose. Studies in this direction will be presented later.

While the above studies were underway, an alternate route to **42** was undertaken from commercially available 2,6-dimethylcyclohexanone (**50**). The sequence under investigation is summarized in Scheme 4.

2,2,6-Trimethylcyclohexanone (**51**) was synthesized in 85% yield from commercially available 2,6-dimethylcyclohexanone (**30**), by treatment with lithium diisopropylamide and iodomethane, by a modification of the procedure reported by Fitjer and Quabeck (35). The product (**51**) contained a minor amount (3%) of 2,2,6,6-tetramethylcyclohexanone (**52**) (as shown by GC). This impurity was tolerated

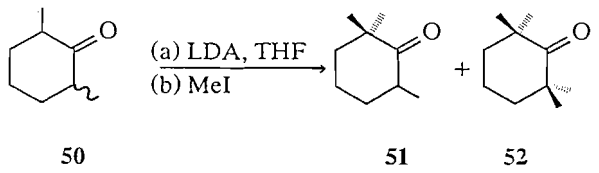
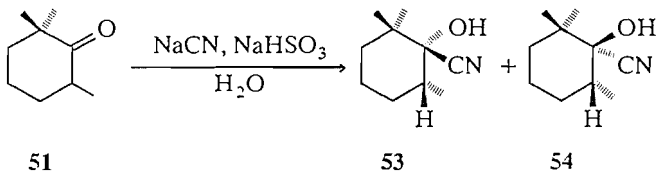
in preference to the impurity of *cis/trans* 2,6-dimethylcyclohexanone as in the synthesis of trimethylcyclohexanone reported by Fitjer.

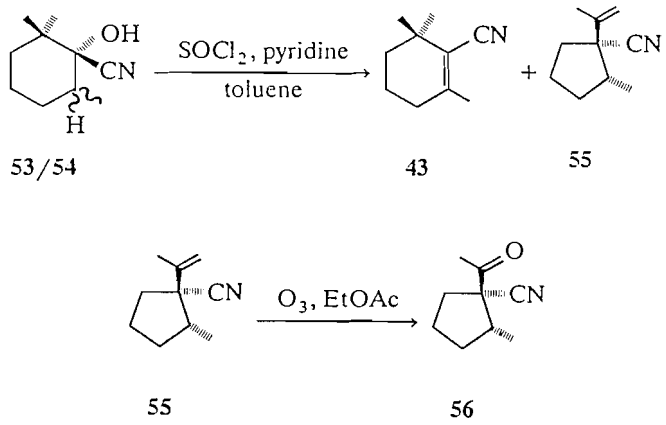


Reaction of **51** with sodium cyanide in aqueous sodium bisulphite solution, a procedure described by Stille and coworkers (36), gave a quantitative yield of a white solid, shown by GC and ^{1}H nmr spectroscopy to contain a 23:77 mixture of the cyanohydrins **53** and **54** respectively.[5] The stereochemistry shown in **53** and **54** follows from a single crystal X-ray analysis of a subsequent product (see later).

The dehydration of the mixture of **53** and **54**, in order to achieve a synthesis of **43**, was attempted with thionyl chloride and pyridine in refluxing benzene and in accord with the procedure employed by Stille (36) in which a high yielding



conversion of a closely related cyanohydrin had been obtained. However, in the present study, the mixture of **53** and **54** was shown to convert to a mixture of nitriles **43** and **55** (94% overall yield) and in an unfavorable ratio (**3**:**14** = 26:74). Apart from the spectral data (see Experimental), further proof of the structure of **55** was provided by ozonolysis. The resulting ketone possessed all the characteristic spectral data consistent with **56**.



The isolation of **43** and **55** is explicable in conformational terms according to Scheme 5 wherein **43** is obtained via diaxial elimination of water from **53** while **54** undergoes rearrangement due to inaccessibility of the requisite β-hydrogen atom for such an elimination process.

An extensive series of experiments was conducted in the hope of altering the ratio of **43**:**55** in the desired direction (Table 2) but, in all cases studied, **55** was observed as the major product. Consequently, attention was focussed on developing a procedure in which the desired nitrile **43** could be obtained efficiently from the mixture of **53** and **54** and, if possible, without isolation of the individual compounds.

Acetylation of the mixture of **53**/**54** (acetic anhydride, acetyl bromide) afforded a 72:28 mixture of the corresponding acetates **56** and **57** respectively (79% overall yield). Subjecting this mixture to vacuum pyrolysis with a furnace temperature of 450°C afforded the desired nitrile **43** (72% yield) and recovery of starting material (ratio of **56**:**57** of 91:9, 28% yield). This result was encouraging in that it indicated a highly selective *cis* elimination occurring with **57** and thereby a possible route to optimizing the yield of the desired **43** from the original mixture of **53** and **54**.

Reaction of the mixture of **53** and **54** (ratio of **53**:**54** of 20:80) with thionyl chloride and pyridine at 4°C in toluene (17 h) revealed *selective* dehydration of **53** to **43**; the resulting mixture of **43** and **54** is directly acetylated to afford a mixture of **43** and **57** from which the latter could be isolated, for the first time, as a pure crystalline solid. Single crystal X-ray analysis (Fig. 1) established the structure and stereochemistry of **57** and, in turn, the earlier proposed structures for the cyanohydrins **53** and **54**.

Based on the above results, an extremely efficient synthesis of the nitrile **43** from 2,2,6-trimethylcyclohexanone (**51**) was achieved without intermediate purification (Scheme 6). The steps followed were treatment of **51** with cyanide, treatment of the resultant mixture with thionyl chloride and pyridine at 4°C ("*trans*" elimination), followed by acetylation of the remaining "*cis*" isomer and finally "*cis*" pyrolytic elimination to give the desired nitrile **43**. The overall yield of **43**, from this four-step conversion, was 81%.

While the above studies were underway, we became aware of an independent program by Picard *et al.* (37), relating to

[5]Conventionally only one of each pair of enantiomers is drawn. The terms "*cis*" and "*trans*" have been adopted for compounds like **53** and **54** to indicate the stereochemistry of a β-proton relative to the hydroxyl group. A "*cis*" compound would have the hydroxyl group and the β-proton on the same side of the ring plane. This convention has been used by others, i.e., Picard *et al.* (37) and Holm (38).

the above. Through private exchange of information,[6] it is clear that their route involving the reaction of **51** with trimethylsilyl cyanide, separation of the resultant *cis* and *trans* products, and subsequent elaboration of the *trans* isomer to **43** is completely different from the sequence described herein.

In conclusion, the process involving the "one-pot" conversion of **51** to **43** (81% overall yield), which in turn affords **42** (47% overall yield from **51**) and **45**, when coupled with the earlier described chemistry provides a highly attractive route to the various damascones from cyclohexanone. In addition, these compounds are important building units; for example, **43** can be efficiently converted to the widespread natural terpenoid β-cyclocitral (**45**) and the latter, in turn, serves as a starting material in the syntheses of various natural products: thujopsene (39), safranal (32, 40, damascenone (**48**) (41), and widdrol (42) as examples.

[6]We are very grateful to Dr. Picard for informing us of his unpublished results.

Experimental

Melting points (with the recrystallization solvents given in parentheses) were determined using a Kofler block melting point apparatus and are uncorrected. Optical rotations were recorded on a Perkin–Elmer 141 automatic polarimeter in chloroform solution using a quartz cell of 10 cm pathlength with the concentration (in g/100 mL) given in parentheses. The infrared spectra were recorded on Perkin–Elmer 710, 710B, and 1710 spectrometers in chloroform solution (using NaCl cells of 0.1 mm pathlength) or as thin film (using NaCl plates). The ultraviolet spectra were recorded on Cary 15 or Unicam SP800 spectrometers using quartz cells of 1 cm pathlength. The ^1H NMR spectra were recorded on Bruker WH-400, AE-200, or Varian XL-300 spectrometers (with solvent given in parentheses) and the chemical shifts are reported on the delta (δ) scale in ppm relative to tetramethylsilane. Assignments, where given, are based on a combination of chemical shift,

coupling constant, decoupling, and nOe difference data. The ^{13}C NMR spectra were recorded on Bruker AE-200 or Varian XL-300 spectrometers and the chemical shifts are reported on the delta (δ) scale in ppm relative to tetramethylsilane. The mass spectra were recorded on AEI-MS-9 or Kratos-MS-50 (using the electron impact ionization method for low and high-resolution analysis) or Delsi Nermag R10-10C (using the chemical ionization method) spectrometers. High-resolution mass measurements were obtained on samples that gave one peak on GC analysis or, in the case of mixtures of isomers, no unidentified peaks on GC analysis. Gas chromatography – mass spectroscopy (GC–MS) analyses were performed using a Varian 6000 chromatograph coupled to a Delsi Nermag R10-10C mass spectrometer. Elemental analyses were determined using a combustion technique by Mr. P. Borda, Microanalytical Laboratory, University of British Columbia. Gas chromatography (GC) was performed on a Hewlett–Packard 5890A gas chromatograph, using a flame ionization detector and a 25 m × 0.2 mm fused silica capillary column coated with cross-linked methyl silicone gum (HP1) or a 14.5 m × 0.252 mm fused silica capillary column coated with cyanopropylphenyl silicone gum (DP1701). Column chromatography was performed unless otherwise stated by modified "flash chromatography" (43) using columns of silica gel (230–400 mesh) with nitrogen gas pressure to obtain a suitable flow. Bulb-to-bulb distillation was performed using a Kugelrohr distillation apparatus obtained from Aldrich Chemical Co. with the air bath temperature at which distillation occurred given in parentheses.

All reactions were performed under a positive pressure of dry nitrogen at room temperature unless otherwise stated. Reactions performed at −78°C were cooled using a Dry Ice/acetone bath. All chromatography solvents were distilled prior to use. The term "petroleum ether" refers to commercially available hydrocarbons boiling in the 35–60°C range. "Active" manganese dioxide was prepared by the method of Attenburrow *et al.* (44) and tested by the method of Fatiadi (33). The source of "thujone" was redistilled Western red cedar leaf oil, which had a total thujone content ranging from 80 to 96%. Western red cedar leaf oil was obtained as a gift from Intrinsic Research and Development Incorporated.

Single crystal X-ray structure determinations were performed by Dr. S. Rettig with data obtained on a Rigaku AFC6S diffractometer (crystal structure data are available in the Appendix).

*(1S,5S) 4,4-Dimethyl-1-(1-methylethyl)-bicyclo[3.1.0]hexan-3-one (**8**) and (1S,2R,5S) 1-(1-methylethyl)-2,4,4-trimethylbicyclo[3.1.0]hexan-3-one (**9**)*

The source of "thujone" was redistilled cedar leaf oil, which had a total 3-(−)-isothujone/3-(+)-thujone content of 86%. Potassium *tert*-butoxide (157.6 g, 1.40 mol) was dissolved in *tert*-butanol (750 mL), diluted with anhydrous tetrahydrofuran (1500 mL), and the resulting solution heated to reflux. To this solution was added dropwise a solution of cedar leaf oil (158.6 g, 0.989 mol of thujone) in anhydrous tetrahydrofuran (750 mL) over 15 min. The reaction was stirred at reflux for a further 3 h, then cooled to room temperature. Iodomethane (88 mL, 1.4 mol) was added to the mixture, which was stirred for 85 min and then added to brine (2500 mL). The aqueous layer was extracted with petroleum ether (3 × 250 mL). The combined organic fractions were washed with brine (2 × 500 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a yellow oil (164.2 g) that contained monomethylated thujone **8** (78.6%) and dimethylated thujone **9** (8.3%) by GC (1-menthol as internal standard). Based on the purity of the starting material, the yield for **8** is 86.4% and for **9** is 8.4%. It is possible to separate **8** from **9** either by repeated flash chromatography using diethyl ether/petroleum ether (1:19) as eluent, or by spinning band distillation.

For personal use only.

singlet and simplified the doublet of doublet of doublets resonating at δ 0.64 ppm to a doublet of doublets (J = 8, 6 Hz).

Dimethylated thujone **9**: bp 68°C/8 Torr; $[\alpha]_D^{22}$ −49.2 ($CHCl_3$, c 3.282); IR ν_{max} (thin film): 2950, 2855, 1740 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: −0.16 (1H, dd, J = 6, 4 Hz, C6-H_{endo}), 0.54 (1H, ddd, J = 8, 6, 2 Hz, C6-H_{exo}), 0.98 (3H, d, J = 7 Hz, C7-CH_3), 0.99 (3H, s, C4-CH_3), 1.03 (3H, d, J = 7 Hz, C2-CH_{3endo}), 1.03 (3H, d, J = 7 Hz, C7-CH_3), 1.09 (3H, s, C4-CH_3), 1.12 (1H, m, C5-H), 1.51 (1H, septet, J = 7 Hz, C7-H), 2.80 (1H, qd, J = 7, 2 Hz, C2-H_{exo}) ppm; MS m/z: 180 (M^+), 165, 137, 123, 109, 83 (100); high-resolution mass measurement calcd. for $C_{12}H_{20}O$: 180.1514; found: 180.1510. Anal. calcd. for $C_{12}H_{20}O$: C 79.96, H 11.18; found: C 79.99, H 11.17. ^1H NMR decoupling experiment: irradiation of the quartet of doublets resonating at δ 2.80 ppm collapsed the doublet resonating at δ 1.03 ppm to a singlet and simplified the signal resonating at δ 0.54 ppm to a doublet of doublets (J = 8, 6 Hz).

*(1S,2R,5S) 1-(1-Methylethyl)-2,4,4-trimethylbicyclo[3.1.0] hexan-3-one (**9**), (1S,2S,5S) 1-(1-methylethyl)-2,4,4-trimethylbicyclo[3.1.0]hexan-3-one (**11**), and (1S,5S) 1-(1-methylethyl)-2,2,4,4-tetramethyl-bicyclo[3.1.0]hexan-3-one (**10**)*

To a solution of anhydrous diisopropylamine (0.93 mL, 6.6 mmol) in anhydrous tetrahydrofuran (50 mL) at −78°C was added *n*-butyllithium (1.55 M in hexanes, 4.25 mL, 6.58 mmol). The reaction was stirred for 50 min, then monomethylated thujone **8** (1.103 g, 6.64 mmol) in anhydrous tetrahydrofuran (20 mL) was added. The reaction was stirred at −78°C for 100 min, warmed to 10°C, and stirred for a further 60 min. Freshly purified iodomethane (1.23 mL, 19.8 mmol) was added and stirring continued for 40 min. The reaction was quenched by the addition of saturated ammonium chloride solution (30 mL) and extracted with diethyl ether (3 × 30 mL). The combined organic fractions were diluted with petroleum ether (150 mL), washed with brine (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a yellow oil (1.132 g) that contained (by GC, 1-menthol as an internal standard) monomethylated thujone **8** (7.1%), dimethylated thujone **9** (24.9%), dimethylated thujone **11** (56.6%), and trimethylated thujone **10** (5.7%). Yield based on the calibration: **8** (7.3%); **9** (23.6%); **11** (53.6%); **10** (5.0%). To this oil (1.126 g) dissolved in ethanol (25 mL) was added potassium hydroxide (ca. 100 mg). The reaction was stirred for 7 h and the solvent evaporated *in vacuo*. The residue was diluted with diethyl ether (100 mL), washed with saturated ammonium chloride solution (3 × 50 mL), water (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a yellow oil (0.9706 g) that contained (by GC, 1-menthol as an internal standard) **8** (7.2%), **9** (83.2%), **11** (1.5%), and **10** (6.0%).

In subsequent reactions a mixture of **8** and **9** was used. Thus, using the above procedure with **8**:**9** = 79:8 (54.405 g), 1.04 equivalents of lithium diisopropylamide, and 3 equivalents of iodomethane, an oil was obtained that was shown by GC (1-menthol as an internal standard) to contain **8** (24%), **9** (34%), **11** (25%), and **10** (10%). A solution of this oil and potassium hydroxide (4.20 g) in ethanol (400 mL) was stirred for 4.5 h. The reaction was quenched with saturated ammonium chloride solution (200 mL) and the organic solvent evaporated *in vacuo*. The residue was diluted with dichloromethane (200 mL) and the aqueous layer extracted with dichloromethane (2 × 200 mL). The combined organic layers were dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to afford an oil (56.34 g) that was shown by GC (1-menthol as an internal standard) to contain **8** (22%), **9** (54%), **11** (1%), and **10** (11%).

Spinning band distillation followed by column chromatography on silica using diethyl ether/petroleum ether (1:19), followed by chromatography using diethyl ether/petroleum ether (2:98) gave pure samples of each of the four compounds. Dimethylated thujone **11**: mp 53–54°C; bp 67°C/8 Torr; $[\alpha]_D^{22}$ +15.6 ($CHCl_3$, c 0.63); IR ν_{max} ($CHCl_3$): 2960, 1740 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: −0.26 (1H, dd, J = 6, 5 Hz, C6-H_{endo}), 0.71 (3H, d, J = 7 Hz, C7-CH_3), 0.72 (1H, m, C6-H_{exo}), 0.98 (3H, d, J = 7 Hz, C7-CH_3), 1.03 (3H, s, C4-CH_3), 1.17 (3H, s, C4-CH_3), 1.26 (3H, d, J = 8 Hz, C2-CH_{3exo}), 1.40 (1H, dd, J = 9, 5 Hz, C5-H), 2.16 (1H, septet, J = 7 Hz, C7-H), 2.31 (1H, q, J = 8 Hz, C2-H_{endo}) ppm; MS m/z: 180 (M^+), 165, 152, 137, 83 (100); high-resolution mass measurement calcd. for $C_{12}H_{20}O$: 180.1514; found: 180.1511. Anal. calcd. for $C_{12}H_{20}O$: C 79.96, H 11.18; found: C 79.84, H 11.17. ^1H NMR decoupling experiments: irradiation of the signal resonating at δ −0.26 ppm affected the multiplet resonating at δ 0.72 ppm and simplified the doublet of doublets resonating at δ 1.40 ppm to a doublet (J = 9 Hz); irradiation of the doublet resonating at δ 1.26 ppm collapsed the quartet resonating at δ 2.31 ppm to a singlet.

Trimethylated thujone **10**: bp 68°C/8 Torr; $[\alpha]_D^{22}$ +15.7 ($CHCl_3$, c 0.70); IR ν_{max} ($CHCl_3$): 2975, 1735 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: −0.24 (1H, dd, J = 6.5, 4 Hz, C6-H_{endo}), 0.66 (1H, dd, J = 8.5, 4 Hz, C6-H_{exo}), 0.76 (3H, d, J = 7 Hz, C7-CH_3), 1.00 (3H, d, J = 7 Hz, C7-CH_3), 1.01 (3H, s), 1.07 (3H, s), 1.19 (3H, s), 1.22 (3H, s), 1.39 (1H, dd, J = 8.5, 6.5 Hz, C5-H), 2.20 (1H, septet, J = 7 Hz, C7-H) ppm; MS m/z: 194 (M^+), 179, 166, 123 (100); high-resolution mass measurement calcd. for $C_{13}H_{22}O$: 194.1671; found: 194.1666. Anal. calcd. for $C_{13}H_{22}O$: C 80.36, H 11.41; found: C 80.51, H 11.39. ^1H NMR decoupling experiments: irradiation of the doublet of doublets resonating at δ −0.24 ppm simplified the doublet of doublets resonating at δ 0.66 ppm to a doublet (J = 8.5 Hz) and simplified the doublet of doublets resonating at δ 1.39 ppm to a doublet (J = 8.5 Hz); irradiation of the septet resonating at δ 2.20 ppm collapsed the doublet resonating at δ 0.76 ppm to a singlet and collapsed the doublet resonating at δ 1.00 ppm to a singlet.

*Equilibration of **9** and **11***

A solution of dimethylthujone **11** (260.5 mg, 1.45 mmol) and potassium hydroxide (128 mg, 2.29 mmol) in ethanol (8 mL) was stirred for 4 h, then quenched with saturated ammonium chloride solution (20 mL). The organic solvent was evaporated *in vacuo* and the residue extracted with diethyl ether (3 × 30 mL). The combined organic fractions were dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a yellow oil (182.0 mg). Purification by flash chromatography using diethyl ether/petroleum ether (1:19) as eluent afforded a colourless oil (169.4 mg, 65% recovery) that was shown by GC (1-menthol as an internal standard) to contain **9** (98.6%) and **11** (1.4%).

A solution of dimethylthujone **9** (149.0 mg, 0.83 mmol) and potassium hydroxide (60 mg, 1.1 mmol) in ethanol (4 mL) was stirred for 4 h. The solvent was evaporated *in vacuo* and diethyl ether (30 mL) was added. The solution was washed with saturated ammonium chloride solution (10 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a yellow oil. Purification by flash chromatography using diethyl ether/petroleum ether (1:19) as eluent afforded a colourless oil (85.9 mg, 58% recovery) that was shown by GC (1-menthol as an internal standard) to contain **9** (98.8%) and **11** (1.2%).

*(1S,2R,3S,5S) 1-(1-Methylethyl)-2,4,4-trimethyl-3-trimethylsiloxybicyclo[3.1.0]hexane-3-carbonitrile (**12**) and (1S,2R,3R,5S) 1-(1-methylethyl)-2,4,4-trimethyl-3-trimethylsiloxybicyclo[3.1.0]hexane-3-carbonitrile (**13**)*

To a mixture of ketone **9** (906 mg, 5.03 mmol) and tetra-*n*-butylammonium cyanide (157 mg, 0.577 mmol) was added trimethylsilylcyanide (1.0 mL, 7.3 mmol). The solution was stirred at 75°C for 8 h, cooled, and added to pentane (50 mL) (the flask being washed with dichloromethane (3 mL)). The solution was filtered, evaporated *in vacuo*, and the residue dissolved in pentane (20 mL). Filtration through Celite followed by evaporation *in vacuo*

gave a yellow oil (1.379 g, 98%) that was shown by GC to contain trimethylsilyl enol ether **14** (2%), trimethylsilyl cyanohydrin **12** (70%), and trimethylsilyl cyanohydrin **13** (28%). The material was used in subsequent reactions without further purification.

Repeating the reaction on a larger scale followed by purification by flash chromatography using hexanes as eluent afforded a pure sample of trimethylsilyl enol ether **14**. Mixtures of **12** and **13** enriched in either **12** or **13** (up to 84%) were obtained.

Silyl cyanohydrins **12/13**: IR ν_{max} (thin film): 2955, 2220 (weak) cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) (signals corresponding to **12**) δ: 0.15 (1H, ddd, J = 8, 5, 1 Hz, C6-H_{exo}), 0.23 (9H, s, Si-$(CH_3)_3$), 0.85 (3H, d, J = 7 Hz, C7-CH_3), 0.87 (2H, m, C5-H, C6-H_{endo}), 0.95 (3H, d, J = 7 Hz, C7-CH_3), 1.06 (3H, s, C4-CH_3), 1.07 (3H, d, J = 7 Hz, C2-CH_3), 1.24 (3H, s, C4-CH_3), 1.50 (1H, septet, J = 7 Hz, C7-H), 2.72 (1H, qd, J = 7, 1 Hz, C2-H_{exo}) ppm; (signals corresponding to **13**) δ: 0.24 (9H, s, Si-$(CH_3)_3$), 0.25 (1H, m), 0.86 (3H, d, J = 7 Hz, C7-CH_3), 0.88 (1H, m), 0.96 (3H, d, J = 7 Hz, C7-CH_3), 1.00 (3H, s, C4-CH_3), 1.22 (3H, d, J = 7 Hz, C2-CH_3), 1.24 (3H, s, C4-CH_3), 1.26 (1H, m), 1.44 (1H, septet, J = 7 Hz, C7-H), 2.40 (1H, qd, J = 7, 1 Hz, C2-H_{exo}) ppm; MS m/z: 264 (M^+-15), 252, 237 (100); CI MS (NH_3): 297 ($M + NH_4^+$), 264; high-resolution mass measurement calcd. for $C_{15}H_{26}NSiO$: 264.1783; found: 264.1782. Anal. calcd. for $C_{16}H_{29}NSiO$: C 68.76, H 10.46, N 5.01; found: C 68.82, H 10.35, N 5.04.

*(1S,2R,5S) 1-(Methylethylene)-2,4,4-trimethyl-3-trimethylsiloxybicyclo[3.1.0]hexane-3-carbonitrile (**15/16**), (1S,2R,5S) 1-acetyl-2, 4, 4-trimethyl-3-trimethylsiloxybicyclo[3.1.0]hexane-3-carbo-nitrile (**17/18**) and (1S,2R,5S) 1-(1-hydroxy-1-methylethyl)-2,4,4-trimethyl-3-trimethylsiloxybicyclo[3.1.0]hexane-3-carbonitrile (**19/20**)*

Ozone was bubbled through a solution of trimethylsilyl cyanohydrins[7] (**12**:**13** = 28:70, 1.899 g, 6.79 mmol) and sodium bicarbonate (2.25 g) in ethyl acetate (400 mL) at 0°C for 8 h. The reaction was flushed with nitrogen, filtered, and evaporated *in vacuo* to give an oil (4.082 g). The residue was dissolved in dichloromethane (80 mL), washed with sodium bicarbonate solution (25 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give an oil (2.355 g). Purification of a portion of this oil (1.330 g) by flash chromatography using ethyl acetate/petroleum ether (1:39) as eluent gave a mixture of epimeric alkenes **15**:**16** (60:40) (16.1 mg, 1%) as a colourless oil. Further elution with ethyl acetate/petroleum ether (1:19) gave a mixture of epimeric ketones **17**:**18** (71:29) (486 mg, 45%) as a colourless oil. Further elution with ethyl acetate/petroleum ether (1:9) gave a mixture of epimeric alcohols **19**:**20** (66:34) (241 mg, 21%) as a white solid.

Alkenes **15/16**: ^1H NMR (400 MHz, $CDCl_3$) (signals corresponding to **15**) δ: 0.23 (9H, s, Si$(CH_3)_3$), 0.58 (1H, ddd, J = 8, 4.5, 1.5 Hz, C6-H_{exo}), 1.03 (3H, d, J = 7 Hz, C2-CH_3), 1.08 (3H, s, C4-CH_3), 1.08 (1H, m), 1.27 (1H, m), 1.28 (3H, s, C4-CH_3), 1.70 (3H, br s, $w_{h/2}$ = 3 Hz, C7-CH_3), 2.88 (1H, qd, J = 7, 1.5 Hz, C2-H), 4.78 (1H, br s, $w_{h/2}$ = 4 Hz, C8-H), 4.85 (1H, br s, $w_{h/2}$ = 5 Hz, C8-H) ppm; (signals corresponding to **16**) δ: 0.23 (9H, s, Si$(CH_3)_3$), 0.69 (1H, ddd, J = 8, 6.5, 1.5 Hz, C6-H_{exo}), 1.05 (3H, s, C4-CH_3), 1.08 (1H, m), 1.18 (3H, d, J = 7 Hz, C2-CH_3), 1.25 (3H, s, C4-CH_3), 1.27 (1H, m), 1.70 (3H, br s, $w_{h/2}$ = 3 Hz, C7-CH_3), 2.56 (1H, qd, J = 7, 1.5 Hz, C2-H), 4.78 (1H, br s, $w_{h/2}$ = 4 Hz, C8-H), 4.85 (1H, br s, $w_{h/2}$ = 5 Hz, C8-H) ppm; MS m/z: 277(M^+), 262, 250, 235, 107 (100); high-resolution mass measurement calcd. for $C_{16}H_{27}NOSi$: 277.1862; found: 277.1863.

Ketones **17/18**: IR ν_{max} (thin film): 2960, 1690 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) (signals corresponding to **17**) δ: 0.24 (9H, s, Si$(CH_3)_3$), 1.12 (3H, s, C4-CH_3), 1.13 (3H, d, J = 7 Hz, C2-CH_3), 1.24 (3H, s, C4-CH_3), 1.25 (1H, m), 1.59 (1H, t, J = 6 Hz), 1.69 (1H, dd, J = 8, 6 Hz), 1.92 (3H, s, $COCH_3$), 3.37 (1H, qd, J = 7, 1 Hz, C2-H) ppm; (signals corresponding to **18**) δ: 0.23 (9H, s, Si$(CH_3)_3$, 1.02 (3H, s, C4-CH_3), 1.25 (1H, m), 1.29 (3H, d, J = 7 Hz, C2-CH_3), 1.29 (3H, s, C4-CH_3), 1.52 (1H, dd, J = 8, 6 Hz), 1.71 (1H, dd, J = 9, 6 Hz), 1.94 (3H, s, $COCH_3$), 2.95 (1H, qd, J = 7, 1 Hz, C2-H) ppm; MS m/z: 279(M^+), 264, 252; high-resolution mass measurement calcd. for $C_{15}H_{25}NO_2Si$: 279.1654; found: 279.1658. Anal. calcd. for $C_{15}H_{25}NO_2Si$: C64. 47, H 9.02, N 5.01; found: C 64.25, H 9.20, N 5.00.

Alcohols **19/20**: mp 35–37°C; IR ν_{max} ($CHCl_3$): 3601 (sharp), 2972 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) (signals corresponding to **19**) δ: 0.23 (9H, s, Si$(CH_3)_3$), 0.45 (1H, ddd, J = 8.5, 5, 1.5 Hz, C6-H_{exo}), 0.95 (1H, t, J = 5 Hz), 1.06 (3H, s, C4-CH_3), 1.10 (1H, dd, J = 8.5, 5 Hz), 1.11 (1H, br s, $w_{h/2}$ = 8 Hz, exchangeable, OH), 1.15 (3H, d, J = 7 Hz, C2-CH_3), 1.16 (3H, s, C4-CH_3), 1.24 (3H, s, C7-CH_3), 1.26 (3H, s, C7-CH_3), 2.92 (1H, qd, J = 7, 1.5 Hz, C2-H) ppm; (signals corresponding to **20**) δ: 0.23 (9H, s, Si$(CH_3)_3$), 0.58 (1H, ddd, J = 8.5, 6.5, 1.5 Hz, C6-H_{exo}), 0.90 (1H, dd, J = 6.5, 4 Hz), 1.02 (3H, s, C4-CH_3), 1.11 (1H, br s, $w_{h/2}$ = 8 Hz, exchangeable, OH), 1.13 (1H, m), 1.19 (3H, s, C4-CH_3), 1.24 (3H, s, C7-CH_3), 1.26 (3H, s, C7-CH_3), 1.30 (3H, d, J = 7 Hz, C2-CH_3), 2.58 (1H, qd, J = 7, 1.5 Hz, C2-H) ppm; MS m/z: 295 (M^+), 280, 277, 262; high-resolution mass measurement calcd. for $C_{16}H_{29}NO_2Si$: 295.1968; found: 295.1966. Anal. calcd. for $C_{16}H_{29}NO_2Si$: C 65.04, H 9.89, N 4.74; found: C 64.81, H 9.93, N 4.87. ^1H NMR decoupling experiments: irradiation of the quartet of doublets resonating at δ 2.58 ppm collapsed the doublet resonating at δ 1.30 ppm to a singlet and simplified the doublet of doublet of doublets resonating at δ 0.58 ppm to a doublet of doublet (J = 8.5, 6.5 Hz); irradiation of the quartet of doublets resonating at δ 2.92 ppm collapsed the doublet resonating at δ 1.15 ppm to a singlet and simplified the doublet of doublet of doublets resonating at δ 0.45 ppm to a doublet of doublet (J = 8.5, 5 Hz).

*(1S,2R,5S) 1-(1-Chloro-1-methylethyl)-2,4,4-trimethyl-3-(trimethylsiloxy)bicyclo[3.1.0]hexane-3-carbonitrile (**23/24**)*

To a solution of alcohols **19**:**20** (60:40, 59.0 mg, 0.227 mmol) in dichloromethane (2 mL) at 0°C was added cold concentrated hydrochloric acid (2 mL). After vigorous stirring for 20 min, the organic fraction was separated, diluted with cold dichloromethane (10 mL), washed with cold brine (10 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a red oil. GC analysis indicated a 60:40 mixture of the unstable chlorides **23/24**. Partial ^1H NMR (400 MHz, $CDCl_3$) (approximately 30% decomposition to alkenes) (signals corresponding to **23**) δ: 0.63 (1H, ddd, J = 8, 6, 1.5 Hz, C6-H_{exo}), 3.11 (1H, qd, J = 7, 1.5 Hz, C2-H) ppm; (signals corresponding to **24**) δ: 0.75 (1H, ddd, J = 9, 7, 1.5 Hz, C6-H_{exo}), 2.78 (1H, qd, J = 7, 1.5 Hz, C2-H) ppm; MS m/z: 315/313 (M^+), 300/298, 277.

*(2R,4S) 4-Chloromethyl-3-(1-methylethylidene)-2,5,5-trimethyl-1-(trimethylsiloxy)cyclopentane-1-carbonitrile (**21**)*

To a solution of alcohols **19**:**20** (60:40, 192.0 mg, 0.650 mmol) in dichloromethane (10 mL) was added concentrated hydrochloric acid (10 mL). The reaction was stirred vigorously for 88 h. The aqueous layer was extracted with dichloromethane (2 × 50 mL). The combined organic fractions were washed with sodium bicarbonate (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a red oil. Purification by flash chromatography using ethyl acetate/petroleum ether (1:19) as eluent afforded a mixture of these three isomeric chlorides (105.4 mg, 52%), of which **21** is predominant (83%): IR ν_{max} (thin film): 2974, 2232, 1673 cm^{-1}. Anal. calcd. for $C_{16}H_{28}NOSiCl$: C 61.22, H 8.99, N 4.46; found: C 61.50, H 9.10, N 4.63.

Further repeated chromatography using diethyl ether/petroleum ether (3:97) as eluent gave a pure sample of chloride **21** as a colourless oil: ^1H NMR (400 MHz, $CDCl_3$) δ: 0.28 (9H, s, Si$(CH_3)_3$), 1.10 (3H, s, C5-CH_3), 1.15 (3H, d, J = 7 Hz, C2-CH_3), 1.25 (3H, s, C5-CH_3), 1.70 (3H, br s, $w_{h/2}$ = 3 Hz, C=C-CH_3), 1.75 (3H, br s, $w_{h/2}$ = 3 Hz, C=C-CH_3), 2.67 (1H, dd, J = 8, 5.5 Hz, C4-H), 3.16 (1H, br q, J = 7 Hz, C2-H), 3.47 (1H, dd, J = 11.5, 5.5 Hz, C4-C*H*Cl), 3.87 (1H, dd, J = 11.5, 8 Hz, C4-

CHCl) ppm; MS *m/z*: 315/313 (M^+), 300/298, 277, 262; high-resolution mass measurement calcd. for $C_{16}H_{28}NOSi^{35}Cl$: 313.1629; found: 313.1631.

(2R) 3-(1-Methylethylidene)-2,6,6-trimethyl-1-(trimethylsiloxy)-cyclohexane-1-carbonitrile (27/28)

A solution of the chlorides obtained in the preceeding section (314.0 mg, 1.00 mmol, containing **21** (83%)), 2,2 azobis(2-methylpropionitrile) (AIBN, 33.0 mg, 0.20 mmol), and tri-*n*-butyltin hydride (1.08 mL, 4.00 mmol) in anhydrous toluene (10 mL) was heated at reflux for 4 h. The solvent was evaporated *in vacuo* to leave an oil (>1 g). Purification by flash chromatography using petroleum ether as eluent removed the tin compound present. Further elution using diethyl ether/petroleum ether (1:199) gave a mixture of alkenes **27/28** (83:17, 193.0 mg, 69%). Further purification by flash chromatography using diethyl ether/petroleum ether (1:199) afforded a pure sample of **27**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.29 (9H, s, $Si(CH_3)_3$), 1.03 (3H, s, C6-CH_3), 1.07 (3H, d, J = 7 Hz, C2-CH_3), 1.09 (3H, s, C6-CH_3), 1.48 (2H, m, C5-H_2), 1.72 (6H, br s, $w_{h/2}$ = 4 Hz, C=C-$(CH_3)_2$), 2.03 (1H, m, C4-H), 2.44 (1H, dtd, J = 14, 3, 1 Hz, C4-H), 3.28 (1H, q, J = 7 Hz, C2-H) ppm.

(1S,2R,5S) 1-(1-Hydroxyethyl)-2,4,4-trimethyl-3-(trimethylsiloxy)bicyclo[3.1.0]hexane-3-carbonitrile (31, 32, 33, 34)

To a solution of ketones **17/18**[8] (504 mg, 1.80 mmol) in ethanol (20 mL) was added sodium borohydride (130 mg, 3.42 mmol). After stirring for 1.5 h at room temperature, the solvent was removed *in vacuo*. Diethyl ether (50 mL) and saturated ammonium chloride solution (50 mL) were added to the residue. The organic layer was washed with brine (20 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give an oil (554 mg). Purification by flash chromatography using ethyl acetate/petroleum ether (1:9) as eluent afforded a mixture of four isomeric alcohols **31, 32, 33, 34** (38:35:14:13) (411.6 mg, 92% based on purity of starting material) as a colourless oil: IR ν_{max} (thin film): 3475 (br), 2960, 2210 (weak) cm^{-1}; ^{1}H nmr (400 MHz, $CDCl_3$) (partial assignments for **31**) δ: 0.23 (9H, s, $Si(CH_3)_3$), 2.94 (1H, qd, J = 7, 1 Hz, C2-H), 3.60 (1H, q, J = 6.5 Hz, C7-H) ppm; (partial assignments for **32**) δ: 0.23 (9H, s, $Si(CH_3)_3$), 2.82 (1H, qd, J = 7, 1 Hz, C2-H), 3.70 (1H, q, J = 6.5 Hz, C7-H) ppm; (partial assignments for **33**) δ: 0.23 (9H, s, $Si(CH_3)_3$), 1.28 (3H, d, J = 7 Hz, C2-CH_3), 2.60 (1H, qd, J = 7, 1 Hz, C2-H), 3.56 (1H, q, J = 6.5 Hz, C7-H) ppm; (partial assignments for **34**) δ: 0.23 (9H, s, $Si(CH_3)_3$), 0.45 (1H, ddd, J = 7, 6, 1 Hz, C6-H_{exo}), 1.02 (3H, s, C4-CH_3), 1.27 (3H, d, J = 7 Hz, C2-CH_3), 2.50 (1H, qd, J = 7, 1 Hz, C2-H), 3.66 (1H, q, J = 6.5 Hz, C7-H) ppm; MS *m/z*: 281 (M^+), 279, 266, 263, 248, 239, 236; high-resolution mass measurement calcd. for $C_{15}H_{27}NO_2Si$: 281.1811; found: 281.1807. Anal. calcd. for $C_{15}H_{27}NO_2Si$: C 64.00, H 9.67, N 4.98; found: C 63.89, H 9.76, N 4.90.

(1S,2R,5S) 1-(1-Chloroethyl)-2,4,4-trimethyl-3-(trimethylsiloxy)bicyclo[3.1.0]hexane-3-carbonitrile (35/36)

To a solution of alcohols **31, 32, 33, 34** (38:35:14:13, 397.2 mg, 1.41 mmol) in dichloromethane (15 mL) was added concentrated hydrochloric acid (17 mL) and the reaction was stirred vigorously for 31 h. The aqueous layer was extracted with dichloromethane (10 mL). The combined organic layers were washed with water (25 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a red oil (419.6 mg), which was shown by GC to contain no starting alcohols. Purification by flash chromatography using diethyl ether/petroleum ether (1:19) as eluent gave a mixture of chlorides **35/36** (63:37, 139.0 mg, 33%, 83% based on recovered starting material). Further elution afforded recovery of starting material (240.0 mg, 60%).

Chlorides **35/36**: IR ν_{max} (thin film): 2950, 2210, 1660 cm^{-1}; ^{1}H NMR (400 MHz, $CDCl_3$) (partial assignment of signals corresponding to **35**) δ: 0.23 (9H, s, $Si(CH_3)_3$), 0.47 (1H, ddd, J = 9, 7, 1.5 Hz, C6-H_{exo}), 1.08 (3H, s, C4-CH_3), 1.13 (3H, d, J = 7 Hz, C2-CH_3), 1.28 (3H, s, C4-CH_3), 1.40 (3H, d, J = 7 Hz, C7-CH_3), 3.03 (1H, qd, J = 7, 1.5 Hz, C2-H), 4.11 (1H, q, J = 7 Hz, C7-H) ppm; (partial assignment of signals corresponding to **36**) δ: 0.23 (9H, s, $Si(CH_3)_3$), 0.40 (1H, ddd, J = 9, 6, 1.5 Hz, C6-H_{exo}), 1.07 (3H, s, C4-CH_3), 1.17 (3H, d, J = 7 Hz, C2-CH_3), 1.29 (3H, s, C4-CH_3), 1.55 (3H, d, J = 7 Hz, C7-CH_3), 3.04 (1H, m, C2-H), 3.75 (1H, q, J = 7 Hz, C7-H) ppm; MS *m/z*: 301/299 (M^+), 286/284, 263; high-resolution mass measurement calcd. for $C_{15}H_{26}NOSi^{35}Cl$: 299.1472; found: 299.1471.

(2R) 3-(1-Ethylidene)-2,6,6-trimethyl-1-(trimethylsiloxy)cyclohexane-1-carbonitrile (37/38)

To a solution of chlorides **35/36** (63:37, 152.3 mg, 0.508 mmol) and AIBN (ca. 10 mg) in anhydrous toluene (4 mL) was added tri-*n*-butylin hydride (179 μl, 0.632 mmol). The reaction was heated at reflux for 2 h, cooled, and diluted with petroleum ether (50 mL). The reaction was washed with water (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give an oil (664.0 mg). Purification by flash chromatography using petroleum ether as eluent removed the tin by-products. Further elution with diethyl ether/petroleum ether (1:49) gave a mixture of predominantly two alkenes **37/38** (72:28) as a colourless oil (127.6 mg, 95%): IR ν_{max} (thin film): 2960, 1660 cm^{-1}; ^{1}H NMR (400 MHz, $CDCl_3$) (partial assignment of signals corresponding to **37**) δ: 0.21 (9H, s, $Si(CH_3)_3$), 1.05 (3H, s, C6-CH_3), 1.20 (3H, d, J = 7 Hz, C2-CH_3), 1.24 (3H, s, C6-CH_3), 1.62 (3H, br d, J = 7 Hz, C7-CH_3), 1.95 (1H, m), 2.48 (1H, dt, J = 14, 4 Hz, C4-H), 2.65 (1H, br q, J = 7 Hz, C2-H), 5.20 (1H, br q, J = 7 Hz, C7-H) ppm; (partial assignment of signals corresponding to **38**) δ: 0.29 (9H, s, $Si(CH_3)_3$), 1.04 (3H, s, C6-CH_3), 1.11 (3H, d, J = 7 Hz, C2-CH_3), 1.11 (3H, s, C6-CH_3), 1.65 (3H, dd, J = 7, 1 Hz, C7-CH_3), 1.93 (1H, m), 3.27 (1H, q, J = 7 Hz, C2-H), 5.41 (1H, qd, J = 7, 1.5 Hz, C7-H) ppm; MS *m/z*: 265 (M^+), 250, 238, 223.

(2R,3S*) 2,4,4-Trimethyl-3-trimethylsiloxycyclohexan-1-one-3-carbonitrile (29) and (2R*,3R*) 2,4,4-trimethyl-3-trimethylsiloxycyclohexan-1-one-3-carbonitrile (30)*

Method A

Ozone was bubbled through a solution of alkenes **37**:**38** (72:28) (80.3 mg, 0.303 mmol) in ethyl acetate (10 mL) at −78°C for 30 min. Dimethyl sulphide (0.5 mL) was then added and the reaction allowed to warm to room temperature. The reaction was diluted with diethyl ether (25 mL), washed with sodium bicarbonate solution (25 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give an oil (119.3 mg). Purification by flash chromatography using ethyl acetate/petroleum ether (1:9) as eluent gave ketone **29** (70.9 mg, 93%), slightly contaminated with its isomer **30** (5%). Further purification gave enriched purity to ketone **29** (purity 98.5%), and a sample enriched in **30** (17%).

Ketone **29**: $[\alpha]_D^{22}$ − 28.0 ($CHCl_3$, c = 0.3); IR ν_{max} (thin film): 2950, 1725 cm^{-1}; ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.23 (9H, s, $Si(CH_3)_3$), 1.17 (3H, s, C4-CH_3), 1.23 (3H, d, J = 7 Hz, C2-CH_3), 1.41 (3H, s, C4-CH_3), 1.60 (1H, ddd, J = 14, 6.5, 2 Hz, C5-H_{eq}), 2.01 (1H, td, J = 14, 5 Hz, C5-H_{ax}), 2.34 (1H, ddd, J = 14, 5, 2 Hz, C6-H_{eq}), 2.45 (1H, td, J = 14, 6.5 Hz, C6-H_{ax}), 2.89 (1H, q, J = 7 Hz, C2-H_{ax}) ppm; MS *m/z*: 253 (M^+), 238 (100); high-resolution mass measurement calcd. for $C_{13}H_{23}NO_2Si$: 253.1498; found: 253.1496. Anal. calcd. for $C_{13}H_{23}NO_2Si$: C 61.62, H 9.15, N 5.53; found: C 61.80, H 9.20, N 5.60. ^{1}H NMR decoupling experiment: irradiation of the quartet resonating at δ 2.89 ppm collapsed the doublet resonating at δ 1.23 ppm to a singlet. ^{1}H NMR nOe difference experiment: irradiation of the quartet resonating at δ 2.89 ppm led to enhancement of the signals resonating at δ 1.23, 1.41, and 2.45 ppm; irradiation of the singlet resonating at δ 0.23 ppm led to enhancement of the signals resonating at δ 1.17 and 1.23 ppm.

Ketone **30**: ^{1}H NMR (400 MHz, $CDCl_3$) (partial signals corre-

[8]Sample contained alcohols **19/20** (60.3 mg).

sponding to **30**) δ: 0.26 (9H, s, $Si(CH_3)_3$), 1.74 (1H, ddd, J = 14, 7, 3 Hz), 1.81 (1H, td, J = 14, 6 Hz), 2.74 (1H, q, J = 7 Hz) ppm. GC–MS of second isomer m/z: 253 (M^+), 238.

Method B

To a solution of cyanohydrins **12**:**13** (63:37) (5.6656 g, 20.27 mmol) in ethyl acetate (300 mL) was added solid sodium bicarbonate (2.0 g). The mixture was cooled to 0°C and ozone bubbled through for 9.5 h. The reaction was flushed with oxygen, diluted with ethyl acetate (400 mL), washed with saturated sodium bicarbonate solution (2 × 100 mL), water (100 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo*. The residue was dissolved in ethanol (200 mL) and sodium borohydride (800 mg, 21.1 mmol) was added. After stirring for 30 min, the solvent was evaporated *in vacuo*. The residue was dissolved in diethyl ether (300 mL), washed with saturated ammonium chloride solution (2 × 100 mL), water (100 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a colourless oil (6.50 g). This was dissolved in dichloromethane (300 mL) and concentrated hydrochloric acid (300 mL). After stirring vigorously for 78.5 h, the aqueous layer was separated and extracted with dichloromethane (100 mL). The combined organic fractions were washed with water (2 × 200 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a yellow oil (5.00 g). To a solution of this oil in anhydrous toluene (165 mL) was added AIBN (400 mg, 2.8 mmol) and tri-*n*-butyltin hydride (8.0 mL, 30 mmol). The reaction was heated at reflux for 4.5 h, cooled, washed with water (100 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give an oil (12.11 g). Purification by flash chromatography using petroleum ether as eluent removed the tin compounds present. Further elution gave a mixture of alkenes (3.3427 g). This oil was dissolved in ethyl acetate (200 mL) and cooled to −78°C. Ozone was bubbled through the solution for 30 min until a blue colouration persists. Dimethyl sulphide (1 mL) was added and the reaction allowed to warm to room temperature. Most of the solvent was removed *in vacuo* and ethyl acetate (200 mL) was added. The solution was washed with saturated sodium bicarbonate solution (50 mL), water (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a colourless oil (3.21 g). Purification by flash chromatography using ethyl acetate/petroleum ether (1:9) as eluent gave ketone **30** contaminated with 5% of ketone **31** (1.8153 g, 35% for five steps).

*2,4,4-Trimethylcyclohex-2-en-1-one-3-carbonitrile (**39**)*

Thionyl chloride (2.1 mL, 29 mmol) was added slowly to a solution of cyanohydrin **29** (1.0000 g, 3.953 mmol) in methanol (55 mL) and the reaction was stirred for 2 h. The solvent was evaporated *in vacuo*, and diethyl ether (75 mL) was added to the residue. The organic solution was washed with saturated sodium bicarbonate solution (30 mL), brine (30 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave an oil (820 mg). Purification by flash chromatography using diethyl ether/petroleum ether (1:9) as eluent gave an unidentified compound as an unstable oil (337.0 mg, 52%). Further elution gave ketone **39** as a colourless oil (306.1 mg, 48%).

Unidentified compound: IR ν_{max} (thin film): 3500 (br), 2950, 2195, 1645, 1580 cm^{-1}; UV λ_{max} (MeOH): 306 nm (ϵ = 4400), 217 nm (ϵ = 4550); ^1H NMR (400 MHz, $CDCl_3$) δ: 1.13 (6H, s, C6-$(CH_3)_2$), 2.05 (3H, s, C2-CH_3), 2.22 (2H, d, J = 6 Hz, C5-H_2), 4.88 (1H, t, J = 6 Hz, C4-H) ppm; MS m/z: 162 (M^+-1, 100).

Ketone **39**: IR ν_{max} (thin film): 2950, 2200, 1690, 1645 cm^{-1}; UV λ_{max} (MeOH): 248 nm (ϵ = 12 000); ^1H NMR (400 MHz, $CDCl_3$) δ: 1.22 (6H, s, C4-$(CH_3)_2$), 1.94 (2H, t, J = 7 Hz, C5-H_2), 2.06 (3H, s, C2-CH_3), 2.57 (2H, t, J = 7 Hz, C6-H_2) ppm; MS m/z: 163 (M^+), 148, 135, 121, 120 (100); high-resolution mass measurement calcd. for $C_{10}H_{13}NO$: 163.0997; found: 163.0994.

*2,4,4-Trimethylcyclohex-2-en-1-ol-3-carbonitrile (**40**)*

Method A

To a solution of enone **39** (163.0 mg, 1.00 mmol) in methanol (2.5 mL) was added cerium III chloride heptahydrate (372 mg, 1.00 mmol) followed by sodium borohydride (38.0 mg, 1.00 mmol). After stirring for 5 min, the reaction was quenched by addition of saturated ammonium chloride solution (30 mL), diluted with diethyl ether (30 mL), and the aqueous layer extracted with diethyl ether (10 mL). The combined organic extracts were washed with water (10 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give allylic alcohol **40** (163.3 mg, 99%) as a viscous oil that crystallized on cooling: mp 25–26°C; IR ν_{max} (thin film): 3400, 2950, 2220, 1645 cm^{-1}; UV λ_{max} (MeOH): 216 nm (ϵ = 8100); ^1H NMR (400 MHz, $CDCl_3$) δ: 1.11 (3H, s, C4-CH_3), 1.17 (3H, s, C4-CH_3), 1.48 (1H, ddd, J = 13.5, 9, 3 Hz) 1.68 (2H, m), 1.90 (1H, m), 2.08 (3H, s, C2-CH_3), 2.58 (1H, br s, $w_{h/2}$ = 28 Hz, exchangeable, OH), 4.03 (1H, t, J = 6 Hz, Cl-H) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 19.8, 27.9, 28.0, 28.3, 33.0, 33.7, 68.3, 117.2, 119.9, 151.9 ppm; MS m/z: 165 (M^+), 150, 123, 109 (100); high-resolution mass measurement: calcd. for $C_{10}H_{15}NO$: 165.1154; found: 165.115. Anal. calcd. for $C_{10}H;1_5NO$: C 72.70, H 9.15, N 8.48; found: C 72.73, H 9.30, N 8.35.

Method B

Thionyl chloride (1.0 mL, 13 mmol) was added slowly to a solution of cyanohydrin **29** (1.659 g, 6.55 mmol) in methanol (65 mL) at −10°C. The reaction was warmed to room temperature, and stirred for 2.5 h. The solvent was evaporated *in vacuo* and diethyl ether (70 mL) was added to the residue. The organic solution was washed with saturated sodium bicarbonate solution (50 mL), water (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave an oil (1.0033 g). This oil was dissolved in methanol (15.5 mL) and cerium III chloride heptahydrate (2.291 g, 6.15 mmol) was added. After cooling to −78°C, sodium borohydride (245.0 mg, 6.48 mmol) was added in small portions. The reaction was allowed immediately to warm to room temperature with stirring proceeding at this temperature for 30 min. The reaction was diluted with diethyl ether (100 mL) and saturated ammonium chloride solution (50 mL). The aqueous layer was extracted with diethyl ether (2 × 50 mL). The combined organic layers were washed with water (20 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a yellow oil (1.028 mg). Purification by flash chromatography using ethyl acetate/petroleum ether (3:7) as eluent gave alcohol **40** (990.5 mg, 92%) as a colourless oil that crystallized on cooling.

Method C

To a solution of unsaturated nitrile **43** (1.1254 g, 7.54 mmol) in carbon tetrachloride (25 mL) was added *N*-bromosuccinimide (1.520 g, 8.54 mmol) and benzoyl peroxide (40 mg, 1.7 × 10^{-1} mmol). The reaction was heated at reflux for 40 min, then cooled and filtered to give a crude sample of bromide **41** (1.8548 g) as a red oil. Water (55 mL) and calcium carbonate (1.07 g, 10 mmol) were added and the reaction heated at reflux for 19 h. The reaction was cooled, diluted with diethyl ether (75 mL), and the aqueous layer extracted with diethyl ether (2 × 75 mL). The combined organic layers were washed with water (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a yellow oil. Purification by flash chromatography using ethyl acetate/petroleum ether (3:7) as eluent gave enone **39** (144.8 mg, 12%) as a colourless oil. Further elution afforded alcohol **40** (987.4 mg, 79%) as a colourless oil that crystallized on cooling.

*2,6,6-Trimethyl-3-bromocyclohex-1-ene-1-carbonitrile (**41**)*

To a solution of alcohol **40** (355.2 mg, 2.15 mmol) in petroleum ether (5 mL) at 0°C was added phosphorus tribromide (225 μL, 2.37 mmol). The reaction was stirred for 1 h at 0°C, then diluted with petroleum ether (25 mL), washed with sodium bicarbonate solution (2 × 20 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give bromide **41** (449.0 mg, 92%) as a colourless oil: IR ν_{max} (thin film): 2965, 2210, 1626 cm^{-1}; UV λ_{max} (MeOH): 229 nm (ϵ = 12 300); ^1H NMR (400 MHz, $CDCl_3$) δ: 1.11 (3H, s, C6-CH_3), 1.24 (3H, s, C6-CH_3), 1.57 (1H, dt, J = 13, 3.5 Hz, C5-H), 1.96 (1H, ddd, J = 13, 10, 6 Hz, C5-H), 2.10 (2H, m, C4-H_2), 2.13 (3H, s, C2-CH_3), 4.63 (1H, t, J = 3 Hz,

C3-H) ppm; MS *m/z*: 229/227 (M^+), 214/212, 148 (100); high-resolution mass measurement calcd. for $C_{10}H_{14}N^{81}Br$: 229.0291; found: 229.0288. Anal. calcd. for $C_{10}H_{14}NBr$: C 52.64, H 6.18, N 6.16; found: C 52.85, H 6.19, N 6.30.

*2,6,6-Trimethylcyclohex-1-ene-1-carbonitrile (**43**)*

A solution of bromide **41** (1.088 g, 4.77 mmol) and sodium iodide (980 mg, 6.54 mmol) in anhydrous dimethyl sulphoxide (100 mL) was stirred at room temperature for 15 min, at which time sodium borohydride (630 mg, 16.5 mmol) and methanol (600 μL, 14.8 mmol) were added. After stirring for a further 1.5 h, the reaction was quenched with water (50 mL) and extracted with diethyl ether (2 × 100 mL). The combined organic layers were dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a colourless oil (932.6 mg). Purification by flash chromatography using diethyl ether/petroleum ether (1:49) as eluent afforded a mixture of nitriles **43** and **44** (22:3, 501.9 mg, 71%). Further elution afforded a pure sample of nitrile **43** (99.8 mg, 14%) as a colourless oil.

Nitrile **43**: IR ν_{max} (thin film): 2930, 2200, 1635 cm^{-1}; UV λ_{max} (MeOH): 214 nm (ϵ = 11 400); ^1H NMR (400 MHz, $CDCl_3$) δ: 1.16 (6H, s, C6-$(CH_3)_2$), 1.46 (2H, m, C5-H_2), 1.61 (2H, m, C4-H_2), 1.96 (3H, s, C2-CH_3), 2.07 (2H, t, J = 6 Hz, C3-H_2) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 19, 24, 28, 32, 34, 37, 116, 118, 152 ppm; MS *m/z*: 149 (M^+), 134 (100); high-resolution mass measurement calcd. for $C_{10}H_{15}N$: 149.1204; found: 149.1204. Anal. calcd. for $C_{10}H_{15}N$: C 80.48, H 10.13, N 9.39; found: C 80.18, H 9.99, N 9.48. ^1H NMR decoupling experiment: irradiation of the triplet resonating at δ 2.07 ppm affected the multiplet resonating at δ 1.61 ppm.

Nitrile **44**: ^1H NMR (400 MHz, $CDCl_3$) (partial signals) δ: 1.82 (3H, br s, $w_{h/2}$ = 7 Hz, C2-CH_3), 2.75 (1H, s, C1-H), 5.65 (1H, br s, $w_{h/2}$ = 8 Hz, C3-H) ppm.

*2,6,6-Trimethylcyclohexa-1,3-diene-1-carbonitrile (**127**)*

Method A

A solution of alcohol **40** (24.6956 g, 149.5 mmol) and *para*-toluenesulphonic acid (5.00 g, 26.3 mmol) was heated at reflux with azeotropic removal of water for 30 h. The reaction was cooled, diluted with diethyl ether (1 L), washed with water (2 × 200 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a red oil (22.6472 g). Purification by distillation (100–120°C, 11 Torr) gave safronitrile (**42**) (16.4631 g, 75%) as a colourless liquid: IR ν_{max} (thin film): 2950, 2180, 1640, 1575 cm^{-1}; UV λ_{max} (MeOH): 285 nm (ϵ = 7200); ^1H NMR (400 MHz, $CDCl_3$) δ: 1.17 (6H, s, C6-CH_3), 2.08 (3H, s, C2-CH_3), 2.22 (2H, dd, J = 4, 2 Hz, C5-H_2), 5.93 (1H, dt, J = 9, 2 Hz, C3-H), 6.07 (1H, dt, J = 9, 4 Hz, C4-H) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 21.8, 27.7, 32.5, 37.7, 114.5, 118.2, 127.2, 131.9, 146.3 ppm; MS *m/z*: 147(M^+), 132; high-resolution mass measurement cald. for $C_{10}H_{13}N$: 147.1048; found: 147.1046. Anal. calcd. for $C_{10}H_{13}N$: C81.59, H 8.90, N 9.51; found: C 81.76, H 8.83, N 9.49.

Method B

A solution of bromide **41** (151.6 mg, 0.664 mmol) and DBU (300 μL, 2.0 mmol) in benzene (10 mL) was heated at reflux for 4 h. After cooling, the reaction was diluted with diethyl ether (30 mL), washed with saturated ammonium chloride solution (10 mL), water (10 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave an oil (153.2 mg). Purification by flash chromatography using diethyl ether/petroleum ether (1:9) as eluent gave **42** (26.5 mg, 27%) as a colourless oil.

*2,6,6-Trimethylcyclohexa-1,3-diene-1-carbaldehyde (**45**)*

To a solution of safronitrile **42** (580.0 mg, 3.94 mmol) in anhydrous benzene (3.5 mL) at 0°C was added DIBAL-H (1.5 M in toluene, 4.9 mL, 7.4 mmol). The reaction was stirred for 2.5 h at room temperature, then added to deoxygenated 5% sulphuric acid (30 mL) along with diethyl ether (20 mL). After stirring vigorously for 15 min, the aqueous layer was extracted with diethyl ether (3 × 50 mL). The combined organic layers were washed with water (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave an orange oil (543 mg). Purification by bulb-to-bulb distillation (100–105°C, 11 Torr) afforded pure safronal (**45**) (371.6 mg, 63%) as a colourless oil: IR ν_{max} (thin film): 2960, 2930, 2870, 1665, 1635 cm^{-1}; UV λ_{max} (MeOH): 309 nm (ϵ = 7500); ^1H NMR (400 MHz, $CDCl_3$) δ 1.20 (6H, s, C6-CH_3), 2.16 (2H, dd, J = 4, 2 Hz, C5-H_2), 2.18 (3H, s, C2-CH_3), 5.93 (1H, dt, J = 10, 2 Hz, C3-H), 6.17 (1H, dt, J = 10, 4 Hz, C4-H), 10.15 (1H, s, CHO) ppm; MS *m/z*: 150 (M^+), 135, 121, 107 (100); high-resolution mass measurement calcd. for $C_{10}H_{14}O$: 150.1045; found: 150.1045. Anal. calcd. for $C_{10}H_{14}O$: C 79.96, H 9.39; found: C 80.18, H 9.42.

*(E)-1-(2,6,6-Trimethylcyclohexa-1,3-dienyl)-but-2-en-1-ol (**46**) and (Z)-1-(2,6,6-trimethylcyclohexa-1,3-dienyl)-but-2-en-1-ol (**47**)*

To a solution of safronal (**45**) (256.7 mg, 1.71 mmol) in anhydrous tetrahydrofuran (12 mL) at 0°C was added 1-propenylmagnesium bromide[9] (1.21 M in tetrahydrofuran, 2.0 mL, 2.4 mmol). The reaction was stirred at 0°C for 10 min, quenched with saturated ammonium chloride solution (15 mL), and extracted with diethyl ether (2 × 30 mL). The combined organic layers were washed with water (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a yellow oil (344.2 mg). Purification by bulb-to-bulb distillation (115–125°C, 11 Torr) afforded a mixture of alcohols **46** and **47** (49:51, 293.9 mg, 89%) as a colourless oil: IR ν_{max} (thin film): 3400 (br), 2960, 1680 (br) cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) (partial signals corresponding to **47**) δ: 1.06 (3H, s, C6′-CH_3), 1.11 (3H, s, C6′-CH_3), 1.40 (1H, br s, $w_{h/2}$ = 8 Hz, exchangeable, O-*H*), 1.74 (3H, dd, J = 8, 1 Hz, C4-H_3), 1.95 (3H, s, C2′-CH_3), 2.07 (2H, t, J = 3 Hz, C5′-H_2), 5.40 (1H, d, J = 9 Hz, C1-H), 5.58 (1H, dqd, J = 11, 8, 1 Hz, C3-H), 5.74 (2H, m, C3′-H, C4′-H), 5.83 (1H, ddq, J = 11, 9, 1 Hz, C2-H) ppm. Purification by flash chromatography of a portion of this oil using ethyl acetate/petroleum ether (1:19) as eluent afforded pure *trans*-alcohol **46** (79.2 mg, 43% overall) as a colourless oil: IR ν_{max} (thin film): 3400 (br), 2960, 1680 (br) cm^{-1}; UV λ_{max} (MeOH): 271 nm (ϵ = 9040); ^1H NMR (400 MHz, $CDCl_3$) δ: 1.04 (3H, s, C6′-CH_3), 1.10 (3H, s, C6′-CH_3), 1.53 (1H, br s, $w_{h/2}$ = 6 Hz, exchangeable, O-*H*), 1.72 (3H, dd, J = 7, 1 Hz, C4-H_3), 1.88 (3H, s, C2′-CH_3), 2.06 (2H, t, J = 4 Hz, C5′-H_2), 5.03 (1H, br d, J = 5 Hz, C1-H), 5.73 (4H, m, C3′-H, C4′-H, C2-H, C3-H) ppm; MS *m/z*: 192 (M^+), 177, 174, 159, 121 (100); high-resolution mass measurement calcd. for $C_{13}H_{20}O$: 192.1514; found: 192.1516. ^1H NMR decoupling experiments: irradiation of the doublet of doublets resonating at δ 1.74 ppm simplified the signal resonating at δ 5.58 ppm to a doublet of doublets (J = 11, 1 Hz) and simplified the signal resonating at δ 5.83 ppm to a doublet of doublets (J = 11, 9 Hz); irradiation of the doublet resonating at δ 5.40 ppm simplified the signal resonating at δ 5.83 ppm to a doublet of quartets (J = 11, 1 Hz) and affected the signal resonating at δ 5.58 ppm.

The *cis*-alcohol **47** decomposed on chromatography.

*(E)-1-(2,6,6-Trimethylcyclohexa-1,3-dienyl)-but-2-en-1-one (β-damascenone) (**48**)*

Method A

To a solution of *trans*-alcohol **46** (18.9 mg, 0.098 mmol) in petroleum ether (3 mL) was added "active" manganese dioxide (170 mg, 1.95 mmol). After stirring for 1 h the reaction was filtered and evaporated *in vacuo* to afford β-damascenone (**48**) (16.7 mg, 100%) as a colourless oil: IR ν_{max} (thin film): 2980, 2950, 1670, 1635, 1610 cm^{-1}; UV λ_{max} (MeOH): 305 nm (ϵ = 2220), 226 nm (ϵ = 13 800); ^1H NMR (400 MHz, $CDCl_3$) δ: 1.05 (6H , s, C6′-$(CH_3)_2$), 1.64 (3H, s, C2′-CH_3), 1.94 (3H, dd, J = 7, 2 Hz, C4-H_3), 2.12 (2H, dd, J = 5, 1 Hz, C5′-H_2), 5.84 (2H, m, C3′-H, C4′-H), 6.20 (1H, dq, J = 16, 2 Hz, C2-H), 6.85 (1H, dq, J = 16, 7 Hz, C3-H) ppm; MS *m/z*: 190 (M^+), 175, 159, 121, 69 (100); high-resolution mass measurement calcd. for $C_{13}H_{18}O$: 190.1357; found:

[9]Prepared as a mixture of isomers 49:51.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12

190.1355. ^{1}H NMR decoupling experiments: irradiation of the doublet of quartets resonating at δ 6.20 ppm simplified the signals resonating at δ 1.94 ppm to a doublet (J = 7 Hz) and simplified the signal resonating at δ 6.85 ppm; irradiation of the signal resonating at δ 6.85 ppm simplified the doublet of doublets resonating at δ 1.94 ppm to a doublet (J = 2 Hz) and affected the signal resonating at δ 6.20 ppm; irradiation of the doublet of doublets resonating at δ 2.12 ppm simplified the signal resonating at δ 5.84 ppm to an AB quartet; irradiation of the signal resonating at δ 1.94 ppm simplified the signal resonating at δ 6.20 ppm to a doublet (J = 16 Hz) and simplified the signal resonating at δ 6.85 ppm to a doublet (J = 16 Hz).

Method B

To a solution of alcohols **46** and **47** (49:51, 139.4 mg, 0.725 mmol) in petroleum ether (30 mL) was added "active" manganese dioxide (700 mg, 8.05 mmol). After stirring for 2 h, a further portion of manganese dioxide (700 mg, 8.05 mmol) was added. After stirring for 1.5 h, the reaction was filtered and evaporated *in vacuo* to afford a mixture of β-damascenone (**48**) and enone **49** (**48**:**49** = 49:51, 138.7 mg, 100%) as a colourless oil. ^{1}H NMR (400 MHz, $CDCl_3$) (signals corresponding to enone **49**) δ: 1.10 (6H, s, C6′-$(CH_3)_2$), 1.74 (3H, s, C2′-CH_3), 2.11 (2H, dd, J = 5, 1 Hz, C5′-H_2), 2.16 (3H, d, J = 7 Hz, C4-H_3), 5.84 (2H, m, C3′-H, C4′-H), 6.20 (2H, m, C2-H, C3-H) ppm. The mixture of ketones and *para*-toluenesulphonic acid (20 mg, 0.1 mmol) in anhydrous tetrahydrofuran was heated at reflux for 20 h. The reaction was cooled and diluted with diethyl ether (150 mL). The organic layer was washed with water (30 mL), saturated sodium bicarbonate solution (50 mL), water (30 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a colourless oil (136.2 mg). Purification by flash chromatography using ethyl acetate/petroleum ether (1:19) as eluent afforded pure β-damascenone (**48**) (105.0 mg, 76%) as a colourless oil.

*2,2,6-Trimethylcyclohexanone (**51**)*

This procedure is a modification of that reported by Fitzer and Quabeck (**35**).

To a solution of diisopropylamine (90 mL, 640 mmol) in anhydrous tetrahydrofuran (2 L) at −78°C was added *n*-butyllithium (1.6 M in hexanes, 405 mL, 648 mmol) dropwise. After the addition was complete, the reaction was stirred for a further 45 min at −78°C and then 2,6-dimethylcyclohexanone[10] (75.00 g, 594.3 mmol) in anhydrous tetrahydrofuran (50 mL) was added over 5 min. The reaction was stirred at −78°C for 1 h, warmed to 0°C, and stirred at this temperature for a further 1 h. Iodomethane (120 mL, 1.93 mol) was added over 15 min, and the reaction was stirred for a further 20 min at 0°C. After quenching with saturated ammonium chloride solution (900 mL), the reaction was extracted with petroleum ether (3 × 600 mL). The combined organic extracts were washed with water (500 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a red oil. Purification by distillation at atmospheric pressure gave a fraction (70.85 g, 85%) that was shown by GC and ^{1}H NMR to contain 97% 2,2,6-trimethylcyclohexanone **51** and 3% 2,2,6,6-tetramethylcyclohexanone **52**.

(1R,6R*) 1-Hydroxy-2,2,6-trimethylcyclohexane-1-carbonitrile (**53**) and (1R*,6S*) 1-hydroxy-2,2,6-trimethylcyclohexane-1-carbonitrile (**54**)*

To a mixture of 2,2,6 trimethylcyclohexanone[11] (**51**) (12.6188 g, 89.94 mmol) and powdered sodium cyanide (9.166 g, 187.0 mmol) in water (23 mL) at 0°C,[12] was added a solution of sodium bisulphite (17.587 g) in water (40 mL). The reaction was stirred for 6 h at 0–15°C, then extracted with diethyl ether (4 × 100 mL). The combined organic layers were dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give an oil (15.0255 g, 100%) that solidified on standing. GC and ^{1}H NMR analysis indicated a mixture of cyanohydrins **54**:**53** = 77:23. Purification by column chromatography using either silica (230–400 mesh) or Florisil® resulted in partial reversion to 2,2,6-trimethylcyclohexanone: mp 38–40°C; IR ν_{max} ($CHCl_3$): 3580 (sharp), 3450 (br), 2930, 2250 (weak) cm^{-1}; ^{1}H NMR (400 MHz, $CDCl_3$) (signals corresponding to **53**) δ: 1.13 (3H, d, J = 7 Hz, C6-CH_3), 1.15 (3H, s, C2-CH_3), 1.17 (3H, s, C2-CH_3), 1.40–1.60 (6H, m), 2.06 (1H, m, C6-H), 2.35 (1H, br s, $w_{h/2}$ = 100 Hz, exchangeable, OH) ppm; (signals corresponding to **13**) δ: 1.01 (3H, s, C2-CH_3), 1.13 (3H, d, J = 7 Hz, C6-CH_3), 1.20 (3H, s, C2-CH_3), 1.33–1.62 (5H, m), 1.72 (1H, m), 1.91 (1H, m, C6-H), 2.35 (1H, br s, $w_{h/2}$ = 100 Hz, exchangeable, OH) ppm; ^{13}C nmr (50 MHz, $CDCl_3$) (signals corresponding to **53**) δ: 16.1, 17.1, 23.2, 26.2, 27.7, 32.6, 35.1, 38.0, 78.2, 121.0 ppm; (signals corresponding to **13**) δ: 16.4, 19.2, 20.6, 26.8, 32.2, 36.3, 37.6, 38.4, 81.4, 119.6 ppm; MS m/z: 167 (M^+), 166, 152, 140, 82 (100); high-resolution mass measurement calcd. for $C_{10}H_{17}NO$: 167.1310; found: 167.1306. Anal. calcd. for $C_{10}H_{17}NO$: C 71.80, H 10.25, N 8.41; found: C 71.60, H 10.24, N 8.31.

(1R,6R*) 1-Acetoxy-2,2,6-trimethylcyclohexane-1-carbonitrile (**56**) and (1R*,6S*) 1-acetoxy-2,2,6-trimethylcyclohexane-1-carbonitrile (**57**)*

Method A

A mixture of cyanohydrins **53** and **54** (30:70, 1.0332 g, 6.18 mmol), acetic anhydride (1.40 mL, 14.8 mmol), and acetyl bromide (100 μL, 1.35 mmol) was heated at 120°C for 6.5 h. The cooled reaction was poured into water (30 mL) and extracted with diethyl ether (100 mL). The organic layer was washed with water (50 mL), saturated sodium bicarbonate solution (2 × 50 mL), water (30 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a deep red oil (1.2004 g). Purification by flash chromatography using ethyl acetate/petroleum ether (1:9) as eluent afforded a mixture of cyanohydrin acetates **56** and **57** (28:72, 1.0200 g, 79%) as a white solid: IR ν_{max} ($CHCl_3$): 2950, 1750 cm^{-1}; ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.10 (0.72 × 3H, s), 2.12 (0.22 × 3H, s) ppm. Data on pure **57** is given below (Method B).

Method B

To a solution of cyanohydrins **53** and **54** (30:70, 328.5 mg, 1.96 mmol) and *N*,*N*-dimethylaminopyridine (DMAP, 72 mg, 0.59 mmol) in dichloromethane (25 mL) was added triethylamine (400 μL, 2.87 mmol) and acetic anhydride (300 μL, 3.18 mmol). After stirring for 78 h at room temperature, the reaction was added to iced water (100 mL). The aqueous layer was extracted with dichloromethane (50 mL). The combined organic layers were washed with water (30 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a brown oil (540.8 mg). Purification by flash chromatography using ethyl acetate/petroleum ether (1:19) as eluent afforded in order of elution: 2,2,6-trimethylcyclohexanone (**51**) (135.1 mg, 51%), a pure sample of acetate **57** (56.3 mg, 14%) as a white solid, and a mixture of acetates **56** and **57** (14:86, 41.0 mg, 10%).

Acetate **57**: mp 67–68°C (ether/hexanes); IR ν_{max} ($CHCl_3$): 2950, 1750 cm^{-1}; ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.06 (3H, s, C2-CH_3), 1.07 (3H, d, J = 7 Hz, C6-CH_3), 1.16 (3H, s, C2-CH_3), 1.48 (4H, m), 1.74 (2H, m), 2.10 (3H, s, OCOCH_3), 2.12 (1H, m, C6-H) ppm; MS m/z: 209 (M^+), 194, 167 (100); high-resolution mass measurement calcd, for $C_{12}H_{19}NO_2$: 209.1416; found: 209.1414. Anal. calcd. for $C_{12}H_{19}NO_2$: C 68.87, H 9.15, N 6.69; found: C

[10]Obtained form Aldrich Chemical Co. as a 77:23 mixture of isomers.

[11]Contains 3% 2,2,6,6-tetramethylcyclohexanone. In this and subsequent reactions this impurity reacted in a similar manner to 2,2,6-trimethylcyclohexanone (except in elimination reactions). However, no compounds derived from this compound were isolated or even characterized in the various spectra. Crude yields reflect the presence of these derivatives, however.

[12]The reaction was repeated at various temperatures, 0°C, 20°C, 30°C, 80°C, with the ratio varying from 20:80 at 0°C up to 30:70 at 60°C.

69.05, H 9.09, N 6.69. Single crystal X-ray structure data is given in the Appendix.

Method C

A mixture of nitrile **43** and cyanohydrin **54** (30:70 by GC, derived as indicated below, Method B, 1.0077 g), acetic anhydride (1.0 mL, 10 mmol), and acetyl bromide (70 μL, 0.95 mmol) was heated at 120°C for 8 h. The cooled reaction was added to iced water (50 ml) and extracted with diethyl ether (3 × 70 mL). The combined organic layers were washed with water (50 mL), saturated sodium bicarbonate solution (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a red oil (1.4386 g). Purification by flash chromatography using ethyl acetate/petroleum ether (1:19) as eluent afforded pure nitrile **43** (289.3 mg, 29%) as a colourless oil. Further elution afforded pure "*cis*"-acetate **57** (807.6 mg, 63%) as a white solid.

*2,6,6-Trimethylcyclohex-1-ene-1-carbonitrile (**43**) and 2-methyl-1-(1-methylethylene)-cyclopentane-1-carbonitrile (**55**)*

Method A

To a solution of cyanohydrins **53** and **54** (23:77, 567.6 mg, 3.39 mmol) in anhydrous benzene (2.5 mL) at 0°C were added pyridine (700 μL, 8.65 mmol) and thionyl chloride (500 μL, 6.36 mmol). The reaction was heated at reflux for 1 h. The cooled reaction was poured into water (10 mL) and extracted with diethyl ether (4 × 30 mL). The combined organic layers were washed with 2 M hydrochloric acid (20 mL), saturated sodium bicarbonate solution (10 mL), water (20 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave an oil (664.6 mg). Purification by flash chromatography using diethyl ether/petroleum ether (1:24) as eluent afforded pure nitrile **55** (82.9 mg, 16%), a mixture of nitriles **55** and **43** (81:19, 335.1 mg, 66%), and pure nitrile **43** (63.2 mg, 12%) as colourless oils.

Nitrile **55**: IR ν_{max} (thin film): 3000, 2910, 2260, 1650 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.10 (3H, d, J = 7 Hz, C2-CH_3), 1.58 (1H, m), 1.75 (1H, m), 1.79 (3H, br s, $w_{h/2}$ = 3 Hz, Cl′-CH_3), 1.95 (3H, m), 2.13 (2H, m), 5.02 (1H, br s, $w_{h/2}$ = 4 Hz, Cl′-H), 5.24 (1H, s, Cl′-H) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 15.0, 18.5, 21.7, 32.1, 37.2, 41.2, 55.4, 114.1, 121.6, 140.6 ppm; MS *m/z*: 149 (M^+), 148, 134, 121, 107, 94 (100); high-resolution mass measurement calcd. for $C_{10}H_{15}N$: 149.1204; found: 149.1206. Anal. calcd. for $C_{10}H_{15}N$: C 80.48, H 10.13, N 9.39; found: C 80.30, H 10.00, N 9.60. ^1H NMR decoupling experiment: irradiation of the doublet resonating at δ 1.10 ppm affected the multiplet resonating at δ 2.13 ppm.

Method B

To a solution of cyanohydrins **53** and **54** (20:80, 6.371 g, 38.08 mmol) in anhydrous toluene (30 mL) at 0°C was added pyridine (8.0 mL, 98 mmol) and thionyl chloride (5.6 mL, 71 mmol). The reaction was stirred at 4°C for 17 h. The reaction was poured into water (200 mL) and extracted with diethyl ether (4 × 200 mL). The combined organic layers were washed with 2 M hydrochloric acid (100 mL), water (100 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave an oil. Purification by flash chromatography using ethyl acetate/petroleum ether (1:19) as eluent afforded a mixture of nitrile **43** and 2,2,6-trimethylcyclohexanone (**51**)(1.3677 g). Further elution gave a mixture of "*cis*"-cyanohydrin **54** and 2,2,6-trimethylcyclohexanone (**51**) (4.696 g).

Repetition of this experiment (using **53**:**54** = 30:70) without purification afforded a mixture of **43** and **54** (30:70, 97%).

Method C

A mixture of acetates **56** and **57** (23:77, 318.0 mg, 1.52 mmol) was vacuum pyrolyzed (furnace temperature 450°C, 11 Torr) to obtain a colourless oil that was dissolved in diethyl ether (100 mL), washed with water (50 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a colourless oil (306.7 mg). Purification by flash chromatography using ethyl acetate/petroleum ether (1:19) as eluent afforded pure nitrile **43** (163.3 mg, 72%). Further elution afforded a mixture of acetates **56** and **57** (91:9, 89.1 mg, 28% recovery).

Method D

To a solution of 2,2,6-trimethylcyclohexanone (**51**) (60.00 g, 428.0 mmol) and powdered sodium cyanide (30.00 g, 612.0 mmol) in water (108 mL) was added a solution of sodium bisulphite (84 g, 800 mmol) in water (192 mL). The reaction was stirred for 48 h at room temperature, then diluted with water (500 mL) and diethyl ether (500 mL). The aqueous layer was extracted with diethyl ether (2 × 500 mL). The combined organic layers were dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give an oil (71.05 g, 99%) that solidified on standing. GC and ^1H NMR analysis indicated a mixture of cyanohydrins **53**:**54** = 20:80. This solid was dissolved in anhydrous toluene (300 mL), cooled to 0°C, and the pyridine (87 mL, 1.1 mol) and thionyl chloride (61 mL, 780 mmol) were added. The reaction was stirred at 4°C for 3 days. The reaction was poured into water (1 L) and extracted with diethyl ether (3 × 500 mL). The combined organic layers were washed with 2 M hydrochloric acid (300 mL), water (300 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a yellow oil (70.52 g). This oil was gently heated at reflux with acetic anhydride (75 mL, 790 mmol) and acetyl bromide (4.5 mL, 61 mmol) for 12 h. The cooled reaction was poured into water (1 L) and extracted with diethyl ether (3 × 500 mL). The combined organic layers were washed with water (300 mL), saturated sodium bicarbonate solution (300 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a deep red oil (110 mL). This oil was flash pyrolyzed (furnace temperature 525–550°C) in 20–25 mL batches. The fractions collected were combined, diluted with diethyl ether (1.5 L), washed with water (300 mL), saturated sodium bicarbonate solution (300 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a deep red oil (65.8 g). Purification by distillation afforded nitrile **43** (bp 99–102°C/11 Torr, 51.95 g, 81% for 4 steps).

(1R,2R*) 1-Acetyl-2-methyl-cyclopentane-1-carbonitrile (**56**)*

A stream of ozone was bubbled into a solution of nitrile **55** (68.9 mg, 0.46 mmol) in ethyl acetate (7 mL) at −78°C until a persistent blue coloration was present. Dimethyl sulphide (300 μL) was added stirring continued for a further 10 min. The reaction was diluted with ethyl acetate (30 mL), washed with saturated sodium bicarbonate solution (30 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to give a colourless oil. Purification by flash chromatography using diethyl ether/petroleum ether (1:24) as eluent afforded ketone **56** (50.9 mg, 73%) as a colourless oil: IR ν_{max} (thin film):2980, 2260, 1725 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.19 (3H, d, J = 8 Hz, C2-CH_3), 1.55 (1H, m, C2-H), 1.80 (1H, m), 1.98 (2H, m), 2.25 (2H, m), 2.40 (1H, m), 2.41 (3H, s, -COCH_3) ppm; ^{13}C NMR (50 MHz, $CDCl_3$) δ: 17, 23, 29, 34, 38, 43, 61, 120, 201 ppm; MS *m/z*: 151 (M^+), 136, 109, 94, 82, 43 (100); high-resolution mass measurement calcd. for $C_9H_{13}NO$: 151.0997; found: 151.0994. Anal. calcd. for $C_9H_{13}NO$: C71.49, H 8.66, N 9.26; found: C 71.30, H 8.68, N 9.10. ^1H NMR decoupling experiment: irradiation of the doublet resonating at δ 1.19 ppm affected the multiplet resonating at δ 1.55 ppm.

*2,6,6-Trimethylcyclohex-1-ene-1-carbaldehyde (**45**)*

This procedure is a modification of that reported by Picard *et. al.* (37).

To a solution of nitrile **43** (500 mg, 3.4 mmol) in anhydrous benzene (3 mL) at 0°C was added DIBAL-H (1.5 M in toluene, 3.2 mL, 4.8 mmol). The reaction was stirred for 1.5 h at 0°C after which a further portion of DIBAL-H (1.5 M, 1.0 mL, 1.5 mmol) was added. The reaction was stirred at 0°C for a further 30 min, then added to deoxygenated 5% sulphuric acid (25 mL) along with diethyl ether (20 mL). After stirring vigorously for 15 min, the aqueous layer was extracted with diethyl ether (3 × 50 mL). The combined organic layers were washed with water (40 mL), dried (over $MgSO_4$), filtered, and evaporated *in vacuo* to leave a yellow oil (546 mg). Purification by bulb-to-bulb distillation (100°C,

15 Torr) afforded pure β-cyclocitral (**45**) (461.1 mg, 90%) as a colourless oil: IR ν_{max} ($CHCl_3$): 2950, 1665, 1610 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.20 (6H, s, C6-CH_3), 1.45 (2H, m), 1.64 (2H, m), 2.11 (3H, s, C2-CH_3), 2.21 (2H, t, J = 7 Hz, C3-H_2), 10.11 (1H, s, -*CH*O ppm; ^{13}C nmr (50 MHz, $CDCl_3$) δ: 18.6, 19.3, 21.4, 27.8, 33.0, 35.7, 40.5, 128.2, 129.0, 192.2 ppm; MS *m/z*: 152 (M^+), 137, (100).

Appendix: X-ray crystallographic analysis of compound 57

Experimental

Crystallographic data appear in Table A1. The final unit-cell parameters were obtained by least squares on the setting angles for 25 reflections with 2θ = 79.5–91.1°. The intensities of three standard reflections, measured every 200 reflections throughout the data collection, remained essentially constant. The data were processed[13] and corrected for Lorentz and polarization effects, and absorption (empirical, based on azimuthal scans for four reflections).

The structure was solved by direct methods, the coordinates of the non-hydrogen atoms being determined from an *E*-map and those of the hydrogen atoms from subsequent difference Fourier syntheses. The non-hydrogen atoms were refined with anisotropic thermal parameters and the hydrogen atoms were refined with isotropic thermal parameters. Neutral atom scattering factors and anomalous dispersion corrections for the non-hydrogen atoms were taken from the *International tables for X-ray crystallography* (45). Final atomic coordinates and equivalent isotropic thermal parameters, bond lengths, and bond angles appear in Tables A2–A4, respectively. Hydrogen atom parameters, anisotropic thermal parameters, bond lengths and angles involving hydrogen, torsion angles, packing diagram, and measured and

Discussion of crystal structure

The crystal structure of **57** consists of well-separated molecules, the shortest intermolecular distance between non-hydrogen atoms ($O(2)\cdots C(12)(-x, -y, -z) = 3.562(4)$ Å) corresponding to a normal van der Waals interaction. The cyclohexane ring has a relatively undistorted chair conformation with the bulky substituents occupying equatorial positions (e.g., at C(1): the -$OC(O)CH_3$ group is equatorial and the -CN group axial; at C(6): the methyl group is equatorial). The ester function is planar within experimental error. Bond lengths and angles (Tables A3 and A4) are generally as expected. The C(1)—C(2) bond, between two fully substituted ring carbon atoms, is lengthened to 1.563(2) Å. The cyano group shows a significant deviation from linearity, N(1)—C(9)—C(1) = 171.0(2)°, presumably as a result of packing forces ($N(1)\cdots H(8)(1 - x, -1/2 - y, 1/2 - z) = 2.76(3)$ Å).

Utilizing appropriate dibenzylbutanolides, for example **7**, obtained via an efficient synthetic route from readily available aldehydes, and cell-free extracts obtained from *Catharanthus roseus* cell cultures, it was possible to achieve enzyme-catalyzed oxidative coupling of **7** to picropodophyllotoxin analogues. Studies are presently underway to convert such compounds to intermediates employed in the synthesis of the commercially important anti-cancer drug, etoposide.

JAMES P. KUTNEY, G. M. HEWITT, TERENCE C. JARVIS, JAN PALATY et STEVEN J. RETTIG. Can. J. Chem. **70**, 2115 (1992).

Utilisant des buténolides appropriés, comme le composé **7**, obtenus par une méthode de synthèse efficace à partir d'aldéhydes facilement disponibles, et des extraits sans cellules obtenus à partir des cultures de cellules du *Catharanthus roseus*, on a pu réaliser un couplage oxydant, catalysé par les enzymes, du composé **7** conduisant à des analogues de la picropodophyllotoxine. Des études sont en cours pour transformer de tels composés en intermédiaires utilisés dans la synthèse de l'étoposide, une drogue anticancéreuse commercialement importante.

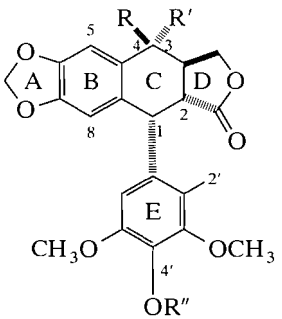
The podophyllotoxin family of natural products exemplified by the structures **1**–**5** have received considerable attention over the years. Excellent reviews (1, 2) of the earlier investigations pertaining to their chemistry and pharmacology are available and the most recent interest due to the important anti-cancer activity of the clinical drug, etoposide (**6**), also extensively reviewed (3, 4), has stimulated continued pursuit of synthetic (5–23) and biosynthetic studies (24). The synthesis of **6** from podophyllotoxin (**1**) is also well established (25–27) and presently provides the commercial route to this clinical drug. However, the latter route requires the



Podophyllotoxin **1**: R = H; R′ = OH; R″ = CH_3
Epipodophyllotoxin **2**: R = OH; R′ = H; R″ = CH_3
Deoxypodophyllotoxin **2**: R = OH; R′ = H; R″ = CH_3
Deoxypodophyllotoxin **3**: R = R′ = H; R″ = CH_3
4′-Demethylpodophyllotoxin **4**: R = H; R′ = OH; R″ = H
4′-Demethylepipodophyllotoxin **5**: R = OH; R′ = H; R″ = H
Etoposic **6**: R = CH_3  ; R′ = H; R″ = H

isolation of **1** via extraction of *Podophyllum peltatum* plants, followed by a two-step chemical process to 4′-demethylepipodophyllotoxin (**4**), the latter being the crucial intermediate for synthesis of **6**.

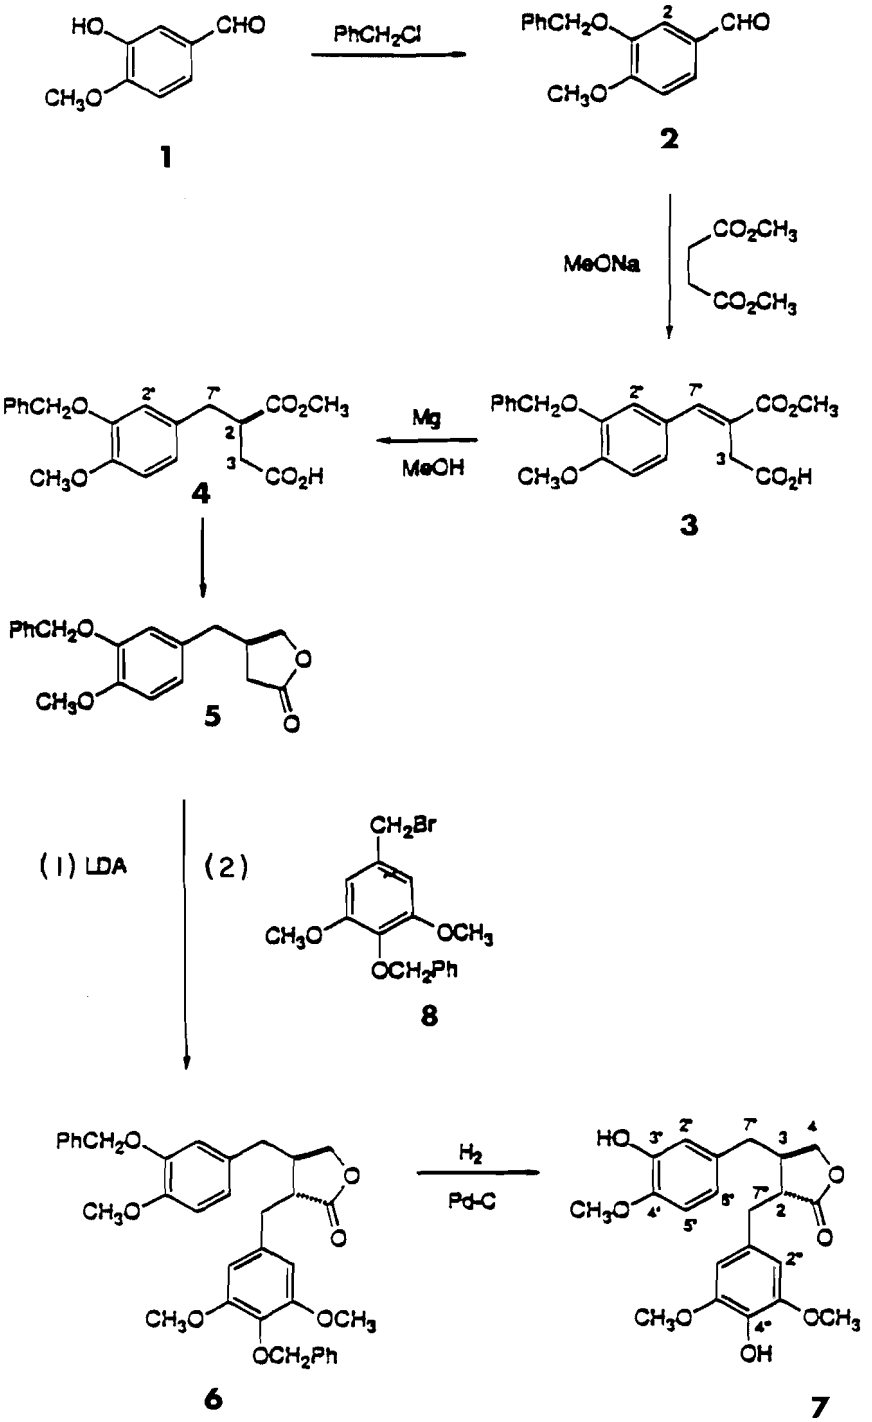
In our program concerning the combined utilization of synthetic chemistry and biotechnological methods, specifically plant cell culture, to develop efficient routes to complex natural products and related biologically active substances (28, 29), we focussed our attention on deriving an efficient route to **4**. In this study, the primary focus was eliminating the dependence on plant extraction and, hopefully, also eliminating some chemical conversions, so as to obtain a more direct synthesis of **4**. This publication presents some results of our studies in this direction.

Our general strategy in utilizing plant cell cultures or enzymes derived from within the cells as "reagents" in organic synthesis, requires initial consideration of "target" synthetic molecules that can subsequently be biotransformed into the desired end products. For this purpose, an understanding of the biosynthetic pathway leading to the podophyllotoxin family is required. It was clear from the detailed studies by Dewick and co-workers (24) that "appropriate" dibenzylbutanolides could act as substrates in enzyme-catalyzed oxidative cyclization reactions to the corresponding podophyllotoxins. In effect, this type of process (see **7** → **9**, Scheme 2) is expected to involve radical intermediates and, within living systems, the latter are usually generated by peroxidase enzymes (30, 31). Indeed such peroxidase enzymes had been produced within our plant cell culture line (coded as AC3) of *Catharanthus roseus* and their role evaluated in the biosynthesis of the clinical anti-cancer drugs vinblastine and vincristine (28). The question as to whether these enzymes could act as "reagents" in catalyzing the cyclization of dibenzylbutanolides to the podophyllotoxin system was of interest and required evaluation.

The first substrate to be studied in incubation experiments with enzymes derived from *C. roseus* plant cell cultures was the butanolide **7** prepared according to Scheme 1.

Isovanillin (**1**) was treated with benzyl chloride and potassium carbonate to give the benzyl ether **2** in quantitative yield and the latter was then subjected to a Stobbe condensation with dimethylsuccinate to afford the conjugated hemisuccinate **3** in 73% yield. Spectral data (see Experimental) indicated that only one geometrical isomer (probably *cis*) was

[1]Author to whom correspondence may be addressed.



SCHEME 1. Synthesis of dibenzylbutanolide 7.

present, as expected, by comparison with the results reported for the analogous reaction with piperonal (32). The double bond of the hemiester **3** was reduced with magnesium in methanol (33) to give the unconjugated hemisuccinate **4** in 89% yield. The ^{1}H NMR spectrum of the product showed H(2), H(3), and H(7′) proton signals as either multiplets or doublets of doublets due to the creation of a chiral centre at C-2. The carbonyl frequency in the IR spectrum, in comparison with that of **3**, had increased to 1720 cm^{-1}, demonstrating the loss of conjugation of the ester group with the aromatic ring.

The reductive lactonization of the hemisuccinate **4** to the butanolide **5** was initially performed using the potassium salt of **4** and calcium borohydride prepared *in situ* (34). However, the crude reaction product was very complex and the yields of **5** were low, but by using the stronger reducing agent lithium borohydride (35) directly with the hemisuccinate **4**, satisfactory yields of pure **5** could be realized. The butanolide **5** was characterized by its ^{1}H NMR spectrum, which showed the two new methylene protons (H(4)) as doublets of doublets at δ 3.91 and δ 4.21, respectively. Formation of the lactone ring was demonstrated by the IR spectrum, which showed the carbonyl absorption at a frequency of 1770 cm^{-1}, well above the value observed for the hemisuccinate **4**.

Alkylation of **5** with the bromide **8** (prepared by the literature procedure (36)) gave the dibenzylbutanolide **6** in 80% yield. The ^{1}H NMR spectrum of the product, in comparison with that of **5**, showed the loss of one H(2) signal but the expected *trans* orientation of the two substituents with respect to the lactone ring could not be confirmed owing to the close proximity of the complex H(2) and H(3) signals.

Finally, the benzyl protecting groups of the butanolide **6** were quantitatively cleaved by hydrogenolysis using palladium-on-carbon as a catalyst, to afford the bis(hydroxybenzyl)butanolide **7** in 87% yield. The ^{1}H NMR spectrum of **7** showed the C(3′) and C(4″) phenolic hydroxyl group singlets, which disappeared with D_2O addition, at δ 5.42 and δ 5.58 respectively. The ^{13}C NMR spectrum showed two benzyl methylene carbon signals (C(7′) and C(7″)), which were identified by the attached proton test (APT). The EI mass spectrum of **7** clearly showed the molecular ion at *m/z* 388 and revealed a fragmentation pattern consistent with the structural assignment. In summary, the dibenzylbutanolide **7** was prepared from isovanillin in six steps in 40% overall yield.

With **7** on hand, studies concerning the biotransformation of this compound with an enzyme preparation (cell-free extract, CFE) previously obtained from our *C. roseus* cell line (AC3) (37–40) were initiated. A large number of experiments with **7** and CFE (prepared as indicated in the experimental section) were conducted. The reaction parameters (pH, H_2O_2 as cofactor, units of peroxidase enzyme per mmol substrate, reaction time) were evaluated in small-scale experiments (10–15 mg of **7**) in order to derive optimum conditions for the biotransformation of **7** to **9** (Scheme 2) and only a summary of the most pertinent features is provided here.

One of the important parameters was the pH (pH_h, the pH of the buffer used to prepare the CFE, Fig. 1) and its effect on the enzymatic activity. Figure 1 summarizes the changes in peroxidase activity and specific activity of the CFE with pH of buffer employed (see Experimental for procedures to measure these activities). A value of 6.3 appeared to be a good compromise between high peroxidase activity and specific activity, or the quotient of peroxidase activity and soluble protein concentration. The protein concentration was determined spectrophotometrically by complexing the dissolved protein with a commercial dye solution (41, 42).

The ideal ratio of peroxidase to substrate was determined using an arbitrary amount of 2.0 molar equivalents of hydrogen peroxide and conducting the reaction at pH 6.3. As shown in Fig. 2, **7** was very nearly consumed within 15 min when an amount of CFE corresponding to 400 units peroxidase per millimole of substrate was used. Increasing the peroxidase: substrate ratio or the reaction time (180 min, Fig. 3) failed to completely convert **7** to **9**: instead, the sole effect was to promote the reaction of aryltetralin **9** to **10** (Scheme 2), a species subsequently identified as the dimer of **9** (see later).

It was concluded that a peroxidase: substrate ratio of approximately 250 units per millimole of butanolide **7** would give optimum yields of the aryltetralin **9**. Higher values promoted dimerization while lower values resulted in incomplete conversion of substrate. The complete structure and stereochemistry of the desired cyclic analogue **9** was established by X-ray diffraction analysis (Fig. 4).

The dimer **10**, also obtained in the biotransformation of **7** was characterized by its ^{1}H NMR and mass spectra. The ^{1}H NMR spectrum of **10** strongly resembled that of the monomer **9** but there was a second signal of equal intensity for all protons shown by **9** except H(5), which is not present. This doubling represents the proton signals of the two diastereomers of the dimer molecules since the monomer units are racemic. The dimeric nature of the compound was demonstrated more clearly by the mass spectrum obtained using desorption chemical ionization (DCI) with ammonia, which showed a peak at *m/z* 788 corresponding to $(\mathbf{10} + NH_4)^+$. There was a very weak molecular ion peak in the EI mas spectrum at *m/z* 770, as well as peaks at *m/z* 784, 798, and 812 resulting from the intermolecular transfer of methyl radicals. In addition, the high degree of fragmentation and the low intensity of the monomer peak at *m/z* 386, in relation to the fragments at *m/z* 167 and 154, were in sharp contrast to the pattern observed in the EI spectrum of the monomer **9**. Unfortunately, neither the EI nor the DCI spectra showed any significant fragments in the region spanned by the molecular weights of the monomer and the dimer, suggesting that the bond between the monomer units is very weak.

In larger scale experiments, a third very minor component could be isolated and based on its spectral data was assigned structure **11**. Its EI mass spectrum was virtually identical to that of **9**. The ^{1}H NMR spectrum was also quite similar except for two *ortho*-coupled (J = 8 Hz) proton signals noted at δ 6.77 and 6.85, thereby suggesting that the ring B hydroxyl group is at C(8) of the aryltetralin rather than at C(6) as in **9**. Other significant features of the spectrum were the three separate methoxy proton signals at δ 3.59, 3.80, and 3.89 and the two *meta*-coupled (J = 2.5 Hz) doublets at δ 5.56 and 6.09, which implied nonequivalence of the two sides of ring E due to the loss of its ability to rotate about the C(1)—C(1′) bond. This was not surprising in view of the proximity of the C(8) hydroxyl to ring E. The low yield of this compound (0.53%) is readily explained by these major steric interactions of the C(8) hydroxyl with ring E.

The optimum hydrogen peroxide: substrate ratio was determined using 250 units peroxidase per millimole of **7** in buffer at pH 6.3. In the absence of hydrogen peroxide, no reaction occurred after 15 min (Fig. 5). A similar result was noted when the reaction was allowed to proceed for 180 min. The yield of **9** and **10** then increased with hydrogen peroxide concentration but remained approximately constant at about 80% when more than 2.0 molar equivalents (3.1 nM) were present. However, these results clearly did not represent the exclusive requirements of the oxidative coupling reactions of **7** and **9** in view of the ability of the CFE alone to consume hydrogen peroxide. This property was demonstrated when the CFE was stirred for 15 min with hydrogen peroxide *prior* to precursor addition. The yield of **9** was only 28% (vs. 64% for the control, where precursor **7**, hydrogen peroxide, and CFE were added simultaneously) after 1 h but had increased sharply to 50% 1 h after a further 2.0 equivalents of hydrogen peroxide were added. These competing processes may have involved the catalytic decomposition of hydrogen peroxide (catalyzed by peroxidase, catalase, or metal ions) or the oxidation of cell material.

It was concluded that 2.0 molar equivalents of hydrogen peroxide would give optimum yields of **9**. Lower values resulted in incomplete biotransformation of **7** while higher ratios promoted the dimerization of **9** to **10**. There appeared to be a distinct decrease in enzyme activity when more than 3 equivalents of hydrogen peroxide were used as cofactors.

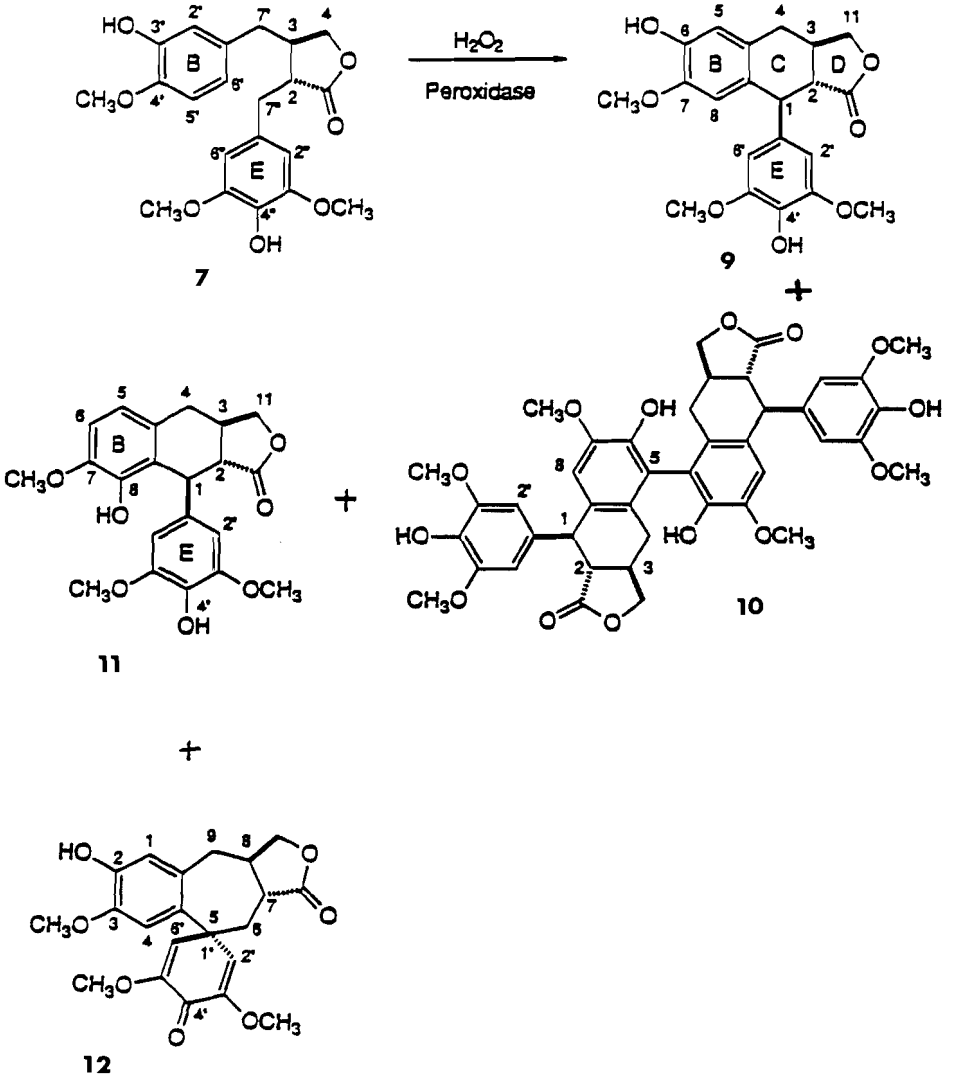

SCHEME 2. Biotransformation of dibenzylbutanolide **7** with cell free extracts of *Catharanthus roseus* cell cultures.

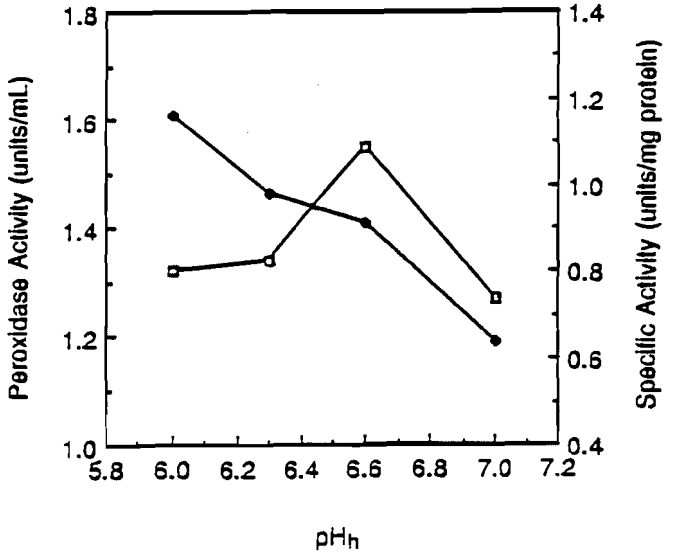

FIG. 1. Effect of pH_h on peroxidase activity and specific activity. □, Peroxidase activity, ◆, specific activity.

The optimum biotransformation pH (pH_r) for the cyclization of **7** to **9** could now be reliably determined, as the ideal peroxidase: substrate and peroxide: substrate ratios had been established. Up to this point, a value of pH 6.3 had been used and found to give good results but it was clearly desirable to identify the optimum value of pH_r more closely. This value (Fig. 6) was found to be about 6.3 based on the yield of **9**, using the optimum conditions established previously. The yield of **9** showed only minor variations over the pH range 6.0–6.6 but decreased markedly at more basic values.

Finally, it was determined that the CFE solution, when stored at 4°C, was quite stable with respect to both the oxidation of pyrogallol (peroxidase assay) and the biotransformation of **7**. The age of the CFE was thus not a significant factor in the reproducibility of individual experiments. In summary, it was found that the biotransformation of **7** to **9** could be accomplished most efficiently using the conditions described in Table 1. The yields of **9** were consistently 70% or higher in the subsequent larger scale experiments (generally 1 g of **7**) and the dimer **10** could be completely suppressed. In these latter studies, a further minor product (usually 1% yield) was isolated and shown to possess the spirodienone structure **12**. The latter was characterized by

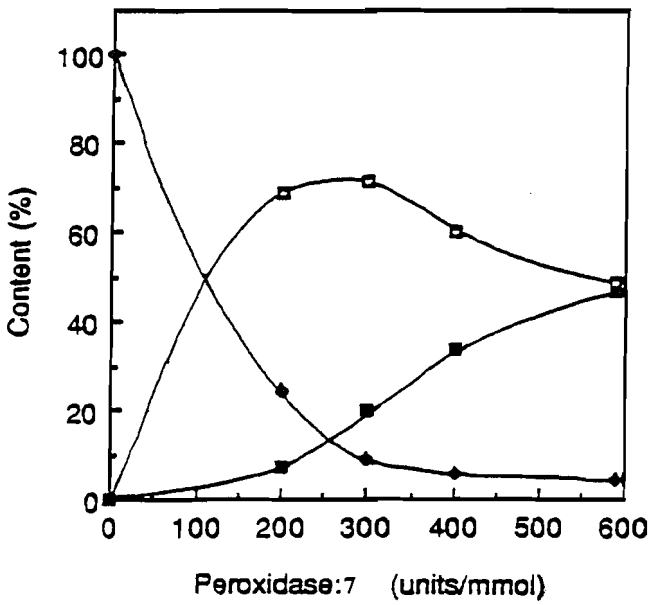

FIG. 2. Effect of peroxidase: substrate ratio on biotransformation of **7**. Reaction time = 15 min; ◆, **7**; □, **9**; ■, **10**.

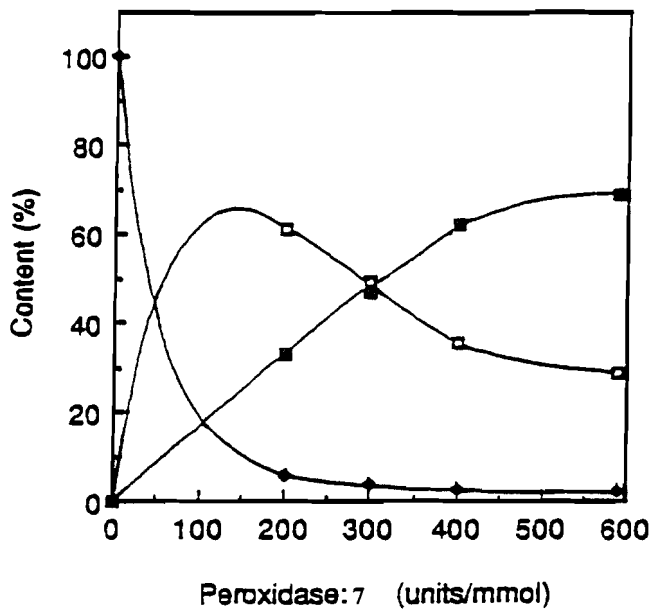

FIG. 3. Effect of peroxidase: substrate ratio on biotransformation of **7**. Reaction time = 180 min; ◆, **7**; □, **9**; ■, **10**.

IR, ^{1}H NMR, and mass spectroscopy. Its IR spectrum showed, in addition to the lactone carbonyl (1774 cm^{-1}), a second carbonyl band at 1673 cm^{-1} that was associated with the C(4′) dienone. The mass spectrum showed the molecular ion as the base peak at *m/z* 386 and virtually no fragmentation. The ^{1}H NMR spectrum showed three distinct methoxy proton signals, two H(6) proton signals (assigned by decoupling H(7)), and two sharp doublets (J = 2.8 Hz) at δ 6.13 and 6.25 that represent H(2′) and H (6′). The chemical shift and coupling constant values of H(2′) and H(6′) were very similar to those reported for a related compound (43).

In summary, it was now clear that the enzymes of *C. roseus* cell cultures, originally developed for the production of indole alkaloids, could tolerate "foreign" substrates of the dibenzylbutanolide family and afford high yields of the desired podophyllotoxin analogues.

It is of interest to note that for the sake of comparison, the biotransformation of **7** to **9** was investigated with commercial horseradish peroxidase. The reaction mixture was complex and the best yields of **9** were 15–19%, thereby revealing that the *C. roseus* derived enzymes are *far superior* for the present study.

In further studies involving enzyme-catalyzed cyclization of dibenzylbutanolides, it was of interest to ascertain whether functionality other than that present in **7** could be tolerated by the *C. roseus* derived enzymes. For this purpose, the butanolide **20** (Scheme 3) was selected as the next substrate to study.

An alternative, superior route to **20** was developed as shown in Scheme 3. The crucial step in the sequence involved a tandem conjugate addition method (44,45) in which the anion of **14** is reacted with butenolide **15** and the resulting intermediate **16**, without isolation, is reacted with **8** to afford **17**.

The dithioacetal **14** was obtained from piperonal (**13**), as shown in Scheme 3, in 98% yield (46). The dithioketal **17** was then prepared in overall 55% yield, as shown, using but-2-en-4-olide (**15**), the latter obtained by a standard procedure (47). The IR spectrum of **17** showed a strong carbonyl band at 1770 cm^{-1}, a frequency substantially higher than that observed for the butenolide (1740 cm^{-1}). The EI mass spectrum showed no significant peaks with *m/z* values greater than 584 ((M$^+$ − SPh) + H) but the fast atom bombardment ionization (FAB) mass spectrum revealed a weak molecular ion at *m/z* 693.

Considerable problems were encountered in the subsequent conversion of the dithioketal **17** to the ketone **18** (R = H or CH_2Ph). Treatment of **17** with perchloric acid (Method 1 in Experimental) (48) gave complex mixtures and poor yields of **18** (R = CH_2Ph) along with the hydroxy ketone **18** (R = H) as a minor product. Varying the reaction time and the amount of perchloric acid failed to improve these results. Treatment of **17** with sulfuryl chloride and wet silica gel (Method 2) (49) gave complex mixtures containing no readily identifiable products. Oxidation with iodine in methanol followed by acid hydrolysis (Method 3) (50), however, gave good yields of the ketone **18** (R = CH_2Ph), which was characterized by ^{1}H NMR, mass, and IR spectroscopy. The ^{1}H NMR spectrum, in comparison with that of the dithioketal **17**, showed a reduction in the number of aromatic protons to five and a considerable downfield shift of the H(3) signal to δ 4.01. The EI mass spectrum exhibited a molecular ion peak at *m/z* 490, and other characteristic fragments consistent with structure **17**.

Hydrogenation (H_2, Pd/C) of **18** (R = CH_2Ph) afforded a mixture of **18** (R = H, 46%) and the alcohol **19** (R = H, 30%), the latter occurring as a mixture of alcohols epimeric at C(7′) (approx. ratio of 3:1). The major isomer was tentatively identified as the alcohol with a β-orientation of the C(7′) hydroxyl for the depicted enantiomer, based on the relative accessibility of the faces of the C(7′) carbonyl group in the most favourable conformation of **18** (R = CH_2Ph) according to Dreiding models, and the results of reductions of closely related dibenzylbutanolides (48). The ^{1}H NMR spectrum of this alcohol mixture showed doublets at δ 1.94

Reaction time (min)	180

and 2.00 and a phenolic hydroxyl singlet at δ 5.40, all of which disappeared upon D_2O addition. The doublets correspond to the C(7′) α and β hydroxyl protons, respectively. The H(3)–H(7′) coupling constants of the two epimers (7.6 and 6.7 Hz for minor and major isomers, respectively) were too similar to be useful in assigning the C(7′) stereochemistry of the individual isomers.

A much preferable route to the alcohol **19** was achieved by low-temperature reduction with sodium borohydride to afford a quantitative yield of **19** (R = CH_2Ph) as an epimeric mixture (4.9:1 in favor of the C(7′) β-hydroxyl group). Studies with the sterically hindered reagent, lithium aluminum tri-tertbutoxy hydride at −78°C, improved the epimeric ratio (5.7:1) but the yields were substantially lower (60%).

When the above mixture of alcohol **19** (R = CH_2Ph) was treated under varying conditions with boron trichloride (4–6 equivalents and different time periods, 30–120 min), the desired dibenzylbutanolide **20** was obtained but only in low yield (generally 25%). Difficulties in chromatographic separation of this very polar compound (recovery of 50% on silica and 67% on Fluorosil) and compound instability are major factors influencing the yield of pure product.

In summary, **20** is available in 12% overall yield for the five-step conversion from piperonal (**13**).

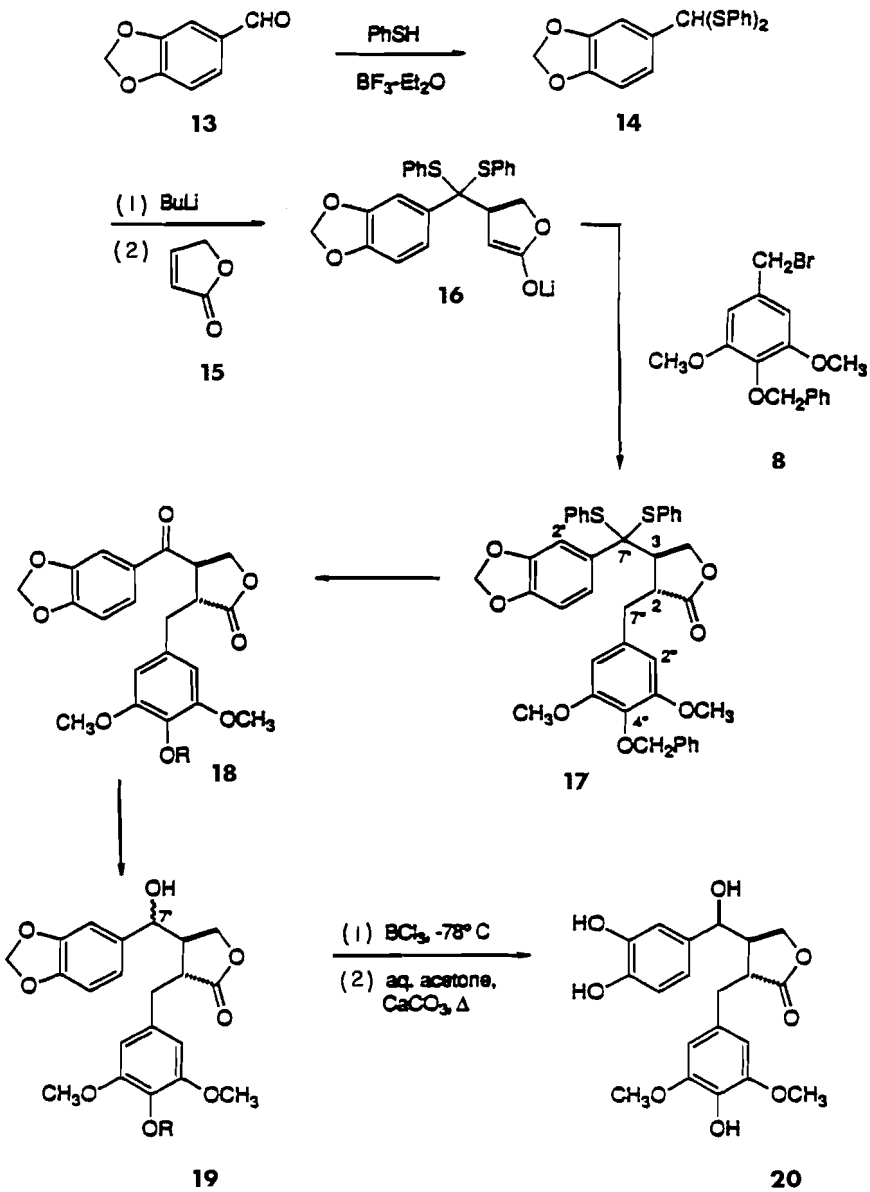

SCHEME 3. Synthesis of dibenzylbutanolide **20**.

We then proceeded to investigate the biotransformation of **20** by the *C. roseus* CFE with the intention of performing the oxidative coupling of **20** to the aryltetralin **21** and (or) the quinone (**22**) (Scheme 4) since both compounds could be converted readily to podophyllotoxin analogues bearing the desired methylene dioxy function in ring B as required for etoposide synthesis. Since catechols are known to react very readily with peroxidase to form *ortho*-quinones (51) and the corresponding diacids (52), the biotransformation of **20**, as described in Table 2, was conducted under oxidizing conditions considerably milder than those employed for **7**. In addition to lower peroxidase:substrate ratio, a higher pH was employed in order to achieve a lower peroxidase reactivity. Nevertheless, the color of the reaction mixture changed from an initial pale yellow to dark purple within 1 min, suggesting extensive oxidation of starting material to quinones. No such color change had been observed in the biotransformation of **7**. A control experiment was also performed in order to determine if hydrogen peroxide, in the absence of CFE, was able to oxidize **20** under the conditions used in the biotransformation. Extraction of the reaction mixture gave 96% recovery of a material consisting exclusively of **20**. No color change was observed. It was concluded that hydrogen peroxide alone was unable to oxidize **20** under the given conditions.

A great deal of difficulty was encountered in the isolation of identifiable products from the various biotransformation experiments with **20**. Recovery of material into organic extracts (ethyl acetate or methanol, for example) was poor and it was clear that extensive decomposition was occurring even in short time incubations (for example, 10 min, Table 2). After much effort, the extraction procedure summarized in Scheme 5 was developed in which sodium borohydride was employed to reduce any resulting unstable quinones and (or) diazomethane was used to convert highly polar and possibly water-soluble carboxylic acids to esters. Under these conditions recovery of identifiable products could be achieved (Table 3).

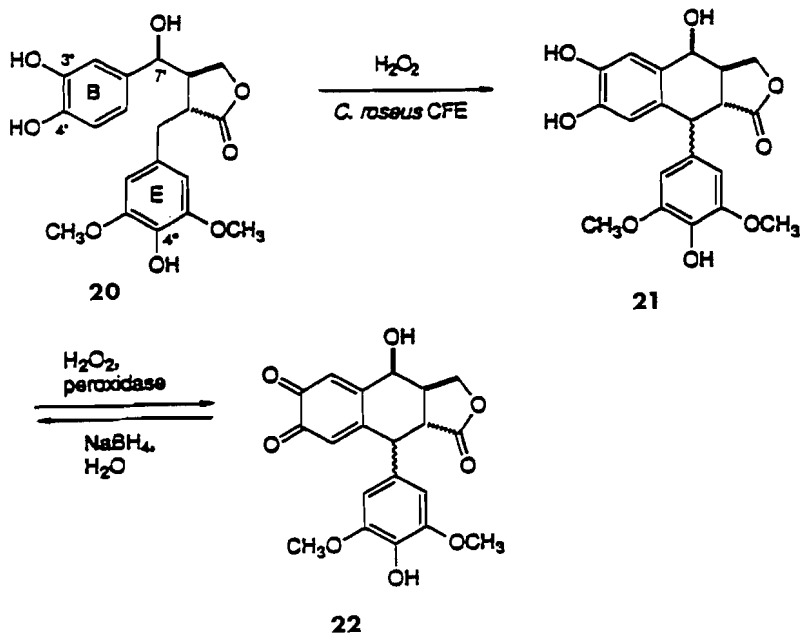


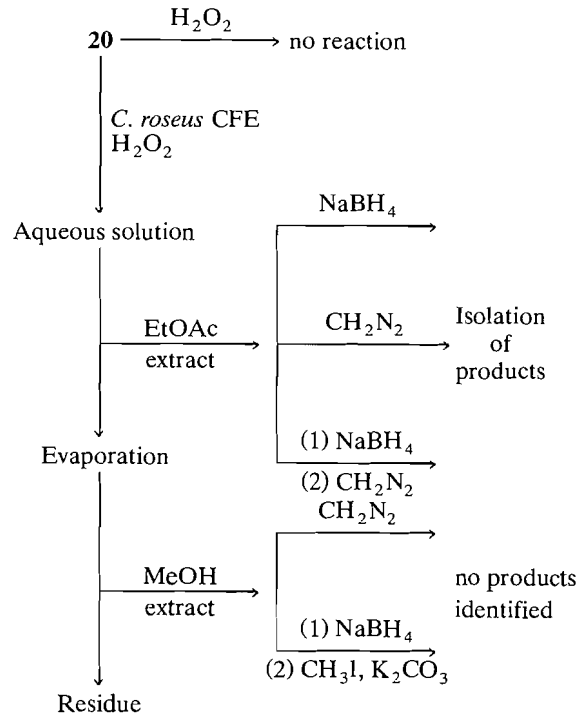
SCHEME 4. Proposed biotransformation of dibenzylbutanolide **20** with cell free extracts of *Catharanthus roseus* cell cultures.

TABLE 2. Catharanthus roseus CFE biotransformation of dibenzylbutanolide **20**

Substrate **20** (mg)	73
pH_h, pH_r	7.0
Hydrogen peroxide (equivalents)	2.0
CFE (units peroxidase per mmol **20**)	120
Reaction time (min)	10
Ethyl acetate extract (mg)	68
Methanol extract (mg)	205

Direct analysis of the ethyl acetate extract by TLC showed the presence of only **20** and very polar unidentified compounds. Addition of sodium borohydride (Table 3, Entry 1) gave a second major component, according to TLC, even prior to the reaction being quenched with dilute hydrochloric acid. The ^{1}H NMR spectrum and other spectral properties were identical with a product obtained in our earlier studies involving the reaction of boron trichloride with **19** (R = H) to which the "retro-lignan" type structure **26** (Scheme 6) had been assigned. The ^{1}H NMR spectrum of **26** showed singlets at δ 3.18 and 3.87 (methoxy protons), singlets at δ 7.12, 7.54, and 7.56 (hydroxyl protons) that disappeared upon D_2O addition, and a total of only four aromatic protons. The trisubstituted ring B aromatic signal pattern was present but the H(2″) signal appeared as only a single proton at δ 6.65. The EI mass spectrum of **26** in contrast to that of **20**, showed a very strong molecular ion peak at m/z 372 and a low degree of fragmentation. The proposed mechanism for the formation of **26** from **20** is shown in Scheme 6.

Only the substrate **20** and partially methylated **20** (**27**) were obtained when the ethyl acetate extract was treated with diazomethane (Entry 2, Table 3). The butanolide **27** was seen as a single spot on TLC analysis and spectroscopic data were consistent with the structural assignment. The ^{1}H NMR spectrum was nearly identical with that of **20** except for two additional methoxy proton signals and an apparent doubling



SCHEME 5. Extraction procedure for reaction mixture obtained in biotransformation of **20** with cell free extracts of *Catharanthus roseus* cell cultures.

of all signals that suggested two very similar compounds (**27***a*, **27***b*).

Successive treatments of the ethyl acetate extract with large excesses of sodium borohydride and freshly prepared diazomethane (Entry 3, Table 3) afforded two new products. One of these, assigned the structure **28**, was characterized by an ^{1}H NMR spectrum that showed a broad doublet at δ 4.22 (H(4)) and an aromatic signal pattern consistent with the trisubstituted aromatic ring at C(4), and the EI mass spectrum that clearly showed the molecular ion at m/z 414.

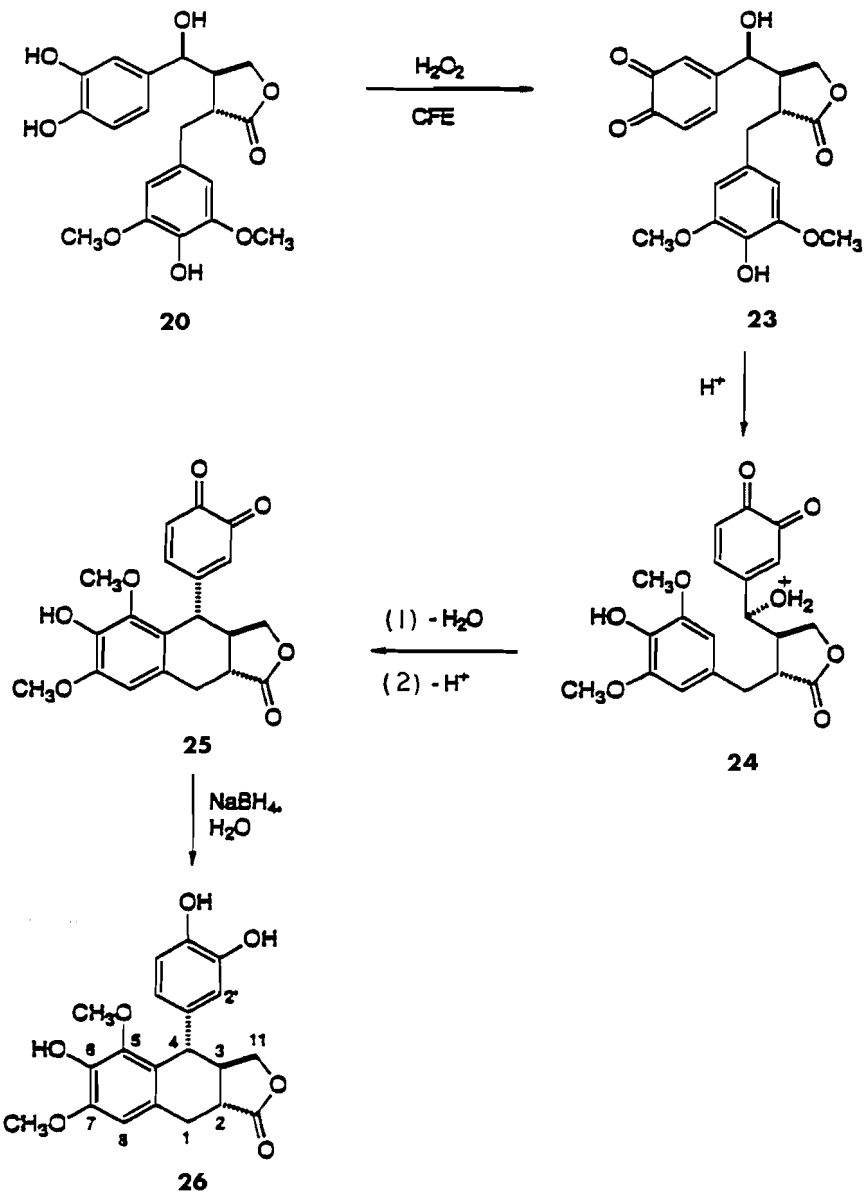

SCHEME 6. Biotransformation of dibenzylbutanolide **20** with cell free extracts of *Catharanthus roseus* cell cultures.

However, the ^{1}H NMR and mass spectral data for the other product, tentatively assigned structure **29**, did not permit an unambiguous structural assignment to be made. It is proposed that the large excess of sodium borohydride in an aqueous medium may have resulted in the hydrolysis of the lactone to the hydroxy acid **29**. Such a structure would be consistent with the polarity of this compound, as acetone was required to elute **29** from the chromatographic column of silica. Further support is provided by the presence of a broad O–H stretch at 3320 cm^{-1} and a carbonyl band at 1670 cm^{-1}

in the IR spectrum, both of which resemble the characteristic stretching frequencies of a carboxylic acid. Both the EI and DCI mass spectra of **29** exhibited a very high degree of fragmentation and peaks of low intensity, as expected for an acyclic compound. However, the acid moiety produced by saponification should have reacted with diazomethane in the subsequent step to afford an ester and this was clearly not the case. Due to its low yield and no direct relevance to

R, R′, R″ = H or CH_3

29

the objectives of this study, more detailed investigations to establish a more definitive structure for **29** were not pursued.

The nature of the unrecovered biotransformation products of **20** is not known. The total recovery of material from the chromatographic separation of the ethyl acetate extract, which had been subjected to reduction and methylation (Entry 3, Table 3), was 82% but only 30% of this material showed aromatic proton signals as determined by ^{1}H NMR spectroscopy. Consequently, the methanol extract of the biotransformation mixture was expected to contain a significant portion of the biotransformation products but TLC analysis showed only baseline (R_f 0) material after treatment with sodium borohydride or diazomethane. Treatment with excess sodium borohydride followed by methylation and isolation of material with an R_f value greater than zero by silica TLC analysis gave only minor amounts of an unidentified compound, assumed to be derived from the CFE.

Although the studies with **20** were not entirely conclusive because of the poor recovery of starting material and products, it gave no evidence of the formation of either the desired aryltetralin **21** or its *ortho*-quinone **22** (Scheme 4). It was thus concluded that the oxidation of ring B in **20** to some unidentified species was too rapid to permit the formation of the quinone methide intermediates required for cyclization to **21**. The low recovery values were probably also the result of a highly reactive substrate resulting from the presence of a catechol-like functionality in ring B.

In conclusion, these studies have thus far indicated that *C. roseus* cell culture derived enzymes, originally developed for production of indole alkaloids, are capable of biotransforming selected dibenzylbutanolides, via oxidative coupling, to compounds closely related to the podophyllotoxins. The process can be highly efficient *if* the substrate, as in the case of **7**, possesses a hydroxyl group at C(3′) of the dibenzylbutanolide system. On the other hand, further activation of the ring system, as in **20** where hydroxyl functionality is present at two adjacent centers (C(3′) and C(4′)), leads to competitive facile oxidation and ring closure reactions become of minimal significance. With these data in hand, further studies with various dibenzylbutanolides and cell cultures of *Podophyllum peltatum*, the plant from which the podophyllotoxins are isolated, will be presented in further publications.

Experimental

Melting points were determined using a Reichert melting point apparatus and are uncorrected. The recrystallization solvents are given in parentheses. Infrared spectra were recorded on Perkin Elmer 1710, 710, or 710B spectrometers, using sodium chloride cells, as a chloroform solution (0.1 mm path length), thin film, or Nujol mull. Band frequencies are reported relative to polystyrene (1601 cm^{-1}). Ultraviolet spectra were recorded as methanol solutions on a Cary 15 spectrometer using 1 cm quartz cells. ^{1}H NMR spectra were recorded on Bruker WH-400, Bruker AC 200, or Varian XL-300 spectrometers. Chemical shift values are reported in ppm relative to tetramethylsilane as an internal standard. ^{1}H COSY NMR spectra were recorded on a Bruker AC 200 spectrometer. ^{13}C NMR spectra were recorded on a Varian XL-300 spectrometer at 75.3 MHz or a Bruker AC-200 spectrometer at 50.2 MHz. Signals with a negative intensity in the attached proton test (APT) are indicated as such by "(−)" and imply the attachment of an odd number of protons. Mass spectra were recorded on AEI-MS-9 (low resolution) or Kratos-MS-50 (high resolution) spectrometers, employing electron impact, fast atom bombardment, or desorption chemical ionization methods. Elemental analyses were performed using combustion analysis by Mr. P. Borda, Microanalytical Laboratory, University of British Columbia. Determination of structures by X-ray crystallography was performed by the X-ray Crystallography Laboratory, University of British Columbia.

Cell suspension culture of the AC3 line of *C. roseus* was obtained from Biological Services of the Department of Chemistry, University of British Columbia. Column chromatography (referred to as "flash chromatography") (53) was performed using columns of silica gel (230–400 mesh, Merck art. 9385) or Florisil (60–100 mesh, Fisher F-100) with air or nitrogen gas pressure to obtain a rapid flow rate. Thin-layer chromatography was performed using commercial aluminum-backed silica gel plates (Merck art. 5554). Visualization was accomplished by spraying with 5% ammonium molybdate in 10% aqueous sulfuric acid followed by heating. High-pressure liquid chromatography was performed using a Waters C^{18} "Radial Pak" liquid chromatography cartridge, a Waters 440 absorbance detector set at 280 nm, and a methanol/water eluent. Circular dichroism analysis was performed using a Jasco J-20 automatic recording spectropolarimeter.

3-Benzyloxy-4-methoxybenzaldehyde (2)

A suspension of isovanillin (**1**, 24.9 g, 164 mmol), potassium carbonate (24.8 g, 179 mmol), benzyl chloride (24.8 g, 194 mmol), sodium iodide (1.0 g, 6.7 mmol), and ethanol (75 mL) was refluxed for 4.5 h while stirring with a mechanical stirrer. Water (50 mL) was added and the ethanol removed *in vacuo*. The slurry was poured into a mixture of 1 M sodium hydroxide (125 mL) and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

ice (50 g). The solids were filtered off and washed with ice-cold water (3 × 25 mL). Drying *in vacuo* gave the benzyl ether **2** (40.2 g, 100%) as a tan solid. A sample was recrystallized from ethyl acetate/hexanes for analysis.

Physical properties of **2**: mp 60.0–60.5°C (ethyl acetate/hexanes), IR ν_{max} ($CHCl_3$): 1690 cm^{-1}; UV λ_{max} (log ϵ): 273 (4.03), 305 (3.91) nm; ^1H NMR δ: 3.97 (3H, s, $-OCH_3$), 5.20 (2H, s, $-OCH_2Ph$), 7.01 (1H, d, H(5), J = 8 Hz), 7.30–7.49 (7H, m, aromatic), 9.81 (1H, br s, $-CHO$); MS *m/z*: 242 (M^+), 214, 181, 168. High-resolution molecular weight determination calcd. for $C_{15}H_{14}O_3$: 242.0943; found: 242.0942. Anal. calcd. for $C_{15}H_{14}O_3$: C 74.36, H 5.82; found: C 74.25, H 5.82.

E-*2-(3-Benzyloxy-4-methoxybenzylidene)butanedioic acid 1-methyl ester (3)*

A solution of sodium methoxide was prepared by the careful addition of sodium (14.6 g, 633 mmol) to dry methanol (250 mL) under nitrogen. A solution of the benzyl ether **2** (95.7 g, 395 mmol) in dimethylsuccinate (81.6 g, 558 mmol) was added dropwise over 40 min at reflux. After an additional 70 min of stirring at reflux, the bulk of the solvent was removed *in vacuo*. The suspension was cooled to O°C and acidified with 6 M hydrochloric acid. The solids were removed by filtration and the filtrate extracted with dichloromethane (2 × 400 mL). The solids were added to the organic extract, washed with brine (400 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo* to yield an oily yellow solid, which was recrystallized from ethyl acetate/hexanes to give the hemisuccinate **3** (102.1 g, 73%) as a yellowish powder.

Physical properties of **3**: mp 123–125°C (ethyl acetate/hexanes); IR ν_{max} ($CHCl_3$): 1700 cm^{-1}; UV λ_{max} (log ϵ): 290 (4.03), 307 (4.03) nm; ^1H NMR δ: 3.51 (2H, s, H(2)), 3.86, 3.93 (3H each, s, s, $-CO_2CH_3$, Ar-OCH_3), 5.22 (2H, s, $-OCH_2Ph$), 6.94 (1H, d, H(5′), J = 8 Hz), 7.05 (1H, dd, H(6′), J = 8, 1 Hz), 7.10 (1H, d, H(2′), J = 1 Hz), 7.37–7.45 (5H, m, phenyl), 7.81 (1H, s, H(7′)). MS *m/z*: 356 (M^+), 324, 296. High-resolution molecular weight determination calcd. for $C_{20}H_{20}O_6$: 356.1260; found: 356.1268.

(±)-2-(3-Benzyloxy-4-methoxybenzyl)butanedioic acid 1-methyl ester (4)

Hemisuccinate **3** (96.4 g, 271 mmol) was added to a suspension of magnesium shavings (66.2 g, 2.72 mol) in dry methanol (750 mL) under nitrogen. After a few minutes stirring, the reaction vessel was immersed in an ice bath and stirred at 0°C for 5 h. The suspension was acidified with 6 M hydrochloric acid and the remaining solids were removed by filtration. The filtrate was extracted with dichloromethane (3 × 400 ml), washed with brine (500 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo* to give the hemisuccinate **4** (86.4 g, 89%) as an amber resin that solidified upon standing at 3°C.

Physical properties of **4**: mp 78–82°C; IR ν_{max} ($CHCl_3$): 1720 cm^{-1}; UV λ_{max} (log ϵ): 279 (3.49) nm; ^1H NMR δ: 2.34 (1H, dd, H(3), J = 18, 4.5 Hz), 2.58–2.72 (2H, m, H(3), H(2)), 2.90–3.10 (2H, m, H(7′)), 3.66 (3H, s, $-CO_2CH_3$), 3.88 (3H, s, Ar-OCH_3), 5.13 (2H, s, $-OCH_2Ph$), 6.70 (2H, m, H(2′), H(6′)), 6.82 (1H, d, H(5′), J = 7.8 Hz), 7.25–7.50 (5H, m, phenyl); MS *m/z*: 358 (M^+), 308, 281. High-resolution molecular weight determination calcd. for $C_{20}H_{22}O_6$: 358.1417; found: 358.1413.

(±)-3-(3-Benzyloxy-4-methoxybenzyl)butanolide (5)

Method 1

The hemisuccinate **4** (2.1 g, 5.7 mmol) was dissolved at 0°C in water (5 mL) with 2 M potassium hydroxide. The solution was neutralized and evaporated *in vacuo* to yield the potassium salt of **4**. A solution of calcium borohydride was prepared by adding a solution of calcium chloride (3.29 g, 28.5 mmol) in methanol (60 mL) to a solution of sodium borohydride (1.62 g, 40.7 mmol) in ethanol (60 mL) at −20°C. Potassium hydroxide (180 mg, 3.2 mmol) was added followed by the potassium salt of **4** dissolved in ethanol (50 mL). The solution was allowed to warm to room temperature and stirred for 4.5 days before being cooled to 0°C, and acidified with 6 M hydrochloric acid. The solution was concentrated *in vacuo*, extracted with dichloromethane (3 × 100 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo*. Purification by flash chromatography using ethyl acetate/petroleum ether (9:11, v/v) gave the β-benzylbutanolide **5** (1.16 g, 65%) as a yellowish oil that solidified upon standing.

Method 2

Lithium borohydride (0.91 g, 42 mmol) in dry THF (150 mL) was added carefully to a solution of the hemisuccinate **4** (14.7 g, 40.9 mmol) in THF (250 mL) at reflux under nitrogen. The solution was stirred for 2 h at reflux and then cooled to room temperature. Water (2 mL) and 6 M hydrochloric acid (9 mL) were added and the solution was stirred at room temperature for 2.5 h. The bulk of the solvent was removed by evaporation *in vacuo* and the resultant mixture extracted with ether (50 mL). The organic extract was washed with saturated sodium bicarbonate (3 × 25 mL) and water (25 mL) before being dried over magnesium sulfate, filtered, and evaporated *in vacuo* to give the pure β-butanolide **5** (11.4 g, 88%) as a clear oil that solidified upon standing.

Physical properties of **5**: mp 51–54°C; IR ν_{max} ($CHCl_3$): 1770 cm^{-1}; UV λ_{max} (log ϵ): 279 (3.48) nm; ^1H NMR δ: 2.19 (1H, dd, H(2), J = 17.6, 6.7 Hz), 2.50 (1H, dd, H(2), J = 17.6, 7.9 Hz), 2.61–2.80 (3H, m, H(3), H(7′)), 3.89 (3H, s, -OCH_3), 3.91 (1H, dd, H(4), J = 9.1, 6.0 Hz), 4.21 (1H, dd, H(4), J = 9.1, 7.0 Hz), 5.16 (2H, s, -OCH_2Ph), 6.65 (1H, d, H(2′), J = 1 Hz), 6.71 (1H, dd, H(6′), J = 8, 1Hz), 6.85 (1H, d, H(5′), J = 8 Hz); MS *m/z*: 312 (M^+), 222, 137. High-resolution molecular weight determination calcd. for $C_{19}H_{20}O_4$: 312.1362; found: 312.1371.

(±)-trans-*2-(4-Benzyloxy-3,5-dimethoxybenzyl)-3-(3-benzyloxy-4-methoxybenzyl)butanolide (6)*

To a solution of diisopropylamine (2.9 mL, 21 mmol) in dry THF (30 mL) at −78°C was added butyllithium (11 mL, 1.6 M solution, 17 mmol) and stirring continued for 15 min at −78°C and then for 30 min at 0°C. The clear solution was cooled to −78°C, β-butanolide **5** (4.3 g, 14 mmol) in THF (15 mL) was added, and the bright yellow solution stirred for 90 min prior to the addition of the bromide **8** (5.5 g, 16 mmol) in THF (15 mL) and stirring for 8 h at −78°C. The solution was warmed to 0°C, acidified with 1 M hydrochloric acid, and extracted with dichloromethane (2 × 150 mL). The combined organic extracts were washed with water (80 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo*. Flash chromatography using ethyl acetate/petroleum ether (9:11, v/v) gave the dibenzylbutanolide **6** (6.2 g, 80%) as a yellowish foam.

Physical properties of **6**: mp 35–37°C, IR ν_{max} ($CHCl_3$): 1770 cm^{-1}; UV λ_{max} (log ϵ): 278 (3.55) nm; ^1H NMR δ: 2.32 (1H, dd, H(7″), J = 14.4, 8.2 Hz), 2.45–2.70 (3H, m, H(7″), H(2), H(3)), 3.06 (1H, dd, H(7′), J = 14.0, 8.0 Hz), 3.32 (1H, dd, H(7′), J = 14.0, 5.4 Hz), 3.74 (1H, dd, H(4), J = 9, 8 Hz), 3.80 (6H, s, -OCH_3(3″, 5″)), 3.88 (3H, s, -OCH_3(4′)), 3.99 (1H, dd, H(4), J = 9.2, 7.0 Hz), 5.05, 5.13 (2H each, s, s, -OCH_2Ph), 6.52–6.58 (3H, m, H(2″), H(6′)), 6.69 (1H, s, H(2′)), 6.77 (1H, d, H(5′), J = 8.0 Hz), 7.25–7.49 (10H, m, phenyl); MS *m/z*: 568 (M^+), 402, 312, 167, 137, 91. High-resolution molecular weight determination calcd. for $C_{35}H_{36}O_7$: 568.2461; found: 568.2457.

(±)-trans-*2-(3,5,-Dimethoxy-4-hydroxybenzyl)-3-(3-hydroxy-4-methoxybenzyl)butanolide (7)*

Palladium-on-charcoal (5%, 1.05 g) was suspended in ethanol (40 mL) and stirred under hydrogen at atmospheric pressure for 1.5 h. The dibenzylbutanolide **6** (6.2 g, 11 mmol) was added as an ethyl acetate/ethanol solution (1:3, v/v, 40 mL) and the resultant suspension stirred for 5 h. The catalyst was filtered off and the solvent evaporated *in vacuo* to yield the bis(hydroxybenzyl)butanolide **7** (3.7 g, 87%) as an amorphous white solid after

*(±)-trans-2-(4-Benzyloxy-3,5-dimethoxybenzyl)-3-(3,4-methylenedioxybenzoyl)butanolide (**18**, R = CH_2Ph) and (±)-trans-2-(3,5-dimethoxy-4-hydroxybenzyl)-3-(3,4-methylenedioxybenzoyl)butanolide (**18**, R = H)*

Method 1

Dithioketal **16** (replace OLi by carbonyl) (34.5 mg, 50.0 μmol) was dissolved in ethyl acetate (6 mL). Perchloric acid (70%, 1 drop) was added and the solution stirred for 4 h. Water (1 mL and ethyl acetate (10 mL) were added and the phases separated. The organic extract was washed with brine (2 mL) and saturated sodium bicarbonate (2 × 2 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo*. Flash chromatography using acetate/dichloromethane (1:19, v/v) gave the ketones **18** (R = CH_2Ph) (10.8 mg, 44%) and **18** (R = H) (2.0 mg, 10%).

Method 2

Sulfuryl chloride (11.8 mg, 87.4 μmol) in dichloromethane (0.4 mL) was added to a mixture of dithioketal **16** (replace OLi by carbonyl) (48.7 mg, 70.3 μmol), silica gel (230–400 mesh, 30 mg), and water (30 mg) in dichloromethane (0.35 mL). After stirring for 2 h, finely powdered anhydrous potassium carbonate was added and stirring continued for 0.5 h. The solids were filtered off and washed with dichloromethane. The filtrate was evaporated *in vacuo* and purified by flash chromatography using acetone/dichloromethane (1:49, v/v) but neither **18** (R = CH_2Ph) nor **18** (R = H) could be identified by ^1H NMR spectroscopy of the major fractions.

Method 3

Iodine (1.46 g, 11.5 mmol) was added to a solution of dithioketal **16** (replace OLi by carbonyl) (1.85 g, 2.68 mmol) in methanol (50 mL) and THF (5 mL). The solution was then stirred at reflux for 1.5 h prior to the addition of saturated sodium thiosulfate (10 mL), brine (10 mL), and water (20 mL). The mixture was extracted with ethyl acetate (100 mL), diluted with water (10 mL) and brine (10 mL), and re-extracted with ethyl acetate (100 mL). The organic extract was washed with water (20 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo*. THF (5 mL) and 3 M hydrochloric acid (6 mL) were added and the suspension stirred at room temperature for 1 h before being diluted with water (10 mL) and extracted with dichloromethane (2 × 50 mL). The organic extract was washed with water (2 × 20 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo*. Ether (25 mL) was added and the suspension sonicated for 5 min, stored at 3°C for 3 days, filtered, and washed with ice-cold ether (2 × 5 mL) to give the ketone **18** (R = CH_2Ph) as a white powder (0.920 g). The filtrate was evaporated and purified by flash chromatography using acetone/dichloromethane (0:1 to 1:49 gradient, v/v) to afford **18** (R = CH_2Ph) (134 mg) for a total yield of 80%.

Physical properties of **18** (R = CH_2Ph): mp 43–44°C (diethyl ether); IR ν_{max} ($CHCl_3$): 1770, 1670 cm^{-1}; UV λ_{max} (log ϵ): 275 (3.82), 314 (3.90) nm; ^1H NMR δ: 3.00 (1H, dd, H(7″), J = 14, 6 Hz), 3.09 (1H, dd, H(7″), J = 14, 5 Hz), 3.55–3.61 (1H, m, H(2)), 3.70 (6H, s, -OCH_3), 4.01 (1H, ddd, H(3) J = 8, 8, 8 Hz), 4.10 (1H, dd, H(4), J = 9, 8 Hz), 4.38 (1H, dd, H(4), J = 9, 8 Hz), 4.92 (2H s, -OCH_2Ph), 6.01, 6.04 (1H each, d, d, -OCH_2O-, J = 1 Hz each), 6.28 (2H, s, H(2″)), 6.80 (1H, d, H(5′), J = 8 Hz), 7.24–7.38 (5H, m, H(2′), H(6′), phenyl), 7.47 (2H, dd, phenyl, J = 7, 1 Hz); MS *m/z*: 490 (M^+), 399, 223, 149, 91. High-resolution molecular weight determination calcd. for $C_{28}H_{26}O_8$:

(±)-trans-*2-(3,5-Dimethoxy-4-hydroxybenzyl)-3-(α-hydroxy-3,4-methylenedioxybenzyl)butanolide (**19**, R = H)*

Method 1

Palladium-on-charcoal (10%, 1.676 g) was suspended in ethanol (100 mL) and stirred for 1 h under hydrogen at atmospheric pressure. A solution of the ketone **18** (R = CH_2Ph) (4.50 g, 9.16 mmol) in ethyl acetate (100 mL) was added and the resultant suspension stirred for 7 h. The catalyst was filtered off and the solution evaporated *in vacuo*. The residue was purified by column chromatography using acetone/dichloromethane (1:19 to 1:9 gradient, v/v) to give ketone **18** (R = Ch_2Ph) (0.685 g, 15%), ketone **18** (R = H) (1.686 g, 46%), and alcohol **19** (R = H) (1.113 g, 30%, 3.3:1 mixture of C(7′) epimers according to ^1H NMR spectroscopy).

Method 2

Sodium borohydride (47 mg, 1.2 mmol) was added to a suspension of the ketone **18** (R = H) (464 mg, 1.16 mmol) in dry methanol (50 mL) at 0°C under nitrogen. After stirring for 2.5 h at O°C, 1 M hydrochloric acid (2 mL) was added to the resultant clear solution, which was then concentrated *in vacuo*, diluted with water (5 mL) and brine (5 mL), and extracted with ethyl acetate (2 × 50 mL). The combined organic extracts were washed with water (15 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo* to give the alcohol **19** (R = H) (443 mg, 95%) as an amorphous white solid. ^1H NMR spectroscopy showed the product to be a 6:1 mixture of C(7′) epimers.

Properties of 3.3:1 mixture of **19** (R = H) (C(7′) β-hydroxyl epimer assumed as major): IR ν_{max} ($CHCl_3$): 3600, 3530, 1770 cm^{-1}; UV λ_{max} (log ϵ): 282 (3.60) nm; ^1H NMR (integrals relative to minor (α) epimer) δ: 1.94 (1H, d, -OH(7′, α), J = 3 Hz), 2.00 (3.3 H, d, -OH(7′, β), J = 3 Hz), 2.51–3.11 (17.2 H, m, H(7″), H(2), H(3)), 3.85 (6H, s, -OCH_3(α)), 3.87 (19.8 H, s, -OCH_3(β)), 3.92–3.96 (6.6 H, m, H(4, β)), 4.17 (1H, dd, H(4, α), J = 9.6, 7.6 Hz), 4.37 (1H, dd, H(7′, α), J = 8.0, 2.5 Hz), 4.40 (1H, dd, H(4, α), J = 9.6, 6.1 Hz), 4.62 (3.3 H, dd, H(7′, β), J = 6.7, 2.9 Hz), 5.40 (4.3 H, s, -OH(4″)), 5.97, 5.98 (3.3 H each, d, d, -OCH_2O-(β), J = 1 Hz), 5.99, 6.00 (1H each, d, d, -OCH_2O-(α), J = 1 Hz), 6.27 (2H, s, H(2″, α)), 6.40 (6.6 H, s, H(2″, β)), 6.61–6.76 (12.9 H, m, H(2′), H(5′), H(6′)). Upon addition of D_2O, all hydroxyl signals disappear and the H(7′) signals collapse to doublets. MS m/z: 402 (M^+), 384, 178, 167, 224, 151, 135, 123. High-resolution molecular weight determination calcd. for $C_{21}H_{20}O_8$: 402.1314; found: 402.1302. Anal. calcd. for $C_{21}H_{22}O_8$: C 62.28, H 5.51; found: C 62.33, H 5.80.

Physical properties of 6:1 mixture of **19** (R = H): mp 43–51°C.

(±)-trans-*2-(3,5-Dimethoxy-4-hydroxybenzyl)-3-(3,4-dihydroxy-α-hydroxybenzyl)butanolide (**20**) and (±)-4-(3,4-dihydroxyphenyl)-5,7-dimethoxy-6-hydroxy-2-hydroxymethyl-1,2,3,4-tetrahydro-2-naphthoic acid γ lactone (**26**)*

Method 1

Alcohol mixture **19** (R = H) (210 mg, 0.52 mmol) dissolved in dichloromethane (10 mL) was added to a solution of boron trichloride (3.1 mmol) in dichloromethane (23.5 mL) at −78°C. After stirring for 2 h at −78°C, saturated potassium bicarbonate (2 mL) was added and the suspension allowed to warm to room temperature. Water (5 mL) and brine (1 mL) were added and the mixture was extracted with ethyl acetate (2 × 50 mL). The organic extract was dried over magnesium sulfate, filtered, and evaporated *in vacuo*. Acetone (4 mL), water (5 mL), and calcium carbonate (330 mg) were added and the suspension stirred for 1.5 h at 65°C. The solids were dissolved by the addition of 6 M hydrochloric acid and the clear solution extracted with ethyl acetate (2 × 50 mL). The organic extract was washed with water (15 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo*. Flash chromatography using acetone/dichloromethane (2:8 to 3:8, v/v) gave the aryltetralin **26** (78 mg, 40%) and the catechol **20** (49 mg, 24%, single epimer by ^1H NMR spectroscopy) as amorphous white solids. A sample of **26** was recrystallized from methanol/chloroform for analysis.

Method 2

Alcohol **19** (R = CH_2Ph) (161 mg, 0.327 mmol) dissolved in dichloromethane (6.5 mL) was added to a stirred solution of boron trichloride (2.0 mmol) in dichloromethane (15.3 mL) at −78°C. After stirring for 2 h, water (3 mL), saturated potassium hydrogen carbonate (1 mL), and brine (1 mL) were added and the mixture allowed to warm to room temperature. The mixture was extracted with ethyl acetate (2 × 40 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo*. Acetone (3 mL), water (6.5 mL), and calcium carbonate (210 mg) were added and the suspension stirred for 1.5 h at 65°C. The solids were dissolved with 6 M hydrochloric acid and the solution extracted with ethyl acetate (2 × 40 mL). The organic extracts were washed with water (10 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo* to afford a yellowish foam. Flash chromatography using acetone/dichloromethane (1:4 to 3:2 gradient, v/v) afforded the alcohols **19** (R = H) (42 mg, 32%, 5:1 mixture of epimers by ^1H NMR spectroscopy) and **20** (33 mg, 26%).

Physical properties of **20**: mp 49–56°C; IR ν_{max} (Nujol): 3380, 1740 cm^{-1}; UV λ_{max} (log ϵ): 281 (3.57) nm; ^1H NMR δ: 2.64–2.77, 2.95–3.05 (4H total, m, m, H(7″), H(2), H(3)), 3.80 (6H, s, -OCH_3), 3.93 (1H, dd, H(4), J = 17, 9 Hz), 3.98 (1H, dd, H(4), J = 17, 8 Hz), 4.55 (1H, d, -OH(7′), J = 3.6 Hz), 4.68 (1H, dd, H(7′), J = 6.0, 3.6 Hz), 6.42 (2H, s, H(2″)), 6.68 (1H, dd, H(6′), J = 8, 2 Hz), 6.80 (1H, d, H(5′), J = 8 Hz), 6.88 (1H, d, H (2′), J = 2 Hz), 6.91 (1H, brs, -OH(4″)), 7.80 (2H, brs, -OH(3′), -OH(4′)). Upon addition of D_2O, all hydroxyl signals disappear and the H(7′) signal collapses to a doublet. ^{13}C NMR δ: 35.619 (C(7″)), 43.787(−), 45.709(−), 56.464(−) (-OCH_3), 68.892 (C(4)), 74.217(−) (C(7′)), 107.994(−) (C(2″)), 114.086(−), 115.787(−), 118.432(−), 129.114, 135.743; 145.227, 145.826, 148.339, 179.568 (C(1)); MS m/z: 390 (M^+), 372, 167, 154, 123, 110. High-resolution molecular weight calcd. for $C_{20}H_{22}O_8$: 390.1315; found: 390.1313.

Physical properties of **26**: mp 222–224°C (methanol/chloroform); IR ν_{max} (Nujol): 3400, 3250, 1730 cm^{-1}; UV λ_{max} (log ϵ): 283 (3.70) nm; ^1H NMR δ: 2.30–2.41 (1H, m, H(3)), 2.51 (1H, ddd, H(2), J = 13.6, 11.7, 4.5 Hz), 2.88–2.92 (1H, m, H(1)), 3.03 (1H, dd, H(1), J = 15.3, 4.5 Hz), 3.18 (3H, s, -OCH_3(5)), 3.87 (3H, s, OCH_3(7)), 4.04 (1H, brd, H(4), J = 10.8 Hz), 4.16–4.20 (2H, m, H(11)), 6.50 (1H, dd, H(6′), J = 8, 2 Hz), 6.55 (1H, d, H(2′), J = 2 Hz), 6.65 (1H, s, H(8)), 6.74 (1H, d, H(5′), J = 8 Hz), 7.12 (1H, s, -OH(6)), 7.54, 7.56 (1H each, s, s, -OH(3′), -OH(4′)). All hydroxyl signals disappear upon addition of D_2O. ^{13}C NMR δ: 41.595(−), 46.525(−), 50.499(−), 56.255(−), 58.614(−), 72.246, 101.389, 107.912(−), 114.565(−), 115(779(−), 118.991(−), 127.733, 139.071, 139.320, 143.913, 145.686, 177.2 (C(1)); MS m/z: 372 (M^+), 262. *(±)-*trans*-2-(4-Benzyloxy-3,5-dimethoxybenzyl)-3-(α-hydroxy-3,4-methylenedioxybenzyl)butanolide (**19**, R = CH_2Ph)*

Method 1

Sodium borohydride (19 mg, 0.51 mmol) was added to a suspension of ketone **18** (R = Ch_2Ph) (173 mg, 0.352 mmol) in dry methanol (25 mL) at 0°C under nitrogen. After stirring for 5 h at 0°C, 1 M hydrochloric acid (3 mL) was added to the resultant clear solution, which was then concentrated *in vacuo*, diluted with brine (2 mL), and extracted with dichloromethane (2 × 40 mL). The combined organic extracts were washed with water (8 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo* to give alcohol **19** (R = CH_2Ph) (172 mg, 99%) as an amorphous white solid. ^1H NMR spectroscopy indicated that the product was a 4.9:1 mixture of epimers.

Method 2

Lithium aluminum tri-*tert*-butoxy hydride (690 mg, 2.7 mmol) in THF (8 mL) was added to a stirred suspension of the ketone **18** (R = Ch_2Ph) (380 mg, 0.78 mmol) in dry ether (25 mL) and THF (5 mL) under nitrogen at −78°C. The mixture was stirred for 3 h and then acidified with 1 M hydrochloric acid (6 mL), diluted with water (15 mL), and extracted with ethyl acetate (2 × 50 mL). The organic extract was washed with saturated sodium bicarbonate (2 × 15 mL) and water (10 mL), dried over magnesium sulfate, filtered, and evaporated *in vacuo* to afford a foam (329 mg) that, by ^1H NMR spectroscopy, contained the alcohol **19** (R = CH_2Ph) (70%, 5.7:1 mixture of epimers) and the ketone **18** (R = CH_2Ph).

Physical properties of 4.9:1 mixture of **19** (R = CH_2Ph) (C(7′) β-hydroxyl epimer assumed as major): mp 46–49°C, IR ν_{max} ($CHCl_3$): 3450, 1770 cm^{-1}; UV λ_{max} (log ε): 284 (3.55) nm; ^1H NMR δ: 1.87 (1h, d, OH(7′, α), J = 3 Hz), 1.96 (4.9 H, d, -OH(7′, β), J = 2.8 Hz), 2.47–3.10 (23.6 H, m, H(2), H(3), H(7′)), 3.78–3.79 (35.4 H, m, $-OCH_3$), 3.89–3.96 (9.8 H, m, H(4, β)), 4.15–4.17 (1H, m, H(4, α)), 4.33 (1H, dd, H(7′, α), J = 7.1, 3 Hz), 4.37 (1H, dd, H(4, α), J = 9.3, 6.4 Hz), 4.60 (4.9 H, dd, H(7′, β), J = 7.1, 2.8 Hz), 5.00 (11.8 H, s, $-OCH_2Ph$), 5.93–6.01 (11.8 H, m, $-OCH_2O-$), 6.25 (2H, s, H(2″, α)), 6.38 (9.8 H, s, H(2″, β)), 6.57–6.78 (17.7 H, m, H(2′), H(5′), H(6′)), 7.22–7.50 (29.5 H, m, phenyl). Upon D_2O addition, both hydroxyl signals disappear and H(7′) signals collapse to doublets. MS m/z: 492 (M^+), 474, 161, 149, 131, 91. High-resolution molecular weight determination calcd. for $C_{28}H_{28}O_8$: 492.1784, found: 492.1784.

Preparation of C. roseus *cell-free extract (CFE)*

Catharanthus roseus (AC 3 line) cell suspension culture was grown in shake flasks in the dark in a 1B5 medium (54) (500 mL) containing agar (7–8 g) at pH 5.5. The cell line was subcultured every 10 days using a 12% (60 mL) inoculum and harvested at age 11 days. The whole cell suspension was filtered with Miracloth, drained thoroughly, washed with water (75 mL/flask), and drained again. The rest of the procedure was carried out at 0–4°C. Potassium phosphate buffer (0.100 M, pH_h, 0.50 mL/g fresh weight) was added and the suspension homogenized with an Ultra-Turrax blender at 20 000 rpm in four 30-s periods with 30-s intervals. The material was centrifuged, using a Sorvall RC-5B centrifuge and Sorvall GSA rotor, at 10 000 g for 30 min and the supernatant (CFE) analyzed for peroxidase activity (55) and protein concentration (41,42,56) using a Bausch and Lomb Spectronic 20 spectrophotometer.

Determination of hydrogen peroxide consumption by C. roseus *CFE*

An aliquot (3.00 mL) of a solution of **7** (15.3 mg, 39.3 μmol) in ethanol/water (8:17, v/v) was added to water (3.00 mL) and hydrogen peroxide (1.00 mL, 81.6 mM solution, 81.6 μmol). Potassium phosphate buffer (0.100 M, pH 6.3, 10.70 mL) and CFE (pH 6.3, specific activity 0.98 units/mg, 7.30 mL, 9.83 units) were added and the solution (Solution A) stirred for 3 h. An identical solution of water, hydrogen peroxide, buffer, and CFE was stirred for 15 min upon the addition of CFE: an aliquot of **7** was then added as before and the solution (solution B) stirred for an additional 3 h. After each solution had been stirred 1 h following addition of **7**, hydrogen peroxide (1.00 mL, 81.6 μmol) was added to Solution B and water (1.00 mL) to Solution A. HPLC analysis was then performed.

*(±)-1-(3,5-Dimethoxy-4-hydroxyphenyl)-6-hydroxy-3-hydroxymethyl-7-methoxy-1,2,3,4-tetrahydro-2-naphthoic acid γ lactone **9**; (±-5,5′-bis(1-(3,5-dimethoxy-4-hydroxyphenyl)-6-hydroxy-3-hydroxymethyl-7-methoxy-1,2,3,4-tetrahydro-2-naphthoic acid γ lactone (**10**), and (±)-1-(3,5-dimethoxy-4-hydroxyphenyl)-8-hydroxy-3-hydroxymethyl-7-methoxy-1,2,3,4-tetrahydro-2-naphthoic acid γ lactone (**11**)*

Catharanthus roseus CFE (pH 6.3, specific activity 1.5 units/mg, 215 mL, 330 units) was added to a solution containing butanolide **7** (1.860 g, 4.79 mmol) in ethanol (25 mL), water (100 mL), and hydrogen peroxide (20 mL, 0.17 M solution, 3.4 mmol). After stirring for 1 h, further hydrogen peroxide (10 mL, 1.7 mmol) was added and stirring continued for an additional 4.5 h. The reaction mixture was diluted with dichloromethane (500 mL), filtered through Celite, and the organic extract dried over anhydrous magnesium sulfate. The dichloromethane extract was purified by column chromatography using acetone/dichloromethane (1:4–1:0, v/v) to afford aryltetralin **9** (901 mg, 48%), dimer **10** (680 mg, 37%), and aryltetralin **11** (9.8 mg, 0.53%).

Physical properties of **9**: mp 240–241°C (chloroform); IR ν_{max} ($CHCl_3$): 3530, 1778 cm^{-1}; UV λ_{max} (log ε): 282 (3.53) nm; ^1H NMR δ: 2.47 (1H, dd, H(2), J = 14, 11 Hz), 2.59 (1H, m, H(3)), 2.90 (1H, br dd, H(4), J = 15, 11 Hz), 2.97 (1H, dd, H(4), J = 14, 5 Hz), 3.64 (3H, s, $-OCH_3$(7)), 3.85 (6H, s, $-OCH_3$(3″)), 3.98 (1H, dd, H(11), J = 11, 8 Hz), 4.07 (1H, br d, H(1), J = 11 Hz), 4.52 (1H, dd, H(11), J = 11, 7 Hz), 5.43, 5.51 (1H each, s, s, -OH(4′), -OH(6)), 6.34, 6.70 (1H each, s, s, H(5), H(8)), 6.45 2H, s, H(2′)). Both hydroxyl signals disappear upon addition of D_2O. ^{13}C NMR δ: 32.661 (C(4)), 40.68(−), 47.037(−), 48.544(−), 56.106(−), 56.558(−), ($-OCH_3$(3′)), 71.384 (C(11)), 107.810(−) C(2′)), 113.754(−), 115.696(−), 115.777(−), 176(C(1)). MS m/z: 386 (M^+), 232, 167, 154, 139. High-resolution molecular weight determination calcd. for $C_{21}H_{22}O_7$: 386.1366; found: 386.1366. Anal. calcd. for $C_{21}H_{22}O_7$: C 65.28, H 5.74; found: C 65.12, H 5.72. Circular dichroism analysis: no Cotton effect observed for 0.208 nM methanol solution (250–320 nm). A sample crystallized from chloroform/dichloromethane (1:1, v/v) by slow evaporation was submitted for X-ray analysis. The X-ray data are attached as an Appendix 1.

Physical properties of **10**: mp 156–168°C; IR ν_{max} ($CHCl_3$): 3540, 1780 cm^{-1}; ^1H NMR δ: 2.40–2.52 (3H, m, H(2) (twice), H(4)), 2.55–2.68 (2H, m, H(3)), 2.90 (1H, br dd, H(4), J = 14, 13 Hz), 2.98 (1H, dd, H(4), J = 14, 4 Hz), 3.48–3.55 (1H, m, H(4)), 3.61 (3H, s, OCH_3(7)), 3.67, 3.67 (3H total, s, s, $-OCH_3$(7)), 3.75 (6H, s, $-OCH_3$(3′)), 3.83, 3.83 (6H total, s, s, $-OCH_3$(3′)), 3.95–4.03 (2H, m, H(11)), 4.14 (2H, br d, H(1), J = 12 Hz), 4.48–4.56 (2H, m, H(11)), 5.44, 5.55, 6.02, 6.05 (4H total, s, s, s, s, -OH), 6.18 (1H, s, -OH(6)), 6.36, 6.36 (1H total, s, s, H(8)), 6.45 (2H, br s, H(2′)), 6.51 (2H, br s, H(2′)), 6.73 (1H, s, H(8)). All hydroxyl signals disappear upon addition of D_2O. DCI MS m/z: 788 (83 + $NH_4)^+$, 404. EI MS m/z: 770 (M^+), 400, 386, 167, 154.

Physical properties of **11**: ^1H NMR δ: 2.36 (1H, m, H(2)), 2.59–2.74 (2H, m, H(3), H(4)), 3.08 (1H, dd, H(4), J = 16, 2 Hz), 3.60 (3H, s, $-OCH_3$), 3.74 (1H, d, H(1), J = 11 Hz), 3.80, 3.89 (3H each, s, s, $-OCH_3$), 4.09 (1H, dd, H(11), J = 10, 9 Hz), 4.61 (1H, dd, H(11), J = 10, 7 Hz), 5.38, 5.43 (1 H each, s, s, -OH(6),

-OH(4′)), 5.56, 6.09 (1H each, d, d, H(2′), H(6′), J = 2.5 Hz each), 6.77, 6.85 (1H each, d, d, H(5), H(6), J = 8 Hz each); MS m/z: 386 (M^+), 154, 139. High-resolution molecular weight determination calcd. for $C_{21}H_{22}O_7$: 386.1366; found: 386.1373.

Attempted biotransformation of trans-*2-(3,5-dimethoxy-4-hydroxybenzyl)-3-(3-hydroxy-4-methoxybenzyl)butanolide (7) without hydrogen peroxide*

Catharanthus roseus CFE (ph 6.3, specific activity 2.5 units/mg, 30.4 mL, 47 units) was added to a solution containing butanolide **7** (61.0 mg, 2.32 mmol), ethanol (3.8 mL), potassium phosphate buffer (0.100 M, pH 6.3, 43.0 mL), and water (20.2 mL). The solution was stirred for 3 h and extracted by the above procedure to afford butanolide **7** (59.3 mg, 97% recovery), which was pure by ^{1}H NMR spectroscopy.

Attempted dimerization of 1-(3,5-dimethoxy-4-hydroxyphenyl)-6-hydroxy-3-hydroxymethyl-7-methoxy-1,2,3,4-tetrahydro-2-naphthoic acid γ lactone (9) without CFE

Aryltetralin **9** (15.2 mg, 39.3 μmol) was dissolved in a solution of ethanol (7.3 mL), water (6.7 mL), hydrogen peroxide (2.16 mL, 81.6 mM solution, 1.76 mmol), and potassium phosphate buffer (0.100 M, pH 6.3, 8.9 mL). The solution was stirred for 17 h and analyzed by HPLC; no products were detected.

(±)-2-Hydroxy-8-hydroxymethyl-6,7,8,9-tetrahydro-3,3′,5′-trimethoxyspiro [5H-benzocycloheptene-5,1′-cyclohexa-2′,5′-dien]-4′-one-7-oic acid γ lactone (12)

Catharanthus roseus CFE (pH 6.3, specific activity 2.5 units/mg, 450 mL, 690 units), was added to a solution containing butanolide **7** (900 mg, 2.32 mmol), ethanol (90 mL), water (150 mL), and hydrogen peroxide (30 mL, 0.17 M solution, 5.1 mmol). The solution was stirred for 3 h and extracted by the standard procedure. The dichloromethane extract was purified by column chromatography using ethyl acetate/chloroform (1:4–9:11, v/v) to afford aryltetralin **9** (633 mg, 71%), butanolide **7** (56 mg, 6%), and spirodienone **12** (9.7 mg, 1.1%).

Physical properties of 12: mp 225–230°C; IR ν_{max} ($CHCl_3$): 3539, 1774, 1673 cm^{-1}; UV λ_{max} (log ε): 272 (3.83) nm; ^{1}H NMR δ: 2.03 (1H, dd, H(6), J = 13.3, 12.8 Hz), 2.32 (1H, dd, H(6), J = 13.7, 2.6), 2.32–2.44 (1H, m, H(8)), 2.68 (1H, ddd, H(7), J = 12.6, 12.6, 2.6 Hz), 2.97 (1H, dd, H(9), J = 15, 2.3 Hz), 3.07 (1H, dd, H(9), J = 14, 10.9 Hz), 3.65 (3H, s, -OCH_3(3)), 3.79, 3.84 (3H each, s, s, -OCH_3(3′), -OCH_3(5′)), 3.98 (1H, dd, -CH_2OCO-, J = 9, 8.4 Hz), 4.51 (1H, dd, -CH_2OCO-, J = 9, 7.6 Hz), 5.55 (1H, br s, -OH(2), disappears upon addition of D_2O), 6.13, 6.25 (1H each, d, d, H(2′), H(6′), J = 2.8 Hz each), 6.78, 6.92 (1H each, s, s, H(1), H(4)). Irradiation of H(7) collapses H(6) signals to doublets (J = 13.6 Hz each) and simplifies H(8) multiplet. MS m/z: 386 (M^+). High-resolution molecular weight determination calcd. for $C_{21}H_{22}O_7$: 386.1366; found: 386.1362.

Control experiment with butanolide 20

Butanolide **20** (4.20 mg, 10.8 μmol) was dissolved in a solution of ethanol (0.28 mL), water (0.87 mL), and potassium phosphate buffer (0.100 M, pH 7.0, 5.16 mL). Hydrogen peroxide (0.28 mL, 81.6 mM solution, 23 μmol) was added and the solution was stirred for 10 min prior to being extracted with ethyl acetate (2 × 50 mL). The organic extract was dried over magnesium sulfate, filtered, and evaporated *in vacuo*. The product (4.01 mg, 95% recovery) was found to be pure butanolide **7** by ^{1}H NMR spectroscopy and TLC.

*Biotransformation of (±)-*trans-*2-(3,5-dimethoxy-4-hydroxybenzyl)-3-(3,4-dihydroxy-α-hydroxybenzyl)butanolide (20)*

Hydrogen peroxide (4.58 mL, 81.6 mM solution, 0.37 mmol) and *C. roseus* CFE (pH 7.0, specific activity 0.51 units/mg, 22.1 mL, 150 units) were added in rapid succession to a solution containing butanolide **20** (73.2 mg, 0.187 mmol), ethanol (4.6 mL), water (14.5 mL), and phosphate buffer (0.100 M, pH 7.00, 63.7 mL). The solution turned dark purple within 1 min. After 10 min of stirring, ethyl acetate (80 mL) and Celite were added and the suspension was stirred vigorously for an additional 5 min and then filtered. Additional ethyl acetate (320 mL) was added and the phases were separated. The organic extract was dried over magnesium sulfate, filtered, and evaporated *in vacuo* to yield a brown solid (60.3 mg). The aqueous residue was subjected to a continuous extraction with ethyl acetate for 2 days. The organic extract was dried over magnesium sulfate, filtered, and evaporated *in vacuo* to afford a brown solid (7.6 mg), which was combined with the previous ethyl acetate extract. The aqueous residue was evaporated *in vacuo* and stirred in refluxing methanol (100 mL) for 16 h. The suspension was filtered while hot and evaporated *in vacuo* to yield brown solids (205.1 mg).

Reduction of ethyl acetate extract (Entry 1, Table 3): (±)-4-(3,4-dihydroxyphenyl)-5,7-dimethoxy-6-hydroxy-2-hydroxymethyl-1,2,3,4-terahydro-2-naphthoic acid γ lactone (26)

A sample of the ethyl acetate extract from the above experiment (Scheme 5, Entry 1, Table 3) (15.47 mg) was dissolved in a mixture of methanol (5 mL) and water (1 mL). Sodium borohydride (1.6 mg, 42 μmol) was added, resulting in an instantaneous color change of the solution from reddish-brown to yellow. After stirring for 5 min, 2 M hydrochloric acid (2 drops) was added, followed by water (2 mL) and brine (1 mL). The mixture was extracted with ethyl acetate (30 mL) and the organic extract was dried over magnesium sulfate, filtered, and evaporated *in vacuo* to afford a brown oil (16.62 mg). Purification by preparative TLC using acetone/dichloromethane (2:3, v/v) gave the aryltetralin **26** (2.23 mg, 14.0%) and **20** (2.06 mg, 12.3%).

Methylation of ethyl acetate extract (Entry 2, Table 3): (±)-2-(3,5-dimethoxy-4-hydroxybenzyl)-3-(3-hydroxy-4-methoxybenzyl-α-hydroxy)butanolide (27a) and (±)-2-(3,5-dimethoxy-4-hydroxybenzyl)-3-(4-hydroxy-3-methoxybenzyl-α-hydroxy)butanolide (27b)

Diazomethane in ethereal solution (approximately 0.4 M) was added to a sample of the ethyl acetate extract from the above experiment (23.19 mg) dissolved in dry methanol (5 mL) until no further effervescence was observed. After stirring for 22 h, aqueous acetic acid (10%, 2 drops) was added and the solution evaporated *in vacuo*. The residue was purified by preparative TLC using acetone/dichloromethane (1:4, v/v) to yield **20** (3.66 mg, 15%) and **27***a* and **27***b* (2.38 mg, 9%, 1:1 mixture of isomers by ^{1}H NMR spectroscopy).

Physical properties of **27***a* and **27***b*: IR ν_{max} ($CHCl_3$): 3600, 3540, 1770 cm^{-1}; ^{1}H NMR δ: 2.64–2.85, 2.85–3.02 (8H total, m, m, H(2), H(3), H(7″)), 4.02–4.15 (4H, m, H(4)), 4.72 (1H, d, H(7′), J = 5.1 Hz), 4.76 (1H, d, H(7′), J = 5.1 Hz), 6.39 (2H, s, H(2″)), 6.40 (2H, s, H(2″)), 6.70–6.92 (6H, m, H(2′), H(5′), H(6′)); EI MS m/z: 418 (M^+), 400, 181, 167, 153. High-resolution molecular weight determination calcd. for $C_{22}H_{26}O_8$: 418.1628; found: 418.1633.

Reduction and methylation of ethyl acetate extract (Entry 3, Table 3): (±)-4-(3,4-dimethoxyphenyl)-3-hydroxymethyl-1,2,3,4-tetrahydro-5,6,7-trimethoxy-2-naphthoic acid γ lactone (28) and unidentified compound (29)

Sodium borohydride (42 mg, 1.1 mmol) was added to a sample of the ethyl acetate extract from the above experiment (26.94 mg) dissolved in a mixture of methanol (4.5 mL) and water (0.5 mL) and the bright yellow solution was stirred at room temperature for 1 h. The solution was acidified with 1 M hydrochloric acid, and water (5 mL) and brine (2 mL) were added. The solution was extracted with ethyl acetate (2 × 60 mL) and the extract was dried over magnesium sulfate, filtered, and evaporated *in vacuo* before

For personal use only.

being redissolved in ethanol (5 mL). Freshly prepared ethereal diazomethane (approximately 0.3 g, 7 mmol) was added and the solution stirred for 15 h. Aqueous acetic acid (10%, 0.2 mL) was added and the solution evaporated *in vacuo* to afford a yellow oil (67.5 mg), which was separated by column chromatography using acetone/dichloromethane (1:19 to 1:0 gradient, v/v) to afford 42.92 mg (64%) of eluted products, including **29** (8.56 mg, 25%) and **28** (6.00 mg, 20%). The column packing was removed and stirred in a mixture of acetate (50 mL), water (30 mL), and calcium carbonate (700 mg) at 45°C for 1 h. The mixture was acidified with 2 M hydrochloric acid and the solids filtered and washed with warm acetone (2 × 30 mL). The filtrate was evaporated *in vacuo* and the final traces of silica removed to afford a yellow oil (12.27 mg, no identifiable material by ^{1}H NMR spectroscopy) for a total column recovery of 82%.

Physical properties of **28**: IR ν_{max} ($CHCl_3$): 1770 cm^{-1}; ^{1}H NMR δ: 2.29–2.74 (2H, m, H(2),H(3)), 2.97–3.09 (1H, m), 3.14 (3H, s, -OCH_3(5)), 3.37 (1H, dd, J = 7.0, 6.6 Hz), 3.5–3.6 (1H, m), 3.69–3.91 (12H, m, -OCH_3), 4.04–4.18 (1H, m), 4.22 (1H, br d, H(4), J = 8.0 Hz), 6.60 (1H, m, H(6')), 6.72–6.84 (2H, m, m H(2'), H(8)), 6.90 (1H, d, H(5'), J = 8 Hz); EI MS m/z: 414 (M^+), 400, 181, 151, 137. High-resolution molecular weight determination calcd. for $C_{23}H_{26}O_7$: 414.1679; found: 414.1678.

Physical properties of **29**: IR ν_{max} ($CHCl_3$): 3320, 2970, 2940, 2870, 1670 cm^{-1}; MS m/z: 432 ($M^+ - H_2O$?), 418, 282, 167.

Methylation of methanol extract (Scheme 5)

Diazomethane in ethereal solution (approximately 0.4 M) was added to a sample of the methanol extract obtained from the above experiment and, in accord with Scheme 5 (90.82 mg), dissolved in dry methanol (10 mL) until no further effervescence was observed. The yellow solution was stirred overnight. Analysis by silica TLC showed no new spots in comparison with the initial methanol extract. In both cases no spots with an R_f value greater than zero were observed using acetone/dichloromethane (1:4, v/v).

Reduction and methylation of methanol extract (Scheme 5)

Sodium borohydride (137 mg, 3.6 mmol) was added to a sample of the methanol extract obtained from the above experiment (108.65 mg) dissolved in a mixture of methanol (9 mL) and water (1 mL) and the solution was stirred at room temperature for 1 h. The solution was acidified with 1 M hydrochloric acid, and water (5 mL) and brine (2 mL) were added. The solution was extracted with ethyl acetate (3 × 60 mL) and the extract was dried over magnesium sulfate, filtered, and evaporated *in vacuo* before being redissolved in dry THF (10 mL). Potassium carbonate (180 mg, 1.3 mmol) and methyl iodide (0.5 mL, 8 mmol) were added and the solution stirred for 1 h. Water (2 mL) was added and the mixture acidified with 2 M hydrochloric acid before being extracted with ethyl acetate (2 × 20 mL). The organic extract was dried over magnesium sulfate, filtered, and evaporated *in vacuo* to afford brown solids (43.9 mg). Sonication in dichloromethane followed by filtration and evaporation *in vacuo* gave tan solids (5.35 mg), which exhibited no aromatic proton signals by ^{1}H NMR spectroscopy.

Appendix: X-ray crystallographic analysis of compound 9

Experimental

Crystallographic data appear in Table A1. The final unit-cell parameters were obtained by least squares on the setting angles for 25 reflections with 2θ = 79.5–91.1°. The intensities of three standard reflections, measured every 150 reflections throughout the data collection, remained essentially constant. The data were processed[2] and corrected for Lorentz and polarization effects, and absorption (empirical, based on azimuthal scans for four reflections).

The structure was solved by direct methods, the coordinates of the non-hydrogen atoms being determined from an E-map. There is one molecule of chloroform in the asymmetric unit along with the molecule of **9**. The non-hydrogen atoms were refined with anisotropic thermal parameters, the OH hydrogen atoms were refined with isotropic thermal parameters, and the remaining hydrogen atoms were fixed in calculated positions (C—H = 0.98 Å, $B_H = 1.2\ B_{bonded\ atom}$). Neutral atom scattering factors and anomalous dispersion corrections for the non-hydrogen atoms were taken from the *International tables for X-ray crystallography* (57). Final atomic coordinates and equivalent isotropic thermal parameters, bond lengths, bond angles, and hydrogen-bond data appear in Tables A2-A5, respectively. Hydrogen atom parameters, anisotropic thermal parameters, bond lengths and angles involving hydrogen, torsion angles, packing dia-

Discussion of crystal structure

The crystal structure of **9** · $CHCl_3$ is dominated by weak hydrogen bonding. The two hydroxyl hydrogen atoms (H(1) and H(1′)) and the chloroform hydrogen atom (H(14)) are each involved in bifurcated hydrogen bonding arrangements (see Table A5). H(1) is intramolecularly H-bonded to O(3) and intermolecularly H-bonded along the *c* axis to O(1). H(1′) is similarly hydrogen-bonded, intramolecularly to O(3′) and intermolecularly to O(1′) of a molecule related by the twofold screw axis along *b*. The chloroform solvate molecule is linked by a pair of C—H···O hydrogen bonds to O(1′) and O(2′) of the same molecule. The molecule **9** is shown in Fig. 1. The junction between the five-membered lactone ring and the central six-membered ring is *trans*. The lactone ring has a C(3)-envelope conformation and the central cyclohexene ring has C(2) and C(3) displaced in opposite directions from the plane defined by C(1), C(8a), C(4a), and C(4). The bulky 4-OH-3,5-$(OMe)_2$-C_6H_2 substituent at C(1) occupies a pseudo-equatorial position. The two aromatic rings are planar to within experimental error. Bond lengths and angles (Tables A3 and A4) are as expected.

Phosphonolipids. 3. Phosphonic acid analogues of phosphatidylinositol and related materials[1,2]

CLIFFORD PRATT, YUE-JIN LIU, TING-YI CHU, KARIN MELKONIAN, BURTON E. TROPP, AND ROBERT ENGEL[3]

Department of Chemistry and Biochemistry, Queens College of the City University of New York, Flushing, NY 11367, U.S.A.

Received February 6, 1992

CLIFFORD PRATT, YUE-JIN LIU, TING-YI CHU, KARIN MELKONIAN, BURTON E. TROPP, and ROBERT ENGEL. Can. J. Chem. **70**, 2135 (1992).

A convergent synthesis of an isosteric phosphonic acid analogue of phosphatidylinositol has been accomplished in which a non-hydrolyzable P—C—C linkage is present in place of the normal P—O—C esteric linkage joining the phosphate and diacylglycerol portions of the molecule. The synthetic route used provides the configuration at each stereogenic center to correspond to that present in the biologically generated phospholipid. In addition, the approach provides asymmetric introduction of acyl functions, placing saturated and unsaturated acyl groups in the terminal and internal positions respectively of the backbone portion of the analogue, corresponding to that present in the biologically generated phospholipid.

CLIFFORD PRATT, YUE-JIN LIU, TING-YI CHU, KARIN MELKONIAN, BURTON E. TROPP et ROBERT ENGEL. Can. J. Chem. **70**, 2135 (1992).

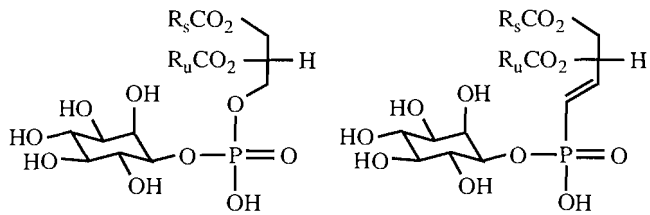
On a réalisé une synthèse convergente d'un acide phosphonique isostère analogue du phosphatidylinositol dans lequel on rencontre une liaison P—C—C à la place de la liaison normale P—O—C de l'ester qui relie les portions phosphate et diacylglycérol de la molécule. La voie de synthèse utilisée permet d'établir que la configuration de chacun des centres stéréogènes correspond à celle qui est présente dans la phospholipide généré d'une façon biologique. De plus, cette approche permet d'introduire des fonctions acyles d'une façon asymétrique, plaçant des groupes saturés et insaturés respectivement dans les positions terminales et internes du squelette de l'analogue, comme on les retrouve dans le phospholipide généré d'une façon biologique.

[Traduit par la rédaction]

Introduction

Phosphoinositides have been the subject of intensive investigation in recent years owing to the recognition of their role for intracellular signalling in response to extracellular stimuli (3). Following the recognition of this biological role for phosphoinositides have come efforts toward the laboratory synthesis of not only phosphatidylinositol (a phosphate diester) (4), but of a variety of analogues designed to probe details of the mechanism of signalling and the potential for regulation of the biochemical processes involved (1, 5).

In the continuing effort of our laboratory concerning the synthesis and investigation of isosteric phosphonic acid analogues of biological phosphates (2, 6), the preparation of an analogue of phosphatidylinositol (**1**) that incorporates all but one of the functional and stereochemical characteristics of the biological material has been undertaken. The structural variation of this analogue (**2**), which is of particular interest and described herein, involves the introduction of a P—C—C linkage in place of the normal P—O—C linkage connecting the phosphate with the diacylglycerol backbone of phosphatidylinositol. In **2** the entire remaining structural elements have been maintained in correspondence with the biological material. Specifically, the configuration at each stereogenic site in **2**, both in the inositol and modified diacylglycerol portions, matches that of the corresponding site of the biological material. Further, the analogue **2** is generated with regiospecific disposition of the acyl groups, saturated (R_s) at the terminal position and unsaturated (R_u) at the internal position. This disposition is in accord with phosphatidylinositol exhibiting preferential interaction with phosphatidylinositol-specific phospholipase C (7).



1 **2**

The route used for the preparation of **2** is a convergent one, separate syntheses of the protected inositol and lipid portions being performed, followed by a coupling and final deprotection sequence. Two approaches are described for the synthesis of the lipid portion, itself an analogue of phosphatidic acid, these being a classical protection/deprotection route and a regioselective epoxide-opening procedure. The latter general approach has also been used for the preparation of a phosphonic acid analogue of PAF.[4]

The analogue **2**, bearing a non-hydrolyzable ester linkage in the phospholipid portion of the molecule, is anticipated to be of use in the investigation of phospholipase C mediated processes of phosphatidylinositol.

Results and discussion

The synthesis of the lipid component of **2**, an isosteric phosphonic acid analogue of phosphatidic acid, has been

SCHEME 2

accomplished by two routes. The first of these, involving a classical approach of protection/deprotection, is illustrated in Scheme 1.

Standard procedures were used for the conversion of D-mannitol to **3**, including the initial protection and cleavage to D-glyceraldehyde acetonide (8), the preparation of the tetraisopropyl methylenebisphosphonate (9), and its use for the synthesis of the diisopropyl (*R*)-(*E*)-3,4-dihydroxybut-1-enyl-1-phosphonate (10).

Selective protection of the terminal hydroxyl group of **3** was accomplished using a 3% excess of *tert*-butyldimethylsilyl chloride with imidazole. Small amounts of the internally silylated and disilylated product were removed easily using flash chromatography.

The verification of the position of silylation in **4** was accomplished by the preparation of a derivative and examination of its ^{1}H NMR spectrum. In the 200 MHz ^{1}H NMR spectrum of **3** the signals for the hydrogens attached to C-3 and C-4 were virtually indistinguishable, appearing as a multiplet at δ 3.7 and integrating for three hydrogens. A sample of the material **4** was acetylated using acetic anhydride to give **8** in nearly quantitative yield (Scheme 2).

The acetate **8** exhibited a downfield shift (to δ 5.3) for a one-hydrogen multiplet corresponding to the C-3 hydrogen while a two-hydrogen multiplet remained at δ 3.7. Differentiation of sites of acylation on a phosphonate lipid backbone have been noted previously by similar shifts for related systems, the differentiation having been confirmed by specific enzymatic action (11).

The material **4** was acylated using oleoyl chloride in pyridine with 4-(dimethylamino)pyridine (DMAP) at 0°C, conditions slightly modified from those known not to permit significant acyl migration (12). Deprotection of the terminal hydroxyl group was performed to generate **5** prior to complete structural and purity analysis. The ^{1}H NMR spectrum of **5** verified that no acyl migration had occurred during the work-up, exhibiting an upfield multiplet for the pair of hydrogens at C-4 and a downfield multiplet for the single hydrogen at C-3. Further acylation placing a saturated fatty-acyl function at the terminal hydroxyl position was accomplished, again using conditions known not to permit significant acyl migration, and cleavage of the phosphonate esters was accomplished using a standard procedure (13).

In light of the success demonstrated for the preparation of symmetric-chain glycerophospholipids starting with optically active glycidyl tosylate (14), an alternative synthesis of **6**, and subsequently **7**, was developed as illustrated in Scheme 3.

The generation of the epoxide **9** from the diol **3** was accomplished in a two-step procedure, the tosylate being formed first, followed by intramolecular displacement to effect ring closure. Although IR and NMR spectra could be obtained which were in accord with the proposed structures of the tosylate and epoxide **9** species, these compounds proved too reactive for storage or satisfactory elemental analysis and were used immediately upon isolation in continuing reactions. Regiospecific ring opening was accomplished using a modification of the previously reported technique (14) facilitated by boron trifluoride etherate. The ^{1}H NMR spectrum of **10** verified the introduction of the acyl function at the terminal position of the chain. (The regiospecificity of this type of reaction has been in-

SCHEME 4

vestigated and is to be published separately.[5]) Finally, **10** was acylated at the internal position using a procedure known not to involve acyl migration in structurally related systems (12). The materials **6** and **7** from the two approaches were identical.

Once prepared, the analogue **7** of phosphatidic acid was ready for coupling with a suitably protected, optically active derivative **11** of inositol for the generation of the target material **2**. The overall route for the preparation of the protected inositol **11** is one that involves modifications of inositol-related and allyl ether cleavage processes previously reported (15–17) and is outlined in Scheme 4.

Resolution of the pentabenzyl-*myo*-inositol is accomplished by the generation of a diastereoisomeric ester mixture using (*S*)-camphanic acid chloride followed by separation of the diastereoisomers using HPLC. The synthesis of **2** is completed by the coupling of **11** with the independently prepared **7** and deprotection as shown in Scheme 5.

[5]Y.-j. Liu and R. Engel, unpublished results of this laboratory.

The use of (*S*)-camphanic acid chloride for the resolution of 2,3,4,5,6-penta-*O*-benzyl-*myo*-inositol has been discussed recently (18). The coupling using trichloroacetonitrile is an adaptation of a procedure used previously in this laboratory and elsewhere (19). The deprotection using iodotrimethylsilane (20) rapidly cleaves benzyl ether linkages selectively compared to other ether linkages and ester linkages, liberating the target material without reduction of the olefinic linkages.

This procedure represents the first preparation of a nominally isosteric phosphonic acid analogue of phosphatidyl inositol in which the esteric oxygen of the normal diacylglycerol backbone has been replaced by a carbon–phosphorus linkage.

Experimental

General

All chemicals were of reagent quality and used without further purification with the following exceptions: chloroform was distilled over phosphorus pentoxide; pyridine was dried over calcium hydride and distilled; dimethylformamide (DMF) was dried over

i. pyridine, trichloroacetonitrile, 50°C, 72 h (20% yield): ii. chloroform, iodotrimethylsilane, 20 min (85% yield).

SCHEME 5

molecular sieves 4A prior to use; oleoyl chloride (commercial source) was kept in the sealed ampoule until immediately prior to use; methanol for chromatographic purposes was distilled prior to use.

(*S*)-(*E*)-3,4-Dihydroxybut-1-enylphosphonic acid diisopropyl ester (**3**) and its precursors were prepared as previously described (10). Racemic 1-*O*-allyl-2,3,4,5,6-tetra-*O*-benzyl-*myo*-inositol and its precursors were prepared as previously described (15). Thin-layer chromatography (TLC) was performed using Polygram Sil N-HR sheets (Brinkmann)(PS) or Kodak Chromagram sheets (Eastman) (KC). Silica gel for flash chromatography was from EM Science (230–300 mesh). HPLC was performed using a Waters 6000A instrument with either a Lichrosorb Si60 (10 μm) column or a Bakerbond Chiral DNBPG (Coval) (5 μm) column. Infrared spectra were measured using a Perkin–Elmer 1600 FTIR instrument, and ^{1}H NMR spectra were measured using an IBM–Bruker WP200SY instrument. Optical rotations were measured using a JASCO DIP-140 digital polarimeter. Elemental analyses were performed by Desert Analytics of Tucson, Arizona, and by Schwarzkopf Microanalytical Laboratories of Woodside, New York.

Preparation of (S)-(E)-*4*-tert-*butyldimethylsiloxy-3-hydroxybut-1-enylphosphonic acid diisopropyl ester (4)*

The (*S*)-(*E*)-3,4-dihydroxybut-1-enylphosphonic acid diisopropyl ester (**3**)(16.14 g, 64 mmol) was dissolved in dry DMF (200 mL) and there was added to it with stirring at room temperature *tert*-butyldimethylsilyl chloride (9.96 g, 66 mmol) and imidazole (10.90 g, 160 mmol). The reaction mixture was stirred at room temperature for 72 h after which time the volatile materials were evaporated under reduced pressure. Water (150 mL) was added to the residue and the aqueous solution was extracted with ethyl acetate (3 × 200 mL). The extracts were combined, dried over calcium chloride, filtered, and volatile materials were evaporated under reduced pressure. The residue was subjected to flash chromatography on a silica gel column (120 g, 5 cm diameter) packed with methylene chloride. The elution of the column was performed with the following order of solvents: 525 mL methylene chloride; 375 mL 1:1 methylene chloride:chloroform; 75 mL chloroform; 150 mL chloroform:ethyl acetate; 775 mL ethyl acetate. Fractions from the ethyl acetate portion of the elution exhibiting a single spot of R_f = 0.67 on TLC (KC, ethyl acetate) as visualized with phosphomolybdate spray reagent were combined to give the pure desired material (15.48 g, 0.042 mol, 66%), which exhibited IR and NMR spectra in accord with the proposed structure (**4**). Specific rotation: $[\alpha]_D$ −34.0 (0.16 M, ethanol). The ^{1}H NMR ($CDCl_3$) exhibited the following signals: δ 0.1, singlet, 6H; δ 0.9, singlet, 9H; δ 1.4, doublet of doublets, 12H; δ 3.5–3.9, multiplet, 3H; δ 4.3, broad, 1H; δ 4.7, multiplet, 2H; δ 5.8–7.5, multiplet, 2H. Anal. calcd. for $C_{16}H_{35}O_5PSi$: C 52.43, H 9.62%; found: C 52.46, H 9.69%. A small amount of material eluted immediately prior to the desired material and exhibited ^{1}H NMR and IR spectra indicating it to be the result of silylation at both hydroxyl groups of the starting diol.

Preparation of (S)-(E)-*4*-tert-*butyldimethylsiloxy-3-acetoxybut-1-enylphosphonic acid diisopropyl ester (8)*

A sample of **4** (100 mg, 0.27 mmol) was dissolved in acetic anhydride (10 mL) and heated at 100°C for 4 h. After this time all volatile materials were removed under reduced pressure. The solid residue was found to exhibit a single spot of R_f = 0.15 on TLC (KC, chloroform) visualized with phosphomolybdate spray reagent. This material exhibited IR and ^{1}H NMR spectra in accord with the proposed structure (**8**) (112 mg, 98.5%). Specific rotation: $[\alpha]_D$ −1.1 (0.054 M, ethanol). The ^{1}H NMR ($CDCl_3$) spectrum exhibited the following signals: δ 0.1, singlet, 6H; δ 0.9, singlet, 9H; δ 1.4, doublet of doublets, 12H; δ 2.2, singlet, 3H; δ 3.7, multiplet, 2H; δ 4.4, multiplet, 2H; δ 4.7, multiplet, 1H; δ 5.8–7.5, multiplet, 2H. Anal. calcd. for $C_{18}H_{37}O_6PSi$: C 52.92, H 9.13%; found: C 53.22, H 9.19%.

Preparation of (S)-(E)-*4-hydroxy-3-oleoyloxybut-1-enylphosphonic acid diisopropyl ester (5)*

The material (**4**) (2.16 g, 5.89 mmol) was dissolved in chloroform (40 mL) and cooled to 0°C in an ice bath. There was then added to it pyridine (0.9 g, 11.38 mmol) and a catalytic amount of 4-dimethylaminopyridine (0.050 g) followed by a solution of oleoyl chloride (2.95 g, 9.8 mmol) in chloroform (5 mL). The reaction mixture was allowed to come to room temperature and was stirred for 4 days. The volatile materials were then removed under reduced pressure, the residue was dissolved in tetrahydrofuran (10 mL), and there was added tetrabutylammonium fluoride (0.7 g, 3.23 mmol) and the reaction mixture was stirred at room temperature for 12 h. Chloroform (100 mL) and water (50 mL) were then added and the mixture was stirred vigorously. The layers were separated and the aqueous layer was washed with chloroform (50 mL). The organic solutions were combined, dried over sodium sulfate, filtered, and volatile materials were removed under reduced pressure. The residue exhibited a single spot of R_f = 0.70 on TLC (KC, ethyl acetate) and IR and ^{1}H NMR spectra in accord with the proposed structure (**5**) (1.09 g, 36%). Specific rotation: $[\alpha]_D$ −1.6 (0.05 M, ethanol). The ^{1}H NMR ($CDCl_3$) spectrum exhibited the following signals: δ 0.9, broad triplet, 3H; δ 1.2–1.7, broad, 34H; δ 2.0, multiplet, 5H (including OH); δ 2.2, multiplet, 2H; δ 3.9, multiplet, 2H; δ 4.7, multiplet, 2H; δ 5.1, multiplet, 2H; δ 5.3, triplet, 1H; δ 5.8–7.5, multiplet, 2H. Anal. calcd. for $C_{28}H_{53}O_6P$: C 65.09, H 10.34%; found: C 64.89, H 10.51%.

Preparation of (S)-(E)-*3,4-epoxybut-1-enylphosphonic acid diisopropyl ester (9)*

The material (**3**) (2.0 g, 7.93 mmol) was dissolved in chloroform (7.8 mL) and cooled to 0°C with an ice bath. Pyridine (1.26 mL) was then added followed by *p*-toluenesulfonyl chloride

(2.22 g, 11.6 mmol) and the reaction mixture was stirred for 2 h. After this time ether (25 mL) and water (6 mL) were added to the reaction mixture. The organic layer was separated and washed with water (2 × 16 mL), dried over calcium chloride, filtered, and the volatile materials were removed under reduced pressure. The ^{1}H NMR ($CDCl_3$) of the crude material (2.2 g) indicated the desired material to be present, exhibiting the following signals: δ 1.4, doublet of doublets, 12H; δ 2.2, broad, 1H; δ 2.5, singlet, 3H; δ 3.5–3.9, multiplet, 3H; δ 4.8, multiplet, 2H; δ 5.8–7.5, multiplet, 2H; δ 7.8 AA′BB′, 4H. The material exhibited one major spot of R_f = 0.25 on TLC (KC, 1:15 ethyl acetate:hexane) as visualized with phosphomolybdate spray reagent and was used without further purification. The isolated tosylate (2.2 g) was dissolved in methanol (24 mL) under nitrogen and potassium carbonate (0.98 g, 7.08 mmol) was added. The reaction mixture was stirred for 2 h at −10°C. After this time ether (24 mL) was added and the mixture was filtered twice through a pad of silica gel. The crude material (1.41 g, 76%) exhibited one major spot of R_f = 0.59 on TLC (KC, ethyl acetate) visualized with phosphomolybdate spray reagent and IR and ^{1}H NMR spectra in accord with the proposed structure. The ^{1}H NMR ($CDCl_3$) spectrum exhibited the following signals: δ 1.4, doublet of doublets, 12H; δ 2.7, multiplet, 1H; δ 3.1, multiplet, 1H; δ 3.4, multiplet, 1H; δ 4.7, multiplet 2H; δ 6.0–7.8, multiplet, 2H. The material proved to be too reactive for storage or elemental analysis and was used immediately upon isolation.

Preparation of (S)-(E)-*3-hydroxy-4 stearoyloxybut-1-enylphosphonic acid diisopropyl ester (**10**)*

Stearic acid (0.34 g, 1.20 mmol), (*S*)-(*E*)-3,4-epoxybut-1-enylphosphonic acid diisopropyl ester (**9**) (0.28 g, 1.20 mmol), and boron trifluoride etherate (0.082 g, 1.20 mmol) in ether (total volume 11 mL) were stirred overnight at room temperature. Volatile materials were removed under reduced pressure and the residue was subjected to flash chromatography (20 g, 2 cm diameter) packed and eluted with chloroform. Fractions exhibiting a single spot of R_f = 0.18 on TLC (KC, chloroform) as visualized with phosphomolybdate spray reagent were combined to give the pure desired material (0.436 g, 70%) which exhibited IR and ^{1}H NMR spectra in accord with the proposed structure (**10**). The ^{1}H NMR ($CDCl_3$) exhibited the following signals: δ 0.9, triplet, 3H; δ 1.2, broad, 42H; δ 2.3, triplet, 2H; δ 3.3, broad, 1H; δ 3.7, multiplet, 1H; δ 4.1–4.9, multiplet, 4H; δ 5.8–7.6, multiplet, 2H. Analysis, $C_{28}C_{55}O_6P$ requires C 64.83%, H 10.69%; found: C 64.71%, H 10.82%. Specific rotation: $[\alpha]_D$ = 8.9 (0.176 M, chloroform).

Preparation of (S)-(E)-*3-oleoyloxy-4-stearoyloxybut-1-enylphosphonic acid diisopropyl ester (**6**)*

*Method A: from **5***

To (*S*)-(*E*)-4-hydroxy-3-oleoyloxybut-1-enylphosphonic acid diisopropyl ester (**5**)(1.66 g, 3.21 mmol) dissolved in chloroform (15 mL) cooled to 0°C with an ice bath was added pyridine (0.9 g, 11.38 mmol) with a catalytic amount of 4-dimethylaminopyridine (0.050 g). There was then added stearic anhydride (1.57 g, 5.52 mmol) under a nitrogen atmosphere and the reaction mixture was stirred for 3 days, being allowed to come to room temperature. The volatile materials were removed under reduced pressure and the residue was subjected to flash chromatography (20 g, 2 cm diameter) packed with chloroform and eluted with ethyl acetate. Fractions exhibiting a single spot of R_f = 0.33 on TLC (KC, ethyl acetate) as visualized with phosphomolybdate spray reagent were combined to give the pure desired material (1.71 g, 68%), which exhibited IR and NMR spectra in accord with the proposed structure (**5**). Specific rotation $[\alpha]_D$ 0.18 (0.2 M, ethyl acetate). The ^{1}H NMR ($CDCl_3$) exhibited the following signals: δ 0.9, broad, 6H; δ 1.3, broad, 64H; δ 1.8–2.5, multiplet, 8H; δ 4.1–5.1, multiplet, 5H; δ 5.3, triplet, 2H; δ 5.8–7.5 multiplet, 2H. Anal. calcd. for $C_{46}H_{87}O_7P$: C 70.55, H 11.20%; found: C 70.41, H 11.24%.

*Method B: from **10***

To (*S*)-(*E*)-3-hydroxy-4-stearoyloxybut-1-enylphosphonic acid diisopropyl ester (**10**) (160 mg, 0.305 mmol) in dry dimethyl formamide (2.5 mL) with pyridine (0.25 mL) and 4-dimethylaminopyridine (0.05 g) at 0°C was added oleic anhydride (0.2 g, 0.366 mmol). The reaction mixture was stirred and allowed to come to room temperature overnight. Volatile materials were removed under reduced pressure and the residue was subjected to flash chromatography (20 g, 2 cm diameter) packed with chloroform and eluted with ethyl acetate:chloroform 3:1. Fractions exhibiting a single spot of R_f = 0.33 on TLC (KC, ethyl acetate) as visualized with phosphomolybdate spray reagent were combined to give the pure desired material (201 mg, 84%), which exhibited IR and ^{1}H NMR spectra and optical rotations identical to those noted for **6** prepared in Method A as noted previously.

Preparation of (S)-(E)-*oleoyloxy-4-stearoyloxybut-1-enlyphosphonic acid (**7**)*

Under a nitrogen atmosphere (*S*)-(*E*)-3-oleoyloxy-4-stearoyloxybut-1-enylphosphonic acid diisopropyl ester (**6**) (0.70 g, 0.89 mmol) was added to diethyl ether (15 mL). To the solution was added dropwise bromotrimethylsilane (0.46 g, 3.0 mmol) and the resultant mixture was stirred at room temperature overnight. The reactant mixture was then washed with water (3 × 35 mL) and the organic layer was separated, dried over anhydrous sodium sulfate, filtered, and evaporated under reduced pressure. The resulting solid was recrystallized from a minimum volume of methanol and the precipitate was subjected to flash chromatography (20 g, 5 cm diameter) packed with chloroform and eluted with chloroform (200 mL) followed by ethyl acetate (4 × 200 mL). Fractions of the ethyl acetate eluent exhibiting a single spot of R_f = 0.14 on TLC (KC, chloroform) as visualized with phosphomolybdate spray reagent were combined to give the pure desired material (466 mg, 75%), which exhibited IR and ^{1}H NMR spectra in accord with the proposed structure (**7**). Specific rotation: $[\alpha]_D$ 1.42 (0.13 M, chloroform). The ^{1}H NMR ($CDCl_3$) exhibited the following signals: δ 0.9, broad triplet, 6H; δ 1.2, broad, 52H; δ 1.8–2.5, multiplet, 8H; 4.3–4.9, multiplet, 3H; δ 5.3, triplet, 2H; δ 5.8–7.5, multiplet, 2H; δ 11.5, singlet, 2H. Anal. calcd. for $C_{40}H_{75}O_7P$: C 68.73, H 10.82%; found: C 68.73, H 11.01%.

*Preparation of (±)-2,3,4,5,6-penta-*O*-benzyl-*myo*-inositol (±)-(**11**)*

The racemic 1-*O*-allyl-2,3,4,5,6-penta-*O*-benzyl-*myo*-inositol (4.38 g, 6.72 mmol) was dissolved in methanol (10 mL) to which water (10 mL) was added. There was then added 10% Pd/C (0.44 g) along with *p*-toluenesulfonic acid monohydrate (0.44 g) and the resulting mixture was heated at reflux for 24 h. Solid materials were removed by filtration and the volatile materials of the filtrate were removed under reduced pressure to leave an oily residue. This residue was partitioned between a water/ether mixture (80 mL of each) and the ether layer was collected, dried over anhydrous magnesium sulfate, filtered, and evaporated under reduced pressure. The oily residue was subjected to flash chromatography (40 g, 2 cm diameter) packed and eluted with chloroform:ether 50:1. Fractions exhibiting a single spot of R_f = 0.62 on TLC (PS, chloroform:ether 50:1) as visualized with iodine were combined to give the pure desired material (1.55 g, 38%) as a clear oil, which crystallized on standing to give white crystals that exhibited IR and ^{1}H NMR spectra in accord with the proposed structure and a melting point in agreement with that previously reported (15). The ^{1}H NMR ($CDCl_3$) exhibited the following signals: δ 2.05–2.46, broad singlet, 1H; δ 3.33–3.62, multiplet, 3H; δ 3.74–3.94, multiplet, 1H; δ 3.96–4.20 multiplet, 2H; δ 4.56–5.13, multiplet, 10H; δ 7.10–7.62, multiplet, 25H.

*Resolution of (±)-2,3,4,5,6-penta-*O*-benzyl-*myo*-inositol (±)-(**11**)*

The (±)-2,3,4,5,6-penta-*O*-benzyl-*myo*-inositol (1.55 g, 2.46 mmol) was dissolved in methylene chloride (37 mL) and to it was added DMAP (0.033 g, 0.27 mmol), triethylamine (0.75 g, 7.43 mmol), and (−)-camphanic acid chloride (0.64 g, 2.95 mmol). The reaction mixture was stirred at room temperature for 24 h, after which time it was washed with water (2 × 30 mL) and saturated

For personal use only.

aqueous sodium chloride solution (20 mL). It was then dried over anhydrous magnesium sulfate, filtered, and the volatile materials were evaporated under reduced pressure. The residual solid was subjected to flash chromatography (40 g, 2 cm diameter) packed and eluted using methylene chloride:ether 99:1. Material exhibiting R_f between 0.5 and 0.75 on TLC (PS, methylene chloride:ether 99:1) as visualized using iodine was separated into two components using HPLC (Lichrosorb Si-60 10 μm) eluting with methylene chloride:ether 99:1. In this way two components (less polar ester, R_f = 0.73, 1.03 g, and more polar ester, R_f = 0.60, 0.99 g, using the above noted TLC conditions) were isolated as pure materials, which exhibited IR and ^{1}H NMR spectra in accord with their proposed structures and which were separately subjected to hydrolysis. The ^{1}H NMR ($CDCl_3$) exhibited the following signals: (less polar ester) δ 0.83–0.96, singlet, 3H; δ 0.96–1.05, singlet, 3H; δ 1.05–1.19, singlet, 3H; δ 1.48–2.02, multiplet, 3H; δ 2.15–2.43, multiplet, 1H; δ 3.50–3.73, multiplet, 2H; δ 4.01–4.32, multiplet, 3H; δ 4.50–5.17, multiplet, 11H; δ 6.90–7.54, multiplet, 25H; (more polar ester) δ 0.74–0.90, singlet, 3H; δ 0.90–1.03, singlet, 3H; δ 1.03–1.22, singlet, 3H; δ 1.43–2.10, multiplet; 3H; δ 2.15–2.46, multiplet, 1H; δ 3.43–3.80, multiplet, 2H; δ 3.90–4.40, multiplet, 3H; δ 4.44–5.70, multiplet, 11H; δ 6.93–7.68, multiplet, 25H.

The more polar and less polar esters were each separately hydrolyzed using the procedure as described here for the more polar ester. The more polar ester (0.99 g, 1.22 mmol) was added to a 0.1 M solution of potassium by hydroxide in ethanol (100 mL) and the mixture was stirred at room temperature for 24 h. After this time the volatile materials were evaporated under reduced pressure and the residue was partitioned between ether:water 10:7 (170 mL). The layers were separated and the aqueous layer was extracted with ether (35 mL). The organic layers were combined, dried over magnesium sulfate, filtered, and volatile materials were evaporated under reduced pressure. The oily residue was subjected to flash chromatography (20 g, 2 cm diameter) packed and eluted with hexane:ether 1:3. The fractions exhibiting a single spot of R_f = 0.81 (PS, hexane:ether 1:3) were combined to give the pure desired material (0.725 g, 94.2%), which exhibited IR and ^{1}H NMR spectra in accord with the proposed structure (−)-(**11**). Specific rotation: $[\alpha]_D$ −9.0 (0.11 M, ethanol). The ^{1}H NMR ($CDCl_3$) exhibited the following signals: δ 2.02–2.26, broad doublet, 1H; δ 3.25–3.60, multiplet, 3H; δ 3.60–3.87, multiplet, 1H; δ 3.87–4.14, multiplet, 2H; δ 4.46–5.08, multiplet, 10H; δ 6.94–7.55, multiplet, 25H.

The equivalent procedure was performed using the less polar ester (1.03 g, 1.27 mmol) leading to the isolation of (+)-(**11**) (0.726 g, 90.9%), which exhibited IR, TLC, and NMR data in accord with the proposed structure. Specific rotation: $[\alpha]_D$ +8.8 (0.11 M, ethanol). The ^{1}H NMR ($CDCl_3$) exhibited the following signals: δ 2.08–2.25, broad doublet, 1H; δ 3.22–3.53, multiplet, 3H; δ 3.60–3.84, multiplet, 1H; δ 3.86–4.08, multiplet, 2H: δ 4.40–5.04, multiplet, 10H; δ 6.88–7.47, multiplet, 25H.

The observed specific rotations were in accord with those previously reported (16).

Preparation of (S)-(E)*-3-oleoyloxy-4-stearoyloxybut-1-enyl-phosphonic acid 2,3,4,5,6-penta-*O*-benzyl-*myo*-inosit-1-yl ester (12)*

To (*S*)-(*E*)-3-oleoyloxy-4-stearoyloxybut-1-enylphosphonic acid (**7**) (70 mg, 0.10 mmol) dissolved in freshly distilled pyridine (0.5 mL) was added (−)-2,3,4,5,6-penta-*O*-benzyl-*myo*-inositol (−)-(**11**) (50 mg, 0.08 mmol), followed by an excess of trichloroacetonitrile (0.45 g). The reaction flask was stoppered under a nitrogen atmosphere and the reaction mixture was stirred for 3 days using a controlled temperature water bath at 51°C. After this time volatile materials were evaporated under reduced pressure and the residue was purified by flash chromatography (10 g, 2 cm diameter) packed and eluted using methylene chloride:ether 50:1. The fractions exhibiting R_f = 0.85 on TLC (PS, methylene chloride:ether 50:1) as visualized with phosphomolybdate spray reagent were combined to give the pure desired material (21 mg, 20%), which exhibited IR and ^{1}H NMR spectra in accord with the proposed structure (**12**). Specific rotation: $[\alpha]_D$ −2.47 (0.0014 M, CCl_4). The ^{1}H NMR ($CDCl_3$) exhibited the following signals: δ 0.9, broad multiplet, 6H; δ 1.1–1.4, broad multiplet, 52H; δ 1.9–2.5, multiplet, 8H; δ 3.3–3.6, multiplet, 3H; δ 3.8–4.0, multiplet, 2H; δ 4.0–5.0, multiplet, 13H; δ 5.2, multiplet, 1H; δ 5.4, triplet, 2H; δ 5.6–7.8, multiplet, 2H; δ 7.0–7.4, multiplet, 25H; δ 12.1, singlet, 1H. Anal. calcd. for $C_{81}H_{115}O_{12}P$: C 74.17, H 8.84%; found: C 73.91, H 9.14%.

Preparation of (S)-(E)*-3-oleoyloxy-4-stearoyloxybut-1-enylphosphonic acid* myo*-inosit-1-yl ester (2)*

The material (*S*)-(*E*)-3-oleoyloxy-4-stearoyloxybut-1-enylphosphonic acid 2,3,4,5,6-penta-*O*-benzyl-*myo*-inosit-1-yl ester (**12**) (7.3 mg, 0.0056 mmol) was dissolved in chloroform (0.5 mL), an excess of iodotrimethylsilane (0.25 mL) was added, and the reaction mixture was stirred at room temperature for 15 min. The reaction was quenched by the addition of methanol (0.75 mL). Volatile materials were removed under reduced pressure and diethyl ether (1 mL) was added to the residue. Saturated aqueous sodium bisulfite solution (2 drops) was added until the material became clear. Volatile materials were removed again under reduced pressure and the residue was subjected to flash chromatography (20 g, 2 cm diameter) packed and eluted with chloroform. Those fractions exhibiting a single spot of R_f = 0.31 (PS, chloroform) were combined to give the pure desired material (3.7 mg, 76.7%), which exhibited IR and ^{1}H NMR spectra in accord with the proposed structure (**2**). Specific rotation: $[\alpha]_D$ −6.38 (0.0021 M, $CHCl_3$). The ^{1}H NMR exhibited the following signals: δ 0.9, broad multiplet, 6H; δ 1.0–1.6, broad multiplet, 52H; δ 1.6–2.5, broad, 8H; δ 3.6, 6H, singlet; δ 3.7–4.5, broad multiplet, 9H; δ 5.4,, triplet, 2H; δ 5.7–7.8, multiplet, 2H. Anal. calcd. for $C_{46}H_{85}O_{12}P$: C 64.16, H 9.95%; found: C 63.90, H 10.10%.

Studies on novel carbacephem analogs: synthesis of 7-methoxy-homo-PS-5 and a 7-methoxy-8-epi-homothienamycin intermediate

S. R. SHAKYA AND T. DURST[1]

Chemistry Department, Ottawa–Carleton Chemistry Institute, University of Ottawa, Ottawa, Ont., Canada K1N 6N5

Received February 5, 1992

S. R. SHAKYA and T. DURST. Can. J. Chem. **70**, 2142 (1992).

The synthesis of two carbacephems bearing a 7-methoxy group and either an additional ethyl (PS-5) or hydroxyethyl (thienamycin) side chain has been completed. Rhodium carbenoid insertion methodology was used to generate the bicyclic ring systems.

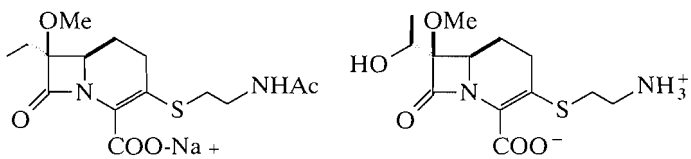
S. R. SHAKYA et T. DURST. Can. J. Chem. **70**, 2142 (1992).

On a réussi la synthèse de deux carbacéphèmes portant un groupe 7-méthoxy ainsi que des chaînes latérales additionnelles éthyle (PS-5) ou hydroxyéthyle (thiénamycine). On a utilisé la méthodologie d'insertion d'un carbénoïde de rhodium pour générer les systèmes bicycliques.

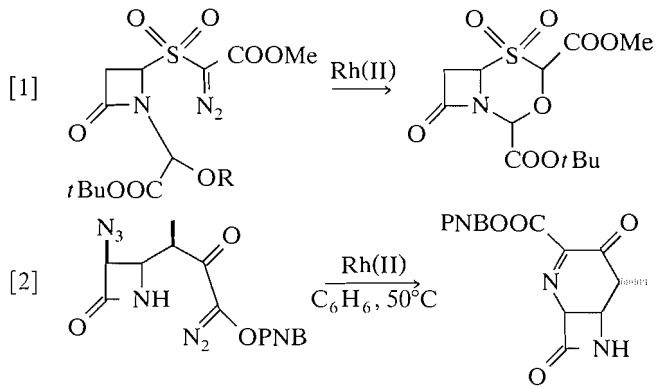
[Traduit par la rédaction]

Introduction

As a part of program of synthesizing unusual bicyclic β-lactams bearing two substituents α to the β-lactam carbonyl group[2] we would like to report our work concerning the preparation of the carbacephem analogs **1** and **2**, which carry a 7β-methoxy group in addition to either an ethyl or hydroxyethyl group typical of PS-5 or thienamycin (2, for general reference) antibiotics, respectively. The most important methodology for the construction of the bicyclic ring system of both carbapenems and carba-cephems is the rhodium carbenoid insertion route developed by Cama[3] and co-workers at Merck (3).[4] Surprisingly, this cyclization procedure has not been applied to examples that carry a methoxy group at C-6 or C-7 in the final product (4). Success in such cases is by no means assured[5] since intramolecular trapping of carbenoids by ether oxygen (eq. [1]) has often been observed and studied in considerable detail (5).[6] Nitrogen substituents,[7] when present at these positions, were shown to interfere in the cyclization process as shown in eq. [2] (6).



1 **2**



The combination of ring size and the 7,7-disubstitution pattern of **1** and **2** are also of interest for structure–activity studies. Carbacephems having a typical amide substituent at C-7 are chemically more stable than the analogous cephalosporins but tend to have comparable biological activity (7). The replacement of the amide nitrogen by an ester oxygen at the carbon α to the β-lactam carbonyl in penicillin and cephalosporin was found to diminish the activity (8). Homothienamycin is more stable than thienamycin, but inactive (9). Some activity has been reported in oxacephems bearing a hydroxyethyl substituent (10). These results indicate that the compounds may not have the high antimicrobial activity displayed by thienamycin. Thus compounds **1** and **2** were considered worthwhile targets, as model compounds, from the methodology point of view.

Results and discussion

Preparation of the β-ketoesters 7 and 11

Both 3,3-disubstituted azetidinones **3** and **8** were available in multigram quantity via reaction of the β-lactam

[1] Author to whom correspondence may be addressed.

[2] See ref. 1.

[3] This reaction was first developed by Cama and Christensen in oxapenam cyclization (17*b*) and extended to carbapenems by Ratcliffe *et al.* (3*a*).

[4] For rhodium carbenoid cyclizations to (1) carbapenems: ref. 3*a* and (2) carbacephems: ref. 9. For other cyclization methods, see refs. 3*b* and 3*c* for carbapenems 3*d*–3*r* and 7*c* for carbacephems. For other methods of preparing β-ketoester precursors for rhodium cyclization: refs. 3*s*–3*u*.

[5] Successful rhodium carbenoid cyclizations were reported in synthesis of 1-methoxy-carbapenem (16), 1-oxapena(e)m (17) and 1-oxacepham nuclei (18). In these examples the ethereal oxygen is one or two carbons removed from the carbenoid centre. These results do not undermine the importance of the present study since the distance and stereochemical relationship of methoxy groups to the carbenoid center are quite different in the problem at hand.

[6] For intramolecular insertion into ether yielding a six-membered ring, see ref. 5*g*.

[7] Successful annulations have been reported in the case of carbacephem (3*s*) and carbapenem (19) with an α-nitrogen substituent. It appears that the substituent and stereochemical relationship govern the product. Oxacephem having an α-nitrogen group has been prepared by this methodology (18*a*). These authors reported a small amount of product derived from the insertion of the carbenoid into the NH bond at C-7.

[3] 
(a) LDA, THF, EtI, −78 to −30°C or CH_3CHO, −78°C; (b) PCC, CH_2Cl_2, NaOAc, 4 Å mol. sieves, 25°C; (c) L-Selectride, TMEDA, THF, −78°C

enolate derived from *N*-*p*-methoxyphenyl-4-cinnamyl-3-methoxyazetidin-2-one (11) with ethyl iodide and acetaldehyde, respectively (eq. [3]).

Diastereomerically pure **8** was obtained by oxidation of the initially produced mixture of 3-hydroxyethyl adducts to the 3-acetyl derivative followed by L-Selectride reduction under non-chelating conditions (11). The *p*-methoxyphenyl (PMP) group in **3** was cleaved using ceric ammonium nitrate (CAN) at −25 to −30°C (12). Ozonolysis of the N-TBDMS derivative (tert-butyldimethylsilyl triflate, TBDMSOTf (13)) **4** was carried out in dichloromethane with traces of methanol and molecular sieves to yield **5** (ir: 1755 and 1740 cm^{-1}; ^1H nmr: 9.61 ppm) in 43% overall yield from **3** (Scheme 1).

The two-carbon homologation to **6** was achieved in excellent yield and in a practical manner on a multigram scale using benzyl(triphenylphosphoranylidene)acetate;[8] both reduction of the double bond and the debenzylation occurred upon hydrogenation with 10% Pd on C. The further elaboration of **6** to β-ketoester was achieved by activation with carbonyldiimidazole and subsequent reaction with the magnesium salt of mono-*p*-nitrobenzylester of malonic acid following the Masamune protocol (14). Methanolic HCl treatment of the *N*-silyl β-ketoester gave the key desilylated compound **7**.

A similar sequence was used to obtain the intermediate **11** having both the 7-methoxy and epithienamycin type side chains at C-3. Thus compound **8** was silylated (TBDMSOTf and 2,6-lutidine) and cleaved with ozone to afford the aldehyde **9** in 81% overall yield from **8**.[9] Removal of the *p*-methoxyphenyl group with CAN afforded the expected aldehyde, which was rather unstable and difficult to handle compared to the *N*-silylated aldehyde **5**. Therefore the aldehyde was quickly purified by column chromatography to a usable state and subjected to the Wittig homologation sequence described above. The carboxylic acid **10** was obtained in 36% overall yield from **9**. The homologation of **10** to β-keto ester **11** was again achieved using Masamune's method (Scheme 2).

Annulation

Diazo transfer between **7** or **11** and 4-carboxybenezenesulfonazide was catalyzed by triethylamine (15). The resulting diazo compounds were refluxed in benzene with about 0.3 mol% of $Rh_2(OAc)_4$ to give **12** (60% from **7**) and **13** (32% from **11**), respectively. No other major products were evident by tlc, thus indicating that interference by the methoxy group in the carbenoid cyclization was not of major concern. The formation of the second ring in both products is evident from the ^1H nmr[10] and ir spectra. The appearance of an AB pattern for the benzylic protons (δ = 5.25 ppm (1H, d, J = 13.9 Hz) and 5.47 ppm (1H, d, J = 13.4 Hz)) and shift of the β-lactam carbonyl from 1740 (monocyclic precursor) to 1752 cm^{-1} (bicyclic ketoester) are expected changes in going from **7** to **12**. The conversion of **11** to **13** shows similar changes. The benzylic protons in **11** (δ = 5.23 ppm (s)) became a quartet in **13** (δ = 5.24 ppm (1H, d, J = 13.7 Hz) and 5.45 ppm (d, J = 13.4 Hz). A con-

SCHEME 1

[8]Wittig reaction resulting in four-carbon homologations using (triphenylphosphoranylidene)-2,2,6-trimethyl-4*H*-1,3-dioxin-4-one has been reported (3*t*). This suggested an alternate route from **5** to **7**. However, in our hands this reagent proved to be difficult to prepare and purify especially on a multigram scale.

[9]See ref. 1 for experimental details of this conversion.

[10]Proton and ^{13}C nmr spectra for all key compounds have been deposited as Supplementary Material and may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada KIA 0S2.

SCHEME 3

comitant shift for the β-lactam carbonyl from 1740 to 1750 cm^{-1} was also observed.

The conversion of **12** to **14** involved the activation of the enol group with diphenylchlorophosphate followed by addition of *N*-acetylaminoethanethiol in the presence of diisopropylethylamine (DIPEA). The epi-homothienamycin analog **15** was obtained in similar manner using carbo-*p*-nitrobenzyloxyaminoethanethiol. Removal of the *p*-nitrobenzyl groups from **14** and **15** via catalytic hydrogenation afforded the crude carboxylic acids (Scheme 3). Reverse-phase column chromatography purification and lyophilization of the resultant aqueous solution gave the compound **1** as a white powder; mp: becomes translucent at 177–178°C and chars at or above 217°C; ir (KBr): 1742 (β-lactam C=O) cm^{-1}. In vitro antibacterial activity of **1** was determined by conventional microtiter dilution procedures. The MIC's were higher than 64 μg/mL for organisms such as *Streptococcus pneumoniae*, *Streptococcus pyogenes*, and *Haemophilus influenzae*, and 128 μg/mL for *Enterococcus faecalis*, *Enterococcus faecium*, *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Staphylococcus haemolypticus*, *Escherichia coli*, *Klebsiella pneumoniae*, *Enterobacter cloacae*, *Proteus mirabilis*, *Proteus vulgaris*, *Morganella morganii*, *Proteus rettgeri*, *Serrafia marcescens*, *Pseudomonas aeruginosa*, *Pseudomonas cepacia*, and *Xanthomonas maltophilia*. The purification of carboxylic acid derived from **15** was unsuccessful on the first attempt. Due to lack of material and the discouraging results observed in the studies of antibacterial activity of **1**, purification of this compound was not repeated.

Conclusion

7-Methoxyhomo-PS-5, **1**, was found to be inactive as an antibacterial compound. From a methodology point of view, this study did indicate that the rhodium carbenoid annulation can be applied in β-lactams having a methoxy group α to the lactam carbonyl. We have successfully applied this methodology to the preparation of several 6-methoxy carbapenems including 6-methoxy-PS **5**. None of these examples display intervention by the α-methoxy group; which will be reported shortly.

Experimental

The analytical instruments used in spectral analysis are given in ref. 1. In addition to these, Bomem Michelson MB100 and Kratos concept 2H instruments were used for infrared and mass spectra, respectively. Solvent purification and chromatographic separation have also been described (1).

1-tert-Butyldimethylsilyl-4-cinnamyl-3-ethyl-3-methoxyazetidin-2-one (4)

A solution of the azetidinone **3** (6.50 g, 19.3 mmol) in 250 mL of MeCN was cooled to −25 to −30°C. (Some material precipitated out after 10 min but the procedure was continued without further addition of the solvent.) CAN (32 g, 58.4 mmol) in 60 mL of ice-cold water was added dropwise over 20 min. The initial greenish-black color turned yellow and at the end of the reaction time, the homogeneous solution was brown. Usual work-up using ethyl acetate for extraction gave a yellow solid, which on trituration with ether gave the free NH β-lactam as a white solid (2.30 g, 52%).

A solution of this intermediate in 50 mL of dry CH_2Cl_2 was cooled to 0°C and 2,6-lutidine (2.32 mL, 19.9 mmol) and TBDMSOTf (3.43 mL, 14.9 mmol) was added via syringe. The reaction mixture was stirred for 30 min at 0°C and 1.5 h at room temperature. Usual work-up and purification by column chromatography (1:15 EtOAc:hexanes) gave 3.40 g (99%) of a pale yellowish oil **4**; ir (film): 1744 (β-lactam C=O) cm^{-1}; ^1H nmr δ: 0.15 (3H, s, CH_3Si), 0.21 (3H, s, CH_3Si), 0.93 (9H, s, *t*BuSi), 0.97 (3H, t, J = 7.3 Hz, CH_3CH_2), 1.79–2.01 (2H, m, CH_2CH_3), 3.43 (3H, s, OCH_3), 3.98 (1H, d, J = 8.7 Hz, CHN), 6.22 (1H, dd, J = 16.0, 8.9 Hz, CH=CHPh), 6.54 (1H, d, J = 16.0 Hz, CH=CHPh), 7.10–7.30 (5H, m, Ph); ms (ei): 345 (M^+, 11), 330 (M^+ − 15, 18), 302 (M^+ − 15−28, 4), 288 (M^+ − 57, 3), 188 (M^+ − 157, 100). Exact Mass (HRMS) calcd. for $C_{20}H_{31}NO_2Si$: 345.2112; found: 345.2118.

1-tert-Butyldimethylsilyl-3-ethyl-4-formyl-3-methoxyazetidin-2-one (5)

Ozone was passed through a solution of **4** (3.40 g, 9.85 mmol) in 50 mL of dry CH_2Cl_2 and 5 mL of MeOH containing about 0.50 g of 4Å molecular sieves at −78°C till the solution was bluish. Excess ozone was removed by bubbling dry nitrogen through the reaction mixture and 3 mL of dimethyl sulfide was added. The re-

For personal use only.

sulting reaction mixture was warmed slowly to 25°C and kept for 18 h. After removal of the solvent, the crude product was purified by column chromatography (1:10 EtOAc:hexanes) to yield 2.20 g (82%) of aldehyde **5** as a colorless oil; ir (film): 1740 (CHO), 1755 (β-lactam C=O) cm^{-1}; ^1H nmr δ: 0.10 (3H, s, CH_3Si), 0.29 (3H, s, CH_3Si), 0.94 (9H, s, *t*Bu), 1.01 (3H, t, J = 7.3 Hz, CH_3CH_2), 1.68–1.88 (1H, m, CH_2CH_3), 1.94–2.12 (1H, m, CH_2CH_3), 3.40 (3H, s, OCH_3), 3.81 (1H, d, J = 3.1 Hz, CHN), 9.61 (1H, d, J = 3.0 Hz, CHO); ms (ei): 272 (M^+ + 1, 3), 244 (M^+ + 1−28, 3), 214 (M^+ − 57, 29), 187 (M^+ +1−28−57, 87), 171 (M^+ − 100, 3).

1-tert-*Butyldimethylsilyl-4-(2-carboxyethyl)-3-ethyl-3-methoxyazetidin-2-one (**6**)*

The solution of benzyl(triphenylphosphoranylidene)acetate (3.99 g, 9.73 mmol) in 100 mL of toluene was stirred with the aldehyde **4** (2.20 g, 8.12 mmol) at 50–60°C for 18 h. Toluene was removed and the residue was triturated with 100 mL of hexanes. Triphenylphosphine oxide was filtered off and the filtrate was concentrated to a yellow oil, which on purification by column chromatography (1:10 EtOAc:hexanes) gave 3.10 g (95%) of a *cis–trans* (1:4) mixture of the corresponding α,β unsaturated ester as a colorless oil.

This ester (3.10 g, 7.69 mmol) was dissolved in 10 mL of EtOH and hydrogenated in the presence of 2 g of Pd–C (10%) at 20 psi (1 psi = 6.9 kPa) for 18 h. Usual work-up gave 2.40 g (99%) of acid **6** as a colorless oil; ir (film): 3127 (COOH), 1741 (C=O), 1676 (COOH) cm^{-1}; ^1H nmr δ: 0.18 (3H, s, CH_3Si), 0.21 (3H, s, CH_3Si), 0.87–0.94 (12H, t with overlapping s, CH_3CH_2, *t*Bu), 1.48–1.68 (1H, m, CH_2CH_3), 1.90–2.12 (3H, m, CH_2CH_3, CH_2), 2.21–2.61 (2H, m, CH_2CO), 3.37 (1H, dd, J = 4.8, 9.2 Hz, CHN), 3.47 (3H, s, OCH_3); ms (ei): 315 (M^+, 5), 300 (M^+ − 15, 14), 272 (M^+ − 15−28, 5), 258 (M^+ − 57, 12), 243 (258−15, 1). Exact Mass (HRMS) calcd. for $C_{15}H_{29}NO_4Si$: 315.1868; found: 315.1867.

3-tert-*Butyldimethylsilyloxyethyl-4-(2-carboxyethyl)-3-methoxyazetidin-2-one (**10**)*

The aldehyde **9** (7.10 g, 18 mmol) was reacted with CAN (29.59 g, 54 mmol) at −10°C to yield 3.50 g (66%) of *N*-deprotected aldehyde as a brown oil after column chromatography (1:4 EtOAc:hexanes). This compound showed the aldehyde proton at 9.61 ppm and was judged to be about 60% pure by ^1H nmr. It was used as such.

Reaction of the aldehyde (3.50 g, 12 mmol) with benzyl(triphenylphosphoranylidene)acetate (7.35 g, 17.9 mmol) gave 2.70 g (36% from **9**) of a brownish oil after column chromatography (1:4 EtOAc:hexanes). The resultant oil was hydrogenated to yield 2.10 g (99%) of **10** as a brown oil; ir (film): 3362 (COOH), 1740 (C=O) cm^{-1}; ^1H nmr δ: 0.02 (3H, s, CH_3Si), 0.04 (3H, s, CH_3Si), 0.84 (9H, s, *t*Bu), 1.21 (3H, d, J = 6.4 Hz, CH_3CH_2), 1.80–1.93 (2H, m, CH_2COO), 2.20–2.55 (2H, m, CH_2CH_2COO), 3.58 (3H, s, OCH_3), 3.59–3.72 (1H, m, overlaps with 3.58 of OCH_3, CHN), 4.10 (1H, q, J = 6.4 Hz, CHO), 6.73 (1H, br, NH); ms (ei): 316 (M^+ − 15, 2), 302 (M^+ − 29, 1), 287 (M^+ − 44, 3), 274 (M^+ − 57, 26), 230 (M^+ − 101, 21). Exact Mass (HRMS) calcd. for $C_{14}H_{26}NO_5Si$ (M^+ − 15): 316.1576; found: 316.1578.

3-Ethyl-3-methoxy-4-(4'-p-*nitrobenzyloxycarbonyl-3-oxobutyl)azetidin-2-one (**7**)*

Carbonyldiimidazole (CDI, 1.50 g, 9.52 mmol) was added to a solution of the acid **6** (2.00 g, 6.35 mmol) in 10 mL of THF and the mixture was stirred at 25°C for 3.75 h. The suspension of the magnesium salt of the mono-*p*-nitrobenzyl ester of malonic acid[11] (3.20 g, 6.39 mmol) was added by cannula and stirred vigorously for 16 h. The reaction mixture was diluted with EtOAc and washed with saturated NaCl solution. Column chromatography (1:4 EtOAc:hexanes) of the resulting crude product afforded 0.70 g (22%) of a colorless oil.

The β-ketoester thus obtained (0.70 g, 1.42 mmol) in 10 mL of MeOH was stirred overnight with 1 mL of 10% aqueous HCl. Excess of the acid was neutralized by adding solid $NaHCO_3$. The crude product obtained after work-up using EtOAc for extraction was purified by column chromatography (6:4 hexanes:EtOAc) to yield 0.39 g (73%) of **7** as a pale yellowish oil; ir (film): 3292 (NH), 1740 (C=O), 1720 (COOR), 1522 and 1348 (NO_2) cm^{-1}; ^1H nmr δ: 0.91 (3H, t, J = 7.4 Hz, CH_3CH_2); 1.62–1.69 (1H, m, CH_2CH_3), 1.86–2.03 (3H, m, CH_2CH_3, CH_2), 2.54–2.69 (2H, m, CH_2CO), 3.41–3.52 (6H, m, overlapping with s at 3.48, OCH_3, $COCH_2COOR$, CHN), 5.24 (2H, s, CH_2PNB), 5.90 (1H, br, NH), 7.50 (2H, d, J = 8.9 Hz, PNB), 8.21 (2H, d, J = 8.9 Hz, PNB); ms (ci): 379 (M^+ + 1, 9), 351 (M^+ + 1−28, 50), 333 (M^+ + 1−28−18, 12), 319 (M^+ + 1−60, 33), 301 (319−18, 1).

*3-Hydroxyethyl-3-methoxy-4-(4-*p-*nitrobenzyloxycarbonyl-3-oxobutyl)azetidin-2-one (**11**)*

The carboxylic acid **10** (2.13 g, 6.43 mmol) gave 1.2 g (37%) of β-ketoester as a yellow oil using the above homologation procedure.

O-Desilylation of the β-ketoester obtained above was effected by treating the methanolic solution of this ester (1.2 g, 2.36 mmol) with 2 mL of 6 N HCl dropwise at 0–25°C for 18 h to afford 630 mg (68%) of **11**, after passage of the crude product through a short silica gel column using EtOAc, as a yellow oil; ir (CH_2Cl_2): 3327 (NH), 1740 (broad C=O), 1523 and 1348 (NO_2) cm^{-1}; ^1H nmr δ: 1.20 (3H, overlapping with EtOAc, CH_3CH_2), 1.80–2.10 (2H, m, CH_2), 2.30–2.70 (2H, m, CH_2), 3.56–3.65 (6H, m with overlapping s due to OCH_3, CHN, CH_2), 4.12 (1H, overlapping with EtOAc), 5.23 (2H, s, CH_2PNB), 6.20 (1H, s, br, NH), 7.49 (2H, d, J = 8.2 Hz, PNB), 8.20 (2H, d, J = 8.8 Hz, PNB); ms (ci): 353 (M^+ + 1−42, 2), 279 (M^+ + 1−116, 2), 274 (M^+ +1−120, 20), 259 (M^+ +1−136, 1), 215 (M^+ + 1−180, 6). This compound was purified after conversion to the corresponding diazo compound.

p-*Nitrobenzyl(7-ethyl-7-methoxy)-3-hydroxyl-1-carba-1-dethia-3-cephemcarboxylate (**12**)*

4-Carboxybenzenesulfonazide (0.37 g, 1.63 mmol) was added to a solution of the compound **7** (0.38 g, 1.00 mmol) in 25 mL of dry MeCN at 0°C. The resulting suspension turned to a clear solution after addition of Et_3N (0.56 mL, 4.02 mmol) and was stirred for 6 h. The cloudy reaction mixture was diluted with EtOAc and washed successively with 5% $NaHCO_3$ and saturated NH_4Cl. Purification of the crude product by column chromatography (2:5 EtOAc:hexanes) gave 0.35 g (85%) of diazo compound as a colorless oil.

The diazo compound obtained above (0.35 g, 0.86 mmol) was dissolved in 30 mL of dry benzene and 15 mL of solvent was distilled off. After cooling to 25°C under N_2, about 1 mg of $Rh_2(OAc)_4$ was added and the solution was refluxed overnight. Purification of the crude product by column chromatography (2:5 EtOAc:hexanes) furnished 0.23 g (70%) of the product **12** as a white solid; mp 125–126°C; ir (KBr): 3435 (br OH), 1752 (C=O), 1518 and 1344 (NO_2) cm^{-1}; ^1H nmr δ: 1.00 (3H, t, J = 7.4 Hz, CH_3CH_2), 1.55 (1H, br, OH), 1.79–2.21 (4H, m, CH_2CH_3, CH_2), 2.47–2.54 (2H, m, CH_2CO), 3.40–3.48 (4H, dd, J = 10.3, 4.4 Hz, overlapping with s, CHN, OCH_3), 5.25 (1H, d, J = 13.9 Hz, CH_AH_BPNB), 5.47 (1H, d, J = 13.4 Hz, CH_BH_APNB), 7.66 (2H, d, J = 8.9 Hz, PNB), 8.21 (2H, d, J = 8.9 Hz, PNB); ms (ei): 376 (M^+, 2), 348 (M^+ − 28, 5), 318 (M^+ − 28−30, 2), 302 (318−16, 0.3), 240 (M^+ − 136, 2). Exact Mass (HRMS) calcd. for $C_{18}H_{20}N_2O_7$: 376.1268; found: 376.1256.

p-*Nitrobenzyl[3-hydroxy-7-1-(1-hydroxyethyl)-7-methoxy]-1-carba-1-dethia-3-cephemcarboxylate (**13**)*

Compound **11** (610 mg, 1.55 mmol) when subjected to the diazo transfer reaction yielded 520 mg (80%) of a yellowish semisolid

[11]See refs. 9 and 14.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

(ir: 2120 cm^{-1}) after usual work-up and column chromatography (1:2, acetone:hexanes).

The rhodium carbenoid insertion reaction of the diazo compound (400 mg, 0.950 mmol) and purification by column chromatography (2:3, acetone:hexanes) gave 370 mg (40%) of **13** as a yellowish oil; ir (film): 1710–1780 (broad peak centered at 1750 C=O), 1520 and 1350 (NO_2) cm^{-1}; ^1H nmr δ: 1.26 (3H, d, J = 6.5 Hz, CH_3CH_2), 1.97–2.14 (2H, m, CH_2CO), 2.48–2.60 (2H, m, CH_2CH_2CO), 3.64 (4H, 2s due to OCH_3 overlapping with CHN), 3.83 (1H, s, COCHCOO), 4.38 (1H, q, J = 6.7 Hz, CHO), 5.24 (1H, d, J = 13.7 Hz, CH_AH_BPNB), 5.45 (1H, d, J = 13.4 Hz, CH_BH_APNB), 7.63 (2H, d, J = 8.3 Hz, PNB), 8.20 (2H, d, J = 9.8 Hz, PNB); nmr looks like a mixture of ketoenol tautomers based on the complexity of the spectrum and two methoxy peaks; ms (ei): 391 ($M^+ - 1$, 0.4), 277 ($M^+ - 115$, 100), 271 ($M^+ - 121$, 15), 256 ($M^+ - 136$, 2), 211 ($M^+ - 180$, 11).

p-*Nitrobenzyl(7-ethyl-7-methoxy)-3*-N-*acetylethanethio-1-carba-1-dethia-3-cephemcarboxylate* (***14***)

Compound **12** (0.20 g, 0.53 mmol) in 5 mL of dry MeCN was cooled to 0°C under N_2. Addition of DIPEA (0.12 mL, 0.69 mmol) gave a yellow-colored solution that disappeared when the reaction mixture was stirred for 1 h after addition of diphenylchlorophosphate (0.13 mL, 0.63 mmol). A solution of *N*-acetylaminoethanethiol (0.12 g, 1.01 mmol) in 2 mL of dry MeCN and DIPEA (0.12 mL, 0.69 mmol) was added and the reaction mixture was stirred for 1 h. After usual work-up using EtOAc as solvent, the column chromatography of the crude product was carried out using a gradient of solvents. EtOAc:hexanes (1:2) gave starting compound **12**; EtOAc:hexanes (3:1) gave *N*-acetylaminoethanethiol; and hexanes:EtOAc:MeCN (20:40:40) gave 0.20 g (81%) of the desired product **14** as a yellowish oil; ir ($CHCl_3$): 3329 (br, NH), 1755 (β-lactam C=O), 1713 (COOR), 1660 (CONH), 1530 and 1361 (NO_2) cm^{-1}; ^1H nmr δ: 0.98 (3H, t, J = 7.4 Hz, CH_3CH_2), 1.75–2.10 (7H, m with overlapping s at 1.90 due to CH_3CO, CH_2, CH_2CH_3), 2.43–2.76 (2H, m, CH_2), 2.79 (2H, t, J = 5.8 Hz, CH_2S), 3.25–3.46 (6H, m, with overlapping s at 3.35 due to OCH_3, CH_2N, CHN), 5.20 (1H, d, J = 13.6 Hz, CH_AH_BPNB), 5.30 (1H, d, J = 13.7 Hz, CH_BH_APNB), 6.76 (1H), br t, NH), 7.52 (2H, d, J = 8.9 Hz, PNB), 8.09 (2H, d, J = 8.9 Hz, PNB); ^{13}C nmr δ: 7.3 (CH_3), 21.3 (CH_2), 22.7 (CH_3), 22.8 (CH_2), 26.6 (CH_2), 30.1 (CH_2), 38.9 (CH_2), 52.7 (CH_3O), 56.7 (CH), 65.7 (CH_2PNB), 90.7 (C-7), 122.6 (C=C), 123.6 (CH of PNB), 128.4 (CH of PNB), 133.2 (C=C), 142.9 (C of PNB), 147.6 (C of PNB), 162.1 (C=O), 166.3 (C=O), 170.7 (C=O); ms : no M^+ ion in ei or ci, 356 ($M^+ - 121$, 1), 328 ($356-28^+$, 4).

p-*Nitrobenzyl(7-hydroxyethyl-7-methoxy-3*-N-*acetylethanethio)-1-carba-1-dethia-3-cephemcarboxylate* (***15***)

Purification solvent mixture (20:20:80 EtOAc:hexanes:MeCN); a yellow oil (68%); ir (film): 3400 (br, OH), 1700–1770 (broad, C=O), 1520 and 1350 (NO_2) cm^{-1}; ^1H nmr δ: 1.26 (3H, d, J = 6.4 Hz, CH_3CH_2), 1.80–2.60 (4H, m, CH_2CH_2), 2.88–2.94 (2H, m, CH_2N), 3.34–3.59 (2H, m, CH_2S), 3.60 (3H, s, CH_3O), 3.63–3.68 (1H, m, CHN), 4.38 (1H, q, J = 6.5 Hz, CHO), 5.16 (2H, s, CH_2PNB), 5.27 (1H, d, J = 13.5 Hz, CH_AH_BPNB), 5.39 (1H, d, J = 13.4 Hz, CH_BH_APNB), 5.59 (1H, br, NH), 7.48 (2H, d, J = 8.8 Hz, PNB), 7.58 (2H, d, J = 9.0 Hz, PNB), 8.19 (4H, d, J = 8.8 Hz, PNB); ms (ei): highest peak is 238 (MW = 630).

Sodium (7-ethyl-7-methoxy)-3-N-*acetylethanethio-1-carba-1-dethia-3-cephemcarboxylate* (***1***)

The PNB ester **14** (0.20 g, 0.42 mmol) in 20 mL of THF:H_2O (1:1) was hydrogenated in the presence of 0.12 g of Pd–C (10%) at 40 psi and 25°C for 7 h. After removal of the catalyst and THF, the suspension was treated with 36 mg of $NaHCO_3$. The resulting mixture was washed with EtOAc and the aqueous layer was lyophilized to give 0.14 g of crude product. Reverse phase column chromatography (10% MeCN in H_2O) yielded 0.13 g (77%) of **1** as a white solid; mp: becomes translucent at 177–178°C and chars at or above 217°C; ir (KBr): 3396 (br, NH), 1742 (β-lactam C=O), 1661 (CONH), 1610 (COO^-) cm^{-1}; ^1H nmr (D_2O) δ: 0.99 (3H, t, J = 7.4 Hz, CH_3CH_2), 1.79–1.91 (1H, m, CH_2CH_3), 1.98 (3H, s, CH_3CO), 2.00–2.17 (3H, m, CH_2CH_3, CH_2), 2.42–2.54 (2H, m, CH_2), 2.80–2.86 (2H, m, CH_2S), 3.31–3.42 (2H, m, CH_2N), 3.44 (3H, s, OCH_3), 3.68 (1H, dd, J = 11.7, 3.4 Hz, CHN); ^{13}C nmr (D_2O) δ: 9.6 (CH_3), 24.1 (CH_2), 24.6 (CH_3), 25.4 (CH_2), 28.8 (CH_2), 32.5 (CH_2), 42.1 (CH_2), 55.5 (CH_3O), 60.6 (CH), 94.2 (C-7), 120.4 (C=C), 134.7 (C=C), 169.7 (C=O), 172.8 (C=O), 177.2 (C=O); ms (ei) of free acid: 342 (M^+, 0.4), 341 ($M^+ - 1$, 2), 314 ($M^+ - 28$, 8), 270 ($M^+ - 72$, 5), 242 ($M^+ - 100$, 2). Exact Mass (HRMS) calcd. for $C_{15}H_{22}N_2O_5S$ (free acid); 342.1235; found: 342.1242.

Ascorbate: antioxidant activity determined in a hydrocarbon phase using quaternary ammonium salts as phase-transfer agents

L. Ross C. Barclay[1] and Kelly A. Dakin
Department of Chemistry, Mount Allison University, Sackville, N.B., Canada E0A 3C0

and

Hayder A. Zahalka
Polysar, Research and Development Department, Sarnia, Ont., Canada N7T 7M2

Received November 22, 1991

L. Ross C. Barclay, Kelly A. Dakin, and Hayder A. Zahalka. Can. J. Chem. **70**, 2148 (1992).

By shaking sodium ascorbate with tetra-*n*-butyl ammonium bromide in a two-phase system consisting of water and organic phases, such as 1,1,2,2-tetrachloroethane (TCE) or chlorobenzene, sufficient concentrations of the quaternary ammonium-ascorbate (quat-ascorbate) are transferred into the organic phase to be useful for antioxidant studies in nonpolar solvents. The antioxidant activity of the quat-ascorbate was determined by measurement of the (inhibition) rate constant, k_{inh}, for the inhibition of autoxidation of styrene initiated thermally by azobisisobutyrylnitrile (AIBN) at 30°C. The k_{inh} of ascorbate in styrene, found to be $(9.63 \pm 2.0) \times 10^4$ M^{-1} s^{-1}, is very much lower than that found for ascorbyl-6-palmitate, $k_{inh} = (110 \pm 11) \times 10^4$ M^{-1} s^{-1} under these conditions. The differences are discussed in terms of the relative effectiveness of hydrogen-atom transfer from the enolic hydroxyl at position 2 of the ascorbate ion compared with the more facile such transfer from position 3 of ascorbyl 6-palmitate in a nonpolar medium.

L. Ross C. Barclay, Kelly A. Dakin et Hayder A. Zahalka. Can. J. Chem. **70**, 2148 (1992).

Lorsqu'on agite de l'ascorbate de sodium avec du bromure de tetra-*n*-butyl-ammonium dans un système à deux phases formé des phases aqueuses et organiques comme le 1,1,2,2-tétrachloroéthane (TCE) ou le chlorobenzène, les concentrations du complexe d'ascorbate qui sont transférées vers la phase organique sont utiles pour des études d'anti-oxydant dans des solvants non-polaires. On a détermiré l'activité anti-oxydante d'ascorbate ainsi transféré en mesurant la constante de vitesse de l'inhibition, k_{inh}, de l'auto-oxydation du styrène initiée thermiquement par l'azobisisobutyronitrile (AIBN), à 30°C. La constante d'inhibition de l'ascorbate dans le styrène, $k_{inh} = (9{,}63 \pm 2{,}0) \times 10^4$ M^{-1} s^{-1}, est beaucoup plus faible que celle observée avec le palmitate du 6-ascorbyle pour lequel $k_{inh} = (110 \pm 11) \times 10^4$ M^{-1} s^{-1} dans les mêmes conditions. On discute des différences en fonction des efficacités relatives du transfert de l'atome d'hydrogène porté par l'hydroxyle énolique en position 2 de l'ion ascorbate par rapport à celui porté en position 3 du palmitate du 6-ascorbyle dans un milieu non-polaire.

[Traduit par la rédaction]

Introduction

The antioxidant property of ascorbic acid is widely recognized and several detailed reviews have appeared on this subject (1–5). The antioxidant action of ascorbate as well as the cooperative or synergistic antioxidant action between ascorbate and vitamin E has been reported in a wide variety of media including homogeneous solution (6, 7), in micelles (8), phospholipid bilayers (9–12), low density lipoproteins (13), and blood platelets (14), but there is recent evidence that vitamin C does not "spare" vitamin E "in vivo" (15, 16).

Several anomalies are reported for the antioxidant or prooxidant behaviour of ascorbic acid and derivatives and results obtained frequently depend on the phase selected for the study. Ascorbate alone is not an effective antioxidant when autoxidation is initiated in the lipid phase of bilayers, whereas it is an active antioxidant against peroxyls in the aqueous phase (11, 12); and it is reported to be the outstanding antioxidant in human blood plasma (17). Pryor *et al.* (18) found that, in a SDS micellar system, lipid-soluble (micellar) 6-ascorbyl palmitate has 65 times the activity of water-soluble ascorbate. However, ascorbic acid has about the same reactivity as 6-steryl ascorbate with a vitamin E radical in solution, whereas the ascorbic ester substituted at the 2 and 6 positions was only 0.01 times as reactive as ascorbic acid (19). Derivatives having an ester group at position 2 were reported by Niki and co-workers (20) to not act as antioxidants in homogeneous solution, suggesting that the enolic 2-OH is the hydrogen donor in inhibition reactions. However, others report that the 2-O-alkylascorbic acids (21) or 3-O-alkylascorbic acids (22) exhibit potent inhibition of lipid peroxidation in rat brain homogenates, indicating that both enolic OH groups can act as H-atom donors. Studies of the antioxidant properties of ascorbate are further complicated by its ease of oxidation (23–25) and its reported behaviour as a *prooxidant* under certain conditions, such as in aqueous solution containing heavy metal ions (26–28).

Considering the significance of vitamin C in biological systems and its potential for application as an inhibitor in other systems, such as inhibition of coloration of wood pulps,[2] it is very surprising that its *intrinsic antioxidant activity against peroxyl radicals is not yet known*. To address this problem properly, several basic requirements need be met:

1. It is necessary to generate peroxyl radicals in an appropriate system at a constant and known rate, the rate of chain initiation (R_i), and where the rate constant of chain propagation, k_p, is reliably known.
2. The antioxidant activity of the ascorbate ion, AH^-, should be determined in a nonpolar medium where polar solvation effects, known to strongly affect antioxidant activities (29), are absent.
3. The antioxidant activity of ascorbate, AH^-, should be

compared with an unionized derivative, such as a solvent-soluble derivative.

To meet requirement 1, we selected the inhibited autoxidation of styrene method (30) where the R_i can be controlled and measured and the k_p is known. The suppressed oxygen uptake with antioxidant present is given by eq. [1]:

$$[1] \quad -d[O_2]/dt = k_p/k_{inh}[RH] \times R_i/n[Inh]$$

where n, the stoichiometric factor, is the number of peroxyl radicals trapped per molecule of inhibitor, Inh, and can be determined when the R_i is known from measurement of the inhibition period, τ, using eq. [2]:

$$[2] \quad R_i = n \times [Inh]/\tau$$

Condition 2 is met by using a quaternary ammonium salt (Q^+X^-) to form the ion-pair quaternary ammonium ascorbate (AH^-Q^+) under solid–liquid phase transfer conditions (31) and transferring this into an organic solvent where the concentration of the salt is measured. The third condition is met by employing the organic solvent-soluble ester 6-ascorbyl palmitate as antioxidant. In addition, antioxidant activities of the ascorbate salt, AH^-, and the ester are compared with that of 2,2,5,7,8-pentamethyl-6-hydroxychroman (PMHC), which has a known activity, k_{inh}, under these conditions (30).

Results

Formation of quaternary ammonium ascorbate (AH^-Q^+)

Equilibration of sodium ascorbate with tetra-*n*-butyl ammonium bromide between water and a larger volume of organic solvent (chlorobenzene or 1,1,2,2-tetrachloroethane) (TCE) by stirring or shaking the mixture under argon gave organic solutions containing ascorbate concentrations suitable for inhibition studies. The procedure using a shaken sealed ampoule yielded more reproducible results and is the preferred method. With the TCE solvent, transferred-ascorbate concentrations were determined spectrophotometrically by reference to a calibration curve using sodium ascorbate in water: methanol (20:80) where ϵ(ascorbate) at 268 nm = 12 090 M^{-1} cm^{-1}. Under the conditions used, shaking in TCE in a sealed ampoule under argon at 30°C, the equilibration time to reach a constant ascorbate concentration (4.0×10^{-4} M) was approximately 2 h. Aliquots of this ascorbate concentration were used for studies of antioxidant activities.

Inhibition rate constants for ascorbate and ascorbyl palmitate compared with PMHC

The AIBN-initiated autoxidation of styrene has certain known advantages as a system to measure antioxidant activities and the inhibition rate constants for a variety of phenolic inhibitors are known in this medium (30). Typical experimental traces for the antioxidant action of phase-transferred ascorbate (AH^-Q^+) ascorbyl palmitate, and PMHC for the inhibited autoxidation of styrene are illustrated in Fig. 1. Experimental traces for AH^-Q^+ induction periods typically gave indistinct breaks and a slow return to the uninhibited rate (e.g., Fig. 1(IB)), a feature observed before with inefficient inhibitors (29).

Inhibition rate constants (k_{inh}) were obtained from measurements of oxygen uptake during the inhibition periods by using the integration expression, eq. [3], for the kinetics during inhibition as explained previously (18, 29, 30):

$$[3] \quad \Delta[O_2]_t = -k_p/k_{inh} \times [RH]\ln(1 - t/\tau)$$

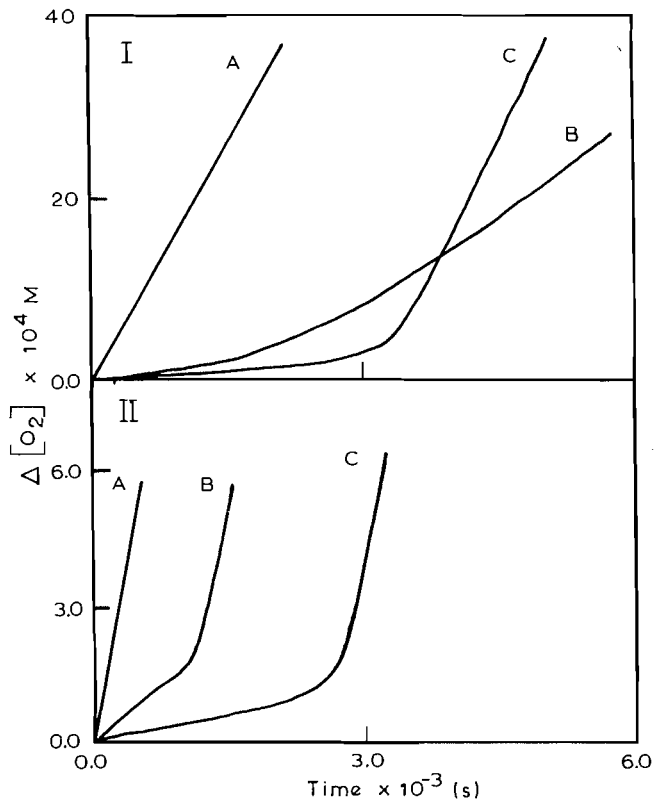

FIG. 1. Antioxidant action on peroxidation of styrene (2.00 mL) thermally initiated by AIBN at 30°C. (I) AIBN, 3.69×10^{-5} mol; (A) uninhibited reaction; (B) inhibited by ascorbate (AH^-Q^+), 3.23×10^{-8} mol; (C) inhibited by PMHC, 9.17×10^{-9} mol; $R_i = 2.62 \times 10^{-9}$ M s^{-1}. (II) AIBN, 3.66×10^{-5} mol; (A) uninhibited reaction; (B) inhibited by ascorbyl 6-palmitate, 1.01×10^{-8} mol; (C) inhibited by PMHC, 7.67×10^{-9} mol; $R_i = 2.74 \times 10^{-9}$ M s^{-1}.

where τ is the total inhibition period, and the oxygen uptake, $[O_2]_t$, is measured at various times, t, during the inhibition period. The rate of chain initiation (R_i) in each experiment was measured by injecting measured amounts of PMHC, known to be an efficient antioxidant which traps two peroxyl radicals per molecule, e.g., its stoichiometric factor, $n = 2$ (30). The k_{inh} for PMHC under these conditions was calculated for each run from the slopes of the plots of $\Delta[O_2]$ versus $-\ln(1 - t/\tau)$ and using the known k_p for styrene autoxidation, 41 M^{-1} s^{-1} (30). These plots were linear for PMHC inhibition at least 70% through the induction period (Fig. 2). The results are summarized in Table 1. The average k_{inh}, 354 ± 31 M^{-1} s^{-1}, agrees with the literature value (30) within experimental error.

The results for determination of k_{inh} for the ascorbate ion and ascorbyl 6-palmitate are summarized in Table 2. Linear plots were obtained for $\Delta[O_2]$ versus $-\ln(1 - t/\tau)$ through about 50% of the inhibition period (Fig. 2) but were nonlinear near the end of the induction period for ascorbate as the chain lengths increased. Concentrations of quat-ascorbate in chlorobenzene were not measured. Calculations of antioxidant activities by the slope method (eq. [3]) do not require the concentration of inhibitor nor the stoichiometric factor n. This factor has been reported to be less than integral values for ascorbate and derivatives due to the loss of inhibitor in other "wasting" reactions. For example, n is reported as 1.5 for ascorbyl palmitate in SDS micelles (18) and it is

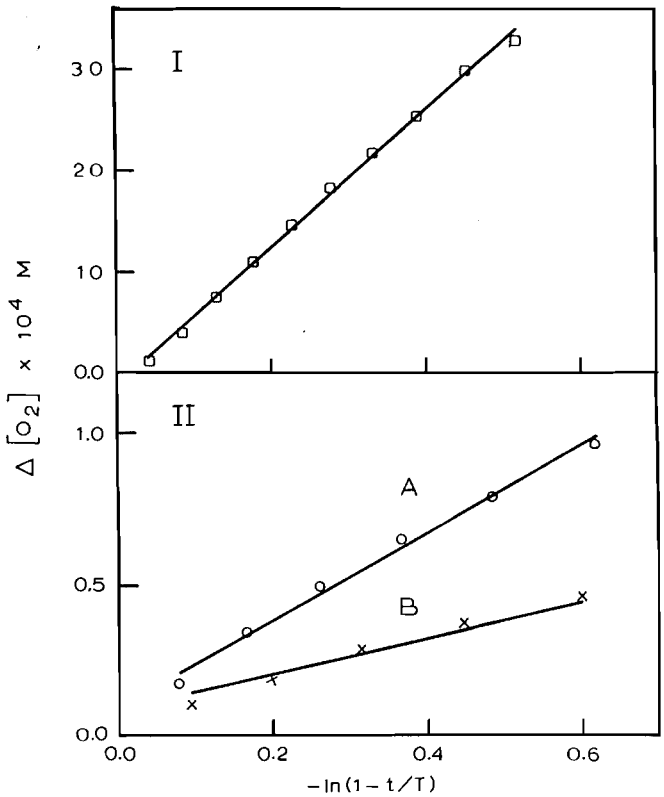

FIG. 2. Plots of oxygen uptake during inhibition periods versus $-\ln(1 - t/\tau)$ during autoxidation of styrene (2.00 mL) thermally initiated by AIBN (3.65×10^{-5} mol) at 30°C. (I) Inhibited by AH^-Q^+, 8.54×10^{-9} mol. (II) (A) Inhibited by ascorbyl 6-palmitate, 1.01×10^{-8} mol; (B) inhibited by PMHC, 7.71×10^{-9} mol.

known to be concentration dependent for vitamin C in aqueous solutions, varying from 2 at low initial concentrations (1 μM) to a low value at high concentrations (1 mM), due to its ease of autoxidation (32). Under our conditions (C = 5 μM), we determined the stoichiometric factor for ascorbyl 6-palmitate to be 0.7 by measurements of the induction period, τ, for this inhibitor under conditions where the R_i was determined by PMHC (e.g., eq. [2].

A few experiments were carried out to determine if ascorbate, (AH^-Q^+), and ascorbyl palmitate could act cooperatively with PMHC, a phenomenon observed before with vitamins C and E (6–12). Combinations of PMHC with AH^-Q^+ extend the efficient inhibition periods of PMHC as illustrated in a typical example in Fig. 3. Similar results were obtained for combinations of PMHC and ascorbyl palmitate (not shown). The extension of the efficient PMHC by AH^-Q^+ is indicative of reductive regeneration of PMHC from its phenoxyl radical. The product of the extension of the induction period of PMHC in each case and the R_i is a measure of the stoichiometric factor, e.g., eq. [4],

$$[4] \quad n = R_i [\tau_{(PMHC + C)} - \tau_{PMHC}]/C$$

The values of n, *under these conditions*, are 0.96 for AH^-Q^+ and 0.81 for ascorbyl palmitate.

A variation in the stoichiometric factor for ascorbate can cause quite large errors in determination of k_{inh} because of the loss of antioxidant by reactions other than inhibition during the measurement, especially at high initial inhibitor concentration. Therefore, inhibition rate constants for the ascorbate ion-pair were determined for a range of initial concentrations (1.7–16 μM) and the results are given in Table 2. Reasonably consistent k_{inh}'s are calculated within any given run as illustrated for the detailed results given in Run No. 1, but variations occur by as much as a factor of 2 between runs, probably due to the loss of ascorbate by autoxidation. A range of k_{inh} for ascorbate ion-pair is taken as $(8–12) \times 10^4$ M^{-1} s^{-1} or an average of $(9.63 \pm 2.0) \times 10^4$ M^{-1} s^{-1}. The value for ascorbyl palmitate determined under these conditions is significantly higher, $(110 \pm 11) \times 10^4$ M^{-1} s^{-1}.

Discussion

In the aprotic hydrocarbon medium in our studies, ascorbyl 6-palmitate is expected to be present as the nonionic form **1**, whereas the ascorbate ion-pair is represented by **2**. Structure **1** has two enolic hydrogens at positions 2 and 3 that might act as hydrogen-atom donors to peroxyl radicals. However, only the radical at position 3 can be stabilized by delocalization over the entire conjugated 5-atom system as represented by **3**. On the other hand, the ascorbate in ion-pair **2** can only donate an enolic hydrogen atom from position 2, resulting initially in a less favoured cross-conjugated enolic radical. Structure **2** can be regarded as a model for the usual form of ascorbate under physiological conditions (pH 7)

where it would be present in such an ionized form, since $pK_{a1} = 4.2$.

Some rate constants for the reaction of ascorbic acid and 6-ascorbyl palmitate with peroxyl radicals, reported by various researchers as illustrated in Table 3, indicate remarkable variations. There is no precedent for the determination of k_{inh} for ascorbic acid or ascorbate under the conditions we used. Various factors could account for such differences in rate constants including the reactivities of the peroxyls involved, the effect of the medium, since protic solvents are known to lower the k_{inh} values of phenolic antioxidants (29)

[b]pr, pulse radiolysis and ia, inhibition of autoxidation methods.

(and presumably of ascorbic acid), and the experimental method. We employed the method of inhibited autoxidation of styrene developed by Ingold and co-workers (30), because it is reproducible and their value for PMHC was obtained in the nonpolar medium of neat styrene. The reaction of HOO· with ascorbic acid would occur by hydrogen-atom donation (Table 3, No. 3) but hydrogen bonding in the aqueous medium is expected to lower the reactivity of the peroxyl radical (33) and reduce the H-atom donating ability of ascorbic acid. Similar solvation effects could account at least in part for lower rate constant values observed in alcohols (No. 4) and aqueous micelles (No. 5). We find the ratios of antioxidant activities of ascorbyl palmitate – ascorbate = 11.5 in styrene significantly different from that of 65.6 reported in SDS micelles (Table 3, Nos. 5 and 6). Solvation effects of the biphasic aqueous-micellar system probably results in differences in absolute and relative reactivities compared with homogenous solution in styrene.

The antioxidant activity of ascorbyl palmitate, **1**, (k_{inh} = 110×10^4 M^{-1} s^{-1}) compares favourably with that of phenolic antioxidants or even of the hydroxy chroman, Trolox (k_{inh} = 110×10^4 M^{-1} s^{-1}), where activities were determined under similar conditions (30). This relatively high activity is interpreted as arising by hydrogen-atom donation to peroxyl radicals from the enolic hydrogen at position 3 of **1**; that is, the k_{inh} is controlled by the stability of the resulting radical, **3**. On the other hand, the ion-pair, **2**, would donate a hydrogen from position 2 in the rate-controlling step resulting in a less stable radical. We realize that this is probably an oversimplification of the mechanism of antioxidant action of ascorbic acid and the ascorbate ion. Our results do not distinguish between other possibilities; for example, electron transfer from ascorbate, **2**, to peroxyls followed by hydrogen-ion transfer would be equivalent overall to hydrogen-atom abstraction from **2** by peroxyls. We also note that our interpretation does not account for the rather surprising finding that ascorbic acid with an ester group at the 2-position is reported not to act as an antioxidant in the oxidation of methyl linoleate in homogeneous solution (20). It is possible that a steric effect may be operating to inhibit the attack of linoleoyl peroxyl at the 3-position when position 2 is occupied by a fatty acid ester.

Our results do distinguish for the first time between the antioxidant action of ascorbic acid as its 6-ester, a remarkably effective antioxidant, and ascorbate ion, a relatively poor one, under *comparable conditions in an aprotic medium*. It is anticipated that these quantitative results will aid our understanding of the varying behaviour of ascorbic acid and ascorbate ion as antioxidants, including antioxidant activities under conditions in which it is either in the protic form or in the ionic form at pH ranges approaching physiological conditions.

Experimental

Chemicals and preparations

Common solvents used, methanol and water, were of HPLC quality. Chlorobenzene, Aldrich highest purity, was distilled from glass and 1,1,2,2-tetrachloroethane was obtained from Fisher Scientific. Styrene (Aldrich) was distilled under reduced pressure and passed through basic alumina to remove traces of peroxides just before use. The quaternary salt, tetrabutylammonium bromide (Aldrich) was dissolved in tetrachloroethane; 90–93 mM. Solutions of 2,2′-azobisisobutyronitrile (AIBN), Polysciences, Inc., were prepared in chlorobenzene and stored at −2°C. Solutions of the inhibitors ascorbyl 6-palmitate, ICN Nutritional Biochemicals, in chlorobenzene ((2.2–4.6) × 10^{-4} M) and 2,2,5,7,8-pentamethyl-6-hydroxychroman (PMHC), a gift from Dr. Graham Burton, National Research Council of Canada, Ottawa, in chlorobenzene ((3.6–4.6) × 10^{-4} M) were stored at −30°C in the dark. Sodium ascorbate (Aldrich) was used as received.

Procedures

Phase transfer and analysis of ascorbate

In a typical phase-transfer experiment, a mixture of solid sodium ascorbate (0.160 g), water (100 μL), tetrachloroethane (4 mL), followed by the addition of 4 mL of a solution of tetrabutylammonium bromide (93 mM) in tetrachloroethane, was either magnetically stirred under argon in a round-bottom flask or shaken in a sealed glass ampoule at 30°C. The latter gave the more consistent analytical results for ascorbate and was used in the inhibition experiments.

Measurement of the concentration of the quat-ascorbate, AH^-Q^+, in the organic phase required the determination of the λ_{max} and ϵ of ascorbate. For this purpose, a calibration plot was prepared for various known concentrations of sodium ascorbate in water:methanol (20:80) containing comparable amounts of tetrachloroethane. The ϵ for ascorbate under these conditions was 12 090 at 268 nm.

Determination of the quat-ascorbate concentration was carried out on the samples after centrifugation to remove possible traces of sodium ascorbate. Aliquots (100 μL) of the organic phase were diluted to 5.0 mL in water:methanol (20:80) and the absorbance measured at 268 nm with the same solvent containing tetrachloroethane as reference. These experiments were conducted after various mixing (or shaking) times to estimate the equilibrium concentration of quat-ascorbate in the organic phase.

Autoxidation and inhibition studies

Autoxidation was carried out on neat styrene (2.00 mL) at 30°C at an initial pressure of 760 Torr (1 Torr = 133.3 Pa) of oxygen using the calibrated dual-channel apparatus described previously (29). The rate of uninhibited oxygen uptake was measured. This was followed by determination of the rate of chain initiation (R_i) by injection of a known amount of PMHC and measurement of the resulting inhibition period. Then known amounts of quat-ascorbate ion-pair solutions, typically 20–30 μL of chlorobenzene or tetrachloroethane containing 4.0×10^{-4} AH^-Q^+, or ascorbyl palmitate, were injected and inhibition periods measured. Separate blank experiments were carried out by injections of similar amounts of these solvents mixed with water and tetra-*n*-butyl ammonium bromide (e.g., without ascorbate). There was no observed effect on the rate or induction period. Some measurements were also made with mixtures of PMHC and ascorbate or ascorbyl palmitate.

A study of computed rotational barriers of methyl groups and ^1H and ^{13}C spin-lattice relaxation rates in some steroids

LAWRENCE D. COLEBROOK[1] AND NING QING

Department of Chemistry and Biochemistry, Concordia University, 1455 de Maisonneuve Blvd. W., Montreal, Que., Canada H3G 1M8

Received November 5, 1990[2]

LAWRENCE D. COLEBROOK and NING QING. Can. J. Chem. **70**, 2154 (1992).

^1H and ^{13}C spin-lattice relaxation rates of the methyl groups of 15 steroids have been measured, and rotational barriers of the methyl groups have been calculated, using force field methods. Correlations between relaxation rates and computed rotational barriers have been investigated. ^1H and ^{13}C relaxation rates are consistent, and correlate with rotational barriers in simpler steroids. Steroids that are highly substituted with polar groups, and that must be investigated in polar solvents, tend to show poor correlations, an observation that is attributed to limitations in the computational model employed, which does not account for the effects of specific solvation or molecular association.

LAWRENCE D. COLEBROOK et NING QING. Can. J. Chem. **70**, 2154 (1992).

On a mesuré les vitesses de relaxation spin-réseau ^1H et ^{13}C des groupes méthyles de 15 stéroïdes et on a calculé les barrières rotationelles des groupes méthyles en utilisant des méthodes de champs de force. On a étudié les corrélations entre les vitesses de corrélation et les valeurs calculées pour les barrières à la rotation. Les constantes de relaxation ^1H et ^{13}C sont cohérentes et il existe une corrélation avec les barrières rotationnelles dans des stéroïdes plus simples. Les stéroïdes portant plusieurs groupements fortement polaires, qui doivent être étudiés dans des solvants polaires, ont tendance à présenter de mauvaises corrélations; cette observation est attribuée aux limitations dans la méthode de calcul utilisée qui ne tient pas compte des effets de solvatation spécifique ou d'associations moléculaires.

[Traduit par la rédaction]

In dilute solution (≤0.1 M in a deuteriated solvent) the spin-lattice relaxation of most ^1H and ^{13}C nuclei is dominated by the intramolecular dipole-dipole mechanism. For a molecule tumbling isotropically, the dipole-dipole contribution, $R_1(\mathrm{dd})$, to the overall relaxation rate is given by eq. [1] in terms of the relaxation contribution between two nonequivalent nuclei, i, j:

$$[1] \quad R_1(\mathrm{dd}) \propto \sum_i \frac{\gamma_i^2 \cdot \gamma_j^2}{r_{ij}^6} \cdot \tau_c(i, j)$$

where γ_i and γ_j are the magnetogyric ratios of the i and j nuclei, r_{ij} is their internuclear separation, and $\tau_c(i, j)$ is the motional correlation time of the vector between them. The net R_1 value for a nucleus is dependent on the overall tumbling rate of the molecule as a unit, plus the contribution from any additional motion of a substituent group that carries that particular nucleus. Because of the $1/r^6$ term in eq. [1], the influence of a relaxation pathway is attenuated very rapidly with increasing distance between nuclei, so that it is the near neighbours of a nucleus which dominate its relaxation.

A methyl proton relaxes largely to its neighbouring protons on the same carbon atom. The carbon atom of a methyl group is relaxed almost exclusively by the protons it carries. Differences between the ^1H relaxation rates of methyl groups in the same molecule arise, therefore, largely from differences in the correlation times for local rotational motion of the methyl groups, while differences between the ^{13}C relaxation rates of methyl groups in the same molecule arise almost exclusively from this origin (1). An *increase* in the rate of methyl group rotation *reduces* the efficiency of the dipole-dipole relaxation mechanism.

Relaxation in small molecules, which experience fast tumbling and fast methyl group rotation, may be complicated by contributions from the spin-rotation mechanism (2), which has an inverse dependence on the rotational rate of the methyl group (3). The effect of the spin-rotation contribution is to reduce the sensitivity of the overall relaxation rate, which is usually dominated by the dipole-dipole mechanism (1), to steric factors that influence the methyl group rotational rate.

The sensitivity of methyl group relaxation in steroids to steric factors was first systematically investigated by ApSimon *et al.* (4). They measured the ^{13}C relaxation times of the 18- and 19-methyl groups for a number of compounds, and proposed a model for methyl group rotation and relaxation based on the number and type of steric interactions experienced by each methyl group. It was assumed that the ground-state and transition-state conformations of these methyl groups in steroids approximate to those in ethane, the former being the usual staggered conformation and the latter the eclipsed. The model assumes that a decrease in steric hindrance from a neighbouring group will stabilize the ground state more than the transition state, thereby increasing the activation energy for rotation of the methyl group with respect to the rest of the molecule. The net effect of the resultant decrease in rotation rate will be an increase in the observed R_1 value. The relative rates of rotation of the 18- and 19-methyl groups of the *trans-anti-trans* androstane/cholestane system were rationalized in terms of the number of *syn*-clinal interactions with axial hydrogen atoms of rings A, B, and C, plus smaller interactions with hydrogen atoms of ring D. Provided that the transition states for rotation are closely similar, it follows from this analysis that the rate of rotation of the 18-methyl group of androstane should be lower, and hence its R_1 value should be greater than that of the 19-methyl group. In a later study, Colebrook and Hall (5) investigated ^1H spin-lattice relaxation in a similar group of steroids. The experimental data of both groups were consistent with this model. Introduction of a double bond at

C-1(2), C-4(5), or C-5(6), with resultant reduction in the number of interactions involving the 19-methyl group, increases the relaxation rate of that group but leaves the 18-methyl group largely unaffected, in accord with the model.

A severe limitation of this qualitative model is the difficulty in predicting the magnitude of the steric interactions affecting a methyl group. The two studies quoted show that it can work well when the methyl group can adopt a staggered, ethane-like geometry, with easily visualized *syn*-clinal interactions, but the predictions become much more difficult when other interactions are involved (5). The net steric influence on the rotational barrier of a methyl group will be the sum of a number of interactions of varying magnitude, which may affect both the ground and the transition states for rotation. What is needed is a quantitative, nonsubjective method for estimating methyl group rotational barriers.

The increasing accessibility and simplicity of operation of molecular mechanics calculations make computation of the barriers to rotation of methyl groups feasible. This offers the possibility of using quantitative estimates of methyl group rotational barriers with experimentally determined R_1 values to interpret ^1H and ^{13}C relaxation rates. The calculations can readily be carried out using a suitably equipped personal computer or workstation. We have evaluated this procedure for a number of steroids containing two or more methyl groups.

A molecular dynamics study of methyl group rotation in some podocarpanes, using force field calculations and ^{13}C relaxation times, has been reported by Bernassau and co-workers (6). Agreement was found between methyl group rotational barriers computed from nmr relaxation measurements and from force field calculations.

Methyl group rotational barriers may be calculated using the "dihedral driver" option of the MM2 and MMP2 algorithms (7), following optimization of the molecular structure (8). In this procedure, the energy of the structure is minimized for each chosen dihedral angle of the group being rotated, so that the energy calculated for the transition state for rotation allows for conformational changes in the rest of the molecule to accommodate rotation. All rotational barriers reported here were calculated by the full dihedral driver procedure.

^1H methyl group relaxation is complicated by the presence of factors that can lead to bi-exponential decay in the relaxation recovery curve used to determine R_1 (9–11). However, by working with data in the initial slope region of the recovery curve (12), where the effects of dipolar cross-correlation have been shown to be negligible (9), the R_1 data can be accurately characterized by a single exponential.

Results and discussion

The steroids examined in this study were classified into four groups according to the effects of structural changes on the 18- and 19-methyl groups:

Series I: Compounds **1**–**5**. Double bonds were successively introduced into ring A, so that nonbonded interactions involving the 19-methyl group were affected, but the 18-methyl group remained essentially unaffected.

Series II: Compounds **6** and **7**. The configurations of substituents (H, CH_3) at C-16 were interchanged, with consequent changes in nonbonded interactions with the 18-methyl groups.

Series III: Compounds **8**–**11**. The configuration of a hydroxyl group at C-11 was inverted and it was replaced by an oxo group to study the influence on rotational barriers and relaxation rates of both the 18- and the 19-methyl groups.

Series IV: Compounds **12**–**14**. The configurations of hydroxyl groups and the oxidation state at C-11 were varied for another series of compounds with a different substitution pattern at C-17.

The influences of structural changes on the rotational barriers and relaxation rates of the 18- and 19-methyl groups were investigated using two types of comparisons. *Internal* comparison permitted direct study of ^1H and ^{13}C spin-lattice relaxation rates of the 18- and 19-methyl groups and their computed rotational barriers within a molecule as structural changes were introduced (Series I and II). Since the relaxation rates of the 18- and 19-methyl groups are being compared within a single molecule, both groups experience similar influences from overall molecular tumbling. Examination of the ^{13}C relaxation rates of the protonated ring carbon atoms of testosterone, **2**, showed no evidence for anisotropic motion of the ring backbone (13), and it is assumed that any effects of overall anisotropic motion on 18- and 19-methyl group relaxation are negligible in all of the compounds examined. *External* comparison was necessary when the effects of structural changes influence both the 18- and 19-methyl groups, requiring study of the relaxation rates and computed rotational barriers in different compounds (Series III and IV). Normalization of the relaxation rates to that of a nucleus remote from the site of structural change is essential when external comparisons are being made, since the effects of differing experimental conditions and molecular tumbling rates must be eliminated (1).

Chemical shift assignments

Reliable ^1H chemical shift assignments based on NOED measurements have been reported for progesterone acetate (14) and 1-dehydrotestosterone, **3** (15). The 18- and 19-methyl group chemical shifts in prednisolone, **9**, were also assigned using this technique. The remaining steroids in this study were assigned (Table 1) by comparing their chemical shifts with those of the models, or by correlation with previously assigned ^{13}C spectra.

Spin-lattice relaxation rates

Since Bernassau and co-workers (6) established that the dipole-dipole mechanism is the sole ^{13}C relaxation mechanism in their podocarpanes, which are similar in molecular weight and geometry to steroids, it was considered unlikely that spin-rotation would make a significant contribution to methyl group relaxation in the present group of compounds. This assumption was verified through ^{13}C-{^1H} heteronuclear NOED measurements on 11α-hydroxyprogesterone, **12**. No significant reduction in the intensities of the ^{13}C 18- and 19-methyl group signals that would be characteristic of a contribution from a nondipolar mechanism was seen (1). It is assumed that contributions to ^1H relaxation mechanisms will parallel those of the ^{13}C nucleus of the same methyl group.

^1H and ^{13}C 18- and 19-methyl group R_1 values are reported for 15 steroids (Tables 2–4). In Series I, androstanolone, **1**, testosterone, **2**, and dehydrotestosterone, **3**, double bonds are successively introduced into the A ring, the rest of the molecule remaining unchanged. Similarly, the pair of compounds, 5α-pregnane-3,20-dione, **4**, and progesterone, **5**, differ by the introduction of a Δ_4 double bond into the latter

(Table 2). It was demonstrated previously that removal of 1,3-nonbonded interactions between axial A-ring hydrogens and the 19-methyl group following the introduction of double bonds influences the ^{1}H and ^{13}C relaxation rates of this group (4, 5). Using qualitative arguments, this effect has been attributed to changes in the rate of rotation of the group resulting from changes in steric interference.

Removal of 1,3-nonbonded interactions is predicted to cause an *increase* in the rotational barrier of the methyl group. In androstanolone, **1**, the compound with the maximum number of nonbonded interactions, the methyl group has no energetically favorable conformation available — its rotational ground state energy is high. As nonbonded interactions are removed, available conformations become energetically more favorable, and the differences between rotational ground and transition state energies increase — the rotational barrier increases (4).

In Series I, the computed rotational barriers for the 18-methyl groups are essentially identical (Table 2), as expected. The computed barriers of the 19-methyl groups reflect the stabilization of the rotational ground state energies as double bonds are successively introduced (Table 2), increasing from 3.22 kcal/mol in androstanolone, **1**, to 5.07 kcal/mol in dehydrotestosterone, **3**. In androstanolone, the computed barrier for the 19-methyl group is smaller (89%) than that of the 18-methyl group; in the other compounds it is larger, 120% and 142% in testosterone and dehydrotestosterone, respectively. Thus, computation supports the qualitative model used previously (4,5).

The ^{13}C R_1 values in this series correlate well with the computed rotational barriers. Thus, in androstanolone, **1**, the 19-methyl group is predicted to have a lower barrier than the 18-methyl, and the observed ^{13}C relaxation rate is lower (85%). However, the ^{1}H relaxation rates of these groups are the same within experimental error in this compound. In the other two compounds, the 19-methyl group is predicted to have a higher barrier than the 18-methyl, and both the observed ^{1}H and ^{13}C R_1 rates are higher.

The dynamic range of ^{1}H R_1 values is much smaller than that of the ^{13}C R_1 values, and the correlation with predicted rotational barriers is not quite as good. In androstanolone, **1**, the 18- and 19-methyl relaxation rates are almost identical despite the predicted higher rate of the 18-methyl group. In the other two compounds, the 19-methyl group ^{1}H R_1 rates correlate well with prediction. Throughout the group, the *changes* in the 19-methyl group relaxation rates correlated well with the predicted changes in the rotational barriers.

Similarly, in the pregnanedione–progesterone pair, **4** and **5**, the predicted 18-methyl rotational barriers are identical, whereas the predicted 19-methyl group rotational barriers increase on the introduction of unsaturation to the A-ring. In both cases, the 19-methyl group is predicted to have a higher rotational barrier than the 18-methyl group. In both cases, the ^{13}C relaxation rates are significantly higher for the 19-methyl group, in accord with prediction. In pregnanedione, **4**, the ^{1}H R_1 values of the 18- and 19-methyl groups are almost identical, despite prediction, but the correlation is better in progesterone, with a higher predicted rotational barrier.

The 16α- (**6**) and 16β-methylpregnenolone (**7**) pair (Series II) differ through a configurational change at C-16, which should affect the 18- more than the 19-methyl group. Internal comparison shows a good correlation between rotational barriers and relaxation rates for both compounds, e.g., the rotational barrier of the 19-methyl group of **6** is higher than that of the 18-methyl group. (3.78 vs. 3.21 kcal/mol), and the ^{1}H R_1 value of the 19-methyl group is higher than that of the 18-methyl group (1.64 vs. 1.35 s^{-1}). Steroid **7** showed as good a correlation as **6**. The ^{1}H R_1 data show that epimerization at C-16 does affect the relaxation rate of the 18-methyl group, as predicted, but there is no detectable influence at the 19-methyl group.

The compounds in Series III provide a somewhat different comparison. Since the changes in the molecules at C-11 should affect both the 18- and the 19-methyl groups, external comparison was applied in this series by normalizing the methyl group R_1 values to those of ^{1}H-4 and ^{13}C-4. The calculated rotational barriers of the 18-and 19-methyl groups in **8** are lower than those of **9** (18-: 2.78 vs. 3.24 kcal/mol; 19-: 4.08 vs. 4.82 kcal/mol, respectively), thus the normalized ^{1}H relaxation rates of both methyl groups in **8** showed lower values than in **9** (18-: 3.67 vs. 4.30; 19-: 3.47 vs. 3.69) (Table 3). The normalized ^{13}C R_1 values, which show a small range, did not give as good correlations as the ^{1}H R_1 values (18-: 0.48 vs. 0.50; 19-: 0.46 vs. 0.42). Similarly, the rotational barriers of **10** and **11** correlated well with the R_1 values except that the ^{13}C R_1 values of both compounds are again similar. Internal comparisons in this series show anomalies that are discussed later.

Comparison of **8** and **10**, and **9** and **11**, shows that removal of 1,3 nonbonded interactions significantly increases the rotational barrier and the ^{1}H relaxation rates of the 19-methyl groups.

Series IV enables comparison of the effects of equatorial and axial hydroxyl and oxo groups in the 11-position of steroids. External comparison shows that both the 18- and the 19-methyl groups are affected by a change in stereochemistry or oxidation state at C-11. The 18-methyl group in 11β-hydroxyprogesterone, **13**, has the highest rotational barrier

13[d]	3.00		3.95	2.20		4.32	0.74		1.09
14	2.67	0.81	2.78	2.09	0.51	4.08	0.78	0.63	1.47

[a]Calculated using the dihedral driver option of MMX.
[b]Determined at 400 (^1H, degassed) or 20.1 (^{13}C, non-degassed) MHz, and calculated by nonlinear regression, unless otherwise noted. The R_1 values are normalized to the R_1 value of ^1H-4 or ^{13}C-4 (= 1.0).
[c]Calculated rotational barrier, kcal/mol.
[d]Determined at 270 MHz (0.1 M in $CDCl_3$, non-degassed), and calculated using the null point method (5).

(3.95 kcal/mol) and the highest normalized (3.00) ^1H R_1 value in the series, while its epimer, 11α-hydroxyprogesterone, **12**, has the lowest rotational barrier (2.47 kcal/mol) and the lowest normalized relaxation rate (2.09). The ketone, **14**, has an intermediate barrier (2.78 kcal/mol) and relative R_1 value (2.67). The 19-methyl groups in this series are less sensitive to the substituent at C-11. The rotational barrier of the 19-methyl group of **12** (4.35 kcal/mol) is slightly higher than that of **13** (4.32 kcal/mol), as is its normalized ^1H R_1 (2.45 vs. 2.20), whereas the ketone, **14**, has the lowest rotational barrier (4.08 kcal/mol) and relative relaxation rates (2.09). Thus, external correlations between rotational barriers and relaxation rates in Series IV are all in the expected sense.

In Series III and IV all 19-methyl groups are predicted to have higher rotational barriers than the 18-methyl groups. However, internal comparison shows that both the ^1H and ^{13}C relaxation rates of all of the 18-methyl groups are higher than those of the 19-methyl groups, with the exception of compound **12**. Since these compounds contain several carbonyl and hydroxyl groups, it is suggested that the methyl group rotational barriers are affected by strong solvation or association in solution.

Limited solubility in nonpolar solvents of steroids highly

TABLE 4. Calculated methyl group rotational barriers[a] and measured relative ^1H spin-lattice relaxation rates[b] of **12** and **15**

	18-Methyl		19-Methyl		Ratio, 19/18	
Solvent	R_1[c]	RB[d]	R_1[c]	RB[d]	R_1	RB
12 DMSO-d_6	2.90 (2.26)	2.47	3.53 (2.75)	4.35	1.22	1.76
12 $CDCl_3$	2.09 (1.44)	2.47	2.45 (1.69)	4.35	1.17	1.76
15 DMSO-d_6	2.76 (3.73)	3.71	2.00 (2.70)	3.79	0.72	1.02
15 $CDCl_3$	1.96 (2.48)	3.71	2.35 (2.97)	3.79	1.20	1.02

[a]Molecular mechanics calculations were carried out on an Olivetti M24 computer, using PCMODEL and MMX.

[b]^1H-R_1 values were determined at 400 MHz, 0.1 M solutions.

[c]R_1 values are relative to that of H-4, except experimental values are in parentheses.

[d]Calculated rotational barrier, kcal/mol.

functionalized with polar groups restricted investigation of solvent effects on methyl group relaxation. However, ^1H relaxation rates in both $CDCl_3$ and DMSO-d_6 solutions of 11α-hydroxyprogesterone, **12**, and cortisone acetate, **15**, could be measured. Average relaxation rates were higher in the more viscous solvent, DMSO-d_6, than in $CDCl_3$ solution in both compounds; e.g., the ^1H R_1 of H-4 in **15** is 1.35 s^{-1} in DMSO-d_6 and 0.79 s^{-1} in $CDCl_3$.

For compound **12**, the normalized (with respect to H-4) R_1 values in DMSO-d_6 of both the 18- and the 19-methyl groups are higher than those in $CDCl_3$, indicating that solvation affects the local motion of both methyl groups (Table 4). Since the molecule has polar functional groups adjacent to both methyl groups (a hydroxyl group centrally located and carbonyl groups flanking the methyl groups), solvation affects both methyl groups. Therefore, the experimental R_1 data for the two methyl groups are consistent with each other, and with the prediction.

For compound **15**, the density of polar functional groups is higher near ring D and, in DMSO-d_6 solution, the spin-lattice relaxation rate of the 18-methyl group is higher than that of the 19-methyl group (3.73 vs. 2.70, normalized), contrary to prediction (Table 4). The same discrepancy has been noted for compounds **8**–**13**. However, in $CDCl_3$ solution, the 18-methyl group of **15** relaxes more slowly than the 19-methyl group (2.48 vs. 2.97, normalized), in accord with prediction. These results indicate that there are differential solvent effects on the spin-lattice relaxation rates of the 18- and 19-methyl groups of **15**, and that the discrepancies from predictions based on molecular modelling occur when the more polar solvent is used.

Conclusions

Bernassau and co-workers (6) established a successful correlation between computed methyl group rotational barriers and experimentally determined barriers derived from ^{13}C relaxation times in five nonpolar podocarpane derivatives, measured in $CDCl_3$ solution. Our data also correlate well when the steroids have few polar substituents and are measured in a relatively nonpolar solvent ($CDCl_3$). However, when the steroid is heavily substituted with polar groups, and when the measurement must be taken in a polar solvent, the correlation between ^1H and ^{13}C spin-lattice relaxation rates and the computed rotational barriers may break down. The discrepancy is most likely attributable to an inadequate model for the force field calculations, which are gas phase, and do not take molecular interactions into account at the level at which the calculations were performed. There is evidence for preferential solvation effects, in which the methyl group adjacent to the polar substituents is more affected than the remote methyl group. Thus, force field calculations of this type may work well, but they should be applied with caution in predicting properties of polar molecules measured in polar solvents.

Experimental

The ^1H nmr spectra were determined (0.1 M in $CDCl_3$ or DMSO-d_6 solution) at 400 MHz using a Bruker WH-400 spectrometer located at the Montreal Regional High Field NMR Laboratory, with the exception of some 270 MHz spectra that were reported previously (5). ^{13}C spectra were determined at 20.1 MHz ($CDCl_3$ solutions) using a Bruker WP-80SY spectrometer fitted with a 10-mm broadband probe. ^1H-R_1 values were usually measured on degassed samples, since paramagnetic contributions from dissolved oxygen contribute to the overall relaxation rate. Samples for ^{13}C measurements were not degassed. The DEPT spectral editing sequence (16) was used as an aid to ^{13}C spectral assignments. The difference technique for measuring ^{13}C nOe enhancements has been described previously (1). R_1 values were measured using the standard inversion-recovery two-pulse sequence (17), followed by nonlinear regression analysis (performed on an Olivetti M24 microcomputer) of data down-loaded from a Bruker Aspect 2000 spectrometer computer. Data analysis was confined to the initial slope region (12), defined by a single exponential. The precision of the measurements was better than 2% or 5% for ^1H and ^{13}C R_1 values, respectively. Samples were used as received from Aldrich and Sigma Chemical Companies.

Molecular mechanics calculations were carried out with an Olivetti M24 microcomputer (with 640k memory, co-processor, hard disk, and Microsoft mouse) using the programs MMX and PCMODEL (18) (Serena Software, Bloomington, Ind., U.S.A.). MMX, a batch program lacking graphics output, is an implementation of the Allinger MMP2 algorithm (7), and includes π-calculations and the dihedral driver option. The version of PCMODEL used has graphics output but does not include π calculations or a dihedral driver (with optimization). It was used for structure input (for PCMODEL and MMX), using a mouse.

The structures of compounds containing conjugated π-systems were optimized using MMX. The structures of compounds without conjugated π-systems were initially optimized using PCMODEL. MMX was used for optimizations preceding dihedral driver calculations.

Acknowledgments

Received January 20, 1992

MARTIN K. EHLERT, STEVEN J. RETTIG, ALAN STORR, ROBERT C. THOMPSON, and JAMES TROTTER. Can. J. Chem. **70**, 2161 (1992).

The reaction of molten trimethylpyrazole (tmpzH) with copper metal shot in air yields a mixture of the trinuclear copper(I) complex $[Cu(tmpz)]_3$, **1**, and the trinuclear copper(I/II) complex $[Cu(3\text{-}CO_2dmpz)(tmpzH)]_2Cu$, **2** (where dmpz is dimethylpyrazolate). Crystals of **1** are monoclinic, $a = 8.403(3)$, $b = 22.453(2)$, $c = 11.362(2)$ Å, $\beta = 95.83(2)°$, $Z = 4$, space group $P2_1/c$. Crystals of **2** are triclinic, $a = 10.988(3)$, $b = 11.009(2)$, $c = 6.457(1)$ Å, $\alpha = 103.13(2)°$, $\beta = 103.02(2)°$, $\gamma = 108.70(2)°$, $Z = 1$, space group $P\bar{1}$. The reaction of molten 4-bromodimethylpyrazole (4-BrdmpzH) with copper metal shot in air gave the binuclear copper(II) complex $[Cu(4\text{-}Br\text{-}3\text{-}CO_2mepz)(4\text{-}BrdmpzH)_2]_2$, **3** (where mepz is methylpyrazolate). There are two crystalline forms of **3**: **3***a*, triclinic, $a = 10.152(3)$, $b = 13.068(3)$, $c = 10.033(3)$ Å, $\alpha = 112.38(2)°$, $\beta = 116.46(2)°$, $\gamma = 70.29(2)°$, $Z = 1$, space group $P\bar{1}$; and **3***b*, monoclinic, $a = 13.470(1)$, $b = 16.005(2)$, $c = 20.174(1)$ Å, $\beta = 98.142(6)°$, $Z = 4$, space group $C2/c$. Magnetic susceptibility studies on a bulk sample of **3** (2.0–300 K) revealed antiferromagnetic coupling between the double pyrazolate bridged copper centres and analysis of the data according to a Heisenberg model for coupled pairs of $S = 1/2$ metal ions gave -75.4 cm^{-1} for the value of the exchange coupling constant, J. The crystal structures of **1**, **2**, **3***a*, and **3***b* were solved by the Patterson method and were refined by full-matrix least-squares procedures to final R values of 0.036, 0.056, 0.042, and 0.042 for 2265, 1764, 2011, and 2575 reflections with $I \geq 3\sigma(I)$, respectively.

MARTIN K. EHLERT, STEVEN J. RETTIG, ALAN STORR, ROBERT C. THOMPSON et JAMES TROTTER. Can. J. Chem. **70**, 2161 (1992).

La réaction du triméthylpyrazole (tmpzH) fondu avec du cuivre métallique pulvérisé dans l'air fournit un mélange du complexe trinucléaire du cuivre(I) $[Cu(tmpz)]_3$, **1**, et le complexe trinucléaire de cuivre(I/II) $[Cu(3\text{-}CO_2dmpz)(tmpzH)]_2Cu$, **2** (dans lesquels dmpz est le diméthylpyrazolate). Les cristaux du produit **1** sont monocliniques, groupe d'espace $P2_1/c$ avec $a = 8{,}403(3)$, $b = 22{,}453(2)$ et $c = 11{,}362(2)$ Å, $\beta = 95{,}83°$ et $Z = 4$. Les cristaux du produit **2** sont tricliniques, groupe d'espace $P\bar{1}$ avec $a = 10{,}988(3)$, $b = 11{,}009(2)$ et $c = 6{,}457(1)$ Å, $\alpha = 103{,}13(2)$, $\beta = 103{,}02(2)$ et $\gamma = 108{,}70(2)°$ et $Z = 1$. La réaction du 4-bromodiméthylpyrazole (4-BrdmpzH) fondu avec du cuivre métallique pulvérisé dans l'air fournit le complexe dinucléaire du cuivre(II) $[Cu(4\text{-}Br\text{-}3\text{-}CO_2mepz)(4\text{-}BrdmpzH)_2]_2$, **3**, dans lequel mepz est le méthylpyrazolate. Il existe deux formes cristallines du produit **3** : **3***a*, triclinique, groupe d'espace $P\bar{1}$ avec $a = 10{,}152(3)$, $b = 13{,}068(3)$ et $c = 10{,}033(3)$ Å, $\alpha = 112{,}38(2)$, $\beta = 116{,}46(2)$ et $\gamma = 70{,}29(2)°$ et $Z = 1$; et **3***b*, monoclinique, groupe d'espace $C2/c$ avec $a = 13{,}470(1)$, $b = 16{,}005(2)$ et $c = 20{,}174(1)$ Å, $\beta = 98{,}142(6)°$ et $Z = 4$. Des études de susceptibilité magnétique sur un échantillon global du produit **3** (2,0–300 K) révèlent la présence d'un couplage antiferromagnétique entre les centres du cuivre doublement ponté au pyrazolate et une analyse des données, suivant le modèle de Heisenberg pour les paires couplées d'ions métalliques avec $S = 1/2$, conduit à une valeur de $-75{,}4$ cm^{-1}, pour la constante de couplage d'échange, J. Les structures cristallines des composés **1**, **2**, **3***a* et **3***b* ont été résolues par la méthode de Patterson et elles ont été affinées par la méthode des moindres carrés (matrice complète) jusqu'à des valeurs de R de 0,036, 0,056, 0,042 et 0,042 pour respectivement 2265, 1764, 2011 et 2575 réflexions avec $I \geq 3\sigma(I)$.

[Traduit par la rédaction]

Introduction

Reactions of copper metal shot with molten pyrazole and substituted pyrazoles in the presence of dioxygen have been successfully employed in the synthesis of the polymeric binary copper(II) pyrazolates, $[Cu(pz^*)_2]_x$ (where pz* = pyrazolate (1), 3-methylpyrazolate,[2] 4-methylpyrazolate (2), 3,5-dimethylpyrazolate (3), and indazolate[2]). By controlling the conditions in order to achieve slow polymer formation it has been possible to obtain the pyrazolate and 4-methylpyrazolate polymeric compounds in crystalline form suitable for single crystal X-ray diffraction studies (1, 2). In the current study, further investigation of this reaction with other substituted pyrazoles has revealed that products other than the binary copper(II) pyrazolates may form depending on conditions and particularly when the pyrazole involved contains methyl substituents in the 3- and 5-positions. In this paper we describe our studies with 3,4,5-trimethylpyrazole (tmpzH) and 4-bromo-3,5-dimethylpyrazole (4-BrdmpzH) in which, by isolation and X-ray structural characterization of the title compounds, we are able to identify an interesting reaction involving oxidation of a methyl substituent to carboxylate.

The trinuclear copper(I) and copper(I/II) complexes, $[Cu(tmpz)]_3$, **1**, and $[Cu(3\text{-}CO_2dmpz)(tmpzH)]_2Cu$, **2**, respectively were isolated from the reaction of molten tmpzH with copper metal shot in air. A similar reaction involving 4-BrdmpzH gave the binuclear copper(II) complex, $[Cu(4\text{-}Br\text{-}3\text{-}CO_2mepz)(4\text{-}BrdmpzH)_2]_2$, **3**. We report here single crystal X-ray diffraction studies on the three complexes and a variable temperature magnetic susceptibility study on the binuclear complex. Binuclear copper(II) complexes that have been structurally characterized, that contain bridging pyra-

zolate ligands, and that exhibit strong antiferromagnetic interactions have been reported previously (4–7). In this earlier work, however, the interpretation of the magnetic data was complicated by the presence, in the complexes, of other bridging ligands in addition to the bridging pyrazolates. The binuclear complex reported here is, to our knowledge, the first example of a structurally and magnetically characterized purely pyrazolate-bridged binuclear copper(II) species.

Experimental

Syntheses

3,4,5-Trimethylpyrazole and 4-bromo-3,5-dimethylpyrazole were prepared as described previously (3).

*[Cu(tmpz)]$_3$, **1**, and [Cu(3-CO$_2$dmpz)(tmpzH)]$_2$Cu, **2***

Copper metal shot (8.18 g, 129 mmol), cleaned by washing with 12 M HCl, water, and then acetone, was combined with tmpzH (4.73 g, 42.9 mmol) and the mixture was heated in air, without stirring, at 142°C for 40 h. After the first 18 h of heating, the neck of the reaction vessel had become plugged with sublimed tmpzH, which limited further contact of the reaction mixture with atmospheric dioxygen. At cessation of the reaction, the mixture was allowed to cool and solidify. The mixture was then extracted with 150 mL of dry THF and suction filtered. This yielded a brown filtrate and a filtercake (~0.08 g) that consisted of an approximately equal mixture of colourless crystals of **1** and pale purple crystals of **2**. Due to their insolubility in all solvents tested the compounds could not be separated by crystallization methods. A few crystals of each were separated by hand for X-ray diffraction studies. Because a bulk sample of **2** could not be isolated its characterization is limited to the X-ray study and an EPR study of a mixture of **1** and **2**. Bulk, microcrystalline **1** was prepared previously via a different route and this together with some characterization of the compound was described elsewhere (3).

*[Cu(4-Br-3-CO$_2$mepz)(4-BrdmpzH)$_2$]$_2$, **3***

Cleaned copper shot (*vide supra*) (~1 g) and 4-BrdmpzH (~2.5 g) were combined and the mixture was heated in air, without stirring, at 140°C for 3 days. After this time the reaction mixture was allowed to cool and solidify. The solid was extracted with CH_2Cl_2 and suction filtered, yielding a green filtrate and a filtercake that consisted of well-formed green crystals of **3**. The crystals were contaminated with small amounts of yellow and bluish-grey materials; the latter were removed by manual separation. The green crystals occur as a mixture of two different morphologies, a consequence of the fact that the molecule crystallizes in both triclinic, **3***a*, and monoclinic, **3***b*, forms. Most crystals were of the triclinic form. Anal. calcd. for $C_{30}H_{34}Br_6Cu_2N_{12}O_4$: Cu 10.30, C 29.22, H 2.78, N 13.63; found: Cu 10.30, C 29.45, H 2.75, N 13.87%.

Physical characterization

Differential scanning calorimetry (DSC) measurements were made with a Mettler DSC 20 standard cell and TC10 TA processor as described previously (8). Infrared spectra (450–4000 cm^{-1}) were obtained using a Perkin–Elmer model 598 spectrophotometer. The samples were mulled in Nujol and contained between KBr plates. A ^{1}H NMR spectrum of 4-BrdmpzH was recorded using a Bruker AC-200 FT NMR spectrometer equipped with a Bruker B-ACS 120 sample changer. The solvent used was $CDCl_3$. Electron paramagnetic resonance (EPR) measurements were made on powdered samples contained in 3 mm i.d. silica tubes employing a Varian E3 X-band spectrometer. The frequency was measured using an HP5255A frequency converter and the magnetic field was calibrated with a custom-built gaussmeter.

Magnetic susceptibilities were measured over the temperature range 2–300 K using a Quantum Design (MPMS) SQUID magnetometer (field = 10 000 Oe). Temperature measurement with this instrument was achieved using a combination of Ge and Pt resistance thermometers. Susceptibility calibration was performed using high-purity Ni and Bi standards. The sample was packed as a powder into a specially constructed sample holder made from PVC. The sample holder possessed a constant cross-sectional area, thus minimizing its contribution to the SQUID signal. Magnetic susceptibilities were corrected for sample holder background signal and diamagnetism: copper, −11; $C_5H_3BrN_2O_2$, −85; $C_5H_7BrN_2$, −90 (values in 10^{-6} cm^3 mol^{-1}). A correction of 60×10^{-6} cm^3 mol^{-1} was applied for temperature independent paramagnetism of the copper(II) ion.

C, H, and N analyses were performed by P. Borda of this department. Cu analysis was by iodometric titration.

X-ray crystallographic analyses

Crystallographic data for **1**, **2**, and two crystal forms of **3** appear in Table 1. The final unit-cell parameters were obtained by least squares on the setting angles for 25 reflections with 2Θ = 31.2–34.4° for **1**, 32.3–36.9° for **2**, 25.3–30.3° for triclinic **3** (**3***a*), and 33.9–70.4° for monoclinic **3** (**3***b*). The intensities of three standard reflections, measured every 200 reflections throughout the data collections, remained constant for all four data collections. The data were processed[3] and corrected for Lorentz and polarization effects, and absorption (empirical, based on azimuthal scans for three reflections).

The analyses of **2**, **3***a*, and **3***b* were initiated in the centrosymmetric space groups ($P\bar{1}$, $P\bar{1}$, and $C2/c$, respectively), these choices being confirmed by the subsequent successful solutions and refinements of the structures. The structures were all solved by the Patterson method, the coordinates of the Cu (and Br atoms for **3***a* and **3***b*) being determined from the Patterson functions and the coordinates of the remaining non-hydrogen atoms from subsequent difference Fourier syntheses. The non-hydrogen atoms were refined with anisotropic thermal parameters and hydrogen atoms were fixed in idealized positions (C—H = 0.98 Å, $B_H = 1.2\ B_{\text{bonded atom}}$). Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the nonhydrogen atoms were taken from the *International tables for X-ray crystallography* (9). Final atomic coordinates and equivalent isotropic thermal parameters are given in Table 2 and bond lengths and angles appear in Tables 3 and 4. Anisotropic thermal parameters, bond lengths and angles involving hydrogen, general torsion angles, intermolecular distances, least-squares planes, and measured and calculated structure factor amplitudes for the four structures are included as supplementary material.[4]

Results and discussion

The 3,4,5-trimethylpyrazole reaction

Attempts to prepare the binary copper(II) trimethylpyrazolate polymer, $[Cu(tmpz)_2]_x$, by the reaction of copper metal shot with molten trimethylpyrazole in air or dioxygen under various conditions invariably resulted in the formation of a mixture of products. Under reaction conditions in which the mixture was kept stirring and freely exposed to air the prin-

[a]Temperature 294 K, Rigaku AFC6S diffractometer, Mo-K_α radiation (λ = 0.71069 Å) or Cu-K_α (λ = 1.54178 Å), graphite monochromator, takeoff angle 6.0°, aperture 6.0 × 6.0 mm at a distance of 285 mm from the crystal, stationary background counts at each end of the scan (scan/background time ratio 2:1, up to 8 rescans), $\sigma^2(F^2) = [S^2(C + 4B) + (pF^2)^2]/\mathrm{Lp}^2$ (S = scan rate, C = scan count, B = normalized background count, p = 0.03 for **1**, **2**, and **3***b*, 0.025 for **3***a*). Function minimized $\Sigma w(|F_o| - |F_c|)^2$ where $w = 4F_o^2/\sigma^2(F_o^2)$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$, and gof = $[\Sigma w(|F_o| - |F_c|)^2/(m - n)]^{1/2}$. Values given for R, R_w, and gof are based on those reflections with $I \geq 3\sigma(I)$.

cipal product was the copper(II) polymer contaminated, however, by other unidentified products. The pure polymer was eventually successfully obtained from the reaction of copper(I) trimethylpyrazolate with dioxygen in molten trimethylpyrazole (3). Nevertheless, curiosity as to the course of the metal – molten tmpzH reaction and the possibility of identifying other products, as well as a desire to obtain the copper(II) polymer in crystalline form suitable for X-ray studies, prompted us to explore this reaction under other conditions. When the reaction is allowed to proceed very slowly, with no stirring and with limited access to air, as described in the experimental section, two copper-containing crystalline products are obtained (colourless prisms and light purple prisms). Examining the reaction mixture prior to separation of the products from the unreacted copper metal shot, we noted that the colourless prisms, identified by single crystal X-ray diffraction as the copper(I) trinuclear species $[Cu(tmpz)]_3$, **1**, formed a layer in contact with the metal shot. The other product, identified by X-ray studies as the copper(I/II) mixed oxidation state trinuclear species $[Cu(3\text{-}CO_2dmpz)(tmpzH)]_2Cu$, **2**, was found forming a second layer surrounding the layer of **1**. This observation as well as the presence of copper in both the +1 and +2 oxidation states in the products suggests a stepwise oxidation of copper metal and also that **1** may be a precursor of **2**. Conversion of copper(I) to copper(II) in such complexes has been verified by clean conversion of **1** to the copper(II) polymer, $[Cu(tmpz)_2]_x$ in molten tmpzH in the presence of dioxygen (3). If **1** is the precursor of **2**, and this is by no means certain, then the oxidation of the methyl groups seen under the conditions employed here presumably takes place on coordinated $tmpz^-$. We cannot rule out oxidation of tmpzH itself; however, we note that the presence of metallic copper, acting perhaps as a catalyst, does seem to be required since no carboxylate-containing products were observed in the reaction of **1** with dioxygen in molten tmpzH in the absence of metallic copper (3).

The structure of **1** is very similar to that recently reported and discussed in detail for $[Cu(3,5\text{-}dmpz)]_3$ (10), and consists of trinuclear molecules (Fig. 1) linked pairwise about crystallographic centres of symmetry by weak Cu ... Cu interactions (Fig. 2). The mean Cu—N and intramolecular Cu ... Cu distances and the mean N—Cu—N bond angle (1.853 Å, 3.212 Å, and 174.4°) for **1** are nearly identical to

[a] $B_{eq} = (8/3)\pi^2\Sigma\Sigma U_{ij} a_i * a_j * (a_i \cdot a_j)$.

the corresponding values for [Cu(3,5-dmpz)]$_3$ (1.852 Å, 3.218 Å, and 174.6°). The intermolecular Cu ... Cu distance of 3.069(1) Å in **1** is significantly longer than the corresponding mean value of 2.946 Å observed for the 3,5-dimethylpyrazolate derivative (10). The copper atom not involved in the weak Cu ... Cu interactions (Cu(1)) lies 3.281 Å from the mean plane of the tmpz ring at the opposite end of the inversion-related trimer; the distance is only slightly longer than the corresponding mean distance of 3.272 Å in [Cu(3,5-dmpz)]$_3$. The difference between the weak metal–metal interactions in [Cu(3,5-dmpz)]$_3$ and **1**, as well as the slightly greater deviation of the central nine-membered Cu_3N_6 ring from planarity (0.129 vs. 0.07 Å) in the present structure, probably results from differences in the crystal packing. The mean N—N distance of

[a]Here and elsewhere, * denotes symmetry operation $1 - x, 1 - y, 1 - z$ for **1** and **2**; $-x, 1 - y, -z$ for ***3a***; and ′ denotes symmetry operation $1 - x, y, 1/2 - z$ for ***3b***.

1.375 Å in **1** is shorter than the value of 1.383 Å reported for [Cu(3,5-dmpz)]$_3$, but longer than that of 1.355(8) Å found for the terminal tmpzH ligand in **2** (see Table 3). This may reflect significant Cu($d\pi$)–tmpz(π^*) interaction as discussed previously (10).

The centrosymmetric, trinuclear, mixed-valence Cu(I)/Cu(II) complex **2** is shown in Fig. 3. The entire molecule, apart from the hydrogen atoms, is planar to within 0.2 Å. The molecules stack in the solid state (Fig. 4), the shortest intermolecular distance being Cu(2) ... O(1)(x, y, $z - 1$) = 3.145(6) Å. The 3-CO_2dmpz ligands in **2** chelate the central copper(II) atom (Cu(1)) via the carboxylate oxygen atom O(1) and the adjacent ring nitrogen atom and also form bridges between Cu(1) and both of the copper(I) atoms (Cu(2) and Cu(2)*), one via a pyrazolate -N—N- bridge and the other via a single-atom bridge involving O(1). This latter bridge involves a very weak copper–oxygen interaction in which the distance involved (Cu(2)—O(1) = 2.638(5) Å) is long for a normal bond between copper(I) and oxygen but is significantly shorter than the sum of the van der Waals radii (2.95 Å (11)). The second oxygen atom of the carboxylate group, O(2), is not involved in coordination to the metal atoms but contributes to the stability of the complex by hydrogen-bonding to the NH proton of the terminal monodentate tmpzH ligand coordinated to Cu(2) (N(4)—H(1) ... O(2)*, H ... O = 1.88 Å, N ... O = 2.859(8) Å).

The central copper(II) atom, Cu(1), has *trans* square-planar coordination geometry with Cu—O = 1.978(5) Å, Cu—N = 1.889(5) Å, and the O–Cu–N bond angle within the five-membered chelate ring is 83.0(2)°. The copper(I) atom, Cu(2), has a T-shaped coordination geometry featuring a nearly linear N–Cu–N unit with strong Cu—N bonds (Cu—N = 1.860(6) and 1.869(6) Å, N–Cu–N = 173.8(3)°) perpendicular to the very weak Cu—O bond involving the asymmetrically bridging carboxylate oxygen atom, O(1) (Cu—O = 2.638(5) Å, N—Cu—O = 90.8(2) and 93.5(2)°). The mean Cu(2)—N bond distance of 1.865(5) Å in **2** is slightly longer than the corresponding mean copper(I)—N bond lengths of 1.853 Å in **1** and 1.852 Å in [Cu(3,5-dmpz)]$_3$ (10). The N—N distances in both of the pyrazole rings (N(1)—N(2) = 1.369(8) and N(3)—N(4) = 1.355(8) Å) are consistent with a weaker Cu–N interaction than is observed in the copper(I) trimers (mean N—N = 1.375 Å in **1**, 1.383 Å in [Cu(3,5-dmpz)]$_3$ (10)).

As described in the experimental section, while it was possible to isolate manually a few crystals of **2** from the mixture of **1** and **2**, the very small size of the crystals made it impractical to obtain a bulk sample of pure **2** by this means. Nonetheless, since **1** is EPR silent it was possible to obtain EPR spectra of **2** employing the mixture ground to a fine

powder. At room temperature, the spectrum shows two regions of absorption centred at $g_\parallel$ and $g_\perp$. Nuclear hyperfine splitting of $g_\parallel$ is observed with two of the four components resolved and the other two obscured by the $g_\perp$ absorption. There is no observable splitting of $g_\perp$. The EPR parameters, calculated to first order, are $g_\parallel = 2.202$, $g_\perp = 2.048$, and $|A_\parallel| = 132 \times 10^{-4}$ cm^{-1}. There is no significant change in the spectrum at 77 K. The two g-value spectrum is as expected for square-coplanar copper(II) with negligible exchange coupling (12). Exchange effects normally broaden the EPR spectra of copper(II) complexes in the solid state to an extent that hyperfine data are masked. The observation of hyperfine splitting of $g_\parallel$ in powdered samples is relatively rare; however, it has been observed previously, for example, in a number of tetrakis(pyridine) complexes of copper(II) (13).

4-Bromo-3,5-dimethylpyrazole reaction

Reaction of the copper metal shot with molten 4-BrdmpzH in air, with vigorous stirring, yields, over a 24 h period, a brown powder identified by elemental analysis to be largely [Cu(4-Brdmpz)$_2$]$_x$. One easily recognizable impurity in the brown powder is small amounts of a substance present as green prisms. By carrying out the reaction under conditions that lead to a slower rate of reaction (no stirring) the green crystals become the major product. The green crystals (two forms) were separated by hand from minor amounts of unidentified by-products. Subsequent characterization by X-ray diffraction revealed the crystals to have the dimeric

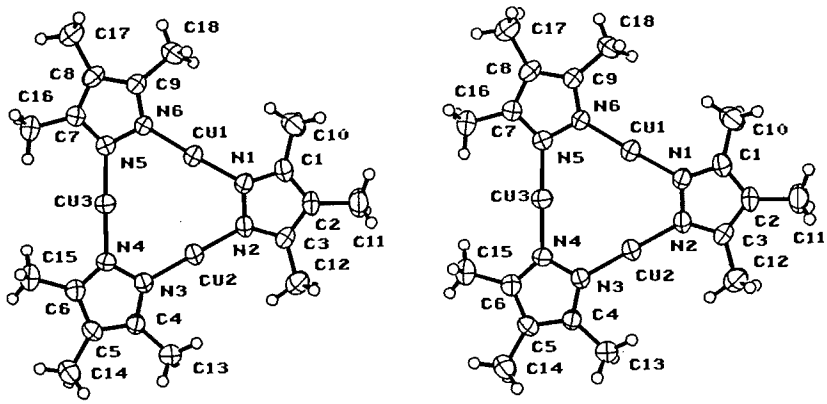

FIG. 1. Stereoview of **1**; 33% probability thermal ellipsoids are shown for the nonhydrogen atoms.

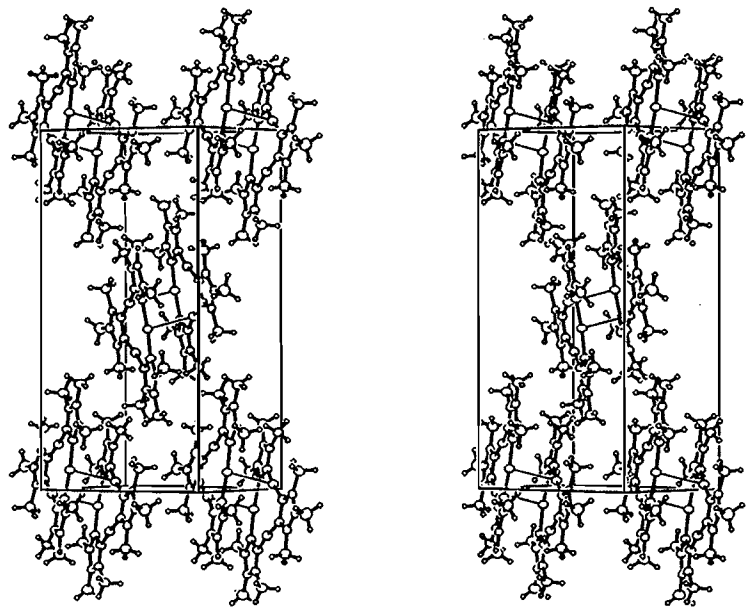

FIG. 2. Stereoview of the packing arrangement for **1**.

composition $[Cu(4\text{-Br-3-}CO_2\text{mepz})(4\text{-BrdmpzH})_2]_2$, **3**. Although the reaction conditions employed here were similar to those described above for the tmpzH reaction, no copper(I) species were seen to form in any significant amounts in this case.

Complex **3** (Fig. 5) is a binuclear copper(II) complex in which the 4-Br-3-CO_2mepz ligand is both bridging (Cu—N—N—Cu) and chelating (one carboxylate oxygen atom and the adjacent ring nitrogen atom). The molecule possesses crystallographic symmetry in both crystal forms: a centre of symmetry in the triclinic form **3***a* and a twofold axis in the monoclinic form **3***b*. The central Cu_2N_4 six-membered ring is exactly planar in **3***a* while in **3***b* it is nonplanar, having a N(2),N(2)′-boat conformation. The maximum deviation from the mean Cu_2N_4 plane in **3***b* is 0.330(5)Å for N(2).

The coordination geometry about the copper atoms in both **3***a* and **3***b* is axially compressed trigonal bipyramidal with the carboxylate oxygen atom and a nitrogen atom of the bridging 4-Br-3-CO_2mepz ligand occupying the axial positions. The equatorial ligand set comprises the chelating nitrogen atom of the 4-Br-3-CO_2mepz ligand and nitrogen atoms of the two terminal 4-BrdmpzH ligands. There is some distortion of the trigonal bipyramid towards a square-pyramidal geometry in which N(5) is apical. This may be responsible (along with steric factors) for the significant lengthening of the Cu—N(5) bond in both polymorphs of **3**. The axial bond lengths in **3***a* and **3***b* do not differ significantly (Cu—O = 1.992(5) and 1.982(4) Å, Cu—N = 1.947(6) and 1.949(5) Å, respectively for **3***a* and **3***b*). The three equatorial Cu—N distances in both **3***a* and **3***b* are significantly different from one another and, for the terminal 4-BrdmpzH ligands, the corresponding bond lengths in the two crystal forms also differ significantly (see Table 3). The average equatorial Cu—N distances in **3***a* and **3***b*, however, are nearly identical: 2.100 Å for **3***a* and 2.107 Å for **3***b*.

Even though the molecular symmetry is different in the two crystal forms of **3**, the hydrogen-bonding motifs are the same in **3***a* and **3***b*. In both crystalline modifications of this material the molecules are linked about crystallographic inversion centres by N—H ... O hydrogen bonds involving the N—H protons of the terminal 4-BrdmpzH ligands to form infinite chains extending along the crystallographic *c* axes

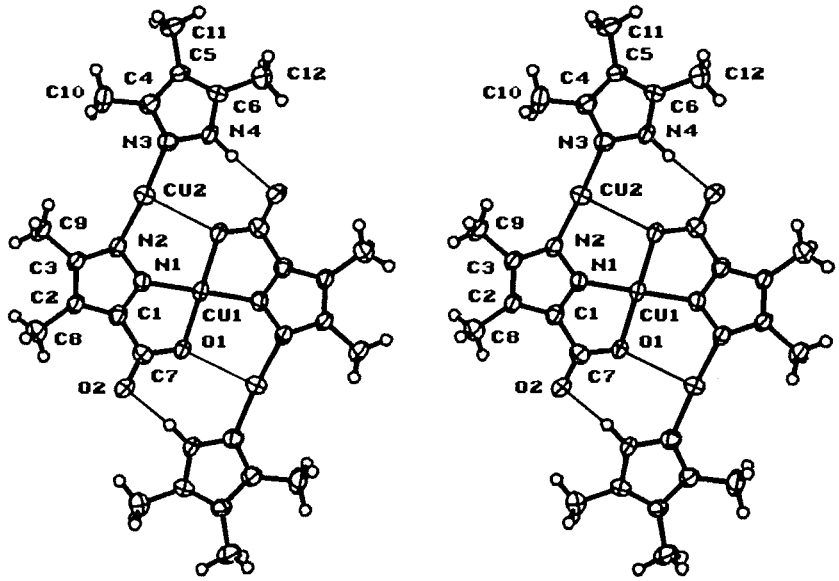

FIG. 3. Stereoview of **2**; 33% probability thermal ellipsoids are shown for the nonhydrogen atoms.

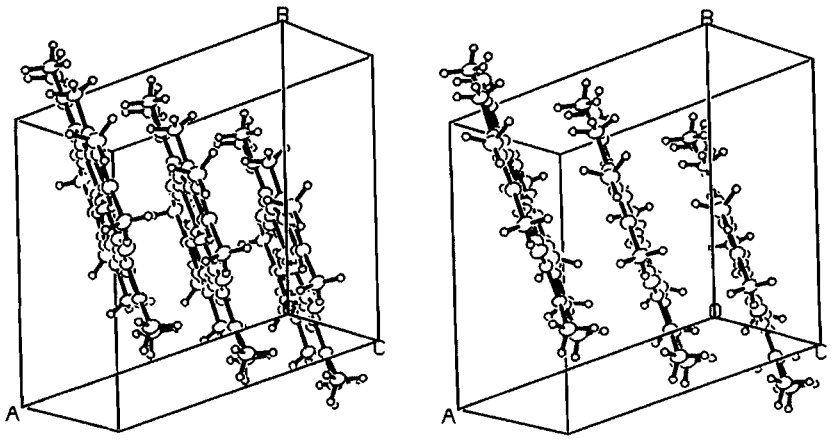

FIG. 4. Stereoview of the packing arrangement for **2**.

(Fig. 6). Each linkage involves two weak and two strong N—H ... O hydrogen bonds (Table 5). The strong hydrogen bonds involve the N(4) proton and the uncoordinated carboxylate oxygen atom, O(2). The weak hydrogen bonds are formed by the N(6) proton and the metal-coordinated oxygen atom, O(1), these atoms being involved in both intra- and intermolecular hydrogen bonds.

The physical characterization of **3**, including magnetic studies, was done on bulk samples composed mainly of crystals of the triclinic ***3a*** form but which contained small amounts, visually estimated at no more than 1%, of the monoclinic, ***3b***, form. The infrared spectrum of **3** was recorded and band frequencies have been deposited (see footnote 4). The compound exhibits thermochromism; it is bluish-green in color at 77 K.

DSC measurements on **3**, in air, show the onset of an endothermic event followed immediately by exothermic decomposition at ~250°C. To investigate the possibility that the endothermic event corresponds to loss of neutral 4-BrdmpzH, and to identify possible products of such a dissociation reaction, a sample of **3** was heated at 165°C under vacuum for 9 h. During the heating process, the compound changed color from green to olive-green and a white solid was seen to sublime from the sample. The white product was identified as 4-BrdmzH by melting point (117–118°C) and by ^{1}H NMR (δ 2.21 (s, 6, CH_3), 11.2 (br s, 1, NH)). The sample of **3** underwent a mass loss of 35% in the heating process, corresponding to the loss of 2.5 moles of 4-BrdmpzH per mole of compound. These observations are consistent with the formation of a compound of nominal composition Cu_4(4-Br-3-CO_2mepz)$_4$(4-BrdmpzH)$_3$. Anal. calcd. for $C_{35}H_{33}Br_7Cu_4N_{14}O_8$: C 26.42, H 2.09, N 12.32; found: C 26.11, H 2.28, N 12.41.

Magnetic susceptibility data for **3** over the temperature range 2–300 K have been deposited (footnote 4) and are shown as a plot versus temperature (20–300 K) in Fig. 7. The susceptibility passes through a broad maximum at 130 K, typical for two antiferromagnetically coupled copper centres. As is common in such systems the susceptibility rises with decreasing temperature at the lowest temperatures studied due to paramagnetic impurity. The magnetic susceptibilities (2–300 K) were fitted to the theoretical expression given by

Bleaney and Bowers for antiferromagnetic dimeric copper(II) systems (14) with allowance made for a paramagnetic component. Allowing for the paramagnetic component, $\%P$, by modelling it as a Curie paramagnet with a g-value equal to that of the bulk sample gives the equation:

$$\chi = \frac{Ng^2\mu_B^2}{kT}\left[[1 - P]\left[\frac{e^{2J/kT}}{1 + 3e^{2J/kT}}\right] + \frac{P}{4}\right]$$

where J is the exchange coupling constant. This modelling procedure gives best fit values of J, g, and $\%P$ of $-74.0(6)$ cm^{-1}, 2.11(1), and 5.15(7) respectively with the fitting function $F = 0.029$. The function F:

$$F = \left[\frac{1}{n}\sum_{i=1}^{n}\frac{[\chi_i^{obs} - \chi_i^{calc}]^2}{[\chi_i^{obs}]^2}\right]^{1/2}$$

is minimized in the fitting procedure and provides a measure of the agreement between the experimental data and the model. A better fit is obtained if the paramagnetic component is modelled as a Curie–Weiss paramagnet. This fit, which is shown in Fig. 7, gives values of J, g, $\%P$, and Weiss constant, θ, of $-75.4(1)$ cm^{-1}, 2.123(2), 5.59(2), and $-0.46(2)$ K respectively ($F = 0.0061$). These parameters are considered valid for the triclinic form, **3***a*. Because of their similar molecular structures, particularly in terms of bond lengths and angles associated with the bridging atoms (Tables 3 and 4), **3***a* and **3***b* are unlikely to have very different magnetic properties. Hence, we would not expect the presence of ~1% **3***b* in the sample to result in experimental susceptibilities that are measurably different from those of pure **3***a*.

Previous studies on nine binary copper(II) pyrazolates that have extended chain structures and four-coordinate CuN_4 metal centres reveal antiferromagnetic exchange with values of $J = -58$ to -105 cm^{-1} (2, 3). Interestingly, in spite of the fact that **3** is dimeric and has five-coordinate metal centres, the magnitude of the exchange between the metal centres is not greatly different from that observed in the polymers. A more useful comparison might be made between **3** and other copper binuclear complexes containing the bridging pyrazolate moiety.

To our knowledge, except for the pyrazolate chain compounds (1, 2), there is no previous report of a structurally and magnetically characterized, purely pyrazolate-bridged polynuclear copper(II) complex. However, there are reports of copper(II) pyrazolate-bridged complexes that contain another bridging ligand. Mazurek *et al.* (4), Nishida and

Kida (5), and Doman *et al.* (6) have reported on a series of pyrazolate-bridged, Schiff-base, square-planar copper(II) dinuclear species where the Schiff base is derived from a diamino straight-chain alcohol backbone and salicylaldehyde. In these complexes the copper(II) ions are also bridged by an alkoxide group. The *J*-values in these complexes range from -120 to -297.5 cm^{-1}. It must be recognized that the alkoxide bridge is very effective in propagating magnetic exchange and is likely to provide an important exchange pathway in these complexes making direct comparisons of their *J* values with that obtained for **3** inappropriate. The binuclear complex $[Cu(L\text{-}S)(pz)(CH_3OH)]_2$ (L-S = 2,6-bis-(4′-cyclohexyl-4′-hydroxy-2′,3′-diazabuta-1′,3′-dien-1′-yl)-4-methyl-thiophenolate) has been reported to be only weakly antiferromagnetic with $J = -1.8$ cm^{-1} (15). In addition to a pyrazolate bridge this compound has a bridging thiophenolate ligand and it seems likely that the latter is having a significant effect on the exchange.

Perhaps the most appropriate comparisons to made with **3** are with the binuclear complexes reported by Ajo, Bencini, and Mani (7) and by Prins *et al.* (16). The former authors reported magnetic studies on the species $[(H_2B(pz)_2)Cu(pz)_2(X)Cu(H_2B(pz)_2)]^-$ (pz = pyrazolate and X = Br, Cl) where square-pyramidally coordinated copper(II) ions are triply bridged by two pyrazolate ligands and one halide ion. *J*-values of -120.5 cm^{-1} and -122 cm^{-1} were found for the chloride and bromide complexes respectively.[5] The authors argue that because the exchange constants are insignificantly different for the bromide and chloride complexes the primary pathway for exchange must be the bridging pyrazolate ligands. Prins *et al.* reported studies on the related bis-triazolate-bridged $[Cu(bpt)(CF_3SO_3)(H_2O)]_2$ (bpt = bis-(pyridin-2-yl)−1,2,4-triazolate). In this complex, the copper(II) ions are present in distorted octahedral coordination environments and $J = -118$ cm^{-1}. The magnitude of the exchange coupling is virtually identical in these three complexes and is significantly greater that in **3**. Some or all of this difference in magnetic coupling may be accounted for by differences in the metal-ligand chromophores. In the previously studied complexes the coordination geometry is either square-pyramidal or tetragonally elongated octahedral with the $d_{x^2-y^2}$ orbital as the magnetic orbital and the bridging ligands bonded in the *xy* plane of each copper ion. In **3** the geometry is trigonal bipyramidal. The magnetic orbital is the d_{z^2} orbital and the pyrazolates bridge such that one nitrogen occupies an axial site on one copper while the other nitrogen occupies an equatorial site on the second copper. Since overlap of the magnetic d_{z^2} orbital with ligand orbitals in the *xy* plane is expected to be weaker than overlap with ligand orbitals on the *z* axis, the exchange pathway provided in this complex would not be expected to be very efficient and this could account for the weaker exchange coupling seen in **3**. Finally, it should be noted that several years ago Barraclough, Brookes, and Martin (17) reported the preparation and magnetic properties (92–280 K) of Cu(acac)(pz) (where acac = acetylacetonato). The compound was assumed to have a binuclear structure with square-coplanar copper ions, terminal acac ligands, and bridging pyrazolates. The exchange coupling was found to be significantly weaker ($J = -35$ cm^{-1}) than that reported here for **3**. The relatively weak exchange in the acac compound is somewhat surprising in view of the above discussion; however, the lack of a definitive structure for the compound and the lack of magnetic data to sufficiently low temperatures (no maximum in χ_m versus *T* was observed) prevents further analysis of these results other than to suggest that the previously proposed structure may be incorrect.

[5]The Hamiltonian used in ref. 7 has the form $-JS_1 \cdot S_2$ while the one here and in the other references quoted is of the form $-2JS_1 \cdot S_2$. Accordingly, for comparison purposes we have halved the *J* values reported in ref.7.

Received January 29, 1992

OLIVIER DANGLES and RAYMOND BROUILLARD. Can. J. Chem. **70**, 2174 (1992).

Copigmentation of malvin (a common anthocyanic pigment) with a series of naturally occurring colourless organic molecules (copigments) has been investigated by UV–visible absorption. The temperature-dependence of the visible spectrum of the copigmented solutions yields the copigmentation enthalpy and entropy changes. The experiments are carried out at pH 3.5 (malvin flavylium cation copigmentation) and pH 5.5 (copigmentation of the malvin quinonoidal bases). Copigmentation appears to be clearly enthalpically driven (exothermic process with unfavourable entropy change) in the case of chlorogenic acid and (+)-catechin. Concerning caffeine and tryptophan, favourable entropy changes, probably arising from solvation effects, have been recorded. Similar experiments in water–ethanol binary solvents have shown that the dramatic weakening of copigmentation on cosolvent addition is essentially entropic in origin. Salt effects on copigmentation have been investigated as well. Most of the results are discussed with a view to pointing out the major contributions to the magnitude of the copigmentation. Finally, relaxation kinetic measurements on the malvin–rutin system give striking evidence of the strong slowing down that a good copigment causes to the anthocyanin fading process (hydration). From the decrease in the apparent first-order rate constant of hydration on copigment addition, a general method for a quick determination of the copigmentation stability constants is proposed.

OLIVIER DANGLES et RAYMOND BROUILLARD. Can. J. Chem. **70**, 2174 (1992).

La copigmentation de la malvine (un pigment anthocyanique courant) par une série de molécules organiques naturelles incolores (copigments) a été étudiée par spectroscopie d'absorption UV–visible. Les modifications spectrales des solutions copigmentées, produites par variation de température, donnent accès aux variations d'enthalpie et d'entropie de copigmentation. Les expériences sont conduites à pH 3,5 (copigmentation du cation flavylium de la malvine) et à pH 5,5 (copigmentation des bases quinoniques de la malvine). La copigmentation est un phénomène sous contrôle enthalpique (processus exothermique accompagné d'une variation d'entropie défavorable) dans le cas de l'acide chlorogénique et de la (+)-catéchine. En ce qui concerne la caféine et le tryptophane, des variations d'entropie favorables, provenant probablement de phénomènes de solvatation, ont été mesurées. Des expériences similaires avec des solvants binaires eau–éthanol ont montré que l'affaiblissement considérable de la copigmentation, produit par l'addition de cosolvant, est essentiellement d'origine entropique. Des effets de sel sur la copigmentation ont également été étudiés. La plupart des résultats sont discutés en vue de mettre en évidence les principales contributions à l'interaction de copigmentation. Enfin, des mesures de cinétique de relaxation sur le système malvine–rutine illustrent de manière frappante le fort ralentissement produit par un bon copigment sur le processus de décoloration du pigment (hydratation). Une méthode générale de détermination des constantes de stabilité de copigmentation est proposée à partir des variations de la constante cinétique apparente d'hydratation (premier ordre) en fonction de la concentration de copigment.

Introduction

Anthocyanins are natural pigments that are responsible for most of the red, blue, and purple colours displayed in flowers and fruits (1–4). Their natural medium, the vacuolar cell sap of flower epidermal tissues, for instance, is essentially aqueous. In nature, anthocyanin molecules are frequently found in association with generally colourless molecules named copigments (4–8) (essentially, polyphenols and flavonoids), which exert a determining influence on the resulting colour (on both shade and intensity). In fact, the pigment–copigment molecular interaction (copigmentation) is certainly one of the key phenomena accounting for colour expression and variation in flowers. When monitored by UV–visible absorption spectrometry, the copigmentation reaction consists in an increase in the visible band intensity for the pigment (hyperchromic effect) and frequently in a shift of this very band toward longer wavelengths (bathochromic effect) (9–12). As previously demonstrated (13), the relative hyperchromic shift at a given wavelength (close to that of the absorption maximum) is the true parameter accounting for the magnitude of the copigmentation from which the thermodynamic parameters of the copigmentation reaction can be estimated (13–17). For a given anthocyanic pigment and at fixed pH and temperature, it depends essentially on the copigment chemical structure. Many quite different compounds (in particular, naturally occurring and biologically active molecules) have been shown to be anthocyanin copigments (9). Moreover, under suitable conditions, the hyperchromic shift produced by a good copigment on the anthocyanin visible band is not only exceptionally large (13, 14) (probably one of the largest reported) but also extremely sensitive to any modification of the medium. For instance, strong cosolvent effects on the copigmentation reaction have been already reported (15).

In this work, using visible absorption measurements, we compare the enthalpic and entropic contributions for diverse pigment–copigment systems to the overall free enthalpy change of copigmentation and show how a typical modification of the medium, such as salt or cosolvent addition, alters these thermodynamic parameters. From these results, we try to discern the most important factors sustaining the pigment–copigment molecular interaction in order to outline some structural features common to what may be called *good copigments*. Finally, we apply relaxation kinetics to the study of the influence of the copigment on the rate of the apparent hydration process for anthocyanin and we use

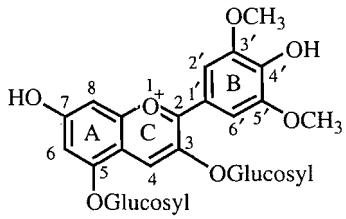
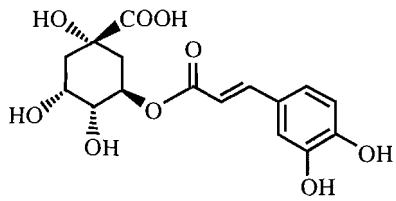
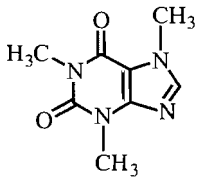
such observations to devise a simple new method for the determination of the copigmentation equilibrium constants. The pigment chosen is malvin (**1**) (malvidin-3,5-diglucoside), a very common and readily available anthocyanin. Copigments have been selected from important families of natural compounds frequently encountered in the plant kingdom. These are chlorogenic acid (**2**), a polyphenol; caffeine (**3**), the well-known purine; and two members of the flavonoid family, (+)-catechin (**4**), a proanthocyanidin or condensed tannin, and rutin (**5**), a flavonol. Amino acids, which up to now have been little investigated for their ability to act as copigments (9), are taken into consideration as well.



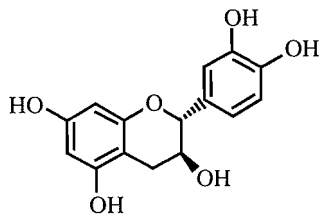
Malvin (**1**)



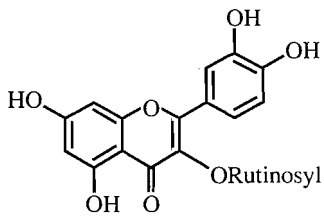
Chlorogenic acid (**2**)



Caffeine (**3**)



(+)-Catechin (**4**)



Rutin (**5**)

Experimental

Materials

Malvin chloride, chlorogenic acid, caffeine, (+)-catechin, and rutin were purchased from Roth. Their purity was checked by UV–vis and ^{1}H NMR spectroscopies. Tryptophan and its methylester (L-series) were provided by Fluka and used as such.

Absorption spectra

Spectra were recorded with a Hewlett–Packard diode-array spectrometer fitted with a quartz cell (d = 1 cm) equipped with a stirring magnet. A constant temperature in the cell was obtained by use of a Lauda water-thermostated bath; temperature measurements were made with a Comark thermocouple.

Thermodynamic measurements

Pigment and copigment titrated solutions are prepared by dissolving the compounds into a buffer (either 0.2 M acetic acid – 0.2 M sodium acetate or 0.1 M citric acid – 0.2 M Na_2HPO_4) whose pH has been adjusted to the desired value. In all experiments, the pigment concentration is held constant. The values of the copigmentation equilibrium constants K (at 25°C) are obtained by measuring the relative hyperchromic shift (at a given wavelength) either as a function of the overall concentration of the copigment, at a fixed pH, or as a function of pH at a fixed overall concentration of copigment. These procedures have already been published (13–15). ΔH^0 and ΔS^0 stem from a temperature variation on the pigment–copigment system at fixed pH and overall copigment concentration. Details are given in the discussion (see eq. [2]). In the study on cosolvent effects, the molar fraction of water in each binary solvent remains larger than 0.9 so that pH correction is not necessary.

Kinetic measurements

(i) Flavylium cation copigmentation

One millilitre of an equilibrated 4×10^{-4} M malvin solution in 0.025 M citric acid (pH about 2.3) is magnetically stirred in the spectrometer cell (T = 25°C); 1 mL of a freshly prepared rutin solution in 0.02 M NaOH at variable copigment concentration (usually ranging from 4×10^{-4} to 2×10^{-3} M) is quickly added to the cell and the visible spectra are immediately recorded, and again every 2 s. The final pH value is always close to 3.4.

(ii) Copigmentation of the quinonoidal bases

The above-described experiment is repeated starting with a 6×10^{-4} M malvin solution in 0.025 M citric acid. Rutin solutions are now prepared in 0.05 M NaOH. Visible spectra are recorded every 20 s just after adding the alkaline solution of rutin (concentrations from 6×10^{-4} to 3×10^{-3} M) to the cell. The final pH value is always close to 5.2.

In both types of experiment, the corresponding rate constant

reference values are gained by adding 1 mL of a NaOH solution without copigment to the initial malvin solution.

Results

Temperature variation experiments in water and binary solvents

Two typical temperature variation experiments on a malvin–copigment system are shown in Figs. 1 and 2. In both cases, the copigment is (+)-catechin. The visible spectra of the solution (at fixed pigment and copigment concentrations) are recorded for different temperatures at pH 3.5 (Fig. 1) and pH 5.5 (Fig. 2). At pH 3.5, a temperature increase from 10 to 30°C leads to a strong decrease in the malvin visible absorption in the presence of the copigment, whereas the corresponding changes in the absence of the copigment are negligible. Thus, the fading of the copigmented solution on increasing temperature is essentially attributable to the copigmentation process itself. Similar observations have already been reported on the malvin – chlorogenic acid and the cyanin – chlorogenic acid couples at pH close to 3.6 (13, 14). These observations remain valid at pH 5.5 (temperature range from 15 to 45°C), although the temperature-dependence of the visible absorption of malvin without copigment is no longer negligible in that case. Note, however, that a rise in temperature leads to opposite changes in the visible band of the pigment depending on whether or not the copigment is present. Thus, here again, copigmentation is responsible for the fading of the copigmented solution on increasing temperature. In fact, the increase in the pigment absorbance of the uncopigmented solution when the temperature is raised from 15 to 45°C is mainly due to thermal buffer effects that slightly alter the pH. However, the pH is the same for both copigmented and uncopigmented solutions at a given temperature, and the temperature-dependence of the pH is weak enough for the theoretical treatment to apply to this case (see eq. [1]). Similar experiments were carried out with other copigments, in particular, caffeine and tryptophan. Finally, some of the experiments were repeated after addition of given amounts of ethanol. Assuming the van't Hoff hypothesis, the temperature-independent ΔH^0 and ΔS^0 for the copigmentation reaction as well as the corresponding K value at 25°C were derived for the different copigments investigated. These parameters are listed in Tables 1 and 2. In Fig. 3 are shown the spectral changes in the visible range of a malvin copigmented solution on addition of increasing amounts of ethanol at fixed temperature and pH.

Salt effects

The influence on the visible spectrum of malvin of large additions of alkali halides to slightly acidic solutions of malvin without copigment are illustrated in Figs. 4 and 5. In Table 3 are listed the values at 25°C of the relative hyperchromic shift caused by caffeine addition to malvin under slightly acidic solutions at a given ionic strength fixed either by LiCl, KCl, or $MgCl_2$. In each case, the corresponding copigmentation equilibrium constant has been roughly estimated.

Relaxation kinetic measurements

Figures 6 and 7 show the time-dependence of the visible absorbance of malvin at a fixed wavelength just after mixing of the pigment and copigment solutions, for different copigment concentrations. The measurements reported in Fig. 6 deal with the flavylium cation (λ = 520 nm; final pH 3.4) whereas those reported in Fig. 7 deal with the quinonoidal bases (λ = 570 nm; final pH 5.2).

Discussion

Most of the results reported here must be discussed in the light of the structural transformations that anthocyanic pigments undergo in aqueous solution (18). First, depending on the pH of the medium, three distinct classes of visible light-absorbing species must be taken into consideration (see Scheme 1; Gl stands for glucosyl): these coloured forms are the flavylium cation AH^+ (usually red) and the forms deriving from successive deprotonations of AH^+ on increasing the pH, that is, the neutral quinonoidal bases A (two forms in tautomeric equilibrium, usually purple) and the ionized quinonoidal bases A^- (usually blue, not shown in the scheme). In the case of malvin, the corresponding pK_a values at 25°C (19) are about 4 for the AH^+/A acid–base couple and 7 for A/A^-. The pH values of the vacuolar cell sap from the coloured epidermal tissues of fresh flowers have been demon-

strated to range from about 2.5 to 7.5 (20); thus, the flavylium cation and the neutral quinonoidal bases are the main anthocyanic forms responsible for colour expression in flowers. However, a lot of blue flowers are displayed in nature and it is good evidence of the occurrence in plants of colour variation phenomena, the most important being copigmentation (4). In fact, copigmentation, which consists in molecular complex formation between the anthocyanin coloured forms and the copigment colourless molecules, leads to a bathochromic shift in the visible band of the pigment known as the *bluing effect* (9–12, 17).

Concerning the other spectral change characteristic of copigmentation, that is, the large hyperchromic shift in the visible band of slightly acidic anthocyanin solutions (see Figs. 1 and 2), it cannot be interpreted without taking into account all anthocyanin structural transformations (see Scheme 1), the more important being the relatively slow flavylium cation hydration (21, 22) giving rise to the colourless hemiacetal B. Since the consecutive opening of the hemiacetal B-ring leading to the pale yellow E-chalcone (C_E) is a very fast process (23) (equilibrium reached within a few milliseconds), the B and C_E forms can be written together in what is an overall hydration equilibrium. The very minor Z-chalcone (C_Z) arising from very slow C—C double-bond iso-

merization in C_E can be neglected. The equilibrium constant of the overall hydration reaction (see Scheme 2) can be expressed as

$$K_h = a_{H^+}([B] + [C_E])/[AH^+]$$

where a_{H^+} is 10^{-pH}. In the case of malvin, pK_h is about 2 at 25°C (19) and typical values range from 2 to 3 for the simplest anthocyanins (18, 24). Consequently, in their natural medium (pH 2.5–7.5), most anthocyanins are essentially present in colourless forms. Thus, the presence in flowers of so many vivid colours cannot be simply due to anthocyanins dissolved in the vacuoles since the corresponding solutions would be very poorly coloured. Some colour-stabilizing effects must take place. In fact, the hydration equilibrium, which connects the highly coloured flavylium cation and the colourless hemiacetal and chalcone forms, is the true phenomenon accounting for colour changes occurring in anthocyanin solutions and any physical or chemical

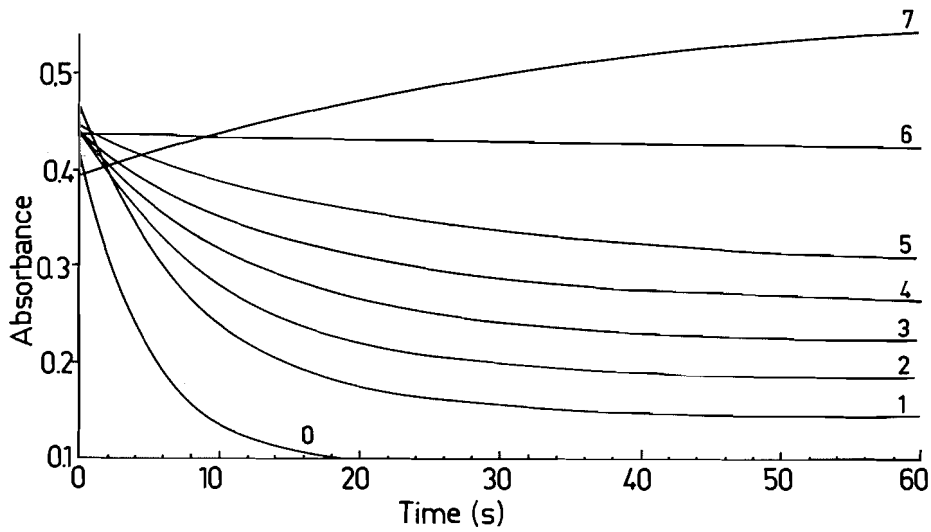

FIG. 6. Time-dependence of the malvin absorbance at 520 nm after mixing equal volumes of a 4×10^{-4} M malvin solution in 0.025 M citric acid and a rutin solution in 0.02 M NaOH. T = 25°C. Rutin concentration (before mixing) is 0 (0), 4×10^{-4} M (1), 8×10^{-4} M (2), 12×10^{-4} M (3), 16×10^{-4} M (4), 2×10^{-3} M (5), 3×10^{-3} M (6), and 6×10^{-3} M (7). Final pH 3.4. The total concentrations of pigment and copigment in the mixtures are half of the above-mentioned values.

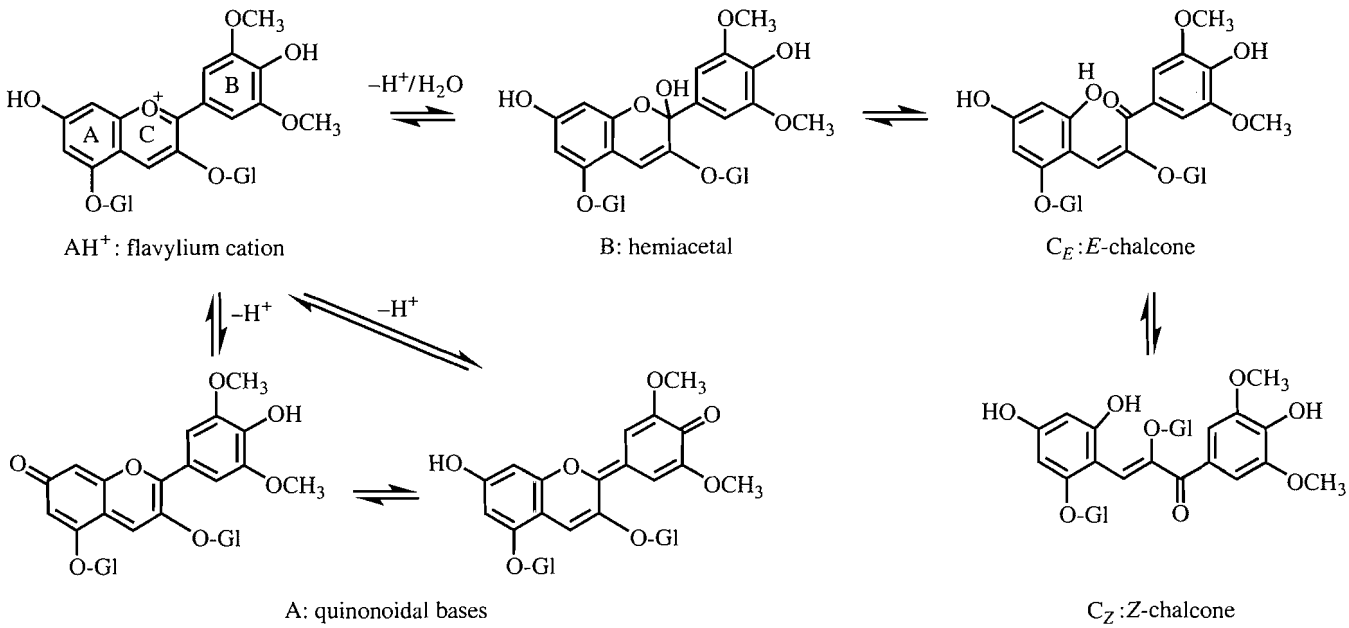
The total concentrations of pigment and copigment in the mixtures are half of the above-mentioned values.



SCHEME 1

process tending to reverse this very equilibrium can be considered as colour stabilizing. Two examples are the reduction of water activity on addition of large amounts of ionic salts (25) and complexation selectively involving the anthocyanin coloured forms (13, 26). In both cases, the nucleophilic attack of water on the pyrylium ring of the flavylium cation is minimized because of a competing process: the hydration of ions produced by salt dissolution in the former case and the molecular association between the pyrylium ring and a copigment molecule in the latter case. Both phenomena cause a displacement of the hydration equilibrium toward the flavylium cation and are thus accompanied by large hyperchromic shifts in the anthocyanin visible band (Figs. 1, 2, 4, and 5). These spectacular gains of colour only occur when the colourless forms are predominant (15, 26), i.e., the pH of the medium must be larger than pK_h. For convenient investigation of colour-stabilizing processes involving anthocyanins, this general condition must be verified. On the contrary, in strongly acidic solutions where the hydration process can be neglected ($pH < pK_h$), copigmentation for instance reduces to a classical complexation of the flavylium cation and it is essentially characterized by a small bathochromic shift in the pigment visible band (15) (the molar absorption coefficients of the free flavylium cation and its complexed form have similar values for all copigments investigated). Whereas it is doubtful that ionic salts in large concentrations (larger than 1 M) should be present in the natural medium of anthocyanins, many in vivo investiga-

tions have shown that anthocyanins are often associated with copigments in flowers (4–8). Moreover, in contrast to copigmentation, the presence of ionic salts does not induce any bathochromic shift in the visible absorption of the pigment and so may not take part in the bluing of the colour. In fact, among the mechanism by which colour is produced and varied in plants, copigmentation deserves particular attention.

Copigmentation thermodynamic data

As mentioned in the previous section, a temperature increase in a slightly acidic solution of malvin without copigment is of weak influence on the visible spectrum of the pigment, a fact largely attributable to the small ΔH^0 value (19) (about 1 kcal mol^{-1}) for the hydration equilibrium. In contrast, a similar experiment performed in the presence of copigment leads to a remarkable weakening of the visible band of the pigment, which can be easily interpreted: the pigment–copigment interaction is exothermic and a temperature increase tends to dissociate the copigmentation complexes, giving more free coloured forms that, through the flavylium cation, are consecutively converted into colourless species, thus leading to a loss of colour (Figs. 1 and 2). In each experiment, the pH value was selected so that only one coloured form of anthocyanin was present in appreciable quantity. In the case of malvin, pH 3.5 was selected for investigating copigmentation involving the flavylium cation (Fig. 1) whereas similar experiments with the neutral quinonoidal bases were carried out at pH 5.5 (Fig. 2). At both pH values, however, the concentrations of the coloured forms of the pigment are not more than a few percent of the overall concentration of the pigment. In such conditions, the recently established general relation (15) giving the relative hyperchromic shift of copigmentation reduces to eq. [1],

$$[1] \quad (D - D_0)/D_0 = rK[L]$$

D_0 and D stand for the absorbances of the anthocyanic chromophore, at a fixed wavelength in the visible range, in the absence and in the presence of copigment, respectively. For good accuracy, the selected wavelength must be close to that of the absorption maximum. Throughout this work, L represents the copigment r is expressed by the following ratio of molar absorption coefficients: $\varepsilon_{AHL^+}/\varepsilon_{AH^+}$ at pH 3.5; $\varepsilon_{AL}/\varepsilon_A$ at pH 5.5. K stands for the copigmentation equilibrium constant and is expressed by $K_1 = [AHL^+]/([AH^+][L])$ for copigmentation involving the flavylium cation (pH 3.5) and by $K_2 = [AL]/([A][L])$ for copigmentation involving the neutral quinonoidal bases (pH 5.5). Typical values of the concentrations used in the present work are about 10^{-2} M for the copigment and 5×10^{-4} M for malvin. Under such conditions, the free copigment concentration [L] is much higher than the concentration of copigment associated with malvin, and thus it is approximately equal to the total concentration of copigment L_t. Moreover, the theoretical treatment does not need to take into account the formation of complexes whose stoichiometry is different than 1:1. The previous quantitative investigations on copigmentation (13, 14, 16, 17) are consistent with this assumption. Finally, any self-association process involving the coloured forms of the pigment (27, 28) (whose actual equilibrium concentrations are less than 10^{-5} M) can also be neglected. Assuming van't Hoff's hypothesis (temperature-independent ΔH^0), eq. [1] transforms into eq. [2]. Hence, a linear plot of $\ln[(D - D_0)/D_0]$ as a reciprocal of temperature gives the values of the copigmentation enthalpy and entropy changes (Table 1). For

$$[2] \quad \ln[(D - D_0)/D_0] = \ln(rL_t) + \Delta S^0/R - \Delta H^0/(RT)$$

each copigment, the r values generally derive from a comparison of the experimental and theoretical plots of $(D - D_0)/D_0$ versus pH (15). However, the $\varepsilon_{AHL^+}/\varepsilon_{AH^+}$ ratio can be directly estimated by measuring D_0 for a 0.2 M HCl malvin solution and then D after addition of a large excess of copigment so that the flavylium cation is entirely complexed (13). At 520 nm, whatever the copigment selected, $\varepsilon_{AHL^+}/\varepsilon_{AH^+}$ and $\varepsilon_{AL}/\varepsilon_A$ were found close to 0.8 and 0.9, respectively.

In all cases presented here, copigmentation appears as an exothermic process. Using a thermodynamic cycle, the copigmentation overall enthalpy change ΔH^0 can be artificially divided into two terms. The first one accounts for the pigment–copigment interaction in the gas phase. It is essentially composed of stabilizing contributions, the major one being the electrostatic and dispersion forces, including for instance π–π overlap between aromatic residues, dipole–dipole interactions, and possible hydrogen bonding. The second term is the sum of the enthalpy changes accompanying the transfer of the free-binding partners from the solvent (water) to the gas phase (desolvation) and of the solvation enthalpy of the molecular complex; it represents the solvent contribution to the overall enthalpy change. The association of the pigment and copigment molecules reduces their surfaces in contact with the solvent so that there is a net desolvation that brings some water molecules from the solvation shells to the bulk solvent. If this contribution is exothermic, it means that a water molecule interacts more strongly with its neighbours in the bulk (other water molecules) than with its neighbours in a solvation shell (the solute molecule and other water molecules). This is certainly true for at least two reasons: first, water is by far the solvent of lowest polarizability (α = 1.47 Å^3). Thus, dispersion interactions between water molecules and solute molecules (even their most apolar parts) must be very weak (29). Secondly, the solvation water molecules are higher in enthalpy than the water molecules within the liquid water network (bulk).

From their investigations on carbohydrate–protein interaction (particularly from Monte Carlo simulations of carbohydrate and protein hydration), Lemieux *et al.* (30) proposed a general model for the association of amphiphilic molecules in water. Since malvin and most copigments investigated in this work (particularly, chlorogenic acid, catechin, and rutin) are hydrophilic through their hydroxyl groups and hydrophobic particularly through their aromatic rings, such a model can be usefully applied to copigmentation. In

this model, hydrogen bonding between a water molecule and a hydroxyl group close to a hydrophobic region in the amphiphilic solute molecule places the water molecule farther from the solute surface, i.e., creates a cavity along the hydrophobic region. In these conditions, the colinear arrangement proper to strongest hydrogen bonding can be achieved. Such cavities have been formed at the cost of an increase in enthalpy so that their partial collapse on molecular association brings a favourable exothermic contribution to the overall copigmentation enthalpy change. In all cases investigated the pigment–copigment interaction was actually found to be exothermic, especially with catechin and chlorogenic acid (Table 1). Whatever the interacting coloured form of anthocyanin (AH^+ at pH close to 3.5, A at pH 5.5), the copigmentation exothermicity decreases in the catechin – chlorogenic acid – caffeine series. The attractive term in the dispersion interaction was pointed out to be one of the major components in the interaction energy between two molecules (29, 31). This seems particularly true in the case of the pigment–copigment interaction, as indicated by the high polarizabilities of the malvin chromophores (computed from atomic increments (32)): 32.8 $Å^3$ for the flavylium chromophore and 32.5 $Å^3$ for the quinonoidal chromophore (the glucosyl moieties have not been taken into account). Taking the copigment molecular polarizability as a rough measure of the copigment ability to establish attractive dispersion forces with the pigment molecule, we computed α values of 33.0, 28.9, and 18.9 $Å^3$ for chlorogenic acid, catechin, and caffeine, respectively. The large polarizabilities of chlorogenic acid and catechin certainly contribute to the strong exothermicity of their association, especially with the flavylium cation. However, in spite of its rather weak polarizability, caffeine interacts strongly with the quinonoidal bases. Some dipole–dipole and (or) inductive attractive forces between these highly polar species could take place, as well as possible hydrogen bonding between the hydroxyl groups of the pigment and caffeine. In the same way, Haslam and coworkers (33, 34) already pointed out remarkable interactions between caffeine and various polyphenols. Using X-ray crystallography and ^1H NMR data, these authors proposed that both hydrophobic interactions and hydrogen bonding should contribute to complex stability. Moreover, replacing malvin by synthetic anthocyanidins (anthocyanins without any sugar residue on their chromophore, such as the 7-hydroxy 3,4′-dimethoxyflavylium cation) in copigmentation experiments with chlorogenic acid and caffeine (35) results in similar copigment effects in the case of only chlorogenic acid. By contrast, whatever the pH, much smaller hyperchromic shifts have been detected in the case of caffeine. In addition, malvin and the 7-hydroxy 3,4′-dimethoxyflavylium cation possess similar abilities to hydrate (pK_h about 2 at 25°C in both cases). Thus, the presence of glycosyl residues on the anthocyanic chromophore appears to be determining for caffeine copigmentation. In fact, hydrogen bonding between the hydroxyl groups of the malvin glycosyl residues and the tertiary amide carbonyl groups of caffeine must be necessary to enforce vertical stacking (demonstrated by ^1H NMR investigations (17)) of the purine ring onto the pyrylium ring. Although tryptophan polarizability (21.6 $Å^3$) is higher than that of caffeine, the tryptophan–flavylium cation interaction is significantly less exothermic than the corresponding interaction involving caffeine. This could be due to particularly strong hydrogen bonds between water and the tryptophan NH_2 and COOH groups, making the desolvation contribution to the overall ΔH^0 less exothermic. Indeed, the replacement of the COOH group by the less solvated COOMe group leads to much more exothermic pigment–copigment interaction (in addition to the small increase in the overall polarizability: 23.5 $Å^3$ for Trp-OMe). The ability of tryptophan to act as a malvin copigment has been observed not only with the flavylium cation (K_1 about 65 M^{-1} at 25°C) but also with the quinonoidal bases. However, the effect is weaker (K_2 about 20 M^{-1} at 25°C). This behaviour seems unique in the amino acid series since the other amino acids investigated, even the most polarizable tyrosine and phenylalanine, do not exhibit appreciable copigment effects. Contrary to previous qualitative investigations (9), copigmentation involving the flavylium cation of cyanin (an anthocyanic pigment analogous to malvin but bearing a catechol group on its terminal B-ring) and proline appeared to be hardly significant (K of the order of unity at 25°C). This remains true for *N*-acetylproline and other small derivatives like the dipeptides Pro-Phe and Pro-Pro. The large hydrophilic character of the NH_2 and COOH groups probably makes the competition between molecular association and solvation of the free partners favour the latter phenomenon. However, for longer peptides, formation of hydrophobic pockets, involving for instance the apolar side chains of aromatic residues, probably allows much stronger interactions with polyphenols in general. Indeed, proanthocyanidins (condensed tannins), whose skeleton is close to that of anthocyanins, are well known for their ability to bind (and, ultimately, precipitate) proteins (33, 34, 36–38).

More than the overall molecular polarizabilities of both free partners, the area of π-overlap is a relevant measure of the interaction energy between aromatic molecules in the gas phase (39). Indeed, among the dispersion forces at work between the pigment and the copigment molecules, $\pi-\pi$ interactions must be of particular importance. For instance, up to now, no copigment has been found that does not possess at least one aromatic or pseudo-aromatic (caffeine-type) structure. Of course, the presence in a given molecule of one aromatic moiety does not necessarily imply that this molecule will act as a copigment (see the examples of tyrosine and phenylalanine). Similarly, tryptophan, which presents a large aromatic structure, is a weak copigment only. Solvation considerations must be taken into account. $\pi-\pi$ interactions between the pigment and copigment molecules have been demonstrated using ^1H NMR analysis (4, 17, 40): when pigment and copigment are mixed together, the chemical shifts of their aromatic protons are significantly displaced. Such displacements are the result of ring current diamagnetic anisotropy in neighbouring aromatic moieties and can be used to estimate the copigmentation equilibrium constant. The hypothesis of determining $\pi-\pi$ interactions in copigmentation permits us to explain why the copigment molecule essentially interacts with the coloured forms rather than with the colourless forms of the pigment. Whereas the coloured forms possess almost planar chromophores with electronic delocalization distributed on three aromatic rings, the colourless hemiacetal and chalcone forms bear only two isolated aromatic rings.

As evidenced by Table 1, the copigmentation entropy change is highly dependent on the copigment structure. Moreover, most of the ΔS^0 values reported here are negative. Indeed, the overall entropy change is composed of an

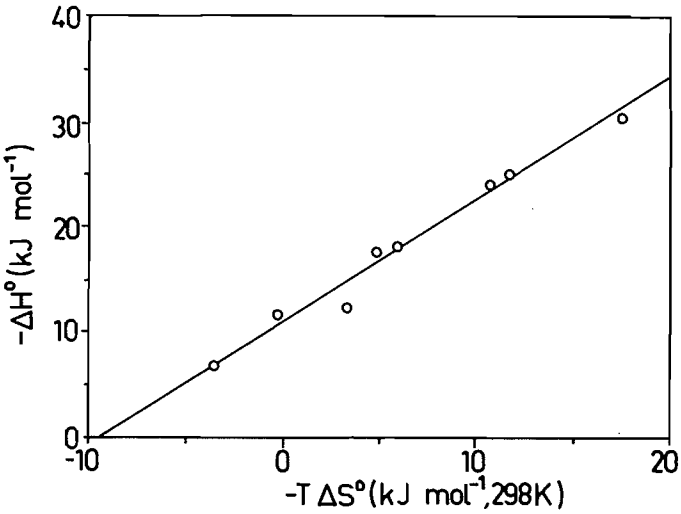

FIG. 8. Enthalpy–entropy compensation for eight pigment–copigment couples. The corresponding ΔH^0 and ΔS^0 values are from Table 1. T = 298 K ρ = 0.988; slope = 1.148 (±0.074); intercept = 11.057 (±0.661).

unfavourable (negative) term accounting for the reduction of the degrees of freedom of both partners when they associate (in the gas phase) and of a second term including the solvent contributions. Following Lemieux *et al.* (30), we may assume that water molecules have greater mobility at the surface of amphiphilic solute molecules, where cavities are present, than in the bulk where water molecules are tightly associated. Thus, an ordering is expected to occur in the water molecules taking part in the net desolvation process accompanying the molecular complexation so that the main contribution of the solvent to the overall entropy change would be an unfavourable (negative) term as well. The experimental entropy changes for most pigment–copigment systems (Table 1) are consistent with this view: copigmentation results in a loss of entropy except in the case of caffeine and tryptophan interacting with the malvin flavylium cation. In those cases, the large planar and rigid molecules of copigment probably allow the formation at their surfaces of well-ordered arrangements of water molecules, which partially collapse on association with the flavylium cation giving a positive net entropy change. Replacing the tryptophan COOH group by a COOMe group strongly alters ΔS^0. In fact, owing to its high ability to establish hydrogen bonds, the COOH group might be inserted in a more organized water cavity than that surrounding the COOMe group. Moreover, the enthalpy and entropy changes are expected to be correlated. For instance, the more intimate the contact between the pigment and copigment molecules, the stronger the reduction of their respective degrees of freedom. Similarly, the looser the contact between solvation water molecules and amphiphilic solute molecules, the stronger the ordering of these water molecules on their release in the bulk (30). Indeed, a plot of $-\Delta H^0$ versus $-T\Delta S^0$ is linear (Fig. 8) suggesting enthalpy–entropy compensation. The compensation temperature has been found equal to 342 (±23) K.

Cosolvent effects

In this paragraph, we consider only the problem of small additions of organic cosolvent (less than 6% molar) in the aqueous medium where copigmentation typically occurs. Indeed, the copigmentation phenomenon is closely connected to the pH-dependent chemical transformations that anthocyanins undergo in water (proton transfers and hemiacetal formation); large additions of cosolvent would pose the difficult problem of pH correction. In our conditions, pH correction is not necessary and cosolvent addition does not markedly affect the visible spectrum of the pigment in the absence of copigment. Thus, in the presence of copigment, the changes occurring in the visible absorption of anthocyanin when water is replaced by a binary solvent, water remaining the main component, are essentially due to cosolvent effect on copigmentation (see Fig. 3, the case of water–ethanol mixtures). These changes, which consist of a strong decrease in the hyperchromic shift characteristic of copigmentation, spectacularly illustrate the influence of the medium on the magnitude of the copigmentation.

Similar effects have been recently reported with a series of organic cosolvents (15). In that series, the less damaging effects were observed with methanol, ethanol, and ethylene glycol, probably because they are, as protic solvents, relatively close to water and are similarly characterized by a network of hydrogen-bonded molecules. Solvent effects in molecular complexation have been widely investigated. In their work dealing with inclusion of apolar solutes in cyclophane cavities, Smithrud and Diederich (29) found the corresponding inclusion complexes to be much more stable in water than in any other solvent. These authors interpreted this result by taking into account at the same time the strong cohesive forces between water molecules in the bulk and the extremely weak polarizability of water. Both factors explain why the water molecules interact much more strongly with themselves than with apolar solutes, thus providing a net driving force for molecular complexation. In this view, changing water into a more polarizable solvent must lead to more favourable solvent–solute dispersion interactions and weaker cohesive forces between solvent molecules in the bulk. Thus, the net desolvation process and finally the overall molecular complexation are expected to be less exothermic. Curiously, in our systems, whatever the copigment used, malvin copigmentation (involving either the flavylium cation or the quinonoidal bases) is significantly more exothermic in water–ethanol mixtures than in water (Table 2). Moreover, the pigment and copigment molecules must be more solvated in protic organic solvents such as ethanol, where they are freely soluble, than in water where their solubility is rather low.

So, how can species that are more solvated in their free state interact in a more exothermic way? A possible explanation would be that the pigment and copigment molecules are better solvated by the binary solvent when they are π-stacked in the complex, than when in their free state. This could be due to a microenvironment of ethanol molecules around the stacks. As has been suggested by Sigel *et al.* (41), the aromatic stacks originally present in water might act as "germs to attract the organic solvent molecules and to form a micelle-like hydrophobic environment." In spite of a more favourable ΔH^0 value, cosolvent effect on copigmentation consists in a strong weakening of the pigment–copigment interaction (whose magnitude is expressed by the K value). It is thus attributable to a more unfavourable entropy change (Table 2). Whereas copigmentation is an enthalpically driven phenomenon (large negative ΔH^0, ΔS^0 being generally unfavourable), cosolvent effect on copigmentation appears to

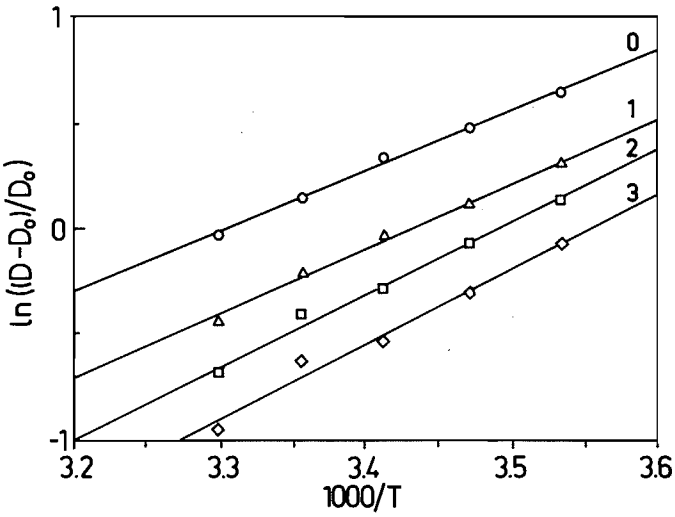

FIG. 9. Plots of $\ln[(D - D_0)/D_0]$ as a reciprocal of the temperature for the malvin – chlorogenic acid system at pH 3.6 in different water–ethanol mixtures. Malvin: 6.7×10^{-4} M. Chlorogenic acid: 6.7×10^{-3} M. D and D_0 are the malvin absorbances at 520 nm with and without chlorogenic acid, respectively. The molar fractions of ethanol are 0 (0), 2.7% (1), 4.1% (2), and 5.4% (3). ρ = 0.996 (0); 0.995 (1); 0.995(2); 0.988 (3). Slope = 2.896 (±0.145) (0); 3.078 (±0.171) (1); 3.429 (±0.197) (2); 3.565 (±0.321) (3). Intercept = −9.57 (±0.50) (0); −10.56 (±0.58) (1); −11.97 (±0.67) (2); −12.67 (±1.10) (3).

be controlled by ΔS^0. Cosolvent molecules in water are expected to partially disrupt the approximately tetrahedral network of water molecules in the bulk. Thus, the release of solvation molecules on molecular complexation should not be so entropically costly as it is in the absence of cosolvent. In fact, the origin of the net decrease in entropy on cosolvent addition is probably to be found in the preferential arrangement of cosolvent molecules around the stacks. The linear plots yielding ΔH^0 and ΔS^0 for the malvin – chlorogenic acid association (pH 3.6) are reported in Fig. 9 for different molar fractions (x) of ethanol. The variations of ΔH^0, ΔS^0, and ΔG^0 (25°C) versus x seem to be roughly linear in the x range investigated (Fig. 10).

Salt effects

Large additions of alkali halides to weakly acidic solutions of malvin without copigment give rise to strong hyperchromic shifts in the visible band of the pigment (Figs. 4 and 5), a phenomenon already pointed out with other anthocyanic pigments (25). Unlike copigmentation, this phenomenon is not accompanied by any shift in the wavelength of the absorption maximum. However, just as with copigmentation, remarkable salt effects in anthocyanin solutions take place only when the pigment is mainly hydrated ($pH > pK_h$), the minor coloured forms being either the flavylium cation or the quinonoidal bases according to the pH of the medium (Fig. 4). This can be interpreted by the decrease in water activity due to ion solvation that, in turn, induces a displacement of the hydration equilibrium toward the flavylium cation. Note that these salt effects are highly dependent on the nature of both the metallic cation and the halide anion. Indeed, the degree of solvation of an ion is a function of its size and its charge density. For instance, the small Li^+ cation is very solvated and is thus expected to produce a stronger

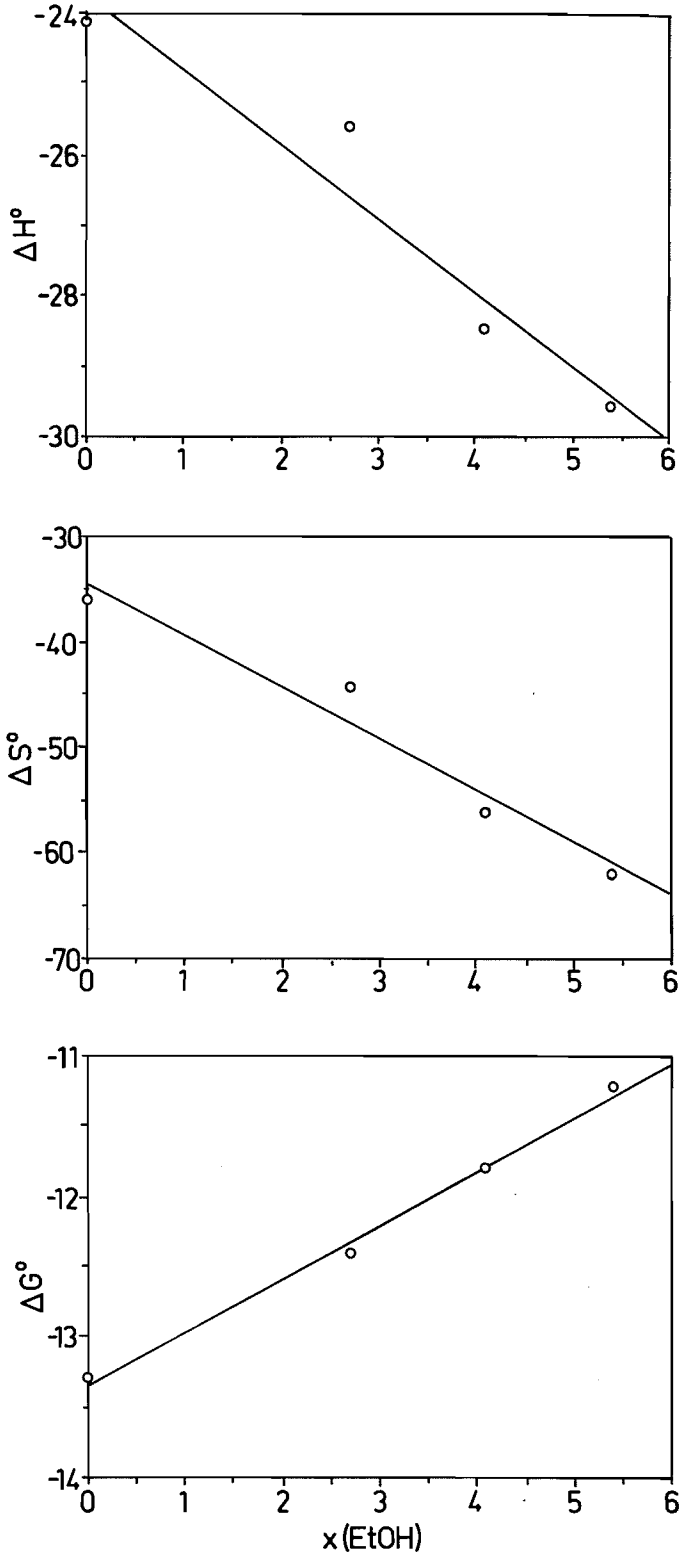

FIG. 10. Molecular association of the malvin flavylium cation with chlorogenic acid in different water–ethanol mixtures. Variations of thermodynamic parameters versus molar fraction of ethanol. Upper part: ΔH^0 (ρ = 0.965). Middle part: ΔS^0 (ρ = 0.979). Lower part: ΔG^0 at 25°C (ρ = 0.997).

hyperchromic effect in the visible band of malvin than the larger Na^+ and K^+ cations (for a given counteranion). Experiment confirms this view (Fig. 4).

For personal use only.

For anions, this simple explanation seems no longer valid. For example, although the bromine anion is larger (and probably less solvated) than the chlorine anion, the stabilizing effect of NaBr on both the flavylium cation and the quinonoidal bases is stronger than that of NaCl. Now, how do these salt effects alter copigmentation? The experiment, whose results are reported in Table 3, consists of measuring the relative hyperchromic shift produced by a given amount of caffeine when added to a malvin solution (pH 3.36) containing a large salt concentration. The salt concentration is 2 M for LiCl and KCl and 2/3 M for $MgCl_2$ so that the ionic strength is about 2 in each case. Whatever the salt, the relative hyperchromic shifts are very close and notably lower than that recorded in the absence of salt (ionic strength about 10^{-3}). Whereas salt addition results in large specific effects on the pigment hydration process, its influence on the magnitude of the intrinsic copigmentation is relatively small and almost non-specific. In fact, the small weakening of copigmentation on large salt additions probably consists only of an ionic strength effect.

Relaxation kinetic measurements as an efficient method for the determination of copigmentation equilibrium constants

Among all the equilibria displayed in Scheme 2, proton transfer and copigmentation equilibria are extremely fast reactions. In contrast, the hydration of the flavylium cation into the colourless hemiacetal B (followed by instantaneous tautomerization into C_E) is a rather slow process. Its rate is highly dependent on the acidity of the medium (21). Typically, the hydration equilibrium is reached within a few tens of seconds in slightly acidic solutions (pH 3–4) but requires several minutes at pH values near neutrality. In the experiments whose results are presented in Figs. 6 and 7, a copigment alkaline solution is quickly added to a malvin acidic solution. In that way, the hydration process is perturbed by both pH-jump and flavylium cation complexation. The change in the visible absorbance, D of the pigment from its initial value just after mixing, D_0, toward its value in the final equilibrium state, D^*, has been recorded as a function of time. D is measured at a given wavelength near that of the absorption maximum, for instance, 520 nm when the coloured form of the pigment present in the medium is the flavylium cation (final pH 3–4) and 570 nm when the quinonoidal bases are largely predominant (final pH 5–6). The copigment selected for this study is rutin (**5**), a member of the flavonol family, among which are found the strongest anthocyanin copigments reported up to now (9, 12). Figure 6 shows the influence of copigmentation on the visible absorption of malvin just after the pH of the pigment solution was quickly raised from 2.3 to 3.4. It points out the remarkable slowing down of the flavylium cation hydration due to flavylium cation – rutin complexation. Raising the pH of an equilibrated acidic solution of malvin without copigment results in a shift of the hydration equilibrium toward the colourless forms of the pigment so that the visible absorbance decreases. When the pH increase is accompanied by the simultaneous addition of the rutin copigment, the instantaneous complexation of the coloured forms (copigmentation) is opposed to the former shift. When the pH-jump effect is predominant, we get $D_0 > D^*$ (positive relaxation amplitude defined as $D_0 - D^*$), i.e., the visible absorbance decreases during the relaxation process. When the copigment concentration is large enough for the copigment effect to prevail, we get $D^* > D_0$ (negative relaxation amplitude), i.e., the visible absorbance increases upon the relaxation process. Both situations can be seen in Fig. 6. Note that pH-jump and copigment effects cancel each other (amplitude zero) at a rutin to malvin molar ratio close to 7.5. The qualitative observations about the influence of copigmentation on the flavylium cation hydration kinetics remain valid for the apparent hydration of the quinonoidal base (through the flavylium cation) when pH goes from 2.3 to 5.2 (Fig. 7): again the hydration process is much slower in the presence of the copigment. In that case, however, no change in the sign of the signal amplitude occurs in the investigated concentration range of the copigment. For good sensitivity of method, it is important to start from an acidic solution of malvin (pH about 2) giving an intense absorption band in the visible range. Under such conditions, signals of large amplitudes can be recorded. When the total concentration of copigment is raised, the differences in the D_0 absorbance values just after mixing of the pigment and copigment solutions (i.e., when the hydration process is still negligible) essentially reflect the differences in the molar absorption coefficients of the free and complexed forms at the selected wavelength. In the case of rutin, ε_{AHL^+} appears to be close to ε_{AH^+} at 520 nm (small differences in the D_0 values in Fig. 6) whereas ε_{AL} must be larger than ε_A at 570 nm (increasing D_0 values on increasing the total concentration of copigment as shown in Fig. 7).

Interestingly, our kinetic results can be applied to the determination of copigmentation equilibrium constants (the theoretical treatment is detailed in the Appendix): the apparent first-order rate constant of hydration k (reciprocal of the relaxation time), is computed at different copigment concentrations from the slope of the linear plot of $\ln|D - D^*|$ versus time. k can be related to k_0, the apparent rate constant of hydration in the absence of copigment, by eqs. [3] and [4]:

$$[3] \qquad \frac{1}{k_0 - k} = \frac{1}{k_1} + \frac{1}{k_1 K_1}\frac{1}{L_t}$$

$$[4] \qquad \frac{1}{k_0 - k} = \frac{K_a 10^{pH}}{k_1} + \frac{K_a 10^{pH}}{k_1 K_2}\frac{1}{L_t}$$

k_1 stands for the elementary rate constant of the flavylium cation hydration process. Equation [3] is valid at a final pH of about 3.5 and a plot of $1/(k_0 - k)$ as a reciprocal of L_t yields the copigmentation constant of the flavylium cation K_1. Equation [4] is valid at final pH 5–6 and the same type of plot yields the quinonoidal base copigmentation constant K_2. Equations [3] and [4] can be used with any copigment provided that its total concentration is much larger than the concentration of the coloured form of the pigment (L_t is approximately equal to [L]).

The considerable advantage of this method over the equilibrium procedure (13, 15) is that the new plot is independent of spectral parameters such as the molar absorption coefficient ratio r, which requires a previous time-consuming (although not so accurate) determination. The corresponding plots with rutin as copigment are reported in Figs. 11 and 12. The following values for K_1 and K_2 have been estimated at 25°C: K_1 = 3370 (±550) M^{-1}, K_2 = 1030

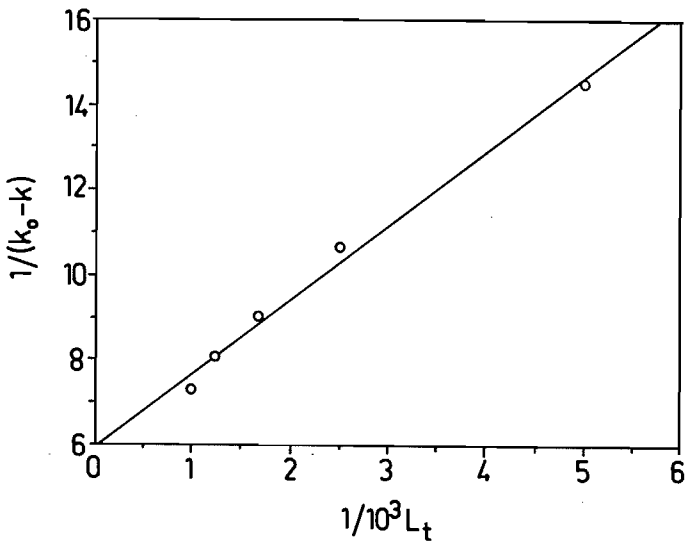

FIG. 11. Molecular association of the malvin flavylium cation and rutin. Double-reciprocal plot of $k_0 - k$ versus L_t. k and k_0 are the apparent first-order rate constants of hydration at pH 3.4 in the presence and in the absence of copigment, respectively. L_t is the total concentration of copigment. T = 25°C. ρ = 0.995; slope = 1.757 (±0.057); intercept = 5.915 (±0.590).

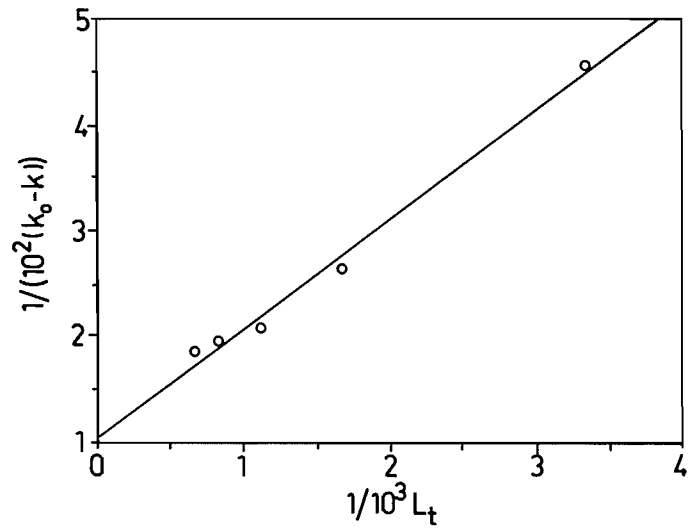

FIG. 12. Molecular association of the malvin quinonoidal bases and rutin. Double-reciprocal plot of $k_0 - k$ versus L_t. k and k_0 are the apparent rate constants of hydration at pH 5.2 with and without copigment, respectively. L_t is the total concentration of copigment. T = 25°C. ρ = 0.995; slope = 1.032 (±0.062); intercept = 1.059, (±0.112).

(±170) M^{-1}. In both cases, consistent k_1 values have been found, 0.169 (±0.017) s^{-1} from the first plot (pH 3.4) and 0.150 (±0.050) s^{-1} from the second plot (pH 5.2). Both values are in good agreement with previously reported values (19). K_1 deduced from relaxation kinetic measurements is slightly lower than that computed from Sadlowski's static experiments (19) on rutin (K_1 about 4000 M^{-1} at 25°C (13)). In comparison, let us mention that Haslam and co-workers (17), using the $\ln[(D) - D_0)/D_0]$ versus $\ln L_t$ plot, recently measured a constant of about 1686 (±58) M^{-1} for the copigmentation of the malvin flavylium cation (T = 22°C) with quercetin-3-β-D-galactoside, another flavonol differing from rutin only by the diosyl residue but markedly more soluble in water. In fact, the water solubility of rutin is very poor (of the order of 10^{-4} M) whereas its solubility in alkaline solutions (where deprotonation of the phenolic OH groups takes place) is quite good (more than 10^{-2} M).

Now, mixing the acidic malvin solution and the alkaline rutin solution yields a slightly acidic solution in which rutin is in a thermodynamically unstable state of supersaturation. This unusual phenomenon may persist for a few minutes before precipitation occurs (19). In classical copigmentation experiments on equilibrated solutions, such a delay is generally not sufficient to be sure that the hydration equilibrium state is entirely established, particularly in the case of experiments dealing with quinonoidal base copigmentation (pH 5–6). Thus, in the case of rutin, our kinetic method for the determination of the copigmentation equilibrium constants seems to be by far more accurate. Since K_1 is much higher than K_2, rutin enters the class of copigments better stabilizing the flavylium cation than the quinonoidal bases. Interestingly, the overall affinity of rutin for malvin is much greater than that of (+)-catechin although the carbon skeletons of these two copigments are similar. In fact, by contrast with catechin, the rutin central ring is unsaturated and quite planar. Hence, the three unsaturated rings in rutin must be almost coplanar, a conformation strongly favouring π–π stacking. Moreover, the very unfavourable entropic terms in the malvin–catechin association (Table 1) might partly reflect the distortion occurring in the catechin central ring for both aromatic side rings to reach the coplanar conformation proper to strongest interaction in the complex. Such a distortion is probably absent in the case of rutin since coplanarity is already achieved in the copigment free state. In addition, for rutin as well as for tryptophan and caffeine, the solvent water might provide a positive contribution to ΔS^0. Thus, more favourable entropy changes are expected. Preliminary results from temperature variation on the flavylium cation – rutin system (ΔS^0 close to zero) seem to confirm that view.

Appendix: how to derive the copigmentation equilibrium constants from relaxation kinetic measurements

(i) Flavylium cation copigmentation

We must take into account the slow hydration equilibrium and the instantaneous copigmentation equilibrium involving the flavylium cation (Scheme 3). For the purpose of clarity, the fast equilibrating B and C_E ring-chain tautomers are represented by B only. The general rate equation can be written as eq. [5]:

$$[5] \quad dc_B/dt = k_1 c_{AH} - k_2 c_B c_H$$

c_i stands for the time-dependent concentration of species i and can be expressed as follows: $c_i = c_i^* + \Delta c_i$ where c_i^* is the c_i value in the final equilibrium state (reached after perturbation) and Δc_i is the time-dependent deviation from this value. At the final equilibrium, eq. [5] becomes eq. [6]:

$$[6] \quad 0 = k_1 c_{AH}^* - k_2 c_B^* c_H^*$$

Thus, substituting the expressions for c_i in eq. [5] and using eq. [6] leads to eq. [7]:

$$[7] \quad d\Delta c_B/dt = k_1 \Delta c_{AH} - k_2 (c_H^* \Delta c_B + c_B^* \Delta c_H + \Delta c_B \Delta c_H)$$

Now, in the buffered citric solution, the final pH value is reached just after mixing the pigment and copigment solutions, i.e., it is not changed by the consecutive relaxation process of the hydration equilibrium. Hence, we get $\Delta c_H << \Delta c_B$. In addition, Δc_B and c_B^* are smaller than the pigment total concentration M_t, which in turn, is of the order of c_H^* (pH = 3.4; $M_t = 2 \times 10^{-4}$ M). Thus, in eq. [7] the sum $c_B^* \Delta c_H + \Delta c_B \Delta c_H$ can be neglected and eq. [7] reduces to eq. [8]:

$$[8] \quad d\Delta c_B/dt = k_1 \Delta c_{AH} - k_2 c_H^* \Delta c_B$$

According to the principle of mass conservation, we have for pigment and copigment, respectively (eqs. [9] and [10]):

$$[9] \quad \Delta c_{AH} + \Delta c_B + \Delta c_{AHL} = 0$$

$$[10] \quad \Delta c_L + \Delta c_{AHL} = 0$$

Since the fast copigmentation equilibrium remains established throughout the relaxation process, the mass law expression gives: $K_1 = c_{AHL}/(c_{AH} c_L) = c_{AHL}^*/(c_{AH}^* c_L^*)$. Substituting the expressions for c_i in this equation leads to eq. [11]:

$$[11] \quad K_1 (c_L^* \Delta c_{AH} + c_{AH}^* \Delta c_L + \Delta c_{AH} \Delta c_L) = \Delta c_{AHL}$$

The principle of mass conservation for pigment in the final equilibrium state gives: $M_t = c_{AH}^* + c_B^* + c_{AHL}^* = c_{AH}^* (1 + K_h/c_H^* + K_1 c_L^*)$. Thus, the total concentration of the coloured forms of the pigment is expressed by: $c_{AH}^* + c_{AHL}^* = c_{AH}^* (1 + K_1 c_L^*) = M_t (1 + K_1 c_L^*)/(1 + K_h/c_H^* + K_1 c_L^*)$. Except in the case of exceptionally stable copigmentation complexes ($K_1 > 10^4$), we have: $1 + K_1 c_L^* << K_h/c_H^*$ (about 25 with $K_h = 10^{-2}$ at 25°C). Thus, $c_{AH}^* + c_{AHL}^*$ is much smaller than M_t, which, consequently, is approximately equal to c_B^*. Moreover, the total concentration of copigment L_t is markedly larger than M_t and, thus, much larger than c_{AHL}^*. We may write: $L_t = c_L^*$. Assuming c_L to remain almost constant throughout the relaxation process ($\Delta c_L << c_L^*$), eq. [11] reduces to eq. [12]:

$$[12] \quad K_1 (L_t \Delta c_{AH} + c_{AH}^* \Delta c_L) = \Delta c_{AHL}$$

Combining eqs. [10] and [12], we get: $K_1 L_t \Delta c_{AH} + (1 + K_1 c_{AH}^*) \Delta c_L = 0$. Assuming $K_1 < 10^4$, we have: $K_1 c_{AH}^* =$

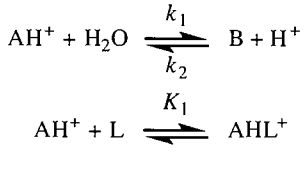


SCHEME 3

$K_1M_tc_H^*/K_h << 1$. Thus, Δc_{AH} and Δc_L are related simply by eq. [13]:

[13] $K_1L_t\Delta c_{AH} + \Delta c_L = 0$

Combining eqs. [9] and [10] leads to eq. [14]:

[14] $\Delta c_{AH} + \Delta c_B = \Delta c_L$

Finally, from eqs. [13] and [14], Δc_{AH} is related to Δc_B according to eq. [15]:

[15] $(1 + K_1L_t)\Delta c_{AH} + \Delta c_B = 0$

Equations [8] and [15] are combined to express the apparent first-order rate constant k for change in B defined by: $d\Delta c_B/dt = -k\Delta c_B$. We get eq. [16]:

[16] $k = k_2c_H^* + k_1/(1 + K_1L_t)$

In the absence of copigment ($L_t = 0$), k becomes k_0, which is expressed by eq. [17]:

[17] $k_0 = k_2\, c_H^* + k_1$

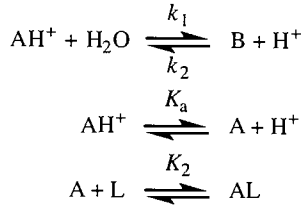
The difference $k_0 - k$ reduces to $k_1K_1L_t/(1 + K_1L_t)$ so that a double-reciprocal plot of $k_0 - k$ versus L_t is linear and yields k_1 and K_1 (see eq. [3]). For each copigment concentration, the k value can be estimated from the time-dependence of the pigment absorption at a fixed wavelength (520 nm for the flavylium cation). Indeed, the visible absorbance D can be written as: $D = \varepsilon_{AH}dc_{AH} + \varepsilon_{AHL}dc_{AHL}$ where d is the optical pathlength. Thus, the absorbance deviation from the equilibrium value D^* is $\Delta D = D - D^* = \varepsilon_{AH}d\Delta c_{AH} + \varepsilon_{AHL}d\Delta c_{AHL}$. The free copigment concentration remains almost constant during the relaxation process ($c_L = c_L^* = L_t$) and c_{AH}^* is much smaller than c_L^*. Thus, eq. [12] can be approximately written as: $K_1L_t\Delta c_{AH} = \Delta c_{AHL}$. Thus, the absorbance deviation becomes $\Delta D = D - D^* = \varepsilon_{AH}d\Delta c_{AH} \times (1 + r_1K_1L_t)$ with $r_1 = \varepsilon_{AHL}/\varepsilon_{AH}$. Finally, using eq. [15], the following expression for ΔD is derived (eq. [18]):

[18] $\Delta D = -\varepsilon_{AH}d\Delta c_B(1 + r_1K_1L_t)/(1 + K_1L_t)$

ΔD is time-dependent in the same way as Δc_B, i.e., $d\Delta D/dt = -k\Delta D$. Thus, the visible absorbance of the pigment varies with time according to $-dD/dt = k(D - D^*)$. On integration, we get $\ln|D - D^*| = \ln|D_0 - D^*| - kt$ where D_0 stands for the initial absorbance just after mixing of the pigment and copigment solutions. Thus, a plot of $\ln|D - D^*|$ versus time must be linear with a slope equal to $-k$. Repeating the experiment at different copigment concentrations gives a series of k values that can be used according to eq. [3] to determine the flavylium cation copigmentation constant K_1.

(ii) Copigmentation of the quinonoidal bases

The equilibria that must be taken into account are summed up in Scheme 4. AH^+ is now a very minor component and its complexation with L has been neglected. The theoretical



SCHEME 4

treatment presented above can be easily transposed to that case. The equations of mass conservation are now eqs. [19] and [20]:

[19] $\Delta c_{AH} + \Delta c_B + \Delta c_A + \Delta c_{AL} = 0$

[20] $\Delta c_L + \Delta c_{AL} = 0$

For the fast copigmentation and acid–base equilibria, the mass law is expressed as eqs. [21] and [22]:

[21] $K_2\,(c_L^*\Delta c_A + c_A^*\Delta c_L + \Delta c_A\Delta c_L) = \Delta c_{AL}$

[22] $c_A^*\Delta c_H + c_H^*\Delta c_A + \Delta c_H\Delta c_A = K_a\Delta c_{AH}$

Assuming $\Delta c_L << c_L^*$, eq. [21] becomes eq. [23]:

[23] $K_2(c_L^*\Delta c_A + c_A^*\Delta c_L) = \Delta c_{AL}$

The apparent hydration equilibrium constant can be written as: $K_h/K_a = c_B^*/c_A^*$. Here again, c_B^* is approximately equal to M_t and we have: $c_A^* = M_tK_a/K_h = M_t/100$ ($K_h = 10^{-2}$; $K_a = 10^{-4}$ at 25°C). Thus, c_H^* and c_A^* are of the same order of magnitude (pH = 5.2; $M_t = 3 \times 10^{-4}$ M). Assuming $\Delta c_H << \Delta c_A$ and $\Delta c_H << c_H^*$, eq. [22] simplifies to eq. [24]:

[24] $c_H^*\Delta c_A = K_a\Delta c_{AH}$

Combining eqs. [20] and [23], we get eq. [25]:

[25] $(1 + K_2c_A^*)\Delta c_L + K_2c_L^*\Delta c_A = 0$

Assuming $K_2 < 10^4$, we have $K_2c_A^* << 1$. Thus, eq. [25] simplifies to eq. [26]:

[26] $\Delta c_L + K_2c_L^*\Delta c_A = 0$

From eqs. [19] and [20], we get eq. [27]:

[27] $\Delta c_{AH} + \Delta c_B + \Delta c_A = \Delta c_L$

Equations [24], [26], and [27] are combined to give eq. [28]:

[28] $\Delta c_{AH}(1 + (1 + K_2c_L^*)K_a/c_H^*) + \Delta c_B = 0$

$(1 + K_2c_L^*)K_a/c_H^*$ is much larger than 1 and eq. [28] finally reduces to eq. [29] (here again, we may take $c_L^* = L_t$):

[29] $\Delta c_{AH}(1 + K_2L_t)K_a/c_H^* + \Delta c_B = 0$

Assuming eq. [8] to remain valid, we combine it with eq. [29] to get the expression for the apparent first-order rate constant k for change in B (eq. [30]):

[30] $$k = k_2c_H^* + \frac{c_H^*}{K_a}\frac{k_1}{1 + K_2L_t}$$

In the absence of copigment, k becomes k_0 (eq. [31]):

[31] $k_0 = k_2\, c_H^* + k_1\, c_H^*/K_a$

Here again, the double-reciprocal plot of $k_0 - k$ versus L_t is linear and yields k_1/K_a and K_2 (see eq. [4]). k_0 and k are de-

termined from linear plots of $\ln|D - D^*|$ versus time. However, at pH about 5 in the presence of rutin the hydration process is generally too slow for the equilibrium state to be reached before rutin precipitation occurs. Thus, a direct experimental determination of D^* is not possible. We get a first D^* value from a rough extrapolation of the curve expressing D versus time. Then, a more accurate estimation is achieved by plotting $\ln|D - D^*|$ versus time for different D^* values close to the extrapolated value and by selecting the one giving the best linear plot.

GHISLAINE MARTIN, JEAN SAULEAU, MICHÈLE DAVID, ARMELLE SAULEAU et SOURISAK SINBANDHIT. Can. J. Chem. **70**, 2190 (1992).

On étudie la réaction entre des époxydes α éthyléniques et des thiophénols ou le phénylthiotriméthylsilane avec ZnI_2 ou *n*BuLi à température ambiante. Ces réactions qui peuvent être régio et stéréospécifiques, conduisent avec de bons rendements à trois types d'hydroxythioéthers éthyléniques isomères de position. La stéréochimie, le degré de substitution des oxiranes et les conditions réactionnelles, gouvernent les sites d'attaques. Durant la réaction de condensation, il peut se produire une migration 1,3 du reste thiophényle. Sous l'action de la lumière, les hydroxythioéthers allyliques subissent, par un mécanisme radicalaire, la rupture de la liaison ArS – reste allylique. On détermine les constantes de vitesse, les conditions du réarrangement ainsi que les composés formés.

GHISLAINE MARTIN, JEAN SAULEAU, MICHÈLE DAVID, ARMELLE SAULEAU, and SOURISAK SINBANDHIT. Can. J. Chem. **70**, 2190 (1992).

Reactions of vinyloxiranes and thiophenols or phenylthiotrimethyl silane with ZnI_2 or *n*BuLi, at room temperature, were studied. These condensations proceed regio and stereospecifically to afford, in good yields, three families of hydroxy aryl ethylenic sulfides. The regiochemistry is determined by the stereochemistry, the substitution of the oxiranes, and the reaction conditions. During the condensation, 1,3 phenylthio migration occurs. Light initiates the rearrangement by bringing about cleavage of the allyl sulfur bond — a radical chain mechanism — of the hydroxy allylphenyl sulfides. Scope, rate constants, and product composition of the rearrangement were studied.

Introduction

Si la littérature relate souvent l'ouverture d'époxydes saturés par des thiols (1), la place réservée aux oxiranes monoéthyléniques est plus restreinte. En effet, seuls les cas des oxydes commerciaux (de butadiène ou d'isoprène) semblent avoir été rapportés (2–4).

Dans cette étude nous étendons la réaction à toute une gamme d'époxydes α éthyléniques notamment à des structures diastéréoisomères *R*R**, *R*S**. La recherche de conditions expérimentales précises a permis d'atteindre des réactions régio et stéréospécifiques.

Il nous a ainsi été possible de synthétiser une série d'hydroxythioéthers insaturés nouveaux où l'hydroxyle et le groupe soufré sont en position allylique ou homoallylique.

Le réarrangement spontané de certains de ces composés, nous a amené à étudier la cinétique et l'influence des substituants sur leur facilité d'isomérisation.

Résultats des condensations époxydes/thiols : voies I, II, III et IV

Les époxydes utilisés ici, synthétisés selon une méthode mise au point par l'un d'entre nous (5), sont soit primaires–tertiaires **1** et **2**, soit secondaires–tertiaires **3** et **4**, de stéréochimie connue.

Le mélange thiophénols/Na/trifluoroéthanol (TFE) ou le phénylthiotriméthylsilane dans le 1,2-dichloroéthane (DCE) conduit à trois types d'hydroxythioéthers **I**, **II** et **III** selon les voies I, II et III.

La voie IV correspond à l'isomérisation des hydroxythioéthers de structure **II** en composés type **III**, lorsque le milieu réactionnel est, à température ambiante, abondonné à la lumière du jour ou à celle d'une lampe à incandescence.

Compte-tenu des deux origines possibles de **III**, nous avons dû éviter ce réarrangement pour déterminer les pourcentages relatifs exacts des produits types **II** et **III** résultant d'une attaque nucléophile sur les époxydes; cela a été possible en ajoutant des quantités catalytiques d'hydroquinone dans le milieu de condensation.

Les résultats des condensations, reportés tableau 1, appellent plusieurs remarques.

Les voies I et II traduisent l'attaque nucléophile de chacun des carbones hétérocycliques de l'oxirane.

1. *En présence de thiophénols* la voie I est préférentielle (hydroxythioéthers type **I** majoritaires) avec les époxydes primaires–tertiaires (**1** et **2**) où le site d'attaque nucléophile est dépourvu de gêne stérique. Dans ces réactions, l'influence de la nature du solvant de condensation (benzène, dioxane) susceptible d'assister l'ouverture de l'oxirane, n'apparaît pas déterminante; en effet, on obtient des résultats très voisins de ceux indiqués, tableau 1, pour le TFE.

La réaction selon la voie II ne se produit qu'avec les époxydes encombrés **3** et **4**. Leur stéréochimie est essentielle puisqu'elle gouverne une éventuelle conjugaison entre le cycle oxygéné et le système éthylénique (6). Celle-ci a pour effet d'orienter l'ouverture du cycle sur le carbone le plus substitué. Ainsi, avec les époxydes **3** *R*R**, **3** *R*S**, **4** *R*R**, cette activation jour pleinement; on obtient 80–95% de composés type **II**.

Avec ces époxydes trisubstitués, si l'on veut favoriser la formation des hydroxythioéthers type **I** au détriment du type **II**, il est nécessaire qu'il y ait empêchement à la conjugai-

SCHÉMA 1

son. C'est ce qui se produit avec l'époxyde **4** *R*S** où le reste méthyle et le groupe éthylénique volumineux (isopropényle) sont tous deux en position *cis*; on explique ainsi le taux de 95% en composé de type **I**.

2. Les hydroxythioéthers de structure **III** sont majoritaires voire uniques dans les mélanges réactionnels, à condition d'employer le *phénylthiotriméthylsilane* en présence de traces de ZnI_2. C'est la complexation de l'oxygène époxydique avec formation d'un intermédiaire cationique, délocalisable jusqu'aux carbones sp_2, qui privilégie la voie III. Le remplacement de ZnI_2 par des quantités catalytiques de *n*BuLi, entraîne des résultats différents. En effet, dans quatre exemples sur six, l'ouverture des époxydes **1–4** est régiospécifique, la voie I est unique, mais les rendements sont parfois faibles.

Par ailleurs, il faut souligner que toutes ces réactions sont stéréospécifiques et procèdent, comme il est couramment admis, avec d'autres nucléophiles (5), par une *trans* addition. Nous avons par exemple vérifié en RMN 300 MHz, que les hydroxythioéthers **9** et **14** (ou **10** et **15**) issus des époxydes **3** *R*S** et **3** *R*R**, sont chacun de stéréochimie différente et unique. Par contre, une vérification par voie chimique a échoué : la transformation **10** (ou **15**) en époxydes **3** (sous l'action du fluoroborate de triméthyloxonium) n'est pas ici stéréospécifique.

L'étude des spectres RMN a permis de différencier aisément les composés de structure **I**, **II** et **III**, dans les mélanges bruts débarrassés du solvant. Par exemple, il nous a été possible de distinguer des signaux à déplacements chimiques voisins : ceux d'un reste méthylène à 3,55 ppm (composé **11**) ne peuvent être confondus avec le proton du reste C*H*OH (3,71 ppm) de **10** ou du reste C*H*-CH_3 (3,27 ppm) dans **9** (tableaux 2 et 3).

La géométrie *Z* ou *E* de la double liaison dans les structures **III** a été déterminée en RMN ^{13}C. Pour les produits où R = H, l'effet γ-*gauche* est concluant : pour **11** par exemple, le déplacement chimique du reste CH_3 (11,50 ppm) porté par un carbone sp_2 est significatif d'une géométrie *E* (pour l'isomère *Z* on trouve 17,20 ppm) (tableau 3). Par contre, dans le cas des composés où R = CH_3, l'attribution de la géométrie est plus délicate; nous nous sommes référés à des éthers phénoliques de structure voisine, préparés par nous (5*c*) ainsi qu'à des données de la littérature (7).

Étude de la transformation spontanée des hydroxythioéthers de type II (voie IV)

Le milieu réactionnel brut — thiophénols/époxydes — en l'absence d'hydroquinone, est étudié après élimination du solvant.[2]

La RMN haute résolution du ^1H et du ^{13}C a permis en particulier :

(*i*) de suivre le réarrangement des composés type **II** en type **III** : par exemple pour le produit **10**, on note la disparition progressive des signaux correspondants au groupe vinyle entre 4,8 et 5,8 ppm (ou 114,1 et 140,3 ppm) et l'apparition simultanée du produit **11** où le reste CH_2, fixé au substi-

[2]Lorsque les condensations sont menées dans le phénylthiotriméthylsilane, aucune isomérisation **II** vers **III** n'est constatée.

	$C_6H_5SSiMe_3$	ZnI_2	18	90	**III** (100)	70/30
		*n*BuLi	28	53	**I** (100)	

[a]L'isomère *E* des hydroxyéthers type **III** est majoritaire (pourcentages difficiles à déterminer à la précision de la RMN $\simeq$ 5%).

tuant thiophényle, est à 3,55 ppm (31,7 ppm) (tableaux 2 et 3).

(*ii*) de déterminer les demi-vies de la transformation en notant la disparition du proton (ou du système protonique) le mieux résolu, en fonction du temps.

Pour chaque composé type **II**, on porte en fonction du temps, le rapport de sa concentration (instant *t*) à sa concentration initiale. Dans tous les cas, l'obtention d'une droite, pour un avancement de la réaction allant au-delà de 95%, indique que la réaction est du premier ordre par rapport aux produits **II** (dans nos conditions). Les résultats inscrits dans le tableau 4 permettent quelques remarques qualitatives : (*i*) les vitesses de conversion diffèrent d'un composé à l'autre : on remarque qu'un méthyle fixé au reste éthylénique des produits type **II**, accélère l'isomérisation (comparer **10** à **19** ou **12** à **21**); (*ii*) la vitesse est liée à la nature du reste migrant; il suffit de comparer **10** à **12**, le temps de demi-vie varie d'un facteur deux.

Enfin, nous avons constaté que les produits type **II** sont stables, même en l'absence d'hydroquinone, à partir du moment où ils sont débarrassés de toutes traces de thiophénols ou de diphényldisulfures (après plusieurs passages sur colonne de gel de silice). Mais, si au produit ainsi stabilisé on ajoute une très faible quantité (M/100) d'un arylthiophénol, son réarrangement réapparaît.

Des études en spectrographie de masse ont confirmé qu'il s'agit d'une transformation radicalaire, avec migration 1,3 d'un radical thiyle.

Deux réactions croisées ont été effectuées et analysées par cette méthode au départ de **10**. Si on ajoute à **10** du *para*-méthylthiophénol ou du *para*-tertiobutylthiophénol, on peut déceler la présence simultanée des ions moléculaires des composés de réarrangement, respectivement **11** et **13** d'une part, **11** et **25** d'autre part (les pourcentages de quelques ions les plus significatifs sont précisés dans le schéma 2).

De plus, si le diphényl disulfure est toujours présent ($\simeq$ 4%), la décomposition de **11** ($M - H_2O^{\ddagger}$: 190) est totalement différente de celle de **13** ou de **25**, composés issus du croisement, où l'on décèle ($M - CH_3 - CHO^{\ddagger}$: 178 ou 220).

Le réarrangement observé pour les composés type **II**, où les groupes thioéther et hydroxyle sont réunis dans la même molécule, constitue à notre connaissance, le premier exemple de la littérature.[3]

Pour expliquer cette isomérisation, nous pouvons nous référer à des arylthioéthers allyliques de structure voisine de

[3]Le réarrangement d'un phénylthiopropényle cyclohexanol, uniquement en présence d'un initiateur radicalaire (azobisisobutyronitrile) vient d'être rapporté (10).

SCHÉMA 2

nos composés type **II**, mais non hydroxylés; il est connu que ceux-ci s'isomérisent soit par un intermédiaire ouvert (8) (chaine radicalaire et entité phénylthiyle) soit par un mécanisme cyclique (9). Dans notre cas, il est probable que la transformation observée procède plutôt par l'intervention d'un système ouvert puisque nous n'avons constaté aucune influence de la stéréochimie *R*S** ou *R*R** des composés type **II**, sur la nature de leurs produits de réarrangement type **III**.

Conclusion

La stéréochimie *R*R** ou *R*S** des époxydes, le choix du réactif soufré, sont des facteurs essentiels réglant la régiosélectivité des réactions étudiées : l'accès à un seul hydroxythioéther de structure définie est alors rendu possible.

Des informations sur la migration 1,3 du groupe aryl thioéther sont apportées : de nature radicalaire, allant jusqu'à modifier les résultats des condensations, elle peut être inhibée dans des conditions qui sont précisées.

Partie expérimentale

Appareillage

RMN Bruker AM 300 WB : 300 MHz (^1H), 75,469 MHz (^{13}C). Les pourcentages figurés dans les tableaux, sont déterminés en RMN ^1H à partir de l'intégration des signaux les mieux résolus; les déplacements chimiques, dans $CDCl_3$, sont exprimés en ppm par rapport au TMS, les constantes de couplage J en hertz (tableaux 2 et 3).

Spectrométrie de Masse (SM) : Varian Matt 311 avec procédé M.I.K.E.; les rapports m/z des principales fragmentations sont suivis, entre parenthèses, des pourcentages par rapport au pic de base. Les ruptures des composés de structure **I**, **II** et **III** indiquées tableaux 2 et 3, sont valables pour tous les autres produits de même type.

Chromatographie phase gazeuse : Fractovap Carlo Erba 4160, colonne capillaire SE 52 de 25 m. Fractovap GT Carlo Erba détecteur à ionisation de flamme, gaz porteur N_2, colonne SE 30 à 10% sur Chromosorb W 60/80 lavé aux acides.

Chromatographie sur colonne gel de silice 60 Merck (70–230 mesh). Eluant : $C_6H_6/CH_3COOC_2H_5$ 95 : 5 pour la séparation des composés **5** et **7**; $C_6H_6/CH_3COOC_2H_5$, 92 : 8 pour la séparation des isomères *E*, *Z* de **7** et de **8**; CH_2Cl_2 dans tous les autres cas.

Pour l'élimination de l'excès de thiophénols et des disulfures dans le milieu réactionnel, on utilise le toluène.

Un contrôle de pureté est réalisé sur chacun des produits, par chromatographie phase vapeur et spectrométrie de masse.

Mode opératoire général

Les réactions sont toutes conduites sous atmosphère inerte d'azote. Eventuellement une quantité d'hydroquinone (nombre de mole d'époxyde $\times 10^{-2}$) est ajoutée au milieu réactionnel.

Utilisation du mélange thiophénols/sodium

À 10.2 mmol de thiophénol (ou de *para*-méthylthiophénol), préalablement purifié sous azote, dissous dans 12 mL de solvant, on ajoute 0,23 g de sodium. Après disparition du sodium et refroidissement, on ajoute sous agitation en une seule fois, 5.1 mmol d'époxyde et éventuellement, 0.05 mmol d'hydroquinone. Tout en maintenant l'agitation à température ordinaire, le terme de la réaction (disparition de l'époxyde) est déterminé par chromatographie en phase gazeuse (colonne SE 30). Le mélange est ensuite versé sur 10 mL d'eau, extrait plusieurs fois à l'éther. Les phases éthérées sont séchées sur Na_2SO_4 et évaporées.

Utilisation du phénylthiotriméthylsilane (3)

Au départ de 8.1 mmol d'époxyde et de 8.3 mmol, de phénylthiotriméthylsilane, on ajoute soit une solution de 0.42 mmol de *n*BuLi dans 12 mL de THF soit une solution de 0.8 mmol de ZnI_2 dissous dans 12 mL de 1,2-dichloroéthane. Après agitation à température ordinaire et contrôle chromatographique (pour le terme de la réaction), le milieu réactionnel est traité par 8 mL de méthanol puis 1.2 mmol d'acide acétique suivi de deux lavages par une solution aqueuse à 10% d'hydroxyde de baryum. Le composé isolé contient parfois un faible pourcentage de son dérivé *O*-silylé. Nous donnons les caractéristiques spectrales RMN et spectrographie de masse des composés silylés **5** et **6**.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

Quel que soit le mode opératoire utilisé, le mélange brut réactionnel est toujours purifié sur colonne de gel de silice.

*Traitement de **10** ou **15** par le tétrafluoroborate de triméthyloxonium*

À une solution de 4.2 mmol de **10** *R*R** (ou **15** *R*S**), dans 30 mL de CH_2Cl_2, maintenue à 0°C et sous azote, on introduit en une seule fois 4.5 mmol de fluoroborate de triméthyloxonium. La solution devient limpide en 1,5 h. On ajoute alors goutte à goutte tout en maintenant à 0°C, 8.5 mL de NaOH 10%. Une fois l'addition terminée, le mélange réactionnel est analysé en chromatographie phase gazeuse (colonne SE 30). La formation de l'époxyde **3** est pratiquement immédiate (10 min). Il se trouve sous forme d'un mélange des diastéréoisomères **3** *R*R** / **3** *R*S** (40 : 60) identifié directement au moyen d'échantillons témoins de stéréochimie pure. Cette réaction n'est donc pas stéréospécifique, dans notre cas, contrairement à ce que Pirkle et Rinaldi (11) ont observé au départ d'hydroxysulfures à restes saturés.

Détermination des constantes de vitesse

Les réactions de transformation ont été suivies en tube RMN scellé; les composés **II** sont en solution dans $CDCl_3$: le signal du trichloro-1,1,1-éthane, constant dans le temps, sert de référence aux intégrales des signaux. La variation de l'aire d'un signal décroissant, mesurée par référence à celle de l'étalon interne a permis de doser les produits type **II** décroissants. Les spectres, à 300 MHz, sont enregistrés à la température de l'aimant.

Les produits **II** sont à concentration moyenne de 8×10^{-5} M, la référence interne de 10^{-5} M. Pour la reproductibilité des résultats, le tube scellé est soumis à la lumière d'une lampe à incandescence de 150 W située à 38 cm de l'échantillon (cas de **17**) tandis que 60 W pour 12 cm sont utilisés pour tous les autres produits type **II**.

Nous avons vérifié que, dans chacun des cas, les pentes expérimentales et les pentes calculées (droites de tendance, méthode des moindres carrés) ont en valeur, un écart inférieur aux erreurs expérimentales (considérées voisines de 5%). Les résultats sont indiqués tableau 4.

Données spectroscopiques complémentaires

Composé **5** silylé : RMN ^1H : 0,10 (s, 9H); 1,45 (s, 3H); 3,04–3,14 (2H, AB, J = 12,62); 5,07–5,27 et 5,94–6,03 (3H, ABX, J_{AB} = 10,59, J_{BX} = 10,66, J_{AX} = 17,03); 7,12–7,37 (m, 5H). ^{13}C : 2,39 ($Si(CH_3)_3$); 26,32 (CH_3); 47,66 (CH_2); 75,9 (C-OSi); 113,32 (=CH_2); 125,55 (C4′); 128,69 (C3′); 128,98 (C2′); 128,07 (C1′); 144,04 (=CH). Isothermes 75°C, des systèmes ternaires limitant le système quaternaire réciproque : H^+, K^+, PO_4^{3-}, SO_4^{2-}, H_2O

NÉJI BOURGUIBA[1] ET TAHAR JOUINI

Département de chimie, faculté des sciences de Tunis, Campus universitaire, 1060 Tunis, Tunisie

Reçu le 18 octobre 1991

NÉJI BOURGUIBA et TAHAR JOUINI. Can. J. Chem. **70**, 2197 (1992).

Les cinq isothermes ternaires limitant le système quaternaire indiqué au titre ont été établies comme première étape de l'étude de ce système à 75°C et 1 atm (101,3 kPa). Cette température a été choisie en vue d'appliquer les résultats à la fabrication industrielle d'engrais phosphopotassiques par attaque sulfurique du minerai phosphaté, dont la température optimale est de 70–80°C. (*i*) Système ternaire réciproque anhydre H_2SO_4–H_3PO_4–K_2SO_4–K_3PO_4. Phases solides : $KHSO_4$, $KH_2PO_4 \cdot KHSO_4$, $KH_5(PO_4)_2$ et une solution solide de substitution $K_8(H_2PO_4)_{1+x}(HSO_4)_{7-x}$, $0 \leq x \leq 1$, continue entre les deux compositions limites $KH_2PO_4 \cdot 7KHSO_4$ et $KH_2PO_4 \cdot 3KHSO_4$ dont les diagrammes de poudre indéxés sont donnés. (*ii*) Système ternaire K_3PO_4–H_3PO_4–H_2O. Phases solides : $KH_5(PO_4)_2$, KH_2PO_4, $3K_2HPO_4 \cdot KH_2PO_4 \cdot 2H_2O$, K_2HPO_4 et $K_3PO_4 \cdot 3H_2O$. (*iii*) Système ternaire K_2SO_4–H_2SO_4–H_2O. Phases solides : K_2SO_4, $K_2SO_4 \cdot KHSO_4$, $K_2SO_4 \cdot 7KHSO_4 \cdot H_2O$ et $KHSO_4$. Un phénomène de solubilité rétrograde en fonction de la teneur en eau y est mis en évidence. (*iv*) Système ternaire K_2SO_4–K_3PO_4–H_2O. Phases solides : K_2SO_4 et $K_3PO_4 \cdot 3H_2O$. (*v*) Le système ternaire H_3PO_4–H_2SO_4–H_2O est constitué d'un seul domaine liquide à 75°C.

NÉJI BOURGUIBA and TAHAR JOUINI. Can. J. Chem. **70**, 2197 (1992).

The five ternary isotherms limiting the quaternary system mentioned in the title have been established as a first step toward the study of this system at 75°C and 1 atm (101.3 kPa). This temperature has been chosen in order to be able to apply the results to the industrial preparation of phosphopotassium fertilizers through a sulphuric treatment of a phosphate ore for which the optimum temperature is 70–80°C. (*i*) Anhydrous reciprocal ternary system : H_2SO_4–H_3PO_4–K_2SO_4–K_3PO_4. Solid phases : $KHSO_4$, $KH_2PO_4 \cdot KHSO_4$, $KH_5(PO_4)_2$, and a solid substituting solution $K_8(H_2PO_4)_{1+x}(HSO_4)_{7-x}$, $0 \leq x \leq 1$, continuous between the two limiting compositions $KH_2PO_4 \cdot 7KHSO_4$ and $KH_2PO_4 \cdot 3KHSO_4$ for which the indexed powder diagrams are given. (*ii*) Ternary system K_3PO_4–H_3PO_4–H_2O. Solid phases: $KH_5(PO_4)_2$, KH_2PO_4, $3K_2HPO_4 \cdot KH_2PO_4 \cdot 2H_2O$, K_2HPO_4, and $K_3PO_4 \cdot 3H_2O$. (*iii*) Ternary system K_2SO_4–H_2SO_4–H_2O. Solid phases: K_2SO_4, $K_2SO_4 \cdot KHSO_4$, $K_2SO_4 \cdot 7KHSO_4 \cdot H_2O$, and $KHSO_4$. A phenomenon of retrosolubility as a function of the water content has been observed. (*iv*) Ternary system K_2SO_4–K_3PO_4–H_2O. Solid phases: K_2SO_4 and $K_3PO_4 \cdot 3H_2O$. (*v*) The ternary system H_3PO_4–H_2SO_4–H_2O is formed by only one liquid phase at 75°C.

[Journal translation]

Introduction

Les techniques de préparation industrielle des engrais sont actuellement orientées vers la fabrication, utilisant des matériaux disponibles, d'engrais combinés les plus riches en éléments fertilisants.

Dans ce cadre figure la fabrication d'engrais phosphopotassiques à partir de minerai phosphaté (apatite) et de sulfate acide de potassium $KHSO_4$ provenant du procédé Pennzoil (1–4)

$$H_2SO_4 + KCl \rightarrow KHSO_4 + HCl$$

L'attaque par $KHSO_4$ de l'apatite produit un mélange hétérogène. Aprés dégagement des composés volatils (HF, SiF_4, CO_2 . . .) et séparation de l'insoluble constitué essentiellement de phosphogypse, la solution aqueuse résultante contient les ions H^+, K^+, PO_4^{3-} et SO_4^{2-}.

On est donc amené à étudier le quaternaire K_2O–SO_3–P_2O_5–H_2O. Il est commode de considérer, à l'intérieur de ce système, celui faisant intervenir les composés présents en milieu aqueux : H_3PO_4, K_2SO_4, H_2SO_4, K_3PO_4. Il s'agit d'un système quaternaire réciproque caractérisé par la réaction de double décomposition:

$$2H_3PO_4 + 3K_2SO_4 \overset{H_2O}{\rightleftharpoons} 3H_2SO_4 + 2K_3PO_4$$

Toute application industrielle devra se baser sur la connaissance de ce diagramme d'équilibre. De plus cette fabrication constitue, en particulier, l'un des objectifs de l'industrie tunisienne.

Nous avons choisi d'établir l'isotherme 75°C. En effet la température optimale de l'attaque sulfurique de l'apatite est de 70–80°C. En s'en écartant trop on risque un blocage de la réaction ou la formation du monohydrogénophosphate $CaHPO_4 \cdot 2H_2O$ qui syncristallise avec le gypse provoquant une perte de phosphate. De plus ce diagramme n'a fait l'objet d'aucune étude dans cet intervalle de température.

Nous présentons en une première étape, dans ce mémoire, les diagrammes limitant cette isotherme.

Partie expérimentale

A. Techniques expérimentales

Les solubilités ont été essentiellement mesurées par analyse chimique des solutions à l'équilibre, saturées par une ou deux phases solides. Quelques déterminations de solubilité ont été effectuées par conductimétrie (5–7). Les résistances ont été mesurées au moyen d'un pont de marque Général-Radio de type impédance bridge B-1650.

L'évolution des mélanges est contrôlée d'une part en examinant les phases solides par diffraction des rayons X sur poudre et au microscope polarisant, d'autre part en mesurant la résistance de la solution. Lorsque l'équilibre est atteint la résistance du liquide prend une valeur constante. Cela nécessite en général quelques jours. Les mélanges visqueux, trés riches en acides, nécessitent une agitation énergique de plusieurs semaines. De plus pour nous assurer de la reproductibilité de nos résultats, la composition de chaque point invariant a fait l'objet de mesures indépendantes sur au moins deux mélanges différents.

Lors de ces analyses répétitives nous avons constaté que pour une

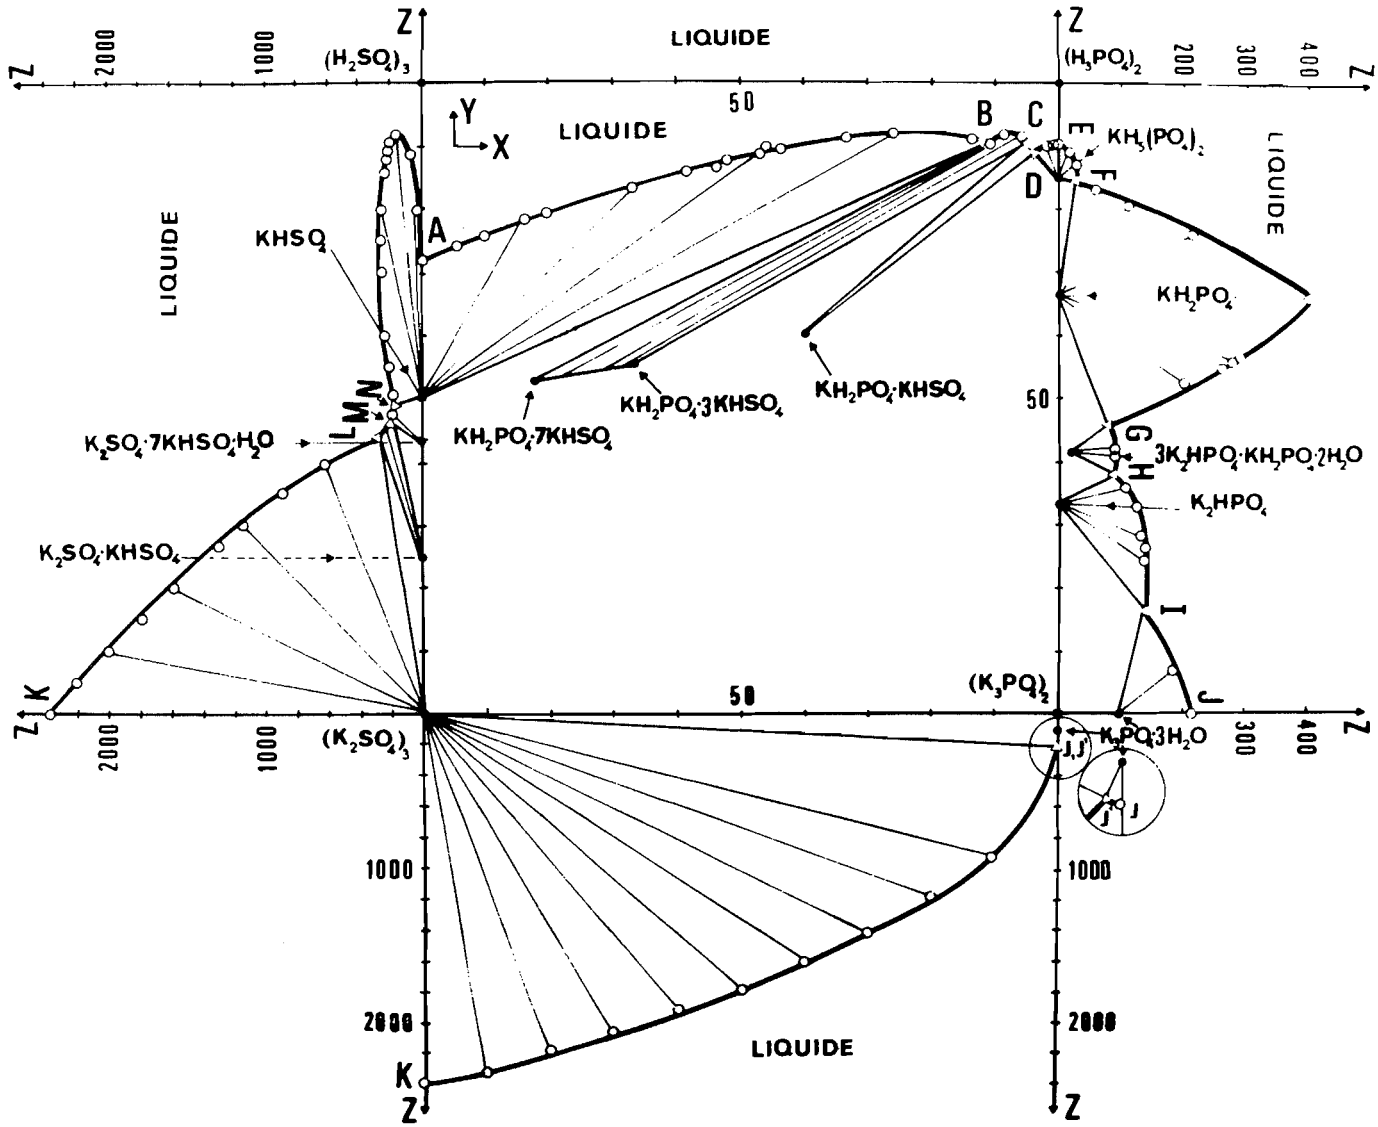

FIG. 1. Isothermes 75°C, des systèmes ternaires limitant le système quaternaire réciproque : H_2SO_4–H_3PO_4–K_2SO_4–K_3PO_4–H_2O, rabattus dans le carré de base.

même composition les coordonnées X et Y fluctuent de 0,5 à 1% et les coordonnées Z de 1 à 2%. Cela conduit à un nombre de chiffres significatifs de 3 à 4, comme c'est en général le cas dans les publications relatives aux digrammes de solubilité. Par exemple dans celles compilées dans l'ouvrage de Linke (8).

Les phases solides connues ont été identifiées par leurs diagrammes de diffraction des rayons X sur poudre effectués sur une chambre de type Guinier–Dewolf de marque Enraf–Nonius permettant le travail en atmosphère contrôlée, dans le cas présent sous air sec pour les sels hygroscopiques. Les phases solides pour lesquelles nous ne disposons pas d'une liste des distances réticulaires ont été au préalable identifiées par les méthodes des restes (9) et des ensembles (10). Les phases solides sont également observées au microscope polarisant et pour les plus caractéristiques d'entre elles identifiées.

B. Produits utilisés

1. Produit du commerce

Nous avons utilisé les produits Merck pour analyse et Prolabo R.P. suivants : l'acide sulfurique à 95%, $\rho = 1{,}83$ g cm^{-3}, l'acide phosphorique à 85%, $\rho = 1{,}7$ g cm^{-3}, l'acide de Nordhausen à 20% d'anhydride sulfurique, le sulfate acide de potassium, le sulfate de potassium, le phosphate diacide de potassium, le phosphate monoacide de potassium et le phosphate tri-potassique dihydraté.

2. Produits préparés au laboratoire

Acide sulfurique anhydre : Il a été préparé par addition, à la burette, d'une quantité calculée d'eau à de l'acide de Nordhausen à 20% d'anhydride sulfurique. L'opération est effectuée dans un récipient plongé dans un mélange de glace et de chlorure de sodium, en évitant toute projection.

$KH_5(PO_4)_2$: Ce produit est utilisé pour préparer les mélanges très riches en H_3PO_4. Sa préparation est basée sur la connaissance du système ternaire K_3PO_4–H_3PO_4–H_2O à 75°C établie au cours de cette étude.

C. Mode de represéntation

Le mode de représentation choisi pour le système quaternaire est celui du prisme droit à base carré de Le Chatelier (11)–Janecke (12).

Les sommets du carré de base représentent les composés de départ. Les arêtes du prisme correspondent aux systèmes binaires limites faisant intervenir l'eau. Les parois verticales du prisme sont des systèmes ternaires limites simples et la base est un système ternaire limite réciproque anhydre.

Un mélange quelconque sera caractérisé par trois coordonnées

M	25,24	39,87	34,89	46,25	171,4	$K_2SO_4 \cdot 7KHSO_4 \cdot H_2O + K_2SO_4 \cdot KHSO_4$
L	22,52	34,15	43,33	44,00	260,0	$K_2SO_4 \cdot KHSO_4 + K_2SO_4$

(*d*) Système : K_2SO_4–K_3PO_4–H_2O

Points invariants	Composition pondérale % K_2O	% P_2O_5	% H_2O	Janecke *X*	*Z*	Phases solides en équilibre
J	43,17	21,69	35,14	100	213,0	$K_3PO_4 \cdot 3H_2O + K_2SO_4$

TABLEAU 2. Paramètres affinés des solutions solides limites $K_8(H_2PO_4)_{1+x}(HSO_4)_{7-x}$, $x = 0$ et $x = 1$

Composés limites	*a*(Å)	*b*(Å)	*c*(Å)	α(°)	β(°)	γ(°)
$KH_2PO_4 \cdot 7KHSO_4$	7,201(3)	7,503(3)	7,582(3)	108,57(4)	88,29(4)	93,70(3)
$KH_2PO_4 \cdot 3KHSO_4$	7,180(4)	7,497(5)	7,599(6)	108,52(6)	88,51(7)	93,77(5)

X, *Y* et *Z*. *X* et *Y* sont respectivement les pourcentages ou fractions molaires d'ions phosphates et de protons :

$$X = 3 \times 10^2 [PO_4^{3-}]/D$$

$$Y = 10^2 [H^+]/D$$

où *D* est la relation qui traduit la neutralité électrique du milieu.

$$D = [H^+] + [K^+] = 2[SO_4^{2-}] + 3[PO_4^{3-}]$$

Les variables entre crochets représentent des nombres de moles. La composition en eau, portée par les arêtes verticales du prisme, s'exprime par :

$$Z = 10^2 [H_2O]/D$$

Il en résulte que le point représentatif de l'eau pure (*D* tendant vers 0) est rejeté à l'infini.

Pour l'une des isothermes ternaires nous avons aussi utilisé le mode de représentation plus classique en triangle équilatéral.

Résultats expérimentaux

Les systèmes ternaires limites étudiés sont représentés à la figure 1. Les compositions des points représentatifs des invariants ternaires isothermes et les phases en équilibre correspondantes sont consignées au tableau 1.

1. Isotherme 75°C du système ternaire réciproque anhydre : H_2SO_4–H_3PO_4–K_2SO_4–K_3PO_4

Ce diagramme n'a à notre connaissance fait l'objet d'aucune étude antérieure. Il est représenté à l'intérieur du carré de la figure 1. Cette étude fait intervenir $KH_5(PO_4)_2$ et H_2SO_4 anhydres. Il en résulte des mélanges très visqueux et hygroscopiques nécessitant des précautions particulières : agitation mécanique très énergique et prolongée (quelques heures à plusieurs jours) et une parfaite étanchéité des tubes laboratoires, assurée par des joints en mercure. Les prélèvements effectués au moyen de pipettes à bout filtrant, des solutions à analyser, sont également rendus difficiles par la viscosité.

Dans ce système on observe en particulier un domaine limité par la courbe de solubilité BC où se manifeste une solution solide continue $K_8(H_2PO_4)_{1+x}(HSO_4)_{7-x}$ avec $0 \leq x \leq 1$. Les compositions limites $KH_2PO_4 \cdot 7KHSO_4$ et $KH_2PO_4 \cdot 3KHSO_4$ (abréviations P.7S et P.3S) ont été déterminées par analyse chimique de cristaux obtenus de la façon décrite ci-aprés. Deux mélanges ont été préparés respectivement dans les deux triangles d'invariance ternaire isotherme situés de part et d'autre du domaine de la solution solide. Ces mélanges sont triphasés : dans chacun d'eux coexistent l'une des solutions solides limites avec le sel appartenant au domaine voisin, en présence de solution. Nous avons fait croître des cristaux de ces phases solides par sursaturation. Les cristaux des solutions solides limites reconnaissables à leur forme de baguettes, sont séparés par triage pour analyse chimique et aux rayons X. Les paramètres de leurs mailles ont été déterminés par étude des cristaux sur chambre de Weissenberg puis affinés par moindres carrés en utilisant les raies des diagrammes de poudre mesurées au moyen d'un diffractomètre automatique à deux cercles «STOE/css». Les paramètres, des deux composés limites, reportés au tableau 2 diffèrent peu malgré l'importante différence stoechiométrique. Cela s'explique par la similitude des dimensions des tétraèdres PO_4^{3-} et SO_4^{2-}. Les dia-

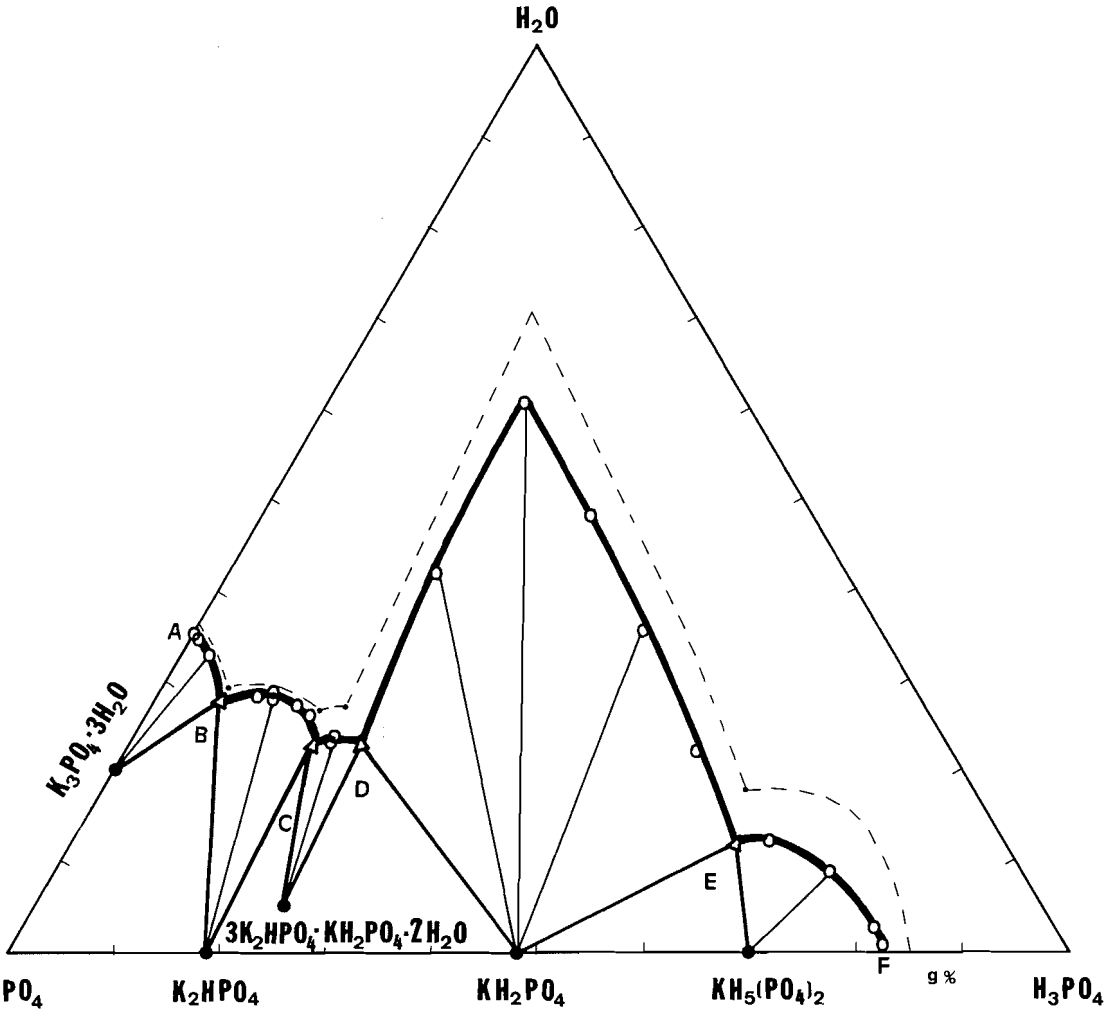

FIG. 2. (——) Isotherme 75°C du système ternaire : K_3PO_4–H_3PO_4–H_2O. (------) Isotherme 50°C du même système (Wendrow et Kobe (21)).

grammes de poudre indéxés de P.7S et P.3S sont donnés dans les tableaux 3 et 4.

On relève dans la littérature que lors d'une étude du système KH_2PO_4–$KHSO_4$ (13) les limites du domaine d'existence de cette solution solide n'ont pu être déterminées avec précision et les diagrammes de poudre, non indexés, fournis comportaient des raies parasites que nous avons attribuées à $KHSO_4$. D'autre part les structures de $KH_2PO_4 \cdot KHSO_4$ (14) et celle de $KHSO_4$ (15) ont été décrites.

2. Système ternaire K_3PO_4–H_3PO_4–H_2O–isotherme 75°C

Les phases solides caractérisées au cours de cette étude sont : $KH_5(PO_4)_2$, KH_2PO_4 (39,29), $3K_2HPO_4 \cdot KH_2PO_4 \cdot 2H_2O$ (76,57), K_2HPO_4(72,74) et $K_3PO_4 \cdot 3H_2O$ (81,15). Les nombres indiqués entre parenthèses représentent pour les sels à solubilité congruente la solubilité dans l'eau à 75°C en grammes de sel pour 100 g de solution saturée. Notons que les mélanges riches en H_3PO_4 donnent lieu à des solutions très visqueuses, nécessitant une agitation prolongée (un à plusieurs jours).

Ce système ayant fait l'objet de nombreux travaux à d'autres températures (16–22), utilisant la représentation en triangle rectangle isocèle ou en triangle équilatéral, nous l'avons également traduit dans ce dernier mode de représentation (figure 2). La comparaison avec l'isotherme 50°C établie par Wendrow et Kobe (21), montre que les mêmes phases solides se manifestent dans les deux diagrammes et que les courbes de solubilité présentent des allures semblables. On observe un très faible écart entre ces dernières dans la région basique. Nous avons vérifié dans la bibliographie (8, 23) qu'effectivement les solubilités relatives à K_2HPO_4 et $K_3PO_4 \cdot 3H_2O$ dans d'autres diagrammes évoluent peu en fonction de la température. On relève également dans la littérature une étude critique sur la solubilité de KH_2PO_4, K_2HPO_4 et K_3PO_4 dans des solutions aqueuses et non aqueuses (24–26).

La structure de KH_2PO_4 a fait l'objet de nombreux travaux dont les plus récents (27–31) sont justifiés par les propriétés optiques et ferroélectriques de cette phase.

3. Système ternaire K_2SO_4–H_2SO_4–H_2O–isotherme 75°C

De nombreuses études ont été consacrées à ce système (32–41). Elles sont justifiées par l'interêt qu'il présente dans la fabrication d'engrais. On relève cependant dans tous ces travaux un désaccord sur la stoechiométrie de l'une des phases solides qui se manifeste dans ce système. Nous avons montré dans un travail antérieur (42), par une détermination structurale aux rayons X, effectuée sur des cristaux que nous avons

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

fait croître, que la formule exacte est : $K_2SO_4 \cdot 7KHSO_4 \cdot H_2O$. Notons que l'allure «tournante» de la courbe de solubilité relative à $KHSO_4$ traduit l'existence d'un phénomène de solubilité rétrograde en fonction de la teneur en eau : des mélanges liquides binaires K_2SO_4–H_2SO_4 tels que $75 < Y < 90$ (figure 1) commencent par précipiter $KHSO_4$ par addition d'eau. Des ajouts supplémentaires d'eau permettent d'obtenir de nouveau un mélange liquide. En effet les points représentatifs de ces mélanges traversent successivement un domaine liquide, un domaine biphasé (solide–liquide) et de nouveau un domaine liquide.

La solubilité de K_2SO_4 à 75°C est de 16,90 g de sel pour 100 g de solution saturée.

La structure de $K_2SO_4 \cdot KHSO_4$ à été récemmment publiée (43).

4. Système ternaire K_2SO_4–K_3PO_4–K_2O–isotherme 75°C

Deux phases solides sont observées : K_2SO_4 et $K_3PO_4 \cdot 3H_2O$. La solubilité de $K_3PO_4 \cdot 3H_2O$ à 75°C est 81,15 g de sel pour 100 g de solution saturée. Le domaine de K_2SO_4 englobe la presque totalité du diagramme. Il en résulte que la courbe de solubilité de $K_3PO_4 \cdot 3H_2O$ se réduit pratiquement au point J du système binaire K_3PO_4–H_2O (figure 1). Ce diagramme ne semble pas avoir été étudié précédemment.

5. L'isotherme : H_2SO_4–H_3PO_4–H_2O est constitué d'un seul domaine liquide puisque les acides H_3PO_4 et H_2SO_4 sont eux-même liquides à 75°C.

Reçu le 6 janvier 1992

EWA D. RACZYŃSKA, CHRISTIAN LAURENCE et MICHEL BERTHELOT. Can. J. Chem. **70**, 2203 (1992).

La basicité de liaison hydrogène des formamidines **1–19** a été mesurée à partir de la constante de formation K_{HB} de leurs complexes avec le *p*-fluorophénol et du déplacement de fréquence $\Delta\nu$(OH) des complexes du méthanol. L'étude de la bande ν(C=N) montre que la liaison hydrogène s'effectue sur l'azote imino. Sur l'échelle de basicité de liaison hydrogène les formamidines se placent au même niveau que les imidazoles et au-dessus des amides et des pyridines correspondantes. L'effet de champ de substituants électroattracteurs et l'effet stérique de groupes alkyles volumineux, fixés sur l'azote imino, diminuent sensiblement la basicité de liaison hydrogène de ce dernier.

EWA D. RACZYŃSKA, CHRISTIAN LAURENCE, and MICHEL BERTHELOT. Can J. Chem. **70**, 2203 (1992).

The basicity of the hydrogen bonds of formamidines **1–19** was measured by means of the formation constant K_{HB} of their complexes with *p*-fluorophenol and the frequency shift $\Delta\nu$(OH) of methanol hydrogen-bonded to **1–19**. The study of the ν(C=N) band shows that hydrogen bonding takes place with the imino nitrogen atom. On the hydrogen-bonding basicity scale, the formamidines appear to be more basic than the corresponding amides and pyridines, and as basic as the imidazoles. The field effect of electron-withdrawing substituents and the steric effect of bulky alkyl groups on the imino nitrogen atom markedly decrease the hydrogen-bonding basicity.

Introduction

Les travaux de Taft et coll. (1–3) ont montré l'intérêt de mesurer la basicité de liaison hydrogène des molécules organiques. En effet la basicité de liaison hydrogène se différencie de la basicité de Brønsted en solution aqueuse (4) et en phase gazeuse (5). L'échelle de basicité de liaison hydrogène initialement construite par Taft et coll. (6, 7) a été développée par Abraham *et al.* (8). Elle repose sur la constante de l'équilibre [1] de *partage de proton* entre la base B et un donneur de liaison hydrogène de référence, le *p*-fluorophénol, dans des conditions standard de solvant (CCl_4) et de température (298 K),

[1] $B(CCl_4) + p\text{-}FC_6H_4OH\ (CCl_4) \leftrightarrows p\text{-}FC_6H_4OH \ldots B\ (CCl_4)$

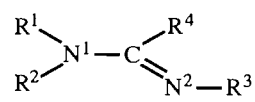
$$K_{HB} = [\text{complexe}]/[B]\ [p\text{-}FC_6H_4OH]$$

de la même manière que la basicité de Brønsted repose sur la constante de l'équilibre [2] de *transfert de proton* en solution aqueuse

[2] $B(aq) + H_2O \leftrightarrows BH^+(aq) + OH^-(aq)$

Pour les molécules neutres, l'échelle $pK_{HB} = \log K_{HB}$ s'étend de −1,1 point «magique» de l'échelle d'Abraham *et al.* (8) à +3,66 pour l'oxyde de triphénylarsine.

La famille très importante des amidines



n'est représentée dans cette échelle que par la tétraméthylguanidine ($R^1 = R^2 = Me$, $R^4 = NMe_2$, $R^3 = H$) dont le pK_{HB} vaut 3,14. Des résultats complémentaires ont par la suite été établis par Vaes *et al.* pour quelques formamidines ($R^4 = H$) (9). Malheureusement ces résultats se rapportent soit à l'éthanol (dans CCl_4, à 298 K) soit à des phénols substitués autres que le *p*-fluorophénol (dans le cyclohexane, à 303 K). Ils ne permettent donc pas de placer directement ces formamidines sur l'échelle de basicité de liaison hydrogène déjà construite. Au contraire les résultats de Raczyńska *et al.* pour d'autres formamidines (10), des acétamidines ($R^4 = Ph$) (11) et des benzamidines ($R^4 = Ph$) (11) permettent d'établir une échelle pK_{HB} d'amidines.

Ces travaux suggèrent, mais n'établissent pas formellement, que le site de fixation de la liaison hydrogène est l'azote imino N^2 plutôt que l'azote amino N^1. De ce point de vue il est important de diversifier les effets stériques et électriques des substituants sur l'azote imino N^2. Puisque les travaux précédents ont été limités aux substituants C_6H_5 (et *o*-, *m*- ou *p*-XC_6H_4), $C_6H_5CH_2$ (et *m*- ou *p*-$XC_6H_4CH_2$), *n*-Pr et i-Bu, nous les étendons maintenant à une nouvelle série de N^1,N^1-diméthylformamidines N^2-substituées **1–19**. Les substituants **1–6** diffèrent principalement par leur effet stérique, les substituants **7–13** par leur effet de champ et les substituants **14–19** par leurs effets de résonance et de champ.

Nous nous proposons de placer ces bases **1–19** sur l'échelle pK_{HB} par la mesure de la constante de l'équilibre [1]. Outre cette échelle thermodynamique, une échelle spectroscopique de basicité de liaison hydrogène (*vide infra*) sera aussi obtenue pour ces composés. Nous pensons de plus mettre en évidence le site de fixation de la liaison hydrogène par l'étude de la vibration de valence ν(C=N). Enfin les corrélations de pK_{HB} avec les paramètres électriques σ_F de Taft et Topsom (12) et stérique υ de Charton (13) doivent permettre de déterminer les effets structuraux majeurs dont dépend la basicité de liaison hydrogène des formamidines substituées sur l'azote imino.

Partie Expérimentale

Produits

La synthèse et la purification des formamidines **1–19** ont déjà été décrites (14). Le tétrachlorure de carbone et le méthanol sont des produits de qualité spectroscopique séchés sur tamis moléculaire respectivement 4 et 3 Å. Le *p*-fluorophénol est purifié par sublimation.

Spectres

Ils sont enregistrés sur un spectromètre IR-TF Bruker IFS 45 WHR à la résolution de 1 cm^{-1} et avec 256 accumulations.

Cellules

Une cellule en quartz de 1 cm et en KBr de 1 mm sont utilisées pour étudier respectivement les régions ν(OH) et ν(C=N). Elles sont thermorégulées à 25°C par effet thermoélectrique.

Constantes d'équilibre

Pour l'équilibre [1] dans CCl_4, C^0_B, la concentration initiale de formamidine et C^0_A, la concentration initiale de *p*-fluorophénol, sont déterminées par pesées. La concentration C_c de complexe à l'équilibre est calculée à partir de l'absorbance de la bande libre ν(OH) du *p*-fluorophénol à 3614 cm^{-1}. La constante K_{HB} de l'équilibre [1] se calcule alors par l'expression : $K_{HB} = C_c/[(C^0_B - C_c)(C^0_A - C_c)]$.

Résultats

pK_{HB}

Le logarithme décimal de la constante de formation (en L mol^{-1}) des complexes du *p*-fluorophénol avec les formamidines **1–19** dans CCl_4 à 298 K est reporté dans le tableau 1. La précision sur les constantes est estimée à ±7% soit une erreur d'environ ±0,03 unité de p*K*.

Δν(OH)

Par complexation, la vibration ν(OH) du *p*-fluorophénol se déplace vers les basses fréquences d'autant plus que les formamidines sont plus basiques. Ce déplacement $\Delta\nu$(OH) = 3614 − ν(OH...) ne peut être mesuré avec précision car la bande ν(OH...) du complexe se recouvre avec le massif ν(CH). C'est pourquoi nous mesurons le déplacement $\Delta\nu$(OH) = 3644 − ν(OH...) de la vibration ν(OH) du méthanol, pour lequel ce recouvrement ne se produit pas car c'est un donneur de liaison hydrogène moins fort que le *p*-fluorophénol. Ces déplacements, donnés dans le tableau 1, constituent une échelle spectroscopique de basicité de liaison hydrogène des formamidines **1–19**.

Cette échelle spectroscopique $\Delta\nu$(OH) est cohérente avec l'échelle thermodynamique pK_{HB}, et valide donc les délicates mesures de constantes d'équilibre, à condition de prendre en compte les caractères spécifiques de chaque échelle. Ainsi une très bonne corrélation est observée sur la figure 1 entre pK_{HB} et $\Delta\nu$(OH) à condition de séparer le sous-ensemble des N^2-phénylformamidines **15–19** de celui des N^2-alkylformamidines **1–13** et, dans ce dernier sous-ensemble, d'éliminer de la corrélation les substituants les plus encombrants (*t*-Pen et 1-Adam). L'origine de ces spécificités, déjà envisagée dans un travail antérieur (10), sera étudiée ultérieurement lors d'une comparaison pK_{HB}/$\Delta\nu$(OH) pour un large ensemble de bases azotées.

Pour les formamidines **8** (R = CH_2CH_2OMe) et **10** (R = $CH_2CH_2C{\equiv}N$) on observe (figure 2) deux bandes de complexe ν(OH...). Pour la formamidine **14** (R = NMe_2) on observe une bande ν(OH...) de complexe anormalement large: la largeur de bande à mi-hauteur vaut 295 cm^{-1} alors qu'elle est comprise entre 200 et 220 cm^{-1} pour les autres formamidines de ce travail.

Fréquence ν(C=N)

La bande très intense (coefficient d'extinction molaire voisin de 1680 L mol^{-1} cm^{-1} pour le composé **4**) ν(C=N) des formamidines **1–19** en solution dans CCl_4 se situe entre 1629 cm^{-1} (**14**, NMe_2) et 1661 cm^{-1} (**1**, Me). La figure 3 montre que par addition de *p*-fluorophénol à une solution tétrachlorocarbonique de formamidine, cette bande diminue d'intensité, et qu'il apparaît une nouvelle bande plus large aux fréquences plus basses. L'abaissement du nombre d'onde varie selon les formamidines de 6 à 10 cm^{-1}. Seule la formamidine **14** (NMe_2) fait exception à ce comportement.

Discussion

Site de fixation de la liaison hydrogène

Les concentrations très diluées de *p*-fluorophénol (~3 × 10^{-3} M) et de formamidines (de 5 × 10^{-4} M à 10^{-2} M) utilisées dans ce travail impliquent la formation exclusive de complexe(s) 1 : 1. Par ailleurs la présence d'une seule bande ν(OH...) de complexe (à l'exception des formamidines **8** et **10**, *vide infra*) implique la formation d'un seul complexe 1 : 1. La question se pose de déterminer si le site de fixation de la liaison hydrogène est l'azote amino ou l'azote imino. Des études antérieures (9, 10) ont suggéré qu'il s'agissait du site imino.

L'étude de la région ν(C=N) confirme cette attribution. La nouvelle bande observée (*vide supra*) dans la région ν(C=N) ne peut être attribuée qu'à la vibration ν(C=N) du complexe, puisqu'elle se forme au détriment de la bande ν(C=N) de la formamidine libre, et que son intensité augmente quand on déplace l'équilibre [1] par addition croissante de *p*-fluorophénol. De plus la liaison hydrogène ne peut se former que sur l'azote imino N^2 car la bande ν(C=N) des formamidines complexées est plus basse que celle des for-

[b]$pK_{HB} = \log K_{HB}$, avec K_{HB} en L mol^{-1}.
[c]Valeurs tirées de la référence 10.
[d]Une deuxième bande associée est observée avec un déplacement de 159 cm^{-1}.
[e]Correspond à la constante totale; pour le seul site imino pK_{HB} = 2,74.
[f]Impossible à mesurer à cause de l'absorption $\nu(\equiv CH)$.
[g]Une deuxième bande associée est observée avec un déplacement de 86 cm^{-1}.
[h]Correspond à la constante totale; pour le seul site imino pK_{HB} = 2,12.
[i]Imprécis à cause de la trop faible solubilité dans CCl_4.

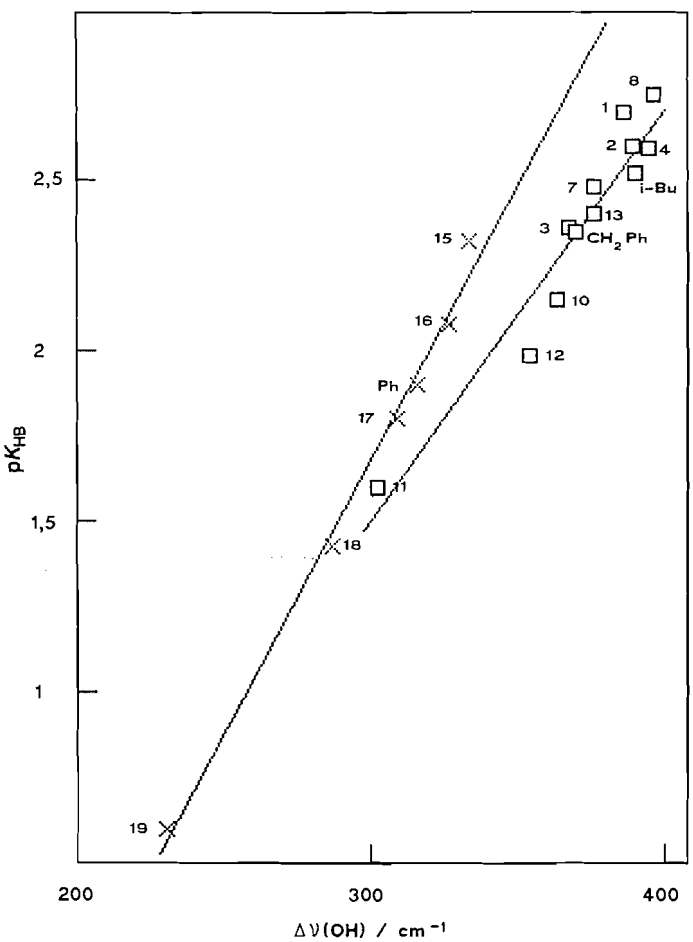

FIG. 1. Corrélation entre échelle thermodynamique (pK_{HB}) et échelle spectroscopique ($\Delta\nu$ OH). Les N^2-phénylformamidines (X) se différencient des N^2-alkylformamidines (□).

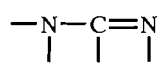
mamidines libres. En effet une fixation sur l'azote amino aurait pour effet de diminuer la conjugaison $n-\pi$ des amidines (15) et donc d'augmenter l'indice de liaison C=N et la constante de force et donc la fréquence de vibration.

Le comportement du motif



des complexes amidines-phénols est donc identique à celui du motif

des complexes amides-phénols dans lesquels la bande ν(C=O) est élargie et abaissée (de 17 cm^{-1} pour le complexe phénol–diméthylformamide) par raport à l'amide libre, ce qui démontre que la liaison hydrogène se forme sur l'oxygène et non sur l'azote (16, 17).

Pour les composés **8** $Me_2N\text{-}CH{=}N\text{-}CH_2CH_2OMe$ et **10** $Me_2N\text{-}CH{=}N\text{-}CH_2CH_2C{\equiv}N$ qui contiennent un site O et $C{\equiv}N$ accepteur de liaison hydrogène, la deuxième bande ν(OH...) observée (figure 2) respectivement à 3485 et 3565 cm^{-1} est proche de celle des complexes méthanol $\text{-}Et_2O$ à 3494 et méthanol -EtC≡N à 3565 cm^{-1} et est donc attribuée respectivement à ν(OH... O) et ν(OH... N≡C). Des constantes (en L mol^{-1}) totales K = 562 pour **8** et K = 141 pour **10** il convient donc de soustraire respectivement les valeurs 10 du complexe *p*-fluorophénol–Et_2O (6) et 8 du complexe *p*-fluorophénol–EtC≡N pour obtenir la contribution propre de basicité de liaison hydrogène de l'azote imino, soit pK_{HB} (imino) = 2,12 au lieu de pK_{HB} (total) = 2,15 pour **10** et 2,74 au lieu de 2,75 pour **8**.

Pour le composé **14** $Me_2N^1\text{-}CH{=}N^2\text{-}N^3Me_2$, on observe une bande ν(OH...) unique et grossièrement symétrique, mais cela ne constitue pas la preuve d'un site unique de fixation, car cette bande est anormalement large et pourrait donc correspondre à la superposition de plusieurs bandes, par exemple ν(OH... N^2) et ν(OH... N^3).

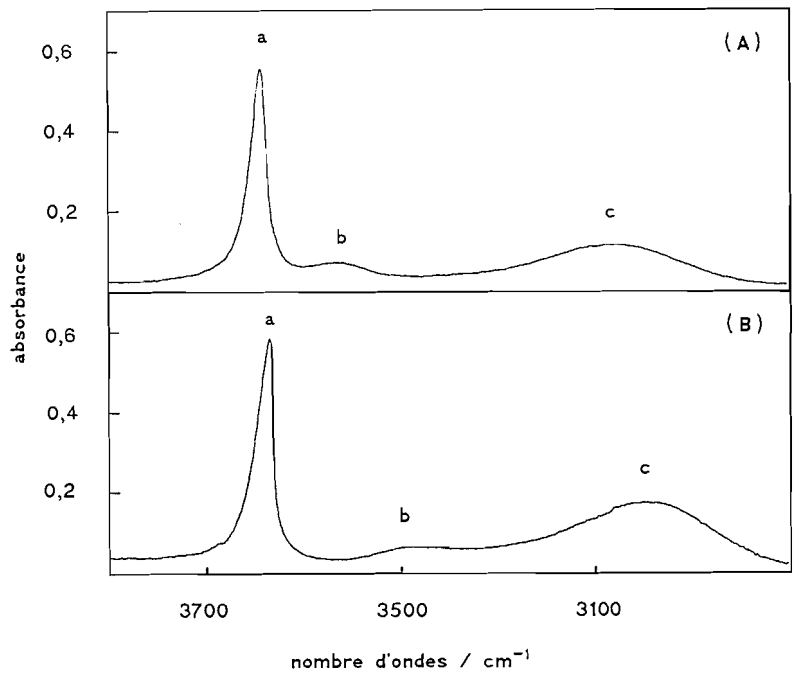

FIG. 2. Spectres IR d'une solution tétrachlorocarbonique de méthanol après addition de la formamidine **10** (*A*) et de la formamidine **8** (*B*). On observe dans chaque cas trois bandes ν(OH) : (a) celle du méthanol libre à 3644 cm^{-1}; (b) celle du complexe OH · · · N≡C (A) ou OH · · · OMe(B); (c) celle du complexe OH · · · N^2.

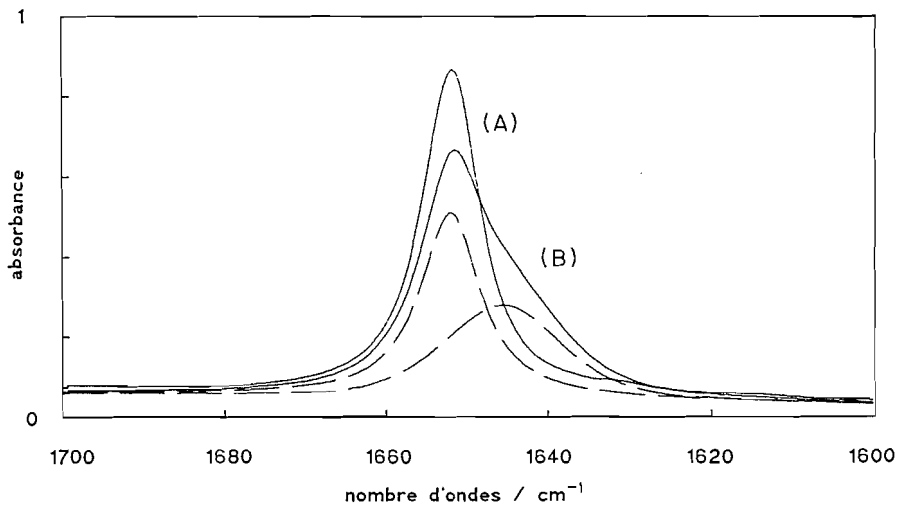

FIG. 3. (*A*) Spectre IR d'une solution tétrachlorocarbonique 5×10^{-3} M de N^1,N^1-diméthyl-N^2-cyclohexylformamidine, (*B*) Même spectre après addition de 4×10^{-3} M de *p*-fluorophénol. La décomposition de ce massif en ses bandes composantes met en évidence la bande ν(C=N) de la formamidine libre à 1653 cm^{-1} et la bande ν(C=N) élargie du complexe formamidine–*p*-fluorophénol à 1646 cm^{-1}.

Position des formamidines dans l'échelle de basicité de liaison hydrogène

Le tableau 2 compare les valeurs de pK_{HB} de la triméthylformamidine **1** et d'autres bases oxygénées et azotées. On observe que la formamidine est plus basique que l'amide et la pyridine correspondante et aussi plus basique que les amines. Elle a la même basicité que le *N*-méthylimidazole alors que dans ce dernier les azotes amino et imino sont substitués par des carbones sp^2 plus électronégatifs que les carbones sp^3 de la triméthylformamidine. L'handicap provoqué par les substituants électronégatifs sur le motif amidine du *N*-méthylimidazole est en fait compensé par la configuration *Z* de ce dernier. Au contraire la triméthylformamidine **1** a la configuration *E*, comme toutes les N^1,N^1-diméthylformamidines (18), et la paire libre de l'azote imino, tournée vers le substituant encombrant Me_2N, est moins accessible au *p*-fluorophénol.

Influence de l'effet de champ des substituants sur l'azote imino

Un effet de champ électroattracteur des substituants sur N^2 diminue la basicité de liaison hydrogène comme l'illustre le substituant CH_2CF_3 (pK_{HB} = 1,60 au lieu de 2,70 pour Me). Si on mesure cet effet de champ par le paramètre σ_F de Taft (12), on obtient la relation approchée [2] pour les substi-

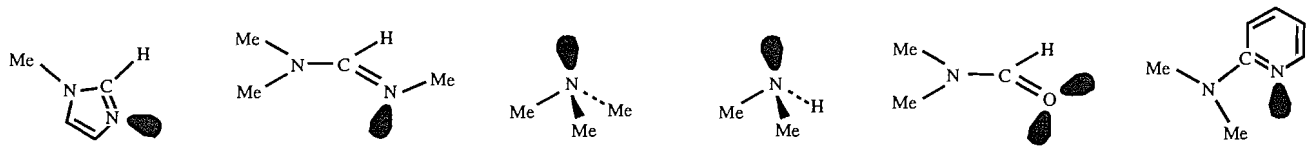
TABLEAU 2. Comparaison des valeurs pK_{HB} de quelques bases de liaison hydrogène



2,71	2,70	2,27	2,15	2,10	1,61

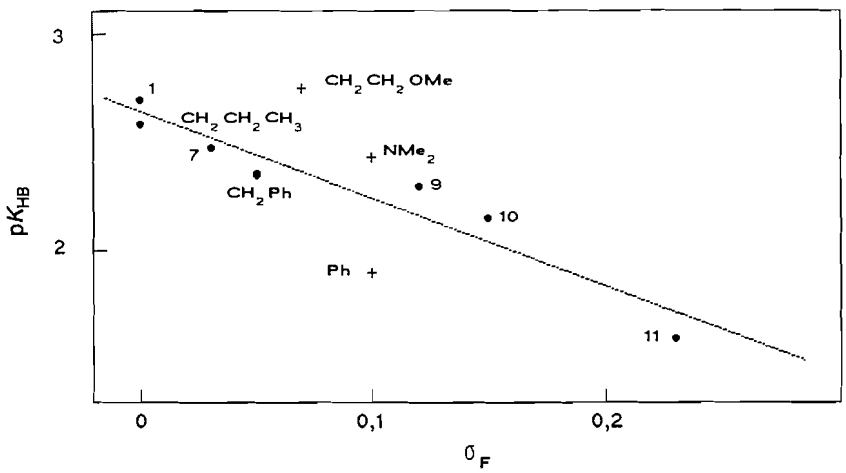


FIG. 4. Corrélation entre le pK_{HB} des composés $Me_2NCH{=}N\text{-}R$ et la constante de substituant σ_F mesurant l'effet de champ du substituant R. Les substituants CH_2CH_2OMe, Ph et NMe_2 n'ont pas été utilisés pour calculer l'équation de la droite de régression.

tuants Me et *n*-Pr ($\sigma_F = 0$), $CH_2CH{=}CH_2$ (0,03), CH_2Ph (0,05), $CH_2C{\equiv}CH$ (0,12), $CH_2CH_2C{\equiv}N$ (0,15) et CH_2CF_3 (0,23) (fig. 4).

[3] $pK_{HB} = -4{,}06\sigma_F + 2{,}64$

(coefficient de corrélation $r = 0{,}965$;
écart-type = 0,11; nombre de points $n = 7$)

La relation [3] permet d'estimer la basicité de liaison hydrogène de l'azote imino de composés particuliers comme $Me_2N\text{-}CH{=}N\text{-}C{\equiv}N$ ou $Me_2N\text{-}CH{=}N\text{-}SO_2Ph$. Si on suppose que les substituants $C{\equiv}N$ ($\sigma_F = 0{,}60$) et SO_2Ph ($\sigma_F = 0{,}63$) agissent uniquement par effet de champ, on calcule respectivement $K_{HB} = 1{,}6$ et 1,2 L mol^{-1} pour les composés correspondants, ce qui représente respectivement 1,3% et 1,6% des constantes totales mesurées pour ces composés dans un travail antérieur (19), soit déjà une contribution négligeable. Cette contribution s'approche de zéro si l'on tient compte de l'effet de résonance électroattracteur de $C{\equiv}N$ ($\sigma^-_R = 0{,}10$) et de SO_2Ph ($\sigma^-_R = 0{,}14$). La relation [3] confirme donc que le site unique de fixation de liaison hydrogène de ces systèmes «push–pull» est l'azote du groupe nitrile ou les oxygènes du groupe sulfonyle.

La figure 4 montre que les substituants NMe_2, Ph et CH_2CH_2OMe n'obéissent pas à la relation [3]. La déviation du substituant Ph peut s'expliquer par son effet de résonance qui n'est pas pris en compte par σ_F. Celle du substituant NMe_2 peut s'expliquer par son effet de résonance et (ou) la possibilité déjà envisagée qu'il constitue un deuxiéme site de fixation de la liaison hydrogène. Celle du substituant CH_2CH_2OMe, pour lequel la correction du deuxième site de fixation de la liaison hydrogène a été effectuée (*vide supra*), reste pour l'instant inexpliquée.

Influence de l'effet stérique des substituants alkyles sur l'azote imino

L'effet stérique des substituant alkyles sur N^2 diminue la basicité de liaison hydrogène comme l'illustre le substituant tert-pentyl ($pK_{HB} = 2{,}26$ au lieu de 2,70 pour Me). Si on mesure cet effet stérique par le paramètre υ de Charton (13), on obtient la relation [4] pour les substituants Me($\upsilon = 0{,}52$), *n*-Pr(0,68), i-Pr(0,76), c-Hex(0,87), i-Bu(0,98), 1-Adam-(1,33) et *t*-Pen(1,63).

[4] $pK_{HB} = -0{,}33\,\upsilon + 2{,}86$

$r = 0{,}925$, $s = 0{,}06$, $n = 7$

Le comportement des substituants alkyles volumineux R est donc tout à fait différent dans les formamidines $Me_2N\text{-}CH{=}N\text{-}R$ où ils diminuent la basicité de celui dans les alcools R-OH (20) où ils augmentent la basicité de liaison hydrogène (par un mécanisme à préciser : polarisabilité, hyperconjugaison et (ou) électronégativité).

Calculated electrostatic potentials and local surface ionization energies of *para*-substituted anilines as measures of substituent effects

MARKUS HAEBERLEIN, JANE S. MURRAY, TORE BRINCK, AND PETER POLITZER[1]
Department of Chemistry, University of New Orleans, New Orleans, LA 70148, U.S.A.

Received February 29, 1992

MARKUS HAEBERLEIN, JANE S. MURRAY, TORE BRINCK, and PETER POLITZER. Can. J. Chem. **70**, 2209 (1992).

Using an *ab initio* self-consistent-field molecular orbital approach, we computed 3-21G//STO-3G* and STO-5G//STO-3G* electrostatic potentials and average local ionization energies for 17 *para*-substituted anilines. Our results demonstrate that the most negative potentials (V_{min}) and the local surface ionization energy minima ($\bar{I}_{S,min}$) associated with the amine nitrogen lone pairs are highly sensitive indicators of the electron-donating and electron-attracting tendencies of the *para* substituents. We find excellent linear relationships between the 3-21G//STO-3G* amine nitrogen V_{min} and $\bar{I}_{S,min}$ and the σ_p^0 Hammett constants of the substituent X; the correlation coefficients are 0.99. Correlations of slightly lesser quality are shown to exist between V_{min}, $\bar{I}_{S,min}$, and σ_p^-, σ_p, and pK_a. Estimates of previously unknown σ_p^0 and pK_a values are given. The presence of ring carbon $\bar{I}_{S,min}$ *meta* to the substituent X also provides a predictive capability for determining σ_m values.

MARKUS HAEBERLEIN, JANE S. MURRAY, TORE BRINCK et PETER POLITZER. Can. J. Chem. **70**, 2209 (1992).

Utilisant une approche de calculs *ab initio* d'orbitales moléculaires en champ auto-cohérent, on a calculé les potentiels électrostatiques ainsi que les énergies moyennes d'ionisation locale de 17 anilines *para*-substituées, aux niveaux 3-21G//STO-3G* et STO-5G//STO-3G*. Nos résultats démontrent que les potentiels les plus négatifs (V_{min}) et les minima de l'énergie d'ionisation de la surface locale ($\bar{I}_{S,min}$) associés avec les paires libres de l'azote de l'amine sont des indicateurs sensibles des tendances des substituants *para* à agir comme électro-donneurs ou électro-accepteurs. On a obtenu une excellente relation linéaire entre les valeurs de V_{min} et $\bar{I}_{S,min}$ de l'azote de l'amine au niveau 3-21G//STO-3G* et les constantes σ_p^0 de Hammett du substituant X; les coefficients de corrélation sont égaux à 0,99. On rapporte des évaluations des valeurs de σ_p^0 et de pK_a qui étaient jusqu'à présent inconnues. La présence de $\bar{I}_{S,min}$ pour le carbone du cycle en *méta* du substituant X fournit aussi une possibilité de prédire les valeurs de σ_m.

[Traduit par la rédaction]

Background

A continuing focus of our computational studies is the interpretation and prediction of chemical reactive behavior (1–7). We recently demonstrated that good correlations exist between two calculated gaseous phase properties (the electrostatic potential $V(\boldsymbol{r})$ and the average local ionization energy $\bar{I}(\boldsymbol{r})$) and several experimentally based indices of reactivity derived from solution studies (5–14), including the Hammett and Taft substituent constants. These are well-established measures of the electron-donating and -attracting tendencies of substituent groups (15–19).[2] The properties $V(\boldsymbol{r})$ and $\bar{I}(\boldsymbol{r})$ are discussed briefly below as background to the present work.

The electrostatic potential $V(\boldsymbol{r})$ has emerged as an effective tool for studying the reactive behavior of molecules in both electrophilic and nucleophilic processes, and also in molecular recognition interactions (1–4, 6, 24, 25). $V(\boldsymbol{r})$ is a real physical property that expresses the net electrical effect of the nuclei and electrons of a molecule, at any point $\boldsymbol{r}$, and is given rigorously by eq. [1].

$$[1] \quad V(\boldsymbol{r}) = \sum_A \frac{Z_A}{|\boldsymbol{R}_A - \boldsymbol{r}|} - \int \frac{\rho(\boldsymbol{r}')d\boldsymbol{r}'}{|\boldsymbol{r}' - \boldsymbol{r}|}$$

Z_A is the charge on nucleus A, located at $\boldsymbol{R}_A$, and $\rho(\boldsymbol{r})$ is the electronic density function of the molecule. The sign of $V(\boldsymbol{r})$ in any particular region depends upon whether the effects of the nuclei or electrons are dominant there. Sites reactive toward electrophiles can be identified and ranked by means of the local minima (most negative values) of $V(\boldsymbol{r})$ (1–4, 6, 10, 13, 14, 24, 25) while the maxima of $V(\boldsymbol{r})$ on the molecular surface serve the same purpose for nucleophilic attack (6, 12–14).

We recently introduced another property, the average local ionization energy $\bar{I}(\boldsymbol{r})$ (5), which is defined by eq. [2].

$$[2] \quad \bar{I}(\boldsymbol{r}) = \sum_i \frac{\rho_i(\boldsymbol{r})\,|\varepsilon_i|}{\rho(\boldsymbol{r})}$$

$\rho(\boldsymbol{r})$ is the electronic density of the ith molecular orbital at the point $\boldsymbol{r}$ and ε_i is the orbital energy. We interpret $\bar{I}(\boldsymbol{r})$ as the average energy required to remove an electron from any point $\boldsymbol{r}$ in the space of an atom or molecule. In a series of studies, we have demonstrated that $\bar{I}(\boldsymbol{r})$ plotted on molecular surfaces is an effective indicator of reactivity toward electrophiles, even in aqueous solution (5, 7, 9, 11). For example, we have shown for a series of monosubstituted benzenes that surface $\bar{I}(\boldsymbol{r})$ minima ($\bar{I}_{S,min}$) provide a quantitative measure of the activating/deactivating and the directing tendencies of the various substituents, and also correlate well with the Hammett constants σ_p and (or) σ_m (5, 7). For several families of acids, we found that the calculated $\bar{I}_{S,min}$ of the conjugate bases correlate well with the respective pK_a values, which can be viewed as reflecting reactivity toward the electrophile H^+ (9, 11).

Present objectives

In an earlier study involving a group of 24 NH_2-X molecules, we demonstrated a good correlation between the electrostatic potential minimum (V_{min}) of the amine nitrogen and the total electron-attracting tendency of X, as measured by the σ_I and σ_R substituent constants (8). More recently, we showed that the nitrogen $\bar{I}_{S,min}$ can also be used for this pur-

pose (13). However, while the NH_2-X framework is effective for studying the electron-attracting power of X, it does not provide an opportunity to assess any tendency for resonance donation of charge by the substituent (8, 13).

For this reason, we have now investigated the use of a different framework, *para*-substituted aniline (**1**), as a tool for studying substituent effects. It was anticipated that this system might allow some degree of resonance donation of

charge by X, which would be reflected in the V_{min} and $\bar{I}_{S,min}$ of the amine group, due to the contribution of structure **1***a*.

We have accordingly computed these properties for a series of 17 *para*-substituted anilines.

Methods and procedure

We have used an *ab initio* self-consistent-field molecular orbital (SCF-MO) procedure (GAUSSIAN 88 (26)) to compute optimized geometries for 17 *para*-substituted aniline derivatives. Due to the sizes of the molecules, the STO-3G* basis set was selected for this purpose. While it is known to exaggerate the pyramidal character of amine nitrogens, past experience suggests that the structures should be generally satisfactory (27). For example, our calculated STO-3G* geometry for aniline is in reasonable agreement with gas phase experimental data (28). The largest discrepancy in bond lengths is in the C—N distance, which we overestimate by 0.042 Å; however, the errors for the other bonds are 0.008 Å (average) for the C—C, 0.028 Å for the N—H, and essentially zero for the C—H. (The STO-3G* basis is identical to the STO-3G for atoms H–Ne; for Na–Xe, the STO-3G* includes a set of polarization functions (27).)

TABLE 2. Correlations between some calculated and experimentally derived properties

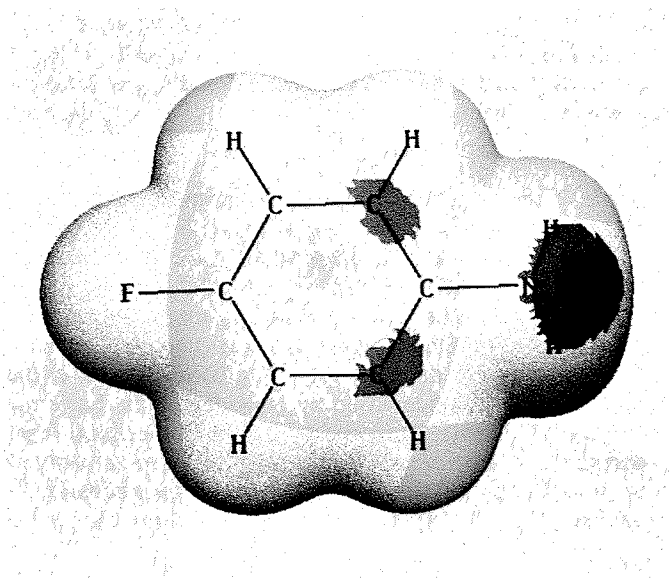

FIG. 1. Calculated $\bar{I}(r)$ on the molecular surface of *para*-fluoroaniline. Three ranges of $\bar{I}(r)$ are depicted, in eV. Black: $\bar{I}(r) < 12.52$; gray: $12.52 < \bar{I}(r) < 13.47$; white: $\bar{I}(r) > 13.47$.

As anticipated, the STO-3G* basis set consistently yields a pyramidal amine group for these aniline derivatives; the variation in the H—N—H angle is only over the range 107°–109°. For comparison, the experimentally determined value for aniline is 113 ± 2° (28). From the standpoint of this study, in which we plan to use the amine V_{min} as a probe, the near constancy of the H—N—H angle is useful, because it means that changes in the magnitude of V_{min} can be attributed to electronic factors rather than structural ones; we showed earlier that amine V_{min}'s are strongly dependent upon the H—N—H angle (6, 8, 29).

Using these structures, we computed $V(r)$ (via eq. [1], using GAUSSIAN 88) and surface $\bar{I}(r)$ (via eq. [2]). The molecular surfaces were defined, following the approach of Bader *et al.* (30), by the 0.002 electrons/bohr^3 contour of the electronic density. The calculations were carried out at

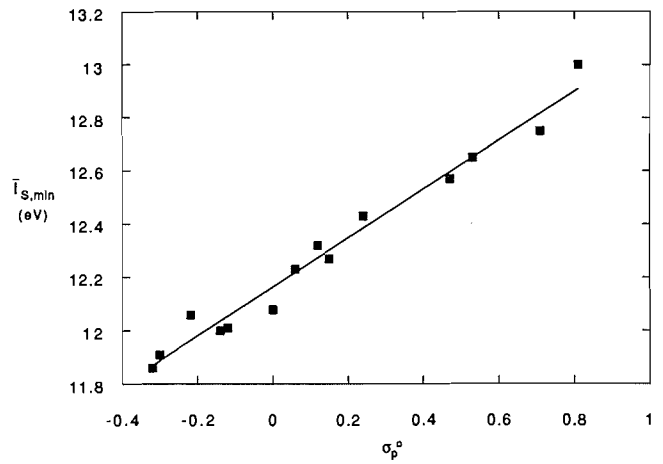

FIG. 2. Correlation between 3–21G//STO-3G* amine nitrogen $\bar{I}_{S,min}$ and σ_p^0 for 15 *para*-substituted anilines. The correlation coefficient is 0.99.

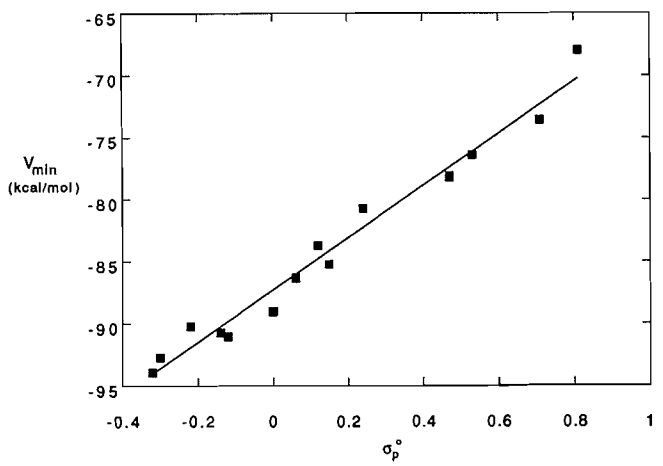

FIG. 3. Correlation between 3–21G//STO-3G* amine nitrogen V_{min} and σ_p^0 for 15 *para*-substituted anilines. The correlation coefficient is 0.99.

both the HF/STO-5G and HF/3-21G levels. We found these basis sets to be satisfactory for $V(\boldsymbol{r})$ and $\bar{I}(\boldsymbol{r})$ (1, 3, 4, 6–10, 12–14).

Results

The electrostatic potential of aniline, presented earlier (31), is positive everywhere in the plane of the ring, with large negative regions above and below this plane that are attributed to the π electrons. The most negative V_{min} is found in the lone pair region of the nitrogen, and is indicative of the basic nature of aniline. This nitrogen is indeed a highly favorable site for protonation (32, 33). The surface $\bar{I}(\boldsymbol{r})$ of aniline is characterized by $\bar{I}_{S,min}$ found in the vicinity of the amine nitrogen and above the *ortho* and *para* carbon positions (5), consistent with these all being favorable sites for electrophilic attack (33, 34).

The calculated amine nitrogen V_{min} and $\bar{I}_{S,min}$ of the 17 *para*-substituted anilines **1** are listed in Table 1, along with the Hammett constants σ_p, σ_p^0, and σ_p^- of the substituents X and the experimentally determined pK_a values of some of these molecules. Positive values of σ_p, σ_p^0, and σ_p^- are interpreted as indicating the degree of electron attraction by a *para* substituent, while negative values measure electron donation. The general trend in Table 1 is that the V_{min} become less negative and the $\bar{I}_{S,min}$ higher as the Hammett constants increase and pK_a decreases. Molecules for which the overall effect of X is electron attraction (σ_p, σ_p^0, $\sigma_p^- > 0$) have V_{min} less negative and $\bar{I}_{S,min}$ higher than those of aniline (X = H), while molecules with electron-donor substituents (σ_p, σ_p^0, $\sigma_p^- < 0$) show V_{min} more negative and $\bar{I}_{S,min}$ lower than aniline. Thus, we find that the computed V_{min} and $\bar{I}_{S,min}$ of the amine nitrogen in the *para*-H_2N-C_6H_4-X framework can indeed reflect either overall electron-donating or electron-attracting tendencies of *para* substituents on aromatic rings.

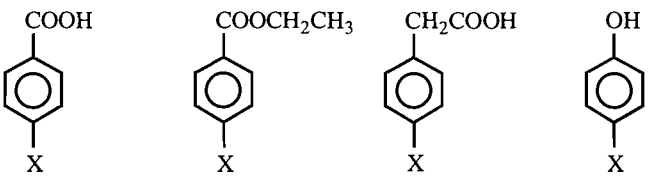
The sensitivities of the amine nitrogen V_{min} and $\bar{I}_{S,min}$ to substituent effects are confirmed by Table 2, which summarizes the correlations with σ_p, σ_p^0, σ_p^-, and pK_a. These relationships will be discussed in detail in the next section.

An interesting feature of the surface $\bar{I}(\boldsymbol{r})$ of the *para*-substituted anilines is that $\bar{I}_{S,min}$ are found above the ring carbons that are *meta* to the substituent X, even if X is an *ortho*/*para* director. For example, the surface $\bar{I}(\boldsymbol{r})$ of *para*-fluoroaniline (Fig. 1) shows $\bar{I}_{S,min}$ above the positions *meta* to the fluorine in addition to the one associated with the amine nitrogen. This presumably reflects the strong *ortho*/*para* directing tendencies of the NH_2 group. (For substituents that are strong resonance donors, there are also $\bar{I}_{S,min}$ *ortho* to X.) The 3-21G $\bar{I}_{S,min}$ values of the *meta* carbons (relative to X) are listed in Table 3 along with the σ_m values of X. There is a linear relationship between these $\bar{I}_{S,min}$ and σ_m, with a correlation coefficient of 0.97 (see Table 2).

Discussion

Table 2 shows that the best correlations with Hammett constants for both $\bar{I}_{S,min}$ and V_{min} are with σ_p^0 at the 3-21G level (correlation coefficients = 0.99; see Figs. 2 and 3), followed by those with σ_p^- and σ_p, also 3-21G. The trends in the STO-5G results follow the same pattern but the relationships are not quite as closely obeyed.

The superiority of the $\sigma_p^0 - \bar{I}_{S,min}$, V_{min} correlations over the σ_p and σ_p^- can be understood by considering the basis for each set of constants. The original σ_p's were obtained from experimental data for the ionizations of *para*-substituted benzoic acids (**2**) and rates of hydrolysis of *para*-substituted benzoates, e.g., **3** (15). However, as seen in Fig. 4*a*, these



systems allow significant "through-resonance" that affects σ_p for resonance donors such as NH_2, OH, and OCH_3, but not for attractors such as CHO, CN, and NO_2 (17). Thus σ_p for a donor substituent is meaningful for systems in which such through-resonance is possible, but it is less applicable when this opportunity is not present.

To develop a set of constants appropriate for systems in which no through-resonance can occur, the effects of substituents X upon the ionization of **4** were determined and used to establish the σ_p^0 scale (17, 18). The absence of through-

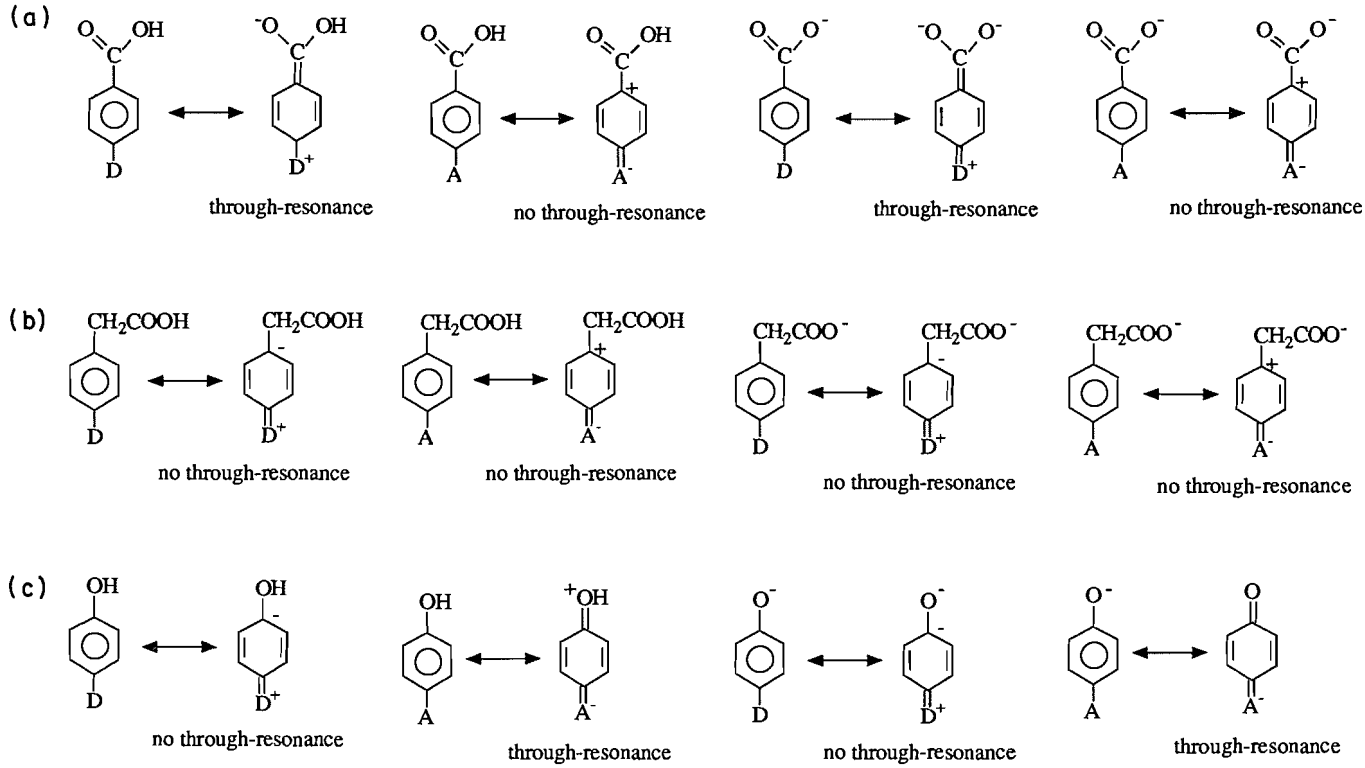

FIG. 4. Resonance structures relevant to Hammett constants σ_p, σ_p^0, and σ_p^-. Both the neutral and the ionized forms of each molecule are included. D and A refer to resonance-donor and -acceptor substituents, respectively.

resonance in this framework can be seen in Fig. 4*b*. The σ_p^0 constants of resonance donors such as NH_2, OH, and OCH_3 are also applicable to reactions, such as the ionization of phenol, which are not expected to be affected by through-resonance with donors (17). (See, e.g., Fig. 4*c*.)

The σ_p^- constants are designed for systems in which substituents that are electron attractors by resonance (e.g., CHO, CN, and NO_2) have the opportunity to participate in through-resonance. The ionizations of *para*-substituted phenols (**5**) (Fig. 4*c*) and anilines (**1**) were used to obtain the σ_p^- values (17). In systems such as these, through-resonance does not occur to any significant degree for donors.

On the basis of the preceding discussion, it can be anticipated that σ_p^0 and σ_p^- should be very similar for resonance donor substituents, while σ_p is more negative. For resonance-attracting groups, on the other hand, σ_p and σ_p^0 should be similar, and σ_p^- more positive. All of these expectations are borne out by the data in Table 1.

Since our analyses use the calculated $\bar{I}_{S,min}$ and V_{min} of the amine nitrogens of *para*-substituted anilines as probes of substituent effects, it would seem that the most successful correlations should be with σ_p^-, however, they are actually found to be with σ_p^0. We believe that this is because the STO-3G basis set, used to optimize geometries, is unable to fully account for the through-resonance interactions with the amine group. This interpretation is consistent with the known limitations of this basis set in describing conjugation (27), which is reflected in the overestimated C—NH_2 bond length in aniline, mentioned earlier.

Our results clearly provide a predictive capability for obtaining σ_p^0 values for substituents for which these are not known, and these should in turn be good estimates of σ_p for resonance attractors and of σ_p^- for resonance donors. Our predicted σ_p^0 for NF_2 and $N(NO_2)_2$ are given in Table 1. It is gratifying that the $\bar{I}_{S,min}$ and V_{min} correlations yield values that are in such close agreement, since the two properties are quite different. It is also pleasing that these σ_p^0 are very similar to estimates of σ_p obtained earlier from an $\bar{I}_{S,min}$ relationship for monosubstituted benzenes (5, 35).

Proceeding to the correlations of $\bar{I}_{S,min}$ and V_{min} with pK_a (Table 2), we again find our 3-21G results to be successful (correlation coefficients of 0.97 and 0.98). (It is noteworthy that the 3-21G $\bar{I}_{S,min}$ and pK_a values fit well into a relationship between these quantities that we recently found for a group of azines and azoles (9); the overall correlation coefficient is 0.95.) Table 1 includes some predicted pK_a values, calculated using the 3-21G equations in Table 2. The results obtained from $\bar{I}_{S,min}$ and V_{min} are again remarkably similar.

The relationship between *meta* carbon $\bar{I}_{S,min}$ and σ_m (Table 2) allows us to estimate the σ_m values for NF_2 and $N(NO_2)_2$ to be 0.54 and 0.87, respectively (Table 3). These are in excellent agreement with earlier predictions (5, 35).

Summary

We have shown that the calculated $\bar{I}_{S,min}$ and V_{min} of the amine nitrogen lone pair regions in *para*-substituted anilines reflect the general electron-donating and electron-attracting tendencies of substituents on aromatic rings. Our 3-21G//STO-3G* amine nitrogen $\bar{I}_{S,min}$ and V_{min} are found to be highly sensitive indicators of substituents effects described by the Hammett constant σ_p^0 and also of pK_a. The very good agreement that is found between predicted σ_p^0 and pK_a obtained from $\bar{I}_{S,min}$ and those based on V_{min} is particu-

For personal use only.

larly significant because the latter two properties are so different in nature. The presence of ring carbon $\bar{I}_{S,min}$ *meta* to the substituent X in the *para*-substituted anilines provides a means of estimating σ_m constants.

Crystal and molecular structures of two triosmium carbonyl cluster complexes containing *ortho*-metalated phenylphosphines (μ-H)$Os_3(CO)_8L[PFcPh(C_6H_4)]$ (L = $PFcPh_2$ or CO)

WILLIAM R. CULLEN,[1] STEVEN J. RETTIG, AND TU CAI ZHENG
Chemistry Department, University of British Columbia, Vancouver, B. C., Canada V6T 1Z1

Received March 5, 1992

WILLIAM R. CULLEN, STEVEN J. RETTIG, and TU CAI ZHENG. Can. J. Chem. **70**, 2215 (1992).

Pyrolysis of $Os_3(CO)_{11}(PFcPh_2)$, **7**, and $Os_3(CO)_{10}(PFcPh_2)_2$, **8**, (FcH = $(Fe(\eta\text{-}C_5H_5)_2$ affords (μ-H)$Os_3(CO)_9$-[$PFcPh(C_6H_4)$], **5**, and (μ-H)$Os_3(CO)_8(FcPPh_2)$[$PFcPh(C_6H_4)$], **6**, respectively. The structures of **5** and **6** are analogous; they both contain a bridging hydride and a μ_3-$PFcPh(C_6H_4)$ moiety resulting from the *ortho*-metalation of one phenyl group and subsequent formation of a η^2-bond from that metalated phenyl to the third osmium atom. Crystals of **5**, are triclinic, a = 11.380(2), b = 15.930(3), c = 9.467(1) Å, α = 92.82(1)°, β = 100.32(1)°, γ = 71.55(1)°, Z = 2, space group $P\bar{1}$, and those of **6** · CH_2Cl_2, are also triclinic, a = 13.151(3), b = 17.177(4), c = 12.619(3) Å, α = 91.98(2)°, β = 104.18(2)°, γ = 67.72(2)°, Z = 2, space group $P\bar{1}$. The structures were solved by heavy atom methods and were refined by full-matrix least-squares procedures to R = 0.028 and 0.026 by using 8080 and 9336 reflections with $I \geq 3\sigma(I)$, respectively.

WILLIAM R. CULLEN, STEVEN J. RETTIG et TU CAI ZHENG. Can. J. Chem. **70**, 2215 (1992).

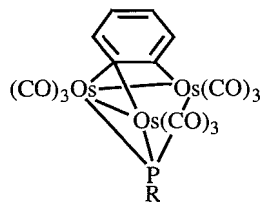
La pyrolyse du $Os_3(CO)_{11}(PFcPh_2)$, **7**, et du $Os_3(CO)_{10}(PFcPh_2)_2$, **8**, fournit respectivement le (μ-H)$Os_3(CO)_9$-[$PFcPh(C_6H_4)$], **5** et (μ-H)$Os_3(CO)_8(FcPPh_2)$[$PFcPh(C_6H_4)$], **6**. Les structures des composés **5** et **6** sont analogues; elles contiennent toutes les deux un pont hydrure et une portion μ_3-$PFcPh(C_6H_4)$ qui résulte de l'*ortho*-métallation d'une groupe phényle et de la formation subséquente d'une liaison η^2 reliant le phényle métallé au troisième atome d'osmium. Les cristaux du composé **5** sont tricliniques, groupe d'espace $P\bar{1}$ avec a = 11,380(2), b = 15,930(3) et c = 9,467(1) Å, α = 98,82(1)°, β = 100,32(1)° et γ = 71,55(1)° et Z = 2 alors que ceux du composé **6** · CH_2Cl_2 sont aussi tricliniques, groupe d'espace $P\bar{1}$ avec a = 13,151(3), b = 17,177(4) et c = 12,619(3) Å, α = 91,98(2)°, β = 104,18(2)° et γ = 67,72(2)° et Z = 2. On a résolu les structures par le méthode des atomes lourds et on les a affinées par la méthode des moindres carrés (matrice entière) jusqu à des valeurs de R de 0,028 et 0,026 respectivement pour 8080 et 9336 réflexions avec $I \geq 3\sigma(I)$.

[Traduit par la rédaction]

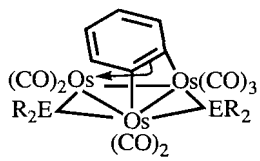
Introduction

Heating $Os_3(CO)_{11}L$ or $Os_3(CO)_{10}L_2$, where L is a tertiary phosphine, usually results in bond cleavage within the ligand L accompanied by loss of CO (1–8). Both C—H and P—C bond cleavage are common and are known for both alkyl and aryl phosphines. For example, $Os_3(CO)_{11}(PEt_3)$ in refluxing nonane undergoes two C—H cleavages to form $H_2Os_3(Et_2PCCH_3)(CO)_9$ (2, 3), and pyrolysis of $Os_3(CO)_{10}$-$(PPh_3)_2$ in refluxing xylene affords six products, all of which involve at least one C—H cleavage, and four of which involve at least one P—C cleavage (4, 5). Mixed alkylarylphosphine complexes also undergo similar reactions (6–8). For example, thermolysis of $Os_3(CO)_{11}(PMePh_2)$ leads to one aryl C—H and two aryl C—P cleavages to give the benzyne derivative $Os_3(\mu_3\text{-}C_6H_4)(\mu_3\text{-}PMe)(CO)_9$, **1**, R = Me (1, 8). Many other phenyl phosphine complexes form benzyne complexes under extensive pyrolysis, and two of the ways in which the benzyne moiety is bound are shown in **1** and **2** (1, 8, 9).

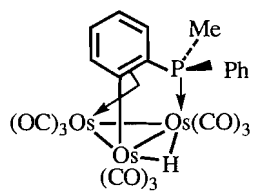
These cluster transformations seem to take place in steps, and some intermediates can be isolated by using a lower reaction temperature or shorter reaction time or a combination of the two. Deeming *et al.* were able to isolate and structurally characterize two intermediates in the transformation of $Os_3(CO)_{11}(PMePh_2)$ to $Os_3(CO)_9(\mu_3\text{-}PMe)(\mu\text{-}C_6H_4)$ (1). One of the intermediates is $HOs_3(CO)_9(\mu_3\text{-}C_6H_4PMePh)$, **3**, containing an *ortho*-metalated phenyl group which is also η^2-bound to the third osmium atom. An analogous intermediate $HOs_3(CO)_9(\mu_3\text{-}C_6H_4PPh_2)$ was also isolated although not structurally characterized (1). We have been interested in studying ferrocenyl phosphines with the objective of obtaining *ortho*-metalated ferrocenyl moieties and from the pyrolysis of $Os_3(CO)_{10}(PFcPh_2)_2$ we were able



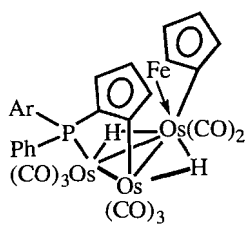
1



2



3



4

to isolate $H_2Os_3(CO)_8[(PPh_2(C_5H_3)Fe(C_5H_4)]$, **4**, in which double metalation has occurred (10). However, given the choice between a Fc- or Ph-group on the same ligand, it seems that *ortho*-metalation is more likely to take place within the phenyl group as judged by the product distributions. Here we report the preparation and structural characterization of

two such complexes, $(\mu\text{-H})Os_3(CO)_9[PFcPh(C_6H_4)]$, **5**, and $(\mu\text{-H})Os_3(CO)_8[PFcPh(C_6H_4)](PFcPh_2)$, **6**.

Experimental

All reactions were carried out under an argon atmosphere. Solvents were predried and distilled prior to use. $^{31}P\{^1H\}$ and ^1H nmr chemical shifts are given in ppm from TMS, and 85% H_3PO_4, respectively, and the spectra were recorded by using Bruker AC-200 or WH-400, or Varian XL-300 spectrometers. FAB mass spectra were recorded by using an AEI MS-9 spectrometer. The exciting gas was argon and the matrix was nitrobenzyl alcohol. Elemental analyses were performed by Mr. Peter Borda of this department. Some spectroscopic data are given in Table 1. Analytical and spectroscopic data for **7** have been published (9).

Preparation of $Os_3(CO)_{11}(PFcPh_2)$, 7, and $Os_3(CO)_{10}(PFcPh_2)_2$, 8

To a stirred solution of triosmium dodecacarbonyl (272 mg, 0.3 mmol) in dichloromethane (20 mL) in a Schlenk tube was added acetonitrile (5 mL, excess) and trimethylamine oxide (23 mg, 0.3 mmol). The reaction mixture was stirred for 2 h at room temperature and the ligand $PFcPh_2$ (112 mg, 0.3 mmol) was added. After a further 2 h the solvent was removed under reduced pressure, and the residue was applied to a silica chromatographic column. By using 3:1 petroleum ether/CH_2Cl_2 as eluent, pure orange product **7** was obtained in 65% isolated yield (240 mg) after solvent evaporation.

Compound **8** was prepared similarly except that 2 molar equivalents of trimethylamine oxide (48 mg, 0.63 mmol) and ferrocenyldiphenylphosphine (230 mg, 0.61 mmol) were used. Pure **8** was obtained in about 60% yield, following chromatography, as yellow crystals. Anal. calcd. for $C_{54}H_{38}Fe_2O_{10}Os_3P_2$: C 40.76, H 2.41; found: C 41.10, H 2.65.

Pyrolysis of $Os_3(CO)_{11}(PFcPh_2)$, 7, and preparation of 5

Pyrolysis of **7** in refluxing octane for 3 h produces mainly **1** (R = Fc) (9). Compound **7** (110 mg) in heptane (20 mL) was refluxed for 5 h. The solution was cooled and the solvent removed under reduced pressure. The orange-red residue was applied to a silica chromatographic column and eluted with 4:1 petroleum ether/CH_2Cl_2. The second band to elute proved to contain **5** and a pure sample was obtained in ~20% yield. Suitable crystals for X-ray structure analysis were grown by slow evaporation of the solvent from the collected fraction. Anal. calcd. for $C_{31}H_{19}FeO_9Os_3P$: C 31.21, H 1.61; found: C 31.35, H 1.58.

Pyrolysis of $Os_3(CO)_{10}(PFcPh_2)_2$, 8, and the preparation of 6

The pyrolysis of **8** has been described previously (10). Compound **6** was eluted as the sixth band in ~15% yield. Suitable crystals for X-ray structure analysis were grown from a 3:1 petroleum ether/CH_2Cl_2 mixture. Anal. calcd. for $C_{53}H_{40}Cl_2Fe_2O_8Os_3P_2$, **6** · CH_2Cl_2: C 39.29, H 2.49; found: C 39.45, H 2.65.

X-ray crystallographic analyses

Crystallographic data for $\{[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4)](C_6H_5)P(\mu{:}\eta^3\text{-}C_6H_4)\}(\mu\text{-H})Os_3(CO)_9$, **5**, and $\{[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4)](C_6H_5)P(\mu{:}\eta^3\text{-}C_6H_4)\}\{[(\eta^5\text{-}C_5H_5)Fe(\eta^5\text{-}C_5H_4)]P(C_6H_5)_2\}(\mu\text{-H})Os_3(CO)_8 \cdot CH_2Cl_2$, **6** · CH_2Cl_2, appear in Table 2. The final unit-cell parameters were obtained by least squares on the setting angles for 25 reflections with 2θ = 53.2–54.9° for **5** and 32.6–36.4° for **6** · CH_2Cl_2. The intensities of three standard reflections, measured every 200 reflections throughout the data collections, remained

[a]Temperature 294 K, Rigaku AFC6S diffractometer, Mo-K_α radiation (λ = 0.71069 Å), graphite monochromator, takeoff angle 6.0°, aperture 6.0 × 6.0 mm at a distance of 285 mm from the crystal, stationary background counts at each end of the scan (scan/background time ratio 2:1, up to 8 rescans), $\sigma^2(F^2) = [S^2(C + 4B) + (pF^2)^2]/Lp^2$($S$ = scan rate, C = scan count, B = normalized background count, p = 0.01 for **5**, 0.02 for **6**), function minimized $\Sigma w(|F_o| - |F_c|)^2$ where $w = 4F_o^2/\sigma^2(F_o^2)$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$, and gof = $[\Sigma w(|F_o| - |F_c|)^2/(m - n)]^{1/2}$. Values given for R, R_w, and gof are based on those reflections with $I \geq 3\ \sigma(I)$.

constant for both compounds. The data were processed[2] and corrected for Lorentz and polarization effects, and absorption (empirical, based on azimuthal scans for four reflections).

Both structures were solved by heavy atom methods, the coordinates of the Os and Fe atoms being determined from the Patterson functions and those of the remaining non-hydrogen atoms from subsequent difference Fourier syntheses. Both structure analyses were initiated in the centrosymmetric space group $P\bar{1}$, these choices being confirmed by the subsequent successful solution and refinement of the structures. There is one molecule of dichloromethane in the asymmetric unit of **6**. All non-hydrogen atoms of both complexes were refined with anisotropic thermal parameters. The metal hydride atoms in both complexes were included in difference map positions but were not refined. All other hydrogen atoms in both structures were fixed in idealized positions (C—H = 0.98 Å, $B_H = 1.2\ B_{bonded\ atom}$). Corrections for secondary extinction were applied for both structures, the final values of the extinction coefficient being 3.14×10^{-7} for **5** and 1.58×10^{-7} for **6** · CH_2Cl_2.

[2]TEXSAN/TEXRAY structure analysis package which includes versions of the following: DIRDIF, direct methods for difference structures, by P. T. Beurskens, ORFLS, full-matrix least-squares, and ORFFE, function and errors, by W. R. Busing, K. O. Martin, and H. A. Levy, ORTEPII, illustrations, by C. K. Johnson. Neutral atom scattering factors and anomalous dispersion corrections for the non-hydrogen atoms were taken from the *International tables for X-ray crystallography* (11). Final atomic coordinates and equivalent isotropic thermal parameters, selected bond lengths, and selected bond angles appear in Tables 3–8, respectively. Hydrogen atom parameters, anisotropic thermal parameters, complete tables of bond lengths and bond angles, torsion angles, intermolecular contacts, least-squares planes, and measured and calculated structure factor amplitudes are included as supplementary material.[3]

[3]Hydrogen atom parameters, anisotropic thermal parameters, complete tables of bond lengths and bond angles, torsion angles, intermolecular contacts, least-squares planes, and measured and calculated structure factor amplitudes for **5** and **6** · CH_2Cl_2 may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada KIA 0S2.

The tables of hydrogen atom parameters have also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 IEZ, U.K.

[a] $B_{eq} = (8/3)\pi^2\Sigma\Sigma U_{ij} a_i * a_j * (a_i \cdot a_j)$.

Results and discussion

When compound **7** is refluxed in octane for 3 h it undergoes two P—C cleavages and one C—H cleavage to form **1** (R = Fc) in high yield (>70%) (9). Both the ^{1}H and ^{31}P nmr spectra show no sign of the formation of the alternative ferrocyne compound, but they do show the formation of intermediates. To optimize isolation of these intermediates, the reaction was carried out in refluxing heptane. Thin-layer chromatographic monitoring showed that one intermediate was at a maximum concentration after 5 h. This compound, **5**, was isolated and the spectroscopic data suggest that it should be formulated as $Os_3(CO)_9(\mu\text{-}H)[PFcPh(C_6H_4)]$. Thus the ^{31}P resonance at ~6.1 ppm ($\Delta\delta$ = 4.6 ppm from **7**) is consistent with the presence of a phosphine ligand on the cluster. The ^{1}H nmr spectrum (Table 1) clearly suggests one ferrocenyl, one phenyl, and one metalated phenyl group on the phosphine ligand. One bridging hydride is also present. The parent peak from the FAB mass spectrum indicates the loss of two carbonyls from the parent compound **7**. These data, however, do not distinguish between two possible structures, one electron deficient, e.g., **9** (12), the other electron precise, e.g., **3** (1) and **10** (13) so a single crystal X-ray analysis was carried out. The electron-precise structure is shown in Fig. 1.

The products of the pyrolysis of $Os_3(CO)_{10}(PFcPh_2)_2$, **8**, are much more numerous. Refluxing in octane for 7 h affords at least eight compounds. One product, **4**, which results from metalation of each of the cyclopentadienyl rings

and formation of an Fe—Os bond, has been fully characterized and was described previously (10). A second product, **6**, has now been isolated in moderate yield. The spectroscopic results show that **6** is very similar to **5**, as is borne out by the X-ray crystallographic study. The structure of **6** is shown in Fig. 2.

In both **5** and **6** the metalated phenyl moiety adopts the unsymmetrical electron-precise structure as in **3** and **10** (1, 13). Both **5** and **6** apparently result from the metalation of one P-C_6 ring and subsequent formation of a π-bond. The C_6H_4PFcPh bridge acts as a five-electron donor to the cluster, two electrons via the P atom, one via the ortho-metalated C, and two via the η^2-bond from the metalated ring. The metrical details for the two structures are very similar so detailed comments will be confined to **6** because the presence of the phosphine ligand at Os(1) adds additional interest.

The three Os—Os bonds of **6** show considerable variation in length ranging from 3.0259(6) Å for the hydrogen-bridged Os(1)—Os(3) through 2.8661(9) Å for Os(3)—Os(2), to 2.7746(8) Å for Os(2)—Os(1). The shortest bond in **6** is *trans* to the tertiary phosphine ligand; it is longer than the corresponding bond in **5** (Os(2)—Os(3) = 2.7576(5) Å). These Os—Os bond lengths are not unusual, the average for

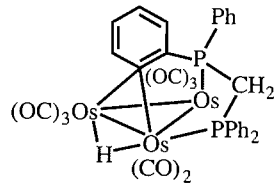
TABLE 7 (*concluded*)

Atom	Atom	Distance	Atom	Atom	Distance
C(21)	C(22)	1.40(1)	C(47)	C(52)	1.374(7)
C(22)	C(23)	1.41(1)	C(48)	C(49)	1.386(8)
C(23)	C(24)	1.41(1)	C(49)	C(50)	1.373(8)
C(25)	C(26)	1.447(7)	C(50)	C(51)	1.360(8)
C(25)	C(29)	1.434(7)	C(51)	C(52)	1.391(7)

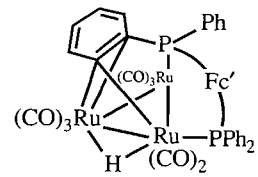
Primes denote symmetry operation: $1 - x$, $1 - y$, $-z$. Cp (1–4) are the centroids of the C(15–19, 20–24, 25–29, 30–34) rings.

$Os_3(CO)_{12}$ being 2.877(3) Å. The Os(1)—P(1) bond (2.342(1) Å) is shorter than Os(3)—P(2) (2.363(1) Å).

The P—Fc bonds in **6** are shorter than the P—Ph bonds and if data from both **5** and **6** are used the two distances are avg. 1.805 Å and avg. 1.828 Å. P—Fc distances in another molecule $Os_3(CO)_8(H)_2[\eta\text{-}C_5H_3PFcPh)Fe(\eta\text{-}C_5H_4)]$ reflect this trend with P—Ph = 1.833(5) Å and P—Fc = 1.801(6) Å (10).



9



10

The Os(2)—C distances in **6** are essentially the same (avg. 2.364 Å). (In **3** the equivalent bonds are of length 2.319(22) and 2.417(18) Å). The Os(1)—C(9) interaction in **6** is shorter (2.141(5) Å) (in **3** it is 2.154(19) Å) and these data support the η^1, η^2-interaction between the C_6-ring and the Os_3 cluster. The metalated C_6-ring in **6** is tilted 45° with respect to the Os_3 plane. Neither P(2) nor Os(1) are coplanar with the C_6-ring, the former is 0.66 Å from the plane and the latter 0.26 Å but on the opposite side. This effect may account for the lengthening of Os(3)—P(2) relative to Os(1)—P(1) mentioned above. The μ_2-bonding involving C(9) and C(10)

of the C_6-ring appears to result in electron localization in the ring. C(9)—C(10) is lengthened to 1.442(6) Å whereas C(13)—C(14) and C(11)—C(12) are shortened to 1.355(7) and 1.358(17) Å respectively. The C—C—C angle at C(9) (113.6(4)°), the metalated carbon atom, is different from the others in the ring that are close to the usual 120°.

The other bond angles and distances in **6** (and **5**) are as expected.

Received December 20, 1991

KEITH VAUGHAN, DONALD L. HOOPER, and MARCUS P. MERRIN. Can. J. Chem. **70**, 2224 (1992).

The kinetics of hydyrolysis of a series of 1-aryl-3-aryloxymethyl-3-methyltriazenes, Ar-N=N-NMe-CH_2OAr', was studied over the pH range 2–7.5. Reactions were followed by the change in UV absorbance spectra of the triazenes. The aryloxymethyltriazenes decompose more slowly at pH 7.5 than the hydroxymethyltriazenes, Ar-N=NMe-CH_2OH; the hydrolysis is favoured by the presence of an electron-withdrawing group in Ar'. A mixed isopropanol/buffer system was developed in order to improve solubility of the aryloxymethyl triazenes. Lowering the pH caused an increase in the rate of hydrolysis and under strongly acidic conditions an electron-withdrawing group in Ar' actually slows down the reaction. A Hammett plot of the pseudo-first-order rate constant, k_{obs}, is curved, indicating that two or more mechanisms operate simultaneously and that the contribution of each mechanism is substituent-dependent. A plot of k_{obs} vs. [buffer] is linear; the slope of the plot affords the rate constant, k_b, for the buffer-catalyzed reaction for each substituent. A Hammett plot of k_b vs. σ is linear with $\rho = +0.55$, suggesting that the buffer-catalyzed reaction involves nucleophilic displacement of the phenoxy group by the buffer anion. Further analysis afforded the specific acid-catalyzed rate constants, k_{H^+}, for each substituent; this component of the reaction has a negative ρ, consistent with a mechanism involving protonation at the ether oxygen. The postulation that specific acid catalysis is a component of the reaction mechanism was confirmed by the observation of a solvent deuterium isotope effect, $2.28 > k_H/k_D > 1.60$. Only the *p*-NO_2 and *p*-CN phenyloxymethyltriazenes showed any spontaneous decomposition.

KEITH VAUGHAN, DONALD L. HOOPER et MARCUS P. MERRIN. Can. J. Chem. **70**, 2224 (1992).

On a déterminé la cinétique de l'hydrolyse d'une série de 1-aryl-3-aryloxyméthyl-3-méthyltriazènes, Ar-N=N-NMe-CH_2OAr', à des pH allant de 2 à 7,5. On a suivi les réactions par le changement du spectre d'absorbance UV des triazènes. À un pH de 7,5, les aryloxyméthyltriazènes se décomposent plus lentement que les hydroxyméthyltriazènes, Ar-N=N-NMe-CH_2OH; l'hydrolyse est favorisée par la présence d'un groupe électro-attracteur dans la portion Ar'. On a développé un système mixte isopropanol/tampon pour améliorer la solubilité des aryloxyméthyltriazènes. Un abaissement du pH provoque une augmentation de la vitesse d'hydrolyse et, dans des conditions fortement acides, un groupe électro-attracteur dans la portion Ar' inhibe complètement la réaction. La courbe de Hammett de la constante de vitesse du pseudo-premier ordre, k_{obs}, n'est pas rectiligne; ceci indique que deux ou plusieurs mécanismes opèrent simultanément et que la contribution de chacun dépend du substituant. Une courbe de k_{obs} vs. [tampon] est linéaire; la pente de la courbe fournit la constante de vitesse, k_b, pour la réaction catalysée par le tampon pour chaque substituant. Une courbe de Hammett de k_b vs. σ est linéaire et $\rho = +0{,}55$, suggérant que la réaction catalysée par le tampon implique une substitution nucléophile du groupe phénoxyle par l'anion du tampon. Une analyse plus approfondie fournit les constantes de vitesse des réactions soumises à une catalyse acide spécifique, k_{H^+}, pour chaque substituant; la valeur de ρ pour cette composante de la réaction est négative et cette valeur est en accord avec un mécanisme impliquant une protonation de l'oxygène de l'éther. Le postulat à l'effet que la catalyse acide spécifique est une composante du mécanisme de la réaction a été confirmé par l'observation d'un effet isotopique du deutérium du solvant, $2{,}28 > k_H/k_D > 1{,}60$. Les seuls phényloxyméthyltriazènes à se décomposer spontanément sont les dérivés *p*-NO_2 et *p*-CN.

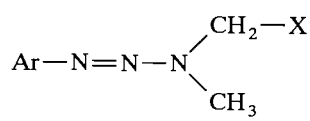
Introduction

1-Aryl-3,3-dimethyltriazenes (**1***a*) have been known for many years (1) to have antitumour activity against murine tumours and one such triazene, DTIC (Dacarbazine, NSC 45388), has found clinical use against human malignant melanoma (2). The presumed mode of action of DTIC involves enzymatic oxidation to a hydroxymethyltriazene (**1***b*), followed by loss of formaldehyde to give the monomethyltriazene, Ar-N=N-NHMe, the putative cytotoxic metabolite. It has been suggested that one of the limitations to DTIC efficacy is the apparent inefficiency of oxidative metabolism in the human liver (3). Thus it would seem to be a worthwhile exercise to search for a triazene derivative of DTIC that would act as a prodrug and not require oxidative metabolism.



1 *a* X = H
b X = OH
c X = OMe
d X = OAc
e X = SAr'

The hydroxymethyltriazene (**1***b*) ("HMT") would seem to be an ideal candidate as a pro-drug, but all of the biological

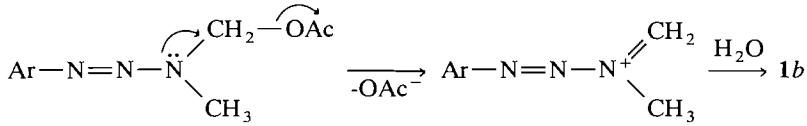

FIG. 1

studies suggest that the hydroxymethyltriazene is a very transient species in vivo. Nevertheless, we were successful in achieving the synthesis of the first stable hydroxymethyltriazene (4), and although these compounds are stable in the crystalline state, they do indeed decompose rapidly in solution under physiological conditions (5). In developing the chemistry of these novel *N*-hydroxymethyl compounds, we were aware of the desirability of preparing a further derivative of HMT with appropriate stability for pro-drug use.

Thus we synthesized the methyl ether derivatives (**1***c*) and the acetoxymethyltriazenes (**1***d*) (6); the difference in chemical behavior of these two apparently similar derivatives is quite striking but can be rationalized by the difference in the facility of the leaving group X. The ether derivatives (**1***c*) with a poor leaving group, OMe, are comparable in stability at pH 7.5 to the dimethyltriazene (**1***a*), whereas the acetoxymethyltriazene (**1***d*) decomposes in solution as rapidly as the hydroxymethyltriazene (**1***b*). Apparently the relatively good leaving group, OAc, is displaced rapidly to afford an iminium ion, which hydrolyses to the HMT (See Fig. 1).

We previously extended the range of hydroxymethyltriazene derivatives to the 1-aryl-3-arylthiomethyl-3-methyltriazenes (**1***e*) (7) and more recently to the 1-aryl-3-aryloxymethyl-3-methyltriazenes (**2***a–h*) (8). The isolation of these compounds is an exciting development in the search for the ultimate triazene pro-drug, since the aryloxy group would be expected to fall in between the methoxy and acetoxy groups in leaving group ability. Furthermore, the extensive variation of the Y-group in **2** should provide for a "tailor-made" leaving group with the appropriate reactivity required in the pro-drug. Accordingly we have undertaken a thorough study of the solution behavior of these new aryloxymethyltriazenes in order to assess their potential as triazene pro-drugs.

Experimental

The compounds used in this study were prepared by established procedures from the literature (5, 6) with the exception of the 3-aryloxymethyl-3-methyltriazenes (**2***a–h*) whose synthesis and characterization are reported in the previous paper in this series (8). All compounds used were recrystallized to constant melting point. Approximately 1.5 mg of each test compound was dissolved in 1 mL of dried, distilled dimethyl sulfoxide. These solutions were stored under refrigeration (−10°C) and thawed for use as required. Buffers were prepared as follows.

MES buffer

2(*N*-Morpholino)ethanesulfonic acid (Sigma M8250) (4.88 g) was dissolved in 250 mL distilled water to give a 0.1 M solution. This was adjusted to pH 5.5 using 0.2 M sodium hydroxide.

Formate buffers (pH 3.3)

0.1 M: 88% formic acid solution (3.206 g) and sodium formate (2.630 g) made up to 1 L. 0.5 M: 88% formic acid solution (16.03 g) and sodium formate (13.17 g) made up to 1 L. 0.01 M: 88% formic acid solution (0.321 g) and sodium formate (0.236 g) made up to 1 L.

HCl pH 2.0 (not a true buffer)

0.2 M Hydrochloric acid (6.5 mL) and 0.2 M potassium chloride (43.5 mL) made up to 100 mL.

NaOH pH 12.0 (not a true buffer)

0.2 M Sodium hydroxide (6.0 mL) and 0.2 M potassium chloride (44 mL) made up to 100 mL.

Phosphate pH 7.5

0.2 M monobasic sodium phosphate (16 mL) and 0.2 M dibasic sodium phosphate (84 mL) made up to 200 mL.

The pH of the buffer solutions was checked periodically using an Accumet model 810 pH meter (Fisher Scientific) standardized with commercial standard buffers at pH 7.00 and 4.00 (Fisher Scientific). The pH measurements were carried out with solutions thermostatted at 38 ± 1°C, but there was no attempt to control the ionic strength of the medium.

UV analysis

UV–visible absorption measurements were made using a Cary 219 spectrophotometer (Varian) with repeat scan and timed delay facilities. The cell chamber was thermostatted at 38 ± 1°C. These measurements were made in one of three modes. For fast hydrolyses ($t_{1/2} < 10$ min) the spectrophotometer was operated at fixed wavelength (320 nm, close to the triazene maximum) with the chart set for time drive to give a continuous trace of decay with time at this wavelength. For intermediate rates (10 min $< t_{1/2} <$ 60 min), the spectrophotometer was set to scan from 450 to 230 nm at 2 nm s^{-1} repeatedly with a 4 min cycle time in overlay mode so that isosbestic points could be observed as a check on spectrophotometer stability. Very slow hydrolyses ($t_{1/2} > 60$ min) were measured at a fixed wavelength (320 nm) with a timed delay so that a measurement was made for 10 sec every hour or every 90 min as appropriate.

Hydrolyses were carried out in stoppered Spectrosil quartz cells (Fisher Scientific) in neat buffer (3 mL) or in a 2:1 buffer–isopro-

panol mixture (2 mL buffer:1 mL isopropanol). An aliquot (50 μL) of the DMSO solution of the compound under investigation was added to the cell, which was then quickly stoppered, inverted once to mix, inserted in the spectrophotometer, and the appropriate program started. Volumes were measured with Eppendorf pipettes.

After each run, absorbances were measured manually and values for ln A calculated according to:

$$[1] \quad \ln A = \ln (A_t - A_\infty)/(A_\infty - A_0)$$

where A_t is the absorbance after time t, A_∞ is the absorbance after complete hydrolysis, and A_0 is the initial absorbance. All experiments were carried out in duplicate. If the corresponding values of ln A for the two runs differed by more than 0.05, then the data were discarded and the experiment repeated. A simple linear least-squares fit program was used to generate plots of these results. The slope of each plot represents the rate constant k_{obs} (s^{-1}). Half-lives were calculated using:

$$[2] \quad t_{1/2} = 60\{(\ln 0.5) - A\}/B$$

where A is the y-intercept and B the slope in min^{-1}. The results of this kinetic analysis are presented in Tables 1–3.

Changes in rate constant k_{obs} with buffer concentration at constant pH were examined by measuring the hydrolysis rate for each compound in formate buffer (pH 3.3) at three concentrations. The original buffers were 0.1, 0.01, and 0.5 M, which on dilution with isopropanol became 0.06, 0.006, and 0.33 M. These rates are shown in Fig. 8 plotted against Hammett σ_p values.

HPLC analyses

HPLC analyses were performed on a Varian model 5000 liquid chromatograph equipped with a microprocessor-controlled binary solvent delivery system. Data were collected with a Varian model 4290 integrator. A 250 × 4 mm, 10 μm Lichrosorb NH_2 (Hibar) column was used with a 3 mm amino guard column (Brownlee Labs). Isocratic elution with isopropanol/*n*-hexane (60:40) at a flow of 1.5 mL min^{-1} gave the best separations. External standards were prepared by dissolving a weighed mass of the desired compound in 25 mL isopropanol as follows.

Compound **2e**	4.9 mg
4-Bromophenol (HOC_4H_4Br)	14.7 mg
Methyl-4-aminobenzoate (M4AB)	2.2 mg
Methyl-4-hydroxybenzoate (M4HB)	0.74 mg

Standards, with the exception of compound **2e**, were reagent grade (Aldrich) used without further purification and were found to be of acceptable purity (>98%). The standards were run in triplicate and their retention times and response factors are given in Table 4.

Hydrolysis of the 4-bromophenyloxymethyltriazene (**2e**) was carried out as follows. Formate buffer (pH 3.3, 25 mL) and isopropanol (12.5 mL) were equilibrated in a water bath. The triazene was dissolved in the isopropanol, which was then added to the buffer. Immediately, and then at ca. 30 min intervals, a 5 mL aliquot was pipetted into a separatory funnel. This aqueous phase was extracted with dichloromethane (3 × 10 mL), and the organic layers were combined, dried with anhydrous sodium sulphate, filtered, and evaporated under vacuum. This material was then dissolved in isopropanol, filtered through a 0.2 μm membrane (Metricel GA-8), and made up to 10 mL.

A test mixture containing suitable amounts of the three likely products was prepared and subjected to the extraction procedure outlined above. The analysis of this extract was compared with the standards to establish the efficiency of the extraction process for each component. For the starting material, the t_0 concentration was established by comparison with the standard and this value then related to the known amount of substrate in the system. The recoveries were as follows: compound **2e**, 76%; M4HB, 97.8%; M4AB, 61.4%; HOC_4H_4Br, 78.5%.

The chromatograms for the hydrolysis experiment are shown in Fig. 2. The results of this analysis are given in Table 5, and the assay of the hydrolysis in Table 6.

Solvent deuterium isotope effect

The *p*-bromophenyloxymethyltriazene (**2e**) was dissolved in dimethyl sulfoxide (1.5 mg/mL) and 50 μL of this solution was added to the buffer/isopropanol mixture (0.1 M, pH/pD 3.07, 40 ± 1°C) in a cuvette. In one experiment, the buffer was made up in H_2O to give the rate constant (k_H); in a second experiment, the buffer was made up in D_2O to give the deuterium isotope rate constant (k_D). The observed k_H/k_D value was 1.60. Since the isopropanol was not deuterated, an exchange can take place, i.e.,

$$i\text{-PrOH} + D_3O^+ \rightleftharpoons i\text{-PrOD} + HD_2O^+$$

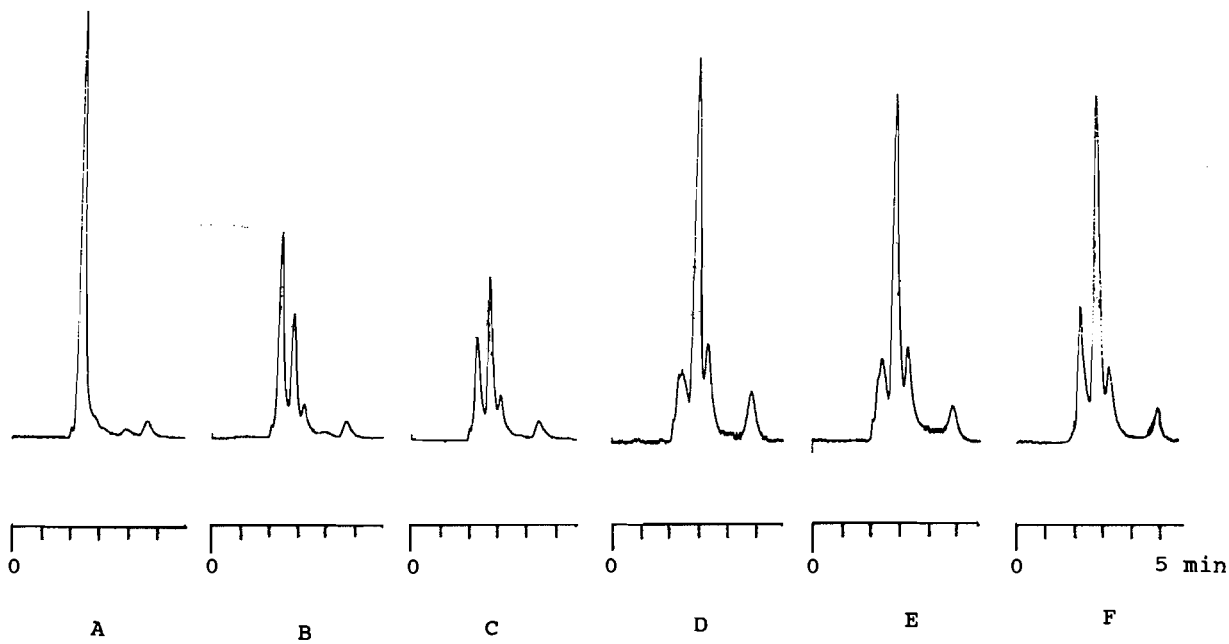

FIG. 2. Hydrolysis of 1-(4-carbomethoxyphenyl)-3-(4-bromophenyloxymethyl)-3-methyltriazene (**2e**) followed by HPLC. A, 0 min; B, 32 min; C, 56 min; D, 92 min; E, 18 h; F, 6 days.

TABLE 5. Results of HPLC analysis of the hydrolysis of compound **2e** measured by disappearance of substrate

Time (min)	Amount in sample ($g/10^{-3}$)	Corrected for recovery ($g/10^{-3}$)	Moles/10^{-5}	ln C^a
0	11.7	15.4	4.08	0
32	6.17	8.11	2.15	−0.641
65	3.49	4.59	1.22	−1.210
92	1.88	2.47	0.654	−1.830
1080	1.03	1.35	0.358	−2.433

[a] ln (M_t/M_0) where M_t is the number of moles present at time t and M_0 is the number of moles present at the start of the experiment.

TABLE 6. Assay of products of HPLC hydrolysis experiment

Time (min)	Assay in moles/10^{-5}		
	M4AB	Bromophenol	M4HB
0		—	—
32	2.19	2.13	0.051
65	2.55	2.86	0.057
92	3.13	3.43	0.055
1080	3.17	3.58	0.053

which implies that k_D(obs) could be expressed as:

$$1/3\ k_H + 2/3\ k_D\ (\text{true}) = k_D\ (\text{obs}) = 5.15 \times 10^{-4}\ s^{-1}$$

(since the reaction solvent is composed of 2/3 buffer and 1/3 isopropanol).

Thus the true k_D could be as low as $3.61 \times 10^{-4}\ s^{-1}$ and the upper limit of k_H/k_D would equal 2.28 (if all the isopropanol was deuterated). The conclusion of the experiment is that there is definitely a solvent deuterium isotope effect in the range $1.60 < k_H/k_D < 2.28$.

Results and discussion

The most reactive compound of the series of aryloxymethyl triazenes (**2a–h**) at physiological pH was predictably the *p*-nitrophenyloxymethyltriazene (**2h**), which decomposed in neat pH 7.5 phosphate buffer in almost exactly the same manner as its parent hydroxymethyltriazene (**3**). A close examination of the UV absorbance decay of the hydrolysis of **2h** (Fig. 3) reveals some subtle differences from the hydrolysis of **3**. Firstly, there is a short induction period at the start of the reaction during which the triazene absorbance at 320 nm does not decay; after this induction period, the UV absorbance decays in a first-order manner to give a pseudo-first-order rate constant, k_2, equal to $1.05 \times 10^{-3}\ s^{-1}$ corresponding to a half-life ($t_{1/2}$) of 11 min. This value is equal, within experimental error, to the half-life of the parent hydroxymethyltriazene (5).

The second feature of Fig. 3 is the observation of a second absorbance at ca. 400 nm that *grows in* during the early stage of reaction. This absorbance can be attributed to the

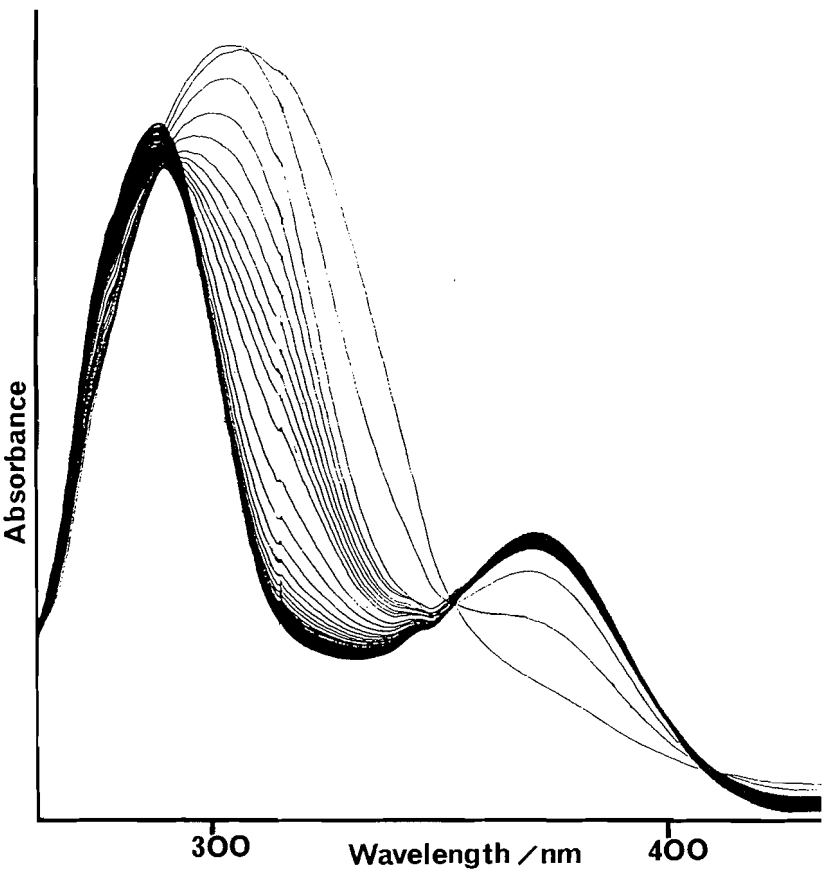

FIG. 3. Repeat-scan (cycle time 1 min) UV spectrum for 1-(4-carbomethoxyphenyl)-3-(4-nitrophenyloxymethyl)-3-methyl triazene (**2h**) in pH 7.5 phosphate buffer.

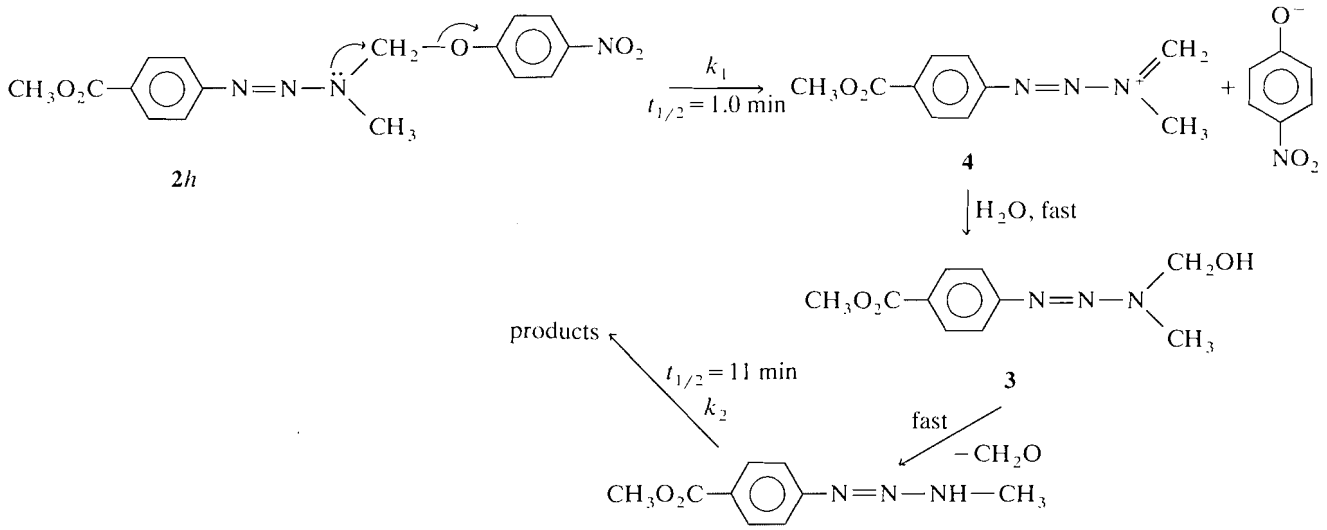

FIG. 4

formation and release of the *p*-nitrophenolate ion during the initial, rapid decomposition of the aryloxymethyltriazene (**2***h*). Kinetic analysis of the growth of the 400-nm peak gives a second pseudo-first-order rate constant, k_1, equal to 1.15×10^{-2} s^{-1}, which converts into a half-life of 1.0 min.

This result can be explained logically by the mechanism shown in Fig. 4, in which the triazene (**2***h*) undergoes spontaneous ionization (k_1) to afford the iminium ion intermediate (**4**) and the *p*-nitrophenolate ion. Fast hydrolysis of the iminium ion by water affords the hydroxymethyltriazene (**3**), followed by rapid loss of formaldehyde to afford the monomethyltriazene, Ar-N=N-NHMe, which then decomposes with the observed half-life (k_2) of 11 min (5). The decomposition of the *p*-nitrophenoxymethyltriazene (**2***h*) under these conditions is unique in our experience in that it represents the first absolute measurement of the fast rate of the initial decomposition of a hydroxymethyltriazene derivative.

The success of the hydrolysis experiment with the *p*-nitrophenoxymethyltriazene (**2***h*) in neat aqueous buffer was not, unfortunately, carried over to the other compounds in this series. With the exception of **2***h*, the solubility of the aryloxymethyltriazenes in the buffer was too low to give concentrations suitable for UV spectrophotometric analysis. The triazene simply precipitated out of solution before any measurable reaction occurred. For this reason, it was deemed desirable to develop a mixed buffer/isopropanol system. An important consideration of using such a system is the establishment of a pH scale for such a mixture. It has been shown that the presence of alcohols in aqueous systems leads to disruption of hydrogen bonding, which in turn leads to a greater number of free water molecules being available to solvate protons and hence a lowering of the effective hydrogen ion concentration (9). The pH values quoted are those obtained from a normal laboratory pH meter and are thus only an approximate indication of acidity.

To compare the reactivity of the new aryloxymethyltriazenes (**2**) with the parent hydroxymethytriazene (**3**) it was necessary to establish the kinetic parameters of **3** at different pH values and in the mixed buffer/isopropanol solvent system.

The decomposition of compound **3** was examined over the pH range 3.3–12.0 and was found to follow first-order behavior in all cases. The kinetic data from these experiments are shown in Table 7. Thus in an alkaline medium at pH 12.0 the hydroxymethyltriazene is surprisingly stable, with a half-life of 14.7 h. In phosphate buffer at pH 7.5, the rate of hydrolysis is 43 times faster, and at acid pH 5.5 the rate of hydrolysis of the HMT (**3**) is increased by a further factor of 23. Lowering the pH further to pH 3.3 has a much smaller effect on the very fast rate of hydrolysis.

TABLE 7. Kinetic data for the hydrolysis of the hydroxymethyltriazene (**3**) for various buffers and pH values

	Neat buffer		Buffer–isopropanol	
pH	$t_{1/2}$	$k_{obs}/10^{-3}$ (s^{-1})	$t_{1/2}$	$k_{obs}/10^{-3}$ (s^{-1})
3.3	18.2 s	44.2	40 s	19.5
5.5	1.59 min	11.9	6.7 min	1.78
7.5	9.81 min	0.52	4.2 h	0.046
12.0	14.7 h	0.012	—	—

Adding isopropanol to the buffer system slows the hydrolysis of the HMT (**3**) by a factor of 11.3 at pH 7.5 and by a factor of 6.7 at pH 5.5. The rate of hydrolysis of **3** at pH 3.3 is much less affected by the presence of the alcohol. These observations are consistent with the presence of isopropanol causing a decrease in the effective hydrogen ion concentration. Furthermore, it can be adduced from this evidence that protonation plays a significant role in the acid-catalyzed decomposition of the hydroxymethyltriazenes.

Tables 1, 2, and 3 show the results for the measurement of kinetic parameters of the aryloxymethyltriazenes (**2**) in isopropanol/buffer systems of pH 2.0, 3.3, and 5.5 obtained from the plots of ln *A* versus time for the loss of the triazene UV absorbance. In all cases the aryloxymethyltriazenes decompose at a significantly lower rate than the parent hydroxymethyltriazene (**3**). For example, the *p*-bromophenyloxymethyltriazene (**2***e*) decomposes from 3 to 190 times more slowly than **3**, depending upon the pH. All sets of data show varying half-life values for the decomposition of the aryloxymethyltriazenes (**2***a*–*h*) as a function of the substituent X in the aryl moiety. It is logical therefore to

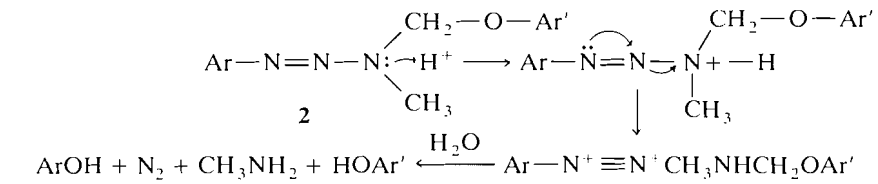

FIG. 5

look for a Hammett correlation for these various substituents.

A general observation from the data in Tables 1–3 is that, for each compound, the lower the pH the faster the reaction. This observation suggests that protonation of the ether oxygen is important in the rate-determining step.

However, at pH 3.3, it is evident that both strongly electron-donating (OCH_3) and electron-withdrawing (NO_2) groups promote the hydrolysis, whereas at pH 5.5 a simpler pattern emerges where the electron-withdrawing ability favours the hydrolysis.

A possible site of protonation in the aryloxymethyltriazenes (**2**) is the N-3 nitrogen, which would ultimately lead to fragmentation of the triazene at the N2—N3 bond as shown in Fig. 5. Subsequent decomposition of the arenediazonium ion leads to a phenol (methyl-4-hydroxybenzoate in the compounds studied) in addition to the phenol produced by the decomposition of the phenoxymethylamine fragment. The HPLC study of the decompositton of the *p*-bromophenoxymethyltriazene (**2*e***) provided evidence that the mechanism depicted in Fig. 5 is *not* operative. Although traces of methyl-4-hydroxybenzoate were detected in the hydrolysis mixture, its level was low (<2 mol%) and constant. This compound was subsequently found to be a ubiquitous contaminant of α-hydroxymethyltriazenes and their derivatives. The $t_{1/2}$ value obtained for compound **2*e*** was 36.4 min by HPLC compared to 35.2 min by UV spectrophotometry.

The HPLC method did have one shortcoming in that over long periods of time a degree of transesterification took place between the solvent isopropanol and the methyl 4-aminobenzoate product. This ester had a retention time almost identical with that of the substrate and was not resolvable by the method in use. This transesterification was slow compared with the hydrolysis of interest, isopropyl 4-aminobenzoate only being detectable after 18 h of hydrolysis.

The actual products of hydrolysis of **2*e*** are principally methyl-4-aminobenzoate and *p*-bromophenol, which is consistent with a fragmentation of **2*e*** at the ether linkage to give *p*-bromophenol and the hydroxymethyltriazene (Fig. 6 and Tables 5 and 6). However, the ultimate question is how does this fragmentation occur, and to find an answer we turn our attention to a Hammett analysis.

Figure 7 is a Hammett plot for the hydrolysis rate constants, k_{obs}, of the aryloxymethyltriazenes (**2**) at the pH values 2.0, 3.3, and 5.5 using the data for k_{obs} in Tables 1, 2, and 3. The curved nature of the Hammett plots at all pH's suggests strongly that there is more than one pathway of decomposition. In addition to a spontaneous decomposition, there is clearly an acid-catalyzed component to the overall reaction, since for every substituent the rate of reaction goes up as the pH is lowered.

A second revealing Hammett plot is that shown in Fig. 8, which shows the effect of changing the buffer concentration while holding the pH constant at 3.3. It is clear from Fig. 8 that the rate of reaction increases for each substituent as the buffer concentration is increased, suggesting that there is a third, buffer-catalyzed component to the overall decomposition of **2**.

Thus it appears that the rate of decomposition of the aryloxymethyltriazenes (**2*a–h*)** is the sum of the rates of three distinct processes: (*i*) the spontaneous decomposition (k_{sp}); (*ii*) an acid-catalyzed reaction (k_{H^+}); and (*iii*) a buffer-catalyzed reaction (k_B). The measured rate constant, k_{obs}, must itself have three components and may be expressed as follows:

$$[3] \quad k_{obs} = k_{sp} + k_{H^+}[H^+] + k_B[B]$$

The only uncertain quantity in this expression is [B], which could be assumed to be either the buffer anion concentration [A^-], or the buffer acid concentration [HA], or the total buffer concentration {[A^+] + [HA]}. As a first step we used the total buffer concentration, which was plotted against the k_{obs} at pH 3.3 for each substituent. The slope of each line affords k_B for the respective substituent and these values are shown in Table 8. A Hammett plot of log k_B versus σ_p gives a good straight line fit with $\rho = +0.55$. Since the ρ-value for

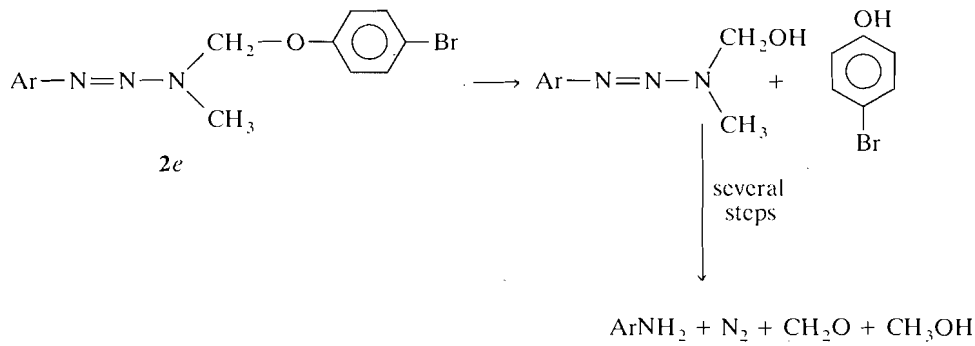

FIG. 6

the specific acid-catalyzed reaction has a negative value (see below), this observation is more consistent with a buffer anion catalyzed S_N2 displacement of the leaving group.

Using the k_B from the analysis above, the next step was to plot, for each substituent, the term $\{k_{obs} - k_B[B]\}$ versus $[H^+]$. The slope of this line gives the k_{H^+} for each substituent, and the intercept at $[H^+] = 0$ gives k_{sp}. The results are tabulated in Table 8, but it should be noted that these values represent an approximation due to the uncertainty in the pH value of the mixed solvent system and also because of the difficulty of relating one buffer system to another with respect to the k_B term in eq. [3].

The kinetic analysis in Table 8 is consistent with the three mechanisms shown in Fig. 9. The spontaneous rate constant turns out to be essentially zero for all but the nitro and cyano substituted compounds (**2***g* and **2***h*), which is consistent with a spontaneous dissociation mechanism, Fig. 9 (*i*), affording the iminium ion and the free phenolate ion. This

pathway is evidently facilitated by the presence of a strongly electron-withdrawing substituent (X), which improves the leaving group character of the aryloxy group beyond the apparent threshold for reactivity.

The Hammett plot of k_{H^+} versus σ_p gives a negative value, consistent with the proton-catalyzed mechanism, Fig. 9 (*ii*). Protonation of the ether oxygen precedes the dissociation step so that this pathway is favoured by an increase in electron

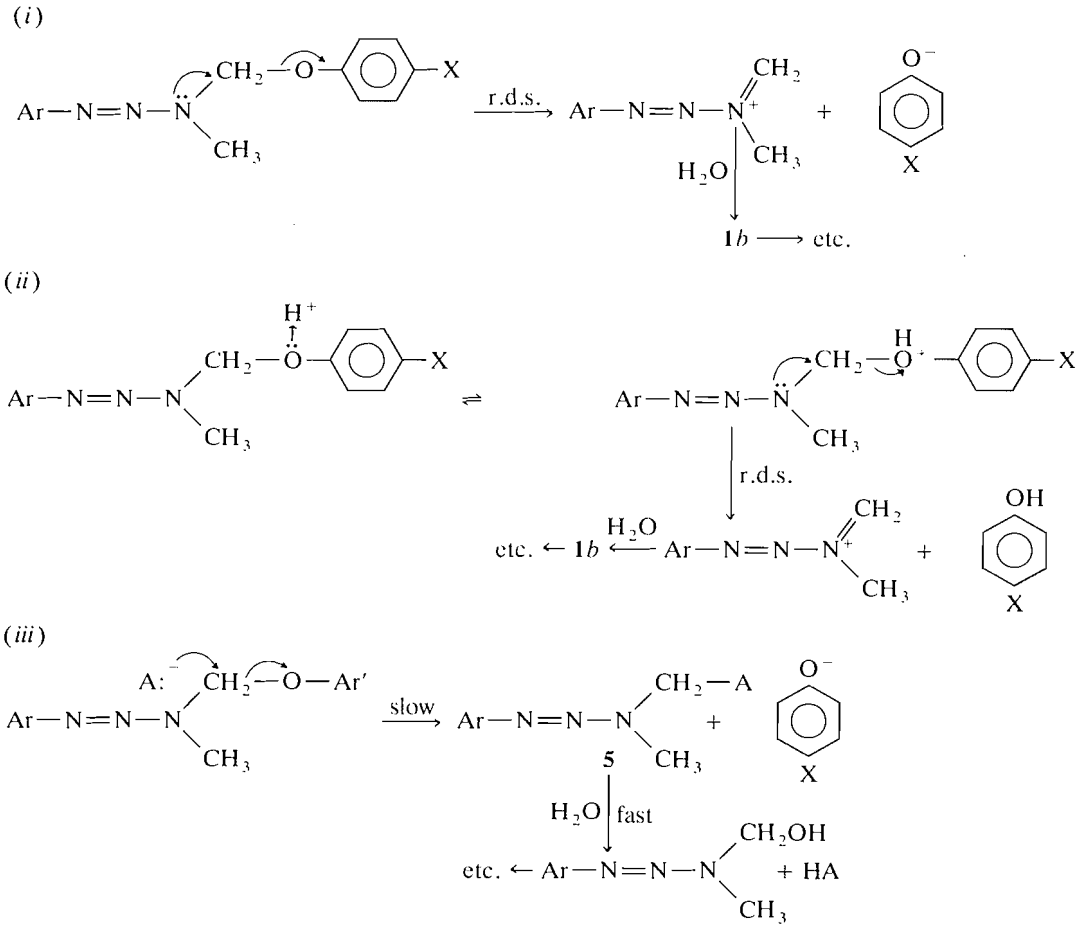

FIG. 9

density at the ether oxygen when an electron-releasing substituent is present at X.

The surprising result of this analysis is the positive ρ-value obtained from the Hammett plot for the buffer-catalyzed reaction. Significantly, the slope of this Hammett plot was still positive when we carried out the analysis using buffer acid concentration [HA] in place of [B] in eq. [4]. If the buffer catalysis was due to general acid catalysis by the buffer acid, HA, then the slope of the Hammett plot should be negative in the same manner as the specific acid catalysis. The positive ρ for the buffer-catalyzyed reaction is consistent with the nucleophilic catalysis mechanism, Fig. 9 (*iii*), in which the anion A^- causes a slow displacement of the aryloxy leaving group followed by fast displacement of A^- by water. When A^- is formate, the intermediate **5** is similar in structure to an acetoxymethyltriazene (**1***d*), which is known to hydrolyse rapidly in buffer solution (6).

If the hypothesis of Fig. 9 (*iii*) is correct, then there should be a similar or possibly better fit of the data to eq. [3] using the buffer anion concentration $[A^-]$ in place of total buffer concentration. The results of such an analysis are shown in Table 9; k_A replaces k_B. The results are essentially the same as those in Table 8; the slope of the specific acid-catalysis Hammett plot turns out to be more negative, indicating a greater sensitivity to the electronic character of X. Thus the analysis presented in Table 9 provides added support to the mechanistic hypothesis in Fig. 9. However, an alternative mechanism involving the displacement of ArOH by S_N2 attack of the buffer anion on the protonated substrate, i.e.,

cannot entirely be ruled out.

To verify that there is specific acid catalysis in the hydrolysis of the aryloxymethyltriazenes, a solvent deuterium isotope experiment was performed with the *p*-bromophenyloxymethyltriazene (**2***e*). The rate of hydrolysis of **2***e* at pH 3.07 in buffer/D_2O (k_D) was compared with the rate of hydrolysis in buffer/H_2O (k_H) at 40°C, using nondeuterated isopropanol as the cosolvent. The observed ratio, k_H/k_D = 1.60, may only be an appparent value due to the possible exchange of deuterium with the solvent; the true value of k_H/k_D could be as high as 2.28. Nevertheless, it can be said categorically that there is a solvent deuterium isotope effect in the hydrolysis of **2***e* at pH 3.07, which supports the prior argument that the hydrolysis is subject to specific acid catalysis.

Conclusion

In conclusion, it is interesting to compare the results of this study with similar work of Iley *et al.* (10)[3] on the kinetics of hydrolysis of the 1-aryl-3-alkoxymethyl-3-methyl triazenes (**1***c*). These compounds hydrolyse in acidic solutions to give the corresponding anilines, and the kinetic study, over the pH range 1–5, showed that the reaction suffers specific acid catalysis. Apparently, the alkoxymethyltriazenes do not decompose spontaneously and do not react by an anion-catalyzed mechanism analogous to that shown in Fig. 9 (*iii*) for the aryloxymethyltriazenes. This behaviour is entirely consistent with the subtle, but significant, difference in structure between the alkoxy- and aryloxy-methyltriazenes, in particular with respect to the leaving group ability. Evidently, the methoxide ion, MeO^-, is not able to dissociate spontaneously, nor is it readily displaced by weak anions, whereas the aryloxide ion can suffer both types of reaction in addition to the specific acid-catalyzed reaction shared by both classes of compound.

Finally, is there any point in considering these aryloxy methyltriazenes as candidates for drug screening? The results reported in this paper clearly show that the stability of these compounds in aqueous media is exquisitely sensitive to the electronic character of the X substituent in the aryloxy moiety; the half-lives range from 1 min to several days! Thus, it is highly probably that a suitable aryloxymethyl triazene can be tailor-made with the perfect chemical stability and slow-release characteristics for use as a pro-drug. Preliminary investigations of the biological activity of these new compounds shows that some members of the series demonstrate stastically significant differential toxicity to several cell lines of the NCI tumour panel.

The acidity of polyhalogenated silanes and silyl radicals

C. F. RODRIQUEZ AND A. C. HOPKINSON[1]
Department of Chemistry, York University, North York, Ont., Canada M3J 1P3

Received January 13, 1992

C. F. RODRIQUEZ and A. C. HOPKINSON. Can. J. Chem. **70**, 2234 (1992).

The results of *ab initio* molecular orbital calculations at the MP4SDTQ/6-31++G(*d*,*p*)//HF/6-31++G(*d*,*p*) level have been used to calculate acidities of fluoro- and chloro-substituted silanes and silyl radicals. The radicals are more acidic than the silanes and substituent effects are also slightly larger in the radicals. For the gas phase deprotonation of fluorosilanes at 298 K, ΔH_r (kcal/mol) values are SiH_4, 378.5; SiH_3F, 374.5; SiH_2F_2 366.7, and $SiHF_3$, 351.0, i.e., interaction between fluorine atoms leads to increased enhancement of acidity. For chlorosilanes substituent effects are larger but strictly additive (13 kcal/mol for each Cl atom) with ΔH_r values SiH_3Cl, 365.4; SiH_2Cl_2 352.5, and $SiHCl_3$ 339.4. The electron affinities of silyl radicals calculated using isogyric reactions at the MP4SDTQ/6-31++G(*d*,*p*) level are too low by ~0.3 eV, but at the MP4SDTQ/6-311++G(*2df*,*p*) level the calculated electron affinity of SiH_3 is 1.39 eV, compared with an experimental value of 1.44 ± 0.03 eV. This higher level of theory gives calculated electron affinities of 1.53 eV for SiH_2F and 1.92 eV for SiH_2Cl. Heats of formation obtained by using isogyric reactions to calculate atomization energies at the MP4SDTQ/6-311++G(*2df*,*p*) level are within 3 kcal/mol of experimental values except for SiH_2F (where the "experimental" value was obtained from linear interpolation between SiH_3 and SiF_3). ΔH_f^0 (298 K) (kcal/mol) calculated for the anions are SiH_3^-, 14.4; SiH_2F^-, −78.0; and SiH_2Cl^-, −37.6.

C. F. RODRIQUEZ et A. C. HOPKINSON. Can. J. Chem. **70**, 2234 (1992).

On a utilisé les résultats de calculs d'orbitales moléculaires *ab initio* au niveau MP4SDTQ/6-31++G(*d*,*p*)//HF/6-31++G(*d*,*p*) pour calculer les acidités de silanes et de radicaux silyles substitués par un chlore ou un fluor. Les radicaux sont plus acides que les silanes et les effets des substituants sont aussi un peu plus prononcés dans les radicaux. Pour la déprotonation en phase gazeuse des fluorosilanes à 298 K, les valeurs du ΔH_r (kcal/mol) sont SiH_4, 378,5; SiH_3F, 374,5; SiH_2F_2, 366,7 et $SiHF_3$, 351,0 ce qui signifie que les interactions entres les atomes de fluor provoquent une plus grande augmentation de l'acidité. Pour les chlorosilanes, les effets des substituants sont plus importants, mais strictement additifs (13 kcal/mol pour chaque atome de Cl) avec des valeurs de ΔH_r de SiH_3Cl, 365,4; SiH_2Cl_2, 352,5 et $SiHCl_3$, 339,4. Les affinités électroniques des radicaux silyles calculées en faisant appel aux réactions isogyriques au niveau MP4SDTQ/6-31++G(*d*,*p*) sont trop basses par ~0,3 eV, mais au niveau MP4SDTQ/6-311++G(*2df*,*p*), l'affinité électronique calculée pour le SiH_3 est égale à 1,39 eV comparée à une valeur expérimentale de 1,44 ± 0,03 eV. Le niveau de théorie plus élevée conduit à des valeurs calculées pour les affinités électroniques de SiH_2F et de SiH_2Cl de 1,53 et 1,92 eV. Les chaleurs de formation obtenues en utilisant les réactions isogyriques pour calculer les énergies d'atomisation au niveau MP4SDTQ/6-311++G(*2df*,*p*) ne different que par 3 kcal/mol des valeurs expérimentales, à l'exception de SiH_2F (alors que la valeur «expérimentale» a été obtenue par interpolation linéaire entre le SiH_3 et le SiF_3). Les valeurs des ΔH_r^0 (298 K) (kcal/mol) calculées pour les anions sont SiH_3^-, 14,4; SiH_2F^-, −78,0 et SiH_2Cl^-, −37,6.

[Traduit par la rédaction]

Introduction

Electron-withdrawing substituents assist in delocalizing negative charge and are strongly stabilizing in carbanions (1–3). By contrast, substituent effects in methanes are relatively small and consequently electron-withdrawing substituents greatly enhance the acidity of methane. Silicon accommodates a negative charge more easily than carbon and silane is more acidic than methane (experimental acidities (4) are 376 and 417 kcal/mol respectively). Stabilization of the anion by substituents then is less of a factor in determining the acidity of silanes, and first-row substituents NH_2 and OH, which both enhance the acidity of methane, actually decrease the acidity of silane (5–7). A fluorine substituent also increases the acidity of methane, but its effect on the acidity of silane is less clear. Hartree–Fock calculations with (DZ + *d*) (5) and 6-31G** (6) basis sets have shown fluorine to increase the acidity of silane by small amounts while the most recent calculations (7), which include correlation energy, show a fluorine substituent to decrease the acidity. Second-row substituents SiH_3, PH_2, SH, and Cl are more polarizable than their first-row counterparts, and all greatly enhance the acidities of both methanes (3) and silanes (7).

Recently, there has been considerable interest in the geminal interactions between fluorine atoms (8) and between oxygen atoms (9). Negative hyperconjugation as illustrated for SiH_2F_2 (structure **1**) involves donation from the lone pair on one fluorine atom F_a to the σ* orbital of the other Si—F bond. The reciprocal interaction, donation from F_b to σ* for Si—F_a, makes an equivalent contribution. The stabilization resulting from these interactions can be estimated from eq. 1. Using this approach, Schleyer has shown the geminal interactions in SiH_2F_2 to be 7.7 kcal/mol and in $SiHF_3$ to be 17.5 kcal/mol (8)

[1] $$SiH_mF_n + (n-1)SiH_4 \rightarrow nSiH_3F$$

In anions, halogen substituents carry a large fraction of the excess negative charge and this enhances their ability to function as π-donors. Also, in anions the molecular orbitals are more weakly bound and, more importantly as regards negative hyperconjugation, the antibonding molecular orbitals are lower in energy and more available for the type of interaction outlined in structure **1**. Both conditions necessary for a strong negative hyperconjugative interaction, namely the presence of a powerful π-donor and a readily available σ* orbital, then are present in geminally substituted anions and the interaction is expected to be larger than in neutral molecules. Any such increased interaction should lead to an increased stabilization of the anions, which in turn

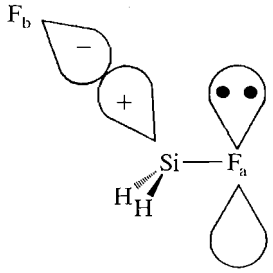
should be reflected in an increase in acidity. The objective of this study, then, is to examine the synergistic effect, if any, of halogen substituents on the acidities of silanes and silyl radicals. We have used all possible combinations of fluorine and chlorine substituents. Our calculations on silyl radicals and silyl anions also permit us, in principle, to make estimates of the electron affinities of radicals. We report calculated electron affinities for several silyl radicals but for the larger radicals they must be considered to be lower estimates as accurate calculation of electron affinities requires extremely high levels of calculation (10–12), higher than is computationally feasible for the larger radicals studied here.



1

Theoretical details

Ab initio molecular orbital calculations were performed with GAUSSIAN 82 (13) and GAUSSIAN 86 (14). Molecular geometries were optimized at the HF/6-31++G(*d*,*p*) level (3, 15–17) employing analytical gradients (18, 19), and structural details, including some already published data on anions (20), are given in Table 1. Vibrational frequency calculations computed at HF/6-31++G(*d*,*p*) showed all the structures to be minima (i.e., no imaginary frequencies) and yielded the zero-point energies given in Table 2. Electron correlation energies were calculated by single-point calculations with frozen core Møller–Plesset perturbation theory (21, 22) including single, double, triple, and quadruple excitations. Electronic energies from three levels of theory, the HF optimization, MP2(full), and MP4SDTQ (frozen core), are given in Table 2. Electronic energies from MP4/6-311++G(2*df*,*p*) (23) calculations on some of the smaller molecules are given in Table 3.

We use the proton affinities of anions as a measure of the acidity of silanes and silyl radicals. The difference in electronic energies of SiH_mX_n and $SiH_{(m-1)}X_n^-$, when corrected for the difference in zero-point energies, gives ΔH(0 K) for the reaction in eq. [2]. Relatively small corrections, the last four terms in eq. [3], are then needed to calculate ΔH(298 K).

[2] $$SiH_mX_n \rightarrow SiH_{(m-1)}X_n^- + H^+$$

[3] $$\Delta H(298\text{ K}) = \Delta E^{elec} + \Delta E^{vib}_{zero\text{-}point} + \Delta E^{vib}_{0-298} + \Delta E^{rot}_{298} + \Delta E^{trans}_{298} + \Delta(PV)_{298}$$

ΔE^{vib}_{0-298} was obtained from standard statistical formulas (24), translational and rotational energies were calculated classically, and a pressure–volume term for the formation of two molecules from one, *RT*, was added. Values of ΔH(298 K) for reaction [2] are given in Table 4.

Calculation of electron affinities using eq. [4] presents a problem since the product silyl anion has one more pair of electrons than the reactants, i.e., there is a difference in correlation energy. Using eq. [4] with calculations in which correlation energy is omitted (i.e., HF level calculations) produces electron affinities that are too small (and often negative). Even medium-sized basis set calculations that include correlation energy often yield unacceptably low values of electron affinities (10, 11).

[4] $$SiH_mX_n^- \rightarrow SiH_mX_n + e$$

A better method, which minimizes problems due to correlation effects, is to use a reaction in which there is an equal number of unpaired electrons in both reactants and products. For silyl radicals the appropriate isogyric reaction is given in eq. [5].

[5] $$SiH_2X^- + 2H \rightarrow SiH_2X + H_2 + e$$

The electron affinity of the radical SiH_nX_m is obtained by first calculating ΔE^{elec} for eq. [5] using energies from *ab initio* molecular orbital calculations, then adding D_e, the dissociation energy of H_2 (0.17447 hartrees), to yield ΔE^{elec} for eq. [4]. Finally, correction for the difference in zero-point energies of SiH_nX_m and $SiH_nX_m^-$ gives the calculated electron affinity. Values obtained with various levels of theory are given in Table 6.

Results and discussion

Structures

The optimized geometries of the fluorosilanes (Table 1) are in excellent agreement with experimental values. Previously reported structural parameters for the fluorosilanes optimised at the Hartree–Fock level with the slightly smaller 6-31G(*d*) basis set are also in excellent agreement (25). Increasing the number of fluorine atoms results in a systematic shortening of the Si—F bond distances by ~0.016 Å per fluorine atom. This same trend, with approximately the same shortening, occurs in the silyl radicals and also in both series of fluorinated anions. Multiple substitution by chlorine atoms also leads to a shortening of Si—Cl bond distances and this is particularly pronounced in the anions (the distance in $SiCl_2^-$ is 0.044 Å shorter than in $SiHCl^-$). Similar systematic changes in the fluoromethanes have been rationalized in terms of electrostatic effects (8, 25–28). Following this argument, increasing the number of fluorine atoms increases the positive charge on the central silicon atom and decreases the covalent radius of the silicon, thereby making the Si—F bond shorter.

The geometries of the silyl anions and radicals in Table 1 differ very slightly from those reported in our previous work (20) because we have now included polarization functions on the hydrogen atoms. Comparison of the structures of Brønsted acid/base pairs show some major differences in geometries. Removal of a proton from silicon results in elongation of the remaining Si—H bonds by 0.06–0.07 Å. The Si—F bonds increase by 0.09 Å and Si—Cl by over 0.2 Å, with the largest change 0.224 Å, in the deprotonation of SiH_2Cl. The Si—Cl bond is weak, particularly in anions where there is a tendency to dissociate into SiH_n and Cl^-, and we were concerned that such ions were not adequately described at the HF/6-31++G(*d*,*p*) level. We therefore optimized SiH_2Cl^- at the MP2(full)/6-31++G(*d*,*p*) level and the result was a somewhat shortened Si—Cl bond (2.247 Å compared with 2.284 Å) but the Si—Cl distance was still 0.178 Å longer than in SiH_3Cl.

[a]Distances in angstroms, angles in degrees.
[b]Experimental geometries are in parentheses. These were taken from ref. 4.
[c]The out-of-plane angle, α, in SiX_2Y is defined as the supplement of the angle between the SiY bond and the line bisecting the SiX_2 angle.
[d]Optimization at MP2/6-31++G(*d*,*p*) gave SiF 1.738; SiH 1.536; HSiH 94.3; FSiH 97.5; and α 78.9. The total energy was −389.84718 a.u., which is 0.3 kcal/mol better than obtained in the MP2(full)/6-31++G(*d*,*p*)//SCF/6-31++G(*d*,*p*) calculation.
[e]Optimization at MP2/6-31++G(*d*,*p*) gave SiCl 2.247; SiH 1.523; HSiH 94.4; ClSiH 95.6; and α 81.7. The total energy was −749.84843 a.u., which is 0.1 kcal/mol better than obtained in the MP2(full)/6-31++G(*d*,*p*)//SCF/6-31++G(*d*,*p*) calculation.

Bond distances in silylene anions, $SiHX^-$, are considerably longer than in silyl radicals, SiH_2X, and also are slightly longer than in the silyl anions. The parent silylene anion, SiH_2^-, has a bond angle of 94.0°, close to the angle of 93.3° calculated for SiH_2 (29, 30). These structures are consistent with the lone pair on silicon being essentially in the 3*s* atomic orbital with only the 3*p* orbitals being involved in bonding. The halide-substituted silylene anions have slightly larger bond angles, with the largest being 98.5° in $SiCl_2^-$.

Acidities

As outlined above, we use ΔH_r for the loss of a proton (eq. [2]) to assess acidities. A low ΔH_r value indicates a high acidity and, applying this criterion to the data in Table 4, $SiHCl_2$ is the most acidic molecule and SiH_4 is the least.

Equation [2] contains the same number of electron pairs in both the reactant molecule and the product ions and the calculated ΔH_r is therefore expected to show little dependence on correlation energy. Inclusion of correlation energy at the MP2(full) and more extensive MP4SDTQ levels results in the same relative order of acidities with the MP4 calculations always giving the lower ΔH_r values, but the difference in calculated ΔH_r values for any molecule is never greater than 1.4 kcal/mol. However, comparison of the SCF and Møller–Plesset results in Table 4 reveal some systematic variations. For the fluorosilanes, comparing the calculated ΔH_r at the SCF level with the MP4 values, there is an incremental decrease of about 2.8 kcal/mol per fluorine atom. For the chlorosilanes the inclusion of correlation energy has the opposite effect and the calculated ΔH_r increases by 1–2 kcal/mol.

Inspection of Table 4 reveals several trends. The parent silyl radical is more acidic than silane ($\Delta\Delta H_r$ is 14.9 kcal/mol), and substituent effects are larger in the radicals. In the 6-31++G(*d*,*p*) calculations, fluorosilane is more acidic than silane, as in earlier relatively low-level calculations, but with the larger 6-311++G(2*df*,*p*) basis set both molecules have essentially the same acidity. Chlorine is a larger, more polarizable atom than fluorine and, as in methane (3, 31), it enhances the acidity of silane. Further chlorine substituents

have the systematic effect of increasing the acidity by ~13 kcal/mol per chlorine, i.e., the effect of chlorine substituents is roughly additive. The same trend occurs in the chlorosilyl radicals. With fluorosilanes and fluorosilyl radicals the situation is dramatically different. With the 6-31++G(*d*,*p*) basis set, monofluorosilane is only slightly more acidic than silane (the difference in ΔH_r is 4.0 kcal/mol), a second fluorine substituent increases the acidity by another 7.8 kcal/mol, and a third fluorine results in a further increase of 15.7 kcal/mol. The same trend, slightly more pronounced, occurs in the fluoro-substituted silyl radicals. These results then clearly demonstrate that fluorine–fluorine interactions have a synergistic effect on the acidity of silanes, but that similar interactions in chlorosilanes do not.

We have used eq. [1] to calculate the stabilization energies resulting from interaction between halogen atoms. The results in Table 5 show modest stabilization in the fluorosilanes, slightly smaller but comparable with values previously reported (8). In the fluorine-substituted silyl anions the stabilization is much larger and this difference in stabilization between an acid and its conjugate base is the origin of the increased acidity. For the deprotonation of fluorosilanes then, the decrease in ΔH_r consists of an increment of ~4 kcal/mol per fluorine atom, attributable to the ability of fluorine to accommodate negative charge by σ-withdrawal, plus a contribution from the increased hyperconjugation in the anion relative to the fluorosilane. For example, $\Delta\Delta H_r$, the difference in acidities between difluorosilane and silane, consists of a term (2 × 4 = 8 kcal/mol) for the inductive stabilization by the two fluorine atoms and a term (4 kcal/mol) for

the difference in hyperconjugative stabilization of $SiHF_2^-$ (9.2 kcal/mol) and SiH_2F_2(5.25 kcal/mol). $\Delta\Delta H_r$ calculated by this method is 12.0 kcal/mol, and this compares with a value of 11.8 kcal/mol from Table 4. A similar calculation for $SiHF_3$ gives $\Delta\Delta H_r = (3 \times 4) + 14.2 = 26.2$ kcal/mol and this compares with a value of 27.5 kcal/mol from Table 4.[2]

There is little or no geminal interaction between chlorine atoms in both neutral molecules and in the anions (Table 5). One chlorine atom increases the acidity of silane by 13.0 kcal/mol and, in the absence of contributions from negative hyperconjugation, the effect of additional chlorine atoms is for each to increase the acidity by a further 13 kcal/mol. The silyl radicals are slightly more sensitive to substituent effects but here again there are negligible contributions from negative hyperconjugation and each chlorine atom increases the acidity by ~14.0 kcal/mol.

[2]Note the energies in Tables 4 and 5 are not strictly comparable. Table 4 contains ΔH_r values at 298 K and Table 5 contains ΔE^{elec}.

Electron affinities

We have calculated electron affinities by both the direct method in eq. [4] and by the more accurate isogyric reaction in eq. [5]. The results are in Table 6. Electron affinities at the SCF level using eq. [4] are the lowest and least reliable due to the neglect of correlation energy in a reaction where the number of electron pairs in the reactant and products differ. Comparison of electron affinities from the MP4 calculations shows the isogyric reaction to consistently give higher calculated values. Unfortunately there is only one experimental value for comparison, but our largest calculation (MP4/6-311++G(2*df*,*p*) on SiH_3 gives a calculated electron affinity of 1.39 eV, within 0.05 eV of the experimental value of 1.44 ± 0.03 eV (32) and within 0.03 eV of Pople's G2 level calculation of 1.42 eV (33). Previous work (12) has shown that molecular orbital calculations at this level consistently give electron affinities within 0.1 eV of the experimental values. We are therefore confident that the calculated electron affinities of 1.53 eV for SiH_2F and of 1.92 eV for SiH_2Cl should be accurate within 0.1 eV.

The MP4/6-31++G(*d*,*p*) calculations using the isogyric reaction clearly underestimate the electron affinities, probably by 0.2–0.3 eV. For the disubstituted radicals it was not computationally feasible to use a higher level of theory and the calculated electron affinities of 1.82 eV for $SiHF_2$, 2.27 eV for $SiHCl_2$, and 2.08 eV for SiHClF should be taken

only as lower estimates, with the correct electron affinity probably being about 0.3 eV higher.

Heats of formation

Recently *ab initio* molecular orbital calculations were used to calculate heats of formation of SiH_n (29, 34–36), SiH_nF_m (35, 37), and SiH_nCl_m (38). When large basis sets are used, and correlation energy is calculated at the MP4 level it is possible to calculate ΔH_f^0(298 K) to at least within 3 kcal/mol (38). Two approaches have been used, one including experimental heats of formation for SiH_n and SiF_4 in isodesmic reactions (35), and the other calculating heats of atomization. We have used the latter procedure with our MP4SDTQ/6-311++G(2*df*,*p*) calculations to obtain the ΔH_f^0 values in Table 7.

We illustrate our method, essentially that introduced by Pople *et al.* (29, 34), by using the example of SiH_2Cl^-. Our initial objective was to obtain ΣD_0, the heat of atomization, for the reaction in eq. [6].

[6] $SiH_2Cl^- \rightarrow Si + 2H + Cl^-$

This reaction is not isogyric and, in an attempt to minimize the difference in correlation energy, we calculated the ΔE^{elec} for eq. [7] and then used a correction of 0.17447 a.u. per hydrogen molecule to obtain ΣD_e = 201.8 kcal/mol for eq. [6].

[7] $4H + SiH_2Cl^- \rightarrow Si + 2H + Cl^- + 2H_2$

Subtraction of the zero-point energy of SiH_2Cl^- gave ΣD_0 = 192.8 kcal/mol. Addition of the electron affinity of chlorine (calculated to be 82.1 kcal/mol at MP4SDTQ/6-311++G(2*df*,*p*)) gave ΣD_0 for eq. [8] to be 274.9 kcal/mol.

[8] $SiH_2Cl^- \rightarrow Si + 2H + Cl + e$

From standard thermochemical tables (39) $\Sigma\Delta H_f^0$ (0 K) for the product atoms in eq. [8] is 238.5 kcal/mol and, combining this with ΣD_0, gives ΔH_f^0 (0 K) = −36.4 kcal/mol. Using standard heat capacities for Si(c), H_2(g), and Cl_2(g) (39) and calculated thermal energy and work terms for SiH_2Cl^- to correct to 298 K gives ΔH_f^0 (298 K) = −37.6 kcal/mol.

For the limited number of molecules for which experimental heats of formation are available, the theoretical ΔH_f^0 (298 K) in Table 7 are mainly within 3 kcal/mol. The one exception is SiH_2F and in this instance the "experimental" value was obtained by interpolation between experimental values for SiH_3 and SiF_3. The other theoretical ΔH_f^0 (298 K) for SiH_2F in the literature (35) is close to our value and, noting that agreement between experiment and theory at this level is usually within 3 kcal/mol, we conclude that the "experimental" value is probably in error by about 4 kcal/mol.

Conclusions

Substitution of one fluorine into silane has little effect on the acidity but when a second is introduced negative hyperconjugation between the two fluorine atoms stabilizes the anion more than the silane and the energy for deprotonation decreases. A third fluorine substituent results in even greater stabilization by negative hyperconjugation and a much larger increase in acidity. By contrast, one chlorine atom enhances the acidity of silane by ~13 kcal/mol, but negative hyperconjugation between chlorine atoms is insignificant and further substitution results in incremental increases of ~13 kcal/mol for each additional chlorine atom. Silyl radicals are more acidic than silanes, but the same trends in substituent effects occur.

To calculate electron affinities it is essential to include correlation energy and from the limited data here it is obvious that a larger basis set than 6-31++G(*d*,*p*) is required. Extensive calculations at MP4SDTQ/6-311++G(2*df*,*p*) have been shown to consistently give electron affinities within 0.1 eV of experimental values and our calculated value for SiH_3 is within this limit (0.05 eV below the experimental value). We therefore believe the calculated electron affinities of SiH_2F (1.53 eV) and of SiH_2Cl(1.92 eV) should be reliable.

For personal use only.

Heats of formation can be calculated within ±3 kcal/mol of experimental values only if very high levels of theory are used. From our MP4SDTQ/6-311++G(2*df*,*p*) calculations we find good agreement both with previous theoretical and experimental ΔH_f^0 (298 K) values. For SiH_2F the "experimental" ΔH_f^0 (298 K) of −49 ± 5 kcal/mol is lower than both the previous (−44.9 kcal/mol) and our (−42.8 kcal/mol) theoretical values. We therefore suggest that the "experimental" value is too low by about 5 kcal/mol.

Synthesis of a series of 3-aryl-1-methyltriazene 1-oxides with substituents in the *ortho* or *para* position in the aryl group

LYNN M. CAMERON AND KEITH VAUGHAN[1]
Department of Chemistry, Saint Mary's University, Halifax, N. S., Canada B3H 4J3

AND

DONALD L. HOOPER

Received January 2, 1992

LYNN M. CAMERON, KEITH VAUGHAN, and DONALD L. HOOPER. Can. J. Chem. **70**, 2241 (1992).

A series of 3-aryl-1-methyltriazene 1-oxides, with a variety of substituents in the *ortho* or *para* position, have been prepared by coupling of the appropriate diazonium salt with *N*-methylhydroxylamine. The substituents range from electron withdrawing, i.e., CO_2Et, NO_2, CN, $COCH_3$, Br, and CF_3, to electron releasing, i.e., OCH_3. In all cases studied, the triazenes exist as the 1-oxide tautomer; there is no evidence for the presence of a 3-hydroxy tautomer in any of these cases. The 1-oxide structures have been confirmed by IR and NMR spectroscopy and by elemental analysis of new compounds. In the case of the -CO_2Et and -CN substituents, a significant change to lower frequency is seen in the N—H vibration frequency in the IR spectra when the substituent is moved from the *para* to the *ortho* position. This change can be readily explained by the presence of intramolecular H-bonding, which is confirmed by the NMR spectra. The presence of an ortho substituent with H-bonding potential (i.e., CO_2Et, -$COCH_3$, or NO_2) causes a downfield shift of the N—H proton resonance.

LYNN M. CAMERON, KEITH VAUGHAN et DONALD L. HOOPER. Can. J. Chem. **70**, 2241 (1992).

Utilisant le couplage d'un sel de diazonium approprié avec la *N*-méthylhydroxylamine, on a préparé une série de 1-oxydes de 3-aryl-1-méthyltriazènes portant divers substituants dans les positions *ortho* et *para*. Les substituants comportent des groupes électro-attracteurs comme CO_2Et, NO_2, CN, $COCH_3$, Br et CF_3 et des groupes électro-donneurs comme OCH_3. Dans tous les cas étudiés, les triazènes existent sous la forme du tautomère 1-oxyde; dans aucun de ces cas, on n'a pu mettre en évidence la présence du tautomère 3-hydroxy. Les structures 1-oxydes ont été confirmées par les spectroscopies IR et RMN et par des analyses élémentaires des nouveaux composés. Dans le cas des composés portant les substituants -CO_2Et et -CN, on observe un déplacement important de la fréquence de vibration du N—H dans l'IR lorsqu'on déplace le substituant de la position *para* vers la position *ortho*. On peut facilement expliquer ce changement par la présence de liaisons hydrogènes intramoléculaires que l'on a pu confirmer par les spectres RMN. La présence d'un substituant en *ortho* pouvant former une liaison hydrogène (comme -CO_2Et, -$COCH_3$ ou NO_2) provoque un déplacement de la résonance du proton du N—H vers les bas champs.

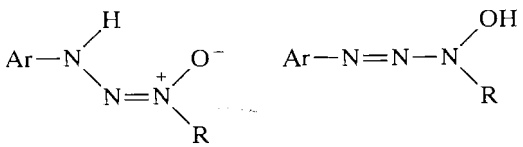
Introduction

3-Aryl-1-alkyltriazene 1-oxides (**I***a*) are commonly synthesized by the reaction of an aryldiazonium salt with *N*-methylhydroxylamine (1) and were originally described as 1-aryl-3-hydroxy-3-methyltriazenes (**I***b*).



I*a*

I*b*

Spectroscopic studies using IR (2) and NMR (3) data suggested that the structure was better described as the 1-oxide (**I***a*), which has been confirmed by the X-ray crystallographic analysis of 3-(4-carbamoylphenyl)-1-methyltriazene 1-oxide (4).

Additional interest in these triazene 1-oxides stems from their observed anti-tumour activity against certain tumours in rodents (5) and from the recent suggestion that a triazene 1-oxide may be implicated in the metabolism of the anti-tumour 1-aryl-3,3-dimethyltriazenes (6).

The tautomerism of **I***a* and **I***b* bears some resemblance to the tautomerism exhibited by 1-aryl-3-alkyltriazenes, Ar·N=N—NHR ⇌ Ar·NH—N=NR ("mono-methyltriazenes"). The monomethyltriazene tautomerism has been shown to be strongly influenced by the presence of electron-withdrawing groups in the *ortho* and *para* positions of the aryl group (7). It is possible that the tautomerism of **I***a* and **I***b* might similarly be affected by the nature and position of substituents in the aryl group, so we have undertaken to synthesize a series of *ortho*- and *para*-substituted 3-aryl-1-methyltriazene 1-oxides and to investigate their structures by spectroscopic analysis.

Experimental

Infrared spectra were recorded with a Perkin Elmer model 299 spectrophotometer. NMR spectra were obtained with Varian EM360 (60 MHZ) and Nicolet 360NB (360 MHZ) spectrometers. Elemental analysis was carried out by the Canadian Microanalytical Service, Vancouver, B.C., Canada.

*3-Aryl-1-methyltriazene 1-oxides (**1–16**)*

The appropriately substituted aniline (0.01 mol) was dissolved in 2 N hydrochloric acid (15 mL, 0.03 mol) and heated if necessary. Once the solution became clear, it was cooled to 0–5°C. A solution of sodium nitrite (0.011 mol) in a minimum amount of water was added slowly to the cold anilinium hydrochloride solution and the resulting mixture was stirred cold for 0.5 h. The cold

diazonium salt solution was filtered, if necessary, to remove any insoluble impurities, and then treated with a solution of *N*-methylhydroxylamine hydrochloride (0.015 mol) in a minimum volume of water. After stirring the mixture for 15 min., a saturated solution of sodium bicarbonate was added until the solution was neutral, whereupon the triazene 1-oxide precipitated and was collected by vacuum filtration. The dry 1-oxide was recrystallized from an appropriate solvent. Yields, melting points, and IR data of the triazene 1-oxides are given in Table 1.

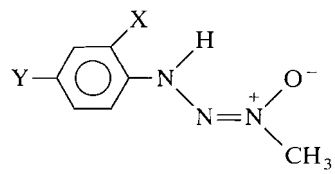
Results and discussion

The diazonium coupling reaction with *N*-methylhydroxylamine gave good yields of all 16 of the 3-aryl-1-methyltriazene 1-oxides and the yield does not appear to be affected by the location of the substituent, i.e., *ortho* or *para*. However, the yield was statistically lower when the electron-releasing methoxyl group was present. Several of the triazene 1-oxides studied here are known compounds; literature mp's and references are footnoted in Table 1. All new compounds were analyzed for the principal elements and the elemental analyses for these nine compounds and known compound **6** are given in Table 2.

All of the compounds prepared in this study showed spectral characteristics of the triazene 1-oxide tautomer (**I***a*) and not the 3-hydroxytriazene (**I***b*). These spectral properties, IR and NMR, are discussed separately in the following sections.

Infrared spectra

The infrared spectra of all the 3-aryl-1-methyltriazene 1-oxides (**1**–**16**) display distinct N—H stretching vibration bands in the range 3190–3298 cm^{-1}, with no evidence of an O—H stretching vibration band. This observation confirms that these compounds exist in the preferred 1-oxide tautomeric form (**I***a*) and not the *N*-hydroxytriazene form (**I***b*). A closer look at the variation of the N—H stretching frequency with the substituent reveals an interesting observation as the substituent is moved from the *para* to the *ortho* position.



1	X = Y = H	**9**	X = $COCH_3$, Y = H
2	X = H, Y = CO_2Et	**10**	X = H, Y = CF_3
3	X = CO_2Et, Y = H	**11**	X = CF_3, Y = H
4	X = H, Y = NO_2	**12**	X = H, Y = m-CF_3
5	X = NO_2, Y = H	**13**	X = H, Y = OCH_3
6	X = H, Y = CN	**14**	X = OCH_3, Y = H
7	X = CN, Y = H	**15**	X = H, Y = Br
8	X = H, Y = $COCH_3$	**16**	X = Br, Y = H

In the case of the nitro, trifluoromethyl, and bromo substituents, the change of position from *para* to *ortho* causes negligible change in the N—H frequency. When the substituent is cyano, a small but significant change of frequency occurs with a slight shift of 21 cm^{-1}. The most significant difference is observed in the case of the acetyl substituent (3274 cm^{-1} for **8** (*para*-$COCH_3$) and 3190 cm^{-1} for **9** (*ortho*-$COCH_3$)) and the ester group (3275 cm^{-1} for **2** (*para*-CO_2Et) and 3229 cm^{-1} for **3** (*ortho*-CO_2Et)). This change is consistent with the presence of an intramolecular H-bond, which causes a slight weakening of the N—H bonding interaction and, hence, a shift to lower vibration frequency. The intramolecular H-bond has a similar effect on the carbonyl stretching vibration band in **3** and **9**.

It may be significant that the electron-releasing methoxy

substituent gives a reverse effect. The N—H frequency is significantly higher in the *ortho*-substituted compound (**14**) than in the *para*-substituted isomer (**13**). However, there is no immediately obvious explanation for this phenomena.

NMR spectra

The most significant feature of the ^{1}H NMR data of the triazene 1-oxides (Table 2) is the variation of the N—H chemical shift as the substituent is moved from the *para* to the *ortho* position. The pattern is consistent with the hypothesis of an intramolecular H-bond derived from the IR spectral data.

In molecules that do not present the possibility of intramolecular H-bonding, the N—H chemical shift is consistent in the range 10.14–10.99 ppm. The presence of an *ortho* substituent with H-bonding potential (i.e., -CO_2Et, -Ac, or -NO_2) causes a downfield shift of the N—H proton to the range 12.40–13.18 ppm. This observation is consistent with the intramolecular H-bonding typified by structure II; interaction of the N—H proton with the electronegative oxygen

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

of the carbonyl (or nitro) group causes a decrease in electron density around the proton.

The NMR data also reveals more subtle effects on N—H chemical shift by electron-withdrawing and -donating groups in the *para* position. An electron-donating group (OMe) (**13**) in the *para* position causes an upfield shift of the N—H resonance compared to the unsubstituted compound (**1**), whereas the electron-withdrawing groups in **2**, **4**, **6**, **8**, and **10** shift the N—H resonance slightly downfield from that in **1**.

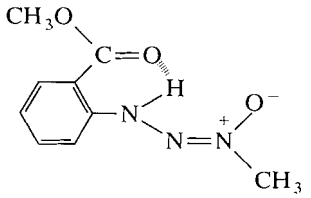
Other features of the ^{1}H NMR spectra are very predictable and show little variation with the nature or placement of the substituent.

The ^{13}C NMR spectra of the 3-aryl-1-methyltriazene 1-oxides (Table 3) confirm the assigned structures, but do not offer any particularly profound information concerning the **I***a* ⇌ **I***b* tautomerism question. The *N*-methyl ^{13}C resonance is consistently in the range 49.66–50.99 ppm and shows little sensitivity to the electron-releasing/withdrawing character or *ortho/para* location of the substituent (X or Y). The ring carbon atom closest to the region of potential tautomeric change, i.e., C-2, shows a little variation in ^{13}C resonance but the variation does not appear to correlate with the nature or position of the substituent. There are significant differences in the ^{13}C resonance of the ring carbons at C-5 and C-7 in the respective *ortho/para* isomeric pairs, but these changes are entirely predictable by consideration of the substituent location and do not indicate any influence from a tautomeric equilibrium.

The IR and NMR spectra of the series of 1-methyl-3-aryltriazene 1-oxides reported here show that these molecules prefer the 1-oxide tautomer (**I***a*) to the still unknown 3-hydroxytriazene structure (**I***b*). The preference for the 1-oxide tautomer may be further enhanced by the presence of a potentially H-bonding substituent in the *ortho* position of the aryl moiety.

Conclusion

The IR and NMR spectra of the series of 1-methyl-3-aryltriazene 1-oxides reported here, show that these molecules prefer the 1-oxide tautomer (**I***a*) to the still unknown 3-hydroxytriazene structure (**I***b*). The preference for the



II

1-oxide tautomer may be further enhanced by the presence of a potentially H-bonding substituent in the ortho position of the aryl moiety as illustrated by structure **II**. These observations have been corroborated by an X-ray crystal structure examination of two of the compounds in this series, namely **2** and **3** (8). The ortho isomer **3** shows definite evidence for the intramolecular hydrogen bond shown in structure **II**.

Synthesis and physico-chemical studies of newer mono and diperoxo heteroligand complexes of vanadium

MANISH BHATTACHARJEE,[1] MIHIR K. CHAUDHURI,[2] AND PRADIP C. PAUL
Department of Chemistry, North-Eastern Hill University, Shillong-793003, India

Received July 9, 1991[3]

MANISH BHATTACHARJEE, MIHIR K. CHAUDHURI, and PRADIP C. PAUL. Can. J. Chem. **70**, 2245 (1992).

The synthesis of monoperoxo-vanadium(V) complexes, $[VO(O_2)QL]$ (Q = 8-quinolinolate and L = EtOH, DMF, DMSO, or THF), and diperoxovanadates(V), $A_3[VO(O_2)_2(HPO_4)] \cdot 2H_2O$ (A = K or NH_4) are described. While the $[VO(O_2)QL]$ complexes have been synthesized from the reaction of V_2O_5 with H_2O_2 and a solution of 8-quinolinol in different donor solvents (L) at pH ca. 2, the oxodiperoxo(hydrophosphato) vanadate(V) dihydrates, $A_3[VO(O_2)_2(HPO_4)] \cdot 2H_2O$, have been prepared from the reaction of V_2O_5 with H_2O_2 and phosphoric acid at pH 6 of the reaction medium. The compounds have been characterized by chemical analyses, magnetic susceptibility, and molar conductance measurements, and by IR, laser Raman, ^1H NMR, and electronic spectroscopic studies. Evidence has been provided for triangularly bonded peroxide (O_2^{2-}) and coordinated heteroligands. The existence and stability of the complex $[VO(O_2)_2(HPO_4)]^{3-}$ in solution have been ascertained from solution Raman spectroscopy and conductance measurements.

MANISH BHATTACHARJEE, MIHIR K. CHAUDHURI et PRADIP C. PAUL. Can. J. Chem. **70**, 2245 (1992).

On décrit la synthèse des complexes monoperoxo–vanadium(V), $[VO(O_2)QL]$ (Q = 8-quinoléinolate et L = EtOH, DMF, DMSO ou THF) et diperoxovanadates(V), $A_3[VO(O_2)_2(HPO_4)] \cdot 2H_2O$ (A = K ou NH_4). Alors que les complexes $[VO(O_2)QL]$ ont été synthétisés par la réaction du V_2O_5 avec du H_2O_2 et une solution du 8-quinoléinol dans divers solvants donneurs (L), à un pH d'environ 2, les dihydrates de l'oxodiperoxy(hydrophosphato)vanadate $A_3[VO(O_2)_2(HPO_4)] \cdot 2H_2O$ ont été préparés par la réaction du V_2O_5 avec le H_2O_2 et de l'acide phosphorique, au pH de 6 du milieu réactionnel. On a caractérisé les produits par des analyses chimiques, par des mesures de susceptibilité magnétique et de conductivité molaire et par des études spectroscopiques IR, Raman au laser, RMN du ^1H et électroniques. On a obtenu des données relatives au peroxyde (O_2^{2-}) lié d'une façon triangulaire et aux hétéroligands qui sont coordonnés. Sur la base de la spectroscopie Raman et des mesures de conductivité, on a établi l'existence et la stabilité du complexe $[VO(O_2)_2(HPO_4)]^{3-}$ en solution.

[Traduit par la rédaction]

Introduction

Peroxo-vanadium systems are important for a variety of reasons including their role in oxidation catalysis (1,2) and biochemical relevance (3–9). Suitable heteroligands are known to bring about stability to such systems enabling isolation in the solid state, for instance, $NH_4[VO(O_2)_2(C_{10}H_8N_2)]$, which was synthesized by Vuletic and Djordjevic (10) and crystallographically characterized by Szentivanyi and Stomberg (11). In addition, the synthesis and structural assessment of several NO-donor–peroxo-vanadium(V) complexes with pyridine-2-carboxylate (1, 12), pyrazine-2-carboxylate (1), pyridine-2,6-dicarboxylate (13), iminodiacetate (14), and *N*-(2-oxidophenyl)salicylidinaminate (2) as the heteroligands are notable contributions to the domain of peroxo-chemistry of the metal. Over the past few years, we have been working in this area (15, 16) and our major emphasis has been on the development of newer synthetic methodologies as well as to synthesize new compounds. The selection of heteroligands is important and the coligands chosen for the present studies include 8-quinolinol and phosphate. While the importance of 8-quinolinol as a ligand has already been emphasized (17, 18), our concern with phosphate was to ascertain if it would form a peroxo(phosphato)vanadium(V) species. Such a complex is expected to be of considerable interest in the context of the vanadate–phosphate antagonism in physiology and the use of phosphate buffers in the reconstitution of vanadium bromoperoxidase. Since a citrate/phosphate buffer was used in the purification process of bromoperoxidases (3, 4, 19) containing vanadium(V), the possibility of phosphate coordination with a peroxovanadate(V) cannot be ruled out. Indeed, there has been definite evidence to support the formation of a mononuclear monophosphato–vanadium complex in aqueous solutions (20, 21).

In this paper, the synthesis and physico-chemical characterization of complexes of the type $[VO(O_2)QL]$ (Q = 8-quinolinolate and L = EtOH, DMSO, DMF, or THF) and $A_3[VO(O_2)_2(HPO_4)] \cdot 2H_2O$ (A = NH_4 or K) are presented. Also reported here are the results of solution Raman and conductance experiments in support of the existence and stability of the complex $[VO(O_2)_2(HPO_4)]^{3-}$ ion in solution.

Experimental

The chemicals used were all reagent grade products. The IR spectra were recorded on a Perkin Elmer model 983 spectrophotometer. The laser Raman (LR) spectra were recorded at ambient temperatures on a SPEX Ramalog model 1403 spectrometer using the line at 6471 Å of a Krypton laser from a Coherent model Innova 90-K(UV) as the excitation source. The UV–visible spectra were recorded in water or DMF solutions on a Hitachi model 330 spectrophotometer. Molar conductances were measured either in conductivity grade water or in DMF using a Systronics type 304 digital direct-reading conductivity bridge. The pH values of the reaction solutions were measured with a Systronics type 335 digital pH meter and also with pH indicator paper (BDH). The ^1H NMR spectra were recorded in deuterated DMSO using a Varian 390 90-MHz spectrometer. Tetramethyl silane (TMS) was used as the internal standard. Carbon, hydrogen, and nitrogen were determined by microanalytical methods (Micro-Analysis Lab., Depart-

ment of Chemistry, NEHU, Shillong-793003). Vanadium, peroxide, and phosphate were estimated by the methods given in our earlier papers (15, 22).

Synthesis of oxoperoxo-8-quinolinolatovanadium(V) complexes, [VO(O$_2$)QL] (Q = 8-quinolinolate, L = EtOH, DMSO, DMF, or THF)

As the methods of synthesis of [VO(O$_2$)QL] compounds are similar, only a representative procedure is described.

V_2O_5 (1 g, 5.49 mmol) was first dissolved in 30% hydrogen peroxide (15 cm^3, 132.36 mmol) to obtain a red solution with liberation of heat. To this was added a solution of 8-quinolinol (1.6 g, 11.02 mmol), made up separately in each of the following donor solvents (100 cm^3), EtOH, DMSO, DMF, or THF, with continuous stirring. The concentration ratio of V:8-quinolinol: H_2O_2 was 1:2:24.1. No colour change or heat liberation was apparent. The reaction mixture was stirred for ca. 30 min in an ice-bath, whereupon a brick-red microcrystalline solid separated out. The pH value of the solution was recorded to be ca. 2. The solid oxoperoxo-8-quinolinolato-vanadium(V) complex [VO(O$_2$)QL] (Q = 8-quinolinolate, L = EtOH, DMSO, DMF, or THF) was filtered off, washed three or four times with ethanol, and finally dried *in vacuo* over concentrated H_2SO_4. The yields of [VO(O$_2$)Q(EtOH)], [VO(O$_2$)Q(DMSO)], [VO(O$_2$)Q(DMF)], and [VO(O$_2$)Q(THF)] were 2.6 g (82%), 2.8 g (80%), 2.9 g (85%), and 2.7 g (78%), respectively.

Anal. calcd. for [VO(O$_2$)Q(EtOH)]: V 17.62, O_2^{2-} 11.07, C 45.7, N 4.84, H 4.15; found: V 17.28, O_2^{2-} 10.85, C 45.56, N 4.96, H 4.2. ^{1}H NMR (DMSO-d_6) δ: 8.85 (d,H), 8.7 (d,H), 7.8(d,H), 7.6(d,H), 7.4(d,H), 7.15(d,H), 3.43(q,2H), 2.5(s,H), 1.06(t,3H).

Anal. calcd. for [VO(O$_2$)Q(DMF)]: V 16.11, O_2^{2-} 10.12, C 45.59, N 8.85, H 4.11; found: V 15.98, O_2^{2-} 10.2, C 45.92, N 9.03, H 4.12. ^{1}H NMR (DMSO-d_6) δ: 8.82(d,H), 8.65(d,H), 7.76(d,H), 7.59(d,H), 7.35(d,H), 7.13(d,H), 7.93(s,H), 2.83(s,3H), 2.7(s,3H).

Anal. calcd. for [VO(O$_2$)Q(DMSO)]: V 15.86, O_2^{2-} 9.96, C 41.14, N 4.35, H 3.73; found: V 15.62, O_2^{2-} 9.81, C 42.10, N 4.42, H 3.78. ^{1}H NMR (DMSO-d_6) δ: 8.86(d,H), 8.7(d,H), 7.85(d,H), 7.68(d,H), 7.38(d,H), 7.10(d,H), 2.3(s,6H).

Anal. calcd. for [VO(O$_2$)Q(THF)]: V 16.16, O_2^{2-} 10.15, C 49.55, N 4.44, H 4.44; found: V 15.94, O_2^{2-} 9.85, C 50.11, N 4.54, H 4.38. ^{1}H NMR (DMSO-d_6) δ: 8.82(d,H), 8.65(d,H), 7.79(d,H), 7.58(d,H), 7.25(d,H), 7.11(d,H), 3.60(m,4H), 1.73(m,4H).

Synthesis of ammonium and potassium oxodiperoxo-(hydrophosphato)vanadate(V) dihydrates, $A_3[VO(O_2)_2(HPO_4)]\cdot 2H_2O$ (A = NH$_4$ or K)

In a typical procedure, a mixture of vanadium pentoxide (1 g, 5.49 mmol) and 88% phosphoric acid (1 cm^3, 17.85 mmol, density 1.75 g cm^{-3}) was reacted with 30% hydrogen peroxide (15 cm^3, 132.36 mmol) in an ice-bath with stirring. A clear red solution thus obtained was stirred for ca.15 min followed by the addition of aqueous ammonia (specific gravity 0.9) or 20% KOH solution until the reaction medium attained a pH value of 6 with its colour turning to yellow. An addition of ethanol to this precipitated out a yellow microcrystalline product. The compound was filtered off, washed two or three times with ethanol, and finally dried *in vacuo* over concentrated H_2SO_4. The yield of $(NH_4)_3[VO(O_2)_2(HPO_4)]\cdot 2H_2O$ was 2.82 g (81%) and that of $K_3[VO(O_2)_2(HPO_4)]\cdot 2H_2O$ was 3.17 g (76%). Anal. calcd. for $(NH_4)_3[VO(O_2)_2(HPO_4)]\cdot 2H_2O$: V 16.07, O_2^{2-} 20.19, PO_4^{3-}, 29.96, N 13.25, H 5.36; found: V 15.92, O_2^{2-} 20.1, PO_4^{3-} 29.21, N 13.11, H 5.32. Anal. calcd. for $K_3[VO(O_2)_2(HPO_4)]\cdot 2H_2O$: V 13.39, O_2^{2-} 16.83, PO_4^{3-} 24.97, H 1.31; found: V 13.13, O_2^{2-} 16.3, PO_4^{3-}, 25.25, H 1.38.

Results and discussion

Vanadium has a strong affinity for peroxide (O_2^{2-}) and the composition of a peroxo-vanadium species is pH dependent (15, 16, 23–26). The number of coordinated O_2^{2-} generally increases as the solution pH value is raised. In one of the present reactions, the interaction of V_2O_5 with hydrogen peroxide and a solution of 8-quinolinol (QH) in each of the donor solvents (L) (L = EtOH, DMSO, DMF, or THF) was conducted at pH 2. This led to the synthesis of new heteroligand monoperoxovanadium(V) compounds of the type [VO(O$_2$)QL] in very high yields. QH was dissolved in the chosen organic solvents (L) so that an option for the formation of quaternary complexes existed. Since monoperoxo complexes of the metal are far less frequently encountered, it was one of our concerns to improvise a route to such species. Accordingly, the pH value of ca. 2 attained spontaneously was not raised so that the goal could be achieved. In contrast, the successful synthesis of complex peroxovanadates(V) containing HPO_4^{2-} as the heteroligand was possible from the reaction of V_2O_5 with phosphoric acid (H_3PO_4) and H_2O_2, only when the pH value was raised to 6. The products isolated at pH values < 6, though containing both peroxide and phosphate, were inconsistent in regard to their compositions. A comparatively higher pH value is believed to have directed the formation of the ternary diperoxovanadate(V), $[VO(O_2)_2(HPO_4)]^{3-}$. The complex was isolated as $A_3[VO(O_2)_2(HPO_4)]\cdot 2H_2O$ (A = K or NH_4) by the addition of ethanol, which facilitated the precipitation. The alkali used to raise the pH of the solution served also as a source of the counter-cation NH_4^+ or K^+ (A^+). The occurrence of an acid phosphate, HPO_4^{2-}, can be rationalized in terms of the pH value maintained in the synthesis.

Both the brick-red [VO(O$_2$)QL] and the yellow $A_3[VO(O_2)_2(HPO_4)]\cdot 2H_2O$ were obtained as microcrystalline products. They are insoluble in nonpolar organic solvents. While the former is insoluble in water, but soluble in polar organic solvents like DMF and DMSO, the latter is soluble only in water. The compounds are stable for a prolonged period and are capable of being stored in closed sample containers. Both the mono- and the diperoxo compounds reported herein are diamagnetic in nature in conformity with the oxidation state of the metal. The molar conductances of [VO(O$_2$)QL] recorded in DMF and those of $A_3[VO(O_2)_2(HPO_4)]\cdot 2H_2O$ recorded in water were found to lie in the ranges 5–10 Ω^{-1} cm^2 mol^{-1}, and 370–380 Ω^{-1} cm^2 mol^{-1}, respectively, in agreement with their formulae. Furthermore, the results of conductance measurements, obtained over a period of 10 days at an interval of 24 h each, were practically similar to those recorded on freshly prepared solutions. This clearly attests to the stability of the compounds in the respective solutions.

Each of the monoperoxo-vanadium(V) and diperoxovanadate(V) complexes exhibited a characteristic spectral pattern in the infrared region. The significant general features are the absorptions at ca. 950, ca. 855, ca. 620, and ca. 580 cm^{-1} assigned to ν(V═O), ν(O—O) (ν_1), ν(V—O$_2$)(ν_2), and ν(V—O$_2$)(ν_3), respectively (15, 16, 27). The occurrence of bands at ca. 855 cm^{-1}, ca. 620, and ca. 580 cm^{-1} clearly indicates the presence of triangularly bonded (C_{2v}) peroxide (15, 16, 27). In addition to the features originating from VO^{3+} and coordinated peroxide, the monoperoxo complexes [VO(O$_2$)QL] show bands due to the coordinated 8-quinolinolate ligand(Q) with the pattern comparing very well with that reported (17, 28) for the 8-quinolinolato coordinated systems. Moreover, the IR spectra of [VO(O$_2$)Q(DMSO)] and [VO(O$_2$)Q(DMF)] exhibit strong bands at 940 cm^{-1} (ν(S═O)) (29) and at 1650 cm^{-1} (ν(C═O)) (30),

respectively. The presence of distinct bands at 940 and 1650 cm^{-1} suggests that the DMSO and DMF are bonded to the metal centre through their O-atoms in the respective cases (29, 30). The bands due to the coordinated EtOH and THF in the complexes [$VO(O_2)QL$] (L = EtOH or THF) could not be identified because of their overlap with those of the 8-quinolinolato ligand.

In addition to the bands due to V=O and coordinated O_2^{2-}, the IR spectra of $A_3[VO(O_2)_2(HPO_4)] \cdot 2H_2O$(A = NH_4 or K) display a strong but broad absorption in the region 1010–1160 cm^{-1} and a medium intensity broad absorption at 2800–2900 cm^{-1}. These resemble, in their shapes and positions, those observed for the coordinated hydrophosphate group (HPO_4^{2-}) (31) and lend support to the contention. The signals at ca. 960, ca. 860, ca. 630, and ca. 580 cm^{-1} due to the ν(V=O), ν(O—O)(ν_1), ν(V—O_2)(ν_2), and ν(V—O_2)(ν_3) modes, respectively, observed in the laser Raman spectra of the compounds, complement the corresponding IR modes. The additional bands at ca. 1640 s, and ca. 3500 s, br cm^{-1} in the IR spectra of the complexes represented the δ(H—O—H) and ν(O—H) modes of uncoordinated water (ref. 29, p. 228). A comparison of the vibrational spectra of the newly synthesized compounds with those of some of our previously reported peroxo-vanadium(V) complexes (15, 16, 32–35) causes us to state that the most significant band [ν(O—O)], characteristic of the bound peroxides, does not appear to show any remarkable variation in its position with changes in the metal coordination sphere (Table 1). The ν(O—O) bands lie in the region 850–890 cm^{-1} in the IR spectra, while similar modes occur between 855 and 880 cm^{-1} in the Raman spectra of the compounds so far investigated by us. In other words, the vibrational spectra of the coordinated peroxide seem to be independent of the nature of the heteroligands present in the complex peroxo-vanadium(V) species.

From the biochemical point of view, the peroxo(hydrophosphato)-vanadate(V) complex, $[VO(O_2)_2(HPO_4)]^{3-}$, is of considerable interest. To furnish evidence for its existence in solution, we sought to show that the use of laser Raman (LR) spectroscopy provided very valuable information in this regard. The LR spectrum of the yellow solution of V_2O_5, phosphoric acid, and H_2O_2 at pH 6 adjusted by the addition of KOH solution (*vide* Experimental) was recorded before isolating the compound. The spectrum exhibited polarized bands at 972, 865, and at 565 cm^{-1} due to ν(V=O), ν(O—O)(ν_1), ν_s(V—O_2)(ν_3), respectively, and a depolarized band at 630 cm^{-1} assigned to ν_{as}(V—O_2)(ν_2). The LR spectral pattern of the corresponding solid $K_3[VO(O_2)_2(HPO_4)]$, including the positions of the Raman signals, was similar to the above with its ν(V=O), ν(O—O)(ν_1), ν_s(V—O_2)(ν_3), and ν_{as}(V—O_2)(ν_2) occurring at 970, 857, 575, and 630 cm^{-1}, respectively. Furthermore, the LR spectrum of a freshly prepared solution of $K_3[VO(O_2)_2(HPO_4)]$ exhibited these bands at positions very close in wave numbers to the LR bands observed for the solution prior to isolating the complex, as well as to bands for the solid $K_3[VO(O_2)_2(HPO_4)]$ as discussed above. Equally significant is the consistent appearance of a very strong but broad signal with its peak at ca. 1065 cm^{-1} in each of the three spectra recorded for the complex under consideration. The band, in terms of its shape and position, compares very well to the corresponding IR band of the coordinated HPO_4^{2-} observed for the solid $K_3[VO(O_2)_2(HPO_4)]$, thereby lending further credence to the contention. These results attest not only to the existence but also to the stability of the complex $[VO(O_2)_2(HPO_4)]^{3-}$ species in solution, at least under the present experimental conditions.

The electronic spectra of [$VO(O_2)QL$] complexes in DMF showed two bands, one each at ca. 268 ($\varepsilon = 1.525 \times 10^4$ L mol^{-1} cm^{-1}) and at 360–410 (broad) nm ($\varepsilon = 2 \times 10^3$ L

mol^{-1} cm^{-1}). While the former has been assigned to the internal transition ($\pi-\pi^*$) of the 8-quinolinolate ligand (28), the latter probably owes its origin to a combination of a peroxo (LMCT) and the internal ($\pi-\pi^*$) transition of the 8-quinolinolato ligand. The UV–visible spectra of the diperoxo compounds $A_3[VO(O_2)_2(HPO_4)] \cdot 2H_2O$ (A = NH_4 or K), recorded in water, exhibited only one (LMCT) band at 320 nm. The transition at 320 nm is similar to that of the other diperoxovanadium compounds containing triangularly bonded peroxide (36).

The ^1H NMR spectra of the monoperoxovanadium(V) complexes, $[VO(O_2)QL]$, were recorded in DMSO-d_6 solvent. The significant features of the NMR spectra are the signals due to the coordinated 8-quinolinolato ligand and the coordinated L (L = EtOH, DMF, or THF). The signals due to coordinated 8-quinolinolato ligands, observed at δ values ca. 8.9, ca. 8.7, ca. 7.8, ca. 7.6, ca. 7.4, and ca. 7.2, are similar to those previously reported for the 8-quinolinolatovanadium complexes (17, 37, 38). Apart from these, the signals due to the coordinated ethanol appear at δ 1.06(t), 2.5(s), and 3.43(q) originating from $-CH_3$, O-H and, $-CH_2-$, respectively (39). The DMF signals, for L = DMF, were observed at δ 7.93(s), 2.83(s), and 2.7(s) assigned to HCO-, $-CH_3$, and $-CH_3$, respectively (ref. 39, p. 344). The THF signals of the corresponding complex appear at δ 1.73(m) and 3.6(m) due to $-CH_2-CH_2-$ and $-CH_2-O-CH_2-$, respectively (ref. 39, p. 348). Thus, the ^1H NMR results show conclusively that the 8-quinolinolato ligand is bonded to the metal center. The results are consistent with the presence of a metal–oxygen covalent bond and a long labile V—N bond (17). The chemical shifts agree with this proposition. The NMR spectroscopic studies also suggest that each of the L molecules, i.e., EtOH, DMF, and THF, is bonded to the metal center.

Short syntheses of rigid acyclic or macrocyclic poly-imine ligands and their use in Ru(II), Fe(III), and alkali metal complexation

ROBERT DASH AND PIERRE G. POTVIN[1]

Department of Chemistry, York University, 4700 Keele Street, North York, Ont., Canada M3J 1P3

Received July 16, 1991

ROBERT DASH and PIERRE G. POTVIN. Can. J. Chem. **70**, 2249 (1992).

Lipophilic derivatives of 2,6-bis(3-pyrazolyl)pyridine and 1,3-bis (3-pyrazolyl)benzene were obtained in acceptable yields by Stork reactions and transformed by *N*-alkylations into three pentadentates, three bis(bidentates), and one macrocyclic octadentate ligand. The parent bis(pyrazolyl) pyridine constituted a terpyridine analogue and readily formed a Ru(II) complex. By comparison of ^{1}H nuclear magnetic resonance patterns, it was found that the alkylations in the bis(pyrazolyl)pyridine series conferred an *anti,anti* conformation of the imino nitrogens. The pentadentates were then able to extract alkali metal ions into $CHCl_3$ with only modest strength and selectivity, but the preferred extraction of Li^+ by one of these was notable. By variation of the reaction conditions, a tri-iron(III) and a di-iron(III) complex were obtained from a bis(bidentate).

ROBERT DASH et PIERRE G. POTVIN. Can. J. Chem. **70**, 2249 (1992).

Des dérivés lipophiles de la 2,6-bis(3-pyrazolyle)pyridine et du 1,3-bis(3-pyrazolyle)benzène furent préparés en rendements acceptables par des réactions de Stork, puis *N*-alkylés pour fournir trois pentadentates, trois bis(bidentate) et un octadentate macrocyclique. En tant qu'analogue de la terpyridine, la bis(pyrazolyle)pyridine forma aisément un complexe au Ru(II). D'après la résonance magnétique nucléaire, les alkylations de la bis(pyrazolyle)pyridine ont forcé l'adoption de conformations *anti,anti* et les pentadentates étaient donc de modestes récepteurs pour les cations alkalins et ont démontré une faible sélectivité en extraction dans le chloroforme. Néanmoins, on souligne l'extraction préferentielle du Li^+ par l'un d'eux. Un bis(bidentate) forma, selon les conditions employées, des complexes bi- et tri-nucléaires avec le Fe(III).

Introduction

Rigid, poly-heterocyclic multidentate ligands/receptors offer a high degree of preorganization for the binding of metal ions and neutral organic molecules (for some recent examples, see ref. 1). For a variety of purposes, we sought rapid access to such molecules and chose the general architecture and the synthetic path illustrated in Scheme 1. Largely for reasons of synthetic simplicity, pyrazoles were chosen as binding sites to flank a central aromatic ring, in spite of the weaker basicity (2) and metal-binding ability (3) of pyrazole itself, relative to pyridine. Although several *N*-linked 2,6-bis(1-pyrazolyl)pyridines were recently prepared by facile reactions of pyrazolate ions with pyridyl halides (4), the linkage in Scheme 1 (*i.e.*, at the pyrazole 3-position) was dictated by a desire to apply the same methodology to develop both monotopic (X = N) and ditopic (X = CH) varieties of ligands. The parent 2,6-bis(3-pyrazolyl)pyridine has been prepared by a Mannich-type condensation (5). However, we additionally required substituents at the pyrazole 4- and 5-positions to ensure good liposolubility and poor solubility in water, and the Mannich reaction was not amenable to this. Claisen condensations involving methyl ketones had been used to prepare two 5-substituted analogues via bis(β-diketones) (6) but, in our hands, a similar condensation with cyclohexanone failed completely. We instead used Stork reactions (7) to form the bis(β-diketone) precursors that we required, and herein present short (two- or three-step) syntheses of a family of poly-heterocyclic ligands derived therefrom. We also report on our explorations of the complexing abilities of some of these and on the implications for future ligand design.

Results and discussion

In a model one-pot reaction, *N*-cyclohexen-1-yl-morpholine and Et_3N (1 equiv.) were treated with benzoyl chloride (1 equiv./0°C/THF) and hydrazine hydrate (1 equiv.). Extraction, chromatography, and recrystallization provided a 64% yield of **1**. However, the analogous one-pot reaction with 2, 6-di (chlorocarbonyl) pyridine (0.5 equiv.) provided only a 29% yield of **2***a* after chromatography and recrystallization, along with a 17% yield of **3** (identified only by nmr). Reasoning that **3** arose from *mono*-reacted material that had reacted further with the morpholine liberated during the hydrazine quench, $AlCl_3$ (0.5 equiv.) was added to the reaction mixture after the acid chloride and the mixture stood overnight before quenching and work-up. This provided a 40% yield of **2***a* and only a trace of **3**.

If the quench was carried out with H_2O, tetraketone **4***a* was obtained in 44% yield after chromatography and recrystallization, and this was quantitatively converted to **2***a* in a second step (2 equiv. $N_2H_4 \cdot H_2O/CH_2Cl_2$/room temp./15 min) with no need for a second chromatographic purification. Thus, the two-step process provided a modest increase in overall yield over the one-pot reaction. In entirely analogous fashion, isophthaloyl chloride was used to produce tetraketone **4***b* in 51% isolated yield, and bis-pyrazole **2***b* in quantitative yield thereafter.

Tetraketones **4***a* and **4***b* are interesting molecules in their own right. In entire analogy with 2,6-bis(3-oxobutanoyl)-pyridine (8) and 1,3-bis(3-oxobutanoyl)benzene (9), **4***b* was actually in the bis-enol form while **4***a* was a mixture of tautomers in $CDCl_3$ solution, and few useful nmr assignments could be made (there were at least three keto isomers present). Attempts to symmetrize its spectra by conversion to the dianion were hampered by its insolubility in purely aqueous solutions of base and by a tendency to undergo base-catalyzed ring-opening reactions in alcoholic solution. In the mass spectrometer (EI) both **4***a* and **4***b* showed molecular ions as well as loss of CO and 2-oxocyclohexyl radical. This, along with elemental analyses and conversions to the bis-pyrazoles, confirmed their structures. Unfortunately, attempts to produce 2:2 complexes (8) of either one with Zn^{2+}, Ni^{2+}, or

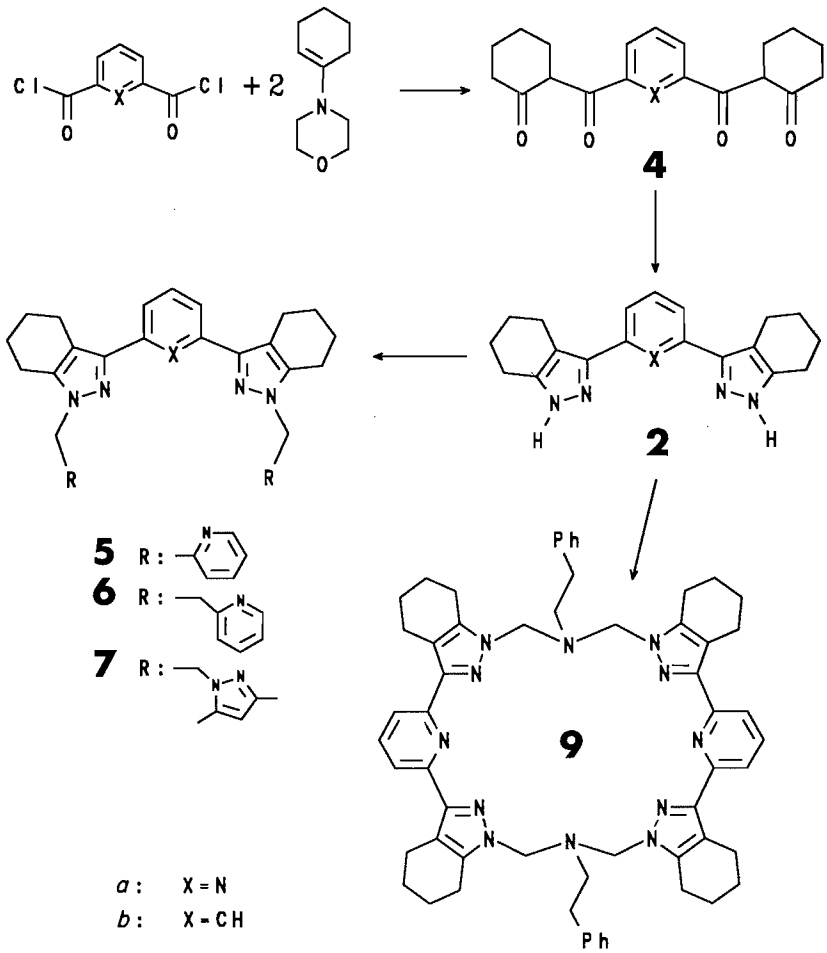
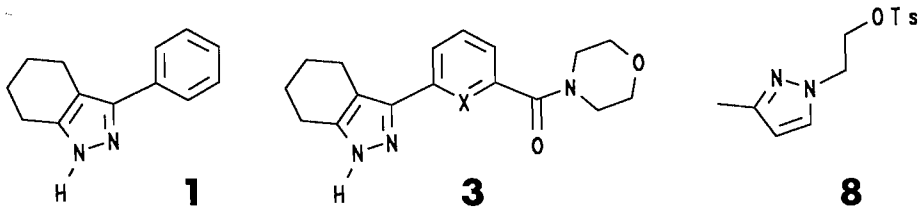


SCHEME 1

$Ti(O^iPr)_4$ met with failure. The bis-pyrazoles **2***a* and **2***b* gave symmetric nmr spectra and were further characterized by mass spectrometry (both showed molecular ions and loss of N_2) and elemental analyses.

As a fairly rigid tridentate, **2***a* readily formed a purple-red Ru(II) complex by reaction with $Ru(DMSO)_4Cl_2$ (10) (0.5 equiv./EtOH/reflux/1 day), followed by precipitation and recrystallization (72% yield). The nmr spectra were symmetric, showing downfield displacements of the signals due to the pyridine nuclei, and the electronic spectrum included a band at 432 nm (ϵ 4.7 mM^{-1} cm^{-1}) more reminiscent of the MLCT bands of the complexes of terpyridine (473 nm, ϵ 16.2 mM^{-1} cm^{-1}) and bipyridine (452 nm, ϵ 14.6 mM^{-1} cm^{-1}) (11) than was that at 377 nm obtained with the *N*-linked analogue, 2,6-bis(1-pyrazolyl)pyridine (12). Its redox chemistry will be reported elsewhere.



In a procedure borrowed from the literature (13), the successive treatment of bis(pyrazolyl)pyridine **2***a* with NaH (2.4 equiv./THF/room temp./2 h) and picolyl chloride (2.3 equiv./THF/room temp./overnight), followed by dilution with H_2O, extraction into CH_2Cl_2, chromatography, and recrystallization provided **5***a* in 69% isolated yield. An entirely similar alkylation with 2-(2-pyridyl)ethyl tosylate afforded **6***a* in 51% yield. Our first attempt to prepare the tetrapyrazole analogue **7***a* involved the condensation of tetraketone **4***a* with 2-hydroxyethylhydrazine. This, unfortunately, gave a mixture of *in/out* isomers, as revealed by ^1H nmr, that were poorly resolved by chromatography. Instead, hydroxyethylhydrazine was converted to **8** by condensation with acetylacetone and tosylation (72% overall yield). When **8** was used in the alkylation of **2***a* as before, **7***a* was obtained in 58% yield.

In entirely similar reactions, bis(pyrazolyl)benzene **2***b* was transformed into **5***b*, **5***b*, and **7***b* in 65, 49, and 59% isolated yields, respectively.

All of these materials were crystalline and H_2O-insoluble. In the mass spectrometer, all fragmented in the same way with loss of their appendages: **5***a*/*b* and **6***a*/*b* lost pyridinyl, pyridinylmethyl and (or) pyridinylethyl radicals, while **7***a*/*b* lost the corresponding dimethylpyrazole-containing radicals. The ^1H and ^{13}C nmr spectra showed symmetry and were entirely as expected, except that the pairs of CH_2 groups in **7***a* and **7***b* coincidentally overlapped in their ^1H nmr spectra, appearing as singlets in each case. Although these alkylations might have produced *in,in* and *in,out* isomers as well as the *out,out* form depicted, a single symmetric isomer was isolated in each case, and the exclusive production of *in,in* isomers would be discountable on steric grounds. Certainly, an *out,out*-directing effect could be expected in the alkylations of **2***a* if its dianion was able to complex Na^+. Moreover, the ability of the resulting series of ligands to complex alkali metal ions (*vide infra*) support this assignment.

Several attempts were made to convert **2***a* to a macrocyclic ligand. The literature reports several pyrazole-containing macrocycles (6, 14, 15). Of special interest to us were a bicyclic cryptand from a 3+2 alkylation of ammonia with a doubly electrophilic 2,2′-bipyrazole (15) and a macromonocycle obtained by 2+2 alkylation of 2,6-bis(5-methylpyrazol-3-yl)pyridine with bis(chloromethyl) ether (6). However, this latter reaction proceeded in only 2% yield and was accompanied by more substantial amounts of the 1+1 product. Several reactions of **2***a* with KBH_4 were carried out with a view to produce macrocyclic (2+2) and macrobicyclic (3+2) pyrazolyl hydridoborates (16), but these were slow and gave only insoluble materials. Reactions with base and coupling with CH_2Cl_2 or CH_2I_2 failed to provide identifiable products. However, reaction with aqueous HCHO[2] was instantaneous and produced an unstable, symmetric bis(*N*-hydroxymethyl) derivative (identified only by nmr). This was condensed with 2-phenylethylamine *in situ* and macrocycle **9** precipitated over a period of several weeks. Filtration, chromatography, and recrystallization provided an 18% yield. That this was indeed a 2+2 condensation product was shown by mass spectrometry: although no molecular (or heavier) ions were seen by either EI or FAB techniques, the heaviest fragments observed (up to *m*/*z* 918) well exceeded the molecular weight of a 1+1 product. Further, **9** in $CDCl_3$ was able to dissolve solid sodium picrate with colour entrainment, severely broadened ligand nmr signals, and the appearance of a singlet due to picrate ion. (Ligands **2***a* and **5***a* gave the same results.) A 1+1 product, arising from *in,in* alkylation, would not be expected to bind metal ions. This also confirmed that alkylation proceeded to give *out,out* products. Complexation studies with **9** and both cations and anions are planned and will be reported in due course. Unfortunately, the analogous condensations with histamine (to furnish pendant imidazole ligating groups) or ammonia (to provide a bicyclic analogue) did not proceed to completion.

With such floppy terminal pyridine and dimethylpyrazole groups, the pyridine series of acyclic ligands could not be expected to be ideally pre-organized for the binding of metal ions in their cavities. An examination of the aromatic regions in the ^1H nmr spectra was instructive in that regard. In Table 1 are reproduced the chemical shifts of the singlet (H-2 in the *b* series), doublet (H-3/5 in the *a* series, H-4/6 in the *b* series), and triplet signals (H-4 in the *a* series, H-5 in the *b* series) from this family of molecules. In the *a* series, the doublet was upfield of the triplet in **2***a* but moved downfield of the triplet upon alkylation. The triplet was less affected, but was shifted slightly upfield, probably a reflection of the electron-donating character of the *N*-CH_2 groups. In the *b* series, the doublet was consistently downfield of the triplet but shifted further downfield in the *N*-alkylated molecules, as did the singlet. The position of the triplet changed little. (The nmr data for the 2,6-bis(5-alkylpyrazol-3-yl)-pyridine (6) were reported in insufficient detail to allow comparisons.) Given that the doublets would normally be expected to appear downfield of the triplet in both pyridine and benzene series on purely electronic grounds (as was the case with the diacid chlorides), our interpretations of the pattern changes are as follows.

(*a*) The bis(pyrazolyl)pyridine **2***a* is in a planar conformation with the nitrogens held *syn* to one another (as must also be true of **2***a* in the Ru complex) by virtue of hydrogen bonds between *in*-NH and pyridine N. (Molecular mechanics calculations suggested that the *anti,anti* and *syn,anti* forms of **2***a* were in fact the most stable, but these calculations could not take hydrogen bonding into account and mostly reflect steric effects.) This would give rise to a shielding of the pyridine H-3/5 by the cyclohexene CH_2 groups.

(*b*) *N*-Alkylation of **2***a* caused a reversion to *anti* forms, analogous to that adopted by 2,2′-bipyridine (17), and a loss of that shielding. (Similarly, "tetraketone" **4***a* probably also preferred *anti* forms.) Complexation with metal ions would be expected to force a *syn,syn* arrangment with the operation of the shielding effect. This appeared to be the case with Ru(II), but could not be confirmed with Na^+ due to signal broadening and overlap (*vide supra*).

(*c*) In the benzene series, the conformational preferences are weaker, and H-2 and H-4/6 were about equally affected by *N*-alkylation.

Therefore, even the bis(pyrazolyl)pyridine cores of **5***a*–**7***a* were not well pre-organized for binding and only moderate binding strengths could then be expected, although this could be offset somewhat by the strongly dipolar nature of the imino sites. However, this and the rapid complex formation and dissociation rates afforded by acyclic ligands such as these are beneficial and necessary characteristics for efficient passive ion transport (18).

To test this, the association constants in $CHCl_3$ between these ligands and a series of picrate salts were measured by Cram's uv method (19), assuming 1:1 complexes. These are displayed in Fig. 1 As expected, the binding was only moderate throughout. It would appear that **5***a* preferred Li^+ and that **6***a* preferred Na^+. However, all three bound K^+ about equally well and Na^+ was bound equally well by **5***a* and **6***a*. Thus, Li^+ rejected **6***a* and **7***a*, and Na^+ rejected **7***a*, likely due to intra-ligand repulsions and distortions induced by these smaller ions. Nevertheless, the extraction of Li^+ by a polyaza acyclic ligand is notable and comparable in efficiency to extractions with rigid, acyclic oligo(tetrahydropyrans) (20). None of the ligands bound well to the large Cs^+ nor to NH_4^+, which ideally requires a tetrahedral array of H-bond acceptors. Clearly, a greater degree of pre-organization would be

[2]J. de Mendoza, personal communication.

TABLE 1. The ^{1}H nmr chemical shifts (in ppm) of singlet (s), doublet (d), and triplet (t) patterns in the aromatic regions

[a]Peak positions of the major product.

required for stronger binding of alkali metal ions. A second covalent linkage between pyridine and pyrazole rings would impose the required *syn,syn* conformation but this would be synthetically difficult to achieve. At least, replacement of the fused cyclohexanes with long alkyl chains at the pyrazole 5-positions would help to reduce the steric hindrance to the adoption of the *syn,syn* conformation in the triaromatic cores.

Ligands **5***b*, **6***b*, and **7***b* are ditopic bisbidentates and should be suitable for two small transition metals ions. We were particularly interested in a biomimetic (21) μ-oxo-bis(μ-carboxylato)di-iron(III) complex. In our first attempt, $FeCl_3 \cdot 6H_2O$ (2.0 equiv./EtOH/room temp.) was added to a solution of **5***b* in EtOH and a red-brown solid, analyzing for (**5***b*)$_2$Fe$_3$Cl$_9$, immediately precipitated in 49% yield, based on ligand. A possible structure is **10**, where the central ligand is in an *anti* conformation, although a *syn* form with possible chloride bridging cannot be excluded. Its visible light spectrum included absorption bands at 330 nm (ε 5043 M^{-1} cm^{-1}) and at 450 nm (ε 744 M^{-1} cm^{-1}), reminiscent of bands by the μ-oxo bis(μ-carboxylato)chlorobipyridine iron(III) dimer of Vincent *et al.* (22) at 329 nm (ε 6060 M^{-1} cm^{-1}) and at 464 nm (ε 387 M^{-1} cm^{-1}). It appeared that the assembly of this trimetallic array was initiated by the rapid binding of one metal to sites from two separate ligands followed by reaction with the pendant sites, leaving unreacted $FeCl_3$ (eq. [1]). This could be used to advantage to prepare hetero-trimetallic complexes and perhaps higher oligomeric materials in a controlled manner by repeated and alternating additions of ligand and metal.

[1] $2\ L + 4\ FeCl_3 \rightarrow L_2Fe_3Cl_9 + FeCl_3$

However, to circumvent this in a second attempt, slow, inverse addition and heat were employed and little precipitation occurred. After treatment with Et_3N and HOAc, and prolonged heating, the solution changed from red to green, the colour typical of μ-oxo-bis(μ-carboxylato)diiron(III) cores (22–24). Filtration and trituration provided light green crystals that analyzed for (**5***b*)$_3$Fe$_2$(OAc)Cl$_5$, for which a symmetric μ-carboxylato structure with unused ligand sites can be drawn (**11**). The yield, based on ligand, was only 27%. Its visible light spectrum consisted of a similar MLCT band at 369 nm (ε 1469 M^{-1} cm^{-1}) and a much broader *d–d* transition centred near 631 nm (ε 127 M^{-1} cm^{-1}), similar to that shown by met-chloro hemerythrin (656 nm, ε 180 M^{-1} cm^{-1}) (25). Though this was not the exclusive product (there was an insoluble brown material produced here as well), the tendency for the metal to bind two ligands was a problem here again.

A third attempt made use of the pre-formed μ-oxo dimer (Et$_4$N)$_2$Fe$_2$OCl$_6$(26) and the more hindered ligand **7***b* in the prescribed manner (23), but this resulted in the recovery of unreacted ligand.

We ascribe our difficulties in forming a μ-oxo complex to the inability of the bidentate units in these ligands to twist

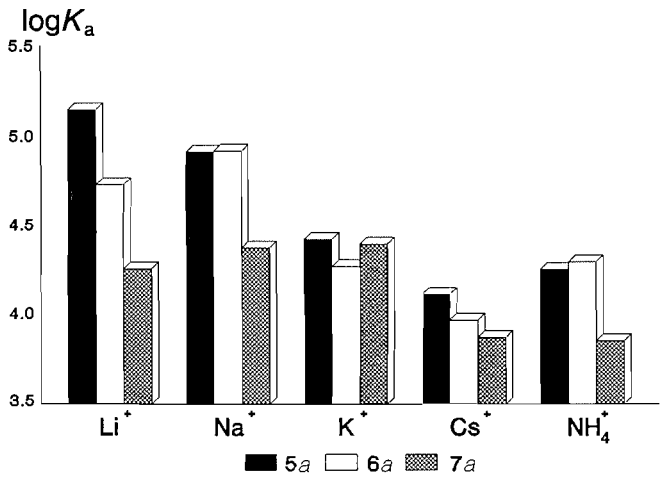

FIG. 1

into sufficient proximity to wrap around a μ-oxo dimer core without hindrance from the benzene H-2 and (or) between the terminal pyridines, although molecular modelling suggested that this should have been possible. One might use a more flexible polymethylene linkage between the metal binding sites but Stork reactions with flexible diacid chlorides are known to not proceed in the required manner (27) and loosely linked ditopic ligands have a tendency to form plynuclear Fe(III) complexes (21). One could instead use phenoxo bridges (28), with ligands based on 2,6-bis(3-pyrazol)phenol. Work on this problem is underway.

Experimental section

All solvents used were reagent grade and used without drying or purification, except for THF, which was distilled over K and benzophenone. The petroleum ether used was the light fraction (bp 30–60°C). *N*-(Cyclohexen-1-yl)morpholine was prepared according to Hünig *et al.* (29). 2-(2-Pyridinyl)-ethyl tosylate was prepared by tosylation in the usual manner of the commercial alcohol. All melting points were determined on a Fisher–Johns apparatus. Nuclear magnetic resonance spectra were measured on a Bruker AM-300 spectrometer, operating at 300.13 MHz (^{1}H) or 75.1 MHz (^{13}C), run either in $CDCl_3$, with TMS as internal reference (at 0.00 ppm in ^{1}H spectra, and at 77.00 ppm for ^{13}C), or in $CDCl_3$/CD_3OD, with TMS or CD_2HOD (3.30 ppm in ^{1}H spectra, and at 49.00 ppm in ^{13}C) as the internal references. Ultraviolet and visible spectra were obtained on a Hewlett–Packard 8451A diode array spectrophotometer. Microanalyses were performed by Canadian Microanalytical Services, Burnaby, B.C., and Guelph Laboratories Ltd., Guelph, Ont.. Molecular modelling was performed using PC-MODEL (Serena Software, Bloomington, Indiana).

1H-3-Phenyl-4,5,6,7-tetrahydrobenzopyrazole, 1

Benzoyl chloride (1.00 mL, 8.54 mmol) was added dropwise to a stirring solution of 1-(cyclohexen-1-yl)morpholine (1.44 mL, 8.60 mmol) and triethylamine (1.20 mL, 8.60 mmol) in THF (25 mL) under nitrogen while cooling in an ice-water bath. A white precipitate (Et_3NHCl) formed immediately. The mixture was stirred for several hours, then treated with hydrazine hydrate (0.42 mL, 8.60 mmol). The mixture was washed with water (10 mL) and the crude product was isolated by extraction with CH_2Cl_2. Purification was carried out by column chromatography on alumina using 2:98 MeOH:CH_2Cl_2 as eluent. The pyrazole was recrystallized from EtOH (1.08 g, 64% yield), mp 123–125°C; ^{1}H nmr ($CDCl_3$) δ: 1.80 (m, 4H), 2.63 (m, 2H), 2.72 (m, 2H), 7.30 (m, 1H), 7.38 (m, 2H), 7.64 (d, 2H, J = 7.3 Hz) ppm, ^{13}C nmr ($CDCl_3$) δ: 22.08, 22.22, 22.66, 23.58, 112.93, 126.58, 127.24, 127.67, 128.50, 132.96, 144.31 ppm; ms, m/z(%) = 198 ($M^{+\cdot}$, 90), 170 (100), 95 (20), 77 (20), 49 (20). Anal. calcd. for $C_{13}H_{14}N_2$: C 78.75, H 7.12, N 14.13; found: C 78.61, H 7.03, N 14.14.

*2,6-Di(2-oxocyclohexanecarbonyl)pyridine, 4*a

A solution of 1-(cyclohexen-1-yl)morpholine (9.08 mL, 54.0 mmol) and Et_3N (7.53 mL, 54.0 mmol) in THF (50 mL) was slowly added to a stirring solution of 2,6-pyridinedicarboxylic acid chloride (5.0 g, 24.5 mmol) in THF (100 mL) under Ar while cooling in an ice-water bath. Et_3NHCl immediately precipitated. Then $AlCl_3$ (1.63 g, 12.2 mmol) was carefully added and the resulting mixture was allowed to stand overnight. After the addition of water (30 mL), the mixture was stirred vigorously for 1 h. The crude product was isolated by extraction with CH_2Cl_2. Purification was carried out by column chromatography on silica gel using 30:70 EtOAc:petroleum ether as eluent. The product was recrystallized from Et_2O to give white crystals (3.52 g, 44% yield), mp 112–114°C. Overlap of ^{1}H nmr signals made assignments impossible; ^{13}C nmr ($CDCl_3$) δ: 21.62, 23.10, 23.26, 23.61, 24.06, 25.34, 25.73, 27.67, 27.79, 29.03, 29.27, 29.40, 33.29, 42.44, 42.65, 42.69, 57.27, 57.70, 58.10, 108.03, 122.93, 124.55, 125.29, 125.44, 127.39, 138.01, 138.35, 138.39, 151.12, 151.54, 154.62, 184.60, 192.06, 197.87, 198.74, 208.09, 208.71, 208.83 ppm; ms, m/z(%): 327 ($M^{+\cdot}$, 100), 299 (35), 271 (50), 243 (16), 230 (10), 202 (23), 176 (77). Anal. calcd. for $C_{19}H_{21}NO_4$: C 69.71; H 6.47, N 4.28; found: C 69.47, H 6.41, N 4.31.

*1,3-Di(2-oxocyclohexanecarbonyl)benzene, 4*b

Following the procedure described above for **4***a*, isophthaloyl dichloride (5.0 g, 24.6 mmol) was used instead. The product was recrystallized from CCl_4 to give white crystals (4.01 g, 51% yield), mp 125–127°C; ^{1}H nmr ($CDCl_3$) δ: 1.63 (m, 4H), 1.78 (m, 4H), 2.41 (m, 4H), 2.50 (m, 4H), 7.49 (t, 1H, J = 7.7 Hz), 7.62 (d, 2H, J = 7.7 Hz), 7.70 (s, 1H), 13.14 (s, 2H) ppm; ^{13}C nmr ($CDCl_3$) δ: 21.71, 23.32, 26.31, 32.64, 107.04, 126.72, 127.98, 129.37, 137.32, 189.92, 190.11 ppm; ms, m/z(%): 326 ($M^{+\cdot}$, 30), 298 (5), 270 (5), 229 (100), 200 (60), 185 (10). Anal. calcd. for $C_{20}H_{22}O_4$: C 73.60, H 6.79; found: C 73.22, H 6.83.

*2,6-Di(1H-4,5,6,7-tetrahydrobenzopyrazol-3-yl)pyridine, 2*a

Hydrazine hydrate (1.10 mL, 22.6 mmol) was added to a solution of tetraketone **4***a* (3.52 g, 10.8 mmol) in CH_2Cl_2 (25 mL) at room temperature. Precipitation occurred and the reaction was complete in 15 min. The product was collected by vacuum filtration, with a second crop obtained after evaporation of the solvent. The product was recrystallized from MeOH to give white crystals (3.43 g, >99% yield), mp 275–277°C; ^{1}H nmr ($CDCl_3$/CD_3OD) δ: 1.88 (br, 8H), 2.73 (br, 4H), 2.85 (br, 4H), 7.46 (d, 2H, J = 7.9 Hz), 7.81 (t, 1H, J = 7.9 Hz ppm; ^{13}C nmr ($CDCl_3$/CD_3OD) δ: 22.19, 22.55, 22.90, 23.20, 113.73, 118.05, 137.33, 148.83 ppm. MS, m/z(%): 319 ($M^{+\cdot}$, 100), 290 (20), 265 (10), 205 (10), 149 (10), 95 (8). Anal. calcd. for $C_{19}H_{21}N_5 \cdot 1/2H_2O$: C 70.45, H 6.69, N 21.62; found: C 70.09, H 6.58, N 21.85.

(2a)$_2$ RuCl$_2$

Bispyrazole **2***a* (0.100 g, 0.31 mmol) and $RuCl_2(DMSO)_4$ (0.080 g, 0.16 mmol) were dissolved in EtOH (5 mL) and the mixture heated to reflux for 1 day. The solution turned pink after 15 min and was a dark purple after overnight reaction. The solution was cooled and most of the solvent was removed. Addition of ether precipitated the purple complex. This was filtered and washed with ether. Recrystallization from CH_3CN/H_2O gave purple crystals (0.090 g, 72%), mp > 350°C; uv–vis (EtOH): 432 nm (ε = 4736 M^{-1} cm^{-1}), 536 nm (ε = 1513 M^{-1} cm^{-1}); ^{1}H nmr ($CDCl_3$/CD_3OD) δ: 1.77 (br, 4H), 1.82 (br, 4H), 2.50 (br, 4H), 2.95 (br, 4H), 7.93 (d, 2H, J = 7.8 Hz), 8.08 (t, 1H, J = 7.8 Hz) ppm; ^{13}C nmr ($CDCl_3$/CD_3OD) δ: 20.17, 20.52, 21.23, 21.99, 115.77, 117.70, 135.22, 142.41, 149.36, 154.01 ppm. Anal. calcd. for $C_{38}H_{42}N_{10}RuCl_2 \cdot 4H_2O$: C 51.72, H 5.70, N 15.87; found: C 51.38, H 5.16, N 16.00.

*1,3-Di(1H-4,5,6,7-tetrahydrobenzopyrazol-3-yl)benzene, 2*b

Following the procedure described above for **2***a*, the tetraketone **4***b* (3.00 g, 9.4 mmol) was treated with hydrazine hydrate

(0.95 mL, 19.5 mmol). The product was recrystallized from MeOH to give light brown crystals (2.93 g, >99% yield), mp 164–166°C; ^{1}H nmr ($CDCl_3/CD_3OD$) δ: 1.86 (br, 8H), 2.73 (br, 8H), 7.47 (t, 1H, J = 7.5 Hz), 7.60 (d, 2H, J = 7.5 Hz), 7.87 (s, 1H) ppm; ^{13}C nmr ($CDCl_3/CD_3OD$) δ: 21.94, 22.17, 22.53, 23.45, 112.74, 124.52, 125.25, 128.57, 132.70, 143.49, 144.78 ppm; ms, m/z(%): 318 ($M^{+\cdot}$, 100), 290 (37), 242 (16), 225 (31), 214 (16), 197 (10), 131 (10), 95 (30). Anal. calcd. for $C_{20}H_{22}N_4 \cdot CH_3OH$: C 71.97, H 7.48; N 15.99; found: C 72.29, H 7.32, N 16.12.

2,6-Di(1-(pyridin-2-yl)methyl-4,5,6,7-tetrahydrobenzopyrazol-3-yl)pyridine **5**a

Bispyrazole **2***a* (0.50 g, 1.57 mmol) was dissolved in THF (15 mL) and slowly added to a stirring suspension of NaH (0.181 g 50% oil dispersion, 3.76 mmol) in THF (15 mL). There was an immediate release of H_2 gas and formation of a white precipitate (sodium pyrazolide salt). The resulting mixture was kept under Ar and stirred for 2 h at room temperature. Picolyl chloride (0.460 g, 3.61 mmol) was added to this solution and the mixture allowed to stand overnight. This solution was then washed with water and the crude product was isolated by extraction with CH_2Cl_2. Purification was carried out by column chromatography on alumina using 80:20 EtOAc:petroleum ether as eluent, and recrystallization from CH_3CN to give light brown crystals (0.540 g, 69% yield), mp 167–168°C; ^{1}H nmr ($CDCl_3$) δ: 1.81 (m, 8H), 2.54 (m, 4H), 3.01 (m, 4H), 5.45 (s, 4H), 6.90 (d, 2H, J = 7.8 Hz), 7.17 (m, 2H), 7.61 (m, 2H), 7.71 (t, 1H, J = 7.7 Hz), 7.88 (d, 2H, J = 7.7 Hz), 8.56 (d, 2H, J = 4.3 Hz) ppm; ^{13}C nmr ($CDCl_3$) δ: 21.58, 22.33, 22.93, 23.18, 54.59, 116.30, 119.36, 121.20, 122.36, 136.41, 137.09, 140.19, 148.07, 149.00, 153.23, 157.21 ppm; ms, m/z(%): 501 ($M^{+\cdot}$, 100), 424 (20), 409 (45), 316 (6), 251 (5), 92 (11). Anal. calcd. for $C_{31}H_{31}N_7$: C 74.22, H 6.23, N 19.55; found: C 73.99, H 6.26, N 19.52.

2,6-Di(1-(2-pyridin-2-yl)ethyl-4,5,6,7-tetrahydrobenzopyrazol-3-yl)pyridine **6**a

Following the procedure described above for **5***a*, bispyrazole **2***a* (0.49 g, 1.54 mmol) was treated with 2-(2-pyridinyl)ethyl tosylate (1.08 g, 3.90 mmol). Recrystallization from CH_3CN gave light brown crystals (0.415 g, 51% yield), mp 138–140°C; ^{1}H nmr ($CDCl_3$) δ: 1.67 (m, 8H), 2.26 (m, 4H), 2.91 (m, 4H), 3.35 (t, 4H, J = 6.9 Hz), 4.42 (t, 4H, J = 6.9 Hz), 6.94 (d, 2H, J = 7.8 Hz), 7.14 (m, 2H), 7.51 (m, 2H), 7.72 (t, 1H, J = 7.7 Hz), 7.85 (d, 2H, J = 7.7 Hz), 8.57 (d, 2H, J = 4.9 Hz) ppm; ^{13}C nmr ($CDCl_3$) δ: 21.45, 22.47, 22.90, 23.32, 38.96, 48.32, 115.09, 119.04, 121.53, 123.77, 136.24, 139.70, 147.74, 149.36, 153.54, 158.66 ppm; ms, m/z(%): 529 ($M^{+\cdot}$, 100), 437 (7), 424 (10), 332 (10), 318 (8), 106 (50). Anal. calcd. for $C_{33}H_{35}N_7$: C 74.83, H 6.66, N 18.51; found: C 74.43, H 6.70, N 18.53.

2.6-Di(1-(2-(3,5-dimethylpyrazol-1-yl))ethyl-4,5,6,7-tetrahydrobenzopyrazol-3-yl)pyridine **7**a

Following the procedure described above for **5***a*, bispyrazole **2***a* (0.51 g, 1.60 mmol) was treated with tosylate **8** (1.13 g, 3.85 mmol). Purification was carried out by column chromatography on alumina using 2:98 MeOH:CH_2Cl_2 as eluent and recrystallization from CH_3CN to give white crystals (0.522 g, 58% yield), mp 140–142°C; ^{1}H nmr ($CDCl_3$) δ: 1.63 (br, 8H), 1.67 (s, 6H), 1.94 (br, 4H), 2.22 (s, 6H), 2.85 (br, 4H), 4.39 (s, 8H), 5.67 (s, 2H), 7.71 (t, 1H, J = 7.7 Hz), 7.81 (d, 2H, J = 7.7 Hz) ppm; ^{13}C nmr ($CDCl_3$) δ: 9.71, 13.37, 20.48, 22.37, 22.72, 23.22, 48.72, 48.92, 104.74, 115.32, 119.06, 136.25, 140.37, 140.88, 148.05, 148.28, 153.31 ppm; ms, m/z(%): 563 ($M^{+\cdot}$, 100), 467 (18), 454 (16), 441 (18), 345 (24), 319 (21), 229 (27), 200 (25), 123 (40). Anal. calcd. for $C_{33}H_{41}N_9$: C 70.31, H 7.33; N 22.36; found: C 70.28, H 7.38, N 22.40.

2-(3,5-Dimethylpyrazol-1-yl) ethyl tosylate **8**

2-Hydroxyethylhydrazine (1.64 mL, 24.2 mmol) was added to 2,4-pentanedione (2.50 mL, 24.2 mmol) in THF (50 mL) and stirred at room temperature for 1 h before the addition of *p*-toluenesulfonyl chloride (5.70 g, 30.0 mmol) and triethylamine (4.18 mL, 30.0 mmol). The resulting mixture was allowed to reflux overnight. This solution was then stirred vigorously for 1 h after the addition of water (30 mL). The crude product was isolated by extraction with CH_2Cl_2. Purification was carried out by column chromatography on alumina gel using 30:70 EtOAc:petroleum ether as eluent and recrystallization from ether/petroleum ether to give white crystals (5.15 g, 72% yield); ^{1}H nmr ($CDCl_3$) δ: 2.11 (s, 3H, CH_3), 2.23 (s, 3H, CH_3), 2.44 (s, 3H, CH_3), 4.19 (t, 2H, J = 5.1 Hz, CH_2), 4.31 (t, 2H, J = 5.1 Hz, CH_2), 5.72 (s, 1H, pyrazole H), 7.28 (d, 2H, J = 8.2 Hz, tosyl H), 7.62 (d, 2H, J = 8.2 Hz, tosyl H) ppm; ^{13}C nmr ($CDCl_3$) δ: 10.87 (pyrazole CH_3), 13.28 (pyrazole CH_3), 21.55 (tosyl CH_3), 47.03 (CH_3), 68.56 (CH_2), 105.18 (pyrazole CH), 127.79 (tosyl CH), 129.76 (tosyl CH), 132.27 (tosyl C), 140.05 (pyrazole C), 144.81 (tosyl C), 148.08 (pyrazole C) ppm.

1,3-Di(1-(pyridin-2-yl)methyl-4,5,6,7-tetrahydrobenzopyrazol-3-yl)benzene **5**b

Following the procedure described above for **5***a*, bispyrazole **2***b* (0.25 g, 0.79 mmol) was treated with picolyl chloride (0.24 g, 1.90 mmol). Recrystallization from CH_3CN gave light brown crystals (0.255 g, 65% yield), mp 154–156°C; ^{1}H nmr ($CDCl_3$) δ: 1.87 (m, 8H), 2.53 (m, 4H), 2.78 (m, 4H), 5.42 (s, 4H), 6.89 (d, 2H, J = 7.8 Hz), 7.16 (m, 2H), 7.44 (t, 1H, J = 7.7 Hz), 7.60 (m, 2H), 7.73 (d, 2H, J = 7.7 Hz), 8.08 (s, 1H), 8.55 (d, 2H, J = 4.6 Hz) ppm; ^{13}C nmr ($CDCl_3$) δ: 21.61, 22.32, 22.51, 23.32, 54.60, 114.42, 121.24, 122.31, 125.24, 125.58, 128.63, 134.44, 137.02, 140.04, 148.15, 149.10, 157.53 ppm; ms, m/z(%): 500 ($M^{+\cdot}$, 100), 408 (95), 315 (20), 250 (7), 93 (32). Anal. calcd. for $C_{32}H_{32}N_6$: C 76.77, H 6.44, N 16.79; found: C 76.31, H 6.36, N 16.64.

(5b)$_2$Fe$_3$Cl$_9$

To a solution of **5***b* (0.125 g, 0.25 mmol) in EtOH (2 mL) was added a solution of $FeCl_3 \cdot 6H_2O$ (0.135 g, 0.50 mmol) in EtOH (3 mL). The immediate red-brown precipitate was collected by filtration, mp 294–302°C. Yield 91 mg (49%). Anal. calcd. for $C_{62}H_{62}Cl_9Fe_3N_{12}$: C 51.66, H 4.34; N 11.30, Cl 21.44; found: C 51.45; H 4.63, N 11.09, Cl 21.31.

(5b)$_3$Fe$_2$(OAc)Cl$_5$

To a stirring solution of $FeCl_3 \cdot 6H_2O$ (0.108 g, 0.40 mmol) in EtOH (10 mL) was slowly added a solution of **5***b* (0.100 g, 0.20 mmol) in EtOH (15 mL). A small amount of white precipitate formed when half of the ligand had been added. The remaining ligand was added at 60°C, whereupon the white precipitate redissolved. After refluxing for 2 h, HOAc (23 μL, 0.40 mmol) and Et_3N (56 μL, 0.40 mmol) were added. The reaction mixture was refluxed for 6-days, during which the colour changed from red to green, and a brown precipitate formed. This was removed by filtration (yield 25 mg) and found to be insoluble in all solvents tested except hot DMF. The filtrate was rid of solvents and the green oily residue was triturated with CH_3CN and recrystallized from that solvent to give light green crystals (33 mg, 27% yield), mp 181–183°C. Anal. calcd. for $C_{98}H_{99}Cl_5Fe_2N_{18}O_2 \cdot H_2O$:C 63.01; H 5.45, N 13.50, Cl 9.49; found: C 62.79; H 5.48, N 13.79, Cl 9.57.

1,3-Di(1-(2-pyridin-2-yl)ethyl-4,5,6,7-tetrahydrobenzopyrazol-3-yl)benzene **6**b

Following the procedure described above for **5***a*, bispyrazole **2***b* (0.11 g, 0.34 mmol) was treated with 2-(2-pyridine)-ethyl tosylate (0.25 g, 0.92 mmol). Recrystallization from CH_3CN/H_2O gave light brown crystals (0.090 g, 49% yield), mp 124–126°C; ^{1}H nmr ($CDCl_3$) δ: 1.68 (m, 8H), 2.25 (m, 4H), 2.69 (m, 4H), 3.35 (t, 4H, J = 7.0 Hz), 4.41 (t, 4H, J = 7.0 Hz), 6.92 (d, 2H, J = 7.8 Hz), 7.13 (m, 2H), 7.46 (t, 1H, J = 7.7 Hz), 7.52 (m, 2H), 7.71 (d, 2H, J = 7.7 Hz), 8.00 (s, 1H), 8.57 (d, 2H, J = 4.7 Hz) ppm; ^{13}C nmr ($CDCl_3$) δ: 21.35, 22.33, 22.38, 23.35, 39.03, 48.25, 113.07, 121.57, 123.86, 125.10, 125.36, 128.59, 134.56, 136.29, 139.64, 147,73, 149.32, 158.67 ppm. Anal. calcd. for $C_{34}H_{36}N_6 \cdot 1/2H_2O$: C 75.95, H 6.94, N. 15.63; found: C 75.65, H 6.51, N 15.63.

1,3-Di(1-(2-(3,5-dimethylpyrazol-1-yl))ethyl-4,5,6,7-tetrahydrobenzopyrazol-3-yl)benzene 7b

Following the procedure described above for **5***a*, bispyrazole **2***b* (0.34 g, 107 mmol) was treated with tosylate **8** (0.73 g, 2.48 mmol). Purification was carried out by column chromatography on alumina using 2:98 MeOH:CH_2Cl_2 as eluent and recrystallization from CH_3CN to give white crystals (0.355 g, 59% yield), mp 158–159°C; ^{1}H nmr ($CDCl_3$) δ: 1.63 (br, 8H), 1.64 (s, 6H), 1.91 (br, 4H), 2.22 (s, 6H), 2.66 (br, 4H), 4.38 (s, 8H), 5.66 (s, 2H), 7.44 (t, 1H, J = 7.7 Hz), 7.68 (d, 2H, J = 7.7 Hz), 7.97 (s, 1H) ppm; ^{13}C nmr ($CDCl_3$) δ: 9.72, 13.45, 20.48, 22.35, 23.38, 48.85, 48.92, 104.75, 113.41, 125.12, 125.50, 128.67, 134.52, 140.47, 140.87, 148.12, 148.38 ppm; ms, m/z(%): 562 ($M^{+\cdot}$, 100), 466 (30), 453 (7), 440 (10), 370 (95), 344 (50), 281 (10), 233 (12), 185 (11), 123 (40). Anal. calcd. for $C_{34}H_{42}N_8$: C 72.57, H 7.52, N 19.91; found: C 72.76, H 7.58, N 19.86.

Macrocycle **9**

Bispyrazole **2***a* (0.42 g, 1.32 mmol) and aqueous formaldehyde (0.20 mL, 2.67 mmol) were stirred for 2 h at room temperature in MeOH (25 mL), before the addition of phenylethylamine (0.17 mL, 1.32 mmol). Although a deposit soon appeared, the reaction mixture was left for several months, which resulted in the slow precipitation of a thick semisolid. The crude product was obtained by decanting off the supernatant. Purification was carried out by column chromatography on alumina using $CHCl_3$ as eluent, and recrystallization from CCl_4/EtOH to give light brown crystals (0.12 g, 18%), mp 144–147°C; ^{1}H nmr ($CDCl_3$) δ: 1.77 (br, 16H), 2.55 (br, 8H), 2.83 (br, 8H), 2.74 (br, 4H), 3.10 (br, 4H), 5.09 (br, 8H), 7.04 (m, 4H), 7.16 (m, 6H), 7.70 (t, 2H, J = 7.6 Hz), 7.89 (d, 4H, J = 7.6 Hz) ppm; ^{13}C nmr ($CDCl_3$) δ: 21.70, 22.51, 23.01, 23.28, 33.71, 51.12, 65.90, 125.86, 128.19, 128.66, 136.24, 116.11, 119.87, 139.18, 140.02, 147.66, 153.41 ppm. Anal. calcd. for $C_{58}H_{64}N_{12} \cdot H_2O$: C 73.54, H 7.02, N 17.74; found: C 73.51, H 6.63, N 18.18.

Extraction experiments

All operations were conducted at room temperature. Absorbances were determined at 380 nm with an Aminco DW-2a UV/VIS spectrophotometer. The picrate salts were dried under high vacuum before use. Aqueous solutions of the picrate salts were prepared in the 0.0118–0.029 M concentration range. Aliquots (0.4 mL) of the appropriate picrate solution were transferred with a Hamilton Gastight syringe into 1 mL Eppendorf tubes. To these tubes, 0.4 mL of 0.004–0.005 M $CDCl_3$ solutions of the hosts was added by syringe. The tubes were covered immediately to prevent evaporation, and shaken thoroughly using a Vortex Genie mixer for 2 min. The tubes were then placed in a centrifuge for 3 min at high speeds. Aliquots of 0.200 mL of the organic phase were carefully removed by syringe and transferred to 5-mL volumetric flasks, which were then brought to the mark with CH_3CN. The absorbance of each sample was then determined and the R and K_a values were calculated according to Cram's equations (19).

The solution structures of chiral Ti^{4+} alkoxides. II. The roles of diolate basicity and side-chain binding group polarity

STEPHEN BIANCHET AND PIERRE G. POTVIN[1]

Department of Chemistry, York University, 4700 Keele Street, North York, Ont., Canada M3J 1P3

Received July 16, 1991[2]

STEPHEN BIANCHET and PIERRE G. POTVIN. Can. J. Chem. **70**, 2256 (1992).

With a view to reproduce the structure in solution of the Katsuki–Sharpless catalyst (the dimeric complex formed by homochiral diisopropyl tartrate with $Ti(O^iPr)_4$), five C_2-symmetric chiral 2,3-butanediols, related to L-threitol but bearing *N*-, S-, and P-containing groups at the 1- and 4-positions, were prepared and their reactions with $Ti(O^iPr)_4$ were examined by nuclear magnetic resonance spectroscopy. The 1,4-dithioether formed a non-fluxional 2:2 tricyclic complex entirely analogous to those formed by alkylated sugar derivatives. The related disulfone formed a similar complex, but only at low temperatures, probably because of oligomerization at higher temperatures. A symmetric 2:1 complex also formed with excess $Ti(O^iPr)_4$, but incompletely and in equilibrium with the 2:2 species. No well-defined complexes were formed with pyrazole or phosphine oxide functionalities. However, in the presence of trifluoroacetic acid (TFA), a 1:2:2 L:Ti:TFA complex was identified with the dimethylpyrazole-containing diol and this resembled the 2:3 complexes formed by tartramides. Generally, the degree of spectral asymmetry and the coupling constant between diolate protons were instrumental in assigning structures and were used to classify all chiral diolate complexes into two groups according to whether or not they exhibited metal chelation and diolate bridging. By comparison of the effects of complexation on the diolate nuclei, a correlation was found between ^{13}C and ^1H nmr signal positions and between the pairs of signals in the spectra of asymmetric complexes, except in four cases where metal-bound side-chain groups induced a shielding of the bridging diolate proton. This could serve as an additional indication of metal chelation and diolate bridging and confirmed that nuclei at bridging positions appeared upfield of terminal ones. Noting that all the diols that readily chelated and bridged possessed electron-releasing side chains, while tartrates and tartramides that did not chelate possessed electron-withdrawing side chains, the basicity of the diolate oxygens is considered the most important determinant of structure. Side-chain polarity was instead found to influence whether or not a well-defined complex could form.

STEPHEN BIANCHET et PIERRE G. POTVIN. Can. J. Chem. **70**, 2256 (1992).

Afin de copier la structure en solution du catalyseur de Katsuki et Sharpless (le dimère formé par un tartrate homochiral avec le $Ti(O^iPr)_4$), cinq 2,3-butanediols homochiraux et C_2-symétriques, apparentés au L-thréitol mais possédant des groupements azotés, sulfurés ou phosphorés aux positions 1 et 4, furent préparés et leurs réactions avec le $Ti(O^iPr)_4$ furent étudiées par la résonance magnétique nucléaire. Comme l'avaient fait trois glycitols alkylés, le diol 1,4-di(thiophényle) forma un complexe 2 : 2 rigide et tricyclique. La 1,4-disulfone correspondante fit de même, mais seulement à basses températures, probablement par tendance à oligomeriser à températures plus élevées. Un complexe symétrique 2 : 1 s'est incomplètement formé en présence d'excès de $Ti(O^iPr)_4$ et était en équilibre avec l'espèce 2 : 2. Les trois autres diols, par contre, n'ont formé aucun complexe distinct sauf, avec un 1,4-dipyrazole, en présence d'acide trifluoroacétique (TFA). Ceci donna un complexe à rapport 1 : 2 : 2 en diol, titane et acide qui ressemblait aux complexes 2 : 3 formés par deux tartramides. En général, la structure d'un complexe pouvait être déduite en examinant le degré d'asymmétrie spectrale et la constante de couplage entre protons, et ces critères pouvaient servir à classer tous les complexes de diols-1,2 chiraux en deux groupes, selon qu'ils chélatent le titane et pontent les deux métaux d'un dimère ou non. En comparant l'effet d'une complexation sur les positions des raies de rmn dues aux noyaux du groupement diol, on a trouvé, qu'en général, le déplacement chimique d'un proton est relié à celui du carbone-13 auquel il est lié et que, dans les complexes asymétriques où les raies sont doublées, la position d'une raie est reliée à la position de son double. Cependant, quatre exceptions à ces règles étaient dues à un blindage du proton du pont par certains groupements terminaux fixés au titane. Ce phénomène révéla que les raies dus aux noyaux des groupements OCH en position pontante sont à champs plus élevés que ceux dus à la position terminale, et peut aussi servir comme indicateur de chélation et de pontage. Comme il est devenu apparent que tous les diols relativement acides forment des ponts alors que les tartrates et les tartramides, qui sont relativement peu acides, ne pontent pas, c'est l'acidité du diol qui, plus que tout autre facteur, détermine la structure du complexe qu'il pourrait former, alors que les groupements terminaux à polarité élevée peuvent nuire à une complexation nette.

Introduction

The epoxidation of allylic alcohols by ^{t}BuOOH catalyzed by complexes of Ti^{4+} with tartrate esters (e.g., H_2**1**) or tartramides, the Katsuki–Sharpless epoxidation (1), is a rare example of a general and catalytic chiral induction system (2, 3). We had found that analogous complexes of three non-tartrate diol ligands, destined for use in reactions where tartrates would not be compatible (e.g., in enolate chemistry), were poorly enantioselective epoxidation catalysts.[3] Similarly, the Sharpless group (3) explored complexes of some 50 related ligands and also failed to duplicate the success with tartrates. We suspected that this difference in enantioselectivity was due to differences in the structures of the complexes in solution. This was confirmed upon examination of the nmr and mass spectra of the complexes of several ligands (H_2**1**–H_2**9**) with $Ti(O^iPr)_4$ (4). Thus, ligands H_2**2**–H_2**4** gave non-fluxional and strongly asymmetric 2:2 complexes showing little coupling between diolate OC*H* units, little temperature dependence, little concentration dependence, and a reluctance to form 2:1 Ti:ligand species in the presence of excess $Ti(O^iPr)_4$. They were therefore assigned generic structure **A**, essentially that found for Ti_2**5**$_2(O^iPr)_4$ in the solid

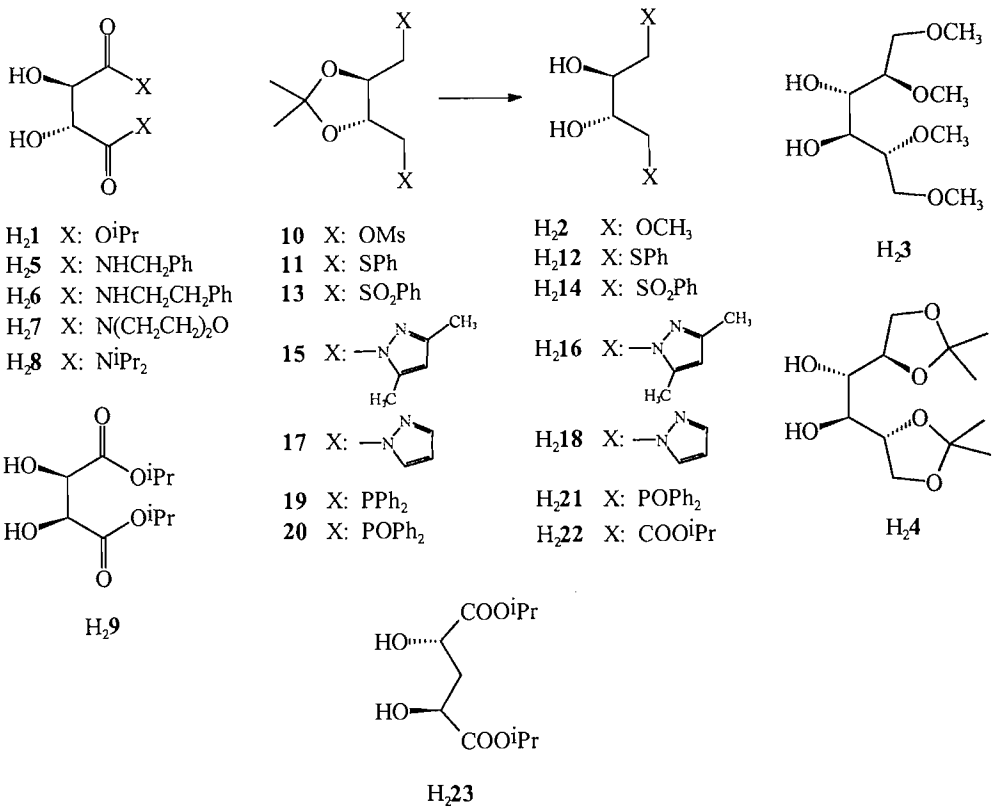
state (5). On the other hand, $Ti_2\mathbf{1}_2(O^iPr)_4$ was fluxional, with rapid equilibration between free and metal-bound ester groups and with rapid TiO^iPr–HO^iPr exchange. At temperatures low enough to arrest these exchanges, the spectra showed only slight asymmetry but strong coupling between skeletal OC*H*. Further, additional $Ti(O^iPr)_4$ produced a mixture of $Ti_2\mathbf{1}_2(O^iPr)_4$ and $Ti_2\mathbf{1}(O^iPr)_6$, which was also fluxional. Upon cooling, the latter dominated and the fluxionality disappeared, giving rise to strongly differentiated but weakly coupled OC*H* groups, as had the non-tartrate complexes at room temperature. With this and other evidence, $Ti_2\mathbf{1}(O^iPr)_6$ at low temperature was assigned structure **B**, the bicyclic analogue of **A**. The *meso* analogue, $Ti_2\mathbf{9}(O^iPr)_6$, behaved in the same way and was assigned an analogous structure. The Katsuki–Sharpless catalyst, $Ti_2\mathbf{1}_2(O^iPr)_4$, was instead assigned a more open structure lacking the diolate bridges (and the metal chelation), **C**, the same structure that had been originally assigned (2) in analogy to the crystal structures of the tartrate salts of transition metal ions (6). With the tartramides $H_2\mathbf{5}$–$H_2\mathbf{8}$, no well-defined species formed at 1:1 stoichiometry, i.e., there was no evidence of the solid-state structure **A** in solution, and we suspected that oligomers had formed. Tartramides had been used in epoxidation with limited success at 2:1 Ti:tartramide ratio (7) but, in our hands, this ratio produced equal amounts of $Ti_3(tartramide)_2(O^iPr)_8$ and free $Ti(O^iPr)_4$ and one cannot explain how such a mixture can produce >75% e.e. without some redistribution in the presence of substrate and (or) product alcohols.



More recently, Finn and Sharpless (8) reported extensive nmr and ir data for tartrate complexes (and only tartrate complexes) and these were interpreted as supporting their assignment of structure **A** to $Ti_2\mathbf{1}_2(O^iPr)_4$. Their ^1H and ^{13}C nmr data matched ours, but these alone are insufficient to differentiate between **A** and **C**. We disagree, however, with some of their interpretations of the ir and ^{17}O nmr data. In particular, the metal-bound C=O stretching frequency assigned to $Ti_2\mathbf{1}(O^iPr)_6$ was higher (1684 cm^{-1}) than that assigned to $Ti_2\mathbf{1}_2(O^iPr)_4$ (1638 cm^{-1}), indicating a *weaker bond in the former*. We think this is due to [2.2.1] bicyclic strain in **B** that is absent in structure **C**. Complexes from tartrate enriched in ^{17}O at the hydroxyls gave rise to two broad ^{17}O nmr peaks some 64–150 ppm apart. This was believed to arise from one terminal and one bridging diolate (as in **A**). The possibility that these peaks arose from two terminal positions in different coordination sites (as in **C**) was dismissed as unlikely, but this was premature as there were no examples of signals from bona fide bridging diolates (in fact, oligomeric $Ti(OEt)_4$, $Ti(O^nBu)_4$, and $Ti(OCH_2Ph)_4$ all showed a single peak in the same region) and because the range of ^{17}O signals was very wide (about 560 ppm), even for simple hydroxyl ^{17}O signals (about 65 ppm).

We attribute the success of $Ti_2\mathbf{1}_2(O^iPr)_4$ to fast reactions on the pentacoordinate template **C** and believe that **A**-like templates are unsuccessful because they react slowly and allow a poorly enantioselective bimetallic mechanism to operate (8). The Sharpless group have discounted a bimetallic mechanism and rather believe that the success of $Ti_2\mathbf{1}_2(O^iPr)_4$ is due to rapid on–off rates for carbonyl binding on an **A**-like template, owing to [2.2.1] bicyclic strain, while all other complexes react more slowly than the trace

amounts of non-enantioselective $Ti(O^iPr)_4$ that may accompany them (8). In any event, it remains that the one really useful complex was also the only one showing its particular nmr spectral features. We believe that one could obtain useful catalysts for other templated reactions if one could reproduce those features with other ligands and we reasoned that the more dipolar side-chains in tartrates and tartramides and the negatively charged side chains of tartrate anion were able to stabilize pentacoordination. Consequently, we have prepared and examined ligands H_2**14**, H_2**16**, H_2**18**, and H_2**21** to test this hypothesis. These ligands bear strongly dipolar secondary binding sites one atom further removed from the alkoxide oxygen than in H_2**1**–H_2**9** and this was expected to also relieve some of the [2.2.1] bicyclic ring strain inherent in tricyclic 2:2 structures like **A** (6). We also examined complexation with the precursor to H_2**14**, the bis-sulfide H_2**12**, with the expectation that it would behave as had the ethers H_2**2**–H_2**4**. In the end, the results support our structural views but our hypothesis was wrong. An examination of the body of available data reveals some common trends that lead to a predictive rationale for the structures formed by chiral diols in general, one formulated in consideration of the basicities of the diolate oxygens as well as the polarities of the side-chain binding groups.

Experimental section

General

THF (dried with K and benzophenone), CH_3CN (CaH_2), CH_2Cl_2 (P_2O_5), TFA (P_2O_5), and $Ti(O^iPr)_4$ were freshly distilled prior to use. $CDCl_3$ was dried over $Mg(ClO_4)_2$. Melting points were obtained on a Reichert apparatus and are uncorrected. The ir spectra were obtained either with neat films on NaCl discs or with mulls in KBr on a Perkin–Elmer 1310 spectrometer. Nuclear magnetic resonance spectroscopy in $CDCl_3$ and spectral simulation, to confirm the chemical shifts and coupling constants in ABX systems, were performed as before (4*b*). The EI and FAB mass spectra were obtained on a ZAB-80 instrument at the McMaster Regional Centre for Mass Spectroscopy, McMaster University. 1,4-Di-*O*-methanesulfonyl-2,3-*O*-isopropylidene-L-threitol (**10**) was prepared by the method of Feit (9), using 2 equivalents of Et_3N in THF rather than pyridine solvent.

(2R,3R)-1,4-Bis(phenylthio)-2,3-dihydroxy-2,3-O-isopropylidenebutane ***11***

Dimesylate **10** (1.437 g, 4.52 mmol) and KBH_4 (1.022 g, 18.95 mmol) were dissolved in dry HO^iPr (20 mL) in a round-bottomed flask, flushed with Ar, and sealed with a septum. While stirring at room temperature, Ph_2S_2 (0.986 g, 4.52 mmol) dissolved in a small amount of HO^iPr was introduced via syringe. After stirring for 48 h, the HO^iPr was removed *in vacuo* and replaced with

EtOAc. This was washed with H_2O, then evaporated to dryness to produce a quantitative yield of an orange oil. This was suitable for the hydrolysis or oxidation steps. A portion (0.384 g) was chromatographed on Silica Gel 60, using 10% EtOAc in hexanes as eluant, to afford 0.330 g of a clear oil (corresponding to an overall 86% yield); ^{1}H nmr δ: 7.38–7.16 (m, 10H, Ph), 4.07 (m, 2H, X part of ABX system, OC*H*), 3.27–3.18 (m, 4H, AB part of ABX system, CH_2), 1.41 (s, 6H, CH_3) ppm; ^{13}C nmr δ: 135.66, 129.41, 128.99, 126.31 (Ph), 109.74 (*C*Me$_2$), 79.01 (OCH), 37.01 (CH_2), 27.30 (CH_3) ppm. Anal. calcd. for $C_{19}H_{22}O_2S_2$: C 65.86, H 6.40, S 18.50; found: C 66.04, H 6.40, S 18.39.

*(2R,3R)-1,4-Bis(phenylthio)-2,3-dihydroxybutane H_2**12***

Crude **11** (0.688 g, 1.96 mmol) was dissolved in MeOH (3 mL) containing CF_3COOH (5 drops) and the mixture heated to reflux for 5 days. After removal of the volatiles *in vacuo*, the pale yellow solid remaining was triturated with hexanes and recrystallized from Et_2O to afford 0.426 g (71% yield) of a flocculent white solid, mp 114.5–115.5°C; ^{1}H nmr δ: 7.37–7.20 (m, 10H, Ph), 3.73 (X part of ABX system, 2H, OC*H*), 3.115 (AB part of ABX system, 4H, Δδ = 0.05 ppm, CH_2), 2.63 (d, 2H, OH) ppm; J_{AB} = 14.2, J_{AX} = 9.14, J_{BX} = 2.68 Hz; ^{13}C nmr δ: 134.82, 130.08, 129.09, 126.73 (Ph), 70.25 (OCH), 38.31 (CH_2) ppm. Anal. calcd. for $C_{16}H_{18}O_2S_2$: C 62.71, H 5.92, S 20.92; found: C 62.47, H. 5.53, S 21.80. For complexation at 1:1 ratio, 81.0 mg of H_2**12** in 2.0 mL of $CDCl_3$ was treated with 79 μL of Ti(O^{i}Pr)$_4$ (total [**12**] = 132 mM). At 2:1 ratio, 42.0 mg of H_2**12** and 82 μL of Ti(O^{i}Pr)$_4$ were used in 1.5 mL of $CDCl_3$ (total [**12**] = 91.4 mM). Aliquots of 0.5 mL were examined by nmr.

Ti$_2$**12**$_2$(O^{i}Pr)$_4$: ^{1}H nmr δ: 7.42–7.15 (m, 20H, Ph), 4.81 (X part of ABX system, 2H, diolate OC*H*), 4.72 (bm, 4H, O^{i}Pr OC*H*), 4.56 (X′ part of A′B′X′ system, 2H, diolate OC*H*), 3.31 (AB part of ABX system, 4H, Δδ = 0.22 ppm, CH_2), 3.18 (A′B′ part of A′B′X′ system, 4H, Δδ = 0.15 ppm, CH_2), 1.20 (d, 24H, O^{i}Pr CH_3) ppm; J_{AB} = 13.52, J_{AX} = 3.29, J_{BX} = 9.91, $J_{XX'}$ = 0, $J_{A'B'}$ = 12.88, $J_{A'X'}$ = 4.30, $J_{B'X'}$ = 8.40 Hz; ^{13}C nmr δ: 136.36, 135.95 (Ar *i*-C), 126.10, 125.95 (Ar *p*-C), 129.41, 128.91, 128.78 (Ar *o*-and *m*-C), 88.41, 83.77 (diolate OCH), 79.28 (O^{i}Pr OCH), 40.44, 37.38 (CH_2), 25.78 (CH_3) ppm.

*(2R,3R)-1,4-Bis(phenylsulfonyl)-2,3-dihydroxy-2,3-*O*-isopropylidenebutane **13***

Crude **11** (0.682 g, 1.97 mmol) in CH_2Cl_2 (10 mL) was treated with 80–85% *meta*-chloroperbenzoic acid (2.02 g) in CH_2Cl_2 (50 mL) via a dropping funnel over the course of 4 h at room temperature. After stirring for 3 days the solvent was removed *in vacuo* and the resulting solid was taken up in saturated $NaHCO_3$, then extracted several times with $CHCl_3$. The combined extracts were dried ($MgSO_4$), filtered, and evaporated. The white solid residue was recrystallized from 1:1 CH_2Cl_2–MeOH to provide 0.655 g, in 2 crops, of a white solid (81% yield); ^{1}H nmr δ: 8.07–7.93 (m, 4H, Ph), 7.69–7.54 (m, 6H, Ph), 4.33 (m, 2H, X part of ABX system, OC*H*), 3.57–3.41 (m, 4H, AB part of ABX system, CH_2), 1.22 (s, 6H, CH_3) ppm; ^{13}C nmr δ: 139.47, 133.97, 129.20, 128.18 (Ph), 110.66 (*C*Me$_2$), 74.49 (OCH), 58.71 (CH_2), 26.69 (CH_3) ppm.

*(2R,3R)-1,4-Bis(phenylsulfonyl)-2,3-dihydroxybutane H_2**14***

Crude **13** was hydrolyzed as was **11**. Recrystallization from $CHCl_3$ afforded an 84% overall yield of a white solid, mp 142.5–143°C; ^{1}H nmr δ: 7.92 (d, 4H, *o*-Ph), 7.70 (t, 2H, *p*-Ph), 7.60 (dd, 4H, *m*-Ph), 4.17 (m, 2H, X part of ABX system, OC*H*), 3.36 (m, 4H, AB part of ABX system, CH_2), 1.57 (bs, 2H, OH) ppm; ^{13}C nmr δ: 138.93 (Ar *i*-C), 134.29 (Ar *p*-C), 129.56 (Ar *o*-C), 127.94 (Ar *m*-C), 67.79 (OCH), 58.73 (CH_2) ppm. Anal. calcd. for $C_{16}H_{18}O_6S_2$: C 51.88, H 4.90, S 17.31; found: C 51.52, H 4.88, S 17.95.

For complexation at 1:1 ratio, 68.4 mg of H_2 **14** in 1.75 mL of $CDCl_3$ was treated with 55 μL of Ti(O^{i}Pr)$_4$ (total [**14**] = 106 mM). At 2:1 ratio, 47.3 mg of H_2**14** and 76 μL of Ti(O^{i}Pr)$_4$ were used in 3.0 mL of $CDCl_3$ (total [**14**] = 42.6 mM). Aliquots of 0.5 mL were examined by nmr.

Ti$_2$**14**$_2$(O^{i}Pr)$_4$: ^{1}H nmr (−23°C) δ: 7.99, 7.93 (2d, 8H, Ph *o*-H), 7.7–7.3 (m, 12H, Ph), 5.22 (X part of ABX system, 2H, diolate OC*H*), 4.81 (X′ part of A′B′X′ system, 2H, diolate OC*H*), 4.12 (bm, 4H, O^{i}Pr OC*H*), 3.66 (AB part of ABX system, 4H, Δδ = 0.35 ppm, CH_2), 3.52 (A′B′ part of A′B′X′ system, 4H, Δδ = 0.45 ppm, CH_2), 1.15 (d, 24H, O^{i}Pr CH_3) ppm; J_{AB} = 14.18, J_{AX} = 9.35, J_{BX} = 0, $J_{X'X'}$ = 0, $J_{A'B'}$ = 14.26, $J_{A'X'}$ = 8.47, $J_{B'X'}$ = 0 Hz; ^{13}C nmr (−53°C) δ: 138.76, 138.55 (Ar *i*-C), 134.22, 133.90 (Ar *p*-C), 129.35, 129.20 (Ar *o*-C), 127.91, 127.78 (Ar *m*-C), 81.82, 79.47 (diolate OCH), 77.20 (O^{i}Pr OCH), 58.85, 57.71 (CH_2), 25.06 (CH_3) ppm. Results

The ligands H_2**12**, H_2**14**, H_2**16**, H_2**18** and H_2**21** were prepared from **10** in straightforward reactions. Compound H_2**21** is apparently not new (3, 10) but, to our knowledge, no details of its preparation have appeared. We found that the bisphosphine analogue of H_2**21** spontaneously oxidized in air and was always contaminated with H_2**21**; it was therefore not studied in complexation experiments.

The bis-sulfide H_2**12** behaved exactly as had the sugar derivatives H_2**2**–H_2**4** in complexation. In a 1:1 mixture with $Ti(O^iPr)_4$, HO^{i}Pr was liberated and a single asymmetric complex formed. It revealed well-resolved and strongly differentiated ligand ^{1}H and ^{13}C nmr signals, even in the phenyl regions. In particular, the diolate O*CH* signals appeared as the uncoupled X portions of separate and overlapping ABX systems downfield of free ligand positions. This was entirely consistent with generic structure **A**. (Unfortunately, both EI and FAB mass spectrometry were totally uninformative.) However, the TiO^{i}Pr and HO^{i}Pr O*CH* signals were unusually broad, indicating rapid TiO^{i}Pr–HO^{i}Pr exchange on an otherwise rigid framework, but these sharpened considerably upon adding excess $Ti(O^iPr)_4$. (No new species had formed with this treatment. Ligands H_2**2**–H_2**4** had shown a similar reluctance to form 2:1 species.) We believe that fast TiO^{i}Pr–HO^{i}Pr exchange in Ti_2**12**$_2(O^iPr)_4$ is due to rapid on–off rates for weaker side-chain binding than in complexed **2**–**4** owing to [2.2.1] bicyclic strain and perhaps to the size and softness of the SPh group, and that extra $Ti(O^iPr)_4$ successfully competes with Ti_2**12**$_2(O^iPr)_4$ in that exchange.

The bis-sulfone H_2**14**, however, behaved very differently. Mixing 1 equivalent of each of H_2**14** and $Ti(O^iPr)_4$ at room temperature (RT) resulted in very broad, indistinguishable ^{1}H and ^{13}C resonances, much as had occurred with tartramides H_2**5** and H_2**6**. However, mixing these while cooling in a $CHCl_3$/Dry Ice bath, and monitoring the spectra while still cold, resulted in a single set of much sharper signals readily attributable to an asymmetric 2:2 **A**-like species. After warming to RT, these signals slowly broadened and overlapped over a few hours, but there was no sign of coalescence during this time, in accord with the formation of a fairly rigid **A**-like structure under conditions of kinetic control while other, perhaps linear and (or) oligomeric species formed under thermodynamic control. The spectral asymmetry was pronounced here also, yet no TiO^{i}Pr signal was visible. Instead, a single, broad O^{i}Pr O*CH* band at 4.12 ppm, accounting for all O^{i}Pr groups, and a single CH_3 doublet appeared. Similarly, a single strong OCH resonance at 77.2 ppm was observed, along with a broad band for HO^{i}Pr O*C*H and a single *C*H_3 signal. Again, excess $Ti(O^iPr)_4$ resolved the one O*CH* resonance into two broad heptets at more normal positions, and this seemed to indicate rapid TiO^{i}Pr–HO^{i}Pr exchanges here too. However, unlike with H_2**12**, treatment with a full second equivalent of $Ti(O^iPr)_4$ also transformed the broad, featureless RT spectrum to reveal a mixture containing the same asymmetric ligand signals, this time showing no tendency to broaden at RT, and a new, symmetric **14**-containing species, presumably Ti_2**14**$(O^iPr)_6$ and accounting for about half the total ligand, along with a corresponding amount of unreacted

For personal use only.

$Ti(O^iPr)_4$. The new diolate OC*H* resonance, part of a single ABX system, appeared at a position between the two resonances due to the putative 2:2 species. Single, albeit somewhat broad, signals were also found in the ^{13}C spectrum. In analogy with H_2**1**, the following equilibrium could then be postulated, with $K \approx 2.9$ (with 0.085 M Ti at RT):

$$Ti_2\mathbf{14}_2(O^iPr)_4 + 2\ Ti(O^iPr)_4 \rightleftharpoons 2\ Ti_2\mathbf{14}(O^iPr)_6$$

Tartrate H_2**1** had more readily formed its 2:1 species at RT ($K \approx 240$), and that equilibrium had shifted in favour of Ti_2**1**$(O^iPr)_6$ upon cooling. Several subtle changes occurred upon cooling the 2:1 mixture of H_2**14**, however, and the situation was much less clear than with H_2**1**. The proportion of free $Ti(O^iPr)_4$ was not readily quantified due to signal overlap and raised baselines. The *ortho* phenyl doublets and, to a lesser extent, the OC*H* signals were helpful in following the equilibrium shifts and coalescence/de-coalescence phenomena during warming or cooling and revealed that the equilibrium shifted toward the right upon cooling with asymmetrization of the 2:1 signals (a new, smaller pair of *o*-Ph doublets also appeared and signaled a third species) and to the left upon heating with coalescence of the 2:2 signals. Similarly, the CH_3 doublet due to free $Ti(O^iPr)_4$ decreased upon cooling and increased upon heating. Apart from the appearance of a third species at low temperature, these changes qualitatively matched the changes seen with H_2**1** in that the putative 2:1 species was symmetric at RT, became asymmetric and more dominant at lower temperatures, and merged with the putative 2:2 species at higher temperatures. However, there was a greater reluctance to form the 2:1 species and the low-temperature OC*H* signals from both 2:1 and 2:2 species overlapped, which we take to indicate that the two have similar ligand environments at low temperature, unlike what was observed with the corresponding 2:1 Ti:H_2**1** mixture (4). Thus, if we assign a **B**-like structure to Ti_2**14**$(O^iPr)_6$ at low temperature (undergoing rapid equilibration at RT), then a non-equilibrating **A**-like structure for Ti_2**14**$_2(O^iPr)_4$ is reasonable, and vice versa. Mass spectrometry (EI, FAB) was attempted with the more stable 2:1 Ti:H_2**14** mixture, but the sample nevertheless decomposed during the process and the spectra were uninformative.

To explain the puzzling, rapid TiO^iPr–HO^iPr exchange and the signal broadening observed only at 1:1 Ti:H_2**14** ratio, both of which were suppressed or slowed with extra $Ti(O^iPr)_4$, we propose the following equilibria, much like those proposed to arise with the tartramides (4*b*), between closed dimeric, linear oligomeric, and 2:1 species, and involving a small amount of open monomer:

$$Ti_2\mathbf{14}_2(O^iPr)_4 + 2\ HO^iPr \rightleftharpoons 2\ Ti(H\mathbf{14})(O^iPr)_3$$

$$n\ Ti(H\mathbf{14})(O^iPr)_3 \rightleftharpoons (Ti\mathbf{14}(O^iPr)_2)_n\ O^iPr + (n-1)\ HO^iPr$$

$$Ti(H\mathbf{14})(O^iPr)_3 + Ti(O^iPr)_4 \rightleftharpoons Ti_2\mathbf{14}(O^iPr)_6 + HO^iPr$$

Since a well-defined 2:2 species could be obtained with H_2**14** by forming the complex at low temperature, a similar strategy was attempted with the tartramides, since only unresolved spectra had previously been obtained at 1:1 stoichiometry (4*b*). Unfortunately, ligands H_2**5**–H_2**7** were too insoluble to form complexes in cold $CDCl_3$ (the complex of H_2**8** precipitated from solution). Inverse addition (ligand to metal) also failed. The dissolution of $CDCl_3$-insoluble H_2**5** in the presence of $Ti(O^iPr)_4$ constitutes an inverse addition, but this required several hours and also resulted in unresolved spectra. The addition of aliquots of H_2**6** to $Ti(O^iPr)_4$, confirmed the 2:3 stoichiometry of the only well-defined species (4*b*).

The bis-pyrazole H_2**16** apparently did not form well-defined complexes at RT at either 1:1 or 2:1 stoichiometries, though liberation of HO^iPr clearly took place, producing a multiplicity of overlapping signals. Cooling or heating failed to clarify the situation and no useful assignments could be made. We surmised that H_2**16** was too bulky and we therefore examined the unsubstituted analogue H_2**18**, but with similar discouraging results. Bulk was therefore not the sole factor. However, a well-defined complex was serendipitously obtained with material that was later determined to be the di-trifluoroacetate salt of H_2**16**, formed when the base treatment was accidentally omitted from the work-up of the TFA-catalyzed hydrolysis of **15**. The preparation of this salt was not entirely reproducible as its melting point, and the shapes and the positions of its ^1H nmr signals were variable, depending on the drying time and upon the age of the material, and this may have been due to varying amounts of trapped TFA. Therefore, this ternary system was instead examined by titration of 1:1–4 ligand–TFA mixtures in $CDCl_3$ with up to 4 equivalents of $Ti(O^iPr)_4$ or, equivalently, of ligand–$Ti(O^iPr)_4$ mixtures with TFA at the same ratios. These experiments revealed two distinct species giving rise to well-resolved spectra.

At a 2:1:2 Ti–H_2**16**–TFA ratio, by either mode of mixing, clear spectra of a single asymmetric **16**-containing species were obtained, with no sign of unreacted H_2**16** or $Ti(O^iPr)_4$ and no detectable broad signals due to binary $Ti(O^iPr)_4$–TFA complexes (examined in control experiments). We presumed, therefore, that this stoichiometry also represented the molecularity of a ternary complex. Mass spectrometry (EI) confirmed this, with fragments at *m/z* 775, 725, 721, and 716, among others, corresponding to loss of $\cdot O^iPr$, cleavage of a side-chain ($C_6H_9N_2\cdot$), loss of $CF_3COO\cdot$ and of two $\cdot O^iPr$, respectively. The signals due to **16** included two aromatic H singlets, one of which was downfield of the corresponding position in the spectrum of free H_2**16**, and four CH_3 singlets with one quite downfield of the other three, as expected for the binding of one side chain per ligand unit. There were also two closely spaced skeletal OC*H* multiplets that were strongly coupled to one another (J = 7.15 Hz) and to separate sets of CH_2 multiplets in an overall ABMM′A′B′ pattern. One CH_2 set was relatively narrow with nearly equal couplings to the attached OC*H* but the other, shifted upfield, was much wider and showed unequal couplings to its attached methine. This coupling pattern, especially the strong coupling between skeletal methines, was very different from those exhibited by the complexes of the other threitol derivatives H_2**2**, H_2**12**, and H_2**14**. This, along with the closely spaced OC*H* signals, indicated the formation here of a different type of complex. Because the same spectra were obtained whether TFA was added last or whether H_2**16** was added to preformed Ti–TFA complexes, because four equally intense TiO^iPr OCH were found, as expected for a 2:1:2 molecularity (the corresponding OC*H* heptets overlapped), and because of the mass spectral data, the TFA was exclusively Ti-bound and not protonating any pyrazole groups. One O^iPr group gave rise to a pair of diastereotopic

TABLE 1. Complexation-induced displacements in ppm of downfield ($\delta_d - \delta_f$) and upfield ($\delta_u - \delta_f$) skeletal OCH signals, and OC*H*–OC*H* coupling constants (J) in Hz

[d] Not reported.

CH_3 doublets that were strongly shielded, probably by a neighbouring bidentate TFA unit.

The modest chemical shift differences for the methine nuclei and the substantial J value were more reminiscent of the 2:2 Ti–tartrate and 3:2 Ti–tartramide complexes (4*b*) than of the complexes of $H_2\mathbf{2}$–$H_2\mathbf{4}$, $H_2\mathbf{12}$, or $H_2\mathbf{14}$, and were consistent with a non-chelating, non-bridging mode of ligation. That only one side chain per ligand was metal-bound without fast exchange implied a certain rigidity that can be rendered by a cyclic structure involving either O^{i}Pr or TFA bridges. Of the several such structures that can be drawn, **D** provides two hexacoordinate metals with an even distribution of TFA units, although no direct evidence of a bridging O^{i}Pr was available and other **D**-like arrangements cannot be ruled out. Similar 7-membered ring structures had been proposed to occur in the 3:2 tartramide complexes, also showing little fluxionality, weak $\Delta\delta$ and large J (entries 2 and 3) (4*b*). They were also found in a crystalline 4:4 tartrate complex (11).

With additional $Ti(O^iPr)_4$ in the mixture (i.e., at 3:1:2 and 4:1:2 Ti–$H_2\mathbf{16}$–TFA stoichiometries) or with more TFA present (i.e., at 3:1:3, 4:1:3, 3:1:4, or 4:1:4 stoichiometries) a new species formed and became dominant. Its spectral features were very similar to those of the putative 2:1:2 species, with only small changes in the positions of the side-chain signals. Broad resonances owing to binary Ti–TFA species were also present. Mass spectrometry of a 4:1:4 sample showed fragments attributable to a mixture of 2:1:4, 2:1:3, and 2:1:2 species at *m/z* 888 ($Ti_2\mathbf{16}(TFA)_4O^iPr$), 829 ($Ti_2\mathbf{16}(TFA)_3(O^iPr)_2$), 775 ($Ti_2\mathbf{16}(TFA)_2(O^iPr)_3$), and 725 ($Ti_2\mathbf{16}(TFA)_2(O^iPr)_4$–$C_6H_9N_2^{\bullet}$, i.e., cleavage of a side chain), among others. Such a mixture could arise by substitution during solvent evaporation. At this time, we cannot fully account for the new species' spectra but they do show that **16** adopts a very similar binding mode (i.e., non-chelating and non-bridging), as in the putative 2:1:2 species.

Unfortunately, the bis-phosphine oxide $H_2\mathbf{21}$ produced unresolved spectra when it was added to either 2 or 1 equivalents of $Ti(O^iPr)_4$ at room temperature or in the cold. Standing, heating, or further cooling failed to improve the resolution. We verified that the P=O group was able to bind by mixing the protected form **20** with $Ti(O^iPr)_4$: the CH_2 multiplet and an *ortho* Ar*H* signal were alone affected. The inability of $H_2\mathbf{21}$ to form a single, well-defined species at least helps explain the complete inability of the Ti–$H_2\mathbf{21}$ mixture to induce enantioselective epoxidation (3, 10).

Discussion

The premise of our structural assignments, essentially whether a diolate moiety is chelating, as in **A** or **B**, or not, as in **C** or *D*, has been based on four criteria: (*a*) rigidity, i.e., slow or fast intra-ligand and TiO^{i}Pr–HO^{i}Pr exchanges (on the nmr timescale), whereby slow exchanges indicate chelation and hexacoordination, and fast exchanges indicate non-chelation and more reactive pentacoordinate metals; (*b*) asymmetry in the signals from the diolate moiety ($\Delta\delta$), whereby strong asymmetry indicates one terminal and one bridging OCH unit per diolate moiety while weak asymmetry indicates a pair of terminal OCH units; (*c*) asymmetry in side-chain signals, whereby strong asymmetry indicates one metal-bound and one free side chain per ligand unit; and (*d*) skeletal conformation, whereby for ligands with one Ti-bound side chain, a weak OC*H*–OC*H* coupling constant (J) is expected from a chelating ligand and a larger J from a non-chelating one. Thus, **A**-like complexes were identified with both $H_2\mathbf{12}$ and $H_2\mathbf{14}$, as previously with $H_2\mathbf{2}$–$H_2\mathbf{4}$ (4), and species lacking chelation were formed from $H_2\mathbf{16}$ and TFA, as previously found with $H_2\mathbf{1}$, $H_2\mathbf{5}$, and $H_2\mathbf{6}$ (4*b*). The complexation behaviour of $H_2\mathbf{14}$, $H_2\mathbf{16}$, and $H_2\mathbf{18}$, and $H_2\mathbf{21}$ certainly did not fit our expectation that their side chains might stabilize pentacoordinate Ti and so give complexes resembling $Ti_2\mathbf{1}_2(O^iPr)_4$. Instead, the side-chain polarity seemed to affect the ease of formation and the stability of well-defined 2:2 or 1:2 complexes.

Upon examination of the entire body of available nmr data, an additional criterion becomes available to further substantiate our view. Table 1 groups the complexes according to the displacements of each of the paired diolate signals in the complexes from their positions in the free ligands ($\delta_d - \delta_f$ and $\delta_u - \delta_f$) and according to measured J values. As described above, two broad groups are apparent: cases with large $\Delta\delta$ ($=\delta_d - \delta_u$) and small J have been associated with

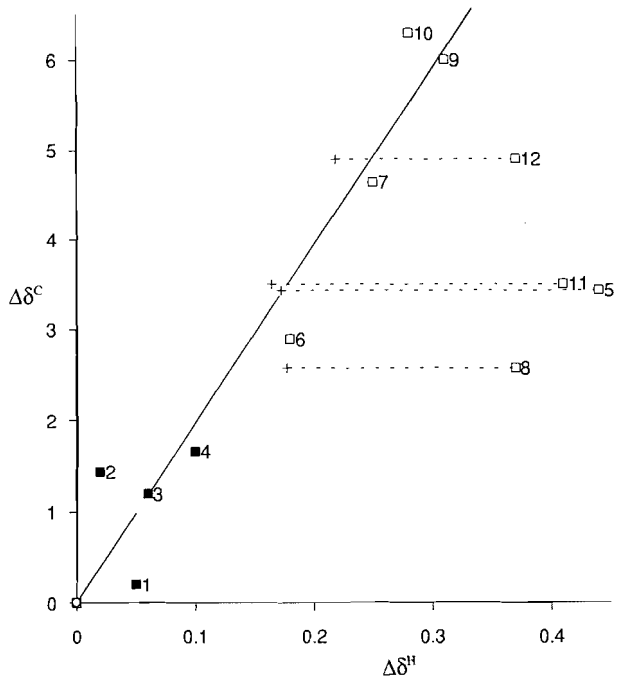

FIG. 1. Plot of $\Delta\delta^C$ vs. $\Delta\delta^H$ for complexes with J = 6.8–7.2 Hz (■) or with $J \leq 2.25$ Hz (□). The least-squares line that excludes the four outliers and that passes through the origin has r = 0.95 and slope 19.6 ± 1.1. If the outliers are "corrected" using interpolated values from Fig. 2 (+), the regression line has r = 0.93 and slope 19.7 ± 0.8 (see text). Numbers on the graph are the entry numbers of Table 1.

metal chelation and diolate bridging whereas those exhibiting small $\Delta\delta$ and large J have been associated with non-chelating and non-bridging modes of ligation. (The *meso* case, entry 6, belongs in the former group even though its *cis* stereochemistry dictates a dissimilar J.) Included in Table 1 is the 2:2 complex of the homotartrate H_2**22** reported (without a value for J) by the Sharpless group (10). It fits into the large $\Delta\delta$-small J group and we thereby agree with the **A**-like structure assigned to it. (It is also noteworthy that Ti_2**22**$_2(O^iPr)_4$ was also a poorly enantioselective epoxidation catalyst.)

It is reasonable to expect that the ^{13}C signal from an OCH grouping be related to its ^1H signal in the degree of downfield displacement resulting from complexation. Consequently, the dissimilarity in ^{13}C chemical shifts between non-equivalent OCH units in a complexed ligand ($\Delta\delta^C$) should correlate with the dissimilarity in the ^1H positions ($\Delta\delta^H$). Figure 1 shows that relation: with the exception of 4 outliers (entries 5, 8, 11, and 12), one can write $\Delta\delta^C \approx 20\Delta\delta^H$ and $(\delta^C - \delta_f^C) \approx 20(\delta^H - \delta_f^H)$. In the four exceptional cases, $\Delta\delta^C$ is unusually small or $\Delta\delta^H$ is unusually large, or both are unusual. Remarkably, one can calculate from Table 1 that $(\delta_u^C - \delta_f^H) = (0.99 \pm 0.06)(\delta_u^C - \delta_f^C)/(\delta_u^H - \delta_f^H)$ for all but the exceptional cases, where $(\delta_u^C - \delta_f^C)/(\delta_u^H - \delta_f^H)$ values are unusually large. In other words, though the ratios of ^{13}C to ^1H displacements vary somewhat from complex to complex, they are usually very much the same within a complex and the downfield positions are correlated to the upfield ones. In fact, a plot of $(\delta^C - \delta_f^C)$ vs. $(\delta^H - \delta_f^C)$ values (Fig. 2) reveals that upfield and downfield partners are connected in a straight line to the origin except in those same four cases where $(\delta^H - \delta_f^H)$ values are unusually small (i.e., their upfield OC*H* signals lie unusually far upfield), leading to the large $\Delta\delta^H$ values in Fig. 1. (If the upfield ^1H displacements are "corrected" in the four exceptional cases by interpolation to the line joining the downfield partners with the origin, then these cases fit the expected correlation of Fig. 1.)

There seems to operate a shielding of the upfield OC*H* in only these four cases. According to Marsi and Roe (12), bridging alkoxide signals are upfield of terminal ones. As well, Grindley and Thangarasa (13) recently found that the bridging OCH nuclei in diols were less affected by complexation to Sn than were terminal ones. Such probably also applies to these Ti–diolate complexes. In one of the exceptional cases, Ti_2**1**$(O^iPr)_6$, we had earlier ascribed the far upfield position of one of the pair of OC*H* signals to a shielding of the bridging OC*H* in **B** by the nearby inward-oriented and metal-bound carbonyl (4*b*) (Fig. 3), an effect not expected in the *meso* analogue of **B** and not apparent from the spectra of Ti_2**9**$(O^iPr)_6$, nor is it expected in complexes lacking chelation. Similar shielding effects appear to be exerted by the sulfonyl group of complexed **14**, by the dimethyldioxolane group of **4**, and by the ester carbonyl of **22**, and assignments of **A**-like structures are therefore fitting. The pyrazole groups of complexed **16** (or **18**) might also be expected to exert this effect; that none was apparent with the ternary complex of H_2**16** further supports the assignment of a non-chelating and non-bridging mode of complexation as in **D**. A similar argument also applies to the parent Katsuki–Sharpless catalyst, Ti_2**1**$_2(O^iPr)_4$: a shielding effect operating in **B** would also be expected in an **A**-like structure; that none was apparent argues against it.

We have thus far been unable to reproduce the spectral behaviour of this catalyst by simply incorporating strongly dipolar groups on a threitol skeleton. Similarly, Burns *et al.* found that Ti_2**22**$_2(O^iPr)_4$ did not resemble nor behave like Ti_2**1**$_2(O^iPr)_4$, but the 2:2 complex of H_2**23** did show ir and nmr similarities to that of **1** and was an enantioselective epoxidation catalyst for primary allylic alcohols (10). The two complexes should therefore have similar structures. Unlike Ti_2**1**$_2(O^iPr)_4$, however, Ti_2**23**$_2(O^iPr)_4$ was poor at kinetic selection between secondary allylic alcohol enantiomers. That observation was arduously rationalized on an **A**-like template (10) but is readily understood in terms of the increased but detrimental flexibility in a **C**-like complex with two extra methylenes. As these authors have pointed out, the major difference between H_2**22** and H_2**23** (or H_2**1**) is *the basicity of the diolate oxygens*: the sp^2 carbons attached to the diol moieties in H_2**1** and H_2**23** render their diolate oxygens less basic than do the sp^3 carbons in H_2**22**. Indeed, this is the major difference between tartrates, tartramides, or H_2**23**, which have electron-withdrawing side–chains and which give small $\Delta\delta$ – large J complexes, on the one hand, and all of the other ligands giving large $\Delta\delta$ – small J complexes with electron-releasing side – chains, on the other. The added basicity in the latter group stabilizes diolate bridges (chelation).

Other effects might conceivably be at play. For instance, the choice of chelation by H_2**14** and H_2**22** might have been influenced by a reduction in bicyclic strain (to [3.2.1]) that the extra methylenes in these ligands afford, but this cannot be the dominant influence since chelation was apparently also obtained with H_2**2**–H_2**4** and H_2**12**. In fact, the difference in C=O chemical shifts between bound and free ester groups

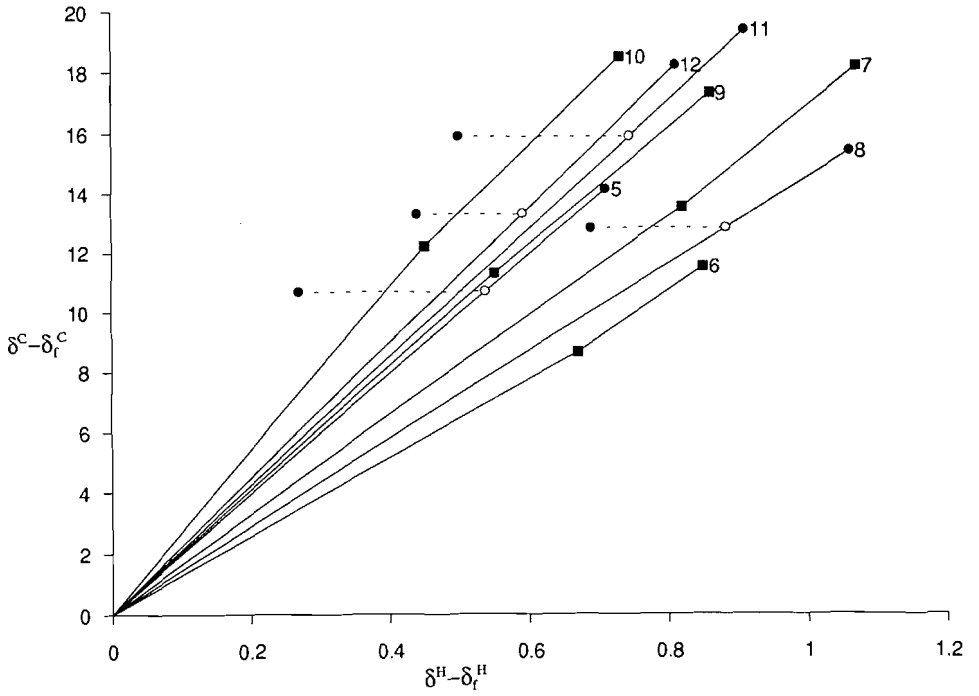

FIG. 2. Plots of $\delta^C - \delta_f^C$ vs. $\delta^H - \delta_f^H$ for strongly asymmetric complexes (i.e., with $J \leq 2.25$ Hz), including outliers (●) and interpolated values (○) (see text). Numbers on the graph are the entry numbers of Table 1.

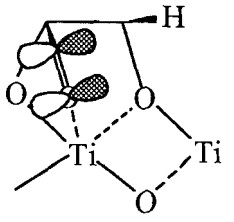

FIG. 3

in $Ti_2\mathbf{22}_2(O^iPr)_4$ was smaller than in $Ti_2\mathbf{1}_2(O^iPr)_4$ (2.1 (10) vs. ≈5 ppm (4*b*) at −10°C) and ν_{CO} for the Ti-bound ester group from **22** was higher (1688 (10) vs. 1635 (8) cm^{-1}) than that from **1**. Both observations indicate *stronger metal–carbonyl bonds* in $Ti_2\mathbf{1}_2(O^iPr)_4$. This is inconsistent with **A**-like structures for both $Ti_2\mathbf{1}_2(O^iPr)_4$ and $Ti_2\mathbf{22}_2(O^iPr)_4$ but is consistent with a **C**-like structure for $Ti_2\mathbf{1}_2(O^iPr)_4$. Therefore, instead of side-chain polarity or bicyclic strain, we now believe that diolate basicity is the most important determinant of complex structure and, by association, of catalyst enantioselectivity.

The lack of diolate bridging and hexacoordination in $Ti_2\mathbf{1}_2(O^iPr)_4$ must be due to bicyclic strain: Consider the fragments of the crystal structures (5) of $Ti_2\mathbf{5}_2(O^iPr)_4$ and $Ti_2det_2(ONPhBz)_2(OEt)_2$ (H_2det = diethyl tartrate) reproduced in Fig. 4. The main effects of the [2.2.1] bicyclic strain in the former are a long bridge (2.173 Å)[4] and a long bond to the carbonyl (2.206 Å)[4], compared to a bridge of normal (14) length (averaging 2.008 Å)[4] and a shorter bond to the carbonyl (averaging 2.084Å)[4] in the latter structure lacking such strain. Overall, the tricyclic core of crystalline $Ti_2\mathbf{5}_2(O^iPr)_4$ appears incompletely formed and "spring-loaded" (3, 10), at a delicate compromise in the tug of war between bridge formation with a poorly basic oxygen and binding to the polar carbonyl, a compromise that could not be guaranteed to persist in solution (it appears not to (4*b*)) and that $Ti_2\mathbf{1}_2(O^iPr)_4$, with less dipolar side–chains, evidently cannot easily reach on its own. In the absence of added univalent bidentates like HONPhBz, the 2:2 tartrate complex appears to make do with pentacoordination, preferring to altogether forego the bridge to, instead, strongly bind the carbonyl uninhibited by bicyclic strain. The pentacoordination can ex-

[4]From atomic positional parameters (supplementary material, ref. 5).

plain the observed high exchange and epoxidation rates. Generally, however, the more basic diolates in non-tartrate complexes favour bridging at the expense of side-chain binding, leading to lower rates, with two qualifications: too polar a side–chain seems to allow complex, ill-resolved mixtures (probably of oligomers) to develop, and the presence of bidentate TFA ligands obviated the need for H_2**16** to form diolate bridges.

With respect to the design of chiral Lewis acids for use in reactions under strongly nucleophilic or basic conditions, we have yet to achieve our goal. However, we are currently endeavouring to prepare ligands with base- and nucleophile-stable, but electron-withdrawing, side-chain groups that reduce the diolate basicity and favour **C**-like structures.

Réduction électrochimique régiosélective d'aroyl-2- ou d'acetyl-2 chromones en milieu non aqueux

PATRICK BOUTOUTE ET GUY MOUSSET[1]

Laboratoire d'électrochimie organique unité associée au centre national de la recherche scientifique n° 434, Thermodynamique et électrochimie en solution, Université Blaise Pascal, 24, Avenue des Landais, 63177 Aubière CEDEX, France

Reçu le 22 janvier 1992

PATRICK BOUTOUTE et GUY MOUSSET. Can. J. Chem. **70**, 2266 (1992).

Le comportement électrochimique de chromones substituées en position 2 par des groupements benzoyle et acétyle a été étudié par voltammétrie cyclique en milieu non aqueux (DMF). La présence d'une fonction phénol sur le groupement benzoyle entraine un phénomène d'auto-protonation. Des macroélectrolyses réalisées en présence d'un donneur de proton ont mis en évidence une réduction régiosélective de la fonction carbonyle du groupement benzoyle avec la benzoyl-2 chromone et de la double liaison pour l'acétyl-2 chromone. L'électrochimie permet, par un choix judicieux du potentiel, de réaliser un second transfert électronique sur les produits de réduction avec formation de structures dimères thermiquement instables conduisant à des radicaux libres par coupure homolytique d'une liaison carbone–carbone.

PATRICK BOUTOUTE and GUY MOUSSET. Can. J. Chem. **70**, 2266 (1992).

The electrochemical behaviour of chromones substituted in position 2 by benzoyl or acetyl groups was studied by cyclic voltammetry in a nonaqueous solvent. Self-protonation reactions were observed with compounds possessing a phenol function on the benzoyl group. Macroelectrolyses achieved in the presence of a proton donor afford a regioselective reduction of the carbonyl function in position 2 of the benzoyl-2 chromone and of the double bond for the acetyl-2 chromone. Moreover the further reduction leads to the formation of thermally unstable dimers, which may give homolytic cleavage to free radicals.

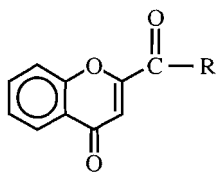
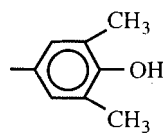
Introduction

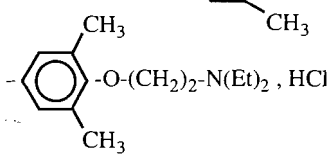
Les chromones et leurs dérivés sont des molécules rencontrées fréquemment dans certains médicaments dont le métabolisme fait intervenir une forme réduite (1–4). Notre travail est consacré à l'étude de la réduction électrochimique d'aroyl-2 ou d'acétyl-2 chromones du type :



R = C_6H_5 **1**; CH_3 **2**; *o*-C_6H_4OH **3**; *p*-C_6H_4OH **4**



5



6

Chacun de ces composés possède, en position 2 du cycle chromone, un substituant comprenant une fonction carbonyle aromatique ou non, conjuguée avec la fonction cétone α,β-éthylénique du cycle de la chromone. La réduction chimique régiosélective de l'une ou l'autre des fonctions carbonyles ou de la double liaison est délicate et fournit souvent des mélanges de produits (5, 6). Le comportement électrochimique des cétones aromatiques ou α,β-éthyléniques aromatiques a donné lieu à de nombreuses études (7–13) et les mécanismes de leur réduction sont maintenant bien établis. Dans ce travail, nous avons étudié la réduction des chromones substituées **1**–**6** en milieu aprotique (DMF) ou en présence d'un donneur de proton essentiellement dans le but de réaliser des réductions sélectives des diverses fonctions présentes dans ces molécules. Ainsi, le choix du potentiel imposé peut permettre de réduire uniquement une fonction de la chromone. Le produit de la réaction étant lui-même électroactif, un nouveau transfert électronique peut être réalisé à un potentiel plus négatif que celui du substrat de départ, avec formation d'un second produit de réduction. Une complémentarité entre les méthodes chimiques et électrochimiques a déjà été mentionnée dans le cas de thiazines substituées (14).

Résultats et discussion

*Cas de la benzoyl-2 chromone **1***

Étude en milieu aprotique

En milieu aprotique (fig. 1), la benzoyl-2 chromone (BC, R = C_6H_5) se réduit en deux étapes monoélectroniques dont les potentiels de pics sont E_{pc1} = −0,63 V et E_{pc2} = −1,16 V. La différence de potentiel entre les pics anodiques et cathodiques est δE_p = 80 mV pour chaque étape considérée donc comme quasi réversible. Le premier transfert correspond à la formation du radical anion et le second au dianion :

$$BC + 1e^- \underset{}{\overset{E_{pc1}}{\rightleftharpoons}} BC^{\cdot -}$$

$$BC^{\cdot -} + 1e^- \underset{}{\overset{E_{pc2}}{\rightleftharpoons}} BC^{2-}$$

La réversibilité du second transfert montre que le dianion n'est pas une base très forte en raison de la délocalisation importante de la charge. Une électrolyse au potentiel de la première étape de réduction, conduite *in situ* dans l'entrefer d'un appareil de RPE a permis d'obtenir le spectre du radical-anion $BC^{\cdot -}$ (fig. 2).

Une structure hyperfine est ainsi observée : elle correspond aux couplages avec l'atome d'hydrogène porté par la double liaison et avec ceux des noyaux aromatiques. Seule

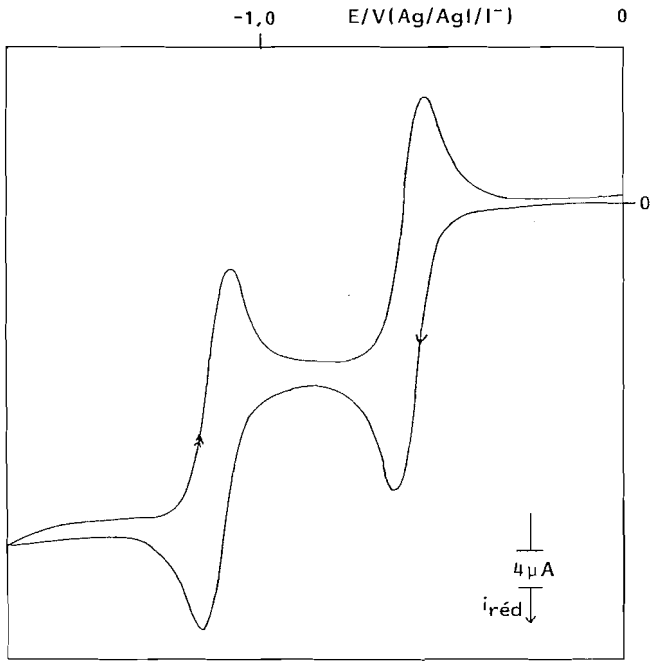

FIG. 1. Voltammogramme de la benzoyl-2 chromone **1** en solution dans le DMF ($C = 5 \times 10^{-3}$ M). Electrolyte support Bu_4NBF_4 (0,1 M). Electrode de carbone vitreux $v = 0{,}02$ V s^{-1}.

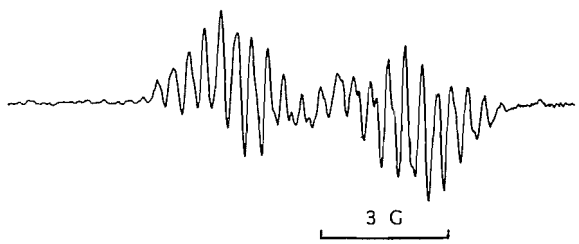

FIG. 2. Spectre de RPE enregistré en cours d'électrolyse sur cathode de Cu/Hg ($A \simeq 1{,}5$ cm^2) de la benzoyl-2 chromone ($c = 5 \times 10^{-3}$ M). Electrolyte support Bu_4NBF_4 (0,1 M). Gain $2{,}5 \times 10^5$. Modulation $1{,}6 \times 10^{-1}$ G. Champ 3270 G. $i = 150$ µA.

la constante de couplage de l'électron avec l'hydrogène éthylénique a été mesurée. Sa valeur $a_{Heth} = 4{,}36$ G permet de déterminer, par la formule de MacConnell et Chesnut (15), une densité de spin assez faible sur ce carbone ($\rho = 0{,}180$). Une microcoulométrie réalisée au potentiel de la première étape fournit la valeur $n = 0{,}84$ F mol^{-1}.

Etude en milieu protique

Nous avons utilisé comme donneur de proton le phénol (PhOH), l'hydrogénosulfate de tétrabutyl ammonium (Bu_4NHSO_4) ou l'acide acétique (AcOH), ce dernier présentant l'inconvénient de donner, pour des quantités importantes d'acide, une étape de réduction du proton.

Des additions successives de phénol (ou de Bu_4NHSO_4) entrainent une augmentation de l'intensité de la première étape de réduction de la benzoyl-2 chromone sans modifier son potentiel (fig. 3). Pour un rapport de concentrations m = [donneur de proton]/[chromone] = 6 l'intensité a presque doublé ce qui indique que le système évolue vers un stade biélectronique. Une coulométrie réalisée dans ces conditions (phénol, $m = 6$) indique une consommation d'électricité correspondant à 1,6 F mol^{-1}. Parallèlement à

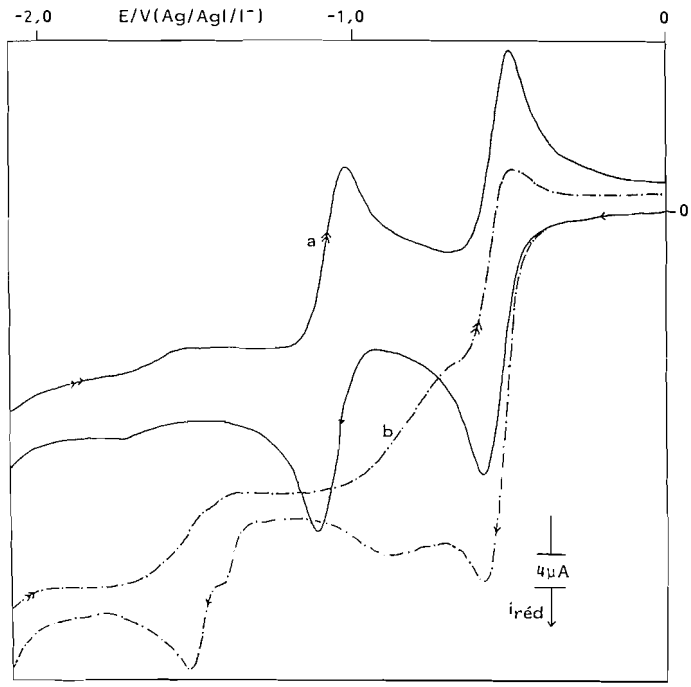

FIG. 3. Voltammogrammes de la benzoyl-2 chromone **1** ($c = 5 \times 10^{-3}$ M) dans le DMF. Electrolyte support Bu_4NBF_4 (0, 1 M). Concentration en phénol (*a*) $c' = 0$; (*b*) $c' = 10^{-2}$ M. Electrode de carbone vitreux $v = 0{,}02$ V s^{-1}.

cette évolution, on note la disparition progressive de la réversibilité de cette étape. Les premières additions de phénol entrainent une diminution de l'intensité de la seconde étape et l'apparition progressive de deux nouveaux pics de réduction à des potentiels plus négatifs ($E_{pc3} = -1{,}42$ V et $E_{pc4} = -1{,}52$ V). Ceux-ci peuvent être liés à la réduction du (ou des) produit(s) formés à la première étape en milieu protique. Nous sommes en présence d'un mécanisme de type biélectronique avec protonation du radical-anion intermédiaire selon :

$$BC \underset{}{\overset{1e^-}{\rightleftharpoons}} BC^{\cdot-} \xrightarrow{PhOH} BCH^{\cdot} \xrightarrow[(\text{ou } BC^{\cdot-})]{1e^-} BCH^- \xrightarrow{PhOH} BCH_2$$

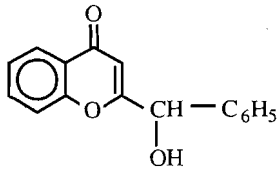
Des additions d'acide acétique entrainent la disparition progressive de la seconde étape de réduction de la chromone et une modification de la première par formation d'une prévague dont l'intensité croit avec la concentration en acide jusqu'à correspondre à un échange biélectronique. Une coulométrie réalisée en présence d'acide dans le rapport m = [acide]/[chromone] = 5 conduit à une consommation d'électricité égale à $n = 1{,}65$ F mol^{-1}. La présence d'un prédstade traduit la formation d'une espèce plus électroactive que la chromone elle-même.

$$BC \overset{AcOH}{\rightleftharpoons} [BC\text{–}HOAc] \xrightarrow[E'_{pc1}]{1e^-} BCH^{\cdot} \xrightarrow[E'_{pc1}]{1e^-} BCH^- \xrightarrow{AcOH} BCH_2$$

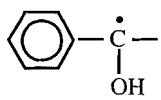
Comme dans le cas du phénol, la première étape de réduction

devient irréversible et son intensité augmente aux dépens de la seconde jusqu'a correspondre à un système biélectronique.

Une macroélectrolyse réalisée en présence de deux équivalents d'acide acétique au potentiel de −0,55 V conduit après consommation de 1,69 F mol^{-1} à l'(hydroxy-1 benzyl)-2 chromone 7



L'effet attracteur du groupement benzoyle a entraîné une localisation préférentielle de l'électron célibataire sur la partie



de la molécule conduisant à la réduction de la fonction carbonyle, le carbanion issu du second transfert étant vraisemblablement protoné plus rapidement que la forme énolate. La structure du produit est confirmée par comparaison avec un échantillon authentique obtenu par réduction chimique avec $NaBH_4$.

Réduction de l'acétyl-2 chromone 2

En milieu aprotique, l'acétyl-2 chromone (AC) **2** se réduit en trois étapes dont les deux premières sont faiblement réversibles (fig. 4(*a*)).

Les potentiels des pics sont respectivement $E_{pc1} = -0,70$ V, $E_{pc2} = -1,15$ V et $E_{pc3} = -1,46$ V. La première étape conduit par un transfert monoélectronique à un radical anion relativement instable.

$$AC + 1e^- \rightleftarrows AC^{\cdot -}$$

La faible réversibilité de cette étape peut provenir d'une protonation partielle du radical anion par des impuretés acides du solvant (SH) ou par le substrat lui-même qui possède des atomes d'hydrogène en α d'une fonction carbonyle (16).

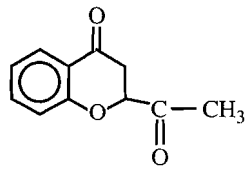
$$AC^{\cdot -} + SH \text{ (ou } AC) \rightarrow ACH^{\cdot} + S^- \text{ (ou } AC^-)$$

La seconde étape qui disparait en présence d'un donneur de proton est attribuée à la réduction du radical-anion en dianion

$$AC^{\cdot -} + 1e^- \rightarrow AC^{2-}$$

La troisième étape dont l'intensité est augmentée par addition d'un donneur de proton peut correspondre à la réduction d'une forme dihydro ACH_2 résultant de la protonation du dianion par un mécanisme ECEC. Il faut cependant noter que l'acétyl-2 chromone donne lieu à d'importants phénomènes de maxima sur électrode de mercure en particulier en présence d'un donneur de proton (fig. 4(*b*)). L'interprétation des voltammogrammes est de ce fait rendue difficile.

Une macroélectrolyse réalisée au potentiel de −0,6 V en présence de deux équivalents d'acide acétique conduit ici à la réduction de la double liaison du cycle chromone avec formation de l'acétyl-2 chromanone



8

Réduction des aroyl-2 chromones substituées ***3–6***

Ces composés pourront jouer le rôle de donneur de proton par l'intermédiaire de leur fonction phénol ou chlorhydrate d'amine. Les anions électrogénérés en milieu de faible acidité seront protonés par le substrat selon un processus d'auto-protonation (17–20). Ainsi, les voltammogrammes des chromones substituées **3–6** présentent tous une étape de

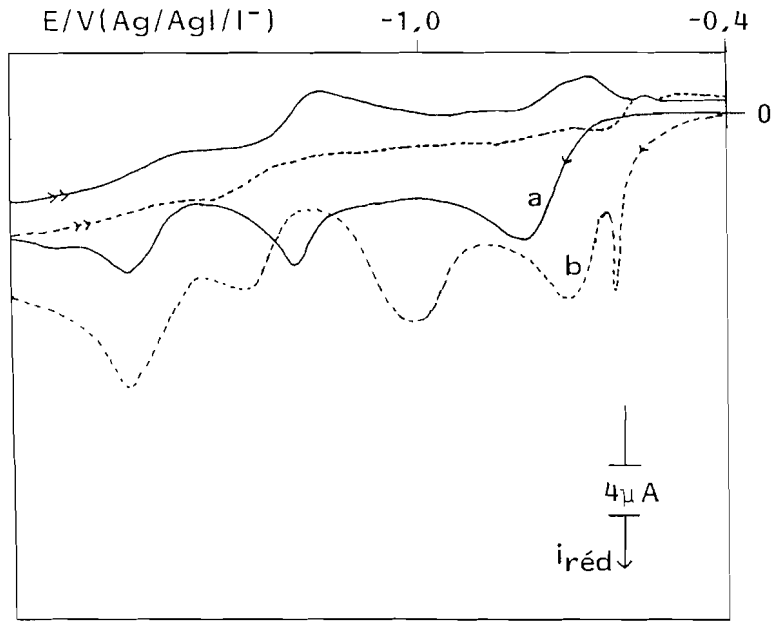


FIG. 4. Voltammogrammes de l'acétyl-2 chromone **2** ($c = 5 \times 10^{-3}$ M) dans le DMF. Electrolyte support Bu_4NBF_4 (0,1 M). Electrode de mercure stationnaire. $v = 0,1$ V s^{-1}. Concentration en CH_3COOH (*a*) $c' = 0$; (*b*) $c' = 10^{-2}$ M.

réduction irréversible C_1 située à un potentiel moins négatif que celui observé pour la benzoyl-2 chromone **1**. Nous étudierons à titre d'exemple (fig. 5) la (diméthyl-3',5' hydroxy-4' benzoyl)-2 chromone ainsi que les *ortho* et *para* hydroxybenzoyl-2 chromones. Les valeurs des potentiels des diverses étapes sont réunies dans le tableau 1. Nous pouvons observer que la première étape de réduction de l'isomère *ortho*-hydroxylé **3** se situe à un potentiel moins négatif que celle de l'isomère *para* **4** (tableau 1). Ce phénomène déjà observé dans le cas de céto-alcools (21) est relié à l'établissement pour l'isomère *ortho* d'une liaison hydrogène entre les fonctions phénol et carbonyle rendant cette dernière plus facilement réductible que pour l'isomère *para* où une telle interaction est impossible. L'étape de réduction irréversible C_1 dont le courant limite est supprimé par addition d'un équivalent de base (Bu_4NOH) correspond logiquement à la réduction du substrat sous sa forme phénolique (BCOH). Le radical-anion formé :

$$BCOH + 1e^- \xrightarrow{C_1} BC^{\cdot}OH$$

est ici protoné par le dépolarisant avec formation du radical neutre $HBC^{\cdot}OH$ plus facilement réductible. L'absence de réversibilité pour le pic C_1 peut se justifier par l'existence d'un deuxième transfert à l'électrode (processus ECE) ou par une dismutation (DISP) (20, 22).

$$BC^{\cdot}OH + BCOH \leftrightarrows HBC^{\cdot}OH + BCO^-$$

$$HBC^{\cdot}OH + 1e^- \xrightarrow[\text{rapide}]{} HBC^-OH$$

ou

$$HBC^{\cdot}OH + BC^{\cdot}OH \rightarrow HBC^-OH + BCOH$$

Afin de déterminer la nature du mécanisme, nous avons réalisé une étude des variations du potentiel de pic E_{pc1} en fonction de la vitesse de balayage ou de la concentration. Aucune réversibilité pour le pic C_1 n'est observée jusqu'à la vitesse de 150 V s^{-1} qui est le maximum que nous puissions obtenir. Pour le composé **4**, la fonction $E_p = f(\log c_o/v)$ est représentée par une droite de pente $dE_p/d(\log c_o/v) = 29{,}9$ mV. La variation du potentiel de pic en fonction de c_o pour une vitesse $v = 0{,}1$ V s^{-1} conduit également à une droite de pente $dE_p/d(\log c_o) = 29{,}6$ mV par décade de concentration. La mesure de la largeur de pic pour différentes vitesses de balayage (0,1–25 V s^{-1}) fournit une valeur moyenne $E_{p/2} - E_p = 58$ mV. L'ensemble de ces résultats est en accord avec un processus de type ECE_{irr} ou DISP 1 (17). L'absence de réversibilité ne permettant pas de définir la valeur de E_o pour le système $BCOH/BCOH^{\cdot-}$, il est difficile de préciser lequel des deux mécanismes intervient dans ce cas. Une coulométrie réalisée au potentiel de l'étape C_1 a fourni une valeur $n = 0{,}82$ F mol^{-1}.

L'étape réversible C_2 prépondérante en milieu basique, correspond à la réduction de l'ion phénate :

$$BCO^- + 1e^- \underset{E_{pA_2}}{\overset{E_{pC_2}}{\rightleftharpoons}} BC^{\cdot}O^-$$

En présence de base, l'intensité du pic cathodique C_2 augmente au détriment de l'étape C_1 qui le précède et sa réversibilité est améliorée. Une électrolyse *in situ* dans la cavité d'un spectromètre de RPE a permis d'enregistrer le spectre du radical dianion en présence d'un équivalent de base (fig. 6).

Le troisième pic C_3 faiblement réversible, dont l'intensité augmente en présence d'un équivalent de base correspond à la réduction de derivés carbonylés formés par destruction de la chromone en milieu fortement basique (6).

La dernière étape C_4 située à potentiel très réducteur rend compte de la réduction de l'espèce formée en C_2 :

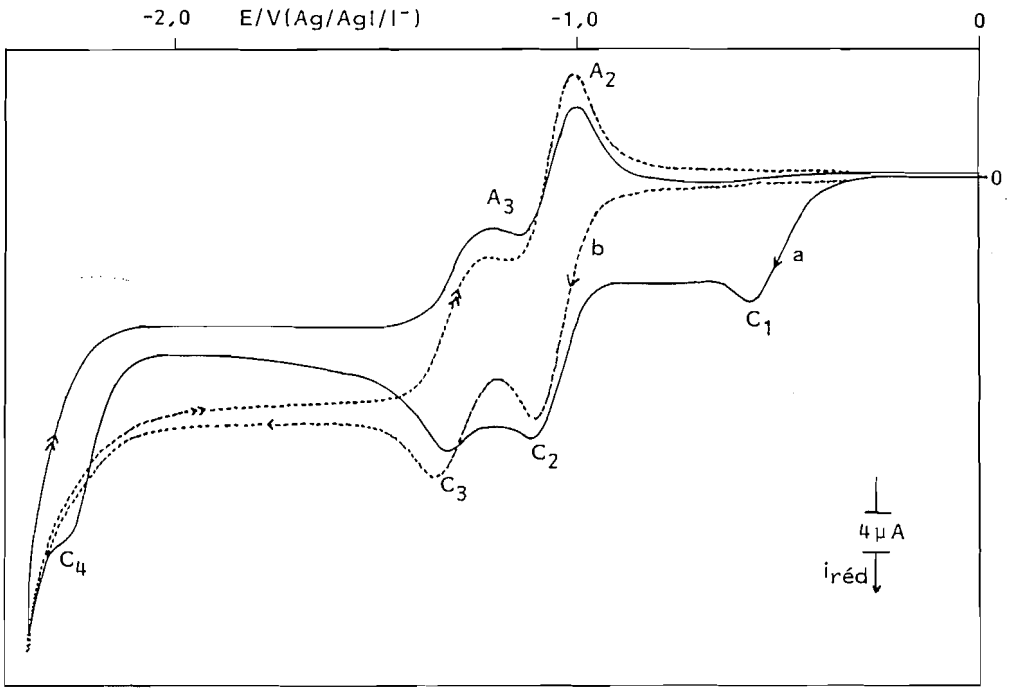

FIG. 5. Voltammogramme de la (diméthyl-3',5' hydroxy-4' benzoyl)-2 chromone **5** ($c = 5 \times 10^{-3}$ M) dans le DMF. Electrolyte support Bu_4NBF_4 (0,1 M). Electrode de carbone vitreux $v = 0{,}02$ V s^{-1}. Concentration en base (Me_4NOH) : (*a*) 0; (*b*) 5×10^{-3} M.

Spectre de RPE enregistré en cours d'électrolyse sur cathode de Cu/Hg ($A \simeq 2{,}5$ cm^2) de la (diméthyl-3′,5′ hydroxy-4′ benzoyl)-2 chromone **5** ($c = 5 \times 10^{-3}$ M) en présence d'un équivalent de base (Me_4NOH). Electrolyte support Bu_4NBF_4 0,1 M. Champ 3270 G. Gain $1{,}6 \times 10^5$ et modulation $1{,}6 \times 10^{-1}$ G. $i = 40$ μA.

$$BC^{\cdot}O^- + le^- \rightarrow BC^{2-}O^- \xrightarrow[\text{rapide}]{\text{solvant}} BCOH^{2-}$$

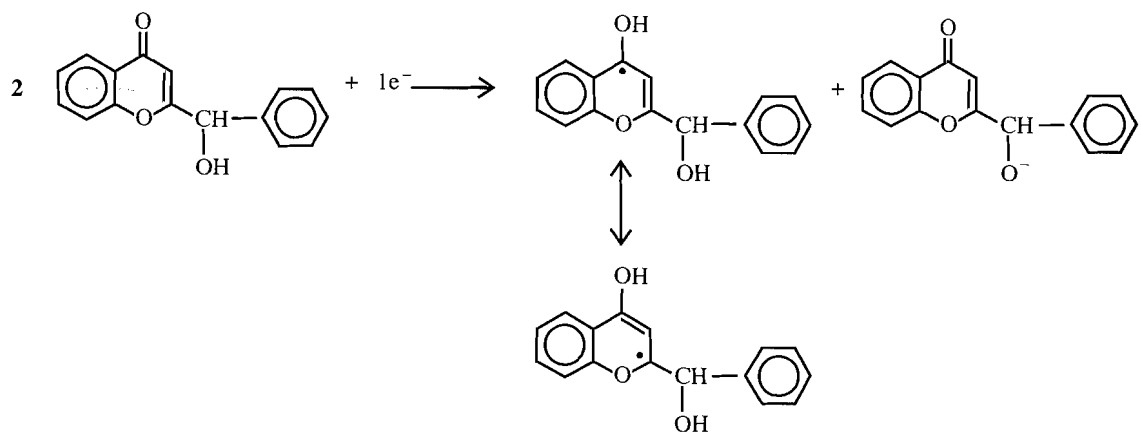
Le trianion qui est une base très forte est protoné rapidement par les impuretés acides du milieu de telle sorte que sa réoxydation ne peut être observée. Des additions de base qui suppriment sa protonation déplacent son potential vers des valeurs plus négatives et ne permettent plus de l'observer de manière nette en raison de la proximité de la vague de réduction de l'électrolyte.

En présence d'un donneur de proton (AcOH), l'étape C_2 disparait au profit de la première C_1 dont l'intensité augmente jusqu'à correspondre à un échange biélectronique. Lorsque l'addition d'acide est réalisée en présence d'un mélange d'(hydroxy-2′-) et d'(hydroxy-4′ benzoyl)-2 chromones **3** et **4**, on constate que la protonation a lieu en premier avec l'(hydroxy-4′ benzoyl)-2 chromone **4**, cette dernière ne possédant pas de liaison hydrogène avec la fonction carbonyle susceptible de rendre la protonation plus difficile (fig. 7).

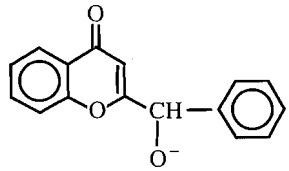
Étude électrochimique des produits obtenus par électroréduction en milieu protique de la benzoyl-2 et de l'acétyl-2 chromone

L'(hydroxy-1 benzyl)-2 chromone **7** et l'acétyl-2 chromanone **8** obtenues lors des macroélectrolyses réalisées avec les chromones **1** et **2** en présence d'acide acétique possèdent encore une fonction carbonyle électroréductible. Le voltammogramme de l'(hydroxy-1 benzyl)-2 chromone obtenu sans addition d'un donneur de proton est constitué de deux pics cathodiques situés aux potentiels $E_{pc'1} = -1{,}38$ V et $E_{pc'2} = -1{,}64$ V et d'un pic anodique dont le potentiel est $E_{pA} = -0{,}50$ V (fig. 8). Le premier pic cathodique est irréversible alors que le second d'intensité moindre possède une faible réversibilité. Une électrolyse au potentiel de la première étape n'entraîne pas la disparition de la seconde dont l'intensité augmente. Des additions d'un donneur de proton (AcOH ou Bu_4NHSO_4) provoquent la disparition de cette seconde étape avec formation d'une vague unique irréversible au potentiel de −1,25 V. Une étude du premier pic de réduction en fonction de la vitesse de balayage montre une irréversibilité totale jusqu'à 150 V s^{-1}. Lorsque la concentration en dépolarisant est augmentée, on constate un déplacement du potentiel de pic vers des valeurs plus positives ($\Delta E_p = 12$ mV lorsque la concentration varie entre $2{,}5 \times 10^{-4}$ M et $2{,}5 \times 10^{-3}$ M). L'ensemble de ces résultats ainsi que la consommation de 1 F mol^{-1} par électrolyse en présence d'acide acétique au potentiel de −1,25 V suggère une dimérisation rapide des radicaux neutres formés.

La molécule de substrat possède une fonction alcool en position benzylique d'une part et allylique d'autre part avec des atomes fortement attracteurs. Celle-ci peut jouer le rôle de donneur de proton vis à vis des anions électrogénérés :



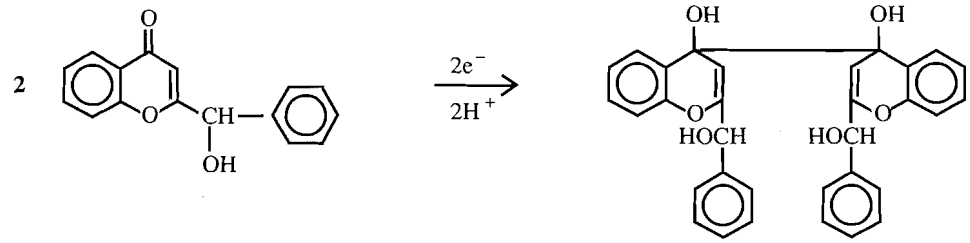
La présence d'une faible réversibilité pour la seconde étape et le fait qu'un donneur de proton entraine sa disparition au profit de la première permet d'envisager à ce stade une réduction monoélectronique de la forme anionique :



Des macroélectrolyses ont été réalisées au potentiel de $-1{,}25$ V en présence de quatre équivalents de donneur de proton (acide acétique ou Bu_4NHSO_4). Le produit de réduction isolé présente une grande instabilité en solution. Les extraits éthérés doivent être séchés sur sulfate de sodium et non sur sulfate de magnésium, ce dernier provoquant l'apparition d'une intense coloration rouge. La présence de traces d'acide entraine immédiatement l'apparition de cette même coloration. Le spectre UV réalisé avec une solution dans $CHCl_3$ en présence d'acide chlorhydrique présente trois nouvelles bandes d'absorption à $\lambda_1 = 265$ nm, $\lambda_2 = 410$ nm et $\lambda_3 = 525$ nm (fig. 9).

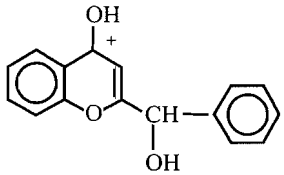
Le produit est également sensible à la température et subit une décomposition dès 30°C. Les spectres de RMN ont fourni avec tous les solvants usuels un ensemble de signaux très élargis qu'il est impossible d'interpréter en termes de couplages. Ce phénomène suggère la présence possible dans la solution, d'espèces paramagnétiques formées par rupture d'une liaison dès que la température s'élève pour atteindre celle de la sonde RMN (environ 34°C). Afin de vérifier cette hypothèse, nous avons réalisé par RPE une étude de l'influence de la température sur le produit solide (fig. 10).

Nous avons pu constater la présence d'espèces paramagnétiques dès la température ambiante, l'intensité du signal augmentant rapidement lorsque la température s'élève. Un spectre infrarouge réalisé en pastille de KBr montre la présence de fonctions alcool et l'absence de groupement carbonyle. Ce résultat est en accord avec une dimérisation des radicaux de manière préférentielle avec l'atome de carbone de la fonction carbonyle pour former le pinacol :



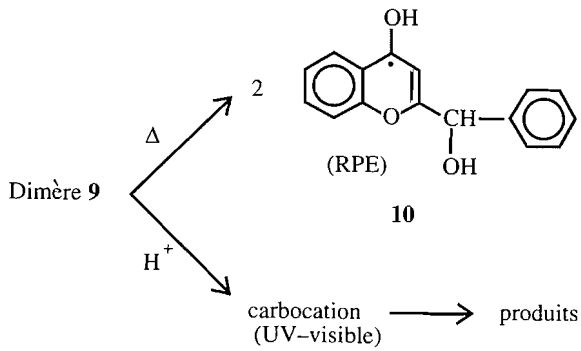
9

Les analyses élémentaires ont fourni des résultats en accord avec cette formule (calc. % C : 75,88; % H : 5,13; % O : 18,97; trouvé % C : 75,35; % H : 5,81; % O : 17,02) et le spectre de masse montre la présence d'un pic important à $m/e = 253$ qui correspond au fragment :



La faible stabilité thermique d'un tel dimère laisse présager une réversibilité pour la réaction de couplage en raison de la rupture homolytique d'une liaison carbone–carbone entraînant la formation de deux radicaux **10**. La molécule de dimère possède également des fonctions alcool en position allyliques et benzyliques susceptibles d'entrainer, en présence de traces d'acide, l'apparition de carbocations d'où l'évolution du spectre UV–visible.

Le voltammogramme de l'(hydroxy-1 benzyl)-2 chromone **7** obtenu avec une électrode de carbone vitreux (fig. 8) montre un croisement des traces cathodiques et anodiques ainsi que la présence d'un pic anodique. Un tel comportement déjà observé dans le cas de dérivés halogénés (23) peut être lié à la formation, dès le début du balayage retour, d'une espèce radicalaire plus facilement réductible. Le pic anodique situé à $E_{pa} = -0{,}50$ V correspond à l'oxydation de l'anion formé après réduction du radical. Un second balayage cathodique réalisé immédiatement après la réoxydation (fig. 8) montre l'apparition d'un nouveau pic cathodique correspondant à la réduction du radical libre formé par oxydation du carbanion. Avec une électrode de mercure stationnaire, l'étape anodique est très fortement perturbée par des phénomènes d'adsorption. Dans les deux cas, la présence d'un donneur de proton entraîne sa disparition.



L'acétyl-2 chromanone **8** présente, en voltammétrie cyclique, un seul pic de réduction $E_{pc} = -1{,}21$ V (fig. 11) et un croisement des traces cathodiques et anodiques encore plus marqué que dans le cas précédent.

Aucun pic anodique n'est par contre observé dans ce cas en raison vraisemblablement d'une protonation rapide de l'anion moins conjugué. La forme très aigüe du pic cathodique laisse présager une désactivation rapide du substrat par les bases électrogénérées. Le produit isolé à partir de macroélectrolyses en présence d'acide acétique a présenté également des caractéristiques d'instabilité comme dans le cas précédent.

En conclusion, la benzoyl-2 et l'acétyl-2 chromone ont

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12

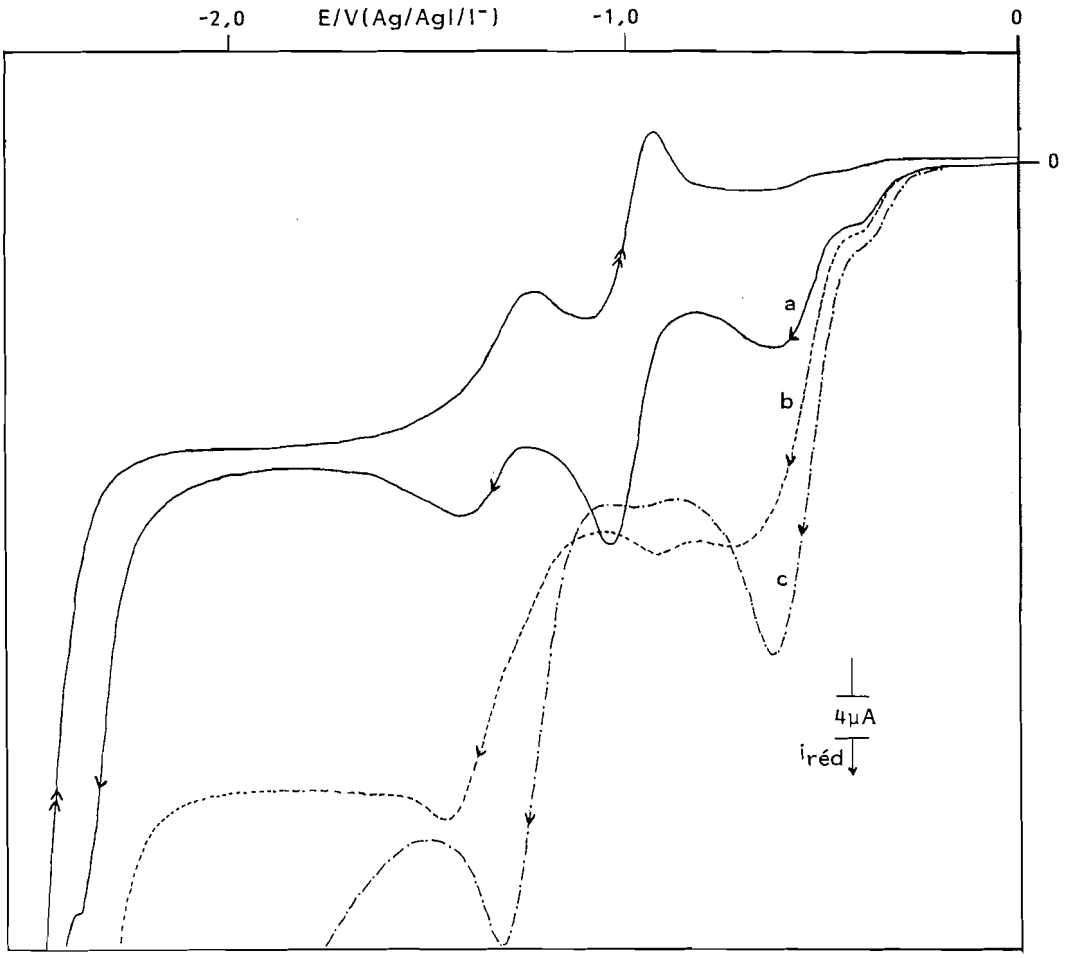

FIG. 7. Voltammogrammes d'un mélange (hydroxy-4′ benzoyl)-2 chromone (70%) – (hydroxy-2′ benzoyl)-2 chromone (30%) dans le DMF ($c = 5 \times 10^{-3}$ M). Electrolyte support Bu_4NBF_4 (0,1 M). Evolution en fonction de la concentration en CH_3COOH (*a*) 0; (*b*) 5×10^{-3}; (*c*) $2,5 \times 10^{-2}$ M. Electrode de carbone vitreux $v = 0,02$ V s^{-1}.

montré des comportements électrochimiques différents. Si la première conduit, en milieu protique, à la réduction de la fonction carbonyle du groupement benzoyle, la seconde permet d'isoler un produit unique correspondant à la réduction de la double liaison du cycle chromone. Les réducteurs chimiques ($NaBH_4$) réduisent seulement la fonction carbonyle en position 2 sur le cycle chromone alors que l'action de l'hydrogène en présence de métaux divisés (6) entraîne des réactions non sélectives affectant les deux fonctions carbonyles et la double liaison du cycle.

Partie expérimentale

Techniques électrochimiques

Le diméthylformamide (DMF) est distillé sous préssion réduite après avoir été séché sur carbonate de sodium. L'électrolyte indifférent est le tétrafluoroborate de tétrabutylammonium à la concentration de 0,1 M. Les tensions sont indiquées par rapport à l'électrode de référence $Ag/AgI/I^-$ (Bu_4NI 0,1 M dans le DMF). L'électrode de travail est constituée soit d'un disque de carbone vitreux, soit d'une goutte de mercure stationnaire. Toutes les mesures ont été réalisées à température ambiante après désaération par un courant d'azote ou d'argon. Les voltammogrammes ont été enregistrés à l'aide d'un ensemble Tacussel comprenant un potentiostat type PRT-20X équipé d'un générateur de signaux triangulaires et d'un amplificateur de type ADTP. Les différentes coulométries ont été réalisées dans une cellule contenant une nappe de mercure agitée pendant toute la durée de l'électrolyse. L'installation comprend un potentiostat PRT 100 et un intégrateur Tacussel IG5N. Chaque essai porte sur environ 25 mg de produit correspondant à une concentration initiale de 5×10^{-3} M.

Synthèse des substrats

La benzoyl-2 chromone a été obtenue par réaction de Friedel et Crafts entre le benzène et le chlorure de l'acide chromone carboxylique-2 (1), ce dernier résultant de la réaction du pentachlorure de phosphore PCl_5 sur l'acide (24). Dans un réacteur muni d'un agitateur, d'un réfrigérant, d'une ampoule à brome, on introduit 4,8 g de chlorure d'aluminum dans 100 cm^3 de benzène. Après avoir refroidi l'ensemble vers 5°C on ajoute très lentement 3,7 g de chlorure d'acide chromone carboxylique-2 en solution dans 40 cm^3 de benzène. L'addition terminée, on agite pendant 24 h. Le milieu réactionnel est versé sur un mélange de 150 cm^3 d'acide chlorhydrique et 300 g de glace. La couche benzénique est décantée, lavée à l'eau, séchée sur sulfate de sodium et évaporée. Le produit obtenu est recristallisé dans l'éthanol après traitement au noir animal. Les composés **3**, **4** et **5** sont obtenus également par une réaction de Friedel et Crafts à partir du chlorure d'acide et des phénols correspondants en présence de $AlCl_3$ selon le mode opératoire décrit par M. Besson (1). Le composé **6** est préparé à partir de **5** par action de K_2CO_3 en présence de *N*,*N*-diéthylamino-2 bromo-1 éthane (1). Un échantillon d'acétyl-2 chromone nous a été fourni par le Professeur M. Paillard (Laboratoire de chimie organique, Faculté des sciences pharmaceutiques de Toulouse) que nous remercions. L'(hydroxy-1 benzyl)-2 chromone a pu être également obtenu par réduction de la benzoyl-2 chromone par le borohydrure de sodium (2).

Electrolyses préparatives

Toutes les électrolyses préparatives ont été effectuées dans une cellule à trois compartiments dont la cathode est une nappe de mercure et l'électrode auxiliaire une plaque de graphite. Après électrolyse, le catholyte est repris par 500 cm^3 d'eau, neutralisé si besoin par l'hydrogénocarbonate de sodium et les produits de réduction sont extraits à l'éther. La phase éthérée est ensuite lavée à l'eau, séchée sur sulfate de magnésium sauf indication contraire, et évaporée sous vide.

Techniques d'analyses des produits

Les spectres de RMN ^1H et ^{13}C ont été réalisés sur les appareils Bruker MSL 300, Varian T60 et Jeol FX60 (RMN ^{13}C).

Les spectres IR ont été enregistrés sur un ensemble Beckmann type Acculab 2.

Les spectres UV–visible ont été obtenus avec un spectrophotomètre UV–visible Beckmann type DU-8.

L'(hydroxy-1 benzyl)-2 chromone **7** et l'acétyl-2 chromanone **8** ont été purifiées sur une colonne de silice Merck Kieselgel 60 avec comme éluant un mélange acétate d'éthyle – hexane dans les proportions 50/50 et 25/75 respectivement pour les composés **7** et **8**.

YOULA S. TSANTRIZOS, KELVIN K. OGILVIE, and ALAN K. WATSON. Can. J. Chem. **70**, 2276 (1992).

Phomopsis convolvulus is a host-specific pathogen which causes leaf spots and anthracnose lesions in the important perennial weed *Convolvulus arvensis* (field bindweed). Investigation of the metabolites produced by the fungus led to the isolation of the known fungal metabolites ergosterol (**1**) and ergosterol peroxide (**2**), in addition to four novel phytotoxins: the phthalides convolvulanic acid A (**3**), convolvulanic acid B (**4**), convolvulol (**5**), and the α-pyrone convolvulopyrone (**6**). The latter compounds were assigned the structures of 4-carboxy-3-hydroxy-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone (**3**), 4-carboxy-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone (**4**), 4-(hydroxymethyl)-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone (**5**), and 3-[4-methoxy-3-methyl-α-pyron-6-yl]-2-methyl-2-butenoic acid (**6**) respectively. Strong herbicidal activity against *C. arvensis* was observed with compounds **3** and **4** at concentrations of $3–5 \times 10^{-4}$ M.

YOULA S. TSANTRIZOS, KELVIN K. OGILVIE et ALAN K. WATSON. Can. J. Chem. **70**, 2276 (1992).

Le *Phomopsis convolvulus* est un pathogène spécifique pour un hôte qui provoque des taches sur les feuilles et des lésions anthracnoses de l'importante herbe persistante *Convolvulus arvensis* (liseron des champs). Une étude des métabolites produits par le champignon a permis d'isoler l'ergostérol (**1**) et le peroxyde d'ergostérol (**2**), des métabolites fongiques connus, en plus de quatre nouvelles phytotoxines : les phtalides de l'acide convolvulanique A (**3**) et B (**4**), le convolvulol (**5**) et l'α-pyrone, convolvulopyrone (**6**), auxquels on a attribué les structures respectives suivantes : 4-carboxy-3-hydroxy-7-méthoxy-6-méthyl-1(3*H*)-isobenzofuranone (**3**), 4-carboxy-7-méthoxy-6-méthyl-1(3*H*)-isobenzofuranone (**4**), 4-(hydroxyméthyl)-7-méthoxy-6-méthyl-1(3*H*)-isobenzofuranone (**5**) et l'acide 3-[4-méthoxy-3-méthyl-α-pyron-6-yl]-2-méthylbut-2-ènoïque (**6**). Avec les composés **3** et **4**, on a observé de fortes activités herbicides contre le *C. arvensis* à des concentrations de 3 à 5×10^{-4} M.

[Traduit par la rédaction]

Introduction

The perennial plant field bindweed (also known as wild morning glory) is a serious agricultural problem around the world with the exception of the tropics. Field bindweed infestations are encountered along roadsides and in city green spaces and cultivated lands throughout most of Canada (1) and it has been classified as one of the most important weeds worldwide (2). Phenoxy herbicides (3, 4) that are presently used for the control of this pest are generally costly and ineffective in suppressing its spread (5).

In the early 1970's, a number of independent studies on the biological control of field bindweed were initiated. Among them, insects and gall mites were considered (6, 7) but were found to be inadequately host-specific causing damage to crop plants in addition to the weed. Fungi which are pathogenic to field bindweed present an alternate possibility for its biological control. The fungus *Phomopsis convolvulus* is a pathogen that was recently isolated and classified (8) and that infects field bindweed causing nectrotic lesions surrounded by yellow haloes, characteristic of phytotoxin production (9). Leaf-puncture bioassays (10) on bindweed using cell-free extracts of *P. convolvulus*, further supported the existence of phytotoxic compounds leading to the formation of necrotic spots in the tissue of young leaf cuttings. The subsequent investigation into the metabolites produced by *P. convolvulus* led to the isolation of the two known steroids **1** and **2**,[3] the phytotoxic phthalides **3**, **4**, **5** and the novel α-pyrone **6**.

Results and discussion

Phomopsis convolvulus cultures were grown on moist barley grains at room temperature for periods of 28–30 days. The extracellular metabolites were initially extracted by washing the grains with methanol and then partitioned between ethyl acetate and dilute aqueous HCl (pH ~3). Biological activity was found only in the organic layer and its mixture of metabolites was further partitioned between CH_2Cl_2 and aqueous $NaHCO_3$. Phytotoxicity against both *Lemna* plants and field bindweed cuttings was observed with both extracts, but the aqueous extract was significantly more potent.

Analysis of the metabolites dissolved in the CH_2Cl_2 layer revealed the presence of two major compounds, metabolites **1** and **2**, which were purified by flash column chromatography (11) and preparative thin-layer chromatography. The remaining minor components of this extract were void of biological activity.

TABLE 1. Nuclear Overhauser enhancement (^{1}H NMR, 300 MHz, acetone-d_6)

Compound **3**		Compound **5**	
δ (irradiated H)	NOE (%)	δ (irradiated H)	NOE (%)
6.91 (H-3)	None	5.22 (H-3)	H-4′, 7-OMe (<2%)
—	—	4.66 (H-4′)	H-5 (12%), H-3 (3%)
8.09 (H-5)	6-Me (14%)	7.31 (H-5)	6-Me (5%), H-4′ (2%)
2.35 (6-Me)	7-OMe (10%), H-5 (4%)	2.26 (6-Me)	H-5 (6%), 7-OMe (2%)
4.14 (7-OMe)	6-Me (14%)	3.90 (7-OMe)	6-Me (<2%), H-5 (<2%)

The structural assignment of metabolite **1** was based primarily on its spectral data, which was identical to that of ergosterol (12, 13). The NMR data and high resolution MS of metabolite **2** led to its identification as ergosta-6,22-dien-5a,8a-epidioxy-3-ol, better known as ergosterol peroxide (**2**). Biological testing of this compound on *Lemna* plants and bindweed leaf-cuttings showed weak toxicity to both, indicating that it may play a role in the disease symptoms observed on bindweed when infected with *P. convolvulus* (14).

Purification of the phytotoxins dissolved in the aqueous $NaHCO_3$ solution proved to be unsuccessful using either silica gel or cellulose chromatography. However, flash column chromatography on C18 reverse phase silica, prepared using Evans' procedure (15) led to a moderate separation of its components. Fractions found to have activity against both *Lemna* and bindweed plants (fractions 18–21, 40–60% MeOH in H_2O) were further purified by HPLC, yielding metabolites **3**–**6**.

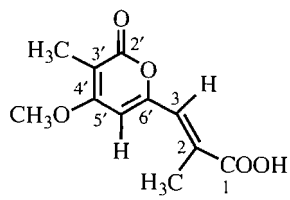
4, R^1 = H, R^2 = COOH
5, R^1 = H, R^2 = CH_2OH



6

Based on the ^{1}H, NOE (Table 1), ^{13}C NMR (Table 2), APT, and DEPT NMR data of metabolite **3** both structures **3** and **7** or their tautomeric mixture were considered possible. The IR spectrum of metabolite **3** showed an OH absorption at 3381 cm^{-1}, —C=C— absorption at 1613 cm^{-1}, and carbonyl absorptions at 1728 and 1773 cm^{-1} due to a carboxylic acid and a phthalide-type lactone. In addition, (NH_3)CI MS was consistent with an elemental composition of $C_{11}H_{10}O_6$ for this compound. Final proof in support of structure **3** was obtained through low temperature ^{1}H–^{13}C coupled NMR experiments and literature ^{13}C NMR values of related compounds.

Most of the ^{13}C NMR experiments were conducted at very low temperatures (−45 to −55°C). At higher temperatures the signals at δ 165.7 and 121.9 were either very broad or non-observable (16). In the fully coupled spectrum of **3** the expected ^1J and ^3J coupling constants were observed for C-5 (δ 139.3), C-3 (δ 97.4), 7-OMe (δ 62.6), and 6-Me (δ 15.7). The signal of C-5 appeared as a doublet of quartets due to additional long-range coupling with the protons of the 6-Me (^1J = 162 Hz, ^3J = 5 Hz). Similarly, 6-Me (δ 15.7) appeared as a quartet of doublets (^1J = 128 Hz, ^3J = 5 Hz) which collapsed to a simple quartet upon decoupling of H-5. The C-3 carbon appeared as a doublet (^1J = 179 Hz) which collapsed to a singlet upon irradiation of the proton at δ 6.91 (H-3). The quaternary carbons at δ 121.9 and 118.3 were singlets in all spectra and they were assigned to C-4 and C-7a respectively. The multiplets of the quaternary carbons at δ 134.2 and 160.5 were assigned to C-6 and C-7 respectively in structure **3** or C-6 and C-5 in structure **7**, since both of them showed long-range coupling with the methyl and methoxy protons.

Both carbonyl carbons (C-1: δ 166.4, ^3J = 4 Hz; C-4′: δ 165.7, ^3J = ~2.5 Hz) and the C-3a signal (δ 149.4, ^3J =

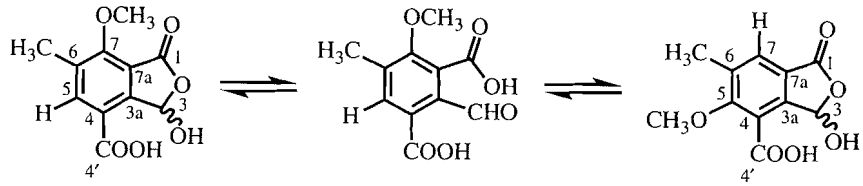
[c]Broad signal due to ^4J coupling between C-4′ and H-3 of ~1–2 Hz.

7.7 Hz) appeared as doublets in the fully coupled spectrum. Selective decoupling of the aromatic proton (^1H: δ 8.09) led to the collapse of the doublet of the C-3a and of the carboxylic acid doublet, but had no affect on the doublet of the lactone, as would be expected for structure **3**. However, these results would be unlikely if tautomer **7** was the correct structure; ^3J coupling between the aromatic proton and the lactone carbonyl of compound **7** should be observed, whereas ^5J coupling with the carboxylic acid should be insignificant. In addition, selective decoupling of H-3 (δ 6.91) led to the collapse of the lactone carbonyl doublet to a sharp singlet, leaving the carboxylic acid signal as a doublet, further supporting **3** as the correct structure.



3 **7**

Metabolite **3** did not exhibit any optical activity due to spontaneous racemization via its aldehyde – carboxylic acid tautomer. However, since only one set of NMR signals was observed (even at −55°C), the lactone **3** must be by far the most predominant structure. A literature search for structurally related compounds revealed, among others, the natural product 4-formyl-3,5-dihydroxy-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone (**8**), an antibacterial metabolite of *Aspergillus duricaulis* (16). Considering the structural similarities between metabolites **3** and **8**, it was expected that approximate chemical shifts for the ^{13}C NMR of **3** could be calculated from those of **8** using empirical parameters for substituted benzene rings (17). In fact, all calculated values were found to be within 0–3 ppm from the experimental shifts of **3** and they are shown in Table 2. The ^{13}C NMR data of several other naturally occurring (18) and synthetic phthalides (19) were also considered. On the bases of all the evidence, the structure of **3** was assigned to 4-carboxy-3-hydroxy-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone and it was given the trivial name convolvulanic acid A.

Compound **4** was the second water-soluble toxin of *P. convolvulus* to be isolated. Its ^1H, ^{13}C (Table 3), APT, and DEPT NMR spectra were almost identical to those of **3** except for one signal, whose change suggested that the C-3 hydroxyl substituent of **3** had been replaced by a proton in **4**. The IR data was also consistent with structure **4** and high resolution $(NH_3)CI$ MS gave a molecular ion of mass 223.0621 (M^+ + 1), supporting the elemental composition of $C_{11}H_{10}O_5$ (calculated mass for M^+ + 1 is 223.0606). Hence, the chemical structure of 4-carboxy-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone (**4**) and the trivial name of convolvulanic acid B were proposed for this compound. In addition, ^1H–^{13}C fully coupled and selectively decoupled NMR experiments were carried out and all of the data obtained were in complete agreement with the proposed structure (Table 3). The ^{13}C chemical shifts of the known compound 4-formyl-5-hydroxy-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone (**9**) (20) were used to calculate "theoreti-

[a]Decoupled proton.

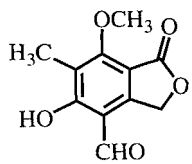
cal" shifts for metabolite **4** and the results obtained were in close agreement with the experimental values (Table 3).



9

The third pthalide (metabolite **5**) was sufficiently soluble in $CDCl_3$ to permit a complete proton spectrum to be observed (Table 1). Close similarities between **4** and **5** were observed in the ^1H, NOE (Table 1), ^{13}C (Table 4), DEPT, and APT NMR spectra. One extra methylene carbon (δ 62.2) was observed in the ^{13}C NMR spectrum and of the six quaternary carbons only one had the appropriate chemical shift for a carboxylic acid or lactone (δ 171.2); the remaining quaternary signals had the chemical shifts very close to those of C-3a, C-6, C-7, and C-7a of metabolite **4** and one was approximately 10 ppm downfield from the C-4 carbon of **4**. The room temperature ^{13}C NMR spectra of **5** did not show any broad signals nor did it show any changes when recorded at low temperatures. These observations, coupled with the fact that a carbonyl carbon was lost and a —CH_2—OH had appeared, suggested that metabolite **5** was a reduced analogue of **4**. NMR data obtained from ^1H–^{13}C fully coupled and selectively decoupled experiments were in complete agreement with the proposed structure (Table 4).

In addition, the IR ($CHCl_3$) of metabolite **5** showed absorptions for only one carbonyl, a lactone at 1762 cm^{-1}. High resolution (NH_3)CI MS gave a molecular ion of 209.0814 ($M^+ + 1$), suggesting an elemental composition of $C_{11}H_{12}O_4$ (calculated mass: 209.0814). Taking into consideration all of these data the structure of 4-(hydroxymethyl)-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone and the trivial name of convolvulol were proposed for **5**. The ^{13}C NMR chemical shifts of the literature compound 5-hydroxy-4-(hydroxymethyl)-7-methoxy-6-methyl-1(3*H*)-isobenzofuranone (**10**) (16) were used in order to calculate "theoretical" chemical shifts for **5**. All of the calculated shifts were within 2 ppm of the experimental values (Table 4).

The last compound (**6**) isolated from the aqueous phytotoxic extract of *P. convolvulus* shared many spectral similarities with the previous metabolites. Its ^1H NMR showed two methyls (δ 1.87 and 2.42), a methoxy (δ 4.04), and two single olefinic protons (δ 6.62 and 6.91) without coupling between any of the signals. The proton at δ 6.91 exhibited positive NOE effects with both the methyl at δ 2.42 and the methoxy at δ 4.04 (Table 5).

The ^{13}C NMR of **6** showed a total of 11 carbons as in all

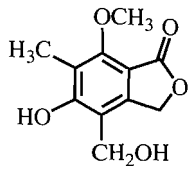
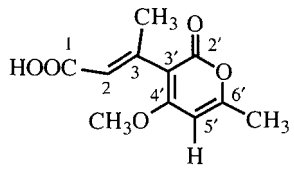
previous cases. A broad carboxylic acid signal (δ 169.4), a lactone (δ 167.9), an olefinic carbon to which the methoxy group was attached (δ 166.4 ppm), a methoxy (δ 57.5), and two methyls (δ 13.6, 8.8) were observed. The differences between **6** and the three phthalides were much more evident in the APT NMR spectrum. Three quaternary carbons at δ 159.2, 143.2, and 105.3 were observed, all of which had a shift difference of at least 10 ppm from the possibly equivalent carbons of compounds **3**, **4**, and **5** (C-3a, C-6, C-7a, respectively). In addition, there were two tertiary carbons at δ 98.4 and 121.8, of which the latter was broad in the normal ^{13}C NMR and almost nonobservable in the APT spectra.



10

The IR spectrum showed absorptions characteristic of conjugated carboxylic acids and α-pyrones (1717 and 1707 cm^{-1}) and high resolution $(NH_3)CI$ MS of **6** gave an intense molecular ion at 225.0739 ($M^+ + 1$), suggesting a molecular composition of $C_{11}H_{12}O_5$ (calculated mass of $M^+ + 1$ is 225.0763). Thus the general structure of the α-pyrone **11** was at first proposed.



11

Assuming that the chemical shift of 6′-Me was at δ 2.42 and H-5′ at δ6.91, the structure of **11** was in reasonable agreement with the ^{1}H, ^{13}C, and NOE NMR data. However, when the ^{1}H NMR spectrum of metabolite **6** was observed in acetone-d_6 containing a few drops of D_2O, the signals at δ 6.62 (1H) and δ 2.42 (CH_3) changed from broad singlets to doublets (J = 1.3 Hz). This coupling was confirmed by COSY NMR (in the same solvent mixture) and additional coupling was observed between the proton at δ 6.91 and the methyl at δ 1.87, the two olefinic protons (δ 6.62 and 6.91), and between the proton at δ 6.91 and the methoxy group (δ 4.04). These results could not support the structure of **11** and the alternate structure of 3-(4-methoxy-3-methyl-α-pyron-6-yl)-2-methyl-2-butenoic acid (**6**) was proposed.

The HETCOR NMR spectrum of metabolite **6** showed the expected coupling for the methoxy and methyl signals and between C-5′ and H-5′ (^{13}C δ 98.4 to ^{1}H δ 6.91), but failed to show a cross-peak resonance for C-3 to H-3 (the existence of a cross-peak resonance between ^{13}C δ 121.8 and ^{1}H δ 6.62 was assumed). Although the carbonyl signals of α-pyrones are more frequently observed at δ ~162, there are many compounds known (including the fungal metabolites nectriapyrone (21) and aurovertin (22)) where the resonance of their carbonyls is at δ ~168–169. In structure **6**, coupling between H-5′ and 3′Me could reasonably be expected as well as between H-5′ and H-3. The latter proton (H-3) would also be coupled to the C-2 methyl.

In considering the NOE effects observed for compound **6**, the energies involved for the two most likely conformers of this molecule were examined. The positive NOE effect observed between H-5′ and 2-Me and the absence of an NOE effect between H-5′ and H-3, strongly suggest that conformer **6** is more stable than **6′**. Molecular modeling calculations[4] for both of these structures gave an energy difference of 3.2 kcal in favor of **6** (Fig. 1), implying an equilibrium ratio of about 99/1 for the two conformers.[5]

A number of different bioassays were initially evaluated for their ability to detect the presence of phytotoxins in crude metabolite mixtures of *P. convolvulus*. The small aquatic plant *Lemna paucicostata* was found to be highly sensitive to these compounds and suitable for measuring inhibition of

[4]A PCMODEL program was used that was obtained from Serena Software, P.O. Box 3076, Bloomington, Indiana, U.S.A.

[5]The energies of several other conformers were also calculated and they were all found to have energy levels higher than that of **6** (−105.4 kcal). However, the existence of these other minimum energies indicated the limitations of these calculations and the possibility that even the −105.4 kcal value may represent a local minimum and not the absolute minimum energy of the compound.

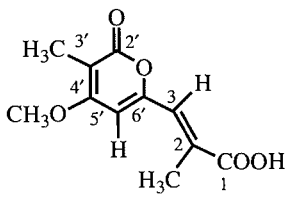
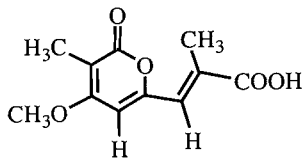
growth and chlorophyll biosynthesis (23), when used under standardized assay conditions (24).



6



6′

Metabolites **3**, **4**, **5**, and **6** were tested at five different concentrations and in each case a 1% ethanol solution in *Lemna* medium was used as the control. Metabolite **4** was found to be the most potent phytotoxin, causing total inhibition of growth and 100% chlorosis of the *Lemna* plants within 12 h at concentrations of 5.9×10^{-4} M and within 24 h at concentrations of 3.5×10^{-4} M. At concentration of 5.9×10^{-4} M, metabolites **3** and **5** were also found to inhibit the growth of *Lemna* plants by approximately 80 and 50% respectively, whereas the effects of metabolite **6** were very minor in comparison with those of the three phthalides.

The principal objective was to isolate active metabolites of *P. convolvulus* that could potentially be used as herbicides for the effective control of field bindweed. Thus, the phytotoxic effects of all isolated compounds were also examined on leaf-cuttings of this weed. Minor effects were observed with metabolites **5** and **6**, whereas intense toxicity symptoms were observed with both **3** and **4**. Metabolite **4** caused wilting and browning of plant tissues after only 4 h at concentrations of 3.5×10^{-4} M. Twelve hours later, the same symptoms appeared on the leaves exposed to metabolite **3** at a 5×10^{-4} M concentration. When several young bindweed shoots (~2 in. long) were placed in a solution of the less potent phytotoxic metabolite **3**, at a concentration of $\sim 1 \times 10^{-3}$ M, the systemic absorption and toxicity of **3** was clearly observed; after 40–48 h the plants exposed to the toxin displayed obvious signs of wilting and at the end of the observation period (~5–6 days later) the leaves of the treated plants were almost completely wilted and brown, whereas the plants in the control solution did not show any signs of deterioration. It is interesting to note that in spite of the strong structural similarities between the metabolites of *P. convolvulus* and those of *A. duricaulis* (e.g., metabolites **3** and **8** respectively), there is no analogous similarity in their biological activity. For example, 0.1 μg of metabolite **8** was shown to exhibit strong antibiotic activity against *Bacillus subtilis* causing an 8-mm inhibition zone on a paper-disk diffusion assay. Under similar bioassay conditions, metabolite **3** failed to inhibit *B. subtilis* even when a 50 μg sample was used.

In conclusion, the metabolites produced by *Phomopsis convolvulus*, a host-specific pathogen of field bindweed (*Convolvulus arvensis*), were investigated. Four phytotoxic compounds (**3**–**6**), believed to be chemical mediators of the disease symptoms inflicted by *P. convolvulus* on its host plant, were isolated and characterized. Metabolites **3**–**6** were shown to be novel fungal metabolites.[6]

Experimental

General

Ultraviolet spectra were recorded on a Hewlett Packard 8451A DIODE ARRAY spectrophotometer. Nuclear magnetic resonance spectra were obtained at 20–22°C (unless otherwise indicated) using Varian XL-200 and XL-300 MHz instruments. ^{1}H and ^{13}C NMR chemical shifts are quoted in ppm and are referenced to the internal deuterated solvent downfield from tetramethylsilane (TMS). All mass spectra were performed at the Biomedical Mass Spectrometry Unit, McGill University. The low resolution $(NH_3)Cl$ MS spectra were obtained using a HP 5980A spectrometer. FAB and high resolution $(NH_3)Cl$ MS spectra were obtained using a ZAB 2F HS instrument.

[6]The synthesis of compounds **4** and **5** were reported in 1953 by Brown and Newbold (25); unfortunately, the amount of spectral data available from that report (i.e., mp and uv) was of limited help in the structural assignment of the natural products.

Chromatography

Silica gel chromatography was performed on Merck Kieselgel 60 (230–400 mesh, #9385) using flash chromatography. Reverse phase flash column chromatography was carried out on silica gel (Merck Kieselgel 60, 230–400 mesh, #9385) reacted with *n*-octadecyltrichlorosilane. All chromatographic solvents were fractionally distilled prior to use with the exception of HOAc.

HPLC

Doubly distilled H_2O and HPLC grade MeOH were filtered through a 0.45 μ filter membrane (Millipore Corp., Bedford, MA) before they were used in HPLC. Analysis and purification was carried out on a reverse phase, C18 column, CSC-S ODS2 (25 cm × 9.4 mm ID, 5 μm particles, Chromatography Science Company Inc., Montreal, Que.) using a Waters instrument (pump model 501, variable wavelength detector model 450, U6K injector). All retention times were recorded after the void volume.

General extraction of active metabolites from P. convolvulus

Stock cultures of *P. convolvulus* (conidia) were maintained at 4°C in slant tubes containing potato carrot agar, covered with mineral oil. An aqueous suspension of conidia was used to inoculate potato dextrose agar (PDA) plates which were then incubated at room temperature for a period of 2–4 weeks. The new conidia were isolated by washing the surface of the agar plates with a small volume (5–10 mL/plate) of sterile water. Large scale cultures were subsequently initiated by inoculating moist barley grains in Erlenmeyer flasks (150 × 250 mL flasks, 20 g of grain plus 30 mL of H_2O in each) under aseptic conditions. The cultures were stored at room temperature, with only occasional shaking. After an incubation period of 28–30 days, 100 mL of H_2O were added to each flask and they were placed overnight on a rotary shaker. Filtration through several layers of cheese cloth and centrifugation at 5,000 rpm for 8 min led to the removal of barley grains and mycelia, separation of conidia, and isolation of a biologically active aqueous mixture of metabolites (Pc1).

The volume of Pc1 (~15 L) was reduced (~3 L) under high vacuum at 30°C and then freeze-dried to obtain ~27 g of a very fine powder. This powder was extracted twice with MeOH (2 × 1.5 L), the first time at 40°C for 3 h and the second time at room temperature overnight. The methanolic solution (Pc2) was filtered through several layers of cheese cloth and centrifuged to remove the undissolved material, which was biologically inactive. The MeOH was then evaporated and the crude metabolite mixture was redissolved in ~100 mL of water to obtain a cloudy suspension that was acidified to pH 2.5–3 with 0.1 M HCl. EtOAc extraction (3 × 150 mL, plus overnight with 300 mL) led to the isolation of a biologically active mixture in the organic layer (Pc3) and a mixture void of biological activity in the aqueous layer. The yields of the combined EtOAc extracts varied greatly (0.25–7.5 mg/g of barley) giving an average of 2.5 mg of a light brown gum (Pc3) per gram of infected barley grains.

The residue Pc3 was suspended in CH_2Cl_2 (100 mL) and extracted with a saturated solution of $NaHCO_3$ (3 × 100 mL) to partition the mixture into Pc4 and Pc5. The organic layer (Pc4) contained mostly steroidal metabolites exhibiting very weak phytotoxicity, whereas the aqueous layer was strongly phytotoxic. The aqueous layer was subsequently acidified to pH ~2.5–3 with 0.1 M HCl, reduced in volume under high vacuum at 30°C and extracted with EtOAc (3 × 100 mL) to recover the phytotoxic mixture of metabolites from Pc5.

Isolation of ergosterol (1) and ergosterol peroxide (2)

Flash column chromatography of residue Pc4 using a solvent mixture of petroleum ether – EtOAc (1:1) led to the isolation of ergosterol (**1**, R_f 0.55) and ergosterol peroxide (**2**, R_f 0.28). Pure, crystalline ergosterol was obtained after a second flash column, eluted with (5:1) petroleum ether – EtOAc (R_f 0.16), followed by recrystallization from EtOH. The crude ergosterol peroxide (**2**) was purified on preparative TLC plates, developed twice with a mixture of petroleum ether – EtOAc (1:1). Since this compound is not UV active, the TLC plates were examined over a light table. The high density band visualized at R_f 0.4–0.5 corresponded to ergosterol peroxide. The silica gel was extracted with EtOAc and pure ergosterol peroxide crystallized from CH_2Cl_2 or EtOH. Both compounds were also present in the mycelia of *P. convolvulus*, and they could be isolated from their dry mass via soxhlet extraction with methylene chloride or acetone.

Preparation of C18 reverse-phase silica gel

Silica gel (40 g, Merck Kieselgel 60, 230–400 mesh) was added to 300 mL of dry CCl_4 (distilled from P_2O_5) in a septum-capped round-bottom flask under a N_2 atmosphere. *n*-Octadecyltrichlorosilane (4 mL) was added and the suspension was stirred at room temperature for 2 h. The product was filtered into a dry seinter-glass funnel and washed free of unreacted silane with dry CCl_4 (3 × 100 mL). Any residual chloride substituents were converted to methoxy groups by washing the silica with dry MeOH (2 × 100 mL, distilled over Mg metal). The product was then quickly washed with dry CH_2Cl_2 (2 × 100 mL, distilled from P_2O_5) and dried briefly under vacuum. A fresh 300 mL volume of dry CCl_4 was added to the bonded silica along with 4 mL of trimethylchlorosilane. The mixture was stirred at room temperature for an additional 2 h, then filtered and washed with dry CH_2Cl_2 (3 × 100 mL). The bonded silica was dried at 40°C overnight and then under high vacuum at room temperature for 24 h.

Reverse-phase flash column chromatography of phytotoxic residue Pc5

A reverse phase silica gel column (1.2 × 32 cm) was packed as a methanolic slurry (~12 g C18 bonded silica) and then *very* slowly equilibrated with H_2O.

The residue Pc5 (~1.3 g) was dissolved in a mixture of H_2O–CH_3OH–CH_2Cl_2 and absorbed onto a small amount of C18 bonded silica gel (1–2 g) by evaporating off the organic solvents. The aqueous slurry obtained (5–10 mL) was added to the top of the reverse-phase column and eluted with a gradient of solvents from 100% H_2O to 100% methanol, at a flow rate of ~1 mL/min. All fractions (8 mL each) were tested for biological activity and phytotoxicity was observed only in fractions 18–21 (40–60% MeOH in H_2O) Metabolites **3** and **5** were isolated from fractions 18 and 19 after HPLC chromatography on a C18 reverse-phase column, using an eluent mixture of 59.8% H_2O, 40% MeOH, and 0.2% HOAc at a flow rate of 2 mL/min. The retention time of **3** was 22–23 min while that of **5** was 16–17 min. Metabolite **5** was rechromatographed on the same HPLC column using a solvent mixture of 54.1% H_2O, 45.8% MeOH, and 0.1% HOAc. At a flow rate of 2 mL/min, its elution time was 10–11 min. HPLC chromatography of fractions 20 and 21, on the same C18 reverse-phase column using 54.4% H_2O, 45.4% MeOH, and 0.2% HOAc as the eluting solvent, led to the isolation of metabolites **4** and **6**. At a flow rate of 2 mL/min, the retention times were 20–22 min for **6** and 27–29 min for **4**.

Ergosterol (1): TLC: petroleum ether – EtOAc (1:1), R_f 0.55, CH_2Cl_2, R_f 0.21; mp: 163–164°C (lit. value 165°C) (13); IR ($CDCl_3$): 3650 (OH), 2960, 2872 (CH), 1601 (C=H) cm^{-1}; UV (CH_3CH_2OH, nm): max 274, 284, min 294 (shd); ^1H NMR (200 MHz, $CDCl_3$): δ 0.61 (s, 3H, 18-CH_3), 0.79–0.88 (2d, J = 6.8 Hz, 6H, 26-CH_3, and 27-CH_3), 0.90 (*d*, J = 6.8 Hz, 3H, 28-CH_3), 0.93 (s, 3H, 19-CH_3), 1.02 (d, J = 6.6 Hz, 3H, 21-CH_3), 1.22–2.03 (m, 19H), 2.26–2.27 (tm, 1H, H-4a), 2.41–2.49 (ddd, 1H, H-4b), 3.60–3.66 (m, 1H, H-3), 5.16–5.20 (2dd, 2 × 1H, H-2 and H-23), 5.35–5.38 (m, 1H, H-7) and 5.54–5.56 (dd, 1H, H-6); ^{13}C NMR (300 MHz, $CDCl_3$): δ 12.09 (C-18), 16.31 (C-19), 17.64 (C-28), 19.65 (C-26), 19.98 (C-27), 21.15 (C-21 and C-11), 23.03 (C-15), 28.26 (C-16), 32.06 (C-2), 33.14 (C-25), 37.10 (C-10), 38.43 (C-1), 39.15 (C-12), 40.41 (C-20), 40.87 (C-4), 42.88 (C-24 and C-13), 46.33 (C-9), 54.61 (C-14), 55.84 (C-17), 70.46 (C-3), 116.36 (C-7), 119.65 (C-6), 132.06 (C-23), 135.60 (C-22), 139.77 (C-5), and 141.37 (C-8); DEPT NMR (300 MHz, $CDCl_3$): 6-CH_3 (δ 12.1, 16.3, 17.6, 19.7, 20.0, 21.1), 7-CH_2 (δ 21.2, 23.0, 28.3,

32.1, 38.4, 39.2, 40.9), 11-CH (δ 33.1, 40.4, 42.9, 46.3, 54.6, 55.8, 70.5, 116.4, 119.7, 132.1, 135.6); APT (D2 = 4 ms) NMR (300 MHz, $CDCl_3$): δ 37.1, 42.9, 139.8, 141.4; MS ($(NH_3)CI$, direct inlet, 220°C), *m/z* (% relative intensity, assignment): 414 (2, $M^+ + NH_3$), 397 (40, $M^+ + 1$), 396 (7, M^+), 379 (100, 397-H_2O).

Ergosterol peroxide (2): TLC: petroleum ether – EtOAc, R_f 0.28; mp: 176–177°C (lit. value 178°C) (13); ^1H NMR (200 MHz, $CDCl_3$): δ 0.82 (s, 3H, 18-CH_3), 0.80–0.85 (2d, 6H, 26-CH_3 and 27-CH_3), 0.89 (s, 3H, 19-CH_3), 0.91 (d, 3H, 28-CH_3), 1.00 (s, 3H, 21-CH_3), 1.2–2.2 (m, 21H, steroid skeleton), ~4 (m br, 1H, H-3), 5.15–5.21 (2dd, 2 × 1H, H-22 and H-23), 6.25 (d, *J* = 8.5 Hz, 1H, H-7), 6.51 (d, *J* = 8.5 Hz, 1H, H-6); DEPT NMR (300 MHz, $CDCl_3$): 6-CH_3 (δ 13.0, 17.7, 18.3, 19.8, 20.1, 21.0), 7-CH_2 (δ 20.8, 23.5, 28.8, 30.2, 34.8, 37.0, 39.4) 11-CH (δ 33.2, 39.9, 42.9, 51.1, 51.8, 56.3, 66.5, 130.7, 132.2, 135.2, 135.4); APT (D2 = 4 ms) NMR (300 MHz, $CDCl_3$): δ 37.1 (C-10), 44.7 (C-13), 79.5 (C-5), 82.2 (C-8); MS (high resolution, (*i*-but) CI, direct inlet, 220°C): *m/z* calculated ($M^+ + 1$) ion 429.33685, found 429.33687.

4-Carboxy-3-hydroxy-7-methoxy-6-methyl-1(3H)-isobenzofuranone (convolvulanic acid A. 3): TLC: CH_2Cl_2–EtOAc–CH_3COOH (5:5:0.2), R_f 0.24; IR (CH_3CN): 3381, 3226 (OH), 1773 (C=O, lactone), 1728 (C=O, carboxylic acid), 1613 (C=C) cm^{-1}; UV (CH_3CH_2OH, nm): max 220, 250 (shd), min 300; ^1H NMR (200 MHz, acetone-d_6): δ 2.35 (s, 3H, 6-CH_3), 4.14 (s, 3H, 7-OCH_3), 6.91 (s, 1H, H-3), and 8.09 (s, 1H, H-5); NOE: data given in Table 1; ^{13}C NMR (300 MHz, acetone-d_6, *T* −46.5°C): δ 15.7 (6-CH_3), 62.6 (7-OCH_3), 97.4 (C-3), 118.3 (C-7*a*), 121.9 (C-4), 134.3 (C-6), 139.3 (C-5), 149.4 (C-3a), 160.5 (C-7), 165.7 (C-4′), and 166.4 (C-1); coupled ^1H–^{13}C NMR: data given in Table 2; APT (D2 = 4 ms) NMR (300 MHz, acetone-d_6, *T* −46.5°C): δ 118.3, 121.9, 134.3, 149.4, 160.5, 165.7, and 166.4 (97.4, 139.3 tertiary carbons); MS ($(NH_3)CI$, direct inlet, 260°C): *m/z* (% relative intensity, assignment): 256 (100, $M^+ + NH_4^+$), 239 (53, $M^+ + 1$), 227 (56, $M^+ + NH_4$ + -CHO), 209 (15, M^+ -CHO).

4-Carboxy-7-methoxy-6-methyl-1(3H)-isobenzofuranone (convolvulanic acid B. 4): TLC: CH_2Cl_2–EtOAc–CH_3COOH (5:5:0.2), R_f 0.45; IR (CH_3CN): 3629, 3542 (OH), 1764 (C=O, lactone), 1725 (sh), 1717 (C=O, carboxylic acid), 1630 (C=C) cm^{-1}; UV (CH_3CH_2OH, nm): max 216, 246 (shd), min 300; ^1H NMR (200 MHz, acetone-d_6): δ 2.34 (s, 3H, 6-CH_3), 4.15 (s, 3H, 7-OCH_3), 5.49 (s, 2H, H-3), and 8.13 (s, 1H, H-5); ^{13}C NMR (acetone-d_6, 300 MHz, *T* −46.5°C): δ 15.6 (6-CH_3), 62.6 (-OCH_3), 70.9 (C-3), 117.6 (C-7a), 120.5 (C-4), 132.2 (C-6), 138.8 (C-5), 150.7 (C-3a), 161.2 (C-7), 166.4 (C-4′), and 168.4 (C-1); coupled ^1H–^{13}C NMR: data given in Table 3; APT (D2 = 4 ms) NMR (acetone-d_6, 300 MHz, *T* −46.5°C): δ 117.6, 120.5, 132.6, 150.7, 161.2, 166.4, and 168.4 (138.8 tertiary carbon); MS (high resolution, $(NH_3)CI$, direct inlet, 250°C): *m/z* for ($M^+ + 1$) ion: calculated 223.0606, found 223.0621.

4-(Hydroxymethyl)-7-methoxy-6-methyl-1(3H)-isobenzofuranone (convolvulol, 5): TLC: CH_2Cl_2–EtOAc–CH_3COOH (5:5:0.2), R_f = 0.38; IR (CH_3CN): 3630, 3540 (OH), 1762 (C=O, lactone), 1600 (C=C) cm^{-1}; UV (CH_3CH_2OH, nm): max 212, 238 (shd), min 300. ^1H NMR (300 MHz, $CDCl_3$, *T* −51.5°C): δ 2.26 (s, 3H, 6-CH_3), 2.6–2.7 (br, 1H, 4′-OH), 3.90 (s, 3H, 7-OCH_3), 4.66 (*d*, *J* = 6 Hz, 2H, H-4′), 5.22 (s, 2H, H-3), and 7.31 (s, 1H, H-5). D_2O exchange causes the disappearance of the signal at δ 2.6–2.7, as expected, and the collapsing of the doublet at δ 4.66 to a singlet. Decoupling of H-5 led to the change of the OH signal from a broad multiplet to a broad triplet ($J_{H8\text{-}OH}$ = ~6 Hz), indicating the presence of long range coupling between H-5 and OH. NOE: data given in Table 1; ^{13}C NMR (300 MHz, CD_3OD): δ 15.4 (6-CH_3), 62.2 (C-4′), 62.5 (7-OCH_3), 70.1 (C-3), 117.9 (C-7a), 132.2 (C-4), 132.7 (C-6), 137.2 (C-5), 146.7 (C-3a), 157.7 (C-7), and 171.2 (C-1); coupled ^1H–^{13}C NMR: data given in Table 4; DEPT NMR (CD_3OD, 300 MHz): 2-CH_3 (δ 15.4, 62.5), 2-CH_2 (δ 62.2, 70.1), 1-CH (δ 137.2); MS (high resolution, $(NH_3)Cl$, direct inlet, 250°C): *m/z* for ($M^+ + 1$) on: calculated 209.0814, found 209.0814.

3-(4-Methoxy-3-methyl-α-pyron-6-yl)-2-methyl-2-butenoic acid (convolvulopyrone, 6): TLC: CH_2Cl_2–EtOAc–CH_3COOH (5:5:0.2), R_f 0.33; IR (CH_3CN): 3628, 3618 (OH), 1717 (C=O, α-pyrone), 1707, 1702 (sh) (C=O, carboxylic acid) cm^{-1}; UV (CH_3CH_2OH, nm): max 238, min 340; ^1H NMR (200 MHz, acetone-d_6): δ 1.87 (s, 3H, 3′-CH_3), 2.42 (s, 3H, 2-CH_3), 4.04 (s, 3H, 4′-OCH_3), 6.62 (s, 1H, H-3) and 6.91 (s, 1H, H-5′); NOE NMR: data given in Table 5; ^{13}C NMR (300 MHz, CD_3OD): δ 8.8 (3′-CH_3), 13.6 (2-CH_3), 57.5 (4′-OCH_3), 98.4 (C-5′), 105.3 (C-3′), 121.8 (C-3), 143.2 (C-2), 159.2 (C-6′), 166.4 (C-4′), 167.9 (C-2′), and 169.4 (br, C-1); Coupled ^1H–^{13}C NMR (400 MHz, CD_3OD): δ 8.8 (m, 3′-CH_3), 13.6 (q, *J* = 129 Hz, 2-CH_3), 57.5 (q, *J* = 147 Hz, 4′-OCH_3), 98.4 (d, *J* = 170 Hz, C-5′), and 121.8 (d, *J* = 165 Hz, C-3); APT (D2 = 4 ms) NMR (300 MHz, CD_3OD): δ 105.3, 143.2, 159.9, 166.4, 167.9, and 169.4 (98.4, 121.8, tertiary carbons); MS (high resolution, $(NH_3)Cl$, direct inlet, 250°C): *m/z* calculated for the ($M^+ + 1$) ion 225.0763, found 225.0739.

Lemna *medium*: *Lemna paucicostata* plants were grown at room temperature, under a growth-lamp (cool-white fluorescent plus incandescent light), in autoclaved Erlenmeyer flasks (250 mL) containing 100 mL of sterile nutrient medium. The nutrient medium was a solution of $Ca(NO_3)_2 \cdot 4H_2O$ (1.4 mM), KNO_3 (1.0 mM), KH_2PO_4 (0.4 mM), NH_4Cl (1.2 mM), $MgSO_4 \cdot 7H_2O$ (0.4 mM), $Na_2MoO_4 \cdot 2H_2O$ (6.1 μM), H_3BO_3 (69.0 μM), K_2H_2EDTA (30.0 μM), $FeCl_3 \cdot 6H_2O$ (56.6 μM), FeNaEDTA (56.7 μM), $MnNa_2EDTA$ (13.8 μM), $ZnNa_2EDTA$ (2.8 μM), $CuNa_2EDTA$ (3.3 μM), and $CoNa_2EDTA$ (4.8 μM). To prevent precipitation of the salts, all EDTA-containing components were added before the $FeCl_3 \cdot 6H_2O$. Finally, the pH of the solution was adjusted to 5.85 using 1.0 M KOH.

Lemna *bioassays*

All tested metabolites (or metabolite mixtures obtained during the initial stages of chromatography) were dissolved in absolute ethanol, aliquots of which (50–5 μl) were added to *Lemna* nutrient broth to make the final test samples. The toxicity of ethanol to *L. paucicostata* was initially evaluated and growth inhibition or chlorosis was only observed when the concentrations of ethanol was greater than 1% (v/v) of the total nutrient medium; thus bioassays were performed with test solutions containing less than 1% ethanol in *Lemna* nutrient medium. In all cases, the observations made with the *Lemna* bioassays were consistent with the results obtained by the leaf-puncture bioassays on field bindweed.

Field bindweed plant production and phytotoxicity assay

A commercial sample of bindweed seeds was used for the production of seedlings. Seeds were scarified with concentrated H_2SO_4 for 30 min, rinsed with distilled H_2O, dried at 21°C, and stored in the dark for approximately 2 months at 4°C. Germinated seeds (3–4) were sown in 10-cm pots in moist potting soil at a depth of 1 cm. Pots were placed in growth cabinets adjusted to a day/night temperature of 25/20°C, with a photoperiod of 15 h (300 μE m^{-2} s^{-1}, cool-white fluorescent plus incandescent light). Relative humidity was maintained at 50–55% until the plants were used for the bioassays. The phytotoxic effects of all metabolites on field bindweed were also evaluated using leaf cuttings, from plants 3–4 weeks old. For each assay, an average of 5–8 leaves were used, which were cut at the base of the stem and placed on a moist piece of filter paper (0.5 mL H_2O) in a covered Petri dish. Only the top two leaves of young shoots were used and they were cut using a sharp scalpel while submerged under water. Half of the leafs were then punctured with the tip of a fine needle and all of them were soaked with the test solution, covered and placed under a growth-lamp for a period of 5 days. The test samples were prepared by dissolving each metabolite in absolute ethanol, and then diluting the samples with doubly distilled water to a total volume of 2 mL. The most concentrated sample of each assay had an ethanol content of 1%; hence, the control solution was also a 1% ethanol solution in water. In leaf-puncture bioassays of field bindweed with aqueous solu-

tions of ethanol, toxicity was not observed at concentrations of up to 2%.

Received December 9, 1991

CARLOS A. BLANCO and MICHAEL J. HYNES. Can J. Chem. **70**, 2285 (1992).

Catalytic effects on the deprotonation rate constants of β-diketones were observed during kinetic studies of the formation reactions of the 1:1 complexes of these ligands. When vanadium(IV), chromium(III), iron(III), cobalt(II), nickel(II), copper(II), and uranium(VI) react with pentane-2,4-dione, heptane-3,5-dione, 1,1,1-trifluoropentane-2,4-dione, 4,4,4-trifluoro-1-(2-thienyl)-butane-1,3-dione, 1-phenylbutane-1,3-dione, and 2-acetylcyclohexanone a significant catalytic effect on the rate of ionization of the keto tautomer of the ligand was observed. A considerable enhancement of the rate of ionization of the enol tautomers of these ligands was observed during the complex formation reactions with Cu^{2+}. A mechanism is proposed that accounts for these catalytic effects. In the case of Cu^{2+} the increased rate of proton removal from the ligands may be rationalized in terms of the relatively large reduction potential of this metal ion.

CARLOS A. BLANCO et MICHAEL J. HYNES. Can. J. Chem. **70**, 2285 (1992).

On a observé des effets catalytiques sur les constantes de vitesse de déprotonation des β-dicétones au cours d'études cinétiques sur les réactions de formation des complexes 1 : 1 de ces coordinats. Lorsqu'on fait réaction du vanadium(IV), du chrome(III), du fer(III), du cobalt(II), du nickel(II), du cuivre(II) et de l'uranium(VI) avec la pentane-2,4-dione, l'heptane-3,5-dione, la 1,1,1-trifluoropentane-2,4-dione, la 4,4,4-trifluoro-1-(2-thiényl)-butane-1,3-dione, la 1-phénylbutane-1,3-dione et la 2-acétylcyclohexanone, on observe un effet catalytique important sur la vitesse d'ionisation du tautomère cétonique du coordinat. On a observé une augmentation considérable de la vitesse d'ionisation des tautoméres énoliques de ces coordinats au cours des réactions de formation de complexes avec le Cu^{2+}. On propose un mécanisme qui explique ces effets catalytiques. Dans le cas du Cu^{2+}, on peut rationaliser l'accélération de la vitesse d'enlèvement du proton des coordinats en fonction d'un relativement grand potentiel de réduction de cet ion métallique.
[Traduit par la rédaction]

Introduction

During the last number of years, the kinetics and mechanisms of the complex formation reactions of β-diketones with a variety of metal and oxo-metal ions have been the focus of considerable attention (1–18). In view of the fact that β-diketones can exist in solution as keto and enol tautomers and as the enolate ion, their complex formation reactions have considerable potential for mechanistic variation. Apart from their intrinsic interest, the reactions of these ligands with metal ions are of interest because of the considerable practical applications of the metal complexes in analytical chemistry, as catalysts for polymerization reactions, as insecticides, for the control of soil-borne fungi, and in laser technology (19).

Metal complexes were first classified as either labile or inert on the basis of the electronic configuration of the metal ion (20). In general, complexes of metal ions with d^3 and low-spin configurations were classified as inert (20). However, the substantial body of kinetic results obtained since Taube's review demonstrate that other properties of metal ions, such as charge and ionic radius, as well as the electronic and structural character of the ligands also have a considerable effect on the rates and mechanisms of ligand substitution processes (21–27).

To evaluate the inherent kinetic nature of metal ions, it has been essential to compare rate constants for complex formation of various metal ions with structurally similar ligands having a range of substituent groups that exert a variety of electronic effect. In the case of the complex formation reactions of β-diketones, some of the kinetic investigations were concerned with the influence of both electron-releasing and electron-withdrawing groups on the reaction mechanisms, others have investigated the effect of the chain length on the reactivity of β-diketones towards metal ions, while more recent investigations have concentrated on medium effects (18). In addition, the nature of the metallic centres (such as their acid–base properties, lability, and hardness) have also been considered. Recent results have highlighted the catalytic effect of Cu^{2+} on the ionization of the keto and enol tautomers of 2-acetylcyclohexanone (28).

As part of our continuing interest in the reactions of metal ions with β-dicarbonylic compounds we now report a comparative study of the catalytic effects of a range of metal ions on the complex formation reactions of metal β-diketonates.

Experimental

$VOSO_4 + H_2O$ (B.D.H.), $Cr(NO_3)_3 \cdot 9H_2O$ (Aldrich), $Fe(NO_3)_3 \cdot 9H_2O$ (AnalaR), $Co(ClO_4)_2 \cdot 6H_2O$ (Johnson Matthey), $Ni(ClO_4)_2 \cdot 6H_2O$ (Johnson Matthey), $Cu(NO_3)_2 \cdot 3H_2O$ (B.D.H.), and $(UO_2)(NO_3)_2 \cdot 6H_2O$ (AnalaR) were used as the source of metal ions. Stock solutions were standardized using recognised procedures (29).

4,4,4-Trifluoro-1-(2-thienyl)-butane-1,3-dione, Htftbd (Koch–Light), and 1-phenylbutane-1,3-dione, Hpbd (Fluka), were used as purchased. Pentane-2,4-dione, Hpd (B.D.H.); heptane-3,5-dione, Hhptd (Kodak); 1,1,1-trifluoropentane-2,4-dione, Htfpd (Koch–Light); 2-acetylcyclohexanone, Hachx (Fluka), were freshly dis-

tilled under reduced pressure prior to use. Stock solutions were standardized by titration with standard sodium hydroxide.

Perchloric acid (B.D.H.) was used as the source of hydrogen ions and all solutions were adjusted to an ionic strength of 0.5 mol dm^{-3} using $NaClO_4$ (Riedel–de Haën) as the inert electrolyte. Unless otherwise indicated, all materials were of analytical reagent grade and were used without further purification.

UV/visible spectra were recorded on a Shimadzu UV-260 spectrophotometer equipped with a chart recorder and a thermostatted cell compartment. pH measurements were made with a PTI6 pH-meter equipped with a Russell combination electrode. From spectrophotometric and potentiometric data a quantitative evaluation of the ligand and complex equilibria was carried out using published procedures (30, 31).

The kinetic data were obtained either on the Shimadzu UV-260 spectrophotometer or on a Hi-Tech SF-20 stopped-flow spectrophotometer that was interfaced to a BBC microcomputer via a Datalab DL901 transient recorder. The pseudo-first-order rate constants were the average of at least three determinations. Data for from three to four half-lives were utilized in these calculations. The standard deviation in individual runs was usually less than one percent.

All measurements were carried out at 25.0 ± 0.01°C.

Results and discussion

The keto–enol equilibrium of β-diketones is usually represented as in eq. [1], where k_e is the rate of enolization

$$[1]\quad HK \underset{k_f}{\overset{k_e}{\rightleftharpoons}} HE$$

and k_f is the rate of ketonization. However, the enolization of β-diketones does not proceed by direct transfer of a proton from carbon to oxygen. Instead, the enolate ion is formed as an intermediate and eq. [2] is a more complete description of the actual mechanism.

$$[2]\quad HK \underset{k_b}{\overset{k_a}{\rightleftharpoons}} H^+ + E^- \underset{k_d}{\overset{k_c}{\rightleftharpoons}} HE$$

In eq. [2] $k_c > k_b > k_d > k_a$ and k_c is diffusion controlled ($\approx 3 \times 10^{10}$ dm^3 mol^{-1} s^{-1}) (32). In terms of the ionization scheme, $k_e = k_a$ and $k_f = K_{HE}k_b$ where K_{HE} is the dissociation constant of the enol tautomer of the ligand.

For many complex formation reactions, the rate constant for loss of a proton by the ligand is considerably greater than the rate of complex formation with the deprotonated form of the ligand. For example, the rate of proton loss from acetic acid is 8.2×10^5 s^{-1} (33) while the rate of reaction of Ni^{2+} with CH_3COO^- is 1.5×10^5 dm^3 mol^{-1} s^{-1} (27). However, in the case of β-diketones it has been found that the rates of proton loss from either the keto or enol tautomer are frequently less than, or of a similar order of magnitude to, the rates of complex formation. Table 1 contains a list of the rates of ionization of the keto and enol tautomers of the β-diketones discussed here. The values of $k_a = k_c$ were determined by a bromination procedure (14, 16). The values of k_d were calculated from the known values of K_{HE} and k_c, assuming that the k_c pathway is diffusion controlled. Relevant kinetic data for the reactions of vanadium(IV), chromium(III), iron(III), cobalt(II), nickel(II), copper(II), and uranium(VI) with β-diketones from our previous published and unpublished work and from the literature (1–18, 28) are summarized in Table 2. The values given include those that are derived on the basis of the previously established mechanisms (18). In Table 2 the rate constants for reaction of the metal species with the keto (k_{HK}) and enol tautomers (k_{HE}) of the β-diketone are compared with the rate of proton loss from both the keto (k_a) and enol tautomers (k_d) respectively. Since the vast majority of these reactions were carried out in neutral or acidic medium where the pH is considerably less than the pK of the ligand, the fraction of the ligand present as the enolate ion is very small indeed. A number of deductions can be made from the data in Table 2. Firstly, it is apparent that the enol tautomer of all the β-diketones studied is considerably more reactive than the keto tautomer. It would appear also that direct reaction with the keto tautomer is restricted to those metal ions which are either very labile or which form relatively stable complexes, e.g., Fe^{3+}, Cu^{2+}, $[UO_2]^{2+}$, and that metal ions such Ni^{2+}, which form complexes of relatively low stability and which are relatively inert, react exclusively with the enol tautomer.

[a]In methanol:water (70:30 v/v).

The second important deduction that can be made from the data in Table 2 is that, with the exception of chromium(III), the rate constants for reaction of metal and oxo-metal ions with either the keto or enol tautomers of all β-diketones are considerably less than would be predicted on the basis of the Eigen–Wilkins mechanism. This retardation has been quantified in terms of the non-dimensional parameter R (34) (eq. [3]).

$$[3]\quad R = (4/3)k_{cf}/k_sK_o$$

In eq. [3] k_{cf} is the rate of complex formation, k_s is the rate of solvent exchange, and K_o is the outer sphere association constant, while the (4/3) is a statistical factor that accounts for the fact that not every solvent exchange leads to complex formation. In the present investigation, in view of the fact that the keto and enol tautomers of β-diketones are uncharged, the Rorabacher modification (35) of the Eigen–Fuoss equation (36, 37) was used to calculate K_o. A value of 0.3 was used throughout.

In the case of chromium(III) the exceptionally slow rate of water exchange together with the fact that it is believed to react by an I_a mechanism (26) make it extremely unlikely that retardation effects such as those exhibited by labile metal ions such as Ni^{2+} and Cu^{2+} would be apparent.

The presence of some catalytic effects on the ionization reactions of β-diketone are indicated by the data in Table 2. Although reversible base-catalyzed transformation of β-diketones into their tautomeric forms (38–40) is well established, such a mechanism would not be operative in the acidic conditions under which the work described here was carried out. The enolization of β-diketones is not an acid-catalyzed

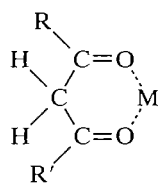

FIG. 1

process (41, 42). The catalytic effects observed during metal complex formation may be explained with reference to the intimate mechanism involved in the reactions of metal ions with β-diketones. The idea that these reactions proceed via a precursor complex was first proposed by Pearson and Anderson during their investigation of the reactions of Cu^{2+} with the keto tautomer of pentane-2,4-dione (1). A possible structure for such a precursor complex is shown in Fig. 1 in which the metal ion is symmetrically bonded to the two oxygens of the keto tautomer. Support for this idea stems from the fact that a number of such complexes have actually been isolated and characterized (43, 44). A similar type of precursor complex could be envisaged for the enol tautomer. The stability of this precursor complex would be an important element in determining the rate of reaction of metal ions with both the keto and enol tautomers of β-diketones. The complex formation in this instance could best be described as a metal-ion-catalyzed proton release from this precursor complex. Undoubtedly, the metal ion does catalyze proton release in those cases where pseudo-first-order rate constants are considerably greater than rates of ligand ionization (see Table 2). The copper(II) ion obviously acts as a catalyst in this step as the overall complex formation reactions are at least 100 times more rapid than loss of proton from the uncoordinated ligand.

Considering the data in Table 2, the formation of $[Cu(acxh)]^+$ is a case where the catalytic effect appears to be particularly high, the rates of complex formation being increased by about 3×10^3 compared to the rate of ionization. This may be related to the relatively slow rate of proton release from this ligand. In this particular case the rate constant for ionization of the keto tautomer of Hachx (k_a) is the smallest by more than one order of magnitude while the rate constant for loss of a proton from the enol tautomer (k_d) is almost two orders of magnitude less than the next smallest value in Table 1. The slow rate of loss of proton from the keto tautomer can be ascribed to the fact that the 2-carbon on Hachx has only one proton attached compared to two on the methine carbon in linear β-diketones. In addition, the acidic

Fe^{3+}	(d^5)	3.6×10^1	−0.04
Co^{2+}	(d^7)	7.2×10^5	−0.28
Ni^{2+}	(d^8)	7.2×10^3	−0.25
Cu^{2+}	(d^9)	1.0×10^9	+0.35

[a] $k_{E-W} = (3/4)k_s K_o$.

proton is attached to a tertiary ring carbon and this may hinder the process of proton removal.

This large catalytic effect is not reproduced in the reaction of any other metal ion with the enol tautomer of a β-diketone. It has been proposed that the ability to accept transferred charge should be related to the standard electrode potential of the metal in aqueous solution (45). The electrode reduction potential of Cu^{2+} (+0.35 V) is considerably greater than the reduction potential of any other 3-*d* transition metal ion, reflecting its greater ability to accept charge (Table 3). This higher tendency for Cu^{2+} to capture electrons may be reflected in its greater ability to stabilize precursor complexes of the type shown in Fig. 1 compared to other transition metal ions. This increased stability will in turn be reflected in an increased rate of proton loss from the precursor complex, leading to increased rate of complex formation.

The catalytic effect is greater when the metal ion reacts with the keto rather than with the enol tautomer of the ligand. There may be two reasons for this. Firstly, the keto tautomer is more inert than the enol tautomer and consequently has a greater potential to exhibit a catalytic effect. Secondly, it may be related to the more facile approach of the metal to the keto tautomer; such an approach would indeed in all probability be hindered by the extensive intramolecular hydrogen bonding present in the enol tautomer. The only exceptions to this are the reactions of copper(II) with 2-acetylcyclohexanone where $k_{HE}/k_d > k_{HK}/k_a$ (Table 2). This may be attributed to the cyclic structure of Hachx.

The arguments presented here give a plausible explanation of the ability of many metal ions to catalyze the ionization of the keto tautomers of β-diketones. Even those metal ions with negative reduction potentials such as Co^{2+} (−0.28 V) and Fe^{3+} (−0.04 V) are able to catalyze proton loss during the complex formation process through electrostatic interaction with oxygen centres. Most striking in this respect is the ability of $Fe(OH)^{2+}$ to catalyze proton loss from the enol tautomer of pentane-2,4-dione. Although it is known that hydroxide complexes of Cr(III), Fe(III), Co(III), and Cu(II) usually give larger rate constants than the aquometal ions (27) for many substitution reactions, the reactivity of $Fe(OH)^{2+}$ towards Hpd is considerably greater than would be predicted for a doubly charged metal. This is similar to the internal conjugate base mechanism proposed by Rorabacher (46) but, in this instance, the hydrogen bonding occurs between the acidic proton on the diketone and the oxygen of the coordinated hydroxide group. Such effects are believed to operate largely via an enhancement of the outer-sphere association constant (47).

The ability of some metal ions to catalyze the ionization of both the keto and enol tautomers of β-diketones has been demonstrated. The effects of the various metal ions have been rationalized in terms of their reduction potentials, their ability to stabilize the proposed precursor complexes, and their ability to increase the outer-sphere association constant via hydrogen bonding.

MARTINE VARACHE-LEMBEGE, ALAIN NUHRICH, GUY DEVAUX, and FRANÇOISE DUBOUDIN. Can. J. Chem. **70**, 2290 (1992).

During the basic treatment of the compound named in the title the expected ketone was not obtained. The Fast Atom Bombardment (FAB) mass spectrum of the new product formed was reported in this paper: the fragmentation pattern shows an S—S bridge sequence in a dimeric compound. This structure was also investigated by ^{1}H and ^{13}C nuclear magnetic resonance spectroscopy, the results of which were in accordance with the mass spectral data. The formation of this compound was explained by the hypothesis of a thiirane intermediate structure that could spontaneously isomerize to the enethiol form and undergo oxidation to the disulfide.

MARTINE VARACHE-LEMBEGE, ALAIN NUHRICH, GUY DEVAUX et FRANÇOISE DUBOUDIN. Can. J. Chem. **70**, 2290(1992).

Lors du traitement basique du composé mentionné dans le titre, il ne se forme pas la cétone attendue mais un nouveau produit dont la structure est élucidée dans cette publication. Les modes de fragmentation déduits du spectre de masse FAB de ce dérivé mettent en évidence l'existence d'un pont disulfure dans un dimère. L'étude des spectres de RMN du ^{1}H et du ^{13}C permet de confirmer les données de la spectrométrie de masse. La formation de ce composé s'expliquerait par une structure thiirane intermédiaire pouvant s'isomériser en une forme ènethiol qui s'oxyderait ensuite en disulfure.

Introduction

To extend our earlier work on a new diuretic thiopyranylidene phenoxyacetic ketone (1), we attempted to synthesize 2,3-dichloro-(1-oxo{5-(4-chlorophenyl)-1,2-dithiol-3-ylidene}-2-ethyl)-4-phenoxyacetic acid **2** (Fig. 1). A method similar to those of Sauvé and Lozac'h (2) was followed. A solution containing the bromide **1** in dry pyridine was refluxed for 1.5 h. The IR spectrum was in agreement with the structure of the expected ketone **2**: in particular, two strong bands at 1590 cm^{-1} and 1540 cm^{-1} were observed, as reported in the 1500–1610 cm^{-1} range for different 5-aryl-1,2-dithiol-3-ylidene acetophenones by Lozac'h (3). However the elemental analysis (Table 1) was in disagreement with

an α-ethylenic ketone structure. The study of the ^1H NMR spectrum of the product obtained, **3**, did not allow us to establish its structure, but it confirmed the presence of a phenoxyacetic group, and aromatic and thiophene rings. This paper reports the structural study of the product **3**.

Results and discussion

Mass spectrum

A dimeric structure was identified by its FAB mass spectrum (Fig. 2). It exhibited a small molecular ion M^+ 1006 and the isotopic figure 6-Cl,6-S. Thus the experimental relative abundances of the isotopic molecular peaks were in excellent agreement with those calculated according to Beynon's method (4).

Fragment ions at *m/z* 535 and 471, which contained respectively (3-Cl,4-S) and (3-Cl,2-S), showed the presence of a disulfide bond. Thus a structure could be proposed (Fig. 3) and was in agreement with the elemental analysis percentage for sulfur and hydrogen (Table 2).

The major fragmentation of the molecular ion followed four pathways: (A) from $[M]^{+\cdot}$ to *m/z* ($M^+ - 503$), 503 (Scheme 1); (B) from $[M]^{+\cdot}$ to *m/z* ($M^+ - R$), 535 and 471 (Scheme 2); (C) from $[M]^{+\cdot}$ to *m/z* (base peak) 247 (Scheme 3); (D) from $[M]^{+\cdot}$ to *m/z* ($M^+ - R$), 256 (Scheme 4).

Pathway A: The presence of a fragment ion at *m/z* 503 and its isotopic figure 3-Cl,3-S showed the cleavage of the di-

sulfide bond in **3** as formulated for the analogous compound (5). The peaks at m/z 473 and 445 are respectively attributed to the loss of a formaldehyde molecule and a carbonyl group, from the fragment ion m/z 503.

Pathway B: Fragment ions at m/z 535 and 471 are explained by a simple S—S bridge α-cleavage from the molecular ion (5). Also, fragment ions at m/z 441 and 413 resulted from the expulsion of a formaldehyde molecule and the expulsion of a carbonyl group from the fragment ion m/z 471, respectively.

Pathway C: The base peak (m/z 247) is formed by a simple carbonyl group α-cleavage as shown in Scheme 3.

Pathway D: A cyclic process may lead to the formation of a radical ion (m/z 256).

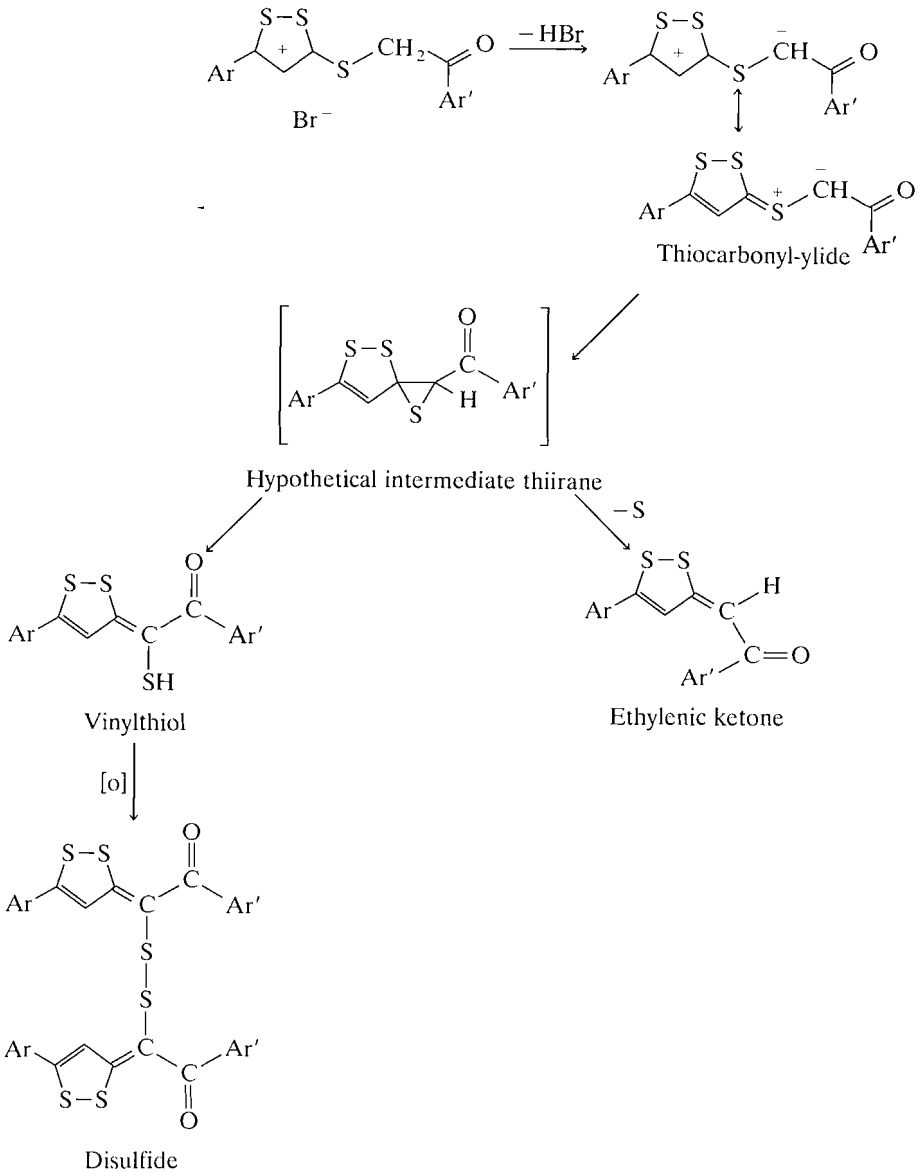
The study of these fragment peaks and their isotopic structures allowed us to propose a dimeric structure (**3**) containing an S—S bridge for the product.

NMR spectra

^{1}H and ^{13}C NMR yielded spectra that confirm the structure of each symmetrical part of **3**.

The ^{1}H chemical shift data of the various protons in compound **3** are given in Table 3.

The ^{13}C spectrum of **3** shows both the resonance at δ_C 65.25, and resonances at δ_C 111.16, 125.39, 127.26, 129.15, and 129.43. Using a DEPT experiment, these were shown to be one CH_2 group and five different CH groups, respectively. It follows that the resonances reported in Table 4 can be assigned to 11 quaternary carbons. The chemical shift of C1 at 178.80 ppm indicated the presence of a carboxylic acid function while the chemical shift of C6 at 187.46 ppm indicated the presence of a carbonyl group. The last value is in agreement with those reported by McKinnon and Abouzeid (6). Calculations using the increment rule (7) allowed us to attribute most of the chemical



SCHEME 5. Hypothetical mechanism.

For personal use only.

shifts to the other quaternary carbons. C8 and C9 were identified at 169.19 ppm.

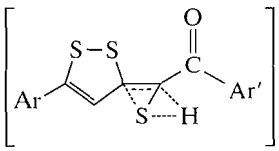
Thus the total number of carbons and the division between the secondary, tertiary, and quaternary carbons were in agreement with the disulfide structure **3**.

Hypothetical mechanism

During the last decade, relatively few papers investigating the chemistry of thiocarbonyl ylides have been published (8–11). Some studies on bis(dimethylamino methylene) sulfonium bromides (5) showed that by deprotonation with a base these compounds produce a thiocarbonyl ylide that could cyclize into unstable non-isolated thiirane. The latter undergoes a very quick isomerization to give an enethiol whose air oxidation leads to the final disulfide product.

On the other hand, other works on thiocarbonyl ylides treated with various bases state that the reaction proceeded either to the formation of a disulfide or to an ethylenic ketone by decomposition of the hypothetical intermediate thiirane with release of elemental sulfur (Table 5).

We hypothesized that the title compound might be formed as indicated in Scheme 5. The rearrangement of the hypothetical intermediate thiirane could be in accordance with that previously reported (15) for unimolecular isomerization of thiirane to vinylthiol through the following intermediate state:



We have never found an ethylenic ketone.

We cannot yet explain the influence of the structure of α-carbon substituents in the initial product on the nature and proportions of the products obtained.

Experimental

The positive ion Fast Atom Bombardment (FAB) mass spectrum was obtained on a VG-ZAB-ZEQ spectrometer. The sample, dissolved in thioglycerol/$HClO_4$, using dioctylphthalate as the internal reference, was analyzed by a direct insertion probe with a source temperature of 0°C.

Nuclear magnetic resonance spectra were measured at 250 MHz (^1H) and 62.9 MHz (^{13}C) with a Bruker AC 250 spectrometer, in acetone as a solvent. Off-resonance and DEPT spectra were recorded. Chemical shifts were measured in ppm (δ) using tetramethylsilane as the internal reference.

We present in this work the results of a rather simplified theoretical approach to some of the processes involved in the inhibition of Zn-containing active sites. Our aim is to calibrate a model in which Zn is replaced by Be. The motivation for this strategy is to provide a qualitatively correct, but fast, approach that can be used in the simulation of many inhibitors interacting with a Zn site. The use of Be allows us to retain some of the essential features of the inhibitor–Zn interaction, while involving much less computation time. It should be noted that we are *not* modeling a Be-containing active site, but processes occurring in a Zn-containing one. We design a scaling transformation that permits us to relate the electronic properties associated with a given Be–ligand distance to the same electronic properties associated with a desired Zn–ligand distance. The results provided by the Be-containing model are comparable to those corresponding to the actual Zn-containing model. One of the processes we are interested in describing here is the effect that the presence of a Zn(II) cation has on the ability of an inhibitor to donate a proton to an acceptor. This process is of importance in the inhibition of Zn-containing enzymes, such as liver alcohol dehydrogenase (LADH). The inhibitory mechanism of LADH seems to involve first the interaction of a ligand with the Zn cation, followed by the transfer of a proton to an acceptor, and finally the binding of the deprotonated ligand to the nicotinamide adenine dinucleotide (NAD^+) coenzyme. In this work, we considered the molecule of formaldehydehydrazone as a model of an inhibitor (e.g., pyrazole). This simplified model contains the strict essentials needed to study proton transfer mediated by a metallic cation. We found a parallelism between the roles of the two metals in the H transfer from this model of inhibitor that allows us to make some qualitative predictions for other processes in Zn from the results obtained exclusively in the presence of Be.

ISABEL ROZAS et GUSTAVO A. ARTECA. Can. J. Chem. **70**, 2296 (1992).

Dans ce travail, on présente les résultats d'une étude théorique assez simplifiée de quelques processus impliqués dans l'inhibition de sites actifs contenant du Zn. Le but du travail est de calibrer un modèle dans lequel le Zn est remplacé par du Be. La motivation de cette stratégie est de fournir une approche qualitativement correcte, mais rapide, qui pourrait être utilisée dans la simulation de plusieurs inhibiteurs qui interagissent avec un site de Zn. L'utilisation du Be permet de retenir quelques-unes des caractéristiques essentielles de l'interaction inhibiteur–Zn tout en demandant moins de temps de calcul. On doit noter que l'on n'examine *pas* un modèle d'un site actif contenant du Be, mais bien les processus se produisant dans un site qui contient du Zn. On a mis au point une transformation scalaire qui permet de relier les propriétés spectroscopiques associées à une distance Be–ligand donnée avec les mêmes propriétés électroniques associées avec une distance donnée Zn–ligand désirée. Les résultats fournis par le modèle contenant du Be sont comparables à ceux correspondants au modèle contenant du Zn. L'un des processus que nous étions intéressés à décrire ici est l'effet de la présence d'un cation Zn(II) sur l'habilité d'un inhibiteur à donner un proton à un accepteur. Ce processus est important dans l'inhibition des enzymes contenant du Zn, comme la déshydrogénase de l'alcool du foie (LADH). Le mécanisme d'inhibition de la LADH semble impliquer au départ une interaction d'un ligand avec un cation Zn, puis le transfert d'un proton vers un accepteur et finalement l'association du ligand déprotoné au coenzyme du dinucléotide de l'adénine nicotinamide (NAD^+). Dans ce travail, on a considéré la molécule d'hydrazone du formaldéhyde comme un modèle d'un inhibiteur (p. ex., pyrazole). Ce modèle simplifié contient le strict minimum requis pour une étude de transfert de proton initié par un cation métallique. On a trouvé un parallélisme entre les rôles des deux métaux sur le transfert d'hydrogène à partir de ce modèle de l'inhibiteur qui nous permet, en se basant uniquement sur des résultats obtenus en présence de Be, de faire quelques prédictions qualitatives pour d'autres processus impliquant du Zn.

[Traduit par la rédaction]

Introduction

In this work we study the interaction between a rather simplified model of pyrazole with Zn(II) and Be(II) cations. The aim is to seek a possible parallelism between the interactions Zn(II)–N and Be(II)–N in order to describe approximately the electronic properties associated with a given Zn(II)–ligand distance from the properties corresponding to a different distance in the computationally more accessible Be(II)–ligand model. The goal is to provide a transformation from the calibrated Be(II) system to the Zn(II) system in which one is actually interested. The motivation for this approach is the appreciable saving of computing time achieved when replacing Zn by Be, especially if the computations are repeated when simulating the behavior of a large number of inhibitors. This approach can be viewed as *a first step* towards the construction of a more detailed (but simplified) model of an actual active site, where the actual ligands at the site are added at a second step.

An application of interest for this Be-calibrated system is found when modeling the more complicated processes occurring in the inhibition of Zn-containing enzymatic active sites. One example of these active sites is found in liver alcohol dehydrogenase (LADH). Essential processes involved in the inhibition of LADH are (*i*) the interaction of a ligand with the metal cation; (*ii*) the transfer of a proton from this ligand to an acceptor, mediated by the presence of the metal. Finally, the binding of the deprotonated ligand to the nicotinamide adenine dinucleotide (NAD^+) coenzyme completes the process (1). Our study of ligand–metal interactions can be relevant to the understanding of the first two processes.

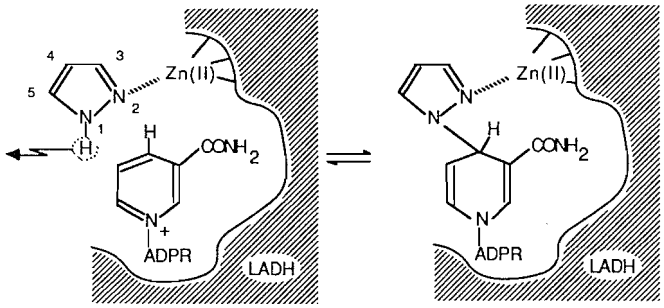

FIG. 1. Scheme of the interaction between LADH, one of its inhibitors (the pyrazole molecule), and the coenzyme NAD^+.

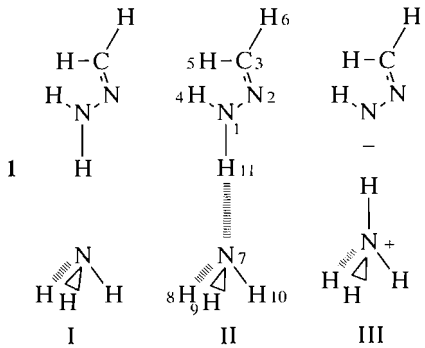

FIG. 2. Proton transfer process between formaldehydehydrazone (1) and ammonia. Structures I, II, and III correspond to the initial arrangement, H-bonded minimum, and final arrangement, respectively.

It has long been known that LADH catalyzes the first step in alcohol metabolism (1*a*). There have been several studies on the structure of the complex LADH–NAD^+ and various inhibitors (2), as well as on their activity. Pyrazole and its derivatives are the strongest inhibitors known for this enzyme (3). They form a strong ternary complex with LADH and NAD^+ (2*a*, 4) (see Fig. 1).

To analyze the effect of the metal cation in the proton transfer process we also studied this step in the absence of the metal. As a model reaction, we considered the molecule of formaldehydehydrazone (a simplified model for pyrazole) as proton donor and ammonia as proton acceptor. The two limiting cases for the proton transfer are given, on the one hand, by the structure where the H is attached to the terminal amine group of formaldehydehydrazone and, on the other hand, by the arrangement involving the NH_4^+ cation (see Fig. 2).

In this approximation to the inhibitor–metal – proton acceptor complex, we look for a relationship between properties that are involved directly in the inhibitor–receptor interaction. These include: N–metal bond order, number of bonding electrons per atom (valency), and atomic charge (5). In a following section we discuss the reaction surface and reaction path for the hydrogen donation. The information obtained from this study is then used to calibrate the Be(II)-containing model that mimics the actual Zn(II)–ligand interaction.

Role of a metal in the proton transfer between formaldehydehydrazone and ammonia

Properties of the system without metals

Formaldehydehydrazone (compound **1**, as shown in Fig. 2) represents a formal "half" of pyrazole (cf. pyrazole in Fig. 1 with compound **1** in Fig. 2). This molecule does not have the aromatic character of pyrazole, but the nature of the interaction with the metal and the geometry for the proton donation can still be described adequately. This is, the intrinsic properties of the inhibitor will be poorly described (due to the absence of a five-membered ring), but this model inhibitor contains all the features needed to describe the N—H···N proton transfer process, which is our aim in this work. To this end, we considered the formaldehydehydrazone molecule as planar, forcing the N(1) atom to adopt an sp^2 hybridization and a geometrical configuration similar to that in pyrazole. All other internal coordinates were optimized.

The calculations were carried out at the *ab initio* level, using the GAUSSIAN 88 series of programs (DEC version) (6), and with the minimal basis set (with polarization functions) STO-3G* (7). This rather small basis set was chosen since we shall later incorporate Zn, and no larger basis set for this system was affordable to us. A more accurate (but costly) description would probably require mixed basis sets (8). To avoid some of the intrinsic problems of the minimal basis set (such as the wrong prediction of single-well reaction barriers for proton transfers (8)), PM3 semiempirical calculations (9) were carried out. For the exploratory analysis performed in this work, these levels of calculation may suffice to indicate the correct qualitative trends in the results.

As a first step, we studied the proton-transfer reaction in this system. A cross section of the reaction surface for this process was calculated at the *ab initio* level, with the STO-3G* minimal basis set (7). This cross section was obtained by calculating the total energy of the system for various placements of the central proton along the N–N internuclear axis. The N(1)—N(7) and N(1)—H(11) distances (Fig. 2) were chosen as the variables defining the cross section. Steps of 0.2 Å were used to compute the cross section. The remaining internal coordinates were optimized, retaining the planarity of the formaldehydehydrazone molecule and orienting the ammonia molecule for a linear transfer of the proton H(11) as shown in Fig. 2.

The linearity in the N—H···N moiety was preserved, since previous calculations in related systems (pyrazole–ammonia (10), ammonium–ammonia (11), pyridine–pyrrole (11*b*)) showed it to be almost or totally linear, a result consistently obtained with basis sets of various qualities.

The cross section obtained for this proton-transfer reaction is represented in Fig. 3. There are two minima corresponding to the limiting states, one when the proton is attached to the formaldehydehydrazone molecule (case I in Fig. 2) and the other when the proton is forming the ammonium cation (case III in Fig. 2). The difference in energy between these two minima is approximately 153.78 kcal mol^{-1} (0.24507 au), at the STO-3G* level of optimization.

Between these two minima, and along the reaction path, we found another shallow minimum, structure II, corresponding to a system type I, in which the interaction between the amine terminal group and the ammonia molecule seems to occur through a hydrogen bond.

This critical point II was localized at the MP2 level of

calculation. This level of correlation is appropriate to describe H-bonded complexes (11*a*), though in our case the description will be modest due to the use of a minimum basis set. The geometrical parameters characterizing minimum II are shown in Table 1. The results are in good agreement with the values obtained for related systems at different levels of calculation (see Table 2). Moreover, our geometrical parameters are quite close to those of Pardo *et al.* (8) obtained when using a STO-3G (ABH:6-31G) mixed basis set (cf. Table 2). The agreement suggests that a minimal STO-3G* basis set may suffice to extract the essential qualitative features of our system, in spite of its known inadequacy to compare H-transfer reaction barriers (8).

At minimum II, the proton is attached mostly to the ni-

trogen atom of molecule **1**. This result is in agreement with the fact that hydrogen bridges longer than 2.65 Å are asymmetric (12). The occurrence of an H-bonded minimum in this proton-transfer reaction is not unexpected, since the formation of such a bond is a necessary condition for all proton-transfer processes of the type: $AH\cdots B = A^-\cdots H^+B$, according to Zundel (13).

The most dramatic changes in the electron density (corresponding to N(1) and N(7)) occur along the direction in space defined by the H bond. The electron distribution is distorted differently for each N. The region between N(1) and H(11) increases its electron population, whereas the region between N(7) and H(11) becomes depleted in electron density. This is consistent with the findings of Scheiner (14), and seems to indicate that the presence of an H bond permits the delocalization of the π system from one molecule to the other, a fact that stabilizes the overall system. Our results indicate a stabilization of about 7.15 kcal mol^{-1} (0.0114 au).

Using the cross section of the reaction surface as a starting point, we calculated the corresponding reaction path (Fig. 3), optimizing each point of the path at the MP2 level (*vide supra*). An energy profile is displayed in Fig. 4(*a*).

As was pointed out before, the main failures of the STO-3G* basis set for describing a proton transfer are known to be in the shape of the reaction barrier (8). For a better description of the reaction barrier, we recalculated the reaction path, optimizing each point with the semiempirical program PM3 as implemented in the MOPAC package (9).

At this level of calculation, a double-minima barrier is obtained. The lowest energy minimum is the same structure as minimum II, obtained before using *ab initio* calculations with the minimal basis set. The other minimum corresponds to a complex where H(11) is almost bonded to the ammonia moiety, at 1.99 Å from the N(5) of the formaldehydehydrazone. The interaction between this H(11) atom and the N(5) seems to be more electrostatic than H-bonding. The geometrical parameters of both minima at the PM3 level are shown in Table 1, and the energy profile obtained is displayed in Fig. 4(*b*). It is worth remembering that our main objective is to analyze the role of the metal cations in the proton transfer, and thus only the proton-bonded minimum II is of interest. This structure II appears to have the same geometry at the *ab initio* as well as at the PM3 level. In both cases, structure II is the lowest-lying minimum.

One can gain a deeper insight into the behavior of the model by analyzing other molecular properties along the reaction path. The formation of the N(7)—H(11) bond and the breaking of the N(1)—H(11) bond appear to be simultaneous (see Fig. 5(*a*)) at the *ab initio* level. This last bond seems to be stronger than the N(7)—H(11) bond according to the respective bond order values (0.356 vs. 0.321). This can be explained by the fact that in formaldehydehydrazone there exists a conjugation with a double bond, resulting in a stronger bond to H(11) than to the ammonium cation.

The valency (number of bonding electrons) of H(11) along the reaction path (Fig. 5(*b*)) shows that, at the minimum II, this atom exhibits the maximum bonding to atoms N(1) (by

For personal use only.

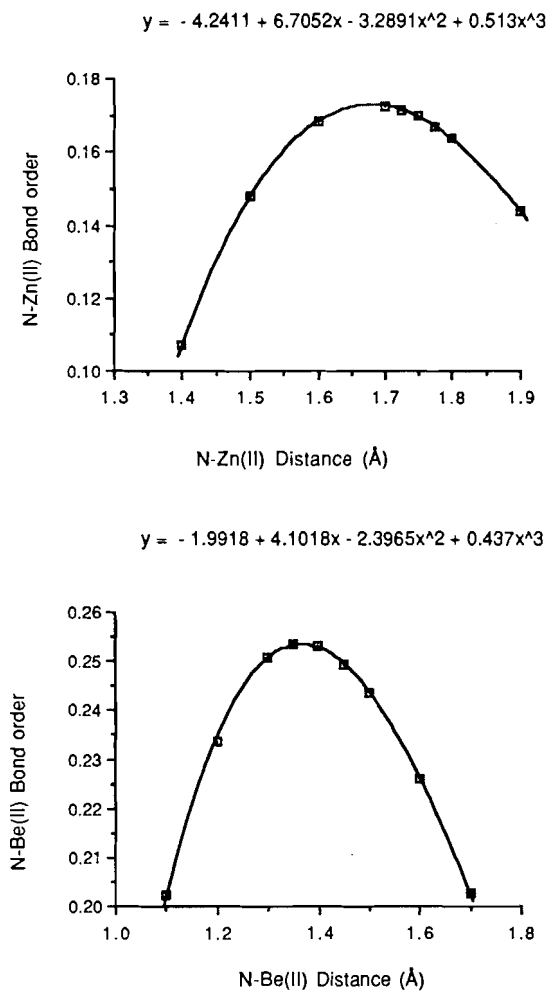

FIG. 6. Curves for Zn(II)—N and Be(II)—N bond orders (obtained by using *ab initio* calculations) as functions of cation–N distances, fitted by least-squares third-degree polynomials for the systems with ammonia as proton acceptor.

a covalent bond) and N(7) (by a hydrogen bond), simultaneously.

Figure 5(*b*) shows a minimum at about 8.0 units of arc length from the reactants. This minimum in valency corresponds to the same structure found to be the second minimum in energy in the PM3 reaction path profile (cf. Fig. 4(*b*)). This fact suggests that in this complex the H(11) atom is the least attached to the rest of the system.

Properties of the systems with Zn(II) and Be(II)

As mentioned before, the inhibition process of LADH by pyrazole is thought to involve first a binding of the N(2) atom of the inhibitor to the Zn(II) cation. After a proton is released from N(1), the unprotonated N(1) atom binds to the nicotinamide ring of the coenzyme (15). Accordingly, the minimum II found above could serve as a model for the interaction of pyrazole with the metal cation, *at the moment of transferring the proton to an acceptor, a separate step that takes place before the binding of the pyrazole anion to the* NAD^+.

It is known that LADH still maintains a catalytic activity if the Zn(II) cation is substituted by Co(II), Cd(II), Ni(II), and Fe(II) (16, and refs. therein). Reconstruction of the enzyme was also possible with Cu(II), Fe(III), and Pb(II), but in these cases the activity is lost (16). One could argue whether our Be(II) model would simulate a Zn(II)- or Be(II)-containing enzyme. A real Be(II)-containing LADH would be inactive. Our aim is not to approximate this latter enzyme, but to construct a simple, "artificial" model with Be(II) that deviates from an actual Be-containing system, but whose behavior would be similar to the natural Zn(II) in the active site.

The simulation of a Zn(II) cation in the active site of an enzyme by a Be(II) cation has been used before. In MO studies of the enzymatic activity of carboxypeptidase A (17), the $[Be(OH)(NH_3)_2]^+$ complex was used to simulate the catalytic Zn(II) coordinated with two histidines and one glutamate. Scheiner and Lipscomb (17) concluded that these electrophiles may serve as an adequate model for the Zn(II) and its ligands in carboxypeptidase A. Moreover, the authors suggested that the *d*-orbitals of Zn might not be fully involved in forming a complex with the substrate. However, Osman and Weinstein (18) carried out a comparative study of Zn(II)- and Be(II)-containing complexes (in order to study the active center of metalloenzymes, as carboxypeptidase and carbonic anhydrase), and concluded that the transition metals seem to play a special role in these biological systems.

In our present case, the metallic cations (Zn(II) or Be(II)) were situated on the same plane as the formaldehydehydrazone. This approach is suggested by results in the literature. For example, the interaction between Zn(II) and imidazole (related to pyrazole) occurs in an energetically favoured planar geometry (19). Consequently, the metal atom was located along the lone pair of N(2) of formaldehydehydrazone.

We studied the systems with Zn(II) and Be(II) at both *ab initio* (using the STO-3G* basis set) and semiempirical (using the program PM3) levels. In these systems, we used the optimized parameters of minimum II, keeping the planarity of the formaldehydehydrazone moiety and the linearity of the H bond. The rest of the internal coordinates were optimized, including those describing the shifting hydrogen. This analysis was repeated for various N(2)–metal distances.

The effect of the N(2)–metal interaction on various properties (bond order, valency, and atomic charge of N(2), Zn(II), and Be(II)) was studied using the STO-3G*. Third-degree polynomials were fitted to each set of data. Results are shown in Figs. 6–8.

The maximum values of bond order (Fig. 7) obtained for N(2)–metal cations are collected in Table 3. An important feature appears in these complexes: *the interaction N(2) – metal cations produces the H transfer from the N(1) of the formaldehydehydrazone to the ammonia molecule.* Thus, starting from the geometrical arrangement of minimum II (neutral molecules linked by an H bond) the interaction with Zn(II) and Be(II) ions generates complexes where the central H(11) forms part of the ammonium cation (see the N—N and N—H distances in Table 4).

Using the N–metal(II) distances obtained for the maximum bond order at the *ab initio* level we calculated the cationic complex using the program PM3. The same H transfer is observed from the formaldehydehydrazone to the ammonia molecule. In addition, the ammonium cation is shifted away from the formaldehydehydrazone–metal(II) complex (see the obtained geometrical parameters in Table 4).

The fact that the approach of a cation can facilitate a pro-

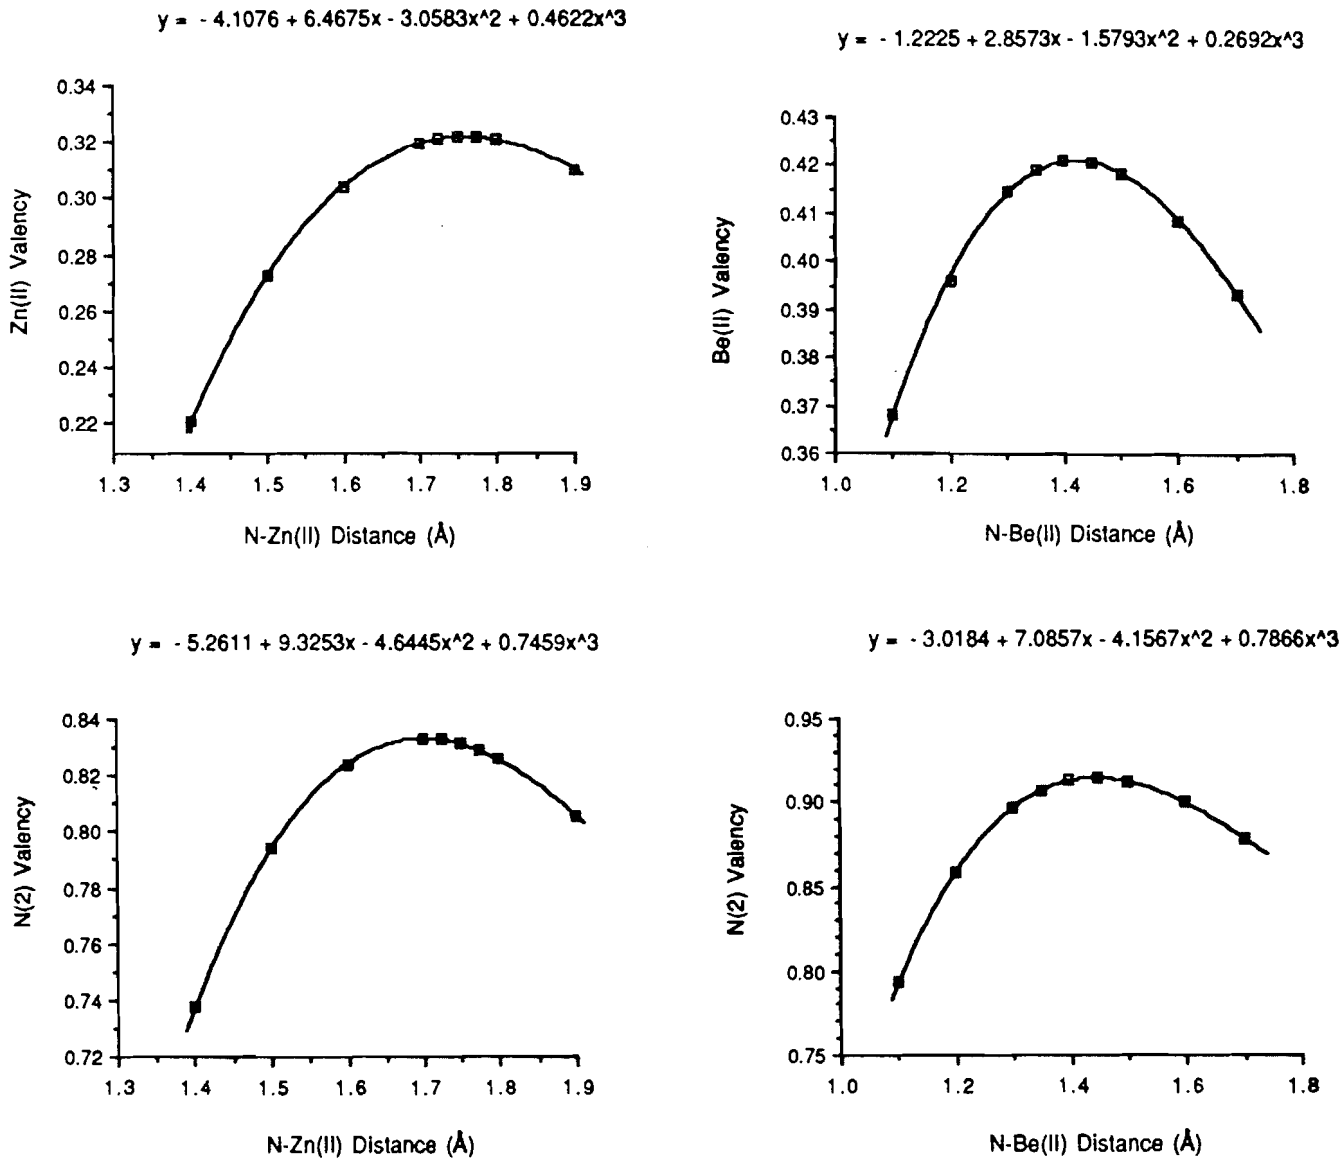

FIG. 7. Curves for N(2), Zn(II), and Be(II) valencies (obtained by using *ab initio* calculations) as functions of cation–N distances, fitted by least-squares third-degree polynomials for the systems with ammonia as proton acceptor.

ton transfer has been observed before for systems other than N—H···N (20). In refs. 20, it was noted that the interaction of Li^+ and Na^+ with an N or an O atom causes the release of an H directly bonded to these atoms. In our case, doubly charged cations of a very different nature, such as Zn(II) and Be(II), induce the transfer of an N-bonded H atom to the proton acceptor.

The effect of Zn(II) in facilitating deprotonation has been observed in imidazole and also in water (21). On the other hand, studies carried out on the role of zinc in LADH show that Zn(II) could be essential for the catalytic action of this enzyme but only in the H-transfer step (22). The results obtained in our calculations are in agreement with this model.

This effect of the metal interaction was observed for both cations and at different levels of calculation, which gives support to the use of Be(II) instead of Zn(II) for subsequent computations.

The maxima of valency (Fig. 7) obtained for Zn(II) and Be(II), using the STO-3G* basis set, are displayed in Table 3 together with the maximum valency for the N(2) atom when interacting with the cations. As expected, larger values are obtained for N(2) due to the multiple bonding of this atom.

The change in the atomic charges as a function of N(2)–metal distances is shown in Fig. 8. The values corresponding to the maxima appear in Table 3.

We conclude that the presence of a proton acceptor makes the whole system more conjugated, and the presence of cations facilitates the H-transfer process to the acceptor (ammonia).

Quantitative relationships between the systems with different metal cations

From the results discussed in the previous sections, it is clear that, to a certain extent, our system with Be(II) behaves similarly to that with Zn(II). In this section we establish a quantitative relationship between the two systems that

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

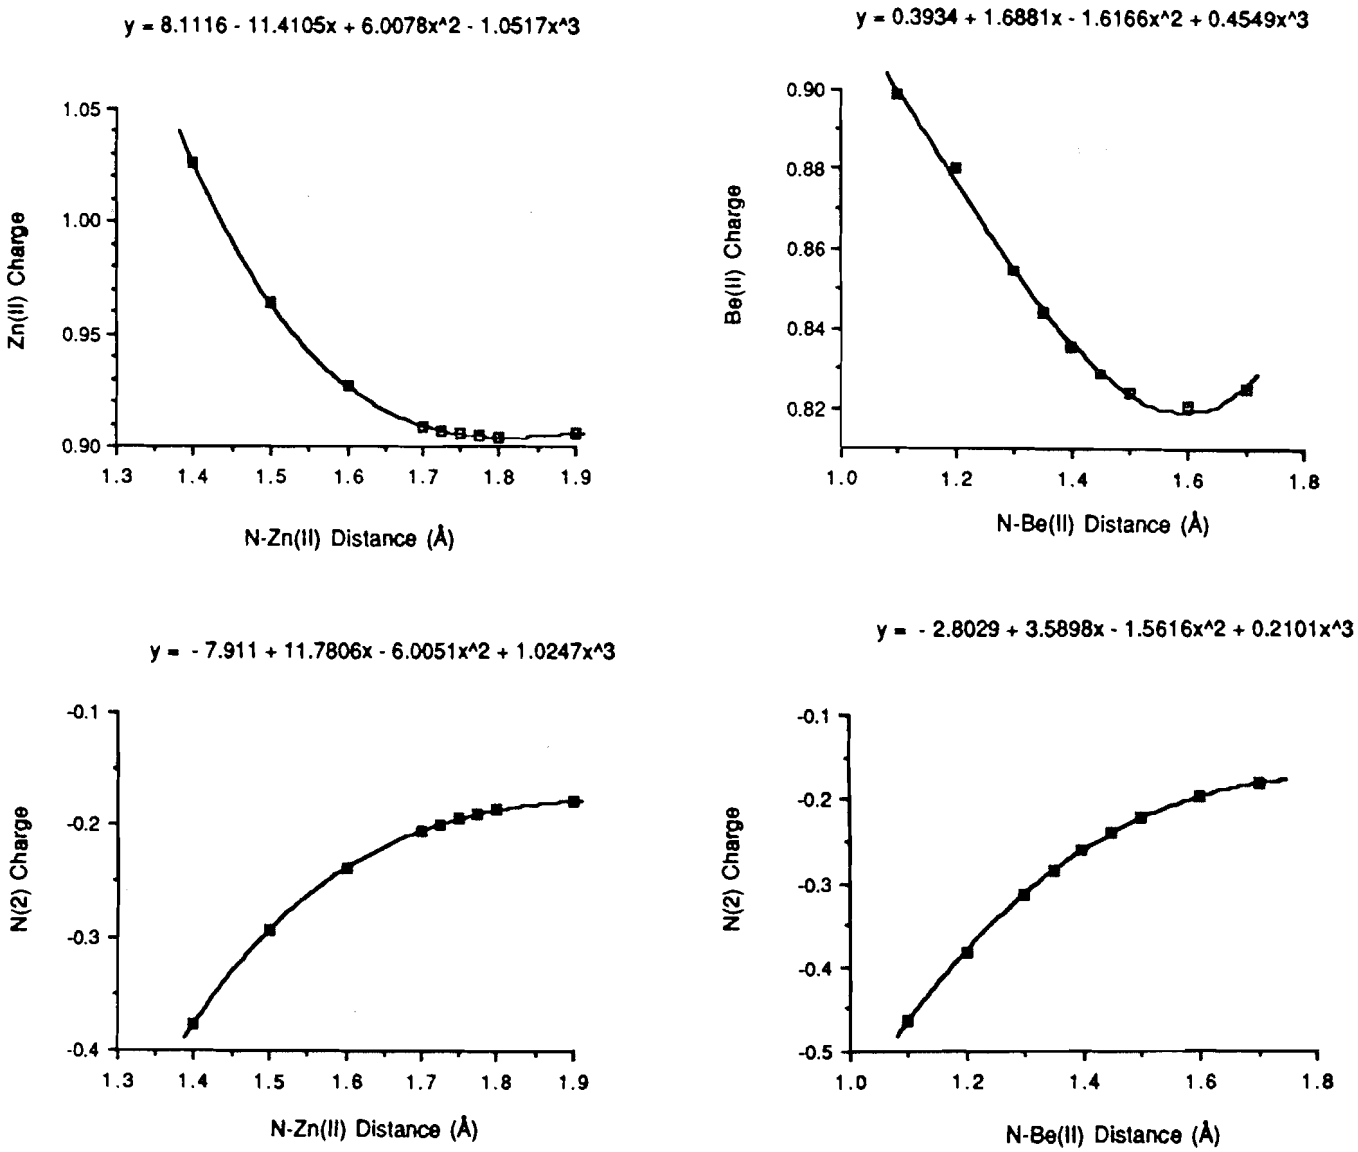

FIG. 8. Curves for N(2), Zn(II), and Be(II) atomic charges (obtained by using *ab initio* calculations) as functions of cation–N distances, fitted by least-squares third-degree polynomials for the systems with ammonia as proton acceptor.

allows us to calibrate a Be(II)-containing model to predict the results in the more costly Zn(II) system.

The approach we follow here is suggested by the fact that the properties of the systems with Zn(II) and Be(II) ions are similar and approximately derivable from one another by appropriate scaling. Thus, starting from a known N—Zn(II) distance (x_1) (the one for the enzyme–inhibitor system), and by taking a scaling factor β, we obtain the corresponding N—Be(II) distance (x_2). With this value x_2, we can determine the approximate property value (y_2) for the Be(II) system and use this to obtain the approximate property value (y_1) for Zn(II) system as follows:

$$x_2 = x_1\,\beta; \qquad y_1(x_1) = \alpha\, y_2(\beta\, x_1)$$

The numerical computation of the α and β parameters is discussed in the Appendix. Taking the bond order as the property y_2, the correlation between the Zn(II) and the Be(II) systems is satisfactory ($J = 3.59 \times 10^{-2}$). The α and β values obtained (2.0817 and 0.7984, respectively) give a good description of this property for Zn(II) by using only Be(II) results. The correlations obtained for the valency are not so good (J\{Zn(II),Be(II)\} = 0.2360 and J\{N[Zn(II)],N[Be(II)]\} = 0.1106). In contrast, the values obtained for the charge of N(2) correlate quite well ($J = 7.75 \times 10^{-3}$). The α and β values in this latter case are 2.8142 and 1.1685, respectively.

According to these results, both the bond order between the cations and the N(2) atom of pyrazole, as well as the atomic charge of N(2), are adequate properties to correlate the effects of Zn(II) and Be(II).

Conclusions

According to the results, the following conclusions are reached:

1. A minimum corresponding to an H-bonded formaldehydehydrazone – proton acceptor model in the cross section

of the corresponding reaction surface was found at the STO-3G* level and characterized. As stated before, formaldehydehydrazone simulates pyrazole as an inhibitor.

2. By using the semiempirical program PM3, a double-well energy profile is obtained. The minimum of lowest energy corresponds with the H-bonded structure obtained at the *ab initio* level. The other minimum obtained shows a non-symmetrical ammonium cation electrostatically attracted to the formaldehydehydrazone anion.

3. Whereas a single minimum was found for the proton transfer at the STO-3G* level, the geometrical description we obtained for the N—H···N hydrogen bond is satisfactory. This result is comparable with those obtained in the literature for other related systems with larger basis sets. In this work we were mostly interested in the effect of a metal on this H-bonded structure. We believe that the minimal basis set STO-3G* should be sufficient to extract these qualitative features correctly.

4. The main result that we found, at both *ab initio* and semiempirical levels, is the effect of the Zn(II) and Be(II) cations on the model inhibitor – ammonia complex. Our results suggest that the presence of these cations causes the transfer of a proton, covalently bonded to the inhibitor (and hydrogen-bonded to ammonia), to the proton acceptor. A similar mechanism was postulated to take place in the natural inhibition of LADH by pyrazole and related compounds. It is remarkable that this crucial feature is already present in a model as simplified as the present one.

5. The results obtained for Zn(II) and Be(II) show a close parallelism of their effect on the model inhibitor – proton acceptor system. A quantitative expression of this effect has been given in terms of the properties of the interacting metal and nitrogen atoms. We have shown how to interrelate the functional dependences on the N(2)–metal distance for two properties (N(2) – metal bond order and charge on N(2)) for the two metallic systems. We developed a scaling procedure that allows us to find the distance at which a Be(II) cation produces an effect similar to the effect exhibited by the Zn(II) ion. This relationship opens the possibility of replacing the more computationally demanding Zn metal by Be in studies of larger molecular systems, and still retain the correct qualitative behavior.

Appendix

Consider two comparable molecular systems, which we shall label as 1 and 2. In our case, these systems will be the inhibitor – proton acceptor complexes in the presence of Zn(II) and Be(II) cations, respectively. The properties of these systems have been studied in the text as functions of the distance between the N(2) of the model inhibitor and the metal ions. In this appendix we discuss how to establish and characterize a quantitative relationship between the two systems.

Let x_1 and x_2 be the N(2)—Zn(II) and N(2)—Be(II) distances, respectively. Consider now a given molecular property in both systems. As discussed in the text, the N(2)–metal bond order and the charge on the N(2) atom appear to be relevant properties to compare the two systems, since they have similar qualitative behavior with the changes in the metal–ligand distances. Let $y_1(x_1)$ and $y_2(x_2)$ be any of these molecular properties, for systems 1 and 2, respectively. For simplicity, we shall represent these properties as polynomials,

$$[1] \quad y_1 = \sum_{s=0}^{N} c_s x_1^s, \qquad y_2 = \sum_{s=0}^{N} a_s x_2^s$$

an approximation that holds reasonably well within a large range of interatomic distances x_1 and x_2. The form of the relation we intend to use is given as:

$$[2] \quad y_1(x_1) \approx \alpha\, y_2(\beta\, x_1)$$

Our goal is to determine a set of two constants α and β, that would allow us to approximate a function value for one polynomial by knowing only a function value for the other one. In other words, if a property y_2 is known for the beryllium system at a N(2)–Be(II) distance x_2, then the same property will have an approximate value $\alpha y_2(x_2)$ for the zinc system at an N(2)–Zn(II) distance equal to x_2/β.

We proceed by least-squares fitting to obtain the best α and β values for eq. [2]. From eqs. [1] and [2], we minimize the following function:

$$[3] \quad J(\alpha,\beta) = \sum_{s=0}^{N} (\alpha\, a_s\, \beta^s - c_s)^2$$

over changes in the variables α and β. Solving for $\partial J/\partial\alpha = 0$, we obtain an expression for α as a function of β. Introducing this result into the equation $\partial J/\partial\beta = 0$, we obtain an algebraic equation for β:

$$[4] \quad \sum_{k=0}^{3N-1} \beta^k\, b_k = 0$$

with the coefficients b_k given as:

$$[5] \quad b_k = \sum_{i=0}^{\mathrm{int}((k+1)/2)} (k + 1 - 3i)\, a_i^2\, a_{k+1-2i}\, c_{k+1-2i}$$

The upper limit in the sum in eq. [5] stands for the integer part of $(k + 1)/2$. It is easily proven that $b_{3N-1} = 0$.

In the actual application we obtained numerically all the positive real roots of eq. [5] for $N = 3$ and selected the one leading to the smallest $J(\alpha,\beta)$. With this β value we immediately calculate the corresponding α value. The results obtained and the quality of the description of the Zn(II) system in terms of the analogous Be(II) system are discussed in the text.

Reçu le 3 décembre 1991

CARMEN DOMINGUEZ, JOAQUÍN PLUMET, ANTOINE GASET et LUC RIGAL. Can. J. Chem. **70**, 2306 (1992).

La réction de condensation de Claisen–Schmidt du 2,5-furanedicarboxaldéhyde (FDC) sur la furylméthylcétone (FMC) conduit à trois produits différents en fonction des conditions opératoires. L'influence de cinq facteurs sur l'orientation de cette réaction est étudiée grâce à la réalisation d'un plan factoriel fractionnaire à deux niveaux.

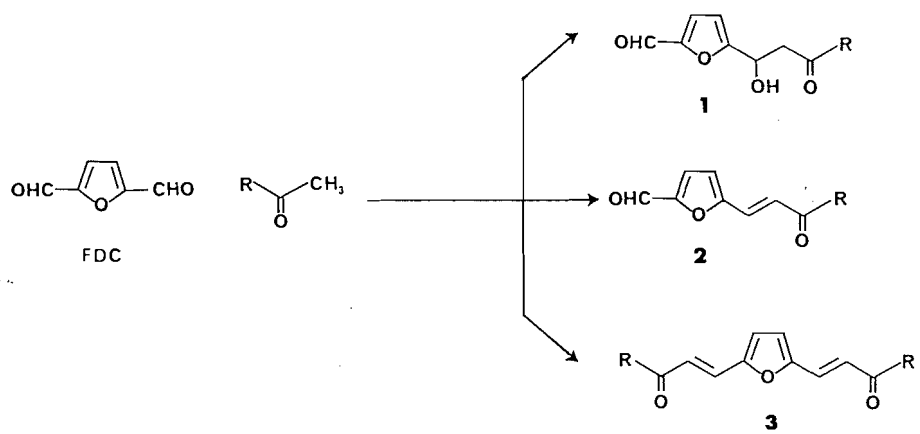
CARMEN DOMINGUEZ, JOAQUÍN PLUMET, ANTOINE GASET, and LUC RIGAL. Can. J. Chem. **70**, 2306 (1992).

The Claisen–Schmidt reaction of 2,5-furandicarboxaldehyde (FDC) with 2-acetylfuran allows for the synthesis of three products as a function of the reaction conditions. The main effects of five factors and their interaction effects on seven responses have been quantified by means of a fractional factorial design.

Introduction

La réaction de Claisen–Schmidt permet une conversion aisée des composés carbonylés en alcools et doubles liaisons éthyléniques dans des conditions, en général, très douces (1). Cette caractéristique est particulièrement intéressante dans le cas de certains aldéhydes issus de la biomasse, à cause de l'instabilité et du craactère polyfonctionnel de ces dérivés. C'est le cas du 2,5-furanedicarboxaldéhyde (FDC), synthétisé directement à partir du D-fructose (2). Celui-ci, grâce à la combinaison de deux fonctions aldéhyde sur un cycle furanique, apparaît comme un intermédiaire très important pour la synthèse d'un grand nombre de dérivés furaniques bifonctionnalisés en positions 2 et 5, qui trouvent des applications dans des domaines aussi variés que la pharmacie ou les macromolécules (3). Par ailleurs, la possibilité de fonctionnalisation non symétrique de cette molécule (fonctionnalisation sélective d'une seule fonction aldéhyde) élargit encore les possibilités de synthèse (4).

Pour notre part, nous avons étudié la réaction de condensation de Claisen–Schmidt du FDC avec plusieurs cétones aromatiques et hétéroaromatiques (5), en milieu basique, conduisant à des dérivés symétriques ou dissymétriques, selon les conditions de réaction mises en oeuvre :



a, R = C_6H_4; *b*, R = *p*-MeO-C_6H_4; *c*, R = *p*-NO_2-C_6H_4; *d*, R = 2-thienyl; *e*, R = 2-furyl

SCHÉMA 1

Les résultats obtenus lors des essais préliminaires ont permis d'envisager l'influence de cinq facteurs sur l'orientation de la réaction : A, rapport molaire FDC/cétone; B, concentration de NaOH dans le milieu réctionnel: C, concentration du FDC dans le milieu réactionnel; D, rapport $EtOH/H_2O$ (solvant); E, température.

L'objectif de ce travail est d'étudier l'influence des différents facteurs sur la réaction du FDC avec la furylméthylcétone (FMC) afin de déterminer les conditions d'obtention de chacun des produits **1***e*, **2***e* et **3***e* avec le meilleur rendement et la plus haute sélectivité. Le choix de la furylméthylcétone (FMC) (5) se justifie par l'intérêt des

dérivés obtenus en tant que molécules à activité biologique et comme intermédiaires de synthèse furaniques.

Partie expérimentale

Les points de fusion ont été mesurés à l'aide d'un appareil Büchi-510 et ils ne sont pas corrigés. Les spectres infra-rouges ont été réalisés sur un spectrophotomètre Perkin–Elmer 298. Les spectres RMN du ^1H ont été enregistrés au moyen d'un appareil Varian T60 A à 60 MHz avec le tétraméthylsilane comme référence interne. Les spectres RMN du ^{13}C ont été réalisés sur un appareil Varian FT 80A.

Le FDC a été synthétisé selon un procédé original mis au point au laboratoire (2).

Synthèse des produits **1***e*, **2***e et* **3***e*

Dans un ballon de 25 mL muni d'une agitation magnétique, et thermostaté à 0°C, on dissout le FDC (250 mg, 2 mmol) dans l'éthanol (8 mL), on ajoute la furylméthylcétone (220 mg, 2 mmol) et une solution de NaOH à 10% (0.5 mL). Après 1 h de réaction à 0°C, on neutralise avec une solution de H_2SO_4 à 10%. Le milieu réactionnel est ensuite extrait trois fois avec du chlorure de méthylène. Après évaporation des solvants organiques, on sépare les différents constituants par chromatographie sur colonne de silicagel 60 (Merck) comme phase stationnaire et un mélange acétate d'éthyle/hexane (1 : 2) comme éluant.

5-[2-(2-Furoyl)-1-hydroxyéthyl]-2-furanecarboxaldéhyde **1***e* : IR(CCl_4). ν : 3400, 1690 cm^{-1}. RMN du ^1H ($CDCl_3$)[1]. δ : 9.51 (s, 1H, CHO), 7.52(d, 1H, J = 2.0 Hz H12), 7.12–7.10(m, 2H, H3, H10), 6.54–6.41(m, 2H, H4, H11), 5.32(t, 1H, J = 5.9 Hz, H6), 3.42(d, 2H, J = 5.9 Hz, H7) ppm.

(E)-5-(2-Furoylvinyl)-2furanecarboxaldehyde **2**e : P_f : 140–142°C (AcOEt) IR(KBr), ν : 1690, 1660 cm^{-1}. RMN du $^1H(CDCl_3)$[2] δ : 9.90(s, 1H, CHO), 7.71(d, 1H, J = 1.9 Hz, H12), 7.62(s, 2H, H6, H7), 7.42(d, 1H, J = 4.1 Hz, H3), 7.31(d, 1H, J = 4.1 Hz, H10), 6.90(d, 1H, J = 4.1 Hz, H4), 6.70(dd, 1H, $J_{10,11}$ = 4.1 Hz, $J_{11,12}$ = 1.9 Hz, H11) ppm. Anal. calc. pour $C_{12}H_8O_4$: C 66.67, H 3.74; tr. : C 66.96, H 3.59.

(E, E)-2,5-Di-[2-(2-furoly)vinyl]furane **3**e : P_f : 170–171°C (EtOH) IR(KBr), ν : 1590, 1645 cm^{-1}. RMN du $^1H(CDCl_3)$, δ : 7.66(d, 2H, J = 2.2 Hz, H9), 7.56, 7.44(AB_q, 4H, J = 14.9 Hz, CH=CH−CO), 7.35(d, 2H, J = 3.5 Hz, H7), 6.78(s, 2H, H1), 6.59(dd, 2H, $J_{8,9}$ = 2.2 Hz, $J_{7,8}$ = 3.5 Hz, H8) ppm.

RMN du ^{13}C ($CDCl_3$), δ: 177.39(C5), 153.67(C6), 153.49(C2), 146.82(C9), 128.98(C4), 120.95(C3), 118.61(C1), 117.87(C7), 112.74(C8) ppm. Anal. calc. pour $C_{18}H_{12}O_5$: C 70.13, H 3.93; tr. : C 70.06, H 3.87.

Analyses quantitatives des milieux réactionnels

Le milieu réactionnel est dosé par chromatographie liquide haute performance (CLHP) dans les conditions suivantes :

Appareil : Perkin–Elmer series 2 avec détecteur UV (λ : 296 nm)
Colonne : LCD 24051 Milton Roy, Spherisorb 5CN (longueur : 25 cm, diamètre interne : 4.6 mm)
Eluant : Acétate de méthyle/hexane (2 : 3)
Débit d'éluant : 0.4 mL/min.

La courbe d'étalonnage est établie pour le FDC, la furylméthylcétone et les produits **1***e*, **2***e* et **3***e* grâce à la méthode de l'étalon interne. L'étalon choisi est le naphtaléne (1 g/L).

Protocole d'un essai type

L'ensemble des 16 essais du plan d'expériences ainsi que les dosages du milieu réctionnel ont été effectués selon le protocole opératoire général suivant : dans un ballon de 50 mL thermostaté et muni d'un agitateur magnétique, on dissout du FDC (200 mg, 1.61 mmol) dans la quantité correspondante de mélange $EtOH/H_2O$. La furylméthylcétone est ensuite ajoutée au milieu. La quantité choisie d'une solution de NaOH est ensuite ajoutée, goutte à goutte.

[2]Le système est numéroté arbitrairement, en considérant les dérivés **1***e* et **2***e* comme des chaines linéaires et en prenant comme carbone 1 le carbone du groupe aldéhyde.

TABLEAU 1. Domaine expérimental pour l'étude des l'influence des différents facteurs

Facteurs	Unité	Niveau inférieur (−)	Niveau supérieur (+)
A : FDC/FMC	—	1/1	1/4
B : [NaOH]	g/L	0.1	2.0
C : [FDC]	g/L	6.0	16.0
D : $EtOH/H_2O$	—	60/40	95/5
E : Température	°C	0	25

TABLEAU 2. Matrice d'expériences du plan factoriel 2^{5-1}

Essais (n°)[a]	A	B	C	D	E

[a]L'ordre des expériences a été tiré au hasard.

Apres 1 h de réction, le milieu est neutralisé avec une solution de H_2SO_4 à 10%. Un millilitre de cette solution est prélevé et mélangé avec 1 mL de solution d'étalon interne. Les différents produits du milieu sont dosés.

Résultats et discussion

La réalisation d'un plan factoriel fractionnaire à deux niveaux permet d'estimer les effets principaux et d'interactions de tous les facteurs étudiés avec la meilleure précision et une bonne efficacité (6–8). En ne retenant que les interactions entre facteurs pris deux à deux (interactions du premier ordre), un plan factoriel fractionnaire 2^{5-1} avec le générateur indépendant défini par la relation : E = ABCD (16 essais) permet de calculer tous les effets principaux et d'interactions de premier ordre.

Le domaine expérimental est défini par les niveaux inférieurs et supérieurs des différents facteurs adoptées dans les essais préliminaires (Tableau 1). Les réponses étudiées sont :

(*i*) rendement en produits **1***e*, **2***e* et **3***e*, défini par les rapports molaires :

$$R_1 = \mathbf{1}e \cdot 100/FDC_i; \qquad R_2 = \mathbf{2}e \cdot 100/FDC_i;$$

$$R_3 = \mathbf{3}e \cdot 100/FDC_i$$

1*e*, **2***e* et **3***e* représentent la quantité des produits **1***e*, **2***e* et **3***e* formée (mol) et FDC_i représente la quantité de FDC introduit (mol).

20	0	61	38	0	61	38	0
Moyenne	—	61.5	38.2	—	61.5	38.2	—
σ	—	2.64	2.63	—	2.64	2.63	—

[a]Conditions expérimentales : A = 1/2.5; B = 1.01 g/L; C = 10 g/L; D 76/24; E = 12°C.

(*ii*) Sélectivité en produits **1***e*, **2***e* et **3***e*, définie par les rapports molaires :

$$S_1 = \mathbf{1}e \cdot 100/\mathrm{FDC_c}; \qquad S_2 = \mathbf{2}e \cdot 100/\mathrm{FDC_c};$$

$$S_3 = \mathbf{3}e \cdot 100/\mathrm{FDC_c}$$

$\mathrm{FDC_c}$ représente la quantité de FDC consommée.

(*iii*) Perte en FDC, définie par la relation :

$$\mathrm{PE} = [\mathrm{FDC_c} - (\mathbf{1}e + \mathbf{2}e + \mathbf{3}e)/\mathrm{FDC_i}]$$

La matrice d'expériences du plan factoriel fractionnaire 2^{5-1} est rapportée dans le Tableau 2. Chaque ligne de la matrice définit un essai par la combinaison des niveaux de chacun des cinq facteurs. L'ensemble des conditions opératoires et des résultats expérimentaux correspondants sont rassemblés dans le Tableau 3. Le dosage des différents constituants des milieux réactionnels a été effectué par chromatographie liquide haute performance (CLHP). La signification des effets calculés par rapport à l'erreur expérimentale est obtenue à partir de l'étude de la répétabilité des résultats expérimentaux (Tableau 4). L'ensemble des calculs concernant les effets principaux et les effets d'interactions a été effectué à l'aide du programme «fraction» inclus dans l'ensemble de programmes NEMROD (9). Les valeurs des effets sont rassemblées dans le Tableau 5.

Dans le domaine expérimental considéré, l'analyse des effets significatifs par rapport à l'erreur expérimentale nous conduit à choisir la combinaison de niveaux A (+) B (−) C (−) D (+) E (+) ou E (−) afin d'obtenir le rendement maximum en produit **1***e*. La réalisation de l'essai correspondant à la combinaison A (−) B (−) C (−) D (+) E (+) nous a permis d'obtenir le produit **1***e* avec une sélectivité de 100% et un rendement de 41% après 9 h de réaction. Ceci confirme l'orientation choisie.

Egalement, l'analyse des effets permet de choisir la combinaison de niveaux A (−) B (+) C (−) D (−) E (+) comme la plus favorable pour obtenir le produit **2***e* avec le maximum de rendement et de sélectivité. La réalisation de l'essai correspondant à cette combinaison nous a permis d'obtenir le produit **2***e* avec 87% de rendement et 100% de sélectivité. Néanmoins, l'essai correspondant à la combinaison de niveaux la plus favorable pour l'obtention de **3***e*, A (+) B (+) C (+) D (−) E (−), permet de l'obtenir avec un rendement de 56%, mais une faible sélectivité (56%).

Ces orientations soulignent l'intérêt de la méthode des plans d'expériences pour l'étude de l'influence de plusieurs facteurs sur les conditions d'une réaction. En effet, en première approche, la conversion de **1***e* en **2***e* qui est une réaction de déshydratation devrait être favorisée par une augmentation de la concentration en soude [B(+)] du rapport $\mathrm{EtO/H_2O}$ [D(+)] et de la température [E(+)]. Or l'analyse des effets principaux et d'interaction montre que la formation de **2***e* est favorisée par la combinaison B(+) D(−) E(+), c'est-à-dire effectivement par une augmentation de la concentration en soude et de la température mais à l'inverse par une diminution du rapport $\mathrm{EtOH/H_2O}$, et donc une augmentation de la quantité d'eau. Ce résultat met en évidence le rôle de stabilisation du produit **1***e* joué par l'éthanol. Ceci pourrait étayer l'hypothèse d'une liaison hydrogène intra-moléculaire dans l'aldol. La présence d'une plus grande proportion d'eau défavoriserait cette liaison, augmentant ainsi la réactivité de l'aldol.

Conclusion

L'influence des cinq facteurs sur les sept réponses ont été évalués grâce à la réalisation d'un plan factoriel fraction-

[a]Les valeurs soulignées sont les valeurs significatives par rapport à l'erreur expérimentale. Chaque effet est calculé en effectuant la moyenne arithmetique des 16 résultats, affectés du signe correspondant au facteur ou à l'interaction entre facteur. Par exemple :

Niveau de A : − + − + − + − + − + − + − + − +
Niveau de B : − − + + − − + + − − + + − − + +
Niveau de AB : + − − + + − − + + − − + + − − +
Résultats : $Y_1\ Y_2\ Y_3\ Y_4\ Y_5\ Y_6\ Y_7\ Y_8\ Y_9\ Y_{10}\ Y_{11}\ Y_{12}\ Y_{13}\ Y_{14}\ Y_{15}\ Y_{16}$

$$\text{Effet de A} = \frac{1}{16}[-Y_1 + Y_2 - Y_3 + Y_4 - Y_5 + Y_6 - Y_7 + Y_8 - Y_9 + Y_{10} - Y_{11} + Y_{12} - Y_{13} + Y_{14} - Y_{15} + Y_{16}]$$

$$\text{Effet de AB} = \frac{1}{16}[+Y_1 - Y_2 - Y_3 + Y_4 + Y_5 - Y_6 - Y_7 + Y_8 + Y_9 - Y_{10} - Y_{11} + Y_{12} + Y_{13} - Y_{14} - Y_{15} + Y_{16}]$$

naire 2^{5-1} en seulement 16 essais, ceci constitue un avantage sur la méthode traditionnelle «facteur pour facteur». Grâce à cette approche, on a pu orienter le choix des conditions expérimentales vers la direction la plus favorable pour l'obtention des produits **1***e* et **2***e* avec de bons rendements et une sélectivité totale. Dans le cas du produit **3***e*, le rendement et la sélectivité sont moyennes. Cette étude ouvre de nouvelles perspectives pour le développement de cette réaction à plus grande échelle du fait de la simplicité du protocole opératoire.

Influence of temperature on the liquid-to-liquid extraction of ethanol from (water + ethanol + 1,2-dichloroethane)

HORACIO N. SÓLIMO[1] AND JOSÉ L. ZURITA

Instituto de Fisica, Facultad de Ciencias Exactas y Tecnologia, Universidad Nacional de Tucumán, Avda. Independencia 1800, 4000 San Miguel de Tucuman, Argentina

Received November 19, 1991

HORACIO N. SÓLIMO and JOSÉ L. ZURITA. Can. J. Chem. **70**, 2310 (1992).

To evaluate the influence of temperature on the extraction of ethanol from aqueous solutions with 1,2-dichloroethane, liquid–liquid equilibrium data for the system water + ethanol + 1,2-dichloroethane were obtained at 298.15, 308.15, and 318.15 K. The binodal curves were determined by the cloud-point method, and conjugate points on the tie-lines were obtained by correlating the refractive index of these curves as a function of composition. The tie-line data at each temperature were satisfactorily correlated using the method of Othmer and Tobias, and the plait-point coordinates were estimated. The experimental data were also compared to values calculated by the UNIFAC group contribution method for the activity coefficients using the isoactivity conditions as restraint equations, and with the NRTL and UNIQUAC models. The UNIFAC method proved to be more accurate than the NRTL and UNIQUAC equations fitted to the experimental data. Under the experimental conditions used, ethanol extraction by 1,2-dichloroethane appears to be independent of the temperature.

HORACIO N. SÓLIMO et JOSÉ L. ZURITA. Can. J. Chem. **70**, 2310 (1992).

Dans le but d'évaluer l'influence de la température sur l'extraction d'éthanol des mélanges aqueux, les données d'équilibre liquide–liquide pour le systeme eau + éthanol + 1,2-dichloroéthane ont été determinés operant à des températures de 298,15, 308,15 et 318,15 K. On a determiné les données des courbes binodales à l'aide de la méthode du point de rosée et on a obtenu les points conjugués de la ligne de jonction pour chacune des températures. Faisant appel à la méthode d'Othmer et de Tobias on a pu établir une bonne corrélation entre les données relatives aux lignes de jonction pour chacune des températures et on a evalué les coordonnées des points plissement. Les données expérimentales ont été comparées avec les valeurs calculées par la méthode de contribution du groupe UNIFAC, et par les modèles NRTL et UNIQUAC, en utilisant les conditions d'isoactivité comme équations limites. Le modèle UNIFAC montre un meilleur accord avec les valeurs expérimentales que les modèles NRTL et UNIQUAC. Nos résultats expérimentaux montrent que l'extraction de l'éthanol avec le 1,2-dichloroéthane ne dépend pas de la température.

Introduction

In recent years, liquid–liquid equilibria (LLE) studies have become increasingly important in chemical technology. The rising cost of energy has made new separation processes based on extraction more attractive than before. Liquid–liquid extraction provides an important alternative to distillation for the recovery of ethanol from dilute aqueous solutions using a nonmiscible solvent.

The aim of this work was to evaluate the potential of 1,2-dichloroethane (DE) for the recovery of ethanol from aqueous solutions. We report the experimental results of LLE studies of ternary mixtures water + ethanol + DE at 298.15, 308.15, and 318.15 K. Several tie-lines were determined for each temperature and the correlation of mutual solubility with tie-line data (Othmer and Tobias' method) permitted the estimation of the plait-point coordinates.

The results were also used to test the validity of the NRTL and UNIQUAC equations and the UNIFAC group contribution method.

Experimental

Anhydrous ethanol (Merck, reagent grade) was dried with magnesium activated with iodine under reflux. The product was then fractionally distilled and the middle fraction collected. The last traces of water were removed by circulating the ethanol through a glass column (0.03 × 2 m) packed with 0.3-nm molecular sieves.

1,2-Dichloroethane (Fisher Scientific Co., certified) was used without further purification.

Water was bidistilled in an all-glass apparatus.

All purified organic chemicals were stored over activated molecular sieves to prevent water absorption.

The binodal curves were determined by the cloud-point method (1), as described earlier (2), in a cell equipped with a magnetic stirrer and a jacket for circulating the isothermal water at the desired temperatures (±0.05 K). Compositions at the ends of the tie-lines were determined in the same cell. Mixtures with compositions within the heterogeneous region were shaken vigorously for at least 2 h at constant temperature for the tie-line determinations, and allowed to settle for 3 h. The compositions of samples taken from both layers were determined by measuring their refractive indices at each temperature with a Jena Abbé refractometer with an accuracy of ±0.0001.

Results and discussion

Figure 1 shows the LLE diagram at 298.15 K for the water + ethanol + DE system. LLE data predicted by the UNIFAC method are also shown. The smoothing curves connecting the experimental data points are hand-drawn, since no attempt to fit the data by an empirical equation was made. Similar plots were obtained for the other two temperatures.[2]

The tie-line data at all the temperatures are satisfactorily correlated by the method of Othmer and Tobias (3). An empirical equation:

$$[1] \quad \log[(1 - W_{11})/W_{11}] = m \log[(1 - W_{33})/W_{33}] + b$$

can represent all the tie-line data with adequate precision.

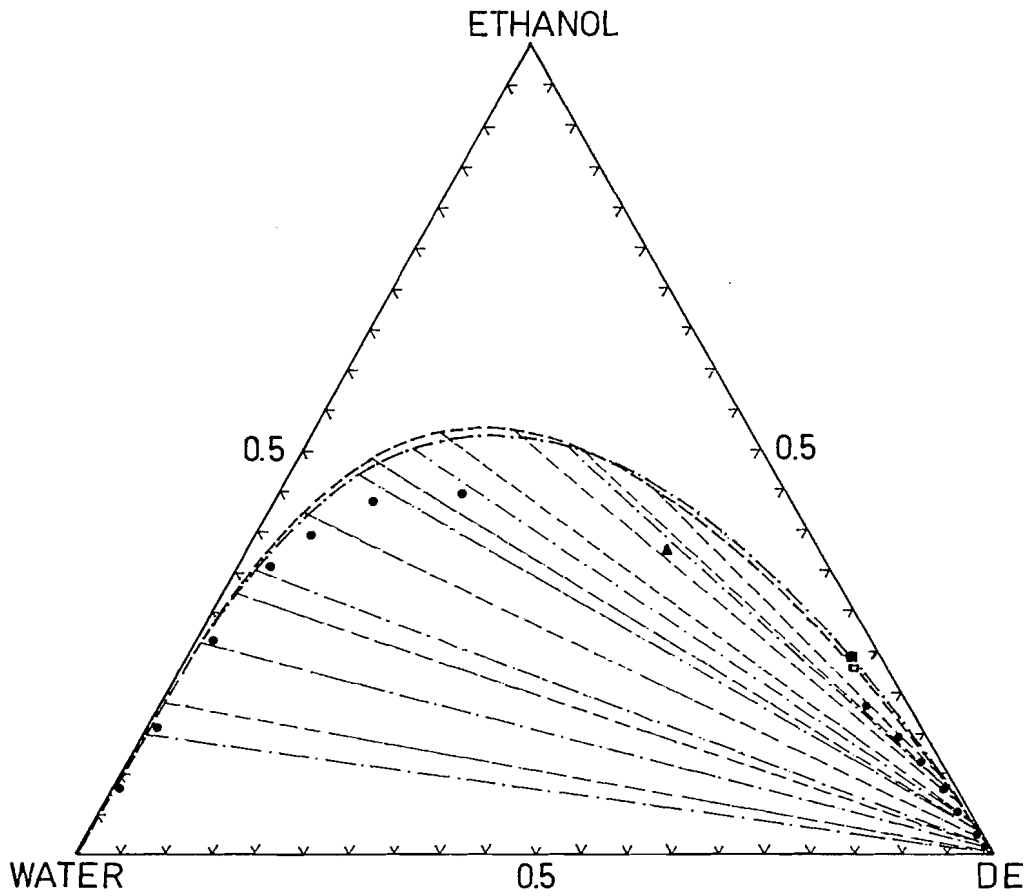

FIG. 3. Binodal curves and tie-lines calculated for the system water(1) + ethanol(2) + DE(3) at 298.15 K using the equations (----, NRTL and (–·–·–) UNIQUAC, together with the corresponding experimental compositions for tie-lines (●). ▲, Experimental PP; ■, UNIQUAC PP; □, NRTL PP.

As shown in Table 1, the ethanol distribution coefficients D_c (defined as the ratio of the ethanol concentration (wt.%) in the organic phase to that in the aqueous phase) are not constant, and have a tendency to increase as the ethanol concentration is increased. A similar conclusion can be derived from the distribution coefficient for water D_w (defined as the equilibrium water content in the solvent phase). The ratio of the ethanol distribution coefficient to the water distribution coefficient yields the separation factor S_w^{EtOH} shown in Table 1. As can be seen, the extraction properties of DE for ethanol do not depend on the temperature, except for the lowest ethanol concentration range.

Zane Egan *et al.* (4) conclude that solvents with experimental distribution coefficients for ethanol greater than 0.15, and a separation factor greater than 10, are potential candidates for extraction processes. These properties are largely exceeded by DE, making it a useful alternative for ethanol extraction. However, at the three temperatures considered, the aqueous layer is richer in ethanol than the organic layer (see Fig. 1). As expected, the size of the two-phase region decreases with an increase in temperature.

Figure 2 shows a selectivity (S) diagram (5) for the three temperatures, considering ethanol as the distributed substance. It shows that the selectivity at 318.15 K is greater than at the other temperatures in the range $0 \leq W_{23} \leq 0.05$, but has approximately the same value for $0.05 \leq W_{23} \leq 0.15$ at all temperatures. This last range of concentration is the most important region for ethanol extraction from fermentation broth. Therefore, ethanol extraction could be carried out at room temperature, thus saving energy while preserving a fairly important heterogeneous zone.

Thermodynamic models, such as the NRTL (6) and UNIQUAC (7), were used to estimate the LLE for this system, with the help of an iterative computer program developed by Sørensen (8). To minimize the values of the two objective functions in terms of activity and molar fractions, a penalty term, designed to reduce the risk of multiple solutions associated with high parameter values, was included. Figure 3 shows the LLE predictions using these models.

The structural parameters of water and ethanol necessary for the UNIQUAC equation were obtained from Anderson and Prausnitz (9). For DE they were calculated from UNIFAC parameters (10).

The nonrandomness of the liquid mixture, which is represented by the third parameter in the NRTL equation (α_{ij}), was set at a value of 0.2 in the present study.

The UNIFAC group contribution method (10) was employed by using the group interaction parameters obtained by Magnussen *et al.* (11).

As can be seen from Figs. 1 and 3, the UNIFAC method is more accurate than both the NRTL and the UNIQUAC equations fitted to the experimental data for this system because the calculated residuals are smaller.

meso-Tetra(2,6-dichloro-3-sulfonatophenyl)porphyrin iron chloride catalyzes the oxidation of 3,4-dimethoxybenzyl alcohol (veratryl alcohol) in aqueous solution to give veratraldehyde along with demethoxylation and ring-cleavage products. The isolation of a direct ring-cleavage product from the oxidation of veratryl acetate in aqueous solution supports the previously proposed ring-cleavage mechanisms. The oxidation in methanol, however, does not lead to ring-cleavage products. When veratryl alcohol was oxidized in methanol, solvent was found to be incorporated into the 3-position of veratryl alcohol, giving new insight into the mechanism of oxidation.

FUTONG CUI et DAVID DOLPHIN. Can. J. Chem. **70**, 2314 (1992).

Le chlorure du *méso*-tétra(2,6-dichloro-3-sulfonatophényl)porphyrine fer catalyse l'oxydation de l'alcool 3,4-diméthoxybenzylique (alcool vératrylique), en solution aqueuse, qui conduit à la formation de vératraldéhyde et des produits de déméthoxylation et de clivage de cycle. Le fait que l'on a pu isoler un produit de clivage direct du cycle au cours de l'oxydation de l'acétate de vératryle, en solution aqueuse, supportent les mécanismes proposés antérieurement pour le clivage de cycle. Toutefois, l'oxydation dans le méthanol ne conduit pas à des produits de clivage de cycle. Lorsqu'on oxyde l'alcool vératrylique dans le méthanol, on a trouvé que le solvant s'incorpore en position 3 de l'alcool; ce résultat jette de la lumière sur le mécanisme de l'oxydation.

Introduction

Lignin is a three-dimensional, irregular, aromatic biopolymer occurring widely in vascular plants. It is the second most abundant organic compound on Earth and comprises about 15–25% of the land-produced biomass. The biodegradation of this highly resistant polymer has interested researchers in many disciplines. Since the first discovery of lignin-degrading enzymes from the white-rot fungus *Phanerochaete chrysosporium Burds* in 1983 (1, 2), rapid progress has been made in understanding the mechanism of lignin biodegradation. The lignin-degrading enzymes, the lignin peroxidases (1–7) (ligninases) and the manganese-dependent peroxidases (3, 5, 8–10), are all hemeproteins and contain one heme (iron protoporphyrin IX) per molecule. Lignin peroxidase when oxidized by a two-electron oxidant (hydrogen peroxide) subsequently oxidizes lignin model compounds by two one-electron transfer processes (11, 12). The manganese-dependent peroxidase requires a Mn(II) cofactor to accomplish a similar cycle (13). One of the unique properties of the lignin-degrading enzymes is their low substrate specificity; substrates varying from polymeric lignin to oligomeric, dimeric, and monomeric lignin model compounds, to polycyclic aromatic hydrocarbons (14) and polychlorinated phenols have been shown to be oxidized (15). It is unlikely that a lignin peroxidase could have an active site to bind this great diversity of substrates. It is assumed, therefore, that the function of the protein of the lignin-degrading enzymes is to protect the highly reactive intermediates of the prosthetic group, the protohemin iron (IV) cation radical (12) and thus simple iron porphyrins could be good models for the enzymes. As both lignin and lignin-degrading enzymes are large molecules, a simple biomimetic porphyrin might be advantageous in degrading lignin in that the interaction of lignin and a small molecular reactant, such as a porphyrin, could be much easier than that between lignin and a large enzymic molecule.

Commercially available iron porphyrins have been used as lignin peroxidase models by Shimada and coworkers (16–19). These porphyrins, however, suffer two major disadvantages. The porphyrins are very unstable and a catalyst to substrate ratio of 1:10 had to be used. In addition, the reactions have to be carried out in organic solvents, conditions quite different from that of the enzymatic reactions. Furthermore, these porphyrins do not closely mimic the enzyme in every case (18). A number of sterically protected, water-soluble porphyrins have been synthesized and used as lignin peroxidase models in our laboratory (20, 21). We report here on the oxidation of veratryl alcohol and veratryl acetate by *meso*-tetra (2,6-dichloro-3-sulfonatophenyl) porphyrin iron chloride (TDCSPPFeCl, **1**) using *m*-chloroperbenzoic acid (*m*CPBA) as oxidant in both aqueous and organic solvents.

Results

Oxidation of veratryl alcohol in methanol

When veratryl alcohol was oxidized by TDCSPPFeCl and *m*CPBA in methanol, vetraldehyde, 2-hydroxymethyl-5-methoxy-2,5-cyclohexadien-1,4-dione (**7**), 4,5-dimethoxy-3,5-cyclohexadien-1,2-dione (**8**), 2-hydroxymethyl-4,4,5-trimethoxy-2,5-cyclohexadien-1-one (**13**), and 2-dimethoxymethyl-4,4,5-trimethoxy-2,5-cyclohexadien-1-one (**14**) were found as products. The yields of the products were found to be dependent on the reaction condition. When the reaction was carried out open to the air with moderate stirring, veratraldehyde and **13** were produced in 49 and 42% yield, respectively, and compound **14** was not isolated. Under highly aerobic condition (open to the air, vigorous stirring), the yields of veratraldehyde, **13**, and **14** were 51, 11, and 32%, respectively; compounds **7** and **8** were produced in very small amounts. Under anaerobic condition, compound **14** was found in trace amounts.

When the reaction was carried out in ethanol (containing a small amount of DMF to increase the solubility of TDCSPPFeCl), **16** was obtained in addition to other prod-

ucts. Treatment of **13** with tetrahydrofuran (THF)/water/concentrated HCl (1:1:0.1) at room temperature for 2 min gave **7** as the sole product. When 4-ethoxy-3-methoxybenzyl alcohol was used as the substrate instead of veratryl alcohol, **15** was the product corresponding to **13**.

Oxidation of veratryl acetate in methanol

In addition to small amounts of veratraldehyde, veratryl acetate, and **10**, oxidation of veratryl acetate with TDCSPPFeCl and *m*CPBA in air gave **17** as the major product (82%). Under anaerobic condition, **17** was also found as a product.

Oxidation of veratryl alcohol in pH 3 phosphate buffer

Oxidation of veratryl alcohol in aqueous solution gave veratraldehyde as the major product (>80%) along with small amounts of **2**, **4**, **5**, and **7**. When 4-ethoxy-3-methoxybenzyl alcohol was used as the substrate, **4** and **5** were also isolated.

Oxidation of veratryl acetate in pH 3 buffer

Although not soluble in aqueous solution, veratryl acetate was successfully oxidized by TDCSPPFeCl and *m*CPBA to give **10**, 3,4-dimethoxyphenol (**11**), and the aromatic ring cleaved product **12**.

Discussion

Veratryl alcohol, a secondary metabolite (22, 23) of lignin degradation by *Phanerochaete chrysosporium*, plays a unique role in lignin biodegradation (24). It has been reported to be able to stimulate lignin degradation (25, 26) and benzo (*a*) pyrene oxidation (27) by lignin peroxidase. It was found later that veratryl alcohol could induce the biosynthesis of lignin peroxidase (28) and protect the enzyme from deactivation by excess oxidant (29–31). In addition, veratryl alcohol has been widely used as a simple lignin model compound. As a secondary metabolite and also a substrate of lignin peroxidase, veratryl alcohol is readily oxidized to veratraldehyde, which in turn is also readily reduced back to veratryl alcohol and accumulates in the ligninolytic culture of *P. chrysosporium* (23). This cyclic redox process, unlike metabolism to carbon dioxide, is energetically wasteful and results in oxidizing power being expended on veratryl alcohol instead of lignin. Leisola and co-workers (32) recently reported that veratryl alcohol was rapidly metabolized to carbon dioxide in carbon-limited cultures of *P. chrysosporium*, compared with the slow and incomplete degradation in nitrogen-limited culture. They also showed that veratraldehyde, the major oxidation product of veratryl alcohol by lignin peroxidase, cannot be metabolized directly by the fungus. It is reduced back quantitatively to

veratryl alcohol by the fungus and then degraded via quinones and ring-cleavage products.

Leisola *et al.* (33) first found aromatic ring-cleavage products, two δ-lactones, of veratryl alcohol in 1985. These reactions have been extensively studied and since then additional products have been isolated and their mechanism of formation proposed (32, 34, 35–38). It now seems clear that an initial one-electron oxidation of veratryl alcohol gives a cation radical; reaction with water then gives a carbon-centered radical. Coupling of the radical with molecular oxygen leads to aromatic ring cleavage, whereas further one-electron oxidation of the radical followed by reaction with water leads to demethoxylation products, i.e., quinones.

Oxidation of veratryl alcohol by TDCSPPFeCl and *m*CPBA at room temperature in air using aqueous pH 3 buffer as solvent gave veratraldehyde as the major product along with small amounts of **2**, **4**, **5**, and **7**. The δ-lactone structure of **4** and **5** was confirmed, in addition to NMR and MS data, by the fact that **4** and **5** were formed when 4-ethoxy-3-methoxybenzyl alcohol was oxidized under the same conditions. Compounds **4** and **5** are δ-lactones, since the ethoxy group was lost during their formation from 4-ethoxy-3-methoxybenzyl alcohol. Compounds **3** and **8**, found in the oxidation of veratryl alcohol by lignin peroxidase and hydrogen peroxide, were not found in our experiments using aqueous buffer as solvent. However, compound **8** was found as a product when using methanol as solvent under otherwise the same conditions.

When veratryl acetate was oxidized in aqueous buffer, **10** (the acetate derivative of **7**), 3,4-dimethoxyphenol, and a direct ring-cleavage product (**12**) were isolated. Quinones **6** and **8** have been previously found as phenyl–alkyl cleavage products of veratryl alcohol (32, 35, 38). To our knowledge, this is the first time a phenol (**11**) has been found as a side-chain cleavage product of a veratryl alcohol derivative. The isolation of the direct ring–cleavage product **12** supports the ring-cleavage mechanism previously proposed (35–38). We learned while preparing this manuscript that Schmidt *et al.* (34) used veratryl alcohol methyl ether as a substrate and found a similar product (**9**). Schmidt *et al.* (34) found veratraldehyde was the major product of the oxidation of veratryl alcohol methyl ether. In the oxidation of veratryl acetate by TDCSPPFeCl and *m*CPBA, however, veratraldehyde was only a minor product and **10** and **12** were the major products. The cleavage of a C_α-ether bond through C_α oxidation has been demonstrated (34, 39). The isolation of veratraldehyde from the oxidation of veratryl acetate, though in low yield, suggests that the C_α-ester bond can also be cleaved in a similar way.

Shimada *et al.* (18) studied the degradation of β-1, β-O-4, and β-5 dimeric lignin model compounds by protohemin (iron protoporphyrin IX chloride) and *t*-BuOOH in chloroform. Though β-1 and β-5 model compounds were oxidatively degraded, the oxidation of the β-O-4 model compound, 4-ethoxy-3-methoxyphenylglycerol-β-guaiacyl ether, did not give the same products as that of the lignin peroxidase catalyzed reaction. The same β-O-4 dimer, however, was oxidatively cleaved by TDCSPPFeCl and *m*CPBA in aqueous solution in the same manner as the ligninase-catalyzed reaction (21). Dordick *et al.* (40) reported that both natural and synthetic lignin were vigorously depolymerized by horseradish peroxidase and other peroxidases in organic solvents but not in water. Their results, however, were later questioned (41).

As TDCSPPFeCl is soluble in both water and polar organic solvents, we have studied solvent effects on the oxidation of veratryl alcohol and veratryl acetate. In addition to veratraldehyde, **7**, and **8**, the solvent-incorporated products **13** and **14** were isolated when veratryl alcohol was oxidized in methanol. A mechanism for the formation of **13** is proposed in Fig. 1. When veratryl acetate was the substrate, compound **10** and veratraldehyde were found as minor products with **17** as the major product. It is interesting to note that when veratryl alcohol was oxidized in ethanol, **16** was isolated and the 3-methoxy group of **16** did not exchange with solvent under the reaction conditions. Another interesting observation was that no ring-cleavage product was found in the reaction using methanol as solvent.

Compound **13**, formed in methanol, is the analog of **7** formed in aqueous solution; however, the analog of **14**, 2-formyl-5-methoxy-2,5-cyclohexedine-1-one (**20**), was not found during the oxidation of veratryl alcohol in aqueous solution.

Shimada *et al.* (35) proposed two possible pathways for aromatic ring-cleavage of veratryl alcohol and suggested that the pathway in which water specifically attacks the C_3 position of the substrate cation radical is more plausible. Although no ring-cleavage products were found when either veratryl alcohol or veratryl acetate was oxidized in methanol, the specific incorporation of methanol into the 3-position to give **13** and **14** clearly supports Shimada's earlier suggestion.

In conclusion, TDCSPPFeCl/*m*CPBA closely mimics the enzymic lignin peroxidase/hydrogen peroxide system in the oxidation of veratryl alcohol in aqueous solution. The isolation of a direct ring-cleavage product of veratryl acetate supports the previously proposed mechanism for ring cleavage. The results of the oxidation of veratryl alcohol and veratryl acetate in aqueous buffer and in methanol clearly demonstrated solvent effects on lignin model compound oxidations.

Experimental

NMR spectra were recorded on Varian XL 300 or Bruker WH 400 spectrometers using tetramethylsilane as internal standard. Low-resolution and high-resolution mass spectra were recorded on an AE1 MS 9 and Cratos MS 50 spectrometers. Preparative thin-layer chromatography (TLC) was carried out on a Model 7924T Chromatotron (Harrison Research) using Silica Gel 60 PF_{254} as absorbent. Merck pre-coated Silica Gel 60 PF_{254} (0.2 mm) was used for analytical purposes. Veratryl alcohol and veratraldehyde were purchased from Aldrich. Veratryl acetate was prepared by acetylation of veratryl alcohol with excess 1:1 acetic anhydride/pyridine at room temperature for 24 h. 4-Ethoxy-3-methoxybenzyl alcohol was prepared as previously reported (42).

Oxidation of veratryl alcohol and veratryl acetate

Substrate (0.3 mmol) and TDCSPPFeCl (0.5 μmol in 0.5 mL water) were dissolved in either pH 3 aqueous buffer or methanol (20 mL) and *m*CPBA (0.6 mmol) was added as a powder and the solution stirred at room temperature for 2 h. The solution was partitioned between saturated sodium bicarbonate (20 mL) and ethyl acetate (20 mL). The aqueous layer was further extracted twice with ethyl acetate (10 mL). The organic extracts were combined and dried over sodium sulphate, evaporated and separated on a Chromatotron using either methanol/methylene chloride (0–1% methanol) or ethyl acetate/hexane (10–30% ethyl acetate) as eluent. When veratryl alcohol was the substrate, the residue was acety-

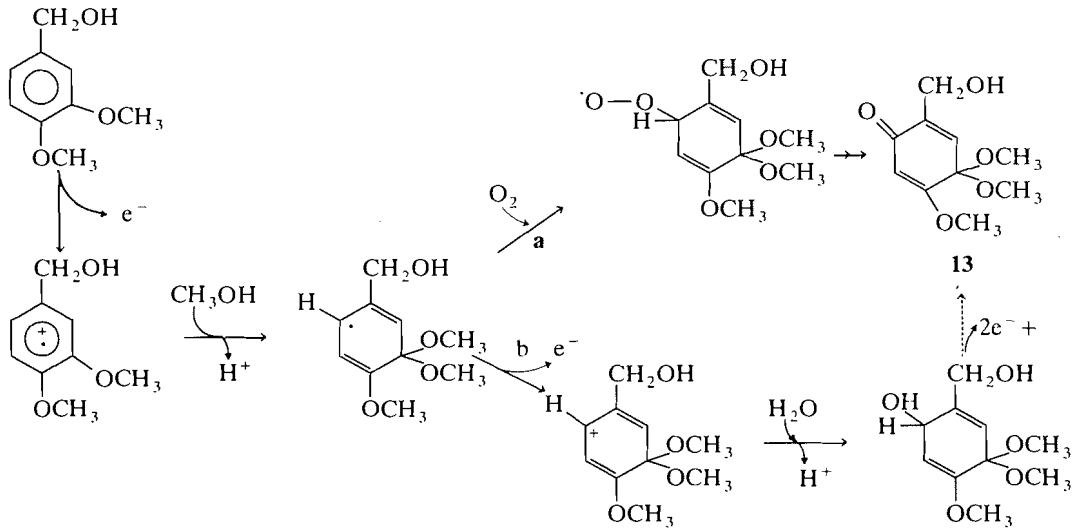

FIG. 1. Possible mechanism for the formation of the methanol-incorporated product **13**.

lated with excess 1:1 acetic anhydride/pyridine at room temperature for 24 h before separation. The purity of each component was checked by analytical TLC using methanol/methylene chloride (1:99) and hexane/ethyl acetate (1:4) as solvents. Impure components were further separated on the Chromatotron. The yields were based on the substrates and estimated by GC.

All the products were characterized by MS and ^{1}H NMR and compared with those reported in the literature. The structure of **12** was confirmed by comparing its NMR spectrum with that of **9**. Compound **13** was characterized by MS, ^{1}H NMR, ^{13}C NMR, and elemental analysis. The structure of **14** was elucidated by comparing its MS and ^{1}H NMR with that of **13**.

Received July 24, 1991

BOUBKER NASSER, CLAUDE MORPAIN, BERNARD LAUDE, and NORBERT LATRUFFE. Can. J. Chem. **70**, 2319 (1992).

Precursors of phospholipids or ether lipids were synthesized from D-mannitol, i.e., 1-*O*-myristoyl-2-*O*-benzyl-*sn*-glycerol **11** and 1-*O*-hexadecyl-2-*O*-benzyl-*sn*-glycerol **13**. The chemical pathways involved sequential protection reactions using allyl, triphenylmethyl, or benzyl groups via 3-*O*-allyl-*sn*-glycerol. Eleven intermediates were isolated and for the first time characterized with their spectrometric (especially ^{1}H nmr) and physical parameters and yield. This work allowed preparation of chemically defined membrane phospholipids from compound **11** as well as ether lipids from compound **13** with cell mediator activities bearing different probes such as photoactivatable, fluorescent, or radioactive groups.

BOUBKER NASSER, CLAUDE MORPAIN, BERNARD LAUDE et NORBERT LATRUFFE. Can. J. Chem. **70**, 2319 (1992).

Divers précurseurs de phospholipides et d'éthers lipidiques, comme le 1-*O*-myristoyl-2-*O*-benzyl-*ns*-glycerol **11** et le 1-*O*-hexadecyl-2-*O*-benzyl-*ns*-glycerol **13**, ont été synthétisés à partir de D-mannitol. Cette méthode implique une séquence de réactions de protections à l'aide des groupes allyle, triphénylméthyle ou benzyle via le 3-*O*-allyl-*ns*-glycérol. Onze intermédiaires ont été isolés et pour la première fois leurs paramètres spectroscopiques (^{1}H rmn) et physiques ont été précisés. Ce travail permet d'accéder à partir du composé **11** à des phospholipides membranaires chimiquement définis ou à partir du compose **13** à des éthers lipidiques médiateurs cellulaires porteurs de diverses sondes (photoactivable, fluorescente ou radioactive).

Introduction

Lipids, especially phospholipids and derivatives, have numerous and essential functions in cell life. For instance, biomembranes are involved in transport, transduction signalling, or enzyme activation through lipid–protein and lipid–lipid interactions. On the other hand, some lipids can exhibit mediator functions such as ether-lipids including PAF acether (1, 2).

Since natural phospholipids are largely heterogenous and generally weakly chemically reactive, advances in knowledge in these fields are largely beneficial to the use of synthetic phospholipids or analogues, chemically defined or eventually modified by the coupling of different probes (photoactivatable, fluorescent, or radioactive groups).

To have access to these tools it is absolutely essential to find the best synthetic pathway and to master all the chemical steps including intermediate isolation and characterization.

For instance, the understanding of the lipid function in the catalytic properties of mitochondrial membrane bound R-3-hydroxybutyrate dehydrogenase was greatly improved by the use of phospholipid analogues (3, 4).

In this paper we report the chemical synthesis that allows the preparation of phospholipid or ether lipid precursors. Indeed, the compound **11** (1-*O*-myristoyl-2-*O*-benzyl-*sn*-glycerol) is a key intermediary in the phospholipid (or analogue) preparation and compound **13** (1-*O*-hexadecyl-2-*O*-benzyl-*sn*-glycerol) leads to the preparation of ether phospholipids, such as PAF and analogues (5–7).

Whereas Eibl and Woolley (8) previously described a similar pathway, we put forward the characterization of all of the intermediary, including physicochemical and spectroscopic parameters, which has not been done before. The principle of this synthesis sequence is summarized in Scheme 1. Traditionally it involved the use of well-known protecting agents such as the *allyl* moiety, which can be easily transposed in a propenyl group that is then eliminated by bromine in buffer medium (8); the *triphenylmethyl* group, which only reacts with primary alcohols and is easily displaced with diluted acids; and *benzyl*, which is generally used to block the (C_2) of glycerol in the PAF acether synthesis (6, 7, 9).

To our knowledge compounds **6–12** have never been described. Compound **13** alone has previously been isolated by other procedures (5–7).

Phospholipids (or analogues) or ether lipids (i.e., PAF acether) can be prepared from compounds **11** and **13**, as has been described (6, 9, 10).

Experimental

Materials and methods

Dimethylformamide, dimethyl sulfoxide, allyl bromide, and benzyl chloride were purchased from Aldrich and distilled prior to use. Triethylamine and pyridine were dried over 4Å molecular

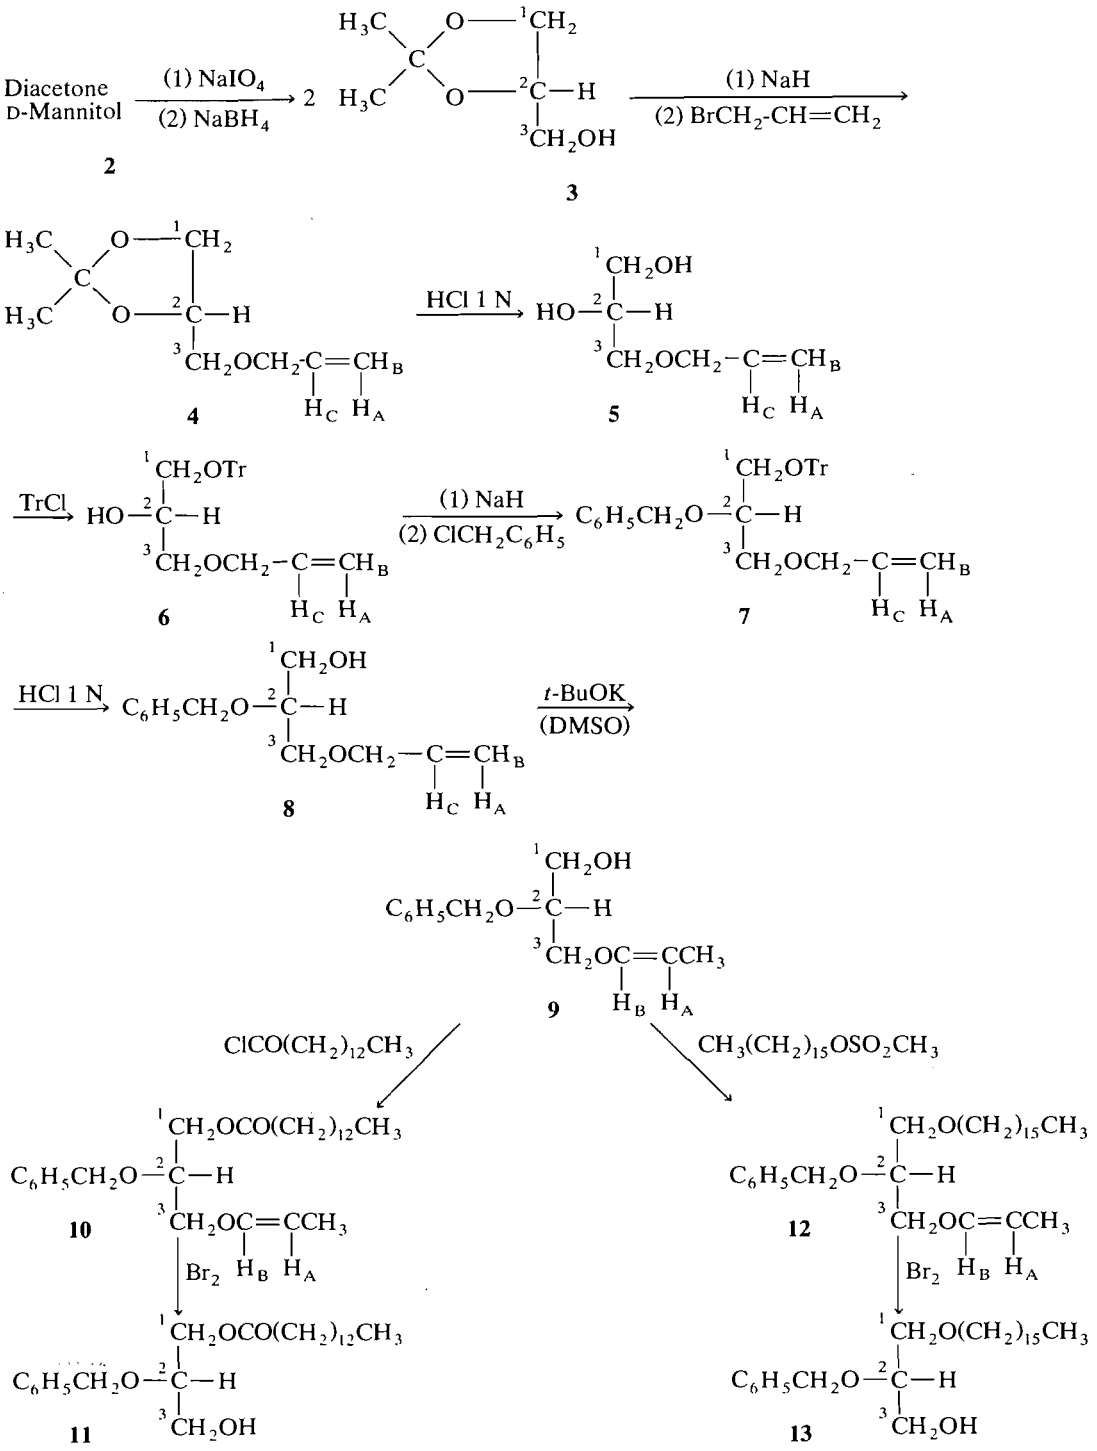

SCHEME 1. Reaction pathway for the synthesis of intermediates of acyl or alkyl phospholipids.

sieves (Merck). Hexadecylmethane sulfonate and hexadecanoyl chloride were prepared according to refs. 11 and 12 respectively. All solvents and reagents were of reagent grade and used as obtained. Thin-layer chromatography (tlc) was carried out by using silica gel (Merck, precoated sheets, 60 F 254). Compound spots in tlc were visualized under uv light or by iodine vapor. Column chromatography was carried out by using silica gel 60 (70–230 mesh, Merck). Melting points were measured with a Kofler hot-stage apparatus and uncorrected. Optical rotations were recorded by means of a Roussel-Jouan 71 micropolarimeter. The ^{1}H nmr spectra were measured on a Bruker Spectrospin AC 200 (200 MHz) using a solution in $CDCl_3$ with tetramethylsilane as internal standard. Infrared spectra were recorded on a Beckman I.R. 33.

Results

*1,2-O-Isopropylidene-*sn*-glycerol (3)*

Di-*O*-acetone-D-mannitol (**2**) (65.5 g, 0.25 mol) was suspended in 600 mL of water by stirring. The sodium metaperiodate (53.5 g, 0.25 mol) was slowly added in several fractions (45 min total time); the temperature had to remain below 30°C. The pH was maintained neutral (pH = 6–7) by

addition of sodium hydroxide pellets. Stirring was maintained for 1.5 h more at room temperature. Methanol (300 mL) was added to precipitate iodate. The mixture was left for 2 h at 20°C. The precipitate was separated, then washed with a solution (200 mL) of methanol–water (1:1). The solution was cooled in an ice-water bath. The sodium tetrahydridoborate (9.5 g, 0.25 mol) was added in portions by stirring. Stirring was continued for 1 h more at 15–20°C. The mixture was neutralized with 2 N hydrochloric acid to pH 7–8. Sodium chloride (200 g) was added. The organic phase was extracted with 250 mL of chloroform (3 times), then dried over sodium sulfate. After removal of solvent under vacuum, the resulting oil was distilled under vacuum: bp 84°C/15 Torr (1 Torr = 133.3 Pa); weight 46.2 g (70%); $[\alpha]_{589}$ +11.5, $[\alpha]_{578}$ +12.2, $[\alpha]_{546}$ +14.1, $[\alpha]_{436}$ +29.6 (*c* 0.024, methanol) (lit. (13)$[\alpha]_{589}$ +11.57, $[\alpha]_{578}$ +12.16, $[\alpha]_{546}$ +14.00, $[\alpha]_{436}$ +25.5° (methanol)).

1,2-O-Isopropylidene-3-O-allyl-sn-*glycerol* (**4**)

This was prepared according to ref 14: bp 85°C/14 Torr; yield 82%; $[\alpha]_{589}$ +16.2, $[\alpha]_{578}$ +16.9, $[\alpha]_{546}$ +19.7, $[\alpha]_{436}$ +33.7 (*c* 0.026, $CHCl_3$); ir: 3090, 1630 (-CH = CH_2), 1370, and 1385 cm^{-1} ($C(CH_3)_2$); ^1H nmr δ ppm: 1.40 (s, 3H, CH_3), 1.45 (s, 3H, CH_3), 3.40–3.60 (AB part of an ABX system located at 3.50 ppm with ^2J = 9.85 Hz; each transition was split with ^3J = 5.75 Hz, 2H, C^1H_2O or C^3H_2O), 3.72 (dd, $^2J_{AB}$ = 8.20 Hz, ^3J = 6.40 Hz, 1H of C^1H_2O or C^3H_2O), 4.0–4.10 (m, 3H, OCH_2-CH = CH_2 and 1H of C^1H_2O or C^3H_2O), 4.20–4.40 (tt, 1H, J = 5.75 Hz and J = 6.40 Hz, C^2HO), 5.20 (ddt, 1H, J_{gem} = 1.80 Hz; J_{cis} = 10.30 Hz; ^4J = 1.25 Hz, H^A), 5.30 (ddt, 1H, J_{gem} = 1.80 Hz; J_{trans} = 17.20 Hz; ^4J = 1.60 Hz, H^B), 5.90 (ddt, 1H, J_{cis} = 10.30 Hz; J_{trans} = 17.20 Hz and ^3J = 4.90 Hz, H^C).

3-O-Allyl-sn-*glycerol* (**5**)

Hydrochloric acid (1 N, 4.5 mL) was added to compound **4** (18 g, 0.18 mol) in methanol (140 mL). The mixture was heated at reflux for 1 h. After cooling, the solution was neutralized with 10% sodium hydrogen carbonate. The solvents were removed under vacuum and the solid phase dried by azeotropic distillation with anhydrous benzene. Vacuum distillation, gave 3-*O*-allyl-*sn*-glycerol (26 g): bp 104–106°C/0.1 Torr; yield 86%; $[\alpha]_{589}$ +0.6, $[\alpha]_{578}$ +0.7, $[\alpha]_{546}$ +1, $[\alpha]_{436}$ +1.3 (*c* 0.017, pyridine); ir: 3400 (υOH), 3080, 3015, 1640 cm^{-1} (CH = CH_2); ^1H nmr ($CDCl_3$) δ ppm: 3.40–3.95 (m, 7H, C^1H_2OH, C^2HOH, and C^3H_2O); 4.05 (dt, ^3J = 5.50 Hz; ^4J = 1.30 Hz, 2H, OCH_2-CH = CH_2), 5.18 (ddt, 1H, J_{gem} = 1.60 Hz; J_{cis} = 10.3 Hz; ^4J = 1.30 Hz, H^A), 5.30 (ddt, 1H, J_{gem} = 1.6 Hz, J_{trans} = 17.20 Hz; ^4J = 1.30 Hz, H^B), 5.90 (ddt, 1H, J_t = 17.20 Hz, J_c = 10.30 Hz, ^3J = 5.5 Hz, H^C).

1-O-Trityl-3-O-allyl-sn-*glycerol* (**6**)

Compound **5** (8.8 g, 0.066 mol) was dissolved in 140 mL of *tert*-butanol. After addition of trityl chloride (23.3 g, 0.084 mol) and triethylamine (9.89 g, 0.098 mol), the mixture was heated to reflux for 1 h. After cooling, 70 mL of diisopropyl ether and 70 mL of water were added. After decantation the aqueous phase was extracted twice with 70 mL of diisopropyl ether. The organic phases were combined and dried over sodium sulfate. After solvent evaporation, the oil was chromatographed on a column (100 g of silica gel) (gradient hexane – ethyl ether). The trityl derivative was eluted with hexane – ether mixtures 90:10 and 80:20. It crystallized from 40 mL of hexane in the presence of a few drops of ether: weight 23.4 g; yield 94%; mp 58°C; R_f: 0.24 (hexane–ether 1/4); $[\alpha]_{589}$ −4.4; $[\alpha]_{578}$ −4.7; $[\alpha]_{546}$ −5; $[\alpha]_{436}$ −9.5° (*c* 0.013, $CHCl_3$); ir: 3480 (υOH), 3030–3100 cm^{-1} (C_6H_5, CH = CH_2); ^1H nmr ($CDCl_3$) δ ppm: 2.50 (d, 1H, J = 4.70 Hz, O*H*), 3.20 (AB part of a system ABX with ^2J = 9.40 Hz; each transition was split with ^3J = 5.50 Hz, 2H, C^1H_2O or C^3H_2O), 3.53 (AB part of a system ABX with $^2J_{AB}$ = 9.70 Hz, $^3J_{AX}$ = 4.40 Hz, $^3J_{BX}$ = 6.30 Hz, 2H, C^1H_2O or C^3H_2O), 3.90–4.05 (dt, located at 3.98 ppm, ^3J = 5.60 Hz, ^4J = 1.40 Hz, OCH_2-CH=CH_2, overlapped at a multiplet 1H, HC_2O), 5.20 (ddt, 1H, J_{gem} = 1.65 Hz; J_{cis} = 10.30 Hz, ^4J = 1.40 Hz, H^A), 5.25 (ddt, 1H, J_{gem} = 1.65 Hz, J_{trans} = 17.20 Hz, ^4J = 1.40 Hz, H^B), 5.90 (ddt, 1H, J_{cis} = 10.30 Hz, J_{trans} = 17.20 Hz, ^3J = 5.60 Hz, H^C), 7.15–7.50 (m, 15H aromatic).

1-O-Trityl-2-O-benzyl-3-O-allyl-sn-*glycerol* (**7**)

The previous compound (8 g, 0.021 mol) was dissolved in 40 mL of anhydrous DMF. Sodium hydride (0.026 mol) was slowly added with magnetic stirring and under dry nitrogen. Benzyl chloride (2.8 g, 0.022 mol) was then added dropwise. After 21 h stirring at room temperature the mixture was poured over ice. The organic phase was extracted 3 times with 100 mL of chloroform, washed with water, and then dried over sodium sulfate. After removal of solvent under vacum, the oil was chromatographed (200 g of silica gel, gradient hexane–ether). The compound was eluted with a hexane–ether mixture 90:10; weight 9.4 g; yield 95%; R_f 0.44 (hexane–ether 4:1); $[\alpha]_{589}$ −10.7, $[\alpha]_{578}$ −11.3, $[\alpha]_{546}$ −13.2, $[\alpha]_{436}$ −22.7 (*c* 0.021, $CHCl_3$); ^1H nmr δ ppm: 3.25 (d, ^3J = 5 Hz, C^1H_2O or C^3H_2O), 3.50–3.70 (AB part of a ABX system, J_{AB} = 10.20 Hz, J_{AX} = 5.95 ppm, J_{BX} = 4.25 Hz, 2H, C^1H_2O or C^3H_2O), 3.75 (ddt, J = 5.95 Hz, J = 4.25 Hz and J = 5 Hz, 1H, C^2HO), 3.96 (ddd, ^3J = 5.45 Hz, ^4J = 1.65 Hz, ^4J = 1.30 Hz, 2H, O-CH_2-CH=CH_2), 4.66 (syst. AB, J_{AB} = 12.35 Hz, 2H, O-CH_2-Ph), 5.15 (ddt, J_{cis} = 10.30 Hz, J_{gem} = 1.85 Hz, ^4J = 1.30 Hz, H^B), 5.23 (ddt, J_{trans} = 17.30 Hz, J_{cis} = 10.30 Hz, ^4J = 1.65 Hz, H^A), 5.86 (ddt, J_{trans} = 17.30 Hz, J_{cis} = 10.30 Hz, ^3J = 5.45 Hz, H^C), 7.15–7.50 (m, 20H aromatic).

2-O-Benzyl-3-O-allyl-sn-*glycerol* (**8**)

The trityl derivative (6 g, 0.013 mol) was dissolved in methanol (35 mL) and acidified with 1 N hydrochloric acid (3.5 mL). The solution was heated at reflux for 1 h with stirring. After cooling, the mixture was diluted with 100 mL of water. The organic phase was extracted 3 times with 50 mL of diisopropyl ether. The ether phase was washed with 20 mL of 1 N sodium hydroxide, and then with water. The organic phase was dried over magnesium sulfate. The solvent was removed and the oil was chromatographed (35 g of silica gel; eluent gradient hexane–ether). The product was eluted with a hexane–ether mixture 75:25; weight 2.33 g; yield 81%; R_f 0.56 (diisopropyl ether); $[\alpha]_{589}$ +26.1, $[\alpha]_{578}$ +27.3, $[\alpha]_{546}$ +31.3, $[\alpha]_{436}$ +53.4 (*c* 0.02, $CHCl_3$); ir: 3420 (υOH), 1670 cm^{-1} (υCH=CH_2) (allyl); ^1H nmr ($CDCl_3$) δ ppm: 2.50 (s, 1H, O*H*), 3.50–3.80 (m, 5H, C^1H_2O + C^2HO + C^3H_2O), 3.98 (dt, 2H, ^3J = 5.50 Hz, ^4J = 1.3 Hz, OCH_2-CH = CH_2), 4.57–4.73 (AB system located at 4.65 ppm with J_{AB} = 11.80 Hz, 2H, $C_6H_5CH_2O$), 5.18 (ddt, 1H, J_{cis} = 10.30 Hz, J_{gem} = 1.75 Hz, ^4J = 1.30 Hz, H^A), 5.28 (ddt, 1H, J_{trans} = 17.50 Hz, J_{gem} = 1.75 Hz, ^4J = 1.30 Hz, H^B), 5.90 (ddt, 1H, J_{trans} = 17.5 Hz, J_{cis} = 10.30 Hz, ^3J = 5.50 Hz, H^C), 7.30 (m, 5H aromatic).

2-O-Benzyl-3-propenyl-sn-*glycerol* (**9**)

Compound **8** was dried by azeotropic distillation with anhydrous benzene (50 mL) (twice) and dissolved in anhydrous and distilled DMSO (30 mL). Dry potassium *tert*-butylate (3 g) was added. The mixture was stirred and heated at 100°C. After 15 min, the reaction was complete (controlled by thin-layer chromatography (tlc); solvent diisopropyl ether: **8**, R_f 0.56, **9**, R_f 0.69). After cooling, the reaction mixture was diluted with chilled water (100 mL). The organic phase was extracted twice with diisopropyl ether then washed 4 times with water (50 mL). After drying over sodium sulfate, the solvent was eliminated under vacuum. The oil was used directly; weight 3.85 g; yield 95%; R_f 0.59 (diisopropyl ether); $[\alpha]_{589}$ +4.3, $[\alpha]_{576}$ +4.6, $[\alpha]_{546}$ +5.20, $[\alpha]_{436}$ +6.9 (*c* 0.014, $CHCl_3$); ir: 3400 (υOH), 1670 cm^{-1} (υCH=CH_2); ^1H nmr ($CDCl_3$) δ ppm: 1.59 (dd, 3H, ^3J = 6.85 Hz, ^4J = 1.70 Hz, CH=CH-CH_3), 2.30 (s, 1H, O*H*), 3.55–3.90 (m, 5H, C^1H_2O + C^2HO + C^3H_2O), 4.42 (dq, 1H, J_{cis} = 6.20 Hz, ^3J = 6.85 Hz, H^A), 4.57–4.75 (AB system located at 4.66 ppm with J_{AB} = 11.70 Hz, 2H, C_6H_5-CH_2O), 5.94 ppm (dq, 1H, J_{cis} = 6.20 Hz, ^4J = 1.70 Hz, H^B), 7.35 ppm (m, 5H, aromatic).

1-O-Hexadecyl-2-O-benzyl-3-O-propenyl-sn-*glycerol* (**12**)

Sodium hydride (0.307 g, 12.8 mmol) was added to a solution of compound **9** (1.42 g, 6.4 mmol) in anhydrous benzene (10 mL). After 30 min a solution of hexadecyl methanesulfonate (2.81 g, 8 mmol) in benzene (10 mL) was added dropwise. The mixture was then heated at 80–90°C for 5 h with stirring. After cooling, methanol (2 mL) was added. The mixture was diluted with water (50 mL). The organic phase was extracted twice with a mixture of chloroform–methanol (2:1) (75 mL), washed with water, then dried over sodium sulfate. The solvent was removed and oil chromatographed (40 g of silica gel, eluent gradient hexane–ether). The product was eluted with a mixture of hexane–ether 95:5; weight 2.27 g; yield 77%; R_f 0.85 (hexane – diisopropyl ether, 1:1); $[\alpha]_{589}$ −5.3, $[\alpha]_{578}$ −5.5, $[\alpha]_{546}$ −6.2, $[\alpha]_{436}$ −11 (*c* 0.026, $CHCl_3$); ir: 1670 cm^{-1} (υCH=CH_2); ^1H nmr ($CDCl_3$) δ ppm: 0.88 (t, 3H, *J* = 6.70 Hz, CH_3, hexadecyl), 1.25 (s, 26H, $(CH_2)_{13}$), 1.59 (dt, 3H, ^3J = 6.85 Hz, ^4J = 1.70 Hz, CH=CH-CH_3 and m, 2H, OCH_2CH_2), 3.43 (t, 3H, *J* = 6.55 Hz, OCH_2CH_2), 3.52 (d, 2H, *J* = 5 Hz, C^1H_2O or C^3H_2O), 3.70–3.95 (m, 3H, C^1H_2O or C^3H_2O and C^2HO), 4.39 (dq, 1H, J_{cis} = 6.20 Hz, ^3J = 6.85 Hz, H^A), 4.70 (s, 2H, $C_6H_5CH_2$), 5.98 (dq, 1H, J_{cis} = 6.20 Hz, ^4J = 1.70 Hz, H^B), 7.35–7.40 (m, 5H aromatic).

1-O-Myristoyl-2-O-benzyl-3-O-propenyl-sn-*glycerol* (**10**)

Myristoyl chloride (1.58 g, 7 mmol) in chloroform (5 mL) was added to a solution of compound **9** (1.42 g, 6.4 mmol) in anhydrous pyridine (3 mL) with stirring. The mixture was allowed to stand at room temperature for 36 h. The excess of acid chloride was destroyed with ice. The organic phase was extracted 3 times with chloroform (75 mL), washed successively with 2 N sulfuric acid, 10% sodium hydrogen carbonate, and water. The organic phase was dried (Na_2SO_4). After removal of solvent, the oil was chromatographed (40 g of silica gel; eluent gradient hexane – diethyl ether). The product was eluted with a mixture of hexane–ether 95:5; weight 2 g; yield 72%; R_f 0.62 (hexane – diisopropyl ether 5:1); $[\alpha]_{589}$ −1.7, $[\alpha]_{578}$ −1.7, $[\alpha]_{546}$ −1.9, $[\alpha]_{436}$ −3.8 (*c* 0.020, $CHCl_3$); ^1H nmr ($CDCl_3$) δ ppm: 0.88 (t, 3H, *J* = 6.70 Hz, CH_3, myristoyl), 1.25 (s, 20H, $(CH_2)_{10}$), 1.60 (dd, 3H, ^3J = 6.85 Hz, ^4J = 1.65 Hz, CH=CH-CH_3 and m, 2H, $COCH_2$-CH_2), 2.32 (t, 2H, *J* = 7.10 Hz, $COCH_2$), 3.70–3.90 (m, 3H, C^2HO + C^1H_2O or C^3H_2O), 4.05–4.35 (m, 2H, C^1H_2O or C^3H_2O), 4.41 (dq, 1H, J_{cis} = 6.20 Hz, ^3J = 6.85 Hz, H^A), 4.70 (s, 2H, $C_6H_5CH_2$), 5.95 (dq, 1H, J_{cis} = 6.20 Hz, ^4J = 1.65 Hz, H^B), 7.35 ppm (m, 5H aromatic).

1-O-Hexadecyl-2-O-benzyl-sn-*glycerol* (**13**)

The previous compound **12** (1.21 g, 2.6 mmol) was dissolved in tetrahydrofuran (5 mL); 0.2 M sodium phosphate buffer (pH 5) (5 mL) was added. Bromine (20 mmol) in tetrahydrofuran (10 mL) was then added dropwise with stirring to obtain a permanent yellow colour (about 1.5 mL). After 15 min, the solution was diluted with water (50 mL). The organic phase was extracted with chloroform (twice), neutralized with 10% sodium hydrogen carbonate (25 mL), washed with water, and dried over Na_2SO_4. The solvent was removed and the oil was chromatographed (40 g of silica gel, gradient hexane–ether). The compound was eluted with a mixture of hexane–ether 75:25 and 70:30; weight 0.66 g; yield 60%; R_f 0.24 (hexane – diisopropyl ether 1:1); $[\alpha]_{589}$ −12.5, $[\alpha]_{578}$ −13, $[\alpha]_{546}$ −14.8, $[\alpha]_{436}$ −25.4 (*c* 0.0189, $CHCl_3$), $[\alpha]_{589}$ −1.14, $[\alpha]_{578}$ −1.14, $[\alpha]_{546}$ −1.26, $[\alpha]_{436}$ −2.14 (*c* 0.016, methanol) (lit. (6) $[\alpha]_D$ −1.15 (methanol); and (7) $[\alpha]_D$ −1.21 (methanol); ir: 3400 cm^{-1} (υOH); ^1H nmr ($CDCl_3$) δ ppm: 0.88 (t, 3H, *J* = 6.7 Hz, CH_3 hexadecyl), 1.25 (s, 26H, $(CH_2)_{13}$), 1.57 (m, 2H, OCH_2CH_2), 2.17 (s broad, 1H, O*H*), 3.44 (t, 3H, *J* = 6.55 Hz, OCH_2CH_2), 3.47–3.85 (m, 5H, C^1H_2O + C^2HO + C^3H_2O), 4.59–4.75 (AB system located at 4.67 ppm with J_{AB} = 11.80 Hz, 2H, $C_6H_5CH_2$-O), 7.35 ppm (m, 5H aromatic).

1-O-Myristoyl-2-O-benzyl-sn-*glycerol* (**11**)

Compound **11** was prepared from compound **10** using the same procedure as for compound **13**; yield 62%; R_f 0.17 (hexane – diisopropyl ether 1:1); $[\alpha]_{589}$ −1.1, $[\alpha]_{578}$ −1.15, $[\alpha]_{546}$ −1.20, $[\alpha]_{436}$ −2.2 (*c* 0.018, $CHCl_3$); ir: 3440 cm^{-1} (υOH); ^1H nmr ($CDCl_3$) δ ppm: 0.88 (t, 3H, *J* = 6.70 Hz, CH_3, myristoyl), 1.25 (s, 20H, $(CH_2)_{10}$), 1.62 (m, 2H, $COCH_2$-CH_2), 2.06 (s broad, 1H, O*H*), 2.32 (t, 2H, *J* = 7.10 Hz, $COCH_2$), 3.55–3.80 (m, 3H, C^1H_2O + C^2HO or C^3H_2O), 4.24 (d, 2H, ^3J = 4.60 Hz, C^1H_2O or C^3H_2O), 4.57–4.75 (AB system located at 4.66 ppm with J_{AB} = 11.70 Hz, 2H, $C_6H_5CH_2$-O), 7.35 (m, 5H aromatic).

Discussion

Compounds **11** and **13** were obtained from D-mannitol with good yield. The removal of the trityl group by acid hydrolysis is easy. The transposition of the allyl double bond in propenyl is fast and complete after 15 min in the presence of dry potassium terbutylate in anhydrous dimethyl sulfoxide. The reaction is stereospecific since it leads to the *cis* isomer only, as checked by ^1H nmr.

Compound **9** is quite unstable; nevertheless we succeeded in purifying it by column chromatography. In some experiments, another compound appeared through the column, indicating a chemical reaction in the column. Compounds **10** and **12** are also unstable and it is advisable to remove the propenyl group rapidly. Once after 2 months storage, we observed the conversion of compounds **10** and **12** into compounds **11** and **13** respectively. After column chromatography, these compounds were isolated with the same physical characteristics. The ^1H nmr patterns were obtained by a selective spin–spin decoupling technique. The

^{1}H nmr assignments of compound **13** are in agreement with literature (6, 9).

Optical rotations of all the compounds are specified. Enantiomeric purity of the isopropylidene-*sn*-glycerol, raw material of all the other intermediates, is the same as that obtained by Hirth and Walther (13). These authors had established by gas phase chromatography of an acetone-glycerol derivative that the optical purity of acetone-glycerol was better than 99.4%.

The optical rotation of compound **13** is very close to that given in the literature (6, 7).

We did not verify the enantiomeric purity or the eventual extent of contamination of each intermediate by a chromatographic study either with a chiral phase, as done by Takagi *et al.* (15–17), or with a normal phase for diastereoisomeric derivatives, as done by Laakso and Christie (18). However, comparison of the optical rotations of our compound **13** with those given in the literature (6, 7) allowed us to believe that the quality of the substances obtained here is sufficient to enter into other reaction sequences.

Thus, different fatty acids can be introduced on carbon-2 of compound **14** (Scheme 2). These acids can vary in fatty acid length, unsaturation, and can be either brominated and then used as fluorescent quenching agents (19) or anchored to different probe positions of fluorescent, photoactivable, or radiolabelled groups (20–25).

The polar head can be also modified from compound **16** (26–30). We synthesized the following compounds from compound **16**: 1,2-di-*O*-myristoyl-*sn*-glycero-3-phosphoryl *N*-pyridinio-2-ethanol (**17**, $R^1 = R^2 = CO(CH_2)_{12}CH_3$, $R^3 = N^+(C_5H_5)$) and 1,2-di-*O*-myristoyl-*sn*-glycero-3-phosphoryl *N*-piperidino-2 ethanol (**17**, $R^1 = R^2 = CO(CH_2)_{12}CH_3$, $R^3 = NC_5H_{10}$). We also studied the influence of an uncharged phospholipid (1,2-di-*O*-myristoyl-*sn*-glycero-3-phosphoryl-2-oxo-1,3,2-dioxaphospholane) (**20**) and of compound **16** ($R^1 = R^2 = CO(CH_2)_{12}CH_3$) on BDH reactivation (30, 31). Fluorescent, photoactivatable, or radiolabelled probes can be added to the polar head (20, 22, 32, 33, 35).

Compounds **15** ($R^1 = CO(CH_2)_{12}CH_3$ and $R^1 = (CH_2)_{15}CH_3$) allow the production of both photoactivatable groups and fluorescent probes either on the glycerol carbon-2 or on the polar head. Such molecules have recently been used in our laboratory to estimate the labelling of R-3-hydroxybutyrate dehydrogenase with phospholipids without the use of radioisotopes (35).

Chiral 2-acetamidoacrylates in conjugate addition – asymmetric enolate trapping reactions. Asymmetric synthesis of phenylalanine

CARLOS CATIVIELA,[1] MARIA DOLORES DIAZ-DE-VILLEGAS, AND JOSÉ ANTONIO GALVEZ
Instituto de Ciencia de Materiales de Aragón, Departamento de Quimica Orgánica, Universidad de Zaragoza-C.S.I.C., 50009 Zaragoza, Spain

Received December 10, 1991

CARLOS CATIVIELA, MARIA DOLORES DIAZ-DE-VILLEGAS, and JOSÉ ANTONIO GALVEZ. Can. J. Chem. **70**, 2325 (1992).

A new route to the asymmetric synthesis of α-amino acids based on the reactivity of chiral 2-acetamidoacrylates with nucleophiles through a conjugate addition followed by diastereoselective protonation of the enolate is described. Phenylalanine precursors are obtained in excellent chemical yields (80–95%) with moderate diastereomeric excess (0–44%) through the reaction of chiral 2-acetamidoacrylates with phenylmagnesium bromide in the presence of CuI followed by diastereoselective enolate protonation.

CARLOS CATIVIELA, MARIA DOLORES DIAZ-DE-VILLEGAS et JOSÉ ANTONIO GALVEZ. Can. J. Chem. **70**, 2325 (1992).

On décrit une nouvelle méthode de synthèse asymétrique des acides α-aminés qui est basée sur l'addition conjuguée de nucléophiles sur des 2-acétamidoacrylates chiraux, suivie d'une protonation diastéréosélective de l'énolate. Faisant appel à une réaction des 2-acétamidoacrylates chiraux avec du bromure de phénylmagnésium en présence de CuI, suivie d'une protonation diastéréosélective de l'énolate, on a obtenu des précurseurs de la phénylalanine avec d'excellents rendements (80–95%) et des excès diastéréoisomériques modérés (0–44%).

[Traduit par la rédaction]

Introduction

Numerous new and useful approaches to the asymmetric synthesis of α-amino acids have appeared in recent years (1), most of them involving the asymmetric hydrogenation of prochiral didehydroamino acids derivatives (2) or the highly stereoselective hydrogenation of chiral, nonracemic, didehydroamino acid derivatives (3). The most recent advances in this field have concentrated on the development of chiral, optically pure, amino acid enolate equivalents (4) and amino acid cation equivalents (5). The attraction of these asymmetric amino acid equivalents is their inherent versatility in the preparation of a diverse array of amino acids from a few common precursors with the appropriate C—C bond-forming technology.

Enantioselective protonation (6) of prochiral substrates has been applied to deracemization and has been used to prepare optically active α-amino acids (7). This procedure is based on deprotonation, with a suitable base, of an asymmetric centre with an attached hydrogen activated by the electron-attracting effect of at least one substituent to afford a nucleophilic prochiral centre. Protonation of the enolate by an optically active proton carrier gives the product in optically active form.

A different methodology would be the diastereoselective protonation of chiral enolates obtained by conjugate addition of nucleophilic reagents on chiral α,β-didehydroamino acid derivatives, which would make it possible to obtain a diverse array of amino acids from a single precursor. This strategy is similar to the one developed by Opplozer and Kingma (8) to obtain chiral compounds from the corresponding α,β-unsaturated compound.

Although it was previously reported (9) that methyl 2-acetamidoacrylate can act as an acceptor in conjugate additions, to the best of our knowledge this synthetic approach has not been used to obtain amino acid derivatives stereoselectively. Therefore, we have studied the behaviour of chiral 2-acetamidoacrylates in conjugate addition – diastereoselective enolate protonation to afford phenylalanine derivatives.

Results and discussion

Chiral 2-acetamidoacrylates **1**, which can be obtained from methyl 2-acetamidoacrylate and the corresponding dimethylaluminum – chiral alcohol complex (10), can be conveniently β-functionalized by Michael addition of phenylmagnesium bromide promoted by copper(I) iodide (11). Diastereoselective protonation of the intermediate enolate in the *E*-configuration favoured by the presence of a coordinating group in the α position using saturated aqueous ammonium chloride solution provides the corresponding *N*-acetylphenylalanine esters in high chemical yields.

To understand the influence of the chiral auxiliary on the diastereofacial differentiation, this reaction was tested on a variety of chiral 2-acetamidoacrylates.

In some cases the nucleophilic prochiral centre and the chiral matrix in the enolate system are not ordered enough to restrict single-bond rotation and chirality transfer during the neutralization process is low (12). However, there are some rationally designed chiral auxiliaries that exhibit excellent reaction diastereoselection as they can incorporate non-bonding interactions to restrict rotation and have a large group that provides an effective barrier to electrophilic approach to one diastereoface of the enolate. Examples are the concave chiral auxiliaries according to Helchem's concept (13).

Conventional chiral auxiliaries (1*R*,2*S*,5*R*-(−)-menthol, 1*S*,2*R*,5*S*-(+)-menthol, and [(1*S*)-*endo*]-borneol) and concave chiral alcohols (1*R*,2*S*,5*R*-(−)-8-phenylmenthol and 1*R*,2*S*,3*R*,4*S*-(−)-*cis*-hydroxyisobornyl neopentyl ether) were used to probe the relationship between the extent of extraannular chirality transfer and the morphological aspect of the chiral alcohol (Table 1). Surprisingly, the best diastereoselectivity was obtained when menthyl esters, whose architectural features are not thought to be optimal, were used (runs 1 and 2).

From these results it can be assumed that β-functionalization of α-acetamidoacrilates provides an intermediate *E*-

7	**1***g*	83	14[b]	1.97, 2.00

[a]The underlined value corresponds to the major diastereoisomer.
[b]Absolute configuration was not determined due to the low diastereoselectivity.

enolate that possesses a large group in the α-position, which forces the chiral matrix as far as possible from the alkene moiety. As a consequence, diastereoselective protonation does not depend on the morphological aspect of the chiral alcohol since non-bonding interactions are restricted.

As previously described (14) carbohydrate ester enolates have peculiar properties because they have a marked complexing ability towards cations. D-Glucofuranose derivatives, which should provide the enolate in a more ordered geometry by intramolecular complexation of the cation, were used to improve diastereoselectivity. However, when the carbohydrate derivative 1,2:5,6-diisopropylidene-D-glucofuranose was used as a chiral auxiliary (run 6), diastereoselectivity was only slightly increased.

To understand the role of the acetamido group in the protonation of the intermediate enolate, methyl 2-acetamidoacrylate was reacted with phenylmagnesium bromide in the presence of CuI followed by protonation with saturated aqueous ammonium chloride solution, deuteration with deuterated water, or methylation with methyl iodide to afford *N*-acetylphenylalanine methyl ester, α-deutero-*N*-acetylphenylalanine methyl ester, and α-methyl-*N*-acetylphenylalanine methyl ester respectively.

From these results it can be concluded that (*a*) the unprotected -NH- group is not acidic enough to react with the organometallic reagent and (*b*) the poor level of diastereoface differentiation is not due to the presence of the -NH- acidic group competing with the electrophile since the -NH- group does not neutralize the enolate but an external proton (or electrophile) source does.

Diastereomeric excess (% d.e.) was determined by ^1H NMR integration of the acetamido singlet of each diastereomer in the crude reaction spectrum. Comparison of the sign of optical rotation at 589 nm of the methyl ester obtained by transesterification with the reported data (15), indicated the absolute configuration of each product.

Experimental

General

All reactions were carried out under Ar with magnetic stirring. Diethyl ether was distilled from sodium/benzophenone ketyl over 4 Å molecular sieves prior to use. Chiral 2-acetamidoacrylates **1***a*–**1***g* were prepared according to the previously described procedure (10). Phenylmagnesium bromide 3.0 M solution in diethyl ether and copper(I) iodide were purchased from Aldrich and were used from freshly opened bottles without purification. "Work-up" denotes extraction with diethyl ether, washing of the organic phase with water, drying with $MgSO_4$, and evaporation (rotatory evaporator).

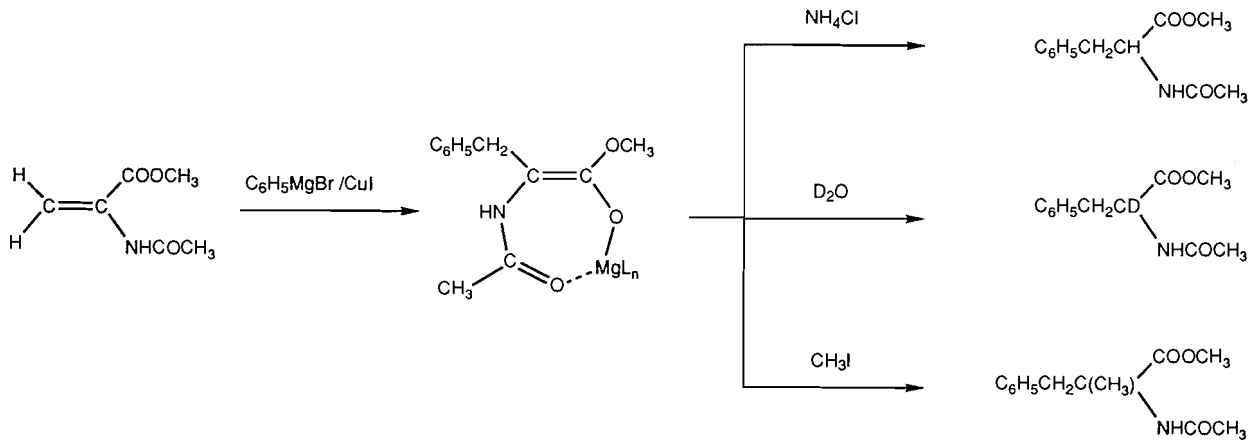

SCHEME 2

Thin-layer chromatography (TLC) was performed on Merck precoated silica gel plates. TLC plates were visualized using UV light and anisaldehyde/sulphuric acid/ethanol (2:1:100). Flash chromatography was performed using 230–400 mesh (Merck) silica gel. NMR spectra were recorded on a Varian Unity 300 MHz spectrometer. Optical rotations were measured on a Perkin–Elmer 241-C polarimeter. For polarimetric determination the measured optical rotations were compared to that of (*S*)-*N*-acetylphenylalanine methyl ester (589 nm), $[\alpha]^{25}$ +103.3 (*c* 1.2, $CHCl_3$).

Conjugate addition of phenylmagnesium bromide and subsequent diastereoselective enolate protonation

A stirred slurry of 0.027 g (0.14 mmol) of CuI in 10 mL of dry diethyl ether under an argon atmosphere was cooled to 0°C in an ice bath. A solution of 0.93 mL (2.8 mmol) of 3.0 M phenylmagnesium bromide in diethyl ether was added and, after 10 min, 1.4 mmol of the corresponding 2-acetamidoacrylate **1** dissolved in 15 mL of diethyl ether was added dropwise and stirring was continued for an additional hour at 0°C. The reaction mixture was then cooled to −80°C and quenched with saturated aqueous NH_4Cl solution. The cold bath was removed after 5 min and the mixture was allowed to warm to room temperature.

(1S,2R,5S)-Menthyl 2-acetamido-3-phenylpropanoate **2**a

Work-up afforded 0.396 g (82%) of a mixture of diastereoisomers (d.e. 27%) as a crude oil that was chromatographed on a silica gel column (230–400 mesh) eluting with methylene chloride/diethyl ether (2:1). ^{1}H NMR of the major diastereoisomer, δ: 0.72 (d, 3H), 0.87 (d, 3H), 0.90 (d, 3H), 0.96–2.10 (m, 9H), 1.96 (s, 3H), 3.00–3.49 (m, 2H), 4.67 (dt, 1H), 4.85 (dd, 1H), 5.84 (d, 1H), 7.11–7.15 (m, 2H), 7.23–7.32 (m, 3H). ^{13}C NMR of the major diastereoisomer, δ: 15.8, 20.8, 21.9, 23.1, 25.8, 31.3, 34.0, 37.9, 40.5, 46.7, 53.3, 76.0, 127.0, 128.5, 129.3, 135.9, 169.5, 171.5. Anal. calcd. for $C_{21}H_{31}NO_3$: C 73.01, H 9.04, N 4.05; found: C 72.98, H, 9.19, N 3.87.

(1R,2S,5R)-Menthyl 2-acetamido-3-phenylpropanoate **2**b

Work-up afforded 0.386 g (80%) of a mixture of diastereoisomers (d.e. 28%) as a crude oil that was chromatographed on a silica gel column (230–400 mesh) eluting with methylene chloride/diethyl ether (2:1). ^{1}H NMR of the major diastereoisomer, δ: 0.72 (d, 3H), 0.87 (d, 3H), 0.90 (d, 3H), 0.96–2.10 (m, 9H), 1.96 (s, 3H), 3.00–3.49 (m, 2H), 4.67 (dt, 1H), 4.85 (dd, 1H), 5.84 (d, 1H), 7.11–7.15 (m, 2H), 7.23–7.32 (m, 3H). ^{13}C NMR of the major diastereoisomer, δ: 15.8, 20.8, 21.9, 23.1, 25.8, 31.3, 34.0, 37.9, 40.5, 46.7, 53.3, 76.0, 127.0, 128.5, 129.3, 135.9, 169.5, 171.5. 1,2:5,6-Di-O-cyclohexylidene-D-glucofuranosyl 2-acetamido-3-phenylpropanoate **2**g

Work-up afforded 0.614 g (83%) of a mixture of diastereoisomers (d.e. 14%) as a crude oil that was chromatographed on a silica gel column (230–400 mesh) eluting with methylene chloride/diethyl ether (3:1). ^{1}H NMR of the major diastereoisomer, δ: 1.25–1.76 (m, 20H), 1.97 (s, 3H), 3.01–3.24 (m, 2H), 3.91–4.39 (m, 4H), 4.50 (d, 1H), 4.83–4.95 (m, 1H), 5.27 (d, 1H), 5.88 (d, 1H), 5.91 (d, 1H), 7.15–7.22 (m, 2H), 7.25–7.35 (m, 3H). ^{13}C NMR of the major diastereoisomer, δ: 22.9, 23.5, 23.7, 23.9, 24.7, 25.0, 34.6, 35.5, 36.2, 36.6, 37.4, 38.1, 52.8, 67.2, 71.9, 77.0, 79.8, 82.6, 104.7, 110.1, 113.0, 127.2, 128.5, 129.4, 135.7, 169.7, 170.7. Anal. calcd. for $C_{29}H_{39}NO_8$: C 65.77, H 7.42, N 2.64; found: C 65.52, H, 7.45, N 2.38.

Transesterification to methyl 2-acetamido-3-phenyl-propanoate

A mixture of diastereoisomers (27% d.e.) of purified (−)-menthyl 2-acetamido-3-phenylpropanoate **1***a* (0.5 g, 1.4 mmol) and absolute methanol saturated with dry HCl gas (30 mL) were placed in a glass pressure tube and the mixture was heated at 75°C for 2 h. Upon cooling, the reaction mixture was evaporated to dryness and the residue was chromatographed on a silica gel column (230–400 mesh) using diethyl ether/hexane (1:1) as eluent to afford the corresponding methyl 2-acetamido-3-phenylpropanoate in 30% optical purity mixture of enantiomers; $[\alpha]^{25}$ +31.7 (*c* 1.2, $CHCl_3$).

WILLIAM R. CULLEN, STEVEN J. RETTIG, and TU CAI ZHENG. Can. J. Chem. **70**, 2329 (1992).

The reaction of $Os_3(CO)_{10}(MeCN)_2$ with PFc_2Ph (Fc = $(\eta\text{-}C_5H_4)Fe(\eta\text{-}C_5H_5)$) affords the unsymmetrical isomer of 1,2-$Os_3(CO)_{10}(PFc_2Ph)_2$, **2**. Crystals of **2** are monoclinic, a = 27.846(4), b = 11.253(4), c = 38.520(3) Å, β = 107.813(9)°, Z = 8, space group $C2/c$. The structure was solved by heavy atom methods and was refined by full-matrix least-squares procedures to R = 0.030 and R_w = 0.027 for 5073 reflections with $I \geq 3\sigma(I)$.

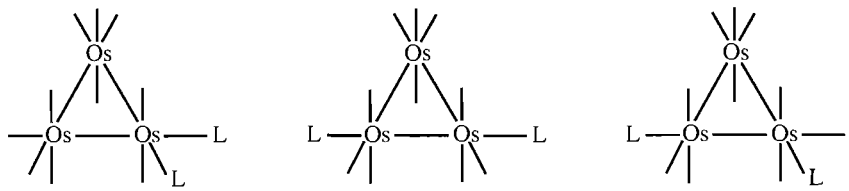
WILLIAM R. CULLEN, STEVEN J. RETTIG et TU CAI ZHENG. Can. J. Chem. **70**, 2329 (1992).

La réaction du $Os_3(CO)_{10}(MeCN)_2$ avec le PFc_2Ph (Fc = $(\eta\text{-}C_5H_4)Fe(\eta\text{-}C_5H_5)$) conduit à l'isomère dissymétrique du composé $Os_3(CO)_{10}$-1,2-$(PFc_2Ph)_2$, **2**. Les cristaux du composé **2** appartiennent au groupe d'espace monoclinique $C2/c$ avec a = 27,846(4), b = 11,253(4), c = 38,520(3) Å, β = 107,813(9)°, Z = 8. On a résolu la structure par la méthode des atomes lourds et on l'a affinée par la méthode des moindres carrés, matrice complète, jusqu'à des valeurs de R = 0,030 et de R_w = 0,027 pour 5073 réflexions avec $I \geq 3\sigma(I)$.

[Traduit par la rédaction]

Introduction

Tertiary phosphine substituted triosmium carbonyl cluster compounds of the type $Os_3(CO)_{10}L_2$ (L = monodentate phosphine) can be synthesized by using a number of procedures (1, 2). Because thermal and photochemical reactions of the phosphines L with $Os_3(CO)_{12}$ usually give a mixture of mono-, di-, and tri-substituted products, $Os_3(CO)_{10}$-$(MeCN)_2$ or $Os_3(CO)_{10}(C_8H_{14})_2$ (C_8H_{14} = cyclooctene) have been widely used as precursors for high-yield syntheses of $Os_3(CO)_{10}L_2$ compounds (1–11). Many compounds of this type have been isolated and some were subjected to structure analyses in order to better understand the bonding in these complexes (1, 2). Phosphines are always found to occupy the equatorial sites due to their bulkiness, but three structural isomers for $Os_3(CO)_{10}L_2$, **1***a*–**1***c*, are possible (10).



1*a* **1***b* **1***c*

The 1,1-isomers **1***a* have to be synthesized by using Os_3 $(CO)_{10}(\eta^4\text{-}C_4H_6)$ (C_4H_6 = *cis*-buta-1,3-diene) as precursor because the diene is coordinated at an axial and an equatorial site at one osmium atom (9, 10, 12). The 1,2-isomers are easily synthesized from the reaction of phosphines with either $Os_3(CO)_{10}(MeCN)_2$ or $Os_3(CO)_{10}(C_8H_{14})_2$ or $Os_3(CO)_{10}(\eta^4$-$C_4H_6)$ (here C_4H_6 = *trans*-buta-1,3-diene) (7, 10). Usually only the symmetrical 1,2-isomers **1***b* are obtained even if different reaction procedures are employed. This has been attributed to the bulkiness of the ligands that tend to react with the cluster so as to be as far away from each other as possible. On this basis smaller phosphines such as PMe_2Ph or PEt_3, of cone angles 122° and 132° respectively (13, 14), might be expected to afford a mixture of **1***b* and **1***c*, or even pure **1***c*. In fact nmr spectroscopic studies show that 1,2-$Os_3(CO)_{10}(PMe_2Ph)_2$ exists as a rapidly interconverting mixture of both isomers **1***b* and **1***c* (7, 10), but 1,2-$Os_3(CO)_{10}(PEt_3)_2$ is reported to exist only as the unsymmetrical isomer **1***c* (15). These results suggest that electronic effects also play a part in determining the molecular geometry.

In this report, we describe the reaction of $Os_3(CO)_{10}$-$(MeCN)_2$ with PFc_2Ph, which affords the unsymmetrical isomer of 1,2-$Os_3(CO)_{10}(PFc_2Ph)_2$, **2**, exclusively. This is a surprising result in view of the fact that PFc_2Ph is a very bulky ligand with a cone angle of 178° (16). The unusual electronic effect of the PFc_2Ph ligand is discussed together with a description of the crystal structure of **2**.

Experimental

Reactions were carried out under an argon atmosphere. The ^1H and ^{31}P nmr chemical shifts are given in ppm from TMS and 85% H_3PO_4, respectively, and were recorded by using a Bruker AC-200 spectrometer. Elemental analysis was performed by Mr. Peter Borda of this department. PFc_2Ph was prepared as previously described (16). The fast atom bombardment (FAB) mass spectrum was obtained by using an AEI MS-9 spectrometer and 3-nitrobenzyl alcohol as matrix.

Preparation of $Os_3(CO)_{10}(PFc_2Ph)_2$, 2

To a stirred solution of triosmium dodecacarbonyl (365 mg, 0.4 mmol) in dichloromethane (50 mL) was added acetonitrile (5 mL, excess) and trimethylamine oxide (67 mg, 0.9 mmol) (6). After 2 h, PFc_2Ph (385 mg, 0.8 mmol) was added to the above mixture and after another 2 h the solvent was removed under reduced pressure. The residue was applied to a silica chromatographic column and eluted with 4:1 petroleum ether/CH_2Cl_2. Some very small bands were not collected. The only major product **2** (75%) eluted as the fourth (orange) band; $^{31}P\{^1H\}$ nmr σ: −25.4, −29.8; ^1H nmr σ: 7.76(m, 2H), 7.28(bm, 8H), 4.54(m, 4H), 4.46(m, 4H), 4.40(m, 2H), 4.24(m, 14H), 4.14(s, 10H), 4.04(m, 2H). Mass spectrum (FAB) *m/z*: 1809 (base peak), 1781, 1753, 1725, 1697, 1669, 1648, 1641, 1620, 1613, 1596, 1585. Anal. calcd. for $C_{62}H_{46}Fe_4O_{10}Os_3P_2$: C 41.21, H 2.57; found: C 41.21, H 2.62.

X-ray crystallographic analysis of 2

X-ray quality crystals of **2** were obtained by slow evaporation of the eluting solvent following chromatographic separation. An orange crystal ca. 0.07 × 0.27 × 0.35 mm in size was mounted on a glass fiber. Unit-cell parameters were refined by least squares on setting angles for 25 reflections (2θ = 28.0–30.6°) measured on a diffractometer with Mo-K_α radiation (λ = 0.71069 Å). Crystal data at 21°C are as follows:

$C_{62}H_{46}Fe_4O_{10}Os_3P_2$ f.w. = 1806.97

Monoclinic, a = 27.846(4), b = 11.253(4), c = 38.520(3) Å, β = 107.813(9)°, V = 11492(5) Å^3, Z = 8, ρ_c = 2.089 Mg m^{-3}, $F(000)$ = 6880, μ(Mo-K_α) = 77.09 cm^{-1}. Absent reflections: *hkl*, *h+k* odd, and *h01*, *l* odd, space group $C2/c$ (No. 15) from structure analysis.

Intensities were measured with graphite-monochromated Mo-K_α radiation on a Rigaku AFC6S diffractometer. An ω scan at 32° min^{-1} over a range of (0.85 + 0.35 tan θ)° in ω (with up to 8 rescans, background/scan time ratio = 0.5) was employed. Data were measured to 2θ = 50°. The intensities of three check reflections, measured every 200 reflections throughout the data collection, showed only small random variations. After data reduction[2] an empirical absorption correction, based on azimuthal scans for three reflections, was applied. Transmission factors range from 0.42 to 1.00. Of the 10 914 reflections measured, 10 662 were unique (R_{merge} = 0.037) and 5073 had intensities greater than or equal to $3\sigma(F^2)$ above background where $\sigma^2(F^2) = [S^2(C + 4B) + (0.01F^2)^2]/Lp^2$ with S = scan speed, C = scan count, B = total background count, and Lp = Lorentz–polarization factor.

The structure was solved by heavy atom methods, the Os and Fe coordinates being determined from the Patterson function. The analysis was initiated in the centrosymmetric space group $C2/c$ on the basis of the Patterson function, this choice being confirmed by the successful solution and refinement of the structure. The remaining non-hydrogen atoms were positioned from subsequent difference Fourier syntheses. The non-hydrogen atoms were refined with anisotropic thermal parameters and the hydrogen atoms were fixed in calculated positions (C—H = 0.98 Å, B_H = 1.2 $B_{bonded\ atom}$). Scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from ref. (17). The weighting scheme $w = 4F_o/\sigma^2(F_o^2)$ gave uniform average values of $w(|F_o|-|F_c|)^2$ over ranges of both $|F_o|$ and sin θ/λ and was employed in the final stages of full matrix least-squares refinement of 730 variables. Reflections with $I < 3\sigma(F^2)$ were not included in the refinement. Convergence was reached at R = 0.030 and R_w = 0.027 for 5073 reflections with $I \geq 3\sigma(I)$. The function minimized was $\Sigma w(|F_o|-|F_c|)^2$, $R = \Sigma||F_o|-|F_c||/\Sigma|F_o|$, $R_w = (\Sigma w(|F_o|-|F_c|)^2/\Sigma w|F_o|^2)^{1/2}$.

[a] Cp(1–8) refer to the unweighted centroids of the C(1–5, 6–10, . . ., 36–40) cyclopentadienyl rings, respectively.

On the final cycle of refinement the maximum parameter shift corresponded to 0.16σ. The mean error in an observation of unit weight was 1.22. The final difference map showed maximum fluctuations of −0.64 to +0.50 e Å^{-3}. The final positional and (equivalent) isotropic thermal parameters for the non-hydrogen atoms appear in Table 1. Selected bond lengths and angles are given in Tables 2 and 3. Complete tables of hydrogen atom parameters, anisotropic thermal parameters, torsion angles, intermolecular contacts, least-squares planes, and structure factors have been deposited.[3]

Results and discussion

The reaction of $Os_3(CO)_{10}(MeCN)_2$ with PFc_2Ph gives a good yield of the expected product 1,2-$Os_3(CO)_{10}(PFc_2Ph)_2$,

[3] Supplementary material mentioned in the text may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0R6.

Table S1 (hydrogen atom coordinates) and the ORTEP stereoview of **2** have also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

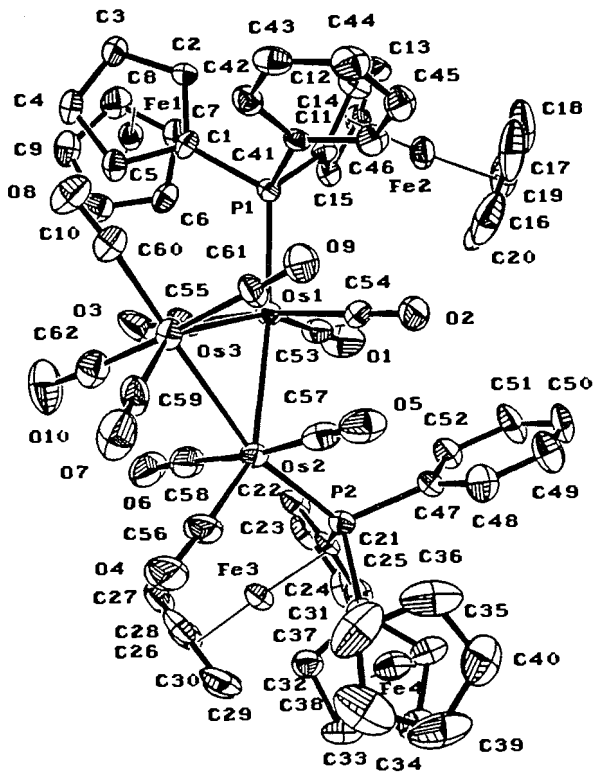

FIG. 1. Stereoview of the $\{[(\eta^5-C_5H_5)Fe(\eta^5-C_5H_4)]_2(C_6H_5)P\}_2Os_3(CO)_{10}$ molecule, **2**; 33% probability thermal ellipsoids are shown for the non-hydrogen atoms.

2. The $^{31}P\{^1H\}$ nmr spectra of **2** run in a range of solvents including $CDCl_3$, CD_3CN, DMSO-d_6, C_6D_6, and C_7D_8 show two sharp signals of equal intensity clearly showing it to be the isomer of structure **1***c*. No evidence for the presence of other isomers was found. This conclusion was confirmed by an X-ray diffraction study.

The molecular structure of **2** is shown in Fig. 1. Like $Os_3(CO)_{12}$ it is a closed Os_3 cluster but one carbonyl group on Os(1) and Os(2) is replaced by the phosphine ligand PFc_2Ph. The Os—Os distances are as usual with Os(2)—Os(3) (2.893(1) Å) being slightly shorter than the other two (2.9237(6) and 2.9259(9) Å). The two bulky phosphines adopt the **1***c* unsymmetrical arrangement. The osmium centers have distorted octahedral geometry, and although the two phosphines are situated on one side of the Os_3 plane (0.4491 Å for P(1) and 0.3369 Å for P(2)), these ligands clearly occupy two equatorial coordination sites. One equatorial carbonyl (C(59)) also lies on the same side of the Os_3 plane (by 0.3213 Å), while the other three alternating equatorial carbonyls (C(53), C(56), and C(60)) are situated on the other side (0.3227, 0.3106, and 0.2167 Å, respectively). As a consequence the six axial carbonyls are distorted from their idealized positions. On the P(1), P(2), C(59) side of the Os_3 plane, C(54), C(57), and C(61) have moved towards Os(2), Os(3), and Os(1), respectively (C(54)—Os(1)—Os(2) 80.8(3)°, C(57)—Os(2)—Os(3) 83.1(3)°, C(61)—Os(3)—Os(1) 81.4(3)°). On the other side of the Os_3 plane, a compensating motion of C(55), C(58), and C(62) occurs towards Os(3), Os(1), and Os(2), respectively (C(55)—Os(1)—Os(3) 83.4(3)°, C(58)—Os(2)—Os(1) 81.3(3)°, C(62)—Os(3)—Os(2) 85.5(3)°).

The Os(1)—C(53) and Os(2)—C(56) bond distances (1.87(1) and 1.88 (1) Å) are probably shorter than the other Os—C distances, while all C—O distances are the same and normal (average 1.14(1) Å) and all Os—C—O bonds linear (average 175(1)°). Both Os—P distances are the same and normal (2.353(2) and 2.359(3) Å). All Fe—C distances are the same and so are the Fe—Cp distances. The Cp rings are parallel with small dihedral angles (2.48° for Fc(1), 3.27° for Fc(3)), but the values for Fc(2) and Fc(4) are larger than usual (6.75° and 9.06°, respectively). This is also indicated by the Cp—Fe—Cp bond angles (Cp(3)—Fe(2)—Cp(4) = 173.5(4)° and Cp(7)—Fe(4)—Cp(8) = 172.7(4)°, while Cp(1)—Fe(1)—Cp(2) = 177.0(2)° and Cp(5)—Fe(3)—Cp(6) = 176.4(3)° are usual).

Many phosphine complexes of the class $M_3(CO)_{10}L_2$ are known but, as discussed in the Introduction, few are reported to be of structures other than **1***b*. Compound **2** is the first molecule of structure **1***c* to be characterized in the solid state. Our recent work with ligands such as $PFcPh_2$, PFc_2Ph, and $PFcPr^i_2$ shows that **2** is not unique and that mixtures of isomers **1***b* and **1***c* can be obtained for both osmium and ruthenium complexes.[4] In view of the considerable steric bulk of these ligands (16) this phenomenon must be somewhat attributable to the electronic effects of these ferrocenyl-

phosphine ligands. The stereospecificity of the product **2** can be attributed to the strong electron-donating ability of the PFc_2Ph ligand. In contrast to phenyl, which is weakly electron withdrawing, ferrocenyl groups are strongly electron releasing. Strongly electron-donating ligands will have a high *trans* influence and this will cause the molecule to adopt the **1***c* geometry where the two phosphines are not *trans* to each other via the Os—Os bond. Electronic effects must also come into play in the case of the PMe_2Ph and PEt_3 complexes described above (both these ligands are less bulky than PFc_2Ph).

Transannular Diels–Alder cyclization of a substituted 13-membered macrocyclic triene. An approach to the A.B.C.[6.6.5] rings of the *Veratrum* alkaloids

MIGUEL QUIMPÈRE, LUC RUEST, AND PIERRE DESLONGCHAMPS[1]

Laboratoire de synthèse organique, Département de chimie, Faculté des sciences, Université de Sherbrooke, Sherbrooke (Québec), Canada J1K 2R1

Received February 24, 1992

MIGUEL QUIMPÈRE, LUC RUEST, and PIERRE DESLONGCHAMPS. Can. J. Chem. **70**, 2335 (1992).

The synthesis and Diels–Alder cyclization of a substituted macrocyclic 13-membered triene **45** is described. Tricyclic compound A.B.C.[6.6.5] **46** having ring junctions of *cis-anti-cis* (CAC) stereochemistry was used to investigate the possibility of introducing a hemiketal oxygen bridge between positions 9 and 4 of the *Veratrum* alkaloid skeleton.

MIGUEL QUIMPÈRE, LUC RUEST et PIERRE DESLONGCHAMPS. Can. J. Chem. **70**, 2335 (1992).

On décrit la synthèse et la cyclisation Diels–Alder d'un macrocycle substitué à 13 chaînons **45**. Le composé tricyclique A.B.C.[6.6.5] **46** de stéréochimie *cis-anti-cis* (CAC) en jonction de cycle a été utilisé pour étudier la possibilité d'introduire un pont d'oxygène hémicétalique entre les positions 9 et 4 des alkaloïdes *Veratrum*.

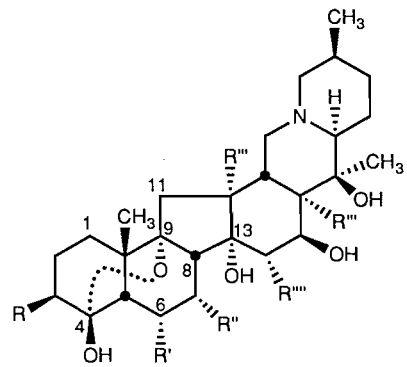
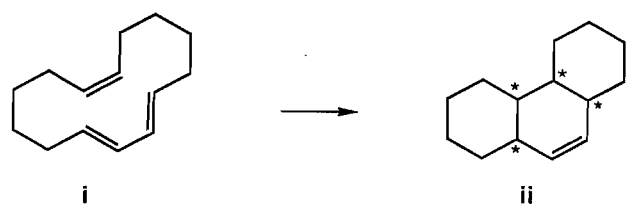
Veratrum alkaloids are an important category of natural compounds (1) obtained from the *Liliaceae* family, from *Veratrum album* in Europa and from *Veratrum viride* in North America. These alkaloids have been known since the early 1800's (2) for their sternutatory properties, but it was only in the late 1940's that their isolation and identification was undertaken systematically (3). At least 40 compounds from this family are now known and they all have the main hexacyclic skeleton presented in Fig. 1. There are four major types, differing in the hydroxylation pattern: germine (**1**) (4), veracevine (**2**) (5), protoverine (**3**) (4*a*, 6), and zygadenine (**4**) (7) and its 3-epimer cevine (**5**). These compounds are found in nature as esters of different carboxylic acids. The biological activity (8) of these steroidal alkaloids, particularly their ability to lower blood pressure (9), was studied in the 1950's.



1 Germine R = β-OH, R' = R''' = H, R'' = R'''' = OH
2 Veracevine R = β-OH, R' = R'' = R'''' = H, R''' = OH
3 Protoverine R = β-OH, R' = R'' = R'''' = OH, R''' = H
4 Zygadenine R = β-OH, R' = R'' = R''' = H, R'''' = OH
5 Cevine R = α-OH, R' = R'' = R'''' = H, R''' = OH

FIG. 1. Ceveratrum major isometric alkamines.

In spite of the large pharmacological potential of these compounds, to our knowledge no group has attempted to devise a total synthesis of a *Veratrum* alkaloid. No doubt the presence of several asymmetric centers (17 in protoverine (**3**)) and an unusual presence of a tertiary hydroxyl group at position 9 (steroid numbering) could account for this situation. A synthetic strategy with a high degree of control on chemo-, regio-, and stereoselectivity has to be used in order to synthesize efficiently molecules of such complexity. Intramolecular processes (10–12) usually give excellent control on these factors. In recent years, our group has shown (13, 14) that the transannular Diels–Alder cyclization of macrocyclic trienes (see general formulation in Scheme 1, i → ii) is an efficient tool to synthesize functionalized 14-membered tricyclic A.B.C.[6.6.6] compounds with a high level of stereoselectivity.



i ii

SCHEME 1. Transannular Diels–Alder cyclization.

Moreover, this strategy was also been applied in a model study by Bérubé and Deslongchamp (15) from our group to synthesize a tricyclic homolog **8** (Scheme 2), namely an A.B.C.[6.6.5] skeleton, starting with a 13-membered macrocyclic *trans-trans-cis* (TTC) triene **7**, which was formed by the internal cyclization of an acyclic malonate chloride **6**. The use of an oxygen substituent on the dienophilic part of the macrocyclic triene showed the interesting possibility of introducing such a substituent at position 9 (steroid numbering) of the resulting tricyclic product. It was shown that the reaction of a *trans-trans-cis* (TTC) macrocyclic triene **7** leads to a mixture of tricyclic compounds **8** having *trans-syn-trans* (TST) and *cis-syn-cis* (CSC) geometries (2:1, respectively) at the ring junctions.

These preliminary results were used to devise a synthetic strategy leading to the A.B.C. rings of the *Veratrum* alkaloids. Indeed, in a recent model study (16) we showed (Scheme 3*a*) that the same strategy could be applied to the synthesis of an A.B.C.[6.6.5] tricyclic compound (see **11**) having the *cis-anti-cis* (CAC) geometry at the ring junctions. In this work and as shown in previous series (14*b*), it

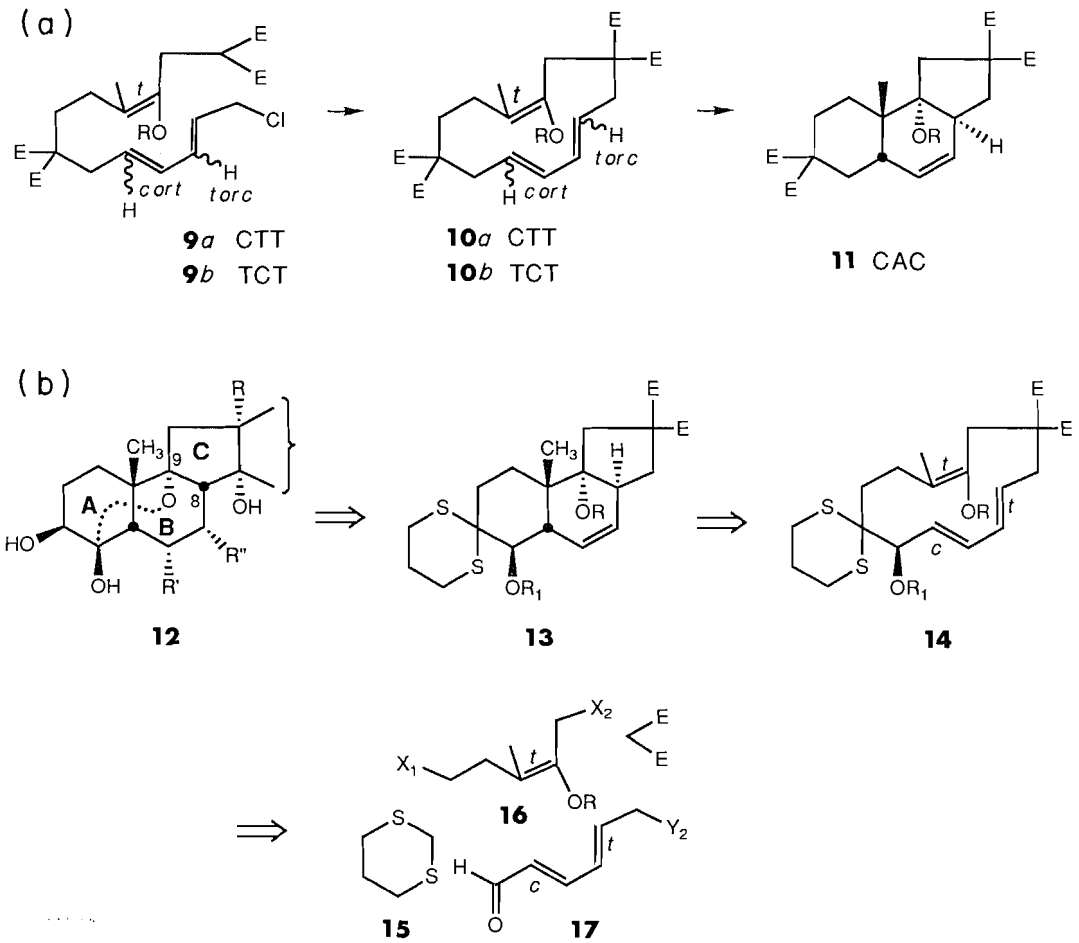

SCHEME 3

was found that both macrocyclic trienes **10***a* (CIT) and **10***b* (TCT) can give access to tricycle **11** (CAC).

The results of the first two model studies led us to devise a new route affording tricyclic intermediates that are more similar to the A.B.C.[6.6.5] portion of the general *Veratrum* skeleton. The retrosynthetic analysis shown in Scheme 3*b* indicates that the A.B.C. system (see **12**) might be formed from a tricyclic compound **13** itself obtained by a transannular Diels–Alder cyclization of macrocycle **14**. This macrocyclic triene might come from the assemblage of 1,3-dithiane (**15**), dienophile **16**, diene **17**, and dimethylmalonate in a highly convergent synthetic sequence. The use of 1,3-dithiane as a connector between dienophile **16** and diene **17** will insure the right oxidation level in the future ring A. The CT geometry in the diene **17** should give a CAC geometry in the final tricycle. The stereochemistry at position 8 will therefore have to be corrected with the help of functionalities left in ring C or B.

We will discuss now the synthesis of dienophile **16** and diene **17** as well as their assemblage to macrocycle **13**. We will then present the results of its Diels–Alder cyclization and we will report chemical transformations carried out on tricycle **13** to set the hemiketal bridge between positions 9 and 4.

SCHEME 4

Dienophile 32

Following the methodology used previously (16), ketone **18** (Scheme 4) was alkylated in good yield with the lithium derivative of methyl methoxymethyloxyacetate (MOMO acetate) to afford a separable mixture of alcohols **19***a* and **19***b*. These, as a mixture, were dehydrated by thionyl chloride (17) in pyridine to α,β-unsaturated esters **20***a* and **20***b* (unseparable mixture) and unconjugated esters **21** and **22** in a ratio of (approximately) 1:1:2:2, respectively. Compounds **20***a* and **20***b* are the *cis* and *trans* isomers, respectively, and the double bond geometry was established by the following observations: a careful separation of diastereoisomers **19***a* and **19***b* provided an opportunity to obtain the pure α,β-unsaturated esters **20***a* and **20***b*, respectively, after dehydration (Scheme 5). These pure conjugated esters **20***a* and **20***b* were separately desilylated to the corresponding alcohols **24***a* and **24***b*. During this transformation, compound **24***a* was partly cyclized to lactone **25**, which was characterized. This cyclization proved that compound **24***a* was the *cis* (*E*) isomer. The two unconjugated esters **21** and **22** (Scheme 4) were converted to esters **20***a* and **20***b* by isomerization of the double bond with potassium methoxide in methanol.

The mixture of *E* and *Z* isomers **20** was reduced to easily separable alcohols **23***a* (*E* isomer) and **23***b* (*Z* isomer) with diisobutylaluminum hydride (DIBAL). Alcohol **23***b*, the *trans* isomer, was acylated with mesitoic acid (18) in the presence of dicyclohexylcarbodiimide (DCC) and *N*,*N*-dimethylaminopyridine (DMAP) to give mesitoate **26**, a hindered ester that is inert to butyllithium and to 1,3-dithiane anion used subsequently (*vide infra*). Desilylation of ether **26** with fluoride ion (19) and mesylation (20) of the resulting alcohol **27** led to mesylate **28**, which was transformed to iodide **29** by sodium iodide in refluxing acetone.

At this point, three 1,3-dithiane connectors were tested in the form of their anions: 1,3-dithiane, 2-trimethylstannyl-1,3-dithiane (21), and 2-tributylstannyl-1,3-dithiane (22). In our

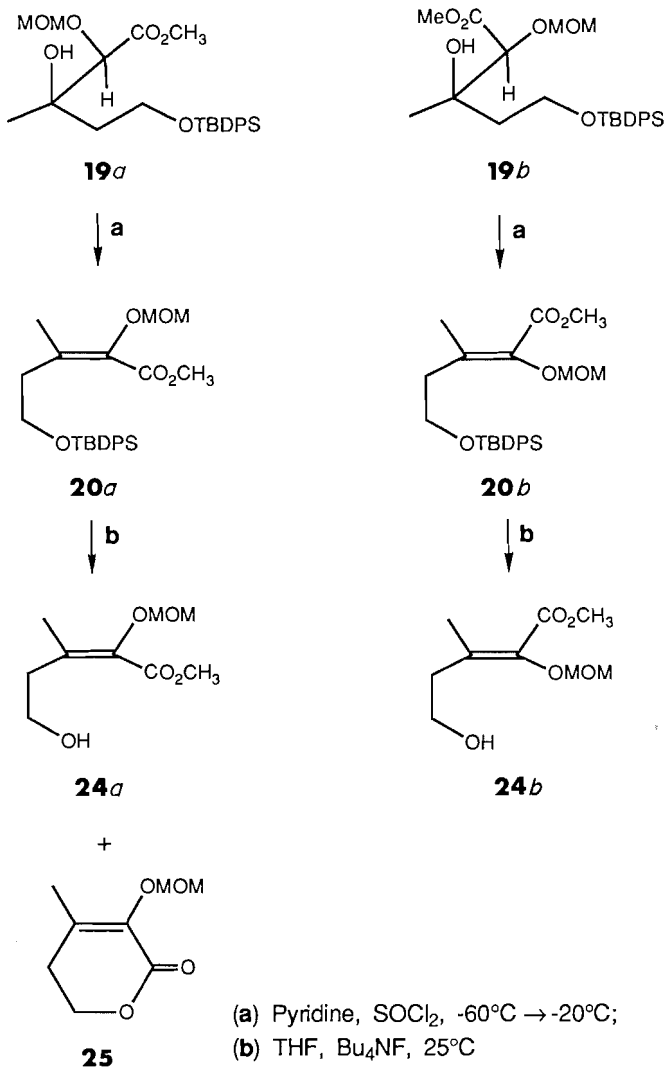

SCHEME 5

hands, following a Seebach procedure (21, 22), the reaction of iodide **29** with 2-lithio-1,3-dithiane gave a low yield for adduct **30** (12%); with 2-lithio-2-trimethylstannyl-1,3-dithiane the yield for compound **31** was only 38%. Nevertheless, the use of 2-lithio-2-tributylstannyl-1,3-dithiane increased the yield to 87% for adduct **32**, the dienophilic synthon that has still to be alkylated with dienic synthon **36** to give the acyclic triene **44**.

Diene 36 and acyclic triene 44

Synthesis of diene **36** began with *cis-trans* diene **33** easily obtained from *cis*-but-2-ene-1,4-diol (14*a*, 16). Following previous work in our group, silylation of alcohol **33** (Scheme 6) with *tert*-butoxydiphenylsilyl chloride (23) led to diene **34** whose tetrahydropyranyl protecting group was then cleaved in *tert*-butanol in the presence of pyridinium *para*-toluenesulfonate (24) to obtain *cis-trans* allylic alcohol **35**. The use of *tert*-butanol instead of *i*-propanol (see ref. 16) eliminated an otherwise extensive exchange of the alkoxy group on the silyl ether moiety. Oxidation of alcohol **35** at low temperature (Swern conditions) (25) furnished aldehyde **36**.

The coupling reaction between dienophile **32** and aldehyde **36** was performed in good yield (86%) at low temperature (−93°C). We observed that the temperature of the reaction mixture has a critical influence on the yields. The *trans*-metallation of stannyl derivative **32** to the lithio derivative was first performed at −93°C by a fast addition of a precooled (−90°C) solution of butyllithium. A cooled (−90°C) solution of aldehyde **36** was then rapidly added to the mixture. Without these specific experimental conditions, several side reactions occurred, such as the formation of adduct **38** which comes from anionic attack on aldehyde **36** by the *para*-methyl group of the mesitoate moiety after its deprotonation by either butyllithium or internally by the 2-lithio-1,3-dithiane anion.

The alcohol function of **37** was silylated with *tert*-butyldimethylsilyl triflate and the resulting protected ester **39** was reduced to alcohol **40** with lithium aluminum hydride. Chloride **41**, obtained (26) from alcohol **40**, was converted to malonate **42** by substitution with methyl sodiomalonate. After selective cleavage of the terminal *tert*-butoxydiphenylsilyl ether of compound **42** with fluoride ion in methylene chloride (23), allylic alcohol **43** was converted to the desired acyclic triene, allylic chloride **44**.

Macrocyclization and transannular Diels–Alder reaction

Slow addition of trienic malonate chloride **44** to a warm (78°C) solution of cesium carbonate and 18-crown-6 ether in acetonitrile led to the formation of macrocyclic triene **45** in 75% yield. Subsequent heating of this compound in toluene (220°C, 7 h) resulted in the smooth formation of a single tricycle **46** (76%) together with a secondary compound (16%) to which structure **47** has been assigned on the basis of its spectroscopic data. At a slightly higher temperature and a shorter reaction time (240°C, 1.5 h) the yield was somewhat lowered (**46** (69%) and **47** (15%)).

The assignment of stereochemistry for tricycle **46** was done on the basis of its nmr data, which show a very small coupling constant (1.8 Hz) between the allylic proton at position 5 (steroid numbering) and the proton at position 4 bearing the *O*-silyl group. This would be consistent with an equatorial–equatorial or an equatorial–axial coupling. The latter possibility has been discarded after the following considerations and analysis of molecular models.

Thus, on the basis of our previous results (14), macrocyclic triene CTT **45** should react to give only tricycle CAC. In the present instance (see Scheme 7), two stereoisomers **46***a* and **46***b*, which are different only in the relative configuration of the silyloxy group (as enantiomeric structures), are possible. Indeed, macrocyclic triene **45** can react through conformation **45**i or **45**ii to produce either tricycle **46***a* or **46***b* in their conformations **46***a*i and **46***b*i, respectively. The process **45**ii → **46***b*i must be disfavored due to the important steric hindrance from the silyloxy substituent, which has to take a pseudo-axial orientation. That steric interaction is absent in the process **45**i → **46***a*i in which the silyloxy substituent is in a pseudo-equatorial orientation. Thus, the favored process should lead to stereoisomer **46***a* in which both protons at positions 4 and 5 are equatorial (see the more stable conformation, **46***a*ii and **46***b*ii of **46***a* and **46***b*). This conclusion was later firmly secured by X-ray diffraction analysis of a crystalline derivative **62** (*vide infra*).

Compound **47** shows three olefinic protons (5.23, 5.45, and 5.60 ppm) and a methyl group attached to a double bond (1.45 ppm) in its nmr spectrum. By 2D nmr experiments it was possible to propose a bicyclic structure **47** for this compound, which could result from a transannular ene-type reaction (see **45**iii or **45**iv → **47**) (Scheme 8), examples of

which were observed and reported previously (14*a*). The geometry of the newly formed double bond and the stereochemistry at the ring junction are still unknown. Molecular models show that this ene reaction may involve either proton H_A (**45**iii) or H_B (**45**iv), leading to different geometries for the trisubstituted olefin.

Towards the A.B.C. rings of Veratrum *alkaloids*

To test the validity of the present model series in an eventual sequence towards the A.B.C. rings of *Veratrum* alkaloids, we investigated the introduction of the oxygen bridge between positions 9 and 4.

The thioketal moiety of tricycle **46** (Scheme 9) was cleaved with mercuric chloride on calcium carbonate (27) in aqueous acetonitrile, and then the obtained ketone **54** was reduced with methanolic sodium borohydride to epimeric separable alcohols **55** and **56**, both useful for this preliminary investigation. The epimers were identified through their benzoate derivatives **57** and **58**, which showed that the proton at C_3 is axial in **57** (and therefore in **55**) (one coupling constant is 12.5 Hz) and equatorial in **58** (and therefore in **56**) (all the coupling constants are smaller than 3 Hz). Cleavage of the MOM protecting group of **57** and **58** in acid medium gave alcohols **59** and **60** selectively and in quantitative yield, leaving the *tert*-butyldimethylsilyl ether moiety unaffected. Subsequent treatment of silyl ether benzoate **59** with tetrabutylammonium fluoride led to hydroxybenzoate lactone **61** (19%) and diol lactone **62** (61%). The basicity of the reaction medium (presence of a catalytic amount of tetrabutyl ammonium hydroxide) was presumably sufficient to promote lactonization of the free 9-hydroxyl group with the adjacent methyl ester of the malonate moiety and to induce

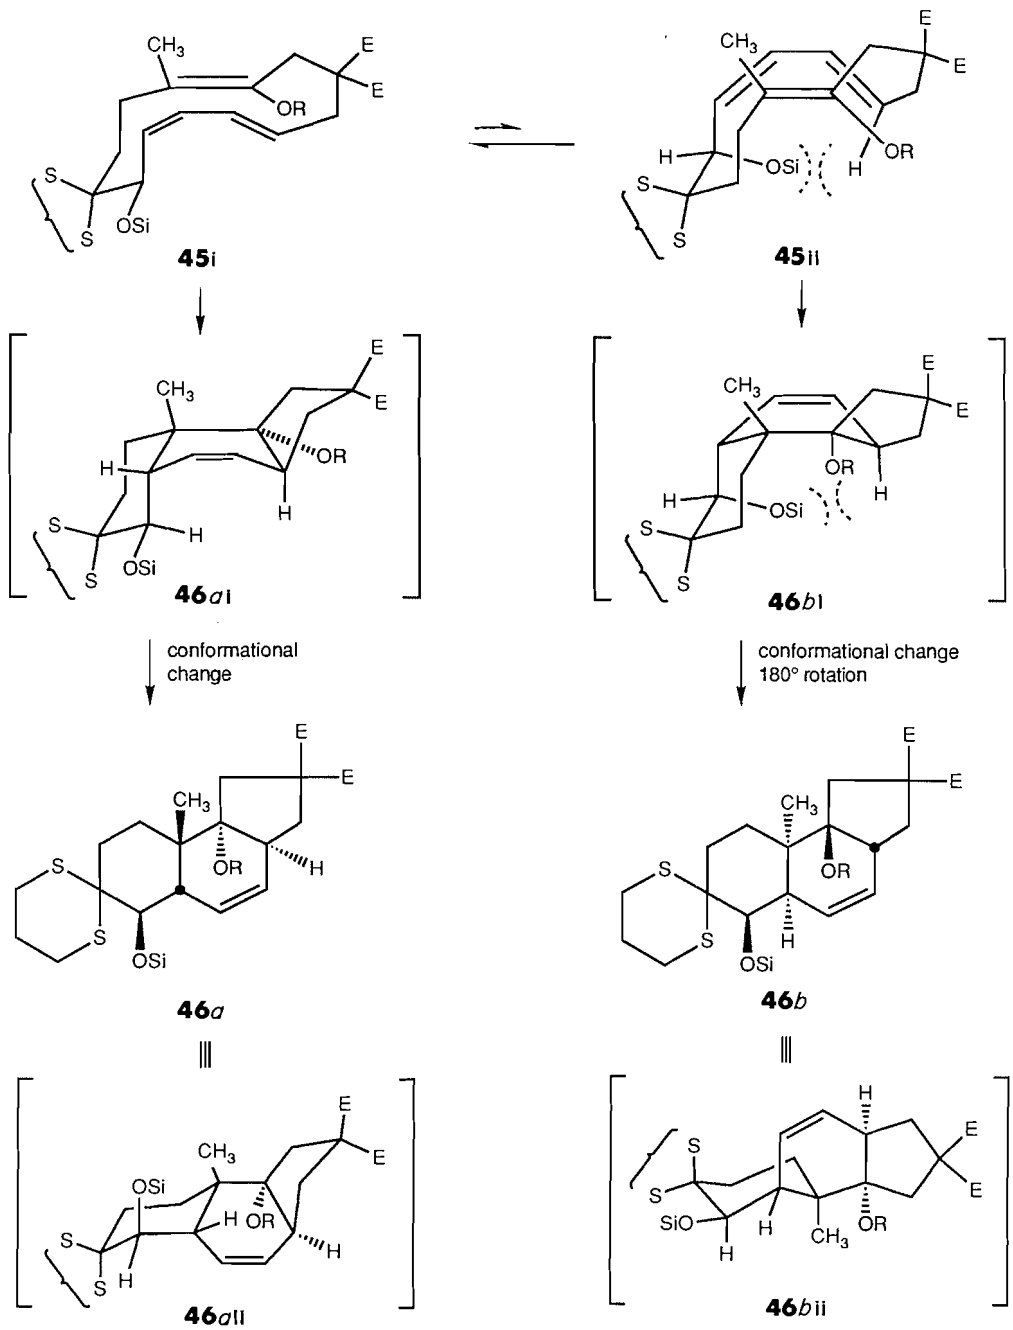
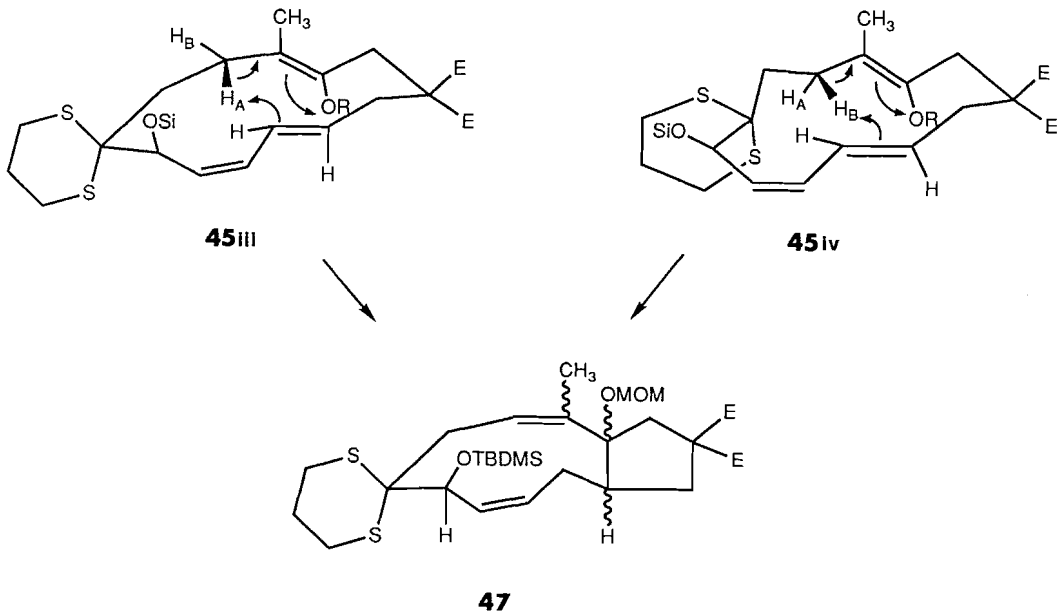


SCHEME 7. R = MOM; E = CO_2CH_3.

transesterification of the equatorial benzoate at position 3. X-ray diffraction analysis (see Fig. 2) of crystalline diol **62** (28) confirmed the α and axial orientation of the proton at C_3, as well as the predicted stereochemistry of all the asymmetric centers of the molecule, in particular the ones that had been formed during the transannular Diels–Alder reaction.

On the other hand, cleavage of silyl benzoate **58** with fluoride ion led to benzoate alcohol lactone **63** in good yield (81%). Even though compound **61** has its 9-hydroxyl inserted into a lactone bridge, and therefore not immediately available for a hemiketal bridging with position 4, we tested the oxidation of the axial β-hydroxyl at position 4 of that compound with PCC and obtained ketone **64** as the only product. We did not investigate any further reaction at this point, having learned that the oxidation of the 4-OH group should be performed before the MOM cleavage. On the other hand the presence of the lactone bridge gives the opportunity of differentiating the two ester moieties of the malonate connector, which is a lead for further studies.

In conclusion, we have shown that it is possible to synthesize in good yield a specifically functionalized tricyclic A.B.C.[6.6.5] skeleton, having a *cis-anti-cis* (CAC) stereochemistry at the ring junction, by a transannular Diels–Alder reaction of a macrocyclic triene. Very recently, Dory (29) from our group showed that the use of a sulfone connector (besides a malonate) and a *trans-trans* diene in a similar general strategy has given access to a CAT tricyclic skeleton. Applied to our problem, this modification should



SCHEME 8

lead to a CAT A.B.C.[6.6.5] skeleton having the desired stereochemistry at the position 8 ring junction. Further studies are in progress in order to use this method and complete the synthesis of the first three rings of the *Veratrum* alkaloid skeleton.

Experimental

All reactions were carried out under an argon or anhydrous nitrogen atmosphere. All solvents were dried before use. Chromatographic separations were made using Merck Kieselgel 60 (230–400 mesh ASTM). The infrared spectra (ir) were taken on a Perkin–Elmer 681 spectrophotometer or on a FT-IR Bomem MB-102. Proton nmr spectra were recorded on a Bruker WP-80 or Bruker WM-250 instrument. Carbon nmr spectra were recorded on a Bruker WM-250 instrument. Chemical shifts are reported in δ values relative to tetramethylsilane or chloroform. Abbreviations used are m: multiplet, s: singlet, d: doublet, t: triplet, dd: double doublets, etc. Mass spectral assays (ms *m/e*) and peak matching were obtained using a VG Micromass ZAB-1F spectrometer.

*Methyl 5-*tert*-butyldiphenylsilyloxy-3-hydroxy-2-methoxymethyloxy-3-methylpentanoate (**19**a and **19**b)*

To a cold (−78°C) solution of lithium diisopropyl amide (LDA), obtained from diisopropylamine (DIPA) (20.5 mL, 146 mmol) and BuLi (1.6 mL in hexane) (90 mL, 144 mmol) in tetrahydrofuran (500 mL) at −20°C, was added dropwise (3.5 h) a solution of methyl methoxymethyloxyacetate (19.43 g, 145 mmol) in tetrahydrofuran (150 mL). The mixture was stirred at −78°C for 15 min and a solution of ketone **18** (23.2 g, 71.17 mmol) in tetrahydrofuran (150 mL) was added dropwise (1 h). After an additional 60 min at −78°C and treatment with a saturated solution of ammonium chloride the mixture was extracted with methylene chloride; the organic layer was dried over sodium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (19:1–7:3) as the eluent to afford alcohols **19***a* and **19***b* (31.9 g, 97.4%). These two diastereoisomers were separated on a small scale for their characterization.

Isomer **19**a (less polar): ir ($CHCl_3$): 3500, 1740 cm^{-1}; ^1H nmr ($CDCl_3$, δ ppm): 1.05 (9H, s, $-C(CH_3)_3$), 1.30 (3H, s, $-CH_3$), 1.90 (2H, m, $-CH_2-CH_2OTBDPS$), 3.33 (3H, s, $-OCH_3$), 3.77 (3H, s, $-CO_2CH_3$), 3.92 (2H, m, $-CH_2-OTBDPS$), 4.09 (1H, s, $-CH(CO_2CH_3)-$), 4.64 (2H, s, $-OCH_2O-$), 7.42 and 7.67 (10H, m, Ph_2).

Isomer **19**b (more polar): ir ($CHCl_3$): 3500, 1740 cm^{-1}; ^1H nmr ($CDCl_3$, δ ppm): 1.04 (9H, s, $-C(CH_3)_3$), 1.30 (3H, s, $-CH_3$), 1.80 (1H, dt, J = 6 and 15 Hz, $-CHH-CH_2OTBDPS$), 2.03 (1H, dt, J = 6 and 15 Hz, $-CHH-CH_2OTBDPS$), 3.38 (3H, s, $-OCH_3$), 3.75 (3H, s, $-CO_2CH_3$), 3.92 (2H, dd, J = 5.4 and 7 Hz, $-CH_2-OTBDPS$), 4.06 (1H, s, $-CH(CO_2CH_3)-$), 4.69 (2H, m, $-OCH_2O-$), 7.42 and 7.67 (10H, m, Ph_2).

*Methyl (2*E*) and (2*Z*)-5-*tert*-butyldiphenylsilyloxy-2-methoxymethyloxy-3-methylpent-2-enoate (**20**a and **20**b)*

Starting from alcohols **19***a* and **19***b* separately or a mixture of both:

To a solution of mixed alcohols **19***a* and **19***b* (29.5 g, 64.1 mmol) in pyridine (400 mL), at −60°C, thionyl chloride (25 mL, 343 mmol) was added all at once. The mixture was stirred at −60°C 15 min, at −30°C for 30 min, and at −20°C for 100 min. A saturated solution of sodium bicarbonate was added and the mixture was extracted with methylene chloride. The organic layer was dried over magnesium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (19:1–7:3) as the eluent to afford a mixture of unseparable α,β-unsaturated esters **20***a* and **20***b* and the two separable isomers **21** and **22** (**20***a* and **20***b* (7.65 g, 27%); **21** and **22** (16.4 g, 58%)).

Starting from isomers **21** and **22**:

To a solution of isomers **21** and **22** (16 g, 36.2 mmol) in anhydrous methanol (250 mL) was added potassium methoxide obtained from potassium (3 g, 77 mmol) dissolved in methanol (250 mL). The mixture was refluxed for 3 h, cooled, and poured into a saturated solution of ammonium chloride. The mixture was acidified to pH 6 with hydrochloric acid and extracted with methylene chloride. The organic layer was dried over sodium sulfate, evaporated, and the residue was purified by flash chromatography using hexane:ethyl acetate (19:1–7:3) as the eluent to afford pure α,β-unsatured esters **20***a* and **20***b* (11.3 g, 71%).

Isomer (E)-**20**a (obtained pure from pure **19***a*): ^1H nmr ($CDCl_3$, δ ppm): 1.03 (9H, s, $-C(CH_3)_3$), 1.90 (3H, s, $-CH_3$), 2.75 (2H, t, J = 7 Hz, $-CH_2-CH_2OTBDPS$), 3.50 (3H, s, $-OCH_3$), 3.71 (3H, s, $-CO_2CH_3$), 3.78 (2H, t, J = 7 Hz, $-CH_2-OTBDPS$), 4.80 (2H, s, $-OCH_2O-$), 7.41 and 7.67 (10H, m, Ph_2).

*Isomer (Z)-**20*** (obtained pure from pure **19***b*): ^1H nmr ($CDCl_3$, δ ppm): 1.04 (9H, s, $-C(CH_3)_3$), 1.98 (3H, s, $-CH_3$), 2.57 (2H, t, J = 7 Hz, $-CH_2-CH_2OTBDPS$), 3.44 (3H, s, $-OCH_3$), 3.77 (3H,

*Methyl (2*E*)-5-hydroxy-2-methoxymethyloxy-3-methylpent-2-enoate (**24**a) and its conversion to 2-methoxymethyloxy-3-methylpent-2-en-5-olide (**25**)*

To a solution of pure **20***a* (22 mg, 0.05 mmol) in tetrahydrofuran (2 mL) was added at 0°C a solution of tetrabutylammonium fluoride (100 μL, 0.1 mmol). The mixture was stirred at room temperature for 2.5 h and the solvent was evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (4:1–3:2) as the eluent to afford pure lactone **25** (2 mg, 23%) and **24** (2.5 mg, 25%) (on silica gel, alcohol **24***a* partly forms lactone **25**). Lactone **25**: ir ($CHCl_3$, ν cm^{-1}): 1720, 1655; ^{1}H nmr ($CDCl_3$, δ ppm): 1.99 (3H, s, -CH_3), 2.50 (2H, t, J = 6.3 Hz, -CH_2CH_2-OCO-), 3.53 (3H, s, -OCH_3), 4.34 (2H, t, J = 6.2 Hz, -CH_2-CH_2-OCO-), 5.00 (2H, s, -OCH_2O-).

*Methyl (2*Z*)-5-hydroxy-2-methoxymethyloxy-3-methylpent-2-enoate (**24**b)*

To a solution of **20***b* (75 mg, 0.17 mmol) in tetrahydrofuran (6.0 mL), was added at 0°C a solution of tetrabutylammonium fluoride (340 μL, 0.34 mmol). The mixture was stirred at room temperature for 2 h and the solvent was evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (3:2) as the eluent to afford pure alcohol **24***b* (25 mg, 72%); ir ($CHCl_3$, ν cm^{-1}): 3600, 3460, 3030, 3010, 2950, 1720, 1640; ^{1}H nmr ($CDCl_3$, δ ppm): 2.09 (3H, s, -CH_3), 2.60 (2H, t, J = 6.3 Hz, -CH_2-CH_2OH), 3.53 (3H, s, -OCH_3), 3.79 (3H, s, -CO_2CH_3), 3.80 (2H, t, J = 6.3 Hz, -CH_2OH), 4.84 (2H, s, -OCH_2O-). Exact Mass calcd. for $C_9H_{16}O_5$: 172.0736 (M^+ − CH_3OH); found: 172.0734 ± 0.0005.

*(2*E*) and (2*Z*)-5-*tert*-Butyldiphenylsilyloxy-2-methoxymethyloxy-3-methylpent-2-en-1-ol (**23**a and **23**b)*

To a cold solution (−78°C) of esters **20** (8.55 g, 19.3 mmol) in methylene chloride (1 L) was added a solution of DIBAL (26 mL, 1.5 M, 39 mmol). The mixture was stirred vigourously for 2 h, then treated with decahydrated sodium sulfate (8 g). The mixture was warmed to room temperature, diluted with acetone (1 L), and stirred overnight. The mixture was dried over anhydrous sodium sulfate, filtered, and the residue on filter washed five times with acetone. Evaporation of the solvent left a residue, which was purified by flash chromatography using hexane:ethyl acetate (4:1–3:2) as the eluent to afford pure alcohols **23***a* (1.28 g, 16%) and **23***b* (6.60 g, 83%); ir (CH_2Cl_2, ν cm^{-1}): 3600, 3480, 3060, 2960, 2940, 2860, 1680. Exact Mass calcd. for $C_{24}H_{34}O_4Si$: 414.2226 (M^+); found: 414.2234 ± 0.0012.

*(*E*) Isomer **23**a* (less polar): ^{1}H nmr ($CDCl_3$, δ ppm): 1.04 (9H, s, -$C(CH_3)_3$), 1.64 (3H, s, -CH_3), 2.34 (2H, t, J = 6.5 Hz, -CH_2-CH_2OTBDPS), 2.93 (1H, t, J = 6 Hz, -OH), 3.50 (3H, s, -OCH_3), 3.66 (2H, t, J = 6.5 Hz, -CH_2OTBDPS), 4.12 (2H, d, J = 6 Hz, -CH_2OH), 4.87 (2H, s, -OCH_2O-), 7.41 and 7.66 (10H, m, Ph_2); ^{13}C nmr ($CDCl_3$, δ ppm): 15.4 (=C-CH_3), 19.0 (-$C(CH_3)_3$), 26.8 (-$C(CH_3)_3$), 35.8 (-CH_2-C=), 56.3 (OCH_3), 58.4 (CH_2-OTBDPS), 62.2 (CH_2-OH), 96.2 (OCH_2O), 119.7 (CH_3-C=C-), 127.7, 129.7, 133.5, 135.6 (C, aromatic), and 149.8 (C=C-OMOM).

*(Z) Isomer **23**b* (more polar): ^{1}H nmr ($CDCl_3$, δ ppm): 1.04 (9H, s, -$C(CH_3)_3$), 1.67 (3H, s, -CH_3), 2.39 (2H, t, J = 7 Hz, -CH_2-CH_2OTBDPS), 2.95 (1H, t, J = 6.4 Hz, -OH), 3.43 (3H, s, -OCH_3), 3.71 (2H, t, J = 7 Hz, -CH_2OTBDPS), 4.13 (2H, d, J = 6.4 Hz, -CH_2OH), 4.72 (2H, s, -OCH_2O-), 7.40 and 7.66 (10H, m, Ph_2); ^{13}C nmr ($CDCl_3$, δ ppm): 16.9 (=C-CH_3), 19.1 (-$C(CH_3)_3$), 26.8 (-$C(CH_3)_3$), 34.6 (-CH_2-C=), 56.2 (OCH_3), 58.5 (CH_2-OTBDPS), 62.3 (CH_2-OH), 96.7 (OCH_2O), 120.2 (CH_3-C=C-), 127.6, 129.6, 133.9, 135.6 (C, aromatic), and 148.9 (C=C-OMOM).

*(2Z)-5-*tert*-Butyldiphenylsilyloxy-2-methoxymethyloxy-3-methyl-1-(2,4,6-trimethylbenzoyloxy)pent-2-ene (**26**)*

To a solution of 2,4,6-trimethylbenzoic acid (mesitoic acid) (784 mg, 4.78 mmol), dicyclohexylcarbodiimide (1.39 g, 6.74 mmol), and 4-dimethylaminopyridine (400 mg, 3.28 mmol) in methylene chloride (8.8 mL) was added a solution of alcohol **23***b* (1.5 g, 3.62 mmol) in methylene chloride (3.7 mL). The mixture was stirred at room temperature for 7 days and a saturated solution of sodium bicarbonate was added. The mixture was extracted with methylene chloride, and the organic layer was dried over magnesium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (9:1–4:1) as the eluent to afford pure ester **26** (1.9 g, 94%); ir (CH_2Cl_2, ν cm^{-1}): 3060, 2960, 2940, 2860, 1720, 1610; ^{1}H nmr ($CDCl_3$, δ ppm): 1.03 (9H, s, -$C(CH_3)_3$), 1.75 (3H, s, -CH_3), 2.24 (6H, s, *ortho*-CH_3 of OMes), 2.27 (3H, s, *para*-CH_3 of OMes), 2.46 (2H, t, J = 7 Hz, -CH_2-CH_2OTBDPS), 3.37 (3H, s, -OCH_3), 3.72 (2H, t, J = 7 Hz, -CH_2-OTBDPS), 4.79 (2H, s, -OCH_2O-), 4.97 (2H, s, -CH_2-OMes), 6.82 (2H, s, CH aromatic), 7.38 and 7.66 (10H, m, Ph_2). Exact Mass calcd. for $C_{34}H_{44}O_5Si$: 503.2254 (M^+ − *tert*-butyl); found: 503.2250 ± 0.0015.

*(2Z)-2-Methoxymethyloxy-3-methyl-1-(2,4,6-trimethylbenzoyloxy)pent-2-en-5-ol (**27**)*

To a cold (0°C) solution of ester **26** (5.15 g, 9.2 mmol) in tetrahydrofuran (225 mL) was added a solution of tetrabutylammonium fluoride (18.4 mL, 18.4 mmol). The mixture was stirred at room temperature for 1.5 h and the solvent was evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (3:2) as the eluent to afford pure alcohol **27** (2.95 g, 99%); ir (CH_2Cl_2, ν cm^{-1}): 3620, 3500, 3060, 2990, 2960, 2930, 1720, 1610; ^{1}H nmr ($CDCl_3$, δ ppm): 1.84 (3H, s, -CH_3), 2.27 and 2.28 (9H, 2s, -CH_3 aromatic), 2.48 (2H, t, J = 6.4 Hz, -CH_2-CH_2OH), 3.46 (3H, s, -OCH_3), 3.73 (2H, t, J = 6.4 Hz, -CH_2-OH), 4.90 (2H, s, -OCH_2O-), 5.01 (2H, s, -CH_2-OMes), 6.84 (2H, s, CH aromatic). Exact Mass calcd. for $C_{18}H_{26}O_5$: 322.1780 (M^+); found: 322.1786 ± 0.0012.

*(2Z)-5-Mesyloxy-2-methoxymethyloxy-3-methyl-1-(2,4,6-trimethylbenzoyloxy)pent-2-ene (**28**)*

To a cold (0°C) solution of alcohol **27** (2.49 g, 7.73 mmol) and triethylamine (4.3 mL, 30.9 mmol) in methylene chloride (100 mL) was added mesyl chloride (950 μL, 12.3 mmol). The mixture was stirred at 0°C for 30 min and a saturated solution of sodium bicarbonate was added. The mixture was extracted with methylene chloride, and the organic layer was dried over sodium sulfate and evaporated. The residue was purified by flash chromatography with hexane:ethyl acetate (3:2) as the eluent to afford pure mesylate **28** (3.09 g, 98%); ir (CH_2Cl_2, ν cm^{-1}): 3060, 2990, 2960, 2930, 1725, 1360; ^{1}H nmr ($CDCl_3$, δ ppm): 1.86 (3H, s, -CH_3), 2.27 (9H, s, -CH_3 aromatic), 2.64 (2H, t, J = 7 Hz, -CH_2-CH_2OMs), 2.97 (3H, s, -SO_2-CH_3), 3.44 (3H, s, -OCH_3), 4.29 (2H, t, J = 7 Hz, -CH_2-OMs), 4.91 (2H, s, -OCH_2O-), 5.01 (2H, s, -CH_2-OMes), 6.84 (2H, s, CH aromatic). Exact Mass calcd. for $C_{19}H_{28}O_7S$: 400.1556 (M^+); found: 400.1563 ± 0.0014.

*(2Z)-5-Iodo-2-methoxymethyloxy-3-methyl-1-(2,4,6-trimethylbenzoyloxy)pent-2-ene (**29**)*

To a solution of mesylate **28** (2.25 g, 5.63 mmol) in acetone (340 mL) was added sodium iodide (38 g, 253 mmol). The mix-

For personal use only.

ture was heated at 56°C for 5.5 h and then acetone was evaporated. The residue was dissolved in ether (500 mL) and filtered. The solvent was evaporated and the residue was purified by flash chromatography using hexane:ethyl acetate (7:3) as the eluent to afford pure iodide **29** (2.2 g, 91%); ir (CH_2Cl_2, ν cm^{-1}): 3060, 2990, 1725, 1610; ^1H nmr ($CDCl_3$, δ ppm): 1.83 (3H, s, $-CH_3$), 2.28 (9H, s, $-CH_3$ aromatic), 2.77 (2H, t, J = 7.5 Hz, $-CH_2-CH_2I$), 3.18 (2H, t, J = 7.5 Hz, $-CH_2I$), 3.46 (3H, s, $-OCH_3$), 4.91 (2H, s, $-OCH_2O-$), 4.99 (2H, s, $-CH_2$-OMes, 6.84 (2H, s, CH aromatic). Exact Mass calcd. for $C_{18}H_{25}O_4I$: 432.0799 (M^+); found: 432.0817 ± 0.0013.

*(2Z)-2-Methoxymethyloxy-3-methyl-6,6-(propylenedithio)-1-(2,4,6-trimethylbenzoyloxy)hex-2-ene (**30**)*

A solution of butyllithium (1.6 M in hexane) (285 μL, 0.46 mmol) was added to a cold (−30°C) solution of 1,3-dithiane (55.7 mg, 0.46 mmol) in tetrahydrofuran (0.6 mL). The mixture was stirred between −35°C and −25°C for 100 min. Then it was cooled to −78°C and a solution of iodide **29** (150 mg, 0.347 mmol) in tetrahydrofuran (0.6 mL) was added. The mixture was stirred at −78°C for 3 h and at −45°C for 1 h. Water was then added and the mixture was extracted with methylene chloride. The organic layer was dried over sodium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (9:1–3:2) as the eluent to afford pure **30** (17 mg, 12%) and iodide **29** (100 mg, 66%). ^1H nmr ($CDCl_3$, δ ppm): 1.79 (3H, s, $-CH_3$), 1.86 (2H, m, $-SCH_2CH_2CH_2S-$), 1.89 and 2.13 (2H, m, $-CH_2-CHS_2$), 2.27 (9H, s, $-CH_3$ aromatic), 2.38 (2H, m, $=C(CH_3)-CH_2CH_2-$), 2.85 (4H, m, $-SCH_2CH_2CH_2S-$), 3.46 (3H, s, $-OCH_3$), 4.02 (1H, t, J = 7 Hz, -S-CH-S-), 4.88 (2H, s, $-OCH_2O-$), 4.99 (2H, s, $-CH_2$-OMes), 6.83 (2H, s, CH aromatic).

*(2Z)-2-Methoxymethyloxy-3-methyl-6,6-(propylenedithio)-6-trimethylstannyl-1-(2,4,6-trimethylbenzoyloxy)hex-2-ene (**31**)*

To a cold (−78°C) solution of 2-trimethylstannyl-1,3-dithiane (864 mg, 3.06 mmol) in tetrahydrofuran (4.3 mL), was added a solution of LDA obtained at 0°C from DIPA (421 μL, 3.01 mmol) and BuLi (1.6 M in hexane) (1.9 mL, 3.04 mmol) in tetrahydrofuran (4.3 mL). The mixture was stirred at −30°C for 3 h and at −78°C for 30 min. Then a solution of iodide **29** (632 mg, 1.46 mmol) in tetrahydrofuran (3 mL) was added. The mixture was stirred at this temperature for an additional 1.5 h, treated with water, and warmed to room temperature. The mixture was extracted with methylene chloride; the organic layer was dried over sodium sulfate, evaporated, and the residue was purified by flash chromatography using hexane:ethyl acetate (19:1–7:3) as the eluent to afford pure **31** (325 mg, 38%) and **30** (111 mg, 18%); ^1H nmr ($CDCl_3$, δ ppm): 0.28 (9H, t, $J_{Sn(119)-H}$ = 27.2 Hz, $J_{Sn(117)-H}$ = 26.1 Hz, $-Sn-(CH_3)_3$), 1.85 (3H, s, $-CH_3$), 2.05 (2H, m, $-SCH_2CH_2CH_2S-$), 2.27 and 2.30 (9H, s, CH_3 aromatic), 2.31 (4H, m, $=C(CH_3)-CH_2-CH_2-$), 2.40 (2H, m, -SCHH-CH_2-CHH-S-), 3.15 (2H, m, -SCHH-CH_2-CHH-S-), 3.45 (3H, s, $-OCH_3$), 4.90 (2H, s, $-OCH_2O-$), 5.02 (2H, s, $-CH_2$-OMes), 6.85 (2H, s, CH aromatic).

*(2Z)-2-Methoxymethyloxy-3-methyl-6,6-(propylenedithio)-6-tributylstannyl-1-(2,4,6-trimethylbenzoyloxy)hex-2-ene (**32**)*

To a solution of 2-tributylstannyl-1,3-dithiane (2 g, 4.9 mmol) in tetrahydrofuran (7 mL) at −78°C, was added a solution of LDA obtained at 0°C from DIPA (690 μL, 4.9 mmol) and BuLi (1.6 M in hexane) (2.9 mL, 4.6 mmol) in tetrahydrofuran (7 mL). The mixture was stirred at −30°C for 3 h and at −78°C for 30 min. Then a solution of iodide **29** (967 mg, 2.24 mmol) maintained in tetrahydrofuran (6 mL) at −30°C was added. The mixture was stirred at this temperature for an additional 75 min and water was added. The solution was warmed to room temperature. The mixture was extracted with methylene chloride and the organic layer was dried with sodium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (19:1–9:1) as the eluent to afford pure **32** (1.383 g, 87%); ir (CH_2Cl_2, ν cm^{-1}): 3060, 2960, 2920, 2860, 1720, 1610; ^1H nmr ($CDCl_3$, δ ppm): 0.90 (9H, t, J = 7.2 Hz, $-(CH_2)_3-CH_3$), 1.08 (6H, m, $-Sn-CH_2-$), 1.34 (6H, m, J = 7 Hz, $-CH_2-CH_2-CH_3$), 1.55 (6H, m, $-Sn-CH_2-CH_2-$), 1.86 (3H, s, $-CH_3$), 2.05 (2H, m, $-SCH_2CH_2CH_2S-$), 2.21 and 2.33 (4H, m, $=C(CH_3)-CH_2-CH_2-$), 2.27 and 2.30 (9H, s, $-CH_3$ aromatic), 2.43 (2H, m, -SCHH-CH_2-CHH-S-), 3.15 (2H, m, SCHH-CH_2-CHH-S-), 3.45 (3H, s, $-OCH_3$), 4.90 (2H, s, $-OCH_2O-$), 5.03 (2H, s, $-CH_2$-OMes), 6.84 (2H, s, CH aromatic). Exact Mass calcd. for $C_{34}H_{58}O_4S_2Sn$: 657.2094 (M^+ − *tert*-butyl); found: 657.2105 ± 0.0018.

*(2Z,4E)-6-*tert*-Butoxydiphenylsilyloxy-1-tetrahydropyranyloxyhexa-2,4-diene (**34**)*

To a solution of alcohol **33** (2.32 g, 11.7 mmol) and triethylamine (2.5 mL, 17.8 mmol) in methylene chloride (50 mL) was added *tert*-butoxydiphenylsilyl chloride (3.2 mL, 12.2 mmol) at 0°C. The mixture was stirred at room temperature for 40 min and a saturated solution of ammonium chloride was added. The mixture was extracted with hexane:ether (4:1); the organic layer was dried with sodium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ether (4:1) as the eluent to afford pure **34** (5.25 g, 99%); ir (CH_2Cl_2, ν cm^{-1}): 3050, 2980, 2940, 2860, 1430; ^1H nmr ($CDCl_3$, δ ppm): 1.31 (9H, s, $-OC-(CH_3)_3$), 1.47–1.86 (6H, m, $-OCH_2-(CH_2)_3-$), 3.49 and 3.87 (2H, m, $-OCH_2-(CH_2)_3-$), 4.20 (1H, dd, J = 7.5 and 12.5 Hz, THPO-CHH-CH=CH-), 4.35 (1H, dd, J = 7.5 and 12.5 Hz, THPO-CHH-CH=CH-), 4.34 (2H, d, J = 4.6 Hz, $-CH_2$-OTBODPS), 4.65 (1H, t, J = 3.5 Hz, -O-CH(O-)-), 5.57 (1H, dt, J = 7 and 10.9 Hz, THPO-CH_2-CH=CH-), 5.83 (1H, dt, J = 5.2 and 15 Hz, $-CH=CH-CH_2$OTBODPS), 6.16 (1H, dd, J = 11.1 and 11.1 Hz, THPO-CH_2-CH=CH-), 6.60 (1H, dd, J = 11.5 and 15 Hz, CH=CH-CH_2OTBODPS), 7.37 and 7.67 (10H, m, Ph_2). Exact Mass calcd. for $C_{27}H_{36}O_4Si$: 395.1679 (M^+ − *tert*-butyl); found: 395.1674 ± 0.0011.

*(2Z,4E)-6-*tert*-Butoxydiphenylsilyloxyhexa-2,4-dien-1-ol (**35**)*

To a solution of **34** (16.7 g, 36.9 mmol) in *tert*-butanol (270 mL) was added pyridinium *para*-toluenesulfonate (1.68 g, 6.7 mmol). The mixture was heated to 60°C for 10 h and then a saturated solution of sodium bicarbonate was added. The mixture was extracted with hexane:ether (4:1), and the organic layer was dried with sodium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (9:1–3:2) as the eluent to afford pure alcohol **35** (6.89 g, 51%) and starting **34** (6.2 g, 37%); ir (CH_2Cl_2, ν cm^{-1}): 3600, 3060, 2980, 2940, 2880; ^1H nmr ($CDCl_3$, δ ppm): 1.31 (9H, s, $-OC(CH_3)_3$), 4.30 (2H, dd, J = 5.7 and 5.7 Hz, $-CH_2OH$), 4.35 (2H, d, J = 5.2 Hz, $-CH_2$-OTBODPS), 5.59 (1H, ddd, J = 7.5, 7.5, and 10.9 Hz, HO-CH_2-CH=CH-), 5.84 (1H, ddd, J = 5, 5, and 15 Hz, $-CH=CH-CH_2$OTBODPS), 6.10 (1H, dd, J = 11.5 and 11.5 Hz, HO-CH_2-CH=CH-), 6.54 (1H, dd, J = 12 and 15 Hz, $-CH=CH-CH_2$OTBODPS), 7.37 and 7.67 (10H, m, Ph_2). Exact Mass calcd. for $C_{22}H_{28}O_3Si$: 311.1103 (M^+ − *tert*-butyl); found: 311.1082 ± 0.0009.

*(2Z,4E)-6-*tert*-Butoxydiphenylsilyloxyhexa-2,4-dien-1-al (**36**)*

To a solution of oxalyl chloride (1.7 mL, 19.5 mmol) in methylene chloride (52 mL) at −78°C was added dimethyl sulfoxide (2.8 mL, 39.5 mmol). The mixture was stirred at −78°C for 10 min and a solution of alcohol **35** (5.5 g, 15.0 mmol) in methylene chloride (42 mL) was added. The mixture was stirred for 50 min at −78°C, and diisopropylethylamine (DIPEA) (10.5 mL, 60.4 mmol) was added. The mixture was stirred for 15 min at −78°C and for 25 min at 0°C, water was added, and the mixture was extracted with methylene chloride. The organic layer was dried over sodium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (9:1) as the eluent to afford pure aldehyde **36** (4.15 g, 76%); ^1H nmr ($CDCl_3$, δ ppm): 1.31 (9H, s, $-OC(CH_3)_3$), 4.45 (2H, d, J = 4 Hz, $-CH_2$-OTBODPS), 5.84 (1H, dd, J = 8 and 11 Hz, HCO-CH=CH-), 6.21 (1H, dt, J = 5 and 15 Hz, $-CH=CH-CH_2$OTBODPS), 6.98 (1H, dd, J = 11.5 and

For personal use only.

11.5 Hz, HCO-CH=CH-), 7.38 and 7.66 (11H, m, Ph_2 and -CH=CH-CH_2OTBODPS), 10.17 (1H, d, J = 8 Hz, HCO-).

*(2Z,8Z,10E)-12-*tert*-Butoxydiphenylsilyloxy-7-hydroxy-2-methoxymethyloxy-3-methyl-6,6-(propylenedithio)-1-(2,4,6-trimethylbenzoyloxy)dodeca-2,8,10-triene (**37**)*

To a cold (−93°C) solution of **32** (485 mg, 0.68 mmol) in tetrahydrofuran (7.6 mL) was added rapidly a cold (−90°C) solution of BuLi (1.6 M in hexane) (850 μL, 1.36 mmol) and, 15 s later, a cold (−93°C) solution of aldehyde **36** (790 mg, 2.16 mmol) in tetrahydrofuran (11 mL) was added. The mixture was stirred at −93°C for 35 min and a saturated solution of ammonium chloride was added. The mixture was warmed to room temperature and extracted with methylene chloride. The organic layer was dried over sodium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (9:1–4:1) as the eluent to afford pure alcohol **37** (462 mg, 86%), and a small amount of **38** (15 mg, 3%).

Compound 37: ir (CH_2Cl_2, ν cm^{-1}): 3050, 2980, 1720; ^{1}H nmr ($CDCl_3$, δ ppm): 1.30 (9H, s, -OC$(CH_3)_3$), 1.77 (3H, s, -CH_3), 1.78 (3H, m, -$SCH_2CH_2CH_2S$- and =C(CH_3)-CH_2-CHH-), 2.01 (1H, ddd, J = 5, 11.7, and 14.5 Hz, =C(CH_3)-CH_2-CHH-), 2.27 (9H, s, -CH_3 aromatic), 2.38 (1H, ddd, J = 4.9, 12.2, and 12.2 Hz, =C(CH_3)-CHH-CH_2-), 2.48 (1H, ddd, J = 5.3, 12.4, and 12.4 Hz, =C(CH_3)-CHH-CH_2-), 2.60 (2H, m, -SCHH-CH_2-CHH-S-), 2.76 (1H, d, J = 2.2 Hz, -CH-OH), 2.92 (2H, m, -SCHH-CH_2-CHH-S-), 3.45 (3H, s, -OCH_3), 4.38 (2H, d, J = 4.1 Hz, -CH_2-OTBODPS), 4.85 (1H, d, J = 6.6 Hz, -OCHHO-), 4.88 (1H, d, J = 6.6 Hz, -OCHHO-), 4.92 (1H, d, J = 10 Hz, -CH-OH), 4.97 (2H, s, -CH_2-OMes), 5.56 (1H, dd, J = 10 and 10.5 Hz, -CH(OH)-CH=CH-), 5.90 (1H, dt, J = 5 and 15 Hz, -CH=CH-CH_2OTBODPS), 6.31 (1H, dd, J = 11.3 and 11.3 Hz, -CH(OH)-CH=CH-), 6.78 (1H, dd, J = 12.5 and 15 Hz, -CH=CH-CH_2OTBODPS), 6.83 (2H, s, CH aromatic), 7.35 and 7.66 (10H, m, Ph_2). *(3Z,9Z,11E)-8-*tert*-Butyldimethylsilyloxy-1,1-bis-methoxycarbonyl-3-methoxymethyloxy-4-methyl-7,7-(propylenedithio)trideca-3,9,11-trien-13-ol (**43**)*

A solution of tetrabutylammonium fluoride (1.0 M in THF, 2.4 mL, 2.4 mmol) was added at 0°C to a solution of **42** (865 mg, 0.99 mmol) in methylene chloride (17 mL). The mixture was stirred at 0°C for 15 min and at room temperature for 3.5 h, then diluted with water. The mixture was extracted with ether and the organic layer was dried over sodium sulfate. Then the solution was filtered on a silica gel pad and the solvent was evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (3:2) as the eluent to afford pure alcohol **43** (539 mg, 88%); ir (CH_2Cl_2, ν cm^{-1}): 3060, 2990, 2960, 2860, 1735; ^1H nmr ($CDCl_3$, δ ppm): 0.01 and 0.10 (6H, 2s, $-OSi(CH_3)_2C(CH_3)_3$), 0.89 (9H, s, $-OSi(CH_3)_2C(CH_3)_3$), 1.64 (3H, s, $-CH_3$), 1.91 (4H, m, $-SCH_2CH_2CH_2S-$ and $=C(CH_3)-CH_2-CH_2-$), 2.38 (2H, m, $=C(CH_3)-CH_2-$), 2.84 (4H, m, $-SCH_2-CH_2-CH_2-S-$), 2.85 (2H, d, J = 7.9 Hz, $-CH_2-CH(CO_2CH_3)_2$), 3.47 (3H, s, $-OCH_3$), 3.71 and 3.72 (6H, 2s, $(CO_2CH_3)_2$), 3.71 (1H, t, J = 7.6 Hz, $-CH(CO_2CH_3)_2$), 4.24 (2H, s large, $-CH_2-OH$), 4.77 (2H, s, $-OCH_2O-$), 4.79 (1H, d, J = 10 Hz, -CH(OTBDMS)-), 5.60 (1H, dd, J = 10.5 and 10.5 Hz, -CH(OTBDMS)-CH=CH-), 5.92 (1H, dt, J = 5 and 15 Hz, $-CH=CH-CH_2OH$), 6.17 (1H, dd, J = 11.2 and 11.2 Hz, -CH(OTBDMS)-CH=CH-), 6.59 (1H, dd, J = 12 and 15 Hz, $-CH=CH-CH_2OH$). Exact Mass calcd. for $C_{29}H_{50}O_8S_2Si$: 618.2716 (M^+); found: 618.2710 ± 0.0018.

*(3Z,9Z,11E)-8-*tert*-Butyldimethylsilyloxy-13-chloro-1,1-bis-methoxycarbonyl-3-methoxymethyloxy-4-methyl-7,7-(propylenedithio)trideca-3,9,11-triene (**44**)*

Mesyl chloride (230 μL, 2.97 mmol) was added to a cold (0°C) solution of alcohol **43** (540 mg, 0.874 mmol), lithium chloride (634 mg, 14.9 mmol), and collidine (660 μL, 5.0 mmol) in dimethylformamide (6 mL). The mixture was stirred at 0°C for 15 min and at room temperature for 4 h and then a saturated solution of ammonium chloride was added. The mixture was extracted with hexane:ether (1:1), and the organic layer was dried over sodium sulfate and evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (7:3) as the eluent to afford pure chloride **44** (484 mg, 87%); ^1H nmr ($CDCl_3$, δ ppm): 0.00 and 0.10 (6H, 2s, $-OSi(CH_3)_2C(CH_3)_3$), 0.88 (9H, s, $-OSi(CH_3)_2C(CH_3)_3$), 1.64 (3H, s, $-CH_3$), 1.95 (4H, m, $-SCH_2CH_2CH_2S-$ and $=C(CH_3)-CH_2-CH_2-$), 2.35 (2H, m, $=C(CH_3)-CH_2-$), 2.81 (6H, m, $-SCH_2-CH_2-CH_2-S-$ and $-CH_2-CH(CO_2CH_3)_2$), 3.47 (3H, s, $-OCH_3$), 3.72 (6H, s, $(CO_2CH_3)_2$), 3.73 (1H, t, J = 7 Hz, $-CH(CO_2CH_3)_2$), 4.15 (2H, d, J = 7 Hz, $-CH_2-Cl$), 4.77 (2H, s, $-OCH_2O-$), 4.76 (1H, d, J = 10 Hz, -CH(OTBDMS)-), 5.65 (1H, dd, J = 10.3 and 10.3 Hz, -CH(OTBDMS)-CH=CH-), 5.88 (1H, dt, J = 7.5 and 15 Hz, $-CH=CH-CH_2Cl$), 6.16 (1H, dd, J = 11.2 and 11.2 Hz, -CH(OTBDMS)-CH=CH-), 6.63 (1H, dd, J = 11.3 and 14.8 Hz, $-CH=CH-CH_2Cl$).

*(3Z,9Z,11E)-8-*tert*-Butyldimethylsilyloxy-1,1-bis-methoxycarbonyl-3-methoxymethyloxy-4-methyl-7,7-(propylenedithio)cyclotrideca-3,9,11-triene (**45**)*

To a warm (78°C) solution of cesium carbonate (1.025 g, 3.14 mmol) and 18-crown-6 (870 mg, 3.29 mmol) in acetonitrile (350 mL) was added dropwise a solution of chloride **44** (390 mg, 0.613 mmol) in acetonitrile (26 mL). The addition was done at a rate of 12 mL in 2 h, 6.5 mL in 2.5 h, and 7.5 mL in 3.5 h. The mixture was heated at 78°C for an additional 8 h, then cooled, filtered, and the solvents were evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (9:1–4:1) as the eluent to afford pure macrocycle **45** (276 mg, 75%); ir (CH_2Cl_2, ν cm^{-1}): 3060, 2990, 2960, 2930, 1735; ^1H nmr ($CDCl_3$, δ ppm): 0.08 and 0.15 (6H, 2s, $-OSi(CH_3)_2C(CH_3)_3$), 0.94 (9H, s, $-OSi(CH_3)_2C(CH_3)_3$), 1.36 (1H, dd, J = 9.6 and 13.5 Hz, $=C(CH_3)-CH_2-CHH-$), 1.58 (3H, s, $-CH_3$), 1.80–2.21 (4H, m, $-SCH_2CH_2CH_2S-$ and $=C(CH_3)-CHH-CHH-$), 2.49 (1H, d, J = 15 Hz, =C(OMOM)-CHH-), 2.59–2.83 (4H, m, $-SCHH-CH_2-CHH-S-$, $=C(CH_3)-CHH-$ and $-CH=CH-CHH-$), 3.19–3.35 (4H, m, $-SCHH-CH_2-CHH-S-$, =C(OMOM)-CHH- and $-CH=CH-CHH-$), 3.52 (3H, s, $-OCH_3$), 3.72 and 3.73 (6H, 2s, $(CO_2CH_3)_2$), 4.67 (1H, d, J = 6.2 Hz, -OCHHO-), 4.82 (1H, d, J = 6.2 Hz, -OCHHO-), 4.94 (1H, d, J = 9.3 Hz, -CH(OTBDMS)-), 5.45 (1H, ddd, J = 5, 11, and 15 Hz, $-CH=CH-CH_2-$), 5.59 (1H, dd, J = 10.5 and 10.5 Hz, -CH(OTBDMS)-CH=CH-), 6.00 (1H, dd, J = 11 and 11 Hz, -CH(OTBDMS)-CH=CH-), 6.55 (1H, dd, J = 10.8 and 15 Hz, $-CH=CH-CH_2-$); ^1H nmr (C_6D_6, δ ppm): 0.21 and 0.29 (6H, 2s, $-OSi(CH_3)_2C(CH_3)_3$), 1.07 (9H, s, $-OSi(CH:i3)_2C(CH_3)_3$), 1.60 (3H, s, $-CH_3$), 1.67 (3H, m, $-SCH_2CH_2CH_2S-$ and $=C(CH_3)-CH_2-CHH-$), 2.05 (1H, m, $=C(CH_3)-CH_2-CHH-$), 2.40 (3H, m, $-SCHH-CH_2-CHH-S-$ and $=C(CH_3)-CHH-$), 2.74 (1H, d, J = 15.3 Hz, =C(OMOM)-CHH-), 2.94–3.18 (4H, m, $-SCHH-CH_2-CHH-S-$, $=C(CH_3)-CHH-$, and $-CH=CH-CHH-$), 3.27 and 3.30 (6H, 2s, $(CO_2CH_3)_2$), 3.38 (3H, s, $-OCH_3$), 3.53 (1H, d, J = 15.3 Hz, =C(OMOM)-CHH-), 3.59 (1H, dd, J = 11.2 and 13.6 Hz, $-CH=CH-CHH-$), 4.59 (1H, d, J = 6.1 Hz, -OCHHO-), 4.72 (1H, d, J = 6.1 Hz, -OCHHO-), 5.23 (1H, d, J = 8.4 Hz, -CH(OTBDMS)-), 5.60 (1H, ddd, J = 5, 11, and 15 Hz, $-CH=CH-CH_2-$), 5.94 (2H, dd, J = 11 Hz, -CH(OTBDMS)-CH=CH-), 6.89 (1H, dd, J = 10 and 14.9 Hz, $-CH=CH-CH_2-$); ^{13}C nmr ($CDCl_3$, δ ppm): −4.4 ($-Si(CH_3)_2-$), 15.5 ($C=C-CH_3$), 18.4 ($-C(CH_3)_3$), 24.1, 25.1, 27.1, 27.6, 32.8, 34.4, 35.3 ($7 \times CH_2$), 26.1 ($-C(CH_3)_3$), 52.5, 52.7 ($-CO_2CH_3$), 55.4, 57.1 ($-C(S_2-$ and $-C(CO_2CH_3)_2-$), 57.0 ($-OCH_3$), 76.7 (-CH(OTBDMS)-), 97.7 ($-OCH_2O-$), 124.9 ($-C=C-CH_3$), 129.6, 130.0, 130.1, 131.1 ($-CH=CH-CH=CH-$), 142.6 (=C-OMOM). Using procedure B, compound **58** (16 mg, 0.026 mmol) afforded, after flash chromatography, compound **60** (14.5 mg, 98%); ir (CH_2Cl_2, ν cm^{-1}): 3600, 3050, 2960, 2930, 2860, 1720; ^{1}H nmr ($CDCl_3$, δ ppm): 0.11 and 0.17 (6H, 2s, $-OSi(CH_3)_2C(CH_3)_3$), 0.93 (9H, s, $-OSi(CH_3)_2C(CH_3)_3$), 1.30 (3H, s, $-CH_3$), 1.53–1.90 (3H, m, $-CH_2$-CHH-CH(OBz)-), 2.07–2.17 (1H, m, $-CH_2$-CHH-CH(OBz)-), 2.15 (1H, s, -C(OH)-CHH-), 2.23 (1H, s, -CH-CH=), 2.34 (1H, s, -C(OH)-CHH-), 2.38–2.47 (1H, m, $-C(CO_2CH_3)_2$-CHH-), 2.74 (1H, s, -CH-CH=), 2.75 (1H, m, $-C(CO_2CH_3)_2$-CHH-), 3.71 and 3.76 (6H, 2s, $(CO_2CH_3)_2$), 4.00 (1H, m, -CH(OTBDMS)-), 5.01 (1H, d, J = 3 Hz, -CH(OBz)-), 5.25 (1H, dm, J = 10 Hz, -CH=CH-), 5.37 (1H, dm, J = 10 Hz, -CH=CH-), 7.42 (2H, m, *meta*-H of OBz), 7.55 (1H, m, *para*-H of OBz), 8.00 (2H, m, *ortho*-H of OBz). Exact Mass calcd. for $C_{31}H_{44}O_8Si$: 555.2778 (M^+ − OH); found: 555.2760 ± 0.0016.

*rel(1S,2R,4R,6S,9S,10R,11S)-11-Benzoyloxy-4-methoxycarbonyl-1-methyltricyclo[7.4.0.0^{2,6}]tridec-7-en-10-ol-4,2-carbolactone (**61**)*

Procedure C

To a solution of **59** (16 mg, 0.028 mmol) in tetrahydrofuran (10 mL) was added a solution of tetrabutylammonium fluoride (56 μL, 0.056 mmol). The mixture was stirred at room temperature for 90 min and the solvent was evaporated. The residue was purified by flash chromatography using hexane:ethyl acetate (3:2) as the eluent to afford pure **61** (2.5 mg, 19%) and **62** (6 mg, 61%).

*Compound **61*** (less polar): ir (CH_2Cl_2, ν cm^{-1}): 3600, 3050, 2980, 1780, 1735, 1715; ^{1}H nmr ($CDCl_3$, δ ppm): 1.42 (3H, s, $-CH_3$), 150–2.22 and 2.35–2.55 (9H, m, 4 × $-CH_2$- and -CH-CH=), 2.80 (1H, m, -CH-CH=), 3.82 (3H, s, CO_2CH_3), 4.23 (1H, dd, J = 2 and 2 Hz, -CH(OH)-), 5.02 (1H, ddd, J = 2.5, 3.5, and 12 Hz, -CH(OBz)-), 5.42 (1H, ddd, J = 2, 2, and 10 Hz, -CH=CH-), 5.73 (1H, ddd, J = 2.5, 2.5 ,and 10 Hz, -CH=CH-), 7.47 (2H, m, *meta*-H of OBz), 7.60 (1H, m, *para*-H of OBz), 8.04 (2H, m, *ortho*-H of OBz). Exact Mass calcd. for $C_{24}H_{26}O_7$: 426.1678 (M^+); found: 426.1675 ± 0.0013.

*Compound **62*** (more polar): ir (CH_2Cl_2, ν cm^{-1}): 3600, 3050, 2980, 1785, 1735; ^{1}H nmr (CD_2Cl_2, δ ppm): 1.32 (3H, s, $-CH_3$), 1.53–2.00 and 2.28–2.46 (9H, m, 4 × $-CH_2$- and -CH-CH=), 2.73 (1H, m, -CH-CH=), 3.60 (1H, ddd, J = 2.5, 3.5, and 12 Hz, -CH(OH)-CH_2-), 3.77 (3H, s, CO_2CH_3), 3.95 (1H, dd, J = 2.8 and 2.8 Hz, $-CH_2$-CH(OH)-CH(OH)-), 5.33 (1H, ddd, J = 2.2, 2.2, and 10.1 Hz, -CH=CH-), 5.64 (1H, ddd, J = 2.7, 2.7, and 10.2 Hz, -CH=CH-). Exact Mass calcd. for $C_{17}H_{22}O_6$: 322.1416 (M^+); found: 322.1413 ± 0.0009.

*rel(1S,2R,4R,6S,9S,10R,11R)-11-Benzoyloxy-4-methoxycarbonyl-1-methyltricyclo[7.4.0.0^{2,6}]tridec-7-en-10-ol-4,2-carbolactone (**63**)*

Using procedure C, compound **60** (7.5 mg, 0.013 mmol) afforded, after flash chromatography, compound **63** (4.5 mg, 81%); ir (CH_2Cl_2, ν cm^{-1}): 3600, 3050, 2980, 1785, 1735, 1710: ^{1}H nmr ($CDCl_3$, δ ppm): 1.42 (3H, s, $-CH_3$), 1.54–2.62 (9H, m, 4 × $-CH_2$- and -CH-CH=), 2.94 (1H, m, -CH-CH=), 3.82 (3H, s, CO_2CH_3), 4.17 (1H, s, -CH(OH)-), 5.17 (1H, d, J = 2.8 Hz, -CH(OBz)-), 5.33 (1H, ddd, J = 2.2, 2.2, and 10.1 Hz, -CH=CH-), 5.60 (1H, ddd, J = 2.7, 2.7, and 10.1 Hz, -CH=CH-), 7.44 (2H, m, *meta*-H of OBz), 7.58 (1H, m, *para*-H of OBz), 7.99 (2H, m, *ortho*-H of OBz). Exact Mass calcd. for $C_{24}H_{26}O_7$: 426.1678 (M^+); found: 426.1688 ± 0.0013.

*rel(1S,2R,4R,6S,9S,11S)-11-Benzoyloxy-4-methoxycarbonyl-1-methyltricyclo[7.4.0.0^{2,6}]tridec-7-en-10-one-4,2-carbolactone (**64**)*

To a solution of **61** (1 mg, 2.2 μmol) in methylene chloride (1 mL) was added pyridinium chlorochromate (5 mg, 23.2 μmol). The mixture was stirred at room temperature for 3 h and was filtered on Florisil using ethyl acetate as a solvent. The solvent was evaporated and the residue was purified by flash chromatography using hexane:ethyl acetate (3:2) as the eluent to afford pure ketone **64** as the only product; ir (CH_2Cl_2, ν cm^{-1}): 3030, 2960, 2930, 2860, 1790, 1740; ^{1}H nmr ($CDCl_3$, δ ppm): 1.30 (3H, s, $-CH_3$), 1.50–2.55 (8H, m, 4 × $-CH_2$-), 3.00 (2H, m, -CH-CH=CH-CH-), 3.83 (3H, s, CO_2CH_3), 5.52 (1H, dd, J = 7.5 and 7.5 Hz, -CH(OBz)-), 5.58 (1H, dm, J = 10 Hz, -CH=CH-), 5.92 (1H, ddd, J = 2.5, 2.5, and 10 Hz, -CH=CH-), 7.5 (3H, m, *meta*-H and *para*-H of OBz), 8.09 (2H, m, *ortho*-H of OBz). Exact Mass calcd. for $C_{24}H_{24}O_7$: 424.1514 (M^+); found: 424.1514 ± 0.0012.

Stereocontrolled chiral synthesis of a *trans-anti-trans* tricycle by a transannular Diels–Alder reaction

ANNE MARINIER[1] AND PIERRE DESLONGCHAMPS[2]

Laboratoire de synthèse organique, Département de chimie, Faculté des sciences, Université de Sherbrooke, Sherbrooke (Québec), Canada J1K 2R1

Received March 2, 1992

ANNE MARINIER and PIERRE DESLONGCHAMPS. Can. J. Chem. **70**, 2350 (1992).

The racemic and chiral synthesis of *trans-cis-cis* macrocyclic triene **5** is described. Heating this compound at 262°C leads via a transannular Diels–Alder reaction to the tricyclic structure **6**, which can be further transformed into tricyclic compound **7**. This work constitutes a preliminary study for the synthesis of corticoids.

ANNE MARINIER et PIERRE DESLONGCHAMPS. Can. J. Chem. **70**, 2350 (1992).

On décrit la synthèse racémique et chirale du triène macrocyclique *trans-cis-cis* **5**. En chauffant à 262°C, ce composé subit une reaction de Diels–Alder transannulaire et conduit à l'adduit tricyclique **6** qui peut être transformé dans le composé **7**. Ce travail constitue une étude préliminaire en vue de la synthèse de corticostéroïdes.

Introduction

Recent interest in organic synthesis focused on macrocyclic compounds. Indeed many naturally occurring molecules containing medium and large rings have been isolated and progress in their synthesis led to the development of good methods of cyclization (1, 2). These investigations also revealed that *intermolecular* reactions of such macrocyclic structures might occur with high chemo, regio, and stereoselectivity (3, 4).

Very recently we pointed out the enormous synthetic potential residing in *intramolecular* reactions of macrocyclics, particularly transannular processes of such systems (5, 6). These transformations occur with high regio and stereoselectivity due to conformational restriction and proximity effects that become operative, increasing the rate of one reaction at the expense of others normally competing. Thus transannular processes on macrocarbocyclics are powerful tools for the synthesis of complex polycyclic skeletons (6*c*). For example, the Diels–Alder reaction of 14- or 13-membered macrocycles (**1** → **2** or **3** → **4**) (Scheme 1) should represent a good synthetic approach to polycyclic systems such as diterpenes, triterpenes, steroids, etc. Recent papers from our laboratory (7) and by Takahashi *et al.* (8) confirmed this prediction and showed the great potential of the transannular Diels–Alder reaction for the synthesis of natural products. We now wish to report our work on a new approach to the synthesis of corticosteroids.

Most of the natural corticosteroids have the *trans-anti-trans* (TAT) ring junction for the A, B, and C rings of the carbon skeleton. However, in recent communications, (7*e*, *d*) we demonstrated that the transannular Diels–Alder strategy is not appropriate for the direct construction of the TAT ring junction. On the contrary, the *trans-syn-cis* (TSC) ring junction is directly and easily accessible by the Diels–Alder reaction of a *trans-cis-cis* (TCC) macrocyclic triene (5). The hydroxyl or the keto group at position 11 in corticosteroids not only provides a route for a subsequent epimerization at C9, thereby delivering systems having TAT stereochemistry, but can also be exploited to induce chirality.

We report herein, as a preliminary study for the synthesis of corticoids, the racemic and chiral syntheses of macrocyclic compound **5** as well as its transformation into tricyclic compound **7** via compound **6** (Scheme 1).

Results and discussion

Racemic synthesis of macrocyclic triene 5

As previously described (7*f*), the synthesis of macrocyclic triene **5** was based on our original convergent approach (7*c*, *e*). Scheme 2 summarizes the preparation of the *Z* dienophile moiety. Thus alcohol **8** (9) was first benzylated, followed by removal of the benzylidene protecting group in acidic medium (85%). Diol **10** was then monosilylated (10) (51%) to afford alcohol **11**, which was oxidized (11) to aldehyde **12**. Without further purification, this crude aldehyde was used in a Wittig reaction with the ylide derived from the phosphonium salt **14**. The latter was prepared by condensing the THP derivative (12) of 2-bromoethanol **13** with ethyltriphenylphosphonium bromide (13*a*). The Wittig reaction provided a 55:45 mixture of *Z* and *E* olefins in a 63% yield from **11**. The geometry of these isomers was easily established by ^{13}C nmr spectroscopy. The C4-methyl in the *E* isomer, which is *cis*-disposed to the chain, displays a higher field chemical shift (17.1) than the corresponding *trans*-disposed methyl in the *Z* isomer (23.8). On the contrary the C5-methylene displays a higher field chemical shift (32.8) in the *Z* isomer than the corresponding C5-methylene in the *E* isomer (39.7). These findings are in complete agreement with assignments for *Z* and *E* olefins (13*b*). Furthermore, the stereochemistry of our olefin was firmly secured by a chemical proof (*vide infra*).

After chromatographic separation, the pure *Z* olefin **15***a* was desilylated (14) to give alcohol **16***a*, which was smoothly converted into the corresponding mesylate **17***a* (92%) followed by conversion into mesylate **20***a* facilitated its intramolecular cyclization to **21**, demonstrating ipso-facto the presence of the *Z* geometry. The same sequence of reactions was effected with the *E* isomer. The *E* compound **20***b* was, however, unable to cyclize in the same conditions used for the *Z* isomer **20***a*.

Dienophile **20***a* and the *trans-cis* diene **22** (7*c*) were coupled in dimethylformamide and tetrahydrofuran (1:1), producing triene **23** in 84% yield (Scheme 3). Subsequent alkylation with the anion of dimethyl malonate at 80°C gave

SCHEME 3

Chiral synthesis of macrocyclic triene 5

The chiral dienophile moiety was synthesized as indicated in Scheme 4. Thus 3-bromobutyric acid **30** was first treated with triphenylphosphine to give the corresponding phosphonium salt **31** (94%). Without further purification, the acid function of the phosphonium salt was esterified to its methyl ester **32** in 81% yield after crystallization. Reduction of ester **32** with diisobutylaluminum hydride produced alcohol **33***a* in 62% yield. The corresponding phosphonium bromide **33***b* was also prepared by methanolysis of the phosphonium salt **14** in the presence of pyridinium *p*-toluenesulfonate (83%).

A Wittig reaction with aldehyde **34** (16) in tetrahydrofuran led to a *Z* and *E* mixture (5:1) of olefins **35** in 60% yield. The respective geometries were assigned by ^{13}C nuclear magnetic resonance as described above. The optical purity of the separated *Z* olefin **35***a* was verified in the following manner. The hydroxyl functionality was protected as a silyl ether (10) leading to **36** (79%), which, after hydrolysis, provided diol **37** in 55% yield. Subsequent monotosylation of diol **37** to alcohol **38** (72%) allowed esterification with the chiral acid **40** and gave Mosher ester **39** (90%). This compound proved to be one single diastereomer by ^1H nmr spectroscopy. The same sequence of reactions was carried out with the *S* enantiomer of silyl ether **36**, already synthesized in our laboratory (7*g*). In this case, a different isomer of compound **39** (99%) was obtained, also homogenous by ^1H nmr spectroscopy.

The *Z* isomer of olefin **35**, purified by column chromatography, was benzoylated (89%) (Scheme 5) and then hydrolyzed to afford diol **42** (87%). After monotosylating diol **42**, the remaining free hydroxyl group was protected via treatment with *p*-methoxybenzyltrichloroacetimidate (17) (73%). Alkylation of benzyl ether **44** with dimethyl malon-

SCHEME 4

ate furnished compound **46** (72%). This adduct was then submitted to the coupling conditions previously described, yielding triene **47** in 87% yield. Alkylation with dimethyl malonate carried out on iodide **45** instead of tosylate **44** gave about the same yield (77%).

Hydrolysis of benzoate **47** in methanol afforded alcohol **48** (94%), which was transformed into mesylate **49** in 97% yield. The same strategy as described above was then applied to mesylate **49**. Thus condensation with the anion originating from dimethyl malonate (84%) followed by a treatment with fluoride ions gave alcohol **51** (94%) via compound **50**. Conversion of this alcohol into the corresponding allylic chloride **52** then allowed the cyclization leading to macrocyclic triene (−)**5** (R = $CH_2C_6H_4OCH_3$) obtained in 78% yield for the last two steps.

Transannular Diels–Alder reaction of macrocyclic trienes 5

When heated at 270°C for 2.75 h, racemic macrocyclic triene **5** (R = CH_2Ph) underwent transannular Diels–Alder reaction to give, in 84% yield, tricyclic compound **6** (R = CH_2Ph) and a mixture of two minor compounds, which were not separable by column chromatography (Scheme 3). The stereochemistry of the five asymmetric centers in the major compound can be predicted by an analysis of the possible transition states (see Scheme 6). Thus, the relative stereochemistry TSC at the ring junctions becomes apparent after examination of such transition states; only transition states 2 and 3 are structurally allowed. Approach 1 is not possible because it is sterically impossible to get the boat form of the central ring with a 1,2-diaxial disposition of ring C. Also, despite the equatorial disposition of the benzyl ether in approach 3 and the 1,3-diaxial interaction between one of the esters E and the benzyl ether in approach 2, the latter will be favored since the benzyl ether is sterically less encumbered and therefore energetically favored. Consequently, the major compound should be compound **6***a* with an equatorial benzyl ether after conformational change. This orientation was confirmed by nmr spectroscopy of the proton adjacent to the

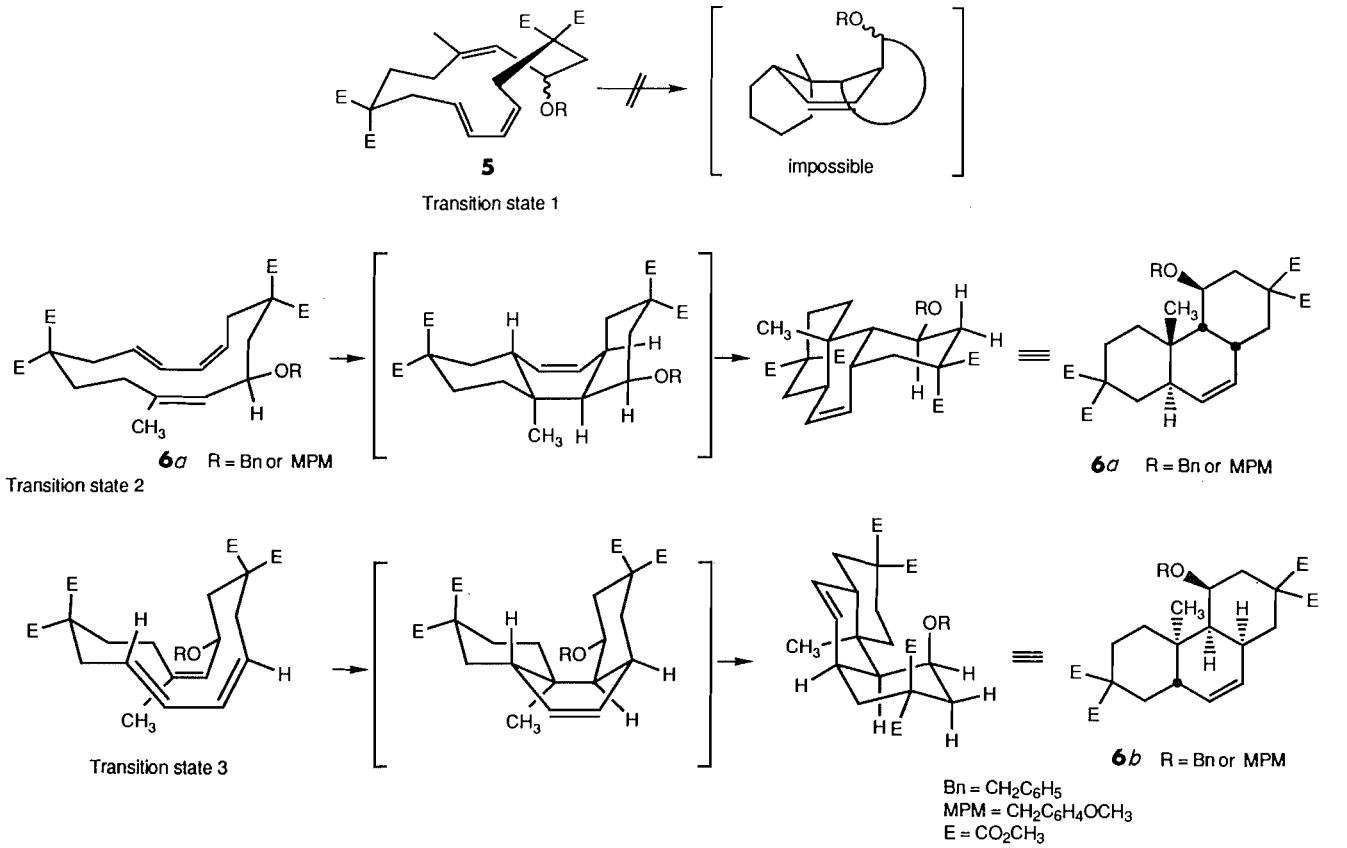
SCHEME 5

benzyl ether (3.76 ppm, doublet of doublets of doublets, 9.9, 9.9, and 4.4 Hz). Two larger coupling constants indicate an axial hydrogen and therefore an equatorial benzyl ether. It can also be predicted that one of the minor compounds should have an axial benzyl ether by virtue of the signal observed at 4.01 ppm (doublet of doublets of doublets, $J = 2.7$ Hz), which corresponds to the proton adjacent to the benzyl ether. Moreover, the TSC stereochemistry of the ring junctions could be established following an unequivocal chemical transformation in the chiral series (*vide infra*).

Diels–Alder reaction of the chiral macrocyclic triene was performed at 262°C in a sealed tube for 3 h (Scheme 5). As for the racemic compound, a major tricyclic compound was isolated in 84% yield along with a mixture of two minor compounds in 15% yield. The ^1H nmr spectrum of the major compound shows the same characteristic peaks observed in



SCHEME 6

the ^1H nmr spectrum of the major racemic tricyclic compound.

Synthesis of the trans-anti-trans *tricyclic compounds 7*

Removal of the benzyl protecting group in the racemic series was achieved with tin tetrachloride in dichloromethane (18) (87%) (Scheme 3) and with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone for the chiral series (76%) (Scheme 5). The resulting alcohol **27** was then oxidized by pyridinium chlorochromate to afford ketone **28** (Scheme 3) in 87% yield. The TSC relative stereochemistry of this ketone was confirmed by a single crystal X-ray diffraction analysis (19).

When these two reactions were performed on the two-compound mixture isolated from the chiral sequence, the same ketone **28** was obtained, thus proving the TSC stereochemistry and hence the structure ***6b*** proposed for one of the compounds in the mixture.[3] Finally, treatment with sodium carbonate in methanol at 65°C over 2.5 h converted ketone **28** into another ketone **7** (94%), which was spectroscopically and chemically different from the former (Scheme 3). This ketone **7** must obviously have the desired TAT stereochemistry obtained by isomerization at position C9. It must finally be noted that acidic treatment of alcohol **27** provided lactone **29** in 86% yield.

Conclusion

The formation of one major diastereomer in the Diels–Alder reaction points out the excellent control of stereochemistry at position C11. This has also been proven by the chiral synthesis of a tricyclic compound starting from an optically active precursor that had the appropriate absolute configuration for the C11 secondary benzyl ether. Moreover, the synthesis of lactone **29** allows a good differentiation of the two esters of a malonate. The carbonyl carbon of this lactone moiety could represent a precursor for the C18 hemiacetal function of aldosterone or other corticoids of this type.

Hence, this preliminary work demonstrates that a transannular Diels–Alder reaction on a suitable macrocycle followed by epimerization gives ready access to a tricyclic compound having a TAT stereochemistry. In addition, this method could be very promising for the synthesis of optically active corticosteroids. Work in this direction is currently underway in our laboratory.

Experimental

Infrared spectra were recorded on a Perkin–Elmer 681 spectrophotometer. The ^1H nmr and ^{13}C nmr spectra were taken on a Bruker WM-250 spectrometer. The following abbreviations are used in the text: s, singlet; d, doublet; t, triplet, q, quadruplet; m, multiplet. Mass spectra (ms) were recorded on a VG-Micromass ZAB-1F mass spectrometer. Melting points (mp) were measured on a Büchi apparatus and were not corrected. Thin-layer chromatography (tlc) was performed using silica gel 60 F-250. For flash chromatography Merck Kiesel gel (no. 9385) was used. Acetonitrile, amines, dimethylformamide (DMF), hexamethylphosphoramide (HMPA), and dichloromethane (CH_2Cl_2) were distilled from calcium hydride; methanol from magnesium and iodine; acetone and ethyl acetate from potassium carbonate; benzene, toluene, diethyl

[3]The second minor product in the mixture was not identified.

ether, and tetrahydrofuran (THF) from sodium and benzophenone ketyl. Unless otherwise specified, all reactions were carried out in a dry apparatus under argon or nitrogen.

*1-Bromo-2-[(2-tetrahydropyranyl)oxy]-ethane (**13**)*

To a stirred solution of 2-bromoethanol (74.93 g, 599.6 mmol) in dichloromethane (35 mL) were added, at 0°C, pyridinium *p*-toluenesulfonate (755 mg, 3.0 mmol) and dihydropyran (3.70 g, 44.0 mmol). The mixture was stirred for 1 h at room temperature. Potassium carbonate was then added and the mixture was filtered. After concentration, the residual oil was purified by column chromatography (5% to 10% of ethyl acetate in hexane) to yield bromide **13** (107.97 g, 86%); bp 70–75°C at 20 Torr (1 Torr = 133.3 Pa); ir ($CHCl_3$) ν: 3010, 2945, 2875, 2850, 1205, 1132, 1122, 1090, 1032 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.68 (1H, t, J = 3.3 Hz, -O-C*H*-O-), 4.02 (1H, dt, J = 11.2, 6.2 Hz, -CH_2OTHP), 3.94–3.85 (1H, m, -CH_2-O-CH-O-), 3.77 (1H, dt, J = 11.4, 6.3 Hz, -CH_2OTHP), 3.57–3.48 (3H, m, -CH_2-O-CH-O- and -CH_2Br), 1.88–1.50 (6H, m, -O-CH_2-(CH_2)$_3$-); ms m/e (70 eV): 207 (M^+ − H). Exact Mass (M^+) calcd: 207.0021; found: 207.0020.

*3-[(2-Tetrahydropyranyl)oxy]-1-methylpropyltriphenylphosphonium bromide (**14**)*

Potassium bis(trimethylsilyl)amide (122.4 mL, 0.5 M in toluene) was added to a suspension of ethyltriphenylphosphonium bromide (22.70 g, 61.2 mmol) in tetrahydrofuran (100 mL) at −78°C. The mixture was stirred at room temperature for 1 h and bromide **13** (19.18 g, 91.8 mmol) was then added at 0°C. The mixture was stirred at room temperature for 48 h. The white solid formed was filtered and dissolved in dichloromethane. After evaporation of dichloromethane, the solid was recrystallized from dichloromethane and hexane to yield the phosphonium salt **14** (24.74 g, 81%); mb 197–198°C; ir ($CHCl_3$) ν: 3010, 2940, 1440, 1240, 1115, 1080, 1035 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 8.03–7.66 (15H, m, 3 × -C_6H_5), 5.09–4.99 (1H, m, $Br^-P^+Ph_3$-C*H*(CH_3)-), 4.60–4.58 (1H, m, -O-C*H*-O-), 4.19–4.09 (1H, m, -O-CH-O-CH_2-), 3.91–3.80 (2H, m, -CH_2OTHP), 3.55–3.46 (1H, m, -O-CH-O-CH_2-), 2.35–2.17 (1H, m, -CH(CH_3)-CH_2-), 1.86–1.36 (7H, m, -CH(CH_3)-CH_2- and -O-CH_2-(CH_2)$_3$-), 1.44 (3H, dd, J = 19.8, 6.9 Hz, -CH(CH_3)-).

*2-Benzyloxy-1,3-propanediol (**10**)*

5-Hydroxy-2-phenyl-1,3-dioxane **8** (4.98 g, 27.7 mmol) (9) was added at 0°C to a stirred suspension of sodium hydride (1.23 g, 60% in oil, 30.7 mmol) in tetrahydrofuran (120 mL). The mixture was stirred at room temperature for 10 min. The temperature was reduced to 0°C and then benzyl bromide (3.62 mL, 30.4 mmol) was added. After stirring the solution at room temperature for 3 h, half of the tetrahydrofuran was evaporated followed by addition of water (36 mL) and 10% aqueous hydrochloric acid (84 mL). The mixture was heated to reflux for 1.5 h, then poured into a saturated solution of sodium carbonate and extracted with ethyl acetate. The organic layers were combined, dried over anhydrous magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (50% to 100% of ethyl acetate in hexane) to afford diol **10** (4.30 g, 85%); ir ($CHCl_3$) ν: 3600, 3580, 3050, 2930, 2880, 1260, 1110, 1060 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.42–7.29 (5H, m, -CH_2-C_6H_5), 4.67 (2H, s, -C$H_2C_6H_5$), 3.84–3.69 (4H, m, -CH_2-CH(OBn)-CH_2-), 3.61 (1H, q, J = 4.6 Hz, -C*H*-(OCH_2-C_6H_5)), 2.05 (2H, s, -CH_2O*H*); ms m/e (70 eV): 182 (M^+), 151 (M^+ − CH_2OH). Exact Mass (M^+) calcd: 182.0943; found: 182.0945.

*3-Benzyloxy-3-[(*tert*-butyldiphenylsilyl)oxy]-propan-1-ol (**11**)*

Imidazole (344.0 mg, 5.05 mmol) and *tert*- butyldiphenylsilyl chloride (1.26 g, 4.57 mmol) were added at 0°C to a stirred solution of diol **10** (0.832 g, 4.57 mmol) in tetrahydrofuran (20 mL). The solution was stirred at room temperature for 3.5 h, after which tetrahydrofuran was evaporated. The residual oil was purified by column chromatography (25% to 100% of ethyl acetate in hexane) to afford alcohol **11** (1.06 g, 55%), doubly protected diol (0.874 g, 29%), and starting material **10** (0.137 g, 16%); ir ($CHCl_3$) ν: 3580, 3070, 3010, 2960, 2930, 2860, 1470, 1430, 1100 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.69–7.66 and 7.45–7.28 (15H, m, -$OCH_2C_6H_5$ and -OSi-(C_6H_5)$_2$*t*Bu), 4.64 (1H, d, J_{AB} = 11.7 Hz, -OCH_2Ph), 4.52 (1H, d, J_{AB} = 11.7 Hz, -OCH_2Ph), 3.84–3.71 (4H, m, -CH_2OH and -CH_2OSiPh$_2$*t*Bu), 3.67–3.60 (1H, m, -C*H*(OBn)-), 2.08 (1H, s, -CH_2O*H*), 1.06 (9H, s, -OSiPh$_2$C(CH_3)$_3$); ms m/e (70 eV): 285 (M^+ − *t*Bu − Ph − H). Exact Mass (M^+ − *t*Bu − Ph − H) calcd: 285.0947; found: 285.0955.

*2-Benzyloxy-3-[(*tert*-butyldiphenylsilyl)oxy]-propanal (**12**)*

Dimethyl sulfoxide (1.64 mL, 23.11 mmol) was added slowly at −78°C to a stirred solution of oxalyl chloride (1.01 mL, 11.56 mmol) in dichloromethane (28 mL). The solution was stirred for 10 mins and a solution of alcohol **11** (1.93 g, 4.60 mmol) in dichloromethane (14 mL) was added at −78°C. The mixture was stirred for 0.75 h and triethylamine (6.44 mL, 46.22 mmol) was then added at −78°C. The temperature of the mixture was raised to −10°C and the solution was stirred for 0.5 h. After addition of water, the mixture was extracted with dichloromethane and the organic layer was dried over magnesium sulfate and concentrated. The residual oil (1.81 g, 94% crude) was used for the next step without any purification; ir ($CHCl_3$) ν: 3070, 3010, 2930, 2860, 1738, 1730, 1430, 1115 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 9.76 (1H, d, J = 1.4 Hz, -C*H*O), 7.69–7.64 and 7.44–7.30 (15H, m, -OSi(C_6H_5)$_2$*t*Bu and -O-$CH_2C_6H_5$), 4.69 (1H, d, J_{AB} = 12.4 Hz, -OCH_2Ph), 4.65 (1H, d, J_{AB} = 12.4 Hz, -OCH_2Ph), 3.98–3.96 (2H, m, -CH_2OSiPh$_2$*t*Bu), 3.91 (1H, dd, J = 4.0 and 1.4 Hz, OHC-C*H*(OBn)-), 1.04 (9H, s, -OSiPh$_2$C(CH_3)$_3$); ms m/e (70 eV): 361 (M^+ − *t*Bu). Exact Mass (M^+ − *t*Bu) calcd: 361.1260; found: 361.1266.

*2-Benzyloxy-1-[(*tert*-butyldiphenylsilyl)oxy]-6-[(2-tetrahydropyranyl)oxy]-4-methylhex-3-ene (**15**)*

Butyllithium (185 μL, 1.6 M in hexane, 0.296 mmol) was added at −78°C to a stirred suspension of phosphonium bromide **14** (0.162 g, 0.325 mmol, dried under vacuum at 115–120°C for 12 h) in tetrahydrofuran (1.5 mL). The mixture was brought to 0°C and stirred until the solution became dark red (≈ 0.5 h). A solution of aldehyde **12** (0.100 g crude, 0.277 mmol) in tetrahydrofuran (1.5 mL) was then added at 0°C. After 10 min, the mixture was poured into a saturated solution of ammonium chloride and was extracted with ethyl ether. The combined organic layers were dried over anhydrous magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (5% ethyl acetate in hexane) to afford *Z* olefin **15***a* (45.2 mg, 43%) and *E* olefin **15***b* (33.8 mg, 32%); ir ($CHCl_3$) ν, *Z* and *E* isomers: 2950, 2855, 1112 cm^{-1}; ^1H nmr ($CDCl_3$) *Z* isomer, δ: 7.71–7.65 and 7.41–7.25 (15H, m, -$OCH_2C_6H_5$ and -OSi(C_6H_5)$_2$*t*Bu), 5.16 (1H, d, J = 10.0 Hz, -C*H*=C(CH_3)-), 4.62 (1H, d, J_{AB} = 12.0 Hz, -OCH_2Ph), 4.48 (1H, m, -O-C*H*-O-), 4.46 (1H, d, J_{AB} = 12.0 Hz, -OCH_2-Ph), 4.29 (1H, m, -C*H*(OBn)-), 3.85–3.68 (2H, m, -CH_2OTHP and -O-CH-O-CH_2-), 3.79 (1H, dd, J_{AB} = 10.5 Hz, J_{AX} = 6.8 Hz, -CH_2OSiPh$_2$*t*Bu), 3.60 (1H, dd, J_{AB} = 11.5 Hz, J_{BX} = 4.6 Hz, -CH_2OSiPh$_2$*t*Bu), 3.50–3.40 (1H, m, -O-CH-O-CH_2-), 3.39–3.28 (1H, m, -CH_2OTHP), 2.36–2.17 (2H, m, =C(CH_3)-CH_2-CH_2-), 1.78 (3H, s, -CH=C(CH_3)-), 1.76–1.42 (6H, m, -O-CH_2(CH_2)$_3$-), 1.05 (9H, s, -OSiPh$_2$C(CH_3)$_3$); ^{13}C nmr ($CDCl_3$) *Z* isomer, δ: 19.6, 23.8, 25.4, 26.9, 30.6, 32.8, 62.2, 65.7, 67.0, 70.2, 76.2, 98.8, 125.5, 127.2, 127.6, 128.2, 129.5, 133.8, 135.7, 138.2, 139.1; ^1H nmr ($CDCl_3$) *E* isomer, δ: 7.74–7.63 and 7.44–7.25 (15H, m, -O-CH_2-C_6H_5 and -OSi(C_6H_5)$_2$*t*Bu), 5.12 (1H, dm, J = 9.0 Hz, -C*H*=C(CH_3)-), 4.62 (1H, d, J_{AB} = 12.1 Hz, -OCH_2Ph), 4.60–4.56 (1H, m, -O-C*H*-O-), 4.43 (1H, d, J_{AB} = 12.1 Hz, -OCH_2Ph), 4.25–4.17 (1H, m, -C*H*(OBn)-), 3.85–3.76 (3H, m, -CH_2OSiPh$_2$-*t*Bu), 3.50–3.43 (2H, m, -CH_2OTHP and -O-CH-O-CH_2-), 2.30 (2H, t, J = 7.0 Hz, =C(CH_3)-CH_2-), 1.84–1.40 (6H, m, -O-CH_2-(CH_2)$_3$-), 1.54 (3H, d, J = 1.6 Hz, -CH=C(CH_3)-), 1.04 (9H, s, -OSiPh$_2$C(CH_3)$_3$); ^{13}C nmr ($CDCl_3$)

*(3Z)-2-Benzyloxy-6-[(2-tetrahydropyranyl)oxy]-4-methylhex-3-en-1-ol (**16**a)*

A solution of tetrabutylammonium fluoride in tetrahydrofuran (1M, 860 μL, 0.860 mmol) was added at 0°C to a stirred solution of silyl ether **15***a* (0.417 g, 0.748 mmol) in tetrahydrofuran (8.5 mL). The mixture was stirred at room temperature for 2 h and then poured into water and extracted with ethyl acetate. The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil obtained was purified by column chromatography (25% to 50% of ethyl acetate in hexane) to yield alcohol **16***a* (0.228 g, 95%); ir ($CHCl_3$) *ν*: 3580, 3470, 3010, 2945, 2875, 1452, 1212, 1120, 1060, 1030 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.36–7.26 (5H, m, -OCH$_2$C$_6$*H*$_5$), 5.22 (1H, d, *J* = 9.4 Hz, -C*H*=C(CH$_3$)-), 4.63 (d, 1H, J_{AB} = 11.6 Hz, -OC*H*$_2$Ph), 4.58–4.54 (1H, m, -O-C*H*-O-), 4.38 (1H, dd, J_{AB} = 11.6 Hz, J_{BX} = 0.9 Hz, -OC*H*$_2$Ph), 4.34–4.24 (1H, m, C*H*(OBn)-), 3.89–3.78 (2H, m, -C*H*$_2$OH and -O-CH-O-C*H*$_2$-), 3.68–3.39 (4H, m, -C*H*$_2$OTHP, -C*H*$_2$OH, and O-CH-O-C*H*$_2$-), 2.57–2.45 (1H, m, -CH$_2$O*H*), 2.34–2.23 (2H, m, =C(CH$_3$)-C*H*$_2$-CH$_2$OTHP), 1.83 (3H, dd, *J* = 1.3 Hz, -CH=C(C*H*$_3$)-), 1.82–1.49 (6H, m, -O-CH$_2$-(C*H*$_2$)$_3$-); ms *m/e* (70 eV): 280 ($M^+ - CH_2OH$). Exact Mass ($M^+ - CH_2OH$) calcd: 289.1804; found: 289.1801.

*(3E)-2-Benzyloxy-6-[(2'-tetrahydropyranyl)oxy]-4-methylhex-3-en-1-ol (**16**b)*

The preceding procedure was applied, using silyl ether **15***b* (99.2 mg, 0.178 mmol), tetrabutylammonium fluoride (1M in tetrahydrofuran, 215 μL, 0.215 mmol), and tetrahydrofuran (2.5 mL), and afforded alcohol **16***b* (50.0 mg, 88%); ^1H nmr ($CDCl_3$) δ: 7.35–7.28 (5H, m, -OCH$_2$C$_6$*H*$_5$), 5.16 (1H, dq, *J* = 9.2, 1.2 Hz, -C*H*=C(CH$_3$)-), 4.62 (1H, d, J_{AB} = 11.6 Hz, -OC*H*$_2$Ph), 4.59 (1H, t, *J* = 3.6 Hz, -O-C*H*-O-), 4.37 (1H, d, J_{AB} = 11.6 Hz, -OC*H*$_2$Ph), 4.31–4.22 (1H, m, -C*H*(OBn)-), 3.90–3.79 (2H, m, -C*H*$_2$OH and -O-CH-O-C*H*$_2$-), 3.64–3.44 (4H, m, -C*H*$_2$OTHP, -C*H*$_2$OH, and -O-CH-O-C*H*$_2$-), 2.36 (2H, t, *J* = 7.0 Hz, =C(CH$_3$)-C*H*$_2$-), 2.20–2.10 (1H, m, -CH$_2$O*H*), 1.83–1.46 (6H, m, -O-CH$_2$-(C*H*$_2$)$_3$-), 1.71 (3H, d, *J* = 1.2 Hz, -CH=C(C*H*$_3$)-).

*(3Z)-2-Benzyloxy-1-methanesulfonyloxy-6-[(2'-tetrahydropyranyl)oxy]-4-methylhex-3-ene (**17**a)*

Triethylamine (520 μL, 3.73 mmol) and methanesulfonyl chloride (160 μL, 2.07 mmol) were added at 0°C to a stirred solution of alcohol **16***a* (0.594 g, 1.86 mmol) in dichloromethane (11 mL). The mixture was stirred for 0.5 h and then poured into water and extracted with dichloromethane. The organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was used for the next reaction without any purification; ir ($CHCl_3$) *ν*: 3010, 3000, 2940, 2870, 1455, 1445, 1170 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.34–7.26 (5H, m, -OCH$_2$C$_6$*H*$_5$), 5.20 (1H, d, *J* = 9.1 Hz, -C*H*=C(CH$_3$)-), 4.62 (1H, d, J_{AB} = 11.7 Hz, -OC*H*$_2$Ph), 4.54–4.44 (2H, m, -O-C*H*-O- and -C*H*(OBn)-), 4.40 (1H, dd, J_{AB} = 11.7 Hz, J_{BX} = 1.1 Hz, -OC*H*$_2$Ph), 4.25–4.17 (2H, m, -C*H*$_2$OSO$_2$CH$_3$), 3.88–3.76 (2H, m, -O-CH-O-C*H*$_2$ and -C*H*$_2$-OTHP), 3.66–3.35 (2H, m, -O-CH-O-C*H*$_2$- and -C*H*$_2$OTHP), 2.98 (3H, s, -SO$_2$C*H*$_3$), 2.49–2.22 (2H, m, =C(CH$_3$)-C*H*$_2$-), 1.83 (3H, d, *J* = 1.4 Hz, -CH=C(C*H*$_3$)-), 1.82–1.46 (6H, m, -O-CH$_2$-(C*H*$_2$)$_3$-), 1.82–1.46 (6H, m, -O-CH$_2$-(C*H*$_2$)$_3$-); ms *m/e* (70 eV): 313 (M^+ − OTHP). Exact Mass (M^+ − OTHP) calcd: 313.1110; found: 313.1106.

*(3E)-2-Benzyloxy-1-methanesulfoxy-6-[(2'-tetrahydropyranyl)oxy]-4-methylhex-3-ene (**17**b)*

The preceding procedure was applied, using alcohol **16***b* (42.1 mg, 0.132 mmol), methanesulfonyl chloride (11 μL, 0.142 mmol), and triethylamine (37 μL, 0.265 mmol), yielding mesylate **17***b* (53.2 mg, 100% crude); ^1H nmr ($CDCl_3$) δ: 7.34–7.28 (5H, m, -OCH$_2$C$_6$*H*$_5$), 5.16 (1H, d, *J* = 9.4 Hz, -C*H*=C(CH$_3$)-), 4.62 (1H, d, J_{AB} = 11.8 Hz, -OC*H*$_2$Ph), 4.62–4.58 (1H, m, -O-C*H*-O-), 4.48–4.37 (1H, m, -C*H*OBn-), 4.40 (1H, d, J_{AB} = 11.8 Hz, -OC*H*$_2$Ph), 4.26–4.13 (2H, m, -C*H*$_2$OSO$_2$CH$_3$), 3.91–3.81 (2H, m, -O-CH-O-CH$_2$- and -CH$_2$OTHP), 3.56–3.45 (2H, m, -O-CH-O-C*H*$_2$- and -C*H*$_2$OTHP), 2.99 (3H, s, -SO$_2$C*H*$_3$), 2.36 (2H, t, *J* = 6.9 Hz, =C(CH$_3$)-C*H*$_2$-), 1.88–1.47 (6H, m, -O-CH$_2$-(C*H*$_2$)$_3$-), 1.70 (3H, d, *J* = 1.3 Hz, -CH=C(C*H*$_3$)-).

*Methyl (5Z)-4-benzyloxy-8-[(2-tetrahydropyranyl)oxy]-2-methoxycarbonyl-6-methyloct-5-enoate (**18**a)*

Dimethyl malonate (1.12 mL, 9.84 mmol) was added at 0°C to a stirred suspension of sodium hydride (0.383 g, 60% in oil, 9.58 mmol) in tetrahydrofuran (5 mL) and dimethylformamide (5 mL). The mixture was stirred at room temperature for 0.5 h and a solution of mesylate **17***a* (0.739 g, 1.86 mmol) in tetrahydrofuran (2.5 mL) and dimethylformamide (2.5 mL) was then added followed by potassium iodide (0.462 g, 2.79 mmol). The mixture was heated at reflux (≈ 80°C) for 48 h, poured into a saturated solution of ammonium chloride, and extracted with a mixture of hexane and ether (2:1). The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (20% ethyl acetate in hexane) to afford malonate **18***a* (0.717 g, 89%); ir ($CHCl_3$) *ν*: 3000, 2945, 2865, 1745, 1730, 1450, 1437, 1205 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.32–7.25 (5H, m, -OCH$_2$C$_6$*H*$_5$), 5.21 (1H, dq, *J* = 8.9, 1.2 Hz, -C*H*=C(CH$_3$)-), 4.57 (1H, t, *J* = 3.5 Hz, -O-C*H*-O-), 4.52 (1H, d, J_{AB} = 11.6 Hz, -OC*H*$_2$Ph), 4.25 (1H, d, J_{AB} = 11.6 Hz, -OC*H*$_2$Ph), 4.16 (1H, ddd, $J_1 = J_2$ = 8.9 Hz, J_3 = 4.5 Hz, -C*H*OBn-), 3.88–3.75 (2H, m, -O-CH-O-C*H*$_2$- and -C*H*$_2$OTHP), 3.66 and 3.65 (6H, 2s, -CH(CO$_2$C*H*$_3$)$_2$), 3.54–3.38 (3H, m, -C*H*(CO$_2$CH$_3$)$_2$, -O-CH-O-C*H*$_2$-, and -C*H*$_2$OTHP), 2.34 (2H, t, *J* = 7.2 Hz, =C(CH$_3$)-C*H*$_2$-), 2.24–2.09 (2H, m, -CH(OBn)-C*H*$_2$-), 1.80 (3H, br s, -CH=C(C*H*$_3$)-), 1.79–1.47 (6H, m, -O-CH$_2$-(C*H*$_2$)$_3$-); ms *m/e* (70 eV): 349 (M^+ − OTHP). Exact Mass (M^+ − OTHP) calcd: 349.1651; found: 349.1649.

*Methyl (5E)-4-benzyloxy-8-[(2-tetrahydropyranyl)oxy]-2-methoxycarbonyl-6-methyloct-5-enoate (**18**b)*

Sodium iodide (0.383 g, 2.55 mmol) was added to a solution of mesylate **17***b* (22.5 mg, 0.057 mmol) in acetone (3 mL). The mixture was heated at reflux for 3 h. After dilution with ethyl ether, the mixture was poured into a saturated solution of sodium thiosulfate and extracted with ethyl ether. The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was quickly purified by column chromatography (10% to 25% ethyl acetate in hexane) to afford the corresponding iodide (11.8 mg, 49%), which was used immediately for the next reaction.

The preceding procedure was applied, using iodide (11.8 mg, 0.027 mmol) instead of mesylate, sodium hydride (6.4 mg, 60% in oil, 0.160 mmol), dimethyl malonate (19 μL, 0.165 mmol), tetrahydrofuran (0.2 mL), and dimethylformamide (0.2 mL), yielding malonate **18***b* (7.1 mg, 60%); ^1H nmr ($CDCl_3$) δ: 7.32–7.25 (5H, m, -OCH$_2$C$_6$*H*$_5$), 5.18 (1H, d, *J* = 8.9 Hz, -C*H*=C(CH$_3$)-), 4.62–4.58 (1H, m, -O-C*H*-O-), 4.52 (1H, d, J_{AB} = 11.7 Hz, -OC*H*$_2$Ph), 4.25 (1H, d, J_{AB} = 11.7 Hz, -OC*H*$_2$Ph), 4.10 (1H, ddd, $J_1 = J_2$ = 8.9 Hz, J_3 = 4.8 Hz, -C*H*OBn-), 3.89–3.79 (2H, m, -O-C*H*-O-CH$_2$- and -C*H*$_2$OTHP), 3.66 and 3.66 (6H, 2s, -CH(CO$_2$C*H*$_3$)$_2$), 3.64 (1H, dd, *J* = 8.2, 7.2 Hz, -C*H*(CO$_2$CH$_3$)$_2$), 3.54–3.44 (2H, m, -O-CH-O-C*H*$_2$- and -C*H*$_2$OTHP), 2.34 (2H, t, *J* = 6.9 Hz, =C(CH$_3$)-C*H*$_2$-), 2.24–2.00 (2H, m, -CH(OBn)-C*H*$_2$-), 1.90–1.50 (6H, m, -O-CH$_2$-(C*H*$_2$)$_3$-), 1.65 (3H, d, *J* = 1.3 Hz, -CH=C(C*H*$_3$)-).

*Methyl (5Z)-4-benzyloxy-8-hydroxy-2-methoxycarbonyl-5-methyloct-5-enoate (**19**a)*

Pyridinium *para*-toluenesulfonate (34.0 mg, 0.135 mmol) was added to a solution of ether **18***a* (74.6 mg, 0.172 mmol) in methanol (10 mL, 95%). The mixture was heated at reflux for 1.5 h, then the solvent was evaporated. The residual oil was purified by

*Methyl-(5E)-4-benzyloxy-8-hydroxy-2-methoxycarbonyl-6-methyloct-5-enoate (**19**b)*

The preceding procedure was applied, using ether **18***b* (7.4 mg, 0.017 mmol), pyridinium *para*-toluenesulfonate (4.0 mg, 0.016 mmol), and methanol (10 mL, 95%), yielding alcohol **19***b* (5.9 mg, 99%); ^1H nmr ($CDCl_3$) δ: 7.33–7.27 (5H, m, -$OCH_2C_6H_5$), 5.20 (1H, dq, J = 8.9, 1.3 Hz, -CH=$C(CH_3)$-), 4.52 (1H, d, J_{AB} = 11.7 Hz, -OCH_2Ph), 4.28 (1H, d, J_{AB} = 11.7 Hz, -OCH_2Ph), 4.13 (1H, ddd, $J_1 = J_2$ = 8.8 Hz, J_3 = 4.8 Hz, -CHOBn-), 3.79–3.61 (3H, m, -$CH(CO_2CH_3)_2$ and -CH_2OH), 3.68 and 3.67 (6H, 2s, -$CH(CO_2CH_3)_2$), 2.30 (2H, t, J = 6.3 Hz, =$C(CH_3)$-CH_2-), 2.28–2.03 (2H, m, -CH_2-$CH(CO_2CH_3)_2$), 1.65 (3H, d, J = 1.3 Hz, -CH=$C(CH_3)$-), 1.58 (1H, s, -CH_2OH).

*Methyl (5Z)-4-benzyloxy-2-methoxycarbonyl-6-methyloct-5-enoate (**20**a)*

The same procedure as that used for **17***a* was applied: alcohol **19***a* (53.2 mg, 0.152 mmol), triethylamine (42 μL, 0.304 mmol), methanesulfonyl chloride (13 μL, 0.167 mmol), and dichloromethane (3 mL) yielding mesylate **20***a* (65.8 mg, 100% crude); ir ($CHCl_3$) ν: 3020, 2950, 1745, 1730, 1457, 1360, 1337, 1215, 1175 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.34–7.26 (5H, m, $OCH_2C_6H_5$), 5.32 (1H, d, J = 9.1 Hz, -CH=$C(CH_3)$-), 4.53 (1H, d, J_{AB} = 11.7 Hz, -OCH_2Ph), 4.26 (1H, d, J_{AB} = 11.7 Hz, -OCH_2Ph), 4.24 (2H, t, J = 6.9 Hz, -CH_2OMs), 4.08 (1H, ddd, $J_1 = J_2$ = 9.0 Hz, J_3 = 4.2 Hz, -CH(OBn)-), 3.68 (1H, dd, J = 6.2 Hz, -$CH(CO_2CH_3)_2$), 3.67 and 3.66 (6H, 2s, -$CH(CO_2CH_3)_2$), 3.01 (3H, s, -OSO_2CH_3), 2.58–2.48 and 2.22–2.00 (4H, 2m, =$C(CH_3)$-CH_2- and -CH_2-$CH(CO_2CH_3)_2$), 1.82 (3H, d, J = 1.4 Hz, -CH=$C(CH_3)$-).

*Methyl (5E)-4-benzyloxy-8-methanesulfonyloxy-2-methoxycarbonyl-6-methyloct-5-enoate (**20**b)*

The preceding procedure was applied, using alcohol **19***b* (10.3 mg, 0.029 mmol), triethylamine (8.2 μL, 0.059 mmol), methanesulfonyl chloride (2.5 μL, 0.032 mmol), and dichloromethane (0.5 mL), yielding mesylate **20***b* (10.1 mg, 80% crude); ^1H nmr ($CDCl_3$) δ: 7.33–7.27 (5H, m, -$OCH_2C_6H_5$), 5.23 (1H, dq, J = 8.8, 1.2 Hz, -CH=$C(CH_3)$-), 4.52 (1H, d, J_{AB} = 11.7 Hz, -OCH_2Ph), 4.30 (2H, t, J = 6.7 Hz, -CH_2OMs), 4.27 (1H, d, J_{AB} = 11.7 Hz, -OCH_2Ph), 4.11 (1H, ddd, $J_1 = J_2$ = 8.8 Hz, J_3 = 4.7 Hz, -CHOBn-), 3.68 and 3.67 (6H, 2s, -$CH(CO_2CH_3)_2$), 3.64 (1H, dd, J = 8.2, 8.8 Hz, -$CH(CO_2CH_3)_2$), 3.00 (3H, s, -OSO_2CH_3), 2.48 (2H, t, J = 6.6 Hz, =$C(CH_3)$-CH_2-), 2.24–2.01 (2H, m, -CH_2-$CH(CO_2CH_3)_2$), 1.67 (3H, d, J = 1.2 Hz, -CH=$C(CH_3)$-).

*(4Z)-7-Benzyloxy-5,5-dimethoxycarbonyl-2-methylcyclohept-1-ene (**21**)*

Sodium bis(trimethylsilyl)amide (45 μL, 1 M in tetrahydrofuran, 0.045 mmol) was added at −78°C to a stirred solution of mesylate **20***a* (19.2 mg, 0.045 mmol) in tetrahydrofuran (5 mL) and dimethylformamide (5 mL). The temperature of the mixture was allowed to reach room temperature and then potassium iodide was added to the solution. The resulting mixture was stirred at 80°C for 4.5 h. After evaporation of the solvents under vacuum, the residual oil was purified by column chromatography (10% ethyl acetate in hexane) to yield cycloheptene **21** (11.5 mg, 77%); ir ($CHCl_3$) ν: 3020, 3010, 2950, 2855, 1728, 1455, 1435, 1245, 1215, 1090 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.35–7.24 (5H, m, -$OCH_2C_6H_5$), 5.54 (1H, m, -CH=$C(CH_3)$-), 4.59 (1H, d, J_{AB} = 12.0 Hz, -OCH_2Ph), 4.55 (1H, d, J_{AB} = 12.0 Hz, -OCH_2Ph), 4.16 (1H, d, J = 11.0 Hz, -CHOBn-), 3.71 and 3.69 (6H, 2s, -$C(CO_2CH_3)_2$-), 2.63 (1H, ddd, J_{AB} = 13.8 Hz, $J_{AX1} = J_{AX2}$ = 1.5 Hz, -CH(OBn)-CH_2-), 2.26 (1H, dd, J_{AB} = 13.8 Hz, J_{BX} = 10.4 Hz, -CH(OBn)-CH_2-), 2.18–2.13 (4H, m, =$C(CH_3)$-CH_2-CH_2-), 1.72 (3H, dd, $J_1 = J_2$ = 1.6 Hz, -CH=$C(CH_3)$-), ms m/e (70 eV): 332 (M^+), 241 (M^+ − CH_2Ph). Exact Mass (M^+) calcd: 332.1624; found: 332.1619.

*(3Z,9Z,11E)-5-Benzyloxy-13-[(tert-butyldiphenylsilyl)oxy]-1-methanesulfonyloxy-7,7-dimethoxycarbonyl-3-methyltrideca-3,9,11-triene (**23**)*

A solution of crude malonate **20***a* (65.8 mg, 0.154 mmol) in tetrahydrofuran (0.5 mL) and dimethylformamide (0.5 mL) was added at 0°C to a stirred suspension of sodium hydride (7.7 mg, 60% in oil, 0.193 mmol) in tetrahydrofuran (0.5 mL) and dimethylformamide (0.5 mL). After stirring for 0.5 h at room temperature the solution was cooled again to 0°C and then a solution of chloride **22** (7*e*) (86.4 mg, 0.232 mmol) in tetrahydrofuran (0.5 mL) and dimethylformamide (0.5 mL) was added at 0°C. The mixture was stirred for 10 h at room temperature and was then poured into a saturated solution of ammonium chloride and extracted with a mixture of hexane and ethyl ether (2:1). The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (25% to 50% of ethyl acetate in hexane) to afford the triene **23** (99.4 mg, 86%); ir (CH_2Cl_2) ν: 3070, 3010, 2945, 2855, 1732, 1425, 1360, 1265, 1110 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.70–7.66, 7.46–7.34, and 7.28–7.16 (15H, 3m, -$OSi(C_6H_5)_2t$Bu, -O-$CH_2C_6H_5$), 6.48 (1H, dd, J = 15.7, 11.1 Hz, -CH=CH-CH=CH-CH_2OSiPh_2tBu), 6.11 (1H, dd, $J_1 = J_2$ = 11.1 Hz, -CH=CH-CH=CH-CH_2OSiPh_2tBu), 5.80 (1H, dt, J = 15.7, 5.1 Hz, -CH=CH-CH_2OSiPh_2tBu), 5.30 (1H, d, J = 9.4 Hz, -CH=$C(CH_3)$-), 5.25–5.14 (1H, m, -CH=CH-CH=CH-CH_2OSiPh_2tBu), 4.40 (1H, d, J_{AB} = 11.1 Hz, -OCH_2Ph), 4.27–4.12 (5H, m, -CH_2OSiPh_2tBu, -$CH_2OSO_2CH_3$, -CHOBn-), 4.16 (1H, d, J_{AB} = 11.1 Hz, -OCH_2Ph), 3.56 and 3.53 (6H, 2s, -$C(CO_2CH_3)_2$-), 2.97 (3H, s, -OSO_2CH_3), 2.87 (2H, d, J = 7.9 Hz, -$C(CO_2CH_3)_2$-CH_2-CH=), 2.55–2.35 (2H, m, =$C(CH_3)CH_2$-), 2.23 (1H, dd, J_{AB} = 14.8 Hz, J_{AX} = 10.3 Hz, -$C(CO_2CH_3)_2$-CH_2-CHOBn-), 2.01 (1H, dd, J_{AB} = 14.8 Hz, J_{BX} = 2.6 Hz, -$C(CO_2CH_3)_2$-CH_2-CHOBn-), 1.79 (3H, d, J = 1.3 Hz, -CH=$C(CH_3)$-), 1.06 (9H, s, -$OSiPh_2C(CH_3)_3$); ms m/e (70 eV): 705 (M^+ − tBu). Exact Mass (M^+ − tBu) calcd: 705.2553; found: 705.2558.

*Methyl (5Z,11Z,13E)-7-benzyloxy-15-[(tert-butyldiphenylsilyl)-oxy]-5-methyl-2,9,9-trimethoxycarbonylpentadeca-5,11,13-trienoate (**24**)*

Dimethyl malonate (100 μL, 0.875 mmol) was added at 0°C to a stirred suspension of sodium hydride (32.4 mg, 60% in oil, 0.810 mmol) in tetrahydrofuran (1 mL) and dimethylformamide (1 mL). The mixture was stirred at room temperature for 0.5 h and a solution of mesylate **23** (131.1 mg, 0.171 mmol) in tetrahydrofuran (1 mL) and dimethylformamide (1 mL) was added at 0°C. Potassium iodide (14 mg, 0.085 mmol) was then added and the mixture was heated at 85°C for 6 h, poured into a saturated solution of ammonium chloride, and extracted with a mixture of hexane and ethyl ether (2:1). The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (10% of ethyl acetate in hexane) to yield malonate **24** (112.9 mg, 83%); ir ($CHCl_3$) ν: 3020, 3000, 2950, 2940, 1730, 1432, 1205, 1110, 1075 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.69–7.66, 7.46–7.35, and 7.28–7.09 (15H, m, -$OSi(C_6H_5)_2t$Bu and -$OCH_2C_6H_5$), 6.50 (1H, ddd, J = 15.0, 11.1, 1.0 Hz, -CH=CH-CH=CH-CH_2OSiPh_2tBu), 6.09 (1H, dd, $J_1 = J_2$ = 11.1 Hz, -CH=CH-CH=CH-CH_2OSiPh_2tBu), 5.79 (1H, dt, J = 15.0, 5.0 Hz, -CH=CH-CH_2SiPh_2tBu), 5.30–5.18 (1H, m,

*Methyl (5Z,11Z,13*E*)-7-benzyloxy-15-chloro-2,9,9-trimethoxycarbonyl-5-methylpentadeca-5,11,13-trienoate (26)*

s-Collidine (32 μL, 0.242 mmol) and methanesulfonyl chloride (19 μL, 0.242 mmol) were added at 0°C to a stirred solution of alcohol **25** (67.7 mg, 0.121 mmol) and lithium chloride (15.4 mg, 0.363 mmol) in dimethylformamide (1 mL). The mixture was stirred at 0°C for 2 h, was poured into water, and then extracted with a mixture of hexane and ethyl ether (2:1). The combined organic layers were washed with an aqueous solution of copper nitrate and with water, dried over magnesium sulfate, filtered, and concentrated. The crude chloride **26** (67.5 mg, 97%) residual oil was used immediately for the next reaction; ir ($CHCl_3$) ν: 2950, 2922, 2855, 1732, 1438, 1235, 1200, 1075 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.33–7.26 (5H, m, -O$CH_2C_6H_5$), 6.47 (1H, ddd, J = 14.9, 11.2, 1.0 Hz, -CH=CH-C*H*=CH-CH_2Cl), 6.07 (1H, dd, J_1 = J_2 = 11.2 Hz, -CH=C*H*-CH=CH-CH_2Cl), 5.80 (1H, dt, J = 14.9, 7.4 Hz, -CH=C*H*-CH_2Cl), 5.40–5.30 (1H, m, -C*H*=CH-CH=CH-CH_2Cl), 5.16 (1H, dq, J = 9.8, 1.2 Hz, -C*H*=C(CH_3)-), 4.41 (1H, d, J_{AB} = 11.1 Hz, -OCH_2Ph), 4.17 (1H, d, J_{AB} = 11.1 Hz, -OCH_2Ph), 4.19–4.06 (1H, m, -C*H*OBn-), 4.07 (2H, d, J = 7.4 Hz, -CH_2Cl), 3.74, 3.73, 3.61, and 3.53 (12H, 4s, 4x -CO_2CH_3), 3.31 (1H, t, J = 7.0 Hz, -C*H*(CO_2CH_3)$_2$), 2.99–2.78 (2H, m, -C(CO_2CH_3)$_2$-CH_2-CH=), 2.28, 2.07–1.92, and 1.84 (6H, dd, J = 14.8, 10.4 Hz, m and s, -CH_2-CH(CO_2CH_3)$_2$, -CHOBn-CH_2, and =C(CH_3)-CH_2-), 1.76 (3H, d, J = 1.2 Hz, -CH=C(CH_3)-).

*(1*E*,3Z,9Z)-8-Benzyloxy-10-methyl-6,6,13,13-tetramethoxycarbonylcyclotetradeca-1,3,9-triene (5)*

To a stirred suspension of cesium carbonate (190.2 mg, 0.584 mmol) in tetrahydrofuran (12 mL) and dimethylformamide (12 mL) at 75°C, was added during 10 hs a solution of chloride **26** (67.5 mg, crude, 0.117 mmol) in tetrahydrofuran (12 mL) and dimethylformamide (12 mL). The mixture was stirred for 10 more hours, then was cooled at room temperature, filtered, and evaporated under vacuum. The residual oil was purified by column chromatography (hexane/ethyl/acetate/dichloromethane, 7.5:0.5:2–7:1:2) yielding carbocycle **5** (48.5 mg, 74%); mp 161–162°C; uv (hexane) λ_{max}: 232, 266 nm; ir ($CHCl_3$) ν: 3010, 2950, 1760, 1437, 1205, 1215, 1175 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.40–7.31 (5H, m, -O$CH_2C_6H_5$), 6.08–5.94 (2H, m, -CH=C*H*-C*H*=CH-), 5.23–5.03 and 4.99–4.86 (2H, 2m, -C*H*=CH-CH=C*H*-), 5.02 (1H, d, J = 9.5 Hz, -C*H*=C(CH_3)), 4.44 (1H, d J_{AB} = 11.6 Hz, -OCH_2Ph), 4.05 (1H, d, J_{AB} = 11.6 Hz, -OCH_2Ph), 4.08–3.99 (1H, m, -C*H*OBn-), 3.77, 3.73, 3.71, and 3.49 (12H, 4s, 4x -CO_2CH_3), 2.98–2.74 (3H, m, -CH_2-CH=CH-CH=CH-CH_2-), 2.41 (1H, dd, J = 14.3, 11.9 Hz, -CH_2-CH=CH-), 2.33 (1H, dd, J = 14.6, 11.6 Hz, -CH(OBn)-CH_2-), 2.17–2.13 (2H m, -CH_2-C(CH_3)=), 1.74 (3H, d, J = 1.3 Hz, -CH=C(CH_3)-), 1.68 (1H, dd, J = 14.6, 2.6 Hz, -CHOBn-CH_2-), 1.42–1.23 (2H, m, -CH_2-CH_2-C(CH_3)=); ms *m/e* (70 eV): 542 (M^+). Exact Mass (M^+) calcd: 542.2516; found: 542.2517.

3β-Benzyloxy-1β-methyl-5,5,12,12-tetramethoxycarbonyl-trans-cisoid-cis-*tricyclo[8.4.0.0^{2,7}]tetradec-8-ene (6)*

A solution of macrocyclic triene **5** (R = CH_2Ph) (16.8 mg, 0.031 mmol) in toluene (0.2 mL) was heated in a sealed tube at 270°C for 2.75 h. The solvent was then evaporated and the residual oil was purified by column chromatography (10% to 25% ethyl acetate in hexane) to afford the tricyclic compound **6** (R = CH_2Ph) (14.2 mg, 85%) and a mixture of two other compounds (2.6 mg, 15%); mp 104–106°C; ir ($CHCl_3$) ν: 3020, 3030, 2955, 1730, 1435, 1455, 1220, 1250, 1265 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.38–7.25 (5H, m, -O$CH_2C_6H_5$), 5.27 (2H, s, H-C8 and H-C9), 4.61 (1H, d, J_{AB} = 10.8 Hz, -OCH_2Ph), 4.43 (1H, d, J_{AB} = 10.8 Hz, -OCH_2Ph), 3.76 (1H, ddd, J_1 = J_2 = 9.9 Hz, J_3 = 4.4 Hz, -C*H*OBn-), 3.70, 3.69, 3.69, and 3.65 (12H, 4s, 4x -CO_2CH_3), 2.93–2.73 and 2.46–1.27 (13H, m H-C2, H-C4, H-C6, H-C7, H-C10, H-C11, H-C13, H-C14), 0.92 (3H, s, -CH_3-C1); ms *m/e* (70 eV): 542 (M^+), 511 (M^+ − OCH_3). Exact Mass (M^+ − OCH_3) calcd: 511.2332; found: 511.2319.

3β-Hydroxy-1β-methyl-5,5,12,12-tetramethoxycarbonyl-trans-cisoid-cis-*tricyclo[8.4.0.0^{2,7}]tetradec-8-ene and (1S,3S)-3-hydroxy-1-methyl-5,5,12,12-tetramethoxycarbonyl*-trans-cisoid-cis-*tricyclo[8.4.0.0^{2,7}]tetradec-8-ene (27)*

Tin tetrachloride (21 μL, 0.179 mmol) was added to a stirred solution of benzyl ether **6** (R = CH_2Ph) (5.4 mg, 0.010 mmol) in dichloromethane (1 mL). The mixture was stirred at room temperature for about 19 h,[4] poured into water, and extracted with dichloromethane. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (40% of ethyl acetate in hexane) to afford alcohol **27** (3.9 mg, 87%).

2,3-Dichloro-5,6-dicyano-1,4-benzoquinone was added to a stirred solution of *para*-methoxybenzyl ether **6** (R = CH_2-$C_6H_4OCH_3$) (8.0 mg, 0.014 mmol) in dichloromethane (8 mL) and water (100 μL). The mixture was stirred at room temperature for 1.5 h, then was poured into water and extracted with dichloromethane. The residual oil was purified by column chromatography (25% to 50% ethyl acetate in hexane) to yield alcohol **27** (4.7 mg, 76%); $[\alpha]_D^{25}$ −88.5 (*c* 0.72, CH_2Cl_2); ir ($CHCl_3$) ν: 3600, 3020, 3010, 2950, 2920, 2850, 1727, 1455, 1450, 1435, 1255, 1245, 1205 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 5.26–5.20 (2H, m, H-C8 and H-C9), 4.03 (1H, ddd, J_1 = J_2 = 9.5 Hz, J_3 = 4.8 Hz, -C*H*OH-) 3.78, 3.70, 3.69, 3.67 (12H, 4s, 4x -CO_2CH_3), 2.88–2.83 and 2.49–1.47 (13H, m, H-C2, H-C4, H-C6, H-C7, H-C10, H-C11, H-C13, and H-C14), 0.92 (3H, s, -CH_3-C1); ms *m/e* (70 eV): 434 (M^+ − H_2O). Exact Mass (M^+ − H_2O) calcd: 434.1941; found: 434.1937.

[4]Variable reaction times. In some cases lactone **29** was also isolated.

1β-Methyl-5,12,12-trimethoxycarbonyl-trans-cisoid-cis-*tricyclo[8.4.0.0^{2,7}]tetradec-8-ene-5,3β-carbolactone (29)*

para-Toluenesulfonic acid (1.0 mg, 0.005 mmol) was added to a stirred solution of alcohol **27** (1.0 mg, 0.002 mmol) in benzene (0.5 mL). The mixture was heated at 65°C for 1.5 h, poured into a solution of sodium bicarbonate (5%), and extracted with dichloromethane. The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (25% of ethyl acetate in hexane) to yield lactone **29** (0.8 mg, 86%); ir ($CHCl_3$) ν: 3015, 2950, 2920, 1780, 1730, 1450, 1435, 1255, 1220 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 5.58 (1H, ddd, J_{AB} = 9.8 Hz, J_{BX1} = J_{BX2} = 2.3 Hz, H-C8 or H-C9), 5.35 (1H, dm, J_{AB} = 9.8 Hz, H-C9 or H-C8), 4.82 (1H, d, *J* = 4.3 Hz, H-C3), 3.78, 3.77, 3.72 (9H, 3s, 3x -CO_2CH_3), 2.81–1.28 (13H, m, H-C2, H-C4, H-C6, H-C7, H-C10, H-C11, H-C13, and H-C14), 0.94 (3H, s, -CH_3-C1); ms *m/e* (70 eV): 420 (M^+). Exact Mass (M^+) calcd: 420.1784; found: 420.1781.

2-Carboxy-1-methylethyltriphenylphosphonium bromide (31)

A stirred mixture of triphenylphosphine (28.88 g, 0.110 mmol) and 3-bromobutanoic acid **30** (18.39 g, 0.110 mmol) in toluene (250 mL) was heated at reflux for 24 h. The solid was filtered and washed with toluene to afford phosphonium salt **31** (44.48 g, 94% crude); ir ($CHCl_3$) ν: 3500–2400, 3030, 3010, 2955, 1730, 1440, 1215 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 8.30 (1H, s, -COO*H*), 7.86–7.69 (15H, m, aromatic protons), 4.61–4.40 (1H, m, $Br^-P^+Ph_3$-$CH(CH_3)$-), 3.18–2.87 (2H, m, -CH_2-CO_2H), 1.41 (3H, dd, *J* = 18.8, 6.9 Hz, $Br^-P^+Ph_3CH(CH_3)$-).

2-Methoxycarbonyl-1-methyltriphenylphosphonium iodide (32)

Sodium iodide (22.54 g, 0.150 mmol), sodium carbonate (10.62 g, 0.100 mmol), and iodomethane (12.5 mL, 0.2 mol) were added to a stirred solution of phosphonium bromide **31** (43.00 g, 0.100 mol) in acetone (1 L). The mixture was heated at reflux for 12 h. The solvent was then evaporated and the residue was dissolved in dichloromethane. After filtration and evaporation of the solvent, the residue was purified by recrystallization from dichloromethane and hexane to afford phosphonium salt **32** (39.85 g, 81%); mp 163–165°C; ir ($CHCl_3$) ν: 3010, 2935, 1735, 1588, 1485, 1455, 1440, 1230, 1215, 1105 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.93–7.71 (15H, m, aromatic protons), 4.90–4.73 (1H, m, $I^-P^+Ph_3$-$CH(CH_3)$-) 3.71 (3H, s, -CO_2CH_3), 2.92 (1H, ddd, J_1 = J_2 = 15.6 Hz, J_3 = 2.9 Hz, -$CH_2CO_2CH_3$), 2.40 (1H, m, -$CH_2CO_2CH_3$), 1.50 (3H, dd, *J* = 18.6, 7.0 Hz, $I^-P^+Ph_3$-$CH(CH_3)$-).

3-Hydroxy-1-methylpropyltriphenylphosphonium iodide (33a)

Diisobutylaluminium hydride (5.0 mL, 7.52 mmol) was added at −78°C to a stirred solution of ester **32** (1.229 g, 2.51 mmol) in dichloromethane (20 mL). The mixture was stirred at −78°C for 2 h. Decahydrated sodium sulfate (775 mg, 2.41 mmol) was then added at −78°C and the mixture was allowed to warm up slowly to room temperature. After stirring for 12 h, anhydrous sodium sulfate was added and the salts were filtered and washed with acetone. The filtrate was concentrated and the residual solid was recrystallized from hexane and dichloromethane to yield phosphonium salt **33** (0.717 g, 62%); mp 219–221°C, ir ($CHCl_3$) ν: 3350, 3020, 2950, 1440, 1215, 1112 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.95–7.86 and 7.78–7.65 (15H, m, aromatic protons), 5.12–4.96 (1H, m, $I^-P^+Ph_3$-$CH(CH_3)$-), 4.48 (1H, dd, *J* = 7.7, 6.6 Hz, -CH_2OH), 4.04–3.92 and 3.80–3.71 (2H, 2m, -CH_2OH), 2.28–2.13 (1H, m, -CH_2-CH_2OH), 1.40 (3H, dd, *J* = 19.5, 6.8 Hz, $I^-P^+Ph_3$-$CH(CH_3)$-), 1.03–1.12 (-CH_2-CH_2OH).

3-Hydroxy-1-methylpropyltriphenylphosphonium bromide (33b)

Pyridinium *para*-toluenesulfonate (861 mg, 3.43 mmol) was added to a stirred solution of phosphonium bromide **14** (17.10 g, 34.27 mmol) in methanol (250 mL). The solution was heated at 50°C for 18 h and then sodium bicarbonate (0.864 g, 10.29 mmol) was added. The mixture was filtered and the filtrate was evaporated. The residual solid was dissolved in dichloromethane and the mixture was again filtered. After evaporation of the filtrate, the residual solid was recrystallized from dichloromethane and hexane to yield phosphonium salt **33***b* (11.81 g, 83%).[5]

(2R)-1,2-O-Isopropylidene-4-methylhex-3-en-1,2,6-triol (35)

Butyllithium (30.2 mL, 1.6 M in hexane, 48.3 mmol) was added at −78°C to a stirred suspension of phosphonium bromide **33** (10.06 g, 24.2 mmol, dried under vacuum at 115–120°C for 48 h) in tetrahydrofuran (62 mL). The temperature was allowed to reach 0°C and the solution was stirred until it became dark red (≈0.5 h). A solution of aldehyde **34** (5.43 g, 41.8 mmol) in tetrahydrofuran (62 mL) was then added at 0°C. After 10 min, the mixture was poured into a saturated solution of ammonium chloride and extracted with dichloromethane and with ethyl acetate. The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (25% ethyl acetate in hexane) to afford *Z* olefin **35***a*[6] (2.23 g, 50%)[7] and *E* olefin **35***b*[6] (0.443 g, 10%)[7]; $[\alpha]_D^{25}$, *E* isomer −12.2 (*c* 4.20, $CHCl_3$); ir ($CHCl_3$) ν, *Z* isomer: 3610, 3480, 3005, 2980, 2930, 2870, 1445, 1370, 1380, 1215, 1155, 1050 cm^{-1}; ir ($CHCl_3$) ν, *E* isomer: 3610, 3480, 3005, 2985, 2935, 2870, 1450, 1320, 1330, 1235, 1228, 1155, 1150 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ, *Z* isomer: 5.39 (1H, d, *J* = 8.5 Hz, -C*H*=C(CH_3)-), 4.78 (1H,

[5]Spectral data are identical with those obtained for **33***a*.

[6]Volatile compounds.

[7]Yield calculated from phophonium salt **33**.

*(2R)-(3Z)-6-Benzoyloxy-4-methylhex-3-en-1,2-diol (**42**)*

para-Toluenesulfonic acid monohydrate (55 mg, 0.29 mmol) was added at 0°C to a stirred solution of acetonide **41** (0.280 g, 0.96 mmol) in methanol (23 mL). The mixture was stirred at room temperature for 1.5 h, then poured into a saturated solution of sodium chloride and extracted with dichloromethane. The combined organic layers were dried with magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (80% of ethyl acetate in hexane then pure ethyl acetate) to afford diol **42** (0.212 g, 87%); mp 47–48°C; $[\alpha]_D^{25}$ −8.9 (*c* 1.06, CHCl$_3$); ir (CHCl$_3$) *ν*: 3600, 3010, 2965, 2935, 1718, 1450, 1275, 1215, 1118 cm^{-1}; ^{1}H nmr (CDCl$_3$) δ: 8.05–8.01, 7.60–7.54, 7.48–7.42 (5H, 3m, -OCOC$_6$*H*$_5$), 5.34 (1H, d, $J = 9.5$ Hz, -C*H*=C(CH$_3$)-), 4.57–4.47 (1H, m, -C*H*OH-), 4.42 (2H, t, $J = 6.8$ Hz, -C*H*$_2$OCOPh), 3.62–3.42 (2H, m, -C*H*$_2$OH), 2.61 (2H, t, $J = 6.8$ Hz, -C*H*$_2$CH$_2$OBz), 2.07 (1H, d, $J = 3.1$ Hz, -CHO*H*-), 1.94 (1H, t, $J = 5.7$ Hz, -CH$_2$O*H*), 1.84 (3H, d, $J = 1.1$ Hz, -CH=C(C*H*$_3$)-); ms *m/e* (70 eV): 219 (M$^+$ −CH$_2$OH).

*(2R)-(3Z)-6-Benzoyloxy-1-[(para-toluenesulfonyl)oxy]-4-methylhex-3-en-2-ol (**43**)*

Triethylamine (110 μL, 0.79 mmol), *para*-toluenesulfonyl chloride (0.179 g, 0.94 mmol), and dimethylaminopyridine (70 mg, 0.58 mmol) were added at 0°C to a stirred solution of diol **42** (0.180 g, 0.72 mmol) in dichloromethane (18 mL). The mixture was stirred at 0°C for 1.5 h, then poured into a saturated solution of ammonium chloride and extracted with dichloromethane. The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (25% to 50% ethyl acetate in hexane, then pure ethyl acetate) to give tosylate **43** (0.210 g, 72%) and diol **42** (25.3 mg, 14%); $[\alpha]_D^{25}$ −33.8 (*c* 1.71, CHCl$_3$); ir (CHCl$_3$) *ν*: 3590, 3020, 2950, 1717, 1600, 1452, 1365, 1275, 1220, 1190, 1175, 1120, 1100 cm^{-1}; ^{1}H nmr (CDCl$_3$) δ: 8.02–7.98, 7.79–7.76, 7.61–7.54, 7.47–7.41, and 7.34–7.31 (9H, 5m, -OCOC$_6$*H*$_5$, -CH$_2$OSO$_2$-C$_6$*H*$_4$CH$_3$), 5.23 (1H, d, $J = 9.0$ Hz, -C*H*=C(CH$_3$)-), 4.72–4.62 (1H, m, -C*H*OH-), 4.37 (2H, t, $J = 6.8$ Hz, -C*H*$_2$OCOPh), 4.01–3.86 (2H, m, -C*H*$_2$OTs), 2.53 (2H, td, $J = 6.8$, 2.2 Hz, -C*H*$_2$CH$_2$OCOPh), 2.43 (3H, s, -OSO$_2$C$_6$H$_4$C*H*$_3$), 2.11 (1H, d, $J = 3.6$ Hz, -CHO*H*-), 1.80 (3H, d, $J = 1.4$ Hz, -CH=C(C*H*$_3$)-).

*(2R)-(3Z)-6-Benzoyloxy-2-[(para-methoxybenzyl)oxy]-1-[(para-toluenesulfonyl)oxy]-4-methylhex-3-ene (**44**)*

A solution of trichloro-*para*-methoxybenzylacetimidate (0.569 g, 2.01 mmol) in ethyl ether (1 mL) was added to a solution of alcohol **43** (0.204 g, 0.50 mmol) in ethyl ether (20 mL). The mixture was cooled to 0°C and trifluoromethanesulfonic acid (40 μL, solution 1 μL in 1 mL of ethyl ether, 0.0005 mmol) was added. The mixture was stirred at 0°C for 3 h, then poured into a saturated solution of sodium carbonate and extracted with dichloromethane. The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (25% of ethyl acetate in hexane and 2% acetone in toluene) to afford ether **44** (0.214 g, 73%); $[\alpha]_D^{25}$ −8.5 (*c* 1.30, CHCl$_3$); ir (CHCl$_3$) *ν*: 3020, 2930, 1718, 1612, 1600, 1515, 1450, 1360, 1275, 1250, 1212, 1178 cm^{-1}; ^{1}H nmr (CDCl$_3$) δ: 8.02–7.99, 7.76–7.73, 7.59–7.53, 7.46–7.40, 7.28–7.25, 7.14–7.11, and 6.84–6.80 (13H, 7m, -OCOC$_6$*H*$_5$, -OSO$_2$C$_6$*H*$_4$CH$_3$, -OCH$_2$C$_6$*H*$_4$OCH$_3$), 5.14 (1H, d, $J = 9.1$ Hz, -C*H*=C(CH$_3$)-), 4.42 (1H, d, $J_{AB} = 11.3$ Hz, -OC*H*$_2$C$_6$H$_4$OCH$_3$), 4.38–4.30 (1H, m, -C*H*(OMPM)-), 4.32 (2H, t, $J = 7.0$ Hz, -C*H*$_2$OCOPh), 4.24 (1H, d, $J_{AB} = 11.3$ Hz, -OC*H*$_2$C$_6$H$_4$OCH$_3$), 4.03–3.92 (2H, m, -C*H*$_2$OTs), 3.78 (3H, s, -OCH$_2$C$_6$H$_4$OC*H*$_3$), 2.46 (2H, t, $J = 7.0$ Hz, -C*H*$_2$-CH$_2$OBz), 2.40 (3H, s, -OSO$_2$C$_6$H$_4$C*H*$_3$), 1.83 (3H, d, $J = 1.2$ Hz, -CH=C(C*H*$_3$)-).

*(2R)-(3Z)-6-Benzoyloxy-1-iodo-2-[(para-methoxybenzyl)oxy]-4-methylhex-3-ene (**45**)*

Sodium iodide (183 mg, 1.221 mmol) and tetrabutylammonium iodide (680 mg, 1.854 mmol) were added to a stirred solution of tosylate **44** (32.0 mg, 0.061 mmol) in acetone (5 mL) and the mixture stirred for 70 h at 50°C. The solvent was then evaporated and the residual solid was purified by column chromatography (25% of ethyl acetate in hexane) to yield iodide **45** (28.9 mg, 99%); $[\alpha]_D^{25}$ +10.1 (*c* 1.34, CHCl$_3$); ir (CHCl$_3$) *ν*: 3010, 1718, 1515, 1278, 1215 cm^{-1}; ^{1}H nmr (CDCl$_3$) δ: 8.03–8.00, 7.59–7.52, 7.46–7.40, 7.27–7.22, and 6.87–6.83 (9H, 5m, -OCOC$_6$*H*$_5$ and -OCH$_2$C$_6$*H*$_4$OCH$_3$), 5.25 (1H, d, $J = 9.0$ Hz, -C*H*=C(CH$_3$)-), 4.49 (1H, d, $J_{AB} = 11.3$ Hz, -OC*H*$_2$C$_6$H$_4$OCH$_3$), 4.40 (2H, dt, $J_1 = J_2 = 6.9$ Hz, -C*H*$_2$OCOPh), 4.34 (1H, d, $J_{AB} = 11.3$ Hz, -OC*H*$_2$C$_6$H$_4$OCH$_3$), 4.22–4.14 (1H, m, -C*H*(OMPM)-), 3.78 (3H, s, -OCH$_2$C$_6$H$_4$OC*H*$_3$), 3.24–3.09 (2H, m, -CH$_2$I), 2.53 (2H, td, $J = 6.9$, 3.8 Hz, -C*H*$_2$-CH$_2$OBz), 1.89 (3H, d, $J = 1.4$ Hz, -CH=C(C*H*$_3$)-); ms *m/e* (70 eV): 480 (M$^+$), 449 (M$^+$−OCH$_3$), 342 (M$^+$−I). Exact Mass (M$^+$) calcd: 480.0799; found: 480.0788.

*Methyl (4S)-(5Z)-8-benzoyloxy-4-[(para-methoxybenzyl)oxy]-2-methoxycarbonyl-6-methyloct-5-enoate (**46**)*

The same procedure as used for **18***a* was applied using the following quantities: sodium hydride (0.133 g, 50% in oil, 2.76 mmol), dimethyl malonate (335 μL, 2.93 mmol), tosylate **44** (0.270 g, 0.51 mmol), potassium iodide (111 mg, 0.67 mmol), tetrahydrofuran (15 mL), dimethylformamide (15 mL), and afforded malonate **46** (0.179 g, 72%) and unreacted tosylate (28.3 mg, 10%).

Similarly, the above procedure was applied using iodide **45** and the following quantities: sodium hydride (16 mg, 60% in oil, 0.400 mmol), dimethyl malonate (48 μL, 0.42 mmol), iodide (28.9 mg, 0.060 mmol), tetrahydrofuran (1.5 mL), dimethylformamide (1.5 mL). Malonate **46** (22.3 mg, 77%) and unreacted iodide (3.3 mg, 11%) were obtained; $[\alpha]_D^{25}$ −16.8 (*c* 1.20, CHCl$_3$);

A solution of macrocyclic triene **5** (R = CH$_2$C$_6$H$_4$OCH$_3$) (8.8 mg, 0.015 mmol) in toluene (0.5 mL) was heated in a sealed tube at 262°C for 3 h. The solvent was evaporated and the residual oil was purified by column chromatography (10% to 25% of ethyl acetate in hexane) to afford tricyclic compound **6** (R = CH$_2$C$_6$H$_4$OCH$_3$) (7.2 mg, 82%) and a mixture of two compounds (1.5 mg, 17%); [α]$_D^{25}$ −49.3 (*c* 0.98, CHCl$_3$); ir (CH$_2$Cl$_2$) ν: 3060, 2990, 2960, 1730, 1615, 1515, 1440, 1270, 1250 cm^{-1}; ^{1}H nmr (CDCl$_3$) δ: 7.32–7.28 and 6.89–6.84 (4H, 2m, -OCH$_2$C$_6$$H_4OCH_3$), 5.27 (2H, s, -C$H$=C$H$-), 4.53 (1H, d, J_{AB} = 10.2 Hz, -OCH_2C$_6$H$_4$OCH$_3$), 4.36 (1H, d, J_{AB} = 10.2 Hz, -OCH_2C$_6$H$_4$OCH$_3$), 3.83–3.63 (1H, m, -CH(OMPM)-), 3.79 (3H, s, -OCH$_2$C$_6$H$_4$OCH_3), 3.71, 3.71, 3.70, 3.69 (12H, 4s, 4x -CO$_2$CH_3), 2.95–1.21 (13H, m, H-C2, H-C4, H-C6, H-C7, H-C10, H-C11, H-C13, and H-C14), 0.91 (3H, s, -CH_3-C1); ms m/e (70 eV): 572 (M$^+$), 554 (M$^+$ − H$_2$O). Exact Mass (M$^+$) calcd: 572.2621; found: 572.2630.

*(2*R*)-(3*Z*)-6-[(tert-Butyldiphenylsilyl)-oxy]-1,2-O-isopropylidene-4-methylhex-3-ene-1,2-diol (**36**)*

Imidazole (23 mg, 0.336 mmol) and *tert*-butyldiphenylsilyl chloride (73 μL, 0.284 mmol) were added to a stirred solution of alcohol **35***a* (48.1 mg, 0.259 mmol) in dimethylformamide (1.5 mL). The mixture was stirred at room temperature for 4 hs, then poured into a saturated solution of ammonium chloride and extracted with ethyl ether. The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (5% to 50% ethyl acetate in hexane) to yield silyl ether **36** (86.1 mg, 79%); [α]$_D^{25}$ (*R*): +3.6 (*c* 1.22, CHCl$_3$); (*S*): −4.5 (*c* 1.49 (CHCl$_3$); ir (CHCl$_3$) ν: 3020, 2930, 2860, 1430, 1215, 1110, 1055 cm^{-1}; ^{1}H nmr (CDCl$_3$)δ: 7.68–7.64 and 7.44–7.35 (10H, 2m, -OSi(C$_6$$H_5$)$_2$*t*Bu), 5.22 (1H, d, J = 8.8 Hz, -CH=C(CH$_3$)-), 4.63 (1H, ddd, J_1 = J_2 = 8.6 Hz, J_3 = 6.0 Hz, -OCH$_2$-CH-O-), 3.84 (1H, dd, J_{AB} = 8.0 Hz, J_{AX} = 6.0 Hz, -OCH_2-CH-O-), 3.74–3.56 (2H, m, -CH_2-OSiPh$_2$*t*Bu), 3.40 (1H, dd, app t, J_{AB} = J_{BX} = 8.0 Hz, -OCH_2-CH-O-), 2.58–2.18 (2H, m, -CH_2-CH$_2$OSiPh$_2$*t*Bu), 1.69 (3H, d, J = 1.4 Hz, -CH=C(CH_3)-), 1.39 and 1.36 (6H, 2s, -O-C(CH_3)$_2$-O-), 1.04 (9H, s, -OSiPh$_2$C(CH_3)$_3$); ms m/e (70 eV): 424 (M$^+$), 409 (M$^+$ − CH$_3$), 367 (M$^+$ − *t*Bu).

*(2*R*)-(3*Z*)-6-[(tert-Butyldiphenylsilyl)oxy]-4-methylhex-3-en-1,2-diol (**37**)*

Pyridinium *para*-toluenesulfonate (10.2 mg, 0.041 mmol) was added at 0°C to a stirred solution of acetonide **36** (86.1 mg, 0.203 mmol) in methanol (2 mL). The mixture was stirred for 4 h at room temperature (until the appearance of triol by TLC). The mixture was poured into a saturated solution of sodium chloride and extracted with dichloromethane. The combined organic layers were dried over magnesium sulfate, filtered, and concentrated. The residual oil was purified by column chromatography (50% ethyl acetate in hexane) to yield diol **37** (42.8 mg, 55%) and starting material **36** (40.1 mg, 45%). The starting material was then recycled twice to afford diol **37** (67.5 mg, 87% total); [α]$_D^{25}$ (*R*): −10.2 (*c* 1.54, CHCl$_3$); (S): +10.8 (*c* 1.59, CHCl$_3$); ir (CHCl$_3$) ν: 3580, 3450, 3015, 2960, 2930, 2860, 1430, 1215, 1110 cm^{-1}; ^{1}H nmr (CDCl$_3$) δ: 7.69–7.64 and 7.45–7.36 (10H, 2m, -OSi(C$_6$$H_5$)$_2$*t*Bu), 5.40 (1H, d, J = 7.8 Hz, -CH=C(CH$_3$)-), 4.35 (1H, ddd, J_1 = J_2 = 7.6 Hz, J_3 = 3.8 Hz, -CHOH-), 3.71–3.44 (4H, m, -CH_2OH and -CH_2OSiPh$_2$*t*Bu), 2.61–2.19 (2H, m, -CH_2-CH$_2$OSiPh$_2$*t*Bu), 1.68 (3H, d, J = 1.3 Hz, -CH=C(CH_3)-), 1.05 (9H, s, -OSiPh$_2$C(CH_3)$_3$); ms m/e (70 eV): 353 (M$^+$ − OCH$_3$). Exact Mass (M$^+$ − OCH$_3$) calcd: 353.1937; found: 353.1935.

*(2*R*)-(3*Z*)-6-[(tert-Butyldiphenylsilyl)oxy]-1-[(para-toluenesulfonyl)-oxy]4-methylhex-3-en2-ol (**38**)*

The procedure used for **43** was applied: diol **37** (31.3 mg, 0.082 mmol), *para*-toluenesulfonyl chloride (17.0 mg, 0.090 mmol), triethylamine (12.5 μL, 0.090 mmol), dimethylaminopyridine (10.0 mg, 0.082 mmol), and dichloromethane (1 mL) yielded tosylate **38** (25.9 mg, 60%) and starting material **37** (8.5 mg, 27%). The starting material was then recycled to afford tosylate **38** (33.2 mg, 76% total); [α]$_D^{25}$ (*R*): − 24.3 (*c* 1.42, CHCl$_3$); (*S*): +25.6 (*c* 1.37, CHCl$_3$); ir (CHCl$_3$) ν: 3450, 3020, 2950, 2930, 2860, 1430, 1362, 1230, 1190, 1175, 1110 cm^{-1}; ^{1}H nmr (CDCl$_3$) δ: 7.80–7.76, 7.66–7.61, 7.47–7.30 (14H, 3m, -OSi(C$_6$$H_5$)$_2$*t*Bu and -OSO$_2$-C$_6$$H_4CH_3$), 5.26 (1H, dq, J = 8.0, 1.2 Hz, -CH=C(CH$_3$)-), 4.49–4.41 (1H, m, -CHOH-), 3.97–3.85 and 3.67–3.59 (4H, 2m, -CH_2OSiPh$_2$*t*Bu and -CH_2OTs), 2.49–2.31 and 2.24–2.14 (2H, 2m, -CH_2-CH$_2$OSiPh$_2$*t*Bu), 2.43 (3H, s, -OSO$_2$C$_6$H$_4$CH_3), 2.09–1.96 (1H, s, -CHOH-), 1.64 (3H, d, J = 1.3 Hz, -CH=C(CH_3), 1.02 (9H, s, -OSiPh$_2$C(CH_3)$_3$.

*(2R)-(3Z)-6-[(*tert*-Butyldiphenylsilyl)oxy]-2-[(2S)-2-methoxy-2-phenylacetoxy]-1[(*para*-toluenesulfonyl)-oxy]4-methylhex-3-ene (**39**)*

(2*S*)-2-Phenyl-2-methoxyacetic acid (**40**) (20) (11.3 mg, 0.068 mmol), dicyclohexylcarbodiimide (14.1 mg, 0.068 mmol), and dimethylaminopyridine (4.0 mg, 0.034 mmol) were added at 0°C to a stirred solution of (*R*) alcohol **38** (18.5 mg, 0.034 mmol) in dichloromethane (1 mL). The mixture was stirred for 0.75 h at 0°C and then filtered on Celite. After evaporation of the solvent, the residual solid was purified by column chromatography (25% ethyl acetate in hexane) to afford ester **39** (24.3 mg, 99%); $[\alpha]_D^{25}$ +48.2 (*c* 1.17, $CHCl_3$); ir ($CHCl_3$) *ν*: 3020, 2930, 2855, 1748, 1430, 1365, 1172, 1110 cm^{-1}; ^1H nmr ($CHCl_3$) δ: 7.70–7.59 and 7.42–7.25 (19H, -OSi(C_6H_5)$_2$*t*Bu, -$OSO_2C_6H_4CH_3$, and -OCOCH(OCH_3)C_6H_5), 5.56–5.48 (1H, m, -*CH*(OCOCH(OCH_3)Ph)-), 4.90 (1H, d, *J* = 9.2 Hz, -*CH*=C(CH_3)-), 4.66 (1H, s, -OCOC*H*(OCH_3)Ph), 3.94–3.92 and 3.65–3.44 (4H, 2m, -CH_2-$OSO_2C_6H_4CH_3$ and -CH_2OSiPh_2*t*Bu), 3.37 (3H, s, -OCOCH-(OCH_3)Ph), 2.47–2.35 and 2.06–1.96 (2H, 2m, -CH_2-CH_2-OSiPh_2*t*Bu), 2.40 (2H, s, -$OSO_2C_6H_4CH_3$), 1.55 (3H, d, *J* = 1.3 Hz, -CH=C(CH_3)-), 0.99 (9H, s, -OSiPh_2C(CH_3)$_3$).

*(2S)-(3Z)-6-[(*tert*-Butyldiphenylsilyl)oxy]-2-[(2S)-2-methoxy-2-phenylacetoxy]-1-[(*para*-toluenesulfonyl)oxy]-4-methylhex-3-ene (**39**)*

The previous procedure was applied: (2*S*)-2-phenyl-2-methoxyacetic acid (**40**) (20) (9.0 mg, 0.055 mmol), dicyclohexylcarbodiimide (11.0 mg, 0.055 mmol), (*S*) alcohol **38** (14.7 mg, 0.027 mmol), dimethylaminopyridine (3.3 mg, 0.027 mmol), and dichloromethane (1 mL) yielded ester **39** (16.8 mg, 90%); $[\alpha]_D^{25}$ +0.9 (*c* 1.13, $CHCl_3$); ^1H nmr ($CDCl_3$) δ: 7.64–7.59, 7.54–7.51, 7.43–7.31, and 7.23–7.19 (19H, 4m, -OSi(C_6H_5)$_2$*t*Bu, -OSO_2-$C_6H_4CH_3$, and -OCOCH(OCH_3)C_6H_5), 5.48–5.39 (1H, m, -*CH*-(OCOCH(OCH_3)Ph),-), 5.07 (1H, d, *J* = 9.4 Hz, -*CH*=C(CH_3)-), 4.69 (1H, s, -OCOC*H*(OCH_3)Ph), 3.81 (2H, d, *J* = 5.2 Hz, -CH_2O-$SO_2C_6H_4CH_3$), 3.69–3.49 (2H, m, -CH_2OSi-Ph_2*t*Bu), 3.36 (3H, s, -OCOCH(O*CH*$_3$)Ph), 3.56–3.45 (1H, m, -*CH*$_2$-CH_2OSiPh_2*t*Bu), 2.39 (3H, s, -$OSO_2C_6H_4CH_3$), 2.17–2.06 (1H, m, -CH_2-CH_2OSi-Ph_2*t*Bu), 1.64 (3H, d, *J* = 1.4 Hz, -CH=C(*CH*$_3$)-), 1.00 (9H, s, -OSiPh_2C(*CH*$_3$)$_3$).

^{1}H nuclear magnetic resonance and molecular orbital estimates of the internal rotational barrier in phenylpropynal in solution and in the vapor

TED SCHAEFER, RUDY SEBASTIAN, AND ROBERT W. SCHURKO[1]
Department of Chemistry, University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received January 24, 1992

TED SCHAEFER, RUDY SEBASTIAN, and ROBERT W. SCHURKO. Can. J. Chem. **70**, 2365 (1992).

The ^{1}H nuclear magnetic resonance spectra of phenylpropynal and 1-phenylpropyne are analyzed for CS_2/C_6D_{12} and acetone-d_6 solutions. The ensuing spin–spin coupling constants over eight formal bonds are used in assessing the conformational dependence of the one in the propynal derivative, as compared to the one over six bonds in benzaldehyde. The eight-bond coupling constant in phenylpropynal implies, via a hindered rotor model, that the twofold barrier to internal rotation is 5.9 ± 1.6 kJ/mol in both solutions. This number is much smaller than that for the internal barrier in benzaldehyde, reflecting the reduced π electron conjugation in phenylpropynal. Molecular orbital computations, with geometry optimization, confirm the essentially purely twofold internal barrier in the free propynal. The theoretical magnitudes are given for AM1 calculations, as well as for *ab initio* computations with STO-3G, 3-21G, 6-31G, and 6-31G* bases. To within experimental error, the barrier magnitudes from the split-valence basis sets agree with those obtained in solution.

TED SCHAEFER, RUDY SEBASTIAN et ROBERT W. SCHURKO. Can. J. Chem. **70**, 2365 (1992).

On a analysé les spectres de résonance magnétique nucléaire du ^{1}H du phénylpropynal et du 1-phénylpropyne en solutions dans le CS_2/C_6D_{12} et dans l'acétone-d_6. On a utilisé les constantes de couplage spin–spin à travers huit liaisons formelles pour déterminer la dépendance conformationnelle de la constante de couplage dans le propynal par comparaison avec celle à travers six liaisons dans le benzaldéhyde. La constante de couplage à travers huit liaisons dans le phénylpropynal implique, en se basant sur un modèle à rotor empêché, que la barrière binaire à la rotation interne est de 5,9 ± 1,6 kJ/mol dans chacune des solutions. Cette valeur est beaucoup plus faible que celle pour la barrière interne dans le benzaldéhyde et elle est le reflet d'une conjugaison π réduite dans le phénylpropynal. Des calculs d'orbitales moléculaires, avec optimisation de géométrie, confirment le caractère essentiellement binaire pur de la barrière interne dans le propynal libre. On rapporte les amplitudes théoriques obtenus par calculs AM1 ainsi que par calculs *ab initio* avec des bases STO-3G, 3-21G, 6-31G et 6-31G*. Aux erreurs expérimentales près, les amplitudes des barrières calculées avec les ensembles à valence partagée sont en bon accord avec celles obtenues en solution.

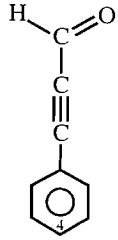
[Traduit par la rédaction]

Introduction

The use of motionally averaged long-range spin–spin coupling constants in conformational analysis has had some success. For example, for benzyl fluoride (1) the barrier to rotation about the exocyclic C—C bond is comparable in magnitude to thermal energies at ambient temperatures and is significantly dependent on the solvent, so much so that the minimum in the internal rotational dependence apparently shifts by 90° in going from polar solvents to the free molecule. Experiments of this kind are feasible for relatively small internal barriers, say those in which their magnitude is less than $6kT$, because otherwise the bonds carrying the coupled nuclei do not sample a satisfactory portion of the rotational potential surface. However, it is just such barriers that are hard to ascertain by lifetime measurements such as in dynamic nmr; also, the latter need a chemical shift marker, unnecessary in the application of motionally averaged coupling constants.

If follows that, while dynamic nmr is successful in assessing the barrier height (free energy of activation) for benzaldehyde in solution, which is likely greater than 30 kJ/mol (ref. 2, a review giving a collection of data and a discussion), ^6J(H, CHO) should be very small, presumably being proportional to sin $^2\theta$, whose expectation value at 300 K is then only about 0.045, where θ is the internal torsion angle. Yet INDO MO FPT computations (3) yield (4, 5) $^6J_{90}$ (θ = 90°) as near −1.0 Hz, so that a measurable value of about −0.05 Hz should appear in a reasonably high-resolution ^{1}H nmr spectrum of benzaldehyde in solution. The formal analysis of the ^{1}H nmr spectra implies ^6J as about −0.015 Hz (5, 6), not yet detected as a splitting in the spectrum. In the presence of two *ortho* chlorine substituents, ^6J is −0.135(3) Hz (7). Combined with STO-3G MO computations (the minimal basis set, of all those employed (8), being in best agreement with experiment for benzaldehyde), this number leads to a $^6J_{90}$ of -0.3_3 Hz (7). A different approach (5), based on ^6J in 2-chlorobenzaldehyde, yields a $^6J_{90}$ of −0.4 Hz. If $^6J_{90}$ lies between −0.3 and −0.4 Hz in benzaldehyde and if the positive component of ^6J is indeed negligible in the absence of ring substituents, then a barrier (9, 10) of 30.5–33.0 kJ/mol entails a ^6J of 0.042 (−0.35 ± 0.05) or −0.015 ± 0.002 Hz in benzaldehyde in solution; this number is consistent with the spectral analyses (5, 6).

Now, consider phenylpropynal, **1**. The π electron conjugation between the formyl and phenyl groups, mediated



1

by the triple bond, will be weaker than in benzaldehyde; its absence would imply essentially free internal rotation, while its presence would favour a planar molecule. The triple bond may reduce the σ–π contribution to ^6J in **1**. If the barrier to

internal rotation is small enough, however, then a precise measurement of ^8J may still lead to an estimate of its magnitude.

In this report, the ^{1}H nmr spectra of **1** and **2**, 1-phenylpropyne, are obtained and analyzed for polar and nonpolar

2

solutions. The ensuing ^8J values yield an estimate of the internal barrier in **1**, which is also calculated for the free molecule at various levels of molecular orbital theory.

Experimental

The compounds, 1-phenylpropyne and phenylpropynal, from Aldrich, were prepared as 5.0 mol% solutions in CS_2/C_6D_{12}/TMS and acetone-d_6/TMS solvent mixtures (see the tables for details). The solutions were filtered into 5 mm o.d. nmr sample tubes, which were degassed by at least four cycles of the freeze–pump–thaw procedure. Careful flame-sealing produced fairly symmetrical tops on the sample tubes.

The ^{1}H nmr spectra were obtained on an AM 300 Bruker spectrometer using acquisition times of 50 s or more, digital resolution of 0.002–0.005 Hz/point, and some resolution enhancement procedures (see figures). Weak irradiation experiments (11–14) established the signs of the long-range coupling constants in the aldehyde and the strongly second-order spectrum of the methyl compound was determined by the signs of its long-range coupling constants, which were already known (15) for its 2,5-dichloro derivative.

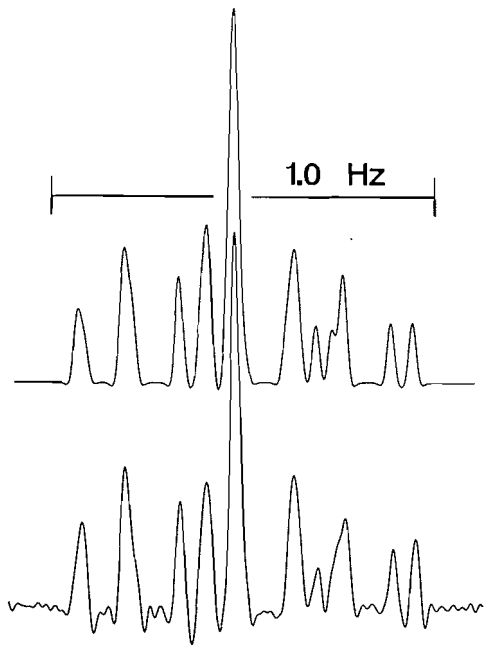

FIG. 1. The ^{1}H nmr spectrum at 300 MHz of the methyl protons of 1-phenylpropyne, as a 5 mol% solution in acetone-d_6 at 300 K, has a linewidth at half height of somewhat less than 0.03 Hz. The acquisition time is 50.0 s and some resolution enhancement is employed. The theoretical spectrum takes the enhancement into account, uses the spectral parameters from Table 1, and assumes a linewidth of 0.025 Hz. The relative signs of the coupling constants to the ring protons follow from the observed pattern in this figure.

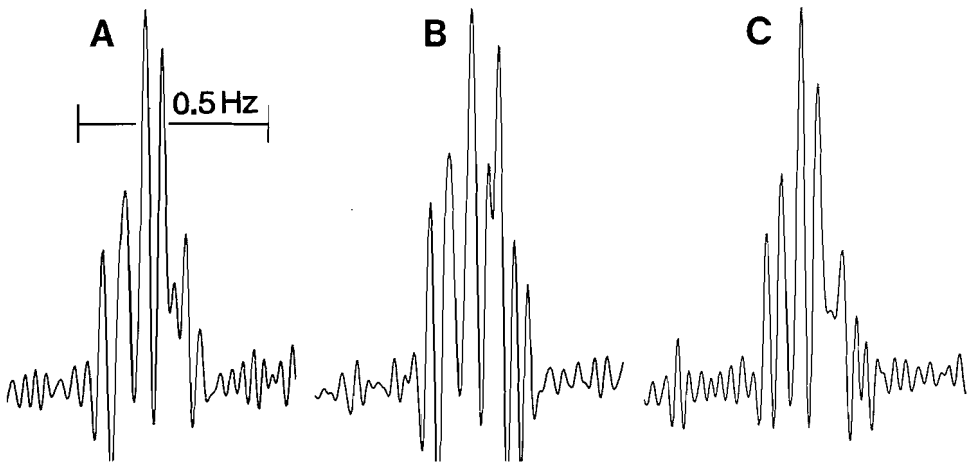

FIG. 2. In A is shown the ^{1}H nmr spectrum at 300 MHz and 300 K of the formyl proton in phenylpropynal as a 5 mol% solution in acetone-d_6. The digital resolution is 0.002 Hz/point, the acquisition time is 51.2 s, and rather severe resolution enhancement, a LB of −0.120 and a GB of 0.600, is applied. In B a weak second radiofrequency field is applied to the doublet (splitting of ca. 0.06 Hz due to the formyl proton) at highest frequency in the spectrum of the *ortho* protons. The spectral pattern is consistent with expectation if ^7J(H, CHO)/$^3J_{23} > 0$ and ^8J(H, CHO)/$^4J_{24} < 0$. In C the peak (split by about 0.04 Hz) near 2280.20 Hz in the *para* proton region is being irradiated. This peak corresponds to opposite spin states for the *meta* and *para* protons, say negative and positive, respectively. If ^6J(H, CHO)/$^4J_{24} < 0$ and ^7J(H, CHO)/$^3J_{34} > 0$, then, with the correct amplitude of the second field, the right-hand peak in the formyl proton spectrum should split (tickling conditions (11)), as observed. Six sets of experiments were performed to confirm the sign relationships given in Table 1 and simulations of the double resonance experiments used the program DOR (13).

Molecular orbital computations utilized the program GAUSSIAN 86 (16), with various basis sets (17). INDO MO FPT (3) calculations of long-range coupling constants employed the geometries obtained from the optimizations in the molecular orbital iterations.

Results and discussions

Spectral analyses

The spectral parameters, obtained with the program NUMARIT (18), extensively reworked by R. Sebastian, appear in Table 1. Figure 1 displays the ^{1}H nmr spectrum of the methyl group in 1-phenylpropyne and Fig. 2 illustrates one of a series of experiments designed to determine the signs of the coupling constants involving the formyl proton in phenylpropynal.

*^{8}J in 1-phenylpropyne, **1**, and phenylpropynal, **2**, and the internal barrier in **1***

In toluene, ^6J(H, CH_3) is −0.602(2) Hz, is a pure σ−π coupling constant (19–22) and hence is proportional to sin $^2\theta$. ^8J in **2** is −0.252(3) Hz (the mean of −0.251(1) and −0.254(1) Hz) and is most likely also a pure σ−π parameter. Therefore the triple bond reduces the σ−π interactions by a factor of 0.42, confirming a previous conclusion (15). $^8J_{90}$ in **2** is thus 0.504(6)Hz, that is, when the C—H bond of the methyl group lies in a plane perpendicular to the molecular plane; the internal barrier is essentially zero, so that ⟨sin $^2\theta$⟩ is 0.5.

The analogous procedure for the aldehyde, **1**, then implies that $^8J_{90}$ is (-0.35 ± 0.05) 0.42 or $-0.14_7 \pm 0.02_1$ Hz. The measured value (Table 1) of ^8J is $-0.036_5 \pm 0.001_5$ Hz. Therefore ⟨sin $^2\theta$⟩ is 0.248 ± 0.047 at 300 K. If the internal barrier is purely twofold, then its magnitude follows as 5.9 ± 1.6 kJ/mol, considerably lower than in benzaldehyde in the vapor, where the internal barrier is predominantly twofold and very near 20 kJ/mol (23–26), or in solution, where the free energy of activation to internal ro-

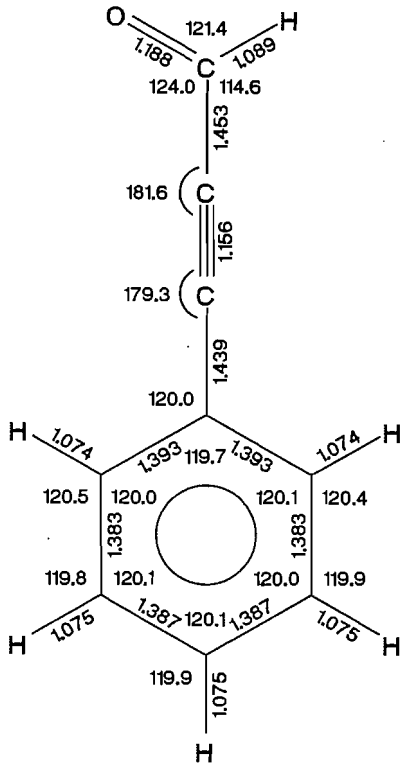

FIG. 3. The 6-31G* structure of planar phenylpropynal is displayed. Calculations with this basis set give C—C and C—H equilibrium bond lengths in a phenyl group longer and shorter, respectively, by very near 0.01 Å than, for example, r_0 values from microwave spectroscopy (35).

TABLE 2. Relative computed energies of various conformers of phenylpropynal, **1**

[d]The total energy is −416.758 514 au.
[e]The total energy is −418.943 554 au.
[f]The total energy is −419.104 150 au.
[g]For this conformation the energy is computed for a geometry that is the average of those for the encompassing values of θ.

tation is nearer 30 kJ/mol. The smaller value in **1** can be understood qualitatively as a consequence of reduced conjugation of the π electron systems in question.

Molecular orbital computations

The results of the calculations with various bases (27–31) of the conformational energies for **1** are summarized in Table 2. During the SCF cycles, the nuclei of the phenyl group were constrained to a plane, but all other bond angles and lengths were optimized. The relative energies in Table 2 are reproducible by an almost purely twofold internal potential, any fourfold component having a magnitude of 0.02 kJ/mol or less. The split-valence basis sets agree with the magnitude of the barrier deduced from ^8J to within experimental error. The perturbation of the barrier by the solvent is not known.[2] It would be of interest to have an experimental value of the internal barrier for the molecule in the gas phase. Figure 3 shows the 6-31G* (polarization functions on the heavy atoms) structure of **1**, probably of use in such studies.

The INDO MO FPT computations confirm that ^8J in **1** varies as sin $^2\theta$, the magnitude depending, as expected, on the geometry. In view of the quantitative discrepancies between theory and experiment for $^6J_{90}$ in benzaldehyde (4, 5, 7), it cannot be said that the computations of $^8J_{90}$ sin $^2\theta$ in **1** necessarily bear out the discussion in the previous section, where $^8J_{90}$ is estimated as −0.15Hz, although the theoretical coefficient of sin $^2\theta$ ranges from −0.15 Hz for the STO-3G to −0.20 Hz for the 6-31G* geometries.

Turning to 1-phenylpropyne, **2**, the computations confirm intuition, even under tight optimization conditions, that the internal rotational barrier vanishes to within the significance of the computed energies. The INDO MO FPT computations of ^8J confirm its dependence on sin$^2\theta$, where θ is the angle by which the C—H bond of the methyl group twists away from the plane containing the phenyl group.

[2]The computed dipole moments of the planar conformers of **1** vary from 1.40 D with AM1 to 4.87 D with the 6-31G basis. For the split-valence bases, the dipole moments decrease by 0.3 D in the perpendicular conformers, so that some solvent stabilization of the planar conformer is possible. The dipole moment of **1** is 3.39 D in benzene solution at 298 K (32), midway between 4.35 D (6-31G*) and 2.33 D (STO-3G).

The other spectral parameters

It may be noted that the ratios of $^{(n+2)}J$(H, CH_3) in 1-phenylpropyne (Table 1) to the corresponding ^nJ(H, CH_3) in toluene (19) range from 0.42_2 to 0.42_9. Because ^4J(H, CH_3) and ^5J(H, CH_3) in toluene contain also σ electron contributions, in addition to the σ−π components (19–22), it appears that the triple bond reduces any σ components of ^6J(H, CH_3) and ^7J(H, CH_3) in 1-phenylpropyne by the same factor with which it reduces the σ−π components. Such a result is not borne out by our INDO MO FPT computations in 1-phenylpropyne. Because, however, such computations are also unsatisfactory for ^5J(H, CH_3) and ^4J(H, CH_3) in toluene (19, 33, 34), more discussion is unwarranted here. Further study of the coupling mechanisms is required.

Turning to the intraring coupling constants, it is interesting that $^3J_{23}$, $^3J_{34}$, $^4J_{26}$, and $^5J_{25}$ are larger in the polar than in the relatively nonpolar solution; the opposite is true for $^4J_{24}$, while $^4J_{35}$ is unchanged by a change in solvent. The solvent perturbations are an order of magnitude larger than the standard deviations in the coupling constants. Exactly the same pattern has now been established (unpublished data) for phenylethyne and cyanobenzene.

The conformational behavior of isobutylbenzene in CS_2/C_6D_{12} solution at 300 K

TED SCHAEFER AND LINA B.-L. LEE
Department of Chemistry, University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received February 24, 1992

TED SCHAEFER and LINA B.-L. LEE. Can. J. Chem. **70**, 2370 (1992).

The ^1H nuclear magnetic resonance spectrum of isobutylbenzene as a dilute solution in CS_2/C_6D_{12} at 300 K is analyzed. The *gauche* conformer (statistical weight 2) predominates, as was previously shown for a jet-cooled stream of this compound. The apparent twofold barrier to rotation about the Csp^2—Csp^3 bond is 10.5 ± 0.5 kJ/mol, as must be the case for the analogous *gauche* conformer of *n*-propylbenzene. The internal barriers are compared for ethylbenzene, *gauche* isobutylbenzene, and neopentylbenzene. AM1 and STO-3G MO computations of the conformer stabilities and barriers are reported, the latter being in better agreement with experiment.

TED SCHAEFER et LINA B.-L. LEE. Can. J. Chem. **70**, 2370 (1992).

On a analysé le spectre de résonance magnétique nucléaire du ^1H de l'isobutylbenzène, en solution diluée dans le CS_2/C_6H_{12}, à 300 K. Comme il a été démontré antérieurement pour un échantillon de ce composé existant sous la forme d'un écoulement refroidi par un jet, le conformère *gauche* (poids statistique de 2) prédomine. La barrière binaire apparente à la rotation autour de la liaison Csp^2—Csp^3 est de 10,5 ± 0,5 kJ/mol, comme ce doit être le cas pour le conformère *gauche* analogue du *n*-propylbenzène. On a comparé les barrières internes avec celles de l'éthylbenzène, de l'isobutylbenzène *gauche* et du néopentylbenzène. On rapporte les résultats obtenus par calculs d'OM AM1 et STO-3G des stabilités et des barrières; l'accord avec les résultats expérimentaux est meilleur dans le dernier cas.

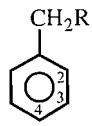
Introduction

Apart from their intrinsic interest, the potentials retarding the motion about the Csp^2—Csp^3 bond in alkylbenzenes are important in the study of liquid crystals (1, 2), many of whose molecules contain such fragments, and for the concept of 1,3-benzylic strain (3), used in the discussion of the stereoselectivity of attack by nucleophiles or electrophiles.

Apart from toluene, in which the internal rotational barrier is almost negligibly small (4), the alkylbenzene most investigated in this respect is ethylbenzene, **1**. Supersonic molecular, jet laser spectroscopy (5) and low- (6) and high- (7) resolution microwave spectra for the vapor show that **4** is the conformation of lowest energy; the latter spectra

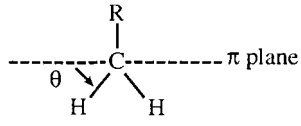


1, R = CH_3

2, R = $CH(CH_3)_2$

3, R = $C(CH_3)_3$

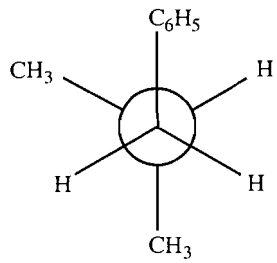
(7) are consistent with an internal barrier ranging from 4.9 to 7.8 kJ/mol, in rough agreement with various (7, 8) *ab initio* molecular orbital computations at the Hartree–Fock or post-Hartree–Fock level of theory, as well as with heat capacity data (9). In solution (8), the long-range coupling



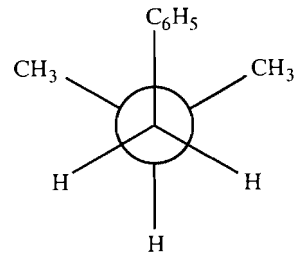
4, perpendicular

constant over six bonds between the methylene and *para* ring protons suggests that the conformational behaviour of ethylbenzene is the same in various solvents and that, if the barrier is purely twofold, its magnitude is $5.3_5 \pm 0.3_5$ kJ/mol.

At low temperatures in a molecular jet (10), the two-color time-of-flight mass spectra of **2**, isobutylbenzene, and its derivatives prove that **4** is the stable conformer, as expected on steric grounds, and further that, at low temperatures at least, the *gauche* conformer, **5**, is present to the exclusion of **6**. Molecular mechanics calculations (10) have **5** as



5



6

2.9 kJ/mol more stable than **6**, which is also disfavored by an entropy of $R \ln 2$. The barrier to rotation about the Csp^2—Csp^3 bond is not known.

In solution, the long-range coupling constant, $^6J(H, CH_2)$, will yield an estimate of the sp^2–sp^3 barrier and $^3J(CH, CH_2)$ in the side chain should confirm the predominant presence of **5**. If the barrier is predominantly of steric origin, that is, caused by repulsions between the group R and the *ortho* C—H bonds, then it should be larger in isobutylbenzene than in ethylbenzene, even if only **5** exists (models). This paper reports the analysis of the ^1H nmr spectrum of isobutylbenzene in a CS_2/C_6D_{12} solvent mixture and discusses the conformational information available from the coupling constants. Apparently the molecule has not been conformationally characterized in solution. The results of the present investigation allow a comparison of the barriers to rotation about the Csp^2—Csp^3 bonds as ethylbenzene is transformed, by successive substitution by methyl groups, into *n*-propyl, isobutyl, and neopentyl benzenes.

Experimental

A 4.0 mol% solution of isobutylbenzene (Aldrich) in a standard CS_2/C_6D_{12}/TMS/C_6F_6 solvent mixture (see Table 1) was filtered into a 5 mm o.d. nmr sample tube. The solution was degassed by five cycles of the freeze–pump–thaw procedure and was flame-sealed under vacuum. At a probe temperature of 300 K, ^1H nmr

[a]4.0 mol% in CS_2, containing also 10 mol% of C_6D_{12} and 0.25 mol% each of tetramethylsilane (TMS) and C_6F_6.

[b]In Hz at 300.135$_2$ MHz to high frequency of internal TMS.

[c]Numbers in parentheses are standard deviations in the last significant figure.

[d]No transitions assigned, very small but finite coupling constants with the six methyl protons causing broadening of a strongly second-order pattern and exacerbated by the tightly coupled ring protons, all of which couple to these methylene protons.

[e]No direct evidence exists for this coupling constant, indirect evidence coming from the assigned transitions of the methyl protons and from the apparent broadening of the methylene proton peaks.

[f]The value of 0.038(2) Hz originates in the iterative analysis of the ^{1}H nmr spectrum of the side-chain protons as part of an A_6BC_2DD' spin system (D and D′ are the *ortho* ring protons) and unfortunately correlates by 0.87 with the chemical shift of the methine proton. The value of 0.015(2) Hz comes from the analysis of the spectrum of the ring protons as part of an $AB_2CC'DD'E$ spin system, that is, ignoring the methyl protons.

[g]Number of transitions calculated for the side-chain protons, there being many, essentially degenerate, transitions.

[h]Number of transitions calculated for the ring protons, again with many degenerate ones; note the essentially zero coupling constants, ^7J(CH, H-4) and ^6J(CH, H-3).

spectra were obtained on an AM 300 Bruker spectrometer, they employed digital resolution of 0.024 Hz/point, an acquisition time of 41 s per free induction decay; the latter were zero-filled twice or four times before transformation to the frequency domain.

Molecular orbital computations used the program GAUSSIAN 86 (11) on an Amdahl 5870 system. Geometry optimization procedures allowed bond angles and lengths to vary, with the constraint that the nuclei of the phenyl group remained in a plane. The AM1 parameterization (12) as well as the *ab initio* minimal basis set, STO-3G (13), were utilized. The latter basis set yields relative conformational energies for ethylbenzene very similar to those obtained from basis sets as large as 6-31G and 6-31G* (7, 8).

Results and discussion

Spectral analysis

The 14 protons of isobutylbenzene constitute an inconveniently large spin system. Fortunately, the methyl protons do not couple significantly to the ring protons, so that a composite analysis proved successful. The ^{1}H nmr spectrum of the side-chain protons was amenable to an analysis based on the spin system, A_6BC_2DD' (two magnetically nonequivalent *ortho* ring protons are included), while that of the ring protons yielded to an analysis based on $AB_2CC'DD'E$. The methine proton couples significantly to the *ortho* protons but its magnitude is somewhat imprecise, as seen in the collection of the spectral parameters in Table 1. The computer program NUMARIT (14), substantially modified by R. Sebastian in this laboratory, was used in the analytical procedures.

Figure 1 and its caption illustrate the spectral quality obtainable for the ring protons.

The apparent twofold barrier

Because $^6J(H, CH_2)$ is a pure σ–π coupling constant (15–20) and is therefore proportional to $\sin^2\theta$, where θ is the angle by which the α C-H twists away from the benzene plane (see **4**), a knowledge of $^6J_{90}$ yields the expectation value of $\sin^2\theta$. This quantity is related to the barrier to rotation about the Csp^2—Csp^3 via a hindered rotor model (21, 22) or a classical averaging procedure; the foldedness of the internal rotational potential enters into this relationship. $^6J_{90}$ depends on the electronegativity of the substituent, R; it is −1.204(4) Hz in toluene (19), R = H, and has been shown to be −0.941(4) Hz in benzyl fluoride, R = F (23). For R = OCH_3, $^6J_{90}$ is −1.02 Hz (24, 25). A linear interpolation implies $^6J_{90}$ as −1.16 Hz for the present molecule, as for ethylbenzene (8).

$^6J(H, CH_2)$ is −0.374(1) Hz for isobutylbenzene (Table 1). Hence $\langle\sin^2\theta\rangle$ at 300 K is 0.322(4), assuming an uncertainty of 0.01 Hz in $^6J_{90}$. Because a rigid **4** has $\langle\sin^2\theta\rangle$ as 0.25, and because a vanishing barrier implies a value of 0.5, it appears that **4** is also the stable conformation in solution. The apparent twofold barrier is 10.5 ± 0.5 kJ/mol, roughly twice that for ethylbenzene (8).

Although *ab initio* molecular orbital computations with geometry optimization would be very time-consuming with higher level basis sets, those with the minimal basis set,

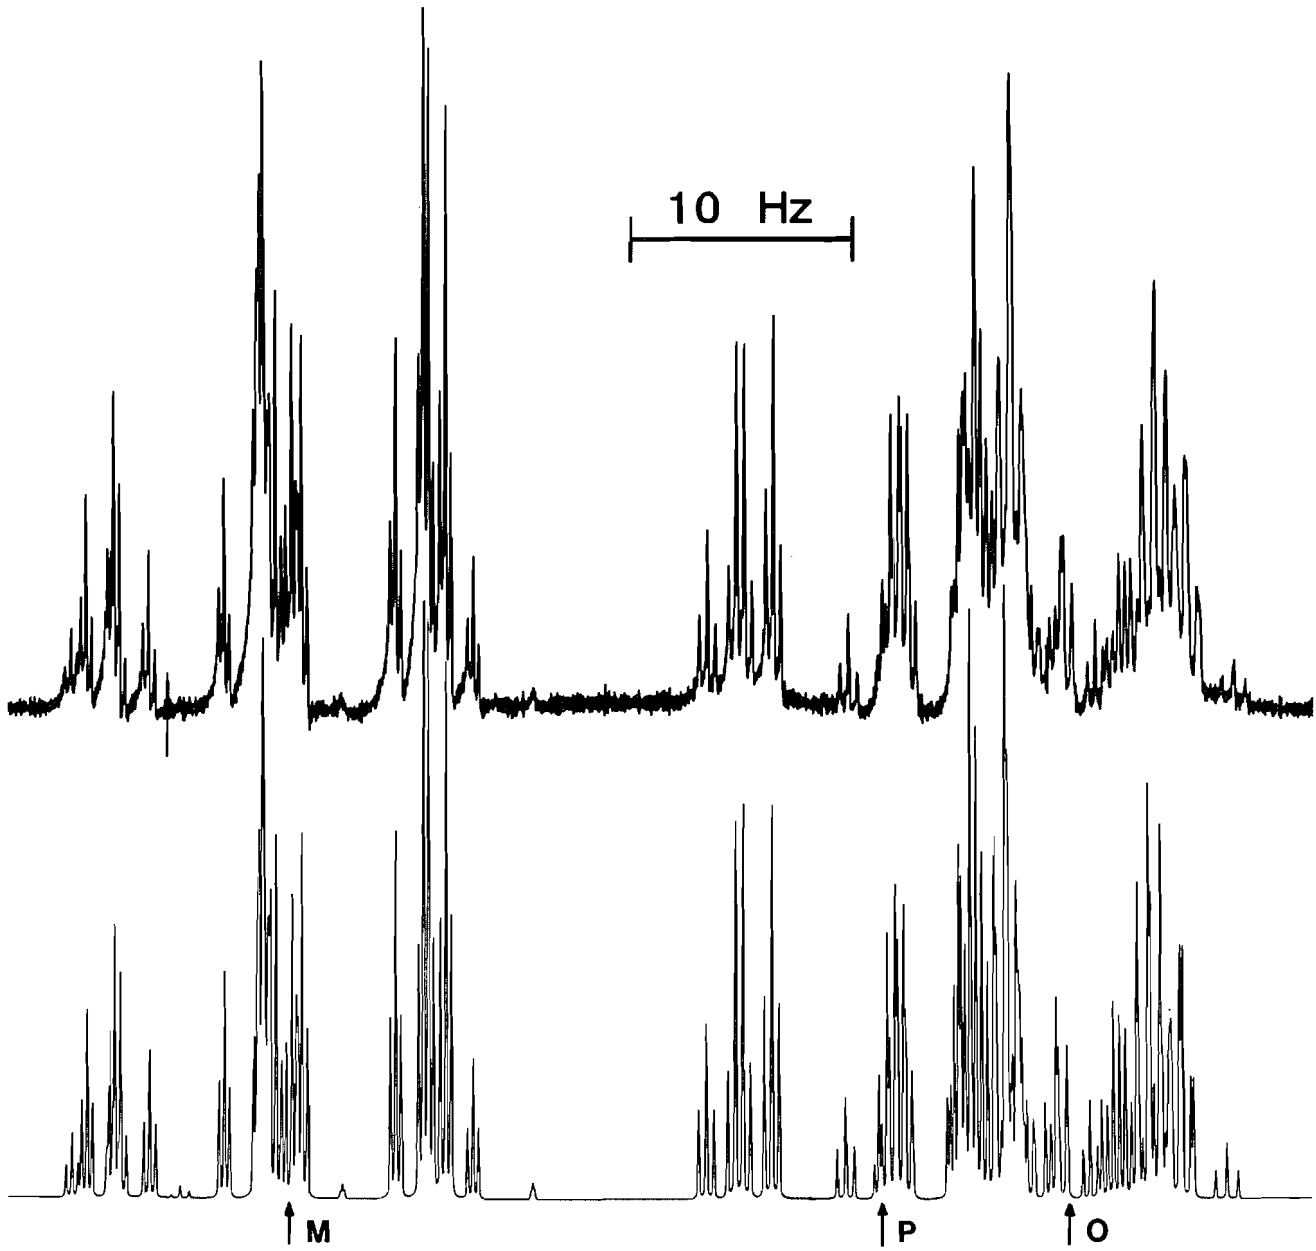

FIG. 1. The ^{1}H nmr spectrum at 300 MHz and 300 K of the ring protons of isobutylbenzene, as a 4.0 mol% solution in CS_2/C_6D_{12}, is displayed. The simulated spectrum employs the parameters in Table 1. The spacings in the triplets from the *meta* protons, when apparent, are about 0.25 Hz in magnitude. Some broadening of the peaks comes from small coupling interactions with the methine and methyl protons in the side chain (see the text and Table 1).

STO-3G, gave **4** as 11.1 kJ/mol more stable than the conformer in which the C(α)—C(β) bond lies in the benzene plane.[1] However, optimization for a range of twist angles gave a minimum energy for a conformation in which the C(α)—C(β) bond lies about 15° from the perpendicular, that is, from **4**. A fit to a Fourier series showed that this minimum must be attributed in the main to a strikingly large eightfold component of the barrier, 2.5 kJ/mol. This somewhat unexpected result can hardly be ruled out by the experimental value of 0.32_2 for $\langle \sin^2\theta \rangle$, the STO-3G data yielding 0.33_1 at 300 K.

[1]AM1 optimizations have this stability as 4.3 kJ/mol, very likely too low; such optimizations yield a barrier height of 2.3 kJ/mol for ethylbenzene, too low by at least a factor of two.

In this connection, the only other available computations (26) for the free molecule are those based on molecular mechanics (MM2 and CAMSEQ) in a comparative study of alkylbenzenes and some arylalkylamines of biological interest. The MM2 computations do indeed have a deviation of 8° from the perpendicular orientation in **4**, but also find **5** and **6** as isoenergetic, an unlikely result (see below). The CAMSEQ parameterization predicts no deviation from perpendicularity in **4**, but favors **5** by 8.4 kJ/mol over **6**, qualitatively correct. The MOMM numbers are 2.9 kJ/mol (10), agreeing with the present STO-3G result of 3.0 kJ/mol.

A rationalization of a small deviation from perpendicularity in the stable conformer, **4**, goes as follows. In **6**, both methyl groups are situated over the phenyl group and, by symmetry, the conformer is perpendicular (make models).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

Now, **6** is certainly less stable than **5**. Apart from an entropy term (see below), attribution of the instability to repulsion between the methyl groups and the phenyl group implies that such a repulsion for a single methyl group in **5** is relieved by a small twist from the perpendicular, increasing the distance between the methyl and phenyl electron clouds. That is indeed the direction of twist predicted by the STO-3G MO computations. Such a rationalization needs support from high-level molecular orbital calculations, which are costly. They would be of real interest, however, because of recent discussions of the nature, attractive or repulsive, of the forces between the π system of the phenyl group and the alkyl group (27).

In this connection, it is of interest that, in CS_2 solution, the enthalpy difference favoring the *trans* conformer of *n*-propyl-3,5-dibromobenzene is 1.9 kJ/mol at 305 K (28). The *gauche* conformer has an additional entropy of R ln 2, so that in solution at this temperature, the *gauche* and *trans* conformers are of roughly equal abundance. In the gas phase at low temperatures, both conformers exist (10) and MOMM computations imply a steric destabilization energy of 1.6 kJ/mol in the *gauche* form. Furthermore, it was predicted that $^6J(H, CH_2)$ in the *gauche* form would be -0.38 Hz (28), very close to the -0.37 Hz now measured for isobutylbenzene, which in solution exists predominantly in the *gauche* form (see below). In that case, rotations about the Csp^2—Csp^3 bonds in the *gauche* forms of *n*-propylbenzene and of isobutylbenzene involve the close approach of one methyl group to the *ortho* C—H bonds; hence they should have very similar barriers and $^6J(H, CH_2)$ values.

In summary, STO 3G MO optimizations predict a barrier height of 6.6 and 12.5 kJ/mol for ethyl (8) and isobutylbenzene, respectively, whereas the apparent twofold barriers in solution are $5.3_5 + 0.3_5$ and 10.5 ± 0.5 kJ/mol. The substitution by one more methyl group, to give neopentylbenzene, **3**, causes at least a second doubling of the experimental internal barrier (29, 30), presumably because of the greater difficulty experienced by the methyl groups in avoiding close H,H contacts with the *ortho* C—H bonds at the height of the barrier.

*The equilibrium between **5** and **6** in solution*

The symmetrical conformer, **6**, is not detectable at low temperatures in a jet-cooled stream (10). In the CS_2 solution at 300 K, $^3J(CH, CH_2)$ is 7.15_4 Hz and is a population weighted average of $(^3J_g + {}^3J_t)/2$ in **5** and $^3J'_g$ in **6**, the two *gauche* coupling constants, ^3J_g and $^3J'_g$, not necessarily being equal. If the barrier to interconversion of **5** and **6** is large compared to thermal energies, as is probably true (31), then the implied assumption of a two-site equilibrium is reasonably reliable.[2] The vicinal coupling constants, in addition to their dihedral angle dependence, are also sensitive to substituent electronegativity and other perturbations. Fortunately, a thorough study of 2-methylbutane (replace the phenyl by a methyl group) exists. Here the equivalent $(^3J_g + {}^3J_t)/2$ and ^3J_g are determined as 7.06 ± 0.01 and 3.52 ± 0.13 Hz, respectively. It is assumed that R ln 2 represents the entropy difference between the conformers analogous to **5** and **6** (32). The application of the parameters for the butane derivative to isobutylbenzene, yields the fractional population of **5** as 1.02 ± 0.01, apparently absurd.

Of course, the electronegativities of phenyl and methyl groups are not identical and the relevant torsion angles may well deviate from regular tetrahedral values by different amounts in **5** and **6** as compared to the analogous conformers of the butane derivative. Another estimate of the population of **5** can be had from the estimates of 12.5 and 2.5 Hz for ^3J_t and ^3J_g in 2,4-diphenylpentane, in which a phenyl group, a methyl group, and an sp^3 carbon centre are bonded to the coupling fragment (33). These numbers, applied to isobutylbenzene, yield the fractional population of **5** as 0.93, using now the relationship $7.15 = P_5\ (12.5 + 2.5)/2 + (1 - P_5)\ 2.5$. It appears that **5** does indeed predominate in CS_2 solution at 300 K. A population of 0.93 would correspond to a free energy difference of 6.4 kJ/mol and an enthalpy difference of 4.7 kJ/mol, favoring **5**.

(i) Absence of $^4J(CH_2, CH_3)$

The iterative analysis of the ^{1}H nmr spectrum gave $^4J(CH_2, CH_3)$ as $-0.009(1)$ Hz; actual splittings assignable to this coupling constant were not detected, although the methyl doublet does display some fine structure, but due to second-order perturbations. Using the theoretical values in column D of ref. 34, $^4J(CH_2, CH_3)$ is calculated as -0.04 Hz in **5** and 0.14 Hz in **6**. These numbers are based on regular tetrahedral geometries and the theoretical values for various dihedral angles are also somewhat uncertain (34), so that this comparison can only be said to indicate consistency with a preponderance of **5** in solution.

(ii) Ring proton, methine proton coupling, $^5J(CH, H\text{-}2)$

Two values for the coupling constant between the methine and *ortho* ring protons came from the separate analyses of the side-chain and ring proton spectra. The A_6BC_2DD' system gave ^5J as 0.038(2) Hz while that of $AB_2CC'DD'E$ yielded 0.015(2) Hz. The larger value correlates by 0.87 with the chemical shift of the methine proton and is very likely not as reliable as the smaller value. The finite value of ^5J quite possibly arises from a close approach of the two C—H bonds carrying the coupled nuclei. As the molecule twists about the Csp^2—Csp^3 bond in the predominant *gauche* conformer (models), the hydrogen atoms of the two bonds could come within 1.8 Å of each other at the extremes of the motion, leading to proximate coupling interactions. In the minor conformer, **6**, this situation does not obtain. The absence of significant coupling between the methyl and ring protons may well be a consequence of the fact that, in the *gauche* conformer, the protons in the distant methyl group remain far from the *ortho* C—H bonds; any coupling interactions are averaged over *all* methyl protons, of course. It seems highly probable that significant coupling constants would be observed in **6** between methyl and *ortho* ring protons (through-space interactions).

(iii) $^4J_o(H\text{-}2, CH_2)$ and $^5J_m(H\text{-}3, CH_2)$

J_o (H-2, CH_2) $\equiv {}^4J_o$ is $-0.538(1)$ Hz and contains a σ in addition to the σ–π component. For toluene, the theoretical expression is $^4J/\text{Hz} = -1.08\ \langle\sin^2\theta\rangle - 0.32\ \langle\cos^2\theta\rangle$, the first term representing the σ–π contribution (35), and predicts -0.70 Hz for $^4J(H,CH_3)$, precisely as measured (19). Just as for $^6J_{90}$, the coefficient of $\langle\sin^2\theta\rangle$ should be reduced by a factor of 1.16/1.20, to yield -1.04 Hz. Based on a $\langle\sin^2\theta\rangle$ of 0.322, obtained from $^6J(H, CH_2)$ above, one has ^4J_o as -0.552 Hz; the $\langle\sin^2\theta\rangle$ from the STO-3G potential, 0.332, entails a ^4J_o of -0.559 Hz. However, a reduction of the

[2]Of course, if the interconversion barrier is not large compared to kT, then the dihedral angle takes on many values other than 60° (^3J_g) or 180° (^3J_t) with high probabilities, and a procedure similar to that described above for ^6J would become essential.

magnitude of the coefficient of $\langle\cos^2\theta\rangle$, from 0.32 to 0.30 Hz, would produce exact agreement with experiment. It is reasonable to conclude that ^4J_o is compatible with the STO-3G potential as well as with an apparent twofold barrier of 10.5 ± 0.5 kJ/mol.

Again, ^5J_m (H-3, CH_2) ≡ ^5J_m is a function of $\langle\sin^2\theta\rangle$ and $\langle\sin^2(\theta/2)\rangle$. The equation suggested for toluene (19) yields ^5J_m in isobutylbenzene as 0.266 and 0.269 Hz, respectively, according to the $\langle\sin^2\theta\rangle$ values from ^6J(H, CH_2) or from the STO-3G potential. The measured ^5J_m is 0.272(1) Hz.

Conclusion

The apparent twofold barrier to rotation about the Csp^2—Csp^3 bond in isobutylbenzene, existing predominantly as the *gauche* conformer at 300 K, is 10.5 ± 0.5 kJ/mol, very close to that in the *gauche* conformer of *n*-propylbenzene (28), and roughly twice that in ethylbenzene (7, 8) and the *trans* conformer of *n*-propylbenzene (28). Substitution by another methyl group at the β carbon atom of isobutylbenzene, to produce neopentylbenzene, raises this barrier to greater than 20 kJ/mol (29, 30); the methyl groups are now unable easily to avoid the *ortho* C—H bonds of the benzene moiety. All these statements refer to experimental results in solution.

Nonbonded C=O · · · S and C—H · · · S interactions in 2-(4-chlorophenylthio) benzaldehyde in solution. An average skew conformation

TED SCHAEFER, LINA B.-L. LEE, AND RUDY SEBASTIAN
Department of Chemistry, University of Manitoba, Winnipeg, Man., Canada R3T 2N2

Received March 16, 1992

TED SCHAEFER, LINA B.-L. LEE, and RUDY SEBASTIAN. Can. J. Chem. **70**, 2375 (1992).

The ^{1}H nuclear magnetic resonance spectral parameters are reported for 4.0 mol% solutions of 2-(4-chlorophenylthio) benzaldehyde in CS_2/C_6D_{12} and acetone-d_6 at 300 K. In CS_2 the *O-syn* conformer is 36% abundant, rising to 50% in acetone-d_6. These abundances are compared to those of the *O-syn* and *O-trans* conformers of 2-(alkylthio) benzaldehydes in CCl_4 solution. On the basis of coupling constants and chemical shifts it is concluded that the skew conformer of the title compound is very likely the one of minimum energy in both solutions. In the skew conformer the plane of the 4-chlorophenyl group lies perpendicular to the CSC plane and also to that of the other aromatic moiety. It is suggested that the S · · · O interaction is rather weak and that the population of the *O-syn* conformer is controlled by the orientation of the mainly 3*p* lone-pair orbital on sulfur. At best, the S · · · O interaction is attractive only when the 3*p* orbital lies perpendicular to the plane of the formyl group. The skew conformation of the title compound is contrasted to the skew conformation of 2-hydroxyphenyl phenyl sulfide in which, however, the role of the two aromatic planes is reversed; the 3*p* orbital now lies in or near the plane of the phenyl group COH due to an attractive O—H · · · 3*p* interaction.

TED SCHAEFER, LINA B.-L. LEE et RUDY SEBASTIAN. Can. J. Chem. **70**, 2375 (1992).

Opérant à 300 K, on a déterminé les paramètres spectraux en résonance magnétique nucléaire du ^{1}H du 2-(4-chlorophénylthio) benzaldéhyde en solution à 4 mol% dans le CS_2/C_6D_{12} et dans l'acétone-d_6. L'abondance du conformère *O-syn* est de 36% dans le CS_2 et elle atteint 56% dans l'acétone-d_6. On a comparé ces abondances à celles des conformères *O-syn* et *O-trans* des 2-(alkylthio) benzaldéhydes en solution dans le CCl_4. En se basant sur les constantes de couplage et sur les déplacements chimiques, on arrive à la conclusion que le conformère *gauche* du composé mentionné dans le titre est très probablement celui qui possède l'énergie minimale dans les deux solutions. Dans le conformère *gauche*, le plan du groupe 2-chlorophényle se trouve dans un plan perpendiculaire à celui du CSC et également au plan de l'unité aromatique. On suggère que l'interaction S · · · O est plutôt faible et que la population du conformère *O-syn* est principalement contrôlée par l'orientation du doublet libre de l'orbitale 3*p* du soufre. Cette interaction S · · · O n'est optimale que lorsque le plan des orbitales 3*p* est perpendiculaire à celui du groupe formyle. La conformation *gauche* du composé mentionné dans le titre est à l'opposé de la conformation *gauche* du sulfure de phényle et de 2-hydroxyphényle dans lequel, cependant, le rôle des deux plans de la portion aromatique est inversé; l'orbitale 3*p* se trouve maintenant dans le plan ou près du plan du groupe phényle COH à cause d'une interaction attractive OH · · · 3*p*.

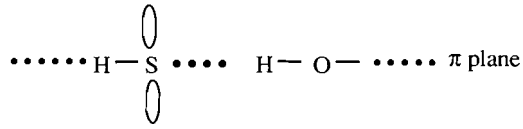
Introduction

A recent review (1) discusses extensive investigations of nonbonded sulfur–oxygen interactions, those in the so-called donor–acceptor region. The S · · · O distances span 2.3–3.2 Å, less than the sum of the van der Waals distances but greater than covalent bond lengths. Semi-quantitative interpretations of these phenomena have been given in terms of valence bond and molecular orbital models (2).

For divalent sulfur, an electrostatic model has some predictive power (3, 4). This model recognizes the relatively large difference in energy between the 3*s* and 3*p* orbitals on sulfur and the concomitant tendency to keep the 3*s* orbital fully occupied during bond formation (5, 6). In addition, for sulfur the 3*p* orbital extends significantly farther from the atomic centre than does the 3*s* orbital (7), in contrast to the situation in oxygen, for example. Hence a qualitative model, in which the two pairs of lone electrons on sulfur are distinguished by their mainly 3*s* and 3*p* characters, rationalizes the fact, pertaining to crystal structures, that electrophiles favor an approach perpendicular to the X—S—Y plane, in line with the directional 3*p* lone-pair. Nucleophiles orient preferentially in the X—S—Y plane, away from the X—S and X—Y bonds (8, 9). Such a model also allows an easy interpretation of the observation that 2-hydroxythiophenol adopts the conformation **2**, and not **1**, in solution (3). The polar O^-—H^+ bond overcomes the 3*p* · · · π conjugative stabilization of **1**

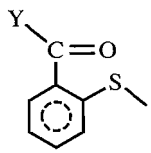


1

2

and twists the mainly 3*p* orbital into the aromatic plane, to produce **2**. Again, the structure of the H_2S,HF and H_2S,HCl complexes in the gas phase, in which the HX direction lies roughly perpendicular to the HSH plane, is in line with such a model (10, 11).

More particularly, in the crystal, methyl 2-(methylthio) benzoate, **3**, is planar, the SCH_3 conjugating with the aryl



3 Y = OCH_3, R = CH_3

4 Y = OCH_3, R = 4-NO_2-C_6H_4

ring. The C=O bond is strongly ionic (12, 13), qualitatively accounting for the observed structure (electrostatics).

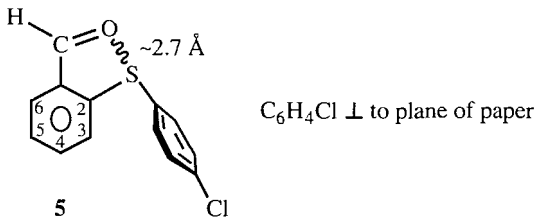
If Y = OCH_3 and R = 4-NO_2-C_6H_4, then the conformation is skew, that is, the 4-nitrophenyl group lies nearly perpendicular to the plane of the page in **4** (14). This conformation is taken (14) to mean that the S · · · O interaction dominates the conjugative interaction between the 3*p* lone-pair and the 4-nitrophenyl moiety; in **4** the 3*p* orbital lies effectively in the plane of the latter (low conjugation). Presumably this conclusion depends also on the assumption that the *ortho* ester and the *para* nitro groups are roughly equally strong π-electron acceptors.

While it appears likely that the S · · · O interaction in **3** and **4** is attractive, sulfur being relatively easily polarized by the $\overset{+}{C}\text{---}\overset{-}{O}$ bond, the argument might well be stronger were Y = H in **3** and **4**. For, it is known (15) that for 2-(methylthio) benzaldehyde, in CCl_4 solution at 305 K, the *O-syn* is less abundant than the *O-trans* conformer, being present to the extent of 40% only. Furthermore, as the methyl group is successively replaced by ethyl, isopropyl, and *tert*-butyl groups, the proportion of the *O-syn* conformer decreases monotonically and is not detectable for the *tert*-butyl derivative. In the latter, the 3*p* lone pair lies mainly in the ring plane and repels the C=O bond. On the basis of ^{13}C nmr chemical shifts and spin–spin coupling constants (16) it is estimated that the perpendicular conformer of *tert*-butyl phenyl sulfide is about 18 kJ/mol more stable than the planar. Consequently the S · · · O interaction is attractive by less than 18 kJ/mol in 2-(*tert*-butylthio) benzaldehyde.

Here we report ^1H nmr spectra of 2-(4-chlorophenylthio) benzaldehyde in CS_2 and acetone-d_6 solutions. If, by analogy to **4** in the crystal, a strong S · · · O attraction dominates the conformational properties, then **5** will predominate. Yet, the skew conformer may be a consequence of the cross-conjugation between the π donor and acceptor (17), in which case the *O-syn* orientation need not be dominant. The stereospecific coupling constant over five formal bonds, ^5J(H, CHO), is a good measure of the *O-syn/O-trans* equilibrium. In **5**, for example, ^5J(H-5, CHO) will be very small or undetectable (15, 18), whereas ^5J(H-3, CHO) will be 0.8 Hz or larger. Again, if the skew conformation is strongly stabilized, then H-3, for example, lies in the shielding cone of the C_6H_4Cl groups and should undergo a characteristic shift to low frequency. Any shift in the *O-syn/O-trans* equilibrium between nonpolar and polar solutions would provide evidence for the importance of intermolecular perturbations of S · · · O interactions.



C_6H_4Cl ⊥ to plane of paper

5

In **5**, the 3*p* orbital is situated in the plane of the C_6H_4Cl group, so that delocalization into the other π-electron system is favored, as expected from cross-conjugation with the π-electron acceptor, the formyl group. The mobile bond order of the S—C_6H_4Cl bond is reduced relative to the other C—S bond, allowing the chlorophenyl plane to orient so as to reduce steric repulsions from the H-3 bond in **5**. On the other hand, a gable (butterfly) conformation also minimizes such repulsions, but places the 3*p* orbital into both aromatic planes. Then only the *O-trans* conformer is expected, together with very little screening of ring protons from delocalization of 3*p* density into the π orbitals of the aromatic moieties.

The chlorine substituent, while providing a polar C—X bond, is not a strong π-electron acceptor or donor, perturbs the shielding of *ortho* and *para* protons relatively little (19), and hence makes possible the disentanglement of spectral peaks arising from the protons in the two aromatic rings.

Experimental

The title compound, from Maybridge Chemicals, was dissolved in CS_2/C_6D_{12}/TMS and acetone-d_6/TMS solvent mixtures (see Table 1 for details). The solutions were filtered into 5 mm o.d. nmr sample tubes. These were degassed by five cycles of the freeze–pump–thaw procedure and were then flame-sealed to produce reasonably symmetric tops.

The ^1H nmr spectra were obtained from a Bruker AM 300 spectrometer at a probe temperature of 300 K. Final shimming was done manually on the free induction decay of tetramethylsilane, the internal reference. Using an acquisition time of 41 s and a digital resolution of 0.006 and 0.012 Hz/point, 64 decays were coadded. Zero-filling to twice the original data, followed by a small amount of resolution enhancement (see Fig. 1) produced peak widths at half height of as little as 0.05 Hz.

Results and discussion

Spectral analyses

The computer program NUMARIT (20), extensively modified by R. Sebastian, was employed to extract the spectral parameters displayed in Table 1. Fortunately, the chemical shift between the protons of the S-C_6H_4-Cl fragment was small, causing a few intense peaks that did not obscure any peaks from the protons in the other fragment of the molecule. Simulation of the AA′BB′ spectra, assuming additivity of substituent perturbations of the coupling constants in benzene (21, 22), demonstrated that the internal chemical shift was ≤0.003 ppm in CS_2 solution and 0.013(1) ppm in acetone-d_6 solution. The sign of the first value could not be determined reliably, but, for the acetone-d_6 solution, small interring, through-space, coupling constants involving H-3 in **5** showed that the protons *meta* to chlorine were more shielded than those placed *ortho* to this substituent.

The O-syn/O-trans *equilibrium*

Previous discussions (15, 18, 23) of the stereospecificity of ^5J(H, CHO) show that ^5J(H-3, CHO)/^5J(H-5, CHO) is a reasonably accurate measure of the ratio of the *O-syn* to *O-trans* populations in benzaldehyde derivatives. The data in Table 1 therefore imply that the *O-syn* fractional population is 0.36 in the CS_2/C_6D_{12} solution at 300 K and is 0.50 in acetone-d_6 solution, corresponding to an increase in stabilization by 1.4 kJ/mol in free energy in the polar solvent. The *O-syn* population in the nonpolar solvent is very similar to that of 0.41 deduced for 2-(methylthio) benzaldehyde (15) as a 4 mol% solution in CCl_4 at 305 K (a 4.0 mol% solution of 2-(4-chlorophenylthio) benzaldehyde in CCl_4 solution gave an ^1H nmr spectrum for the formyl proton that was almost identical to that in CS_2 solution, implying a negligible difference of *O-syn* populations in the two solutions).

In this connection, it is of interest that a recent study of the torsional motion of the thiomethyl group in the thiomethyl compound deduces an average twist angle, actually arc cos $\langle\cos^4\theta\rangle^{1/4}$, of 19(2)°, roughly 7(3)° lower than for thioanisole (24). This result is in qualitative agreement with

TABLE 1. The ^{1}H nmr spectral parameters for dilute solutions of 2-(4-chlorophenylthio) benzaldehyde in CS_2/C_6D_{12} and acetone-d_6 solutions at 300 K

Parameter	Solvent		Parameter	Solvent	
	CS_2/C_6D_{12}[a]	Acetone-d_6		CS_2/C_6D_{12}[a]	Acetone-d_6[b]

[a]As a 4.0 mol% solution in CS_2, containing also 10.0 mol% of C_6D_{12} and 0.5 mol% of TMS.
[b]As a 4.0 mol% solution in acetone-d_6, containing also 0.5 mol% of TMS.
[c]In Hz at 300.135$_2$ MHz to high frequency of internal TMS.
[d]In the CS_2 solution, the standard deviations in the last significant figures are all 0.002 Hz while in acetone-d_6 solution they are 0.001 Hz or less.
[e]For the benzaldehyde ring. For the C_6H_4Cl group, the chemical shifts of the *ortho* and *meta* protons are 7.244 ± 0.006 ppm in the CS_2 solution; in acetone-d_6 solution, the protons *ortho* to chlorine resonate at 7.465(1) ppm, those *meta* at 7.451(1) ppm relative to TMS.

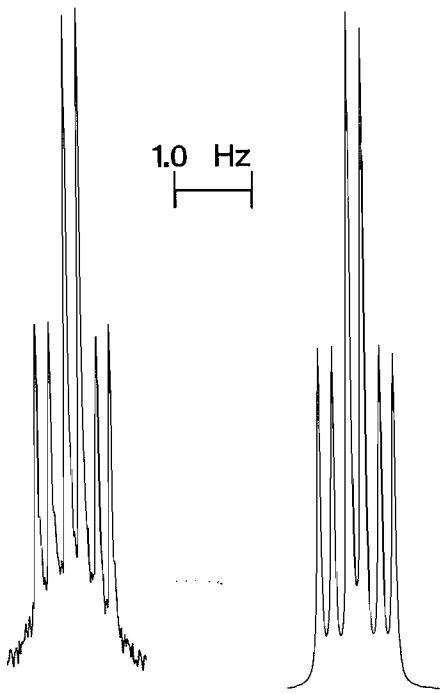

FIG. 1. The ^{1}H nmr spectrum at 300 MHz of the formyl proton is shown for a 4.0 mol% solution of 2-(4-chlorophenylthio) benzaldehyde in acetone-d_6 at 300 K. The computed spectrum assumes the spectral parameters in Table 1. ^5J(H-3, CHO) and ^5J(H-5, CHO) differ by 0.006(2) Hz, according to the full analysis, causing the 1:2:1 appearance of spectrum, the line widths being 0.05 Hz. The small splittings arise from ^4J(H-6, CHO), which is −0.182(1) Hz.

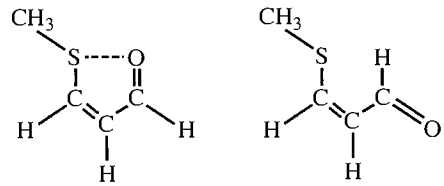
the small increased shielding of the proton placed *para* to the thiomethyl group in this compound, a lower average twist angle allowing more effective $3p \cdots \pi$ conjugation (25).

Treating 2-(methylthio) benzaldehyde as planar allows a comparison with a recent molecular orbital computation (2) of the relative energies of the model conformers **6** and **7**. The energy of **6** is computed as lower than that of **7** by 0.54, 3.72, and 12.0 kJ/mol with the basis sets STO-3G, 3-21G,



6 **7**

and 3-21G augmented with sulfur *d* orbitals, respectively. Insofar as **6** and **7** model 2-(methylthio) benzaldehyde and insofar as differences in the entropies and zero-point energies of the two conformers are small, none of the computations agree with the experimental free energy difference of 0.9 kJ/mol favoring the *O-trans* conformer in CCl_4 solution at 305 K. Accordingly, geometry-optimized STO-3G MO computations on the planar *O-syn* and *O-trans* conformers of 2-(methylthio) benzaldehyde were performed, with the result that the *O-syn* was calculated as *less* stable than the *O-trans* conformer by 1.88 kJ/mol. If this energy difference is equated to a difference in free energy, then the *O-syn* abundance is 32% at 300 K. The measured value is 41% in CCl_4 solution.

Experimentally, it appears that the *O-syn* population is controlled by the extent to which the 3*p* orbital twists into the benzene plane. The arc sin $\langle \sin^2\theta \rangle^{1/2}$ values, rough measures of average torsion angles, for C_6H_5—S—R in solution are 31, 40, 49, and 74° for R = CH_3, CH_2CH_3, $CH(CH_3)_2$, and $C(CH_3)_3$, respectively (16). For the corresponding 2-(S—R) benzaldehydes, the *O-syn* populations in CCl_4 solutions are 0.41, 0.23, 0.09, and 0.0, implying that no significant *O-syn* population occurs for an average twist

angle of as low as 60°. If, however, arc cos $\langle \cos {}^4\theta \rangle^{1/4}$ values are used for thioanisole and 2-(methylthio) benzaldehyde, which are 26° and 19°, respectively (25), and the additional assumption is made that similar differences exist for the other alkyl groups, then this limiting twist angle becomes about 50°, approximately half way to coplanarity of the 3*p* orbital with the aromatic ring.

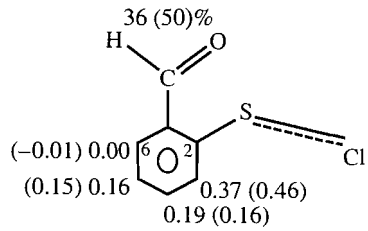
The barriers to rotation about the Csp^2—S bond of C_6H_5SR in solution are 5.4, 1.9, −1.4, and 18.8 kJ/mol, respectively (16), for the sequence R = CH_3 to $C(CH_3)_3$, a negative number indicating that the planar conformation is least stable, whereas the free energy differences favoring the *O-trans* conformer are 0.9, 3.1, and 5.9 kJ/mol in the sequence R = CH_3, CH_2CH_3, $CH(CH_3)_2$. Allowance of, say, a 5–10% error in all these numbers (18, 26) emphasizes the similarity in the range of the two energy sequences and, by implication, the relatively weak S · · · O interaction.

Now, in 2-(4-chlorophenylthio) benzaldehyde the *O-syn* population is nearly that for the 2-methylthio derivative. Hence the skew conformation, **5**, analogous to **4** in the crystal, appears likely in solution; a twisted conformation, as in diphenyl sulfide (17, 27, 28), would display a substantial twist about the Csp^2—S bond of the benzaldehyde ring and therefore a lower *O-syn* population.

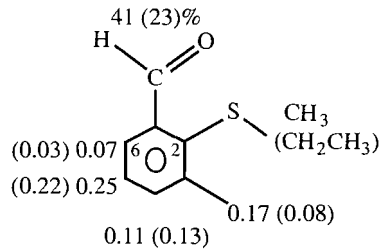
The average conformation of 2-(4-chlorophenythio) benzaldehyde

(i) Ring proton shifts

Relative to those in benzaldehyde, at the same concentrations in the same solvent mixtures (29), the chemical shifts are shown in **8**. Those in parentheses are for the acetone-d_6 solution, given in ppm, positive values indicating an increase in shielding relative to benzaldehyde. In the putative skew conformation, oscillations of significant amplitude will occur about the C—S bonds because the barrier to rotation about these bonds is not very large compared to thermal energies. Thus, the barrier in thioanisole is 5.4 kJ/mol (26) in solution, only about twice as large as *RT* at 300 K. In **8**, the barrier to rotation near the minima (a planar conformer would, of course, experience large steric repulsions be-



8



9

tween the *ortho* C—H bonds, the interhydrogen distance then being only about 0.5 Å) will likely be less than in thioanisole because the 3*p* lone pair, whose partial delocalization is associated with a partial double bond character of the C—S bonds and hence with a barrier to rotation about these bonds, is to some extent at least shared with both aromatic moieties. Nevertheless, on the assumption that **8** represents an energy minimum in both solvents, the numbers in **8** can be examined as to their consistency with such an assumption.

First, the *para* protons in both phenyl vinyl sulfide (unpublished data from this laboratory) and in diphenyl sulfide (30) in CS_2 and CCl_4 solutions are shielded by 0.08–0.09 ppm relative to benzene. In both molecules this is attributed to partial delocalization of the 3*p* lone pair into the two π systems present in each molecule. In diphenyl sulfide, the *para* proton is 7 Å, or somewhat more, distant from the centre of the neighbouring phenyl, so that shielding perturbations from the diamagnetic anisotropy of the latter (ring currents) are small (31) and, in view of the datum for phenyl vinyl sulfide, are here taken as negligible. Then, for ethyl phenyl sulfide (unpublished work) and thioanisole (32), the *para* protons are shielded by 0.20(1) ppm relative to benzene in CS_2 and CCl_4 solutions. In **8**, the excess shielding at H-5, *para* to sulfur, is 0.16 ppm, suggesting that more of the 3*p* lone pair is delocalized into this aromatic moiety than into the C_6H_4Cl group. In a rigid **8** this bias would be complete, the second ring lying in the plane of the 3*p* orbital.

Second, in **9**, the excess shielding at H-5 is 0.25 ppm in CCl_4 solution for R = CH_3 and 0.22 ppm for R = CH_2CH_3 (15), again implying that, in **8**, the delocalization into the benzaldehyde moiety is greater than that into the C_6H_4Cl group.

Third, in a rigid skew conformation, H-3 lies in the shielding cone of the chlorophenyl ring. Whatever the actual magnitude of the induced magnetic dipole, the shielding of H-3 is here estimated to be larger than that of H-4 by a factor of 2.3; this factor rises to 22 for H-5. Of course, the C_6H_4Cl group undergoes torsion about the C—S bond, so that such shielding due to its diamagnetic anisotropy will decrease due to the torsion (deshielding of H-3 and H-4 occurs for coplanar rings, naturally). Comparison of excess shifts in **8** and **9** implies consistency with **8** as the conformer of minimum energy. In **8**, H-6 lies in the deshielding cone of the second aromatic ring; however, it is so distant from this ring that its vanishing excess shift can hardly be attributed to ring currents.

Fourth, in CS_2 solution the internal chemical shift in the C_6H_4Cl group is ≤0.003 ppm, the deshielding, relative to benzene, being 0.02 ppm. In a rigid **8** the vector from the proton situated *ortho* to sulfur in C_6H_4Cl intersects the induced magnetic moment vector of the other ring at about 55°, the anisotropic shift therefore being near zero ($3\cos^2 55 - 1 = 0.01$). At the *meta* position a chlorine substituent shields a proton by 0.05 ppm (33) in the presence of a *para* SCH_3 group. Hence the *ortho* protons are deshielded by 0.07 ppm, relative to expectations. In fact, it is known that protons

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

placed *ortho* to a 3*p* orbital lying in the aromatic plane are deshielded (4, 15). In particular, in 2-(*tert*-butylthio) benzaldehyde, in which such an orientation of the 3*p* orbital roughly obtains, the deshielding amounts to 0.11 ppm (15). Attribution of the 0.07 ppm in **8** to such a cause is once more consistent with the putative skew conformation as that of lowest energy. Similarly, the *meta* protons in thioanisole, at 7.14 ppm, and those in 4-chlorothioanisole, at 7.19 ppm (32), when compared to the 7.24 ppm in **8** and 7.22 ppm for benzene in CS_2, imply that the increased screening caused by $3p\cdots\pi$ conjugation has been reduced in **8**. While these protons, *ortho* to chlorine, lie in the deshielding cone of the other ring, they are at least 6.2 Å removed from its centre. Hence their chemical shift is again consistent with a bias towards the skew conformation.

(ii) The shift of the formyl proton

In the 2-(alkylthio) benzaldehydes, the chemical shift of the formyl proton is dependent on the proximity of the 3*p* orbital on sulfur. As this orbital twists into the benzene plane, the proton is deshielded, being 10.697 ppm in the *tert*-butyl, and 10.267 ppm in the methyl, derivative (15). In **8**, the value of 10.273 ppm in CS_2 solution is consistent, first, with the very similar proportions of the *O-syn* conformers of **8** and **9** and, second, with similar degrees of twisting about the Csp^2—S bonds in these molecules.

(iii) Coupling constants

In the 2-(alkylthio) benzaldehydes many of the coupling constants between the aromatic protons are sensitive to the out-of-plane twist of the alkyl group (15). Those for the ethyl and methyl derivatives are in best agreement with the coupling constants in Table 1 (CS_2 solution); the average deviations between sets of six coupling constants are 0.02 Hz, whereas for the *tert*-butyl derivative the average rises to 0.09 Hz. These comparisons are consistent with the above conclusions concerning the preferred skew conformation of the diphenyl sulfide derivative.

Evidence for the anticipated substantial oscillational amplitudes of the C_6H_4Cl plane about its C—S bond comes from the extra broadening of 0.1 Hz observed for the H-3 peaks in both solvents. A twist of about 30° about this bond brings the *ortho* protons of the C_6H_4Cl group to within 2.3 Å of the midpoint of the C—H (−3) bond of the other ring. Under such conditions, substantial through-space interring coupling could occur (33, 34). The coupling magnitude is an average of those to the two *ortho* protons; that to the distant proton vanishes. The through-space mechanism depends crucially on the interproton distance but very likely also on the relative arrangement of the C—H bonds (35). Hence an average torsion angle cannot be deduced here.

The shifts and coupling constants in acetone-d_6 *solution*

The decrease in screening of protons of polar molecules dissolved in polar solvents is often attributed to the reaction in field induced in the dielectric continuum of the solvent; this field increases the polarity of the solute molecule. Be that as it may, it is observed in this laboratory that those protons in the solute that are protected from a close approach of acetone-d_6 molecules are deshielded rather less than those on the periphery. It is interesting, therefore, that H-3 in **8** is deshielded by only 0.07 ppm in passing from CS_2 to acetone-d_6 solution. By way of contrast, the protons *ortho* to sulfur in the C_6H_4Cl group are deshielded by 0.22 ppm, those *meta* to sulfur by 0.21 ppm. These three numbers emphasize the distinctions between the positions on the molecular topology occupied on average by these protons and are again consistent with a low-energy skew conformation. The somewhat larger excess shift, 0.46 ppm, see **8**, of H-3 in acetone-d_6 solution is most likely a consequence of the lower solvent effect on this "hidden" site of the molecule and not of a greater rigidity of the skew conformer. True, the population of the *O-syn* conformer has risen to 50% in acetone-d_6 solution and, in terms of the previous arguments, would imply a lower twist away from perpendicularity of the 3*p* orbital in **8**. However, the excess shifts of the other protons are not very different in the two solutions. This may be caused by differential solvent shifts of the protons on the "exposed" sites, so that the above explanation appears sensible.

The solvent dependence of intraring coupling constants (Table 1) is not unique to the present compound, similar patterns being observed in this laboratory for many aromatic derivatives. These patterns will be discussed in due course.

Conclusion

The S···O interaction in 2-alkylthio- and 2-phenylthiobenzaldehydes is relatively weak in solution. The *O-syn* population appears to be controlled by the orientation of the 3*p* lone pair on sulfur and not vice versa. A rather flexible skew conformation of 2-(4-chlorophenylthio) benzaldehyde is very likely the one of lowest energy in polar and nonpolar solvents, the *O-syn* population being 36% in the former and 50% abundant in the latter. The compound is a solid at room temperature; it would be interesting to ascertain its conformation in the crystal, particularly with regard to the orientation of the formyl group. It is interesting that 2-hydroxyphenyl phenyl sulfide also adopts a skew conformation (4) with the distinction that the conformational roles of the two aromatic rings are now reversed (see **2**). Here an attractive O—H···3*p* interaction occurs.

Reactions of nitriles with binuclear rhodium hydrides. The stepwise reduction of a carbon–nitrogen triple bond at two metal centres

MICHAEL D. FRYZUK,[1] WARREN E. PIERS,[2] AND STEVEN J. RETTIG[3]

Department of Chemistry, University of British Columbia, 2036 Main Mall, Vancouver, B.C., Canada V6T 1Z1

Received April 28, 1992

MICHAEL D. FRYZUK, WARREN E. PIERS, and STEVEN J. RETTIG. Can. J. Chem. **70**, 2381 (1992).

The reaction of simple nitriles, R′CN (R′ = CH_3, Ph, *o*-tol) with the electron-rich binuclear rhodium hydride derivatives $[(R_2PCH_2CH_2PR_2)Rh]_2(\mu\text{-}H)_2$ (R = Pr^i: [(dippe) $Rh]_2(\mu\text{-}H)_2$; R = OPr^i: [(dipope)$Rh]_2(\mu\text{-}H)_2$) results in the formation of alkylideneimido derivatives $[(R_2PCH_2CH_2PR_2)Rh]_2(\mu\text{-}H)(\mu\text{-}N{=}CHR')$, apparently by insertion of the nitrile moiety into a bridging hydride bond; this was confirmed by the reaction of nitriles with the dideuteride [(dippe)$Rh]_2(\mu\text{-}D)_2$, which resulted in the formation of [(dippe)$Rh]_2(\mu\text{-}D)(\mu\text{-}N{=}CHR')$. Further reduction can take place by addition of H_2 to generate the corresponding amide hydride derivatives [(dippe)$Rh]_2(\mu\text{-}H)(\mu\text{-}NHCH_2R')$; this represents an overall stoichiometric reduction of a nitrile to a coordinated amide at a binuclear centre. These same amido-hydride complexes can be accessed by addition of amine to the starting binuclear rhodium hydride derivatives. The X-ray structure of $[(Pr^i_2PCH_2CH_2PPr^i_2)Rh]_2(\mu\text{-}H)(\mu\text{-}N{=}CHCH_3)$ was undertaken to confirm the structure of these particular intermediates. Crystals of this material are monoclinic, a = 19.036(2), b = 15.139(1), c = 13.604(1) Å, β = 104.119(7)°, Z = 4, space group $P2_1/c$. The structure was solved by heavy atom methods and was refined by full-matrix least-squares procedures to R = 0.038 and R_w = 0.041 for 5814 reflections with $I \geq 3\sigma(I)$.

MICHAEL D. FRYZUK, WARREN E. PIERS et STEVEN J. RETTIG. Can. J. Chem. **70**, 2381 (1992).

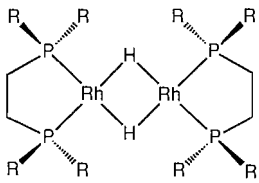
La réaction des nitriles simples, R′CN (R′ = CH_3, Ph, *o*-tol) avec les dérivés d'hydrures du rhodium riches en électrons $[(R_2PCH_2CH_2PR_2)Rh]_2(\mu\text{-}H)_2$ (R = Pr^i: [(dippe)$Rh]_2(\mu\text{-}H)_2$; R = OPr^i: [(dipope)$Rh]_2(\mu\text{-}H)_2$) conduisent à la formation de dérivés alkylidèneimido $[(R_2PCH_2CH_2PR_2)Rh]_2(\mu\text{-}H)(\mu\text{-}N{=}CHR')$ apparemment par simple insertion de l'unité nitrile dans l'hydrure ponté; cette conclusion a été confirmée par la réaction des nitriles avec le dideutérure [(dippe)$Rh]_2(\mu\text{-}D)_2$ qui conduit à la formation du [(dippe)$Rh]_2(\mu\text{-}D)$ $(\mu\text{-}N{=}CHR')$. On peut obtenir une réduction plus poussée en ajoutant du H_2 pour générer les dérivés hydrures amides correspondants [(dippe)$Rh]_2(\mu\text{-}H)(\mu\text{-}NHCH_2R')$; ceci représente une réduction stoechiométrique globale d'un nitrile en un amide coordonnée à un centre binucléaire. On peut accéder à ces mêmes complexes amido-hydrures en ajoutant une amine aux dérivés d'hydrure de rhodium binucléaire de départ. Dans le but d'établir la structure de ces intermédiaires particuliers, on a étudié la structure du dérivé $[Pr^i_2PCH_2CH_2PPr^i_2)Rh]_2$-$(\mu\text{-}H)$ $(\mu\text{-}N{=}CHCH_3)$ par diffraction de rayons X. Les cristaux de ce composé appartiennent au groupe d'espace monoclinique $P2_1/c$, avec a = 19,036(2), b = 15,139(1) et c = 13,604(1) Å, β = 104,119(7)° et Z = 4. On a résolu la structure par des méthodes des atomes lourds et on l'a affinée par la méthode des moindres carrés (matrice complète) jusqu'à des valeurs de R = 0,038 et de R_w = 0,041 pour 5814 réflexions avec $I \geq 3\sigma$ (I).

[Traduit par la rédaction]

Introduction

A possible reason for the paucity (1–4) of homogeneous systems for the catalytic hydrogenation of nitriles (R—C≡N) may be due to a fundamental preference for binding to a metal centre via the nitrogen lone pair rather than the carbon–nitrogen triple bond (C≡N) π system. Although some examples of side-bonded nitrile ligands are known (5–8), insertion of a carbon–nitrogen triple bond into a late transition metal – hydride bond is relatively rare (9–11). On the other hand, heterogeneous catalysts such as Pd/C or Raney nickel are effective in the hydrogenation of nitriles (12), suggesting that multiple metal bonding sites may be necessary for the success of the reduction process. This notion is supported by the observed *stoichiometric* hydrogenation of RC≡N on the face of a trinuclear iron carbonyl species (13–16). The complete characterization of intermediates en route to the fully hydrogenated μ_3-NCH_2R product showed that all three metal centres were apparently involved in the hydrogenation process. Unfortunately, desorption of the product amine from this cluster was not facile under conditions required to maintain cluster stability and thus the reaction is not catalytic.

Although the above example involved a trinuclear complex, in principle the stepwise reduction process could be carried out by only two metal centres since the effect and importance of a third metal centre is debatable. The coordinatively unsaturated binuclear rhodium hydrides **1***a* (17) and **1***b* (18) react rapidly with simple organic nitriles R′—C≡N (R′ = CH_3, C_6H_5, *o*-$CH_3C_6H_5$) to provide binuclear μ-alkylideneimido-hydride derivatives apparently resulting from the insertion of the nitrile C≡N bond into a Rh—H bond.



1*a* : R = Pr^i ⟹ [(dippe)$Rh]_2(\mu\text{-}H)_2$

1*b* : R = OPr^i ⟹ [(dipope)$Rh]_2(\mu\text{-}H)_2$

These compounds react further with dihydrogen to yield binuclear μ-amido-hydride complexes in which the nitrile moiety has been fully hydrogenated. We report here the details of these studies, along with the X-ray crystallographic characterization of one of the μ-alkylideneimido hydride compounds. Unlike the reactions of **1***a* and **1***b* with imines (19), intermediates in these reactions could not be observed spectroscopically; however, a reasonable mechanism may be proposed, based on analogy to the results of the imine reactions.

Experimental

General procedures

General laboratory procedures have been reported elsewhere (20). Benzonitrile, *ortho*-tolynitrile, and benzylamine were purchased from the Aldrich Chemical Company and distilled prior to use. Spectrograde acetonitrile (BDH) was dried either by refluxing over calcium hydride under argon for 12 h (large quantities) or by letting sit over activated 3Å molecular sieves for 8 h (small quantities). In the latter case, the acetonitrile was then degassed by vacuum transferring away from the molecular sieves followed by two freeze–pump–thaw cycles. Ethylamine was obtained from Matheson Gas Products and condensed prior to use; it was then vacuum transferred from a −10°C bath to minimize transfer of any water present. Literature procedures were used to prepare [(dippe)Rh]$_2$(μ-H)$_2$ (**1***a*), [(dippe)Rh]$_2$(μ-D)$_2$ (d_2-**1***a*), (17), and [(dipope)Rh]$_2$(μ-H)$_2$ (**1***b*) (18).

*X-ray crystallographic analysis of [(dippe)Rh]$_2$[μ-N=C(H)CH$_3$]-(μ-H), 2*a

A crystal ca. 0.16 × 0.23 × 0.37 mm in size was mounted in a Lindemann glass capillary. Unit-cell parameters were refined by least squares on setting angles for 25 reflections (2θ = 40.0–47.2°) measured on a diffractometer with Mo-K$_\alpha$ radiation ($\lambda_{K\alpha1}$ = 0.70930, $\lambda_{K\alpha2}$ = 0.71359 Å). Crystal data at 21°C are as follows: $C_{30}H_{69}NP_4Rh_2$ f.w. = 773.59 Monoclinic, a = 19.036(2), b = 15.139(1), c = 13.604(1) Å, β = 104.119(7)°, V = 3801.9(6) Å^3, Z = 4, ρ_c = 1.351 Mg m^{-3}, F(000) = 1624, μ(Mo-K$_\alpha$) = 10.39 cm^{-1}. Absent reflections: *h*0*l*, odd, and 0*k*0, *k* odd, uniquely indicate the space group $P2_1/c$ (No. 14).

Intensities were measured with graphite-monochromated Mo-K$_\alpha$ radiation on an Enraf–Nonius CAD4-F diffractometer. An ω–2θ scan at 1.6–10.1° min^{-1} over a range of (0.90 + 0.35 tan θ)° in ω (scan extended by 25% on each side for background measurement) was employed. Data were measured to 2θ = 55°. The intensities of three check reflections, measured every hour of X-ray exposure time throughout the data collection, showed only small random variations. The data were processed[4] and corrected for Lorentz and polarization effects and absorption (analytical method). Transmission factors range from 0.674 to 0.876. Of the 8710 independent reflections measured, 5814 (66.8%) had intensities greater than or equal to 3σ(I) above background where $\sigma^2(I) = [C + 2B + (0.04(C - B))^2]$ with C = scan count, B = normalized total background count.

The structure was solved by heavy atom methods, the coordinates of the rhodium and phosphorus atoms being determined from the Patterson function. The non-hydrogen atoms were refined with anisotropic thermal parameters and the carbon-bound hydrogen atoms were fixed in idealized positions (C(sp^2)—H = 0.97, C(sp^3)—H = 0.98 Å, $U_H \propto U_{\text{bonded atom}}$). The metal hydride was refined with an isotropic thermal parameter. Scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from ref. 21. The weighting scheme $w = 1/\sigma^2(F)$ gave uniform average values of $w(|F_o| - |F_c|)^2$ over ranges of both $|F_o|$ and sin θ/λ and was employed in the final stages of full-matrix least-squares refinement of 338 variables. Reflections with $I < 3\sigma(I)$ were not included in the refinement. Convergence was reached at R = 0.038 and R_w = 0.041 for 5814 reflections with $I \geq 3\sigma(I)$. The function minimized was $\Sigma w(|F_o| - |F_c|)^2$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$. On the final cycle of refinement the maximum parameter shift corresponded to 0.14σ. The mean error in an observation of unit weight was 1.59. The largest peak on the final difference map, 1.72 e Å^{-3}, is near Rh(2).

trile (2–3 drops). The deep green to orange-red colour change accompanying the reaction was instantaneous. The toluene and excess acetonitrile were removed *in vacuo* and the residues recrystallized from toluene/hexanes (1:1). After washing with cold hexanes, the yield of red crystals was 0.089 g (84%). ^{1}H NMR (C_6D_6, ppm): N=C*H*CH$_3$, 8.75 (m, 1H, ^3J_H = 4.4 Hz, ^4J_P couplings of 15.6, 8.8, and 4.8 Hz); C*H*(CH$_3$)$_2$, 2.23, 2.04–2.20 (overlapping dsp, 8H, ^2J_P = 2.0–4.0 Hz, ^3J_H = 6.4–7.6 Hz); N=CHC*H*$_3$, 2.06 (d, 3H); CH(C*H*$_3$)$_2$, 1.43, 1.40, 1.32, 1.31, 1.20, 1.15, 1.14, 1.11 (overlapping dd, 48H, ^3J_P = 12.4–13.4 Hz); PC*H*$_2$C*H*$_2$P, signals buried underneath methyl resonances; Rh-*H*-Rh, −7.54 (m, $^1J_{Rh}$ = 20.8–21.7 Hz). ^{31}P{^{1}H} NMR (C_6D_6, ppm): $P_{trans(N)}$, 104.0 (dd, $^1J_{Rh}$ = 153.4 Hz, ^2J_P = 26 Hz); $P_{trans(N)}$, 102.6 (dd, $^1J_{Rh}$ = 153.0 Hz, ^2J_P = 24 Hz); $P_{cis(N)}$, 87.0 (br dm, $^1J_{Rh}$ = 195.6 Hz, $^4J_P \approx$ 32 Hz); $P_{cis(N)}$, 83.3 (br dm, $^1J_{Rh}$ = 193.2 Hz). ^{13}C{^{1}H} NMR(C_6D_6, ppm): N=*C*HCH$_3$, 159.1 (s); N=CH*C*H$_3$, obscured by ligand resonances between 19 and 30 (overlapping signals). Anal. calcd. for $C_{30}H_{69}P_4Rh_2N$: C 46.58, H 8.99, N 1.81%; found: C 46.80, H 9.11, N 1.71%.

Reaction of [(dippe)Rh]$_2$(μ-D)$_2$, d$_2$-***1a****, with CH$_3$CN*

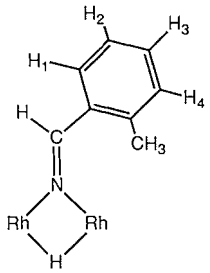
An identical procedure to that described above was followed using *d*$_2$-**1***a* (0.033 g, 0.04 mmol). In the ^{1}H NMR spectrum of the product the signals due to the ethylideneimido proton and the bridging hydride ligand were absent; ^{2}H NMR spectroscopy confirmed the presence of the label in these positions.

Synthesis of [(dippe)Rh]$_2$[μ-N=C(H)C$_6$H$_5$](μ-H), ***3****a*

To a stirred solution of [(dippe)Rh]$_2$(μ-H)$_2$, **1***a* (0.185 g, 0.25 mmol), in toluene (5 mL) was added a solution of distilled benzonitrile (0.029 g, 0.27 mmol) in toluene (1 mL). The solution changed colour instantly from deep green to dark red. The toluene was removed *in vacuo* and the residues recrystallized from toluene/hexanes (1:1) at −20°C. After washing with cold hexanes, 0.173 g (82%) of dark red-purple crystals was isolated. ^{1}H NMR (C_7D_8, ppm): N=C*H*C$_6$H$_5$, 9.00 (br m, 1H, coupled to four phosphorus nuclei); H_{ortho}, 7.97 (d, 2H, $^3J_{H_{meta}}$ = 7.2 Hz); H_{meta}, 7.15 (m, 2H, $^3J_{H_{para}}$ = 7.2 H); H_{para}, 7.09 (m, 1H); C*H*(CH$_3$)$_2$, 2.05–2.25 (br overlapping dsp, 8H, ^3J_H = 6.6–7.6 Hz); CH(C*H*$_3$)$_2$, 1.34, 1.33, 1.30, 1.21, 1.05, 0.97, 0.96, 0.95 (overlapping dd, 48H, ^2J_P = 12.0–14.0 Hz); PC*H*$_2$C*H*$_2$P, 1.1 (br m, 8H); Rh-*H*-Rh, −7.82 (m, $^1J_{Rh}$ = 21.4–22.0 Hz): ^{31}P{^{1}H} NMR (C_6D_6, ppm): $P_{trans(N)}$, 108.9 (dd, $^1J_{Rh}$ = 153.7 Hz, ^2J_P = 27 Hz); $P_{trans(N)}$, 108.3 (dd, $^1J_{Rh}$ = 153.9 Hz, ^2J_P = 28 Hz); $P_{cis(N)}$, 94.4 (br dm, $^1J_{Rh}$ = 195.9 Hz, $^4J_P \approx$ 32 Hz); $P_{cis(N)}$, 87.5 (br dm, $^1J_{Rh}$ = 193.9 Hz). ^{13}C{^{1}H} NMR (C_6D_6, ppm): N=*C*HC$_6$H$_5$, 159.9 (s, ^1J_H = 163.6 Hz); C_{ipso}, 143.9; other aromatic carbons, 129.1, 127.6, 127.1; ligand resonances, 19–28. Anal. calcd. for $C_{35}H_{71}P_4Rh_2N$: C 50.31, H 8.56, N 1.68%; found: C 50.00, H 8.40, N 1.50%.

Synthesis of [(dippe)Rh]$_2$[μ-N=C(H)-o-CH$_3$-C$_6$H$_4$](μ-H), ***4****a*

To a stirred solution of [(dippe)Rh]$_2$(μ-H)$_2$, **1***a* (0.100 g, 0.14 mmol), in toluene (5 mL) was added to a solution of distilled *o*-tolylnitrile (0.018 g, 0.15 mmol) in toluene (1 mL). The solution changed colour instantly from deep green to dark red. The toluene was removed *in vacuo* and the residues recrystallized from toluene/hexanes (1:1) at −20°C. After washing with cold hexanes, 0.105 g (88%) of dark red-purple crystals was isolated. ^{1}H



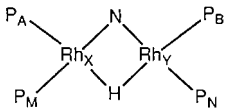
NMR (C_6D_6, ppm): N=C*H*, 10.09 (br m, coupled to 4 phosphorus nuclei); C-*H*$_1$, 8.18 (dd, 1H, ^3J_H = 5.6 Hz, ^4J_H = 3.9 Hz); C-*H*$_2$ and C-*H*$_3$, 7.06 (m, 2H); C-*H*$_4$, 6.93 (m, 1H); C-C*H*$_3$, 2.41 (s, 3H); C*H*(CH$_3$)$_2$, 2.18 (8H, overlapping dsp); CH(C*H*$_3$)$_2$, PC*H*$_2$C*H*$_2$P, 0.9–1.4 (56H, br overlapping signals); Rh-*H*-Rh, −8.92 (ttt, $^2J_{P_{trans}}$ = 60.4 Hz, $^2J_{P_{cis}}$ = 11.6 Hz, $^1J_{Rh}$ = 21.6 Hz). ^{31}P{^{1}H} NMR (C_6D_6, ppm): $P_{trans(N)}$, 107.9 (dd, $^1J_{Rh}$ = 152.6 Hz, ^2J_P = 26.9 Hz); $P_{trans(N)}$, 107.8 (dd, $^1J_{Rh}$ = 152.5 Hz, ^2J_P = 26.8 Hz); $P_{cis(N)}$, 94.1 (br dm, $^1J_{Rh}$ = 193.9 Hz) $^4J_P \approx$ 32 Hz); $P_{cis(N)}$, 82.9 (br dm, $^1J_{Rh}$ = 193.8 Hz). ^{13}C{^{1}H} NMR (C_6D_6, ppm): N=*C*H, 159.8 (s); $C_{ipso(N)}$, 143.5; $C_{ipso(CH3)}$, 135.3; other aromatic carbons, 130.2, 129.1, 127.1, 125.7; C-*C*H$_3$, obscured by ligand resonances in region 19–29. Anal. calcd. for $C_{36}H_{73}P_4Rh_2N$: C 50.89, H 8.66, N 1.65%; found: C 51.22, H 8.59, N 1.74%.

Reaction of [(dippe)Rh]$_2$(μ-D)$_2$, d$_2$-***4****a, with* o-*CH$_3$-C$_6$H$_4$CN*

An identical procedure to that described above was followed using *d*$_2$-**1***a* (0.036 g, 0.05 mmol). In the ^{1}H NMR spectrum of the product the signals due to the *o*-tolylideneimido proton and the bridging hydride ligand were absent; ^{2}H NMR spectroscopy confirmed the presence of the label in these positions.

Synthesis of [(dipope)Rh]$_2$[μ-N=C(H)CH$_3$](μ-H), ***2****b*

To a stirred solution of [(dipope)Rh]$_2$(μ-H)$_2$, **1***b* (0.152 g, 0.18 mmol), in toluene (5 mL) was added two drops of acetonitrile. The reaction was allowed to stir for a further 30 min at which time the toluene was removed *in vacuo*. The orange residue was recrystallized from hexanes, yielding 0.122 g (77%) of **2***b*. ^{1}H NMR (C_6D_6, ppm): N=C*H*CH$_3$, 9.24 (m, 1H, ^3J_H = 4.9 Hz, and couplings of 20.0, 13.6, 6.4, and 1.8 Hz to phosphorus); OC*H*(CH$_3$)$_2$, 5.17, 5.01, 4.75, 4.66 (dsp, 2H each, ^3J_H = 5.6–6.4 Hz, ^2J_P = 2.0–3.0 Hz); N=CHC*H*$_3$, 2.47 (d, 3H); PC*H*$_2$C*H*$_2$P, 1.73 (m, 8H); OCH(C*H*$_3$)$_2$, 1.42, 1.35, 1.34, 1.33, 1.21, 1.20, 1.20, 1.19 (d, 48H); Rh-*H*-Rh, −6.42 (ttt, $^2J_{P_{trans}}$ = 76.0 Hz, $^2J_{P_{cis}}$ = 4–5 Hz, $^1J_{Rh}$ = 21.2 Hz). ^{31}P{^{1}H} NMR (C_6D_6): simulation of the spectrum



of **2***b* was performed using the following parameters: δ_A = 5220.0 Hz (actual chemical shift 189.3 ppm); δ_B = 4945.4 Hz (actual chemical shift 186.9 ppm); δ_M = 7640.0 Hz (actual chemical shift 209.1 ppm); δ_N = 7500.8 Hz (actual chemical shift 207.8

24.6–25.6; C-CH_3, obscured in methyl region. Anal. calcd. for $C_{36}H_{71}O_8P_4Rh_2N$: C 44.23, H 7.53, N 1.43%; found: C 43.99, H 7.56, N 1.39%.

Synthesis of [(dippe)Rh]$_2$[μ-(H)N(CH_2CH_3)](μ-H), 5a

Method A

Solid [(dippe)Rh]$_2$[μ-N=C(H)CH_3](μ-H), **2***a* (0.072 g, 0.09 mmol), was loaded into a small reactor bomb along with toluene (5 mL) and a magnetic stir bar. The solution was degassed on a vacuum line and cooled to −196°C. Dihydrogen was admitted to 1 atm (101.3 kPa) of pressure and the solution was allowed to warm to room temperature. Vigorous stirring was continued for 6–7 h during which time a red to yellow-orange colour change occurred. The toluene was removed *in vacuo* and the residues recrystallized from toluene/hexanes (1:1) yielding 0.059 g (78%) of oily yellow crystals. ^{1}H NMR (C_6D_6, ppm): N-*H*, 3.97 (br s, 1H); H-NCH_2, 3.69 (br m, 2H); C*H*(CH_3)$_2$, 2.40, 2.28, 2.06, 1.92 (dsp, 8H, ^2J_P = 2.0–4.0 Hz, ^3J_H = 7.3–8.0 Hz); CH(CH_3)$_2$, 1.50, 1.33, 1.31, 1.20, 1.17, 1.13, 1.12, 1.01 (dd, 48H, ^3J_P = 12.0–14.4 Hz); NCH_2CH_3, PCH_2CH_2P, obscured under methyl resonances; Rh-*H*-Rh, −7.30 (ttt, $^2J_{Ptrans}$ = 61.2 Hz, $^2J_{Pcis}$ = 13.2 Hz, $^1J_{Rh}$ = 21.2 Hz). ^{31}P{^{1}H} NMR (C_6D_6, ppm): $P_{trans(N)}$, 104.2 (dm, $^1J_{Rh} \approx$ 154 Hz); $P_{cis(N)}$, 87.1 (dm, $^1J_{Rh} \approx$ 193 Hz). ^{13}C{^{1}H} NMR (C_6D_6, ppm): H-NCH_2, 52.7; NCH_2CH_3, ligand resonances 17–28. Anal. calcd. for $C_{30}H_{71}P_4Rh_2N$: C 46.46, H 9.23, N 1.81%; found: C 46.09, H 9.27, N 1.81%.

Method B

A solution of [(dippe)Rh]$_2$(μ-H)$_2$, **1***a* (0.103 g, 0.14 mmol), in toluene (5 mL) was loaded into a small reactor bomb equipped with a magnetic stir bar. The solution was degassed on a vacuum line and dihydrogen admitted to a pressure of 1 atm. To this solution of the tetrahydride was added acetonitrile (0.1 mL) via syringe under a strong flow of dihydrogen. The reaction mixture was cooled to −196°C and the Kontes valve port sealed completely. Stirring was continued for 16 h during which time a slow brown to yellow-orange colour change ensued. The toluene, excess dihydrogen, and excess acetonitrile were removed *in vacuo* and the residues recrystallized from toluene/hexanes (1:1) yielding 0.070 g (64%) of crystals of **5***a*. The product was found to be spectroscopically identical to that obtained in the reaction of **2***a* and dihydrogen.

Method C

A solution of [(dippe)Rh]$_2$(μ-H)$_2$, **1***a* (0.092 g, 0.12 mmol), in toluene (5 mL) was loaded into a small reactor bomb equipped with a magnetic stir bar. The solution was degassed on a vacuum line. A moderate excess of ethylamine was then vacuum transferred into the vessel from a −10°C bath. The reaction was stirred until the green to yellow colour change was complete (8–12 h). The toluene and excess ethylamine were removed under reduced pressure and the residues recrystallized from toluene/hexanes (1:1) yielding 0.082 g (84%) of crystals of **5***a*. The product was spectroscopically identical to samples of **5***a* and obtained via the routes described above.

Synthesis of [(dippe)Rh]$_2$[μ-(H)N($CH_2C_6H_5$)](μ-H), 6a

Method A

An identical procedure to method A described above was employed using **3***a* (0.093 g, 0.11 mmol). Yellow crystals of the μ-benzylamido hydride complex **6***a* were obtained (0.086 g, 81%). ^{1}H NMR (C_6D_6, ppm): H_{ortho}, 8.01 (d, 2H, $^3J_{H_{meta}}$ = 7.6 Hz); H_{meta}, 7.24 (m, 2H, $^3J_{H_{para}}$ = 7.5 Hz); H_{para}, 7.14 (t, 1H); H-NCH_2, 5.17 (br m, 2H, $J_P \approx$ 3.0 Hz); N-*H*, 4.10 (br s, 1H); C*H*(CH_3)$_2$, 2.45, 2.16, 2.13, 1.95 (dsp, 8H, ^2J_P = 2.0–4.0 Hz, ^3J_H = 7.2–8.2 Hz); CH(CH_3)$_2$, 1.56, 1.45, 1.34, 1.18, 1.09, 1.07, 1.01, 0.78 (dd, 48H, ^3J_P = 11.4–15.2 Hz; PCH_2CH_2P, 1.26 (m, 8H); Rh-*H*-Rh, −7.44 (ttt, $^2J_{Ptrans}$ = 60.2 Hz, $^2J_{Pcis}$ = 12.6 Hz, $^1J_{Rh}$ = 21.6 Hz). ^{31}P{^{1}H} NMR (C_6D_6, ppm): $P_{trans(N)}$, 103.7 (dm, $^1J_{Rh} \approx$ 152 Hz); $P_{cis(N)}$, 85.8 (dm, $^1J_{Rh} \approx$ 193 Hz). Anal. calcd. for $C_{35}H_{73}P_4Rh_2N$: C 50.18, H 8.78, N 1.67%; found: C 49.96, H 8.73, N 1.80%.

Method B

An identical procedure to method B described above was employed using **1***a* (0.103 g, 0.14 mmol) and benzonitrile (0.72 g in 0.5 mL toluene, 5 equivalents). The product, **6***a*, was isolated in 75% yield (0.088 g) and was spectroscopically identical to the product obtained in the reaction of **3***a* with dihydrogen.

Method C

To a stirred solution of [(dippe)Rh]$_2$(μ-H)$_2$, **1***a* (0.087 g, 0.11 mmol), in toluene (5 mL) was added pure benzylamine (0.064 g, 5 equivalents). The reaction was stirred for 2 h while a green to yellow-orange colour change occurred. Removal of the toluene, followed by recrystallization, yielded 0.087 g (88%) of yellow-orange crystals of **6***a*. This product was spectroscopically identical to samples of **6***a* obtained via the routes described above.

Synthesis of [(dippb)Rh]$_2$[μ-(H)N(CH_2CH_3)](μ-H), 6d

A solution of the tetrahydride [(dippb)Rh]$_2$(H)(μ-H)$_3$, **5***c* (18) (0.098 g, 0.12 mmol), in toluene (5 mL) was loaded into a small reactor bomb equipped with a magnetic stir bar. Acetonitrile (1 mL) was added and the reaction mixture degassed on a vacuum line via two freeze–pump–thaw cycles; the vessel was back-filled with pure dinitrogen. The reaction was stirred at 70°C for 3 days, at which time a colour change from brown-green to yellow was complete. Toluene and excess acetonitrile were removed *in vacuo* and the residues analyzed by ^{1}H and ^{31}P{^{1}H} NMR spectroscopy. ^{1}H NMR (C_6D_6, ppm): N-*H*, 3.41 (br s, 1H); H-NCH_2, 3.27 (br m, 2H); C*H*(CH_3)$_2$, 2.35, 2.18, 2.15, 1.96 (dsp, 8H, ^2J_P = 2.0–4.0 Hz, ^3J_H = 7.4–8.0 Hz); NCH_2CH_3, 1.70 (t, 3H, ^3J_H = 7.6 Hz); CH(CH_3)$_2$, 1.58, 1.55, 1.46, 1.32, 1.30, 1.21, 1.19, 1.17 (dd, 48H, ^3J_P = 12.0–14.0 Hz); P(CH_2)$_4$P, resonances obscured by methyl signals; Rh-*H*-Rh, −10.87 (ttt, $^2J_{Ptrans}$ = 57.2 Hz, $^2J_{Pcis}$ = 13.2 Hz, $^1J_{Rh}$ = 21.6 Hz). ^{31}P{^{1}H} NMR (C_6D_6, ppm): $P_{trans(N)}$, 61.2 (dm, $^1J_{Rh} \approx$ 154 Hz); $P_{cis(N)}$, 33.7 (dm, $^1J_{Rh} \approx$ 195 Hz).

Results and discussion

The observed reactivity between the dihydrides [(dippe)-Rh]$_2$(μ-H)$_2$, **1***a*, and [(dipope)Rh]$_2$(μ-H)$_2$, **1***b*, and the carbon–nitrogen double bonds of imines (19) led us to explore the behaviour of these dimers towards the carbon–nitrogen triple bonds of simple nitrile substrates. The dihydrides were found to react smoothly with one or more equivalents of R′CN (R′ = CH_3, C_6H_5, *o*-CH_3-C_6H_4) at room temperature to produce the red or red-purple, air-sensitive μ-alkylideneimido hydride complexes **2**–**4***a* and **2**–**4***b* (eq. [1]). The reactions were spectroscopically clean, producing the product in >95% yield by ^{1}H and ^{31}P{^{1}H} NMR spectroscopy; isolated yields for **2**–**4***a* were 82–88%, whereas the more soluble compounds of the dipope series, **2***b*–**4***b*, were isolated in 72–78% yield. Similar to the trends in the reactions with imines (19), the dippe dimer **1***a* reacted instantly with the nitriles employed, while the dipope dihydride required about 30 min to undergo the same transformations.

The related binuclear hydride, [(dippp)Rh]$_2$(μ-H)$_2$, where dippp is 1,3-bis(diisopropylphosphino)propane ($Pr^i_2PCH_2CH_2CH_2PPr^i_2$) (20), undergoes a slow reaction with acetonitrile at elevated temperatures, but fails to react with either benzonitrile or *o*-tolynitrile. The presence of the μ-ethylideneimido dippp product was noted spectroscopically, but the prohibitively slow rate of this transformation discouraged complete characterization of this complex.

The ^{1}H, ^{13}C{^{1}H}, and ^{31}P{^{1}H} NMR spectral data collected for these complexes were consistent with the proposed structure for these molecules; in addition, a single crystal X-ray analysis on **2***a* confirmed the structural assignment (*vide infra*). In the ^{1}H NMR spectra of these compounds, the signals of interest are those for alkylideneimido

[1]

proton and the bridging hydride ligand. The alkylideneimido protons resonate downfield in the region 8.75–10.5 ppm, and give rise to a complex signal with coupling to four inequivalent phosphorus nuclei present (no Rh–H coupling was observed; therefore this coupling is <2.5 Hz). The μ-hydrido ligands also show coupling to four inequivalent phosphorus atoms; one-bond rhodium coupling constants of ≈20–22 Hz are also observed.

In the $^{13}C\{^1H\}$ NMR spectra, the μ-alkylideneimido carbon atom resonates at ≈159 ppm for the dippe *a* series of compounds and ≈168 ppm in the complexes of the dipope *b* series. Little ^{13}C NMR data has been reported for μ-alkylideneimido complexes, but these chemical shifts do fall in the range in which the imine carbon in free imines usually resonate (≈160 ppm) (22).

As expected, the $^{31}P\{^1H\}$ NMR spectra for these compounds are complex, particularly in the dippe series. Four inequivalent phosphine environments and the long-range P–P and Rh–P couplings between opposite sides of the dimer generate an ABMNXY spin system, which we have successfully simulated for the dipope derivative **2***b*; see experimental section. A large four-bond coupling between the two phosphorus nuclei *cis* to the ethylideneimido ligand is observed ($^4J_{P-P}$ = 68.3 Hz) and substantial three-bond couplings of 11.3 and 12.2 Hz from the *cis* phosphorus nuclei to the distal rhodiums are also present. In general, the spectra of the dippe compounds **2–4***a* are broader with less well-defined couplings.

*The solid state structure of [(dippe)Rh]$_2$[μ-N=C(H)CH$_3$] (μ-H), 2*a

Characterization of this family of compounds was completed via a single crystal X-ray analysis of the dippe ethylideneimido hydride complex **2***a*; two views of the ORTEP diagram of the binuclear complex are shown in Figure 1, while Tables 2 and 3 give bond distances and angles, respectively. Each rhodium centre in the dimer is of a distorted square planar geometry. When viewed looking down the Rh–Rh vector, the two square planes are slightly bent with respect to each other. The angle between the mean-square planes containing a rhodium atom and the four ligand atoms is 25.5°. The parameters associated with the chelating phosphine ligands are unremarkable; Rh—P bond lengths and the P—Rh—P angles of 86.44° and 85.89° are nearly identical to analogous values found in other structurally characterized rhodium complexes containing the dippe ligand (17, 20, 23–25). The angles P(2)—Rh(1)—Rh(2) and P(4)—Rh(2)—Rh(1) are 145.1° and 148.6°, respectively, and partially account for the large four-bond coupling between P(2) and P(4) (*vide supra*). The bridging hydride ligand was located and refined isotropically and was found to symmetrically bridge the two metal centres. The Rh—H bond lengths of 1.74(5)Å are about 0.1 Å shorter than those in other [(dippe)Rh]$_2$(μ-X)(μ-H) (17, 23, 24) complexes, which average ≈1.84 Å in length, but are comparable to the 1.70 Å distances found in the parent dihydride **1***a* (20). The "tighter" molecular core is also reflected by a slightly shorter than normal (≈2.86 Å) Rh—Rh separation of 2.7992(4) Å.

Bond and angle parameters in the μ-ethylideneimido ligand are typical of a bridging bonding mode with no π-donation from the C=N bond to either of the metal centres. The C=N bond length of 1.255(5) Å is slightly shorter than an average carbon–nitrogen double bond (1.28 Å) (26), but coincides well with other known C=N distances in complexes incorporating the μ-alkylideneimido ligand (9–11, 14, 27, 28).

The N—C(29)—C(30) bond angle of 128.3° suggests sp^2 hybridization about C(29) (the other two angles, i.e., N—C(29)—H and C(30)—C(29)—H, are idealized since the ethylideneimido proton was not refined). This is also supported by large $^1J_{C-H}$ coupling constants of ≈168 Hz in the alkylideneimido C—H bonds (22).

The discrepancy between Rh(1)—N—C(29) (128.8°) and Rh(2)—N—C(29) (141.3°) indicates that the μ-ethylideneimido ligand is slightly tilted such that the methyl group, C(30), is moved away from the isopropyl groups on P(4). Presumably, with the larger phenyl and *o*-tolyl substituents on C(29), this steric interaction would be exacerbated. It also provides a possible rationale for why the bulkier nitriles Bu^tCN and Pr^iCN do not react with **1***a* or **1***b* to produce the corresponding μ-alkylideneimido hydride complexes.

Mechanistic considerations

The reaction of d_2-**1***a* with acetonitrile or *o*-tolynitrile yielded d_2-**2***a* and d_2-**4***a*, respectively (eq. [2]), in which the deuterium label appears in the μ-alkylideneimido and μ-hydrido positions. Unlike the reactions involving **1***a* and imines (19), intermediates in the reactions with nitriles were not observed when the reactions were monitored at low temperatures; at −80°C, only peaks for the dihydride and the final product **4***a* were observed in the $^{31}P(^1H)$ NMR spectrum of the reaction between **1***a* and *o*-tolylnitrile. Nonetheless, it

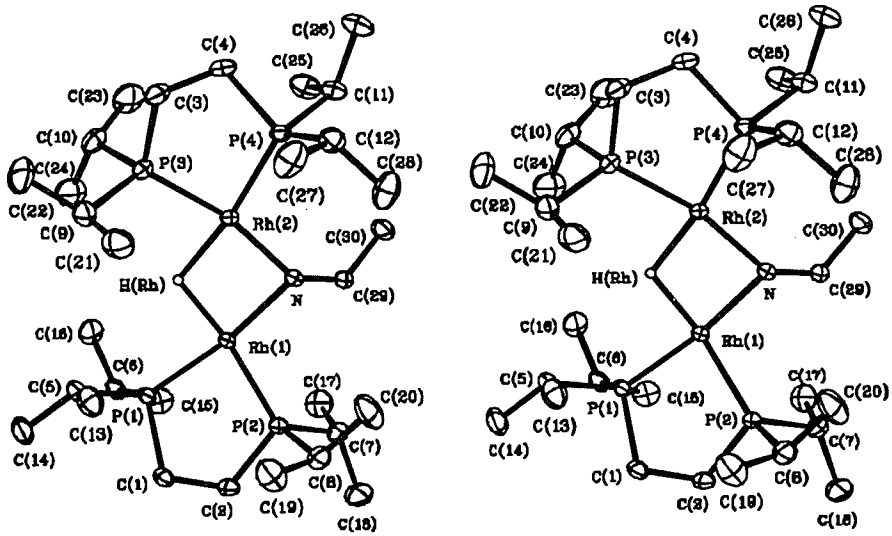

FIG. 1. Stereoview and numbering scheme for **2***a*; 50% probability thermal ellipsoids are shown for the non-hydrogen atoms.

seems reasonable to postulate a similar reaction course to the one proposed for the reactions of **1***a* and **1***b* with imines, i.e., activation of substrate via σ–π donation to adjacent coordinatively unsaturated metal centres, followed by Rh—H bond cleavage and finally insertion of the C≡N into the newly formed Rh—H terminal linkage. If such a mechanism is operative here, it is probable that the greater π-donating ability of C≡N compared to C=N is responsible for accelerating the rate-limiting migration of a bridging hydride into a terminal position, such that observation of intermediates is precluded in this system. The results of the labelling experiment are consistent with an insertion of the C≡N triple bond into a rhodium hydride bond, but based on the imine/dihydride study we consider it likely that both metal centres are involved in the formation of the alkylideneimido products.

The reactions of μ-alkylideneimido complexes with dihydrogen and related processes

The complete stoichiometric reduction of the nitrile C≡N bond is accomplished via the reaction of the alkylideneimido complexes with excess dihydrogen (eq. [3]). The reactions proceed nearly quantitatively, yielding primary amido hydride products akin to those produced in the reactions of the dihydrides with imines (19). Like their secondary analogs, the amido-hydrides **5***a* and **6***a* (R′ = CH_3 and C_6H_5, respectively) were relatively inert to further reaction with dihydrogen and were thus isolated in 85–92% yield. The overall sequence from **1***a* and R′C≡N to the amido hydrides represents a stoichiometric reduction of the nitrile to an amine mediated by two metal centres. Although stepwise reduction of R′C≡N on trinuclear clusters has been observed previously (M_3 = Fe_3 (13–16), Os_3 (9, 28)), this is the first example of this transformation occurring on a binuclear cluster. The amido hydrides also obtain when the tetrahydride hydrogen adduct of **1***a* (formed *in situ* from **1***a* and dihydrogen (20)) is treated with the nitriles. A related transformation is the reaction of the thermally stable tetrahydride [(dippb)Rh]$_2$(μ-H)$_3$(H) (20) [dippb = $Pr^i_2PCH_2CH_2$-$CH_2CH_2PPr^i_2$] with acetonitrile to generate the μ-ethylamido product (eq. [4]). Although no intermediates could be observed in these last two reactions, presumably alkylideneimido-type intermediates are involved but with additional hydride ligands present.

Mechanistically, the reaction in eq. [3] likely proceeds through an intermediate incorporating a μ–η^2–σ iminyl ligand, similar in nature to an intermediate observed in the **1***a*/imine reactions. Whether the reaction proceeds via hydrogenolysis of the Rh—N bond, or by H_2 oxidative-addition/N-H reductive-elimination sequence, the intermediate formed is probably similar to species **A**, shown below, which subsequently proceeds very rapidly to generate the amido-hydride products.

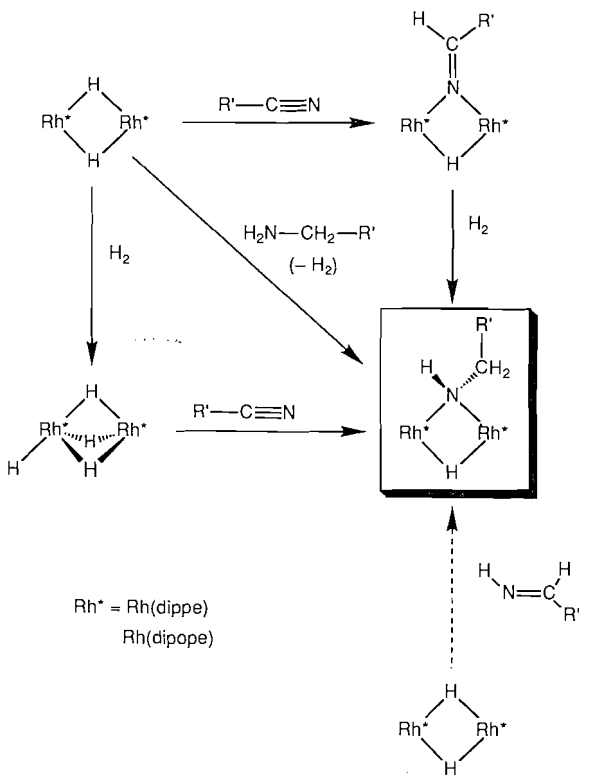
A



SCHEME 1

The thermodynamic stability of the amido-hydride derivatives is apparent from the number of routes to these complexes (Scheme 1). In addition to the reactions of **1***a* and **1***b* with imines and nitriles/H_2 (or H_2/nitriles), the stoichiometric reduction of isonitriles with the dihydride $\{[(Pr^iO)_3P]_2Rh\}_2(\mu\text{-}H)_2$ and dihydrogen produces related amido-hydride products (29). Another route is the reaction of primary amines with the dihydrides; this reaction, the reverse of which would be the last step in a catalytic cycle, proceeds smoothly with elimination of dihydrogen.

While the reactions of **1***a* with the amines were slowly reversible in the presence of excess dihydrogen at normal temperatures and pressures, obviously the presence of a four-electron donor in the bridging position is preferred over a two-electron donor hydride ligand. The thermodynamic stability of the amido-hydride functionality in these complexes is undoubtedly the reason homogeneous hydrogenation of both imines and nitriles fails for these systems.

Tetramethylguanidino-substituted pyrylium and thiopyrylium salts

WLODZIMIERZ GALEZOWSKI,[1] KENNETH T. LEFFEK, AND PRZEMYSLAW PRUSZYNSKI[2]
Department of Chemistry, Dalhousie University, Halifax, N. S., Canada B3H 4J3

Received March 2, 1992

WLODZIMIERZ GALEZOWSKI, KENNETH T. LEFFEK, and PRZEMYSLAW PRUSZYNSKI. Can. J. Chem. **70**, 2390 (1992).

Four new tetramethylguanidino-substituted pyrylium and thiopyrylium salt dyes have been prepared and their absorption maxima in the visible region measured. The positions of the absorption maxima are similar to those observed for thiopyrylium salt dyes used in photoconductive film compositions. The λ_{max} values for the new dyes, when compared to those of other pyrylium and thiopyrylium dyes in the literature, yield a σ_p value of -0.86 ± 0.04 and a σ^+ value of -1.8 ± 0.1 for the tetramethylguanidino group, in good agreement with previous determinations.

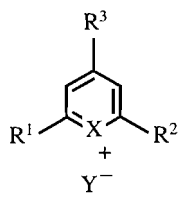
WLODZIMIERZ GALEZOWSKI, KENNETH T. LEFFEK et PRZEMYSLAW PRUSZYNSKI. Can. J. Chem. **70**, 2390 (1992).

On a préparé quatre colorants de la famille des sels de pyrylium et de thiopyrylium substitués par un groupe tétraméthylguanidino et on a mesuré leurs maxima d'absorption dans le région visible. Les positions des maxima d'absorption sont semblables à celles observées avec les colorants des sels de thiopyrylium utilisés dans des compositions de films photoconducteurs. Les valeurs des λ_{max} des nouveaux colorants, lorsqu'elles sont comparées à celles d'autres colorants du pyrylium et du thiopyrylium rapportées dans la littérature, permettent de déterminer une valeur de σ_p de $-0{,}86 \pm 0{,}04$ et une valeur de σ^+ de $-1{,}8 \pm 0{,}1$ pour le groupe tétraméthylguanidino, ce qui est en bon accord avec les valeurs déterminées antérieurement.

[Traduit par la rédaction]

Introduction

Pyrylium and thiopyrylium dye salts have been used for a number of years in photoconductive film compositions in electrophotographic technology (1) and the structure and properties of such photoconductive films have been reviewed by Perlstein (2). The typical structure of these dye salts is shown in **1** where X is O or S and R^1, R^2, and R^3 are aromatic groups with one or more of the groups, usually a



1

phenyl ring, substituted with a dimethylamino group (3, 4). Other similar thiopyrylium salts have also been prepared for the same purpose (5, 6). Our previous work on substituted phenyltetramethylguanidines (7, 8) showed that the tetramethylguanidino group (TMG) has a very large electron-donating power with a $\sigma_p = -0.8$ to -0.88. This suggested that dye salts of structure **1** with one of the phenyl rings *para*-substituted with the tetramethylguanidino group might provide new photosensitizing dyes additional to those already available.

Results and discussion

Since thiopyrylium salts of structure **1** are easily obtained from their pyrylium analogues by reaction with Na_2S (9), the synthesis focused on the pyrylium salts themselves. The direct reaction of 2,6-diphenylpyrylium perchlorate with 2-*N*-phenyl-1,1,3,3-*N*-tetramethylguanidine in acetic anhydride, by analogy with the method used by Kröhnke and Dickoré (10) to prepare the 4-(*p*-aminophenyl) flavylium perchlorate, failed in this case. This method was used by Katritzky *et al.* (4) in ethanol solvent to prepare *p*-dimethylamino derivatives, among others, of thiopyrylium salts of structure **1**. The method of Wizinger, Grüne, and Jacobi (11) of heating dialkyl anilines with diphenylpyrones in the presence of $POCl_3$ was also tried, using 2-*N*-phenyl-1,1,3,3-*N*-tetramethylguanidine, but this failed to give the desired product.

The pyrylium and thiopyrylium dyes with a TMG group *para*-substituted on the 4-phenyl ring were successfully synthesized in the form of guanidinium diperchlorates using the series of reactions shown in Scheme 1.

Solutions of 1,1,3,3-*N*-tetramethyl-2*N*-[4-(2,6-diphenyl-4-thiopyrylio)phenyl]guanidinium diperchlorate **9** in DMSO turn from dark yellow to blue upon dilution to a concentration of about 2×10^{-5} M. The visible spectrum of **9** itself was obtained in the presence of perchloric acid, which prevented the loss of a proton from the nitrogen atom, and shows a strong absorption band at $\lambda_{max} = 428$ nm ($\epsilon = 34\,000$). The spectrum of 2.5×10^{-5} M **9** in DMSO without the addition of $HClO_4$ shows only one absorption at $\lambda_{max} = 596$ nm ($\epsilon = 42\,000$). This band is ascribed to the structure **1** with $R^1 = R^2 = C_6H_5$, $R^3 = C_6H_4N{=}C(N(CH_3)_2)_2$, X = S, and $Y = ClO_4$. The corresponding compound with $R^3 = C_6H_4N(CH_3)_2$ was reported by Wizinger and Ulrich (9) to have a $\lambda_{max} = 583$ nm, a bathochromic shift of 13 nm. A plot of λ_{max} for the three thiopyrylium salts with *para* substituents H, $-OCH_3$, and $-N(CH_3)_2$, studied by Wizinger and Ulrich (9), against the Hammett substituent constant σ_p (correlation coefficient 0.9978) and the λ_{max} of the deprotonated form of **9** may be used to determine σ_p for the TMG group. This procedure gives a σ_p value for TMG of -0.89.

For deprotonated **9** it would be expected that a considerable amount of through conjugation would exist between the N—C double bond and positively charged pyrylium ring so that Hammett σ^+ values would be appropriate. When these are plotted against the λ_{max} values of Wizinger and Ulrich (9) for their three dyes, a linear relationship is obtained but with a relatively poor correlation coefficient of 0.9763. This relationship yields a σ^+ for the TMG group of -1.90. These

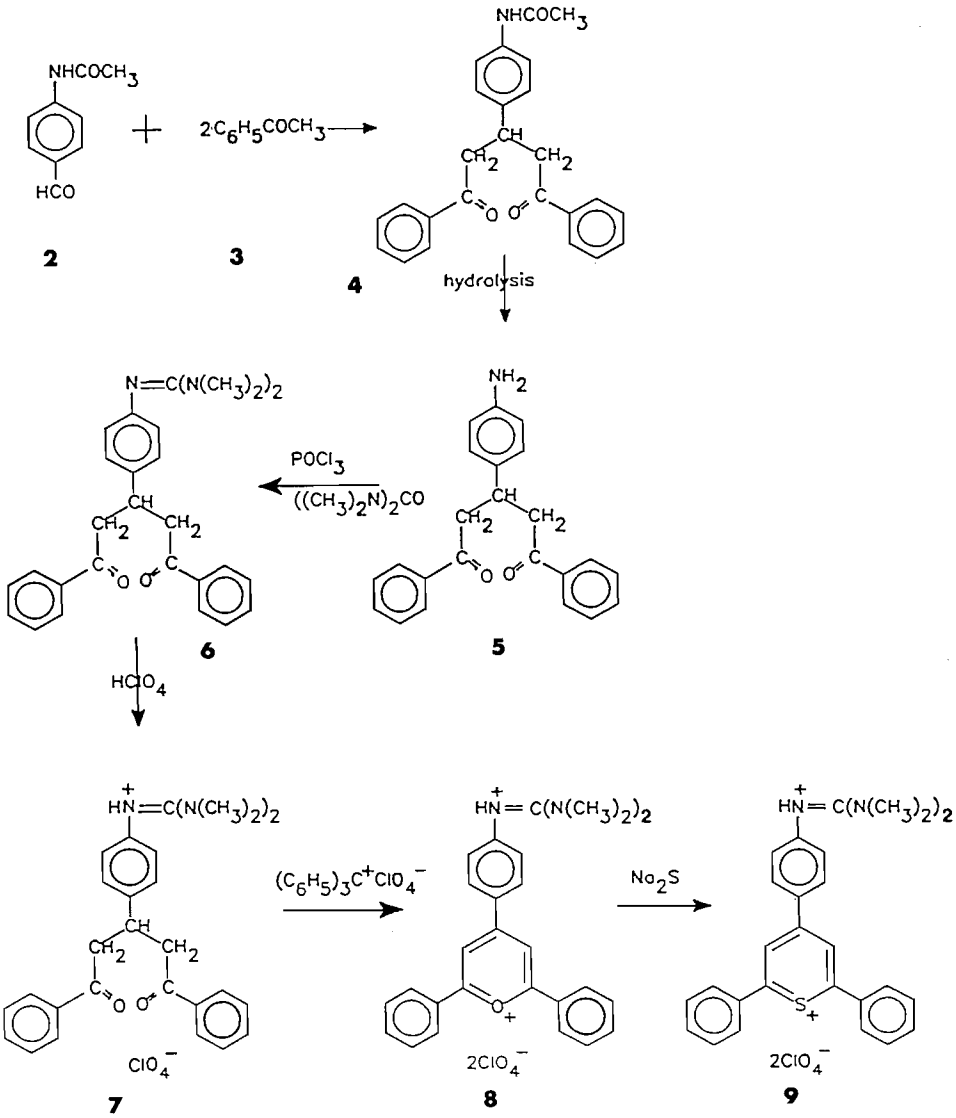

SCHEME 1

σ determinations may contain considerable error since they are based on only three measurements from the literature. However, we do have four different dyes, the absorption maxima of which can be used to obtain four separate estimates of σ.

The visible absorption peak for solutions of 1,1,3,3,-*N*-tetramethyl-2-*N*-[4-(2,6-diphenyl-4-pyrylio)phenyl]guanidinium diperchlorate **8** in DMSO has a λ_{max} = 422 nm (ε = 42 000) in the presence of $HClO_4$. The deprotonated compound showed λ_{max} = 555 nm (ε = 45 000). This latter peak combined with the data of Wizinger and Ulrich gives σ_p = −0.90 and σ^+ = −1.9. Again the correlation coefficients are better with σ_p (0.9999) than with σ^+ (0.9880).

The diperchlorate dyes with the TMG group substituted at the *para* position of the R^2 phenyl group of structure **1** were prepared by a series of reactions summarized in Scheme 2. The spectrum of the thiopyrylium dication **16** in DMSO with $HClO_4$ gave a peak, λ_{max} = 454 nm (ε = 14 000). A dilute solution in DMSO in the absence of acid gave the spectrum of the thiopyrylium salt dye and showed a λ_{max} = 610 nm (ε = 14 000). The pyrylium diperchlorate **15** gave a peak λ_{max} = 452 nm (ε = 12 000) in DMSO with acid, and λ_{max} = 565 nm (ε = 12 000) in the absence of acid. When these absorption maxima were compared to Hammett plots generated from absorption maxima reported by Wizinger and Ulrich (9), the thiopyrylium salt gave σ_p = −0.82 and σ^+ = −1.75 and the pyrylium salt gave σ_p = −0.815 and σ^+ = −1.7.

A possible source of error in these determinations is the difference in the solvents used in determining the visible spectra. Wizinger and Ulrich used glacial acetic acid, whereas ours were determined in DMSO. However, the λ_{max} values are not sensitive to this solvent change. Wizinger and Ulrich reported λ_{max} = 540 nm for the dimethylamino analogue of deprotonated **8** in glacial acetic acid. A sample of this compound prepared by us gave λ_{max} = 544 nm (ε = 53 000) in DMSO, so that the average σ values quoted below for the TMG group are probably reliable to within the stated standard deviations. The average σ values for the four determinations given above are σ_p = −0.86 ± 0.04 and σ^+ = −1.8 ± 0.1. There are now three determinations of σ_p for the TMG group, from nqr spectra (7) giving −0.88, from pK_a

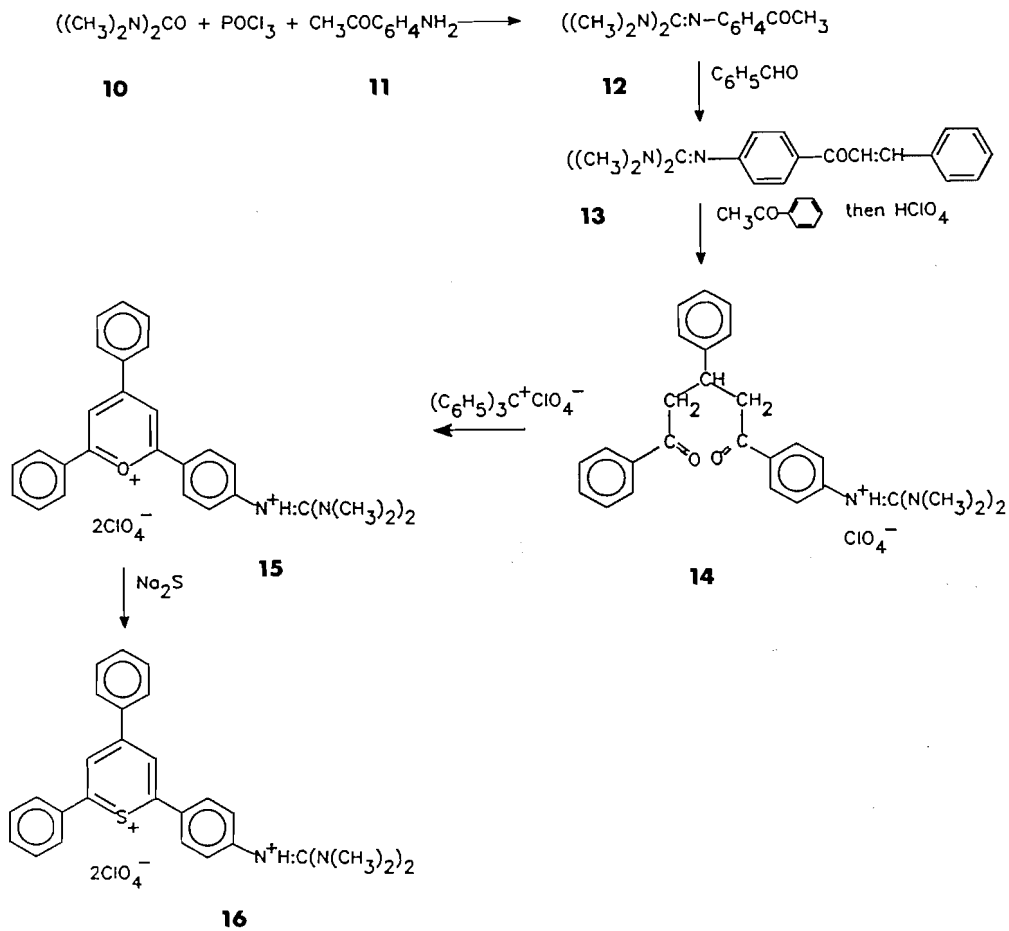

SCHEME 2

measurements (8) giving −0.80, and the present work from visible spectra giving −0.86. Thus the electron-releasing capacity of the TMG group is well established and is shown to be slightly greater than that of the dimethylamino group, which has a σ_p value of −0.83 (12).

The tetramethylguanidino-substituted pyrylio and thiopyrylio dyes are most readily prepared and stored as the diperchlorates because of the high basicity of the TMG group. However, the proton is lost in dilute DMSO solutions, giving dyes with visible absorption maxima very similar to those of the dimethylamino-substituted analogues. Thus the TMG dyes might be suitable sensitizing dyes in electrophotographic processes.

Experimental

*Preparation of 1,1,3,3-*N*-tetramethyl-2*N*-[4-(2,6-diphenyl-4-thiopyrylio)phenyl]guanidinium diperchlorate*

A mixture of 4-acetamidobenzaldehyde **2** (Aldrich) (8.16 g, 0.05 mol) and acetophenone **3** (12 g, 0.1 mol), in 150 mL ethanol in which NaOH (2 g, 0.05 mol) had been dissolved, was heated under reflux for 2 h, during which time the solution turned red-brown. A standard work-up yielded the white 3-(4-aminophenyl)-1,5-diphenyl-1,5-pentadione **5**; 2.7 g (16% yield); mp 120–122°C; ^{1}H nmr δ: 3.26 (2H, dd, −16.4, 7.1 Hz), 3.45 (2H, dd, −16.4, 7.0 Hz), 3.55 (2H, br s), 3.95 (1H, q, 7.0 Hz), 6.58–7.06 (4H), 7.41–7.56 (6H, m), 7.93–7.97 (4H, m). Anal. calcd. for $C_{23}H_{21}NO_2$: C 80.44, H 6.16, N 4.08%; found: C 80.2, H 6.46 N 4.04%. The main product was 3-(4-acetylaminophenyl)-1,5-diphenyl-1,5-pentadione **4** (42% yield).

The amine **5** was reacted with tetramethylurea using the method of Bredereck and Bredereck (13) but with a large excess of the reagent. The substituted phenylguanidine **6** was obtained as a resinous material; ^{1}H nmr δ: 2.7 (12H, s), 3.25–3.45 (4H, m), 3.8–4.2 (1H, m), 7.3–7.65 (6H), 7.9–8.05 (4H).

The product **6** was dissolved in a small amount of ethanol, then treated with excess 60% $HClO_4$, dropwise, and finally with H_2O dropwise until the solution became cloudy. Crystallization of the perchlorate salt **7** took place overnight and a recrystallization was made from a dichloromethane/hexane mixture, mp 168–169°C; ^{1}H nmr δ: 2.9 (12H, s), 3.2–3.6 (4H, m), 3.8–4.2 (1H, m), 6.8–7.6 (10H, m), 7.8–8.1 (4H, m), 8.5 (1H, s).

A mixture of **7** (0.325 g, 6×10^{-4} mol), triphenylmethyl perchlorate (0.217 g, 6.6×10^{-4} mol), and 2.0 mL glacial acetic acid was refluxed (14) with stirring for 5 min with the reaction mixture protected from atmospheric moisture. The resulting yellow solid 1,1,3,3-*N*-tetramethyl-2*N*-[4-(2,6-diphenyl-4-pyrylio)phenyl]-guanidinium diperchlorate **8** was filtered, washed with glacial acetic acid and ether, and dried under vacuum, 0.33 g (yield 88%). Recrystallization was made from glacial acetic acid even though the solubility is very low, since this gave fine yellow crystals that melted, with decomposition at about 315°C; ^{1}H nmr δ: 3.02 (12H, s), 7.33 and 8.73 (4H), 7.81 (4H, t), 7.88 (2H, t), 8.59 (4H, d) 9.11 (2H, s). Anal. calcd. for $C_{28}H_{29}Cl_2N_3O_9$: C 54.03, H 4.69, Cl 11.39, N 6.75%; found: 53.8, H 4.7, Cl 11.7, N 6.6%.

The pyrylio function was converted to thiopyrylio by the method

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

of Wizinger and Ulrich (9), except that some DMSO was added to the solvent to improve the solubility of **8**.

A solution of **8** (0.781 g, 1.25×10^{-3} mol) in DMSO (5.0 mL) was diluted with acetone (25 mL) and treated with $Na_2S \cdot 9H_2O$ (0.63 g in 6.0 mL H_2O). The resulting red-brown solution was acidified with $HClO_4$ (7 mL 20% $HClO_4$ in 25 mL H_2O) and shiny golden crystals of 1,1,3,3,-tetramethyl-2*N*-[4-(2,6-diphenyl-4-thiopyrylio)phenyl]guanidine diperchlorate **9** formed, 0.78 g (97%). Recrystallization from acetic acid gave dark yellow needles, mp 318–320°C with decomposition; ^{1}H nmr δ: 3.01 (12H, s), 7.31 and 8.56 (4H), 7.78–7.84 (6H, m), 8.30 (4H, d), 9.24 (2H, s). Anal. calcd. for $C_{28}H_{29}Cl_2N_3O_8S$: C 52.67, H 4.58, Cl 11.10, N 6.58, S 5.02%; found: C 52.1, H 4.5, Cl 11.9, N 6.4, S 4.8%.

Preparation of 1,1,3,3,-N-*tetramethyl-2*-N-*[4-(4,6-diphenyl-2-thiopyrylio)phenyl]guanidinium diperchlorate*

2-*N*-(4-Acetophenyl) tetramethylguanidine **12** was prepared by the method of Bredereck and Bredereck (13) as white crystals, after recrystallization from hexane, mp 57–59°C (lit. (15) mp 59°C), yield 31%.

A mixture of **12** (4.7 g, 0.02 mol), benzaldehyde (2.0 g, 0.02 mol), NaOH (0.4 g, 0.01 mol) in ethanol (30 mL) was refluxed for 3 h. A standard work-up yielded a thick yellow oil of 1,1,3,3 -*N*-tetramethyl-2*N*-[4-(1-oxo-3-phenyl -2-propenyl)phenyl]-guanidine **13**, yield 6.0 g (97%); ^{1}H nmr δ: 2.75 (12H, s), 6.7 and 8.0 (4H), 7.3–7.8 (7H, m).

A mixture of **13** (3.2 g, 0.01 mol), acetophenone (4.8 g, 0.04 mol), and NaOH (1.0 g, 0.025 mol) in ethanol (100 mL) was refluxed for 3.5 h. Acid work-up with 20% $HClO_4$ yielded an oil that was triturated with ether to give solid 1,1,3,3-*N*-tetramethyl-2*N*-[4-(1,5-dioxo-3,5-diphenylpentyl)phenyl]guanidinium perchlorate **14**, yield 2.5 g (46%); ^{1}H nmr δ: 3.0 (12H, s), 3.2–3.6 (4H, m), 3.8–4.2 (1H, m) 6.9–8.1 (14H, m), 9.0 (1H, s). Anal. calcd. for $C_{28}H_{32}ClN_3O_6$: C 62.05, H 5.94, Cl 6.54, N 7.75%; found: C 60.9, H 5.8, Cl 7.0, N 7.4%.

Treatment of **14** (0.75 g, 1.7×10^{-3} mol) with triphenylmethyl perchlorate (0.6 g, 1.75×10^{-3} mol) in glacial acetic acid (10 mL) gave dark yellow crystals of 1,1,3,3-*N*-tetramethyl-2-*N*-[4-(4,6-diphenyl-2-pyrylio)phenyl]guanidinium diperchlorate **15**, yield 0.68 g (79%). After recrystallization from a DMSO/acetone/acetic acid mixture, mp 306–310°C with decomposition; ^{1}H nmr δ: 3.02 (12H, s), 7.34 and 8.65 (4H), 7.78–7.89 (6H, m), 8.57–8.60 (4H, m), 9.10 (2H, s). Anal. calcd. for $C_{28}H_{29}Cl_2N_3O_9$: C 54.03, H 4.69, Cl 11.39, N 6.74%; found: C 52.4, H 4.9, Cl 10.5, N 6.2%.

A solution of **15** (0.31 g, 5×10^{-4} mol) in acetone (10 mL) and DMSO (1 mL) was treated with $Na_2S \cdot 9H_2O$ (0.25 g, 1×10^{-3} mol) dissolved in water (2.5 mL) (9). The reaction mixture was acidified with 20% $HClO_4$ (2.5 mL) and dark orange crystals of crude 1,1,3,3-*N*-tetramethyl-2-*N*-[4-(4,6-diphenyl-2-thiopyrylio)phenyl]guanidinium diperchlorate **16** were obtained, yield 0.27 g (81%). After recrystallization from acetic acid, orange crystals were obtained, mp 305–307°C with decomposition; ^{1}H nmr δ: 3.00 (12H, s), 7.33 and 8.39 (4H), 7.7–7.8 (6H, m), 8.3 (2H, d), 8.42 (2H, d), 9.22 (2H, s). Anal. calcd. for $C_{28}H_{29}Cl_2N_3O_8S$: C 52.69, H 4.58, Cl 11.10, N 6.58, S 5.02%; found: C 51.7, H 4.4, Cl 11.5, N 6.4, S 4.9%.

Ionic dissociation in complexes of iodine with triphenylphosphine and triphenylamine

YING RU ZHANG, SEYMOUR ARONSON,[1] AND P. GARY MENNITT

Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, NY, U.S.A. 11210

Received August 28, 1991[2]

YING RU ZHANG, SEYMOUR ARONSON, and P. GARY MENNITT. Can. J. Chem. **70**, 2394 (1992).

An electrochemical technique has been employed to study the ionization of the iodine complexes of $(C_6H_5)_3N$ and $(C_6H_5)_3P$. Comparison of the results with a previous study indicates that, at high iodine concentrations, the phosphorus compound behaves like $(C_6H_5)_3As$ and $(C_6H_5)_3Sb$ with the formation of a doubly charged ionic species, $(C_6H_5)_3PI_2^{2+}$. The nitrogen compound resembles pyridine in its behavior. Chemical shift data on the $(C_6H_5)_3P$–I_2 system using ^{31}P NMR indicates the presence of additional equilibrium processes.

YING RU ZHANG, SEYMOUR ARONSON and P. GARY MENNITT. Can. J. Chem. **70**, 2394 (1992).

On a utilisé une technique électrochimique pour étudier l'ionisation des complexes de l'iode avec le $(C_6H_5)_3N$ et le $(C_6H_5)_3P$. Une comparaison de nos résultats avec ceux obtenus au cours d'une étude antérieure indique que, à des concentrations élevées d'iode, le composé du phosphore se comporte comme le $(C_6H_5)_3As$ et le $(C_6H_5)_3Sb$ et il conduit à la formation d'espèces ioniques doublement ionisées, $(C_6H_5)_3PI_2^{2+}$. Le comportement du composé de l'azote ressemble à celui de la pyridine. Les données relatives aux déplacements chimiques observés avec le système $(C_6H_5)_3P$–I_2, en faisant appel à la RMN du ^{31}P, indiquent qu'il existe d'autres processus d'équilibre.

[Traduit par la rédaction]

Introduction

The triphenyl compounds, Ph_3M, of nitrogen, phosphorus, arsenic, and antimony form complexes with iodine in organic solution (1–3). In a recent study (4), we presented data on the ionization of the iodine complexes of Ph_3As, Ph_3Sb, and pyridine (Py) in the polar organic solvent 1,2-dichloroethane. At high iodine concentrations, we observed that pyridine produced only the ionic species PyI^+, whereas the ionic species, Ph_3MI^+ and $Ph_3MI_2^{2+}$, were produced from Ph_3As and Ph_3Sb.

Ph_3N and Ph_3P are isostructural with Ph_3As and Ph_3Sb. The question arises as to whether the behavior of Ph_3N and Ph_3P in their interaction with iodine is more similar to the behavior of Ph_3As and Ph_3Sb or to that of pyridine. Nitrogen and phosphorus are essentially covalent in their chemistry, whereas arsenic and antimony show increasing tendencies towards cationic behavior (5). All four Group VA elements have available electron pairs and can act as donors. Only phosphorus, arsenic, and antimony, however, have empty *d* orbitals of fairly low energy which have the potential to interact with electrons from an acceptor atom to create additional bonding (5). It is, therefore, possible that Ph_3N may behave like pyridine and that Ph_3P may behave like Ph_3As and Ph_3Sb.

In the present study, we have utilized an electrochemical technique previously used to investigate the interaction of iodine with Ph_3As, Ph_3Sb, and pyridine to obtain information on the ionization of the iodine complexes of Ph_3N and Ph_3P. We have also used ^{31}P NMR to obtain chemical shift information on the iodine complexes of Ph_3P in an effort to further elucidate equilibrium processes in the system.

Experimental

Triphenylamine (Ph_3N), triphenylphosphine (Ph_3P), and tetraethylammonium iodide (TEAI) were obtained in the highest commercial grades available from Aldrich Chemical Co. Spectrophotometric grades of 1,2-dichloroethane (DCE) and $CHCl_3$ and reagent grade iodine were also obtained from Aldrich.

Details of the electrochemical technique using cells of the type Pt|R, I_2‖R, I_2, TEAI|Pt, where R represents the organic molecule, have been discussed previously (4).

^{31}P NMR measurements were made with a Bruker 250 MHz high-resolution Fourier transform nuclear magnetic resonance spectrometer. Triphenylphosphine–iodine complexes in 1,2-dichloroethane were contained in 10 mm cylindrical Pyrex tubes. A lock signal was obtained by using a capillary tube containing D_2O inserted into the sample tube. Eighty-five percent orthophosphoric acid in a sealed 10 mm tube, obtained from Wilmad Glass Co. Inc., Buena N.J., was used as an external reference standard.

Results and discussion

The reaction schemes used to analyze the data for Ph_3As, Ph_3Sb, and pyridine are applicable to Ph_3P and Ph_3N. Readers are referred to the previous paper (4) for details of the mathematical treatment of the electrochemical data. The numbers assigned to identify the various reactions in Sects. A and B of this paper are the same as those used in the previous paper.

A. High iodine concentrations

The following reaction scheme is used for high concentration ratios of iodine to organic molecule in DCE.

$$[1] \quad R + I_2 \rightarrow RI_2$$

$$[2] \quad RI_2 + I_2 \rightleftharpoons RI^+ + I_3^-$$

$$[3] \quad RI^+ + 2I_2 \rightleftharpoons RI_2^{2+} + I_3^-$$

$$[4] \quad I_2 + TEAI \rightarrow I_3^- + TEA^+$$

R represents the organic molecule. The same assumptions used previously apply here.

The electrochemical data obtained on the Ph_3N and Ph_3P compounds are shown in Tables 1 and 2 respectively. The equilibrium reaction represented by reaction [2] was used to interpret the emf data in Table 1. The only ionic complex of Ph_3N which forms is Ph_3NI^+. The value of the equilibrium constant, K_2, which best fits the data, 4.8×10^{-3}, is close

TABLE 1. The emf values for triphenylamine–iodine solutions at high iodine concentrations

$c(I_2)^a$ (M × 10)	c(TEAI) (M × 10^3)	Emf (mV)^b Experimental	Calculated
1.50	0.455	9.5	9.3
1.50	0.833	16.0	15.5
1.50	1.15	19.6	20.1
1.50	1.43	23.0	23.6
2.25	1.50	20.4	22.5
2.25	3.00	31.7	35.5

[a]The symbol *c* represents the "total concentration". It is the number of moles of I_2, TEAI, or Ph_3N added to a liter of DCE solution. Dissociation and interaction in solution are not considered. The total Ph_3N concentration in all these measurements was 1.50×10^{-3} M.

[b]The equilibrium constant, K_2, used to calculate the emf values was 4.8×10^{-3}.

TABLE 2. The emf values for triphenylphosphine–iodine solutions at high iodine concentrations

$c(I_2)^a$ (M × 10)	c(TEAI) (M × 10^3)	Emf (mV)^b Experimental	Calculated
1.13	0.500	7.0	6.6
1.13	0.750	8.6	9.3
1.13	1.50	17.0	16.3
1.13	3.00	26.5	26.4
0.750	0.500	6.8	7.0
0.750	0.750	9.4	9.9
0.750	1.50	16.4	17.0
0.750	3.00	27.6	27.3
0.375	0.500	8.4	7.3
0.375	0.750	11.0	10.3
0.375	1.50	19.3	17.6
0.375	3.00	33.1	27.9

[a]See the footnote in Table 1 for the definition of *c*, the "total concentration." The total Ph_3P concentration in all these measurements was 1.50×10^{-3} M.

[b]The equilibrium constant, K_3, used to calculate the emf values was 1.2×10^{-2} M^{-1}.

to the equilibrium constant for the pyridine reaction, 3.9×10^{-3} (4).

The data in Table 2 on Ph_3P is best fitted by assuming that reaction [2] has proceeded all the way to the right and that the equilibrium shown in reaction [3] is operative. The equilibrium constant, K_3, used to calculate the emf values, 1.2×10^{-3} M^{-1}, is reasonably close to the values of 2.9×10^{-2} M^{-1} and 3.8×10^{-2} M^{-1} obtained for Ph_3As and Ph_3Sb respectively (4).

It will be noted that there is some discrepancy in the bottom set of data in each table between the calculated and experimental emf values. The calculated values in Table 1 are higher than the experimental values. The reverse is true for the data in Table 2. A suggested reason for the discrepancy in Table 1 is that reaction [3] begins to be operative at the high I_2/Ph_3N concentration ratio of 150. This would result in lower than expected experimental values for the emf. In the case of Ph_3P in Table 2, at the low I_2/Ph_3P concentration ratio of 25, reaction [2] may not go to completion, resulting in higher than expected experimental values of the emf.

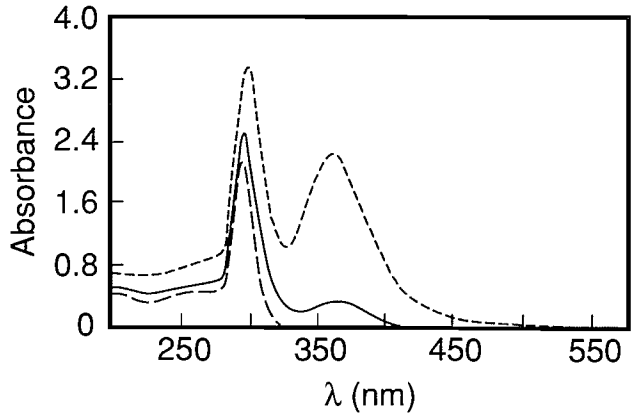

FIG. 1. UV–visible spectra of Ph_3P–I_2 solutions in DCE: (———)$c(Ph_3P)$ 2×10^{-3} M, $c(I_2)$ 2×10^{-4} M;(——)$c(Ph_3P)$ 1×10^{-3} M, $c(I_2)$ 2×10^{-4} M;(-----)$c(Ph_3P)$ 2×10^{-4} M, $c(I_2)$ 2×10^{-4} M;

The above results indicate that Ph_3P, in its interaction with iodine, behaves like Ph_3As and Ph_3Sb, whereas Ph_3N resembles pyridine in its behavior. Whether or not the lack of low energy *d* orbitals in nitrogen is responsible for this difference in behavior requires further theoretical consideration.

B. High Ph_3P concentrations

The behavior of the triphenyl compounds at high organic concentrations is less consistent than at high iodine concentrations. In the previous paper (4), the electrochemical data for Ph_3Sb could not be interpreted on the basis of a simple mechanism. In the case of Ph_3As, analysis could only be made at a Ph_3As/I_2 concentration ratio above 500. In the present investigation, the data on Ph_3N could not be easily interpreted. The Ph_3P data can be analyzed using the same mechanism which was applied to Ph_3As.

The reaction scheme is

[1] $R + I_2 \rightarrow RI_2$

[11] $RI_2 \rightleftharpoons RI^+ + I^-$

In Fig. 1 is shown the UV–visible spectroscopic changes which occur as the Ph_3P/I_2 concentration ratio changes from 1 to 10. It is observed that the I_3^- signal at 360 nm decreases as the Ph_3P/I_2 ratio increases and is absent at a ratio of 10. We assume that reaction [11] is operative at that ratio and above.

The data for Ph_3P at ratios of 10 and 20 are shown in Table 3. An equilibrium constant, K_{11}, equal to 2.24×10^{-4} M, gave good agreement between the calculated and experimental emf values. The corresponding equilibrium constant for Ph_3As at a Ph_3As/I_2 concentration ratio of 500 was 2.4×10^{-5} M.

C. ^{31}P NMR spectra

P-31 has a significant NMR signal, which can be used to further investigate complex formation and ionization in the Ph_3P–I_2 system. The sensitivity of the NMR technique is such that concentrations of iodine complex in the range of 0.01 M and above are required. Concentrations of complex in the range of 0.001 M were used in the electrochemical mea-

[a]Orthophosphoric acid (85%) was used as an external standard.
[b]See Fig. 2.
[c]This sample also contained 0.0500 M TEAI.

surements. The low sensitivity of the NMR method and the limited solubilities of I_2 and Ph_3P in organic solvent limited the concentration ratios of Ph_3P/I_2 for which good data could be obtained to the range between 0.1 and 10. At these concentration ratios, reactions [2] and [11] and not reaction [3] would be operative.

NMR spectra were obtained in two solvents, $CHCl_3$ and DCE. Significant ionization of the I_2 complex of Ph_3P does not occur in $CHCl_3$ because of its low dielectric constant. By comparing the spectra in $CHCl_3$ and DCE, the effects of ionization could be investigated.

Spectra obtained in $CHCl_3$ are summarized in Table 4. The high-field signal at −3.6 ppm is attributable to Ph_3P. Muller *et al.* (6) reported a value of −5.9 ppm for Ph_3P in an unidentified solvent. The down-field signal at 35.3 ppm is presumably that for the unionized complex. As the concentration ratio of I_2/Ph_3P increased, the Ph_3P signal disappeared and the down-field signal was observed to shift to 40.8 ppm and 48.6 ppm.

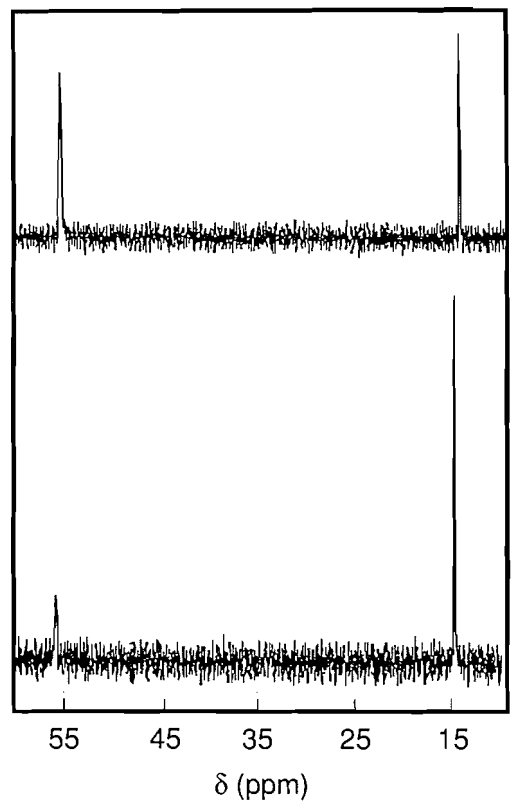

FIG. 2. Lower spectrum: ^{31}P NMR spectrum of $Ph_3P–I_2$ in DCE: $c(Ph_3P)$ 0.05 M, $c(I_2)$ 0.25 M. Upper spectrum: ^{31}P NMR spectrum of $Ph_3P–I_2$ in DCE: $c(Ph_3P)$ 0.05 M, $c(I_2)$ 0.25 M, c(TEAI) 0.05 M.

We suggest a reason for this movement of the signal with change in concentration. We postulate that at high concentration ratios of Ph_3P/I_2 the complex formed is $(Ph_3P)_2I_2$, whereas at low ratios the complex formed is Ph_3PI_2. The equilibrium reaction involved in the case of excess Ph_3P is

$$[5] \quad Ph_3PI_2 + Ph_3P \rightleftharpoons (Ph_3P)_2I_2$$

and in the case of excess I_2 is

$$[6] \quad (Ph_3P)_2I_2 + I_2 \rightleftharpoons 2Ph_3PI_2$$

We further postulate a rapid exchange of Ph_3P between the equilibrium concentrations of $(Ph_3P)_2I_2$ and Ph_3PI_2 in the solution which results in an averaging effect on the position of the merged signals. At high concentration ratios of Ph_3P/I_2, only the $(Ph_3P)_2I_2$ complex is present with a signal at about 35 ppm. At low ratios, only the Ph_3PI_2 complex is present with a signal at about 49 ppm. At ratios in between, both complexes are present, resulting in signals appearing at intermediate positions.

NMR data obtained on $Ph_3P–I_2$ samples in DCE are summarized in Table 4. We identify signal 3 with the compound Ph_3P. Signals 1 and 2 are attributed to the unionized complex and the ionized complex respectively. The signal for the unionized complex gradually moves from a value of 36 ppm for $(Ph_3P)_2I_2$ to a value of 57 ppm for Ph_3PI_2, with intermediate values corresponding to equilibrium mixtures of the two complexes. A plot of the chemical shift as a function of $\log[c(I_2)/c(Ph_3P)]$ is shown in Fig. 3. The reasons for the small changes in the positions of signals 2 and

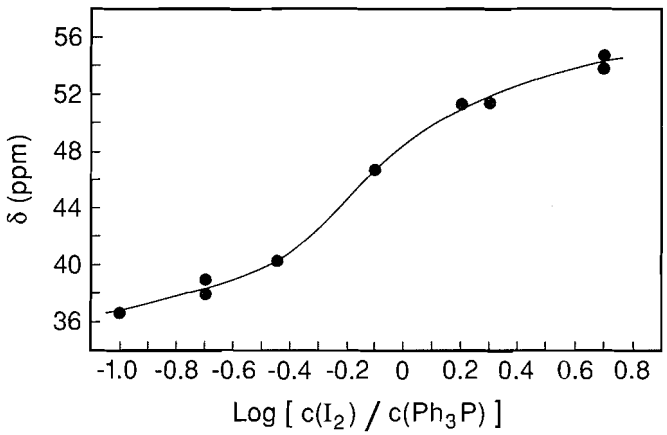

FIG. 3. ^{31}P chemical shift as a function of the $c(I_2)/c(Ph_3P)$ ratio.

3 in Table 4 are not known but may involve experimental factors or effects of concentration.

A comparison of the spectra in Fig. 2, corresponding to the last two columns in Table 4, shows the effect of adding TEAI to the system. The addition of TEAI shifts the equilibrium in reaction [2] to the left. The addition of TEAI suppresses the concentration of the unionized complex. This results in an increase in the magnitude of signal 1 at the expense of signal 2.

If the equilibria described by reactions [5] and [6] are operative, reactions [1] and [11], at high concentration ratios of Ph_3P/I_2, cannot be correct. We would have to invoke reactions of the type

[7] $2R + I_2 \rightarrow R_2I_2$

[8] $R_2I_2 \rightleftharpoons R_2I^+ + I^-$

[8′] $R_2I_2 \rightleftharpoons RI^+ + I^- + R$

The application of reaction [8] instead of reaction [11] would not effect the mathematical treatment used above and would yield the same value, 2.24×10^{-4} M, for K_8 as was used for K_{11}. The application of reaction [8′] would, however, require some modification of the mathematical treatment. Additional spectroscopic and electrochemical data are required to further elucidate the equilibrium processes in the concentration range in which neither Ph_3P nor I_2 is present in large excess.

FATHI M. ASSEID, JACK M. MILLER, and JAMES H. CLARK. Can. J. Chem. **70**, 2398 (1992).

ZnF_2, CdF_2, and CuF_2 have been adsorbed onto the surface of montmorillonite K10, and the infrared and ^{19}F, ^{27}Al, and ^{29}Si MAS NMR spectra of the resulting reagents over a range of loadings and activation temperatures have been obtained. CuF_2 was observed to attack the SiO_2 layer and form the complex $CuSiF_6$, ZnF_2 tends to attack the aluminium oxide layer, in which Zn isomorphously replaces Al, and forms AlF_3 and AlF_4^- complexes. The spectroscopic evidence rules out the formation of any Al–F and (or) Si–F species as CdF_2 is adsorbed on the surface of montmorillonite K10. The reactivity of MF_2–K10 reagents towards the Friedel–Crafts reaction of benzene with benzyl chloride varies from one reagent to another. ZnF_2–K10 was observed to be the most reactive and CuF_2 was the least reactive.

FATHI M. ASSEID, JACK M. MILLER et JAMES H. CLARK. Can. J. Chem. **70**, 2398 (1992).

On a adsorbé du ZnF_2, du CdF_2 et du CuF_2 sur la surface de la montmorillonite K10 et on a déterminé les spectres infrarouges et RMN MAS du ^{19}F, du ^{27}Al et du ^{29}Si des réactifs ainsi obtenus dans un large intervalle de charge et de température. On a observé que le CuF_2 attaque la couche de SiO_2 pour former un complexe de $CuSiF_6$ alors que le ZnF_2, quant à lui, tend à s'attaquer à la couche d'oxyde d'aluminium dans laquelle le zinc isomorphe remplace l'aluminium et forme des complexes de AlF_3 et de AlF_4^-. Les preuves spectroscopiques éliminent la formation de toute espèce Al–F et (ou) Si–F lorsque le CdF_2 est adsorbé sur la surface de la montmorillonite K10. La réactivité des réactifs de MF_2–K10 par rapport à la réaction de Friedel et Crafts du benzène avec le chlorure de benzyle varie d'un réactif à l'autre. On a observé que le ZnF_2–K10 est le plus réactif et que le moins réactif est le CuF_2.

[Traduit par la rédaction]

Introduction

The fluorination of metal oxide catalysts causes changes in catalytic activity. The catalytic activity, surface structure, and the nature of active centres of fluorinated alumina and silica–alumina have been studied extensively. Fluorination of silica–alumina generally leads to generation of new Lewis acid sites (1). Fluorination of alumina results in a strong Lewis acid centre (2), and the strength of this acidity is highly dependent on the content of F^- and on the activation temperature. The prime technique used for studying fluorinated metal oxides is infrared spectroscopy (3). Solid state ^{19}F NMR spectroscopy is the most recent technique to be used for studying fluorinated silica and aluminosilicates (4, 5). Miller and co-workers recently combined both IR and ^{19}F MAS NMR spectroscopy to study the adsorption of alkali metal fluorides on the surface of silica gel (6), alumina (7), and montmorillonite K10 (8).

Interest has been growing in recent years in transition metal exchanged montmorillonite K10 (9). Given their importance in the catalysis of organic reactions such as Friedel–Crafts alkylations, a number of approaches have been developed to obtain optimum results. Laszlo and Mathy have doped montmorillonite K10 with a series of transition metal cations (10), to obtain reasonably effective catalysts for Friedel–Crafts reaction with halides, alcohols, and olefins. Montmorillonite K10 supported transition metal chlorides were also studied (11), and the Friedel–Crafts activity and selectivity of these reagents improved over unsupported MCl_2 and the standard Lewis acids such as $AlCl_3$ and BF_3. The final approach is the acid treatment of montmorillonite K10 as support for MCl_2 (12), which also becomes an effective catalyst for Friedel–Crafts alkylation. These types of reagents have been analyzed using ^{29}Si and ^{27}Al MAS NMR spectroscopy (13), to monitor possible changes that may occur within the SiO_2 tetrahedral layer or the octahedral aluminium layer.

Magic Angle Spinning (MAS) is one of the line-narrowing techniques available, which significantly improves the resolution of peaks in the NMR spectrum of a solid, and allows direct determination of the isotropic chemical shift. ^{29}Si and ^{27}Al MAS NMR have been extensively used to analyze aluminosilicates such as zeolites and clays. Since silicon has a low chemical shift anistropy (CSA), the line broadening can be removed at easily achievable spinning rates, whereas ^{27}Al requires high field and high spinning rates to overcome the quadrupolar interactions. ^{19}F MAS NMR has received much less attention, however; two recently described applications are in the analysis of fluorinated polymers (14), and of fluorohydroxyapatite (15). We are now studying the adsorption of ZnF_2, CdF_2, and CuF_2 onto the surface of montmorillonite K10 using FT-IR and ^{19}F, ^{27}Al, and ^{29}Si MAS NMR spectroscopy, and the activity of these reagents towards Friedel–Crafts alkylation.

Experimental

ZnF_2 (Aldrich) 99%, CdF_2 (Aldrich) 98%, and CuF_2 (Aldrich) 98% were used without further purification. Montmorillonite K10 clay (surface area 220–270 m^2/g) was obtained from Fluka. K10 is a commercial support material prepared by acid washing. Our samples have an extractable iron content of between 0.3 and 1.3%.

On removing iron by five successive extractions with 50 mL of 3 M HNO_3, we extracted a total of 1.3% iron, after which no significant iron could be removed (this material contained about 3.0% iron according to Fluka spec. sheets; the difference is presumably tightly bonded iron). We could not detect changes in either our IR or ^{19}F NMR, with the additional extraction. Sodium, potassium, and calcium are all below 0.1% extractable, with any additional being found in the lattice sites. The silica gel was Merck Kieselgel 100, 70–230 mesh. The alumina was Merck 90 neutral, 70–230 mesh, activity 1, for chromatography.

The MF_2–K10 regents were prepared at loadings of 0.5, 1.0, 3.5, and 5.0 mmol/g by dissolving the appropriate quantity of MF_2 in water and adding the solution to K10 clay to form a slurry. The water was then removed on a rotary evaporator until the reagent had caked to the wall of the flask, and the reagents were then dried in air at various temperatures, usually overnight. MF_2–silica reagents were also prepared at a loading of 6.5 mmol/g.

Infrared spectra were obtained on an Analect FX6260 Fourier Transform spectrometer, attached to a MAP-66 data system. Samples were prepared as KBr discs, using a KBr/reagent ratio of about 20:1 by weight.

^{19}F and ^{29}Si MAS NMR spectra were obtained on a Bruker AC200 instrument at 188.3 and 39.74 MHz, respectively, using our home-built MAS probes. Samples were spun in Derlin rotors at about 3300 Hz. Since the spinning rate is considerably less than the CSA of fluorine (the CSA of KF is 323 ppm, which is equivalent to 65 KHz in a 200-MHz field, for example (16)), spinning side bands are seen in most of the spectra. Peaks of the ^{19}F spectra were referenced to external $CFCl_3$, and the ^{29}Si spectra were referenced to external tetramethylsialane (TMS). The ^{27}Al MAS NMR spectra were recorded on a Bruker AM-500 at the NMR facility at McMaster University, at a frequency of 130.32 MHz, line broadening of 100 Hz, and a relaxation of 1.0 s. The samples were spun at 8.0 KHz. ^{27}Al chemical shifts are reported in ppm with respect to standard aluminium nitrate, $Al(NO_3)_3\alpha H_2O$, in aqueous medium.

The reaction of benzyl chloride with benzene were carried out with 0.05 mol of benzyl chloride and 0.8 mol of benzene warmed to 70°C, then 4.0 g of the MF_2–K10 catalyst to be tested was added. After refluxing and stirring for 30 min the reaction was stopped, the catalyst was filtered off, and the unreacted benzene was removed by a rotary evaporator. The reaction of paraformaldehyde with benzene used 0.025 mol of paraformaldehyde and 0.5 mol of benzene. The mixture was warmed up to 80°C, then 10 g of 1.0 mmol/g of MF_2–K10 was added. After refluxing and stirring for 4 h the catalyst was filtered off and the unreacted benzene was removed by a rotary evaporator, resulting in the isolated product, diphenylmethane. The diphenylmethane yield was determined by GC analysis and confirmed with ^1H NMR and GC–MS.

Results

Infrared analysis

Each of ZnF_2–, CdF_2–, and CuF_2–K10 reagents was prepared at several loadings and dried over a range of temperatures. IR spectra of ZnF_2–K10 reagents dried at 573 K, shown in Fig. 1, reveal certain changes from the spectrum of the parent clay as the loading of ZnF_2 increases from 1.0 to 5.0 mmol/g. One of the changes is the gradual diminishing of the band at 802 cm^{-1} (lit. value 799 cm^{-1} (17)), which corresponds to tetrahedral SiO_4 groups, and the other is the development of a new band at 663 cm^{-1} that is presumably due to AlF_3 (lit. value 668 cm^{-1} (18)). To insure that these significant changes were really taking place, an additional loading of 6.5 mmol/g was prepared and analyzed. A sample dried at low temperature (373 K) shows an additional band at 755 cm^{-1} corresponding to AlF_4^- (lit. value 760 cm^{-1} (19)). The spectrum of the high-temperature

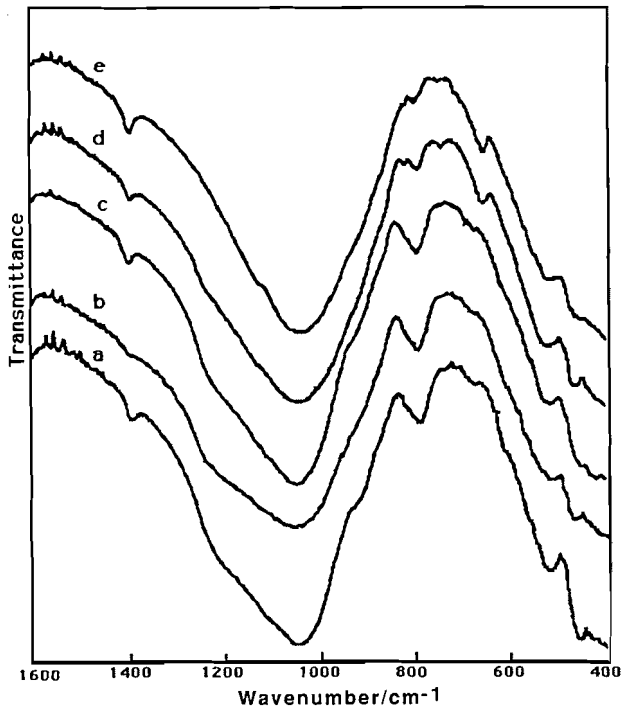

FIG. 1. Infrared spectra of ZnF_2–K10 reagents dried at 573 K; (*a*) montmorillonite K10, (*b*) 0.5 mmol/g, (*c*) 1.0 mmol/g, (*d*) 3.5 mmol/g, (*e*) 5.0 mmol/g.

(873 K) dried sample shows a new band at 570 cm^{-1} that is presumably due to skeletal ZnO_4 species (lit. value 570 cm^{-1} (19)).

IR spectra of CdF_2–K10 reagents show no obvious changes as content of CdF_2 increases. The band corresponding to layer SiO_4 groups at 802 cm^{-1} remains unchanged for all reagents. On the other hand, spectra of CuF_2–K10 appear rather different from those of the above reagents (Fig. 2). As the loading of CuF_2 increases, the band at 802 cm^{-1} gradually disappears, and consequently a new band at 743 cm^{-1} and an AlF_3 band at 665 cm^{-1} appears. The band at 743 cm^{-1} corresponds to the SiF_6^{2-} complex (lit. value 740 cm^{-1} (19)). The band at 743 cm^{-1} diminishes as calcining temperature increases (not shown). This is due to decomposition of SiF_6^{2-} to gaseous SiF_4 and free F^-.

Infrared spectra of 5.0 mmol/g of ZnF_2–silica, CdF_2–silica, and CuF_2–silica reagents dried at 373 K are shown in Fig. 3. These spectra clearly indicate that CuF_2–silica is the only reagent that results in a band at 743 cm^{-1}, which corresponds to the SiF_6^{2-}complex. The ZnF_2–silica reagents show a shoulder on the side of the band at 802 cm^{-1}, which is probably due to distortion to the SiO_2 tetrahedral structure or the presence of surface Si–F species. The infrared spectrum of CdF_2–silica (not shown) showed no clear absorption that may indicate presence of surface Si–F species.

^{19}F MAS NMR analysis

^{19}F MAS NMR spectra of MF_2–K10 reagents show significant differences at high loadings and high drying temperatures. All reagents at the low loading of 1.0 mmol/g (which represents monolayer coverage) show spectra of similar line shape, i.e., a central peak appears at −151 ppm and is surrounded by a set of asymmetric spinning side bands

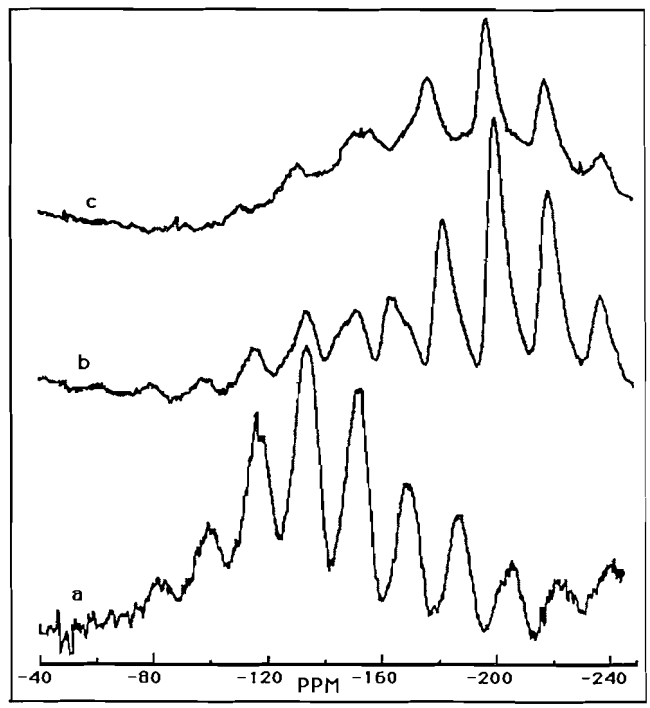

FIG. 5. ^{19}F MAS NMR spectra of CdF_2–K10 reagents dried at 873 K; (*a*) 1.0 mmol/g, (*b*) 3.5 mmol/g, (*c*) 5.0 mmol/g.

that presumably correspond to chemisorption of F^- on the surface the clay. These groups can be either surface Al–F and (or) Si–F groups. As the loading increases to 5.0 mmol/g dried at 573 K, ZnF_2–K10 reagent tends to show symmetrical spinning side bands around the central peak positioned at −153 ppm that closely approximate the spectrum of the AlF_4^- and AlF_6^{3-} mixture (Fig. 4). As the drying temperature increases to 873 K the line shape of the spectrum tends to broaden, which can be an indication of formation of AlF_3 (which usually results in a broad line, due to high dipole–dipole interactions (5)) from decomposed AlF_4^- or AlF_6^{3-}.

^{19}F MAS NMR spectra of CdF_2–K10 of the high-loading reagent dried at 573 K did not change significantly from those of the spectra of the low-loading reagents. However, as the calcining temperature increased to 873 K (Fig. 5), a sharp peak appeared at −197 ppm, which corresponds to CdF_2 (lit. value −197 ppm (20)) and, by a comparison of the spectrum of CdF_2, to that of highly loaded, highly dried CdF_2–K10 reagent. The reformation of CdF_2 is probably due to the

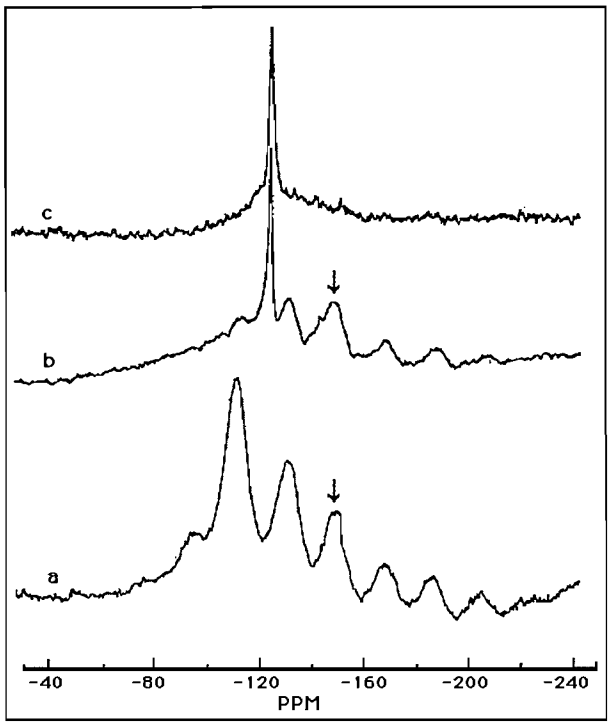

FIG. 6. ^{19}F MAS NMR spectra of MF_2–silica reagents dried at 373 K; (*a*) CuF_2–silica, (*b*) ZnF_2–silica, (*c*) CdF_2–silica.

high affinity of the ligand F^- for Cd^{2+}. Spectra of the high loading of CuF_2–K10 reagents also produced spectra with the central peak slightly shifted to −149 ppm. ^{19}F MAS NMR (Fig. 6) experiments on MF_2–silica gel to examine the reactivity of MF_2 towards the SiO_2 tetrahedral layer were performed, and appear to be quite consistent with the IR results. CuF_2–silica resulted in a peak at −149 ppm surrounded by asymmetrical spinning side bands, which presumably indicate physisorption of SiF_6^{2-} on the silica surface. ZnF_2–silica resulted in a sharp and intense peak at −124 ppm, which corresponds to free F^- ion or probably $F^-H_3O^+$ species (lit. value −125 ppm (21)). In addition it resulted in a weak peak at −149 ppm, which also indicates presence of physisorbed SiF_6^{2-} complex on the silica surface. CdF_2 proved to be unreactive towards the silica layer, since ^{19}F NMR spectra of CdF_2–silica resulted in no evidence of any Si–F species. The only ^{19}F NMR signal observed is located at −124 ppm, which corresponds to free F^-, or probably $F^-H_3O^+$.

^{29}Si MAS NMR analysis

The effect of MF_2 content on the structure of montmorillonite K10 can be monitored clearly by ^{29}Si MAS NMR spectroscopy. Spectra of ZnF_2–K10 reagents dried at 573 K (Fig. 7) show gradual changes to the original peak of the parent clay as content of ZnF_2 increases. At low ZnF_2 loadings, the signal position did not change from that of the parent peak at −107 ppm. Then as concentration of ZnF_2 increases to an intermediate level (3.5 mmol/g), a new peak at −97 ppm results. At the maximum ZnF_2 concentration (5.0 mmol/g) the original peak at −107 ppm is removed and the new peak at −95 ppm dominates the spectrum. We believe that as content of ZnF_2 increases, Zn replaces Al isomorphously and, consequently, Al replaces Si atoms in the SiO_2 tetrahedral layer resulting in a new ^{29}Si environment responsible for the new peak at −95 ppm.

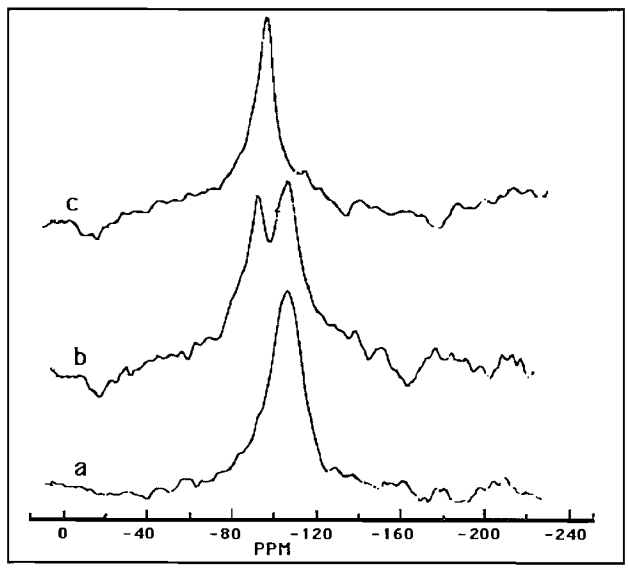

FIG. 7. ^{29}Si MAS NMR spectra of ZnF_2–K10 reagents dried at 573 K; (*a*) 1.0 mmol/g, (*b*) 3.5 mmol/g, (*c*) 5.0 mmol/g.

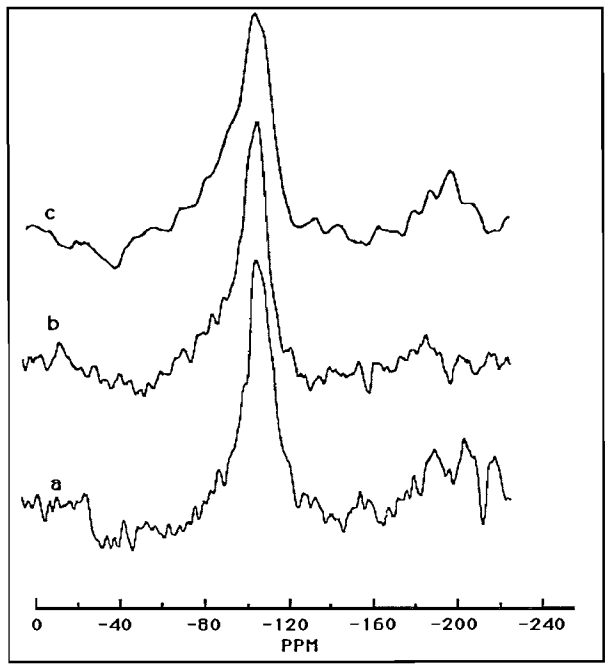

FIG. 8. ^{29}Si MAS NMR spectra of CuF_2–K10 reagents dried at 573 K; (*a*) montmorillonite K10, (*b*) 1.0 mmol/g, (*c*) 3.5 mmol/g.

^{29}Si MAS NMR spectra of CuF_2–K10 reagents (Fig. 8) also show changes as loading increases, but rather different from those observed for ZnF_2–K10. At the maximum concentration of CuF_2 (5.0 mmol/g) the spectrum (not reproduced here) still shows a peak at −107 ppm but with an observable shoulder at −95 ppm, which could indicate partial substitution of Si by Al atoms in the SiO_2 tetrahedral layer. Spectra of CdF_2–K10 reagents, on the other hand, show no changes from the parent clay spectrum as concentration of CdF_2 is maximized, which presumably indicates less isomorphous replacement of Al by Cd due to the large size of the divalent Cd^{2+} ion compared to size of Al^{3+}.

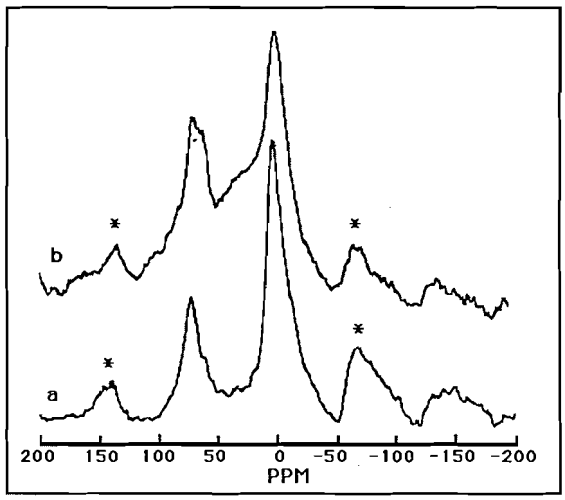

FIG. 9. ^{27}Al MAS NMR spectra of 5.0 mmol/g of CuF_2–K10 dried at (*a*) 573 K, (*b*) 873 K (* spinning side bands).

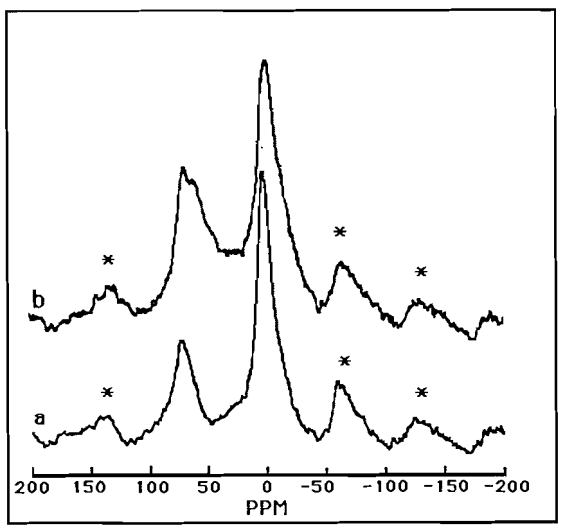

FIG. 10. ^{27}Al MAS NMR spectra of 5.0 mmol/g of CdF_2–K10 reagents dried at (*a*) 573 K, (*b*) 873 K (* spinning side bands).

^{27}Al MAS NMR analysis

^{27}Al MAS NMR spectra of MF_2–K10 reagents revealed certain information about the aluminium coordination for the different reagents at different calcining temperatures. Spectra of all reagents show two signals centred at 0 and 61–70 ppm, which generally correspond to octahedral and tetrahedral coordinated aluminium, respectively. Spectra of low loading (1.0 mmol/g) and high loading (5.0 mmol/g) of ZnF_2–K10 reagents show no observable differences in their peak positions or intensities. As activation temperature is increased to 873 K the spectra show an increase in the intensity in tetrahedral signal accompanied by a slight shift in position from 69 ppm at low activation temperature to 61 ppm at the activation temperature of 873 K. In addition, this shows a hint of a peak at 30 ppm, which is presumably due to five-coordinated aluminium (Fig. 9).

The most important feature of the ^{27}Al MAS NMR spectra for the CdF_2–K10 high loading, high-temperature-dried, reagent (Fig. 10) is the observation of two types of Al tetrahedral environments at 61 and 70 ppm. No significant shift

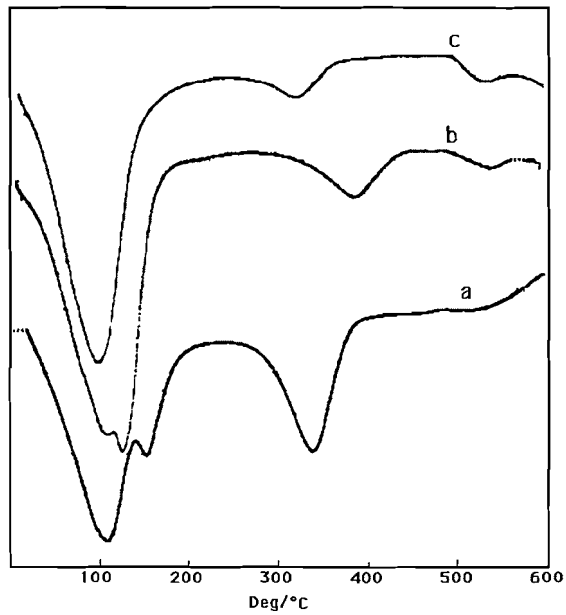

FIG. 11. Differential Scanning Calorimetry (DSC) spectra of 5.0 mmol/g MF_2–K10 reagents (*a*) CuF_2–K10, (*b*) ZnF_2–K10, (*c*) CdF_2–K10.

is observed for the octahedrally coordinated aluminium positioned at 3 ppm, but there has been, however, a noticeable decrease in the intensity of this signal as calcining temperature increased to 873 K. Spectra of CuF_2–K10 did not vary much from those of the CdF_2–K10 reagents. A noticeable shoulder at 30 ppm can be clearly seen for the highly dried samples. This shoulder again indicates the presence of penta-coordinated aluminium.

Thermal analysis

Differential scanning calorimetry (DSC) results for the high loading 5.0 mmol/g MF_2–K10 reagents indicate certain changes taking place as activation temperature increases. The DSC data for this series of reagents (Fig. 11) show a characteristic endotherm at 100–110°C, which is associated with dehydration of the interlayer within montmorillonite K10. A notable difference can be seen for the additional endotherms, at 340°C for CuF_2–K10, at 300°C for CdF_2–K10, and at 400°C for ZnF_2–K10. We believe that the endotherm at 340°C for CuF_2–K10 is associated with the thermal decomposition of the species SiF_6^{2-} to gaseous SiF_4 and possibly CuF_2 or HF (24), and the endotherm at 400°C for ZnF_2–K10 is possibly due to generation of the gaseous $HAlF_4$ component resulting from the reaction of solid AlF_3 and HF gas.

$$AlF_3\,(s) + HF\,(g) \xrightarrow{400°C} AlF_4H\,(g)$$

Reaction studies

The reactivity of the above reagents towards Friedel–Crafts alkylation varied from one reagent to another. We have successfully employed all of the different loadings of MF_2–K10 reagents dried at different temperatures in the Friedel–Crafts reaction of benzene with benzyl chloride and reaction with paraformaldehyde. The reactivity of the reagents was observed to be highly dependent on the reagent loading and the activation temperature employed. The reactivity of the low-loading reagents (1.0 mmol/g) seems to decrease as the activation temperature increases. This is deduced from

[b]Yield determined by GC analysis, and confirmed by GC–MS and ^1H NMR.

the poor conversion of benzyl chloride, and the low yield of diphenylmethane obtained. The high activation temperature had no significant effect on the highly loaded reagents. In fact, highly loaded and high-temperature-calcined reagents seem to be more active than highly loaded and moderately dried reagents.

Table 1 shows the conversion of benzyl chloride and the calculated yield of diphenylmethane. ZnF_2–K10 was observed to be the most reactive of the series, and CuF_2–K10 showed significantly lower reactivity in the series. To further evaluate the catalysts, another Friedel–Crafts reaction was selected, which involves the alkylation of benzene with paraformaldehyde. This reaction presumably involves the solid acid depolymerizing the polymer $-(CH_2O)_n-$ to provide a source of CH_2O, as well as a Friedel–Crafts reaction. ZnF_2–K10 was again observed to be the most reactive.

Discussion

The results of infrared, and ^{19}F, ^{29}Si, ^{27}Al MAS NMR spectroscopic studies indicate significant changes taking place on the surface and within the structure of montmorillonite K10 when treated with MF_2. Evidence from infrared spectroscopy studies of the different reagent loadings clearly indicates structural rearrangement within the silica framework, since the IR band at 802 cm^{-1}, corresponding to the free silica layer SiO_2, diminishes as ZnF_2 and CuF_2 loadings increase. This rearrangement presumably involves the isomorphous replacement of Si by Al in the SiO_2 framework. The IR spectra of ZnF_2–K10 reagents showed bands at 755 and 663 cm^{-1}, which suggest the formation of AlF_4^- and AlF_3, respectively, and spectra of CdF_2–K10 remained nearly unchanged from the original spectrum of montmorillonite K10. IR spectra of CuF_2–K10 showed a band at 743 cm^{-1}, which suggests the formation of the SiF_6^{2-} complex. We obtained similar results for MF_2–silica reagents, which led to the conclusion that only CuF_2 has the tendency to attack the SiO_2 layer. Thus ZnF_2 is like PbF_2 and seems only to affect the Al part of the structure.

^{19}F NMR spectra of low-loading ZnF_2–K10 reagent resulted in a line shape of asymmetrical spinning side bands with the central peak at −151 ppm, which corresponds to either surface Si–F or Al–F groups. The high-loading samples showed symmetrical spinning side bands with the centre peak at −153 ppm, and the highly dried samples resulted in a very broad line suggesting the formation of AlF_3. ^{19}F NMR results of CdF_2–K10 were similar to those of ZnF_2–K10, except for the highly loaded reagents dried at high temperature, which resulted in a signal at −197 ppm suggesting the reformation of CdF_2. Spectra of CuF_2–K10 reagents also showed a signal at −151 ppm corresponding to either surface Si–F or Al–F groups.

^{29}Si MAS NMR spectra of ZnF_2–K10 reagents suggest that as the loading of ZnF_2 increases, further replacement of Si by Al takes place, which is indicated by the change in the ^{29}Si environment from $^{29}Si(OSi)_3(OAl)$ to $^{29}Si(OSi)_2(OAl)_2$. Spectra of CuF_2–K10 indicated only partial replacement of Si by Al, whereas spectra of CdF_2–K10 gave no indication of any changes regarding the ^{29}Si environment. ^{27}Al NMR spectra of the high-loading, highly dried samples of MF_2–K10 reagents show some differences, which appear mainly around the tetrahedral Al signal at 61–69 ppm. ZnF_2–K10 reagent showed an intense peak at 61 ppm, whereas CdF_2–K10 and CuF_2–K10 showed an additional signal at 69 ppm. The signal observed at 61 ppm presumably corresponds to the dehydroxylated tetrahedral aluminium in the SiO_2 tetrahedral layer, and the signal at 69 ppm corresponds to hydroxylated tetrahedral aluminium.

Upon combining the results of IR and DSC for high-loading (5.0 mmol/g) CuF_2–K10 reagent, we can clearly observe the thermal decomposition of the species SiF_6^{2-}. As was discussed earlier, the IR spectrum of the high-loading low-temperature-dried CuF_2–K10 reagent showed a band at 740 cm^{-1} due to the SiF_6^{2-} complex; then, as it is calcined to 600°C, this band diminished. A number of attempts were made to trap the gaseous species SiF_4, but the rapid hydrolysis of the gas by HF and (or) residual H_2O to H_2SiF_6 acid prevented the monitoring of pure SiF_4. IR spectra of the gas trapped in the cell gave very strong bands at 741 and 480 cm^{-1}, which are presumably due to SiF_6^{2-} of H_2SiF_6 (lit. values 740 and 483 cm^{-1}, respectively (19)) (pH analysis of

TABLE 2. Electronegativities and atomic radii of Zn, Al, Cu, and Cd

Element	Electronegativity[a]	Atomic radii[b] (Å)
Al	1.61	1.25
Zn	1.65	1.35
Cd	1.69	1.55
Cu	1.90	1.35

[a]Electronegativity values from Pauling (1967).
[b]Atomic radii from Slater (1964, 1972).

the condensed matter in the cell indicated strong acidity). An additional weak band at 1072 cm^{-1} corresponds to SiF_4 (lit. value 1070 cm^{-1} (25))

$$2SiF_4\,(g) + 2H_2O(g) \rightarrow H_2SiF_6 + SiO_2 + 2HF$$

$$SiF_4\,(g) + 2HF\,(g) \rightarrow H_2SiF_6$$

The reactivity of MF_2–K10 reagents in the catalysis of Friedel–Crafts benzylation of benzene with benzyl chloride is considerably greater than that of cation exchanged M(II)–K10 (10) and MCl_2–K10 reagents (11). ZnF_2–K10 was observed to be the most reactive of the series, and CuF_2–K10 showed significantly low reactivity compared to the other MF_2–K10 reagents. The cause of the difference in the strength of the observed Lewis acidity is not fully understood. The only valid possibility is the newly formed surface Al–F groups, which have been reported to contribute to Lewis acidity (3, 22). At low loadings and high calcining temperatures, the metal fluorides were totally lost with a resultant decrease in activity. The other possibility, which cannot ruled out, is the formation of the strongly acidic species HF_2^-, but there is no definite spectroscopic evidence that shows the presence of such species. Recent ^{19}F NMR studies (23) reported different values of HF_2^- chemical shifts (ranging from −167 to −146 ppm), which fall in the range obtained for some of the MF_2–K10 reagents. Table 2 compares the values of electronegativities and atomic radii of Al to those of Zn, Cd, and Cu. The Zn atom, whose size and electronegativity appear to be very close to those of the Al atom, replaces Al quite extensively. The size of the Cu atom is also comparable to that of Al, but its electronegativity is high; as a result Cu did not replace Al as extensively. The large size of Cd is probably the only factor inhibiting the replacement of Al by Cd.

In conclusion, we believe the above study has demonstrated the complexity of what really goes on as a transition metal fluoride is adsorbed onto montmorillonite K10, and can be of good use to those who are studying fluorinated or transition-metal-supported clay. The reagents we have presented show a significant improvement in the catalysis of Friedel–Crafts benzylation of benzene over commonly used standard Lewis-acid catalysts. We consider these reagents to be new, environmentally friendly, catalysts, and reasonably safe to handle at any possible scale needed.

Thermal and photochemical reactions of steroidal α-azido ketones[1,2]

O. E. EDWARDS, J. L. DOUGLAS,[3] D. C. HORWELL,[3] W. RANK,[3] AND T. SANO[3]
Department of Chemistry, Carleton University, Ottawa, Ont., Canada K1S 5B6

Received March 5, 1992

O. E. EDWARDS, J. L. DOUGLAS, D. C. HORWELL, W. RANK, and T. SANO. Can. J. Chem. **70**, 2405 (1992).

Photolysis of 9α-azido-3β,20β-diacetoxy-5α-pregnan-11-one in methanol gave the *N*-acyl imine 11-aza-3β,20β-diacetoxy-C-homo-5α-pregn-9,11-en-12-one **4** and the aminoketone 9a-aza-3β,20β-diacetoxy-9-methoxy-B-homo-5α-pregnan-11-one **7**. In dichloromethane containing triethylamine the irradiation of this azide gave the *N*-acyl imine **4** and the α,β-unsaturated amino ketone 9a-aza-3β,20β-diacetoxy-B-homo-5α-pregn-8-en-11-one **8**. Thermolysis or photolysis of 12α-azido-3α,20β-diacetoxy-5β-pregnan-11-one gave the *N*-acyl imine 12-aza-3α,20β-diacetoxy-C-homo-5β-pregn-12-en-11-one **10** as major product. Photolysis of 20β-acetoxy-12α-azido-3α-hydroxy-5β-pregnan-11-one gave the 3-hydroxy analogue of **10**. Transformation products of the *N*-acyl imines are described.

O. E. EDWARDS, J. L. DOUGLAS, D. C. HORWELL, W. RANK et T. SANO. Can. J. Chem. **70**, 2405 (1992).

La photolyse de la 9α-azido-3β,20β-diacétoxy-5α-pregnan-11-one, en solution dans le méthanol, conduit à la *N*-acyl imine, 11-aza-3β,20β-diacétoxy-C-homo-5α-pregn-9,11-èn-12-one, **4**, et à l'aminocétone, 9a-aza-3β,20β-diacétoxy-9-méthoxy-B-homo-5α-pregnan-11-one, **7**. Dans du dichlorométhane contenant de la triéthylamine, l'irradiation de cet azoture fournit la *N*-acyl imine **4** et la cétone aminée α,β-insaturée, 9a-aza-3β,20β-diacétoxy-B-homo-5α-pregn-8-èn-11-one **8**. La thermolyse ou la photolyse de la 12α-azido-3α,20β-diacétoxy-5β-pregnan-11-one fournit la *N*-acyl imine, 12-aza-3α,20β-diacétoxy-C-homo-5β-pregn-12-èn-11-one **10** comme produit principal. La photolyse de la 20β-acétoxy-12α-azido-3α-hydroxy-5β-pregnan-11-one conduit à l'analogue 3-hydroxy, **10**. On décrit les produits de transformation des *N*-acyl imines.

[Traduit par la rédaction]

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

The discovery (1) that photolysis[4] of two steroidal α-azido ketones gave moderate yields of isolable *N*-acyl imines led to much interest, in our laboratories, in this class of compound. This was reinforced by the possibility that many biologically active natural products could have *N*-acylimines as precursors (2). Furthermore we were attracted by the possibility that azasteroids with strategically located *N*-acyl imine functions would act as hormone mimics, irreversibly binding to receptor sites in hormone-dependent tumor cells (3; see also reviews cited in ref. 16).

We now present a full account of the photolysis of three steroidal azido ketones, thermolysis of one of these, and reactions of the products.

Results

The preparation of 9α-azido-3β,20β-diacetoxy-5α-pregnan-11-one (**3**) from 11-ketoprogesterone (**1**) (5) was improved by use of lithium in ammonia reduction of the conjugated ketone, and Sarett (6) or pyridinium chlorochromate (7) oxidation of the intermediate hydroxy azide **2**.

Photolysis of **3** in dry methanol gave two major products. The most abundant one was the *N*-acyl imine **4**. The characteristic identifying features were the carbonyl (ν_{max} 1698 cm^{-1}) and imine (ν_{max} 1668 cm^{-1}) infrared frequencies and the ^{13}C nmr singlets at 186 (C=O) and 180 (C=N) ppm. The action of dry *p*-toluenesulfonic acid in benzene on **4** converted it into the enamide **5**. The amide carbonyl of **5** had $\nu_{max}(CCl_4)$ 1660 cm^{-1} and a ^{13}C nmr signal at 176 ppm. The double bond carbons resonated at 137.8 and 124.6 ppm, and **5** had λ_{max} 232 nm (ε 6200).

The second important product from the photolysis in methanol was a very weak base (pK_a 3.8 in 95% ethanol). It had a ketone carbonyl ($\nu_{max}(CCl_4)$ 1715 cm^{-1}; 209.4 ppm) and a methoxyl group. When a benzene solution of this base was treated with a catalytic amount of *p*-toluenesulfonic acid on silica gel, methanol was eliminated giving an α,β-unsaturated amino ketone ($\nu_{max}(CH_2Cl_2)$ 1682 cm^{-1}; λ_{max} 236 nm (ε 4500) and 297.5 nm (ε 2400)). The double bond gave two ^{13}C nmr singlets at 140 and 115.5 ppm. These data, analysis, and complete spectra were consistent with structure **7** for the methoxy-keto base and **8** for the conjugated unsaturated amino-ketone.

Irradiation of **3** in dichloromethane gave enamide **5** as a readily crystallized product (30%). If, however, a small amount of triethylamine was present the *N*-acyl imine **4** (40%) and the α,β-unsaturated amino-ketone **8** (ca. 45%) were the major products.

Photolysis of 12α-azido-3α,20β-diacetoxy-5β-pregnan-11-one **9** on a one-gram scale in dichloromethane gave a good yield (47.5%) of *N*-acyl imine **10**. The unusual amide carbonyl (ν_{max} 1715 cm^{-1}; ^{13}C nmr signal at 190 ppm) and the imine ^{13}C nmr doublet at 169 ppm with the proton on the imine carbon resonating at δ7.94 indicated the type-structure. Its reactions confirmed this. Acidic methanol converted **10** into a carbinolamide ether **11**. This was now a normal secondary amide (ν_{max} 3230 and 1670 cm^{-1}; ^{13}C nmr for the carbonyl 179.9 ppm), while exposure of an aqueous dioxane solution of **10** to a sulfonic acid resin gave carbinolamide **12**. Acidic methanol converted **12** to **11**. Hydrogenation of **10** produced a saturated lactam **13** (ν_{max} 3230 and 1670 cm^{-1}), which was also produced when **11** was partially reduced by lithium aluminum hydride, followed by

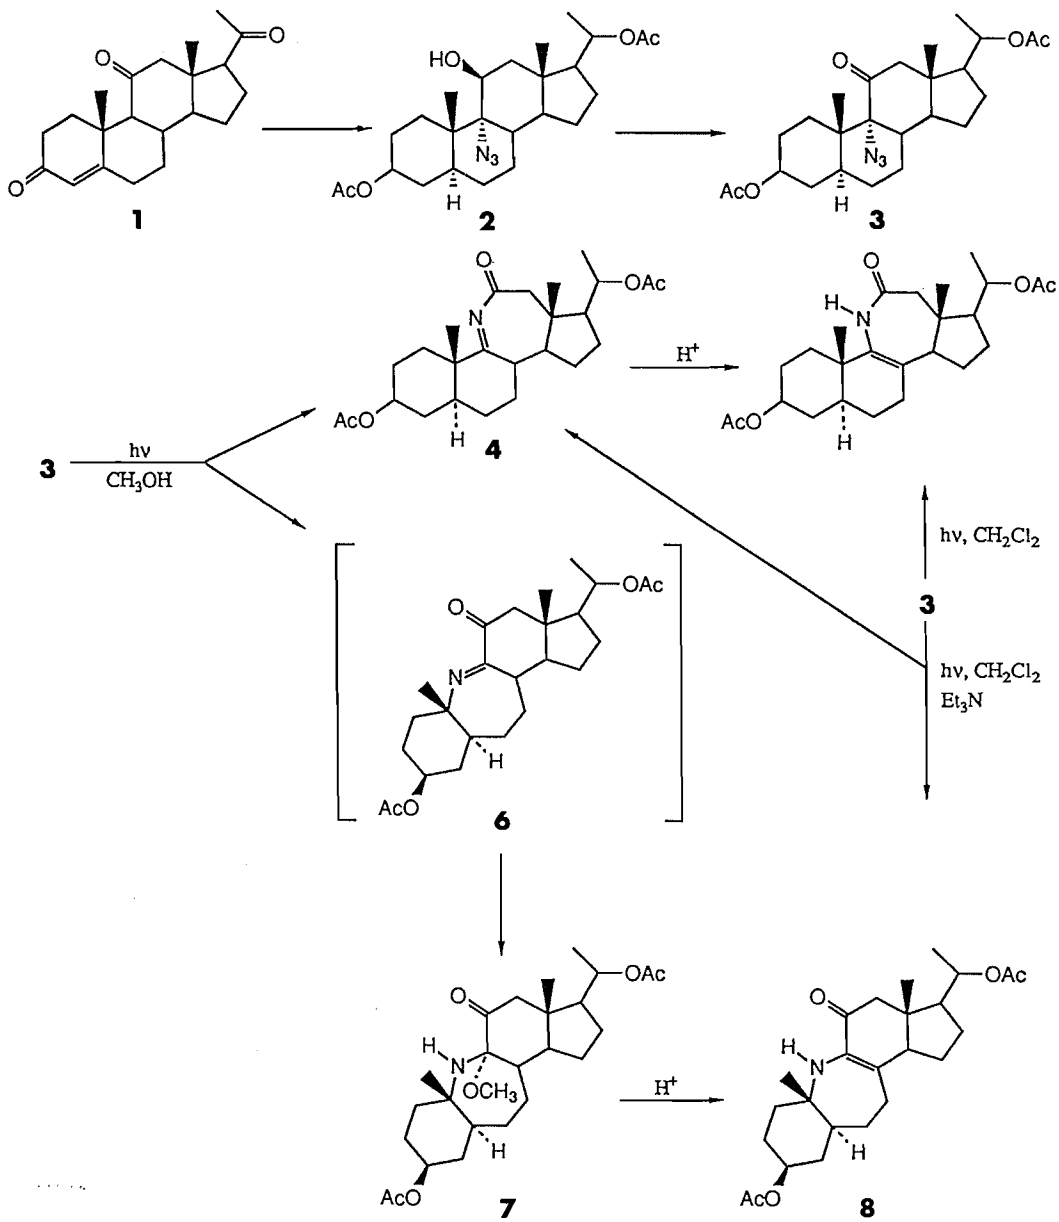
[3]Research Associates, National Research Council of Canada.

[4]The photolysis was proposed by Dr. N. F. Elmore as a method of preparing 12-imino 11-ketones from the azido ketones following Barton and Starratt (4), and he did preliminary studies on **9**. We gratefully acknowledge this contribution.

reacetylation. Finally, an X-ray crystallographic analysis (8) confirmed the structure and gave bond lengths and angles for **10**.

More-polar fractions from the large-scale photolysis of **9** contained much carbinolamide **12** since treatment with acidic methanol gave a 14% yield (based on starting material) of ether **11**. Thus the overall yield of products resulting from acyl migration onto nitrogen was 61%.



Attempts to reproduce the photolysis of **9** on a smaller scale, or carry it out using a Vycor flask and a Rayonet photoreactor with lamps giving peak radiation at 300 nm on a 100–200 mg scale, gave low yields of **10**. This was eventually attributed to traces of acid formed from the dichloromethane and traces of water carried into the reaction. Addition of dry triethylamine prior to the photolysis eliminated the problem, and isolated yields of around 60% of **10** were consistently obtained. We were unable to isolate the imine **14** (R^1 = Ac) or products derived from it. However the total ether-soluble products from these photolyses gave a ^1H nmr signal at δ7.56 in addition to the major one at δ7.95(*N*-acyl imine), suggestive of its presence. Subsequent handling of the noncrystalline products after removal of most of **10** led to fractions containing aldehyde hydrogens (δ10.0 and 9.7) and new carbonyl groups (207.3 and 206.4 ppm). Thus products formed by opening of ring C of **10** and **14** (R^1 = Ac) seemed to be present.

Photolysis of **9** in dry methanol using Pyrex-filtered ultraviolet light gave a 56% yield of pure **11** ($R^1 = R^2$ = Ac).

The observation of slow nitrogen loss from **9** above its melting point prompted a study of its thermolysis. Because of the evident sensitivity of **10** to acid we chose to do the thermolysis in dry dimethylaniline, thus providing an adequately high boiling point and a weakly basic medium. Heating at ca. 200°C in this solvent for 13.5 h did indeed

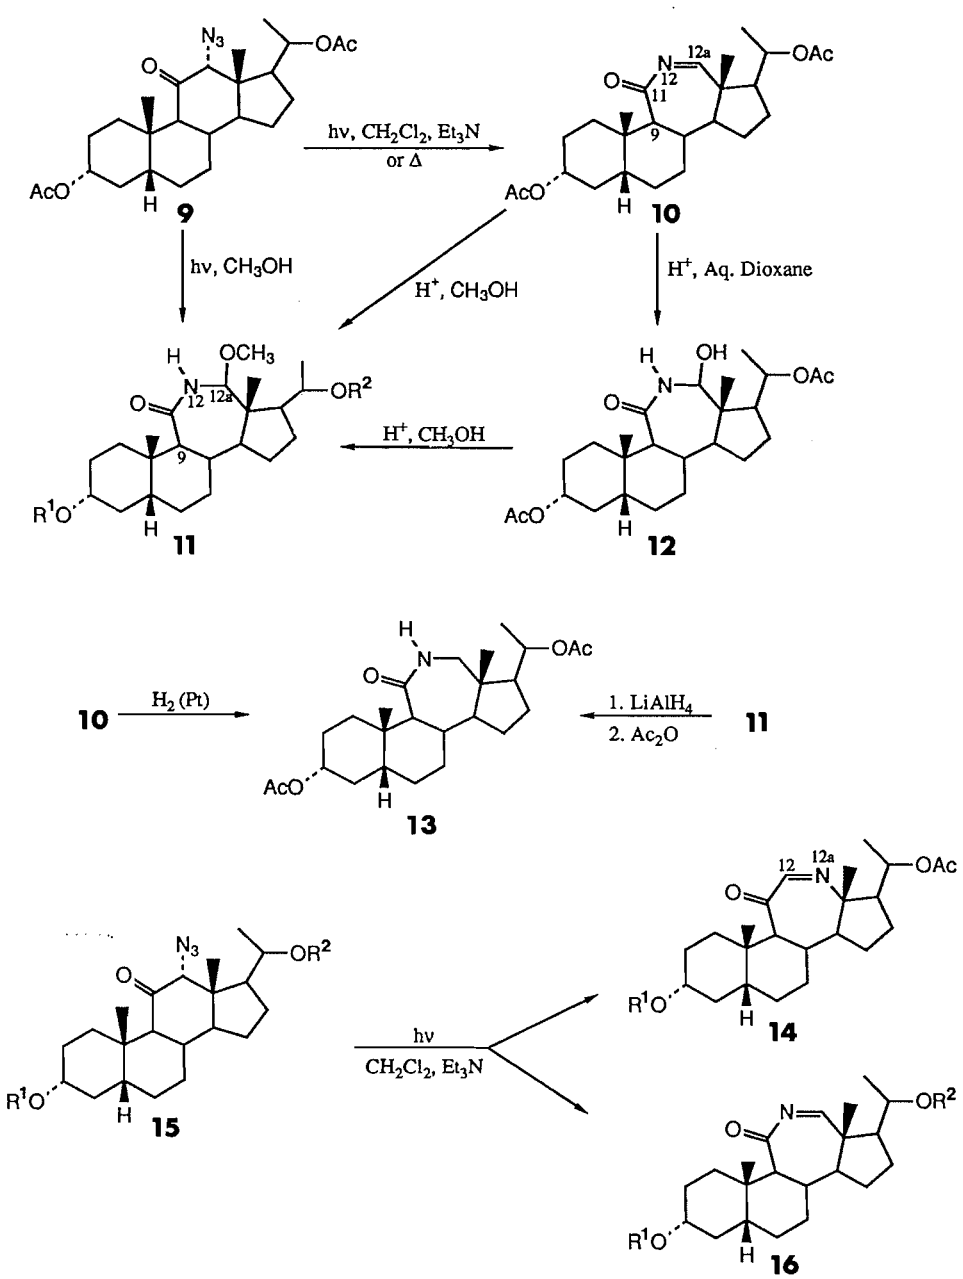
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

convert **9** into products, from which **10** was isolated in a yield of 51%.

Stepwise hydrolysis of the acetoxy groups of the carbinolamide ether lactam **11** ($R^1 = R^2 = Ac$) was possible using sodium methoxide in methanol. The 3-acetoxy group was much more reactive, so that the 3-hydroxy-20-acetoxy ether **11** ($R^1 = H$, $R^2 = Ac$) and the dihydroxy ether **11** ($R^1 = R^2 = H$) could be prepared. After two days in 1 M sodium methoxide in methanol, the diacetoxy *N*-acyl imine **10** gave an 87% yield of the dihydroxy ether **11** ($R^1 = R^2 = H$).

Similar hydrolysis of the diacetoxy azide **9** gave the 3-hydroxy-20-acetoxy azide **15** ($R^1 = H$, $R^2 = Ac$) and the corresponding diol **15** ($R^1 = R^2 = H$).

Photolysis of the 3-hydroxy-20-acetoxy azide **15** ($R^1 = H$, $R^2 = Ac$) in dichloromethane containing triethylamine gave a 60% isolated yield of the *N*-acyl imine **16** ($R^1 = H$, $R^2 = Ac$) after chromatography on neutral alumina. Evidence was obtained for the presence of the keto imine **14** ($R^1 = H$) (δ7.5; 206.7 and 160.9 ppm) in the products, but no pure **14** could be isolated on the small scale used. The *N*-acyl imine **16** ($R^1 = H$) survived, in part, quick chromatography on "flash" silica gel and elution with 1% methanol in dichloromethane. Its melting point in an evacuated capillary was 185°C with slight bubbling, but the melt didn't really liquefy until above 220°C, indicating probable intermolecular solvation of the imine in the melt.



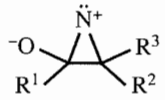
In contrast, photolysis of the dihydroxy azide **15** ($R^1 = R^2 = H$) as for the monoacetate gave no detectable *N*-acyl imine (nmr). However, a keto imine (δ7.53; 205.1 and 160.8 ppm) appeared to be present, but could not be isolated. When **15** ($R^1 = R^2 = H$) was irradiated in dichloromethane–triethylamine at −25°C, then the product treated with metha-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

nol and a sulfonic acid resin, a 56% yield of the dihydroxy methyl ether **11** ($R^1 = R^2 = H$) was obtained.

Discussion

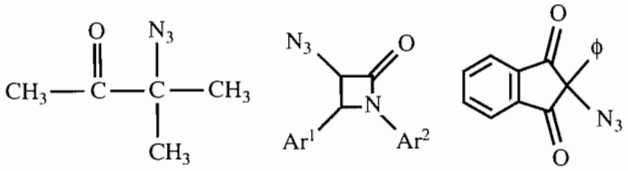
The mechanism of the photolysis of α-azido ketones, esters, and amides has been discussed (9). Transient formation of a singlet nitrene seems probable, with a zwitterion **17** as a likely intermediate between this and the rearranged prod-



17

ucts. The axial orientation of the azide groups in **3** and **9** would make formation of such intermediates very favorable.

The competition between alkyl and acyl migration onto electron-deficient nitrogen in the photolysis of our examples of α-azido ketones slightly favors the latter (see also ref. 9).

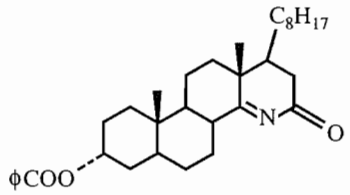


18 **19** **20**

However, Margaretha and Steffen (10) only observed alkyl migration when **18** was photolyzed. Thus the only other observation of photochemical acyl migration onto nitrene-like nitrogen appears to be that of Moriarty *et al.* (11) on dimethyl diazidomalonate. Pyrolytic acyl migration onto the nitrogen of a decomposing azide was observed by Moriarty and Serridge for methyl diazidomalonate (12), Millership and Suschitzky (13) for **19**, Moore and co-workers (14) for **20**, and Ogilvie and Rank (15) for ethyl 2,2-diazido-3-keto-butyrate.

The near coplanarity of the carbonyl and the lone pair on nitrogen in the cyclic *N*-acyl imines means that amide resonance does not exist. This is reflected in their high infrared stretching frequency (1698 and 1715 cm^{-1} for **4** and **10** respectively) and the ^{13}C nmr shifts (186 and 190 ppm) of the carbonyl groups. The restoration of the amide resonance in solvation products such as **11** may provide a 15–20 kcal/mol driving force for the reaction, resulting in the sensitivity of the *N*-acyl imines to alcohols or water. Since this sensitivity should extend to sulfhydryl and amine groups, this suggested the possibility of preparing analogues of the steroid hormones containing *N*-acyl imine functions with biological alkylating potential. These could act as very specific chemotherapeutic agents for hormone-sensitive tumors (3). Our studies show that the *N*-acyl imine function in a steroid skeleton can be resistant enough at physiological pH to enable delivery to target sites in the body.

Unfortunately we have been unable to prepare steroidal *N*-acyl imines with *normal ring sizes* and nitrogen in rings A or D for biological studies[5] (see also the work of Back *et al.*, ref. 16). Only one other steroidal *N*-acyl imine **21** seems to have been isolated (17).



21

Experimental

Ultraviolet spectra were taken in 95% ethanol; infrared spectra on a Perkin–Elmer model 683 grating spectrometer were taken of dichloromethane solutions unless otherwise stated. The ^1H nmr and ^{13}C nmr spectra were taken of deuteriochloroform solutions on EM-360 Varian CW, Varian Gemini 200 FT, or Bruker AMX 400 FT spectrometers as indicated in the text. Melting points were in Pyrex capillaries.

5α-Pregnan-3,11,20-trione

A solution of 20 g of 11-ketoprogesterone in 250 mL of dry tetrahydrofuran was added slowly with stirring to a solution of 3 g of lithium in 1 L of anhydrous ammonia. Five minutes after completion of the addition, *tert*-butyl alcohol was added slowly until the blue color disappeared (ca. 40 mL), then 23 g of ammonium chloride was added slowly with stirring. The ammonia was evaporated in a stream of argon, then the tetrahydrofuran was removed on a rotating evaporator. The products were distributed between water and chloroform. The mixture was acidified (pH 2), then the chloroform extract and washings dried and distilled. The residual brown oil was dissolved in 200 mL of acetone, the solution cooled in ice, then 47 mL of Jones reagent (18) was added slowly. After 5 min the excess reagent was reduced using isopropyl alcohol. The supernatant liquid and acetone washings of the precipitate were evaporated, then the residue distributed between water and chloroform. The latter yielded a yellowish-brown solid on evaporation. This was dissolved in a minimum amount of 9:1 (v/v) benzene–chloroform, then adsorbed onto 400 g of neutral alumina (Act. III). The same solvent eluted 11 g of the desired 5α-pregnan-3,11,20-trione, mp 214–218°C. The catalytic reduction previously used (5) gave a mixture of 5α and 5β isomers.

9α-Azido-3β,20β-diacetoxy-5α-pregnan-11-one ***3***

The oxidation of 9α-azido-3,20-diacetoxy-11β-hydroxy-5α-pregnane (**2**) was improved from the previous report (5) by using either Sarett oxidation (6) or pyridinium chlorochromate (7).

(*a*) A solution of 590 mg of azido alcohol (**2**) in 6 mL of dry pyridine was added to a solution of 590 mg of chromium trioxide in 7 mL of pyridine. The mixture was stirred at room temperature for 17 h. It was then diluted with 60 mL of water and the products extracted into ether. The ether was washed with 5% aqueous acetic acid, water, then 10% sodium carbonate solution, dried, and evaporated. The residue gave 500 mg of **3**, mp 205–207°C after crystallization from acetone–hexane.

(*b*) A solution of 730 mg of **2** in 10 mL of dry dichloromethane was added to a suspension of 700 mg of pyridinium chlorochromate (7) in 20 mL of the same solvent. The mixture was stirred at room temperature for 3.3 h, then poured into 100 mL of dry ether. The precipitate was removed by filtration through Celite, then the filtrate passed through a 4 cm × 2.5 cm column of Florisil. The filtrate and ether washings were evaporated, then the residue crystallized from ethyl acetate – hexane. The prisms of **3** (670 mg) had mp 198–201°C.

Irradiation of 9α-azido-3β,20β-diacetoxy-5α-pregnan-11-one (***3***)

(a) In methanol

A solution of 305 mg of azide **3** in 70 mL of dry methanol was irradiated in a Vycor vessel at 15°C using a Rayonet photoreactor

with lamps giving peak emission at 300 nm. After 1 h the azide had been destroyed (ir). The solution was evaporated below room temperature, the residue dissolved in dichloromethane, then this solution washed with water. The organic layer was dried and distilled giving a residue that crystallized from acetone, giving 85 mg of crude methoxy base **7**. Separation of the main product on 1.5 mm alumina plates using dichloromethane gave more **7** (total 95 mg; 31%; R_f 0.7) and 82 mg of the *N*-acyl imine **4** (29%; R_f 0.5).

Irradiation of azide **3** in methanol using a 100-W Hanovia high-pressure mercury lamp and Pyrex filter took 3 h for completion. The yield of methoxy base **7** was 33% and of *N*-acyl imine **4** was 41%.

(b) In dichloromethane

A solution of 249 mg of azide **3** in 35 mL of dichloromethane was irradiated using a 100-W high-pressure Hanovia mercury lamp in a quartz vessel. The photolysis was complete in 3 h. The products were adsorbed from benzene onto 2 g of neutral alumina, Activity IV. Benzene eluted 125 mg, rich in enamide **5**. After crystallization from hexane, and recrystallization from acetone–hexane, this gave 70 mg (30%) of **5** as needles, mp 205–207°C.

(c) In dichloromethane–triethylamine

A solution of 80 mg of azide **3** in 15 mL of dry dichloromethane containing 39 mg of triethylamine was irradiated in a Vycor vessel at 10°C using 300 nm lamps in a Rayonet apparatus for 1 h. The yellow solution was evaporated below room temperature, then the residue taken up in dry ether. The undissolved solid (ca. 2 mg of triethylamine hydrochloride) was removed by filtration. When concentrated the filtrate yielded 30 mg (40%) of crystalline *N*-acyl imine **4**. The mother liquor was evaporated and the residue dried under 0.5 Torr (1 Torr = 133.3 Pa). Its ^{13}C nmr spectrum showed that it contained approximately 30% of *N*-acyl imine but that the major component was the α,β-unsaturated amino-ketone **8** (estimated yield 45%) (23 major signals coincident with those for pure **8**). An attempt to purify this on a 1 mm alumina plate using dichloromethane gave only 14 mg (19%) of **8** (R_f 0.6). The major components (20 mg) now had low R_f, corresponding to hydrated products.

11-Aza-3β,20β-diacetoxy-C-homo-5α-pregn-9(11)-en-12-one **4**

The *N*-acyl imine **4** upon recrystallization from ether–hexane formed needles with mp 220–223°C and $[\alpha]_D$ 30.6 (*c* 1.08, in 95% ethanol). It had ν_{max} (CH_2Cl_2) 1728, 1686, and 1660 cm^{-1}; and λ_{max} 278 nm (ε 500). It gave ^1H nmr signals at δ 4.8(2H, br m), 3.0(1H, d, J = 14 Hz), 2.6(1H, d, J = 14 Hz), 2.05(6H, s), 1.22(3H, s), 1.15(3H, d, J = 6 Hz), and 0.82(3H, s) and ^{13}C nmr signals at 185.7 (s), 179.9(s), 170.4(s), 170.2(s) 72.6(d), 72.2(d), 56.4(d), 50.6(t), 48.6(d), 46.9(d), 44.9(d), 43.5(s), 41.1(s), 33.3(t), 32.6(t), 28.3(t), 27.4(t), 27.0(t), 24.9(t), 21.3(q) (double intensity), 19.9(q), 17.1(q), and 15.9(q) ppm. Anal. calcd. for $C_{25}H_{37}NO_5$: C 69.57, H 8.64, N 3.25; found: C 69.30, H 8.84, N 3.42.

11-Aza-3β,20β-diacetoxy-C-homo-5α-pregn-8-en-12-one **5**

The *N*-acyl imine **4** (46 mg) was added to a solution of 10 mg of *p*-toluenesulfonic acid hydrate, 50 mg of acetic acid, and 50 mg of acetic anhydride in 3 mL of dry benzene. The mixture was heated under gentle reflux for 2 h. The benzene was evaporated *in vacuo*, the residue dissolved in dichloromethane, then this solution stirred for 0.5 h with 5% aqueous sodium carbonate. The organic layer yielded 47 mg of product, which crystallized from acetone as stout needles mp 204–209°C. Recrystallization from acetone gave 29 mg (mp 205–210°C) of enamide **5**. This had ν_{max}(CCl_4) 3200, 1740, 1660, and 1250 cm^{-1} and λ_{max} 232 nm(ε 6200). It gave ^1H nmr signals at δ6.39 (1H, s), 4.73(2H, m), 2.89(1H, d, J = 14 Hz), 2.66(1H, t, J = 10 Hz), 2.07(3H, s) and 2.05(3H, s), 1.19(2H, d, J = 6 Hz), 1.09 (3H, s), and 0.72(3H, s). Its ^{13}C nmr spectrum had signals at 176.0, 170.8, 170.7, 137.8, 124.6, 73.4, 73.0, 56.1, 50.7, 49.5, 45.3, 40.5, 37.0, 33.33, 32.0, 27.6, 26.9, 26.3, 24.7, 21.7, 21.6, 19.9, 18.5, and 17.0 ppm. Its EI mass spectrum gave M^+ 431.26604; calcd. for $C_{25}H_{37}NO_5$: 431.26716.

9a-Aza-3β,20β-diacetoxy-9α-methoxy-B-homo-5α-pregnan-11-one **7**

After crystallization from acetone–hexane this had mp 189–191°C. In an evacuated capillary it had mp 232–235°C. It had ν_{max}(CCl_4) 1740, 1715, and 1250 cm^{-1} and ν_{max}(nujol) 3380(NH), 1742, and 1702 cm^{-1}. It had λ_{max} 255 nm(ε 58) and 315 nm(ε 58) and pK_a 3.8 in 95% ethanol. It gave ^1H nmr signals δ4.8(2H, m), 3.42(3H, s), 3.1(1H, m), 2.82 and 2.70(pair of 1H doublets, J = 12.3 Hz), 2.03(3H, s), 2.02(3H, s), 1.17(3H, d, J = 6.1 Hz), 1.02(3H, s), and 1.00(3H, s). Its ^{13}C nmr (100.6 MHz) spectrum had signals at 209.4 s, 170.5 s, 170.3 s, 91.9 s, 73.3d, 72.7 d, 54.1 d, 53.7 d, 52.3 t, 51.6 q, 48.7d, 47.2 s, 44.2 s, 38.0 t, 35.3 d, 33.5 t, 31.1 t, 29.4 t, 27.9 t, 26.6 t, 25.8 t, 21.5 q, 19.9 q, 15.6 q, and 14.4 q ppm. Anal. calcd. for $C_{26}H_{41}NO_6$: C 67.36, H 8.91, N 3.20; found: C 67.54, H 9.10, N 3.19. Its EI mass spectrum gave a weak peak at m/z 463 but a strong one at m/z 431 (M − 32).

9a-Aza-3β,20β-diacetoxy-B-homo-5α-pregn-8-en-11-one **8**

A suspension of 57 mg of methoxy base **7** and 49 mg of dry *p*-toluenesulfonic acid on silica gel (3% acid) in 3 mL of dry benzene was stirred under argon for 21 h. The mixture was filtered and the solid washed with benzene. The benzene solution yielded 52 mg of residue, which crystallized as fine needles from acetone–hexane. The silica gel was suspended in benzene containing 10% of pyridine. The solvent extracted 9 mg, which also crystallized. This and the mother liquor from the main crop of crystals was put on a 30 cm × 20 cm, 0.25 mm alumina plate and separated using chloroform (3/4% ethanol). The main zone (R_f 0.56) gave 7 mg of crystalline base. The combined crystals (45 mg, 85%) had mp 119–125°C. Recrystallization from aqueous methanol gave **8** as stout needles, mp 182–187°C. This had ν_{max} 3410, 1724, and 1682 cm^{-1} and λ_{max} 235.8 (ε 4500) and 297.5(ε 2400). Its ^1H nmr spectrum gave signals at δ5.40(1H, s), 4.87(1H, m), 4.60(1H, m), 3.21(1H, t, J = 9 Hz), 2.034 (3H, s), 2.026 (3H, s), 1.22(3H, s), 1.20(3H, d, J = 5 Hz), 0.94(3H, s) and its ^{13}C nmr spectrum gave signals at 208.4, 170.8, 170.7, 139.9, 115.5, 72.95, 72.56, 59.26, 53.24, 51.68, 50.37, 44.19, 37.96, 36.82, 36.46, 34.0, 30.83, 26.66, 26.0, 25.37, 21.58, 21.45, 19.79, 14.83, and 9.39 ppm. Its EI mass spectrum had M^+ 431.26516; calcd. for $C_{25}H_{37}NO_5$: 431.26716.

Photolysis of 12α-azido-3α,20β-diacetoxy-5β-pregnan-11-one **9**

(*a*) A solution of 1.44 g of azido ketone **9** (5) in 100 mL of dry dichloromethane was irradiated for 7 h using a 100 W high-pressure Hanovia mercury lamp in a water-cooled Pyrex well. By this time all the azide had been transformed. The solvent was removed on a rotating evaporator, the residue dissolved in benzene, then this solution passed through a column of 40 g of neutral alumina (Act. IV). Benzene (ca. 300 mL) eluted 1.0 g, rich in *N*-acyl imine **10**. This crystallized from ether–hexane mixtures giving **10** as prisms, (645 mg, 49.5%). Dichloromethane eluted 124 mg of yellow gum. A 1% solution of methanol in dichloromethane eluted 347 mg of amorphous solid. Its reactions (see below) showed it to contain much (ca. 14% yield) carbinolamide **12** or equivalent amido-aldehyde and polymer. Attempts to repeat this on a smaller scale gave much reduced yields of *N*-acyl imine **10**, apparently due to traces of water and traces of acid produced from the dichloromethane.

In a comparable experiment on 272 mg of azide **9** in 70 mL of dichloromethane but containing 1 mL of dry triethylamine the photolysis was complete in 2 h. After work-up as above, 153 mg (60%) of crystalline *N*-acyl imine **10** was obtained.

(*b*) When a solution of 100 mg of azide **9** in 17 mL of dry dichloromethane containing 69 mg of dry triethylamine (5A molecular sieve) was irradiated in a Vycor flask at 10°C using a Rayonet reactor with 300 nm lamps the photolysis was complete in 1 h. The pale yellow solution was evaporated to dryness. Dry ether (10 mL) was added, then the solution filtered to remove 9 mg of solid. The ether was evaporated, and the residue dried briefly at 90°C, 0.5 Torr. The ^1H nmr spectrum of this mixture showed it to be mainly *N*-acyl imine **10** (δ7.94) but to contain a component (ca.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

25%) giving a signal at δ7.56. This corresponds to the expectation for the C-12 of keto imine **14** (R^1 = Ac). The ^{13}C nmr spectrum was mainly that of **10**, but again a signal at 160.74 ppm corresponded to the C-12 of **14** (22% of the height of the signal for C-12a of **10**). Chromatography of the ether-soluble products on Activity IV neutral alumina as in (*a*) partially decomposed the compounds. The yield of crystalline *N*-acyl imine **10** was 54 mg (58%). The ^1H nmr spectrum of the mother liquor from crystallization of **10** showed the presence of **10** and at least two aldehydes (δ9.7 and 10.0), probably the products of hydrolytic opening of ring C of **10** and **14**. Chloroform eluates from the column (17 mg) gave 5 mg of prisms from ether–hexane. These gave ^1H nmr signals at δ6.73(1H, s), 4.9(1H, m), 4.7(1H, m), 4.55(1H, d, J = 3 Hz), 2.10(3H, s), 2.02(3H, s), 1.30(3H, s), 1.18(3H, d, J = 6 Hz), and 1.07(3H, s) corresponding to those expected for carbinolamide **12**.

(*c*) A comparable photolysis to that described in (*b*), but using 3500 Å lamps in a Rayonet apparatus took longer for completion (5 h). A 58% yield of **10** was again obtained.

(*d*) A solution of 740 mg of azide **9** in 60 mL of dry methanol was irradiated at 0°C for 16.5 h through Pyrex using a 100-W high-pressure Hanovia lamp. Evaporation of the methanol left a gum. This was adsorbed from benzene on 15 g of neutral alumina (Act. IV). Elution with benzene gave 650 mg, rich in carbinolamide ether **11**. This crystallized from acetone–hexane, giving 420 mg (56%) of pure **11**.

Thermolysis of azido ketone ***9***

Two millilitres of dry dimethylaniline (4A molecular sieve) was added to 201 mg of azido ketone **9** in a dry flask. This was placed in a bath at 210°C, and allowed to reflux gently for 13.5 h. A small amount of azide persisted. The bulk of the dimethylaniline was removed at 110°C, 0.5 Torr, leaving a yellow gum. This was adsorbed from benzene onto 2 g of Activity IV neutral alumina. Benzene eluted 198 mg, which crystallized from ether–hexane giving 96 mg (51%) of crystalline *N*-acyl imine **10**.

12-Aza-3α,20β-diacetoxy-C-homo-5β-pregn-12-en-11-one ***10***

This had mp 190–192°C, $[\alpha]_D$ 184 (*c* 0.13, in 95% ethanol); $\nu_{max}(CCl_4)$ 1742, 1715, 1662, and 1245 cm^{-1}; and λ_{max} 288 nm(ε 1080). Its ^1H nmr spectrum had signals at δ 7.94 (1H, s), 4.77(2H, m), 2.02 (6H, s), 1.38(3H, s), 1.21(3H, d, J = 6 Hz), and 0.90(3H, s). Its ^{13}C nmr (100.6 MHz) spectrum had signals at 189.9 s, 170.5 s, 170.0 s, 168.9 d, 73.7d, 72.3 d, 52.8 d, 52.1 d, 50.4 s, 46.5 d, 42.2 d, 38.4 d, 35.0 t, 34.2 s, 31.8 t, 27.6 t, 27.5 t, 27.1 t, 26.0 t, 24.3q, 23.2t, 21.4 q, 21.2 q, 19.5 q, and 12.1 q ppm. Anal. calcd. for $C_{25}H_{37}NO_5$: C 69.57, H 8.64, N 3.25; found: C 69.43, H 8.82, N 3.19.

12-Aza-3α,20β-diacetoxy-12a-methoxy-C-homo-5β-pregnan-11-one ***11***

This formed prisms from acetone–hexane with mp 208–209°C, $[\alpha]_D$ 144 (*c* 0.286, in 95% ethanol), and ν_{max} 3230, 1740, 1670, and 1250 cm^{-1}. Its ^1H nmr spectrum (200 MHz) had signals at δ6.65(NH), 4.75(2H, m), 4.21(1H, d, J = 6 Hz), 3.40(3H, s), 2.04(6H, s), 1.29(3H, s), 1.16(3H, d, J = 6 Hz), and 0.63(3H, s). Its ^{13}C nmr spectrum (125.7 MHz) had signals at 179.9 s, 170.7 s, 170.0 s, 87.3 d, 74.1 d, 72.8 d, 55.5 q, 52.2 d, 49.2 s, 48.4 d, 44.6 d, 43.3 d, 35.4 t, 34.7 s, 32.8 d, 31.6 t, 27.5 t, 26.4 t, 26.0 q, 25.1 t, 23.7 t, 21.7 q, 21.5 q, 19.8 q, and 12.3 q ppm. Anal. calcd. for $C_{26}H_{41}NO_6$: C 67.36, H 8.91, N 3.02; found: C 67.18, H 9.03, N 3.16.

12-Aza-3α,20β-diacetoxy-12a-hydroxy-C-homo-5β-pregnan-11-one ***12***

Polar eluate from alumina of the products of photolysis of **9** in dichloromethane crystallized in part from ether as prisms. These melted partly around 140°C, resolidified, and melted at 207°C. The crystals had ν_{max} 3520, 3405, 1730, and 1680 cm^{-1} and gave ^1H nmr signals (400 MHz) at δ6.73(NH), 4.92 (1H, m), 4.75 (1H, m), 4.55 (1H, d, J = 3 Hz), 2.60(1H, d, J = 4 Hz, OH), 2.10(3H, s), 2.02(3H, s), 1.30(3H, s), 1.18(3H, d, J = 6 Hz), and 1.07(3H, s). Its ^{13}C nmr spectrum gave signals at 176.3, 170.6, 169.8, 74.8, 74.0, 72.7, 60.9, 59.6, 55.5, 42.6, 41.4, 35.9, 35.7, 32.0, 31.5, 26.7, 26.67, 26.3, 26.1, 23.2, 21.42, 21.41, 19.5, and 15.9 ppm (24 signals; 25 expected).

Acid-catalysed reactions of N-acyl imine ***10***

(*a*) A solution of 21 mg of **10** in 15 mL of dry methanol, containing 5 mg of *p*-toluenesulfonic acid hydrate, was left at room temperature for 1 h. The mixture was neutralized using sodium bicarbonate, then the solvent removed *in vacuo*. The residue was extracted with dichloromethane, the organic layer washed with water, dried, then distilled. The crystalline residue was recrystallized from acetone–hexane giving 18 mg of prisms, mp 206–208°C. This was identical (mixture mp, spectra) to carbinolamide ether **11**.

(*b*) A suspension of 0.5 mL of Rexyn 101 (H^+) beads in 5 mL of methanol containing 10 mg of *N*-acyl imine **10** was stirred at room temperature for 5 min. The resin was removed by filtration, then the methanol evaporated, giving 9.5 mg of carbinolamide ether **11**, pure by ir and tlc.

(*c*) Eighty-six milligrams of *N*-acyl imine **10** was dissolved in 5 mL of dioxane and 1 mL of water. After addition of ca. 0.3 mL of Rexyn 101(H^+) beads the mixture was stirred for 20 min, the Rexyn was removed by filtration, then the solvents removed under reduced pressure. The residue showed one spot on tlc and had ν_{max} 3520, 3405, 1730, and 1680 cm^{-1} consistent with carbinolamide structure **12**. This was converted to carbinolamide ether **11** by stirring overnight with Rexyn 101 (H^+) in methanol.

Action of acidic methanol on crude carbinolamide ***12***

The amorphous polar product from photolysis (*a*) above (347 mg) was dissolved in anhydrous methanol (30 mL) containing 15 mg of *p*-toluenesulfonic acid. After 1 h the mixture was worked up as for experiment (*a*). The product gave 195 mg of crystalline carbinolamide ether **11** after chromatography on Activity IV alumina and crystallization from acetone–hexane (14% yield based on azide photolyzed).

12-Aza-3α,20β-diacetoxy-C-homo-5β-pregnan-11-one ***13***

(*a*) Lithium aluminum hydride (300 mg) was added to a solution of 93 mg of carbinolamide ether **11** (R^1 = R^2 = Ac) in 20 mL of dry ether. The mixture was heated under gentle reflux for 20 h, then the excess hydride destroyed using wet ether. The crude product recovered from the ether (80 mg) was acetylated overnight in 1:1 pyridine – acetic anhydride. The product was adsorbed from benzene onto 2 g of neutral alumina (Act. IV). Benzene (25 mL) eluted a mixture of four products, followed (100 mL) by 40 mg of homogeneous product. This did not crystallize readily, so was distilled at 180°C under 1×10^{-4} Torr. The colorless glass had $[\alpha]_D$ 49 (*c* 0.25, in 95% ethanol) and ν_{max} 3230, 1740, 1670, and 1250 cm^{-1}. Its ^1H nmr spectrum had signals at δ6.16(NH), 4.75(2H multiplet), 3.7–2.9(2H broad), 2.03(6H, s), 1.37(3H, s), 1.17(3H, d, J = 6 Hz), and 0.61(3H, s). The broad bands between 3.7 and 2.9 collapsed to a pair of doublets centered at δ3.3 with ΔAB = 27 Hz, J_{AB} = 15 Hz after treatment with a trace of *p*-toluenesulfonic acid in D_2O. Anal. calcd. for $C_{25}H_{39}NO_5$: C 69.25, H 9.07, N 3.23; found: C 69.39, H 9.16, N 3.30.

(*b*) Ninety-five milligrams of *N*-acyl imine **10** in 10 mL of 95% ethanol containing 111 mg of 5% palladium-on-charcoal was stirred in a hydrogen atmosphere for 4 h. The catalyst was removed and the solvent evaporated. Purification as in (*a*) gave 80 mg of a glass identical by ir and tlc with the product from the lithium aluminum hydride reduction of **11** followed by acetylation.

*Deacetylation of 12-aza-3α,20β-diacetoxy-12a-methoxy-C-homo-5β-pregnan-11-one (***11***) (R^1 = R^2 = Ac)*

To a solution of 30 mg of diacetoxy-methoxy lactam **11** in 1 mL of methanol was added a solution of sodium methoxide (from 25 mg of sodium) in 2 mL of dry methanol. The mixture was stirred at room temperature for 30 min, then the solvent evaporated *in vacuo* below room temperature. The products were distributed between water and chloroform. The dried chloroform layer was

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

distilled then the residue allowed to crystallize from an ethyl acetate – hexane mixture. The material in the mother liquor was separated on a 0.5 mm silica gel plate using 10% methanol in chloroform. The zone with R_f 0.7 proved identical to the above crystals, and was identified as the 3-hydroxy-20-acetoxy-12a-methoxy lactam **11** (R^1 = H, R^2 = Ac) (22 mg total, 80%). The other major zone (R_f 0.3) contained the dihydroxy-methoxy lactam **11** (R^1 = R^2 = H) (5 mg, 20%). Comparable conditions, but 24 h reaction, effected complete hydrolysis to the diol **11** (R^1 = R^2 = H).

*Action of sodium methoxide in methanol on N-acyl imine **10***

N-Acyl imine **10** was dissolved in 10 mL of methanol and 1 mL of 1 M sodium methoxide in methanol. After 48 h tlc showed the reaction to be complete. Evaporation of the solvent and extraction of the residue with dichloromethane gave 73 mg of organic product. Trituration of this with ether left 66 mg (87%) of dihydroxy-methoxy lactam identical to the diol **11** (R^1 = R^2 = H) produced from deacetylation of **11** (R^1 = R^2 = Ac).

*20-Acetoxy-12-aza-3α-hydroxy-12a-methoxy-C-homo-5β-pregnan-11-one **11** (R^1 = H, R^2 = Ac)*

This crystallized from ethyl acetate – hexane as needles, mp 134–137 or 175–180°C. It had ν_{max} 3595, 3385, 1726, and 1665 cm^{-1}. Its ^1H nmr spectrum (500 MHz) had signals at δ5.82(1H, d, J = 6.1 Hz), 4.76(1H, m), 4.13(1H, d, J = 6.2 Hz), 3.63(1H, m), 3.40(3H, s), 2.92(1H, d, J = 11.4 Hz), 2.22(1H, q, J_1 = 20 Hz, J_2 = 10 Hz), 2.00(3H, s), 1.28(3H, s), 1.13(3H, d, J = 6.0 Hz), and 0.63(3H, s). A ^1H–^1H COSY spectrum showed the proton at δ4.76 to be coupled to the methyl doublet at δ1.13 and the proton (H-17) at δ2.22. A second weak set of signals indicated the presence of another isomer, presumably the 12aβ-methoxy compound. (see ref. 5 for evidence on the stereochemistry.)

*12-Aza-3α,20β-dihydroxy-12a-methoxy-C-homo-5β-pregnan-11-one (**11**, R^1 = R^2 = H)*

This was not obtained crystalline. It had ν_{max} ($CHCl_3$) 3600, 3400, and 1660 cm^{-1} and gave ^1H nmr signals at δ5.9(1H, d, J = 6 Hz) (NH), 4.8(1H, d, J = 6 Hz), 3.7(2H, m), 3.45(3H, s), 3.01(1H, d, J = 11 Hz), 1.33(3H, s), 1.15(3H, d, J = 6 Hz), and 0.75(3H, s).

*Hydrolysis of 12α-azido-3α,20β-diacetoxy-5β-pregnan-11-one (**9**)*

A solution of sodium methoxide prepared from 60 mg of sodium and 2 mL of dry methanol was added to a stirred suspension of 194 mg of diacetoxy azide **9** (R^1 = R^2 = Ac) in 4 mL of methanol. The azide dissolved within 5 min at room temperature. After 2 h the solution was concentrated to a syrup *in vacuo* below room temperature. Water and chloroform were added. The dried chloroform extracts yielded 190 mg of froth, which according to its ^1H nmr spectrum was mainly the monoacetate **15** (R^1 = H, R^2 = Ac). This was adsorbed from benzene onto 6 g of neutral alumina (Act. IV). Benzene and dichloromethane eluted the monoacetate (110 mg, 62%). The azido diol **15** (R^1 = R^2 = H) (60 mg, 41%) and minor polar impurities were eluted with 10% methanol in chloroform. Hydrolysis of **9** as above, but for 20 h, gave complete conversion to **15** (R^1 = R^2 = H).

*20β-Acetoxy-12α-azido-3α-hydroxy-5β-pregnan-11-one (**15**, R^1 = H, R^2 = Ac)*

The monoacetate crystallized from acetone–hexane as prisms, mp 163–164°C. It gave ν_{max} 3590, 2100, and 1727 cm^{-1} and ^1H nmr signals (500 MHz) at δ4.74(1H, br m), 3.61(1H, m), 3.58(1H, s), 2.84(1H, d, J = 11.2 Hz), 2.37(1H, dt, J_1 = 14.4, J_2 = 3.4 Hz), 2.22(1H, q, J_1 = 20, J_2 = 10 Hz), 2.03(3H, s), 1.17(3H, d, J = 6 Hz), 1.13(3H, s), and 0.60(3H, s). Irradiation at δ4.74 decoupled the methyl doublet at δ1.17 and partially collapsed the signals at δ2.22.

*12α-Azido-3α,20β-dihydroxy-5β-pregnan-11-one (**15**, R^1 = R^2 = H)*

An ethyl acetate – hexane solution of the diol (160 mg) deposited 25 mg of fine needles, mp 196–225°C. The remainder eventually crystallized from solvent mixtures richer in hexane as prisms, or as short rods, mp 167–169°C. This had ν_{max} 3590, 3450, 2100, and 1709 cm^{-1} and gave ^1H nmr signals (200 MHz) at δ4.05(1H, s), 3.67(2H, m), 2.87(1H, d, J = 11 Hz), 2.43(1H, dt, J_1 = 14.2, J_2 = 3.1 Hz), 1.19(3H, d, J = 6.2 Hz), 1.17(3H, s), and 0.72(3H, s).

The minor higher-melting product was shown by its ^1H nmr spectrum to be a mixture of the major azido diol with an isomer. The mixture had ν_{max} 3590, 3400, 2100, and 1707 cm^{-1} and its ^1H nmr spectrum had signals at δ4.50(s) and 0.89(s) in addition to those for the 169° azidodiol.

*Irradiation of 20β-acetoxy-12α-azido-3α-hydroxy-5β-pregnan-11-one **15** (R^1 = H, R^2 = Ac)*

A solution of 53 mg of the 12-azido monoacetate **15** (R^1 = H, R^2 = Ac) and 0.1 mL of triethylamine in dry dichloromethane was irradiated in a Vycor vessel at 10°C using Rayonet 300 nm lamps for 1 h. An infrared spectrum showed that all the azide had been transformed. The solvent and amine were removed *in vacuo*, finally under 0.1 Torr. The residue was suspended in dry ether, then filtered. Approximately 8 mg of triethylamine hydrochloride was removed. The yellow filtrate was evaporated and the residue freed of volatile material at 60°C under 0.1 Torr. Its nmr spectra (500 MHz) showed that a major component was the *N*-acyl imine **16** (R^1 = H, R^2 = Ac) (δ7.93; 190.1, 168.8 ppm), and a minor one had signals consistent with it being the keto imine **14** (R^1 = H) (δ7.53; 207.6 or 206.7, 160.9 ppm) (ratio 5:1). Traces of aldehydes (δ9.64 and 9.63) were present. The product was adsorbed from benzene onto a 20-fold ratio of neutral alumina (Act. IV). Benzene, then dichloromethane eluted 37 mg, which crystallized from ether–hexane mixtures, giving 30 mg of nearly pure *N*-acyl imine **16** (R^1 = H, R^2 = Ac) (56%).

*20β-Acetoxy-12-aza-3α-hydroxy-C-homo-5β-pregn-12-en-11-one **16** (R^1 = H, R^2 = Ac)*

Crystals of **16** (R^1 = H, R^2 = Ac) melted at 185°C in an evacuated capillary (immersed at 170°C) but did not become completely liquid until 220°C. It had ν_{max} 3595, 1730, 1702, and 1695 cm^{-1} and ^1H nmr (400 MHz) signals at δ7.93(1H, s), 4.78(1H, m), 3.64(1H, m), 2.03(3H, s), 1.37(3H, s), 1.22(3H, d, J = 6.05 Hz), and 0.90(3H, s). Its ^{13}C nmr spectrum (100.6 MHz) had signals at 190.1, 170.1, 168.8, 72.3, 72.1, 52.8, 52.0, 50.4, 46.6, 42.3, 38.4, 35.7, 35.3, 34.2, 31.1, 27.7, 27.5, 26.2, 24.4, 23.2, 21.2, 19.5, and 12.1 ppm. Its EI mass spectrum had m/z 389.2559 (M^+); calcd. for $C_{25}H_{35}NO_4$: m/z 389.2566.

*Irradiation of 12α-azido-3α,20β-dihydroxy-5β-pregnan-11-one **15** (R^1 = R^2 = H)*

(*a*) A solution of 79 mg of **15** (R^1, = R^2, = H) in 30 mL of dry dichloromethane was irradiated at 5°C in a Vycor vessel using a Rayonet photoreactor with light peaked at 300 nm. After 1 h no azide was left. The solution was evaporated below room temperature, leaving a white solid residue. This gave a milky suspension in acid-free deuteriochloroform. This was filtered through sintered glass under pressure. The fairly clear filtrate gave a ^1H nmr singlet at δ7.52. Its ^{13}C nmr spectrum had signals at 208.0, 205.1, 176.0, and 160.8. Thus no *N*-acyl imine seems to have survived (expected δ7.9 and 190 ppm). The signals are consistent with the presence of **14** (R^1 = H, 20-hydroxy).

(*b*) Irradiation of 132 mg of **15** (R^1 = R^2 = H) in 100 mL of dichloromethane containing 0.1 mL of triethylamine using a 100-W high-pressure Hanovia mercury lamp in a Pyrex well at −20 to −30°C required 7 h for complete reaction of the azide. After evaporation of solvent the residue was treated with Rexyn 101 (H^+) in methanol for 25 min. From the products a 56% yield of pure methyl ether **11** (R^1 = R^2 = H) was obtained after purification on

a silica gel plate (1:1 chloroform–acetone). It was identical (tlc and ^{1}H nmr to that produced by hydrolysis of **11** ($R^1 = R^2 = Ac$).

Received March 16, 1992

LIU YIXIAN, J. A. KONINGSTEIN, and Y. YEVDOKIMOV. Can. J. Chem. **70**, 2413 (1992).

Aspects of the electronic structure of tautomers of tetrakis(*N*-methyl-4-pyridyl)porphyrin (H_2TMpyP4) complexed to DNA have been determined from a study of the resonance Raman excitation profiles of normal modes of H_2TMpyP4 in buffer solutions containing monomeric and aggregated molecules and of a H_2TMpyP4/DNA complex with $r(c) \sim 25$. Maxima of the excitation profiles of the complex have been assigned to electronic origins for transitions between the ground state and states in the Soret absorption region of intercalated and externally groove-bound tautomers of H_2TMpyP4. The positions of the electronic origins support the assignment of the CD spectrum of the complex. From the shift of the C_β—H bending mode of the selectively excited resonance Raman spectra of tautomers of the porphyrin molecules it can be concluded that the pyridyl rings of externally bound H_2TMpyP4 molecules are twisted to a lesser degree than those rings for intercalated H_2TMpyP4. Raman intensity studies also reveal that the resonance-enhanced Raman intensity of modes of aggregated H_2TMpyP4 is greater than those of the monomer.

LIU YIXIAN, J. A. KONINGSTEIN et Y. YEVDOKIMOV. Can. J. Chem. **70**, 2413 (1992).

En se basant sur une étude des profils d'excitation de la résonance Raman des modes normaux du H_2TMpyP4, dans des solutions tamponnées contenant des molécules monomères et agrégées, et d'un complexe H_2TMpyP4/ADN avec $r(c) \sim 25$, on a déterminé les aspects de la structure électronique des tautomères de la tétrakis(*N*-méthyl-4-pyridyl)porphyrine (H_2TMpyP4) complexée avec l'ADN. On a attribué les maxima des profils d'excitation du complexe aux origines électroniques de la transition entre l'état fondamental et les états de la région d'absorption de Soret des tautomères de la H_2TMpyP4 intercalés et liés d'une façon externe. Les positions des origines électroniques sont en accord avec l'attribution du spectre CD du complexe. En se basant sur le déplacement du mode de déformation de la liaison C_β—H du spectre d'excitation de la résonance Raman des molécules de porphyrine, on peut conclure que les cycles pyridyles des molécules de H_2TMpyP4 liées d'une façon externe sont moins déformés que ceux des cycles correspondants des molécules de H_2TMpyP4 intercalées. Les études menées sur les intensités du spectre Raman révèlent aussi que l'intensité des spectres Raman rehaussés par la résonance est plus grande pour les modes des molécules de H_2TMpyP4 agrégées que pour ceux des monomères.

[Traduit par la rédaction]

Introduction

It is well known that the two inner hydrogen atoms (the NH protons) in free-base porphyrins exhibit tautomerization that results in protons being attached to different pairs of nitrogen atoms of the core. In symmetrical as opposed to asymmetrical porphyrins (1–4), the NH tautomers cannot be distinguished and have identical electronic spectra (1). The rate of tautomerization depends mainly on temperature and (or) whether the molecule resides in the ground state or an electronically excited state (1–3).

In this work we discuss the results of a resonance Raman study of the compound tetrakis(*N*-methyl-4-pyridyl)porphyrin (H_2TMpyP4). The structure of this symmetrical porphyrin molecule is different from the free-base porphyrin molecule in that four methylpyridyl groups are attached to diagonally opposed pyrrole rings, see Fig. 1. If dissolved in buffer solutions that contain DNA, complexes can be formed between the H_2TMpyP4 molecule and the large biological molecule. Depending on the concentration, porphyrin molecules intercalate and also become externally groove-bound to the double helix. The intercalated and groove-bound complexes have been extensively studied using various spectroscopic methods such as fluorescence (5, 6), circular dichroism (7, 8), linear dichroism (9), NMR (10), and resonance Raman spectroscopy (11–13). The H_2TMpyP4/DNA complexes are described by the $r(c)$ number, i.e., the concentration of base pairs of DNA relative to the total concentration of H_2TMpyP4.

According to the literature (6), the porphyrin molecule intercalates with DNA for $r(c) > 7000$; with a decrease in $r(c)$, porphyrins become externally groove-bound instead and an equilibrium distribution over the two sites occurs for $r(c) < 200$. Resonance Raman excitation profiles (RRP) of Raman bands in the electronic ground state give valuable information on the excited states of molecules. We have obtained RRP's of modes of H_2TMpyP4/DNA complexes that enable us to comment on the electronic states of tautomers for intercalated and externally bound porphyrin molecules.

Experimental

Instrumental

RRP's at a resolution of 1 nm were recorded using a Jobin–Yvon double monochromator for buffer solutions of H_2TMpyP4 and of H_2TMpyP4 with B-form DNA. The Raman spectra were excited with 7-ns pulses from a tunable dye laser (Lumonics model

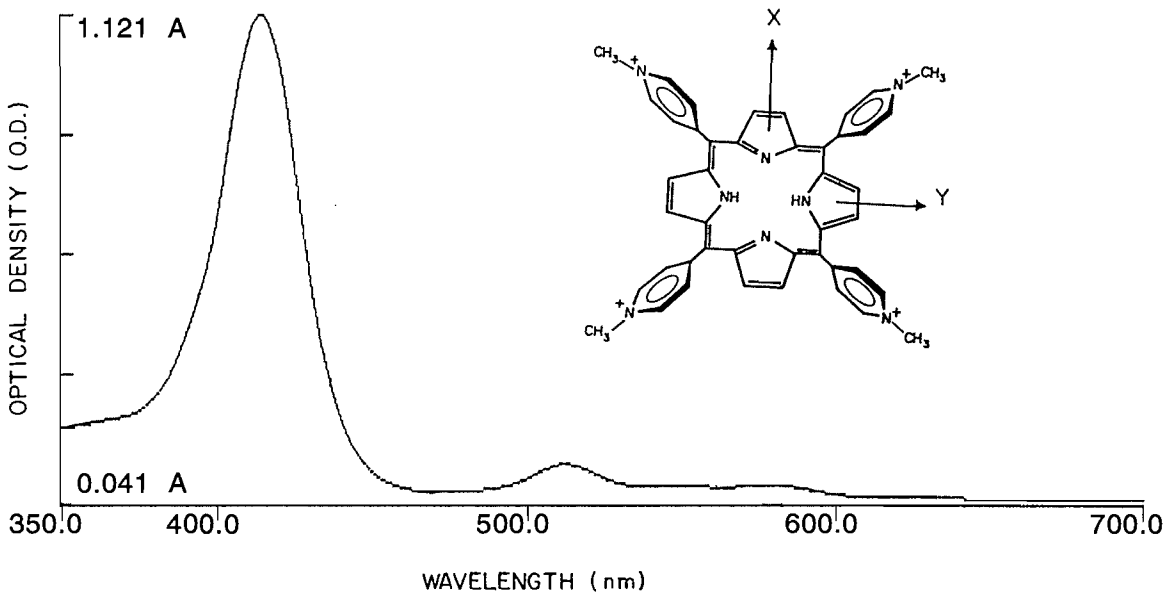

FIG. 1. Visible absorption spectrum of $H_2TMpyP4$ ($c = 1.5 \times 10^{-5}$ M) in buffer solution, and its chemical structure.

HYperDYE-300), which was pumped by an excimer laser (Lumonics model TE-430) operating at 25 Hz with a typical output of 4–7 mW. This radiation was used both focussed and unfocussed on the sample cell and the scattered light was observed at a 90° angle (4–7 cm^{-1} slit widths). Signals emerging from the exit slit of the monochromator were detected with a cooled RCA 31034 A photomultiplier tube (PMT). The output of the PMT was processed by a boxcar operating with a 3-ns gate (Stanford Research Associates models SR 250, 235, 275, and 245) and spectra were either recorded or stored in a computer.

Sample handling

Raman spectra were obtained from solutions that were prepared from a stock buffer solution containing $H_2TMpyP4$ and another stock solution of B-form DNA isolated from chicken blood erythrocytes (OD = 1.0 at 256 nm). The buffer solution (pH = 7) contained 0.01 M sodium phosphate, 0.3 M NaCl, and 1.47×10^{-3} M $H_2TMpyP4$. Fresh samples were prepared for each measurement and spectra were taken from solutions in air-tight cells. Spectroscopic data were obtained from monomeric as well as aggregated $H_2TMpyP4$ in solution and of $H_2TMpyP4$/DNA complexes with $r(c) \sim 25$. Earlier experiments (6)[3] for complexes in solutions with $r(c) \sim 25$ indicate that in addition to being intercalated or externally bound, a small amount of porphyrin remains in solution. However, the concentration of these free molecules is too small to be detected in the Raman spectra discussed below. All of the experiments were carried out at room temperature (20°C).

Results and discussion

Spectral aspects of $H_2TMpyP4$ in solution

The chemical structure and the absorption spectrum of $H_2TMpyP4$ in the visible spectral region is shown in Fig. 1. The molecule has D_{2h} symmetry and the planar aromatic structure enables the molecule to intercalate between adjacent base pairs of double-stranded nucleic acids without inducing major distortions to the B-form DNA. The principal absorption bands (9) of $H_2TMpyP4$ in the buffer solution are at 420 nm (Soret), 520 nm ($Q(y)$), and 580 nm ($Q(x)$). The fluorescence spectrum of the compound shows a rather broad band centered around 690 nm. The fluorescence lifetime $\tau(f)$ for $H_2TMpyP4$ in a buffer solution is ~5 ns and the rotational correlation time, $\tau(r)$, equals ~300 ps.[3] If excited with radiation of a laser tuned to the wavelength of the Soret band, the Raman spectrum of water as well as that of the porphyrin with shifts <1700 cm^{-1} is free from interference of the red fluorescence. The intensity of the Raman shift of water at ~3500 cm^{-1} is used as an internal standard to obtain the RRP of the porphyrin molecule in the ground state. Part of the Raman spectrum between 950 and 1700 cm^{-1} is shown in Fig. 2 while the assignment of the bands (13) is given in Table 1.

In our experiments, Raman spectra are obtained from 10^{-5} M solutions using pulsed radiation (7 ns duration, 25 Hz) from an excimer-pumped dye laser tuned to the Soret band. For a power level of 3 mW, the light source delivers 10^{13} photons/pulse to 10^{15} molecules in the irradiated volume (diameter of laser is 4 mm, length L of laser path is 1 cm). Thus, for an unfocussed laser beam, there are more molecules than photons. However, the number of molecules decreases to 3×10^{11} if the laser is focussed with a 10-cm lens and we find that the number of photons per pulse of 7 ns exceeds the number of molecules by a factor of 30. Therefore, once these photons are absorbed, then effective population saturation (via ground-state bleaching) of an excited state with a lifetime of >230 ps could take place. The effect of ground-state bleaching is to reduce the intensity of ground-state Raman scattering and as a result changes are expected in the contour of the RRP. These changes are expected to be most pronounced if the laser is tuned to the maximum of the Soret absorption band.

Figure 3*a* shows the RRP (unfocussed radiation) for a Raman band of $H_2TMpyP4$ at 1251 cm^{-1} together with the contour of the Soret absorption band. The Raman intensities are linear in laser intensity, yet if the laser beam is focussed in the solution with a 10-cm cylinder lens, a decrease is observed, see Fig. 3*b*, in the intensity of the Raman band for exciting radiation tuned to the region of 421–425 nm. The decrease is caused by the onset of ground-state bleaching.

If unfocussed laser radiation is used, bleaching does not occur and the contour of the RRP follows that of the Soret absorption band. With an increase in the concentration of the porphyrin molecule in the buffer solution, aggregates are formed (6). This is seen by comparing the absorption spectrum of the 3×10^{-5} M solution shown in Fig. 4 with that of the less concentrated solution in Fig. 3. The Soret band is broader and the center of the band is shifted from 415 to 420 nm. The RRP (unfocussed laser radiation) between 420 and 440 nm for the more concentrated solution is shown in Fig. 4. When Fig. 4 is compared to Fig. 3 for monomeric porphyrin, the

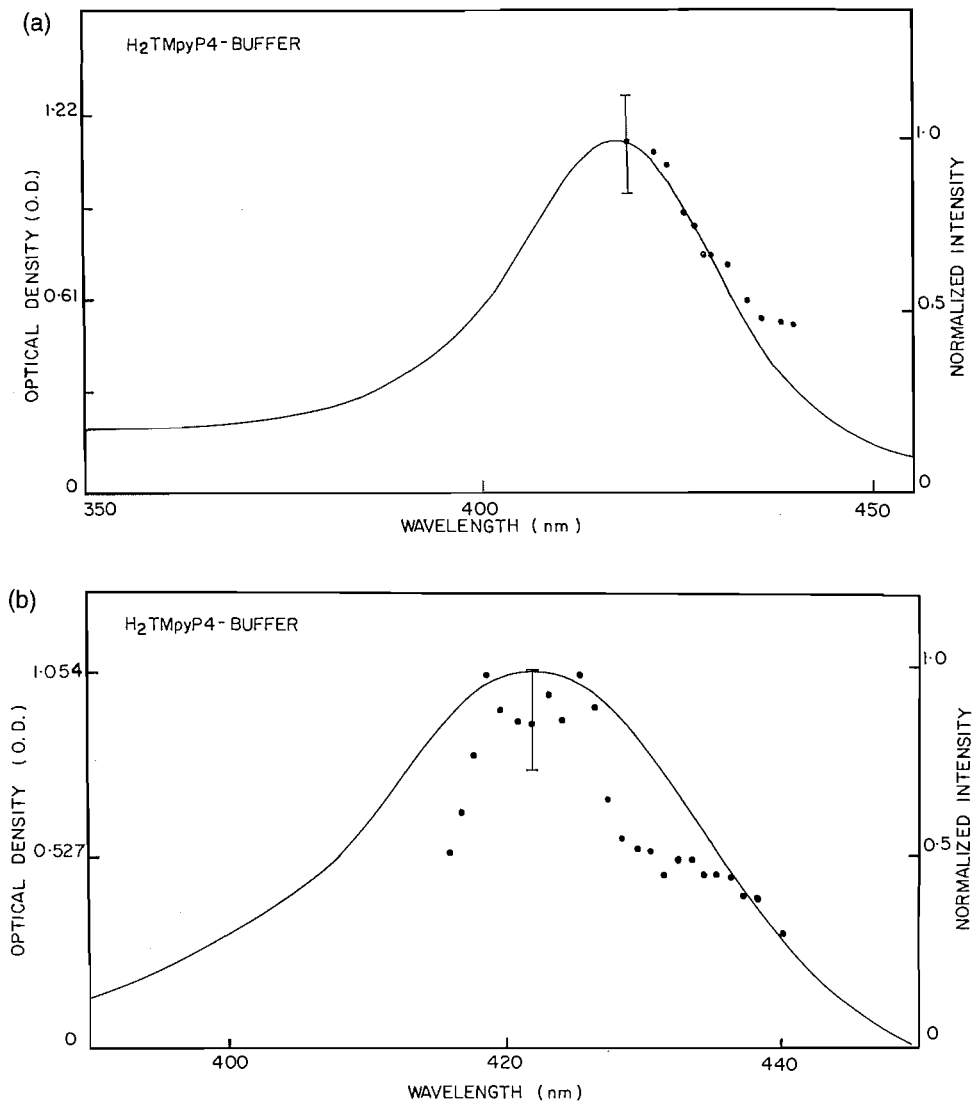

FIG. 3. (*a*) The resonance Raman excitation profile (dots) for the intensity of the shift at 1251 cm^{-1} for monomeric $H_2TMpyP4$ in buffer solution with concentration of 1.5×10^{-5} M in comparison to that of the contour of the Soret band. The data points are normalized at 420 nm, laser beam not focussed. (*b*) RRP for the intensity of the 1251 cm^{-1} band of monomeric $H_2TMpyP4$ in buffer solution with concentration of 1.5×10^{-5} M. Also shown is the absorption spectrum in the Soret band. A cylinder lens with $f = 10$ cm is used to excite the Raman spectra.

RRP is seen to be shifted to 431 nm. Within the spectral interval over which the RRP could be determined, no evidence is found for a maximum in the profile at 415 nm (for monomeric $H_2TMpyP4$). Thus we assign the enhancement of the intensity for excitation between 420 and 440 nm to resonance Raman scattering of aggregated porphyrin molecules in the buffer solution and conclude that the intrinsic intensity of Raman bands of the aggregate is greater than that of the monomeric $H_2TMpyP4$. The RRP does not indicate the presence of multiple maxima in case of a different electronic structure of the $H_2TMpyP4$ tautomers of the aggregate.

RRP and tautomeric structure of $H_2TMpyP4$/DNA complexes

The CD spectrum of a $H_2TMpyP4$/DNA complex with $r(c) \sim 10$ is shown in Fig. 5. As is well known (7, 8), the positive signal, which peaks at ~425 nm, is caused by porphyrin molecules that are externally groove-bound and the negative signal at ~431 nm is associated with the intercalated molecule. Figure 5 shows that the positive as well as the negative CD signals have side bands at 426 and 445 nm respectively. Compared to monomeric porphyrins, the broadened Soret band of the $H_2TMpyP4$/DNA complex is centered around 431 nm.

If excited with blue light, fluorescence from the complex is observed between 600 and 780 nm (5, 6). Time-resolved spectroscopy reveals (6, and footnote 3) that the emission is composed of contributions from both intercalated porphyrins peaking at 654 and 718 nm and externally bound porphyrins with bands at 667 and 725 nm for $r(c) > 50$, the fluorescence decay times being 10.0 ± 0.5 ns and 1.7 ± 0.2 ns, respectively. Preferential excitation of the fluorescence spectrum of intercalated porphyrins occurs if the laser radiation is tuned to 440 nm, while the emission of externally bound $H_2TMpyP4$ is stronger for radiation tuned to 415 nm.

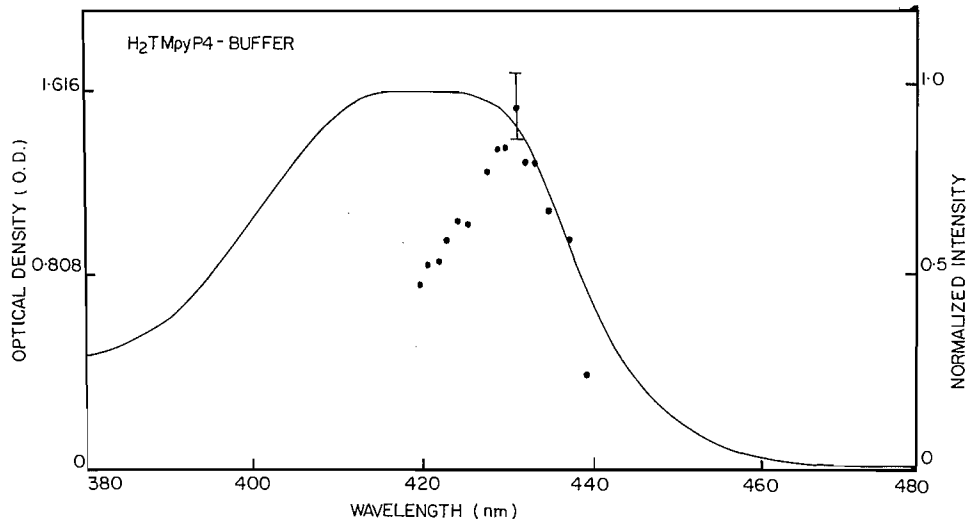

FIG. 4. RRP (dots) for a solution of $H_2TMpyP4$ ($c = 3 \times 10^{-5}$ M), which contains monomer as well as aggregates. The Soret band (see Fig. 3) is broadened towards longer wavelength and the dotted points are those for the intensity of the mode at 1251 cm^{-1} of an aggregate.

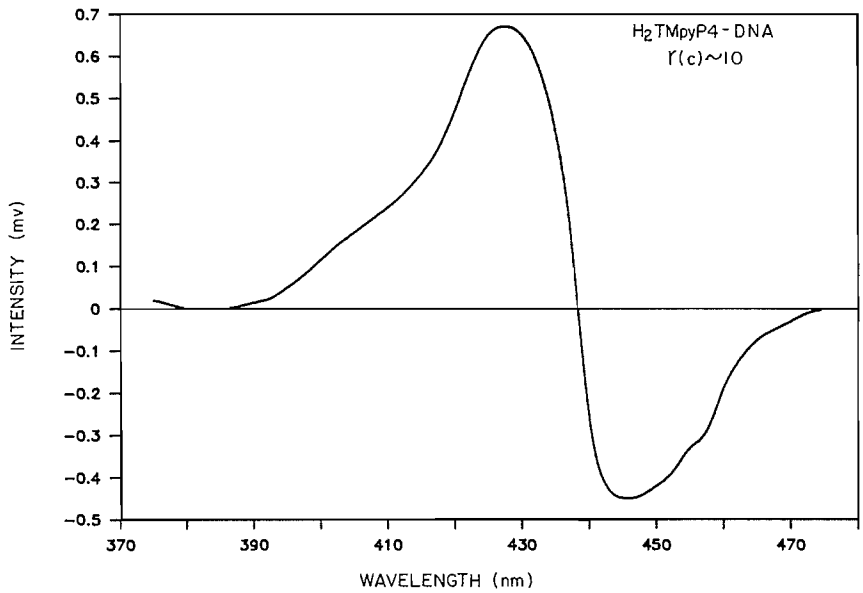

FIG. 5. The CD spectrum of a $H_2TMpyP4$/DNA complex in a buffer solution with $r(c) \sim 10$.

Although the absorption, CD, and time-resolved fluorescence spectra permit the assignment of transitions that originate in externally bound or intercalated porphyrin molecules, information on the spectroscopic signature of tautomeric structures of porphyrin of the $H_2TMpyP4$/DNA complex is not available. Resonance Raman excitation profiles for the intensity of normal modes of the ground state contain more information on the structure of the resonating electronic state than can be obtained from the contour of the absorption band, which is composed of transitions between the electronic surfaces of ground and (resonating) electronic states. The RRP of Fig. 6 for the intensity of the Raman band at 1251 cm^{-1} of the $H_2TMpyP4$ complex in comparison with the contour of the Soret absorption band is clearly no exception. As compared to the absorption band, the RRP shows maxima at four wavelengths. Table 1 shows the assignments of modes with shifts between 900 and 1650 cm^{-1} and, with the exception of the RRP of the band at 1100 cm^{-1}, all other modes follow the contour of the RRP of Fig. 6. Based on the interpretation of absorption spectra, CD spectra, and other information, we assign the maxima at 419 and 427 nm to electronic origins (which are hidden in the Soret band) for externally bound porphyrin molecules and the maxima of the profile at 433.5 and 441 nm to electronic origins of intercalated porphyrin molecules.

Molecular modelling (14) for porphyrin molecules that intercalate with DNA reveals that a rotation of the methylpyridyl (PYR) groups is required such that the rings become more parallel to the plane of the central core. For the free molecule, the two independent PYR rings of each half-

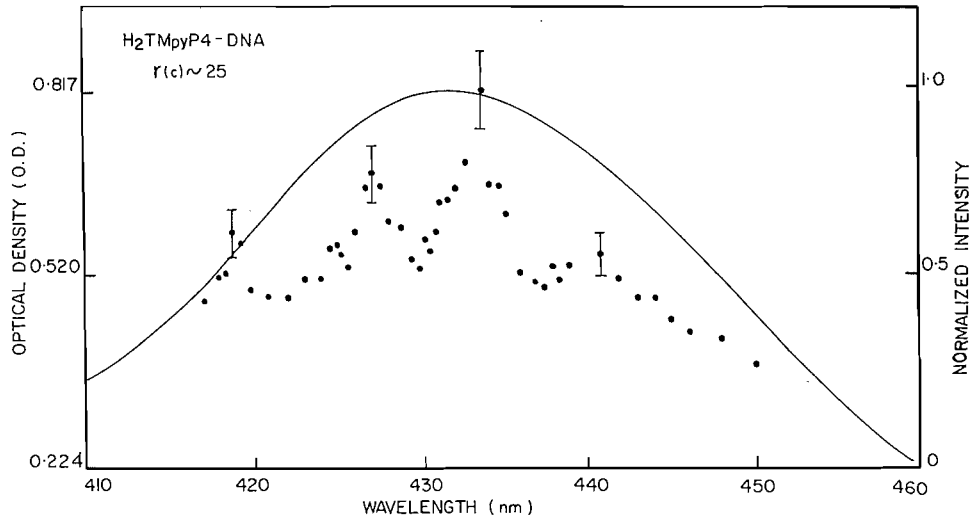

FIG. 6. The resonance Raman excitation profile for the intensity of the Raman band at 1251 cm^{-1} for a $H_2TMpyP4/DNA$ $r(c) \sim 25$ complex. Also shown is the contour of the Soret band of the complex.

molecule are inclined at 65.7° and 71.5° respectively with respect to the core (14). This suggests that the electronic structure for tautomers is identical because the protons are attached to nonadjacent core N atoms, resulting in a symmetrical configuration. Conversely, for intercalated porphyrins, the degree of rotation of the PYR rings does not have to be equivalent. In other words, the interaction of π-electrons of the core may not be symmetric about the pseudo fourfold rotation axis of the $H_2TMpyP4$ molecule, resulting in different electronic structures for the tautomers due to asymmetric configurations. The assignment is partially based on the discussion above and on results presented below but also on the fact that the maxima are at the same wavelength for a number of modes, which excludes the possibility that peaks in the profile at 427 and 419 nm are due to 1–0 vibronic side band resonances.

The existence of an asymmetric configuration for intercalated porphyrin becomes clear if the Raman spectra of Fig. 7 are compared with that of $H_2TMpyP4$ in the buffer solution. If excited with radiation at 441 and 434 nm, the positions of the shift of the C_β—H bending vibration of porphyrin (13) are at 1115 and 1135 cm^{-1} respectively. The corresponding and narrower Raman band of porphyrin in the buffer solution is at 1095 cm^{-1}. Rotation of the PYR rings towards the plane of the core, required for intercalation, results in larger shifts for the bending vibration. The shift of this mode for the tautomers does not have to be at the same position because nonequivalent force fields can exist for C_β—H bending modes in the asymmetric tautomeric half-molecules. It is relevant that the RRP of the mode is different from that of the other modes.

The RRP for the bending mode of externally bound porphyrin follows that of the other modes (Fig. 6) and the position of the Raman band of the tautomers does not change. The inclination of the PYR rings has not changed although the broadened Raman band suggests that small changes of the angles of inclination may exist among the externally bound porphyrin molecules.

The position of the maxima of the RRP's and the intensity of the C_α—C_m and C_α—N stretches at 1003 and 1365 cm^{-1}, respectively, yield information on the interaction of the π-electrons of the core with the different parts of the DNA molecule. In addition to the different positions of electronic origins (and thus different interaction for the π-electrons of the core), the RRP's reveal that the energy gap of the maxima for externally bound porphyrins is 447 cm^{-1}, in contrast to 392 cm^{-1} for intercalated $H_2TMpyP4$. These results may be correlated with data on intensity measurements where (within the experimental error) we find that the sum of the above-mentioned intensities of the modes with

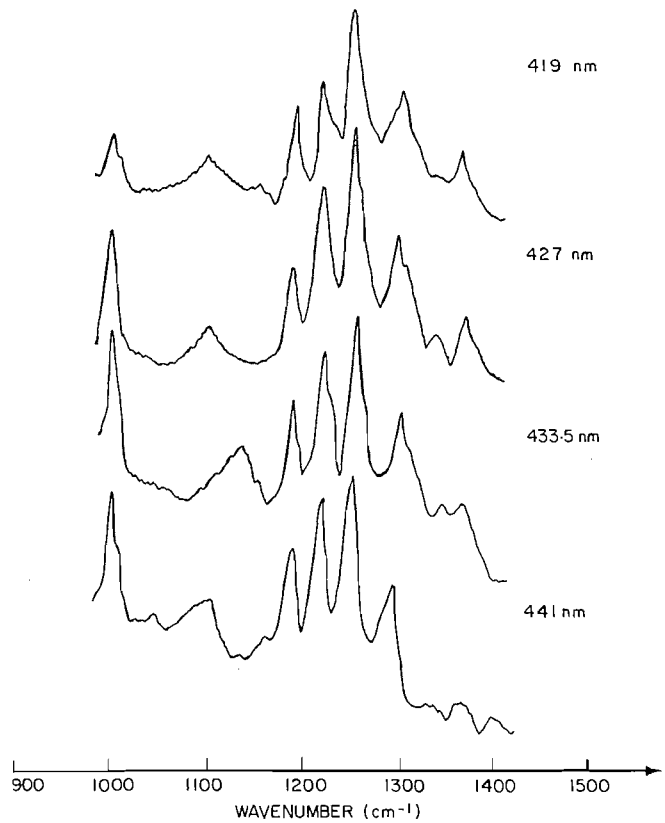

FIG. 7. Selectively excited resonance Raman spectra of the tautomers of intercalated (433.5 and 441 nm) and externally bound porphyrins (419 and 427 nm).

displacements along the conjugated path of the core is the same as that of the tautomers for intercalated, externally bound, and porphyrin in solution without DNA. However, the ratio R of these intensities for intercalated tautomers ($R = 5$) > externally bound tautomers ($R = 1.5$) > porphyrin in solution ($R = 0.66$).

Conclusions

Resonance Raman excitation profiles are reported for the intensity of normal modes of tetrakis(*N*-methyl-4-pyridyl)porphyrin in solution with and without B-form DNA. The RRP's of porphyrin/DNA complexes provide information on the position of electronic excited states of the tautomers of H_2TMpyP4 that are intercalated or externally bound to DNA. Part of the electronic structure of the tautomers has been discussed by comparing the resonance Raman studies with earlier data on fluorescence and CD absorption spectra.

From the position of a Raman shift of the C_β—H bending mode it is concluded that the pyridyl rings of the tautomers of intercalated H_2TMpyP4 are twisted to a larger degree than the rings of externally bound porphyrin.

Boron-11, boron-10, and nitrogen-14 NMR relaxation rates and quadrupole coupling constants in BH_3NH_3

GLENN H. PENNER,[1] STEPHEN I. DALEMAN,[2] AND ANGELA R. CUSTODIO

Department of Chemistry and Biochemistry, Guelph-Waterloo Centre for Graduate Work in Chemistry, University of Guelph, Guelph, Ont., Canada N1G 2W1

Received July 18, 1991[3]

GLENN H. PENNER, STEPHEN I. DALEMAN, and ANGELA R. CUSTODIO. Can. J. Chem. **70**, 2420 (1992).

The ^{11}B, ^{10}B, and ^{14}N spin–lattice relaxation times (T_1) for aqueous solutions of BH_3NH_3 were measured by NMR spectroscopy. The results of this investigation are consistent with the nuclear quadrupolar coupling constants reported in previous nuclear quadrupolar resonance and microwave studies. The activation energy associated with rotational reorientation of BH_3NH_3 in aqueous solution is 11.7 ± 0.6 kJ/mol. Electric field gradients were calculated at various levels of *ab initio* molecular orbital theory, in order to obtain theoretical ^{14}N and ^{11}B quadrupolar coupling constants. At the highest level of calculation (CI(SD)/6-31G**//MP2/6-31G**), these are in agreement with recently reported microwave results but not with previously reported NQR experiments.

GLENN H. PENNER, STEPHEN I. DALEMAN et ANGELA R. CUSTODIO. Can. J. Chem. **70**, 2420 (1992).

Faisant appel à la RMN, on a mesuré les temps (T_1) de relaxation spin–réseau du ^{11}B, du ^{10}B et du ^{14}N de solutions aqueuses de BH_3NH_3. Les résultats de nos travaux sont en accord avec les constantes de couplage quadripolaire nucléaire obtenues lors d'études de résonance quadripolaire nucléaire et de micro-ondes antérieures. L'énergie d'activation associée à la réorientation rotationnelle du BH_3NH_3 en solutions aqueuses est de 11,7 ± 0,6 kJ/mol. Dans le but de déterminer les constantes théoriques du couplage quadripolaire du ^{14}N et du ^{11}B, on a calculé les gradients de champs électriques à divers niveaux *ab initio* de la théorie des orbitales moléculaires. Les valeurs obtenues au niveau de calcul le plus élevé (CI(SD)6-31G**//MP2/6-31G**), sont en bon accord avec les valeurs rapportées récemment et basées sur les résultats de micro-onde; elles ne sont toutefois pas en accord avec les résultats antérieurs de RQN.

[Traduit par la rédaction]

Introduction

Since it was first synthesized and isolated by Shore and Parry (1, 2), the physical properties of borane ammoniate, BH_3NH_3 (amminetrihydroboron), have been investigated by many workers. The microwave spectra of nine isotopomers of BH_3NH_3 (substitution with ^2H, ^{10}B, and ^{15}N) have been measured. Analyses of these spectra have yielded the gas-phase geometry, dipole moment, and barrier to internal rotation (3, 4). Three crystal structure investigations have been reported (5–7). The most recent (7) suggests that there is an order–disorder phase transition in solid BH_3NH_3 at 225 K. Solution dipole moments have been studied (8) and the vibrational modes of BH_3NH_3 have been assigned (9). There is also an NQR study of BH_3NH_3 in which the ^{11}B and ^{14}N nuclear electric quadrupolar coupling constants have been reported (10). There have been numerous theoretical investigations of the molecular structure and the physical properties of BH_3NH_3, including studies of geometry (11–19), dipole moment (19–21), electric fields, electric field gradients, diamagnetic shielding and susceptibility (20), B—N bond dissociation energy (15–17), torsional barrier (14, 19), and vibrational frequencies (21).

The ^{11}B, ^{14}N, ^{15}N, and ^1H chemical shifts and spin–spin coupling constants in BH_3NH_3 have been measured in a number of solvents (22–27). The coupling constants have been compared with those calculated using the SOS–CI method (28). The only reported NMR relaxation study is a ^1H and ^{11}B T_1 investigation of the rotation of the BH_3 and NH_3 moieties about the B—N bond in solid BH_3NH_3 (29). In light of the fact that no ^{11}B, ^{10}B, or ^{14}N T_1 investigation of solvated BH_3NH_3 has been reported and that the quadrupolar coupling constants are now available for both the condensed phase (NQR) (10) and gas phase (microwave) (30), we have undertaken a ^{11}B, ^{10}B, and ^{14}N T_1 study of BH_3NH_3 in aqueous solution, together with high level *ab initio* molecular orbital calculations of the electric field gradients.

Theory

Boron-11, boron-10, and nitrogen-14 are quadrupolar nuclei with spins, I, of 3/2, 3, and 1, respectively. All three nuclei are expected to relax entirely by the quadrupolar mechanism (31). Under conditions of extreme narrowing the relaxation rate for a quadrupolar nucleus of spin I is given by [1], where

$$[1] \qquad R_1 = \frac{1}{T_1} = \frac{3\pi^2(2I+3)}{10I^2(2I-1)}\left(1+\frac{\eta^2}{3}\right)\chi^2\tau_c$$

τ_c is the integral of the reorientational correlation function, η is the asymmetry parameter, and χ is the quadrupolar coupling constant. The quadrupolar coupling constant is proportional to the quadrupolar moment, Q, which is a nuclear property, and the electric field gradient, q_{zz}, at the nucleus, which is a molecular property. Boron and nitrogen nuclei are expected to be in axially (cylindrically) symmetric environments in BH_3NH_3, thus η is zero. Substitution of the appropriate I values into eq. [1] yields eqs. [3]–[5] for ^{11}B, ^{10}B, and ^{14}N, respectively.

$$[2] \qquad \chi = \frac{e^2 q_{zz} Q}{h}$$

$$[3] \qquad R_1(^{11}B) = \frac{1}{T_1}(^{11}B) = \frac{2}{5}\pi^2\chi^2\tau_c$$

[1]Author to whom correspondence may be addressed.
[2]Undergraduate Research Participant, 1990–1991.
[3]Revision received May 14, 1992.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12

$$[4] \quad R_1(^{10}B) = \frac{1}{T_1}(^{10}B) = \frac{3}{50}\pi^2\chi^2\tau_c$$

$$[5] \quad R_1(^{14}N) = \frac{1}{T_1}(^{14}N) = \frac{3}{2}\pi^2\chi^2\tau_c$$

Although quadrupolar coupling constants cannot be obtained from T_1 measurements without explicit knowledge of τ_c, the ratios of χ^2 can be obtained if the two quadrupolar nuclei share the same reorientational correlation time, τ_c. The situation in which two or more nuclei lie on the molecular symmetry axis, and hence share the same reorientational correlation time, has been frequently exploited as an aid to analysis of T_1 data (32–38). This is the case for BH_3NH_3, where both boron and nitrogen nuclei lie on the molecular symmetry axis. The T_1 values can be related to the χ values through eq. [6].

$$[6] \quad \frac{T_1(^{14}N)}{T_1(^{11}B)} = \frac{4\chi^2(^{11}B)}{15\chi^2(^{14}N)}$$

Experimental

Samples of BH_3NH_3 were of commercial origin (Aldrich). These samples were of technical grade (~90%). Fortunately the impurities were insoluble in water and the spectra showed only the presence of BH_3NH_3. Because of this, concentrations of the prepared samples were only approximate. Approximately 1 M samples were prepared in D_2O and a 1:1 (by volume) mixture for ethylene glycol:methanol.

Spectra were obtained using a Varian UNITY-400 (B_0 = 9.4 T) NMR spectrometer. The T_1 measurements employed the inversion–recovery pulse sequence (39). The $\pi/2$ pulse widths were as follows: 8.4 μs for ^{11}B, 24.0 μs for ^{10}B (both using a 5 mm probe), and 78 μs for ^{14}N (using a 10 mm probe). Typically 8 scans at each variable delay, $d2$, in the inversion–recovery experiment were carried out. All T_1 values were calculated using between 9 and 15 different delay ($d2$) values. All experiments were performed in duplicate or triplicate.

Molecular orbital calculations were performed using GAUSSIAN 90 (40) on a Silicon Graphics Power Series 8 computer.

Results and discussion

Boron-11 relaxation

The ^{11}B spin–lattice relaxation times for a 1 M solution of BH_3NH_3 in D_2O at several temperatures are given in Table 1. The temperature dependence of the ^{11}B spin–lattice relaxation time is given by eq. [7],

$$[7] \quad \ln T_1 = \frac{-1439(37)}{T} + 1.53(61)$$

where the numbers in parentheses are standard deviations obtained from a linear regression analysis. The slope corresponds to an activation energy for molecular reorientation of 12.0 ± 0.3 kJ/mol. This can be compared to a value of 10.6 ± 0.9 kJ/mol for an aqueous solution of the isoelectronic species $CH_3NH_3^+$ (41).

To calculate τ_c values from T_1 data, a value for the ^{11}B quadrupolar coupling constant is required. Nuclear quadrupolar coupling constants are often strongly dependent on the intermolecular interactions present. In the gas phase the value for $\chi(^{11}B)$ is 2.584 MHz (30), whereas the solid state value is 1.504 MHz (9). These probably represent the upper and lower limits to $\chi(^{11}B)$. The corresponding τ_c values are given in Table 1. Boron-11 T_1 values at several concentrations are given in Table 2. Reducing the concentration of BH_3NH_3 in D_2O to 0.1 M yields essentially no change in T_1 (39.5 ms) and increasing the concentration to 4 M caused a small decrease in T_1 of only 1.9 ms. A very slow evolution of gas, presumably hydrogen due to molecular decomposition, was observed at the highest temperature and at concentrations above 4 M. As a result these were the upper limits for temperature and concentration.

[a]Estimated error is ±1 K.
[b]Estimated error is less than 5%.
[c]Columns A and B calculated using the $\chi(^{11}B)$ value from NQR and MW experiments, respectively.

tional reorientation is 12.1(5) kJ/mol, in excellent agreement with the value obtained from the temperature dependence of the ^{11}B T_1 values.

Using the τ_c values from the ^{11}B NQR and $^{11}BT_1$ measurements (Table 1) and the T_1 values for ^{10}B (Table 3) yields a χ value for ^{10}B of 3.11 ± 0.04 MHz (the average of 6 values). The quadrupolar coupling constants for different isotopes of the same nucleus are related through their quadrupole moments, Q, according to eq. [9] (42–46).

$$[9] \quad \frac{\chi(^{10}B)}{\chi(^{11}B)} = \frac{Q(^{10}B)}{Q(^{11}B)}$$

The quadrupole moments of ^{10}B and ^{11}B are 0.085×10^{-28} m^2 and 0.041×10^{-28} m^2, respectively (47). Using the NQR value of $\chi(^{11}B)$ the ratio of quadrupole moments predicts a $\chi(^{10}B)$ value of 3.118 ± 0.021 MHz, in excellent agreement with that obtained from our ^{10}B T_1 measurements. Equation [9] predicts a $\chi(^{10}B)$ value of 5.34 MHz for BH_3NH_3 in the gas phase.

Nitrogen-14 relaxation

The ^{14}N T_1 values for 1 M BH_3NH_3 in D_2O at several temperatures are given in Table 4. The nitrogen-14 quadrupolar coupling constants are calculated for the three lowest temperatures, where ^{14}N and ^{11}B experiments were performed at the same temperature (within probe temperature error limits). The $\chi(^{11}B)$ values, as obtained from NQR and MW experiments, were used together with ^{11}B and ^{14}N T_1 measurements to calculate $\chi(^{14}N)$. The values of $\chi(^{14}N)$ using the MW data and NQR $\chi(^{11}B)$ values are well within experimental error of those directly measured by MW and NQR. The ratio of $\chi^2(^{11}B)$ to $\chi^2(^{14}N)$ predicted by our T_1 measurements is 1.49. This is in excellent agreement with the ratios of 1.44 and 1.48 obtained from NQR and MW experiments. Therefore our T_1 results are consistent with both nuclear quadrupolar resonance and microwave spectroscopic results. For a molecule such as BH_3NH_3 T_1 measurements in the high temperature extreme narrowing regime allow only the determination of the ratio of nuclear quadrupolar coupling constants. The absolute values of the quadrupolar coupling constants can be obtained from the T_1 minimum. Unfortunately the samples of BH_3NH_3 in D_2O froze before the T_1 minimum was reached. Nitrogen-14 T_1 measurements were also performed on a 1 M sample for BH_3NH_3 in 1:1 ethylene glycol:methanol but the T_1 values fell below the limits of our spectrometer (100 μs) before a T_1 minimum was reached. In aqueous solution the NH_3 hydrogens undergo rapid exchange with the solvent, as shown by the lack of NH_3 proton coupling to ^{14}N, ^{11}B, or ^{10}B and by the lack of a ^3J(BH, NH) coupling in the proton spectrum. Exchange of the NH protons may affect the ^{14}N relaxation via the scalar coupling mechanism of the first kind (31, 39). It is much more common for scalar relaxation to affect T_2 (and hence the linewidth) than T_1. The dominance of the ^{14}N spin–lattice relaxation by the quadrupolar interaction is confirmed by the excellent agreement of ^{11}B and ^{14}N T_1 measurements with eq. [6]. The results presented here suggest that, at the temperatures studied, molecular reorientation is the dominant pathway for ^{14}N relaxation.

TABLE 5. *Ab initio* MO calculations of the electric field gradients at the boron and nitrogen nuclei of BH_3NH_3 and boron-11 and nitrogen-14 quadrupolar coupling constants.

[a]Calculated using eq. [11] and Q values of 0.041×10^{-28} m^2 for ^{11}B and 0.0193×10^{-28} m^2 for ^{14}N (47).
[b]From ref. 30.
[c]Taken from ref. 10; only absolute values are available.

A plot of ln T_1 as a function of inverse temperature is best fit by the linear equation [10].

$$[10] \quad \ln T_1 = \frac{-1335(97)}{T} + 0.29(30)$$

The corresponding activation energy is 11.0 ± 0.8 kJ/mol, in good agreement with the values obtained from the ^{11}B and ^{10}B data.

Electric field gradient calculations

Electric field gradients (EFG's) at the boron and nitrogen of BH_3NH_3, calculated at the STO-3G, 6-31G**, MP2/6-31G**, and CI(SD)/6-31G** //MP2/6-31G** levels are given in Table 5. The quadrupolar coupling constant, χ (in MHz), can be related to the nuclear quadrupole moment, Q (in units of 10^{-28} m^2), and the electric field gradient, q_{zz}, at the nucleus (in atomic units) by eq. [11] (49).

$$[11] \quad \chi = -237Qq_{zz}$$

We have chosen the most recent experimental Q value for ^{14}N (48), which agrees closely with the latest molecular orbital calculations (49, 50). The χ values calculated from the molecular orbital generated q_{zz} values (the largest EFG) are also given in Table 5.

The χ values calculated at the MP2/6-31G** level are in

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 109.225.110.28 on 09/08/12
For personal use only.

very good agreement with the gas-phase experimental values but are a factor of about 1.7–1.8 larger in magnitude than the solid state values. A single point calculation at the CI(SD)/6-31G** level yielded little change in $\chi(^{11}B)$ but increased the magnitude of $\chi(^{14}N)$ slightly. Our calculations and the gas-phase microwave results are also in very good agreement with previous *ab initio* calculations of $\chi(^{11}B)$ and $\chi(^{14}N)$ (52). Molecular orbital calculations of nuclear quadrupolar coupling constants are usually in good agreement with gas-phase experimental values if the calculations are performed with second-order correlation effects taken into account (49, 50, 52).

Conclusions

The spin–lattice relaxation times for ^{14}N, ^{11}B, and ^{10}B in aqueous solutions of BH_3NH_3 are completely dominated by the quadrupolar mechanism. Measurements of T_1 as a function of temperature for ^{14}N, ^{11}B, and ^{10}B yield a set of results that are consistent with both NQR and MW experiments and predict an effective activation energy for reorientation of the B—N bond of 11.7 ± 0.6 kJ/mol. It is interesting to note that although the T_1 measurements provide only the ratios of the ^{14}N and ^{11}B quadrupolar coupling constants these values are in excellent agreement with the ratios for *both* the gas phase (microwave) and solid state (NQR) quadrupolar coupling constants. Unfortunately, T_1 minima and hence absolute values of $\chi(^{11}B)$, $\chi(^{10}B)$, or $\chi(^{14}N)$, could not be obtained. *Ab initio* molecular orbital calculations yield nuclear quadrupole coupling constants that are in excellent agreement with the values obtained from microwave spectroscopy experiments. The NQR values of $\chi(^{11}B)$ and $\chi(^{14}N)$ are about a factor of 1.8 smaller.

Received February 10, 1992

STEVEN M. SOCOL, CHIHAE YANG, DEVON W. MEEK, and ROBERT GLASER. Can. J. Chem. **70**, 2424 (1992).

The chelating tritertiary phosphine $C_6H_5P(CH_2CH_2CH_2P(C_6H_{11})_2)_2$ (Cyttp) in octahedral six-coordinate iridium(III) complexes $[IrH_2Z(Cyttp)]^{(0\text{ or }1+)}$ (Z = Cl, CO, CH_3CN, and related ligands) is meridionally bound. The conformation of the Cyttp ligand is such that the phenyl group of the central phosphorus lies out of the meridional plane. This leads to diastereomers in which the Z group is *syn* or *anti* to the phenyl group in question. These diastereomers were readily characterized by a general nuclear Overhauser effect difference NMR technique involving an intensity change to the apical-hydrido absorbance *syn*-to-phenyl upon irradiation of phenyl-*ortho* protons. A single diastereomer, *cis-anti-mer*-[IrH_2Cl(Cyttp)] (**6***a*), was prepared by (*a*) refluxing $[IrCl(COD)]_2$ and Cyttp in ethanol or (*b*) treatment of [IrCl(COD)(Cyttp)] in benzene with excess dihydrogen. The stereochemical course for ligand substitution reactions on **6***a* was determined using the Cyttp phenyl group as a stereochemical label. Of six chloro-ligand metathesis reactions performed on *cis-anti-mer*-[IrH_2Cl(Cyttp)] (**6***a*), four gave mixtures of the two *cis-syn-mer-/cis-anti-mer*-$[IrH_2Z(Cyttp)]^{(0\text{ or }1+)}$ diastereomers (Z = CH_3CN, CN, PMe_2Ph, and $P(OCH_2)_3CEt$), one gave inversion only (the *cis-syn-mer* compound (Z = CO)), and only one gave retention (*cis-anti-mer*-[IrH_2I(Cyttp)]. A dissociative mechanism is proposed for the substitution reactions. Loss of stereochemical integrity in **6***a* was also observed in other reactions. Insertions of CS_2 into the iridium–meridonal-hydride bond and $SnCl_2$ into the iridium–chlorine bond produced mixtures of *cis-syn-mer/cis-anti-mer* diastereomers. Electrophiles ($C_7H_7^+$ in the presence of CH_3CN, I_2, HCl, and HOAc in the presence of Tl^+) attack only the meridonal hydride to yield various ratios of geometric and (or) *syn/anti* isomers. Trends in the relative chemical shifts of the hydride protons and ^{31}P nuclei in *syn* versus *anti* isomers are noted and rationalized.

STEVEN M. SOCOL, CHIHAE YANG, DEVON W. MEEK et ROBERT GLASER. Can. J. Chem. **70**, 2424 (1992).

La phosphine chélatante tritertiaire $C_6H_5P(CH_2CH_2CH_2P(C_6H_{11})_2)_2$ (Cyttp) présente dans les complexes hexa-coordonnés octaédriques de l'iridium(III) $[IrH_2Z(Cyttp)]^{(0\text{ ou }1+)}$ (Z = Cl, CO, CH_3CN et autres ligands apparentés) est liée d'une façon méridionale. La conformation du ligand Cyttp est telle que le groupe phényle du phosphore central ne se trouve pas dans le plan méridional. Cette situation conduit à l'existence de diastéréoisomères dans lesquels le groupe Z est soit *syn* ou *anti* par rapport à ce phényle. La RMN permet de caractériser facilement ces diastéréoisomères grâce à une différence générale d'effet Overhauser nucléaire impliquant un changement d'intensité d'absorption de l'hydrure apical *syn* par rapport au phényle lorsqu'on irradie les protons *ortho* du phényle. Nous avons préparé un diastéréoisomère spécifique, le *cis-anti-mer*-[IrH_2Cl(Cyttp)] (**6***a*), (*a*) par chauffage au reflux du $[IrCl(COD)]_2$ avec du Cyttp dans l'éthanol ou (*b*) par traitement du [IrCl(COD)(Cyttp)] en solution dans le benzène avec un excès de dihydrogène. Nous avons déterminé la stéréochimie des réactions de substitution du ligand sur le composé **6***a* en utilisant le groupe phényle comme sonde stéréochimique. Parmi les six réactions de métathèse réalisées sur le *cis-anti-mer*-[IrH_2Cl(Cyttp)] (**6***a*), quatre ont conduit à des mélanges des deux diastéréoisomères *cis-syn-mer-/cis-anti-mer*-$[IrH_2Z(Cyttp)]^{(0\text{ ou }1+)}$ (Z = CH_3CN, CN, PMe_2Ph et $P(OCH_2)_3CEt$. Une autre n'a conduit qu'à une inversion (conduisant au produit *cis-syn-mer* (Z = CO)) et une seule a donné lieu à une rétention de configuration *cis-anti-mer*-[IrH_2I(Cyttp)]. On propose un mécanisme dissociatif pour les réactions de substitution. Nous avons également observé une perte d'intégrité stéréochimique de **6***a* dans d'autres réactions. Les insertions de CS_2 dans la liaison iridium–hydrure méridional et de $SnCl_2$ dans la liaison iridium–chlore conduisent à des mélanges des diastéréoisomères *cis-syn-mer/cis-anti-mer*. Les électrophiles ($C_7H_7^+$ en présence de CH_3CN, I_2, HCl et HOAc en présence de Tl^+) n'attaquent que l'hydrure méridional et fournissent des rapports variés d'isomères géométriques et (ou) *syn/anti*. Nous avons noté et rationalisé des differences des déplacements chimiques entre les protons des hydrures et des noyaux de ^{31}P dans divers isomères *syn* vs. *anti*.

[Traduit par la rédaction]

Previously we (1) and others (2) have reported the syntheses of some iridium(III) dihydride complexes of Cyttp, $C_6H_5P(CH_2CH_2CH_2P(C_6H_{11})_2)_2$, **1** (3), and ttp = $C_6H_5P(CH_2CH_2CH_2P(C_6H_5)_2)_2$, **2** (4, 5), (bis((3-di(cyclohexyl or phenyl)-phosphino)propyl) phosphine). The tridentate Cyttp ligand **1** was found to be meridonally bound in the octahedral iridium(III) complexes by NMR spectroscopic and single crystal X-ray diffraction techniques (1*a*, 6). Similar results were obtained for ttp **2** (2, 7). Two isomers are possible for octahedral complexes of ttp-type ligands which have the formula *apical* (*H*,*Z*)-[MHYZ(L-L-L)]. These isomers are described as being *syn* or *anti*, and are defined by analogy to the procedure used for olefinic *E*,*Z* diastereomers (8). In this method, the Cahn–Ingold-Prelog sequence rule (9) is used to classify the relative priority of the two *apical* ligands. The *syn* diastereomer is defined as that in which the highest priority *apical* ligand and the phenyl group are both

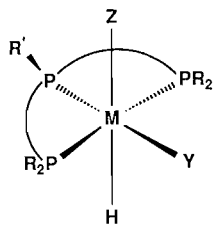
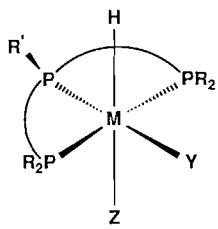
on the same side of the three-phosphorus reference plane. The *anti*-diastereomer is defined as that in which these moieties are located on opposite sides of the reference plane. By this definition, **3** is a *syn* diastereomer, whereas **4** is an *anti* diastereomer.



3

Syn **diastereomer**



4

Anti **diastereomer**

Triphosphine ligand = $R_2P(CH_2)_3PR'(CH_2)_3PR_2$

This type of isomerism was first noted in a series of six-coordinate ruthenium(II) complexes of ttp: *cis-syn-mer-/cis-anti-mer-/trans-mer*-[RuH($P(OMe)_3)_2$(ttp)][BF_4], **5** (7). Configurational assignments for **5** were made on the basis of ^1H and ^{31}P {^1H} NMR spectroscopy (*cis* vs. *trans*), and single crystal X-ray diffraction analysis of one of the *cis*-diastereomers (*syn* vs. *anti*) (7). This type of isomerism has also been proposed for some octahedral iridium(III) and rhodium(III) complexes which contain the triphosphine ligand *t*-BuP($CH_2CH_2CH_2PPh_2)_2$ and some ruthenium(II) hydride complexes which contain Cyttp (10). We have previously shown that the *syn/anti* configuration in octahedral metal complexes of Cyttp can be determined via a relatively facile and general nuclear Overhauser effect (difference NOE (11)) technique (1*a*, 10*c*).

This paper reports the syntheses of iridium(III) complexes **6***a–i*, **7***a–c*, **8***a–c* and their ^1H and ^{31}P NMR spectral parameters. It will be shown that a number of ligand substitution and insertion reactions on *cis-syn-mer*-[IrH_2Cl(Cyttp)] **6***a* proceed with a loss of configurational integrity of the starting material. In addition, this paper demonstrates that some of the NMR parameters of the diastereomeric products of these reactions show correlations with their *syn/anti* configurations.

Experimental

Elemental analyses were preformed by MHW Laboratories, Phoenix, AZ. Infrared spectra were recorded on a Perkin–Elmer 283B spectrophotometer. Proton NMR spectra (11.7 T) were recorded in acetone-d_6 solution (except when noted otherwise) at 500 MHz on a Bruker AM-500 Fourier transform spectrometer (equipped with an Aspect 3000 data system) at The Ohio State University Chemical Instrument Center. ^{13}C NMR spectra (11.7 T) were recorded in dichloromethane-d_2 solution at 125 MHz on the above-mentioned Bruker AM-500 spectrometer. Deuterated solvents were used for internal lock and the carbon or residual protio-solvent resonances were used as internal secondary references (relative to tetramethylsilane). ^{31}P NMR spectra (2.1 T) were recorded in acetone solution (except when noted otherwise) at 36.43 MHz on a Bruker HX-90 Fourier transform spectrometer. For ^{31}P NMR spectra, an acetone-d_6 solution of trimethyl phosphate [$(CH_3O)_3P{=}O$] in a coaxial tube was used for deuterium lock and a secondary ^{31}P reference (1.549 ppm relative to 85% H_3PO_4), respectively. The ^{31}P NMR spectra of isomer mixtures were assigned by comparing signal intensity ratios with the ^1H NMR. In **6***g,h* the assignments of the ^{31}P NMR spectra were made by means of ^1H {sel ^{31}P} NMR techniques. For all NMR spectra, negative chemical shifts are upfield from the respective reference standards. Protons were decoupled from the carbon and phosphorous nuclei by broad-band irradiation. NOE experiments were performed in the difference NOE mode. Iteration calculations and simulated NMR spectra were calculated with the use of the PANIC program (12). PANIC is a microcomputer version of the LAOCOON (13) program. All reactions were carried out under an atmosphere of high purity nitrogen by using standard Schlenk techniques. Solutions of air-sensitive reagents were transferred between reaction vessels with syringes flushed with nitrogen, stainless steel needles, or a glass transfer tube equipped with a

Teflon stopcock. Solvents were purged with nitrogen for 30 min prior to use. Iridium trichloride trihydrate (Matthey Bishop Inc. or Englehard Industries, Inc.), ethereal tetrafluoroboric acid (Cationics Inc.), dimethylphenylphosphine (Aldrich Chemical Co.), and 1,5-cyclooctadiene (Aldrich Chemical Co.) were purchased from commercial sources and used as received. Bis((3-di(cyclohexyl)-phosphino)propyl)phenylphosphine (Cyttp, **1**) was prepared as previously described (3). $[IrCl(COD)]_2$ (14) and $P(OCH_2)_3CEt$ (15) were prepared by literature methods.

*[IrCl(COD)(Cyttp)], **12***

To a solution of $[IrCl(COD)]_2$ (300 mg, 0.45 mmol) in benzene was added a 0.25 M benzene solution of **1** (3.6 mL, 0.90 mmol). The solution changed color from red to yellow upon stirring for 0.5 h. After removal of the solvent *in vacuo*, the residual yellow solid was suspended in hexane, collected on a frit, washed with hexane, and dried *in vacuo* to yield 531 mg (64%) of **12**; ^1H NMR (C_6D_6) δ: 8.0–7.0 (m, 5H, aromatic H), 3.9 (m, 4H, olefinic H), 3.0–0.7 (m, 64H, aliphatic H); $^{31}P\{^1H\}$ NMR (C_6D_6) δ: −7.8 (s, free Cy_2P), −23.1 (d, bound Cy_2P, J_{PP} 42 Hz), −27.5 (d, bound Ph*P*, J_{PP} 42 Hz). Anal. calcd. for $C_{44}H_{73}ClIrP_3$: C 57.28, H 7.98, Cl 3.84; found: C 56.88, H 8.28, Cl 4.05.

cis-anti-mer-*[IrH_2Cl(Cyttp)]*, **6**a

*Method A (1*a*)*

To a solution of $[IrCl(COD)]_2$ (500 mg, 0.74 mmol) in absolute ethanol (50 mL) was added a 0.25 M benzene solution of **1** (6.0 mL, 1.5 mmol). Upon heating to reflux 2 h, the solution changed color from red to yellow. After removal of the solvent *in vacuo*, the residue was dissolved in dichloromethane (30 mL), and absolute ethanol (30 mL) was added. A solid separated upon removal of most of the dichloromethane under reduced pressure. The solid was collected on a frit, washed with ether, and dried *in vacuo* to yield 490 mg (40%) of **6***a*.

Method B

A benzene solution of **12** (1.62 mmol) was prepared *in situ* by the method described above and stirred for 0.5 h. Hydrogen gas was bubbled into the reaction mixture over a period of 2 h. After removal of the solvent *in vacuo*, the residue was dissolved in tetrahydofuran (30 mL). A solid separated upon repeated treatments consisting of addition of absolute ethanol (30 mL), followed by removal of half the solvent under reduced pressure. The solid was collected on a Schlenk frit, and dried *in vacuo* to yield 529 mg (40%) of **6***a*. Infrared, ^1H, and $^{31}P\{^1H\}$ NMR spectral analysis showed this material to be identical in all respects to that produced by method A. Anal. calcd. for $C_{36}H_{63}ClIrP_3$: C 52.94, H 7.78, Cl 4.34; found: C 53.13, H 7.67, Cl 4.07.

cis-anti-mer-*[IrD_2Cl(Cyttp)]*

The reaction vessel and a syringe were rinsed with deuterium oxide and baked in an oven at 100°C for several hours. After evaporation *in vacuo* of a 0.25 M benzene solution of **1** (2.00 mL, 0.50 mmol) for 12 h, the oily residue was dissolved in ethanol-d_6 (2 ML), combined with $[IrCl(COD)]_2$ (167 mg, 0.25 mmol), and stirred for 1 day. The solvent was evaporated *in vacuo* and the residue was washed with acetone-d_6 and dried *in vacuo* to yield 162 mg (40%) of the title compound; ^2H NMR (C_6H_6) δ: −8.9 (d, *mer*-D, $^2J_{PD}$ 19 Hz), −22.0 (s, *apical*-D).

mer-*[IrH_3(Cyttp)]·C_2H_5OH, **6**b·*EtOH*

Method A

To a solution of $[IrCl(COD)]_2$ (206 mg, 0.31 mmol) in absolute ethanol (20 mL) was added a 0.25 M benzene solution of **1** (2.5 mL, 0.62 mmol), followed by a solution of KOH (50 mg, 0.89 mmol) dissolved in absolute ethanol (20 mL). The solution gradually changed color from red to cream. After stirring overnight, the white precipitate was filtered on a frit, and recrystallized (tetrahydrofuran/absolute ethanol) to give 224 mg (44%) of **6***b* as monoethanolate solvate.

Method B

To a solution of **6***c* (15 mg, 0.018 mmol) in tetrahydrofuran (20 mL) was added $NaBH_4$ (30 mg, 0.27 mmol). The mixture was allowed to stir for 20 min after which ethanol (10 mL) was added and the mixture allowed to stir for an additional 1 h. The solvent was removed under reduced pressure. Tetrahydrofuran (10 mL) was added to dissolve the product. After filtration, a ^{31}P NMR spectrum of the crude product showed complete conversion to **6***b*. Anal. calcd. for $C_{36}H_{64}IrP_3 \cdot C_2H_5OH$: C 55.10, H 8.52, Cl 0.00; found: C 54.52, H 8.76, Cl trace.

Mixture of cis-syn-mer- *and* cis-anti-mer-*[$IrH_2(CH_3CN)$(Cyttp)] [BF_4]*, **6**c

To a suspension of **6***a* (332 mg, 0.400 mmol) in CH_3CN (10 mL) was added $TlBF_4 \cdot 6H_2O$ (166 mg, 0.421 mmol). The reaction was allowed to stir for 2 h, during which time **6***a* reacted and went into solution and TlCl precipitated. The mixture was then filtered. The filtrate was evaporated *in vacuo* and the residue was washed with water and then dried *in vacuo* to yield 234 mg (63%) of **6***c*. The ^1H NMR spectrum revealed the presence of *cis-syn-mer* and *cis-anti-mer* isomers in 3:2 ratios, respectively. Anal. calcd. for $C_{38}H_{66}BF_4IrNP_3$: C 50.22, H 7.32, N 1.54; found: C 50.07, H 7.41, N 1.76.

cis-syn-mer-*[$IrH_2(CO)$(Cyttp)][BF_4]*, **6**d

To a solution of **6***a* (0.26 g, 0.32 mmol) and $TlBF_4 \cdot 6H_2O$ (0.12 g, 0.30 mmol) in tetrahydrofuran (30 mL) a slow stream of CO bubbles was introduced for a period of 3 h. The solution was then purged with N_2 for 15 min. The TlCl was removed by filtration, after which the solvent was removed under reduced pressure. The product, **6***d*, was separated from the starting material **6***a* by extraction of **6***d* with acetone. The acetone was removed under reduced pressure and the product was washed with water and recrystallized from acetone/ether to yield 0.10 g (35%) of **6***d*. Anal. calcd. for $C_{37}H_{63}BF_4IrOP_3$: C 49.61, H 7.09, P 10.37; found: C 49.78, H 7.29, P 10.10.

cis-anti-mer-*[IrH_2I(Cyttp)]*, **6**e

Method A

To a solution of **6***a* (152 mg, 0.19 mmol) in tetrahydrofuran (50 mL) was added solid NaI (1.30 g, 8.67 mmol). After stirring 4 h, the solvent was removed *in vacuo* and the residue was dissolved in benzene (30 mL). After filtering on a frit, absolute ethanol (60 mL) was added and a solid separated. Evaporation of the solvent *in vacuo* gave 144 mg (85%) of **6***e*.

Method B

To a solution of $[IrCl(COD)]_2$ (200 mg, 0.30 mmol) in acetone (15 mL) was added a solution of NaI (90 mg, 0.60 mmol) in acetone (10 mL). The resulting deep-purple slurry was stirred for 2 h, the solvent was removed *in vacuo*, and the residue was dissolved in benzene (10 mL). After filtering on a frit, half the solvent was removed *in vacuo*, and a solid separated upon addition of excess ether. The solid was collected on a frit, washed with acetone and then ether, and then dried *in vacuo* (0.1 Torr (1 Torr = 133.3 Pa)) to afford 133 mg (52%) of $[IrI(COD)]_2$ as an intermediate product. Starting with $[IrI(COD)]_2$, the same method B as for **6***a* yielded 40% of the title compound. Infrared, ^1H, and $^{31}P\{^1H\}$ NMR spectral analysis showed this material to be identical in all respects to that produced by method A. Anal. calcd. for $C_{36}H_{63}IIrP_3$: C 47.62, H 7.01, I 13.98; found: C 47.55, H 7.08, I 13.76.

Mixture of cis-syn-mer- *and* cis-anti-mer-*[$IrH_2(CN)$(Cyttp)]*, **6**f

To a solution of **6***a* (266 mg, 0.28 mmol) in a mixture of tetrahydrofuran (30 mL) and 95% ethanol (30 mL) was added KCN (602 mg, 0.24 mmol). After stirring for 12 h, the solvent was removed *in vacuo*, the residue was dissolved in benzene, and the solution was filtered. Upon addition of a 1:1 mixture of 95% ethanol/water, a solid separated. The solid was collected on a frit and dried *in vacuo* to give 154 mg (69%) of **6***f*. The ^1H NMR spectrum revealed the presence of *cis-syn-mer* and *cis-anti-mer* isomers in 1:9 ratio respectively. Anal. calcd. for $C_{37}H_{63}IrNP_3$: C 55.07, H 7.87, N 1.74; found: C 54.91, H 7.89, N 1.77.

Mixture of cis-syn-mer- *and* cis-anti-mer-*[$IrH_2(P(OCH_2)_3CEt)(Cyttp)$][$BF_4$]*, **6**g*

To a solution of **6***a* (300 mg, 0.37 mmol) in tetrahydrofuran (25 mL) was added $TlBF_4 \cdot 6H_2O$ (150 mg, 0.38 mmol) followed by $P(OCH_2)_3CEt$ (75 mg, 0.46 mmol). After stirring for 3 h, during which time TlCl precipitated, acetone (25 mL) was added and the mixture was filtered. The filtrate was evaporated *in vacuo* and the residue was washed with water and then recrystallized (acetone/ether) to give 299 mg (79%) of **6***g*. The ^{1}H NMR spectrum revealed the presence of *cis-syn-mer* and *cis-anti-mer* isomers in 2:1 ratio, respectively. Anal. calcd. for $C_{42}H_{74}BF_4IrO_3P_4$: C 52.53, H 7.43, P 12.32; found: C 52.46, H 7.45, P 12.09.

Mixture of cis-syn-mer- *and* cis-anti-mer-*[$IrH_2(SnCl_3)(Cyttp)$]*, **6**i*

To a solution of **6***a* (100 mg, 0.12 mmol) in dichloromethane (40 mL) was added anhydrous $SnCl_2$ (24 mg, 0.13 mmol). After stirring for 3 h, the mixture was filtered and the solvent was removed *in vacuo*. The solid was suspended in hexane, collected on a frit, washed with hexane, and dried *in vacuo* to yield 80 mg (65%) of **6***i*. The ^{1}H NMR spectrum revealed the presence of *cis-syn-mer* and *cis-anti-mer* isomers in 3:2 ratio, respectively. Anal. calcd. for $C_{36}H_{63}Cl_3IrP_3Sn$: C 42.98, H 6.31, Cl 10.57; found: C 42.88, H 6.10, Cl 10.80.

cis-anti-mer-*[$IrHCl_2(Cyttp)$]*, 7*a

To a solution of **6***a* (100 mg, 0.122 mmol) in tetrahydrofuran (20 mL) was added 1 mL of 6 M aqueous HCl. The solution was allowed to stir for 3 h. After removing the solvent under reduced pressure and washing with hexanes, 85 mg (81%) of 7*a* was obtained. Anal. calcd. for $C_{36}H_{62}Cl_2IrP_3$: C 50.82, H 7.34, Cl 8.33; found: C 51.00, H 7.42, Cl 8.19.

Mixture of cis-syn-mer- *and* cis-anti-mer-*[$IrH(CS_2H)(Cyttp)$][AsF_6]*, 7b

To a solution of **6***a* (184 mg, 0.23 mmol) in tetrahydrofuran (25 mL) was added $TlAsF_6 \cdot 6H_2O$ (120 mg, 0.24 mmol) followed by CS_2 (5 mL). The solution immediately became yellow in color as TlCl precipitated. After stirring for 20 min, most of the solvent was removed under a stream of nitrogen and the remainder was removed *in vacuo*. Acetone (25 mL) was added to the residue, the mixture was filtered, and the solvent was removed *in vacuo*. The residue was washed with water, dried *in vacuo*, and recrystallized (acetone/ether) to give 179 mg (76%) of 7*b*. The ^{1}H NMR spectrum revealed the presence of *cis-syn-mer-* and *cis-anti-mer* isomers in 7:3 ratio, respectively. Anal. calcd. for $C_{37}H_{63}AsF_6IrP_3S_2$: C 42.48, H 6.07, S 6.13; found: C 42.29, H 6.10, S 6.00.

cis-syn-mer-*[$IrH(O_2CCH_3)(Cyttp)$][AsF_6]*, 7c

To a solution of **6***a* (85 mg, 0.10 mmol) in tetrahydrofuran (30 mL) was added $TlAsF_6 \cdot 6H_2O$ (53 mg, 0.11 mmol) followed by glacial acetic acid (0.50 mL, 8.7 mmol). After stirring for 0.5 h, the solvent was removed *in vacuo*, the residue was extracted with acetone (30 mL), and the solvent volume was reduced to about 10 mL under a stream of nitrogen. A solid separated upon addition of excess ether. The solid was filtered, washed with water, and dried *in vacuo* to give 71 mg (66%) of 7*c*. Anal. calcd. for $C_{38}H_{65}AsF_6IrO_2P_3$: C 44.36, H 6.38, F 11.08; found: C 45.14, H 6.42, F 11.41.

apical(H,CH_3)-anti-mer-*[$IrH(CH_3)(CO)(Cyttp)$][BPh_4]*, **8**a

A solution of $[IrCl(COD)]_2$ (541 mg, 0.81 mmol) and $AgBF_4$ (378 mg, 1.94 mmol) in absolute ethanol (25 mL) was heated gently for 5 min and the precipitated AgCl was removed by filtration. A 0.25 M benzene solution of **1** (6.5 mL, 1.63 mmol) was added to the filtrate and the solution was refluxed for 1 h. The solution changed color from red to pale yellow. The solid which separated upon addition of excess $NaBPh_4$ (750 mg, 2.19 mmol) was collected on a frit, washed with absolute ethanol, recrystallized from CH_2Cl_2/ethanol, and dried *in vacuo* to give 600 mg (32%) of **8***a*. Anal. calcd. for $C_{62}H_{85}BIrOP_3$: C 65.19, H 7.50, P 8.13; found: C 64.68, H 7.49, P 7.79.

Mixture of apical(H,Cl)-syn-mer-, *and* apical(H,I)-syn-mer-, apical(H,Cl)-anti-mer-, *and* apical(H,I)-anti-mer-*[$IrHCl(Cyttp)$]*, **8**b*

A solution of **6***a* (100 mg, 0.12 mmol) and iodine (40 mg, 0.16 mmol) in tetrahydrofuran (20 mL) was stirred for 1 h. The resultant precipitate was collected on a frit, washed with acetone, and dried *in vacuo* to yield 88 mg (76%) of **8***b*. The ^{1}H NMR spectrum revealed the presence of two *apical(H,X)-syn-mer* and two *apical(H,X)-anti-mer* isomers in (1:1):(7:11) ratio, respectively. Anal. calcd. for $C_{36}H_{62}ClIIrP_3$: C 45.88, H 6.63, I 13.47; found: C 45.76, H 6.55, I 13.29.

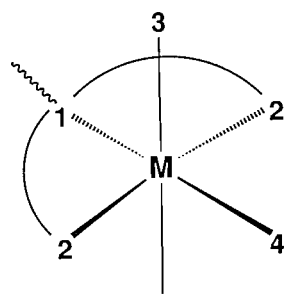
Mixture of apical(H,Cl)-syn-mer, *and* apical(H,CH_3CN)-anti-mer-*[$IrHCl(CH_3CN)(Cyttp)$][BF_4]*, **8**c*

A solution of $C_7H_7BF_4$ (35 mg, 0.20 mmol) in CH_3CN (20 ml) was added to a solution of **6***a* (150 mg, 0.18 mmol) via a stainless steel needle. The resulting mixture was stirred for 5 h after which the solvent was evaporated *in vacuo*. The product was redissolved in methylene chloride and filtered. The solution volume was reduced to 5 mL and the product was precipitated upon the addition of Et_2O to yield 112 mg (64%) of **8***c*. Anal. calcd. for $C_{38}H_{65}BClF_4IrNP_3$: C 48.38, H 6.95, N 1.48; found: C 48.23, H 6.68, N 1.31.

Results and discussion

Determination of syn-/anti *configuration*[5]

The configurational assignment of complexes **6**–**8** was based on ^{1}H NMR spectroscopic analysis of the heteronuclear AMRX$_2$ five-spin system (diagram **9**). The *apical-* and *mer*-hydrido protons (nuclei 3 and 4, respectively) are readily differentiated on the basis of their respective geminal heteronuclear coupling constants to phosphorus. For the *apical*-hydrido proton, the two heteronuclear coupling constants ($^2J_{13}$ and $^2J_{23}$) are with *cis*-coupled nuclei. For the *mer*-hydrido proton, this relationship is true for only one coupling constant ($^2J_{24}$), whereas the other ($^2J_{14}$) arises from a *trans* internuclear relationship and, as such, is expected to be considerably larger in magnitude (16). The *syn-/anti*-configurational orientation of nucleus 3 vis-a-vis the phenyl group was determined by nuclear Overhauser effect (difference NOE) experiments involving irradiation of the phenyl-ring *ortho* protons (nuclei 5 and 6), see diagrams **10** and **11**. Typical NOE intensity enhancements for nucleus 3 were ca. 5–7% (5, 6).



9

[5]The *cis* and *mer* descriptors will be eliminated for simplicity and only the *syn/anti* descriptors for Ir-Cyttp complexes **6**, **7** will be used from now on in the text. All the six-coordinate iridium(III) Cyttp complexes discussed in this paper have *cis* stereochemistry. Since all the complexes **6**–**8** discussed in this paper have *mer*-coordinated Cyttp ligands, the *mer* descriptors will also be eliminated for simplicity in the case of complexes **6**–**8**.

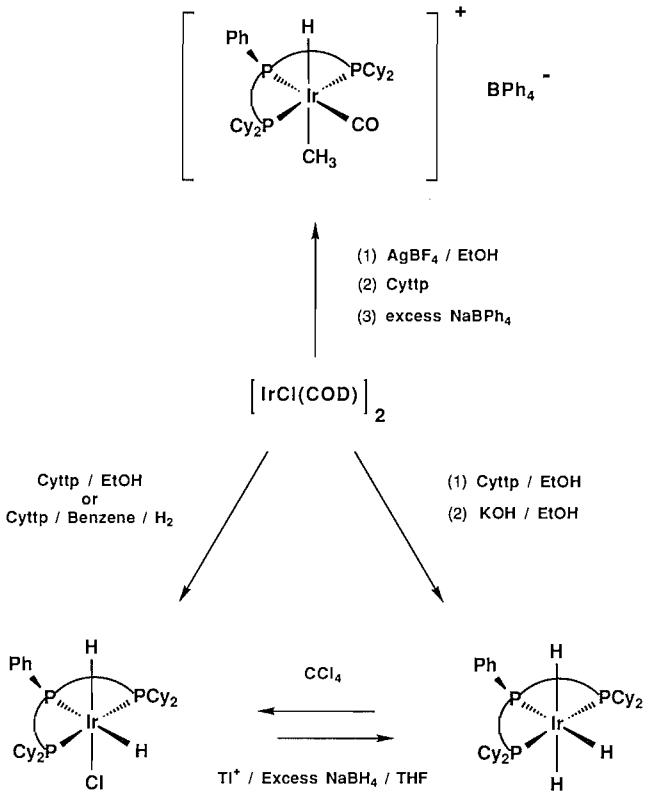
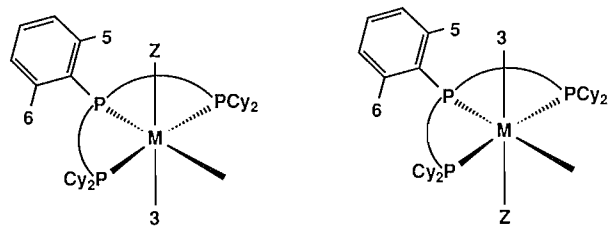


SCHEME 1



10 11

The two signals at δ ca. 8.1 and δ ca. 7.6 (ratio 2:3, respectively) in 500 MHz ^{1}H NMR spectra of complexes **6–8** were assigned to the *ortho* and *meta/para* aromatic protons, respectively. Only for the *anti* configuration (diastereomer **11**) is a NOE expected for nucleus 3 upon irradiation of nuclei 5 and 6 (11). It is noted that the analogous ttp complexes are not amenable to NOE {Ph–H} determination of *syn/anti* configuration, since ttp has phenyl groups on both sides of the meridional plane.

Preparation of complexes

Scheme 1 illustrates syntheses routes for *anti*-[IrH_2Cl(Cyttp)], ***6a***. We have previously reported that ***6a*** can be prepared directly by treating $[IrCl(COD)]_2$ with Cyttp in boiling ethanol (1*a*). The dideuteride analogue can be prepared by reacting $[IrCl(COD)]_2$ with Cyttp in ethanol-d_6. We have also found that ***6a*** can be synthesized by a two-step procedure in which the five-coordinate complex [IrCl(COD)(Cyttp)], **12**, is prepared as an intermediate by the reaction of $[IrCl(COD)]_2$ with Cyttp in benzene. This compound can be isolated as a yellow solid. The ^{31}P NMR of **12** shows only two of the three phosphorus atoms of the ligand are bound to iridium. An analogous five-coordinate iridium(I) complex, [IrCl(COD)$(PMe_3)_2$] has previously been reported (17). One of the two terminal phosphorus atoms in **12** is unbound (−7.8 ppm) and shows the value as the corresponding unbound phosphorus in [$PtMe_2$(Cyttp)] (18). Treatment of **12**, generated *in situ*, with H_2 gas also produced only one dihydride complex, *anti*-[IrH_2Cl(Cyttp)] ***6a***.

It was previously reported by Dahlenburg and co-workers (2) that treatment of $[IrCl(C_8H_{14})_2]_2$ with ttp in toluene resulted in complete displacement of the monodentate olefin ligand to yield the four-coordinate iridium(I) complex [IrCl(ttp)]. Introduction of hydrogen gas into a toluene solution of [IrCl(ttp)] produced an unspecified isomer of *cis-mer*-[IrH_2Cl(ttp)] (2). We found that [IrCl(Cyttp)] prepared in an analogous manner was somewhat unstable and forms a compound which we have so far been unable to characterize.[6,7] Preliminary results indicate, however, that the addition of H_2 to benzene solutions of [IrCl(Cyttp)] produced both *syn*- and *anti*-[IrH_2Cl(Cyttp)].[7]

Reaction of $[IrCl(COD)]_2$ with an ethanolic solution of $AgBF_4$, filtration of the AgCl precipitate, followed by addition of the Cyttp ligand resulted in the isolation of one diastereomer of the [$IrH(CH_3)$(CO)(Cyttp)][BPh_4] complex, ***8a***, upon treatment of the reaction mixture with $NaBPh_4$. The configuration of this diastereomer was determined by multinuclear NMR spectroscopy to be *apical(H,CH_3)-antimer*. The hydrido proton was found to be in an *apical* orientation on the same side of the three-phosphorus atom reference plane as the phenyl ring by ^{1}H NMR difference NOE spectroscopy. The carbonyl group, which is seen both in IR and ^{13}C NMR spectra, is *trans* to phosphorus on the basis of the large $^2J_{PC}$ coupling constant. The sixth ligand site (*trans* to the hydride) is occupied by a methyl group as evidenced by ^{13}C NMR DEPT (19) experiments (positive intensity versus ca. null in 135° versus 90° pulse-width spectra). The very high-field (−33.61 ppm) methyl carbon signal is consistent with CH_3 bound to a platinum metal (20). Abstraction of carbon monoxide from boiling alcoholic solvents by phosphine complexes of platinum metals has been well documented (21). The removal of chloride from iridium apparently opens up a site for decarbonylation to take place. The facility of the reaction in this case is most unusual.

The trihydride complex *mer*-[IrH_3(Cyttp)], ***6b***, was prepared by reaction of ligand with $[IrCl(COD)]_2$ followed by treatment with ethanolic KOH. Single crystal X-ray diffraction studies of ***6b*** · EtOH confirm the presence of three hydrides in a *mer* configuration (6). Structural constraints imposed by a chelating ligand can be an important factor in promoting isomer stability, as shown by the fact that only ^{1}H NMR resonances attributable to the *mer*-isomer ***6b*** were noted in C_6D_6 solution (*vide infra*) as opposed to [$IrH_3(PPh_3)_3$] which shows *mer/fac* isomerization in the same solvent (22).

Iridium–hydride reactivity

The reaction conditions and product stereochemistry of complexes discussed in this and in the following section are summarized in Table 1. Early workers in iridium(III) hydride chemistry found that hydrido ligands *trans* to phosphorus ligands are labile to attack by mineral acids, whereas hydride ligands *trans* to chloro ligands are stable (22, 23). For example, it was noted that *cis-mer*-[$IrH_2Cl(PEt_2Ph)_3$]

[a]All reactions were performed in THF, unless noted otherwise, and at ambient temperature.
[b]Solvent = CH_3CN.
[c]Solvent blend = 95% EtOH/THF (1:1).
[d]Solvent = CH_2Cl_2.
[e]X = Cl or I.

reacted with HCl in ethanol to yield *cis-mer*-[$IrHCl_2(PEt_2Ph)_3$] (22). Likewise, we have found that the addition of aqueous HCl to THF solutions of *anti*-[IrH_2Cl(Cyttp)] (**6***a*) produced only one diastereomer, *anti*-[$IrHCl_2$(Cyttp)], **7***a*, in a stereoselective manner.

On the other hand, the reaction of *anti*-[IrH_2Cl(Cyttp)], **6***a*, with an electrophilic reagent, I_2, afforded four products. Partial configurational assignments of the two major *apical(H,Cl)/apical(H,I)-anti* isomers (54%, 34%) and of the two minor *apical(H,Cl)/apical(H,I)-syn* isomers (7%, 5%) of [IrHClI(Cyttp)], **8***b*, were made on the basis of ^{1}H NMR spectroscopy. In a mixed sample containing all four species, the single hydrido signal from each of the four diastereomers exhibited only *cis* $^2J_{HP}$ coupling constants characteristic of *apical*-hydrido ligands, whereas only the apical protons in the two major species showed NOE intensity enhancement (5 (6)).

The reaction of *anti*-[IrH_2Cl(Cyttp)] **6***a* with the electrophile $C_7H_7^+$ in CH_3CN solution forms two products of the formulation *mer*-[$IrHCl(CH_3CN)$(Cyttp)][BF_4] **8***c*. The major (>80%, $\delta_{H(3)} = -20.30$) and minor ($\delta_{H(3)} = -20.40$) products both show an NOE intensity enhancement for the *apical* hydride {$H_{phenyl\text{-}ortho}$} in solution. These isomers are thus assigned as geometric isomers in which either Cl or CH_3CN is *trans* to the hydride. Since it has been shown here and elsewhere (22, 23) that hydride ligands *trans* to phosphorus ligands tend to be inert, it is most likely that the hydride ligand attacked is the hydride ligand which is initially *trans* to chlorine, and the two geometric isomers are formed via a five-coordinate intermediate. Ciani and co-workers (24) have previously proposed that the substitution of metal hydrides with $C_7H_7^+$ in the presence of donor species takes place by a two-step mechanism in which the first step is the abstraction of the H^- ligand.

Transition-metal complexes which contain labile ligands are known to insert CS_2 (25). For example, the reaction of $IrH_3(PPh_3)_3$ with CS_2 in benzene produced $IrH_2(S_2CH)(PPh_3)_2$ (26). It was found that *anti*-[IrH_2Cl(Cyttp)] (**6***a*) did not react with refluxing CS_2, most likely due to the tendency of the chelating triphosphine ligand not to dissociate (26). However, introduction of $TlAsF_6$ to a solution of **6***a* and CS_2 in THF at ambient temperature resulted in the formation of 2:1 *syn-/anti*-[$IrH(S_2CH)$(Cyttp)][AsF_6], **7***b*. The existence of the dithiofomate moiety was confirmed by signals in the ^{1}H NMR spectrum (acetone-d_6) at δ 13.9 and δ 14.2 for the dithioformyl proton in the *syn* and *anti* diastereomer, respectively (25).

Lack of an NOE suggested the *syn* configuration for the single [$IrH(O_2CCH_3)$(Cyttp)][AsF_6] diastereomer, **7***c*, stereoselectively formed from the reaction of *anti*-[IrH_2Cl(Cyttp)] **6***a*, $TlAsF_6$, and acetic acid in THF. Configurational inversion in the product was confirmed by single-crystal X-ray diffraction analysis which indicated that the acetato ligand was bound to both the *mer* position and to an *apical* site on the same side as the phenyl moiety vis-a-vis the three-phosphorus atom reference plane.[8]

The monohydrido products **7** and **8** discussed above all share a common structural feature; the hydrido ligand is always found in an *apical* binding site. The *syn/anti* configurations, however, varied. In the single diastereomeric product [$IrHCl_2$(Cyttp)] (**7***a*) the *anti* geometry was retained. On the other hand, in the single diastereomeric product [$IrH(O_2CCH_3)$(Cyttp)][AsF_6] **7***c*, an inversion to the *syn* configuration was noted. Finally, in the case of [IrHClI(Cyttp)] **8***b* and [$IrH(HCS_2)$(Cyttp)][AsF_6] **7***b* products, stereochemical integrity was lost as evidenced by the appearance of both *syn* and *anti* species.

Metal hydride complexes are also known to react with halogenated solvents to form the corresponding metal chlorides (27). When [IrH_3(Cyttp)] **6***b* was dissolved in CCl_4 in an NMR tube at ambient temperature, *anti*-[IrH_2Cl(Cyttp)] **6***a* and *anti*-[$IrHCl_2$(Cyttp)] **7***a* were formed in a 4:1 ratio as shown by the $^{31}P\{^1H\}$ NMR spectrum recorded after 15 min. At room temperature *anti*-[IrH_2Cl(Cyttp)] **6***a* was found to be surprisingly stable in CCl_4, although it was found that refluxing for four h resulted in ca. 20% conversion to *anti*-[$IrHCl_2$(Cyttp)] **7***a*. It is significant that syntheses by multiple routes (three for **6***a* and two for **7***a*) afforded the same chloro ligand containing iridium(III) complexes only in the *anti* configuration. In light of the generally observed loss of

starting material configurational integrity (e.g., **7***b*,*c* and **8***b*), this apparent stereoselectivity for **6***a* and **7***a* is likely to reflect a thermodynamic bias.

Iridium–chloride bond reactivity

Previously we have reported that the iridium–chloride bond in *anti*-[IrH_2Cl(Cyttp)] **6***a* can be metathesized by CO, CH_3CN (both in the presence of $TlBF_4$), and I^- in THF solution to form products with differing stereochemical configurations (the single *syn* diastereomer of [IrH_2(CO)(Cyttp)][BF_4] (**6***d*); a 3:2 mixture of *syn*/*anti* diastereomers of [IrH_2(CH_3CN)(Cyttp)][BF_4] (**6***c*); and only the single *anti* diastereomer of [IrH_2I(Cyttp)] (**6***e*) (1*a*)). Other metathesis reactions were investigated in which the chloro ligand was replaced by cyanide, $P(OCH_2)_3CEt$, or PMe_2Ph.

In contrast to the metathesis of *anti*-[IrH_2Cl(Cyttp)] (**6***a*) by iodide in THF, reaction with cyanide (in THF/95% EtOH (1:1)) afforded a mixture of *syn*-/*anti*-[IrH_2(CN)(Cyttp)] diastereomers, **6***f*, in a ratio of ca. 1:9, respectively. Diastereomeric product mixtures were also observed when $P(OCH_2)_3CEt$ or PMe_2Ph were reacted with THF solutions of **6***a* in the presence of $TlBF_4$. In the case of the [IrH_2($P(OCH_2)_3CEt$)(Cyttp)][BF_4] (**6***g*) reaction product, the *syn*/*anti* ratio was ca. 2:1, respectively, whereas for [IrH_2(PMe_2Ph)(Cyttp)][BF_4] (**6***h*) the ratio was ca. 3:4, respectively.

Acetonitrile coordinated to iridium(III) has been shown to be somewhat labile (28, 29) and replaceable by stronger ligands (30). Accordingly it was found that the addition of $P(OCH_2)_3CEt$ to a THF solution of a ratio 3:2 of *syn*-/*anti*-[IrH_2(CH_3CN)(Cyttp)][BF_4] (**6***c*) resulted in the displacement of CH_3CN to form the corresponding **6***g* complex (*syn*-*anti* ratio ca. 2:1). The mixture of *syn*-/*anti*-[IrH_2($P(OCH_2)_3CEt$)(Cyttp)][BF_4] diastereomers (**6***g*) was found to be stable overnight in CH_3CN. The CH_3CN ligand in the diastereomeric mixture of **6***c* did not exchange noticeably overnight in acetone, THF, or ethanol solutions. This is in accordance with reports by Moore and co-workers (28) that coordinated acetone is 10^5 times more labile than coordinated acetonitrile in complexes of the $[IrH_2(PPh_3)_2(solvent)_2]^+$ type and the work of Crabtree *et al.* (29) which showed that CH_3CN is more strongly bound in these complexes than is acetone, THF, ethanol, or water.

We have previously shown that the acetonitrile ligand in both diastereomers of [IrH_2(CH_3CN)(Cyttp)][BF_4] (**6***c*), *syn*/*anti* ratio of 1:2, can be metathesized by bubbling CO gas into the THF solution to yield only the *syn* diastereomer of [IrH_2(CO)(Cyttp)][BF_4] (**6***d*) (1*a*). The same single *syn* isomer of **6***d* is also formed by the direct treatment of *anti*-[IrH_2Cl(Cyttp)] with $TlBF_4$ and CO bubbled into the THF solvent (1*a*). The configurational characterization of the *syn* diastereomer **6***d* was made on the basis of the lack of an NOE between hydride and phenyl and subsequently confirmed by single crystal X-ray diffraction analysis.[8] The presence of only the single *syn* diastereomer **6***d* suggests that a common intermediate arises from both the *syn*- and the *anti*-[IrH_2(CH_3CN)(Cyttp)][BF_4] **6***c* starting materials.

In contrast to the reactions of RuH_4(Cyttp) with neutral monodentate ligands, where steric factors seem to determine the stereochemistry of the initial complexes formed (10*c*), the factors which determine the stereochemical outcome of the substitution reactions reported herein are not obvious, although the fact that inversion does sometime take place is indicative of a dissociative mechanism in which the configurational integrity of the starting material is lost. The fact that the addition of Tl^+ facilitates these reactions supports this conclusion. A dissociative mechanism has previously been proposed for solvent exchange with $[Ir(PR_3)_2(solvent)_2H_2]^+$ (28). Although the fact that *syn*-[IrH_2CO(Cyttp)]$^+$ is synthesized stereospecifically by two routes suggests a thermodynamic bias, the relative importance of thermodynamic and kinetic factors in the remainder of the substitution reactions is unclear.

The iridium–chlorine bond in *anti*-[IrH_2Cl(Cyttp)] (**6***a*) can be reduced with $NaBH_4$ to produce [IrH_3(Cyttp)] **6***b*. The trihydride complex, **6***b*, is also produced by the reaction of [IrH_2(CH_3CN)(Cyttp)][BF_4] **6***c* diastereomers and $NaBH_4$, with the latter reaction being much faster. The **6***c* diastereomeric mixture was quantitatively converted to *mer*-[IrH_3(Cyttp)] (**6***b*) after 20 min at ambient temperature. On the other hand, no reaction was observed for the case of **6***a* under the same conditions, whereas refluxing the reaction mixture for 2 h afforded an 80% conversion to **6***b*. The $NaBH_4$ reaction with **6***a* became more facile upon the addition of excess Tl^+, and a 95% conversion to **6***b* was noted after 15 min at room temperature (during which time Tl(I) was reduced to Tl(0)).

Iridium(III) chloride complexes have also been known to insert $SnCl_2$ (31). The addition of $SnCl_2$ to CH_2Cl_2 solutions of *anti*-[IrH_2Cl(Cyttp)] **6***a* produced a *syn*/*anti* mixture of [IrH_2SnCl_3(Cyttp)] diastereomers, **6***i*, in the ratio of 3:2, respectively. The ^1H NMR parameters of the **6***i* diastereomers are consistent with those observed for *cis*-*mer*-[$IrH_2SnCl_3(PPh_3)_3$], **13** (32). Single crystal X-ray diffraction analysis of **13** confirmed the *mer* arrangement of the three phosphine ligands and the *cis* relationship of the two hydrido protons (32).
