Les triméthoxy-dihydrodibenzocycloheptènes **4–7** ont été synthetisés selon quatre voies différentes dans le cadre d'une étude de relation structure–activité concernant l'inhibition de polymérisation de la tubuline in vitro : (1) la synthèse du composé **4** a été effectuée à partir du 2,3-diméthoxybenzaldéhyde via l'intermédiaire aldéhydique **17** suivi d'une extension de chaîne vers l'acide propionique **20**, donnant, après cyclization, la cétone **21** dont la fonction carbonyle a finalement été réduite. (2) Le composé **5** a été obtenu par élimination du groupement méthoxy encombré de l'alcool **25** ou de l'oxime **26** par réduction métallique. (3) Le composé **6** a été synthétisé à partir de l'aldéhyde biphénylique **34**, obtenu par une réaction de Grignard sur l'oxazoline **32** selon la méthode de Meyer. (4) Le composé **7** provient de la déoxygénation réductive de l'éther de tétrazolyle du *N*-acétylcolchinol **41**. Le rôle clé des atomes d'oxygène aromatiques de la colchicine et des dérivés de type «allo», en tant que points d'interaction avec leur site de fixation sur la tubuline, a été demontré par l'absence de propriétés inhibitrices des composés **4–7**. Les acétamides **8***a*,*b* isomères en position 5 du *N*-acétylcolchinyl méthyl éther **2** ont été obtenues après résolution chimique de l'amine **47**. La configuration absolue des isomères optiques **47***a*,*b* et **8***a*,*b* a été determinée par des mesures de RMN et de dichroïsme circulaire. Ces composés se sont révélés inactifs en tant qu'inhibiteurs de polymérisation de la tubuline.

Mapping and full characterization of the colchicine binding site on tubulin remains a challenging and multifaceted research project (1, 2). Modification of natural (−)-(a*S*, 7*S*) colchicine **1** or the parent compound *N*-acetylcolchinol methyl ether **2** offers a possibility to gain valuable information on how these molecules bind to tubulin and inhibit its polymerization. Phenolic congeners of colchicine **1**, especially 1-demethylcolchicine, were found to be less potent than colchicine itself (1–4) as inhibitors of tubulin polymerization, with activity partially restored on esterification (5, 6). After the finding of the high potency of 6,7-dihydro-1,2,3,9-tetramethoxy-5*H*-dibenzo[*a*,*c*]cycloheptene (DBCH) **3** (7*a*), the systematic synthesis of its demethoxy derivatives **4–7** was undertaken in order to investigate the contribution of each aromatic oxygen atom in the binding process. The acetamido group in **1** and **2** is not required for binding to tubulin, as indicated by the high activity of compound **3** (7*a*). The investigation included a synthesis of the optically active amides **8***a*,*b*, with the acetamido group at C(5). Determination of their absolute configurations, a primary factor in tubulin binding ability, was made by ^{1}H NMR and CD.

[1]The results of this investigation were presented by O. Boyé at a poster session of the 200th meeting of the American Chemical Society in Washington, D.C., August 26–31, 1990 (Division of Medicinal Chemistry; Abstr. 68).

Chemistry

DBCH 4 from 2,3-dimethoxybenzaldehyde (Scheme 1)

The synthesis of **4** followed a route used earlier in the synthesis of **3** (7*a*, *b*) which started from 2,3,4-trimethoxybenzaldehyde and gave ketone **24** as an intermediate. Azalactone **9**, prepared from 2,3-dimethoxybenzaldehyde and *N*-acetyl glycine, was hydrolyzed to give pyruvic acid **10***a* and acetylated enamine **10***b* as a by-product. The 16-step synthesis of **4** was handicapped by the relatively low yield encountered in the preparation of keto-ester **13** from pyruvic acid **10***a* via Robinson annelation with methyl vinyl ketone (8). The cyclization of acid **20** to ketone **21** in $(CF_3CO)_2O/CF_3COOH$ solution was greatly improved in comparison to previous work (7*a*) by conducting the reaction at low temperature.

DBCH 5 by sodium–isopropanol reduction (Scheme 2)

Reductive removal of the hindered methoxy group in alcohol **26**, obtained by reduction of ketone **24** (7*a*, *b*), was accomplished with sodium in refluxing isopropanol (12, 13) to afford DBCH **5**. This reaction is reminiscent of methoxy group eliminations observed in the aporphine alkaloid series with sodium in liquid ammonia (18, 19). DBCH **5** could also be obtained starting with oxime **25**, which, treated in the same manner as **26**, was demethoxylated and reduced in a one-pot procedure. Exhaustive methylation of amine **27** afforded quaternary salt **28***b*, which underwent Hofmann elimination to olefin **29**. Reduction of the latter afforded **5**. This material was identical with that directly obtained from **26** on treatment with sodium in isopropanol.

DBCH 6 by Meyers' biphenyl synthesis (Scheme 3)

The synthesis of **6** was tailored after Meyers' efficient synthesis of biphenyl aldehydes from phenyloxazolines with Grignard reagents (14–16).

Reaction of Grignard **31**, prepared from 5-bromoveratrole, with oxazoline **32** (obtained from 2,5-dimethoxybenzoic acid (14–16)) afforded oxazoline **33**. Deprotection of **33** was accomplished by quaternization with methyltriflate, reduction of the quaternary salt with sodium borohydride, and hydrolysis with oxalic acid to give aldehyde **34** (16). Conversion of aldlehyde **34** into ketone **38**, olefin **40**, and DBCH **6** followed the route used for the preparation of **3** and **4**.

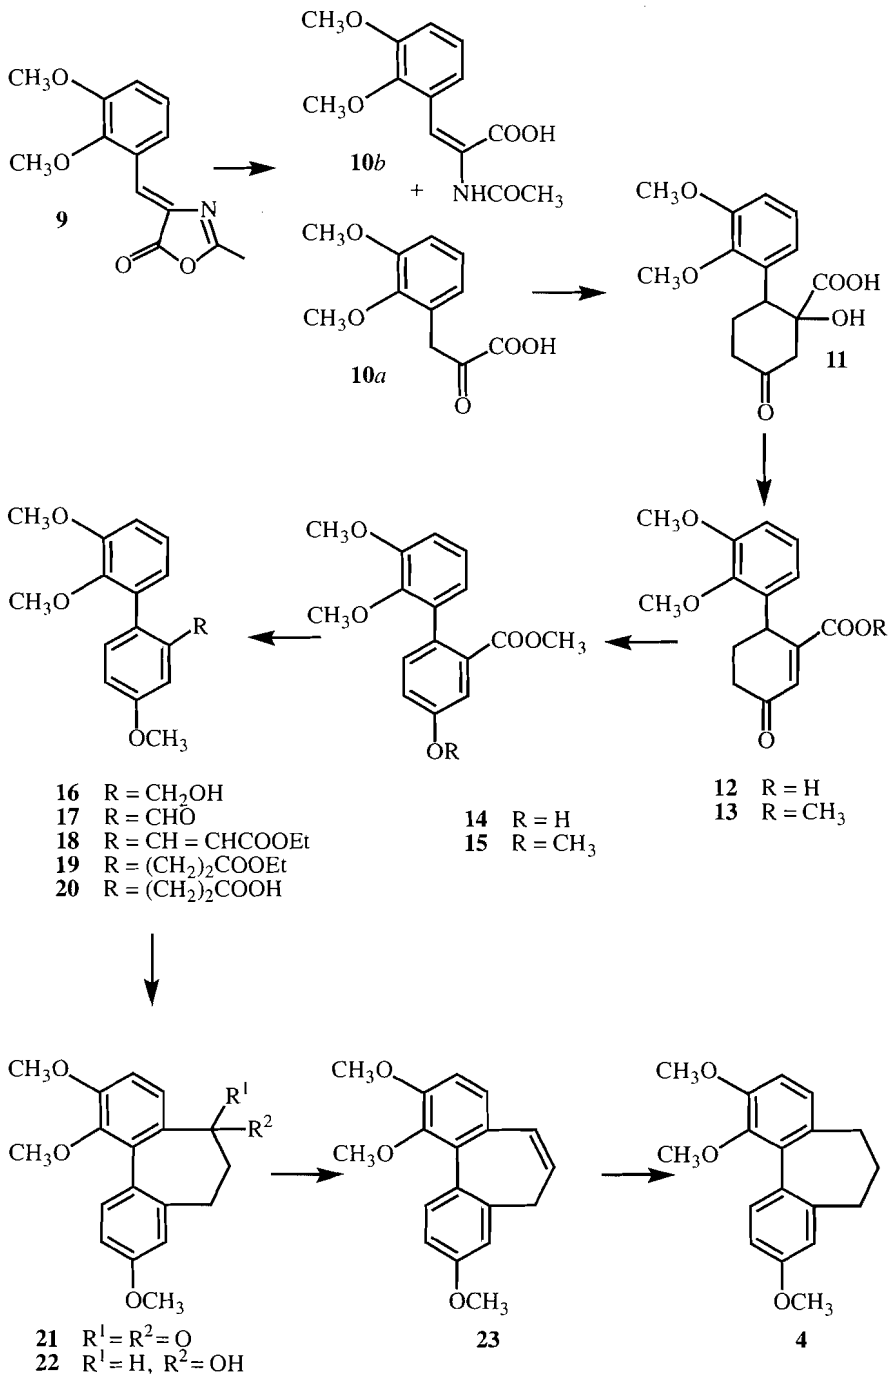

SCHEME 1

DBCH 7 from N-*acetylcolchinol* ***41*** *(Scheme 4)*

N-Acetylcolchinol, prepared from colchicine **1** by a published procedure (17), was deoxygenated by catalytic reduction of its phenyltetrazolyl ether **42** over Pd/C catalyst in acetic acid (20, 21), affording amide **43**. The latter on acid hydrolysis gave amine **44**, which after quarternization with methyl iodide and Hofmann degradation afforded olefin **46** and DBCH **7** on further reduction.

Synthesis of optically active 5-acetamidodeaminocolchinyl methyl ethers **8**a,b *(Scheme 5)*

Oxime **25** was also used to prepare the optically active isomers **8***a*,*b* (Scheme 5). Reduction of oxime **25** with hydrazine in the presence of Raney nickel catalyst afforded the racemic amine **47**, which was resolved with (+)- and (−)-dibenzoyltartaric acids in isopropanol to afford the optically active amines **47***a*,*b* after recrystallization from MeOH. Further acetylation gave the optically active amides **8***a*,*b*. The optical purity of the amines was measured by HPLC analysis of their urea derivatives **48***a*,*b*. The absolute configuration of compounds **47***a*,*b* and **8***a*,*b* was established by ^{1}H NMR spectroscopy and CD analysis. We have previously shown that natural (−)-7*S*-colchicine **1** and derived allo congeners exhibit negative Cotton effects at 260 nm (9, 10). This optical behavior results from the presence of the noncoplanar biaryl system. Ring C is twisted out of the plane

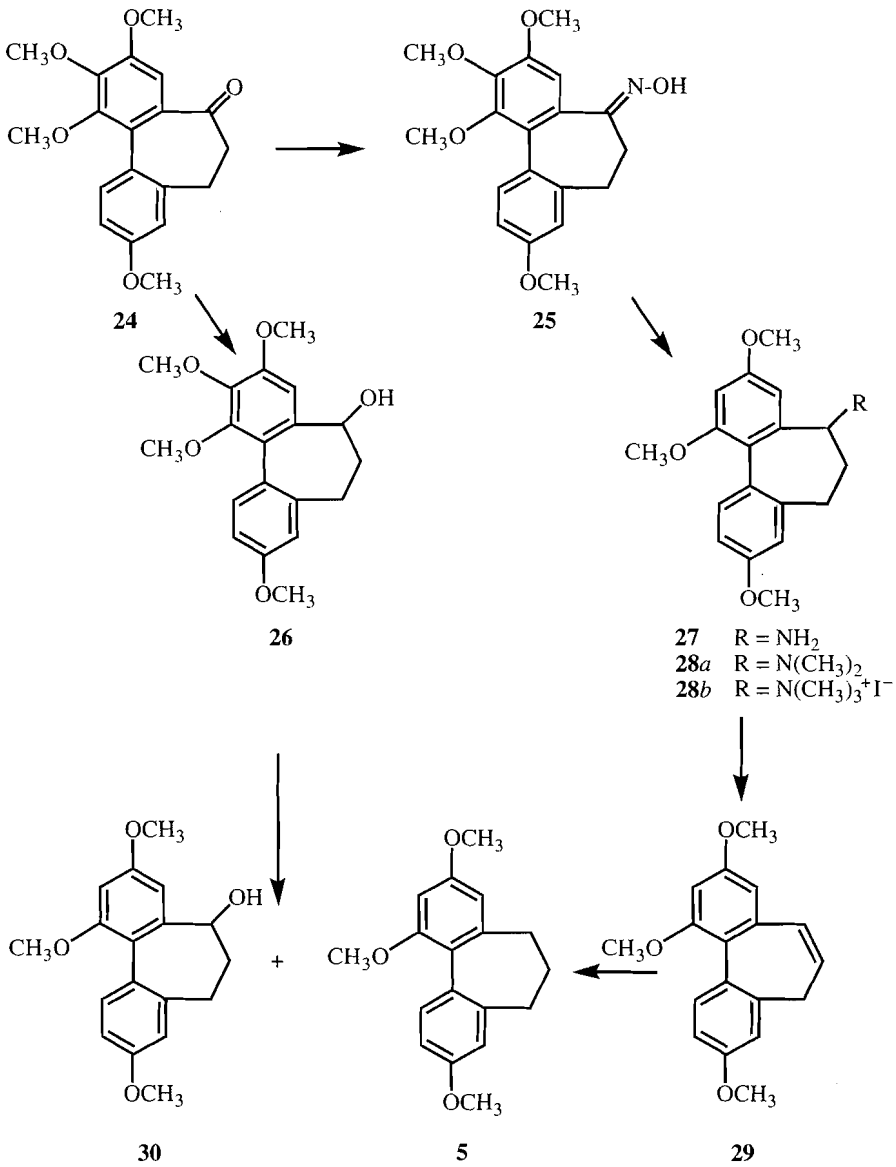

SCHEME 2

formed by ring A in a counterclockwise arrangement with a dihedral angle between the planes of ca. 53° (8). This gives an a*S* assignment to natural (−)-7*S*-colchicine, after consideration of the order of the *ortho–ortho'* substituents of the central bond, according to the chirality rules of Prelog and Helmchen (11). Counterclockwise arrangement of the biaryl systems is manifested by all the biologically active colchicinoids and their allo congeners and is considered to be an important molecular feature in their ability to bind to tubulin. Unnatural (+)-7*R*-colchicine, which has the biaryl system arranged in a clockwise fashion and has a positive Cotton effect at 260 nm, does not bind to tubulin.

Conformational equilibria and absolute configurations of 5-aminodeaminocolchinyl methyl ethers **47***a*,b *and derived acetamides* **8***a*,b

The optically active amines **47***a,b* and the derived acetamides **8***a,b* are in a solvent-dependent conformational equilibrium (Scheme 5). The absolute configurations of **47***a* and **8***a* were established as follows: the observed negative Cotton effect at 260 nm in ethanol (Fig. 1*a*) for **47***a* and **8***a* suggests that the phenyl rings in these compounds are arranged in a counterclockwise fashion, as in natural (−)-(a*S*,7*S*)-colchicine **1**. Despite the identical helicity of the biaryl system the configuration of **47***a* and **8***a* is a*R* due to the change occurring in the priority of the *ortho–ortho'* substituents as compared to (−)-colchicine (11). In conjunction with this finding, the 5*S* absolute configuration of these molecules was then derived by measuring vicinal proton coupling between H-C(5) and $H_{a,b}$-C(6) (Table 1). The dihedral angles between these protons were evaluated using the Karplus rule (23, 24). By examining the Dreiding model with the biphenyl system arranged in a counterclockwise configuration, one can conclude that H-C(5) in both compounds is axially oriented with the amino or acetamido groups in an equatorial position. This leads to a 5*S* absolute configuration for **47***a* and **8***a*. The solvent dependency of the conformational equilibrium is different for **47***a* and **8***a*. Whereas the ^{1}H NMR proton signal for H-(5) in amine **47***a* does not change significantly on switching solvents from CD_3OD to $CDCl_3$ and the negative Cotton effect at 260 nm is still sub-

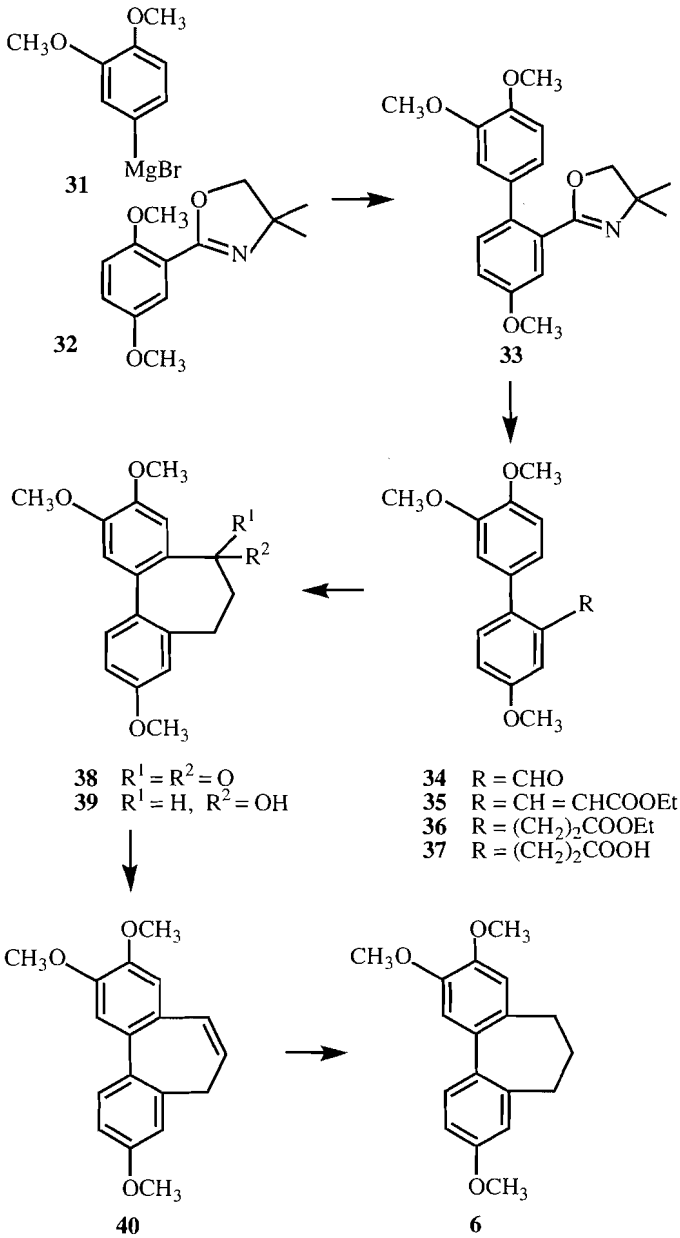

SCHEME 3

stantial, these situations are drastically different in the case of acetamide **8***a*. In $CDCl_3$, proton H-C(5) for **8***a* gives two ^1H NMR signals of nearly equivalent intensity, indicating a displacement of the conformational equilibrium toward the a*S* isomer, with the biphenyl system arranged in a clockwise fashion and with the acetamido group axially oriented. The existence of two isomers cannot be explained by a simple *cis–trans* rotameric arrangement of the amide group. This is shown by the optical behavior of **8***a*. The equilibration between a*R*- and a*S*-**8***a* conformers is demonstrated by the drastic decrease in the absorption at 260 nm in the CD spectra in $CHCl_3$ compared to the one displayed in ethanol (Fig. 1*a*, *b*). The specific optical rotation of **8***a* remains constant on standing in methanol and changes very little after several days in chloroform solution. This clearly indicates that the proportion of **8***a* (a*R*,5*S*) and (a*S*,5*S*) isomers present in solution is rapidly established and strongly influenced by the solvent. The optical isomer **8***b*, which was also analyzed, showed similar optical behavior.

Biological evaluation

Method (25)

The compounds were tested as potential inhibitors of the polymerization of purified bovine brain tubulin in vitro. Reaction components were 1.0 mg/mL (10 μM) tubulin, 1.0 M monosodium glutamate (inducer of polymerization), 1.0 mM $MgCl_2$, and 0.4 mM GTP (an essential cofactor for polymerization). All compounds were dissolved in dimethyl sulfoxide (with a final solvent concentration of 4%(v/v), which did not affect the polymerization reaction). All components except GTP were preincubated at 37°C for 15 min to permit the interaction of slow binding agents with tubulin. Reaction mixtures were chilled on ice and after addition of GTP were transferred to thermostated cuvettes held at 0°C in a recording spectrophotometer. Polymerization was initiated by a 75-s temperature jump to 37°C, and the reaction was followed turbidimetrically at 350 nm. For each compound an IC_{50} value was obtained in at least three independent experiments. The IC_{50} value was defined as the drug concentration that inhibits the extent of polymerization by 50% after a 20-min incubation. Values over 50 μM represent negligible activity in this assay, while the lowest IC_{50} value yet obtained has been 1.2 μM (i.e., 50% inhibition of polymerization when at most 12% of the tubulin in the reaction mixture has bound the inhibitor).

Results and discussion

Of the newly prepared compounds, only **5**, **29**, and **43** retained some activity as inhibitors of tubulin polymerization when compared with data obtained for colchicine **1** and *N*-acetylcolchinol methyl ether **2** (Table 2). *This marks dihydrodibenzo[*a,c*]cycloheptene **3** as the simplest tricyclic structure of this series that shows a high antitubulin activity.*

Any replacement of methoxy groups by hydrogen in **3** results in a substantial loss of activity, which is much greater than the loss observed in going from colchicine **1** to demethylated congeners (Table 2). This clearly demonstrates the importance of oxygen atoms at positions C(1), C(3), and C(9) (C(10) in colchicine) as major points of electrostatic interaction with the binding site while the oxygen in C(2) is slightly less important. The substituent at C(1) is also particularly critical because it affects the a*R*–a*S* equilibrium through steric hindrance with H-C(11). Switching the acetamido group from C(7) as in **2** to C(5), despite a proper counterclockwise absolute configuration for **8***a*, afforded inactive compounds **8***a*,*b*. Even an amino group at position C(5), as in **47***a*, resulted in complete loss of activity. This suggests that substitution at this position interferes with the tubulin binding process.

Experimental

General

TLC: silica gel GHLF plates from Analtech; visualization with UV light, I_2, Dragendorff's solution. Flash chromatography: silica gel 60 (Fluka), 230–400 mesh, 60 Å. Melting point (uncorrected): Fisher–Johns melting point apparatus. IR spectra: Beckman IR 4230. ^1H NMR spectra: Varian XL 300 (300 MHz). CIMS:

Synthesis of DBCH ***4*** *(Scheme 1)*

*3-Methyl-4-[(2,3-dimethoxyphenyl)-methylidene]-5(4*H*)-oxazolone* ***9***

Oxazolone **9** was prepared according to published procedure (*7b*) and recrystallized from toluene as a bright yellow powder (39%): mp 130°C; IR ($CHCl_3$): 3020 (CH_3), 1810, 1770 (O-C=O), 1660 (C=NH), 1260 (Ph-O-CH_3) cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.40 (s, CH_3), 3.89 (s, CH_3O), 3.90 (s, CH_3), 7.00 (dd, J = 8.1 and 1.3 Hz, 1H, 4′-H), 7.14 (t, J = 8.1 Hz, 1H, 5′-H), 7.65 (s, 1H, Ph-CH=), 8.23 (dd, J = 8 and 1.4 Hz, 1H, 6′-H); CIMS (NH_3) m/z: 248 (MH^+). Anal. calcd. for $C_{13}H_{13}O_4N$ (247.25): C 63.15, H 5.30, N 5.66; found: C 63.06, H 5.33, N 5.60.

3-(2,3-Dimethoxyphenyl)pyruvic acid ***10***

A solution of **9** (50.0 g, 0.2 mol) in aqueous HCl (10%, 90 mL) and dioxane (180 mL) was refluxed for 3 h. After cooling, the solvents were evaporated to give a residue that was dissolved in ethyl acetate and washed with H_2O. The acid was extracted from the organic layer with concentrated ammonium hydroxide. The aqueous layer was washed with ethyl acetate, then acidified with concentrated HCl. The acid was then extracted with ethyl acetate. After washing with H_2O until neutral, and drying (Na_2SO_4), the solvent was evaporated to give 22 g of **10** (yield 49%), which was recrystallized from toluene to give a yellow powder: mp 123–124°C; IR ($CHCl_3$): 3460 (OH), 3000 (CH_3), 1690 (C=O), 1475, 1270 (CH_3O) cm^{-1}; ^1H NMR ($CDCl_3$) δ: 3.88 (s, CH_3O), 3.9 (s, CH_3O), 6.92 (d, J = 8.1 Hz, 1H, 4′-H), 6.94 (s, 1H, Ph-CH=), 7.12 (t, J = 8 Hz, 1H, 5′-H), 7.33 (d, J = 7.9 Hz, 1H, 6′-H); CIMS (NH_3) m/z: 242 ($MH^+ + NH_3$), 224 (M^+). Anal. calcd. for $C_{11}H_{12}O_5$(224.21): C 58.93, H 5.39; found: C 58.68, H 5.43.

1-Hydroxy-5-oxo-2-(2,3-dimethoxyphenyl)-1-cyclohexanecarboxylic acid ***11***

Acid **11** was prepared by published procedure (*7b*) as a crude mixture (57 g, 81%); a sample of the product (4 g) was flash chromatographed for analysis (SiO_2, $CHCl_3$–MeOH–CH_3COOH 9.25:0.5:0.25), giving **11** as a translucide oil (0.5 g, 10%): ^1H NMR ($CDCl_3$) δ: 1.45–2.26 (m, 4H, CH_2), 2.35 (d, J = 15 Hz, 1H, $CH_2C(OH)COOH$), 2.72 (d, J = 14.9 Hz, 1H, $CH_2C(OH)COOH$), 3.42 (dd, J = 12.9 and 3.7 Hz, 1H, CH), 3.58 (s, 3H, CH_3O), 3.62 (s, 3H, CH_3O), 5.68 (s, 1H, OH), 6.57 (d, J = 8.1 Hz, 1H, 4′-H), 6.63 (d, J = 8 Hz, 1H, 6′-H), 6.74 (t, J = 7.9 Hz, 1H, 5′-H). Recrystallization from ethyl acetate gave white crystals; mp 209–212°C (dec.); IR (film): 3460 (OH), 2930, 1720 (C=O), 1655–1620 (C=O), 1470 cm^{-1}; CIMS (NH_3) m/z: 329 ($MH^+ + 2NH_3$), 312 ($MH^+ + NH_3$), 295 (MH^+), 276 ($MH^+ - H_2O$).

3-Oxo-6-(2,3-dimethoxyphenyl)-1-cyclohexenecarboxylic acid ***12***

Acid **12** was prepared from crude compound **11** by published procedure (*7b*), obtained as a yellow oil (98%, crude), and used without further purification in the preparation of ester **13**; CIMS (NH_3) m/z: 294 ($MH^+ + NH_3$), 276 (M^+), 259 ($MH^+ - OH$).

Mixture of methyl 3-oxo-6(2,3-dimethoxyphenyl)-1-cyclohexene-1-carboxylate and methyl 5-oxo-2-(2,3-dimethoxyphenyl)-1-cyclohexene-1-carboxylate ***13***

K_2CO_3 (40.0 g, 0.29 mol) and MeI (25 mL, 0.4 mol) were added to a solution of acid **12** (44 g, crude, 0.15 mol) in anhydrous THF (250 mL). The mixture was refluxed for 4 h under N_2. After cooling, K_2CO_3 was removed by filtration and washed with Et_2O. The filtrate was evaporated to give a residue that was dissolved in ethyl acetate. The organic layer was washed with brine and dried (Na_2SO_4) to give, after evaporation, 42 g of a brown oil. The

From ***29****:* olefin **29** (21 mg, 0.07 mmol) in acetic acid (4 mL)

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

was hydrogenated at 1 atm (101.3 kPa) for 3 h in the presence of Pd black (20 mg). After filtration of the catalyst on Celite and evaporation of the filtrate, the residue was dissolved in Et_2O, washed with brine, and dried (Na_2CO_3). Evaporation of the solvent gave an oil, which was crystallized from petroleum ether to give **5** as white crystals (20 mg, 95%).

*Synthesis of DBCH **6** (Scheme 3)*

*2-(2,5-Dimethoxyphenyl)-4,4-dimethyl-2-oxazoline **32***

Oxazoline **32** was prepared according to Meyers' procedure (16). The first acyl chloride intermediate (16), precursor of **32**, was distilled in a Kugelrohr apparatus at 105°C and 0.05 Torr. The oxazoline **32** was purified by distillation in the same manner at 120°C and 0.05 Torr and obtained as a translucent oil (93.4%, 100% pure by GC): IR ($CHCl_3$): 2960 (C-H), 1640 (C=N), 1490, 1460, 1420, 1200 (Ph-O-CH_3), 1140 (C-O) cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.39 (s, 6H, CH_3), 3.78 (s, 3H, CH_3O), 3.83 (s, 3H, CH_3O), 4.09 (s, 2H, CH_2), 6.88 (d, J = 9.1 Hz, 1H, 3'-H), 6.95 (dd, J = 3 and 9 Hz, 1H, 4'-H), 7.27 (d, J = 3 Hz, 1H, 6'-H); CIMS (NH_3) m/z: 236 (MH^+).

*4,3',4'-Trimethoxy-2-oxazolinyl-1,1'-biphenyl **33***

Magnesium (4.0 g, 0.17 mmol) and a few crystals of iodine were added to a three-neck, flame-dried, round-bottom flask under argon and heated at 40°C. 4-Bromoveratrole (26 g, 0.12 mol) dissolved in anhydrous THF (150 mL, distilled over $LiAlH_4$) was added dropwise while the temperature was raised to 80°C. The black mixture was stirred at 80°C for 2 h. **32** (7.0 g, 0.03 mol), dissolved in anhydrous THF (100 mL), was added slowly to the Grignard reagent and the mixture stirred under argon at room temperature for 30 h. An aqueous solution of NH_4Cl (100 mL) was added, followed by H_2O (150 mL), and the product was extracted with Et_2O. The organic layer was washed with brine and dried ($MgSO_4$). Evaporation of solvent gave a yellow oil, which was distilled in a Kugelrohr apparatus. Most of the impurities and nonreacted starting material distilled between 80°C and 120°C at 0.05 Torr while the crude product remained in the flask. Oxazoline **33** was purified by chromatography (SiO_2, ethyl acetate – hexanes 3:7, 1:1) to give 8.5 g of yellow oil, which crystallized after drying (84%, 100% pure by GC): mp 73–75°C; IR ($CHCl_3$): 3000, 2970 (C-H), 1640 (C=N), 1600, 1490, 1250–1200 (Ph-O-CH_3), 1040 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.31 (s, 6H, CH_3), 3.82 (s, 2H, CH_2), 3.86 (s, 3H, CH_3O), 3.88 (s, 3H, CH_3O), 3.91 (s, 3H, CH_3O), 6.89 (m, 2H, 6-H, 2'-H), 6.92 (dd, J = 2 and 8.1 Hz, 1H, 5-H), 7.01 (dd, J = 2.8 and 8.5 Hz, 1H, 6'-H), 7.22 (d, J = 2.7 Hz, 1H, 3-H), 7.28 (d, J = 8.3 Hz, 1H, 5'-H); CIMS (NH_3) m/z: 342 (MH^+). Anal. calcd. for $C_{20}H_{23}O_4N$: C 70.36, H 6.79, N, 4.10; found: C 70.09, H 6.75, N 3.99.

*3',4',4-Trimethoxy-1,1'-biphenyl-2-carbaldehyde **34***

Aldehyde **34** was prepared according to Meyers' procedure (16), purified by column chromatography (SiO_2, ethyl acetate – hexanes 1:4), and obtained as white crystals (30%, 100% pure by GC): mp 98°C; IR ($CHCl_3$): 3000, 2950 (C-H), 1680 (C=O), 1600, 1480, 1460, 1250–1200 (Ph-O-CH_3), 1020, 900 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 3.92 (s, 3H, CH_3O), 3.93 (s, 3H, CH_3O), 3.96 (s, 3H, CH_3O), 6.89 (m, 2H, 2'-H, 5-H), 6.97 (d, J = 8.7 Hz, 1H, 6-H), 7.21 (dd, J = 2.8 and 8.5 Hz, 1H, 6'-H), 7.40 (d, J = 8.6 Hz, 1H, 5'-H), 7.5 (d, J = 2.8 Hz, 1H, 3-H), 10.0 (s, 1H, CHO); CIMS (NH_3) m/z: 273 (MH^+), 255 ($MH^+ - H_2O$). Anal. calcd. for $C_{16}H_{16}O_4$: C 70.58, H 5.92; found: C 70.39, H 5.96.

*Ethyl 3-(3',4,4'-trimethoxy-1,1'-biphenyl-2-yl)prop-2-enoate **35***

Ester **35** was prepared by published procedure (7*a*) and obtained as white crystals after purification by column chromatography (SiO_2, ethyl acetate – hexanes 1:4) (79%): mp 74–75°C; IR ($CHCl_3$): 3020–2800 (CH_3), 1710 (C=O), 1640 (-CH=CH-), 1600 (Ph), 1500, 1470, 1440, 1340–1140, 1030 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.29 (t, J = 7.1 Hz, 3H, CH_3), 3.88 (s, 6H, CH_3O), 3.93 (s, 3H, CH_3O), 4.22 (q, J = 7.1 Hz, 2H, CH_2), 6.37 (d, J = 15.9 Hz, 1H, =CH-CO), 6.81 (d, J = 1.9 Hz, 1H, 2'-H), 6.82 (dd, J = 1.9 and ~8 Hz, 1H, 5-H), 6.93 (d, J = 8 Hz, 1H, 6-H), 6.99 (dd, J = 2.5 and 8.5 Hz, 1H, 6'-H), 7.17 (d, J = 2.6 Hz, 1H, 3-H), 7.31 (d, J = 8.5 Hz, 1H, 5'-H), 7.76 (d, J = 16 Hz, 1H, PhCH=); CIMS (NH_3) m/z: 360 ($MH^+ + NH_3$), 343 (MH^+), 297 ($MH^+ -$ OEt). Anal. calcd. for $C_{20}H_{22}O_5$: C 70.16, H 6.48; found: C 70.11, H 6.53.

*Ethyl 3',4',4-trimethoxy-1,1'-biphenyl-2-propionate **36***

Ester **36** was prepared by published procedure (7*a*) (91%): IR ($CHCl_3$): 3010–2820 (CH_3), 1730 (C=O), 1600 (Ph), 1480, 1350–1120 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.2 (t, J = 7.1 Hz, 3H, CH_3), 2.43 (t, J ~ 8 Hz, 2H, CH_2CO), 2.92 (t, J ~ 8 Hz, 2H, $PhCH_2$), 3.83 (s, 3H, CH_3O), 3.88 (s, 3H, CH_3O), 3.92 (s, 3H, CH_3O), 4.07 (q, J = 7.2 Hz, 2H, OCH_2), 6.78–6.84 (m, 4H, 2'-H, 6'-H, 3-H, 5-H), 6.9 (d, J = 8 Hz, 1H, 6-H), 7.14 (d, J = 8.2 Hz, 1H, 5'-H); CIMS (NH_3) m/z: 345 (MH^+) 300 ($MH^+ -$ OEt).

*3',4',4-Trimethoxy-1,1'-biphenyl-2-propionic acid **37***

Acid **37** was prepared by published procedure (7*a*) and obtained as a white powder (98.3%): mp 148–149°C: IR ($CHCl_3$): 3010, 2940 (CH_3), 1710 (C=O), 1610 (Ph), 1490, 1460, 1290–1190, 1170, 1130 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.48 (t, J ~ 8 Hz, 2H, CH_2CO), 2.93 (t, J ~ 8 Hz, 2H, $PhCH_2$), 3.83 (s, 3H, CH_3O), 3.87 (s, 3H, CH_3O), 3.92 (s, 3H, CH_3O), 6.78–6.83 (m, 4H, 2'-H, 6'-H, 3-H, 5-H), 6.9 (d, J = 8.3 Hz, 1H, 6-H), 7.14 (d, J = 8.2 Hz, 1H, 5'-H); CIMS (NH_3) m/z: 334 ($MH^+ + NH_3$), 317 (MH^+), 299 ($MH^+ - H_2O$). Anal. calcd. for $C_{18}H_{20}O_5$: C 68.34, H 6.37; found: C 68.17, H 6.40.

*6,7-Dihydro-2,3,9-trimethoxy-5*H*-dibenzo[*a,c*]cyclohepten-5-one **38***

Acid **37** (510 mg, 1.61 mmol) was suspended in $(CF_3CO)_2O$ (20 mL) at low temperature (ice + NaCl). CF_3COOH (20 mL) was then added dropwise and the solution stirred for 2.5 h at 0°C. The reaction was followed by GC. The solvent was evaporated, the residue taken up in ethyl acetate, washed with $NaHCO_3$ solution, brine, and dried (Na_2SO_4). Evaporation of the solvent gave an oily yellow compound, which was crystallized from ethyl acetate – hexanes and obtained as a white powder (450 mg, 93%): mp 142–143°C; IR ($CHCl_3$): 3020, 2960, 2940 (C-H), 1660 (C=O), 1600 (Ph), 1500, 1460, 1440, 1350, 1290–1120 (Ph-O-CH_3), 1160 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.94 (s, 4H, CH_2), 3.86 (s, 3H, CH_3O), 3.96 (s, 3H, CH_3O), 3.98 (s, 3H, CH_3O), 6.82 (d, J = 2.6 Hz, 1H, 8-H), 6.86 (s, 1H, 1-H), 6.89 (dd, J = 2.7 and 8.5 Hz, 1H, 10-H), 7.3 (s, 1H, 4-H), 7.35 (d, J = 8.5 Hz, 1H, 11-H); CIMS (NH_3) m/z: 299 (MH^+). Anal. calcd. for $C_{18}H_{18}O_4$: C 72.47, H 6.08; found: 72.26, H 6.12.

*6,7-Dihydro-2,3,9-trimethoxy-5*H*-dibenzo[*a,c*]cyclohepten-5-ol **39***

Alcohol **39** was prepared by published procedure (7*a*) and obtained as white crystals (92%): dec. >260°C; IR ($CHCl_3$): 3620 (OH), 3020, 2940 (CH_3), 1610 (Ph), 1490, 1460 (-CH_2-), 1290–1180 (Ph-O-CH_3), 1150, 1130, 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.48–2.62 (m, 4H, CH_2), 3.85 (s, 3H, CH_3O), 3.92 (s, 3H, CH_3O), 3.96 (s, 3H, CH_3O), 4.60 (dd, J = 6.9 and 9.8 Hz, 1H, 5-H), 6.82 (d, J = 2.6 Hz, 1H, 8-H), 6.87 (s, 1H, 1-H), 6.87 (dd, J = 2.7 and 8.3 Hz, 1H, 10-H), 7.2 (s, 1H, 4-H), 7.27 (d, J = 8.5 Hz, 1H, 11-H); CIMS (NH_3) m/z: 300 (M^+), 283 ($MH^+ - H_2O$).

*2,3,9-Trimethoxy-7*H*-dibenzo[*a,c*]cycloheptene **40***

Cycloheptene **40** was prepared by published procedure (7*a*) and obtained as white crystals after recrystallization from $MeOH/H_2O$ (92%): mp 115–116°C; IR ($CHCl_3$): 3020 (CH_3), 1610 (Ph), 1500, 1470 (-CH_2-), 1290–1180 (Ph-O-CH_3), 1140, 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.93 (br s, 2H, CH_2), 3.77 (s, 3H, CH_3O), 3.86 (s, 3H, CH_3O), 3.90 (s, 3H, CH_3O), 6.02 (dt, J = 6.8 and 10 Hz, 1H, 6-H), 6.43 (d, J = 10 Hz, 1H, 5-H), 6.70 (d, J = 2.7 Hz, 1H, 8-H), 6.72 (s, 1H, 1-H), 6.78 (dd, J = 2.7 and 8.6 Hz, 1H, 10-H), 7.04

(s, 1H, 4-H), 7.35 (d, J = 8.5 Hz, 1H, 11-H); MS (CI/NH_3) m/z: 283 (MH^+). Anal. calcd. for $C_{18}H_{18}O_3 \cdot 0.5\ H_2O$: C 74.34, H 6.41; found: C 74.34, H 6.26.

*6,7-Dihydro-2,3,9-trimethoxy-5*H-*dibenzo*[a,c]*cycloheptene* ***6***

Dihydrocycloheptene **6** was prepared by published procedure (*7a*) and crystallized as white crystals from MeOH–H_2O (72%): mp 75–76°C; IR ($CHCl_3$): 3010, 2940, 2860 (CH), 1600 (Ph), 1480, 1460 (-CH_2-), 1240, 1200 (Ph-O-CH_3), 1150, 1130, 1050, 1020 cm^{-1}; ^1H NMR ($CDCl_3$), δ: 2.07 (m, 2H, CH_2), 2.34–2.43 (m, 4H, CH_2), 3.77 (s, 3H, CH_3O), 3.84 (s, 3H, CH_3O), 3.85 (s, 3H, CH_3O), 6.69 (s, 1H, 1-H), 6.73 (d, J = 2.7 Hz, 1H, 8-H), 6.79 (dd, J = 2.7 and 8.3 Hz, 1H, 10-H), 6.81 (s, 1H, 4-H), 7.21 (d, J = 8.3 Hz, 1H, 11-H); CIMS (NH_3) m/z: 285 (MH^+).

Synthesis of DBCH 7 (Scheme 4)

*(S)-5-Acetamido-6,7-dihydro-9,10,11-trimethoxy-5*H-*dibenzo*[a,c]*cyclohepten-3-yl-1-phenyl-1*H-*5-tetrazolyl ether* ***42***

A mixture of *N*-acetylcolchinol (2.0 g, 5.6 mmol), 5-chloro-1-phenyl-1*H*-tetrazole (1.4 g, 7.7 mmol), and K_2CO_3 (1.9 g, 13.7 mmol) in DMF (50 mL, anhydrous, distilled over molecular sieves) was stirred under argon at 80°C for 6 h, then at room temperature for 3 days. H_2O was added and a white solid precipitated that was collected by filtration, dissolved in $CHCl_3$–*i*PrOH, and washed with brine. After drying ($MgSO_4$) and evaporation of solvent, a yellow oil was obtained that was crystallized from Et_2O to give a white powder (2.8 g, 99%): mp 192–193°C $[\alpha]_D^{25}$ −100.2 (c = 0.51, MeOH); IR ($CHCl_3$): 3500–3300 (-CO-NH-R), 3000, 2940 (CH_3), 1670 (C=O), 1600 (Ph), 1530, 1500, 1480, 1450, 1230–1200, 1150, 1100 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.53 (s, $COCH_3$), 1.83–1.95 (m, 1H, CH_2), 2.05 (s, $COCH_3$), 2.32–2.55 (m, 3H, CH_2), 3.46 (s, 3H, OCH_3), 3.84 (s, 3H, OCH_3), 3.86 (s, 3H, OCH_3), 4.78–4.87 (m, 1H 82%, 7-H), 5.12 (m, 1H 18%, 7-H), 5.22 (br d, NH), 5.87 (d, J = 7.8 Hz, NH), 6.59 (s, 1H, 4-H), 7.30 (dd, J = 2.7 and 8.5 Hz, 1H, 10-H), 7.46 (d, J = 2.6 Hz, 1H, 8-H), 7.49–7.63 (m, 5H, Ph), 7.84 (d, J = 7.9 Hz, 1H, 11-H); CIMS (NH_3) m/z: 502 (MH^+).

*(S)-7-Acetamido-6,7-dihydro-1,2,3-trimethoxy-7*H-*dibenzo*[a,c]*cycloheptene* ***43***

A mixture of tetrazolyl ether **42** (2.8 g, 5.6 mmol) and 10%Pd/C (3 g) in AcOH (30 mL) was hydrogenated on a Parr apparatus at 50°C under 50 psi (1 psi = 6.89 kPa) of H_2 for 48 h. The catalyst was filtered and washed with AcOH. After evaporation of solvent the residue was dissolved in $CHCl_3$ and washed with NaOH (5%), H_2O, and dried (Na_2SO_4). Evaporation gave a white powder (1.87 g), which was recrystallized from ethyl acetate – hexanes (98%; 100% pure by GC): mp 189°C $[\alpha]_D^{25}$ −33.1 (c = 0.68, MeOH); IR ($CHCl_3$): 3440 (-CO-NH-R), 3000, 2940, (CH_3), 1670 (C=O), 1600, 1500, 1480, 1400, 1250–1200 (Ph-O-CH_3), 1140, 1100 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.58 (s, $COCH_3$), 1.67–1.84 (m, 1H, CH_2), 2.06 (s, $COCH_3$), 2.3–2.49 (m, 3H, CH_2), 3.52 (s, CH_3O), 3.58 (s, CH_3O), 3.9 (s, 3H, CH_3O), 3.93 (s, 3H, CH_3O), 4.80–4.89 (m, 1H 78%, 7-H), 5.16–5.18 (m, 1H 22%, 7-H), 5.24 (m, NH), 5.75–5.78 (m, NH), 6.57 (s, 1H, 4-H), 7.25–7.4 (m, 3H, Ph), 7.5 (m, 1H, Ph); CIMS (NH_3) m/z: 359 ($MH^+ + NH_3$), 341 (MH^+).

*(S)-7-Amino-6,7-dihydro-1,2,3-trimethoxy-7*H-*dibenzo*[a,c]*cycloheptene* ***44***

Acetamide **43** (1.8 g, 5.3 mmol) in H_2SO_4 (20%, 100 mL) and MeOH (50 mL) was refluxed for 3 days, when the reaction was found to be complete by GC. After cooling, the solution was made basic with NaOH (5%), then NaOH pellets. The product was extracted with ethyl acetate, washed with H_2O until neutral, and dried (Na_2SO_4). Evaporation of solvent gave an oil, which was chromatographed (SiO_2, $CHCl_3$–MeOH 95:5) to give **44** as white crystals (1.5 g, 95%): mp 95–96°C; $[\alpha]_D^{25}$ −45 (c = 0.61, MeOH); IR ($CHCl_3$): 3000, 2940 (CH_3), 1600 (Ph), 1480, 1450, 1400, 1340, 1250–1180 (Ph-O-CH_3), 1140, 1090, 1000 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.68–1.78 (m, 1H, CH_2), 2.28–2.5 (m, 3H, CH_2), 3.64 (s, 3H, CH_3O), 3.83–3.88 (m, 1H, 7-H), 3.92 (s, 6H, CH_3O), 6.60 (s, 1H, 4-H), 7.3–7.42 (m, 2H, 9-H, 10-H), 7.46 (d, J = 7.3 Hz, 1H, 8-H), 7.61 (d, J = 8.2 Hz, 1H, 11-H); CIMS (NH_3) m/z: 300 (MH^+), 283 ($MH^+ - NH_3$).

*1,2,3-Trimethoxy-5*H-*dibenzo*[a,c]*cycloheptene* ***46***

Amine **44** (250 mg, 0.84 mmol) was dissolved in a solution of anhydrous THF (10 mL) and MeI (10 mL). *t*BuOK (200 mg, 1.78 mmol) was added and the mixture stirred for 3 days at room temperature under argon. At this point the amount of ammonium salt **45** formed was very small and the mixture contained mainly the dimethyl amine derivative of **44**. The inorganic material was removed by filtration and the filtrate was evaporated to give a yellow oil that was stirred in MeI (10 mL) for 2 days. The yellow precipitate formed was collected (180 mg) and heated at 190°C for 3 h in a solution of ethylene glycol (4 mL), H_2O (4 mL), and KOH (10 g). After cooling, 20 mL of H_2O was added and the aqueous phase was extracted with Et_2O. The organic layer was washed with H_2O, dried ($MgSO_4$), and evaporated, leaving a yellow oil that was chromatographed (SiO_2, ethyl acetate – hexanes 1:4) to give 100 mg of pure cycloheptene **46**. Recrystallization from MeOH afforded white crystals (42%): mp 124–125°C; IR ($CHCl_3$): 3000, 2940 (CH_3), 1590 (Ph), 1480, 1400, 1330, 1250–1180 (Ph-O-CH_3), 1140, 1110, 1090, 1000 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.78 (dd, J = 5.5 and 12.9 Hz, 1H, 5a-H), 3.05 (dd, J = 8.1 and 12.9 Hz, 1H, 5b-H), 3.45 (s, 3H, CH_3O), 3.90 (s, 3H, CH_3O), 3.91 (s, 3H, CH_3O), 6.24 (m, 1H, 6-H), 6.56–6.58 (m, 2H, 4-H, 7-H), 7.26–7.33 (m, 3H, 8-H, 9-H, 10-H), 7.81 (d, J = 7.5 Hz, 1H, 11-H); CIMS (NH_3) m/z: 300 ($MH^+ + NH_3$), 283 (MH^+). Anal. calcd. for $C_{18}H_{18}O_3 \cdot 1/2\ H_2O$: C 74.34, H 6.41; found: C74.70, H 6.28.

*6,7-Dihydro-1,2,3-tetramethoxy-5*H-*dibenzo*[a,c]*cycloheptene 7*

Cycloheptene **46** (70 mg, 0.25 mmol) in AcOH (10 mL) was hydrogenated at room temperature and 50 psi in a Parr hydrogenator for 3 h over Pd black catalyst (150 mg). Pd was removed by filtration through Celite and washed with AcOH. Evaporation of the filtrate gave **7** as an oil, which was purified by column chromatography (SiO_2, ethyl acetate – hexanes 1:4) (50 mg, 71%): IR ($CHCl_3$): 3020, 2940, 2860 (C-H), 1600 (Ph), 1490, 1460, 1410, 1350, 1320, 1280–1180 (Ph-O-CH_3), 1150, 1110, 1090, 1010 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.08–2.13 (m, 2H, CH_2), 2.25–2.6 (m, 4H, CH_2), 3.6 (s, 3H, CH_3O), 3.92 (s, 3H, CH_3O), 3.93 (s, 3H, CH_3O), 6.6 (s, 1H, 4-H), 7.24–7.31 (m, 3H, 8-H, 9-H, 10-H), 7.48 (d, J = 7 Hz, 1H, 11-H); CIMS (NH_3) m/z: 302 ($MH^+ + NH_3$), 285 (MH^+).

Synthesis of 5-acetamidodeaminocolchinyl methyl ether (Scheme 5)

*5-Amino-6,7-dihydro-1,2,3,9-tetramethoxy-5*H-*dibenzo*[a,c]*cycloheptene* ***47***

Oxime **25** (250 mg, 0.73 mmol) was dissolved in EtOH (50 mL) and heated at 85–90°C. Raney nickel (3 g) and hydrazine hydrate (10 mL) were added and the mixture stirred at 85–90°C for 1 h. The catalyst was removed by filtration through Celite and the filtrate was evaporated. The residue was dissolved in HCl (5%) and washed with Et_2O. The aqueous layer was then basified with NaOH (30%) and the product extracted with Et_2O, washed with brine, and dried (Na_2CO_3). Evaporation of the solvent gave amine **47** as a colorless oil (230 mg, 95.8%, 98% pure by GC): IR ($CHCl_3$): 3010, 2945, 2845, (CH_3), 1610 (CH-NH_2), 1580, 1490, 1460 (-CH_2-), 1400, 1330, 1300, 1260–1200 (Ph-O-CH_3), 1160, 1135, 1080, 1000 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.86 (m, 1H, CH_2), 2.4–2.6 (m, 3H, CH_2), 3.57 (s, 3H, CH_3O), 3.8 (m, 1H, *CH*NH_2), 3.85 (s, 3H, CH_3O), 3.88 (s, 3H, CH_3O), 3.92 (s, 3H, CH_3O), 6.78, (d, J = 2.6 Hz, 1H, 8-H), 6.85 (dd, J = 2.7 and 8.5 Hz, 1H, 10-H), 7.03 (s, 1H, 4-H), 7.38 (d, J = 8.5 Hz, 1H, 11-H); CIMS (NH_3) m/z: 330 (MH^+), 313 ($MH^+ - NH_3$).

*(−)-(a*R,5S*)-5-Amino-6,7-dihydro-1,2,3,9-tetramethoxy-5*H-*dibenzo[*a,c*]cycloheptene **47***a

Amine **47** (350 mg, 1.06 mmol) dissolved in *i*PrOH (5 mL) was resolved with (+)-dibenzoyl-D-tartaric acid in *i*PrOH (10%, 5 mL) and the salt was recrystallized twice from MeOH. Treatment of this salt with NH_4OH (30%) and extraction with ethyl acetate afforded amine **47***a* (120 mg, 68.7%): $[\alpha]_D^{25}$ −85 (*c* = 0.62, MeOH). Phenylethylurea **48***a* was prepared with *S*-(−)-1-phenylethyl isocyanate in CH_2Cl_2 (22): mp 90–93°C; $[\alpha]_D^{25}$ −55.3 (*c* = 0.93, MeOH); CIMS (NH_3) *m/z*: 477 (MH^+). HPLC purity 100%, retention time 12.6 min (ethyl acetate – hexanes 3:2, 1 mL min^{-1}).

*(+)-(a*S,5R*)-5-Amino-6,7-dihydro-1,2,3,9-tetramethoxy-5*H-*dibenzo[*a,c*]cycloheptene **47***b

The amine prepared from the mother liquor of the resolution of **47***a* afforded a salt on treatment with (−)-*o,o'*-dibenzoyl-L-tartaric acid in *i*PrOH. After recrystallization from methanol (×2) and basification with NH_4OH (30%), extraction with ethyl acetate gave the oily amine **47***b* (97 mg, 55.6%): $[\alpha]_D^{25}$ +85 (*c* = 0.59, MeOH). Phenylethylurea **48***b* prepared with *S*-(−)-1-phenylethyl isocyanate in CH_2Cl_2 (22): mp 242–243°C; $[\alpha]_D^{25}$ −58.9 (*c* = 0.19, MeOH); CIMS (NH_3) *m/z*: 477 (MH^+). HPLC purity 99.3%, retention time 10.6 min (ethyl acetate – hexanes 3:2, 1 mL min^{-1}).

*5-Acetamido-6,7-dihydro-1,2,3,9-tetramethoxy-5*H-*dibenzo[*a,c*]cyclohepten **8***a,b

Acetic anhydride (0.13 mL, 1.38 mmol) was added, after cooling, to a THF suspension (20 mL) of **47***a,b* (45 mg, 0.14 mmol) and K_2CO_3 (200 mg, 1.4 mmol), and the mixture was stirred at room temperature for 2 h. Saturated $NaHCO_3$ was added and the amide was extracted with Et_2O. The combined extracts were washed with saturated $NaHCO_3$, H_2O, and dried ($MgSO_4$). Evaporation of the solvent gave 66 mg of a colorless oil, which on addition of H_2O gave a white powder.

Compound **8***a*: 99%, mp 98–101°C; $[\alpha]_D^{25}$ −68.2 (*c* = 0.505, MeOH); IR ($CHCl_3$): 3440 (-CO-NH-), 3000, 2930, 2840 (CH_3), 1660 (C=O), 1600, 1570 (Ph), 1480, 1450 (-CH_2-), 1400, 1320, 1300, 1240–1200 (Ph-O-CH_3), 1085 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 2.09 (s, 3H, $COCH_3$), 2.3–2.7 (m, 4H, CH_2), 3.56 (s, 3H 45%, CH_3O), 3.59 (s, 3H 55%, CH_3O), 3.84 (s, 3H 43%, CH_3O), 3.87 (s, 3H 57%, CH_3O), 3.89 (s, 3H, CH_3O), 3.90 (s, 3H 50%, CH_3O), 3.92 (s, 3H 50%, CH_3O), 4.64 (m, 1H 46%, 5-H), 5.06 (m, 1H 54%, 5-H), 5.18 (d, *J* = 8.8 Hz, NHCO), 6.16 (br s, NHCO), 6.61 (s, 1H 39%, 4-H), 6.67 (s, 1H 61%, 4-H), 6.76 (d, *J* = 2.6 Hz, 8-H), 6.82–6.94 (m, 1H, 10-H), 6.86 (d, *J* = 2.7 Hz, 8-H), 7.41 (d, *J* = 8.4 Hz, 1H 52%, 11-H), 7.42 (d, *J* = 8.3 Hz, 1H 48%, 11-H); EIMS *m/z*: 371 (M^+), 312 (M^+ − $NHCOCH_3$), 281.

Compound **8***b*: 99%, mp 94–95°C; $[\alpha]_D^{25}$ +71.8 (*c* = 0.545, MeOH).

Received April 2, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

FRANK BOTTOMLEY and ROBERT W. DAY. Can. J. Chem. **70**, 1250 (1992).

Reduction of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ with zinc powder gave a mixture of products, of which $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ (**1**), $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ (**2**), $(\eta\text{-}C_5H_5)_2Ti(SH)(\mu\text{-}O)Ti(\eta\text{-}C_5H_5)(\mu\text{-}S)_2Ti(\eta\text{-}C_5H_5)_2$ (**3**), $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (**4**), and $[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)]_4$ (**5**) were identified by a combination of fractional crystallization and X-ray diffraction, electron spin resonance spectroscopy, or mass spectrometry. The source of the oxygen in **2**, **3**, and **4** is believed to be the zinc oxide coating on the zinc powder. A similar mixture of products was obtained from the reaction between $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ and H_2S in the presence of small quantities of water. The structures of **2** and **3** are discussed in detail. **2** has a trigonal bipyramidal arrangement of Ti atoms (average Ti(ax)—Ti(eq) 3.22 Å, average Ti(eq)—Ti(eq) distance 3.24 Å) except for one long equatorial Ti—Ti edge of 3.60 Å, which is spanned by the $\mu_3\text{-}S_2$ unit. **2** is monoclinic, $P2_1/n$, a = 10.585(1), b = 28.133(4), c = 31.408(2) Å, β = 91.20(1)°, Z = 4 (for three independent molecules of **2** and one $C_6H_5CH_3$), R = 0.071 for 6911 observed reflections and 1141 refined parameters. **3** is triclinic, $P\bar{1}$, a = 9.146(1), b = 12.290(1), c = 13.027(1) Å, α = 100.72(1), β = 104.39(1), γ = 110.55(1)°, Z = 2, R = 0.037 for 3046 observed reflections and 304 parameters. The Ti—O—Ti unit in **3** has an angle of 175.6(2)°.

FRANK BOTTOMLEY et ROBERT W. DAY. Can. J. Chem. **70**, 1250 (1992).

La réduction du $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ avec de la poudre de zinc conduit à un mélange dans lequel on a identifié le $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ (**1**), $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ (**2**), $(\eta\text{-}C_5H_5)_2Ti(SH)(\mu\text{-}O)Ti(\eta\text{-}C_5H_5)(\mu\text{-}S)_2Ti(\eta\text{-}C_5H_5)_2$ (**3**), $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (**4**) et $[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)_4$ (**5**) par une combinaison de cristallisation fractionnée, de diffraction des rayons-X, de spectroscopie de résonance paramagnétique électronique et de spectrométrie de masse. On croit que la source de l'oxygène dans les composés **2**, **3** et **4** est l'oxyde de zinc recouvrant la poudre de zinc. On a obtenu un mélange semblable de produits lors de la réaction du $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ et le H_2S, en présence de faibles quantités d'eau. On discute en détail des structures des composés **2** et **3**. Dans le composé **2**, les atomes de Ti possèdent un arrangement trigonal bipyramidal (Ti(ax)—Ti(éq) moyen = 3,22 Å; Ti(éq)—Ti(éq) moyen = 3,24 Å) à l'exception d'une liaison Ti—Ti équatoriale qui est particulièrement longue, à 3,60 Å, et qui est étendue par une unité de μ_3-S. Le composé **2** est monoclinique, $P2_1/n$, avec a = 10,585(1), b = 28,133(4) et c = 31,408(2) Å, β = 91,20°, Z = 4 (pour trois molécules indépendantes de **2** et une de $C_6H_5CH_3$) et R = 0,071 pour 6911 réflexions observées et 1141 paramètres affinés. Le composé **3** est triclinique, $P\bar{1}$, avec a = 9,146(1), b = 12,290(1) et c = 13,027(1) Å, α = 100,72(1), β = 104,39(1) et γ = 110,55(1)°, Z = 2 et R = 0,037 pour 3046 réflexions observées et 304 paramètres. L'angle de l'unité Ti—O—Ti dans le composé **3** est de 175,6(2)°.

[Traduit par la rédaction]

Introduction

We have shown previously that the organometallic oxide $[(\eta\text{-}C_5H_5)Ti]_6(\mu_3\text{-}O)_8$ and sulfide $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ can be obtained by oxidation of $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ with H_2O or H_2S respectively (1–3). Floriani and co-workers obtained $[(\eta\text{-}C_5H_5)Ti]_6(\mu_3\text{-}Cl)_n(\mu_3\text{-}O)_{8-n}$ (n = 0, 2, 4) by reduction of the Ti(4+) complexes $[(\eta\text{-}C_5H_5)TiCl_2]_2(\mu\text{-}O)$ or $[(\eta\text{-}C_5H_5)\text{-}TiCl(\mu\text{-}O)]_4$ with aluminum or zinc powder (4). We wished to extend this preparation of (cyclopentadienyl)metal oxides by reductive aggregation of (cyclopentadienyl)metal oxo complexes to (cyclopentadienyl)metal sulfides and selenides. Therefore we investigated the reduction of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ (5) with zinc powder. We found previously that reductions with zinc powder introduce oxygen from the zinc oxide coating, which is invariably present on the metal surface, into the reactions (6–8). Because of this, reduction of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ with zinc powder produced not only the expected $[(\eta\text{-}C_5H_5)_2Ti]_5(\mu_3\text{-}S)_6$ but also several products containing oxygen, among which were $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ and $(\eta\text{-}C_5H_5)_2Ti(SH)(\mu\text{-}O)Ti(\eta\text{-}C_5H_5)(\mu\text{-}S)_2Ti(\eta\text{-}C_5H_5)_2$, which are new compounds. We also found that oxidation of $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ with H_2S in the presence of trace amounts of H_2O gave a similar mixture to that obtained by the reduction of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$. The reactions and characterization of many of the products are reported here in detail.

Results and discussion

Reduction of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ with zinc powder

Several products were formed when a toluene solution of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ was reduced with zinc powder. This was evident from the ESR spectra of the reaction solutions after removal of the excess zinc, zinc sulfide, and other insoluble materials. The spectra showed five major signals due to species containing titanium, as well as a number of minor features. The relative intensities varied with the conditions of the reaction, but all of the signals were consistently observed. A representative spectrum is shown in Fig. 1. The ESR signals have g values of 1.979, 1.992, 1.994, 2.004, and 2.010.

The signal with g = 1.994 was readily identified as being due to $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ (**1**) (literature value 1.993 (1)).

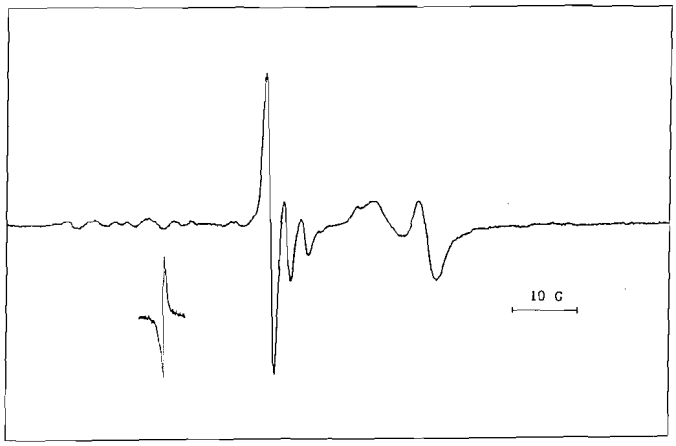

FIG. 1. The ESR spectrum of the product of the reduction of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ by zinc powder.

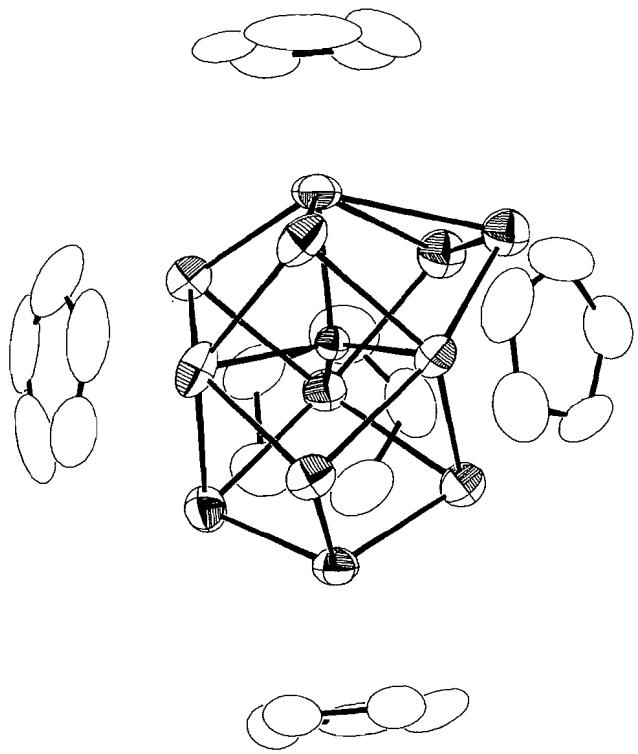

FIG. 2. ORTEP plot of one of the three independent molecules of $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ (**2**). Only a disordered molecule is shown.

The other signals must be due to species with one unpaired electron per molecule, or with unpaired electrons that do not interact with one another, since the signals are relatively sharp even at room temperature. Three methods were used to identify the compounds present: fractional crystallization from the toluene solution; mass spectrometry (performed on the solid obtained by removal of toluene under vacuum); and comparison of the ESR spectra of the mixture with those of known compounds or of compounds prepared as described below.

Fractional crystallization yielded **1**, $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ (**2**, Fig. 2), and $(\eta\text{-}C_5H_5)_2Ti(SH)(\mu\text{-}O)Ti(\eta\text{-}C_5H_5)(\mu\text{-}S)_2Ti(\eta\text{-}C_5H_5)_2$ (**3**, Fig. 3). Cluster **1** was identified by mass spectrometry, ESR spectroscopy, and by

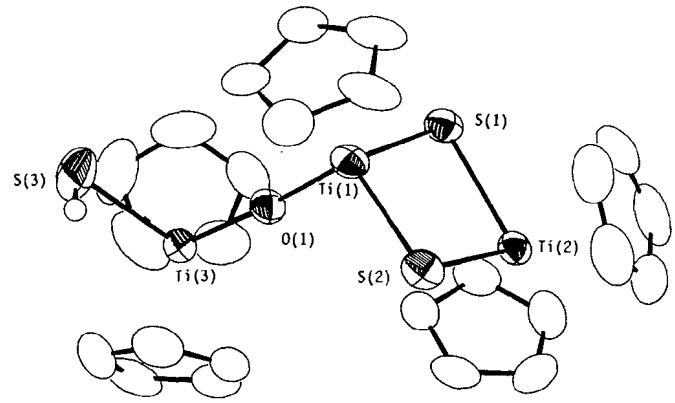

FIG. 3. ORTEP plot of $(\eta\text{-}C_5H_5)_2Ti(SH)(\mu\text{-}O)Ti(\eta\text{-}C_5H_5)(\mu\text{-}S)_2Ti(\eta\text{-}C_5H_5)_2$ (**3**).

comparison of the cell dimensions with the literature (1, 2). Compounds **2** and **3** were identified by X-ray diffraction (see Table 1). Their structures are discussed in detail below. We found previously that the zinc oxide coating present on the surface of zinc powder provided oxygen when oxochloro(cyclopentadienyl) derivatives of niobium and molybdenum were reduced (6–8). We believe that this zinc oxide is the source of the oxygen atoms in **2** and **3**, since normal precautions were taken to exclude oxygen and moisture from the solvents and reagents (9).

The mass spectrum of the reaction product showed a clear parent ion peak for $\mathbf{1}^+$ (*m/e* 757, relative intensity 17%) but not for **2** (M = 805). Peaks at *m/e* 739 (relative intensity 5%) and 580 (relative intensity 12%) were assigned to $\{[(C_5H_5)Ti]_4(S_2)_4(O)_2\}^+$ ($\mathbf{4}^+$) and $[(C_5H_5)TiS]_4^+$ ($\mathbf{5}^+$) respectively. The structure of **4** (see Fig. 4) is discussed below. The mass spectrum of the mixture also showed fragmentation of **1**, **4**, and **5** (principally by loss of C_5H_5), as well as peaks assignable to $[(C_5H_5)_2Ti(SH)_2]^+$ and $[(C_5H_5)_2TiS]^+$. The latter is probably derived from $[(\eta\text{-}C_5H_5)_2Ti(\mu\text{-}S)]_2$, which is, in turn, obtained from the starting material $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ by the equilibrium [1] (2, 10).

[1] $2\,(\eta\text{-}C_5H_5)_2Ti(SH)_2 \rightleftharpoons [(\eta\text{-}C_5H_5)_2Ti(\mu\text{-}S)]_2 + H_2S$

The ESR spectrum of crystalline $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ (**2**) showed a single-line signal at g = 1.980, and we assign the signal at 1.979 in the mixture of products obtained by reducing $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ with zinc powder to **2**. Since **2** formally contains Ti_5^{19+} it has only one cluster electron, and therefore it would show a single-line ESR spectrum regardless of its molecular structure. The compound $(\eta\text{-}C_5H_5)_2Ti(SH)(\mu\text{-}O)Ti(\eta\text{-}C_5H_5)(\mu\text{-}S)_2Ti(\eta\text{-}C_5H_5)_2$ (**3**) contains Ti_3^{12+}, and $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (**4**) contains Ti_4^{16+}. Therefore neither **3** nor **4** can show any ESR signal. The cluster $[(\eta\text{-}C_5H_5)TiS]_4$ (**5**), which was observed by mass spectrometery, is known to be a diamagnetic cubane (11), as predicted by extended Hückel molecular orbital calculations (12). Therefore no ESR signal would be expected. However, independent experiments established that mixtures of $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ and $[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)]_4$ showed ESR signals at g = 1.994 and 1.987. These could arise from the equilibrium [2].

[2] $[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)]_4 + [(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$
$\rightleftharpoons \{[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)]_4\}^+ + \{[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6\}^-$

[a]For $\{[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)\}_3 \cdot C_6H_5CH_3$.
[b]For $[(\eta\text{-}C_5H_5)Ti]_4(\mu\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O) \cdot 0.5C_6H_5CH_3$.

The alternative salt, $\{[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6\}^+\{[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)]_4\}^-$, is highly unlikely because it would require one titanium to have a formal oxidation state of (2+). Cationic and anionic derivatives of $[(\eta\text{-}C_5H_5)V]_5(\mu_3\text{-}S)_6$ (13) and $[(\eta\text{-}C_5H_5)M(\mu_3\text{-}S)]_4$ (M = V, Fe, Co, Mo) (11, 14–17) were observed previously. We assign the ESR signal at $g = 1.987$ to $[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)]_4^+$.

The signals at $g = 2.004$ and 2.010 cannot be identified from the above experiments, nor can they be accounted for by the products obtained from the reaction between $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ and H_2S in the presence of H_2O, which are described below. It is possible that they, like the signal at $g = 1.987$, are also due to equilibria that produce radicals, for example $\mathbf{4}^-$. However, if an anion of **4** was formed, it is not certain that the unpaired electron would be localized on titanium, since the S_2 unit could conceivably absorb an electron. In this respect the fact that the unassigned signals have g values greater than 2.002 may be significant.

Independent experiments established that **1** did not react with either H_2O or Ag_2O to form **2**, nor to form any characterizable cluster. The oxygen atoms present in **2**, **3**, and **4** must have been inserted during redox reactions between $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ and the zinc/zinc oxide powder. The S_2^{2-} ligand present in **2** and **4** must also be a product of these redox reactions. Compounds **2**, **3**, and **4** all contain at least one titanium atom bearing only one $\eta\text{-}C_5H_5$ ring. Four of the five titanium atoms in **2**, and all of the titanium atoms in **3** and **4**, have the formal oxidation state of 4+. The substitution of an $\eta\text{-}C_5H_5$ ligand in the titanium(4+) compound $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ by O^{2-} would be extremely slow, due to the very low concentration of O^{2-} in solution (18). The combination of Ti(4+) with a single $(\eta\text{-}C_5H_5)$ ligand is therefore further evidence that redox reactions are responsible for the insertion of O^{2-} in **2**, **3**, and **4**.

Oxidation of $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ in the presence of traces of oxygen

Since the reduction of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ with zinc powder gave clusters containing oxygen as well as sulfur, we were interested in the effect of oxygen (either as O_2 or H_2O) on the oxidation of $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ by H_2S. In the absence of oxygen this reaction gave $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ according to eq. [3] (1, 2). There was no evidence for other paramagnetic species in the ESR spectrum of the reaction

$$[3]\quad 10\,(\eta\text{-}C_5H_5)_2Ti(CO)_2 + 12\,H_2S \rightarrow 2\,[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6 + 14\,H_2 + 20\,CO + 5\,(C_5H_6)_2$$

solutions. However, when the reaction was conducted in the presence of traces of oxygen, in the form of H_2O, the ESR spectra of the reaction solutions were similar to those of the

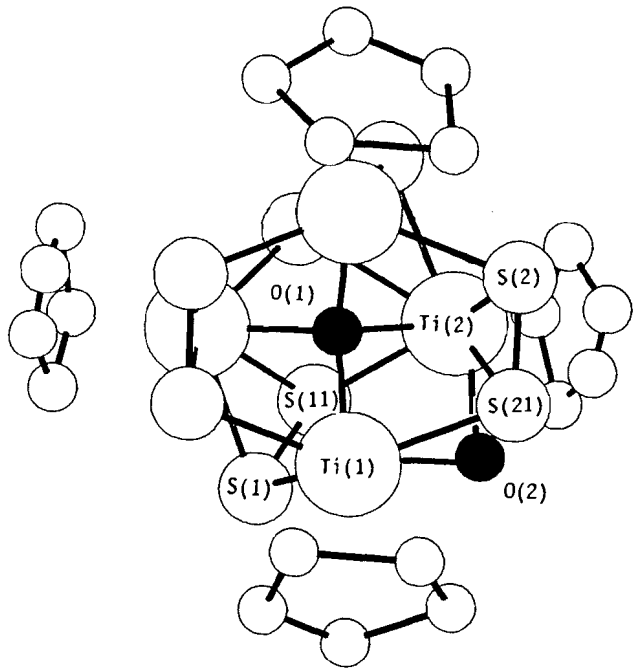

FIG. 4. The structure of $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (**4**). Only one of the several disordered forms is shown.

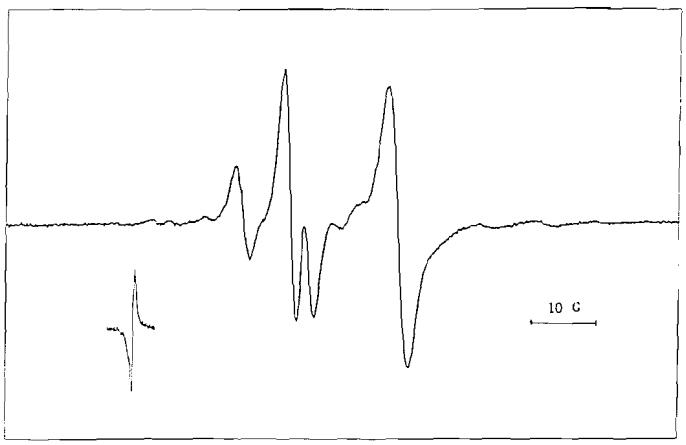

FIG. 5. The ESR spectrum of the product of the oxidation of $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ by H_2S in the presence of water.

solutions obtained by reducing $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ with zinc powder. A representative example is shown in Fig. 5; this may be compared with Fig. 1. In summary, signals were observed at g = 1.979, 1.987, 1.992, 1.994, and 2.007. The signals at 1.979, 1.987, and 1.994 were readily assigned to **2**, $\mathbf{5}^+$, and **1** respectively, as discussed above.

As with the reaction between $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ and zinc powder, we attempted to identify the species responsible for the ESR signals at g = 1.992 and 2.007 by fractional crystallization of toluene solutions, produced by reacting $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ with H_2S in the presence of H_2O. These attempts gave crystalline **1**, **2**, and **4**. Compound **4** (Fig. 4) had been observed in the mass spectrum of the reaction between $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ and zinc powder, but not otherwise identified. The structure of the $\eta\text{-}C_5H_4Me$ derivative of **4** was completely determined by X-ray crystallography by Rauchfuss

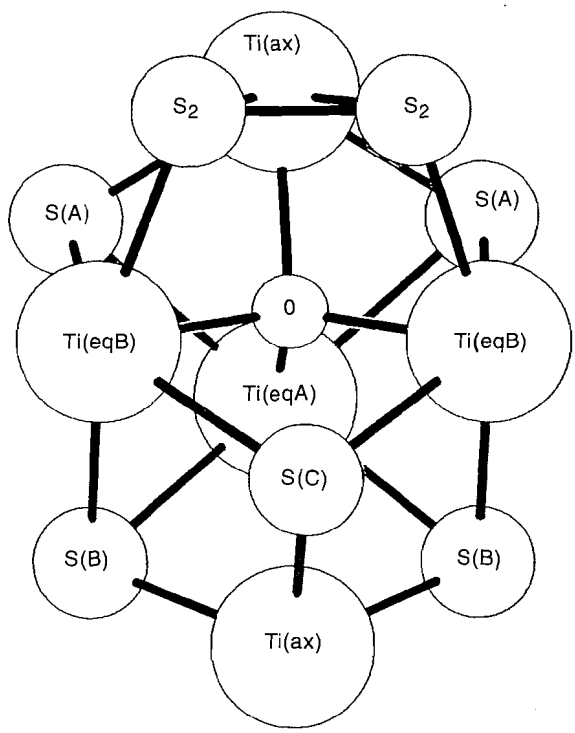

FIG. 6. Diagram of the $Ti_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ core of **2**, with numbering scheme.

and co-workers (19). The core of **4** also appears in $[TiCl]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}Cl)_2(\mu_4\text{-}O)$ (20), with chlorine replacing both $(\eta\text{-}C_5H_5)$ and the μ_2-oxygen, which is disordered over two positions in the structure of **4** (see Fig. 4). Because of serious disorder amongst the $\eta\text{-}C_5H_5$, S_2, and O ligands, and the presence of an ill-defined toluene molecule in the crystal lattice, the present analysis was only accurate enough to characterize the product unambiguously as $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$.

The source of the oxygen atoms present in compounds **2** and **4**, obtained when $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ was oxidized with H_2S, is believed with some certainty to be H_2O. There was no decrease in the amount of **2** when the H_2S was thoroughly degassed by freeze–thaw methods. This procedure would remove O_2 but not H_2O. However the amount of **2** increased markedly when small quantities of H_2O were deliberately added to the toluene solution of $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ immediately prior to incubation with H_2S. The relative amount of **2** could be easily assessed from the ESR spectra, but there was no convenient method of detecting **3** or **4**. The introduction of oxygen by water is consistent with the preparation of $[(\eta\text{-}C_5H_5)Ti]_6(\mu_3\text{-}O)_8$ from $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ and H_2O (2), but is in contrast to the preparation of $[(\eta\text{-}C_5H_4Me)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ and $[(\eta\text{-}C_5H_4Me)Ti]_4S_8O$, where the source of oxygen was O_2 (19).

Structure of $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ (2)

The crystal of **2** contained four asymmetric units per cell, each unit consisting of three independent molecules of **2** and one of toluene. Including the disordered atoms there were 135 non-hydrogen and 88 hydrogen atoms to be refined, all in general positions, giving a total of 1141 parameters. Some of the available structure refinement programs do not ac-

Ti(eqA)—Cp	2.060 (3, 14, 7)
Ti(eqA)—Cp	2.081 (6, 14, 25)
S—S	2.02 (5, 1, 2)

[a]Ti(ax) are the axial Ti atoms; Ti(eqA) is the unique equatorial Ti; Ti(eqB) are the equatorial Ti atoms which are bridged by the μ_3-S_2 unit (see Fig. 6).

[b]The first digit in parentheses is the number of parameters that have been averaged; the second digit is the average e.s.d.; the third digit is the maximum deviation from the mean.

[c]The S(A) and S(B) atoms are the μ_3-S that are attached to the unique equatorial Ti(eqA). The S(A) atoms are in the half of the trigonal bipyramid of titanium atoms that contains the μ_3-S_2 and μ_4-O units. The S(B) atoms are in the other half of the trigonal bipyramid (see text and Fig. 6).

[d]Distances are averaged to each sulfur of the S_2 moiety.

[e]The S(C) atoms are the μ_3-S that are attached to the Ti(eqB) atoms and are in the opposite half of the trigonal bipyramid to the μ_3-S_2 and μ_4-O units (see text and Fig. 6).

[f]Cp is the centroid of the C_5 ring of the C_5H_5 ligand.

commodate such a large number of atoms. The latest version of NRCVAX (21), which was used for the refinement, accommodated the atoms but only allowed a block refinement. In the final refinement the Ti, S, and all C atoms having unit occupancy were refined anisotropically. The solution of the structure was complicated by positional disorder involving the μ_3-S, μ_3-S_2, and μ_4-O ligands. The disorder is best described, with the aid of Fig. 6, by noting that **2** can be derived from **1** by replacing one μ_3-S by one μ_3-S_2 and at the same time placing a μ_4-O in that half of the trigonal bipyramid of titanium atoms that has the μ_3-S_2 ligand. In the crystal, the molecules were disordered so that the exchange of μ_3-S_2 for μ_3-S appeared to have taken place at two of the six possible sites, with a site occupancy for each position of less than unity. The site occupancies were different in each of the three independent molecules. The μ_4-O was disordered over two sites to follow the μ_3-S/μ_3-S_2 disorder. Figures 4 and 6 show only an undisordered molecule for clarity. Because of the disorder, the μ_3-S and μ_3-S_2 units were superimposed on one another in the observed structure. The site occupancies were determined by refinement, fixing the thermal parameters at the average isotropic value of the undisordered μ_3-S atoms. This refinement, in collaboration with the observed S—S and S—O distances, showed conclusively that the ligands in **2** were μ_3-S, μ_3-S_2, and μ_4-O, and that neither S_3^{2-} nor S_2O^{2-} was present. Because of the disorder, the S—S distance in the μ_3-S_2 unit was very poorly, and the Ti—μ_3-S_2, Ti—μ_4-O, and Ti—μ_3-S(C) distances were poorly, determined. The Ti—Ti, Ti—μ_3-S(A), Ti—μ_3-S(B), and Ti—C distances were well determined (see Fig. 6 for the definition of S(A), S(B), and S(C)). Table 2 lists the important distances, averaged over the three independent molecules. Surprisingly, only one of the 15 independent η-C_5H_5 rings showed evidence of disorder (that attached to Ti(34)), and this was treated as such.

As noted above, **2** is derived from **1** by replacement of one μ_3-S ligand by one μ_3-S_2 and one μ_4-O ligand. Both of the replacement ligands enter the same half of the trigonal bipyramid of titanium atoms. The axial Ti atoms are defined as those with the lower coordination numbers, and the two "halves" of the trigonal bipyramid are related by the twofold axis. The presence of the μ_3-S_2 ligand causes one equatorial Ti—Ti edge of the trigonal bipyramid to lengthen to 3.60 Å, compared to the other equatorial edges (3.24 Å), and to the axial–equatorial edges (3.22 Å) (see Fig. 6 and Table 2). In **1** the Ti(ax)—Ti(eq) distances average 3.18 Å (1). The Ti(ax)—μ_3-S distances in **2** average 2.38 Å for the S(A) atoms in the half of the trigonal bipyramid containing the μ_3-S_2 and μ_4-O ligands. This is much longer than the average Ti(ax)—S(B) distance of 2.31 Å; the latter can be compared to the Ti(ax)—μ_3-S distances in **1**, which average 2.28 Å, and to the Ti—μ_3-S distances in $[(\eta\text{-}C_5H_4Me)Ti(\mu_3\text{-}S)]_4$, 2.36 and 2.40 Å (11). The average Ti(eqA)—S(B) distance of 2.55 Å may also be compared to the Ti(eq)—μ_3-S distance of 2.47 Å in **1** (1). It is seen that **1** is more compact than **2**, probably because the μ_4-O must be accommodated in the core. The Ti—S_2 distances are the same for both the axial and equatorial titanium atoms within experimental error, averaging 2.54 Å. This is very similar to the average value of 2.55 Å in $[(\eta\text{-}C_5H_4Me)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (19). Because of the disorder it is unwise to attach much significance to the Ti—O distances in **2**, but the range, 2.01–2.07 Å, includes the values observed in $[(\eta\text{-}C_5H_4Me)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (2.06 Å (19)) and in $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}Se)(\mu_3\text{-}Se)_2(\mu_3\text{-}Se_2)_2(\mu_4\text{-}O)$ (1.95, 2.17 Å (22)). Cluster **2** appears to be the first example of a μ_4-oxygen enclosed in a trigonal bipyramidal arrangement of metal atoms.

The axial titanium attached to the S_2 unit is eight-coordinate, the other axial titanium is six-coordinate; Ti(eqA) is seven-coordinate, and Ti(eqB) is eight-coordinate. The different coordination numbers are the reason for the different Ti—Cp and Ti—S(C) distances, and contribute to the differences in the Ti—S and Ti—O distances discussed above.

Structure of

*$(\eta\text{-}C_5H_5)_2Ti(SH)(\mu\text{-}O)Ti(\eta\text{-}C_5H_5)(\mu\text{-}S)_2Ti(\eta\text{-}C_5H_5)_2$ (**3**)*

The structure of **3** is shown in Fig. 3 and a list of important distances and angles is given in Table 3. The asymmetry in the Ti(1)—(μ-O)—Ti(3) bridge (Ti—O—Ti 175.6(2)°, Ti(1)—O 1.807(2), Ti(3)—O 1.844(2) Å) and in the Ti(1)—(μ-$S)_2$—Ti(2) bridge (average Ti—S—Ti 88.06(4)°, average Ti(1)—S 2.288(1), average Ti(2)—S 2.416(1) Å) is caused by the different coordination numbers of the titanium atoms. The Ti(1) atom is six-coordinate, whereas Ti(2)

		Ti(1)—O(1)—Ti(3)	175.6 (2)

[a]Estimated standard deviations in brackets.
[b]Cp is the centroid of the C_5 ring of $\eta\text{-}C_5H_5$.
[c]Cp(1) is the average of the two disordered C_5 rings attached to Ti(1).
[d]Cp(21) is the centroid of C(21)—C(25), Cp(22) of C(26)—C(30), Cp(31) of C(32)—C(35), Cp(32) of C(36)—C(40) (see Table 4).

and Ti(3) are eight-coordinate. Otherwise the distances and angles are very similar to those in related compounds such as $(\eta\text{-}C_5H_5)_2Ti(SMe)_2$ (23), $(\eta\text{-}C_5H_5)_2Ti(SC_2H_5)_2$ (24), $(\eta\text{-}C_5Me_5)_2Ti(SH)_2$ (2), $[(\eta\text{-}C_5H_5)_2TiCl(\mu\text{-}O)]_2[(\eta\text{-}C_5H_5)TiCl]$ (25), and $[(\eta\text{-}C_5H_5)_2Ti(C_2H_5)]_2(\mu\text{-}O)$ (26).

Experimental

General techniques and reagents

All experiments were carried out under argon or vacuum using standard vacuum-line techniques (9). Volumes of H_2S were measured using a manometer and calibrated bulb. Solvents were predried by standard drying agents, stored over Bu^{n}Li, and distilled under vacuum. Literature methods were used to prepare $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ (27) and $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ (10); H_2S was purchased from Canadian Liquid Air, Montreal, and used as received. Zinc dust (<325 mesh, Aldrich) was evacuated prior to use and transferred to the reaction flask under argon. All other chemicals were reagent grade. Instruments used were a Varian XL-200 NMR spectrometer, a Kratos MS50 mass spectrometer, and a locally modified version of the Varian E-4 ESR spectrometer.

Reaction between $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ and zinc powder

A solution of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ (1.022 g, 4.18 mmol) in toluene (150 cm^3) was stirred with zinc powder (0.269 g, 4.12 mmol) at room temperature for 3 days. The mixture was filtered, and the red filtrate was set aside. After 7 days the solution had deposited crystals of $(\eta\text{-}C_5H_5)_2Ti(SH)(\mu\text{-}O)Ti(\eta\text{-}C_5H_5)(\mu\text{-}S)_2Ti(\eta\text{-}C_5H_5)_2$ (**3**) (approx. 5%) and $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ (**2**) (approx. 10%). These were removed by filtration and structurally characterized by X-ray diffraction (see below). In addition **2** was characterized by the following data: ESR spectrum (toluene solution) g = 1.980; Anal. calcd. for $C_{82}H_{83}O_3S_{21}Ti_{15}$ ($\{[(C_5H_5)Ti]_5S_7O\}_3 \cdot C_6H_5CH_3$): C 39.3, H 3.4, S 26.8%; found: C 41.0, H 3.6, S 23.7%.

The volume of the filtrate was reduced to 100 cm^3 under vacuum, and the red solution layered with hexane (50 cm^3). This procedure gave $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ (0.71 g, 2.9 mmol 70%), as determined by NMR spectroscopy (^{1}H, 200 MHz ($CDCl_3$ solution): 6.27 ppm (10 H), 3.36 ppm (2 H)) and mass spectrometry (EI, m/e 243 ($[(C_5H_5)_2Ti(SH)S]^+$); 210 ($[(C_5H_5)_2TiS]^+$)). Further reduction in volume to 50 cm^3 and further layering with hexane (50 cm^3) gave a red precipitate, which was a mixture of $(\eta\text{-}C_5H_5)_2Ti(SH)_2$ and $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ (approx. 10%), as determined by mass spectrometry (EI, m/e 757 ($[(C_5H_5)_5Ti_5S_6]^+$); 243 ($[(C_5H_5)_2Ti(SH)_2-H]^+$), 210 ($[(C_5H_5)_2TiS]^+$)) and NMR spectroscopy (^{1}H, 200 MHz, ($CDCl_3$ solution): 14.68 ppm (15 H, $(\eta\text{-}C_5H_5)_5Ti_5S_6$), 9.65 ppm (10 H, $(\eta\text{-}C_5H_5)_5Ti_5S_6$), 6.27 ppm (10 H, $(\eta\text{-}C_5\mathit{H}_5)_2Ti(SH)_2$), 3.36 ppm (2 H, $(\eta\text{-}C_5H_5)_2Ti(SH)_2$).

Reaction between $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ and H_2S in the presence of water

To a solution of $(\eta\text{-}C_5H_5)_2Ti(CO)_2$ (1.532 g, 6.5 mmol) in toluene (100 cm^3) were added two drops of water. The solution was incubated with H_2S (7.8 mmol), with stirring, at 80°C for 72 h. Over this period the color of the solution changed from red to yellow-green and a dark brown precipitate of $[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)]_4$ (0.94 g, 1.10 mmol, 50%) deposited. The precipitate was removed by filtration, and the solution set aside. After 8 days, crystals of both $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ (**1**) (approx. 10%) (identified by comparison of cell dimensions with the literature (1)) and of $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (**4**) (approx. 5%) were obtained. Compound **4** was characterized by X-ray crystallography as described below and by ^{1}H NMR (200 MHz, C_6D_6 solution): 6.21 (10 H), 5.65 (10 H), assigned to the two types of C_5H_5 ring. The crystals were removed by filtration and the filtrate was layered with hexane (50 cm^3), giving a dark-green powder. This was shown by a combination of NMR, ESR, and mass spectroscopies to be a mixture of $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_6$ (**1**) (ESR: g = 1.993; MS, m/e 757, 692, 627 ($(C_5H_5)_nTi_5S_6^+$, n = 5, 4, 3)); $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (**4**) (MS, m/e 740 ($(C_5H_5)_4Ti_4S_8O_2^+$), ^{1}H NMR (C_6D_6 solution): 6.21, 5.65 ppm, each 10 H); $[(\eta\text{-}C_5H_5)Ti]_5(\mu_3\text{-}S)_5(\mu_3\text{-}S_2)(\mu_4\text{-}O)$ (**2**) (ESR: g = 1.979); $[(\eta\text{-}C_5H_5)Ti(\mu_3\text{-}S)]_4$ (**5**) (MS, m/e 580, 515, 450 ($(C_5H_5)_nTi_4S_4^+$, n = 4, 3, 2), ^{1}H NMR (200 MHz, ^{2}H, $CHCl_3$ solution): 5.98 ppm); and $[(\eta\text{-}C_5H_5)TiS]_4^+$ (ESR: g = 1.988).

X-ray crystallography

X-ray diffraction experiments were carried out on an Enraf–Nonius CAD4 diffractometer operating under the control of the NRCCAD software (28). The radiation was Mo Kα, λ = 0.71073 Å. Data were collected using the θ/2θ scan method. Refinement used the NRCVAX suite of programs (21). The weighting scheme was of the form $w = 1/(\sigma(F)^2 + kF^2)$. Scattering factors were taken from ref. 29. Crystal and refinement data for **2**, **3**, and **4** are collected in Table 1. In the final refinements hydrogen atoms were included as fixed contributors (C—H = 0.96 Å, isotropic B equal to that of the carbon atom to which they were attached).

The structural analysis of **3** was uneventful. Atomic coordinates for **3** are given in Table 4 and important distances and an-

[a]Estimated standard deviations, given in parentheses, refer to the last digit printed.
[b]B_{iso} is the mean of the principal axes of the thermal ellipsoid.
[c]C(11)—C(15) and C(11A)—C(15A) refer to a disordered C_5H_5 ring attached to Ti(1); each of these carbons was given an occupancy of 0.5.

gles in Table 3. Other data have been deposited.[2] Analysis of **4** was complicated by poor data and disorder in all atoms except Ti and μ_4-O. These are the reasons for the high *R* value. Brief attempts to refine the structure in space groups $P4_2/ncm$ or the cubic $P23$ showed that the disorder was not removed. In view of the previous determination of the structure of $[(\eta\text{-}C_5H_4Me)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$ (19), further investigation was deemed unnecessary. The experiments clearly characterized **4** as $[(\eta\text{-}C_5H_5)Ti]_4(\mu_2\text{-}S_2)_4(\mu_2\text{-}O)(\mu_4\text{-}O)$. All structural parameters for **4** have been deposited.[2] The structural analysis of **2** posed major problems of refinement, which are outlined in the Discussion above. The final atomic coordinates are given in Table 5 and the important averaged distances in Table 2. Other data, including a comprehensive table of distances and angles, and a listing of site occupancies, have been deposited.[2]

[2]Supplementary material available: Atom numbering scheme, tables of hydrogen atom positions, thermal parameters, site occupancies, distances and angles (33 pages), and a table of $|F_o|$ and $|F_c|$ (34 pages) for **2**. Atom numbering scheme, tables of hydrogen atom positions, thermal parameters, distances and angles (7 pages), and a table of $|F_o|$ and $|F_c|$ (15 pages) for **3**. Atom numbering scheme, atomic parameters for all atoms, thermal parameters, distances and angles (7 pages), and a table of $|F_o|$ and $|F_c|$ (7 pages) for **4**. This material may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2.

Atom numbering schemes, tables of hydrogen atom positions (for **2** and **3**) and atomic parameters (for **4**), distances and angles have also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, U.K.

Received July 31, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

BALDWIN S. MOOTOO, CUMANDÁ JÁTIVA, WINSTON F. TINTO, WILLIAM F. REYNOLDS, and STEWART MCLEAN. Can J. Chem. **70**, 1260 (1992).

Ecuadorin (**1**), $C_{29}H_{34}O_{10}$, a novel tetranortriterpenoid, has been isolated from *Guarea kunthiana* (Meliaceae) collected in Ecuador. Its structure has been established by spectroscopic methods, mainly 2-D NMR spectroscopy; the value of the FLOCK pulse sequence in the determination of 2- and 3-bond $^{13}C-^{1}H$ connectivities is illustrated. Ecuadorin has been reduced to the dihydro and tetrahydro derivatives (**2** and **3**), and these have provided information regarding the stereochemistry of ecuadorin. Stereochemical arguments have been based on observed vicinal $^{1}H-^{1}H$ coupling constants and NOE measurements, as well as on biosynthetic hypothesis.

BALDWIN S. MOOTO, CUMANDÁ JÁTIVA, WINSTON F. TINTO, WILLIAM F. REYNOLDS et STEWART MCLEAN. Can. J. Chem. **70**, 1260 (1992).

On a isolé l'écuadorine (**1**), $C_{29}H_{34}O_{10}$, un nouveau tétranortriterpènoïde, à partir de *Guarea kunthiana* (Meliaceae) recueilli en Équateur. On a déterminé sa structure par des méthodes spectroscopiques, principalement par la RMN en 2-D; on illustre la valeur de la séquence de pulsation FLOCK dans la détermination des connectivités $^{13}C-^{1}H$ avec 2 et 3 liaisons. On a réduit l'écuadorine en dérivés dihydro et tétrahydro (**2** et **3**) et ces composés ont fournit de l'information concernant la stéréochimie de l'écuadorine. Les arguments stéréochimiques sont basés sur les constantes de couplages $^{1}H-^{1}H$ vicinales observées, sur des mesures d'EON ainsi que sur une hypothèse biosynthétique.

[Traduit par la rédaction]

The plant family Meliaceae has been a rich source of biosynthetically modified triterpenes that have useful biological activity; some are insect antifeedants, and some are cytotoxic and may be useful medicinally (*1*). Their structural complexity and diversity attracts the attention of the chemist. We have begun a study of the Meliaceae of Ecuador, and we report here on the elucidation of the structure of a new tetranortriterpenoid which we have isolated from *Guarea kunthiana* A. Juss, and to which we assign the name ecuadorin. The plant was collected in Pichincha province, and extraction of its aerial parts afforded ecuadorin.

Ecuadorin was obtained as colorless crystals, mp 237–238°C, $C_{29}H_{34}O_{10}$ (by HRMS); the IR spectrum included strong peaks at 1752, 1737, 1715, and 1660 cm^{-1}, and the UV spectrum showed peaks at 208 nm (ϵ, 11 000) and 236 nm (ϵ, 8 200). After the ^{1}H and ^{13}C NMR spectra has been obtained, a one-bond 2-D $^{13}C-^{2}H$ shift-correlation experiment was used to label carbons with their attached protons. Our FLOCK pulse sequence (*2*) was then used to determine *n*-bond ($n > 1$) $^{13}C-^{1}H$ connectivities; FLOCK provides excellent sensitivity while suppressing one-bond peaks, and can, in favorable cases, be used to distinguish between two-bond and three-bond connectivities. COSY-45 spectra were used to confirm $^{1}H-^{1}H$ connectivities. The data obtained from these NMR experiments are assembled in Table 1. The observed $^{13}C-^{1}H$ *n*-bond connectivities are sufficient to establish that ecuadorin has the molecular skeleton of **1** since all C–C connectivities are shown by them implicitly (often in several ways). The nonprotonated carbons C-8 and C-9 are exceptions since the three-bond connectivity between H-30 and C-9 was not observed, and the cross peak between H-11 and C-8 was extremely weak; in both cases it seems that $^{3}J_{CH}$ couplings are unusually small. However, it should be noted that, with all other C–C connectivities explicitly defined, only structure **1**, with C-8 and C-9 directly linked, can accommodate the molecular formula and the other spectroscopic data. To verify that C-8 and C-30 are part of an oxirane moiety, the $^{1}J_{CH}$ at C-30 was measured and found to be 179 Hz, a value that establishes that the carbon is in a three-membered ring (*3*). These NMR experiments were carried out with a solution of 20 mg of ecuadorin in benzene-d_6 since all significant signals were well resolved in this solvent, although the chemical shift between the C-11 methylene protons was effectively zero. As a result, these protons showed virtual coupling to the C-12 methylene protons, and only an average vicinal coupling (J = 6.7 Hz) was observed. In $CDCl_3$ solution, although some other signals were more poorly resolved, the C-11 methylene protons were observed at δ 2.18 and δ 2.35 with a geminal coupling of 15.6 Hz; in this solvent, the C-12 methylene protons appeared at δ 1.85 and δ 1.56, and all four vicinal couplings between the C-11 and C-12 protons were nonequivalent and observed.

Vicinal $^{1}H-^{1}H$ coupling constants were of limited value for making stereochemical assignments: the *trans*-diaxial relationship between the protons at C-5 and C-10 is clear from their 12.6 Hz coupling, but the 2.9 Hz coupling between the protons at C-5 and C-6 does not establish the relative con-

OCH_3	51.81	3.20	—
O_2CCH_3	169.54	—	1.66, 5.41
O_2CCH_3	20.10	1.66	—

[a] Spectral data were obtained on a Varian XL-400 spectrometer equipped with a 5-mm multinuclear probe with a solution of 20 mg ecuadorin in ca. 0.5 mL of benzene-d_6.

[b] ^{13}C chemical shifts in ppm from Me_4Si measured at 100.6 MHz.

[c] ^1H chemical shifts in ppm from Me_4Si measured at 400 MHz, and ^1H–^1H coupling constants (Hz) in parentheses; couplings are with single protons except where triplet (t) or quartet (q) splittings are indicated. The ⟨mean δ_H⟩ is shown for an incompletely resolved CH_2 multiplet.

[d] Hydrogens showing n-bond connectivities to the ^{13}C; n = 2 or 3 unless otherwise indicated. Strong (s), weak (w), or very weak (vw) cross peaks are indicated where appropriate.

[e] Assignment of methyl groups based on nOe experiment. Irradiation at δ 1.22 produces 4% nOe for H-10 and 4% for H-3; irradiation at δ 0.88 produces 5% nOe for H-5 and 9% for H-3. The weak cross peak between H-5 and C-28 in the n-bond connectivity experiment is consistent with their having *anti* orientation.

figuration at C-6. Other stereochemical relationships were determined from NOE difference spectra. In benzene-d_6 solution, irradiation of the C-30 proton produced a 10% NOE at the C-17 proton and a 7% NOE at the δ 2.22 proton of the C-15 methylene. The C-30 and C-17 protons can be brought closely enough together to produce the 10% NOE only when the two six-membered rings are *cis*-fused and the relative configuration at the five contiguous centres from C-30 to C-17 is as shown. Besides confirming this stereochemistry, the NOE at the δ 2.22 proton confirms the chemical shift assignments for the individual protons of the CH_2 group. It is apparent that these stereochemical features are divided into two sections by the C-2 to C-30 single bond and, while the stereochemical relationships *within* each section are secure as described above, the configurational relationship *between* the cyclohexenone ring and the polycylic part of the molecule is not established from the available data.

Further stereochemical information was obtained by treating ecuadorin with acidic sodium cyanoborohydride, which reduced first the C-9 carbonyl group to provide the dihydroecuadorin **2**, and then the α,β-unsaturated C-1 carbonyl, producing the tetrahydroecuadorin **3**. Structural and spectroscopic assignments based on one-bond ^{13}C–^1H connectivities were carried out on **2** and **3**, and the assignments are listed in Table 2. One feature that became immediately apparent was that reduction of the carbonyl groups significantly changed the conformational preference of the molecule. Both ^1H and ^{13}C spectra of dihydroecuadorin **2** showed significant peak broadening at room temperature, particularly for signals associated with the fused bicyclic portion of the molecule (C-8, C-9, and C-11 to C-18), and the spectra sharpened significantly when the sample was warmed to 50°C. The vicinal coupling constants from H-14 to the two protons at C-15 increase slightly from **1** (4.9, 8.0 Hz) to **2** (6.3, 8.1 Hz). These observations suggest that dihydroecuadorin is undergoing a slow chair-to-chair interconversion at room temperature. By constrast, tetrahydroecuadorin **3** gives sharp ^1H and ^{13}C spectra at room temperature; further-

[a] ^{13}C chemical shifts in ppm from Me_4Si measured at 100.6 MHz for solution in $CDCl_3$; assignments based on one-bond connectivities.

[b] ^{1}H chemical shifts in ppm from Me_4Si measured at 400 MHz for solution in $CDCl_3$. The δ_H for each identifiable proton (or methyl) is listed; the ⟨mean δ_H⟩ is reported for unresolved CH_2 multiplets.

[c] ^{1}H–^{1}H coupling constants (Hz) for couplings with single protons unless quartet (q) splitting is indicated. Complex or unresolved multiplets are designated (m).

more, H-14 now shows vicinal coupling constants of 6.9 and 11.1 Hz to the protons at C-15. In addition, a number of carbons well removed from C-1 (the point of difference between **2** and **3**) show surprisingly large chemical differences between the dihydro and tetrahydro derivatives; e.g., compare the ^{13}C chemical shifts at positions 8, 9, 12, 15, and 17 (Table 2). Similarly, there is a large difference between the H-17 chemical shifts of **2** and **3**. All of these observations suggest an inversion of the conformational preference of the *cis*-fused rings between ecuadorin and tetrahydroecuadorin. In **1** H-14 is equatorial to the lactonic ring and axial to the carbocyclic ring, while in **3**, with the alternative chair–chair conformation, H-14 is axial to the lactonic ring and equatorial to the carbocyclic ring. In the same way, H-17, which is axial in **1**, becomes equatorial in **3**, and the chemical shift also changes.

The vicinal coupling constants observed at H-9 in both **2** and **3** require this hydrogen to be equatorial, and the C-9 OH is, consequently, axial (and *trans* to H-14). In **3** the H-1 must be pseudoaxial and *trans* to H-10 (J = 9.1 Hz), and the C-1 OH is, therefore, pseudoequatorial; the *trans*-diaxial relationship between H-10 and H-5 is verified by the observed vicinal coupling (11.3 Hz). The OH peaks in the spectrum of **3** appear as a very broad signal centred near δ 4.25, even though the solution is quite dilute. The low-field shift and the broadness of the peak suggest that the OH groups are intramolecularly hydrogen-bonded to each other (with slow proton interchange). Rotation about the 2,30 single bond is consequently inhibited, the cyclohexene unit has a preferred orientation relative to the polycyclic part of the molecule, and NOE experiments can now give useful information about the stereochemical relationship *between* these two parts of the molecule. No measureable NOE was observed for H-9 on irradiation of H-1 (or vice versa) at room temperature. However, irradiation of H-9 produced a 4% enhancement of the H-3 signal, while irradiation of H-1 produced 2% enhancements of the H-30 and H-5 signals. These results show the preferred orientation of the cyclohexene ring relative to the polycylic part of the molecule is as shown in **3**; the conformational preference of the *cis*-fused rings has already been established, the C-1 and C-9 OH groups are hydrogen-bonded, and the configurational relationship between C-1 and the centres on the other side of the 2,30 bond can now be determined. Examination of molecular models shows that

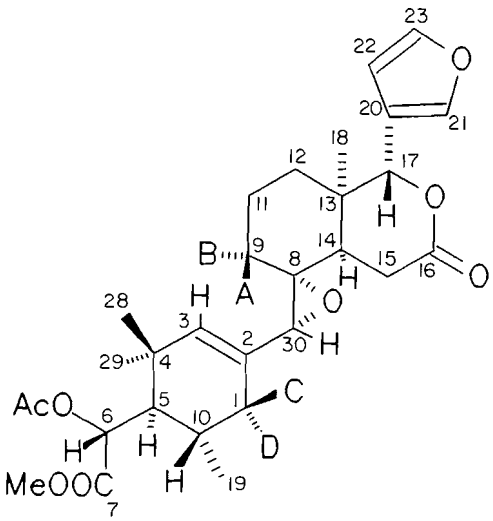
only a molecule with the configuration shown can be placed in a conformation that is compatible with all of the data assembled. Experiments with a sample of **3** at 55°C gave results that differed in an interesting and informative way from those carried out at room temperature: the OH signal sharpened and moved to higher field (ca. δ 3.95), and positive NOE enhancements were observed at both H-1 and H-3 on irradiation of H-9. It follows that at the higher temperature two conformations, corresponding to a rotation about the 2,30 bond, must be populated to a significant extent.



1 A + B = C + D = O

2 A = OH; B = H; C + D = O

3 A = OH; B = H; C = OH; D = H

The arguments for the configurational relationship between the two parts of the molecule are less securely based than those for the relative configuration within each part, but they gain additional support from a reasonable hypothesis concerning the biosynthetic origin of ecuadorin. Although its structural type is new, the relationship of ecuadorin to limonoids with the swietenine skeleton is easily seen; the structure and absolute configuration of swietenine (**4**) have been established unequivocally by an X-ray crystal structure analysis (4). The hypothetical biosynthetic precursor to ecuadorin has the 8,30 double bond of swietenine epoxidized, and C-9 is hydroxlyated; a retro-aldol reaction can then disconnect C-9 from C-10 and produce the ecuadorin skeleton, and a simple elimination introduces the 2,3 double bond. A swietenine derivative incorporating the 8,30 epoxide with the correct configuration but lacking the C-9 OH has been isolated from *Swietenia macrophylla* (5). The simplicity of the biosynthetic hypothesis and the existence of a limonoid incorporating all but one of the required features in the hypothetical precursor provide strong support for the biosynthetic proposal and collateral support for our stereochemical assignments. The configuration shown at C-6 is that expected on biosynthetic grounds. We would like to have used X-ray crystallography to provide unequivocal confirmation for all of our structural and stereochemical assignments, but no derivative of ecuadorin has yet provided crystals suitable for this purpose.

Experimental

Guarea kunthiana was collected in Pichincha Province, Ecuador, in October 1986. A voucher specimen (QCA No. 1124) is lodged in the Herbarium of the Catholic University of Ecuador, Quito. Air-dried aerial parts of the plant (2.3 kg) were ground and extracted with cold dichloromethane. The extract afforded a dark green gum (17.9 g), which was partitioned into hexane-soluble (5.7 g) and hexane-insoluble (10.5 g) fractions. A portion (930 mg) of the latter fraction was treated with decolorizing charcoal in refluxing ethyl acetate, and then chromatographed on silica gel. Elution with hexane containing increasing amounts of ethyl acetate led, when the solvent contained 90% or more ethyl acetate, to the isolation of *ecuadorin* (**1**) (61 mg) as colorless needles, mp 237–328°C (recrystallized from methanol), $[\alpha]_D$ + 4.2 (*c* 0.7, $CHCl_3$); IR (Nujol): 1752, 1737, 1715, 1600 cm^{-1}; UV (EtOH) λ_{max}: 208 nm (ε, 11 000), 236 nm (ε, 8 200); HREIMS *m/z*: 542.2122; calcd. for $C_{29}H_{34}O_{10}$: 542.2152.

Dihydroecuadorin 2 and tetrahydroecuadorin 3

A solution of **1** (73 mg) in 5 mL of tetrahydrofuran was brought to approximately pH 1 by addition of 1 N hydrochloric acid, and sodium cyanoborohydride (84 mg) was then added in small portions; the pH was kept constant by the addition of acid when required. After 0.5 h, solvent was removed under reduced pressure, 5 mL of water was added, and the mixture was thoroughly extracted with dichloromethane. The extract afforded a residue (70 mg) that was subjected to preparative layer chromatography on silica gel with elution by 5:1 chloroform–acetate. Less polar fractions afforded *dihydroecuadorin 2* (16 mg), mp 248–249°C (recrystallized from $CHCl_3$–MeOH) $[\alpha]_D$ −16.4 (*c* 0.25, $CHCl_3$); UV (EtOH) λ_{max}: 221 nm (ε, 7 800), 238 nm (ε, 7 600); HREIMS *m/z*: 544.2292; calcd. for $C_{29}H_{36}O_{10}$: 544.2309. The more polar fractions afforded *tetrahydroecuadorin 3* (15 mg), mp 241–242°C (recrystallized from MeOH–$CHCl_3$), $[\alpha]_D$ −13.9 (*c* 0.6, $CHCl_3$); HREIMS *m/z*: 546.2449; calcd. for $C_{29}H_{38}O_{10}$: 546.2465.

Introduction

Previous studies in our laboratory, on the intramolecular Michael addition of cyclic β-ketoesters onto conjugated olefinic ketones, showed that it was possible to form 5- to 8-membered rings with fairly good yields (1). In addition it was shown that the analogous addition onto conjugated acetylenic ketones produced 5- to 7-membered rings (2). In yet another study, it was demonstrated that it was possible to use the intramolecular Michael reaction to close 9- and 10-membered rings, but the yields were moderate compared with the cyclization of smaller rings (3). At that time it was predicted that this synthetic strategy could lead to excellent yields (≥80%) in macrocyclization, provided that transannular steric interactions and conformational mobility could be decreased.

In this paper we wish to report the results of the study of the formation of 14-membered carbocycles by the intramolecular Michael addition of substituted malonates onto conjugated acetylenic and olefinic ketones. We describe first the preparation of several cyclization precursors (ynones **14**, **28**, and **34** and enones **30** and **36**), and then the macrocyclization of each of these compounds.

Results and discussion

Synthesis of the cyclization precursors

Our study began with ynone **14**, which was prepared from 3-butyn-1-ol **1** as shown in Scheme 1. **1** was protected as its tetrahydropyranyl ether **2** (74%), which was then treated with *n*-butyllithium in a mixture of tetrahydrofuran–hexamethylphosphoramide (HMPA) (3:2), followed by oxirane to give alcohol **3** (90%). It should be noted that replacing HMPA by other polar solvents such as HMPT (hexamethylphosphorous triamide) or DMPU (1,3-dimethyl-3,4,5,6-tetrahydro-2(1*H*)pyrimidinone) gave unsatisfactory yields of alcohol **3**.

Alcohol **3** was transformed into the mesylate **4** (95%), which was displaced by dimethylmalonate to form diester **5** (78%). The alkylation of diester **5** with iodide **6** (73%), available in two steps from tetrahydrofuran (4), followed by hydrolysis of the acetal with magnesium bromide etherate (5) gave alcohol **8** (82%).

The second malonate group was introduced as before, via mesylate **9** (99%), to obtain compound **10** in 87% yield. Hydrolysis of the silyl ether gave alcohol **11** (62%), which was in turn oxidized to aldehyde **12** (96%) using the Swern reaction conditions (6). The acetylenic group was introduced by the addition of acetylene anion to aldehyde **12** (74%). The resulting propargylic alcohol **13** was then oxidized with Jones' reagent (7) to give ynone **14** (88%).

The synthesis of compounds **28**, **30**, **34**, and **36** starts with 4-pentyn-1-ol protected as tetrahydropyranyl ether **16** (96%) (see Scheme 2). The sequence of reactions to malonate **19** was the same as previously described for compound **5**. Malonate **19** was then alkylated with iodide **20** to give diester **21** (74%). The iodide **20** was itself synthesized in two standard steps from 3-chloro-1-propanol. The rest of the synthesis of ynone **28** was done as described for compound **14** (Schemes 2 and 3).

To form enone **30**, aldehyde **26** was condensed with vinylmagnesium bromide to give allylic alcohol **29** (52%), which was then oxidized to **30** with Jones' reagent (72%).

To make compounds **34** and **36**, alkyne **25** was hydrogenated to the *cis* alkene **31** with hydrogen and Lindlar's catalyst (98%) (Scheme 4). Oxidation of the resulting alcohol **31**, using the Swern reaction conditions, gave aldehyde **32** (64%). The rest of the synthesis of ynone **34** was accomplished following the procedure previously described for ynone **14**. The last macrocyclization precursor, enone **36**, was synthesized from aldehyde **32** using the same reaction sequence as for enone **30**.

Macrocyclization

All the macrocyclizations were performed using the same reaction conditions. The ynone or enone, dissolved in acetonitrile, was added slowly over ca. 2.5 h to a solution of cesium carbonate in acetonitrile. The final concentration of the reaction mixture was 2×10^{-3} M. This pseudo high-dilution technique was used to minimize polymerization or dimerization.

Cyclization of ynone **14** (Scheme 5) gave macrocycle **37** in 90% yield as a mixture of *cis* and *trans* isomers (12:88). Ynone **28** gave macrocycle **38** as an 87:13 *cis–trans* mixture of isomers in 48% yield, while ynone **34** gave macrocycle **40** with a 20:80 ratio of *cis* and *trans* in 45% yield. The macrocyclizations of enones **30** and **36** afforded macrocycles **39** and **41** with 82% and 76% yields, respectively.

The configurations and ratios of *cis* and *trans* conjugated

enones obtained from the macrocyclizations of the ynones were determined by proton nmr. These assignments were based on the coupling constants ($J_{H,H}$ (*cis*) ≈ 12.3 Hz and $J_{H,H}$ (*trans*) ≈ 16.9 Hz) observed for the olefinic hydrogens.

The modest yields obtained for the ynones macrocyclizations might be attributable to the fact that polymerization may occur. This fact was previously observed (8). To improve the yields of the macrocyclizations of the ynones, we tried several reaction conditions (Table 1) using the same pseudo high-dilution technique. However none of these conditions improved the initial results.

In summary, we have shown that the intramolecular Michael reaction can indeed be used to form carbocycles

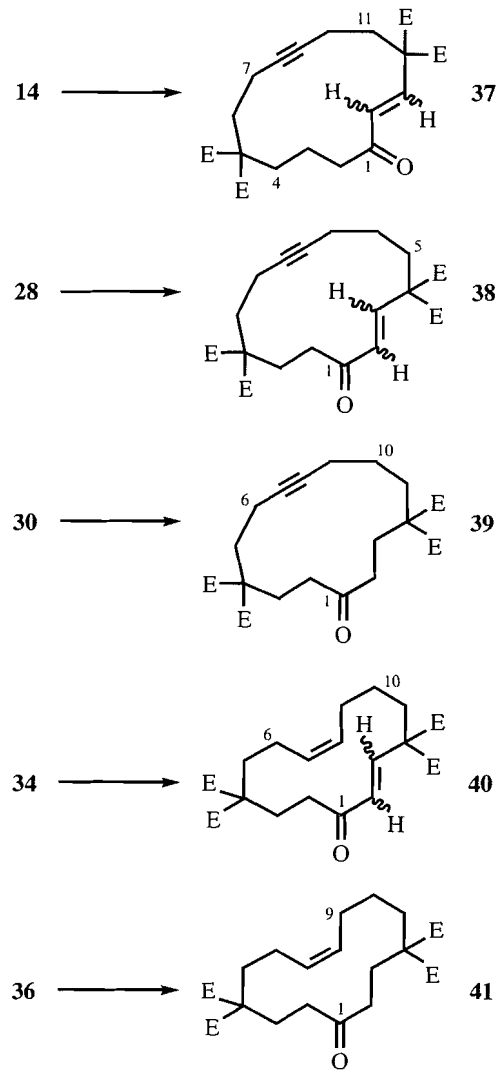
SCHEME 4



SCHEME 5

when the conditions of reduced transannular steric interactions and restricted mobility are met. The reaction is particularly efficient when an enone is used as the Michael acceptor. The yields for the preparation of macrocyclic enones might be improved by cyclizing an enone substituted with a labile group in the β position, which could then be used to introduce the desired α, β unsaturation.

The highly functionalized macrocycles described herewith are excellent substrates for further transformations. Thus, we obtained some promising preliminary results when we carried out the intramolecular Diels–Alder reaction on the silylated enol ether of macrocycle **40**. Subsequent hydrolysis of the silyl enol ether afforded a tricyclo-[8.4.0.$0^{2,7}$]tetradecan-8-one. Application of this strategy to the synthesis of steroids is under way in our laboratories.

Experimental

The infrared spectra (ir) were taken on a Perkin–Elmer 681 spectrophotometer. Protons nmr spectra were recorded on a Bruker WM-250 spectrometer. Chemical shifts are reported in δ relative to deuterated chloroform as the internal standard. Abbrevations used are m: multiplet, s: singlet, d: doublet, t: triplet, q: quartet. Mass spectral assays (ms *m/e*) and exact masses were obtained using a

Acetylene 2

To a solution of alcohol **1** (10.8 mL, 0.143 mol) and *p*-toluenesulfonic acid (1.4 g, 0.007 mol) in tetrahydrofuran (60 mL) at room temperature was added 3,4-dihydropyran (30 mL, 0.329 mol). After stirring for 2 h, a saturated solution of sodium bicarbonate was added. The aqueous phase was extracted three times with diethyl ether. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The residue was purified by distillation (90°C, 12 Torr; 1 Torr = 133.3 Pa) affording **2** (16.3 g, 74%); ir (neat): 3330, 2940–2870, 1440, 1355, 1200, 1130, 1035 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.64 (1H, m, OC*H*O), 3.93–3.79 (2H, m, CH_2O), 3.61–3.47 (2H, m, CH_2O), 2.48 (2H, td, J = 7.0, 2.7 Hz, $CH_2C{\equiv}C$), 1.97 (1H, t, J = 2.7 Hz, $C{\equiv}CH$), 1.90–1.45 (6H, m, $(CH_2)_3$).

Alcohol 3

To a solution of **2** (5.00 g, 32.43 mmol) in tetrahydrofuran (45 mL) and HMPA (30 mL) at −78°C was added *n*-butyllithium (1.6 M in hexane, 21 mL, 34.05 mmol). The mixture was stirred for 5 min at −78°C. Liquid oxirane (25 mL, 486 mmol) was then added, and the reaction was allowed to warm gradually to room temperature (the oxirane was condensed in a bottle and was kept in the freezer prior to the reaction; it was syringed into the reaction using a cold syringe). After 22 h, a saturated solution of ammonium chloride was added and the aqueous phase was extracted three times with diethyl ether. The combined organic layers were washed twice with a 10% copper sulfate solution, then with brine, dried over magnesium sulfate, filtered and evaporated. The crude material was purified by column chromatography (30% increasing to 50% ethyl acetate in hexane) affording alcohol **3** (5.83 g, 90%). This alcohol can be distilled under reduced pressure (250 mTorr, 110°C); ir (neat): 3600–3200, 2980–2820, 1440, 1350, 1200–1020 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.64 (1H, m, OC*H*O), 3.92–3.76 (2H, m, CH_2O), 3.67 (2H, q, J = 6.2 Hz, CH_2OH), 3.60–3.48 (2H, m, CH_2O), 2.51–2.39 (4H, m, $CH_2C{\equiv}CCH_2$), 1.96 (1H, t, J = 6.2 Hz, CH_2OH), 1.82–1.49 (6H, m, $(CH_2)_3$).

Mesylate 4

To a solution of alcohol **3** (14.6 g, 73.63 mmol) and triethylamine (14.4 mL, 103 mmol) in dichloromethane (245 mL) at 0°C, methanesulfonyl chloride (6.8 mL, 88.36 mmol) was added. The mixture was stirred for 3 h, letting the temperature rise to room temperature. Water was then added and the aqueous phase was extracted three times with dichloromethane. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and concentrated. The crude material was purified by column chromatography (30% ethyl acetate in hexane) affording mesylate **4** (19.34 g, 95%); ir (neat): 2980–2840, 1440, 1355, 1175, 1070, 1035, 100–800 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.62 (1H, m, OC*H*O), 4.26 (2H, t, J = 6.9 Hz, CH_2OMs), 3.87–3.74 (2H, m, CH_2O), 3.54–3.47 (2H, m, CH_2O), 3.04 (3H, s, OSO_2CH_3), 2.62 (2H, tt, J = 6.9, 2.4 Hz, $C{\equiv}CCH_2CH_2OMs$), 2.46 (2H, tt, J = 7.0, 2.4 Hz, $C{\equiv}CCH_2CH_2OTHP$), 1.80–1.51 (6H, m, $(CH_2)_3$).

Malonate 5

To a suspension of sodium hydride (60% in oil, 650 mg, 16.25 mmol) in *N*,*N*-dimethylformamide (65 mL), dimethylmalonate (1.93 mL, 16.93 mmol) was added slowly. The mixture was heated at ≈50°C, using a water bath, to help solubilize the formed anion. The reaction mixture was then added using a cannula to a solution of mesylate **4** (1.83 g, 6.62 mmol) and potassium iodide (1.1 g, 6.62 mmol) in tetrahydrofuran (60 mL). The mixture was refluxed for 18 h and then cooled to room temperature. A saturated solution of ammonium chloride was added and the aqueous phase was extracted three times with a mixture of diethyl ether and hexane (1:1). The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and concentrated. The crude product was purified by column chromatography (5% increasing to 50% ethyl acetate in hexane) affording ester **5** (1.61 g, 78%); ir (neat): 2980–2840, 1770–1720, 1440, 1370–1120, 1090–1010 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.63 (1H, m, OC*H*O), 3.87–3.75 (2H, m, CH_2O), 3.74 (6H, s, CO_2CH_3), 3.61 (1H, t, J = 7.3 Hz, $CH(E)_2$), 3.56–3.39 (2H, m, CH_2O), 2.44 (2H, tt, J = 7.1, 2.3 Hz, CH_2CH_2OTHP), 2.27–2.20 (2H, m, $CH_2CH_2CH(E)_2$), 2.10–2.05 (2H, m, $CH_2CH(E)_2$), 1.75–1.49 (6H, m, $(CH_2)_3$).

Iodide 6

To a solution of tetrabutylammonium iodide (45.0 g, 0.122 mol) and tetrahydrofuran (11.4 mL, 0.122 mol) in chloroform (140 mL), at room temperature, boron trifluoride etherate (15.0 mL, 0.122 mol) was aded. The mixture was refluxed for 24 h, cooled, and a saturated solution of sodium bicarbonate was added. The aqueous phase was extracted three times with dichloromethane. The combined organic layers were washed with a 10% solution of sodium thiosulfate, then brine, dried over magnesium sulfate, filtered, and evaporated. The crude material was then triturated with diethyl ether affording crude 4-iodobutanol (16.9 g), which was used without further purification owing to fast decomposition by light.

To a solution of the crude iodobutanol (16.9 g, 0.085 mol) and imidazole (14.5 g, 0.20 mol) in dichloromethane (60 mL) at room temperature, *tert*-butyldimethylchlorosilane (15.3 g, 0.1 mol) was added. After stirring for 2 h, water was added and the aqueous phase was extracted three times with dichloromethane. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (5% increasing to 50% ethyl acetate in hexane) affording iodide **6** (24.26 g, 66%); ir (neat): 2980–2820, 1470, 1205, 1105 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.63 (2H, t, J = 6.1 Hz, CH_2OSi), 3.22 (2H, t, J = 7.0 Hz, CH_2I), 1.90 (2H, m, CH_2CH_2OSi). 1.60 (2H, m, CH_2CH_2I), 0.89 (9H, s, *t*-Bu), 0.05 (6H, s, $(CH_3)_2Si$).

Alkyne 7

To a suspension of sodium hydride (134 mg, 3.36 mmol) in *N*,*N*-dimethylformamide (32 mL) and tetrahydrofuran (18 mL), malonate **5** (1.0 g, 3.2 mmol) dissolved in tetrahydrofuran (10 mL) was added. The mixture was stirred for 2–3 min at ≈50°C using a water bath, to help solubilize the anion formed. Iodide **6** (1.1 g, 3.52 mmol) was added at 50°C and then the bath was removed. After stirring for 20 h at room temperature, a saturated solution of ammonium chloride was added and the aqueous phase was ex-

tracted three times with a mixture of hexane and diethyl ether (1:1). The combined organic layers were washed with a 10% solution of sodium thiosulfate, then brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (5% increasing to 30% ethyl acetate in hexane) affording alkyne **7** (684.3 mg, 73%); ir (neat): 2980–2840, 1735, 1460, 1440, 1260–1030 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.63 (1H, m, OC*H*O), 3.87–3.69 (2H, m, CH_2O), 3.70 (6H, s, CO_2CH_3), 3.58 (2H, t, J = 6.3 Hz, CH_2OSi), 3.55–3.45 (2H, m, CH_2O), 2.47–2.41 (2H, m, CH_2CH_2OTHP), 2.12–2.06 (4H, m, $CH_2C{\equiv}CCH_2$), 1.92–1.45 (10H, m, $CH_2C(E)_2$ CH_2CH_2OSi, $(CH_2)_3$), 1.26–1.16 (2H, m, $CH_2CH_2CH_2OSi$), 0.88 (9H, s, *t*-Bu), 0.08 (6H, s, $(CH_3)_2Si$).

Alcohol 8

To a solution of alkyne **7** (2.138 g, 4.29 mmol) in anhydrous diethyl ether (66 mL) at 0°C, magnesium bromide etherate (3.7 g, 12.87 mmol) was added. The reaction was stirred for 16 h, while allowing the mixture to warm gradually to room temperature, then water was added and the aqueous phase was extracted three times with diethyl ether. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (20–30% ethyl acetate in hexane) affording alcohol **8** (1.455 g, 82%); ir (neat): 3600–3200, 2980–2840, 1735, 1460–1430, 1260, 1100, 1050 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.72 (6H, s, CO_2CH_3), 3.67 (2H, q, J = 6.2 Hz, CH_2OH), 3.59 (2H, t, J = 6.3 Hz, CH_2OSi), 2.40 (2H, t, J = 6.2 Hz, CH_2CH_2OH), 2.14 (4H, s, $C{\equiv}CCH_2$ $CH_2C(E)_2$), 1.99 (1H, t, J = 6.2 Hz, O*H*), 1.94–1.87 (2H, m, $CH_2(CH_2)_3OSi$), 1.57–1.46 (2H, m, CH_2CH_2OSi), 1.26–1.16 (2H, m, $CH_2CH_2CH_2OSi$), 0.88 (9H, s, *t*-Bu), 0.03 (6H, s, $(CH_3)_2Si$).

Mesylate 9

Mesylate **9** was synthesized using the same procedure as that for the preparation of mesylate **4**, from alcohol **8** (1.45 g, 5.0 mmol), dichloromethane (12 mL), triethylamine (0.7 mL, 5.0 mmol), and methanesulfonyl chloride (325 μL, 4.2 mmol). The crude product was purified by column chromatography (20–40% ethyl acetate in hexane) affording mesylate **9** (1.63 g, 99%); ir (neat): 3000–2860, 1480–1440, 1360, 1175, 1255, 1100, 1000–780 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.25 (2H, t, J = 7.0 Hz, CH_2OMs), 3.71 (6H, s, CO_2CH_3), 3.59 (2H, t, J = 6.3 Hz, CH_2OSi), 3.04 (3H, s, $S(O)_2CH_3$), 2.60 (2H, t, J = 7.0 Hz, CH_2CH_2OMs), 2.10 (4H, s, $C{\equiv}CCH_2CH_2C(E)_2$), 1.92–1.85 (2H, m, $CH_2(CH_2)_3OSi$), 1.56–1.45 (2H, m, CH_2CH_2OSi), 1.27–1.17 (2H, m, $CH_2(CH_2)_2OSi$), 0.88 (9H, s, *t*-Bu), 0.03 (6H, s, $(CH_3)_2Si$).

Ester 10

Ester **10** was synthesized using the same procedure as for the preparation of ester **5**, from sodium hydride (60% in oil, 336 mg, 8.4 mmol), *N*,*N*-dimethylformamide (44 mL), dimethyl malonate (1 mL, 8.75 mmol), mesylate **9** (1.634 g, 3.5 mmol), potassium iodide (581 mg, 3.5 mmol), and tetrahydrofuran (20 mL). The crude product was purified by column chromatography (5–40% ethyl acetate in hexane) affording ester **10** (1.607 g, 87%); ir (neat): 3000–2840, 1770–1720, 1450, 1370–1090 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.75 (6H, s, $CH(CO_2CH_3)_2$), 3.71 (6H, s, $R_2C(CO_2CH_3)_2$), 3.62–3.55 (3H, m, $CH(E)_2$, CH_2OSi), 2.26–2.20 (2H, m, $C{\equiv}CCH_2CH_2CH(E)_2$), 2.12–2.02 (6H, m, $CH_2CH_2C(E)_2$, $CH_2CH(E)_2$), 1.92–1.85 (2H, m, $CH_2(CH_2)_3OSi$), 1.55–1.48 (2H, m, CH_2CH_2OSi), 1.26–1.16 (2H, m, $CH_2CH_2CH_2OSi$), 0.88 (9H, s, *t*-Bu), 0.03 (6H, s, $(CH_3)_2Si$).

Alcohol 11

To a solution of ester **10** (1.607 g, 3.04 mmol) in tetrahydrofuran (15 mL), at 0°C, a solution of tetrabutylammonium fluoride (1M, 3.65 mL, 3.65 mmol) was added. The mixture was stirred for 18 h, while allowing the reaction to warm gradually to room temperature. A saturated solution of ammonium chloride was then added, and the aqueous phase was extracted three times with diethyl ether. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (50–100% ethyl acetate in hexane) affording alcohol **11** (756 mg, 62%); ir (neat): 3600–3200, 2980–2840, 1770–1700, 1450, 1370–1150, 1050 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.75 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.65 (2H, t, J = 6.4 Hz, CH_2OH), 3.55 (1H, t, J = 7.3 Hz, $CH(E)_2$), 2.25–2.20 (2H, m, $CH_2CH_2CH(E)_2$), 2.15–2.02 (7H, m, O*H*, $CH_2CH_2C(E)_2$, $CH_2CH(E)_2$), 1.95–1.88 (2H, m, $CH_2(CH_2)_3OH$), 1.63–1.54 (2H, m, CH_2CH_2OH), 1.32–1.18 (2H, m, $CH_2CH_2CH_2OH$).

Aldehyde 12

To a solution of oxalyl chloride (182 μL, 2.09 mmol) in dichloromethane (2 mL) at −78°C, dimethyl sulfoxide (0.3-mL, 4.18 mmol) was added. The reaction was stirred for 5 min. Alcohol **11** (786 mg, 1.9 mmol) dissolved in dichloromethane was then added. After stirring for 15 min, triethylamine (1.3 mL, 9.5 mol) was added and the mixture stirred for another 5 min, allowing the reaction to warm slowly to room temperature. Water was then added and the aqueous phase was extracted three times with dichloromethane. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording aldehyde **12** (751 mg, 96%); ir (neat): 3000–2820, 2750, 1770–1700, 1450, 1370–1140, 1100, 1050 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 9.75 (1H, t, J = 1.3 Hz, C(O)*H*), 3.75 (6H, s, $CH(CO_2CH_3)_2$), 3.73 (bH, s, $R_2C(CO_2CH_3)_2$), 3.57 (1H, t, J = 7.3 Hz, $CH(E)_2$), 2.47 (2H, td, J = 7.1, 1.3 Hz, $CH_2C(O)H$), 2.25–2.20 (2H, m, $CH_2CH_2CH(E)_2$), 2.19–2.04 (6H, m, $CH_2CH_2C(E)_2$), $CH_2CH(E)_2$), 1.93–1.86 (2H, m, $CH_2(CH_2)_2$-C(O)H), 1.58–1.48 (2H, m, $CH_2CH_2C(O)H$).

Alcohol 13

To *n*-butyllithium (1.6 M, 4.5 mL, 7.24 mmol) in tetrahydrofuran (3 mL) at −78°C, was added acetylene (14.48 mmol). The mixture was stirred for 5 min at −78°C and aldehyde **12** (748 mg, 1.81 mmol) dissolved in tetrahydrofuran (7 mL) was added. The reaction was stirred for another 15 min at −78°C, after which time a saturated solution of ammonium chloride was added and the aqueous phase was extracted three times with diethyl ether. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (30% increasing to 50% ethyl acetate in hexane) affording alcohol **13** (586 mg, 74%); ir (neat): 3600–3340, 3290, 3000–2840, 1770–1700, 1440, 1350–1150, 1110, 1050 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.08 (1H, dq, J = 5.5, 2.1 Hz, $HC{\equiv}CCH(R)OH$), 3.75 (6H, s, $CH(CO_2CH_3)_2$) 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.57 (1H, t, J = 7.3 Hz, $CH(E)_2$), 2.47 (1H, t, J = 2.1 Hz, $C{\equiv}CH$), 2.26–2.20 (2H, m, $CH_2CH_2CH(E)_2$), 2.13–2.02 (6H, m, $CH_2CH(E)_2$), $CH_2CH_2C(E)_2$), 1.96–1.90 (3H, m, $CH_2(CH_2)_2CH(R)OH$), 1.77–1.68 (2H, m, $CH_2CH(R)OH$), 1.43–1.36 (2H, m, $CH_2CH_2CH(R)OH$).

Ynone 14

To a solution of alcohol **13** (583 mg, 1.33 mmol) in acetone (4 mL) at 0°C, Jones' reagent was added until a red color persisted for 15 min. Isopropanol was then added until a green color appeared. Water was then added and the aqueous phase was extracted three times with dichloromethane. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording alkyne **14** (512 mg, 88%); ir (neat): 3250, 3000–2840, 2100, 1770–1700, 1700–1670, 1450, 1350–1050 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.75 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.58 (1H, t, J = 7.3 Hz, $CH(CO_2CH_3)_2$), 3.24 (1H, s, $C{\equiv}CH$), 2.61 (2H, t, J = 7.0 Hz, $CH_2C(O)C{\equiv}CH$), 2.22–2.19 (2H, m, CH_2CH_2CH-$(CO_2CH_3)_2$), 2.13–2.02 (6H, m, $CH_2CH(CO_2CH_3)_2$, $C{\equiv}CCH_2$-$CH_2C(CO_2CH_3)_2$), 1.92–1.85 (2H, m, $CH_2(CH_2)_2C(O)C{\equiv}CH$), 1.59–1.52 (2H, m, $CH_2CH_2C(O)C{\equiv}CH$); ms *m/e* (70 eV): 436 (M^+).

Acetylene ***16***

Acetylene **16** was synthesized using the same procedure as for the preparation of acetylene **2**, from 4-pentyn-1-ol (1.65 mL, 17.83 mmol), *p*-toluenesulfonic acid (0.03 g, 1.17 mmol), tetrahydrofuran (10 mL), and dihydropyran (3.8 mL, 41 mmol). The crude product was purified by column chromatography (10% ethyl acetate in hexane) affording **16** (2.89 g, 96%); ir (neat): 3300, 2980–2850, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.60 (1H, m, OC*H*O), 3.91–3.81 (2H, m, CH_2O), 3.54–3.43 (2H, m, CH_2O), 2.30 (2H, td, J = 7.3, 2.6 Hz CH_2C≡CH), 1.94 (1H, t, J = 2.6 Hz, C≡C*H*), 1.87–1.48 (8H, m, THPOCH$_2$CH_2, (CH_2)$_3$; ms m/e (70 eV): 176 (M^+).

Alcohol ***17***

Alcohol **17** was synthesized using the same procedure as for the preparation of alcohol **3**, from alkyne **16** (2.0 g, 11.89 mmol), tetrahydrofuran (30 mL), hexamethylphosphoramide (HMPA) (10 mL), *n*-butyllithium (1.6 M in hexane, 8.2 mL, 13.1 mmol), and oxirane (9 mL, 178.4 mmol). The crude product was purified by column chromatography (30–50% ethyl acetate in hexane) affording alcohol **17** (2.07 g, 82%); ir (neat): 3600–3200, 2980–2840, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.59 (1H, m, OC*H*O), 3.92–3.81 (2H, m, CH_2O), 3.67 (2H, q, J = 6.2 Hz, CH_2OH), 3.54–3.43 (2H, m, CH_2O), 2.42 (2H, tt, J = 6.2, 2.3 Hz, C≡CCH_2CH$_2$OH), 2.29 (2H, tt, J = 7.0, 2.3 Hz, CH_2C≡CCH$_2$CH$_2$OH), 1.98 (1H, t, J = 6.2 Hz, O*H*), 1.84–1.48 (8H, m, (CH_2)$_3$, THPOCH$_2$CH_2); ms m/e (70 eV): 211 (M^+ – H), 181 (M^+ – CH$_2$OH).

Mesylate ***18***

Mesylate **18** was synthesized using the same procedure as for the preparation of mesylate **4**, from alcohol **17** (2.05 g, 9.64 mmol), triethylamine (2 mL, 13.5 mmol), dichloromethane (32 mL), and methanesulfonyl chloride (0.9 mL, 11.6 mmol). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording mesylate **18** (2.55 g, 92%); ir (neat): 2980–2850, 1450, 1350, 1180, 1250–1000, 1000–750 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.58 (1H, m, OC*H*O), 4.25 (2H, t, J = 6.9 Hz, CH_2OMs), 3.90–3.76 (2H, m, CH_2O), 3.54–3.41 (2H, m, CH_2O), 3.04 (3H, s, OSO$_2$CH_3), 2.61 (2H, tt, J = 6.9, 2.4 Hz, CH_2CH$_2$OMs), 2.26 (2H, tt, J = 7.1, 2.4 Hz, CH_2(CH$_2$)$_2$OTHP), 1.82–1.40 (8H, m, THPOCH$_2$CH_2), (CH_2)$_3$).

Malonate ***19***

Malonate **19** was synthesized using the same procedure as for the preparation of malonate **5**, from sodium hydride (50% in oil, 2.0 g, 42.33 mmol), *N*,*N*-dimethylformamide (172 mL), dimethyl malonate (5.0 mL, 43.05 mmol), mesylate **18** (5.0 g, 17.22 mmol), potassium iodide (2.9 g, 17.22 mmol), and tetrahydrofuran (172 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording **19** (4.22 g, 75%); ir (neat): 2980–2850, 1750, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.58 (1H, m, OC*H*O), 3.86–3.71 (2H, m, CH_2O), 3.74 (6H, s, (CO$_2$CH_3)$_2$), 3.61 (1H, t, J = 7.3 Hz, C*H*(CO$_2$CH$_3$)$_2$), 3.52–3.40 (2H, m, CH_2O), 2.28–2.19 (4H, m, THPO(CH$_2$)$_2$CH_2C≡CCH_2), 2.10–2.05 (2H, m, CH_2CH(E)$_2$), 1.81–1.51 (8H, m, CH_2CH$_2$OTHP, (CH_2)$_3$); ms m/e (70 eV): 326 (M^+).

Iodide ***20***

A solution of chloropropanol (8.8 mL, 106 mmol) and sodium iodide (17 g, 117 mmol) in acetone (100 mL) was refluxed for 24 h. The mixture was cooled to room temperature and sodium thiosulfate was added to discolour the solution. Most of the solvent was evaporated and hexane was then added to precipitate the sodium chloride. The mixture was filtered on Celite. Hexane was added and the mixture was filtered and evaporated a second time. The resulting crude iodopropanol was then dissolved in dichloromethane (400 mL) and imidazole (18 g, 265 mL) was added followed by *t*-butyldimethylchlorosilane (19 g, 127 mmol). The reaction was stirred at room temperature for 2 h. Water was then added and the aqueous phase was extracted three times with dichloromethane. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (5–40% ethyl acetate in hexane) affording iodide **20** (26.96 g, 85%); ir (neat): 2980–2840, 1470, 1360, 1200–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.67 (2H, t, J = 5.7 Hz, CH_2OSi), 3.28 (2H, t, J = 6.7 Hz, CH_2I), 2.03–1.94 (2H, m, CH$_2$CH_2CH$_2$), 0.89 (9H, s, *t*-Bu), 0.07 (6H, s, (CH$_3$)$_2$Si); ms m/e (70 eV): 243 (M^+ – *t*-Bu).

Alkyne ***21***

To a suspension of sodium hydride (492 mg, 1.05 mmol) in *N*,*N*-dimethylformamide (9.75–mL), malonate **19** (3.18 g, 9.75 mmol) dissolved in tetrahydrofuran (15 mL) was added. The reaction mixture was heated at ≈50°C in a water bath to dissolve the anion formed. Iodide **20** (3.2 g, 10.7 mmol) was added at 50°C, and then the bath was removed. The mixture was stirred at room temperature for 20 h, and a saturated solution of ammonium chloride was then added. The aqueous phase was extracted three times with a mixture of diethyl ether and hexane (1:1). The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording alkyne **21** (3.60 g, 74%); ir (neat): 2980–2840, 1740, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.59 (1H, m, OC*H*O), 3.87–3.70 (2H, m, CH_2O), 3.71 (6H, s, 2x CO$_2$CH_3), 3.58 (2H, t, J = 6.3 Hz, CH_2OSi), 3.49–3.43 (2H, m, CH_2O), 2.27–2.21 (2H, m, CH_2(CH$_2$)$_2$OTHP), 2.11–2.08 (4H, m, C≡CCH_2CH_2C(E)$_2$), 1.96–1.81 (2H, m, C≡CCH$_2$CH$_2$C(E)$_2$CH_2), 1.78–1.51 (8H, m, CH_2-CH$_2$OTHP, (CH_2)$_3$), 1.41–1.34 (2H, m, CH_2CH$_2$OSi), 0.88 (9H, s, *t*-Bu), 0.03 (6H, s, (CH$_3$)$_2$Si); ms m/e (70 eV): 498 (M^+), 441 (M^+ – *t*-Bu).

Alcohol ***22***

Alcohol **22** was synthesized using the same procedure as for the preparation of alcohol **8** from alkyne **21** (1.04 g, 1.98 mmol), anhydrous diethyl ether (100 mL), and magnesium bromide etherate (6.18 g, 21.66 mmol). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording alcohol **22** (1.33 g, 78%); ir (neat): 3600–3200, 2980–2850, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.75–3.70 (2H, m, CH_2OH), 3.71 (6H, s, 2× CO$_2$CH_3), 3.59 (2H, t, J = 6.2 Hz, CH_2OSi), 2.28–2.22 (2H, m, CH_2(CH$_2$)$_2$OH), 2.13–2.09 (4H, m, C≡CCH_2CH_2C(E)$_2$), 1.96–1.90 (2H, m, CH_2(CH$_2$)$_2$OSi), 1.73–1.67 (3H, m, CH_2CH$_2$O*H*), 1.40–1.34 (2H, m, CH_2CH$_2$OSi), 0.88 (9H, s, *t*-Bu), 0.03 (6H, s, (CH$_3$)$_2$Si); ms m/e (70 eV): 415 (M^+), 399 (M^+ – CH$_3$), 383 (M^+ – CH$_3$O), 357 (M^+ – *t*-Bu).

Mesylate ***23***

Mesylate **23** was synthesized using the same procedure as for the preparation of mesylate **9**, from alcohol **22** (1.38 g, 3.33 mmol), dichloromethane (20 mL), triethylamine (0.6 mL), and methanesulfonyl chloride (2.28 mL, 4.2 mmol). The crude product was purified by column chromatography (25% ethyl acetate in hexane) affording mesylate **23** (1.44 g, 94%); ir (neat): 2980–2850, 1450, 1350, 1180, 1300–1000, 1000–750 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.33 (2H, t, J = 6.1 Hz, CH_2OMs), 3.71 (6H, s, 2× CO$_2$CH_3), 3.59 (2H, t, J = 6.2 Hz, CH_2OSi), 3.03 (3H, s, OSO$_2$CH_3), 2.35–2.27 (2H, m, CH_2(CH$_2$)$_2$OMs), 2.10 (4H, m, C≡CCH_2CH_2C(E)$_2$), 1.96–1.87 (4H, m, CH_2CH$_2$OMs, CH_2(CH$_2$)$_2$OSi), 1.45–1.30 (2H, m, CH_2CH$_2$OSi), 0.88 (9H, s, *t*-Bu), 0.04 (6H, s, (CH$_3$)$_2$Si).

Ester ***24***

Ester **24** was synthesized using the same procedure as for the preparation of ester **10**, from sodium hydride (60% in oil, 356 mg, 7.42 mmol), *N*,*N*-dimethylformamide (40 mL), dimethylmalonate (0.9 mL, 7.73 mmol), mesylate **23** (1.42 g, 3.09 mmol), potassium iodide (512 mg, 3.09 mmol), and tetrahydrofuran (40 mL). The crude product was purified by column chromatography (20% ethyl acetate in hexane) affording ester **24** (1.23 g, 77%); ir (neat): 2980–2850, 1740, 1450, 1350, 1300–

1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.73 (6H, s, $CH(CO_2CH_3)_2$), 3.70 (6H, s, $R_2C(CO_2CH_3)_2$) 3.57 (2H, t, J = 6.2 Hz, CH_2OSi), 3.38 (1H, m, $CH(E)_2$), 2.18–2.02 (6H, m, $CH_2C{\equiv}CCH_2CH_2C(E)_2R$), 1.99–1.61 (4H, m, $CH_2CH(E)_2$, $CH_2(CH_2)_2OSi$), 1.60–1.33 (4H, m, CH_2CH_2OSi, $CH_2CH_2CH(E)_2$), 0.87 (9H, s, *t*-Bu), 0.03 (6H, s, $(CH_3)_2Si$).

Alcohol 25

To a solution of ester **24** (2.38 g, 4.77 mmol) and *p*-toluenesulfonic acid (1.36 g, 7.16 mmol) in tetrahydrofuran (16 mL) at 0°C, a solution of tetrabutylammonium fluoride (1 M, 3.65 mL, 3.65 mmol) was added. The mixture was stirred for 6 h, allowing the reaction to warm gradually to room temperature. A saturated solution of ammonium chloride was then added and the aqueous phase was extracted three times with diethyl ether. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (50% ethyl acetate in hexane) affording alcohol **25** (1.65 g, 83%); ir (neat): 3600–3200, 3010–2840, 1770–1700, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.74 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$) 3.67–3.60 (2H, m, CH_2OH), 3.38 (1H, t, J = 7.5 Hz, $CH(E)_2$), 2.18–2.11 (6H, m, $CH_2C{\equiv}CCH_2CH_2C(E)_2R$), 2.01–1.93 (4H, m, $CH_2CH(E)_2$, $CH_2(CH_2)_2OH$), 1.62–1.24 (5H, m, CH_2CH_2OH, $CH_2CH_2CH(E)_2$); ms m/e (70 eV): 397 (M^+ – OH), 383 (M^+ – OCH_3).

Aldehyde 26

Aldehyde **26** was synthesized using the same procedure as for the preparation of aldehyde **12**, from oxalyl chloride (0.12 mL, 1.33 mmol), dichloromethane (3 mL), dimethyl sulfoxide (0.19 mL, 2.66 mmol), alcohol **25** (500 mg, 1.21 mmol), dichloromethane (7 mL), and triethylamine (0.85 mL, 6.05 mmol). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording aldehyde **26** (456 mg, 91%); ir (neat): 3000–2880, 2840, 2740, 1760–1700, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 9.74 (1H, s, C(O)*H*), 3.74 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.38 (1H, t, J = 7.5 Hz, $CH(E)_2$), 2.48 (2H, t, J = 7.6 Hz, $CH_2C(O)H$), 2.25–2.11 (8H, m, $CH_2C{\equiv}CCH_2CH_2C(E)_2CH_2$), 2.02–1.93 (2H, m, $CH_2CH(E)_2$), 1.52–1.46 (2H, m, $CH_2CH_2CH(E)_2$); ms m/e (70 eV): 412 (M^+).

Alcohol 27

Alcohol **27** was synthesized using the same procedure as for the preparation of alcohol **13**, from tetrahydrofuran (3 mL), *n*-butyllithium (1.6 M in hexane, 2.75 mL, 4.4 mmol), acetylene (24.5 mL/mmol, 215 mL, 8.8 mmol), aldehyde **26** (454 mg, 1.1 mmol), and tetrahydrofuran (5 mL). The crude product was purified by column chromatography (40% ethyl acetate in hexane) affording alcohol **27** (262 mg, 54%); ir (neat): 3600–3340, 3300, 3000–2840, 1770–1700, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 4.42–4.31 (1H, m, C*H*-OH), 3.74 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.39 (1H, t, J = 7.6 Hz, $CH(E)_2$), 2.48 (1H, d, J = 2.0 Hz, C≡C*H*), 2.18–2.10 (8H, m, $CH_2C{\equiv}CCH_2(CH_2C(E)_2CH_2)$, 2.09–1.93 (3H, m, $CH_2CH(E)_2$, O*H*), 1.66–1.45 (4H, m, $CH_2CH_2CH(E)_2CH_2CH(OH)C{\equiv}CH$); ms m/e (70 eV): 439 (MH^+), 421 (M^+ – OH), 402 (M^+ – OCH_3).

Ynone 28

Ynone **28** was synthesized using the same procedure as for the preparation of ynone **14**, from alcohol **27** (252 mg, 0.574 mmol), Jones' reagent, and acetone (5 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording alkyne **28** (220 mg, 88%); ir (neat): 3265, 3000–2840, 2100, 1770–1710, 1700–1680, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.74 (6H, s, $CH(CO_2CH_3)_2$), 3.73 (6H, s, $R_2C(CO_2CH_3)_2$), 3.38 (1H, t, J = 7.6 Hz, $CH(E)_2$), 3.24 (1H, s, C≡C*H*), 2.66–2.61 (2H, m, $CH_2C(O)$), 2.28–2.11 (8H, m, $CH_2C{\equiv}CCH_2CH_2C(E)_2CH_2$), 2.02–1.93 (2H, m, $CH_2CH(E)_2$), 1.52–1.46 (2H, m, $CH_2CH_2CH(E)_2$); ms m/e (70 eV): 436 (M^+), 304 (M^+ – OCH_3).

Alcohol 29

To a solution of aldehyde **26** (338 mg, 0.82 mmol) in anhydrous diethyl ether (20 mL) at −78°C, vinylmagnesium bromide (1 M in THF, 4.1 mL, 4.1 mmol) was added. The mixture was stirred for 15 min, and a saturated solution of sodium bicarbonate was added. The aqueous phase was extracted three times with diethyl ether. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (40% ethyl acetate in hexane) affording alcohol **29** (188 mg, 52%); ir (neat): 3600–3200, 3000–2840, 1760–1700, 1450, 1350 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.84 (1H, ddd, J = 17.2, 10.4, 6.1 Hz, CH(OH)C*H*=CH_2), 5.24 (1H, d, J = 17.2 Hz, CH(OH)CH=C*H* (*cis* to alkyl group)), 5.13 (1H, d, J = 10.4 Hz, CH(OH)CH=C*H* (*trans* to alkyl group)), 4.18–4.00 (1H, m, C*H*(OH)), 3.74 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.39 (1H, t, J = 7.5 Hz, $CH(E)_2$), 2.19–2.09 (6H, m, $CH_2C{\equiv}CCH_2CH_2C(E)_2CH_3$), 2.09–1.90 (4H, m, $CH_2CH(E)_2$, $CH_2CH_2CH(OH)$), 1.67–1.64 (1H, O*H*), 1.58–1.38 (4H, m, $CH_2CH_2CH(E)_2$, $CH_2CH_2CH(OH)$); ms m/e (70 eV): 440 (M^+).

Enone 30

Enone **30** was synthesized using the same procedure as for the preparation of ynone **14**, from alcohol **29** (183 mg, 0.415 mmol), Jones' reagent, and acetone (5 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording alkene **30** (131 mg, 72%); ir (neat): 300–2840, 1770–1700, 1700–1680, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 6.32 (1H, dd, J = 17.7, 10.1 Hz, C(O)-C*H*=CH_2), 6.24 (1H, dd, J = 17.7, 1.8 Hz, C(O)CH=C*H* *cis* to the ketone), 5.83 (1H, dd, J = 10.1, 1.8 Hz, C(O)CH=C*H* *trans* to the ketone), 3.74 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.38 (1H, t, J = 7.5 Hz, C*H*$(CO_2CH_3)_2$), 2.62–2.56 (2H, m, $CH_2(C(O))$, 2.24–2.11 (8H, m, $CH_2C{\equiv}CCH_2CH_2C(E)_2CH_2$), 2.04–1.92 (2H, m, $CH_2CH(E)_2$), 1.51–1.45 (2H, m, $CH_2CH_2CH(E)_2$); ms m/e (70 eV): 423 (M^+ – OH), 409 (M^+ – OCH_3).

Alcohol 31

Hydrogen was bubbled for 15 min in a solution of alkyne **25** (292 mg, 0.70 mmol) in ethyl acetate (10 mL) containing Lindlar's catalyst (30 mg). The mixture was stirred for 5.5 h under an hydrogen atmosphere. The mixture was then filtered on Celite and concentrated affording alkene **31** (286 mg, 98%); ir (neat): 3600–3200, 3010, 3000–2840, 1780–1680, 1450, 1350 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.36–5.32 (2H, t, J = 4.7 Hz, C*H*=C*H*), 3.73 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.68–3.61 (2H, m, CH_2OH), 3.35 (1H, t, J = 7.5 Hz, C*H*$(CO_2CH_3)_2$), 2.04–1.84 (10H, m, $CH_2C(E)_2CH_2CH_2CH{=}CHCH_2CH_2CH_2CH(E)_2$), 1.71–1.65 (1H, m, O*H*), 1.48–1.25 (4H, m, CH_2CH_2OH, $CH_2CH_2CH(E)_2$); ms m/e (70 eV): 417 (MH^+).

Aldehyde 32

Aldehyde **32** was synthesized using the same procedure as for the preparation of aldehyde **12**, from oxalyl chloride (0.18 mL, 2.08 mmol), dichloromethane (5 mL), dimethyl sulfoxide (0.30 mL, 4.16 mmol), alcohol **31** (0.785 mg, 1.89 mmol), dichloromethane (11 mL), and triethylamine (1.3 mL, 9.5 mmol). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording aldehyde **32** (504 mg, 64%); ir (neat): 3010, 3000–1840, 1770–1700, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 9.75 (1H, s, C(O)*H*), 5.36–5.32 (2H, m, C*H*=C*H*), 3.74 (6H, s, $CH(CO_2CH_3)_2$), 3.71 (6H, s, $R_2C(CO_2CH_3)_2$), 3.35 (1H, t, J = 7.5 Hz, C*H*$(CO_2CH_3)_2$), 2.51–2.44 (2H, t, J = 7.5 Hz, $CH_2C(O)H$), 2.25–2.18 (2H, m, $CH_2CH_2C(O)H$), 2.06–1.98 (2H, m, $CH_2CH(E)_2$), 1.93–1.84 (6H, m, $RC(E)_2CH_2CH_2$-CH=CHCH_2), 1.58–1.33 (2H, m, $CH_2CH_2CH(E)_2$); ms m/e (70 eV): 415 (MH^+).

Alcohol 33

Alcohol **33** was synthesized using the same procedure as for the preparation of alcohol **13**, from tetrahydrofuran (3 mL), *n*-butyllithium (1.6 M in hexane, 1.8 mL, 2.9 mmol), acetylene (24.5 mL/mmol, 150 mL, 6.12 mmol), aldehyde **32** (301 mg, 0.726 mmol), and tetrahydrofuran (7 mL). The crude product was purified by column chromatography (40% ethyl acetate in hexane) affording alcohol **33** (294 mg, 92%); ir (neat): 3600–3200, 3300, 3010, 3000–2840, 1770–1700, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.36–5.32 (2H, m, C*H*=C*H*), 4.38 (1H, qd, *J* = 6.0, 2.1 Hz, C*H*(OH)), 3.74 (6H, s, $CH(CO_2CH_3)_2$), 3.73 (6H, s, $R_2C(CO_2CH_3)_2$), 3.35 (1H, t, *J* = 7.5 Hz, C*H*($CO_2CH_3)_2$), 2.5 (1H, d, *J* = 2.1 Hz, C≡C*H*), 2.30 (1H, d, *J* = 6.0 Hz, O*H*), 2.13–1.97 (4H, m, $CH_2CH_2CH(OH)$, $CH_2CH(E)_2$), 1.93–1.84 (6H, m, $(E)_2CCH_2CH_2CH$=CHCH_2), 1.66–1.57 (2H, $CH_2(CH(OH))$, 1.42–1.32 (2H, m, $CH_2CH_2CH(E)_2$); ms *m/e* (70 eV): 441 (MH^+).

Ynone 34

Ynone **34** was synthesized using the same procedure as for the preparation of ynone **14**, from alcohol **33** (288 mg, 0.654 mmol), Jones' reagent, and acetone (10 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording alkyne **34** (219 mg, 76%); ir (neat): 3280, 3010, 3000–2840, 2100, 1770–1700, 1680, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.34–5.30 (2H, m, C*H*=C*H*), 3.73 (12H, s, 2× $(CO_2CH_3)_2$), 3.35 (1H, t, *J* = 7.5 Hz, C*H*($CO_2CH_3)_2$), 3.25 (1H, s, C≡C*H*), 2.66–2.59 (2H, m, $CH_2C(O)C$≡CH), 2.28–2.21 (2H, m, $CH_2CH_2C(O)C$≡CH), 2.03–1.90 (2H, m, $CH_2CH(CO_2CH_3)_2$), 1.98–1.84 (6H, m, $(E)_2CH_2CH_2CH$=CHCH_2), 1.56–1.32 (2H, m, $CH_2CH_2CH(CO_2CH_3)_2$); ms *m/e* (70 eV): 439 (MH^+).

Alcohol 35

To a solution of aldehyde **32** (190 mg, 0.458 mmol) in anhydrous diethyl ether (2 mL) at −78°C, was added vinylmagnesium bromide (1 M in THF, 4.6 mL, 4.6 mmol). The mixture was stirred for 20 min, and a saturated solution of ammonium chloride was added. The aqueous phase was extracted three times with diethyl ether. The combined organic layers were washed with brine, dried over magnesium sulfate, filtered, and evaporated. The crude product was purified by column chromatography (40% ethyl acetate in hexane) affording alcohol **35** (120 mg, 59%); ir (neat): 3600–3200, 3010, 3000–2840, 1770–1700, 1450, 1350, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.85 (1H, ddd, *J* = 17.2 10.4, 6.1 Hz, CH_2=C*H*CH(OH)), 5.36–5.32 (2H, m, C*H*=C*H*), 5.25 (1H, dt, *J* = 17.2, 1.4 Hz, C*H*=CHCH(OH) *cis* to alkyl group), 5.13 (1H, dt, *J* = 10.4, 1.3 Hz, C*H*=CHCH(OH) *trans* to alkyl group), 4.15–4.05 (1H, m, CH_2=CH-C*H*(OH)), 3.73 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2C(CO_2CH_3)_2$), 3.38 (1H, t, *J* = 7.6 Hz, C*H*($E)_2$), 2.08–2.02 (4H, m, $CH_2CH_2CH(OH)$, $CH_2CH(E)_2$), 1.99–1.79 (6H, m, $(E)_2CH_2CH_2CH$=CHCH_2), 1.47–1.32 (5H, m, $CH_2CH_2CH(E)_2$, $CH_2CH(OH)$).

Enone 36

Enone **36** was synthesized using the same procedure as for the preparation of ynone **14**, from alcohol **35** (116 mg, 0.262 mmol), Jones' reagent, and acetone (10 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording alkene **36** (83 mg, 72%); ir (neat): 3110, 3000–2840, 1770–1700, 1690, 1620, 1450, 1350, 1300–1000, 900 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 6.35 (1H, dd, *J* = 17.7, 9.8 Hz, C(O)C*H*=CH_2), 6.22 (1H, dd, *J* = 17.7, 1.8 Hz, C(O)CH=C*H* *cis* to the ketone), 5.84 (1H, dd, *J* = 9.8, 1.8 Hz, C(O)CH=C*H* *trans* to the ketone), 5.36–5.30 (2H, m, RC*H*=C*H*R), 3.73 (6H, s, $CH(CO_2CH_3)_2$), 3.72 (6H, s, $R_2CO_2CH_3)_2$), 3.35 (1H, t, *J* = 7.5 Hz, C*H*($CO_2CH_3)_2$), 2.63–2.56 (2H, m, $CH_2C(O)$). 2.24–2.19 (2H, m, $CH_2CHC(O)$), 2.06–2.00 (2H, m, $CH_2CH(CO_2CH_3)_2$), 1.98–1.84 (6H, m, CH_2CH_2CH=CHC$H_2CH_2CH_2CH(CO_2CH_3)_2$), 1.57–1.32 (2H, m, $CH_2CH_2CH(CO_2CH_3)_2$); ms *m/e* (70 eV): 441 (MH^+).

Macrocycle 37 (General procedure)

Ynone **14** (203 mg, 0.466 mmol) dissolved in acetonitrile (30 mL) was added slowly over 2.5 h, using a syringe pump, to a suspension of cesium carbonate (151 mg, 0.466 mmol) in acetonitrile (200 mL). When the addition was completed, the mixture was stirred for another 30 min. The mixture was then filtered on Celite and evaporated. The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording macrocycle **37** as a mixture of *cis* and *trans* olefin isomers (88:12) (184 mg, 90%); ir ($CHCl_3$): 3010, 2900, 1770–1700, 1690, 1620, 1450, 1300–150 cm^{-1}; ^1H nmr ($CDCl_3$) δ: (for numbering see Scheme 5) *cis*: 6.74 (1H, d, *J* = 12.3 Hz, 3) 6.46 (1H, d, 12.3 Hz, 2), 3.77 (6H, s, 2× CO_2CH_3), 3.70 (6H, s, 2× CO_2CH_3), *trans*: 7.32 (1H, d, *J* = 16.9 Hz, 3), 6.00 (1H, d, *J* = 16.9 Hz, 2) 3.74 (6H, s, 2× CO_2CH_3), 3.71 (6H, s, 2× CO_2CH_3), *cis* and *trans*: 2.50 (2H, t, *J* = 2.5 Hz, $CH_2C(O)C$=C), 2.43 (2H, t, *J* = 6.7 Hz, $CH_2CH_2C(O)CH$=CH)), 2.19–2.02 (8H, m, CH_2-CH_2C≡CC H_2CH_2), 1.64–1.21 (2H, m, $CH_2CH_2C(O)CH$=CH); ^{13}C nmr ($CDCl_3$) δ: 201.9 (enone C=O, 1), 171.0 and 169.8 (esters C=O, 15, 17, 19, 21), 140.4 (*C*H=CH, 13), 128.7 (*C*H=CH, 14), 80.6 and 79.9 (*C*≡*C*, 8 and 9), 58.7 and 58.4 (5 and 12), 53.0 and 52.4 (16, 18, 20, 22), 43.6 (CH_2C=O, 2), 31.7 and 31.6 (6 and 11), 29.6 (4), 20.2 (3), 14.4 and 14.2 (7 and 10). Exact Mass (M^+) calcd.: 436.1733; found: 436.1728.

Macrocycle 38

Macrocycle **38** was synthesized using the general procedure for macrocyclization from ynone **28** (216 mg, 0.495 mmol) in acetonitrile (30 mL), cesium carbonate (161 mg, 0.495 mmol), and acetonitrile (220 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording macrocycle **38** as a mixture (87:13) of isomers *cis* and *trans* (104 mg, 48%); ir ($CHCl_3$): 3010, 1740, 1700, 1450, 1300–1180 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.38 (1H, d, *J* = 16.9 Hz, 3 *trans*), 6.50 (1H, d, *J* = 16.9 Hz, 2 *trans*), 6.74 (1H, d, *J* = 12.3 Hz, 3 *cis*), 6.36 (1H, d, *J* = 12.3 Hz, 2 *cis*), 3.76(6H, s, $(CO_2CH_3)_2C(R)CH$=CH, 15), (6H, s, $R_2C(CO_2CH_3)_2$, 16), 2.53–2.49 (2H, m, 10), 2.43–2.39 (2H, m, 7), 2.27–2.09 (8H, m, 5, 11, 13, 14), 1.30–1.20 (2H, m, 6); ^1H nmr (C_6D_6) δ: 7.87 (1H, d, *J* = 16.9 Hz, 3 *trans*), 6.87 (1H, d, *J* = 12.3 Hz, 3 *cis*), 6.70 (1H, d, *J* = 16.9 Hz, 2 *trans*), 5.80 (1H, d, 12.3 Hz, 2 *cis*), 3.42 (6H, s, $(CO_2CH_3)_2$ *cis*), 3.24 (6H, s, $(CO_2CH_3)_2$ *trans*), 3.21 (6H, s, $(CO_2CH_3)_2$ *cis*), 3.20 (6H, s, $(CO_2CH_3)_2$ *trans*), 2.72–1.80 (12H, m, not interpretable), 1.20–1.06 (2H, m, methylene 6). Exact Mass (M^+) calcd.: 436.1730; found: 436.1733.

Macrocycle 39

Macrocycle **39** was synthesized using the general procedure for macrocyclization, from enone **30** (126 mg, 0.287 mmol) in acetonitrile (30 mL), cesium carbonate (94 mg, 0.287 mmol), and acetonitrile (113 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording macrocycle **39** (104 mg, 82%); ir ($CHCl_3$): 3010, 2880, 1750–1710, 1450, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 3.71 (12H, s, esters), 2.46 (4H, s, 5, 6), 2.45–2.30 (4H, m, 2, 14), 1.84–1.78 (2H, m, 9), 1.60–1.17 (2H, m, 10); ^1H nmr (C_6D_6) δ: 3.39 (6H, s, $(CO_2CH_3)_2$), 3.33 (6H, s, $CO_2CH_3)_2$), 3.00–2.17 (14H, m, not interpretable), 2.03–1.98 (2H, m, 9), 1.33–1.30 (2H, m, 10). Exact Mass (M^+) calcd.: 438.1890; found: 438.1886.

Macrocycle 40

Macrocycle **40** was synthesized using the general procedure for macrocyclization, from ynone **34** (216 mg, 0.493 mmol) in acetonitrile (30 mL), cesium carbonate (161 mg, 0.493 mmol), and acetonitrile (215 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording macrocycle **40** as a mixture (20:80) of *cis* and *trans* isomers (98 mg, 45%); ir ($CHCl_3$): 3010, 2860, 1700–1680, 1655, 1450, 1300–1000 cm^{-1}; ^1H nmr ($CDCl_3$) δ: *cis*: 6.62 (1H, d, *J* = 12.8 Hz, C*H*=CHC(O)), 6.39 (1H, d, *J* = 12.8 Hz, CH=C*HC*(O)), 3.74 (6H, s, CH=CHC($CO_2CH_3)_2$), 3.72 (6H, s, $CH_2C(CO_2CH_3)_2CH_2$),

trans: 7.33 (1H, d, J = 17.0 Hz, CH=CHC(O)), 5.99 (1H, d, J = 17.0 Hz, CH=CH_2C(O)), 3.78 (6H, CH=CHC(CO_2CH_3)$_2$), 3.73 (6H, CH_2C(CO_2CH_3)$_2$$CH_2$), *cis* and *trans*: 2.55–2.41 (2H, m, CH_2C(O)CH=CH), 2.20–1.87 (6H, m, C(E)$_2$$CH_2$$CH_2$CH=CH-$CH_2$), 1.44–1.35 (2H, m, $CH_2$$CH_2$C(E)$_2$CH=CHC(O)); ^{1}H nmr ($C_6D_6$) δ: 7.62 (1H, d, J = 16.4 Hz, 13 *trans*), 6.68 (1H, d, J = 12.6 Hz, 13 *cis*), 6.25 (1H, d, J = 12.6 Hz, 14 *cis*), 5.74 (1H, d, J = 16.4 Hz, 14 *trans*), 5.35–5.25 (2H, m, 7 and 8), 3.25 (6H, s, esters), 3.24 (6H, s, esters), 2.50–2.40 (2H, m, 2), 2.32–2.20 (4H, m, 3 and 11), 2.12–2.01 (2H, m, 5), 1.94–1.82 (2H, m, 6), 1.82–1.72 (2H, m, 9), 1.43–1.30 (2H, m, 10). Exact Mass (M^+) calcd.: 438.1890; found: 438.1886.

Macrocycle ***41***

Macrocycle **41** was synthesized using the general procedure for macrocyclization, from enone **36** (80 mg, 0.181 mmol) in acetonitrile (30 mL), cesium carbonate (59 mg, 0.181 mmol), and acetonitrile (60 mL). The crude product was purified by column chromatography (30% ethyl acetate in hexane) affording macrocycle **41** (61 mg, 76%); ir ($CHCl_3$): 3010, 2880, 1730, 1450, 1270–1170 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 5.47–5.40 (2H, m, CH=CH), 3.73 (6H, s, (CO_2CH_3)$_2$), 3.72 (6H, s, (CO_2CH_3)$_2$), 2.30 (8H, s, $CH_2$$CH_2$C(O)$CH_2$$CH_2$), 2.05–1.78 (8H, m, R(E)$_2$C$CH_2$$CH_2$CH=CH$CH_2$$CH_2$$CH_2$C(E)$_2$R), 1.29–1.15 (2H, CH=CHCH$_2$$CH_2$$CH_2$-C(E)$_2$R); ^{1}H nmr ($C_6D_6$) δ: 5.36–5.30 (2H, m, 7 and 8), 3.28 (6H, s, esters), 3.27 (6H, esters), 2.55–2.48 (2H, m, 14), 2.48–2.40 (2H, m, 2), 2.16–2.10 (2H, m, 13), 2.10–2.02 (4H, m, 3 and 5), 1.98–1.80 (4H, m, 6 and 11), 1.80–1.71 (2H, m, 9), 1.30–1.14 (2H, m, 10). Exact Mass (M^+) calcd.: 440.2046; found: 440.2043.

β-Enolization in α-phenyl-α,α′,α′-trimethylcycloalkanones[1]

WENDY SIFTON, J. B. STOTHERS, AND SHIRLEY E. THOMAS
Department of Chemistry, University of Western Ontario, London, Ont., Canada N6A 5B7

Received August 16, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

WENDY SIFTON, J. B. STOTHERS, and SHIRLEY E. THOMAS. Can. J. Chem. **70**, 1274 (1992).

Ring expansion through β-proton abstraction from α-methyl groups has been observed for the α-phenyl-α,α′,α′-trimethyl derivatives of cyclopentanone and cyclohexanone upon treatment with *t*-BuO⁻/*t*-BuOH/185°C. This contrasts with the lack of rearrangement found for the α,α,α′,α′-tetramethyl derivatives but is analogous to the behavior of some α-phenyl acyclic ketones. However, this process is reversible in the cyclic systems, but irreversible in the acyclic cases. For all of these α-phenyl substituted ketones, rearrangement is in competition with Haller–Bauer type cleavage. In the cyclic systems, a minor process was observed whereby some of the ring-expanded product is reduced to the corresponding secondary alcohol but there was no evidence of rearrangement through γ-enolate formation involving phenyl proton abstraction, which is a minor process in the α-phenyl acyclic systems.

WENDY SIFTON, J. B. STOTHERS et SHIRLEY E. THOMAS. Can. J. Chem. **70**, 1274 (1992).

Lors du traitement des dérivés α-phényl-α,α′,α′-triméthylés de la cyclopentanone et de la cyclohexanone par du *t*-BuO⁻/*t*-BuOH/185°C, on a observé une extension de cycle qui a été initiée par l'abstraction d'un proton-β des groupes méthyles-α. Ce comportement diffère de celui observé avec les dérivés α,α,α′,α′-tétraméthylés qui ne donnent pas de transpositions; il est toutefois analogue à celui observé avec quelques cétones acycliques portant un groupe α-phényle. Ce processus est toutefois réversible en série cyclique et irréversible dans les composés acycliques. Pour toutes ces cétones substituées par un groupe phényle, la transposition est en compétition avec un clivage du type de Haller–Bauer. Dans les systèmes cycliques, on a observé un processus mineur par lequel une partie du produit résultant de l'extension de cycle est réduit en alcool correspondant; on n'a toutefois pas de données suggérant qu'une transposition s'effectue par le biais de la formation d'un γ-énolate impliquant l'abstraction d'un proton d'un phényle; cette réaction est un processus mineur dans les systèmes acycliques portant un phényle en α.

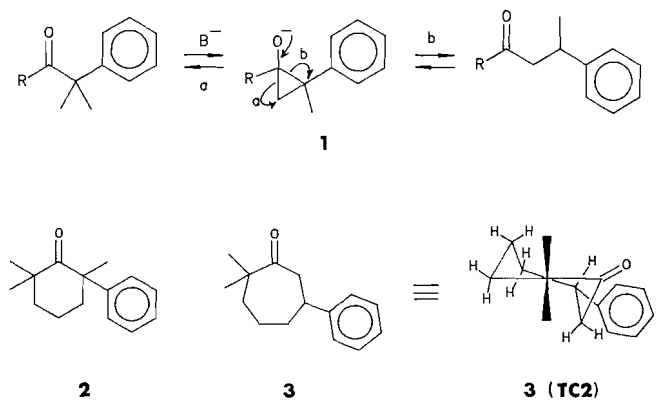
Introduction

Rearrangements of several acyclic and polycyclic monoketones occur by homoenolization through proton abstraction from centres other than the α-carbons, generally from β-carbons via β-enolates (1). Competition with α-enolization has been blocked, in most cases, through α-methyl substitution and (or) structurally, such that only anti-Bredt enolates could form. In several polycyclic examples, rearrangement via β-enolization at the α-methyl carbons was not observed, although, in many cases, it was shown that these sites undergo H/D exchange. In contrast, chain extension occurred in acyclic monoketones through β-enolization at the α-methyl carbons (2).Furthermore, this rearrangement is accelerated by the presence of α-phenyl groups, presumably because of the stability of the benzylic carbanion generated from the putative β-enolate **1** formed via methyl proton abstraction, i.e., cleavage *b* leading to the chain-extended isomer. Evidence supporting cyclopropoxide species as intermediates in the α-methyl exchange process for cyclic systems has been presented (3).

While the only process observed for the aliphatic examples was slow conversion to the chain-extended ketones, the rearrangement of the α-phenyl systems was accompanied by Haller-Bauer type cleavage and, as a minor process, a 1,3-acyl shift from alkyl to aryl carbon. Examination of α,α,α′,α′-tetramethylcycloalkanones had shown earlier that the ketones with 5- to 8-membered rings are stable under typical homoenolization conditions, exhibiting H/D exchange at the methyl carbons with no evidence of isomerization (4). It became of interest, therefore, to examine derivatives in which one methyl is replaced with a phenyl group. The behavior of two examples contrasted sharply with that found for the tetramethyl analogs and differed significantly from that for acyclic α-phenyl ketones; the results of this study are described in this paper.



Results and discussion

Homoenolization experiments

The initial ketone selected for examination was 2-phenyl-2,6,6-trimethylcyclohexanone (**2**), which was readily prepared from commercially available 2-phenylcyclohexanone. Following our usual procedures (5), **2** was dissolved in anhydrous *t*-BuO⁻/*t*-BuOH to give a solution 0.25 M in ketone and 1.0 M in base. Aliquots of this solution were placed in dry Pyrex tubes under nitrogen, degassed, and sealed un-

[1]Part 143 in ^{13}Cmr studies. For Part 142 see ref. 2.

TABLE 1. Composition[a] of the product mixtures from **2**

Time (h)	Neutral fraction[b]			Acid fraction
	2	**3**	**8**	**12**
24	47	15	<2	30
48	31	16	<4	46
96	22	18	5	52

der vacuum before heating at 185°C in an oil bath for various times. After cooling, the tube contents were diluted with brine and the neutral product isolated by ether extraction. The aqueous phase was acidified and extracted with ether to obtain any acidic product. Analysis by gas–liquid chromatography (GLC) showed that the neutral extract contained one new major component **3**, in addition to the initial ketone, together with small amounts of other material. The proportion of **3** in the neutral fraction slowly increased with reaction time: 24%, 24 h; 32%, 48 h; 40%, 96 h; but larger quantities of an acidic product were formed, exceeding 50% of the total product after 96 h (Table 1). The latter was found to be a single acid by NMR examination.

Flash chromatography of the neutral fraction furnished pure samples of component **3**. Strong carbonyl absorption at 1701 cm^{-1} and δ_C 216.6 indicated that it was a ketone, which was shown to be isomeric with **2** by precise mass measurement. NMR data, from ^1H, ^{13}C, and $^{13}C\{^1H\}$ COSY spectra, readily revealed its structure. Most notably, there were only two methyl absorptions and one quaternary carbon; a methyl and a quaternary carbon had been converted to methylene and methine carbons, consistent with ring expansion of **2** to a cycloheptanone system. Furthermore, the 2-methyl carbon of **2** must be involved in the generation of the new ketone because the *gem*-dimethyl unit was retained in the new ketone. The proton spectrum contained two sharp 3-proton singlets (δ_H 1.12, 1.13) and the long-range $^{13}C\{^1H\}$ COSY spectrum revealed that these methyl groups are bonded to the quaternary carbon, δ_C 47.8. It follows that the new ketone has structure **3**.

The ^1H spectrum of **3** clearly shows that it strongly favors a single conformation with the 3-phenyl group presumably serving as an effective "anchor." Conformational analysis of some dimethylated cycloheptanones through low-temperature ^1H studies and theoretical calculations led St-Jacqueus *et al.* (6) to deduce that these ketones exhibit a strong preference for twist-chair conformations with the carbonyl group at the "TC-2" position. The ^1HMR data for **3** are entirely consistent with this conclusion, indicating that **3(TC-2)** is the favored form.

The lowest field methylene protons at δ 2.43 (ddd, J = 10.5, 2.0, 1.5 Hz) and 3.20 (dd, J = 10.5, 12.1 Hz) exhibit geminal coupling comparable to that found for the α-methylene protons of 2,2-dimethylcycycloheptanone at low temperature, J = 10.4 Hz (6). This is clearly indicative of the orientation of the 2-methylene protons relative to the carbonyl group in **3(TC-2)**. The less shielded of these protons is strongly coupled (J = 12.1 Hz) with the 3-methinyl proton at δ 2.73 to which its partner is only weakly coupled (J = 2.0 Hz). The remaining coupling for the 2-proton at δ 2.43 arises from long-range interaction with the 4-methylene proton at δ 2.01; 1.5 Hz is a typical value for a four-bond coupling through a planar W pathway. The H-3 pattern contains another 12-Hz coupling to the other 4-methylene proton, δ 1.60. The latter multiplet has two more 12-Hz couplings: one with its 4-methylene partner (δ 2.01) and the second with one of the 5-protons, δ 1.37. Each of the protons at δ 3.20 (H-2), 2.73 (H-3), 1.60 (H-4), and 1.37 (H-5) exhibits vicinal antiperiplanar couplings of 12 Hz and, thus, is "axial." Their "equatorial" counterparts appear at δ 2.43 (H-2), 2.01 (H-4), and 1.8_5 (H-5), with the latter partially obscured by the 6-methylene pattern centred near δ 1.8 that could not be analyzed. These data neatly fit the **3(TC-2)** conformer; the NMR data are collected in Table 2.

The isomerization of **2** → **3** must involve proton abstraction leading to the intermediate β-enolate **4**, or its equivalent, which can suffer cleavage in two ways: path *a*, to regenerate **2**, or path *b*, to form a benzylic carbanion, protonation of which furnishes **3** (see Scheme 1). There was no evidence of products arising from proton abstraction from either of the 6-methyl sites that would give rise to **5** and lead to the isomeric cycyloheptanones **6**.

Proton abstraction from C-3 in **2** could produce β-enolate **7** whose cleavage to the benzylic anion would generate **8**. Analysis of neutral fractions from the longer reaction times by GLC revealed a small peak with a retention time slightly longer than that of **2**, but we were unable to isolate pure samples of this component free from **2**. The ^{13}CMR spectra of mixtures with **2**, however contained two new carbonyl signals at δ 223.3 and 223.1; these are indicative of a cyclopentanone derivative, present as a pair of diastereomers. There were two sets of eight sp^3 carbon signals, each arising from one quaternary, two methine, two methylene, and three methyl sites, as well as signals for two slightly different phenyl groups. The relative intensities of these two sets of signals were found to be 60:40. These data constituted strong evidence for the formation of **8**, as a diastereomeric mixture, though β-enolate **7** (Scheme 1).

The diastereomeric mixture **8** was prepared from 2,2-dimethylcyclopentanone by α-alkylation with 1-phenylethyl bromide and gave rise to the same two sets of ^{13}C signals in the same ratio as that found for the homoenolization product. GLC analysis of this sample showed two closely spaced peaks, one having the same retention time as **2**. Small samples of each of the two diastereomers were obtained by preparative GLC, with each containing ca. 20% of the other form.

From these results it is evident that the α-phenyl group in **2** biases cleavage of β-enolates **4** and **7** to generate the benzylic anions that lead to skeletal rearrangement. This is in sharp contrast to the behavior of 2,2,6,6-tetramethylcyclohexanone, which is virtually unchanged after treatment under the same conditions for 375 h (4).

At the outset, we recognized that the α-phenyl group in **2** could render cleavage of the Haller–Bauer type through **9** to be a major competitive process. It had been found that ketones **10** and **11** (R = ethyl, dimethylallyl, benzyl) undergo Haller–Bauer cleavage exclusively upon treatment with *t*-BuO^-/*t*-BuOH (7, 8). However, the more hindered carbonyl group in **2** could reduce its susceptibility to attack by

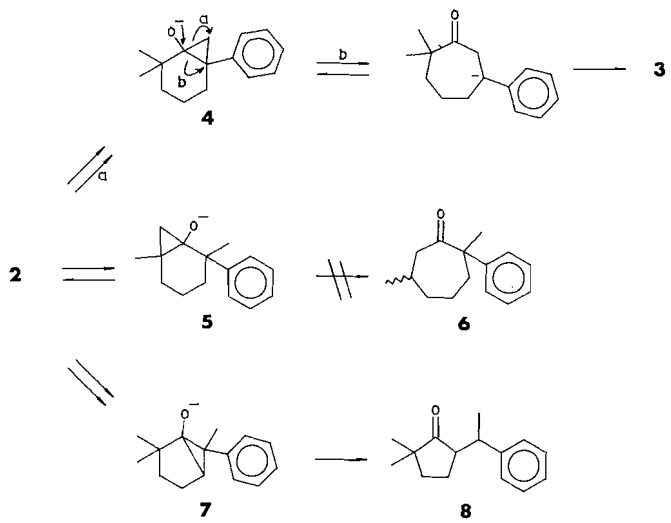


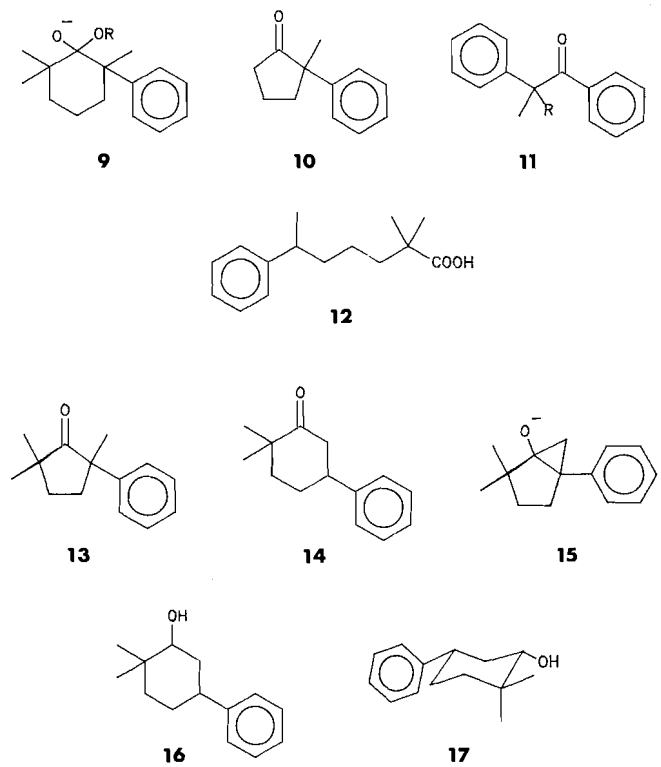
SCHEME 1

base because "ideally, the site of Haller–Bauer cleavage should not be subjected to any element of serious steric compression" (8) and this was found to be the case. Earlier studies have shown that the *tert*-butyl esters formed in Haller–Bauer cleavage of species such as **9** do not survive under the reaction conditions and the corresponding carboxylic acids are generated. Thus, the acidic product must be examined.

The acidic fraction contained one component, $C_{15}H_{22}O_2$, by precise mass measurement, having structure **12** according to its NMR spectra. The ^{1}HMR spectrum contained two methyl signals, δ 1.15 (s, 6H) and 1.24 (d, J = 6.9 Hz), with the latter coupled to one proton at δ 2.72 (m, 1H), methylene patterns at δ 1.2–1.3 (2H) and 1.5–1.7 (4H), and aryl absorption at δ 7.15–7.35 (5H). The ^{13}C spectrum contained 13 signals: CH_3, 22.3, 24.8, 25.0; CH_2, 22.9, 38.7, 40.4; CH, 39.6; C, 42.1; aryl CH, 125.9, 126.9 (2), 128.3 (2); aryl C, 147.7; C=O, 185.1.

From the results of these experiments with **2**, it became clear that its isomerization to **3** by β-enolization is significantly slower than Haller–Bauer cleavage whereas these two processes exhibit comparable rates in acyclic α-phenyl systems (2).

In a second series of experiments, the behavior of the 5-ring analog, 2-phenyl-2,5,5-trimethylcyclopentanone (**13**), was examined under the same conditions. Reaction of phenyl magnesium bromide with 2-chlorocyclopentanone gave 2-phenylcyclopentanone, which was methylated with MeI/$NaNH_2$ to furnish **13** in 86% yield.



Upon treatment with t-BuO^-/t-BuOH in sealed tubes at 185°C, ketone **13** was found to be much more reactive than **2**. After 3 h, more than 50% of the starting material had reacted to afford a neutral fraction containing two new components, in addition to **13**, and a one-component acidic fraction.

The major new neutral compound, $C_{14}H_{18}O$ by precise mass measurement, exhibited strong carbonyl absorption at 1709 cm^{-1} and δ_C 215.2, indicative of a cyclohexanone derivative. The ^{13}CMR spectrum contained signals for two methyl (δ_C 25.2_0, 25.1_8), three methylene (29.3, 39.9, 45.3), one methine (45.4), a quaternary (44.6), and the carbons of a phenyl group (126.6 (2), 126.7, 128.7 (2), 144.4). Clearly, a methyl/quaternary pair of carbons has become a methylene/methine pair. The two methyl groups gave singlets in the ^{1}HMR spectrum (δ 1.05, 1.19) and, from the ^{13}C{^{1}H} COSY spectrum, are bonded to the quaternary carbon. Thus,

TABLE 3. Composition[a] of the product mixtures from **13**

Time (h)	Neutral fraction[b] 13	14	16	Acid fraction 18
3	45	9	7	27
6	33	20	9	33
9	17	27	10	38
12	11	34	10	39
24	6	27	10	48

[a]Given as the proportion, on a % molar basis, of the isolated material.
[b]Estimated by GLC analysis on a SE-30 column, estimated precision ±2%.

the new ketone is **14**, formed through β-enolate **15**, or an equivalent species, by proton abstraction from the 2-methyl group of **13**.

The second neutral compound was found to have the molecular formula $C_{14}H_{20}O$ by precise mass measurement and exhibited strong, broad hydroxyl absorption at 3420 cm^{-1}. In addition to a carbinyl signal at δ_C 77.7, the ^{13}C spectrum contained quaternary (35.1), methine (43.5), methylene (29.6, 38.0, 39.2), methyl (17.6, 29.0), and phenyl signals (126.2, 126.8 (2), 128.4 (2), 146.1). These data indicate that **14** is reduced to the corresponding alcohol **16**. The major features of the ^1H spectrum included two methyl singlets (δ 0.89, 0.98), a 4-line pattern at δ 3.45 (1H, J = 4.3, 11.4 Hz), and a 1-proton multiplet centred at δ 2.6 with a half-width of ca. 30 Hz. These two multiplets are readily assigned to axial protons on C-1 and -3, respectively, thus, the hydroxyl and phenyl groups are equatorial as in **17**.

The sole component in the acid fraction was readily shown to be **18** from its NMR spectra. The ^1HMR spectrum contained two methyl singlets (δ 1.13, 1.15) and a methyl doublet (δ 1.23, J = 6.9 Hz), with the latter coupled to a 1-proton multiplet at δ 2.60, as well as methylene (δ 1.30–1.65, m, 4H) and phenyl absorption (δ 7.14–7.34, 5H). Its ^{13}C spectrum exhibited signals for three methyl (δ 22.6, 24.7, 25.2), two methylene (33.2, 38.6), one methine (40.4), a quaternary (42.0), and six phenyl carbons (126.0, 127.0 (2), 128.4 (2), 147.3) as well as a carboxyl signal (184.5).

The distribution of the components in the product mixtures from **13** as a function of time is given in Table 3, from which it is apparent that the proportion of **14** passes through a maximum around 12 h and then diminishes. This finding indicated that the stability of **3** and **14** under homoenolization conditions should also be studied. To this end, the rearranged ketones were treated with t-BuO^-/t-BuOH in sealed tubes at 185°C for various times and the product mixtures analyzed.

The results of these two series of experiments are summarized in Table 4 from which it is clear that **3** and **14** are not stable under the reaction conditions. Within 24 h, almost 50% of **3** had been consumed primarily through isomerization to **2** and its cleavage to acid **12**; traces of **8** were also present. In addition, small amounts of a fourth neutral component were detected by GLC in each of the neutral products and the ^{13}C spectra contained a set of weak peaks, one of which appeared at δ_c 79.9, indicative of the presence of an alcohol. The retention time of this component coincided with that of a small signal in the gas chromatograms

[b]Unidentified neutral components.

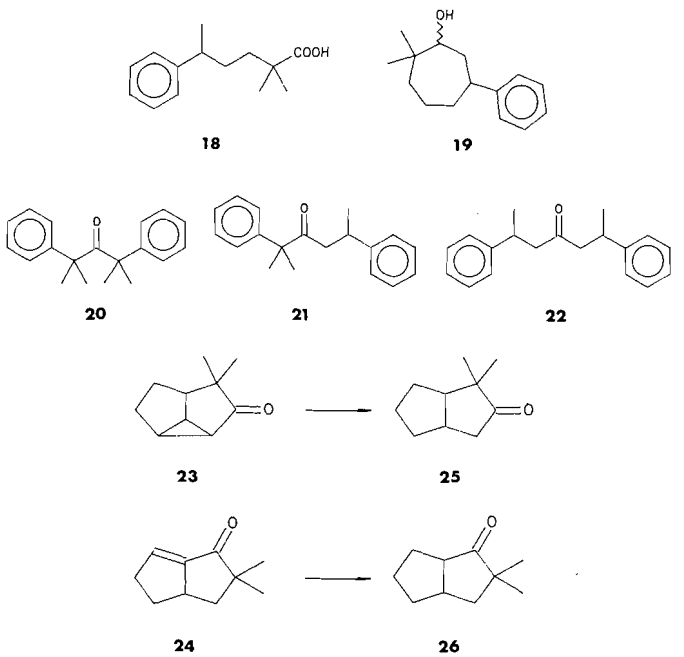
of the neutral fractions obtained by homoenolization of **2**, indicating that trace amounts were present therein. To confirm this point, the neutral product mixtures from several experiments with **2** were combined and the components separated by column chromatography on alumina. This procedure provided a sample of the desired material as well as a clean sample of **8**, establishing the formation of both products in the homoenolization of **2**. The ^{13}C spectrum of the new component, however, revealed it to be a 2:1 mixture of isomeric alcohols; the formula was found to be $C_{15}H_{22}O$ by precise mass measurement. Thus, these were tentatively identified as **19**.

Ketone **14** was found to react at a rate comparable to that of **3**. The product mixtures contained **14**, alcohol **16**, acid **18**, and small amounts of unidentified material, but none of the isomeric ketone **13** was detected. Clearly, the cleavage of **13** to **18** is sufficiently rapid to destroy **13** as it is formed from **14**.

The reversible formation of **3** and **14** contrasts sharply with the findings for the acyclic cases. For example, **20** is isomerized unidirectionally to **21**, which, in turn, is converted to **22** under the same reaction conditions (2). These results showed that cleavage of **1** (R = $-C(CH_3)_2C_6H_5$ and $-CH_2CH(CH_3)C_6H_5$) proceeded irreversibly through path *b*. In the cyclic systems, however, the corresponding intermediates **4** and **15** are generated readily from the isomeric pairs **2**/**3** and **13**/**14**, respectively, presumably because the ring systems impose conformational constraints that favor formation of these intermediates.

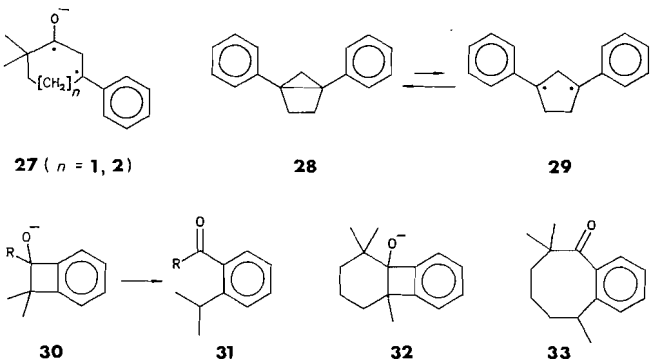
To confirm the structures of **16** and **19**, ketones **3** and **14** were reduced with sodium borohydride. A 2:1 mixture of two alcohols was obtained from **3** and, interestingly, the minor alcohol was found to be identical to the major alcohol isolated from homoenolizations of **2** and **3**. Definitive stereochemical assignments for these isomeric cycloheptanols, however, cannot be made. From **14**, a 9:1 mixture of isomeric alcohols was obtained in which the major component was identical to **16**; the ^{13}CMR data for the minor alcohol were those expected for the *trans* isomer bearing an axial hydroxyl.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.



The reduction of **3** and **14** to the corresponding alcohols **19** and **16**, respectively, is puzzling and we were unable to isolate any oxidized products that could shed light on the process involved. We are aware of two other systems in which reduction occurs under homoenolization conditions and in each case an unsaturated grouping was affected, leading to a saturated ketone, not an alcohol; the isomeric ketones **23** and **24** were reduced to the [3.3.0] ketones **25** and **26**, respectively (9, 10). It was suggested that these processes involve single electron transfer from the *tert*-butoxide anion. Interestingly, there was no reduction in the homoenolizations of the α-phenyl acyclic ketones examined in our earlier study (2). However, in the cyclic systems the intermediates, depicted as **4** and **15**, are formed readily and reversibly. It is conceivable that these species undergo reduction, possibly initiated by homolysis of the more substituted bond in the cyclopropoxide ring to produce a diradical, e.g., **27**, which could then gain hydrogen from solvent molecules to produce the small amounts of alcohols observed. A precedent for the formation of such intermediates is provided by the observation that 1,4-diphenylbicyclo-[2.1.0]pentane (**28**) is in rapid equilibrium with 1,3-cyclopentanediyl **29**, through homolysis of the very weak 1,4-bond (11), and it has been shown that an oxy anion substituent has a sizable bond-weakening effect on adjacent bonds (12). Thus, it seems reasonable to suggest that **27** may be generated in these systems. It may be noted that **29** slowly undergoes a 1,2-hydrogen shift to give 1,3-diphenylcyclopentene at temperatures above 100°C; an analogous shift in **27** would regenerate **3** or **14** as their α-enolates.

A minor process detected in the homoenolization of the acyclic α-phenyl ketones involved an acyl shift from alkyl to aryl carbon through a cyclobutoxide intermediate **30** opening unidirectionally to **31**. The analogous reaction for **2** would lead to the tricyclic species **32**, which, in principle, could return to **2** or cleave to a 2,3-benzocyclooctanone. In fact, the benzocyclobutenol formed by protonation of **32** has been shown to cleave entirely to **2** and the amide of **12** upon treatment with $NaNH_2$/glyme (13). Thus, the formation of **32** would be undetectable in our experiments. It may be noted, however, that preliminary examination of the reaction of **2** with lithium 2,2,6,6-tetramethylpiperide has revealed the formation of **32** as well as rearrangement to **3**. Interestingly, photolysis of the benzocyclobutenol from **32** provides a synthetic route to **33** (14). The behavior of **2**, **13**, and related ketones upon treatment with nitrogen bases is now under investigation.



Summary

From the foregoing data, it is apparent that isomerization through proton abstraction from the 2-methyl group in **13** is approximately an order of magnitude faster than that for **2**. This is in agreement with the earlier finding that β-proton abstraction from the methyl sites in 2,2,5,5-tetramethylcyclopentanone is ten times faster than that in 2,2,6,6-tetramethylcyclohexanone (4). Both **2** and **13** are consumed more rapidly than the α-phenyl acyclic ketones examined previously under the same reaction conditions (2), but the present results also reveal other major differences in behavior between the cyclic and acyclic systems. The ready reversibility of β-enolate formation in these cyclic ketones stands in striking contrast to the results for the acyclic ketones and renders the ring expansion of little preparative utility because of the competitive Haller–Bauer cleavage; the latter process is also faster in the cyclic systems. The unusual minor process through which **3** and **14** undergo reduction was not observed for the α-phenyl acyclic systems perhaps owing to constraints imposed by the ring system that are lacking in the acyclic cases. The preliminary results obtained upon changing the base to lithium 2,2,6,6-tetramethylpiperide seem to indicate one way to minimize Haller–Bauer cleavage and the reduction process.

Experimental

Gas–liquid chromatography was carried out on a Varian 3300 instrument using a column of 5% SE-30 on Chromosorb W 80–100. Ether was dried over sodium and freshly distilled before use. Technical grade 2-phenylcyclohexanone and 2-chlorocyclopentanone are commercially available.

Infrared spectra were recorded using a Bruker/IBM FTIR 32 spectrometer. Mass spectral data were obtained with a Finnigan MAT 8230 instrument at 70 eV for routine spectra and at 20 eV for exact mass measurements.

Proton and carbon NMR spectra of each compound were recorded with Varian XL-200 (^{1}H) and XL-300 (^{13}C) spectrometers. The protonation level for each carbon signal was found by recording the APT spectrum. Specific assignments for the sp^3-carbon signals of **3** were obtained by heteronuclear correlation with its ^{1}H spectrum. The one-bond interactions were revealed with the HETRES sequence (15*a*), utilizing a 2048 × 144 data point matrix, with a 6 kHz spectral width for ^{13}C and 1 kHz for ^{1}H, and transforming 2048 and 512 points, respectively. A 0.90 s relaxa-

tion delay and a fixed time of 0.037 s were employed. Two- and three-bond correlations for the methyl protons were identified with the FLOCK sequence (15*b*). This spectrum was obtained using a 2048 × 120 data point matrix, with 6 kHz (^{13}C) and 1 kHz (^{1}H) spectral widths, and transforming 2048 and 512 points, respectively; a relaxation delay of 0.83 s, with Δ_1 = 0.090 s and Δ_2 = 0.024 s, was employed.

2-Phenylcyclopentanone

To a cold, stirred solution of phenylmagnesium bromide, from bromobenzene (9.3 mL) and magnesium (2.2 g) in 50 mL of dry ether, was added a solution of 2-chlorocyclopentanone (8.4 mL) in dry ether (30 mL) over 30 min. This mixture was heated under gentle reflux for 2 h before cooling to room temperature. The cooled mixture was treated with ice and dilute hydrochloric acid before extraction with benzene. The organic layer was washed with dilute sodium hydroxide and then with water before drying over anhydrous sodium sulfate. Evaporation of the benzene left a darkly colored residue, which was distilled to yield a light yellow oil (6 g), bp 112–116°/2 Torr (1 Torr = 133.3 Pa). Flash chromatography (hexane:ether; 19:1) gave 2-phenylcyclopentanone as a colorless oil (5.5 g, 41% yield) that slowly crystallized on standing to afford white crystals, mp 35–36°C (lit. (16) mp 36–37°C); IR($CHCl_3$): 1740 cm^{-1}; ^{13}CMR($CDCl_3$) δ: CH_2, 20.6, 31.5, 38.2; CH, 55.0; aryl CH, 127.9 (2), 128.3 (2), 126.6; aryl C, 138.3; C=O, 217.7. Exact Mass calcd. for $C_{11}H_{12}O$: 160.0888; found: 160.0894.

Preparation of the α-phenyl-α,α′,α′-trimethylcycloalkanones

To a stirred suspension of freshly powdered anhydrous sodium amide (0.12 mol) in dry ether (20 mL) was added a solution of the ketone (0.01 mol) in dry ether (10 mL) and the mixture heated under reflux for 2 h with vigorous stirring. The mixture was cooled and methyl iodide (0.05 mol) added slowly before refluxing for 2 h. Equivalent quantities of methyl iodide were added at intervals of 2, 2, and 15 h before a final reflux period of 2 h. After cooling, water (60 mL) was added. The ether layer was separated and the aqueous phase extracted with ether (3 × 20 mL). The combined extracts were washed with water and saturated NaCl solution before drying over anhydrous Na_2SO_4. Removal of the solvent afforded an oily residue, which was examined by GLC to check that the major product was fully methylated. In each case, the crude product was purified by flash chromatography (petroleum ether:ether, 19:1).

2-Phenyl-2,6,6-trimethylcyclohexanone (2): 85% yield: IR (liquid film): 1698 cm^{-1}; ^{1}HMR ($CDCl_3$) δ: 0.61 (s, 3H, Me), 1.06 (s, 3H, Me), 1.26 (s, 3H, Me), 1.50–2.10 (m, 5H), 2.65 (m, 1H), 7.15–7.30 (m, 5H, aryl H's); ^{13}CMR ($CDCl_3$) δ: CH_3, 27.2, 27.4, 30.6; CH_2, 18.2 (C-4), 36.1 (C-5), 40.4 (C-3), C, 45.7 (C-6), 52.4 (C-2); aryl CH, 125.6 (*ortho*), 128.6 (*meta*), 126.4 (*para*); aryl C, 142.8; C=O, 217.1. Exact Mass calcd. for $C_{15}H_{20}O$: 216.1514; found: 216.1511.

2-Phenyl-2,6,6-trimethylcyclopentanone (13): 86% yield; IR (liquid film): 1734 cm^{-1}; ^{1}HMR ($CDCl_3$) δ: 0.90 (s, 3H, Me), 1.04 (s, 3H, Me), 1.28 (s, 3H, Me), 1.67 (m, 2H), 1.90 (m, 1H), 2.36 (m, 1H), 7.05–7.30 (m, 5H); ^{13}CMR ($CDCl_3$) δ: CH_3, 24.9, 25.3, 26.3; CH_2, 34.5, 34.7; C, 45.3, 53.4; aryl CH, 126.1 (2), 126.4, 128.4 (2); aryl C, 143.3; C=O, 224.0. Exact Mass calcd. for $C_{14}H_{18}O$: 202.1358; found: 202.1368.

Homoenolization experiments

The general procedure for these experiments has been described previously (5). A solution of the desired ketone in *t*-BuO^-/*t*-BuOH, prepared from potassium metal and *t*-BuOH (H_2O content <200 μg/mL), was made up under nitrogen in a mole ratio: ketone/*t*-BuO^-/*t*-BuOH, 1:4:40. Aliquots were then transferred to predried, thick-walled glass tubes quickly and the solutions degassed before sealing under vacuum. The tubes were heated in an oil bath at 185°C for varying periods of time. After cooling, the reaction mixture was washed from the tube with water and saturated NaCl solution. The product was extracted with ether and the combined extracts washed with water before drying over anhydrous Na_2SO_4. Evaporation of the solvent gave the crude neutral fraction, which was initially examined by GLC. The individual components in each of the mixtures were identified from their NMR spectra and analytical samples were characterized after isolation by preparative GLC or column chromatography (see text).

3-Phenyl-7,7-dimethylcycloheptanone (3): IR (liquid film): 1701 cm^{-1}; ^{1}H and ^{13}CMR data: see text. Exact Mass calcd. for $C_{15}H_{20}O$: 216.1514; found: 216.1513.

3-Phenyl-6,6-dimethylcyclohexanone (14): IR (liquid film): 1709 cm^{-1}; NMR data: see text. Exact Mass calcd. for $C_{14}H_{18}O$: 202.1358; found: 202.1362.

cis-*3-Phenyl-6,6-dimethylcyclohexanol (16):* IR (liquid film): 3420 cm^{-1}; NMR data: see text. Exact Mass calcd. for $C_{14}H_{20}O$: 204.1514; found: 204.1509.

The aqueous phase was acidified with 5% HCl solution before the acidic fraction was isolated by ether extraction and the product identified by ^{1}HMR, ^{13}CMR, and precise mass measurement.

The experiments with **2** and **3** gave one acid having the formula $C_{15}H_{22}O_2$. Exact Mass calcd. for $C_{15}H_{22}O_2$: 234.1620; found: 234.1625. This was identified as **12** by the NMR spectra described in the text.

The reactions of **13** and **14** with strong base also gave a single acid. Exact Mass calcd. for $C_{14}H_{29}O_2$: 220.1463; found: 220.1459. This compound was shown to be **18** from its NMR spectra (see text).

Sodium borohydride reduction of 3 and 14

Sodium borohydride (18 mg, 0.5 mmol) was mixed with methanol (5 mL) before the addition of an ethereal solution of the ketone (1 mL) and the mixture was stirred. After 1 h, GLC analysis showed that the ketone had reacted completely and the product was isolated by ether extraction after dilution with water. The ether extracts were dried over anhydrous $MgSO_4$ before the solvent was evaporated to obtain the product.

Ketone **14** (20 mg) gave a colorless liquid (19.5 mg, >95% yield), which was found to be a 9:1 mixture of alcohols by ^{13}CMR. The major component was identical to alcohol **16**, described above, which was isolated from the reaction of **13** with *t*-BuO^-/*t*-BuOH. The ^{13}CMR spectrum of the minor alcohol contained signals for two methyl (δ_C 24.9, 27.6), three methylene (29.4, 33.4, 36.7), two methine (37.1, 75.2), one quaternary (34.0), and phenyl carbons (126.0, 127.0 (2), 128.4 (2), 146.7). These data are consistent with those expected for the *trans* isomer of **16** bearing an axial hydroxyl group.

Ketone **3** (7 mg) gave a colorless oil (6.8 mg, >95% yield), which was a 2:1 mixture of the 3-phenyl-7,7-dimethylcycloheptanols (**19**) from its ^{13}C spectrum; IR (liquid film): 3400 cm^{-1}. Exact Mass calcd. for $C_{15}H_{22}O$: 218.1671; found: 218.1670. The minor alcohol was identical to that isolated from the homoenolization experiments with **2**; ^{13}CMR ($CDCl_3$) δ_C: 21.8, 28.6 (CH_3's), 21.4, 38.7, 40.7, 41.2 (CH_2's), 44.8, 79.9 (CH's), 37.4 (quat C), 125.9, 126.7(2), 128.4(2) (aryl CH's), and 148.5 (aryl C); ^{1}HMR ($CDCl_3$) δ: 0.87 (s, 3H, CH_3), 1.00 (s, 3H, CH_3), 1.05–2.05 (m, CH_2), 2.70 (m, 1H), 3.4 (dd, 1H), and 7.05–7.20 (m, aryl H's). The major alcohol gave the following NMR spectra: ^{13}CMR ($CDCl_3$) δ_C: 26.1, 27.5 (CH_3's), 22.0, 36.2, 37.7, 39.4 (CH_2's), 38.1, 76.8 (CH's), 38.3 (quat C), 125.7, 126.9(2), 128.4(2) (aryl CH's), and 149.4 (aryl C); ^{1}HMR ($CDCl_3$) δ: 0.93 (s, 3H, CH_3), 0.95 (s, 3H, CH_3), 1.05–2.05 (m, CH_2), 3.08 (m, 1H), 3.55 (dd, 1H), and 7.05–7.20 (m, aryl H's).

2-(1-Phenylethyl)-5,5-dimethylcyclopentanone (8)

To a stirred solution of LDA, prepared from diisopropylamine (1.5 mL), *n*-BuLi (4 mL, 2.5 M in hexane), and THF (10 mL), at −78°C was added 2-methylcyclopentanone (1.16 g) dropwise. After stirring at −78°C for 0.5 h, the mixture was warmed to 0°C and left for 3 h before methyl iodide (1 mL) was added slowly. Stirring was continued for 3 h after which time GLC analysis of the reaction mixture indicated the absence of the monomethyl ketone. The re-

action mixture was quenched with water and the product isolated by ether extraction to yield 2,2-dimethylcyclopentanone (0.67 g, 68% yield), which was used without further purification.

To a solution of LDA (diisopropylamine (1.1 mL) and *n*-BuLi (2.8 mL, 2.5 M in hexane) in 10 mL of THF) at 0°C was added a solution of 2,2-dimethylcyclopentanone (150 mg) in THF (5 mL) dropwise. This mixture was stirred at 0°C for 0.3 h before 1-phenylethyl bromide (1.36 g) in THF (5 mL) was added slowly. After 5 h at 0°C, an identical addition of the bromide was made and the reaction mixture was left stirring overnight. Water was added and the product extracted with ether. Evaporation of the ether after drying the combined extracts over anhydrous $MgSO_4$ gave an oil (2.26 g) that was mainly the alkyl bromide. Most of the bromide was removed by chromatography on silica gel to yield a crude product (280 mg), which by GLC analysis contained ca. 75% of the diastereomeric mixture **8** in a 60:40 ratio, virtually the same as that found for the sample isolated from the homoenolization experiments with **2**. Small samples of each diastereomer, each of which contained about 20% of the other, were obtained by preparative GLC. Precise mass data for each diastereomer were obtained by GC/MS. The major diastereomer had the following properties: IR (liquid film): 1730 cm^{-1}; ^{13}CMR ($CDCl_3$) δ_c: 15.5, 23.1, 24.7 (CH_3's), 20.8, 36.3 (CH_2's), 38.0, 55.8 (CH's), 45.5 (quat C), 126.2, 127.4 (2), 128.4 (2) (aryl CH's), 145.4 (aryl C), and 223.1 (C—O). Exact Mass calcd. for $C_{15}H_{20}O$: 216.1514; found: 216.1512. The minor diastereomer exhibited the following data: IR (liquid film): 1730 cm^{-1}; ^{13}CMR ($CDCl_3$) δ_c: 19.6, 22.7, 24.5 (CH_3's), 21.9, 36.2 (CH_2's), 39.2, 55.3 (CH's), 45.4 (quat C), 126.4, 128.1 (2), 128.3 (2), (aryl CH's), 144.2 (aryl C), and 223.3 (C=O). Exact Mass calcd. for $C_{15}H_{20}O$: 216.1514; found: 216.1510.

Acknowledgements

We are grateful for the continued financial support of the Natural Sciences and Engineering Research Council of Canada and to Dr. B. Rangaswamy for some preliminary experiments. The assistance of Professor Wm. F. Reynolds through provision of the HETRES and FLOCK pulse sequences as well as his helpful comments on the proper choice of operating parameters are gratefully acknowledged. We wish to thank Professors R. R. Fraser and E. W. Warnhoff for valuable discussions concerning possible modes for the reduction process. This paper was taken in part from the honors B.Sc. thesis of W.S.

Received July 9, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

L. A. BLAIS, J. W. APSIMON, B. A. BLACKWELL, R. GREENHALGH, and J. D. MILLER. Can. J. Chem. **70**, 1281 (1992).

Dried mycelia from a 15 L stirred-jar fermentation culture of *Fusarium avenaceum* (DAOM 196490) were extracted with dichloromethane and partitioned between hexane and methanol/water. Recrystallization of the hexane fraction yielded 6.750 g of a crude mixture of enniatins. Fast atom bombardment mass spectrometry showed, in accord with previous studies, that enniatin A was the predominant enniatin present, with smaller amounts of enniatins A1 and B1. HPLC purification of 500 mg of the enniatin mixture resulted in the isolation of 300 mg of enniatin A, 114 mg of enniatin A1, 9 mg of enniatin B1, and 46 mg of a new, *N*-methylleucine-containing enniatin (A2). This is the first reported isolation of a pure *N*-methylleucine-containing enniatin from *Fusarium*, though the existence of such compounds had previously been inferred from hydrolysis and NMR data. The purification and complete characterization of enniatins A1, B1, and A2 are reported.

L. A. BLAIS, J. W. APSIMON, B. A. BLACKWELL, R. GREENHALGH et J. D. MILLER. Can. J. Chem. **70**, 1281 (1992).

Utilisant du dichlorométhane, on a extrait des mycéliums séchés d'une culture effectuée dans un récipient de 15 L agité de *Fusarium avenaceum* (DAOM 196490) et on a fait la partition entre de l'hexane et un mélange de méthanol/eau. La recristallisation de la fraction hexanique fournit 6,750 g d'un mélange brut d'enniatines. La spectrométrie de masse par bombardement avec des atomes rapides a montré, en accord avec des études antérieures, que l'enniatine A est l'enniatine prédominante aux côtes de quantités plus faibles d'enniatines A1 et B1. Une purification par CLHP de 500 mg du mélange d'enniatine permet d'isoler 300 mg d'enniatine A, 114 mg d'enniatine A1, 9 mg d'enniatine B1 et 46 mg d'une nouvelle enniatine (A2) contenant de la *N*-méthylleucine. Même si l'existence de tels composés avait été suggérée antérieurement sur la base d'une hydrolyse et de données de RMN, il s'agit de la première enniatine contenant de la *N*-méthylleucine à être isolée à l'état pur à partir du *Fusarium*. On rapporte la purification et la caractérisation complète des enniatines A1, B1 et B2.

[Traduit par la rédaction]

Introduction

Fusarium avenaceum (Fr.) Sacc. (section *Roseum*) is chiefly a fungus of temperate zones and is a common pathogen of overwintering cereals. It is responsible for root-rot in both seedlings and mature plants of these cereals as well as of legumes and conifers. It has been associated with damping-off disease of nursery seedlings and is also involved in "spring yellows." *Fusarium avenaceum* has also been linked to wilt in a variety of plants (1).

Fusarium avenaceum (DAOM 196490) has been isolated from the phylloplane of needles from balsam fir infested with spruce budworm (*Choristoneura fumiferana* Clem.) by Miller *et al.* (2). This fungus was found by Strongman *et al.* to produce a group of cyclohexadepsipeptides, the enniatins, in liquid culture (3). Purification of crude extracts of the mycelia resulted in the isolation of a mixture of the enniatins A, A1, and B1, which was found to be toxic to spruce budworm larvae at concentrations of 400 ppm (3). In addition, the enniatins have been reported to be toxic to wheat seedlings (4), to have moderate insecticidal activity against blowfly and mosquito larvae (5), to show moderate antibiotic activity against some gram positive bacteria (6), and to be implicated in *Fusarium* wilt of tomato plants (7).

The enniatins were first isolated in 1947, by Gaumann *et al.* (8), and have been characterized as cyclodepsipeptides containing alternating D-2-hydroxyisovaleric acid (HyIv) and L-amino acid residues to form an 18-membered cyclic backbone. The amino acid residues can be either *N*-methylisoleucine (NMeIle) (enniatin A) (**1**), *N*-methylvaline (NMeVal) (enniatin B) (**2**), or mixtures of the two (enniatins A1 (**3**) and B1 (**4**)) (Fig. 1). Of these, only enniatins A and B have been obtained in the pure form and fully characterized (3, 9, 13). The presence of *N*-methylleucine (NMeLeu)-containing enniatins has been inferred from amino acid analysis of enniatin mixtures (10, 13), and although enniatin C (**5**) (containing only NMeLeu and HyIv) has been synthesized (12), no NMeLeu-containing enniatins have been purified and characterized previous to this work.

This work details the isolation and complete characterization of enniatins A1 and B1 in addition to a new, NMeLeu-containing enniatin, A2 (**6**). This is the first reported isolation and characterization of an *N*-methylleucine-containing enniatin from a *Fusarium* species.

Results and discussion

Strongman *et al.* (3) have shown that the major enniatin produced by *Fusarium avenaceum* DAOM 196490 is enniatin A.

HPLC purification of 500 mg of crude enniatins yielded five fractions. The largest fraction, peak 5, contained 300 mg of pure enniatin A. The identity of this compound

FIG. 1. Structures of the enniatins.

was confirmed by comparison to published melting point, mass spectral, and NMR data (3). The ^1H NMR chemical shifts and coupling constants and ^{13}C NMR chemical shifts for enniatin A are listed in Tables 1 and 2.

The structures of enniatins A1 and B1 have been determined from amino acid analysis and mass spectral data (10, 12). However, they have never been purified and fully characterized.

Peak 3 from the HPLC separation of the enniatin mixture yielded 114 mg of pure enniatin A1. The colourless, needle-shaped crystals melted at 66–67°C and exhibited an optical rotation of −62.8 (*c* 2.3 in chloroform at 25°C). The FAB mass spectrum showed a molecular ion at *m/z* 668.5 (M^+ + H), indicating a molecular weight of 667. This was confirmed by solid probe EI/MS, which also showed a molecular ion at *m/z* 667. Previous amino acid analyses of mixtures of enniatins containing enniatin A1 suggested a structure for this enniatin in which there are two *N*-methylisoleucine residues and one *N*-methylvaline residue alternating with D-2-hydroxyisovaleric acid residues to form the cyclohexadepsipeptide. The 500 MHz ^1H NMR spectrum of enniatin A1 is shown in Fig. 2(*a*). Comparison of these data with those obtained for enniatin A (see Table 1) indicates the presence of *N*-methylisoleucine, shown by a pair of doublets at 4.62 and 4.66 ppm (J = 9.2 Hz), which integrate for two protons. The multiplet resonances at 2.01 ppm (βCH), 1.04 and 1.42 ppm (γCH_2 AB), and overlapping triplets at 0.83 and 0.85 (δCH_3) are also due to NMeIle. The doublet at 4.42 ppm, with a coupling constant of 10.3 Hz, is assigned as the αCH of NMeVal by comparison to published ^1H NMR data for enniatin B (12). In addition, the multiplet at 2.28 ppm and the doublets at 1.03 and 0.87 ppm correspond to the βCH and γCH_3 resonances for this amino acid. There are two *N*-methyl singlets in this spectrum at 3.10 ppm (3 protons) and 3.08 (6 protons), which are assigned to NMeVal and the two NMeIle residues respectively. Finally, the αCH HyIv resonances have been assigned to the three overlapping doublets at 5.11 ppm. The βCH resonances and γCH_3 resonances for the HyIv residues are given in Table 1.

The 62.5 MHz ^{13}C NMR spectrum of enniatin A1 confirms the presence of two NMeIle residues and one NMeVal residue. The αCH region for the amino acids shows resonances at 63.4 ppm and 61.4 ppm, corresponding to the αCH groups of NMeVal and NMeIle respectively. Although integration of ^{13}C spectra is usually not accurate, in this case the peak at 61.4 ppm is approximately twice the height of the peak at 63.4 ppm, which would indicate the presence of two NMeIle residues. There are three resonances in the *N*-methyl region at 33.4, 32.8, and 32.7 ppm. Comparison to the spectra of enniatins A and B shows that the downfield resonance is due to NMeVal and the two upfield resonances to NMeIle. Finally, resonances that correspond to the γCH_3 groups of NMeVal occur at 19.5 and 20.5 ppm; the δCH_3 resonance of NMeIle occurs at 10.9 ppm and the γ-methyl resonance for this amino acid residue occurs at 16.2 ppm. The electron-impact mass spectrum shows fragment ions characteristic of the loss of alternating HyIv and amino acid moieties from the parent compound. The ion at *m/z* 423 accounts for a loss of 244 mass units from the parent enniatin A1, which corresponds to a dimer of HyIv–NMeIle. Loss of NMeVal from the remaining tetramer results in the ion at *m/z* 296, and loss of another HyIv residue yields the ion at *m/z* 196. Thus the GC/MS and ^1H and ^{13}C NMR data for enniatin A1 agree with the assigned structure of cyclo-[(NMeIle-HyIv)$_2$-NMeVal-HyIv].

The first peak from the HPLC separation of the enniatin mixture yielded 9 mg of enniatin B1. FAB mass spectra of this compound showed a molecular ion at *m/z* 654.5 (M^+ + H), indicating a molecular weight of 653. Solid probe EI/MS confirmed this molecular weight. Comparison with the literature indicated that this compound was enniatin B1. The structure of this compound was proposed to be a homologue of enniatin A1, in which one of the NMeIle residues is replaced by a second NMeVal residue.

The 500 MHz ^1H NMR spectrum of enniatin B1 is shown in Fig. 2(*b*). This spectrum is similar to the ^1H NMR spectrum of enniatin A1, except that the number of doublets and integration values representing the αCH of NMeIle and NMeVal are reversed. In addition, the singlets at 3.08 and 3.10 ppm, representing the methyl groups on the nitrogens of NMeIle and NMeVal respectively, show reversed intensities to those in the spectrum of enniatin A1. There is also a difference in the intensities for the βCH protons. In the spectrum of enniatin A1, the resonance for the βCH of NMeVal is a shoulder on that of HyIv (2.26 ppm). The observed intensity is only slightly greater for these overlapped βCH multiplets (integrating for four protons) than for the multiplet at 2.01 ppm corresponding to the βCH of NMeIle, which integrates for two protons. In the spectrum of enniatin B1, the overlapping of the βCH multiplets at 2.24 ppm (integrating for five protons) results in an observed intensity of at least four times that of the multiplet at 2.04 ppm (in-

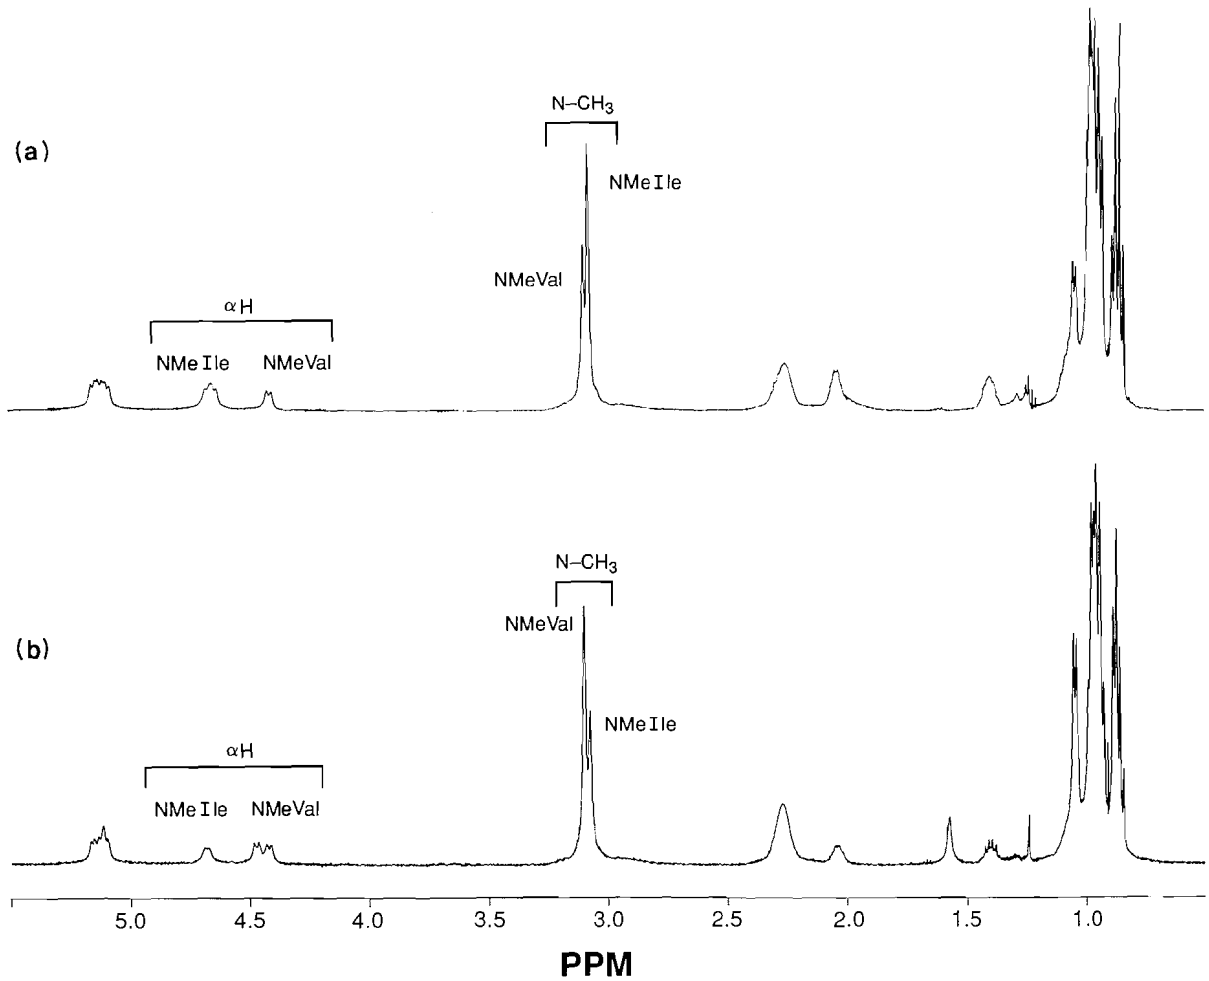

FIG. 2. 500 MHz ^{1}H NMR spectra of enniatin A1 (*a*) and enniatin B1 (*b*). Spectra were referenced to deuterochloroform at 7.24 ppm and reported relative to tetramethylsilane (Me_4Si).

tegrating for one proton). Finally, differences in intensity of the individual resonances can also be seen in the aliphatic methyl region.

The ^{13}C NMR spectrum of enniatin B1 also shows strong similarities to that of enniatin A1. There are two resonances, at 63.4 and 63.5 ppm, corresponding to the αCH of the two NMeVal residues, and one resonance at 61.5 ppm for the αCH of NMeIle, as well as two downfield resonances at 33.3 and 33.4 ppm corresponding the *N*-methyl groups of the NMeVal residues, and one resonance at 32.7 ppm for the *N*-methyl group of NMeIle. The aliphatic region of the spectrum is virtually identical to that of enniatin A1. Thus, the NMR data confirm the structure of enniatin B1 to be cyclo-[(NMeVal-HyIv)$_2$-NMeIle-HyIv].

In addition to the three known enniatins, a fourth enniatin, designated enniatin A2, was isolated as a shoulder on the HPLC peak corresponding to enniatin A1. This compound was recrystallized to give 46 mg of colourless needle-shaped crystals with a melting point of 123–125°C. The FAB mass spectrum showed a molecular ion at *m/z* 682.5, identical to that of enniatin A, indicating a molecular weight of 681. This was confirmed by solid probe EI/MS. Although this compound shows an identical molecular weight to enniatin A, its retention time on HPLC is 2 min less than that for enniatin A. The only structure that would correspond to this molecular weight involves the replacement of one or more of the NMeIle residues with NMeLeu residues. Although the presence of NMeLeu-containing enniatins has been suggested by amino acid analysis (10) and ^{13}C NMR spectra (3) of enniatin mixtures, and enniatin C (cyclo-[NMeLeu-HyIv]$_3$, MW 681) has been synthesized (12), no NMeLeu-containing enniatins have ever been purified from natural sources and characterized.

The 500 MHz ^{1}H NMR chemical shifts for enniatin A2 show that this compound is definitely an enniatin, but it is not enniatin A (Fig. 3). The presence of one NMeIle residue was determined by comparison to the spectrum of enniatin A, and was assigned to the resonances at 4.60 (αCH), 2.00 (βCH), 1.40 and 1.07 (γCH_2), 0.92 (γCH_3), 0.84 (δCH_3), and 3.09 ppm (N-CH_3). Integration of the resonance at 2.00 ppm accounted for two protons, indicating the presence of two NMeIle residues. By using ^{1}H/^{1}H correlation spectroscopy (COSY), another set of resonances were assigned to the second NMeIle residue. A triplet at 0.83 ppm, showing a coupling constant of 7.4 Hz, was assigned as the δCH_3 group. A second AB system at 1.06 and 1.33 ppm was attributed to the γCH_2 group, and the second multiplet at 2.00 ppm to the βCH. The doublet at 4.60 ppm was broadened in the ^{1}H NMR spectrum and integrated for two protons. However, a ^{1}H/^{13}C heteronuclear correlation

[a]NMeIle: *N*-methylisoleucine; NMeVal: *N*-methylvaline; NMeLeu: *N*-methylleucine; HyIv: D-2-hydroxyisovaleric acid.

spectrum (HETCOR) showed that this second αCH resonance did not correspond to NMeIle; rather, the correct αCH resonance had shifted downfield to 5.02 ppm. This assignment was confirmed from the COSY spectrum, which showed coupling between the resonance at 5.02 ppm and the resonance at 2.00 ppm. The *N*-methyl group was assigned to the resonance at 3.14 ppm, based on the downfield shift of the αCH proton. Comparison of the chemical shifts of the remaining resonances with those of enniatin C and a standard of *N*-methylleucine showed that the third amino acid in the molecule must be NMeLeu. The αCH of NMeLeu was assigned to the second broadened doublet at 4.59 ppm. This signal would be expected to appear as a double doublet due to coupling to the nonequivalent protons of the neighbouring CH_2 group. However, overlapping of these signals with the αCH resonance of NMeIle results in a broadened, poorly resolved pair of doublets. This resonance showed coupling in the COSY spectrum to an AB system at 1.81 and 1.72 ppm, which were assigned to the βCH_2 group. These latter multiplets showed coupling to a multiplet at 1.52 ppm, corresponding to the γCH group of NMeLeu, which in turn coupled to doublets at 0.90 and 0.92 ppm (δCH_3 groups). The *N*-methyl group of NMeLeu was assigned to the remaining singlet at 3.05 ppm. The downfield resonance at 5.18 ppm was assigned to the αCH of HyIv next to an NMeLeu residue by comparison to the data for enniatin C; the βCH resonance at 2.28 ppm was also attributed to this hydroxy acid. The upfield doublet at 4.92 ppm was assigned to the αCH of HyIv next to the second NMeIle, and the resonance at 5.05 ppm to the αCH of HyIv next to the other NMeIle. The βCH resonances for both of these hydroxy acid residues were assigned to the overlapped multiplets at 2.21 ppm.

The ^{13}C NMR spectrum of this compound was assigned

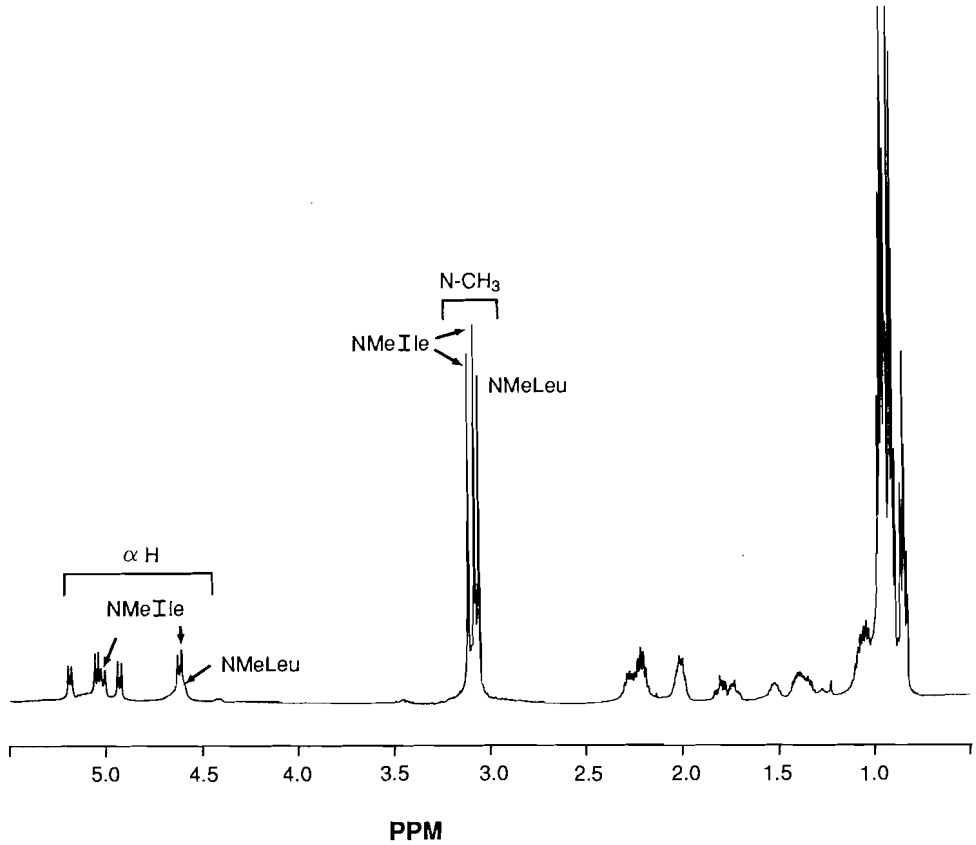

FIG. 3. 500 MHz ^{1}H NMR spectrum of enniatin A2. Spectrum was referenced to deuterochloroform at 7.24 ppm and reported relative to tetramethylsilane (Me_4Si).

by comparison to the spectrum of enniatin A and from the HETCOR. There are six carbonyl resonances for this compound. The resonances at 170.8 and 169.7 ppm correspond to the ester and amide carbonyl for HyIv next to NMeLeu; the other resonances at 170.5 and 169.4 ppm are the ester and amide carbonyls of NMeIle-HyIv. The resonances at 77.2 and 75.0 ppm represent the αCH carbons of HyIv next to the NMeIle residues, and the resonance at 75.2 ppm corresponds to the αCH of HyIv next to NMeLeu. The two downfield resonances at 61.4 and 60.0 ppm are the αCH carbons of the two NMeIle residues. The resonance at 57.4 ppm is that of the αCH of NMeLeu; the reduced intensity of the signal is presumably due to C–N coupling. The resonance at 37.9 ppm corresponds to the βCH_2 of NMeLeu. Resonances at 25.3 ppm (γCH), and 23.2 and 21.5 ppm (δCH_3) complete the NMeLeu residue. The *N*-methyl shifts have been assigned to 33.9 and 32.5 ppm (NMeIle) and 31.6 ppm (NMeLeu). The rest of the ^{13}C NMR chemical shift assignments for enniatin A2 are given in Table 2.

The presence of an NMeLeu residue in enniatin A2 was confirmed by amino acid analysis of the acid hydrolysate. A standard of *N*-methylleucine derivatized with MTBSTFA showed a retention time on GC/MS of 11.24 min, and a molecular ion at *m/z* 360. The standard of *N*-methylvaline had a retention time of 6.61 min and showed a molecular ion at *m/z* 346. GC/MS of the derivatized hydrolysate showed a peak at 8.83 min with a molecular ion at *m/z* 347; however, the intensity pattern of the fragment ions and the retention time did not match those of NMeVal. This peak could possibly have been due to HyIv present in the sample, as the structure of this acid is similar to that of valine. There were two peaks at 11.23 and 11.37 min with molecular ions at *m/z* 360. Comparison of the mass spectra with those of the standard of NMeLeu resulted in the assignment of the peak at 11.23 minutes to NMeLeu. The other peak, with an identical molecular ion and a similar mass spectrum, was assigned as NMeIle.

From the above data, the structure of enniatin A2 is assigned as cyclo-[(NMeIle-HyIv)$_2$-NMeLeu-HyIv]. This is the first reported *N*-methylleucine-containing enniatin to be isolated and characterized in the pure form from *Fusarium*.

A fifth fraction (7 mg) was obtained by separation of the crude mixture using HPLC. ^{1}H NMR of this fraction showed the presence of two enniatin-like compounds, with five singlets in the *N*-methyl region. The small amount of material did not permit separation of these compounds. However, as these compounds chromatograph as a shoulder following peak 1 (enniatin B1), two possible structures could be suggested: an enniatin containing two *N*-methylvaline residues and one *N*-methylleucine residue, or an enniatin containing one each of *N*-methylvaline, *N*-methylisoleucine, and *N*-methylleucine.

Previous reports in the literature have indicated the relatively nonspecific nature of the enzyme enniatin synthetase towards the branched-chain amino acids valine, isoleucine, and leucine. The isolation of the mixed enniatins A1, B1, and A2 agrees with these findings. The presence of large amounts of *N*-methylisoleucine-containing enniatins from extracts of *Fusarium avenaceum* DAOM 196490 would seem to indicate either a preference by the enzyme for isoleucine, or an

accumulation of the isoleucine pools relative to those of valine and leucine.

Experimental

Infrared spectra were obtained on either a Bomem Michealson 100 FT-IR or a Perkin Elmer 1600 series FT-IR. All compounds were run as films on NaCl plates.

Solid probe electron impact (EI) spectra were obtained on a Finnegan MAT 4500 GC/MS system with an INCOS data system. Probe temperature was programmed from 40 to 350°C, ion source temperature was 140°C, electron energy 70 eV, multiplier 1200 V. Fast atom bombardment spectra (FAB) were recorded on a high-resolution, double-focussing, reversed geometry Finnegan MAT-312 mass spectrometer equipped with an Ion Tech saddle-field atom gun and an INCOS data station. No heating was applied to the ion source. The acceleration potential was kept at 3 kV and the electron multiplier at 2 kV whereas the atom gun was operated with Xenon gas (99.9995%, Matheson) at 8 kV. The matrix used was diethanolamine (Aldrich Chemical Co., cat. no. D8, 330-3).

^1H and ^{13}C NMR spectra were run on Bruker AM 250 and AM 500 NMR spectrometers equipped with ASPECT 3000 data systems. Chemical shifts were referenced to deuterochloroform at 7.24 and 77.0 ppm for ^1H and ^{13}C, respectively, and reported relative to tetramethylsilane (Me_4Si). ^{13}C chemical shift assignments were made by using DEPT pulse sequence, $^1H/^{13}C$ heteronuclear correlation spectroscopy (HETCOR), and by comparison with known enniatins. Confirmation of ^1H chemical shift assignments was made by the use of $^1H/^1H$ homonuclear correlation spectra (COSY). The ^1H and ^{13}C NMR data for enniatins A, A1, B1, and A2 are given in Tables 1 and 2.

Preparative HPLC was conducted on a Varian Vista 5500 series chromatograph equipped with a Varian 2550 UV detector operating at 245 nm. A 10 μm Whatman Magnum 9 Partisil ODS-3 semi-preparative reverse-phase column (9.4 mm i.d. × 25 cm) was used with a solvent system of 80% acetonitrile/20% water for initial separation, and 70% acetonitrile/30% water for final purification, at a flow rate of 4 mL min^{-1}.

Amino acid analysis of enniatin A2

Ten milligrams of enniatin A2 was refluxed under nitrogen in 6 M HCl (2 mL) for 20 h. The pH of the hydrolysate was adjusted to 7 using triethylamine, followed by dilution with water until a concentration of 250 nM in each amino acid was obtained.

Standards of *N*-methyl-L-leucine and *N*-methyl-L-valine were dissolved in water to a concentration of 2.5 mM each. Twenty-five microlitres of each standard and the hydrolysate were transferred to 1-mL Reactivials, followed by removal of the water using an air stream. To each sample was added 0.2 μL of dichloromethane, and the samples were redried under nitrogen. The samples were then derivatized by addition of 15 μL of MTBSTFA (Pierce) and 16 μL of pyridine and triethylamine solution (100:7, v/v). The vials were capped, shaken, and heated at 90°C for 20 min, then cooled and analyzed by GC/MS. Samples were run on an HP-5 column with a 1/20 inlet split using two different temperature programs: (1) 110°C, then 12°/min to 194°C; 16°/min to 265°C, followed by an 8-min hold (ALLBSC); (2) 170°C, then 10°/min to 290°C; hold 1 min (MTXBSC).

Chemicals

Standards of *N*-methylleucine and *N*-methylvaline were obtained from the Sigma Chemical Company. A standard mixture of enniatins A, A1, and B1 was kindly provided by Dr. D. Strongman, Canadian Forestry Service–Maritimes, Fredericton, N.B., Canada.

All solvents used for isolation and purification were HPLC grade glass distilled purchased from Caledon or Anachemia.

Merck TLC grade silica gel G was used for vacuum liquid chromatography.

Fermentation of Fusarium avenaceum *(DAOM 196490)*

To obtain sufficient amounts of enniatins for isolation and characterization, *Fusarium avenaceum* DAOM 196490 was grown in a 15-L stirred-jar fermentor using the method of Miller and Blackwell (11), except that the production medium used was identical to that used for the seed culture (glucose (20 g), malt extract (2 g), yeast extract (2 g), peptone (2 g), KH_2PO_4 (2 g), $MgSO_4.7H_2O$ (2 g), $FeSO_4.7H_2O$ (0.2 g), and ammonium chloride (3 g); amounts given per litre water; distilled water put through a Barnstead Nanopure II system; 18.3 MΩ cm^{-1}). After 1 week, the culture was filtered through Whatman No. 1 filter paper and the mycelia were dried at 40°C under vacuum.

Extraction and purification of enniatins

Dried mycelia (71.540 g) were ground in a mortar, then extracted using the method of Strongman *et al.* (3). Partitioning of the dichloromethane extract of the mycelia (18.243 g) between hexane and methanol/water (1:1, v/v) yielded 12.751 g of hexane soluble material and 5.095 g of water soluble material.

FAB-MS of the hexane extract showed the presence of enniatins B1, A1, and A by molecular ions at *m/z* 654.5, 668.5, and 682.5 ($M^+ + H$). In addition, ions corresponding to the K^+ adducts at *m/z* 692.5, 706.5, and 720.5 were also present in the spectrum, as were ions corresponding to the addition of the diethanolamine matrix (*m/z* 759.5, 773.5, and 787.5 respectively).

TLC of the extract using a solvent system of CCl_4/diethyl ether (1:1, v/v) and visualization by iodine vapour showed the presence of three spots corresponding to fatty-acid type compounds (R_f 0.95), enniatins (R_f 0.44), and ergosterol (R_f 0.16), by comparison to standards of oleic acid and ergosterol.

The enniatins were purified from the crude extract using vacuum liquid chromatography with CCl_4/diethyl ether (3:2, v/v) as the eluting solvent. Twenty-four fractions (150 mL each) were collected and monitored by TLC as previously described. Fractions 7–24 (7.436 g) contained mainly enniatins. This fraction was recrystallized from ethanol–water at −20°C to give 6.750 g of colourless needles.

A 500 mg sample of the crystals dissolved in 5 mL of acetonitrile and chromatographed by HPLC showed the presence of five separate peaks. Peak 1 (enniatin B1) (**4**) ($C_{34}H_{59}N_3O_9$) was isolated as a pale yellow oil (9 mg): $[\alpha]_D$ +173.8 (*c* 0.6, $CHCl_3$, 25°C); IR ν_{max} (NaCl): 2966 (C-H, alkane), 1744 (C=O, ester), 1654 (C=O, amide); *m/z*: 653.4250 (calcd. 653.4254); solid probe MS EI *m/z*: 42(base), 55(26), 69(56), 86(89), 100(48), 112(8), 126(12), 142(20), 154(21), 169(42), 182(32), 196(72), 210(38), 228(6), 282(15), 296(19), 310(18), 423(6), 552(5), 571(4), 653(M^+).

Peak 3 (enniatin A1) (**3**) ($C_{35}H_{61}N_3O_9$) was isolated as a pale yellow oil. Recrystallization from ethanol/water yielded 114 mg of colourless needle crystals: mp 66–67°C; $[\alpha]_D$ −62.8 (*c* 2.3, $CHCl_3$, 25°C); IR ν_{max} (NaCl): 2965 (C-H, alkane), 1740 (C=O, ester), 1662 (C=O, amide); *m/z*: 667.4404 (calcd. 667.4410); solid probe MS EI *m/z*: 42(base), 55(20), 69(59), 86(51), 100(86), 112(8), 126(12), 142(18), 153(20), 169(29), 183(48), 196(52), 210(68), 228(11), 282(11), 296(18), 310(19), 324(10), 397(4), 423(7), 667(M^+).

Peak 4 (enniatin A2) (**6**) ($C_{36}H_{63}N_3O_9$) was isolated as a yellow oil, which was recrystallized from ethanol/water to give 46 mg of colourless needle crystals: mp 123–125°C; $[\alpha]_D$ −34.4 (*c* 4.1, $CHCl_3$, 25°C); IR ν_{max} (NaCl): 2965 (C-H, alkane), 1744 (C=O, ester), 1661 (C=O, amide); *m/z*: 681.4612 (calcd. 681.4567); solid probe MS EI *m/z*: 71(28), 83(20), 100(base), 112(9), 128(9), 143(12), 155(20), 169(15), 183(43), 196(19), 210(60), 228(8), 296(14), 310(8), 324(12), 681(M^+).

Peak 5, isolated as a yellow oil, was recrystallized, yielding 301 mg of colourless needle crystals, which were identified as enniatin A by comparison to published mass spectral and ^1H NMR data, melting points, and optical rotation.

The ^1H NMR of peak 2 showed the presence of two compounds. All attempts to separate these compounds were unsuccessful, and because of the small amount of material (7 mg), no further work was done on this fraction.

Acknowledgements

The authors would like to thank Dr. Peter Summers of the Department of Biology at Carleton University for the amino acid analysis of enniatin A2, and Mr. Pierre Lafontaine and Mr. Garry Montgomery for the solid probe EI mass spectra. In addition, we thank Mr. John Nikiforuk for the NMR spectra. This work was supported by a Natural Sciences and Engineering Research Council of Canada (NSERC) post graduate scholarship (L.B.) and by an NSERC strategic grant.

A general synthesis of 5,7-diaminoimidazo[4,5-*b*]pyridine ribosides ("2-amino-1-deazaadenosines") from 5-amino-4-imidazolecarboxamide riboside (AICA riboside)

JOHN E. FRANCIS[1] AND MICHAEL A. MOSKAL

Research Department, Pharmaceuticals Division, CIBA–GEIGY Corporation, Summit, NJ 07901, U.S.A.

Received July 31, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

JOHN E. FRANCIS and MICHAEL A. MOSKAL. Can. J. Chem. **70**, 1288 (1992).

A short general synthesis of 5-substituted 5,7-diaminoimidazo[4,5-*b*]pyridines from 5-amino-4-imidazolecarboxamide riboside (AICA riboside) was designed to prepare isosteres of substituted 2-aminoadenosines that are selective adenosine A_2 receptor agonists. AICA riboside was converted to a hydroxyl-protected 5-amino-4-imidazolecarbonitrile riboside and reacted with an *N*,*N*-disubstituted acetamide in the presence of phosphoryl chloride. Sodium hydride treatment completed the ring closure and introduced the 7-amino group. The hydroxyl protecting groups were removed under standard conditions. *N*-Substitution of the acetamide by one benzyl moiety led to a 5-*N*-substituted derivative through hydrogenolysis whereas *N*,*N*-dibenzylacetamide led to the 5,7-diamino compound. A 6-methyl analog was obtained from an *N*,*N*-disubstituted propionamide. This synthesis may be adapted to other heterocyclic systems, as illustrated by the preparation of an example of the imidazo[4,5-*b*]pyrrolo[3,2-*e*]pyridine ring system.

JOHN E. FRANCIS et MICHAEL A. MOSKAL. Can. J. Chem. **70**, 1288 (1992).

Dans le but de préparer des isostères des 2-aminoadénosines substituées qui sont des agonistes sélectifs du récepteur A_2 de l'adénosine, on a développé une courte méthode générale de synthèse des 5,7-diamino-imidazo[4,5-*b*]pyridines substituées en position 5 utilisant le riboside du 5-amino-4-imidazolecarboxamide (riboside du AICA) somme produit de départ. On a transformé le riboside du AICA en un riboside du 5-amino-4-imidazolecarbonitrile dont l'hydroxyle était protégé et on a fait réagir ce dernier avec un acétamide *N*,*N*-disubstitué, en présence de chlorure de phosphoryle. Un traitement avec de l'hydrure de sodium a permis de compléter la fermeture du cycle et l'introduction du groupe 7-amino. Utilisant des conditions standard, on a alors enlevé les groups protégeant les hydroxyles. La *N*-substitution de l'acétamide par une portion benzylique a conduit par hydrogénolyse à la formation d'un dérivé 5,*N*-substitué; dans les mêmes conditions, un *N*,*N*-dibenzylacétamide conduit au composé 5,7-diamino. À partir d'une propanamide *N*,*N*-disubstituée, on a obtenu un analogue portant un groupement méthyle en position 6. On peut adapter cette synthèse à d'autres systèmes hétérocycliques et on l'a illustré avec la préparation d'un exemple du système cyclique imidazo[4,5-*b*]pyrrolo[3,2-*e*]-pyridine.

Adenosine (**1***a*), an endogenous purine nucleoside, was reported by Drury and Szent-Gyorgyi to have potent hypotensive and bradycardic activity in 1929 (*1*). In 1963, Berne (2) spurred additional interest when he proposed that adenosine plays an important role as the mediator of metabolically regulated coronary flow. Based on subsequent investigations (3), the role of adenosine as a local regulator of blood flow in other tissues was postulated. Although this short-acting compound seems an excellent lead structure for the design of novel cardiovascular drugs through molecular modification, research has not yet produced such a drug, except for the natural product itself, which was recently marketed[2] for the intravenous treatment of supraventricular tachycardia (4).

A recent rebirth of interest in modification of the adenosine structure (5) followed the recognition and characterization of purinergic receptors in peripheral cell membranes (6), particularly the A_1 and A_2 receptors (7, 8). The negative dromo-, chrono-, and inotropic effects of adenosine are thought to be A_1 mediated (9) whereas the vasodilatory effects are A_2 mediated (10).

Our interest in vasodilators led to a search for selective A_2 receptor agonists. A lead compound was the moderately A_2 selective agonist 2-anilinoadenosine (**1***b*) (11), which had been characterized as a coronary dilator in anaesthetized dogs (12) at the time we began our research. Subsequent modification of **1***b* led us to a series of 2-substituted aminoadenosines which were highly selective A_2 receptor agonists that lowered blood pressure effectively in spontaneously hypertensive rats (13).

Since 7-amino-3-(β-D-ribofuranosyl)imidazo[4,5-*b*]pyridine (1-deazaadenosine, **2***a*) showed adenosine-like activity (14), it seemed worthwhile to prepare 1-deaza analogs structurally related to **1***b* and our active 2-aminoadenosines, i.e., 5,7-diaminoimidazo[4,5-*b*]pyridine ribosides of the general structure **2***b*. Ethyl *N*-(7-chloro-3*H*-imidazo[4,5-*b*]pyridin-5-yl)carbamate (**3**), prepared in nine steps from chelidamic acid (**4**) (15), was converted in nine further steps to structures of type **2***b* in which the R′ group is hydrogen and the *R*″ group is hydrogen, alkyl, or substituted alkyl (16).

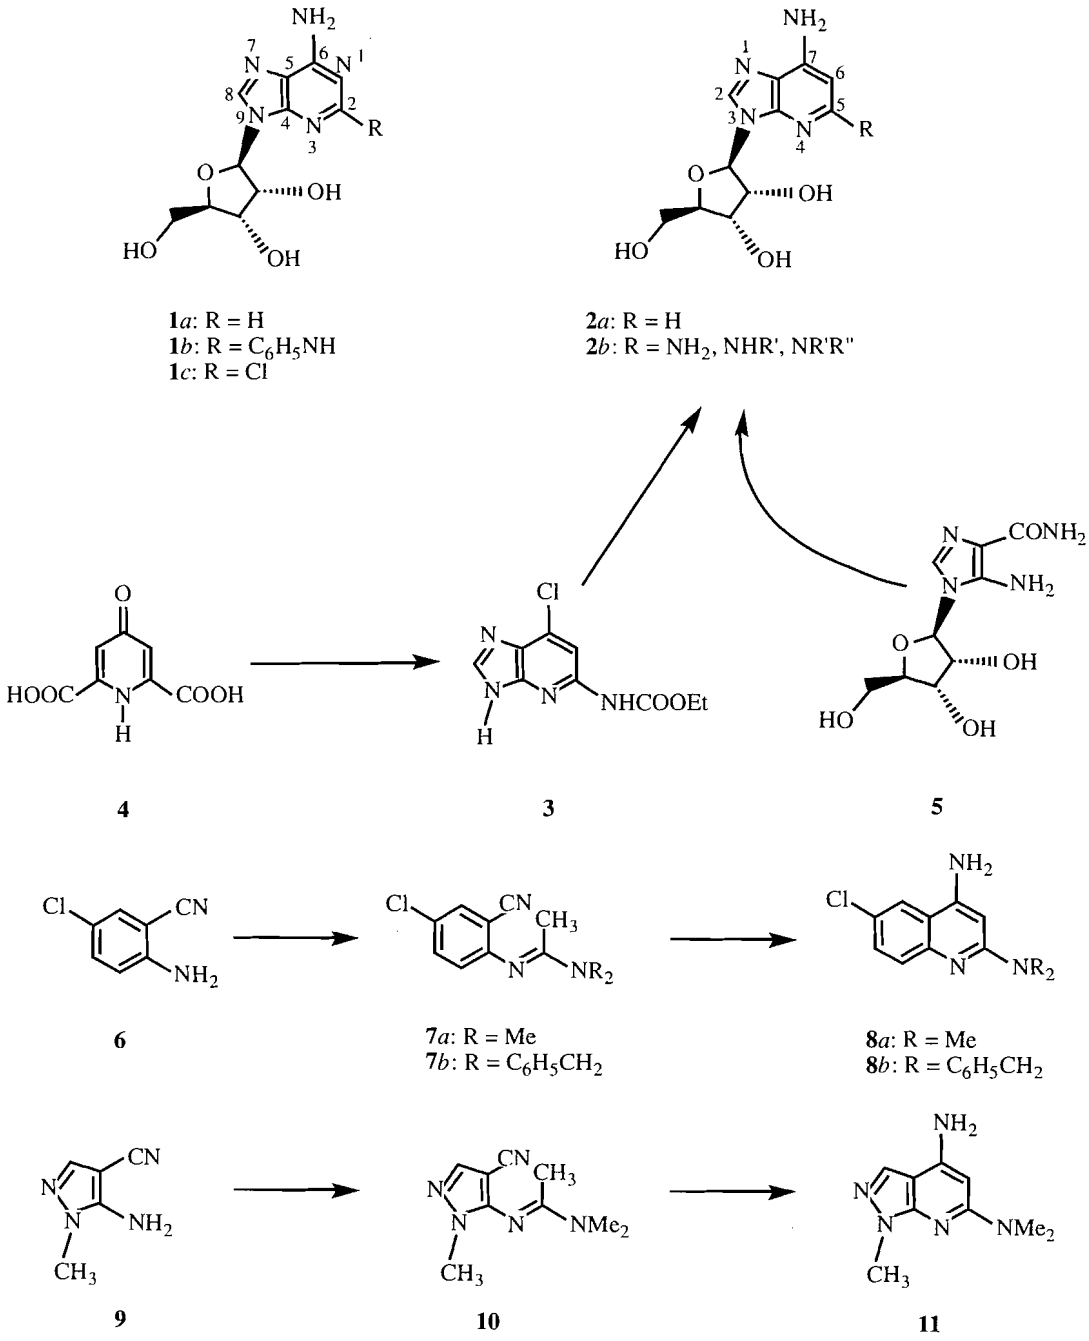
Herein we report a much shorter and more general synthesis starting from 5-amino-1-(β-D-ribofuranosyl)imidazole-4-carboxamide (AICA riboside, **5**), accessible chemically from inosine (17) or by fermentation (18). This had been used as a building block for **1***b* and many related 2-aminoadenosines (19) and contains all of the chiral centres and most of the atoms present in the compounds we planned to synthesize.

A route similar to the preparation of 2-alkylaminoadenosines from 2-chloroadenosine (**1***c*) (13) was not feasible in the 7-aminoimidazo[4,5-*b*]pyridine series because a halide at position 5 is not easily displaced. The report of a convenient synthesis of 2,4-diaminoquinoline derivatives (20) from anthranilonitriles suggested a viable route to our target compounds. We studied some variations of the published

[1]Author to whom correspondence may be addressed.

[2]Adenocard® (Fujisawa Pharmaceutical Company).

methodology through model reactions. We found that 5-chloroanthranilonitrile (**6**) reacted with dimethylacetamide dimethyl acetal in refluxing cyclohexane to form the intermediate **7***a* in 79% yield and this could be converted conveniently with sodium hydride in refluxing dioxane to **8***a* in 80% yield. Similarly, the aminocyanopyrazole **9** was converted via intermediate **10** (in this case prepared in refluxing acetonitrile) to the pyrazolo[3,4-*b*]pyridine **11** in 50% overall yield.



AICA riboside (**5**) was converted to the 2′,3′-protected aminonitrile **12** by a six-step literature route (21) in 25% yield. Reaction of this intermediate with commercial dimethylacetamide dimethyl acetal gave the expected product **13** under the mild conditions of overnight treatment at room temperature. The same result was obtained by the use of dimethylacetamide treated with dimethyl sulphate and neutralized with sodium methoxide. Cyclization with sodium hydride/dioxane at 110°C over 1 h followed by deprotection with 90% trifluoroacetic acid at 0°C in 0.5 h gave **2***c* (R = NMe_2) in 83% yield. Attempted removal of the isopropylidene protecting group with dilute hydrochloric acid, 80% acetic acid, or 50% formic acid resulted in some loss of the ribosyl moiety.

The paucity of commercially available orthoamides limits the general utility of this approach. Since condensation of an orthoester with the aminonitrile followed by displacement of the alkoxide group by a secondary amine was shown

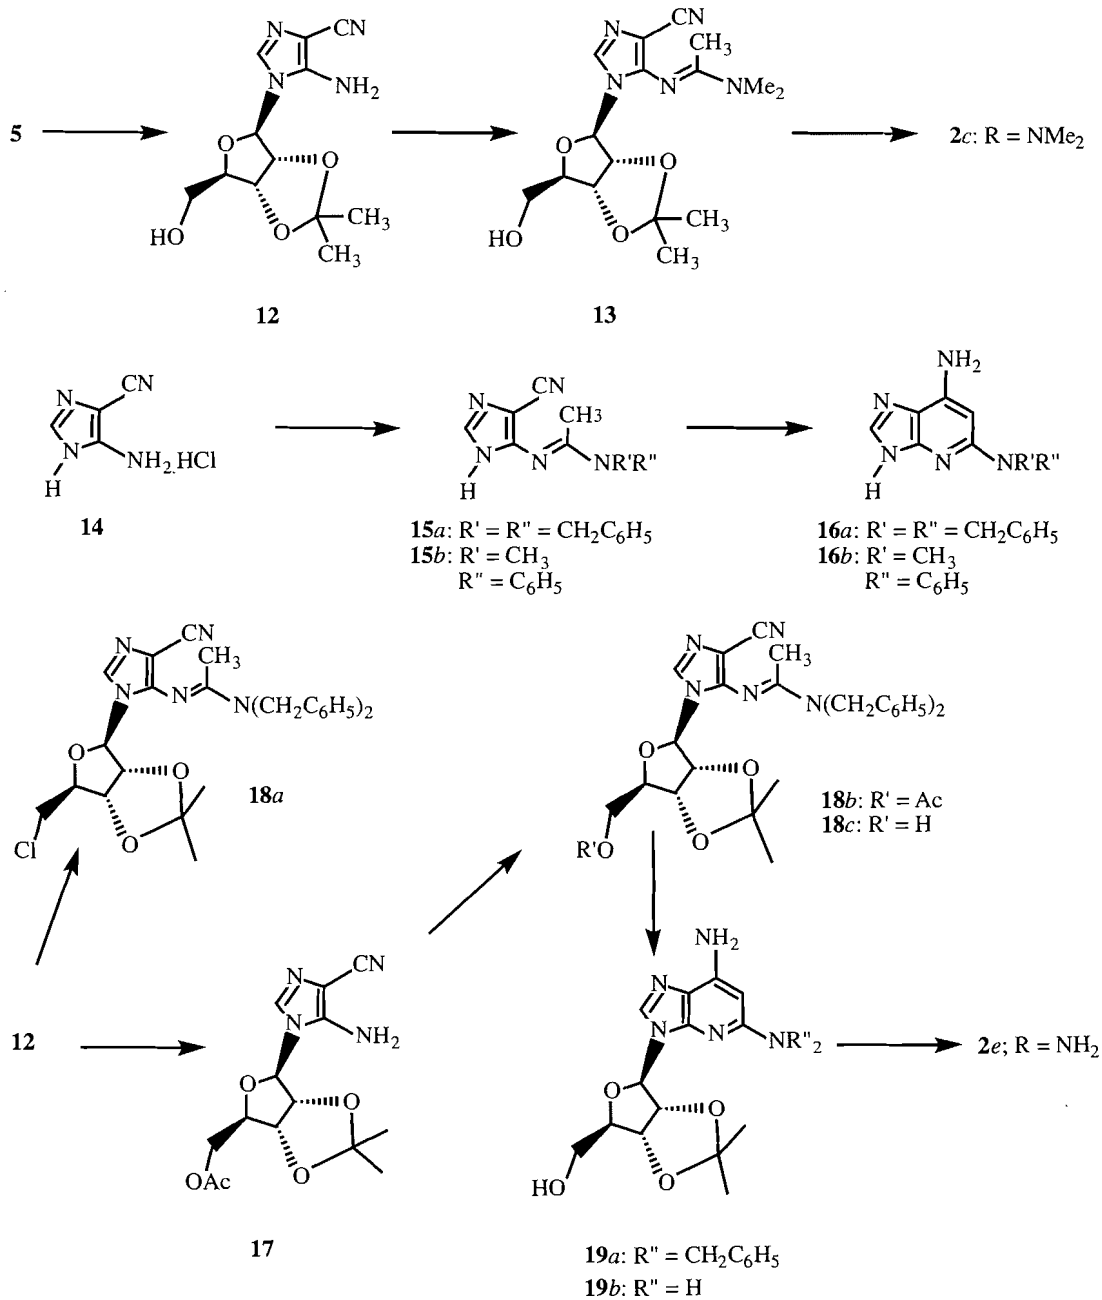
to involve temperatures of 150°C in each step (20), we did not pursue this alternate two-step approach. Replacement of dimethylacetamide with other tertiary amides revealed a further disadvantage of the orthoamide approach. Reaction of **12** with *N*-methylacetanilide/dimethyl sulphate/sodium methoxide gave none of the desired compound **2***d* (R = $N(Me)C_6H_5$). *N*-Methylaniline was detected as a product of the reaction, indicative of preferential C—N bond cleavage rather than C—O cleavage with alkoxide elimination. The result is not surprising since the ready displacement of *N*-methylaniline anion rather than alkoxide from an amide acetal at basic pH has been observed previously (22).

We turned to the method of activating the tertiary amide through conversion to its imidinium chloride. Treatment of *N*,*N*-dibenzylacetamide with phosphoryl chloride in acetonitrile at room temperature followed by addition of **6** gave the desired intermediate **7***b* in 67% yield, which was converted to **8***b* with sodium hydride. By the same route, 5-amino-(1*H*)imidazole-4-carbonitrile (**14**) was converted to **15***a* and cyclized to **16***a*, a potential building block for a wide variety of 5,7-diaminoimidazo[4,5-*b*]pyridines. Substitution of *N*-methylacetanilide as the tertiary amide led to **15***b* and **16***b*. The synthesis of **10** from **9** with dimethylacetamide and phosphoryl chloride was achieved in 97% yield.



The remaining target compounds were then prepared in the following manner. Intermediate **12** was protected at the 5′-position as the acetate (**17**) before condensation with an imidinium chloride. Omission of this step in the reaction with dibenzylacetamide led to a significant amount of the 5′-chloro derivative **18***a*. Condensation of **17** with *N*,*N*-dibenzylacet-

For personal use only.

amide/phosphoryl chloride in acetonitrile at room temperature over 16 h gave the desired intermediate **18***b* as an oil that was hydrolysed with methanolic ammonia to afford **18***c* in 90% overall yield. Cyclization with sodium hydride in dioxane produced crude **19***a* as a foam. Removal of both benzyl groups was achieved with hydrogen over palladium hydroxide in ethanol at 50°C and 45 psi (1 psi = 6.89 kPa) to afford **19***b* in nearly quantitative yield. Removal of the remaining protecting group with 90% trifluoroacetic acid gave **2***e* (R = NH_2), characterized as both the trifluoroacetate and dihydrochloride. When *N*-benzylacetanilide was substituted for *N*,*N*-dibenzylacetamide in the sequence, the target compound **2***f* (R = NHC_6H_5) was obtained. Targets **2***g* (R = $NHCH_2CH_2C_6H_4$-*p*-$CH_2CH_2C_6H_5$) and **2***h* (R = $NHCH_2CH_2$-C_6H_4-*p*-CH_2CH_2COOH) were also prepared. For **2***h*, the *p*-substituent was introduced conveniently by Heck reaction conditions (23) from the N^5-*p*-bromophenethyl intermediate with the 2′ and 3′ hydroxyls protected.

Substitution in the 6-position by methyl was achieved through the use of an *N*-substituted *N*-benzylpropionamide, as illustrated by the synthesis of **20**. Finally, annelation of the imidazopyridine ring system at the 5- and 6-positions was accomplished through the use of an *N*-benzylated lactam. Specifically, *N*-benzylbutyrolactam was converted through the usual steps to the tricyclic compound **21**, an example of the previously unreported imidazo[4,5-*b*]pyrrolo[3,2-*e*]pyridine ring system.

21

Some biochemical and pharmacological results on this series will be reported separately. Since these 1-deazaadenosine derivatives cannot be metabolized to intermediates that can form Watson–Crick base pairs (24), we hope that these compounds will show fewer side effects than their purine riboside isosteres.

Experimental

All reactions were carried out under nitrogen. Melting points (uncorrected) were determined on a Thomas–Hoover capillary apparatus. Proton NMR were determined on a Varian XL-300, Varian XL-400, Bruker AC-300, or Bruker AC-250 instrument with tetramethylsilane as internal standard in deuterated dimethyl sulphoxide unless otherwise stated. Spectral shifts are reported as δ (ppm) values. Solvents used were spectral or HPLC grade. Chromatography was done under nitrogen pressure with silica gel 60 (230–400 mesh) from E. Merck. Where noted, compounds analysed for C, H, and N within ±0.4 units unless otherwise stated. IR spectra, taken in Nujol mulls, were recorded on a Perkin–Elmer model 457 spectrometer and peaks are expressed in reciprocal centimeters. Mass spectra were taken with a Hewlett–Packard 5985B mass spectrometer in the Cl mode. Silica gel 60 TLC plates were obtained from EM Science.

*5-Chloro-2-[1-dimethylamino)ethylideneamino]benzonitrile (7*a*)*

A mixture of 5-chloroanthranilonitrile (9.5 g, 62 mM), dimethylacetamide dimethylacetal (ca. 90%, containing methanol, 9.7 mL), and cyclohexane (70 mL) was heated in a Dean–Stark apparatus at reflux until 40 mL of liquid were collected (ca. 4.5 h). The red solution was concentrated to dryness at 70°C under water pump vacuum, taken up in hot cyclohexane (100 mL), and filtered. The filtrate was treated with hexane (50 mL) as it cooled and crystals began to form. The mixture was refrigerated overnight and the off-white needles were collected and air dried to afford 10.47 g (79%), mp 84–87°C. A sample was sublimed for analysis at 60°/0.1 Torr (1 Torr = 133.3 Pa) to a pure white solid, mp 85–87°C; IR: 2222, 1602, 1586, 1300, 1191, 841; ^{1}HMR: 1.9 (s, 2 CH_3), 3.0 (s, CH_3), 6.8 (d, H at 3), 7.5 (dd, H at 4), 7.73 (d, H at 6); MS: 222 (M + 1). Anal. $C_{11}H_{12}ClN_3$: C, H, N.

*4-Amino-6-chloro-2-dimethylaminoquinoline (8*a*)*

A mixture of **7***a* (1.11 g, 5 nM), 50% sodium hydride in oil (0.5 g), and dioxane (15 mL) was heated under reflux for 5.5 h during which time a yellow solid began to form. The mixture was cooled and the product was collected, washed with a little dioxane, and suspended in ether (30 mL) in a separatory funnel to which water (20 mL) was cautiously added. The clear ether layer was collected and the aqueous layer extracted twice with ether (2 × 10 mL). The ether extract was dried (Mg_2SO_4) and concentrated to dryness at reduced pressure. The residue was triturated with hexane and collected as an off-white solid, pure by TLC (R_f = 0.1 with 3:1 toluene – ethyl acetate vs. starting material, R_f = 0.7) (0.89 g, 80%, mp 155–160°C). Recrystallization from toluene gave pure white crystals, mp 165–167°C; IR: 3341, 3188, 1643, 1591, 1503, 825; ^{1}HMR: 3.05 (s, 2 CH_3), 6.1 (s, H at 3), 6.4 (s, NH_2, exchangeable with D_2O), 7.35 (m, H, s at 3 and 4), 8.0 (s, H at 6). Anal. $C_{11}H_{12}ClN_3$: C, H, N.

*5-[1-(Dimethylamino)ethylideneamino]-1-methylpyrazole-4-carbonitrile (**10**)*

A mixture of 5-amino-1-methylpyrazole-4-carbonitrile (**9**) prepared by the literature method (25) (0.61 g, 5 nM), dimethylacetamide dimethyl acetal (1 mL), and acetonitrile (21 mL) was stirred at 90°C for 4 h. It was concentrated to dryness at 70°C under water vacuum to a dark oil and triturated with hexane to yellow-orange solid **10** (0.74 g, 77%, mp 45–50°C), pure by TLC (R_f = 0.5, 4:1 CH_2Cl_2–EtOAc vs. starting material, R_f = 0.33), and used directly to prepare **11**.

A mixture of **9** (0.8 g, 6.5 mM), dimethylacetamide (2.35 g), and acetonitrile (10 mL) was treated dropwise at room temperature with phosphoryl chloride. After 5 min, TLC (1:1 CH_2Cl_2–EtOAc) indicated complete reaction. The mixture was poured into ice-cold ammonium hydroxide and extracted with ethyl acetate (2 × 40 mL). The organic extract was washed with brine, dried (Na_2SO_4), and concentrated to dryness at reduced pressure. Treatment of the oily residue with hexane with seed crystals yielded **10** as a yellow solid (1.12 g, 90%, mp 59–61°C); IR: 2215, 1597, 1511, 1029; ^{1}HMR: 2.0 (s, N-CH_3), 3.1 (d, 2 CH_3), 3.5 (s, C-CH_3), 7.7 (s, H at 3). Anal. calcd. for $C_9H_{13}N_5$: C 56.53, H, N; found: C 57.08.

*4,6-Diamino-1,N^6,N^6-trimethylpyrazolo[3,4-b]pyridine (**11**)*

A mixture of **10** (0.74 g, 3.9 mM), 50% sodium hydride in oil (0.39 g), and dioxane (10 mL) was stirred at reflux for 1.5 h. It was cooled and filtered free of white solid (**caution ! nasal irritant !**) and concentrated at reduced pressure to a semisolid. This was triturated with ether, and water was then added to form a yellow solid, insoluble in both solvents. The material was collected, washed with water (3 × 10 mL), then with hexane (2 × 10 mL), and vacuum oven dried at 80°C/10 Torr) to afford **11** (0.47 g, 64%), mp 174–177°C. It was recrystallized from toluene to form the pure product as yellow crystals, mp 178–181°C; IR: 3352, 3210, 1606, 1592, 1165, 985; ^{1}HMR: 3.0 (s, 2 CH_3), 3.75 (s, N-CH_3), 5.55 (s, H at 5), 6.3 (s, NH_2, exchangeable with D_2O), 7.75 (H at 3); MS: 192 (M + 1). Anal. $C_9H_{13}N_5$: C, H, N.

*5-[1-(Dimethylamino)ethylideneamino]-1-[2′,3′-O-(1-methylethylidene)-β-D-ribofuranosyl]-1H-imidazole-4-carbonitrile (**13**)*

To a suspension of 5-amino-1-[2′,3′-*O*-)1-methylethyidene)-β-D-ribofuranosyl)]imidazole-4-carbonitrile (**12**), prepared as described in the literature (21), (0.56 g, 2 mM) in acetonitrile (10 mL) was added dimethylacetamide dimethylacetal (1.0 mL) and the mixture stirred at room temperature overnight. It was concentrated under high vacuum (0.1 Torr) and the residue was redissolved in ether–acetonitrile (1:1), treated with charcoal, filtered, and the filtrate was concentrated to dryness at reduced pressure and triturated with ether to afford **13** (0.45 g, 64%), mp 122–125°C. It was recrystallized from ethyl acetate to give the pure material, mp 127–129°C; IR: 2210, 1609; ^{1}HMR ($CDCl_3$): 1.35 (s, CH_3), 1.58 (s, CH_3), 2.13 (s, CH_3), 3.1 (s, 2 CH_3), 3.85 (m, 5′-CH_2), 4.1 (br s, OH), 4.33 (m, 4′-H), 4.95 (m, 3′ + 2′-H), 5.75 (d, H at 1′), 7.8 (s, H at 8); MS: 350 (M + 1). Anal. $C_{16}H_{23}N_5O_4$: C, H, N.

*5,7-Diamino-3-[β-D-ribofuranosyl]-N^5,N^5-dimethyl-3H-imidazo[4,5-b]pyridine(**2**c)*

Sodium hydride (60% in oil, 1.2 g) was prewashed with hexane, suspended in dioxane (60 mL), then treated with **13** (2.6 g, 7.4 mM), and the mixture was stirred at 110°C for 1 h. It was poured into ice-water (200 mL) and extracted with ethyl acetate (3 × 100 mL). The organic layer was washed with brine, dried (Na_2SO_4), decolorized with charcoal, filtered, and evaporated at reduced pressure to a semisolid. This was triturated with ether and collected as a white solid (1.95 g, 75%), which was pure *5,7-diamino-3-[2′,3′-O-(1-methylethylidene)-β-D-ribofuranosyl]-N^5,N^5-dimethyl-3H-imidazo[4,5-b]pyridine*, mp 176–178°C; $[\alpha]_D^{25}$ −8.15 (*c* = 1.36, DMSO); IR: 3437, 3361, 3248, 3098, 1637, 1598, 1510; ^{1}HMR ($CDCl_3$): 1.4 (s, CH_3), 1.65 (s, CH_3), 3.1 (s, 2 CH_3), 3.85 (m, 5′-CH_2), 4.4 (m, 4′-H), 4.9 (br s, NH_2), 5.15 (m, 3′-H), 5.6 (m, 2′-H), 5.75 (s, H at 6), 5.9 (d, 1′-H), 7.8 (s, H at 2); MS: 350 (M + 1), 178 (aglycone). Anal. $C_{16}H_{23}N_5O_4$: C, H, N. This intermediate (0.70 g, 2 mM) was stirred in an ice-cold 9:1 mixture of trifluoroacetic acid and water (5 mL) at 0–5°C for 1 h. Ether (75 mL) was added and after 10 min the trifluoroacetic acid salt of **2***c* was collected as a while solid (0.81 g, 95%). It was added to 8% aqueous sodium bicarbonate solution and, after several minutes, the free base crystallized. This was washed with water and dried under vacuum to afford white crystals (0.52 g, 85%, mp 219–222°C); $[\alpha]_D^{25}$ −36.87 (*c* = 1.55, DMSO); IR: 3408, 3312, 3218, 3125, 1634, 1602, 1522, 1078, 1032; ^{1}HMR: 2.9 (s, 2 CH_3), 3.6 (m, 5′-CH_2), 3.75 (m, 4′-H), 4.15 (dd, 3′-H), 4.65 (dd, 2′-H), 4.85 (br s, OH), 5.1 (br s, OH), 5.3 (br s, OH), 5.7 (s, H at 6), 5.8 (d, 1′-H), 5.95 (s, NH_2), 7.9 (s, H at 2); MS: 310 (M + 1), 178 (aglycone). Anal. $C_{13}H_{19}N_5O_4$: C, H, N.

*2-[1-(Dibenzylamino)ethylideneamino]-5-chlorobenzonitrile (**7**b)*

A stirring mixture of 5-chloroanthranilonitrile (1.52 g, 10 mM) and *N,N*-dibenzylacetamide (9.56 g, 40 mM) in acetonitrile (25 mL) was treated dropwise with phosphoryl chloride (3.06 g, 20 mM) and stirred 3 h at room temperature. The mixture was poured into ice-cold ammonium hydroxide and extracted with ethyl acetate (2 × 100 mL). The organic layer was washed with brine, dried (Na_2SO_4), and concentrated to dryness at reduced pressure to a red oil. The oil was triturated several times with hexane and the hexane wash discarded. The residue was triturated with isopropanol and the product obtained as a white solid after vacuum oven drying (2.48 g, 67%), mp 101–110°C; IR: 2220, 1592, 698; ^{1}HMR: 2.0 (s, CH_3), 4.7 (s, 2 CH_2), 6.9 (d, 3-H), 7.3 (m, 10 aromatic H), 7.57 (dd, 4-H), 7.8 (d, 6-H). Anal. $C_{23}H_{20}ClN_3$: C, H, N. By the same procedure, 5-aminoimidazole-4-carbonitrile hydrochloride (**14**) (26) was converted to **15***a*, a foam, mp 144–148°C, in 42% yield. Anal. $C_{20}H_{19}N_5$: C, H, N. Similarly, **17**, prepared as described by Suzuki and Kumashiro (27), was converted to **18***b*, an oil, in 88% yield; MS: 544 (M + 1). *N*-Methylacetanilide, combined with **14** and phosphoryl chloride by the same procedure, led to **15***b*, mp 222–225°C, in 67% yield. Anal. $C_{13}H_{13}N_5 \cdot 0.25H_2O$: C, H, N.

*2,4-Diamino-N^2,N^2-dibenzyl-6-chloroquinoline (**8**b)*

A mixture of **7***b* (0.37 g, 1 mM) and sodium hydride (60% in oil, 0.16 g) in dioxane (5 mL) was heated 3 h at reflux. It was poured into ice-water, extracted with ethyl acetate, and the organic layer was washed with brine, dried (Na_2SO_4), treated with charcoal, filtered, and concentrated to dryness at reduced pressure to a reddish-brown solid (0.28 g, 76%). This residue was triturated with hexane–ether to afford the pure material (0.21 g), mp 217–220°C; IR: 3490, 3305, 3175, 1638, 1592, 1497, 1215, 736; ^{1}HMR: 4.8 (2 CH_2), 6.1 (H at 3), 6.4 (NH_2, exchangeable with D_2O), 7.2–7.4 (m, 12 H), 8.0 (s, H at 5). Anal. $C_{23}H_{20}ClN_3$: C, H, N. By the same procedure, **15***a* was converted to **16***a*, mp 196–198°C, in 69% yield. Anal. $C_{20}H_{19}N_5$: C, H, N. Similarly, **15***b* was converted to **16***b*, mp 214–216°C, in 71% yield. Anal. $C_{13}H_{13}N_5$: C, H, N.

*5,7-Diamino-3-(β-D-ribofuranosyl)imidazo[4,5-b]pyridine (**2**e)*

A mixture of **18***b* (7.0 g, 13 mM) and methanol saturated with ammonia (250 mL) was stirred overnight at room temperature. The mixture was concentrated to dryness at room temperature and the residue was taken up in ethyl acetate (300 mL), washed with water (3 × 100 mL), then with brine (100 mL), dried (Na_2SO_4), and concentrated to dryness at reduced pressure to afford crude **18***c* as a foam. This was chromatographed on a 220 × 50 mm column with 2:1 methylene chloride – ethyl acetate as eluent (4 × 600 mL fractions) followed by ethyl acetate alone (30 mL) fractions. The product was collected in ethyl acetate fractions 19–60 and concentrated at reduced pressure to afford chromatographically pure **18***c* as a foam (5.9 g, 91%). The foam (5.8 g, 11.5 mM) was added in dioxane (50 mL) to sodium hydride (60% in oil, 1.85 g, prewashed with hexane) in dioxane (100 mL) and the mixture was heated at 100°C for 1 h. The reaction mixture was poured into ice-water, extracted with ethyl acetate (3 × 100 mL), and the extract washed with brine (50 mL), dried (Na_2SO_4), and concentrated to dryness to afford **19***a* as a foam (5.7 g, 98%). The cyclized intermediate **19***a* (5.6 g) was hydrogenated in the presence of palladium hydroxide (5.6 g) in 95% ethanol (200 mL) in a Parr apparatus at 45 psi and 50°C for 4.5 h. The mixture was filtered and the filtrate concentrated to dryness at reduced pressure to give **19***b*, the 2′,3′-*O*-(1-methylethylidene) derivative of **2***e*, as a colorless foam (3.3 g, 94%). This acetonide (2.65 g, 8.2 mM) was stirred in an ice-cold solution of 90% aqueous trifluoroacetic acid until TLC (9:1 CH_2Cl_2–NH_3-saturated methanol) showed complete loss of starting material, R_f = 0.5, with product R_f = 0.0. The solution was diluted with ether (375 mL), stirred 15 min, and the precipitated crude trifluoroacetate salt of **2***e* collected and air dried (3.2 g, 100%), mp 124–127°C. A portion (0.5 g) was dissolved in acetonitrile (50 mL), filtered, and the filtrate saturated with dry HCl under ice cooling. A turbid mixture formed that during 18 h at room temperture became a white solid. The product (0.35 g), mp 105°C (dec.), was the dihydrochloride of **2***e*; $[\alpha]_D^{25}$ −67.4 (*c* = 1, H_2O); ^{1}HMR (CD_3OD): 3.9 (m, 5′-CH_2), 4.3 (m, 4′-H + 3′-H), 4.45 (dd, 2′-H), 5.9 (s, H at 6), 5.95 (d, 1′-H), 8.55 (s, H at 2); MS: 150 (aglycone, M + 1). Anal. calcd. for $C_{11}H_{17}Cl_2N_5O_4$: C, H, N, Cl 20.01; found: Cl 19.57.

*7-Amino-5-anilino-3-(β-D-ribofuranosyl)imidazo[4,5-b]pyridine (**2**f)*

N-Benzylacetanilide, bp 135–150°C at 3 Torr, prepared by reacting *N*-benzylaniline with a 50% excess of triethylamine and a 40% excess of acetyl chloride at room temperature over 42 h (6.4 g, 28.8 mM), and **17** (2.3 g, 7.2 mM) in acetonitrile (25 mL) were treated dropwise under stirring with phosphoryl chloride (2.2 g, 14.4 mM). After 48 h, the mixture was quenched in ice-cold sodium bicarbonate solution, extracted with ethyl acetate, and the extract washed several times with dilute bicarbonate, then with water and brine, dried (Na_2SO_4), and concentrated to dryness at reduced pressure to an oily residue (3.8 g). The oil was flash

For personal use only.

chromatographed with methylene chloride – ethyl acetate (5:1) and 60 35-mL fractions were collected. A 1:1 solvent mixture was used for the next 20 35-mL fractions. Combined fractions 41–80, one spot by TLC, were concentrated to dryness to afford the pure material (1.1 g, 29%) as an oil. This intermediate was stirred overnight in ammonia-saturated methanol (50 mL) and concentrated to dryness at reduced pressure. The residue was taken up in ethyl acetate (25 mL), washed with water (4 × 10 mL), then with brine, dried (Na_2SO_4), and concentrated to dryness to an off-white foam. This was combined with material from a similar run and flash chromatographed with 1:1 methylene chloride ethyl acetate (100 mL × 12 fractions) followed by ethyl acetate alone (100 mL × 4 fractions). Fractions 4–14 were combined and concentrated to a white foam, mp 68–78°C (1.85 g, 94%). This 5′-alcohol (1.8 g, 3.7 mM) in dioxane (15 mL) was added dropwise to a suspension of sodium hydride (60% in oil, 0.6 g, 14.8 mM, washed 3 times with hexane) in dioxane (30 mL) and heated at reflux for 1.5 h. The mixture was quenched in ice-water and extracted with ethyl acetate (3 × 70 mL). The extract was washed with water, then with brine, dried (Na_2SO_4), and concentrated at reduced pressure to a foam (1.8 g), which contained a trace of impurity (TLC). It was flash chromatographed with 3:1 methylene chloride – ethyl acetate, followed by a 1:1 mixture, then by ethyl acetate alone. The pure product was found in the ethyl acetate eluent. Evaporation of the combined fractions yielded the 2′,3′-*O*-(1-methylethylidene) derivative of N^5-benzyl **2***f* as a foam, mp 93–99°C (1.63 g, 90%). Anal. $C_{27}H_{29}N_5O_4$: C, H, N. The *N*-benzyl compound (1.5 g) was hydrogenolized in 95% ethanol (150 mL) with palladium hydroxide (1.5 g) at 50°C and 50 psi for 6 h, then with fresh catalyst for another 6 h. The mixture was filtered and the solvent removed at reduced pressure to afford the crude 2′,3′-*O*-(1-methylethylidene) derivative of **2***f* (1.0 g, 83%). Recrystallization from ethyl acetate gave pure material, mp 225–228°C; $[\alpha]_D^{25}$ 9.68 (c = 0.91, DMSO); ^{1}HMR: (CD_3OD): 1.4 (s, CH_3), 1.6 (s, CH_3), 3.65 (m, 5′-CH_2), 4.3 (m, 4′-H), 4.95 (dd, 3′-H), 5.45 (dd, 2′-H), 6.0 (s, H at 6), 6.1 (d, 1′-H), 6.9 (dd, *p*-H), 7.25 (dd, 2 *m*-H), 7.5 (d, 2 *o*-H), 8.0 (s, H at 2); MS: 398 (M + 1). Anal. $C_{20}H_{23}N_5O_4$: C, H, N. The acetonide (0.6 g) was stirred at 0–5°C in 90% aqueous trifluoroacetic acid (4 mL) for 1 h. It was diluted with ether (20 mL) and, after 20 min, the trifluoroacetate salt (320 mg) was collected, suspended in dilute sodium bicarbonate solution, extracted with ethyl acetate, and the organic extract washed with brine, dried (Na_2SO_4), and concentrated to dryness to an off-white solid (220 mg) containing trace impurities. The material was chromatographed with mixtures of methylene chloride and ammonia-saturated methanol, 15:1 for the first 44 × 25-mL fractions, followed by 5:1 for the next 8 × 25-mL fractions. Fractions 21–48 were combined and concentrated to pure **2***f* obtained as a foamy solid (160 mg, 30%). The analytical sample was recrystallized from water, mp 192–195°C; $[\alpha]_D^{25}$ −19.33 (c = 1.29, DMSO); ^{1}HMR: 3.8 (m, 5′-CH_2), 4.1 (dt, 4′-CH_2), 4.3 (dd, 3′-H), 4.75 (dd, 2′-H), 5.95 (d, 1′-H), 6.1 (s, H at 6), 6.9 (m, *p*-H), 7.25 (m, 2 *m*-H), 7.4 (m, 2 *o*-H), 8.05 (s, H at 2); MS: 358 (M + 1). Anal. $C_{17}H_{19}N_5O_4 \cdot 0.25H_2O$: C, H, N.

5,7-Diamino-N^5*-[2-[4-(2-phenylethyl)phenyl]ethyl]-3-(*β-D-*ribofuranosyl)imidazo[4,5-*b*]pyridine (***2***g)*

A mixture of 2-(4-bromophenyl)ethylamine (Aldrich, 50 g, 0.25 M), and benzaldehyde (26.5 g, 0.25 M) in petroleum ether (700 mL) and acetic acid (200 mL) was treated dropwise under stirring at room temperature with borane–pyridine complex (Fluka, 23 g, 0.25 M) and, after 2 h, 5 N hydrochloric acid (150 mL) was added slowly to give a white precipitate. The precipitated salt was collected and the filtrate was extracted with ether and the ether layer discarded. The solid was added to the aqueous acidic layer, made basic with ice-cold sodium hydroxide solution, and extracted with ether. The ether layer was washed with brine, dried (Na_2SO_4), and concentrated at reduced pressure to an oil (63.7 g), which was chromatographed with 5:1 methylene chloride – ethyl acetate. Fractions containing the desired product were combined and concentrated to afford N-*benzyl-2-(4-bromophenyl)ethylamine* as an oil (42.7 g, 59%; ^{1}HMR ($CDCl_3$): 1.65 (NH), 2.8 (m, 2 CH_2), 3.8 (s, CH_2), 7.05–7.45 (m, 9 aryl H)) used directly in the next step. A mixture of the amine (42.6 g, 147 mM) and triethylamine (22.3 g, 220 mM) in cold methylene chloride (400 mL) was treated dropwise under stirring with an ice-cold solution of acetyl chloride (12.6 g, 162 mM) and stirred for 18 h at ambient temperature. The solution was extracted with 1 N hydrochloric acid (4 × 100 mL), water (100 mL), dilute aqueous sodium bicarbonate (2 × 100 mL), and water (100 mL), then dried (Na_2SO_4) and concentrated to dryness at reduced pressure. The oily product (48.3 g) was distilled to give 42.5 g (87%) of N-*acetyl*-N-*benzyl-2-(4-bromophenyl)ethylamine*, bp 216–218°C at 0.5 Torr; IR (neat): 3028, 1646, 1489, 1419, 1011. Anal. $C_{17}H_{18}BrNO$: C, H, N. A mixture of this amide (20 g, 60 mM), styrene (8.1 g, 78 mM), palladium acetate (0.14 g, 0.6 mM), tri-*o*-tolylphosphine (0.73 g, 2.4 mM), and triethylamine (39.4 g, 0.39 M) was heated at reflux for 18 h. The residue was treated with ice-cold 2 N hydrochloric acid (300 mL) and extracted with methylene chloride (3 × 400 mL). The organic layer was washed with water, dried (Na_2SO_4), and concentrated to dryness at reduced pressure. The residue was recrystallized from ethanol to afford pure N-*acetyl*-N-*benzyl-2-[4-(2-phenylethenyl)phenyl]ethylamine* (14.3 g, 67%), mp 136–138°C: Anal. $C_{25}H_{25}NO$: C, H. N. This material (14.2 g, 40 mM) was reacted with **17** (3.22 g, 10 mM) and phosphoryl chloride (3.06 g, 20 mM) and worked up as described in **2***f* to afford the desired adduct as a foam (4.1 g, 62%). This was saponified with methanolic ammonia as described and obtained as one-spot material by TLC in quantitative yield. Cyclization with sodium hydride in dioxane (reflux, 2 h) and subsequent work-up gave *5,7-diamino-*N^5*-benzyl-*N^5*-[2-[4-(2-phenylethenyl)phenyl]ethyl]-3-[2′,3′-*O*-(1-methylethylidene)-*β-D-*ribofuranosyl]imidazo[4,5-b]pyridine*, mp 174–177°C; MS: 618 (M + 1). Anal. $C_{37}H_{39}N_5O_4$: C, H, N. This intermediate (2.6 g, 4.2 mM) was hydrogenated in 95% ethanol (200 mL) containing 1 N hydrochloric acid (10 mL) in the presence of palladium hydroxide (5.2 g) at 50 psi at room temperature over 6 h. The mixture was filtered and the filtrate was stirred with propylene oxide (10 mL) for 30 min. Removal of the solvent gave a crystalline mass, which was triturated with ether to afford the 2′,3′-*O*-(1-methylethylidene) derivative of **2***g* (1.7 g, 77%) as a foam; IR: 3327, 3221, 3135, 1655, 1625, 1605, 1514; MS: 530 (M + 1). The acetonide (1.6 g, 3 mM) was stirred in 90% trifluoroacetic acid (10 mL) at 0–5°C for 1 h. Ether (15 mL) was added and after 15 min the salt was collected (1.6 g). It was dissolved in methanol (75 mL), filtered, and the filtrate treated with 6.5 N HCl in methanol (0.5 mL). The dihydrochloride salt of **2***g* crystallized as a white solid (1.1 g, 65%), mp 150–156°C; $[\alpha]_D^{25}$ −14.9 (c = 1.01, DMSO); IR: 3455, 3403, 3321, 3294, 3234, 2720 (br), 1678, 1659, 1574, 1513, 1093; ^{1}HMR: 2.8 (m, 3 CH_2), 3.4 (dd, CH_2-N), 3.65 (m, 5′-CH_2), 4.05 (dt, 4′-H), 4.15 (dd, 3′-H), 4.4 (dd, 2′-CH_2), 5.75 (s, H at 6), 5.9 (d, 1′-H), 7.2-7.3 (m, 9 aryl H), 8.7 (br s, H at 2); MS: 490 (M + 1 of base, weak), 358 (M + 1, aglycone). Anal. $C_{27}H_{31}N_5O_4 \cdot 2HCl$: C, H, N.

5,7-Diamino-N^5*-[2-[4-(2-carboxyethyl)phenyl]ethyl]-3-(*β-D-*ribofuranosyl)imidazo[4,5-*b*]pyridine (***2***h)*

N-Acetyl-*N*-benzyl-2-(4-bromophenyl)ethylamine (25.6 g, 80 mM) was reacted with **17** (6.44 g, 20 mM) and phosphoryl chloride (6.12 g, 40 mM) in acetonitrile and worked up as described for **2***f* to afford the crude adduct containing residual amide. This material was saponified with methanolic ammonia as described previously and chromatographed with 2:1 methylene chloride – ethyl acetate followed by ethyl acetate to afford 8.8 g (75%) of foamy solid. This material was reacted with a fourfold excess of sodium hydride as described for **2***f* to afford *5,7-diamino-*N^5*-benzyl-*N^5*-[2-(4-bromophenyl)ethyl]-3-[2′,3′-*O*-(1-methylethylidene)-*β-D-*ribofuranosyl]imidazo[4,5-b]pyridine* in 80% yield; MS: 594/596 (M + 1); Anal. $C_{29}H_{32}BrN_5O_4 \cdot H_2O$: C, H, N. This interme-

For personal use only.

diate (1.78 g, 3 mM) was mixed with benzyl acrylate (0.64 g, 3.9 mM), palladium acetate (7 mg, 0.03 mM), tri-*o*-tolylphosphine (36 mg, 12 mM), and triethylamine (1.97 g, 19.5 mM) and the whole refluxed over 18 h. The mixture was treated with dilute sodium bicarbonate solution, extracted with methylene chloride, and the organic extract dried (Na_2SO_4) and concentrated to dryness under vacuum (0.1 Torr). The crude product (1.7 g, 85%) was chromatographed with 20:1 methylene chloride – methanol and the product collected as a foam. It was triturated with methanol to produce crystals (0.57 g, 28%), mp 152–155°C; MS: 676 (M + 1). Anal. $C_{39}H_{41}N_5O_6 \cdot 0.5H_2O$: C, H, N. This product (0.54 g, 0.8 mM) was hydrogenated in 95% ethanol (100 mL) with palladium hydroxide (1.0 g) at 60°C and 45 psi for 5 h. The mixture was filtered and filtrate concentrated to an oil (0.35 g). The product crystallized on addition of a little methanol (0.32 g, 80%), mp 107–117°C. This intermediate (0.30 g, 0.6 mM) was treated with 90% trifluoroacetic acid over 1 h. Ether was added and HCl gas was bubbled through the mixture for ca. 5 min to afford **2***h* as a dihydrochloride dihydrate (210 mg, 62%), mp 63–78°C (dec.); $[\alpha]_D^{25}$ −38.36 (*c* = 2, MeOH); IR: 3400–3200 (br), 2760–2670 (br), 1742, 1679, 1081, 1019; MS: 458 (M + 1, free base, weak), 326 (M + 1, aglycone). Anal. $C_{22}H_{27}N_5O_6 \cdot 2HCl \cdot 2H_2O$: C, H, N.

*5,7-Diamino-*N^5*-[2-(4-fluorophenyl)ethyl]-6-methyl-3-(*β-D-*ribofuranosyl)imidazo[4,5-*b*]pyridine (**20**)*

Benzaldehyde was condensed with 2-(4-fluorophenyl)ethylamine in the presence of borane – pyridine as described previously to afford *N*-benzyl-2-(4-fluorophenyl)ethylamine in 44% yield as an oil; ^{1}HMR ($CDCl_3$): 1.35 (s, NH), 2.8 (m, 2 CH_2), 3.8 (s, CH_2), 6.9–7.4 (m, 9 aryl H). An ice-cold mixture of this amine (10.5 g, 46 mM) and triethylamine (7.0 g, 69 mM) in methylene chloride (150 mL) was treated dropwise with propionyl chloride (4.7 g, 51 mM) in methylene chloride (50 mL) and stirred overnight at ambient temperature. The mixture was worked up as described for previous amides and the crude material was distilled to afford pure N-*benzyl*-N-*propionyl-2-(4-fluorophenyl)ethylamine* (10.9 g, 83%), bp 162–163°C at 0.9 Torr; IR (neat): 1648, 1510, 1221, 1158, 827, 733. Anal. $C_{18}H_{20}FNO$: C, H, N. The amide was reacted with **17** and phosphoryl chloride as described previously and the amidine isolated after chromatography with 5:1 methylene chloride – ethyl acetate as an oil in 41% yield. Saponification of the 5′-ester with methanolic ammonia gave the 5′-alcohol as an oil in 85% crude yield. Cyclization of the amidine alcohol with sodium hydride in dioxane was achieved after 2 h reflux to afford crude product as an oil. Trituration with ether gave *5,7-diamino-*N^5*-benzyl-*N^5*-[2-[4- fluorophenyl]ethyl]- 6-methyl- 3-[2′,3′-*O*-(1-methylethylidene)-*β-D-*ribofuranosyl]imidazo[4,5-*b*]pyridine* as a white solid (0.7 g, 42%), mp 146–147°C; IR: 3470, 3377, 3127, 1626, 1603, 1227, 1066; ^{1}HMR: (CD_3OD): 1.35 (s, CH_3), 1.6 (s, CH_3), 2.15 (s, CH_3), 2.75 (m, CH_2), 3.3 (m, CH_2 + MeOH), 3.65 (m, 5′-CH_2), 4.25 (m, CH_2 + 4′-H), 5.05 (m, 3′-H), 5.45 (m, 2′-H), 6.1 (d, 1′-H), 6.85–7.1 (m, 9 aryl H), 8.1 (s, H at 2). Anal. $C_{30}H_{34}FN_5O_4$: C, H, N. Additional material from the mother liquor was combined in the following step. The intermediate (1.65 g, 3 mM) was hydrogenated in 95% ethanol (200 mL) containing 1 N hydrochloric acid (5 mL) with palladium hydroxide (3.3 g) at 50 psi for 6 h at room temperature. The catalyst was filtered off and the filtrate treated with propylene oxide (5 mL) for 30 min. Evaporation of the solvent and trituration with ether gave the 2′,3′-*O*-(1-methylethylidene) derivative of **20** as a solid (0.83 g, 56%), mp 199–205°C (dec); MS: 458 (M + 1). Anal. $C_{23}H_{28}FN_5O_4 \cdot 1.5\ H_2O$: C, H, N. This acetonide (0.8 g, 1.8 mM) was stirred in ice-cold 90% trifluoroacetic acid for 1 h. TLC indicated a single new product. Addition of ether formed a hygroscopic solid. This material was dissolved in a little isopropanol and treated with HCl in ethanol but no crystals formed. Propylene oxide was added and, after 30 min, the mixture was concentrated to dryness at reduced pressure. The residue was dissolved in ethyl acetate and washed with bicarbonate solution, then with brine, dried (Na_2SO_4), and concentrated to dryness to a foam. TLC indicated two products. The material was flash chromatographed with 15:1 methylene chloride – methanol followed by a 10:1 mixture. The first product isolated (foam, 110 mg) was shown to be the aglycone of **20**; ^{1}HMR (CD_3OD): 1.9 (s, CH_3), 2.9 (t, CH_2), 3.6 (t, CH_2), 7.0 (m, 2 aryl H), 7.2 (m, 2 aryl H), 7.7 (H at 2). The second product (foam, 270 mg, 36%) was **20**. This second product was triturated with ether to form a white solid (240 mg), mp 157–160°C; $[\alpha]_D^{25}$ +7.2 (*c* = 1, EtOH); ^{1}HMR: (CD_3OD): 1.9 (s, CH_3), 2.9 (t, CH_2), 3.55–3.85 (m, CH_2 + 5′-CH_2 + 4′-H), 4.1 (dd, 3′-H), 4.4 (dd, 2′-H), 5.95 (d, 1′-H), 7.0 (m, 2 aryl H), 7.25 (m, 2 aryl H), 7.95 (s, H at 2); MS: 418 (M + 1), 286 (aglycone). Anal. $C_{20}H_{24}FN_5O_4$: C, H, N.

*8-Amino-6,7-dihydro-3-(*β-D-*ribofuranosyl)imidazo[4,5-b]pyrrolo[2,3-*e*]pyridine (**21**)*

A solution of *N*-benzyl-2-pyrrolidinone (Aldrich, 4.9 g, 28 mM), **17** (2.25 g, 7 mM), and acetonitrile (30 mL) was treated dropwise with phosphoryl chloride (2.14 g, 14 mM) and stirred at room temperature overnight. After the usual work-up, the oily product was chromatographed with 1:1 methylene chloride – ethyl acetate to give the desired intermediate as an oil (2.75 g, 82%); IR (neat): 2885, 2217, 1746, 1616, 1299; MS 480 (M + 1). Saponification of 2.7 g (5.6 mM) with methanolic ammonia gave the 5′-alcohol as a foam in 95% yield; IR (KBr): 3280 (br), 2936, 2215, 1618, 1081; MS: 438 (M + 1), 266 (aglycone). Reaction of 2.2 g (5 mM) of this product with sodium hydride in dioxane (reflux, 2 h) followed by the standard work-up gave the cyclized product as a solid in 95% yield. It was recrystallized from methanol to afford pure *8-amino-5-benzyl-3-[2′,3′-*O*-(1-methylethylidene)-*β-D-*ribofuranosyl]imidazo[4,5-b]pyrrolo[2,3-*e*]pyridine* (1.2 g, 55%), mp 184–185°C; ^{1}HMR: 1.25 (s, CH_3), 1.5 (s, CH_3), 2.75 (dd, CH_2), 3.3 (dd, CH_2), 3.5 (m, 5′-CH_2), 4.1 (ddd, 4′-H), 4.45 (q, CH_2), 4.9 (dd, 3′-H), 5.05 (t, OH), 5.35 (dd, 2′-H), 5.9 (s, NH_2), 6.05 (d, 1′-H) 7.25 (m, 5 aryl H), 7.85 (H at 2); MS: 438 (M + 1), 266 (aglycone). Anal. $C_{23}H_{27}N_5O_4$: C, H, N. This material (2.0 g, 4.5 mM) was dissolved in 95% ethanol (200 mL) containing 1 N hydrochloric acid (10 mL) and hydrogenolysed with palladium hydroxide (4.0 g) at room temperature and 50 psi over 6 h. The catalyst was filtered off and propylene oxide (10 mL) added to the filtrate. After 30 min the solution was concentrated to dryness at reduced pressure to an oil (1.6 g) that contained two products (TLC). This was taken up in methanol and reevaporated under high vacuum to a mixture of oil and hard foam. The foam (0.65 g, still a mixture) was separated mechanically from the oil, which was a single component. The oil was dissolved in methanol (90 mL) and treated at 0°C with 90% trifluoroacetic acid, whereupon a solid began to form. It was diluted with ether to produce the debenzylated acetonide as a tan solid (0.24 g, 15%); MS: 348 (M + 1), 176 (agylcone). Treatment of the foam with 90% trifluoroacetic acid at 0°C produced an intractable mixture. The desired intermediate was deprotected cleanly with 90% trifluoroacetic acid (2.5 mL) at 0°C in 1 h and, on dilution with ether, a tan solid salt of **21** was obtained (0.16 g, 47%), mp 120–124°C (dec.); $[\alpha]_D^{25}$ −31.95 (*c* = 1.13, DMSO); IR: 3359, 3185, 3152, 2800–2500 (br), 1677, 1659, 1198, 723; ^{1}HMR: 3.0 (dd, CH_2), 3.75 (dd, CH_2), 3.8 (m, 5′-CH_2), 4.25 (m, 4′-H + 3′-H), 4.4 (m, 2′-H), 5.85 (d, 1′-H), 8.1 (s, H at 2); MS: 308 (M + 1, weak), 176 (aglycone). Anal. $C_{13}H_{17}N_5O_4 \cdot 2CF_3COOH$: C, H, N.

Acknowledgments

π-Facial diastereoselectivity in the Diels–Alder reactions of *cis*-cyclohexa-3,5-diene-1,2-diol and derivatives with *N*-phenylmaleimide

JAMES R. GILLARD AND D. JEAN BURNELL[1]

Department of Chemistry, Memorial University of Newfoundland, St. John's, Nfld., Canada A1B 3X7

Received August 8, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

JAMES R. GILLARD and D. JEAN BURNELL. Can. J. Chem. **70**, 1296 (1992).

N-Phenylmaleimide undergoes Diels–Alder cycloaddition predominantly to the face of *cis*-cyclohexa-3,5-diene-1,2-diol (**3**) *syn* to the oxygen functions. Derivatization can be used to alter the π-facial diastereoselectivity in a synthetically useful manner. The best cases are the exclusive, high yield, production of the *syn*-addition product with the trimethylsilyl ether derivative (**8**), and the *exo*-benzylidine derivative (**26**) gave a 96:4 *anti/syn* ratio of adducts.

JAMES R. GILLARD et D. JEAN BURNELL. Can. J. Chem. **70**, 1296 (1992).

La *N*-phénylmaléimide subit une cycloaddition de Diels–Alder qui se produit principalement par la face du *cis*-cyclohexa-3,5-diène-1,2-diol (**3**) qui est *syn* par rapport aux fonctions oxygénées. On peut faire appel à des dérivés pour altérer la diastéréosélectivité π-faciale d'une manière qui soit utile d'un point de vue synthétique. Les meilleurs cas sont ceux de la production exclusive, avec un excellent rendement, du produit d'addition *syn* avec l'éther triméthylsilyle **8** alors que le dérivé *exo*-benzylidine (**26**) conduit à un rapport 96 : 4 des adduits *anti/syn*.

[Traduit par la rédaction]

Introduction

1,3-Cyclopentadiene substituted at C-5 with an oxygen or a nitrogen function undergoes Diels–Alder cycloadditions by attachment of the dienophile to the face of the diene *syn*[2] to the heteroatom (1, 2). Many hypotheses have been forwarded to explain this π-facial diastereoselectivity (2–7), which does not seem to be controlled by steric factors. On the other hand, substitution at C-5 by some larger heteroatoms (sulfur, selenium, chlorine, bromine, and iodine) leads to Diels–Alder adducts mainly by *anti* addition (2, 7–9).

Plane-nonsymmetric 1,3-cyclohexadiene systems have received less attention, even though their synthetic utility must be similar to that of the cyclopentadienes. Auksi and Yates (10) reported that Diels–Alder adducts derived from diene **1** arise exclusively by addition to the face of the diene *syn* to the oxygen. This could be explained in terms of steric interactions, and steric effects were deemed important, but not the only significant effect, in Diels–Alder reactions involving some dienes in which the plane-nonsymmetric moieties were alkyl and acyl (11). Recently, we demonstrated that the addition of carbon dienophiles to benzene oxide and some of its derivatives (**2**) is exclusively *anti*, and we suggested that steric factors are important with these systems, too (12). In the early 1970's there were reports of the production of *cis*-cyclohexa-3,5-diene-1,2-diol (**3**) directly from benzene by the action of *Pseudomonas putida* (13, 14). In the last five years this type of diene has emerged as a very useful synthetic building block and of considerable interest in mechanistic studies (15). Diels–Alder reactions of some simple derivatives of **3** were carried out with maleic anhydride (13), 4-(4-bromophenyl)-1,2,4-triazoline-3,5-dione (16), and some acyclic dienophiles (17). While our work was in progress, Werbitzky *et al.* reported a reaction with a chiral nitroso dienophile (18), and Pittol *et al.* (19) disclosed the results of a study of the Diels–Alder reactions of the acetonide derivative of a trifluoromethyl analog of **3**. In all of these reports, the adducts were shown as arising by reaction exclusively, or in just one case preferentially (19), on the face of the diene *anti* to the oxygens, i.e., the π-facial selectivity of these reactions appeared consistent with steric control. However, the theories regarding π-facial selectivity, by and large based on the cyclopentadiene results, would predict that plane-nonsymmetric oxygen substituents on a 1,3-cyclohexadiene system should direct addition predominantly *syn*, just like with the 1,3-cyclopentadienes. Thus, we undertook a systematic and rigorous examination of the Diels–Alder reactions of *cis*-cyclohexa-3,5-diene-1,2-diol (**3**) and some of its derivatives. We chose *N*-phenylmaleimide as the dienophile for all the reactions because it is relatively reactive in thermal reactions giving *endo*-addition products that are often stable and crystalline, and its symmetry would not introduce unnecessary complications in the interpretation of the nmr spectra of its adducts.[3]

Results and discussion

The Diels–Alder reaction of **3** with *N*-phenylmaleimide was a simple matter of stirring the addends together in boiling chloroform solution. The adducts were not very soluble in the chloroform, and they precipitated during the reaction. The 300-MHz ^1H nmr spectrum of the crude reaction mixture showed signals for two adducts, which, by careful integration, were calculated to be in a ratio of 95:5. Each

pure adduct was heated in chloroform solution for 36 h after which time we could find no evidence of equilibration. The assignment of structure **4** to the major adduct and structure **5** to the minor adduct was made initially by chemical correlation with the adducts of some derivatives (see below). These structures have since been corroborated in an X-ray crystallographic study.[4]

The synthetic utility of dienes such as **3** would be enhanced if one could manipulate the diene so that the *anti*-addition product could be obtained, too. Hydrogen bonding between the diol diene **3** and the dienophile cannot be discounted as an important contributor to the π-facial selectivity of **3**. Therefore, a survey of the influence of different solvents on the π-facial selectivity was made. The results are summarized in Table 1. Variations were small, and there was no obvious correlation with the polarity of the solvent.

Many of the theories regarding π-facial selectivity would explain the π-facial selectivity of **3** in terms of some form of donation of electron density from the oxygens of **3**. Thus, our first three derivatives **6**, **7**, and **8**, were chosen to modulate the electron-donating ability of the oxygens. Furthermore, the derivatives could not hydrogen bond, and they would present more steric hindrance on the *syn* face than does diol **3**. Dienes **6** and **8** were obtained from **3** in a straightforward manner. The dimethoxy diene **7** was prepared in a phase-transfer reaction of **3** with dimethyl sulfate using the procedure of Merz (21). Two more derivatives, **9** and **10**, which might loosely be considered as cyclic analogues of **7** and **8**, respectively, were chosen because there would be less ambiguity regarding the conformations of these derivatives during reactions. The acetonide **9** was prepared by exchange with 2,2-dimethoxypropane. For the rather moisture-sensitive diene **10** we followed a procedure by Orr and Monder (22), and its Diels–Alder reaction was effected immediately in its original solution.

All of these dienes reacted smoothly with *N*-phenylmaleimide in chloroform solution to give Diels–Alder adducts in very high yield. The relative amounts of the adducts from these reactions were determined by integration of ^{1}H nmr spectra of the crude reaction products, and the results are given in Table 2. The rates of reaction of these dienes were determined in an approximate manner relative to 1,3-cyclohexadiene by means of competitive reactions with mixtures of two dienes and *N*-phenylmaleimide. This information appears in Table 2, also. The diacetate diene **6** was the least reactive, and, as expected, it showed less π-facial selectivity than did **3**, but the difference was small. Dienes **7** and **8** were also less reactive than 1,3-cyclohexadiene, but steric hindrance by the plane-nonsymmetric heteroatom substituents was clearly not a factor influencing π-facial selectivity in their reactions. Their adducts were overwhelmingly the results of *syn* addition. Indeed, we were unable to find any evidence of a minor adduct (**16**) in the product of the reaction of **8**, even though this diene bears the groups that are potentially the most sterically hindering. Thus, derivatization of **3** by these simple groups had little effect on the π-facial selectivity, i.e., they all direct *syn*. These findings are consistent with the cyclopentadiene results (1) and with the observation of Deslongchamps *et al.* (23) of a complete lack of π-facial selectivity in the Diels–Alder reaction of diene **21** with butenone.

The two dienes with cyclic derivatives **9** and **10**, were more reactive than **3**, but their π-facial selectivity was much lower than that of **3**. This was consistent with a result in work by Pittol *et al.* (19), who reported two adducts from the Diels–Alder reaction of the trifluoromethyl analogue of **9** with *N*-ethylmaleimide.

The two adducts obtained from the reaction of our acetonide diene **9** were stable and readily separable by flash

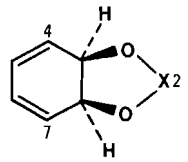
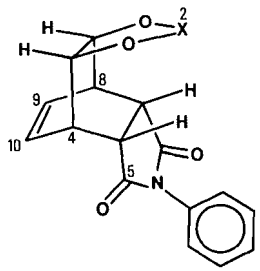
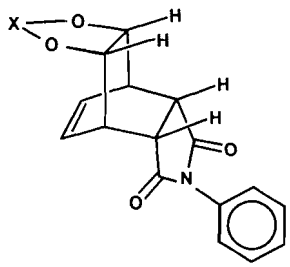
column chromatography. Measurement of nOe enhancements in the ^1H nmr spectrum of the major adduct established the proximity of the hydrogens on C-4a and C-7a with one of the acetonide's methyl groups (the "*syn*" methyl), as well as the proximity of the alkenic hydrogens with the hydrogens on C-3a and C-8a. Therefore, the major adduct had structure **17**, the result of *endo* addition *syn* to the oxygen functions of **9**. Conversely, nOe measurements in the ^1H nmr spectrum of the minor isomer showed that one acetonide methyl was near the alkenic hydrogens, and the hydrogens on C-3a and C-8a were in the proximity of the hydrogens on C-4a and C-7a. Thus, the minor isomer was **18**, also the result of an *endo* addition, but in this instance *anti* to the oxygen functions of **9**. (Measurements of nOe enhancements confirmed the structures of **19** and **20** in the same way.)



9 X = $C(CH_3)_2$
10 X = $Si(CH_3)_2$
22 X = B-CH_2-CH_3
34 X = CH_2



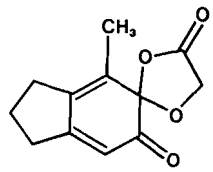
17 X = $C(CH_3)_2$
19 X = $Si(CH_3)_3$
23 X = B-CH_2-CH_3



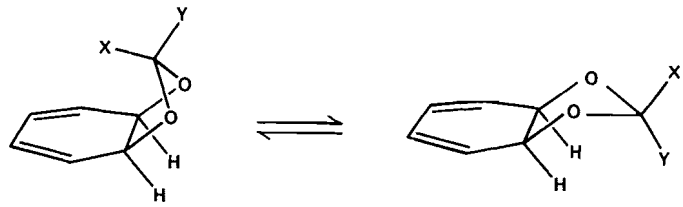
18 X = $C(CH_3)_2$
20 X = $Si(CH_3)_2$
24 X = B-CH_2-CH_3

With the structures for the major and minor acetonide adducts clearly established, we could confirm the structures of the other adducts. The two acetonide adducts, **17** and **18**, were hydrolysed separately under vigorous acidic conditions to give **4** and **5**, respectively, the products of the Diels–Alder reaction of **3**. The major adducts **11**, **13**, **15**, and **19** were made from **4**, and the minor adducts **12**, **14**, and **20** were made from **5**. In addition, the putative minor isomer **16** was produced from **5**, and it was confirmed that signals arising from **16** would not have been hidden by other signals in the ^1H nmr spectrum of the crude product of the Diels–Alder reaction of **8**.

The greater reaction rate (on both faces of the diene) of each cyclic derivative of **3** relative to its acyclic counterpart was attributable simply to the fact that the derivative ring would force the cyclohexadiene ring into a more planar, therefore more reactive, conformation. However, the lower π-facial selectivities suggested that the increase in reactivity was offset on the *syn* face by an unfavorable interaction. It seems likely that this was a steric interaction, although one cannot discount some subtle stereoelectronic effect at work. Thus, one might expect a significant amount of conformer **A** (X = Y = CH_3) as well as conformer **B** in solution, and clearly in **A** the *syn* face would be very hindered.



21



A **B**

It is opportune at this juncture to make some comment about the relationship between the relative rates shown in Table 2 and two of the theories that have been forwarded to explain how π-facial selectivity is governed by allylic heteroatoms. Anh (3) and later Kahn and Hehre (4) proposed what is in essence a nucleophilic role for the oxygen vis-à-vis the incoming dienophile. A logical extension of this to our dienes would be that the *syn* faces, which would be more nucleophilic, should be more reactive than the faces of 1,3-cyclohexadiene. This was not the case. In fact, one of the least reactive dienes (**8**) reacted exclusively by *syn* addition. Work by le Noble and co-workers (5) and by Macaulay and Fallis (2) supported the notion that π-facial selectivity in some Diels–Alder reactions is controlled by the σ-donor ability of the *anti* substituent (24). Whereas it might be argued that our derivatives must have had C—O bonds of varying σ-donor ability, the *anti* substituents were always hydrogens. Thus, it is difficult to reconcile the widely differing rates of *syn* addition of our substituted cyclohexadiene systems with this hypothesis.

Although we had conditions that gave a very high degree of selectivity for *syn* addition with dienes such as **3**, these first derivatization experiments had not managed to tip the selectivity in favor of the *anti* addition. π-Facial selectivity was very modestly affected by derivatization by the electron-withdrawing acetyls of diene **6**, and the cyclic derivatives suggested that steric interactions could be made important if the populations of the two major conformers could be controlled. These two options for increasing the proportion of the *anti*-addition product were explored further.

Firstly, we attempted to modify more drastically the electron-donating ability of the oxygens of **3** by using a boron derivative. A carefully measured amount of lithium triethylborohydride (25) was added to **3** to give the cyclic derivative **22**. This was not purified; *N*-phenylmaleimide was added immediately. The ^1H nmr of the reaction mixture showed two adducts, in a ratio of 55:45. The nmr data collected directly on this mixture of adducts included for the major adduct a 12% nOe enhancement of the signals due to the hydrogens on carbons 3a and 8a on saturation of the signals due to the hydrogens on carbons 4a and 7a. Thus, the major adduct was assigned structure **24**, the adduct result-

ing from *anti* addition. Given the planar geometry about boron, this result can be interpreted as a stereoelectronically derived modification of π-facial selectivity.

Whereas the result with **22** was interesting as a phenomenon, the proportion of *anti*-addition product was still not synthetically useful. We sought to increase steric interactions on the *syn* face by using a benzylidine derivative of **3**. The acid-catalysed reaction of **3** with benzaldehyde dimethyl acetal gave exclusively one of the two possible derivatives. The nOe data for this derivative showed that it had the "*endo*" relative stereochemistry **25**. To obtain both **25** and the "exo" isomer **26** it was necessary to proceed via the (racemic) dibromo-diol **27** by double derivatization followed by double dehydrobromination. We prepared this precurusor from 1,4-cyclohexadiene by literature methods (26, 27). The isomeric (racemic) dibromides **28** and **29** were readily separated by crystallization and chromatography as described by Yang *et al.* (27), then double dehydrobromination provided the dienes.

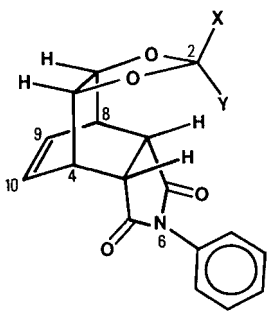
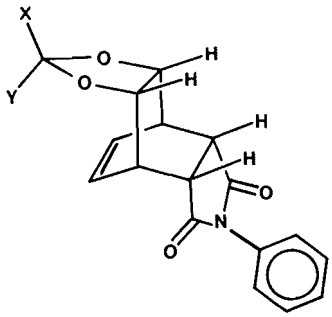
38 X = NO_2

Diene **25** reacted with *N*-phenylmaleimide at about one third the rate of diene **9**, and two adducts were evident, in a ratio of 72:28, in the ^{1}H nmr spectrum of the crude product. The two adducts were separable by flash chromatography. The nmr data for the major product included the following key observation: saturation of the signal due to the hydrogens on C-3a and C-8a led to an nOe enhancement of the acetal hydrogen signal (18%) and of the signal due to the hydrogens on C-4a and C-7a (16%). This established that the major product had arisen by *endo* addition to the face of **25** *anti* to the oxygen functions, i.e., it was **31**. In the ^{1}H nmr data for the minor adduct was evidence by nOe of the proximity of the hydrogens on C-3a and C-8a to the acetal hydrogen (12%) and to the alkenic hydrogens (2%). Furthermore, significant nOe enhancements confirmed that the hydrogens on C-4a and C-7a were located near the benzylidine aromatic ring. Thus, the minor adduct was **30**, the *syn-endo*-addition product. Neither product was the result of epimerization at the acetal center. It is worthy of note that the formation of the benzylidine derivative from **4** by a method that should give the thermodynamically preferred product gave only **30**, and from **5** only **31** was obtained.

The isomeric benzylidine diene **26** was prone to dimerize on standing, and it showed greater π-facial selectivity than did **25** in its Diels–Alder reaction with *N*-phenylmaleimide: the ratio of adducts, produced essentially quantitatively, was 96:4. It was gratifying that saturation of the signal due to the hydrogens on C-3a and C-8a in the ^{1}H nmr spectrum of the pure major adduct led to an nOe enhancement of the signal due to the hydrogens on C-4a and C-7a (14%), and saturation of the alkenyl proton signals gave a 4% nOe enhancement to the acetal hydrogen signal. Clearly, the very predominant adduct from this diene was the *anti-endo*-addition product **33**. The ^{1}H nmr data of the minor adduct showed an important nOe enhancement (9%) of the acetal hydrogen's signal on saturation of the signal due to the hydrogens on C-4a and C-7a. Thus, the minor adduct was the *syn-endo*-adduct **32**. In spite of the demonstrated thermodynamic preference for **30** over **32**, and **31** over **33**, we saw no evidence for epimerization at the acetal center during the reaction of **26**.





30 X = H, Y = C_6H_5
32 X = C_6H_5, Y = H
39 X = H, Y = $C_6H_4NO_2$
41 X = $C_6H_4NO_2$, Y = H

31 X = H, Y = C_6H_5
33 X = C_6H_5, Y = H
40 X = H, Y = $C_6H_4NO_2$
42 X = $C_6H_4NO_2$, Y = H

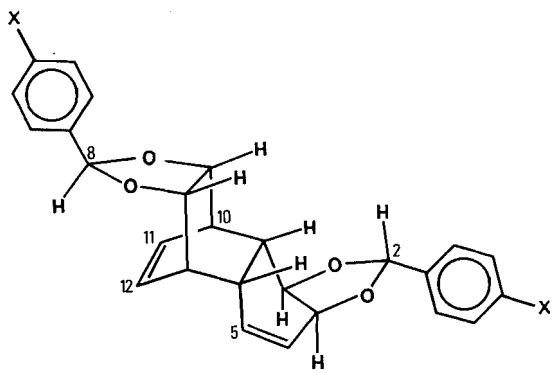
The reason for greater π-facial diastereoselectivity in the reaction of **26** over that of **25** may be related to their conformations. Both molecules might assume conformations with the phenyl group pseudoequatorial or pseudoaxial with respect to the 1,3-dioxolane moiety. Diene **26** should have a preference for conformer **A** (X = H, Y = C_6H_5), in which the phenyl is pseudoequatorial. In conformer **B** (X = H, Y = C_6H_5) of **26** there would be an unfavorable interaction between the phenyl group and the hydrogens on C-3a and C-7a. The acetal hydrogen of the preferred conformer **A** of **26** would be well positioned to hinder attack by the dienophile

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

on the *syn* face. By the same token, conformation **A** of **25** (X = C_6H_5, Y = H) should completely block *syn* addition, but **25** is likely to have a preference for the pseudoequatorial phenyl in conformation **B** (X = C_6H_5, Y = H), in which the *syn* face of the diene is relatively unencumbered. A rationalization of the selectivities of **26** (likely mainly **A**) and **25** (probably mainly **B**) based on a large stereoelectronic component would not be supported by *ab initio* calculations on **34**, which revealed that the differences in the π-orbitals in conformers **A** and **B** (X = Y = H) are very small indeed.[5]

Further support for steric rather than stereoelectronic control came from the reactions of the *para*-nitro analogues **35** and **36**, which were prepared via **27** and the dibromides **37** and **38**. The nmr spectra of the adducts derived from **35**, **39**, and **40** were similar to those from **25**, and their relative amounts (27:73, respectively) were not significantly different, either.[6] In the same way, **36** reacted in a manner reminiscent of **26**, producing adducts **41** and **42** (5:95, respectively). The lack of sensitivity with regard to the addition of the electron-withdrawing group is certainly consistent with steric interactions rather than stereoelectronic ones being of primary importance in the control of π-facial selectivity with the benzylidine dienes.

The *exo*-benzylidine dienes, **26** and **36**, dimerized readily by a Diels–Alder reaction. The structures of the dimers, **43** and **44**, were evident from measurements of nOe enhancements in their ^{1}H nmr spectra. Each arose by a process in which both the diene and dienophile partners underwent addition to their *anti* faces, the result that would be expected in a sterically controlled reaction.



43 X = H
44 X = NO_2

Finally, as we had done with our first adducts from **3**, it was important to address the possibility that we had produced the thermodynamically preferred, rather than kinetically preferred, adducts from the derivatives. We tested a cross section of pure adducts for equilibration. Chloroform solutions of some major (**11**, **15**, **17**, **31**, **33**, **40**, and **42**) and some minor adducts (**12**, **14**, **18**, **30**, **32**, and **39**) were heated under reflux for 36 h. In no instance was there any evidence for the production of an isomeric adduct.

[5]A manuscript describing the results of our parallel computational study of π-facial diastereoselectivity is in preparation.

[6]The facial selectivity of **35** leads one to assume that it, like **25**, must also exist to a significant degree in its less favourable conformation, **A**. Whether this conformer might be stabilized by a "π-stacking" arrangement in chloroform was examined in a cursory manner. Running the Diels–Alder reaction of **35** in benzene led to an adduct mixture of 24:76 (**39** to **40**, respectively), which was not significantly different from the ratio in chloroform. Also, an nOe study failed to reveal proximity between the nitrophenyl moiety and the hydrogens on the diene portion of **35**.

Experimental

Melting points (mp) were determined on a Fisher–Johns apparatus and are uncorrected. Ultraviolet (uv) spectra were run on a Perkin–Elmer 202 instrument. Infrared (ir) spectra were recorded on a Mattson Polaris FT instrument; these abbreviations apply: s = strong; m = medium; w = weak; br = broad. Mass spectral data were from a V.G. Micromass 7070HS instrument, or from the model 5970 mass selective detector that is part of a Hewlett–Packard gas chromatograph – mass spectrometer (gc–ms) system. The ms data have this format: *m/z* (% of base peak). Nuclear magnetic resonance (nmr) spectra were obtained on a General Electric GE 300-NB instrument, except in a few instances in which a (60 MHz) Varian EM-360 instrument was employed. The ^{1}H shifts of $CDCl_3$ solutions were measured relative to internal tetramethylsilane, but in other solvents shifts were calibrated to a solvent resonance. Standard abbreviations apply, as well as br = broad and nar = narrow. All ^{13}C shifts were calibrated to a solvent resonance. For some carbon resonances for which rigorous assignments are not provided the number of attached protons (APT) may be indicated in parentheses after the chemical shift. Assignments were aided by COSY and heteronuclear 2-D spectra and by nuclear Overhauser effect (nOe) enhancement measurements, which also led to the assignment of stereochemistry. The nOe measurements were made from sets of interleaved ^{1}H experiments (16K) of 8 transients cycled 12 to 16 times through the list of frequencies to be saturated. The decoupler was gated on in CW mode for 6 s with sufficient attenuation to give a 70–90% reduction in intensity of the irradiated peak. Frequency changes were preceded by a 60-s delay. Four scans were used to equilibrate spins before data acquisition, but a relaxation delay was not applied between scans at the same frequency. The nOe difference spectra (28) were obtained from zero-filled 32K data tables to which a 1–2 Hz exponential line-broadening function had been applied. The nOe data are reported in this format: irradiated signal (enhanced signal, enhancement). Reactions were run under an atmosphere of dry nitrogen. Dry benzene was distilled from CaH_2 and stored over sodium wire; pyridine was distilled from, and stored over, KOH; tetrahydrofuran (THF) was freshly distilled from sodium/benzophenone. Routine solvents were distilled, and aqueous solutions are implied for saturated NaCl, etc. Flash column chromatography used 230–400 mesh silica gel, and elution was with hexane containing an increasing proportion of ethyl acetate.

Diels–Alder reaction of ***3****: (3aα,4α,7α,7aα,8S*,9R*)- (****4****) and (3aα,4α,7α,7aα,8R*,9S*)-3a,4,7,7a-tetrahydro-8,9-dihydroxy-2-phenyl-4,7-ethano-1H-isoindole-1,3(2H)-dione (****5****)*

A solution of diene **3** (Aldrich; 48 mg, 0.43 mmol) and *N*-phenylmaleimide (75 mg, 0.43 mmol) in $CHCl_3$ (5 mL) was heated under reflux for 16 h. During this time a precipitate formed that was composed of the adduct mixture. Evaporation of the solvent under vacuum left 115 mg (93%) of a colorless solid. This was dissolved completely in C_5D_5N, and the ^{1}H nmr spectrum of this mixture revealed signals for **4** and **5** in a ratio of 95:5, respectively, by integration. Repeated crystallization of the mixture from 25% methanol in ethyl acetate provided a pure sample (30 mg) of **4**: mp 218.5–220°C; ir (KBr) ν_{max}: 3423 (br), 2960, 1768 (w), 1693 (s), 1502, 1392, 1184, 689 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.36–7.48 (3H, m), 7.18 (2H, br d, *J* = 7.3 Hz), 6.22 (2H, apparent dd, *J* = 3.3, 4.3 Hz), 3.84 (2H, br s), 3.50 (2H, br s), 3.42 (2H, br s), 2.97 (2H, br s); ^{1}H nmr (C_5D_5N) δ: 7.30–7.52 (3H, m), 6.26 (2H, dd, *J* = 3.2, 4.4 Hz), 5.14 (2H, OH's), 3.98 (2H, s, C-8H and C-9H), 3.88 (2H, s, C-3aH and C-7aH), 3.61 (2H, br s, C-4H and C-7H); ^{13}C nmr (C_5D_5N) δ: 179.5, 133.6, 132.2 (C-5 and C-6), 129.3, 128.6, 127.5, 63.7 (C-8 and C-9), 40.3 (C-4 and C-7), 38.6

(C-3a and C-7a); ms: 285 (M^+, 26), 256 (4), 226 (89), 120 (28), 119 (83), 105 (17), 91 (25), 79 (100), 78 (53). Exact Mass calcd. for $C_{16}H_{15}NO_4$: 285.1000; found: 285.0996.

A sample of **5** was obtained by hydrolysis of **18** (see below). The ^1H and ^{13}C nmr spectra were entirely in accord with the data for the minor component of the adduct mixture. For **5**: mp (after recrystallization from ethyl acetate/CH_3OH) 260–261°C; ir (KBr) ν_{max}: 3450, 3383 (br), 2901, 1775 (w), 1705, 1393, 1200, 734 cm^{-1}; ^1H nmr (C_5D_5N) δ: 7.28–7.55 (5H), 6.47 (2H, apparent t, $J \approx 3.7$ Hz), 5.04 (OH's), 4.32 (2H, s), 3.74 (2H, m), 3.33 (2H, s); ^{13}C nmr (C_5D_5N) δ: 177.6, 133.4, 131.3, 129.3, 128.7, 127.4, 69.2, 42.0, 40.9; ms: 285 (M^+, 18), 267 (4), 226 (95), 120 (23), 119 (100), 105 (11), 91 (24), 79 (67), 78 (60), 77 (24). Exact Mass calcd. for $C_{16}H_{15}NO_4$: 285.1000; found: 285.0993.

cis-*5,6-Diacetyloxy-1,3-cyclohexadiene (6)*

Acetic anhydride (1.0 mL) was added to a solution of **3** (0.240 g, 2.14 mmol) in pyridine (1.0 mL). After stirring at room temperature for 2 h, tlc indicated completion of the reaction. The volatiles were removed under vacuum, and flash chromatography of the residue gave **6** as a colorless oil (0.368 g, 88%): uv (CH_3OH) λ_{max}: 256 nm (ε = 3900); ir (film) ν_{max}: 1740 (s), 1371 (s), 1241 (s), 1064 (s) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 6.15 (2H, m), 5.90 (2H, m), 5.54 (2H, nar m), 2.07 (6H, s); ^{13}C nmr ($CDCl_3$) δ: 170.1 (0), 126.1 (1), 125.1 (1), 66.8 (1), 20.7 (3); ms: 196 (M^+, 0.9), 154 (3), 136 (13), 112 (60), 95 (98), 94 (100), 83 (19), 78 (33), 77 (24), 66 (66), 43 (100). Exact Mass calcd. for $C_{10}H_{12}O_4$: 196.0735; found: 196.0725.

cis-*5,6-Dimethoxy-1,3-cyclohexadiene (7)*

The diol **3** (0.311 g, 2.77 mmol), dimethyl sulfate (2.10 g, 16.6 mmol), and tetra-*n*-butylammonium hydroxide (1.0 g, 40% w/w in H_2O) were added to a two-phase system of CH_2Cl_2 (100 mL) and 50% NaOH in H_2O. This was stirred vigorously for 3 days at room temperature. More H_2O (100 mL) was added. The organic layer was washed with H_2O (100 mL), saturated $NaHCO_3$ (100 mL), and saturated NaCl (100 mL), then it was dried ($MgSO_4$) and concentrated under vacuum. Flash chromatography provided **7** as a colorless liquid (0.296 g, 76%): uv (CH_3OH) λ_{max}: 262 nm (ε = 2500); ir (film) ν_{max}: 2929 (s), 1464, 1122 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.99–6.08 (4H, m), 3.81 (2H, nar m), 3.44 (6H, s); ^{13}C nmr ($CDCl_3$) δ: 126.9 (1), 124.8 (1), 73.9 (1), 56.2 (3); ms (from gc–ms): 140 (M^+, 18), 125 (7), 109 (14), 97 (23), 82 (21), 78 (28), 77 (25), 75 (100), 65 (50). Exact Mass calcd. for $C_8H_{12}O_2$: 140.0837; found: 140.0834.

cis-*5,6-Bis(trimethylsilyloxy)-1,3-cyclohexadiene (8)*

Chlorotrimethylsilane (600 μL, 4.73 mmol) was added to a solution of **3** (0.232 g, 2.07 mmol) in pyridine (2 mL) at 0°C. The mixture was stirred for 1 h while it attained room temperature. After addition of CCl_4 (10 mL) the resulting precipitate was removed by filtration. The filtrate, after evaporation of most of the solvent under vacuum, was purified by flash chromatography to provide **8** as a colorless oil (0.456 g, 86%): uv (CH_3OH) λ_{max}: 259 nm (ε = 4000); ir (film) ν_{max}: 3043 (m), 2958 (s), 2898 (m), 2796 (w), 1412 (m), 1252 (s), 1119 (s), 840 (s) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.97 (2H, m), 5.87 (2H, m), 4.14 (2H, nar m), 0.15 (18H, s); ^{13}C nmr ($CDCl_3$) δ: 130.4 (1), 124.0 (1), 68.9 (1), 0.2 (3); ms: 256 (M^+, 21), 191 (10), 151 (17), 147 (36), 75 (23), 73 (100). Exact Mass calcd. for $C_{12}H_{24}O_2Si_2$: 256.1314; found: 256.1314.

cis-*3a,7a,Dihydro-2,2-dimethyl-1,3-benzodioxole (9)*

A solution of **3** (0.200 g, 1.78 mmol) and *p*-toluenesulfonic acid (*p*TsOH) (10 mg) in 2,2-dimethoxypropane (15 mL) was stirred at room temperature for 1 h. After addition of CH_2Cl_2 (50 mL) the mixture was washed with 0.1 M NaOH (50 mL), saturated $NaHCO_3$ (50 mL), and saturated NaCl (50 mL). The organic solution was dried ($MgSO_4$) and concentrated under vacuum. Flash chromatography of the residue gave **9** as a colorless liquid (0.226 g, 83%): uv (CH_3OH) λ_{max}: 257 nm (ε = 3500); ir (film) ν_{max}: 3045 (m), 2987 (s), 2935 (m), 2888 (m), 1379 (s), 1209 (s), 1032 (s) cm^{-1}; ^1H nmr ($CDCl_3$) δ: 6.00 (2H, m), 5.89 (2H, m), 4.66 (2H, apparent t, J = 1.7 Hz), 1.43 (3H, s), 1.40 (3H, s); ^{13}C nmr ($CDCl_3$) δ: 125.2, 123.6, 104.4, 70.2, 26.6, 24.6; ms: 152 (M^+, 1.4), 137 (42), 95 (100), 94 (96), 78 (32), 77 (53), 68 (24), 66 (94), 65 (50), 43 (87). Exact Mass calcd. for $C_8H_9O_2$ ($M^+ - CH_3$): 137.0602; found: 137.0599.

cis-*3a,7a-Dihydro-2,2-dimethyl-1,3,2-benzodioxasilole (10)*

This reaction was best followed by nmr. Diacetoxydimethylsilane (222 μL, 1.26 mmol) was added to a solution of **3** (0.141 g, 1.26 mmol) in $CDCl_3$ (approx. 0.5 mL) and pyridine (10 μL) in an nmr tube. The tube was spun in the probe of a 60-MHz nmr instrument for 10 min after which time the spectrum indicated quantitative conversion to **10**. The solvent could be removed under vacuum: uv (CH_3OH) λ_{max}: 260 (ε = 3500); ir (film) ν_{max}: 3044, 2962, 2902, 1413, 1258 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.94 (2H, m), 5.84 (2H, m), 4.70 (2H, nar m), 0.27 (3H, s), 0.23 (3H, s); ^{13}C nmr ($CDCl_3$) δ: 126.3, 123.2, 69.1, −1.3, −1.9; ms: 168 (M^+, 90), 167 (100), 153 (99), 151 (16), 135 (20), 133 (17), 94 (45), 91 (40), 77 (36), 75 (64), 66 (24), 65 (20), 45 (34). Exact Mass calcd. for $C_8H_{12}O_2Si$: 168.0606; found: 168.0587; calcd. for $C_8H_{11}O_2Si$ ($M^+ - H$): 167.0528; found: 167.0522.

Diels–Alder reaction of 6: (3aα,4α,7α,7aα,8S,9R*)- (11) and (3aα,4α,7α,7aα,8R*,9S*)-8,9-bis(acetyloxy)-3a,4,7,7a-tetrahydro-2-phenyl-4,7-ethano-1H-isoindole-1,3(2H)-dione (12)*

A solution of the diacetate diene **6** (0.214 g, 1.09 mmol) and *N*-phenylmaleimide (0.190 g, 1.10 mmol) in $CHCl_3$ (30 mL) was heated under reflux for 2 days. Evaporation of the solvent under vacuum provided a colorless mixture (0.402 g) that ^1H nmr showed was composed very predominantly of the *syn* (**11**) and the *anti* (**12**) adducts in a ratio of 88:12, respectively, along with only a trace of unreacted dienophile and residual solvent. The nmr signals of the adducts correlated exactly with authentic materials produced as follows. A solution of the *syn* diol adduct **4** (70.6 mg, 0.247 mmol) and acetic anhydride (1 mL) in pyridine (2 mL) was stirred overnight at room temperature. Evaporation of the volatiles under vacuum gave a colorless powder (94.6 mg), which was crystallized from ethyl acetate to provide **11**: mp 235–237°C; ir (film) ν_{max}: 1755, 1712, 1377, 1247 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.35–7.49 (3H, m), 7.17 (2H, d, J = 7.1 Hz), 6.30 (2H, apparent dd, J = 3.0, 4.4 Hz), 4.90 (2H, br s, C-8H and C-9H), 3.48 (4H, br s), 2.10 (6H, s); ^{13}C nmr ($CDCl_3$) δ: 177.4, 169.4, 131.5 (C-1'), 131.3 (C-5 and C-6), 129.1, 128.7, 126.3, 64.7, 38.0, 36.5, 20.5; ms: 369 (M^+, 10), 327 (24), 310 (1), 285 (5), 226 (29), 119 (15), 91 (13), 79 (18), 43 (100). Exact Mass calcd. for $C_{18}H_{17}NO_5$ ($M^+ - C_2H_2O$): 327.1106; found: 327.1107.

Similarly, the *anti* diol **5** (43.0 mg, 0.151 mmol) and acetic anhydride (1 mL) in pyridine (5 mL) were stirred overnight, and evaporation of the volatiles under vacuum gave a colorless powder (55.8 mg), which was crystallized from 3:2 ethyl acetate/hexane to provide **12** (20.8 mg, 37%): mp 235.5–237°C; ir (film) ν_{max}: 1738, 1711, 1376, 1254, 1191 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.35–7.49 (3H, m), 7.17 (2H, br d, $J \approx 7.0$ Hz), 6.35 (2H, apparent dd, J = 3.2, 4.2 Hz), 5.15 (2H, nar m, C-8H and C-9H), 3.52 (2H, m, C-4H and C-7H), 3.12 (2H, nar m, C-3aH and C-7aH), 2.04 (6H, s); ^{13}C nmr ($CDCl_3$) δ: 175.7, 169.9, 131.5 (C-1'), 130.4 (C-5 and C-6), 129.2, 128.9, 126.3, 69.8, 40.6 (C-3a and C-7a), 36.6 (C-4 and C-7), 20.5; ms: 369 (M^+, 10), 327 (40), 285 (7), 226 (43), 143 (10), 119 (22), 91 (14), 79 (25), 43 (100). Exact Mass calcd. for $C_{20}H_{19}NO_6$: 369.1211; found: 369.1216.

Diels–Alder reaction of 7: (3aα,4α,7α,7aα,8S,9R*)- (13) and (3aα,4α,7α,7aα,8R*,9S*)-3a,4,7,7a-tetrahydro-8,9-dimethoxy-2-phenyl-4,7-ethano-1H-isoindole-1,3(2H)-dione (14)*

A solution of **7** (67 mg, 0.48 mmol) and *N*-phenylmaleimide (59 mg, 0.34 mmol) in $CHCl_3$ (5 mL) was stirred at room temperature for 16 h. The solvent was evaporated under vacuum to provide an orange solid (113 mg). The ^1H nmr spectrum of this material in-

For personal use only.

dicated some unreacted **7**, a small amount of unreacted *N*-phenylmaleimide, and the remainder was almost exclusively **13** (ratio of **13**/**14** estimated conservatively at 99:1). Recrystallization of this crude product from benzene afforded some **13**: mp 195–196°C; ir (KBr) ν_{max}: 2966, 2891, 1767 (w), 1709 (s), 1497, 1371, 1177, 730 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.36–7.44 (3H, m), 7.19 (2H, d, J = 7.1 Hz), 6.22 (2H, dd, J = 3.1, 4.5 Hz), 3.51 (8H, br s), 3.43 (4H, br s); ^1H nmr (C_5D_5N) δ: 7.40–7.43 (4H, m), 7.31 (1H, br m), 6.20 (2H, dd, J = 3.2, 4.6 Hz), 3.62 (2H, t, J = 1.6 Hz, C-3aH and C-7aH), 3.51 (2H, br m, C-4H and C-7H), 3.34 (6H, s), 3.27 (2H, t, J = 1.5 Hz, C-8H and C-9H); nOe data (C_5D_5N): 6.20 (3.51, 16%; 3.27, 1%); 3.62 (3.34, 1%), 3.51 (6.20, 9%; 3.62, 6%; 3.34, 1%; 3.27, 6%), 3.34 (3.62, 2.5%; 3.51, 6%; 3.27, 3%), 3.27 (6.20, 2.5%; 3.51, 11%; 3.34, 2%); ^{13}C nmr (C_5D_5N) δ: 179.0, 133.4, 131.9 (C-5 and C-6), 129.3, 128.6, 127.4, 73.9 (C-8 and C-9), 58.0 (2 × CH_3), 38.7 (C-3a and C-7a), 37.4 (C-4 and C-7); ms: 314 (M^+ + 1, 0.7), 313 (M^+, 0.4), 282 (0.5), 173 (1), 134 (3), 126 (1), 119 (15), 91 (19), 88 (100), 78 (18), 77 (17), 73 (31), 45 (25). Exact Mass calcd. for $C_{18}H_{19}NO_4$: 313.1313; found: 313.1322. The nmr spectra of this adduct were identical with the spectra of material prepared as follows: 2.5 mol equivalents of KH, then 2.5 mol equivalents of iodomethane were added to a THF (30 mL) solution of **4** (55 mg, 0.19 mmol). This was heated under reflux for 18 h to effect complete reaction. After cooling, CH_2Cl_2 (150 mL) was added, and the solution was washed with H_2O (2 × 100 mL) and saturated NaCl (100 mL), then dried ($MgSO_4$) and concentrated under vacuum. Flash chromatography of the residue provided **13** (51 mg, 85%).

Signals for the minor adduct in the ^1H nmr spectrum correlated with the spectrum of **14**, which was made from **5** as above, except the reaction was over in 2 h at room temperature. Crystallization of the residue from $CHCl_3/CCl_4$ provided **14** (94%): mp 220–223°C; ir (KBr) ν_{max}: 2956, 2876, 1777 (w), 1708, 1498, 1385, 1180, 723 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.37–7.48 (3H, m), 7.17 (2H, d, J = 7.0 Hz), 6.32 (2H, dd, J = 3.1, 4.4 Hz), 3.69 (2H, br s), 3.60 (2H, br m, C-4H and C-7H), 3.47 (6H, 2 × CH_3), 2.94 (2H, t, J = 1.4 Hz); ^{13}C nmr ($CDCl_3$) δ: 176.6, 131.6, 130.2, 129.1, 128.8, 126.3, 79.2 (C-8 and C-9), 58.5 (2 × CH_3), 40.9, 36.1; ms: 314 (M^+ + 1, 0.2), 313 (M^+, 0.05), 299 (0.6), 281 (0.6), 226 (11), 173 (1), 134 (4), 119 (22), 91 (26), 88 (100), 78 (27), 77 (24), 45 (34). Exact Mass calcd. for $C_{14}H_{12}NO_2$ (M^+ − $C_4H_7O_2$ = loss of the C-8 and C-9 bridge with H transfer): 226.0867; found: 226.0862.

Diels–Alder reaction of ***8****: (3aα,4α,7α,7aα,8S*,9R*)-3a,4,7,7a-tetrahydro-2-phenyl-8,9-bis[(trimethylsilyl)oxy]-4,7-ethano-1H-isoindole-1,3(2H)-dione (****15****)*

A solution of diene **8** (92 mg, 0.36 mmol) and *N*-phenylmaleimide (62 mg, 0.36 mmol) in $CHCl_3$ (6 mL) was stirred at room temperature for 20 h. Evaporation of the solvent under vacuum gave a pale yellow solid (120 mg). The ^1H nmr spectrum of this material showed major signals for **15** and minor signals for unreacted addends; no signals attributable to **16** were detected. The signals of this adduct were identical with the signals of the only product obtained as follows. Adduct **4** (60 mg, 0.21 mmol) and chlorotrimethylsilane (1.0 mL) in dry pyridine (2.0 mL) were stirred at room temperature for 24 h. Addition of CCl_4 gave a precipitate, which was removed by filtration. Evaporation of the filtrate gave a colorless solid that was crystallized from 25% hexane in CCl_4: mp 143–144°C; ir (KBr) ν_{max}: 3047, 2955, 2898, 1773 (w), 1710, 1391, 1183, 898, 753 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.35–7.46 (3H, m), 7.17 (2H, br d, J = 7.1 Hz), 6.17 (2H, apparent dd, J = 3.3, 4.5 Hz), 3.72 (2H, nar m, C-8H and C-9H), 3.54 (2H, nar m, C-3aH and C-7aH), 3.18 (2H, m, C-4H and C-7H), 0.17 (18H, s); ^{13}C nmr ($CDCl_3$) δ: 179.1, 132.0 (C-1′), 131.5 (C-5 and C-6), 129.0, 128.4, 126.5, 65.3 (C-8 and C-9), 40.6 (C-4 and C-7), 37.9 (C-3a and C-7a), 0.3; ms: no M^+, 414 (1), 324 (3), 204 (100), 147 (10), 73 (51). Exact Mass calcd. for $C_{21}H_{28}NO_4Si_2$ (M^+ − CH_3): 414.1555; found: 414.1588; calcd. for $C_{18}H_{18}NO_3Si$ (M^+ − $C_4H_{13}OSi$): 324.1055; found: 324.1046.

(3aα,4α,7α,7aα,8R,9S*)-3a,4,7,7a-Tetrahydro-2-phenyl-8,9-bis[(trimethylsilyl)oxy]-4,7-ethano-1H-isoindole-1,3(2H)-dione (****16****)*

Addition of chlorotrimethylsilane (1.0 mL) to a solution of (mainly) adduct **5** (33.1 mg, 0.116 mmol) in dry pyridine (5.0 mL) immediately gave a white precipitate. Nevertheless, this was stirred at room temperature for a further 16 h before CCl_4 (10 mL) was added. The precipitate was removed by filtration, and evaporation of the filtrate under vacuum left **16** as a colorless solid (40.6 mg, 82%): mp 166–171°C; ir (KBr) ν_{max}: 3055, 2962, 1778 (w), 1718, 1499, 1385, 1109, 909, 843 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.32–7.47 (3H, m), 7.16 (2H, br d, $J \approx 7.1$ Hz), 6.32 (2H, apparent dd, J = 3.1, 4.4 Hz), 3.95 (2H, br s, C-8H and C-9H), 3.26 (2H, m, C-4H and C-7H), 2.93 (2H, nar m, C-3aH and C-7aH), 0.16 (18H, s); ^{13}C nmr ($CDCl_3$) δ: 176.7, 131.6 (C-1′), 130.3 (C-5 and C-6), 129.0, 128.6, 126.3, 70.9 (C-8 and C-9), 41.2 (C-3a and C-7a), 40.3 (C-4 and C-7), 0.2; ms: no M^+, 414 (1), 324 (5), 204 (100), 147 (14), 132 (24), 116 (39), 73 (90). Exact Mass calcd. for $C_{18}H_{18}NO_3Si$ (M^+ − $C_4H_{13}OSi$): 324.1055; found: 324.1078.

Diels–Alder reaction of ***9****: (3aα,4α,4aβ,7aβ,8α,8aα)- (****17****) and (3aα,4β,4aα,7aα,8β,8aα)-4a,7a,8,8a-tetrahydro-2,2-dimethyl-6-phenyl-4,8-etheno-4H-1,3-dioxolo[4,5-f]isoindole-5,7(3aH,6H)-dione (****18****)*

A solution of diene **9** (66 mg, 0.41 mmol) and *N*-phenylmaleimide (77 mg, 0.44 mmol) in $CHCl_3$ (6 mL) was stirred at room temperature for 24 h. Evaporation of the solvent under vacuum gave a mixture of adducts, the ^1H nmr spectrum of which revealed a mixture of **17** and **18** in a ratio of 60:40, respectively. Preparative tlc (SiO_2; 2:1 hexane/EtOAc)) afforded samples of these adducts. For **17**: mp 189–190.5°C; ir (KBr) ν_{max}: 2981, 2913, 1773 (w), 1711, 1501, 1397, 1187, 1047 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.32–7.45 (3H, m), 7.16 (2H, br d, J = 7.1 Hz), 6.21 (2H, apparent dd, J = 2.8, 4.3 Hz), 4.16 (2H, nar m), 3.48 (4H, s), 1.50 (3H, s), 1.35 (3H, s); ^1H nmr (C_6D_6) δ: 7.41 (2H, br d, J = 7.3 Hz), 7.18 (2H, m), 7.04 (1H, br t, J = 7.4 Hz), 5.68 (2H, dd, J = 3.0, 4.4 Hz), 3.60 (2H, nar m), 3.29 (2H, m), 3.19 (2H, nar m), 1.35 (3H, s), 1.10 (3H, s); nOe data (C_6D_6): 5.68 (3.60, 1.5%; 3.29, 4.5%), 3.60 (5.68, 1.5%; 3.29, 7%; 1.10, 1.5%), 3.29 (5.68, 5%; 3.60, 5.5%; 3.19, 4%), 3.19 (3.29, 5.5%; 1.35, 1%), 1.35 (3.19, 4%; 1.10, 1%), 1.10 (3.60, 7%; 1.35, 2%); ^{13}C nmr ($CDCl_3/C_6D_6$) δ: 178.3/177.7, 131.7/133.1 (C-1′), 131.4/131.6 (C-9 and C-10), 128.8/128.9, 128.3/128.1 (C-4′), 126.2/126.6, 112.2/112.2 (C-2), 73.7/74.0 (C-3a and C-8a), 37.5/37.9 (C-4a and C-7a), 36.8/37.3 (C-4 and C-8), 26.1/26.4 (*syn* CH_3), 24.0/24.1 (*anti* CH_3); ms: 325 (M^+, 8), 310 (17), 296 (7), 268 (20), 267 (22), 239 (17), 222 (31), 120 (39), 119 (55), 100 (47), 93 (47), 92 (54), 91 (100), 43 (45). Hydrolysis of ***17***

Adduct **17** (93 mg, 0.33 mmol) in 4 M HCl (15 mL) was heated under reflux for 1 h. After cooling, CH_2Cl_2 (15 mL) was added, and the organic layer was washed with saturated $NaHCO_3$ (100 mL) and saturated NaCl (100 mL), then dried ($MgSO_4$). Evaporation of the solvent under vacuum provided **4** (47 mg, 58%).

Hydrolysis of ***18***

Adduct **18** (80 mg, 0.28 mmol) was treated similarly to the above to provide **5** (37 mg, 53%).

Diels–Alder reaction of ***10****: (3aα,4α,4aβ,7aβ,8α,8aα)-* ***(19)*** *and (3aα,4β,4aα,7aα,8β,8aα)-4a,7a 8,8a-tetrahydro-2,2-dimethyl-6-phenyl-4,8-etheno-4H-1,3,2-dioxasilolo[4,5-f]isoindole-5,7(3aH,6H)-dione* ***(20)***

To the solution of **10**, prepared in an nmr tube exactly as described above, was added *N*-phenylmaleimide (0.217 g, 1.25 mmol) in $CDCl_3$ (0.5 ml). The reaction was followed at room temperature. After 3 h no **10** remained, and the formation of the adducts appeared to be quantitative. The ^1H nmr spectrum of the solution revealed signals for **19** and **20** in a ratio of 60:40, respectively.[7] The nmr signals matched exactly the signals of the individual adducts, prepared as follows. Diacetyloxydimethylsilane (32 μL, 0.18 mmol) was added to a solution of **4** (51.8 mg, 0.182 mmol) in C_5D_5N (approx. 0.5 mL). The reaction was complete within 15 min (by nmr), and the volatiles were evaporated under vacuum to leave **19** as a white powder (62.6 mg, 100%): mp 200–205°C; ^1H nmr ($CDCl_3$) δ: 7.36–7.47 (3H, m), 7.17–7.21 (2H, m), 6.22 (2H, apparent dd, J = 3.1, 4.5 Hz), 4.17 (2H, apparent t, J = 1.8 Hz, C-3aH and C-8aH), 3.49 (2H, m, C-4H and C-8H), 3.37 (2H, apparent t, J = 1.6 Hz, C-4aH and C-7aH), 0.37 (3H, s), 0.26 (3H, s); ^1H nmr (C_5D_5N) δ: 7.28–7.42 (5H, m), 6.22 (2H, apparent dd, J = 3.1, 4.4 Hz), 4.21 (2H, nar m, C-3aH and C-8aH), 3.65 (2H, nar m, C-4aH and C-7aH), 3.59 (2H, m, C-4H and C-8H), 0.32 (3H, s), 0.22 (3H, s); nOe data ($CDCl_3$): 6.22 (3.49, 3.5%), 4.17 (6.21, 3%; 3.49, 11%), 3.49 (6.22, 7%; 4.17, 6%; 3.37, 3%), 3.37 (3.49, 6%; 0.37, 2.5%), 0.37, (3.37, 6%); ^{13}C nmr (C_5D_5N) δ: 178.9, 133.5 (C-1′), 132.2 (C-9 and C-10), 129.4, 128.8, 127.5, 71.8 (C-3a and C-8a), 39.7 (C-4 and C-8), 38.5 (C-4a and C-7a), −0.1, −1.0; ms: 341 (M^+, 5), 285 (7), 226 (32), 119 (39), 116 (100), 79 (40), 78 (33). (2α,3aβ,7aβ)-3a,7a-Dihydro-2-phenyl-1,3-benzodioxole (25)

From 3

A solution of **3** (77 mg, 0.67 mmol), benzaldehyde dimethyl acetal (100 μL, 0.67 mmol), and *p*TsOH (1.4 mg) in $CDCl_3$ (approximately 1 mL) was stirred overnight. The analysis of the ^{1}H nmr spectrum revealed mainly signals for **25** (but no other derivative) and benzaldehyde along with some phenol. Diene **25** made in this way was purified by rotary thin-layer chromatography (SiO_2; 20% CH_2Cl_2 in hexane) in a yield of only 15%.

From 28

Based on a procedure by Yang *et al.* (27), a solution of **28** (0.356 g, 0.983 mmol) and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU; 0.60 g, 3.9 mmol) in dry benzene (50 mL) was heated under reflux for 16 h. After cooling, the solution was decanted from a white precipitate. The precipitate was extracted with more benzene (50 mL), and the combined benzene solutions were washed with saturated $NaHCO_3$ (3 × 100 mL), H_2O (100 mL), and saturated NaCl (100 mL), then dried ($MgSO_4$) and concentrated under vacuum. Flash chromatography afforded **25** (0.114 g, 58%): ir (film) ν_{max}: 3044, 2883, 1459, 1401, 1217, 1061 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.46–7.50 (2H, m), 7.32–7.36 (3H, m), 6.01–6.08 (2H, m, C-5H and C-6H), 5.94–6.00 (2H, m, C-4H and C-7H), 5.64 (1H, s), 4.66 (2H, apparent t, J = 1.6 Hz); nOe data: 5.64 (7.46–7.50, 3.5%; 4.66, 4%), 4.66 (5.94–6.00, 4%; 5.64, 8.5%); ^{13}C nmr ($CDCl_3$) δ: 136.5 (C-1′), 129.4 (C-4′), 128.2 (C-3′ and C-5′), 126.8 (C-2′ and C-6′), 124.1 (C-4 and C-7), 123.8 (C-5 and C-6), 98.2 (C-2), 71.0 (C-3a and C-7a); ms: 200 (M^+, 4), 199 (3), 172 (6), 154 (39), 106 (35), 105 (90), 94 (100), 78 (64), 77 (86), 66 (100), 51 (50). Exact Mass calcd. for $C_{13}H_{12}O_2$: 200.0837; found: 200.0836.

(2α,3aα,7aα)-3a,7a-Dihydro-2-phenyl-1,3-benzodioxole (26)

By a procedure very similar to that for **25**, **29** (1.23 g, 3.34 mmol) and DBU (2.07 g, 13.4 mmol) gave **26** without chromatography as a yellow oil (0.490 g, 72%): ir (film) ν_{max}: 3043, 2927, 1641 (m), 1217, 1068 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.47–7.55 (2H, m), 7.32–7.40 (3H, m), 6.05 (2H, m), 5.91 (2H, m), 5.83 (1H, s), 4.86 (2H, nar m); ^{13}C nmr ($CDCl_3$) δ: 137.4 (C-1′), 129.0 (C-4′), 128.2 (C-3′ and C-5′), 126.3 (C-2′ and C-6′), 124.9 (C-5 and C-6), 124.6 (C-4 and C-7), 100.7 (C-2), 70.6 (C-3a and C-7a); ms (from gc–ms): 199 ($M^+ - H$, 0.4), 153 (0.5), 128 (3), 122 (4), 105 (46), 94 (59), 78 (100), 77 (46), 66 (54), 51 (28). Exact Mass calcd. for $C_{13}H_{12}O_2$: 200.0837; found: 200.0828. Note that neat **26** will dimerize to **43** readily at room temperature (see below), but it can be stored in solution over moderate periods of time if kept refrigerated.

Diels–Alder reaction of 25: (2α,3aβ,4β,4aα,7aα,8β,8aβ)- (30) and (2α,3aβ,4α,4aβ,7aβ,8α,8aβ)-4a,7a,8,8a-tetrahydro-2,6-diphenyl-4,8-etheno-4H-1,3-dioxolo[4,5-f]isoindole-5,7-3aH,6H)-dione (31)

A solution of diene **25** (81.8 mg, 0.409 mmol) and *N*-phenylmaleimide (71.4 mg, 0.357 mmol) in $CHCl_3$ (2.0 mL) was stirred at room temperature for 16 h. Evaporation of the solvent under vacuum gave a mixture that ^{1}H nmr showed was a 28:72 mixture of **30** and **31**, respectively, along with some unreacted dienophile. Flash chromatography provided **31** (61.6 mg, 62%), but **30** co-eluted with *N*-phenylmaleimide (total fraction: 58.1 mg, which, by ^{1}H nmr integration, was 33% **30**). Careful crystallization of the mixture of **30** and *N*-phenylmaleimide from 1:1:1 $CHCl_3$/ethyl acetate/hexane gave a sample of **30**: mp 210–211.5°C; ir (film) ν_{max}: 2922, 1774 (w), 1712 (s), 1500, 1384, 1182, 1053, 710 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.34–7.51 (8H, m), 7.18 (2H, d, J = 7.1 Hz), 6.31 (2H, dd, J = 3.1, 4.1 Hz), 5.94 (1H, s, C-2H), 4.26 (2H, s, C-3aH and C-8aH), 3.66 (2H, br s, C-4H and C-8H), 3.59 (2H, s, C-4aH and C-7aH); ^{1}H nmr (C_6D_6) δ: 7.52 (2H, d, J = 6.5 Hz), 7.35 (2H, d, J = 7.3 Hz), 7.12–7.24 (5H, m), 7.02 (1H, d, J = 7.4 Hz), 5.67 (2H, dd, J = 3.0, 4.5 Hz), 5.61 (1H, s, C-2H), 3.60 (2H, t, J = 2.0 Hz, C-3aH and C-8aH), 3.37 (2H, br m, C-4H and C-8H), 3.24 (2H, t, J = 1.6 Hz, C-4aH and C-7aH); nOe data (C_6D_6): 5.67 (3.60, 1%; 3.37, 6.5%), 5.61 (7.52, 1.5%; 3.60, 4.5%), 3.60 (5.67, 2%; 5.61, 12%; 3.37, 6%), 3.37 (5.67, 4.5%; 3.60, 4%; 3.24, 4%), 3.24 (7.52, 3%; 3.37, 5.5%); ^{13}C nmr ($CDCl_3$) δ: 178.1, 135.9, 131.8 (C-9 and C-10), 129.6, 129.1, 128.6, 126.4, 126.3, 105.8 (C-2), 74.8 (C-3a and C-8a), 37.9 (C-4a and C-7a), 36.8 (C-4 and C-8); ms: 373 (M^+, 10), 372 (12), 344 (43), 326 (11), 298 (2), 267 (9), 239 (15), 222 (25), 211 (8), 194 (4), 147 (14), 119 (47), 105 (40), 91 (100), 77 (29). Exact Mass calcd. for $C_{23}H_{19}NO_4$: 373.1313; found: 373.1312. The nmr data were identical with the product of this procedure: a solution of **4** (64 mg, 0.22 mmol), benzaldehyde dimethyl acetal (34 μL), and a catalytic amount of *p*TsOH in CH_2Cl_2 (15 mL) was stirred at room temperature for 14 h. The solution was washed with 10% NaOH and saturated NaCl, dried ($MgSO_4$), and evaporated under vacuum to provide **30** (78 mg, 93%).

For **31**: mp 231–234.5°C; ir (film) ν_{max}: 2896, 1778 (w), 1711 (s), 1498, 1395, 1186, 1065, 745 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.35–7.48 (8H, m), 7.20 (2H, d, J = 7.0 Hz), 6.30 (2H, dd, J = 3.3, 4.1 Hz), 5.66 (1H, s, C-2H), 4.37 (2H, s, C-3aH and C-8aH), 3.70 (2H, s, C-4H and C-8H), 2.95 (2H, s, C-4aH and C-7aH); nOe data: 6.30 (3.70, 12%), 5.66 (4.37, 2%), 4.37 (5.66, 18%; 3.70, 13%; 2.95, 16%), 3.70 (6.30, 11%; 4.37, 6%; 2.95, 11%), 2.95 (4.37, 15%; 3.70, 12%); ^{13}C nmr ($CDCl_3$) δ: 176.1, 135.4, 131.6, 130.1 (C-9 and C-10), 129.9, 129.1, 128.8, 128.3, 127.2, 126.3, 103.8 (C-2), 77.8 (C-3a and C-8a), 40.5 (C-4a and C-7a), 36.6 (C-4 and C-8); ms: 373 (M^+, 7), 372 (11), 344 (5), 267 (15), 239 (21), 222 (25), 211 (8), 194 (3), 147 (15), 119 (50), 105 (76), 91 (100), 77 (29). Exact Mass calcd. for $C_{23}H_{19}NO_4$: 373.1313; found 373.1281; calcd. for $C_{22}H_{18}NO_3$ ($M^+ - H - CO$): 344.1287; found 344.1301. The nmr data were identical with the product of this procedure: **5** (51 mg, 0.18 mmol) was suspended in a solution of CH_2Cl_2, and benzaldehyde dimethyl acetal (30 μL) and catalytic *p*TsOH were added. After stirring overnight, the clear solution was worked up as above to afford **31** (66 mg, 99%).

Diels–Alder reaction of 26: (2α,3aα,4α,4aβ,7aβ,8α,8aα)- (32) and (2α,,3aα,4β,4aα,7aα,8β,8aα)-4a,7a,8,8a-tetrahydro-2,6-diphenyl-4,8-etheno-4H-1,3-dioxolo[4,5-f]isoindole-5,7-3aH,6H)-dione (33)

A solution of **26** (0.393 g, 1.96 mmol) and *N*-phenylmaleimide (0.337 g, 1.95 mmol) in $CHCl_3$ (10 mL) was stirred at room temperature overnight. The solvent was evaporated under vacuum, and the ^{1}H nmr spectrum of the residue revealed **32** and **33** in a ratio of 4:96, respectively. Flash chromatography of the residue provided some unreacted *N*-phenylmaleimide (60 mg), **32** (26 mg, 4%), **33** (0.520 g, 87%), and 31 mg of dimer **43**. For **32**: mp 232–234°C; ir (KBr) ν_{max}: 3056, 2926, 1772 (w), 1710 (s), 1598, 1502, 1397, 1191, 1086, 745 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.35–7.47 (8H, m), 7.19 (2H, d, J = 7.2 Hz), 6.47 (1H, s, C-2H), 6.24 (2H, dd, J = 2.9, 3.9 Hz), 4.15 (2H, s, C-3aH and C-8aH), 3.62 (4H, br s); ^{1}H nmr (10% $CDCl_3$ in CCl_4) δ: 7.24–7.42 (8H, m), 7.16 (2H, d, J = 7.2 Hz), 6.40 (1H, s, C-2H), 6.21 (2H, dd, J = 3.1, 4.1 Hz), 4.08 (2H, s, C-3aH and C-8aH), 3.57 (2H, br m, C-4H and C-8H), 3.54 (2H, s, C-4aH and C-7aH); nOe data (10% $CDCl_3$ in CCl_4): 6.40 (3.54, 3%), 6.21 (4.08, 2%; 3.58, 7%), 4.08 (6.40, 2%; 6.21, 2.5%; 3.57, 11%); 3.57 (6.21, 6.5%; 4.08, 8%), 3.54

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

GERTRUDE C. KASITU, JOHN W. APSIMON, BARBARA A. BLACKWELL, DAVID A. FIELDER, ROY GREENHALGH, and J. DAVID MILLER. Can. J. Chem. **70**, 1308 (1992).

Liquid culture fermentations of *Fusarium culmorum* yield a wide variety of secondary metabolites. In addition to known isoprenoids, such as the trichothecenes and modified trichothecenes, four new derivatives of culmorin have been isolated and characterized by spectral analysis. These compounds are 15-hydroxyculmorone (**7**), and 5-hydroxy- (**8**), 12-hydroxy- (**10**), and 15-hydroxyculmorin (**9**). The structure of culmorone is confirmed. The biosynthesis of culmorin from farnesyl pyrophosphate is substantiated through the use of ^{13}C-acetate and the oxidation of these derivatives is discussed.

GERTRUDE C. KASITU, JOHN W. APSIMON, BARBARA A. BLACKWELL, DAVID A. FIELDER, ROY GREENHALGH et J. DAVID MILLER. Can. J. Chem. **70**, 1308 (1992).

Des fermentations liquides de cultures du *Fusarium culmorum* fournissent une grande variété de métabolites secondaires. En plus des isoprénoïdes connus, comme les trichothécènes et les trichothécènes modifiés, quatre nouveaux dérivés de la culmorine ont été isolés et caractérisés par analyse spectrale. Ces composés sont la 15-hydroxyculmorone (**7**) et les 5-hydroxy- (**8**), 12-hydroxy- (**10**) et 15-hydroxyculmorine (**9**). On a confirmé la structure de la culmorone. Utilisant un ^{13}C-acétate, on a ajouté des indices suggérant que la biosynthèse de la culmorine peut se faire à partir du pyrophosphate de farnésyle et on discute de l'oxydation de ces dérivés.

[Traduit par la rédaction]

Introduction

There are 24 toxigenic species of *Fusarium* and these are distributed worldwide. In North America, species such as *F. graminearum, F. culmorum,* and *F. crookwellense* infect cereals of economical importance including wheat, corn, and barley. These *Fusarium* species are closely related and are known to produce a wide variety of secondary metabolites including the trichothecene mycotoxins. Infected grains primarily contain 4-deoxynivalenol (vomitoxin, DON), 15- or 3-acetyldeoxynivalenol, and zearalenone (1). Trichothecenes are phytotoxic to the host species as well as toxic to both animals and humans upon consumption of contaminated grain (2). Animal studies with naturally infected feed containing known amounts of DON showed greater toxicity than feed fortified with the same level of DON (3). Efforts to study this difference in toxicity have included the isolation and characterization of minor metabolites present in both the mycelia and the fermentation broth, as well as testing component metabolites for synergism.

Previous studies showed that in addition to the major metabolite 3-acetyldeoxynivalenol (3-ADON) (**1**) *Fusarium culmorum* CMI 14764 (HLX1503) produces other secondary metabolites of various types such as butenolide (4-acetamido-4-hydroxy-2-butenoic acid γ lactone, $C_6H_7O_3N$) (4, 5), additional trichothecenes including calonectrin and isotrichodermin and their acylated and deacylated derivatives (5), as well as some modified trichothecenes such as sambucinol, sambucoin, 3α- and 3β-hydroxy-11-epiapotrichothecene (**2**) (6), 9α-hydroxytrichotriol (**3**) (7), and other isoprenoids including cyclonerodiol (8), cyclonerotriol (**4**) (9), culmorin (**5**), and culmorone (**6**) (see Fig. 1). A typical gas chromatogram of a crude extract of the fermentation broth of *F. culmorum* is presented in Fig. 2. This figure shows the variety of secondary metabolites produced in a typical culture as well as the relative retention times of several of the compounds described here. Since this extract was collected after 85 hours fermentation, culmorin and other metabolites are found in greater abundance than 3-ADON. Later during the fermentation 3-ADON predominates (10).

The present study reports the isolation and characterization of the derivatives of culmorin and culmorone. The parent sesquiterpene culmorin was first isolated in 1937 from *Fusarium culmorum* by Ashley *et al.* (11). Its structure was established by Barton and Werstiuk (12) and independently by Shilling (13) in 1967. Culmorin has since been detected and isolated from two other *Fusarium* species, namely, *F. graminearum* (*F. roseum* "graminearum") (14*a*) and *F. crookwellense* (15). Additional reports on culmorin include its synthesis (16), biosynthesis (17*a*,*b*), and toxicity (18).

The production of culmorin and culmorone by *F. roseum* was reported earlier, but these compounds were not fully characterized (14). Here we reexamine the structure of culmorone and the assignments of culmorin using ^{1}H, ^{13}C, and 2D techniques. These data facilitate characterization of the four new hydroxy derivatives. This is the first report of the isolation of trichotriol from *F. culmorum*. Revised NMR assignments for cyclonerotriol based on 2D NMR data are also reported.

FIG. 1. Structures of secondary metabolites isolated from *F. culmorum*.

Results and discussion

The extraction, separation, and isolation of the secondary metabolites from a large-scale liquid fermentation of *Fusarium culmorum* CMI 14764 was carried out as described in the experimental section.

Culmorin, culmorone, and hydroxyculmorone

Barton and Werstiuk (12) used extensive chemical degradation and ^{1}H NMR spectra to determine the structure and absolute stereochemistry of culmorin ($C_{15}H_{26}O_2$, MW 238) (**5**). The ^{1}H NMR spectrum of culmorin shows two resonances at 3.80 and 4.33 ppm, which integrate for one hydrogen each, consistent with a hydrogen geminal to a hydroxyl group. Four quaternary methyl groups (0.81, 0.91, 0.94, and 1.02 ppm) are also present. The latter two exhibit geminal coupling as indicated by their reduced intensity and the presence of a cross peak in the ^{1}H/^{1}H correlation (COSY) spectrum. This spectrum, obtained in deuteromethanol, also shows the presence of "W"-coupling between the carbinyl hydrogen H-8 (3.81 ppm) and the H-10β (1.59 ppm), which is further coupled to H-11 (4.30 ppm). In methanol, the H-10 methylenic hydrogens are nonequivalent and H-8 shows "W"-coupling to H-10β, whereas in chloroform the H-10 hydrogens are coincidental and the coupling to H-8 is minimized. This effect is observed in all the hydroxyl derivatives as well. The difference between the spectra in these two solvents is attributed to the different conformation of the molecule induced by hydrogen bonding in methanol. The hydrogen bonding present in methanol provides additional rigidity, which facilitates "W"-coupling, whereas greater molecular flexibility in chloroform reduces this effect through motional averaging. The methyl groups were assigned unambiguously by nOe difference spectra. Irradiation of the H-12 resonance enhances those of H-13, H-8β, and H-10β. Irradiation of H-13 enhances H-12, H-11, H-10, and H-1 resonances. Irradiation of the CH_3-14β resonance produces enhancements of CH_3-15α, H-1, and H-7, while irradiation of the CH_3-15α group enhances CH_3-14, H-7, and H-8. The proton assignments thus determined are reported in Table 1, and improve those of Barton and Werstiuk (12). The ^{13}C NMR spectrum is also consistent with the structure and was assigned with the aid of Distortionless Enhancement by Polarization Transfer (DEPT) and ^{1}H/^{13}C heteronuclear correlation (HETCOR) spectra (Table 2).

The oxidation of culmorin with chromic acid has been reported to produce two hydroxy mono keto isomers, namely 8- and 11-keto culmorin (12). In 1985, we isolated a minor metabolite from a liquid culture of *Fusarium roseum* ATCC

[a]Spectrum obtained in CD_3OD.

28114 (*F. graminearum*), which was identical to one of these compounds and was named culmorone (**6**) (14*b*).

The molecular formula of culmorone ($C_{15}H_{24}O_2$, *m/z* 236) was derived from its high-resolution and chemical ionization mass spectra. Absorptions in the infrared spectrum at 3420 and 1725 cm^{-1} are indicative of hydroxyl and carbonyl moieties, respectively. The presence of these functional groups is confirmed by resonances at 78.0 ppm (hydroxyl) and 216.5 ppm (carbonyl) in the ^{13}C NMR spectrum. The resonances of the remaining 13 carbon atoms are compatible with the oxidized form of culmorin (Table 2). The location of the keto group was assigned from the ^1H spectrum of culmorone. The signal at 4.01 ppm is assigned to H-8. It is coupled to H-7 (1.20 ppm, doublet) and to the hydroxyl hydrogen at 1.77 ppm (doublet), which disappears upon exchange with deuterium oxide. Furthermore, H-8 shows "W" coupling to H-10β of the methylene AB system at 1.83 and 2.59 ppm (both doublets, J = 18.6 Hz). The H-10α (2.59 ppm) is coupled to CH_3-12. The large geminal coupling constant ($J_{10\alpha,10\beta}$ = 18.6 Hz) is consistent with an sp^2 center, i.e., a keto group adjacent to the methylene group (19). If the keto group was located at C-8 there would be no methylene group adjacent. The presence of a cross peak between H-10β and H-7 in a Relayed Coherence (RELAY) spectrum (resulting from the coupling pattern H-7 to H-8 and H-8 to H-10β) confirms the above assignment, placing the keto group at C-11. Thus the structure of the culmorone isomer isolated as a natural product is identical to 8-hydroxyculmor-11-one (**6**), prepared by Barton and Werstiuk.

The distribution of secondary metabolites isolated during this study is shown in Table 3. Fraction 14, containing mainly culmorin, also afforded a compound (**7**) with molecular weight 252, indicative of a molecular formula $C_{15}H_{24}O_3$ (HRMS). Both the ^1H and ^{13}C NMR spectra are similar to those of culmorone (Tables 1 and 2). However, the ^1H spectrum shows that one of the four methyl groups of culmorone has been replaced by a methylenic AB system at 3.30 and 3.46 ppm, and in the ^{13}C spectrum a new hydroxy methylene appears at 72.2 ppm. Comparison of the ^{13}C chemical shifts with those of culmorone suggests that one of the *gem*-dimethyl groups is oxidized. The ^1H NMR spectrum indicates that the CH_3-15 group is hydroxylated, since the H-7 resonance shifts downfield by 0.23 ppm from that of culmorone, due to the deshielding effect of the C—OH bond. This is corroborated by the nOe effect observed between irradiated H-1 and H-7, H-14, while irradiation of H-8 enhances H-12 and H-15. The above data are consistent with the structure 15,8-dihydroxyculmor-11-one (**7**).

Hydroxy culmorins

Three isomeric hydroxy culmorins (**8**, **9**, and **10**) were isolated from the more polar fractions obtained upon column chromatography of the dichloromethane extract (see Table 3). Their mass spectra showed the same molecular ion, *m/z* 254, indicating a molecular formula $C_{15}H_{26}O_3$, which differs from that of culmorin by a single oxygen atom. The ^1H spectra show that this additional oxygen is present as a hydroxyl group in each case.

For isomer **8**, the hydroxyl group is assigned to C-5 in the eight-membered ring of culmorin. The COSY spectrum (Fig. 3) shows that the carbinyl hydrogens at 4.37 ppm (H-11), 3.75 ppm (H-8), and 3.43 ppm (H-5) are coupled to their respective hydroxyl hydrogens at 1.36 ppm (overlapping doublets, OH-8 and OH-11) and 1.22 ppm (doublet, OH-5). In addition, the OH-5 at 1.22 ppm shows long-range coupling to the CH_3-15 group at 1.15 ppm, which is further coupled to the geminal CH_3-14 at 0.86 ppm. The ^{13}C NMR data (Table 2) show that the resonances assigned to C-4 and C-6 are shifted downfield by 8.8 and 4.9 ppm, respectively, compared to culmorin. This is consistent with carbon atoms situated β to a hydroxyl group (20), thus confirming the location of the hydroxyl group at C-5. The HETCOR spectrum of this compound in CD_3OD (Fig. 4) allows determination of the ^{13}C assignments of the four methyl groups and the three hydroxyl-bearing carbons. Note that the most deshielded hydroxyl hydrogen (H-11) corresponds to the most shielded carbon C-11, and the reverse is true for H-5/C-5. Furthermore, the ambiguity between C-10 and C-4 is resolved. The resonance at 36.4 ppm is assigned to C-10, since this signal couples to H-10 at 1.67 ppm in the ^1H spectrum, assigned from the $^1H/^1H$ coupling to H-8 and

[a]Methylene dichloride mother liquors after ppt of ADON.
[b]ADON = 3-acetyldeoxynivalenol; SAM = sambucinol; COL = culmorone; CUL = culmorin; DHCAL = 7,8-dihydroxy-calonectrin; APO = 3α/3β-hydroxyepiapotrichothecene; OH-CUL = 5-/12-/15-hydroxyculmorin; TCT = trichotriol; CNT = cyclonerotriol.

H-11. The hydroxyl group is shown to have a β configuration by nOe difference spectra. Positive nOe enhancements were observed between CH_3-15 and the hydrogens H-5α, H-8, and H-7, which are in the plane of the molecule, while irradiation of the CH_3-14 resonance enhances those of H-1 and H-7.

Based on the ^1H NMR spectra of isomers **9** and **10**, the hydroxyl groups of these compounds are associated with the quaternary methyl groups of the parent molecule culmorin. In compound **9**, it is one of the *gem*-dimethyl groups that is hydroxylated. As in 15-OH culmorone (**7**), in isomer **9**, H-7 is shifted downfield to 2.03 ppm from 1.72 ppm in culmorin, suggesting that the hydroxyl group is at C-15. The nOe difference experiments confirm this since H-1 and H-7 are enhanced upon irradiation of CH_3-14, while H-7 and CH_3-15 are enhanced upon irradiation of H-8. Comparison of the ^{13}C NMR spectrum with that of compound **7** confirms the position of hydroxylation. These data are consistent with a structure of 15-hydroxyculmorin for compound **9**.

In compound **10** the downfield shift of the H-8 resonance (from 3.81 to 4.30 ppm) relative to culmorin is indicative of a hydroxyl group at C-12. This is supported by ^{13}C NMR data in which the resonance at 13.1 ppm in culmorin is replaced by one at 65.8 ppm, associated with a hydroxylated methylene, and C-9 at 52.2 ppm shifts to 55.6 ppm (β shift from hydroxylated carbon) (Table 2). In addition, the irradiation of the CH_3-15 resonance in the nOe experiment enhances H-8 and H-7, while irradiation of H-8 resonance enhances those of H-12 and H-15, thus providing further proof for the structure of compound **10** as 12-hydroxyculmorin.

The NMR spectra of ^{13}C-enriched culmorin isolated from fermentor growths of *Fusarium culmorum* to which either ^{13}C-1 and ^{13}C-2 acetate have been added are shown in Fig. 5. Previous studies (10) have shown that culmorin is produced early in the fermentation and competes more successfully for the pool of enriched acetate than the other major metabolite 3-ADON. After biosynthesis of culmorin ceases (~60 h of fermentation), enrichment in ADON increases. ^{13}C-1 acetate (carbonyl group) results in enrichment of positions C-11, C-7, C-9, C-2, C-6, and C-4, while ^{13}C-2 acetate (methyl group) enriches positions C-1, C-8, C-3, C-5, C-10, C-12, C-13, C-14, and C-15. Signal enhancement of all positions occurs with approximately a factor of four. Carbon–carbon coupling resulting from enrichment at adjacent locations is seen at C-6/C-7 and C-2/C-9. This enrichment pattern is consistent with the proposal that culmorin is derived from one molecule of farnesyl pyrophosphate, which has folded in such a manner that the C-1 of farnesyl pryophosphate, which becomes C-7 of culmorin, has linked to the terminal *gem* dimethyl of farnesyl, which results in C-14 and C-15 of culmorin, as first proposed by Hanson and Nyfeler (17).

The isolation of an array of oxygenated culmorin derivatives is reminiscent of the variety of oxygenated trichothecenes and modified trichothecenes produced by the various *Fusaria*. The great variety of oxygenation patterns in these isolated metabolites has suggested the operation of a metabolic grid rather than a unique oxidative pathway (21), and indicates oxidative enzyme systems that are very flexible in substrate selection. However, a striking similarity exists between the general locus of oxygenation in both the trichothecenes (and related trichodienoids) and the culmorin derivatives described herein, once more suggesting the operation of a metabolic grid rather than a unique oxygenation pathway. Hanson and Nyfeler (17*b*) proposed that C-8 is the site of primary oxidation. The compounds isolated in this study support this hypothesis since all possess an oxygen atom at C-8 and imply that C-11 is the site of secondary oxidation, followed by less specific oxidation at postitions C-5, C-12, and C-15. To date, the C-8 monohydroxy intermediate has not been isolated.

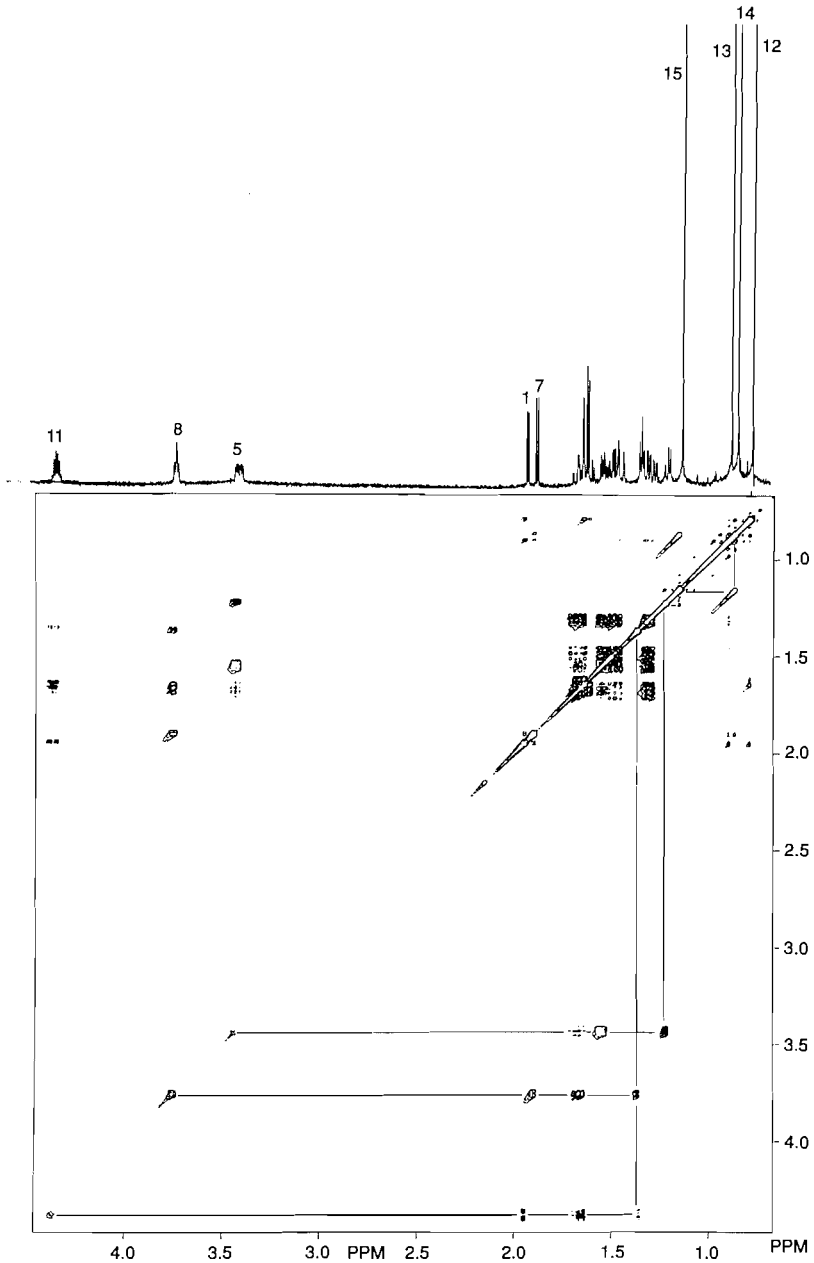

FIG. 3. $^1H/^1H$ correlation (COSY-45) spectrum of 5-OH culmorin (**8**) obtained in $CDCl_3$. A single pulse spectrum is shown as the projection.

Recent toxicological studies have shown that culmorin enhances the toxicity of DON in bioessays with caterpillars (18), and is currently under investigation with animal species. The synergistic effects of the hydroxyculmorin derivatives are also under investigation.

Experimental

Instrumentation

Gas chromatography (GC) was performed on a Varian Vista 5500 gas chromatograph coupled to a Finnigan ion trap (GC/ITD) operating with a split injector (10:1). Underivatized crude extracts were chromatographed on a DB-5 fused silica capillary column (20 m × 0.32 mm i.d., 0.25 μm film). The column temperature was programmed from 120 to 280°C at 20°C/min, holding for 12 min at the end of each run. Helium (10 psi; 1 psi = 6.89 kPa) was used as the carrier gas. The temperature of the detector was set at 300°C and that of the injector at 230°C. All data were acquired by an IBM PC using an Ion Trap Detection System (ITDS) software program. Gas chromatography – mass spectrometry (GC/MS) was performed on a Finnigan GC/MS system, model 4500, with a DS400 data system. High-resolution electron impact (HREI), fast atom bombardment (FAB), and chemical ionization (CI) mass spectrometry were performed on a Finnigan MAT 312 mass spectrometer. Mass spectra were calibrated against perfluorokerosene; the relative peak intensity (%) is indicated in parentheses.

Silica gel (Kieselgel 60, Merck) 70–230 and 230–400 mesh was used for normal and flash column chromatography, respectively. High-performance liquid chromatography (HPLC) was carried out on a Varian model 5500 equipped with a UV-200 variable wavelength detector set at 205 nm. Semi-preparative scale separations were done isocratically with CSC-S nitrile or silica columns using mixtures of isopropyl alcohol and hexane as mobile phases.

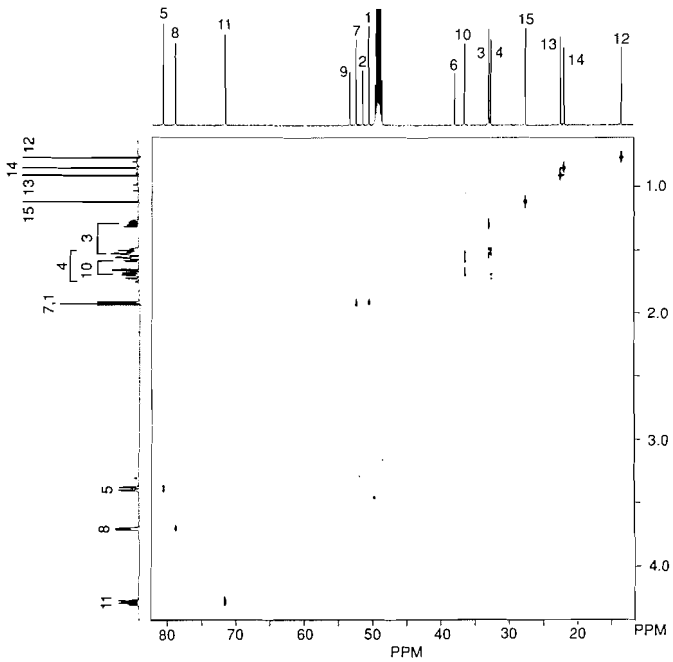

FIG. 4. $^1H/^{13}C$ correlation spectrum of 5-OH culmorin (**8**) obtained in CD_3OD. The projections constitute the single pulse spectra.

Melting points were obtained on a Fisher Johns melting point apparatus and are uncorrected. Optical rotations were determined on a Perkin–Elmer 241 polarimeter.

^1H and ^{13}C nuclear magnetic resonance (NMR) spectra were obtained on Bruker WM250 or AM500 NMR spectrometers in deuterochloroform ($CDCl_3$) or deuteromethanol (CD_3OD) using 5-mm dual probes. Chemical shifts were referenced to $CDCl_3$ at 7.24 ppm (^1H) and 77.00 ppm (^{13}C) or CD_3OD at 3.30 and 49.0 ppm relative to tetramethylsilane (TMS).

Typical spectra used a 32K data point set, 60° pulse, and 3–6 s recycle time. ^1H spectra were resolution enhanced. COSY spectra were run at 500 MHz and employed 512 FID's of 2K data points each, using a 90° pulse of 12 μs. The data matrix was processed using sine-bell squared functions shifted $\Pi/2$ in $F1$ and zero-filled for a final data resolution of 3 Hz per point. RELAY spectra were acquired similarly. $^1H/^{13}C$ HETCOR spectra and DEPT spectra were used to make unambiguous spectral assignments.

Fermentation, extraction, and isolation

Large-scale liquid fermentation of *Fusarium culmorum* CMI 14764 (HLX 1503) was carried out according to Greenhalgh *et al.* (14). The mycelia were separated from the broth by filtration and the broth was extracted successively with hexane and dichloromethane. The dichloromethane extract afforded the major trichothecene 3-ADON (**1**) by precipitation with ethanol. The mother liquors remaining after precipitation of 3-ADON were chromatographed on a silica gel column (75 × 12 cm, Kieselgel 60, Merck, 70–230 mesh, 3 kg). A sample (100 g) in dichloromethane (250 mL) was applied to the column, together with the dichloromethane rinses (2 × 50 mL). The column was eluted with dichloromethane, dichloromethane–methanol mixtures, and pure methanol to afford 23 fractions (Table 3). The fractions 1–9 contained phthalates as determined by GC/MS.

*Isolation of culmorin (**5**) and culmorone (**6**)*

These compounds were found in fractions 13–16. Fractions 15 and 16 (total 16 g) afforded pure culmorin (4 g) upon repeated crystallization from ethyl acetate. The physical (mp and $[\alpha]_D$) and spectral (MS and NMR) data of the sample were identical to those previously reported (14). The isolation of culmorone from *Fusarium roseum* (ATCC 28114) by us is reported elsewhere (14*b*). ^{13}C-enriched culmorin was prepared from a stirred-jar fermentor culture (10 L) of *F. culmorum* CMI 14764 according to Miller and Blackwell (10) and isolated as above.

*Isolation of 15-hydroxyculmorone (**7**)*

Fraction 14 (12 g, heavy oil) contained ADON, culmorin, 7,8-dihydrocalonectrin, and sambucinol, in addition to an unknown compound (**7**). This fraction was subjected to column chromatography on silica gel (4 × 35 cm) and eluted with chloroform (2 L) and methanol/chloroform mixtures, 2% (0.5 L), 5% (0.2 L), and 10% (0.5 L). The first two fractions (total 5 g) were combined and rechromatographed on a similar column, which was eluted isocratically with 40% ethyl acetate in hexane. Twenty-four fractions (100 mL) were collected. Recrystallization of the combined fractions 13–20 from ethyl acetate gave sambucinol (310 mg). The mother liquors were again chromatographed on silica gel (150 g, 3 cm i.d. column) and eluted with ethyl acetate in hexane (50%, 2 L) and (60%, 0.5 L), ethyl acetate (0.5 L), and methanol (0.5 L). The combined ethyl acetate and methanol fractions were evaporated to dryness and gave a white solid (718 mg), which crystallized from ethyl acetate as a white amorphous powder, mp 135–136°C; R_f 0.33 (10% hexane in ethyl acetate); $[\alpha]_D^{26}$ −4.2 (*c* 0.004 g/mL, $CHCl_3$); ^1H and ^{13}C NMR spectra, see Tables 1 and 2; HRMS, calcd. for $C_{15}H_{24}O_3$: 252.1726; found: *m/z* 252.1711 (19), 234 (100), 219 (47).

*Isolation of 5-hydroxyculmorin (**8**)*

Fraction 22 (620 mg, oil) was crystallized repeatedly from acetone to give compound **8** (450 mg) as colourless prisms; mp 210°C; R_f 0.22 (10% hexane in ethyl acetate); $[\alpha]_D^{26}$ +3.1 (*c* 0.01, MeOH); ^1H and ^{13}C NMR spectra, see Tables 1 and 2; HRMS, calcd. for $C_{15}H_{26}O_3$: 254.1883; found: *m/z* 254.1871 (3), 236 (100), 221 (47), 218 (78).

*Isolation of 15-hydroxyculmorin (**9**), cyclonerotriol (**4**), 9α-hydroxytrichotriol (**3**), and 12-hydroxyculmorin (**10**)*

Fraction 20 (5 g, yellowish oil) was crystallized from ethyl acetate – hexane and gave 15-hydroxyculmorin (**9**) (2 g); mp 161–163°C; R_f 0.10 (10% hexane in ethyl acetate) or 0.23 (10% methanol in chloroform); $[\alpha]_D^{26}$ −2.1 (*c* 0.01 g/mL, MeOH); ^1H and ^{13}C NMR spectra, see Tables 1 and 2; HRMS, calcd. for $C_{15}H_{26}O_3$: 254.1883; found: *m/z* 254.1898 (4), 236 (16), 218 (10), 206 (100).

The mother liquors from Fraction 20 (2 g) were fractionated by flash column chromatography (5 × 20 cm) and eluted with ethyl acetate. Eight fractions (A–H, 100 mL each) were collected.

Fraction D (174 mg) was rechromatographed on a silica gel column (2 × 25 cm) and eluted successively with 10% and 20% isopropyl alcohol in hexane (each 100 mL). The latter eluent gave a colourless oil (93 mg) that, after successive semipreparative HPLC separations on silica and CSC-S nitrile columns with 8% and 10% isopropyl alcohol/hexane, respectively, at 2 mL/min, gave cyclonerotriol (**4**) as a colourless solid (20 mg). This solid crystallized from chloroform as colourless prisms, mp 111.5–112.5°C; R_f 0.31 (10% hexane/ethyl acetate); $[\alpha]_D^{26}$ −20.0 (*c* 0.001 g/mL, MeOH); IR ν_{max}: 3381 cm^{-1} (hydroxyl); ^1H NMR ($CDCl_3$, 500 MHz) δ: 5.40 (t, 7.22, H-10), 3.98 (s, 2H-12), 2.10 (m, 2H-9), 1.85 (m, H-6 and H-5), 1.66 (m, H-4), 1.66 (s, 3H-15), 1.60–1.53 (m, H-2, H-4, H-5), 1.50 (t, 8.33, 2H-8), 1.24 (s, 3H-14), 1.16 (s, 3H-13), 1.03 (d, 6.78, 3H-1); ^{13}C NMR ($CDCl_3$, 125 MHz) δ: 134.9 (C-11), 126.1 (C-10), 81.3 (C-3), 74.8 (C-7), 68.7 (C-12), 54.3 (C-6), 44.3 (C-2), 40.3 (C-4), 40.1 (C-8), 26.0 (C-13), 25.3 (C-14), 25.0 (C-5), 24.3 (C-9), 14.5 (C-1), 13.6 (C-15). The ^1H and ^{13}C NMR assignments are based on COSY and HETCOR spectra and are similar to those reported by Hanson *et al.* (9). We have, however, revised the assignments for C-5, C-13, and C-14. HRMS, calcd. for $C_{15}H_{26}O_2$: 238.1934 (M − H_2O); found: 238.1945 (3), 223 (15), 220 (6), 205 (23), 139 (22), 125 (50), 107 (17), 95 (17), 81 (28).

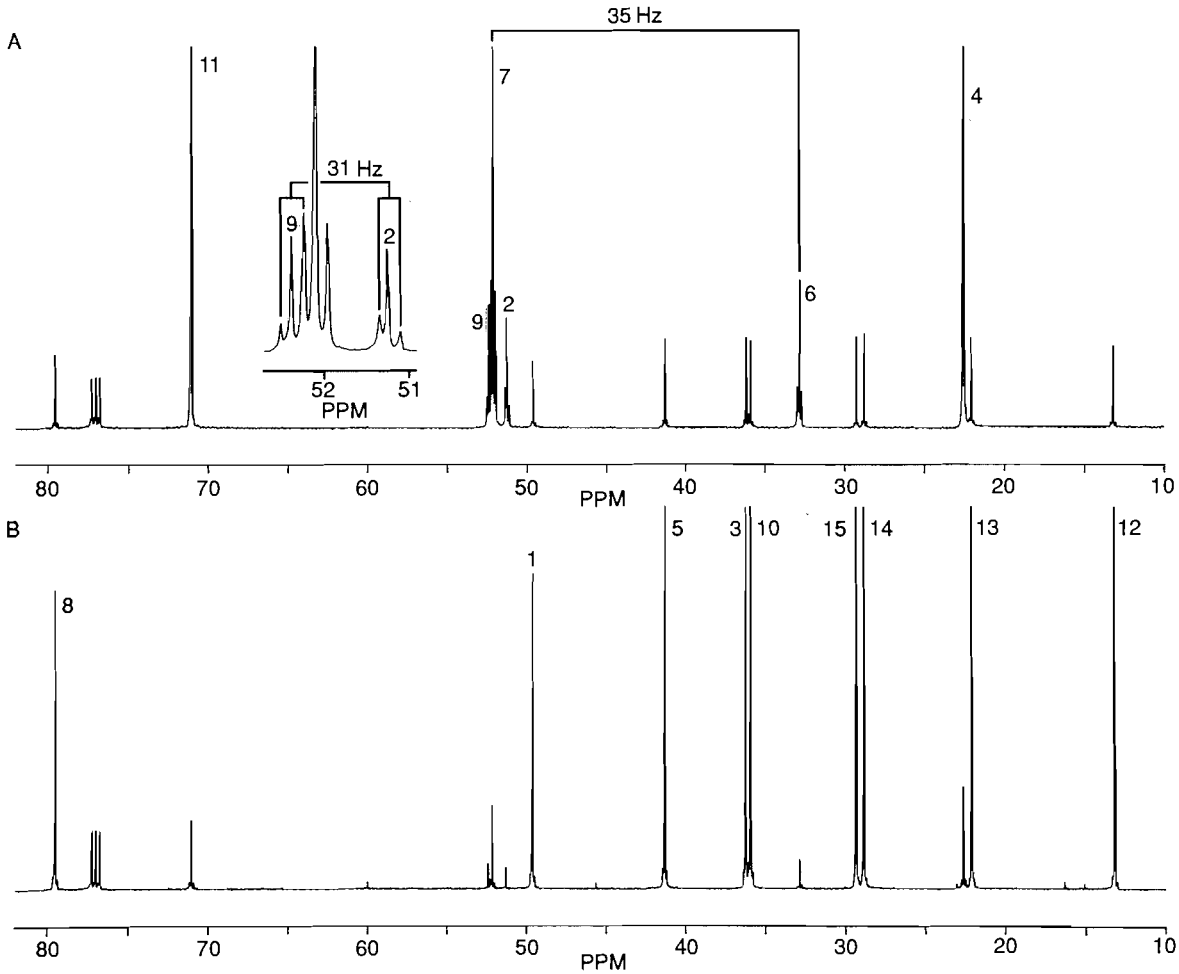

FIG. 5. 125 MHz ^{13}C NMR spectra of culmorin derived from (A) [^{13}C-1]-acetate, and (B) [^{13}C-2)]-acetate. The resonances that are enriched are assigned in each spectrum. The inset of spectrum (A) shows the ^{13}C–^{13}C coupling that occurs between C-2/C-9 and C-6/C-7 as a result of the folding pattern of farnesyl pyrophosphate.

A portion of Fraction F (54 mg) was rechromatographed by semi-preparative HPLC on CSC-S nitrile column using 15% isopropyl alcohol/hexane as eluent at flow rate of 2 mL/min. A colourless solid (26 mg, r.t. 20 min) which had the same MS and NMR spectra as an authentic sample of 9α-hydroxytrichotriol, was obtained. R_f 0.17 (10% hexane/ethyl acetate); ^1H NMR ($CDCl_3$, 500 MHz) δ: 5.69 (brd, 10.11, H-10), 5.51 (d, 10.11, H-11), 4.21 (App.q, 5.53, H-3), 3.64 (d, 4.47, H-2), 3.50 (d, 3.95, H-13), 2.97 (d, 3.95, H-13), 2.08 (dd, 13.3, 8.04, H-4), 1.79 (m, H-7), 1.71 (dd, 13.3, 6.35, H-4), 1.65 (m, H-7 and H-8), 1.30 (brd, 13.72, H-8), 1.24 (s, 3H-16), 1.05 (s, 3H-14), 0.87 (s, 3H-15); ^{13}C NMR ($CDCl_3$, 125 MHz) δ: 136.2 (C-10), 131.3 (C-11), 77.5 (C-2), 69.3 (C-12), 69.0 (C-3), 65.5 (C-9), 50.0 (C-13), 43.7 (C-5), 41.8 (C-4), 39.4 (C-6), 33.8 (C-8), 30.7 (C-16), 25.8 (C-7), 21.2 (C-15), 20.4 (C-14).

HPLC chromatography of a larger sample of Fraction F (428 mg) gave 8 fractions (F1–F8). Fraction F2 (101 mg), eluting 13–15 min before trichotriol, was rechromatographed using 5% isopropyl alcohol/hexane as mobile phase at a flow rate of 4 mL/min, and it gave 5 fractions (F2a–F2f). Fraction F2d (21 mg) containing 15-hydroxyculmorin (**9**) and 12-hydroxyculmorin (**10**) was subjected to preparative thin-layer chromatography (silica gel 150Å PLK5, Whatman) and developed three times in 10% methanol/chloroform. The higher R_f band was extracted with methanol–chloroform and gave 12-hydroxyculmorin (**10**) (7 mg, colourless solid), R_f 0.10 (10% hexane/ethyl acetate) or 0.38 (10% methanol in chloroform); ^1H and ^{13}C NMR spectra, see Tables 1 and 2; HRMS, calcd. for $C_{15}H_{26}O_3$: 254.1883; found: 254.1877 (0.15), 236 (6), 218 (100).

2,2-Dimethylsuccinic acid derivatives in isoprenoid synthesis: a 2,2-dimethylvinyl anion equivalent in the synthesis of *ar*-atlantone, *ar*-turmerone, and prenylated aromatic compounds

GEORGE M. STRUNZ[1] AND LI YA

Forestry Canada – Maritimes Region, P.O. Box 4000, Fredericton, N.B., Canada E3B 5P7

Received July 29, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

GEORGE M. STRUNZ and LI YA. Can. J. Chem. **70**, 1317 (1992).

The anion of methyl 2,2-dimethylsuccinate was alkylated with benzylic bromides to give the corresponding 3-substituted-2,2-dimethylsuccinates. Hydrolysis to the dicarboxylic acids, followed by bisdecarboxylation with lead tetraacetate, afforded 1-aryl-3-methyl-2-butenes, which are model prenylated aromatic compounds. Acylation of methyl 2,2-dimethylsuccinate with *E*-3-(4′-methylphenyl) crotonyl chloride gave the substituted succinate **9**. Hydrolysis of the ester groups and acid-catalyzed decarboxylation of the resulting β-ketoacid produced the keto acid **10**, which was decarboxylated by the Kochi method, furnishing *ar*-atlantone. Hydrogenation of **10** yielded **12**, which on similar decarboxylation afforded *ar*-turmerone.

GEORGE M. STRUNZ et LI YA. Can. J. Chem. **70**, 1317 (1992).

On a procédé à l'alkylation de l'anion du 2,2-diméthylsuccinate de méthyle par des bromures benzyliques pour obtenir les 2,2-diméthylsuccinates correspondants, substitués en position 3. Leur hydrolyse en acides dicarboxyliques, suivie d'une bisdécarboxylation à l'aide du tétraacétate de plomb, conduit aux 1-aryl-3-méthylbut-2-ènes qui sont des modèles de composés aromatiques prénylés. L'acylation du 2,2-diméthylsuccinate de méthyle par le chlorure de *E*-3-(4′-méthylphényl) crotonyle conduit au succinate substitué **9**. L'hydrolyse des groupes esters et la décarboxylation acido-catalysée du β-céto-acide qui en résulte fournit l'acide cétonique **10** qui, par décarboxylation par la méthode de Kochi, mène à la *ar*-atlantone. L'hydrogénation du produit **10** fournit le produit **12** qui, par une décarboxylation semblable, livre la *ar*-turmérone.

Derivatives of 2,2-dimethylsuccinic acid have the potential for the synthesis of certain isoprenoids that has not, to our knowledge, been exploited hitherto. Thus, anions of 2,2-dimethylsuccinate esters can be alkylated or acylated to give products that, upon hydrolysis, afford 3-substituted-2,2-dimethylsuccinic acids. The latter can be decarboxylated to produce compounds having the dimethylvinyl group characteristic of many isoprenoid natural products (Scheme 1). Used in this manner, a 2,2-dimethylsuccinate ester is a masked 2,2-dimethylvinyl anion equivalent that may, in some situations, prove a useful alternative to 2-methyl-1-propenyl Grignard or cuprate reagents (1) (cf. the methallyl dithiocarbamate of Nakai *et al.* (2)). Whereas a 3-halo derivative of the same ester, **2** (R′ = hal), possesses the reverse polarity at C-3 and might, in principle, constitute a masked *electrophilic* 2,2-dimethylvinyl equivalent, steric hindrance prevents such halo-esters from being useful general alkylating agents. (The anhydride of 2,2-dimethylsuccinic acid may, however, be considered as a possible masked senecioyl (3-methyl-2-butenoyl) equivalent.)

In this paper we report some examples of syntheses using the methodology summarized in Scheme 1. Alkylation and acylation of dimethyl 2,2-dimethylsuccinate were employed in the synthesis, respectively, of the model prenylated aromatic compounds, 1-phenyl-3-methyl-2-butene, **3** (R′ = $PhCH_2$) (2, 3) and 1-(2′-methoxyphenyl)-3-methyl-2-butene, **3** (R′ = *o*-$MeOPhCH_2$) (4), and the isoprenoids *ar*-atlantone, **11** (5), and racemic *ar*-turmerone, **13** (6). The latter, with *S*-configuration, is found in the essential oil from rhizomes of turmeric, *Curcuma longa* Linn. (6); the former, though not yet reported as a natural product, is an aromatic derivative of *E*-α-atlantone, a constituent of *Cedrus deodara* (7).

The enone carboxylic acid, **10**, serves as a common intermediate for the synthesis of both isoprenoids. In the synthesis of *ar*-turmerone, the presence of the carboxyl group allows the ready introduction of a new double bond in the desired position after hydrogenation of **10**.

1-Phenyl-3-methyl-2-butene, **3** *(R′ = $PhCH_2$): (Scheme 1)*

The anion of dimethyl 2,2-dimethylsuccinate, prepared by treatment of the ester with a slight excess of lithium diisopropylamide (LDA), was alkylated with benzyl bromide to produce **2** (R = CH_3, R′ = $PhCH_2$) in 89% yield. Alkaline hydrolysis afforded an 87% yield of the trisubstituted succinic acid **2** (R = H, R′ = $PhCH_2$) and the latter was bisdecarboxylated by treatment with lead tetraacetate (8), affording the target prenylated benzene **3** (R′ = $PhCH_2$) (3) in 68% yield.

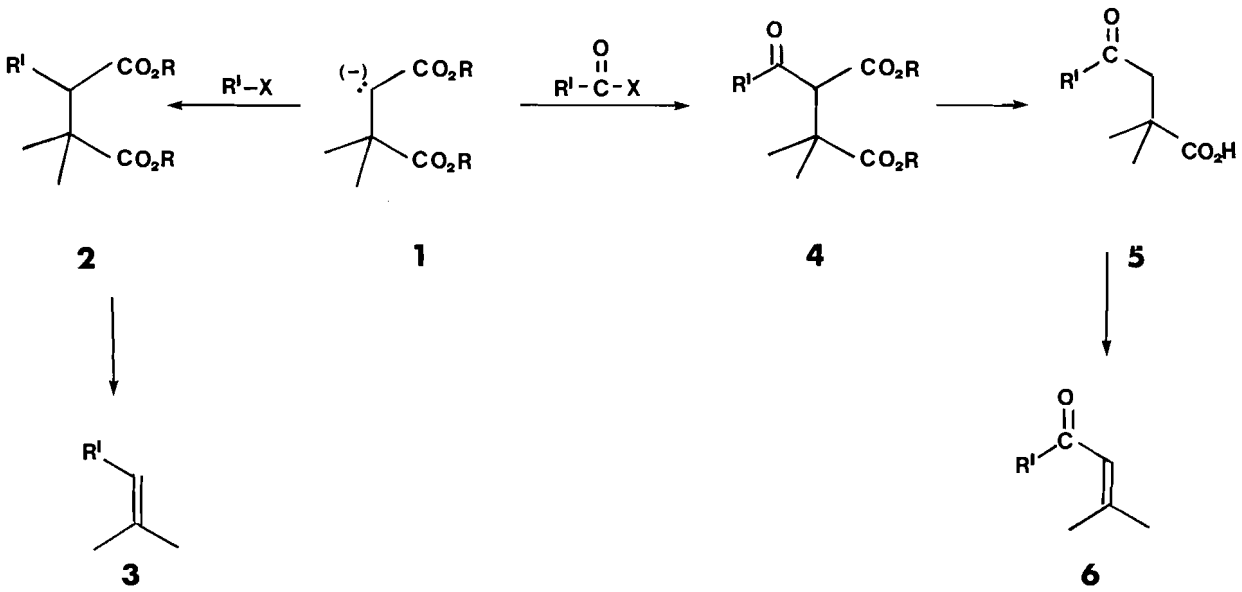
1-(2′-Methoxyphenyl)-3-methyl-2-butene,
3 *(R′ = o-$MeOPhCH_2$) (Scheme 1)*

The anion of dimethyl 2,2-dimethylsuccinate was alkylated as above using 2-methoxybenzyl bromide, prepared by bromination of 2-methylanisole with *N*-bromosuccinimide. The product **2** (R = CH_3, R′ = *o*-$MeOPhCH_2$), obtained in 81% yield, was hydrolyzed, then bisdecarboxylated with lead tetraacetate (8), furnishing **3** (R′ = *o*-$MeOPhCH_2$)(4) in an overall yield of 40% from the halide.

ar-Atlantone, **11** *(Scheme 2)*

3-(4′-Methylphenyl) crotonic acid ethyl ester, **7** (R = C_2H_5) was prepared as a mixture of *E* and *Z* isomers (9:1) from 4-methylacetophenone and triethyl phosphonoacetate according to Wadsworth and Emmons (9). The predominant *E* isomer, **7** (R = C_2H_5), could be separated by chro-

[1]Author to whom correspondence may be addressed.



SCHEME 1

matography, and the corresponding acid **7** (R = H) was transformed into the acid chloride **8**. Acylation of the anion of dimethyl 2,2-dimethylsuccinate with this acid chloride afforded **9** in 44% yield. A by-product, isolated in yields of around 41%, was the amide derived from reaction of **8** with diisopropylamine. The amine, produced during proton abstraction from 2,2-dimethylsuccinate by LDA, evidently competes significantly as a nucleophile with the sterically encumbered anion **1** (R = CH_3). Attempts to avoid or suppress this competitive reaction, using as base potassium hydride or the lithium amide from 2,2,6,6-tetramethylpiperidine (which releases a more hindered amine) were not fruitful. As the amide by-product may be hydrolyzed back to **7** (R = H) and thus recycled, this side reaction, although undesirable, is not a major obstacle. (The yield for the conversion of **8** to **9**, based on consumed acid chloride not converted to amide, was 74%.)

Base-catalyzed hydrolysis of **9** and subsequent decarboxylation of the resulting β-keto acid under acidic conditions produced an 86% yield of **10**, which was decarboxylated by the Kochi method (10), furnishing *ar*-atlantone, **11**, with spectroscopic properties in accord with literature data (5). The yield for the transformation of **10** to **11** was 58%.

ar-Turmerone, **13** *(Scheme 2)*

Compound **10**, possessing a latent dimethylvinyl group, can serve as a common intermediate for the synthesis of both *ar*-atlantone, **11**, and *ar*-turmerone, **13**. Thus, hydrogenation of **10** produced **12** quantitatively, and decarboxylation with lead tetraacetate (10) afforded a 68% yield of enone isomers, convertible in quantitative yield under acid catalysis to racemic *ar*-turmerone, **13**, whose spectroscopic characteristics were in accord with published data (6).

Further studies illustrating the utility of 2,2-dimethylsuccinate as a dimethylvinyl synthon in isoprenoid synthesis are in progress and will be reported in the future.

Experimental

Melting points were determined on a hot-stage apparatus and are uncorrected. Infrared spectra were recorded on a Philips Pye Unicam PU 9516 infrared spectrophotometer, and ultraviolet spectra on a Philips PU 8800 uv/vis spectrophotometer. Proton and carbon magnetic resonance spectra were run on a Varian XL-200 instrument, operating at frequencies of 200.068 and 50.308 MHz, respectively. Accurate mass measurements were made on a Kratos MS-50 instrument. Microanalyses were performed by Spang Microanalytical Laboratory, Eagle Harbor, Michigan.

Dimethyl 2,2-dimethylsuccinate

A solution of 2,2-dimethylsuccinic acid (4.0 g; 27.4 mmol) in dry methanol (50 mL) containing concentrated sulfuric acid (15 drops) was heated at reflux under anhydrous conditions. After 5 h, the solution was concentrated to near dryness on a rotary vacuum evaporator. The oily residue was redissolved in ethyl acetate and the solution was washed successively with saturated $NaHCO_3$ and brine before being dried over anhydrous $MgSO_4$. The solvent was removed under reduced pressure, affording a quantitative yield of dimethyl 2,2-dimethylsuccinate as a colorless oil that was sufficiently pure to be used directly in subsequent operations without further purification; ir ($CHCl_3$) (inter alia): 2960, 1735, 1180, 1150, and 1140 cm^{-1}, ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.27 (6H, s) 2.60 (2H, s), 3.66 (3H, s), 3.70 (3H, s); mass spectrum (inter alia), *m/e* (relative intensity) (ion): 174 (1.5) ($C_8H_{14}O_4$; M^+), 143 (37) $(M - OCH_3)^+$, 115 (51) $(M - CO_2CH_3)^+$, 101 (22) $(M - CH_2CO_2CH_3)^+$, 73 (100) $(CH_2CO_2CH_3)^+$.

Dimethyl 2,2-dimethyl-3-benzylsuccinate, **2** *(R = CH_3, R′ = Ph CH_2)*

To a solution of dry diisopropylamine (1.11 g; 11 mmol) in anhydrous THF (10 mL) at −78°C under argon was added *n*-butyllithium (4.4 mL of 2.5 M solution; 11 mmol) dropwise. The resulting yellow solution was stirred at −78°C for 30 min. A solution of dimethyl 2,2-dimethylsuccinate (1.74 g: 10 mmol) in anhydrous THF (ca. 3 mL) was added slowly with stirring to the lithium diisopropylamide (LDA) solution, and the reaction mixture was stirred at −78°C under argon for 1 h. (At this stage virtually complete conversion to the anion was demonstrated by removal of a small aliquot, which was quenched with D_2O.) To the anion solution was added a solution of benzyl bromide (1.71 g; 10 mmol) in dry THF (2.0 mL). The reaction mixture was allowed to attain ambient temperature during 2 h with stirring. A 10% aqueous HCl solution (10 mL) was then added, and the mixture was extracted with ether (15 mL). The aqueous phase was re-extracted with 2 × 20 mL ether, and the combined extracts were washed

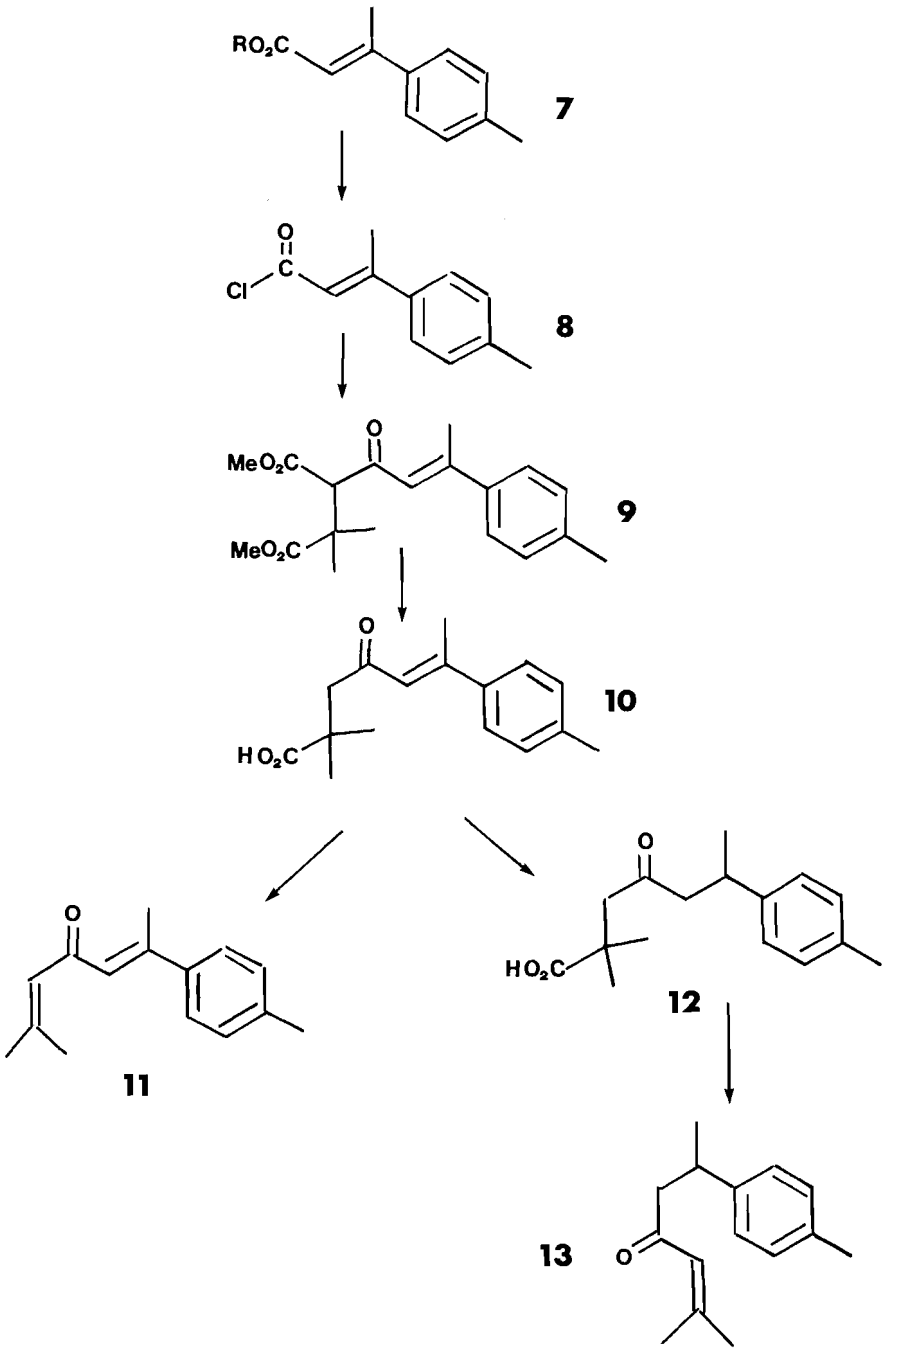

SCHEME 2

successively with saturated solutions of $NaHCO_3$ and brine. After drying over anhydrous $MgSO_4$, the solution was evaporated on a rotary vacuum evaporator. The crude product (3.07 g) was purified by flash chromatography (11) on a silica gel column, using hexane – ethyl acetate (1:0, 4:1) as eluent. The desired product **2** (R = CH_3, R′ = $PhCH_2$) (2.36 g; 89.4%) was an almost colorless oil; ir ($CHCl_3$) (inter alia): 2960, 1730 cm^{-1}, ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.26 (3H, s), 1.34 (3H, s), 2.63–3.17 (3H, m), 3.51 (3H, s), 3.71 (3 H, s), 7.12–7.26 (5H, m); hrms (inter alia), *m/e* (relative intensity) (ion): 264.1340 (6.3) ($M^{\ddagger}$) (calcd. for $C_{15}H_{20}O_4$: 264.1362), 163.0754 (100) ($M - (CH_3)_2CCO_2CH_3)^+$ (calcd. for $C_{10}H_{11}O_2$: 163.0759), 91.0547 (74) $(C_7H_7)^+$ (calcd. for C_7H_7: 91.0548). Anal. calcd. for $C_{15}H_{20}O_4$: C 68.16, H 7.63%; found: C 68.18, H7.77%.

2,2-Dimethyl-3-benzylsuccinic acid: **2** *(R = H, R′ = $PhCH_2$)*

The ester (2.36 g; 8.9 mmol) was hydrolyzed by refluxing for 20 h in aqueous methanol (60 mL) (H_2O:MeOH, 2:1) containing sodium hydroxide (2 g). Most of the methanol was removed under reduced pressure, and addition of 20% aqueous HCl solution to the residue resulted in the separation of a white precipitate. The mixture was extracted with 4 × 50 mL ether and the combined extracts were washed with brine, dried over Na_2SO_4, and evaporated to dryness to yield 1.84 g (87%) of crystalline **2** (R = H, R′ = $PhCH_2$). A sample, recrystallized from aqueous methanol, melted at 140–143°C; ir ($CHCl_3$) (inter alia); 3680–2400, 1710, and 1600 cm^{-1}; ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.35 (6H, s), 2.82–3.17 (3H, m), 7.17–7.30 (5H, m); hrms (inter alia), *m/e* (relative intensity) (ion): 236.1028 (2.7) ($M^{\ddagger}$) (calcd. for $C_{13}H_{16}O_4$: 236.1049),

218.0934 (45) $(M - H_2O)^+$ (calcd. for $C_{13}H_{14}O_3$: 218.0943), 149.0611 (23) $(M - (CH_3)_2CCO_2H)^+$ (calcd. for $C_9H_9O_2$: 149.0603) 91.0541 (100) $(C_7H_7)^+$ (calcd. for C_7H_7: 91.0548).

1-Phenyl-3-methyl-2-butene **3** *(R′ = $PhCH_2$)*

A stream of oxygen was passed through dry pyridine (7.0 mL) for 15 min. The trisubstituted succinic acid, **2** (R = H, R′ = $PhCH_2$) (0.5 g, 2.1 mmol), and lead tetraacetate (1.86 g, 4.2 mmol) were added with stirring and the flask was immersed in an oil bath at 75°C. When evolution of carbon dioxide ceased, the mixture was cooled, poured into excess dilute nitric acid, and extracted with 4 × 30 mL ether. The extracts were washed successively with saturated $NaHCO_3$ solution and brine. After drying over $MgSO_4$, removal of solvent *in vacuo* afforded an oily product (0.316 g). Flash chromatography on a column of silica gel with hexane – ethyl acetate (1:0, 9.5:0.5, 9:1) as eluent, yielded the pure olefin **3** (R′ = $PhCH_2$) as an almost colorless oil (0.21 g; 68%); ir ($CHCl_3$) (inter alia): 2925, 1603, 1500, 1455, and 1380 cm^{-1}; ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.72 (3H, s), 1.75 (3H, d, $J \sim 1.3$ Hz), 3.34 (2H, br d, $J \sim 7.4$ Hz), 5.29–5.37 (1H, m), 7.13–7.33 (5H, m); mass spectrum, *m/e*: 146 $(M)^+$ $(C_{11}H_{14})$.

Dimethyl 2,2-dimethyl-3-(o-methoxybenzyl) succinate, **2** *(R = CH_3, R′ = o MeOPhCH$_2$)*

The ester **1** (R = CH_3) was alkylated with 2-methoxybenzyl bromide, essentially as described above, to give **2** (R = CH_3, R′ = *o*-MeOPhCH_2) in 81% yield: ir ($CHCl_3$) (inter alia): 2960, 1730, 1603, and 1590 cm^{-1}; ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.27(3H, s), 1.35 (3H, s), 2.81–3.16 (3H, m), 3.50 (3H, s), 3.69 (3H, s), 3.81 (3H, s), 6.79–7.22 (4H, m); hrms (inter alia) *m/e* (relative intensity) (ion): 294.1428 (9.4) (M^+) (calcd. for $C_{16}H_{22}O_5$: 294.1467), 263.1308 (77) $(M - OCH_3)^+$ (calcd. for $C_{15}H_{19}O_4$: 263.1283), 193.0854 (76) $(M - C_5H_9O_2)^+$ (calcd. for $C_{11}H_{13}O_3$: 193.0865), 161.0602 (100) $(o\text{-MeOPh-CH=CH-C}{\equiv}O)^+$ (calcd. for $C_{10}H_9O_2$ 161.0603), 121.0655 (51) $(C_8H_9O)^+$ (calcd. 121.0653), 102.0672 (22) $(C_5H_9O_2H)^+$ (calcd. 102.0681), 91,0553 (42) $(C_7H_7)^+$ (calcd. for C_7H_7: 91.0568). Anal. calcd. for $C_{16}H_{22}O_5$: C 65.29, H 7.54%; found: C 65.32, H 7.59%.

2,2-Dimethyl-3-(o-methoxybenzyl) succinic acid, **2** *(R = H R′ = o MeOPhCH$_2$)*

Hydrolysis of dimethyl 2,2-dimethyl-3-(*o*-methoxybenzyl) succinate, **2** (R = CH_3, R′ = *o*-MeOPhCH_2), as described above, afforded the corresponding trisubstituted succinic acid in 80% yield: ir ($CHCl_3$) (inter alia): ~3000 (br), 1720, and 1600 cm^{-1}; ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.20 (3H, s), 1.21 (3H, s), 2.69–2.99 (3H, m), 3.72 (3H, s), 6.67–7.07 (4H, m); hrms (inter alia), *m/e* (relative intensity) (ion): 266.1101 (3.9) (M^+) (calcd. for $C_{14}H_{18}O_5$ 266.1154), 248.1044 (49) $(M - H_2O)^+$ (calcd. for $C_{14}H_{16}O_4$: 248.1049), 178.0629 (22) $(o\text{-MeOPh-CH=CHCO}_2H)^+$ (calcd. for $C_{10}H_{10}O_3$ = 178.0630), 161.0738 (69) $(o\text{-MeOPh-CH=CH-C}{\equiv}O)^+$ (calcd. for $C_{10}H_9O_2$ 161.0603), 121.0656 (100) $(C_8H_9O)^+$ (calcd. 121.0653).

1-(o-Methoxyphenyl)-3-methyl-2-butene, **3** *(R′ = o-MeOPhCH$_2$)*

The trisubstituted succinic acid (0.50 g; 1.88 mmol) in dry oxygenated pyridine (8.0 mL) was decarboxylated through the agency of lead tetraacetate (1.75 g; 3.95 mmol) as described above. The yield of pure olefin, **3**(R′ = *o*-MeOPhCH_2), after chromatography was 61%; ir ($CHCl_3$), (inter alia): 2925, 1600, 1590, and 1495 cm^{-1}; ^1H nmr ($CDCl_3$, 200 Mz) δ: 1.71 (3H, s), 1.73 (3H, d, $J \sim 1$ Hz), 3.32 (2H, br d, $J \sim 7.4$ Hz), 3.83 (3H, s), 5.26–5.35 (1H, m), 6.82–7.21 (4H, m); mass spectrum (inter alia), *m/e* (relative intensity) (ion): 176 (75) (M^+) $(C_{12}H_{16}O)^+$, 161 (100) $(M - CH_3)^+$ $(C_{11}H_{13}O)^+$, 121 (30) $(C_8H_9O)^+$.

Ethyl E-3-(4′-methylphenyl) crotonate, **7** *(R = C_2H_5)*

Sodium hydride (2.0 g, 60% suspension in mineral oil; 1.2 g; 0.05 mol) was washed free of oil with 3 × 5 mL pentane. After addition of dry dimethoxyethane (100 mL), triethyl phosphonoacetate (11.21 g; 0.05 mol) was introduced dropwise with stirring. The mixture was stirred for 1 h, when evolution of hydrogen ceased. The temperature was maintained below 25°C while 4-methylacetophenone (6.71 g; 0.05 mol) was added dropwise to the yellow solution. The mixture was set aside with stirring at ambient temperature for ca. 8 h, when a gummy precipitate was observed to have separated. Water (300 mL) was added and the mixture was extracted with 4 × 50 mL ether. The combined extracts were dried over anhydrous $MgSO_4$, and removal of solvent *in vacuo* afforded an oily residue (10.31 g). The nmr spectrum of the crude product revealed the presence of two isomers (*vide infra*) in the approximate ratio 9:1. These were separated by flash chromatography on a column of silica gel, using hexane – ethyl acetate (10:0, 9.5:0.5, 9:1) as eluent. The total yield of combined *E* and *Z* isomers was 67%. The major, *E*, isomer, **7** (R = C_2H_5) was an almost colorless oil, ir ($CHCl_3$) (inter alia): 1708, 1630, and 1170 cm^{-1}; uv λ_{max} (EtOH): 273 nm (ε 16 700); ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.32 (3H, t, $J = 7.2$ Hz), 2.37 (3H, s), 2.56 (3H, s), 4.21 (2H, q, $J = 7.2$ Hz), 6.13 (1H, s), 7.28 (4H, approx. ABq, $J_{AB} = 8.2$ Hz, $\Delta\nu_{AB} = 42.4$ Hz); ^{13}C nmr ($CDCl_3$) δ: 14.3 (q), 17.8 (q), 21.2 (q), 59.8 (t), 116.3 (d), 126.2 (d), 129.2 (d), 139.1 (s), 139.2 (s), 155.4 (s), 167.0 (s); hrms (inter alia), *m/e* (relative intensity) (ion): 204.1159 (82) (M^+) (calcd. for $C_{13}H_{16}O_2$: 204.1150), 159.0811 (100) $(M - OC_2H_5)^+$ (calcd. for $C_{11}H_{11}O$): 159.0810), 91.0546 (22) $(C_7H_7)^+$ (calcd. 91.0548).

The presence of the minor, *Z*, isomer in the crude reaction product was manifested in the ^1H nmr spectrum by the following signals: δ 1.12 (t), 2.16 (d, $J \sim 1.4$ Hz), 2.35 (s), 4.02 (q, $J \sim 7.1$ Hz), 5.88 (d, $J \sim 1.4$ Hz). A pure sample of the *Z* isomer showed uv λ_{max} (EtOH): 253 (ε 6420).

E-3-(4′-Methylphenyl) crotonyl chloride, **8**

The ester, **7** (R = C_2H_5) (2.9 g, 0.014 mol) was hydrolyzed by refluxing for ca. 8 h in a water–methanol mixture (2:1) (45 mL) containing sodium hydroxide (2 g). After most of the methanol was removed *in vacuo*, the mixture was made acidic by addition of concentrated HCl solution. The resulting mixture was extracted with 4 × 50 mL ether, and the extracts washed with brine, dried over anhydrous Na_2SO_4, and evaporated to yield 2.45 g (98%) of crystalline acid, **7** (R = H), mp 113–125°C; ir ($CHCl_3$) (inter alia): 3525–2400, 1690, and 1625 cm^{-1}; ^1H nmr ($CDCl_3$, 200 MHz) δ: 2.38 (3H, s), 2.59 (3H, d, $J = 1.2$ Hz), 6.17 (1H, apparent d, $J = 1.3$ Hz), 7.33 (4H, approx. ABq, $J_{AB} = 8.3$ Hz, $\Delta\nu_{AB}$ 34.8 Hz).

The acid, **7** (R = H) was dissolved in 95% ethanol (30 mL) and converted to its sodium salt by addition of an equimolar quantity of aqueous sodium hydroxide solution. The solvent was removed *in vacuo*, and the solid residue was powdered and dried to constant weight (2.69 g) under high vacuum. The powdered sodium salt (2.61 g, 13.2 mmol) was suspended in dry benzene (10.0 mL) containing five drops of dry pyridine. Oxalyl chloride (3.0 mL, 4.37 g, 34.4 mmol) was introduced gradually with stirring and ice-cooling. After the vigorous reaction had subsided, the mixture was allowed to attain ambient temperature and was stirred for an additional 3 h. Solid salt(s) were removed by filtration, and evaporation of the filtrate afforded 2.38 g (93%) of yellow oily product: ir ($CHCl_3$) (inter alia): 1798, 1770 cm^{-1}; ^1H nmr ($CDCl_3$, 200 MHz) δ: 2.39 (3H, s), 2.54 (3H, d, $J = 1.1$ Hz), 6.46 (1H, apparent d, $J = 1.1$ Hz), 7.33 (4H, approx. ABq, $J_{AB} = 8.2$ Hz, $\Delta\nu_{AB} = 42$ Hz).

Dimethyl 2,2-dimethyl-3-acylsuccinate, **9**

Dimethyl 2,2-dimethyl succinate (1.62 g, 9.3 mmol) in anhydrous THF (15 mL) was converted to its anion by treatment with LDA (9.2 mmol) as described above. The anion solution was introduced slowly with stirring at −78°C under argon to a solution of the acid chloride (1.8 g; 9.2 mmol) in dry THF (5.0 mL). The reaction mixture was set aside with stirring at −78°C for 4 h. Dilute HCl solution was then added and the mixture was extracted with ether (20 mL), and then with 3 × 50 mL ether. The combined extracts were washed successively with saturated $NaHCO_3$ and brine,

For personal use only.

dried over $MgSO_4$, and evaporated *in vacuo* to yield 3.56 g of yellow amorphous residue. Flash chromatography on a silica gel column afforded the dimethyl 2,2-dimethyl-3-acylsuccinate, **9** (1.34 g; 44%); ir ($CHCl_3$) (inter alia): 2960, 1732, 1682, 1595, 1560, 1510, and 1437 cm^{-1}; ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.37 (3H, s), 1.38 (3H, s), 2.38 (3H, s), 2.53 (3H, d, J = 1.2 Hz), 4.14 (1H, s), 6.47 (1H, apparent d, J = 1.2 Hz), 3.70 (3H, s), 3.73 (3H, s), 7.29 (4H, approx. ABq, J_{AB} = 8.3 Hz, $\Delta\nu_{AB}$ = 37.8 Hz); hrms (inter alia), *m/e* (relative intensity) (ion): 332.1600 (2.1) (M^+) (calcd. for $C_{19}H_{24}O_5$: 323.1624), 159.0793 (100) (*p*-MePhC(CH_3)CHC≡O^+) (calcd. for $C_{11}H_{11}O$: 159.0810). Anal. calcd. for $C_{19}H_{24}O_5$: C 68.65, H, 7.28%; found: C 68.75, H 7.14%.

A by-product (980 mg: 41%), the amide resulting from reaction of the acid chloride, **8**, with diisopropylamine, was also obtained from the chromatographic fractionation: ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.18 (6H, d, J = 6.7 Hz), 1.47 (6H, d, J = 6.7 Hz), 2.20 (3H, s), 2.36 (3H, s), 3.5–3.75 (1H, m), 4.05–4.2 (1H, m), 6.24 (1H, s), 7.26 (4H, approx. ABq, J_{AB} = 8.0 Hz, $\Delta\nu_{AB}$ = 39.8 Hz).

Ketoacid **10**

A solution of acylated succinic ester, **9** (1.0 g; 3.01 mmol) in methanol–water (1:2) (30 mL) containing sodium hydroxide (2.0 g) was heated under reflux for 3 h. Most of the methanol was removed *in vacuo*, and the aqueous phase was made acidic by addition of 20% HCl, resulting in separation of a white precipitate. The suspension was warmed on a water bath at 40°C. When evolution of carbon dioxide ceased, the mixture was extracted with 4 × 30 mL ether. The combined extracts were washed with brine, dried over anhydrous Na_2SO_4, and evaporated *in vacuo*, yielding 670 mg (86%) of crystalline product: ir ($CHCl_3$) (inter alia): 3525–2400, 1710, 1600, 1565, 1510, 1095, and 915 cm^{-1}; ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.29 (3H, s), 1.31 (3H, s), 2.38 (3H, s), 2.54 (3H, s), 2.90 (2H, s), 6.43 (1H, s), 7.29 (4H, approx. ABq, J_{AB} = 7.9 Hz, $\Delta\nu_{AB}$ = 40 Hz); hrms (inter alia), *m/e* (relative intensity) (ion): 260.1406 (14.2) (M^+) (calcd. for $C_{16}H_{20}O_3$: 260.1412), 245.1192 (11) ($M - CH_3$)$^+$ (calcd. for $C_{15}H_{17}O_3$: 245.1178), 159.0805 (*p*-MePhC(CH_3)CHC ≡ O^+) (calcd. for $C_{11}H_{11}O$: 159.0810).

ar-*Atlantone*, **11**

To the green solution that resulted from dissolving the keto acid **10** (380 mg; 1.46 mmol) and cupric acetate (100 mg) in dry pyridine (0.5 mL) and benzene (15 mL) was added lead tetraacetate (2.19 g; 4.94 mmol). The reaction mixture was set aside with stirring under an argon atmosphere at ambient temperature in the dark for 2 h.

The mixture was then heated at 80°C for 1 h, during which vigorous evolution of carbon dioxide occurred. When the reaction was complete, inorganic material was removed by filtration, and the filtrate was washed with water, 10% HCl solution, and saturated $NaHCO_3$. The organic phase was dried over $MgSO_4$, and removal of solvent on a rotary vacuum evaporator afforded a yellow oil (270 mg). The crude product was subjected to flash chromatography on a column of silica gel, with hexane – ethyl acetate (10:0, 9:1, 8:2) as eluent, to furnish pure *ar*-atlantone (180 mg; 58%) as an almost colorless oil: ir ($CHCl_3$) (inter alia): 2960, 2930, 2870, 1664, 1618, 1592, 1570, 1510, 1445, 1380, and 1120 cm^{-1}; uv λ_{max} (EtOH): 232 nm (ε 10 800), 305 nm (ε 23 600); ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.92 (3H, s), 2.21 (3H, s), 2.37 (3H, s), 2.56 (3H, s), 6.18 (1H, apparent d, J = 1.2 Hz), 6.48 (1H, apparent d, J = 1.1 Hz), 7.29 (4H, approx. ABq, J_{AB} = 8.0 Hz, $\Delta\nu_{AB}$ = 44.5 Hz); ^{13}C nmr ($CDCl_3$) δ: 18.1 (q), 20.7 (q), 21.2 (q), 27.8 (q), 126.2 (d), 126.3 (d), 127.7 (d), 129.2 (d), 139.0 (s), 140.0 (s), 151.1 (s), 154.8 (s), 191.7 (s); hrms (inter alia), *m/e* (relative intensity) (ion): 214.1332 (31.5) (M^+) (calcd. for $C_{15}H_{18}O$: 214.1358), 199.1113 (100) ($M - CH_3$)$^+$ (calcd. for $C_{14}H_{15}O$: 199.1123), 159.0795 (45) ($M - C_4H_7$)$^+$ (calcd. for $C_{11}H_{11}O$: 159.0810), 148.0854 (41) ($C_{10}H_{12}O$)$^+$ (calcd. 148.0889), 119.0862 (42) (C_9H_{11})$^+$ (calcd. 119.0861).

Keto-acid **12**

The enone-acid **10**, (67 mg 0.257 mmol) in ethyl acetate (25 mL) was stirred under a hydrogen atmosphere with a prehydrogenated 10% palladium-on-charcoal catalyst (20 mg) for 30 min, when the theoretical volume of hydrogen had been taken up. The catalyst was removed by filtration, and evaporation of solvent *in vacuo* furnished a quantitative yield (100%) of crystalline keto-acid, **12**: mp 108–112°C, ir ($CHCl_3$) (inter alia): 3525–2400, 1710, 1515, and 915 cm^{-1}, ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.17 (3H, s), 1.20 (3H, s), 1.23 (3H, d, J = 7.0 Hz), 2.31 (3H, s), 2.59–2.65 (4H, m), 3.2–3.35 (1H, m), 7.09 (4H, s); hrms (inter alia), m/e (relative intensity) (ion): 262.1577 (3.5) (M^+) (calcd. for $C_{16}H_{22}O_3$: 262.1569), 244.1471 (5) ($M - H_2O$)$^+$ (calcd. for $C_{16}H_{20}O_2$: 244.1463), 229.1221 (25) ($M-H_2O-CH_3$)$^+$ (calcd. for $C_{15}H_{17}O_2$: 229.1228), 161.0977 (15) (*p*-MePhCH(CH_3)CH_2-C≡O^+) (calcd. for $C_{11}H_{13}O$: 161.0966), 119.0858 (100) (C_9H_{11})$^+$ (calcd. 119.0861). Anal. calcd. for $C_{16}H_{22}O_3$: C 73.25, H 8.45%; found: C 73.39, H 8.29%.

ar-*Turmerone*, **13**

Keto-acid **12** (340 mg. 1.30 mmol) in benzene (15 mL) and pyridine (0.4 mL) was decarboxylated through the agency of lead tetraacetate (2.0 g, 4.50 mmol) and cupric acetate (100 mg) as described above. The crude yellow oily product (300 mg) was subjected to flash chromatography as described above for *ar*-atlantone, furnishing 191 mg (68%) of oily product, apparently homogeneous on tlc. The ^1H nmr spectrum, however, indicated that the product contained a mixture of conjugated and non-conjugated enones. (The diagnostic peaks for the latter were signals at δ 4.75 and 4.91 for a pair of terminal olefinic protons, and a signal at 1.65 for the protons of a vinylic methyl group.) The mixture (130 mg, 0.601 mmol) was heated under reflux for 3 h in benzene containing a catalytic quantity of *p*-toluenesulfonic acid. The solution was washed successively with saturated $NaHCO_3$ and brine solutions, and dried over $MgSO_4$. Removal of solvent under reduced pressure afforded *ar*-turmerone **13** (130 mg, 100%) as an oil: ir ($CHCl_3$) (inter alia): 2975, 2930, 1685, 1620, and 1515 cm^{-1}; uv λ_{max} (EtOH): 236 nm (ε 12 600); ^1H nmr ($CDCl_3$, 200 MHz) δ: 1.24 (3H, d, J = 6.9 Hz), 1.85 (3H, s), 2.10 (3H, s), 2.31 (3H, s), 2.5–2.8 (2H, m), 3.2–3.35 (1H, m), 6.03 (1H, s), 7.10 (4H, s); ^{13}C nmr ($CDCl_3$) δ: 20.7 (q), 20.9 (q), 22.0 (q), 27.6 (q), 35.2 (d), 52.6 (t), 124.0 (d), 126.6 (d), 129.1 (d), 135.5 (s), 143.6 (s), 155.1 (s), 199.8 (s), hrms (inter alia), *m/e* (relative intensity) (ion): 216.1509 (44) (M^+) (calcd. for $C_{15}H_{20}O$: 216.1514), 201.1269 (21) ($M - CH_3$)$^+$ (calcd. for $C_{14}H_{17}O$: 201.1279), 132.0935 (21) ($C_{10}H_{12}$)$^+$ (calcd. 132.0939), 119.0857 (85) (C_9H_{11})$^+$ (calcd. 119.0861), 83.0493 (100) (C_5H_7O)$^+$ (calcd. 83.0497).

Acknowledgments

An alternative synthesis of (±)-7-(3-methylpiperazin-1-yl)-6-fluoro-1-(2,4-difluorophenyl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acid hydrochloride **4**, a potent antibacterial agent, was developed. The method was characterized by regiospecific displacement of the 4-fluoro of the 2,4,5-trifluoroacetophenone by 2-methylpiperazine to produce the key intermediate, 2,5-difluoro-4-(3-methylpiperazin-1-yl)acetophenone **12**, which was subsequently converted to **4** via an intramolecular nucleophilic displacement cyclization reaction.

DANIEL T. W. CHU, ISABELLA M. LICO, AKIYO K. CLAIBORNE et HERMANN FAUBL. Can. J. Chem. **70**, 1323 (1992).

On a mis au point une nouvelle méthode de synthèse du chlorhydrate de l'acide (±)-7-(3-méthylpipérazin-1-yl)-6-fluoro-1-(2,4-difluorophényl)-1,4-dihydro-4-oxoquinoléine-3-carboxylique (**4**), un agent antibactérien très puissant. La méthode est caractérisée par une substitution régiospécifique du fluor en position 4 de la 2,4,5-trifluoroacétophénone par une 2-méthylpipérazine pour préparer l'intermédiaire clé, la 2,5-difluoro-4-(3-méthylpipérazin-1-yl)acétophénone (**12**), que l'on peut transformer subséquemment en **4** par le biais d'une réaction de cyclisation impliquant un substitution nucléophilique intramoléculaire.

Introduction

Recently many potent clinically important antibacterial agents having the 1,4-dihydro-4-oxoquinoline-3-carboxylic acid moiety, collectively known as quinolones, have been discovered. Representative examples of these are norfloxacin **1** (1), ciprofloxacin **2** (2), and enoxacin **3** (3). An excellent and comprehensive review of the synthetic chemistry associated with these antibacterial agents has been published (4). The most common synthetic methodology used to prepare ethyl 1-alkyl-1,4-dihydro-4-oxoquinoline-3-carboxylate is the reaction of an arylamine with diethyl ethoxymethylene malonate to yield an anilinomethylene malonate that may be cyclized by heating (the Gould–Jacobs reaction) or by the use of a Friedel–Crafts catalyst to yield the 4-hydroxyquinoline-3-carboxylate. Alkylation of this derivative with an alkyl halide followed by hydrolysis yields the desired quinolone. Another approach requires the reaction of an isatoic anhydride with sodio ethyl formylacetate, leading efficiently to the quinolone ester (5).

4

Temafloxacin hydrochloride **4** ((±)-7-(3-methylpiperazin-1-yl) - 6-fluoro-1-(2,4 - difluorophenyl)-1,4 - dihydro-4-oxoquinoline-3-carboxylic acid hydrochloride) is a potent quinolone antibacterial agent. It is currently under clinical development and an NDA has been filed in the United States. An approval for clinical use has been obtained in Italy and it will be in market shortly. It possesses excellent activity against both Gram-positive and Gram-negative bacteria (6). The general synthetic methods for the introduction of an N-1 substituent require the alkylation of 1,4-dihydro-4-oxoquinoline-3-carboxylic ester with a reactive alkyl halide. This process, however, makes the introduction of a 2,4-difluorophenyl group at the N-1 position difficult. Temafloxacin was synthesized via an intramolecular nucleophilic displacement cyclization reaction as illustrated in Scheme 1 (7–9).

Although this reported synthesis of temafloxacin hydrochloride is fairly efficient, it provides some problems during commercial production. Our manufacturing facility is not well equipped for the low-temperature reaction required in the preparation of the β-ketoester **8**. The oxidation of 2,4,5-trifluoroacetophene **6** to the 2,4,5-trifluorobenzoic acid **7** by the use of commercial bleach offers a physical problem since the reaction conditions required high dilution with vigorous agitation. The reaction time may not be constant due to the variations in agitation. While the above problems may be solved by engineering and modification of reaction conditions, the low yield (between 42 and 49%) of the displacement of **11** with 2-methylpiperazine to afford the desired product prompted us to investigate an alternative synthesis. This paper deals with a new and efficient route for the synthesis of temafloxacin hydrochloride.

Results and discussion

Our previous reported synthetic pathway to temafloxacin was designed to generate a common intermediate having the basic ring skeleton with a leaving group at the 7-position, such as **11**. Displacement at the 7-position with different amines would generate many derivatives for biological testing. A fluorine atom was chosen as the leaving group since aromatic fluorine groups are very susceptible to nucleophilic displacement. Unfortunately, the displacements of the fluorine atom with 2-methylpiperazine did not give a high-

SCHEME 1

yield reaction. To avoid this low-yield reaction, as well as the other manufacturing problems mentioned above, we investigated a synthetic route that required an intermediate which could allow for addition of the C-7 amino group prior to the formation of the bicyclic nucleus. The 2,4,5-trifluoroacetophenone **6** was chosen as the appropriate intermediate since it is readily available.

Displacement of the C-4 fluoro moiety of **6** with 2-methylpiperazine in pyridine in the presence of excess triethylamine followed by precipitation with hydrochloric acid yielded the 2,5-difluoro-4-(3-methylpiperazin-1-yl)acetophenone hydrochloride (**12**) in 92% yield. The fluoro groups at C-2 or C-4 of **6** are both activated by the electron-withdrawing character of the carbonyl group and could be replaced by an appropriate amine. However, the displacement reaction proceeded regioselectively to give the desired key intermediate **12** as a single product. The signal of the critical acetyl proton in the ^1H NMR of **12** in DMSO-d_6 was obscured by the solvent peak. Since **12** is not soluble in $CDCl_3$, a small amount was converted to the free base by neutralization for detailed NMR analysis. The ^1H NMR spectrum of 2,5-difluoro-4-(3-methylpiperazin-1-yl)acetophenone in $CDCl_3$ shows a doublet at δ 2.57 (J_{H-F} = 5 Hz) (corresponding to the acetyl group), due to the long-range coupling[2] with the *ortho* fluorine atom on the benzene ring. Hence, the site of the displacement was assigned as position 4. Additional confirmation of this assignment was provided by the conversion of **12** to temafloxacin hydrochloride by the synthetic route outlined in Scheme 2.

Protection of the secondary amino group as a *tert*-butoxycarbonyl group was achieved by reaction of **12** with di-*tert*-butyl dicarbonate in methylene dichloride in the presence of triethylamine, yielding **13** (mp 100–102°C, 87%). Condensation of 2,5-difluoro-4-(3-methyl-4-*tert*-butoxycarbonylpiperazin-1-yl)acetophenone (**13**) with two molar equivalents of sodium hydride in diethylcarbonate in the presence of a catalytic amount of ethanol yielded the ethyl 2,5-difluoro- 4 -(3-methyl- 4 -*tert*-butoxycarbonylpiperazin-1-yl)benzoylacetate (**14**) (mp 105–108°C, 63%), which existed in both keto and enol forms in approximately 2:1 ratio. Its ^1H NMR spectrum showed the presence of a doublet at δ 2.91 (J_{H-F} = 4 Hz) corresponding to the two keto methylene protons and a singlet at δ 5.81 corresponding to the enol

[2]Long-range coupling was observed with 2,4,6-trifluoroacetophenone (9).

olefinic proton. The ratio of intensities of these two signals was about 4:1. The long-range coupling with the *ortho* fluorine atom on the benzene ring observed for the methylene protons of the ketoester moiety[3] further confirmed our assignment of the substitution at position 4. Reaction of the ketoester (**14**) with triethylorthoformate in acetic anhydride gave the one-carbon homolog enol ether intermediate, which, upon evaporation of solvent, was allowed to react with a slight excess of 2,4-difluoroaniline in methylene chloride at room temperature to give ethyl 3-(2,4-difluoroanilino)-2-[2,5-difluoro- 4 -(3-methyl- 4 -*tert* - butoxycarbonylpiperazin-1-yl)]benzoylacrylate (**15**). Without purification, **15** was converted to ethyl 7-(3-methyl-4-*tert*-butoxycarbonylpiperazin-1-yl)-6-fluoro-1-(2,4-difluorophenyl)-1,4-dihydro-4-oxoquinoline-3-carboxylate (**16**) (mp 120–123°C, 72%) upon treatment with 1 molar equivalent of sodium hydride in refluxing tetrahydrofuran. Hydrolysis of **16** with 6 N hydrochloric acid yielded temafloxacin hydrochloride (**4**) in 98% yield. The structure of **4** was confirmed by direct comparison with authentic samples prepared by reported methods (9, 11).

In summary, we have developed an alternative synthesis of temafloxacin hydrochloride with an overall yield of 35.6% compared to 20.8% with the reported synthesis. The requirement for low-temperature reactions was also avoided. The key features for this synthesis are the use of easily accessible 2,4,5-trifluoroacetophenone as starting material and the regiospecific displacement of the 4-fluoro of the above acetophenone with 2-methylpiperazine to produce key intermediate **12** in high yield.

Experimental

Unless otherwise noted, materials were obtained from commercial suppliers and used without further purification. Melting points were taken in a Thomas–Hoover capillary apparatus and was uncorrected. NMR spectra were determined on a General Electric

[3]Similar long-range couplings were reported for ethyl 2,3,4,5,6-pentafluorobenzoylacetate (10*a*) and for ethyl 2,3,5-trifluoro-4-(4-methyl-1-piperazinyl)benzoylacetate (10*b*).

GN-300 spectrometer operating at 300.1 MHz. Chemical shifts are expressed in ppm downfield from internal tetramethylsilane. Significant ^{1}H NMR data are tabulated in the order: multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; b, broad; dd, double doublet), coupling constants, number of protons, and designation. The IR spectra were recorded on a Perkin–Elmer model 710A infrared spectrometer. Mass spectra were obtained with a Hewlett–Packard 5985A mass spectrometer or a Kratos MS-50 instrument with EI source (70 eV). The IR, NMR, and mass spectral data of all compounds were consistent with the assigned structures. Solutions were dried over magnesium sulfate. E. Merck silica (230–400 mesh) obtained from VWR Scientific was used for column chromatography, and yields of the reactions were not optimized. Elemental analyses were performed by the Abbott analytical department and IR, NMR, and mass spectra were recorded by the Abbott structural chemistry department.

2,5-Difluoro-4-(3-methylpiperazin-1-yl)acetophenone hydrochloride (**12**)

To a stirring solution of 2,4,5-trifluoroacetophenone (**6**) (8.7 g, 50 mmol) in pyridine (25 mL) and triethylamine (21 mL) was added 2-methylpiperazine (5.5 g, 55 mmol). After 2 days, the mixture was concentrated to an orange solid, which was dissolved in water (150 mL). Concentrated hydrochloric acid was added until the mixture became acidic, yielding a precipitate. The solid was collected by filtration and washed with small amounts of water, ethanol, and ether. The filtrate was basified with dilute sodium hydroxide solution and extracted with ethyl acetate, and dried and concentrated to give a red oil. 1 N Hydrochloric acid was added and the solid was collected as above. The combined solid was dried to yield **12** (mp >250°C, 13.4 g, 92%). IR (KBr): 1660 cm^{-1} (CO). ^{1}H NMR (DMSO-d_6)δ: 1.39 (d, J = 6.5 Hz, 3H, CH_3), 2.53 (d, J_{H-F} = 4.8 Hz, 3H, $COCH_3$: this signal is partly covered by solvent peak), 3.14 (m, 4H, NCH_2) 3.40 (m, 1H, NCH), 3.68 (m, 2H, NCH_2), 7.08 (dd, 1H, aromatic H), 7.54 (dd, 1H, aromatic H), 9.45 (bs, 1H, NH). Anal. calcd. for $C_{13}H_{17}ClF_2N_2O$: C 53.71, H 5.89, N 9.64; found: C 53.48, H 5.77, N 9.50.

A small amount of **12** was shaken with dilute sodium hydroxide solution and extracted with methylene chloride to yield the free amine of **12**. mp 86–89°C. ^{1}H NMR ($CDCl_3$) δ: 1.12 (d, J = 6.5 Hz, 3H, CH_3), 1.74 (bs, 1H, NH), 2.47 (m, 1H, NCH_2), 2.57 (d, J_{H-F} = 5 Hz, 3H, $COCH_3$), 2.83 (m, 1H, NCH_2), 3.04 (m, 3H, NCH_2 and NCH), 6.56 (dd, 1H, aromatic H), 7.55 (dd, 1H, aromatic H). Anal. calcd. for $C_{13}H_{16}F_2N_2O \cdot 1/5\ H_2O$: C 60.56, H 6.29, N 10.87; found: C 60.76, H 6.29, N 10.76.

*2,5-Difluoro-4-(3-methyl-4-*tert*-butoxycarbonylpiperazin-1-yl)acetophenone* (**13**)

To a suspension of **12** (12.45 g, 42.9 mmol) in methylene chloride (100 mL) in an ice bath was added triethylamine (18 mL, 129 mmol). After the addition of di-*tert*-butyl dicarbonate, the ice bath was removed and the reaction was allowed to warm up slowly to room temperature. After 3 h, the mixture was washed with 1 M H_3PO_4, saturated $NaHCO_3$, and brine solution in sequence. The organic solvent was dried and concentrated. The residue was crystallized from hexane, yielding **13** (13.18 g, 87%), mp 100–102°C. IR ($CDCl_3$): 1620, 1680 cm^{-1} (CO). ^{1}H NMR ($CDCl_3$) δ: 1.31 (d, J = 6.5 Hz, 3H, CH_3), 1.50 (s, 9H, $C(CH_3)_3$), 2.58 (d, J_{H-F} = 4.8 Hz, 3H, $COCH_3$), 2.55 (m, 1H, NCH_2), 2.99 (m, 1H, NCH_2), 3.27 (m, 1H, NCH_2), 3.45 (m, 2H, NCH_2), 3.96 (m, 2H, NCH_2), 4.34 (m, 1H, NCH), 6.53 (dd, 1H, aromatic H), 7.57 (dd, 1H, aromatic H). Anal. calcd. for $C_{18}H_{24}F_2N_2O_3$: C 61.00, H 6.83, N 7.90; found: C 60.97, H 6.82, N 7.87.

*2,5-Difluoro-4-(3-methyl-4-*tert*-butoxycarbonylpiperazin-1-yl)benzoylacetate* (**14**)

To a solution of **13** (3.6 g, 10.17 mmol) in diethyl carbonate (50 mL) was added sodium hydride (60% in oil suspension) (0.853 g, 21.3 mmol) at room temperature under nitrogen atmosphere. The temperature was raised to 80°C and 1 drop of ethanol was added. After 1 h, the mixture was cooled and acetic acid (2 mL) was added. It was concentrated to a red oily residue, which was partitioned between ether and water. The organic layer was separated and dried and concentrated. Flash chromatography of the residue (200 g silica, 1:7 ethyl acetate/hexane as eluent) yielded **14** (2.72 g, 63%). This oil solidified after standing a few days, mp 105–108°C. IR (thin film): 1620, 1695, 1740 cm^{-1} (CO). ^{1}H NMR ($CDCl_3$) δ: 1.27 and 1.33 (each t, J = 7 Hz, 3H, ethyl CH_3), 1.30 (d, J = 6.5 Hz, CH_3), 1.48 (s, 9H, $C(CH_3)_3$), 2.91 (m, 2H, NCH_2), 3.26 (m, 1H, NCH_2), 3.42 (m, 2H, NCH_2), 3.91 (d, J_{H-F} = 4 Hz, 2H × 2/3, $COCH_2COO$), 3.96 (m, 1H, NCH_2), 4.21 (q, J = 7 Hz, 2H × 2/3, ethyl CH_2), 4.21 (q, J = 7 Hz, 2H × 1/3, ethyl CH_2), 4.33 (m, 1H, NCH), 5.81 (s, 1H × 1/3, vinyl H), 6.51 (dd, 1H × 2/3, aromatic H), 6.57 (dd, 1H × 1/3, aromatic H), 7.54 (dd, 1H × 1/3, aromatic H), 7.61 (dd, 1H × 2/3, aromatic H), 12.72 (s, 1H × 1/3, enol OH). Anal. calcd. for $C_{21}H_{28}F_2N_2O_5$: C 59.14, H 6.62, N 6.57; found: C 59.43, H 6.69, N 6.55.

*Ethyl 7-(3-methyl-4-*tert*-butoxycarbonylpiperazin-1-yl)-6-fluoro-1-(2,4-difluorophenyl)-1,4-dihydro-4-oxoquinoline-3-carboxylate* (**16**)

A mixture of **14** (1 g, 2.3 mmol), acetic anhydride (0.96 g, 9.4 mmol), and triethylorthoformate (0.7 g, 4.7 mmol) was heated at 110°C for 2 h with the removal of the ethyl acetate formed during the reaction. The mixture was evaporated under reduced pressure to an oil, which was then dissolved in methylene chloride (25 mL). 2,4-Difluoroaniline (0.33 g, 2.6 mmol) in methylene chloride (5 mL) was then added to the solution. After 1.5 h, the solution was evaporated to dryness. The residue was dissolved in ether and washed with 1 N acetic acid to remove excess difluoroaniline and then water. The organic layer was dried and concentrated. A small amount of this residue was purified by flash chromatography on silica (using 5% ethyl acetate in methylene chloride as eluent) to yield pure **15**. The remaining residue was dissolved in tetrahydrofuran. To this cold solution was slowly added a 60% sodium hydride-in-oil suspension (0.105 g, 2.6 mmol). The mixture was heated at reflux for 2 h under nitrogen atmosphere and was cooled. A few drops of acetic acid were added. The mixture was concentrated. The residue was dissolved in methylene chloride and washed with water and dried. Upon evaporation of the solvent to dryness, the residue was purified by column chromatography on silica using 3% methanol in methylene chloride as eluent, yielding **16** (0.92 g, 72% from **14**), mp 120–123°C. IR (KBr): 1625, 1725 cm^{-1} (CO). ^{1}H NMR ($CDCl_3$) δ: 1.29 (d, J = 6.5 Hz, 3H, CH_3), 1.39 (t, J = 7 Hz, 3H, ethyl CH_3), 1.45 (s, 9H, $C(CH_3)_3$), 2.63 (m, 1H, NCH_2), 2.81 (m, 1H, NCH_2), 3.24 (m, 3H, NCH_2), 3.91 (m, 1H, NCH_2), 4.30 (m, 1H, NCH), 4.38 (q, J = 7 Hz, 2H, ethyl CH_2), 4.30 (m, 1H, NCH), 4.38 (q, J = 7 Hz, 2H, ethyl CH_2), 6.11 (d, J_{H-F} = 7 Hz, 1H, C_8-H), 7.17 (m, 2H, aromatic H), 7.51 (m, 1H, aromatic H), 8.08 (d, J_{H-F} = 13 Hz, 1H, C_5-H), 8.31 (s, 1H, olefinic H). Anal. calcd. for $C_{28}H_{30}F_3N_3O_5$: C 61.64, H 5.54, N 7.70; found: C 61.48, H 5.52, N 7.62.

Difluoroanilinobenzoylacrylate (**15**): IR ($CDCl_3$): 1625, 1675, 1685 cm^{-1} (CO). ^{1}H NMR ($CDCl_3$), 2 sets of signals, δ: 1.04, 1.15 (each t, J = 7 Hz, 3H, ethyl CH_3), 1.33, 1.34 (each d, J = 6.5 Hz, 3H, CH_3), 1.49 (s, 9H, $C(CH_3)_3$), 2.80 (m, 1H, NCH_2), 2.92 (m, 1H, NCH_2), 3.25 (m, 1H, NCH_2), 3.38 (m, 2H, NCH_2), 3.96 (m, 1H, NCH_2), 4.14, 4.15 (each q, J = 7 Hz, 2H, ethyl CH_2), 4.84 (m, 1H, NCH), 6.49 (m, 1H, aromatic H), 6.96 (m, 2H, aromatic H), 7.34 (m, 1H, aromatic H), 8.25, 8.43 (each d, J_{H-J} = 13 Hz, 1H, aromatic H), 10.90, 12.30 (each bd, J = 13 Hz, 1H, NH). Anal. calcd. for $C_{28}H_{31}F_4N_3O_5$: C 59.46, H 5.52, N 7.43; found: C 59.28, H 5.79, N 7.24.

Temafloxacin hydrochloride (**4**)

To a solution of **16** (0.26 g, 0.47 mmol) in acetic acid (1 mL) at 100°C under nitrogen atmosphere added 6 N HCl (10 mL). The mixture was heated at 100°C for 2.5 h. It was concentrated. The residue was crystallized from ethanol–water to yield temafloxacin hydrochloride (**4**) (0.212 g, 98%), mp > 300°C. IR (KBr): 1625, 1725 cm^{-1} (CO). ^{1}H NMR (DMSO-d_6) δ: 1.26 (d, J = 7 Hz, 3H,

CH_3), 2.95 (m, 1H, NCH), 3.11 (m, 2H, NCH_2), 3.48 (m, 2H, 2 NCH_2), 6.41 (d, J_{H-F} = 7 Hz, 1 H, C_8-H), 7.46 (m, 1H, aromatic H), 7.75 (m, 1H, aromatic H), 7.95 (m, 1H, aromatic H), 8.04 (d, J_{H-F} = 12 Hz, 1H, C_5-H), 9.52 (bs, 1H, NH), 14.87 (bs, 1H, OH). Anal. calcd. for $C_{21}H_{19}ClF_3N_3O_3 \cdot 1/2\ H_2O$: C 54.49, H 4.36, N, 9.08; found: C 54.64, H 4.25, N 9.03. **4** is identical in TLC and HPLC to the authentic samples prepared by the reported method.

A series of quinoline and naphthyridine antibacterial agents possessing an acyclic or cyclic *gem*-disubstituted piperazine substituent at the C-7 position have been prepared and evaluated in vitro and in vivo for antibacterial activity against a variety of Gram-positive and Gram-negative organisms. They are, however, not as active as quinolones or naphthyridines with a monosubstituted piperazine substituent at C-7. The chemical synthesis of these derivatives is also described.

DANIEL T. W. CHU, AKIYO K. CLAIBORNE, JACOB J. CLEMENT et JACOB J. PLATTNER. Can. J. Chem. **70**, 1328 (1992).

On a préparé un série d'agents antibactériens dérivés de quinoléines et de naphtyridines portant comme substituant en position C-7 une pipérazine *gem*-disubstituée sur la portion aliphatique ou cyclique; on a évalué leur activité antibactérienne in vitro et in vivo contre une variété d'organismes Gram-positifs et Gram-négatifs. Ils ne sont toutefois pas aussi actifs que les quinolones ou les naphtyridines portant une pipérazine monosubstituée en position C-7. On décrit aussi la synthèse chimique de ces dérivés.

[Traduit par la rédaction]

Introduction

Since the introduction of nalidixic acid **1** (1) into clinical practice in 1963, a large number of related analogs have been synthesized. Recently, several highly potent broad-spectrum antibacterial agents of this class have been made. All of them possess a 1-substituted-1,4-dihydro-4-oxo-pyridine-3-carboxylic acid moiety and a fluorine atom at the C-6 position and are collectively known as quinolones. These agents include norfloxacin **2** (2), temafloxacin **3** (3), ciprofloxacin **4** (4), lomefloxacin **5** (5), fleroxacin **6** (6), ofloxacin **7** (7), and tosufloxacin **8** (8). They have been shown to inhibit DNA gyrase (9, 10). Chirality in the quinolone molecule may have a great impact on the biological activity. The *S* enantiomer of ofloxacin **9** (11, 12) and *S*-25930 **10** (13) were recently reported to possess greater biological activities (10- to 100-fold) than their antipodes. The enantiomers of the 3-ethylaminomethylpyrrolidin-1-yl derivative **11**, however, were reported to have similar biological activity (14).

Recently, it has been shown that coadministration of enoxacin and theophylline to rats causes an increase of elimination half-life of theophylline, leading to an increase in its plasma concentration (15). This results in increased theophylline-related adverse reactions such as headache, nausea, and tachycardia. It is suggested that enoxacin competitively inhibits the binding of theophylline to cytochrome P-448 (15). The coplanarity between the C-7 piperazinyl group and the naphthyridine nucleus of enoxacin may be a possible explanation for this interaction. To avoid this undesirable interaction with theophylline, it is highly desirable to produce a potent quinoline with a bulky substituent on the piperazine of the C-7 substituent so that the coplanarity between the C-7 substituent and the quinolone nucleus can be avoided by steric interaction.

We have synthesized both enantiomers of temafloxacin. They were found to possess identical antibacterial activities (16), suggesting that there may be a large pocket at the enzymatic site that allows a substituent at both the α and β position of the C-3 of the piperazin-1-yl group. As a continuation of our search for a potent quinolone without interaction with theophylline, we synthesized a series of 1-substituted-6-fluoro-1-(3-*gem*-disubstituted-piperazin-1-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acids (or naphthyridine analogs) **12** for biological evaluation. In addition to *gem*-dimethyl substitution, these derivatives also included a 3-spirocyclopropane ring since substitution at N-1 of the quinoline ring with cyclopropyl group has been shown to dramatically increase in in vitro potency (17).

Chemistry

The synthesis of the desired 1-substituted-6-fluoro-7-(3-*gem*-disubstituted-piperazin-1-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acids and their corresponding naphthyridine derivatives **12** (*a–j*) (Tables 1–3) is outlined in Scheme 1. They were prepared by displacement of the 7-halo of the known ethyl 1-substituted 6,7,8-trifluoro-1,4-dihydro-4-oxoquinoline-3-carboxylate, ethyl 1-substituted-6,7-difluoro-1,4-dihydro-4-oxoquinoline-3-carboxylate, or ethyl 1-substituted-6-fluoro-7-chloro-1,4-dihydro-4-oxo-1,8-naphthyridine-3-carboxylate (**14**) with the appropriate 2-spiro-substituted piperazine (**13***a*,*b*) followed by acid hydrolysis. The *gem*-dimethyl derivatives were prepared by direct displacement of the 7-halo of the quinoline or naphthyridine-3-carboxylic acid derivatives (**16**) with 2,2-dimethylpiperazine (**13***c*).

The requisite 6,9-diazaspiro[4,5]decane (**13***a*) was prepared by the reaction sequence outlined in Scheme 2. Esterification of 1-amino-1-cyclopentanecarboxylic acid (**17**) with thionyl chloride in ethanol yielded the α amino acid ethyl ester hydrochloride (**18**). Condensation of **18** with carbobenzyloxyglycyl-*O*-succinimide in the presence of sodium bicarbonate gave the protected dipeptide (**19**). Removal of the protecting group by hydrogenolysis provided the free amino derivative, which cyclized to yield the diketopiper-

[1]A preliminary account of this work was presented at the 30th Interscience Conference on Antimicrobial Agents and Chemotherapy, October, 1990, Atlanta; Abstr. No. 394.

azine derivative (**20**). Borane–THF reduction of **20** gave the desired 6,9-diazaspiro[4,5]decane (**13***a*).

The above synthetic methodology was not regioselective for the synthesis of the 4,7-diazaspiro[2,5]octane (**13***b*). The key intermediate (**23**) not only provided the desired diketopiperazine **24** but also gave a substantial amount of the homoketopiperazine by-product **25** as illustrated in Scheme 3. It could be reasonable that displacement of the ethoxy group by the free amino group in **23** provided **24**. However, because of the presence of the ester function attached to the cyclopropane ring, the free amino group could also attack the carbon atom on the cyclopropane, generating a ring-opened product. To avoid this undesired ring opening, the previous reaction sequence was reversed. The desired 4,7-diazaspiro[2,5]octane (**13***b*) was prepared by a route shown in Scheme 4.

N-Protection of the 1-amino-1-cyclopropane carboxylic acid **21** with carbobenzyloxy-*O*-succinimide in the presence of sodium bicarbonate in THF gave the protected acid **26**. Activation of the carboxylic acid function of **26** with dicyclohexylcarbodiimide and *N*-hydroxyl-*O*-succinimide gave the *O*-succinimide derivative **27**. Treatment of **27** with ethyl glycine yielded the protected dipeptide **28**. Removal of the *N*-protecting group by hydrogenolysis yielded the free amino derivative **29**. Cyclization of **29** with DBU in refluxing toluene gave the desired diketopiperazine **24**. No ring opening by product was isolated. Borane–THF reduction of **24** provided the desired 4,7-diazaspiro[2,5]octane (**13***b*).

The 2,2-dimethylpiperazine (**13***c*) was prepared by the same reaction sequence as the preparation of 6,9-diazaspiro[4,5]decane (**13***a*) but using 2-amino-2-methylpropanoic acid instead of 1-amino-1-cyclopentanecarboxylic acid.

Results and discussion

Tables 4–6 summarize the in vitro antibacterial activity activity of the 7-*gem*-disubstituted piperazinyl quinolone derivatives (**12***a–j*) against ten Gram-positive bacteria (*Staphylococcus aureus* ATCC6538P, *Staphylococcus aureus* A5177, *Staphylococcus aureus* 642A, *Staphylococcus aureus* NCTC10649, *Staphylococcus aureus* CMX553, *Staphylococcus epidermidis* 3519, *Enterococcus faecium* ATCC 8043, *Streptococcus bovis* A5169, *Streptococcus agalactiae* CMX508, *Streptococcus pyogenes* EES61), and seven Gram-negative organisms (*Escherichia coli* Juhl, *Enterobacter aerogenes* ATCC13048, *Klebsiella pneumoniae* ATCC8045, *Pseudomonas aeruginosa* BMH10, *Pseudomonas aeruginosa* A5007, *Pseudomonas aeruginosa* K799/61, *Acinetobacter sp.* CMX669). The in vitro antibacterial activities are reported as minimum inhibitory concentration (MIC) in μg/mL determined by conventional agar dilution procedure. The data for ciprofloxacin (Cipro), a clinically useful antibacterial agent, are included for comparison.

The antibacterial activity for these compounds indicated that the 7-(4,7-diazaspiro[2,5]octan-7-yl)-quinolones and naphthyridines were more active than 7-(3,3-dimethylpiperazin-1-yl)-quinolones and naphthyridine derivatives, which were more active than 7-(6,9-diazaspiro[4,5]decan-9-

yl)-quinolones and naphthyridine derivatives. Although both enantiomers of temafloxacin were reported to possess identical antibacterial activity, the presence of two bulky substituents at C-3 of the piperazin-1-yl group reduced the antibacterial activity as did the 6,9-diazaspiro[4,5]decan-9-yl substituent. In general, the 1-substituted-6-fluoro-7-(4,7-diazaspiro[2,5]octan-7-yl)-1,4 - dihydro-4-oxoquinoline - 3-carboxylic acids and naphthyridine derivatives were more active against Gram-positive organisms than Gram-negative organisms. This is in contrast to traditional quinolones, which are more active against Gram-negative organisms. The 4,7-diazaspiro[2,5]octan-7-yl derivative **12***b* was the most active compound in this series and was found to be more active than ciprofloxacin against Gram-positive bacteria and slightly less active against Gram-negative bacteria.

To determine in vivo efficacy, several of these compounds were evaluated in mouse protection tests. Ciprofloxacin (Cipro) was used as a standard. The compounds were administered either orally (po) or subcutaneously (sc) with a specific amount of the test compound divided equally, to be administered 1 and 5 h after the injection. The potency is given in ED_{50} values, which are expressed as a total dose of the compound in mg/kg required to protect 50% of mice challenged intraperitoneally with the organism indicated. The results against *Staphylococcus aureus* and *E. coli* systemic infections are shown in Table 7. With the exception of **12***b*, all the compounds tested were inferior to ciprofloxacin. **12***b* possessed potency similar to ciprofloxacin against *S. aureus* infection in the mouse protection test.

In summary, we have synthesized a series of *gem*-disubstituted piperazin-1-yl quinolone derivatives with good antibacterial activity. However, they were found to be somewhat inferior to ciprofloxacin, which is currently used clinically as a broad spectrum antibacterial agent. This new series provided better anti-Gram-positive activity than anti-Gram-negative activity, an observation contrary to classical quinolone SAR.

Experimental

Unless otherwise noted, materials were obtained from commercial suppliers and used without further purification. Melting points were taken in a Thomas–Hoover capillary apparatus and were uncorrected. NMR spectra were determined on a General Electric GN-300 spectrometer operating at 300.1 MHz. Chemical shifts are expressed in ppm downfield from internal tetramethylsilane. Significant ^1H NMR data are tabulated in the order: multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; dd, double doublet; b, broad), coupling constants(s), number of protons, and designation. The IR spectra were recorded on a Perkin–Elmer model 710A infrared spectrometer. Mass spectra were obtained with a Hewlett–Packard 5985A mass spectrometer or a Kratos MS-50 instrument with EI source (70 eV). The IR, NMR, and mass spectral data of all compounds were consistent with the assigned structures. Solutions were dried over magnesium sulfate. E. Merck silica

gel (230–400 mesh) obtained from VWR Scientific was used for column chromatography, and yields of the reactions were not optimized. Elemental analyses were performed by the Abbott analytical department and IR, NMR, and mass spectra were recorded by the Abbott structural chemistry department.

In vitro antibacterial activity

The in vitro antibacterial activity of the test compounds was tested in a side-by-side comparison with temafloxacin and determined by conventional agar dilution procedures. The organisms were grown overnight in brain–heart infusion (BHI) broth (Difco 0037-01-6) at 36°C. Twofold dilutions of the stock solution (2000 μg/mL) of the test compound were made in BHI agar to obtain test concentrations ranging from 200 to 0.005 μg/mL. They were then incubated at 36°C for 18 h. The minimal inhibitory concentration (MIC) was the lowest concentration of the test compund that yielded no visible growth on the plate.

In vivo antibacterial activity

The in vivo antibacterial activity of the test compounds was determined in CF-1 female mice weighing approximately 20 g. Aqueous solutions of the test compounds were made by dissolving the hydrochloride salt in distilled water and diluting it with distilled water to the desired volume. The median lethal dose of the test organisms was determined as follows.

After 18 h of incubation, the cultures of test organism in BHI broth were serially diluted by using 10-fold dilutions in 5% (w/v) hog gastric mucin. Cultures (0.5 mL), dilution from 10^{-1} to 10^{-8}, were injected intraperitoneally into mice. The LD_{50} for the test organism was calculated from cumulative mortalities on the sixth day by using the Reed and Muench procedure (18).

After 18 h, cultures of the above were diluted in 5% (w/v) hog gastric mucin to obtain 100 times the LD_{50}, and 0.5 mL was injected intraperitoneally into mice. The mice were treated subcutaneously (sc) or orally (po) with a specific amount of the test compound divided equally to be administered 1 and 5 h after injection. A group of 10 animals each for at least three dose levels was thus treated, and the deaths were recorded daily for 6 days. Ten mice were left untreated as infection control. ED_{50} values were calculated from the cumulative mortalities on the sixth day after infection by using the trimmed version of the logit method (19).

1-Amino-1-ethoxycarbonylcyclopentane hydrochloride (18)

To a stirred mixture of 1-amino-1-cyclopentanecarboxylic acid (50 g, 387 mmol) in absolute ethanol (600 mL) at 0°C was added,

1-N-Carbobenzyloxyglycylamino-1-ethoxycarbonyylcyclopentane (19)

A solution of carbobenzyloxyglycine succinimido ester (19.4 g, 63 mmol) in THF (150 mL) was added dropwise to a solution of 1-amino-1-ethoxycarbonylcyclopentane hydrochloride (**18**) (11.6 h, 60 mmol) and sodium bicarbonate (15.1 g, 180 mmol) in water (200 mL) at 0°C. After the addition, the reaction was allowed to warm up to room temperature and was stirred for 16 h. The solvent was removed under reduced pressure and the residue was taken up in methylene chloride (350 mL) and washed twice with water. The organic portion was separated and dried. Removal of the solvent yielded 17.6 g (88%) of **19**, mp 99°C. IR

Anal. calcd. for $C_{18}H_{24}N_2O_5$: C 62.05, H 6.94, N 8.04; found: C 62.04, H 7.05, N 8.12.

By use of this procedure, reacting ethyl 2-amino-2-methylpropionate hydrochloride instead of 1-amino-1-ethoxycarbonyl-cyclopentane hydrochloride (**18**) with carbobenzyloxyglycine succinimido ester, ethyl 2-*N*-carbobenzyloxyglycylamino-2-methylpropionate was obtained in 89% yield, mp 85°C. IR ($CDCl_3$): 1682, 1727 (CO) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 1.27 (t, J = 7 Hz, 3H, ethyl CH_3), 1.56 (s, 6H, CH_3×2), 3.85 (d, J = 6Hz, 2H, CH_2), 4.20 (q, J = 7 Hz, 2H, ethyl CH_2), 5.14 (s, 2H, benzyl CH_2), 5.37 (bs, 1H, NH), 6.54 (bs, 1H, NH), 7.36 (m, 5H, aromatic H). Anal. calcd. for $C_{16}H_{22}N_2O_5$: C 59.63, H 6.83, N 8.70; found: C 59.72, H 6.92, N 8.67.

By use of the above procedure, ethyl 1-amino-1-cyclopropanecarboxylate (20) yielded ethyl 1-*N*-carbobenzyloxyglycylamino-1-cyclopropanecarboxylate (**22**) in 86% yield, mp 90–91°C. IR ($CDCl_3$): 1700, 1730 (CO) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 1.14 (m, 2H, CH_2), 1.21 (t, J = 7 Hz, 3H, ethyl CH_3), 1.56 (m, 2H, CH_2), 3.87 (d, J = 6 Hz, 2H, NCH_2), 4.11 (q, J = 7 Hz, 2H, ethyl CH_2), 5.12

(s, 2H, OCH_2), 5.58 (bs, 1H, NH), 6.73 (bs, 1H, NH), 7.34 (m, 5H, aromatic H). Anal. calcd. for $C_{16}H_{20}N_2O_5$: C 59.99, H 6.29, N 8.75; found: C 60.06, H 6.28, N 8.74.

*6,9-Diaza-7,10-dioxospiro[4,5]decane (**20**)*

A solution of **19** (17.6 g, 53 mmol) in ethanol (250 mL) was hydrogenated at 4 atmospheres (1 atm = 101.3 kPa) of hydrogen with 10% palladium on carbon for 18 h. The solution was then filtered and the residue was washed with ethanol. The combined solution was filtered through a 0.45 μm Nylon filter to remove the residual catalyst. Concentration of the filtrate to dryness yielded a solid, which was crystallized in acetonitrile yielding 6.35 g (71.4%) of **20**, mp >255°C. IR (KBr): 1675 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 1.66 (m, 6H, $CH_3\times2$), 2.06 (m, 2H, CH_2), 3.74 (d, J = 3 Hz, 2H, NCH_2), 7.93 (bs, 1H, NH), 8.35 (bs, 1H, NH). Anal. calcd. for $C_8H_{12}N_2O_2$: C 57.13, H 7.19, N 16.66; found C 57.33, H 7.36, H 16.78.

Using similar reaction conditions as above, ethyl 2-*N*-carbobenzyloxyglycylamino-2-methylpropionate produced 2,2-dimethyl-3,6-dioxopiperazine in 98% yield, mp 258–261°C. IR (KBr): 1680 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 1.29 (s, 6H, $CH_3\times2$), 3.78 (d, J = 2.5 Hz, 2H, CH_2), 7.91 (bs, 1H, NH), 8.23 (bs, 1H, NH). Anal. calcd. for $C_6H_{10}N_2O_2$: C 50.70, H 7.04, N 19.72; found: C 50.55, H 7.14, N 19.79.

*2,2-Dimethylpiperazine dihydrochloride (**13**c)*

2,2-Dimethyl-3,6-dioxopiperazine (15 g, 106 mmol), was suspended in THF (650 mL). A 433 mL sample of 1 M borane–tetrahydrofuran complex (433 mmol) was then added dropwise to the above stirring suspension over 1 h. Gas evolution occurred and the mixture became nearly homogeneous at the end of the addition. The mixture was heated at 60°C for 20 h. It was cooled to room temperature and 200 mL of methanol was added over a 1 h period. Gas evolution occurred and the reaction mixture was concentrated to dryness. The residue was redissolved in methanol (150 mL), excess methanolic HCl solution (500 mL) was added, and the solution was refluxed for 2 h. It was cooled and allowed to stand at room temperature overnight. The reaction was evaporated to dryness. The mixture and added acetonitrile were boiled with stirring for 0.5 h, then cooled, and the acetonitrile was decanted off. The residue was dissolved in a small amount of hot methanol. Upon cooling, crystals appeared. After addition of ether, they were filtered inside a dry-box and the residue was dried under vacuum yielding 16.5 g (84%) 2,2-dimethylpiperazine dihydrochloride (**13***c*). This solid was very hygroscopic. Upon exposure to air, it turned watery within several seconds. The IR spectrum showed no carbonyl absorption signal. ^1H NMR (D_2O) δ: 1.54 (s, 6H, $CH_3\times2$), 3.42 (s, 2H, CH_2), 3.52 (m, 2H, CH_2), 3.60 (m, 2H, CH_2). Exact Mass calcd. for $C_6H_{15}N_2$: 115.1235; measured: 115.1235.

By use of this procedure, borane–THF reduction of 6,9-diaza-7,10-dioxospiro[4,5]decane (**20**) yielded 6,9-diazaspiro[4,5]decane dihydrochloride (**13***a*) in 99% yield. This compound behaved as **13***c* and was very hygroscopic. The IR spectrum showed no carbonyl absorption signal. ^1H NMR (DMSO-d_6) δ: 1.62 (m, 2H, CH_2), 1.75 (m, 2H, CH_2), 1.90 (m, 2H, CH_2), 1.99 (m, 2H, CH_2), 3.28 (bs, 4H, $NCH_2\times2$), 3.48 (m, 2H, NCH_2), 9.98 (bs, 2H, $NH\times2$). Exact Mass calcd. for $C_8H_{17}N_2$: 141.1392; measured: 141.1392.

By use of the above procedure, borane–THF reduction of 4,7-diaza-5,8-dioxospiro[2,5]octane (**24**) yielded 4,7-diazaspiro[2,5]-octane dihydrochloride (**13***b*) in 98% yield. This compound was very hygroscopic. The IR spectrum showed no absorption signal for carbonyl group. ^1H NMR (DMSO-d_6) δ: 0.99 (m, 2H, CH_2), 1.21 (m, 2H, CH_2), 3.48 (m, 6H, $NCH_2\times3$), 9.85 (bs, 2H, NH_2Cl), 10.29 (bs, 2H, NH_2Cl). Exact Mass calcd. for $C_{16}H_{13}N_2$: 113.1079; measured: 113.1079.

Hydrogenolysis of 22

A solution of **22** (18.5 g, 58 mmol) in ethanol (250 mL) was hydrogenated at 4 atmospheres of hydrogen with 10% palladium on carbon for 18 h. The solution was then filtered and the residue was washed with ethanol. The combined solution was filtered through a 0.45 μm Nylon filter to remove the residual catalyst. Concentration of the filtrate to dryness yielded a residue, which was suspended in acetonitrile and boiled for 10 min. It was cooled and filtered, yielding 3.17 g of two products in about 1:1 ratio by TLC. ^1H NMR showed the presence of two compounds; one corresponding to **24** that had an identical spectrum to an authentic samples prepared by another route. The remaining signals in this spectrum indicated the presence of **25**. Repeated purification through several chromatographies yielded a small amount of **25** for ^1H NMR analysis. ^1H NMR ($CDCl_3$) δ: 1.22 (m, 5H, CH_2 and ethyl CH_3), 1.58 (m, 2H, NCH_2), 1.89 (bs, 1H, NH), 3.32 (bs, 2H, NCH_2CO), 3.72 (m, 1H, NCH), 4.14 (q, J = 7 Hz, 2H, ethyl CH_2), 7.70 (bs, 1H, CONH). The mass spectrum showed a m/z (M + 1) at 187 consistent with the structure assigned.

*1-N-Carbobenzyloxyamino-1-cyclopropanecarbonylic acid (**26**)*

A solution of *N*-benzyloxycarbonyloxy succinimide (60.7 g, 24 mmol) in THF (300 mL) was added to a solution of 1-amino-1-cyclopropanecarboxylic acid hydrochloride (24.5 g, 17.8 mmol) in water (45 mL). At ice temperature, a solution of sodium bicarbonate (82 g, 96 mmol) in water (500 mL) was poured into the mixture. After the addition, the reaction was allowed to warm up to room temperature and was stirred for 16 h. The solvent was removed under reduced pressure. The residue was suspended in 200 mL of methylene chloride and extracted with water (500 mL). The water solution was acidified with acetic acid and the precipitate was filtered yielding **26** (18 g, 43%), mp 157°C. IR (KBr): 1690, 1710 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 1.01 (m, 2H, CH_2), 1.31 (m, 2H, CH_2), 5.02 (s, 2H, OCH_2), 7.34 (m, 5H, aromatic H), 7.88 (s, 1H, NH), 12.42 (bs, 1H, OH). Anal. calcd. for $C_{12}H_{13}NO_4$: C 61.27, H 5.51, N 5.95; found: C 61.33, H 5.60, N 5.96.

*Preparation of active ester (**27**)*

Dicyclohexylcarbodiimide (7.74 g, 37.6 mmol) in THF (15 mL) was added dropwise to a mixture of **26** (8.83 g, 37.5 mmol) and *N*-hydroxysuccinimide (4.53 g, 39.4 mmol) in THF (60 mL). The mixture was allowed to stir at room temperature for 18 h. The precipitate was removed by filtration. The filtrate was concentrated to a residue, which was dissolved in ethyl acetate (300 mL). The organic solvent was washed with sodium bicarbonate solution. The organic layer was dried and concentrated to yield **27** (9.87 g, 79.2%), mp 119–120°C. IR (KBr): 1745, 1785, 1810 cm^{-1}. ^1H NMR ($CDCl_3$) δ: 1.46 (bs, 2H, CH_2), 1.86 (bs, 2H, CH_2), 5.15 (bs, 2H, OCH_2), 5.47 (bd, 1H, NH), 7.35 (m, 5H, aromatic H). Anal. calcd. for $C_{16}H_{16}N_2O_6$: C 57.83, H 4.85, N 8.43; found: C 57.84, H 4.88, N 8.38.

*Preparation of dipeptide (**28**)*

The active ester (**27**) (2 g, 6 mmol) in THF (15 mL) was added to a chilled solution of glycine ethyl ester hydrochloride (0.8 g, 5.1 mmol) in water (5 mL). Sodium bicarbonate solution (1.4 g in 20 mL of water) was then added to the reaction mixture. After the addition, the reaction was allowed to warm up to room temperature and was stirred for 18 h. The solvent was removed under reduced pressure and the residue was washed with water and extracted with methylene chloride. The organic layer was dried and concentrated to a solid under reduced pressure, yielding a solid **28** (1.88 g, 97.5%), mp 97–98°C. IR (KBr): 1675, 1740 (CO) cm^{-1}. ^1H NMR ($CDCl_3$) δ: 1.07 (bs, 2H, CH_2), 1.27 (q, J = 7 Hz, 3H, ethyl CH_3), 1.59 (m, 2H, CH_2), 3.99 (d, J = 5 Hz, 2H, NCH_2), 4.19 (q, J = 7 Hz, 2H, ethyl CH_2), 5.43 (s, 2H, OCH_2), 5.58 (s, 1H, NH), 6.98 (bs, 1H, NH), 7.34 (s, 5H, aromatic H). Anal. calcd. for $C_{16}H_{20}N_2O_5$: C 59.99, H 6.29, N 8.74; found: C 60.06, H 6.27, N 8.74.

*4,7-Diaza-5,8-dioxospiro[2,5]octane (**24**)*

A solution of the dipeptide (**28**) (8.63 g, 27 mmol) in ethyl acetate (250 mL) was hydrogenated under a hydrogen atmosphere at 4 atmospheres pressure with 10% palladium on carbon for 18 h. The

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

solution was filtered and the filtrate was concentrated under reduced pressure to a residue, **29**. ^{1}H NMR (DMSO-d_6) δ: 0.77 (dd, J = 4.5 Hz, 2H, CH_2), 1.05 (dd, J = 4.5 Hz, 2H, CH_2), 1.19 (t, J = 7 Hz, 3H, ethyl CH_3), 2.31 (bs, 2H, NH×2), 3.84 (d, J = 6.5 Hz, 2H, NCH_2), 4.09 (q, J = 7 Hz, 2H, ethyl CH_2), 8.43 (t, J = 6.5 Hz, 1H, CONH). The residual liquid **29** was dissolved in toluene (200 mL). To this solution was added DBU (2 mL). After heating at 115°C for 22 h, the mixture was cooled to room temperature to yield **24** (3.2 g, 89%), mp >260°C. IR (KBr): 1685, 1695 (CO) cm^{-1}. ^{1}H NMR (DMSO-d_6) δ: 0.94 (dd, J = 4.5 Hz, 2H, CH_2), 1.16 (dd, J = 4.5 Hz, 2H, CH_2), 3.85 (d, J = 2.5 Hz, 2H, NCH_2), 8.02 (bs, 1H, NH), 8.27 (bs, 1H, NH). Anal. calcd. for $C_6H_8N_2O_2$: C 51.42, H 5.75, N 20.00; found: C 51.10, H 5.66, N 19.80.

*1-Cyclopropyl-6-fluoro-7-(3,3-dimethylpiperazin-1-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acid hydrochloride (**12**h)*

2,2-Dimethylpiperazine dihydrochloride (**13***c*) (423 mg, 2.3 mmol) was added to a mixture of 1-cyclopropyl-6,7-difluoro-1,4-dihydro-4-oxoquinoline-3-carboxylic acid (21) (500 mg, 1.9 mmol) and triethylamine (10 mL) in *N*-methyl pyrrolidinone (20 mL). The reaction mixture was heated at 50°C for 18 h. The reaction was cooled to room temperature and concentrated under reduced pressure to dryness. Ethanol was added and digested under reflux for 30 min. The mixture was cooled and filtered, yielding **12***h* (525 mg, 70%), mp >260°C. IR (KBr): 1730 (CO) cm^{-1}. ^{1}H NMR (D_2O) δ: 1.22 (m, 2H, CH_2), 1.44 (m, 2H, CH_2), 1.58 (s, 6H, CH_3×2), 3.43 (s, 2H, NCH_2), 3.58 (m, 4H, NCH_2×2), 3.73 (m, 1H, CH), 7.52 (d, J_{H-F} = 6.5 Hz, 1H, C8-H), 7.54 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.67 (s, 1H, C2-H). Anal. calcd. for $C_{19}H_{23}ClFN_3O_3$: C 57.65, H 5.82, N 10.62; found: C 57.73, H 6.02, N 10.42.

By use of this procedure, 1-(2,4-difluorophenyl)-6-fluoro-7-(3,3-dimethylpiperazin-1-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acid hydrochloride **12***i* was prepared by reaction of **13***c* with 1-(2,4-difluorophenyl)-6,7-difluoro-1,4-dihydro-4-oxoquinoline-3-carboxylic acid (16) in 77% yield, mp >260°C. IR (KBr): 1730 (CO) cm^{-1}. ^{1}H NMR (D_2O) δ: 1.48 (s, 6H, CH_3×2), 3.25 (s, 2H, NCH_2), 3.36 (m, 2H, NCH_2), 3.42 (m, 2H, NCH_2), 6.47 (d, J_{H-F} = 6 Hz, 1H, C8-H), 7.37 (m, 2H, aromatic H), 7.72 (m, 1H, aromatic H), 7.92 (d, J_{H-F} = 12 Hz, 1H, C5-H), 8.82 (s, 1H, C2-H). Anal. calcd. for $C_{22}H_{21}ClF_3N_3O_3 \cdot 1/4\ H_2O$: C 55.93, H 4.56, N 8.90; found: C 55.85, H 4.68, N 8.90.

By use of this procedure, 1-(2,4-difluorophenyl)-6-fluoro-7-(3,3-dimethylpiperazin-1-yl)-1,4-dihydro-4-oxo[1,8]naphthyridine-3-carboxylic acid hydrochloride (**12***j*) was prepared by reaction of **13***c* with 1-(2,4-difluorophenyl)-6-fluoro-7-chloro-1,4-dihydro-4-oxo[1,8]-naphthyridine-3-carboxylic acid (22) in 94% yield, mp >260°C. IR (KBr): 1730 (CP) cm^{-1}. ^{1}H NMR (CF_3COOH) δ: 1.43 (s, 3H, CH_3), 1.47 (s, 3H, CH_3), 3.56 (m, 2H, NCH_2), 4.03 (bs, 2H, NCH_2), 4.26 (m, 2H, NCH_2), 7.28 (m, 2H, aromatic H), 7.75 (m, 1H, aromatic H), 8.33 (d, J_{H-F} = 13 Hz, 1H, C5-H), 9.26 (s, 1H, C2-H). Anal. calcd. for $C_{21}H_{20}ClF_3N_4O_3$: C 53.79, H 4.27, N 11.95; found: C 53.58, H 4.28, N 11.73.

*Ethyl 1-cyclopropyl-6-fluoro-7-(4,7-diazaspiro[2,5]octan-7-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylate (**15**a)*

4,7-Diazaspiro[2,5]octane dihydrochloride (**13***b*) (1.5 g, 8 mmol) was added to a solution of ethyl 1-cyclopropyl-6,7-difluoro-1,4-dihydro-4-oxoquinoline-3-carboxylate (**14***a*) (750 mg, 2.6 mmol) in 1-methyl-2-pyrrolidione (30 mL) at 75°C. 1,8-Diazabicyclo[5.4.0]undec-7-ene (DBU) (1.2 g, 10.2 mmol) was then added to the reaction mixture. The mixture was heated at 100°C for 16 h. The solvent was removed by vacuum distillation. Column chromatography of the residue on silica gel using 5% methanol in methylene chloride as eluent yielded **15***a* (0.4 g, 40%), mp 223–225°C. IR ($CDCl_3$): 1680, 1720 (CO) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 0.68 (m, 2H, CH_2), 0.72 (m, 2H, CH_2), 1.14 (m, 2H, CH_2), 1.21 (m, 2H, CH_2), 1.49 (t, J = 7 Hz, 3H, ethyl CH_3), 3.10 (s, 2H, NCH_2), 3.21 (m, 4H, NCH_2×2), 3.43 (m, 1H, CH), 4.48 (q, J = 7 Hz, 2H, ethyl CH_2), 7.22 (d, J_{H-F} = 7 Hz, 1H, C8-H), 8.04 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.53 (s, 1H, C2-H). Anal. calcd. for $C_{21}H_{24}FN_3O_3 \cdot 1/2\ H_2O$: C 63.94, H 6.39, N 10.65; found: C 64.09, H 6.23, N 11.04.

By use of this procedure, reaction of **13***b* with ethyl 1-cyclopropyl-6,7,8-trifluoro-1,4-dihydro-4-oxoquinoline-3-carboxylate (**14***b*) gave ethyl 1-cyclopropyl-6,8-difluoro-7-(4,7-diazaspiro[2,5]octan-7-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylate (**15***b*) in 42% yield. IR ($CDCl_3$): 1685, 1725 (CO) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 0.62 (m, 2H, CH_2), 0.69 (m, 2H, CH_2), 1.09 (m, 2H, CH_2), 1.23 (m, 2H, CH_2), 1.40 (t, J = 7 Hz, 3H, ethyl CH_3), 3.11 (m, 2H, NCH_2), 3.16 (s, 2H, NCH_2), 3.33 (m, 2H, NCH_2), 3.87 (m, 1H, CH), 4.38 (q, J = 7 Hz, 2H, ethyl CH_2), 7.90 (dd, J_{H-F} = 13 Hz, 1H, C5-H), 8.54 (s, 1H, C2-H). Anal. calcd. for $C_{21}H_{23}F_2N_3O_3 \cdot 1/4\ H_2O$: C 61.38, H 5.81, N 10.30; found: C 62.06, H 5.81, N 10.43.

Using a similar procedure, reaction of **13***b* with 1-cyclopropyl-6-fluoro-7-chloro-1,4-dihydro-4-oxo[1,8]naphthyridine-3-carboxylate (**14***c*) gave ethyl 1-cyclopropyl-6-fluoro-7-(4,7-diazaspiro-[2,5]octan-7-yl)-1,4 -dihydro- 4 -oxo[1,8]naphthyridine-3-carboxylate (**15***c*) in 46% yield, mp 174–175°C. IR ($CDCl_3$): 1685, 1725 (CO) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 0.62 (m, 2H, CH_2), 0.66 (m, 2H, CH_2), 1.02 (m, 2H, CH_2), 1.18 (m, 2H, CH_2), 1.41 (t, J = 7 Hz, 3H, ethyl CH_3), 3.11 (m, 2H, NCH_2), 3.47 (m, 1H, CH), 3.70 (s, 2H, NCH_2), 3.83 (m, 2H, NCH_2), 4.39 (q, J = 7 Hz, 2H, ethyl CH_2), 8.09 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.50 (s, 1H, C2-H). Anal. calcd. for $C_{20}H_{23}FN_4O_3$: C 62.16, H 6.00, N 14.50; found: C 62.31, H 5.94, N 14.93.

By use of this procedure, reacting **13***b* with ethyl 1-(2,4-difluorophenyl)-6-fluoro-7-chloro-1,4-dihydro-oxo[1,8]naphthyridine-3-carboxylate (**14***d*) gave ethyl 1-(2,4-difluorophenyl)-6-fluoro-7-(4,7-diazaspiro[2,5]octan-7-yl)-1,4-dihydro-4-oxo[1,8]naphthyridine-3-carboxylate (**15***d*) in 53% yield, mp 172–174°C. IR ($CDCl_3$): 1685, 1725 (CO) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 0.34 (m, 2H, CH_2), 0.54 (m, 2H, CH_2), 1.41 (t, J = 7 Hz, 3H, ethyl CH_3), 2.91 (t, J = 4 Hz, 2H, NCH_2), 3.42 (s, 2H, NCH_2), 3.56 (m, 2H, NCH_2), 3.39 (q, J = 7 Hz, 2H, ethyl CH_2), 7.06 (m, 2H, aromatic H), 7.49 (m, 1H, aromatic H), 8.11 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.39 (s, 1H, C2-H). Anal. calcd. for $C_{23}H_{21}F_3N_4O_3 \cdot 1/4\ H_2O$: C 59.67, H 4.68, N 12.10; found: C 59.57, H 4.72, N 12.06.

By a similar procedure, reaction of 6,9-diazaspiro[4,5]decane dihydrochloride (**13***a*) with quinolone ester (**14***a*) gave ethyl 1-cyclopropyl- 6-fluoro-7-(6,9 -diazaspiro[4,5]decan-9-yl)-1, 4 -dihydro-4-oxoquinoline-3-carboxylate (**15***e*) in 48% yield, mp >255°C. IR ($CDCl_3$): 1685, 1720 (CO) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 1.13 (m, 2H, CH_2), 1.34 (m, 2H, CH_2), 1.41 (t, J = 7 Hz, 3H, ethyl CH_3), 1.77 (m, 2H, CH_2), 2.04 (m, 2H, CH_2), 2.17 (m, 4H, CH_2×2), 3.35 (s, 2H, NCH_2), 3.43 (m, 2H, NCH_2), 3.57 (m, 2H, NCH_2), 4.40 (q, J = 7 Hz, 2H, ethyl CH_2), 7.31 (d, J_{H-F} = 6 Hz, 1H, C8-H), 8.10 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.55 (s, 1H, C2-H). Exact Mass calcd. for $C_{23}H_{28}FN_3O_3$: 413.2115; measured: 413.2113.

By use of the above procedure, reaction of **13***a* with ethyl 1-(2,4-difluorophenyl)-6,7-difluoro-1,4 -dihydro- 4 -oxoquinoline-3 -carboxylate (**14***e*) gave ethyl 1-(2,4-difluorophenyl)-6-fluoro-7-(6,9-diazaspiro[4,5]decan-9-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylate (**15***f*) in 39% yield, mp 216–218°C. IR ($CDCl_3$): 1690, 1725 (CO) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 1.49 (t, J = 7 Hz, 3H, ethyl CH_3), 1.59 (m, 4H, CH_2×2), 1.79 (m, 4H, CH_2×2), 2.89 (m, 4H, NCH_2×2), 3.01 (m, 2H, NCH_2), 4.39 (q, J = 7 Hz, 2H, ethyl CH_2), 6.12 (d, J_{H-F} = 6.5 Hz, 1H, C8-H), 7.15 (m, 2H, aromatic H), 7.50 (m, 1H, aromatic H), 8.06 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.31 (s, 1H, C2-H). Anal. calcd. for $C_{26}H_{26}F_3N_3O_3 \cdot 1/2\ H_2O$: C 63.15, H 5.50, N 8.50; found: C 63.25, H 5.32, N 8.53.

Using a similar procedure, reaction of **13***a* with quinoline ester (**14***d*) gave ethyl 1-(2,4-difluorophenyl)-6-fluoro-7(6,9-diazaspiro[4,5]decan-9-yl)-1,4 -dihydro-4-oxo[1,8]naphthyridine-3-carboxylate (**15***g*) in 81% yield, mp 120–122°C. IR ($CDCl_3$): 1690, 1725 (CO) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ: 1.40 (t, J = 7 Hz, 3H, ethyl CH_3), 1.46 (m, 4H, CH_2×2), 1.56 (m, 2H, CH_2), 1.68 (m, 2H, CH_2), 2.90 (t, J = 5 Hz, 2H, NCH_2), 3.42 (m, 2H, NCH_2), 3.53 (m, 2H, NCH_2), 4.49 (q, J = 7 Hz, 2H, ethyl CH_2), 7.06 (m, 2H,

aromatic H), 7.39 (m, 1H, aromatic H), 8.11 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.38 (s, 1H, C2-H). Anal. calcd. for $C_{25}H_{25}F_3N_4O_3 \cdot 1/4\ H_2O$: C 61.15, H 5.23, N 11.41; found: C 61.13, H 5.26, N 11.20.

*1-Cyclopropyl-6-fluoro-7-(4,7-diazaspiro[2,5]octan-7-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acid hydrochloride (**12**a)*

A suspension of **15***a* (80 mg, 0.2 mmol) in 6 N HCl (3 mL) was refluxed for 48 h. The solvent was then concentrated to dryness under reduced pressure. Ethanol (5 mL) was added to digest the residue for 15 min under reflux. It was cooled, filtered, and dried to give 35 mg **12***a* (43%), mp 247–255°C (dec.). IR (KBr): 1720 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 0.95 (m, 2H, CH_2), 1.05 (t, J = 7 Hz, 3H, ethyl CH_3), 1.15 (m, 2H, CH_2), 1.19 (m, 2H, CH_2), 1.32 (m, 2H, CH_2), 3.42 (m, 2H, NCH_2), 3.45 (s, 2H, NCH_2), 3.62 (m, 2H, NCH_2), 3.84 (m, 1H, CH), 7.59 (d, J_{H-F} = 7 Hz, 1H, C8-H), 7.96 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.68 (s, 1H, C2-H), 9.72 (bs, 2H, NH_2Cl), 15.13 (s, 1H, OH). Anal. calcd. for $C_{19}H_{21}ClFN_3O_3 \cdot 1/2\ H_2O$: C 56.64, H 5.50, N 10.43; found: C 56.60, H 5.50, N 10.15.

By use of a similar procedure, hydrolysis of **15***b* with 6 N HCl gave 1-cyclopropyl-6,8-difluoro-7-(4,7-diazaspiro[2,5]octan-7-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acid hydrochloride (**12***b*) in 81% yield, mp >250°C. IR (KBr): 1725 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 0.93 (m, 2H, CH_2), 1.14 (m, 2H, CH_2), 1.20 (m, 4H, CH_2×2), 3.35 (m, 2H, NCH_2), 3.47 (s, 2H, NCH_2), 3.65 (m, 2H, NCH_2), 4.12 (m, 1H, CH), 7.88 (dd, J_{H-F} = 12 Hz, 1H, C5-H), 8.71 (s, 1H, C2-H), 9.74 (bs, 2H, NH_2Cl), 14.66 (bs, 1H, OH). Anal. calcd. for $C_{19}H_{20}ClF_2N_3O_3 \cdot 1/2\ H_2O$: C 54.22, H 4.99, N 9.99; found: C 54.12, H 4.82, N 9.92.

Under similar conditions, hydrolysis of **15***c* with 6 N HCl gave 1-cyclopropyl-6-fluoro-7-(4,7-diazaspiro[2,5]octan-7-yl)-1,4-dihydro-4-oxo[1,8]naphthyridine-3-carboxylic acid hydrochloride (**12***c*) in 77% yield, mp >250°C. IR (KBr): 1720 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 0.97 (m, 2H, CH_2), 1.12 (m, 4H, CH_2×2), 1.20 (m, 2H, CH_2), 3.40 (m, 2H, NCH_2), 3.72 (m, 1H, CH), 4.02 (s, 2H, NCH_2), 4.18 (m, 2H, NCH_2), 8.17 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.64 (s, 1H, C2-H), 9.92 (bs, 2H, NH_2Cl), 15.07 (bs, 1H, OH). Anal. calcd. for $C_{18}H_{20}ClFN_4O_3 \cdot 1/2\ H_2O$: C 53.53, H 5.20, N 13.88; found: C 53.25, H 5.31, N 13.74.

Hydrolysis of **15***d* in trifluoroacetic acid and 6 N HCl mixture yielded 1-(2,4-difluorophenyl)-6-fluoro-7-(4,7-diazaspiro[2,5]octan-7-yl)-1,4-dihydro-4-oxo[1,8]naphthyridine-3-carboxylic acid trifluoroacetic acid salt **12***d*, mp 229–230°C. IR (KBr): 1675, 1730 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 0.53 (m, 2H, CH_2), 0.93 (m, 2H, CH_2), 3.24 (m, 2H, NCH_2), 3.66 (m, 2H, NCH_2), 3.88 (m, 2H, NCH_2), 7.37 (m, 1H, aromatic H), 7.64 (m, 1H, aromatic H), 7.83 (m, 1H, aromatic H), 8.25 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.93 (s, 1H, C2-H), 9.39 (bs, 2H, CF_3COONH_2), 14.86 (bs, 1H, OH). Anal. calcd. for $C_{23}H_{18}F_6N_4O_5$: C 50.74, H 3.33, N 10.29; found: C 50.83, H 3.53, N 10.20.

Hydrolysis of **15***e* with 6 N HCl gave 17-cyclopropyl-6-fluoro-7-(6,9-diazaspiro[4,5]decan-9-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acid hydrochloride (**12***e*), mp >250°C. IR (KBr): 1720 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 1.18 (m, 2H, CH_2), 1.33 (m, 2H, CH_2), 1.69 (m, 2H, CH_2), 1.82 (m, 4H, CH_2×2), 1.98 (m, 2H, CH_2), 3.36 (m, 4H, NCH_2×2), 3.50 (m, 2H, CH_2), 3.83 (m, 1H, CH), 7.03 (d, J_{H-F} = 7 Hz, 1H, C8-H), 7.98 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.70 (s, 1H, C2-H), 9.30 (bs, 2H, NH_2Cl), 15.12 (bs, 1H, OH). Exact Mass calcd. for $C_{21}H_{24}FN_3O_3$: 385.1802; measured: 385.1803.

Hydrolysis of **15***f* with 6 N HCl yielded 1-(2,4-difluorophenyl)-6-fluoro-7-(6,9-diazaspiro[4,5]decan-9-yl)-1,4-dihydro-4-oxoquinoline-3-carboxylic acid hydrochloride (**12***f*), mp >250°C. IR (KBr): 1730 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 1.62 (m, 2H, CH_2), 1.82 (m, 6H, CH_2×3), 3.20 (m, 6H, NCH_2×3), 6.41 (d, J_{H-F} = 7 Hz, 1H, C8-H), 7.45 (m, 1H, aromatic H), 7.75 (m, 1H, aromatic H), 7.94 (m, 1H, aromatic H), 8.05 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.88 (s, 1H, C2-H), 9.52 (bs, 2H, NH_2Cl), 14.84 (bs, 1H, OH). Anal. calcd. for $C_{24}H_{23}ClF_3N_3O_3 \cdot 1/4\ H_2O$: C 57.83, H 4.75, N 8.43; found: C 57.66, H 4.70, N 8.41.

Hydrolysis of **15***g* in a mixture of trifluoroacetic acid and 6 N HCl yielded 1-(2,4-difluorophenyl)-6-fluoro-7-(6,9-diazaspiro[4,5]decan-9-yl)-1,4-dihydro-4-oxo[1,8]naphthyridine-3-carboxylic acid trifluoroacetic acid salt (**12***g*), mp 255°C. IR (KBr): 1680, 1735 (CO) cm^{-1}. ^1H NMR (DMSO-d_6) δ: 1.28 (m, 2H, CH_2), 1.64 (m, 6H, CH_2×3), 3.23 (m, 2H, NCH_2), 3.59 (m, 2H, NCH_2), 3.85 (m, 2H, NCH_2), 7.38 (m, 1H, aromatic H), 7.66 (m, 1H, aromatic H), 7.84 (m, 1H, aromatic H), 8.26 (d, J_{H-F} = 13 Hz, 1H, C5-H), 8.90 (s, 1H, C2-H), 9.19 (bs, 2H, CF_3COONH_2), 14.87 (bs, 1H, OH). Anal. calcd. for $C_{25}H_{22}F_6N_4O_5 \cdot 1/4\ H_2O$: C 52.04, H 3.90, N 9.71; found: C 51.82, H 3.85, H 9.60.

Metabolites of the fungus *Arthropsis truncata*

WILLIAM A. AYER,[1] PETER A. CRAW, AND JOHN NEARY
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received July 9, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

WILLIAM A. AYER, PETER A. CRAW, and JOHN NEARY. Can. J. Chem. **70**, 1338 (1992).

The structures of 12 new polyketide metabolites produced in liquid cultures of the fungus *Arthropsis truncata* have been determined by a combination of chemical and spectroscopic methods. Four of these metabolites possess an unusual 2-oxaspiro[4.5]decane skeleton, and the structure assigned to one of these metabolites **20** has been confirmed by an X-ray crystallographic study of the dibenzoyl derivative **21**. The absolute stereochemistry of these compounds has been predicted by application of the Harada–Nakanishi dibenzoate rule to arthropsolide D tribenzoate (**32**).

WILLIAM A. AYER, PETER A. CRAW et JOHN NEARY. Can. J. Chem. **70**, 1338 (1992).

Faisant appel à une combinaison de méthodes chimiques et spectroscopiques, on a déterminé les structures de 12 nouveaux polycétides obtenus à partir de cultures liquides du champignon *Arthropsis truncata*. Quatre de ces métabolites possèdent le squelette inhabituel du 2-oxaspiro[4.5]décane et la structure attribuée au métabolite **20** a été confirmée par une étude de diffraction des rayons X réalisée sur le dérivé dibenzoylé **21**. On a prédit la stéréochimie absolue de ces composés en appliquant la règle du dibenzoate de Harada–Nakanishi au tribenzoate **32** de l'arthropsolide D.

Introduction

As part of our investigations of the chemistry of fungi associated with the economically important blue-stain disease of lodgepole pine (*Pinus contorta* Dougl. var *latifolia* Engelm.), we described the isolation of (−)arthrographol, which is produced in liquid cultures of the fungus *Arthrographis pinicola* Sigler and Yamaoka (1), and the total synthesis of (+/−)arthrographol from vanillin (2). We believe that arthrographol may be responsible for the antagonism observed between *Arthrographis pinicola* and *Ophiostoma clavigerum* (Robins.-Jeff. & Davids.) Harrington, a fungus strongly associated with tree mortality caused by the blue-stain fungi (3).

Recently we examined a number of species of fungi, thought to be morphologically related to *Arthrographis pinicola,* to see whether they might produce metabolites similar to those produced in our liquid cultures of *A. pinicola,* thereby providing chemotaxonomic evidence to support the classification of these new species of fungi in the same genus as *A. pinicola*. One of these species, *Arthropsis truncata* Sigler, Dunn & Carmichael, which was isolated from primary forest leaf litter near Puca Urquillo, Peru (4), produces a series of previously unreported polyketide metabolites when grown in liquid culture. Subsequently we observed *Arthropsis truncata* to be antagonistic to the growth of the blue-stain fungus *Ophiostoma clavigerum*. The structures of the metabolites produced by *Arthropsis truncata* are the subject of this report. Biosynthetic studies dealing with these compounds will be the subject of a subsequent paper.

Results and discussion

Arthropsis truncata was grown in shake culture on a modified malt extract medium for 4 weeks. The filtered culture broth was extracted with ethyl acetate and the metabolites were isolated by extensive chromatography and fractional crystallizations.

Arthropsadiol A (1)

Arthropsadiol A (**1**) was obtained as needles, mp 78–79°C, $[\alpha]_D$ −245.7. High-resolution electron impact mass spectrometry (hreims) and chemical ionization mass spectrometry (cims) indicated a molecular formula of $C_{12}H_{16}O_4$. The presence of an α,β-unsaturated ketone was apparent from a maximum at 229 nm in the ultraviolet (uv) spectrum, a strong carbonyl absorption at 1689 cm^{-1} in the Fourier transform infrared (Ftir) spectrum, and signals at δ 6.68 (H5) and δ 6.08 (H6) in the ^1H nmr spectrum and δ 199.51 (C7), δ 154.65 (C5), and δ 125.02 (C6) in the ^{13}C nmr spectrum (see Table 1). The presence of an (*E*)-propenyl unit was suggested by signals at δ 5.53 (H2), δ 5.09 (H3), and δ 1.61 (H1) in the ^1H nmr spectrum, and signals at δ 129.03 (C3), δ 132.21 (C2), and δ 17.55 (C1) in the ^{13}C nmr spectrum. The coupling constants between the signals for H2 and H3 (J = 15.2–15.5 Hz) in the ^1H nmr spectrum and the position of the vinyl methyl signal in the ^{13}C nmr spectrum are consistent with an (*E*)-propenyl unit. Finally, the presence of a methyl ketone was indicated by a 3H singlet at δ 2.13 in the ^1H nmr spectrum and signals at δ 209.74 (C11) and δ 25.59 (C12) in the ^{13}C nmr spectrum. As the molecular formula requires the presence of five units of unsaturation, four of which have been accounted for by the two carbonyl and four alkene sp^2 carbon signals in the ^{13}C nmr spectrum, arthropsadiol A (**1**) must be monocyclic. The remaining two oxygen atoms in the molecular formula can be accounted for by two hydroxyl groups as the Ftir spectrum displays a broad OH absorption at 3450 cm^{-1}, the ^1H nmr spectrum contains D_2O exchangeable signals at δ 3.87 and δ 3.89, and the ^{13}C nmr contains carbinol signals at δ 75.27 (C10) and δ 72.12 (C8).

The presence of two hydroxyl groups is also confirmed by formation of diacetate **2** upon acetylation of arthropsadiol A (**1**). The structure of arthropsadiol A (**1**) was readily apparent from analyses of ^1H–^1H and ^1H–^{13}C COSY spectra of the diacetate **2**. The large coupling constants between the signals of H4 and H9 (J = 9.5–10.3 Hz) and the signals of H8 and H9 (J = 10.8–13.1 Hz) in the ^1H nmr spectra of both arthropsadiol A (**1**) and the diacetate (**2**) suggest *trans,trans*-stereochemistry of the cyclohexenone substituents at C4, C8,

TABLE 1. Nuclear magnetic resonance spectral parameters for arthropsadiol A (**1**) and arthropsolide A (**20**)[a]

and C9. This is supported by nuclear Overhauser enhancements (nOe) observed in the ^1H nmr spectrum of arthropsadiol A (**1**) from the signals of H4–H8 (7.2%), H8–H4 (3.4%), and H9–H3 (4.4%) (Fig. 1). We are unable to assign the relative configuration at C10 due to the failure of attempts to prepare either the acetonide or carbonate derivatives of arthropsadiol A (**1**). We were hopeful that the size of the H9–H10 coupling constant in either of these derivatives would have allowed us to assign the stereochemistry at C10, provided no epimerization occurred at C10 during preparation of the acetonide or carbonate.

Arthropsadiol B (3)

Arthropsadiol B (**3**) was obtained as an oil that resisted attempts at crystallization. The hreims, uv, Ftir, and ^{13}C nmr spectra of this material indicated a close structural similarity to arthropsadiol A (**1**). The signals of an α,β-unsaturated ketone and an (*E*)-propenyl unit in the ^1H nmr spectrum of arthropsadiol B (**3**) are very similar to those in the spectrum of arthropsadiol A (**1**). However, a 3H doublet at δ 1.39 (J = 7.5 Hz) and a broad quartet of doublets at δ 4.36 (J = 7.0, 4.0 Hz) suggested the presence of a 2-hydroxy-1-propanone substituent at C9 in arthropsadiol B (**3**) rather than a 1-hydroxy-2-propanone unit as in arthropsadiol A (**1**). This was confirmed by a ^1H–^1H COSY spectrum of arthropsadiol B (**3**). The relative stereochemistry of arthropsadiol B (**3**) also differs from that of arthropsadiol A (**1**), but this difference is not readily discernable from the ^1H nmr spectra of either arthropsadiol B (**3**) or the corresponding diacetate **4** determined in $CDCl_3$ due to overlapping of the signals of H4 and H9. However, the signals of H4 and H9 are well separated in the ^1H nmr spectrum of the diacetate **4** determined in benzene-d_6. Thus, the H8–H9 coupling constant (J = 12.7 Hz) in the latter spectrum is consistent with a *trans* relationship of the C8 and C9 substituents (Fig. 1). The signal of H9 also shows coupling to an apparent quartet (J = 6.0 Hz) at δ 3.14 due to H4. A nOe is observed from H8 to H3 (6.1%) in the ^1H nmr spectrum of arthropsadiol B (**3**) determined in $CDCl_3$, and between H8 and H3 (7.3%, 4.3%) in the spectrum of the diacetate **4** also determined in $CDCl_3$. Furthermore, a nOe is observed from H4 to H9 (14.4%) in the ^1H nmr spectrum of the diacetate **4** determined in ben-

zene-d_6. Thus, we conclude that the C4 and C8 substituents are *trans* in arthropsadiol B (**3**) and the C4 and C9 substituents are *cis*. The relative configuration at C11 remains unassigned.

Arthropsatriols A (5) and B (6)

Two triols were isolated from the broth extract that did not give M^+ ions in their respective hreims. However, weak ions were observed in both spectra at m/z 208 ($M^+ - H_2O$) suggesting a molecular formula of $C_{12}H_{18}O_4$ for each triol, which was supported in each case by ions at m/z 244 ($M^+ + NH_4^+$) in the cims. The ^{13}C nmr spectra of each triol displayed signals for one non-conjugated ketone carbon, 4 non-conjugated alkene sp^2 carbons, and 3 carbinol carbons. Thus we concluded that arthropsatriols A (**5**) and B (**6**) are the epimeric triols derived from reduction of the C7 carbonyl group of arthropsadiol A (**1**), and this was supported by an examination of the ^1H nmr spectra of the triols and their respective triacetate derivatives **7** and **8**.

The relative stereochemistry of each of the triols was more readily assigned by examination of the ^1H nmr spectra of the triacetates of arthropsatriols A (**5**) and B (**6**) as the hydrogen signals are better dispersed in these spectra and allow more conclusive nOe experiments. In the spectra of both triacetates determined in $CDCl_3$ the large coupling constants between H4 and H9 (J = 9.5–10.5 Hz) and between H8 and H9 (J = 12.0–12.5 Hz) support a *trans,trans* relative stereochemistry of H4, H8, and H9 as in arthropsadiol A (**1**). The H7–H8 coupling constant (J = 8.5 Hz) in the spectrum of arthropsatriol B triacetate (**8**) is considerably larger than that (J = 3.8 Hz) in arthropsatriol A triacetate (**7**) and supports the relative stereochemistry assigned to each epimer at C7. The C7 stereochemistry assigned to arthropsatriol A triacetate (**7**) is also supported by a nOe from H7 to H8 (13.0%) and from H8 to H7 (16.5%) in the ^1H nmr spectrum determined in $CDCl_3$. Furthermore, nOe's from H4 to H8 (10.7%) and H8 to H4 (7.6%) support the *cis* relationship of H4 and H8 in arthropsatriol A triacetate (**7**). In the ^1H nmr spectrum of arthropsatriol B triacetate (**8**) determined in $CDCl_3$ the signal for H7 was obscured in a multiplet also containing the signals for H2, H5 and H6. However, in the spectrum of **8** determined in benzene-d_6 the signals for H2, H5, H6, and H7 are well resolved. The C4, C7, C8, and C9 relative stereochemistry assigned to arthropsatriol B triacetate (**8**) is supported by nOe's from H7 to H9 (6.5%), H9 to H7 (9.5%), and H4 to H8 (8.2%). As is the case for arthropsadiol A (**1**) the relative configuration at C10 of arthropsatriols A (**5**) and B (**6**) remains unassigned.

Cycloarthropsadiol C (9)

This compound was obtained as an oil and has a molecular formula of $C_{12}H_{16}O_5$ as determined by hreims. The Ftir spectrum shows absorptions characteristic of hydroxyl (3434 cm^{-1}) and C—O groups (1144–1091 cm^{-1}) as well as a strong ketone carbonyl absorption at 1743 cm^{-1}. The presence of a ketone group is also supported by a signal at δ 202.3 (C10) in the ^{13}C nmr spectrum. As 6-membered cyclic ketones usually have absorption near 1715 cm^{-1} in the infrared, the position of the ketone absorption in the Ftir of cycloarthropsadiol C (**9**) may reflect the effect of the two electronegative α-oxygen substituents on the ketone stretching absorption (5). These two α-oxygen substituents may also account for the upfield position of the ketone signal in the ^{13}C nmr spectrum. The presence of an (*E*)-propenyl unit was readily apparent from signals at δ 5.64 (H2), δ 5.46 (H3), and δ 1.67 (H1) in the ^1H nmr spectrum as well as signals at δ 129.1, δ 127.6 (C3, C2), and δ 18.0 (C1) in the ^{13}C nmr spectrum. The remaining signals in the ^{13}C nmr spectrum may be assigned to an acetal (C11, δ 100.1), a hemiacetal (C7, δ 94.1), two sp^3 mono-oxygenated carbons (C8, δ 78.4 and C5, δ 73.5), a CH_2 group (C6, δ 56.1) with 3 oxygen groups attached to the adjacent carbon atoms, a CH group (C9, δ 51.3) located α to the C10 ketone, a CH group (C4, δ 37.2) attached to the (*E*)-propenyl unit, and a methyl carbon (C12, δ 19.5).

The ^1H nmr spectrum of **9** is consistent with the structure assigned to cycloarthropsadiol C but unfortunately the signals for H5 and H8 overlap as an unresolved broad doublet at δ 4.24. To separate the signals due to H5 and H8 in the ^1H nmr, and to confirm the hydrogen connectivities in cycloarthropsadiol C (**9**) by ^1H–^1H COSY and nOe experiments, the compound was acetylated to give mainly the corresponding diacetate **10** and a trace of the monoacetate **11**. The ^1H nmr spectrum of the diacetate **10** was readily assigned with the aid of a ^1H–^1H COSY spectrum. In the COSY spectrum a weak cross peak exists between the signals for H5 (δ 4.25) and H9 (δ 2.99) due to W-coupling (J = 1.7–2.0 Hz). The position of the signal due to H5 is largely unchanged from that in cycloarthropsadiol C (**9**), but the signal for H8 is shifted significantly downfield to δ 5.27 in the monoacetate **11** and to δ 6.09 in the diacetate **10**. The signal for H8 in the spectrum of the diacetate **10** is a doublet (J = 4.0 Hz) and significant nOe's are observed to the signals of H4, H6α, and H9, thereby supporting the relative stereochemistry assigned to C8, as well as that of C4. Irradiation of the C12 methyl singlet at δ 1.44 in the spectrum of the diacetate **10** results in only a small nOe to the acetate singlets at δ 2.094 and δ 2.085 (1.2% combined) but nevertheless is consistent with the structure assigned to cycloarthropsadiol C (**9**).

Cycloarthropsone (12)

Cycloarthropsone (**12**) was obtained as an optically inactive yellow solid that gave an ion at m/z 220 in the hreims with a molecular formula of $C_{12}H_{12}O_4$, and an ion at m/z 238 ($M^+ + NH_4^+$) in the cims. The Ftir spectrum contains intense hydroxyl (3450, 3170 cm^{-1}) and conjugated ketone carbonyl (1685 cm^{-1}) absorptions, and the uv spectrum shows maxima at 236, 286, and 387 nm, which undergo a bathochromic shift in the presence of dilute sodium hydroxide. The ^1H nmr spectrum is relatively simple and displays signals for two *ortho*-coupled aromatic hydrogens (δ 6.99, δ 6.93, J = 8.8 Hz), an (*E*)-propenyl chain (δ 7.08, 6.27, 1.78), and a methyl singlet (δ 1.43). The aromatic carbon signals in the ^{13}C mr spectrum of cycloarthropsone (**12**) were assigned by comparison with the calculated chemical shifts of the aromatic carbons in 7-hydroxy-4(*E*)-propenyl-3(2*H*)-benzofuranone (**13**), which in turn were obtained by addition of the substituent effects for introduction of a 7-hydroxyl group and a 4(*E*)-propenyl group to the reported spectrum of 3(2*H*)-benzofuranone (**14**) (6) (see Table 2). The hydroxy and (*E*)-propenyl substituent effects were determined by comparison of the spectra of phenol and (*E*)-propenylbenzene with that of benzene (7). The positions of the signals for C4, C6, C7, and C8 are in good agreement with the calculated positions, but those of C5 and C9 differ significantly from the calculated positions. The additional

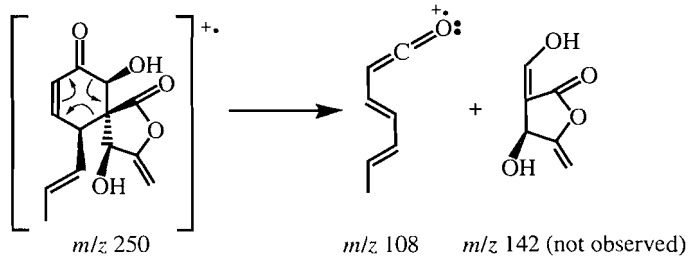

FIG. 2. Possible mass spectral fragmentation of arthropsolide A (**20**).

shielding of C5 and C9 is probably the result of conjugation between the C10 ketone and the (*E*)-propenyl group. This conjugation would also account for the shielding of C3 and the deshielding of C2 relative to the positions of the corresponding propenyl sp^2 carbon signals in the spectrum of (*E*)-propenylbenzene.

Acetylation of cycloarthropsone (**12**) gave the corresponding diacetate **15** as a clear oil. In the ^{13}C nmr spectrum of diacetate **15** the signals of C4 and C6 are shifted downfield by ca. 6 ppm and the signal of C7 is shifted upfield by 7.5 ppm relative to the positions of the corresponding signals in cycloarthropsone (**12**). These shifts are in accordance with those expected from a comparison of the spectra of phenol and phenyl acetate (7).

*Arthropsatriols C (**16**) and D (**17**)*

An inseparable mixture of arthropsatriol C (**16**) and D (**17**) was obtained by fractional crystallization of one of the combined fractions from flash chromatography of the crude broth extract. A molecular formula of $C_{12}H_{14}O_4$ was established for the mixture by hreims, and an ion at *m/z* 240 in the cims ($M^+ + NH_4^+$) is consistent with this formula. The Ftir spectrum displayed strong absorptions at 3406 and 1678 cm^{-1}, confirming the presence of hydroxyl and conjugated carbonyl groups, as well as a strong absorption at 1603 cm^{-1} due to C=C stretching. Maxima in the uv spectrum at 229, 255, and 321 nm are consistent with a tetralone, and the position of the $\pi \rightarrow \pi^*$ absorption at 255 nm is in agreement with the calculated position of 256 nm for 7-hydroxytetralone (8). The mixture was acetylated to give a mixture of the two diacetates **18** and **19**, which were separable by flash chromatography. Both diacetates gave ions at *m/z* 306 (M^+) in their hreims, confirming molecular formulae of $C_{16}H_{18}O_6$. The Ftir of each diacetate displayed absorptions for aliphatic and aromatic acetate groups, a conjugated ketone, and also a hydroxyl absorption at 3492 cm^{-1} indicating the presence of a tertiary hydroxyl group in each parent triol. The ^1H nmr spectra of the diacetates are very similar and in each case the coupling of the aromatic hydrogen signals indicates the presence of a 1,2,4-trisubstituted aromatic ring. The most noticeable difference between the ^1H nmr spectra of the two diacetates is the size of the H2–H3 coupling constants. In the spectrum of arthropsatriol D diacetate (**19**) this coupling is 10.6 Hz and supports a *trans* relationship of H2 and H3, whereas in the spectrum of arthropsatriol C diacetate (**18**) the H2–H3 coupling constant is 4.3 Hz. The structures assigned to the diacetates were confirmed by nOe experiments. Significant nOe's are observed between the signals of H3 and H5, and between the *ortho*-aromatic hydrogens (H5, H6) in the spectra of each diacetate, and therefore the aromatic acetate group must be located at C7. The stereochemistry assigned to arthropsatriol C diacetate (**18**) at C2, C3, and C11 is supported by nOe's from H12 to H1 (1.5%), H1 to H3 (6.1%), and between H2 and H3 (11.8%, 13.9%). For arthropsatriol D diacetate (**19**) a nOe from H12 to H3 (14.0%) confirms the relative configuration at C11 and C3 and a large nOe from H1 to H3 (10.2%) supports the *trans* relationship of C2 and C3 substituents. Accordingly arthropsatriols C (**16**) and D (**17**) differ only in their stereochemistry at C3.

*Arthropsolide A (**20**)*

This compound was obtained as needles, mp 142–145°C, $[\alpha]_D$ −302.4, which had a molecular formula of $C_{13}H_{14}O_5$ (*m/z* 250) as suggested by hreims, and confirmed by an ion at *m/z* 268 ($M^+ + NH_4^+$) in the cims. The base peak in the hreims at *m/z* 108 may arise via retro Diels–Alder fragmentation to give the ketene-heptadiene fragment shown in Fig. 2. The Ftir spectrum shows absorptions attributable to hydroxyl (3400 cm^{-1}), conjugated ketone (1685 cm^{-1}), and γ-lactone (1798 cm^{-1}) groups. The presence of the exocyclic methylene group is probably responsible for the shift of the lactone absorption from that of butyrolactone at 1770 cm^{-1} (cf. 2(3*H*)-furanone absorbs at 1790 cm^{-1} (5)). The ^1H nmr spectrum (Table 1) contains a number of features in common with that of arthropsadiol A (**1**), especially with regard to the α,β-unsaturated ketone and the (*E*)-propenyl group. A ^1H–^1H COSY spectrum of arthropsolide A (**20**) displays cross peaks between the vinyl hydrogen signals of both of these groups and a signal at δ 3.94 (H4), but in the absence of a hydrogen at C9 in arthropsolide A (**20**) the signal for H10 shows no further coupling (cf. in the spectrum of arthropsadiol A (**1**) the signal of H4 is coupled to H9, which in turn is coupled to the signals of H8 and H10). Two additional isolated spin systems are observed in the ^1H–^1H COSY spectrum of arthropsolide A (**20**), between H8 (δ 4.69) and 8-OH (δ 4.45), and between the methylene hydrogens (H12, δ 4.75, 4.62), H10 (δ 5.30), and 10-OH (δ 3.79).

The ^{13}C nmr spectrum of arthropsolide A (**20**) displays 13 signals (Table 1) and is fully consistent with the structure proposed for this compound. To establish the relative stereochemistry at the four asymmetric carbons, arthropsolide A (**20**) was converted into the corresponding dibenzoate **21** since the proximity of the signals of H12A, H12B, and H8 in the ^1H nmr spectrum of **20** complicated selective irradiation of these hydrogens during nOe experiments. The signals due to these hydrogens are well separated in the spectrum of the dibenzoate **21** as are those of the remaining hydrogens, with the exception of H10 (δ 6.31), which nearly overlaps with the H6 signal (δ 6.26). Irradiation of the H8

For personal use only.

signal (δ 6.10) results in nOe's to the signals of H10 (4.9%) and H4 (10.7%), thereby establishing the relative stereochemistry at C4, C8, C9, and C10 in a single experiment. This is supported by a large nOe from H4 to H8 (16.0%). The signals due to H12A and H12B were also differentiated with the help of nOe experiments. Thus, the H12B signal (δ 4.62) shows nOe's to both the H10 (3.7%) and H12A (δ 4.96, 41.3%) signals, while the H12A signal shows a nOe only to the H12B signal (42.6%).

The structure derived for arthropsolide A (**20**) on the basis of the spectroscopic data was unequivocally confirmed by an X-ray crystal structure determination carried out on the dibenzoate **21** (Fig. 3).[2] After determining the structure of **21** we became aware of a very similar series of fungal metabolites containing a 2-azaspiro[4.5]decane skeleton (e.g., spirostaphylotrichin K (**22**)) that were recently isolated from liquid cultures of *Staphylotrichum coccosporum* and mutant strains of this fungus (9–11). Two other 2-azaspiro[4.5]-decane fungal metabolites, triticone A (**23**) and triticone B (**24**) (= spirostaphylotrichin D and C respectively) have been isolated from *Drechslera tritici-repentis* (12).

[2]The X-ray crystallographic study was carried out by Dr. B. Santasiero, Structure Determination Laboratory, Chemistry Department, University of Alberta, Edmonton, Alberta T6G 2G2. Inquiries regarding the crystallographic results should be directed to Dr. Santasiero at the above address quoting report number SDL:WAA9002.

Arthropsolides B (25) and C (26)

These two compounds were obtained as an inseparable (tlc, hplc) mixture that decomposed slowly on standing. The hreims spectrum gave a weak ion at *m/z* 248, which suggested a molecular formula of $C_{13}H_{12}O_5$, and this is consistent with an ion at *m/z* 266 ($M^+ + NH_4^+$, 100%) in the cims. The base peak at *m/z* 108 in the hreims corresponds to a heptadiene-ketene fragment as in the spectrum of arthropsolide A (**20**). The ^1H nmr spectrum of arthropsolide B (**25**) and C (**26**) displays two sets of signals which are each very similar to the spectrum of arthropsolide A (**20**). However, the spectrum differs from that of arthropsolide A (**20**) by the absence of signals attributable to a hydrogen at C10, and by the downfield shift of the signals due to the exocyclic methylene group (H12) due to conjugation with the C10 ketone. Furthermore, in the absence of a hydrogen at C10 the signals of the exocyclic methylene hydrogens are simplified from a doublet of doublets in the spectrum of arthropsolide A (**20**) (δ 4.75, 4.62) to doublets in the spectrum of arthropsolides B (**25**) and C (**26**) (δ 5.15, 5.10, 4.63, 4.57). The ^{13}C nmr spectrum of arthropsolides B (**25**) and C (**26**) also reflects the effects of oxidation of only the C10 alcohol of arthropsolide A (**20**). Thus, the signal for C11 shifts upfield to δ 150.29 (cf. δ 156.88 for arthropsolide A (**20**)) and the signals for C12 are shifted downfield to δ 96.47, 95.90 (cf. δ 88.60 for arthropsolide A (**20**)) due to conjugation between the exocyclic double bond and the C10 ketone. Oxidation of arthropsolide A (**20**) with pyridinium chlorochromate gave a mixture of arthropsolides B (**25**) and C (**26**) as the only isolable product.

Arthropsolide B (**25**) and C (**26**) are very similar in terms of structure and instability to the inseparable mixtures of spirostaphylotrichin G (**27**) and H (**28**) from *Staphylotrichum coccosporum* (10), and triticone A (**23**) and B (**24**) from *Staphylotichum coccosporum* (9) and *Drechslera tritici-repentis* (12). *Drechslera tritici-repentis* is a major pathogen of wheat and it has been suggested that the retro-aldol intermediate **29** by which triticone A and B readily interconvert may be responsible for the lesions produced on wheat plants by this fungus (12). In an analogous fashion arthropsolide B (**25**) and C (**26**) may interconvert via the retroaldol intermediate **30** and these compounds may be responsible for inhibiting the growth of the blue-stain fungus *Ophiostoma clavigerum*.

Arthropsolide D (31)

The final compound from chromatography of the crude broth extract of our liquid culture of *A. truncata* was an oily solid that gave a weak ion at *m/z* 252 in the hreims and an ion at *m/z* 270 ($M^+ + NH_4^+$, 100) in the cims, thereby confirming a molecular formula of $C_{13}H_{16}O_5$. Several features in the ^1H and ^{13}C nmr spectra of this compound indicate that it is derived from reduction of the C7 ketone of arthropsolide A (**20**) to the corresponding allylic alcohol. Thus, in the absence of conjugation the signals for H6 and H5 in the ^1H nmr spectrum occur at δ 5.49 and δ 5.69, respectively (cf. δ 6.19, 6.65 for arthropsolide A (**20**)), while the signal of H8 (δ 3.69) shows coupling (^1H–^1H COSY) to the signal for H7 (δ 4.80) as well as to a hydroxyl signal at δ 5.60. The ^{13}C nmr spectrum of arthropsolide D (**31**) is also consistent with reduction of the C7 ketone of arthropsolide A (**20**). Thus, only one carbonyl signal (C13) and an extra carbinol signal (C7) are observed and the signals for C5 and C6 occur between δ 127 and 130.

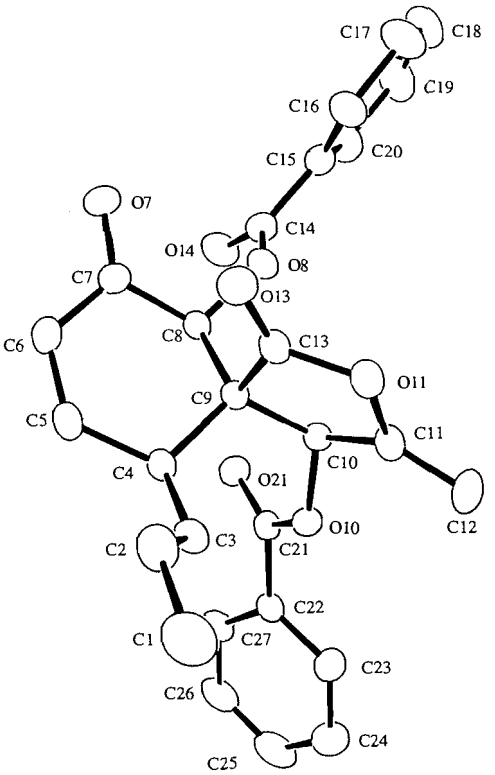

FIG. 3. A computer-generated perspective drawing of the final X-ray model of arthropsolide A dibenzoate (**21**) (hydrogen atoms have been omitted for clarity).

The relative configuration of arthropsolide D (**31**) was not readily apparent from an examination of the coupling constants of the signals due to H7 and H8 in the ^{1}H nmr spectrum, as both these signals appear as broad singlets. Furthermore, the proximity of these signals to other hydrogen signals made it difficult to do selective irradiations during nOe experiments. Since the dibenzoate of arthropsolide A had proven useful in this regard, the tribenzoate **32** of arthropsolide D was prepared. In the ^{1}H spectrum of the tribenzoate **32** the 8.5 Hz coupling between the signals due to H8 (δ 6.09, d, J = 8.5 Hz) and H7 (δ 6.42, dddd, J = 8.5, 3.0, 2.0, 2.0 Hz) suggested an antiperiplanar relationship of these hydrogens. Significant nOe's are observed from H8 to H10 (7.8%) and H4 (9.0%), and from H4 to H8 (11.1%) and H10 (1.4%), and allow the relative configuration of arthropsolide D (**31**) and the tribenzoate **32** at C4, C7, C8, C9 and C10 to be assigned as shown.

The CD spectrum of tribenzoate **32** shows a strong positive Cotton effect at 236 nm. Application of the Harada–Nakanishi dibenzoate rule (13) thus indicates a positive chirality between the benzoate at C8 and that at C7, indicating that the absolute configuration of **32** and, by inference, the other new metabolites discussed, is as indicated in the structural drawings.

Experimental

For general experimental details see publication 14 from these laboratories. For ease of spectral comparisons (^{1}H, ^{13}C nmr) the numbering of each compound is in accordance with that indicated diagrammatically for each carbon skeleton, and not the IUPAC nomenclature for each compound. The IUPAC name is provided with the experimental description of the compound. The numbering system used in the text is based on biosynthetic considerations which will be discussed in a subsequent paper. Signals indicated (*) or (**) in the ^{13}C nmr may be interchanged. Hexanes refers to Stanchem Ltd. (Edmonton) light petroleum, bp 62–70°C. Unless otherwise indicated, the following procedure was used for acetylations. The alcohol was stirred with acetic anhydride (10–20 equiv.), pyridine (10–20 equiv.), and a crystal of 4-dimethylaminopyridine (DMAP) in dichloromethane (5 mL) until tlc indicated complete reaction. The reaction mixture was then evaporated using benzene to assist with the azeotropic removal of pyridine, and the product was purified by flash chromatography eluting with ethyl acetate – Skellysolve B (1:3) to give the acetylated derivative.

Growth of Arthropsis truncata *and isolation of metabolites*

Freeze-dried cultures of *Arthropsis truncata* Sigler, Dunn & Carmichael (UAMH 4430) were obtained from Mrs. L. Sigler, University of Alberta Microfungus Herbarium, Edmonton. Lyophilized cultures were inoculated onto, and maintained on, plates of malt extract agar. After 6 weeks growth one plate was blended with water (100 mL) and used to inoculate five 2-L Erlenmeyer flasks each containing 1 L of modified malt extract medium (20 g malt extract (Difco), 20 g D-glucose, 1.0 g bacto-peptone (Difco), 1 L water). The cultures were grown on a rotary shaker (at 150 rpm) at room temperature for 4 weeks, then the black arthroconidia and mycelial fragments were separated by filtration through cheesecloth. The filtered culture broth was concentrated at reduced pressure to approximately 500 mL and then extracted with ethyl acetate (4 × 500 mL). The combined extracts were dried over magnesium sulfate and evaporated to give a brown oil (2.35 g).

A portion of the extract (1.20 g) was dissolved in ethyl acetate – methanol, adsorbed onto silica gel (5 g), and dried in air with gentle warming. The dried extract – silica gel mixture was poured onto the top of a column of silica gel (150 g) packed with ethyl acetate – hexanes (1:2), and 25-mL fractions were eluted successively with ethyl acetate – hexanes (1:2, fractions 1–36), ethyl acetate – hexanes (2:3, fractions 37–55), ethyl acetate – hexanes (1:1, fractions 56–72), ethyl acetate (fractions 73–112), and ethyl

acetate – methanol (20:1, fractions 113–130). Fractions containing similar components (tlc) were combined and further purified by fractional crystallization or additional chromatography.

Fractions 4–7 (7 mg) contained a mixture of triglycerides (^{1}H nmr). Fractions 12–17 (20 mg) were chromatographed, eluting with ethyl acetate – hexanes (1:3), to give an inseparable mixture of arthropsolides B (**25**) and C (**26**) (14 mg). Fractions 20–26 (22 mg) contained a mixture of diglycerides (^{1}H nmr). Fractions 27–32 (29 mg) crystallized from dichloromethane to give cycloarthropsone (**12**) (14 mg). Fractions 37–53 (164 mg) were crystallized from ethyl acetate – hexanes to give arthropsolide A (**20**) (55 mg). Column chromatography of the crystallization mother liquours from fractions 37–53, eluting with dichloromethane–methanol (20:1), gave arthropsadiol A (**1**) (28 mg) followed by further arthropsolide A (**20**) (31 mg). Fractions 63–71 (44 mg) were crystallized from dichloromethane to give an inseparable mixture of an arthropsatriols C (**16**) and D (**17**) (21 mg). Fractions 72–86 (59 mg) were chromatographed, eluting with dichloromethane–methanol (20:1), to give arthropsadiol B (**3**) (8 mg) followed by cycloarthropsadiol C (**9**) (12 mg). Fractions 87–112 (30 mg) were chromatographed, eluting with dichloromethane–methanol (20:1 then 10:1), to give arthropsolide D (**31**) (16 mg). Fractions 113–130 (48 mg) were chromatographed to give a mixture of arthropsatriols A (**5**) and B (**6**) (22 mg), which was separated by preparative tlc after developing several times with dichloromethane–methanol (15:1) to afford arthropsatriol A (**5**) (8 mg) and arthropsatriol B (**6**) (6 mg).

*Arthropsadiol A (**1**)* ((4*S**,5*S**6*S**)-6-hydroxy-5-(1-hydroxy-2-oxopropyl)-4-[(*E*)-prop-1-enyl[-2-cyclohexen-1-one) crystallized on standing, as thin needles, mp 78–79°C, $[\alpha]_D^{25}$ −245.7 (*c* 1.05, CH_3OH); cd (*c* 0.39 mM, CH_3OH): $[\theta]_{244}$ -5.14×10^6, $[\theta]_{328}$ -5.08×10^5; uv (CH_3OH) λ_{max} (log ϵ): 229 nm (3.88); Ftir ($CHCl_3$ cast): 3450, 1689, 1108, 1052, 1044 cm^{-1}; ^{1}H nmr ($CDCl_3$): see Table 1; nOe ($CDCl_3$): irradiate δ 4.32 (H8): 3.49 (H4, 3.4%); irradiate δ 3.49 (H4): 6.68 (H5, 3.9%), 5.53 (H2, 9.0%), 5.09 (H3, 3.4%), 4.54 (H10, 2.5%), 4.32 (H6, 7.2%); irradiate δ 2.39 (H5): 5.09 (H7, 4.4%), 4.54 (H10, 6.0%), 2.16 (H12, 2.7%); ^{13}C nmr ($CDCl_3$): see Table 1; hreims (probe 100°C), *m/z* calcd. for $C_{12}H_{16}O_4$ (M^+): 224.1049; found: 224.1050 (1.9), 181 (M^+ − CH_3CO, 100), 151 (20), 150 (26), 135 (38), 107 (28), 80 (21), 79 (27), 43 (30); cims: 242 ($M^+ + NH_4^+$, 100), 225 ($M^+ + NH_4^+$, 29).

Acetylation of arthropsadiol A (**1**) gave the diacetate **2** as a clear oil; uv (CH_3OH) λ_{max} (log ϵ): 225 nm (4.06); Ftir ($CHCl_3$ cast): 1752, 1729, 1701, 1372, 1232 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 6.64 (1H, dd, *J* = 10.0, 2.2 Hz, H5), 6.05 (1H, dd, *J* = 10.2, 3.0 Hz, H6), 5.67 (1H, dq, *J* = 15.5, 7.0 Hz, H2), 5.34 (1H, d, *J* = 1.9 Hz, H10), 5.27 (1H, d, *J* = 13.1 Hz, H8), 5.13 (1H, ddq, *J* = 15.0, 9.5, 1.5 Hz, H3), 3.45 (1H, dddd, *J* = 10.0 ,10.0, 2.7, 2.7 Hz, H4), 3.02 (1H, ddd, *J* = 12.7, 10.0, 2.0 Hz, H9), 2.20, 2.18, (3H each, 2 s, 8-OAc, 10-OAc), 2.08 (3H, s, H12), 1.65 (3H, dd, *J* = 7.0, 1.5 Hz, H1); ^{13}C nmr ($CDCl_3$) δ: 204.44 (C11), 192.29 (C7), 169.87 (OAc), 169.81 (OAc), 152.52 (C5), 131.50 (C2), 129.76 (C3), 126.76 (C6), 75.37 (C10), 72.28 (C8), 46.98 (C9), 41.91 (C4), 26.74 (C12), 20.52 (OAc), 20.45 (OAc), 17.45 (C1); hreims (probe 150°C), *m/z* calcd. for $C_{16}H_{22}O_6$ (M^+): 308.1260; found: 308.1269 (0.1), 248 (M^+ − HOAc, 6), 188 (M^+ − 2HOAc, 6), 135 (33), 43 (100); cims: 326 ($M^+ + NH_4^+$, 100).

*Arthropsadiol B (**3**)* ((4*S**,5*S**,6*R**)- 6-hydroxy- 5-(2- hydroxy-1-oxopropyl)-4-[(*E*)]-prop-1-enyl]-2-cyclohexen-1-one) was obtained as a clear oil; $[\alpha]_D^{25}$ −389 (*c* 0.32, CH_3OH); uv (CH_3OH) λ_{max} (log ϵ): 235 nm (3.65); Ftir ($CHCl_3$ cast): 3448, 3426, 1716, 1687, 1096 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 6.80 (1H, dd, *J* = 10.0, 5.5 Hz, H5), 6.13 (1H, dd, *J* = 10.0, 1.0 Hz, H6), 5.59 (1H, dq, *J* = 15.5, 6.5 Hz, H2), 5.29 (ddq, *J* = 15.0, 8.2, 1.5 Hz, H3), 4.71 (1H, d, *J* = 12.0 Hz, H8), 4.36 (1H, br qd, *J* = 7.0, 4.0 Hz, H11), 3.52 (1H, d, *J* = 5.7 Hz), 3.48 (1H, m), 3.40 (1H, br d, *J* = 4.5 Hz), 1.68 (3H, dd, *J* = 6.5, 1.5 Hz, H1), 1.39 (3H, d, *J* = 7.5 Hz, H12); nOe ($CDCl_3$): irradiate δ 4.71 (H8): 5.29 (H3, 6.1%); irradiate δ 4.36 (H11): 3.52 (8.1%), 1.39 (H12, 2.0%); irradiate δ 1.39 (H12): 5.29 (H3, 1.0%), 4.71 (H8, 3.3%), 4.36 (H11, 10.8%); ^{13}C nmr ($CDCl_3$) δ: 208.78 (C10), 198.77 (C7), 150.60 (C5), 131.58 (C2), 125.57 (C3), 124.09 (C6), 71.94 (C8), 68.93 (C11), 52.27 (C9), 42.06 (C4), 19.68 (C12), 17.98 (C1); hreims (probe 120°C), *m/z* calcd. for $C_{12}H_{16}O_4$ (M^+): 224.1049; found: 224.1045 (1.5), 206 (M^+ − H_2O, 1.1), 180 (26), 152 (100), 134 (20), 123 (24), 108 (22), 105 (20), 91 (25), 84 (23), 80 (34), 79 (34), 77 (24), 71 (44), 45 (23), 43 (24).

Acetylation of cycloarthropsadiol C

A solution of cycloarthropsadiol C (**9**) (4.8 mg), acetic anhydride (60 μL), pyridine (40 μL), and a crystal of DMAP in dichloromethane (1 mL) was stirred at room temperature for 3 h, then evaporated to dryness. The resulting oil was chromatographed, eluting with ethyl acetate – hexanes (1:3) to give cycloarthropsadiol C diacetate (**10**) (4.3 mg, 66%) which crystallized on standing; ^{1}H nmr ($CDCl_3$) δ: 6.09 (1H, d, *J* = 4.0 Hz, H8), 5.66 (1H, dqd, *J* = 15.0, 6.5, 1.0 Hz, H2), 5.42 (ddq, *J* = 15.5, 7.8, 1.5 Hz, H3), 4.25 (1H, br dddd, *J* = 3.8, 2.0, 2.0, 2.0 Hz, H5), 3.14 (1H, br d, *J* = 7.8 Hz, H4), 2.99 (1H, ddd, *J* = 4.0, 3.0, 1.7 Hz, H9), 2.79 (1H, dd, *J* = 13.0, 2.0 Hz, H6α), 2.60 (1H, dd, *J* = 13.0, 4.3 Hz, H6β), 2.094 (3H, s, OAc), 2.085 (3H, s, OAc), 1.67 (3H, dd, *J* = 6.5, 1.0 Hz, H1), 1.44 (3H, s, H12); nOe ($CDCl_3$): irradiate δ 6.09 (H8): 3.14 (H4, 6.9%), 2.99 (H9, 10.4%), 2.79 (H6α, 2.3%); irradiate δ 4.25 (H5): 5.42 (H3, 3.1%), 3.14 (H4, 5.2%), 2.79 (H6α, 2.4%), 2.60 (H6β, 5.2%); irradiate δ 3.14 (H4): 6.09 (H8, 10.7%), 5.66 (H2, 8.4%), 5.42 (H3, 4.7%), 4.25 (H5, 8.4%), 2.99 (H9, 7.7%), 2.79 (H6α, 4.7%), 2.60 (H6β, −1.4%); irradiate δ 2.99 (H9): 6.09 (H8, 9.8%), 5.66 (H2, 1.9%), 5.42 (H3, 3.5%), 3.14 (H4, 2.7%); irradiate δ 2.79 (H6α): 6.09 (H8, 8.3%), 4.25 (H5, 7.8%), 3.14 (H4, 5.3%), 2.60 (H6β, 29.6%); irradiate δ 2.60 (H6β): 4.25 (H5, 11.4%), 2.79 (H6α, 20.2%); hreims (probe 120°C), *m/z* calcd. for $C_{15}H_{20}O_6$ (M^+ − CO); 296.1260; found: 290.1260 (13), 152 (30), 134 (29), 108 (64), 43 (100); cims: 342 ($M^+ + NH_4^+$, 51), 325 ($M^+ + H^+$, 20), 282 (80), 265 (100).

Further elution of the column with ethyl acetate – hexanes (1:2) gave cycloarthropsadiol C-8-acetate (**11**) (1.5 mg, 27%); ^{1}H nmr ($CDCl_3$) δ: 5.66 (1H, dqd, *J* = 15.5, 6.5, 1.0 Hz, H2), 5.43 (1H, ddq, *J* = 15.5, 7.5, 1.5 Hz, H3), 5.27 (1H, d, *J* = 2.7 Hz, H8), 4.27 (1H, br dddd, *J* = 3.8, 2.0, 2.0, 2.0 Hz, H5), 3.07 (1H, br d, *J* = 7.5 Hz, H4), 2.98 (1H, ddd, *J* = 3.5, 3.5, 1.8 Hz, H9), 2.46 (1H, dd, *J* = 13.1, 4.0 Hz, H6), 2.14 (3H, s, OAc), 2.03 (1H, dd, *J* = 13.1, 1.8 Hz, H6), 1.67 (3H, dd, *J* = 6.5, 1.0 Hz, H1), 1.39 (3H, s, H12).

Arthropsatriol A (**5**) ((1*R**,4*S**,5*S**,6*S**)-5-(1-hydroxy-2-oxopropyl)-4-[(*E*)-prop-1-enyl]-2-cyclohexene-1,6-diol) was obtained as a clear oil; Ftir ($CHCl_3$ cast): 3400, 1708, 1357, 1234, 1110, 1074, 1031, 973 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 5.82 (1H, ddd, *J* = 9.5, 5.5, 2.5 Hz, H6), 5.59 (1H, dd, *J* = 10.0, 2.5 Hz, H5), 5.37 (1H, dq, *J* = 15.2, 6.5 Hz, H2), 5.02 (1H, ddq, *J* = 15.5, 9.5, 1.5 Hz, H3), 4.60 (1H, br s, OH), 4.19 (1H, br dd, *J* = 4.5, 4.5 Hz, H7), 3.94 (1H, br s, H10), 3.81 (1H, dd, *J* = 10.5, 4.3 Hz, H8), 3.15 (1H, br s, OH), 2.97 (1H, br dddd, *J* = 9.5, 9.5, 2.5, 2.5 Hz, H4), 2.60 (1H, v br s, OH), 2.21 (1H, ddd, *J* = 10.5, 9.5, 1.5 Hz, H9), 2.17 (3H, s, H12), 1.57 (3H, dd, *J* = 6.5, 1.5 Hz, H1); ^{13}C nmr ($CDCl_3$) δ: 210.71 (C11), 135.98 (C5), 131.32 (C3), 129.92 (C2), 124.86 (C6), 75.16 (C10), 69.05 (C8), 65.86 (C7), 43.75 (C9), 39.67 (C4), 25.70 (C12), 17.49 (C1); hreims (probe 100°C), *m/z* calcd. for $C_{12}H_{16}O_3$ ($M^+ - H_2O$): 208.1099; found: 208.1103 (0.7), 190 ($M^+ - 2H_2O$, 1.3), 183 ($M^+ - CH_3CO$, 29), 165 (50), 147 (25), 135 (71), 134 (31), 119 (48), 110 (25), 107 (51), 95 (38), 95 (56), 93 (20), 91 (100), 81 (34), 79 (50), 77 (37), 74 (44), 73 (41), 71 (38), 67 (35), 57 (22), 55 (25), 53 (26); cims: 244 ($M^+ + NH_4^+$, 71), 226 (53), 209 (100).

Acetylation of arthropsatriol A (**5**) gave the corresponding triacetate **7** as a clear oil; Ftir ($CHCl_3$ cast): 1746, 1710, 1371, 1241, 1230, 1060, 1028, 1016 cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 5.72 (1H, ddd, *J* = 10.5, 5.5, 2.3 Hz, H6), 5.67 (1H, dd, *J* = 9.5, 2.1 Hz, H5), 5.53 (1H, dq, *J* = 15.0, 6.5 Hz, H2), 5.45 (1H, ddd, *J* = 5.0, 3.8, 1.0 Hz, H7), 5.34 (1H, d, *J* = 1.8 Hz, H10), 5.07 (1H, ddq, *J* = 15.2, 9.5, 1.6 Hz, H3), 4.94 (1H, dd, *J* = 12.2, 3.8 Hz, H8), 3.10 (1H, br dddd, *J* = 9.5, 9.5, 2.0, 2.0 Hz, H4), 2.80 (1H, ddd, *J* = 12.2, 10.5, 2.0 Hz, H9), 2.16, 2.12, 2.09, 2.01 (3H each, 4 s, 3 × OAc, H12), 1.61 (3H, dd, *J* = 6.5, 1.5 Hz, H1); nOe ($CDCl_3$): irradiate δ 5.45 (H7): 5.72 (H6, 9.0%), 4.94 (H8, 13.0%); irradiate δ 5.34 (H10): 4.94 (H8, 2.8%), 2.80 (H9, 10.8%); irradiate δ 4.94 (H8): 5.45 (H7, 16.5%), 3.10 (H4, 7.6%); irradiate δ 3.10 (H4): 5.67 (H5, 14.7%), 5.53 (H2, 10.7%), 5.07 (H3, 6.6%), 4.94 (H8, 10.7%); irradiate δ 2.80 (H9): 5.34 (H10, 16.6%), 5.07 (H3, 10.8%); hreims (probe 150°C), *m/z* calcd. for $C_{14}H_{18}O_4$ (M^+ −HOAc − CH_2CO): 250.1205; found: 250.1208 (0.6), 232 (M^+ −2HOAc, 0.6), 147 (27), 135 (28), 134 (27), 129 (28), 116 (25), 91 (27), 43 (100); cims: 370 ($M^+ + NH_4^+$, 100).

Arthropsatriol B (**6**) ((1*S**,4*S**,5*S**,6*S**)-5-(1-hydroxy-2-oxopropyl)-4-[(*E*)-prop-1-enyl]-2-cyclohexene-1,6-diol) was obtained as a clear oil; $[\alpha]_D^{25}$ − 216 (*c* 1.00, CH_3OH); ^{1}H nmr ($CDCl_3$) δ: 5.53 (1H, br ddd, *J* = 10.0, 2.0, 2.0 Hz, H6), 5.38–5.26 (2H, m, H5, H2), 4.95 (1H, ddq, *J* = 15.5, 9.5, 1.5 Hz, H3), 4.62 (1H, br s, OH), 4.25 (1H, br s, H10), 4.19 (1H, br d, *J* = 7.5 Hz, H7), 3.64 (1H, dd, *J* = 10.6, 8.0 Hz, H8), 2.99 (1H, br dddd, *J* = 9.5, 9.5, 5.5, 2.5 Hz, H4), 2.14 (3H, s, H12), 2.07 (1H, br dd, *J* = 10.2, 10.2 Hz, H9), 1.55 (3H, dd, *J* = 6.5, 1.5 Hz, H1); ^{13}C nmr ($CDCl_3$) δ: 210.65 (C11), 131.66 (C5), 131.53 (C3), 129.80 (C2), 127.67 (C6), 74.85 (C10), 72.98 (C7), 72.74 (C8), 47.53 (C9), 39.74 (C4), 25.78 (C12), 17.52 (C1); hreims (probe 120°C), *m/z* calcd. for $C_{12}H_{16}O_3$ ($M^+ - H_2O$): 208.1099; found: 208.1099 (0.9), 165 (37), 147 (30), 135 (100), 134 (43), 119 (40), 110 (43), 107 (52), 95 (61), 91 (74), 81 (29), 79 (35), 77 (26), 74 (56), 73 (24), 71 (22), 67 (28), 57 (25), 56 (23), 55 (21), 53 (20); cims: 244 ($M^+ + NH_4^+$, 100).

Acetylation of arthropsatriol B (**6**) gave the triacetate **8** as a clear oil; ^{1}H nmr ($CDCl_3$) δ: 5.56–5.45 (4H, m, H2, H5, H6, H7), 5.21 (1H, d, *J* = 2.0 Hz, H10), 5.12 (1H, dd, *J* = 12.0, 8.5 Hz, H8), 4.99 (1H, ddq, *J* = 15.5, 9.8, 1.5 Hz, H3), 3.18 (1H, br dd, *J* = 10.0, 10.0 Hz, H4), 2.63 (1H, ddd, *J* = 12.5, 10.5, 2.0 Hz, H9), 2.17 (3H, s, OAc), 2.05 (3H, s, OAc), 2.03 (6H, s, OAc, H12), 1.59 (3H, dd, *J* = 6.5, 1.5 Hz, H1); ^{1}H nmr (C_6D_6) δ: 5.73 (1H, dddd, *J* = 8.5, 3.0, 2.0, 2.0 Hz, H7), 5.42 (1H, d, *J* = 2.3 Hz, H10), 5.41 (1H, dd, *J* = 11.6, 8.2 Hz, H8), 5.38 (1H, ddd, *J* = 9.8, 2.2, 2.2 Hz, H6), 5.24 (1H, ddd, *J* = 10.0, 2.2, 2.2 Hz, H5), 5.20 (1H, dq, *J* = 15.5, 6.5 Hz, H2), 4.78 (1H, ddq, *J* = 15.0, 9.6, 1.5 Hz, H3), 3.09 (1H, br dddd, *J* = 9.6, 9.6, 5.6, 2.6 Hz, H4), 2.51 (1H, ddd, *J* = 12.5, 10.3, 2.0 Hz, H9), 1.840, 1.792, 1.690, 1.687 (3H each, 4s, 3 OAc, H12), 1.34 (3H, dd, *J* = 6.5, 1.8 Hz, H1); nOe (C_6D_6): irradiate δ 5.73 (H7): 5.38 (H6, 8.3%), 2.51 (H9, 6.5%); irradiate δ 4.78 (H3): 3.09 (H4, 1.9%), 2.51 (H9, 4.9%); irradiate δ 3.09 (H4): 5.41 (H8, 8.2%), 5.24–5.20 (H5, H2, 9.1%), 4.78 (H3, 3.0%); irradiate δ 2.51 (H9): 5.73 (H7, 9.5%), 5.42 (H10, 10.3%), 4.78 (H3, 7.8%).

Arthropsatriol C (**16**) and *arthropsatriol D* (**17**) ((2*S**, 3*R**,4*S**)- and (2*S**,3*R**,4*R**)-3,4-dihydro-2,3-dimethyl-2,4,6-trihydroxy-1(2*H*)-naphthalenone) were obtained as a white solid; uv (CH_3OH) λ_{max} (log ε): 229 (4.00), 255 (3.91), 321 nm (3.43); Ftir (KBr): 3406, 1678, 1603, 1445, 1390, 1315, 1223, 1166, 1154, 1135, 1011, 968, 834 cm^{-1}; ^{1}H nmr (CD_3OD) δ: (major epimer, arthropsatriol C): 7.32 (1H, d, *J* = 8.5 Hz, H5), 7.22 (1H, d *J* = 2.5 Hz, H8), 6.98 (1H, dd, *J* = 8.2, 2.5 Hz, H6), 4.96 (1H, d, *J* = 4.5 Hz, H3), 2.29 (1H, qd, *J* = 7.0, 4.6 Hz, H2), 1.29 (3H, s, H12), 0.94 (3H, d, *J* = 7.0 Hz, H1); δ (minor epimer, arthropsatriol D): 7.47 (1H, dd, *J* = 8.5, 1.0 Hz, H5), 7.21 (1H, d, *J* = 2.5 Hz, H8), 7.01 (1H, dd, *J* = 8.5, 2.6 Hz, H6), 4.33 (1H, d, *J* = 9.8 Hz, H3), 2.00 (1H, dq, *J* = 9.5, 6.8 Hz, H2), 1.19 (3H, d, *J* = 6.9 Hz, H1), 1.08 (3H, s, H12); hreims (probe 150°C), *m/z* calcd. for $C_{12}H_{14}O_4$ (M^+): 222.0892; found: 222.0888 (4.6), 204 (38), 162 (34), 161 (90), 150 (23), 122 (53), 121 (100), 65 (23), 43 (46), 39 (20); cims: 240 ($M^+ + NH_4^+$, 100).

Acetylation of the mixture of arthropsatriols C and D

A solution of the mixture of arthropsatriols C and D (20 mg), acetic anhydride (0.25 mL), pyridine (0.25 mL), and a crystal of DMAP in dichloromethane (5.5 mL) was stirred at room temperature for 4 h, then diluted with ethyl acetate and washed successively with 1 M hydrochloric acid, water, and saturated sodium hydrogen carbonate. Evaporation of the dried solution gave an oil that was subjected to preparative tlc. Several developments with dichloromethane – methanol (100:1) gave 3 bands, which were

eluted with ethyl acetate to give, in order of decreasing R_f: a mixture of 2 triacetates (2.0 mg, 6%); arthropsatriol D diacetate (**19**) (7.4 mg, 27%), and arthropsatriol C diacetate (**18**) (10.3 mg, 37%).

Arthropsatriol D diacetate (**19**) was obtained as a clear oil; uv (CH_3OH) λ_{max} (log ϵ): 218 (4.09), 243 (4.05), 292 nm (3.36); Ftir ($CHCl_3$ cast): 3492, 1765, 1749, 1693, 1609, 1371, 1230, 1206, 1190, 759 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.76 (1H, d, J = 2.5 Hz, H8), 7.35 (1H, dd, J = 8.5, 2.5 Hz, H6), 7.27 (1H, d, J = 8.5 Hz, H5), 6.03 (1H, d, J = 10.6 Hz, H3), 3.87 (1H, s, OH), 2.38 (1H, dq, J = 10.6, 6.8 Hz, H2), 2.33 (3H, s, 7-OAc), 2.25 (3H, s, 3-OAc), 1.28 (3H, s, H12), 1.22 (3H, d, J = 6.5 Hz, H1); nOe ($CDCl_3$): irradiate δ 7.27 (H5): 7.35 (H6, 3.8%), 6.03 (H3, 2.4%); irradiate δ 6.03 (H3): 7.27 (H5, 4.0%); irradiate δ 2.38 (H2): 1.22 (H1, 1.7%); irradiate δ 1.28 H12): 6.03 (H3, 14.0%); irradiate δ 1.22 (H1): 6.03 (H3, 10.2%); ^{13}C nmr ($CDCl_3$) δ: 200.15 (C10), 171.07 (OAc), 169.01 (OAc), 150.76 (C7), 138.97 (C4), 130.11 (C9), 128.29 (C6), 128.14 (C8), 120.14 (C5), 75.96 (C11), 72.29 (C3), 45.39 (C2), 21.01 (OAc), 20.92 (OAc), 19.58 (C12), 10.61 (C1); hreims (probe 140°C), m/z calcd. for $C_{16}H_{18}O_6$ (M^+): 306.1103; found: 306.1100 (1.1), 246 (18), 204 (77), 203 (21), 192 (24), 162 (57), 161 (100), 150 (45), 149 (25).

Arthropsatriol C diacetate (**18**) was obtained as a clear oil; uv (CH_3OH) λ_{max} (log ϵ): 212 (4.21), 246 (4.01), 294 nm (3.23); Ftir ($CHCl_3$ cast): 3492, 1767, 1740, 1694, 1608, 1371, 1234, 1205, 1191, 757 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 7.75 (1H, d, J = 2.5 Hz, H8), 7.53 (1H, d, J = 8.5 Hz, H5), 7.33 (1H, dd, J = 8.5, 2.5 Hz, H6), 6.27 (1H, d, J = 4.3 Hz, H3), 3.57 (1H, br s, OH), 2.58 (1H, qd, J = 7.0, 4.5 Hz, H2), 2.33 (3H, s, 7-OAc), 2.12 (3H, s, 3-OAc), 1.42 (3H, s, H12), 1.21 (3H, d, J = 7.0 Hz, H1); nOe ($CDCl_3$): irradiate δ 7.53 (H5): 7.33 (H6, 13.6%), 6.27 (H3, 9.1%); irradiate δ 7.33 (H6): 7.53 (H5, 11.1%); irradiate δ 6.27 (H3): 7.53 (H5, 10.7%), 2.58 (H2, 13.9%); irradiate δ 2.58 (H2): 6.27 (H3, 11.8%); irradiate δ 1.42 (H12): 1.21 (H1, 1.5%); irradiate δ 1.21 (H1): 6.27 (H3, 6.1%), 2.58 (H2, 15.3%); ^{13}C nmr ($CDCl_3$) δ: 200.86 (C10), 170.62 (OAc), 169.06 (OAc), 151.28 (C7), 137.59 (C4), 131.49 (C8)*, 130.69 (C9), 128.28 (C6)*, 120.57 (C5), 75.26 (C11), 69.89 (C3), 41.12 (C2), 22.44 (C12), 20.99 (OAc), 10.20 (C1), one signal obscured; hreims (probe 110°C), m/z calcd. for $C_{16}H_{18}O_6$ (M^+): 306.1103; found: 306.1102 (1.8), 246 (37), 204 (100), 192 (21), 162 (49), 161 (78), 150 (41), 149 (22), 43 (57).

Arthropsolide A (**20**) ((4*S**,5*R**,6*S**,10*S**)-4,6-dihydroxy-3-methylidene-10-[(*E*)-prop-1-enyl]- 2- oxospiro[4.5]dec- 8-en-1,7-dione) crystallized from dichloromethane as fine needles, mp 142–145°C, $[\alpha]_D^{25}$ −302 (*c* 1.00, CH_3OH); cd (*c* 0.40 mM, CH_3OH): $[\theta]_{241}$ -4.85×10^6, $[\theta]_{332}$ -4.49×10^5; uv (CH_3OH) λ_{max} (log ϵ): 204 (4.39), 236 nm (4.07); Ftir ($CHCl_3$ cast): 3400, 1798, 1685, 1164, 1143, 1117, 1080 cm^{-1}; ^1H nmr ($CDCl_3$): see Table 1; ^{13}C nmr ($CDCl_3$): see Table 1; hreims (probe 120–180°C), m/z calcd. for $C_{13}H_{14}O_5$ (M^+): 250.0841; found: 250.0838 (1.1), 232 ($M^+ - H_2O$, 3.3), 214 ($M^+ - 2H_2O$, 1.3), 108 (100), 100 (20), 80 (93), 79 (46), 77 (24), 39 (23); cims: 268 ($M^+ + NH_4^+$, 100).

Benzoylation of arthropsolide A

A solution of arthropsolide A (**20**) (9.0 mg), benzoyl chloride (40 μL), pyridine (50 μL), and a crystal of DMAP in dichloromethane (2 mL) was stirred at room temperature for 3 days under argon. The mixture was diluted with ethyl acetate and washed successively with 1 M hydrochloric acid, water, and saturated sodium hydrogen carbonate. Evaporation of the dried solution and flash chromatography of the product, eluting with ethyl acetate – hexanes (1:3), gave successively arthropsolide A dibenzoate (**21**) (12.3 mg, 74%), and a monobenzoate of arthropsolide A (3.5 mg, 25%). Arthropsolide A dibenzoate (**21**) crystallized from acetone–dichloromethane–hexanes as prisms, mp 182–184°C; Ftir ($CHCl_3$ cast): 1809, 1737, 1709, 1682, 1600, 1583, 1452, 1250, 1111, 1071, 1061, 1022, 972, 755, 708 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 8.15–8.04 (4H, m, ArH), 7.73–7.42 (6H, m, ArH), 6.58 (1H, dd, J = 10.1, 2.5 Hz, H5), 6.31 (1H, dd, J = 2.2, 2.2 Hz, H10), 6.26 (1H, dd, J = 10.1, 3.0 Hz, H6), 6.10 (1H, s, H8), 5.82 (1H, dq, J = 15.2, 6.5 Hz, H2), 5.62 (1H, ddq, J = 15.2, 8.0, 1.5 Hz, H3), 4.96 (1H, dd, J = 3.0, 3.0 Hz, H12A), 4.62 (1H, dd, J = 2.5, 2.5 Hz, H12B), 3.71 (1H, br ddd, J = 8.0, 2.5, 2.5 Hz, H4), 1.76 (3H, dd, J = 6.3, 1.5 Hz, H1); nOe ($CDCl_3$): irradiate δ 6.10 (H8): 6.31 (H10, 4.9%), 3.71 (H4, 10.7%); irradiate δ 4.96 (H12A): 4.62 (H12B, 42.6%); irradiate δ 4.62 (H12B): 6.31 (H10, 3.7%), 4.96 (H12A, 41.3%); irradiate δ 3.71 (H4): 6.58 (H5, 10.6%), 6.31 (H10, 1.0%), 6.26 (H6, −1.0%), 6.10 (H8, 16.0%), 5.82 (H2, 6.9%), 5.62 (H3, 8.8%); hreims (probe 200°C), m/z calcd. for $C_{27}H_{22}O_7$ (M^+): 458.1365; found: 458.1370 (1.3), 336 $M^+ - C_6H_5CO_2H$, 3.7), 105 (100), 77 (23).

Arthropsolide B (**25**) and *arthropsolide C* (**26**) ((5*R**,6*S**,10*S**)- and (5*R**,6*R**,10*S**)-6-hydroxy-3-methylidene-10-[(*E*)-prop-1-enyl]-2-oxaspiro[4.5]dec-8-en-1,4,7-trione respectively) were obtained as an unstable pink oil; uv (CH_3OH) λ_{max} (log ϵ): 213 (3.93), 242 nm (3.93); Ftir ($CHCl_3$ cast): 3480, 1814, 1753, 1698, 1649, 1260, 1116 cm^{-1}; ^1H nmr ($CDCl_3$) δ (major epimer): 6.67 (1H, dd, J = 10.0, 2.3 Hz, H5), 6.30 (1H, dd, J = 10.5, 3.3 Hz, H6), 5.70 (1H, dq, J = 15.0, 6.8 Hz, H2), 5.49 (1H, d, J = 3.4 Hz, H8), 5.29 (1H, ddq, J = 14.9, 8.8, 1.5 Hz, H3), 5.15 (1H, d, J = 2.8 Hz, H12), 4.57 (1H, d, J = 2.0 Hz, H12), 3.80 (1H, d, J = 2.3 Hz, OH), 3.76 (1H, ddd, J = 9.2, 2.5, 2.5 Hz, H4), 1.66 (3H, dd, J = 6.6, 2.0 Hz, H1); (minor epimer): 6.68 (1H, dd, J = 10.0, 2.3 Hz, H5), 6.30 (1H, dd, J = 10.5, 3.3 Hz, H6), 5.80 (1H, dq, J = 15.0, 6.8 Hz, H2), 5.39 (1H, d, J = 2.7 Hz, H8), 5.23 (1H, ddq, J = 15.2, 9.5, 2.0 Hz, H3), 5.10 (1H, d, J = 3.3 Hz, H12), 4.63 (1H, d, J = 2.2 Hz, H12), 3.86 (1H, ddd, J = 9.5, 2.5, 2.5 Hz, H4), 3.70 (1H, d, J = 1.9 Hz, OH), 1.67 (3H, dd, J = 6.6, 2.0 Hz, H1); ^{13}C nmr ($CDCl_3$) δ: 194.41 (C10), 193.52/193.36 (C7), 169.83/168.55 (C13), 150.29 (C11), 148.38/148.04 (C5), 134.44/134.38 (C6), 126.42/126.38 (C3), 123.91/123.63 (C2), 96.47/95.90 (C12), 73.21/72.78 (C8), 61.41 (C9), 45.26/44.56 (C4), 17.84 (C1); hreims (probe 80–150°C), m/z calcd. for $C_{13}H_{12}O_5$ (M^+): 248.0685; found: 248.0688 (0.5), 219 ($M^+ - CHO$, 0.5), 191 ($M^+ - C_2HO_2$, 0.5), 191 ($M^+ - C_3H_5O$, 0.3), 165 ($M^+ - C_4H_3O_2$, 2.8), 108 ($M^+ - C_6H_4O_4$, 100), 80 (75), 79 (40); cims: 266 ($M^+ + NH_4^+$, 100).

Arthropsolide D (**31**) ((4*S**,5*R**,6*S**,7*S**,10*S**)-3-methylidene- 10-[(*E*)-prop-1-enyl]-4,6,7-trihydroxy- 2-oxaspiro[4.5]dec-8-en-1-one was obtained as an oily solid; $[\alpha]_D^{25}$ −239 (*c* 1.09, CH_3OH); Ftir ($CHCl_3$ cast): 3400, 1784, 1679, 1099, 1063 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 5.69 (1H, br d, J = 9.5 Hz, H5), 5.63 (1H, dq, J = 15.0, 7.0 Hz, H2), 5.60 (1H, br d, J = 6.0 Hz, OH), 5.49 (1H, br dd, J = 10.0, 1.5 Hz, H6), 5.28 (1H, ddq, J = 15.5, 8.5, 1.8 Hz, H3), 5.19 (1H, br ddd, J = 6.5, 2.0, 2.0 Hz, H10), 4.80 (1H, br s, H7), 4.75 (1H, dd, J = 2.2, 2.2 Hz, H12), 4.65 (1H, dd, J = 2.2, 2.2 Hz, H12), 4.24 (1H, br s, OH), 3.69 (1H, br s, H8), 3.60 (1H, br d, J = 8.5 Hz, H4), 2.48 (1H, br s, OH), 1.60 (3H, dd, J = 6.5, 1.5 Hz, H1); ^{13}C nmr ($CDCl_3$) δ: 174.49 (C13), 157.02 (C11), 131.07 (C2)*, 129.78 (C6)*, 127.28 (C5)*, 127.20 (C3)*, 88.67 (C12), 72.22 (C10)**, 69.70 (C8)**, 69.14 (C7)**, 57.72 (C9), 39.40 (C4), 17.81 (C1); hreims (probe 150°C), m/z calcd. for $C_{13}H_{16}O_5$ (M^+): 252.0997; found: 252.0980 (1.0), 234 ($M^+ - H_2O$, 38), 162 (62), 161 (100), 147 (37), 134 (41), 133 (29), 125 (20), 121 (25), 110 (38), 107 (32), 105 (24), 95 (79), 91 (55), 88 (36), 81 (43), 79 (40), 77 (46), 73 (48), 72 (43), 71 (34), 70 (51), 43 (20); cims: 270 ($M^+ + NH_4^+$, 100).

Benzoylation of arthropsolide D

A solution of arthropsolide D (**31**) (8.0 mg), benzoyl chloride (110 μL), pyridine (100 μL), and a crystal of DMAP in dichloromethane (2 mL) was stirred at room temperature for 24 h under argon. The mixture was diluted with ethyl acetate and washed successively with 1 M hydrochloric acid, water, and saturated sodium hydrogen carbonate. Evaporation of the dried solution and flash chromatography of the product, eluting with ethyl acetate – hexanes (1:5), gave arthropsolide D tribenzoate (**32**) as an oil (7.3 mg, 41%); cd (*c* 0.135, CH_3OH) 25°C: $[\theta]_{236}$ $+4.65 \times 10^4$; ^1H nmr ($CDCl_3$) δ: 8.14–7.33 (15H, m, ArH), 6.42 (1H, dddd,

J = 8.5, 3.0, 2.0, 2.0 Hz, H7), 6.25 (1H, dd, J = 2.2, 2.2 Hz, H10), 6.09 (1H, d, J = 8.5 Hz, H8), 5.91 (1H, ddd, J = 10.5, 2.6, 2.6 Hz, H6), 5.78 (1H, dqd, J = 15.5, 6.5, 1.0 Hz, H2), 5.62 (1H, ddd, J = 10.5, 2.2, 2.2 Hz, H5), 5.54 (1H, ddq, J = 15.5, 8.2, 1.5 Hz, H3), 4.86 (1H, dd, J = 2.6, 2.6 Hz, H12A), 4.48 (1H, dd, J = 3.2, 2.6 Hz, H12B), 3.57 (1H, br dddd, J = 8.0, 2.5, 2.0, 2.0 Hz, H4), 1.71 (3H, dd, J = 6.5, 1.0 Hz, H1); nOe ($CDCl_3$): irradiate δ 6.42 (H7): 5.91 (H5, 9.8%); irradiate δ 6.25 (H10): 6.09 (H8, 9.3%), 4.48 (H12B, 1.6%); irradiate δ 6.09 (H8): 6.25 (H10, 7.8%), 3.57 (H4, 9.0%); irradiate δ 5.91 (H6): 6.42 (H7, 12.4%), 5.62 (H5, 12.9%); irradiate δ 5.62 (H5): 5.91 (H6, 14.2%), 3.57 (H4, 8.1%); irradiate δ 4.86 (H12A): 4.48 (H12B, 39.5%); irradiate δ 4.48 (H12B): 6.25 (H10, 4.1%), 4.86 (H12A, 37.0%); irradiate δ 3.57 (H4): 6.25 (H10, 1.4%), 6.09 (H8, 11.1%), 5.78 (H2, 7.2%), 5.62 (H5, 8.3%), 5.54 (H3, 9.4%).

Oxidation of arthropsolide A

Pyridinium chlorochromate (20 mg) was added to a stirred solution of arthropsolide A (**20**) (5.0 mg) in dichloromethane (1 mL) and the mixture was stirred at room temperature for 30 min. Further pyridinium chlorochromate (30 mg) was added and stirring continued for an additional 2 h. The mixture was poured onto a pad of silica gel and eluted with ethyl acetate – hexanes (1:1). Evaporation of the filtrate and flash chromatography of the product, eluting with ethyl acetate – hexanes (1:2), gave a mixture of arthropsolides B (**25**) and C (**26**) as a clear oil (1.4 mg); ^{1}H nmr identical with that of the mixture of arthropsolides B and C isolated from the culture broth.

Biosynthesis and biogenetic interrelationships of metabolites of the fungus *Arthropsis truncata*

WILLIAM A. AYER[1] AND PETER A. CRAW
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received November 11, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

WILLIAM A. AYER and PETER A. CRAW. Can. J. Chem. **70**, 1348 (1992).

The incorporation of sodium [1-^{13}C]acetate and sodium [1,2-$^{13}C_2$]acetate into a number of polyketide metabolites produced by the fungus *Arthropsis truncata* has been examined. The location of sodium [1-^{13}C]acetate incorporation into arthropsadiol A (**1**), cycloarthropsone (**2**), and arthropsatriol C (**3**) has been determined by ^{13}C nuclear magnetic resonance spectra of the corresponding diacetate derivatives, and a biosynthetic pathway is proposed to account for the formation of **1–3**. Multiple incorporation of sodium [1,2-$^{13}C_2$]acetate into arthropsadiol A (**1**) leads to a complicated pattern of satellite multiplets in the ^{13}C nmr spectrum of the corresponding diacetate **6** that are interpreted with the aid of 2D-INADEQUATE spectra. A biosynthesis of arthropsolide A (**5**) is proposed and the absence of **5** and related metabolites in cultures of the *Arthropsis truncata* fed with ^{13}C-labelled sodium acetate is discussed.

WILLIAM A. AYER et PETER A. CRAW. Can. J. Chem. **70**, 1348 (1992).

On a étudié l'incorporation du [1-^{13}C] acétate de sodium et du [1,2-$^{13}C_2$]acétate de sodium dans un certain nombre de métabolites polycétides produits par le champignon *Arthropsis truncata*. En se basant sur le spectre RMN du ^{13}C des diacétates correspondants, on a déterminé la position d'incorporation du [1-^{13}C] acétate de sodium dans l'arthropsadiol A (**1**), la cycloarthropsone (**2**) et l'arthropsatriol C (**3**) et on propose une voie de biosynthèse qui tient compte de la formation des produits **1–3**. L'incorporation multiple du [1,2-^{13}C] acétate de sodium dans l'arthropsadiol A (**1**) conduit à un patron compliqué de multiplets satellites dans le spectre RMN du ^{13}C du diacétate correspondant **6** que l'on a pu interpréter à l'aide de spectres 2D-INADEQUATE. On propose une voie de biosynthèse de l'arthropsolide A (**5**) et on discute de l'absence de **5** et des métabolites apparentés dans les cultures de l'*Arthropsis truncata* dans lesquelles on a ajouté de l'acétate de sodium marqué au ^{13}C.

[Traduit par la rédaction]

Introduction

In the preceding paper we described the isolation and structure determination of 12 new polyketide metabolites produced in liquid cultures of the fungus *Arthropsis truncata* (1). As a continuation of our investigations of the chemistry of this fungus we have examined the incorporation of sodium [1-^{13}C]acetate and sodium [1,2-$^{13}C_2$]acetate by the fungus with the aim of elucidating the biosynthesis and biogenetic interrelationship of these interesting polyketide metabolites.

Discussion

Incorporation of sodium [1-^{13}C]acetate

Arthropsis truncata was grown as before (1) in liquid shake culture on a modified malt extract medium and was periodically supplemented with injections of a sterile solution of sodium [1-^{13}C]acetate. Chromatography of the ethyl acetate extract of the culture broth gave mainly arthropsadiol A (**1**) and lesser amounts of cycloarthropsone (**2**), and arthropsatriols C (**3**) and D (**4**). Surprisingly, none of the 2-oxaspiro[4.5]dec-8-ene metabolites (e.g., arthropsolide A (**5**)) isolated from our previous cultures of *Arthropsis truncata* were isolated from several cultures of the fungus that were fed sodium [1-^{13}C]acetate (arthropsolide A (**5**) was the major metabolite (35 mg/L) isolated previously).

Arthropsadiol A (**1**) isolated from cultures of *Arthropsis truncata* that had been injected with sodium [1-^{13}C]acetate was acetylated so that the intensities of each of the signals in the ^{13}C nmr spectrum could be normalized (2) to those of the introduced acetate carbonyl and methyl signals. This allows for direct comparison with the corresponding normalized signal intensities in the spectrum of natural ^{13}C abundance arthropsadiol A diacetate (**6**). The two spectra were recorded successively using identical nmr instrument parameters and similar concentrations of arthropsadiol A diacetate (**6**). Enhancements of the signals due to C2, C4, C6, C8, and C10 were observed (Table 1), and a starter effect (3) was apparent from the slightly greater enhancement

SCHEME 1. Possible biosynthesis of arthropsadiol A (**1**) from a hexaketide precursor.

of the signal for C2. The signal of the terminal methyl group (C12) showed no enhancement.

The ^{13}C labelling of arthropsadiol A diacetate (**6**) suggests that the carbon skeleton of this metabolite is derived from a polyketide such as **7** assembled from six acetate units (Scheme 1).[2] Reduction of the C2, C4, and C6 ketone groups of **7** followed by elimination of three equivalents of water would give the triene **8**. Epoxidation of **8** to give the C6–C7 epoxide **9** and ensuing S_N2'-like reaction with a C9 anion might then give the cyclohexenone intermediate **10**. Isomerization of the α-hydroxy ketone moiety in **10** to the conjugated α′-hydroxy enone would give intermediate **11**, which possesses the cyclohexenone unit of arthropsadiol A (**1**). Methylation of the terminal acetate unit at C11 by methionine, followed by oxidative decarboxylation of the enzyme-bound carboxyl group (C12′), would form the three-carbon chain (C10–C12), and account for the lack of enhancement of the signal for C12 in the ^{13}C nmr spectrum of arthropsadiol A diacetate (**6**).

In the ^{13}C nmr spectrum of the arthropsadiol A diacetate (**6**) incorporating sodium [1-^{13}C]acetate the signals due to C6 (δ 126.8) and C8 (δ 72.3) display satellite peaks ($^2J_{CC}$ = 15.0) resulting from multiple incorporation of sodium [1-^{13}C]acetate

[2]The numbering of the biosynthetic intermediates corresponds to that used previously for the metabolites (1).

into some molecules of arthropsadiol A (**1**). This $^2J_{CC}$ is comparable to the 15.2 Hz coupling reported between C1 and C3 of 2-butanone (4). Excessive incorporation of ^{13}C-labelled precursors leading to multiple ^{13}C labels within a single molecule is often encountered during pulse feeding of ^{13}C-labelled biosynthetic precursors (5).

The ^{13}C nmr spectra of two further metabolites incorporating sodium [1-^{13}C]acetate were also obtained after conversion into their corresponding diacetate derivatives (Table 1). In the ^{13}C nmr spectra of both cycloarthropsone diacetate (**12**) and arthropsatriol C diacetate (**13**) the signals of C2, C4, C6, C8, and C10 are enhanced, but again there is no apparent enhancement of the signals due to C12. These results lead us to propose that cycloarthropsone (**2**) and arthropsatriols C (**3**) and D (**4**) are formed from arthropsadiol A (**1**) as outlined in Scheme 2. Thus oxidation of arthropsadiol A (**1**) at C8 (path a) gives the α-diketone **14**, which upon aromatization would give the catechol **15**. Oxidation at C10 and cyclization between the C8 phenolic oxygen and C11 then leads to formation of cycloarthropsone (**2**). Alternatively, dehydration of arthropsadiol A (**1**) (path b) would give the phenol **16**. Epoxidation of the C2–C3 olefin and enolization of the C11 carbonyl group gives intermediate **17**, which may cyclize in the indicated fashion to give arthropsatriols C (**3**) and D (**4**).

Incorporation of sodium [1,2-$^{13}C_2$]acetate

In Scheme 1 it was postulated that the terminal acetate of a polyketide precursor of arthropsadiol A (**1**) is methylated by methionine and the enzyme-bound carboxyl group is removed, possibly by an oxidative decarboxylation process. Accordingly, if sodium [1,2-$^{13}C_2$]acetate is incorporated by *Arthropsis truncata* into arthropsadiol A (**1**), the signals for C11 and C12 in the ^{13}C nmr spectrum of labelled **1** should appear as singlets whereas the signals for C1–C10 might be expected to display satellite peaks due to $^1J_{CC}$ from incorporation of intact acetate units. Chromatography of the ethyl acetate extract of the broth from a culture of *Arthropsis truncata* that had periodically been supplemented with a solution of sodium [1,2-$^{13}C_2$]acetate gave arthropsadiol A (**1**) as the major isolable metabolite along with lesser amounts of arthropsatriols C (**3**) and D (**4**). No arthropsolide A (**5**) or related 2-oxaspiro[4.5]dec-8-ene metabolites were isolated.

In the ^{13}C nmr spectrum of the diacetate (**6**) from sodium [1,2-$^{13}C_2$]acetate labelled arthropsadiol A the signal for C12 occurs as a singlet, confirming that C11 and C12 of arthropsadiol A (**1**) are not derived from incorporation of a single acetate unit. However, the signal for C11 is not a singlet due to multiple incorporation of labelled acetate in some molecules of **1**. The signal for C11 displays satellite peaks with $J_{C10-C11}$ 43 Hz as a result of successive incorporation of two labelled acetate units at C9–C10 and C11–C12′. Similar multiple incorporation of labelled acetate into other molecules of arthropsadiol A (**1**) results in complex multiplets for the signals of C2–C10. The signal of C1, being the methyl terminus of the postulated polyketide intermediates (Scheme 1), displays only a single intense pair of satellites (J_{C1-C2} 42 Hz). The signals of C2 and C3 display asymmetric satellites (Fig. 1). The signal for C2 (δ 131.4) shows the expected satellite peaks *a* (J_{C1-C2} 43 Hz) due to molecules that have incorporated sodium [1,2-$^{13}C_2$]acetate at C1–C2 but not C3–C4 (Table 2). Molecules that have incorporated sodium [1,2-$^{13}C_2$]acetate at both C1–C2 and C3–C4 display a C2 signal having the appearance of a doublet of doublets *b* (J_{C2-C3} 72 Hz, J_{C2-C1} 43 Hz), the centre of which occurs slightly downfield from δ 131.4 due to an isotope shift. The signal for C3 at δ 129.8 displays a satellite doublet *c* (J_{C3-C4} 44 Hz) due to molecules that contain sodium [1,2-$^{13}C_2$]acetate at C3–C4, and an isotope-shifted doublet of doublets *d* (J_{C3-C2} 68 Hz, J_{C3-C4} 44 Hz) due to molecules that contain sodium [1,2-$^{13}C_2$]acetate at C3–C4 and C1–C2.

The additional satellite multiplets for the signals of C4–C10 in the ^{13}C nmr spectrum of **6**, which arise from multiple incorporation of sodium [1,2-$^{13}C_2$]acetate into some molecules of arthropsadiol A (**1**), have been assigned in Table 2. The assignments are consistent with correlations observed in 2D-INADEQUATE (6) spectra of **6** that were optimized for J_{CC} 20 Hz (Fig. 2) and J_{CC} 40 Hz (Fig. 3). As in the ^{13}C nmr spectrum of **6** incorporating sodium [1-^{13}C]acetate (see Table 1), a $^2J_{CC}$ is observed between C6 and C8 (15 Hz) in the ^{13}C nmr spectrum of **6** incorporating sodium [1,2-

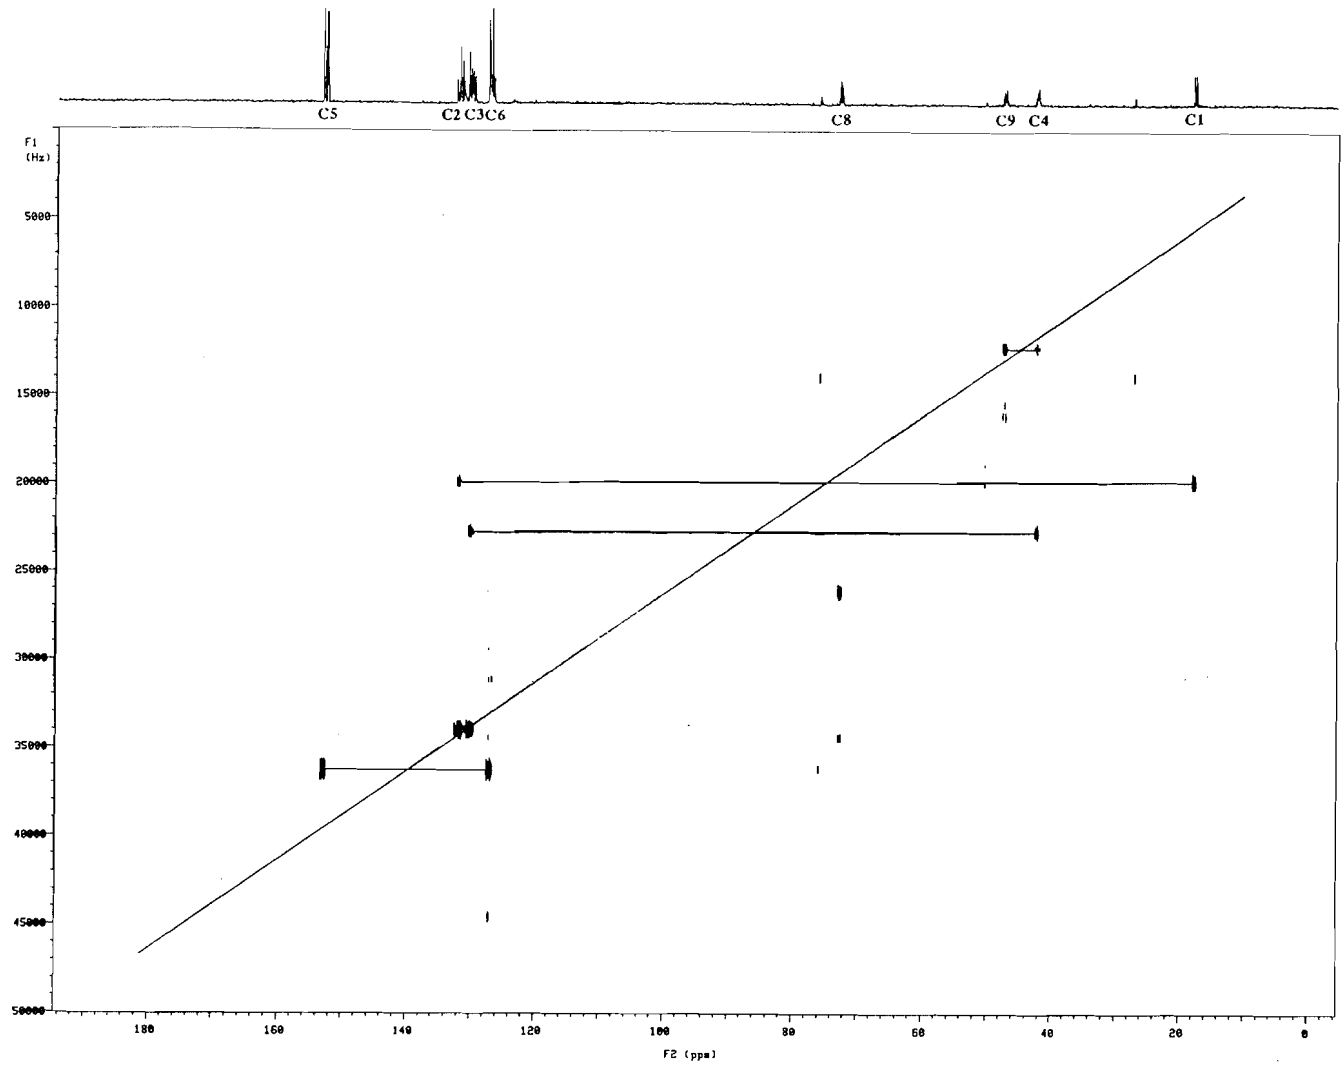

FIG. 2. 2D-INADEQUATE spectrum (optimized for J_{CC} 20 Hz) of arthropsadiol A diacetate (**6**) incorporating sodium [1,2-$^{13}C_2$]acetate.

$^{13}C_2$]acetate (Fig. 1). The signal for C4 displays a strong satellite doublet (J_{C4-C3} 43 Hz) due to incorporation of an intact [1,2-$^{13}C_2$]acetate unit at C3–C4. In the 2D-INADEQUATE spectra of **6** the signal of C4 is correlated not only to the signal of C3 but also to C5 and C9. This suggests that a significant number of molecules of arthropsadiol A (**1**) have multiple incorporation of sodium [1,2-$^{13}C_2$]acetate at C3–C4, C5–C6, and C9–C10. Assuming that J_{CC} between C4 and C9 is approximately 35–40 Hz, then incorporation of sodium [1,2-$^{13}C_2$]acetate at C3–C4, C5–C6, and C9–C10 would result in a ddd of satellite peaks due to coupling of C4 to C3, C5, and C9. If the ddd overlaps both the C4 singlet due to natural abundance ^{13}C, and the dd due to incorporation of sodium [1,2-$^{13}C_2$]acetate at C3–C4, then a pattern of satellites similar to that observed for the signal of C4 (Fig. 4) might be expected. The C4–C9 coupling of 35–40 Hz is not immediately apparent from examination of the signal due to C9 because the dd of satellites (J_{C9-10} 35 Hz, J_{C9-C8} 35 Hz) due to multiple sodium [1,2-$^{13}C_2$]acetate incorporation at C7–C8 and C9–C10 is coincident with the dd of satellites (J_{C9-C4} 35–40 Hz, J_{C9-C10} 35 Hz) due to sodium [1,2-$^{13}C_2$]acetate incorporation at C3–C4 and C9–C10.

The fact that C11 is derived from acetate in the sodium [1,2-$^{13}C_2$]acetate feeding experiment suggests that C12 is derived from the one carbon pool, not from the incorporation of propionate (or lactate) during the assembly of the polyketide chain.

*Possible biosynthesis of arthropsolide A (**5**) and related metabolites*

Arthropsolide A (**5**) and the related 2-oxaspiro[4.5]dec-8-ene metabolites isolated from *Arthropsis truncata* (1) are structurally very similar to a number of metabolites (spirostaphylotrichins A–T) isolated recently from the fungus *Staphylotrichum coccosporum* (7–9). The biosynthesis of a number of the compounds produced by *Staphylotrichum coccosporum* has been investigated, and it has been proposed that a pentaketide precursor and aspartic acid combine to give an amide that undergoes ring formation to generate the 2-azaspiro[4.5]dec-8-ene skeleton common to spirostaphyotrichins A–T (10). In an analogous fashion (Scheme 3) we propose that the 2-oxaspiro[4.5]dec-8-ene skeleton of arthropsolide A (**5**) might be formed by the condensation of a pentaketide precursor and malic acid to give the ester **18**. The γ-lactone intermediate **19** could then arise from C9–C10 bond formation and subsequent ketone re-

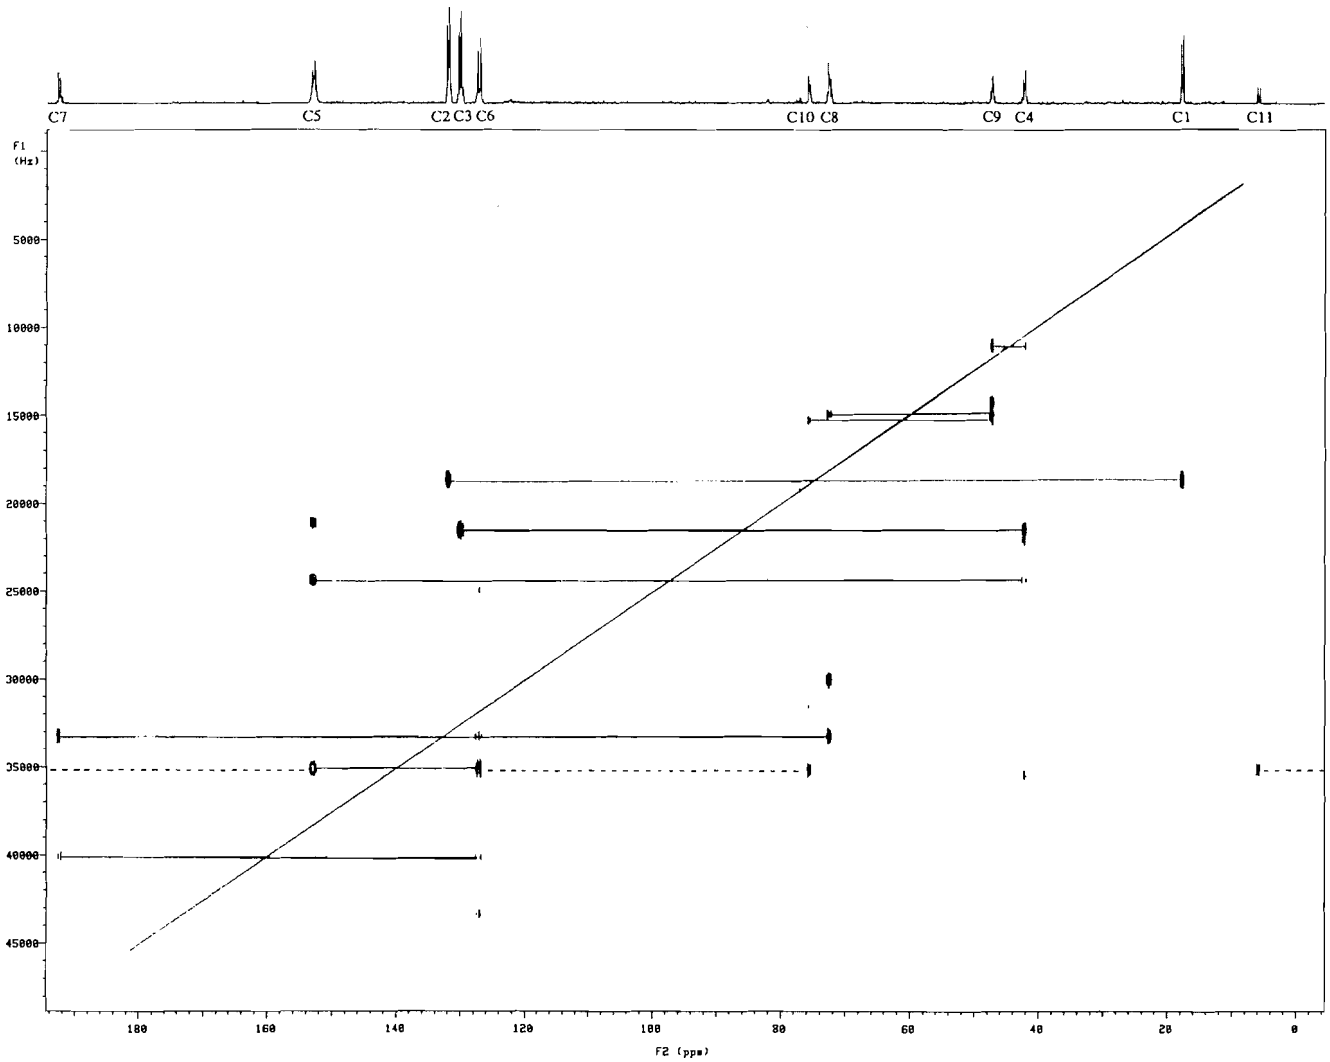

FIG. 3. 2D-INADEQUATE spectrum (optimized for J_{CC} 40 Hz) of arthropsadiol A diacetate (**6**) incorporating sodium [1,2-$^{13}C_2$]acetate. Note the folded signal of C11.

ductions and elimination of water to give triene intermediate **20**. Epoxidation of **20** to give the C6–C7 epoxide **21** and ensuing S_N2'-like reaction with a C9 anion would form the 2-oxaspiro[4.5]dec-8-ene precursor **22** of arthropsolides A–D.

Unfortunately we were unable to isolate arthropsolides A–D from three successive liquid cultures of *Arthropsis truncata* that were periodically fed sodium [1-^{13}C]acetate. In one culture the production of arthropsolide A (**5**) was detected by hplc of an aliquot of the culture medium at day 9 following inoculation (sodium [1-^{13}C]acetate was added at day 5), and in another culture arthropsolide A (**5**) was detected at day 11 (sodium [1-^{13}C]acetate added at days 3 and 6). However, in each case, when the cultures were harvested several days later arthropsolide A (**5**) was not detected in the ethyl acetate extract of the culture broth. We must at this stage postulate that the addition of sodium acetate to the culture broth of *Arthropsis truncata* alters the balance between biosynthesis of C_{12} metabolites such as arthropsadiol A (**1**), and the biosynthesis of C_{13} metabolites such as arthropsolide A (**5**) to favor the predominant formation of C_{12} metabolites.

The possibility that arthropsolide A (**5**) is converted into arthropsadiol A (**1**) via hydrolysis of the γ-lactone moiety and subsequent decarboxylation (Scheme 4) can be discounted on the basis of the results from incorporation of sodium [1,2-$^{13}C_2$]acetate into arthropsadiol A (**1**). Thus if arthropsadiol A (**1**) were formed from arthropsolide A (**5**), then C9 and C10 in **1** would not be derived from a single acetate unit and accordingly these two carbon atoms should not display coupling in the ^{13}C nmr spectrum of arthropsadiol A diacetate (**6**). However, as can be seen in the ^{13}C nmr data for arthropsadiol A diacetate (**6**) labelled with sodium [1,2-$^{13}C_2$]acetate (Table 2), C9 and C10 display a J_{CC} of 35 Hz. The coupling between C9 and C10 was confirmed by the 2D-INADEQUATE spectrum optimized for J_{CC} 40 Hz. Hence we believe that the conversion of arthropsolide A (**5**) into arthropsadiol A (**1**) as in Scheme 4 does not account for the absence of **5** among the metabolites isolated from cultures of *Arthropsis truncata* that have been fed ^{13}C labelled sodium acetate.

Experimental

For general experimental details see ref. 1. High-performance liquid chromatography (hplc) was performed with a Waters model

6000A solvent delivery system and a Waters model 480 LC spectrophotometer set at 254 nm. Analytical hplc was carried out using a Waters Radial Compression Z module fitted with a Waters 8MBC1810μ Radial Pak liquid chromatography cartridge (8 mm i.d.), and semi-preparative scale hplc was carried out on a Waters μ-Bondapak C18 column (7.8 × 300 mm). Sodium [1-^{13}C]acetate (99 at.% ^{13}C) and sodium [1,2-$^{13}C_2$]acetate (99 at.% ^{13}C) were purchased from MSD Isotopes (Montreal). Acetylations were performed as described previously (1). 2D-INADEQUATE and ^{1}H-decoupled ^{13}C nmr spectra of sodium [1,2-$^{13}C_2$]acetate labelled arthropsadiol A diacetate (**6**) were recorded in $CDCl_3$ solution at 125 MHz using a Varian Unity 500 spectrometer.

Biosynthetic studies of Arthropsis truncata *metabolites*

Incorporation of sodium [1-^{13}C]acetate

Arthropsis truncata was grown in liquid shake culture on a sterile modified malt extract medium (4 × 1 L) as described in the experimental section of the previous paper (1). After 3 days' growth a sterile solution of sodium [1-^{13}C]acetate (5 mL, 0.2 mol L^{-1}) was injected into each of the flasks, then further sodium [1-^{13}C]acetate (5 mL, 0.2 mol L^{-1}) was added to each of the flasks at day 6 and day 9 following inoculation of the liquid culture. At day 12 the culture was filtered through cotton wool and the culture broth extracted with ethyl acetate (1.5 L) for 24 h. The ethyl acetate extract was dried over magnesium sulfate and evaporated to give a yellow-brown foam (0.56 g).

The extract was adsorbed onto a small amount of silica gel using ethyl acetate, then dried in air with gentle warming and poured onto a column of silica gel slurry packed using dichloromethane–methanol (10:1). Fractions of 7 mL were eluted from the column using dichloromethane–methanol (10:1) to give fractions containing arthropsadiol A (**1**) (fractions 8–11, 35 mg), cycloarthropsone (**2**) (fractions 12–21, 52 mg), and mixtures of arthropsatriol C (**3**) and arthropsatriol D (**4**) (fractions 22–33, 27 mg).

The crude arthropsadiol A (**1**) was purified by hplc (methanol–water (50:50), 2 mL min^{-1}) to give arthropsadiol A (19 mg), which crystallized on standing; ^{1}H nmr identical with that reported previously (1). Acetylation gave arthropsadiol A diacetate (**6**); ^{1}H nmr identical with that reported previously (1).

The impure cycloarthropsone (**2**) was chromatographed, eluting with ethyl acetate – hexanes (1:2) to give cycloarthropsone (3.1 mg), which crystallized as a yellow solid; ^{1}H nmr identical with that reported previously (1). Acetylation of this material gave cycloarthropsone diacetate (**12**); ^{1}H nmr identical with that reported previously (1).

The mixture containing arthropsatriol C (**3**) and arthropsatriol D (**4**) was acetylated and the product mixture separated by preparative tlc on silica gel. After two developments with dichloromethane–methanol (100:1) two main bands were observed which were then separately eluted from the silica gel using ethyl acetate, and further purified by hplc (methanol–water (60:40)) to give arthropsatriol D diacetate (3.6 mg) and arthropsatriol C diacetate (**13**) (5.1 mg). The ^{1}H nmr spectra of each of these diacetates were identical with those reported previously (1).

Incorporation of sodium [1,2-$^{13}C_2$]acetate

Arthropsis truncata was grown in liquid shake culture on a sterile modified malt extract medium (4 × 1 L) as described in the experimental section of the previous paper (1). After 3 days' growth a sterile solution of sodium [1,2-$^{13}C_2$]acetate (5 mL, 0.1 mol L^{-1}) was injected into each of the flasks, then further sodium [1,2-$^{13}C_2$]acetate (5 mL, 0.1 mol L^{-1}) was added to each of the flasks at day 6, day 9, and day 12. At day 17 the culture was filtered and the culture broth extracted with ethyl acetate (2 L) for 24 h. The ethyl acetate extract was dried over magnesium sulfate and evaporated to give an orange-brown foam (1.10 g).

Chromatography of the ethyl acetate extract as above using dichloromethane–methanol (20:1, fractions 1–50; then 10:1, fractions 51–78) successively gave fractions containing arthropsadiol A (**1**) (fractions 14–18, 30 mg), and arthropsatriol C (**3**) and arthropsatriol D (**4**) (fractions 51–63, 26 mg).

The fractions containing arthropsadiol A (**1**) were subjected to hplc as above to give arthropsadiol A (18 mg), which crystallized on standing; ^{1}H nmr identical with that reported previously (1). Acetylation gave arthropsadiol A diacetate (**6**); ^{1}H nmr identical with that reported previously (1).

The fractions containing arthropsatriol C (**3**) and arthropsatriol D (**4**) were acetylated and the product mixture was separated as above to give arthropsatriol D diacetate (3.2 mg) and arthropsatriol C diacetate (**4**) (5.7 mg). The ^{1}H nmr spectra of each of these diacetates were identical with those reported previously (1).

2-Cyclohexenone rings that form part of a larger structural assembly are amenable to peracid oxidation with formation of an epoxy lactone. These intermediates are readily transformed under acidic, basic, or neutral conditions to ring-contracted aldehydo lactones, which are then subjected to condensation with a slight excess of Tebbe reagent. These conditions result in methylenation of carbonyl groups and set the stage for operation of a Claisen rearrangement. When the latter is catalyzed by Tribal, the sigmatropic process occurs at room temperature. With systems typified by **17** and **24**, the isomerization is complete within 15 min. The presence of a proximate angular methyl group as in **9***b*, **29**, and **37** exerts a retarding kinetic effect. In such examples, a period of 6 h is required to achieve completion. Swern oxidation completes the conversion to the 4-cyclooctenones, where the two carbons stemming from the Tebbe reagent are inserted between the original carbonyl and α-olefinic carbons. The overall process is tolerant of ether functionality and additional sites of unsaturation.

LEO A. PAQUETTE, CHRISTOPHE M. G. PHILIPPO et NHA HUU VO. Can. J. Chem. **70**, 1356 (1992).

Il est possible de soumettre des cyclohexèn-2-ones faisant partie de l'assemblage de grandes structures à des oxydations par les peracides avec formation d'une époxy-lactone. On peut facilement transformer ces intermédiaires, dans des conditions acidique, basique ou neutre, en aldéhydo-lactones ayant subi une contraction de cycle; ces dernières sont alors soumises à une condensation avec un léger excès de réactif de Tebbe. Ces conditions permettent d'effectuer la méthylénation des deux groupes carbonyles permettant de procéder à une transposition de Claisen. Quand on effectue celle-ci à l'aide de Tribal comme catalyseur, le processus sigmatropique que se produit à la température ambiante. Avec des systèmes comme **17** et **24**, l'isomérisation est complète en 15 min. La présence d'un groupe méthyle angulaire à proximité comme il en existe dans les composés **9***b*, **29** et **37**, exerce un effet cinétique qui ralentit la réaction. Dans ces exemples, il faut 6 h pour arriver à une réaction complète. Une oxydation de Swern complète la conversion en cyclo-octèn-4-ones dans lesquelles les deux carbones provenant du réaction de Tebbe sont insérés entre les carbones du carbonyle original et celui du carbone α-oléfinique. On peut effectuer l'ensemble des ces opérations en présence d'une fonction éther et d'autres sites d'insaturation.

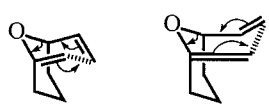
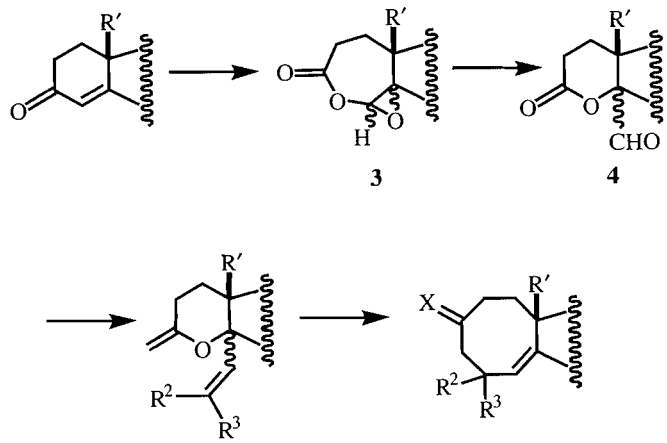
Previous accounts from this laboratory (1) dealt with development of the alicyclic Claisen rearrangement (2) for accessing eight-membered-ring natural products by ring expansion. These studies established the feasibility of incorporating, in stepwise fashion, all of the essential features of 4-cyclooctenones into their 2-methylene-6-vinyltetrahydrofuran precursors. The latter were produced by Tebbe olefination (3) of the related lactones obtained, in turn, by means of various highly stereoselective pathways. The fundamental issue of stereochemical transmission during the [3,3] sigmatropic event in these systems is customarily controlled by thermodynamic factors, chair–chair transition states related to **1** being adopted to the exclusion of boat–chair options (e.g., **2**) to skirt production of unstable *trans*-4-cyclooctenone products (1, 4).



1 **2**



3 **4** **5** **6**

SCHEME 1

The present study demonstrates the workability of a new variant of this ring expansion strategy within the context of a synthetically useful two-carbon insertion (5, preliminary communication). We envisioned that a short three-stage sequence could be implemented to considerable advantage. The first step necessitates exhaustive peracid oxidation of a 2-cyclohexenone to give epoxy lactone **3**, with ensuing isomerization to aldehydo lactone **4** (Scheme 1). Conversions of this type are, in fact, known (6) and have been effected in a single reaction vessel. As will be discussed, efficiency is improved if **3** is first isolated. Subsequent condensation of **4** with [bis(cyclopentadienyl)titanium]-(μ-chloro)(μ-methylidene)dimethylaluminum (3*a*, 3*b*) was viewed as a ready means of performing dual olefination at both car-

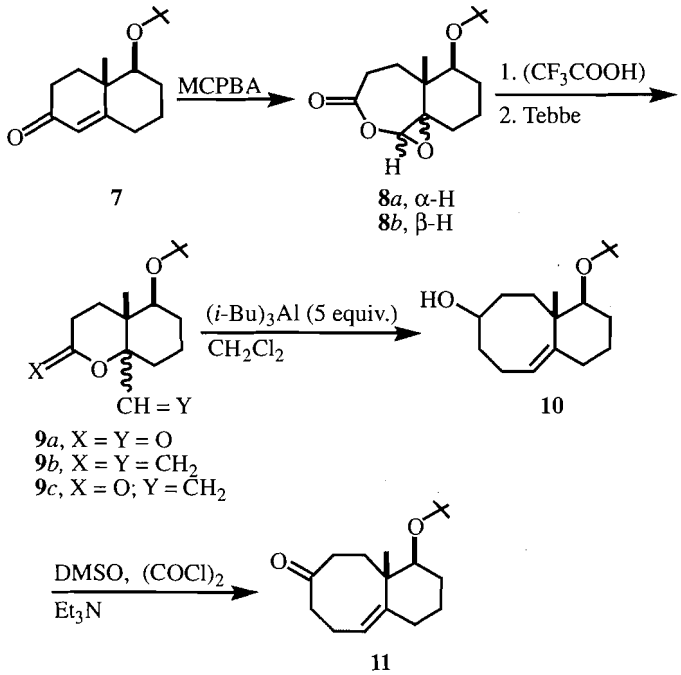


SCHEME 2

bonyl sites with formation of **5**. In light of the widely differing reactivities of aldehyde and lactone carbonyl groups, added scope could be potentially infused into the protocol by performing a chemoselective Wittig reaction[2] on **4** prior to condensation with the Tebbe reagent. In this way, R^2 and R^3 in **6** could be extended beyond the level of hydrogen as desired or needed.

Finally, catalysis of the Claisen rearrangement of **5** with triisobutylaluminum (Tribal) (1*e*, 8) should permit operation of the targeted ring expansion at room temperature, if necessary to safeguard thermally sensitive functional groups. Otherwise, recourse could be made to conventional thermal conditions.

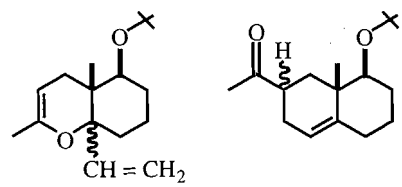
Results and discussion

The readily availability of enantiomerically homogeneous ketone **7** from the regioselective sodium borohydride reduction (9) and *tert*-butylation of optically active Wieland–Mischer ketone (10) prompted its initial utilization. Oxidation with 3 equivalents of MCPBA gave rise to **8** as a 1:3 mixture of α- and β-oxido isomers (Scheme 2). The stereochemical assignments to these epoxy lactones follow convincingly from their ^{1}H nmr spectra. Thus, while the oxiranyl proton in **8***a* appears as a singlet at δ 4.75 that in **8***b* experiences greater magnetic shielding and appears at somewhat higher field (δ 4.67). These characteristics extend as well to the aldehydic protons of the ring-contracted isomers **9***a*. The thermodynamically more stable *trans* isomer (6*c*) exhibits an absorption at δ 9.87 (in $CDCl_3$), in excess of 0.2 ppm downfield from the signal observed for its *cis* counterpart (δ 9.63). The conversion to **9** was found to proceed efficiently under catalysis by trifluoroacetic acid. Equal success was realized under neutral (165°C for 15 min) or basic conditions (aqueous methanolic NaOH at 0°C).

[2]Lactone carbonyls are commonly, but not always, unreactive toward Wittig reagents (7).

An important aspect of the twofold Tebbe reaction is proper control of the stoichiometry in order to avoid internal isomerization of the exocyclic vinyl ether double bond in the product. The latter process is thermodynamically driven and known to occur with ease (1). This prototypic isomerization came to be recognized as a reaction equally prone to catalysis by the aluminum coreagent. It is therefore crucial that only a modest excess (2.5 equiv.) of the Tebbe reagent be employed and that the quenched reaction mixture be purified as rapidly as possible. The use of freshly prepared Tebbe reagent was found to be especially advantageous. Finally, all glassware must be base washed, a consideration that extends to the nmr tubes used for spectral analysis. Failure to exercise this precaution results in isomerization of the *cis* and *trans* allyl vinyl ethers while in C_6D_6 solution, albeit at somewhat different rates (Table 1).

The Tribal-promoted Claisen rearrangement of **9***b* required an unexpectedly long time (6 h at 25°C) to proceed to completion. Attempts to perform this isomerization at lower temperatures (−20 and −78°C) resulted only in the formation of **12**. The [3,3] sigmatropic product **10** constitutes a diastereomeric mixture, oxidation of which under Swern conditions provided **11** exclusively (62%). The direct conversion of **9***b* to **1** could be accomplished thermally in base-coated soft-glass tubes (**1***a*) at 190°C for 48 h. In Pyrex tubes, the starting material was diverted to **12** prior to ultimate conversion to **13**. In a similar vein, the prototropic isomerization to give **12** (and subsequently **13**) became the dominant thermal pathway if organometallic residues from the Tebbe reaction were not completely removed during the chromatographic purification of **9***b*.



12 **13**

Evidence suggesting that the angular methyl group in **9** is responsible for sterically imposed kinetic retardation of the Al(III)-catalyzed Claisen process was gained from an in-depth examination of the less substituted octalone **14**. Oxidation of **14** according to DeBoer and Ellwanger (6*e*) cleanly produced **15**, the acid-catalyzed isomerization of which provided the *trans*-fused aldehydo lactone **16** (Scheme 3). Once **17** became available, its exposure to an excess of Tribal, as before, was met with substantial acceleration of the Claisen process. The conversion to a stereochemically pure isomer of cyclooctenol **18** (86%) was complete within 15 min at room temperature. Ensuing oxidation furnished ketone **19** in 86% yield. The direct conversion of **17** to **19** could be accomplished at 180°C, but the product was invariably contaminated with a minimum 13% of the acetyl derivative **20**.

The favorable accelerating influence of an angular C—H substituent was tested further by making recourse to manool (**21**) as starting material. Following Grant's procedure (6*f*), this terpenic alcohol was transformed into epoxy lactone **22** (Scheme 4), thereby setting the stage for quantitative base-catalyzed isomerization to **23** and twofold methylenation to give **24**. Like **17**, **24** isomerized approximately 20 times faster than **9***b* when admixed with Tribal in CH_2Cl_2 solution at

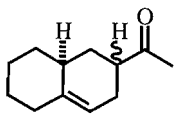
25°C. Again, in contrast to the thermal Claisen rearrangement, the Lewis-acid-accelerated alternative appears insensitive to the presence of metal impurities carried over from the Tebbe homologation reaction.



20

The synthetic versatility of this two-carbon insertion process is further demonstrated by the ease with which it can be successfully applied to steroidal systems. As summarized in Scheme 5, silylation of the secondary hydroxyl group of testosterone (**26*a***) followed by enone oxidation with 3 equivalents of MPCBA in refluxing CH_2Cl_2 furnished the epoxylactones **27**. The latter were cleanly transformed into aldehydo lactones **28** following admixture with a catalytic quantity of *d*-camphor-10-sulfonic acid in benzene solution. At this stage, it proved an easy matter to effect homologation to **29**. In agreement with our earlier observations involving **9*b***, the Tribal-promoted Claisen rearrangement of **29** required 6 h to achieve complete conversion to the cyclooctenol (64% after chromatographic purification). In this instance, different aluminum catalysts (e.g., diethylaluminum chloride in combination with triphenylphosphine (11) and methylaluminum bis(4-bromo-2,6-di-*tert*-butylphenoxide (12)) were briefly examined, but these proved ineffective. Ketone **30** was arrived at by oxidation of the cyclooctenol as well as by heating **29**. The latter reaction also produces isomerized vinyl ether **31** and acetyl cyclohexene **32** in relative amounts sufficient to permit their independent characterization.

17β-Methyltestosterone (**33**) underwent the oxidation reaction without prior need for hydroxyl-group protection (Scheme 6). Upon treatment with a catalytic amount of *d*-camphor-10-sulfonic acid, **34** was isomerized to **35**. Recourse to anhydrous perchloric acid in CH_2Cl_2 for the same purpose led instead to **36**. Evidently, this reagent system is more conducive to generation of the tertiary carbocation. A Wagner–Meerwein shift of the C-18 methyl group ensues with net overall dehydration (13). The resulting aldehydo lactone **36** reacts very efficiently with the Tebbe reagent to provide **37** (91%). Since this vinyl ether has no additional oxygen substituents, its relatively slow (6 h, 25°C) rate of [3,3] sigmatropic rearrangement in the presence of excess

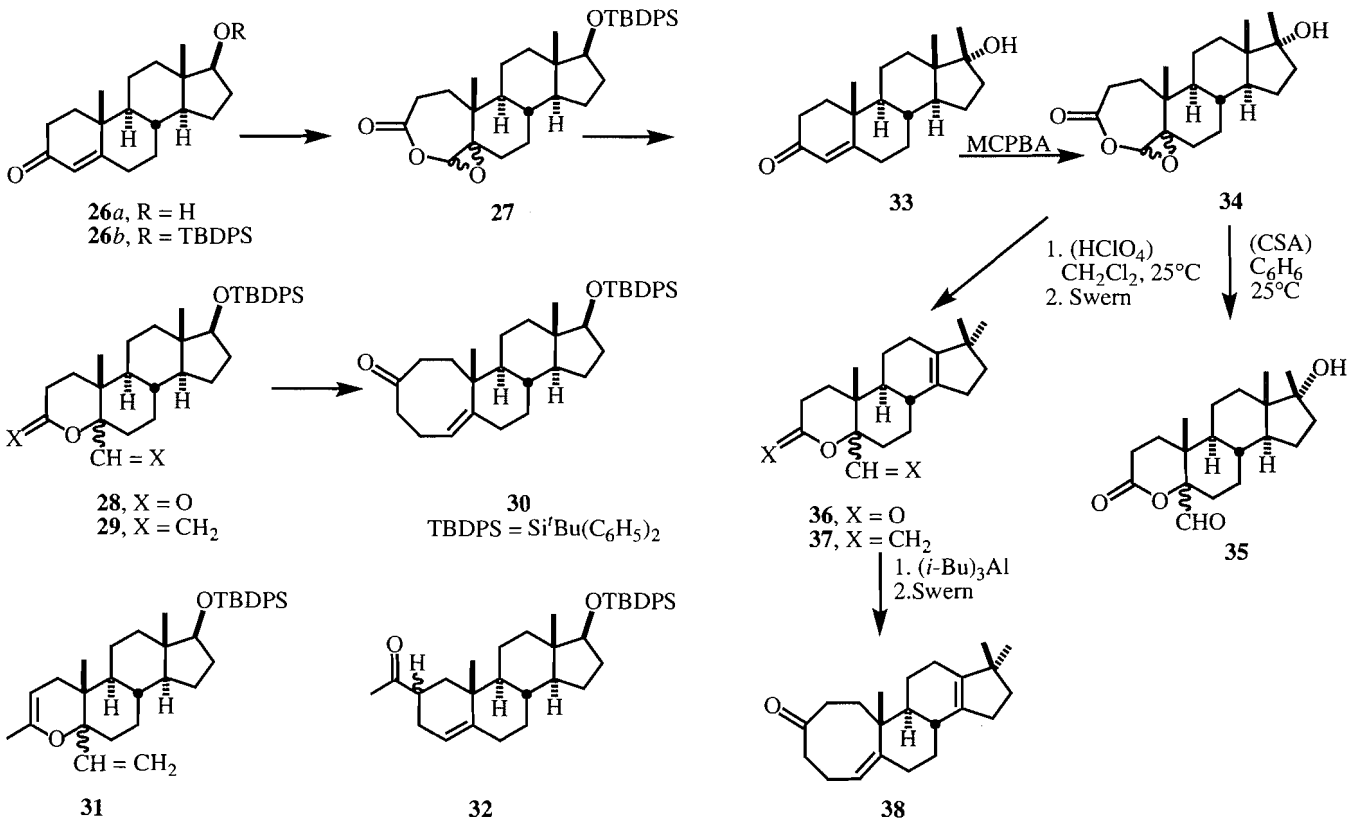
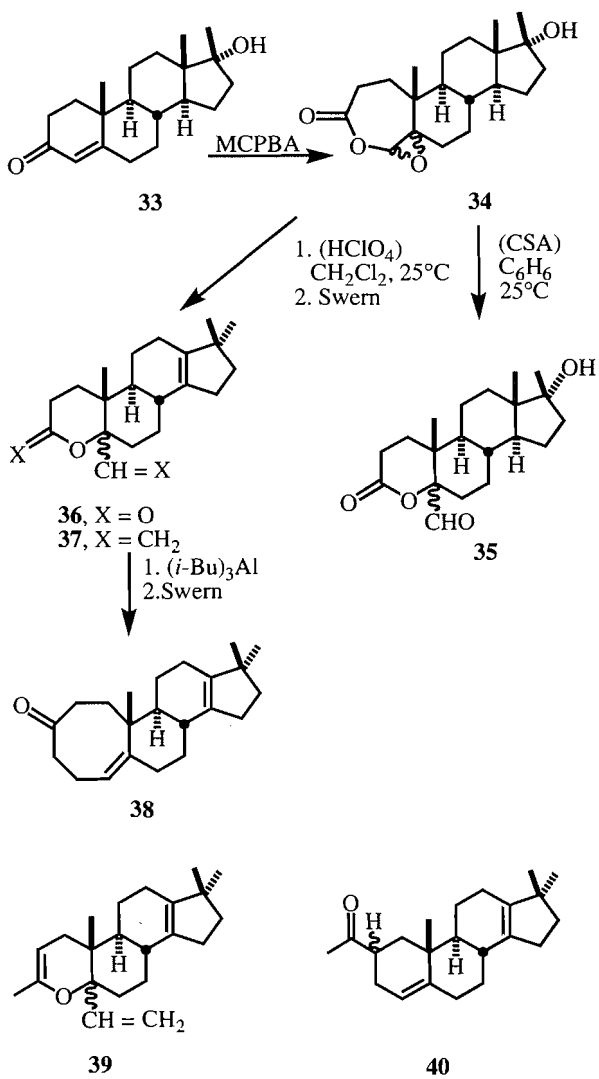


SCHEME 5



SCHEME 6

Tribal can be attributed with confidence to steric hindrance imposed by the C-19 methyl substituent. Heating **37** at 190°C for 46 h in base-coated soft-glass tubes served as an alternative means of securing **38** (40%), but with concomitant production of **39** (18%) and its Claisen product **40** (30%).

Within the context of a ready means for the ring expansion of 2-cyclohexenones to 4-cyclooctenones, the transformations documented above serve as an ample illustrative precedent. The two carbon atoms that become inserted are introduced simultaneously by Tebbe olefination of both carbonyl groups in an aldehydo lactone and ultimately connected during Claisen rearrangement. The ring juncture stereochemistry in the allyl vinyl ether is not of consequence since [3,3] sigmatropy in either isomer necessarily proceeds via that transition state guaranteed to generate a *cis* double bond within the medium-sized ring. The less sterically hindered examples undergo the Claisen rearrangement efficiently when thermally activated. The presence of a quaternary carbon in close proximity to the reaction site is the source of significant kinetic retardation and side reactions operate competitively. In these instances, Tribal catalysis plays a particularly attractive and serviceable role. This modification, which allows Claisen rearrangements to be conducted routinely at room temperature and gives rise cleanly to 4-cyclooctenols, merits increased use as an effective cationic counterpart of the more established anionic oxy-Cope process (14).

Experimental

Melting points are uncorrected. Infrared spectra were recorded on a Perkin–Elmer model 1320 spectrometer. The ^{1}H nmr spectra were recorded at 300 MHz and the ^{13}C nmr data obtained at either 75 or 20 MHz as indicated. Mass spectra were measured on a Kratos MS-30 instrument by Mr. Dick Weisenberger at The Ohio State University Chemical Instrumentation Center. Elemental analyses were performed at the Scandinavian Microanalytical Laboratory, Herlev, Denmark. All flash chromatographic separations were carried out on Merck silica gel 60 (60–200 mesh) and reactions were routinely performed under an inert atmosphere (nitrogen or argon) unless otherwise indicated. Solvents were reagent grade and dried prior to use.

(4aS,5S)-4,4a,5,6,7,8-Hexahydro-5-hydroxy-4a-methyl-2(3H)-naphthalenone 7

To a solution of Wieland–Miescher ketone (1.0 g, 5.6 mmol) exhibiting $[\alpha]_D^{25}$ +100 (*c* 1.0, toluene) in methanol (30 mL) at 0°C was added, dropwise, a solution of $NaBH_4$ (0.14 g, 3.7 mmol) in methanol (20 mL). The solution was stirred at 0°C for 30 min and several drops of acetic acid were added. The mixture was concentrated under vacuum, water was added, and the product was extracted into ether (3 × 20 mL), dried, concentrated, and purified by flash chromatography (elution with 30% ethyl acetate in petroleum ether) to give 0.980 g (97%) of the 2β-ol-5-one as a colorless oil; $[\alpha]_D^{25}$ +183 (*c* 1.7, $CHCl_3$); ir ($CHCl_3$): 3600, 3450, 1665, and 1620 cm^{-1}; ^{1}H nmr (300 MHz, $CDCl_3$) δ; 5.73 (s, 1H), 3.37 (dd, *J* = 11.5, 4.4 Hz, 1H), 2.66 (br s, 1H), 2.45–2.10 (series of m, 6H), 1.82 (m, 2H), 1.64 (m, 1H), 1.45 (m, 1H), 1.15 (s, 3H); ^{13}C nmr (75 MHz, $CDCl_3$): 199.84, 169.04, 125.17, 77.95, 41.58, 34.10, 33.59, 31.96, 30.09, 23.08, 15.19 ppm; ms *m/z* (M^+) calcd.: 180.1150; found: 180.1167.

To a cold (−78°C) solution of the keto alcohol (0.90 g, 5.42 mmol) in CH_2Cl_2 (20 mL) was added liquified isobutylene (40 mL). The mixture was stirred for 16 h at room temperature, then cooled to −10°C and poured into dilute KOH solution. The mixture was extracted with ether (3 × 40 mL), the combined organic phases were dried and concentrated, and the residue was purified by flash chromatography on silica gel (elution with 60% ether in petroleum ether) to give 0.914 g (76%) of **7** as a viscous, colorless oil; $[\alpha]_D^{25}$ +108 (*c* 4.1, $CHCl_3$); ir ($CHCl_3$): 1660 and 1620 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ: 5.69 (s, 1H), 3.15 (dd, *J* = 11.2, 4.1 Hz, 1H), 2.30 (m, 2H), 2.15 (m, 1H), 2.05 (m, 1H), 1.75 (m, 5H), 1.31 (m, 1H), 1.13 (s, 9H), 1.11 (s, 3H); ^{13}C nmr (75 MHz, $CDCl_3$): 199.60, 169.40, 124.82, 77.36, 73.32, 41.54, 34.69, 33.87, 32.23, 30.22, 29.00 (3C), 22.99, 16.18 ppm; ms/fab *m/z* (M^+ + 1) calcd.: 237.36; found: 237.26.

Peracid oxidation of ***7*** *to epoxylactone* ***8***

To a solution of **7** (0.120 g, 0.51 mmol) in CH_2Cl_2 (30 mL) was added $NaHCO_3$ (0.40 g) and MCPBA (0.26 g, 1.5 mmol). The mixture was refluxed for 1 day, quenched with water, and extracted with ether (3 × 60 mL). The combined ethereal layers were dried and concentrated, and the residue was purified by flash chromatography on silica gel (elution with 40% ether in petroleum ether) to give 0.086 g (63%) of **8**; ir ($CHCl_3$): 1750 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ: 4.75 (s, 1H, ***8a***), 4.67 (s, 1H, ***8b***), 3.42 (dd, *J* = 10.6, 4.2 Hz, 1H), 2.54 (m, 2H), 1.97–1.03 (series of m, 8H), 1.16 (s, 9H), 1.14 (s, 3H, ***8a***), 1.12 (s, 3H, ***8b***); ^{13}C nmr (75 MHz, $CDCl_3$): 171.68, 171.55, 87.48, 84.81, 74.22, 73.91, 73.67, 73.57, 72.33, 69.63, 41.41, 41.00, 31.29, 31.08, 30.75, 29.62, 29.47, 29.24, 29.19 (6C), 28.99, 27.45, 19.84, 19.02, 17.54, 16.39 ppm; ms *m/z* ($M^+ - [C_4H_8]$) calcd.: 212.1048; found: 212.1081.

*(4aR,5S)-5-*tert*-Butoxy-8a-formylhexahydro-4a-methyl-hydrocoumarin* ***9a***

To a solution of ***9a*** (80 mg, 0.299 mmol) in CH_2Cl_2 (10 mL), trifluoroacetic acid (10 drops) was added. The mixture was stirred for 24 h at room temperature and diluted with ether. The ethereal phase was washed with saturated $NaHCO_3$ solution, dried, and concentrated. The residue was purified by flash chromatography on silica gel (elution with 15% ethyl acetate in petroleum ether) to give 70.5 mg (88%) of ***9a*** as a white solid, mp 132–135°C; ir ($CHCl_3$): 1735 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) (major isomer) δ: 9.87 (s, 1H), 3.77 (dd, *J* = 10.6, 4.4 Hz, 1H), 2.60 (m, 2H), 2.20–1.08 (series of m, 8H), 1.14 (s, 9H), 1.04 (s, 3H); ^{13}C nmr (75 MHz, $CDCl_3$): 200.06, 199.05, 171.23, 171.05, 90.96, 88.99, 73.71, 73.58, 71.92, 67.61, 41.25, 38.39, 29.31, 29.19, 29.07 (3C), 28.85 (3C), 28.17, 27.21, 26.66, 26.58, 26.15, 18.52, 18.36, 16.61, 13.16 (1C not observed) ppm; ms *m/z* ($M^+ - [C_4H_8]$) calcd.: 212.1049; found: 212.1031. *(4aR,5S)-5-*tert*-Butoxyhexahydro-4a-methyl-2-methylene-8a-vinylchroman* **9**b

A solution of ***9a*** (53 mg, 0.20 mmol), pyridine (3 drops), THF (2 mL), and CH_2Cl_2 (1 mL) was prepared under argon. The mixture was cooled to −40°C and 0.5 M Tebbe reagent (1.0 mL, 0.5 mmol) in toluene was added dropwise. The solution was kept at this temperature for 15 min, then warmed to 25°C and stirred at this temperature for 90 min before being returned to −40°C and quenched with 10% KOH solution (1 mL). A 0.5% triethylamine solution in ether was added and the mixture was filtered through a pad of basic alumina (act. III). Most of the solvent was evaporated and the residue was purified by chromatography on basic alumina (act. III) (elution with pentane) to provide 43.3 mg (63%) of ***9b*** as a light yellow oil; ir (neat): 1670, 1260, 1190, and 1060 cm^{-1}; ^1H nmr (300 MHz, C_6D_6) δ: 6.10 (dd, *J* = 17.1, 11.0 Hz, 1H), 5.63 (dd, *J* = 17.1, 1.9 Hz, 1H), 5.23 (dd, *J* = 11.0, 1.2 Hz, 1H), 4.52 (*d*, *J* = 1.8 Hz, 1H), 4.11 (d, *J* = 1.7 Hz, 1H), 3.29 (m, 1H), 2.50 (m, 1H), 2.41 (m, 1H), 1.90 (m, 2H), 1.59–0.92 (series of m, 6H), 1.24 (s, 9H), 1.02 (s, 3H); ^{13}C nmr (75 MHz, C_6D_6): 157.68, 140.16, 117.74, 89.69, 81.55, 73.34, 72.78, 34.78, 31.34, 30.25, 29.14, 29.03 (3C), 24.56, 19.81, 13.74 ppm; ms *m/z* ($M^+ - [C_4H_8]$) calcd.: 208.1463; found: 208.1445.

*(4aR,5S)-5-*tert*-Butoxyhexahydro-4a-methyl-8a-vinylhydrocoumarin* **9**c

To a solution of methyltriphenylphosphonium bromide (357 mg, 1 mmol) in THF (3 mL) at −10°C was added KHMDS (1.90 mL, 0.95 mmol). The mixture was stirred for 30 min and a solution of ***9a*** (0.15 g, 0.71 mmol) in THF (1 mL) was introduced. The reaction mixture was stirred for 1 h at room temperature and quenched with water. After the usual extractive work-up with ether and purification by flash chromatography (silica gel, elution with 5% ether in petroleum ether) 138 mg (93%) of ***9c*** was obtained as a white solid, mp 110°C; ir ($CHCl_3$): 1720 cm^{-1}; ^1H nmr (300 MHz, $CHCl_3$) (major isomer) δ: 6.40 (dd, *J* = 17.0, 11.1 Hz, 1H), 5.38 (dd, *J* = 17.0, 1.1 Hz, 1H), 5.32 (dd, *J* = 11.1, 1.1 Hz, 1H), 3.48 (m, 1H), 2.54 (m, 2H), 2.00–1.06 (series of m, 8H), 1.16 (s, 9H), 1.03 (s, 3H); ^{13}C nmr (75 MHz, $CHCl_3$): 172.85, 172.63, 138.79, 138.64, 116.16, 115.07, 89.31, 86.18, 73.48, 73.33, 72.84, 68.03, 41.28, 39.77, 33.40, 32.61, 29.81, 29.58, 29.22 (3H), 28.95 (3C), 28.19, 27.16, 26.37, 25.60, 19.44, 19.19, 17.24, 12.60 ppm; ms *m/z* ($M^+ - [C_4H_8]$) calcd.: 210.1256; found: 210.1242.

*(4S,4aS)-4-*tert*-Butoxy-1,2,3,4,4a,5,6,7,8,9-decahydro-4a-methyl-7-benzo-cyclooctenol* ***10***

To a solution of ***9b*** (42 mg, 0.16 mmol) in CH_2Cl_2 (2 mL) was added, at room temperature and under argon, a solution of Tribal in toluene (0.8 mL, 0.8 mmol). The mixture was stirred for 6 h. Ether was then added followed by water. After the usual extractive work-up with ether and purification by flash chromatography (silica gel, elution with 30% ether in petroleum ether) 26.2 mg (62%) of **10** was obtained as a viscous oil; ir ($CHCl_3$): 3600 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) (major isomer) δ: 5.34 (m, 1H), 4.07 (m, 1H), 3.39 (dd, *J* = 10.9, 4.5 Hz, 1H), 2.68 (br s, 1H), 2.49 (br s, 1H), 2.36–0.87 (series of m, 14H), 1.19 (s, 9H), 1.05 (s, 3H); ^{13}C nmr (62.5 MHz, $CDCl_3$) (major isomer) 145.32, 121.85, 73.08, 72.75, 65.30, 46.71, 36.14, 35.96, 35.89, 32.33, 30.82, 30.66, 29.52 (3C), 23.00, 22.21 ppm; ms *m/z* ($M^+ - [C_4H_8]$) calcd.: 210.1620; found: 210.1628.

Aldehydo lactone **36** (126.4 mg, 0.40 mmol) was dissolved in pyridine (6 drops), THF (3 mL), and CH_2Cl_2 (2 mL), cooled to −45°C, and treated with the Tebbe reagent (2 mL, 0.5 mmol). The reaction mixture was warmed to room temperature and stirred for 1 h. The solution was cooled to −40°C and a 5% solution of KOH was carefully added. The reaction mixture was passed through a pad of basic alumina (act. III), concentrated under vacuum, and purified by flash chromatography on basic alumina (act. III) (elution with pentane) to give 113.6 mg (91%) of **37** as a light yellow oil; ir (neat): 1680, 1460, 1260, 1100, and 1020 cm^{-1}; ^1H nmr (300 MHz, C_6D_6) δ: 6.15 (dd, *J* = 17.0, 11.0 Hz, 1H), 5.60 (dd, *J* = 17.0, 2.0 Hz, 1H), 5.13 (dd, *J* = 11.0, 2.0 Hz, 1H), 4.52 (d, *J* = 1.1 Hz, 1H), 4.07 (d, *J* = 1.4 Hz, 1H), 2.40–0.93 (series of m, 18 H), 1.05 (s, 3H), 1.03 (s, 3H), 1.00 (s, 3H); ^{13}C nmr (75 MHz, C_6D_6): 157.91, 140.82, 136.06, 128.05, 116.87, 88.09, 45.88, 39.95, 36.34, 36.12, 34.81, 32.40, 29.99, 29.24, 27.14, 27.01 (2C), 26.59, 24.36, 22.95, 22.60, 15.27 ppm; ms *m/z* (M^+) calcd.: 312.2453; found: 312.2450.

Tribal-promoted Claisen rearrangement of **37**

To a solution of **37** (104 mg, 0.33 mmol) in CH_2Cl_2 (2 mL) was added, at room temperature and under argon, a solution of Tribal in toluene (2 mL, 2 mmol). The mixture was stirred for 15 min, then treated with ether and water. After the usual extractive work-up with ether and purification by flash chromatography (silica gel, elution with 20% ether in petroleum ether) 90 mg (63%) of the cyclooctenol was obtained as a 3:1 mixture of isomers; viscous oil; ir ($CHCl_3$): 3600 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) (major isomer) δ: 5.38 (t, *J* = 9.1 Hz, 1H), 3.82 (m, 1H), 2.55–0.88 (series of m, 22 H), 1.00 (s, 3H), 0.96 (s, 3H), 0.94 (s, 3H) (hydroxyl signal not observed); ^{13}C nmr (75 MHz, $CDCl_3$): 147.36, 141.49, 136.19, 121.33, 119.16, 72.06, 68.49, 45.35, 45.29, 43.47, 43.09, 40.07, 39.66, 37.16, 37.07, 36.90, 35.90, 35.57, 33.31, 32.57, 32.41, 32.30, 32.20, 31.91, 31.46, 29.75, 29.67, 29.33, 27.28, 26.84, 26.74, 26.70, 26.50, 23.56, 23.40, 23.34, 23.14, 23.09, 22.94, 22.63, 22.50, 22.34, 21.53, 21.24 ppm; ms *m/z* (M^+) calcd.: 314.2210; found: 314.2190.

*17,17-Dimethyl-*A*-dihomo-18-norandrosta-4b,13-dien-3-one* **38**

Oxalyl chloride (66 μL) was added to a solution of DMSO (140 μL) in CH_2Cl_2 (2 mL) at −78°C and under argon. The mixture was stirred for 15 min and a solution of the above cyclooctenol (21 mg, 0.067 mmol) in CH_2Cl_2 (2 mL) was added. The mixture was warmed to −45°C, stirred for 20 min, cooled back to −78°C, and quenched by the addition of triethylamine (300 μL). The mixture was allowed to warm to room temperature and water was added. After the usual extractive work-up with ether and purification by flash chromatography on silica gel (elution with 5% ether in petroleum ether) 16.1 mg (86%) of **38** was obtained as a viscous oil; $[\alpha]_D^{25}$ +31.4 (*c* 1.12, $CHCl_3$); ir ($CHCl_3$): 1695 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ: 5.36 (t, *J* = 9.0 Hz, 1 H), 3.10 (m, 1H), 2.68 (m, 2H), 2.52–0.84 (series of m, 18H), 1.05 (s, 3H), 0.96 (s, 3H), 0.95 (s, 3 H); ^{13}C nmr (75 MHz, C_6D_6): 211.82, 146.52, 141.38, 135.90, 120.20, 45.46, 45.31, 43.65, 43.57, 40.85, 39.62, 36.92, 36.74, 32.88, 31.84, 29.74, 26.68, 26.5, 23.14, 22.68, 22.29 (1C not observed) ppm; ms *m/z* (M^+) calcd.: 312.2453; found: 312.2450. Anal. calcd. for $C_{22}H_{32}O$: C 84.56, H 10.32; found: C 84.35, H 10.37.

Thermal Claisen rearrangement of **37**

A solution of **37** (50 mg, 0.16 mmol) in toluene (1 mL) was sealed under vacuum in a potassium hydroxide-coated soft-glass tube (8 mm o.d.) and heated at 190°C for 46 h. The tube was opened and rinsed three times with ether. After evaporation of solvent, the residue was purified by flash chromatography on silica gel (elution with 5% ether in petroleum ether) to give 9 mg (18%) of isomerized vinyl ether **37**, 15 mg (30%) of **40**, and 20 mg (40%) of cyclooctenone **38**.

For **39**: ir ($CHCl_3$): 1680 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ: 6.29 (dd, *J* = 17.0, 10.9 Hz, 1H), 5.29 (dd, *J* = 17.0, 1.7 Hz, 1H), 5.10 (dd, *J* = 10.0, 1.7 Hz, 1H), 4.41 (t, *J* = 1.3 Hz, 1H), 2.20–1.00 (series of m, 16H), 1.80 (s, 3H), 0.97 (s, 3H), 0.96 (s, 3H), 0.91 (s, 3 H); ^{13}C nmr (62.5 MHz, $CDCl_3$): 147.93, 141.27, 138.72, 135.47, 114.04, 95.65, 80.88, 45.38, 45.20, 39.54, 36.57, 36.16, 34.45, 32.00, 29.66, 26.97, 26.76, 26.40, 22.94, 22.27, 19.95, 14.37 ppm; ms *m/z* (M^+) calcd.: 312.2453; found: 312.2458.

For **40**: ir ($CHCl_3$): 1700 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) (major isomer) δ: 5.32 (m, 1H), 2.60 (m, 1H), 2.24–0.86 (series of m, 18H), 2.18 (s, 3H), 1.03 (s, 3H), 0.96 (s, 3H), 0.94 (s, 3 H); ^{13}C nmr (75 MHz, $CDCl_3$): 211.98, 211.80, 145.97, 144.31, 135.85, 135.30 (2C), 117.38 (2C), 116.75, 52.19, 48.33, 45.22, 45.15, 44.67, 44.51, 39.39, 38.26, 37.72, 37.41, 36.83, 36.23, 33.30, 32.54, 32.36, 32.07, 29.68, 29.60, 27.93, 27.61, 27.53, 26.59, 26.51, 26.33, 26.30, 23.30, 22.93, 22.25, 22.04, 21.36, 19.05 (3C not observed) ppm; ms *m/z* (M^+) calcd.: 312.2453; found: 312.2460.

Acknowledgments

The financial support of this work by the National Institutes of Health (Grant GM-30827) is gratefully acknowledged. We also thank the Upjohn Company for providing us with **26***a* and **33**, and especially Dr. Peter K. Grant (University of Otago) for a generous supply of manool together with revised instructions for its conversion to **22**.

Synthesis and characterization of derivatized capped porphyrins

HANG TANG, TILAK P. WIJESEKERA, AND DAVID DOLPHIN[1]

Department of Chemistry, University of British Columbia, 2036 Main Mall, Vancouver, B.C., Canada V6T 1Z1

Received August 8, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

HANG TANG, TILAK P. WIJESEKERA, and DAVID DOLPHIN. Can. J. Chem. **70**, 1366 (1992).

The syntheses of porphyrins carrying either a fully hydrophobic cavity with a benzene moiety (**32***a*,*b*) or a polar cavity with an amidobenzene (**32***c*–*d*) are described. Terephthaldehyde (**1**) was converted to benzene-bisalkanoic acids (**8**, **10**) and nitrobenzene-bisalkanoic acids (**13** and **16**) by using standard methods. The corresponding diacid chlorides **17***a*–**d** were used to acylate two equivalents of a β-unsubstituted pyrrole, and the ketonic groups were reduced by diborane. Following the transformation of the nitro function to the acetamide, appropriate modifications of the ethyl ester functions afforded the key bisformylpyrroles **25***a*–*d*. The cyanoacrylate-protected formyl pyrrole derivatives were monochlorinated at the α-methyl groups and condensed with two equivalents of an α-unsubstitutued pyrrole to give the dipyrromethane dimers. Strong aqueous alkali caused saponification of the two ester groups and deprotection of the formyl functions to produce the dipyrromethane dimer **30**, which, after thermal decarboxylation, was cyclized intramolecularly in acidic medium to give the porphyrins **32** (n = 4 or 5, X = H or $NHCOCH_3$).

HANG TANG, TILAK P. WIJESEKERA et DAVID DOLPHIN. Can. J. Chem. **70**, 1366 (1992).

On décrit la synthèse de porphyrines portant soit une cavité complètement hydrophobe avec une portion benzénique (**32***a*,*b*) soit une cavité polaire avec un amidobenzène (**32***c*–*d*). Utilisant des méthodes courantes, on a transformé le téréphtaldéhyde (**1**) en acides benzène-bisalcanoïques (**8**, **10**) et en acides nitrobenzène-bisalcanoïques (**13** et **16**). On a utilisé les chlorures d'acides correspondants (**17***a*–*d*) pour acyler deux équivalents d'un pyrrole non substitué en position β, puis on a réduit les groupes cétoniques avec du diborane. Après avoir transformé les fonctions nitro en acétamide, des modifications appropriées des fonctions esters éthyliques ont fourni les bis-formyl pyrroles **25***a*–*d* clés. On a effectué une monochloration des dérivés du formyl pyrrole protégés par le cyanoacrylate sur les groupes méthyles en α et on a condensé les produits avec deux équivalents d'un pyrrole non substitué en α afin d'obtenir des dimères dipyrrométhanes. Sous l'influence de solutions alcalines aqueuses concentrées, il se produit une saponification des deux groupes esters et une déprotection des fonctions formyles pour conduire au dimère dipyrrométhane **30** qui, après décarboxylation thermique et sous l'influence d'un acide, se cyclise d'une façon intramoléculaire pour donner les porphyrines **32** (n = 4 ou 5; X = H ou $NHCOCH_3$)

[Traduit par la rédaction]

Introduction

Dioxygen and carbon monoxide binding propertites of hemoglobin and myoglobin are largely controlled by steric and electrostatic effects provided by the protein. Hemoglobin has a lower affinity for carbon monoxide relative to dioxygen (1, 2), when compared with simple iron-porphyrin systems, due to the steric hindrance on the distal side of the heme (2, 3–6) and the porphyrin skeletal deformations (7, 8). Hydrogen bonding between the bound dioxygen and the histidine E7 residue (9) increases the stability of the dioxygen complex, and therefore leads to a higher O_2 affinity. The H-bonding was demonstrated by a neutron diffraction study of oxymyoglobin (10) and X-ray analysis of oxyhemoglobin (11).

To evaluate the influence of the immediate protein environment on the ligand binding, it is necessary to construct models with the minimum of added molecular structure essential to mimic the active site behaviour of a hemoprotein. By designing different model compounds with different structural features, it is possible to investigate separately the effects of the heme environment on its reactivity. Continued efforts to overcome the problems associated with synthetic dioxygen carriers have led to the development of several model hemes, the syntheses and structural features of which have been surveyed in a recent review (12). Simple ferrous porphyrins undergo rapid and irreversible oxidation in the absence of a large excess of base to yield μ-oxo Fe(III) species (13, 14), while in the presence of excess base a six-coordinate ferrous porphyrin is formed that is incapable of binding dioxygen (15). Synthetic model compounds have been prepared to sterically retard the formation of both the hexacoordinated system and the μ-oxo dimer.

Non-functionalized hydyrocarbon strapped porphyrins (16) were prepared by us for distorting the porphyrin plane and the methodology developed was later extended to prepare durene-capped porphyrins (17), a myoglobin model with a fully hydrophobic cavity. With the latter, the influence of distal steric effects on CO and O_2 binding were examined in the absence of stabilizing electrostatic interaction, and the relative contribution of steric effects, both proximal and distal, for R- and T-state heme systems were revealed (18). Introduction of a polar function to such heme model systems was expected to help clarify the contribution of electrostatic effects to the discriminatory binding of CO and O_2 in hemoglobin and myoglobin. For this purpose, an amide-substituted benzene-capped porphyrin model system has been designed and synthesized to mimic the hydrogen bonding between bound dioxygen and histidine E7 in hemoglobin and myoglobin. The corresponding unsubstituted benzene-capped porphyrins were also synthesized for comparison.

Results and discussion

The synthetic strategy involved the transformation of terephthaldehyde (**1**) into benzene-bisalkanoic acids (Scheme 1; **8** and **10**) and nitrobenzene-bisalkanoic acids (**13** and **16**),

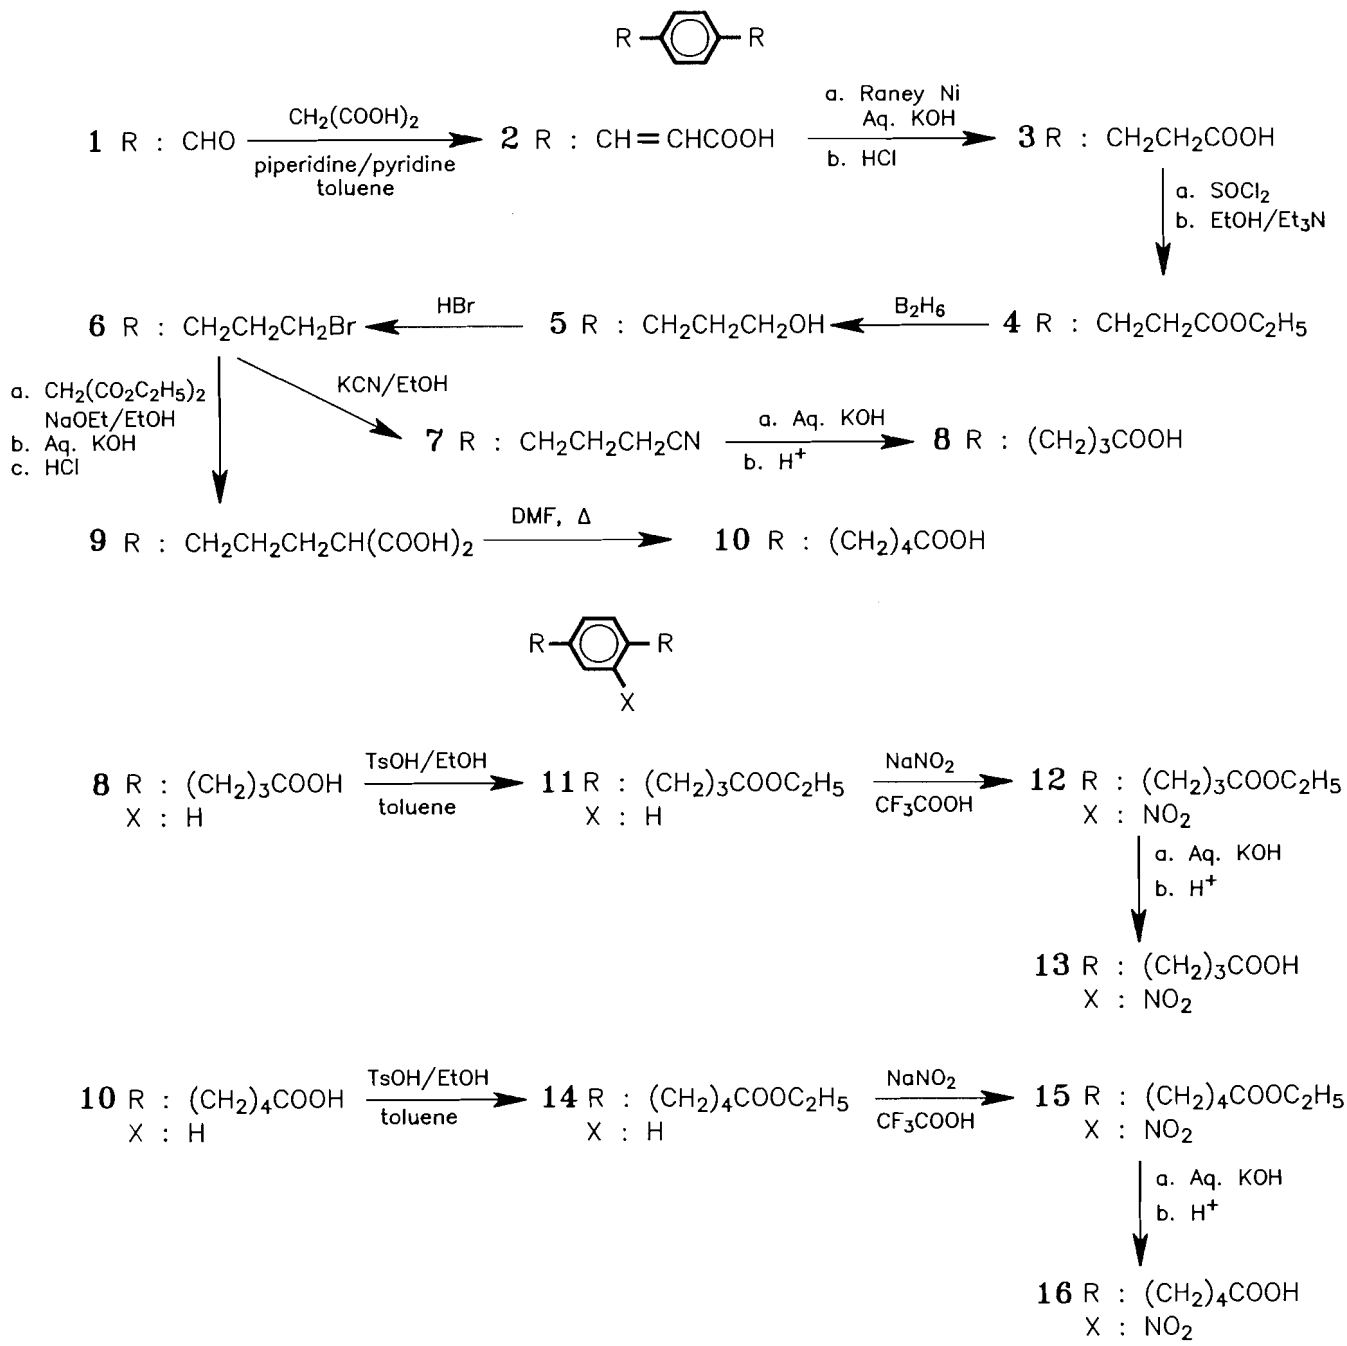

SCHEME 1

the latter to be modified to give the anilide cap. These bis-alkanoic acids could then be transformed into the capped porphyrins using the chemistry developed for the synthesis of the deformed porphyrins (16) and the durene-capped porphyrins (17).

Terephthaldehyde (**1**) was reacted with malonic acid in the presence of piperidine and pyridine to produce the diacid **2**, which was catalytically hydrogenated to give the dicarboxylic acid **3**. The transformation of **3** to the diol **5** (in order to carry out further chain extension) was effected via the more soluble diester **4** using diborane and was subsequently converted to the more reactive bisbromopropyl derivative **6**. The diacid **8**, which required the extension of the methylene side chain by one carbon, was readily prepared via the nitrile **7** using KCN in ethanol, followed by hydrolysis in aqueous alkali. To generate the bispentanoic acid **10**, a malonate synthesis was employed on the dibromide **6**. The tetraester was not isolated, but saponified *in situ* to give the tetracid **9**. The benzene-bispentanoic acid **10** was obtained by decarboxylation of **9** in boiling DMF.

The synthetic strategy for the porphyrins involved the transformation of the diacids to chain-linked bispyrroles and dipyrromethane dimers followed by an intramolecular cyclization. Since the pyrrole nucleus is sensitive to strong

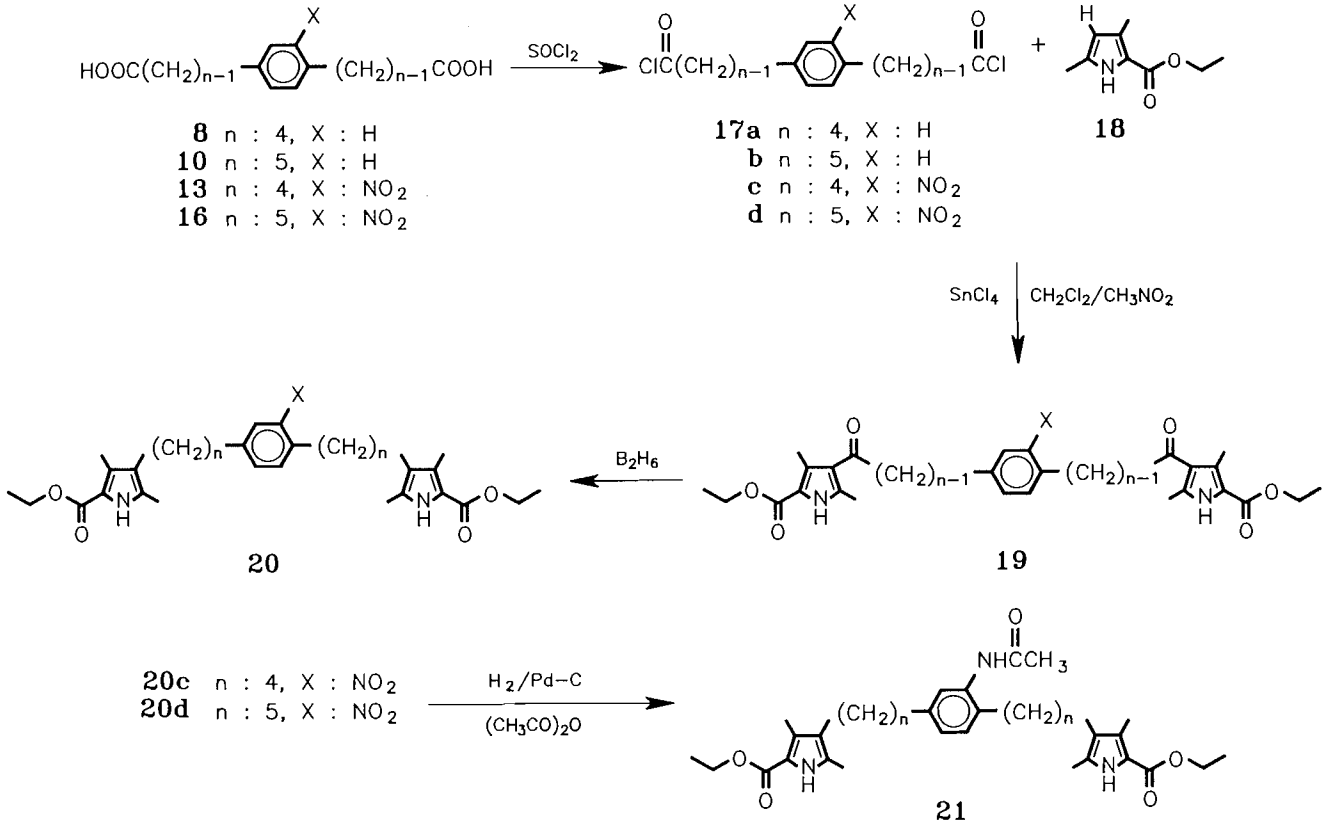

SCHEME 2

oxidizing agents, all efforts to nitrate the chain-linked bispyrrolic derivatives led to decomposition. Therefore, the nitro functionality had to be introduced before the coupling of pyrroles. Nitration of diacids **8** and **10** were found not to be practical due to the insolubility of the starting materials and the products. Therefore, nitration of the diester analogues was preferred. A sodium nitrite-trifluoroacetic acid (19) mixture was found to nitrate the diesters **11** and **14** successfully in reasonable yields (65–73%). The nitrobenzene-bisalkanoic acids **13** and **16** were obtained by hydrolysis with aqueous alkali.

The first step towards the strapped porphyrin was to link the dicarboxylic acids to two β-unsubstituted pyrroles **18** (20, 21) via Friedel–Crafts alkylation reactions. The pyrroles were acylated with the corresponding bisacid chloride **17** in a mixture of methylene chloride and nitromethane using anhydrous stannic chloride as the catalyst. The ketonic carbonyls of the resulting bispyrrole diketones **19** were reduced by diborane in yields >80% (Scheme 2).

With the chain in place, the next step was transformation of the α-ethyl ester into the synthetically useful α-formyl group. This included the removal of the ethyl ester, thermal decarboxylation of the resulting diacid, and formylation of the unsubstituted α-position by the Vilsmeier reaction (20–22). Since the direct saponification of the ethyl ester **20** led to extensive decomposition, the acids could only be obtained via a transbenzylation–debenzylation route. For the two bispyrrolic ethyl esters without the nitro function (**20***a* and **20***b*), the transesterification was effected in refluxing benzyl alcohol by using a solution of sodium in benzyl alcohol as the catalyst (Scheme 3). After quenching the reaction mixture with a mixture of acetic acid and methanol, the product was crystallized out by diluting with water. However, the two nitro-substituted bisethyl esters **20***c* and **20***d* were sensitive to the strongly basic conditions of transbenzylation at high temperature. Therefore, the nitro function was converted to the acetamide at this stage by catalytic hydrogenation in the presence of acetic anhydride (Scheme 2). Transbenzylation of the amide derivatives **21***c* and **21***d* was carried out at a lower temperature (100°C) and 12 Torr (1 Torr = 133.3 Pa) pressure to give a 60–70% yield of the bisbenzyl ester **22**.

The bisbenzyl ester **22** was cleaved by catalytic hydrogenolysis in THF and the resulting diacid **23** was decarboxylated in refluxing DMF. The formyl function was introduced by using phosphorus oxychloride – DMF (for **24***a* and **24***b*) or benzoyl chloride – DMF (for **24***c* and **24***d*) as the Vilsmeier reagent (22). The resulting iminium salt was hydrolyzed by using aqueous sodium bicarbonate, to give the chain-linked bis-α-formylpyrrole **25**. The formyl groups were protected by a Knoevenagel condensation with methyl cyanoacetate under basic conditions (23), in preparation for the subsequent oxidation of the α-methyl groups. This also helps in purifying the formylpyrrole **25** by chromatography.

The synthesis of the dipyrromethane dimer was carried out in two stages. In the first stage, the α-methyl groups of the protected bispyrroles (**26**) were monochlorinated and the resulting monochloro derivatives reacted with two equivalents of the α-unsubstituted pyrrole **28** (20, 21) in warm glacial acetic acid (Scheme 4). Deprotection of the formyl groups and

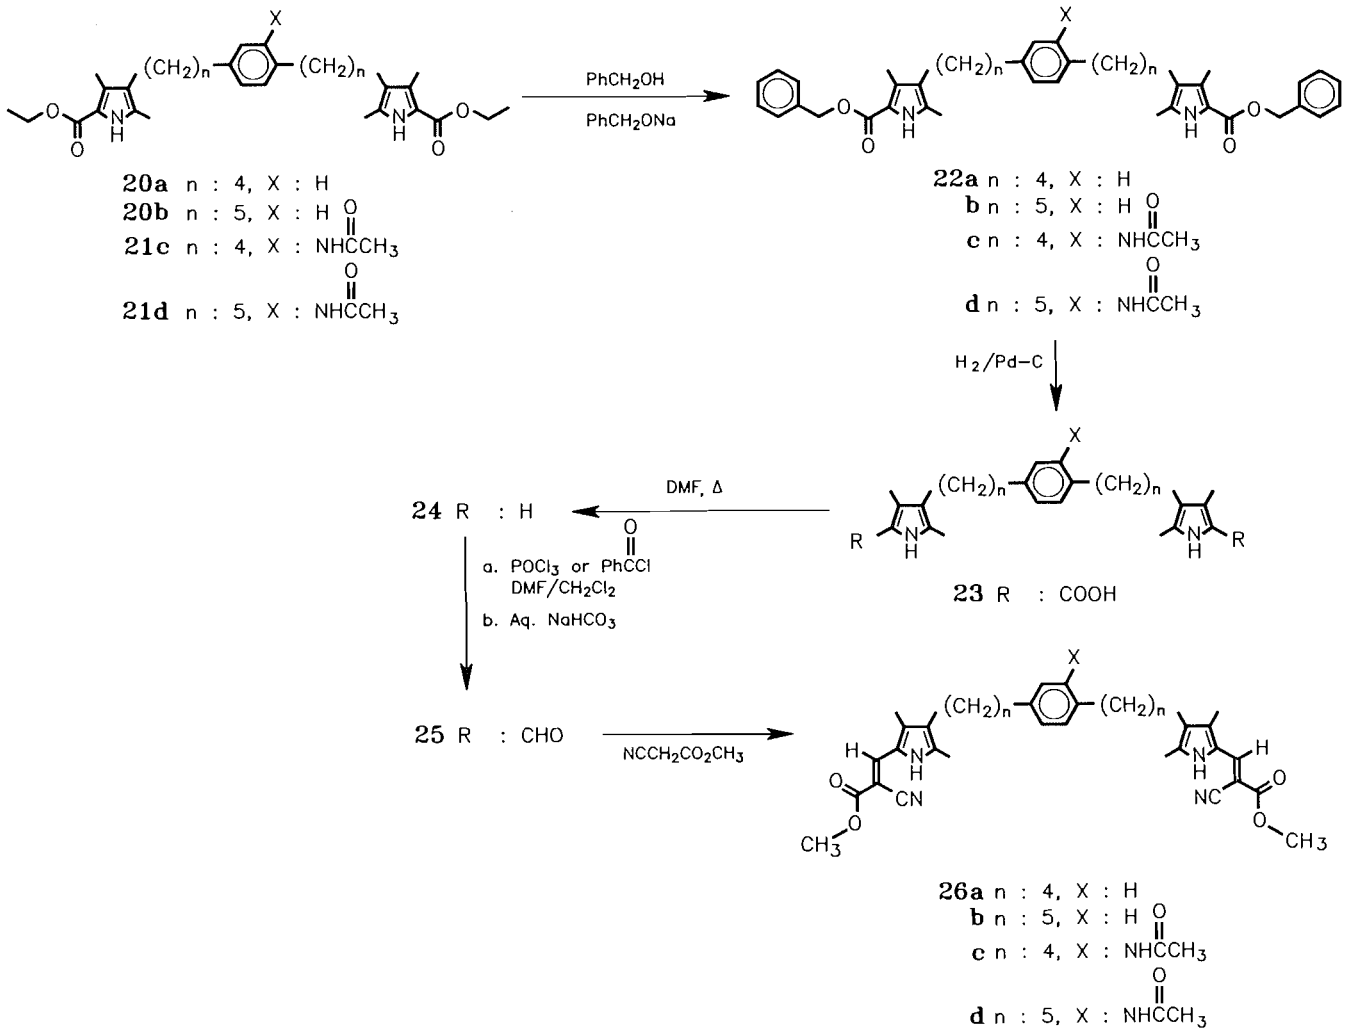

SCHEME 3

saponification of the esters of **29** were effected in one step using aqueous alkali. Because of the sensitivity of the acetamide substituents of **29***c* and **29***d* towards alkali, the reaction had to be performed under controlled conditions. A 30:1 molar ratio of base to starting material with a base concentration of 1.5 M in water and a mixed solvent system of water:*n*-propanol of ratio 2:1 were found to be optimal.

Decarboxylations of compounds **30** were carried out in refluxing DMF under nitrogen and the reaction was monitored by uv/visible spectroscopy. The absorption maximum at 280 nm (due to the carboxypyrrole group) was observed to be reduced to a shoulder within 2 h. The solution was concentrated *in vacuo*, diluted with methylene chloride, and the remaining DMF removed by extraction with water. To improve the solubility of the product **31**, the methylene chloride solution was concentrated to a small volume and diluted with THF. The cyclization to the porphyrin was accomplished by adding the THF solution of the 5-unsubstituted-5-formyldipyrromethane dimer **31** to a solution of *p*-toluenesulfonic acid in methanol/methylene chloride by means of a syringe pump. The high dilution conditions were required during cyclization in order to effect an *intra* molecular reaction leading to the desired product. The monomeric capped porphyrins **32** were isolated and purified by chromatography. The yields, dependent on the purity of the starting material, varied between 19 and 45%.

The proton nmr spectra of **32***a–d* exhibit significant upfield shifts for some of the methylene strap proton resonances and the benzene protons, resulting from the shielding effect of the porphyrin diamagnetic ring current. The signals due to the porphyrin methyl and methine protons split to two singlets, because of the asymmetry resulting from the strap.

Work describing the formation of Fe(III) and Fe(II) derivatives of these capped porphyrins and thermodynamic data on the binding of CO and O_2 to the latter (26) will be published elsewhere.

Experimental

Melting points were obtained using a Thomas model 49 Micro Hot Stage apparatus equipped with a Bristoline 6548-J17 microscope and are uncorrected. Elemental analysis was performed by Mr. P. Borda of the Microanalytical Laboratory, U.B.C. The proton nmr spectra were obtained in the indicated solvents, using a Varian XL-300 Fourier-transform spectrometer or a Bruker WH-400 spectrometer. Experimental details and analytical data for compounds **2–16** and selected examples of chain-linked mono- and

dipyrrolic precursors to the porphyrins are available as supplementary material.[2]

*1,4-Bis[4-(5-ethoxycarbonyl-2,4-dimethylpyrrol-3-yl)-4-oxobutyl]benzene (**19**a)*

1,4-Bis(3-carboxylpropyl)benzene (**8**) (10 g, 0.04 mol) and thionyl chloride (19 g, 0.16 mol) were refluxed on a steam bath for 30 min and the excess thionyl chloride removed by evaporation under reduced pressure. After repeated evaporations with CCl_4 (4 × 25 mL) the dark red residue of the bis-acid chloride was taken into distilled CH_2Cl_2 (30 mL), transferred into a flask containing 2-ethoxy-3,5-dimethylpyrrole (**18**) (16.7 g, 0.1 mol), distilled CH_2Cl_2 (140 mL), and nitromethane (150 mL) under nitrogen, and treated rapidly with anhydrous stannic chloride (41.7 g, 0.16 mol). The reaction mixture was stirred overnight at room temperature and the dark brown solution was poured into 0.1 M aqueous hydrochloric acid (100 mL) and stirred for 15 min. The precipitated yellow solid was filtered, washed with water, CH_2Cl_2, and methanol, and a second crop was collected from the combined filtrate. Overall yield was 12.5 g (57%).

An analytical sample was recrystallized by adding methanol to a concentrated solution of **19***a* in CH_2Cl_2 and minimum trifluoroacetic acid; mp 185.0–186.5°C; ^{1}H nmr (300 MHz, δ, 10% TFA/$CDCl_3$): 1.48 (t, 6H, J = 6 Hz), 1.99–2.09 (m, 4H), 2.53 (s, 6H), 2.57 (s, 6H), 2.74 (t, 4H, J = 6 Hz), 2.90 (t, 4H, J = 6 Hz), 4.45 (q, 4H, J = 6.2 Hz), 7.15 (s, 4H), 10.25 (bs, 2H); mass spectrum (*m/e* (relative intensity)): 548 (M^+, 4), 340 (17), 209 (100), 194 (66), 148 (74). Mol. wt. calcd. for $C_{32}H_{40}N_2O_6$: 548.2886; found by high resolution mass spectrometry: 548.2894. Anal. calcd. for $C_{32}H_{40}N_2O_6$: C 70.05, H 7.35, N 5.11; found: C 70.00, H 7.35, N 5.24.

*1,4-Bis[4-(5-ethoxycarbonyl-2,4-dimethylpyrrol-3-yl)butyl]-benzene (**20**a)*

The diketone **19***a* (14 g, 0.0255 mol) was suspended in anhydrous THF (150 mL) (N_2 atmosphere) and treated with a 1 M borane–THF solution (10 mL). The resulting mixture was stirred for 1 h, during which time the starting material went into solution. Following tlc analysis of an aliquot, a further 10 mL of BH_3–THF solution was added and the mixture was stirred for another hour, when the reaction was found to be complete.

The excess BH_3 was destroyed with methanol (20 mL), the solution concentrated under reduced pressure, and methanol added to crystallize the white product, yield 10.6 g (80%); mp 162–163°C; ^{1}H nmr (300 MHz, δ, $CDCl_3$): 1.35 (t, 6H, J = 7.5 Hz), 1.44–1.51 (m, 4H), 1.58–1.68 (m, 4H), 2.18 (s, 6H), 2.26 (s, 6H), 2.38 (t, 4H, J = 7.5 Hz), 2.59 (t, 4H, J = 9.4 Hz), 4.30 (q, 4H, J = 7.5 Hz), 7.08 (s, 4H), 8.70 (bs, 2H); mass spectrum (*m/e* (relative intensity)): 520 (M^+, 19), 474 (23), 428 (13), 206 (100), 180 (71), 134 (94). Mol. wt. calcd. for $C_{32}H_{44}N_2O_4$: 520.3301; found by high resolution mass spectrometry: 520.3307. Anal. calcd. for $C_{32}H_{44}N_2O_4$: C 73.81, H 8.52, N 5.38; found: C 73.69, H 8.52, N 5.45.

*1,4-Bis[4-(5-ethoxycarbonyl-2,4-dimethylpyrrol-3-yl)butyl]-2-acetamidobenzene (**21**c)*

1,4-Bis[4-(5-ethoxycarbonyl-2,4-dimethylpyrrol-3-yl)butyl]-2-nitrobenzene (**20***c*) (7.3 g, 12.9 mmol) was dissolved in THF (200 mL), treated with 10% Pd/C (0.7 g), acetic anhydride (10 mL), and sodium acetate (0.5 g), and the solution stirred under a hydrogen atmosphere (1 atm (101.3 kPa)) overnight. The solution had to be retreated with fresh catalyst and hydrogenated again for complete reaction.

The catalyst was filtered off and the product was crystallized out by concentrating the solution, in the presence of hexane, yield 90% (6.7 g); mp 215.5–216.5°C; ^{1}H nmr (400 MHz, δ, $CDCl_3$): 1.27 (t, 6H, J = 8 Hz), 1.35–1.58 (m, 8H), 2.10 (s, 9H), 2.18 (s, 6H), 2.28–2.34 (m, 4H), 2.44–2.54 (m, 4H), 4.22 (q, 4H, J = 6.7 Hz), 6.83–6.87 (s, d, 2H), 7.00 (d, 1H, J = 8 Hz), 7.48 (s, 1H), 8.49 (b, 2H); mass spectrum (*m/e* (relative intensity)): 577 (M^+, 15), 531 (18), 485 (14), 206 (16), 180 (46), 134 (100). Mol. wt. calcd. for $C_{34}H_{47}N_3O_5$: 577.3516; found by high resolution mass spectrometry: 577.3514. Anal. calcd. for $C_{34}H_{47}N_3O_5$: C 70.68, H 8.20, N 7.27; found: C 70.44, H 8.39, N 7.07.

*1,4-Bis[4-(5-benzyloxycarbonyl-2,4-dimethylpyrrol-3-yl)-butyl]benzene (**22**a)*

1,4-Bis[4-(5-ethoxycarbonyl-2,4-dimethylpyrrol-3-yl)butyl]-benzene (**20***a*) (7.8 g, 15 mmol) and distilled benzyl alcohol (100 mL) were heated to reflux under nitrogen and treated (in 1-mL portions) with a concentrated solution of sodium in benzyl alcohol. After addition of 3 mL of the catalyst, no further effervescence (corresponding to ethanol) could be observed and the hot solution was carefully poured into methanol (150 mL) with sufficient acetic acid (10 mL) to quench the catalyst. Water was added slowly to precipitate the product, which was filtered and washed with 50% MeOH/water. The dibenzylester was obtained in 86% yield (8.3 g); mp 147–149°C; ^{1}H nmr (400 MHz, δ, $CDCl_3$): 1.42–1.49 (m, 4H), 1.57–1.66 (m, 4H), 2.16 (s, 6H), 2.27 (s, 6H), 2.37 (t, 4H, J = 8 Hz), 2.58 (t, 4H, J = 8 Hz), 5.29 (s, 4H), 7.07 (s, 4H), 7.31–7.43 (m, 10H), 8.54 (bs, 2H); mass spectrum (*m/e* (relative intensity)): 644 (M^+, 8), 536 (4), 509 (7), 401 (10), 268 (23), 108 (31), 91 (100). Mol. wt. calcd. for $C_{42}H_{48}N_2O_4$: 644.3614; found by high resolution mass spectrometry: 644.3610. Anal. calcd. for $C_{42}H_{48}N_2O_4$: C 78.23, H 7.50, N 4.34; found: C 78.04, H 7.59, N 4.38.

*1,4-Bis[4-(5-benzyloxycarbonyl-2,4-dimethylpyrrol-3-yl)butyl]-2-acetamidobenzene (**22**c)*

1,4-Bis[4-(5-ethoxycarbonyl-2,4-dimethylpyrrol-3-yl)butyl]-2-acetamidobenzene (**21***c*) (1 g, 1.73 mmol) was placed in distilled benzyl alcohol (10 mL) and treated with metallic sodium (0.05 g). The resulting mixture was heated at 100°C under 12 Torr pressure for 30 min when all of the starting material dissolved, resulting in a brownish yellow solution. The solution was cooled to room temperature (still under vacuum) and neutralized with acetic acid.

Benzyl alcohol was distilled off under vacuum (0.1 Torr), and the pink residue taken into methylene chloride (30 mL) and washed with water (3 × 30 mL) to remove salts. After evaporating the methylene chloride, the solid was dissolved in ethyl acetate (10 mL), and cooled in a refrigerator at 4°C.

The white solid was filtered off and washed with cold ethyl acetate to give 0.91 g product (75%); mp 187–189°C; ^{1}H nmr (400 MHz, δ, $CDCl_3$): 1.42–1.65 (m, 8H), 2.16 (s, 9H), 2.27 (s, 6H), 2.35–2.41 (m, 4H), 2.52–2.61 (m, 4H), 5.29 (s, 4H), 6.86 (b, 1H), 6.92 (bd, 1H), 7.06 (bd, 1H), 7.32–7.45 (m, 10H), 7.56 (b, 1H), 8.53 (b, 2H); mass spectrum (*m/e* (relative intensity)): 701 (M^+, 3), 593 (3), 458 (9), 108 (69), 91 (100). Mol. wt. calcd. for $C_{44}H_{51}N_3O_5$: 701.3829; found by high resolution mass spectromemtry: 701.3834. Anal. calcd. for $C_{44}H_{15}N_3O_5$: C 75.29, H 7.32, N 5.99; found: C 75.13, H 7.50, N 5.78.

*1,4-Bis[4-(5-formyl-2,4-dimethylpyrrol-3-yl)butyl]benzene (**25**a)*

*(i) Debenzylation of **22**a*

The dibenzylester **22***a* (5 g, 9.62 mmol) and 10% Pd/C (0.5 g) in THF (150 mL) were stirred under hydrogen (1 atm) overnight. When the uptake of hydrogen ceased, the catalyst was filtered and the solution checked by tlc for any unconverted starting material. The solvents were evaporated *in vacuo*, and the bis(carboxy)pyrrole **23***a* was used in the next step without purification.

*(ii) Decarboxylation of **23**a*

The crude bis(carboxy)pyrrole **23***a* was refluxed in DMF (100 mL) under nitrogen. The uv absorption spectrum showed a

[2]Experimental details and analytical data for compounds **2**–**16**, **19***b*–*d*, **20***b*–*d*, **21***d*, **22***b*,*d*, **23***b*,*d*, **23***b*–*d*, **24***b*–*d*, **25***b*–*d*, **26***b*–*d*, **29***b*–*d*, and **30***b*–*d* are available as supplementary material and may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2.

For personal use only.

reduction of the band at 282 nm to just a shoulder, within 2 h. The solution containing the bis α-free pyrrole **24***a* was cooled to room temperature and used directly in the next reaction.

(iii) Vilsmeier formylation of ***24***a

To an ice-cooled solution of DMF (11 mL) in dry CH_2Cl_2 (40 mL), phosphorus oxychloride (9.8 mL) was added dropwise and the Vilsmeier reagent thus prepared was added rapidly to the chilled DMF solution of the bis α-free pyrrole **24***a* prepared earlier. The solution was stirred for a further 30 min and poured onto crushed ice (100 g). Solid sodium bicarbonate was added carefully until the solution became basic, and CH_2Cl_2 was boiled off. Water (300 mL) was added and the mixture was heated at 75°C for 1 h. The grey-colored solid that crystallized out was filtered and washed with water. An overall yield of 85% of crude **25***a* was obtained from the dibenzylester **22***a*. An analytically pure sample of the bisformylpyrrole was prepared by deprotecting the cyanoacrylate derivative **26***a* with aqueous potassium hydroxide in *n*-propanol; mp 217–219°C; ^{1}H nmr (300 MHz, δ, $CDCl_3$): 1.40–1.51 (m, 4H), 1.58–1.68 (m, 4H), 2.21 (s, 6H), 2.25 (s, 6H), 2.38 (t, 4H, J = 7.5 Hz), 2.60 (t, 4H, J = 7.5 Hz), 7.07 (s, 4H), 9.47 (s, 4H); mass spectrum (*m/e* (relative intensity)): 432 (M^+, 44), 404 (34), 389 (18), 296 (10), 136 (100), 108 (58). Mol. wt. calcd. for $C_{28}H_{36}N_2O_2$: 432.2777; found by high resolution mass spectrometry: 432.2783. Anal. calcd. for $C_{28}H_{36}N_2O_2$: C, 77.74; H, 8.39; N, 6.48; found: C 77.57, H 8.28, N 6.32.

*1,4-Bis{4-[5-(2-cyano-2-methoxycarbonylvinyl)-2,4-dimethylpyrrol-3-yl]butyl}benzene (****26****a)*

The crude 1,4-bis[4-(5-formyl-2,4-dimethylpyrrol-3-yl)butyl]-benzene (**25***a*) (1 g, 2.31 mmol) was taken up in toluene (50 mL) with methyl cyanoacetate (0.56 g, 5.65 mmol) and cyclohexylamine (0.5 mL). The mixture was heated at reflux under nitrogen. The reaction was monitored by tlc and was found to be complete in 2 h. The solvent was evaporated, *in vacuo*, and the residue was taken to dryness on a vacuum line.

The crude product was dissolved in CH_2Cl_2 and chromatographed on silica gel (50 g). The solvent polarity was gradually increased, 0.5% ethyl acetate/CH_2Cl_2 and then 1% ethyl acetate/CH_2Cl_2, to facilitate elution without causing the impurities to move. The bright yellow product was crystallized from the eluates by concentrating, in the presence of methanol, to yield 1.06 g (76.9%). The solid thus obtained was analytically pure; mp 198.3–200.3°C; ^{1}H nmr (400 MHz, δ, $CDCl_3$); 1.43–1.50 (m, 4H), 1.58–1.66 (m, 4H), 2.15 (s, 6H), 2.28, 2.29 (s, s, 6H), 2.38–2.43 (m, 4H), 2.60 (t, 4H, J = 8 Hz), 3.86 (s, 6H), 7.07 (s, 4H), 7.20, 7.91 (s, s, 2H), 9.48 (bs, 2H); mass spectrum (*m/e* (relative intensity)): 594 (M^+, 49), 562 (14), 530 (26), 217 (68), 185 (100). Mol. wt. calcd. for $C_{36}H_{42}N_4O_4$: 594.3206; found by high resolution mass spectrometry: 594.3207. Anal. calcd. for $C_{36}H_{42}N_4O_4$: C 72.70, H 7.12, N 9.42; found: C 72.87, H 7.27, N 9.32.

*1,4-Bis{4-[2-((5-ethoxycarbonyl-3-ethyl-4-methylpyrrol-2-yl)methyl)-5-(2-cyano-2-methoxycarbonylvinyl)-4-methylpyrrol-3-yl]butyl}benzene (****29****a)*

(i) Monochlorination of the α-methyl group of ***26***a

1,4-Bis(4-[5-(2-cyano-2-methoxycarbonylvinyl)-2,4-dimethylpyrrol-3-yl]butyl)benzene (**26***a*) (0.44 g, 0.74 mmol) in dry methylene chloride (50 mL) was treated, dropwise, with a solution of sulfuryl chloride (0.22 g, 1.63 mmol) in methylene chloride (10 mL) over a period of 10 min at room temperature. The pale yellow solution, which turned orange during addition, was stirred for a further 0.5 h. The solvent was removed *in vacuo*, and the yellow residue of the corresponding α-chloromethyl derivative **27***a* was used directly in the next reaction without purification.

(ii) Condensation of ***27***a *with* ***28***

The α-chloromethyl derivative **27***a*, prepared above, was suspended in glacial acetic acid (50 mL) together with 2-ethoxycarbonyl-4-ethyl-3-methylpyrrole **28** (0.35 g, 1.9 mmol) and heated under nitrogen. When the temperature reached 70°C, all of the starting material went into solution, resulting in a clear dark-red solution. After the reaction mixture was heated for a further 30 min, tlc analysis of the reaction mixture indicated a single product (colored violet by bromine vapor). The mixture was evaporated to dryness *in vacuo*, the residue taken up in methylene chloride (50 mL), and the remaining acid removed by extraction with saturated aqueous sodium bicarbonate (3 × 50 mL) and water (3 × 50 mL). The dried methylene chloride solution was then chromatographed on silica gel (50 g). The excess α-free pyrrole starting material **28** was eluted with methylene chloride and the product was eluted with 5–10% ethyl acetate/methylene chloride. Since attempted crystallization of the product failed, it was isolated as a non-crystallizable glass, by evaporating the solvents, yield 0.65 g (92%). An analytically pure sample was obtained using a chromatotron (silica gel, 1-mm plate, 0.5% methanol/methylene chloride as the eluent); mp 244°C (dec.); ^{1}H nmr (400 MHz, δ, $CDCl_3$): 1.01 (t, 6H, J = 8 Hz), 1.31, 1.29–1.40 (t, m, 10H), 1.55–1.64 (m, 4H), 2.10, 2.11, 2.12 (s, s, s, 6H), 2.29 (s, 6H), 2.33–2.43 (m, 8H), 2.53–2.61 (m, 4H), 3.78, 3.83 (s, s, 6H), 3.87–4.20 (m, 4H), 4.24 (q, 4H, J = 8 Hz), 7.06 (s, 4H), 7.20, 7.84, 7.85 (s, s, s, 2H), 9.00 (b, 2H), 9.37 (b, 2H); mass spectrum (*m/e* (relative intensity)): 952 (M^+, 3), 906 (15), 860 (20), 698 (29), 666 (20). Mol. wt. calcd. for $C_{56}H_{68}N_6O_8$: 952.5099; found by high resolution mass spectrometry: 952.5090. Anal. calcd. for $C_{56}H_{68}N_6O_8$: C 70.56, H 7.19, N 8.82; found: C 69.83, H 7.36, N 8.36.

*1,4-Bis{4-[2-((5-carboxy-3-ethyl-4-methylpyrrol-2-yl)methyl)-5-formyl-4-methylpyrrol-3-yl]butyl}benzene (****30****a)*

In a 25-mL round-bottom flask fitted with a Claisen adaptor, a nitrogen inlet, and a reflux condenser was placed a stirred suspension of 1,4-bis{4-[2-((5-ethoxycarbonyl-3-ethyl-4-methylpyrrol-2-yl)methyl)-5(2-cyano-2-methoxycarbonylvinyl)-4-methylpyrrol-3-yl]butyl}benzene (**30***a*) (0.46 g, 0.48 mmol), KOH (0.81 g, 14.5 mmol), and water (9.6 mL). The magnetically stirred suspension was heated to reflux and treated with *n*-propanol (4.8 mL) when the yellow starting material went into solution immediately, resulting in a pale brown solution. Refluxing was continued and the reaction was monitored using uv/visible spectroscopy. During the reaction, the absorption band at 388 nm (corresponding to the starting material) diminished in intensity with a simultaneous increase in the intensity of the peak at 280 nm and the appearance of a new peak at 324 nm. In 3 h, the peak at 388 nm had disappeared completely, indicating the complete removal of the cyanoacrylate protecting groups. The lower wavelength bands (now at 268 nm and 322 nm) were very intense.

n-Propanol was evaporated off until the reflux temperature reached 100°C, and the solution was cooled to room temperature, while under nitrogen, when the product partially separated out as a brown slimy material. The solution was filtered under suction and the brown material was dissolved in more water. The clear aqueous solution was cooled in ice and acidified with glacial acetic acid. The brown powder was collected by filtration and washed with water. The final product was dried in a vacuum desiccator over KOH for 2 days, yield 0.33 g (93%); mp 179–181°C; ^{1}H nmr (300 MHz, δ, DMSO-d_6): 0.90 (m, 6H), 1.04–1.60 (b, 8H), 2.12 (s, 12H), 2.20–2.36 (m, 8H), 2.40–2.56 (m, 4H), 3.80 (s, 4H), 7.00 (s, 4H), 9.44 (s, 2H), 11.06–11.48 (m, 4H); mass spectrum (*m/e* (relative intensity)): 734 (M^+, from FAB), 646 [$(M - 2COO)^+$, 3], 617 (3), 508 (5), 169 (11), 122 (42), 109 (58), 94 (100).

*7,17-Diethyl-2,8,12,18-tetramethyl-3,13-[phenylene-1,4-bis(tetramethylene)]-porphyrin (****32****a)*

(i) Decarboxylation of ***30***a

The magnetically stirred solution of the dipyrromethane derivative **30***a* (0.31 g, 0.42 mmol) in DMF (100 mL) was heated at its reflux under nitrogen and the decarboxylation monitored by uv-visible spectroscopy. The intensity of the 280 nm band decreased considerably relative to that of the 318 nm band, which was an indication of the extent of decarboxylation. In 2 h, the 280 nm band was reduced to a shoulder.

The solution was cooled to room temperature under nitrogen, concentrated to 10 mL, methylene chloride (100 mL) added, and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

the solution extracted with water (3 × 50 mL). The dried organic phase was evaporated to 10 mL and diluted to 200 mL with distilled THF to be used in the subsequent cyclization reaction.

(ii) Intramolecular 2+2 coupling

The cyclization was carried out in two 2-L Erlenmeyer flasks, covered with aluminum foil; each flask contained toluene-*p*-sulphonic acid (4.0 g) dissolved in methanol (25 mL) and diluted with distilled methylene chloride (600 mL). The dipyrromethane derivative prepared above was added to the magnetically stirred acid catalyst solution by means of a syringe pump. The syringe pump, operating at its slowest speed, took approximately 9 h to empty one 50-mL syringe.

Once the addition was complete (20 h), the reddish-violet solution was concentrated down to 10 mL and taken into methylene chloride (100 mL) and extracted with saturated aqueous sodium bicarbonate (3 × 50 mL). It was then taken to dryness *in vacuo* and the residue was purified by chromatography.

The crude porphyrin was first chromatographed on silica gel (120 g, activity I) using methylene chloride as the solvent. Some pink materials that eluted first were discarded. The solvent was then changed to 1% MeOH/CH_2Cl_2 and the porphyrin eluted with some brown impurities.

The partially purified porphyrin was chromatographed again on alumina (30 g, 4% water added) with methylene chloride as the eluting solvent. Some brown, fast moving impurities initially eluted out, and then the porphyrin eluted cleanly, leaving all other impurities adsorbed at the origin. Crystallization from a solution of MeOH/CH_2Cl_2 afforded 89.2 mg (34.8%) of the purple porphyrin; mp > 300°C; visible spectrum (CH_2Cl_2), λ_{max} (nm) (log ε): 404 (5.26), 506 (4.08), 542 (4.10), 572 (3.91), 626 (3.60); ^{1}H nmr (400 MHz, δ, CD_2Cl_2): 9.98 (s, 2H, methine protons 10-H and 20-H), 9.77 (s, 2H, methine protons 5-H and 15-H), 4.08 (q, 4H, J = 6.7 Hz, -CH_2CH_3), 3.96–4.05 (m, 2H, one proton each at chain termini), 3.63–3.70 (m, 2H, one proton each at chain termini), 3.63 (s, 6H, $2CH_3$), 3.44 (s, 6H, $2CH_3$), 2.38 (s, 4H, benzene-H), 1.87 (t, 6H, J = 8 Hz, -CH_2CH_3), 1.36–1.50 (m, 2H, chain protons), 1.18–1.27 (m, 2H, chain protons), 0.83–0.91 (m, 2H, chain protons), 0.07–0.18 (m, 4H, chain protons), −0.08–0.02 (m, 2H, chain protons), −3.26 (bs, 2H, nH). Mol. wt. calcd. for $C_{42}H_{48}N_4$: 608.3879; found by high resolution mass spectrometry: 608.3883. Anal. calcd. for $C_{42}H_{48}N_4$: C 82.85, H 7.95, N, 9.20; found: C 82.40, H 7.87, N 8.95.

*7,17-Diethyl-2,8,12,18-tetramethyl-3,13-[phenylene-1,4-bis(pentamethylene)]porphyrin (***32***b)*

This porphyrin was prepared and purified in the same way as described for porphyrin **32***a*. The yield was 19.1%; mp > 300°C; visible spectrum (CH_2Cl_2), λ_{max} (nm) (log ε): 400 (5.10), 498 (3.90), 543 (3.77), 568 (3.46), 622 (3.13). ^{1}H nmr (400 MHz, δ, CD_2Cl_2): 10.19 (s, 2H, methine protons 10-H and 20-H), 10.09 (s, 2H, methine protons 5-H and 15-H), 4.34–4.41 (m, 2H, one proton each at chain termini), 4.22–4.32 (m, 2H, -CH_2CH_3), 4.06–4.15 (m, 2H, -CH_2CH_3), 3.95–4.05 (m, 2H, one proton each at chain termini), 3.67 (s, 6H, $2CH_3$), 3.54 (s, 6H, $2CH_3$), 2.68 (s, 4H, benzene-H), 2.17–2.27 (m, 2H, chain protons), 1.91, 1.87–1.91 (t, m, 8H, -CH_2CH_3, chain protons), 0.86–0.97 (m, 6H, chain protons), 0.28–0.35 (m, 2H, chain termini), −0.13 to −0.24 (m, 2H, chain protons), −1.13 (m, 2H, chain protons), −3.58 (bs, 2H, NH). Mol. wt. calcd. for $C_{44}H_{52}N_4$: 636.4192: found by high resolution mass spectrometry: 636.4189. Anal. calcd. for $C_{44}H_{52}N_4$: C 82.97, H 8.23, N 8.80; found: C 80.72, H 8.62, N 8.57.

*7,17-Diethyl-2,8,12,18-tetramethyl-3,13-[2-acetamido-phenylene-1,4-bis(tetramethylene)]porphyrin (***32***c)*

The procedure used in preparation of this porphyrin was the same as that employed in the preparation of porphyrin **32***a*.

This porphyrin was found to be adsorbed onto silica gel more strongly than **32***a* and **32***b*. Activity I silica gel, 2% MeOH/CH_2Cl_2, was necessary to move the porphyrin. The porphyrin eluate, which contained some impurities, was purified again using a chromatotron with a 1-mm Al_2O_3 plate and a gradient of 1:1 decreasing to 1:3 hexane/CH_2Cl_2. The porphyrin product was obtained by evaporating the solvents. The residue was dried under vacuum for 3 days to give a 44.8% yield. Crystallization was achieved by evaporating a hexane/CH_2Cl_2 solution of the porphyrin; mp > 300°C; visible spectrum (CH_2Cl_2), λ_{max} (nm) (log ε): 404 (5.23), 506 (4.07), 542 (4.09), 572 (3.89), 624 (3.60); ^{1}H nmr (400 MHz, δ, CD_2Cl_2): 9.94 (d, 2H, J = 16 Hz, methine protons 10-H and 20-H), 9.77 (d, 2H, J = 16 Hz, methine protons 5-H and 15-H), 5.54, 5.36 (s, s, 2H, benzene-H), 3.94–4.14 (m, 6H, -CH_2CH_3, one proton each at chain termini), 3.60–3.78 (m, d, 9H, one proton each at chain termini, two CH_3, one benzene-H), 3.41 (d, 6H, two CH_3), 1.86–1.92 (m, 6H, -CH_2CH_3), 1.59 (s, 3H, NHCOCH_3), 1.31–1.59 (m, 2H, chain protons), 0.70–0.95 (m, 2H, chain protons), 0.01–0.20 (b, 4H, chain protons), −0.10 to −0.35 (b, 4H, chain protons), −3.30 (b, 2H, NH). Mol. wt. calcd. for $C_{44}H_{51}N_5O$: 665.4095; found by high resolution mass spectrometry: 665.4093.

*7,17-Diethyl-2,8,12,18-tetramethyl-3,13-[2-acetamido-phenylene-1,4-bis(pentamethylene)] porphyrin (***32***d)*

This compound was obtained by the same method described for **32***c*. The yield was 28.6%; mp > 300°C; visible spectrum (CH_2Cl_2), λ_{max} (nm) (log δ): 400 (5.26), 500 (4.20), 536 (4.13), 568 (3.96), 622 (3.82); ^{1}H nmr (400 MHz, δ, CD_2Cl_2): 10.17 (d, 2H, methine protons 10-H and 20-H), 10.07 (d, 2H, methine protons 5-H and 15-H), 5.62 (m, 2H, benzene-H), 4.32–4.42 (m, 2H, one proton each at chain termini), 4.21–4.32 (m, 2H, -CH_2CH_3), 4.05–4.16 (m, 2H, -CH_2CH_3), 3.95–4.05 (m, 2H, two proton each at chain termini), 3.68 (s, 6H, $2CH_3$), 3.54 (s, 8H, $2CH_3$, two benzene-H), 2.22 (b, 2H, chain protons), 1.86, 1.91 (m, t, 8H, -CH_2CH_3 and chain protons), 1.55 (s, 3H, NHCOCH_3), 0.83–1.03 (m, 6H, chain protons), 0.10–0.24 (m, 2H, chain protons), −0.23 (m, 2H, chain protons), −1.23, −1.38 (b, b, 2H, chain protons), −3.82 (b, 2H, NH). Mol. wt. calcd. for $C_{46}H_{55}N_5O$: 693.4407; found by high resolution mass spectrometry: 693.4423. Anal. calcd. for $C_{46}H_{55}N_5O$: C 79.61, H 7.99, N 10.09; found: c 79.44, H 8.09, N 9.86.

Received September 6, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

TSE-LOK HO, WEN-LUNG YEH, JOHN YULE, and HSING-JANG LIU. Can. J. Chem. **70**, 1375 (1992).

A formal synthesis of longifolene in racemic form is concluded starting from the Diels–Alder reaction of 6,6-dimethylfulvene and maleic anhydride. Key steps are cyclodehydration, conjugate methylation, and ring expansion.

TSE-LOK HO, WEN-LUNG YEH, JOHN YULE et HSING-JANG LIU. Can. J. Chem. **70**, 1375 (1992).

On a réalisé une synthèse formelle du longifolène racémique par le biais d'une réaction de Diels–Alder entre le 6,6-diméthylfulvène et l'anhydride maléique. Les étapes clés sont une cyclodéshydratation, un méthylation conjuguée et une extension de cycle.

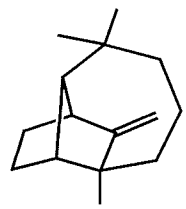
[Traduit par la rédaction]

Introduction

Longifolene (**1**), a tricyclic sesquiterpene isolated from *Pinus longifolia* occupies a significant position in natural products chemistry (1). Its structural elucidation marked the transition from the classical degradation period to routine application of X-ray crystallographic diffraction techniques. The full report of the first total synthesis of longifolene (2) also promulgated the retrosynthetic analysis that revolutionized, systematized, and elevated carbogenic synthesis to a level of sophistication and efficiency unmatched by other scientific disciplines.

Corey's inspiring approach was based on an intramolecular Michael reaction of a homodecalin system for constructing the tricyclic framework. Later, McMurry and Isser (3) modified this route to achieve the cyclization by an alkylation step, with the necessary ring expansion maneuver at a later stage. Johnson's synthesis (4) was an extension of a serendipitous discovery of bisannelation during solvolysis of a cyclopentenol by participation of an alkynyl sidechain. Oppolzer and Godel (5) exploited an intramolecular de Mayo reaction with great effectiveness in the assemblage of the bridged ring skeleton. The key step of the synthesis by Schultz and Puig (6) was a vinylcyclopropane to cyclopentene rearrangement that transformed a fused tricyclic system to the bridged ring isomer. Kuo and Money's route (7), predicated on the known Wagner–Meerwein rearrangement of isolongiborneol, relied on an intramolecular aldol condensation and construction of the required intermediate from 8-bromocamphor. Finally, an intramolecular Diels–Alder method described by Lei and Fallis (8) concluded a long search for a proper cyclopentadiene that would undergo the cycloaddition without yielding to the facile [1,5]-sigmatropic rearrangement.

In our investigation directed towards the synthesis of longifolene the merits of an intermolecular Diels–Alder reaction were considered. Specifically, we sought a norbornane derivative bearing functionalized carbon chains that are suitable to be elaborated into the seven-membered ring.



1

Results and discussion

In longifolene the presence of a *gem*-dimethyl group in the four-carbon bridge spanning C-2 and C-7 of a norbornane skeleton is a structural feature that attracted our attention. It led us to recognize a correlation between a potential *seco*-longifolene precursor and the *exo*-adduct **2***a* of 6,6-dimethylfulvene and maleic anhydride (Scheme 1). This adduct, possessing readily differentiated double bonds, was identified as a useful synthetic intermediate based on the speculation that bond formation between one of the carbonyl groups and the dimethylated carbon atom is feasible, since they project into the same space and are four bonds apart. Upon bridging, ring expansion can be effected. The other carbonyl group of the anhydride unit represents a latent exocyclic methylene pendant.

We became aware of the work by Alder and Ruhlmann (9) who reported the formation of a dihydrolactone acid (the saturated version of **3**) from the cycloadduct of 6,6-dimethylfulvene and maleic anhydride. Such a compound fits our purpose well, as we expected a ready transformation of the corresponding ester into a 3-methyl-2-cyclohexenone derivative on reaction with polyphosphoric acid. Sacrifice of one methyl group in the process would not be detractive, because restoring the substitution pattern of the bridging ring by conjugate methylation (10) should be rather straightforward. Ring expansion, removal of the ketone group, and degradation of the carboxylic residue would culminate in Johnson's norketone. On the other hand, a strained α,β-unsaturated ester may be created for the introduction of the angular methyl group.

As will be mentioned later, the idea of using citraconic anhydride as a dienophile in the initial Diels–Alder reaction

(a) PhH, reflux, 48 h; (b) 50% H_2SO_4, 20°C, 48 h, 53%; (c) H_2SO_4, MeOH, 20°C, 16 h, 100%; (d) H_2, 5% Pd–C, EtOAc, 20°C, 6 h, 98%

SCHEME 1

was also entertained. This modification represents a more direct pathway as all the carbon atoms present in the initial adduct would be preserved in the target molecule. The dissymmetry conferred to the adduct was deemed inconsequential; in fact it was anticipated that the carboxyl group attached to the quaternary carbon atom would tilt slightly toward the tetrasubstituted double bond, rendering its bond formation with that moiety more favorable.

Owing to the literature precedence and the lower cost of maleic anhydride our initial studies were devoted to the route traversing the simpler intermediates. Scheme 1 summarizes the preparation of dihydrolactone *exo*-ester **5***a* from 6,6-dimethylfulvene over four synthetic steps in an overall yield of 35%. The Diels–Alder addition of maleic anhydride to 6,6-dimethylfulvene, performed in refluxing benzene, gave almost exclusively the desired *exo* adduct **2***a*. Treatment of this compound with 50% sulfuric acid followed by esterification of the resulting lactone acid **3** gave rise to lactone ester **4**. Subsequent hydrogenation using 5% palladium on carbon as a catalyst furnished the dihydro-derivative **5***a*.

When compound **5***a* was subjected to treatment with phosphorus pentoxide and methanesulfonic acid (11) at 65°C, it underwent cyclodehydration to give the epimeric enones **6***a* and **6***b* in a 3:1 ratio and a combined yield of 37% (Scheme 2). Gratifyingly, much improved results emerged when the cyclodehydration was carried out with *endo*-ester **5***b*, readily obtained by epimerization of **5***a* using sodium methoxide in methanol. In this case, a high yield (82%) of enone **6***b* was produced along with a minute amount (1%) of the epimer **6***a*.

The reaction of enone **6***b* with lithium dimethylcuprate occurred readily to give keto ester **7** in nearly quantitative yield (Scheme 3). This set the stage for the construction of the ring skeleton of longifolene via ring expansion. Towards this end, keto ester **7** was treated with ethyl diazoacetate in the presence of boron trifluoride etherate (12). The reaction proceeded smoothly to give, in quantitative yield, an isomeric (regio-, stereo-, and enolic) mixture of the desired homologation products. While we expected the ring expansion to show a better regioselectivity (12, 13), the generation of two regioisomers **8***a* and **8***b* in a ratio of ca. 2.5:1[2] was not detrimental. Functionalities in the seven-membered ring were to be deleted immediately afterwards. In the event, decarbethoxylation of the ring expansion products with moist lithium iodide in refluxing collidine afforded a mixture of regioisomeric keto acids **9***a* and **9***b* as a result of concomitant demethylation of the methyl ester. This ester group was subsequently restored using methyl iodide and potassium carbonate in refluxing acetone. Keto esters **10***a* and **10***b*[3] thus obtained in a combined yield of 86% over two steps could not be separated. The ^1H nmr spectrum of the mixture displayed a ratio of 2.5:1 for **10***a* and **10***b*, respectively.

Much effort was directed towards the supposedly trivial deoxygenation of the ketone carbonyl. A number of experiments carried out to effect Wolff–Kishner reduction led invariably to extensive decomposition. Attempted thioacetalization using 1,2-ethanedithiol and boron trifluoride etherate in methylene chloride at 0°C resulted in the formation of several products whose spectral data were inconsistent with those expected. Consequently, a less direct approach was explored. Sodium borohydride reduction of keto esters **10***a* and **10***b* furnished a 85% yield of alcohols **11***a* and **11***b*, each as an approximately 1:1 mixture of epimers (Scheme 4). These alcohols were readily converted to the corresponding xanthates **12***a* and **12***b*, chlorides **13***a* and **13***b*, and mesylates **14***a* and **14***b* under usual conditions. The attempted re-

[2]The ratio of **8***a* and **8***b* follows from subsequent transformations.

[3]These compounds were also obtained in pure form and characterized as such by oxidation of each of the corresponding alcohols **11***a* and **11***b* with pyridinium chlorochromate on alumina (14) (see Experimental).

SCHEME 3

duction of the xanthates and chlorides using tri-*n*-butyltin hydride and a catalytic amount of azobisisobutyronitrile in refluxing toluene failed to give any of the desired product **15**. Mesylates **14***a* and **14***b*, on the other hand, gave rise to a mixture of **15** and olefins **16** upon heating with sodium iodide and zinc dust (15) in tetrahydrofuran at reflux temperature. Subsequent hydrogenation of this inseparable mixture using Adams catalyst furnished ester **15** in 75% overall yield from the mixture of alcohols **11***a* and **11***b*.

With ester **15** in hand, the introduction of a double bond conjugated to the ester group via selenation-oxidative elimination (16) was attempted in light of the prospect that it would permit conjugate addition of the required methyl group. The maneuver proved unfruitful. Under no conditions examined could a phenylselenenyl group be incorporated. In fact we were unable to deuterate ester **15** by consecutive treatment with lithium diisopropylamide and deuterium oxide. At this stage, the conversion of **15** into Johnson's norketone **24** was initiated. Accordingly, the ester group was reduced with lithium aluminium hydride (**15** → **17**) (Scheme 5), but since conversion of the primary alcohol to the corresponding selenide using known procedures (**17**, **18**) failed, the formation of an exocyclic methylene group via selenoxide pyrolysis could not be executed. Problems were also encountered during a Barbier–Wieland degradation. Although the addition of phenyllithium and the dehydration of the resulting alcohol **18** to olefin **19** with copper(II) sulfate on silica gel (19) could be easily carried out, the ensuing ozonolysis did not give any detectable amount of norketone **24**.

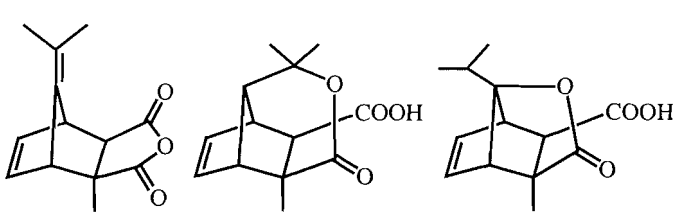
(a) $NaBH_4$, MeOH, 0°C, 1 h, 82%; (b) NaH, THF, 0°C, 0.5 h; then CS_2, 0°C; then MeI, 20°C, 4.5 h, 95%; (c) $SOCl_2$, Py, CH_2Cl_2, reflux, 13 h, 64%; (d) MsCl, Et_3N, Py, CH_2Cl_2, 0°C, 0.5 h, 85%; (e) NaI, Zn, THF, reflux, 15 h, 90%; (f) H_2, PtO_2, MeOH, 20°C, 24 h, 98%

SCHEME 4

The conversion of ester **15** into **24** was finally accomplished via the following synthetic sequence. Saponification of **15** with aqueous potassium hydroxide followed by treatment of the resulting acid **20** with methyllithium gave rise to an 87% yield of ketone **21**, which was subjected to Baeyer–Villiger oxidation using trifluoroperacetic acid in the presence of disodium hydrogen phosphate as a buffer (20). Acetate **22** thus formed, in 48% yield, was hydrolyzed with alkali and the resulting alcohol **23** oxidized with pyridinium chlorochromate on alumina to generate an 80% yield of norketone **24**, which was identified by spectroscopic comparison (ir, ^{1}H nmr, ^{13}C nmr, and ms) with an authentic sample. Accordingly, a formal synthesis of (±)-longifolene is complete.

Regarding the route involving citraconic anhydride it turned out to be a disappointment. Firstly, an *endo*-selectivity of the Diels–Alder reaction was observed; at best the desired *exo* adduct **25** was obtained in a 30% yield when the reaction was carried out in refluxing benzene. All attempts at ameliorating the situation by changing solvents, reaction temperatures, and the addition of Lewis acid catalysts seemed to elicit a counter effect. Secondly, the desired δ-lactone **26** was produced in poor yield (18%), in the subsequent step, along with a small amount (8%) of γ-lactone **27**. The tedious separation and low yields in these steps forced us to abandon the alternative synthesis.



25 **26** **27**

Experimental

General

Melting points were recorded on a Köfler hot stage apparatus and are uncorrected. Infrared spectra (ir) were recorded using Nicolet 7199 FTIR or Nicolet MX-1 FTIR spectrometers. High-resolution mass spectra (ms) were obtained using a Kratos AEI MS50 high-resolution mass spectrometer. Elemental analyses were carried out by the microanalytical laboratory of this department. Proton nuclear magnetic resonance spectra (^{1}H nmr) were obtained using the following spectrometers: Bruker WH-200 (200 MHz), Bruker WH-400 (400 MHz), and Bruker AM-300 (300 MHz). Coupling constants are reported to within ±0.5 Hz. Carbon-13 nuclear magnetic spectra (^{13}C nmr) were recorded on a Bruker AM-300 (75.47 MHz) spectrometer. Carbon-13 mutiplicities were derived from off-resonance decoupling or Carr–Purcel–Meiboom–Gill spin echo *J*-modulated experiments (APT or Attached Proton Test). Methylene groups and quaternary carbons appear as signals in phase (p) with respect to the deuteriochloroform signal while the signals having an antiphase (a) to that of deuteriochloroform are for the methyl and methine groups. The following abbreviations were used: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, and br = broad.

Materials

Other then hydrogenation, all reactions were carried out under a positive pressure of argon gas. Anhydrous magnesium sulfate was used for drying organic solutions. Still's procedure (21) for flash chromatography using silica gel of mesh 230–400 was routinely used for separations. Thin-layer chromatography was performed on aluminum-backed plates precoated with silica gel 60 F_{254} as supplied by E. Merck, Darmstadt. Skellysolve B was distilled prior to use. Other solvents were purified as follows: benzene by distillation from lithium aluminum hydride; diethyl ether and tetrahydrofuran by distillation from a blue or purple solution of sodium

SCHEME 5

benzophenone ketyl under argon; dichloromethane by distillation from calcium hydride; acetone by distillation first over potassium permanganate and then magnesium and iodine; and methanol by distillation from magnesium and a trace amount of carbon tetrachloride. Pyridine and trimethylsilyl chloride were distilled prior to use. Copper(I) iodine was purified according to the procedure described by Dieter *et al* (22).

(1R,2R,6S,7S)-10-Isopropylidene-4-oxatricyclo[5.2.1.$0^{2,6}$]non-8-ene-3,5-dione (2a) and (1R,2S,6R,7S)-10-isopropylidene-4-oxatricyclo[5.2.1.$0^{2,6}$]non-8-ene-3,5-dione (2b)

A solution of 6,6-dimethylfulvene (8.82 g, 0.083 mol) and maleic anhydride (10.58 g, 0.108 mol) in benzene (76 mL) was heated under reflux for 48 h. Cooling this solution produced a large amount of yellow-white solid that was filtered and recrystallized from pet. ether – ether to furnish the white crystalline anhydride **2***a*. The filtrate and mother liquor were combined, concentrated, and recrystallized to give more of **2***a*. The remaining filtrate and mother liquor were then combined, concentrated, and subjected to flash chromatography (5–33% ether in pet. ether) to give starting fulvene (1.1 g, 12% recovery), followed by *endo*-isomer **2***b* (37 mg, 0.25% based on consumed fulvene): ir ($CHCl_3$ cast): 1783 cm^{-1} (C=O); ^1H nmr (200 MHz, $CDCl_3$) δ: 6.46 (m, 2H), 3.94 (m, 2H), 3.40 (m, 2H), and 1.61 (s, 6H); ms: M^+ 204.0788 (calcd. for $C_{12}H_{12}O_3$: 204.0787). Continued elution gave *exo* isomer **2***a*: mp 138–140°C; ir ($CHCl_3$ cast): 1771 cm^{-1} (C=O); ^1H nmr (300 MHz, $CDCl_3$) δ: 6.45 (dd, J = 2, 2 Hz, 2H), 3.87 (dd, J = 2, 2 Hz, 2H), 3.04 (s, 2H), and 1.60 (s, 6H); ms: M^+ 204.0779 (calcd. for $C_{12}H_{12}O_3$: 204.0787). The *exo* product **2***a* obtained by recrystallization and chromatography gave a combined yield of 10 g (67% based on consumed fulvene).

(1S,5S*,6S*,9R*,10R*)-10-Carboxy-4,4-dimethyl-3-oxatricyclo[4.3.1.$0^{5,9}$]dec-7-en-2-one (3)*

The Diels–Alder adduct **2***a* (9.25 g, 45.3 mmol) was dissolved in 50% sulfuric acid (45 mL). The solution was stirred at room temperature for 48 h. The resulting dark red-brown solution was then diluted with water (50 mL) and filtered through Celite. The filtrate was then extracted with ethyl acetate (4 × 20 mL). The combined extracts were dried, concentrated, and recrystallized from ethyl acetate to give acid **3** (5.3 g, 53% yield) as a white crystalline solid: mp 174–176°C; ir ($CHCl_3$ cast): 3440 (br, COOH) and 1721 cm^{-1} (C=O); ^1H nmr (400 MHz, $CDCl_3$) δ: 6.63 (ddd, J = 6, 3, 1 Hz, 1H), 6.15 (ddd, J = 6, 3, 1 Hz, 1H), 3.41 (m, 1H), 3.26 (m, 1H), 2.87 (ddd, J = 8, 1.5, 1.5 Hz, 1H), 2.49 (dd, J = 8, 1.5 Hz, 1H), 1.98 (m, 1H), 1.40 (s, 3H), and 1.35 (s, 3H); ms: M^+ 222.0877 (calcd. for $C_{12}H_{14}O_4$: 222.0892).

(1S,5S*,6S*,9R*,10R*)-10-Carbomethoxy-4,4-dimethyl-3-oxatricyclo[4.3.1.$0^{5,9}$]dec-7-en-2-one (4)*

Acid **3** (4.4 g, 19.7 mmol) was dissolved in methanol (25 mL). Concentrated sulfuric acid (ca, 20 mg) was added. The resulting solution was stirred at room temperature for 16 h. At the end of this time, the reaction flask was filled with a white solid. Filtration gave white crystalline ester **4** (2.5 g). The filtrate was concentrated and then dissolved in chloroform. The chloroform solution was washed

with water, 5% aqueous sodium bicarbonate, and saturated aqueous sodium chloride. The organic solution was then dried and concentrated to give more of ester **4** (2.1 g). The combined yield of ester **4** was 4.6 g (100% yield). This material was used in the following step without further purification: mp 159–160°C; ir ($CHCl_3$ cast): 1748 (C=O) and 1731 cm^{-1} (C=O); ^1H nmr (300 MHz, $CDCl_3$) δ: 6.61 (ddd, J = 6, 3, 1 Hz, 1H), 6.14 (ddd, J = 6, 3, 1 Hz, 1H), 3.70 (s, 3H), 3.45 (m, 1H), 3.24 (m, 1H), 2.85 (ddd, J = 8, 1.5, 1.5 Hz, 1H), 2.43 (d, J = 8 Hz, 1H), 1.97 (dd, J = 1.5, 1.5 Hz, 1H), 1.39 (s, 3H), and 1.34 (s, 3H); ms: M^+ 236.1047 (calcd. for $C_{13}H_{16}O_4$: 236.1049). Anal. calcd. for $C_{13}H_{16}O_4$: C 66.08, H 6.83; found: C 65.87, H 6.76.

(1S,5S*,6S*,9R*,10R*)-10-Carbomethoxy-4,4-dimethyl-3-oxatricyclo[4.3.1.0^{5,9}]dec-2-one (**5**a)*

Ester **4** (5.53 g, 23.4 mmol) was dissolved in ethyl acetate (50 mL). 5% Palladium on carbon (100 mg) was added. The mixture was hydrogenated under 20 psi (1 psi = 6.9 kPa) of hydrogen for 6 h using a Parr hydrogenation apparatus. The mixture was then filtered and concentrated to give *exo*-ester **5***a* (5.47 g, 98% yield) as a white solid: mp 118–120°C; ir ($CHCl_3$ cast): 1736 cm^{-1} (br, C=O); ^1H nmr (300 MHz, $CDCl_3$) δ: 3.68 (s, 3H), 2.97 (m, 2H), 2.63 (br d, J = 5.5 Hz, 1H), 2.58 (d, J = 7.5 Hz, 1H), 1.87 (m, 2H), 1.68 (m, 1H), 1.50–1.42 (m, 2H), 1.46 (s, 3H), and 1.39 (s, 3H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 171.97 (p), 171.77 (p), 82.60 (p), 54.33 (a), 52.10 (a), 49.07 (a), 48.60 (a), 39.96 (a), 38.87 (a), 31.96 (p), 31.14 (a), 26.36 (a), and 25.33 (p); ms: M^+ 238.1209 (calcd. for $C_{13}H_{18}O_4$: 238.1205). (1S,5S*,6S*,9R*,10S*)-10-Carbomethoxy-4,4-dimethyl-3-oxatricyclo[4.3.1.0^{5,9}]dec-2-one (**5**b)*

A solution of sodium methoxide in methanol was prepared by dissolving sodium metal (0.49 g, 21.3 g-atom) in methanol (25 mL). *Exo*-ester **5***a* (4.59 g, 19.3 mmol) was added and the resulting solution was heated under reflux for 8 h. The solution was then acidified with 1 N hydrochloric acid and extracted with chloroform (3 × 30 mL). The combined extracts were dried and concentrated to give the *endo*-ester **5***b* (4.28 g, 93% yield) as a white solid: mp 91–93°C; ir ($CHCl_3$ cast): 1737 cm^{-1} (C=O); ^1H nmr (200 MHz, $CDCl_3$) δ: 3.74 (s, 3H), 3.10 (m, 1H), 2.88 (m, 1H), 2.73 (m, 1H), 2.50 (d, J = 5 Hz, 1H), 2.06 (dd, J = 3, 1.5 Hz, 1H), 1.78 (m, 1H), 1.62–1.47 (m, 3H), 1.48 (s, 3H), and 1.44 (s, 3H); ms: M^+ 238.1193 (calcd. for $C_{13}H_{18}O_4$: 238.1205). Anal. calcd. for $C_{13}H_{18}O_4$: C 65.53, H 7.61; found: C 65.39, H 7.77.

(1S,5R*,6S*,9R*,10R*)-10-Carbomethoxy-4-methyltricyclo[4.3.1.0^{5,9}]dec-3-en-2-one (**6**a) and (1S*,5R*,6S*,9R*,10S*)-10-carbomethoxy-4-methyltricyclo[4.3.1.0^{5,9}]dec-3-en-2-one (**6**b)*

Preparation of P_2O_5–$MeSO_3H$ reagent

Phosphorus pentoxide (9 g) was added to freshly distilled methanesulfonic acid (95 g). The mixture was stirred at room temperature overnight. The resulting clear solution was stored at room temperature.

From exo-*ester* **5**a

A solution of *exo*-ester **5***a* (0.20 g, 0.84 mmol) in dichloromethane (1 mL) was added to the P_2O_5–$MeSO_3H$ reagent (2.01 g) and the resulting solution was then stirred at 65°C for 40 h. At the end of this time the dark brown solution was diluted with dichloromethane and poured into water (10 mL). The organic layer was then removed and washed with water, 5% aqueous sodium bicarbonate, and water. The organic solution was dried and concentrated to give a brown oil. Flash chromatography (50% ether in Skelly B) gave enone **6***b* (16 mg, 9% yield) as a white solid: mp 39–40°C; ir ($CHCl_3$ cast): 1739 (C=O ester), 1676 (C=O ketone), and 1623 cm^{-1} (C=C); ^1H nmr (300 MHz, $CDCl_3$) δ: 5.75 (m, 1H), 3.71 (s, 3H), 3.02 (m, 1H), 2.78 (m, 1H), 2.70 (m, 1H), 2.61 (m, 1H), 2.51 (m, 1H), 2.03 (d, J = 1.5 Hz, 3H), 1.73–1.54 (m, 3H), and 1.39 (m, 1H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 202.07 (p), 173.21 (p), 161.79 (p), 124.30 (a), 54.76 (a), 54.10 (a), 51.88 (a), 50.43 (a), 47.07 (a), 42.28 (a), 28.18 (p), 24.89 (p), and 23.73 (a); ms: M^+ 220.1098 (calcd. for $C_{13}H_{16}O_3$: 220.1100). Anal. calcd. for $C_{13}H_{16}O_3$: C 70.89, H 7.32; found: C 70.98, H 7.37. Continued elution gave enone **6***a* (52 mg, 28% yield) as a yellow oil: ir ($CHCl_3$ cast): 1733 (C=O ester), 1681 (C=O ketone), and 1623 cm^{-1} (C=C); ^1H nmr (300 MHz, $CDCl_3$) δ: 5.64 (m, 1H), 3.54 (s, 3H), 2.98 (m, 1H), 2.93 (br d, J = 8.5 Hz, 1H), 2.89 (d, J = 8.5 Hz, 1H), 2.65 (m, 1H), 2.33 (s, 1H), 1.99 (d, J = 2 Hz, 3H), 1.88–1.63 (m, 3H), and 1.27 (m, 1H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 201.00 (p), 176 (p), 163.44 (p), 124.65 (a), 57.51 (a), 53.49 (a), 51.72 (a), 51.51 (a), 49.15 (a), 42.16 (a), 32.12 (p), 25.78 (p), and 23.58 (a); ms: M^+ 220.1098 (calcd. for $C_{13}H_{16}O_3$: 220.1100).

From endo-*ester* **5**b

A solution of *endo*-ester **5***b* (4.23 g, 17.8 mmol) in dichloromethane (20 mL) was added to the P_2O_5–$MeSO_3H$ reagent (43 g) and the resulting solution was stirred at 65°C for 40 H. At the end of this time the dark brown solution was diluted with dichloromethane and poured into water (100 mL). The organic layer was then removed and washed with water, 5% aqueous sodium bicarbonate, and water. The organic solution was dried and concentrated to give a brown oil. Flash chromatography (50% ether in Skelly B) gave enones **6***b* (3.21 g, 82% yield) and **6***a* (12 mg, 1% yield).

(1S,5R*,6S*,9R*,10S*)-10-Carbomethoxy-4,4-dimethyltricyclo[4.3.1.0^{5,9}]decan-2-one (**7**)*

Purified copper(I) iodide (5.20 g, 27.3 mmol) was added to ether (160 mL) at 0°C. Methyllithium (1.6 M in ether, 34.1 mL, 54.6 mmol) was added dropwise to this stirred suspension and the mixture was stirred at 0°C until all the yellow-brown solid had dissolved (ca. 1 h). A solution of **6***b* (2.00 g, 9.07 mmol) in ether (10 mL) was added dropwise to the lithium dimethylcopper reagent and the resulting solution stirred at 0°C for 2 h. The reaction was then quenched by addition of 1 N hydrochloric acid. Chloroform was added and the mixture filtered through Celite. The organic layer was removed and the aqueous layer extracted with chloroform (2 × 50 mL). The combined organic extracts were then washed with water, dried, concentrated, and purified by flash chromatography (50% ether in Skelly B) to give keto ester **7** (2.07 g, 96% yield) as a white solid: mp 93–93.5°C; ir ($CHCl_3$ cast): 1736 (C=O ester) and 1714 cm^{-1} (C=O ketone); ^1H nmr (400 MHz, $CDCl_3$) δ: 3.68 (s, 3H), 2.91 (s, 1H), 2.89 (m, 1H), 2.72 (m, 1H), 2.35 (d, J = 18 Hz, 1H), 2.31 (d, J = 5 Hz, 1H), 2.23 (d, J = 18 Hz, 1H), 1.71 (m, 2H), 1.48 (m, 2H), 1.27 (m, 1H), 1.13 (s, 3H), and 1.02 (s, 3H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 212.22 (p), 173.09 (p), 59.50 (a), 55.86 (a), 51.86 (a), 49.50 (p), 45.37 (a), 43.61 (a), 42.03 (a), 34.04 (p), 32.37 (a), 29.64(a), 27.21 (p), and 25.82 (p); ms: M^+ 236.1413 (calcd. for $C_{14}H_{20}O_3$: 236.1413). Anal. calcd. for $C_{14}H_{20}O_3$: C 71.16, H 8.53; found: C 70.85, H 8.64.

(1S,6R*,7S*,10R*,11S*)-3-Carbethoxy-11-carbomethoxy-5,5-dimethyltricyclo[5.3.1.0^{6,10}]undecan-2-one (**8**a) and (1S*,6R*,7S*,10R*,11S*)-2-carbethoxy-11-carbomethoxy-5,5-dimethyltricyclo[5.3.1.0^{6,10}]undecan-3-one (**8**b)*

Boron trifluoride etherate (1.60 mL, 12.95 mmol) was added to a solution of keto ester **7** (2.00 g, 8.47 mmol) in ether (50 mL) at 0°C. Ethyl diazoacetate (1.36 mL, 12.95 mmol) was then added to this solution. The reaction mixture was allowed to warm up to room temperature and left to stir in the dark for 17 h. At the end of this time, the solution was neutralized with saturated aqueous sodium bicarbonate and then extracted with chloroform (3 × 50 mL). The combined extracts were washed with water, dried, concentrated, and purified by flash chromatography (50% ether in Skelly B) to give a mixture of the desired ring expansion products (2.73 g, 100% yield) as a yellow oil. The ^1H nmr spectrum (300 MHz, $CDCl_3$) of this mixture was very complex due to the likely presence of all six possible isomers (regioisomers **8***a* and **8***b*

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

and their respective stereoisomers and enols). Only the following few isolated signals could be clearly identified δ: 13.10, 12.95 (-C(COOEt)=C(O*H*)-), 4.05–4.25 (-COO*CH*$_2$CH$_3$), 3.70 (-COO-C*H*$_3$). During the flash chromatography, a small amount of regioisomer **8***a* was isolated. This material was shown by the following spectral data to exist as a pair of epimers (10% each) and in the corresponding enol form (80%): ir ($CHCl_3$ cast): 1739 (C=O, ester), 1704 (C=O, ketone), 1636 (C=O, enol ester), and 1608 cm^{-1} (C=C, enol); ^1H nmr (300 MHz, $CDCl_3$) δ: 13.1 (s, 0.8H), 4.20 (q, *J* = 6.5 Hz, 2H), 3.70 (s, 3H), 3.47 (m, 1H), 3.12 (m, 0.1H), 3.19 (m, 0.1H), 2.93 (d, *J* = 3.5 Hz, 1H), 2.65 (m, 1H), 2.44 (d, *J* = 18.5 Hz, 1H), 2.32 (d, *J* = 18.5 Hz, 1H), 2.32 (d, *J* = 5 Hz, 1H), 1.60 (m, 2H), 1.46 (m, 1H), 1.29 (t, *J* = 6.5 Hz, 3H), 1.24–1.13 (m, 2H), 1.06 (s, 3H), and 0.92 (s, 3H); ms: M^+ 322.1779 (calcd. for $C_{18}H_{26}O_5$: 322.1781).

*(1*S*,*6*R*,*7*S*,*10*R*,*11*S*)-11-Carbomethoxy-5,5-dimethyltricyclo[5.3.1.0^{6,10}]undecan-2-one (**10***a*) and (1S*,6R*,7S*,10R*,11S*)-11-carbomethoxy-5,5-dimethyltricyclo[5.3.1.0^{6,10}]undecan-3-one (**10**b)*

*From carboxylic acids **9**a and **9**b*

A mixture of **8***a* and **8***b* (2.93 g, 9.10 mmol) was dissolved in collidine (40 mL) in a flask wrapped in aluminum foil. Lithium iodide (9.77 g, 73.0 mmol) and water (1.3 ml, 73.0 mmol) were added. The mixture was heated under reflux for 3 h. The resulting solution was cooled and poured into ice-cold 10% hydrochloric acid (100 mL). Ether (100 mL) was then added. The ether layer was removed, washed with 10% hydrochloric acid (2 × 100 mL) and water. The ether solution was then dried and concentrated to give a mixture of carboxylic acids **9***a* and **9***b* (1.94 g, 90% yield) as a brown oil. This mixture (1.94 g, 8.23 mmol) was then dissolved in acetone (45 mL) and potassium carbonate (2.85 g, 20.64 mmol) was introduced. After stirring at room temperature for 2.5 h, methyl iodide (2.6 ml, 41.29 mmol) was added and the resulting mixture heated to reflux for 12 h. The reaction mixture was then acidified with 1 N hydrochloric acid and extracted with chloroform (3 × 50 mL). The combined extracts were washed with saturated aqueous sodium bisulfide and water, dried, and concentrated to give a yellow oil that was purified by flash chromatography (50% ether in Skelly B) to give an inseparable mixture of **10***a* and **10***b* (1.96 g, 95% yield) in a ratio of 2.5:1 on the basis of 300 MHz ^1H nmr integration.

*Keto ester **10**a from alcohol **11**a*

To a solution of alcohol **11***a* (37 mg, 0.15 mmol) in dichloromethane (1 mL), pyridinium chlorochromate on alumina (0.93 mmol/g, 246 mg, 0.22 mmol) was added. The resulting mixture was stirred at room temperature for 17 h and then filtered through Celite. The filtrate was concentrated and purified by flash chromatography (30% ether in Skelly B) to give keto ester **10***a* (35 mg, 95% yield) as a white crystalline solid: mp 97–99°C; ir ($CHCl_3$ cast): 1738 (C=O, ester) and 1697 cm^{-1} (C=O, ketone); ^1H nmr (300 MHz, $CDCl_3$) δ: 3.68 (s, 3H), 3.13 (ddd, *J* = 5, 5, 2.5 Hz, 1H), 2.93 (d, *J* = 5 Hz, 1H), 2.61 (m, 2H), 2.39 (d, *J* = 5 Hz, 1H), 2.32 (ddq, *J* = 16, 5, 1 Hz, 1H), 1.81 (dd, *J* = 14, 14 Hz, 1H), 1.70–1.57 (m, 2H), 1.51–1.12 (m, 4H), and 1.06 (s, 6H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 212.50 (p), 173.25 (p), 63.65 (a), 58,32 (a), 52.02 (a), 48.43 (a), 41.41 (a), 40.00 (a), 38.56 (p), 35.58 (p), 33.60 (p), 31.01 (a), 29.63 (a), 29.12 (p), and 25.97 (p); ms: M^+ 250.1564 (calcd. for $C_{15}C_{22}O_3$: 250.1570). Anal. calcd. for $C_{15}H_{22}O_3$: C 71.97, H 8.86; found: C 71.64, H 8.96.

*Keto ester **10**b from alcohol **11**b*

To a solution of alcohol **11***b* (29 mg, 0.12 mmol) in dichloromethane (1 mL) was added pyridinium chlorochromate on alumina (0.93 mmol/g, 249 mg, 0.23 mmol). After stirring at room temperature for 11 h, the reaction mixture was filtered through Celite, concentrated, and purified by flash chromatography (30% ether in Skelly B) to give keto ester **10***b* (26 mg, 90% yield) as a white solid: mp 101–103°C; ir ($CHCl_3$ cast): 1726 (C=O, ester) and 1687 cm^{-1} (C=O, ketone); ^1H nmr (300 MHz, $CDCl_3$) δ: 3.70 (s, 3H), 3.18 (ddd, *J* = 5, 5, 2.5 Hz, 1H), 2.76 (d, *J* = 12 Hz, 1H), 2.65 (m, 2H), 2.42 (m, 1H), 2.31 (dd, *J* = 16, 3 Hz, 1H), 2.18 (br d, *J* = 12 Hz, 1H), 2.02 (d, *J* = 4.5 Hz, 1H), 1.70–1.56 (m, 2H), 1.46 (m, 1H), 1.37–1.15 (m, 2H), 1.11 (s, 3H), and 1.00 (s, 3H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 210.61 (p), 174.58 (p), 62.68 (a), 55.29 (p), 51.78 (a), 51.59 (a), 49.37 (p), 41.81 (a), 41.69 (a), 39.50 (a), 33.71 (p), 30.88 (a), 30.60 (a), 29.78 (p), and 25.62 (p); ms: M^+ 250.1565 (calcd. for $C_{15}H_{22}O_3$: 250.1570). Anal. calcd. for $C_{15}H_{22}O_3$: C 71.97, H 8.86; found: C 71.99, H 8.76.

(1S,6R*,7S*,10R*,11S*)-11-Carbomethoxy-5,5-dimethyltricyclo[5.3.1.0^{6,10}]undecan-2-ol (**11**a) and (1S*,6R*,7S*,10R*,11S*)-11-carbomethoxy-5,5-dimethyltricyclo[5.3.1.0^{6,10}] undecan-3-ol (**11**b)*

The 2.5:1 mixture of **10***a* and **10***b* (33 mg, 0.13 mmol) was dissolved in methanol (1 mL). Sodium borohydride (10 mg, 0.26 mmol) was then added to this solution at 0°C. The resulting mixture was stirred at 0°C for 1 h. It was then acidified with 1 N hydrochloric acid and extracted with ether (3 × 2 mL). The combined extracts were washed with water, dried, concentrated, and subjected to flash chromatography (70% ether in Skelly B) to give a 1:1 mixture of epimeric alcohols **11***a* (4 mg, 12% yield): ir ($CHCl_3$ cast): 3450 (br, OH) and 1736 cm^{-1} (C=O); ^1H nmr (400 MHz, $CDCl_3$) δ: 4.12 (br dd, *J* = 11, 4 Hz, 0.5H), 3.71 (s, 1.5H), 3.68 (s, 1.5H), 3.63 (br t, *J* = 8 Hz, 0.5H), 3.32 (m, 0.5H), 2.78 (td, *J* = 5, 2.5 Hz, 0.5H), 2.52 (t, *J* = 4.5 Hz, 0.5H), 2.46 (t, *J* = 4.5 Hz, 0.5H), 2.38 (d, *J* = 4.5 Hz, 0.5H), 2.35 (d, *J* = 6.5 Hz, 0.5H), 2.25 (br d, *J* = 6.5 Hz, 0.5H), 2.07 (d, *J* = 4.5 Hz, 0.5H), 1.94–1.70 (m, 2H), 1.67–1.51 (m, 3H), 1.49–1.39 (m, 2H), 1.35–1.07 (m, 3H), 1.02 (s, 1.5H), 1.01 (s, 1.5H), 0.98 (s, 1.5H), and 0.97 (s, 1.5H); ms: M^+ 252.1719 (calcd. for $C_{15}H_{24}O_3$: 252.1726). Continued elution gave a mixture of **11***a* and **11***b* (19 mg, 58% yield) and then **11***b* (4 mg, 12% yield) in a ratio of 3:2: ir ($CHCl_3$, cast): 3370 (br, OH) and 1735 cm^{-1} (C=O); ^1H nmr (400 MHz, $CDCl_3$)[4] δ: 3.94 (m, 0.4H), 3.81 (m, 0.6H), 3.67 (s, 3H), 2.87 (td, *J* = 5.5, 2.5 Hz, 0.4H), 2.64 (td, *J* = 5.5, 3 Hz, 0.6H), 1.06, 1.08 (both s, total 3H), 0.99, and 1.00 (both s, total 3H); ms: M^+ 252.1727 (calcd. for $C_{15}H_{24}O_3$: 252.1726). The epimeric mixture of alcohols **11***b* was subjected to flash chromatography again to give the major epimer as a solid: mp 83–85°C; ^1H nmr (300 MHz, $CDCl_3$) δ: 3.81 (tdd, *J* = 11, 5, 2.5 Hz, 1H), 3.66 (s, 3H), 2.64 (td, *J* = 5, 2.5 Hz, 1H), 2.38 (t, *J* = 4 Hz, 1H), 2.30 (m, 1H), 2.07–1.98 (m, 2H), 1.65 (m, 2H), 1.59–1.30 (m, 4H), 1.28–1.09 (m, 3H), 1.07 (s, 3H), 1.01 (s, 3H). Anal. calcd. for $C_{15}H_{24}O_3$: C 71.39, H 9.59; found: C 71.39, H 9,84. The combined yield of **11***a* and **11***b* was 27 mg (82% yield).

(1S,2R*,7S*,8R*,11S*)-11-Carbomethoxy-3,3-dimethyl-6-(methylmercaptothiocarbonyloxy)tricyclo[5.3.1.0^{2,8}]-undecane (**12**a) and (1S*,2R*,7S*,8R*,11S*)-11-carbomethoxy-3,3-dimethyl-5-(methylmercaptothio-carbonyloxy)tricyclo[5.3.1.0^{2,8}]undecane (**12**b)*

Sodium hydride (80% dispersion in mineral oil, 38 mg, 1.27 mmol) was added to a solution of alcohols **11***a* and **11***b* (44 mg, 0.17 mmol) in tetrahydrofuran (1 mL) at 0°C and the resulting solution was stirred at 0°C for 30 min. At the end of this time, the solution was treated with carbon disulfide (136 μL, 2.26 mmol), followed by methyl iodide (70 μL, 1.13 mmol). After stirring at room temperature for 4.5 h, the solution was poured into ice-water (10 mL) and extracted with ether. The organic layer was washed with water, dried, and concentrated. Flash chromatography (5% ether in Skelly B) of the residue gave an inseparable mixture of xanthates **12***a* and **12***b* (57 mg, 95% yield) as a yellow oil: ir ($CHCl_3$ cast): 1738 (C=O) and 1048 cm^{-1} (C=S); ^1H nmr (300 MHz, $CDCl_3$) (see, footnote 4) δ: 5.92, 5.80, 5.46, 5.02 (all m, total 1H), 3.60 (s, 3H), 2.53 (s, 1.5H), 2.52 (s, 1.5H), 1.17

[4]This ^1H nmr spectrum is too complex to be fully analyzed. Only characteristic signals are cited.

(s, 3H), and 1.07 (s, 3H); ms: M^+ 342.1328 (calcd. for $C_{17}H_{26}O_3S_2$: 342.1325).

(1S,2R*,7S*,8R*,11S*)-11-Carbomethoxy-6-chloro-3,3-dimethyltricyclo[5.3.1.0^{2,8}]undecane (**13**a) and (1S*,2R*,7S*,8R*,11S*)-11-carbomethoxy-5-chloro-3,3-dimethyltricyclo[5.3.1.0^{2,8}]undecane (**13**b)*

Pyridine (1 mL) was added to a solution of alcohols **11***a* and **11***b* (19 mg, 0.08 mmol) in dichloromethane (0.5 mL) and the solution was kept at 0°C. To this solution thionyl chloride (55 μL, 0.75 mmol) was added and the resulting solution heated to reflux for 13 h. At the end of this time, the dark mixture was diluted with ether (1 mL) and water (1 mL). The organic layer was removed and the aqueous layer extacted with ether (3 × 1 mL). The combined organic solutions were washed with 1 N hydrochloric acid and water, dried, concentrated, and purified by flash chromatography (Skelly B) to give an inseparable mixture of **13***a* and **13***b* (13 mg, 64% yield) as a yellow solid: ir ($CHCl_3$ cast): 1736 cm^{-1} (C=O); ^1H nmr (300 MHz, $CDCl_3$) (see, footnote 4) δ: 4.39 (m, 0.5H), 4.16 (m, 0.5H), 3.63 (s, 1.5H), 3.62 (s, 1.5H), 3.21 (m, 0.5H), 2.83 (td, J = 5.5, 2.5 Hz, 0.5H), 1.03 (s, 1.5H), 0.98 (s, 3H), and 0.91 (s, 1.5H); ms: M^+ 270.1379 (calcd. for $C_{15}H_{23}O_2Cl$: 270.1388).

(1S,2R*,7S*,8R*,11S*)-11-Carbomethoxy-3,3-dimethyl-6-methanesulfonyloxytricyclo[5.3.1.0^{2,8}]undecane (**14**a) and (1S*,2R*,7S*,8R*,11S*)-11-carbomethoxy-3,3-dimethyl-5-methanesulfonyloxytricyclo[5.3.1.0^{2,8}]undecane (**14**b)*

Pyridine (1.30 mL, 16.30 mmol), methanesulfonyl chloride (1.3 mL, 16.30 mmol) and triethylamine (2.3 mL, 16.30 mmol) were added sequentially to a solution of alcohols **11***a* and **11***b* (0.82 g, 3.26 mmol) in dichloromethane (30 mL) at 0°C. The resulting mixture was stirred at 0°C for 30 min. Water was added and the resulting solution diluted with ether (20 mL) and acidified with 1 N hydrochloric acid. The organic layer was removed and the aqueous layer extracted with ether (2 × 30 mL). The combined organic solutions were washed with 1 N hydrochloric acid and water, dried, and concentrated. The residue was subjected to flash chromatography (30–50% ether in Skelly B) to give an inseparable mixture of mesylates **14***a* and **14***b* (0.92 g, 85% yield) as a yellow oil: ^1H nmr (300 MHz, $CDCl_3$) (see, footnote 4) δ: 5.01, 4.90, 4.79, 4.48 (all m, total 1H), 3.69, 3.67 (both s, total 3H), 3.04, 2.56, 2.54 (all s, total 3H), 1.09, 1.07, 1.02, and 0.98 (all s, total 6H); ms: *m/z* 299.1314 ($M^+ - CH_3$, calcd. for $C_{15}H_{23}O_4S$: 299.1318).

(1S,2R*,7S*,8R*,11S*)-11-Carbomethoxy-3,3-dimethyltricyclo[5.3.1.0^{2,8}]undecane (**15**)*

Sodium iodide (2.07 g, 13.8 mmol) and zinc dust (30-mesh granular, 1.82 g, 27.8 g-atom) were added to a solution of **14***a* and **14***b* (0.92 g, 2.77 mmol) in tetrahydrofuran (25 mL). The resulting mixture was heated under reflux for 15 h. The mixture was then cooled and filtered through Celite. The filtrate was washed with water and saturated aqueous sodium chloride, dried, concentrated, and applied to flash chromatography (5–50% ether in Skelly B) to give a mixture of compounds **15** and **16** (0.50 g, 90% yield based on consumed starting mesylates) in a ratio of 1:1 as determined by ^1H nmr analysis. Continued elution gave the starting mesylates (0.13 g, 15% recovery). The mixture of **15** and **16** (0.50 g, 2.12 mmol) was dissolved in methanol (50 mL). Platinum(IV) oxide (44 mg) was added. The mixture was hydrogenated at room temperature under 30 psi (1 psi = 6.9 kPa) of hydrogen for 24 h using a Parr apparatus. It was then filtered, concentrated, and purified by flash chromatography (2% ether in Skelly B) to give ester **15** (0.49 g, 98% yield) as a white solid: mp 59–61°C; ir ($CHCl_3$ cast): 1736 cm^{-1} (C=O); ^1H nmr (300 MHz, $CDCl_3$) δ: 3.67 (s, 3H), 2.76 (ddd, J = 5, 4, 2 Hz, 1H), 2.39 (dd, J = 4, 4 Hz, 1H), 2.18 (dd, J = 6, 5 Hz, 1H), 2.03 (d, J = 4.5 Hz, 1H), 1.75 (m, 1H), 1.55–1.01 (m, 10H), and 0.92 (s, 6H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 175.83 (p), 62.86 (a), 53.32 (a), 51.44 (a), 43.42 (a), 41.71 (a), 40.27 (a), 40.07 (p), 33.22 (p), 32.66 (p), 32.08 (a), 30.16 (p), 29.91 (a), 25.55 (p), and 21.29 (p); ms: M^+ 236.1777 (calcd. for $C_{15}H_{24}O_2$: 236.1777). Anal. calcd. for $C_{15}H_{24}O_2$: C 76.23, H 10.24; found: C 76.29, H 10.33.

(1S,2R*,7S*,8R*,11S*)-3,3-Dimethyl-11-(hydroxymethyl)-tricyclo[5.3.1.0^{2,8}]undecane (**17**)*

To a solution of ester **15** (22 mg, 0.09 mmol) in tetrahydrofuran (1 mL), lithium aluminum hydride (13 mg, 0.34 mmol) was added. The resulting mixture was stirred at room temperature for 20 min, poured slowly into water (10 mL), and extracted with ether (3 × 10 mL). The extracts were combined and washed with 1 N hydrochloric acid and water. The organic solution was dried and concentrated to give alcohol **17** (19 mg, 100% yield) as a white solid: ir ($CHCl_3$ cast): 3310 cm^{-1} (br, OH); ^1H nmr (300 MHz, $CDCl_3$) δ: 3.65 (m, 1H), 3.51 (m, 1H), 2.23 (t, J = 4 Hz, 1H), 2.12 (m, 1H), 2.04 (d, J = 4.5 Hz, 1H), 1.79 (m, 1H), 1.70–1.00 (m, 12H), 0.98 (s, 3H), and 0.97 (s, 3H); ms: M^+ 208.1826 (calcd. for $C_{14}H_{24}O$: 208.1828).

(1S,2R*,7S*,8R*,11S*)-3,3-Dimethyl-11-(diphenylhydroxymethyl)-tricyclo[5.3.1.0^{2,8}]undecane (**18**)*

To a solution of phenyllithium (2.0 M in ether, 64 μL, 0.13 mmol) in tetrahydrofuran (1 mL) at 0°C, was added dropwise a solution of ester **15** (10 mg, 0.04 mmol) in tetrahydrofuran (0.5 mL). The resulting solution was stirred at room temperature for 1.5 h and then heated to reflux for 3 h. At the end of this time the reaction was quenched with ice. The resulting mixture was extracted with ether (2 mL). The extract was washed with saturated aqueous sodium chloride, dried, and concentrated. Purification of the residue by flash chromatography (5% ether in Skelly B) gave alcohol **18** (15 mg, 100% yield) as a colorless oil: ir ($CHCl_3$ cast): 3600 (OH) and 1600 cm^{-1} (Ph); ^1H nmr (300 MHz, $CDCl_3$) δ: 7.63 (m, 2H), 7.52 (m, 2H), 7.36 (m, 2H), 7.23 (m, 3H), 7.13 (m, 1H), 3.15 (m, 1H), 2.44 (br s, 1H), 2.34 (br t, J = 4 Hz, 1H), 2.11 (d, J = 5 Hz, 1H), 1.94–1.82 (m, 2H), 1.68–1.27 (m, 10H), 1.08 (s, 3H), and 0.99 (s, 3H); ms: M^+ 360.2451 (calcd. for $C_{26}H_{32}O$: 360.2455).

(1S,2R*,7S*,8R*)-3,3-Dimethyl-11-(diphenylmethylidene)-tricyclo[5.3.1.0^{2,8}]undecane (**19**)*

A mixture of alcohol **18** (14 mg, 0.04 mmol) and copper(II) sulfate on silica gel (1 mmol/g, 38 mg, 0.04 mmol) in carbon tetrachloride (1 mL) was heated under reflux for 30 min. The resulting solution was diluted with Skelly B (2 mL), filtered, concentrated, and purified by flash chromatography (Skelly B) to give olefin **19** (12 mg, 92% yield): ir (CH_2Cl_2 cast): 1600 cm^{-1} (Ph); ^1H nmr (300 MHz, $CDCl_3$) δ: 7.35–7.11 (m, 10H), 2.88 (d, J = 6 Hz, 1H), 2.82 (d, J = 3.5 Hz, 1H), 2.24 (d, J = 4 Hz, 1H), 1.78 (br t, J = 12.5 Hz, 1H), 1.70–1.15 (m, 10H), 1.01 (s, 3H), and 0.97 (s, 3H); ms: M^+ 342.2345 (calcd. for $C_{26}H_{30}$: 342.2349).

(1S,2R*,7S*,8R*,11S*)-11-Carboxy-3,3-dimethyltricyclo-[5.3.1.0^{2,8}]undecane (**20**)*

A 20% aqueous potassium hydroxide solution (15 mL) was added to a solution of ester **15** (76 mg, 0.32 mmol) in tetrahydrofuran (2 mL). The reaction mixture was heated to reflux for 39 h. It was then poured into 1 N hydrochloric acid (100 mL) and extracted with ether (3 × 100 mL). The combined extracts were washed with water, dried, and concentrated to give acid **20** (73 mg, 100% yield) as a white solid: mp 156–157°C, ir ($CHCl_3$ cast): 3030 (br COOH) and 1698 cm^{-1} (C=O); ^1H nmr (300 MHz, $CDCl_3$) δ: 2.90 (ddd, J = 5, 4, 2 Hz, 1H), 2.51 (t, J = 4 Hz, 1H), 2.22 (br t, J = 5 Hz, 1H), 2.13 (d, J = 4.5 Hz, 1H), 1.84 (m, 1H), 1.76–1.21 (m, 10H), and 1.00 (s, 6H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 181.15 (p), 62.86 (a), 53.20 (a), 43.31 (a), 41.66 (a), 40.31 (a), 40.03 (p), 33.23 (p), 32.59 (p), 32.09 (a), 30.16 (p), 29.90 (a), 25.49 (p), and 21.26 (p); ms: M^+ 222.1619 (calcd. for $C_{14}H_{22}O_2$: 222.1621). (1S,2R*,7S*,8R*,11S*)-3,3-Dimethyltricyclo[5.3.1.0^{2,8}]-undecan-11-ol (23)*

A 1 N aqueous sodium hydroxide solution (0.5 mL) was added to a solution of ester **22** (13 mg, 0.05 mmol) in methanol (0.5 mL) and the resulting solution was stirred at room temperature for 5 h. The solution was then acidified with 1 N hydrochloric acid and extracted with ether (3 × 2 mL). The combined extracts were washed with water, dried, concentrated, and purified by flash chromatography (30% ether in Skelly B) to give alcohol **23** (10 mg, 93% yield) as a white solid: mp 68–70°C; ir ($CHCl_3$ cast): 3320 cm^{-1} (br, OH); ^{1}H nmr (300 MHz, $CDCl_3$) δ: 4.23 (br t, J = 4.5 Hz, 1H), 2.17 (dd, J = 4.5, 3 Hz, 1H), 1.98 (d, J = 4.5 Hz, 1H), 1.77 (m, 2H), 1.61–1.15 (m, 11H), 0.91 (s, 3H), and 0.88 (s, 3H); ms: M$^+$ 194.1672 (calcd. for $C_{13}H_{22}O$: 194.1672).

(1S,2R*,7S*,8R*)-3,3-Dimethyltricyclo[5.3.1.0^{2,8}]undecan-11-one (24)*

Pyridinium chlorochromate on alumina (0.9 mmol/g, 176 mg, 0.16 mmol) was added to a solution of alcohol **23** (10 mg, 0.045 mmol) in dichloromethane (1 mL) and the mixture was stirred at room temperature for 1.5 h. The mixture was then filtered through Florisil, concentrated, and purified by flash chromatography (10% ether in Skelly B) to give **24** (8 mg, 86% yield) as a colorless oil: ir ($CHCl_3$ cast): 1739 cm^{-1} (C=O); ^{1}H nmr (300 MHz, $CDCl_3$) δ: 2.57 (br d, J = 4 Hz, 1H), 2.49 (m, 1H), 2.02–1.05 (m, 12H), 1.01 (s, 3H), and 0.91 (s, 3H); ^{13}C nmr (75 MHz, $CDCl_3$) δ: 223.80 (p), 60.90 (a), 51.33 (a), 50.47 (a), 38.75 (a), 37.17 (p), 33.56 (p), 30.94 (a), 29.67 (p), 29.30 (p), 28.89 (a), 24.28 (p), and 20.32 (p); ms: M$^+$ 192.1516 (calcd. for $C_{13}H_{20}O$: 192.1515).

(1S,2S*,6R*,7R*)-10-Isopropylidene-2-methyl-4-oxatricyclo-[5.2.1.0^{2,6}]non-8-ene-3,5-dione (25)*

Citraconic anhydride (9.7 mL, 0.11 mol) and 6,6-dimethylfulvene (8.81 g, 0.08 mol) were dissolved in benzene (75 mL). The solution was heated under reflux for 14–16 h. The reaction was monitored closely by tlc after about 14 h for the buildup of a second spot on the tlc attributed to the undesired *endo* adduct. Once this began, the reaction was cooled to room temperature and concentrated. At this point a solid appeared coated with a yellow oil of the unreacted fulvene. This mixture was filtered and washed with pet. ether to remove most of the yellow oil. The residue was purified by flash chromatography (5% ether in pet. ether) to remove any remaining fulvene (1.1 g, 17% recovery). Continued elution with a solution of pet. ether, ether, and ethyl acetate (3:4:1) gave the desired anhydride **25** (4.7 g, 30% yield based on consumed fulvene) as a white solid: mp 107–109°C; ir ($CHCl_3$ cast): 1850 and 1768 cm^{-1} (C=O); ^{1}H nmr (300 MHz, $CDCl_3$) δ: 6.49 (m, 2H), 3.83 (m, 1H), 3.58 (m, 1H), 2.47 (d, J = 1 Hz, 1H), 1.57 (s, 6H), and 1.32 (s, 3H); ms: M$^+$ 218.0943 (calcd. for $C_{13}H_{14}O_3$: 218.0943).

(1S,5S*,6S*,9R*,10R*)-10-Carboxy-1,4,4-trimethyl-3-oxatricyclo[4.3.1.0^{5,9}]dec-7-en-2-one (26) and (1S*,4S*,5R*,8S*,9R*)-9-carboxy-4-isopropyl-1-methyl-3-oxatricyclo[3.3.1.0^{4,8}]non-6-en-2-one (27)*

Anhydride **25** (4.0 g, 0.02 mol) was dissolved in 50% sulfuric acid (20 mL). The reaction mixture was stirred at room temperature for 48 h. At the end of this time, the solution was diluted with water and filtered through Celite leaving a large amount of a brown solid residue on the Celite. The filtrate was extracted with ethyl acetate (3 × 20 mL), dried, concentrated, and recrystallized from ethyl acetate to give acid **26** (0.79 g, 18% yield): mp 214–217°C; ir ($CHCl_3$ cast): 1737 (C=O, lactone) and 1705 cm^{-1} (C=O, acid); ^{1}H nmr (200 MHz, $CDCl_3$) δ: 6.59 (m, 1H), 6.19 (m, 1H), 5.44 (br s, 1H), 3.40 (s, 1H), 3.01 (s, 1H), 2.12 (d, J = 1.5 Hz, 1H), 2.00 (d, J = 1.5 Hz, 1H), 1.41 (s, 3H), and 1.33 (s, 6H); ms: M$^+$ 236.1036 (calcd. for $C_{13}H_{16}O_4$: 236.1049). Anal. calcd. for $C_{13}H_{16}O_4$: C 66.08, H 6.83; found: C 65.70, H 6.69. The solid residue from the filter was recovered and extracted with chloroform. The extract was then concentrated and recrystallized from ethyl acetate to give acid **27** (0.21 g, 5% yield): mp 208–210°C; ir ($CHCl_3$ cast): 1784 (C=O, lactone) and 1706 cm^{-1} (C=O, acid); ^{1}H nmr (400 MHz, $CDCl_3$) δ: 6.58 (m, 1H), 5.83 (m, 1H), 3.18 (dd, J = 2, 2 Hz, 1H), 3.01 (dd, J = 2, 2 Hz, 1H), 2.19 (s, 1H), 2.17 (septet, J = 7 Hz, 1H), 1.40 (s, 3H), 1.00 (d, J = 7 Hz, 3H), and 0.91 (d, J = 7 Hz, 3H); ms: M$^+$ 236.1045 (calcd. for $C_{13}H_{16}O_4$: 236.1049).

Annulation sequences employing methyl (*E*)- and (*Z*)-6-iodo-3-trimethylstannyl-2-hexenoates and related bifunctional reagents. Preparation of *cisoid cis* and *cisoid trans* bicyclic dienes

EDWARD PIERS,[1] RICHARD W. FRIESEN, AND STEVEN J. RETTIG

Department of Chemistry, University of British Columbia, 2036 Main Mall, University Campus, Vancouver, B.C., Canada V6T 1Z1

Received July 15, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

EDWARD PIERS, RICHARD W. FRIESEN, and STEVEN J. RETTIG. Can. J. Chem. **70**, 1385 (1992).

A useful annulation method leading to the stereospecific synthesis of structurally novel, functionalized bicyclic dienes is described. Alkylation of 2-(methoxycarbonyl)cyclopentanone (**34**) and 2-(methoxycarbonyl)cyclohexanone (**35**) with methyl (*E*)- and (*Z*)-6-iodo-3-trimethylstannyl-2-hexenoates (**27**, **28**) provided the keto diesters **36–39**. Conversion of these substances into the corresponding enol triflates **47–50**, followed by palladium(0)-catalyzed ring closure of the latter compounds, afforded the bicyclic dienes **55–58**. In similar fashion, the keto esters **34** or **35** were transformed into the dienes **59–65**. An X-ray crystallographic analysis of the *p*-nitrobenzoate **69**, which was derived from the *cisoid cis* diene **64**, showed that, in **69**, the dihedral angle between the two carbon–carbon double bonds is −54.0(5)°.

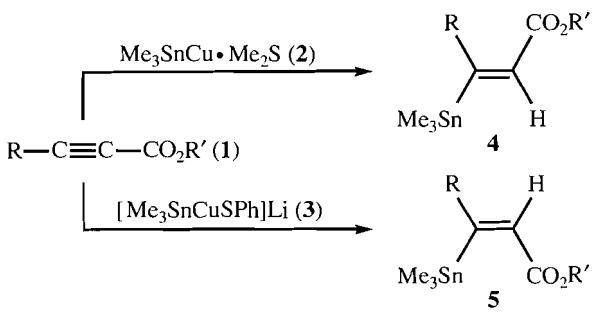
EDWARD PIERS, RICHARD W. FRIESEN et STEVEN J. RETTIG. Can. J. Chem. **70**, 1385 (1992).

On décrit un méthode d'annellation utile pour la synthèse stéréospécifique de dienes bicycliques fonctionnalisés et nouveaux de par leur structure. L'alkylation de la 2-(méthoxycarbonyl)cyclopentanone (**34**) et de la 2-(méthoxycarbonyl)cyclohexanone (**35**) avec les (*E*)- et (*Z*)-6-iodo-3-triméthylstannylhexèn-2-oates de méthyle (**26**, **28**) conduit aux céto diesters **36–39**. La conversion de ces substances en triflates énoliques correspondants (**47–50**), suivie d'une cyclisation de ces derniers composés catalysée par le palladium(0), fournit les dienes bicycliques **59–65**. Une étude du *p*-nitrobenzoate **69**, obtenu à partir du diène *cisoïde cis* **64**, a été réalisée par diffraction des rayons X; elle montre que, dans cet ester, l'angle dièdre entre les deux doubles liaisons carbone–carbone est égal à −54,0(5)°.

[Traduit par la rédaction]

Introduction

It has been shown (1) that geometrically isomeric alkyl (*E*)- and (*Z*)-3-trimethylstannyl-2-alkenoates (**4** and **5**, respectively) can be prepared readily by reaction of α,β-acetylenic esters **1** with a suitable (trimethylstannyl)copper(I) reagent. Thus, under appropriate experimental conditions (1), reaction of **1** with $Me_3SnCu \cdot Me_2S$ (**2**) (2, 3), provides, highly stereoselectively, the *E* isomers **4**, while stereoselective conversion of **1** into the *Z* isomers **5** can be accomplished conveniently by use of the cuprate reagent $(Me_3SnCuSPh)Li$ (**3**) (2).



Other recent work has shown that substances containing vinylstannane and alkyl halide functions are, or can be converted into, very useful bifunctional reagents. For example, compounds **6** (4), **7** (5), and **8** (6) can readily be transformed into novel reagents that can be employed to carry out synthetically valuable methylenecyclopentane, methylenecyclohexane, and (*Z*)-ethylidenecyclopentane annulation sequences, respectively. Furthermore, the vinylstannane iodides **9** have been used effectively to develop a new type of annulation method that culminates in the formation of conjugated bicyclic dienes (7). This method can be represented in general terms by the conversion of **12** into **13** (*n* = 1, 2, or 3). We wished to extend this work, with the aims of preparing dienes more highly functionalized than **13**, of studying the chemistry of these structurally novel systems, and of using (some of) these substances for natural product synthesis. More explicitly, we wanted to determine whether the new annulation method (**12** → **13**) would be amenable to the synthesis of dienes of general structures **14** and **15** (*n* = 2, *W* = CO_2Me, CH_2OR, or Et). To achieve these goals, alkylating agents **10** and **11** (W = CO_2Me, CH_2OR, or Et) would have to be prepared. Presumably, the previously described methods (**1** → **4** or **5**) would serve well in this regard. We report in this paper the details of our studies[2] that have led to the stereospecific preparation of a variety of structurally unique bicyclic dienes of general structures **14** and **15** (*n* = 2, W = CO_2Me, CH_2OR, or Et).

Results and discussion

Preparation of methyl (E)- and (Z)-6-iodo-3-trimethylstannyl-2-hexenoates 27 and 28 and the related alkylating agents 29–33

Commercially available 5-chloro-1-pentyne was readily transformed into methyl 6-chloro-2-hexynoate (**16**). By use of the methods developed earlier (1), along with standard functional group manipulations, compound **16** served as a suitable synthetic precursor for all the alkylating agents **27–33** (Chart 1) that were employed in this study.

Treatment (THF, −78°C, 3 h) of **16** with $Me_3SnCu \cdot Me_2S$ (**2**) provided methyl (*E*)-6-chloro-3-trimethylstannyl-2-hexynoate (**17**) in 79% yield (Chart 1). On the other hand, reaction (THF, −48°C, 4 h) of **16** with $(Me_3SnCuSPh)Li$ (**3**) gave the *Z* isomer **18** in 87% yield. Reduction (*i*-Bu_2AlH, Et_2O) of the esters **17** and **18** produced the corresponding alcohols **19** and **20**, which could readily be converted by standard methods into the methoxymethyl (MOM) ethers **21** and **22** or the *tert*-butyldimethylsilyl (TBDMS) ethers **23** and **24**.

CHART 1

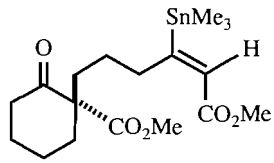
Conversion of the alcohol **19** into the acetate **25**, followed by reaction (9) of the latter substance with Me_2CuLi in Et_2O afforded (*E*)-7-chloro-3-trimethylstannyl-3-heptene (**26**) in excellent yield.

Reaction of each of the primary chlorides **17**, **18**, **21**–**24**, and **26** with NaI in refluxing acetone gave excellent yields of the corresponding iodides **27**–**33**. These substances were quite stable when stored at −20°C under an argon atmosphere and, generally, were not distilled prior to use.

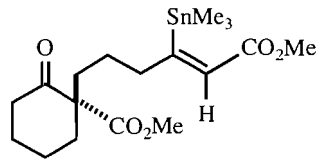
*Alkylation of the β-keto esters **34** and **35** with the iodides **27**–**33** (see Table 1)*

Treatment of 2-(methoxycarbonyl)cyclopentanone (**34**) with KH in THF, followed by reaction of the resultant enolate anion with each of the iodides **27**–**30**, provided the corresponding alkylation products **36**, **38**, **40**, and **42**, respectively. In similar fashion, employing 2-(methoxycarbonyl)cyclohexanone (**35**) (10) and the iodides **27**–**33** as starting materials, the keto esters **37**, **39**, **41**, and **43**–**46** were prepared. The results of these alkylation reactions are summarized in Table 1. The yields of the purified products, which ranged from 57 to 88%, were generally quite good, and, in each case, analysis (glc, ^1H nmr) of the crude product showed that it contained none of the *O*-alkylated product. The alkylation reactions proceeded smoothly with primary alkyl iodides containing an α,β-unsaturated ester function (**27**, **28**) or allylic CH_3OCH_2O (**29**, **30**) or *t*-$BuMe_2SiO$ (**31**, **32**) moieties.

The alkylation products **36**–**46** displayed spectra in full accord with structural assignments. With respect to the configuration of the carbon–carbon double bond in each of these substances, the ^1H nmr spectra were particularly instructive. For example, the ^1H nmr spectra of the geometrically isomeric diesters **37** and **39** displayed signals due to the olefinic protons at δ 5.96 (*t*, J = 1.3 Hz, $^3J_{Sn-H}$ = 72 Hz) and 6.34 (*t*, J = 1 Hz, $^3J_{Sn-H}$ = 118 Hz). It is well known (11) that when an R_3Sn group and a proton are vicinal on a carbon–carbon double bond, the $^3J_{Sn-H}$ value is much larger when these moieties are *trans* than when they are *cis*.



37



39

*Preparation of the dienes **55**–**65** (see Table 2)*

Preparation of the enol trifluoromethanesulfonates (triflates) **47**–**54** was carried out via a method developed by McMurry and Scott (12). Thus, deprotonation (*i*-Pr_2NLi, THF, −48°C) of the keto esters **36**–**43**, followed by trapping of the resultant enolate anions with *N*-phenyltrifluoromethanesulfonimide (Tf_2NPh) (THF, −48°C to room temperature) provided the desired products **47**–**54** (Table 2, entries 1–5, 7, 8, 10) in good to excellent yields. In a similar manner, the keto esters **44**–**46** were transformed into the corresponding enol triflates. However, in these cases, the latter substances were not isolated (Table 2, entries 11–13).

Synthesis of the bicyclic dienes **55**–**65** (Table 2) was conveniently achieved by use of intramolecular versions of the synthetically valuable coupling method developed by Stille *et al.* (13, 14).[3] Thus, treatment of the vinylstannane-enol triflates **47**–**54** with 0.05 equivalents of tetrakis(triphenylphosphine)palladium(0) in a suitable solvent (THF, **47**–**51**, **53**, **54**; MeCN, **52**) provided the corresponding dienes **55**–**62** in very good to excellent yields (Table 2, entries 1–5, 7, 8, 10). Alternatively, the overall conversion of the keto esters **40**, **42**, and **44**–**46** into the dienes **59**, **61**, and **63**–**65**, respectively, was accomplished conveniently via a "one-pot" protocol in which the intermediate enol triflates were not isolated. In each of these cases, addition of 0.05 equivalents of $(Ph_3P)_4Pd$ to the reaction mixture derived from formation of the enol triflate, followed by refluxing of the

[3]Stille and his group studied in detail the Pd(0)-catalyzed intermolecular coupling of vinylstannanes with enol triflates (13, 14). Prior to our investigations (7, 8), the intramolecular version of this versatile coupling process had not been described or utilized.

resultant solution, afforded the corresponding diene directly (Table 2, entries 6, 9, 11–13).

Several points should be made regarding the data given in Table 2.

The preparation of the dienes **55–65** constitutes a significant extension to the annulation method reported previously (7). Each of the intramolecular coupling processes cataloged in Table 2 was clean and the desired diene could easily be obtained in pure form by subjection of the crude product to flash chromatography (15) and distillation. Even the sterically encumbered *cisoid cis* dienes **57**, **58**, **61**, **62**, and **64** (Table 2, entries 3, 4, 8–10, 12) were obtained cleanly and efficiently.

The overall conversion of keto vinylstannanes (e.g., **40**, **42**, **44–46**) into the corresponding dienes (e.g., **59**, **61**, **63–65**, entries 6, 9, 11–13) via a "one-pot" procedure is particularly attractive. This protocol precludes the necessity of isolating and purifying the intermediate enol triflates, which are rather unstable and tend to decompose when subjected to column chromatography in silica gel. Furthermore, use of the "one-pot" method usually provides yields of dienes better than those derived from a two-step procedure (compare entries 5 and 6, Table 2).

Two of the intramolecular coupling processes were carried out with both $(Ph_3P)_4Pd$ and $Pd(OAc)_2$ (Table 2, entries 11 and 12). The yields of the dienes derived from the two procedures, although similar, were slightly lower when $Pd(OAc)_2$ was employed. Presumably, in these latter cases, the active catalyst is produced by *in situ* reduction of palladium(II) to palladium(0).

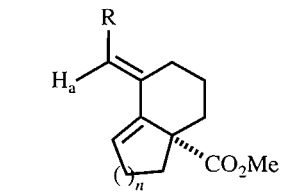
It should be noted explicitly that the Pd(0)-catalyzed ring closure reactions are completely stereospecific. Although this finding was not unexpected (13, 14), it is, from a synthetic viewpoint, of some importance. Thus, the reactions summarized in Table 2 have led to the smooth production of five pairs of structurally novel, geometrically isomeric, dienes. Of particular note is the clean, efficient synthesis of the *cisoid cis* dienes **57**, **58**, **61**, **62**, and **64**.

Proton nmr spectroscopy was especially useful in corroborating the stereochemical assignments with respect to the dienes **55–65**. In the ^1H nmr spectra of each pair of diastereomers of general structure **66** and **67**, the proton H_a of the *trans* isomer resonated at lower field than the corresponding proton H_b of the *cis* isomer ($\Delta\delta$ = 0.18–0.30 ppm). These observations may be rationalized by noting that H_a in **66** is influenced by the deshielding cone of the nearby endocyclic carbon–carbon double bond. In appropriate cases, nuclear Overhauser enhancement (nOe) difference experiments provided clear-cut evidence for the stereochemical assignments. For example, in the ^1H nmr spectrum of the diene **60**, irradiation at δ 5.82 (H_a signal) caused enhancement of the resonance due to H_b (δ 5.57). On the other hand, irradiation at δ 5.59 (H_c) in the spectrum of the isomeric diene **62** increased the intensity of the signals (δ 4.19–4.21) due to the allylic CH_2OMOM protons.

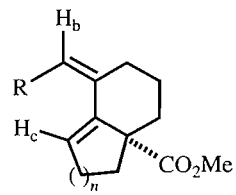
X-ray crystal structure of the p*-nitrobenzoate* ***69***

Molecular models show that, for substances **55–65**, conformations in which the conjugated diene units are planar would be destabilized by angle and torsional strain, particularly with respect to the six-membered ring bearing the exocyclic double bonds. Furthermore, the planar conformations of the *cisoid cis* dienes of general structure **67** would be additionally destabilized by steric strain between the R group and H_c. Clearly, the chemical reactivity of these substances in, for example, Diels–Alder reactions would be significantly influenced by the actual conformation of the conjugated diene system. Therefore, it was of interest to determine the extent to which the diene unit of a particular *cisoid cis* diene deviated from planarity. For this purpose, it was decided to convert the silyl ether **64** into a crystalline derivative that would be suitable for a single crystal X-ray structure determination.

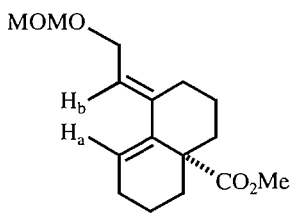
Treatment of **64** with tetra-*n*-butylammonium fluoride in THF, followed by reaction of the resultant alcohol **68** with *p*-nitrobenzoyl chloride (CH_2Cl_2, Et_3N, 4-(*N*,*N*-dimethylamino)pyridine), provided the benzoate **69**. Recrystallization of this material from hexane provided crystals (mp 131–132°C) suitable for an X-ray study.



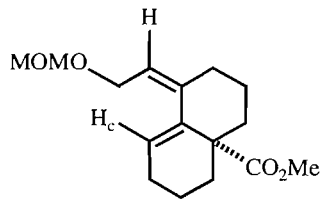
66



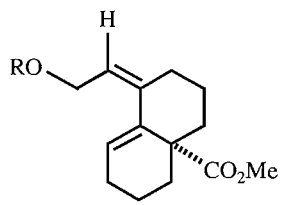
67



60



62



64 R = Me_2(*t*-Bu)Si
68 R = H
69 R = *p*-nitrobenzoyl

The stereoview of **69** is shown in Fig. 1. In the solid state, molecules are linked along the *b* axis by C—H···O hydrogen bonds (C(18)—H(18)···O(4), (*x*, *y* − 1, *z*), H···O = 2.38 Å, C···O = 3.321(4) Å, C—H···O = 163°). The chains are reinforced by possible weak C—H···O interactions (C(21)—H(21)···O(5) (*x*, *y* + 1, *z*), H···O = 2.50 Å, C···O = 3.431(5) Å, C—H···O = 160°). The significance of the latter interaction is evidenced by the fact that the nitro group N—O bond involved (N—O(5) = 1.216(4) Å) is longer than the otherwise chemically equivalent N—O bond (N—O(6) = 1.197(4) Å).

The aromatic ring, the nitro group, and the two ester functions are all planar to within experimental error. The *p*-nitrobenzoate moiety as a whole is nearly planar, the angles between normals to the mean plane of the aromatic ring and those of the nitro and ester groups being 1.3° and 3.7°, respectively. The effects of ring strain and steric interactions

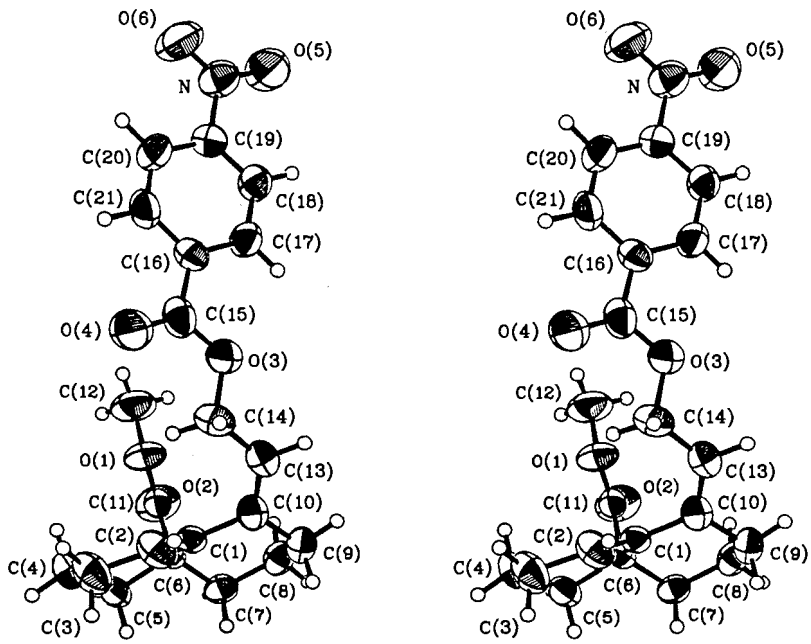


FIG. 1. Stereoview of the *p*-nitrobenzoate **69**; 50% probability thermal ellipsoids are shown for the non-hydrogen atoms.

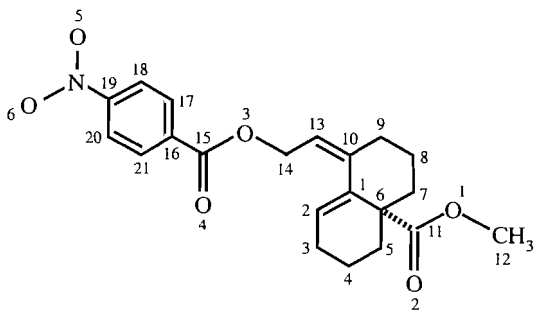
are evidenced by non-planarity about both of the carbon–carbon double bonds (e.g., torsion angles C(6)—C(1)=C(2)—C(3) = −5.5(5)° and C(1)—C(10)=C(13)—C(14) = 2.0(5)°. Within the fused-ring system, the six-membered ring containing the exocyclic double bonds has a chair conformation that is slightly flattened about the sp^2-hybridized atoms C(1) and C(10). On the other hand, the cyclohexene ring (C(1)–C(6)) has a twisted C(4)-sofa conformation. Bond lengths and angles (Tables 5 and 6, experimental section) are normal.



69

The C(2)—C(1)—C(10)—C(13) torsion angle, which defines the angle between the C(1)=C(2) and C(10)=C(13) double bonds, is −54.0(5)°. The C(2)···C(14) and C(2)···H(14a) distances are 3.111(5) and 2.57 Å, respectively. Thus, it is evident that the diene unit in **69** is far from being planar and, if the crystal structure data accurately reflect the ground state conformation of the molecule in solution, it is not surprising that the *cisoid cis* diene **64** (from which **69** was derived) undergoes Diels–Alder reactions very sluggishly (8).

Conclusion

The work described in this paper demonstrates the effectiveness and versatility of a new annulation sequence leading to the stereospecific synthesis of functionalized bicyclic dienes. The two key steps of the sequence involve (a) the alkylation of 2-(methoxycarbonyl)cycloalkanones with a variety of bifunctional reagents derived from methyl (*E*)- and (*Z*)-6-chloro-3-trimethylstannyl-2-hexenoates and (b) the palladium(0)-catalyzed ring closure of the vinylstannane-enol triflates obtained from the alkylation products. The application of this and other similar annulation methods to the total synthesis of natural products will be the subject of future reports.[4]

Experimental

General information

Distillation temperatures, which refer to short-path (Kugelrohr) distillations, are uncorrected. Proton nuclear magnetic resonance (^{1}H nmr) spectra were taken on $CDCl_3$ solutions. Signal positions (δ values) for compounds containing the Me_3Sn group were measured relative to the $CHCl_3$ signal (δ 7.25). The tin–proton coupling constants (J_{Sn-H}) are given as an average of the ^{117}Sn and ^{119}Sn values. Carbon nuclear magnetic resonance (^{13}C nmr) spectra were recorded at 75.3 MHz and signal positions are given relative to the signal for $CDCl_3$ (δ 77.0). For compounds containing the Me_3Sn moiety, high-resolution mass spectrometric measurements are based on ^{120}Sn (unless otherwise noted) and were made on the (M^+ − Me) peak. Flash chromatography (15) was carried out with 230–400 mesh silica gel (E. Merck). Gas–liquid chromatography (glc) was carried out on instruments equipped with 25 m × 0.21 mm fused silica columns coated with cross-linked SE-54. Thin-layer chromatography (tlc) was carried out with commercial silica gel plates. Reagents and solvents were purified and dried using standard methods. Aqueous NH_4Cl–NH_4OH (pH 8) refers to a solution prepared by addition of ~50 mL of aqueous NH_4OH (58%) to ~1 L of saturated aqueous NH_4Cl.

Note: Unless otherwise noted, all reactions were carried out under an atmosphere of argon in flame- or oven-dried glassware.

Note: All compounds for which high resolution mass measurements are given exhibited one spot on the tlc analysis and, for those

substances that could be distilled, essentially one peak by glc analysis.

*Methyl 6-chloro-2-hexynoate (**16**)*

To a cold (−78°C), stirred solution of 5-chloro-1-hexyne (5.13 g, 50.0 mmol) in dry THF (100 mL) was added a solution of methyllithium in Et_2O (46.0 mL, 55.0 mmol) and the resultant solution was stirred at −78°C for 10 min, warmed to −20°C, and then stirred for a further 1 h. Methyl chloroformate (4.64 mL, 60.0 mmol) was added and the mixture was stirred at −20°C for 30 min and at room temperature for 30 min. Saturated aqueous $NaHCO_3$ (50 mL) and Et_2O (50 mL) were added. The organic phase was separated, dried ($MgSO_4$), and concentrated. Distillation (65–75°C/0.1 Torr (1 Torr = 133.3 Pa)) of the residual oil afforded 7.50 g (93%) of **16** as a colorless oil that displayed ir (neat): 2228, 1712, 1433, 1259, 1080, 755 cm^{-1}; ^1H nmr (80 MHz) δ: 2.08 (m, 2H), 2.61 (br t, 2H, J = 6.5 Hz), 3.66 (t, 2H, J = 6 Hz), 3.78 (s, 3H). Exact Mass calcd. for $C_7H_9{}^{35}ClO_2$: 160.0292; found: 160.0290.

*Methyl (E)-6-chloro-3-trimethylstannyl-2-hexenoate (**17**)*

To a cold (−78°C), stirred solution of $Me_3SnCu \cdot Me_2S$ (**2**) (2, 3) (24.3 mmol) in dry THF (180 mL) was added, dropwise, a solution of the α,β-acetylenic ester **16** (3.0 g, 18.7 mmol) in dry THF (40 mL). After the mixture had been stirred at −78°C for 3 h, it was treated sequentially with aqueous NH_4Cl–NH_4OH (pH 8) (100 mL) and Et_2O (60 mL). The mixture was opened to the atmosphere, allowed to warm to room temperature, and was stirred vigorously until the aqueous phase was deep blue. The layers were separated and the aqueous phase was extracted with Et_2O (2 × 60 mL). The combined organic extracts were washed with aqueous NH_4Cl–NH_4OH (pH 8) until the washings were colorless, and then were dried ($MgSO_4$) and concentrated. Flash chromatography (240 g silica gel, 20:1 petroleum ether – Et_2O) of the remaining material, followed by distillation (115–120°C/0.6 Torr), yielded 4.79 g (79%) of **17**, a colorless oil that showed ir (neat): 1710, 1595, 1195, 1175, 777 cm^{-1}; ^1H nmr (80 MHz) δ: 0.21 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.60–2.10 (m, 2H), 3.00 (br t, 2H, J = 7 Hz), 3.53 (t, 2H, J = 6.5 Hz), 3.65 (s, 3H), 5.99 (t, 1H, J = 1 Hz, $^3J_{Sn-H}$ = 71 Hz). Exact Mass calcd. for $C_9H_{16}{}^{35}ClOSn$ (M^+ − Me): 310.9861; found: 310.9853.

*Methyl (Z)-6-chloro-3-trimethylstannyl-2-hexenoate (**18**)*

To a cold (−78°C), stirred solution of $(Me_3SnCuSPh)Li$ (**3**) (2) (24.3 mmol) in dry THF (180 mL) was added, dropwise, a solution of the α,β-acetylenic ester **16** (3.0 g, 18.7 mmol) in dry THF (40 mL). The mixture was stirred at −78°C for 15 min, warmed to −48°C, and then stirred for 4 h. After sequential addition of MeOH (40 mL) and petroleum ether (100 mL), the vigorously stirred mixture was allowed to warm to room temperature. The resulting yellow slurry was filtered through a plug of Celite and the collected material was washed with petroleum ether (100 mL). The filtrate was concentrated and the residual material was subjected to flash chromatography (240 g silica gel, 20:1 petroleum ether – Et_2O). Distillation (106–116°C/0.6 Torr) of the liquid thus obtained afforded 5.3 g (87%) of **18**, a colorless oil that exhibited ir (neat): 1701, 1600, 1210, 778 cm^{-1}; ^1H nmr (80 MHz) δ: 0.21 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 1.60–2.10 (m, 2H), 2.59 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 46 Hz), 3.51 (t, 2H, J = 6.5 Hz), 3.73 (s, 3H), 6.40 (t, 1H, J = 1.5 Hz, $^3J_{Sn-H}$ = 117 Hz). Exact Mass calcd. for $C_9H_{16}{}^{35}ClO_2Sn$ (M^+ − Me): 310.9861; found: 310.9862.

*(E)-6-Chloro-3-trimethylstannyl-2-hexen-1-ol (**19**)*

To a cold (−78°C), stirred solution of the ester **17** (3.1 g, 9.5 mmol) in dry Et_2O (70 mL) was added slowly a solution of diisobutylaluminum hydride (23.8 mmol) in hexane. The mixture was stirred at −78°C for 1 h, warmed to 0°C, and then stirred for 2 h. Saturated aqueous NH_4Cl (10 mL) was added and the mixture was warmed to room temperature. Anhydrous $MgSO_4$ was added to the resultant slurry and the mixture was filtered through a plug of Celite. The collected material was washed with Et_2O (70 mL). Concentration of the filtrate and distillation (100–110°C/0.03 Torr) of the remaining liquid provided 2.52 g (89%) of **19**, a colorless oil that displayed ir (neat): 3300, 1020, 770 cm^{-1}; ^1H nmr (80 MHz) δ: 0.15 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.65 (br s, 1H, exchanges with D_2O), 1.60–2.00 (m, 2H), 2.45 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 67 Hz), 3.50 (t, 2H, J = 6 Hz), 4.25 (m, 2H, d after D_2O addition, J = 6 Hz), 5.82 (tt, 1H, J = 0.5, 6 Hz, $^3J_{Sn-H}$ = 75 Hz). Exact Mass calcd. for $C_8H_{16}{}^{35}ClOSn$ (M^+ − Me): 282.9912; found: 282.9919.

*(Z)-6-Chloro-3-trimethylstannyl-2-hexen-1-ol (**20**)*

Following a procedure identical with that described above, 3.44 g (10.6 mmol) of the ester **18** was converted into 3.03 g (97%, distillation temperature 100–110°C/0.03 Torr) of the alcohol **20**, a colorless oil that showed ir (neat): 3350, 1010, 777 cm^{-1}; ^1H nmr (80 MHz) δ: 0.19 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.41 (t, 1H, exchanges with D_2O, J = 5.5 Hz), 1.60–2.00 (m, 2H), 2.40 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 49 Hz), 3.48 (t, 2H, J = 6 Hz), 4.08 (m, 2H, d after D_2O addition, J = 6 Hz), 6.24 (tt, 1H, J = 1.5, 6 Hz, $^3J_{Sn-H}$ = 134 Hz). Exact Mass calcd. for $C_8H_{16}{}^{35}ClOSn$ (M^+ − Me): 282.9912; found: 282.9917.

*(E)-6-Chloro-1-(methoxymethoxy)-3-trimethylstannyl-2-hexene (**21**)*

To a cold (0°C), stirred solution of the alcohol **19** (740 mg, 2.49 mmol) in dry CH_2Cl_2 (5 mL) was added sequentially ethyldiisopropylamine (0.65 mL, 3.74 mmol) and chloromethyl methyl ether (0.28 mL, 3.74 mmol). The mixture was allowed to warm to room temperature and was stirred for 15 h. Removal of the solvent, followed by distillation (95–105°C/0.6 Torr) of the crude liquid, gave 802 mg (94%) of **21**, a colorless oil that exhibited ir (neat): 1152, 1104, 1042, 772 cm^{-1}; ^1H nmr (80 MHz) δ: 0.14 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.60–2.00 (m, 2H), 2.47 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 62 Hz), 3.36 (s, 3H), 3.48 (t, 2H, J = 7 Hz), 4.15 (br d, 2H, J = 6 Hz), 4.63 (s, 2H), 5.78 (tt, 1H, J = 1.3, 6 Hz, $^3J_{Sn-H}$ = 75 Hz). Exact Mass calcd. for $C_{10}H_{20}{}^{35}ClO_2Sn$ (M^+ − Me): 327.0174; found: 327.0163.

*(Z)-6-Chloro-1-methoxymethoxy)-3-trimethylstannyl-2-hexene (**22**)*

Following a procedure identical with that described above, 1.9 g (6.39 mmol) of the alcohol **20** was transformed into 1.90 g (87%, distillation temperature 100–105°C/0.6 Torr) of the ether **22**, a colorless oil that displayed ir (neat): 1156, 1110, 1040, 778 cm^{-1}; ^1H nmr (80 MHz) δ: 0.20 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.60–2.00 (m, 2H), 2.38 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 48 Hz), 3.35 (s, 3H), 3.49 (t, 2H, J = 6.5 Hz), 4.00 (br d, 2H, J = 6 Hz), 4.62 (s, 2H), 6.38 (tt, 1H, J = 1.3, 6 Hz, $^3J_{Sn-H}$ = 134 Hz). Exact Mass calcd. for $C_{10}H_{20}{}^{35}ClO_2Sn$ (M^+ − Me): 327.0174; found: 327.0172.

*(E)-1-*tert*-Butyldimethylsiloxy-6-chloro-3-trimethylstannyl-2-hexene (**23**)*

To a solution of the alcohol **19** (4.1 g, 13.8 mmol) in dry *N*,*N*-dimethylformamide (40 mL) at room temperature was added *t*-$BuMe_2SiCl$ (2.5 g, 16.6 mmol) and imidazole (2.35 g, 34.5 mmol) and the mixture was stirred for 15 h. After Et_2O (100 mL) had been added, the solution was washed with saturated aqueous $NaHCO_3$ (3 × 75 mL) and then was dried ($MgSO_4$) and concentrated. Distillation (155–170°C/11 Torr) of the remaining oil gave 4.75 g (84%) of **23**, a colorless oil that showed ir (neat): 1256, 1088, 1006, 839, 775 cm^{-1}; ^1H nmr (80 MHz) δ: 0.08 (s, 6H), 0.13 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 0.91 (s, 9H), 1.65–2.00 (m, 2H), 2.43 (br t, 2H, J = 7 Hz), 3.49 (t, 2H, J = 6 Hz), 4.21, 4.36 (d, d, 1H each, J = 6 Hz in each case), 5.74 (br t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 76 Hz). Exact Mass calcd. for $C_{14}H_{30}{}^{35}ClOSiSn$ (M^+ − Me): 397.0777; found: 397.0782.

*(Z)-1-*tert*-Butyldimethylsiloxy-6-chloro-3-trimethylstannyl-2-hexene (**24**)*

Following a procedure identical with that described above, 3.9 g (13.1 mmol) of the alcohol **20** was converted into 5.4 g (89%, distillation temperature 155–170°C/11 Torr) of the silyl ether **24**, a colorless oil that exhibited ir (neat): 1256, 1093, 1061, 1006, 838,

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12

776 cm^{-1}; ^1H nmr (80 MHz) δ: 0.06 (s, 6H), 0.19 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 0.90 (s, 9H), 1.63–2.00 (m, 2H), 2.35 (br t, 2H, J = 6 Hz), 3.50 (t, 2H, J = 6 Hz), 4.02, 4.18 (d, d, 1H each, J = 6 Hz in each case), 6.16 (br t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 138 Hz). Exact Mass calcd. for $C_{14}H_{30}{}^{35}ClOSiSn$ (M^+ − Me): 397.0777; found: 397.0780.

(E)-7-Chloro-4-trimethylstannyl-3-heptene (26)

To a stirred solution of the alcohol **19** (1.0 g, 3.36 mmol), 4-*N*,*N*-dimethylaminopyridine (41 mg, 0.34 mmol) and Et_3N (0.7 mL, 5.0 mmol) in dry CH_2Cl_2 (20 mL) at room temperature was added, dropwise, Ac_2O (0.48 mL, 5.0 mmol). The mixture was stirred for 15 h and then was poured into brine (50 mL). The phases were separated and the aqueous layer was extracted with CH_2Cl_2 (2 × 30 mL). The combined organic phases were dried ($MgSO_4$) and concentrated and the remaining liquid was distilled (90–100°C/0.03 Torr) to give 1.11 g (97%) of the acetate **25**, a colorless oil that showed ir (neat): 1741, 1230, 1028, 769 cm^{-1}; ^1H nmr (400 MHz) δ: 0.16 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 1.81 (quintet, 2H, J = 7 Hz), 2.07 (s, 3H), 2.48 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 60 Hz), 3.49 (t, 2H, J = 7 Hz), 4.64–4.70 (m, 2H), 5.74 (br t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 68 Hz). Exact Mass calcd. for $C_{10}H_{18}{}^{35}ClO_2Sn$ (M^+ − Me): 325.0018; found: 325.0021.

To a cold (0°C), stirred suspension of $CuBr \cdot Me_2S$ (1.21 g, 5.9 mmol) in dry Et_2O (80 mL) was added a solution of MeLi (11.8 mmol) in Et_2O (9 mL) and the solution was stirred for 5 min. A solution of the acetate **25** (1.0 g, 2.95 mmol) in dry Et_2O (20 mL) was added and the mixture was stirred for 15 min. Saturated aqueous NH_4Cl (100 mL) was added slowly; the mixture was opened to the air and was stirred vigorously at room temperature until the aqueous phase became deep blue. The phases were separated and the aqueous layer was extracted with Et_2O (2 × 50 mL). The combined organic phases were dried ($MgSO_4$) and concentrated. Distillation (85–95°C/15 Torr) of the residual liquid afforded 757 mg (87%) of the alkene **26**, a colorless oil that displayed ir (neat): 1609, 776 cm^{-1}; ^1H nmr (400 MHz) δ: 0.12 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 0.98 (t, 3H, J = 7 Hz), 1.80 (quintet, 2H, J = 7 Hz), 2.14 (quintet, 2H, J = 7 Hz, $^4J_{Sn-H}$ = 58 Hz), 2.42 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 61 Hz), 3.50 (t, 2H, J = 7 Hz), 5.60 (t, 1H, J = 7 Hz, $^3J_{Sn-H}$ = 72 Hz). Exact Mass calcd. for $C_9H_{18}{}^{35}ClSn$ (M^+ − Me): 281.0119; found: 281.0114.

General procedure for the conversion of primary chlorides into the corresponding iodides

A stirred solution of the primary chloride (1 equiv.) and NaI (5–10 equiv.) in dry acetone (~4 mL per mmol of the chloride) was refluxed until analysis (glc) showed the absence of the starting material (24–48 h). The mixture was concentrated and the residual material was partitioned between Et_2O and water. The aqueous phase was separated and extracted three times with Et_2O. The combined organic phases were dried ($MgSO_4$) and concentrated and the remaining liquid was distilled to produce the iodide.

Methyl (E)-6-iodo-3-trimethylstannyl-2-hexenoate (27)

Following the general procedure, 1.0 g (3.07 mmol) of the chloride **17** was converted into 1.2 g (94%, distillation temperature 125–135°C/0.6 Torr) of the iodide **27**, a colorless oil that displayed ir (neat): 1712, 1559, 1195, 1175, 772 cm^{-1}; ^1H nmr (80 MHz) δ: 0.22 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.70–2.20 (m, 2H), 2 .95 (br t, 2H, J = 7.5 Hz), 3.17 (t, 2H, J = 7 Hz), 3.66 (s, 3H), 5.99 (t, 1H, J = 1 Hz, $^3J_{Sn-H}$ = 71 Hz). Exact Mass calcd. for $C_9H_{16}IO_2Sn$ (M^+ − Me): 402.9217; found: 402.9212.

Methyl (Z)-6-iodo-3-trimethylstannyl-2-hexenoate (28)

By means of the general procedure, 1.8 g (5.54 mmol) of the chloride **18** was converted into 2.26 g (98%, distillation temperature 110–116°C/0.6 Torr) of **28**, a colorless oil that showed ir (neat): 1706, 1601, 1225, 1210, 780 cm^{-1}; ^1H nmr (80 MHz) δ: 0.21 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 1.70–2.10 (m, 2H), 2.55 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 46 Hz), 3.15 (t, 2H, J = 7 Hz), 3.73 (s, 3H), 6.40 (t, 1H, J = 1.5 Hz, $^3J_{Sn-H}$ = 117 Hz). Exact Mass calcd. for $C_9H_{16}IO_2Sn$ (M^+ − Me): 402.9219; found: 402.9231.

(E)-6-Iodo-1-(methoxymethoxy)-3-trimethylstannyl-2-hexene (29)

Following the general procedure, 1.69 g (4.95 mmol) of the chloride **21** was transformed into 2.03 g (95%, distillation temperature 110–115°C/0.6 Torr) of **29**, a colorless oil that showed ir (neat): 1156, 1108, 1042, 774 cm^{-1}; ^1H nmr (80 MHz) δ: 0.15 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.60–2.10 (m, 2H), 2.42 (br t, 2H, J = 7 Hz), 3.14 (t, 2H, J = 7 Hz), 3.37 (s, 3H), 4.16 (br d, 2H, J = 6 Hz), 4.64 (s, 2H), 5.78 (tt, 1H, J = 1.2, 6 Hz, $^3J_{Sn-H}$ = 75 Hz). Exact Mass calcd. for $C_{10}H_{20}IO_2{}^{116}Sn$ (M^+ − Me): 414.9527; found: 414.9532.

(Z)-6-Iodo-1-(methoxymethoxy)-3-trimethylstannyl-2-hexene (30)

Using the general procedure, 1.9 g (5.57 mmol) of the chloride **22** was converted into 2.26 g (94%, distillation temperature 110–115°C/0.6 Torr) of the iodide **30**, a colorless oil that displayed ir (neat): 1156, 1105, 1035, 779 cm^{-1}; ^1H nmr (80 MHz) δ: 0.20 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.70–2.10 (m, 2H), 2.34 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 48 Hz), 3.14 (t, 2H J = 7 Hz), 3.36 (s, 3H), 4.00 (m, 2H), 4.62 (s, 2H), 6 .21 (tt, 1H, J = 1.2, 6 Hz, $^3J_{Sn-H}$ = 134 Hz). Exact Mass calcd. for $C_{10}H_{20}IO_2Sn$ (M^+ − Me): 418.9530; found: 418.9530.

*(E)-1-*tert*-Butyldimethylsiloxy-6-iodo-3-trimethylstannyl-2-hexene (31)*

Following the general procedure, 5.27 g (12.8 mmol) of the chloride **23** was transformed into 5.97 g (93%, distillation temperature 175–185°C/11 Torr) of **31**, a colorless oil that exhibited ir (neat): 1256, 1099, 837, 775 cm^{-1}; ^1H nmr (80 MHz) δ: 0.08 (s, 6H), 0.13 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 0.91 (s, 9H), 1.63–2.03 (m, 2H), 2.25–2.50 (m, 2H), 3.13 (t, 2H, J = 7 Hz), 4.23, 4.38 (d, d, 1H each, J = 6 Hz in each case), 5.71 (tm, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 76 Hz). Exact Mass calcd. for $C_{14}H_{30}IOSiSn$ (M^+ − Me): 489.0133; found 489.0126.

*(Z)-1-*tert*-Butyldimethylsiloxy-6-iodo-3-trimethylstannyl-2-hexene (32)*

By means of the general procedure, 5.4 g (13.1 mmol) of the chloride **24** was converted into 5.65 g (86%, distillation temperature 175–185°C/11 Torr) of **32**, a colorless oil that displayed ir (neat): 1256, 1099, 837, 776 cm^{-1}; ^1H nmr (80 MHz) δ: 0.08 (s, 6H), 0.19 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 0.90 (s, 9H), 1.63–2.05 (m, 2H), 2.20–2.45 (m, 2H), 3.15 (t, 2H, J = 7 Hz), 4.03, 4.08 (d, d, 1H, J = 6 Hz in each case), 6.18 (br t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 138 Hz). Exact Mass calcd. for $C_{14}H_{30}IOSiSn$ (M^+ − Me): 489.0133; found: 489.0130.

(E)-7-Iodo-4-trimethylstannyl-3-heptene (33)

By means of the general procedure, 1.45 g (4.91 mmol) of the chloride **26** was converted into 1.78 g (94%, distillation temperature 95–105°C/15 Torr) of the iodide **33**, a colorless oil that showed ir (neat): 1609, 1220, 776 cm^{-1}; ^1H nmr (400 MHz) δ: 0.12 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 0.99 (t, 3H, J = 7 Hz), 1.85 (quintet, 2H, J = 7 Hz), 2.16 (quintet, 2H, J = 7 Hz), 2.38 (br t, 2H, J = 7 Hz, $^3J_{Sn-H}$ = 53 Hz), 3.16 (t, 2H, J = 7 Hz), 5.59 (br t, 1H, J = 7 Hz, $^3J_{Sn-H}$ = 78 Hz). Exact Mass calcd. for $C_9H_{18}ISn$ (M^+ − Me): 372.9477; found: 372.9475.

*General procedure for alkylation of the β-keto esters **34** and **35** with the iodides **27–33***

To a well-stirred suspension of KH (1.1 equiv.) in dry THF (3 mL per mmol of β-keto ester) at room temperature was added, dropwise, a solution of the β-keto ester (1 equiv.) in dry THF (1 mL per mmol of ester). The mixture was stirred for 30–45 min and then a solution of the iodide (1.1 equiv.) in dry THF (1 mL per mmol of iodide) was added. The reaction mixture was refluxed and, after the reaction was determined to have reached completion (analysis by glc and (or) tlc), the mixture was cooled and concentrated. Direct flash chromatography of the remaining oil–salt mixtures, followed by distillation of the liquid thus obtained, provided the desired alkylation product. The following compounds were prepared by use of this procedure.

Keto diester ***36***

Alkylation of 2-(methoxycarbonyl)cyclopentanone (**34**) (155 mg, 1.09 mmol) with the iodide **27** (500 mg, 1.2 mmol, reaction time 18 h), followed by flash chromatography (27 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product and distillation (169–173°C/0.6 Torr) of the acquired liquid, provided 366 mg (78%) of **36**, a colorless oil that showed ir (neat): 1750, 1720, 1170, 775 cm^{-1}; ^1H nmr (400 MHz) δ: 0.20 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.30–1.50 (m, 2H), 1.62 (ddd, 1H, J = 4.5, 11.5, 13.5 Hz), 1.80–2.05 (m, 4H), 2.25 (m, 1H), 2.39 (m, 1H), 2.54 (m, 1H), 2.80–3.00 (m, 2H), 3.68 (s, 3H), 3.69 (s, 3H), 5.96 (br s, 1H, $^3J_{Sn-H}$ = 72 Hz). Exact Mass calcd. for $C_{16}H_{25}O_5Sn$ (M^+ – Me): 417.0723; found: 417.0710.

Keto diester ***37***

Flash chromatography (35 g silica gel, 14:1 petroleum ether – EtOAc) of the crude product derived from alkylation of 2 -(methoxycarbonyl)cyclohexanone (**35**) (200 mg, 1.28 mmol) with the iodide **27** (588 mg, 1.41 mmol, reaction time 9 h), followed by distillation (176–181°C/0.6 Torr) of the resultant liquid, gave 322 mg (57%) of **37**, a colorless oil that displayed ir (neat): 1710, 1195, 1170, 775 cm^{-1}; ^1H nmr (400 MHz) δ: 0.19 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.20–1.50 (m, 3H), 1.55–1.80 (m, 4H), 1.85–2.05 (m, 2H), 2.20–2.55 (m, 3H), 2.75–3.00 (m, 2H), 3.68 (s, 3H), 3.72 (s, 3H), 5.96 (t, 1H, J = 1.3 Hz, $^3J_{Sn-H}$ = 72 Hz). Exact Mass calcd. for $C_{17}H_{27}O_5Sn$ (M^+ – Me): 431.0880; found: 431.0873.

Keto diester ***38***

The keto ester **34** (300 mg, 2.11 mmol) was alkylated with the iodide **28** (967 mg, 2.32 mmol, reaction time 18 h). Flash chromatography (50 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product and distillation (185–189°C/0.6 Torr) of the liquid thus obtained afforded 564 mg (63%) of **38**, a colorless oil that exhibited ir (neat): 1750, 1720, 1705, 1210, 780 cm^{-1}; ^1H nmr (400 MHz) δ: 0.15 (s, 9H, J_{Sn-H} = 53 Hz), 1.23–1.50 (m, 2H), 1.52 (dt, 1H, J = 4.5, 13 Hz), 1.80–2.05 (m, 4H), 2.25 (dt, 1H, J = 19, 8 Hz), 2.34–2.48 (m, 3H), 2.53 (m, 1H), 3.69 (s, 3H), 3.71 (s, 3H), 6.31 (t, 1H, J = 1 Hz, $^3J_{Sn-H}$ = 119 Hz). Exact Mass calcd. for $C_{16}H_{25}O_5Sn$ (M^+ – Me): 417.0723; found: 417.0718.

Keto diester ***39***

Alkylation of the keto ester **35** (300 mg, 1.92 mmol) with the iodide **28** (881 mg, 2.1 mmol, reaction time 18 h), followed by flash chromatography (50 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product and distillation (201–204°C/0.6 Torr) of the acquired liquid, produced 610 mg (71%) of **39**, a colorless oil that displayed ir (neat): 1710, 1210, 780 cm^{-1}; ^1H nmr (400 MHz) δ: 0.16 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.20–1.80 (m, 7H), 1.86 (dt, 1H, J = 4.5, 13 Hz), 2.00 (m, 1H), 2.35–2.60 (m, 5H), 3.72 (s, 3H), 3.73 (s, 3H), 6.34 (t, 1H, J = 1 Hz, $^3J_{Sn-H}$ = 118 Hz). Exact Mass calcd. for $C_{17}H_{27}O_5Sn$ (M^+ – Me): 431.0880; found: 431.0881.

Keto ester ***40***

Flash chromatography (18 g silica gel, 8:1 petroleum ether – EtOAc) of the crude product obtained from alkylation of the keto ester **34** (100 mg, 0.70 mmol) with the iodide **29** (335 mg, 0.77 mmol, reaction time 13 h), followed by distillation (159–164°C/0.6 Torr) of the liquid thus obtained provided 210 mg (67%) of **40**, a colorless oil that showed ir (neat): 1750, 1725, 1155, 1050, 775 cm^{-1}; ^1H nmr (400 MHz) δ: 0.11 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.15–1.44 (m, 2H), 1.53 (ddd, 1H, J = 4.5, 12, 13.5 Hz), 1.78–2.04 (m, 4H), 2.17–2.33 (m, 3H), 2.37 (m, 1H), 2.52 (m, 1H), 3.35 (s, 3H), 3.67 (s, 3H), 4.11 (d, 2H, J = 6 Hz), 4.62 (s, 2H), 5.72 (t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 77 Hz). Exact Mass calcd. for $C_{17}H_{29}O_5Sn$ (M^+ – Me): 433.1037; found: 433.1038.

Keto ester ***41***

Alkylation of the keto ester **35** (670 mg, 4.29 mmol) with the iodide **29** (2.04 g, 4.72 mmol, reaction time 6 h), followed by flash chromatography (100 g silica gel, 5:1 petroleum ether – EtOAc) of the crude product and distillation (164–167°C/0.6 Torr) of the acquired liquid, provided 1.46 g (74%) of **41**, a colorless oil that showed ir (neat): 1710, 1055, 772 cm^{-1}; ^1H nmr (400 MHz) δ: 0.11 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.12–1.35 (m, 2H), 1.42 (m, 1H), 1.52 (dt, 1H, J = 4.5, 13 Hz), 1.58–1.80 (m, 3H), 1.86 (ddd, 1H, J = 4.5, 13, 13.5 Hz), 1.99 (m, 1H), 2.29 (br t, 2H, J = 7.5 Hz, $^3J_{Sn-H}$ = 53 Hz), 2.40–2.45 (m, 2H), 2.49 (m, 1H), 3.37 (s, 3H), 3.71 (s, 3H), 4.14 (d, 2H, J = 6 Hz), 4.63 (s, 2H), 5.72 (br t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 77 Hz). Exact Mass calcd. for $C_{18}H_{31}O_5Sn$ (M^+ – Me): 447.1193; found: 447.1196.

Keto ester ***42***

The keto ester **34** (670 mg, 4.71 mmol) was alkylated with the iodide **30** (2.24 g, 5.18 mmol, reaction time 14 h). Flash chromatography (100 g silica gel, 7:1 petroleum ether – EtOAc) of the crude product and distillation 170–175°C/0.6 Torr) of the oil thus obtained provided 1.43 g (68%) of **42**, a colorless oil that displayed ir (neat): 1747, 1720, 1155, 1040, 780 cm^{-1}; ^1H nmr (400 MHz) δ: 0.18 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 1.20–1.42 (m, 2H), 1.53 (dt, 1H, J = 4.5, 13 Hz), 1.80–2.05 (m, 4H), 2.20–2.32 (m, 3H), 2.39 (m, 1H), 2.54 (m, 1H), 3.35 (s, 3H), 3.69 (s, 3H), 4.01 (d, 2H, J = 6 Hz), 4.61 (s, 2H), 6.12 (t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 136 Hz). Exact Mass calcd. for $C_{17}H_{29}O_5Sn$ (M^+ – Me): 433.1037; found: 433.1035.

Keto ester ***43***

Alkylation of the keto ester **35** (740 mg, 4.74 mmol) with the iodide **30** (2.25 g, 5.2 mmol, reaction time 19 h), followed by flash chromatography (120 g silica gel, 7:1 petroleum ether – EtOAc) of the crude product and distillation (174–177°C/0.6 Torr) of the acquired liquid, gave 1.53 g (70%) of **43**, a colorless oil that displayed ir (neat): 1715, 1040, 779 cm^{-1}; ^1H nmr (400 MHz) δ: 0.15 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.13–1.33 (m, 2H), 1.37–1.77 (m, 5H), 1.84 (dt, 1H, J = 4.5, 13.5 Hz), 1.97 (m, 1H), 2.10–2.30 (m, 2H), 2.37–2.44 (m, 2H), 2.48 (m, 1H), 3.35 (s, 3H), 3.70 (s, 3H), 3.99 (d, 2H, J = 6.3 Hz), 4.60 (s, 2H), 6.12 (t, 1H, J = 6.3 Hz, $^3J_{Sn-H}$ = 131 Hz). Exact Mass calcd. for $C_{18}H_{31}O_5Sn$ (M^+ – Me): 447.1193; found: 447.1195.

Keto ester ***44***

The keto ester **35** (400 mg, 2.56 mmol) was alkylated with the iodide **31** (1.42 g, 2.82 mmol, reaction time 24 h). Flash chromatography (50 g silica gel, 10:1 petroleum ether – EtOAc), followed by distillation (200–210°C/0.03 Torr) of the oil thus obtained, produced 1.21 g (81%) of **44**, a colorless oil that exhibited ir (neat): 1741, 1718, 1254, 1093, 837, 776 cm^{-1}; ^1H nmr (400 MHz) δ: 0.07 (s, 6H), 0.11 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 0.90 (s, 9H), 1.12–1.34 (m, 2H), 1.37–1.57 (m, 2H), 1.60–1.88 (m, 3H), 1.85 (dt, 1H, J = 4.5, 13 Hz), 1.99 (m, 1H), 2.23 (br t, 2H, J = 8 Hz, $^3J_{Sn-H}$ = 61 Hz), 2.36–2.45 (m, 2H), 2.49 (m, 1H), 3.71 (s, 3H), 4.26 (d, 2H, J = 5.5 Hz), 5.66 (br t, 1H, J = 5.5 Hz, $^3J_{Sn-H}$ = 79 Hz). Exact Mass calcd. for $C_{22}H_{41}O_4SiSn$ (M^+ – Me): 517.1796; found: 517.1792.

Keto ester ***45***

The keto ester **35** (400 mg, 2.56 mmol) was alkylated with the iodide **32** (1.42 g, 2.82 mmol, reaction time 24 h). Distillation (200–210°C/0.03 Torr) of the liquid derived by flash chromatography (50 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product afforded 940 mg (69%) of **45**, a colorless oil that showed ir (neat): 1741, 1718, 1255, 1095, 837, 776 cm^{-1}; ^1H nmr 400 MHz) δ: 0.07 (s, 6H), 0.17 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 0.90 (s, 9H), 1.15–1.34 (m, 2H), 1.39–1.58 (m, 2H), 1.62–1.79 (m, 3H), 1.85 (ddd, 1H, J = 4.5, 13, 13.5 Hz), 2.00 (m, 1H), 2.20 (br t, 2H, J = 7 Hz), 2.40–2.54 (m, 3H), 3.72 (s, 3H), 4.10 (d, 2H, J = 6 Hz), 6.10 (t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 140 Hz). Exact Mass calcd. for $C_{22}H_{41}O_4SiSn$ (M^+ – Me): 517.1796; found: 517.1790.

Keto ester ***46***

Alkylation of the keto ester **35** (1.12 g, 7.18 mmol) with the iodide **33** (2.94 g, 7.90 mmol), reaction time 20 h), followed by flash chromatography (180 g silica gel, 15:1 petroleum ether – EtOAc) of the crude product and distillation (140–150°C/0.3 Torr) of the

For personal use only.

liquid thus obtained, provided 2.23 g (75%) of **46**, a colorless oil that displayed ir (neat): 1740, 1716, 1211, 767 cm^{-1}; ^1H nmr (400 MHz) δ: 0.09 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 0.97 (t, 3H, J = 7 Hz), 1.12–1.33 (m, 2H), 1.39–1.80 (m, 5H), 1.88 (dt, 1H, J = 4, 13 Hz), 2.00 (m, 1H), 2.11 (quintet, 2H, J = 7 Hz), 2.25 (br t, 2H, J = 8 Hz), 2.40–2.55 (m, 3H), 3.72 (s, 3H), 5.53 (br t, 1H, J = 7 Hz, $^3J_{Sn-H}$ = 73 Hz). Exact Mass calcd. for $C_{17}H_{29}O_3Sn$ (M^+ − Me): 401.1138; found: 401.1131.

General procedures for the synthesis of bicyclic dienes via the corresponding (isolated) enol trifluoromethanesulfonate intermediates (Table 2, Entries 1–5, 7, 8, 10)

To a cold (−48°C), stirred solution of lithium diisopropylamide (LDA, 1.1–1.5 equiv.) in dry THF (~10 mL per mmol of β-keto ester) was added, dropwise, a solution of the β-keto ester (1 equiv.) in dry THF (~5 mL per mmol of β-keto ester) and the resultant mixture was stirred at −48°C for 1 h. Solid finely ground $PhN(SO_2CF_3)_2$ ($PhNTf_2$) (1.17–1.57 equiv.) was added and the solution was warmed to room temperature over a period of 30 min. Concentration of the reaction mixture under reduced pressure was followed by flash chromatography of the residual oil on silica gel. The enol triflate thus obtained was characterized and then was used as soon as possible in the subsequent reaction.

To a stirred solution of the enol triflate (1 equiv.) in dry THF or MeCN (5 mL per 0.1 mmol of substrate) at room temperature was added $Pd(PPh_3)_4$ (0.05 equiv.) as a solid and the resulting solution was refluxed. When the reaction was determined to have reached completion (by glc and (or) tlc analyses), the mixture was cooled to room temperature and concentrated. The residual oil was purified by flash chromatography and the liquid thus obtained was distilled to provide the expected diene.

The following compounds were prepared via these procedures.

Diene 55

The keto ester **36** (190 mg, 0.44 mmol) was converted into the enol triflate **47** (141 mg, 57%, flash chromatography on 40 g of silica gel, 10:1 petroleum ether – EtOAc), using 0.48 mmol of LDA and 0.52 mmol of $PhNTf_2$. Compound **47** displayed ir (neat): 1734, 1719, 1642, 1599, 1423, 1210, 1143, 772 cm^{-1}; ^1H nmr (80 MHz) δ: 0.22 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.20–3.20 (m, 10H), 3.69 (s, 3H), 3.72 (s, 3H), 5.76 (br s, 1H), 5.98 (t, 1H, J = 1 Hz, $^3J_{Sn-H}$ = 72 Hz). Exact Mass calcd. for $C_{17}H_{24}F_3O_7SSn$ (M^+ − Me): 549.0216; found: 549.0212.

Compound **47** (100 mg, 0.178 mmol) was converted (THF, reflux, 3.5 h) into 39 mg (89%) of **55** (flash chromatography on 20 g of silica gel, 10:1 petroleum ether – EtOAc; distillation temperature 117–121°C/0.6 Torr), a colorless oil that exhibited ir (neat): 1710, 1620 cm^{-1}; ^1H nmr (400 MHz) δ: 1.43 (dt, 1H, J = 3.5, 13 Hz), 1.51 (ddq, 1H, J = 3, 4.5, 13 Hz), 1.78–1.88 (m, 2H), 2.06 (m, 1H), 2.35–2.50 (m, 4H), 3.65 (s, 3H), 3.67 (m, 1H), 3.69 (s, 3H), 5.97 (d, 1H, J = 2.5 Hz), 6.01 (br s, 1H). Exact Mass calcd. for $C_{14}H_{18}O_4$: 250.1205; found: 250.1206.

Diene 56

Flash chromatography (40 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product derived from sequential treatment of the keto ester **37** (200 mg, 0.45 mmol) with LDA (0.50 mmol) and $PhNTf_2$ (0.53 mmol) gave 160 mg (62%) of the enol triflate **48**, a colorless oil that showed ir (neat): 1732, 1712, 1594, 1415, 1210, 772 cm^{-1}; ^1H nmr (80 MHz) δ: 0.20 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.20–2.40 (m, 10H), 2.85 (m, 2H), 3.68 (s, 3H), 3.72 (s, 3H), 5.87 (t, 1H, J = 4 Hz), 5.97 (t, 1H, J = 1.1 Hz). Exact Mass calcd. for $C_{18}H_{26}F_3O_7SSn$ (M^+ − Me): 563.0373; found: 563.0383.

Cyclization of **48** (110 mg, 0.19 mmol) was carried out in THF (reflux, 3.5 h). Flash chromatography (18 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product and distillation (118–122°C/0.6 Torr) of the acquired liquid produced 45 mg (90%) of **56**, a colorless oil that showed ir (neat): 1710, 1615 cm^{-1}; ^1H nmr (400 MHz) δ: 1.35–1.50 (m, 4H), 1.66 (m, 1H), 1.77 (m, 1H), 2.01 (dddt, 1H, J = 2.5, 2.5, 5.5, 13.5 Hz), 2.14 (m, 2H), 2.20 (dd, 1H, J = 5, 11 Hz), 2.30 (m, 1H), 3.65 (s, 3H), 3.69 (s, 3H), 3.82 (br d, 1H, J = 4 Hz), 5.85 (d, 1H, J = 2 Hz), 5.96 (t, 1H, J = 4 Hz). Exact Mass calcd. for $C_{15}H_{20}O_4$: 264.1362; found: 264.1362.

Diene 57

Treatment of the keto ester **38** (300 mg, 0.70 mmol) with LDA (0.77 mmol) and $PhNTf_2$ (0.82 mmol), followed by flash chromatography (40 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product, furnished 250 mg (64%) of the enol triflate **49**, a colorless oil that exhibited ir (neat): 1739, 1703, 1645, 1600, 1422, 1215, 770 cm^{-1}; ^1H nmr (80 MHz) δ: 0.20 (s, 9H, $^2J_{Sn-H}$ = 55 Hz), 1.20–2.75 (m, 10H), 3.74 (s, 6H), 5.76 (m, 1H), 6.35 (t, 1H, J = 1 Hz, $^3J_{Sn-H}$ = 118 Hz). Exact Mass calcd. for $C_{17}H_{24}F_3O_7SSn$ (M^+ − Me): 549.0216; found: 549.0215.

Compound **49** (125 mg, 0.222 mmol) was converted (THF, reflux 19 h) into 42 mg (75%) of **57** (flash chromatography on 27 g of silica gel, 10:1 petroleum ether – EtOAc; distillation temperature 114–117°C/0.6 Torr), a colorless oil that showed ir (neat): 1725, 1630 cm^{-1}; ^1H nmr (400 MHz) δ: 1.45 (dt, 1H, J = 4, 13.5 Hz), 1.69 (tq, 1H, J = 4, 13.5 Hz), 1.77–1.90 (m, 2H), 2.19 (ddt, 1H, J = 2, 5, 13.5 Hz), 2.33 (br d, 1H, J = 13.5 Hz), 2.38–2.49 (m, 3H), 2.63 (dddd, 1H, J = 2.5, 8.5, 8.5, 17.5 Hz), 3.63 (s, 3H), 3.66 (s, 3H), 5.68 (d, 1H, J = 2 Hz), 6.10 (t, 1H, J = 2.5 Hz). Exact Mass calcd. for $C_{14}H_{18}O_4$: 250.1205; found: 250.1206.

Diene 58

The keto ester **39** (220 mg, 0.495 mmol) was converted into the enol triflate **50** (194 mg, 64%; flash chromatography on 50 g of silica gel, 10:1 petroleum ether – EtOAc), using 0.54 mmol of LDA and 0.58 mmol of $PhNTf_2$. Compound **50** exhibited ir (neat): 1738, 1707, 1601, 1415, 1220, 1150, 779 cm^{-1}; ^1H nmr (80 MHz) δ: 0.19 (s, 9H, $^2J_{Sn-H}$ = 54 Hz), 1.20–2.55 (m, 12H), 3.73 (s, 3H), 3.74 (s, 3H), 5.87 (t, 1H, J = 4 Hz), 6.34 (t, 1H, J = 1 Hz, $^3J_{Sn-H}$ = 117 Hz). Exact Mass calcd. for $C_{18}H_{26}F_3O_7SSn$ (M^+ − Me): 563.0373; found: 563.0374.

Compound **50** (150 mg, 0.26 mmol) was converted (THF, reflux, 16 h) into 52 mg (75%) of the diene **58** (flash chromatography on 27 g of silica gel, 10:1 petroleum ether – EtOAc; distillation temperature 116–118°C/0.6 Torr), a colorless oil that displayed ir (neat): 1728, 1633; ^1H nmr (400 MHz) δ: 1.40–1.68 (m, 5H), 1.79 (m, 1H), 2.10 (dddd, 1H, J = 3, 6, 9.5, 18.5 Hz), 2.15–2.26 (m, 3H), 2.30 (m, 1H), 3.63 (s, 3H), 3.66 (s, 3H), 5.60 (d, 1H, J = 2 Hz), 5.99 (dd, 1H, J = 3, 4 Hz). Exact Mass calcd. for $C_{15}H_{20}O_4$: 264.1362; found: 264.1364.

Diene 59

Sequential treatment of the keto ester **40** (700 mg, 1.57 mmol) with LDA (2.35 mmol) and $PhNTf_2$ (2.46 mmol), followed by flash chromatography (120 g silica gel, 8:1 petroleum ether – EtOAc) of the crude product, gave 798 mg (88%) of the enol triflate **51**, a colorless oil that showed ir (neat): 1732, 1643, 1420, 1210, 770 cm^{-1}; ^1H nmr (80 MHz) δ: 0.10 (s, 9H, $^2J_{Sn-H}$ = 52 Hz), 1.20–2.70 (m, 10H), 3.35 (s, 3H), 3.68 (s, 3H), 4.10 (d, 2H, J = 6 Hz), 4.61 (s, 2H), 5.73 (m, 2H). Exact Mass calcd. for $C_{18}H_{28}F_3O_7SSn$ (M^+ − Me): 565.0529; found: 565.0520.

Cyclization of **51** (87 mg, 0.15 mmol) was carried out in THF (reflux, 6 h). Flash chromatography (18 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product and distillation (105–110°C/0.6 Torr) of the acquired liquid provided 33 mg (83%) of the diene **59**, a colorless oil that displayed ir (neat): 1720, 1640 cm^{-1}; ^1H nmr (400 MHz) δ: 1.35 (dt, 1H, J = 3.5, 13 Hz), 1.48 (ddq, 1H, J = 3, 3.5, 13 Hz), 1.72–1.93 (m, 3H), 2.30–2.45 (m, 3H), 2.49 (br d, 1H, J = 13 Hz), 2.62 (br d, 1H, J = 13 Hz), 3.38 (s, 3H), 3.65 (s, 3H), 4.13 (m, 2H), 4.62, 4.65 (d, d, 1H each, J = 6 Hz in each case), 5.73 (dt, 1H, J = 2.5, 7 Hz), 5.84 (t, 1H, J = 2.5 Hz). Exact Mass calcd. for $C_{15}H_{22}O_4$: 266.1519; found: 266.1524.

matography (180 g silica gel, 10:1 petroleum ether – EtOAc) of the crude product, afforded 1.19 g (92%) of the enol triflate **52**, a colorless oil that exhibited ir (neat): 1732, 1420, 1210, 770 cm^{-1}; ^1H nmr (80 MHz) δ: 0.14 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.20–2.45 (m, 12H), 3.38 (s, 3H), 3.73 (s, 3H), 4.13 (d, 2H, J = 6 Hz), 4.64 (s, 2H), 5.74 (br t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 76 Hz), 5.87 (t, 1H, J = 4 Hz). *Exact Mass* calcd. for $C_{19}H_{30}F_3O_7SSn$ (M^+ − Me): 579.0686; found: 579.0670.

Cyclization of **52** (660 mg, 1.11 mmol) was carried out in MeCN (reflux, 15 h). Flash chromatography (120 g silica gel, 12:1 petroleum ether – EtOAc) of the crude product and distillation (120–124°C/0.6 Torr) of the liquid thus obtained gave 262 mg (84%) of **60**, a colorless oil that exhibited ir (neat): 1721, 1640 cm^{-1}; ^1H nmr (400 MHz) δ: 1.30–1.50 (m, 4H), 1.62 (m, 1H), 1.73 (m, 1H), 1.86 (br t, 1H, J = 12 Hz), 2.11 (m, 3H), 2.33 (br d, 1H, J = 12 Hz), 2.65 (br d, 1H, J = 14 Hz), 3.37 (s, 3H), 3.65 (s, 3H), 4.09 (dd, 1H, J = 7, 12 Hz), 4.14 (dd, 1H, J = 7, 12 Hz), 4.61, 4.64 (d, d, 1H each, J = 6 Hz in each case), 5.57 (dt, 1H, J = 2.4, 7 Hz), 5.82 (t, 1H, J = 4 Hz). In a nOe difference experiment, irradiation at δ 5.82 caused enhancement of the signal at δ 5.57. Exact Mass calcd. for $C_{16}H_{24}O_4$: 280.1675; found: 280.1679.

*Diene **61***

The keto ester **42** (700 mg, 1.57 mmol) was converted into 766 mg (84%) of the enol triflate **53** (flash chromatography on 90 g of silica gel, 8:1 petroleum ether – EtOAc), using 2.35 mmol of LDA and 2.46 mmol of $PhNTf_2$. Compound **53** exhibited ir (neat): 1739, 1650, 1422, 1218, 1147, 778 cm^{-1}; ^1H nmr (80 MHz) δ: 0.18 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.10–2.70 (m, 10H), 3.36 (s, 3H), 3.71 (s, 3H), 4.00 (d, 2H, J = 6 Hz), 4.62 (s, 2H), 5.75 (br s, 1H), 6.13 (br t, 1H, J = 6 Hz, $^3J_{Sn-H}$ = 132 Hz). Exact Mass calcd. for $C_{18}H_{28}F_3O_7SSn$ (M^+ − Me): 265.0529; found: 265.0527.

The enol triflate **53** (230 mg, 0.397 mmol) was transformed (THF, reflux, 2 h) into 91 mg (86%) of the diene **61** (flash chromatography on 40 g of silica gel, 7:1 petroleum ether – EtOAc; distillation temperature 99–105°C/0.6 Torr), a colorless oil that showed ir (neat): 1724, 1640 cm^{-1}; ^1H nmr (400 MHz) δ: 1.32 (dt, 1H, J = 3.5, 13 Hz), 1.46 (ddq, 1H, J = 3, 4, 13 Hz), 1.68 (m, 1H), 1.77 (dt, 1H, J = 13.5, 9.5 Hz), 2.04 (br t, 1H, J = 13 Hz), 2.19–2.28 (m, 2H), 2.33 (ddt, 1H, J = 9.5, 16.5, 2.5 Hz), 2.40–2.53 (m, 2H), 3.31 (s, 3H), 3.57 (s, 3H), 4.10 (ddd, 1H, J = 2.5, 6, 12 Hz), 4.17 (ddd, 1H, J = 1, 7.5, 12 Hz), 4.58, 4.60 (d, d, 1H each, J = 7 Hz in each case), 5.43 (ddd, 1H, J = 2, 6, 7.5 Hz), 5.60 (t, 1H, J = 2.5 Hz). In a nOe difference experiment, irradiation at δ 5.60 caused enhancement of the signals at δ 4.10 and 4.17. Exact Mass calcd. for $C_{15}H_{22}O_4$: 266.1519; found: 266.1517.

*Diene **62***

Sequential treatment of the keto ester **43** (820 mg, 1.78 mmol) with LDA (2.7 mmol) and $PhNTf_2$ (2.8 mmol), followed by flash chromatography (100 g silica gel, 8:1 petroleum ether – EtOAc) of the crude product, furnished 950 mg (90%) of the enol triflate **54**, a colorless oil that displayed ir (neat): 1736, 1675, 1418, 1219, 776 cm^{-1}; ^1H nmr (80 MHz) δ: 0.17 (s, 9H, $^2J_{Sn-H}$ = 53 Hz), 1.10–2.50 (m, 2H), 3.36 (s, 3H), 3.71 (s, 3H), 3.98 (d, 2H, J = 6 Hz), 4.60 (s, 2H), 5.85 (t, 1H, J = 4 Hz), 6.13 (br t, 1 H, J = 6 Hz, $^3J_{Sn-H}$ = 132 Hz). Exact Mass calcd. for $C_{19}H_{30}F_3O_7SSn$ (M^+ − Me): 579.0686; found: 579.0678.

Cyclization (THF, reflux, 2h) of **54** (190 mg, 0.32 mmol) provided 78 mg (87%) of the diene **62** (flash chromatography on 40 g of silica gel, 7:1 petroleum ether – EtOAc; distillation temperature 108–111°C/0.6 Torr), a colorless oil that showed ir (neat): 1726, 1645 cm^{-1}; ^1H nmr (400 MHz) δ: 1.36–1.59 (m, 4H), 1.61 (m, 1H), 1.72 (m, 1H), 2.00–2.20 (m, 4H), 2.26 (m, 1H), 2.35 (m, 1H), 3.39 (s, 3H), 3.63 (s, 3H), 4.19 (ddd, 1H, J = 2.3, 6, 12 Hz), 4.21 (ddd, 1H, J = 1.2, 7.3, 12 Hz), 4.65, 4.68 (d, d, 1H each, J = 6.5 Hz in each case), 5.39 (ddd, 1H, J = 2, 6, 7.3 Hz), 5.59 (dd, 1H, J = 3, 4.6 Hz). In a nOe difference experiment, irradiation at δ 5.59 caused enhancement of the resonances at δ 4.19 and 4.21. Exact Mass calcd. for $C_{16}H_{24}O_4$: 280.1675; found: 280.1666.

General procedure for the preparation of bicyclic dienes in a "one-pot" process from keto vinylstannanes (Table 2, Entries 6, 9, 11–13)

To a cold (−78°C), stirred solution of LDA (1.5 equiv.) in dry THF (~10 mL per mmol of β-keto ester) was added dry HMPA (2 equiv.) and the resultant solution was stirred at −78°C for 10 min and then at 0°C for 10 min. The mixture was recooled to −78°C and a solution of the β-keto ester (1 equiv.) in dry THF (~5 mL per mmol of substrate) was added dropwise. The mixture was stirred at −78°C for 10 min and at 0°C for 1 h. Solid, finely ground $PhNTf_2$ (1.57 equiv.) was added and the solution was stirred at room temperature for 30 min. Solid $Pd(PPh_3)_4$ (0.03 equiv.) or $Pd(OAc)_2$ (0.03 equiv.) was added and the solution was heated under reflux. When the reaction was determined to have reached completion (analyses by glc and (or) tlc), the solution was cooled to room temperature and then was concentrated. Flash chromatography of the remaining material on silica gel, followed by distillation of the liquid thus obtained, provided the desired diene.

The following compounds were prepared by means of this procedure. Unless otherwise noted, $Pd(PPh_3)_4$ was employed as the catalyst in the cyclization step.

*Diene **59***

The keto ester **40** (300 mg, 0.672 mmol) was converted into the diene **59** (151 mg, 84%; cyclization reaction time 30 min; flash chromatography on 50 g of silica gel, 8:1 petroleum ether –EtOAc; distillation temperature 100–108°C/0.5 Torr). The spectral data for the product were identical with those summarized above.

*Diene **61***

The keto ester **41** (300 mg, 0.672 mmol) was transformed into the diene **61** (131 mg, 73%; cyclization reaction time 30 min; flash chromatography on 50 g of silica gel, 8:1 petroleum ether – EtOAc; distillation temperature 100–105°C/0.6 Torr). This product exhibited spectra identical with those summarized above.

*Diene **63***

The keto ester **44** (500 mg, 0.94 mmol) was converted into 200 mg (61%) of the diene **63** (flash chromatography on 90 g of silica gel, 15:1 petroleum ether – EtOAc; distillation temperature 135–145°C/0.03 Torr). The cyclization reaction time was 3 h. The diene **63**, a colorless oil, displayed ir (neat): 1729, 1650, 835, 776 cm^{-1}; ^1H nmr (400 MHz) δ: 0.06 (s, 6H), 0.90 (s, 9H), 1.29–1.48 (m, 4H), 1.58–1.87 (m, 3H), 2.05–2.14 (m, 3H), 2.32 (m, 1H), 2.55 (br d, 1H, J = 13 Hz), 3.63 (s, 3H), 4.18 (ddd, 1H, J = 1, 6.5, 13 Hz), 4.26 (ddd, 1H, J = 1, 6.5, 13 Hz), 5.53 (dt, 1H, J = 2, 6.5 Hz), 5.78 (t, 1H, J = 3.8 Hz). Exact Mass calcd. for $C_{20}H_{34}O_3Si$: 350.2278; found: 350.2274.

In a separate, identical experiment, but using $Pd(OAc)_2$ in place of $Pd(PPh_3)_4$, 1.15 g (2.17 mmol) of **44** was transformed into 381 mg (50%) of **63**.

*Diene **64***

The keto ester **45** (500 mg, 0.94 mmol) was converted into the diene **64** (215 mg, 65%; cyclization reaction time 14 h; flash chromatography on 90 g of silica gel, 20:1 petroleum ether – Et_2O; distillation temperature 140–150°C/0.03 Torr). The product, a colorless oil, exhibited ir (neat): 1731, 1650, 837, 776 cm^{-1}; ^1H nmr (400 MHz) δ: 0.07, 0.08 (s, s, 3H each), 0.92 (s, 9H), 1.31–1.76 (m, 6H), 2.01–2.38 (m, 6H), 3.63 (s, 3H), 4.26, 4.27 (d, d, 1H each, J = 6.5 Hz in each case), 5.35 (dt, 1H, J = 2.0, 6.5 Hz), 5.60 (br t, 1H, J = 4.0 Hz). Exact Mass calcd. for $C_{20}H_{34}O_3Si$: 350.2278; found: 350.2276.

In an identical experiment, but using $Pd(OAc)_2$ in place of $Pd(PPh_3)_4$, 2.04 g (3.84 mmol) of **45** was converted into 820 mg (61%) of **64**.

*Diene **65***

The keto ester **46** (2.232 g, 5.38 mmol) was converted into the diene **65** (764 mg, 61%; cyclization reaction time 3.5 h; flash

chromatography on 240 g of silica gel, 15:1 petroleum ether – Et_2O; distillation temperature 70–80°C/0.03 Torr). The diene **65**, a colorless oil, exhibited ir (neat): 1726, 1649, 813 cm^{-1}; ^{1}H nmr (400 MHz) δ: 0.96 (t, 3H, J = 7 Hz), 1.24–1.83 (m, 7H), 1.94–2.13 (m, 5H), 2.31 (br d, 1H, J = 12 Hz), 2.59 (br d, 1H, J = 12 Hz), 3.64 (s, 3H), 5.41 (dt, 1H, J = 2, 7 Hz), 5.73 (t, 1H, J = 4 Hz). Exact Mass calcd. for $C_{15}H_{22}O_2$: 234.1620; found: 234.1618.

Preparation of the p*-nitrobenzoate* ***69***

To a solution of the diene **64** (215 mg, 0.613 mmol) in dry THF (10 mL) was added a solution of n-Bu_4NF in THF (1.23 mL of a 1 M solution, 2 equiv.). The resulting mixture was stirred at room temperature for 3 h and then was poured into water (25 mL). The organic phase was removed and the aqueous phase was extracted with Et_2O (2 × 25 mL). The combined organic phases were dried ($MgSO_4$) and concentrated. The residual oil was dissolved in dry CH_2Cl_2 (20 mL). To the resulting solution of the alcohol **68** was added, sequentially, Et_3N (1.53 mL, 1.23 mmol), 4-*N*,*N*-(dimethylamino)pyridine (7 mg, 0.06 mmol), and *p*-nitrobenzoyl chloride (153 mg, 0.41 mmol). The mixture was stirred for 15 min and then was poured into water (25 mL). The layers were separated and the aqueous phase was extracted with CH_2Cl_2 (2 × 25 mL). The combined organic phases were dried ($MgSO_4$) and concentrated. Flash chromatography (27 g of silica gel, 8:1 petroleum ether – Et_2O) provided 94 mg (45%) of the diester **69**, which exhibited mp 131–132°C (from hexane); ir ($CHCl_3$): 1719, 1609, 1530, 1347 cm^{-1}; ^{1}H nmr (400 MHz) δ: 1.40–2.40 (m, 12H), 3.62 (s, 3H), 5.00 (ddd, 1H, J = 2, 6, 12 Hz), 5.07 (dd, 1H, J = 7.5, 12 Hz), 5.50 (ddd, 1H, J = 1.5, 6, 7.5 Hz), 5.66 (dd, 1H, J = 3, 4 Hz), 8.24 (d, 2H, J = 9 Hz), 8.29 (d, 2H, J = 9 Hz); ^{13}C nmr (75.3 MHz) δ: 18.9, 24.3, 25.6, 35.7, 36.9, 38.1, 49.4, 51.8, 63.9, 118.1, 123.4, 127.5, 130.6, 135.7, 135.9, 146.6, 150.4, 164.6, 176.4. Exact Mass calcd. for $C_{21}H_{23}NO_6$: 385.1525; found: 385.1531. Anal. calcd. C 65.44, H 6.02, N 3.63; found: C 65.36, H 5.94, N 3.48.

X-ray crystallographic analysis of the p-*nitrobenzoate* ***69***

Crystallographic data appear in Table 3. Final unit-cell parameters were obtained by least squares on 2 sin θ/λ values for 25 reflections with 2θ = 30–40°. The intensities of three standard reflections, measured each 4000 s of X-ray exposure time throughout the data collection, showed only small random fluctuations. The data were corrected for Lorentz and polarization effects but, in view of the low value of μ, not for absorption.[5]

The structure analysis was initiated in the centrosymmetric space group $P\bar{1}$, this choice being verified by subsequent calculations. The structure was solved by direct methods, the coordinates of all non-hydrogen atoms being determined from an *E*-map. In the final stages of full-matrix least-squares refinement the non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were fixed in idealized positions (methyl orientation based on observed positions, C(sp^2)—H = 0.97 Å, C(sp^3)—H = 0.98 Å, $U_H \propto U_{\text{bonded atom}}$). Neutral atom scattering factors were taken from ref. 17. Final positional and equivalent isotropic thermal parameters ($U_{eq} = \frac{1}{3}$ trace of diagonalized U) for the non-hydrogen atoms are listed in Table 4. Bond lengths and angles are given in Tables 5 and 6, respectively. Hydrogen atom parameters, anisotropic thermal parameters, intra-annular torsional angles, a complete listing of torsion angles, and measured and calculated structure factors (Tables S1–S5) have been supplied as supplementary material.[6]

[5]The computer programs used include locally written programs for data processing and locally modified versions of the following: ORFLS, full-matrix least squares, and ORFFE, function and errors, by W. R. Busing, K. O. Martin, and H. A. Levy; FORDAP, Patterson and Fourier syntheses, by A. Zalkin; ORTEP II, illustrations, by C. K. Johnson; AGNOST, absorption corrections, by J. A. Ibers; MULTAN 80, multisolution program by P. Main, S. J. Fiske, S. E. Hull, L. Lessinger, G. Germain, J. P. Declercq, and M. M. Woolfson.

[6]These data may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2.

Table S1 (hydrogen atom parameters) has also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from the Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, Lensfield Road, Cambridge, CB2 1EW, U.K.

Received August 8, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

OLIVER E. EDWARDS, DUSAN DVORNIK, RALPH J. KOLT, and BARBARA A. BLACKWELL. Can. J. Chem. **70**, 1397 (1992).

Imines derived from the alkaloid atisine gave *N*-acetyl 1,20-cycloatidane derivatives when heated with acetic anhydride. Vigorous alkaline hydrolysis cleaved the cyclopropane ring, regenerating the parent imine. The ^1H and ^{13}C NMR spectra of several 1,20-cyclo derivatives have been assigned and compared to those of the parent imines **2**. All of the *N*-acetyl compounds showed doubling of the majority of the NMR resonances, due to amide rotamers. The effects of the cyclopropane ring current are noted.

OLIVER E. EDWARDS, DUSAN DVORNIK, RALPH J. KOLT et BARBARA A. BLACKWELL. Can. J. Chem. **70**, 1397 (1992).

Par chauffage avec l'anhydride acétique, des imines provenant de l'alcaloïde atisine conduisent à des dérivés du *N*-acétyl 1,20-cycloatidane. Une hydrolyse alcaline vigoreuse coupe le cyclopropane en régénérant l'imine de départ. On a attribué les spectres RMN du ^1H et du ^{13}C de plusieurs dérivés 1,20-cyclo et on les a comparés à ceux des imines parentes **2**. Dans les spectres RMN des composés *N*-acétylés, on observe pratiquement toujours un dédoublement des résonances; ce résultat est attribuable à la présence des rotamères de l'amide. On a noté les effets du courant de cycle du cyclopropane.

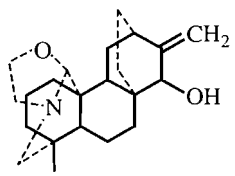
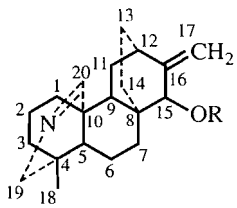
During the course of our early work on the structure of atisine **1** and related diterpenoid alkaloids, attempts were made to use the readily available (1) imine (azomethine) **2** to obtain the nitrogen-free skeleton. One of these approaches succeeded (2), but another, based on a hoped-for

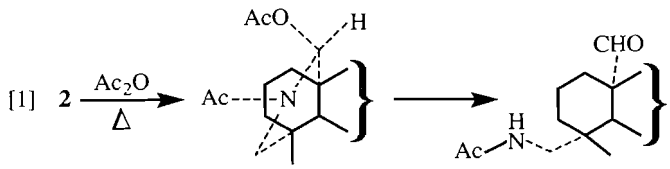


1



2

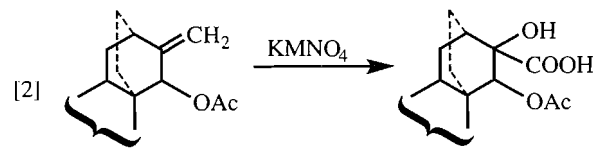
sequence shown in eq. [1], was abortive (3). This paper deals with the structure of the major product formed in the reac-



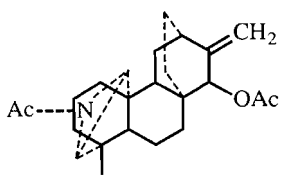
tion with acetic anhydride, and its anomalous alkaline cleavage to parent imino alcohol **2** (R=H).

Results

The main product formed when **2** was heated in refluxing acetic anhydride for 20 h was an *O*,*N*-diacetyl compound (neutral, ν_{max} 1725 and 1630 cm^{-1}) analysing for $C_{24}H_{33}NO_3$. This result was confirmed by Pelletier and Parthasarathy (4). Thus it did not have the new *O*-acetyl group expected from eq. [1]. The formula required that a new double bond or ring had been formed, since the infrared spectrum showed the exocyclic methylene to be unchanged. Oxidation of the product with potassium permanganate gave a hydroxy acid analyzing for $C_{24}H_{33}NO_6$. This, and the analyses and IR spectra of its methyl ester and the dihydroxy acid produced by gentle alkaline hydrolysis, indicated that only the allyl acetate group had been oxidized as in eq. [2], and hence confirmed this function was intact in the unknown product.



Finally, a 60 MHz ^1H NMR spectrum indicated the absence of any new vinyl hydrogen. Thus it appeared that a new ring had been formed. It was suggested that this was an aziridine ring and that the product from **2** had structure **3** (3).



3

The formation of **3** and its hydrolysis under vigorous alkaline conditions back to **2** (R=H) could be rationalized (3).

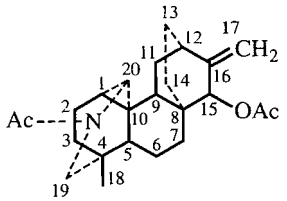
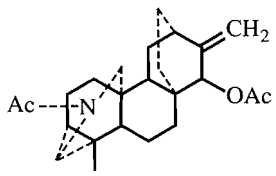
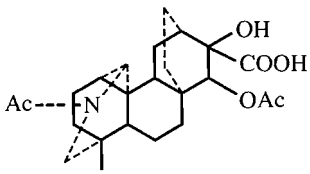
However, reinvestigation of the problem using more sophisticated NMR equipment and techniques showed clearly that three hydrogens were present on carbons attached to nitrogen (δ 2.6–3.9) instead of the two required for **3**. It was thus clear that a new carbocyclic ring was present instead of the aziridine ring. Mechanistic considerations (see discussion) and the spectra (^{13}C NMR showed the sequence -CH_2-NAc-CH-) suggested structures **4** (R=Ac) or **5** for the product, with **4** strongly favoured. Finally an X-ray crystallographic analysis confirmed that structure **4** (*N*-acetyl



4



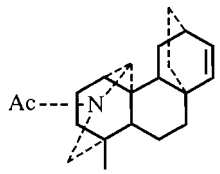
5



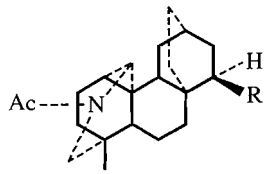
6

15-acetoxy-1,20-cyclo-16,17-didehydro-4-methylatidane) was correct (5). The hydroxy acid derived from **4** thus had structure **6**. Simplified analogues of **4**, compounds **7**, **8**, and **9**, were prepared in early studies of the reaction.

The slow hydrolysis of **4** in triethylene glycol containing potassium hydroxide at 150°C to give imino alcohol **2** (R=H) was confirmed repeatedly.



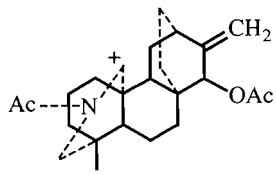
7



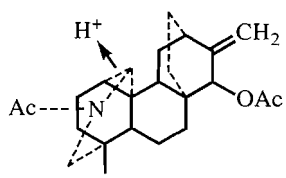
8 R = H
9 R = OAc

Discussion

The first reactive intermediate in the formation of **4** was undoubtedly the *N*-acetyl cation **10** (some charge delocalization onto nitrogen). The formation of a cyclopropane ring

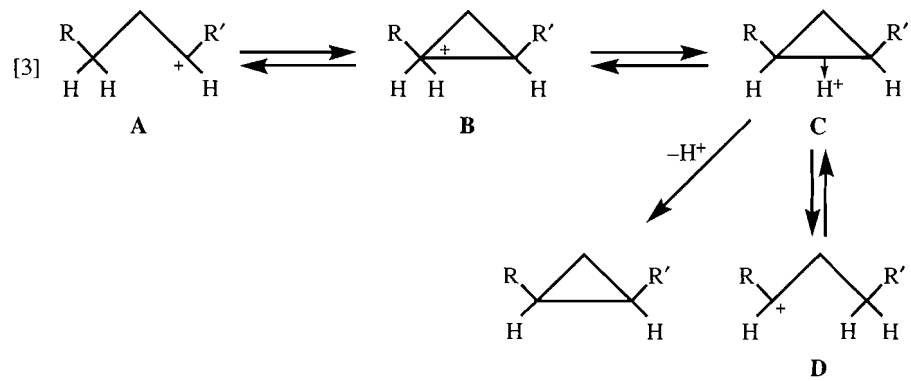


10



11

from such a cation has parallels in the chemistry of monoterpenes and the behaviour of α-acyl carbocations (6, 7). The biochemical formation of cyclopropane rings is a vital part of the squalene-to-steroid pathway in plants. However, attempts to duplicate this in the laboratory have so far failed (8). Thus a delicate balance seems to exist between an initial cation **A**, corner-protonated cyclopropane **B**, edge-protonated cyclopropane **C**, and rearranged (Wagner–Meerwein) cation **D** as illustrated in eq. [3]. The counterion or sol-



[3]

A **B** **C** **D**

vent can capture ions **A** and **D** or remove a proton from **C** to give the cyclopropane (6). The edge-protonated cyclopropane precursor to **4** would be cation **11**.

The alkaline hydrolysis of **4** to give **2** (R=H) was surprising. It was first discovered when **4** was subjected to Wolff–Kischner reduction conditions in the hope that the compound had the amido aldehyde structure shown in eq. [1]. We view the cleavage as an analogue of the Haller–Bauer fission of non-enolizable ketones (9). The ready base-initiated cleavage of cyclopropanes with heavy electronegative loading is a well-known phenomenon (10).

Thus the process can be visualized as attack of hydroxide ion on **4** to give anion **12**, followed by cleavage to anion **13**. Then proton abstraction from solvent would give **2** (R=H) (eq. [4]). The overall conversion to **4** and reversion to **2** is efficient enough (30%) that the reaction could be used as a method of masking the reactive imine function while other transformations were carried out on the molecule.

12 **13**

NMR spectra

The ^{13}C and ^{1}H NMR spectral assignments for the parent azomethine **2**, the 1,20-cyclo amides **4**, **7**, **8**, and **9**, and the

For personal use only.

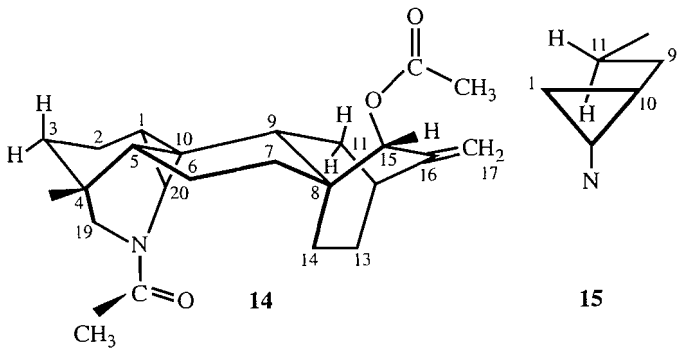
reference *N*-acetyl compound **16** determined by a variety of 2D NMR experiments are given in Tables 1 and 2. The spectra of the *N*-acetyl 1,20-cyclo derivatives are noteworthy because of the long-range effects of the *N*-acetyl group, the anisotropic shielding due to this group, and a marked shielding by the cyclopropane ring. Molecular models suggested that **16** had a normal chair conformation for ring A in contrast to the 1,20-cyclo cases in which ring A is considerably flattened (5). This probably results in moving the *N*-acetyl group closer to ring B, with some effect on chemical shifts.

The NMR spectra of the starting material (**2**) showed the presence of only one form in solution ($CDCl_3$) and therefore was the simplest to assign. The ^{13}C assignments afforded by $^1H/^1H$ and $^1H/^{13}C$ correlation spectra agreed for the most part with those previously reported by Mody and Pelletier (11). The only exception was a reversal of the assignments to C-1 and C-3. The $^1H/^1H$ correlation spectrum discriminates between the spin systems on carbons 1, 2, and 3 and those on 5, 6, and 7. This enabled assignment of resonances at 1.3 and 1.44 ppm to H-2 and at 1.05 and 1.55 ppm to C-6. These resonances correlate in the HETCOR spectrum with methylenic resonances at 20.1 and 19.5 ppm respectively. The assignment of H-5 to 0.99 ppm is confirmed by the presence of W-coupling to H-20. C-1 and C-3 are distinguished by the presence of W-coupling of the protons of position 3 to those on C-19. These H-3 signals at 1.2 and 1.4 ppm correlate to the carbon resonance at 42.4 ppm. The anisotropy of the C=N group seems responsible for the rather large chemical shift difference between the α and β hydrogens[3] on C-6 (0.5 ppm) and C-7 (0.65 ppm). The assignment of the quaternary positions C-4, C-8, and C-10 was confirmed by heteronuclear correlation optimized for long-range coupling. The resonance at 42.5 ppm showed correlation to proton resonances assigned to H-1, H-9, and CH_3-18, while the resonance at 37.9 ppm showed correlation to proton resonances assigned to H-15, H-14, H-11, and H-6, thus enabling assignment of these resonances to C-10 and C-8, respectively. The assignment of C-4 to the quaternary resonance at 32.3 ppm is confirmed by correlation to the protons on C-5 and C-18.

A major feature of the NMR spectra of the *N*-acetyl derivatives near room temperature is the doubling of most signals due to the presence of two rotamers about the CO-N bonds (Tables 1 and 2). The effect is most marked for those resonances in close proximity to the nitrogen, i.e., positions 19 and 20, as well as 18, 4, and 10, but extends even to position 17. The extent of doubling is more easily seen in the ^{13}C spectra, since the ^1H spectra are complicated by homonuclear coupling and extensive overlap in the methylene region. The effect of the cyclopropane ring is seen by comparing the chemical shift assignments of compounds **2** and **16** with **4**.

The NMR spectra of **4** were assigned by a combination of techniques. The combined information from DEPT and $^1H/^{13}C$ correlation spectra permitted the assignment of the methylene protons in the highly overlapped region (0.5–2.5 ppm) in the ^1H spectrum. $^1H/^1H$ correlation and RELAY spectra distinguished between the coupled systems H-1, H-2, and H-3; H-5, H-6, and H-7; and H-12, H-13, H-14, which are the three similar $CH\text{-}CH_2\text{-}CH_2$ systems in the molecule. Finally, a long-range heteronuclear correlation spectrum confirmed the assignment of the quaternary carbons. The $^1H/^{13}C$ correlation spectrum of **4** (Fig. 1) illustrates these points. The projections of the spectrum are the single pulse $^1H/^{13}C$ spectra that show the effect of the amide anisotropy. Every ^{13}C resonance is doubled, with the exception of the methyl resonance of the OAc group, the effect varying from 3 ppm at C-19 to 0.1–0.2 ppm at C-8 and C-9. In general, the effect decreases with distance from the amide bond. However, some unusually long-range effects occur at C-7 (0.7 ppm), C-13 (0.6 ppm), and C-17 (0.5 ppm). The population of the rotamers in deuterochloroform is approximately 2:1. The ^1H spectra of the *N*-acetyl compounds were also doubled where the signals were simple enough to permit analysis (Table 1). Again the most dramatic shifts were for hydrogens close to the amide function, but the effects were noted as distant as C-17.

A parallel observation was made earlier on the long-range effect of remote polar substituents in rigid molecules on the pK_a of a basic nitrogen (3, 13). Three possible causes of these effects could exist: through bond effects, *trans* spatial effects through the centre of the molecule, or solvent shell reorganization. In view of the long-range effects observed, and the fact that these effects vary with solvent, we now favour the latter possibility. Figure 2 shows the effect of temperature on the rotamer population of **4** in dimethylformamide (DMF). The ^1H and ^{13}C spectra at room temperature (30°C, A and B) again show doubling, although the rotamer population in this solvent is now 1:1, and the magnitude of the effect as seen on the resonances due to H-15 and H-17 is different. At 125°C (C and D), the doubling collapses reversibly and there are some temperature-induced chemical shifts. Thus the barrier to rotation in the amide is large. However an X-ray crystallographic study of compound **4** showed that it crystallizes as one amide rotamer (5). The



14 **15**

^1H NMR data for **4** show that H-20 of the major isomer in solution resonates at higher field than the minor isomer (3.8 ppm). In addition, the chemical shift difference for the two hydrogens on C-19 is much larger (0.7 ppm) for the major isomer than for the minor one (0.2 ppm). This would be expected if the dominant isomer was one in which the carbonyl of the *N*-acetyl group was oriented towards C-19. Thus the dominant rotamer in deuterochloroform is the opposite to the one observed for the crystals (5) (see **14**).

The cyclopropane ring of the 1,20-cyclo compounds had two important effects on the ^1H NMR spectra. The well-known effect on protons attached to the ring resulted in upfield shifts of H-1 to near 0.9 ppm and of H-20 to near

[3]Although atisine belongs to the *ent* series, we have used α and β in the original steroid sense, i.e., below and above the main plane of the molecule.

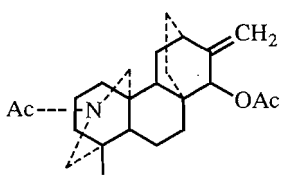
2.9 ppm in the major rotamer. The second major effect was on the 11α hydrogen. As illustrated in **15** this hydrogen is close to and orthogonal to the plane of the cyclopropane ring. As was observed earlier (12), the cyclopropane "ring current" shields this zone. As a consequence the 11α hydrogens resonate between 0.5 and 0.75 ppm in the major rotamers (Table 1). The magnitude and sign of the smaller effect on the other hydrogens is made uncertain by changing proximity of these to the amide group in the 1,20-cyclo compounds compared to the reference amide **16**.



16

The H-5 resonance shifts from 0.95 in **16** to near 1.4 in the 1,20-cyclo examples. Since not much effect from the ring current is expected, it appears that a change in relation to the anisotropic amide function as ring A flattens in the 1,20-cyclo compounds is responsible for this (see above).

In all the compounds studied there was a large geminal shift difference (ca. 1 ppm) between the 14-hydrogens. This is a consequence of the proximity of the 14α hydrogen to the C=N or amide functions, resulting in marked shielding (see ref. 5). Similar proximity between hydrogens on 14 and 20 has been invoked to account for the abnormal basic strength of atisine-type oxazolidines (3, 13) (note the numbering change).

Comparison of the ^{13}C NMR spectra of the 1,20-cyclo amides with **16** reveals the expected large upfield shift for C-1 (to ca. 13 ppm), C-10 (to 23 ppm), and C-20 (to 35 ppm). The C-2 and C-5 resonances are affected to a lesser extent (ca. 4 ppm upfield shift) while C-9 is more influenced by substituents in ring D. Both C-2 and C-6 resonances are at high field, probably as a result of shielding by either the C=N or *N*-acetyl groups. The reversal of assignment for these carbons for **16** needs justification. The homo- and heteronuclear correlation spectra of **16** showed clearly that the resonances at 17.4 ppm correlated with proton resonances at 1.4 and 1.5 ppm. Since these were coupled to H-5 at 0.95 ppm, this confirms the assignment of this signal to C-6, hence the signal at 20.9 to C-2. Again we suggest that **16** has ring A in a chair conformation with the *N*-acetyl group closer to ring A than in the 1,20-cyclo analogues, resulting in the changed shielding.

Experimental

Infrared spectra were obtained on a Perkin–Elmer model 683 grating spectrophotometer in dichloromethane solutions, unless

otherwise indicated. Initial NMR spectra were obtained on Varian EM360 and Bruker WP80 spectrometers. For assignment purposes, ^1H and ^{13}C NMR spectra were obtained at 500.13 and 125.77 MHz, respectively, on a Bruker AM 500 spectrometer. Samples of 10–20 mg were dissolved in deuterochloroform and chemical shifts are referenced to $CDCl_3$ at 7.24 ppm and 77.0 ppm for ^1H and ^{13}C, respectively, and are reported relative to tetramethylsilane (TMS). ^1H NMR assignments were made using $^1H/^1H$ homonuclear shift correlation (COSY-45) and, occasionally, relayed coherence transfer (RELAY). In all cases, the data matrix was acquired as 512W by 2KW data set and zero-filled in $F1$ to give a final digital resolution of 1.8 Hz/pt. ^{13}C NMR spectra were assigned with the aid of DEPT and $^1H/^{13}C$ correlation spectra (HETCOR). HETCOR spectra were acquired as 256 FID's of 4K each. Sine-bell squared functions shifted $\pi/4$ in $F1$ and $\pi/2$ in $F2$ were used for processing. The matrix was zero-filled in $F1$ and spectra were plotted as power spectra. The resolution was sufficient to assign the rotamer pairs belonging to each position in compounds **4**, **8**, and **16**. The assignments of the quaternary carbons 4, 8, and 10 in compounds **2** and **4** were confirmed using heteronuclear correlation optimized for long-range coupling acquired in inverse mode. Over a narrow ^{13}C sweep width (15–50 ppm), 128 FID's of 2K each were obtained, using a 0.7 s delay optimizing for J_{CH} = 7 Hz. ^1H NMR spectra in the text were observed at 60 MHz unless otherwise indicated.

Azomethine acetate 2 (R=Ac)

This was prepared as described earlier (1). An 80% yield was obtained after purification. It had mp 151–153°C and gave ^1H NMR signals at 7.85 (1H, brs), 5.13 (1H, brs), 4.97 (1H, brs), 3.37 (2H, brs), 2.13 (3H, s), and 0.80 (3H, s). A modified version of this internal Hoffman reaction was reported by Mody and Pelletier (11) to give a 91% yield.

Azomethine alcohol 2 (R=H)

Hydrolysis of **2** (R=Ac) using KOH in refluxing methanol gave the alcohol. It formed shimmering plates from acetone, mp 179–180°C, and gave ^1H NMR signals (250 MHz, C_6D_6) at 7.91 (1H, q, J_1 = 4, J_2 = 2 Hz), 5.12 (1H, t, J = 1.7 Hz), 4.98 (1H, t, J = 1.9 Hz), 3.63 (1H, brs, OH), 3.48 (2H, d, J = 2.6 Hz), 2.58 (1H, brs), 2.15 (1H, t, J = 2.9 Hz), and 0.64 (3H, s). Its ^{13}C spectrum is given in Table 2.

N-Acetyl 15-acetoxy-1,20-cyclo-16,17-didehydro-4-methylatidane (4, R=Ac)

The initial experiments leading to **4** involved heating **2** in 17% (v/v) acetic acid in acetic anhydride containing 4% by weight of sodium acetate at 145°C for 24 h. When the sodium acetate, then the acetic acid, were eliminated the yield increased moderately.

Azomethine acetate **2** (R=Ac) (519 mg) in 8 mL of acetic acid was kept in a bath at 145–150°C for 27.5 hr. The mixture was then evaporated to a thick syrup at 60°C under 0.5 Torr (1 Torr = 133.3 Pa). The residue was heated for 15 min in methanol, then the solvent removed *in vacuo*. The product was dissolved in 15 mL of dichloromethane. Two extractions with 5-mL portions of 6 N sulfuric acid were followed by a sodium carbonate wash (emulsion, centrifuged). The aqueous layers were reextracted with 10 mL of dichloromethane. The combined dichloromethane solutions yielded 685 mg of gum. This crystallized from acetone–hexane solution giving 445 mg of crude **4** (R=Ac). After recrystallization, and recovery of more material from mother liquors by separation on silica gel plates using 20% hexane in ethyl acetate, 299 mg (51%) of nearly pure *N*-acetyl cyclopropane acetate was obtained (mp 195–198°C). No other neutral product was characterized.

Further recrystallization from acetone – ethyl acetate gave **4** (R=Ac) as laths with mp 196–199°C. It had $[\alpha]_D$ +80 (*c* 1.0 in ethanol) and ν_{max} ($CHCl_3$): 1725, 1630, and 905 cm^{-1}. Its ^1H NMR spectrum had signals at δ: 5.25 (1H, brs), 5.07–4.83 (2H, m), 3.9–3.35 (1H, m), 3.2–2.6 (2H, m), 2.16 (6H, s), and 0.87 (3H, s). Its ^{13}C NMR spectrum (125 MHz) is reported in Table 2. Anal. calcd. for $C_{24}H_{33}NO_3$: C 75.16, H 8.67, N 3.65; found: C 75.07, H 8.73, N 3.58.

N-Acetyl 1,20-cyclo-15-hydroxy-16,17-didehydro-4-methylatidane (4, R=H)

Hydrolysis of acetate **4** (R=Ac) using a refluxing solution of KOH in 90% methanol – 10% water, then chromatography on a 20-fold ratio of neutral alumina (act. 2–3) gave a 61% yield of nearly pure alcohol, mp 188°C. Recrystallization from methanol–

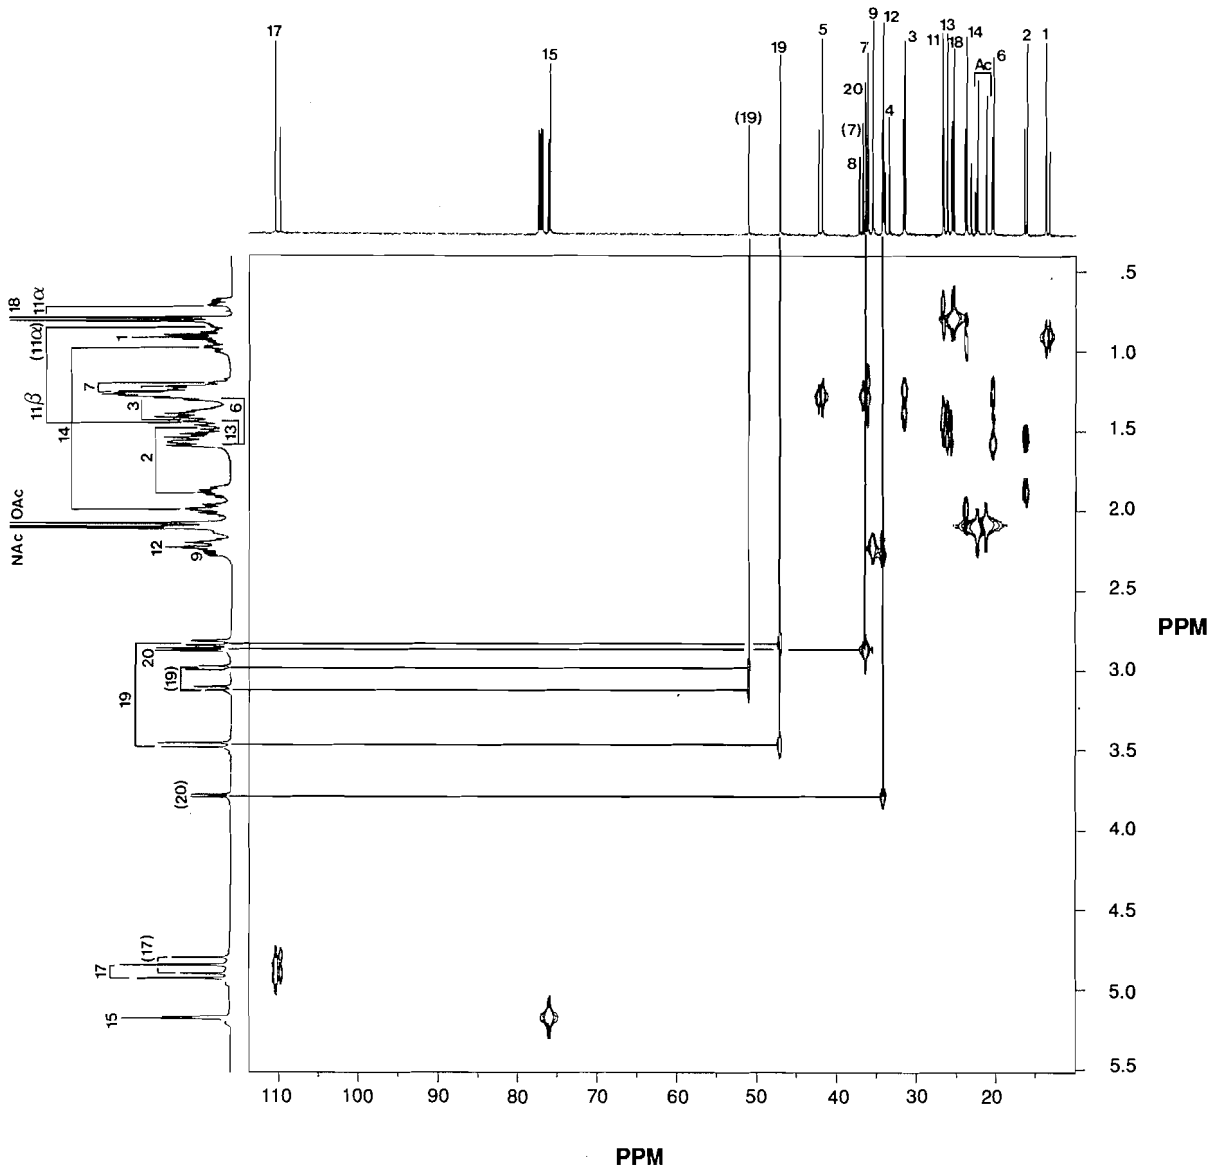

FIG. 1. $^{13}C/^{1}H$ correlation spectrum of **4** acquired in $CDCl_3$. The projections are shown as the single pulse spectra. The presence of the two rotamers can be seen in both spectra, and the assignment of resonances of the minor component are shown in parentheses, for those resonances close to the amide bond. The correlation spectrum resolves the highly overlapped methylene protons in the 0.5–2.5 ppm range of the ^{1}H spectrum.

ether gave pure material with mp 193–194°C (lit. (4) mp 191–192°C). This had ν_{max} (CH_2Cl_2): 3590, 3410, and 1630 cm^{-1}; and ^{1}H NMR signals at δ: 4.9–5.2 (2H, m), 3.6–4.0 (1H, m), 2.6–3.2 (2H, m), 2.16 (3H, s), and 0.87 (3H, s).

Carboxylic acid **6**

A mixture of 18 mL of acetone, 2 mL of water, and 0.5 mL of acetic acid was prepared. The *N*-acetylcyclopropane acetate **4** (R=Ac) (185 mg) was dissolved in 5 mL of this mixture. A solution of 400 mg of potassium permanganate in 10 mL of the above solvent mixture was prepared. Five milliliters of the permanganate solution was added to the solution of **4**. After 3 h, 2 mL of permanganate solution was added. An excess oxidant was still present after a further 5.5 h. This was reduced using aqueous sodium hydrogen sulfite, then the manganese dioxide removed by filtration. The filtrate and acetone washings were evaporated under reduced pressure, then the residue was taken up in dichloromethane. Acids were extracted into dilute aqueous sodium carbonate solution. The residual neutral material weighed 66 mg (some unchanged **4**). The carbonate solutions yielded 122 mg of acids that crystallized readily from acetone. The crystalline acid (79 mg) had mp 238–247°C. Recrystallization from methanol gave a product with mp 246–247°C (dec.) and ν_{max} (Nujol): 3460, 1742, 1719, 1620, and 1238 cm^{-1}. Anal. (dried 25 h at 100°C, 10^{-3} Torr) calcd. for $C_{24}H_{33}NO_6$: C 66.80, H 7.71; found: C 67.22, H 7.74.

Its methyl ester (CH_2N_2) crystallized from methanol–ether mixtures with mp 210°C. It had ν_{max} (Nujol): 3230, 1750 (sh), 1735, and 1647 cm^{-1}. Anal. calcd. for $C_{25}H_{35}NO_6$: 1-OCH_3 6.95; found: OCH_3 7.02.

Dihydroxy acid **6** *(15-hydroxyl)*

Hydrolysis of acetoxy acid **6** (R^1=H, R^2=Ac) for 1 h in refluxing methanol containing potassium hydroxide gave the dihydroxy acid. After recrystallization from acetone this had mp 222–227°C and ν_{max} (Nujol): 3060 (br) 1743, 1632, and 1248 cm^{-1}. Anal. calcd. for $C_{22}H_{31}NO_5$: C 67.84, H 8.02; found: C 67.90, H 8.01.

Vigorous alkaline treatment of **4** *(R=Ac)*

Crushed potassium hydroxide pellets (749 mg) were added to a solution of 124 mg of **4** (R=Ac) (mp 195°C) in 4 mL of triethy-

lene glycol. The mixture was heated under argon in a bath at 174°C for 23 h. The dark solution was cooled, diluted with 10 mL of water, then the products extracted into benzene (3 × 5 mL). The combined benzene layers were extracted twice with 5-mL portions of 3 N sulfuric acid. The aqueous layers were made basic using sodium carbonate, then the bases were extracted into dichloromethane. The 87 mg of base so obtained crystallized from hexane containing a few percent of acetone, yielding 38 mg of **2** (R=H), mp 167–169°C. Separation of the mother liquors on a 500 μm SiO_2 plate using 5% pyridine and 2.5% methanol in dichloromethane gave 6 mg (R_f 0.7) rich in **2**. The yield of moderately pure **2** (R=H) was thus 54%. In comparable runs the yield never exceeded 64% based on unrecovered neutral products. However, one of the contaminants of the crude bases was shown to be **4** (R=H), making the true yield higher.

Further plate purification as above, and recrystallization from acetone–hexane, gave crystals of base (shimmering plates) with mp 176–177°C. It showed no mixture mp depression with authentic **2** (R=H), had $[\alpha]_D$ −13 (*c* 1.1 in absolute ethanol), and gave identical IR spectrum and ^1H and ^{13}C NMR spectra in benzene-d_6.

N-*Acetyl 1,20-cyclo-15,16-didehydro-17-nor-4-methylatidane 7*

The azomethine *N*,20,15,16-tetradehydro-17-nor-4-methylatidane (1) (151 mg) in 4.5 mL of 15% acetic acid in acetic anhydride (v/v) was held at 140°C for 24 h in a sealed tube under nitrogen. Work-up as for **4** gave 138 mg of neutral product, which crystallized. After three recrystallizations from aqueous acetone, **7** (41 mg) had mp 152–153°C and ν_{max} (Nujol): 1649 cm^{-1}. Its ^1H NMR spectrum gave signals at δ: 6.45–5.7 (2H, m), 3.9–2.6 (3H, m), 2.17 (3H, s), 0.84 (3H, s). Its ^{13}C nmr spectrum is given in Table 2. Anal. calcd. for $C_{21}H_{29}NO$: C 80.98, H 9.39; found: C 80.77, H 9.28.

N-*Acetyl 1,20-cyclo-17-nor-4-methylatidane 8*

The azomethine *N*,20-didehydro-17-nor-4-methylatidane (126 mg) (1) was heated under reflux for 23 h in 17% acetic acid in acetic anhydride (v/v). Work-up as for **4** gave a 94% yield of neutral product. This was purified by chromatography on a 20-fold ratio of neutral alumina activity III. The hexane and 1:1 benzene–hexane eluates (80 mg) crystallized from aqueous acetone, giving **8** with mp 152–154°C and ν_{max} (Nujol): 1645 cm^{-1}. It gave ^1H NMR signals at δ: 3.9–3.35 (1H, m), 3.2–2.6 (2H, m), 2.16 (3H, s), and 0.84 (3H, s). Anal. calcd. for $C_{21}H_{31}NO$: C 80.46, H 9.97; found: C 80.36, H 9.88.

N-*Acetyl 15-acetoxy-1,20-cyclo-17-nor-4-methylatidane 9*

The azomethine *N*,20-didehydro-15-hydroxy-17-nor-4-methyl atidane (1) (185 mg) in 2 mL of acetic anhydride was heated in a bath at 150°C for 24 h under argon. The brown solution was worked up as for **4**, giving 8 mg of base and 200 mg of neutral product. The latter was purified on two 20 cm × 20 cm 1000 μm silica gel plates using 5% methanol in chloroform. The main zone (R_f 0.75) gave 155 mg of nearly pure **9**. The preceding zone (30 mg) contained around 20% of **9** and two faster-moving products. The estimated yield of **9** was 71% based on unrecovered base. It could be distilled over a short path at 170°C, 0.1 Torr, or freed from a trace of colour by passage of a dichloromethane solution through a short bed of Act. II neutral alumina. After long standing it crystallized, forming prisms from ethyl acetate – heptane, mp 156–159°C. It gave ^1H NMR signals at δ: 4.60 (1H, q, J_1 = 10, J_2 = 3 Hz) 3.9–2.8 (3H, m), 2.19, 2.18, 2.09, 2.10, 2.19, 2.18 (6H), 0.89, 0.87 (3H singlets), 0.69–0.61. Its EI mass spectrum gave peaks at 371.2504 ($C_{23}H_{33}NO_3$ requires 371.2462), 329.236 [M − CH_2CO]$^+$, and 311.2277 [M − CH_3COOH]$^+$.

N-*Acetyl 15-acetoxy-16,17-didehydro-4-methylatidane 16*

Excess sodium borohydride reduced imine **2** in methanol to give the corresponding secondary amine (partial hydrolysis of the ester). The product was acetylated at room temperature, using acetic anhydride in pyridine, during 22 h. The reagents were removed under reduced pressure, traces of anhydride destroyed using methanol, then a dichloromethane solution of the product was washed with dilute sulfuric acid, followed by sodium bicarbonate solution. The product **16** crystallized as rectangular plates from ethyl acetate, mp 165–167°C. Its ^1H NMR spectrum had signals at δ: 5.05 (1H, s), 5.0–4.8 (2H, m), 4.45–2.55 (3H, m), 2.4–2.3 (1H, m), 2.1, 2.06, 2.04 (6H), and 0.802, 0.805 (3H). Its ^{13}C NMR spectrum is given in Table 2. Its EI mass spectrum had a peak at *m/z* 385.26192. Exact Mass calcd. for $C_{24}H_{35}NO_3$: 385.26168.

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

JEAN-FRANÇOIS LAVALLÉE, CLAUDE SPINO, RÉJEAN RUEL, KEITH T. HOGAN, and PIERRE DESLONGCHAMPS. Can. J. Chem. **70**, 1406 (1992).

The base-catalyzed cycloaddition and double Michael cyclization of substituted Nazarov reagents and of 1-phenylsulfinyl analogs, with 2-carbomethoxy-2-cyclohexen-1-one **1** yielding *cis*-decalins is reported. The reaction is highly stereoselective affording *cis,cis*- or *cis,trans*-decalins. Mechanistic aspects are briefly discussed.

JEAN-FRANÇOIS LAVALLÉE, CLAUDE SPINO, RÉJEAN RUEL, KEITH T. HOGAN et PIERRE DESLONGCHAMPS. Can. J. Chem. **70**, 1406 (1992).

On décrit la cycloaddition catalysée par des bases des réactifs de Nazarov substitués, ainsi que d'un analogue 1-phénylsulfinylé, avec la 2-carbométhoxy-2-cyclohexénone **1** produisant des *cis*-décalines. La réaction est hautement stéréosélective générant des *cis,cis*- ou *cis,trans*-décalines. Les mécanismes de ces réactions sont brièvement discutés.

Introduction

Substituted decalins have been prepared in a number of ways, among which the Robinson annelation and the Diels–Alder cycloaddition occupy a prominent place (1). Whereas the Robinson annelation usually gives rise to dehydrodecalins with one new asymmetric center, the Diels–Alder cycloaddition can produce *cis*-decalin systems with the introduction of up to four asymmetric centers. Decalins have been used extensively as intermediates in the synthesis of numerous natural products, in particular terpenoids and steroids (1). Thus, the stereocontrolled synthesis of substituted decalins is highly desired. Decalins with a β-alkyl substituent at C8 (*cis,cis*-decalins) have been prepared via a Lewis acid-catalyzed Diels–Alder cycloaddition of 2-carbomethoxy-2-cyclohexenone **1** (2) and various substituted 1,3-dienes (3). The stereocontrol at the C8-substituent was in the order of 7:1 in favor of the more desirable β isomer.

In a preliminary communication we reported the highly stereoselective synthesis of *cis,cis*-decalins via a base-catalyzed [2+4] cycloaddition of substituted Nazarov reagents like **2** with 2-carbomethoxy-2-cyclohexenone **1** (4) (Scheme 1). We now wish to report a full account of this work, which includes cycloadditions between Nazarov reagents substituted at positions 4 and 5 and various substituted 2-cyclohexenones. Their use in the construction of polycyclic compounds as well as a novel synthesis of substituted Nazarov reagents (5) is also disclosed. In addition, the mechanistic aspect of the reaction is discussed briefly.

Results and discussion

Synthesis of Nazarov reagents

There are many ways to prepare substituted Nazarov reagents (6, 7). Bodalski and co-workers (7*a*) as well as Van Den Goorbergh and Van Der Gen (7*b*) report that substituted Nazarov reagents like **7** can be obtained in one step from the condensation of the phosphonate dianion derived from **6** and aldehydes or ketones (Scheme 2). We prepared the previously unknown *tert*-butyl γ-diethoxyphosphono β-keto esters **9***a* and **9***b* in 67 and 45% yields by *C*-phosphorylation of the dianion of β-keto esters **8***a* and **8***b*, respectively (8). The dianion of **9***a* (7*c*) was condensed with the known aldehyde **10***a* (9), to obtain the substituted Nazarov reagent **11***a* in 35% yield (Scheme 2). Also, substituted Nazarov reagents **11***b* and **11***c* were obtained in 76 and 33% yields, respectively, from the condensation of the dianion of **9***a* with aldehydes **10***b* and **10***c*. The latter were prepared in two standard steps from the corresponding diols. The dianions of phosphonate **9***a* and the methyl-substituted phosphonate **9***b* were condensed with aldehyde **12** to give, respectively, a 77 and 44% yield of the *trans* olefinic products **13***a* and **13***b* as the only detectable isomers. Aldehyde **12** was prepared in a 72% yield via the alkylation of the lithium salt of 1-trimethylsilylpropyne **14** with protected 3-bromo-1-tetrahydropyranyloxy-propane **15** followed by deprotection and oxidation of the resulting product. The cleavage of the silyl groups, in **13***a* and **13***b*, was effected in 90 and 86% yields, respectively, with tetrabutylammonium fluoride in tetrahydrofuran (THF) (10). Treating the resulting products with sodium hydride followed by butyllithium generated their dianion whose acylation with methyl chloroformate gave, respectively, 93 and 51% yields of the Nazarov reagents **16***a* and **16***b*. Selective catalytic hydrogenation of **16***a* gave **17**.

While this method proved to be highly selective and very expedient for the construction of Nazarov reagents with an *E*-double bond, the reaction proved sensitive to the presence of functional groups on the aldehyde, as well as substitution on the phosphonate reagent, giving somewhat lower yields (cf. **11***a*, **11***c*, and **13***b*). Another, more general, method for the preparation of Nazarov reagents is depicted in Scheme 3. For example, α,β-unsaturated aldehyde **18***a* was treated with the zinc enolate of *tert*-butyl bromoacetate **19** to produce the corresponding β-hydroxy ester, which was oxidized to the desired substituted Nazarov reagent **20***a* in a 61% overall yield by treatment with manganese dioxide in ethyl acetate. Nazarov reagents **20***b*–**20***d* were prepared by the same method from the known aldehydes **18***b*–**18***d* (for

(a) Cs_2CO_3 in solvent, 25°C, 3.5 h; (b) *p*-TsOH in benzene at reflux, 1.5 h; (c) Cs_2CO_3 in acetonitrile, −15°C, 0.5 h

SCHEME 1

18*c* see ref. 11) in 49, 45, and 57% overall yields, respectively. Aldehyde **18***e* was synthesized in a 68% overall yield by the reduction and protection of 2-bromocyclohexenone following lithiation and formylation, according to the method reported by Smith *et al.* (12). The reaction of **18***e* with the zinc enolate of **19**, followed by oxidation of the resulting β-hydroxy ester, gave β-keto ester **20***e* in a 62% yield for the two steps. Lastly, the aldehyde **18***f* was treated in the same manner to afford the Nazarov reagent **20***f* in a 41% overall yield. The aldehyde **18***f* was synthesized in six steps from methyl acetoacetate, as depicted in Scheme 4, in an overall yield of 30%.

The β-keto sulfoxide **26** could be prepared directly by the condensation of the anion of methylphenylsulfoxide **25** (13) with methyl crotonate in a 56% yield (Scheme 4). Oxidation of **26** with *m*-chloroperbenzoic acid in dichloromethane gave a 67% yield of β-keto sulfone **27**.

Cycloadditions with substituted Nazarov reagents

β-Keto esters

The base-catalyzed [2+4] cycloaddition of substituted Nazarov reagent **2** with 2-carbomethoxy-2-cyclohexenone **1** afforded, after decarboxylation with *p*-toluenesulfonic acid in refluxing benzene, the known (3) *cis,cis* and *cis,trans* bicyclic diketones **3** and **4** with a very high degree of stereoselectivity (4*a*, 8) (Scheme 1). The ratios were determined by gas chromatographic analysis and the results are summarized in Table 1. The selectivity of the reaction was found to be highly dependent on the solvent used (4*a*). The use of more polar solvents (entries 1, 2, and 3) led to mixtures of isomers **3** and **4**, whereas the use of less polar solvents (entries 5 and 6) gave almost exclusively the *cis,cis* isomers **3**. The best results were obtained using chloroform (entry 6), where the selectivity was greater than 99.5% with an overall yield of 69%. The counterion also had some effect on the selectivity, as can be seen from entry 2 vs. entry 3.

Adding a substituent on the diene at the 4-position had no effect on the selectivity of the reaction. The cycloaddition–decarboxylation sequence between β-keto ester **20***b* and dienophile **1** gave stereoselectivity, in 65% yield, the *cis*-decalins **28** and **29** in a 7:3 ratio (Scheme 5). In the case of **20***c* the two isomers **30** and **31** were isolated in 66% yield in a 1:1 ratio. Each of those four isomers could be isolated in pure form by flash chromatography. The ratios obtained are a reflection of the equilibrium mixture, since the same ratios of isomers **28** and **29**, as well as **30** and **31**, were recovered when each of these compounds was separately resubmitted to the acidic decarboxylation conditions. The structure and stereochemistry of **30** and **31** were assigned based on a single crystal X-ray crystallographic analysis of **30** (14) and ^1H nmr data. The structures of **28** and **29** were based on the following ^1H nmr experiments: irradiation of one of the methyls on the major isomer **28** revealed a doublet at 3.07 ppm of $J = 5$ Hz. This coupling constant must be that of H_b and H_c (Fig. 1), thereby establishing the *cis* relationship of the two methyl groups. The same experiment with **29** clearly showed the *trans* arrangement of the two methyls by virtue of a 13 Hz coupling between protons H_b and H_c.

The fact that **28** was formed in preference to **29** in equilibrating acidic media tends to show that C8-substituted *cis*-decalins like **3** adopt conformation **A** rather than conformation **B** (R^2 = H, Fig. 1). This was supported by MM2 calculations, which indicated that **28** in conformation **A** is more stable than **29** in conformation **B** by a value of 1.8 kcal/mol. It was also possible to correlate the ^1H nmr chemical shifts of H_b and the C8-methyl group in the different adducts to those of compounds **28** and **29**. Table 2 lists the chemical shifts of these protons for the different adducts. The C8-methyl resonates below 1.0 ppm in compounds thought to have the stereochemistry shown in **A** and above 1.0 ppm in those having the stereochemistry shown in **B**. Proton H_b in compounds of conformation **A** resonances at a higher field than expected for a proton in such a chemical environment (above 2.5 ppm), probably due to the deshielding anisotropic effect of the C1-carbonyl. The same proton is found below 2.5 ppm in compounds thought to have conformation

SCHEME 2

B. The coupling pattern of H_a and H_c with adjacent protons were also characteristic for the two conformations. It should therefore be possible to assign the stereochemistry of future Diels–Alder adducts, with a good degree of confidence, by inspection of their ^1H nmr spectra. In addition, knowing the preferred conformation of those adducts might help in understanding the stereochemical outcome of reactions in their elaboration into synthetic intermediates.

When a methyl group was present at position 5 of the starting β-keto ester, *cis* to the keto ester moiety, as in **20***d*, the reaction stopped at the single Michael adduct stage to give **32** (Scheme 5). It is interesting to note that this single adduct was formed in 57% yield in acetonitrile, and 29% yield in chloroform.

If the chain at position 5 of the Nazarov reagent contains an appropriately located functional group, interesting polycyclic compounds can, in principle, be prepared. For example, when tosylate **39**, prepared in four steps from the cycloaddition of Nazarov reagent **11***b* (Scheme 6), was treated with potassium *tert*-butoxide in a mixture of tetrahydrofuran–*tert*-butanol, an 86% yield of the known tricyclic compound **40** was isolated (15). However, the corresponding higher homolog **35** obtained from **11***c* via **33** gave none of the tricyclic adducts **36**. Also, **34** was not obtained from the corresponding **33**, which was formed *in situ* from **11***c*. The formation of the 5-membered ring to give **40** is possible since the proper geometry for backside attack of the ketone enolate on the carbon bearing the tosylate can be achieved. A similar cyclization might be prevented by steric interactions and angle strain in the formation of a 6-membered ring as indicated in Fig. 2. The cyclization of bicyclic ketones, by intramolecular Michael addition to an α,β-unsaturated ester, to form tricyclic compounds having an additional 6-membered ring was also unsuccessful as shown in

is quite clear form the above results. However, it is possible to effect the desired C8–C14 aldol reaction when the alternative is not possible (4, 16).

Double Michael addition of the β-keto sulfoxide and sulfone analogues of the methyl substituted Nazarov reagent

Diketone **4** can be prepared stereoselectively by the use of 1-phenylsulfoxide or 1-phenylsulfonyl analogues of the Nazarov reagents (17) (Scheme 8). When compound **26** was treated with cesium carbonate and **1** under the same reaction conditions as for the corresponding β-keto ester **2**, dehydrodecalin **52** was isolated in 70% yield after column chromatography. It was found that the elimination of the phenylsulfoxide moiety took place on the silica gel during chromatography. Catalytic hydrogenation of bicyclic compound **52** furnished a 13:1 ratio of the decalinedione **4** and a second bicyclic product in a combined chemical yield of 60%. This demonstrated that the dehydrodecalin adduct **52** from the cycloaddition had in fact α stereochemistry at C8. The minor isomer in the catalytic reduction had spectral data different from those of compound **3** and is thought to be the *trans*-decalin resulting from the α attack of the hydrogen molecule.

This complete reversal of stereoselectivity observed with the sulfoxide analog of the Nazarov reagent is somewhat surprising and its cause remains unclear at present. In addition, the stereoselectivity was shown to be independent of the solvent used for the reaction. For example, similar results were obtained in acetonitrile or dimethylformamide as solvents.

The double Michael addition of β-ketosulfone **27** on **1** afforded bicyclic adduct **53** (50%), which was reduced with aluminium amalgam (18) to give **4** as the sole product in 48% yield (79% based on recovered starting material) (Scheme 8). However, the reaction between **27** and **1** was slower than that with **26**. The cycloaddition using β-keto sulfoxides and sulfones appears to be complementary to the one using β-keto esters. Applications of this reaction to the synthesis of natural products are underway in our laboratory.

Cycloadditions with substituted-2-cyclohexenones

Substituents around the cyclohexenone ring in **1** can be used to direct the approach of the incoming diene, while retaining the same relative stereochemistry of the newly formed asymmetric centers in the Diels–Alder adducts. Results are summarized in Table 3. Cycloaddition of Nazarov reagent **2** with racemic 4-methyl-2-carbomethoxy-2-cyclohexenone **54** (entry 1) gave adduct **55** in 73% yield, where the diene added *anti* to the methyl group. *Anti* addition is also predominant in the alkylcuprate 1,4-addition to 4-methyl cyclohexenones (19). When (−)-2-carbomethoxy-5-methylethenyl-2-cyclohexen-1-one **56** ($[\alpha]_D$-18.6, c = 2, $CHCl_3$, 25°C), derived from (−)-carvone, was allowed to react with **2** (entry 2), three compounds were formed in a 85:11:4 ratio. The major compound could be purified and was assigned structure *57* ($[\alpha]_D$ + 117.3, c = 1, $CHCl_3$, 25°C) based on a correlation of its ^1H nmr spectrum with a related steroidal compound of known structure (16). Again addition *anti* to the isopropenyl group was expected by analogy to the 1,4-additions of alkyl cuprates on similar systems (1, 19). The other two isomeric compounds could not be obtained in pure form and therefore their structures could not be secured. The use of compound **56** allows the synthesis of optically pure bicyclic adducts in which the isopropenyl might serve as a handle for further elaboration of the A ring of these adducts. The synthesis of **56** was carried out starting from the known epoxide **63** (20) (Scheme 9) derived from (−)-carvone. Opening of the epoxide in **63** occurred with sulfuric acid in tetrahydrofuran to give a 1:1 mixture of *cis*-diol **64** and its corresponding *trans* isomer. Only the desired *cis*-diol underwent cleavage with sodium periodate and after treat-

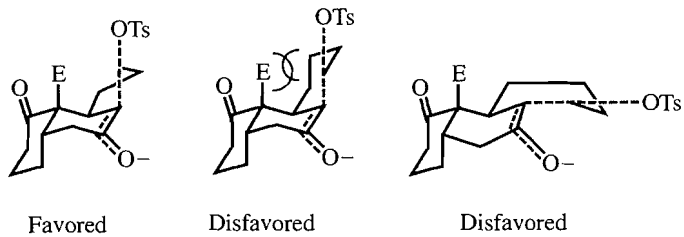

FIG. 2

ment with ethylene glycol and acid the resulting acetal-glycidyl ester was transesterified with sodium methoxide in methanol to give compound **65** (21). Then, in two steps, the methyl ester was transformed into β-keto ester **66** (22), which was then treated with aqueous acetic acid to give the desired compound **56** (23).

The cycloaddition can also be carried out on 4,4-disubstituted cyclohexenones. Reaction of substituted Nazarov reagent **2** with 4,4-dimethyl-2,5-cyclohexadienone derivative **58** (entry 3) gave the expected adduct **59** in 60% yield. The reaction of **58** with Nazarov reagents produces compounds that have the advantage of having an additional olefin functionality for further elaboration. However, its cycloaddition is slower and a large excess of the diene is needed. The stereochemistry in **59** was deduced by its transformation to a known structure (compound **33** in ref. 27*b*), using a sequence of reactions involving reduction of the ketone in the 6-position, tosylation, and elimination. Reaction using the 4-ketal derivative **60** gave, after decarboxylation, a 93% isolated yield of the expected adduct **61**. This dienophile has the marked advantage of being more reactive and more stable than **1** to the basic reaction conditions used in the Diels–Alder cycloaddition. Thus no excess of this reagent was needed to achieve completion of the cycloaddition reaction with **2** in higher yield. The protected ketone at the 4 position might then be used to epimerize the proton at C4a and thus give *trans*-decalins.

Mechanistic aspects of the reaction

Diels–Alder vs. double Michael

The reaction of a dienolate with a conjugated ketone can in principle follow a sequential double Michael addition or a Diels–Alder cycloaddition pathway (24). Determining which of these two processes is operative in any particular case can be very difficult. In such a reaction, the asynchronicity of the Diels–Alders (25) might be large enough so that differentiation between the two mechanisms becomes almost redundant. In addition, we cannot exclude the possibility that both mechanisms may be involved at the same time. The cycloaddition reaction might be favored by the fact that the diene is really an enolate ion. By analogy with the anionic oxy-Cope rearrangement (26), the negative charge on the oxygen enriches the diene in electron density and thus activates it. Note that the *silyl enol ether* of the β-keto ester **2** and of the β-keto sulfoxide **26** did not yield any trace of the Diels–Alder adducts when heated in toluene in the presence of dienophile **1** or when catalyzed by tin tetrachloride at low temperature. In both cases, only decomposition products were isolated.

TABLE 3. Cycloadditions of diene **2** with substituted cyclohexenones

Entry	Dienophile	Diketone product	Yield (%)
		E=CO_2Me	
1	 **54**	 **55**	73
2	 **56**	 **57**	64
3	 **58**	 **59**	60
4	 **60**	 **61**	93

The results presented below indicate that the solvent greatly influences the pathway that the reaction will take. The solvent also affects the stereoselectivity of the reaction when β-keto esters are used as the diene. However, it would be wrong to assume that the degree of selectivity can be an indication of the mechanism involved. In other words, it is possible that the selectivity can be affected by the properties of the solvent for a given mechanism. We also observed differences in reactivity and rates of reaction in the different solvents.

The single Michael adduct **5** was isolated in 53% yield from the cesium carbonate catalyzed reaction of **1** and **2** in acetonitrile at −15°C (Scheme 1). But when the same reaction was carried out in chloroform at −15°C, only starting material was recovered, even after several hours. In addition, the mono-adduct **5** could not be cyclized in chloroform at 25°C. However, resubmitting **5** to the same reaction conditions at 25°C in acetonitrile afforded a 55% yield of a 7:3 mixture of decalin products **3** and **4**, after the usual decarboxylation reaction. These results indicate that the double Michael addition pathway is the preferred one in polar solvents such as acetonitrile and that the cycloaddition mechanism would be operative in less polar solvents such as chloroform.

In the case of the reaction of β-keto sulfoxide **26** with **1**, at −5°C in acetonitrile or at 0°C in dichloromethane, the single Michael adduct **68** was isolated along with starting material (Scheme 8). This adduct could be cyclized to the *cis*-decalin product **52** when resubmitted to the same reaction conditions at 25°C in either solvent. Here, the double Michael mechanism seems to be the preferred pathway no matter what solvent is used. Note, however, that in acetonitrile, at −5°C, the dehydrodecalin **52** was also isolated. This result likely reflects a faster rate of ring closure of the mono-adduct **68** in acetonitrile than in dichloromethane, although we cannot rule out the Diels–Alder mechanism in this case.

Mechanism and stereochemistry of the decalin products

Table 1 gives a summary of the different ratios of decalin products **3** and **4** obtained via the double Michael addition of Diels–Alder cycloaddition of dienolates to dienophile **1**, as well as via the Michael addition of single-Michael adducts. In cases where a Diels–Alder mechanism is thought to operate (entries 5 and 6), the preferred formation of the *cis,cis*-decalin **3** probably results from a most sterically favored approach of the diene and the dienophile as well as secondary orbital interaction between the ester function and the diene (*endo* rule due to the ester function) (27). Liu and

Ngooi also explained, in this way, the selectivity observed in the tin tetrachloride catalyzed [2+4] cycloadditions of dienes to dienophile **1** (3).

The selectivity observed in those cases where the double Michael addition is thought to be the preferred pathway is not easily explained. The exclusive formation of the *cis*-fused decalin is explained on the basis of stereoelectronic control (28) at the stage of the second Michael reaction. The formation of *cis*-fused decalin by an intramolecular Michael reaction has been previously demonstrated (4*a*,4*c*). As for the stereochemistry of the C8-alkyl substituent, it is thought to be thermodynamically controlled because of the fact that the monoadduct **5** gave, upon cyclization in base, the same product ratio as for the reaction of **1** with the corresponding dienolate **2** (Table 1, entry 10 vs. entry 3). (On the other hand, compound **67** lacking the additional ester function gave after basic cyclization a reverse ratio of **3** and **4**, Table 1, entry 9.) Correspondingly, the single Michael adduct **68** gave only the dehydrodecalin **52** when cyclized, as was found for the reaction of **1** and the diene-sulfoxide **26** (entries 8 and 12, respectively). One likely explanation is that the formation of the second bond is reversible and that the relative stabilities of the intermediates determine the final stereochemical outcome of the reaction.

Conclusion

The cycloaddition or double Michael addition of substituted Nazarov reagents with 2-carbomethoxy-2-cyclohexenones gives stereoselectively *cis,cis*-decalins or *cis, trans*-decalins. The reaction is quite general and proceeds with various substituted Nazarov reagents containing different functional groups. We wish to emphasize that these results are important with respect to natural products synthesis. Indeed, this type of stereochemistry is found at the A, B, and C ring junctions in several steroids and terpenoids. Work to further develop this approach for various natural products, including quassinoids, is presently being pursued in our laboratory.

Experimental

Unless otherwise stated, all reagents were used as received from the supplier. Tetrahydrofuran and diethyl ether were distilled over sodium and benzophenone. Dimethylformamide, chloroform, dichloromethane, and diisopropylamine were distilled over calcium hydride. Methylphenylsulfoxide and methyl iodide were distilled prior to use. Sodium hydride suspension in oil was washed with hexane prior to use except in reactions using less than 0.1 mmol where it was used as received. Potassium *tert*-butoxide was prepared freshly prior to use. *tert*-Butyldimethylsilyltriflate was prepared and distilled before us. *p*-Toluenesulfonyl chloride was recrystallized from benzene. Zinc granules were washed with 1 N hydrochloric acid, water, and acetone and dried prior to use. Pure aluminium foil was obtained from BDH.

Reactions were carried out under argon unless specified otherwise. Anhydrous magnesium sulfate was used as drying agent in the work-up of reactions. Flash chromatography was performed using Kieselgel 60 (230–400 mesh ASTM) silica gel from Merck. Infrared (ir) spectra were registered in chloroform solution (unless stated otherwise) on a Perkin–Elmer 681 spectrophotometer; the following abbreviations were used in ir: w = weak, m = medium, s = strong, b = broad. Proton or ^{13}C nuclear magnetic resonance (nmr) spectra were recorded on a Bruker WP-80, or WM-250 instrument; the following abbreviations were used in nmr: s = singlet, d = doublet, t = triplet; q = quartet, qi = quintet, m = multiplet, b = broad. Deuterated chloroform was used as solvent and internal standard. Mass spectra (ms) were recorded on a VG Micromass ZAB-1F mass spectrometer. All new compounds have been proven homogeneous by tlc and gc where possible prior to taking their H 250 MHz nmr and mass spectra.

IUPAC numbering was used for all compound names.

Preparation of substituted Nazarov reagents

tert-*Butyl 3-oxo-4-diethylphosphonyl-butanoate (**9**a)*

tert-Butyl acetoacetate (10 g, 0.063 mol) was slowly added to a suspension of NaH (2.78 g, 0.069 mol) in 500 mL of anhydrous THF at 0°C. After all evolution of H_2 had ceased, the reaction was stirred for 0.5 h at 0°C and *n*-BuLi (39.5 mL, 0.063 mol) was added over a period of 1 h. The resulting mixture was stirred at 0°C for an extra 30 min and diethylchlorophosphate (5.45 g, 0.032 mol) was slowly added. After the reaction mixture was stirred for 1 h at room temperature, an additional 19.75 mL of *n*-BuLi (0.031 mol) was slowly added. Then it was stirred for 30 min and diethylchlorophosphate (5.45 g, 0.032 mol) was slowly added. After it was stirred for 1 h at 0°C, the reaction mixture was poured into 500 mL of saturated aqueous ammonium chloride and 200 mL of ice cold 1 N HCl. The aqueous phase was extracted several times with diethyl ether, the combined organic layers were washed with brine, dried, and evaporated *in vacuo* to give an orange oil. Chromatography with hexane – ethyl acetate 1:3 afforded 12.6 g (67%) of a slightly yellow oil; ir (cm^{-1}): 1740, 1720, 1040; ^1H nmr (δ): 4.10 (4H, dq, J = 7.1, 8.3 Hz, -(OCH_2CH$_3$)$_2$), 3.51 (2H, s, -CO-CH_2-CO$_2$-), 3.20 (2H, d, J = 22.7 Hz, -PO-CH_2-CO-), 1.40 (9H, s, -CO$_2$C(CH_3)$_3$), 1.28 (6H, t, J = 7.1 Hz, -(OCH$_2$(CH_3)$_2$); ms (m/e): 294 (M^+), 239 (M^+ + 2 − C(CH$_3$)$_3$), 221 (M^+ − OC(CH$_3$)$_3$). Exact Mass calculated for $C_{12}H_{23}O_6P$: 294.1232; found: 294.1230.

tert-*Butyl 3-oxopentanoate (**8**b)*

tert-Butyl acetoacetate (10 g, 0.063 mol) was slowly added to a suspension of NaH (2.78 g, 0.069 mol) in 500 mL of anhydrous THF at 0°C. After all evolution of H_2 had ceased, the reaction was stirred for 30 min at 0°C and *n*-BuLi (39.5 mL, 0.063 mol) was added over a period of 1 h. The resulting mixture was stirred at 0°C for an extra 30 min and methyl iodide (9.35 g, 0.066 mol) was slowly added. After the reaction mixture was stirred for 1 h at room temperature, it was poured into 750 mL of ice cold 1 N HCl, the aqueous phase was extracted several times with diethyl ether, the combined organic phase was washed with brine, dried, and evaporated *in vacuo* to give an orange oil. Distillation (100°C/0.25 Torr (1 Torr = 133.3 Pa)) afforded 7.35 g (68%) of *tert*-butyl 3-oxopentanoate as a pale yellow oil; ir (cm^{-1}): 3000–2800, 1730 (bs); ^1H nmr (δ): 3.35 (s, 2H, O=C-CH_2-CO$_2$R), 2.55 (q, 2H, J = 7.0 Hz, CH$_3$-CH_2-C=O), 1.45 (s, 9H, OC(CH_3)$_3$), 1.08 (t, 3H, J = 7.0 Hz, CH_3-CH$_2$-C=O); ms (*m/e*): 115 (M^+ − *t*-Bu), 100, 57.

tert-*Butyl 3-oxo-4-diethylphosphonyl-pentanoate (**9**b)*

tert-Butyl 3-oxopentanoate (10.0 g, 0.058 mol) was treated in the same way as for the preparation of *tert*-butyl 3-oxo-4-diethoxyphosphonyl-butanoate **9***a*. This time 2.6 g (0.064 mol) of NaH, 36.2 and 18.1 mL (0.058 and 0.029 mol) of *n*-BuLi, and 2 × 5.01 g (0.029 mol) of diethylchlorophosphate were used in the reaction. After column chromatography (hexane – ethyl acetate 1:5), 8.05 g (45%) of the desired product **9***b* was isolated as a pale yellow oil; ir (cm^{-1}): 1740, 1720, 1040; ^1H nmr (δ): 4.15 (dq, 4H, J_{HH} = 8.5 and J_{PH} = 7.0 Hz, 2 × CH$_3$-CH_2-OP), 3.79 (d, 1H, J = 15.5 Hz, O=C-CH_2-CO$_2$R), 3.50 (m, 1H, O=P-(CH$_3$)C*H*-C=O), 3.54 (d, 1H, J = 15.5 Hz, O=C-CH_2-CO$_2$R), 1.7–1.2 (m, 9H, 2 × CH_3-CH$_2$-OP and O=P-(CH_3)CH-C=O), 1.46 (s, 9H, OC(CH_3)$_3$).

tert-*Butyl 9,9-dimethoxy-3-oxo-4-nonenoate (**11**a)*

To a stirred solution of phosphonate **9***a* (65 mg, 0.220 mmol) in THF (3 mL) was added sodium hydride (10 mg, 60% in oil, 0.250 mmol). After 15 min at room temperature, the solution was cooled to −30°C and a solution of *n*-BuLi (138 μL, 1.6 M in hex-

For personal use only.

ane, 0.22 mmol) was added. After 10 min, a solution of the known aldehyde **10***a* (29 mg, 0.198 mmol) in THF (1 mL) was added and, after 5 min, the solution was warmed to room temperature for a period of 30 min. The mixture was then poured into a saturated solution of ammonium chloride (10 mL) at 0°C. The aqueous layer was extracted with diethyl ether (4 × 10 mL). The combined organic layers were washed with brine (1 × 10 mL), dried, filtered and the solvents were removed under reduced pressure. The residue was purified by flash chromatography with hexane – ethyl acetate (3:1) to afford substituted Nazarov reagent **11***a* (22 mg, 35%); ir (cm^{-1}): 1725, 1690, 1670, 1630, 1600, 1150; ^1H nmr (δ): 11.50 (<1H, d, J = 1.5 Hz, enol form), 7.10–6.30 (1H, 2 dt, J = 6.8, 16.1 Hz, =C*H*-CH_2-), 6.30–5.60 (1H, dt and dq, J = 1.5, 16.1 Hz, -CO-C*H*=), 4.89 (<1H, s, =C*H*-CO_2- enol form), 4.36 (1H, t, J = 5.4 Hz, -O-C*H*-O-), 3.47 (<2H, s, -CO-CH_2-CO_2-), 3.32, (6H, s, -C(OCH_3)$_2$), 2.25 (2H, m, =CH-CH_2-), 1.75–1.50 (4H, m), 1.49 (<9H, s, -CO_2(CH_3)$_3$), 1.46 (<9H, s, -CO_2(CH_3)$_3$).

tert-*Butyl 8*-tert-*butyldiphenylsilyloxy-3-oxo-4-octenoate (**11**b)*

The substituted Nazarov reagent **11***b* was prepared in the same manner as **11***a* except that the saturated solution of ammonium chloride was replaced by a solution of hydrochloric acid (1 N). The aldehyde **10***b* (102 mg, 0.312 mmol) gave, after purification, substituted Nazarov reagent **11***b* (110 mg, 76%); ir (cm^{-1}): 1730, 1690, 1670, 1630, 1600, 1150; ^1H nmr (δ): 11.48 (<1H, d, J = 3.9 Hz, enol form), 7.80–7.30 (10H, m, aromatic protons), 7.00–6.40 (1H, 2, dt, J = 6.8, 15.6 Hz, -CH_2-C*H*=), 6.30–5.60 (1H, dt and dq, J = 1.7, 15.6 Hz, -CO-C*H*=), 4.89 (<1H, s, =CH-CO_2- enol form), 3.70 (2H, t, J = 5.9 Hz, -CH_2-O-), 3.47 (<2H, s, -CO-CH_2-CO_2-), 2.30 (2H, m, =CH-CH_2-), 1.70 (2H, m, -CH_2-CH_2-O-), 1.50 (9H, s, -CO_2C(CH_3)$_3$), 1.10 (9H, s, -SiC(CH_3)$_3$), 0.03 (6H, s, -Si-(CH_3)$_2$-C(CH_3)$_3$).

tert-*Butyl 9*-p-*toluenesulfonyloxy-3-oxo-4-nonenoate (**11**c)*

The substituted Nazarov reagent **11***c* was prepared in the same manner as **11***b*. The aldehyde **10***c* (44 mg, 0.172 mmol) gave, after purification, substituted Nazarov reagent **11***c* (22 mg, 33%); ir (cm^{-1}): 1730, 1690–1660, 1630, 1600, 1365, 1175; ^1H nmr (δ): 11.51 (<1H, d, J = 1.5 Hz, enol form), 7.90–7.20 (4H, 2d, J = 8.5 Hz, aromatic protons), 7.00–6.25 (1H, 2 dt, J = 6.8, 15.6 Hz, =C*H*-CH_2-), 6.20–5.50 (1H, dt and dq, J = 1.5, 15.6 Hz, -CO-C*H*=), 4.88 (<1H, s, -C*H*=C-O- enol form), 4.04 (2H, t, J = 5.9 Hz, -CH_2-OSO_2-), 3.46 (<2H, s, -CO-CH_2-CO_2-), 2.45 (3H, s, =C-CH_3), 2.20 (2H, m, =CH-CH_2-), 1.70–1.30 (4H, m, -(CH_2)$_2$-CH_2-OSO_2-), 1.49 (<9H, s, -CO_2C(CH_3)$_3$), 1.45 (<9H, s, -CO_2C(CH_3)$_3$).

*3-Bromo-1-tetrahydropyranyloxy-propane (**15**)*

To a solution of 3-bromopropanol (10.0 g, 0.072 mol) in 500 mL of anhydrous THF at 0°C were added 7.84 g of dihydropyran (0.093 mol) and 1.3 g of *p*-toluenesulfonic acid (0.007 mol). The resulting mixture was stirred at 0°C for 1 h and at room temperature for 12 h, then it was poured into 750 mL of saturated sodium bicarbonate. The aqueous phase was extracted several times with diethyl ether, the combined organic phase was washed with brine, dried, and evaporated *in vacuo* to give an yellow oil. Distillation (95°C/3.5 Torr) afforded 14.70 g (92%) of 1-bromo-3-tetrahydropyranyloxy-propane as a colorless oil; ir (cm^{-1}): 3000–2800, 1475, 1370, 1150(s); ^1H nmr (δ): 4.56 (m, 1H, O-C*H*-O), 4.0–3.3 (m, 6H, 2 × RCH_2-O and Br-CH_2), 2.10 (qi, 2H, J = 7.0 Hz, CH_2-CH_2-CH_2), 1.9–1.2 (m, 6H, O-CH_2-(CH_2)$_3$-CH-O); ms (*m/e*): 224 (M^+), 223, 222 (M^+), 142, 140.

*6-Trimethylsilyl-5-hexynal (**12**)*

A solution of *n*-BuLi in hexanes (1.6 M, 8.4 mL, 13.5 mmol) was placed in a 100 mL round bottom flask. The solvent was removed under vacuum at 20°C and 60 mL of anhydrous diethyl ether was added. After cooling the mixture to −15°C, tetramethylethylenediamine (1.57 g, 13.5 mmol) was added followed by 1-trimethylsilyl-1-propyne (1.51 g, 13.5 mmol) and the resulting mixture was stirred at −10°C for 3 h. Then 1-bromo-3-tetrahydropyranyloxy-propane (1.50 g, 6.7 mmol) was added and the resulting reaction mixture was stirred overnight at a temperature between −10 and −3°C. After 12 h, a yellow precipitate formed. The reaction mixture was poured into 100 mL of ice cold 1 N hydrochloric acid, the aqueous phase was extracted several times with diethyl ether, the combined organic layers were washed with saturated sodium bicarbonate, then with brine, dried, and evaporated *in vacuo* to give an orange oil. Distillation (110–115°C/0.25 Torr) afforded 1.79 g (99%) of 6-tetrahydropyranyloxy-1-trimethylsilyl-1-hexyne as a colorless oil; ir (cm^{-1}): 3000–280, 2170, 1455, 1445, 1250, 1140, 1120, 1075, 1035(s), 850 (s); ^1H nmr (δ): 4.55 (m, 1H, O-C*H*-O), 3.2–4.0 (m, 4H, 2 × RCH_2-O-R), 2.26 (t, 2H, J = 6.5 Hz, CH_2-CH_2-C≡CTMS), 1.7–1.4 (m, 10H), 0.15 (s, 9H, Si(CH_3)$_3$); ms (m/e): 254 (M^+), 239, 225, 211, 209.

A solution of 6-tetrahydropyranyloxy-1-trimethylsilyl-1-hexyne (4.79 g, 18.8 mmol) in 60 mL of anhydrous methanol was cooled to 0°C and 459 mg (1.83 mmol) of pyridinium *p*-toluenesulfonate acid was added. The mixture was stirred at room temperature for 24 h. Then solid potassium bicarbonate (700 mg, 7.0 mmol) was added and the solvent was removed *in vacuo*. The residue was taken up in diethyl ether and was washed with 2 × 25 mL of water, dried, and evaporated *in vacuo* to give a yellow oil. Chromatography with hexane – ethyl acetate 5:1, then 3:1, afforded 2.61 g (82%) of 6-trimethylsilyl-5-hexyn-1-ol as a colorless oil; ir (cm^{-1}): 3600, 3000–2800, 2175, 1250, 1230–1200(s), 1045, 850(s); ^1H nmr (δ): 3.72 (bt, 2H, J = 5.5 Hz, HO-CH_2-), 2.28 (t, 2H, J = 6.5 Hz, CH_2-CH_2-C≡CTMS), 1.85–1.45 (m, 4H), 1.30 (bs, 1H, *H*O-CH_2-), 0.18 (s, 9H, Si(CH_3)$_3$); ms (*m/e*): 169 (M^+ − 1), 155, 153, 139, 137, 127, 126.

Dimethyl sulfoxide (2.31 g, 0.027 mol) was slowly added to a solution of oxalyl chloride (1.89 g, 0.015 mol) in 130 mL of anhydrous dichloromethane at −78°C. After 15 min., 6-trimethylsilyl-5-hexyn-1-ol (2.61 g, 0.027 mol), was added and the mixture was stirred for 15 min. Triethylamine (6.5 g, 0.064 mol) was added and the reaction was allowed to warm to room temperature. The solvent was then removed *in vacuo* and the residue was taken up in hexane, washed with water (2 × 50 mL), dried, and evaporated under reduced pressure to give 1.70 g (78%) of 6-trimethylsilyl-5-hexynal **12** as a yellow oil that was used directly in the next reaction.

tert-*Butyl (4E)-3-oxo-10-trimethylsilyl-4-decen-9-ynoate (**13**a)*

Sodium hydride (60% in oil, 430 mg, 10.8 mmol) was washed twice with 5 mL of hexane; 100 mL of anhydrous THF was added and the suspension was cooled down to 0°C. *tert*-Butyl 3-oxo-4-diethylphosphonylbutanoate **9***a* (3.1 g, 10.4 mmol) was added slowly and the mixture was stirred for 15 min, then it was cooled to −30°C and *n*-BuLi (1.6 M in hexanes, 6.5 mL, 10.4 mmol) was added. After stirring for 10 min, 6-trimethylsilyl-5-hexynal (1.70 g, 10.1 mmol) in 10 mL of THF was added and the resulting mixture was stirred for 5 min, then it was allowed to warm to room temperature and stirred for another 30 min. The reaction mixture was poured into 100 mL of ice cold 1 N hydrochloric acid, the aqueous phase was extracted several times with diethyl ether, the combined organic layers were washed with brine, dried, and evaporated *in vacuo* to give an orange oil. Chromatography with hexane – ethyl acetate 8:1 afforded 2.41 g (77%) of *tert*-butyl (3*E*)-3-oxo-10-trimethylsilyl-4-decen-9-ynoate (**13***a*) as a colorless oil; ir (cm^{-1}): 3100–3000, 3000–2800, 2180, 1725, 1675, 1625, 1600, 1370, 1250, 1215(s), 1150, 850(s); ^1H nmr (δ): 12.35 (s, <1H, *H*O-C=CH-CO_2R), 6.85 (dt, <1H, J = 15.5, 6.5 Hz, O=C-CH=C*H*-), 6.36 (dt, <1H, J = 15.5, 6.5 Hz, HO-C=CH=C*H*-), 6.15 (dt, <1H, J = 15.5, 1.5 Hz, O=C-C*H*=CH-), 5.77 (dt, <1H, J = 15.5, 1.5 Hz, HO-C=C*H*=CH-), 4.87 (s, <1H, HO-C=C*H*=CO_2R), 3.44 (s, <2H, O=C-CH_2-CO_2R), 2.5–2.1 (m, 4H), 1.9–1.1 (m, 3H), 1.45 (s, <9H, OC(CH_3)$_3$, enol), 1.41 (s, <9H, OC(CH_3)$_3$), 0.12 (s, 9H, Si(CH_3)$_3$); ms (*m/e*): 251 (M^+ − *t*-Bu), 237, 235, 219, 107. Exact Mass calculated for $C_{13}H_{19}O_3Si$: 251.1103; found: 251.1107.

tert-*Butyl (4*E*)-4-methyl-3-oxo-10-trimethylsilyl-4-decen-9-ynoate (**13***b*)

This procedure was identical to that used in the preparation of *tert*-butyl (3*E*)-3-oxo-10-trimethylsilyl-4-decen-9-ynoate **13***a*. *tert*-Butyl 3-oxo-4-diethylphosphonylpentanoate **9***b* (2.74 g, 8.91 mmol), sodium hydride (374 mg, 9.35–mmol), *n*-BuLi (5.56 mL, 8.91 mmol), 6-trimethylsilyl-5-hexynal **12** (1.50 g, 8.91 mmol) in 10 mL of THF gave 1.12 g (44%) of the desired β-keto ester **13***b*; ir (cm^{-1}): 3100–3000, 3000–2800, 2180, 1730, 1675, 1630, 1380, 1250(s), 1150, 850(s); ^1H nmr (δ): 6.57 (bt, 1H, J = 5.5 Hz, O=C-C(CH_3)=C*H*-), 3.60 (s, 2H, O=C-CH_2-CO_2R), 2.39 (q, 2H, J = 5.5 Hz, C(CH_3)=CH-CH_2), 2.26 (t, 2H, J = 5.5 Hz, CH_2-CH_2-CH_2-C≡CTMS), 1.83 (d, 3H, J = 1.0 Hz, O=C-C(CH_3)=CH-), 1.68 (qi, 2H, J = 5.5 Hz, CH_2-CH_2-CH_2-C≡CTMS), 1.46 (s, 9H, OC(CH_3)$_3$), 0.15 (s, 9H, Si(CH_3)$_3$); ms (*m/e*): 265 (M^+ − *t*-Bu), 251, 249, 233. Exact Mass calculated for $C_{14}H_{21}O_3Si$: 265.1260; found: 265.1260.

tert-*Butyl (4*E*)-3-oxo-10-carbomethoxy-4-decen-9-ynoate (**16***a*)

Tetrabutylammonium fluoride (1 M in THF, 2.78 mL, 2.78 mmol) was added to a solution of *tert*-butyl (4*E*)-3-oxo-10-trimethylsilyl-4-decen-9-ynoate **13***a* (715 mg, 2.32 mmol) in 10 mL of anhydrous THF at 0°C. The reaction mixture was stirred at 0°C for 1 h. Then it was poured into 50 mL of brine, the aqueous phase was extracted several times with diethyl ether, the combined organic layers were dried and evaporated *in vacuo* to give an orange oil. Chromatography with hexane – ethyl acetate 15:1 afforded 468 mg (90%) of a colorless oil; ir (cm^{-1}): 3100–3000, 3000–2800, 2180, 1725, 1675, 1625, 1600, 1370, 1250, 1215(s), 1150, 850(s); ^1H nmr (δ): 12.31 (s, <1H, *H*O-C=CH-CO_2R), 6.83 (dt, <1H, J = 15.5, 6.5 Hz, O=C-CH=C*H*-), 6.36 (dt, <1H, J = 15.5, 6.5 Hz, HO-CH=C*H*-), 6.10 (dt, <1H, J = 15.5, 1.5 Hz, O=C-C*H*=CH-), 5.69 (dt, <1H, J = 15.5, 1.5 Hz, HC=C(OH)-CH=CH), 4.78 (s, <1H, HO-C=C*H*-CO_2R), 3.34 (s, <2H, O=C-CH_2-CO_2R), 2.4–0.9 (m, 7H), 1.36 (s, <9H, OC(CH_3)$_3$, enol), 1.33 (s, <9H, OC (CH_3)$_3$); ms (*m/e*): 179 (M^+ − *t*-Bu), 163, 153, 136, 134, 122. Exact Mass calculated for $C_{10}H_{11}O_3$: 179.0708; found: 179.0711.

Sodium hydride (66 mg, 1.66 mmol) was added to a solution of *tert*-butyl (4*E*)-3-oxo-4-decen-9-ynoate (208 mg, 0.83 mmol) in 10 mL of anhydrous THF at 0°C. After 30 min, the mixture was cooled to −78°C and *n*-BuLi (0.52 mL, 0.83 mmol) was slowly added. The resulting mixture was stirred for 10 min at −78°C and then warmed slowly to 0°C and stirred at that temperature for 15 min. Then it was cooled again to −78°C and methyl chloroformate (78 mg, 0.83 mmol) was added. The reaction mixture was stirred while warming slowly to room temperature. Then it was poured into 20 mL of saturated aqueous ammonium chloride, the aqueous phase was extracted several times with diethyl ether, the combined organic layers were washed with brine, dried, and evaporated *in vacuo* to give an orange oil. Chromatography with hexane – ethyl acetate 8:1 afforded 226 mg (93%) of **16***a* as a colorless oil; ir (cm^{-1}): 3100–3000, 3000–2800, 2180, 1725, 1675, 1625, 1600, 1370, 1250, 1215(s), 1150, 850(s); ^1H nmr (δ): 12.01 (s, <1H, *H*O-C=CH-CO_2R), 6.83 (dt, <1H, J = 15.9, 6.9 Hz, O=C-CH=C*H*-), 6.55 (dt, <1H, J = 15.9, 6.9 Hz, HO-C-CH=C*H*-), 6.20 (dt, <1H, J = 15.9, 1.5 Hz, O=C-C*H*=CH-), 5.78 (dt, <1H, J = 15.9, 1.5 Hz, HC=C(OH)-C*H*=CH-), 4.90 (s, <1H, OH-C=C*H*-CO_2R), 3.76 (s, 3H, O=C-OCH_3), 3.48 (s, <2H, O=C-CH_2-CO_2R), 2.45–2.25 (m, 4H, -CH_2CH_2CH_2-), 1.76 (qi, 2H, J = 7.5 Hz, -CH_2C$H_2$$CH_2$-), 1.49 (m, <9H, OC(C$H_3$)$_3$, enol), 1.45 (m, <9H, OC(CH_3)$_3$); ms (*m/e*): 239 (M^+ − *t*-Bu), 189, 179, 162, 160, 138. Exact Mass calculated for $C_{12}H_{13}O_5$: 237.0763; found: 237.0759.

tert-*Butyl (4*E*)-4-methyl-3-oxo-10-carbomethoxy-4-decen-9-ynoate (**16***b*)

The title compound was prepared as described in the preparation of *tert*-butyl (3*E*)-3-oxo-10-carbomethoxy-4-decen-9-ynoate **16***a*. The removal of the trimethylsilyl group was achieved using 1.12 g of *tert*-butyl (4*E*)-4-methyl-3-oxo-10-trimethylsilyl-4-decen-9-ynoate **13***b* (3.60 mmol) and 4.36 mL of tetrabutylammonium fluoride (4.36 mmol). Chromatography using hexane – ethyl acetate 15:1 gave 786 mg (86%) of *tert*-butyl (4*E*)-4-methyl-3-oxo-4-decen-9-ynoate as a colorless liquid; ir (cm^{-1}): 3100–3000, 3000–2800, 2180, 1725, 1675, 1625, 1600, 1370, 1250, 1215(s), 1150, 850(s); ^1H nmr (δ): 6.57 (dt, 1H, J = 5.0, 1.0 Hz, O=C-C(CH_3)=C*H*-), 3.59 (s, 2H, O=C-CH_2-CO_2R), 2.39 (q, 2H, J = 5.5 Hz, C(CH_3)=CH-CH_2), 2.24 (dt, 2H, J = 5.5, 1.8 Hz, CH_2-CH_2-CH_2-C≡CH), 1.98 (t, 1H, J = 1.8 Hz, CH_2-CH_2-CH_2-C≡C*H*), 1.81 (d, 3H, J = 1.0 Hz, O=C-C(CH_3)=CH-), 1.70 (qi, 2H, J = 5.5 Hz, CH_2-CH_2-CH_2-C≡CH), 1.43 (s, 9H, OC(CH_3)$_3$); ms (*m/e*): 193 (M^+ − *t*-Bu), 177, 167, 150, 148, 136. Exact Mass calculated for $C_{11}H_{13}O_3$: 193.0865; found: 193.0866.

Then 160 mg of *tert*-butyl (4*E*)-4-methyl-3-oxo-4-decen-9-ynoate (0.64 mmol), 51 mg of sodium hydride (1.30 mmol), 0.42 mL of *n*-BuLi (0.64 mmol), and 60 mg of methyl chloroformate (0.64 mmol) were used for the reaction. Chromatography using hexanes – ethyl acetate 8:1 gave 101 mg (51%) of **16***b* as a colorless liquid; ir (cm^{-1}): 3100–3000, 3000–2800, 2180, 1725, 1675, 1625, 1600, 1370, 1250, 1215(s), 1150, 850(s); ^1H nmr (δ): 6.54 (dt, 1H, J = 6.0, 1.0 Hz, O=C-C(CH_3)=C*H*-) , 3.76 (s, 3H, O=COCH_3), 3.60 (s, 2H, 2H, O=C-CH_2-CO_2R), 2.39 (t, 2H, J = 7.0 Hz, CH_2-CH_2-CH_2-C≡C-), 2.38 (q, 2H, J = 7.0 Hz, C(CH_3)=CH-CH_2), 1.81 (d, 3H, J = 1.0 Hz, O=C-C(CH_3)=CH-), 1.76 (qi, 2H, J = 7.0 Hz, CH_2-CH_2-CH_2-C≡C-), 1.44 (s, 9H, OC(CH_3)$_3$); ms (*m/e*): 251 (M^+ − *t*-Bu), 203, 193, 162, 160, 138. Exact Mass calculated for $C_{13}H_{15}O_5$: 251.0919; found: 251.0916.

tert-*Butyl (4*E*,9*Z*)-3-oxo-10-carbomethoxy-4,9-decadienoate (**17**)*

tert-Butyl (4*E*)-3-oxo-10-carbomethoxy-4-decen-9-ynoate **16***a* (50 mg, 0.17 mmol) was dissolved in 2.5 mL of ethyl acetate. Then 2.5 mg of Lindlar's catalyst (5% w/w) was added and hydrogen was bubbled through the solution while the reaction was monitored by tlc. When all the starting material had gone, the mixture was filtered on Celite and the solvent evaporated *in vacuo* to give a yellow oil. Chromatography on silica gel using hexane – ethyl acetate 6:1 gave 30 mg (59%) of the desired *cis* olefin; ir (cm^{-1}): 3100–3000, 3000–2800, 2180, 1725, 1675, 1625, 1600, 1370, 1250, 1215(s), 1150, 850(s); ^1H nmr (250 MHz δ): 12.02 (s, <1H, *H*O-C=CH-CO_2R), 6.87 (dt, <1H, J = 15.9, 6.8 Hz, O=C-CH=C*H*-), 6.61 (dt, <1H, J = 15.9, 6.8 Hz, HO-CH=C*H*-), 6.28–6.12 (m, 2H, -C*H*=C*H*-CO_2CH_3), 5.85–5.74 (m, 1H, O=C-C*H*=CH- and enol), 4.88 (s, <1H, HO-C=CH_2-CO_2R), 3.71 (s, 3H, O=C-OCH_3), 3.48 (s, <2H, O=C-CH_2-CO_2R), 2.70 (m, 2H, CH_2-CH_2-CH_2-), 2.26 (m, 2H, CH_2-CH_2-CH_2-), 1.63 (m, 2H, CH_2-CH_2-CH_2-), 1.49 (m, <9H, OC(CH_3)$_3$), enol), 1.46 (m, <9H, OC(CH_3)$_3$); ms (*m/e*): 241 (M^+ − *t*-Bu), 191, 181, 166, 164, 162, 140. Exact Mass calculated for $C_{12}H_{15}O_5$: 239.0919; found: 239.0915.

tert-*Butyl (4*E*)-3-oxo-4-hexanoate (**2**)*

To zinc granules (3.92 g, 60.0 mmol) in THF (6 mL) was added *tert*-butyl bromoacetate (0.6 mL, 3.7 mmol) and one crystal of iodine. This mixture was refluxed under argon for 5 min and when the reaction had started, *tert*-butyl bromoacetate (7.4 mL, 45.6 mmol) in THF (25 mL) was added dropwise in order to maintain a gentle reflux. Reflux was continued for 1 h after the addition, then the mixture was cooled to room temperature and transferred, via a cannula, into a stirred solution of crotonaldehyde (2.71 g, 38.5 mmol) in diethyl ether (50 mL) at 0°C. After 30 min, a saturated ammonium chloride solution was added and the aqueous layer was extracted with diethyl ether (3 × 30 mL). The combined organic layers were dried, filtered, and the solvents were evaporated. The oily residue was chromatographed on silica gel (hexane:ethyl acetate, 2:1) to give *tert*-butyl (4*E*)-3-hydroxy-4-hexenoate (6.0 g, 83%); ir (cm^{-1}): 3600–3300, 171; ^1H nmr (δ):

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

5.90–5.30 (2H, m, olefinic), 4.42 (1H, m, -C*H*-OH), 2.97 (1H, d, J = 4.0 Hz, -CHO*H*), 2.44 (2H, d, J = 5.8 Hz, -CH_2-), 1.68 (3H, dd, J = 1.0, 4.9 Hz, CH_3-CH), 1.45 (9H, s, -C(CH_3)$_3$).

To a stirred solution of *tert*-butyl (4*E*)-3-hydroxy-4-hexenoate (1.34 g, 7.21 mmol) in ethyl acetate (105 mL) was added, at 25°C, manganese dioxide (12.6 g, 144.9 mmol). After stirring 5 h under argon, the mixture was filtered through silica gel and the solvent was evaporated and the residue purified by flash chromatography (dichloromethane – diethyl ether, 95:5) to give *tert*-butyl (4*E*)-3-oxo-4-hexenoate (967 mg, 73%); ir (cm^{-1}): 1730, 1690, 1670 (enol), 1630, 1600; ^{1}H nmr (δ): 7.10–6.30 (1H, dq, J = 6.8, 17.0 Hz, =C*H*-CH$_3$), 6.30–5.65 (1H, 2 dq, J = 1.5, 17.0 Hz, CO-C*H*=CH), 4.86 (<1H, s, C=C*H*-CO$_2$, of enol form), 3.46 (<2H, s, -CH$_2$-), 1.92 (3H, 2 dd, J = 1.5, 6.8 Hz, =CH-C*H*$_3$), 1.45 (9H, 2s, -CO$_2$C(C*H*$_3$)$_3$).

tert-*Butyl 4-methyl-3-oxo-4-hexenoate (**20**b)*

To a stirred suspension of granular zinc (412 mg, 6.3 mmol) in THF (15 mL) at room temperature and under an argon atmosphere, were added *tert*-butyl bromoacetate (0.68 mL, 4.2 mmol) and a crystal of iodine. The mixture was heated to reflux for 1 h and then cooled to 0°C. A solution of commerically available *trans*-2-methyl-2-butenal (234 mg, 2.5 mmol) in ether (5 mL) was then added via a cannula to the Reformatsky reagent. After stirring for 1 h, a saturated ammonium chloride solution (10 mL) was added, and the salts formed were dissolved in water (40 mL). The separated aqueous layer was extracted with diethyl ether (4 × 25 mL). The combined organic layers were washed with brine (25 mL), dried, and the solvents evaporated under reduced pressure. Flash chromatography (hexane – ethyl acetate 4:1) yielded 389 mg (70%) of the corresponding allylic alcohol; ir (neat, cm^{-1}): 3440 (OH), 1740–1710 (C=O ester); ^{1}H nmr (δ): 5.55 (1H, m, CH$_3$C*H*=C(CH$_3$)-), 4.37 (1H, m, -C*H*OH), 2.92 (1H, d, J = 3.4 Hz, -O*H*, exchanges with D$_2$O), 2.50 (1H, dd, J = 15.8, 8.5 Hz, -CH(OH)C*H*$_2$CO$_2$-), 2.40 (1H, dd, J = 15.8, 4.3 Hz, -CH(OH)C*H*$_2$CO$_2$-), 1.61 (3H, s, CH$_3$CH=C-C*H*$_3$-), 1.60 (3H, dd, J = 8.3, 0.8 Hz, C*H*$_3$CH=C-CH$_3$-), 1.45 (9H, s, -CO$_2$(C*H*$_3$)$_3$).

To a stirred solution of *trans-tert*-butyl-3-hydroxy-4-methyl-4-hexenoate (127 mg, 0.6 mmol) in ethyl acetate (15 mL) was added manganese dioxide (825 mg, 9.5 mmol). After stirring for 15 h at room temp., the mixture was filtered through silica gel and the solvent was evaporated under reduced pressure. Flash chromatography (hexane – ethyl acetate (3:17)) yielded 88 mg (70%) of β-keto ester **21**; ir (neat, cm^{-1}): 1735 (C=O ester), 1690 (C=O conjugated ketone); ^{1}H nmr (δ): 12.35 (<1H, s, -CH=C-O*H*), 6.65 (>1H, m, CH$_3$C*H*=C(CH$_3$)-), 5.07 (<1H, s, -C*H*=C-OH), 3.60 (2H, s, -COC*H*$_2$CO$_2$-), 1.88 (3H, dd, J = 6.9, 1.0 Hz, C*H*$_3$CH=C(CH$_3$)-), 1.80 (>3H, m, CH$_3$CH=C-C*H*$_3$, enol form and β-keto ester, and C*H*$_3$CH=C-CH$_3$, enol form), 1.50 (<9H, s, -CO$_2$C(C*H*$_3$)$_3$), 1.45 (9H, s, -CO$_2$(C*H*$_3$)$_3$).

tert-*Butyl 3-(1-cyclohexen-1-yl)-3-oxopropanoate (**20**c)*

The procedure described for the synthesis of substituted Nazarov reagent **2** was performed using 1-formyl-1-cyclohexene (100 mg, 0.9 mmol), granular zinc (119 mg, 1.8 mmol), *tert*-butyl bromoacetate (0.22 mL, 1.4 mmol). Flash chromatography yielded 142 mg (69%) of a β-hydroxy-ester; ir (neat, cm^{-1}): 3440 (OH), 1750–1700 (C=O ester); ^{1}H nmr (δ): 5.73 (1H, m, -C*H*=C), 4.33 (1H, ddd, J = 7.5, 5.0, 3.8 Hz, -C*H*OH, becomes dd, J = 7.5, 5.0 Hz upon treatment with D$_2$O), 2.93 (1H, d, J = 3.8 Hz, -CHO*H*, exchanges with D$_2$O), 2.80–1.45 (10H, m), 1.45 (9H, s, -CO$_2$C(C*H*$_3$)$_3$); ms (*m/e*): 170 (MH$^+$ – C$_4$H$_9$), 152 (MH$^+$ – C$_4$H$_9$-H$_2$O). Exact Mass calculated for C$_9$H$_{14}$O$_3$ (MH$^+$ – C$_4$H$_9$): 170.0943; found: 170.0940.

This β-hydroxy ester (140 mg, 0.6 mmol) was dissolved in ethyl acetate (10 mL) and the procedure described for allylic oxidation leading to **2** was followed using manganese dioxide (808 mg, 9.3 mmol). The *tert*-butyl β-keto ester **20***c* was purified by flash chromatography (hexane – ethyl acetate 4:1), which yielded 90 mg (65%); ir (neat, cm^{-1}): 3440 (OH), 1750–1700 (C=O ester); ^{1}H nmr (δ): 12.27 (<1H, s, -CH=C-O*H*), 6.87 (>1H, m, -C*H*=C-), 5.02 (<1H, s, -C*H*=C-OH), 3.58 (2H, s, -COC*H*$_2$CO$_2$-), 2.81–1.52 (>8H, m), 1.46 (<9H, s, -CO$_2$C(C*H*$_3$)$_3$), 1.45 (9H, s, -CO$_2$C(C*H*$_3$)$_3$); ms (*m/e*): 168 (MH$^+$ – C$_4$H$_9$), 150 (MH$^+$ – C$_4$H$_9$ – H$_2$O). Exact Mass calculated for C$_9$H$_{12}$O$_3$ (MH$^+$ – C$_4$H$_9$): 168.0787; found: 168.0781.

tert-*Butyl 5-methyl-3-oxo-4-hexenoate (**20**d)*

The procedure described for the preparation of Nazarov reagent **2** was performed using 3-methyl-2-butenal (230 mg, 2.5 mmol), granular zinc (412 mg, 6.3 mmol), *tert*-butyl bromoacetate (0.68 mL, 4.2 mmol) in THF (20 mL) and ether (5 mL). The corresponding β-hydroxy ester was purified by flash chromatography (hexane – ethyl acetate (3:1) to yield 416 mg (74%); ir (neat, cm^{-1}): 3440 (OH), 1740–1720 (C=O ester); ^{1}H nmr (δ): 5.17 (1H, dt, J = 8.7, 1.3 Hz, (CH$_3$)$_2$C=C*H*-), 4.71 (1H, m, -C*H*OH), 2.91 (1H, d, J = 3.3 Hz, -CHO*H*), 2.45 (1H, dd, J = 16.3, 8.1 Hz, -C*H*$_2$CO$_2$-), 2.35 (1H, dd, J = 16.3, 4.6 Hz, -C*H*$_2$CO$_2$-), 1.71 (3H, d, J = 1.1 Hz, -C=C(C*H*$_3$)$_2$), 1.69 (3H, d, J = 1.3 Hz, -C=C(C*H*$_3$)$_2$), 1.45 (9H, s, -CO$_2$(C*H*$_3$)$_3$); ms (*m/e*): 144 (MH$^+$ – C$_4$H$_9$), 129 (MH$^+$ – C$_4$H$_9$ – CH$_3$), 111 (MH$^+$ – OC$_4$H$_9$ – OH). Exact Mass calculated for C$_7$H$_{12}$O$_3$ (MH$^+$ – C$_4$H$_9$): 144.0786; found: 144.0789.

The β-hydroxy ketone (400 mg, 2.0 mmol) was dissolved in ethyl acetate (30 mL) and the procedure described for the preparation of **2** was performed using manganese dioxide (3.5 g, 40.0 mmol). Flash chromatography (hexane – ethyl acetate 17:3) of the crude product yielded 305 mg (77%) of β-keto ester **20***d*; ir (neat, cm^{-1}): 1735 (C=O ester), 1690 (C=O conjugated ketone); ^{1}H nmr (δ): 6.11 (1H, t, J = 1.3 Hz, (CH$_3$)$_2$C=C*H*-), 3.34 (2H, s, -COC*H*$_2$CO$_2$-), 2.15 (3H, d, J = 0.9 Hz, -C=C(C*H*$_3$)$_2$), 1.90 (3H, d, J = 1.3 Hz, -C=C(C*H*$_3$)$_2$), 1.46 (9H, s, -CO$_2$C(C*H*$_3$)$_3$); ms (*m/e*): 198 (M$^+$), 183 (M$^+$ – CH$_3$), 142 (MH$^+$ – C$_4$H$_9$). Exact Mass calculated for C$_{11}$H$_{18}$O$_3$: 198.1256; found: 198.1259.

*2-Formyl-1-methoxy-2-cyclohexene (**18**e)*

2-Bromo-2-cyclohexenone (10.0 g, 57.0 mmol) was dissolved in 500 mL of ethanol and the solution was cooled to 0°C. Cerium chloride heptahydrate (23.31 g, 63.0 mmol) was then added followed by sodium borohydride (2.15 g, 57.0 mmol) and the reaction mixture was stirred for 1 h. It was then poured into 500 mL of ice cold 1 N hydrochloric acid, the aqueous phase was extracted several times with dichloromethane, the combined organic layers were washed with brine, dried, and evaporated *in vacuo* to give an orange oil. Distillation at 100–105°C (400 mTorr) afforded 9.71 g (96%) of 2-bromo-2-cyclohexen-1-ol as a white solid; mp: 39–41°C; ir (cm^{-1}): 3600(s, free OH), 3700–3400(bs), 3100–3000, 3000–2800, 2180, 1650, 1445, 1385, 1335, 1220(bs), 1050, 995, 980(s); ^{1}H nmr (δ): 6.20 (t, 1H, J = 4.0 Hz, Br-C=C*H*-CH$_2$-), 4.20 (bt, 1H, J = 4.5 Hz, HO-C*H*-CBr=CH-), 2.23 (bd, 1H, J = 4.5 Hz, O*H*), 2.2–1.55 (m, 6H, -C*H*$_2$-C*H*$_2$-C*H*$_2$-); ms (*m/e*): 178 (M$^+$), 176 (M$^+$), 160, 158, 150, 148. Exact Mass calculated for C$_6$H$_9$O^{79}Br: 175.9837; found: 175.9824.

Potassium hexamethyldisilazide (56.9 mL, 56.0 mmol), 1 M solution in toluene) was added to a −78°C solution of 2-bromo-2-cyclohexen-1-ol (9.2 g, 52.0 mmol) in 250 mL of dry THF and the reaction mixture was stirred for 1 h at −78°C. Then methyl iodide (14.68 g, 0.104 mol) was added and the solution stirred for 1 h. It was then poured into 250 mL of saturated aqueous ammonium chloride, the aqueous phase was extracted several times with diethyl ether, the combined organic layers were washed with brine, dried, and evaporated *in vacuo* to give an orange oil. Distillation (90°C at 0.3 Torr) afforded 9.02 g (95%) of 1-bromo-5-methoxy-1-cyclohexene as a pale yellow oil; ir (cm^{-1}): 3100–3000, 3000–2800, 1645, 1455, 1370, 1195, 1095(s), 1070, 955, 945; ^{1}H nmr (δ): 6.24 (dd, 1H, J = 5.0, 3.5 Hz, Br-C=C*H*-CH$_2$-), 3.75 (m, 1H, CH$_3$-O-C*H*-C=CH-), 3.45 (s, 3H, C*H*$_3$-O-), 2.20–1.95–1.55 (m, 6H, -C*H*$_2$-C*H*$_2$-C*H*$_2$-); ms (*m/e*): 192 (M$^+$), 190 (M$^+$), 164, 162, 160, 158, 121, 119. Exact Mass calculated for C$_7$H$_{11}$O^{79}Br: 189.9994; found: 189.9989.

For personal use only.

1-Bromo-5-methoxy-1-cyclohexene (132 mg, 0.30 mmol) was dissolved in 5 mL of dry THF and the solution was cooled to −78°C. *n*-BuLi (132 mg, 0.30 mmol) was then added slowly and the reaction mixture was stirred for 1 h at −78°C. Then *N*,*N*-dimethylformamide (132 mg, 0.30 mmol) was added and the mixture was stirred at this temperature for another 2 h, after which it was poured into 100 mL of ice cold 1 N hydrochloric acid. The aqueous phase was extracted several times with diethyl ether, the combined organic layers were washed with brine, dried, and evaporated *in vacuo* to give an orange oil. Chromatography on silica gel with hexane – ethyl acetate 4:1 gave 4.93 g (75%) of the desired aldehyde **18***e*; ir (cm^{-1}): 3110, 2950, 2815, 1690(s), 1650, 1215(bs), 1170, 1095, 1070; ^1H nmr (δ): 9.46 (s, 1H, O=C*H*-C=CH-), 6.94 (dd, 1H, J = 5.0, 2.8 Hz, -C=C*H*-CH_2-), 4.13 (t, 1H, J = 3.5 Hz, CH_3-O-C*H*-C=CH-), 3.41 (s, 3H, CH_3-O-), 2.47 (ddt, 1H, J = 20.6, 5.0, 1.0 Hz, -C=CH-CH_2-, β), 2.24 (ddddd, 1H, J = 20.6, 10.5, 7.0, 2.8, 0.5 Hz, -C=CH-CH_2-, α), 2.10 (dq, 1H, J = 14.0, 3.5 Hz, RO-CH-CH_2-CH_2-CH_2-, α), 1.82 (dddt, 1H, J = 14.0, 10.5, 5.0, 3.5 Hz, CH_2-CH_2-CH_2-CH=C-, β), 1.72 (m, 1H, CH_2-CH_2-CH_2-CH=C-, α), 1.34 (tt, 1H, J = 14.0, 3.5 Hz, RO-CH-CH_2-CH_2-CH_2-, β); ms (*m*/*e*): 140 (M^+), 125, 122, 111, 108.

2-{1-Carbo-tert-*butoxyacetyl}-1-methoxy-2-cyclohexene (**20***e*)

The procedure was identical to that described for the preparation of **18***a*. The aldehyde **18***e* (4.0 g, 28.0 mmol) was added to the zinc enolate prepared from *tert*-butyl bromoacetate (10.02 g, 51.0 mmol) and zinc powder (3.91 g, 59.0 mmol). Isolation of the product and chromatography on silica gel with hexane – ethyl acetate 5:1 gave 5.1 g (71%) of the desired β-hydroxy ester 2-{1-carbo-*tert*-butoxy-2-hydroxyethan-2-yl}-1-methoxy-2-cyclohexene as a 1:1 mixture of diastereomers; ir (cm^{-1}): 3700–3400(b), 3100–3000, 3000–2800, 1720(s), 1455, 1370, 1215, 1155(bs), 1095, 1070; ^1H nmr (δ): 5.90 and 5.89 (m, 1H, -C*H*=C-CHOH), 4.55 and 4.45 (m, 1H, -CH=C-C*H*OH), 3.96 and 3.80 (bt, 1H, -CH=C-C*H*OCH_3), 3.47 and 3.45 (s, 3H, -CH=C-CHOCH_3), 2.66–2.46 (m, 2H, HOCH-CH_2-CO_2-), 2.2–1.4 (m, 12H), 1.44 and 1.42 (s, 9H, -$CO_2C(CH_3)_3$); ms (*m*/*e*): 256 (w, M^+), 238, 200, 199, 183, 182, 168. Exact Mass calculated for $C_{14}H_{24}O_4$: 256.1674; found: 256.1674.

This β-hydroxy ester (500 mg, 1.96 mmol) and a large excess of manganese dioxide (4.0 g, 53.0 mmol) were then used to afford 440 mg (88%) of **20***e* after chromatography on silica gel using hexane – ethyl acetate 5:1; ir (cm^{-1}): 3100–3000, 3000–2800, 1730(bs), 1675, 1370, 1325, 1150(bs), 1095, 1070; ^1H nmr (δ): 6.99 (dd, 1H, J = 5.0, 2.5 Hz, -C*H*=C-C=O), 4.21 (t, 1H, J = 3.0 Hz, -CH=C-C*H*OCH_3), 3.58 (ABq, 2H, O=C-CH_2-CO_2-), 3.38 (s, 3H, -OCH_3), 2.38 (ddt, 1H, J = 20.6, 5.0, 1.0 Hz, -C=CH-CH_2-, β), 2.24 (ddddd, 1H, J = 20.6, 10.5, 7.0, 2.8, 0.5 Hz, -C=CH-CH_2-, α), 2.07 (dq, 1H, J = 13.0, 3.0 Hz, RO-CH-CH_2-CH_2-CH_2-, α), 1.82 (dddt, 1H, J = 13.0, 10.5, 5.0 3.0 Hz, CH_2-CH_2-CH_2-CH=C-, β), 1.72 (m, 1H, CH_2-CH_2-CH_2-CH=C-, α), 1.35 (tt, 1H, J = 13.0, 3.0 Hz, RO-CH-CH_2-CH_2-CH_2-, β), 1.46 (s, 9H, -$CO_2C(CH_3)_3$); ms (*m*/*e*): 255 (M^+ + 1), 231, 213, 200, 199, 198. Exact Mass calculated for $C_{14}H_{23}O_4$: 255.1596; found: 255.1598.

*2-(Methyl 2-ethanoyl)-2-(4-penten-1-yl)-1,3-dioxolane (**21**)*

Methyl 3-oxo-7-octenoate (5.0 g, 29.4 mmol), ethylene glycol (4.56 g, 73.4 mmol), and *p*-toluenesulfonic acid monohydrate (56 mg, 0.29 mmol) were added to 300 mL of benzene in a 500 mL round bottom flask equipped with a Dean–Stark apparatus. The solution was heated to reflux for 24 h. Then it was cooled and 5 g of K_2CO_3 were added. The suspension was filtered through silica gel topped with a layer of $MgSO_4$, and washed with dichloromethane. Evaporation of the solvents and distillation (110–110°C at 0.2 Torr) gave **21** as a colorless oil (5.19 g, 82%); ^1H nmr (δ): 6.0–5.5 (m, 1H, CH_2=C*H*-), 5.15–4.8 (m, 2H, CH_2=CH-), 3.97 (s, 4H, -O(CH_2)$_2$-O-), 3.67 (s, 3H, O=COCH_3), 2.65 (s, 2H, O=C-CH_2-CO_2CH_3), 2.2–1.2 (m, 6H, CH_2=CH-(CH_2)$_3$).

*3-Oxo-7-octen-1-ol (**22**a)*

The ester **21** (6.56 g, 0.031 mol) was dissolved in 300 mL of anhydrous THF and the solution was cooled to 0°C. Lithium aluminium hydride (871 mg, 0.23 mol) was then slowly added and the resulting suspension was stirred at 0°C for 1 h. Then, ice cold 1 N HCl was added to destroy the excess hydride and the reaction mixture was poured into 300 mL of ice cold 1 N HCl and stirred at room temperature for 4 h. The aqueous phase was extracted several times with diethyl ether, the combined organic layers were washed with brine, dried, and evaporated *in vacuo* to give 3-oxo-7-octen-1-ol **22** as a colorless oil (4.22 g, 73% crude). The crude product was used without purification in the next reaction. A small sample was purified for characterization; ^1H nmr (δ): 6.0–5.5 (m, 1H, CH_2=C*H*-), 5.2–4.8 (m, 2H, CH_2=CH-), 3.83 (t, 2H, J = 5.6 Hz, O=C-CH_2-CH_2-OH), 2.63 (t, 2H, J = 5.6 Hz, O=C-CH_2-CH_2-OH), 2.44 (t, 2H, J = 7.0 Hz, CH_2=CH-CH_2-(CH_2)$_2$-), 2.2–1.4 (m, 4H, CH_2=CH-CH_2-(CH_2)$_2$-).

*(2E)-7-Oxo-9-*tert-*Butyldimethylsilyloxy-2-nonenal (**18***f*)*

3-Oxo-7-octen-1-ol (4.22 g, 1.19 mmol) was dissolved in 200 mL of anhydrous dichloromethane and cooled to 0°C. Diisopropylethylamine (0.50 mL, 2.82 mmol) followed by *tert*-butyldimethylsilyl triflate (0.30 mL, 1.30 mmol) were added and the reaction mixture was stirred 1 h at 0°C, after which it was poured into 200 mL of saturated aqueous $NaHCO_3$. The aqueous layer was extracted with dichloromethane and the combined organic layers were dried and the solvent evaporated *in vacuo* to give a yellow oil. Chromatography on silica gel eluting with hexane – ethyl acetate 10:1 afforded 7.21 g (90%) of 3-oxo-1-*tert*-butyldimethylsilyloxy-7-octene a colorless oil; ir (cm^{-1}): 3100–3000, 3000–2800, 1710, 1640, 1470, 1465, 1370, 1260, 1210(s), 1090(bs), 915, 850(s); ^1H nmr (δ): 6.0–5.5 (m, 1H, CH_2=C*H*-), 5.15–4.8 (m, 2H, CH_2=CH-), 3.89 (t, 2H, J = 6.5 Hz, O=C-CH_2-CH_2-OR), 2.58 (t, 2H, J = 6.5 Hz, O=C-CH_2-CH_2-OR), 2.47 (t, 2H, J = 7.0 Hz, CH_2=CH-CH_2-(CH_2)$_2$-), 2.2–1.5 (m, 4H, CH_2=CH-CH_2-(CH_2)$_2$-), 0.86 (s, 9H, $OSi(CH_3)_2C(CH_3)_3$), 0.03 (s, 6H, $OSi(CH_3)_2C(CH_3)_3$).

Ozone was bubbled through a −78°C solution of 3-oxo-1-*tert*-butyldimethylsilyloxy-7-octene (1.0 g, 3.90 mmol) in 50 mL of anhydrous dichloromethane until a blue color developed in the solution. Excess triphenylphosphine was then added at this temperature and the solution was left to warm to room temperature and stirred for 2 h. Then, 350 mL of hexane were added to precipitate the triphenylphosphine oxide and the suspension was filtered through Celite. The solvent was evaporated *in vacuo* and the residue was taken up in hexane. Filtration through Celite and evaporation of the solvent afforded the expected aldehyde essentially free of triphenylphosphine oxide. Chromatography on silica gel eluting with hexane – ethyl acetate 7:1 gave 870 mg (83%) of pure 7-*tert*-butyldimethylsilyloxy-5-oxoheptanal; ir (cm^{-1}): 3100–3000, 3000–2800, 1720, 1640, 1470, 1465, 1260, 1215(bs), 1100(bs), 840(s); ^1H nmr (δ): 9.85 (t, 1H, J = 1.5 Hz, O=C*H*-(CH_2)$_3$-), 3.88 (t, 2H, J = 6.5 Hz, O=C-CH_2-CH_2-OR), 2.55 (t, 2H, J = 6.5 Hz, O=C-CH_2-CH_2-OR), 2.45 (t, 2H, J = 7.0 Hz, O=CH-CH_2-(CH_2)$_2$-), 2.0–1.3 (m, 4H, O=CH-CH_2-(CH_2)$_2$-), 0.89 (s, 9H, $OSi(CH_3)_2C(CH_3)_3$), 0.02 (s, 6H, $OSi(CH_3)_2C(CH_3)_3$).

A solution of 7-*tert*-butyldimethylsilyloxy-5-oxo-heptanal (870 mg, 3.4 mmol) and phosphorane **23** (1.126 g, 3.7 mmol) in 50 mL of benzene were heated to reflux for 18 h. After cooling to room temperature the mixture was diluted with 100 mL of diethyl ether and filtered through silica gel, washing several times with diethyl ether. Evaporation of the solvents under reduced pressure gave an orange oil that was chromatographed on silica gel eluting with hexane – ethyl acetate 4:1. Evaporation of the solvents gave 814 mg (84%) of **18***f*; ^1H nmr (δ): 9.5 (d, 1H, J = 7.5 Hz, O=C*H*-CH=CH-(CH_2)$_3$-), 6.82 (dt, 1H, J = 15.0, 6.5 Hz, O=CH-CH=C*H*-(CH_2)$_3$-), 6.10 (ddt, 1H, J = 15.0, 7.5, 1.0 Hz, O=CH-C*H*=CH-(CH_2)$_3$-), 3.85 (t, 2H, J = 6.5 Hz, O=C-CH_2-CH_2-OR), 2.7–1.5 (m, 8H), 0.90 (s, 9H, $OSi(CH_3)_2C(CH_3)_3$), 0.02 (s, 6H, $OSi(CH_3)_2C(CH_3)_3$).

*tert-Butyl (4E)-3,9-dioxo-11-tert-butyldimethylsilyloxy-4-undecenoate (**20**f)*

Zinc powder (466 mg, 7.12 mmol) was activated by stirring for 1 h in 1 N HCl, following washing several times with distilled water, acetone, and diethyl ether, successively. After drying under vacuum overnight, it was charged in a 100 mL round bottom flask and flushed with argon. Anhydrous THF (50 mL) was added followed by ~10% of the *tert*-butyl bromoacetate (0.98 mL, 6.01 mmol) and one small crystal of iodine. The solution was heated to reflux for 10 min. Then the rest of the bromoacetate was slowly syringed in over 1 h. After completing the addition, the solution was further refluxed for 1 h and then cooled to room temperature. Then **18***f* (248 mg, 1.47 mmol) was added while cooling the solution to 0°C (prior cooling to 0°C may result in the precipitation of the magnesium enolate). The solution was then warmed to room temperature and stirred overnight, after which it was poured into 100 mL of ice cold saturated aqueous ammonium chloride. The aqueous phase was extracted several times with diethyl ether, the combined organic layers were washed with brine, dried, and evaporated *in vacuo* to give an orange oil. Chromatography with hexane – ethyl acetate 3:1 afforded 289 mg (70%) of *tert*-butyl (4*E*)-3-hydroxy-9-oxo-11-*tert*-butyldimethylsilyloxy-4-undecenoate as a colorless oil: ^{1}H nmr (δ): 5.55 (m, 2H, HO-CH-CH=C*H*-), 4.42 (m, 1H, HO-C*H*-CH=CH-), 3.87 (t, 2H, J = 6.5 Hz, O=C-CH$_2$-C*H*$_2$-OR), 2.7–1.1 (m, 10H), 1.45 (s, 9H, -CO$_2$C-(C*H*$_3$)$_3$), 0.88 (s, 9H, OSi(CH$_3$)$_2$(C*H*$_3$)$_3$), 0.03 (s, 6H, OSi(C*H*$_3$)$_2$-C(CH$_3$)$_3$).

The *tert*-butyl (4*E*)-3-hydroxy-9-oxo-11-*tert*-butyldimethylsilyloxy-4-undecenoate (651 mg, 1.62 mmol) was dissolved in 50 mL of ethyl acetate and 2.82 g (32.4 mmol) of manganese dioxide were added. The suspension was stirred at room temperature for 24 h (more manganese dioxide was added if needed). The suspension was then filtered through Celite and the solvent removed *in vacuo* to yield a yellow oil. Chromatography on silica gel eluting with hexane – ethyl acetate 5:1 gave 375 mg (58%) of the desired β-keto ester **20***f*; ^{1}H nmr (δ): 6.83 (dt, 1H, J = 16.0, 7.0 Hz, O=C-CH=C*H*-(CH$_2$)$_3$-), 6.15 (dt, 1H, J = 16.0, 0.5 Hz, O=C-C*H*=CH-(CH$_2$)$_3$-), 3.87 (t, 2H, J = 6.2 Hz, O=C-CH$_2$-C*H*$_2$-OR), 3.47 (s, 2H, RO$_2$C-C*H*$_2$-C=O), 2.57 (t, 2H, J = 6.2 Hz, O=C-C*H*$_2$-CH$_2$-OR), 2.49 (t, 2H, J = 7.0 Hz, CH=CH-CH$_2$-CH$_2$-C*H*$_2$-), 2.22 (dt, 2H, J = 7.0 Hz, CH=CH-C*H*$_2$-CH$_2$-Ch$_2$-), 1.75 (qi, 2H, J = 7.0 Hz, CH=CH-CH$_2$-C*H*$_2$-CH$_2$-), 1.45 (s, 9H, -CO$_2$C(C*H*$_3$)$_3$), 0.86 (s, 9H, OSi(CH$_3$)$_2$C(C*H*$_3$)$_3$), 0.03 (s, 6H, OSi(C*H*$_3$)$_2$C(CH$_3$)$_3$).

Preparation of 1-phenylsulfinyl analogs of Nazarov reagents

*(3E)-1-Phenylsulfinyl-2-oxo-3-pentene (**26**)*

A 500 mL, one-neck round bottom flask, oven dried and flushed with argon, was charged with 5.82 mL (41.5 mmol) of dry diisopropylamine and 500 mL of anhydrous THF. After cooling the solution to −78°C, 25.3 mL of *n*-BuLi (1.6 M in hexanes, 40.5 mmol) was slowly added and the reaction mixture was stirred 30 min at 0°C. Then it was cooled to −78°C again and methylphenylsulfoxide (5.55 g, 39.6 mmol) was slowly added via a syringe. After stirring at that temperature for 5 min methyl crotonate (2.1 mL, 19.8 mmol) was added. The reaction mixture was stirred at −78°C for 30 min after which time it was poured into 500 mL of saturated aqueous ammonium chloride. The aqueous phase was extracted with diethyl ether (3 × 100 mL) and the combined organic layers were washed with brine, dried, and evaporated under reduced pressure to give a pale yellow oil. Multiple chromatography on silica gel with hexane – ethyl acetate 1:1 furnished 2.3 g of pure keto sulfoxide **26** (56%) along with 110 mg of a side product (3%) resulting from a Michael addition of methylphenylsulfoxide as a 1:1 mixture of diastereomers. Data for β-keto sulfoxide **26**; ir (cm^{-1}): 3100–3000, 3000–2800, 1735, 1700–1650, 1630; ^{1}H nmr (δ): 7.7–7.4 (m, 5H, C$_6$*H*$_5$-SO-), 6.86 (dq, 1H, J = 15.8, 6.9 Hz, O=C-CH=C*H*-CH$_3$), 6.15 (dq, 1H, J = 15.8, 1.6 Hz, O=C-C*H*-CH-CH$_3$), 4.09 (d, 1H, J = 13.5 Hz, O=C-C*H*$_2$-SOPh), 3.88, (d, 1H, J = 13.5 Hz, O=C-C*H*$_2$-SOPh), 1.90 (dd, 3H, J = 6.9, 1.7 Hz, O=C-CH=CH-C*H*$_3$); ms (*m/e*): 208 (M$^+$), 193, 160, 145, 136, 132, 127, 124, 119. Exact Mass calculated for C$_{11}$H$_{12}$O$_2$S: 208.0558; found: 208.0553. Data for Michael addition products; ir (cm^{-1}): 3100–3000(s), 3000–2800, 1735, 1445, 1305, 1230–1200, 1035. ^{1}H nmr (δ): 7.7–7.5 (m, 10H, C$_6$*H*$_5$-SO-), 3.68 (s, 3H, -CO$_2$C*H*$_3$) and 3.67 (s, 3H, -CO$_2$C*H*$_3$), 3.0–2.3 (m, 10H), 1.24 (d, 3H, J = 6.0 Hz, PhSO-CH$_2$-CH-C*H*$_3$) and 1.16 (d, 3H, J = 6.3 Hz, PhSO-CH$_2$-CH-C*H*$_3$); ms (*m/e*): 241 (M$^+$), 215, 211, 209.

*(3E)-1-Phenylsulfonyl-2-oxo-3-pentene (**27**)*

(3*E*)-1-Phenylsulfinyl-2-oxo-3-pentene **26** (247 mg, 1.19 mmol) was dissolved in 8 mL of dichloromethane and cooled to 0°C. *m*-Chloroperbenzoic acid (80% purity, 306 mg, 1.42 mmol) was added quickly and the reaction mixture was stirred at 0°C for 30 min. Then it was poured into 50 mL of saturated sodium bicarbonate and the aqueous phase was extracted with dichloromethane. The combined organic layers were washed with brine, dried, and evaporated under reduced pressure. Chromatography of the resulting yellow oil eluting with hexane – ethyl acetate gave 166 mg (67%) of **27** as a colorless oil; mp: 68–70°C; ir (cm^{-1}): 3100–3000, 3000–2800, 1695 (s), 1675 (s), 1630 (vs), 1510, 1450, 1325 (vs), 1160 (vs), 975; ^{1}H nmr (δ): 8.0–7.5 (m, 5H, C$_6$*H*$_5$-SO$_2$-), 6.99 (dq, 1H, J = 15.5, 6.8 Hz, O=C-CH=C*H*-CH$_3$), 6.30 (dq, 1H, J = 15.5, 1.5 Hz, O=C-C*H*=CH-CH$_3$), 4.27 (s, 2H, O=C-C*H*$_2$-SO$_2$Ph), 1.95 (dd, 3H, J = 6.8, 1.5 Hz, O=C-CH=CH-C*H*$_3$); ms (*m/e*): 224 (M$^+$), 161, 160, 159, 145. Exact Mass calculated for C$_{11}$H$_{12}$O$_2$S: 208.0507; found: 208.0501.

Preparation of substituted cyclohexenones (dienophiles)

*2,3-Dihydroxy-5β-methylethenyl-2-methylcyclohexanone (**64**)*

A solution of the known epoxide **63** (37.95 g, 0.228 mol) and concentrated sulfuric acid (5 mL) in 300 mL of dry THF and 15 mL of water was heated to reflux for 3 h. Then, dichloromethane was added and the organic extracts were washed with saturated sodium bicarbonate, dried, and the solvents were evaporated *in vacuo*. Flash chromatography of the residue using hexane – ethyl acetate 3:1 afforded the desired *cis* diol **64** (21.1 g, 50%) and a 1:1 mixture of *cis* and *trans* diols (17.3 g, 41%). Data for *cis* diol **64** [α]$_D$ +57.36 (*c* = 4.13, CHCl$_3$); ir (cm^{-1}): 3460, 2960, 1720, 1650, 1380, 1170, 1135, 1055; ^{1}H nmr (δ): 4.82 (bs, 1H, -C=C*H*$_2$), 4.78 (bs, 1H, -C=C*H*$_2$), 4.26 (bs, 1H, -O*H*), 4.07 (t, 1H, J = 2.9 Hz, C*H*-OH), 2.97 (bs, 1H, -O*H*), 2.89 (m, 1H, CH$_2$=C-C*H*-CH$_2$), 2.18 (m, 2H, -CH-C*H*$_2$-C=O), 1.89 (m, 2H, -CH-C*H*$_2$-CH-OH), 1.76 (s, 3H, CH$_2$=C-C*H*$_3$), 1.40 (s, 3H, HO-C-C*H*$_3$). ^{13}C nmr (δ): 212.8 (s, *C*=O), 146.4 (s, CH$_3$-*C*=CH$_2$), 110.2 (t, CH$_3$-C=*C*H$_2$), 78.2 (s, CH$_3$-*C*-OH), 75.8 (d, -*C*H(OH)-), 41.5 (t, -CH-*C*H$_2$-C=O), 39.7 (d, CH$_2$=C-*C*H-CH$_2$), 33.0 (t, -CH-*C*H$_2$-CH-OH), 23.2 (q, *C*H$_3$-C=CH$_2$), 20.4 (q, *C*H$_3$-C-OH).

*Ketal ester **65***

A solution of sodium metaperiodate (6.23 g, 29.3 mmol) in 30 mL of water was added slowly to a vigorously stirred (overhead stirrer) solution of *cis* diol **64** (2.38 g, 12.9 mmol) in 20 mL of methanol, while maintaining the temperature below 20°C. The reaction mixture was stirred vigorously for 1 h and then filtered through Celite, washing with excess ethyl acetate. The organic layer was washed several times with brine, dried, and concentrated under reduced pressure to give the crude aldehyde-acid. This product was dissolved in 30 mL of benzene and ethylene glycol (3 mL, 48.0 mmol) was added followed by *p*-toluenesulfonic acid (33 mg, 0.17 mmol). The reaction flask was equipped with a Dean–Stark apparatus and the mixture was heated to reflux for 6 h. The organic layer was washed with aqueous sodium bicarbonate, water, brine, dried, and the solvents were removed under reduced pressure. The resulting crude ketal-ester, dissolved in 25 mL of methanol, was transesterified with 28% sodium methoxide in methanol (2 mL). After stirring the reaction overnight, the solution was neutralized with acetic acid to pH 7.5 and the solvent was removed under reduced pressure. The residue was extracted with diethyl ether, the organic layer was washed with water, then brine,

dried, and concentrated *in vacuo*. Flash chromatography eluting with hexane – ethyl acetate 3:1 afforded 2.03 g (73%) of **65** as a clear liquid. $[\alpha]_D$ + 12.56 (c = 3.24, $CHCl_3$); ir (cm^{-1}): 3080, 2960, 2885, 1740, 1650, 1440, 1140; ^1H nmr (δ): 4.80 (dd, 1H, J = 9.6, 3.8 Hz, -CH_2CH-($O(CH_2)_2O$)), 4.79 (s, 2H, -C=CH_2), 3.95 (m, 2H, -O-CH_2-CH_2-O-), 3.81 (m, 2H, -O-CH_2-CH_2-O-), 3.63 (s, 3H, -CO_2CH_3), 2.83 (m, 1H, CH_2=C-CH-CH_2), 2.50 (dd, 1H, J = 14.9, 6.4 Hz, -CH-CH_2-C=O), 2.39 (dd, 1H, J = 14.9, 8.8 Hz, -CH-CH_2-C=O), 1.80 (m, 1H, -CH_2-CH-C($O(CH_2)_2O$), 1.69 (s, 3H, CH_2=C-CH_3), 1.66 (m, 1H, -CH_2-CH-C($O(CH_2)_2O$). ^{13}C nmr (δ): 172.3 (s, C=O), 145.9 (s, CH_3-C=CH_2), 111.7 (t, CH_3-C=CH_2), 103.0 (d, -CH_2-CH-($O(CH_2)_2O$)), 64.5 (2t, -O-(CH_2)$_2$O-), 51.1 (q, -CO_2CH_3), 39.3 (d, CH_2=C-CH-CH_2), 38.7 (t, -CH_2-CH-C($O(CH_2)_2O$)), 37.0 (t, -CH-CH_2-C=O), 18.9 (q, CH_3-C=CH_2). Exact Mass calculated for $C_{10}H_{15}O_3$: 183.1021; found: 183.1018.

β-Keto ester ***66***

A mixture of ketal ester **65** (12.5 g, 58.43 mmol) and potassium hydroxide (4.9 g, 87.33 mmol) in 60 mL of ethanol was heated to reflux for 1.5 h. Water (60 mL) was added and the reaction mixture was washed with diethyl ether. The aqueous layer was acidified with 1 N hydrochloric acid to pH 4–5 and 60 mL of brine were added following extraction with diethyl ether. The combined organic extracts were dried and concentrated under reduced pressure. Toluene was added and evaporated until the residue was free of excess water. The crude ketal-acid and carbonyl diimidazole (10.4 g, 64.38 mmol) in 125 mL of dry THF were heated to 50°C for 1 h. The reaction mixture was then cooled to 0°C and added to a previously prepared solution of monomethyl malonate (17.28 g, 0.146 mol) and isopropyl magnesium chloride (2 M in THF, 146 mL, 0.293 mol) in 100 mL of dichloromethane cooled to 0°C. The resulting solution was allowed to warm to room temp. and stirred for 12 h. The hetereogeneous solution was then cooled to 0°C and 0.5 N HCl was added with continuous stirring for 15 min. Diethyl ether was added and the organic layer was washed with saturated sodium bicarbonate, then brine, dried, and concentrated under reduced pressure. Flash chromatography eluting with hexane – ethyl acetate 3:1 afforded 14.4 g (96%) of the desired β-keto ester **66** as a clear liquid. $[\alpha]_D$ + 11.54 (c = 3.38, $CHCl_3$); ir (cm^{-1}): 2960, 2895, 1755, 1720, 1650, 1440, 1320, 1145; ^1H nmr (δ): 4.78 (t, 1H, J = 4.9 Hz, -CH_2-CH-($O(CH_2)_2O$)), 4.77 (s, 2H, -C=CH_2), 3.93 (m, 2H, -O-CH_2-CH_2-O-), 3.79 (m, 2H, -O-CH_2-CH_2-O-), 3.71 (s, 3H, -CO_2CH_3), 3.43 (s, 2H, -CO$CH_2CO_2CH_3$), 2.88 (qi, 1H, J = 7.1 Hz, CH_2=C-CH-CH_2-), 2.72 (dd, 1H, J = 16.6, 9.6 Hz, -CH-CH_2-C=O), 2.62 (dd, 1H, J = 16.6, 11.0 Hz, -CH-CH_2-C=O), 1.81 (ddd, 1H, J = 14.0, 7.5, 3.6 Hz, -CH_2-CH-C($O(CH_2)_2O$), 1.70 (s, 3H, CH_2=C-CH_3), 1.65 (m, 1H, -CH_2-CH-C($O(CH_2)_2O$); ^{13}C nmr (δ): 200.7 (s, C=O), 167.0 (s, CO_2CH_3), 146.1 (s, CH_3-C=CH_2), 111.1 (t, CH_3-C=CH_2), 102.6 (d, -CH_2-CH-($O(CH_2)_2O$)), 64.2 (t, -O-(CH_2)$_2$O-), 64.1 (t, -O-(CH_2)$_2$O-), 51.5 (q, CO_2CH_3), 48.6 (t, -CO$CH_2CO_2CH_3$), 46.6 (t, -CH_2-CH-C($O(CH_2)_2O$)), 37.3 (d, CH_2=C-CH-CH_2), 36.8 (t, -CH-CH_2-C=O), 19.2 (q, CH_3-C=CH_2). Exact Mass calculated for $C_{13}H_{20}O_5$: 256.1311; found: 256.1308.

2-Carbomethoxy-5β-methylethenyl-2-cyclohexen-1-one ***(56)***

A solution of β-keto ester **66** (512 mg, 2.00 mmol) in 50% aqueous acetic acid (25 mL) was stirred under argon for 24 h. Then water (25 mL) and brine (25 mL) were added and the solution was extracted with diethyl ether. The combined organic extracts were washed with water, saturated sodium bicarbonate, water, and brine. After drying the solvent was removed under reduced pressure. The crude product was filtered through a small plug of Florisil eluting with diethyl ether. The solvent was removed under reduced pressure to give the desired cyclohexenone **56** as a pale yellow oil (398 mg, 100%); $[\alpha]_D$ −18.6 (c = 2.38, $CHCl_3$); ir (cm^{-1}): 3080, 2960, 1750, 1720, 1650, 1440, 1380, 1275, 1082, 900; ^1H nmr (δ): 7.74 (dd, 1H, J = 5.9, 2.9 Hz, -C=CH-), 4.84 (bs, 1H, -C=CH_2), 4.78 (s, 1H, -C=CH_2), 3.81 (s, 3H, -CO_2CH_3), 2.67 (m, 3H), 2.44 (m, 2H), 1.75 (s, 3H, CH_2=C-CH_3). Exact Mass calculated for $C_{11}H_{14}O_3$: 194.0943; found: 194.0935.

2-Carbomethoxy-4,4-ethylenedioxy-2-cyclohexenone ***(60)***

A solution of 1,4-cyclohexanedione, mono-ethylene ketal (1.0 g, 6.4 mmol), in 5 mL of dry THF, was added via an addition funnel to a suspension of sodium hydride (793 mg, 19.8 mmol) and dimethyl carbonate (1.44 g, 16.0 mml) in 10 mL of THF at reflux. After 2 min of addition, KH (24 mg, 0.6 mmol) was added and the addition of 1,4-cyclohexanedione, monoethylene ketal, was continued over 1 h. The reaction mixture was heated under reflux for 0.5 h and cooled to 0°C. Acetic acid (10 mL, 3 M in water) was slowly added and the resulting solution was added to 50 mL of brine. The aqueous layer was separated and extracted with dichloromethane. The combined organic layers were washed with brine, dried, and evaporated under reduced pressure to give a white solid. The product was chromatographed on silica gel with hexane – ethyl acetate 5:1 to give 1.21 g (88%) of 2-carbomethoxy-4,4-ethylenedioxy-1-cyclohexanone; mp: 60–61°C; ir (cm^{-1}): 3100–3000, 3000–2800, 1745, 1720, 1660, 1620, 1440, 1350, 1290, 1230, 1215, 1195, 1060; ^1H nmr (δ): 12.80 (s, 1H, HOC=C-CO_2CH_3), 4.00 (m, 4H, -O(CH_2)$_2$O-), 3.75 (s, 3H, -CO_2CH_3), 2.52 (t, 2H, J 6.5 Hz, O=C-CH_2-CH_2-), 2.48 (s, 2H, $(RO)_2$-CH_2-C=C-), 1.86 (t, 2H, J = 6.5 Hz, O=C-CH_2-CH_2-); ms (m/e): 214 (M^+), 183, 182, 157.

This product was then treated according to the procedure described by Liotta *et al.* (2). 2-Carbomethoxy-4,4-ethylenedioxy-1-cyclohexanone (250 mg, 1.17 mmol), phenylselenyl chloride (234 mg, 1.23 mmol), pyridine (102 mg, 1.28 mmol), and hydrogen peroxide (0.1 mL, 1.20 mmol) were used as the reagents. The product **60** (237 mg, 96%) was used without further purification in the next step; ir (cm^{-1}): 3100–3000, 3000–2800, 1745, 1720, 1690, 1440, 1355, 1290, 1230, 1215, 1135, 1055; ^1H nmr (δ): 7.14 (s, 1H, -CH=C-CO_2CH_3), 4.06 (m, 4H, -O(CH_2)$_2$O-), 3.80 (s, 3H, -CO_2CH_3), 2.70 (t, 2H, J = 6.5 Hz, O=C-CH_2-CH_2-), 2.22 (t, 2H, J = 6.5 Hz, O=C-CH_2-CH_2-); ms (m/e): 212 (M^+), 184, 181, 170, 169.

Base-catalyzed cycloaddition or double Michael cyclization of substituted Nazarov reagents

General procedure

2-Carbomethoxy-2-cyclohexenone **1** was slowly added over the indicated period of time to a suspension of cesium carbonate and the substituted Nazarov reagent in a dry solvent at room temperature using a syringe pump. After the required period of time, the reaction mixture was filtered through a pad of Celite or silica gel rinsing first with dichloromethane and then with plenty of ethyl acetate. The solvents were then removed under reduced pressure. Single Michael adducts were prepared in the same way at the indicated temperatures.

Decarboxylations

Method A. The crude product from the cycloaddition was treated directly with *p*-toluenesulfonic acid (0.1 equiv.) in refluxing benzene for the required period of time. Excess solid sodium bicarbonate or pyridine was added to neutralize the mixture and the suspension was stirred for 5 min, then filtered and the solvents evaporated *in vacuo*.

Method B. The crude product from the cycloaddition was dissolved in trifluoroacetic acid (usually 10 mL per mmol) and the solution was stirred at room temperature for 2 h. The excess acid was removed *in vacuo* and the product was found from all acid traces by dissolving it in benzene and evaporating *in vacuo* several times. The remaining product was dissolved in benzene and refluxed for the required period of time. The solvent was then evaporated under reduced pressure.

8aβ-Carbomethoxy-8β-methyl-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione ***(3)***

A solution of 2-carbomethoxy-2-cyclohexenone **1** (89 mg, 0.577 mmol) in chloroform (4 mL) was added over a period of

25 min to cesium carbonate (89 mg, 0.273 mmol) and *tert*-butyl (4*E*)-3-oxo-4-hexenoate **2** (149 mg, 0.808 mmol) in chloroform (10 mL) according to the general procedure. The mixture was stirred for 3 h after the end of the addition. The crude product was decarboxylated according to method A for 1.5 h and neutralized with pyridine (20 μL, 0.24 mmol). Flash chromatography on silica gel (hexane – ethyl acetate 2:1) gave 1-carbomethoxy-10-methyl-bicyclo[4.4.0]decane-2,8-dione **3** (95 mg, 69%); mp: 71–72°C; ir (cm^{-1}): 1740, 1715; ^1H nmr (δ): 3.72 (3H, s, $-CO_2CH_3$), 3.18 (1H, m, CH_2-*H*C-CH_2), 2.95 (1H, m, *H*C-CH_3), 2.80 (1H, dd, J = 5.0, 14.0 Hz, CH(CH_3)-C*H*$_2$-C=O), 2.55–2.00 (6H, m), 2.00–1.90 (2H), 1.56 (1H), 0.88 (3H); ^{13}C nmr (δ): 209.5, 206.2, 170.5, 63.7, 52.5, 45.2, 42.6, 40.2, 39.1, 33.4, 27.0, 22.5, 16.2. Exact Mass calculated for $C_{13}H_{18}O_4$: 238.1205; found: 238.1203.

Single Michael adduct ***5***

To a stirred solution of 2-carbomethoxy-2-cyclohexenone **1** (43 mg, 0.279 mmol) and *tert*-butyl (4*E*)-3-oxo-4-hexenoate **2** (62 mg, 0.337 mmol) in acetonitrile (6 mL) at −15°C was added cesium carbonate (45 mg, 0.138 mmol) and the reaction mixture was stirred for 30 min. The crude product was purified by flash chromatography with hexane – ethyl acetate 4:1 to afford single Michael adduct **5** as a colorless oil (50 mg, 53%); ir (cm^{-1}): 1735, 1710, 1690, 1650, 1630; ^1H nmr (δ): 7.20–6.60 (1H, m, -CH=C*H*-CH_3), 6.60–6.00 (1H, m, -CO-C*H*=CH-), 3.90–3.60 (5H, m, $-CO_2CH_3$, 2 × -CO-C*H*-CO_2-), 2.60–1.60 (7H), 2.00–1.80 (3H, m, =CH-CH_3), 1.55–1.40 (9H, m, $-CO_2$-C(CH_3)$_3$).

Cyclization of single Michael adduct ***5***

Single Michael adduct **5** (8 mg, 0.023 mmol) in acetonitrile (4 mL) and cesium carbonate (6 mg, 0.018 mmol) were stirred for 1 h at room temperature. The crude product was decarboxylated according to method A and neutralized with pyridine (2 μL, 0.025 mmol). The solution was then filtered through silica gel, washing with ethyl acetate, and the solvents evaporated to afford a mixture of *cis*-decalin **3** and **4** (3 mg, 55%), in a 68:32 ratio, as determined by gas chromatography. For spectroscopic data of isomer **4** see ref. 2.

*8aβ-Carbomethoxy-7β,8β-dimethyl-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**28**) and its 7α isomer (**29**)*

A solution of *tert*-butyl β-keto ester **20***b* (84 mg, 0.4 mmol), 2-carbomethoxy-2-cyclohexen-1-one **1** (47 mg, 0.31 mol), and cesium carbonate (44 mg, 0.13 mmol) in chloroform (7.5 mL) were stirred for 3 h. The crude product was then decarboxylated using method B. Flash chromatography (hexane – ethyl acetate 7:3 yielded 50 mg (65%) of a mixture of epimeric compounds **28**:**29** (7:3). Data for compound **28**: mp: 91–92°C (heptane); R_f 0.29 (hexene – ethyl acetate (4:1); ^1H nmr (δ): 3.74 (3H, s, -COOC*H*$_3$), 3.20 (1H, m, -CH_2C*H*CH_2-), 3.05 (1H, qd, J = 6.6, 5.1 Hz, -(CH_3)C*H*CO-), 2.89 (1H, qd, J = 7.3, 5.1 Hz, -(CH_3)C*H*-CH(CH_3)CO-), 2.55–1.49 (8H, m), 1.00 (3H, d, J = 6.6 Hz, -(C*H*$_3$)CHCO-), 0.64 (3H, d, J = 7.3 Hz, -(C*H*$_3$)CHCH(CH_3)CO-; irradiation of this doublet transforms the signal (qd) at d 2.89 ppm in a doublet, J = 5.1 Hz). Data for compound **29**: mp: 84–86°C (heptane); R_f 0.26 (hexane – ethyl acetate 4:1); ^1H nmr (δ): 3.80 (3H, s, -COOC*H*$_3$), 3.09 (1H, dq, J = 11.2, 5.0 Hz, -CH_2-C*H*CH_2-), 2.72 (1H, dq, J = 12.1, 6.5 Hz, -(CH_3)C*H*CO-), 2.44–1.50 (9H, m), 1.12 (3H, d, J = 6.9 Hz, -(C*H*$_3$)CHCO-), 1.08 (3H, d, J = 6.5 Hz, -(C*H*$_3$)CHCH(CH_3)C -); simultaneous irradiation of the doublets at d 1.12 and 1.08 ppm transformed the signal (dq) at d 2.72 ppm in a doublet, J = 12.1 Hz).

Compounds ***30*** *and* ***31***

A solution of *tert*-butyl β-keto ester **20***c* (173 mg, 0.77 mmol), 2-carbomethoxy-2-cyclohexen-1-one **1** (166 mg, 1.1 mmol), and cesium carbonate (113 mg, 0.34 mmol) in chloroform (19 mL) was stirred for 3 h. The crude product was then decarboxylated using method B. Flash chromatography (hexane – ethyl acetate 4:1) yielded 142 mg (66%) of a 1:1 mixture of epimeric compounds **30** and **31**. Data for mixture: ir (cm^{-1}): 1740–1710 (C=O ester and ketone); ms (*m/e*): 278 (M^+), 246 ($M^+ - CH_3OH$), 197 ($MH^+ - C_6H_{10}$). Exact Mass calculated for $C_{16}H_{22}O_4$ (M^+): 278.1518; found: 278.1514. Data for compound **30**: mp 175–177°C (heptane); R_f 0.41 (hexane – ethyl acetate (1:1)); ^1H nmr (δ): 3.74 (3H, s, -COOC*H*$_3$), 3.20 (1H, m, -CH_2C*H*CH_2-), 2.98 (1H, m, -CHC*H*CO-), 2.84 (1H, dt, J = 12.0, 5.0 Hz, -C*H*CHCO-), 2.58–0.97 (16H, m). *8aβ-Carbomethoxy-8aβ-{(2Z)-1-Carbomethoxy-1-penten-5-yl}-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**41**)*

Compound **41** was prepared according to the general procedure for 2 h and decarboxylated using method A for 2 h. Dichloromethane (5 mL), *tert*-butyl (3*E*,9*Z*)-3-oxo-10-carbomethoxy-4.9-decadienoate **17** (150 mg, 0.49 mmol), 2-carbomethoxy-2-cyclohexenone **1** (114 mg, 0.68 mmol), and cesium carbonate (71 mg, 0.22 mmol) afforded, after chromatography on silica gel and eluting with hexane – ethyl acetate 3:1, 20 mg (69%) of the decalin product; ir (cm^{-1}): 3020, 3000–2800, 1700, 1690, 1435, 1260(bs), 1215(bs), 1080; ^{1}H nmr (δ): 6.14 (dt, 1H, J = 11.5, 7.5 Hz, CH_3O_2C-CH=CH-CH_2-), 5.76 (dt, 1H, J = 11.5, 1.6 Hz, CH_3O_2C-CH=CH-CH_2-), 3.75 (s, 3H, -CO_2CH_3), 3.69 (s, 3H, CO_2CH_3), 3.13 (m, 1H, O=C-CH_2-CH-$(CH_2)_3$-C=O), 2.8–1.03 (m, 17H), ms (*m/e*): 350 (M^+), 251, 237, 223. Exact Mass calculated for $C_{19}H_{26}O_6$: 350.1729; found: 350.1732.

*8aβ-Carbomethoxy-8β-{1-carbomethoxy-1-pentyn-5-yl}-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**42**a)*

Compound **42***a* was prepared according to the general procedure (2 h) and decarboxylated using method A for 2 h. Dichloromethane (5 mL), β-keto ester **16***a* (150 mg, 0.51 mmol), 2-carbomethoxy-2-cyclohexenone (119 mg, 0.71 mmol), and cesium carbonate (75 mg, 0.23 mmol) afforded, after chromatography on silica gel and eluting with hexane – ethyl acetate 3:1, 71 mg (40%) of product **42***a*; ir (cm^{-1}): 3020, 3000–2800, 2240, 1710, 1435, 1260(bs), 1215(bs), 1080; ^{1}H nmr (δ): 3.76 (s, 3H, -CO_2CH_3), 3.72 (s, 3H, -CO_2CH_3), 3.10 (m, 1H, O=C-CH_2-CH-$(CH_2)_3$-C=O), 2.78–2.65 (m, 2H, -CH-$(CH_2)_3$-C≡C- and O=C-CH_2-CH-$(CH_2)_3$-C≡C-, β), 2.55–2.10 (m, 8H), 2.00–1.88 (m, 2H), 1.80–1.50 (m, 5H); ^{13}C nmr (62.5 MHz, δ), 209.7 (s, *C*=O), 206.3 (s, *C*=O), 170.4 (s, -*C*O_2CH_3), 168.9 (s, -*C*O_2CH_3), 64.3 (s, CH_3O_2C-*C*-C=O), 52.7 (q, -CO_2CH_3), 52.5 (q, -CO_2CH_3), 42.8 (t), 41.4 (t), 40.1 (t), 39.9 (d, O=C-CH_2-*C*H-$(CH_2)_3$-C=O), 38.0 (d, -*C*H-$(CH_2)_3$-C≡C-), 28.4 (t), 27.0 (t), 25.2 (t), 22.7 (t), 18.3 (t); ms (*m/e*): 348 (M^+), 251, 237, 223. Exact Mass calculated for $C_{19}H_{24}O_6$: 348.1572; found: 348.1569.

*8aβ-Carbomethoxy-8β-{1-carbomethoxy-1-pentyn-5-yl}-7-methyl-2,3,4,4a,5,7,8,8a-octahydronapthalene-1,6-dione (**42**b)*

Compound **42***b* was prepared according to the general procedure (2 h) and decarboxylated using method A for 2 h. Dichloromethane (5 mL), β-keto ester **16***b* (150 mg, 0.49 mmol), 2-carbomethoxy-2-cyclohexenone (114 mg, 0.68 mmol), and cesium carbonate (71 mg, 0.22 mmol) afforded, after chromatography on silica gel, eluting with hexane – ethyl acetate 3:1, 89 mg (52%) of product **42***b* as a mixture of α- and β-methyl isomers in a 5:2 ratio; ir (cm^{-1}): 3020, 3000–2800, 2240, 1710, 1435, 1260(bs), 1215(bs), 1080. ^{1}H nmr (δ): 3.75 (s, 6H, 2 × -CO_2CH_3), 3.16 (m, 1H, O=C-CH_2-CH-$(CH_2)_3$-C=O), 3.03 (m, 1H, O=C-C$H$$CH_3$), 2.67 (q, 1H, J = 4.8 Hz, -CH-$(CH_2)_3$-C≡C-), 2.6–1.0 (m, 14H), 1.03 (d, 3H, J = 6.5 Hz, O=C-CHCH_3). Signals distinguishable for the other isomers: 3.81 (s, <3H, -CO_2CH_3), 2.79 (m, <1H, O=C-C$H$$CH_3$), 1.14 (s, <3H, O=C-CHC$H_3$). ms (*m/e*): 362 ($M^+$), 265, 251, 237. Exact Mass calculated for $C_{20}H_{26}O_6$: 362.1728; found: 362.1727.

*Tricyclic aldehyde **46***

The tricyclic aldehyde **46** was obtained according to the general procedure (1 h) and decarboxylated using method A for 45 min. Substituted Nazarov reagent **11***a* (28.5 mg, 0.100 mmol) and 2-carbomethoxy-2-cyclohexenone **1** (19 mg, 0.123 mmol) gave, after purification, tricyclic aldehyde **46** (9 mg, 32%); mp: 134–137°C; ir (cm^{-1}): 1720, 1710, 1665, 1635; ^{1}H nmr (δ): 10.14 (1H, s, -CHO), 3.71 (3H, s, -CO_2CH_3), 3.35 (1H, dd, J = 8.3, 13.9 Hz, HβC12), 2.80 (2H, m), 2.50–1.20 (13H, m); ms (*m/e*): 276 (M^+), 217 (M^+ – CO_2CH_3). Exact Mass calculated for $C_{16}H_{20}O_4$: 276.1361; found: 276.1361.

*Compound **48***

Compound **48** was prepared according to the general procedure (5 h) and decarboxylated using method A for 3 h. Dichloromethane (50 mL), β-keto ester **20***e* (684 mg, 2.69 mmol), 2-carbomethoxy-2-cyclohexenone (584 mg, 3.76 mmol), and cesium carbonate (350 mg, 1.07 mmol) afforded, after chromatography on silica gel and eluting with hexane – ethyl acetate, 3:1, 386 mg (52%) of product **48**, which can be recrystallized from hexane – ethyl acetate 3:1; mp: 137–138°C. ir (cm^{-1}); 3010, 3000–2800, 1740, 1715, 1685, 1620, 1215(vs); ^{1}H nmr (δ): 6.99 (q, 1H, J = 4.0 Hz, CH_2-CH=C-C=O), 3.74 (s, 3H, -CO_2CH_3), 3.30 (m, 1H, CH_2-CH-C=CH-), 2.97 (m, 1H, -CH-CH_2-C=O), 2.48 (m, 2H), 2.34 (dd, 2H, J = 8.1, 6.2 Hz), 2.24 (m, 2H), 2.1–1.4 (m, 8H); ms (*m/e*): 277 (M^+ + 1), 276 (M^+), 258, 245, 244, 218, 217, 216. Exact Mass calculated for $C_{16}H_{20}O_4$: 276.1358; found: 276.1361. X-ray analysis (see footnote 3).

*8aβ-Carbomethoxy-5-carbo-*tert*-butoxy-8β-{1-tert-butyldimethylsilyloxy-3-oxo-hexan-6-yl}-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**49**)*

Compound **49** was prepared according to the general procedure (2 h). Dichloromethane (5 mL), β-keto ester **20***f* (100 mg, 0.25 mmol), 2-carbomethoxy-2-cyclohexenone (54 mg, 0.35 mmol),

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

and cesium carbonate (33 mg, 0.10 mmol) afforded, after chromatography on silica gel and eluting with hexane – ethyl acetate 6:1, 85 mg (75%) of the product **49**; ir (cm^{-1}); 3000–2800, 1735, 1710, 1685, 1620, 1470, 1465, 1260, 1215(bs), 1100(bs), 840(s); ^1H nmr (δ): 12.44 (s, 1H, RO_2C-C=CO*H*), 3.85 (t, 2H, J = 6.3 Hz, O=C-CH_2-CH_2-OR), 3.67 (s, 3H, -CO_2CH_3), 3.41 (dd, 1H, J = 12.0, 4.5 Hz, -CH-$CH(CO_2C(CH_3)_3)_3$), 2.56 (t, 2H, J = 6.3 Hz, O=C-CH_2-CH_2-OR), 2.5–2.3 (m, 6H), 2.15–1.1 (m, 9H), 1.49 (s, 9H, -$CO_2C(CH_3)_3$), 0.86 (s, 9H, $OSi(CH_3)_2C(CH_3)$), 0.03 (s, 6H, $OSi(CH_3)_2C(CH_3)_3$). ms (*m/e*): 550 (w, M^+), 493, 436, 418. Exact Mass calculated for $C_{29}H_{46}O_8Si$: 550.2962; found: 550.2966.

*Tetracyclic compound **51***

Compound **49** (74 mg, 0.13 mmol) was decarboxylated using method A. The product was chromatographed on silica gel eluting with hexane – ethyl acetate 5:1, to afford 18 mg (32%) of the decarboxylated decalin **50** and 6 mg (14%) of the nondecarboxylated decalin. The silyloxy group had been eliminated in both compounds. Compound **50**: ^1H nmr (δ): 6.33 (dd, 1H, J = 17.7, 10.0 Hz, -C*H*=CH_2), 6.18 (dd, 1H, J = 17.7, 1.6 Hz, -CH=C*H*$_2$, *trans*), 5.82 (dd, 1H, J = 10.0, 1.6 Hz, -CH=C*H*$_2$, *cis*), 3.67 (s, 3H, -CO_2CH_3), 3.42 (dd, 1H, J = 11.6, 4.0 Hz, -CH-C*H*$CO_2C(CH_3)_3)_3$), 2.6–1.1 (m, 16H), 1.50 (s, 9H, -$CO_2C(CH_3)_3$). Minor compound: ^1H nmr (δ): 6.30 (dd, 1H, J = 17.5, 10.0 Hz, -C*H*=CH_2), 6.15 (dd, 1H, J = 17.5, 1.5 Hz, -CH=C*H*$_2$, *trans*), 5.79 (dd, 1H, J = 10.0, 1.5 Hz, -CH=C*H*$_2$, *cis*), 3.72 (s, 3H, -CO_2CH_3), 3.13 (m, 1H, O=C-CH_2-C*H*-$(CH_2)_3$-C=O), 2.9–1.1 (m, 17H).

The major compound **50** (18 mg, 0.043 mmol) was resubmitted to the same conditions and 17 mg (94%) of tetracyclic compound **51** as a 2:2:1 mixture of three isomers were isolated after column chromatography with hexane – ethyl acetate 1:1. One isomer (eluting first) could be purified and was characterized; ir (cm^{-1}): 3000–2800, 1735–1710(bs), 1470, 1450, 1435, 1260, 1215(bs), 1160, 1105; ^1H nmr (δ): 4.1–3.9 (m, 2H, -O-C*H*$_2$-CH_2-C=O), 3.72 (s, 3H, -CO_2CH_3), 3.52 (ddt, 1H, J = 14.0, 6.25, 2.0 Hz, O=C-CH_2-C*H*-$(CH_2)_3$-C=O), 2.88 (m, 1H), 2.7–1.1 (m, 17H). ms (*m/e*): 320 (M^+), 302, 288, 277, 261, 260, 243. Exact Mass calculated for $C_{18}H_{24}O_5$: 320.1624; found: 320.1624.

*8aβ-Carbomethoxy-7α-methyl-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**52**)*

To a solution of 100 mg (0.5 mmol) of (3*E*)-1-phenylsulfinyl-2-oxo-3-pentene **26** in 5 mL of anhydrous dichloromethane, was added 63 mg of cesium carbonate (0.19 mmol). Then, 2-carbomethoxy-2-cyclohexenone **1** (104 mg, 0.67 mmol) was added over a period of 1 h and the resulting suspension was stirred 1 h at room temperature, after which it was filtered through a pad of silica gel and washed with ethyl acetate. The crude product was chromatographed on silica gel (10 g, at least 100:1 w/w of silica gel to product) eluting with hexane – ethyl acetate 3:1, to yield 79 mg (70%) of pure **52** as a white crystalline compound; mp: 80–82°C; ir (cm^{-1}): 3010 (s), 3000–2800 (m), 1750, 1735, 1720, 1675(s), 1440, 1235; ^1H nmr (δ): 5.99 (bd, 1H, J = 2.0 Hz, O=C-C*H*-C-), 3.75 (s, 3H, -CO_2CH_3), 3.23 (ddq, 1H, J = 6.9, 4.8, 3.2 Hz, H_3C-C*H*-CH_2-), 2.90 (dddd, 1H, J = 14.9, 12.5, 4.9, 2.0 Hz, O=C-CH_2-CH_2-C*H*$_2$-C=CH-C=O), β), 2.75 (dd, 1H, J = 17.8, 4.8 Hz, O=C-C*H*$_2$-CH_2-CH_2-C=CH-C=O), 2.7–2.5 (m, 3H, O=C-CH_2-CH_2-C*H*$_2$-C=CH-C=O, α and H_3C-CH-C*H*$_2$-), 2.30 (ddd, 1H, J = 17.8, 3.2, 0.9 Hz, O=C-C*H*$_2$-CH_2-CH_2-C=CH-C=O), 2.12 (m, 1H, O=C-CH_2-C*H*$_2$-CH_2-C=CH-C=O), 1.7 (m, 1H, O=C-CH_2-C*H*$_2$-CH_2-C=CH-C=O), 0.95 (d, 3H, J = 6.9 Hz, *H*$_3$C-CH-). ^{13}C nmr (δ): 203.5 (s, *C*=O), 197.4 (s, *C*=O), 156.3 (s, -*C*O_2CH_3), 127.0 (d, -C=*C*H), 126.1 (s, -*C*=CH), 66.4 (s, CH_3O_2C-*C*-C=CH), 53.5 (q, CO_2CH_3), 42.6 (t, -*C*H_2C=O), 40.1 (t, -CH_2C=O), 34.5 (d, -*C*H-CH_3), 33.0 (t, -*C*H_2-C=CH-), 20.7 (t, -CH_2-*C*H_2-CH_2-), 16.0 (q, -CH-*C*H_3). ms (*m/e*): 236 (M^+), 208, 194, 179, 177, 176, 163, 162, 135, 134. Exact Mass calculated for $C_{13}H_{16}O_4$: 236.1049; found: 236.1046.

*Monoaddition product **68***

To a solution of 100 mg (0.5 mmol) of (3*E*)-1-phenylsulfinyl-2-oxo-3-pentene **26** and 2-carbomethoxy-2-cyclohexenone **1** (104 mg, 0.67 mmol) in 5 mL of anhydrous dichloromethane at 0°C (or −5°C in acetonitrile) was added 63 mg of cesium carbonate (0.19 mmol). The resulting suspension was stirred at that temperature for 1 h. Then it was filtered through a pad of silica gel and washed with ethyl acetate. The crude product was chromatographed on silica gel, eluting with hexane – ethyl acetate 3:1 (200 mL) and then 1:1, to yield 81 mg (46%, 68% based on recovered starting material of pure **68** as a mixture of diastereomers along with 33 mg of the starting sulfoxide **26**. Both diastereomers of adduct **68** exist as a mixture of keto and enol forms; ir (cm^{-1}): 3010 (s), 3000–2800 (m), 1740, 1715, 1655, 1620, 1445, 1225, 1205, 1045; ^1H nmr (δ): 12.67 and 12.60 (s, C=C-O*H*), 7.7–7.4 (m), 6.83 (dq, J = 15.7, 6.9 Hz), 6.7;–6.3 (m), 5.77 and 5.66 (dq, J = 6.9, 1.6 Hz), 4.47 (d, J = 12.0 Hz, (C=O)C*H*-SOPh), 4.29 (d, J = 7.1 Hz, (C=O)C*H*-SOPh), 4.2–4.0 (m), 3.87 (s, -$COCH_3$), 3.84 (s, -$COCH_3$), 2.9–1.5 (m), 1.76 and 1.66 (dd, J = 6.9, 1.6 Hz, -CH-CH_3). ms (*m/e*): 362 (M^+), 346, 345, 344, 314, 313, 312. Exact Mass calculated for $C_{19}H_{22}O_5S$: 362.1195; found: 362.1188.

*Cyclization of adduct **68***

To a solution of 29 mg (0.08 mmol) of adduct **68** in 0.5 mL of anhydrous dichloromethane was added 10 mg of cesium carbonate (0.032 mmol) and the resulting suspension was stirred for 1 h at room temperature. Then it was filtered through a pad of silica gel, washing with ethyl acetate. The crude product was chromatographed on silica gel (2.9 g, at least 100:1 w/w of silica gel/product), eluting with hexane – ethyl acetate 3:1 (100 mL) and then 1:1, to yield 11 mg (58%) of a compound whose spectral data were identical with those of compound **52**.

*Catalytic hydrogenation of compound **52***

Palladium on charcoal (3 mg, 10% w/w) was added to a solution of 30 mg (0.13 mmol) of **52** in 1 mL of ethyl acetate. The flask was then flushed with hydrogen several times and the solution was stirred under a positive pressure of hydrogen for 72 h. The reaction mixture was then filtered through a pad of Celite and the solvent was evaporated under reduced pressure yielding a colorless oil. Chromatography on silica gel eluting with hexane – ethyl acetate 3:1 furnished 19 mg (60%) of the known compound **4** (2); ir (cm^{-1}): 3100–3000, 3000–2800, 1735, 1730–1700; ^1H nmr (δ): 3.81 (s, 3H, -CO_2CH_3), 3.0-2.7 (m, 3H), 2.5–1.5 (m, 9H), 1.15 (d, 3H, J = 6.9 Hz, CH-CH_3).

*8aβ-Carbomethoxy-7-methyl-5-phenylsulfonyl-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**53**)*

A solution of 60 mg (0.5 mmol) of (3*E*)-1-phenylsulfonyl-2-oxo-3-pentene **27** in 2 mL of anhydrous dichloromethane was treated with cesium carbonate (35 mg, 0.11 mmol) and 2-carbomethoxy-2-cyclohexenone **1** (58 mg 0.37 mmol) in the same way as for (3*E*)-1-phenylsulfinyl-2-oxo-3-pentene **26**. Chromatography on silica gel, eluting with hexane – ethyl acetate 3:1, yielded 46 mg (45%) of pure **53**; ir (cm^{-1}): 3120, 3000–2800, 1720(s), 1450, 1435, 1320, 1310, 1250, 1215, 1150, 1080; ^1H nmr (δ): 7.8–7.5 (m, 5H, C_6H_5-SO_2-), 4.00 (m, 1H), 3.86 (s, 3H, -CO_2CH_3), 3.58 (d, 1H, J = 6.6 Hz), 2.8–2.5 (m, 4H), 2.4–1.5 (m, 5H), 1.09 (d, 3H, J = 6.1, CH-CH_3). ms (*m/e*): 378 (M^+), 363, 347, 319, 292, 265, 237, 236, 233. Exact Mass calculated for $C_{19}H_{22}O_6S$: 378.1137; found: 378.1144.

*Reduction of sulfone **53***

The sulfone **53** (20 mg, 0.53 mmol) was dissolved in 1 mL of a mixture of THF and water (9:1). Aluminium foil (BDH, 23 mg, 0.84 mmol) was cut in small chunks, soaked in an aqueous mercuric chloride solution (2%) for 15 s, and rinsed with absolute ethyl alcohol and diethyl ether. The chunks were then dropped in the reactant solution and the mixture was stirred at room temperature for 4.5 h. The aluminium foil had completely dissolved after 2 h and the solution then took on a grayish color. The solution was then

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

filtered through a pad of Celite and the solvents were evaporated under reduced pressure. The residue was taken up in ether, washed with saturated sodium bicarbonate and then with brine, dried and the solvents evaporated under reduced pressure. Chromatography on silica gel, eluting with hexane – ethyl acetate 3:1, furnished 6 mg (48%, 79% based on recovered starting material of **4** and 8 mg of starting sulfone **53**.

*8aβ-Carbomethoxy-4β,8β-dimethyl-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**55**)*

A solution of *tert*-butyl (4*E*)-3-oxo-4-hexenoate **2** (459 mg, 2.5 mmol), 2-carbomethoxy-4-methyl-2-cyclohexenone **54** (344 mg, 2.0 mmol), and cesium carbonate (365 mg, 1.12 mmol) in chloroform (60 mL) was stirred for 3 h. The crude product was then decarboxylated using method B. Data for the bis-β-keto ester (before decarboxylation): ^{1}H nmr (δ): 12.67 (1H, s, -C=O*H*), 3.65 (3H, s, -COC*H*$_3$), 3.26 (1H, d, *J* = 12.5 Hz, -(CH$_3$)$_2$CC*H*C=C-OH), 2.80–1.52 (8H, m), 1.48 (9H, s, -C(C*H*$_3$)$_3$), 1.14 (3H, d, *J* = 7.1 Hz, -CH(C*H*$_3$), 0.97 (3H, d, *J* = 7.3 Hz, -CH$_2$C(C*H*$_3$)CH-); ms, (*m/e*): 334 (M$^+$ – H$_2$O), 295 (M$^+$ – C$_4$H$_9$).

β-Keto ester **55** (73% yield): mp: 86–88°C; ir (cm^{-1}): 1735–1720 (C=O ester and ketones); ^{1}H nmr (δ): 3.79 (3H, s, -COOC*H*$_3$), 2.75–1.43 (11H, m), 1.08 (3H, d, *J* = 6.5 Hz, -CH(C*H*$_3$), 1.04 (3H, d, *J* = 6.3 Hz, -CH$_2$CH(C*H*$_3$)CH-); ^{13}C nmr (δ): 208.9, 207.8 (2s, -*C*=O), 171.4 (s, -*C*O$_2$CH$_3$), 64.7 (s, O=C-*C*(CO$_2$CH$_3$)-C-), 52.1 (q, -CO$_2$*C*H$_3$), 48.0 (d, -CH$_2$CH(CH$_3$)*C*HCH$_2$-), 45.5, 41.9, 38.2, 32.8 (4t, -*C*H$_2$), 33.3 (d, -*C*H(CH$_3$), 31.1 (d, -CH$_2$*C*H(CH$_3$)-CH-), 19.4 (q, -CH$_2$CH(*C*H$_3$)CH-), 16.3 (q, -CH(*C*H$_3$)).

*8aβ-Carbomethoxy-8β-methyl-3β-methylethenyl-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**57**)*

A solution of *tert*-butyl (4*E*)-3-oxo-4-hexenoate **2** (285 mg, 1.5 mmol), 2-carbomethoxy-5β-methylethenyl-2-cyclohexenone **56** (600 mg, 3.1 mmol), cesium carbonate (250 mg, 0.8 mol) in CHCl$_3$ (38 mL) was stirred for 3 h. The crude product was then decarboxylated using method B to afford ester **57** as the major compound of a (85:11:4) mixture of three compounds (75% total yield). Compound **57** was isolated pure by means of flash chromatography (hexane – ethyl acetate 7:3) while the two diastereomeric side products could not be separated from each other: R_f for **57** and its isomers were 0.30 and 0.25, respectively, in hexane – ethyl acetate 7:3). **57** was recrystallized in a 20:1 mixture of heptane and dichloromethane: mp: 97–98°C; $[\alpha]_D$ + 117.3 (*c* = 1.3, CHCl$_3$); ir (CH$_2$Cl$_2$, cm^{-1}): 1740–1710 (C—O ester and ketones); ^{1}H nmr (δ): 4.81, 4.74, (2H, 2s, -C=C*H*$_2$), 3.76 (3H, s, -CO$_2$C*H*$_3$), 3.22–1.55 (11H, m), 1.72 (3H, s, -(C*H*$_3$)C=CH$_2$), 0.84 (3H, d, *J* = 7.4 Hz, -CHC*H*$_3$); ^{13}C nmr (δ): 209.7, 205.5 (2s, -*C*=O), 170.5 (s, -*C*O$_2$CH$_3$), 146.3 (s, -(CH$_3$)*C*=CH$_2$), 110.7 (t, -(CH$_3$)C=*C*H$_2$), 62.7 (s, O=C-*C*(CO$_2$CH$_3$)-C-), 52.8 (q, -CO$_2$*C*H$_3$), 45.8, 45.1, 52.7, 32.5, (4t, -*C*H$_2$), 40.8, 37.2 (2d, -*C*H), 33.5 (d, -*C*HCH$_3$), 20.5 (q, -C(*C*H$_3$)=CH$_2$), 16.5 (q, -CH*C*H$_3$); unseparated mixture of minor compounds: ^{1}H nmr (δ): 4.82–4.74 (>2H, m, -C=C*H*$_2$), 3.82 (<3H, s, -CO$_2$C*H*$_3$), 3.81 (3H, s, -CO$_2$C*H*$_3$), 3.20–1.45 (11H, m), 1.73 (>3H, s, -(C*H*$_3$)C=CH$_2$), 1.16 (<3H, d, *J* = 6.9 Hz, -CH-C*H*$_3$), 1.14 (3H, d, *J* = 6.6 Hz, -CH-C*H*$_3$).

*8aβ-Carbomethoxy-4,4,8β-trimethyl-4,4a,5,7,8,8a-hexahydronaphthalene-1,6-dione (**59**)*

To a stirred solution of *tert*-butyl (4*E*)-3-oxo-4-hexenoate **2** (77 mg, 0.42 mmol) and 2-carbomethoxy-4,4,dimethylcyclohexadienone **58** (603 mg, 3.3 mmol) in acetonitrile (10 mL) was added cesium carbonate (60 mg, 0.19 mmol). After 3 h, the cesium carbonate was filtered through silica gel and the solvent was evaporated under reduced pressure. Flash chromatography (hexane – ethyl acetate 4:1) yielded 106 mg (70%) of bis-β-keto ester; ^{1}H nmr (δ): 12.79 (1H, s, -C=C-O*H*), 6.61 (1H, d, *J* = 10.2 Hz, -C*H*=CH-CO-), 5.89 (1H, d, *J* = 10.2 Hz, -CH=C*H*-CO-), 3.77 (1H, s, -(CH$_3$)$_2$CC*H*C=C-OH), 3.63 (3H, s, -CO$_2$C*H*$_3$), 2.55–2.40 (3H, m), 1.48 (9H, s, -CO$_2$(C*H*$_3$)$_3$), 1.20, 1.06 (6H, 2s, -C(C*H*$_3$)$_2$), 1.10 (3H, d, *J* = 6.2 Hz, -CHC*H*$_3$); ms (*m/e*): 364 (M$^+$), 333 (M$^+$ – OCH$_3$), 307 (M$^+$ – C$_4$H$_9$).

This crude product was then decarboxylated using method B. Flash chromatography (hexane – ethyl acetate 3:2) of the residue yielded 66 mg (86%) of **59** as a solid. The product could be recrystallized in heptane; mp: 88–89°C; ir (CH$_2$Cl$_2$, cm^{-1}): 1740–1710 (C=O ester and ketone), 1680 (C=O conjugated ketone); ^{1}H nmr (δ): 6.54 (1H, d, *J* = 10.3 Hz, -C*H*=CH-CO-), 5.96 (1H, d, *J* = 10.3 Hz, -CH=C*H*-CO-), 3.75 (3H, s, -CO$_2$C*H*$_3$), 3.04 (1H, t, *J* = 6.0 Hz, -(CH$_3$)$_2$CC*H*CH$_2$-), 2.75–2.20 (5H, m), 1.20 (3H, s, -C(C*H*$_3$)$_2$), 1.12 (3H, s, -C(C*H*$_3$)$_2$), 1.09 (3H, d, *J* = 6.4 Hz, -CHC*H*$_3$); ^{13} C nmr (δ): 209.5 (s, *C*=O), 196.0 (s, -C=C-*C*=O), 171.4 (s, -*C*O$_2$CH$_3$), 156.8 (d, -*C*H=CH-CO-), 124.6 (d, -CH—*C*H-CO-), 60.0 (s, O=C-*C*(CO$_2$CH$_3$)-C-), 52.3 (q, -CO$_2$*C*H$_3$), 45.2 (t and d, -*C*H$_2$ and -(CH$_3$)$_2$*C*CHCH$_2$-), 40.0 (t, -*C*H$_2$), 36.3 (s, -*C*(CH$_3$)$_2$), 33.3 (d, -*C*H-CH$_3$), 30.8, 25.6 (2q, -C(*C*H$_3$)$_2$), 16.6 (q, -CH-*C*H$_3$); ms (*m/e*): 264 (M$^+$), 249 (M$^+$ – CH$_3$), 232 (M$^+$ – CH$_3$OH); Exact Mass calculated for C$_{15}$H$_{20}$O$_4$ (M$^+$): 264.1361; found: 264.1363.

*8aβ-Carbomethoxy-4,4-ethylenedioxy-8β-methyl-2,3,4,4a,5,7,8,8a-octahydronaphthalene-1,6-dione (**61**)*

Dichloromethane (5 mL), β-keto ester **2** (288 mg, 1.67 mmol), 4,4-ethylenedioxy-2-carbomethoxy-2-cyclohexenone **60** (237 mg, 1.12 mmol), and cesium carbonate (146 mg, 0.45 mmol) were stirred for 2 h. Chromatography on silica gel with hexane – ethyl acetate 5:1 afforded 441 mg (98%) of a colorless oil; ir (cm^{-1}); 3000–2800, 1740, 1710, 1645, 1395, 1295, 1225, 1210(s), 1155; ^{1}H nmr (δ): 12.4 (s, <1H, -C=CO*H*), 4.0–3.7 (m, 4H, -O(C*H*$_2$)$_2$O-), 3.66 (s, <3H, -CO$_2$C*H*$_3$), 3.65 (s, <3H, -CO$_2$C*H*$_3$), 3.20 (m, 1H), 2.74 (m, 2H), 2.45–2.35 (m, 3H), 2.1–1.95 (m, 2H), 1.46 (s, 9H, -CO$_2$C(C*H*$_3$)$_3$), 1.06 (d, <3H, *J* = 7.0 Hz, -CH-C*H*$_3$), 1.05 (d, <3H, *J* = 7.0 Hz, -CH-C*H*$_3$). ms (*m/e*): 396 (M$^+$), 340, 323, 322, 309, 296, 295, 294. Exact Mass calculated for C$_{20}$H$_{28}$O$_8$: 396.1780; found: 396.1784.

This product (220 mg, 0.55 mmol) was then decarboxylated according to method A to afford, after chromatography on silica gel eluting with hexane – ethyl acetate 3:1, 151 mg (93%) of decalin **61**; ir (cm^{-1}): 3000–2800, 1715(s), 1225(s), 1125, 1090, 1045; ^{1}H nmr (δ): 4.05–3.95 (m, 4H, -O(C*H*$_2$)$_2$O-), 3.78 (s, 3H, -CO$_2$C*H*$_3$), 3.22 (t, 1H, *J* = 5.8 Hz, (RO)$_2$C-C*H*-CH$_2$-C=O), 3.0 (m, 1H, H$_3$C-C*H*-CH$_2$-), 2.8–2.55 (m, 3H), 2.5–2.3 (m, 2H), 2.1–1.9 (m, 3H), 1.05 (d, 3H, *J* = 7.0 Hz, -CH-C*H*$_3$); ms (*m/e*): 296 (M$^+$), 281, 237, 195. Exact Mass calculated for C$_{15}$H$_{20}$O$_6$: 296.1265; found: 296.1260.

Received August 8, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

LEONARD LERMER, EDWARD G. NEELAND, JAMES P. OUNSWORTH, RUSSELL J. SIMS, SAMUEL A. TISCHLER, and LARRY WEILER. Can. J. Chem. **70**, 1427 (1992).

Two new methods to synthesize macrocyclic β-keto lactones have been developed. The first involves the synthesis of ω-halo-β-keto esters and an intramolecular alkylation of the dianions to these compounds. The reaction is complicated by elimination in the small and medium ring systems and by difficulties in purifying the final products. However, it is possible to obtain modest yields of the desired β-keto lactones. This procedure was used to synthesize the 25- and 27-membered ring β-hydroxy lactones that are the constituents of termite defense compounds. The second method involves the thermolysis of acylated Meldrum's acid derivatives, which leads directly to β-keto lactones. This process gives modest yields of macrocyclic systems and good yield of the unsubstituted 3-oxopentan-5-olide (**25**). The 14-membered macrocyclic β-keto lactone **9*j*** has a complex ^{1}H NMR spectrum, which has been interpreted in terms of multiple conformations. The temperature dependence of the NMR spectrum of **9*j*** is consistent with entropic, rather than enthalpic, control of the equilibrium. Quasiharmonic entropy calculations are consistent with this model.

LEONARD LERMER, EDWARD G. NEELAND, JAMES P. OUNSWORTH, RUSSELL J. SIMS, SAMUEL A. TISCHLER et LARRY WEILER. Can. J. Chem. **70**, 1427 (1992).

On a mis au point deux nouvelles méthodes de synthèse de β-céto lactones macrocycliques. La première implique la synthèse des β-cétoesters ω-halogénés et une alkylation intramoléculaire des dianions de ces composés. La réaction est compliquée par une réaction d'élimination dans les systèmes comportant des petits cycles et des cycles moyens et par des difficultés à purifier les produits finals. Toutefois, il est possible d'obtenir des rendements modestes des β-céto lactones désirées. On a utilisé cette procédure pour synthétiser les β-hydroxy lactones à 25 et à 27 chainons qui font partie des produits de défense des termites. La seconde méthode implique la thermolyse de dérivés acylés de l'acide de Meldrum et elle conduit directement aux β-céto lactones. Cette méthode donne des rendements modestes des systèmes macrocycliques et un bon rendement du 3-oxopentan-5-olide (**25**). Le spectre RMN du ^{1}H de la β-céto lactone macrocyclique à 14 chainons (**9*j***) est complexe et on l'a interprété en fonction de conformations multiples. La relation entre le spectre RMN du composé **9*j*** et la température est en accord avec un contrôle entropique, plutôt qu'enthalpique, de l'équilibre. Des calculs d'entropie quasiharmonique sont en accord avec ce modèle.

Introduction

β-Keto lactones have been found in a number of macrocyclic natural products. Picromycin (**1**) (ref. 1*a*, structure; 1*b*, synthesis), narbomycin (**2**) (ref. 2*a*, structure; 2*b*, synthesis), and kromycin (**3**) (see ref. 1*a* for structure; for synthesis, ref. 3) are 14-membered β-keto lactone antibiotics that have attracted interest as synthetic targets. The β-keto lactone moiety led to confusion in the initial structural work on these compounds (4). This particular array of functional groups also generated one of the most challenging aspects of the synthesis of these compounds. Indeed, in three of the syntheses of these compounds, a β-hydroxy lactone was

[1]Author to whom correspondence may be addressed.

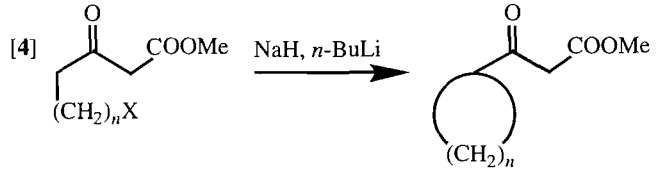
synthesized and subsequently oxidized to the β-keto lactone at a very late stage in the synthesis.

Boeckman and Pruitt used an ingenious cyclization of a hydroxy ketene to give the β-keto lactone directly (eq. [1]) (3). In model studies directed towards the synthesis of simple β-keto lactones, Ireland and Brown provided a direct route to such systems through a sulfide contraction of the product from an intramolecular reaction of an α-halo ester and a thioamide (eq. [2]) (5) and Booth *et al.* found that ω-hydroxy-β-keto thioesters can be cyclized to macrocyclic β-keto lactones (eq. [3]) (6).

For several years we have been interested in the synthesis and reactivity of β-keto ester derivatives. The mono anions of ω-halo-β-keto esters cyclize rather slowly. As a result, we were able to generate the dianions of these compounds and cyclize the resulting intermediate to the β-keto esters shown in eq. [4] (7). This suggested a possible route to β-keto lactones via the intramolecular alkylation of the dianions of ω-halo-β-keto esters **4**.[2]



β-Keto esters substituted on the alcohol fragment are readily obtained from alcoholysis of the acyl Meldrum's acid derivative **5** (9). Thus, alcoholysis of **5** with the halo alcohols **6** gave the desired ω-halo-β-keto esters **4** in good to excellent yields (eq. [5] and Table 1). The ω-halo alcohols **6** were prepared according to literature procedures (see Experimental).

[2] A preliminary account of a portion of this work has appeared (8).

5 **4**

We then undertook an extensive study of the cyclization of the β-keto esters **4** via their dianions. Treatment of **4***a* with two equivalents of lithium diisopropylamide (LDA) gave a complex mixture of products from which we were unable to isolate any cyclic β-keto lactone or other identifiable product. Lowering the reaction temperature did not lead to any improvement in the reaction. The addition of β-keto ester **4***b* to a solution of two equivalents of LDA in THF gave a single product by TLC that was isolated in 58% yield. The NMR and IR spectra of the product clearly showed that it was an olefinic β-keto ester and the spectral data were consistent with the structure of the product being **7**. This was confirmed by an independent synthesis of **7** from acetyl Meldrum's acid **5** and 2-propen-1-ol.

7 **8**

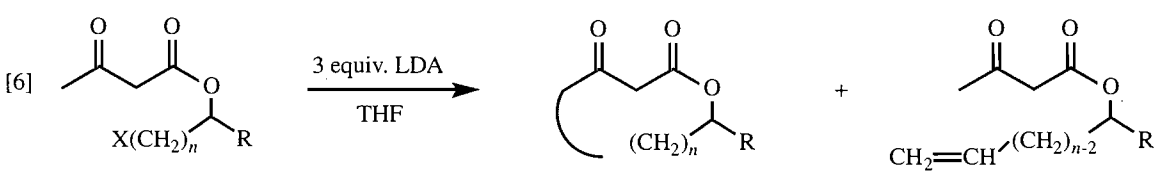
Treatment of **4***c* and **4***d* with two equivalents of LDA in THF gave only unreacted starting material even on prolonged reaction conditions. Verification of dianion formation was obtained by the addition of one equivalent of methyl iodide to the solution of **4***c* in base. This reaction gave the γ-alkylated product **8** in 75% yield. The fact that exclusive γ-alkylation had occurred was readily shown from the NMR data. With the question of dianion formation no longer in doubt, it appeared that the failure of the cyclization was linked either to the poor leaving group ability of the chloride or to the geometric requirements of the cyclization. The chloride in **4***c* was replaced with iodide. Attempted cyclization of this iodide gave only the elimination product.

From a study of molecular models, we concluded that the formation of 8- to 11-membered β-keto lactones via the intramolecular alkylation would be difficult because of the need for the halide chain to span four contiguous planar sp^2 carbons. This analysis suggested that the first ring that we might expect to form under these conditions would be the 12-membered system. To test this hypothesis and to determine the chain length at which cyclization becomes competitive with other side reactions, we prepared the series of β-keto esters **4***e*–**4***l*. An extensive study of cyclization of **4***l* to give the 16-membered lactone was carried out.

When the β-keto ester **4***l* was added to a solution of two equivalents of LDA in THF, two new products were formed in addition to some unreacted starting material. The major product was shown to be the desired 3-oxopentadecanolide (**9***l*) from its spectroscopic data and the minor product was the alkene (**10***l*) formed in an elimination reaction. Increasing the amount of LDA in the reaction mixture to three equivalents led to complete reaction of the starting material. The ^{1}H NMR of the crude product indicated that it contained mainly the desired β-keto lactone along with a small amount of the elimination product. Careful chromatographic purification of the product gave approximately a 50% yield of the desired lactone. Other methods of purification were not successful. Subsequently we found that these β-keto lactones are relatively unstable to chromatography and distillation.

Adding HMPA to the solvent led to increased yields of the alkene **10***l*. Reaction in less polar solvents, such as hexane, gave lower yields of lactone and increased recovery of starting material. The reaction was sensitive to temperature and maximum yields were obtained when the addition of **4** to the base was carried out at either −78°C or 0°C and the reaction mixture allowed to warm to room temperature. No cyclization could be detected at temperatures below −10°C. Yet at 0°C, the proportion of β-keto lactone began to diminish prior to complete consumption of starting material. At lower temperatures increased recovery of starting material occurred. We were unable to improve the yield of product using other metal counterions or leaving groups. Thus we returned to the original conditions of LDA in THF to study the cyclization of the ω-bromo-β-keto esters shown in Table 2.

The cyclization for 14-membered and larger rings proceeded in reasonable yield. However, we obtained only elimination products and no cyclization in those reactions directed towards generating smaller β-keto lactones. These cyclizations are not run under dilute conditions and they are not complicated by formation of dimers and trimers (see for example refs. 5, 6, and 10). No doubt the formation of the



4 **9** **10**

For personal use only.

dianionic intermediates suppresses bimolecular reactions that complicate many macrocyclization reactions (11). We did find that the resulting β-keto lactones slowly decompose in the strongly basic reaction mixture. This, along with their instability to chromatography and distillation, is the major reason for the modest yields of the macrocyclic β-keto lactones.

In a detailed study of the rates of cyclization versus elimination of bromo phenoxides, Cort *et al.* suggested that elimination is favoured over substitution for medium sized rings, and even for larger rings the transition state for elimination is less strained than that for intramolecular substitution (12). Pross and Shaik concluded that the geometric requirements for substitution are more stringent than those for elimination in bimolecular reactions (13). If the transition state for an intramolecular substitution is tighter than that for elimination, this could be the origin of the marked change in reactivity in going from the 13-membered (entry *h*) to the 14-membered ring (entry *i*) in Table 2.

Prestwich and Collins found that β-hydroxy lactones **11***a* and **11***b* containing 25- and 27-membered rings are major components of the cephalic secretions of soldier termites (14). It has been suggested that the wounds on ants and other insects bitten by the termite mandibles receive a coating of these anithealant compounds leading to their death. These β-hydroxy lactones are a key element in the termite's defense mechanism. We have synthesized **11***a* and **11***b* as shown in Scheme I. Alcoholysis of acetyl Meldrum's acid with **15***a* or **15***b* gave the complex β-keto esters **16***a* and **16***b* in excellent yield. The cyclization reactions were not as high yielding as above. We had hoped that the *cis* double bond might facilitate the formation of the large ring. The final products **11***a* and **11***b* are crystalline solids with spectral data fully consistent with their structures. The natural product was an inseparable mixture of the two isomers **11***a* and **11***b*, which prevented a direct comparison of their spectral data with that of the pure synthetic compounds.

The ^{1}H NMR spectra of **11***a* and **11***b* did show some interesting differences, which we attribute to differences between their conformations. The C-24 methylene group of **11***a* is a complex multiplet at δ 4.15, which collapses to an AB quartet (J = 12 Hz) on irradiation of the C-23 methylene protons at δ 1.64. Thus **11***a* must exist in conformation(s) in which the asymmetry due to C-3 renders the two protons on C-24 chemically nonequivalent. On the other hand, the C-26 methylene protons in **11***b* are a triplet (J = 6 Hz) at δ 4.19, which collapses to a singlet when the C-25 protons at δ 1.66 are irradiated. Thus **11***b* exists in conformation(s) in which the coupling constants of the protons on C-26 with those on C-25 are averaged to give an apparent triplet, and the two protons on C-25 are chemically equivalent.

An alternate strategy for the preparation of β-keto lactones using Meldrum's acid derivatives was also briefly examined. In this approach, the key cyclization step involves lactonization through intramolecular alcoholysis of an acyl Meldrum's acid derivative as shown in Scheme 2 for the synthesis of 3-oxo-13-tridecanolide (**9***i*). To minimize intermolecular reactions the alcohol **21** was slowly added to a refluxing THF solution to give the desired lactone **9***i* in 25% overall yield from 11-hydroxyundecanoic acid.

The generality of this methodology in modified form was explored as outlined below. The ω-benzyloxy carboxylic acids **22** (n = 2–10) were converted into their acid chlorides and condensed with Meldrum's acid to give **23** (n = 2–10). The benzyl protecting group was removed to give **24** (n = 2–10). In this reaction a catalytic amount of acid greatly accelerated the reaction (15). The cyclizations were attempted by slowly adding a dilute THF solution of **24** to refluxing THF. The 6-membered ring compound, 3-oxo-5-pentanolide (**25**), was obtained in 87% in this way. However, we could not detect any monomeric lactone with any of the other systems except for n = 2 or 10. When **23** (n = 3) was hydrogenolyzed, the enol ether **26** was obtained directly in 80% yield (Scheme 3), demonstrating the strong kinetic preference for formation of 5-membered rings over 7-membered rings (16).

It is interesting to note that although many 3-oxo-5-pentanolide derivatives have been synthesized (17), the unsubstituted parent **25** has only been reported recently (18). Fetizon *et al.* have prepared the corresponding ketal (17*c*). The β-keto lactone **25**, although a solid, is unusually labile. Hydrolysis occurs readily on standing unless moisture is carefully excluded. The high reactivity of this lactone is due to the significant dipole–dipole interactions of the *s-cis* ester moiety and the additional carbonyl in this system (19). The solution infrared spectrum of **25** has carbonyl stretching bands at 1745 and 1780 cm^{-1} with the lower frequency band notably stronger, which is consistent with a significant degree of strain in the molecule. The larger ring β-keto lactones have two carbonyl stretches of equal intensity at approximately 1710 and 1735 cm^{-1}. It is unclear why the C-5 substituted derivatives of **25** (17) are so much more stable than **25**. Compound **25** has no significant enol content in chloroform solution from its NMR or IR spectrum, which is unusual for these β-keto δ-lactones (for example, see ref. 20). The NMR spectrum of an acetone solution of **25** and its solid state infrared spectrum indicate substantial amounts of enol (18).

The conformation of these macrocyclic β-keto lactones both in solution and the solid state is of interest. X-ray studies of the highly substituted macrolide antibiotics **1–3** illustrate that the substituents on these molecules significantly influence their solid state conformation. All have the expected (21) *s-trans* conformation about the C—O—CO—C bond of the lactone. More recently Booth *et al.* provided X-ray data on a number of simpler β-keto lactones and this same restriction is seen even more clearly (6). These researchers also found that the two carbonyl groups often have their dipoles in a nonplanar arrangement. In addition, the two carbonyl groups are oriented so as to minimize their dipolar repulsions.[3] The solution conformation of these β-keto lactones is not well understood. However, based on solution NMR and CD data, it has been suggested that pikromycin and narbomycin adopt a different conformation in solution than in the solid state (22).

We have used NMR, IR, and molecular mechanics calculations to probe the conformation of the above lactones in solution. The IR spectra of **9***i*–**9***l* had one carbonyl band at 1705–1715 cm^{-1} and a second band at 1730–1740 cm^{-1}. This is consistent with the carbonyl groups adopting a strain-free conformation in which the CO dipoles are not aligned in the

[3]Recently the X-ray structure of (−)-menthyl 2-oxocyclopentanecarboxylate was solved and found to have the two carbonyl groups in approximately a *trans* coplanar arrangement: C. P. Decicco and J. N. Bridson, Memorial University of Newfoundland, personal communication, 1991.

SCHEME 1

same plane. The ^1H NMR spectra of the unsubstituted β-keto lactones consisted of a triplet (J = 6–8 Hz) at δ 4.2 ppm for the ω-methylene, a singlet at δ 3.45 ppm for the C-2 methylene, and a triplet (J = 6–8 Hz) at δ 2.6 ppm for the C-4 methylene. For the 14-membered ring compound **9*i***, these signals did not change on cooling to −100°C. Similarly the ^{13}C NMR spectra of these compounds contained the expected number of signals and we could not detect any conformational equilibria in the case of **9*i*** on cooling to −100°C. From this we conclude that these β-keto lactones either are a single conformation at room temperature or, more likely, they are a mixture of rapidly interconverting conformations that could not be frozen out on cooling to −100°C. To provide some insight into which of these two possibilities might be occurring we carried out molecular mechanics calculations on the 14-membered β-keto lactone.

A search for the possible conformations of **9*i*** using MACROMODEL's internal coordinate Monte Carlo methodology (23) and the MM2 force field (24) gave the global minimum conformation as **27**. However, there are 55 or so conformations within 2 kcal/mol of the global minimum. Thus we conclude that in fact **9*i*** is a mixture of conformational isomers at room temperature. The next lowest three conformations, **28**–**30**, are shown below with their relative energies in parentheses. Note that conformations **27** and **28** are [3434][4] conformations, **29** is an irregular conformation with the two carbonyl groups *syn* coplanar, and **30** is a [3344] conformation. In the conformations **27**, **28**, and **30** the car-

[4]We have used the conformational descriptors for large rings proposed by Dale (26*b*).

bonyl groups point in opposite directions and the geometries of the ketone and lactone moieties are very similar.

The infrared spectrum of the methyl substituted lactone **9*j*** also indicated that the carbonyls were unstrained in either the *trans* coplanar or nonplanar conformation(s). The ^1H NMR spectrum of **9*j*** was much more complex than that of **9*i*** as a result of the diastereomeric methylene protons. For example, in $CDCl_3$ the C-2 methylene group is an AB quartet at δ 3.35 and 3.46 with J = 13.5 Hz. The C-4 methylene protons are a multiplet at δ 5.0, which depends on temperature and solvent. In fact the entire NMR spectrum shows significant changes with solvent and temperature. For example, the C-2 methylene protons at room temperature consist of an AB quartet *plus* a *singlet* (Fig. 1). These signals are assigned to two sets of conformations that are not rapidly interconverting on the NMR time scale. It is not entirely clear why one of the barriers to conformational change in the methyl-substituted lactone **9*j*** is so much higher than that in **9*i***. Cooling a CD_3OD solution of **9*j*** produced the changes shown in Fig. 2. From these data we see that the AB quartet diminishes in intensity relative to solvent on cooling, while the lower-field singlet increases. We interpet this data as follows. The singlet in this case overlaps with the second lowest field line of the AB quartet and is due to conforma-

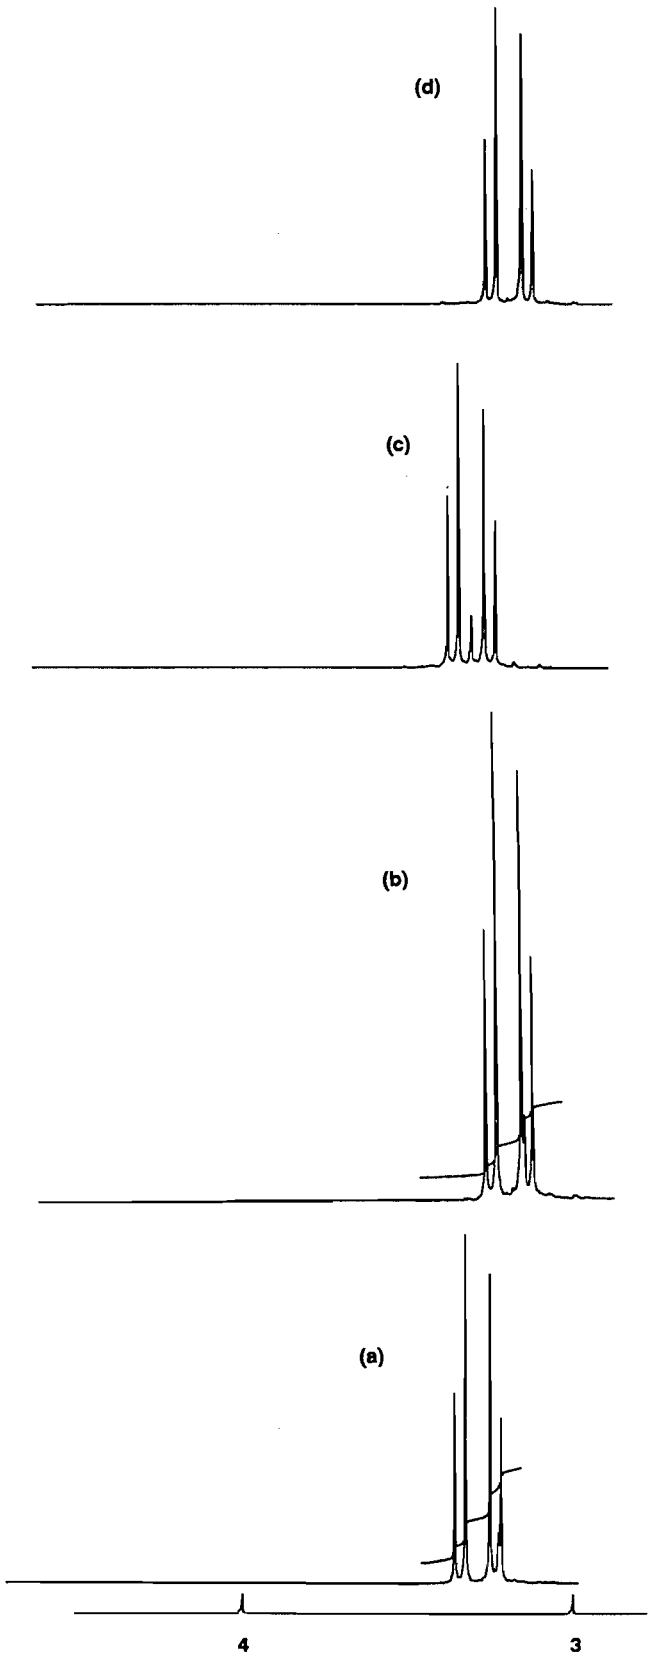

FIG. 1. ^{1}H NMR spectrum of the C-2 methylene protons of **9*i*** in various solvents; (*a*) C_6D_6; (*b*) C_6D_6–$CDCl_3$ (4:1); (*c*) C_6D_6–$CDCl_3$ (1:4); (*d*) $CDCl_3$. Note the small peak that is a shoulder on the high-field line of the AB quartet in (*a*) and moves to lower field as more chloroform is added, until (*d*) in which this signal overlaps with the second lowest field line of the AB quartet.

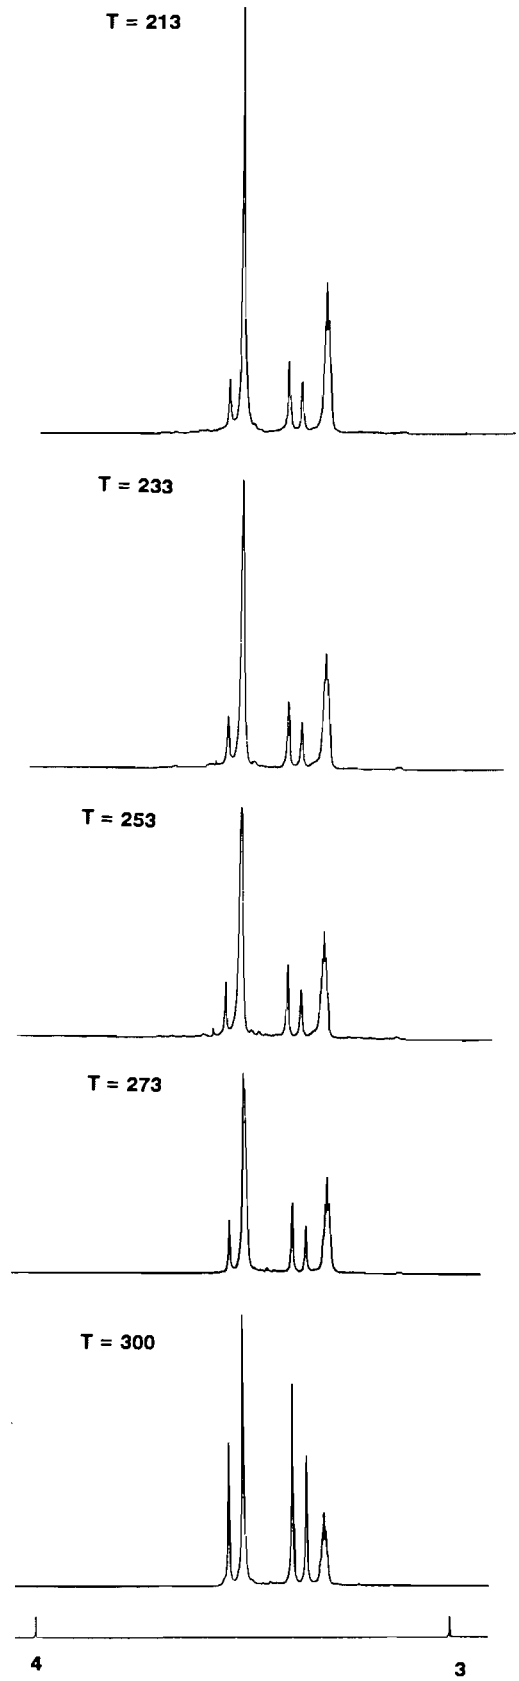

FIG. 2. ^{1}H NMR spectrum of the C-2 methylene protons of **9*i*** at various temperatures in CD_3OD (the peak at δ 3.3 is due to solvent).

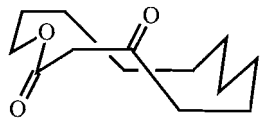
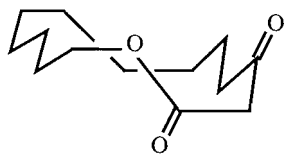
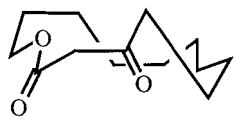
tion **34**, which is a minor component of the room temperature ensemble but, on cooling, becomes the major component at the expense of the conformations **31** and **32**, which are responsible for the AB quartet and are the major conformers at room temperature.



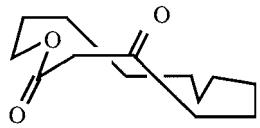
27 (0.0 kcal/mol)



28 (0.15 kcal/mol)



29 (0.60 kcal/mol)



30 (0.60 kcal/mol)

The barrier to interconversion of conformations **31** ⇆ **32** involves the change of three torsional angles in the hydrocarbon chain remote from the functional groups. The barrier to this equilibrium should be comparable to that found in cyclotetradecane for the barrier conformational interconversion, which is in the range 5–7 kcal/mol (25). The interconversion of **31** and (or) **32** with **34** involves torsional changes about six bonds, one of which involves the ketone carbon. The mechanism for the interconversion of two [3434] conformations in cyclotetradecane is suggested to involve a pseudorotation process (25, 26*a*); such a process in the interconversion of **31** ⇆ **34** would force the two carbonyl groups out of their *trans* coplanar geometry and add to the barrier to such a process. In addition, in **34** the methyl group on C-13 is brought into a 1,3 diaxial relation with a hydrogen on C-11 that is also expected to affect the barrier to the interconversion of **31** ⇆ **34**.

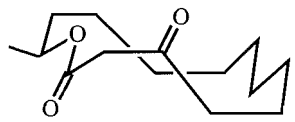
We carried out MACROMODEL calculations to determine the feasibility of such a model. A search of conformational space showed that there were about 30 conformations within 2 kcal/mol of the global minimum. The four lowest three conformations, **31**–**34**, are shown below with their relative energies in parentheses. Note that conformations **31**, **33**, and **34** are all [3434] conformations and **32** is a [3344] conformation. There is no low-energy conformation comparable to **30** for **9***j*. In these four conformations the carbonyl groups point in opposite directions and geometries of the ketone and lactone moieties are very similar. This may be important in rationalizing the chemical reactivity of this compound.

The coupling constant $J_{H_{4,4'}}$ in **9***j* is 18.5 Hz, which is very large for a geminal coupling constant. Barfield and Grant found that geminal coupling constants for methylenes adjacent to π systems are at a maximum when the π bond bisects the H—C—H angle of the adjacent methylene group (27). This is the geometry of the ketone carbonyl and the C-4 methylene group in conformations **31**–**34**. The coupling constant $J_{H_{2,2'}}$ is 13.5 Hz, which is low for a geminal coupling constant with adjacent π systems. Barfield and Grant state that this will occur when the π bond is aligned with one of the C═H bonds of the adjacent methylene group (27). This is the geometry in conformations **31** and **34** and very close to the geometry in **32** and is consistent with our suggestion that these conformations are the major ones to consider in analyzing the conformation of **9**j.

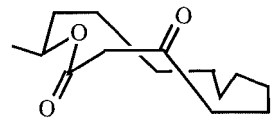
TABLE 3. Quasiharmonic entropy calculations of conformations **31**–**34** in cal deg^{-1} mol^{-1}

Temperature (K)	**31**	**32**	**33**	**34**
300	230	236	232	232
273	227	233	234	238
253	223	228	228	246
213	219	221	221	226

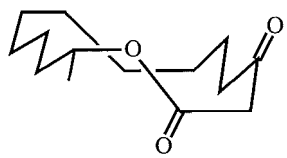
Next we applied temperature-dependent molecular dynamics calculations to the four lowest energy conformations to compute the quasiharmonic entropies of these conformations. A summary of the results of these conformations for the conformations **31**–**34** is given in Table 3. The calculated entropy difference between **31** and **34** at 300 K gives a $T\Delta S$ term of 0.6 kcal/mol, which is comparable to the enthalpy difference from the strain energy calculations. However, at 253 K the $T\Delta S$ value for **31** ⇄ **34** is 5.8 kcal/mol, which is significantly larger than the ΔH difference between these conformations. This highlights a difficulty in analyzing the conformations of large rings. Exclusive use of enthalpy (strain) energy differences may be misleading in these systems with large numbers of conformations close to the global minimum. Entropy differences may be required to correctly rationalize the physical and chemical properties of these compounds.



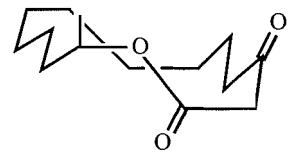
31 (0.0 kcal/mol)



32 (0.53 kcal/mol)



33 (0.62 kcal/mol)



34 (0.74 kcal/mol)

In conformation **33** the torsional angle between the lactone carbonyl and the C-13 methine hydrogen is close to 180°. Schweizer and Dunitz (21) observed a preference for esters of secondary esters to exist in a conformation in which the C—O—C—H torsional angle is within the range 0–40°. We have shown that this rule also applies to 14-membered lactones of secondary alcohols (28). Thus we have neglected conformation **33** in our analysis of the conformation of **9***j*. The origins of the torsional angle preference for secondary esters and lactones may well be electronic and hence not handled properly by the current molecular mechanics force fields.

The C-13 methine proton of **9***j* has couplings of 5.1 and 6.6 Hz with the C-12 methylene protons in CD_3OD and C_6D_6, while in CD_3Cl these couplings are 3.4 and 8.0 Hz. Again we attribute these differences to a solvent-dependent distribution of conformations. A similar solvent effect was observed for the coupling of the C-4 and C-5 protons. A solution to the coupling constants in CD_3Cl is that the conformational equilibrium is 13% **31**, 49% **32**, and 38% **34**, which is in reasonable agreement with the values calculated above from the molecular mechanics data. We have been unable to develop a model with a small number of conformations that is consistent with the observed values for these coupling constants in CD_3OD or C_6D_6. However, we believe that the bulk of the data is consistent with a fast, on the NMR time scale, equilibrium between **31** $\rightleftarrows$ **32**, which are the predominant conformations at room temperature and these conformations are in a slow, on the NMR time scale, equilibrium with **34**, which is the predominant conformation at lower temperatures.

In conclusion we have generated two new methods to synthesize macrocyclic β-keto lactones. The spectral and physical properties of these lactones are consistent with each being a mixture of conformations, which will no doubt complicate their chemistry.

Experimental section

General procedures

Melting points were determined on a Kofler hot stage microscope and are uncorrected. Kugelrohr distillations were performed by means of a Büchi Kugelrohr thermostat. Infrared spectra were recorded in chloroform solution on Perkin–Elmer model 700 or 710B spectrophotometers, and were calibrated with the 1601 cm^{-1} band of polystyrene. Proton nuclear magnetic resonance spectra were recorded on a Varian T-60 (60 MHz), a Bruker WP-80 (80 MHz), or a Bruker WH–400 (400 MHz) spectrometer. Chemical shifts are reported on the δ scale, with deuterochloroform as solvent and tetramethylsilane as an internal standard. The multiplicity, coupling constants (if observable), and integrated peak area are indicated in parentheses after each signal. Low-resolution mass spectra were recorded on an Atlas CH-4B or a Kratos-AEI MS-50 mass spectrometer, and high-resolution mass measurements were obtained using a Kratos-AEI MS-9 or MS-50 mass spectrometer. All instruments were operated at an ionizing potential of 70 eV. Elemental analyses were performed by Mr. Peter Borda, Microanalysis Laboratory, University of British Columbia, Vancouver, B.C.

Silica gel $PF_{254+366}$ supplied by E. Merck was used for both analytical and preparative thin-layer chromatography, while 100–200 mesh ASTM was employed for column chromatography. Flash chromatography (29) was performed using Silica Gel 60, 230–400 mesh ASTM, supplied by E. Merck. All solvent systems are expressed in ratios by volume (v/v).

Materials

The petroleum ether used was of boiling range 30–60°C. Dry solvents and reagents were prepared as follows: diethyl ether and tetrahydrofuran by distillation from lithium aluminum hydride or sodium–benzophenone; dichloromethane by distillation from phosphorus pentoxide; *N*,*N*-dimethylformamide and hexamethyl phosphoramide by distillation from calcium hydride at reduced pressure; benzene, 1,2-dichloroethane, diisopropylamine, pyridine, triethylamine, and toluene by distillation from calcium hydride; and ethanol and methanol by distillation from magnesium. Methyllithium (in ether) *n*-butyllithium (in hexane), and methylmagnesium chloride (in THF) were obtained from Aldrich Chemical Company. The alkyllithium solutions were standardized either by titration against 0.1 M *tert*-butanol in benzene using 1,10-phenanthroline as indicator (30*a*) or by titration against 1,3-diphenyl-2-propanone tosylhydrazone in THF (30*b*). Sodium hydride (Aldrich Chemical Company) was weighed as a 60% dispersion in mineral oil and was washed with dry ether to remove the oil prior to use. All other reagents and solvents were either of reagent grade and used directly, or purified according to literature procedures (31). All reactions were run under a dry nitrogen or argon atmosphere. Organic extracts were dried over anhydrous magnesium sulphate.

2,2-Dimethyl-1,3-dioxan-4,6-dione (Meldrum's acid)

A 250-mL Erlenmeyer containing a large magnetic stirring bar was charged with malonic acid (52 g, 0.50 mol) and acetic anhydride (60 mL, 0.60 mol). To the resulting suspension was added concentrated sulfuric acid (1.5 mL) with constant stirring. Most of the malonic acid dissolved with spontaneous cooling. Acetone (40 mL, 0.55 mol) was introduced slowly while cooling to 20–25°C and the reaction mixture was allowed to stand in the fridge overnight. The resultant crystals were filtered by suction, washed with ice water (3 × 75 mL), and allowed to air dry. The resulting white solid was dissolved in acetone (110 mL), filtered to remove any undissolved material, and diluted with water (220 mL). Filtration gave a flocculent white solid, which was dried in a vacuum desiccator over phosphorus pentoxide to yield 35 g (49%) of product, mp 93–94°C (lit. (32) mp 94–95°C); IR ν_{max}: 1755 cm^{-1}; ^1H NMR (60 MHz) δ: 1.78 (s, 6H), 3.57 (s, 2H); MS *m*/*z* (relative intensity): 144 (M^+, 1), 129 (100), 100 (88), 72 (20), 69 (72), 61 (40), 59 (35), and 58 (34).

*5-(1'-Hydroxyethylidene)-2,2-dimethyl-1,3-dioxan-4,6-dione (**5**)*

A 250-mL, two-necked round bottom flask was charged with Meldrum's acid (10.0 g, 69.4 mmol) and 150 mL of dry dichloromethane. The solution was cooled to 0°C in an ice-water bath and dry pyridine (10.99 g, 139 mmol) was added. After stirring for 10 min, acetyl chloride (6.0 g, 76 mmol) was introduced dropwise and the reaction mixture was allowed to stand at 0°C for 1 h, then at room temperature for 1 h. The dichloromethane solution was washed with 5% hydrochloric acid (2 × 25 mL) and water (2 × 50 mL), then dried. Removal of the solvent under reduced pressure followed by recrystallization from ethyl ether gave 10.5 g (81%) of **5** as a pale yellow solid. An analytical sample was prepared by sublimation (60°C/0.35 Torr; 1 Torr = 133.3 Pa) and had the following properties: mp 83.5–84.5°C; IR ν_{max}: 3600–3300, 1740, 1665, and 1580 cm^{-1}; ^1H NMR (60 MHz) δ: 1.75 (s, 6H), 2.67 (s, 3H), and 15.0 (bs, 1H); MS *m*/*z* (relative intensity): 186 (M^+, 47), 171 (17), 128 (100), 111 (16), 85 (36), 84 (55), and 69 (36). Anal. calcd. for $C_8H_{10}O_5$: C 51.61, H 5.41; found: C 51.82, H 5.22.

*4-Chloro-1-butanol (**6***c*)

A 250-mL, three-necked round bottom flask was charged with 1,4-butanediol (20 g, 0.22 mol) and dry pyridine (17.6 g, 0.22 mmol). The flask was placed in a water bath maintained at 55°C and thionyl chloride (26.4 g, 0.22 mol) was added dropwise over 1 h. The temperature of the water bath was then raised to 80°C for 1 h as sulfur dioxide was vented off. The reaction mixture was cooled and extracted with ether (3 × 100 mL). The ethereal extracts were washed with 5% hydrochloric acid (50 mL), water (50 mL), brine (50 mL), then dried. The solvent was removed under reduced pressure and the residue fractionally distilled to give 8.7 g (36%) of **6***c* as a colourless liquid; bp 67–69°C/5.0 Torr (lit. (33) bp 84–85°C/16 Torr); IR ν_{max}: 3620, 3450, and 2950 cm^{-1}; ^1H NMR (60 MHz) δ: 1.70–2.00 (m, 4H), 2.65 (s, 1H), and 3.43–3.72 (m, 4H); MS *m*/*z* (relative intensity): 108 (M^+ ^{35}Cl, 1), 92 (14), 90 (59), 71 (100), 62 (23), 57 (13), and 55 (78).

5-Acetoxy-1-bromopentane

This compound was prepared according to the literature procedure (34) from anhydrous zinc chloride (ca. 20 mg), tetrahydropyran (8.61 g, 0.10 mol), and acetyl bromide (7.99 g, 0.065 mol) in 88% (11.0 g) distilled yield: bp 89–91°C/4.5 Torr (lit. (34) bp

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

106–107°C/12 Torr); IR ν_{max}: 1720 cm^{-1}; ^1H NMR (60 MHz) δ: 1.53–2.10 (m, 6H), 2.03 (s, 3H), 3.37 (t, J = 7 Hz, 2H), and 4.03 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 210 (M^+ ^{81}Br, 0.5), 208 (M^+ ^{79}Br, 0.5), 150 (35), 148 (35), 73 (18), 69 (100), 68 (28), and 61 (45).

*5-Bromo-1-pentanol (**6**d)*

A solution of the above acetate (10.8 g, 0.052 mol) in dry methanol (150 mL) was prepared in a 250-mL round bottom flask. Anhydrous potassium carbonate (16 g, 0.12 mol) was then added in portions and the resulting suspension was stirred vigorously for 4 h at room temperature. Dilute hydrochloric acid was added until the mixture became acidic and the solution was extracted with ethyl acetate (3 × 100 mL). The combined organic extracts were washed with water (50 mL) and brine (50 mL), then dried. Removal of the solvent under reduced pressure, followed by vacuum distillation of the crude material, gave 5.71 g (66%) of **6***d* as a colourless liquid: bp 53–56°C/0.20 Torr (lit. (35) bp 75–76°C/0.5 Torr); IR ν_{max}: 3620 and 3400 cm^{-1}; ^1H NMR (60 MHz) δ: 1.30–2.03 (m, 6H), 2.50 (s, 1H, exchangeable with D_2O), 3.40 (t, J = 6 Hz, 2H), and 3.60 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 168 (M^+ ^{81}Br, 0.1), 166 (M^+ ^{79}Br, 0.1), 1.50 (4), 148 (4), 137 (5), 135 (5), 122 (1), 120 (1), 109 (2), 107 (2), 70 (9), 69 (100), 68 (16), 57 (10), 56 (13), and 55 (26).

6-Chloro-2-hexanone

A 1-L, two-necked round bottom flask equipped with a large magnetic stirring bar and an addition funnel was charged with a solution of sodium hypochlorite in water (400 mL of a 5% solution). The flask was cooled to 0°C and 1-methylcyclopentanol (10 g, 0.10 mol) in carbon tetrachloride (2.0 mL) was added dropwise. A solution of glacial acetic acid (40 mL) in carbon tetrachloride (5 mL) was introduced and the reaction mixture was vigorously stirred for 5.5 h. The greenish-yellow carbon tetrachloride layer was combined with carbon tetrachloride extracts of the aqueous phase (3 × 10 mL), washed with a saturated sodium carbonate solution (2 × 10 mL), and dried. Filtration of the drying agent left 1-methylcyclopentyl hypochlorite in carbon tetrachloride solution, ready for the rearrangement step. The carbon tetrachloride solution was refluxed for 1.5 h, then the solvent was removed under reduced pressure. Excess saturated aqueous sodium bisulfite was added and the resulting addition compound was washed with ether (25 mL), then decomposed with warm aqueous sodium carbonate solution. The aqueous layer was extracted with ether (2 × 50 mL) and the ethereal solution dried. Removal of the solvent under reduced pressure followed by vacuum distillation gave 4.0 g (30%) of 6-chloro-2-hexanone as a colourless liquid: bp 64–66°C/3.8 Torr lit. (36*a*) bp 52.5–54°C/2.3 Torr); IR ν_{max}: 1710 cm^{-1}; ^1H NMR (60 MHz) δ: 1.60–1.90 (m, 4H), 2.16 (s, 3H), 2.48 (t, J = 7 Hz, 2H), and 3.52 (t, J = 7 Hz, 2H); MS m/z (relative intensity): 136 (M^+ ^{37}Cl, 0.25), 134 (M^+ ^{35}Cl, 0.75), 118 (6), 99 (13), 98 (46), 71 (21), 58 (100), and 55 (58).

*6-Chloro-2-hexanol (**6**f)*

A 50-mL, two-necked round bottom flask was charged with 6-chloro-2-hexanone (4.0 g, 30 mmol) and ethanol (25 mL). The flask was cooled to 0°C and sodium borohydride (1.13 g, 30 mmol) was added slowly in portions. The reaction mixture was allowed to warm to room temperature and stand for 4.5 h. The ethanol was removed under reduced pressure and 5% hydrochloric acid solution was added cautiously to the residue. The aqueous solution was then extracted with ether (4 × 25 mL) and the combined organic extracts were washed with water (20 mL), and brine (20 mL). The ethereal solution was dried and the solvent was removed under reduced pressure, leaving the desired alcohol as a yellow liquid. Vacuum distillation of the crude material gave 2.8 g (70%) of **6***f* as a colourless liquid: bp 78–79°C/2.3 Torr (lit. (36*b*) bp (58°C/1.1 Torr); IR ν_{max}: 3620 and 3470 cm^{-1}; ^1H NMR (60 MHz) δ: 1.17 (d, J = 6 Hz, 3H), 1.30–1.90 (m, 6H), 2.07 (s, exchanged with D_2O, 1H), 3.50 (t, J = 7 Hz, 2H), and 3.50–3.90 (m, 1H); MS m/z (relative intensity): 138 (M^+ ^{37}Cl, 0.4), 136 (M^+ ^{35}Cl, 1), 123 (28), 121 (100), 102 (17), 85 (56), 67 (53), 57 (48), 56 (46), and 55 (100).

*General procedure for the preparation of (1,*n*) bromo alcohols from (1,*n*)-diols*

A solution of the diol in 48% HBr was placed in a 100-mL liquid–liquid extractor. The solution was heated in an oil bath while being continuously extracted with an appropriate solvent. The solution was cooled and the organic layer separated, washed with saturated sodium bicarbonate solution, water, then dried. Removal of the solvent under reduced pressure gave the crude bromo alcohol, which was further purified by vacuum distillation.

*6-Bromo-1-hexanol (**6**e)*

This compound was prepared according to the general procedure for bromo alcohol formation using 1,6-hexanediol (6.00 g, 50.9 mmol) and 48% hydrochloric acid (12 mL). The solution was heated to 75–80°C and the extraction was continued for 39 h using toluene (50 mL) as solvent. Distillation of the crude product gave 5.16 g (56%) of **6***e* as a colourless liquid: bp 59–62°C/0.10 Torr (lit. (37) bp 105–106°C/5.0 Torr); IR ν_{max}: 3620 and 3450 cm^{-1}; ^1H NMR (60 MHz) δ: 1.30–2.00 (m, 8H), 2.27 (s, exchangeable with D_2O, 1H), 3.43 (t, J = 7 Hz, 2H), and 3.63 (t, J = 6Hz, 2H); MS m/z (relative intensity): 164 (M^+ −16, 6), 162 (6), 136 (14), 134 (14), 83 (63), 32 (16), and 55 (100).

*7-Bromo-1-heptanol (**6**g)*

This compound was prepared according to the general procedure for bromo alcohol formation using 1,7-heptanediol (7.00 g, 53.0 mmol) and 48% HBr (36 mL). The solution was heated to 75–80°C and the extraction was continued for 16 h using toluene (100 mL) as solvent. Distillation of the crude product gave 4.85 g (47%) of **6***g* as a colourless liquid: bp 107–108°C/4.0 Torr (lit. (38) bp 111–112°C/4 Torr); IR ν_{max}: 3640 and 3450 cm^{-1}; ^1H NMR (60 MHz) δ: 1.30–2.00 (m, 10H), 3.02 (s, exchangeable with D_2O, 1H), 3.37 (t, J = 6 Hz, 2H), and 3.60 (t, J = 7 Hz, 2H); MS m/z (relative intensity): 195 (M^+ −1, 1), 193 (1), 150 (24), 148 (24), 97 (22), 69 (48), 68 (20), and 55 (100).

*8-Bromo-1-octanol (**6**h)*

This compound was prepared according to the general procedure for bromo alcohol formation using 1,8-octanediol (6.00 g, 41.2 mmol) and 48% HBr (6 mL). The solution was heated to 90°C and the extraction was continued for 72 h using toluene (100 mL) as solvent. The crude material was distilled to give 3.86 g (45%) of **6***h* as colourless liquid: bp 95–100°C/0.27 Torr (lit. (39) bp 77–78°C/0.01 Torr); IR ν_{max}: 3620 and 3450 cm^{-1}; ^1H NMR (60 MHz) δ: 1.10–2.00 (m, 12H), 2.08 (s, exchangeable with D_2O, 1H), 3.40 (t, J = 7 Hz, 2H), and 3.58 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 192 (M^+ −18, 3), 190 (3), 164 (14), 162 (14), 150 (14), 148 (14), 111 (11), 82 (38), 69 (80), 68 (34), 67 (14), 56 (20), and 55 (100).

*9-Bromo-1-nonanol (**6**i)*

This compound was prepared according to the general procedure for bromo alcohol formation using 1,9-nonanediol (6.00 g, 37.4 mmol) and 48% HBr (8 mL). The solution was heated to 90°C and the extraction was continued for 72 h using toluene (100 mL) as solvent. The crude material was distilled to give 3.19 g (38%) of **6***i* as a colourless liquid: bp 92–94°C/0.06 Torr (lit. (40) bp 97–000°C/0.06 Torr); IR ν_{max}: 3630 and 3450 cm^{-1}; ^1H NMR (60 MHz) δ: 1.27–2.00 (m, 14H), 2.00 (s, exchangeable with D_2O, 1H), 3.35 (t, J = 7 Hz, 2H), and 3.57 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 206 (M^+ −18, 1), 204 (1), 169 (3), 167 (3), 150 (11), 148 (11), 137 (35), 135 (35), 97 (43), 69 (80), 68 (20), 57 (13), 56 (16), and 55 (100).

*10-Bromo-1-decanol (**6**k)*

This compound was prepared according to the general procedure for bromo alcohol formation using 1,10-decanediol (6.00 g, 34.4 mmol) and 48% HBr (27 mL). The solution was heated to 90–95°C and the extraction was continued for 65 h using petroleum ether, bp 100–115°C (100 mL) as solvent. Vacuum distillation gave

For personal use only.

5.33 g (65%) of **6***k* as a colourless liquid: bp 115–117°C/0.30 Torr (lit. (41) bp 166–169°C/10 Torr); IR ν_{max}: 3625 and 3445 cm^{-1}; ^1H NMR (60 MHz) δ: 1.33–2.00 (m, 16H), 3.10 (s, exchangeable with D_2O, 1H), 3.37 (t, J = 7 Hz, 2H), and 3.58 (t, J = 7 Hz, 2H); MS m/z (relative intensity): 220 (M^+ −18, 1) 218 (1), 192 (3), 190 (3), 164 (6), 162 (6), 150 (28), 148 (28), 137 (16), 135 (16), 97 (26), 69 (90), 68 (25), 57 (20), 56 (20), and 55 (100).

10-Oxoundecanoic acid

A mixture of 36.8 g (0.20 mol) of 10-undecenoic acid, 12.6 g (40 mmol) of mercuric acetate, 5 mL of water, and 400 mL of acetone was stirred at room temperature. To this mixture was added 150 mL of Jones reagent over a period of 3.5 h while the temperature of the reaction mixture was maintained at 25 ± 5°C by means of an ice-water bath. The resulting mixture was stirred at room temperature for an additional 20 h, then the acetone layer was decanted, concentrated under reduced pressure, and diluted with ether. The residue was dissolved in water and the resulting aqueous layer was extracted three times with ether. The combined ether layers were washed twice with brine, dried, and concentrated under reduced pressure to give 54.8 g of crude product as a pale yellow solid. Two recrystallizations from petroleum ether – ether (5:1) afforded 37.2 g (93%) of the desired keto acid as a white solid; mp 55–57°C (lit. (42) mp 56–57°C); IR ν_{max}: 2950 and 1715 cm^{-1}; ^1H NMR (80 MHz) δ: 1.10–1.93 (m, 12H), 2.13 (s, 3H), 2.20–2.57 (m, 4H), and 10.87 (s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 200 (M^+, 1), 182 (2), 152 (2), 142 (2), 125 (15), 124 (4), 97 (10), 96 (5), 84 (9), 83 (10), 81 (5), 73 (6), 71 (12), 69 (13), 60 (7), 59 (14), 58 (71), 55 (35), 45 (7), and 43 (100).

10-Bromo-2-decanone

This compound was prepared by means of a modified Hunsdiecker reaction (43). A 500-mL three-necked round bottom flask equipped with a pressure-equalizing dropping funnel, a heavier-than-water, liquid–liquid extractor and condenser, and a stopper was charged with 5.0 g (25 mmol) of the above carboxylic acid and 3.4 g (7.8 mmol) of red mercuric oxide. A total of 200 mL of carbon tetrachloride was added to the liquid–liquid extractor and reaction flask. The mixture was heated at rapid reflux for 20 min and a solution of 5.0 g (32 mmol) of bromine in 5 mL of carbon tetrachloride was added over a period of 40 min while heating was maintained. After heating at reflux for an additional 1 h, the mixture was cooled and filtered. The filtrate was washed three times with 10% aqueous sodium hydroxide and twice with brine, dried, and concentrated under reduced pressure to give 5.85 g (100%) of the crude bromo ketone as a yellow oil. This crude product, containing a small amount of 1,8-dibromooctane, was used without further purification in the preparation of the bromo alcohol **6***j*, Kugelrohr distillation of a small amount of this material afforded pure bromo ketone as a colourless oil; bp (Kugelrohr distillation) 100°C/0.15 Torr; IR ν_{max}: 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.00–2.20 (m, 12H), 2.12 (s, 3H), 2.20–2.62 (m, 2H), and 3.38 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 236 (M^+ ^{81}Br, 7), 234 (M^+ ^{79}Br, 7), 221 (5), 219 (6), 178 (16), 176 (21), 155 (16), 97 (31), 82 (21), 81 (20), 80 (22), 71 (98), 69 (68), 67 (27), 59 (87), 58 (99), 57 (29), 55 (92), 44 (60), and 43 (100). Exact Mass calcd. for $C_{10}H_{19}BrO$: 236.0600, 234.0619; found: 236.0617, 234.0625.

*10-Bromo-2-decanol (**6**j)*

To a solution of 8.83 g (37.6 mmol) of the above bromo ketone in 75 mL of ethanol at room temperature was added 1.42 g (37.6 mmol) of sodium borohydride. After stirring for 30 min, the reaction was quenched with 1 M HCl, concentrated under reduced pressure, and diluted with ether. The organic phase was washed twice with 1 M HCl, twice with saturated aqueous sodium bicarbonate, and once with brine, dried, and concentrated under reduced pressure to give 7.71 g of crude bromo alcohol as a yellow oil. Purification by flash chromatography using petroleum ether – ethyl acetate (4:1) as eluant gave 5.60 g (63% from carboxylic acid) of alcohol **6***j* as a pale yellow oil. Distillation of a portion of this material afforded pure **6***m* as a colourless oil; bp 98–100°C/0.15 Torr; IR ν_{max}: 3630 and 3480 cm^{-1}; ^1H NMR (60 MHz) δ: 1.13–2.22 (m, 14H), 1.17 (d, J = 6 Hz, 3H), 1.58 (s, 1H, exchangeable with D_2O), 3.38 (t, J = 6 Hz, 2H), and 3.57–3.98 (m, 1H); MS m/z (relative intensity): 237 (M^+ ^{81}Br, 0.3), 235 (M^+ ^{79}Br, 0.3), 223 (2), 221 (2), 220 (2), 218 (2), 192 (3), 190 (2), 137 (3), 135 (3), 123 (4), 97 (6), 95 (2), 83 (5), 81 (4), 71 (3), 69 (9), 67 (3), 57 (5), 56 (4), 55 (16), 46 (3), and 45 (100). Anal. calcd. for $C_{10}H_{21}BrO$: C 50.64, H 8.92, Br 33.69; found: C 50.88, H 9.00, Br 33.55.

*General procedure for the alcoholysis of the acyl Meldrum's acid **5***

A 50-mL, single-necked round bottom flask equipped with a reflux condenser fitted with a nitrogen inlet was charged with **5** (1.2 equiv.), the appropriate alcohol (1.0 equiv.), and dry tetrahydrofuran (25 mL). The reaction mixture was heated to reflux for 4 h, cooled to room temperature, and transferred to a separatory funnel containing 50 mL of ether. The solution was washed with saturated sodium bicarbonate solution (1 × 15 mL), water (1 × 15 mL), and brine (1 × 10 mL), then dried. Removal of the solvent under reduced pressure gave the crude β-keto ester.

*(2′-Bromo-1′-ethyl)-3-oxobutanoate (**4**a)*

This compound was prepared according to the general procedure using **5** (3.60 g, 19.4 mmol) and 2-bromoethanol (Aldrich Chemical, 1.99 g, 16.0 mmol). Distillation of the crude material gave 2.27 g (67%) of **4***a* as a colourless liquid: bp 62–64°C/0.18 Torr; IR ν_{max}: 1755 and 1725 cm^{-1}; ^1H NMR (60 MHz) δ: 2.27 (s, 3H), 3.46 (s, 2H), 3.48 (t, J = 6 Hz, 2H), and 4.40 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 210 M^+ ^{81}Br, 19), 208 (M^+ ^{79}Br, 19), 168 (30), 166 (29), 129 (52), 109 (100), 107 (100), and 102 (59). Anal. calcd. for $C_6H_9BrO_3$: C 34.47, H 4.34; found: C 34.66, H 4.29.

*(3′-Bromo-1′-3-propyl)-oxobutanoate (**4**b)*

This compound was prepared according to the general procedure using **5** (1.20 g, 6.45 mmol) and 3-bromo-1-propanol (Aldrich Chemical, 742 mg, 5.34 mmol). Vacuum distillation of the crude material gave 953 mg (80%) of **4***b* as a colourless liquid: bp 80–82°C/0.40 Torr; IR ν_{max}: 1745, 1720, and 1663 cm^{-1}; ^1H NMR (60 MHz) δ: 2.27 (s, 3H), 1.93–2.36 (m, 2H), 3.43 (t, J = 6 Hz, 2H), 3.43 (s, 2H), and 4.25 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 224 (M^+ ^{81}Br, 32), 222 (M^+ ^{79}Br, 32), 206 (24), 204 (24), 182 (78), 180 (78), 143 (100), 123 (48), 122 (77), 121 (48), 120 (78), 103 (73), 102 (53), and 101 (35). Anal. calcd. for $C_7H_{11}BrO_3$: C 37.69, H 4.97; found: C 37.65, H 5.10.

*(4′-Chloro-1′-butyl)-3-oxobutanoate (**4**c)*

This compound was prepared according to the general procedure for alcoholysis using **5** (3.60 g, 19.2 mmol) and **6***c* (1.72 g, 16.0 mmol). Vacuum distillation of the crude material gave 2.44 g (79%) of **4***c* as a colourless liquid: bp 87–88°C/0.18 Torr; IR ν_{max}: 1745 and 1720 cm^{-1}; ^1H NMR (60 MHz) δ: 1.70–1.90 (m, 4H), 2.26 (s, 3H), 3.43 (s, 2H), 3.50 (t, J = 5.5 Hz, 2H), and 4.13 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 194 (M^+ ^{37}Cl, 9), 192 (M^+ ^{35}Cl, 18), 157 (12), 152 (11), 150 (33), 116 (17), 115 (23), 103 (100), and 102 (53). Anal. calcd. for $C_8H_{13}ClO_3$: C 49.88, H 6.80; found: C 49.82, H 6.91.

*(5′-Bromo-1′-pentyl)-3-oxobutanoate (**4**d)*

This compound was prepared according to the general procedure for alcoholysis using **5** (2.23 g, 12.0 mmol) and **6***d* (1.67 g, 10.0 mmol). Vacuum distillation of the crude material gave 1.87 g, (74%) of **4***d* as a colourless liquid: bp 98–99°C/0.2 Torr; IR ν_{max}: 1740, 1720, and 1660 cm^{-1}; ^1H NMR (60 MHz) δ: 1.50–2.00 (m, 6H), 2.27 (s, 3H), 3.40 (t, J = 7 Hz, 2H), 3.45 (s, 2H), and 4.13 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 252 (M^+ ^{81}Br, 0.6), 250 (M^+ ^{79}Br, 0.6), 210 (0.3), 208 (0.3), 171 (1), 150 (7), 148 (10), 103 (38), 85 (33), and 69 (100). Exact Mass calcd. for $C_9H_{15}BrO_3$: 252.0184, 250.0205; found: 252.0175, 250.0205.

*(6'-Bromo-1'-hexyl)-3-oxobutanoate (**4**e)*

This compound was prepared according to the general procedure for alcoholysis using **5** (2.47 g, 13.3 mmol) and **6***e* (2.00 g, 11.1 mmol). Solvent removal gave 2.53 g (86%) of crude **4***e* as a yellow liquid, which was homogeneous by TLC analysis. A small sample was purified by preparative TLC on silica gel using 3:1 ether – petroleum ether and gave **4***e* as a colourless liquid: R_f 0.75; bp (Kugelrohr distillation) 97–100°C/0.12 Torr; IR ν_{max}: 1740 and 1718 cm^{-1}; ^1H NMR (60 MHz) δ: 1.30–1.96 (m, 8H), 2.28 (s, 3H), 3.44 (t, J = 7 Hz, 2H), 3.48 (s, 2H), and 4.18 (t, J = 6.5 Hz, 2H); MS m/z (relative intensity): 266 (M^+ ^{81}Br, 0.1), 264 (M^+ ^{79}Br, 0.1), 164 (3), 162 (3), 103 (100), 85 (44), 83 (81), and 55 (73). Exact Mass calcd. for $C_{10}H_{17}BrO_3$: 266.0341; found: 266.0346. Anal. calcd. for $C_{10}H_{17}BrO_3$: C 45.30, H 6.46; found: C 45.82, H 6.70.

*(6'-Chloro-2'-hexyl-3-oxobutanoate (**4**f)*

This compound was prepared according to the general procedure for alcoholysis using **6***f* (4.62 g, 2.48 mmol) and **5** (2.80 g, 2.06 mmol). Vacuum distillation of the crude material gave 3.82 g (85%) of **4***f* as a colourless liquid: bp 96–98°C/0.20 Torr; ν_{max}: 1740 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.27 (d, J = 6 Hz, 3H), 1.40–2.00 (m, 6H), 2.23 (s, 3H), 3.41 (s, 2H), 3.48 (t, J = 6 Hz, 2H), and 4.77–5.07 (m, 1H); MS m/z (relative intensity): 222 (M^+ ^{37}Cl, 0.70), 220 (M^+ ^{35}Cl, 2), 118 (58), 103 (74), and 85 (100). Anal. calcd. for $C_{10}H_{17}ClO_3$: C 54.42, H 7.76; found: C 54.44, H 7.79.

*(7'-Bromo-1'-heptyl)-3-oxobutanoate (**4**g)*

This compound was prepared according to the general procedure for alcoholysis using **5** (1.92 g, 10.3 mmol) and **6***g* (1.67 g, 8.56 mmol). Solvent removal gave 2.02 g (84%) of crude **4***g* as a pale yellow liquid, which was homogeneous by TLC analysis. A small sample was purified by preparative TLC on silica gel using ether as solvent to give **4***g* as a colourless liquid: R_f 0.81; bp (Kugelrohr distillation) 120–125°C/0.50 Torr; IR ν_{max}: 1735 and 1710 cm^{-1}; ^1H NMR (60 MHz) δ: 1.30–1.98 (m, 10H), 2.30 (s, 3H), 3.44 (t, J = 7 Hz, 2H), 3.49 (s, 2H), and 4.18 (t, J = 7 Hz, 2H); MS m/z (relative intensity): 280 (M^+ ^{81}Br, 0.1), 278 (M^+ ^{79}Br, 0.1), 188 (2), 186 (2), 150 (4), 148 (4), 103 (100), 97 (42), 85 (30), 69 (20), and 55 (70). Anal. calcd. for $C_{11}H_{19}BrO_3$: C 47.32, H 6.86; found: C 47.42, H 6.77.

*(8'-Bromo-1'-octyl)-3-oxobutanoate (**4**h)*

This compound was prepared according to the general procedure for alcoholysis using **5** (1.07 g, 5.74 mmol) and **6***h* (1.00 g, 4.78 mmol). Evaporation of the solvent gave 1.20 g (86%) of crude **4***h* as a yellow liquid, which was homogeneous by TLC analysis. A small sample was purified by preparative TLC on silica gel using 3:1 ether – petroleum ether and gave **4***h* as a colourless liquid: R_f 0.77; bp (Kugelrohr distillation) 115–118°C/0.40 Torr; IR ν_{max}: 1740 and 1713 cm^{-1}; ^1H NMR (60 MHz) δ: 1.14–1.97 (m, 12H), 2.28 (s, 3H), 3.43 (t, J = 7 Hz, 2H), 3.47 (s, 2H), and 4.17 (t, J ≈ 7 Hz, 2H); MS m/z (relative intensity): 294 (M^+ ^{81}Br, 0.2), 292 (M^+ ^{79}Br, 0.2), 2.13 (3), 192 (4), 190 (4), 164 (4), 162 (4), 150 (7), 148 (7), 137 (4), 135 (4), 111 (18), 103 (100), 85 (19), 69 (35), and 55 (21). Anal. calcd. for $C_{12}H_{21}BrO_3$: C 49.07, H 7.38; found: C 49.29, H 7.35.

*(9'-Bromo-1'-nonyl)-3-oxobutanoate (**4**i)*

This compound was prepared according to the general procedure for alcoholysis using **5** (1.00 g, 5.38 mmol) and **6***i* (1.00 g, 4.48 mmol). Evaporation of the solvent gave 1.21 g (88%) of crude **4***i* as a yellow liquid, which was homogeneous by TLC analysis. A small sample was purified by preparative TLC on silica gel using 3:1 ether – petroleum ether and gave **4***i* as a colourless liquid: R_f 0.78; bp (Kugelrohr distillation) 110–113°C/0.12 Torr; IR ν_{max}: 1735 and 1710 cm^{-1}; ^1H NMR (60 MHz) δ: 1.30–1.96 (m, 14H), 2.27 (s, 3H), 3.42 (t, J = 7 Hz, 2H), 3.46 (s, 2H), and 4.16 (t, J ≈ 7 Hz, 2H); MS m/z (relative intensity): 308 (M^+ ^{81}Br, 0.1), 306 (M^+ ^{79}Br, 0.1), 150 (1), 148 (1), 137 (1), 135 (1), 103 (100), 85 (18), 83 (9), 69 (21), and 55 (19). Exact Mass calcd. for $C_{13}H_{23}BrO_3$: 308.0812, 306.0830; found: 308.0814, 306.0832.

*(10'-Bromo-2'-decyl)-3-oxobutanoate (**4**j)*

This compound was prepared according to the general procedure for alcoholysis using **5** (9.17 g, 49.0 mmol) and alcohol **6***j* (9.75 g, 41.0 mmol) in 50 mL of THF. Work-up as usual gave 14.0 g (85%) of crude **4***j* as a red oil. Filtration, with suction, of this oil through a short column of silica using petroleum ether – ethyl acetate (9:1) as eluant, followed by removal of solvent, yielded 13.3 g (98%) of **4***j* as a pale yellow oil. Distillation of a small amount of this material gave pure **4***j* as a colourless oil: bp (Kugelrohr distillation) 130°C/0.2 Torr; IR ν_{max}: 1745 and 1720 cm^{-1}; ^1H NMR (60 MHz) δ: 1.07–2.03 (m, 17H), 2.25 (s, 3H), 3.40 (t, J = 7 Hz, 2H), 3.40 (s, 2H), and 4.77–5.17 (m, 1H); MS m/z (relative intensity): 322 (M^+ ^{81}Br, 1), 320 (M^+ ^{79}Br, 1), 220 (15), 218 (16), 150 (6), 148 (7), 104 (5), 103 (100), 102 (13), 97 (17), 87 (7), 85 (56), 83 (22), 71 (10), 69 (26), 67(5), 58 (7), 57 (17), 56 (10), 55 (39), 45 (13), and 43 (88). Anal. calcd. for $C_{14}H_{25}BrO_3$: C 52.34, H 7.84, Br 24.87; found: C 52.59, H 8.00, Br 24.61.

*(10'-Bromo-1'-decyl)-3-oxobutanoate (**4**k)*

This compound was prepared according to the general procedure for alcoholysis using **5** (2.00 g, 11.1 mmol) and **6***k* (2.00 g, 9.00 mmol). Removal of the solvent gave 2.49 g (92%) of crude **4***k* as a yellow oil, which was homogeneous by TLC analysis. A small sample was purified by preparative TLC using 3:1 ether – petroleum ether and gave **4***k* as a colourless liquid: R_f 0.79; bp (Kugelrohr distillation) 120–125°C/0.12 Torr; IR ν_{max}: 1740 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.30–1.96 (m, 16H), 2.29 (s, 3H), 3.46 (t, J = 7 Hz, 2H), 3.48 (s, 2H), and 4.17 (t, J = 7 Hz, 2H); MS m/z (relative intensity): 322 (M^+ ^{81}Br, 0.1), 320 (M^+ ^{79}Br, 0.1), 192 (13), 190 (14), 164 (36), 162 (34), 150 (67), 148 (68), 137 (44), 135 (46), 103 (100), 85 (88), 69 (99), 57 (72), 56 (82), 55 (100), and 54 (65). Anal. calcd. for $C_{14}H_{25}BrO_3$: C 52.34, H 7.84; found: C 52.75, H 8.09.

*(11'-Bromo-1'-undecyl)-3-oxobutanoate (**4**l)*

This compound was prepared according to the general procedure for alcoholysis using **5** (1.78 g, 9.57 mmol) and 11-bromo-1-undecanol (Aldrich Chemical, 2.00 g, 7.97 mmol). Work-up as usual gave 2.26 g (85%) of crude **4***l* as a yellow liquid, which was homogeneous by TLC analysis. A small sample was purified by preparative TLC using chloroform as solvent and gave **4***l* as a colourless liquid: R_f 0.40; bp (Kugelrohr distillation) 135–140°C/0.13 Torr; IR ν_{max}: 1740 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.25–1.95 (m, 18H), 2.28 (s, 3H), 3.43 (t, J = 7 Hz, 2H), 3.45 (s, 2H), and 4.15 (t, J = 6.5 Hz, 2H); MS m/z (relative intensity): 336 (M^+ ^{81}Br, 2), 334 (M^+ ^{79}Br, 2), 318 (3), 316 (3), 255 (14), 164 (26), 162 (26), 150 (40), 148 (40), 85 (100), and 69 (100). Anal. calcd. for $C_{15}H_{27}BrO_3$: C 53.73, H 8.12; found: C 53.92, H 8.08.

*(2'-Propen-1'-yl)-3-oxobutanoate (**7**)*

This compound was prepared according to the general procedure for alcoholysis using **5** (2.40 g, 12.9 mmol) and 2-propene-1-ol (624 mg, 10.8 mmol). Vacuum distillation of the crude material gave 1.37 g (90%) of **7** as a colourless liquid: bp 71–72°C/25 Torr; IR ν_{max}: 1742, 1715, and 1650 cm^{-1}; ^1H NMR (60 MHz) δ: 2.24 (s, 3H), 3.45 (s, 2H), 4.57 (d, J = 5 Hz, 2H), and 5.00–6.17 (m, 3H); MS m/z (relative intensity): 142 (M^+, 9), 100 (15), 84 (100), and 58 (100). Anal. calcd. for $C_7H_{10}O_3$: C. 59.14, H 7.09; found: C 59.24, H 7.16.

*General procedure for the attempted cyclization of β-keto esters **4**a–l*

A solution of diisopropylamine (3 equiv.) in dry THF was prepared in a 200-mL, two-necked round bottom flask equipped with a pressure-equalizing dropping funnel and a nitrogen inlet. The flask was cooled to 0°C in an ice-water bath and three equivalents of *n*-butyllithium as a 1.6 M solution in hexane was added dropwise. The colourless to pale yellow solution was stirred for 10 min and a solution of one equivalent of the halo β-keto ester in THF was added dropwise. The reaction mixture was then stirred for 5 h and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

the solution was slowly allowed to warm to room temperature over this period. On work-up, water and ether were added, and the organic phase was separated. The organic extract was washed with water and brine, then dried. Removal of the solvents under reduced pressure gave the crude products.

(2'-Propen-1'-yl)-3-oxobutanoate (7) from the attempted cyclization of **4**b

Following the above general procedure, diisopropylamine (222 mg, 2.20 mmol) in 12 mL of THF, 1.55 mL of *n*-butyllithium (1.43 M, 2.20 mmol), and 223 mg of **4***b* (1.00 mmol) in 3 mL of THF were stirred at 0°C for 30 min. Work-up followed by purification gave 82.5 mg (58%) of a pale yellow oil, which exhibited identical spectral properties to those reported above for compound **7**.

(4'-Chloro-1'-butyl)-3-oxopentanoate (8)

Following the above general procedure for cyclization, 223 mg of diisopropylamine (2.20 mmol) in 12 mL of THF, 1.38 mL of *n*-butyllithium (1.6 M, 2.20 mmol), and 193 mg of a solution of **4***c* (1.00 mmol) in 3 mL of THF was stirred at 0°C for 30 min, then the reaction mixture was quenched with methyl iodide (143 mg, 1.00 mmol). On work-up, the solution was treated with 5% HCl solution until acidic, then diluted with ether (25 mL). The ethereal layer was separated, washed with water (10 mL), then dried. Removal of the solvent under reduced pressure gave **8** as a yellow oil. Preparative TLC of this crude material on silica gel using chloroform gave 155 mg (75%) of **5** as a colourless liquid: R_f 0.41; bp (Kugelrohr distillation) 70–72°C/0.13 Torr; IR ν_{max}: 1745 and 1718 cm^{-1}; ^1H NMR (60 MHz) δ: 1.09 (t, J = 7 Hz, 3H), 1.85 (m, 4H), 2.56 (q, J = 7 Hz, 2H), 3.46 (s, 2H), 3.58 (t, J = 6 Hz, 2H), and 4.20 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 208 (M^+ ^{37}Cl, 3), 206 (M^+ ^{35}Cl, 7), 171 (5), 116 (8), 98 (15), 93 (37), and 91 (100). Anal. calcd. for $C_9H_{15}ClO_3$: C 52.30, H 7.32; found: C 52.30, H 7.39.

*(4'-Penten-1'-yl)-3-oxobutanoate (**10**d)*

This compound was generated in the general procedure for cyclization using diisopropylamine (1.52 g, 15.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (9.38 mL, 15.0 mmol), and **6***d* (1.27 g, 5.00 mmol). Flash chromatography of the crude material using chloroform as eluant gave 353 mg (41%) of **10***d* as a colourless liquid: bp (Kugelrohr distillation) 40–42°C/0.20 Torr; IR ν_{max}: 1742, 1720, and 1645 cm^{-1}; ^1H NMR (60 MHz) δ: 1.63–2.19 (m, 4H), 2.28 (s, 3H), 3.46 (s, 2H), 4.19 (t, J = 7 Hz, 2H), 4.97–5.16 (m, 2H), and 5.64–7.03 (m, 1H); MS m/z (relative intensity): 170 (M^+, 6), 103 (5), 85 (30), 69 (21), 68 (100), and 67 (35). Anal. calcd. for $C_9H_{14}O_3$: C 63.51, H 8.29; found: C 63.65, H 8.30.

*(7'-Hexen-1'-yl)-3-oxobutanoate (**10**e)*

This compound was generated in the general procedure for cyclization using diisopropylamine (1.21 g, 12.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (7.50 mL, 12.0 mmol), and **6***e* (1.06 g, 4.00 mmol). Flash chromatography of the crude material using petroleum ether – ethyl acetate (9:1) as eluant gave 331 mg (45%) of **10***e* as a colourless liquid: bp 30–45°C/0.20 Torr; IR ν_{max}: 1735, 1718, and 1645 cm^{-1}; ^1H NMR (60 MHz) δ: 1.26–1.80 (m, 4H), 1.92–2.20 (m, 2H), 2.28 (s, 3H), 3.46 (s, 2H), 4.18 (t, J = 6 Hz, 2H), 4.93–5.12 (m, 2H), and 5.64–7.04 (m, 1H); MS m/z (relative intensity): 184 (M^+, 0.3), 137 (8), 103 (10), 85 (43), 82 (100), 67 (59), 56 (44), and 55 (85). Anal. calcd. for $C_{10}H_{16}O_3$: C 65.19, H 8.75; found: C 65.36, H 8.90.

*(6'-Hepten-1'-yl)-3-oxobutanoate (**10**g)*

This compound was generated in the general procedure for cyclization using diisopropylamine (1.21 g, 12.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (7.50 mL, 12.0 mmol), and **6***g* (1.12 g, 4.00 mmol). Flash chromatography of the crude material using petroleum ether – ethyl acetate (9:1) as eluant gave 457 mg (57%) of **10***g* as a colourless liquid: bp (Kugelrohr distillation) 45–48°C/0.23 Torr; IR ν_{max}: 1735, 1718, and 1635 cm^{-1}; ^1H NMR (60 MHz) δ: 1.26–1.80 (m, 6H), 1.94–2.12 (m, 2H), 2.28 (s, 3H), 3.45 (s, 2H), 4.16 (t, J = 6 Hz, 2H), 4.92–5.09 (m, 2H), and 5.63–7.03 (m, 1H); MS m/z (relative intensity): 198 (M^+, 0.1), 102 (72), 96 (63), 85 (67), 81 (41), 69 (25), 68 (59), 67 (69), 56 (28), 55 (100), and 54 (74). Anal. calcd. for $C_{11}H_{18}O_3$: C 66.64, H 9.15; found: 66.71, H 9.25.

*(7'-Octen-1'-yl)-3-oxobutanoate (**10**h)*

This compound was generated in the general procedure for cyclization using diisopropylamine (1.21 g, 12.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (7.50 mL, 12.0 mmol), and **6***h* (1.17 g, 4.00 mmol). Flash chromatography of the crude material using petroleum ether – ethyl acetate (9:1) as eluant gave 348 mg (41%) of **10***h* as a colourless liquid: bp (Kugelrohr distillation) 60–63°C/0.4 Torr; IR ν_{max}: 1740, 1718, and 1650 cm^{-1}; ^1H NMR (60 MHz) δ: 1.26–1.85 (m, 8H), 1.93–2.10 (m, 2H), 2.28 (s, 3H), 3.46 (s, 2H), 4.17 (t, J = 6 Hz, 2H), 4.93–5.10 (m, 2H), and 5.66–7.04 (m, 1H); MS m/z (relative intensity): 212 (M^+, 0.1), 103 (87), 95 (20), 85 (87), 82 (50), 81 (58), 69 (100), 68 (84), 67 (80), 66 (11), 56 (79), and 55 (100). Anal. calcd. for $C_{12}H_{20}O_3$: C 67.89, H 9.50; found: C 67.94, H 9.55.

*3-Oxotridecan-13-olide (**9**i)*

This compound was prepared according to the general procedure for cyclization using diisopropylamine (1.21 g, 12.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (7.50 mL, 12.0 mmol), and **6***i* (1.23 g, 4.00 mmol). Purification by flash chromatography using petroleum ether – ethyl acetate (9:1) as eluant gave 389 mg (43%) of **9***i* as a colourless semi-solid: sublimation temperature 103–105°C/0.18 Torr; IR ν_{max}: 1750 and 1725 cm^{-1}; ^1H NMR (60 MHz) δ: 1.25–1.81 (m, 16H), 2.61 (t, J = 7 Hz, 2H), 3.44 (s, 2H), and 4.24 (t, J = 5 Hz, 2H); MS m/z (relative intensity): 226 (M^+, 8), 208 (6), 124 (23), 103 (25), 82 (36), 69 (46), 67 (29), 56 (23), and 55 (100). Anal. calcd. for $C_{13}H_{22}O_3$: C 68.99, H 9.80; found: C 68.78, H 9.84.

*3-Oxotetradecan-13-olide (**9**j)*

This compound was prepared according to the general procedure for cyclization using diisopropylamine (1.90 mL, 13.6 mmol), *n*-butyllithium as a 1.0 M solution in hexane (13.6 mL, 13.6 mmol), and **6***j* (2.00 g, 6.20 mmol). Flash chromatography using petroleum ether – ethyl acetate (9:1) as eluant yielded 694 mg (47%) of **9***j* as a very pale yellow oil. Preparative TLC of a small amount of this material using petroleum ether – ethyl acetate as solvent gave a pure sample of **9***j* as a colourless oil; bp (Kugelrohr distillation) 80°C/0.01 Torr; IR ν_{max}: 1740 and 1715 cm^{-1}; ^1H NMR (400 MHz) δ: 1.17–1.81 (m, 16H), 1.26, (d, J = 7 Hz, 3H), 2.51 (dt, $J_{4a,4b}$ = 18.5 Hz, $J_{4a,5a}$ = $J_{4a,5b}$ = 7 Hz, 1H), 2.70 (dt, $J_{4a,4b}$ = 18 Hz, $J_{4b,5a}$ = $J_{4b,5b}$ = 7 Hz, 1H), 3.35 (d, $J_{2a,2b}$ = 14 Hz, 1H), 3.46 (d, $J_{2a,2b}$ = 13.5 Hz, 1H), and 4.98–5.06 (m, 1H); ^{13}C NMR (100 MHz) δ: 20.29, 21.00, 22.91, 24.66, 25.17, 26.03, 26.11, 26.27, 35.15, 40.57, 50.83, 71.95, 166.71, and 202.10; MS m/z (relative intensity): 240 (M^+, 6), 222 (8), 181 (80), 180 (8), 138 (22), 103 (56), 102 (33), 97 (28), 96 (39), 85 (34), 83 (36), 82 (30), 81 (30), 69 (45), 68 (34), 67 (30), 56 (22), and 55 (100). Anal. calcd. for $C_{14}H_{24}O_3$: C 69.96, H 10.07; found: C 69.77, H 10.20.

*3-Oxotetradecan-14-olide (**9**k)*

This compound was prepared according to the general procedure for cyclization using diisopropylamine (1.21 g, 12.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (7.50 mL, 12.0 mmol), and **6***k* (1.28 g, 4.00 mmol). Purification by flash chromatography using petroleum ether – ethyl acetate (9:1) as eluant gave 432 mg (45%) of **9***k* as a colourless semi-solid: bp (Kugelrohr distillation) 85-88°C/0.10 Torr; IR ν_{max}: 1742 and 1718 cm^{-1}; ^1H NMR (60 MHz) δ: 1.20–1.82 (m, 18H), 2.57 (t, J = 7 Hz, 2H), 3.46 (s, 2H), and 4.22 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 240 (M^+, 1), 148 (17), 103 (19), 96 (24), 83 (19), 82 (31), 81 (20), 69 (33), 68 (28), 67 (27), 56 (14), 55 (100), and 54 (17). Anal. calcd. for $C_{14}H_{24}O_3$: C 69.96, H 10.07; found: C 70.00, H 10.14.

*3-Oxopentadecan-15-olide (**9l**)*

This compound was prepared according to the general procedure for cyclization using diisopropylamine (1.21 g, 12.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (7.50 mL, 12.0 mmol), and **6*l*** (1.34 g, 4.00 mmol). Flash chromatography of the crude product using petroleum ether – ethyl acetate (7:1) as eluant gave 498 mg (49%) of **9*l*** as a colourless semi-solid: sublimation temperature 110–113°C/0.25 Torr; IR ν_{max}: 1735 and 1710 cm^{-1}; ^1H NMR (60 MHz) δ: 1.20–1.80 (m, 20H), 2.56 (t, J = 6.5 Hz, 2H), 3.46 (s, 2H), and 4.22 (t, J = 5 Hz, 2H); MS m/z (relative intensity): 254 (M^+, 26), 236 (22), 152, (55), 103 (100), 95 (68), and 55 (91). Anal. calcd. for $C_{15}H_{26}O_3$: C 70.83, H 10.30; found: C 70.65, H 10.17.

*(10-Hydroxydecyl)triphenylphosphonium bromide (**13**a)*

A solution of bromo alcohol **6*k*** (11.85 g, 50 mmol) and 13.1 g of triphenylphosphine (50 mmol) in 50 mL of dry acetonitrile was heated to reflux for 16 h. The solvent was removed *in vacuo* to give a yellow glass, which was extracted with 60 mL of hot ether to dissolve any unreacted starting materials. The final residue crystalized under vacuum to give 24.0 g (96%) of a crude product, which was used directly in the next step; mp 75–78°C (lit. (44) mp 82–84°C).

*(11-Hydroxyundecyl)triphenylphosphonium bromide (**13**b)*

Using the same procedure as above, a solution of bromo alcohol **12*b*** (10.04 g, 40 mmol) and 10.5 g of triphenylphosphine (40 mmol) in 80 mL of dry acetonitrile was heated to reflux for 16 h. The solvent was removed *in vacuo* to give a yellow glass, which was extracted with 60 mL of hot ether to dissolve any unreacted starting materials. The final residue crystalized under vacuum to give 12.4 g (60%) of a crude product, which was used directly in the next step; mp 85–87°C (lit. (44) mp 85–86°C).

*10-Bromodecanal (**14**a)*

A mixture of alcohol **6*k*** (17.7 g, 75 mmol) and pyridium chlorochromate (PCC, 16.1 g, 75 mmol) was stirred in 200 mL of dichloromethane at room temperature. After 4 h, the mixture was poured into ether and the residue was washed with 3 × 75 mL of ether. The combined organic extracts were dried and evaporated. The residue was dissolved in ether and passed through a Florisil column. Evaporation of the solvents gave 16.7 g (95%) of a crude product, which was used directly in the next step; IR ν_{max}: 2750 and 1735 cm^{-1}; ^1H NMR (60 MHz) δ: 1.1–1.8 (m, 14H), 2.4 (m, 2H), 3.37 (t, J = 7 Hz, 2H), and 9.77 (t, J = 2 Hz, 1H).

*11-Bromoundecanal (**14**b)*

A mixture of alcohol **12*b*** (Aldrich Chemical, 7.0 g, 28 mmol) and PCC (6.0 g, 28 mmol) was stirred in 100 mL of dichloromethane at room temperature. After 4 h, the mixture was poured into ether and the residue was washed with 3 × 75 mL of ether. The combined organic extracts were dried and evaporated. The residue was dissolved in ether an passed through a Florisil column. Evaporation of the solvents gave 6.7 g (96%) of a crude product, which was used directly in the next step; IR ν_{max}: 2750 and 1725 cm^{-1}; ^1H NMR (60 MHz) δ: 1.1–1.85 (m, 16H), 2.4 (m, 2H), 3.38 (t, J = 7 Hz, 2H), and 9.72 (t, J = 1.5 Hz, 1H).

*20-Bromo-(10Z)-eicosen-1-ol (**15**a)*

A suspension of the phosphonium salt **13*a*** (23.2 g, 46.5 mmol) in 300 mL of dry THF was cooled to −30°C and treated with 54.7 mL of 1.7 M *n*-butyllithium (93 mmol). The resulting red solution was stirred at −30°C for 2 h. Some salt remained undissolved. The solution was cooled to −78°C and treated with a solution of aldehyde **14*a*** (10.9 g, 46.5 mmol) in 30 mL of THF. This mixture was stirred at −78°C for 2 h and allowed to warm to room temperature over 16 h. The reaction was quenched with 100 mL of a saturated aqueous solution of NH_4Cl. The aqueous layer was extracted with 2 × 75 mL of ether. The organic extracts were combined, washed with 50 mL of 1 M HCl, then saturated brine (2 × 50 mL), and dried. Evaporation of the solvents gave 22.3 g of a light yellow solid, which was purified by flash chromatography using petroleum ether – ethyl acetate (4:1) to give 8.1 g (47%) of **15*a***; mp 30–32°C; IR ν_{max}: 3460, 3450, 2940, and 2870 cm^{-1}; ^1H NMR (80 MHz) δ: 1.2–1.6 (m, 29H), 1.8–2.1 (m, 4H), 3.43 (t, J = 8 Hz, 2H), 3.65 (t, J = 8 Hz, 2H), and 5.38 (t, J = 4 Hz, 2H); MS m/z (relative intensity): 376 (M^+ ^{81}Br, 0.2). 374 (M^+ ^{79}Br, 0.2), 358 (12), 356 (12), 294 (8), 138 (12), 137 (12), 124 (18), 123 (19), 110 (29), 109 (29), 96 (77), 83 (52), 82 (100), 81 (55), 69 (67), 68 (47), 67 (59), 55 (98), and 54 (90). Exact Mass calcd. for $C_{20}H_{39}BrO$: 376.2163, 374.2184; found: 376.2142, 374.2155.

*22-Bromo-(11Z)-docosen-1-ol (**15**b)*

A suspension of the phosphonium salt **13*b*** (12.4 g, 24 mmol) in 250 mL of dry THF was treated with 28 mL of 1.7 M *n*-butyllithium (48 mmol) and a solution of aldehyde **14*b*** (6.7 g, 24 mmol) in 20 mL of the THF as above. Work-up gave 22.3 g of a light yellow gum, which was purified by flash chromatography using petroleum ether – ethyl acetate (4:1) to give 5.4 g (56%) of **15*b***; mp 30–31°C; IR ν_{max}: 3600, 3430, 3010, 2940, and 2860 cm^{-1}; ^1H NMR (80 MHz) δ: 1.1-1.6 (m, 32H), 1.8–2.1 (m, 5H), 3.45 (t, J = 8 Hz, 2H), 3.65 (t, J = 8 Hz, 2H), and 5.38 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 404 (M^+ ^{81}Br, 0.5), 402 (M^+ ^{79}Br, 0.5), 386 (3), 384 (3), 322 (7), 278 (7), 152 (10), 138 (10), 137 (10), 124 (14), 123 (14), 110 (23), 109 (23), 96 (65), 95 (40), 83 (51), 82 (84), 81 (48), 69 (59), 68 (37), 67 (48), 55 (100), and 54 (35). Exact Mass calcd. for $C_{22}H_{43}BrO$: 404.2476, 402.2445; found: 404.2492, 402.2471.

*(20′-Bromo-(10′Z)-1′-eicosenyl)-3-oxobutanoate (**16**a)*

This compound was prepared according to the general procedure for alcoholysis using **5** (4.2 g, 19 mmol) and bromo alcohol **15*a*** (8.1 g, 19 mmol) in 50 mL of THF. Work-up gave 9.62 g (97%) of crude **16*a*** as a light yellow oil, which was homogeneous by TLC and GC analysis. IR ν_{max}: 1750 and 1725 cm^{-1}; ^1H NMR (400 MHz) δ: 1.2–1.5 (m, 24H), 1.64 (m, 2H), 1.85 (q, J = 7 Hz, 2H), 2.0 (m, 4H), 2.27 (s, 3H), 3.40 (t, J = 6 Hz, 2H), 3.43 (s, 2H), 4.13 (t, J = 8 Hz, 2H), and 5.35 (t, J = 4 Hz, 2H); MS m/z (relative intensity): 460 (M^+ ^{81}Br, 2), 458 (M^+ ^{79}Br, 2), 358 (12), 356 (14), 124 (12), 110 (16), 109 (16), 103 (100), 97 (17), 96 (38), 95 (28), 85 (30), 69 (37), and 55 (56). Exact Mass calcd. for $C_{24}H_{43}BrO_3$: 460.2375, 458.2395; found: 460.2382, 458.2397.

*(22′-Bromo-(11′Z)-docosen-1′-yl)-3-oxobutanoate (**16**b)*

This compound was prepared according to the general procedure for alcoholysis using **5** (1.2 g, 6.2 mmol) and bromo alcohol **15*b*** (2.5 g, 6.2 mmol) in 100 mL of THF. Work-up and flash chromatography using petroleum ether – ethyl acetate 9:1 gave 2.78 g (95%) of **16*b*** as a light yellow oil, which crystallized below room temperature. IR ν_{max}: 1745 and 1720 cm^{-1}; ^1H NMR (270 MHz) δ: 1.1–1.4 (m, 28H), 1.63 (m, 2H), 1.76 (m, 2H), 2.0 (m, 4H), 2.27 (s, 3H), 3.45 (s, 2H), 3.51 (t, J = 6 Hz, 2H), 4.12 (t, J = 8 Hz, 2H), and 5.47 (t, J = 4 Hz, 2H); MS m/z (relative intensity): 488 (M^+ ^{81}Br, 3), 486 (M^+ ^{79}Br, 3), 386 (9), 384 (10), 124 (10), 110 (14), 109 (14), 103 (100), 97 (19), 96 (35), 95 (26), 85 (30), 69 (37), and 55 (58). Exact Mass calcd. for $C_{26}H_{47}BrO_3$: 488.2688, 486.2734; found: 488.2678, 486.2721.

*14Z-3-Oxotetracosen-24-olide (**17**a)*

This compound was prepared according to the general procedure for cyclization of **4** using diisopropylamine (1.26 mL, 9.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (5.62 mL, 9.0 mmol), and **16*a*** (1.38 g, 3.0 mmol). Purification by flash chromatography using petroleum ether – ethyl acetate (95:5) as eluant gave 440 mg (39%) of **17*a*** as white crystals: mp 55–57°C; IR ν_{max}: 1750 and 1725 cm^{-1}; ^1H NMR (400 MHz) δ: 1.2–1.41 (m, 28H), 1.62 (m, 4H), 2.04 (m, 2H), 2.53 (t, J = 8 Hz, 2H), 3.41 (s, 2H), 4.15 (t, J = 6Hz, 2H), and 5.35 (t, J = 4 Hz, 2H); MS m/z (relative intensity): 378 (M^+, 23), 360 (20), 110 (21), 103 (48), 97 (26), 96 (51), 95 (42), 82 (56), 81 (53), 69

(65), 67 (29), 57 (23), and 55 (100). Exact Mass calcd. for $C_{24}H_{42}O_3$: 378.3133; found: 378.3119.

*15Z-3-Oxohexacosen-26-olide (**17**b)*

This compound was prepared according to the general procedure for cyclization using diisopropylamine (1.26 mL, 9.0 mmol), *n*-butyllithium as a 1.6 M solution in hexane (5.62 mL, 9.0 mmol), and **16***b* (1.46 g, 3.0 mmol). Purification by flash chromatography using petroleum ether – ethyl acetate (95:5) as eluant gave 447 mg (37%) of **17***b* as white crystals: mp 68–70°C; IR ν_{max}: 1750 and 1720 cm^{-1}; ^1H NMR (270 MHz) δ: 1.15–1.5 (m, 32H), 1.6 (m, 4H), 2.04 (m, 2H), 2.51 (t, J = 8 Hz, 2H), 3.40 (s, 2H), 4.13 (t, J = 6 Hz, 2H), and 5.36 (t, J = 4 Hz, 2H); MS m/z (relative intensity): 406 (M^+, 22), 389 (21), 388 (35), 135 (14), 124 (15), 123 (18), 121 (18), 110 (28), 109 (32), 103 (14), 97 (25), 96 (68), 95 (59), 82 (65), 81 (63), 69 (52), 67 (60), and 55 (100). Exact Mass calcd. for $C_{26}H_{46}O_3$: 406.3446; found: 406.3450.

3-Oxotetracosan-24-olide

A suspension of 20 mg of PtO_2 in 5 mL of ethyl acetate was hydrogenated at atmospheric pressure overnight. A solution of alkene **17***a* (592 mg, 1.51 mmol) in 5 mL of ethyl acetate was added to the activated catalyst mixture and this was hydrogenated at atmospheric pressure for 2 days. The catalyst was filtered off and the solvents evaporated to give 584 mg (98%) of a crystalline solid: mp 50–52°C; IR ν_{max}: 1745 and 1720 cm^{-1}; ^1H NMR (400 MHz) δ: 1.25–1.4 (m, 34H), 1.63 (m, 4H), 2.53 (t, J = 8 Hz, 2H), 3.41 (s, 2H), and 4.15 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 380 (M^+, 35), 362 (22), 115 (12), 111 (14), 107 (16), 102 (17), 97 (29), 96 (23), 91 (21), 85 (23), 83 (34), 82 (26), 81 (20), 69 (45), 57 (41), and 55 (100). Exact Mass calcd. for $C_{24}H_{44}O_3$: 380.3291; found: 380.3301.

3-Oxohexacosan-26-olide

The alkene **17***b* (53 mg, 0.13 mmol) was hydrogenated as above to yield 40 mg (75%) of saturated β-keto lactone: mp 53–54°C; IR ν_{max}: 1745 and 1725 cm^{-1}; ^1H NMR (400 MHz) δ: 1.22–1.4 (m, 38H), 1.62 (m, 4H), 2.53 (t, J = 8 Hz, 2H), 3.42 (s, 2H), and 4.14 (t, J = 8 Hz, 2H); MS m/z (relative intensity): 408 (M^+, 41), 390 (24), 306 (8), 115 (14), 111 (15), 110 (14), 103 (86), 102 (16), 98 (17), 97 (37), 96 (27), 95 (19), 83 (39), 82 (27), 81 (27), 69 (57), 57 (43), and 55 (100). Exact Mass calcd. for $C_{26}H_{48}O_3$: 408.3603; found: 406.3607.

*3-Hydroxytetracosan-24-olide (**11**a)*

A solution of the above 25-membered ring β-keto lactone (127 mg, 0.33 mmol) in 10 mL of ether was treated with 1.2 mL of a 0.14 M solution of $Zn(BH_4)_2$ in ether (0.16 mmol) and the resulting solution was stirred at 0°C for 3 h, then at room temperature for 24 h. The reaction mixture was diluted with 30 mL of ether and washed with 2% aqueous HCl (2 × 10 mL) and saturated brine (20 mL). The extracts were dried and the solvents removed to give 101 mg of a colourless gum, which was purified by flash chromatography using petroleum ether – ethyl acetate (5:1) to give 60.4 mg (48%) of **11***a*: mp 36–38°C; IR ν_{max}: 3550 and 1725 cm^{-1}; ^1H NMR (400 MHz) δ: 1.2–1.4 (m, 38H), 1.64 (m, 2H), 2.45 (AB q, J = 8 and 16 Hz, 1H), 2.54 (AB q, J = 4 and 16 Hz, 1H), 4.0 (m, 1H), and 4.15 (m, 2H); MS m/z (relative intensity): 382 (M^+, 15), 364 (51), 346 (12), 292 (15), 111 (22), 105 (32), 97 (44), 96 (39), 95 (27), 89 (34), 83 (54), 82 (44), 81 (32), 71 (41), 69 (66), 57 (61), and 55 (100). Exact Mass calcd. for $C_{24}H_{46}O_3$: 382.3444; found: 382.3446.

*3-Hydroxyhexacosan-26-olide (**11**b)*

The 27-membered ring β-keto lactone (41.5 mg, 0.10 mmol) was reduced with $Zn(BH_4)_2$ (0.14 mmol) as above to give 96% yield of **11***b*: mp 71–74°C; IR ν_{max}: 3525 and 1730 cm^{-1}; ^1H NMR (400 MHz) δ: 1.2–1.4 (m, 43H), 1.64 (m, 2H), 2.53 (AB q, J = 8 and 16 Hz, 1H), 2.67 (AB q, J = 4 and 16 Hz, 1H), 4.12 (m, 1H), and 4.19 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 410 (M^+, 1), 392 (43), 374 (10), 332 (6), 326 (7), 97 (38), 96 (39), 95 (29), 89 (20), 83 (46), 82 (46), 81 (32), 69 (60), 57 (47), and 55 (100). Exact Mass calcd. for $C_{26}H_{50}O_3$: 410.3760; found: 410.3773.

tert-*Butyldimethylsilyl 11*-tert-*butyldimethylsiloxyundecanoate (**18**)*

A 50-mL, single-necked round bottom flask was charged with 11-hydroxyundecanoic acid (1.52 g, 7.50 mmol), *tert*-butyldimethylchlorosilane (2.70 g, 18.0 mmol), imidazole (2.55 g, 37.5 mmol), and dimethylformamide (15 mL). The resulting solution was stirred for 72 h, then water (15 mL) and ether (15 mL) were added. The organic layer was separated, and the aqueous layer was further extracted with ether (2 × 20 mL). The combined organic extracts were washed with water (15 mL), brine (15 mL), then dried. Removal of the solvent, followed by vacuum distillation, gave 3.06 g (95%) of **18** as a colourless liquid: bp 154–156°C/0.20 Torr; IR ν_{max}: 1710 and 835 cm^{-1}; ^1H NMR (60 MHz) δ: 0.00 (s, 6H), 0.20 (s, 6H), 0.86 (s, 9H), 0.90 (s, 9H), 1.10–1.69 (m, 16H), 2.28 (t, J = 7 Hz, 2H), and 3.54 (t, J = 6Hz, 2H); MS m/z (relative intensity): 430 (M^+, 1), 415 (10), 373 (100), 357 (49), 241 (35), 149 (36), 147 (32), 83 (20), 81 (13), 75 (97), 73 (94), and 55 (23). Anal. calcd. for $C_{23}H_{50}O_3Si_2$: C 64.12, H 11.70; found: C 64.34, H 11.60.

11-tert-*Butyldimethylsiloxyundecanoic acid (**19**)*

A 50-mL, single-necked round bottom flask was charged with the silyl ester **18** (3.13 g, 7.28 mmol) and 25 mL of 10% sodium hydroxide solution. The resulting solution was stirred for 4 h, then it was acidified with dilute HCl. The aqueous layer was extracted with ethyl acetate (3 × 20 mL) and the organic extracts were washed with water (15 mL), brine (15 mL), and dried. Removal of the solvent followed by vacuum distillation gave 2.23 g (97%) of **19** as a thick, colourless oil: bp 148–150°C/0.10 Torr; IR ν_{max}: 3550–2550, 1718, and 845 cm^{-1}; ^1H NMR (60 MHz) δ: 0.00 (s, 6H), 0.86 (s, 9H), 1.20–172 (m, 16H), 2.34 (t, J = 7 Hz, 2H), 3.58 (t, J = 6 Hz, 2H), and 10.13 (bs, 1H); MS m/z (relative intensity): 316 (M^+, 1), 283 (8), 259 (20), 241 (100), 149 (6), 83 (14), 81 (11), 75 (29), 73 (25), and 55 (20). Anal. calcd. for $C_{17}H_{36}O_3Si$: C 64.50, H 11.46; found: C 64.57, H 11.35.

*5-(11'-*tert-*Butyldimethylsiloxy-1'-hydroxyundecylidene)-2,2-dimethyl-1,3-dioxane-4,6-dione (**20**)*

A 50-mL, single-necked round bottom flask was charged with **19** (1.74 g, 4.18 mmol) and 30 mL of dichloromethane. *N,N*-Carbonyldiimidazole (981 mg, 6.05 mmol) was added in portions and the reaction mixture was stirred until gas evolution ceased. A 100-mL, single-necked round bottom flask was charged with Meldrum's acid (1.13 g, 6.07 mmol) and 40 mL of dichloromethane. Pyridine (1.07 g, 13.5 mmol) was introduced in a single portion and the reaction mixture was stirred for 1 h. The contents of the first flask were syringed into the second flask and the combined reaction mixture stirred for an additional 14 h. On work-up, the dichloromethane solution was washed with dilute hydrochloric acid, water, brine, then dried. Removal of the solvent gave 1.45 g (78%) of **20** as a yellow semi-solid: IR ν_{max}: 1730, 1635, and 835 cm^{-1}; ^1H NMR (60 MHz), δ: 0.10 (s, 6H), 0.97 (s, 9H), 1.27–1.83 (m, 16H), 1.81 (s, 6H), 2.90 (t, J = 7 Hz, 2H), and 3.47 (t, J = 6 Hz, 2H).

*5-(11'-Hydroxy-1'-hydroxyundecylidene)-2,2-dimethyl-1,3-dioxane-4,6-dione (**21**)*

A 100-mL, single-necked round bottom flask was charged with **20** (1.25 g, 2.83 mmol), tetra-*n*-butylammonium fluoride (1.85 g, 7.07 mmol), and 50 mL of THF. The resulting solution was stirred for 3.5 h, then 5% HCl (15 mL) and ether (25 mL) were added. The organic layer was separated, washed with water and brine, then dried. Removal of the solvent gave 866 mg (98%) of **21** as a yellow oil: IR ν_{max}: 3400, 1735, and 1635 cm^{-1}; ^1H NMR (60 MHz)

δ: 1.20–1.65 (m, 16H), 1.73 (s, 6H), 2.90 (t, J = 7 Hz, 2H), 3.53 (t, J = 6 Hz, 2H), and 3.56 (bs, 2H, exchangeable with D_2O); MS m/z (relative intensity): 311 (M^+ − OH, 0.1), 269 (6), 211 (12), 126 (12), 100 (14), 98 (15), 86 (31), 84 (48), 77 (40), 75 (100), 72 (43), 71 (40), 67 (30), 61 (59), and 58 (82). Exact Mass calcd. for $C_{17}H_{27}O_5$ (M^+ − OH): 311.1858; found: 311.1858.

*3-Oxotridecan-13-olide (**9**i) from thermolysis of the acyl Meldrum's acid derivative **21***

To a 200-mL, two-necked round bottom flask equipped with a pressure-equalizing dropping funnel was added 100 mL of THF. The solvent was heated to reflux and a solution of **21** (850 mg, 2.73 mmol) in 20 mL of THF was added dropwise over 5 h. The reaction mixture was allowed to cool and ether (75 mL) was introduced. The organic phase was washed with saturated sodium bicarbonate (2 × 25 mL), water (2 × 25 mL), brine (25 mL), then dried. Removal of the solvent, followed by purification via flash chromatography using petroleum ether – ethyl acetate (9:1), gave 213 mg (35%) of **9***i* as a pale yellow semi-solid with identical spectral properties to **9***i* prepared above.

*3-Benzyloxypropanoic acid (**22**, n = 2)*

This compound was prepared from 10 mL (0.16 mol) of β-propiolactone and 100 mL of benzyl alcohol according to the procedure of Bloomfield (45). Distillation afforded 21.6 g (76%) of **22** (n = 2) as a colourless oil, which crystallized on standing to give an amorphous white solid; mp 30–32°C (lit. (45) mp 31.5–33.5°C); bp 130–132°C/0.05 Torr (lit. (45) bp 124–130°C/0.01 Torr); IR ν_{max}: 3550–2820 and 1720 cm^{-1}; ^1H NMR (60 MHz) δ: 2.63 (t, J = 6 Hz, 2H), 3.73 (t, J = 6 Hz, 2H), 4.53 (s, 2H), 7.35 (s, 5H), and 11.48 (s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 180 (M^+, 20), 108 (11), 107 (100), 106 (8), 105 (8), 92 (13), 91 (63), 90 (6), 89 (7), 79 (35), 77 (16), 73 (6), 65 (15), 51 (9), 45 (7), and 39 (9).

General procedure for the preparation of benzyloxycarboxylic acids from lactones (ref. 46)

A mixture of the lactone, potassium hydroxide, freshly distilled benzyl chloride, and dry toluene was heated at reflux for 14–16 h. The cooled mixture was diluted with water and the aqueous phase was washed once with ether, acidified with concentrated HCl, and extracted three times with ether. The combined ether extracts were washed with brine, dried, and concentrated under reduced pressure.

*4-Benzyloxybutanoic acid (**22**, n = 3)*

This compound was prepared according to general procedure using 8.9 mL (0.12 mol) of γ-butyrolactone, 32.5 g (0.58 mol) of potassium hydroxide, 40 mL (0.35 mol) of benzyl chloride, and 200 mL of toluene. Work-up of the reaction mixture yielded 19.1 g of crude product as a yellow oil. Distillation gave 16.5 g (73%) of desired acid as a colourless oil; bp 133–134°C/0.05 Torr (lit. (47) bp 133–134°C/0.5 Torr); IR ν_{max}: 3540–2850 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.63–2.30 (m, 2H), 2.30–2.62 (m, 2H), 3.50 (t, J = 6 Hz, 2H), 4.48 (s, 2H), 7.33 (s, 5H), and 11.02 (s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 194 (M^+, 14), 108 (18), 107 (83), 105 (7), 92 (21), 91 (100), 90 (5), 89 (7), 87 (10), 85 (28), 79 (21), 77 (12), 70 (5), and 65 (19).

*5-Benzyloxypentanoic acid (**22**, n = 4)*

This compound was prepared according to general procedure using 5.0 mL (54 mmol) of δ-valerolactone, 15.1 g (0.27 mol) of potassium hydroxide, 20 mL (0.16 mol) of benzyl chloride, and 125 mL of toluene. Work-up of the reaction mixture yielded 11.3 g of crude product as a yellow oil. Distillation gave 8.5 g (75%) of protected acid as a colourless oil; bp 140–144°C/0.1 Torr; IR ν_{max}: 3550–2850 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.40–1.80 (m, 4H), 2.07–2.42 (m, 2H), 3.18–3.57 (m, 2H), 4.37 (s, 2H), 7.20 (s, 5H), and 10.82 (s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 208 (M^+, 12), 108 (17), 107 (68), 101 (12), 99 (16), 92 (22), 91 (100), 90 (5), 89 (5), 83 (5), 79 (14), 77 (8), 73 (6), 71 (6), and 65 (15). Anal. calcd. for $C_{12}H_{16}O_3$: C 69.21, H 7.74; found: C 68.76, H 7.58.

*6-Benzyloxyhexanoic acid (**22**, n = 5)*

This compound was prepared according to general procedure using 10.0 mL (90 mmol) of ϵ-caprolactone, 25 g (0.45 mol) of potassium hydroxide, 30 mL (0.27 mol) of benzyl chloride, and 200 mL of toluene. Work-up of the reaction mixture yielded 19.2 g of crude product as a yellow oil and distillation gave 17.0 g (85%) of the desired protected acid as a colourless oil; bp 148–150°C/0.07 Torr; IR ν_{max}: 3550;–2850 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ-: 1.23–1.80 (m, 6H), 2.12–2.47 (m, 2H), 3.25–3.60 (m, 2H), 4.43 (s, 2H), 7.25 (s, 5H), and 11.57 (s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 222 (M^+, 12), 113 (12), 108 (13), 107 (59), 105 (5), 98 (5), 97 (5), 92 (25), 91 (100), 89 (5), 79 (12), 77 (6), 73 (8), 69 (8), 67 (6), and 65 (15). Exact Mass calcd. for $C_{13}H_{18}O_3$: 222.1255; found: 222.1255.

6-Benzyloxy-1-chlorohexane

This compound was prepared by treating 1.64 g (41 mmol) of sodium hydride dispersion in 60 mL of THF, with 4.00 g (29 mmol) of 6-chloro-1-hexanol (48), 5.2 mL (44 mmol) of benzyl bromide, and 60 mL of THF. The reaction was refluxed for 16 h and worked up to give 8.4 g of crude product as a yellow oil. Distillation yielded 5.99 g (90%) of pure benzyl ether as a colourless oil: bp 112–114°C/0.2 Torr; IR ν_{max}: 1100 cm^{-1}; ^1H NMR (60 MHz) δ: 1.13–1.97 (m, 8H), 3.30–3.67 (m, 4H), 4.50 (s, 2H), and 7.37 (s, 5H); MS m/z (relative intensity): 228 (M^+ ^{37}Cl, 0.8), 226 (M^+ ^{35}Cl, 2), 208 (1), 182 (2), 135 (1), 130 (1), 119 (2), 117 (5), 108 (10), 107 (7), 105 (4), 93 (8), 92 (71), 91 (100), 81 (6), 79 (10), 77 (8), 65 (16), and 55 (10). Exact Mass. calcd. for $C_{13}H_{19}OCl$: 228.1095, 226.1124; found: 228.1011, 226.1130.

8-Benzyloxy-1-chlorooctane

This compound was prepared as above using 1.70 g (43 mmol) of sodium hydride dispersion, 5.00 g (30 mmol) of 8-chloro-1-octanol (48), 5.4 mL (46 mmol) of benzyl bromide, and 60 mL of THF. Work-up of the reaction mixture gave 9.7 g of crude product as a yellow oil. Distillation yielded 7.48 g (97%) of pure chloro ether as a colourless oil; bp 133–135°C/0.2 Torr; IR ν_{max}: 1100 cm^{-1}; ^1H NMR (60 MHz) δ: 1.13–1.97 (m, 12H), 3.27–3.63 (m, 4H), 4.47 (s, 2H), and 7.32 (s, 5H); MS m/z (relative intensity): 256 (M^+ ^{37}Cl, 0.4), 254 (M^+ ^{35}Cl, 1), 236 (0.3), 208 (0.7), 182 (0.7), 165 (1), 163 (2), 145 (2), 144 (2), 124 (2), 123 (2), 110 (2), 109 (18), 108 (9), 107 (7), 93 (8), 92 (84), 91 (100), 79 (8), 77 (6), 69 (7), 65 (12), and 55 (15). Exact Mass calcd. for $C_{15}H_{23}OCl$: 256.1408, 254.1438; found: 256.1411, 254.1434.

*9-Benzyloxynonanoic acid (**22**, n = 8)*

A Grignard reagent was prepared from a mixture of magnesium turnings (664 mg, 26.5 mmol) and 4.00 g of 6-benzyloxy-1-chlorohexane (17.7 mmol) in dry THF under a nitrogen atmosphere. One drop of 1,2-dibromoethane was added to initiate the reaction. The mixture was heated to reflux for 2.5 h and was cooled to room temperature, resulting in a grey suspension of the Grignard reagent. In a second flask, 1.34 mL of β-propiolactone (21.2 mmol) in 20 mL of THF was added to 8.9 mL of a 0.1 M solution of lithium tetrachlorocuprate (0.89 mmol) in THF. This solution was cooled to −10°C and the solution of the Grignard reagent was added via cannulation at such a rate that the internal temperature of the reaction mixture remained below 0°C. The reaction mixture was stirred at −10°C for 1 h, then was quenched with 1 M HCl and diluted with ether. The organic phase was extracted repeatedly with 5% aqueous potassium hydroxide. The combined aqueous extracts were acidified with concentrated HCl and extracted three times with ether. The combined ether layers were washed twice with brine, dried, and concentrated under reduced pressure to give 4.47 g of crude acid product as well as 1.2 g (34%) of quenched Grignard reagent. Distillation afforded a small forerun of 3-chloropropanoic acid (bp 54°C/0.2 Torr) followed by 2.77 g (59%) of **22** (n = 8) as a colourless oil; bp 176–178°C/0.3 Torr; IR ν_{max}: 3640–2850 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.10–1.90 (m,

12H), 2.33 (t, J = 6 Hz, 2H), 3.47 (t, J = 6 Hz, 2H), 4.50 (s, 2H), 7.35 (s, 5H), and 11.10 (br s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 264 (M^+, 13), 246 (2), 218 (2), 155 (6), 144 (5), 138 (5), 123 (6), 108 (17), 107 (77), 106 (9), 105 (19), 97 (10), 92 (33), 91 (100), 84 (9), 83 (7), 79 (11), 73 (15), 69 (15), 68 (9), 65 (9), 60 (18), and 55 (39). Exact Mass calcd. for $C_{16}H_{24}O_3$: 264.1724; found: 264.1724.

*11-Benzyloxyundecanoic acid (**22**, n = 10)*

This compound was prepared according to the above procedure, using 860 mg (35.4 mmol) of magnesium turnings, 6.00 g (23.6 mmol) of 8-benzyloxy-1-chlorooctane, and 20 mL of THF to generate the Grignard reagent. The second solution was prepared from 11.8 mL (1.18 mmol) of a 0.1 M solution of lithium tetrachlorocuprate in THF, 3.0 mL (47 mmol) of β-propiolactone, and 20 mL of THF. Work-up of the reaction mixture gave 5.95 g of crude acid as well as 1.77 g (34%) of quenched Grignard reagent. Distillation afforded a forerun of 3-chloropropanoic acid (0.90 g; bp 54°C/0.2 Torr), followed by 3.89 g (56%) of **22** (n = 10) as a colourless oil, which solidified on standing to give a white amorphous solid; mp 30–32°C; bp 188°C/0.05 Torr; IR ν_{max}: 3620–2820 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.08–1.90 (m, 16H), 2.33 (t, J = 7 Hz, 2H), 3.45 (t, J = 6 Hz, 2H), 4.50 (s, 2H), 7.33 (s, 5H), and 11.50 (s, 1H, exchangeable); MS m/z (relative intensity): 292 (M^+, 12), 109 (11), 108 (14), 107 (50), 100 (10), 92 (49), 91 (100), 79 (9), 77 (8), 73 (17), 71 (9), 69 (16), 65 (9), 60 (13), and 55 (32). Exact Mass calcd. for $C_{18}H_{28}O_3$: 292.2038; found: 292.2038.

5-(3'-Benzyloxy-1'-hydroxypropylidene)-2,2-dimethyl-1,3-dioxan-4,6-dione

To 5.12 g (28.4 mmol) of carboxylic acid **22** (n = 2) was added 5.0 mL (57 mmol) oxalyl chloride and the resulting solution was stirred for 2.5 h at room temperature. The excess oxalyl chloride was then removed under reduced pressure and the residual acid chloride was dissolved in 30 mL of dry dichloromethane. This acid chloride solution was added to a solution of 3.72 g (25.8 mmol) of Meldrum's acid and 6.3 mL (77 mmol) of pyridine in 50 mL of dichloromethane at 0°C. The reaction was stirred at 0°C for 1 h and allowed to warm to room temperature for 1 h. Work-up of the reaction mixture gave 7.72 g of crude product as a red syrup. Purification by flash chromatography using petroleum ether – ethyl acetate (4:1) as eluant afforded 5.99 g (76%) of acylated Meldrum's acid as a yellow oil; IR ν_{max}: 3600–3300, 1740, 1680, and 1580 cm^{-1}; ^1H NMR (60 MHz) δ: 1.70 (s, 6H), 2.68–2.92 and 3.36–3.62 (2 multiplets, 2H; enol and keto forms), 3.68–3.97 (m, 2H), 4.57 (s, 2H), 7.35 (s, 5H), and 15.35 (br s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 306 (M^+, 5), 248 (9), 144 (5), 143 (40), 142 (8), 125 (22), 124 (21), 114 (5), 113 (5), 108 (7), 107 (31), 106 (5), 105 (6), 98 (26), 96 (8), 91 (100), 89 (6), 79 (10), 77 (8), 65 (17), 59 (15), and 58 (12). Exact Mass calcd. for $C_{16}H_{18}O_6$: 306.1104; found: 306.1116.

*5-(4'-Benzyloxy-1'-hydroxybutylidene-2,2-dimethyl-1,3-dioxan-4,6-dione (**23**, n = 3)*

The acid chloride of carboxylic acid **22** (n = 3) was prepared as above, using 5.0 g (26 mmol) of **22** (n = 3), 2.25 mL (25.8 mmol) of oxalyl chloride, 2.1 mL (26 mmol) of pyridine, and 30 mL of dichloromethane. This acid chloride was treated with 3.38 g (24 mmol) of Meldrum's acid, and 5.7 mL (71 mmol) of pyridine in 30 mL of dichloromethane as above. Work-up of the reaction mixture gave 7.25 g of crude product as a red syrup. Purification by flash chromatography using petroleum ether – ethyl acetate (2:1) as eluant afforded 6.34 g (84%) of **23** (n = 3) as a yellow oil; IR ν_{max}: 3640–3300, 1740, 1670, and 1580 cm^{-1}; ^1H NMR (60 MHz) δ: 1.70 (s, 6H), 1.73–2.27 (m, 2H), 2.30–2.70 and 3.03–3.33 (2 multiplets, 2H; enol and keto forms), 3.37–3.70 (m, 2H), 4.47 (6, 2H), 7.33 (s, 5H), and 15.20–15.53 (br s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 320 (M^+, 0.8), 262 (7), 157 (6), 155 (8), 139 (5), 128 (14), 112 (13), 111 (5), 108 (6), 107 (29), 105 (8), 92 (14), 91 (100), 87 (6), 85 (18), 84 (16), 79 (9), 77 (9), 69 (12), 65 (14), and 57 (10). Exact Mass calcd. for $C_{17}H_{20}O_6$: 320.1260; found: 320.1278.

*5-(5'-Benzyloxy-1'-hydroxypentylidene)-2,2-dimethyl-1,3-dioxan-4,6-dione (**23**, n = 4)*

The acid chloride of **22** (n = 4) was prepared from 1.00 g (4.8 mmol) of acid, 0.41 mL (4.8 mmol) of oxalyl chloride, 0.39 mL (4.8 mmol) of pyridine, and 15 mL of dichloromethane. This acid chloride was treated with 0.63 g (4.4 mmol) of Meldrum's acid, and 1.1 mL (13 mmol) of pyridine in 10 mL of dichloromethane. Work-up of the reaction mixture gave 1.53 g of crude product as a red syrup. Purification by flash chromatography using petroleum ether – ethyl acetate (4:1) as eluant afforded 1.16 g (80%) of **23** (n = 4) as a yellow oil; IR ν_{max}: 3650–3400, 1740, 1670, and 1580 cm^{-1}; ^1H NMR (60 MHz) δ: 1.50–1.93 (m, 4H), 1.73 (s, 6H), 2.27–2.57 and 2.90–3.25 (2 multiplets, 2H; enol and keto forms), 3.37–3.63 (m, 2H), 4.48 (s, 2H), 7.33 (s, 5H), and 15.20–15.53 (br s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 334 (M^+, 3), 276 (7), 258 (3), 208 (6), 185 (5), 176 (4), 170 (6), 169 (6), 167 (5), 152 (8), 141 (8), 124 (5), 108 (8), 107 (32), 101 (13), 99 (15), 92 (18), 91 (100), 83 (5), 79 (9), 77 (6), 71 (8), 69 (7), 65 (13), and 58 (14). Exact Mass calcd. for $C_{18}H_{22}O_6$: 334.1416; found: 334.1428.

*5-(6'-Benzyloxy-1'-hydroxyhexylidene)-2,2-dimethyl-1,3-dioxan-4,6-dione (**23**, n = 5)*

The acid chloride of **22** (n = 5) was prepared from 2.14 g (9.6 mmol) of acid, 0.84 mL (9.6 mmol) of oxalyl chloride, 0.78 mL (9.6 mmol) of pyridine, and 20 mL of dichloromethane. This acid chloride was treated with 1.26 g (8.7 mmol) of Meldrum's acid, 2.2 mL (26 mmol) of pyridine, and 20 mL of dichloromethane. Work-up of the reaction mixture gave 3.22 g of crude product as a red syrup. Purification by flash chromatography using petroleum ether – ethyl acetate (4:1) as eluant afforded 2.53 g (83%) of **23** (n = 5) as a yellow oil; IR ν_{max}: 3620–3420, 1740, 1670, and 1575 cm^{-1}; ^1H NMR (60 MHz) δ: 1.40–1.90 (m, 6H), 1.72 (s, 6H), 2.13–2.50 and 2.90–3.27 (2 multiplets, 2H; enol and keto forms), 3.33–3.63 (m, 2H), 4.48 (s, 2H), 7.32 (s, 5H), and 15.13–15.50 (br s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 348 (M^+, 0.2), 290 (3), 272 (0.5), 222 (3), 199 (3), 141 (3), 115 (4), 113 (4), 108 (4), 107 (17), 97 (4), 92 (10), 91 (55), 79 (7), 77 (5), 73 (4), 69 (7), 65 (9), 59 (7), 58 (28), 44 (34), and 43 (100). Exact Mass calcd. for $C_{19}H_{24}O_6$: 348.1572; found: 348.1571.

*5-(9'-Benzyloxy-1'-hydroxynonylidene)-2,2-dimethyl-1,3-dioxan-4,6-dione (**23**, n = 8)*

The acid chloride of **22** (n = 8) was prepared from 2.0 g (7.6 mmol) of acid, 0.66 mL (7.6 mmol) of oxalyl chloride, 0.61 mL (9.6 mmol) of pyridine, and 15 mL of dichloromethane. This acid chloride was treated with 0.99 g (6.9 mmol) of Meldrum's acid, and 1.7 mL (21 mmol) of pyridine in 15 mL of dichloromethane. Work-up of the reaction mixture gave 2.49 g of crude product as a red syrup. Purification by flash chromatography using petroleum ether – ethyl acetate (4:1) as eluant afforded 1.69 g (63%) of **23** (n = 8) as a yellow oil; IR ν_{max}: 3620–3400, 1740, 1670, and 1575 cm^{-1}; ^1H NMR (60 MHz) δ: 1.15–1.87 (m, 12H), 1.73 (s, 6H), 2.13–2.50 and 2.92–3.27 (m, 12H), 1.73 (s, 6H), 2.13–2.50 and 2.92–3.27 (2 multiplets, 2H; enol and keto forms), 3.47 (t, J = 6 Hz, 2H), 4.50 (s, 2H), 7.35 (s, 5H), and 15.17–15.50 (br s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 390 (M^+, 0.3), 375 (0.3), 332 (4), 265 (8), 155 (5), 108 (13), 107 (50), 97 (5), 95 (5), 92 (24), 265 (8), 155 (5), 108 (13), 107 (50), 97 (5), 95 (5), 92 (24), 91 (89), 79 (7), 77 (5), 71 (9), 69 (6), 65 (9), 59 (6), 58 (33), 57 (5), 55 (15), 44 (57), and 43 (100). Exact Mass calcd. for $C_{19}H_{24}O_5$ (M^+ − acetone): 332.1623; found: 332.1616.

*5-(11'-Benzyloxy-1'-hydroxyundecylidene)-2,2-dimethyl-1,3-dioxan-4,6-dione (**23**, n = 10)*

The acid chloride of **22** (n = 10) was prepared from 1.46 g (5.0 mmol) of acid, 0.41 mL (5.0 mmol) of oxalyl chloride,

0.40 mL (5.0 mmol) of pyridine, and 15 mL of dichloromethane. This acid chloride was treated with 0.79 g (5.5 mmol) of Meldrum's acid, and 1.3 mL (17 mmol) of pyridine in 15 mL of dichloromethane. Work-up of the reaction mixture gave 1.87 g of crude product as a red syrup. Purification by flash chromatography using petroleum ether – ethyl acetate (4:1) as eluant afforded 1.05 g (50%) of pure **23** (n = 10) as a yellow oil; IR ν_{max}: 3620–3400, 1740, 1670, and 1575 cm^{-1}; ^1H NMR (60 MHz) δ: 1.03–1.92 (m, 16H), 1.73 (s, 6H), 2.08–2.58 and 2.90–3.27 (2 multiplets, 2H; enol and keto forms), 3.47 (t, J = 6 Hz, 2H), 4.50 (s, 2H), 7.35 (s, 5H), and 15.17–15.50 (br s, 1H, exchangeable with D_2O); MS m/z (relative intensity): 418 (M^+, 1), 403 (1), 401 (1), 360 (4), 342 (1), 312 (1), 293 (3), 292 (14), 183 (3), 123 (3), 108 (14), 107 (64), 92 (28), 91 (10), 85 (7), 83 (7), 81 (8), 79 (8), 77 (7), 71 (15), 69 (11), 67 (7), 65 (10), 60 (7), 59 (8), and 58 (21). Exact Mass calcd. for $C_{21}H_{28}O_5$ (M^+ − acetone): 360.1937; found: 360.1954.

*5-(1',3'-Dihydroxypropylidene)-2,3-dimethyl-1,3-dioxan-4,6-dione (**24**, n = 2)*

A mixture of 710 mg (2.32 mmol) of the above acetylated Meldrum's acid and 70 mg of 10% palladium-on-charcoal in 10 mL of ethanol – ethyl acetate (1:1) was stirred under a hydrogen atmosphere (1 atm = 101.3 kPa) at room temperature. After 57 mL (1 equiv.) of hydrogen had been absorbed during a period of 2 h, the uptake of hydrogen ceased. The catalyst was removed by filtration and was washed with ethyl acetate. The filtrate was concentrated under reduced pressure to give 448 mg (89%) of **24** (n = 2) as a pale yellow oil; IR ν_{max}: 3640–3350, 1740, 1680, and 1580 cm^{-1}; ^1H NMR (60 MHz) δ: 1.70 (s, 6H), 2.56–2.83 and 3.13–3.53 (2 multiplets, 2H; enol and keto forms), and 3.67–4.07 (m, 2H); MS m/z (relative intensity); 216 (M^+, 1), 159 (15), 158 (32), 141 (14), 140 (13), 114 (27), 105 (13), 91 (12), 73 (57), 69 (19), 59 (79), and 58 (14). Exact Mass calcd. for $C_9H_{12}O_6$: 216.0634; found: 216.0634.

*3-Oxopentan-5-olide (**25**)*

To 25 mL of dry THF heated at reflux under a nitrogen atmosphere was added a solution of 302 mg (1.40 mmol) of alcohol **24** (n = 2) in 15 mL of THF over a period of 4 h, using a constant-rate addition funnel. The solution was heated at reflux for an additional 30 min. Removal of solvent gave 235 mg of a yellow oil. Distillation, in glassware that had been treated with trimethylsilyl chloride and pyridine, then rinsed with water, and dried, gave 139 mg (87%) of **25** as a colourless oil, which slowly crystallized to give an amorphous white solid. ^1H NMR analysis indicated that the product was ca. 95% pure; mp 61–64°C; bp (Kugelrohr distillation) 130°C/0.1 Torr; IR ν_{max}: 1780 and 1745 cm^{-1}; ^1H NMR (60 MHz) δ: 2.72 (t, J = 6 Hz, 2H), 3.60 (s, 2H), and 4.63 (t, J = 6 Hz, 2H); MS m/z (relative intensity): 114 (M^+, 8), 105 (3), 104 (3), 91 (3), 85 (5), 77 (4), 73 (3), 72 (5), 71 (5), 70 (3), 69 (5), 60 (4), 58 (3), 56 (7), 55 (51), 45 (4), 44 (7), 43 (25), and 42 (100). Exact Mass calcd. for $C_5H_6O_3$: 114.0317; found: 114.0319.

*5-(Tetrahydro-2'-furylidene)-2,2-dimethyl-1,3-dioxan-4,6-dione (**26**)*

A mixture of 1.93 g (6.0 mmol) of **23** (n = 3) and 0.19 g of 5% palladium-on-charcoal in 15 mL of ethyl acetate was stirred under a hydrogen atmosphere (1 atm) at room temperature. After 208 mL (141% of 1 molar equivalent) of hydrogen had been absorbed during a period of 19 h, the uptake of hydrogen ceased. The catalyst was removed by filtration and was washed with dichloromethane. The filtrate was concentrated under reduced pressure to give 1.03 g crude **26** as pale yellow crystals. Recrystallization from petroleum ether – ethyl acetate gave 0.89 g (70%) of **26** as a white solid; mp 145.0–146.5°C; IR ν_{max}: 1755 and 1715 cm^{-1}; ^1H NMR (60 MHz) δ: 1.73 (s, 6H), 1.93–2.53 (m, 2H), 3.50 (t, J = 8 Hz, 2H), and 4.73 (t, J = 7 Hz, 2H); MS m/z (relative intensity): 212 (M^+, 13), 197 (13), 156 (6), 155 (55), 154 (29), 113 (8), 111 (20), 110 (100), 69 (28), 53 (11), 52 (8), 44 (7), 43 (47), and 42 (78). Exact Mass calcd. for $C_{10}H_{12}O_5$: 212.0685; found: 212.0685.

Approach to the synthesis of candelabrone and synthesis of 3,7-diketo-12-hydroxyabieta-8,11,13-triene

ROBERT H. BURNELL[1] AND STÉPHANE CARON
Chemistry Department, Université Laval, Québec, Que., Canada G1K 7P4

Received July 30, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

ROBERT H. BURNELL and STÉPHANE CARON. Can. J. Chem. **70**, 1446 (1992).

An approach to the synthesis of aromatic diterpenes was tested for its generality. Phenylacetonitriles with increasing substitution on the aromatic ring were prepared and alkylated with geranyl bromide and the resulting dienes subjected to cationic cyclization. The less-substituted examples afforded tricyclic products of the required stereochemistry while the more highly substituted compounds cyclized with reduced yields or not at all. One of the intermediates was used to synthesize nimosone (3,7-diketo-12-methoxyabieta-8,11,13-triene), a natural diterpene isolated originally from *Chamaecyparis formosensis* and recently from *Azadirachta indica*.

ROBERT H. BURNELL et STÉPHANE CARON. Can. J. Chem. **70**, 1446 (1992).

Une serie de phénylacétonitriles substitués par une chaîne géranyle et un nombre croissant de groupements méthoxyles a été soumise à des conditions de cyclisation cationique pour déterminer la généralité de la réaction. Seulement les substrats les moins encombrés ont réagis efficacement donnant les produits tricycliques de la stéréochimie requise et un de ces derniers a servi comme intermédiaire clé pour la synthèse de la nimosone, une dicétone diterpènique isolée de *Chamaecyparis formosensis* et plus récemment de *Azadirachta indica*.

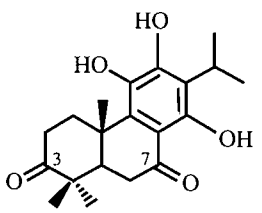
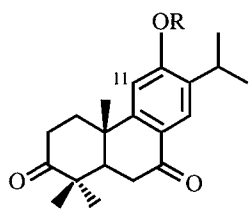
In recent years more examples of aromatic diterpenes with oxygen functions in the A ring have appeared in the literature. Hypagenins A, D, and E (1), candelabrone (2) and several coleons (3) fall in this category and the neem tree, *Azadirachta indica*, is a rich source of these new compounds (4). Few syntheses are reported for these products since many of the schemes that start with simpler naturally occuring chiral terpenes, such as podocarpic and dehydroabietic acids (5), do not lend themselves readily to the introduction of functions into the A ring past the quaternary centres at C4 and C10. A more total approach could be advantageous but, unlike those derived from chiral precursers, the final products from most sequences would be racemic.



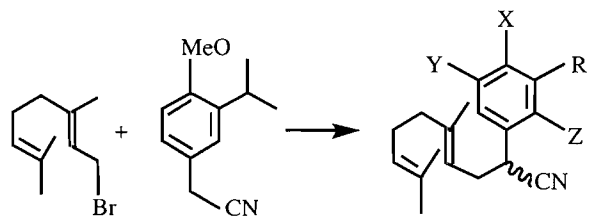
1



2*a* R = H
2*b* R = Me

After first probing the application of radical cyclizations of the type described by Snider *et al.* (6) it was decided to test the generality of the cationic equivalent as championed by Livinghouse and co-workers (7). Ultimately we hope to apply the scheme to the synthesis of candelabrone **1** but the first objective was the simpler 3,7-diketo-12-hydroxyabieta-8,11,13-triene **2***a* originally isolated from *Chamaecyparis formosensis* (8) and more recently from *Azadirachita indica* when it was given the name nimosone (4*a*).

This synthetic approach involves the cyclization of nonconjugated dienes such as **5***a* in which half the molecule comes from the naturally derived geranyl bromide **3** and the other 10 skeletal carbon atoms are provided by substituted phenylacetonitriles, such as **4**. Specifically the latter has been prepared from *o*-isopropylanisole **6***a* in an overall yield of close to 65%. Bromination of **6***a* by potassium bromide and *m*-CPBA in the presence of 18-crown-6 afforded 84% of the bromo derivative **6***b* and the yields were as good or better in the followingGrignard reaction (with DMF, 98% **6***c*), hydride reduction (97% **6***d*), and the two substitutions (first with PBr_3, pyridine 98% **6***e* and then KCN, 18-crown-6, 80% **4**).



3 **4**

5*a* X = OMe R = isoPr Y = Z = H

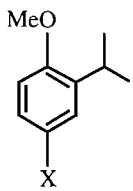
5*c* X = Y = Z = OMe R = isoPr
5*d* X = Z = OMe R = isoPr Y = H

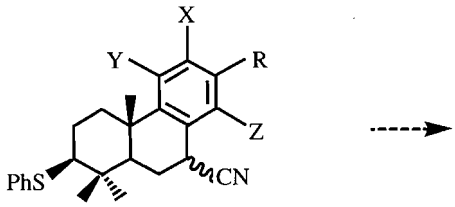


6*a* X = H
6*b* X = Br
6*c* X = CHO
6*d* X = CH_2OH
6*e* X = CH_2Br → **4**

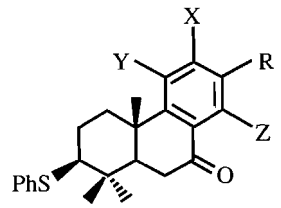
The anion of nitrile **4** coupled with the reactive geranyl bromide **3** at room temperature to afford the diene **5***a* (85%). Attempts to cyclize the latter using published procedures (9) were disappointing so, for experimentation, a simpler model **5***b* was prepared (in 92% yield) by alkylating phenylaceto-

[1]Author to whom correspondence may be addressed.

nitrile with geranyl bromide. Finally, using methyl benzenesulfenate with boron trifluoride in nitromethane (*7b*),[2] this model diene gave the cyclized product **7***b* in reasonable yield (63%). In the same manner, the methoxy isopropyl analog **5***a* afforded the tricyclic **7***a* with slightly better results (76%). The ring closures produced specifically the AB *trans* geometry, the relative configuration at C3 was mostly β, while the two epimers at C7 were roughly equally represented. No particular effort was made to separate these diasteromers since their stereochemical peculiarities would disappear in subsequent steps as the carbonyl groups were established at these positions. Both the simple models **7***b* and **7***a* were subjected to the following reactions, the former serving as an expendable forerunner to determine the most rewarding experimental conditions.

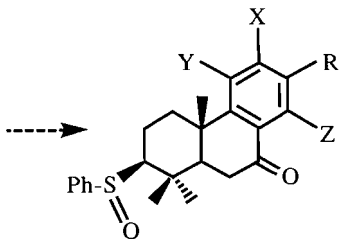


7*a* R = isoPr X = OMe Y = Z = H
7*b* R = X = Y = Z = H
7*c* R = isoPr X = Y = Z = OMe
7*d* R = isoPr X = Z = OMe Y = H



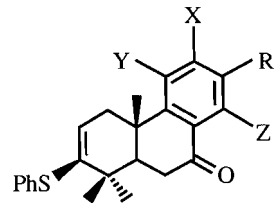
8*a* R = isoPr X = OMe Y = Z = H
8*b* R = X = Y = Z = H

8*d* R = isoPr X = Z = OMe Y = H



9*a* R = isoPr X = OMe Y = Z = H
9*b* R = X = Y = Z = H

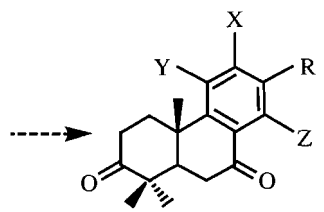
9*d* R = isoPr X = Z = OMe Y = H



10*a* R = isoPr X = OMe Y = Z = H
10*b* R = X = Y = Z = H

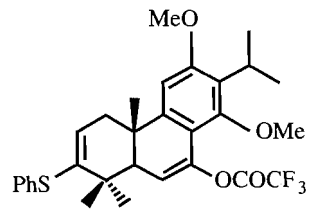
Bubbling oxygen into solutions containing the anions of **7***a* and **7***b* and reduction of the hydroperoxy intermediates gave the C7 ketones **8***a* and **8***b* (55% and 50%, respectively). The phenylthio residues were smoothly oxidized to the sulfoxides (**9***a* and **9***b*) but when the latter were treated with trifluoroacetic anhydride, Pummerer rearrangement led to the enolthio-ethers **10***a* and **10***b*. Hydrolysis of these vinyl ethers under the influence of titanium tetrachloride gave the diketones **11***a* and **11***b*. The phenol **2***a* arising from the demethylation of **11***a* (**2***b*) gave spectra identical in all respects with those of the natural product, 3,7-diketo-12-hydroxyabieta-8,11,13-triene (now named nimosone (*4a*) provided by Dr. Yu-Shia Cheng (8). The synthetic product was racemic of course.

To continue towards candelabrone **1***a* it had been hoped that **2***a* could be oxidized to the *o*-quinone but neither Fremy's salt, salcomine, nor phenylselenenic anhydride afforded any recognisable products. This suggested that the only route to candelabrone would be to place the aromatic substituents from the outset. The necessary trimethoxy-isopropylphenylacetonitrile **15***a* was prepared from methyl 2,6-dimethoxybenzoate **12***a* via di-*O*-methyl-2-isopropylresorcinol **12***d* (Grignard, dehydration, and hydrogenation). After methylation of the phenol **13***a* obtained by *m*-CPBA oxidation of **12***d*, the product **13***b* was brominated exclusively to the 1,2,4-trimethoxy-5-bromo derivative **13***c* and then the same steps used to prepare **4** were followed (Grignard → **13***d*, reduction → **13***e*, substitutions → **13***f*, and then **15***a*). The nitrile **15***a* was readily alkylated with geranyl bromide **3** to form the diene **5***c* (yield 97%).



11*a* R = isoPr X = OMe Y = Z = H
11*b* R = X = Y = Z = H

11*d* R = isoPr X = OMe Z = OH Y = H



17

When subjected to the cyclization reaction none of the tricyclic product **7***c* was obtained, not even when the more efficient Ph-S-O-CH_2-CH_2-O-CH_3 was used in conjunction with BF_3/CH_3NO_2 (see footnote 2). The activation afforded by a methoxyl group *ortho* to the site of ring closure is apparently offset by the two *meta* effects and the steric crowding on the aromatic ring.

Some indication of the relative importance of the elec-

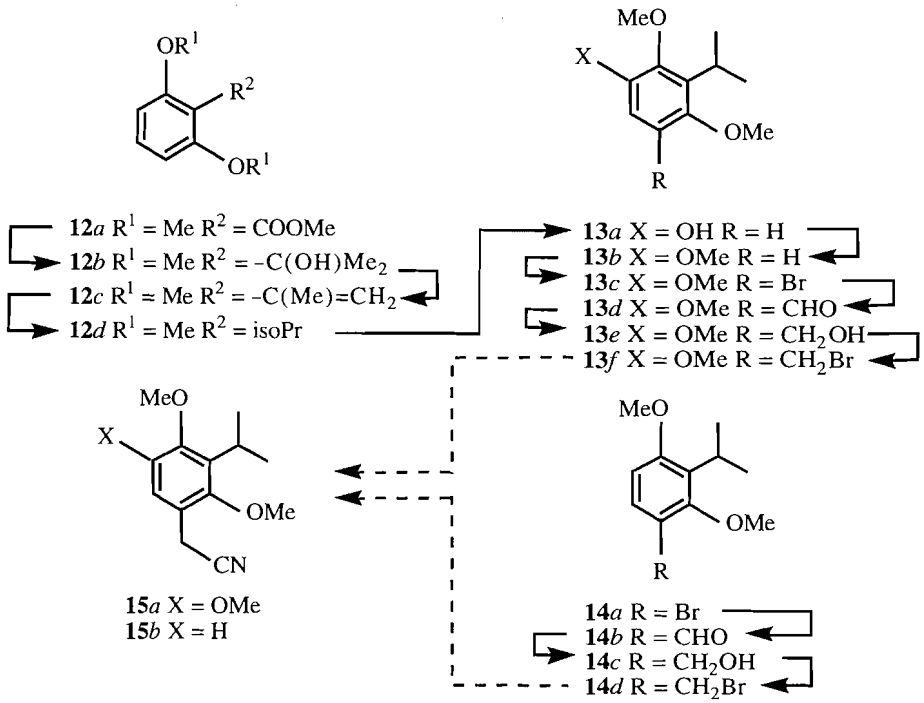
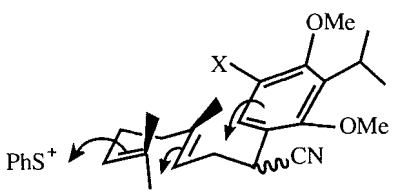
For personal use only.

tronic and steric factors that prevented the cyclization could be inferred from the reaction of the dimethoxy analog **5***d*. It is well known that the 11-position in tricyclic compounds such as **2***b* is resistant to Friedel–Crafts acylation and forcing such reactions leads to C13 *ipso* substitution and the replacement of the isopropyl by the acyl moiety (10). The diene **5***c* must be unable to assume the appropriate geometry for synchronous cyclization as shown in **16***c* whereas the absence of the methoxyl in **5***d* could allow such a pretransition regrouping (**16***d*).



The diene **5***d* was prepared from the dimethoxyisopropylbenzene **12***d* using the same sequence as in the synthesis of **4**(**14***a* → **14***b* → **14***c* → **14***d* → **15***b*) and finally **15***b* was coupled with geranyl bromide **3**. After methyl benzenesulfenate provoked cyclization several products were present and spectral evidence suggested some structures in which only the A ring had closed during the reaction. The product from double annelation **7***d* was isolated in 41% yield and despite numerous attempts this could never be improved. The subsequent reactions proceeded almost normally. The carbonyl at C7 was introduced using the same conditions that had lead to **8***a* and **8***b* and high yields were obtained of the sulfoxide **9***d*. The product isolated after treating the latter with trifluoroacetic anhydride was actually the enol trifluoracetate **17**. As expected, the final reaction (hydrolysis with $TiCl_4$) not only established the C3 carbonyl but also hydrolysed the methoxyl *peri* to the conjugated ketone to give the chelated **11***d*.



16*c* X = OMe
16*d* X = H

In conclusion one can say that, not surprisingly, this type of cyclization is seriously hampered by increasing substitution on the aromatic ring. As demonstrated by the synthesis of the natural product **2***a*, the approach is excellent for less-substituted members of this class of terpenes.

Experimental

Unless otherwise stated, the conditions used to characterize the products were as follows: melting points, Electrothermal, uncorrected; ultraviolet spectra, λ_{max} ethanol solutions (ϵ in parentheses), Perkin–Elmer Lambda 5; infrared spectra, carbon tetrachloride solutions, Mattson Sirius 100 FTIR; 200 MHz proton and 50 MHz carbon-13 magnetic resonance spectra, deuteriochloroform solutions (multiplicity, integrated peak areas, coupling constants in hertz and where necessary, assignments in parentheses), "dis. D_2O" signifies that the peak in question disappeared on shaking the solution with a small volume of D_2O, Varian XL-200 (300 MHz spectra courtesy of Prof. D. J. Burnell, Memorial University, Newfoundland; 400 MHz spectra were performed at the Laboratoire régional de RMN à haut champ, Université de Montréal); mass spectra, Hewlett Packard 5992 and Exact Mass measurements at the Centre régional de spectrométrie de masse, Université de Montréal. Chromatography implies the use of Terochem silica gel (for flash chromatography) with the solvents determined by prior thin-layer chromatography using DC-Alufolien Kieselgel 60 F_{254} precoated aluminium sheets. Reactions were normally carried out under nitrogen or argon. Elemental analyses were by Galbraith Laboratories, Knoxville, Tenn.

Simple products are numbered according to normal rules but for easier comparison, the dienes **5***a–d* and all subsequent compounds are numbered as tricyclic diterpenes. For ^{13}C figures, all skeletal carbons are listed first and after "and" all the peripheral groups are given (Me-O, Ph-S, CN, etc.). The assignments result

from COSY, HETCOR, and APT experiments, which are not described in the text.

Preparation of nitrile ***4***

Bromination of o-*isopropylanisole* ***6***a

Following the procedure of Srebnik *et al.* (11), KBr (82.01 g; 0.69 mmol), 18-crown-6 (4.29 g), and the isopropylanisole ***6a*** (21.45 g; 0.143 mmol) were suspended in vigorously stirred CH_2Cl_2(300 mL) under argon and cooled to 0°C. *m*-CPBA (58.82 g of 80%; 0.272 mmol) in CH_2Cl_2(160 mL) was slowly added and stirring continued for 30 min. The mixture was poured into ether (800 mL) and washed with 10% aqueous sodium bisulfite (400 mL), saturated $NaHCO_3$, saturated NaCl, and dried. After concentration, the residue was chromatographed (pet. ether) to give *4-bromo-2-isopropylanisole* ***6b*** (27.57 g; 84%): ^{1}Hmr δ: 1.21 (d, 6H, J = 7.0 Hz), 3.29 (q, 1H, J = 7.0 Hz), 3.81 (s, 3H), 6.71 (d, J = 8.6 Hz), 7.25 (dd, J = 8.6 and 2.3 Hz), and 7.29 (d, J = 2.3 Hz); ^{13}Cmr δ: 155.7, 139.2, 129.0, 112.9, 129.0, 111.9, 26.8, 22.5, and 55.5; mass *m/z*: 230 (9), 228(8), 215(17), 213(18), 104(12), 91(38), 83(100), and 77(35).

Grignard reaction to give aldehyde ***6***c

The Grignard reagent was prepared from the bromo derivative ***6b*** (5.01 g; 21.9 mmol) and magnesium (0.817 g) in anhydrous THF (30 mL) in the usual manner. To the cooled mixture was added dropwise anhydrous DMF (8.50 mL; 115 mmol) and after the vigorous reaction had subsided the solution was refluxed for 5 min, cooled, and then treated with saturated NH_4Cl (50 mL). The oil obtained by ether extraction was chromatographed (pet. ether/ether 7:1) to give the *4-methoxy-3-isopropylbenzaldehyde* ***6c*** (3.80 g; 98%): ir: 1690 cm^{-1}; ^{1}Hmr δ: 1.20 (d, 6H, J = 7.0 Hz), 3.29 (q, 1H, J = 7.0 Hz), 3.86 (s, 3H), 6.90 (d, J = 8.6 Hz), 7.66 (dd, J = 8.6 and 2.3 Hz), 7.72 (d, J = 2.3 Hz), and 9.83 (s, 1H); ^{13}Cmr δ: 161.7, 137.7, 130.3, 129.5, 126.8, 109.9, 190.9, 26.5, 22.3, 22.3, and 55.5; mass *m/z*: 178(47), 163(100), 147(18), 135(20), 120(11), 105(35), 103(18), 91(25), and 77(36). Exact Mass (showed that the aldehyde had oxidized to the acid during transport) calcd. for $C_{11}H_{14}O_3$: 194.0919; found: 194.0931.

Reduction of the aldehyde ***6***c

Excess $NaBH_4$ 2.05 g; 54 mmol) was added to the aldehyde ***6c*** (8.68 g; 48.8 mmol) in MeOH (125 mL) at 0°C. After stirring 12 min, water was added and the product extracted into ether, *2-isopropyl-4-hydroxymethylanisole* ***6d*** (8.53 g; 97%) sufficiently pure for the next step: ir: 3550–3100 (br OH) cm^{-1}; ^{1}Hmr δ: 1.21 (d, 6H, J = 6.6 Hz), 2.05 (br s, dis. D_2O), 3.33 (q, J = 6.6 Hz), 3.83 (s, 3H), 4.59 (s, 2H, 2H-C7), 6.83 (d, J = 8.2 Hz), 7.15 (dd, J = 8.2 and 2.3 Hz), and 7.22 (d, J = 2.3 Hz); ^{13}Cmr δ: 156.2, 137.0, 125.2, 132.8, 125.5, 110.2, 65.2, 26.7, 22.7, 22.7, and 55.4.

Formation of the benzyl bromide ***6***e

Based on the procedure of Hess and co-workers (12) the alcohol ***6d*** (4.88 g; 27.1 mmol) was dissolved in benzene (180 mL) under argon. Pyridine (1.25 mL; 15.5 mmol) was added followed by PBr_3 (2.60 mL; 14.3 mmol) dropwise, which resulted in the appearance of a white precipitate. The mixture was stirred for 3 h and then water (50 mL) was added and the product obtained by extraction, *2-isopropyl-4-bromomethylanisole* ***6e*** (6.47 g; 98%), which was used without further purification in the next step: ^{1}Hmr δ: 1.28 (d, 6H, J = 7.0 Hz), 3.36 (q, 1H, J = 7.0 Hz), 3.86 (s, 3H), 4.56 (s, 2H, 2H-C7), 6.84 (d, J = 8.1 Hz), 7.25 (dd, J = 8.1 and 2.2 Hz), and 7.29 (d, J = 2.2 Hz); ^{13}Cmr δ: 156.7, 137.2, 126.9, 127.3, 110.2, 34.6, 26.8, 22.5, and 55.3; mass *m/z*: 244(2) and 242(2), 163(100), 148(10), 133(23), 91(8), and 77(10). Exact Mass calcd. for $C_{11}H_{15}O^{79}Br$: 242.0344; found: 242.0325.

Substitution to give nitrile ***4***

As suggested by Liotta and co-workers (13) the bromide ***6e*** (3.16 g; 13.01 mmol) and 18-crown-6 (0.586 g) were dissolved in CH_3CN (12 mL). After adding KCN (4.76 g; 73.5 mmol) the suspension was heated at 60°C for 1 h and the product extracted into ether and chromatographed (pet. ether/ether 6:1) giving *4-methoxy-3-isopropylphenylacetonitrile* ***4*** (2.83 g: 80%): ir: 2250 cm^{-1}; ^{1}Hmr δ: 1.22 (d, 6H, J = 7.0 Hz), 3.33 (q, 1H, J = 7.0 Hz), 3.67 (s, 2H, CH_2CN), 3.82 (s, 3H), 6.83 (J = 9.0 Hz), 7.10 (dd, J = 9.0 and 2.5 Hz), and 7.14 (d, J = 2.5 Hz); ^{13}Cmr δ: 137.6, 125.5, 130.3, 156.2, 110.5, 125.8, 22.8, 121.4, 26.7, 22.4, 22.4, and 55.3; mass *m/z*: 189(18), 174(100), 159(10), 147(12), 134(24), 131(12), 130(11), 117(38), 115(32), 104(28), 103(32), 91(52), and 77(63). Exact Mass calcd. for $C_{12}H_{15}NO$: 189.1154; found: 189.1185.

In the absence of the crown ether (KCN, DMSO, 85°C) the yield was only 67%.

Alkylation of nitrile ***4*** *with geranyl bromide* ***3***

Under argon, THF (40 mL) containing diisopropylamine (2.00 mL; 14.3 mmol) was cooled to −78°C and *n*-butyllithium (5.21 mL of 2.5 M in hexane; 13.0 mmol) was introduced dropwise. The mixture was allowed to warm to 0°C for 15 min and then recooled to −78°C before adding the nitrile ***4*** (2.487 g; 13.2 mmol) in THF (30 mL). After stirring for 5 min, geranyl bromide (2.65 mL; 13.4 mmol) was added and the temperature allowed to rise to ambient as stirring was continued for 3 h. The mixture was poured onto ice and extracted with ether. The liquid left after concentration was chromatographed (pet. ether) to afford the *2-geranyl-2-(3-isopropyl-4-methoxyphenyl)acetonitrile* ***5a*** (3.635 g; 85%) as a colorless oil: ir: 2240 cm^{-1}; ^{1}Hmr (400 MHz) δ: 1.21 (d, 6H, J = 6.9 Hz, iso-Pr methyls), 1.55 (s, 3H, Me_{trans}-C4), 1.61 (s, 3H, C10-Me), 1.69 (s, 3H, Me_{cis}-C4), 2.05 (m, 4H, H-C1 and C2), 2.57 (m, 2H, H-C6), 3.31 (t, 1H, J = 6.9 Hz, iso-Pr CH), 3.72 (t, 1H, J = 7.0 Hz, CH-CN), 3.83 (s, 3H, Me-O), 5.08 (t, 1H, J = 6.6 Hz, H-C3), 5.20 (t, 1H, J = 7.2 Hz, H-C5), 6.82 (d, 1H, J = 7.9 Hz, H-C11), 7.11 (d, 1H, J = 2.4 Hz, H-C14), and 7.13 (dd, 1H, J = 7.9 and 2.4 Hz, H-C9); ^{13}Cmr δ (carbons numbered as in the cyclized diterpene): 39.6, 26.5, 123.9, 131.5, 118.6, 34.4, 37.2, 127.9, 125.1, 139.8, 110.4, 156.4, 137.5, 125.4, 26.8, 22.5, 22.5, 17.6, 16.2, 25.6, and 55.4, and 121.2(CN); mass *m/z*: 325(M^+, 1.4), 190(12), 189(100), 156(23), 137(14), 91(5), 81(20), and 77(6). Exact Mass calcd. for $C_{22}H_{31}NO$: 325.2406; found: 325.2415.

Cyclization of diene ***5***a

Based on the Livinghouse conditions,[2] a solution of methyl benzenesulfenate (0.126 g; 0.875 mmol, prepared from diphenyldisulfide following the methods of Mueller and Butler (14) and Denny and co-workers (15), in $MeNO_2$ (11.9 mL) was cooled to −30°C under argon. Previously prepared $BF_3/MeNO_2$ (1.34 mL of 1.24 M) was added and after stirring 2.5 min the diene ***5a*** (0.207 g; 0.817 mmol) was added in $MeNO_2$ (2 mL) and stirring was continued for 2 h at −30°C. Saturated $NaHCO_3$ (20 mL) was introduced and once the mixture had warmed to room temperature, it was extracted with ether and washed with $NaHCO_3$, NaCl, water, and again with NaCl. The dried solution ($MgSO_4$) was concentrated and the residue chromatographed (pet.ether/ether 6:1) to give the cyclized product ***7a*** (0.224 g; 76%), mp 194–195°C, *7-cyano-3-phenylthio-12-methoxyabieta-8,11,13-triene*: ir: 2227 cm^{-1}; ^{1}Hmr (300 MHz) δ: 1.02 (s, 3H, Me_α-C4), 1.18 and 1.19 (2d, 6H, J = 6.9 Hz, iso-Pr methyls), 1.23 (s, 3H, Me_β-C4), 1.40 (s, 3H, Me-C10), 1.51 and 2.25 (2m, H-C1), 1.76 (dd, 1H, J = 11.9 and 1.2 Hz, H-C5), 2.04 (m, 2H, H-C6), 2.02 and 2.25 (2m, 2H, H-C2), 2.95 (dd, 1H, J = 9.1 and 7.7 Hz, H-C3), 3.21 (sept, 1H, J = 6.9 Hz, H-C15), 3.77 (s, 3H, Me-O), 4.06 (d, 1H, J = 5.2 Hz, H-C7), 6.65 (s, 1H, H-C11), 7.01 (s, 1H, H-C14), 7.25 (m, 3H, *meta* and *para* H of Ph-S), and 7.40 (m, 2H, *ortho* H of Ph-S); ^{13}Cmr (75 MHz) δ: 38.7, 23.9, 60.3, 38.1, 49.6, 24.5, 31.9, 122.4, 147.2, 37.9, 106.7, 156.8, 135.8, 126.7, 26.5, 22.5, 22.4, 29.5, 27.7, 17.9 and 55.3, 119.3(CN), 136.2, 131.4, 128.9, 126.5(*ipso*,*ortho*,*meta*, and *para* C of Ph-S); mass *m/z*: 433(M^+, 16), 309(12), 308(52), 255(37), 254(19), 241(19), 240(41), 229(35), 228(100), 227(31), 226(32), 185(25), 110(41), and 97(23). Exact Mass calcd. for $C_{28}H_{35}NOS$: 433.2269; found: 433.2354.

Preparation of model diene **5**b

Using exactly the same procedure as described for **5***a*, phenylacetonitrile (5.80 g) was alkylated with geranyl bromide (9.83 mL) to afford the diene **5***b*, *2-geranyl-2-phenylacetonitrile* (11.59 g; 92%); ir: 2242 cm^{-1}; ^{1}Hmr δ: 1.53 (s, 3H, Me_{trans}-C4), 1.61 (s, 3H, Me-C10), 1.70 (s, 3H, Me_{cis}-C4), 2.04 (m, 4H, H-C1 and C2), 2.61 (m, 2H, H-C6), 3.78 (t, 1H, J = 7.0 Hz, CH-CN), 5.09 (m, 1H, =C3-H), 5.20 (t, 1H, J = 7.3 Hz, =C5-H), and 7.35 (br s, 5H, arom. H); ^{13}Cmr δ: 39.6, 26.4, 123.8, 131.4, 118.2, 34.3, 37.7, 135.5, 127.2, 140.0, 128.7, 127.8, 127.2, 17.7, 16.1, 25.7, and 120.6(CN); mass *m/z*: 253(M^+, 8), 210(9), 138(9), 137(82), 124(14), 117(64), 116(100), 89(24), 81(42), and 77(10). Exact Mass calcd. for $C_{18}H_{23}N$: 253.1783; found: 253.1807.

Cyclization of **5**b *to* **7**b

As described for **9***a*, the diene **5***b* (5.06 g) reacted with Ph-SOMe to afford **7***b*, *9-cyano-2-phenylthio-1,1,4a-trimethyl-1,2,3,4,4a,9,10,10a-octahydrophenanthrene* (4.475 g; 62%) as a white foam: ir: 2239 cm^{-1}; ^{1}Hmr (300 MHz) (numbered as a desisopropyl abietatriene) δ: 1.02 (s, Me_α-C4), 1.25 (s, Me_β-C4), 1.32 (s, Me-C10), 1.45 and 2.40 (2m, 2H, H-C1), 1.74 (dd, J = 12.0 and 1.7 Hz, H-C5), 2.01 (m, 2H, H-C6), 2.01 and 2.40 (2m, 2H, H-C2), 2.85 (t, J = 8.2 Hz, CH-SPh), 4.09 (m, 1H, CH-CN), 7.20 (m, 6H), and 7.38 (m, 3H, arom H); ^{13}Cmr δ: 38.5, 23.7, 60.3, 37.7, 49.3, 27.6, 32.7, 127.4, 148.4, 37.6, 125.4, 128.8, 126.5, 128.3, 29.8, 24.9, 17.6 and 121.9(CN), 121.9, 136.2, 131.4, 128.8, 126.4(-S-Ph); mass *m/z*: 361(M^+, 27), 252(34), 237(16), 236(76), 183(24), 182(32), 169(22), 168(53), 167(20), 157(20), 156(100), 142(36), 141(30), 129(30), 110(60), and 109(49). Exact Mass calcd. for $C_{24}H_{27}NS$: 361.1786; found: 361.1825.

Oxidation of **7**a *to the C7 ketone* **8**a

This procedure is based on that of Selikson and Watt (16). Diisopropylamine (0.27 mL; 1.9 mmol) and THF (10 mL) were cooled to −78°C under argon and *n*-butyllithium (0.75 mL of 2.5 M in hexane; 1.9 mmol) was added. The solution was allowed to warm to 0°C and then cooled to −78°C again before adding the nitrile **7***a* (0.526 g; 1.21 mmol) in THF (20 mL). After stirring for 5 min, a gentle stream of purified oxygen was passed through the solution for 1 h. The mixture was then warmed to 0°C and a solution of 1 M $SnCl_2$/2 M HCl (4 mL) was added and after stirring for 30 min the product was obtained by ether extraction. The ether was well washed with 1 M NaOH and saturated NaCl and dried, and the solid left on concentration was chromatographed (pet.ether/ether 6:1) to give the ketone **8***a* (0.276 g; 55%), *7-oxo-3-phenylthio-12-methoxyabieta-8,11,13-triene*, mp 130–132°C: uv: 205(28 900), 227(21 300), and 277(15 200) nm, ir: 1671 cm^{-1}; ^{1}Hmr δ: 1.09 (s, Me_α-C4), 1.19 and 1.21 (2d, 6H, J = 7.0 Hz, iso-Pr Me), 1.28 (s, 6H, Me_β-C4 and Me-C10), 1.65 (m, 1H, H_α-C1), 1.99 (dd, J = 11.7 and 5.9 Hz, H-C5), 2.07 (m, 2H, H-C2), 2.33 (dt, J = 12.8 and 3.3 Hz, H_β-C1), 2.71 (d, 1H, J = 11.7 Hz, H_β-C6), 2.73 (d, 1H, J = 5.9 Hz, H_α-C6), 2.89 (m, 1H, H-C3), 3.24 (sept, 1H, J = 7.0 Hz, iso-Pr CH), 3.85 (s, 3H, Me-O), 6.68 (s, 1H, H-C11), 7.27 (m, 3H) and 7.42 (m, 2H, S-Ph protons), and 7.89 (s, 1H, H-C14); ^{13}Cmr δ: 38.2, 27.4, 60.5, 38.4, 51.0, 36.4, 197.5, 123.6, 155.2, 38.1, 104.3, 161.5, 135.3, 125.3, 26.7, 22.3, 22.4, 29.3, 23.1, 17.4, and 55.3, 136.2, 131.4, 128.8, 126.4 (S-Ph carbons); mass *m/z*: 422(M^+, 11), 313(17), 297(29), 271(17), 245(34), 243(26), 217(100), 215(29), 203(25), 110(44), and 109(38). Exact Mass calcd. for $C_{27}H_{34}O_2S$: 422.2287; found: 422.2283.

NOTE: Using the MoOPh reagent (17) afforded the same product but in only 48% yield.

Oxidation to the model C7 ketone 8b

As described above, the model **7***b* (1.092 g) was treated with oxygen under basic conditions to afford the ketone **8***b* (0.529 g; 50%), amorphous solid, *9-keto-3-phenylthio-1,1,4a-trimethyl-1,2,3,4,4a,9,10,10a-octahydrophenanthrene*; uv: 205(40 400) and 253(19 400) nm; ir: 1682 cm^{-1}; ^{1}Hmr δ: 1.10 (s, 3H), 1.29 (s, 3H), 1.57 (m, 1H), 1.98 (dd, 1H, J = 11.7 and 5.9 Hz), 2.06 (m, 2H), 2.36 (dt, 1H, J = 12.9 and 3.5 Hz), 2.76 (d, 1H, J = 11.7 Hz), 2.78 (d, 1H, J = 5.9 Hz), 2.92 (m, 1H), 7.32 (m, 8H) 8.01 (dd, J = 7.4 and 1.6 Hz, arom H adjacent to ketone); ^{13}Cmr δ: 38.2, 27.5, 60.5, 38.4, 50.7, 36.6, 198.6, 130.4, 155.0, 38.1, 123.6, 134.0, 126.5, 127.2, 29.3, 23.3, 17.4 and 136.2, 131.5, 128.8, 126.2; mass *m/z*: 350(M^+, 29), 241(45), 226(17), 225(100), 199(21), 185(11), 181(12), 173(47), 171(69), 157(44), 145(99), and 109(38). Exact Mass calcd. for $C_{23}H_{26}OS$: 350.1690; found: 350.1697.

Oxidation of the thio-ether **8**a *to the sulfoxide* **9**a

To the thio-ether **8***a* (0.466 g; 1.10 mmol) in CH_2Cl_2 (10 mL) at −78°C under argon, was added *m*-CPBA (0.640 g; 2.97 mmol) as a suspension in CH_2Cl_2 (5 mL). After stirring for 1 h, saturated $NaHSO_3$ (10 mL) was added and the temperature allowed to rise to ambient. Ether extraction, washing with saturated $NaHSO_3$, saturated $NaHCO_3$, and saturated NaCl, drying, and concentrating gave a solid that was chromatographed (ether) to afford the sulfoxide **9***a* (0.443 g; 92%), *7-keto-3-phenylsulfinyl-12-methoxyabieta-8,11,13-triene*, mp 187–189°C: ir: 1672 cm^{-1}; ^{1}Hmr δ: 1.13 (2d, 6H, J = 6.6 Hz, iso-Pr Me), 1.24 (s, 3H, Me_α-C4), 1.31 (s, 3H, Me_β-C4), 1.37 (s, 3H, Me-C10), 1.50 (m, 2H, H_α-C1 and H-C2), 1.85 (dd, 1H, J = 11.0 and 6.6 Hz, H-C5), 2.15 (m, 2H, H-C2 and H-C3), 2.39 (m, 1H, H_β-C1), 2.67 (d, 1H, J = 11.0 Hz, H_β-C6), 2.68 (d, 1H, J = 6.6 Hz, H_α-C6), 3.17 (sept, 1H, J = 6.6 Hz, iso-Pr CH), 3.78 (s, 3H, O-Me), 6.60 (s, 1H, H-C11), 7.49 (m, 5H, S(O)-Ph protons), and 7.82 (s, 1H, H-C14); ^{13}Cmr δ: 36.9, 30.3, 75.2, 38.1, 51.0, 35.5, 197.0, 123.5, 154.7, 37.4, 104.3, 161.5, 135.5, 125.4, 26.4, 22.3, 22.4, 22.8, 18.3, 13.6 and 55.3, 143.5, 123.9, 128.8, 130.1(S(O)-Ph carbons); mass *m/z*: facile elimination of Ph-S(O) resulted in no molecular ion, 314(16), 313(70), 312(18), 297(36), 271(24), 245(48), 243(25), 231(31), 230(50), 229(56), 217(100), 215(98), 173(26), 128(38), 126(70), 109(36), and 78(70).

Model sulfoxide **9**b

Similar oxidation of **8***b* (0.911 g) with *m*-CPBA afforded the sulfoxide **9***b* (0.812 g: 85%): ir: 1677 cm^{-1}; ^{1}Hmr δ: 1.26 (s, 3H), 1.34 (s, 3H), 1.39 (s, 3H), 1.53 (m, 2H), 1.90 (dd, 1H, J = 11.0 and 6.6 Hz), 2.17 (m, 2H), 2.44 (dd, 1H, J = 9.9 and 3.2 Hz), 2.74 (d, 1H, J = 11.0 Hz), 2.76 (d, 1H, J = 6.6 Hz), 7.2 to 7.3 (m, 2H), 7.4 to 7.56 (m, 6H), and 7.97 (dd, 1H, J = 7.7 and 1.5 Hz); ^{13}Cmr δ: 36.7, 30.2, 75.1, 37.9, 50.6, 35.7, 198.1, 130.2, 154.4, 37.4, 123.6, 134.0, 126.3, 127.2, 23.0, 18.3, 13.6 and 143.5, 123.9, 128.8, 130.1; mass *m/z*: no molecular ion, 242(18), 240(100), 225(27), 223(11), 199(15), 185(16), 173(38), 172(11), 171(57), 159(33), 158(41), 157(47), 145(88), 128(50), and 115(35). Exact Mass calcd. for $C_{25}H_{26}O_2S$: 366.1532; found: 366.1593.

Formation of the enol thioether **10**a

Using the Matsumoto method (18), the sulfoxide **9***a* (0.251 g; 0.574 mmol) in CH_2Cl_2 (10 mL) at 0°C under argon was treated with trifluoroacetic anhydride (0.81 mL; 5.7 mmol) and pyridine (1.16 mL). After stirring at room temperature for 5 h, water (25 mL) was added slowly and the product, extracted and washed (H_2O, saturated $NaHCO_3$, H_2O, dilute HCl, saturated NaCl), was chromatographed (pet.ether/ether 10:1) to afford the enol ether **10***a* (0.174 g; 72%), white solid mp 183–184°C, *7-keto-3-phenylthio-12-methoxyabieta-2,8,11,13-tetraene*: ^{1}Hmr δ: 1.19 (s, 3H, Me_β-C4), 1.20 and 1.22 (2d, 6H, J = 7.0 Hz, iso-Pr Me), 1.22 (s, 3H, Me_α-C4), 1.39 (s, 3H, Me-C10), 2.30 (t, 1H, J = 8.8 Hz, H-C5), 2.42 (dd, 1H, J = 17.2 and 1.8 Hz, H_α-C1), 2.69 (d, 2H, J = 8.4 Hz, H-C6), 2.79 (dd, 1H, J = 17.2 and 6.6 Hz, H_β-C1), 3.25 (sept, 1H, J = 6.96 Hz, iso-Pr CH), 3.87 (s, 3H, O-Me), 5.92 (dd, 1H, J = 6.6 and 1.8 Hz, H-C2), 6.71 (s, 1H, H-C11), 7.24 (m, 3H) and 7.42 (m, 2H, S-Ph protons), and 7.91 (s, 1H, H-C14); ^{13}Cmr δ: 40.8, 130.2, 141.6, 40.0, 48.1, 36.8, 197.1, 123.6, 153.4, 37.1, 105.5, 161.8, 135.8, 124.9, 26.6, 22.5, 22.4, 29.6, 23.0, 21.2 and 55.4, 136.9, 130.2, 128.8, 126.3(S-Ph carbons); mass *m/z*: 420(M^+, 40), 257(16), 230(23), 229(17), 228(13), 227(17), 217(35), 216(28), 215(100), 203(20), 190(74), 175(63), 115(55),

108(70), and 86(83). Exact Mass calcd. for $C_{27}H_{32}O_2S$: 420.2163; found: 420.2143.

Transformation of model sulfoxide **9**b *to thio-enol-ether* **10**b

In the same manner, the sulfoxide **9***b* (19 mg) reacted with TFAA and pyridine to give the enol ether **10***b* (15 mg: 83%): ir: 1685 cm^{-1}; ^{1}Hmr δ: 1.20, 1.23 and 1.39 (3s, each 3H), 2.32 (t, 1H, J = 8.4 Hz), 2.39 (dd, 1H, J = 17.6 and 1.8 Hz), 2.75 (d, 2H, J = 8.4 Hz), 2.81 (dd, 1H, J = 17.6 and 6.6 Hz), 5.92 (dd, 1H, J = 6.6 and 2.2 Hz), 7.1–7.6 (m, 5H), 7.55 (ddd, 1H, J = 7.7, 7.7, and 1.5 Hz), and 8.06 (dd, 1H, J = 7.7 and 1.5 Hz); ^{13}Cmr δ: 40.7, 130.4, 141.4, 40.0, 47.8, 37.0, 198.1, 130.3, 153.2, 38.7, 125.3, 134.3, 126.4, 126.8, 29.5, 23.2, 21.1 and 138.6, 130.2, 128.8, 126.4; mass m/z: 348(M^+, 57), 209(10), 191(16), 190(58), 189(19), 179(23), 175(60), 165(36), 158(52), 145(31), 141(31), 129(56), 115(100), 109(59), and 79(59). Exact Mass calcd. for $C_{23}H_{24}OS$: 348.1474; found: 348.1511.

Formation of the 3,7-diketone **11**a

Based on the method of Trost *et al.* (19), $TiCl_4$ (0.78 mL; 7.3 mmol) was added to a suspension of the enol ether **10***a* (0.749 g; 1.78 mmol) in glacial HOAc (10 mL). The orange mixture was stirred for 20 min, then diluted with water (2.40 mL) and refluxed for 1 h. After cooling, the product was obtained by dilution with more water, extraction, washing, and chromatography (pet. ether/ether 1:1), white solid, mp 150–151°C, *3,7-diketo-12-methoxyabieta-8,11,13-triene* **11***a*: uv: 207(15 800), 230(16 200), and 280(13 200) nm; ir: 1710 and 1671 cm^{-1}; ^{1}Hmr δ: 1.12 (s, 3H, Me_α-C4), 1.18 (s and 2d, 9H, J = 7.0 Hz, Me_β-C4 and iso-Pr Me), 1.44 (s, 3H, Me-C10), 2.02 (dt, 1H, J = 13.2 and 5.1 Hz, H_β-C1), 2.30 (dd, 1H, J = 13.6 and 4.0 Hz, H-C5), 2.58 (dd, 1H, J = 17.6 and 4.0 Hz, H_β, H_β-C6), 2.75 (dd, 1H, J = 17.6 and 13.6 Hz, H_α-C6), 2.53 (ddd, 1H, J = 17.9, 5.1, and 2.9 Hz, H_β-C2), 2.81 (m, 1H, H_α-C2), 2.88 (m, 1H, H_α-C1), 3.23 (sept, 1H, J = 7.0 Hz, iso-Pr CH), 3.88 (s, 3H, O-Me), 6.69 (s, 1H, H-C11), and 7.89 (s, 1H, H-C14); ^{13}Cmr δ: 36.9, 34.5, 214.1, 47.3, 49.6, 36.1, 196.7, 123.6, 153.5, 37.8, 104.7, 161.7, 136.0, 125.6, 26.6, 22.5, 22.4, 25.0, 22.6, 21.5, and 55.5; mass m/z: 328(M^+, 69), 313(100), 271(13), 257(13), 243(28), 232(23) < 229(29), 217(21), 215(39), 201(20), 175(20), and 125(52, typical of C3 ketones with 4,4-dimethyl grouping). Exact Mass calcd. for $C_{21}H_{28}O_3$: 328.2011; found: 328.2025.

Model diketone **11**b

Prepared from **10***b* (150 mg) by the procedure described above. After chromatography the *3,9-diketo-1,14a-trimethyl-1,2,3,4,4a,9,10,10a-octahydrophenanthrene* **11***b* (84 mg; 77%) was obtained as a white solid, mp 113–114°C; uv: 206(21 900), 250(10 900), and 291(1800) nm; ^{1}Hmr δ: 1.11 and 1.18 (2s, each 3H), 1.43 (δ, 3H, J = 1.1 Hz), 2.01 (ddt, 1H, J = 13.2, 5.5, and 1.1 Hz), 2.31 (dd, 1H, J = 13.6 and 4.4 Hz), 2.37 (m, 5H), 7.30 (m, 2H), 7.53 (ddd, 1H, J = 8.1, 7.7, and 1.4 Hz), and 8.00 (dd, 1H, J = 7.7 and 1.4 Hz); ^{13}Cmr δ: 36.9, 34.5, 214.0, 47.3, 49.6, 36.3, 197.7, 130.4, 153.3, 37.6, 124.0, 134.2, 126.7, 127.4, 25.0, 22.8, 21.4; mass m/z: 256(M^+, 100), 223(19), 213(21), 200(50), 199(86), 185(22), 171(52), 159(58), 145(40), 128(49), 125(58), 115(69), and 91(53). Exact Mass calcd. for $C_{17}H_{20}O$: 256.1458; found: 256.1461.

Demethylation to the (±) natural product **2**a

At 0°C under argon, BBr_3 (0.21 mL; 2.2 mmol) was introduced to a solution of diketone **13***a* (0.156 g; 0.476 mmol) in CH_2Cl_2 (2.0 mL). The temperature was allowed to rise to ambient and stirring was continued overnight. The mixture was diluted with water and extracted with ether, which was washed (water, aqueous sodium thiosulfate, saturated NaCl) and concentrated. Chromatography of the residue (pet. ether/ether 1:1) gave the phenol **2***a* (0.136 g; 91%), mp 190–191°C, unchanged by sublimation (lit. (8) mp 213–215°C), *3,7-diketo-12-hydroxyabieta-8,11,13-triene*: uv: 207(15 800), 233(14 300), and 290(12 200) nm; ir: 3500–3050(br OH), 1707, and 1684 cm^{-1}; ^{1}Hmr (400 MHz) δ: 1.14 (s, 3H, Me_α-C4), 1.21 (s, 3H, Me_β-C4), 1.25 (t, 6H, J = 7.0 Hz, isp-Pr Me), 1.43 (s, 3H, Me-C10), 1.97 (dt, 1H, J = 13.7 and 5.2 Hz, H_β-C1), 2.30 (dd, 1H, J = 13.8 and 3.7 Hz, H-C5), 2.51 (dd, 1H, J = 19.6 and 3.4 Hz, H_β-C2), 2.64 (dd, 1H, J = 17.7 and 3.7 Hz, H_β-C6), 2.78 (dd, 1H, J = 17.7 and 13.8 Hz, H_α-C6), 2.80 (m, 1H, H_α-C2), 2.88 (m, 1H, H_α-C1), 3.18 (sept, 1H, J = 7.0 Hz, iso-Pr CH), 6.52 (br s, 1H, OH – dis. D_2O), 6.71 (s, 1H-C11), and 7.93 (s, 1H-C14); ^{13}Cmr δ: 36.7, 34.6, 214.5, 47.4, 49.6, 36.2, 197.1, 124.0, 153.6, 37.4, 110.3, 158.7, 133.6, 126.8, 26.8, 22.4, 22.3, 25.0, 22.7, 21.6; mass m/z: 314(M^+, 41), 299(30), 258(13), 257(16), 243(12), 229(41), 218(52), 217(24), 216(18), 215(36), 203(21), 201(36), 187(24), and 125(100). Exact Mass calcd. for $C_{20}H_{26}O_3$: 314.1888; found 314.1885.

Direct comparison of the ^{1}Hmr spectrum with that of the natural product kindly provided by Dr. Yu-Shia Cheng (National Taiwan University, Republic of China) showed the two to be identical.

Synthesis of the trimethoxy diene **5**c

Grignard reaction on methyl 2,6-dimethoxybenzoate **12**a

Excess Grignard reagent was prepared from Mg (1.104 g) and CH_3I (4.1 mL) in ether (100 mL) and cooled to 0°C. The ester **12***a* (1.636 g) in ether (40 mL) was added dropwise and the mixture then refluxed for 10 min. After cooling, saturated NH_4Cl (150 mL) was added and the product obtained by ether extraction. Concentration and chromatography gave the *1,3-dimethoxy-(2-hydroxyisopropyl)benzene* **12***b* (1.531 g; 94%): ^{1}Hmr δ: 1.65 (s, 6H), 3.81 (s, 6H), 5.0 (br s, 1H, dis. D_2O), 6.59 (d, 2H, J = 8.1 Hz), and 7.14 (t, 1H, J = 8.1 Hz); ^{13}Cmr δ: 157.5, 124.0, 157.5, 105.8, 127.4, 105.8, 74.0, 30.9, and 56.0; mass m/z: 196(3), 181(100), 163(46), 151(39), 148(23), 135(48), 107(24), 105(33), 91(22), and 77(28).

Dehydration of the alcohol to **12**c

The alcohol **12***b* (12.29 g) was refluxed in glacial HOAc (75 mL) for 2 h. The cooled mixture was diluted with water (250 mL) and the ether extract was well washed with 10% NaOH, water, and saturated NaCl. The olefin (10.94 g; 98%) was obtained by evaporation of the dried solution followed by chromatography (pet.ether/ether 6:1), *1,3-dimethoxy-2-isopropenylbenzene* **12***c*: ^{1}Hmr δ: 2.08 (d, 3H, J = 1.5 Hz), 3.83 (s, 6H), 4.93 and 5.38 (2q, each 1H, J = 1.5 Hz), 6.61 (d, 2H, J = 8.4 Hz), and 7.22 (t, 1H, J = 8.4 Hz); ^{13}Cmr δ: 157.0, 115.5, 157.0, 103.9, 127.7, 103.9, 121.2, 138.9, 23.4, and 55.8; mass m/z: 178(100), 164(86), 163(86), 148(72), 147(75), 136(57), 135(68), 133(55), 131(48), and 120(35). Exact Mass calcd. for $C_{11}H_{14}O_2$: 178.0997; found: 178.0958.

Hydrogenation to 1,3-dimethoxy-2-isopropylbenzene **12**d

The alkene (1.056 g) was shaken in a Parr apparatus with 5% Pd/C (40 mg) in ether (40 mL) under hydrogen at 40 psi (1 psi = 6.89 kPa) for 19 h. The catalyst was filtered (Celite) and the ether evaporated to give the isopropyl derivative (1.036 g; 97%) pure enough for the next step: ^{1}Hmr δ: 1.40 (d, 6H, J = 7.0 Hz), 3.73 (sept, 1H, J = 7.0 Hz), 3.88 (s, 6H), 6.63 (d, 2H, J = 8.1 Hz), and 7.19 (t, 1H, J = 8.1 Hz); ^{13}Cmr δ: 158.5, 124.3, 158.5, 104.4, 126.4, 104.5, 24.1, 20.7, and 55.6; mass m/z: 180(23), 166(11), 165(100), 135(7), 105(13), and 91(9).

Hydroxylation to the compound **13**a

According to the Srebnik and Mechoulam procedure (20) the product **12***d* (1.527 g; 8.48 mmol) in CH_2Cl_2 (20 mL) was added to a stirred solution of *m*-CPBA (2.851 g; 13.22 mmol) in CH_2Cl_2 (50 mL) at 0°C under argon. After 5 h at room temperature more *m*-CPBA (0.805 g; 3.73 mmol) was added and stirring was continued for 2 h. The mixture was poured into aqueous $NaHSO_3$ (100 mL of 5%) and the product was extracted into ether and well washed ($NaHSO_3$, saturated $NaHCO_3$, and saturated NaCl). Concentration and chromatography (pet.ether/ether 6:1) gave first some unreacted **12***d* (0.370 g) and then the phenol **13***a* (0.812 g; 64% adjusted for the recuperated starting material), *1-3-dimethoxy-4-hydroxy-2-isopropylbenzene*: ^{1}Hmr δ: 1.35 (d, 6H, J = 7.0 Hz), 3.40 (sept, 1H, J = 7.0 Hz), 3.78 (s, 6H), 5.47 (br s, 1H, dis.

D_2O), 6.56 (d, 1H, J = 8.8 Hz), and 6.76 (d, 1H, J = 8.8 Hz); ^{13}Cmr δ: 145.1, 129.8, 152.7, 108.0, 112.1, 142.9, 25.9, 21.1, and 55.8, 61.8; mass *m/z*: 196(87), 181(100), 166(40), 133(15), 125(27), 123(12), 91(11), and 77(13). Exact Mass calcd. for $C_{11}H_{16}O_3$: 196.1099; found: 196.1101.

O-Methylation of the phenol ***13****a*

Methyl iodide (5.0 mL) was added to a solution of the phenol **13***a* (1.629 g) in acetone (150 mL) containing anhydrous K_2CO_3 (5.0 g) and the mixture was refluxed for 5 days after which it was cooled, filtered, and concentrated. The residue was lixiviated with warm ether and the latter well washed (water, saturated NaCl) and concentrated. Chromatography of the residue (pet.ether/ether 10:1) gave the *1,2,4-trimethoxy-3-isopropylbenzene* **13***b* (1.538 g; 88%): ^{1}Hmr δ: 1.34 (d, 6H, J = 7.0 Hz), 3.57 (sept, 1H, J = 7.0 Hz), 3.77 (s, 3H), 3.82 (s, 6H), 6.56 (d, 1H, J = 8.8 Hz), and 6.70 (d, 1H, J = 8.8 Hz); ^{13}Cmr δ: 147.7, 130.6, 152.7, 106.1, 109.4, 147.2, 25.2, 21.2, 21.2 and 55.8, 56.0, 60.9; mass *m/z*: 210(82), 195(100), 180(69), 165(25), 152(16), 137(28), 135(17), 105(12), 91(15), and 77(15). Exact Mass calcd. for $C_{12}H_{18}O_3$: 210.1256; found: 210.1268.

Bromination leading to ***13****c*

Using exactly the same conditions for the preparation of **6***b*, the trimethoxy compound **13***b* (5.321 g) gave *5-bromo-1,2,4-trimethoxy-3-isopropylbenzene* **13***c* (6.308 g; 88%): ^{1}Hmr δ: 1.32 (d, 6H, J = 7.3 Hz), 3.45 (sept, 1H, J = 7.3 Hz), 3.76, 3.80, and 3.82 (3s, 9H), and 6.92 (s, 1H); ^{13}Cmr δ: 148.9, 129.6, 149.9, 110.8, 114.1, 136.6, 26.8, 21.9, 21.9 and 56.0, 60.8, 61.5. Exact Mass calcd. for $C_{12}H_{17}O_3{}^{79}Br$: 288.0361; found: 288.0359.

Grignard reaction to give the benzaldehyde ***13****d*

As described for the reaction with **6***b*, the bromo compound **13***c* (6.308 g) was converted to the Grignard reagent and reacted with DMF to give the aldehyde **13***d* (4.626 g; 89%), *2,4,5-trimethoxy-3-isopropylbenzaldehyde*: ir: 1682 cm^{-1}; ^{1}Hmr δ: 1.33 (d, 6H, J = 7.0 Hz), 3.42 (sept, 1H, J = 7.0 Hz), 3.81, 3.84, and 3.90 (3s, 9H), 7.22 (s, 1H), and 10.25 (s, 1H, CHO); ^{13}Cmr δ: 155.1, 135.5, 156.8, 124.4, 107.7, 150.0, 189.1, 25.4, 21.6, 21.6 and 55.8, 60.8, 65.3; mass *m/z*: 238(M$^+$, 100), 223(97), 208(16), 205(26), 193(22), 180(24), 177(21), 166(27), 165(25), 147(20), 135(30), 91(36), and 77(35).

Reduction of the aldehyde ***13****d*

Sodium borohydride reduced the aldehyde **13***d* (1.864 g) as described earlier for **6***d*. The product (1.875; 100%) was isolated after 15 min and was pure enough to continue without further purification, *2,4,5-trimethoxy-3-isopropylbenzyl alcohol* **13***e*: ^{1}Hmr δ: 1.33 (d, 6H, J = 7.0 Hz), 2.15 (br s, 1H, dis. D_2O), 3.38 (sept, 1H, J = 7.0 Hz), 3.70, 3.82, and 3.83 (3s, 9H), 4.66 (s, 2H), and 6.78 (s, 1H); ^{13}Cmr δ: 149.4, 135.0, 149.5, 128.6, 110.1, 148.1, 61.3, 25.9, 21.9, 21.9 and 55.8, 60.7, 62.4; mass *m/z*: 240(M$^+$, 100), 225(18), 206(52), 195(17), 192(18), 177(17), 155(36), 140(38), 91(38), and 77(41).

NOTE: longer periods of stirring resulted in increasing quantities of the corresponding dibenzyl ether.

Bromination of the benzyl alcohol ***13****e*

When treated as described earlier, the alcohol **13***e* (67 mg) afforded the pure bromide **13***f* (83 mg; 96%), *2,4,5-trimethoxy-3-isopropylbenzyl bromide*: ^{1}Hmr δ: 1.33 (d, 6H, J = 7.0 Hz), 3.38 (sept, 1H, J = 7.0 Hz), 3.80, 3.83, and 3.85 (3s, 9H), 4.57 (s, 2H), and 6.77 (s, 1H); ^{13}Cmr δ: 149.7, 135.3, 150.0, 125.5, 111.8, 149.5, 29.4, 26.4, 21.8, 21.8 and 55.8, 60.7, 62.3; mass *m/z*: 304(4) and 302(4), 223(100), 208(72), 193(28), 178(19), 161(31), 91(28), and 77(20).

NOTE: treating the dibenzyl ether from the previous reaction with 48% HBr in benzene gave this same bromide (88%).

Transformation of the bromide ***13****f to the nitrile* ***15****a*

In the presence of 18-crown-6, KCN replaced the bromine in **13***f* (2.82 g) to give after chromotography (pet.ether/ether 4:1) the *2,4,5-trimethoxy-3-isopropylphenylacetonitrile* **15***a* (2.098 g: 91%) as described for the substitution of **6***e*: ir: 2250 cm^{-1}; ^{1}Hmr δ: 1.32 (d, 6H, J = 7.0 Hz), 3.35 (sept, 1H, J = 7.0 Hz), 3.69 (s, 2H, CH_2CN), 3.67, 3.82, and 3.83 (3s, 9H), and 6.77 (s, 1H); ^{13}Cmr δ: 149.0, 135.3, 149.7, 117.9, 110.2, 148.7, 18.4, 26.0, 21.7, 21.7 and 55.8, 60.6, 61.9, 118.2(CN); mass *m/z*: 249(M$^+$, 100), 234(63), 207(57), 194(16), 177(10), 166(15), 164(11), 151(12), 149(10), 91(13), and 77(13). Exact Mass calcd. for $C_{14}H_{19}NO_3$: 249.1365; found: 249.1362.

Alkylation with geranyl bromide to give ***5****c*

In exactly the same manner as described for **5***a*, the nitrile **15***a* (1.242 g) was alkylated with geranyl bromide to afford the diene **5***c* (1.857 g; 97%) after chromatography (pet.ether/ether 6:1). *2-Geranyl-2-(2,4,5-trimethoxy-3-isopropylphenyl)acetonitrile*: ir: 2239 cm^{-1}; ^{1}Hmr δ: 1.32 and 1.35 (2d, 6H, J = 7.3 Hz, iso-Pr Me), 1.56 (d, 3H, J = 1.5 Hz, Me_{trans}-C4), 1.59 (s, 3H, Me-C10), 1.67 (s, 3H, Me_{cis}-C4), 2.02 (m, 2H, H-C1 and H-C2), 2.55 (t, 2H, J = 7.3 Hz, H-C6), 3.34 (sept, 1H, J = 7.3 Hz, iso-Pr CH), 3.69, 3.84, and 3.85 (3s, 9H, Me-O), 4.07 (t, 1H, J = 7.3 Hz, H-C7), 5.08 (m, 1H, H-C3), 5.24 (t, 1H, J = 7.3 Hz, H-C5), and 6.79 (s, 1H, H-C9); ^{13}Cmr δ: 39.7, 23.6, 123.8, 131.5, 118.7, 33.4, 31.9, 123.5, 109.3, 139.9, 148.2, 148.9, 135.2, 149.8, 26.6, 21.8, 17.7, 25.7, 16.2 and 55.0, 60.7, 62.6, 121.4; mass *m/z*: 385(M$^+$, 65), 251(11), 250(87), 249(100), 248(100), 235(17), 234(99), 233(30), 221(62), 218(48), 205(27), 191(29), 190(37), 186(48), and 179(54). Exact Mass calcd. for $C_{24}H_{35}NO_3$: 385.2612; found: 385.2597.

When subjected to the cyclization conditions described above for diene **5***a* (with Ph-S-OMe or with Ph-S-O-CH_2-CH_2-O-Me), the diene **5***c* gave a variety to products, none of which showed the properties expected for the tricyclic compound.

Preparation of the dimethoxy diene ***5****d*

Bromination of dimethoxyisopropylbenzene ***12****d*

The dimethoxy compound **12***d* (0.322 g) was brominated following the procedure described for **6***a* affording after chromatography (pet.ether) *1,3-dimethoxy-4-bromo-isopropylbenzene* **14***a*: ^{1}Hmr δ: 1.32 (d, 6H, J = 7.0 Hz), 3.50 (qt, 1H, J = 7.0 Hz), 3.78 (s, 6H), 6.54 (d, 1H, J = 8.8 Hz), and 7.30 (d, 1H, J = 8.8 Hz); ^{13}Cmr δ: 158.9, 131.5, 154.9, 108.5, 130.1, 108.7, 26.2, 20.9, 20.9 and 55.5, 61.4; mass *m/z*: 260(44) and 258(46), 245(97) and 243(100), 230(17) and 228(31), 164(11), 149(28), 134(50), 110(27), and 77(18).

Grignard reaction to give the aldehyde ***14****b*

Using the same conditions as for **6***c*, the Grignard reagent prepared from **14***a* (0.250 g) reacted with DMF to give the aldehyde **14***b* (0.170 g; 85%) after chromatography (pet.ether/ether 10:1), *2,4-dimethoxy-3-isopropylphenylacetaldehyde*: ir: 1685 cm^{-1}; ^{1}Hmr δ: 1.30 (d, 6H, J = 7.0 Hz), 3.49 (sept, 1H, J = 7.0 Hz), 3.82 and 3.85 (2s, 6H), 6.72 (d, 1H, J = 8.4 Hz), 7.70 (d, 1H, J = 8.4 Hz), and 10.17 (s, 1H); ^{13}Cmr δ: 164.6, 129.4, 161.8, 122.8, 128.3, 107.5, 189.0, 24.7, 20.7, 20.7 and 55.5, 64.5; mass *m/z*: 208(29), 194(13), 193(97), 163(15), 135(11), and 91(15).

Reduction of aldehyde ***14****b*

As detailed earlier, the aldehyde **14***b* (1.212 g) was reduced with $NaBH_4$ to the alcohol **14***c* (1.222 g; quant), *2,4-dimethoxy-3-isopropylbenzyl alcohol*: ^{1}Hmr δ: 1.33 (d, 6H, J = 7.0 Hz), 2.31 (br s, 1H, dis. D_2O), 3.45 (sept, 1H, J = 7.0 Hz), 3.76 and 3.80 (2s, 6H), 4.63 (s, 2H), 6.64 (d, 1H, J = 8.4 Hz), and 7.12 (d, 1H, J = 8.4 Hz); ^{13}Cmr δ: 159.5, 129.5, 156.4, 126.3, 126.3, 107.3, 61.5, 25.4, 20.9, 20.9 and 55.3, 62.2; mass *m/z*: 210(96), 195(98), 177(99), 165(100), 149(67), 119(64), 105(55), 91(49), and 77(40).

Preparation of the benzyl bromide ***14****d*

Treatment of the alcohol **14***c* (1.170 g) with PBr_3, as described earlier, gave the bromo derivative **14***d* (1.330 g; 87%), *2,4-dimethoxy-3-isopropylbenzyl bromide*, mp 49–50°C: ^{1}Hmr δ: 1.33 (d, 6H, J = 7.3 Hz), 3.46 (sept, 1H, J = 7.3 Hz), 3.81 and 3.86 (2s, 6H), 4.60 (s, 2H), 6.55 (d, 1H, J = 8.8 Hz), and 7.21 (d, 1H, J = 8.8 Hz); ^{13}Cmr δ: 160.3, 129.1, 156.5, 128.2, 128.2, 107.7,

29.9, 25.7, 20.9, 20.9 and 55.3, 62.3; mass *m/z*: 274(3) and 272(3), 193(100), 165(30), 153(24), 135(29), 91(25), and 77(14).

Formation of the nitrile ***15***b

Potassium cyanide in the presence of 18-crown-6 converted the bromide **14***d* (1.169 g) to the nitrile **15***b* (0.724 g; 77%) after chromatography (pet.ether/ether 4:1), *2,4-dimethoxyisopropylphenylacetonitrile*: ir: 2251 cm^{-1}; ^{1}Hmr δ: 1.33 (d, 6H, *J* = 7.0 Hz), 3.41 (sept, 1H, *J* = 7.0 Hz), 3.67 (s, 2H), 3.74 and 3.80 (2s, 6H), 6.66 (d, 1H, *J* = 8.4 Hz), and 7.14 (d, 1H, *J* = 8.4 Hz); ^{13}Cmr δ: 159.8, 129.9, 155.8, 115.7, 126.9, 107.7, 18.4, 25.7, 20.7, 20.8 and 55.4, 61.9; mass *m/z*: 219(24), 204(54), 175(100), 147(14), 134(14), 119(14), 117(17), 115(17), 91(21), and 77(14). Exact Mass calcd. for $C_{13}H_{17}NO_2$: 219.1259; found: 219.1260.

Alkylation with geranyl bromide

Catalysed by LDA prepared *in situ* as described previously (see **5***a*), the nitrile **15***b* (0.429 g) was alkylated with geranyl bromide to give, after chromatography (pet. ether/ether 10:1) the diene **5***d* (0.666 g; 96%), *2-geranyl-2-(2,4-dimethoxy-3-isopropylphenyl)-acetonitrile*: ^{1}Hmr δ: 1.31 and 1.34 (2d, 6H, *J* = 7.0 Hz, iso-Pr Me), 1.57 (s, 3H, Me_{trans}-C4), 1.60 (s, 3H, Me-C10), 1.68 (s, 3H, Me_{cis}-C4), 2.03 (m, 4H, H-C1 and C2), 2.54 (dd, 2H, *J* = 8.1 and 7.3 Hz, H-C6), 3.40 (sept, 1H, *J* = 7.0 Hz, iso-Pr CH), 3.74 and 3.80 (2s, 6H, Me-O), 4.02 (t, 1H, *J* = 8.1 Hz, H-C7), 5.08 (m, 1H, H-C3), 5.23 (t, 1H, *J* = 7.3 Hz, H-C5), 6.67 (d, 1H, *J* = 8.4 Hz), and 7.22 (d, 1H, *J* = 8.4 Hz); ^{13}Cmr δ: 39.7, 25.9, 129.3, 131.4, 118.9, 33.4, 31.8, 121.3, 126.0, 139.6, 1071.7, 159.6, 129.6, 155.3, 26.6, 20.8, 20.8, 17.7, 16.2, 25.7 and 55.3, 62.5, 121.5(CN); mass *m/z*: 355(M^+, 1), 220(14), 219(99), 218(37), 204(20), 191(13), 188(24), 137(12), and 91(10).

Cyclization of diene ***5***d

The diene **5***d* (1.006 g) was cyclized in the manner described previously (see **7***a*). Chromatography (pet.ether/ether 6:1) afforded many unidentifiable fractions and the product **7***d* (0.543 g; 41%), *7-cyano-3-phenylthio-12,14-dimethoxyabieta-8,11,13-triene*, mp 213–215°C (dec.): ir: 2250 cm^{-1}; ^{1}Hmr δ: 1.01 (s, 3H, Me_α-C4), 1.21 (s, 3H, Me_β-C4), 1.29 and 1.31 (2d, 6H, *J* = 7.0 Hz, iso-Pr Me), 1.40 (s, 3H, H-C10), 1.56 (m, 1H, H_α-C1), 1.74 (d, 1H, *J* = 11.7 Hz, H-C5), 2.00 (dd, 1H, *J* = 11.7 Hz, H_α-C6), 2.03 (m, 1H, H_β-C6), 2.22 (dd, 1H, *J* = 7.3 and 1.1 Hz, H_β-C1), 2.03 and 2.22 (2m, 2H, H-C2), 2.95 (m, 1H, H-C3), 3.33 (sept, 1H, *J* = 7.0 Hz, iso-Pr CH), 3.75 and 3.84 (2s, 6H, Me-O), 4.15 (dd, 1H, *J* = 5.9 and 1.8 Hz, H-C7), 6.49 (s, 1H, H-C11), 7.23 (m, 3H), and 7.45 (ddd, 2H, Ph-S arom H); ^{13}Cmr δ: 38.9, 24.1, 60.4, 38.3, 49.7, 24.8, 31.8, 114.5, 148.0, 38.2, 104.0, 159.9, 126.7, 156.0, 25.9, 20.9, 20.8, 29.6, 27.9, 18.2 and 55.2, 62.2, 122.6, 136.3, 131.4, 128.9, 126.5; mass *m/z*: 463(M^+, 11), 258(12), 224(11), 135(18), 123(16), 110(100), 109(76), 97(11), and 77(10). Exact Mass calcd. for $C_{29}H_{37}NO_2S$: 463.2545; found: 463.2545.

Oxidation to the ketone ***8***d

Oxygen bubbled into the basic solution of **7***d* (0.270 g) as described for the preparation of **8***a*, gave the ketone **8***d* (0.154 g; 58%) after chromatography (pet.ether/ether 4:1), *7-keto-3-phenylthio-12,14-dimethoxyabieta-8,11,13-triene*, mp 140–142°C; ^{1}Hmr δ: 1.08 (s, 3H, Me_α-C4), 1.24 and 1.25 (2d, 6H, *J* = 7.0 Hz, iso-Pr Me), 1.26 (s, 3H, Me_β-C4), 1.30 (s, 3H, Me-C10), 1.61 (m, 1H, H_β-C1), 1.91 (dd, 1H, *J* = 11.0 and 7.0 Hz, H-C5), 2.03 (t, 1H, *J* = 3.3 Hz, H_β-C2), 2.03 (dd, 1H, *J* = 12.8 and 4.8 Hz, H_α-C2), 2.26 (dt, 1H, *J* = 12.8 and 3.3 Hz, H_β-C1), 2.69 (d, 1H, *J* = 11.0 Hz, H_β-C6), 2.71 (d, 1H, *J* = 7.0 Hz, H_α-C6), 2.91 (m, 1H, H-C3), 3.54 (sept, 1H, *J* = 7.0 Hz, iso-Pr CH), 3.74 and 3.82 (2s, 6H, Me-O), 6.52 (s, 1H, H-C11), 7.25 (m, 3H), and 7.40 (dt, 2H, Ph-S arom H); ^{13}Cmr δ: 38.8, 23.1, 60.7, 49.7, 27.6, 196.4, 114.6, 147.1, 38.3, 101.6, 160.0, 129.0, 156.6, 24.5, 21.0, 38.1, 29.3, 17.4 and 55.2, 62.3, 136.4, 131.4, 128.8, 126.5; mass *m/z*: 452(M^+, 51), 438(30), 437(100), 343(21), 327(18), 275(25), 247(33), and 207(20). Exact Mass calcd. for $C_{28}H_{36}O_3S$: 452.2385; found: 452.2312.

Oxidation to the sulfoxide ***9***d

In the same manner as the preparation of **9***a*, the previous product **8***d* (0.069 g) was oxidized to the sulfoxide **9***d* (0.065 g; 91%) after chromatography (pet.ether/ether 1:3), *7-keto-3-phenylsulfinyl-12,14-dimethoxyabieta-8,11,13-triene*, mp 179–180°C: ^{1}Hmr δ: 1.22 (s, 3H) and 1.34 (s, 3H, Me-C4), 1.22 and 1.26 (2d, 6H, *J* = 7.0 Hz, iso-Pr Me), 1.38 (s, 3H, Me-C10), ca 1.5 (br m, 2H, H_α-C1 and H-C2), 1.84 (dd, 1H, *J* = 10.6 and 7.7 Hz, H-C5), 2.15 (m, 2H, H_β-C1 and H-C3), 2.70 (m, 2H, H-C6), 3.48 (sept, 1H, *J* = 7.0 Hz, iso-Pr CH), 3.73 and 3.78 (2s, 6H, Me-O), 6.47 (s, 1H, H-C11), and 7.51 (m, 5H, Ph-SO arom H); ^{13}Cmr δ: 37.5, 30.2, 75.5, 38.5, 49.7, 37.2, 195.9, 118.2, 156.0, 37.5, 101.6, 163.1, 128.5, 159.8, 24.5, 21.0, 20.8, 18.3, 13.9 and 55.2, 62.4, 143.8, 123.9, 128.9, 130.1; mass *m/z*: no molecular ion, 343(M − 125, 37), 342(22), 327(100), 275(11), 247(16), 203(10), 126(38), and 78(37).

Formation of the enol thioether enol trifluoroacetate ***17***

Employing the procedure described above (see preparation of **10***a*), the sulfoxide **9***d* (47 mg) was treated with TFAA and the product chromatographed (pet.ether/ether 10:1) to afford **17** (45 mg; 82%): ^{1}Hmr δ: 1.10 (s, 3H) and 1.25 (s, 3H, Me-C4), 1.30 and 1.31 (2d, 6H, *J* = 7.0 Hz, iso-Pr Me), 1.34 (s, 3H, Me-C10), 2.58 and 2.59 (2d, 2H, *J* = 3.3 Hz, H_α-C1 and H-C5), 2.63 (d, 1H, *J* = 5.9 Hz, H_β-C1), 3.45 (sept, 1H, *J* = 7.0 Hz, iso-Pr CH), 3.77 and 3.81 (2s, 6H, Me-O), 5.87 (dd, 1H, *J* = 5.5 and 2.9 Hz, H-C7), 6.49 (s, 1H, H-C11), 6.81 (d, 1H, *J* = 2.9 Hz, H-C6), and ca. 7.35 (br m, 5H, Ph-S arom H); ^{13}Cmr δ: 39.3, 129.5, 141.2, 36.8, 50.0, 144.6, 117.9, 113.9, 144.7, 39.8, 102.9, 160.8, 127.9, 158.0, 25.3, 20.9, 20.8, 30.0, 22.9, 22.0 and 55.3, 63.3, 154.5 and 110.4 (O-CO-CF_3, respectively), 136.3, 130.5, 129.0, 126.6; mass *m/z*: no molecular ion, 461(M − 85, 24), 460(33), 459(100), 350(55), 334(18), 308(60), 283(37), 282(72), 269(57), and 190(94).

Hydrolysis to the diketone ***11***d

The ether **17** (75 mg) was dissolved in HOAc and treated with $TiCl_4$ as described above. After chromatography (pet.ether/ether 1:1) the diketone **11***d* (44 mg: 93%) was obtained as a white solid, mp 150–152°C: ir: 1701 (br) cm^{-1}; ^{1}Hmr δ: 1.13 and 1.19 (2s, 6H, Me-C4), 1.26 (d, 6H, *J* = 7.0 Hz, iso-Pr Me), 1.42 (s, 3H, Me-C10), 2.03 (m, 1H, H_α-C1), 2.24 (dd, 1H, *J* = 13.6 and 4.0 Hz, H-C5), 2.53 (ddd, 1H, *J* = 9.5 and 3.3 Hz, H_β-C2), 2.59 (dd, 1H, *J* = 17.9 and 4.0 Hz, H_β-C6), 2.83 (t, 1H, *J* = 9.5 Hz, H_α-C2), 2.85 (dd, 1H, *J* = 17.9 and 13.6 Hz, H_α-C6), 2.88 (m, 1H, H_α-C1), 3.54 (sept, 1H, *J* = 7.0 Hz, iso-Pr CH), 3.86 (s, 3H, Me-O), 6.31 (s, 1H, H-C11), and 13.26 (s, 1H, OH – dis. D_2O); ^{13}Cmr δ: 36.8, 34.5, 213.9, 47.2, 49.1, 36.0, 202.3, 109.8, 143.4, 37.8, 98.1, 162.9, 120.8, 154.0, 23.5, 20.2, 20.2, 24.9, 22.6, 21.7 and 55.5; mass *m/z*: 344(M^+, 26), 330(26), 329(100), 283(13) and 282(33). Exact Mass calcd. for $C_{21}H_{28}O_4$: 344.1988; found: 344.1988.

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

JAMES P. KUTNEY, GARY M. HEWITT, GIN LEE, KRYSTYNA PIOTROWSKA, MALCOLM ROBERTS, and STEVEN J. RETTIG. Can. J. Chem. **70**, 1455 (1992).

A detailed study of metabolites produced by the plant cell culture line of *Tripterygium wilfordii*, a Chinese herbal plant, is presented. Eighteen compounds within the diterpene and triterpene families have been isolated and fully characterized. Of these, five are novel compounds, and their structures were determined by a combination of spectral analysis, chemical correlation and single crystal X-ray diffraction. The interest of these compounds in the treatment of rheumatoid arthritis, skin allergies, and for male contraception is noted.

JAMES P. KUTNEY, GARY M. HEWITT, GIN LEE, KRYSTYNA PIOTROWSKA, MALCOLM ROBERTS et STEVEN J. RETTIG. Can. J. Chem. **70**, 1455 (1992),

On rapporte une étude détaillée des métabolites produits par une lignée de culture cellulaire du *Tripterygium wilfordii*, un plante galénique chinoise. On a isolé et caractérisé 18 composés des familles des di- et des triterpènes. Cinq de ces produits sont de nouveaux composés; on a déterminé leur structure par une combinaison d'analyses spectrales, de corrélations chimiques et de diffraction des rayons X par des cristaux uniques. On a noté l'intérêt de ces composés pour le traitement de l'arthrite rhumatismale, d'allergies de la peau et comme contraceptifs pour les males.

[Traduit par la rédaction]

Tripterygium wilfordii Hook f is a perennial twining vine of the family *Celastraceae*, which is cultivated in many parts of southern China such as Zhejiang, Anhui, Jiangxi, Fujian, and Guangdong provinces and also in Taiwan. The herb is commonly known in China as Lei Gong Teng (Thunder God vine) or Mang Cao (rank grass). Its use in Chinese traditional medicine dates back many centuries, and it is first mentioned in the Saint Peasant's Scripture of Materia Medica (1), written about two thousand years ago, as being used for the treatment of fever, chills, oedema, and carbuncle. Chinese gardeners used the powdered root to protect their crops from chewing insects. Most recently, crude extracts and refined extracts (a so-called multi-glycoside extract, or GTW) have been used increasingly to treat such disorders as rheumatoid arthritis, ankylosing spondilitis, and a variety of dermatological disorders (2–4).

In 1972, Morris Kupchan *et al.* first isolated the novel diterpenoid triepoxides, tripdiolide (**1**), triptolide (**2**), and triptonide (**2***a*) from the roots of *Tripterygium wilfordii* (5) and showed that **1** and **2** have significant antileukaemic activity. The biological properties of **1** and **2** stimulated studies in our laboratory directed at developing a plant cell culture line that would hopefully produce these compounds in higher yield and under laboratory controlled conditions. The earlier studies, with these objectives in mind, have been published (6, 7) and the stable cell line, coded as TRP4a, was shown to produce **1** in yields 40 times that of the living plant. As these studies were underway, we became aware of more recent research data from various laboratories in the People's Republic of China that revealed an increasing interest in the clinical use of extracts from *T. wilfordii* plants. Various disorders (rheumatoid arthritis, skin disorders) have been treated with hot water or alcohol extracts of the dried root xylem (8). Toxic side effects are minimal (9–12).

Observed effects of these extracts on the reproductive system have stimulated a great deal of research, particularly relating to the male reproductive system, and their possible use as a birth control agent. Studies in animals (13–15) and in humans (16–18) have provided considerable encouragement for the development of a novel non-steroidal male contraceptive agent.

In view of the increased current interest, the present investigation is aimed at a more comprehensive investigation of the metabolites present in the tissue culture cell line TRP4a than that published earlier (6, 7).

To isolate sufficient quantities of extracts (and later, metabolites) from the tissue culture cells (TRP4a cell line) for biological screening, it was necessary to produce large-scale quantities of the suspension culture. Batch fermentations were carried out on 10–17 L scale in glass or in steel air-lift fermentors. Suspension cultures were grown according to the procedure described earlier (6, 7). The cells were separated from the spent medium (that is, the supernatant liquid obtained after cells were removed by filtration).

A general extraction procedure was developed in which the cells and the spent medium were extracted separately (Figs. 1 and 2).

Samples of the extracts from an initial 15-L bioreactor experiment (TRP#221, Tables 1 and 2) were submitted for preliminary screening of biological activity to laboratories in Shanghai and Nanjing, People's Republic of China (see Acknowledgement). Assays for immunosuppressive activity and antifertility activity were carried out.

The results of the preliminary screening of the crude extracts showed that the ethyl acetate extracts had both immunosuppressive activities and antifertility activity while the methanol extracts were inactive in both cases.

Three further batches of the TRP4a cell suspension cultures were grown and harvested in the same way (Table 1). Extraction of the cells and the spent medium was carried out as above to give ethyl acetate and methanol extracts (Table 2). These data illustrate the relative weights of the extracts (EtOAc and MeOH) obtained to illustrate the production capabilities of the stable TRP4a cell line.

The ethyl acetate extracts from batches TRP#222, TRP#224, and TRP#225 were combined to give 3.73 g of cell extract and 1.71 g of spent medium extract. The methanol extracts were not further investigated since no biological activity of interest was detected. The ethyl acetate extracts were subjected to partial separation in order to give crude fractions for further preliminary biological screening.

Partial separation of the cell extract was carried out by vacuum liquid chromatography (vlc) as described by Pelletier *et al.* (19) and Coll and Bowden (20) (see Experimental) to afford eight crude fractions containing complex mixtures of metabolites. Fractions 2–7 were yellow to orange-brown solids containing sterols, diterpenes, and triterpenes (0.39, 0.27, 0.27, 0.51, 0.29, and 0.18 g respectively). Fraction 8 was a dark brown solid (1.22 g) containing the polar material.

Biological screening of the fractions showed that fractions 6 and 7 were active in antifertility and in inhibition of lymphocyte proliferation (immunosuppressive activity). Further studies, as noted below, revealed that fractions 6 and 7 contained triterpenes as the major constituents.

Partial separation of the spent medium extract was similarly conducted by means of vlc to afford ten fractions containing complex mixtures of compounds. Fractions 1–5 consisted of complex mixtures of diterpenes, sterols, etc. (4, 24, 14, 61, and 129 mg respectively), and were all yellow-brown solids. Fraction 6 (ethyl acetate elution) consisted of triptolide (**2**) and a number of triterpenes as the major constituents (206 mg). Fraction 7 (ethyl acetate elution) consisted of tripdiolide (**1**) and triterpenes as the major con-

stituents (205 mg). Elution with ethyl acetate – methanol (1:1) provided fractions 8, 9, and 10 (brown solids, 52, 304, and 77 mg respectively). Fraction 8 contained triterpenes as minor components and other polar material, while fractions 9 and 10 contained only polar material.

Biological screening of the spent medium fractions showed that fractions 6 and 7 possessed the highest antifertility activity while fraction 8 showed moderate activity. Fractions 6 and 7 also demonstrated inhibitory activity against lymphocyte proliferation.

In summary, the screening data on the above crude fractions suggested that interesting biological activity resides in both the "diterpene" and "triterpene" fractions, thus demanding a further study to complete structural elucidation of the "active" compounds. For this purpose, additional fermentations (total, 78 L of broth) were carried out to obtain sufficient quantities of cell and broth-derived extracts for proper chromatographic separation and purification. Figures 3 and 4 illustrate the overall separation and purification of the various metabolites isolated from the cells (Fig. 3) and broth (Fig. 4) of the fermentation experiments. Table 3 summarizes the yields of the various metabolites (structures **1–6**; **12–25**) isolated from the 78-L fermentation experiment. A total of 18 compounds (5 new and 13 known) were isolated and characterized. Tripdiolide (**1**), triptolide (**2**), oleanolic acid (**23**), β-sitosterol (**24**), pulpunonic acid (**25**), the diterpene **20**, dehydroabietic acid (**21**), and celastrol (**22**) were isolated in our previous study (6, 7) so it is now appropriate to discuss the additional and novel compounds obtained in the present study.

The triterpene **3** was isolated as optically active ($[\alpha]^{22}$ +92.9) colourless prisms (mp 268–270°C) with a molecular formula of $C_{30}H_{46}O_4$ (high-resolution mass spectrometry) and with characteristic ir adsorption bands for hydroxyl and carboxylic acid functions. Strong evidence for an oleanene-type triterpene skeleton is given in the fragmentation pattern of the mass spectrum of **3**. A retro Diels–Alder (RDA) fragmentation is characteristic of the oleanene skeleton where the DE ring fragment maintains the positive charge. The AB ring fragment also maintains the positive charge, but to a much lesser extent (21, 22). This fragmentation places the double bond at C12.

Nuclear magnetic resonance spectra (^{1}Hmr and ^{13}Cmr) revealed characteristic signals for an oleanene-type system (see Experimental) and final confirmation of structure was established through chemical correlation with triterpene **6** (Fig. 6), the latter having been subjected to X-ray analysis (see later).

The triterpene **4**, isomeric with **3**, was isolated as optically active ($[\alpha]^{22}$ +84.4) colourless prisms (mp 289–290°C). Its spectroscopic data revealed a close relationship to **3** and its structure was also correlated with that of **6** (Fig. 6).

The dihydroxy triterpene **5** was isolated as optically active ($[\alpha]^{22}$ +55.0) colourless prisms (mp 281–283°C) with a molecular formula of $C_{30}H_{48}O_4$. Again, nmr data (^1H and ^{13}C) supported the structure indicated but final confirmation was established via chemical correlation with **3** and **6** (Fig. 6).

The dihydroxy triterpene **6** was isolated as optically active ($[\alpha]^{22}$ +93.5) colourless prisms (mp 293–298°C) with a molecular formula of $C_{30}H_{48}O_4$. Spectroscopic data revealed an oleanene-type structure closely related to the above triterpenes.

25

The structure and relative stereochemistry of **6** were confirmed by a single crystal X-ray analysis (Fig. 5). The computer-generated X-ray structure depicts ring E in a chair conformation placing the C20α carboxylic acid and the C22α hydroxyl group in equatorial orientations. The C3 hydroxyl group is also shown to be equatorial (C3β) as predicted from the ^1Hmr spectrum. The crystal exists as the 1:1 methanol solvate, with the methanol oxygen coordinating with the hydroxyl groups of the triterpene.

With the complete structure of **6** available from the above studies, the chemical correlations between **3–5** and **6** were now considered (Fig. 6).

The triterpenes **3** and **4** were both reduced with sodium borohydride to the corresponding alcohols. Triterpene **3** yielded a compound with identical tlc, mp, ir, ms, and ^1Hmr spectra to those of **5**, while **4** yielded a compound with identical tlc, mp, ir, ms, and ^1Hmr spectra to those of **6**. Esterification of **6–10** followed by oxidation with pyridinium

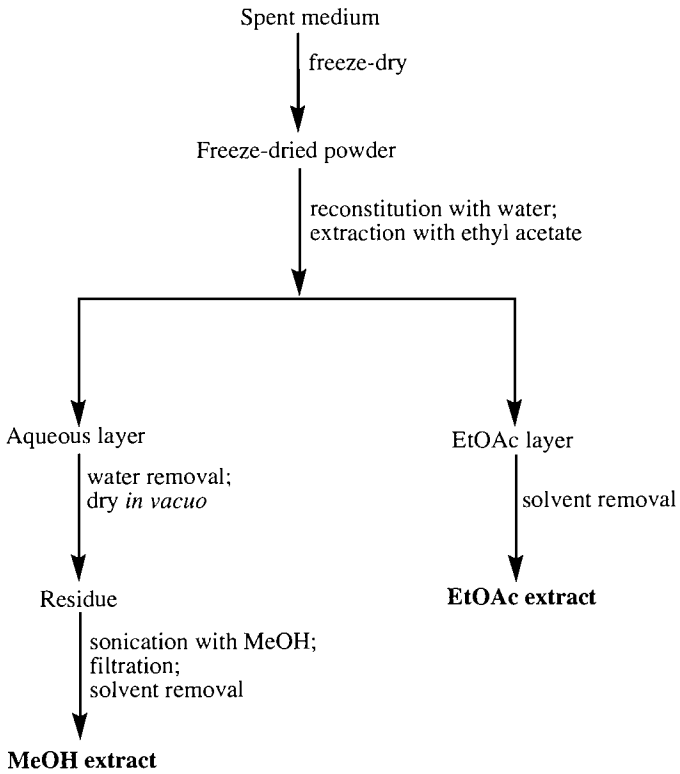

FIG. 2 Extraction procedure for the TRP4a spent medium.

TABLE 1. Volumes and growth times for initial batches of TRP4a suspension cultures for preliminary biological screening

Batch no.	Culture vol. (L)	Incubation time (days)	R.I. on harvesting
TRP#221	15.0	33	1.3345
TRP#222	10.0	48	1.3338
TRP#224	16.0	42	1.3345
TRP#225	10.5	30	1.3335

chlorochromate yielded the diketone, **11**, as an optically active ($[\alpha]^{22}$ +5.7) white solid (mp 180.5–182°C) with a molecular formula of $C_{31}H_{46}O_4$. Its ir spectrum shows carbonyls at 1721 and 1698 cm^{-1} and C-O absorption at 1218 cm^{-1}. The ^{1}Hmr spectrum shows four signals corresponding to protons adjacent to the carbonyl at δ 2.39 (1H, ddd, C2αH), 2.48 (1H, d, C21βH), 2.56 (1H, ddd, C2βH), and 2.99 (1H, d, C21αH).

Esterification and oxidation of **5** in the same manner yielded a compound with identical tlc, mp, ir, ms, and ^{1}Hmr spectra to those of **11**.

The spectral data and chemical interconversions establish that **3** is 22β-hydroxy-3-oxoolean-12-en-29-oic acid, **4** is 22α-hydroxy-3-oxoolean-12-en-29-oic acid, **5** is 3β,22β-dihydroxyolean-12-en-29-oic acid, and that **6** is 3β,22α-dihydroxyolean-12-en-29-oic acid.

The known triterpenes α-amyrin (**12**) and β-amyrin (**13**), isolated for the first time from the TRPa cell line, were established via spectral comparison with authentic samples.

The abietane-type diterpene, **14**, was isolated as optically active ($[\alpha]^{22}$ +44.4) colourless needles (mp 157–158°C) with a molecular formula of $C_{21}H_{32}O_2$. The mass spectrum of **14** has a molecular ion peak at *m/z* 316 and a base peak at *m/z* 283 corresponding to $M^+ - CH_3$, H_2O. The remaining peaks are of low intensity; however, diagnostic peaks are observed at *m/z* 215 and 189 (Fig. 7) (23). In the ^{1}Hmr spectrum, signals are present for 3 tertiary methyl groups (δ 0.96, 1.05, and 1.20), an isopropyl group (δ 1.20, d, CH_3; δ 1.21, d, CH_3 and δ 3.28, septet, benzylic methine), and a methoxyl group at δ 3.72. Also observed are signals at δ 2.76 (1H, ddd, H7α) and 3.02 (1H, br dd, H7β) indicating a benzylic methylene, δ 3.51 (1H, br t, $W_{1/2}$ = 7.0 Hz, C*H*OH) indicating an axially oriented hydroxyl functionality, and two aromatic signals at δ 7.04 (1H, s) and 7.05 (1H, s).

The characteristic signals in the ^{13}Cmr spectrum of **14** are seen at δ 60.2 (OCH_3), 75.5 (CHOH), and 6 aromatic signals at δ 120.4, 123.7, 128.5, 137.9, 148.9, and 154.8. The APT spectrum confirms the presence of 6 methyl groups (δ 22.1, C10-CH_3; 23.9, 24.0, isopropyl methyl groups; 24.7, 25.9, C4 methyl groups and 60.2, OCH_3), a secondary alcohol (δ 75.5), and a tetrasubstituted benzene ring (the signals at δ 120.4 and 123.7 are inverted).

A 2D ^{1}H–^{1}H COSY spectrum of **14** shows coupling of the downfield proton at δ 3.51 with 2 other protons (3β/2, 3β/2′) that show geminal coupling (2/2′) and show cross peaks to 2 other protons (2′/1, 2′/1′, 2/1, and 2/1′). The benzylic proton at C15 shows the expected coupling with a cross peak to the isopropyl methyl groups (15/16, 17) while the benzylic protons at C7 show cross peaks to the protons at C6 (7β/6, 7β/6′, 7α/6, and 7α/6′). Coupling of H5 with H6 and H6′ is obscured by diagonal crowding.

A SINEPT experiment was carried out on **14** to determine whether the methoxyl group is attached to C11 or C12. Irradiation of the signal at δ 3.28 (H15) in the ^{1}Hmr spectrum was expected to enhance carbons 12 and 14 in the ^{13}Cmr spectrum (enhancement of carbon through three bonds ($^3J_{C,H}$) via polarization transfer from hydrogen). Irradiation of the signal at δ 3.28 (H15), however, resulted in enhancement of signals in the ^{13}Cmr spectrum at δ 123.7, 128.5, 137.9,

TABLE 2. Weights of extracts from TRP4a suspension cultures

Batch no.	Wet wt. cells (kg)	Spent medium vol. (L)	EtOAc extract (g)		MeOH extract (g)	
			Cells	Spent medium	Cells	Spent medium

148.9, and 154.8. Since the experiment was set up to enhance the $^3J_{C,H}$ coupled carbons (i.e., C12 and C14), the result was rather surprising. Nevertheless, the result indicates that attachment of the methoxyl group is at C12 since only one of the unsubstituted benzene carbons is enhanced (δ 123.7). Also, the quaternary carbon at δ 154.8 (the most deshielded carbon) is not observed in the ^{13}Cmr spectrum, but is quite strongly enhanced in the SINEPT spectrum, placing the methoxyl group at C12.

A series of nOe difference experiments were carried out

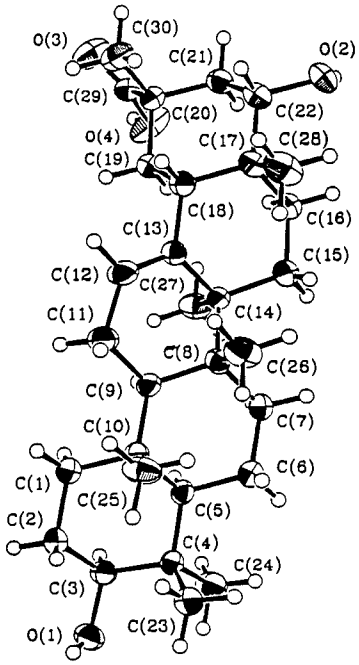

FIG. 5. Computer generated X-ray structure of triterpene **6**.

in order to confirm that the hydroxyl group is situated at C3 and to provide further evidence for the location of the methoxyl group at C12. Irradiation of OCH_3 at δ 3.72 shows enhancement of the isopropyl methine proton at δ 3.28 while irradiation of the latter produced enhancement of the OCH_3 signal. This evidence supports the assignment of the OCH_3 group to C12. Irradiation of the signal at δ 3.51 (C*H*OH) produced enhancements of both the C4 methyl groups at δ 0.96 and 1.05, confirming the location of the hydroxyl group at C3α (axial).

In summary, the spectral evidence confirms the structure of **14** as 12-methoxyabieta-8,11,13-trien-3α-ol, a novel diterpene isolated for the first time from the tissue cultures of *Tripterygium wilfordii*.

The quinone methide, **15**, was isolated as optically active ($[\alpha]^{22}$ −82.6) dark orange crystals (mp 140–142°C) with a molecular formula of $C_{28}H_{36}O_3$. The uv spectrum provided maxima typical of a quinone methide (λ_{max} 225 (ε 5.13 × 10^3), 256 (ε 8.20 × 10^3), and 424 nm (ε 8.72 × 10^3)). The mass spectrum of **15** shows a strong molecular ion peak at *m/z* 420, and principal fragment ions occurring at *m/z* 406, 405, 267, 253, 241, 227, 202, and 201, consistent with fragmentation at rings C and D of quinone methide triterpenes (23). The remaining spectral data (^{1}Hmr, COSY, see Experimental) were in support of structure **15** but a single crystal X-ray analysis established the structure and relative stereochemistry shown in **15** (Fig. 8). This compound is therefore identical to tingenone, and comparison with an authentic sample confirmed its identity.

The isolation of tingenone constitutes its first isolation from tissue cultures of *T. wilfordii*. Furthermore, the present X-ray study establishes, unambiguously, the relative stereochemistry of this quinone methide, a matter that was not entirely clear from the earlier isolations of this compound (24, 25). The X-ray structure shows rings C, D, and E in the chair conformation and the incorporation of ethyl acetate (crystallization solvent) in the crystal lattice.

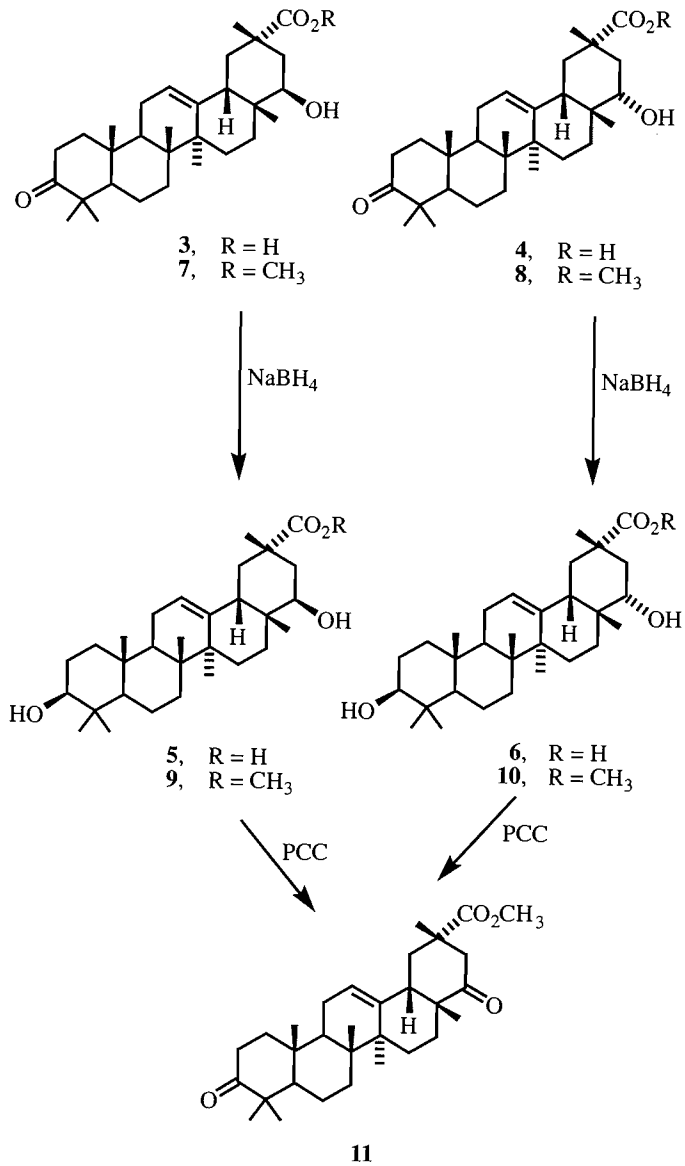

FIG. 6. Chemical correlation of the triterpenes **3**, **4**, **5**, and **6**.

The friedelane methyl ester, **16**, was isolated as optically active ($[\alpha]^{22}$ +101.4) yellow crystals (mp 150–151°C) with a molecular formula of $C_{30}H_{46}O_5$. Confirmation of the structure of **16** was achieved by a single crystal X-ray analysis. The absolute stereochemistry (by anomalous dispersion) is that shown in the computer-generated X-ray structure (Fig. 9). The methyl ester is established at C5 and all the rings are in the expected chair conformation. The friedelane methyl ester, **16**, is a novel triterpene exhibiting an unusual oxidation at C5.

The quinone methide, **17**, was isolated as optically active ($[\alpha]^{22}$ −484.6) dark orange crystals (mp 220–224°C) with a molecular formula of $C_{28}H_{36}O_4$. Its spectral data (see Experimental) revealed a close relationship to tingenone but the unambiguous assignment of an additional hydroxyl function, as suggested by the mass and ^{1}Hmr spectral data, was established by a single crystal X-ray analysis (Fig. 10) to be 22β-hydroxytingenone, the first isolation of this triterpene from the tissue cultures of *T. wilfordii*. Previous studies with several plants of the *Celastraceae* family, including

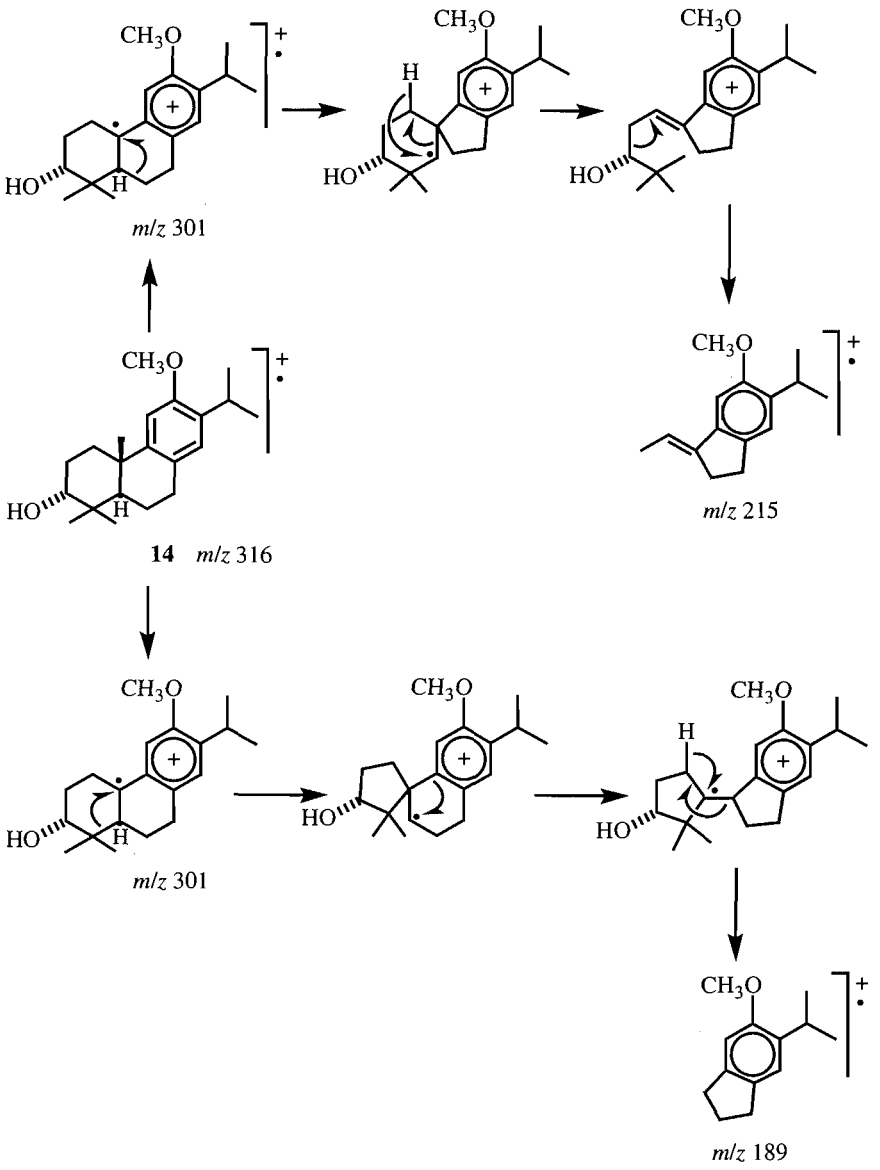

FIG. 7. Mass spectral fragmentation for diterpene **14**.

Euonymus tingens and various *Maytenus* species (24–30), have indicated the isolation of **17**, but an authentic sample could not be obtained.

The dihydroxyoleanene, **18**, was isolated as optically active ($[\alpha]^{22}$ +115.9) colourless prisms (mp 241–242°C) with a molecular formula of $C_{30}H_{50}O_2$. Although the extensive spectral data obtained for this compound (see Experimental) strongly suggested an oleanene-type structure, the conclusive location of the hydroxyl groups, particularly the hydroxymethyl group, was established via X-ray analysis (Fig. 11).

The isolation of **18** constitutes its first isolation from tissue cultures of *T. wilfordii*. A compound with a similar structure is reported to be isolated from *Celastrus paniculatus* and given the name paniculatadiol (31) but no spectral data are presented and an authentic sample could not be obtained for comparison.

Extensive studies into the pharmacological effects of oleanene-type compounds by Shibata and coworkers (32–36) have revealed the importance of a hydroxymethyl group in such compounds in terms of their ability to inhibit stress-induced peptic ulcer, activity against allergies, anti-tumour and analgesic activity, etc. As yet, no data are available with respect to **18**.

The dihydroxy triterpene, **19**, was isolated as optically active ($[\alpha]^{22}$ +55.3) colourless prisms (mp 230–234°C) with a molecular formula of $C_{30}H_{50}O_2$. Spectral data (see Experimental) suggested a β-amyrin type system. Final confirmation of structure and relative stereochemistry of **19** as 11α-hydroxy-β-amyrin was provided by a single crystal X-ray analysis (Fig. 12). A previous isolation of a compound corresponding to **19** has been reported in the gummy secretion of *Salvia glutinosa* (37) but again an authentic sample was unavailable.

In summary, the extraction of the TRP4a suspension cultures and separation of the extracts led to the isolation of 18 compounds, mainly triterpenes and also some diterpenes. Twelve of the compounds, of which five are new com-

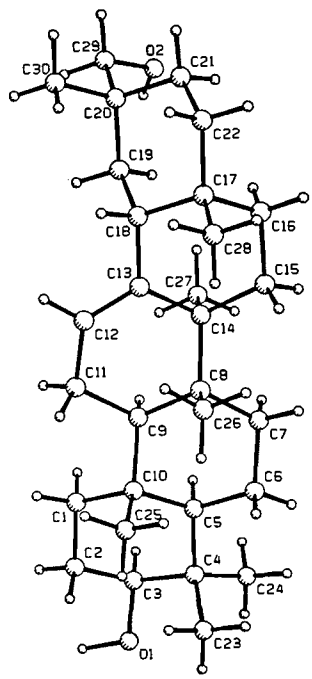

FIG. 11. Computer generated X-ray structure of **18**.

pounds (**3**, **4**, **5**, **14**, and 16), were not isolated previously from the TRP4a cultures. Pharmacological evaluation of some of these in terms of male contraceptive, immunosuppressive, and other activities is presently in progress and these results will be published elsewhere.

Experimental

TRP4a cell suspension cultures were grown in glass or in steel air-lift fermentors (Microferm, New Brunswick Scientific or an in-house fabricated fermentor, respectively). The spent medium was freeze-dried using a Dura-Dry freeze-dryer with a Dura-Top Bulk Tray Dryer (FTS Systems Inc.).

The ^{1}Hmr spectra were run at 300 and 400 MHz using Varian XL 300 and Bruker WH 400 spectrometers, respectively. Tetramethylsilane was used as the internal standard and all peaks are recorded in ppm (δ) relative to TMS (δ 0.00 ppm). The ^{13}Cmr spectra were run at 75.3 MHz using a Varian XL 300 spectrometer, using the ^{13}C signals of the deuterated solvents as the internal standards.

Low-resolution mass spectra were recorded using Kratos

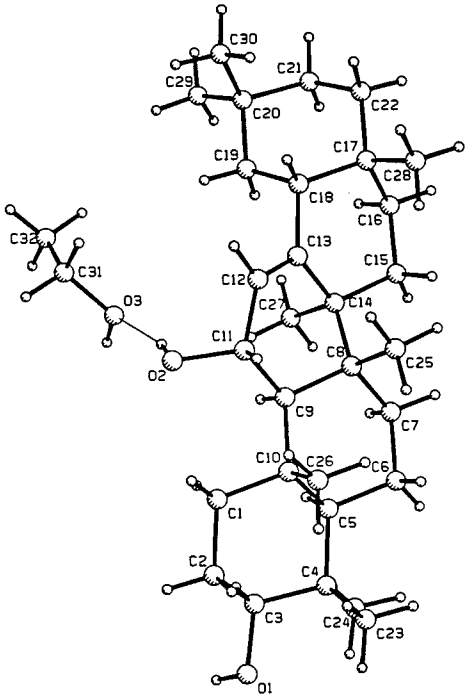

FIG. 12. Computer generated X-ray structure of **19**.

MS 50 and MS 80 mass spectrometers. High-resolution mass spectra were run on a Kratos MS 50 mass spectrometer. Chemical ionization mass spectra were recorded on a Delsi–Nermag R10-10C mass spectrometer using isobutane as the carrier gas.

The ir spectra were recorded on a Perkin Elmer 710B infrared spectrophotometer, and Fourier transform ir spectra were recorded on a Perkin Elmer 1710 infrared Fourier transform spectrophotometer. Optical rotations were recorded on a Perkin Elmer 141 polarimeter at the sodium D line. The uv spectra were recorded on a Unicam SP 800B ultraviolet spectrophotometer.

All melting points were recorded on a Reichert melting point apparatus or a Fisher–Johns melting point apparatus and are uncorrected.

Column chromatography was carried out using Merck silica gel 60, 230–400 mesh, while analytical and preparative tlc was performed using Merck precoated silica gel 60 F_{254} tlc plates. Vacuum liquid chromatography (vlc) was carried out using Merck silica gel 60G in sintered glass funnels with medium glass frits. Preparative hplc separations were performed on a Waters Associates Prep LC/System 500 installed with PrepPAK-500/silica cartridges and a refractive index detector. All solvents used for chromatography were BDH Omnisolv glass-distilled spectro-grade solvents.

Synthetic samples were visualized on analytical tlc plates (Merck) by uv and by spraying with a 5% solution of ammonium molybdate in 10% sulphuric acid, followed by heating at 125°C until blue spots developed. Tissue culture extracts were visualized on tlc spraying first with a 30% solution of concentrated sulphuric acid in glacial acetic acid, then with a 5% solution of anisaldehyde in isopropanol, followed by heating at 125°C for approximately 10 min.

Growth conditions for the TRP4a cell suspension cultures

The cultures were grown and maintained as discussed previously (6, 7) in PRD_2Co_{100} medium at 26°C for 22 days and then resuspended as a 10% inoculum in $MSNA_{0.5}K_{0.5}$ production medium. The cultures were incubated at 26°C in air-lift fermentors for 33–48 days before harvesting. The cells were harvested by filtration through Miracloth (Calbiochem) and were frozen until the time of extraction. The spent medium was freeze-dried and stored frozen until the time of extraction.

Extraction of the TRP4a cell suspension cultures

This is a typical procedure followed for the various bioreactor experiments, for example, TRP#221.

Cells (compare Fig. 1)

The cells were thawed and homogenized in a Waring blender with ethyl acetate (1 L). The cells were then filtered using Celite, and washed with ethyl acetate (300 mL). The filtrate was separated and the aqueous layer was extracted with ethyl acetate (3 × 200 mL) and discarded. The ethyl acetate layers were combined, dried over sodium sulphate (anhydrous), and the solvent was evaporated. The orange-brown extract was dried under vacuum and kept frozen until further use.

The filtered cell homogenate was suspended in methanol (500 mL) and sonicated for 2 h. Filtration and solvent evaporation gave a brown gummy extract which was dried under vacuum and kept frozen until further use.

Spent medium (compare Fig. 2)

The freeze-dried spent medium was reconstituted in water (300–500 mL) and extracted with ethyl acetate (3 × 200 mL). The organic layers were combined, dried over sodium sulphate (anhydrous), and the solvent was evaporated. The dark brown extract was dried under vacuum and frozen until further use. The aqueous layer was evaporated and the residue was sonicated with methanol (200 mL) and filtered. The filtrate was evaporated and the brown extract was dried under vacuum and frozen until further use.

Extraction of batches TRP#221, 222, 224, and 225, according to the above procedures, provides the weights of the extracts as given in Tables 1 and 2.

Preparation of crude samples for bioassay

Samples of the crude TRP#221 culture extracts were forwarded for immunological assay and for antifertility assay to the laboratories indicated in the Acknowledgement.

The solids obtained from the ethyl acetate extracts were prepared in a manner (see below) so as to generate emulsions in water (*vide infra*) while the solids obtained from the methanol extracts were forwarded without further preparation.

The ethyl acetate cell extract (0.84 g) from batch TRP#221 was dissolved in ethanol (15 mL) and polyvinylpyrrolidone (PVP, 4.20 g) was added. The solvent was evaporated and the residue was dried under vacuum to give 5.03 g of a water emulsifiable solid. The procedure was repeated with the ethyl acetate spent medium extract (0.44 g, with 2.19 g of PVP) to give 2.65 g of a water emulsifiable solid.

Partial separation of the ethyl acetate cell extracts for biological assay

The remaining ethyl acetate cell extracts (from batches TRP#222, 224, and 225) were combined (3.73 g) and separated into 8 partially purified fractions by vacuum liquid chromatography using Merck silica gel 60G (80 g) packed into a sintered glass funnel (150 mL, medium frit), attached to a bell jar with a sidearm, which was connected to a water aspirator. Fifty-milliliter fractions were collected and stepwise elution was carried out using: (*i*) hexanes – ethyl acetate 4:1 (6 × 50 mL); (*ii*) hexanes – ethyl acetate 3:1 (6 × 50 mL); (*iii*) hexanes – ethyl acetate 2:1 (6 × 50 mL); (*iv*) hexanes – ethyl acetate 1:1 (6 × 50 mL); and (*v*) ethyl acetate (6 × 50 mL). The column was flushed with ethyl acetate – methanol 1:1 (250 mL) to elute the polar material.

Elution with hexanes – ethyl acetate 4:1 yielded an oily fraction (378.76 mg) containing fatty acid-like compounds (fraction 1). Further elution with hexanes – ethyl acetate 4:1 and hexanes – ethyl acetate 3:1 yielded fraction 2 (389.66 mg), containing nonpolar diterpenes and sterols. Elution with hexanes – ethyl acetate 3:1 and 2:1 yielded fraction 3 (273.60 mg) as a brown solid containing several terpenoid components. Further elution with hexanes – ethyl acetate 2:1 gave fraction 4 (267.59 mg) while elution with hexanes – ethyl acetate 1:1 yielded fraction 5 (505.63 mg). Both fractions contained triterpenoid components. Elution with ethyl acetate gave fraction 6 (291.01 mg) as a light brown solid con-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12

For personal use only.

taining polar triterpenes. Elution with ethyl acetate and ethyl acetate – methanol 1:1 gave fraction 7 (175.80 mg) as a light brown solid containing polar triterpenes. Fraction 8 (1.22 g) was eluted with ethyl acetate – methanol 1:1, yielding polar material as a dark brown solid.

Partial separation of the spent medium ethyl acetate extracts for biological assay

The remaining ethyl acetate spent medium extracts (from batches TRP#222, 224, and 225) were combined (1.17 g) and partially separated by vacuum liquid chromatography using a sintered glass funnel (60 mL, medium frit, Merck silica gel 60G, 30 g). Thirty-milliliter fractions were collected to give 10 partially purified fractions. Stepwise elution was carried out using: (*i*) hexanes (5 × 30 mL); (*ii*) hexanes – ethyl acetate 19:1 (5 × 30 mL); (*iii*) hexanes – ethyl acetate 9:1 (5 × 30 mL); (*iv*) hexanes – ethyl acetate 4:1 (5 × 30 mL); (*v*) hexanes – ethyl acetate 1:1 (5 × 30 mL); and (*vi*) ethyl acetate (5 × 30 mL). The polar material was eluted from the column using ethyl acetate – methanol 1:1 (150 mL).

Elution with hexanes and hexanes – ethyl acetate 19:1 gave fraction 1 (4.32 mg) as a yellow solid containing nonpolar terpenoid components. Elution with hexanes – ethyl acetate 19:1, 9:1, and 4:1 gave fraction 2 (23.89 mg) and elution with hexanes – ethyl acetate 4:1 gave fraction 3 (14.28 mg). Both fractions contained several terpenoid components. Further elution with hexanes – ethyl acetate 4:1 and 1:1 yielded fraction 4 (60.64 mg) as a light brown solid containing diterpenoid and triterpenoid metabolites. Elution with hexanes – ethyl acetate 1:1 and ethyl acetate yielded fraction 5 (128.52 mg) as a brown solid containing diterpenoids and triterpenoids. Elution with ethyl acetate gave fraction 6 (206.21 mg) as a yellow-brown solid containing triptolide (**2**) and several triterpenes. Further elution with ethyl acetate yielded fraction 7 (204.75 mg) as a yellow-brown solid containing tripdiolide (**1**) and several triterpenes. Elution with ethyl acetate and ethyl acetate – methanol 1:1 gave fraction 8 (52.43 mg) as a brown solid containing triterpenes and polar material. Elution with ethyl acetate – methanol 1:1 gave fraction 9 (303.69 mg) while further elution with ethyl acetate – methanol 1:1 yielded fraction 10 (76.54 mg) as polar material in the form of brown solids.

Preparation of the partially purified extracts for biological assay

All the fractions were treated as above with polyvinylpyrrolidone (5:1, PVP:fraction, w/w) in order to obtain samples capable of forming emulsions in water. The samples were then forwarded for immunological and antifertility assays.

Isolation of pure metabolites from the TRP4a cell suspension cultures

To obtain large quantities of cells and spent medium, 6 batches (10–17 L) were grown in bioreactors for 25–39 days to afford a total of 78 L (Table 3). The batches were combined on harvesting and filtered through Miracloth. The cells (wet weight 8.94 kg) were frozen and the spent media (60.6 L) were concentrated to 1.4 L by freeze-drying.

Extraction of the combined cells and the combined spent media was performed as described above, with the 5-fold increase of the extraction solvent and omission of a sonication with methanol. Cell extraction yielded 13.08 g of a dark orange extract. Spent media extraction gave 14.73 g of an orange-brown extract.

Chromatographic separation of the cell extract metabolites

Initial purification of the cell extract (13.08 g) was carried out by filtration through silica gel (Merck silica gel 230–400 mesh, 60 mL) using ethyl acetate, to remove the polar material. Evaporation of the solvent yielded 9.04 g of crude extract as an orange solid; 3.01 g of this extract was purified following the procedure described as Method A, 5.83 g was purified by Method B (compare Fig. 3).

Method A

The cell extract (3.01 g) was partially separated by vacuum liquid chromatography using a 150-mL sintered glass funnel (medium frit, Merck silica gel 60G, 90 g). Stepwise elution using (*i*) benzene (5 × 30 mL); (*ii*) benzene–acetone 4:1 (25 × 30 mL); (*iii*) benzene–acetone 3:1 (15 × 30 mL); (*iv*) benzene–acetone 2:1 (18 × 30 mL); and (*v*) ethyl acetate (300 mL) gave 10 fractions. Fractions 1 (349.11 mg) and 2 (45.70 mg) were colorless oily fractions consisting of fatty acid-like compounds. Fraction 3 (1.17 g), a dark orange fraction, contained diterpenes, sterols, triterpenes, and quinone methides (see below for the separation of this fraction). Fraction 4 yielded oleanolic acid (**23**, 432.26 mg). Fraction 5 (162.39 mg) consisted of triterpenes **3** and **4** and fraction 6 (147.96 mg) contained triterpenes **3**, **4**, **5**, and **6**. Fraction 7 (92.80 mg) contained triterpenes **4**, **5**, and **6**, while fraction 8 (75.03 mg) contained a small quantity of triterpenes **5** and **6**. Fractions 9 and 10 (347.58 and 52.42 mg respectively) consisted of triterpene **6** and some polar material.

Separation of fractions 5–8 was carried out by preparative tlc (Merck silica 60G, 6 × 0.5 mm silica gel plates) using methylene chloride – methanol–acetic acid 100:2:1 (the plates were eluted four times) to give triterpene **3** (27.25 mg), triterpene **4** (65.77 mg), triterpene **5** (20.85 mg), and triterpene **6** (21.80 mg). Fractions 9 and 10 were combined and washed with methanol to give a further quantity of **6** (157.13 mg).

In summary, chromatographic separation yielded oleanolic acid (**23**, 432.26 mg) and triterpenes **3** (27.25 mg), **4** (65.77 mg), **5** (20.85 mg), and **6** (157.13 mg).

Method B

The cell extract (5.83 g) was partially separated by vacuum liquid chromatography using a 150-mL sintered glass funnel (medium frit, Merck silica gel 60G, 90 g). Stepwise elution was carried out using: (*i*) benzene (5 × 30 mL); (*ii*) benzene–acetone 4:1 (15 × 30 mL); (*iii*) benzene–acetone 3:1 (10 × 30 mL); (*iv*) benzene–acetone 2:1 (30 mL); (*v*) benzene–acetone 1:1 (10 × 30 mL); and (*vi*) ethyl acetate (250 mL), yielded 10 crude fractions. Fraction 1 (756.14 mg) was an oily fraction consisting of fatty acid-like compounds. Fraction 2 (2.38 g) containing diterpenes, sterols, triterpenes, and quinone methides was subsequently combined with fraction 3 from Method A for further separation (*vide infra*). Fraction 3 (126.58 mg) was a mixture of oleanolic acid (**23**) and triterpene **3**, while fraction 4 (281.26 mg) contained triterpenes **3** and **4**. Fractions 5 and 6 (74.93 mg and 62.50 mg respectively) consisted of mainly triterpene **4** and a small quantity of triterpene **5**. Fraction 7 (219.67 mg) contained triterpenes **4** and **5**, while fraction 8 (106.61 mg) contained triterpenes **4**, **5**, and **6**. Fractions 9 and 10 (569.53 mg and 534.98 mg respectively) contained triterpene **6** and polar material.

Fractions 3–8 were combined and separated by column chromatography (Merck silica gel 230–400 mesh, methylene chloride – methanol acetic acid 100:2:1) to give oleanolic acid (**23**, 101.97 mg), a mixture of **3** and **4** (101.97 mg), triterpene **4** (167.69 mg), triterpene **5** (181.17 mg), and triterpene **6** (85.34 mg). The mixture of **3** and **4** was separated by further column chromatography (Merck silica gel 230–400 mesh, methylene chloride – methanol – acetic acid 100:1:1) to give **3** (55.80 mg) and a further quantity of **4** (121.74 mg). Fractions 9 and 10 were combined and washed with methanol to give **6** (359.65 mg).

In summary, chromatographic separation via Method B yielded oleanolic acid (**23**, 101.97 mg) and triterpenes **3** (55.80 mg), **4** (289.43 mg), **5** (181.17 mg), and **6** (444.99 mg).

*3β,22β-Dihydroxyolean-12-en-29-oic acid (**5**)*

Colorless prisms (MeOH–H_2O); mp 281–283°C; $[\alpha]^{22}$ +55.0 (*c* 0.60, MeOH); uv (MeOH) λ_{max} 216 (ε 835); ir (KBr) cm^{-1}: 3467 (OH), 3422 (OH), 2976 (CH), 2640 (OH), 1698 (C=O); ^{1}Hmr (C_5D_5N) δ: 0.76 (3H, s), 0.85 (6H, s), 1.02 (3H, s), 1.03 (3H, s), 1.08 (3H, s), 1.63 (3H, s), 0.62–2.63 (24H, m), 3.22 (1H, dd, $H_3\alpha$, *J* = 6, 9.5), 3.80 (1H, brd, H22α, *J* = 4.5), 5.21 (1H, t, H12); ^{13}Cmr (C_5D_5N) δ: 15.8, 16.6, 17.2, 18.7, 21.0, 23.8, 24.9, 25.5, 26.3, 28.0, 28.7, 28.8, 30.7, 33.2, 37.2, 37.7, 38.0, 39.1, 39.3, 39.9, 41.5, 42.4, 44.6, 48.0, 55.7, 75.3, 77.9, 123.1, 144.2, 181.0; ms *m/z* (rel. int., %): 472 (M^+, 6.1), 454 (5.0), 439 (2.6), 426 (2.0), 411 (2.1), 393 (1.5), 264 (99.7), 246 (53.0), 231 (15.4), 217 (100.0), 207 (59.9), 190 (45.2), 175 (39.3), 161 (22.7), 147 (37.9), 135 (74.1), 119 (49.9), 107 (48.2), 95 (52.4), 81 (49.9), 69 (48.6), 55 (48.7), 43 (30.7). High-resolution mass measurement: calcd. for $C_{30}H_{48}O_4$: 472.3554; found: 472.3567. Anal. calcd. for $C_{30}H_{48}O_4 \cdot H_2O$: C 73.43, H 10.27; found: C 73.53, H 10.40.

*3β-22α-Dihydroxyolean-12-en-29-oic acid (**6**)*

Colourless prisms (MeOH); mp 293–298°C (subl.); $[\alpha]^{22}$ +93.5 (*c* 0.46, MeOH); uv (MeOH) λ_{max} 212 (ε 1509); ir (KBr) cm^{-1}: 3475 (OH), 3387 (OH), 2946 (CH), 2550 (OH), 1698 (C=O); ^{1}Hmr (C_5D_5N) δ: 0.98 (3H, s), 1.03 (3H, s), 1.04 (3H, s), 1.23 (3H, s), 1.28 (3H, s), 1.37 (3H, s), 1.58 (3H, s), 0.82–2.74 (24H, m), 3.42 (1H, dd, H3α, *J* = 6, 10), 4.01 (1H, dd, H22β, *J* = 5.5, 13), 5.38 (1H, t, H12); ^{13}Cmr (C_5D_5N) δ: 15.8, 16.6, 17.0, 18.8, 19.9, 21.4, 23.9, 25.4, 26.1, 26.3, 28.0, 28.7, 32.9, 37.2, 38.6, 39.1, 39.4, 40.2, 41.2, 42.4, 47.2, 47.9, 55.6, 74.7, 78.0, 123.1, 144.2, 181.1; ms *m/z* (rel int., %): 472 (M^+, 0.2), 454 (2.6), 436 (1.7), 421 (1.3), 410 (0.6), 393 (1.2), 342 (1.1), 325 (0.6), 314 (0.9), 299 (2.0), 264 (2.7), 246 (100.0), 218 (21.6), 207 (18.1), 201 (15.5), 190 (35.6), 175 (20.3), 159 (14.8), 145 (20.1), 131 (22.5), 119 (32.2), 107 (23.2), 95 (25.9), 81 (17.7), 69 (12.2), 55 (14.7). High-resolution mass measurement: calcd. for $C_{30}H_{48}O_4$: 472.3554; found: 472.3540. Anal. calcd. for $C_{30}H_{48}O_4$:[2] C 76.23, H 10.23; found: C 76.10, H 10.33.

[2]All the data for this compound were obtained on a sample that was recrystallized from ethanol, except for the X-ray analysis. Recrystallization from methanol was shown by X-ray analysis to yield crystals as the 1:1 methanol solvate.

*Oleanolic acid (**7**)*

The isolated sample was compared (mp, identical ir, ^{1}Hmr, and ms spectra) with an authentic sample available in our sample collection.

*Reduction of 22α-hydroxy-3-oxoolean-12-en-29-oic acid (**4**)*

The acid **4** (11.24 mg, 0.02 mmol) was dissolved in ethanol (1 mL) and sodium borohydride (4.52 mg, 0.12 mmol) was added. The reaction mixture was stirred at room temperature for 30 min and ethyl acetate (30 mL) was added. The solution was washed with 10% HCl (2 × 5 mL) and water (2 × 10 mL) and the solvent was evaporated to give 8.63 mg (76.4%) of **6** as a white solid (tlc, mp, ^{1}Hmr, and ms were identical with those of isolated **6**).

*Reduction of 22β-hydroxy-3-oxoolean-12-en-29-oic acid (**3**)*

The acid **3** (6.18 mg, 0.01 mmol) was treated as above with sodium borohydride, which yielded, after work-up, 5.92 mg (95.3%) of **5** as a white solid (tlc, mp, ^{1}Hmr, and ms were identical with those of isolated **5**).

*Esterification of **3**, **4**, **5**, and **6***

Suspensions of the triterpenes **3**, **4**, **5**, and **6** in ether (3 mL) were treated with an ethereal solution of excess diazomethane at room temperature overnight. Evaporation of the solvent gave the methyl esters **7**, **8**, **9**, and **10** as white solids. They were then crystallized (MeOH as solvent) to provide the pure compounds with constant melting points.

*Methyl-22β-hydroxy-3-oxoolean-12-en-29-oate (**7**)*

White solid; mp 195–197°C; $[\alpha]^{22}$ +82.3 (*c* 1.15, $CHCl_3$); ir ($CHCl_{33}$) cm^{-1}: 3425 (OH), 2910 (CH), 1719 (C=0), 1698 (C=O); ^{1}Hmr ($CDCl_3$) δ: 0.90 (3H, s), 1.04 (3H, s), 1.06 (3H, s), 1.08 (3H, s), 1.10 (3H, s), 1.14 (3H, s), 1.36 (3H, s), 0.82–2.27 (20H, m), 2.38 (1H, ddd, H2α, *J* = 4, 6, 16), 2.55 (1H, ddd, H2β, *J* = 4, 11, 16), 3.55 (1H, dd, H22α, *J* = 3, 4), 3.69 (3H, s, OCH_3), 5.33 (1H, t, H12); ms *m/z* (rel. int., %): 484 (M^+, 42.5), 469 (4.6), 466 (7.9), 453 (10.4), 425 (16.9), 407 (4.7), 391 (3.5), 375 (6.3), 278 (100.0), 265 (57.1), 260 (25.7), 247 (43.3), 231 (83.2), 219 (35.5), 205 (40.5), 200 (41.7), 187 (27.9), 171 (58.1), 161 (16.9), 144 (40.7), 125 (60.7), 112 (37.7), 95 (26.7), 81 (20.1), 69 (16.7), 55 (15.7). High-resolution mass measurement: calcd. for $C_{31}H_{48}O_4$: 484.3552; found: 484.3554.

*Methyl-22α-hydroxy-3-oxoolean-12-en-29-oate (**8**)*

White solid; mp 149–151°C; $[\alpha]^{22}$ +92.9 (*c* 0.85, $CHCl_3$); ir ($CHCl_3$) cm^{-1}: 3600 (OH), 2930 (CH), 1718 (C=O), 1698 (C=O); ^{1}Hmr ($CDCl_3$) δ: 1.02 (3H, s), 1.04 (3H, s), 1.07 (3H, s), 1.08 (3H, s), 1.11 (3H, s), 1.18 (3H, s), 1.26 (3H, s), 1.35–2.23 (20H, m), 2.38 (1H, ddd, H2α, *J* = 4, 6, 16), 2.55 (1H, ddd, H2β, *J* = 4, 11, 16), 3.59 (1H, dd, H22β, *J* = 4, 12), 3.68 (3H, s, OCH_3), 5.28 (1H, t, H12); ms *m/z* (rel. int., %): 484 (M^+, 18.5), 466 (5.0), 452 (21.2); 437 (3.4), 406 (3.4), 391 (3.5), 340 (2.3), 326 (4.1), 299 (1.9), 278 (43.3), 265 (6.8), 260 (13.3), 246 (100.0), 231 (28.9), 218 (18.2), 205 (29.8), 185 (21.6), 171 (23.0), 159 (13.1), 147 (21.0), 131 (19.2), 120 (22.3), 107 (17.8), 95 (27.9), 81 (10.5), 69 (1.9), 55 (9.1). High-resolution mass measurement: calcd. for $C_{31}H_{48}O_4$: 484.3552; found: 484.3570.

*Methyl-3β,22β-dihydroxyolean-12-en-29-oate (**9**)*

White solid; mp 228–229°C; $[\alpha]^{22}$ +64.0 (*c* 0.88, $CHCl_3$); ir ($CHCl_3$) cm^{-1}: 3665 (OH), 3586 (OH), 2900 (CH), 1718 (C=O); ^{1}Hmr ($CDCl_3$) δ: 0.80 (3H, s), 0.90 (3H, s), 0.96 (3H, s), 0.99 (3H, s), 1.01 (3H, s), 1.13 (3H, s), 1.36 (3H, s), 0.73–2.27 (23H, m), 3.23 (1H, dd, H3α, *J* = 4, 10), 3.55 (1H, dd, H22α, *J* = 4, 8), 3.68 (3H, s, OCH_3), 5.30 (1H, t, H12); ms *m/z* (rel. int., %): 486 (M^+, 13.3), 471 (1.2), 468 (3.0), 455 (3.6), 427 (2.0), 409 (1.5), 354 (1.4), 330 (1.4), 304 (1.3), 292 (3.4), 278 (100.0), 260 (23.6), 246 (23.3), 231 (79.5), 219 (23.3), 207 (47.9), 200 (47.3), 189 (25.6), 171 (60.2), 144 (43.0), 135 (34.8), 119 (37.3), 112 (37.6), 107 (28.1), 95 (27.3), 81 (23.1), 69 (17.0), 55 (18.5). High-res-

olution mass measurement: calcd. for $C_{31}H_{50}O_4$: 486.3711; found: 486.3722.

*Methyl-3α-22α-dihydroxyolean-12-en-29-oate (**10**)*

White solid; mp 118–121°C; $[\alpha]^{22}$ +74.9 (*c* 0.90, $CHCl_3$); ir ($CHCl_3$) cm^{-1}: 3655 (OH), 3600 (OH), 2932 (CH), 1718 (C=O); ^{1}Hmr ($CDCl_3$) δ: 0.80 (3H, s), 0.94 (3H, s), 0.98 (3H, s), 1.00 (6H, s), 1.17 (3H, s), 1.26 (3H, s), 0.73–2.22 (23H, m), 3.23 (1H, dd, H3α, *J* = 4, 10), 3.58 (1H, dd, H22β, *J* = 4, 12), 3.67 (3H, s, OCH_3), 5.26 (1H, t, H12); ms *m/z* (rel. int., %): 486 (M^+, 3.1), 468 (1.1), 454 (4.7), 436 (1.9), 421 (1.2), 409 (0.7), 393 (1.0), 342 (0.8), 328 (1.1), 314 (0.9), 300 (1.7), 278 (16.9), 246 (100.0), 231 (14.9), 218 (17.6), 207 (24.1), 190 (35.0), 175 (15.6), 159 (11.9), 147 (15.8), 131 (16.1), 119 (20.6), 107 (14.5), 95 (22.5), 81 (9.3), 69 (7.5), 55 (7.7). High-resolution mass measurement: calcd. for $C_{31}H_{50}O_4$: 486.3711; found: 486.3695.

*Methyl-3,22-dioxoolean-12-en-29-oate (**11**)*

Excess pyridinium chlorochromate was added to a stirred solution of **9** (10.00 mg, 0.02 mmol) in methylene chloride (1.0 mL) and the reaction mixture was stirred at room temperature for 30 min. The reaction mixture was filtered through Florisil (30 mL) and the Florisil was washed with ether. The washing and the filtrate were combined and the solvent was evaporated to give 8.23 mg (83.0%) of **11** as a white solid, mp 180.5–182°C; $[\alpha]^{22}$ +5.7 (*c* 4.75, $CHCl_3$); ir ($CHCl_3$) cm^{-1}: 3000 (CH), 2940 (CH), 1721 (C=O), 1698 (C=O); ^{1}Hmr ($CDCl_3$) δ: 1.03 (3H, s), 1.04 (3H, s), 1.07 (3H, s), 1.09 (3H, s), 1.11 (3H, s), 1.16 (3H, s), 1.24 (3H, s), 1.21–2.11 (20H, m), 2.32 (1H, dd, H19β, *J* = 3.5, 15), 2.39 (1H, ddd, H2α, *J* = 4, 6, 16), 2.48 (1H, d, H21β, *J* = 14.5), 2.56 (1H, ddd, H2β, *J* = 4, 11, 16), 2.99 (1H, d, H21α, *J* = 14.5), 3.71 (3H, s, OCH_3), (1H, t, H12); ms *m/z* (rel. int., %): 482 (M^+, 18.4), 467 (2.3), 464 (2.7), 451 (1.8), 423 (2.0), 405 (1.6), 339 (1.7), 298 (0.8), 276 (100.0), 263 (11.1), 247 (16.4), 215 (17.6), 205 (13.5), 199 (16.7), 187 (13.8), 173 (9.8), 159 (9.9), 142 (25.5), 134 (24.3), 119 (20.5), 114 (68.7), 105 (13.2), 93 (9.4), 81 (8.8), 69 (4.9), 55 (10.3). High-resolution mass measurement: calcd. for $H_{31}H_{46}O_4$: 482.3398; found: 482.3405.

*Oxidation of **10***

Excess pyridinium chlorochromate was added to a stirred solution of **10** (5.03 mg, 0.01 mmol) in methylene chloride (1.0 mL) and the reaction mixture was stirred at room temperature for 30 min. The reaction mixture was filtered through Florisil (30 mL) and the Florisil was washed with water. The washings and the filtrate were combined and the solvent was evaporated to give 3.76 mg (75.4%) of **11** as a white solid.

Separation and identification of the metabolites from fraction 3 (from Method A) and fraction 2 (from Method B) (compare Fig. 3)

Fraction 3 (1.17 g) from Method A and fraction 2 (2.38 g) from Method B (*vide supra*) were combined (3.55 g) and partially separated by column chromatography (Merck silica gel 230–400, 350 g). Stepwise elution was carried out using: (*i*) hexanes (250 mL); (*ii*) hexanes – ethyl acetate 9:1 (500 mL); (*iii*) hexanes – ethyl acetate 4:1 (1500 mL); (*iv*) hexanes – ethyl acetate 3:1 (1000 mL); (*v*) hexanes – ethyl acetate 2:1 (1000 mL); and (*vi*) ethyl acetate (1000 mL) to give 12 crude fractions. Fractions A and B (126.30 and 178.25 mg respectively) were complex mixtures of minor components and were not further investigated, while fractions C and D (198.84 and 49.34 mg respectively) consisted of two major components (see below for the separation). Fractions E and F (489.19 and 64.06 mg respectively) yielded β-sitosterol (**24**), while fractions G, H, and I (69.81, 46.35, and 38.15 mg respectively) were complex mixtures and were not further investigated. Fractions J and K (815.16 and 195.71 mg respectively) contained orange-coloured quinone methides and polpunonic acid (**25**) (see below for the separation), and fraction L yielded oleanolic acid (**23**, 564.65 mg).

The identities of β-sitosterol, polpunonic acid, and oleanolic acid were confirmed by comparison with authentic samples.

Separation of fractions C and D

Fractions C and D were subjected to preparative tlc (Merck silica gel 60 F_{254}, 2 mm) using methylene chloride – ethyl acetate 19:1 (the plate was eluted twice) and a further separation using methylene chloride – hexanes 1:1 (the plate was eluted three times), to give an inseparable mixture (121.81 mg) of two compounds that spectral data suggests is a mixture of α-amyrin (**12**) and β-amyrin (**13**), and the diterpene **14** (49.68 mg).

*α-Amyrin (**12**) and β-amyrin (**13**)*

The identity of this mixture was confirmed by comparing a 1:1 mixture of authentic α- and β-amyrins by nmr spectroscopy (^{1}Hmr and ^{13}Cmr).

*12-Methoxyabieta-8,11,13-trien-3α-ol (**14**)*

Colourless needles (hexanes); mp 157–158°C; $[\alpha]^{22}$ +44 (*c* 0.72, $CHCl_3$); ir ($CHCl_3$) cm^{-1}: 3620 (OH), 2951 (CH); ^{1}Hmr ($CDCl_3$) δ: 0.96 (3H, s, C4-CH_3), 1.05 (3H, s, C4-CH_3), 1.20 (3H, s, C10-CH_3), 1.20 (3H, d, $CH(CH_3)_2$, *J* = 7), 1.21 (3H, d, $CH(CH_3)_2$, *J* = 7), 1.26–2.17 (11H, m), 2.76 (1H, ddd, H7α, *J* = 2, 7, 16), 3.02 (1H, dd, H7β, *J* = 7, 16), 3.28 (1H, septet, H15), 3.51 (1H, brt, H3β, $W_{1/2}$ = 7), 3.72 (3H, s, OCH_3), 7.04 (1H, s, H11), 7.05 (1H, s, H14); ^{13}Cmr ($CDCl_3$) δ: 18.2, 22.1, 23.9, 24.0, 24.7, 24.8, 25.9, 26.0, 28.1, 29.7, 31.7, 37.7, 43.3, 60.2, 75.5, 120.4, 123.7, 128.5, 137.9, 148.9, 154.8; ms *m/z* (rel. int., %): 316 (M^+, 20.9), 301 (4.7), 283 (100.0), 241 (4.6), 215 (5.1), 199 (3.6), 189 (6.9), 173 (5.7), 159 (4.1), 147 (4.8), 129 (4.5), 115 (3.9), 91 (4.1), 81 (2.0), 69 (3.4), 55 (5.6), 43 (9.8). High-resolution mass measurement: calcd. for $C_{21}H_{32}O_2$: 316.2404; found: 316.2411.

Separation of fractions J and K

Fractions J (815.16 mg) and K (195.71 mg) were combined (1.01 g) and partially separated by column chromatography (Merck silica gel 230–400 mesh, 100 g). Gradient elution was carried out using: (*i*) methylene chloride – ethyl acetate 19:1 (750 mL); (*ii*) methylene chloride – ethyl acetate 9:1 (700 mL); and (*iii*) ethyl acetate (200 mL) to give 9 fractions. Fractions 1 and 2 (13.18 and 36.17 mg respectively) contained a major orange-coloured compound and a minor compound, while fraction 3 (62.11 mg) consisted of two orange-coloured compounds. Fractions 4 and 5 (25.97 and 21.21 mg respectively) consisted of a major orange-coloured compound and a minor component. Fractions 6 and 7 (28.69 and 232.43 mg respectively) showed two compounds on tlc, while fractions 8 and 9 (411.67 and 40.97 mg respectively) consisted of one major compound and several minor compounds.

Separation of fractions 1 and 2 by preparative tlc (Merck silica F_{254}, 0.5 mm, chloroform–methanol 98.2), followed by a further separation using toluene – ethyl acetate – chloroform – formic acid 35:15:16:1 yielded tingenone (**15**, 15.30 mg) and the friedelane methyl ester (**16**, 13.62 mg). Separation of fraction 3 by preparative tlc (Merck silica F_{254}, 0.5 mm, toluene – ethyl acetate – chloroform – formic acid 35:15:16:1, plate eluted twice) gave tingenone (**15**, 14.00 mg) and 22β-hydroxytingenone (**17**, 13.04 mg). Fractions 4 and 5 were separated by preparative tlc (Merck silica F_{254}, 0.5 mm, chloroform–methanol 98:2) to yield 22β-hydroxytingenone (**17**, 15.55 mg) and an unidentified mixture (9.12 mg). Column chromatography of fraction 7 (Merck silica gel 230–400 mesh, 25 g, methylene chloride – ethyl acetate 5:1) gave the dihydroxy triterpene, **18** (50.75 mg), an unidentified mixture (27.27 mg), and the triterpene, **19** (28.48 mg). Column chromatography of fractions 8 and 9 (Merck silica gel 230–400 mesh,

For personal use only.

50 g, methylene chloride – ethyl acetate 5:1) gave polpunonic acid (**25**, 247.13 mg).

In summary, chromatographic separation yielded tingenone (**15**, 29.30 mg), the friedelane methyl ester, **16** (13.62 mg), 22β-hydroxytingenone (**17**, 28.59 mg), the dihydroxy triterpenes, **18** (50.75 mg) and **19** (28.48 mg), and polpunonic acid (**25**, 247.13 mg).

*Tingenone (**15**)*

The identity of the isolated sample was confirmed by comparison of the physical and spectral data with those of the authentic sample.

*Methyl-22β-hydroxy-3,21-dioxo-D:A-friedo-29-noroleanan-24-oate (**16**)*

Yellow crystals (EtOH); mp 250–251°C; $[\alpha]^{22}$ +101.4 (*c* 0.22, MeOH); uv (meOH) λ_{max} 203 (ε 1810); ir ($CHCl_3$) cm^{-1}: 3460 (OH, br), 3010, 2950 (CH), 1725 (C=O, sh), 1710 (C=O), 1700 (C=O, sh); ^{1}Hmr ($CDCl_3$) δ: 0.80 (3H, s), 0.84 (3H, s), 0.91 (3H, d), 0.94 (3H, s), 1.07 (3H, d), 1.36 (3H, s), 3.64 (3H, s, OCH_3), 1.16–1.85 (14H, m), 2.02 (1H, m), 2.15–2.38 (5H, m), 2.60–2.65 (2H, m), 2.77 (1H, m, H20α), 3.66 (1H, s, OH), 4.61 (1H, brd, H22α); ms *m/z* (rel. int., %): 486 (M^+, 100.0), 471 (3.1), 468 (5.2), 426 (75.2), 411 (7.6), 399 (16.7), 398 (16.7), 385 (19.5), 357 (5.7), 340 (13.4), 317 (27.0), 257 (27.5), 231 (15.0), 217 (29.5), 203 (14.0), 189 (16.7), 177 (17.5), 163 (21.2), 149 (25.8), 135 (36.5), 121 (81.1), 109 (67.7), 95 (55.2), 81 (51.3), 67 (44.2), 55 (60.6). High-resolution mass measurement: calcd. for $C_{30}H_{46}O_5$: 486.3343; found: 486.3352.

*22β-Hydroxytingenone (**17**)*

All physical and spectral data of the isolated sample were identical with the data published earlier (26–30).

*3β,29-Dihydroxyolean-12-ene (**18**)*

Colourless prisms (EtOH); mp 241–242°C; $[\alpha]^{22}$ +115.9 (*c* 0.82, MeOH); ir (KBr) cm^{-1}: 3294 (OH), 2946 (CH); ^{1}Hmr ($CDCl_3$) δ: 0.80 (3H, s), 0.85 (3H, s), 0.91 (3H, s), 0.94 (3H, s), 0.97 (3H, s), 1.00 (3H, s), 1.14 (3H, s), 0.73–2.02 (25H, m), 3.22 (1H, dd, H3α, J = 3.5, 11), 3.27 (2H, d, H29, J = 5.5), 5.21 (1H, t, H12); ms *m/z* (rel. int., %): 442 (M^+, 6.1), 427 (1.8), 411 (9.6), 393 (0.5), 288 (0.7), 273 (1.0), 234 (100.0), 219 (8.7), 203 (21.1), 201 (21.3), 187 (21.6), 175 (13.1), 161 (8.1), 147 (14.3), 135 (18.5), 119 (19.1), 107 (19.8), 95 (28.0), 81 (22.9), 69 (18.0), 55 (21.9). High-resolution mass measurement: calcd. for $C_{30}H_{50}O_2$: 442.3813; found: 442.3805.

Chromatographic separation of the spent medium extract metabolites (compare Fig. 4)

The spent medium extract (3.06 g) was partially separated by vlc using a 150-mL sintered glass funnel (medium frit, Merck silica 60G, 90 g). Stepwise elution was carried out using: (*i*) benzene (5 × 30 mL); (*ii*) benzene–acetone 5:1 (19 × 30 mL); (*iii*) benzene–acetone 4:1 (19 × 30 mL); (*iv*) benzene–acetone 3:1 (12 × 30 mL); (*v*) benzene–acetone 2:1 (230 mL); (*vi*) benzene–acetone 1:1 (18 × 30 mL), and (*vii*) ethyl acetate (250 mL) to give 22 crude fractions. All the fractions were complex mixtures of metabolites. Fractions 3, 4, 5, 6, and 7 (204.68, 117.77, 158.08, 72.62, and 58.75 mg, respectively) were separated further by preparative tlc (Merck silica F_{254}, 4 × 2 mm plates, fractions 6 and 7 were combined) using toluene – ethyl acetate – chloroform-formic acid 35:15:161 (the plates were eluted three times) to give oleanolic acid (**23**, 59.66 mg), the hydroxy acid, **20** (134.63 mg), triptolide (**2**, 179.09 mg), and a complex mixture (168.31 mg) that was not further investigated. Fractions 8, 9, 10, 11, 12, and 13 (71.00, 113.66, 44.34, 84.0, 63.94, and 222.09 mg, respectively) were separated by preparative tlc (Merck silica F_{254}, 5 × 2 mm plates, 1 × 0.5 mm plate (fraction 10), toluene – ethyl acetate – chloroform – formic acid 35:15:16:1, the plates were eluted four times) to give **3** (13.22 mg), a mixture of **3** and **4** (10.30 mg), **4** (21.72 mg), a mixture of **4**, **5**, and **6** (42.48 mg), **5** (8.73 mg), **6** (25.53 mg), tripdiolide (**1**, 199.77), and a complex mixture (166.65 mg). Fractions 14, 15, and 16 (80.90, 38.65, and 10.96 mg, respectively) were separated by preparative tlc (Merck silica F_{254}, 1 × 2 mm plate (fraction 14), 1 × 0.5 mm plate (fractions 15 and 16), toluene – ethyl acetate – chloroform – formic acid 35:15:16:1, the plates were eluted three times) to give **6** (48.10 mg). Fractions 17 and 18 (56.27 and 151.71 mg, respectively) were separated by preparative tlc (1 × 0.5 mm plate and 1 × 2 mm plate, respectively, benzene–methanol – acetic acid 90:5:5, the plates were eluted three times) to give a further quantity of **6** (30.67 mg). Attempted separation of fractions 19–22 (174.08, 83.45, 39.59, and 49.50 mg, respectively) by preparative tlc (Merck silica F_{254}, 2 × 2 mm plates, benzene–methanol – acetic acid 90:5:5, the plates were eluted three times) was unsuccessful due to the complexity of the mixture of polar compounds.

The identity of all isolated compounds was confirmed by comparison of physical and spectral data with those of the original samples and (or) with data published earlier.

Appendix A

X-ray crystallographic analyses of compounds 6, 15, 16, 17, 18, and 19.

Experimental

X-ray crystallographic analyses of ***6***·*MeOH,* ***15***·*1/2EtOAc,* ***16****,* ***17***·*1/2* H_2O*,* ***18****, and* ***19***·*EtOH*

Crystallographic data for the six compounds appear in Table A1. The final unit-cell parameters were obtained by least squares on the setting angles for 25 reflections with 2θ = 34.0–41.3, 40.1–56.5, 46.6–76.3, 20.0–35.8, 40.4–72.5, and 40.1–70.8° for **6**·MeOH, **15**·1/2EtOAc, **16**, **17**·1/2 H_2O, **18**, and **19**·EtOH, respectively. The intensities of three standard reflections, measured every hour of X-ray exposure time for **6**·MeOH and every 150 reflections for the remaining compounds throughout the data collections, remained essentially constant except for **15**·1/2 EtOAc and **19**·EtOH where 4.6% and 19.2% decay, respectively, were noted. The data were processed[3] and corrected for Lorentz and polarization effects, linear decay for **15**·1/2 EtOAc and **19**·EtOH, and absorption for **15**·1/2 EtOAc, **16**, **17**·1/2 H_2O, **18**, and **19**·EtOH (empirical, based on azimuthal scans for four reflections).

The structure analyses of **16** and **19**·EtOH were initiated in the noncentrosymmetric space group $P2_1$ on the basis of the known chirality of these compounds. The structures were solved by direct methods, the coordinates of the non-hydrogen atoms being determined from *E*-maps and subsequent difference Fourier syntheses. The asymmetric units of **15**, **16**, and **18** each contain two molecules and those of **6**, **15**, **17**, and **19** contain solvent molecules (methanol, ethyl acetate, water (1/2 molecule), and ethanol respectively). The solution of the structure of **16** by direct methods was not routine. The structure was eventually solved by excluding all *h*0*l* reflections from the phase determination. This led to the isolation of *one* correctly oriented, but incorrectly positioned, molecule. This oriented fragment was then positioned and the atoms of the second molecule in the asymmetric unit were located by direct methods for difference structures using the computer program DIRDIF.[3] The ethyl acetate solvate molecule in **15**·1/2 EtOAc was disordered. Site occupancy factors were initially estimated from relative Fourier map peak heights and were subsequently adjusted[4] to result in approximately equal equivalent isotropic thermal parameters for the eight positions included in the model. All non-hydrogen atoms were refined with anisotropic thermal parameters. Oxygen-bound hydrogen atoms were refined with isotropic thermal parameters (**6**·MeOH and **16**) or placed in difference map positions, and for all six structures the carbon-bound hydrogen atoms were fixed in idealized positions (C(sp^2)—H = 0.97, C(sp^3)—H = 0.98 Å, $U_H \propto U_{\text{bonded atom}}$ for **6**·MeOH and C—H = 0.98 Å, $B_H = 1.2\,B_{\text{bonded atom}}$ for the other five structures). Neutral atom scattering factors and anomalous dispersion corrections for the non-hydrogen atoms were taken from the *International tables for X-ray crystallography* (38). The absolute configurations of **6**, **15**, and **17**–**19** are based on known configurations for one or more of the chiral centres and that of **16** has been determined by anomalous scattering. Parallel refinements of the opposite enantiomers were carried out for the four structures determined with Cu radiation, resulting in marginally higher residuals in each case. For compound **16**, the R and R_w ratios are both 1.003, representing a confidence level of 99.5%. Final atomic coordinates and equivalent isotropic thermal parameters, bond lengths, bond angles, and intra-annular torsion angles appear in Tables A2–A5, respec-

[3]Computer programs used include locally written programs for data processing and locally modified versions of the following for the structure of **6**·MeOH: MULTAN80, multisolution program by P. Main, S. J. Fiske, S. E. Hull, L. Lessinger, G. Germain, J. P. Declercq, and M. M. Woolfson; ORFLS, full-matrix least squares, and ORFFE, function and errors, by W. R. Busing, K. O. Martin, and H. A. Levy; FORDAP, Patterson and Fourier syntheses, by A. Zalkin; ORTEP II, illustrations, by C. K. Johnson. The TEXSAN/TEXRAY structure analysis package, which includes versions of the following, was employed for the other five structures: MITHRIL, integrated direct methods, by C. J. Gilmore; DIRDIF, direct methods for difference structures, by P. T. Beurskens; ORFLS, full-matrix least squares, and ORFFE, function and errors, by W. R. Busing, K. O. Martin, and H. A. Levy; ORTEP II, illustrations, by C. K. Johnson.

[4]Attempts to refine even some of the population parameters led to nearly singular matrices due to high correlations with the thermal parameters.

[a]Temperature 294 K, function minimized $\Sigma w(|F_o| - |F_c|)^2$ where $w = 4F_o^2/\sigma^2(F_o^2)$, $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$, $R_w = (\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2)^{1/2}$, and gof $[\Sigma(|F_o| - |F_c|)^2/(m - n)]^{1/2}$. Values given for R, R_w, and gof are based on those reflections with $I \geq 3\sigma(I)$.

[b]Enraf–Nonius CAD4-F diffractometer, Mo-K_α radiation ($\lambda K_{\alpha 1}$ = 0.70930, $\lambda K_{\alpha 2}$ = 0.71359 Å), graphite monochromator, takeoff angle 2.7°, apertu (2.0 + tan θ) × 4.0 mm at a distance of 173 mm from the crystal, scan range extended by 25% on both sides for background measurement, $\sigma^2(I) = C + 2B$ $[0.04(C - B)]^2$ (S = scan rate, C = scan count, B = normalized background count).

[c]Rigaku AFC6S diffractometer, Cu-K_α(λ = 1.54178 Å) or Mo-K_α(λ = 0.71069 Å) radiation, graphite monochromator, takeoff angle 6.0°, aperture 6.0 6.0 mm at a distance of 285 mm from the crystal, stationary background counts at each end of the scan (scan/background time ratio 2:1, up to 8 rescans $\sigma^2(F^2) = [S^2(C + 4B) + (0.04F^2)^2]/Lp^2$($S$ = scan rate, C = scan count, B = normalized background count).

tively. Hydrogen atom parameters, anisotropic thermal parameters, stereoviews of the molecules, packing diagrams (where relevant), and measured and calculated structure factor amplitudes for the six structures are included as supplementary material.[5]

Discussion of crystal structures

The crystal structure of **6**·MeOH features extensive hydrogen bonding, the methanol solvate molecule being involved in two hydrogen bonds: a very strong hydrogen bond to the carboxylic acid function and a strong hydrogen bond to a hydroxyl group (O(4)—H(O4)···O(5) and O(5)—H(O5)···O(1), O···H = 1.65(4) and 1.84(6) Å, O···O = 2.595(4) and 2.742(4) Å, O—H···O = 167(4) and 175(5)°). There are also two weaker hydrogen bonds directly linking each molecule of **6** to four others (O(1)—H(O1)···O(2) and O(2)—H(O2)···O(3), O···H = 2.07(5) and 2.00(6) Å, O···O = 2.813(4) and 2.848(4) Å, O—H···O = 176(5) and 168(4)°). All of the saturated six-membered rings have chair conformations and the unsaturated C ring has a sofa conformation. The saturated ring fusions A:B, B:C, and D:E are *trans*, *trans*, and *cis*, respectively.

The crystal structure of **15**·1/2 EtOAc consists of molecules of **15** and ethyl acetate, those of the triterpene being linked into infinite chains extending along the c axis by O—H···O hydrogen bonds between the O(2) hydroxyl group and the O(1) carbonyl oxygen atom (O(2)—H(36)···O(1′) and O(2′)—H(36′)···O(1), H···O = 1.83 and 1.83 Å, O···O = 2.726(6) and 2.659(7) Å, O—H···O = 153 and 136°,

[5]Supplementary material mentioned in the text may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0R6.

Tables of hydrogen atom parameters, stereoviews of the molecules, and relevant packing diagrams have also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW, U.K.

respectively). The same atoms are also involved in intramolecular hydrogen bonds (O(2)—H(36)···O(1) and O(2′)—H(36′)···O(1′), H···O = 2.27 and 2.11 Å, O···O = 2.673(6) and 2.683(7) Å, O—H···O = 104 and 113°, respectively). The solvent molecules are not involved in any short intermolecular contacts. The saturated ring junctions C:D and D:E are *trans* and *cis*, respectively. The aromatic A ring deviates slightly from planarity while the B ring has an irregular C(9)-envelope conformation and the C, D, and E rings have chair conformations. The two independent molecules exhibit some structural differences, particularly in the torsion angles (see Table A5). These differences (also noted for the crystallographically independent molecules of **16** and **18**) are not chemically significant and most likely arise from asymmetry in the packing arrangement.

The structure of **16** consists of molecules separated by normal van der Waals distances; the most significant intermolecular contact is O(2)···H(51) = 2.55 Å. As for compound **15**, there is intramolecular hydrogen bonding between the O(3)/O(8) hydroxyl group and the adjacent O(2)/O(7) carbonyl function (O(3)—H(1)···O(2) and O(8)—H(47)···O(7), H···O = 1.91(8) and 2.09(8) Å, O···O = 2.628(5) and 2.621(6) Å, O—H···O = 117(6) and 116(6)°, respectively). The A:B, B:C, C:D, and D:E ring junctions are *trans*, *trans*, *trans*, and *cis*, respectively. All five rings of the triterpene skeleton have chair conformations. Only minor differences are noted for the two crystallographically independent molecules.

The lattice-held water molecule in **17**·1/2 H_2O lies on a crystallographic C_2 axis and is hydrogen-bonded to

the carbonyl oxygen atoms O(1) of two molecules of **17**(O(5)—H(37)···O(1), H···O = 1.96 Å, O···O = 2.910(6) Å, O—H···O = 176°). O(1) is also hydrogen-bonded to the O(4) hydroxyl group (at C(22)) of another molecule of **17** related by a screw axis, forming a one-dimensional H-bonded array of molecules of **17** and water (O(4)—H(36)···O(1), H···O = 1.91 Å, O···O = 2.809(5) Å, O—H···O = 165°). The saturated ring junctions C:D and D:E are *trans* and *cis*, respectively. The aromatic A ring deviates slightly from planarity; the B ring has a flattened C(9)-envelope conformation; and the C, D, and E rings have chair conformations.

The structure of **18** is dominated by O—H···O hydrogen bonding which is not the same for the two independent molecules. All of the hydroxyl groups are hydrogen bond donors, but the unprimed molecule O(1) accepts one strong H-bond and O(2) accepts two (one weak and one strong) while the primed molecule acts as an acceptor for only one hydrogen bond (via O(2′)) (O(1)—H(49)···O(2), O(2)—H(50)···O(1), O(1′)—H(49′)···O(2′), and O(2′)—H(50′)···O(2); H···O = 2.41, 1.64, 1.83, and 1.70 Å; O···O = 2.710(5), 2.710(5), 2.693(5), and 2.747(4) Å; O—H···O = 117, 160, 134, and 167°; respectively). The A:B and B:C ring junctions are *trans* and the D:E junction is *cis*. The unsaturated C ring has a C(8)-sofa conformation and the other four rings all have chair conformations.

In the solid state structure of **19**·EtOH, molecules of **19** are directly hydrogen-bonded to one another and to the ethanol solvate molecules, each of the three hydroxyl groups (two from **19** and that of the EtOH solvate) acting as both donor and acceptor (O(1)—H(54)···O(2), O(2)—H(55)···O(3), and O(3)—H(56)···O(1); H···O = 1.70, 1.66, and 1.80 Å; O···O = 2.758(4), 2.739(5), and 2.768(5) Å; O—H···O = 163, 153, and 169°; respectively). The ring junctions and ring conformations within the triterpene skeleton are as noted above for **18**.

Bond lengths and angles for all six structures are generally as expected (see Tables A3 and A4). There is some shortening of distances resulting from thermal motion, for example in the EtOH solvate molecule of **19**·EtOH, and some lengthening due to steric effects such as the long bond between fully substituted ring junction atoms in **6**(C(8)—C(14) = 1.592(4) Å).

Aluminum chloride catalyzed Diels–Alder reactions of bicyclic dienones of the hexalone type with 1,3-butadiene, isoprene, (*E*)-piperylene, and (*E*)-1-methoxy-1,3-butadiene are described. Structure analysis of the adducts by NMR spectroscopy is presented. The site-, *endo–exo*-, and face-selectivity of the reactions are discussed.

LUCIO MINUTI, ROBERTA SELVAGGI, ALDO TATICCHI, MING GUO et ERNEST WENKERT. Can. J. Chem. **70**, 1481 (1992).

On décrit des réactions de Diels–Alder catalysées par le chlorure d'aluminium entre des diénones bicycliques du type de l'hexalone et le buta-1,3-diène, l'isoprène, le (*E*)-pipérylène et le (*E*)-1-méthoxybuta-1,3-diène. On présente une analyse structurale des adduits qui est basée sur la spectroscopie RMN. On discute des sélectivités entre les sites, *endo/exo* et entre les faces de ces réactions.

Recently it was shown that hexalone **2***a* undergoes cycloaddition with (*E*)-1-methoxy-1,3-butadiene (**3***d*) and 2,3-dimethyl-1,3-butadiene at its least substituted (i.e., γ, δ) carbon–carbon double bond site, providing a facile route of synthesis of functionalized hydrophenanthrenones (2). To determine the generality of the process, reactions now have been carried out with 1,3-butadiene (**3***a*), isoprene (**3***b*), and (*E*)-piperylene (**3***c*). Furthermore, since the hydrophenanthrenones could be envisaged to serve as intermediates en route to steroids and (or) tricarbocyclic diterpenes, if the angular methyl group were located at the proper bridgehead, Diels–Alder reactions of hexalone **2***b* with dienes **3***a–d* were undertaken also.[3]

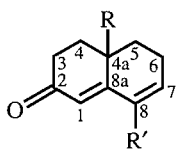
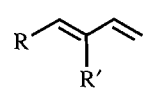
a, R = Me, R′ = H; *b*, R = H, R′ = Me



2



3*a*, R = R′ = H
b, R = H, R′ = Me
c, R = Me, R′ = H
d, R = OMe, R = H

The cycloadditions of hexalones **2***a* and **2***b*, prepared from octalone **1***b* (4) by dehydrogenation with chloranil (2, 5), were performed in dry toluene solution under aluminum chloride catalysis except for the reaction with dienol ether **3***d*, which was executed under non-catalytic, thermal conditions. Interactions of dienone **2***a* with 1,3-butadiene (**3***a*) and isoprene (**3***b*) afforded adducts **4***a* and **4***b* in 33 and 18% yield, respectively, and with (*E*)-piperylene (**3***c*) a 9:1 mixture of adducts **4***c* and **5** in 62% yield. All products were kinetically based Diels–Alder adducts, as shown by the constancy of the product ratio throughout the course of the last reaction, by the absence of appearance of other volatile products (monitored by gc analysis) during all reactions, and, finally, by the maintenance of product integrity on resubmission of pure adducts **4** and **5** to the reaction conditions.

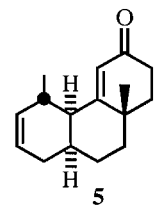
b, R = H, R′ = Me
c, R = Me, R′ = H



5

The Diels–Alder reaction of dienone **2***b* with 1,3-butadiene (**3***a*) furnished adducts **7***a* and **6***a* as a 2.3:1 mixture in 37% yield. Observation of the reaction progress by gc analysis revealed isomerization of adduct **6***a* into ketone **7***a*. Furthermore, exposure of pure tricycle **7***a* to the reaction conditions led to its nearly quantitative recovery, whereas the same treatment of adduct **6***a* yielded a **6***a*–**7***a* mixture enriched in the latter ketone. The cycloaddition of dienone **2***b* with isoprene (**3***b*) was so poor as to preclude isolation of any adduct.[4] On the other hand, interaction of hexalone **2***b* with (*E*)-piperylene (**3***c*) gave products **8**, **6***b*, and **7***b* as a 1.4:1.1:1 mixture in 45% yield. As in the aforementioned butadiene reaction, adduct **6***b* was transformed into ketone **7***b* throughout the course of the reaction (gc analytically monitored).

Finally, cycloaddition of dienone 2b with (*E*)-1-methoxy-1,3-butadiene (**3***d*) at 170°C without catalyst led to ketones **6***c*, **9**, **10**, and **7***c* as a 6.3:4.6:2.4:1 mixture in 42% yield. Whereas samples of pure adducts **7***c* and **9** proved stable to the reaction conditions, adduct **10** was transformed into a **9**–**10** mixture and adduct **6***c* decomposed into intractable material.

10

Product structures

The structure determination of all cycloaddition products rests mostly on their NMR analyses. Comparison of the carbon shifts of the **2***a*-based adducts (Table 1) and inspection of the $^1H-^1H$ and $^1H-^{13}C$ connectivities (COSY spectra) of the tricycles **4***b* and **4***c* reveals their regiochemistry. The all-*cis* arrangement of H(10a), H(4a), and the 8a-methyl group of compounds **4** emanates from the similarity of the chemical shifts of relevant carbons and the coupling characteristics of relevant hydrogens with those of Diels–Alder adducts of like stereochemistry and etablished configuration (2). Finally, the absence of a γ-effect on C(10a) and the observation of a strong *peri* interaction with H(5) (i.e., considerable deshielding of this hydrogen) shows the 4-methyl group of ketone **4***c* to be equatorial and hence a 4α substituent.

2D NMR analysis of adducts **5** and a strong β-effect exerted on C(4a) by the neighboring methyl group reveal the regiochemistry of ketone **5**. The ca. 3 ppm deshielding of its angular methyl group (vs. the methyl shift of ketone **1***a* and ketones **4**) indicates the removal of a γ-effect (i.e., the loss of the axial H(4aβ)) and thus an inversion of the C(4a) and C(10a) stereochemistry. The deshielding of C(1) and C(9), showing the disappearance of a reciprocal γ-effect, is in accord with the inverted configuration at the two cycloaddition centers. Finally, the absence of any H(3)–H(4) coupling, indicative of a ca. 90° H(3)—C(3)—C(4)—H(4) dihedral angle, limits the 4-methyl group to an equatorial (hence 4α) configuration.

NMR analysis of the **2***b*-based Diels–Alder adducts (Table 2) shows them to fit into two structure patterns, *a* (**6** and **10**) and *b* (**7** and **9**), leaving ketone **8** as a unique system. The latter's carbonyl infrared absorption band (1707 cm^{-1}) and carbonyl carbon shift (211.8 ppm) show tricycle **8**, in contrast to the other substances, to be a non-conjugated enone. Furthermore, the appearance of two strongly coupled (20 Hz) C(5) hydrogens (2.67 and 3.07 ppm) in the ^1H NMR spectrum and of non-protonated, olefinic carbon signals in the ^{13}C NMR spectrum is in accord with the β,γ-unsaturated ketone structure depicted in formula **8**. The simplest stereochemical differentiation of the adducts of structure type *a* from those of *b* is the strong, reciprocal γ-effect exhibited by C(1) and C(9) in *a*-like compounds (as earlier in ketones **4**), indicative of the axiality of C(1) toward the central ring and hence of a *cis*-β relationship of the 4a-methyl group with H(8a) and H(10a).

Examination of the hydrogen connectivities (by the COSY method) of all cyclohexene-substituted substances reveals the secondary methyl group or the methoxy function to be attached to C(4), thus settling the regiochemistry of ketones **6**–**10**. Shift comparison of *a*-like ethers **6***c* and **10** shows C(10a) of the latter strongly shielded, indicative of a γ-effect, of a 1,3-diaxial MeO–H(10a) relationship and of the presence of a β-methoxy group in ketone **10** and a 4α-ether in ketone **6***c*. Comparison of the angular methyl shifts of ethers **7***c* and **9** portrays the methyl group of the former to be strongly shielded (γ-effect), characteristic of a *cis* methoxy-methyl relationship in compound **7***c* and a *trans*-diaxial one in ether **9**. The H(3)–H(4) coupling behavior of the four ethers confirms their methoxy configurations. Thus 3–4 Hz coupling in ketones **9** and **10** is in agreement with the presence of an equatorial H(4α) substituent in these compounds. Nearly zero coupling in ketones **6***c* and **7***c*, indicative of a ca. 90° dihedral H(3)—C(3)—C(4)—H(4) bonding arrangement, points to an axial H(4β) for these ethers. The C(4) shift of the ethers is also diagnostic of their configurations. The strong C(4) shielding of ketone **10** (vs. **6***c*) shows a γ-effect from C(5), blocked by the methoxy group in ketone **6***c*, and the strong C(4) shielding of cycloadduct **7***c* (vs. **9**) due to γ-effects exerted by C(8a) and C(10) is precluded in adduct **9** by the 4β-methoxy group. Great similarity of carbon shifts of comparable sites of ketones **6***b* and **6***c* as well as of compounds **7***b* and **7***c* reveals that the secondary methyl compounds to possess stereochemistry identical to their ether counterparts. The shielding of the secondary methyl hydrogens of tricycle **7***b* (vs. **6***b*) reflects (as seen in models) the methyl function being more in the shielding zone of the C(4b)–C(5) double bond in this compound vs. its isomer **6***b*. The interconvertibility of ketones **6***b* and **7***b* and the lack of isomerization of either substance into a β,γ-unsaturated ketone (*vide supra*) suggests the immediate precursor of ketone **8** to be 4-epi-**6***b* or 4-epi-**7***b*. The ^1H NMR spectrum of the non-conjugated ketone reveals its secondary methyl hydrogens to be quite shielded (0.87 ppm), a fact accommodated most readily by a *trans*-diaxial relationship of the two methyl groups, placing, as a consequence, the secondary methyl group within the shielding cone of the C(4b)–C(8b) double bond.

Discussion

Several interesting facts emerge from the above cycloaddition processes. Firstly, as in the earlier two examples (2), the reactions are fully site-selective and regioselective. Secondly, reactions at γ, δ sites of dienones afford lower product yields than those at α, β sites of enones, especially with dienes, e.g., isoprene (**3***b*), which are sterically encumbering in the transition state. Thirdly, the reactions of dienone **2***a* are mostly *anti*-diastereoselective, in accord with expectations (6). Its interaction with (*E*)-piperylene (**3***c*) leads predominantly to *anti-endo* product accompanied by some *syn-exo* product, reflecting the interplay of stabilizing secondary orbital interactions with destabilizing nonbonded steric repulsions in the transition states resulting from diene attack on the two dienone faces in *endo* or *exo* mode (7). Fourthly, the major product of the **2***b*–**3***c* reaction (under either acid catalysis or thermal conditions) is a ketone (**8**) of anomalous structure, which could be shown experimentally not to be derived from its accompanying products **6***b* and **7***b*. It presumably represents a product of rapid double bond isomerization of an elusive 4-epi-**7**.

The most surprising result is the discovery of the Diels–Alder reactions of dienone **2***b* being strongly under thermodynamic control, permitting conversion of *anti* adducts into *syn* adducts. [4+2] Cycloreversions are rare among substances liberating acyclic dienes and the reason for the facile cycloreversion of ketones **6** and **10** in the face of the stability of ketones **4** remains an enigma.

Experimental section[5]

*4,4a,5,6-Tetrahydro-8-methyl-2(3*H*)-naphthalenone (***2***b)*, prepared according to a known procedure (2, 5) by oxidation of octalone **1***b* (4) (H-8β isomer: ^{1}H NMR δ: 0.95 (d, 3, J = 6 Hz, Me), 5.70 (s, 1, H-1); ^{13}C NMR δ: 17.1 (Me), 25.1 (C-6), 28.2 (C-4), 34.3 (C-5), 35.1 (C-7), 36.0 (C-3), 37.9 (C-4a, C-8), 120.6 (C-1), 170.8 (C-8a), 200.0 (C-2). H-8α isomer: ^{1}H NMR δ: 0.97 (d, 3, J = 6 Hz, Me), 5.67 (s, 1, H-1); ^{13}C NMR δ: 19.4 (C-6), 20.1 (Me), 28.9 (C-4), 31.9 (C-7), 33.4 (C-4a), 34.0 (C-5), 36.1 (C-3), 37.4 (C-8), 123.5 (C-1), 171.9 (C-8a), 199.9 (C-2)) with chloranil in *tert*-butanol: colorless liquid (52% yield); bp 87–88°/0.15 Torr (1 Torr = 133.3 Pa); IR: C=O 1648 (s), C=C 1624 (s), 1581 (m) cm^{-1}; ^{1}H NMR δ: 1.84 (br s, 3, Me), 5.92 (s, 1, H-1), 6.15 (br s, 1, H-7); ^{13}C NMR δ: 18.9 (Me), 25.9 (C-6), 29.5 (C-4), 30.2 (C-5), 35.7 (C-4a), 37.5 (C-3), 120.8 (C-1), 131.6 (C-8), 136.9 (C-7), 159.1 (C-8a), 200.4 (C-2); MS *m/e* (rel. intensity): 162 (M^+, 56), 134 (80), 119 (20), 105 (33), 91 (base), 77 (21). Anal. calcd. for $C_{11}H_{14}O$: C 81.44, H 8.70; found: C 81.40, H 8.70.

General procedure for the Diels–Alder reactions

The mixtures of the starting materials were prepared in a dry box and the cycloadditions were carried out in degassed solutions. Table 3 delineates the conditions of the Diels–Alder reactions, the following discussion describing the **2***a*–**3***a* reaction in greater detail.

A solution of 1.00 g (6.2 mmol) of ketone **2***a* in 6.5 mL of dry toluene was added slowly to 5.6 mL (5.6 mmol) of a stirring 1.0 M solution of $AlCl_3$ in nitrobenzene at room temperature and stirring was continued for 40 min. A 4.0 M toluene solution (18.5 mL, 74 mmol) of 1,3-butadiene (**3***a*) was added and the ampule was sealed under vacuum and heated at 55°C for 117 h. The ampule was cooled and opened and the contents poured into ice water. The mixture was extracted with ether and the extract was washed with 10% $NaHCO_3$ solution and saturated brine, dried (Na_2SO_4), and evaporated under vacuum. Nitrobenzene was removed by vacuum distillation and the residue purified by medium-pressure chromatography on a prepacked Merck Lichoprep Si 60 column and elution with 33:1 hexane – ethyl acetate, leading to 400 mg (30%) of ketone **4***a*.

*8aβ-Methyl-1,4,4aβ,8,8a,9,10,10aβ-octahydro-6(7*H*)-phenanthrenone (***4***a):* colorless, crystalline solid; mp 84–85°C (hexane); IR: C=O 1660 (s), C=C 1610 (w) cm^{-1}; ^{1}H NMR δ: 1.29 (s, 3, Me), 2.76 (br t, 1, J = 4 Hz, H-4a), 5.58 (s, 2, H-2, H-3), 5.75 (s, 1, H-5); MS *m/e* (rel. intensity): 216 (M^+, 60), 134 (73), 91 (base), 79 (56), 77 (55). Anal. calcd. for $C_{15}H_{20}O$: C 83.29, H 9.32; found: C 83.40, H 9.35.

*2,8aβ-Dimethyl-1,4,4aβ,8,8a,9,10,10aβ-octahydro-6(7*H*)-phenanthrenone (***4***b):* colorless, crystalline solid; mp 118–119°C (hexane): IR: C=O 1660 (s), C=C 1610 (w) cm^{-1}; ^{1}H NMR δ: 1.29 (s, 3, Me), 1.57 (br s, 3, 2-Me), 2.70 (br t, 1, J = 4 Hz, H-4a), 5.28 (br s, 1, H-3), 5.74 (s, 1, H-5); MS *m/e* (rel. intensity): 230 (M^+, 53), 163 (95), 134 (base), 105 (43), 91 (70). Directed *ortho* metalation – radical-induced cyclization synthetic connections. A route to highly substituted benzofurans[1]

MASAO TSUKAZAKI AND VICTOR SNIECKUS
Guelph–Waterloo Centre for Graduate Work in Chemistry, University of Waterloo, Waterloo, Ont., Canada N2L 3G1

Received September 30, 1991

MASAO TSUKAZAKI and VICTOR SNIECKUS. Can. J. Chem. **70**, 1486 (1992).

The synthesis of benzofurans **20***a–c*, which constitute analogues of 5-lipoxygenase inhibitors **4**, is described. The route, representing a potential general method for benzofuran construction, proceeds from phenyl carbamate **11** and involves key directed *ortho* metalation (**11** → **12**), anionic *ortho*-Fries rearrangement (**12** → **13***a*), and radical-induced cyclization (**17***a–c* → **18***a–c*) steps.

MASAO TSUKAZAKI et VICTOR SNIECKUS. Can. J. Chem. **70**, 1486 (1992).

On décrit la synthèse des benzofuranes **20***a–c* qui constituent des analogues des produits **4**, des inhibiteurs de la 5-lipoxygénane. La voie, qui correspond à une méthode générale potentielle de synthèse des benzofuranes, utilise le carbamate de phényle **11** comme produit de départ et elle implique une métallation orientée en *ortho* (**11** → **12**), une transposition anionique *ortho*-Fries (**12** → **13***a*) et une cyclisation induite par des radicaux (**17***a–c* → **18***a–c*).

Steeped in the fundamental studies of radical reactivity (1), the 5-*exo*-trig ring closure of aryl butenyl systems has emerged as a versatile and broadly useful synthetic reaction especially for heteroannelation routes to benzofuran (2) and indole (3) ring systems. As part of a dominant theme of linking the directed *ortho* metalation strategy (4) to other modern synthetic methods (5), we previously developed a radical-induced cyclization route to benzodihydrofurans, **2** → **3** (Scheme 1) (2*a*) whose regiochemistry is determined by regiospecific halogen introduction, **1** → **2**, courtesy of the synergistic effects of *meta*-related directed metalation groups (DMGs). The major consequence of this fact is the ability to derive, from rationally formulated aromatics (**1**), a variety of substituted benzofurans (**3**) whose construction normally involves difficult and prolonged classical sequences (6).

Since 2- and 3-substituents may be conveniently introduced into benzofurans by metalation (7) and electrophilic substitution (6), we focussed on demonstrating the value and efficacy of the combined metalation – radical cyclization chemistry by incorporating scope in the assemblage of **1**. Thus the recent reports by Merck Frosst chemists of a new benzofuran class (**4**) of 5-lipoxygenase inhibitors, of potential value in treatment of inflammatory and allergic diseases,[2] sparked our interest because of its display of a diverse array of benzene ring substituents. Herein we report a successful route to such systems (**19**, **20**) that not only constitutes a new and potentially general benzofuran assemblage but also complements the previous very comprehensive synthetic work (9) in that it delivers unavailable substitution patterns in **4**. The strategy is based on constructing pentasubstituted benzenes **5** as key intermediates for radical cyclization using *O*-aryl carbamate metalation chemistry (**6**). The envisaged retrosynthesis, in-between metalation (step 1) followed by anionic *ortho*-Fries rearrangement (10) (step 2) and *ipso* bromo desilylation (11) (step 3), has previously found utility for the preparation of polysubstituted aromatics (10) and elaboration of natural products (12, 13). The faster rate of metal–halogen exchange compared to DMG-induced deprotonation (4) precludes consideration of direct introduction of the bromo substituent (step 3).

In initial experiments, the synthesis of the differentially *O*-protected tetrasubstituted aromatic **10** (Scheme 2) was explored from the OMOM carbamate **7**. Metalation followed by silylation afforded the expected **8**, which upon a second metalation under standard −78°C conditions and chlorination led exclusively to the carbamoyl migration product **9**. Although synthetically befitting in other situations (12, 13) (see below), this result points to the facility of the anionic *ortho*-Fries rearrangement in sterically encumbered systems (14). The required product **10** was obtained by carrying out the metalation and chlorination at −100°C but in a yield (48%) that discouraged the continuation of this sequence.

In the ultimately successful sequence, bis-carbamate **11** (Scheme 3), prepared from commercial 4-chlororesorcinol, was subjected to metalation–silylation to give **12** with excellent regioselectivity and in high yield. A minor amount of bis-silylated by-product was easily separated (see experimental section). Anionic *ortho*-Fries rearrangement proceeded smoothly to give **13***a*, which, upon standard methylation, afforded **13***b*. The silylation – carbamate rearrangement was also carried out in a one-pot procedure to give a satisfactory yield (68%) of **13***a*. Although *ipso* bromodesilylation of **13***b* to give **16** occurred in high yield, the conversion of this product to the corresponding phenol was not achieved even under forcing conditions (20% NaOH/EtOH–H_2O/reflux), presumably owing to steric effects. Attempts to hydrolyze the carbamate **13***b* under mild basic conditions (3% LiOH/THF) furnished only the desilylated material **15***a*; only under more vigorous base treatment (10% NaOH/EtOH–H_2O) was decarbamoylation achieved but also with loss of the TMS group to give phenol **15***b*. With this material available and an eye on Occam's razor, classical electrophilic bromination was pursued and gave, pleasantly, the key bromophenol **14** in excellent yield.

To set the stage for radical-induced cyclization, com-

[1]Dedicated to Denny Valenta with appreciation and respect for his many imaginative leaps in synthetic organic chemistry.

[2]See ref. 8*a* for chemistry, ref. 8*b* for chemistry and biology, of these compounds.

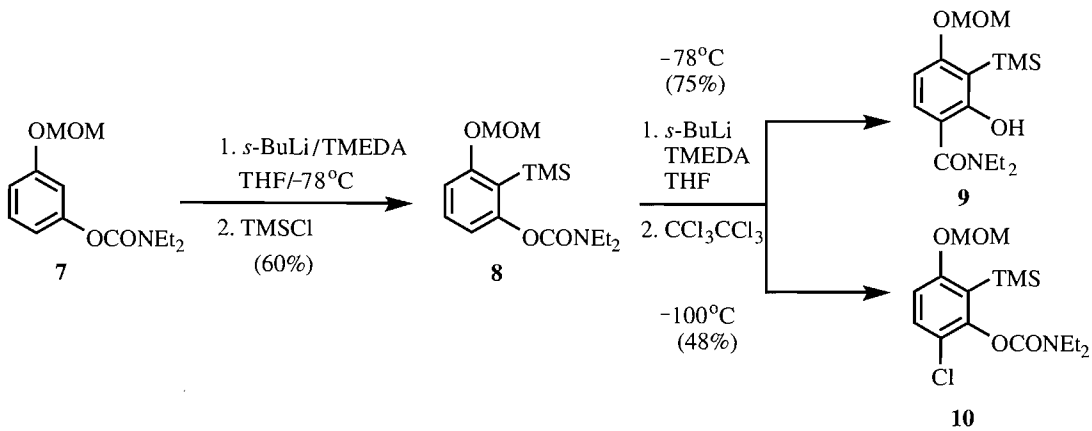

SCHEME 2

pound **14** (Scheme 4) was converted into the *O*-allyl (**17***a*), *O*-propargyl (**17***b*), and *O*-acryloyl (**17***c*) derivatives. Application of standard cyclization conditions (Bu_3SnH/AIBN/PhH/reflux) afforded benzofurans **18***a* (93%), **18***b* (39%), and **18***c* (35%). The unsatisfactory yields of functionalized products **18***b* and **18***c*, expected for **17***b* (2*a*) and due to partial reduction for **17***c*, necessitated the development of dehydrogenation conditions for conversion of **18***a* into benzofuran **19**. After numerous attempts with reagents known to effect this transformation (DDQ/PhH or dioxan/reflux/5–11 days (54–68%); NBS/CCl_4/room temp./12 h (35%); Pd–C/MeCN/reflux/24 h (0%), use of activated MnO_2 was found to give the desired **19** in reasonable yield and time frame.

pK_a considerations (4, 15) argue in favor of deprotonation of **19** at the 2- rather than at the 6-position. In the event, treatment with *n*-BuLi/THF/0°C and LDA/THF/0°C followed by TMSCl quench (−78°C) afforded the 2-silylated benzofurans **20***a* in 54% and 71% yield, respectively. Application of the more favorable conditions for benzoyl chloride and *p*-anisaldehyde electrophiles led to the corresponding products **20***b* and **20***c* in similar yields.

In summary, several new benzofuran analogues to the Merck Frosst 5-lipoxygenase inhibitors **4** have been synthesized.[3] The synthesis takes advantage of regiospecific di-

[3]Selected compounds prepared in this study were subjected to broad screening by Merck Frosst Canada and showed insignificant activity (Dr. R. N. Young, personal communication).

rected *ortho* metalation and anionic rearrangement of *O*-aryl carbamates (**11** → **12** → **13**) to construct key intermediates (**14**) for radical-induced cyclization (**17** → **18**). In view of the existing rich metalation chemistry (4), the use of this new strategy for the general construction of benzofurans with aromatic ring substitution patterns not readily achieved by other methods is anticipated. For the potential preparation of congeners to **4**, we note that reduction of 2-benzoyl derivatives analogous to **20***b* have previously been reported (9) and further directed metalation-mediated C-6 functionalization may be feasible.

Experimental section

General procedures

Melting points were recorded on a Buchi SMP-20 apparatus and are uncorrected. IR spectra were recorded on a Perkin–Elmer 983

spectrometer. ^{1}H NMR spectra were recorded on Bruker AM-250 and AC-200 instruments in $CDCl_3$ with tetramethylsilane as an internal standard. Microanalyses were performed by Oneida Research Services, Whitesboro, N.Y. Mass spectra were determined on a high-resolution Varian MAT-CH7 instrument.

n-BuLi, *s*-BuLi, *t*-BuLi, diisopropylamine (DIA), *N,N,N',N'*-tetramethylethylenediamine (TMEDA) and 4-chlororesorcinol were purchased from Aldrich Chemical Co. The titer of all alkyllithiums were determined prior to use with 2,5-dimethoxybenzylalcohol as a standard. DIA and TMEDA were dried and distilled from CaH_2 and stored under argon. THF was freshly distilled from sodium benzophenone ketyl prior to use. Metalation reactions were performed in oven- or flame-dried glassware under argon, using syringe – septum cap techniques. The phrase "standard work-up" is the equivalent of addition of saturated NH_4Cl solution, extraction with diethyl ether, washing the organic extract with brine, drying ($MgSO_4$), filtration, and evaporation to dryness *in vacuo*. TLC was performed on E-Merck silica gel 60 strips and medium pressure column chromatography was carried out on BDH silica gel 60 (0.04–0.063 and 0.063–0.20 mm with hexane/EtOAc (1:1 to 10:1) eluent unless otherwise indicated.

N,N-*Diethyl O-(3-methoxymethoxyphenyl) carbamate (7)*

To a solution of *N,N*-diethyl *O*-(3-methoxyphenyl) carbamate (17.8 g, 80.0 mmol) in CH_2Cl_2 (200 mL) was added BBr_3 (11.3 mL, 120 mmol) at −78°C. The mixture was warmed to room temperature and stirred overnight. After cooling to −78°C, the reaction was quenched with MeOH. Standard work-up followed by recrystallization gave *N,N*-diethyl *O*-(3-hydroxyphenyl) carbamate (15.4 g, 92%): mp 62–63°C (Et_2O–hexane) (lit. (16) mp 64–66°C); IR ($CHCl_3$) ν(max): 1695 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 1.23 (t, 6H, J = 7.1 Hz), 3.43 (q, 4H, J = 7.1 Hz), 6.52–6.74 (m, 3H), 7.08–7.29 (m, 2H); MS *m/e* (rel. intensity): 209 (M^+, 100). A solution of *N,N*-diethyl (3-hydroxyphenyl) carbamate (10.5 g, 50.0 mmol) in DMF was added to a suspension of NaH (60 mmol) in DMF at 0°C. After 1 h, chloromethyl methyl ether (4.56 mL, 60.0 mmol) was added and the mixture was warmed to room temperature and stirred overnight. Standard work-up followed by distillation afforded **7** (9.98 g, 79%): bp 138–140°C (1.2 Torr); IR (neat) ν(max): 1710 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 1.21 (t, 6H, J = 7.1 Hz), 3.42 (q, 4H, J = 7.1 Hz), 3.45 (s, 3H), 5.15 (s, 2H), 6.71–6.94 (m, 3H), 7.24 (dd, 1H, J = 7.3 and 8.8 Hz); MS *m/e* (rel. intensity): 253 (M^+, 100). Anal. calcd. for $C_{13}H_{19}NO_4$: C 61.64, H 7.56, N 5.52; found: C 61.65, H 7.76, N 5.26.

N,N-*Diethyl O-(3-methoxymethoxy-2-trimethylsilylphenyl) carbamate (8)*

A solution of **7** (5.06 g, 20.0 mmol) dissolved in dry THF (5 mL) was added dropwise to a stirred solution of 1:1 *s*-BuLi–TMEDA (24.0 mmol) mixture in dry THF (200 mL) at −78°C. After 1 h, TMSCl (3.81 mL, 30.0 mmol) was added slowly and the reaction mixture was allowed to warm to room temperature. Standard work-up afforded crude product, which was purified by column chromatography followed by distillation to give pure **8** (3.84 g, 60%); bp 160–162°C (1.5 Torr); IR (neat) ν(max): 1716 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 0.30 (s, 9H), 1.19 (t, 3H, J = 7.1 Hz), 1.24 (t, 3H, J = 7.1 Hz), 3.38 (q, 2H, J = 7.1 Hz), 3.44 (q, 2H, J = 7.1 Hz), 3.46 (s, 3H), 5.15 (s, 2H), 6.62 (dd, 1H, J = 8.1 and 0.6 Hz), 6.91 (dd, 1H, J = 8.3 and 0.6 Hz), 7.26 (dd, 1H, J = 8.1 and 8.3 Hz); MS *m/e* (rel. intensity): 325 (M^+, 1). HRMS calcd. for $C_{16}H_{27}No_4Si$: 325.1710; found: 325.1687.

N,N-*Diethyl 2-hydroxy-4-methoxymethoxy-3-trimethylsilylbenzamide (9)*

Using the above procedure, **8** (1.63 g, 5.00 mmol) was treated with *s*-BuLi–TMEDA (6.00 mmol) at −78°C. Standard work-up followed by column chromatography gave pure **9** (1.27 g, 78%); mp 49–50°C (Et_2O–hexane); IR (KBr) ν(max): 1615 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 0.34 (s, 9H), 1.26 (t, 6H, J = 7.1 Hz), 3.47 (s, 3H), 3.49 (q, 4H, J = 7.1 Hz), 5.16 (s, 2H), 6.54 (d, 1H, J = 8.7 Hz), 7.21 (d, 1H, J = 8.7 Hz), 10.53 (s, 1H); MS *m/e* (rel. intensity): 325 (M^+, 36). HRMS calcd. for $C_{16}H_{27}NO_4Si$: 325.1710; found: 325.1704.

N,N-*Diethyl O-(6-chloro-3-methoxymethoxy-2-trimethylsilyl) carbamate (10)*

The procedure for the preparation of **8** was followed except that the metalation was carried out at −100°C. From **8** (0.650 g, 2.00 mmol) and *s*-BuLi–TMEDA (2.40 mmol) in THF and hexachloroethane (0.615 g, 2.60 mmol) as the electrophile, there was obtained 0.345 g (48%) of **10** as an oil; IR (neat) ν(max): 1724 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 0.30 (s, 9H), 1.20 (t, 3H, J = 7.2 Hz), 1.29 (t, 3H, J = 7.2 Hz), 3.29–3.65 (m, 4H), 3.46 (s, 3H), 5.13 (d, 1H, J = 6.7 Hz), 5.15 (d, 1H, J = 6.7 Hz), 6.90 (d, 1H, J = 8.8 Hz), 7.30 (d, 1H, J = 8.8 Hz); MS *m/e* (rel. intensity): 359 (M^+, 1). HRMS calcd. for $C_{16}H_{27}NO_4SiCl$: 359.1321; found: 359.1310.

N,N-*Diethyl O-[4-chloro-3-(*N,N-*diethylcarbamoyloxy)phenyl] carbamate (11)*

A solution of 4-chlororesorcinol (7.23 g, 50.0 mmol) and *N,N*-diethyl carbamoyl chloride (15.2 mL, 120 mmol) in pyridine (50 mL) was refluxed for 12 h. The solvent was removed and the resulting residue was dissolved in ether (200 mL). The ether layer was washed successively with water, 2 N HCl, 2 N NaOH, and brine and dried ($MgSO_4$). Removal of ether *in vacuo* followed by distillation gave pure **11** (14.2 g, 83%, bp 178–180°C/0.1 Torr); IR (neat) ν(max): 1717 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 1.07–1.33 (m, 12H), 3.31–3.52 (m, 8H), 6.96 (dd, 1H, J = 2.7 and 8.8 Hz), 7.11 (d, 1H, J = 2.7 Hz), 7.37 (d, 1H, J = 8.8 Hz); MS *m/e* (rel. intensity): 342 (M^+, 2). Anal. calcd. for $C_{16}H_{23}N_2O_4Cl$: C 56.06, H 6.76, N 8.17; found: C 55.96, H 6.57, N 8.28.

N,N-*Diethyl O-[4-chloro-3-(*N,N-*diethylcarbamoyloxy)-2-trimethylsilylphenyl] carbamate (12)*

To a stirred solution of **11** (3.43 g, 10.0 mmol) in THF (150 mL) at −78°C was added a solution of *t*-BuLi (6.67 mL of 1.65 M solution, 11.0 mmol). After stirring for 30 min, the solution was treated with TMSCl (1.90 mL, 15.0 mmol) and then allowed to warm to room temperature. Standard work-up followed by column chromatography gave **12** (3.53 g, 85%): mp 58–59°C (hexane); IR (KBr) ν(max): 1717 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 0.30 (s, 9H), 1.19 (t, 3H, J = 7.1 Hz), 1.20 (t, 3H, J = 7.1 Hz), 1.23 (t, 3H, J = 6.8 Hz), 1.30 (t, 3H, J = 7.1 Hz), 3.26–3.66 (m, 8H), 6.83 (d, 1H, J = 8.7 Hz), 7.37 (d, 1H, J = 8.7 Hz); MS *m/e* (rel. intensity): 415 (M^+ +1, 92). Anal. calcd. for $C_{19}H_{31}N_2O_4SiCl$: C 54.99, H 7.53, N 6.75; found: C 54.96, H 7.53, N 6.71.

N,N-*Diethyl 5-chloro-4-(*N,N-*diethylcarbamoyloxy)-2-hydroxy-3-trimethylsilylbenzamide (13*a*)*

According to the procedure for the preparation of **9**, **12** (2.06 g, 4.97 mml) was treated with *s*-BuLi–TMEDA (5.56 mmol). Standard work-up followed by recrystallization gave **13***a* (1.64 g, 80%); mp 103–104°C (Et_2O–hexane); IR (KBr) ν(max): 1616, 1717 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 0.33 (s, 9H), 1.21 (t, 3H, J = 7.1 Hz), 1.27 (t, 6H, J = 7.0 Hz), 1.31 (t, 3H, J = 7.0 Hz), 3.29–3.64 (m, 8H), 7.29 (s, 1H), 10.37 (s, 1H); MS *m/e* (rel. intensity): 415 (M^+ +1, 1). Anal. calcd. for $C_{19}H_{31}N_2O_4SiCl$: C 54.99, H 7.53, N 6.75; found: C 54.91, H 7.48, N 6.69.

N,N-*Diethyl 5-chloro-4-(*N,N-*diethylcarbamoyloxy)-2-methoxy-3-trimethylsilylbenzamide (13*b*)*

A mixture of **13***a* (1.87 g, 4.52 mmol), methyl iodide (1.13 mL, 1.81 mmol), and K_2CO_3 (6.21 g, 45.2 mmol) in acetone was refluxed for 1 h. Standard work-up followed by column chromatography and recrystallization gave **13***b* (1.63 g, 84%); mp 85–86°C (Et_2O–hexane); IR (KBr) ν(max): 1627, 1721 cm^{-1}; ^{1}H NMR δ ($CDCl_3$): 0.31 (s, 9H), 1.07 (t, 3H, J = 7.0 Hz), 1.20 (t, 3H, J = 7.0 Hz), 1.25 (t, 3H, J = 7.1 Hz), 1.29 (t, 3H, J = 7.1 Hz), 3.18–3.71 (m, 8H), 3.76 (s, 1H), 7.29 s, 1H); MS *m/e*

For personal use only.

(rel. intensity): 429 (M^+ +1, 1). Anal. calcd. for $C_{20}H_{33}N_2O_4SiCl$: C 55.99, H 7.75, N 6.53; found: C 55.99, H 7.82, N 6.56.

N,N-*Diethyl 2-bromo-5-chloro-4-hydroxy-2-methoxybenzamide (**14**)*

To a stirred solution of **15***b* (4.34 g, 16.8 mmol) and triethylamine (3.51 mL, 25.2 mmol) in $CHCl_3$ at 0°C was added dropwise Br_2 (1.07 mL, 20.2 mmol). After stirring for 30 min, the mixture was quenched with 5% $Na_2S_2O_3$ aqueous solution. Standard work-up followed by recrystallization gave **14** (5.21 g, 92%); mp 150–151°C (CH_2Cl_2–Et_2O); IR (KBr) ν(max): 1608 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.06 (t, 3H, *J* = 7.1 Hz), 1.25 (t, 3H, *J* = 7.1 Hz), 3.17 (q, 2H, *J* = 7.1 Hz), 3.37–3.82 (m, 2H), 3.87 (s, 3H), 6.47 (br s, 1H), 7.20 (s, 1H); MS *m/e* (rel. intensity): 336 (M^+ +1, 25). Anal. calcd. for $C_{12}H_{15}NO_3ClBr$: C 42.82, H 4.49, N 4.16; found: C 42.69, H 4.66, N 4.12.

N,N-*Diethyl 5-chloro-4-hydroxy-2-methoxybenzamide (**15**b)*

13*b* (5.15 g, 12.0 mmol) was dissolved into 10% NaOH/EtOH–H_2O solution (100 mL) and refluxed for 4 h. After removal of EtOH, the solution was acidified with concentrated HCl. The resulting white solid was collected and recrystallized to give **15***b* (2.78 g, 91%): mp 190–191°C (CH_2Cl_2–EtO_2); IR (KBr) ν(max): 1617 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.05 (t, 3H, *J* = 7.1 Hz), 1.23 (t, 3H, *J* = 7.1 Hz), 3.16 (q, 2H, *J* = 7.1 Hz), 3.54 (q, 3H, *J* = 7.1 Hz), 3.69 (s, 3H), 6.49 (s, 1H), 7.06 (br s, 1H), 7.09 (s, 1H); MS *m/e* (rel. intensity) 258 (M^+ +1, 31). Anal. calcd. for $C_{12}H_{16}NO_3Cl$: C 55.93, H 6.26, N 5.43; found: C 55.70, H 6.84, N 5.43.

N,N-*Diethyl 3-bromo-5-chloro-4-(*N,N-*diethylcarbamoyloxy)-2-methoxybenzamide (**16**)*

13*b* (0.429 g, 1.00 mmol) and Br_2 (0.11 mL, 2.0 mmol) were dissolved in CH_2Cl_2 (20 mL) and the solution was refluxed for 2 h. Standard work-up followed by column chromatography gave **16** (0.413 g, 95%) as an oil; IR (neat) ν(max): 1638, 1737 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.06 (t, 3H, *J* = 7.1 Hz), 1.23 (t, 3H, *J* = 7.1 Hz), 1.25 (t, 3H, *J* = 7.1 Hz), 1.35 (t, 3H, *J* = 7.1 Hz), 3.16 (q, 2H, *J* = 7.1 Hz), 3.36–3.57 (m, 5H), 3.67–3.80 (m, 1H), 3.87 (s, 2H), 7.27 (s, 1H); MS *m/e* (rel. intensity): 436 (M^+ +2, 8). HRMS calcd. for $C_{17}H_{24}N_2O_4ClBr$: 434.0609; found: 434.0598.

N,N-*Diethyl 3-bromo-5-chloro-2-methoxy-4-(2-propenyloxy)benzamide (**17**a)*

A mixture of **14** (0.522 g, 1.55 mmol), allyl bromide (0.27 mL, 3.1 mmol), and K_2CO_3 (1.07 g, 7.75 mmol) in acetone was heated at reflux for 2 h. Standard work-up followed by column chromatography gave **17***a* (0.574 g, 98%) as an oil; IR (neat) ν(max): 1635 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.07 (t, 3H, *J* = 7.1 Hz), 1.25 (t, 3H, *J* = 7.1 Hz), 3.16 (q, 2H, *J* = 7.1 Hz), 3.7 (m, 1H), 3.8 (m, 1H), 4.57 (ddd, 2H, *J* = 1.2, 1.3, and 5.9 Hz), 5.31 (dd, 1H, *J* = 1.2, 1.4, and 10.3 Hz), 5.46 (ddd, 1H, *J* = 1.5, 1.6, and 17.1 Hz), 6.17 (ddt, 1H, *J* = 10.3, 17.1, and 5.9 Hz), 7.23 (s, 1H); MS *m/e* (rel. intensity): 377 (M^+ +2, 10). Anal. calcd. for $C_{15}H_{19}NO_3ClBr$: C 47.83, H 5.08, N 3.72; found: 47.84, H 4.97, N 3.94.

N,N-*Diethyl 3-bromo-5-chloro-2-methoxy-4-(2-propynyloxy)benzamide (**17**b)*

The procedure for the preparation of **17***a* was followed. From **14** (0.337 g, 1.00 mmol), propargyl bromide (0.22 mL, 2.0 mmol), and K_2CO_3 (0.69 g, 5.0 mmol) there was obtained 0.367 g (98%) of **17***b* as an oil; IR (neat) ν(max): 1631 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.07 (t, 3H, *J* = 7.1 Hz), 1.25 (t, 3H, *J* = 7.1 Hz), 2.58 (t, 1H, *J* = 2.3 Hz), 3.15 (q, 2H, *J* = 7.1 Hz), 3.32–3.46 (m, 1H), 3.66–3.80 (m, 1H), 3.87 (s, 3H), 4.78 (d, 2H, *J* = 2.3 Hz), 7.24 (s, 1H); MS *m/e* (rel. intensity): 375 (M^+ +2, 31). HRMS calcd. for $C_{15}H_{17}NO_3ClBr$: 373.0081; found: 373.0083.

N,N-*Diethyl 4-acryloyloxy-3-bromo-5-chloro-2-methoxybenzamide (**17**c)*

To a solution of **14** (0.337 g, 1.00 mmol) in ether (20 mL) at 0°C were successively added triethylamine (0.28 mL, 2.0 mmol) and acryloyl chloride (0.12 mL, 1.5 mmol). The reaction mixture was stirred for 3 h at 0°C and warmed to room temperature. Standard work-up followed by column chromatography gave **17***c* (0.363 g, 93%) as an oil; IR (neat) ν(max): 1636, 1757 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.09 (t, 3H, *J* = 7.1 Hz), 1.26 (t, 3H, *J* = 7.1 Hz), 3.21 (q, 2H, *J* = 7.1 Hz), 3.32–3.50 (m, 1H), 3.66–3.82 (m, 1H), 3.88 (s, 3H), 6.14 (dd, 1H, *J* = 0.6 and 10.5 Hz), 6.39 (dd, 1H, *J* = 10.5 and 17.2 Hz), 6.72 (dd, 1H, *J* = 0.6 and 17.2 Hz), 7.30 (s, 1H); MS *m/e* (rel. intensity): 391 (M^++2, 17). HRMS calcd. for $C_{15}H_{17}NO_4ClBr$: 389.0030; found: 388.9992.

*7-Chloro-5-(*N,N-*diethylcarbamoyl)-4-methoxy-3-methyl-2,3-dihydrobenzofuran (**18**a)*

A solution of **17***a* (1.13 g, 3.00 mmol), Bu_3SnH (1.62 mL, 6.00 mmol), and AIBN (15 mg) in benzene (300 mL) was refluxed for 1 h. After removal of benzene, the residue was dissolved in CH_3CN (200 mL), washed with hexane (30 mL × 3), and evaporated. The product was purified by column chromatography to give **18***a* (0.830 g, 93%); mp 64–65°C (Et_2O–hexane); IR (KBr) ν(max): 1624 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.07 (t, 3H, *J* = 7.1 Hz), 1.24 (t, 3H, *J* = 7.1 Hz), 1.36 (d, 3H, *J* = 6.9 Hz), 3.20 (q, 2H, *J* = 7.1 Hz), 3.35–3.79 (m, 3H), 3.83 (s, 3H), 4.27 (dd, 1H, *J* = 5.5 and 8.9 Hz), 4.76 (t, 1H, *J* = 8.9 Hz), 7.01 (s, 1H); MS *m/e* (rel. intensity): 297 (M^+, 25). Anal. calcd. for $C_{15}H_{20}NO_3Cl$: C 60.50, H 6.77, N 4.70; found: 60.42, H 6.75, N 4.65.

*7-Chloro-5-(*N,N-*diethylcarbamoyl)-4-methoxy-3-methylene-2,3-dihydrobenzofuran (**18**b)*

The procedure for the preparation of **18***a* was followed. From **17***b* (0.356 g, 0.95 mmol), Bu_3SnH (0.51 mL, 1.90 mmol), and AIBN (10 mg) there was obtained 0.109 g (39%) of **18***a* as an oil; IR (neat) ν(max): 1620 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.07 (t, 3H, *J* = 7.1 Hz), 1.25 (t, 3H, *J* = 7.1 Hz), 3.14–3.78 (m, 4H), 3.85 (s, 3H), 5.16–5.21 (m, 3H), 5.72–5.76 (m, 1H), 7.07 (s, 1H); MS *m/e* (rel. intensity): 295 (M^+, 4).

*7-Chloro-5-(*N,N-*diethylcarbamoyl)-4-methoxy-3-methyl-2(3*H*)-benzofuranone (**18**c)*

The procedure for the preparation of **18***a* was followed. From **17***c* (0.365 g, 0.93 mmol), Bu_3SnH (0.50 mL, 1.07 mmol), and AIBN (10 mg) there was obtained 0.109 g (35%) of **18***c* as a oil; IR (neat) ν(max): 1624, 1820 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.09 (t, 3H, *J* = 7.1 Hz), 1.26 (t, 3H, *J* = 7.1 Hz), 1.64 (d, 3H, *J* = 7.6 Hz), 3.20 (q, 2H, *J* = 7.1 Hz), 3.34–3.77 (m, 3H), 3.87 (s, 3H), 7.17 (s, 1H); MS *m/e* (rel. intensity): 310 (M^+ −1, 66). HRMS calcd. for $C_{15}H_{18}NO_4Cl$: 311.0925; found: 311.0909.

*7-Chloro-5-(*N,N-*diethylcarbamoyl)-4-methoxy-3-methylbenzofuran (**19**)*

A mixture of **18***a* (0.100 g, 0.34 mmol) and MnO_2 (0.29 g) in benzene was heated under reflux for 12 h with azeotropic removal of water. The MnO_2 was removed by filtration and the filtrate was evaporated to dryness. The crude material was subjected to column chromatography to afford **19** (0.069 g, 69%); mp 90–91°C (Et_2O–hexane); IR (KBr) ν(max): 1624 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.06 (t, 3H, *J* = 7.1 Hz), 1.28 (t, 3H, *J* = 7.1 Hz), 2.36 (d, 3H, *J* = 1.3 Hz), 3.23–3.77 (m, 4H), 3.92 (s, 3H), 7.14 (s, 1H), 7.41 (q, 1H, *J* = 1.3 Hz); MS *m/e* (rel. intensity): 295 (M^+, 17). Anal. calcd. for $C_{15}H_{18}NO_3Cl$: C 60.91, H 6.13, N 4.74; found: C 60.96, H 6.17, N 4.70.

*7-Chloro-5-(*N,N-*diethylcarbamoyl)-4-methoxy-3-methyl-2-trimethylsilylbenzofuran (**20**a)*

To a solution of LDA (0.41 mmol, prepared *in situ* from *n*-BuLi and diisopropylamine) in THF (15 mL) was added a solution of **19** (0.100 g, 0.41 mmol) in THF at −78°C. The solution was warmed to 0°C and stirred for 30 min. After cooling to −78°C again, TMSCl (0.064 mL, 0.51 mmol) was added and the mixture was warmed to room temperature. Standard work-up followed by column chromatography gave **20***a* (0.090 g, 71%); mp 86–87°C (Et_2O–hexane); IR (KBr) ν(max): 1635 cm^{-1}; ^1H NMR δ ($CDCl_3$): 0.40 (s, 9H), 1.04 (t, 3H, *J* = 7.1 Hz), 1.27 (t, 3H, *J* = 7.1 Hz), 2.43 (s,

3H), 3.17–3.88 (m, 4H), 3.89 (s, 3H), 7.10 (s, 1H); MS *m/e* (rel. intensity): 367 (M^+, 33). HRMS calcd. for $C_{18}C_{26}NO_3SiCl$: 367.1372; found: 367.1356.

*2-Benzoyl-7-chloro-5-(*N,N*-diethylcarbamoyl)-4-methoxy-3-methylbenzofuran (**20**b)*

The procedure for the preparation of **20***a* was followed except that benzoyl chloride was added at −100°C. From **19** (0.178 g, 0.60 mmol), LDA (0.78 mmol), and benzoyl chloride (0.14 mL, 1.20 mmol) there was obtained 0.172 g (72%) of **20***b*; mp 89–90°C (Et_2O–hexane); IR (KBr) ν(max): 1624, 1646 cm^{-1}; ^1H NMR δ ($CDCl_3$): 1.08 (t, 3H, J = 7.1 Hz), 1.30 (t, 3H, J = 7.1 Hz), 2.80 (s, 3H), 3.2 (m, 2H), 3.4 (m, 1H), 3.8 (m, 1H), 3.97 (s, 3H), 7.32 (s, 1H), 7.49–7.67 (m, 3H), 8.12–8.16 (m, 2H); MS *m/e* (rel. intensity): 399 (M^+, 36). Anal. calcd. for $C_{22}H_{22}NO_4Cl$: C 66.08, H 5.55, N 3.50; found: C 66.05, H 5.45, N 3.48.

*7-Chloro-5-(*N,N*-diethylcarbamoyl)-4-methoxy-2-[(4-methoxyphenyl)hydroxymethyl]-3-methylbenzofuran (**20**c)*

The procedure for the preparation of **20***a* was followed. From **19** (0.296 g, 1.00 mmol) LDA (1.20 mmol), and *p*-anisaldehyde (0.164 mL, 1.20 mmol) there was obtained 0.328 g (76%) of **20***c*: mp 200–201°C (CH_2Cl_2–hexane); IR (KBr) ν(max): 3371, 1607 cm^{-1}; NMR δ ($CDCl_3$): 1.03 (t, 3H, J = 7.1 Hz), 1.27 (t, 3H, J = 7.1 Hz), 2.35 (s, 3H), 2.78 (br s, 1H), 3.2 (m, 2H), 3.4 (m, 1H), 3.7 (m, 1H), 3.81 (s, 3H), 3.88 (s, 3H), 5.96 (d, 1H, J = 5.6 Hz), 6.91 (d, 2H, J = 8.7 Hz), 7.09 (s, 1H), 7.42 (d, 2H, J = 8.7 Hz); MS *m/e* (rel. intensity): 431 (M^+, 51). Anal. calcd. for $C_{23}H_{26}NO_5Cl$: C 63.96, H 6.07, N 3.17; found: C 63.77, H 6.06, N 3.17.

The synthesis of norbornanes with functionalized carbon substituents at a bridgehead. 1-(3-Oxonorborn-1-yl)ethanone and 1-(3-oxonorborn-1-yl)-2-propanone

PETER YATES AND MAGDY KALDAS
Lash Miller Chemical Laboratories, University of Toronto, Toronto, Ont., Canada M5S 1A1

Received August 16, 1991

Dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

PETER YATES and MAGDY KALDAS. Can. J. Chem. **70**, 1492 (1992).

Treatment of 2-norobornene-1-carboxylic acid (**7**) with one equivalent of methyllithium in ether followed by a second molar equivalent after dilution with tetrahydrofuran gave 1-(norborn-2-en-lyl)ethanone (**10**) and only a trace of the tertiary alcohol **11**. Reaction of **7** with formic acid followed by hydrolysis gave a 4:3 mixture of *exo*-3- and *exo*-2-hydroxynorbornane-1-carboxylic acid (**16** and **17**), whereas oxymercuration–demercuration gave only the *exo*-3-hydroxy isomer **16**. Oxidation of **16** and **17** gave 3- and 2-oxonorbornane-1-carboxylic acid (**27** and **29**), respectively. Oxymercuration–demercuration of **10** gave exclusively 1-(*exo*-3-hydroxynorborn-1-yl)ethanone (**30**), which was also prepared by treatment of **16** with methyllithium in analogous fashion to that used for the conversion of **7** to **10**. Oxidation of **30** gave 1-(3-oxonorborn-1-yl)ethanone (**1**). Dehydrobromination of *exo*-2-bromonorbornane-1-acetic acid and dehydration of 2-hydroxy-norbornane-2-acetic acid derivatives gave 1-(norborn-2-ylidene)acetic acid derivatives to the exclusion of norborn-2-ene-1-acetic acid derivatives. Treatment of *exo*-5-acetyloxy-2-norobornanone (**52**) with ethyl bromoacetate and zinc gave ethyl *exo*-5-acetyloxy-2-hydroxynorbornane-*exo*- and *endo*-2-acetate (**53** and **54**). Reaction of **53** with hydrogen bromide gave initially ethyl *endo*-3-acetyloxy-*exo*-6-bromonorbornane-1-acetate (**59**), which was subsequently converted to a mixture of **59** and its *exo*-3-acetyloxy epimer **61**. Catalytic hydrogenation of this mixture gave a mixture of ethyl *endo*- and *exo*-3-acetyloxynorbornane-1-acetate (**62** and **63**). Basic hydrolysis of this gave a mixture of the corresponding hydroxy acids, **70** and **71**; the former was slowly converted to the latter at pH 5. Oxidation of the mixture of **70** and **71** gave 3-oxonorbornane-1-acetic acid (**72**). Treatment of the mixture with methyllithium as for **16** gave a mixture of 1-(*endo*- and *exo*-3-hydroxynorborn-1-yl)-2-propanone (**73** and **74**), which was oxidized to 1-(3-oxonorborn-1-yl)-2-propanone (**2**). Reaction of *exo*-2-hydroxynorbornane-1-acetic acid lactone (**75**) with methyllithium in ether gave (1-(*exo*-2-hydroxynorborn-1-yl)-2-propanone (**76**), which on oxidation gave the 2-oxo isomer **78** of **2**.

PETER YATES et MAGDY KALDAS. Can. J. Chem. **70**, 1492 (1992).

Le traitement de l'acide norborn-2-ène-1-carboxylique (**7**) par un équivalent de méthyllithium dans l'éther, suivi par un deuxième équivalent molaire après dilution avec du tétrahydrofurane, fournit de la 1-(norborn-2-èn-1-yl) éthanone (**10**) et que des traces de l'alcool tertiaire **11**. La réaction du produit **7** avec de l'acide formique, suivie d'une hydrolyse, fournit un mélange 4 : 3 des acides *exo*-3- et *exo*-2-hydroxynorbornane-1-carboxyliques (**16** et **17**) alors que l'oxymercuration suivie d'une démercuration ne donne que l'isomère *exo*-3-hydroxy **16**. Les oxydations des produits **16** et **17** conduisent respectivement aux acides 3- et 2-oxonorbornane-1-carboxyliques (**27** et **29**). L'oxymercuration–démercuration de **10** fournit exclusivement de la 1-(*exo*-3-hydroxynorborn-1-yl)éthanone (**30**) que l'on a aussi préparée par traitement du composé **16** avec du méthyllithium d'une façon analogue à celle utilisée pour transformer le composé **7** et **10**. L'oxydation de **30** fournit d la 1-(3-oxonorborn-1-yl)éthanone (**1**). L'enlèvement d'acide bromhydrique de l'acide *exo*-2-bromonorbornane-1-acétique et la déshydratation de dérivés de l'acide 2-hydroxy-norbornane-2-acétique fournit des dérivés de l'acide 1-(norborn-2-ylidène)acétique à l'exclusion de dérivés de l'acide norborn-2-ène-1-acétique. Le traitement de la *exo*-5-acétyloxy-norbornan-2-one (**52**) avec du bromoacétate d'éthyle et du zinc fournit des *exo*-5-acétyloxy-2-hydroxynorbornane-*exo*- et *endo*-2-acétates d'éthyle (**53** et **54**). La réaction du produit **53** avec du bromure d'hydrogène fournit initialement du *endo*-3-acyloxy-*exo*-6-bromonorbornane-1-acétate d'éthyle (**59**) qui se transforme subséquemment en un mélange du produit **59** et de son épimère *exo*-3-acétyloxy **61**. L'hydrogenation catalytique de ce mélange fournit un mélange des *endo*- et *exo*-3-acétyloxynorbornane-1-acétates d'éthyle (**62** et **63**). L'hydrolyse basique de ce mélange fournit un mélange des hydroxy-acides correspondants, **70** et **71**; à un pH de 5, le premier se transforme lentement vers le second. Une oxydation du mélange de **70** et de **71** fournit de l'acide 3-oxonorbornane-1-acétique (**72**). Le traitement du mélange avec un méthyllithium, suivant une procédure analogue à celle utilisée pour le composé **16**, fournit un mélange des 1-(*endo*- et *exo*-3-hydroxynorborn-1-yl) propan-2-ones (**73** et **74**) que l'on peut oxyder en 1-(3-oxonorbornyl-1-yl) propan-2-one (**2**). Le réaction de la lactone de l'acide *exo*-2-hydroxynorbornane-1-acétique (**75**) avec du méthyllithium dans l'éther donne de la 1-(*exo*-2-hydroxynorborn-1-yl) propan-2-one (**76**), qui par oxydation conduit à l'isomère 2-oxo **78** du produit **2**.

[Traduit par la rédaction]

In the course of our studies of the photochemistry of norbornanones (bicyclo[2.2.1]heptanones) (1), we undertook the synthesis of the diketones, 1-(3-oxonorborn-1-yl)ethanone (**1**) and 1-(3-oxonorborn-1-yl)-2-propanone (**2**). These relatively simple molecules turned out to be more difficult of access than we had anticipated. However, in the course of our synthetic investigations we made a number of observations of intrinsic interest, which we now report. The structures of compounds **1** and **2** and their precursors[1] follow from their elemental composition and methods of preparation, and from their spectra and the relationship of these to the spectra of related compounds (see Experimental).[2]

[1]All products are racemic and their structures are drawn without any implication of their absolute configurations.

[2]Their ^{13}C nmr spectra will be discussed elsewhere.

1-(3-Oxonorborn-1-yl)ethanone (1)

Of the relatively few known norbornane derivatives with a functionalized carbon substituent at a bridgehead, we chose 2-norbornene-1-carboxylic acid (**7**) as the starting material. This was prepared by the method of Wilt *et al.* (2) from *exo*-2-bromonorbornane-1-carboxylic acid (**5**), itself prepared from the diastereomeric mixture of norbornane-2-carboxylic acids (**4**) obtained on hydrogenation of the Diels–Alder adducts **3** of acrylic acid and cyclopentandiene (3) (Scheme 1). A key step in this sequence is the skeletal rearrangement in the bromination of **4** to give **5** (cf. ref. 4). The final dehydrobromination of the ester **6** followed by hydrolysis gives a mixture of the desired product **7** and the retro-rearrangement product **8** (cf. refs. 3 and 5). We found that the ratio of these products is critically dependent on the quality of the potassium *tert*-butoxide used in the dehydrobromination. When commerical potassium *tert*-butoxide was used, only compound **8** was isolated: when freshly prepared potassium *tert*-butoxide was used under scrupulously anhydrous conditions compound **7** was obtained to the virtual exclusion of **8**. We also found, as did Wilt *et al.* (2), that treatment of the bromo acid **5** with potassium *tert*-butoxide under anhydrous conditions gave predominantly the rearranged acid **8**, and thus it appears that the formation of **8** from **6** results from hydrolysis of the latter to **5** by potassium hydroxide in the commerical potassium *tert*-butoxide. Facilitation of rearrangement in the acid can be interpreted as resulting from stabilization of the transition state **9** by the carboxylate ion (Scheme 2).[3]

In our first route for the conversion of **7** to the target **1**, we investigated its conversion to 1-(norborn-2-en-1-yl)ethanone (**10**). Treatment with two molar equivalents of methyllithium in ether gave a 10:3 mixture of **10** and a tertiary alcohol that was not fully characterized, but which is considered to be **11** (Scheme 3). Although several of the modifications that are known to minimize the formation of the tertiary alcohol by-product (6) were exercised, formation of **11** could not be avoided. However, the use of tetrahydrofuran as solvent in the reaction with the second molar equivalent of methyllithium solved the problem. Our procedure involved addition of the first molar equivalent of methyllithium under minimun solvation conditions, i.e., with enough ether to dissolve **7** but not its lithium salt **12**, thus allowing the latter to precipitate, thereby rendering it relatively unreactive. After gas evolution had ceased, a second molar equivalent of ethereal methyllithium was added followed by tetrahydrofuran, which immediately dissolved **12**, and complete reaction was rapidly achieved to give what is presumed to be **13**. Aqueous acid work-up gave **10** containing only a trace of **11**; distillation provided pure **10** in 93% yield.

In a second route for the conversion of **7** to **1** we investigated the hydration of its ethylenic double bond. We considered that the use of methods involving cationic intermediates would favor the formation of the desired 3-hydroxy relative to the 2-hydroxy products because formation of an intermediate of type **14** rather than **15** would be preferred owing to the greater electrostatic destabilization by the carboxyl group in the latter. Treatment of **7** with formic acid gave a mixture of formates that, on basic hydrolysis, afforded a 4:3 mixture of *exo*-3-hydroxy-norbornane-1-carboxylic acid (**16**) and the known (5, 7) *exo*-2-hydroxy-norbornane-1-carboxylic acid (**17**) (Scheme 4). Although this reaction was highly stereoselective, its regioselectivity is poor, albeit qualitatively in accord with expectation. The reaction of **7** with mercuric acetate followed by sodium hydroxide and sodium borohydride was next examined. Oxymercuration–demercuration occurred very rapidly with both high stereoselectivity and high regioselectivity to give the *exo*-3-hydroxy compound **16** as the sole product (Scheme 4). The stereoselectivity is in accord with previous observations of *exo* nucleophilic attack on norbornyl cations (8). Brown *et al.* (9), for example, have previously observed high *exo* stereoselectivity in the addition of hydroxide ion to the intermediate **19**, formed on mercuration of 1-methyl-2-norbornene (**18**), to give **20** and **21** (Scheme 5). No significant regioselectivity was observed in this case. We consider that the high regioselectivity in the present case reflects both an electrostatic preference for **22** over **23** (cf. **14** vs. **15**) and interaction between the

[3]Alternatively, α- or β-lactonic intermediates may be involved (cf. ref. 2).

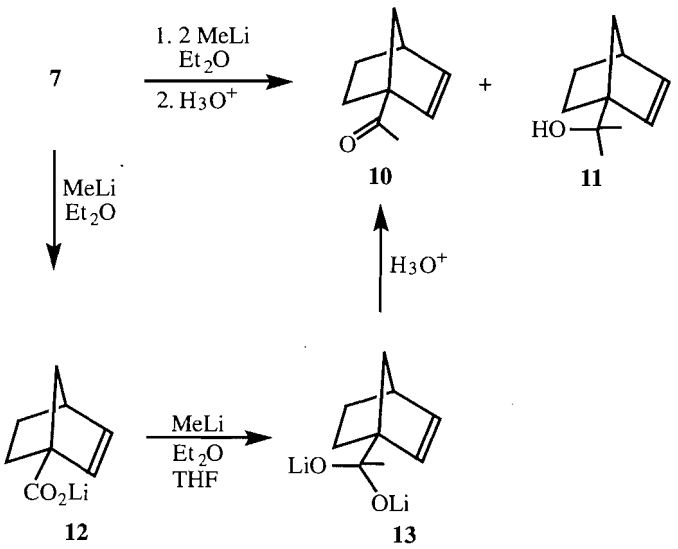

SCHEME 3

carbonyl group and mercury as in **24**.[4] That the hydroxyl group of the carboxylic acid **7** is not involved as such in this effect was established by the demonstration that **25**, the *tert*-butyl ester of **7**, prepared by treatment of the bromo methyl ester **6** with potassim *tert*-butoxide and *tert*-butyl alcohol (2), gave the *exo*-3-hydroxy ester **26** (Scheme 6) with high regioselectivity and stereoselectivity upon oxymercuration–demercuration.

Oxidation of *exo*-3-hydroxynorbornane-1-carboxylic acid (**16**) and its *tert*-butyl ester **26** with chromic acid and aqueous sulfuric acid in acetone (Jones reagent) gave 3-oxonorbornane-1-carboxylic acid (**27**) and its *tert*-butyl ester **28**, respectively. For comparison, the known 2-oxonorbornane-1-carboxylic acid **29** (5, 7) was prepared by Jones oxidation (11) of the 2-hydroxy acid **17**, itself prepared by treatment of the bromo acid **5** with aqueous acid (Scheme 6).

The two routes now converged on the target, 1-(3-oxonorborn-1-yl)ethanone (**1**). 1-(Norborn-2-en-1-yl)ethanone (**10**) on oxymercuration–demercuration gave exclusively 1-(*exo*-3-hydroxynorborn-1-yl)ethanone (**30**), which on oxidation with Jones reagent gave **1**. Compound **16** on treatment with two molar equivalents of methyllithium in ether followed by one equivalent in tetrahydrofuran in analogous fashion to the conversion of **7** to **10**, also gave **30** (Scheme 7).

[4]For a discussion of the effect of other C-1 substituents on the regioselectivity in the oxymercuration–demercuration and formylation of 2-norbornenes, see ref. 10.

1-(3-Oxonorborn-1-yl)-2-propanone (2)

In our initial approaches to the synthesis of the diketone **2** we sought to employ intermediates that we have utilized in the synthesis of **1**. The hydroxyl group of the hydroxy acid **16** was protected by conversion of the latter to *exo*-3-acetyloxynorbornane-1-carboxylic acid (**31**) by treatment with acetic anhydride, 4-(dimethylamino)pyridine, and triethylamine preparatory to attempting an Arndt–Esitert homologation to **32**. However, this sequence foundered when **31** could not be converted to its acid chloride **33** with oxalyl chloride, giving instead the acid anhydride **34**. An Arndt–Eistert homologation of *exo*-2-bromonorbornane-1-carboxylic acid (**5**) to **35** was also undertaken in the hope that the latter could be converted to 2-norbornene-1-acetic acid (**36**).[5] Here there was no problem in preparing the acid chloride **37**, which had been prepared previously (12), by treatment of **35** with oxalyl chloride, but attempted conversion of this with diazomethane to the α-diazo ketone **38** gave a mixture of products; this approach was discontinued owing to the difficulty of separating the components of this mixture.

We next investigated the utilization of ethyl *exo*-2-bromonorbornane-1-acetate (**39**), which is was planned to convert to the unsaturated ester **40**. The mixture of diastereomeric ethyl 2-hydroxynorbornane-2-carboxylates (**41**) prepared by the Reformatsky reaction of 2-norbornanone with ethyl bromoacetate and zinc (13), on treatment with hydrogen bromide in acetic acid gave **39** as the major product, accompanied by the corresponding bromo acid **35**, which is also obtained on hydrolysis of **39** with aqueous acid (Scheme 8). These reactions, which find analogy in the conversion of camphene-8-carboxylic acid (**42**) to the chloro acid **43** on treatment with hydrogen chloride (14) (cf. ref. 15), must proceed via Wagner–Meerwein rearrangement as in **44**. Treatment of **39** with potassium *tert*-butoxide in *tert*-butyl alcohol followed by hydrolysis gave a mixture of the rearranged dehydrobromination products (*E*)- and (*Z*)-(norborn-1-ylidene)acetic acid (**45** and **46**). These were formed in higher yield when **39** was treated with ethanolic sodium ethoxide followed by hydrolysis. In this case a third, unconjugated unsaturated acid was detected, which is considered to be **47**. Compounds **45** and **46** and their ethyl esters **48** and **49** are also formed on treatment of **35** and **41** with bases (Scheme 8). Compound **48** had been obtained previously in low yield by metalation of norcamphene (**50**) with amylsodium followed by carboxylation (16) (cf., also, ref. 17), and esters **48** and **49** by a Wittig reaction of 2-norbornanone (18).

[5]Wilt *et al.* (2) had previously prepared **36** by the Arndt–Eistert homologation of **7**; however, the modesty of the overall yield (15%) led us to seek other methods for its preparation.

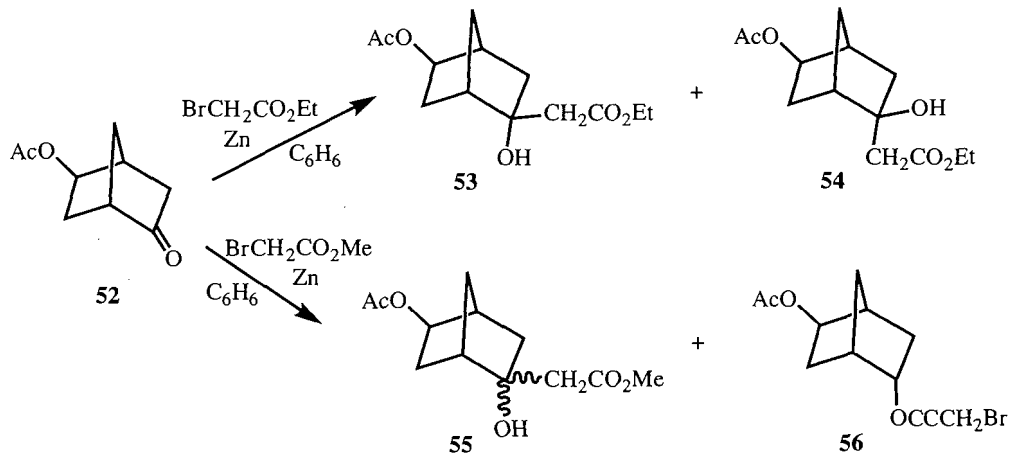
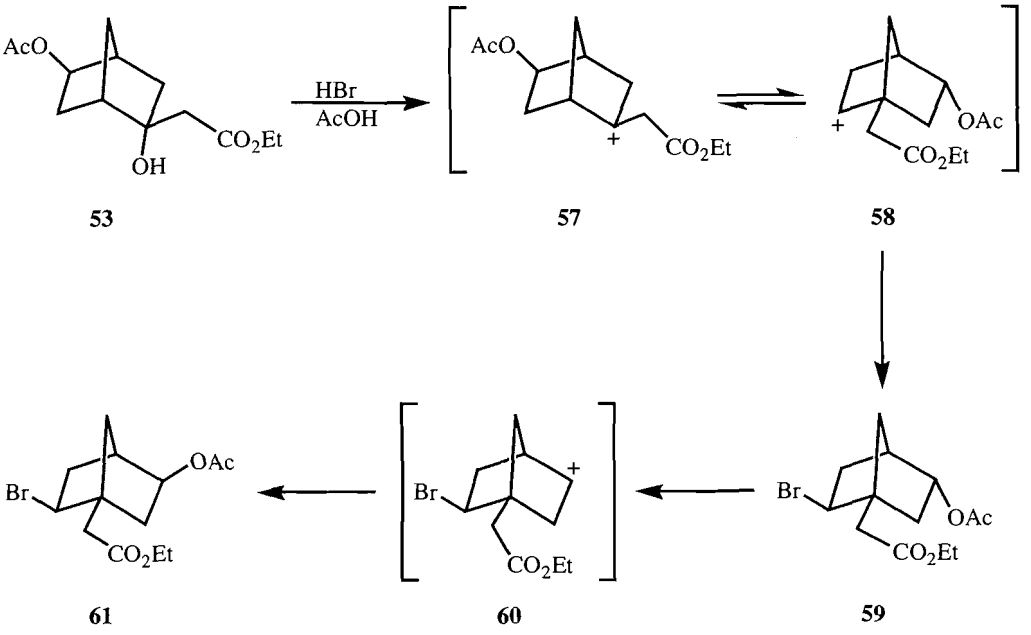


SCHEME 9



SCHEME 10

The rearrangement during dehydrobromination of halo acids and esters of these types to norborn-2-ylidene derivatives can be interpreted in terms of processes of the kind shown in **51**, facilitated by conjugation of the developing ethylenic double bond with the carbonyl group. The overall sequences **41** → **39** (**35**) → **48**, **49** (**45**, **46**) represent rearrangement – retro-rearrangement processes analogous to the sequence **4** → **5** → **8** and this type of route is not applicable to the synthesis of **2**.

In devising a different approach to **2** we sought a strategy that avoided dehydrobromination. This led us to investigate the Reformatsky reaction of *exo*-5-acetyloxy-2-norbornanone (**52**) (19). Reaction with ethyl bromoacetate and zinc gave a mixture of ethyl 2-hydroxynorbornane-*exo*- and *endo*-2-acetates (**53** and **54**), from which the major component could be isolated in 57% yield by fractional distillation (Scheme 9). This is considered to be **53** on the ground that attack of the Reformatsky reagent would occur preferentially on the less hindered, *exo* face of **52**. When methyl bromoacetate was used in the Reformatsky reaction a third product was obtained in addition to the hydroxy esters **55**. This is considered to be the bromo ester **56**, formed via reduction of **52** followed by transesterification by methyl bromoacetate. The introduction of the freshly activated zinc in small portions at a time and addition of a crystal of iodine increased the **55**:**56** product ratio.

Treatment of the acetyloxy ester **53** with hydrogen bromide gave initially ethyl *endo*-3-acetyloxy-*exo*-6-brononorbornane-1-acetate (**59**), which was partially converted to its *exo*-3-acetyloxy epimer **61** in the presence of hydrogen bromide. These products are considered to arise via Wagner–Meerwein rearrangement of cation **57** to **58** and by slower conversion of **59** to the cation **60** and reaction of this to give **61** (Scheme 10).

It was next necessary to remove reductively the bromine from compounds **59** and **61**. Since these are unstable and

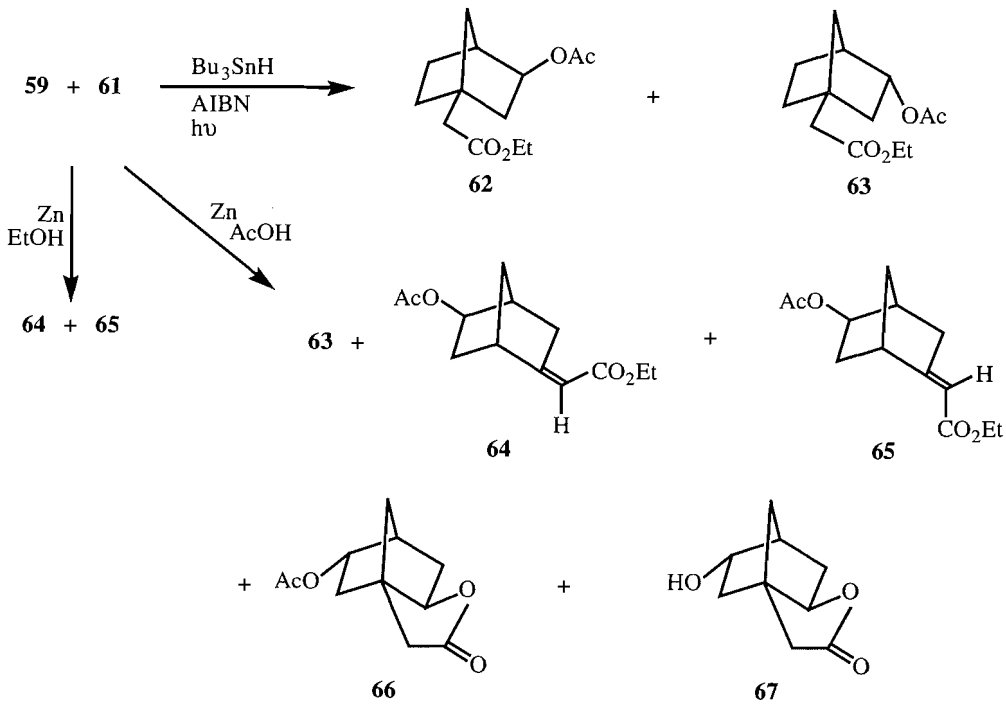
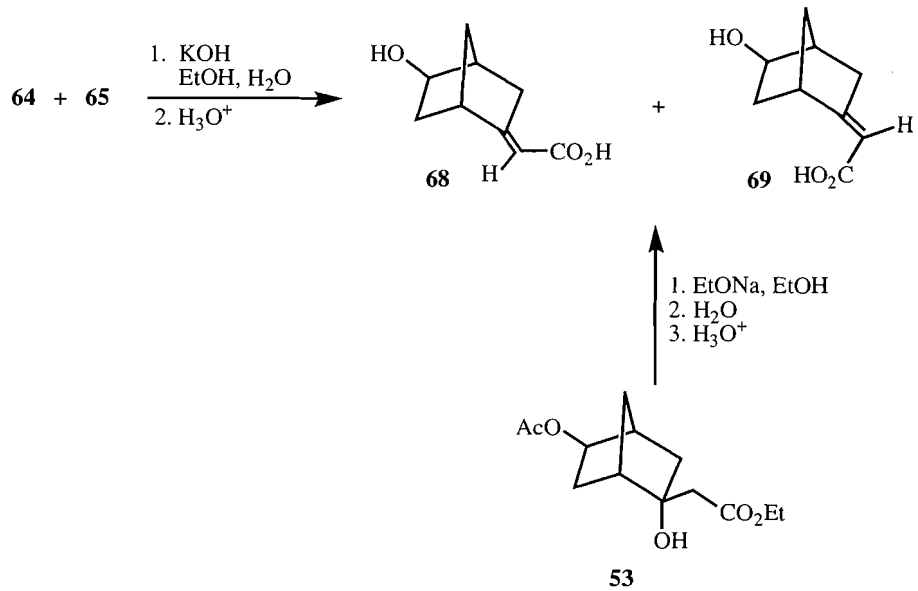


SCHEME 11



SCHEME 12

decompose on standing at room temperature their separation was not attempted; this did not present a problem, other than complicating spectroscopic interpretations, since the acetyloxy groups were eventually destined to be converted to a carbonyl group. Reduction of the mixture with tributyltin hydride initiated by photolysis of azobisisobutyronitrile (AIBN) (20) gave a mixture of the desired products, ethyl *exo*- and *endo*-3-hydroxynorbornane-1-acetate (**62** and **63**); however, these were accompanied by other products and were difficult to purify. Treatment of the mixture of **59** and **61** with freshly activated zinc and acetic acid gave **63**, together with ethyl (*E*)- and (*Z*)-2-(*exo*-5-acetyloxynorborn-2-ylidene)-acetate (**64** and **65**), and two lactones, which are tentatively assigned structures **66** and **67** (Scheme 11). Treatment of the mixture of **59** and **61** with zinc and ethanol gave only **64** and **65**. Hydrolysis of this mixture with aqueous ethanolic potassium hydroxide gave a mixture of the unsaturated hydroxy acids **68** and **69** whose spectra were identical with those of a mixture of **68** and **69** obtained by treatment of **53** with ethanolic sodium ethoxide followed by hydrolysis (Scheme 12).

The method of choice for the reduction of the mixture of **59** and **61** to the desired acetyloxy esters **62** and **63** was discovered to be catalytic hydrogenation (Scheme 13). The

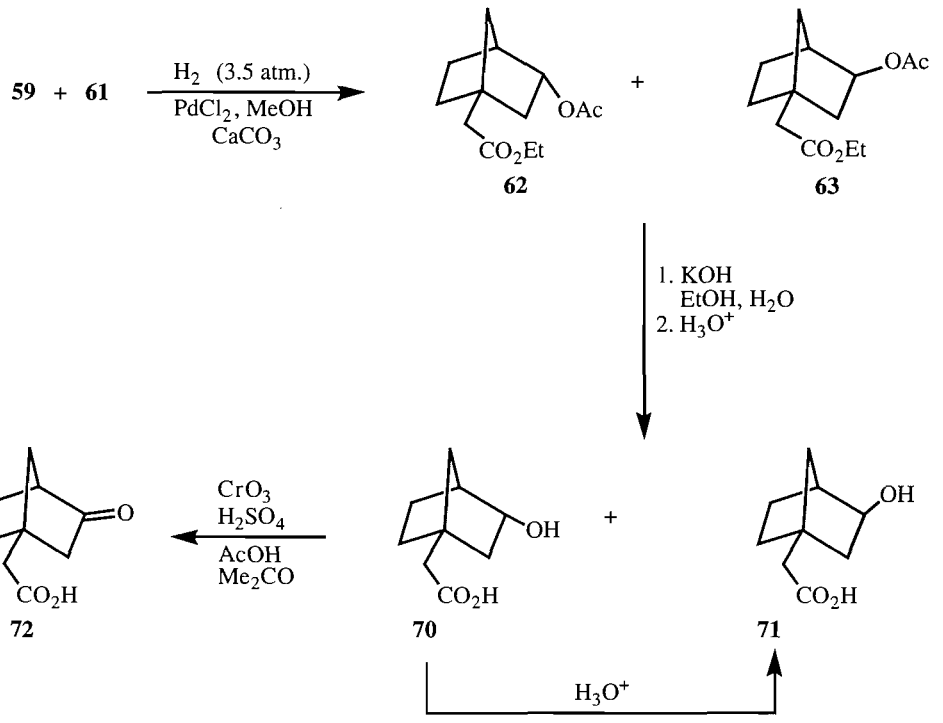
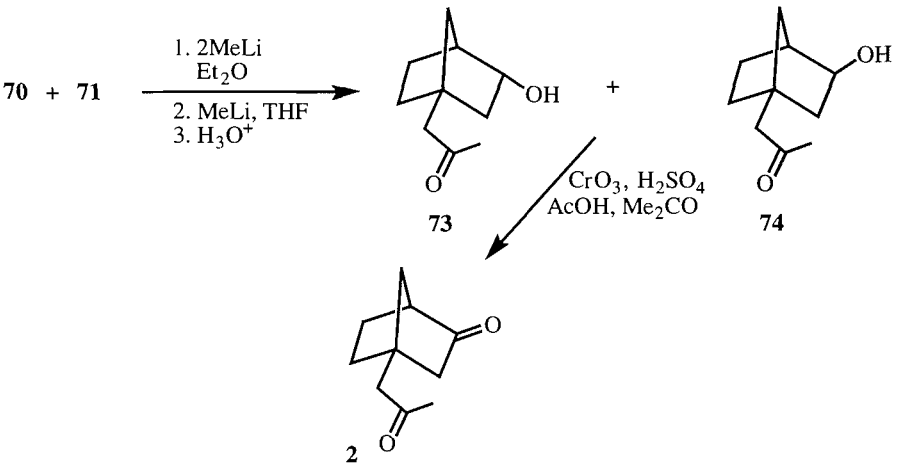


SCHEME 13



SCHEME 14

latter mixture was hydrolyzed by base to give a mixture of *endo*- and *exo*-3-hydroxynorbornane-1-acetic acids (**70** and **71**). Treatment of this mixture with dilute hydrochloric acid at pH 5 slowly converted the *endo* isomer **70** to the *exo* isomer **71**, presumably via carbonium ion formation (cf. **59** → **61** via **60**). This permitted the isolation of the pure *exo* isomer **17**; after treatment for 3 days at pH 5 crystallization gave **71** in 53% yield. Oxidation of the mixture of **70** and **71** with Jones reagent gave a single keto acid, 3-oxonorbornane-1-acetic acid (**72**).

The synthesis of 1-(3-oxonorborn-1-yl)-2-propanone (**2**) was now completed by reaction of the mixture of hydroxy acids **70** and **71** with three molar equivalents of methyllithium in ether and tetrahydrofuran as in the case of **16** to give a mixture of 1-(*endo*- and *exo*-3-hydroxynorborn-1-yl)-2-propanone (**73** and **74**), and oxidation of this with Jones reagent (Scheme 14; our overall synthetic route to **2** is summarized in Scheme 15).

For the purpose of spectroscopic comparison the 2-keto isomer of **7**, 1-(2-oxonorborn-1-yl-2-propanone (**78**), was prepared via treatment of the lactone **75** with methyllithium in ether to give a mixture of 1-(*exo*-2-hydroxy-norborn-1-yl)-2-propanone (**76**) and the diol **77**. These were separated and oxidized individually with Jones reagent to give **78** and the hydroxy ketone **79** (Scheme 16).

Experimental

Melting points were taken with a Fisher–Johns melting point apparatus and are uncorrected. The ir spectra were recorded in chloroform and the ^{1}H nmr spectra were recorded at 60 MHz in deuterochloroform. Low-resolution mass spectra were recorded with a Bell and Howell CEC 21-490 mass spectrometer and Exact Mass

prepared potassium *tert*-butoxide in *tert*-butyl alcohol under scrupulously anhydrous conditions followed by basic hydrolysis (2).

(*i*) Under anhydrous conditions a solution of **7** (690 mg, 5.00 mmol) in ether (20 mL) was cooled in an ice bath and stirred as a solution of methyllithium (1.3 M in ether; 10 mmol) was added dropwise over ca. 90 min. The temperature was raised slowly to room temperature and the solution was stirred for 10 h. The reaction mixture was poured into cold 4 N hydrochloric acid (300 mL). Additional ether (300 mL) was added and the ether layer was washed with aqueous 5% sodium bicarbonate (100 mL) and water (3 × 50 mL), dried, and concentrated under reduced pressure to give a yellow oil (655 mg), which was found by ^{1}H nmr spectroscopy to be a 10:3 mixture of **10** and an alcohol considered to be 1-(2-norbornenyl)-1-methylethanol (**11**). The crude product was chromatographed on a column of Florisil that had been packed in chloroform–benzene (1:1). Elution with the same solvent afforded ketone **10** (354 mg, 52%) as a colorless oil. Molecular distillation (63–64°C, 0.025 Torr) (1 Torr = 133.3 Pa) gave an analytical sample; ir ν_{max}: 1700 (s) cm^{-1}; ^{1}H nmr δ: 0.80–2.15 (m, 6H), 2.24 (s, 3H), 2.9 (m, 1H), 6.15 (m, 2H); ms *m/z*: 136 (25) M$^+$). Anal. calcd. for $C_9H_{12}O$: C 79.37, H 8.83; found: C 79.05, H 9.10.

(*ii*) Under anhydrous conditions **7** (690 mg, 5.00 mmol) was stirred while a solution of methyllithium (1.38 M in ether; 5.00 mmol) was added dropwise at room temperature. The mixture was occasionally warmed in a water bath (40°C). After the evolution of gas had ceased, methyllithium (1.38 M in ether; 5 mmol) was added dropwise at room temperature and stirring was continued for 3 h. Tetrahydrofuran (20 mL) was added to the stirred solution via a syringe. After 1 h the reaction mixture was poured into well-stirred hydrochloric acid – ice–water (pH 2; 750 mL). The combined mixture was thoroughly extracted with ether (5 × 100 mL). The combined ether layers were washed with aqueous 5% sodium bicarbonate (100 mL) and water (2 × 50 mL), dried, and concentrated under reduced pressure to give a pale yellow oil that was molecularly distilled (60–65°C, 0.03 Torr) to give the ketone **10** (531 mg, 78%) as a colorless oil. Its spectral data were identical with those of **10** obtained by procedure (*i*) above.

Treatment of **7** *with formic acid followed by basic hydrolysis. Formation of* exo-*3-hydroxynorbornane-1-carboxylic acid* (**16**) *and* exo-*2-hydroxynorbornane-1-carboxylic acid* (**17**)

A solution of acid **7** (500 mg, 3.6 mmol) in 90% formic acid (15 mL) was boiled under reflux for 12 h. The solution was cooled, poured into water (15 mL), and distilled to remove formic acid and water. Distillation of the residue afforded a mixture (510 mg, 77%) of *exo*-3- and *exo*-2-formyloxynorbornane-1-carboxylic acid; ^{1}H nmr δ: 1.24–2.13 (m, 9H), 2.44 (m, 1H), 4.90 (m, 1H), 8.00 (s, 1H), 10.92 (s, 1H; absent after D_2O treatment); ms *m/z*: 184 (5), (M$^+$).

To a solution of the mixture (510 mg, 2.77 mmol) in ethanol (30 mL) and water (3 mL) potassium hydroxide (6 g) was added and the solution was heated on a steam bath for 3 h; it was then diluted with water (150 mL) and distilled until the temperature reached 98°C. The distillate was cooled in an ice bath and acidified with concentrated hydrochloric acid. The solution was extracted with ethyl acetate (2 × 100 mL), and the combined extracts were washed with water (2 × 100 mL), dried, and concentrated under reduced pressure to give a mixture of the hydroxy acids **16** and **17** as a viscous yellow oil that solidified on standing (294 mg, 68%); mp 105–112°C; ir ν_{max}: 3450–2380 (br, m), 1698 (s) cm^{-1}; ^{1}H nmr δ: 1.25–2.61 (m, 9H), 3.94 (m, 1H), 7.34 (br s,; absent after D_2O treatment; 2H); ms *m/z*: 156 (10) (M$^+$). Crystallization from ether gave **16** (134 mg, 31%), mp 118–119.5°C, whose ir, ^{1}H nmr, and mass spectra were identical with those of a sample of **16** prepared by oxymercuration–demercuration of **7** (*vide infra*).

Oxymercuration–demercuration of **7**. *Formation of* exo-*3-hydroxynorbornane-1-carboxylic acid* (**16**)

To a stirred mixture of mercuric acetate (3.19 g, 10.00 mmol) in water (10 mL) and tetrahydrofuran (10 mL) was added **7** (1.38 g, 10.00 mmol), and the mixture was stirred for 10 min at room temperature by which time the oxymercuration was complete. Aqueous sodium hydroxide (3 M, 10 mL) was added followed by a solution of sodium borohydride (0.5 M in 3 M aqueous NaOH, 10 mL). Reduction of the oxymercurial was almost instantaneous. The mercury was allowed to settle and was separated, and the aqueous layer was cooled, acidified with 6 N hydrochloric acid, saturated with sodium chloride, and extracted with ethyl acetate (3 × 25 mL). The ethyl acetate extracts were dried and concentrated under reduced pressure. The residue was crystallized from dichloromethane–ether to give **16** (889 mg, 57%) as colorless plates, mp 118–119.5°C; ir ν_{max}: 3450–2470 (m), 1700 (s) cm^{-1}; ^{1}H nmr δ: 1.00–2.09 (m, 9H), 2.26 (m, 1H), 3.90 (d of m, J_{app} 5 Hz, 1H, 7.43 (s, 2H; absent after D_2O treatment); ms *m/z*: 156 (12) (M$^+$). Anal. calcd. for $C_8H_{12}O_3$: C 61.52, H 7.74; found: C 61.21, H 7.73.

Oxymercuration–demercuration of tert-*butyl norborn-2-ene-1-carboxylate* (**25**). *Formation of* tert-*butyl* exo-*3-hydroxynorbornane-1-carboxylate* (**26**)

To a stirred mixture of mercuric acetate (3.19 g, 10.00 mmol), water (10 mL), and tetrahydrofuran (20 mL) ester **25** (2), (2.10 g, 10.00 mmol) was added and the mixture was stirred for 10 min at room temperature. Aqueous sodium hyroxide (3 M, 10 mL) was added followed by a solution of sodium borohydride (0.5 M in 3 M aqueous NaOH, 10 mL). Reduction of the oxymercurial was almost instantaneous. The mercury was allowed to settle and removed. Additional tetrahydrofuran (50 mL) was added and the tetrahydrofuran layer was separated and concentrated under reduced pressure. The residue was dissolved in dichloromethane, and the solution was dried and concentrated under reduced pressure to give **26** as a colorless oil (1.93 g, 91%); ir ν_{max}: 3510 (w), 3390 (w), 1720 (s), cm^{-1}; ^{1}H nmr δ: 0.92–2.03 (m, with prominent s at 1.50; 17H), 2.24 (m, 1H), 3.16 (s, 1H; absent after D_2O treatment), 3.86 (d of m, J_{app} = 5 Hz; 1H). This was used without further purification.

Oxidation of **16**. *Formation of 3-oxonorbornane-1-carboxylic acid* (**27**)

A solution of **16** (780 mg, 5.00 mmol) in acetone was cooled to 5–10°C, stirred, and titrated with a freshly prepared solution of Jones reagent (11) until the orange color persisted for 1 h. The excess oxidant was destroyed by dropwise addition of methanol. The acetone layer was concentrated under reduced pressure, and the residue was dissolved in dichloromethane. The solution was dried, and the solvent was removed. Crystallization of the residue from dichloromethane–ether afforded **27** (732 mg, 95%) as white plates, mp 96–97°C; ir ν_{max}: 3470–2450 (br m), 1751 (s), 1700 (s), cm^{-1}; ^{1}H nmr δ: 1.24–2.45 (m, with prominent s at 2.00; 8H), 2.75 (m, 1H), 10.00 (s, 1H; absent after D_2O treatment); ms *m/z*: 154 (50) (M$^+$). Anal. calcd. for $C_8H_{10}O_3$: C 62.32, H 6.54; found: C 62.43; H 6.57.

Oxidation of **26**. *Formation of* tert-*butyl 3-oxonorbornane-1-carboxylate* (**28**)

A solution of **26** (1.696 g, 8.00 mmol) in acetone (100 mL) was cooled to ca. 5°C, stirred, and titrated with Jones reagent (11) until the orange color persisted for 30 min. The excess oxidant was destroyed by dropwise addition of methanol. The solution was concentrated under reduced pressure and the residue was dissolved in dichloromethane. The solution was dried, and the solvent was removed under reduced pressure. Sublimation of the residue afforded **26** as white needles (1.646 g, 98%) mp 53–54°C; ir ν_{max}: 1740 (s), 1718 (s), cm^{-1}; ^{1}H nmr δ: 1.12–2.34 (m, with prominent s at 1.46; 17H), 2.67 (m, 1H). Exact Mass calcd. for $C_{12}H_{18}O_3$: 210.1252; found: 210.1252. Anal. calcd. for $C_{12}H_{18}O_3$: C 68.55, H 8.63; found: C 68.35, H 8.59.

Treatment of **16** *with methyllithium. Formation of 1-(*exo-*3-hydroxynorborn-1-yl)ethanone* (**30**)

Under anhydrous conditions a solution of methyllithium (1.38 M in ether, 15.00 mmol) was added dropwise to a stirred

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

solution of **16** (780 mg, 5.00 mmol) in dry ether (30 mL), which was cooled in an ice bath. The temperature was raised slowly to room temperature and the solution was stirred for 8 h. The reaction mixture was poured into saturated aqueous ammonium chloride (250 mL). Additional ether (250 mL) was added and the ether layer was washed with water (2 × 50 mL), dried, and concentrated under reduced pressure to give a pale yellow oil that was chromatographed on a column of silica gel that had been packed in dichloromethane–ether (9:1). Elution with the same solvent gave **30** (431 mg, 56%) as a colorless oil that was molecularly distilled (123–125°C, 0.025 Torr) to give an analytical sample of **30**; ir ν_{max}: 3610 (m), 3450 (m), 1695 (s), cm^{-1}; ^1H nmr δ: 1.10–2.24 (m, with prominent s at 2.15; 12H) 3.02 (br s, 1H; absent after D_2O treatment), 3.85 (d of m, J_{app} = 6 Hz; 1H). Exact Mass calcd. for $C_9H_{14}O_2$: 154.0992; found: 154.1000.

A further amount of **30** (218 mg, 28%) was obtained from the column by elution with ether.

*Oxymercuration–demercuration of **10**. Formation of **30***

To a stirred mixture of mercuric acetate (1.59 g, 5.00 mmol), water (5 mL), and tetrahydrofuran (5 mL) unsaturated ketone **10** (680 mg, 5.00 mmol) was added and the mixture was stirred for 10 min at room temperature by which time the oxymercuration was completed. Aqueous sodium hydroxide (3 M, 5 mL) was added followed by a solution of sodium borohydride (0.5 M in 3 M aqueous NaOH, 5 mL). The mercury was immediately separated by three successive suction filtrations. Ether (50 mL) was added to the filtrate, and this was saturated with sodium chloride. The ether layer was separated, washed with cold aqueous 5% sodium bicarbonate (10 mL), and water (2 × 10 mL), dried, and concentrated under reduced pressure. Molecular distillation of the residue gave **30** (547 mg, 71%) as a colorless oil. Its R_f value and spectra were identical with those of **30** obtained from the methyllithium treatment of **16** (*vide supra*).

*Oxidation of **30**. Formation of 1-(3-oxonorborn-1-yl)ethanone (**1**)*

A solution of **30** (616 mg, 4.00 mmol) in acetone (75 mL) was cooled in an ice bath, stirred, and titrated with Jones reagent (11) until the orange color persisted for 15 min. The excess oxidant was destroyed by dropwise addition of methanol until the solution was colorless. The solution was concentrated under reduced pressure, and the residue was dissolved in dichloromethane. The solution was dried, and concentrated under reduced pressure. Molecular distillation (153–156°C, 0.125 Torr) of the residue afforded **1** (547 mg, 90%) as a colorless oil. ir ν_{max}: 1754 (s), 1709 (s) cm^{-1}; ^1H nmr δ: 1.10–2.20 (m, 8H), 2.22 (s, 3H), 2.66 (m, 1H). Anal. calcd. for $C_9H_{12}O_2$: C 71.03, H 7.95; found: C 71.04, H 8.00.

*Acetylation of **16**. Formation of* exo*-3-acetyloxynorbornane-1-acetic acid (**31**)*

To a solution of **16** (1.56 g, 10.0 mmol) in triethylamine (10 mL) was added acetic anhydride (2 g) and a catalytic amount of 4-(dimethylamino)pyridine (100 mg). The mix was stirred at room temperature for 5 h. Water (100 mL) was added and the mixture was extracted with ethyl acetate (3 × 75 mL). The ethyl acetate extracts were combined, washed with water several times, and concentrated under reduced pressure. The residue was crystallized from ether – ethyl acetate and sublimed to give **31** (1.80 g, 91%) as needles, mp 86–88°C; ir ν_{max}: 3310–2880 (m), 1745 (s), 1704 (s), cm^{-1}; ^1H nmr δ: 1.17–2.00 (m, 8H), 2.03 (s, 3H), 2.41 (m, 1H), 4.68 (m, 1H), 10.90 (br s, 1H; absent after D_2O treatment). Anal. calcd. for $C_{10}H_{14}O_4$: C 60.59, H 7.12; found: C 60.47, H 7.13.

*Treatment of a mixture of ethyl 2-hydroxynorbornane-*exo*- and* endo*-2-acetate (**41**) with hydrogen bromide. Formation of* exo*-2-bromonorbornane-1-acetic acid (**35**) and its ethyl ester (**39**)*

A solution of a mixture of the epimeric esters **41**, prepared by treatment of 2-norbornanone with zinc and ethyl bromoacetate (13) (1.00 g, 5.00 mmol) in a 32% solution of hydrogen bromide in acetic acid (10 mL) was stirred at room temperature. After 20 h the brown reaction mixture was poured into stirred ice-water (75 g) and extracted with ether (5 × 50 mL). The combined ether extracts were washed with aqueous 5% sodium bicarbonate (50 mL) and water (4 × 50 mL), and dried. The solvent was removed to give a yellow oil, which was molecularly distilled (84–87°C, 0.125 Torr) to give the bromo ester **39** (970 mg, 72%) as a colorless oil; ir ν_{max}: 1730 (s) cm^{-1}; ^1H nmr δ: 1.14–2.02 (m, with prominent t at 1.25, J = 7 Hz; 10H), 2.15–2.33 (m, 2H), 2.76 (ABq, J = 17 Hz; 2H), 4.14 (q, J = 7 Hz; 2H), 4.23–4.47 (m, 1H); ms m/z: 260 (1), 262 (1), (M^+). Anal. calcd. for $C_{11}H_{17}BrO_2$: C 50.59, H 6.56, Br 30.60; found: C 50.91, H 6.46, Br 30.90).

The aqueous layer was cooled in an ice–salt bath, acidified (pH 2) by dropwise addition of concentrated hydrochloric acid, and extracted immediately with ether (3 × 50 mL). The combined ether extracts were washed with water (2 × 50 mL) and dried, and the solvent was removed to give a yellowish white solid, which was crystallized from chloroform to give the bromo acid **35** (160 mg, 14%) as needles. Sublimation (30°C, 0.125 Torr) gave long needles, mp 125–127°C; ir ν_{max}: 3510–2325 (m), 1706 (s) cm^{-1}; ^1H nmr δ: 1.14–2.00 (m, 6H), 2.20–2.36 (m, 3H), 2.86 (ABq, J_{AB} = 17 Hz; 2H), 4.28–4.50 (m, 1H), 11.42 (br s, 1H; absent after D_2O treatment); ms m/z: 232 (1), 234 (1) (M^+). Anal. calcd. for $C_9H_{13}BrO_2$: C 46.37, H 5.62; found: C 46.89, H 5.66.

Acid **35** could also be prepared by acidic hydrolysis of its ethyl ester **39**.

*Treatment of **39** with ethanolic sodium ethoxide. Formation of ethyl (*E*)- and (*Z*)-(norborn-2-ylidene)acetate (**48** and **49**)*

Under anhydrous conditions, a solution of **39** (530 mg, 2.00 mmol) in ethanol (25 mL) was added to a cold stirred solution of sodium ethoxide (6.10 mmol) prepared by addition of sodium (140 mg) to ethanol (100 mL), and the mixture was boiled under reflux with stirring. After 6 h the mixture was cooled, neutralized with 3 N hydrochloric acid, and extracted with ether. The extract was washed with water several times and dried. Removal of solvent and molecular distillation (76°C, 0.05 Torr) afforded a mixture of the known (16) **48** and **49** as a colorless oil (188 mg, 52%); ir ν_{max}: 1702 (s), 1658 (m) cm^{-1}; ^1H nmr δ: 1.12–2.34 (m, with prominent t at 1.29, J = 7 Hz; 10H), 2.49 (m, 2H), 2.82 (m, 1H), 4.13 (q, J = 7 Hz, 2H), 5.53 and 5.73 (2 m in a ratio of 1:4, 1H); ms m/z: 180 (33) (M^+).

*Dehydration of **41** with ethanolic sodium ethoxide. Formation of **48** and **49***

Under anhydrous conditions, a solution of **41** (198 mg, 1.00 mmol) in ethanol (20 mL) was added to a stirred solution of sodium ethoxide (1.20 mmol) prepared by addition of sodium (28 mg) to ethanol (20 mL), and the mixture was boiled under reflux for 9 h. The mixture was cooled, neutralized with concentrated hydrochloric acid, and extracted with ether. The extract was washed with water several times, and dried. The solvent was removed to give **48** and **49** (164 mg, 91%) as a yellow oil, which displayed ir and ^1H nmr spectra and tlc behavior identical with those of the mixture from the dehydrobromination of **39**.

*Hydrolysis of **48** and **49**. Formation of (*E*)- and (*Z*)-(norborn-2-ylidene)acetic acid (**45** and **46**)*

A mixture of **48** and **49** (360 mg, 2.00 mmol) and aqueous 5% sodium bicarbonate (300 mL) was stirred at room temperature. After 58 h the solution was washed with ether, cooled in an ice bath, stirred, and acidified to pH 2 by dropwise addition of concentrated hydrochloric acid. The acidic solution was extracted with dichloromethane (2 × 200 mL). The combined extracts were dried and the solvent was removed to give a viscous, colorless oil, which was sublimed to give a mixture of the known (14, 15) **45** and **46** (131 mg, 43%) as a waxy white solid, mp 24–61°C; ir ν_{max}: 3450–2325 (br m), 1681 (s), 1656 (s) cm^{-1}; ^1H nmr δ: 1.00–2.90 (m, 10H), 55.53 and 5.73 (2 m in a ratio of 1:3, 1H), 11.12 (br s, 1H; absent after D_2O treatment). Exact Mass calcd. for $C_9H_{12}O_2$: 152.0837; found: 152.0835.

*Treatment of **39** with ethanolic sodium ethoxide followed by hydrolysis. Formation of (E)- and (Z)-norborn-2-ylidene)acetic acid (**45** and **46**)*

Under anhydrous conditions a solution of **39** (520 mg, 2.00 mmol) in ethanol (30 mL) was added to a cold stirred solution of sodium ethoxide (8.70 mmol) prepared by addition of sodium (200 mg) to ethanol (100 mL), and the mixture was boiled under reflux with stirring. After 4 h, water (2 mL) was added and refluxing was continued for another 6 h. The reaction mixture was concentrated under reduced pressure, diluted with water (200 mL), and washed with ether (2 × 50 mL). The aqueous solution was cooled, acidified with 6 N hydrochloric acid, and extracted with chloroform (3 × 100 mL). The combined extracts were dried and the solvent was removed to give a 3:1 mixture of **45** and **46** accompanied by a small amount of a third product, considered to be **47** on the basis of ^{1}H nmr spectroscopy.

Treatment of **39** with potassium *tert*-butoxide in *tert*-butyl alcohol followed by hydrolysis in analogous fashion also gives **45** and **46**.

Reformatsky reaction of exo-*5-acetyloxy-2-norbornanone (**52**). Formation of ethyl* endo- *and* exo-*2-hydroxy*-exo-*5-acetyloxynorbornane-2-acetate (**53** and **54**)*

A mixture of **52** (19) (7.80 g) 46.40 mmol) and ethyl bromoacetate (7.80 g, 46.40 mmol) in benzene (30 mL) was added dropwise to freshly activated zinc (21) (3.10 g) suspended in boiling benzene (25 mL). The mixture was boiled under reflux for 28 h, cooled; and washed with 10% sulfuric acid, 5% sodium carbonate, and water. The mixture was dried and the solvent was removed to give **53** and **54** (11.18 g, 93%) as a yellow oil. Fractional distillation gave **53** as a colorless oil (8.89 g, 57%), bp 64°C, 0.025 Torr; ir ν_{max}: 3495 (m), 1721 (s), 1712 (s) cm^{-1}; ^{1}H nmr δ: 1.04–2.80 (m, with prominent t at 1.29, J = 7 Hz, and s's at 2.00 and 2.57; 16H), 3.51 (br s, 1H; absent after D_2O treatment), 4.16 (q, J = 7 Hz, 2H), 4.69 (d of d, J = 3 and 7 Hz; 1H). Exact Mass calcd. for $C_{13}H_{20}O_5$: 256.1309; found: 256.1320. Anal. calcd. for $C_{13}H_{20}O_5$: C 60.93, H 7.86; found: C 61.41, H 8.00.

*Treatment of **53** with hydrogen bromide. Formation of ethyl* exo-*2-bromo*-endo- *and* exo-*5-acetyloxynorbornane-1-acetate (**59** and **61**)*

A solution of **53** (5.00 g, 19.50 mmol) in a 32% solution of hydrogen bromide in acetic acid (50 mL) was stirred at room temperature. After 18 h the brown reaction mixture was poured into stirred ice-water (200 g) and the mixture was extracted with dichloromethane (3 × 100 mL). The combined extracts were washed with aqueous 5% sodium bicarbonate (100 mL) and water (2 × 100 mL), and dried. The solvent was removed to give a yellow oil, which was molecularly distilled (92–95°C, 0.025 Torr) to give a 1:1 mixture of **59** and **61** (5.85 g, 94%) as a colorless oil; ir ν_{max}: 1730 (s) cm^{-1}; ^{1}H nmr δ: 1.0–2.8 (m, with prominent s at 1.98, ABq at 2.66, J = 16.5 Hz; 15H), 4.07 (q, J = 7 Hz; 2H), 4.10 (m, 1H), 4.40 (m, 0.5H), 4.72 (m, 0.5H). Exact Mass calcd. for $C_{13}H_{19}BrO_4$: 318.0459, 320.0453; found: 318.0463, 320.0456.

After shorter reaction times the **59**:**61** ratio was greater.

*Hydrogenolysis of **59** and **61**. Formation of ethyl* endo- *and* exo-*3-acetyloxynorbornane-1-acetate (**62** and **63**)*

To a solution of 1:1 mixture of **59** and **61** (3.19 g, 10.00 mmol) in methanol (300 mL) was added palladium chloride (100 mg) and calcium carbonate (5.00 g), and the mixture was shaken under hydrogen (3.5 atm (1 atm = 101.325 kPa)) at ca. 50°C for 22 h. The reaction mixture was filtered and stripped of methanol under reduced pressure to give a yellow oil (2.41 g), which was molecularly distilled (88–91°C, 0.05 Torr) to give a 1:1 mixture of **62** and **63** (2.26 g, 94%) as a colorless oil; ir ν_{max}: 1721 (s) cm^{-1}; ^{1}H nmr δ: 1.10–3.00 (m, with prominent t at 1.24, J = 7.5 Hz and s at 2.02; 17H), 4.07 (q, J = 7.5 Hz; 2H), 4.52 (m, 0.5H), 4.92 (m, 0.5H); ms m/z: 240 (33) (M^+). Anal. calcd. for $C_{13}H_{20}O_4$: C 64.98, H 8.39; found: C 64.95, H 8.23.

Treatment of **59** and **61** with tributyltin hydride and azobisisobutyronitrile initiated by photolysis (20) also gave a mixture containing **62** and **63**, as shown by ^{1}H nmr spectroscopy, but these could not be purified.

*Treatment of **59** and **61** with zinc and ethanol. Formation of ethyl (E)- and (Z)-(*exo-*5-acetyloxynorborn-2-ylidene)acetates (**64** and **65**)*

To a solution of **59** and **61** (362 mg, 1.19 mmol) in ethanol (10 mL) was added freshly activated zinc dust (155.6 mg, 2.38 mmol) and water (1 mL). The mixture was boiled under reflux with stirring for 8 h, filtered to remove zinc, diluted with water (100 mL), and extracted with ether (3 × 100 mL). After the extracts had been dried, the ether was removed under reduced pressure to give a viscous, yellow oil (273 mg). Its ^{1}H nmr and ir spectra indicated that it was a mixture of **64** and **65**, which was confirmed by its hydrolysis to a mixture of the corresponding hydroxy acids, **68** and **69** (*vide infra*).

*Treatment of **59** and **61** with zinc and acetic acid. Formation of **63–65**,* endo-*5-acetyloxy*-exo-*2-hydroxynorbornane-1-acetic acid lactone (**66**) and* endo-2-exo-*5-dihydroxynorbornane-1-acetic acid γ-lactone (**67**)*

To a stirred solution of **59** and **61** (9.57 mg, 3.00 ml) in acetic acid (15 mL) was added freshly activated zinc dust (1.00 g). The mixture was heated at 90°C for 5 h, cooled to room temperature, and filtered. The filtrate was concentrated under reduced pressure, diluted with water, extracted with dichloromethane (33 × 100 mL), and the combined extracts were washed with water (4 × 100 mL) and dried. The solvent was removed to give a yellow oil (921 mg), which was chromatographed on a silica-gel column that had been packed in dichloromethane/benzene (1:1). Elution with dichloromethane–benzene (1:1) and concentration of the eluate (260 mL) afforded the lactone **66** (120 mg, 19%), mp 91–96°C.[6] Crystallization from ether gave **66** as plates, mp 65–66°C; ir ν_{max}: 1773 (s), 1764 (s) cm^{-1}; ^{1}H nmr δ: 1.0–2.7 (with prominent s's at 2.03 and 2.56, 12H); 4.27 (dd, J = 3 and 7 Hz, 1H)), 5.10 (m, 1H); ms m/z: 210 (7) (M^+). Anal. calcd. for $C_{11}H_{14}O_4$: C 62.84, H 6.71; found: C 62.21, H 6.73.

Further elution with dichloromethane–benzene – ethyl acetate (5:4:1) afforded a mixture of **63–65**, as shown by ^{1}H nmr spectroscopy.

*Treatment of **64** and **65** with base. Formation of (E)- and (Z)-(*exo-*5-hydroxynorborn-2-ylidene)acetic acid (**68** and **69**)*

The mixture of **64** and **65** formed from **59** and **61** was dissolved in ethanol (15 mL) and potassium hydroxide (1.00 g) was added with continuous swirling. The mixture was heated on a steam bath for 30 min followed by stirring without external heating for 3 h. Water (50 mL) was added, and the mixture was concentrated under reduced pressure to ca. 10 mL. The concentrate was cooled in ice-water and acidified to pH 5 with 6 N sulfuric acid. The solution was immediately extracted with ethyl acetate (5 × 10 mL) and dried. The solvent was removed and the residue was sublimed to give white plates (88.00 mg, 44%) of **68** and **69**, mp 179–183°C; shown by ir, ^{1}H nmr, and tlc comparison to be identical with the products obtained below from treatment of **53** with base.

*Treatment of **53** with base. Formation of **68** and **69***

Under anhydrous conditions a solution of **53** (768 mg, 3.00 mmol) in ethanol (20 mL) was added to a cold stirred solution of sodium ethoxide (10.00 mmol) prepared by addition of sodium (230 mg) to ethanol (10 mL), and the mixture was boiled under reflux with stirring. After 5 h, water (2 mL) was added, and boiling was continued for another 5 h. The reaction mixture was concentrated under reduced pressure, diluted with water (150 mL), and washed with ether (3 × 50 mL). The aqueous so-

[6]This material contained a small amount of the lactone **67**, as shown by ^{1}H nmr spectroscopy. Compounds **66** and **67** have been independently synthesized (P. Yates and M. Kaldas, to be submitted for publication).

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

lution was cooled, acidified with 6 N hydrochloric acid, and extracted with dichloromethane (4 × 50 mL). The extracts were dried and the solvent was removed to give the crude product (408 mg, 81%) as a yellowish white solid. This was chromatographed on a column of silica gel (5 g) that had been packed in dichloromethane; 100-mL fractions were collected. Elution with dichloromethane (8 fractions) gave a mixture (31 mg) that was not investigated further. Elution with ether–methanol (9:1) (2 fractions) gave **68** and **69** in a 4:3 ratio (228 mg, 45%) as a white solid; mp 191–196°C; ir ν_{max}: 3585 (w), 3510 (w), 1681 (s), 1667 (m), cm^{-1}; ^1H nmr (acetone-d_6) δ: 1.09–2.80 (m, 8H), 3.87 (m, 1H), 5.16 (br s; absent after D_2O treatment; 2H), 5.53 and 5.73 (2 m, 1H). Exact Mass calcd. for $C_9H_{12}O_3$: 168.0785; found: 168.0786. Anal. calcd. for $C_9H_{12}O_3$: 64.27, H 7.19; found: C 63.88, H 7.20.

*Hydrolysis of **62** and **63**. Formation of* endo- *and* exo-*3-hydroxynorbornane-1-acetic acids (**70** and **71**)*

To a stirred solution of **62** and **63** (2.40 g, 10.00 mmol) in 95% ethanol (50 mL) was added potassium hydroxide (5.60 g). The mixture was heated on a steam bath for 1 h, cooled to room temperature, and stirred for 5 h. The solution was diluted with water (200 mL) and distilled to remove ethanol. The aqueous solution was cooled in an ice bath and titrated by dropwise addition of concentrated hydrochloric acid with stirring to ca. pH 6. The solution was extracted with ethyl acetate (3 × 100 mL), the combined extracts were dried, and the solvent was removed to give a mixture of **70** and **71** as a white solid (1.30 g, 76%). This crude product was used for the preparation of **72** (*vide infra*).

In a further run the product mixture was crystallized from ethyl acetate – ether to give the *exo* epimer **71** (663 mg, 39%) as needles, mp 113–4°C; ir ν_{max}: 3625–2835 (br, m), 1709 (s) cm^{-1}; ^1H nmr (acetone-d_6) δ: 1.28–2.15 (m, 9H), 2.18 (ABq, J = 20 Hz; 2H), 3.62 (m, 1H), 5.87 (br s, 2H); absent after D_2O treatment); Exact Mass calcd. for $C_9H_{14}O_3$: 170.0941; found: 170.0941.

In another run, after hydrolysis the solution was acidified with hydrochloric acid to pH 5 and stirred at room temperature for 3 days. The solution was saturated with sodium chloride, and extracted with ethyl acetate; the extract was dried and concentrated under reduced pressure. The residue was crystallized from ethyl acetate – ether to give the *exo* epimer **71** (901 mg, 53%).

*Oxidation of **70** and **71**. Formation of 3-oxonorbornane-1-acetic acid (**72**)*

A solution of **70** and **71** (646 mg, 3.80 mmol) in acetone was cooled in an ice bath, stirred, and titrated with Jones reagent (11) until the orange color persisted for 20 min. The excess oxidant was destroyed by dropwise addition of methanol until the solution became colorless. The solution was concentrated under reduced pressure, and the residue was dissolved in dichloromethane. The solution was dried and the solvent was removed. Molecular distillation (103–105°C, 0.05 Torr) of the residue afforded **72** (530 mg, 83%) as a colorless oil that solidified on standing; mp 62–3°C; ir ν_{max}: 3570–2440 (m), 1736 (s), 1706 (s) cm^{-1}; ^1H nmr δ: 1.00–2.70 (m, with prominent s's at 2.44 and 2.66; 11H), 11.15 (br s, 1H; absent after D_2O treatment). Exact Mass calcd. for $C_9H_{12}O_3$: 168.0785; found: 168.0784.

*Treatment of **70** and **71** with methyllithium. Formation of 1-(*endo- *and* exo-*3-hydroxynorborn-1-yl)-2-propanone (**73** and **74**)*

Under anhydrous conditions a solution of methyllithium (1.48 M in ether, 6.00 mmol) was added dropwise to a stirred solution of a mixture of **70** and **71** (340 mg, 2.00 mmol) in dry ether (25 mL), and the mixture was stirred for 13 h. The reaction mixture was added dropwise to cold 3 N hydrochloric acid (200 mL) with stirring. Additional ether (100 mL) was added and the ether layer was washed with water (2 × 50 mL), dried, and concentrated under reduced pressure to give a yellow oil that was molecularly distilled (71–73°C, 0.105 Torr) to give a mixture of **73** and **74** as a colorless oil (205 mg, 61%); ir ν_{max}: 3510 (w), 3450 (w), 1715 (s), cm^{-1}; ^1H nmr δ: 1.00–2.00 (m, H), 2.12 (s, 3H), 2.46 (s, 2H), 2.53 (s, 1H; absent after D_2O treatment), 3.67 (m, 0.56H), 4.30 (m, 0.44H). Anal. calcd. for $C_{10}H_{16}O_2$: C 71.39, H 9.59; found: C 71.28, H 9.87.

*Oxidation of **73** and **74**. Formation of 1-(3-oxonorborn-1-yl)-2-propanone (**2**)*

A solution of **73** and **74** (168 mg, 1.00 mmol) in acetone (100 mL) was stirred and titrated with Jones reagent (11) until the orange color persisted for 20 min. The excess oxidant was destroyed by dropwise addition of methanol until the solution became colorless. The reaction mixture was concentrated under reduced pressure, and the residue was dissolved in dichloromethane. The solution was dried, and the solvent was removed. Molecular distillation (77–79°C, 0.025 Torr) of the residue gave **2** (165 mg, 99%) as a colorless oil; ir ν_{max}: 1751 (s), 1724 (s) cm^{-1}; ^1H nmr δ: 0.80–1.85 (m, 6H), 2.14 (s, 3H), 1.95–2.73 (m, 2H). Exact Mass calcd. for $C_{10}H_{14}H_2$: 166.0992; found: 166.0996. Anal. calcd. for $C_{10}H_{14}H_2$: C 72.26, H 8.49; found: C 72.37, H 8.53.

Treatment of exo-*2-hydroxynorbornane-1-acetic acid lactone (**75**) with methyllithium. Formation of 1-(*exo-*2-hydroxynorborn-1-yl)-2-propanone (**76**) and 1-(2-hydroxynorborn-1-yl)-2-methyl-2-propanol (**77**)*

Under anhydrous conditions a solution of methyllithium (1.3 M in ether, 5.00 mmol) was added dropwise to a stirred solution of **75**[7] (760 mg, 5.00 mmol) in dry ether (15 mL), and the mixture was stirred for 6 h and poured into ice-cold 3 N hydrochloric acid (300 mL). Additional ether (200 mL) was added and the ether layer was washed with water (3 × 25 mL), dried, and concentrated under reduced pressure to give a pale yellow (819 mg) that was chromatographed on a column of silica gel that had been packed in dichloromethane. Elution with dichloromethane gave unchanged starting material (153 mg, 20%), followed by **76** as an oil (267 mg, 32%); ir ν_{max} 3333 (m), 1710 (s) cm^{-1}. Anal. calcd. for $C_{10}H_{16}O_2$: C 71.39, H 9.59; found: C 71.36, H 9.63.

Further elution with ether afforded **77** (171 mg, 10%), which was crystallized from ether to give white needles, mp 90–92°C; ir ν_{max}: 3510 (w), 3335 (w), cm^{-1}; ^1H nmr δ: 0.87–2.32 (m, with prominent s's at 1.27 and 1.33, and ABq at 1.90, J = 15 Hz; 17H), 3.86 (d of m, 1H), 4.36 (br s, 2H; absent after D_2O treatment). Anal. calcd. for $C_{11}H_{20}O_2$: C 71.69, H 10.94; found: C 71.52, H 10.88.

*Oxidation of **76**. Formation of 1-(2-oxonorborn-1-yl)-2-propanone (**78**)*

A solution of **76** (260 mg, 1.60 mmol) in acetone was cooled in an ice bath, stirred, and titrated with a freshly prepared solution of Jones reagent until the orange color persisted for 10 min. The excess oxidant was destroyed by dropwise addition of methanol until the solution became colorless. The solution was concentrated under reduced pressure, and the residue was dissolved in dichloromethane. The solution was dried, and the solvent was removed. Molecular distillation (100–103°C, 0.125 Torr) of the residue afforded **78** (231 mg, 88%) as a colorless oil; ir ν_{max}: 1754 (s), 1724 (s), cm^{-1}; ^1H nmr δ: 0.80–2.64 (m, with prominent s at 2.16; 12H), 2.79 (ABq, J = 17 Hz; 2H). Exact Mass calcd. for $C_{10}H_{14}O_2$: 166.0992; found: 166.1000. Anal. calcd. for $C_{10}H_{14}O_2$: C 72.26, H 8.49; found: C 72.31, H 8.51.

*Oxidation of **77**. Formation of 1-(2-oxonorborn-1-yl)-2-methyl-2-propanol (**79**)*

A solution of **76** (162 mg, 0.90 mmol) in acetone as cooled in an ice bath, stirred, and titrated with a freshly prepared solution of Jones reagent (11) until the orange color persisted for 20 min. The excess oxidant was destroyed by dropwise addition of methanol until the solution became colorless. The solution was concentrated under reduced pressure, and the residue was dissolved in ether. The so-

[7]Lactone **75** was prepared by treatment of **41** with strong acids (P. Yates and M. Kaldas, accepted for publication).

lution was dried, and the solvent was removed. Molecular distillation (63–65°C, 0.025 Torr) of the residue afforded **79** (144 mg, 90%) as a colorless oil; ir ν_{max}: 3390 (w), 1727 (s), cm^{-1}; ^1H nmr δ: 1.24 (s, 6H), 1.24–2.40 (m, with an ABq at 2.09, J = 17 Hz; 10H), 2.60 (m, 1H), 2.98 (br s, 1H; absent after D_2O treatment).

Glaciasterols A and B, 9,11-secosteroids from the marine sponge *Aplysilla glacialis*

JANA PIKA, MARK TISCHLER, AND RAYMOND J. ANDERSEN[1]

Departments of Chemistry and Oceanography, University of British Columbia, Vancouver, B.C., Canada V6T 1Z4

Received August 7, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

JANA PIKA, MARK TISCHLER, and RAYMOND J. ANDERSEN. Can. J. Chem. **70**, 1506 (1992).

The glaciasterols, a family of cytotoxic 9,11-secosteroids, have been isolated from extracts of the northeastern Pacific sponge *Aplysilla glacialis*. The structures of glaciasterol A (**2**) and glaciasterol B (**3**) were elucidated by a combination of spectroscopic analysis and chemical interconversions on the native steroid **2** and the diacetate **5** of glaciasterol B (**3**).

JANA PIKA, MARK TISCHLER et RAYMOND J. ANDERSEN. Can. J. Chem. **70**, 1506 (1992).

On a isolé les glaciastérols, appartenant à la famille des seco-9,11 stéroides cytotoxiques, à partir des extraits de l'éponge du Pacifique Nord Est *Aplysilla glacialis*. On a élucidé la structure du glaciastérol A (**2**) et du glaciastérol B (**3**) en faisant appel à l'analyse spectroscopique et à des interconversions chimiques du stéroide naturel **2** et du diacétate **5** de glaciastérol B (**3**).

Many highly oxygenated steroids (**1**), including a small number of 9,11-secosteroids (2–4), have been isolated from marine invertebrates in recent years. A representative example is herbasterol (**1**), which was isolated from Australian specimens of the sponge *Dysidea herbacea* (4). Herbasterol was found to have both icthyotoxic and antimicrobial properties. As part of our earlier investigations of the terpenoid metabolism of the Northeastern Pacific marine sponge *Aplysilla glacialis* (5), we discovered that the polar fractions from silica gel chromatography purification of the organic soluble *A. glacialis* metabolites exhibited moderate in vitro cytotoxicity. Further bioassay guided separation of the active fractions led to the isolation of the glaciasterols, a new family of cytotoxic 9,11-secosteroids. In this paper we describe the structural elucidation of glaciasterols A (**2**) and B (**3**).

Samples of *A. glacialis* were collected in Sydney Inlet and Barkley Sound, British Columbia. Freshly collected sponge specimens were extracted sequentially with methanol and 1:1 methanol/CH_2Cl_2 and the extracts were combined. Chromatographic fractionation of the combined extracts yielded pure glaciasterol A (**2**) and an inseparable mixture of related sterols. Acetylation of the inseparable mixture expedited the purification of one of the major components, glaciasterol B diacetate (**5**).

Glaciasterol A (**2**) was isolated as a white amorphous solid that gave a parent ion in the EIHRMS at m/z 416.2936 Da appropriate for a molecular formula of $C_{26}H_{40}O_4$ (ΔM +0.9 mmu). The ^{1}H NMR spectrum of glaciasterol A (Table 1) contained resonances that could be assigned to the two tertiary methyl groups (δ 0.68, s, 3H and 1.24, s, 3H) and three secondary methyl groups (δ 0.94, d, J = 6.7 Hz, 6H and 1.02, d, J = 6.8 Hz, 3H) that are typically present in steroids. Additional evidence in support of the steroidal nature of glaciasterol A came from the COSY data, which contained correlations that readily identified the truncated side chain **i** found in many C26 steroids (6) (Table 1: δ 1.02 (Me21), 2.13 (H20), 5.27 (H22), 5.29 (H23), 2.22 (H24), 0.94 (Me25 and Me26)). The ^{13}C NMR spectrum of glaciasterol A contained deshielded resonances that could be assigned to one disubstituted and one trisubstituted olefin (Table 1: δ 132.2(CH), 134.2(C), 136.0(CH), and 139.3(CH)) and to an α,β-unsaturated ketone (δ 201.8 (C)). Since there was no additional ^{13}C NMR evidence for unsaturated functional groups in glaciasterol A, the remaining four sites of unsaturation required by the molecular formula ($C_{26}H_{40}O_4$: requires 7 sites of unsaturation) were attributed to rings.

Correlations in the COSY and ^{1}H Detected Heteronuclear Multiple Quantum Coherence (HMQC) spectra of glaciasterol A (**2**) identified proton (Table 1: δ 3.69 and 3.81 (H11, H11′); 1.15 and 1.63 (H12, H12′)) and carbon resonances (Table 1: δ 59.1 (CH_2, C11) and 40.4 (CH_2, C12)) that could be assigned to an isolated ethyl fragment bearing an oxygen substituent at one terminus (i.e., C11). Acetylation of **2** with acetic anhydride and pyridine gave the diacetate **4**. The geminal methylene resonances found at δ 3.69 and 3.81 in **2** were shifted downfield to δ 4.10 and 4.19 in **4**, demonstrating that the oxygen substituent on the ethyl fragment in **2** was an alcohol functionality. Since the structure of the side chain in **2** had already been established as **i**, the spin-isolated ethyl fragment had to be present in the nucleus of glaciasterol A. This requirement demanded a ring-opened structure for the nucleus. The chemical shifts of the carbon atoms in the hydroxyethyl fragment in **2** were almost identical to the chemical shifts assigned to the C11 and C12 carbon atoms (δ 58.9 and 41.2) in herbasterol (**1**) (4), suggesting that glaciasterol was also a 9,11-secosteroid.

The formation of the diacetate **4** showed that two of the four oxygen atoms in glaciasterol A were part of alcohol functionalities and the ^{13}C NMR data for **2** (δ 201.8 (C)) showed that a third oxygen was part of an unsaturated ketone functionality. A pair of resonances at δ 63.3 (C) and 53.5 (CH) in the ^{13}C NMR spectrum of **2** were tentatively assigned to a trisubstituted epoxide functionality, which accounted for the final oxygen atom. Treatment of the diacetate **4** with perchloric acid in THF followed by acetylation of the resulting diol gave the triacetate **6**, confirming the presence of an epoxide in glaciasterol A. Subtracting the epoxide ring from the total of four rings earlier determined to be present in glaciasterol A revealed that three carbocyclic rings were present in the remainder of the nucleus, in agreement with a secosteroid structure.

COSY45, HMQC, and ^{1}H Detected Multiple Bond Het-

[1]Author to whom correspondence may be addressed.

eronuclear Multiple Quantum Coherence (HMBC) data for the diacetate **4** were used to establish the functionality on the A and B rings of glaciasterol A. Starting from a deshielded ^{1}H NMR resonance at δ 4.99 (HMQC correlation to δ 70.7), assigned to a methine proton attached to a carbon bearing an acetoxy group, COSY45 and HMQC correlations elaborated an isolated proton spin system consisting of -CH_2-CH_2-CHOAc-CH_2- (Table 2: C1 to C4, respectively). This four-carbon fragment could only be accommodated by the A ring of a steroid skeleton. An HMBC correlation between a carbon resonance at δ 27.6 (C1), assigned to the terminal methylene carbon furthest removed from the acetoxy functionality in the four-carbon fragment, and a proton resonance (δ 1.22, s, 3H) assigned to Me19 situated the fragment in a manner such that the acetoxy functionality was at the standard C3 position in the A ring. Additional HMBC correlations from the Me19 proton resonance at δ 1.22 to the ketone carbonyl resonance at δ 200.0 and to the quaternary epoxide carbon resonance at δ 63.0 located the carbonyl functionality at C9 and the trisubstituted epoxide functionality at C5, C6. The epoxide methine proton resonance at δ 3.37 (H6: HMQC correlation to δ 53.4 (C6)) showed a COSY45 correlation to an olefinic resonance at δ 6.76 (d, J = 4.5 Hz: HMQC correlation to δ 138.6) indicating that there was a $\Delta^{7,8}$ trisubstituted olefin in ring B. Conjugation between the $\Delta^{7,8}$ olefin and the C9 ketone accounted for the relatively shielded chemical shift of the ketone carbon resonance (δ 200.0) in **4**.

relation to δ1.64, 1.26) and 43.8 (CH: HMQC correlation to δ 3.22) assigned to C12 of the isolated acetoxyethyl fragment and C14 of the D ring, respectively. The deshielded chemical shift of the H14 resonance (δ 3.22), which indicated that it was an allylic proton, was consistent with linkage of the AB ring system to the D ring through a C8/C14 bond. HMBC correlations between H7 (δ 6.76) and C14 (δ 43.8) and between H14 (δ 3.22) and C7 (δ 138.6) and C8 (δ 141.2) confirmed the C8/C14 linkage. Diacetate **4** had a λ_{max} 254 nm in the UV spectrum, in close agreement with the reported λ_{max} 242 nm for the model steroid **9** (7), once the standard increment of 10 nm for the additional α-alkyl substituent in **4** was added (8). The NMR experiments described above established the constitution of glaciasterol A; however, the small amounts of pure glaciasterol A (**2**) and its diacetate **4** that were available were insufficient for complete elucidation of the stereochemical features of the molecule. Therefore, the stereochemical details of glaciasterol A and B were elucidated on the more accessible glaciasterol B diacetate **5**.

Glaciasterol B diacetate **5** was isolated as white needles (mp 55–57°C) that gave a parent ion in the EIHRMS at m/z 516.3451 Da appropriate for a molecular formula of $C_{31}H_{48}O_6$ (ΔM 0.0 mmu). The NMR data for glaciasterol B diacetate **5** (Table 2) showed that it had a nucleus identical with glaciasterol A diacetate **4** and a side chain identical with the side chain of cholesterol.

A number of spectroscopic and chemical experiments were used to unravel the stereochemistry of glaciasterols A (**2**) and B (**3**). Simultaneous irradiation of the H20 (δ 2.13) and H24 (δ 2.22) resonances in the ^1H NMR spectrum of **2** collapsed the H22/H23 multiplet at δ 5.27–5.28 to an AB doublet with a coupling constant of 15.3 Hz consistent with an *E* olefinic geometry. The observation of a *trans* diaxial coupling between $H4_{ax}$ (δ 2.24, dd, J = 12.5, 12.6 Hz) and H3, in conjunction with the observation of an NOE between the $H4_{ax}$ (δ 2.24) and Me19 (δ 1.23) proton resonances in glaciasterol B diacetate **5**, showed that the A ring of the glaciasterols was in a chair conformation and that the 3-acetoxy substituent had the β configuration. Irradiation of the H14 resonance (δ 3.22) in glaciasterol B diacetate **5** induced an NOE in one of the H11 resonances (δ 4.10) consistent with the expected *trans* relationship between H14 and Me18. C17 and C20 were assumed to have the standard steroidal configurations in the glaciasterols; however, these configurations were not verified experimentally.

Spectroscopic evidence failed to unambiguously establish the 5,6-epoxide stereochemistry. Therefore, the diacetate **5** was treated with aqueous perchloric acid in THF to give the *trans* diol **7**. It had previously been shown that the re-

lated steroidal epoxide **10** underwent reaction with aqueous perchloric acid in THF to give the *trans* diol **11**, resulting from backside nucleophilic attack of water at the allylic carbon rather than at the tertiary carbon of the epoxide (9). To confirm that water had attacked the diacetate **5** at C6, a separate ring opening experiment was carried out using perchloric acid in ≈1:1 $H_2{}^{16}O/H_2{}^{18}O$ and THF. The ^{13}C NMR resonance assigned by HMQC correlations to C6 (δ 72.4) in the resulting isotopically labelled diol **7** showed a 2.9 Hz splitting due to the $^{16}O/^{18}O$ isotope shift and none of the other resonances in the spectrum showed splitting. Diol **7** was acetylated with acetic anhydride in pyridine to give the triacetate **8**. Comparison of the ^{1}H NMR data for **8** recorded in $CDCl_3$ with the data recorded in pyridine-d_5 revealed a large Δδ for the H3α resonance (+0.58 ppm), consistent with an α configuration for the hydroxyl group at C5. The ring opening and pyridine shift experiments together demonstrated that the epoxide functionality in the glaciasterols had the 5α,6α configurations as shown.

Glaciasterol A (**2**) showed in vitro cytotoxicity in murine leukemia L1210 (ED_{50} ≈ 7 μg/mL) and human breast cancer (ED_{50} ≈ 20 μg/mL) cell line assays.[2]

Experimental

Isolation and purification of glaciasterol A (2) and glaciasterol B diacetate (5)

Samples of *A. glacialis* was collected by hand using SCUBA (−5 m) in Sydney Inlet and Barkley Sound, British Columbia.

[2]The murine leukemia L1210 assays were conducted by Dr. T. Allen, Department of Pharmacology, University of Alberta, and the breast cancer cell line assays were conducted by Dr. J. Emerman, Department of Anatomy, U.B.C. For bioassay details see ref. 10.

Freshly collected sponge specimens (160 g wet wt.) were extracted with methanol and 1:1 methanol/CH_2Cl_2. The extracts were combined and concentrated *in vacuo* to give an aqueous suspension that was partitioned between brine and ethyl acetate. Separation of the ethyl acetate soluble materials by gradient silica gel flash chromatography (hexanes/ethyl acetate/methanol) gave a fraction containing a complex mixture of glaciasterols (148 mg). The ^{1}H NMR spectrum of the mixture showed that the glaciasterols possessed a common nucleus attached to a variety of side chains. A small amount (≈1 mg) of pure glaciasterol A (**2**) was obtained from the mixture by sequential application of $AgNO_3$ – silica gel radial TLC (ethyl acetate/benzene 2:3) and reversed phase HPLC (H_2O/methanol 3:7). The remainder of the glaciasterols were not separable in their native forms so the mixture was acetylated. Pure glaciasterol B diacetate (**5**) was obtained from the acetylated steroid mixture by sequential application of silica gel flash chromatography (methanol/CH_2Cl_2 1:99), silica gel radial TLC (methanol/CH_2Cl_2 1:99), and reversed phase HPLC (H_2O/methanol 15:85).

Glaciasterol A (2): amorphous white solid; ^{1}H NMR (Table 1); ^{13}C NMR (Table 1); EILRMS *m/z*: 416, 400, 383, 365, 301, 239, 97; EIHRMS *m/z*: 416.2936 ($C_{26}H_{40}O_4$, ΔM + 0.9 mmu).

Acetylation of glaciasterol A (2)

Glaciasterol A (**2**) (1 mg) was stirred overnight with pyridine and acetic anhydride (0.5 mL each). Excess reagent was removed *in vacuo* to yield pure *glaciasterol A diacetate (4):* white solid; UV (CH_2Cl_2) λ_{max}: 254 nm (ε = 2850); IR (film): 1737, 1685, 1240 cm^{-1}; ^{1}H NMR (Table 2); ^{13}C NMR (Table 2); EILRMS *m/z*: 500, 440, 424, 364, 349, 327, 267, 97; EIHRMS *m/z*: 500.3139 ($C_{30}H_{44}O_6$, ΔM +0.1 mmu).

Acid-catalyzed ring opening of the 5,6-epoxide of glaciasterol A diacetate (4)

Glaciasterol A diacetate (**4**) was stirred for 2 h with THF (0.5 mL) and perchloric acid (20 μL, 69–72%). Excess acid was neutralized with 5% $NaHSO_3$(aq.) and the resulting aqueous solution was extracted with dichloromethane. The organic extracts were pooled, dried over Na_2SO_4, filtered, and evaporated *in vacuo*. The resulting diol was acetylated as previously described and purified by reversed phase HPLC (H_2O/methanol 1:4) to yield the triacetate **6**: white solid; IR (film): 3402, 1738, 1688 cm^{-1}. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.68 (s, Me18), 0.95 (d, *J* = 6.7 Hz, Me25, Me26), 1.03 (d, *J* = 6.8 Hz, Me21), 1.35 (s, Me19), 2.01 (s, OAc), 2.04 (s, OAc), 2.13 (s, OAc), 3.29 (dd, *J* = 10.4, 7.6 Hz, H14), 4.17–4.28 (m, H11, H11′), 5.09 (m, H3), 5.19 (d, *J* = 5.1 Hz, H6), 6.34 (d, *J* = 5.1 Hz, H7); EIHRMS *m/z*: 560.3340 ($C_{32}H_{48}O_8$, ΔM −0.9 mmu).

Glaciasterol B diacetate (5): white needles (H_2O/methanol), mp 55–57°C; IR (film): 1735, 1684 cm^{-1}; CD (MeOH) Cotton effects: λ_{max} (molar elipticities) 335 nm (+8.0 × 10^3), 263 nm (−1.7 × 10^4), 201 nm (−2.6 × 10^4); ^{1}H NMR (Table 2); ^{13}C NMR (Table 2); EILRMS *m/z* (rel. intensity): 516(7), 456(34), 440(16), 343(7: M^+ − (HOAc + C_8H_{17})); EIHRMS *m/z*: 516.3451 ($C_{31}H_{48}O_6$, ΔM 0.0 mmu).

Acid-catalyzed ring opening of the 5,6-epoxide of glaciasterol B diacetate (5)

Glaciasterol B diacetate (**5**) (4 mg) was stirred for 4 h with THF (0.25 mL) and perchloric acid (25 μL). The reaction work-up was identical to that described above for the reaction of glaciasterol A diacetate (**4**). The resulting white solid was purified by reversed phase HPLC (H_2O/methanol 1:4) to yield 5α,6β-dihydroxy glaciasterol B diacetate (**7**). Acetylation of the diol, as described above, gave 5α-hydroxyglaciasterol B triacetate (**8**).

5α,6β-Dihydroxyglaciasterol B diacetate (7): white solid; IR (film): 1739, 1714, 1677 cm^{-1}; ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.76 (s, Me18), 0.87 (d, *J* = 6.6 Hz, Me26, Me27), 0.99 (d, *J* = 6.7 Hz, Me21), 1.38 (s, Me19), 2.00 (s, OAc), 2.04 (s, OAc), 3.29 (dd, *J* = 11.0, 8.6 Hz, H14), 4.03 (d, *J* = 5.1 Hz, H6), 4.12–4.25 (m, H11, H11′), 5.11 (m, H3), 6.42 (d, *J* = 4.9 Hz, H7); ^{13}C NMR (125 MHz, benzene-d_6, partial assignments from HMQC data) δ: 202.3(C9) 170.3(OAc), 170.1(OAc), 138.2(C7), 137.3(C8), 76.5(C5), 72.4(C6), 70.7(C3), 61.5(C11), 50.5, 48.2, 46.4, 43.2(C14), 39.9, 37.4, 35.9, 35.8, 35.1, 28.3, 27.8, 27.1, 26.8, 26.4, 25.0, 23.0(C27), 22.8(C26), 21.5(C19), 21.0, 20.7, 19.2, 17.4(C18); EIHRMS *m/z*: 534.3560 ($C_{31}H_{50}O_7$, ΔM +0.3 mmu).

5α-Hydroxyglaciasterol B triacetate (8): white solid; IR (film): 3448, 1739, 1683 cm^{-1}; ^{1}H NMR (400 MHz, benzene-d_6) δ: 0.66 (s, Me18), 0.90 (d, *J* = 6.6 Hz, Me26, Me27), 0.98 (d, *J* = 6.7 Hz, Me21), 1.27 (s, Me19), 1.70 (s, OAc), 1.72 (s, 6H, OAc), 3.40 (dd, *J* = 10.8, 8.9 Hz, H14), 4.44 (m, 2H, H11, H11′), 5.04 (d, *J* = 5.0 Hz, H6), 5.15 (m, H3), 6.27 (d, *J* = 5.1 Hz, H7); EIHRMS *m/z*: 576.3670 ($C_{33}H_{52}O_8$, ΔM +0.8 mmu).

Acid-catalyzed ring opening of the 5,6-epoxide of glaciasterol B diacetate (5) with $H_2{}^{18}O$

Glaciasterol B diacetate (**5**) (4 mg) was stirred for 4 h with THF (0.25 mL), H_2O (100 μL), $H_2{}^{18}O$ (97.5 at.% ^{18}O, 125 μL), and perchloric acid (25 μL). The reaction work-up was identical to that described above to yield ^{18}O-labelled 5α,6β-dihydroxyglaciasterol B diacetate (**7**).

Received December 6, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

RÉMY CROMER, ULRIKE SPOHR, DEVESHWARI P. KHARE, JACQUES LEPENDU, and RAYMOND U. LEMIEUX. Can. J. Chem. **70,** 1511 (1992).

The H-type 2 human blood group-related trisaccharide (α-L-Fuc-(1c→2b)-β-D-Gal-(1b→4a)-β-D-GlcNAc-OMe (**52**)) is bound by the anti-H lectin of *Galactia tenuiflora* very differently than by the lectin I of *Ulex europaeus*. The reason why the *Galactia* lectin binds the H-type 1 related trisaccharide (α-L-Fuc-(1c→2b)-β-D-Gal-(1b→3a)-β-D-GlcNAc-OMe (**5**)) more strongly and methyl α-L-fucopyranoside much more weakly than does the *Ulex* lectin is that, for the *Galactia* lectin, the hydroxyl groups at positions 3a, 3b, 4b, and 4c are indispensable to complex formation whereas it is the hydroxyl groups at positions 3b, 2c, 3c, and 4c which provide the key polar intractions in the case of the *Ulex* lectin. The H-type 2 (**52**) · *Galactia* lectin complex appears to have the hydroxyl groups at positions 6b, 2c, and 3c at or near the periphery of the combining site and the three key hydroxyl groups hydrogen bonded to the protein deep within the combining site and sheltered from water. The CH_3O-1a, NHAc-2a, and CH_2OH-6a groups likely remain in the aqueous phase remote from the surface of the protein.

RÉMY CROMER, ULRIKE SPOHR, DEVESHWARI P. KHARE, JAQUES LEPENDU et RAYMOND U. LEMIEUX. Can. J. Chem. **70,** 1511 (1992).

On observe que la liaison entre le trisaccharide du groupe sanguin H-de type 2 (α-L-Fuc-(1c→2b)-β-D-Gal-(1b→4a)-β-D-GlcNAc-OMe (**52**)) et la lectine anti-H de *Galactia tenuiflora* est très différente de celle qui le lie à la lectine I de l'*Ulex europaeus*. La raison de la liaison entre la lectine de *Galactia* et le trisaccharide relié groupe H de type 1 (α-L-Fuc-(1c→2b)-β-D-Gal-(1b→3a)-β-D-GlcNAc-OMe (**5**)) qui est plus forte — et la liaison avec l'α-L-fucopyranoside de méthyle qui est beaucoup plus faible — que celles avec la lectine d'*Ulex* est que, pour la lectine de *Galactia*, les groupes hydroxyles aux positions 3a, 3b, 4b et 4c sont indispensables pour la formation de complexe alors que ce sont les groupes hydroxyles en positions 3b, 2c, 3c et 4c qui fournissent les interactions polaires clés dans le cas de la lectine d'*Ulex*. Le complexe groupe H de type 2 (**52**) · la lectine de *Galactia* semble posséder des groupes hydroxyles dans les positions 6b, 2c et 3c au niveau de, ou à la proximité de, la périphérie du site de liaison alors que les trois groupes hydroxyles clés sont liés par des ponts hydrogènes avec la protéine qui se trouve à l'intérieur du site de liaison, protégé de l'eau. Les groupes CH_3O-en la, NHAc- en 2a et Ch_2OH- en 6a restent vraisemblablement dans la phase aqueuse qui se trouve éloignée de la surface de la protéine.

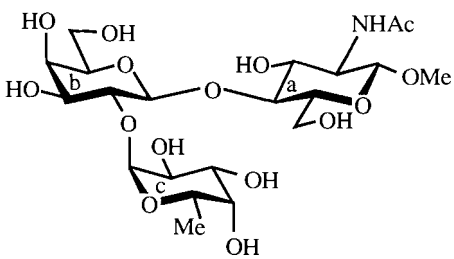
Introduction



H-type 2 (**52**)

We recently reported detailed studies of the binding of the H-type 2 determinant (α-L-Fuc-(1→2)-β-D-Gal-(1→4)-β-D-GlcNAc-OMe (**52**)) both by the lectin I of *Ulex europaeus* (1, 2) and by a monoclonal anti-H-type 2 antibody (2). It was concluded that the interactions leading to complex formation are very similar in that the 3b, 2c, 3c, and 4c hydroxyl groups provide the key polar interactions for binding by the *Ulex* lectin whereas that by the antibody involves the 3b, 2c, and 3c hydroxyl groups. In each case, the remaining hydroxyl groups were found to reside either at the periphery of the combining site or remote from the protein and exposed to interaction with bulk water molecules. These similar interactions for a lectin and an antibody are in sharp contrast to the difference between how the Lewis-b human blood group determinant-related tetrasaccharide (α-L-Fuc-(1→2)-β-D-Gal-(1→3)-[α-L-Fuc-(1→4)]-β-D-GlcNAc-OMe) is bound by the lectin IV of *Griffonia simplicifolia* (3) and by a monoclonal anti-Lewis b antibody (4). In the case of the lectin, the key polar interactions are established by OH-3, OH-4 of the β-D-Gal unit and OH-4 of the α-L-Fuc-(1→4) unit, whereas for the antibody only the involvements of OH-3 of the β-D-Gal and OH-2 of the α-L-Fuc-(1→2) units are essential. We now report that the binding of the H-type 2 trisaccharide (**52**) by a recently reported lectin from the seeds of the plant *Galactia tenuiflora* (5) is much different from that previously reported (1) for the lectin I of *Ulex europaeus*.

Discussion

Synthesis

The starting material for the synthesis of the methyl glycoside of the H-type 1 trisaccharide **5** (Scheme 1) was the alcohol **2** obtained from the previously described disaccharide **1** (6). Compound **2** was reacted with tri-*O*-benzyl fucosyl bromide (**3**) (6, 7) under halide ion catalyzed conditions (8) to produce the trisaccharide **4** in 73% yield. Hydrogen-

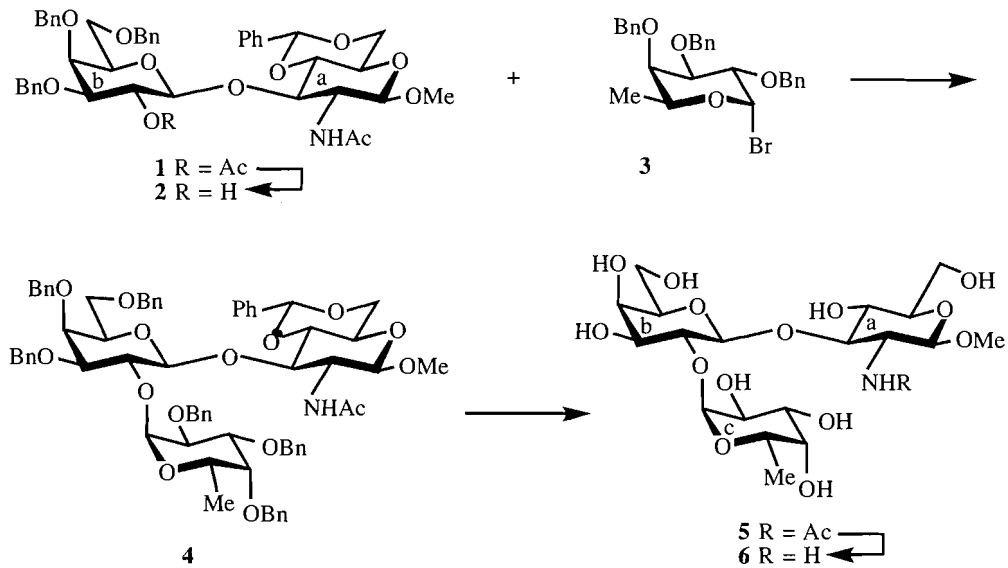

SCHEME 1

ation of **4** over 5% palladium-on-carbon provided **5** in 82% yield. Treatment of **5** with 85% hydrazine hydrate at 140°C for 12 days afforded the amine (**6**) in 66% yield. The ^{13}C nmr data presented in Table 1 and ^{1}H nmr parameters reported in the experimental section fully support the structural assignment.

The syntheses of the 4a- and 6a-deoxy derivatives of **5** are outlined in Scheme 2. Reductive cleavage of the benzylidene ring of **1** with sodium cyanoborohydride – hydrogen chloride (9) produced both the alcohols **7** (73%) (6) and **8** (17%). The Robins and Wilson modification (10) of the Barton–McCombie reaction (11) was used to prepare the deoxy derivative **10** by way of **9** in 50% overall yield. The de-*O*-acetylated derivative (**11**) was α-L-fucosylated to **12** in 57% yield and this product was de-*O*-benzylated in the usual fashion to provide 4a-deoxy-H-type 1-OMe (**13**) in 60% yield.

The **6a**-deoxy-H-type 1-OMe congener (**19**) was prepared first by tosylation of **8** to **14**, then replacement of the tosyloxy group by iodine to form **15** followed by reduction with tributyltin hydride. The overall yield from **8** was 51%. Deacetylation to **17** and subsequent α-L-fucosylation provided **18** in 90% yield which was de-*O*-benzylated in 98% yield to the desired compound **19**.

The 6b-deoxy-*nor*-compound **24** was prepared as outlined in Scheme 3. The known disaccharide **20** (12) was deacetylated to **21** and the 3b and 4b were positions protected by benzylidenation with α,α-dimethoxytoluene in the presence of *p*-toluenesulfonic acid to provide **22** in 90% yield. α-L-Fucosylation in the usual way gave **23** in 81% yield. Catalytic hydrogenolysis removed both the benzyl and benzylidene groups to afford **24** in 92% yield.

To synthesize 3a-deoxy H-type 2-OMe (**33**) (Scheme 4), the disaccharide **27** was prepared, in 53% yield, by reaction of the bromide **25** (13) with alcohol **26** (6) under Helferich conditions. Compound **27** was deallylated to the alcohol **28**, which was deoxygenated at the 3a position in the manner described above for the conversion of **7** to **10**. The origin of the 3-*O*-phenoxycarbonyl derivative of **28**, isolated as a by-product in 8.3% yield, was not determined. The structural assignments were confirmed by fab-mass and ^{1}H nmr spectroscopy. Deacetylation of **30** gave the alcohol **31** which was α-L-fucosylated in the usual way to provide **32** in 69% yield. Catalytic hydrogenolysis afforded the desired congener (**33**). The overall yield from **27** was 42%.

The coupling constants for H-1a and H-2a listed in Table 2 for compounds **27**, **30**–**32** in $CDCl_3$ are much smaller than the near 8 Hz expected should the substituted β-D-GlcNAc residue be in the $^{4}C_{1}$ conformation (**A**) that is normally observed for all-*trans gluco* compounds. Evidently, important contributions to these time-averaged coupling constants are made by these hydrogens in *syn*-clinal relationship. The presence of such conformers could arise from the formation, in an aprotic solvent, of an intramolecular hydrogen bond between the AcN-H group and O-4a in *syn*-axial relationship as shown in Table 2 for the β-D-GlcNAc residue in either the $^{1}C_{4}$ (**B**) or $^{3,0}B$ (**C**) conformations. This must be the case since, as seen in Table 2, the $^{4}C_{1}$ conformation becomes highly populated when the solvent is changed to CD_3OD. The actual ring conformational preferences are surely in between the extremes presented in Table 2, and, therefore, analyses of the coupling constants can only provide qualitative assessments of the conformational equilibria.

The influence of solvent on the equilibrium presented in Table 2 is reminiscent of the conformational preferences for 1,3-diols (14). The fact that the alcohol **28** (R=OH) retains the $^{4}C_{1}$ conformation for the β-D-GlcNAc residue in $CDCl_3$ can be attributed to the highly favorable O-5b→HO-3a intramolecular hydrogen bond (15). An importantly destabilizing nonbonded interaction is expected to occur in **27** between the allyloxy group and O-5b of the β-D-Gal unit. Therefore, the O-4a→HN-2a hydrogen-bonded conformer becomes more abundant, as reflected by the smaller value for $J_{1a,2a}$, when the allyloxy group is replaced by hydrogen. In an aprotic solvent, OH-2b of alcohol **31** (R=H) can be expected to tend to form a hydrogen bond with O-4a and, thereby, weaken the competing O-4a→H-N-2a bond. This would explain the larger value for $J_{1a,2a}$ of **31** as compared to that of **30** (see Table 2). The fact that the substitution of

the 2b-*O*-acetyl group of **30** by the much bulkier 2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl group of **32** has little effect on the conformational equilibrium in $CDCl_3$ is in accord with expectation based on an important contribution to conformational preference by the *exo*-anomeric effect (16). Since this stereoelectronic effect stabilizes the *anti*-periplanar relationship for the C-4a and C-2b atoms, it will favor projection of the substituted β-D-GlcNAc unit away from the *O*-benzylated α-L-Fuc residue. It is noteworthy that the values of the coupling constants assigned to the β-D-GlcNAc unit of compounds **58** and **64** also indicate important contributions to the conformational equilibria in $CDCl_3$ by conformers that allow the intramolecular hydrogen bond depicted in Table 2.

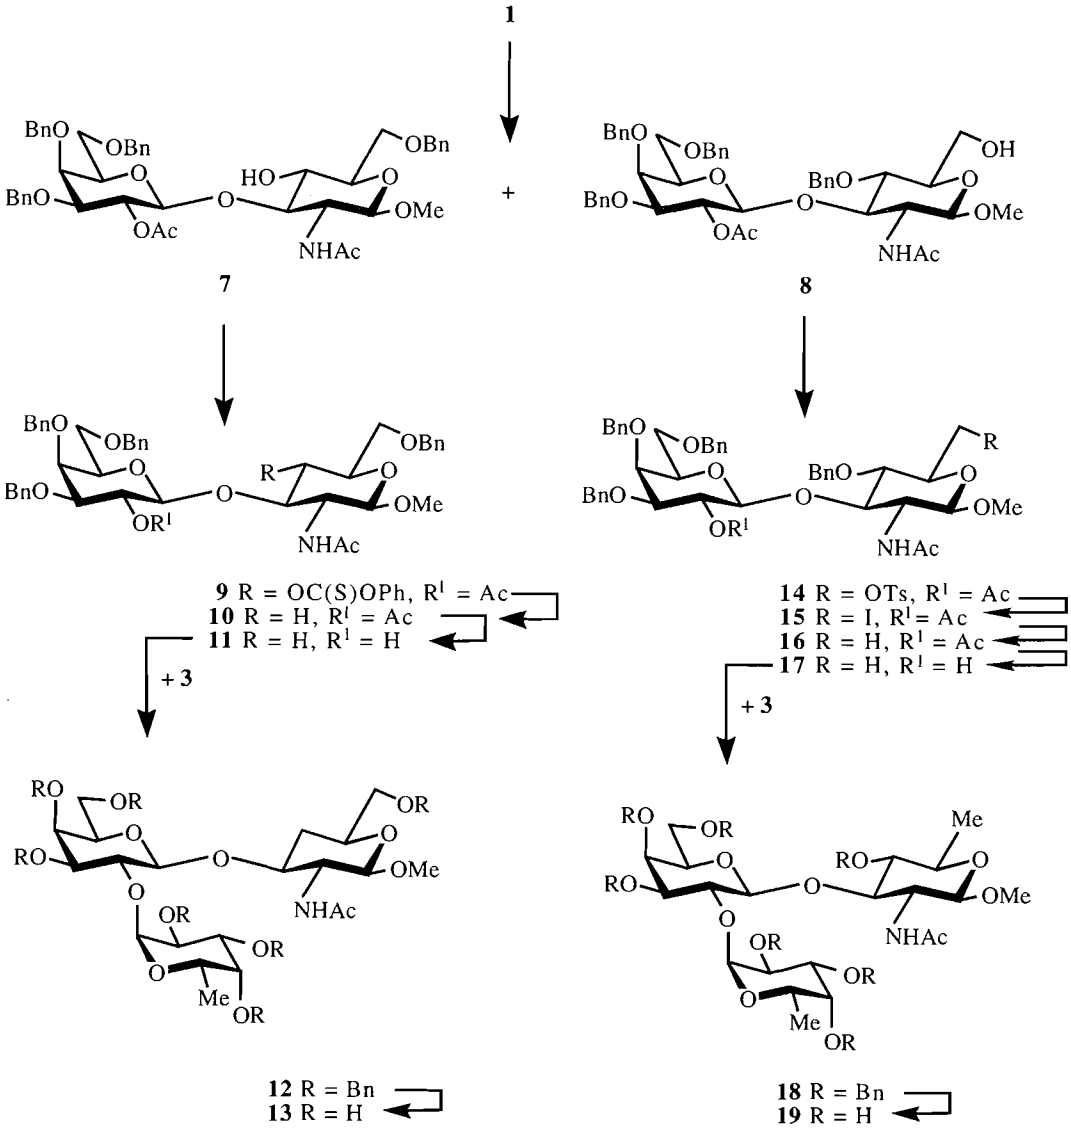
The syntheses of H-type 2-OMe (**52**) (17), which served as the reference inhibitor, and its 3b-, 2c-, 3c-, and 4c-deoxy congeners (**53–56**) are outlined in Scheme 5. Reductive cleavage (9) of methyl 2-acetamido-3-*O*-benzyl-4,6-*O*-benzylidene-2-deoxy-β-D-glucopyranoside (18) provided **39**, which was condensed with bromide **40** (19) under Helferich conditions (66% yield). This product was deacetylated to produce **42**. Benzylidenation with α,α-dimethoxytoluene in the presence of *p*-toluenesulfonic acid then provided the diol **43** in 87% yield. Selective benzoylation of **43** with benzoyl chloride at −78°C provided **44**, which was α-L-fucosylated to the blocked trisaccharide **45** in 74% yield. Debenzoylation and hydrogenolysis of the product (**46**) then produced the H-type 2 trisaccharide as its methyl β-glycoside (**52**). The overall yield from the diol **43** was 41%.

The blocked trisaccharide **46** was also used for the preparation of blocked 3b-deoxy-H-type 2-OMe (**48**), in 52% overall yield, by way of the intermediate 3b-phenylthionocarbonate (**47**). Since partial decomposition occurred in the course of the catalytic hydrogenation to remove the benzyl groups of **48**, the product had to be processed by way of its acetate to obtain pure 3b-deoxy-H-type 2-OMe (**53**) and a meaningful yield cannot be provided.

To prepare 2c-deoxy-H-type 2-OMe **54** (Scheme 5), the disaccharide **44** was reacted with a tenfold excess of bromide **38** (20) under halide-ion-catalyzed conditions. After deacetylation, **49** was isolated in 44% yield and was deblocked by catalytic hydrogenolysis to provide **54** (79% yield).

The 3- and 4-deoxy-α-L-fucopyranosyl bromides (**36** and **37**) were prepared from **34** and **35**, which were obtained by hydrolyses of methyl 2,4-di-*O*-benzyl-3,6-dideoxy- (21) and methyl 2,3-di-*O*-benzyl-4,6-dideoxy-α-L-*xylo*-hexopyranosides.[4] Halide-ion-catalyzed reactions of the bromides **36** and **37** with **44** then produced the 3c- and 4c-deoxy blocked trisaccharides **50** and **51** in 86 and 91% yields. Debenzoyla-

[4]P. Bird and R. U. Lemieux, unpublished results.



SCHEME 2

tion and subsequent catalytic hydrogenation led to the target molecules **55** (61% yield) and **56** (75% yield).

Scheme 6 outlines the synthesis leading to the 6b-deoxy-H-type 2 congener (**62**). Mercuric cyanide promoted glycosylation of **39** with 6-deoxy acetobromogalactose (**57**) (22) provided the blocked disaccharide **58** in 68% yield. Deacetylation to **59** followed by benzylidenation with α,α-dimethoxytoluene in the presence of *p*-toluenesulfonic acid afforded the alcohol **60** in near quantitative yield. α-L-Fucosylation of **60** provided **61** in 81% yield. The target compound **62** was then obtained in 78% yield by hydrogenolysis in the usual manner.

For the synthesis of 4b-deoxy-H-type 2-OMe congener (**66**) (Scheme 7), the alcohol **39** was glycosylated with the previously reported bromide **63** (12) under Helferich conditions. The disaccharide **64** was isolated in only 19% yield. Since sufficient material was obtained, no optimization was attempted. Deacetylation of **64** was followed by α-L-fucosylation with **3** to give **65** (62% yield). The benzyl groups of **65** were then removed by catalytic hydrogenation to provide the desired 4b-deoxy derivative (**66**) of **52** in 94% yield.

Structural and conformational assignments

The ^{13}C nmr data for H-type 2-OMe (**52**), H-type 1-OMe (**5**), and congeners are reported in Tables 2 and 3. These data together with the ^{1}H nmr parameters reported in the experimental section are in full agreement with the structural assignments. The characteristic interunit deshielding of H-1c for both **52** and **5** by 0.54 and 0.41 ppm, respectively, in comparison to H-1 of α-L-FucOMe, is interpreted as resulting from the proximity of H-1c to O-3b of the βDGal unit (23, 24). Similar specific interunit deshieldings of H-5c of **52** and **5** by 0.19 and 0.26 ppm, respectively, can be attributed to the proximity of H-5c to O-4a in **52**, and to O-3a in **5** (23). Except for 3b-deoxy-H-type 2-OMe (**53**), these deshieldings, relative to H-1 and H-5 of α-L-FucOMe and its monodeoxy derivatives, are observed for all the H-type 2 and H-type 1 congeners. However, whereas deoxygenation of H-type 2-OMe at the 3b position to produce **53** did not affect the chemical shift for H-5c, the signal for H-1c was shifted upfield by 0.33 ppm. A similar specific interunit effect of the chemical shift of H-1d was recently observed on deoxygenation of the 3b-position of the Lewis b tetrasac-

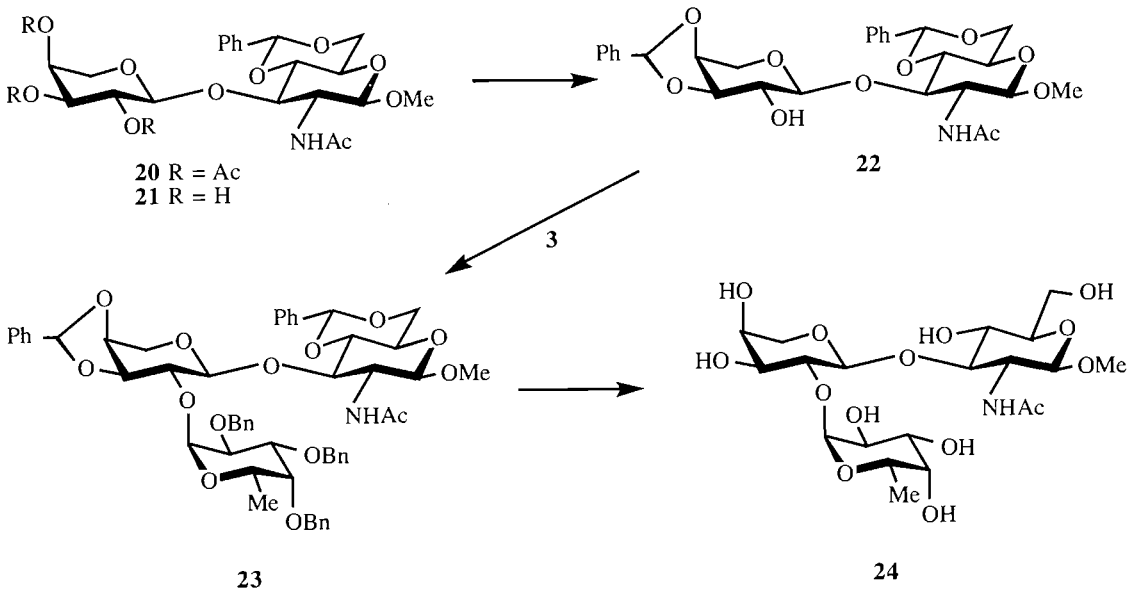
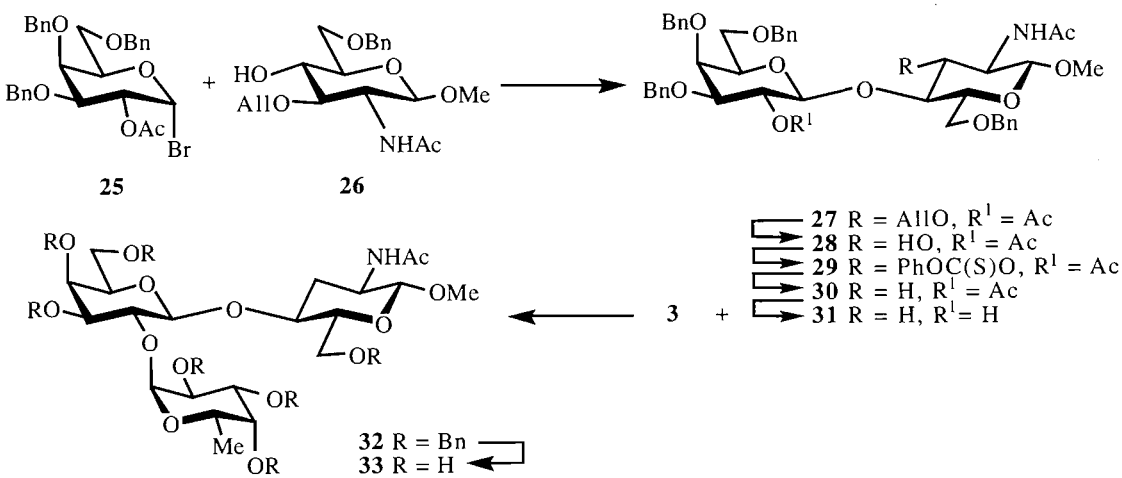


SCHEME 3



SCHEME 4

charide (12). Thus, the ^{1}H nmr data indicate that the conformational preferences for the interunit glycosidic bonds are not significantly changed by the structural modifications leading to the various H-type 1 and H-type 2 congeners. Consequently, the interpretations attached to the immunochemical data will be based on the HSEA conformers (23), which well accommodate the ^{1}H nmr data. In fact, as will be seen below, the interpretations are highly attractive.

Immunochemical studies

The immunochemical data are based on a previously reported solid-phase competitive radioimmunoassay (3) by which the amounts of haptens required for 50% inhibition of the binding of an ^{125}I-labelled H-type 2-BSA artificial antigen by the immobilized lectin are determined. The results are reported in Tables 4–6.

LePendu *et al.* (5) reported that the *Galactia* lectin has a specificity for the H-type 2 blood group determinant. However, the present investigation has revealed the lectin to also have an affinity for the H-type 1 trisaccharide (**5**) that is only 2–3 times less than that for H-type 2 trisaccharide (**52**). To ensure that the H-type 1 specificity is due to a cross-reaction and not to the presence of a second lectin with an H-type 1 affinity, the lectin preparations were affinity purified both on H-type 2- and H-type 1-Synsorb® columns and the products examined by SDS gel electrophoresis under non-reducing conditions (25). Both the preparations provided bands at 27 and 29 kDa of the same relative intensity of 3:1 as was found in previous preparations (5) and appeared identical. It is concluded, therefore, that the preparation is a single lectin that has an affinity for both the type 1 and type 2 structures (**5** and **52**, respectively) and that these epitopes share common structural features. This can be appreciated from the surfaces presented in Fig. 1 which conform with the following inhibition data.

As seen in Table 4, the H-type 2 related structure (**52**) is only three times more potent an inhibitor of the H-type 2 artificial antigen than is the diastereoisomeric H-type 1-OMe (**5**). That the β-D-GlcNAc unit is involved in the binding of **52** is surely indicated by the inactivity of its 3a-deoxy de-

rivative (**33**). Since the 4a-hydroxyl group of **5** is expected, as seen in Fig. 1, to project toward the β-D-Gal unit in a very similar manner as does OH-3a in **52** (1), the inactivity of 4a-deoxy-H-type 1-OMe (**13**) was not surprising. The difucose derivatives **68** and **76** were also inactive. In view of the high activity retained by the variety of compounds (**69**–**75**) obtained by modifying the CH_2OH group of the GlcNAc unit of **52**, this hydroxyl group is surely not involved in the binding and remains in the aqueous phase. It would be expected, therefore, that *N*-deacetylation of **5** to produce **6** would not materially affect the binding, as was indeed the case. Clearly, however, in the complex, the CH_2OH-5a group of **52** and the NHAc-2a group of **5** must be at the periphery of the combining site (Table 4). This conclusion is in accord with the conformational preferences assigned to these compounds (Fig. 1), which infer that these groups are in close proximity to OH-4c, one of the four hydroxyl groups that, as will be seen below, provide key polar interactions. In view of these observations, the remote methyl aglycons of **52** and **5** were not expected to be directly involved in the complexation. This was confirmed by the high activity of **67**. It appears that the aglycon of **67** contributes a small hydrophobic stabilization of the complex.

Since OH-3a of **52** (or OH-4a of **5**) is essential to complex formation, it could be expected that an H-related disaccharide would be inactive. However, as seen in Table 4, **77** is only about 12 times less potent an inhibitor than is **52**. Evidently, the polar group of the lectin that forms a hydrogen bond with OH-3a of **52** (or OH-4a of **5**) can come into contact with the aqueous phase. Therefore, it is not the loss of the hydrogen bond with the GlcNAc unit that leads to the inactivities displayed by the deoxy compounds **33** and **13**. Instead, these inactivities must result from the resistance by the polar group of the protein to shed its water of hydration in order to form the complex when it is faced with the hydrophobic environment presented by the deoxy compounds. This observation provides experimental support for the postulation earlier made in this regard (26). The about 1.5 kcal/mol lower stability of the complex provided by the H-disaccharide must be related to the changes in protein structure required to accommodate the water molecules that remain attached to the polar group of the combining site.

The involvement of the β-D-Gal unit in the complex formed by the *Galactia* lectin with either H-type 2-OMe (**52**) or H-type 1-OMe (**5**) can be appreciated from the data presented in Table 5 with reference to Fig. 1. It is seen in Fig. 1 that the topography presented by this unit is the same for both the epitopes. Since the changes at the 3b or 4b positions resulted in inactive compounds, these hydroxyl groups provide key polar interactions deep in the combining site where the resulting hydrogen bonds are sheltered from exchange with water. The inactivity of the 6b-deoxy-*nor* derivative (**24**) of H-type 1-OMe (**5**) implies that the CH_2-5b group comes into contact with the combining site. That this nonpolar interaction is at the periphery is indicated by the high activity of the 6b-deoxy H-type 2 compound (**62**). It is to be recognized that, as recently demonstrated (27), the reduced activity does not necessarily mean that OH-6b becomes engaged in a hydrogen bond with the protein. Instead, small changes in the stability of a complex that result from a structural modification of the ligand may indicate that the modification occurred near the surface of the protein and thereby affected the energy of hydration (28).

The results presented in Table 6 require that both OH-4c and Me-5c of the fucose unit are involved in the complexation of **52** by the *Galactia* lectin. Although the replacement of either one of these groups by hydrogen resulted in important loss in activity, complex formation could be detected since the losses in stability were less than 2 kcal/mol. Whereas the removal of OH-4c leads to the loss of a polar interaction, the substitution of the methyl group by hydrogen leads to a loss of complementarity. The OH-2c and OH-3c groups clearly remain in contact with the aqueous phase. It is noteworthy that the methyl glycosides of α-L-fucose (**81**) and *N*-acetyl-β-lactosamine (**80**) are essentially inactive although both provide structural features essential to the epitope.

SCHEME 5

According to the foregoing interpretations of the experimental data, the lower activity of H-type 1-OMe (**5**) as compared to that of H-type 2-OMe (**52**) is related to the difference in hydration about the acetamido group of **52** to that about the hydroxymethyl group of the β-D-GlcNAc unit of **5**. We have unequivocally established in the case of the binding of the Lewis b-OMe tetrasaccharide by the lectin IV of *Griffonia simplicifolia* (28) that decreases in the stability of a complex by as much as 0.7 kcal/mol can occur by substitutional changes in groups that are near the periphery of the combining site but remain in bulk water solution. These observations are of major significance to attempts at drawing conclusions as to the size of combining sites. Thus, for example, the binding of linear, regular oligosaccharides has been observed on several occasions to increase with increasing chain length (29). Normally, after the trisaccharide level, the increases are less than 0.5 kcal/mol. In view of the present findings (27), changes of this magnitude do not necessarily relate to the size of the combining site. Instead, these may be related to changes in the hydration of the complex that result from increasing the chain length by sugar units that are close to, but not in contact with, the protein.

In contrast to the *Galactia* lectin, which binds the H-type 2 trisaccharide (**52**) only three times more strongly than the H-type 1 isomer (**5**) (see Table 4), we have now determined that the lectin I of *Ulex europaeus* binds **52** 100 times more strongly than it does **5**. As previously reported (30), de-*N*-acetylation of **5** provides a much superior inhibitor. Indeed, we now find that the amine (**6**) is only four times less potent

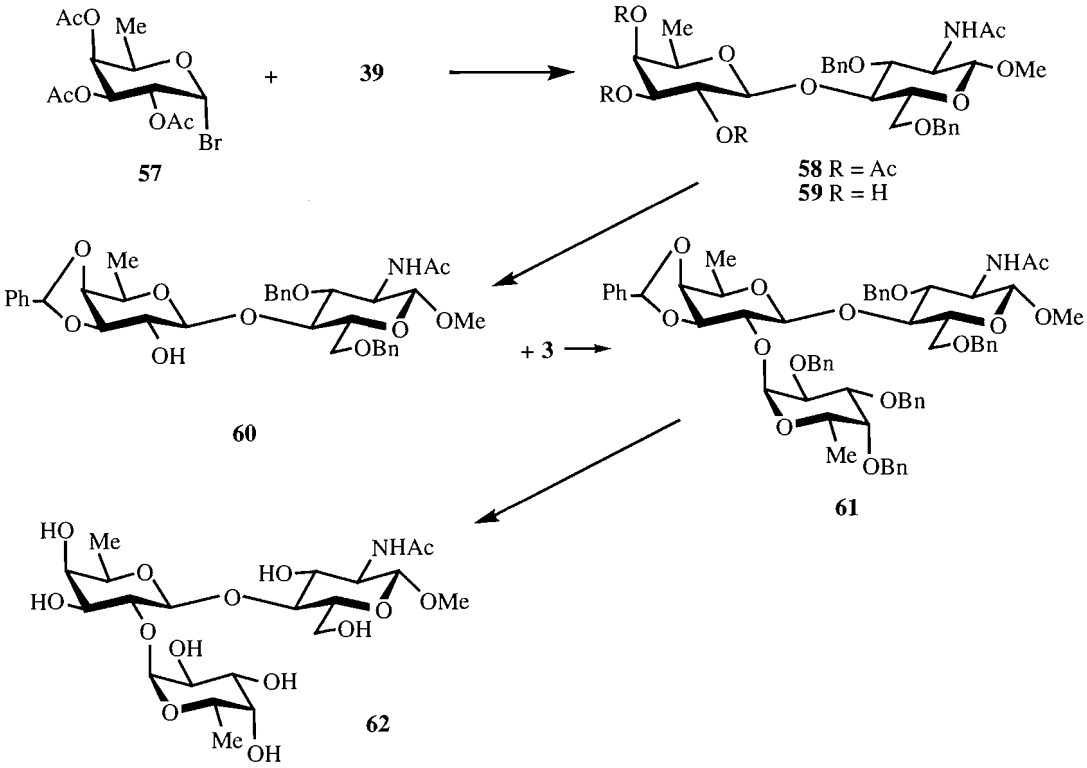
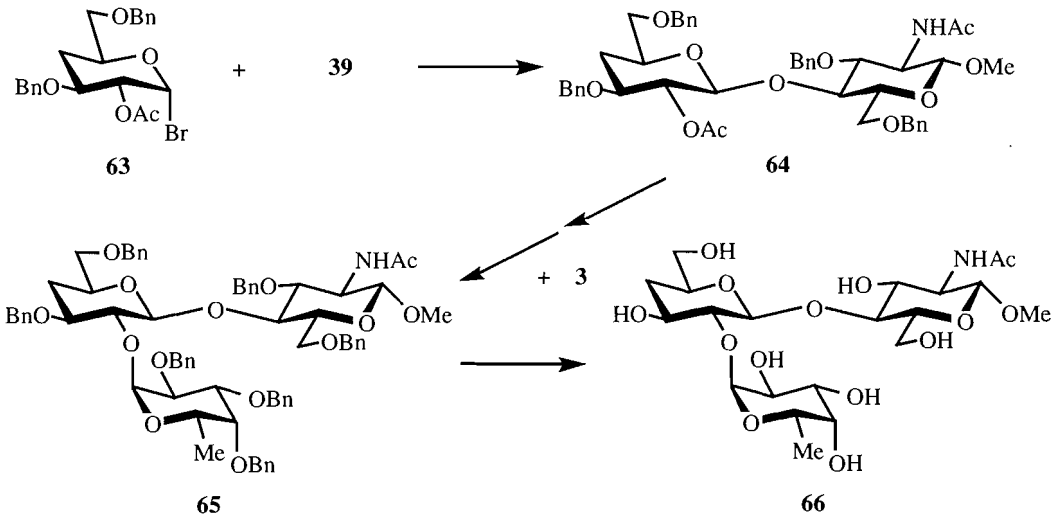


SCHEME 6



SCHEME 7

an inhibitor than is **52**. These results are readily appreciated from the structures presented in Fig. 2.

The probing of the combining site of the *Ulex* lectin has shown (2) that the binding of **52** involves the polyamphiphilic surface presented in Fig. 2 wherein the four hydroxyl groups known to provide key polar interactions are displayed. Much the same surface can be presented by the H-type 1 isomer (**5**). The main difference is that the acetamido group of **5** is projected to near the region that is bound. In view of the activity of **6**, the involvement of the acetamido group must be at the periphery of the combining site. Also the 6a-methylene group of the β-D-GlcNAc unit of **52** must be at, or close to, the periphery of the combining site since the 6a-hydroxyl group, in contrast to earlier indications (1), is not directly involved in the binding reaction (2). These data therefore allow the important conclusion that the surface recognized by the lectin is much smaller than that suggested on the basis of probing experiments (1). Indeed, the binding appears to be restricted to the rather small hydrophilic, but polyamphiphilic, surface presented in Fig. 2. The data also lend strong support to the conformational preferences assigned to the trisaccharides (**5** and **52**).

Experimental

Methods

The isolation of the lectin of *Galactia tenuiflora* was carried out as described (5). Approximately 200 mg of the affinity-purified lectin were isolated from 50 g mature seeds. Stock solutions of the lectin in phosphate buffer solution (3) were of light brownish colour.

The radioimmunoassays were performed following the procedure recently described (3) using an ^{125}I-labelled [α-L-Fuc-(1→2)-β-D-Gal-(1→4)-β-D-GlcNAcO-$(CH_2)_8$CONH]$_{16}$–BSA antigen with an initial activity of 250 000 cpm/100 μL provided by Chembiomed Ltd., Edmonton, Canada. The coated polystyrene vials were prepared with the affinity-purified lectin at a concentration of 100 μg/mL in PBS buffer. In the absence of inhibitor, the coated tubes acquired about 120 000 cpm.

The ^1H nmr spectra were measured at 300, 360, and 400 MHz (Bruker AM 300, WM 360, and WH 400) with tetramethylsilane as internal standard for $CDCl_3$ solutions. Reference standard for D_2O solutions was acetone (2.225 ppm). The ^{13}C nmr spectra were recorded at 100 and 75 MHz (Bruker WH 400 and AM 300) using as a solvent either $CDCl_3$ (77.0 ppm) or D_2O with dioxane (67.4 ppm) as internal standard. Optical rotations were measured at room temperature (23 ± 1°C) in a 1-dm cell on a Perkin Elmer 241 polarimeter. Thin-layer chromatograms were performed on precoated plates of silica gel (60-F 254, E. Merck, Darmstadt) and visualized by spraying with 10% sulfuric acid in ethanol followed by heating. For column chromatography, silica gel 60 (230–240 mesh, E. Merck) and distilled solvents were used. Solvents and reagents were purified and dried according to standard procedures. Melting points are uncorrected.

Methyl 2-acetamido-4,6-O-benzylidene-2-deoxy-3-O-(3,4,6-tri-O-benzyl-β-D-galactopyranosyl)-β-D-glucopyranoside (2)

Compound **1** (5.0 g, 6.27 mmol) (6) was dissolved in a mixture of methanolic 0.05 N sodium methoxide (110 mL) and dichloromethane (50 mL) and left at room temperature for 1 day. Deionization with Amberlite IRC 50 H^+ followed by evaporation left a white solid that was recrystallized from chloroform – ethyl acetate to give pure **2** (4.12 g, 87%); mp 212–213°C; $[\alpha]_D$ −39 (*c* 0.5, dichloromethane); ^1H nmr ($CDCl_3$) δ: 7.5–7.2 (m, 20H, 4Ph), 6.07 (d, 1H, $J_{NH,2a}$ 7.0 Hz, NH), 5.52 (s, 1H, C*H*Ph), 4.91 and 4.60 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.78 (d, 1H, $J_{1a,2a}$ 8.5 Hz, H-1a), 4.65 and 4.63 (ABq, 2H, $J_{A,B}$12.0 Hz, CH_2Ph), 4.42 and 4.39 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.39 (d, overlapped by CH_2Ph, $J_{1b,2b}$ ~ 8.0 Hz, H-1b), 4.35 (dd, 1H, $J_{6a,6a'}$ 10.5 Hz, $J_{6a,5a}$ 5.0 Hz, H-6a), 4.30 (t, 1H, $J_{2a,3a}$ 9.0 Hz, $J_{3a,4a}$ 9.0 Hz, H-3a), 4.0 (dt, 1H, $J_{2b,3b}$ 9.5 Hz, $J_{2b,OH}$ 1.5 Hz, H-2b), 3.91 (d, 1H, $J_{4b,3b}$ 2.5 Hz, H-4b), 3.79 (t, 1H, $J_{5a,6a'}$ 10.0 Hz, H-6a'), 3.65 (t, 1H, $J_{4a,5a}$ 9.0 Hz, H-4a), 3.49 (s, overlapped, CH_3O), 3.34 (dd, 1H, H-3b), 2.9 (s, 1H, OH), 1.91 (s, 3H, CH_3CO). Anal. calcd. for $C_{43}H_{49}NO_{11}$: C 68.33, H 6.53, N 1.85; found: C 67.92, H 6.44, N 1.79.

2,3,4-Tri-O-benzyl-α-L-fucopyranosyl bromide (3) (7)

Bromide **3** was prepared just prior to use from 2,3,4-tri-*O*-benzyl-L-fucopyranose (7) as reported (6), which is according to the preparation of bromide **36**.

Methyl 2-acetamido-4,6-O-benzylidene-2-deoxy-3-O-[3,4,6-tri-O-benzyl-2-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (4)

A solution of freshly prepared bromide **3** (8.51 mmol) in dichloromethane (10 mL) was added to a solution of **2** (3.0 g,

3.97 mmol) and tetraethylammonium bromide (840 mg, 4.00 mmol) in dichloromethane (15 mL) and *N,N*-dimethylformamide (4 mL) containing 4 Å molecular sieves (10 g). The mixture was stirred for 20 h, then methanol (2 mL) was added and stirring continued for two more hours. It was diluted with dichloromethane, filtered through a pad of Celite, washed with aqueous saturated sodium hydrogencarbonate and water, dried, and evaporated. The crude product was applied to a silica gel column (hexane – ethyl acetate, 2:1; dichloromethane – ethyl acetate, 2:1) to provide the title compound **4** (3.4 g, 73%) as a foam; $[\alpha]_D$ −83 (*c* 0.5, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.5–7.1 (m, 35H, 7Ph), 6.46 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.52 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 5.50 (s, 1H, C*H*Ph), 3.49 (s, CH_3O), 3.37 (m, 1H, H-2a), 1.82 (s, 3H, CH_3CO), 1.22 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{70}H_{77}NO_{15}$: C 71.72, H 6.62, N 1.19; found: C 71.83, H 6.58, N 0.91. Further development with ethyl acetate eluted the starting material **2** (680 mg, 23%).

*Methyl 2-acetamido-2-deoxy-3-*O*-[2-*O*-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (5)*

Compound **4** (100 mg, 0.09 mmol) in 95% ethanol (7 mL) was hydrogenated for 2 days over 5% palladium-on-carbon (100 mg) at 110 psi (1 psi = 6.89 kPa). After filtration, evaporation of the solvent, and twofold precipitation of the product from methanol – ethyl acetate, compound **5** (38.0 mg, 82%) was obtained as a white powder; $[\alpha]_D$ −77.3 (*c* 0.62, water); ^{1}H nmr (D_2O) δ: 5.18 (d, 1H, $J_{1c,2c}$ 3.8 Hz, H-1c), 4.63(d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.34 (d, 1H, $J_{1a,2a}$ 8.5 Hz, H-1a), 4.30 (q, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{4c,5c}$ < 1.0 Hz, H-5c), 3.98 (dd, 1H, $J_{2a,3a}$ 10.0 Hz, $J_{3a,4a}$ 8.5 Hz, H-3a), 3.94 (dd, 1H, $J_{6a,6a'}$ 12.0 Hz, $J_{5a,6a}$ 1.5 Hz, H-6a), 3.88 (dd, 1H, $J_{3b,4b}$ 3.3 Hz, H-4b), 3.83 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-3b), 3.78 (H-2a), 3.76 (H-6a′), 3.76 (H-4c), 3.75 (H-2c), 3.68 (H-3c), 3.67 ± 0.02 (H-5b), 3.58 (dd, 1H, H-2b), 3.49 (H-4a), 3.48 (H-5a), 3.48 (CH_3O), 2.04 (s, 3H, CH_3CO), 1.22 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 1.

*Methyl 2-amino-2-deoxy-3-*O*-[2-*O*-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (6)*

A solution of **5** (35 mg, 0.06 mmol) in hydrazine hydrate 85% (6 mL) was heated in a metal bomb at 140°C for 12 days. After evaporation and codistillation with water and methanol, the crude product was applied to a column of Sephadex LH 20 and eluted with ethanol–water 1:1. After another gel filtration, the product was precipitated from methanol – ethyl acetate to provide **6** (21.3 mg, 66%); $[\alpha]_D$ −69 (*c* 0.6 water); ^{1}H nmr (D_2O) δ: 5.30 (d, 1H, $J_{1c,2c}$ 2.5 Hz, H-1c), 4.72 (d, 1H, $J_{1b,2b}$ 7.8 Hz, H-1b), 4.37 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.32 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 3.94 (dd, overlapped, $J_{5a,6a}$ 1.9 Hz, H-6a), 3.92 (overlapped, H-4b), 3.90 (dd, overlapped, $J_{3b,4b}$ 3.3 Hz, H-3b), 3.81 (H-4c), 3.80 (H-2c), 3.74 (H-6a′), 3.71 (H-3a), 3.70 (H-2b), 3.55 (CH_3O), 3.48 (H-5a), 2.83 (dd, 1H, $J_{2a,3a}$ 10.0 Hz, H-2a), 1.22 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 1.

*Methyl 2-acetamido-3-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-4-*O*-benzyl-2-deoxy-β-D-glucopyranoside (8)*

Compound **8** was obtained as a minor compound (17%) besides the main product **7** (73%) when **1** was treated with sodium cyano-

borohydride as reported (6). Chromatography of the mother liquor of **7** on a column of silica gel (ethyl acetate) provided **8** as a white powder; $[\alpha]_D$ −12.5 (*c* 1.0, chloroform); ^1H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 6.03 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.28 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.60 (d, 1H, H-1b), 4.45 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.10 (t, 1H, $J_{3a,4a} \sim J_{2a,3a} \sim$ 8.0 Hz, H-3a), 3.93 (bd, 1H, $J_{3b,4b}$ 3.0 Hz, $J_{4b,5b} <$ 1 Hz, H-4b), 3.61 (t, 1H, $J_{4a,5a}$ 8.0 Hz, H-4a), 3.52 (dd, overlapped, H-3b), 3.42 (s, 3H, CH_3O), 2.05 and 1.92 (2s, each 3H, $2CH_3CO$). Anal. calcd. for $C_{45}H_{53}NO_{12}$: C 67.57, H 6.68, N 1.75; found: C 67.66, H 6.74, N 1.75. An analytical sample was acetylated conventionally (pyridine, acetic anhydride). The ^1H nmr spectrum of the resulting di-*O*-acetate showed a doublet (2H, $J_{5a,6a} \sim$ 4 Hz, H_2-6a) at 4.32 ppm.

Methyl 2-acetamido-3-O-(2-O-acetyl-3,4,6-tri-O-benzyl-β-D-galactopyranosyl)-6-O-benzyl-2-deoxy-4-O-phenoxythiocarbonyl-β-D-glucopyranoside (9)

A mixture of **7** (100 mg, 0.125 mmol), 4-dimethylaminopyridine (519 mg, 4.25 mmol), and phenyl chlorothionocarbonate (346 μL, 2.5 mmol) in dry acetonitrile (4 mL) was boiled under reflux for 20 h and then left at room temperature for 20 h. The mixture was diluted with dichloromethane and sequentially washed

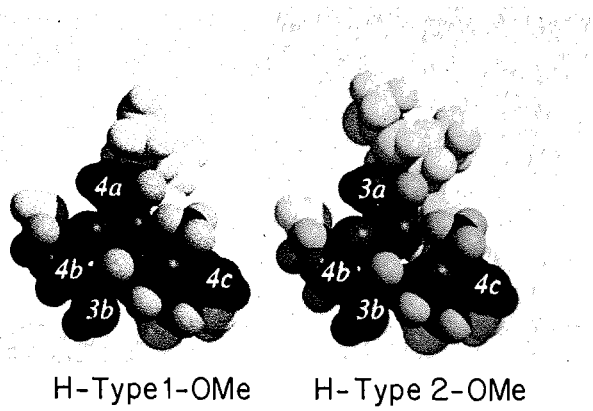

FIG. 1. The surface common to the H-type 1 (**5**) and H-type 2 (**52**) trisaccharides that is recognized by the lectin of *Galactia tenuiflora* is represented by the darkly colored atoms. The off-white groups are expected to remain solvated by water.

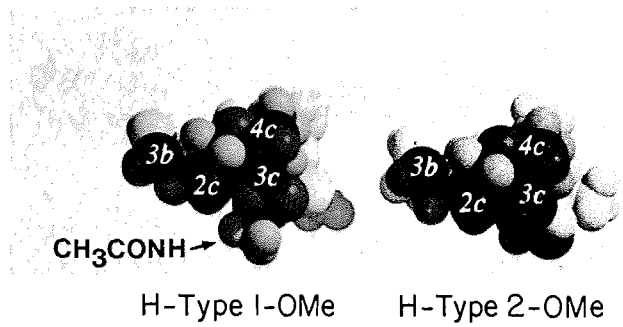

FIG. 2. The surface of the H-type 2 trisaccharide (**52**) that is recognized by the lectin I of *Ulex euroaeus* and the very similar surface present in the H-type 1 trisaccharide (**5**). It is seen that de-*N*-acetylation of the H-type 1 compound will improve the complementarity to the combining site of the lectin by rendering the surface more similar to that presented by the H-type 2 isomer.

with ice-cold 0.5 N hydrochloric acid, saturated aqueous sodium hydrogencarbonate, and water, followed by drying and evaporation. The resultant material was recrystallized from methanol–ether–hexane to provide **9** (76 mg, 65%); mp 173.5–174°C; $[\alpha]_D$ +17.5 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.00 (m, 25H, 5Ph), 5.73 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.51 (t, 1H, $J_{3a,4a} \sim J_{4a,5a}$ 7.5 Hz, H-4a), 5.29 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{1b,2b}$ 8.0 Hz, H-2b), 4.91 (d from ABq, 1H, $J_{A,B}$ 12.0 Hz, 1CH_2Ph), 4.78 (d, 1H, $J_{1a,2a}$ 7.0 Hz, H-1a), 4.47 (d, 1H, H-1b), 3.96 (bd, 1H, $J_{3b,4b}$ 2.5 Hz, $J_{4b,5b}$ < 1 Hz H-4b), 3.48 (s, 3H, CH_3O), 2.02 and 1.93 (2s, each 3H, 2CH_3CO). Anal. calcd. for $C_{52}H_{57}NO_{13}S$: C 66.72, H 6.14, N 1.50, S 3.42; found: C 66.77, H 6.23, N 1.34, S 3.23.

*Methyl 2-acetamido-3-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-*β*-D-*galactopyranosyl)-6-O-*benzyl-2,4-dideoxy-*β*-D-*xylo-*hexopyranoside (**10**)*

Argon was passed through a solution of **9** (290 mg, 0.31 mmol) in toluene (18 mL) for 50 min at 80°C. Then 2,2′-azobis(isobutyronitrile) (46 mg, 0.28 mmol) and tributyltin hydride (0.83 mL, 3.1 mmol) were added. After 2 h at 80°C, the mixture was allowed to reach room temperature and was washed with aqueous potassium fluoride solution and water, followed by drying and evaporation. The crude product was applied to a column of silica gel (dichloromethane–methanol, 98:2) and eluted in 77% yield (188 mg). The analytical sample was recrystallized from methanol–ether–hexane; mp 201–203°C; $[\alpha]_D$ +4.2 (*c* 0.8, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 5.66 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.28 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.90 (d, from ABq, 1H, $J_{A,B}$ 12.0 Hz, 1CH_2Ph), 4.80 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.65–4.30 (m, 7H, CH_2Ph), 4.44 (d, 1H, H-1b), 3.90 (bd, 1H, $J_{3b,4b}$ 3.0 Hz, $J_{4b,5b}$ < 1 Hz, H-4b), 3.66 (bm, 1H, H-5a), 3.47 (s, 3H, CH_3O), 2.94 (ddd, 1H, $J_{2a,3a} \sim$ 9.0 Hz, H-2a), 2.15 (bdd, 1H, $J_{4aeq,4aax}$ 13.0 Hz, $J_{3a,4aeq} \sim$ 6 Hz, $J_{4aeq,5a} \sim$ 2 Hz, H-4aeq), 2.01 and 1.92 (2s, each 3H, 2CH_3CO), 1.51 (q, 1H, $J_{4aax,5a} \sim J_{3a,4aax} \sim$ 11 Hz, H-4aax). Anal. calcd. for $C_{45}H_{53}NO_{11}$: C 68.88, H 6.81, N 1.79; found: C 68.66, H 6.93, N 1.75.

*Methyl 2-acetamido-6-*O*-benzyl-2,4-dideoxy-3-*O*-(3,4,6-tri-*O*-benzyl-*β*-D-*galactopyranosyl)-*β*-D-*xylo-*hexopyranoside (**11**)*

A solution of acetate **10** (180 mg, 0.23 mmol) in methanolic 0.05 N sodium methoxide (25 mL) was kept overnight at room temperature. The mixture was neutralized with Amberlite IRC 50 (H^+) resin and evaporated to leave **11** (150 mg, 88%) as a solid. An analytical sample was recrystallized from dichloromethane–hexane; mp 202–204°C; $[\alpha]_D$ −4.7 (*c* 1.4, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 6.19 (d, 1H, $J_{NH,2a}$ 7.0 Hz, NH), 4.85–4.37 (m, 8H, 4CH_2Ph), 4.77 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.28 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 3.90 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, H-2b), 3.85 (bd, 1H, $J_{3b,4b}$ 3.0 Hz, $J_{4b,5b}$ < 1 Hz, H-4b), 3.70 (bm, 1H, H-5a), 3.48 (s, 3H, CH_3O), 3.34 (dd, 1H, H-3b), 3.11 (ddd, 1H, $J_{2a,3a}$ 10.0 Hz, H-2a), 3.09 (bs, 1H, OH), 2.17 (bddd, 1H, $J_{4aeq,4aax}$ 13.0 Hz, $J_{3a,4aeq}$ 5.5 Hz, $J_{4aeq,5a}$ 2.0 Hz, H-4aeq), 1.91 (s, 3H, CH_3CO), 1.51 (ddd, 1H, $J_{4aax,5a} \sim J_{3a,4aax}$ 11.0 Hz, H-4aax). Anal. calcd. for $C_{43}H_{51}NO_{10}$: C 69.62, H 6.93, N 1.89; found: C 69.73, H 6.89, N 1.83.

*Methyl 2-acetamido-6-*O*-benzyl- 2,4-dideoxy-3-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-*α*-L-*fucopyranosyl)-*β*-D-galactopyranosyl]-*β*-D-*xylo-*hexopyranoside (**12**)*

A solution of bromide **3** (0.62 mmol) in dichloromethane (0.7 mL) was transferred into a stirred mixture of alcohol **11** (150 mg, 0.202 mmol), tetraethylammonium bromide (63 mg, 0.30 mmol), 4 Å molecular sieves (powdered, 2g), and *N,N*-dimethylformamide (0.5 mL) in dichloromethane (3 mL). After stirring for 24 h, methanol (0.5 mL) was added and stirring continued for 1 h. Usual processing followed by column chromatography on silica gel (dichloromethane–methanol, 98.5:1.5) provided pure **12** (134 mg, 57%) after recrystallization from ether–hexane; mp 83–85°C; $[\alpha]_D$ −61.4 (*c* 0.8, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.10 (m, 35H, 7Ph), 5.95 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.60 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.95–4.42 (m, 14H, 7CH_2Ph), 4.46 (d, 1H, H-1b), 4.44 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.25 (q, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{4c,5c}$ < 1 Hz, H-5c), 4.16 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, $J_{1b,2b}$ 8.0 Hz, H-2b), ~4.04 (bm, 1H, H-5a), 4.01 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), ~3.88 (m, 2H, $J_{3c,4c} \sim$ 2.5 Hz, H-3c, H-4c), 3.77 (bd, 1H, $J_{3b,4b}$ 2.5 Hz, $J_{4b,5b}$ < 1 Hz, H-4b), 3.45 (s, 3H, CH_3O), 3.38 (H-2a), 2.17 (bdd, 1H, $J_{4aeq,4aax}$ 12.5 Hz, $J_{4aeq,3a}$ 4.5 Hz, $J_{4aeq,5a} \sim$ 1 Hz, H-4aeq), 1.86 (s, 3H, CH_3CO), 1.54 (bq, 1H, $J_{3a,4aax} = J_{4aax,5a}$ 12.0 Hz, H-4aax), 1.18 (d, 3H, H_3-6c). Anal. calcd. for $C_{70}H_{79}NO_{14} \cdot 1H_2O$: C 71.45, H 6.94, N 1.19; found: C 71.21, H 6.88, N 1.27.

*Methyl 2-acetamido-2,4-dideoxy-3-*O*-[2-*O*-(*α*-L-*fucopyranosyl)-*β*-D-galactopyranosyl]-*β*-D-*xylo-*hexopyranoside (**13**)*

A mixture of **12** (110 mg, 0.095 mmol) and 5% palladium-on-carbon (115 mg) in 95% ethanol (20 mL) was hydrogenated at atmospheric pressure for 16 h. Filtration and solvent evaporation left a residue that was passed through a column of Biogel P-2 (ethanol–water, 1:9). Freeze-drying an aqueous solution provided **13** (30 mg, 60%) as a light white powder; $[\alpha]_D$ −88 (*c* 0.3, water); ^{1}H nmr (D_2O) δ: 5.17 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 4.60 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.25 (q, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{4c,5c}$ < 1 Hz, H-5c), 4.24 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.08 (ddd, 1H, $J_{3a,4aax} = J_{2a,3a}$ 11.0 Hz, $J_{3a,4aeq}$ 5.0 Hz, H-3a), 3.88 (bd, 1H, $J_{3b,4b}$ 3.3 Hz, $J_{4b,5b}$ < 1 Hz, H-4b), 3.80 (dd, H-3b), 3.53 (dd, 1H, $J_{2b,3b}$ 9.8 Hz, $J_{1b,2b}$ 8.0 Hz, H-2b), 3.46 (s, 3H, CH_3O), 2.14 (bdd, $J_{4aax,4aeq}$ 13.0 Hz, $J_{4aeq,5a}$ 1.3 Hz, H-4aeq), 2.03 (s, 3H, CH_3CO), 1.47 (ddd, 1H, $J_{4aax,5a}$

11.0 Hz, H-4aax), 1.19 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 1.

*Methyl 2-acetamido-3-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-4-*O*-benzyl-2-deoxy-6-*O*-p-toluenesulfonyl-β-D-glucopyranoside (**14**)*

A solution of *p*-toluenesulfonyl chloride (200 mg, 1.05 mmol) in dichloromethane (8 mL) was added to a solution of **8** (644 mg, 0.81 mmol) in pyridine (10 mL) at ice-bath temperature. After 2 h, another portion of *p*-toluenesulfonyl chloride (150 mg, 0.79 mmol) was added and the mixture was kept at room temperature for another two hours. It was poured into ice-water, extracted with dichloromethane, evaporated and codistilled with toluene. The resulting material was purified on a column of silica gel (dichloromethane – ethyl acetate, 1:2) to provide in the first main fraction compound **14** (565 mg, 74%) as a solid. The analytical sample was recrystallized from ethyl acetate – hexane; mp 146–147°C; $[\alpha]_D$ −1, $[\alpha]_{365}$ −4 (*c* 0.6, chloroform); ^1H nmr ($CDCl_3$) δ: 7.80 (d, 2H, J = 8.0 Hz, Ts), 7.40–7.20 (m, 22H, Ph), 5.80 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH), 5.30 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.52 (d, 1H, H-1b), 4.45 (d, 1H, $J_{1a,2a}$ 6.0 Hz, H-1a), 4.26 and 4.21 (ABq, 2H, $J_{6a,6a'}$ 10.0 Hz, $J_{5a,6a}$ 5.5 Hz, $J_{5a,6a'}$ 3.5 Hz, H-6a, H-6a′), 4.09 (t, 1H, $J_{2a,3a} \sim J_{3a,4a} \sim$ 6.5 Hz, H-3a), 3.93 (d, 1H, $J_{3b,4b}$ 3.0 Hz, $J_{4b,5b} <$ 1 Hz, H-4b), 3.75 (m, 1H, H-5a), 3.65 (ddd, 1H, H-2a), 3.52–3.42 (m, 5H, H-4a, H-3b, H-5b, 2H-6b), 3.32 (m, 3H, CH_3O), 2.40 (s, 3H, CH_3-Ts), 2.00 and 1.85 (2s, each 3H, CH_3CO). Anal. calcd. for $C_{52}H_{59}NO_{14}S$: C 65.46, H 6.23, N 1.47, S 3.35; found: C 65.35, H 6.14, N 1.63, S 3.57.

*Methyl 2-acetamido-3-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-4-*O*-benzyl-2,6-dideoxy-6-iodo-β-D-glucopyranoside (**15**)*

A mixture of **14** (1.09 g, 1.14 mmol) and potassium iodide (2.2 g, 13.3 mmol) in *N,N*-dimethylformamide (30 mL) was heated at 100°C for 5.5 h. It was diluted with dichloromethane, and washed successively with water, aqueous sodium thiosulfate solution, and water, followed by evaporation. The reaction product was purified on a column of silica gel (dichloromethane – ethyl acetate, 1:1) to provide solid **15** (817 mg, 83%); mp 75–76°C; $[\alpha]_D$ 0, $[\alpha]_{365}$ 0 (*c* 0.7, chloroform); ^1H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 5.80 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH), 5.34 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.96, 4.93, 4.67 (3d from 3ABq, each 1H, $J_{A,B}$ 11.5, 10.5, 12.0 Hz, CH_2Ph), 4.60–4.46 (m, 5H, CH_2Ph, H-1a, H-1b), 4.38 and 4.30 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.20 (t, 1H, $J_{3a,4a} \sim J_{2a,3a}$ 7.5 Hz, H-3a), 3.94 (d, 1H, $J_{3b,4b}$ 3.0 Hz, $J_{4b,5b} <$ 1 Hz, H-4b), 3.44 (s, 3H, CH_3O), 2.07 and 1.88 (2s, each 3H, $2CH_3CO$). Anal. calcd. for $C_{45}H_{52}INO_{11}$: C 59.41, H 5.76, I 13.95, N 1.54; found: C 59.26, H 5.61, I 13.79, N 1.57.

*Methyl 2-acetamido-3-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-4-*O*-benzyl-2,6-dideoxy-β-D-glucopyranoside (**16**)*

A mixture of **15** (775 mg, 0.85 mmol), 2,2′-azobis(isobutyronitrile) (35 mg, 0.21 mmol), and tributyltin hydride (1 mL, 3.72 mmol) in toluene (10 mL) was heated at 80°C for 25 min. The solvent was evaporated and the reaction product was purified on a column of silica gel (hexane – ethyl acetate, 3:1, dichloromethane – ethyl acetate, 2:1, 1:1) to afford **16** (555 mg, 83%); mp 58–60°C; $[\alpha]_D$ −5 (*c* 0.5, chloroform); ^1H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 5.60 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH), 5.35 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.95 (d from 2ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.68 (d from ABq, 1H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.50 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.55 (d, 1H, H-1b), 4.36 and 4.28 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.18 (t, 1H, $J_{2a,3a} \sim J_{3a,4a}$ 8.5 Hz, H-3a), 3.92 (d, 1H, $J_{3b,4b}$ 3.0 Hz, $J_{4b,5b} <$ 1 Hz, H-4b), 3.41 (s, 3H, CH_3O), 3.18 (t, 1H, $J_{4a,5a}$ 8.0 Hz, H-4a), 2.05 and 1.90 (2s, each 3H, $2CH_3CO$), 1.34 (d, 3H, $J_{5a,6a}$ 6.3 Hz, H_3-6a). Anal. calcd. for $C_{45}H_{53}NO_{11}$: C 68.88, H 6.81, N 1.79; found: C 68.53, H 6.62, N 1.65.

*Methyl 2-acetamido-4-*O*-benzyl-3-*O*-(3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-2,6-dideoxy-β-D-glucopyranoside (**17**)*

Compound **16** (280 mg, 0.36 mmol) was treated with methanolic 0.05 N sodium methoxide (16 mL) for 1 day. The solution was made neutral with Amberlite IRC 50 (H^+), filtered, and evaporated to provide **17** (260 mg, 98%) as a solid. The analytical sample was purified by column chromatography on silica gel (dichloromethane – ethyl acetate, 1:1); mp 58–60°C; $[\alpha]_D$ −9 (*c* 0.2, chloroform); ^1H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 6.20 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 4.90 (d from 2ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.72 (d from ABq, 1H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.71 (d, 1H, $J_{1a,2a}$ 7.0 Hz, H-1a), 4.64, 4.58, 4.54 (3d from 2ABq, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.36 and 4.30 (ABq, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.36 (d, overlapped, 1H, $J_{1b,2b}$ 8.5 Hz, H-1b), 3.91 (d, 1H, $J_{3b,4b}$ 3.0 Hz, H-4b), 3.46 (s, 3H, CH_3O), 3.28 (t, 1H, $J_{4a,5a}$ 8.0 Hz, H-4a), 3.31 (bs, 1H, OH), 1.85 (s, 3H, CH_3CO), 1.37 (d, 3H, $J_{5a,6a}$ 6.5 Hz, H_3-6a). Anal. calcd. for $C_{43}H_{51}NO_{10}$: C 69.62, H 6.93, N 1.89; found: C 69.42, H 7.11, N 1.75.

*Methyl 2-acetamido-4-*O*-benzyl-2,6-dideoxy-3-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-*galactopyranosyl]-β-D-glucopyranoside (**18**)*

A solution of bromide **3** (1.3 mmol) in dichloromethane (1.4 mL) was transferred into a stirred mixture of alcohol **17** (280 mg, 0.38 mmol), tetraethylammonium bromide (170 mg, 0.81 mmol), 4 Å molecular sieves (powdered, 4g), and *N,N*-dimethylformamide (1 mL) in dichloromethane (6 mL). After stirring for 30 h, methanol (0.5 mL) was added and stirring continued for 2 h. Usual work-up was followed by column chromatography on silica gel (hexane – ethyl acetate, 1:1 and dichloromethane – ethyl acetate, 3:1) to provide crystalline **18** (392 mg, 90%). The analytical sample was recrystallized from ether–hexane; mp 114–115°C; $[\alpha]_D$ −55.7 (*c* 0.7, chloroform); ^1H nmr ($CDCl_3$) δ: 7.40–7.08 (m, 35H, 7Ph), 5.71 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 5.68 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 4.55 (d, overlapped, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.51 (d, overlapped, $J_{1a,2a}$ 8.5 Hz, H-1a), 4.37 (overlapped, H-5c), 4.24 (dd, 1H, $J_{2b,3b}$ 9.0 Hz, H-2b), 4.17 (dd, 1H, $J_{3a,4a}$ 8.0 Hz, $J_{2a,3a}$ 9.5 Hz, H-3a), 4.02 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.97 (d, 1H, $J_{3b,4b}$ 2.5 Hz, $J_{4b,5b} <$ 1 Hz, H-4b), 3.92 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.85 (bd, 1H, H-4c), 3.44 (s, 3H, CH_3O), 3.06 (t, 1H, $J_{4a,5a}$ 8.5 Hz, H-4a), 1.89 (s, 3H, CH_3CO), 1.34 (d, 3H, $J_{5a,6a}$ 6.0 Hz, H_3-6a), 1.20 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{70}H_{79}NO_{14}$: C 72.58, H 6.87, N 1.21; found: C 72.10, H 6.93, N 1.29.

*Methyl 2-acetamido-2,6-dideoxy-3-*O*-[2-*O*-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (**19**)*

Compound **18** (150 mg, 0.13 mmol) and 5% palladium-on-carbon (150 mg) in 95% ethanol (30 mL) were hydrogenated at atmospheric pressure for 11 h. Work-up and gel filtration as described for **13** provided trisaccharide **19** (67 mg, 98%) as a light white powder after freeze-drying an aqueous solution. $[\alpha]_D$ −96.7 (*c* 0.3, water); ^1H nmr (D_2O) δ: 5.17 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 4.62 (d, 1H, $J_{1b,2b}$ 7.8 Hz, H-1b), 4.32 (d, 1H, $J_{1a,2a}$ 8.2 Hz, H-1a), 4.30 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 3.93 (dd, 1H, $J_{2a,3a}$ 10.2 Hz, $J_{3a,4a}$ 9.0 Hz, H-3a), 3.87 (d, 1H, $J_{3b,4b}$ 3.3 Hz, H-4b), 3.82 (dd, 1H, $J_{3b,2b}$ 9.8 Hz, H-3b), 3.57 (dd, 1H, H-2b), 3.54 (dq, 1H, overlapped by H-2b, $J_{4a,5a}$ 9.5 Hz, $J_{5a,6a}$ 6.0 Hz, H-5a), 3.22 (t, 1H, H-4a), 2.05 (s, 3H, CH_3CO), 1.33 (d, 3H, H_3-6a), 1.21 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 1.

*Methyl 2-acetamido-4,6-*O*-benzylidene-3-*O*-(3,4-*O*-benzylidene-α-L-arabinopyranosyl)-2-deoxy-β-D-*glucopyranoside (**22**)

A pure isomer **20** (12) (190 mg, 0.327 mmol) in 0.05 N methanolic sodium methoxide (15 mL) and dichloromethane (3 mL) was kept at room temperature for 5 h. After neutralization with Amberlite IRC 50 H^+, filtration, and evaporation to dryness, the resulting powder (**21**) was desolved in *N,N*-dimethylformamide (7 mL) and acetonitrile (15 mL) and then treated with α,α-dimethoxytoluene (0.24 mL, 1.5 mmol) and *p*-toluenesulfonic acid (25 mg) for 1 day. The mixture was neutralized with triethylamine and evaporated to dryness. Recrystallization from dichloro-

methane–ether gave the title compound **22** (160 mg, 90%); mp 255–257°C; $[\alpha]_D$ −36.8 (*c* 0.7, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.58–7.30 (m, 10H, 2Ph), 5.95 (s, 1H, C*H*Ph), 5.84 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.53 (s, 1H, C*H*Ph), 4.75, 4.45 (2d, each 1H, *J* = 8.5 Hz, *J* = 7.5 Hz, H-1a, H-1b), 3.53 (s, 3H, CH_3O), 3.12 (d, 1H, $J_{OH,2b}$ 3.0 Hz, OH), 2.03 (s, 3H, CH_3CO). Anal. calcd. for $C_{28}H_{33}NO_{10}$: C 61.87, H 6.12, N 2.58; found: C 61.80, H 5.97, N 2.59.

*Methyl 2-acetamido-4,6-*O*-benzylidene-3-*O*-[3,4-*O*-benzylidene-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-α-L-arabinopyranosyl]-2-deoxy-β-D-glucopyranoside (23)*

Alcohol **22** (140 mg, 0.26 mmol) was reacted with bromide **3** (0.92 mmol) as described for the preparation of **4**. Usual work-up after 30 h, followed by chromatography on a column of silica gel (dichloromethane–methanol, 98.5:1.5) and crystallization from dichloromethane–ether–hexane provided **23** (200 mg, 81%); mp 187–188°C; $[\alpha]_D$ −67.1 (*c* 0.6, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.50–7.25 (m, 25H, 5Ph), 5.90 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH), 5.82 (s, 1H, C*H*Ph), 5.50 (s, 1H, C*H*Ph), 5.44 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 4.71 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.64 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.08 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 3.45 (s, 3H, CH_3O), 1.82 (s, 3H, CH_3CO), 1.18 (d, 3H, H_3-6c). Anal. calcd. for $C_{55}H_{61}NO_{14}$: C 68.81, H 6.40, N 1.46; found: 68.53, H 6.42, N 1.58.

*Methyl 2-acetamido-2-deoxy-3-*O*-[2-*O*-(α-L-fucopyranosyl)-α-L-arabinopyranosyl]-β-D-glucopyranoside (24)*

Compound **23** (150 mg, 0.16 mmol) in 95% ethanol (35 mL) was hydrogenated in the presence of 5% palladium-on-carbon (150 mg) at atmospheric pressure for 22 h. Work-up and gel filtration as described for **13** provided **24** (74 mg, 92%) as a light white powder after freeze-drying an aqueous solution; $[\alpha]_D$ −86 (*c* 0.4); ^{1}H nmr (D_2O) δ: 5.15 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 4.56 (d, 1H, $J_{1b,2b}$ 7.0 Hz, H-1b), 4.34 (d, 1H, $J_{1a,2a}$ 8.5 Hz, H-1a), 4.25 (q, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{4c,5c}$ < 1 Hz, H-5c), 3.93 (m, H-6a, H-5beq), 3.92 (H-4b), 3.85 (dd, overlapped, $J_{2b,3b}$ 9.0 Hz, $J_{3b,4b}$ 3.3 Hz, H-3b), ~3.83 (H-3a, overlapped), 3.68 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, $J_{3c,4c}$ 3.0 Hz, H-3c), 3.59 (H-5bax, overlapped by H-2b), 3.58 (H-2b), 3.48 (s, 3H, CH_3O), 2.04 (s, 3H, CH_3CO), 1.21 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 1.

*Methyl 2-acetamido-4-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-3-*O*-allyl-6-*O*-benzyl-2-deoxy-β-D-glucopyranoside (27)*

A solution of bromide **25** (13) (4.50 mmol) in toluene-nitromethane (1:1, 10 mL) was added to a stirred mixture of alcohol **26** (6) (1.2 g, 3.28 mmol), mercuric cyanide (1.6 g, 6.3 mmol), powdered calcium sulfate (1 g), and 4 Å molecular sieves (1 g) in toluene–nitromethane (1:1, 30 mL). After 3 h, the mixture was filtered through a pad of Celite and poured into a mixture of aqueous sodium hydrogencarbonate and dichloromethane. The organic solution was washed with water, dried, and evaporated. The reaction product was purified on a column of silica gel (hexane – ethyl acetate, 3:1 to 1:2) to provide **27** (1.47 g, 53%) as a white solid; mp 132–133°C; $[\alpha]_D$ −30.2 (*c* 0.6, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 6.28 (d, 1H, $J_{NH,2a}$ 9.5 Hz, NH), 5.80 (m, 1H, CH_2=C*H*), 5.28 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 5.18 and 5.07 (2 m, 2H, CH_2=CH), 4.92 (d from ABq, $J_{A,B}$ 12.0 Hz, 1CH_2Ph), 4.46 (d, 1H, $J_{1a,2a}$ 4.0 Hz, H-1a), 4.33 (d, 1H, H-1b), 4.08 (m, 2H, CH_2=CH-CH_2), 4.00 (ddd, 1H, $J_{2a,3a}$ = $J_{1a,2a}$ 4.0 Hz, H-2a), 3.96 (bd, 1H, $J_{3b,4b}$ ~ 2.5 Hz, $J_{4b,5b}$ < 1 Hz, H-4b), 3.92 (t, 1H, $J_{3a,4a}$ ~ $J_{4a,5a}$ ~ 4 Hz, H-4a), 3.69 (t, 1H, H-3a), 3.40 (s, 3H, CH_3O), 2.02 and 2.00 (2s, each 3H, CH_3CO). Anal. calcd. for $C_{48}H_{57}NO_{12}$: C 68.44, H 6.84, N 1.67; found: 68.56, H 6.83, N 1.87.

*Methyl 2-acetamido-4-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-6-*O*-benzyl-2-deoxy-β-D-glucopyranoside (28)*

A mixture of **27** (800 mg, 0.95 mmol), tris(triphenylphosphine)rhodium(I)chloride (75 mg, 0.08 mmol), and 1.4-diazabicyclo[2.2.2]octane (33 mg, 0.29 mmol) in 95% ethanol–toluene–water (7:3:1, 68 mL) was boiled under reflux for 19 h. The solvent was removed and the resulting material was taken up in acetone (60 mL) containing mercuric oxide (12 mg). A solution of mercuric chloride (1.87 g) in acetone–water (9:1, 30 mL) was added and the mixture stirred for 30 min. Then the solvent was evaporated and the remainder dissolved in dichloromethane. The solution was washed with aqueous saturated potassium bromide and water, followed by drying with sodium sulfate and evaporation. Two recrystallizations from ethyl acetate gave pure **28** (603 mg). Chromatography of the mother liquor on a column of silica gel (ethyl acetate) provided more product (70 mg, total yield 88%); mp 198–198.5; $[\alpha]_D$ +9.7 (*c* 0.4, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 5.52 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.33 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.91 (d, from ABq, 1H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.59 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.34 (d, 1H, H-1b), 3.89 (d, overlapped, H-4b), 3.50 (s, 3H, CH_3O), 3.42 (dd, 1H, $J_{3b,4b}$ 3.0 Hz, H-3b), 1.98 and 1.97 (2s, each 3H, 2CH_3CO); ^{1}H nmr after addition of trichloroacetyl isocyanate ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 6.17 (d, 1H, $J_{NH,2a}$ 9.5 Hz, NH), 5.20 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{1b,2b}$ 8.0 Hz, H-2b), 5.07 (dd, 1H, $J_{2a,3a}$ 10.0 Hz, $J_{3a,4a}$ 9.0 Hz, H-3a), 4.37 and 4.32 (2d, 2H, *J* 8.0 Hz, H-1a, H-1b), 4.13 (ddd, 1H, $J_{2a,3a}$ 10.0 Hz, H-2a), 3.93 (t, 1H, $J_{4a,5a}$ 9.0 Hz, H-4a), 3.85 (d, 1H, $J_{3b,4b}$ 3.0 Hz, H-4b), 3.74 (d, 2H, $J_{5a,6a}$ 2.5 Hz, H_2-6a), 3.64 (dd, 1H, $J_{6b,6b'}$ 9.0 Hz, $J_{5b,6b}$ 6.5 Hz, H-6b), 3.53 (m, 2H, H-6b', H-5a), 3.44 (s, 3H, CH_3O), 3.40 (t, 1H, $J_{5b,6b'}$ 6.5 Hz, H-5b), 3.34 (dd, 1H, H-3b), 2.00, 1.89 (2s, each 3H, 2CH_3CO). Anal. calcd. for $C_{45}H_{53}NO_{12}$: C 67.57, H 6.68, N 1.75; found: C 67.37, H 6.72, N 1.55.

*Methyl 2-acetamido-4-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-6-*O*-benzyl-2-deoxy-3-*O*-phenoxythiocarbonyl-β-D-glucopyranoside (29)*

A mixture of **28** (230 mg, 0.29 mmol) 4-dimethylaminopyridine (160 mg, 1.43 mmol), and phenyl chlorothionocarbonate (0.2 mL, 1.45 mmol) in dry dichloromethane (10 mL) was stirred at room temperature under argon for 38 h. The yellowish mixture was then washed with water, dried, and evaporated to dryness. Flash chromatography on a column of silica gel (dichloromethane–methanol, 99.5:0.5) afforded **29** (208 mg, 77%) as a yellowish gum; $[\alpha]_D$ −16.5 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.00 (m, 25H, 5Ph), 5.94 (d, 1H, $J_{NH,2a}$ 9.5 Hz, NH), 5.66 (t, 1H, $J_{2a,3a}$ = $J_{3a,4a}$ 7.5 Hz, H-3a), 5.28 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.89 (d from ABq, 1H, $J_{A,B}$ 12.0 Hz, 1CH_2Ph), 4.47 (overlapped, $J_{1a,2a}$ 7.0 Hz, H-1a), 4.37 (overlapped, H-1b), 4.23 (ddd, 1H, H-2a), 4.07 (t, 1H, $J_{4a,5a}$ 7.5 Hz, H-4a), 3.96 (bd, 1H, $J_{3b,4b}$ 3.0 Hz, $J_{4b,5b}$ < 1 Hz, H-4b), 3.75 (d, 2H, $J_{5a,6a}$ 4.0 Hz, H_2-6a), 3.68–3.47 (m, 4H, H-5a, H-5b, 2H-6b), 3.46 (s, 3H, CH_3O), 3.41 (dd, 1H, H-3b), 1.96 (s, 6H, 2CH_3CO); fab-ms, *m/z*: 958 (0.98, $[M + Na]^+$), 936.5 (1.86, $[M + H]^+$), 935.5 (0.35, M^+), 904 (3.37, $[M - OMe]^+$). Anal. calcd. for $C_{52}H_{57}NO_{13}S$: C 66.72, H 6.14, N 1.50; found: C 66.37, H 6.42, N 1.57.

A minor compound (22 mg, 8.3%) was isolated on further elution of the column and identified as *methyl 2-acetamido-4-*O*-(2-*O*-acetyl,3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-6-*O*-benzyl-2-deoxy-3-*O*-phenoxycarbonyl-β-D-glucopyranoside;* mp 169–171°C (methanol–ether); $[\alpha]_D$ −10 (*c* 0.2, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40;–6.95 (m, 25H, 5Ph), 5.81 (d, 1H, $J_{NH,2a}$ 9.0 Hz, NH), 5.19 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.90 (dd, 1H, $J_{3a,4a}$ 8.5 Hz, $J_{2a,3a}$ 10.0 Hz, H-3a), 4.31, 4.27 (2d, each 1H, *J* 8.0 Hz, H-1a, H-1b), 4.00 (ddd, 1H, H-2a), 3.88 (d, t, 2H, $J_{3b,4b}$ ~ 3 Hz, H-4b, and $J_{4a,5a}$ 8.5 Hz, H-4a), 3.36 (s, 3H, CH_3O), 3.30 (dd, 1H, H-3b), 1.85 and 1.65 (2s, each 3H, CH_3CO); fab-ms, *m/z*: 942 (0.24, $[M + Na]^+$), 920.5 (1.28, $[M + H]^+$), 919 (0.44, M^+), 888 (1.04, $[M - OMe]^+$). Anal. calcd. for $C_{52}H_{57}NO_{14}$: C 67.89, H 6.24, N 1.52; found: C 67.72, H 6.33, N 1.53.

*Methyl 2-acetamido-4-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-6-*O*-benzyl-2,3-dideoxy-β-D-*xylo*-hexopyranoside (30)*

Argon was passed through a solution of **29** (280 mg, 0.22 mmol) in toluene (15 mL) at 80°C for 1 h. Then tributyltin hydride

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12

*Methyl 2-acetamido-6-*O*-benzyl-2,3-dideoxy-4-*O*-(3,4,6-tri-*O*-benzyl-*β*-*D*-galactopyranosyl)-*β*-*D*-*xylo*-hexopyranoside (31)*

Compound **30** (140 mg, 0.18 mmol) was deacetylated in methanolic 0.05 N sodium methoxide (15 mL) for 1 day. Neutralization with Amberlite IRC 50 H^+, filtration, evaporation, and precipitation from dichloromethane–hexane afforded **31** (130 mg, 98%) as a powder; $[\alpha]_D$ −7.1 (*c* 1.0, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 6.44 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 4.90–4.41 (m, 8H, 4CH_2Ph), 4.39 (d, 1H, $J_{1a,2a}$ 4.0 Hz, H-1a), 4.33 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 3.94 (overlapped, H-4b), ~ 3.90 (m, 3H with H-2a and H-2b), 3.40 (s, 3H, CH_3O), 3.38 (dd, overlapped, $J_{3b,4b}$ 2.8 Hz, H-3b), 2.32 (ddd, $J_{3aeq,3aax}$ 14.0 Hz, $J_{3a,4a} \sim J_{3a,2a} \sim$ 4 Hz, H-3a), 1.85 (s, 3H, CH_3CO), 1.81 (td, 1H, $J_{3a',4a} \sim J_{2a,3a'} \sim$ 6.5 Hz, H-3a′); ^{1}H nmr (MeOD-d_4, Me signal set at 3.20 ppm) δ: 7.40–7.10 (m, 20H, 4Ph), 4.70–4.30 (m, 8H, 4CH_2Ph), 4.20 (d, 1H, $J_{1a,2a}$ 7.5 Hz, H-1a), 4.14 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 3.34 (s, 3H, CH_3O), 2.30 (td, 1H, $J_{3aeq,3aax}$ 13.0 Hz, $J_{2a,3aeq} = J_{3aeq,4a}$ 5.0 Hz, H-3aeq), 1.78 (s, 3H, CH_3O), 1.49 (td, 1H, $J_{2a,3aax} \sim J_{3aax,4a} \sim$ 11 Hz, H-3aax). Anal. calcd. for $C_{43}H_{51}NO_{10} \cdot 1H_2O$: C 68.14, H 7.04, N 1.85; found: 67.84, H 7.12, N 1.68.

*Methyl 2-acetamido-6-*O*-benzyl-2,3-dideoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-*α*-*L*-fucopyranosyl)-*β*-*D*-galactopyranosyl]-*β*-*D*-*xylo*-hexopyranoside (32)*

Alcohol **31** (120 mg, 0.16 mmol) was reacted with bromide **3** (0.69 mmol) as described for the preparation of **4**. After 24 h, conventional work-up was followed by column chromatography on silica gel (dichloromethane–methanol, 98.5:1.5) to provide the title compound **32** (130 mg, 69%) as a gum; $[\alpha]_D$ −40.7 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.35–7.05 (m, 35H, 7Ph), 6.76 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.73 (d, 1H, $J_{1c,2c} \sim$ 3.8 Hz, H-1c), 4.58 (overlapped, H-1b), 4.40 (H-5c), 4.39 (d, $J_{1a,2a}$ 2.5 Hz, H-1a), 4.18 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, $J_{1b,2b}$ 8.0 Hz, H-2b), 4.03 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.96 (bd, 1H, overlapped by H-3c, $J_{3b,4b}$ 2.5 Hz, $J_{4b,5b} < 1$ Hz, H-4b), 3.94 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.90 (bm, 1H, H-2a), 3.81 (bm, 2H, with H-4a), 3.74 (dd, 1H, H-3b), 3.70 (bm, 2H, with H-4c), 3.47 (s, 3H, CH_3O), 2.17 (ddd, 1H, $J_{3aeq,3aax}$ 14.0 Hz, $J_{2a,3a} \sim J_{3a,4a}$ 3.5 Hz, H-3a), 1.94 (ddd, 1H, $J_{3a',4a} = J_{2a,3a'}$ 4.8 Hz, H-3a′), 1.74 (s, 3H, CH_3CO), 1.16 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{70}H_{79}NO_{14}$: C 72.58, H 6.87, N 1.21; found: C 72.53, H 7.15, N 1.10.

*Methyl 2-acetamido-2,3-dideoxy-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-xylo-hexopyranoside (33)*

Compound **32** (112 mg, 0.097 mmol) in 95% ethanol (20 mL) was hydrogenated in the presence of 5% palladium-on-carbon (115 mg) for 14 h. Processing and gel filtration as described for the preparation of **13** provided **33** (51 mg, 97%) as a light white powder after freeze-drying an aqueous solution; ^{1}H nmr (D_2O) δ: 5.30 (d, 1H, $J_{1c,2c}$ 2.5 Hz, H-1c), 4.52 (d, 1H, $J_{1b,2b}$ 7.8 Hz, H-1b), 4.42 (d, 1H, $J_{1a,2a}$ 8.5 Hz, H-1a), 4.22 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c) 3.94 (dd, 1H, $J_{5a,6a}$ 1.8 Hz, $J_{6a,6a'}$ 12.0 Hz, H-6a), 3.88 (bd, 1H, $J_{3b,4b}$ 3.0 Hz, $J_{4b,5b} < 1$ Hz, H-4b), 3.65 (dd, 1H, $J_{5b,6b}$ 4.5 Hz, $J_{5b,6b'}$ 7.5 Hz, H-5b), 3.60 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 3.50 (s, 3H, CH_3O), 2.44 (td, 1H, $J_{3aeq,3aax}$ 13.0 Hz, $J_{3aeq,4a} = J_{3aeq,2a}$ 4.5 Hz, H-3aeq), 1.98 (s, 3H, CH_3CO), 1.64 (td, 1H, $J_{3aax,4a} = J_{2a,3aax}$ 11.5 Hz, H-3aax), 1.22 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 3.

*2,4-Di-*O*-benzyl-3,6-dideoxy-*L*-xylo-hexopyranose (34)*

Methyl 2,4-di-*O*-benzyl-3,6-dideoxy-α-L-*xylo*-hexopyranoside (21) (2.3 g, 6.72 mmol) was dissolved in 60 mL of 70% aqueous trifluoroacetic acid and kept at room temperature for 16 h. Solvent removal and codistillation with toluene left a syrupy residue that was applied to a column of silica gel using hexane – ethyl acetate (2:1) as eluent. Evaporation of the main fraction gave **34** (1.96 g, 89%) as a syrup. On storage in the fridge for several months, very slow crystallization occurred. The analytical sample was recrystallized from ether–hexane; mp 67–70°C; $[\alpha]_D$ −17.6 (*c* 0.8, methanol, no mutarotation after 24 h); ^{1}H nmr ($CDCl_3$, α:β = 5:3) δ: 7.43–7.2 (m, 10H, 2Ph), 5.29 (bs, H-1α), 4.80–4.39 (m, 2CH_2Ph and H-1β), 4.14 (dq, $J_{5,6}$ 6.5 Hz, $J_{4,5}$ 1.5 Hz, H-5α), 3.87 (ddd, $J_{1,2}$ 3.0 Hz, $J_{2,3eq}$ 5.0 Hz, $J_{2,3ax}$ 11.5 Hz, H-2α), 3.67 (dq, $J_{4,5}$ 1.0 Hz, $J_{5,6}$ 6.5 Hz, H-5β), 3.53 (ddd, $J_{1,2}$ 7.5 Hz, $J_{2,3eq}$ 5.0 Hz, $J_{2,3ax}$ 12.0 Hz, H-2β), 3.45 (bs, H-4α), 3.37 (bs, H-4β), 2.37 (ddd, $J_{3eq,3ax}$ 13.5 Hz, $J_{3eq,4}$ 3.0 Hz, H-3βeq), 2.16 (m, $J_{3eq,3ax}$ 13.0 Hz, $J_{3eq,4}$ 3.0 Hz, $J_{3eq,1}$ 1.0 Hz, H-3αeq), 1.84 (ddd, $J_{3ax,4}$ 2.5 Hz, H-3αax), 1.46 (ddd, $J_{3ax,4}$ 2.5 Hz, H-3βax), 1.26 (d, H_3-6β), 1.19 (d, H_3-6α). Anal. calcd. for $C_{20}H_{24}O_4$: C 73.15, H 7.37; found: C 72.99, H 7.32.

*2,3-Di-*O*-benzyl-4,6-dideoxy-*L*-xylo-hexopyranose (35)*

A solution of methyl 2,3-di-*O*-benzyl-4,6-dideoxy-α-L-*xylo*-hexopyranoside[4] (2.3 g, 6.72 mmol) in 70% aqueous trifluoroacetic acid (60 mL) was kept at room temperature for 13 h. Evaporation and codistillation with toluene left a syrupy residue that was purified by column chromatography (silica gel, hexane – ethyl acetate, 3:1) to provide **35** (2.03 g, 92%) as a syrup; $[\alpha]_D$ −47.7 (*c* 0.7, methanol, no mutarotation after 24 h); ^{1}H nmr ($CDCl_3$, α:β = 1:1) δ: 7.44–7.20 (m, 10H, 2Ph), 5.23 (t, $J_{1,2}$ 3.5 Hz, $J_{1,OH}$ 2.0 Hz, H-1α), 4.94–4.66 (m, 4H, 2CH_2Ph), 4.61 (dd, $J_{1,2}$ 7.5 Hz, $J_{1,OH}$ 5.5 Hz, H-1β), 4.13 (m, 1H, $J_{5,6}$ 6.5 Hz, $J_{4ax,5}$ 12.0 Hz, $J_{4eq,5}$ 2.0 Hz, H-5α), 3.90 (ddd, $J_{3,4eq}$ 5.0 Hz, $J_{3,4ax}$ 12.0 Hz, $J_{2,3}$ 9.0 Hz, H-3α), 3.59 (ddd, $J_{2,3}$ 9.0 Hz, $J_{3,4ax}$ 12.0 Hz, $J_{3,4eq}$ 5.0 Hz, H-3β), 3.56 (m, 1H, $J_{5,6}$ 6.0 Hz, $J_{4eq,5}$ 2.0 Hz, $J_{4ax,5}$ 12.0 Hz, H-5β), 3.48 (dd, H-2α), 3.34 (d, OH-β), 3.24 (dd, 1H, H-2β), 2.99 (d, 1H, OH-α), 2.09 (ddd, $J_{4eq,4ax}$ 13.0 Hz, H-4αeq), 2.06 (ddd, $J_{4eq,4ax}$ 13.0 Hz, H-4βeq), 1.44 (q, H-4βax), 1.36 (q, H-4αax), 1.27 (d, H_3-6β), 1.18 (d, 3H, H_3-6α). Anal. calcd. for $C_{20}H_{24}O_4$: C 73.15, H 7.37; found: C 73.46, H 7.46.

*2,4-Di-*O*-benzyl-3,6-dideoxy-α-*L*-xylo-hexopyranosyl bromide (36)*

A solution of oxalyl bromide (0.25 mL, 2.5 mmol) in dichloromethane (1.5 mL) was added in portions to a stirred solution of **34** (650 mg, 1.98 mmol) in dichloromethane (3 mL) and *N*,*N*-dimethylformamide (0.2 mL) under nitrogen. The mixture was stirred for 20 min, then diluted with dichloromethane and poured into ice-water. The organic layer was washed three times with ice-water, dried with sodium sulfate and 4 Å molecular sieves, and concentrated to a smaller volume, before being transferred into the glycosidation mixture. **36** was freshly prepared before use; ^{1}H nmr ($CDCl_3$) δ: 7.43–7.20 (m, 10H, 2Ph), 6.69 (bs, 1H, H-1), 4.7–4.37 (4H, CH_2Ph), 4.12 (dq, 1H, $J_{5,6}$ 6.5 Hz, $J_{4,5}$ 1.0 Hz, H-5), 3.78 (ddd, 1H, $J_{1,2}$ 3.0 Hz, $J_{2,3eq}$ 5.0 Hz, $J_{2,3ax}$ 10.0 Hz, H-2), 3.50 (bs, 1H, H-4), 2.17 (m, 1H, $J_{3eq,3ax}$ 13.0 Hz, $J_{3eq,4}$ 3.0 Hz, $J_{1,3eq} \sim$ 1 Hz, H-3eq), 1.99 (ddd, 1H, $J_{3ax,4}$ 2.5 Hz, H-3ax), 1.23 (d, 3H, H_3-6).

*2,3-Di-*O*-benzyl-4,6-dideoxy-α-*L*-xylo-hexopyranosyl bromide (37)*

Compound **35** (750 mg, 2.28 mmol) was reacted with oxalyl bromide (315 μL, 3.25 mmol) and *N*,*N*-dimethylformamide (0.2 mL) to form **37** as described for the preparation of **36**. It was prepared just prior to use. ^{1}H nmr ($CDCl_3$) δ: 7.4–7.2 (m, 10H, 2Ph), 6.45 (d, 1H, $J_{1,2}$ 3.5 Hz, H-1), 4.8–4.6 (4H, CH_2Ph), 4.19 (m, 1H,

$J_{5,6}$ 6.5 Hz, $J_{4ax,5}$ 12.0 Hz, $J_{4eq,5}$ 2.0 Hz, H-5), 3.98 (ddd, 1H, $J_{3,4eq}$ 5.0 Hz, $J_{3,4ax}$ 12.0 Hz, $J_{2,3}$ 9.0 Hz, H-3), 3.4 (dd, 1H, H-2), 2.13 (ddd, 1H, $J_{4ax,4eq}$ 13.0 Hz, H-4eq), 1.48 (q, 1H, H-4ax), 1.23 (d, 3H, H_3-6).

*Methyl 2-acetamido-3,6-di-*O*-benzyl-2-deoxy-*β*-*D*-glucopyranoside (**39**)*

Ether saturated with hydrogen chloride was added at 0°C to a stirred mixture of methyl 2-acetamido-3-*O*-benzyl-4,6-*O*-benzylidene-2-deoxy-β-D-glucopyranoside (**18**) (7.5 g, 18.1 mmol), sodium cyanoborohydride (12.5 g, 198.9 mmol), and a crystal of methyl orange in dry tetrahydrofuran (200 mL) until the colour of the indicator turned red and gas evolution occurred. When tlc indicated the reaction to be complete, the mixture was diluted with dichloromethane and poured into aqueous saturated sodium hydrogencarbonate. The organic solution was washed with water, dried, and evaporated. The reaction product was purified by column chromatography on silica gel (dichloromethane–methanol, 19:1) and crystallization from ethyl acetate to afford **39** (5.0 g, 66%); mp 169–170°C; $[\alpha]_D$ − 14.5 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 10H, 2Ph), 5.54 (d, 1H, $J_{NH,2}$ 7.5 Hz, NH), 4.80 and 4.71 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.76 (d, 1H, $J_{1,2}$ 7.5 Hz, H-1), 4.63 and 4.57 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 3.99 (dd, 1H, $J_{2,3}$ 10.0 Hz, $J_{3,4}$ 8.5 Hz, H-3), 3.79 and 3.75 (ABq, 2H, $J_{5,6} \sim J_{5,6'} \sim 5$ Hz, $J_{6,6'}$ 11.0 Hz, H-6, H-6'), 3.69 (ddd, 1H, $J_{4,5}$ 9.5 Hz, $J_{3,4}$ 8.5 Hz, $J_{4,OH}$ 2.2 Hz, H-4), 3.54 (m, 1H, H-5), 3.31 (m, 1H, H-2), 2.81 (d, 1H, OH), 1.90 (s, 3H, CH_3CO). Addition of trichloroacetyl isocyanate into the nmr tube resulted in a new spectrum with δ H-4 at 5.09 ppm (t, $J_{3,4} = J_{4,5}$ 9.0 Hz); ^{13}C nmr ($CDCl_3$) δ: 170.55 (CO), 100.97 (C-1), 56.91, 56.67 (C-2, CH_3O), 23.66 (*C*H_3CO). Anal. calcd. for $C_{23}H_{29}NO_6$: C 66.49, H 7.04, N 3.37; found: C 65.77, H 6.99, N 3.32.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-2-deoxy-4-*O*-(2,3,4,6-tetra-*O*-acetyl-*β*-*D*-galactopyranosyl)-*β*-*D*-glycopyranoside (**41**)*

A solution of 2,3,4,6-tetra-*O*-acetyl-α-D-galactopyranosyl bromide (**40**) (19) (5.34 g, 13.0 mmol) in benzene–nitromethane (1:1, 25 mL) was added to a stirred mixture of **39** (3.6 g, 8.67 mmol), mercuric cyanide (4.38 g, 17.3 mmol), and powdered calcium sulfate (10.0 g) in the same solvent (175 mL). After stirring for 6 h at 40°C, more bromide solution (5.34 g, 13.0 mmol in 25 mL) was added and heating continued for 20 h. Then the reaction mixture was cooled to room temperature, diluted with dichloromethane, and washed with aqueous saturated sodium hydrogen carbonate and water. The material obtained on evaporation was applied to a column of silica gel and eluted with dichloromethane–methanol (19:1). Evaporation of the major fraction provided **41** (4.24 g, 66%); mp 75–76°C; $[\alpha]_D$ −23 (*c* 1.1, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.45–7.25 (m, 10H, 2Ph), 5.93 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH), 5.32 (d, 1H, $J_{3b,4b}$ 3.5 Hz, H-4b), 5.12 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{1b,2b}$ 8.0 Hz, H-2b), 4.91 (dd, 1H, H-3b), 4.76 and 4.65 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.67 and 4.49 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.65 (overlapped, H-1a), 4.49 (overlapped, H-1b), 3.71 (m, 1H, H-2), 3.46 (s, 3H, CH_3O), 2.15–1.93 (5s, each 3H, 5CH_3CO); ^{13}C nmr ($CDCl_3$) δ: 101.17, 99.83 (C-1 and C-1'). Anal. calcd. for $C_{37}H_{47}NO_{15}$: C 59.59, H 6.35, N 1.88; found: C 60.06, H 6.64, N 1.92.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-2-deoxy-4-*O*-(β-*D*-galactopyranosyl)-β-*D*-glucopyranoside (**42**)*

Compound **41** (4.0 g, 5.37 mmol) was treated with methanolic 0.08 N sodium methoxide (80 mL) for 16 h. Neutralization with Amberlite IRC 50 H^+, evaporation, and column chromatography on silica gel (dichloromethane–methanol, 19:1) provided **42** (2.7 g, 87%), which was crystallized from methanol–ether; mp 105–106°C; $[\alpha]_D$ −6.3 (*c* 0.7, methanol).

*Methyl 2-acetamido-3,6-di-*O*-benzyl-4-*O*-(4,6-*O*-benzylidene-β-*D*-galactopyranosyl)-2-deoxy-β-*D*-glucopyranoside (**43**)*

A mixture of **42** (2.0 g, 3.46 mmol), α,α-dimethoxytoluene (1.02 mL, 6.80 mmol), and *p*-toluenesulfonic acid monohydrate (25 mg) in dry acetonitrile (35 mL) was stirred for 1 h at room temperature. Neutralization with triethylamine and solvent evaporation gave a residue that was dissolved in methanol and precipitated from ether as a white solid (2.0 g, 87%). An analytical sample was recrystallized from hot ethyl acetate; mp 204–205°C; $[\alpha]_D$ −51.5 (*c* 0.5, methanol); ^{1}H nmr ($CDCl_3$) δ: 7.50–7.20 (m, 15H, 3Ph), 5.63 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.48 (s, 1H, C*H*Ph), 4.75, 4.51 (2d, each 1H, *J* 7.5 Hz, *J* 8.0 Hz, H-1a, H-1b), 3.50 (s, 3H, CH_3O), 1.90 (s, 3H, CH_3CO). Anal. calcd. for $C_{36}H_{43}NO_{11}$: C 64.95, H 6.51, N 2.10; found: C 64.44, H 6.49, N 2.29.

*Methyl 2-acetamido-4-*O*-(3-*O*-benzoyl-4,6-*O*-benzylidene-β-*D*-galactopyranosyl)-3,6-di-*O*-benzyl-2-deoxy-β-*D*-glucopyranoside (**44**)*

Compound **43** (1.8 g, 2.70 mmol) and pyridine (1.4 mL, 17.3 mmol) were dissolved in dry dichloromethane (50 mL). Benzoyl chloride (0.47 mL, 4.05 mmol) was added within 30 min at −78°C. Examination by tlc then showed the completion of the reaction. The excess of reagent was destroyed by the addition of methanol (1.0 mL). The mixture was allowed to reach room temperature and poured into ice-water. Washing of the organic layer with water, followed by drying and evaporation, left a white residue that was recrystallized from hot ethyl acetate to provide **44** (1.44 g, 69%) as white needles; mp 207–208°C; $[\alpha]_D$ +51.7 (*c* 0.5, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 8.20, 7.60–7.20 (d, 2H, m, 18H, 4Ph), 5.64 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.44 (s, 1H, C*H*Ph), 4.98 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{3b,4b}$ 3.5 Hz, H-3b), 4.78, 4.65 (2d, each 1H, *J* 7.5 Hz, *J* 8.0 Hz, H-1a, H-1b), 4.35 (d, 1H, H-4b), 3.48 (m, 3H, CH_3O), 3.40 (m, H-2a), 1.90 (s, 3H, CH_3CO); ^{13}C nmr ($CDCl_3$) δ: 103.47, 101.10, 100.76 (C-1a, C-1b, *C*HPh). Anal. calcd. for $C_{43}H_{47}NO_{12}$: C 67.09, H 6.15, N 1.82; found: C 66.69, H 6.16, N 1.92.

*Methyl 2-acetamido-4-*O*-[3-*O*-benzoyl-4,6-*O*-benzylidene-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-3,6-di-*O*-benzyl-2-deoxy-β-*D*-glucopyranoside (**45**)*

Bromide **3** (1.62 mmol) was reacted with alcohol **44** (500 mg, 0.65 mmol) as described for the preparation of **4**. After 20 h, the mixture was processed in the normal way and purified by column chromatography on silica gel (dichloromethane–methanol, 98:2) to provide **45** (570 mg, 74%). The analytical sample was recrystallized from methanol as white needles; mp 124–125°C; $[\alpha]_D$ −23.6 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.97, 7.50–7.05 (d, 2H, m, 33H, 7Ph), 5.69 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.45 (s, 1H, C*H*Ph), 5.43 (d, 1H, $J_{1c,2c}$ 3.8 Hz, H-1c), 5.13 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{3b,4b}$ 3.5 Hz, H-3b), 4.78 (d, 1H, $J_{1a,2a}$ 7.0 Hz, H-1a), 4.54 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.40 (d, 1H, H-4b), 4.33 (t, overlapped, H-2b), 4.09 (t, 1H, $J_{3a,4a} \sim J_{4a,5a} \sim 7.5$ Hz, H-4a), 4.03 (dd, 1H, $J_{2a,3a}$ 9.0 Hz, H-3a), 3.84 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.47 (s, 3H, CH_3O), 3.40 (m, 1H, H-2a), 1.87 (s, 3H, CH_3CO), 1.21 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). ^{13}C nmr ($CDCl_3$) δ: 170.32, 165.85 (2CO), 101.19, 100.88, 100.75, 97.47 (C-1a, C-1b, C-1c, PhC*H*), 23.58 (*C*H_3CO), 16.79 (C-6c). Anal. calcd. for $C_{70}H_{75}NO_{16}$: C 70.87, H 6.37, N 1.18; found: C 70.68, H 6.30, N 1.18.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-4-*O*-[4,6-*O*-benzylidene-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-2-deoxy-β-*D*-glucopyranoside (**46**)*

Compound **45** (500 mg, 0.42 mmol) was treated with methanolic 0.07 N sodium methoxide (14 mL) for 5 days. After neutralization with Amberlite IRC 50 (H^+), filtration, and evaporation, the resulting product was chromatographed on a column of silica gel (dichloromethane–methanol, 19:1) to provide **46** (400 mg, 88%) as a white powder; $[\alpha]_D$ −65.8 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.50–7.10 (m, 30H, 6Ph), 5.67 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.55 (s, 1H, C*H*Ph), 5.00 (overlapped by CH_2Ph, H-1c), 3.75 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 3.45 (s, 3H, CH_3O), 1.12 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c).

*Methyl 2-acetamido-3,6-di-*O*-benzyl-4-*O*-[4,6-*O*-benzylidene-3-*O*-phenoxythiocarbonyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-2-deoxy-β-D-glucopyranoside (**47**)*

A mixture of **46** (300 mg, 0.28 mmol), 4-dimethylaminopyridine (180 mg, 1.47 mmol), and phenyl chlorothionocarbonate (0.13 mL, 0.94 mmol) in dry acetonitrile (20 mL) was kept at 50°C for 24 h. The solvent was evaporated and the resulting material was applied to a column of silica gel (hexane – ethyl acetate, 7:3) to provide **47** (273 mg, 80%) as a pale yellow solid; mp 88–89°C; $[\alpha]_D$ −11.4 (*c* 0.9, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.50–6.85 (m, 35H, 7Ph), 5.68 (d, 1H, $J_{NH,2a}$ 7.0 Hz, NH), 5.52 (s, 1H, C*H*Ph), 5.35 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{3b,4b}$ 3.5 Hz, H-3b), 5.33 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.52 (d, overlapped, H-1b), 4.28 (dd, 1H, $J_{1b,2b}$ 7.5 Hz, H-2b), 3.49 (s, 3H, CH_3O), 3.35 (m, 1H, H-2a), 1.86 (s, 3H, CH_3CO), 1.22 (d, 3H, $J_{5c,6c}$ 6.2 Hz, H_3-6c). Anal. calcd. for $C_{70}H_{75}NO_{17}S$: C 68.11, H 6.13, N 1.13; found: C 68.66, H 6.17, N 1.23.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-4-*O*-[4,6-*O*-benzylidene-3-deoxy-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-xylo-hexopyranosyl]-2-deoxy-β-D-glucopyranoside (**48**)*

A solution of **47** (250 mg, 0.20 mmol) in dry toluene (15 mL) was heated to 75°C under nitrogen for 30 min. Then 2,2′-azobis(isobutyronitrile) (45 mg, 0.27 mmol) and tributyltin hydride (0.8 mL, 2.97 mmol) were added. After 4 h at 75°C, the solvent was evaporated and the remainder purified on a column of silica gel (dichloromethane – ethyl acetate, 6:4) to provide **48** (140 mg, 65%) as a white solid; mp 74–75°C; $[\alpha]_D$ −71.1 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.50–7.20 (m, 30H, 6Ph), 5.75 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.46 (s, 1H, C*H*Ph), 4.95 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.76 (d, 1H, $J_{1a,2a}$ 7.0 Hz, H-1a), 4.50 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.04 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-1c), 3.48 (s, 3H, CH_3O), 3.46 (H-2a), 2.39 (m, 1H, $J_{3bax,3beq}$ 13.5 Hz, H-3beq), 1.88 (s, 3H, CH_3CO), 1.56 (m, 1H, H-3bax), 1.17 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). ^{13}C nmr ($CDCl_3$) δ: 170.20 (CO), 103.14, 101.35, 101.06, 94.93 (C-1a, C-1b, C-1c, and PhCH), 33.53 (C-3b), 23.59 (CH_3CO), 16.78 (C-6c). Anal. calcd. for $C_{63}H_{71}NO_{14}$: C 70.97, H 6.71, N 1.31; found: C 70.08, H 6.60, N 1.56.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-4-*O*-[4,6-*O*-benzylidene-2-*O*-(2,6-dideoxy-α-L-lyxo-hexopyranosyl)-β-D-galactopyranosyl]-2-deoxy-β-D-glucopyranoside (**49**)*

A solution of freshly prepared 3,4-di-*O*-acetyl-2,6-dideoxy-α-L-*lyxo*-hexopyranosyl bromide (**38**, 1.30 mmol) (20) in dichloromethane (3.0 mL) was added to a stirred mixture of **44** (100 mg, 0.13 mmol), tetraethylammonium bromide (37 mg, 0.18 mmol), 4 Å molecular sieves (powdered, 1.5 g), and *N*,*N*-dimethylformamide (0.30 mL) in dichloromethane (3.0 mL). After stirring for 2 h, the reaction was quenched by the addition of methanol (0.5 mL). Usual work-up was followed by column chromatography on silica gel (dichloromethane–methanol, 98:2). The resultant impure product was deacylated in methanolic 0.17 N sodium methoxide (3 mL) for 12 h. Neutralization with Amberlite IRC 50 H^+, filtration, and evaporation gave a residue that was chromatographed on a column of silica gel (dichloromethane–methanol, 19:1), to provide **49** (45 mg, 44%) as a white solid, mp 120–121°C; $[\alpha]_D$ −73 (*c* 0.6, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 15H, 3Ph), 5.65 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.50 (s, 1H, C*H*Ph), 5.44 (d, 1H, $J_{1c,2eax}$ 3.5 Hz, $J_{1c,2eeq}$ < 1 Hz, H-1c), 4.83 (d, 1H, $J_{1a,2a}$ 7.5 Hz, H-1a), 4.36 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.24 (q, overlapped, $J_{5c,6c}$ 6.5 Hz, H-5c), 3.49 (s, 3H, CH_3O), 3.30 (m, 1H, H-2a), 1.96 (bdd, $J_{2eax,2eeq}$ 13.0 Hz, $J_{2eeq,3c}$ 4.5 Hz, H-2ceq), 1.91 (s, 3H, CH_3CO), 1.74 (ddd, 1H, $J_{3c,2eax}$ 12.5 Hz, H-2cax), 1.29 (d, 3H, H_3-6c); ^{13}C nmr ($CDCl_3$) δ: 170.40 (CO), 101.57, 101.03 (2C), 97.63 (C-1a, C-1b, C-1c, PhCH), 32.74 (C-2c), 23.59 (CH_3CO), 16.78 (C-6c). Anal. calcd. for $C_{42}H_{53}NO_{14}$: C 63.38, H 6.71, N 1.76; found: C 62.49, H 6.68, N 1.82.

*Methyl 2-acetamido-4-*O*-[3-*O*-benzoyl-4,6-*O*-benzylidene-2-*O*-(2,4-di-*O*-benzyl-3,6-dideoxy-α-L-xylo-hexopyranosyl)-β-D-galactopyranosyl]-3,6-di-*O*-benzyl-2-deoxy-β-D-glucopyranoside (**50**)*

Freshly prepared bromide **36** (0.30 mmol) was reacted with alcohol **44** (100 mg, 0.13 mmol) as described for the preparation of **4**. After stirring for 20 h, methanol (0.5 mL) was added, followed by the usual processing and column chromatography of the resulting product on silica gel. Elution with dichloromethane–methanol (98:2) provided the title compound **50** (120 mg, 86%) as a white solid; mp 99–100°C; $[\alpha]_D$ −9.9 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 8.02, 7.60–6.90 (d, 2H, m, 28H, 6Ph), 5.70 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.45 (s, 1H, PhC*H*), 5.38 (d, 1H, $J_{1c,2c}$ 3.2 Hz, H-1c), 5.19 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, $J_{3b,4b}$ 3.5 Hz, H-3b), 4.78 (d, 1H, $J_{1a,2a}$ 7.5 Hz, H-1a), 4.62 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.42 (bd, 1H, H-4b), 4.39 (dd, 1H, H-2b), 4.09 and 4.05 (2t, AB, 2H, $J_{3a,4a} \sim J_{4a,5a} \sim$ 7.5 Hz, H-4a, $J_{2a,3a}$ 8.0 Hz, H-3a), 3.70 (td, 1H, $J_{2c,3cax}$ 11.5 Hz, $J_{2c,3ceq} \sim$ 4.5 Hz, H-2c), 3.47 (s, 3H, CH_3O), 3.41 (m, 1H, H-2a), 1.98 (dt, 1H, $J_{3cax,3ceq}$ 12.5 Hz, H-3ceq), 1.88 (s, 3H, CH_3CO), 1.71 (m, 1H, $J_{3cax,4c} \sim$ 2 Hz, H-3cax), 1.24 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c); ^{13}C nmr ($CDCl_3$) δ: 170.27 and 165.84 (2CO), 101.35, 100.99, 100.79, 96.76 (C-1a, C-1b, C-1c, PhCH), 27.84 (C-3c), 23.60 (CH_3CO), 16.61 (C-6c). Anal. calcd. for $C_{63}H_{69}NO_{15}$: C 70.05, H 6.44, N 1.29; found: C 69.92, H 6.39, N 1.55.

*Methyl 2-acetamido-4-*O*-[3-*O*-benzoyl-4,6-*O*-benzylidene-2-*O*-(2,3-di-*O*-benzyl-4,6-dideoxy-α-L-xylo-hexopyranosyl)-β-D-galactopyranosyl]-3,6-di-*O*-benzyl-2-deoxy-β-D-glucopyranoside (**51**)*

The disaccharide **44** (55 mg, 0.07 mmol) was glycosylated with bromide **37** (0.30 mmol) as described for the preparation of **4**. After stirring for 20 h, the mixture was processed in the usual way. The resultant product was purified by column chromatography (dichloromethane–methanol, 98:2) to provide the title compound **51** (70 mg, 91%). Compound **51** had mp 94–95°C; $[\alpha]_{365}$ + 21.9 (*c* 0.9, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 8.0, 7.5–7.05 (d, 2H, m, 28H, 6Ph), 5.72 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 5.45 (s, 1H, PhC*H*), 5.37 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 5.12 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, $J_{3b,4b}$ 3.5 Hz, H-3b), 4.82 (d, 1H, $J_{1a,2a}$ 7.2 Hz, H-1a), 4.54 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.39 (d, 1H, H-4b), 4.33 (dd, 1H, H-2b), 4.10 and 4.07 (2t, AB, 2H, $J_{3a,4a} \sim J_{4a,5a}$ 7.5 Hz, H-4a, $J_{2a,3a} \sim$ 8.5 Hz, H-3a), 3.88 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.50 (s, 3H, CH_3O), 3.38 (overlapped, H-2a), 2.03 (m, 1H, $J_{4cax,4ceq}$ 12.5 Hz, $J_{4ceq,5c} \sim$ 2 Hz, $J_{4ceq,3c}$ 5.0 Hz, H-4ceq), 1.88 (s, 3H, CH_3CO), 1.32 (m, 1H, $J_{4cax,3c} \sim J_{4cax,5c} \sim$ 12 Hz, H-4cax), 1.20 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{63}H_{69}NO_{15}$: C 70.05, H 6.44, N 1.29; found: C 69.64, H 6.49, N 1.47.

*Methyl 2-acetamido-2-deoxy-4-*O*-[2-*O*-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (**52**)*

Compound **46** (0.09 mmol) and 5% palladium-on-carbon (100 mg) in 95% ethanol (4 mL) were hydrogenated at 120 psi for 18 h. Removal of the catalyst by filtration, evaporation, and gel filtration of the remainder through a column of Sephadex LH 20 (ethanol–water, 1:1) provided **52** (40 mg, 80%) as a white solid after lyophilization of an aqueous solution. Compound **52** had mp 215–216°C; $[\alpha]_D$ −94.3 (*c* 0.9, water) and ^{1}H and ^{13}C nmr data identical to those reported previously (14) (Table 3).

*Methyl 2-acetamido-2-deoxy-4-*O*-[3-deoxy-2-*O*-(α-L-fucopyranosyl)-β-D-xylo-hexopyranosyl]-β-D-glucopyranoside (**53**)*

Trisaccharide **48** (125 mg, 0.12 mmol) and 5% palladium-on-carbon (125 mg) in 95% ethanol (8 mL) were hydrogenated at 120 psi for 36 h. Examination by tlc (isopropanol–water, 4:1) indicated a mixture of three compounds. After removal of the catalyst and evaporation, the remainder was acetylated conventionally (pyridine – acetic anhydride, 2:1) overnight. The product obtained on evaporation and codistillation with toluene was applied to a column of silica gel (dichloromethane–methanol, 49:1). The major fraction was evaporated and the remainder was deacety-

For personal use only.

lated conventionally in methanolic 0.1 N sodium methoxide, followed by neutralization with Amberlite IRC 50 H^+ and evaporation. Purification on a column of Sephadex LH-20 (ethanol–water, 1:1) then provided **53** (20 mg, 32.3%) as a white powder after freeze-drying an aqueous solution; mp 209–210°C; $[\alpha]_D$ − 125.5 (*c* 0.8, water); ^{1}H nmr (D_2O) δ: 4.98 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.63 (d, 1H, $J_{1b,2b}$ 7.8 Hz, H-1b), 4.46 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.17 (bq, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{5c,4c}$ < 1 Hz, H-5c), 4.03 (H-4b), 4.01 (dd, overlapped, $J_{6a,6a'}$ 12.0 Hz, $J_{6a,5a}$ 1.8 Hz, H-6a), 3.51 (s, 3H, CH_3O), ~ 3.46 (overlapped, H-5a), 2.37 (ddd, 1H, $J_{3bax,3beq}$ 14.0 Hz, $J_{3beq,2b}$ 5.0 Hz, $J_{3beq,4b}$ 3.5 Hz, H-3beq), 2.04 (s, 3H, CH_3CO), 1.72 (ddd, 1H, $J_{3bax,2b}$ 11.0 Hz, $J_{3bax,4b}$ 2.8 Hz, H-3bax), 1.24 (d, 3H, H_3-6c). ^{13}C nmr data are reported in Table 3.

*Methyl 2-acetamido-2-deoxy-4-*O*-[2-*O*-(2,6-dideoxy-*α*-L-lyxo-hexopyranosyl)-*β*-D-galactopyranosyl]-*β*-D-glucopyranoside (**54**)*

Trisaccharide **49** (40 mg, 0.05 mmol) and 5% palladium-on-carbon (40 mg) were hydrogenated as described for the preparation of **52**. Usual work-up and gel filtration provided **54** (21 mg, 79%) as a white powder after freeze-drying an aqueous solution; mp 204–205°C; $[\alpha]_D$ −77.8 (*c* 0.4, water); ^{1}H nmr (D_2O) δ: 5.32 (dd, 1H, $J_{1c,2cax}$ 3.5 Hz, $J_{1c,2ceq}$ < 1 Hz, H-1c), 4.47 (d, 1H, $J_{1b,2b}$ 7.8 Hz, H-1b), 4.43 (dd, 1H, $J_{1a,2a}$ 8.2 Hz, H-1a), 4.12 (m, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{5c,4c}$ < 1 Hz, H-5c), 3.97 (m, 2H, H-6a and H-3c), 3.90 (d, 1H, $J_{3c,4c}$ 3.5 Hz, H-4c), 3.49 (s, 3H, CH_3O), 3.46 (m, H-5a), 2.02 (s, 3H, CH_3CO), 1.96 (dd, 1H, $J_{2cax,2ceq}$ 13.2 Hz, $J_{2ceq,3c}$ 5.0 Hz, H-2ceq), 1.88 (dt, $J_{2cax,3c}$ 12.0 Hz, H-2cax), 1.22 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 3.

*Methyl 2-acetamido-2-deoxy-4-*O*-[2-*O*-(3,6-dideoxy-*α*-L-xylo-hexopyranosyl)-*β*-D-galactopyranosyl]-*β*-D-glucopyranoside (**55**)*

Compound **50** (100 mg, 0.09 mmol) was debenzoylated as described for the preparation of **46**, followed by chromatography on silica gel (dichloromethane–methanol, 19:1). The debenzoylated material (80 mg) and 5% palladium-on-carbon (80 mg) were hydrogenated in 95% ethanol (5 mL) at 120 psi for 20 h. Usual work-up and gel filtration as described for **52** provided **55** (30 mg, 61%) as a white solid after freeze-drying an aqueous solution; mp 194–195°C; $[\alpha]_D$ −78 (*c* 0.8, water); ^{1}H nmr (D_2O) δ: 5.25 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.56 (d, 1H, $J_{1b,2b}$ 7.8 Hz, H-1b), 4.45 (d, 1H, $J_{1a,2a}$ 8.2 Hz, H-1a), 4.18 (q, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{4c,5c}$ < 1 Hz, H-5c), 4.04 (td, overlapped by H-6a, $J_{2c,3cax}$ 11.5 Hz, $J_{2c,3ceq}$ 5.0 Hz, H-2c), 4.03 (dd, $J_{6a,6a'}$ 12.0 Hz, $J_{5a,6a}$ 2.0 Hz, H-6a), 3.66 (dd, $J_{2b,3b}$ 10.0 Hz, H-2b), 3.51 (s, 3H, CH_3O), 3.47 (m, H-5a), 2.04 (s, 3H, CH_3CO), 2.01 (ddd, 1H, $J_{3cax,3ceq}$ 13.0 Hz, $J_{3ceq,4c}$ 3.0 Hz, H-3ceq), 1.92 (ddd, 1H, $J_{3cax,4c}$ 2.5 Hz, H-3cax), 1.12 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 3.

*Methyl 2-acetamido-2-deoxy-4-*O*-[2-*O*-(4,6-dideoxy-*α*-L-xylo-hexopyranosyl)-*β*-D-galactopyranosyl]-*β*-D-glucopyranoside (**56**)*

Trisaccharide **51** (60 mg, 0.06 mmol) was debenzoylated as described for the preparation of **46**, followed by chromatography on a column of silica gel (dichloromethane–methanol, 19:1) to provide a white solid (50 mg). This material and 5% palladium-on-carbon (50 mg) were hydrogenated with subsequent gel filtration of the hydrogenation product as described for **52**. After lyophilization of an aqueous solution, **56** (22 mg, 75%) was obtained as a light white solid; mp 168–170°C; $[\alpha]_D$ −82 (*c* 0.5, water); ^{1}H nmr (D_2O) δ: 5.32 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.54 (d, 1H, $J_{1b,2b}$ 7.8 Hz, H-1b), 4.45 (d, 1H, $J_{1a,2a}$ 8.2 Hz, H-1a), 4.22 (m, 1H, H-5c), 4.03 (dd, 1H, $J_{6a,6a'}$ 12.5 Hz, $J_{6a,5a}$ 1.8 Hz, H-6a), 3.65 (dd, overlapped, $J_{2b,3b}$ 10.0 Hz, H-2b), 3.51 (s, 3H, CH_3O), 3.49 (dd, overlapped, $J_{2c,3c}$ 10.0 Hz, H-2c and H-5a), 2.06 (ddd, $J_{4cax,4ceq}$ 12.0 Hz, $J_{4ceq,3c}$ 5.0 Hz, $J_{4ceq,5c}$ 2.0 Hz, H-4ceq), 2.04 (s, 3H, CH_3CO), 1.40 (ddd, 1H, $J_{4cax,3c}$ ~ $J_{4cax,5c}$ ~ 12.0 Hz, H-4cax), 1.22 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). The ^{13}C nmr data are reported in Table 3.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-2-deoxy-4-*O*-(2,3,4-tri-*O*-acetyl-6-deoxy-*β*-D-galactopyranosyl)-*β*-D-glucopyranoside (**58**)*

A solution of freshly prepared bromide **57** (22) (1.7 mmol) in benzene–nitromethane (1:1, 5.0 mL) was added to a stirred mixture of **39** (200 mg, 0.48 mmol), mercuric cyanide (243 mg, 0.96 mmol), and powdered calcium sulfate (1 g) in the same solvent (25 mL). After stirring for 48 h at 40°C, it was worked up in the usual way and the resulting material was applied to a column of silica gel (dichloromethane–methanol, 19:1). Evaporation of the major fraction gave a white foamy solid **58** (225 mg, 68%); mp 79–80°; $[\alpha]_D$ −15.4 (*c* 1.1, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 5.98 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH), 5.17 (bd, 1H, $J_{4b,5b}$ < 1 Hz, $J_{3b,4b}$ 3.5 Hz, H-4b), 5.11 (dd, 1H, $J_{2b,3b}$ 10.5 Hz, $J_{1b,2b}$ 8.0 Hz, H-2b), 4.92 (dd, 1H, H-3b), 4.76 and 4.68 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.64 and 4.50 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.62 (d, overlapped, $J_{1a,2a}$ 5.0 Hz, H-1a), 4.46 (d, 1H, H-1b), 4.00 (t, 1H, $J_{3a,4a}$ ~ $J_{4a,5a}$ ~ 5.5 Hz, H-4a), 3.91 (t, 1H, $J_{2a,3a}$ ~ 6 Hz, H-3a), 3.85 (dd, overlapped by H-2a, $J_{5a,6a}$ 5.5 Hz, $J_{6a,6a'}$ 10.0 Hz, H-6a), 3.79 (dd, $J_{5a,6a'}$ 4.5 Hz, H-6a'), 3.67 (q, 1H, H-5a), 3.55 (q, 1H, $J_{5b,6b}$ 6.5 Hz, H-5b), 3.44 (s, 3H, CH_3CO), 2.18, 2.04, 1.98, 1.95 (4s, each 3H, $4CH_3CO$). Anal. calcd. for $C_{35}H_{45}NO_{13}$: C 61.12, H 6.60, N 2.04; found: C 61.25, H 6.82, N 2.04.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-2-deoxy-4-*O*-(6-deoxy-*β*-D-galactopyranosyl)-*β*-D-glucopyranoside (**59**)*

Compound **58** (200 mg, 0.29 mmol) was deacetylated in methanolic 0.08 N sodium methoxide (4 mL) for 16 h. The solution was made neutral with Amberlite IRC 50 H^+ and the solvent evaporated. The remainder was subjected to column chromatography on silica gel (dichloromethane–methanol, 9:1) to provide **59** (150 mg, 92%) as a white powder; mp 194–195°C; $[\alpha]_D$ + 0.8 (*c* 0.8, methanol). Anal. calcd. for $C_{27}H_{39}NO_{10}$: C 62.02, H 7.00, N 2.49; found: C 61.38, H 6.89, N 2.58.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-4-*O*-(3,4-*O*-benzylidene-6-deoxy-*β*-D-galactopyranosyl)-2-deoxy-*β*-D-glucopyranoside (**60**)*

To a solution of **59** (140 mg, 0.25 mmol) in dry acetonitrile (5.0 mL) were added α,α-dimethoxytoluene (73 μL, 0.49 mmol) and *p*-toluenesulfonic acid monohydrate (3 mg). After 30 min, the reaction was neutralized and the solvent evaporated. The remainder was purified by column chromatography on silica gel (dichloromethane–methanol, 19:1) to provide **60** (160 mg, 99%) as a white powder. The ^{1}H nmr data showed it to be a 1:1 mixture of two isomers with *exo* and *endo* phenyl groups; mp 89–90°C; $[\alpha]_D$ +162.3 (*c* 1.2, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.50–7.20 (m, 15H, 3Ph), 6.12, 5.93 (2s, 1H, PhC*H*), 5.64 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 3.48, 3.47 (2s, 3H, CH_3O), 1.870, 1.865 (2s, 3H, CH_3CO), 1.34, 1.29 (d, 3H, $J_{5b,6b}$ 6.5 Hz, H_3-6b). Anal. calcd. for $C_{36}H_{43}NO_{10}$: C 66.55, H 6.67, N 2.16; found: C 65.75, H 6.51, N 2.22.

*Methyl 2-acetamido-3,6-di-*O*-benzyl-4-*O*-[3,4-*O*-benzylidene-6-deoxy-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-*β*-D-galactopyranosyl]-2-deoxy-*β*-D-glucopyranoside (**61**)*

Disaccharide **60** (120 mg, 0.18 mmol) was fucosylated with bromide **3** (0.7 mmol) as described for the preparation of trisaccharide **4**. After stirring for 20 h, the mixture was processed in the usual way and the resulting product was purified by column chromatography on silica gel (dichloromethane–methanol, 98:2) to provide solid **61** (160 mg, 81%) as a 1:1 mixture of isomers with *exo* and *endo* phenyl groups; mp 78–79°C; $[\alpha]_D$ −41 (*c* 1.6, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.50–7.20 (m, 30H, 6Ph), 6.07, 5.89 (2s, 1H, PhC*H*), 5.69 (2d, 1H, NH), 5.58, 5.47 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 3.48, 3.47 (2s, 3H, CH_3O), 1.89, 1.84 (2s, 3H, CH_3CO), 1.34, 1.31 (2d, 3H, $J_{5b,6b}$ 6.5 Hz, H_3-6b), 1.19, 1.13, (2d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{63}H_{71}NO_{14}$: C 70.97, H 6.71, N 1.31; found: C 70.73, H 6.77, N 1.41.

Methyl 2-acetamido-2-deoxy-4-O-[6-deoxy-2-O-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (62)

Compound **62** (120 mg, 0.11 mmol) was hydrogenated in the presence of 5% palladium-on-carbon (120 mg) as described for **52**. Gel filtration and freeze-drying of an aqueous solution provided **62** (46 mg, 78%) as a white powder; mp 178–179°C; $[\alpha]_D$ −107.8 (*c* 0.8, water); ^{1}H nmr (D_2O) δ: 5.34 (d, 1H, $J_{1c,2c}$ 3.2 Hz, H-1c), 4.51 (d, 1H, $J_{1b,2b}$ 7.8 Hz, H-1b), 4.46 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.24 (q, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{4c,5c}$ < 1 Hz, H-5c), 3.99 (dd, 1H, $J_{6a,6a'}$ 12.0 Hz, $J_{5a,6a}$ 1.5 Hz, H-6a), 3.88 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{3b,4b}$ ~ 3.5 Hz, H-3b), 3.74 (overlapped, H-2a), 3.64 (dd, 1H, H-2b), 3.52 (s, 3H, CH_3O), 3.49 (H-5a), 2.05 (s, 3H, CH_3CO), 1.25, 1.23 (2d, *J* 6.5 Hz, H_3-6c, H_3-6b). The ^{13}C nmr data are reported in Table 3.

Methyl 2-acetamido-4-O-(2-O-acetyl-3,6-di-O-benzyl-4-deoxy-β-D-xylo-hexopyranosyl)-3,6-di-O-benzyl-2-deoxy-β-D-glucopyranoside (64)

Alcohol **39** (320 mg, 0.77 mmol) was glycosylated with 2-*O*-acetyl-3,6-di-*O*-benzyl-4-deoxy-α-D-*xylo*-hexopyranosyl bromide (**53**, 1.46 mmol) (12) as described for the preparation of **27**. After 16 h, the mixture was worked up and the resulting product was purified by column chromatography on silica gel (dichloromethane–methanol, 98:2) to afford **64** (112 mg, 19%); mp 124–126°C; $[\alpha]_D$ −6 (*c* 0.1, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.20 (m, 20H, 4Ph), 6.07 (d, 1H, $J_{NH,2a}$ 9.0 Hz, NH), 4.84 (dd, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.72–4.45 (m, 9H, 4CH_2Ph, with H-1a, d, at 4.51), 4.33 (d, 1H, H-1b), 3.98 (m, overlapped, H-2a), 3.96 (t, overlapped, $J_{3a,4a}$ ~ $J_{4a,5a}$ 5.0 Hz, H-4a), 3.80 (d, 2H, $J_{5a,6a}$ 5.0 Hz, H_2-6a), 3.76 (t, 1H, $J_{2a,3a}$ 5.5 Hz, H-3a), 3.70 (m, 1H, H-5a), 3.42 (s, 3H, CH_3O), 2.20 (ddd, 1H, $J_{4beq,4bax}$ 12.0 Hz, $J_{4beq,5b}$ 2.0 Hz, $J_{4beq,3b}$ 5.0 Hz, H-4beq), 2.04 and 1.94 (2s, each 3H, 2CH_3CO), 1.50 (q, 1H, $J_{4bax,3b}$ = $J_{4bax,5b}$ 12.0 Hz, H-4bax); fab-ms, *m/z*: 807.76 (0.43, $[MH + Na]^+$), 806.74 (0.98, $[M + Na]^+$), 784.74 (1.04, MH^+), 783.67 (0.16, M^+), 753.52 (1.73, $[MH - OMe]^+$), 752.50 (3.91, $[M - OMe]^+$).

Methyl 2-acetamido-3,6-di-O-benzyl-2-deoxy-4-O-[3,6-di-O-benzyl-4-deoxy-2-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-β-D-xylo-hexopyranosyl]-β-D-glucopyranoside (65)

Compound **64** (87 mg, 0.11 mmol) was treated with methanolic 0.05 N sodium methoxide (5 mL) for 18 h. The solution was neutralized with Amberlite IRC 50 H^+, evaporated to dryness, and the resulting alcohol crystallized from methanol–ether. This alcohol (85 mg, 0.11 mmol) was fucosylated with bromide **3** (0.77 mmol) as described for the preparation of **4**. Usual work-up after 18 h and subsequent column chromatography on silica gel (dichloromethane – ethyl acetate, 3:1) of the crude product provided, after precipitation from ether–hexane, trisaccharide **65** (80 mg, 62%) as a white powder; $[\alpha]_D$ −35 (*c* 0.1, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.10 (m, 35H, 7Ph), 5.73 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 5.64 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 4.89–4.35 (m, 16H, 7CH_2Ph, with H-1a, H-1b at 4.72 and 4.45), 4.31 (bq, 1H, $J_{5c,6c}$ 6.5 Hz, $J_{4c,5c}$ < 1H, H-5c), 4.03 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.95 (overlapped, $J_{3c,4c}$ 2.5 Hz, H-4c), 3.83 (dd, 1H, H-3c), 3.47 (s, 3H, CH_3O), 2.22 (bdd, 1H, $J_{4beq,4bax}$ 12.0 Hz, $J_{4beq,5b}$ ~ 1 Hz, $J_{3b,4beq}$ ~ 4 Hz, H-4beq), 1.86 (s, 3H, CH_3CO), 1.38 (bq, $J_{4bax,5b}$ ~ $J_{3b,4bax}$ ~ 12 Hz, H-4bax), 1.21 (d, 3H, H_3-6c); fab-ms, *m/z*: 1181.57 (0.48, $[MH + Na]^+$), 1180.53 (0.61, $[M + Na]^+$), 1158.57 (0.34, MH^+), 1157.51 (0.06, M^+), 1127.43 (0.62 $[MH - OMe]^+$), 1126.45 (0.81 ($[M - OMe]^+$).

Methyl 2-acetamido-2-deoxy-4-O-[4-deoxy-2-O-(α-L-fucopyranosyl)-β-D-xylo-hexopyranosyl]-β-D-glucopyranoside (66)

Compound **66** (49 mg, 0.042 mmol) in 95% ethanol (5 mL) was hydrogenated over 10% palladium-on-carbon (22 mg) at 35 psi for 14 h. Usual work-up and gel filtration on Sephadex LH 20 (ethanol–water, 1:1) provided **66** (21 mg, 94%) as a white powder after lyophilization of an aqueous solution; $[\alpha]_D$ −136.5 (*c* 0.2, water); ^{1}H nmr (D_2O) δ: 5.35 (d, 1H, $J_{1c,2c}$ 3.0 Hz, H-1c), 4.50 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.44 (d, 1H, $J_{1a,2a}$ 8.5 Hz, H-1a), 4.24 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.01 (dd, overlapped, H-6a), 3.98 (ddd, $J_{2b,3b}$ 10.0 Hz, H-3b), ~3.80 (m, H-2c, H-3c, H-4c), 3.51 (s, 3H, CH_3O), 3.48 (H-5a), 3.39 (dd, 1H, H-2b), 2.07 (s, 3H, CH_3CO), 1.96 (ddd, 1H, $J_{4beq,4bax}$ 12.5 Hz, $J_{4beq,3b}$ 5.0 Hz, $J_{4beq,5b}$ 1.5 Hz, H-4beq), 1.48 (q, 1H, $J_{4bax,5b}$ ~ $J_{4bax,3b}$ ~ 12.5 Hz, H-4bax), 1.23 (d, 3H, H_3-6c). The ^{13}C nmr data are reported in Table 3.

The synthesis of (−)-(*R*)-7-azatryptophan (**2**) from commercially available 7-azaindole (**4**) is described. The key step involved the diastereoselective alkylation of *tert*-butyl [(1*R*,4*R*)-bornylideneamino]acetate (**3**) with 1-(*tert*-butyloxycarbonyl-3-(iodomethyl)-7-azaindole (**19**) derived from 3-formyl-7-azaindole (**14**). The alkylation, conducted at −100°C in a THF/HMPA solvent using potassium hexamethyldisilazide as the base, afforded **7** in greater than 98% diastereomeric excess. Hydrolysis and deprotection gave (−)-(*R*)-7-azatryptophan.

RUBÉN SÁNCHEZ-OBREGÓN, ALEX G. FALLIS et ARTHUR G. SZABO. Can J. Chem. **70**, 1531 (1992).

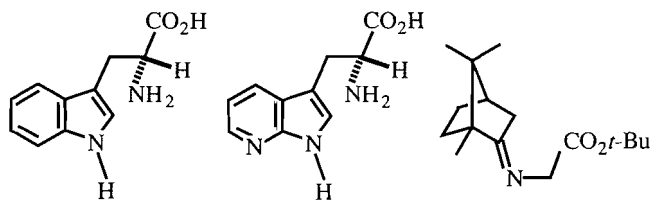
On décrit la synthèse du (−)-(*R*)-7-azatryptophane (**2**) réalisée à partir du 7-azaindole (**4**) disponible commercialement. L'étape clé implique une alkylation disastéréosélective du [(1*R*,4*R*)-bornylidènamino]acétate de *tert*-butyle (**3**) par du 1-(*tert*-butyloxycarbonyl-3-(iodométhyl)-7-azaindole (**19**) obtenu à partir du 3-formyl-7-azaindole (**14**). L'alkylation, réalisée à 100°C, dans un mélange de THF/HMPA et utilisant de l'hexaméthyldisilazure de potassium comme base, conduit au composé **7** avec un excès de diastéréo-isomère de plus de 98%. Son hydrolyse et sa déprotection fournissent le (−)-(*R*)-7-azatryptophane.

[Traduit par la rédaction]

Introduction

There is considerable current interest in the fluorescence decay of aromatic amino acids, such as tryptophan (**1**), as a vehicle for probing the structure and dynamics of proteins and peptides. The sensitivity of molecular excited state relaxation rates to the local microenvironment has prompted the development of numerous fluorescence methods (1) and intense study of the photophysics of tryptophan (2–4). In spite of these studies the relationship between tryptophan fluorescence decay and its ground state structure is not well understood. Consequently additional spectroscopic investigations continue to be reported on tryptophan derivatives using fluorescence (5) and related spectroscopic techniques (6).

A promising candidate for further study owing to its unique spectroscopic properties and the fact that it can be substituted for tryptophan in many biological systems is 7-azatryptophan (**2**). Unfortunately it is not available as a single enantiomer and efforts to resolve it have proved unrewarding.[3] 7-Azatryptophan is of additional interest owing to its effect on nitrogen fixation in certain algae (7). The racemate was synthesized several years ago from 7-azagramine (3-(dimethyaminomethyl)-7-azaindole) (8). We wish to report the first synthesis of (−)-(*R*)-7-azatryptophan (**2**) via the intermediacy of the (1*R*,4*R*)-camphor imine of *tert*-butyl glycinate **3**.



1 **2** **3**

Results and discussion

In view of the commercial availability of 7-azaindole the most straightforward strategy for the synthesis of **2** was to effect the selective functionalization of the intact indole system and thus avoid *de novo* construction of the heterocyclic nucleus. Provided a diastereoselective alkylation with a suitably functionalized indole species such as **5** was employed, rapid preparation of the amino acid should be possible. Asymmetric alkylation of glycine derivatives has received considerable attention with a variety of chiral auxiliaries to provide amino acids of known configuration in high optical purity (9–14). In their study of the alkylation of the enolate, obtained from the (1*R*,4*R*)-camphor imine of *tert*-butyl glycinate McIntosh *et al.* (13) determined that the π electron density and steric effects in the electrophile significantly influenced the diastereomeric excess. The best results (>98% diasteromeric excess (de)) were achieved with benzyl bromides. The presence of an aryl moiety was criti-

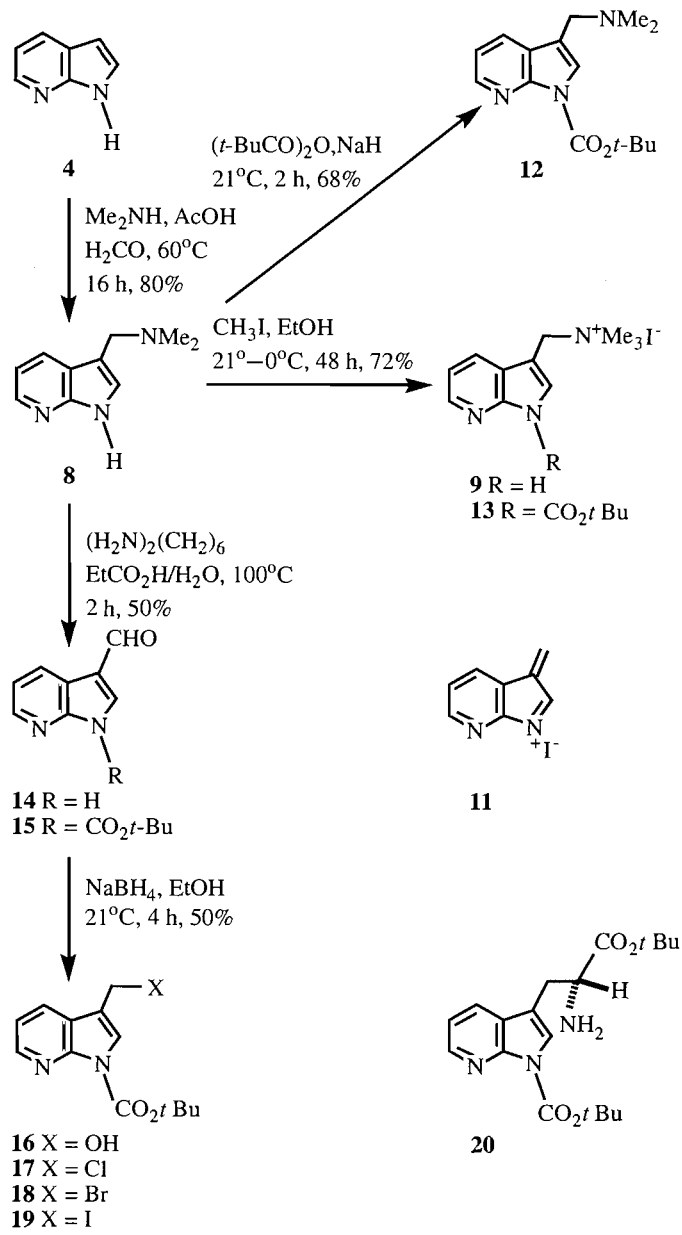
SCHEME 1

cal in order to obtain high selectivity. It therefore appeared reasonable to anticipate a similarly high level of induction with the aromatic azaindole system, which is also capable of π complexation with the lithium atom of the enolate derived from **3**. As illustrated in Scheme 1, alkylation of **3** should generate species of type **6** that could be transformed into the desired amino acid.

To investigate this possibility 7-azaindole (**4**) was treated under Mannich conditions to afford 7-azagramine (**8**) in 80% yield by analogy with previous studies with indole (15). Conversion of **8** into its ammonium salt **9** occurred readily with excess methyl iodide (Scheme 2). The (1*R*,4*R*)-camphor-imine **3** was prepared by $BF_3 \cdot Et_2O$ mediated condensation of natural (1*R*,4*R*)-camphor with *tert*-butyl glycinate (**10**) (15). The requisite amino ester **10** was synthesized following literature procedures (16) commencing with *tert*-butyl bromoacetate followed by azide displacement and reduction.

As will become apparent, a detailed study of the alkylation of **3** was necessary to achieve a respectable level of diastereomeric excess. The yield of **6** was 26% when the ammonium salt **9** was employed in tetrahydrofuran/dimethylformamide (THF/DMF) at −78°C using lithium diisopropylamide (LDA) as the base. This was disappointing, but of greater concern was the absence of any diastereoselectivity. This may be a consequence of the known tendency of these systems to undergo facile Hofmann elimination so that the product probably arose by an elimination–addition sequence involving the intermediacy of **11**. Substitution of the indole nitrogen will block, or at least retard, this pathway and thus 7-azagramine (**8**) was converted to its *tert*-butyloxycarbonyl derivative **12**. Excess methyl iodide afforded the blocked ammonium salt **13**. As summarized in Table 1 (entries 2, 3), the alkylation reaction with this material was unsuccessful, although at −10°C a 33% yield of the deprotected product was obtained. However, no diastereomeric excess was oberved, and thus it seems likely that deprotection preceded alkylation. To improve the reactivity better leaving groups were required.

The aldehyde **14** was prepared from **8** with hexamethylenetetramine and aqueous propionic acid following the method of Robison and Robison (17). The *tert*-butyloxycarbonyl derivative **15** was generated in a 96% yield and reduced to the primary alcohol **16** with $NaBH_4$ (Scheme 2). Treatment of this alcohol separately with triphenylphosphine/carbon tetrachloride and triphenylphosphine/carbon tetrabromide afforded the corresponding chloride **17** and bromide **18**, respectively. The iodide **19** was prepared by displacement of the chloride with sodium iodide in acetone at room temperature. However, even under these mild conditions it decomposed slowly and the bromide was also



SCHEME 2

troublesome during chromatography on silica gel, so Florisil was utilized instead.

Guided by the earlier studies of McIntosh and co-workers (13, 15) plus related investigations of diastereoselective conjugate additions of lithiated camphor imines of glycine esters (18), the additional alkylations listed in Table 1 were examined. Unfortunately in all cases the chemical yields were very modest. A referee has suggested that these yields are not satisfactory and we agree they are disappointing. However, we have been unable to establish conditions that afford both a good chemical yield and retain a high level of diastereomeric excess in spite of considerable experimentation. Nevertheless, results such as these help drive organic chemistry and may stimulate novel synthetic improvements for these and related cases in the future. A reactive alkylating agent was required even for these allylic species since the chloride **17** was unreactive (entries 4–6) at the temperature

examined. Unfortunately, raising the temperature in the case of the bromide **18** (entries 8 and 9) did not improve the chemical yield and resulted in a decrease in diastereoselectivity. To achieve reasonable success it was necessary to counterbalance several interrelated factors. These included the instability of the iodide **19** coupled with the limited solubility of the reactants, including the enolate, at the low temperatures required. Previously McIntosh and Mishra (15*b*) had shown that one equivalent of hexamethylphosphoramide (HMPA) does not lower the selectivity but excess was deleterious. In spite of this potentially adverse effect, excess HMPA was essential and reasonable results were achieved (entry 14) by conducting the alkylation at −100°C in a THF/HMPA solvent using potassium hexamethyldisilazide as the base. These conditions afforded **7** in greater than 98% diastereomeric excess.

The camphor methyl groups displayed separate, readily integrated singlets for each diastereomer in the ^1H nmr spectrum, facilitating this analysis. In the case of entry 14 only a single diastereomer could be detected. It should be noted (entries 12 and 13) that for reactions conducted under the same conditions the potassium base afforded both higher yields and better diastereomeric excess (65 vs. 83% de) than did LDA. Possibly other counterions will also facilitate this alkylation, improve the enolate solubility, and consequently the chemical yield in spite of the limitation of the low temperatures required for high diastereoselectivity.

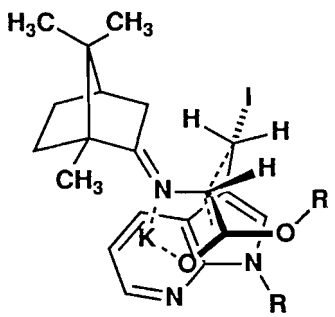

FIG. 1. π-Associated alkylation transition state.

Consistent with the McIntosh model, preferential attack occurred from the sterically less emcumbered bottom (re face) of the enolate to afford the *R* product. Benzylic halides have been shown to introduce a favourable π-π electrostatic interaction with the enolate π-system in related systems. This resulted in an enhanced steric bias and higher selectivity. These features are illustrated in Fig. 1, which represents a possible π-associated transition state for the alkylation.

To complete the synthesis a series of hydrolysis steps were required. The camphor auxiliary was removed in the presence of hydroxylamine hydrochloride and sodium acetate to provide the protected amino ester **20**. The optically active tris-[3-(heptafluoropropylhydroxymethylene)-(+)-camphor eu-

ropium(III) nmr shift reagent was added to a sample of **20** but there was no evidence of the presence of the other enantiomer. We were surprised to find that the optical rotation values were so small in these compounds in view of the fact that none of the minor diastereomer of **7** could be detected by ^{1}H nmr analysis. To be certain that the values were accurate the rotations were also determined independently on a second polarimeter in a different institution. In spite of the efforts of Brewester several years ago to establish a predictive set of rules they are not suffiently general to allow an estimate of the 7-azaindoyl substituent (19). Hydrolysis of the tertiary butyl esters was accomplished with trifluoroacetic acid at room temperature to afford (−)-(*R*)-7-azatryptophan (**2**) as a crystalline solid (from H_2O) 69% yield, mp 26–261°C(dec.) $[\alpha]_D^{22}$ −1.2 (c = 0.5, H_2O).

In summary, a direct synthesis of **2** has been achieved via the (1*R*,4*R*)-camphor imine ester **3** as a chiral template. It is known that with lithium enolates HMPA can alter the aggregation and chelation of the transition state complex owing to competition for lithium coordination (20). Further study is required, with potassium enolates in the presence of added salts and complexing agents, in order to increase our understanding of these transition state interactions. In due course this knowledge will lead to improved chemical yields and more sophisticated applications. The majority of natural amino acids possess the *S* (or L) configuration and thus to obtain material for incorporation into peptides it will be necessary to repeat the synthesis commencing with *tert*-butyl[(1*S*,4*S*)-bornylideneamino]acetate, the enantiomer of **3**. It was established earlier that the steady-state absorption and fluorescence properties of 7-azatryptophan may be distinguished from tryptophan so as to allow its use as a non-invasive *in situ* probe of protein structure and dynamics (22).[4] The spectroscopy of **2** will be described in due course.

Experimental

Melting points were determined in capillary tubes with a Thomas–Hoover Uni-Melt or a Fisher–Johes melting point apparatus, and are uncorrected. Infrared (ir) spectra were recorded on a Perkin–Elmer 783 spectrophotometer or a Bomem MB100 FTIR spectrometer. Proton magnetic resonance spectra (^{1}H nmr) were measured at 200 MHz with a Varian Gemini spectrometer or at 300 MHz with a Varian XL-300 spectrometer in deuterochloroform unless otherwise stated. Carbon magnetic resonance spectra (^{13}C nmr) were measured at 50 MHz (Varian Gemini) or at 75 MHz (Varian XL-300). The residual solvent signal ($CDCl_3$) was used as an internal lock; $CDCl_3$; ^{1}H: δ 7.262, ^{13}C: δ 77.0. Chemical shifts are reported in ppm downfield from tetramethylsilane (δ scale) as an internal standard. The multiplicity, number of protons, coupling constants, and proton assignments are indicated in parentheses. Mass spectra (ms) were determined on a V.G. micromass 7070 HS instrument using an ionization energy of 70 eV. Elemental analyses were conducted by M-H-W Laboratories, Phoenix, Ariz., U.S.A. Optical rotations were measured using a Perkin–Elmer 243 polarimeter (sodium light, cell length = 10 cm, c = g/100 mL). Analytical thin-layer chromatography (tlc) employed commercial aluminum sheets precoated (0.2 mm layer thickness) with silica gel 60 F_{254} (E. Merck). Flash column chromatography using E. Merck silica gel 60 (230–400 mesh) was employed for all column chromatography.

Petroleum (pet) ether refers to a fraction with boiling range 30–60°C. Anhydrous diethyl ether (ether) and diisopropylamine were obtained by distillation from $LiAlH_4$ and anhydrous tetrahydrofuran (THF) from potassium/benzophenone. Absolute ethanol was dried by distillation from magnesium. Dry benzene, dimethylformamide (DMF), and carbon tetrachloride (CCl_4) were prepared by distillation from phosphorus pentoxide. Anhydrous hexamethylphosphoramide (HMPA) was obtained by distillation from calcium hydride, and acetone was dried by distillation from anhydrous K_2CO_3. Solutions in organic solvents were dried over anhydrous magnesium sulfate and stripped of solvents with a Büchi rotatory evaporator connected to a water aspirator. Unless otherwise indicated, all the alkylation reactions were conducted under an atmosphere of dry nitrogen.

tert-*Butyl glycinate*

This ester was prepared by the method of Moore and Rydon (17) using *tert*-butylbromoacetate (Aldrich) and oxalic acid to isolate the glycine *tert*-butyl ester; bp 55–62°C, 18 Torr (1 Torr = 133.3 Pa); (lit. (21) bp 68°C, 21 Torr); ir (neat): 3395, 3330 (NH), 1740 (C=O) cm^{-1}; ^{1}H nmr δ: 3.28 (s, 2H, -CH_2-), 1.43 (s, 9H, $(CH_3)_3$C); ms m/z: 130 (M^+ −1).

tert-*Butyl [(1R,4R)-Bornylideneamino]acetate (3) (ref. 15)*

(1*R*,4*R*)-(+)-Camphor (1.52 g, 0.01 mol), *tert*-butyl glycinate (1.31 g, 0.01 mol), dry benzene (40 mL), and $BF_3 \cdot Et_2O$ (0.1 mL) were refluxed for 48 h in a Dean–Stark trap with azeotropic removal of water. The solution was cooled, washed with brine, dried, filtered, and concentrated. Chromatography (20% ethyl acetate/hexane) afforded the imine **3** (1.9 g, 72%): ir (neat): 1690 (C=N), 1745 (C=O) cm^{-1}; ^{1}H nmr δ: 3.94 (AB q 2H, J = 16 Hz, N-CH_2-CO), 2.35–2.20 (m, 1H), 1.95–1.35 (m, 5H), 1.43 (s, 9H, *t*-Bu), 1.25–1.06 (m, 1H), 0.95 (s, 3H, Me), 0.90 (s, 3H, Me), 0.75 (s, 3H, Me); ^{13}C nmr δ: 187.0, 169.3, 80.8, 54.5, 54.0, 47.2, 43.7, 35.6, 31.8, 28.0, 27.3, 19.5, 18.9, 11.2. Exact Mass calcd. for $C_{16}H_{27}NO_2$: 265.2041; found: 265.2024.

3-(N-*Dimethylaminomethyl)-7-azaindole (7-azagramine, 8) (ref. 17)*

Glacial acetic acid (7.2 g, 0.119 mol) was added to a stirred 40% aqueous dimethylamine solution (6 g, 0.054 mol) maintained at 5°C. Formalin (37%, 4.2 g, 0.051 mol) was added to this solution and the mixture was poured into the 7-azaindole (**4**) (6 g, 0.051 mol, Aldrich) and stirred until homogeneous. The reaction was heated at 60°C for 16 h and neutralized with aqueous NaOH (7.2 g in 50 mL). Cooling afforded pale yellow crystals of **8** (7.15 g, 80%): mp 160–162°C (lit.(17) mp 157–158.5°C); ir ($CHCl_3$): 3466, 3147 (N-H), 2819, 2776 (-CH-N<, -CH_2-N-) cm^{-1}; ^{1}H nmr δ: 11.74 (br, s, 1H, N-*H*); 8.33–8.22 (dd, 1H, J = 1.6, 4.8 Hz), 8.07–7.96 (dd, 1H, J = 1.6, 7.8 Hz), 7.23 (br s, 1H), 2.1–7.0 (dd, 1H, J = 4.8, 7.8 Hz), 3.58 (s, 2H), 2.24 (s, 6H); ^{13}C nmr δ: 148.8, 142.5, 127.3, 124.9, 119.8, 115.1, 110.7, 54.5, 44.9. Exact Mass calcd. for $C_{10}H_{13}N_3$: 175.1117; found: 175.1110.

1-tert-*Butyloxycarbonyl-3-(N-dimethylaminomethyl)-7-Azaindole (12)*

To a stirred suspension of sodium hydride (80% dispersion in mineral oil, 0.3 g, 0.01 mol, Aldrich) in HMPA (10 mL), was added 3-(*N*-Dimethylaminomethyl)-7-azaindole (**8**) (1.75 g, 0.01 mol) in HMPA (15 mL). After stirring for 0.5 h, di-*tert*-butyl carbonate (2.4 g, 0.011 mol, Aldrich) in HMPA (10 mL) was added and stirring continued at 21°C for 2 h. The reaction was quenched with water (40 mL), and extracted with ether (4 × 40 mL). The combined organic layers were washed with brine, water, dried, filtered, and concentrated. Chromatography (20% methanol/ethyl acetate) afforded **12** (1.87 g, 68%): mp 94–96°C (petroleum ether); ir ($CHCl_3$): 2820, 2790 (-CH-N<, -CH_2-N-), 1755 (C=O), 1425 (C-N) cm^{-1}; ^{1}H nmr δ: 8.42–8.35 (dd, 1H, J = 2.5, 5 Hz), 7.92–7.87 (dd, 1H, J = 2.5, 5 Hz), 7.42 (s, 1H), 7.11–7.01 (dd, 1H, J = 5.0, 5.0 Hz), 3.40 (s, 2H), 2.15 (s, 6H), 1.55 (s, 9H); ^{13}C nmr (DMSO-d_6) δ: 148.5, 147.2, 145.0, 128.2, 124.5, 123.1, 118.2, 115.6, 83.7, 54.6, 45.4, 28.0. Exact Mass calcd. for $C_{15}H_{21}N_3O$: 275.1634; found: 275.1622.

3-(N-Dimethylaminomethyl)-7-azaindole ammonium iodide (9)

Methyl iodide (3 g, 0.02 mol) was added dropwise to a stirred solution of compound **8** (3 g, 0.02 mol) dissolved in anhydrous ethanol (60 mL). The mixture was allowed to stand at room temperature (21°C) for 24 h followed by a further 24 h at 0°C. The resulting salt **9** (4.8 g, 72%) was collected by filtration (water aspirator) and washed with anhydrous ethanol (3 × 10 mL) and anhydrous ether (3 × 30 mL); mp 205–207°C (dec.); ir (KBr): 3450 (NH) cm^{-1}; ^1H nmr (DMSO-d_6) δ: 8.40–8.22 (m, 2H), 7.92–7.81 (m, 1H), 7.30–7.17 (m, 1H), 4.84 (s, 1H), 4.72 (s, 1H); ms *m/z*: 317 (M^+).

*1-(*tert*-Butyloxycarbonyl)-3-(N-dimethylaminomethyl)-7-azaindole ammonium iodide (13)*

Methyl iodide (0.5 g, 3.5 mmol) was added dropwise to a stirred solution of **12** (0.83 g, 3 mmol) in anhydrous ethanol (10 mL) maintained at 0°C with an external ice bath. The mixture was allowed to stand at 0°C for 1 h and then at 5°C for 4 days. The product **13** (1.06 g, 84%) was collected by filtration, washed with anhydrous ether (3 × 3 mL), and dried under vacuum: mp 165–166°C (dec.); ir (KBr): 1750 (C=O) cm^{-1}; ^1H nmr δ: 8.64–8.52 (dd, 1H, *J* = 1.5, 8 Hz), 8.51–8.46 (dd, 1H, *J* = 1.5, 4.7 Hz), 8.14 (s, 1H), 7.29–7.19 (m, 1H), 5.26 (s, 2H), 3.45 (s, 9H), 1.61 (s, 9H); ms *m/z*: 275 ($M^+ - CH_3I$).

3-Formyl-7-azaindole (14)

This compound was prepared by the method of Robison and Robison (17) using a solution of 3-(*N*-dimethylaminomethyl)-7-azaindole (**8**) (15 g, 0.0857 mol) and hexamethylenetetramine (12 g, 0.0857 mol, Aldrich) in 66% aqueous propionic acid (65 mL). This was added to a second solution of hexamethylenetetramine in propionic acid (45 mL). After 1 h at 21°C the reaction was heated at 100°C for 2 h, cooled, water added, and the mixture cooled further (0°C) to afford white crystals of **14** (6.24 g, 50%): mp 221–223°C (water) (lit. (17) mp 214–215°C); ir (KBr): 2788 (C-H), 1658 (C=O) cm^{-1}; ^1H nmr (acetone-d_6) δ: 10.03 (s, 1H, H-C=O), 8.60–8.47 (dd, 1H, *J* = 1.3, 7.8 Hz, C(6)Ar-H), 8.39 (br s, 2H, N-CH=C, C(4)Ar-H), 7.39–7.25 (dd, 1H, *J* = 4.7, 7.8 Hz, C(5)Ar-H); ^{13}C nmr (DMSO-d_6) δ: 185.7, 149.5, 145.0, 138.9, 129.3, 118.5, 116.7, 116.6; ms *m/z*: 146 (M^+), 145 ($M^+ - 1$).

*1-(*tert*-Butyloxycarbonyl)-3-formyl-7-azaindole (15)*

3-Formyl-7-azaindole (**14**) (6 g, 0.041 mol) dissolved in dry HMPA (50 mL) was added dropwise to a stirred suspension of sodium hydride (1.23 g, 0.041 mol, 80% dispersion in mineral oil) in HMPA (40 mL) at 21°C. Stirring was continued until a transparent solution was obtained, a solution of di-*tert*-butyl dicarbonate (9.84 g, 0.045 mol, Aldrich) in HMPA (40 mL) added and the reaction stirred for a further 3 h. The reaction was quenched with water (200 mL), ether (200 mL) was added, and the organic layer separated. The aqueous layer was extracted with ether (2 × 200 mL) and the combined organic layers were washed with saturated aqueous $NaHCO_3$ solution (3 × 150 mL), brine, water dried, filtered, and concentrated. Recrystallization of the residue from hexane afforded compound **15** (9.9 g, 98%); mp 13–132°C (hexane); ir ($CHCl_3$): 1763 (N-COO-), 1678 (C=O) cm^{-1}; ^1H nmr δ: 10.04 (s, 1H, H-C=O), 8.64–848 (m, 2H, C(6)Ar-H, C(4)Ar-H), 8.24 (s, 1H, N-CH=C), 7.4–7.25 (m, 1H, C(5)Ar-H), 1.68 (s, 9H, *t*-Bu); ^{13}C nmr δ: 185.4, 148.5, 146.9, 146.8, 136.3, 130.8, 120.3, 119.0, 118.9, 85.9, 27.9. Exact Mass calcd. for $C_{13}H_{14}N_2O_3$: 246.1004; found: 246.1018.

*1-(*tert*-Butyloxycarbonyl)-3-(hydroxymethyl)-7-azaindole (16)*

1-(*tert*-Butyloxycarbonyl)-3-formyl-7-azaindole **15** (8 g, 32.5 mmol) and sodium borohydride (0.308 g, 8.14 mmol) in 95% ethanol (65 mL) were stirred at 21°C for 4 h. The reaction was concentrated and the residual oil triturated with 1.0 N NaOH (98 mL). The alkaline solution was extracted with ether (1 × 200 mL) and ethyl acetate (1 × 200 mL). The combined organic extracts were washed with brine, water, dried, filtered, and concentrated. Chromatography (50% ethyl acetate/hexane) yielded the alcohol **16** (4.85 g, 60%): mp 156–158°C (ethyl acetate); ir ($CHCl_3$): 3620 (-OH), 1752 (C=O) cm^{-1}; ^1H nmr δ: 8.52–8.47 (dd, 1H, *J* = 1.4, 4.8 Hz, C(6)Ar-H), 7.98–7.92 (dd, 1H, *J* = 1.4, 7.5 Hz, C(4)Ar-H), 7.59 (s, 1H, N-CH=C), 7.22–7.14 (dd, 1H, *J* = 4.8, 7.58 Hz, C(5)Ar-H), 4.80 (br s, 2H, CH_2-O), 1.64 (s, 9H, *t*-Bu); ^{13}C nmr δ: 148.3, 147.8, 145.1, 128.0, 123.7, 121.9, 118.3, 117.9, 84.0, 56.9, 28.0; ms *m/z*: 248 (M^+). Anal. calcd. for $C_{13}H_{16}N_2O$: C 62.89, H 6.50, N 11.28; found: C 63.00, H 6.56, N 11.40.

*1-(*tert*-Butyloxycarbonyl)-3-(chloromethyl)-7-azaindole (17)*

1-(*tert*-Butyloxycarbonyl)-3-(hydroxymethyl)-7-azaindole (**16**) (4.5 g, 0.018 mol), triphenylphosphine (4.8 g, 0.018 mol, Aldrich), dry CCl_4 (110 mL), and dry DMF (40 mL) were stirred at room temperature (21°C) for 4.5 days. The solvents were removed with the aid of a vacuum pump (0.5 Torr). Chromatography (50% ethyl acetate/hexane) of the residue afforded the chloride **17** (2.19 g, 45%): mp 87–89°C; ir ($CHCl_3$): 1755 (C=O), 765 (C-Cl) cm^{-1}; ^1H nmr δ: 8.57–8.47 (m, 1H, C(6)Ar-H), 8.02–7.92 (dd, 1H, *J* = 1.6, 7.9 Hz, C(4)Ar-H), 7.65 (s, 1H, N-CH=C), 7.26–7.17 (m, 1H, C(5)Ar-H), 4.71 (s, 2H, CH_2-Cl), 1.63 (s, 9H, *t*-Bu); ^{13}C nmr δ: 148.1, 145.8, 145.7, 127.8, 125.2, 121.4, 118.6, 114.5, 84.4, 37.6, 28.0; ms *m/z* = 266 (M^+), 268 ($M^+ + 2$). Anal. calcd. for $C_{13}H_{15}N_2O_2Cl$: C 58.54, H 5.64, N 10.50, Cl 13.29; found: C 5873, H 5.96, N 1046, Cl 13.46.

*1-(*tert*-Butyloxycarbonyl)-3-(bromomethyl)-7-azaindole (18)*

1-(*tert*-Butyloxycarbonyl)-3-(hydroxymethyl)-7-azaindole (**16**) (0.124 g, 0.5 mmol), triphenylphosphine (0.137 g, 0.52 mmol, Aldrich), and carbon tetrabromide (0.175 g, 0.53 mmol, Aldrich) in dry DMF (2 mL) were stirred at 21°C for 20 h. The solvent was removed with the aid of a vacuum pump (0.5 Torr) and the residue chromatographed on Florisil (methylene chloride/ether) to give the bromo derivative **18** (0.060 g, 39%); mp 79–82°C; ir ($CHCl_3$): 1738 (C=O), 774 (C-Br) cm^{-1}; ^1H nmr δ: 8.61–8.5 (dd, 1H, *J* = 1.6, 4.8 Hz, C(6)Ar-H), 8.10–7.98 (dd, 1H, *J* = 1.6, 7.9 Hz, C(4)Ar-H), 7.69 (s, 1H, N-CH=C), 7.34–7.22 (m, 1H, C(5)Ar-H), 4.61 (s, 2H, CH_2-Br), 1.63 (s, 9H, *t*-Bu); ms *m/z*: 313 ($M^+ + 2$).

*1-(*tert*-Butyloxycarbonyl)-3-(iodomethyl)-7-azaindole (19)*

The chloroderivative **17** (2.10 g, 7.8 mmol) was dissolved in dry acetone (15 mL) and added to a stirred acetone solution (15 mL) of anhydrous NaI (1.2 g, 8 mmol). The reaction was stirred at 21°C for 24 h, and filtered. Concentration of the filtrate yielded the iodo compound **19** (2.7 g, 96%): mp 102–104°C; ir ($CHCl_3$): 1748 (C=O), 760 C-I) cm^{-1}; ^1H nmr δ: 8.54–8.43 (dd, 1H, *J* = 1.5, 4.7 Hz, C(6)Ar-H), 7.99–7.88 (dd, 1H, *J* = 1.6, 7.9 Hz, C(4)Ar-H), 7.70 (s, 1H, N-CH=C), 7.18–7.27 (m, 1H, C(5)Ar-H), 4.48 (s, 2H, CH_2-I), 1.60 (s, 9H, *t*-Bu); ^{13}C nmr δ: 145.8, 128.0, 123.9, 121.6, 118.3, 115.7, 84.4, 83.9, 28.0, 18.5; ms *m/z*: 231 ($M^+ - I$).

General procedure for the alkylation of camphor imine 3

1. LDA alkylation

LDA (1.25 mmol) was prepared at 0°C in dry THF (5 mL) under nitrogen and then cooled to −78°C. Imine **3** (0.265 g, 1 mmol) in THF (2 mL) was added. The solution was stirred at −100° to −78°C for 30 min and then the desired alkylating agent (**9**, **13**, **17**, **18**, or **19**) dissolved in THF, or DMF, or HMPA was added (see Table 1). The reaction was stirred at −100° to −10°C for 2–5 h depending on the entry (Table 1). The reaction was quenched with water (5 mL) and allowed to warm to room temperature. Ether (10 mL) was added and the organic layer separated. The aqueous layer was extracted with ether (3 × 10 mL), the combined organic layers washed with brine, water, dried, filtered, concentrated, and chromatographed (50% ethyl acetate/hexane) to give the product **6** or **7**.

2. $KNSi_2Me_6$ alkylation

Potassium bis(trimethylsilyl)amide in toluene (7.5 mmol) was added to dry THF (15 mL) under nitrogen. The reaction was cooled to −100° to −78°C and the camphor imine **3** (2 g, 7.5 mmol) in

dry THF (40 mL) was added accompanied by HMPA (2–4 equiv.). Stirring was continued for 30 min, then the alkylating agent **19** (1 equiv.) dissolved in dry THF (40 mL) was added. The mixture was allowed to stir for 2.5–3 h (see Table 1), quenched with water (60 mL), allowed to warm to room temperature, and extracted with ether (3 × 80 mL). The combined organic extracts were washed with brine, water, dried, filtered, and concentrated. Chromatography (50% ethyl acetate/hexane) afforded the compound **7**.

Alkylation product ***6****:* mp 155–157°C (ethyl acetate/hexane); ir ($CHCl_3$): 3480 (N-H), 1735 (C=O) cm^{-1}; ^1H nmr δ: 8.9 (b, 1H), 8.28–8.19 (dd, 1H, J = 1.4, 4.7 Hz), 8.02–7.92 (bd, 1H, J = 7.8 Hz), 7.12 (b, s, 1H), 7.08–6.96 (m, 1H), 4.12–3.98 (m, 1H), 3.41–3.06 (m, 2H), 2.27–2.07 (m, 1H), 1.83–1.02 (m, 6H), 1.39 and 1.37 (2s, 9H each 2 isomers), 0.92–0.68 (5s, for camphor CH_3's); ^{13}C nmr δ: 184.9, 171.2, 170.9, 148.6, 142.3, 142.2, 127.7, 123.6, 123.5, 120.4, 115.1, 115.0, 111.4, 111.2, 80.8, 66.2, 65.9, 54.0, 53.8, 46.9, 46.4, 43.6, 43.4, 35.6, 31.9, 31.5, 28.4, 28.0, 27.3, 27.1, 19.4, 18.8, 18.7, 18.4, 11.5, 11.3; ms m/z 395 (M^+).

Alkylation product ***7****:* $[\alpha]_D^{22}$ −0.6 (c=1, $CHCl_3$); ir (neat): 1734 (C=O) cm^{-1}; ^1H nmr δ: 8.48–8.41 (dd, 1H, J = 1.5, 4.8 Hz, C(6)Ar-H), 7.96–7.82 (dd, 1H, J = 1.5, 7.8 Hz, C(4)Ar-H), 7.38 (s, 1H, N-CH=C), 7.19–7.09 (dd, 1H, J = 4.8, 7.8 Hz, C(5)Ar-H), 4.04–3.93 (dd, 1H, J = 4.2, 9.6 Hz, =N-CH-CO), 3.33–3.28 (dd, 1H, J = 4.2, 9.6 Hz, HC-Ar), 3.18–3.01 (dd, 1H, J = 9.6, 12 Hz, HC-Ar), 2.3–1.61 (m, 6H), 1.58 (s, 9H, *t*-BOC), 1.38 (s, 1H, *t*-Bu), 0.93 (s, 3H, Me), 0.80 (s, 3H, Me), 0.69 (s, 3H, Me); ^{13}C nmr δ: 185.5, 170.7, 148.0, 145.0, 127.7, 124.6, 123.3, 118.1, 114.7, 83.6, 81.1, 64.8, 53.9, 47.0, 43.4, 35.8, 31.8, 28.1, 28.0, 27.2, 19.4, 18.8, 11.5; ms m/z 495. Anal. calcd. for $C_{29}H_{41}N_3O_4$: C 70.27, H 8.33, N 8.47; found: C 70.14, H 8.23, N 8.27.

A typical diastereomeric mixture displayed camphor methyl signals major (minor) as follows: 0.95(0.92), 0.82(0.79), 0.71(shoulder). The chemical shifts varied slightly with the mixture due to the anisotropic nature of the heterocyclic ring system.

Hydrolysis of ***7*** *to give* tert*-butyl α-amino-β-(1-*tert*-butyloxycarbonyl-7-azaindolyl)propionate (****20****)*

Hydroxylamine hydrochloride (0.12 g, 1.72 mmol), sodium acetate (0.14 g, 1.7 mmol), and **7** (0.85 g, 1.7 mmol) were added to 95% ethanol (8 mL) and stirred for 3 days at 21°C. The solvent was evaporated with the aid of a vacuum pump (0.5 Torr) and the residue triturated with THF (25 mL) and filtered. The filtrate was concentrated and chromatographed (ethyl acetate) to give the α-amino-β-(1-*tert*-butyloxycarbonyl-7-azaindole)propionic acid *tert*-butylester (**20**) (0.423 g, 69%) as a yellow viscous oil: $[\alpha]_D^{22}$ −0.8 (c = 1.24, $CHCl_3$); ir (neat): 3392 (-NH), 1736 (C=O) cm^{-1}; ^1H nmr δ: 8.53–8.42 (dd, 1H, J = 1.6, 4.8 Hz, C(6)Ar-H), 7.92–7.84 (dd, 1H, J = 1.6, 7.8 Hz, C(4)Ar-H), 7.44 (s, 1H, N-CH=C), 7.20–7.10, (dd, 1H, J = 4.8, 7.8 Hz, C(5)Ar-H), 3.71–3.59 (m, 1H, HC-CO_2), 3.16–3.0 (dd, 1H, J = 6, 14 Hz, HC-Ar), 3.0–2.82 (dd, 1H, J = 8, 14 Hz, HC-Ar), 1.8–1.61 (br s, 2H, NH_2), 1.60 (s, 9H, *t*-BOC), 1.36 (s, 9H, CO_2*t*-Bu); ^{13}C nmr δ: 174.1, 148.4, 147.6, 145.2, 127.6, 124.4, 123.2, 118.2, 113.7, 83.9, 81.4, 55.1, 30.4, 28.0, 27.9; ms m/z: 361 (M^+). Anal. calcd. for $C_{19}H_{27}N_3O_4$: C 63.14, H 7.53, N 11.63; found: C 62.44, H 7.65, N 11.35.

Hydrolysis and deprotection of ***20*** *: (−)-(R)-7-azatryptophan (****2****)*

The amino ester **20** (0.210 g, 0.582 mmol) was dissolved in trifluoroacetic acid (1.33 g, 0.9 mL, 11.68 mmol) and allowed to stir at 21°C for 2 h. Evaporation of the mixture with the aid of a vacuum pump (0.5 Torr) and addition of ammonium hydroxide afforded, after cooling and recrystallization from water, (−)-(*R*)-7-azatryptophan (**2**) (0.082 g, 69%): mp 260-–261°C (dec.); $[\alpha]_D^{22}$ −1.2 (c = 0.5, H_2O); ir (KBr): 3427–2338 (superimposed -OH and NH_3^+ stretching bands), 1627, 1584, 1418 (-COO^--) cm^{-1}; ^1H nmr (DMSO-d_6:D_2O) δ: 8.2–8.0 (m, 2H), 7.28 (br s, 1H), 7.19–7.10 (m, 1H), 3.85–3.73 (m, 1H), 3.40–3.10 (m, 2H). Exact Mass calcd. for $C_{10}H_{11}N_3O_2$: 205.0855; found: 205.0865.

An enantiospecific route to C,D ring synthons for steroid synthesis

J. Andrew Clase and Thomas Money[1]

Chemistry Department, University of British Columbia, Vancouver, B.C., Canada V6T 1Z1

Received July 9, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

J. Andrew Clase and Thomas Money. Can. J. Chem. **70**, 1537 (1992).

A simple enantiospecific route to a hydrindenone intermediate for steroid synthesis has been accomplished. The introduction of a wide variety of side-chain units is made possible by stereoselective alkylation of a bicyclic ester **13** derived from (+)-camphor **4**.

J. Andrew Clase et Thomas Money. Can. J. Chem. **70**, 1537 (1992).

On a réalisé une synthèse énantiospécifique simple d'un intermédiaire hydrindénone nécessaire dans la synthèse de stéroïdes. L'introduction d'une grande variété de chaines latérales est rendue possible par l'alkylation stéréosélective de l'ester bicyclique **13** obtenu à partir du (+)-camphre (**4**).

The recent resurgence of interest in steroid synthesis (1) is due, in part, to the important role of 1α,25-dihydroxycholecalciferol **1** and other metabolites of vitamin D_3 in calcium homeostasis (2*a–e*) and in the regulation of cell differentiation and proliferation (2*f–k*). The important biological activity of a variety of steroids with structurally diverse side chains (insect moulting hormones, plant growth-promoting steroids, anti-tumor steroids, marine steroids, etc.) has also provided a stimulus for synthetic efforts in this area. Most of the published synthetic effort (3) has concentrated on the development of imaginative new ways of synthesizing hydrindanone and hydrindenone derivatives (cf. **2** and **3**) that may be regarded as synthetic precursors of the C,D ring system and side-chain unit in steroids.

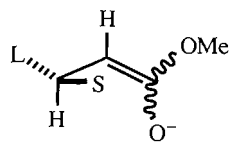
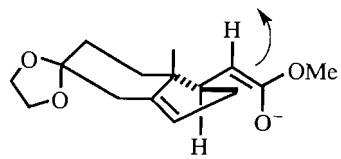
3

Our research objective was to develop a convenient, simple route from camphor to a suitably functionalized hydrindenone that could be used as an intermediate in the synthesis of steroids and triterpenoids. It is important to note that the late Professor R. V. Stevens and his co-workers previously established that the C,D ring system of steroids could be synthesized by ring cleavage of functionalized C(9) camphor derivatives (3*a*,*b*). The initial stages of our synthetic route (Scheme 1) are based on our previous investigations, which established that (+)-9,10-dibromocamphor **5**, readily derived (4, 5) from (+)-camphor **4**, undergoes efficient ring cleavage (5) with base to provide hydroxy-acid **6** in 88% yield. The potential of this compound as a ring D synthon in steroid synthesis is obvious and, indeed, hydroxy-acid **6** was used as an intermediate in a recent synthesis of estrone (6).

For the present purpose, hydroxy-acid **6** was converted to unsaturated diester **9**, which was then reduced with Mg/MeOH (7) to provide diester **10** in ~80% overall yield. Cyclization of the corresponding diacid **11** with trifluoroacetic anhydride (8) followed by methanol work-up produced hydrindenone ester **12** in ~80% yield. The chiral centres at C(13) and C(17) (steroid numbering) in ester **12** originate from the C(7) and C(4) positions in (+)-9,10-dibromocamphor **5** and have the same absolute configuration as the corresponding centres in the steroid target compounds. The remaining objective was the stereoselective introduction of a side-chain unit into the C(20) position (steroid numbering) of ester **12** and creation of the correct 20*R* stereochemistry. Literature reports have shown that acyclic (9), monocyclic (10), bicyclic (11), and steroidal esters (12) undergo stereoselective alkylation when the ester group is flanked by a chiral centre containing hydrogen and two groups with significantly different steric effects. In general, the diastereoselective alkylation of esters of this type has been explained by postulating approach of the electrophile from the less hindered face of the ester enolate ion (*anti* to largest



13*a*



13*b*

group) in a conformation represented by **13***a* or, in the particular case of ketal-ester **13**, by conformation **13***b*. Evans described (13) this π-facial stereoselectivity as "stereorational extraannular chirality transfer" and theoretical explanations for this general phenomenon have been proposed (14–16). By analogy with the literature examples cited above, we expected that alkylation of ketal-ester **13** would be almost completely stereoselective (cf. **13***b*) and subsequent experiments confirmed this prediction. Thus alkylation of ketal-ester **13** with 5-iodo-2-methylpent-2-ene followed by reduction with $LiAlH_4$ provided hydroxy-ketal **15** in ~85% yield. The relative configuration of the C(20) position in hydroxy-ketal

SCHEME 1

15 was established by X-ray crystallographic analysis[2] and its diastereomeric purity was estimated to be ~100% by glc and by examination of the ^1H NMR (400 MHz) spectrum of the corresponding Mosher (17) ester **16**. However, the ^{19}F NMR (282 MHz) spectrum of **16** did exhibit a small peak at 4.896 ppm adjacent to the major signal at 4.936 ppm, suggesting that a small amount (~3–5%) of the 20*S* stereoisomer was formed during the alkylation of ketal-ester **13**. Finally, conversion of hydroxy-ketal **15** to the corresponding mesylate, followed by reduction with lithium triethylborohydride (18) and subsequent acid hydrolysis, provided the required hydrindenone **18** in 85% yield.

The synthetic route described above (Scheme 1) can provide intermediates (cf. **18**) with the correct absolute configuration at C(13), C(17), and C(20) (steroid numbering) and in which the nature of the steroidal side-chain unit is predetermined by the choice of an appropriate electrophilic reagent in the alkylation of ketal-ester **13**. The conversion of simple derivatives of **12** to steroids and triterpenoids may be possible by the application of literature methods (3*i*, 19–21) and this is the objective of current investigations in our laboratory.

Experimental

All reagents used were of commercial grade and were not purified unless otherwise specified. (+)-*endo*-3-Bromocamphor was purchased from Aldrich Chemical Co. Dry solvents and reagents were obtained as follows: diethyl ether (Et_2O) was distilled from lithium aluminum hydride ($LiAlH_4$); tetrahydrofuran(THF) was distilled from Na/benzophenone; benzene (C_6H_6), toluene, and dichloromethane (CH_2Cl_2) were distilled from calcium hydride; methanol (MeOH) was distilled from Mg turnings in the presence of I_2; triethylamine (Et_3N) and pyridine were distilled from KOH; and dimethyl sulphoxide (DMSO) and hexamethyl phosphoramide (HMPA) were stored over 4Å molecular sieves. Low-boiling petroleum ether (PE, bp 30–60°C) was distilled prior to use in chromatography.

All reactions involving air- or moisture-sensitive reagents were performed in flame- or oven-dried glassware under an atmosphere of argon. Where not specified, reactions were performed at room temperature (rt). Unless otherwise specified, all aqueous solutions of salts used in work-up were saturated.

Thin-layer chromatography (TLC) was performed on Merck 5735 Precoated Silica Gel 60, PF_{254} on plastic sheets, visualizing the plates with either I_2 (g) or an ammonium molybdate/H_2SO_4 spray. Gas–liquid chromatography (GC) was performed on a Hewlett–Packard HP5830A instrument, using a 0.2 mm × 11 m column of OV-101, with He as the carrier gas. Column chromatography was performed on Merck Silica Gel 60, of either 70–230 or 230–400 mesh, column dimensions are given as diameter × height. Radial

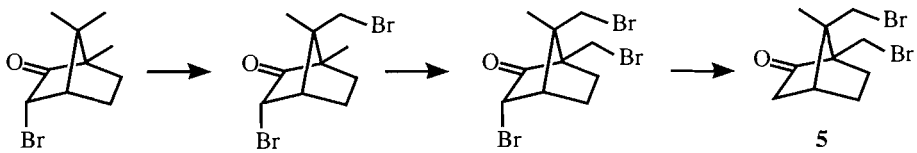
chromatography was performed under an atmosphere of argon on a Harrison Research Chromatotron® 7924T, using plates of Merck Silica Gel 60, PF_{254}, containing gypsum, of 1, 2, or 4 mm thickness and 4.0–11.25 cm radius.

Infrared (IR) spectra were recorded on a Perkin–Elmer 710B scanning spectrophotometer, either as neat films between NaCl plates or as solutions in NaCl cells of 0.1-mm path length. Proton nuclear magnetic resonance (^{1}H NMR) spectra were recorded at 300 MHz on a Varian XL-300 spectrometer, and at 400 MHz on a Bruker WH-400 spectrometer, with signal positions referenced to tetramethylsilane (TMS). ^{13}C NMR spectra were recorded at 75 MHz on a Varian XL-300 spectrometer, with signal positions referenced to TMS. ^{19}F NMR spectra were recorded at 282 MHz on a Varian XL-300 spectrometer, with signal positions referenced to trifluoroacetic acid. Low-resolution mass spectra (MS) were recorded on a Kratos MS-80 spectrometer and high-resolution mass spectra were recorded on a Kratos MS-50 spectrometer. Specific rotations ([α]) were recorded on a Perkin–Elmer 141 polarimeter, in a 1-dm cell at ambient temperature, using the sodium D line (589 nm); all compounds for which specific rotations were recorded were analytically pure and exhibited single spots on TLC and single peaks on GC. Melting points (mp) were measured on a Reichert heating stage, and are uncorrected. Boiling points (bp) were determined either as the temperature at the still head for those samples which were distilled in bulk, or as the temperature of the oil bath, when small-scale distillation was performed. Elemental analyses were performed by Mr. P. Borda, Microanalytical Laboratory, Department of Chemistry, U.B.C.; all compounds submitted for elemental analysis exhibited a single spot by TLC and a single peak by GC, with the exception of those consisting of diastereomeric mixtures. X-ray structural determinations were performed by Dr. S. Rettig, U.B.C.

(+)-9,10-Dibromocamphor (**5**)

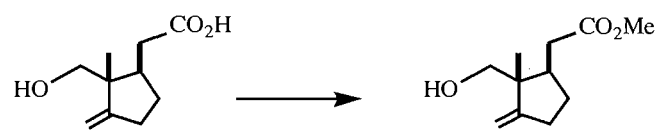


5

A solution of bromine (35 mL, 110 g, 0.68 mol) in chlorosulphonic acid (80 mL) was added cautiously to a cooled flask containing (+)-*endo*-3-bromocamphor (100 g, 0.43 mol) and after 5 min the ice bath was removed. The reaction was then stirred at room temperature for 1.5 h before being quenched by carefully pouring the solution into a slurry of $NaHSO_3$ (25 g) and ice (250 g). The mixture was allowed to stand with occasional stirring, until the orange colour of bromine had faded. The aqueous solution was decanted and the residual off-white solid triturated with water (5 × 250 mL), collected by suction filtration, and washed further with $NaHCO_3$ (aq) (2 × 50 mL) and water (50 mL). The wet solid was dissolved in CH_2Cl_2 (500 mL), the water separated, and the solution dried over $MgSO_4$. Methanol (75 mL) was added and the solvents removed by rotary evaporation until the first crystals appeared. The solution was then cooled and allowed to crystallize, affording (+)-*endo*-3,9-dibromocamphor as a white crystalline solid; yield: 80.0 g, 60%. The mother liquor was concentrated and a second crop of pale yellow crystals (21 g) was obtained; total yield: 101 g, 72%; mp 157–159°C (lit.(19) mp 157–159°C); [α]^{23} 91(*c* 0.43, $CHCl_3$) (lit.(22) [α]^{19} 100(*c* 1, $CHCl_3$)). IR ($CHCl_3$)*ν*: 2980, 2895 (C-H); 1755 (C=O) cm^{-1}. ^{1}H NMR ($CDCl_3$)δ: 1.02 (3H, s, C(10)H_3), 1.10 (3H, s, C(8)H_3), 1.48–1.57 (1H, ddd, *J* = 16, 7, 5 Hz, C(6) *endo* H), 1.73 (1H, ddd, *J* = 16, 12, 4 Hz, C(5) *endo* H), 1.84–1.94 (1H, m, C(5) *exo* H), 2.19 (1H, ddd, *J* = 16, 10, 4 Hz, C(6) *exo* H), 2.70 (1H, t, *J* = 4 Hz, C(4)H), 3.29, 3.65 (2H, q_{AB}, *J* = 11 Hz, C(9)H_2Br), 4.57 (1H, dd, *J* = 4, 1 Hz, C(3)H). MS (70 eV) *m/z* (%): 312, 310, 308 (M^+, 4.6, 9.5, 5.4); 231, 229 (25.9, 27.1); 203, 201 (29.6, 32.1); 81 (100). Mass calcd. for $C_{10}H_{14}Br_2O$: 311.9371, 309.9391, 307.9411; measured: 311.9381, 309.9387, 307.9433. (+)-3,9-Dibromocamphor (105 g, 0.34 mol) was placed in a 500 mL flask equipped with a stir bar, and cooled in an ice bath. A solution of bromine (26 mL, 81 g, 0.51 mol) in chlorosulphonic acid (100 mL) was added cautiously. After sitrring at 0°C for 15 min the ice bath was removed and stirring was continued with bromine (10 mL) and chlorosulphonic acid (10 mL) being added after 3 days and again after 6 days. After 8 days, the reaction was quenched by cautiously pouring into a slurry of $NaHSO_3$ (50 g) and ice (500 g). The mixture was extracted with $CHCl_3$ (2 × 250 mL), and the combined organic solvents were washed with water (100 mL) and $NaHCO_3$ (3 × 100 mL, until the washings were basic), and dried over $MgSO_4$. Evaporation of the solvents yielded crude (+)-3,9,10-tribromocamphor (124 g, 70% pure by GC) as an orange viscous oil, which was used without further purification.

A solution of crude 3,9,10-tribromocamphor in 1:1 Et_2O:AcOH (500 mL) was cooled in an ice bath and stirred with an overhead mechanical stirrer. Zinc (50 g, 0.76 mol) was added in portions over 90 min, maintaining the temperature below 20°C. Following the addition the mixture was stirred for a further 3 h, after which Celite (5 g) was added and the mixture filtered. The solution was washed with 50% brine (200 mL), water (2 × 100 mL), $NaHCO_3$ (6 × 100 mL, until the washings were basic), and brine (100 mL), and dried over $MgSO_4$. The solvent was evaporated to provide an orange solid, which was triturated with methanol to give yellow crystals. Recrystallization from methanol provided (+)-9,10-dibromocamphor (**5**) as a white crystalline solid; yield: 55 g, 52% over two steps; mp 97–8°C (lit.(4) mp 98–100°C); [α]^{22} 67(*c* 1.1, $CHCl_3$)(lit.(4)[α]^{20} 68(*c* = 2, MeOH))). IR($CHCl_3$)*ν*: 2975, 2900 (C-H); 1740 (C=O) cm^{-1}. ^{1}H NMR ($CDCl_3$)δ: 1.10(3H, s, C(8)H_3), 1.43–1.58(2H, m, C(5) and C(6) *endo* H), 1.98 (1H, d_{AB}, *J* = 18 Hz, C(3) *endo* H), 2.05(1H, ddd_{AB}, J_{AB} = 18 Hz, *J* = 5, 4 Hz, C(3) *exo* H), 2.25–2.35 (1H, m, C(6) *exo* H), 2.41(1H, dt, *J* = 19, 4 Hz, C(5) *exo* H), 2.60 (1H, t, *J* = 5 Hz, C(4)H), 3.48 and 3.59 (1H each), 3.70 (2H) ($3d_{AB}$, *J* = 12 Hz, C(9)H_2Br and C(10)H_2Br). MS (70 eV) *m/z* (%): 312, 310, 308 (M^+, 0.5, 0.9, 0.4); 231, 229 (33.1, 33.4); 203, 201 (1.5, 1.3); 107 (100). Mass calcd. for $C_{10}H_{14}Br_2O$: 311.9371, 309.9391, 307.9411; measured: 311.9377, 309.9396, 307.9449.

Hydroxy-ester **7**



6 **7**

Hydroxy-acid **6** (5) (2.33 g, 12.6 mmol) was dissolved in dry DMF (35 mL) and anhydrous K_2CO_3 (3.50 g, 25.3 mmol) was added. The suspension was stirred under Ar for 1.5 h, after which CH_3I (1.6 mL, 3.6 g, 25 mmol) was added by syringe, and stirring continued in the dark for 3 h. The mixture was poured into brine (50 mL), extracted with Et_2O (3 × 30 mL), and the combined extracts were washed with brine (30 mL) and water (30 mL), and dried over $MgSO_4$. The solvents were evaporated to

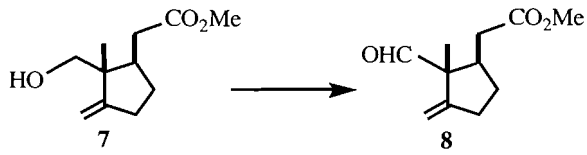
provide a yellow oil, which was purified by column chromatography (15 × 3.5 cm, 230–400 mesh silica gel), eluting with 4:1 PE-Et_2O to provide hydroxy-ester **7** as a pale yellow oil; yield: 2.42 g, 96%; bp 102°C/0.05 Torr (1 Torr = 133.3 Pa); $[\alpha]^{24}$ −25.1 (*c* 1.66, $CHCl_3$). IR (neat)ν: 3450 (O-H); 3090 (vinyl C-H); 2950, 2880 (C-H); 1730 (C=O); 1655 (C=CH_2); 885 (vinyl C-H) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 0.87 (3H, s, CH_3), 1.31–1.43 (1H, m), 1.79 (1H, br s, -OH), 1.90–1.99 (1H, m), 2.21 (1H, dd, J = 17, 11 Hz), 2.28–2.40 (1H, m), 2.42–2.55 (3H, m), 3.41, 3.54 (2H, br q_{AB}, J = 12 Hz, -CH_2O), 3.70 (3H, s, -CO_2CH_3), 4.83 and 5.02 (1H each, 2 t, J = 2 Hz, 2 Hz, =CH_2). MS (70 eV) *m/z* (%): 198 (M^+, 0.2), 180 (0.7), 168 (25.1), 167 (20.0), 135 (12.2), 107 (100), 94 (99.1). Anal. calcd. for $C_{11}H_{18}O_3$: C 66.64, H 9.15%; found: C 66.45, H 9.15%.

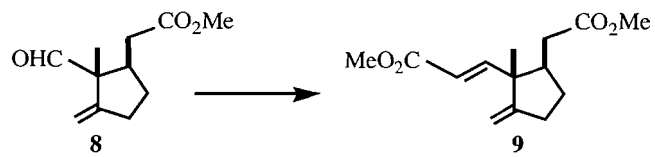
Aldehyde-ester **8**



7 **8**

A solution of oxalyl chloride (2.64 mL, 3.85 g, 30.3 mmol) in dry CH_2Cl_2 was cooled under Ar to −78°C. A solution of DMSO (2.15 mL, 2.37 g, 30.3 mmol) in dry CH_2Cl_2(20 mL) was added dropwise over 20 min, keeping the temperature below −60°C. After stirring an additional 15 min, a solution of hydroxy-ester **7** (5.00 g, 25.2 mmol) in dry CH_2Cl_2(40 mL) was added over 20 min, again keeping the temperature below −60 °C. Following the addition, the solution was stirred for 1.5 h, after which triethylamine (10.5 mL, 7.65 g, 75.6 mmol) was added and the temperature was allowed to increase to rt overnight. Water (50 mL) was added, the layers were separated, and the aqueous phase was extracted with CH_2Cl_2(25 mL). The combined organics were washed with 1 N HCl (2 × 25 mL), $NaHCO_3$(25 mL), and brine (25 mL), and dried over $MgSO_4$. Evaporation of the solvent afforded a pale orange oil, which was purified by column chromatography (70–230 mesh SiO_2, 4.5 × 15 cm), eluting with 5:1 PE:Et_2O to provide the aldehyde-ester **8** as a pale yellow mobile liquid; yield: 4.68 g, 95%; bp 75°C (0.1 Torr); $[\alpha]^{24}$ −47.4 (*c* 2.07, $CHCl_3$). IR (neat)ν: 3090 (=C-H); 2960, 2895, 2850 (C-H); 2820, 2725 (-CO-H); 1740 (C=O, ester); 1710 (C=O, aldehyde); 1650 (C=C); 895 (=CH_2) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 1.05 (3H, s, CH_3), 1.51 (1H, qd, J = 12, 8.5 Hz), 1.98–2.06 (1H, m), 2.34 (2H, dd, J = 7, 1.5 Hz, -CH_2CO_2Me), 2.38–2.47 (1H, m), 2.52 (1H, d_{AB}dq, J = 17, 8.5, 2 Hz), 2.77 (1H, dq, J = 12, 7 Hz), 3.67 (3H, s, -OCH_3), 4.78 and 5.12 (1H each, 2 t, J = 2 Hz, 2Hz, =CH_2), 9.30 (1H, s, -CHO). MS (70 eV) *m/z* (%): 182 (M^+, 10.5), 168 (12.6), 167 (24.5), 166 (11.8), 165 (17.4), 123 (19.9), 107 (100.0). Anal. calcd. for $C_{11}H_{16}O_3$: C 67.32, H 8.22%; found: C 67.21, H 8.36%.

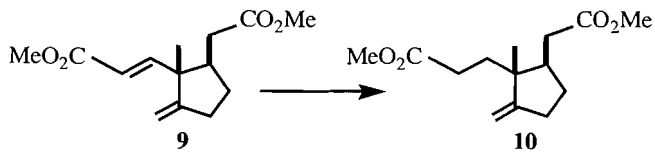
Unsaturated diester **9**



8 **9**

A suspension of NaH (1.35 g, 56.0 mmol) in dry THF (100 mL) was stirred under argon, and a solution of trimethyl phosphonoacetate (10.2 g, 56.0 mmol) in dry THF (50 mL) was added dropwise over 15 min, forming a thick white suspension. This was stirred an additional 1 h before a solution of the aldehyde-ester **9** (9.16 g, 46.7 mmol) in dry THF (100 mL) was added dropwise over 30 min. The mixture was stirred overnight, after which water (100 mL) and Et_2O (100 mL) were added. The layers were separated and the organic phase was washed with brine (2 × 50 mL). The combined aqueous phases were extracted with Et_2O (2 × 40 mL) and the combined organic solvents were dried over $MgSO_4$. Evaporation of the solvents produced a yellow oil, which was purified by column chromatography (70–230 mesh SiO_2, 6.5 × 12 cm), eluting with 5:1 PE:Et_2O, to afford unsaturated diester **9** as a pale yellow, mobile liquid; yield: 10.2 g, 86%. IR (neat)ν: 3090 (=C-H); 2960, 2925, 2855 (C-H); 1735 (C=O, saturated); 1720 (C=O, unsaturated); 1650 (C=C); 890 (=CH_2) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 1.02 (3H, s, CH_3), 1.43–1.53 (1H, m), 1.97–2.05 (1H, m), 2.11–2.20 (1H, m), 2.28–2.39 (2H, m), 2.40–2.48 (1H, m), 2.50–2.58 (1H, m), 3.65 and 3.75 (3H each, 2 s, 2 × -OCH_3), 4.70 and 4.93 (1H each, 2 t, J = 2.5 Hz, 2.5 Hz, =CH_2), 5.85 (1H, d, J = 16 Hz, -C(O)C*H*=CH-), 6.88 (1H, d, J = 16 Hz, -C(O)CH=C*H*-). MS (70 eV) *m/z* (%): 252 (M^+, 10.6), 232 (1.7), 221 (23.6), 220 (72.6), 205 (8.4), 192 (26.8), 119 (100.0). Anal. calcd. for $C_{14}H_{20}O_4$: C 66.65, H 7.99%; found: C 66.76, H 7.90%.

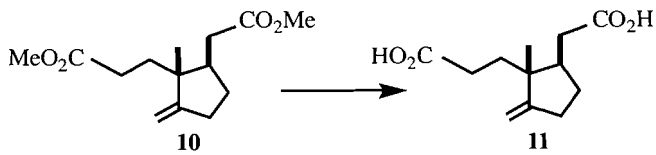
Diester **10**



9 **10**

A solution of unsaturated ester **9** (10.2 g, 40.4 mmol) in dry MeOH (300 mL) was cooled to 0°C and Mg (2.95 g, 120 mmol) was added in one portion. The suspension was stirred at 0°C for 2 h and at rt for a further 2 h before water (100 mL) was added. Just enough 6 N HCl was added to dissolve the solids and the mixture was diluted further with water (300 mL), extracted with 1:1 PE:Et_2O (4 × 200 mL), and the combined extracts were washed with $NaHCO_3$ (50 mL) and brine (50 mL), and dried over $MgSO_4$. The solvents were evaporated to provide the saturated diester **10** as a pale yellow oil, which was used without further purification; yield: 10.1 g, 98%; bp 140°C (0.1 Torr); $[\alpha]^{21}$ −29.8 (*c* 0.752, $CHCl_3$). IR (neat)ν: 3090 (=C-H); 2955, 2880, 2850 (C-H); 1740 (C=O); 1650 (C=C); 885 (=CH_2) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 0.89 (3H, s, CH_3), 1.27–1.37 (1H, m), 1.70–1.85 (2H, m), 1.86–1.94 (1H, m), 2.10–2.18 (2H, m), 2.22–2.34 (3H, m), 2.36–2.47 (2H, m), 3.66 and 3.68 (3H each, 2 s, 2 × -OCH_3), 4.73 and 4.93 (1H each, 2 t, J = 2 Hz, 2 Hz, =CH_2). MS (70 eV) *m/z* (%): 254 (M^+, 3.2), 224 (11.4), 223 (51.3), 222 (56.3), 220 (10.8), 207 (15.5), 180 (65.2), 107 (100.0). Anal. calcd. for $C_{14}H_{22}O_4$: C 66.12, H 8.72%; C 66.11, H 8.65%.

Diacid **11**



10 **11**

A solution of KOH (11.4 g, 0.20 mol) in water (200 mL) was added to a stirred solution of the diester **10** (10.1 g, 39.7 mmol) in MeOH (200 mL). After stirring for 2 h the solution was acidified to pH 2 with 6 N HCl and immediately extracted with EtOAc (4 × 100 mL). The combined extracts were washed with brine (2 × 50 mL) and dried over $MgSO_4$. Evaporation of the solvent provided an off-white solid, which was recrystallized from hexane/EtOAc to afford diacid **11** as white crystals; yield: 7.08 g, 77%; mp 90–91°C; $[\alpha]^{23}$ −58.7 (*c* 1.54, $CHCl_3$). IR ($CHCl_3$)ν: 3450–2300 (broad, -COOH); 2960, 2945 (C-H); 1710 (C=O); 1655 (C=C); 885 (=CH_2) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 0.89 (3H, s, CH_3), 1.30–1.42 (1H, m), 1.85 and 1.91 (2H, q_{AB}t, J = 14, 7.5 Hz, -$CH_2CH_2CO_2H$), 2.00–2.10 (2H, m), 2.13–2.20 (1H, m), 2.24–2.38 (3H, m), 2.43–2.55 (2H, m), 4.72 and 4.93 (1H each, 2 t, J = 2.5 Hz, 2 Hz, =CH_2), 11.20–12.50 (2H, broad, 2 × -COOH). MS (70 eV) *m/z* (%): 208 ($M^+ - H_2O$, 23.0), 190 (6.7), 180 (5.7), 166 (50.7), 153 (100.0). Anal. calcd. for $C_{12}H_{18}O_4$: C 63.70, H

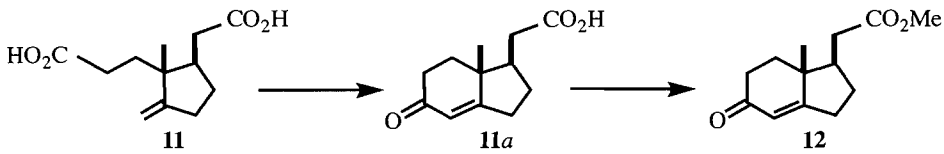
8.02%; found: C 63.66, H 7.89%. Mass calcd.: 226.1205; measured: 226.1205.

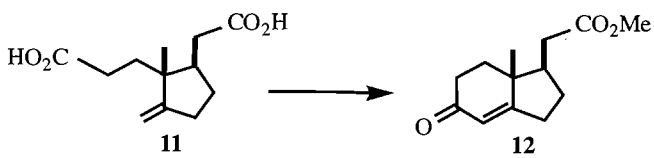
Bicyclic enone-ester **12***: Method A*

A solution of diacid **11** (285 mg, 1.26 mmol) in dry CH_2Cl_2 (25 mL) was stirred under Ar, and trifluoroacetic anhydride (0.54 mL, 790 mg, 3.8 mmol) was added by syringe. The solution was stirred for 1 h before the CH_2Cl_2 was removed and replaced with MeOH (20 mL). Saturated $NaHCO_3$ (5 mL) was added and the solution was stirred for 1 h, after which it was diluted with water (30 mL), and acidified to pH 2 with 6 N HCl. The mixture was extracted with EtOAc (3 × 20 mL) and the combined extracts were washed with water (20 mL) and brine (20 mL), and dried over $MgSO_4$. Evaporation of the solvent provided a viscous yellow oil, which was purified by column chromatography (60–100 mesh Florisil, 1 × 15 cm), eluting with 1:2 PE:Et_2O, to provide the bicyclic enone-acid **11***a* as a pale yellow oil; yield: 148 mg, 56%. IR (neat)ν: 3700–2300 (broad, -COOH); 2980, 2900 (C-H); 1720 (C=O, acid); 1660 (C=O, enone) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 1.06 (3H, s, CH_3), 1.50–1.67 (1H, m), 1.83 (1H, d_{AB}dd, J = 15, 14, 5 Hz), 2.02 (1H, d_{AB}dd, J = 15, 6, 2 Hz), 2.07–2.20 (2H, m), 2.29–2.36 (1H, m), 2.37–2.44 (1H, m), 2.47–2.61 (3H, m), 2.71 (1H, d_{AB}dt, J = 20, 11, 2 Hz), 5.81 (1H, broad s, =C-H). MS (70 eV) m/z (%): 208 (M^+, 21.1), 190 (11.1), 180 (11.3), 166, (15.0), 149 (20.9), 148 (24.7), 121 (100.0). Mass calcd. for $C_{12}H_{16}O_3$: 208.1099; measured: 208.1100.



The bicyclic enone-acid **11***a* (203 mg, 0.97 mmol) was dissolved in dry DMF (5 mL) and K_2CO_3 (210 mg, 1.5 mmol) was added. The suspension was stirred vigorously for 1.5 h, after which CH_3I (0.093 mL, 210 mg, 1.5 mmol) was added by syringe, and stirring was continued overnight in the dark. The mixture was diluted with Et_2O (30 mL) and washed with water (3 × 5 mL). The washings were extracted with Et_2O (5 mL) and the combined Et_2O was washed with 10% $Na_2S_2O_3$ (5 mL) and dried over $MgSO_4$. Evaporation of the solvent provided an orange oil, which was purified by radial chromatography (1 mm plate), eluting with 1:1 PE:Et_2O, to afford the ester **12** as a pale yellow oil; yield: 144 mg, 66%; bp 110°C (0.1 Torr); $[\alpha]^{24}$ 85.7 (*c* 0.62, $CHCl_3$). IR (neat)ν: 2950 (C-H); 1740 (C=O, ester); 1660 (C=O, enone) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 1.05 (3H, s, CH_3), 1.54–1.66 (1H, m), 1.80 (1H, d_{AB}dd, J = 15, 14, 5 Hz), 1.97 (1H, d_{AB}dd, J = 15, 6, 2 Hz), 2.05–2.14 (2H, m), 2.30 (1H, d_{AB}d, J = 15, 9 Hz), 2.39 (1H, d_{AB}dd, J = 18, 5, 2 Hz), 2.44–2.57 (3H, m), 2.68 (1H, d_{AB}dt, J = 20, 11, 2 Hz), 3.71 (3H, s, -OCH_3), 5.80 (1H, s, =C-H). MS (70 eV) m/z (%): 222 (M^+, 33.6), 207 (15.4), 194 (22.4), 191 (21.8), 180 (43.2), 121 (100.0). Anal. calcd. for $C_{13}H_{18}O_3$: C 70.24, H 8.16%; found: C 69.98, H 8.00%. Mass calcd.: 222.1256; measured: 222.1260.

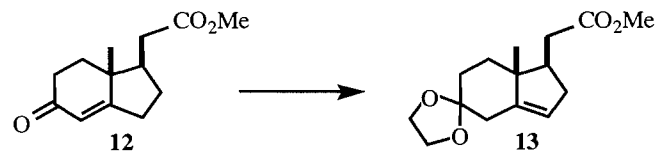
Bicyclic enone-ester **12***: Method B*



Trifluoroacetic anhydride (8.60 mL, 12.8 g, 60.8 mmol) was added by syringe to a solution of diacid **11** (5.50 g, 24.3 mmol) in dry CH_2Cl_2 (350 mL) and the solution was stirred under Ar for 1.25 h. The solvent was removed and replaced with dry MeOH (100 mL), and TsOH (460 mg, 2.4 mmol) was added. The solution was stirred overnight before the MeOH was evaporated and the orange-brown residue was partitioned between water (100 mL) and EtOAc (50 mL). The layers were separated and the aqueous phase was extracted with EtOAc (2 × 50 mL). The combined organic solvents were washed with brine (50 mL) and dried over $MgSO_4$. Evaporation of the solvents provided a viscous, orange oil, which was purified by column chromatography (70–230 mesh SiO_2, 4.5 × 16 cm), eluting with 2:3 PE:Et_2O to afford the bicyclic enone-ester **12** as a pale yellow mobile oil; yield: 4.42 g, 82%. The spectral characteristics of this compound were identical to those described above.

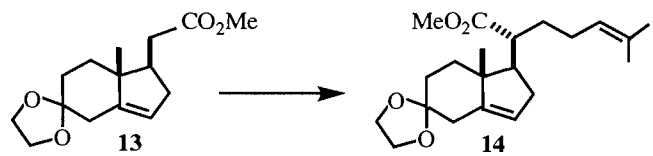
Further elution provided a small quantity (300 mg) of the corresponding bicyclic enone-acid **11***a* as a viscous, pale yellow oil.

Ketal-ester **13**



A solution of ethylene glycol (1.70 mL, 1.86 g, 30 mmol) and PPTS[79] (120 mg, 0.46 mmol) in dry C_6H_6 (50 mL) was refluxed in a Dean–Stark apparatus for 30 min. After cooling briefly, a solution of enone-ester **12** (684 mg, 3.08 mmol) in dry C_6H_6 (10 mL) was added and the mixture was heated again to reflux, overnight. The solution was cooled, poured into brine (100 mL), and the layers were separated. The aqueous phase was extracted with Et_2O (2 × 25 mL) and the combined organic solvents were dried over $MgSO_4$. After evaporation of the solvents, the resultant orange oil was purified by column chromatography (70–230 mesh SiO_2, 2 × 7 cm), eluting with 3:1 PE:Et_2O to afford ketal **13** as a pale yellow, mobile liquid; yield: 615 mg, 75%; $[\alpha]^{25}$ 16.6 (*c* 1.16, $CHCl_3$). IR (neat)ν: 3050 (=C-H); 2960, 2900, 2860 (C-H); 1740 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 0.92 (3H, s, CH_3), 1.51–1.59 (1H, m), 1.65–1.74 (2H, m), 1.79–1.88 (1H, m), 1.99–2.07 (1H, m), 2.32–2.52 (6H, m), 3.67 (3H, s, -OCH_3), 3.93–4.00 (4H, m, -$O(CH_2)_2O$-), 5.33 (1H, s, =C-H). MS (70 eV) m/z (%): 266 (M^+, 2.1), 235 (1.2), 99 (100.0). Anal. calcd. for $C_{15}H_{22}O_4$: C 67.65, H 8.33%; found: C 67.47, H 8.30%. Mass calcd.: 266.1518; measured: 266.1522.

Ketal-ester **14**



A solution of diisopropylamine (0.30 mL, 210 mg, 2.1 mmol) in dry THF (10 mL) was cooled under argon to 0°C and "BuLi (1.6 M/hexane, 1.2 mL, 2.0 mmol) was added by syringe. After stirring at 0°C for 30 min, the solution was cooled to −78°C and a solution of ketal-ester **13** (433 mg, 1.63 mmol) in dry THF (5 mL) was added by cannula. After a further 40 min, 5-iodo-2-methyl-2-pentene (526 mg, 2.50 mmol) was added by syringe and the solution was stirred at −78°C for 1.5 h; the temperature was then

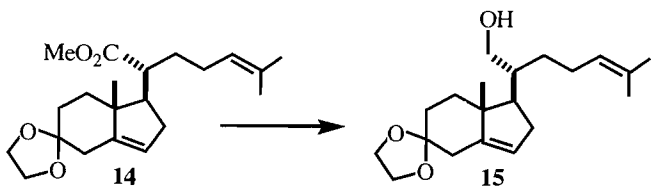
For personal use only.

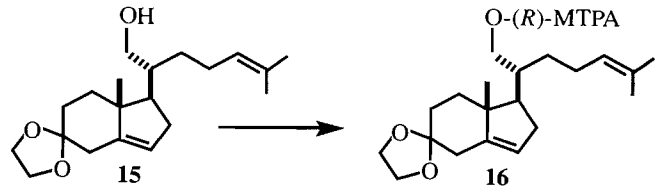
allowed to increase to rt overnight. NH_4Cl (5 mL) and water (5 mL) were added, and the mixture was diluted with Et_2O (30 mL). The layers were separated and the organic phase was washed with water (10 mL), 10% $Na_2S_2O_3$ (10 mL), and brine (10 mL), and dried over $MgSO_4$. Evaporation of the solvents afforded an orange, mobile liquid, which was purified by radial chromatography (2-mm plate), eluting with 4:1 PE:Et_2O, to afford the ketal-ester **14** as a pale yellow, mobile liquid; yield: 541 mg, 95%; $[\alpha]^{25}$ 26.0 (*c* 0.534, $CHCl_3$). IR (neat)ν: 3050 (=C-H); 2945, 2900 (C-H); 1735 (C=O) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 0.99 (3H, s, angular CH_3), 1.47–1.67 (5H, m), 1.58 and 1.69 (3H each, 2 s, 2 allylic CH_3's), 173–1.79 (1H, m), 1.89 and 1.93 (2H, q_{AB}, J = 8 Hz), 1.96–2.01 (1H, m), 2.17–2.24 (1H, m), 2.31–2.42 (3H, m), 2.52 (1H, td, J = 11.5, 4.5 Hz), 3.68 (3H, s, $-OCH_3$), 3.91–3.98 (4H, m, $-O(CH_2)_2O-$), 5.08 (1H, t, J = 7 Hz, $-CH_2CH{=}C(CH_3)_2$), 5.31 (1H, s, ring =C-H). MS (70 eV) m/z (%): 348 (M^+, 12.5), 317 (2.1), 267 (2.8), 266 (7.1), 99 (100.0). Anal. calcd. for $C_{21}H_{32}O_4$ (348.5): C 72.38, H 9.26%; found: C 72.51, H 9.19%. Mass calcd.: 348.2300; measured: 348.2306.

Hydroxyl-ketal **15**



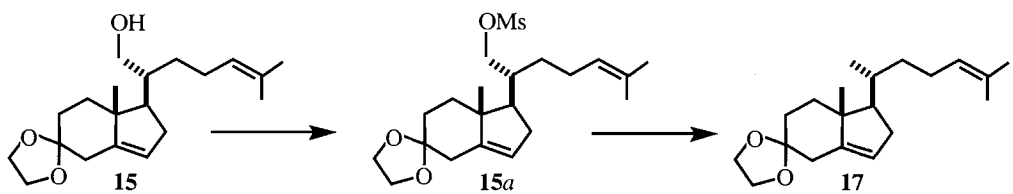
A suspension of $LiAlH_4$ (68 mg, 1.8 mmol) in dry THF (10 mL) was cooled under Ar to 0°C. A solution of ester **14** (514 mg, 1.47 mmol) in dry THF (5 mL) was added by cannula and the mixture was stirred at 0°C for 1 h and then at rt for 2 h, before $Na_2SO_4.10H_2O$ (100 mg) was added and the mixture was diluted with Et_2O (10 mL). After stirring vigorously overnight, $MgSO_4$ was added and the mixture was filtered. Evaporation of the solvents provided a viscous, colourless oil, which was purified by radial chromatography (2-mm plate), eluting with 1:1 PE:ET_2O, to afford hydroxy-ketal **15** as a viscous, colourless oil that solidified on standing; yield: 412 mg, 87%; mp 83–84°C; $[\alpha]^{25}$ 19.8 (*c* 0.656, $CHCl_3$). Recrystallization of a small amount of ketal **15** from Et_2O/PE afforded white needles (mp 72–73°C), which were submitted for X-ray structural determination. The X-ray structure indicated that the crystal contained 1/2 equivalent of water of crystallization. IR (neat)ν: 3425 (O-H); 3060, 3040 (=C-H); 2975, 2950, 2900 (C-H); 1190 (C-O) cm^{-1}. ^1H NMR ($CDCl_3$)δ: 0.97 (3H, s, angular CH_3), 1.09–1.21 (1H, m), 1.35–1.42 (1H, m), 1.48–1.58 (2H, m), 1.61 and 1.69 (3H each, 2 s, 2 × allylic CH_3), 1.63–1.69 (1H, m), 1.71 (1H, broad s, -OH), 1.80–2.08 (6H, m), 2.31–2.40 (3H, m), 3.62 (1H, d_{AB}d, J = 12, 6 Hz) and 3.76 (1H, d_{AB}d, J = 12, 3.5 Hz, $-CHCH_2OH$), 3.92–3.99 (4H, m, $-O(CH_2)_2O-$), 5.13 (1H, t, J = 8 Hz, $-CH_2CH{=}C(CH_3)_2$), 5.34 (1H, s, ring =C-H). MS (70 eV) m/z (%): 320 (M^+, 20.5), 302 (4.9), 292 (5.1), 291 (5.4), 290 (15.9), 289 (15.8), 99 (100.0). Anal. calcd. for $C_{20}H_{32}O_3$: C 72.91, H 10.10% (M + 1/2 H_2O); found: C 72.62, H 10.16%. Mass calcd.: 320.2351; measured: 320.2343.

Mosher ester **16**



A solution of hydroxy-ketal **15** (301 mg, 0.94 mmol) in dry CH_2Cl_2 (10 mL) was stirred under argon, and pyridine (0.25 mL, 250 mg, 3.1 mmol) and a solution of MTPACl (475 mg, 2.0 mmol) in dry CH_2Cl_2 (2 mL) were added by syringe. The solution was stirred for 3 days, when TLC indicated that none of the alcohol remained. After adding Et_2O (20 mL), the solution was washed with water (2 × 5 mL), 1 N HCl (5 mL), $NaHCO_3$ (5 mL), and brine (5 mL), and dried over $MgSO_4$. Evaporation of the solvents provided a viscous, yellow oil, which was purified by radial chromatography (2-mm plate), eluting with 4:1 PE:Et_2O to afford ester **16** as a viscous, colourless oil; yield: 402 mg, 80%; $[\alpha]^{25}$ 29.1 (*c* 0.412, $CHCl_3$). IR (neat)ν: 3050 (=C-H); 2960, 2900 (C-H); 1755 (C=O); 1460 (C=C, aromatic), 800, 760, 715 (aromatic C-H bend cm^{-1}). ^1H NMR ($CDCl_3$)δ: 0.98 (3H, s, angular CH_3), 120–1.30 (1H, m), 1.36–1.45 (1H, m), 1.46–1.64 (2H, m), 1.56 and 1.67 (3H each, 2 s, 2 allylic CH_3's), 1.74 (1H, dt, J = 13, 3 Hz), 1.81 (1H, d_{AB}d, J = 14, 4 Hz), 1.84–2.05 (5H, m), 2.29–2.41 (3H, m), 3.54 (3H, s, $-OCH_3$), 4.15 (1H, d_{AB}d, J = 12, 6 Hz) and 4.56 (1H, d_{AB}d, J = 12, 4 Hz, $-CHCH_2O-$), 4.99 (1H, t, J = 8 Hz, $-CH_2CH{=}C(CH_3)_2$), 5.31 (1H, s, ring =C-H), 7.37–7.42 (3H, m) and 7.51–7.55 (2H, m). ^{19}F NMR ($CDCl_3$)δ: 4.936 (s, CF_3 of major diastereomer), 4.896 (s, CF_3 of minor diastereomer). MS (70 eV) m/z (%): 536 (M^+, 0.2), 450 (0.3), 302 (1.3), 189 (9.0), 99 (100.0). Anal. calcd. for $C_{30}H_{39}F_3O_5$: C 67.15, H 7.33%; found: C 67.36, H 7.51%. Mass calcd.: 536.2749; measured: 536.2751.

Ketal **17**



A solution of hydroxy-ketal **15** (88 mg, 0.27 mmol) and DMAP (cat.) in dry CH_2Cl_2 (2 mL) was stirred under argon and Et_3N (0.27 mL, 190 mg, 1.9 mmol) and methanesulphonyl chloride (0.075 mL, 110 mg, 0.97 mmol) were added by syringe. The solution was stirred for 1.5 h after which it was diluted with Et_2O (15 mL) and water (5 mL). The layers were separated and the Et_2O was washed with water (5 mL) and dried over $MgSO_4$. Evaporation of the solvents provided mesylate **15***a* as a pale yellow, viscous oil, which was used without further purification, yield: 120 mg.

A solution of crude mesylate **15***a* (120 mg, 0.27 mmol maximum) in dry THF (5 mL) was cooled to 0°C under argon and $LiEt_3BH$ (1 M/THF, 1.1 mL, 1.1 mmol) was added by syringe. The solution was stirred for 3 h, allowing the temperature to increase to room temperature. Et_2O (20 mL) was added and the solution was washed with 1 N HCl (2 × 5 mL) and brine (5 mL), and dried over $MgSO_4$. Evaporation of the solvents provided a pale yellow oil, which was purified by radial chromatography (1-mm plate), eluting with 19:1 PE:Et_2O, to afford bicyclic ketal **17** as a colourless mobile liquid; yield: 69.2 mg, 84% over two steps; $[\alpha]^{24}$

Received July 16, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

HSING-JANG LIU, GERARDO ULÍBARRI, and ERIC N. C. BROWNE. Can J. Chem. **70**, 1545 (1992).

Diels–Alder additions to keto ester **2** proceed in moderate to high yields with a variety of dienes under selected Lewis acid and thermal conditions. Thermal conditions provide the highest total yields for non-functionalized dienes, but Lewis acid catalysts, particularly stannic chloride, provide highly selective additions in greater net yields. A study of several functionalized dienes shows that zinc chloride is particularly effective in catalyzing additions to **2**. No difference in stereoselectivity is observed between zinc chloride and thermal reactions for highly functionalized dienes. The significance of the regiochemical and stereochemical results of the Diels–Alder reactions is discussed.

HSING-JANG LIU, GERARDO ULÍBARRI et ERIC N. C. BROWNE. Can. J. Chem. **70**, 1545 (1992).

Les réactions d'addition de Diels–Alder sur le céto-ester **2** s'effectuent avec des rendements allant de modérés à très élevés avec un certain nombre de dièenes dans certaines conditions thermiques et avec certains acides de Lewis. Les conditions thermiques fournissent les rendements les plus élevés avec les dièenes non fonctionnalisés, mais les catalyseurs acides de Lewis, en particulier le chlorure stannique, conduisent à une addition hautement sélective avec un rendement net plus élevé. Une étude de plusieurs dièenes fonctionnalisés montre que le chlorure de zinc est particulièrement efficace comme catalyseur des additions sur le composé **2**. On n'observe aucune différence de stéréosélectivité entre le chlorure de zinc et les réactions thermiques impliquant les dièenes très fonctionnalisés. On discute de la signification des résultats régiochimiques et stéréochimiques des réactions de Diels–Alder.

[Traduit par la rédaction]

Introduction

In conjunction with synthetic studies on the marine sesquiterpene acetate spirodysin (**1**) (1) we have studied Diels–Alder reactions of the cyclopentenone ester **2**. Cycloaddition of **2** with a 1,3-difunctionalized Danishefsky-type diene would provide a key intermediate such as **3**, which is ideally suited for conversion to spirodysin. While this group made a large-scale investigation of larger ringed cross-conjugated dicarbonyl dienophiles (2–5) and Wenkert's group examined primarily cyclohexenones, in a series of papers,[3] relatively few examples (7–9) of Diels–Alder additions to cross-conjugated 5-membered ring unsaturated carbonyl compounds are known.

Cyclopentenones have generally performed poorly in Diels–Alder additions (10–12) and consequently have not been extensively studied. Wenkert and co-workers (13, 14) demonstrated the expected improvement in reactivity of simple cyclopentenones **4** with Lewis acid catalysis. Caine *et al.* (7) reported a very brief study of enone ester **2** using a rationale based in part on our work. In the same report he also noted the complete failure of the simpler enone **5** to produce adducts.

Detailed examination of the Diels–Alder reactivity of **2** will expand on our previous studies and offer further insight into the stereoelectronic effects relating to Diels–Alder reactions in general. Furthermore, this study should provide essential data required to select the specific diene best suited to use in the synthesis of spirodysin.

Results and discussion

The brief study of Caine *et al.* (7) used keto eter **2**, which they prepared essentially in six steps from ethyl acetoacetate via coupling of methyl 3-bromo-2-methoxycrotonate (15) and isobutyraldehyde in reportedly "low yield." For our Diels–Alder study and the planned synthesis of spirodysin we required a supply of **2** by a simpler route and in useful yield and so the efficient preparation of the reagent was examined first.

Several alternative approaches that might be applied to the formation of **2** are reported in the literature. One (16) employs a protected acyloin condensation of the ethyl diester of 3,3-dimethylglutaric acid obtained (16) in 92% yield from the inexpensive commercial diacid. The intermediate bis-silyl enol ether **6** is hydrolyzed to the unsaturated ketone **5** (63% overall yield in three steps). Another approach (17) to intermediate **5** in slightly lower yield uses vinylic oxidation of olefin aldehyde **7** obtained (18) in one step by coupling of isobutyraldehyde and allyl alcohol. The resulting keto aldehyde undergoes aldol condensation to give **5** in 49% overall yield (three steps) from isobutyraldehyde. Conversion of **5**[4] from either route to dienophile **2** would require reduction of the double bond, regioselective carbomethoxylation,[5] and oxidation to regenerate the double bond. Clearly, a simpler approach than either of these lengthy (six-step) procedures is desirable.

In a fundamentally different approach, keto ester **8** was prepared (20) in high yield from commercial 3,3-dimethyl glutaric acid by a modified Dieckmann condensation on the dimethyl ester (67% overall yield in two steps). A fourth approach (21) to enone ester **2** uses a Wolff rearrangement of the diazoketone **9**, which can be prepared (22) from dimedone, to give the keto ester **8** (72% overall yield in two steps). Oxidation of **8** at the α-position would provide dienophile **2**. This last approach would be preferable since it

[3]For the most recent paper in the series see ref. 6.

[4]Ketone **5** is available at very high cost from Aldrich Chemical Co.

[5]This carbomethoxylation has already been reported in 60–63% yield by two other groups (19, 20).

would produce the β-keto ester directly in highest yield in only three or four steps from commercial materials.

Thus, photolysis of **9** by the established method (21) gave **8**, which was brominated with *N*-bromosuccinimide to give **10** (93% yield). Dehydrobromination of **10** with 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) was unsuccessful and the use of lithium chloride in dimethylformamide (23) gave the desired product **2** in only 20% yield. Considering the observed difficulty in achieving dehydrobromination, we examined the popular and reliable selenylation – oxidative elimination approach previously used successfully (24) to prepare **2** in unreported yield. Keto ester **8** was treated with phenylselenenyl chloride and pyridine (3, 25, 26). The intermediate selenide was oxidized with hydrogen peroxide to give dienophile **2** in 95% overall yield from **8**.

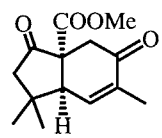
In general enone ester **2** was reacted with a selection of Lewis acids and dienes in ether solution at ambient or subambient temperatures with a stoichiometric excess of the diene and one equivalent or a slight excess of the Lewis acid. For comparison, a series of thermal Diels–Alder reactions was also run on a small scale (~50 mg). The reaction mixtures (ether solutions) of **2** developed colorful complexes with some Lewis acids; pink–red with stannic chloride, violet with ferric chloride, and green with aluminum chloride. However, these Lewis acids were accompanied by considerable polymerization of the diene. In contrast, the reactions with zinc chloride (27) and boron trifluoride etherate were colorless, less polymerization occurred, and the purification of the adducts was considerably easier to accomplish. The details of the reactions and structural assignments will be presented individually for each diene studied, followed by discussion of the stereoelectronic effects that control the product structure.

Reactions with isoprene

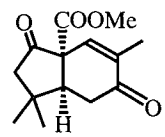
The reactions of **2** with isoprene are summarized in Table 1. In general, adducts are formed in moderate to high yields at routine temperatures. In each case a single adduct **11** was obtained, except with thermal and boron trifluoride etherate catalyzed conditions where an inseparable isomeric product **12** was coproduced. Gross examination of the analytical data of the pure major product **11** clearly confirmed that a normal Diels–Alder adduct had been formed and the regiochemistry was tentatively assigned on the basis of the ^{1}H nmr spectrum. The C-6 vinylic proton (δ 5.37) showed couplings to two *gem*-coupled (18 Hz) methylenic signals at δ 2.86 (4 Hz) and δ 2.03 (2.5 Hz). As established in structural analyses of similar adducts in these laboratories (2, 8), the downfield shift of the proton at δ 2.86 is characterisic of the *peri*-deshielding effect of the adjacent ketone carbonyl on the β-proton at C-7.

The regiochemistry of **11** was conclusively demonstrated by conversion to keto enone **13** in 41% yield by photooxygenation (28). The distinctive β-proton of the enone system at δ 6.58 appeared as a doublet of doublets with couplings to the ring junction (δ 3.31, 5 Hz) and allylic methyl (δ 1.85, 2 Hz) protons. If the major Diels–Alder product were the anti-*para* adduct **12**, the signal for the enone hydrogen in the photo-oxygenation derivative **14** would be a singlet.[6] Also, in the ^{1}H nmr spectrum of **13** the bridgehead hydrogen (δ 3.31) shows couplings to the vinylic proton (δ 6.58, 5 Hz) and to the allylic methyl (δ 1.85, 1.5 Hz). The isomeric derivative **14** would show no couplings between those protons but would show couplings between the bridgehead proton and the keto-methylene protons at C-4.[7]

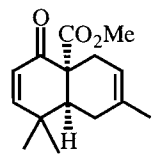
The structure of the inseparable minor adduct **12** was assigned based on the ^{1}H nmr and ^{13}C nmr spectra of the 1:1 mixture originating from the thermal reaction, which showed closely corresponding sets of peaks not present in the spectra of pure **11**. Similar correspondence has been observed between isomeric adducts **15** and **16** obtained in a related study (2).



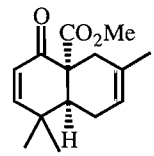
13



14



15



16

Reactions with trans*-piperylene*

Cycloadditions of **2** with *trans*-piperylene are summarized in Table 2. Adducts were easily obtained in moderate to high yields, giving almost invariably chromatographically separable mixtures of the two epimeric products **17** and **18** except in the case of boron trifluoride etherate where pure **17** was obtained.

[6]Indeed the ^{1}H nmr spectrum of **14** prepared by an unambiguous alternate route (*vide infra*) shows the β-proton as a very finely split doublet of quartets (δ 6.69, $J = J' = 1$ Hz) due to long-range couplings with the vinylic methyl (δ 1.83) and the C-3a hydrogen (δ 3.17).

[7]The proton of authentic **14** (*vide infra*) at δ 3.17 showed two identical couplings (5 Hz) to the C-4 methylenic protons (δ 2.67).

$BF_3 \cdot OEt_2$ (1)	10	90	20	73	**17**
Thermal[c]	20	6	200	90	**17/18** (2:1)

[a]Starting material was recovered in 34%.
[b]Based on consumed starting material.
[c]Reaction was run with no solvent.

The gross structure of the pure major isomer **17** was evident from the analytical data. The bridgehead proton (δ 2.67) showed two couplings (7 and 2.5 Hz) to adjacent protons, one of which (δ 2.39) also showed a geminal coupling (15 Hz) thus confirming the regiochemistry of the addition. For the pure minor isomer **18** the ring junction proton was obscured by a complex signal (δ 2.35); however, the two adjacent *gem*-coupled (16 Hz) methylene protons were clearly identified (δ 2.38, δ 2.06). Neither showed the effect of downfield shifting by an adjacent ketone carbonyl, confirming the regiochemistry as shown and confirming that **18** is epimeric with the major isomer **17**. Preliminary indication of the stereochemistry was defined by the shift of the C-7 methine proton, which in **17** (δ 2.85) showed the expected downfield shift due to the *peri*-effect of the ketone carbonyl, while the same signal in **18** (part of the complex signal at δ 2.35) showed no such deshielding.

The stereochemistry of the methyl at C-7 was confirmed by nOe experiments on both epimers **17** and **18**. Compound **17** showed an enhancement of the ester methyl (δ 3.75, 4%) and C-3a proton (δ 2.67, 2%) signals upon irradiation of the C-7 methyl (δ 1.18). Irradiation of the C-3a proton (δ 2.67) enhanced the C-7 methyl (δ 1.18, 11%) and ester methyl (δ 3.75, 8%). Irradiation of the C-7 methyl of the minor isomer **18** (δ 1.21) gave no enhancement to either the ester methyl (δ 3.70) or the C-3a proton (δ 2.35). With these observations we concluded that the stereochemistry of **17** and **18** at C-7 is as shown.

Reactions of furan

Additions of furan to **2** (Table 3) gave modest to poor yield of the 1,4-addition product **19**[8] or decomposition products

[8]The stereochemistry of this compound could not be unambiguously assigned based on the available spectral data. The tentative assignment was made assuming that the facile epimerization of the β-keto ester system would allow for the exclusive formation of the more stable *trans* isomer.

rather than the expected Diels–Alder adduct **20**. Production of a similar 1,4-addition product was previously observed for addition of furan to the unsaturated γ-lactone dienophile **21** (8).

Reactions of C-1 functionalized dienes **22***a* *and* **22***b*

A study of the Diels–Alder cycloaddition of functionalized dienes to keto ester **2** was undertaken to determine which dienes would be suitable for the planned synthesis of spirodysin. The C-1 functionalized diene **22***a* (29) was prepared by condensation of *trans*-2-methyl-2-butenal (tiglic aldehyde) with trimethylsilyl chloride in the presence of zinc chloride and triethylamine. It was extremely sensitive to the acidity of the Lewis acid catalysts and could only be used successfully in the thermal Diels–Alder reaction (Table 4).

The thermal reaction of **22***a* gave a mixture of epimers, which was separated by flash chromatography on silica gel. The ^1H nmr spectrum of epimer **24***a*, which eluted first, displayed an allylic signal for the C-7 hydrogen at δ 4.72 as a singlet. The C-3a hydrogen was at δ 2.70 (dd, $J = J' =$ 8 Hz). The second epimer to be eluted was compound **23***a*. In its ^1H nmr spectrum the vinylic hydrogen appeared at δ 5.67 (dd, $J = 6$, $J' = 5$ Hz), the C-7 hydrogen at δ 4.40 (singlet), and the C-3a hydrogen at δ 2.83 (dd, $J = 7$, $J' =$ 4 Hz). The multiplicity of these sets of signals confirmed the regiochemistry of the two adducts.

The stereochemistry at the C-7 carbon of the two epimers was confirmed by a simple nOe experiment. Irradiation of compound **24***a* at the C-3a proton (δ 2.70) gave enhancement of the C-7 hydrogen signal (δ 4.72, 2%). Irradiation at δ 4.72 produced an enhancement of the ester methyl signal (δ 3.68, 4%) and the C-3a proton (δ 2.70, 2%). On the other hand, irradiation of the C-7 proton (δ 4.40) of compound **23***a* produced no enhancement at C-3a (δ 2.83). Based on these results, the stereochemistry at C-7 in epimers **23***a* and **24***a* was assigned as shown.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

The regiochemistry of the Diels–Alder reaction was confirmed by independent decarbomethoxylations of the epimers **23***a* and **24***a* using lithium iodide dihydrate in refluxing collidine (30). The same aromatic compound **25** was obtained in 54% yield in each case, apparently by concurrent displacement of the trimethylsiloxy group and aromatization of the resulting diene. The ^{1}H nmr of **25** showed a *peri*-deshielded signal for the C-7 aromatic proton at δ 7.50 as a broadened singlet, conclusively proving the position of the methyl at C-6.

The *tert*-butyldimethylsilyloxy diene **22***b* was also studied to determine if it would be more stable in the presence of a Lewis acid during the reaction. This diene could not be prepared by the method used for **22***a*. Instead, tiglic aldehyde was deprotonated with lithium diisopropylamide and the resulting enolate was trapped with *tert*-butyldimethylsilyl chloride (31). The silyloxy diene **22***b*[9] was slightly more stable to the acidic conditions of the Diels–Alder cycloadditions and an adduct was obtained (Table 4) with zinc chloride as the catalyst. A poor yield (~17% after 168 h) of an inseparable 1:1 mixture of epimers **23***b* and **24***b* that could not be completely purified was obtained. When stannic chloride was used, complete decomposition of the diene took place. The ratio of the mixture of adducts **23***b* and **24***b* was obtained from the ^{1}H nmr spectrum of the crude mixture.

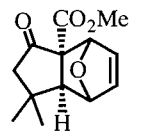
Reactions of C-2 functionalized diene ***26***

Diene **26** (31) was prepared from 3-methyl-3-buten-2-one by deprotonation with lithium diisopropylamide and trapping of the resulting enolate produced with *tert*-butyldimethylsilyl chloride. The diene was obtained in 80% yield after being distilled in a Kugelrohr apparatus at 90°C (15 Torr; 1 Torr = 133.3 Pa).

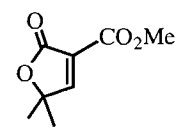
The Diels–Alder reaction of diene **26** with dienophile **2** gave only adduct **27** (Table 5). The reaction proceeded very cleanly when zinc chloride was used, giving a better yield than with the thermal reaction. When stannic chloride was used as the catalyst a messy reaction took place and none of the adduct **27** or the starting material was recovered. Instead only the difficult to purify hydrolyzed ketone **28** (3.8:1) was collected in low yield. Pure **28** was prepared directly from pure **27**. Hydrolysis of silyl enol ether **27** with dilute hydrochloric acid gave ketone **28** as a mixture (3.8:1) of epimers at C-6. The ^{1}H nmr spectrum of **28** displayed a complex set of doubled signals that did not allow confident assignment of stereochemistry at C-6 for each epimer.

Reactions of difunctionalized diene ***29***

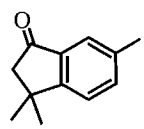
Diene **29**[10] can be prepared (31) from 4-ethoxy-3-methyl-3-buten-2-one (32) and purified by bulb-to-bulb distillation (2.0 Torr, 60°C). Diels–Alder cycloaddition of dienophile **2** with diene **29** (Table 6) proceeded smoothly when zinc chloride or thermal conditions were used, but when stannic chloride, a stronger Lewis acid, was used as a catalyst no initial Diels–Alder adduct could be isolated from the messy reaction. Instead, only the hydrolysis product ketone **14** was recovered in 36% yield. This again showed the great acid sensitivity of this type of dienes, making the Diels–Alder reactions with them subject to some limitations. Nevertheless, use of the less acidic Lewis acid zinc chloride allowed cycloaddition to take place, giving a 1:1 mixture of epimeric silyl enol ethers **30** and **31** in good yield. The chromatographic separation of the epimers was accomplished with great difficulty and was done only for the purpose of identification since the C-7 chiral center would be destroyed upon hydrolysis of the enol ethers in any planned synthetic scheme. Compound **30** was the first epimer to be eluted. The ^{1}H nmr spectrum of compound **30** displayed the C-7 hydrogen (δ 4.49) as a broad singlet, thus confirming the orientation of the addition. Interestingly, the methylenic hydrogens at the ethoxyl chain appeared as two sets of peaks at δ 3.46 (q, J = 7 Hz), and at δ 3.35 (q, J = 7 Hz). The C-3a hydrogen (δ 2.91) appeared as a doublet of doublets ($J = J'$ = 8 Hz).



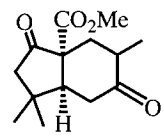
20



21



25



28

The ^{1}H nmr spectrum of compound **31**, the second epimer to be eluted, showed the C-7 hydrogen (δ 4.35) as a singlet and the C-3a hydrogen (δ 3.16) as a doublet of doublets (J = 7.5, J' = 1.5 Hz), again confirming the regiochemistry. The methylenic hydrogens of the ethoxyl group were displayed together at δ 3.42 (q, J = 7 Hz). Irradiation of the vinylic methyl signal at δ 1.63 (d, J = 2 Hz), to induce decoupling affected only the signal at δ 2.71 due to one of the C-4 methylenic protons, indicating a homo-allylic coupling with this particular hydrogen.

Although a confident assignment of the stereochemistry at C-7 for epimers **30** and **31** was not possible with the data obtained from the ^{1}H nmr spectrum, it was interesting to observe that the methylene hydrogens in the ethoxyl chain appeared as separate signals in the case of compound **30** at δ 3.46 and δ 3.35 and in one single signal in compound **31** at δ 3.42. If there were an interaction between the ethoxyl chain and the ester group causing the methylene hydrogens to appear as separate signals, then silyl enol ether **30** would be the epimer with the ethoxyl group *cis* to the ester moiety. Also the C-3a hydrogen in compound **30** is at higher field (δ 2.91) in the ^{1}H nmr spectrum than the same hydrogen of the epimer **31** (δ 3.16), indicating that the C-3a hydrogen in compound **30** could be within the shielding area of the ether oxygen. This is not the case for silyl enol ether **31**. Because the center at C-7 would be destroyed in a later stage in the

[9]This compound obtained in 40% yield showed the following spectral data: ^{1}H nmr (400 MHz, $CDCl_3$) δ: 6.40 (br s, 1H, -OC*H*=), 6.28 (dd, J = 16, J' = 12 Hz, 1H, -C*H*=), 4.97 (d, J = 16 Hz, 1H, *H*HC=), 4.82 (d, J = 12 Hz, 1H, H*H*C=), 1.70 (s, 3H, =C(CH_3)-), 0.93 (s, 9H, -SiC(CH_3)$_3$), and 0.15 (s, 6H, -Si(CH_3)$_2$); ir (neat): 1732 (C=C) and 1255 (Si-CH$_3$) cm^{-1}.

[10]This compound, obtained in 45% yield, showed the following spectral data: ^{1}H nmr (400 MHz, $CDCl_3$) δ: 6.67 (br s, 1H, -OC*H*=), 4.22 (d, J = 1 Hz, 1H, *H*HC=), 4.12 (d, J = 1 Hz, 1H, H*H*C=), 3.87 (q, J = 6 Hz, 2H, -CH_2CH$_3$), 1.72 (s, 3H, =C(CH_3)-), 1.28 (t, J = 6 Hz, 3H, -CH$_2$CH_3), 0.96 (s, 9H, -SiC(CH_3)$_3$), and 0.18 (s, 6H, -Si(CH_3)$_2$); ir (neat): 1641, 1657 (C=C), and 1253 (Si-CH$_3$) cm^{-1}.

planned synthesis of spirodysin, the stereochemistry at this position was not essential to our study. As the ratio of stereoisomers obtained was always 1:1 there was no noteworthy stereoselectivity expressed in the Diels–Alder cycloaddition of **29**.

Degradation of the adduct mixture provided conclusive proof of the Diels–Alder orientation. Hydrolysis of the mixture of silyl enol ethers **30** and **31** with aqueous 0.1 N hydrochloric acid in tetrahydrofuran gave the α,β-unsaturated ketone **14** in 70% yield. The ^1H nmr spectrum of compound **14** displayed the C-7 hydrogen of the unsaturated ketone at δ 6.69 (dq, $J = J' = 1$ Hz), with a long-range W-coupling to the vinylic methyl and to the C-3a hydrogen. The C-3a hydrogen was displayed at δ 3.17 (ddd, $J = J' = 5$, $J'' = 1$ Hz) and the adjacent C-4 hydrogens appeared together at δ 2.67 (d, $J = 5$ Hz).

Orientation effects

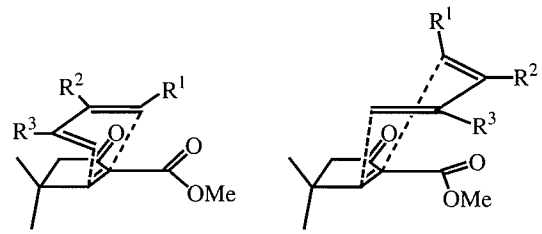
As we demonstrated with related dienophiles (2–5, 8), additions to keto ester **2** showed stereochemical and electronic influences in the orientations of the additions which were reflected in the structures of the adducts. Additions of isoprene showed significant proportions of the *anti*-para adduct **12** in the thermal and boron trifluoride catalyzed cases. We interpreted this result as due to the steric interaction between diene and dienophile methyl groups in the keto-*endo* transition state **A** ($R^1 = R^2 = H$, $R^3 = CH_3$). Weaker Lewis acids capable of accepting bidentate ligand complexes showed complete predominance of the *para* product of addition by ester-*endo* transition state **B** ($R^1 = R^2 = H$, $R^3 = CH_3$). In that transition state steric interaction between the methyl groups would be absent.

Additions of *trans*-piperylene as well as functionalized dienes **22***a* and **22***b* proceeded exclusively according to the expected *ortho* rule and the complete regiospecificity observed in *para* addition of silyloxy diene **26** was in the direction predicted by normal empirical priority rules for predicting the controlling substituent. Similarly, additions of bifunctional diene **29** gave exclusively the *ortho*-rule products.

Dienophile **2** was somewhat unusual relative to the other systems we studied in that *exo-endo* selectivity of the addition was very low in most cases. High ratios of one epimer, in each case the product of ester-*endo* addition (transition state **B**, $R^1 = CH_3$; $R^2 = R^3 = H$), were only obtained for *trans*-piperylene additions under boron trifluoride and stannic

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

chloride catalysis. The other dienophiles each showed a clear preference for keto-*endo* addition (2) or ester-*endo* addition (3–5, 8) under the various preferred reaction conditions. In fact we regard the production of the keto-*endo* product **31**, which must be formed by addition of **29** through transition state **A** (R^1 = OEt, R^2 = CH_3, R^3 = OTBDMS), as quite remarkable. Steric interaction of the large silyloxy group with the *gem*-dimethyl of **2** should at first glance have a large destabilizing effect on the transition state and promote formation of the epimeric product **30**. The reasons for the absence of this expected steric effect and for the general *exo-endo* orientational ambivalence of additions to **2** are unclear. Further investigations into the effects influencing *exo-endo* selectivity in this and other cross conjugated dicarbonyl dienophiles is the subject of ongoing investigation in this laboratory.



A **B**

Conclusions

Keto ester **2** is a general and potentially versatile intermediate for the assembly of indene ring synthons useful in the synthesis of natural products. As a dienophile, **2** shows the expected stereoelectronic influences on the regiochemistry of the adducts. With functionalized dienes zinc chloride is a particularly suitable choice as the catalyst.

Towards the synthesis of spirodysin (**1**), at this point it would only be necessary to modify an intermediate such as **14** or **28** into a system that would allow for dialkylation at the α-position of the ketone in the cyclopentanone ring. Further studies on both intermediate ring systems are under way in these laboratories.

Experimental

General

Melting points were measured on a Köfler hot stage apparatus and are uncorrected. Elemental analyses were carried out using a Perkin Elmer 240-B elemental analyzer for C, H, and N detection. Infrared spectra (ir) were obtained on a Nicolet 7199 FTIR spectrophotometer. Mass spectra (ms) were determined using a AEI Kratos MS-50 high-resolution mass spectrometer attached to a Data General Nova 2 with Kratos DS-55 software. Proton nuclear magnetic resonance spectra (^{1}H nmr) were obtained using one of the following spectrometers: Bruker WH-200 (200 MHz), Bruker AM-300 (300 MHz), or Bruker AM-400 (400 MHz). Coupling constants are recorded to within ±0.5 Hz. Carbon nuclear magnetic resonance spectra (^{13}C nmr) were run on a Bruker AM-300 (75 MHz), or a Bruker AM-400 (100.6 MHz). Two methods were used to determine the carbon-13 multiplicities: the distortionless enhancement by polarization transfer (DEPT) experiment with proton decoupling using a Bruker software microprogram (DETP.AUR) and the attached proton test (APT) (used for most compounds). Peaks in antiphase (a) with deuteriochloroform were assigned as methyls or methines, while peaks in phase (p) correspond to methylenes or quaternary carbons. Aldehydic carbonyls appear in antiphase with $CDCl_3$ and other carbonyls in phase with the deuteriochloroform signal. Nuclear Overhauser enhancement (nOe) experiments were obtained after computer subtraction of the uncoupled spectrum from the irradiated spectrum. Positive enhancements are defined as signals in antiphase with the enhanced irradiated signal. Immediately before the experiment each sample was deoxygenated by passing helium gas through the solution for 10 min. Reaction yields are quoted with a degree of purity better than 95% as determined by NMR spectroscopy.

Materials

Products were purified either by flash chromatography using silica gel 60 (230–400 mesh), distillation using a bulb-to-bulb Kugelrohr apparatus, or by fractional crystallization. Reactions were monitored by thin-layer chromatography using Merck aluminum-backed plates precoated with silica gel 60 GF_{254}. Solvents were dried and distilled prior to use as follows: ethyl ether from a blue–purple solution of sodium benzophenone ketyl under an argon atmosphere: benzene, pyridine, and dichloromethane from calcium hydride or lithium hydride. Dienes **22***a* (29) and **26** (31) were prepared according to the reported procedures. Dienes **22***b* and **29** were prepared from *trans*-2-methyl-2-butenal and 4-ethoxy-3-methyl-3-buten-2-one (32) respectively, using the same procedure as described for the preparation of diene **26** (31).

*1-Bromo-4,4-dimethyl-2-oxocyclopentane-1-carboxylic acid, methyl ester (**10**)*

2-Carboxymethoxy-4,4-dimethylcyclopentan-1-one (**8**) (0.70 g, 4.1 mmol) was dissolved in carbon tetrachloride (10 mL). *N*-Bromosuccinimide (890 mg, 5.0 mmol) was added and the solution was stirred at room temperature for 10 h. The solid formed during the reaction was filtered and the filtrate was concentrated to give a yellowish oil (950 mg, 3.8 mmol, 93%); ir ($CHCl_3$ cast): 1761 (ester) and 1723 (ketone) cm^{-1}; ^{1}H nmr (400 MHz, $CDCl_3$) δ: 3.80 (s, 3H, -OC*H*$_3$), 2.89 (d, *J* = 15 Hz, 1H, -C*H*HCOCBr-), 2.50 (d, *J* = 15 Hz, 1H, -CH*H*COCBr-), 2.41 (d, *J* = 10 Hz, 1H, -COCBrC*H*H-), 2.37 (d, *J* = 10 Hz, 1H, -COCBrCH*H*-), 1.28 (s, 3H, -C*H*$_3$), and 1.10 (s, 3H, -C*H*$_3$); ^{13}C nmr APT (100.6 MHz, $CDCl_3$) δ: 206.2 (a), 168.3 (a), 59.3 (a), 54.0 (p), 52.2 (a), 51.0 (a), 34.0 (a), 29.6 (p), and 29.4 (p); ms; M^+: 250.0026 (248.0027) (calcd. for $C_9H_{13}O_3Br$: 250.0027 (248.0048)).

*3,3-Dimethyl-5-oxo-1-cyclopentene-1-carboxylic acid, methyl ester (**2**)*

Phenylselenenyl chloride (7.5 g, 32 mmol) was dissolved in dichloromethane (200 mL) and the solution was cooled in an ice–water bath. Dry pyridine (3.20 mL, 40 mmol) was slowly added and the solution was stirred for 45 min. Then 2-carboxymethoxy-4,4-dimethylcyclopentan-1-one (**8**) (5.46 g, 32 mmol) dissolved in dichloromethane (30 mL) was added to the reaction mixture. The solution was stirred at 0°C for 45 min then poured into an ice – 5% hydrochloric acid mixture (200 mL). The organic layer was washed with aqueous 5% hydrochloric acid (3 × 10 mL) and dried ($MgSO_4$). Hydrogen peroxide (30%, 6 mL) was added to the dichloromethane solution at 0°C and allowed to react for 10 min. Additional hydrogen peroxide (30%, 6 mL) was then added. After another 10 min the reaction was quenched with water (20 mL). The aqueous layer was extracted with dichloromethane (3 × 5 mL). The organic extracts were combined, washed with water (2 × 5 mL), aqueous 5% sodium bicarbonate (1 × 5 mL) and brine (1 × 5 mL), dried ($MgSO_4$), filtered, and concentrated. Purification by flash chromatography on silica gel (0–20% ether in petroleum ether) gave a colorless oil (3.22 g, 20 mmol, 62%); ir ($CHCl_3$ cast): 1754 (ester), 1724 (ketone), and 1621 (olefin) cm^{-1}; ^{1}H nmr (400 MHz, $CDCl_3$) δ: 8.07 (s, 1H, -C(COOCH$_3$)=C*H*-), 3.74 (s, 3H, -OC*H*$_3$), 2.34 (s, 2H, -C*H*$_2$CO-), and 1.20 (s, 6H, 2 × -C*H*$_3$); ^{13}C nmr APT (100.6 MHz, $CDCl_3$) δ: 202.2 (p), 180.2 (a), 162.2 (p), 133.7 (p), 51.8 (a), 51.0 (p), 38.8 (p), and 27.3 (a); ms, M^+: 168.0987 (calcd. for $C_9H_{12}O_3$: 168.0987). Anal. calcd. for $C_9H_{12}O_3$: C 64.15, H 6.95%; found: C 64.26, H 7.19%.

*Diels–Alder reactions of keto ester **2***

well as quantities of diene and Lewis acid relative to **2** are noted in Tables 1–6. Purification and separation of the adducts were carried out using 0–10% ether in petroleum ether as eluant. When separation occurred, the products are reported in order of elution.

*7aα-Carbomethoxy-2,3,3aα,4,7,7a-hexahydro-3,3,5-trimethylindene-1-one (**11**) and 7aα-carbomethoxy-2,3,3aα,4,7,7a-hexahydro-3,3,6-trimethylinden-1-one (**12**)*

Lewis acid catalyzed conditions (other than zinc chloride)

Keto ester **2** (25 mg, 0.15 mmol) was dissolved in dry ether (1 mL) and placed under an argon atmosphere. The reaction mixture was cooled with an ice-water bath. Tin(IV) chloride (18 μL, 0.15 mmol) was added and the resulting mixture stirred for 15 min. Isoprene (150 μL, 1.5 mmol) was introduced with a syringe. The reaction mixture was stirred for 10 h at 0°C, then quenched by the addition of saturated aqueous sodium bicarbonate (1 mL). The aqueous layer was extracted with ether (3 × 1 mL). The organic extracts were combined, washed with water (2 × 2 mL) and brine (1 × 1 mL), dried ($MgSO_4$), filtered, and concentrated. Purification by flash chromatography on silica gel (0–5% ether in petroleum ether) gave pure compound **11** (30 mg, 86%): ir ($CHCl_3$ cast): 1752 (ester) and 1731 (ketone) cm^{-1}; ^1H nmr (400 MHz, $CDCl_3$) δ: 5.37 (br dd, J = 4, J' = 2.5 Hz, 1H, -C(CH_3)=C*H*-), 3.71 (s, 3H, -OCH_3), 2.86 (ddd, J = 18, J' = 4, J'' = 2 Hz, 1H, -C*H*HCH=), 2.79 (br d, J = 8 Hz, 1H, -C(CH_3)$_2$C*H*CH_2-), 2.37 (s, 2H, -CH_2CO-), 2.17 (ddd, J = 18, J' = 8, J'' = 2 Hz, 1H, -CHC*H*HC(CH_3)=), 2.03 (ddd, J = 18, J' = 2.5, J'' = 2 Hz, -CH*H*CH=), 1.93 (br dd, J = 18, J' = 2 Hz, 1H, -CHCH*H*C(CH_3)=), 1.69 (s, 3H, -CH=C(CH_3)-), 1.20 (s, 3H, -CH_3), and 0.88 (s, 3H, -CH_3); ^{13}C nmr APT (100.6 MHz, $CDCl_3$) δ: 214.3 (p), 172.5 (p), 132.6 (p), 117.3 (a), 57.4 (p), 53.1 (p), 52.8 (a), 47.1 (a), 37.2 (p), 30.0 (a), 27.2 (p), 25.3 (p), 23.6 (a), and 23.5 (a); ms, M^+: 236.1413 (calcd. for $C_{14}H_{20}O_3$: 236.1413). Anal. calcd. for $C_{14}H_{20}O_3$: C 71.14, H 8.53%; found: C 71.21, H 8.49%.

Zinc chloride catalyzed Diels–Alder conditions

Zinc chloride (45 mg, 0.33 mmol) was added to dry ether (2 mL) and stirred at room temperature until all the solid had dissolved (~30 min). A solution of keto ester **2** (43 mg, 0.26 mmol) in dry ether (1 mL) was added to the cloudy solution of zinc chloride followed immediately by isoprene (260 μL, 2.6 mmol). The reaction mixture was stirred at room temperature for 10 h, then a saturated aqueous solution of sodium bicarbonate (1 mL) was added. The aqueous layer was extracted with ether (3 × 2 mL). The combined organic extracts were washed with water (2 × 2 mL) and brine (1 × 2 mL), dried ($MgSO_4$), filtered, and concentrated. Purification of the residual oil by flash chromatography on silica gel (0–5% ether in petroleum ether) gave adduct **11** (46 mg, 75%).

Thermal conditions

Keto ester **2** (50 mg, 0.30 mmol) was introduced into a small thick-walled glass container. Isoprene (0.90 mL, 9 mmol) was added with a syringe and argon was passed through the solution for 5 min. The glass container was cooled with liquid nitrogen until the solution had solidified. While the ampule was still in the nitrogen it was sealed and allowed to warm to room temperature over 20 min. The ampule was placed in a protected oven and heated to 200°C for 10 h. The oven was turned off and the temperature was allowed to cool to ambient temperature. Concentration, followed by flash chromatography of the residue on silica gel (0–5% ether in petroleum ether) gave an inseparable 1:1 mixture of compounds **11** and **12** (70 mg, 98%). This mixture showed the following signals, which were not present in the spectra of pure compound **11**: ^1H nmr (400 MHz, $CDCl_3$) δ: 5.41 (br s, 1H, -C(CH_3)=C*H*-), 3.68 (s, 3H, -OCH_3), 2.71 (br s, 2H, -CH_2C(CH_3)=), 2.67 (d, J = 6 Hz, 1H, -C*H*CH_2CH=), 2.37 (s, 2H, -CH_2CO-), 1.69 (s, 3H, -CH=C(CH_3)-), 1.18 (s, 3H, -CH_3), and 0.88 (s, 3H, -CH_3), other peaks were overlapped with those of isomer **11**; ^{13}C nmr APT (100.6 MHz, $CDCl_3$) δ: 214.0 (p), 172.2 (p), 130.4 (p), 119.5 (a), 58.9 (p), 53.2 (p), 52.6 (a), 46.1 (a), 37.1 (p), 31.1 (p), 30.0 (a), 23.5 (a), 23.4 (a), and 21.1 (p).

The other adducts showed the following spectral data.

*7aα-Carbomethoxy-2,3,3aα,4,7,7a-hexahydro-3,3,7α-trimethylinden-1-one (**17**) and 7aα-carbomethoxy-2,3,3aα,4,7,7a-hexahydro,3,3,7β-trimethylinden-1-one (**18**)*

*7aα-Carbomethoxy-3,3aα,7,7a-tetrahydro-3,3,5-trimethyl-2*H*-indene-1,6-dione (**13**)*

Oxygen was passed for 10 min through a dichloromethane (0.5 mL) solution of keto ester **11** (25 mg, 0.10 mmol), dry pyridine (15 μl, 0.18 mmol), acetic anhydride (20 μL, 0.21 mmol), a catalytic quantity of 4-(dimethylamino)pyridine (~5 mg), and a catalytic quantity of 5,10,15,20-tetraphenyl-21*H*,23*H*-porphine (~5 mg). The solution was irradiated with a tungsten lamp (200 W) for 10 h while oxygen was continuously passed through the solution. The reaction was quenched with saturated aqueous sodium bicarbonate solution (1 mL) and the aqueous layer was extracted with dichloromethane (3 × 2 mL). The organic extracts were combined and washed with aqueous 10% hydrochloride acid (3 × 2 mL), saturated aqueous copper(II) sulfate (1 × 2 mL) and brine (1 × 2 mL), dried ($MgSO_4$), filtered, and concentrated. Purification by flash chromatography on silica gel eluting with 0–10% ether in petroleum ether gave recovered keto ester **11** (5 mg, 20%). Further elution gave diketone **13** as a colorless oil (9 mg, 0.036 mmol, 41% yield): ir ($CHCl_3$ cast): 1753 (ester), 1732 (ketone), and 1679 (enone) cm^{-1}; ^{1}H nmr (400 MHz, $CDCl_3$) δ: 6.58 (dq, J = 5, J' = 2 Hz, 1H, -CHC*H*=C(CH$_3$)CO-), 3.72 (s, 3H, -OCH_3), 3.31 (dq, J = 5, J' = 1.5 Hz, 1H, -C*H*CH=C(CH$_3$)CO-), 3.14 (d, J = 17 Hz, 1H, -C*H*HCOC(CH$_3$)=), 2.69 (d, J = 17 Hz, 1H, -CH*H*COC(CH$_3$)=), 2.46 (d, J = 11 Hz, 1H, -C*H*HCO-), 2.42 (d, J = 11 Hz, 1H, -CH*H*CO-), 1.85 (dd, J = 2, J' = 1.5 Hz, 3H, -CHCH=C(CH_3)CO-), 1.40 (s, 3H, -CH_3), and 1.05 (s, 3H, -CH_3); ^{13}C nmr APT (100.6 MHz, $CDCl_3$) δ: 211.0 (p), 194.4 (p), 171.8 (p), 139.1 (a), 136.3 (p), 63.7 (p), 55.1 (p), 53.3 (a), 51.4 (a), 38.5 (p), 38.4 (p), 28.6 (a), 25.2 (a), and 16.3 (a); ms, M^+: 250.1204 (calcd. for $C_{14}H_{18}O_4$: 250.1205).

*3,3,6-Trimethyl-2,3-dihydroinden-1-one (**25**)*

Compound **23***a* (24 mg, 0.074 mmol) was dissolved in 2,4,6-collidine under argon atmosphere. Anhydrous lithium iodide (40 mg, 5 equiv.) was added followed by water (14 μL, 10 equiv.). The mixture was refluxed for 4 h, cooled down, and poured into aqueous 5% hydrochloric acid (2 mL). The aqueous layer was extracted with ether (3 × 2 mL). The organic layer was washed with aqueous 5% hydrochloric acid (2 × 2 mL), water (1 × 2 mL), and brine (1 × 2 mL), dried ($MgSO_4$), filtered, and concentrated. Purification by flash chromatography on silica gel (0–3% ether in petroleum ether) gave pure compound **25** (7 mg, 54%): ir ($CHCl_3$ cast): 1736 (ketone) and 825 (aromatic) cm^{-1}; ^{1}H nmr (400 MHz, $CDCl_3$) δ: 7.50 (br s, 1H, C-7 H), 7.44 (dd, J = 8, J' = 1 Hz, 1H, C-5 H), 7.38 (d, J = 8 Hz, C-4 H), 2.60 (s, 2H, -CH_2CO-), 2.40 (s, 3H, C-6-CH_3), 1.40 (s, 6H, -C(CH_3)$_2$); ms, M^+: 174.1043 (calcd. for $C_{12}H_{14}O$: 174.1042).

*7aα-Carbomethoxy-2,3,3aα,4,7,7a-hexahydro-3,3,6-trimethylindene-1,5-diones (**28**)*

Silyl enol ether **27** (50 mg, 0.14 mmol) was hydrolyzed in tetrahydrofuran (2 mL) with aqueous 0.1 N hydrochloric acid (1 mL). The solution was stirred at room temperature for 24 h. Water (2 mL) was added and the aqueous layer was extracted with ether (3 × 2 mL). The combined organic extracts were washed with water (2 × 2 mL) and brine (1 × 1 mL), dried ($MgSO_4$), filtered, and concentrated. Purification of the resulting oil by flash chromatography on silica gel (0–5% ether in petroleum ether) gave the epimeric mixture **28** (3.8:1) as a colorless oil (29 mg, 0.11 mmol, 78%): ir ($CHCl_3$ cast): 1751 (ester), 1716 (ketone) cm^{-1}; ^{1}H nmr (400 MHz, $CDCl_3$), major isomer, δ: 3.77 (s, 3H, -OCH_3), 3.16 (ddd, J = 7.5, J' = 5, J'' = 1 Hz, 1H), 2.75–2.30 (complex, 4H), 1.61 (dd, J = J' = 9 Hz, 1H), 1.35 (dd, J = 6, J' = 1 Hz, 2H), 1.18 (s, 3H, -CH_3), 1.03 (d, J = 6 Hz, 3H, -CH_3), and 0.95 (s,

3H, -CH_3); minor isomer, δ: 3.72 (s, 3H, -OCH_3), 3.09 (dd, J = 7.5, J' = 5.5 Hz, 1H), 1.96 (dd, J = 12, J' = 9 Hz, 1H), 1.15 (s, 3H, -CH_3), 1.04 (d, J = 6 Hz, 3H, -CH_3), and 0.91 (s, 3H, -CH_3), other peaks were overlapped with those of the major isomer; ^{13}C nmr APT (100.6 MHz, $CDCl_3$), major isomer, δ: 211.9 (p), 211.5 (p), 171.5 (p), 59.1 (p), 53.3 (p), 53.1 (a), 50.7 (a), 40.6 (a), 37.2 (p), 37.0 (p), 34.8 (p), 29.3 (a), 24.5 (a), and 14.4 (a); minor isomer, δ: 212.8 (p), 211.2 (p), 172.2 (p), 63.7 (p), 59.9 (p), 51.9 (p), 48.9 (a), 40.2 (a), 38.5 (p), 36.2 (p), 30.2 (a), 24.9 (a), 17.7 (a), and 15.3 (a); ms, M^+: 252.1359 (calcd. for $C_{14}H_{20}O_4$: 252.1356).

*7aα-Carbomethoxy-3,3,aα,4,7a-tetrahydro-3,3,6-trimethyl-2*H-*indene-1,5-dione (**14**)*

A mixture of silyl enol ethers **30** and **31** (115 mg, 0.28 mmol) was hydrolyzed in tetrahydrofuran (THF, 2 mL) with aqueous 0.1 N hydrochloric acid (1 mL). The solution was stirred at room temperature for 24 h before water (2 mL) was added. The aqueous layer was extracted with ether (3 × 2 mL). The combined organic extracts were washed with water (2 × 2 mL) and brine (1 × 1 mL), dried ($MgSO_4$), filtered, and concentrated. Purification of the resulting oil by flash chromatography on silica gel (0–10% ether in petroleum ether) gave compound **14** as a colorless oil (50 mg, 0.20 mmol, 70%): ir ($CHCl_3$ cast): 1756 (ester), 1727 (ketone), and 1679 (enone) cm^{-1}; ^{1}H nmr (400 MHz, $CDCl_3$) δ: 6.69 (dq, J = J' = 1 Hz, 1H, -CH=C(CH_3)CO-), 3.77 (s, 3H, -OCH_3), 3.17 (ddd, J = J' = 5, J'' = 1 Hz, 1H, -CHCH_2CO-), 2.67 (d, J = 5 Hz, 2H, -CHCH_2CO-), 2.50 (d, J = 17 Hz, 1H, -CHHCO-), 2.29 (d, J = 17 Hz, 1H, -CHHCO-), 1.83 (s, J = 1 Hz, 3H, -CH=C(CH_3)CO-), 1.24 (s, 3H, -CH_3), and 0.79 (s, 3H, -CH_3); ^{13}C nmr DEPT (100.6 MHz, $CDCl_3$) δ: 209.0 (s), 196.3 (s), 169.5 (s), 138.8 (d), 136.9 (s), 60.7 (s), 53.7 (t), 53.4 (q), 48.2 (d), 37.6 (t), 33.9 (t), 27.6 (q), 23.5 (q), and 16.0 (q); ms, M^+: 250.1200 (calcd. for $C_{14}H_{18}O_4$: 250.1205). Anal. calcd. for $C_{14}H_{18}O_4$: C 67.17, H 7.25%; found: C 67.04, H 7.16%.

The 3,4-dihydroisoquinolinium salt **1** and its enantiomer have been converted readily and stereoselectively into (+)- and (−)-1,2,3,4-tetrahydro-6,7-dimethoxy-1-methylisoquinoline-1-carboxylic acids. The synthetic route described should be applicable to the enantioselective synthesis of a variety of 1-alkyl- or 1-aryl-1,2,3,4-tetrahydroisoquinoline-1-carboxylic acids. The absolute configuration of the amino acid hydrochloride **11** was established to be as depicted in Scheme 2.

ZBIGNIEW CZARNOCKI, DENNIS SUH, DAVID B. MACLEAN, PHILIP G. HULTIN et WALTER A. SZAREK. Can. J. Chem. **70**, 1555 (1992).

Le sel de 3,4-dihydroisoquinoléinium (**1**) et son énantiomère ont pu facilement et stéréosélectivement être transformés en acides (+)- et (−)-1,2,3,4-tétrahydro-6,7-diméthoxy-1-méthylisoquinoléine-1-carboxyliques. La voie de synthèse décrite devrait être applicable à la synthèse énantiosélective d'une variété d'acides 1-alkyl- ou 1-aryl-1,2,3,4-tétrahydroisoquinoléine-1-carboxyliques. On a pu déterminé que la configuration absolue du chlorhydrate de l'acide aminé **11** est celle décrite dans le schéma 2.

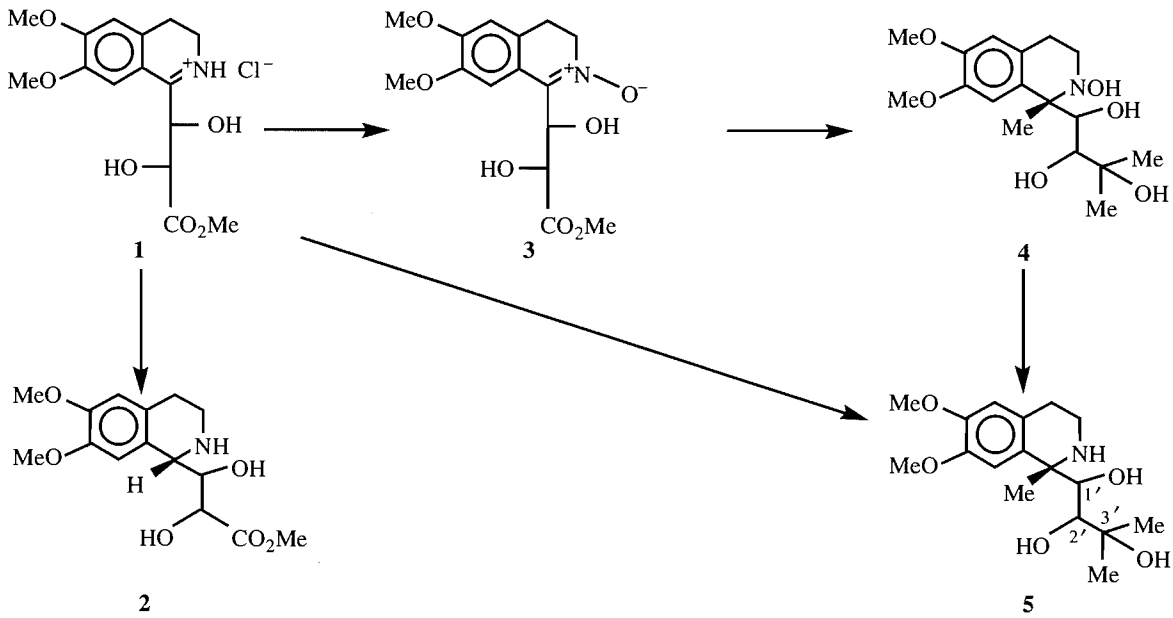
Tetrahydroisoquinolines in which C-1 is a quaternary centre have been found in nature, and include a number of cactus alkaloids (1), several mammalian alkaloids (2), and the spirobenzylisoquinoline alkaloids (3). Brossi and coworkers (4) have prepared enantiomeric 1-alkyltetrahydroisoquinoline-1-carboxylic acids by resolution of racemic mixtures. Here we describe an enantioselective synthesis of (+)- and (−)-tetrahydro-6,7-dimethoxy-1-methylisoquinoline-1-carboxylic acids; the work is to our knowledge the first report of the enantioselective synthesis of this class of compounds.

Dörnyei and Szántay (5) reported the preparation of **1** and showed that it undergoes stereoselective reduction with hydrides, or with hydrogen in the presence of a catalyst, to the corresponding tetrahydroisoquinoline **2**. We employed the enantiomer of **2** in the enantioselective synthesis of a number of tetrahydroisoquinoline alkaloids having the (*S*) configuration at C-1 of the tetrahydroisoquinoline system (6). Here we show that **1** and its enantiomer may be converted readily and stereoselectively into (+)- and (−)-tetrahydro-6,7-dimethoxy-1-methylisoquinoline-1-carboxylic acids.

The synthesis of the target amino acids from **1** or its enantiomer requires alkylation at C-1 followed by transformation of the three-carbon side chain at C-1 into a carboxylic acid group. In the first approach to the synthesis we proceeded through the nitrone **3** (Scheme 1). A variety of methods were investigated for the conversion of **1** into **3**. The most satisfactory method proved to be an oxidation using hydrogen peroxide in the presence of sodium tungstate. This procedure was originally used for epoxidation of α,β-unsaturated acids (7). Organic peroxy acids have been used also to convert imines into a mixture of nitrones and oxaziranes (8), and a mixture of hydrogen peroxide and sodium tungstate has been used to convert primary amines into oximes (9). In our case, the conversion of imine **1** into nitrone **3** proceeded in 87% yield. The nitrone was characterized through its spectroscopic properties.

Alkylation of **3** was accomplished by treatment with a large excess of methyllithium, a reaction that afforded hydroxylamine **4** in 40% yield. Addition of methyllithium to the carbon–nitrogen double bond was accompanied by alkylation at the ester function to afford a tertiary alcohol. The structure of **4** was deduced from its ^{1}H and ^{13}C nmr spectra. The ^{1}H nmr spectrum had three singlets corresponding to C-Me groups, two singlets attributed to OMe groups, two signals attributed to adjacent CHOH groups, two signals corresponding to aromatic protons, and signals corresponding to the four protons associated with C-3 and C-4 of the tetrahydroisoquinoline system. The signals were assigned through the use of nuclear Overhauser enhancement (nOe) difference spectra and through $^{1}H,^{13}C$ chemical-shift correlation experiments. The nOe experiments showed that irradiation of the C-Me signal at δ 1.59 enhanced the signals at 6.44 and 4.25, whereas irradiation of the C-Me signal at δ 1.13 enhanced the signals at 2.95 and 4.25. On this basis the signal at 1.59 was assigned to the methyl group at C-1 and that at 1.13 to one of the two methyl groups at C-3′. It follows that the signals at δ 2.95, 4.25, and 6.44 may be assigned to H-2′, H-1′, and H-8, respectively. Using these data and the information derived from the $^{1}H,^{13}C$ chemical-shift correlation experiments it was possible to assign virtually all signals in the ^{1}H and ^{13}C nmr spectra of **4**.

[1]Authors to whom correspondence may be addressed.



SCHEME 1

The oxidation of **4** with lead tetraacetate afforded an aldehyde in low yield (13%) as an unstable oil that decomposed rapidly at room temperature. Reduction of **4** with hydrogen over Adams' catalyst converted it in high yield into the secondary amine **5**, a stable compound, which appeared to be a suitable intermediate for elaboration to the target molecule. Thus, an alternative route to **5** was investigated in the hope that the compound might be obtained in higher overall yield.

It was found that **1** upon treatment with an excess of methyllithium afforded **5** in 80% yield. This procedure provided a convenient route to **5** and established that the addition of methyllithium to the nitrone and to the imine proceeded in the same stereochemical sense; however, it was not possible at this stage to establish the configuration at C-1 of **4** or **5**.

The signals of the ^{1}H and ^{13}C nmr spectra of **5** were assigned in a manner similar to that used for **4** through application of nOe difference spectra and $^{1}H,^{13}C$ chemical-shift correlation experiments. Irradiation of the C-Me signal at δ 1.55 enhanced the signals at δ 3.01, 4.07, and 6.45 whereas irradiation of the C-Me signal at δ 1.08 enhanced the signal at 2.98. Also, irradiation at δ 2.55 enhanced the signals at 6.57 and 3.01. Thus, the nOe experiments enabled the signals at δ 1.08, 1.55, 2.55, 2.98, 3.01, 4.07, 6.45, and 6.57 to be assigned, respectively, to a C-Me at C-3′, the C-Me at C-1, an H at C-4, H-2′, a hydrogen at C-3 or C-4, H-1′, H-8, and H-5. These data, together with $^{1}H,^{13}C$ chemical-shift correlation experiments, enabled us to assign the majority of signals in the ^{1}H and ^{13}C spectra of **5**. With the structure of **5** secure it now remained to oxidize the side chain at C-1 to a carboxylic acid (Scheme 2).

The oxidation of the side chain was effected with sodium periodate. When the starting material had been consumed a large excess of sodium borohydride was added to the reaction mixture in order to reduce the aldehyde formed in the oxidation step to a primary alcohol. Upon completion of the reduction reaction the alcohol **6** was isolated in 76% yield from the reaction mixture. Its spectroscopic properties were in agreement with the assigned structure.

The amino alcohol **6** was converted into its 2-ethoxycarbonyl derivative **7** by treatment of **6** with sodium hydroxide and ethyl chloroformate under carefully controlled conditions in a two-phase system. If the reaction time were extended beyond the optimum, compound **7** was slowly converted into the 3*H*-oxazolo[4,3-*a*]isoquinolin-3-one **8**; compound **8** was the major product when the reaction period was 2 h. Also, compound **8** was obtained when methyl chloroformate was substituted for ethyl chloroformate, under the conditions used to prepare **7**.

The oxidation of the primary alcohol group of **7** was now examined. Treatment of **7** with Jones' reagent or with a variety of other common oxidizing agents afforded the aldehyde **9**, which was seemingly impervious to further oxidation. Eventually it was found that oxidation to the carboxylic acid **10** could be effected by treatment of **7** with ruthenium dioxide and sodium periodate (10). Compound **7** was converted, first, into **9** and then much more slowly into **10**. The final step in the synthesis, the hydrolysis of the ethoxycarbonyl group, was effected with aqueous ethanolic hydrochloric acid. The overall yield in the five steps from **1** to **11** was 35%. The spectroscopic properties of compounds **6**–**11** were in accord with the assigned structures.

The absolute configuration of the amino acid **11** was established in the following manner. Brossi and co-workers (4) performed a resolution of racemic salsoline-1-carboxylic acid (**12**) in the form of its methyl ester **12***a* according to the sequence outlined in Scheme 3. The critical step, the separation of the diastereomers **13** and **14**, was accomplished by chromatography. The diastereomerically pure ureas, **13** and **14**, were converted into the hydantoins, **15** and **16**, respectively, and thence into the amino acid hydrochlorides, **17** and **18**. The (+)-enantiomer **17** as its hydrobromide salt was shown by X-ray diffraction to have the (*S*) configuration (4).

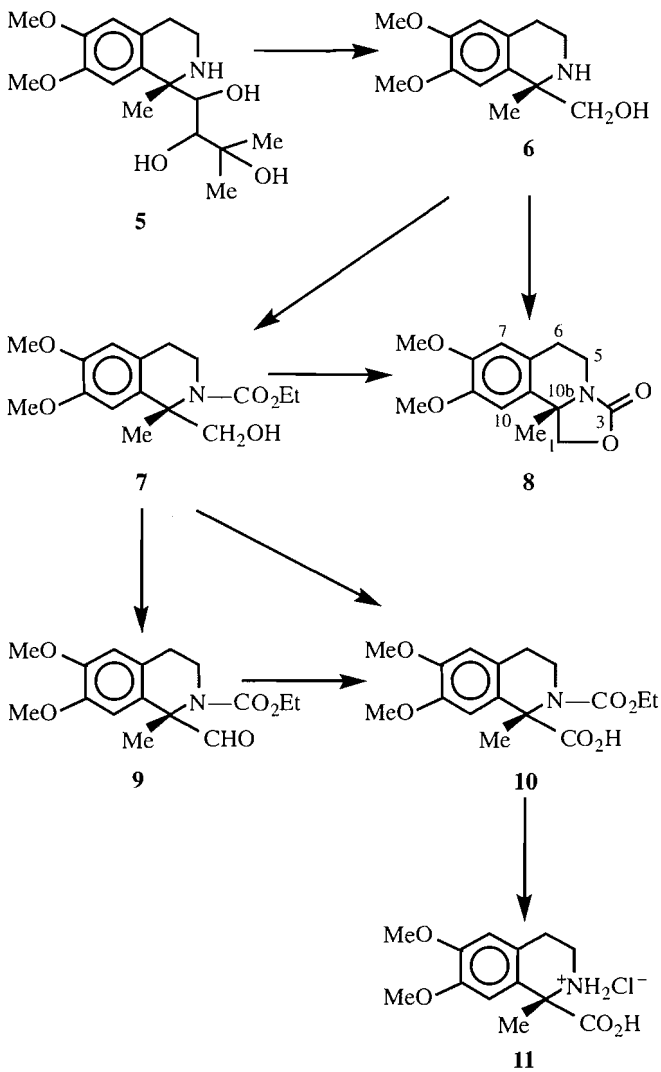

SCHEME 2

It follows, therefore, that the ureas, **13** and **14**, and hydantoins, **15** and **16**, must have the configurations depicted in Scheme 3.

We prepared **13** and **14** by the procedure of Brossi and coworkers (4). Treatment of each isomer with diazomethane afforded the hydantoins, **19** and **20**, respectively. In this reaction the phenolic hydroxyl group was *O*-methylated and, surprisingly, the urea underwent cyclization to the hydantoin. Vigorous hydrolysis of the (*R*,*R*) isomer **20** yielded **22**, the (*R*)-(−)-amino acid hydrochloride. By inference the (+)-enantiomer **21** must have the (*S*) configuration.

In our synthesis the (+)-enantiomer was derived from **1**, which owes its chirality to L-(+)-tartaric acid ((*R*,*R*)-tartaric acid). It is apparent that the methyl group is added from the top face of the molecule to the carbon–nitrogen double bond. The stereoselectivity of the addition reaction may be accounted for if one assumes that the C-1′ oxygen and the imine nitrogen are coordinated with lithium in a five-membered ring. Under these circumstances the bottom face of the molecule is effectively shielded, from attack, by C-2′ and C-3′ and their associated groups (see Fig. 1). The enantiomeric amino acid **22** was obtained through the same reaction sequence using D-(−)-tartaric acid ((*S*,*S*)-tartaric acid) as starting material.

The synthetic route described here should be applicable to the enantioselective synthesis of a variety of 1-alkyl- or 1-aryl-1,2,3,4-tetrahydroisoquinoline-1-carboxylic acids. Further application of the methodology will be reported.

Experimental

The ^{1}H nmr spectra were recorded on a Bruker AM400 or Bruker AM500 spectrometer at 400 or 500 MHz, or a Varian EM390 spectrometer at 90 MHz; $CDCl_3$ was the solvent and tetramethylsilane (TMS) was used as the internal standard, unless otherwise stated. Chemical shifts are reported in ppm (δ) downfield from the signal of TMS. The symbols, s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), and br (broadened), are used to report the multiplicity and shape of signals. The ^{13}C nmr spectra were recorded at 125.76 MHz on a Bruker AM500 FT spectrometer or at 100.6 MHz on a Bruker AM400 spectrometer at ambient temperature. Nuclear Overhauser enhancement (nOe) difference spectra were obtained by subtraction of the off-resonance control FID from the on-resonance FID. The signal of interest was selectively saturated for 5.0 s and the decoupler was gated off during acquisition. This saturation period also served as the relaxation delay. Either 8 or 16 scans were acquired for each irradiation with the cycle of irradiations repeated 4–10 times. Free induction decays were processed using exponential multiplication (line broadening: 4–5 Hz) before Fourier transformation. Samples were not degassed. EI mass spectra were recorded on a VG Micromass 7070F mass spectrometer at an ionizing voltage of 70 eV or on a VG Analytical ZAB-E mass spectrometer, and CI spectra were recorded using NH_3 at ~1 Torr (1 Torr = 133.3 Pa) as reagent gas; data are given as *m/z* (% relative intensity.) The exact masses were determined under EI conditions for those compounds which gave molecular ions in their EI spectra, and under CI conditions using methane as reagent gas for those compounds which did not have molecular ions in their EI spectra. The high-resolution measurements were performed by peak matching using perfluorokerosene as a reference standard and at a resolution of ~4000.

Melting points were determined using a Gallenkamp or a Fisher–Johns apparatus and are uncorrected. Optical rotations were measured using a Perkin–Elmer 247MC or 241 polarimeter in a 1-mL microcell that is 1 dm in length. Flash chromatography was performed on Kieselgel 60 (230–400 mesh). Preparative high-pressure liquid chromatography (HPLC) was performed using a Waters PrepLC System 500 instrument fitted with a PrepPAK 500 silica column.

The homogeneity of the products was established on the basis of chromatographic and spectroscopic (^{1}H nmr and mass spectral) examination.

Preparation of the nitrone 3

A stirred solution of **1** (5) (7.10 g) in water (25 mL) was cooled to 0°C in an ice–salt bath and treated first with sodium tungstate dihydrate (6.10 g) and then with a saturated aqueous solution of sodium hydrogencarbonate (50 mL). To the resulting mixture hydrogen peroxide (30%, 10 mL) was added over a period of 10 min and the solution stirred for an additional 30 min. The solution was then treated with sodium chloride (10 g) and extracted four times with chloroform. The extract was washed with a saturated aqueous solution of sodium chloride, dried over sodium sulfate, and taken to dryness. The crystalline residue was recrystallized from chloroform–ether to afford **2** (5.83 g, 87%) as colorless crystals; mp 178–180°C (dec.); $[\alpha]_D^{23}$ −150.24 (*c* 8.16, $CHCl_3$); ν_{max}(KBr): 1600, 1615, 1735, 1755 cm^{-1}; ^{1}H nmr (90 MHz) δ: 2.96–3.23 (2H, m, C-4 H's), 3.76 (3H, s, CO_2CH_3), 3.93 and 3.98 (3H each, s, 2 × $ArOCH_3$), 4.03–4.23 (2H, m, C-3 H's), 4.63 (1H, d, J = 3.6 Hz, H-2′), 5.27 (1H, d, J = 3.6 Hz, H-1′), 6.80 and 6.98 (1H each, s, H-5 and H-8), the OH protons appear as a broad signal in the

region 3.5–4.5; ms (EI): 325 (M^+) (10), 308 (10), 248 (11), 236 (100), 219 (82), 204 (14); ms (CI, NH_3): 326 $(M + H)^+$ (95), 308 (37), 292 (10), 276 (15), 220 (100). Exact Mass calcd. for $C_{15}H_{19}NO_7$: 325.1161; found (hrms): 325.1159.

*Treatment of nitrone **3** with methyllithium*

A solution of methyllithium in diethyl ether (1.5 M, 55 mL) was added slowly over a period of 20 min to a stirred solution of **3** (3.00 g) in tetrahydrofuran (100 mL) at −70°C. The mixture was stirred at the same temperature for 40 min, the cooling bath removed, and first methanol (20 mL), and then acetic acid (5 mL), were added slowly. The resulting mixture was evaporated to dryness and a saturated aqueous solution of sodium chloride (30 mL) was added to the residue. The mixture was extracted three times with 30-mL portions of chloroform, and the extract was washed, dried, and evaporated to dryness. Chromatography of the residue on silica (Merck, 230–400 mesh) was effected with chloroform–methanol (98:2, v/v) to afford **4** as a brown oil that crystallized on standing. Recrystallization from a mixture of chloroform – diethyl ether – petroleum ether gave **4** as long needles (40%), mp 158–160°C (dec.); $[\alpha]_D^{25}$ +170.9 (*c* 1.5, $CHCl_3$); ^1H nmr (500 MHz) δ: 1.09 and 1.13 (3H each, s, CH_3's at C-3′), 1.59 (3H, s, CH_3 at C-1), 2.62 (1H, d, J = 15.0 Hz, H-4_{ax}), 2.95 (1H, s, H-2′), 3.08 and 3.12 (2H, m, H-3_{ax}, H-3_{eq}), 3.15 (1H, m, H-4_{eq}), 3.75 and 3.79 (3H each, s, 2 × ArOCH_3), 4.25 (1H, s, H-1′), 6.43 and 6.52 (1H, each, s's, H-8 and H-5, resp.), the OH protons appear as 3 broad signals centered at 3.51, 5.35, and 7.50; ^{13}C nmr ($CDCl_3$) δ: 17.5 (CH_3 at C-1), 24.9 and 27.4 (CH_3's at C-3′), 29.4 (C-4), 48.1 (C-3), 55.7 and 59.9 (OCH_3), 67.9 (C-1), 74.0 (C-3′), 74.2 (C-2′), 78.0 (C-1′), 108.6 (C-8), 111.2 (C-5), 126.3 (C-8a), 130.2 (C-4a), 147.6 and 147.9 (C-6 and C-7); ms (CI, NH_3): 342 $(M + H)^+$ (10), 326 (12), 222 (50), 206 (100), 190 (20). Exact Mass calcd. for $C_{17}H_{28}NO_6$ $(M + H)^+$: 342.1916; found (hrms): 342.1913.

*Reduction of hydroxylamine **4** to amine **5***

A sample of **4** (90 mg) was dissolved in methanol (30 mL) containing distilled water (10 mL) and acetic acid (4 drops), PtO_2 catalyst (20 mg) was added, and the stirred mixture was treated with hydrogen at atmospheric pressure for 4 h. The catalyst was removed, the volatile solvents evaporated, and the residual solution was made basic by addition of an aqueous solution of sodium carbonate (10%, 10 mL) and then extracted with chloroform (3 × 15 mL). The extract was washed, dried, and evaporated to afford a residue that was purified by chromatography on silica (230–400 mesh). Residual starting material was eluted using chloroform–methanol (98:2, v/v) and the product **5** using chloroform–methanol (4:1, v/v). Compound **5** was obtained as a colorless oil (71 mg, 83%); $[\alpha]_D^{25}$ +81.9 (*c* 2.83, $CHCl_3$). (See below for spectroscopic data.)

*Preparation of **5** by treatment of **1** with methyllithium*

A suspension of **1** (4.50 g) in dry 1,2-dimethoxyethane (150 mL) at −10 to −5°C was treated with methyllithium in diethyl ether (1.5 M, 90 mL) over a period of 30 min under a nitrogen atmosphere. The mixture was stirred at the same temperature for 3 h and then treated with methanol (30 mL) to destroy the excess of reagent. The volatile solvents were removed by evaporation, water (45 mL) was added to the residue, and the mixture was extracted with chloroform (5 × 30 mL). The extract was washed, dried, and evaporated to afford a residue that was chromatographed on silica (70–230 mesh) using chloroform–methanol (98:2, v/v) to remove nonpolar impurities. Further elution using chloroform–methanol (4:1, v/v) gave **5** as a brownish oil (3.37 g, 80%); $[\alpha]_D^{25}$ +80.5 ±2 (*c* 2.30, $CHCl_3$) (the rotation was difficult to measure because of the dark solution); ^1H nmr (500 MHz) δ: 1.08 and 1.18 (3H each, s's, C-CH_3's at C-3′), 1.55 (3H, s, CH_3 at C-1), 2.55 (1H, m, H-4_{ax}), 2.98 (1H, s, H-2′), 2.99 (1H, m, H-4_{eq}), 3.01 and 3.10 (2H, m, H-3's), 3.77 and 3.82 (3H each, s's, 2 × OCH_3), 4.07 (1H, s, H-1′), 6.45 and 6.57 (1H each, s's, H-8 and H-5, resp.), OH and NH signals appear as a broad singlet at 4.50; ^{13}C nmr ($CDCl_3$) δ: 24.1 and 27.6 (CH_3's at C-3′), 25.7 (CH_3 at C-1), 29.8 (C-4), 37.9 (C-3), 59.7 (C-1), 74.0 (C-3′), 74.6 (C-2′), 75.5

(C-1′), 108.5 (C-8), 112.1 (C-5), 127.7 (C-8a), 130.5 (C-4a), 147.5 (C-6 and C-7); ms(EI): 310 $(M - 15)^+$ (5), 266 (8), 206 (100), 190 (4); ms(CI, NH_3): 326 $(M + 1)^+$ (100), 206 (14); Exact Mass calcd. for $C_{17}H_{28}NO_5$ $(M + H)^+$: 326.1967; found (hrms): 326.1963.

*Preparation of 1,2,3,4-tetrahydro-1-hydroxymethyl-6,7-dimethoxy-1-methylisoquinoline (**6**)*

The amine **5** (608 mg) in methanol (100 mL) at −5°C was treated all at once with a solution of sodium periodate (1.0 g) in water (5 mL). The progress of the reaction was monitored by thin-layer chromatography (TLC) (chloroform–methanol (4:1, v/v), silica gel), and, when the starting material was consumed (~40 min), a large excess of sodium borohydride was added over a period of 15 min. The mixture was allowed to warm to room temperature, filtered to remove inorganic matter, and the filtrate evaporated to dryness. The residue was quenched with water (40 mL) and the mixture extracted with chloroform (4 × 25 mL). The extract was dried, evaporated, and the residue chromatographed on silica (230–400 mesh) using chloroform–methanol (19:1, v/v) to remove nonpolar impurities, and then chloroform–methanol (4:1, v/v) to elute **6**. Removal of solvent afforded **6** as a yellowish oil in 76% yield. A solution of **6** in chloroform decomposed rapidly; $[\alpha]_D^{25}$ −9.2 (*c* 3.09, $CHCl_3$); ^{1}H nmr (90 MHz) δ: 1.38 (3H, s, C-CH_3), 2.57 (2H, br s, NH, OH, disappeared on addition of D_2O), 2.66 (2H, m, H-4_{ax} and H-4_{eq}), 3.02 (2H, m, H-3_{ax} and H-3_{eq}), 3.43 and 3.85 (2H, AB q, J = 7.5 Hz, CH_2OH), 3.88 (6H, s, 2 × OCH_3), 6.58 and 6.65 (1H each, s's, H-5 and H-8); ms (CI, CH_4): 238 $(M + 1)^+$ (25), 220 (7), 206 (100), 192 (15); ms (CI, NH_3): 238 $(M + H)^+$ (100), 220 (15), 206 (85), 192 (8). Exact Mass calcd. for $C_{13}H_{20}NO_3$ $(M + H)^+$: 238.1443; found (hrms); 238.1453.

*2-Ethoxycarbonyl-1,2,3,4-tetrahydro-1-hydroxymethyl-6,7-dimethoxy-1-methylisoquinoline (**7**)*

A solution of **6** (602 mg) in chloroform (15 mL) and an aqueous solution composed of sodium hydroxide (4.5 g) and acetic acid (0.5 g) in water (15 mL) were mixed and vigorously stirred. To this two-phase system ethyl chloroformate (3 mL) was added in two portions at 5-min intervals and the stirring continued for 15 min. The temperature was kept below 20°C. The organic layer was separated, washed with an aqueous solution of sodium chloride, dried, and evaporated to afford **7** as a homogeneous oil (TLC, chloroform–methanol (19:1, v/v)). The compound crystallized slowly from petroleum ether containing a small amount of benzene, yield 89%; mp 106–108°C; $[\alpha]_D^{23}$ +137.3 (*c* 1.87, $CHCl_3$); ^{1}H nmr (500 MHz) δ: 1.31 (3H, t, J = 7.1 Hz, CH_2CH_3), 1.68 (3H, s, CH_3 at C-1), 2.62 (1H, distorted d, J = 15.5 Hz, H-4_{ax}), 2.84 (1H, m, H-4_{eq}), 3.28 (1H, m, H-3_{eq}), 3.79 (1H, d, J = 12.2 Hz, C*H*-OH), 3.86 (6H, s, 2 × OCH_3), 4.18 (2H, q, J = 7.1 Hz, CH_2CH$_3$) and (1H, m, H-3_{ax}), 4.25 (1H, d, J = 12.2 Hz, C*H*-OH), 4.80 (1H, br s, OH, disappears on addition of D_2O), 6.56 and 6.77 (1H each, s's, H-5 and H-8); ms(EI): 278 $(M - 31)^+$ (18), 263 (16), 248 (100), 205 (5), 190 (10); ms (CI, NH_3): 310 $(M + H)^+$ (7), 281 (100), 264 (55), 248 (10). Exact Mass calcd. for $C_{16}H_{24}NO_5$ $(M + H)^+$: 310.1654; found (hrms): 310.1653.

*1,5,6,10b-Tetrahydro-8,9-dimethoxy-10b-methyl-3H-oxazolo[4,3-a]isoquinolin-3-one (**8**)*

The title compound was isolated in 70% yield when methyl chloroformate was substituted for ethyl chloroformate under the conditions described above for the preparation of **7**. It was isolated also in reactions with ethyl chloroformate when the reactions were allowed to proceed for periods longer than 15–20 min, and is the preponderant product at reaction times greater than 2 h. Compound **8** was isolated as a colorless oil, $[\alpha]_D^{23}$ +213.9 (*c* 1.88, $CHCl_3$); ^{1}H nmr (90 MHz) δ: 1.63 (3H, s, CH_3 at C-1), 2.50–3.43 (3H, m, H-4_{ax}, H-4_{eq}, H-3_{ax}), 3.88 (6H, s, 2 × OCH_3), 3.95–4.17 (1H, m, H-3_{eq}), 4.38 (2H, AB q, J = 9.0 Hz, CH_2-OH), 6.57 and 6.65 (1H each, s's, H-5 and H-8); ms(EI): 263 $(M)^+$ (35), 248 (100); ms (CI, NH_3); 264 $(M + H)^+$ (30), 248 (100). Exact Mass calcd. for $C_{14}H_{18}NO_4(M + H)^+$: 264.1236; found (hrms): 264.1234.

*Preparation of 2-ethoxycarbonyl-1,2,3,4-tetrahydro-6,7-dimethoxy-1-methylisoquinoline-1-carboxaldehyde (**9**)*

A solution of **7** (164 mg) in acetone (distilled from $KMnO_4$, 10 mL) was treated dropwise with stirring at room temperature with Jones' reagent (0.23 mL). After 5 min the excess of oxidant was destroyed by addition of methanol (0.5 mL) and the resulting mixture evaporated to dryness. A saturated aqueous solution of sodium chloride (10 mL) was added to the residue and the mixture extracted with chloroform (3 × 5 mL). The extract was washed, dried, and evaporated to afford a residue that was chromatographed on silica gel using chloroform as eluant. Compound **9** was obtained as a colorless oil (61%), $[\alpha]_D^{23}$ −72.1 (*c* 2.32, $CHCl_3$); ^{1}H nmr (90 MHz) δ: 1.30 (3H, t, J = 7.0 Hz, CH_2CH_3), 1.73 (3H, s, CH_3 at C-1), 2.58–3.23 (3H, m, H-4_{ax}, H-4_{eq}, H-3_{ax}), 3.85 and 3.88 (3H each, s's, 2 × OCH_3), 4.25 (2H, q, J = 7.0 Hz, CH_2CH$_3$, and 1H, m, H-3_{eq}), 6.58 and 6.65 (1H each, s's, H-5 and H-8), 9.15 (1H, s, CH=O); ms (CI, NH_3): 308 $(M + H)^+$ (100), 278 (12), 206 (8). Exact Mass calcd. for $C_{16}H_{22}NO_5$ $(M + H)^+$: 308.1497; found (hrms): 308.1498.

*Preparation of 2-ethoxycarbonyl-1,2,3,4-tetrahydro-6,7-dimethoxy-1-methylisoquinoline-1-carboxylic acid (**10**)*

A solution of **7** (410 mg) in a mixture of acetone (35 mL) and water (7 mL) was treated with $RuO_2 \cdot xH_2O$ (13% water, Alfa Products) (10 mg) and sodium periodate (99.8%, Aldrich) (600 mg). The mixture was stirred for ~48 h at room temperature or until the reaction was complete as indicated by TLC (chloroform–methanol (19:1, v/v)). (It was established that the alcohol **7** was completely converted into aldehyde **9** after 2–3 h.) The reaction mixture was then treated with water (50 mL) and ethylene glycol (10 mL). The volatile solvent was removed, the residual liquid made basic with sodium hydroxide, and the basic solution extracted with chloroform (3 × 15 mL). The aqueous solution was acidified with hydrochloric acid and extracted with chloroform (3 × 20 mL). The latter extract was dried and evaporated to afford a residual oil that crystallized from water to afford compound **10** (274 mg, 64%), mp 191–193°C; $[\alpha]_D^{25}$ +65.6 (*c* 0.57, $CHCl_3$); ^{1}H nmr (90 MHz) δ: 1.24 (3H, t, J = 7.0 Hz, CH_2CH_3), 1.82 (3H, s, CH_3 at C-1), 2.50–3.40 (3H, m, H-4_{ax}, H-4_{eq}, H-3_{ax}), 3.80 and 3.85 (3H each, s's, 2 × OCH_3), 4.14 (2H, q, J = 7.0 Hz, CH_2CH$_3$, and 1H, m, H-3_{eq}), 6.62 and 6.82 (1H each, s's, H-5 and H-8), 8.70 (1H, br s, CO_2H, disappears on addition of D_2O); ms (CI, NH_3): 341 $(M + NH_4)^+$ (95), 324 $(M + H)^+$ (100), 278 (85), 264 (24), 206 (62); ms (EI): 278 (100), 264 (88), 250 (35), 206 (53), 190 (34). Exact Mass calcd. for $C_{16}H_{22}NO_6$ $(M + H)^+$: 324.1447; found (hrms): 324.1452.

*Preparation of 1,2,3,4-tetrahydro-6,7-dimethoxy-1-methylisoquinoline-1-carboxylic acid hydrochloride (**11**)*

Compound **10** (213 mg) was dissolved in a solution of water (4 mL), ethanol (2 mL), and concentrated hydrochloric acid (0.5 mL) and the solution heated gently at reflux temperature for 7 days; the progress of the reaction was monitored by TLC (methanol–chloroform (1:9, v/v)). The residue obtained on evaporation of the reaction mixture was dried overnight in a vacuum desiccator over P_2O_5. The residue was taken up in the minimum amount of isopropyl alcohol and then diisopropyl ether was added to afford a fine, hygroscopic powder (187 mg) in 98% yield (based on **10**), mp 210°C (dec.); $[\alpha]_D^{25}$ +44.6 (*c* 1.12, CH_3OH); ^{1}H nmr (400 MHz, D_2O, sodium 3-(trimethylsilyl)-1-propanesulfonate as internal standard) δ: 1.85 (3H, s, CH_3 at C-1), 3.01 (2H, m, H-4_{ax} and H-4_{eq}), 3.48 (2H, m, H-3_{ax} and H-3_{eq}), 3.83 (3H, s, OCH_3 at C-7), 3.87 (3H, s, OCH_3 at C-6), 6.85 (1H, s, H-5), 7.16 (1H, s, H-8); ms (CI, NH_3): 503 $(2M + H)^+$(6), 252 $(M + H)^+$ (15), 234 (12), 220 (10), 206 (100), 192 (26). Exact Mass calcd. for $C_{13}H_{18}NO_4$ $(M + H)^+$: 252.1236; found (hrms): 252.1232.

The enantiomer of **11** was prepared by the same sequence of reactions, starting with the enantiomer of **1**, and had mp 250–253°C (dec.); $[\alpha]_D$ −52.2 (*c* 0.58, H_2O).

*(±)-1,2,3,4-Tetrahydro-6-hydroxy-7-methoxy-1-methoxycarbonyl-1-methylisoquinoline (**12**a)*

(3-Hydroxy-4-methoxyphenyl)ethylamine hydrochloride (1.905 g, 9.35 mmol) was dissolved in aqueous ammonia (2.9 mL). Distilled pyruvic acid (1.24 g, 14 mmol) was added cautiously, with cooling to control the vigorous exothermic reaction. The pH of the solution was adjusted to 7 with concentrated hydrochloric acid, and the reaction mixture was stirred at 32°C for 18 h. The precipitated product was isolated by filtration, and was dried under vacuum at 50°C to afford the racemic amino acid **12** as pale yellow crystals (1.99 g, 89%). An analytical sample was obtained by recrystallization from water to afford white needles; mp 260°C (dec.) (lit. (11) mp 254°C (dec.)); ^{1}H nmr (400 MHz, D_2O, K_2CO_3, sodium 3-(trimethylsilyl)-1-propanesulfonate as internal standard) δ: 1.46 (3H, s, CH_3 at C-1), 2.51–2.68 (2H, m, H-4 and H-4′), 2.97 (2H, m, H-3 and H-3′), 3.65 (3H, s, OCH_3), 6.32 (1H, s, H-5), 6.80 (1H, s, H-8).

Acid **12** was immediately esterified (see ref. 4). A suspension of the acid (1.99 g, 8.39 mmol) in dry methanol (20 mL) was cooled in an ice bath while thionyl chloride (4 mL, 50 mmol) was slowly added. During the addition, the suspension cleared, and then became turbid again. The cooling was terminated, and the mixture was stirred at reflux temperature for 5 h and then at 20°C overnight. TLC (1-butanol–water – acetic acid (4:1:1, v/v)) indicated that the reaction was incomplete; accordingly, the reaction mixture was heated at reflux temperature for an additional 1.5 h. The mixture was cooled, quenched with a saturated aqueous solution of sodium hydrogen carbonate (20 mL), and extracted with chloroform. The extract was dried over anhydrous magnesium sulfate and concentrated to give a solid. Recrystallization from dichloromethane–hexanes gave the ester **12***a* (1.16 g, 55%); mp 154–156°C (lit. (4) mp 156–157°C); ^{1}H nmr (400 MHz) δ: 1.62 (3H, s, CH_3 at C-1), 2.50–2.61 (1H, m, H-4), 2.68–2.80 (1H, m, H-4′), 3.00–3.09 (2H, m, H-3 and H-3′), 3.70 (3H, s, ester OCH_3), 3.85 (3H, s, ether OCH_3), 6.60 (1H, s, H-5), 6.87 (1H, s, H-8).

Acidification of the aqueous layer, concentration to dryness, and extraction of the solid residue with methanol allowed recovery of racemic **12** as its hydrochloride salt (0.522 g, 1.9 mmol). Taking this into account, the yield of **12***a* was 71%.

*(1S)-1,2,3,4-Tetrahydro-6-hydroxy-7-methoxy-1-methoxycarbonyl-1-methyl-2-[{(R)-1-phenylethyl}carbamoyl]isoquinoline (**13**) and its (1R) diastereomer (**14**)*

The ester **12***a* (1.159 g, 4.61 mmol) was dissolved in dry chloroform (20 mL). The solution was cooled to 0°C, and (*R*)-(+)-α-methylbenzyl isocyanate (730 μL, 5.08 mmol) was added dropwise (see ref. 4). The reaction was allowed to proceed at 0°C for 2 h and then the mixture was warmed to 20°C. Removal of solvent afforded a residue that solidified on standing under vacuum. The crude mixture of diastereomers (2.13 g) was resolved by preparative HPLC on silica using hexanes – ethyl acetate (3:1, v/v) as eluant. The product fractions (500 mL) were identified by TLC; the plates were developed 6 times (hexanes – ethyl acetate (3:1, v/v)) in order to separate the two diastereomers. The less-polar diastereomer **13** (757 mg, 41%) was obtained as a glassy foam, and the more-polar isomer **14** (702 mg, 38%) as crystals. Compound **13**: $[\alpha]_D^{25}$ +61.9 (*c* 1.7, $CHCl_3$) (lit. (4) $[\alpha]_D^{25}$ +56.1 (*c* 1.5, $CHCl_3$)). According to ref. 4 compound **13** has the (*S*,*R*) configuration; ^{1}H nmr (400 MHz) δ: 1.46 (3H, d, J = 7.0 Hz, $CHCH_3$), 1.77 (3H, s, CH_3 at C-1), 2.75 (1H, ddd, $J_{3ax,4eq}$ = 5.0 Hz, $J_{3eq,4eq}$ = 6.0 Hz, J_{gem} = 15.0 Hz, H-4_{eq}), 2.90 (1H, ddd, $J_{3eq,4ax}$ = 4.5 Hz, $J_{3ax,4ax}$ = 8.0 Hz, J_{gem} = 15.0 Hz, H-4_{ax}), 3.39 (3H, s, ester OCH_3), 3.42–3.36 (1H, m, H-3_{ax}), 3.56 (1H, ddd, $J_{3eq,4ax}$ = 4.5 Hz, $J_{3eq,4eq}$ = 6.0 Hz, J_{gem} = 12.0 Hz, H-3_{eq}), 3.78 (3H, s, ether OCH_3), 4.73 (1H, d, J = 7.0 Hz, NH), 4.98 (1H, dq, $J_{to\ NH}$ = 7.0 Hz, $J_{to\ CH_3}$ = 7.0 Hz, benzylic H), 5.63 (1H, s, OH), 6.65 (1H, s, H-5 or H-8), 6.69 (1H, s, H-5 or H-8), 7.17–7.34 (5H, m, phenyl H's). Compound **14**: mp 138–140°C; $[\alpha]_D^{25}$ −36.5 (*c* 1.2, $CHCl_3$) (lit.(4) mp 139–140°C; $[\alpha]_D^{25}$ −34.3 (*c* 1.2, $CHCl_3$)). According to ref. 4 compound **14** has the (*R*,*R*) configuration; ^{1}H nmr (400 MHz) δ: 1.47 (3H, d, J = 7.0 Hz, $CHCH_3$), 1.74 (3H, s, CH_3 at C-1), 2.78 (1H, ddd, $J_{3ax,4eq}$ = 3.5 Hz, $J_{3eq,4eq}$ = 5.5 Hz, J_{gem} = 15.5 Hz, H-4_{eq}), 2.93 (1H, ddd, $J_{3eq,4ax}$ = 4.0 Hz, $J_{3ax,4ax}$ = 9.0 Hz, J_{gem} = 15.5 Hz, H-4_{ax}), 3.32 (1H, ddd, $J_{3ax,4eq}$ = 3.5 Hz, $J_{3ax,4ax}$ = 9.0 Hz, J_{gem} = 12.0 Hz, H-3_{ax}), 3.62 (3H, s, ester OCH_3), 3.66–3.53 (1H, m, H-3_{eq}), 3.80 (3H, s, ether OCH_3), 4.69 (1H, d, $J_{to\ benzylic\ H}$ = 7.2 Hz, NH), 5.03 (1H, dq, $J_{to\ NH}$ = 7.2 Hz, $J_{to\ CH_3}$ = 7.0 Hz, benzylic H), 5.60 (1H, s, OH), 6.66 (1H, s, H-5 or H-8), 6.72 (1H, s, H-5 or H-8), 7.20–7.40 (5H, m, phenyl H's).

*(10bS)-6,10b-Dihydro-8,9-dimethoxy-10b-methyl-2-[(R)-1-phenylethyl]-5H-imidazo[4,3-a]isoquinoline-1(2H),3(4H)-dione (**19**)*

The less-polar phenol **13** (620 mg, 1.56 mmol) was dissolved in methanol (5 mL), and the solution was cooled to 0°C. A solution of diazomethane in ether (~10 mmol) was added gradually. The cooling was terminated, and the reaction mixture was stirred for 16 h at 23°C. The excess of diazomethane was evaporated under a stream of nitrogen, and the remaining solvent was evaporated. The resulting semi-solid was triturated with ether to afford **19** as white crystals (518 mg, 87%); mp 127–130°C; $[\alpha]_D^{25}$ +112.9 (*c* 1.15, $CHCl_3$); ^{1}H nmr (400 MHz) δ: 1.61 (3H, s, CH_3 at C-10b), 1.77 (3H, d, $J_{to\ benzylic\ H}$ = 7.3 Hz, $CHCH_3$), 2.59 (1H, dd, $J_{5ax,6eq}$ = 4.0 Hz, J_{gem} = 16.3 Hz, H-6_{eq}), 2.95 (1H, ddd, $J_{5eq,6ax}$ = 6.0 Hz, $J_{5ax,6ax}$ = 12.7 Hz, J_{gem} = 16.3 Hz, H-6_{ax}), 3.17 (1H, ddd, $J_{5ax,6eq}$ = 4.0 Hz, $J_{5ax,6ax}$ = 12.7 Hz, J_{gem} = 13.3 Hz, H-5_{ax}), 3.85 (3H, s, OCH_3 at C-9), 3.90 (3H, s, OCH_3 at C-8), 4.31 (1H, dd, $J_{5eq,6eq}$ = 6.0 Hz, J_{gem} = 13.3 Hz, H-5_{eq}), 5.33 (1H, q, J = 7.3 Hz, $CHCH_3$), 6.56 (1H, s, H-10), 7.24 (1H, s, H-7), 7.22–7.46 (5H, *m*-phenyl H's); ^{13}C nmr (100.6 MHz, $CDCl_3$) δ: 17.2($CHCH_3$), 26.4 (CH_3 at C-10b), 27.5 (C-6), 35.4 (C-5), 50.5 ($CHCH_3$), 55.8 (OCH_3), 56.0 (OCH_3), 60.8 (C-10b), 108.6 (C-7), 111.3 (C-10), 124.8 (C-10a), 125.8 (C-6a), 127.0 (*o*-phenyl C's), 127.5 (*p*-phenyl C), 128.4 (*m*-phenyl C's), 140.1 (phenyl quaternary C), 147.9 (C-8 or C-9), 148.6 (C-8 or C-9), 155.6 (C-3), 175.0 (C-1). Exact Mass calcd. for $C_{22}H_{24}N_2O_4$: 380.1737; found (hrms): 380.1733.

*(10bR)-6,10b-Dihydro-8,9-dimethoxy-10b-methyl-2-[(R)-1-phenylethyl]-5H-imidazo[4,3-a]isoquinoline-1(2H),3(4H)-dione (**20**)*

The more-polar phenol **14** (640 mg, 1.61 mmol) was treated with diazomethane as described above. Trituration and filtration provided white crystals of **20** (612 mg, ~100%). A sample was recrystallized from diisopropyl ether to afford colorless needles; mp 132°C; $[\alpha]_D^{25}$ −72.9 (*c* 1.29, $CHCl_3$); ν_{max}(KBr): 1760 (m), 1700 (s), 1605, 1512, 1400, 1250 cm^{-1}; ^{1}H nmr (400 MHz) δ: 1.67 (3H, s, CH_3 at C-10b), 1.80 (3H, d, J = 7.3 Hz, $CHCH_3$), 2.61 (1H, dd, $J_{5ax,6eq}$ = 4.0 Hz, J_{gem} = 16.5 Hz, H-6_{eq}), 2.98 (1H, ddd, $J_{5eq,6ax}$ = 6.0 Hz, $J_{5ax,6ax}$ = 12.0 Hz, J_{gem} = 16.5 Hz, H-6_{ax}), 3.16 (1H, ddd, $J_{5ax,6eq}$ = 4.0 Hz, $J_{5ax,6ax}$ = 12.0 Hz, J_{gem} = 13.5 Hz, H-5_{ax}), 3.85 (3H, s, OCH_3 at C-9), 3.91 (3H, s, OCH_3 at C-8), 4.28 (1H, dd, $J_{5eq,6eq}$ = 6.0 Hz, J_{gem} = 13.5 Hz, H-5_{eq}), 5.36 (1H, q, J = 7.3 Hz, $CHCH_3$), 6.57 (1H, s, H-10), 7.25 (1H, s, H-7), 7.23–7.46 (5H, *m*-phenyl H's); ^{13}C nmr (100 MHz, $CDCl_3$) δ: 17.3 ($CHCH_3$), 26.4 (CH_3 at C-10b), 27.4 (C-6), 35.3 (C-5), 50.3, ($CHCH_3$), 55.8 (OCH_3), 56.0 (OCH_3), 61.1 (C-10b), 108.6 (C-7), 111.3 (C-10), 124.9 (C-10a), 125.8 (C-6a), 127.0 (*o*-phenyl C's), 127.6 (*p*-phenyl C), 128.4 (*m*-phenyl C's) 140.0 (phenyl quaternary C), 147.8 (C-8 or C-9), 148.6 (C-8 or C-9), 155.5 (C-3), 175.3 (C-1). Exact Mass calcd. for $C_{22}H_{24}N_2O_4$: 380.1737; found (hrms): 380.1744.

*(R)-1,2,3,4-Tetrahydro-6,7-dimethoxy-1-methylisoquinoline-1-carboxylic acid hydrochloride (**22**)*

The (*R*,*R*)-hydantoin **20** (350 mg, 0.92 mmol) was dissolved in methyl cellosolve (3.5 mL). An aqueous 20% sodium hydroxide solution (3 mL) was added, and the mixture was heated at reflux temperature for 3.5 h. The reaction mixture was cooled and acidified to pH 2 with concentrated hydrochloric acid. The mixture was filtered, the filtrate concentrated, and the residue taken up in 2-propanol. The mixture was filtered and the filtrate was concentrated to dryness. The residue was fractionated by column chro-

matography (1-butanol – acetic acid – methanol (5:1:1, v/v)). Compound **22** was obtained as white crystals (78 mg, 31%) that were recrystallized from methanol – isopropyl ether; mp 255–262°C (dec.); $[\alpha]_D^{25}$ −56.3 (*c* 1.2, H_2O). The ^1H nmr spectrum (400 MHz, D_2O) was identical with that obtained for compound **11**.

Received August 7, 1991

This paper is dedicated to Professor Zdenek (Denny) Valenta on the occasion of his 65th birthday

F. GREIN and P. DESLONGCHAMPS. Can. J. Chem. **70**, 1562 (1992).

Geometry optimizations at the 6-31G** level were performed on various conformers of $XH_mCH_2YH_n$ and $XH_mCH_2YH_{n+1}^+$ (protonated), with X, Y = N, O. The resulting anomeric stabilization energies were decomposed into steric, electrostatic (lone pair – lone pair, lone pair – hydrogen), and electronic contributions. Using approximate values for steric and electrostatic terms, the electronic energy was determined to be about −2 kcal/mol for the anomeric effect to arise from O, and −2.5 kcal/mol if it arises from N. For protonated systems, an additional energy term for the reverse anomeric effect had to be added, having a value of −4 kcal/mol for O in $OH\text{-}CH_2\text{-}NH_3^+$ and −5 kcal/mol for N in $NH_2\text{-}CH_2\text{-}NH_3^+$. The anomeric effect due to N drives $NH_2\text{-}CH_2\text{-}OH_2^+$ to a charge-dipole complex of the type $NH_2{=}CH_2^+ \ldots OH_2$. The energy parameters obtained have been applied to predict relative stabilities of various conformers of methanetriol, aminomethanediol, and protonated methanetriol, with good success.

F. GREIN et P. DESLONGCHAMPS. Can. J. Chem. **70**, 1562 (1992).

On a effectué des optimisations de géométries, au niveau 6-31G**, pour divers conformères de $XH_mCH_2YH_n$ et $XH_mCH_2YH_{n+1}^+$ (protonés) dans lesquels, X, Y = N, O. Les énergies de stabilisation anomériques qui en résultent ont été décomposées en contributions stériques, électrostatiques (paire libre/paire libre, paire libre/hydrogène) et électroniques. Utilisant des valeurs approximatives pour les termes stériques et électrostatiques, on a déterminé que l'énergie électronique de l'effet anomérique est d'environ −2,0 kcal/mol s'il est dû à l'oxygène et d'environ −2,5 kcal/mol s'il est dû à l'azote. Pour les systèmes protonés, on a dû ajouter un terme additionnel d'énergie pour l'effet anomérique inverse; sa valeur est de −4 kcal/mol pour O dans $HO\text{-}CH_2\text{-}NH_3^+$ et de −5 kcal/mol pour N dans $NH_2\text{-}CH_2\text{-}NH_3^+$. L'effet anomérique dû au N force le $NH_2\text{-}CH_2\text{-}OH_2^+$ vers un complexe de charge dipolaire du type $NH_2{=}CH_2^+ \ldots OH_2$. On a appliqué les paramètres d'énergie obtenus pour prédire avec succès les stabilités relatives de divers conformères du méthanetriol, de l'aminométhanediol et du méthanetriol protoné.

[Traduit par la rédaction]

Introduction

A vast amount of literature, both experimental and theoretical, has appeared on the anomeric effect. Suitable reviews can be found in the books by Deslongchamps (1) and Kirby (2), and in the review article by Gorenstein (3).

It has been known for a long time that quantum chemical calculations are quite capable of reproducing the experimental findings on stabilization energies and geometry changes (4). Many theoretical studies have been performed on large systems, of immediate interest to the organic chemist, as well as on small model systems such as simple acetals and simple esters. The ease and speed of computations on small systems allows for systematic investigations into the nature of the anomeric effect.

In this paper, a model will be presented for decomposing the anomeric stabilization energy as obtained from *ab initio* calculations into components based upon familiar terms like steric, electrostatic, and electronic energies.

In the literature, several energy decomposition schemes have appeared. Smits *et al.* (5) considered *anti* and *gauche* conformers of systems XH_mCH_2OH, with X = F, O, N, C. Using localized nonorthogonal molecular orbitals (MO), they write the one-electron density as a sum of quasi-classical, interference, and charge-transfer terms, and decompose the energy correspondingly. In this scheme, the anomeric effect is found to result mainly from XCH_2O interference interactions, in particular from a weakening of the destructive CX-CO interference as the electronegativity of X increases.

Reed and Schleyer (6, 7) used the concept of natural bond orbitals (NBO) for an analysis of the energy stabilization as well as geometry changes. By checking the occupancy of the n and σ^* localized orbitals, the significance of $n \rightarrow \sigma^*$ negative hyperconjugation to the anomeric stabilization can be checked. Furthermore, by deleting in the Fock matrix the matrix element corresponding to $n \rightarrow \sigma^*$, the calculated increase in energy can be taken as a measure of the energetic stabilization due to the $n \rightarrow \sigma^*$ interaction. A detailed study of $FSNH_2$ with NBO's shows that the $n_N \rightarrow \sigma_{SF}^*$ hyperconjugation can account for the very strong anomeric effect in this system, as well as in others.

Wiberg and Murcko (8) estimated for $OCH_3\text{-}CH_2\text{-}OCH_3$ (DMM) a quantity corresponding to the lone pair – lone pair (lp) repulsion (notation of this paper) to be 1.4 kcal/mol, by calculating energy differences between corresponding conformers of methyl propyl ether. From this, the anomeric stabilization energy of DMM, corrected for lp–lp repulsions, is calculated to be 4.7 kcal/mol.

Energy decomposition schemes can be developed in two ways. Either highly accurate energy terms (depending on the model) are obtained for one particular system, or average parameters are developed that fit a class of systems. In the

second case, the loss in accuracy for a specific system is compensated for by more general applicability, and by predictive capabilities. The latter approach is taken in this work.

In the following, anomeric stabilization energies, calculated by *ab initio* methods for simple hydroxyl and amino compounds and corresponding protonated species, will be decomposed into steric, electrostatic, and electronic components. Basically, steric and electrostatic energies will be subtracted from the total energy of anomeric stabilization, to arrive at the underlying electronic energy. The latter is considered to be a fundamental quantity, similar in many systems, whereas steric and electrostatic energies are incidental, depending on the particular conformation. The forthcoming analysis will confirm the fundamental nature of the electronic energy component involved in anomeric stabilization.

2. Methods and molecules studied

Geometry optimizations were performed at the SCF level using the 6-31G** basis set (unless noted otherwise). All calculations were carried out with the GAUSSIAN 86 computer programs (9).

For the systems XH_m-CH_2-YH_n, with X, Y, = N, O (neutral systems) and XH_m-CH_2-YH_{n+1}^+ (protonated systems, same X and Y), the dihedral angles of one XH_m and one YH_n hydrogen were fixed in order to define the desired conformation, whereas all other internal coordinates were optimized. For each system the energies relative to the most stable conformer will be listed. Since the emphasis will be placed upon an analysis of the energy differences, and not upon geometries, only CX and CY optimized bond distances will be given.

All of the neutral systems discussed in this paper have received theoretical treatment in the past. Only the most recent references will be cited. As mentioned earlier, systems XCH_2OH, with X = CH_3, NH_2, OH, and F, were studied by Smits *et al.* (5). Work on NH_2-CH_2-NH_2 was recently reported by Aped et al. (10). The system OCH_3-CH_2-OCH_3 was studied in detail by Wiberg and Murcko (8), as was mentioned above.

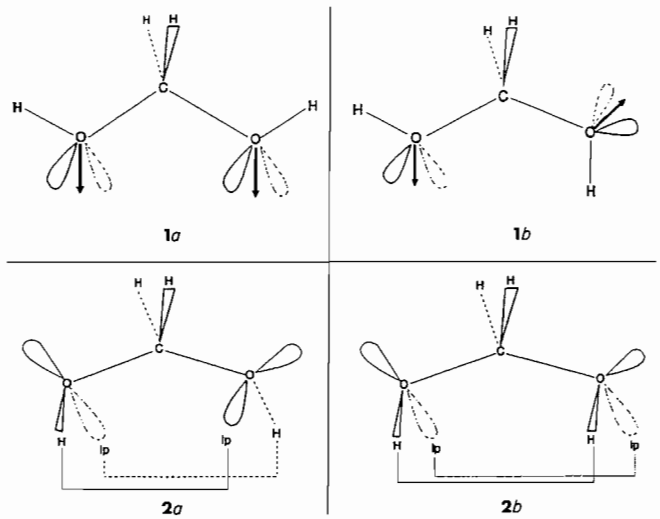
Only few calculations were reported on the protonated molecules of interest here. Wipff (11), Williams *et al.* (12), and Maggiora and Williams (13) considered OH-CH_2-OH_2^+, whereas Lehn and Wipff (14) described OH-CH_2-NH_3^+.

3. Model for energy decomposition

Due to the anomeric effect (ae), systems XH_m-CH_2-YH_n are stabilized when a hydrogen, say on Y, is moved from the *anti* to the *gauche* position (relative to CX). With X and Y being electronegative substituents (like O and N), the model system may have 0 ae when a hydrogen from both X and Y is *anti* relative to CY and CX, respectively, or 1 ae when a hydrogen from XH_m or YH_n is *anti* while the other hydrogens are *gauche*, or 2 ae when all hydrogens are *gauche*. This formulation is simplified by considering idealized sp^3 lone pairs on both X and Y. The anomeric effect (also called generalized ae) is active when one lone pair, or two lone pairs, one from X and one from Y, are antiperiplanar (app) to the other polar bond.

From *ab initio* calculations on systems XH_m-CH_2-YH_n, the energy differences between conformers with 0, 1, or 2 ae's can be calculated. It is desirable to subtract components corresponding to steric and electrostatic effects (e.g., lone pair repulsions) from the energy of stabilization, in order to be left with the electronic energy responsible for the energy lowering. It is assumed that the electronic energy causing the anomeric effect is a fundamental quantity, more so than observed or calculated total energies of stabilization, which are conditioned by various steric and electrostatic effects. It will be seen that for different systems the total energy lowerings upon anomeric stabilization may be large or small, but after correction for steric and electrostatic effects the underlying electronic energies of stabilization are the same or very similar.

In detail, the (*ab initio*) energy differences will be decomposed into a steric component for 1,3-diaxial H–H repulsion (denoted by parameter r, always positive), into electrostatic components for 1,3-diaxial lp–lp repulsion (parameter l, always positive), and for intramolecular "hydrogen bonding," meaning 1,3-diaxial H–lp interaction (parameter h, always negative or stabilizing), and finally into an electronic energy component, applicable when a lone pair is antiperiplanar to a polar bond (parameter e, always negative). In the above, lp stands for a sp^3 lone pair. The use of lone pairs can be avoided by considering the interaction of local dipole moments. If they are parallel (**1***a*), they destabilize the system; if antiparallel (**1***b*) they stabilize it.

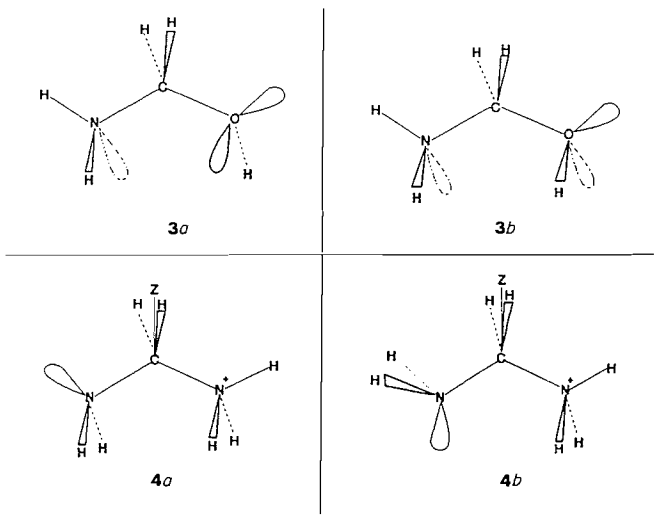


First, the quantities r, l, and h will be estimated, such that values for e can be obtained from the calculated energy differences. The 6-31G** energy difference between g,g-OH-CH_2-OH (**2***a*) and g,g^*-OH-CH_2-OH (**2***b*) is 3.57 kcal/mol. For NH_2-CH_2-OH in the 1 ae(O) conformation, the sterically favored form **3***a* is 4.37 kcal/mol (6-31G**) more stable than the less favored form **3***b*. Using the above energy decomposition scheme, $\Delta E = l + r - 2h$ for both systems. The methoxy systems, to be discussed later, will show that $h \cong -1$ kcal/mol; therefore, $l + r$ is chosen to be 2 kcal/mol. (In order to have a wide range of applicability, only integral or half integral numbers (in kcal/mol) will be used for the energy parameters.) The above data do not allow for a distinction between l and r. Using a 6-31G** basis set and optimized geometries, a Fourier analysis on OH-CH_2-OH performed by Grein and Deslongchamps (15) gave for the a-OH-CH_2-OH system $V_1 = -4.69$ kcal/mol. V_1 corresponds to the energy difference between structures **1***a* and

TABLE 1. Energy differences ΔE in kcal/mol for neutral systems, relative to most stable conformer, obtained by 6-31G** geometry optimizations

XH_m-CH_2-YH_n	OH-CH_2-OH	OH-CH_2-OCH_3	OCH_3-CH_2-OCH_3	NH_2-CH_2-NH_2	NH_2-CH_2-OH
0 ae	8.35	6.78	5.30	0.82	5.06
1 ae(X)	3.86	2.51	2.27	0.64	0.17
1 ae(Y)	3.86	3.79	2.27	0.64	0.95
2 ae	0.0	0.0	0.0	0.0	0.0

1*b* when only the 180° component of the energy is considered. (The 90° component V_2, corresponding to the electronic part of the anomeric energy, and the 60° component V_3, corresponding to the repulsion between the rotating H with the three bonds on C, have been separated out). For the *s*-OH-CH_2-OH system, V_1 = 3.82 kcal/mol (15). Starting from structure **1***b*, in the first case the 180° rotation results in two lp–lp repulsions (**1***a*), being 4.69 kcal/mol less stable than **1***b*, whereas in the second case the rotation results in in-plane H–H repulsion, being 3.82 kcal/mol less stable than **1***b*. These data show that the lp–lp and H–H repulsions are of similar magnitude. Therefore, the assumption $r \cong l \cong 1$ kcal/mol will be made, such that $l + r \cong 2$ kcal/mol as required.



In the following, the electronic component of the anomeric stabilization energy will be deduced for the systems investigated. In all cases, the above values of the parameters for steric and electrostatic effects will be retained. It is not the purpose of this work to optimize the values of the energy parameters for each individual system, but to allow for enough flexibility such that the energy decomposition model has predictive qualities.

4. Results and energy analysis for neutral systems

In Table 1, the calculated (6-31G**) energy differences are given for the neutral systems XH_m-CH_2-YH_n, with X, Y = O, N. The various conformers, designated by the notation 0 ae, 1 ae, and 2 ae, are shown in Fig. 1. In Table 2, the optimized CO and CN distances are given. Using MP2/6-31G** geometry optimizations on OH-CH_2-OH, the ΔE values are (in kcal/mol) 9.19 for 0 ae, 4.48 for 1 ae, and 0 for 2 ae, while the CO distances are (in Å) 1.402 for 0 ae, 1.391 and 1.415 for 1 ae, and 1.406 for 2 ae. For the purpose of the general energy model to be applied here, the differences in ΔE between MP2 and RHF optimizations are of little significance. Bond distances generally increase when electron correlation is added to RHF wavefunctions that have polarization functions in the basis set.

Table 1 shows that for all neutral systems the most stable conformer is 2 ae (ΔE = 0), while 0 ae is the least stable, as one would expect. However, there are large differences in ΔE (0 ae). While ΔE(0 ae) is about 8, 7, and 5 kcal/mol, for systems with OH or OCH_3, it is only 0.82 kcal/mol for NH_2-CH_2-NH_2. It will be shown that such huge differences in the 0 ae energies can be explained by steric and electrostatic effects, while the electronic components for anomeric stabilization are virtually the same in all cases. In Table 3, the energy analysis for the neutral systems is presented. For OH-CH_2-OH, the 0 ae conformer has 2 lone pair repulsions ($2l$), whereas 2 ae has 2 hydrogen bonds ($2h$) in addition to $2e$ from the two anomeric effects. Using l = 1 and h = −1 kcal/mol, one obtains $e \cong -2$ kcal/mol. On the other hand, for NH_2-CH_2-NH_2, the 0 ae conformer has $2h$, whereas 2 ae has $2e_N + 2r$. Using $l = r = -h = 1$ kcal/mol leads to $e_N = -2.5$ kcal/mol. In the process of going to the favorable conformation 2 ae, the electrostatic effects destabilize whereas the electronic effects stabilize the molecule. In balance, there is only a small energy gain of 0.82 kcal/mol between 0 ae and 2 ae.

For the mixed system NH_2-CH_2-OH, the previously obtained energy parameters, with $e_O = -2$ and $e_N = -2.5$ kcal/mol, predict the calculated energy differences within 0.5 kcal/mol. This is the first successful test of the model.

Tables 1 and 3 also contain results for the methoxy compounds OH-CH_2-OCH_3 and OCH_3-CH_2-OCH_3. Whereas the 1,3-diaxial H–lp interaction was energy lowering (h = −1 kcal/mol), a corresponding CH_3–lp 1,3-diaxial interaction is not expected to be. Therefore, in comparison with the OH compounds, the parameter h is omitted from the energy formula for OCH_3. This explains nicely why the 0 ae energy drops from 8.35 to 6.78 to 5.30 kcal/mol as one moves across the top of Table 1 from the hydroxyl to the methoxy compounds. It also provides justification, as mentioned earlier, for the introduction of the energy parameter h, with an approximate value of −1 kcal/mol.

For neutral systems, the energy decomposition model gave values for the electronic parameter of −2 kcal/mol for oxygen, and −2.5 kcal/mol for nitrogen.

5. Results and energy analysis for protonated systems

In Tables 4 and 5, ΔE values and optimized bond distances are given for the various conformers of the protonated systems, as shown in Fig. 2. For the protonated systems XH_m-CH_2-YH_{n+1}^+, geometry optimizations often lead to unusual structures, mostly caused by the desire of the sys-

tem to move towards a charge-dipole complex, but unable to do so due to fixed dihedral angles for one XH_m and one YH_{n+1} hydrogen, as are required for defining the conformation. The resulting energies also reflect unusual stabilizations, and are not suitable for an energy analysis. Therefore, the results of Tables 4 and 5 were obtained for a "restricted series" of optimizations, where the dihedral angles of all XH_m and YH_{n+1} hydrogens have been frozen at 0 or $\pm 120°$, according to the diagrams in Fig. 2.

Table 4 shows that for the systems $OH\text{-}CH_2\text{-}OH_2^+$ and $NH_2\text{-}CH_2\text{-}OH_2^+$, the 2 ae conformer is no longer the most stable one. Similarly, for $NH_2\text{-}CH_2\text{-}NH_3^+$ and $OH\text{-}CH_2\text{-}NH_3^+$, unexpected situations occur. They will be discussed in the light of the energy decomposition scheme.

For the energy analysis of the protonated systems, the parameters r, l, and h will be used again. For a start, they are retained at the values 1 and -1 kcal/mol, as before. Also, the electronic energy component e will be given the same values as before, -2 kcal/mol for anomeric stabilization due to a lone pair on O, and -2.5 kcal/mol due to a lone pair on N, except in the case of complex stabilization. Lone pairs on O^+ (these are only formal charges, and do not imply actual positive partial charges on O) are expected to be weaker, and the electronic parameter e_{O^+} will be determined by comparison with the *ab initio* energies.

Table 5 shows that two conformers of $NH_2\text{-}CH_2\text{-}OH_2^+$, 1 ae(N) and 2 ae, optimized to charge-dipole complexes, with CO bonds of 2.381 Å, and associated large stabilization energies (13 to 15 kcal/mol relative to 0 ae).

The energy decomposition scheme is given in Table 6. A choice of 0 for e_{O^+} of $OH\text{-}CH_2\text{-}OH_2^+$ gives ΔE values close to the *ab initio* values for this system, with a maximum de-

viation of 0.8 kcal/mol. For $NH_2\text{-}CH_2\text{-}OH_2^+$ a charge-dipole complex is obtained whenever the lone pair on N is app to CO. Therefore, the parameter e_N has to be reevaluated. Using $e_{O^+} = 0$, e_N is found to be −15 kcal/mol, reflecting the large complex destabilization. Omitting in the formula $h + r$ for 1 ae(X) and $2r$ for 2 ae, due to the large CO distance in $NH_2\text{-}CH_2\text{-}OH_2^+$, changes the prediction for 2 ae to 0 kcal/mol from 2.

A special situation is encountered for $NH_2\text{-}CH_2\text{-}NH_3^+$. When optimizing the 1 ae conformer, starting with dihedral angles of ±120° for the NH_2 hydrogens (relative to

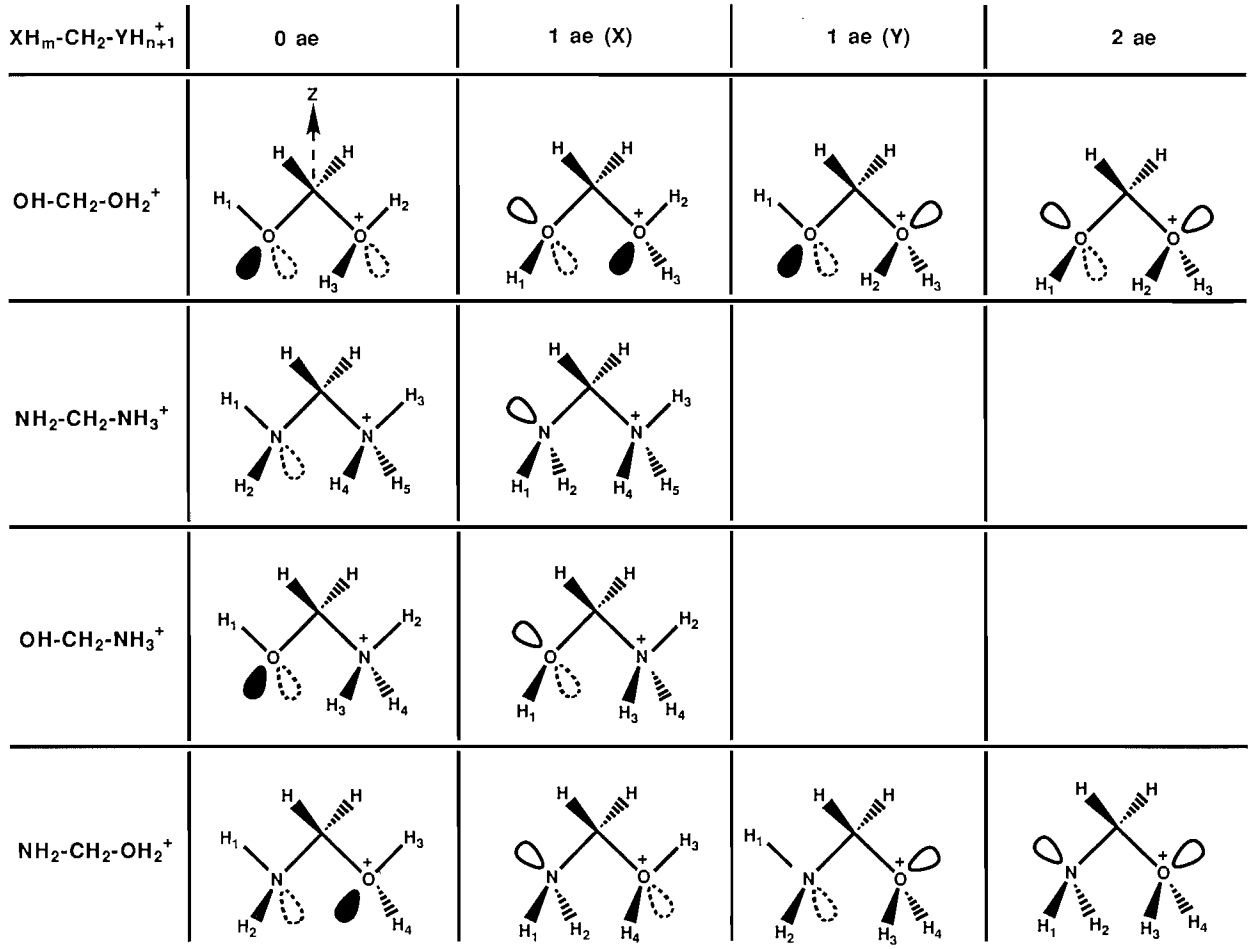

FIG. 2. Conformers of $OH\text{-}CH_2\text{-}OH_2^+$, $NH_2\text{-}CH_2\text{-}NH_3^+$, $OH\text{-}CH_2\text{-}NH_3^+$, and $NH_2\text{-}CH_2\text{-}OH_2^+$, corresponding to 0, 1, and 2 anomeric effects. See text for details.

Z—C—N, structure **4***a*), the NH_2 group inverts, leading to structure **4***b*, which is 5.62 kcal/mol more stable than **4***a*. Situations where the expected anomeric stabilization does not take place, and another conformer is more stable, have been referred to as the "reverse anomeric effect" (rae). Lemieux and Morgan (16) and Lemieux (17), who introduced the term reverse anomeric effect, discovered that in certain pyridinium glycosides the pyridinium group acquired equatorial rather than the expected axial position, contrary to the predictions for the anomeric effect. They attributed this exceptional behavior to destabilizing electrostatic effects arising from a positively charged atom (usually N) in axial orientation at the anomeric center. In the spirit of the present model, one may attribute the increased stability of **4***b* over **4***a* to the proximity of the lone pair on N to the positive charge on NH_3^+, which supersedes the stabilization due to the antiperiplanar lone pair. It is known that α-pyridinium glycosides prefer to exist in the twist-boat rather than the chair conformation. Using our model, this unexpected behavior, referred to as the reverse anomeric effect, is simply rationalized by the fact that there is maximum electrostatic attraction between the ring oxygen lone pairs and the equatorially oriented pyridinium group when the tetrahydropyranyl ring adopts the twist-boat conformation.

For the energy analysis, a new parameter v is required (v for reverse ae). For $NH_2\text{-}CH_2\text{-}NH_3^+$, ΔE betwen 0 ae and 1 ae is well explained with $e_N = -2.5$ kcal/mol. For the inverted structure, however, a value of $v_N = -5$ kcal/mol is needed to fit the *ab initio* energies.

The system $OH\text{-}CH_2\text{-}NH_3^+$ is clearly in favor of the reverse ae, having 0 ae more stable than 1 ae. Retaining e_O as −2 kcal/mol leads to $v_O = -4$ kcal/mol, again showing that the rae stabilization exceeds the ae stabilization by a significant amount.

Obviously, it will be interesting to investigate changes in bond distances and atomic charges due to the reverse anomeric effect. Such items, however, exceed the scope of the present paper, which deals exclusively with the energy model, and will be referred to future publications.

6. Application of energy decomposition model to methanetriol and aminomethanediol

Figure 3 shows optimized C—O distances for six of the seven conformers of methanetriol that can be formed by having a lone pair or hydrogen of one OH group antiperiplanar to one of the other C—O bonds. In the triangular diagrams (see structure **5** as example) a lobe on O_A, lined up with the line O_A–O_B, indicates that a lone pair on O_A is antiperiplanar to O_B. A short line on O_A, lined up with O_A–O_C, would indicate a hydrogen on O_A being antiperiplanar to C–O_C. The second lone pair on O_A is shown pointing to the inside of the triangle, towards C. For this lone pair, O–lp is

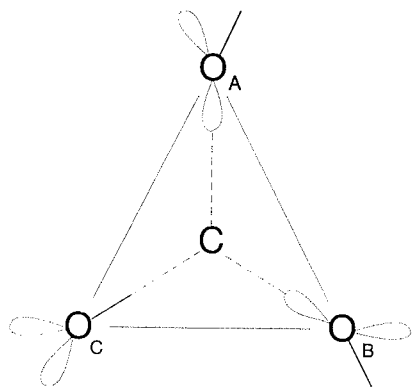
anti to CH. In this way, the triangular diagrams uniquely define the conformations of $CH(OH)_3$ for the purpose of the present analysis.

The number labelling the diagrams in Fig. 3, e.g., 4 in 4A, gives the number of anomeric effects, whereas the letter corresponds to an (arbitrary) sequence of conformations. In the diagrams of Fig. 3 (and following figures) the three CO distances are shown. The lone pairs or hydrogens on the inside of the triangle have been omitted to allow for lines connecting O with C.



5

In Table 7, an energy analysis equivalent to the one performed on methanediol is applied. For example, for structure **5** (4B of Fig. 3) there are four ae's ($4e$), four internal hydrogen bonds ($4h$), and two lp–lp repulsions ($2l$). Using $e_O = -2$ kcal/mol, and $l = r = -h = 1$ kcal/mol, as before, leads to the prediction that structure 4A, 4B, or 5A should be the most stable one (column "ΔE"). In the last column of Table 7, the *ab initio* energy differences (4-31G basis set) are given. It is seen that 4B is most stable, and that

5A	$e_N + 4e_O + h + 2l + 3r$	6	6.93

4A and 5A differ by 1–2 kcal/mol from 4B. In general, ΔE_{abin} is larger than the formula value, the largest deviation (3.27 kcal/mol) occurring for structure 6A. In this case, the formula contains $3l + 3r$, the maximum number of repulsion terms. From this, an adjustment of the formula values of l and r, from 1 to 1.5 kcal/mol, is suggested, in order to achieve better agreement between ΔE and ΔE_{abin}. Adjusted formula values, ΔE^*, also given in Table 7, show a marked improvement. Now the largest deviation occurs for 4A, which has the same formula as the most stable structure 4B, and does therefore not benefit from a change of the repulsion parameters. Intuitively one expects repulsion on the more crowded methanetriols to be higher than in the corresponding methanediols. An adjustment of the repulsion parameters from 1 to 1.5 kcal/mol may not be necessary for 6-31G* energy differences (assuming 6-31G* geometry optimizations), since 6-31G* energy differences are usually smaller than corresponding 4-31G (or 3-21G) values. For lack of computer resources, only 4-31G optimizations were performed on methanetriol. Single point calculations in 6-31G**, using the 4-31G optimized geometries (6-31G**//4-31G), gave energies that were found less suitable for interpretation.

Many other adjustments and refinements to the parame-

ters, and to the formula, have been tried. For example, one might distinguish between "outer" and "inner" l, r, and h interactions, where "outer" and "inner" are most easily defined by inspecting structure **5**. However, it is important to retain the simplicity of the formula, and to have steric and electrostatic parameters as general and transferable as possible.

As another example, aminomethanediol may be investigated. There are 15 conformers having a lone pair or hydrogen antiperiplaner to another CX bond. Figure 4 shows six of them. A simple energy analysis, with $e_O = 2$, $e_N = -2.5$, $l = r = 1.5$, and $h = -1$ kcal/mol, predicts structure 3D to be most stable (Table 8). Indeed, this was found to be the case. Structure 2A is predicted to be least stable, again to be confirmed. Table 8 gives calculated ΔE values (3-21G basis set) and the formula for the energy analysis together with the predicted ΔE value. The agreement is quite satisfactory. Details for systems $CHNH_2(OH)_2$, as well as $CH(NH_2)_2OH$ and $CH(NH_2)_3$, will be published elsewhere.

7. Application of energy decomposition model to protonated methanetriol

In Fig. 5 six of the 15 conformers of $CH(OH)_2OH_2^+$ are shown, where again either a lone pair or a hydrogen is app to one of the other C—O bonds. The C—O bond distances, optimized with the 4-31G basis set, are given.

In Table 9 the energy formulae, as well as ΔE's obtained from the formula and ΔE_{abin} values (4-31G), are given. The standard parameters for triols, $e_O = -2$, $e_{O^+} = 0$, $h = -1$, and $l = r = 1.5$ kcal/mol have been used. While the largest deviation between ΔE and ΔE_{abin} is 4.3 kcal/mol (2C), most ΔE's agree within 1–2 kcal/mol. Structure 3B has the lowest *ab initio* energy, predicted at 1.5 kcal/mol by the formula, while 4A has the lowest predicted energy, at 1.72 kcal/mol by *ab initio* calculations. For a simple energy decomposition model as applied here, the predictive ability is judged to be quite satisfactory. As was noticed for protonated methanediols, energy predictions for protonated systems are much more difficult to perform than for neutral systems. Special situations would arise in cases of the reverse ae and of charge-dipole complexes. Details on protonated triols, and on other protonated systems of the type $CH(OH)_m(NH_2)_nH^+$, with $m + n = 3$, will be published elsewhere.

8. Discussion

In the energy decomposition scheme presented in this paper, approximate energy parameters have been used in order to decompose anomeric stabilization energies for compounds XH_m-CH_2-YH_n, with X, Y = N, O. After deducting steric (H–H interactions) and electrostatic (lp–lp and lp–H interactions) terms from the stabilization energies, electronic components are left, having values of 2 for O and 2.5 kcal/mol for N, and acting towards stabilization of the *gauche* over the *anti* conformer. The larger stabilization energy of N, compared with O, is explained by N being a better electron donor than O, and OH being a better leaving group than NH_2.

Frank (18) placed the experimental value of the anomeric stabilization energy (electronic part) for *O*-alkyl systems at a minimum of 2.1 kcal/mol, whereas a previous estimate by Deslongchamps *et al.* (19) gave a minimum of 1.4 kcal/mol. Wolfe *et al.* (20) found a theoretical value of 2.8 kcal/mol.

A new theoretical interpretation of the reverse anomeric effect is offered. For the first time, to the best of our knowledge, estimates have been obtained for the energy stabilization due to this effect. The systems OH-CH_2-NH_3^+ and NH_2-CH_2-NH_3^+ prefer comformations where the lone pair on O or N is not app to CN^+ but is located in the proximity of the (formal) positive charge on N. Apparently, the lp–N^+ electrostatic attraction exceeds the desire of lp delocalization, corresponding to the regular anomeric effect. The energy parameters v for the reverse anomeric effect are found to be -4 for the OH, and -5 kcal/mol for the NH_2 system, twice the amounts obtained for the respective anomeric stabilization energies.

In an investigation into the nature of the anomeric effect, Grein and Deslongchamps (15) studied the systems XH_m-CH_2-OH, with X = F, O, N, and C. For a given conformation of XH_m, the OH group was held at dihedral angles of 0°, 60°, 90°, 120°, and 180°. By Fourier analysis, and by comparison with properties of the $CH_2{=}OH^+$ cation, it could be shown that anomeric stabilization for X = F and O is π-driven, whereby the CH_2-OH portion of XH_m-CH_2-OH is trying to assume the optimal structure of $CH_2{=}OH^+$. For X = N and C, however, the OH *gauche* conformer is no longer the most stable one, and there is no anomeric stabilization due to the lone pair on oxygen. A similar analysis has been performed for systems XH_m-CH_2-NH_2 and for the corresponding protonated systems with OH or NH_2 rotation (to be published). The energy parameters obtained by Fourier analysis can be roughly classified as electronic, steric, and electrostatic, and therefore some relation can be obtained with the energy parameters of the present paper (the terms are not identical). It should be emphasized again that the energy parameters used in this work are approximate, designed to cover a wide range of compounds rather than one compound accurately. Applications to methanetriol and protonated methanetriol, as well as to aminomethanediol, allow for predicting the energies of all *anti* conformers (lp or H in *anti* position relative to other CO or CN) with reasonable accuracy. Adjustment of the repulsion parameters l and r from 1

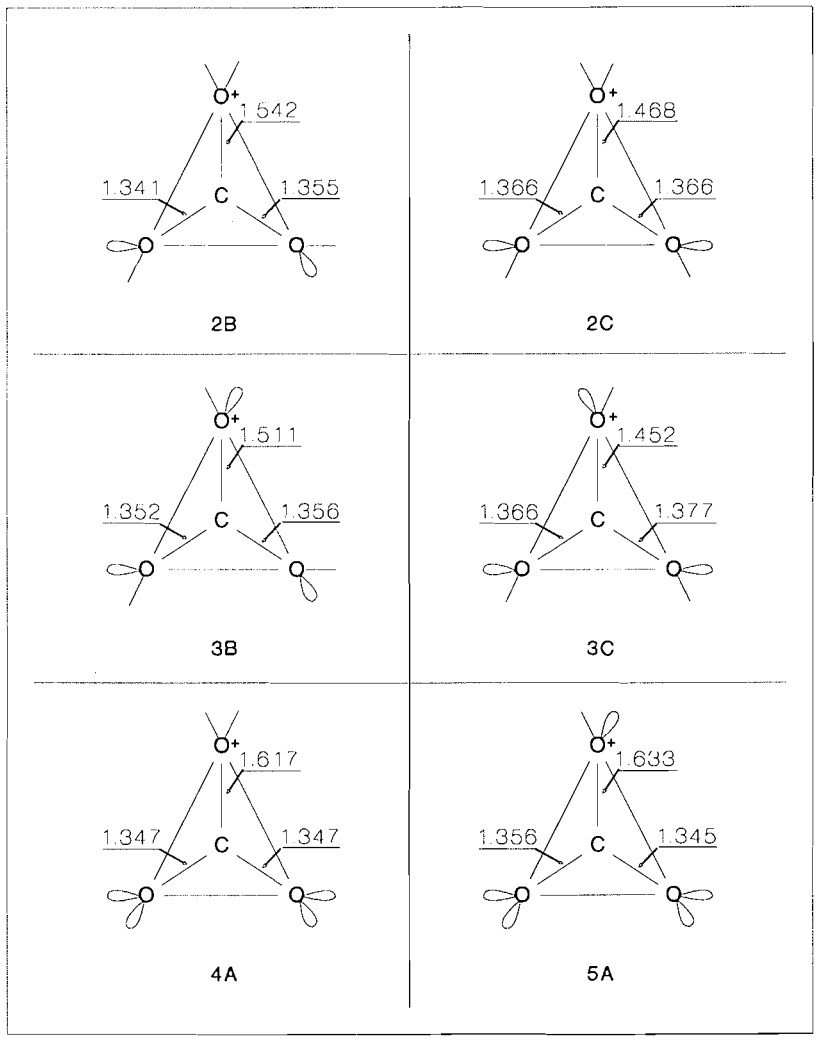

FIG. 5. Schematic diagrams of $CH(OH)_2OH_2^+$, showing 6 of the 15 conformers having a lone pair or hydrogen on O *anti* to other CO bond. For conventions see text and structure **5**.

to 1.5 kcal/mol improves the agreement. Such increase either reflects the increased repulsion in triols over diols, or is due to the lower level basis sets used for calculations on the triol systems (or both).

9. Summary and future work

A simple energy decomposition scheme, as proposed earlier by Grein and Deslongchamps (21), has been developed. In this scheme, the anomeric stabilization energies for acetal and protonated acetal-type systems XH_m-CH_2-YH_n and XH_m-CH_2-YH_{m+1}^+, with X, Y = N, O, are decomposed into steric (H–H), electrostatic (H–lp and lp–lp), and electronic terms. The validity of this model, which is easy to use, has been tested by application to methanetriol and protonated methanetriol, with good success. The important energy parameter is the electronic energy of anomeric stabilization, calculated by subtracting steric and electrostatic terms from the total energy of stabilization as obtained from *ab initio* calculations. The electronic energy is the basic underlying driving force in anomeric stabilizations, and has indeed been found to be very similar for all systems studied, even if the total energies of stabilization differ by large amounts.

For protonated systems, the anomeric effect may be so strong that the molecule separates to form a charge-dipole complex. In such cases, the (formal) electronic energy of stabilization is very large. For two of the protonated systems studied here, the conformation expected to be the most stable one was found to be less stable than a conformation allowing the lone pair(s) (on O or N) to be close to the (formal) positive charge (on N). A new parameter, for the reverse anomeric effect, has been introduced, with energies exceeding, as expected, the electronic energy for the regular anomeric effect.

A recent paper by Schleifer *et al.* (22) concludes that based on a systematic analysis of hundreds of carbohydrate structures "the structural parameters are the most characteristic manifestation of the anomeric effect rather than the energy (relative stability) factors". We believe that by accounting not only for steric but also for electrostatic effects, in the manner shown above, the remaining electronic energy can be a useful part of demonstrating the anomeric effect. However, it is readily admitted that estimating steric and electrostatic energies is not always easy, and that accurate values for such energy components are hard to come by. We hope that the present paper opens the way for more work in this field.

In future work, the energy decomposition scheme presented here will be extended to anionic acetal systems as well

as to esters and protonated esters. A rationalization of the energy parameters on the basis of energy components obtained by Fourier analysis will be attempted. More detailed studies of the geometry changes occurring for systems that are governed by the reverse anomeric effect will be of interest.

Acknowledgement

Computational help by several undergraduate students, in particular Michelle Carnell and Amy Wortman, as well as the grant of operating funds by the Natural Sciences and Engineering Research Council of Canada and the allocation of computer time by the University of New Brunswick are gratefully acknowledged. We would also like to thank Robert Mawhinney for preparing most of the figures. Special thanks go to Dr. Z. Valenta for his interest in this project and for helpful discussions.

Synthesis of the thymidine building blocks for a nonhydrolyzable DNA analogue

STEPHEN H. KAWAI, DAGUANG WANG, AND GEORGE JUST[1]
Department of Chemistry, McGill University, Montréal, Que., Canada H3A 2K6

Received July 11, 1991

This paper is dedicated to Dr. Zdenek (Denny) Valenta on the occasion of his 65th birthday

STEPHEN H. KAWAI, DAGUANG WANG, and GEORGE JUST. Can. J. Chem. **70**, 1573 (1992).

The 3′-deoxy-3′-*C*-(2″-hydroxyethyl)thymidine derivatives **4** and **13** were efficiently synthesized from either thymidine via a known 3′-radical allylation, or from the branched-chain furanose **5** involving the removal of the 2′-hydroxyl after stereospecific nucleosidation. The 5′-deoxy-5′-thiothymidine **20** was prepared via a regiospecific Mitsunobu coupling, providing the third unit required for the synthesis of sulfide-linked DNA analogues.

STEPHEN H. KAWAI, DAGUANG WANG et GEORGE JUST. Can. J. Chem. **70**, 1573 (1992).

On peut synthétiser les dérivés **4** et **13** de la 3′-désoxy-3′-*C*-(2″-hydroxyéthyl)thymidine d'une façon efficace soit à partir de la thymine par le biais d'une allylation du radical-3′ soit à partir du furanose **5** à chaine ramifiée en enlevant la fonction 2′-hydroxyle après une nucléosidation stéréospécifique. On a préparé la 5′-désoxy-5′-thiothymidine **20** par le biais d'un couplage régiospécifique de Mitsunobu et l'on a ainsi obtenu la troisième unité nécessaire pour la synthèse d'analogues de l'ADN liés par un pont sulfure.

Introduction

Since the discovery, a decade ago, that bacterial gene expression is naturally regulated by the binding of specific messenger RNA species by complementary RNA strands, the antisense strategy has developed into a major field of investigation (1). Much work has been devoted to both natural and modified oligonucleotides that are capable of forming stable double-helices with complementary mRNA, thus blocking translation to the protein product. Many of these systems bear uncharged phosphodiester group analogues that facilitate the uptake of the oligonucleotide strands into cells and confer increased stability towards degradation by celular nucleases.

A factor that makes these systems attractive is the fact that they can be prepared in a relatively straightforward manner by small modifications to existing automated DNA synthetic techniques. However, such phosphate-modified systems, which include methylphosphonate (2), phosphoramidate (3, 4), and phosphorothioate-linked (5) oligodeoxynucleotide analogues, possess some inherent drawbacks. Modification or replacement of one of the phosphoryl oxygens (or both by different groups) gives rise to a chiral phosphorus center that results in a mixture of diastereomeric oligonucleotide products. In addition, the removal of the negative charge on the internucleoside linkage results in the loss of the high chemical stability associated with phosphodiesters. The absence of the charged phosphodiester group has also been implicated in the reduced stability exhibited by hybrid (P-modified/natural) helices (6).

As an alternative to phosphate-modified systems, a few examples of DNA analogues in which the nucleoside units are altered and joined by the natural phosphodiester linkages have been studied. These include both mixed and homogeneous oligomers bearing α-anomeric (7, 8) and L-2′-deoxynucleosides (9, 10). There have also been a number of examples of DNA analogues in which the phosphodiester groups have been replaced altogether with hydrolytically stable, nonchiral linkages. Notable examples of such "dephospho" analogues are those containing sulphur atoms. Benner and co-workers have reported the details of the syntheses of 3′,5′-bis-homo-thionucleosides (11), whose short polysulfone-oligomers were found to bind to complementary RNA. A dinucleoside analogue in which the phosphodiester is replaced with a sulfonyl ester and which exhibits surprising chemical stability was recently described (12).

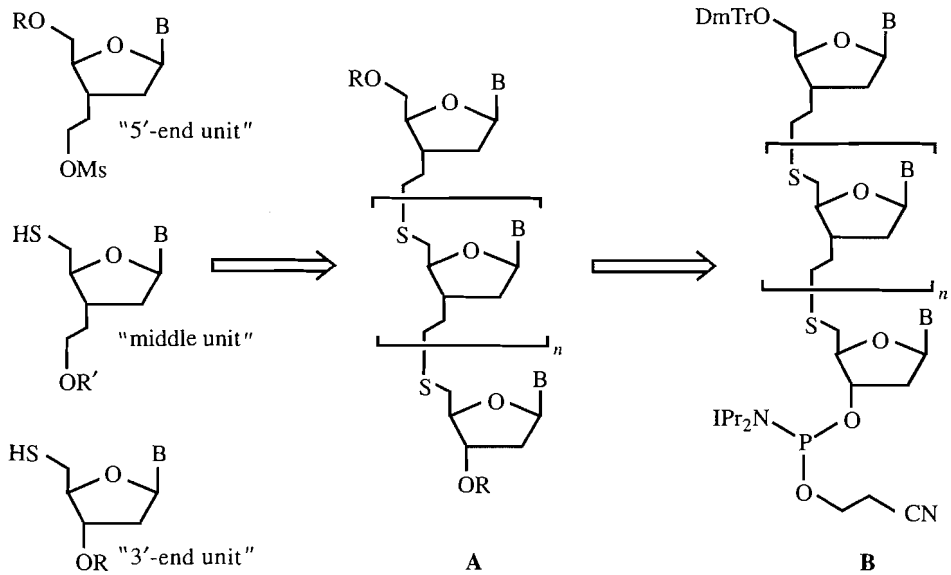
In tandem with our work with sulfide-linked oligoribonucleotide analogues (13), we are presently involved in the synthesis of nonhydrolyzable oligodeoxyribonucleotide strands of type **A**. In addition to the poly-sulfide (or sulfone) homopolymers, systems in which short modified regions are incorporated into natural DNA are being prepared. Such mixed molecules are of interest since it has been shown that the addition of backbone-modified units to the 3′ and 5′ ends of otherwise unaltered DNA greatly increases the strands' stability towards nuclease degradation (2, 14, 15). We believe that proper protection or activation of the sulphur-containing fragments (as in **B**) will allow for straightforward incorporation of the pieces into DNA by standard automated techniques.

In the present work, we describe the preparation of the three thymidine nucleoside units required for the construction of systems such as **A** and **B**. The syntheses are also important in that they represent an efficient and general route to 2′,3′-dideoxy-3′-*C*-substituted nucleosides, which are presently receiving much attention for their potential as antiviral agents (16).

Results and discussion

Key intermediates in the preparation of the target sulfide-linked DNA analogues are the 3′-deoxy-3′-*C*-(2″-hydroxyethyl)thymidine "5′-end" and "middle" units shown in Scheme 1. Two basic approaches exist for the synthesis of these molecules: the direct two-carbon homologation of nucleosides, or the preparation of the branched-chain sugar followed by the attachment of the nitrogenous base. The recent report (17) that the tributyltin-mediated radical allylation using 3′-thiocarbonate derivatives of thymidine occurs with high stereoselectivity provided us with a rapid entry to the branched-chain system. The oxidative cleavage of the olefinic bond of the 3′-*C*-allyl nucleoside **1** to the aldehyde

[1]Author to whom correspondence may be addressed.



SCHEME I

has also been reported (18) but no experimental details were given. We found that treatment of **1** with osmium tetroxide and sodium periodate (Scheme 2) following the two-phase "ether–water method" (19) gave best results, the aldehyde **2** being obtained in 74% yield. Subsequent reduction with sodium borohydride in methanol cleanly provided, in 85% yield, the 3′-*C*-(2″-hydroxyethyl) nucleoside **3**. Mesylation afforded the thymidine "5′-unit" **4** in 90% yield.

The principal drawback of this approach is that the radical allylation is not generally applicable to all the purines and pyrimidines that will eventually be required. Attempts to allylate 2′-deoxy-3′-*O*-phenoxythiocarbonyl cytidine derivatives resulted in complex mixtures. In addition, 2′-deoxynucleosides other than thymidine are very expensive starting materials. We therefore developed a route to the branched-chain nucleosides following the second approach, namely, attachment of the hydroxyethyl group prior to base attachment.

This scheme proceeds from 3′-deoxy-3-*C*-(2′-hydroxyethyl)-1,2-*O*-isopropylidene-5-*O*-trityl-D-ribofuranose **5**, which is efficiently prepared in large scale from monoacetone xylofuranose in four steps and in 61% overall yield (20). The 2′-hydroxyl group of the sugar was protected as the *p*-methoxyphenyl ether, formed under Mitsunobu conditions using diethyl azodicarboxylate and triphenylphosphine in THF, to give **6** in 91% yield. The acetolysis of this sugar in a mixture of acetic acid and acetic anhydride containing camphorsulfonic acid heated to 70°C resulted in simultaneous cleavage of both the trityl and isopropylidene groups, affording the β-triacetate **7** in 69% yield, accompanied by a small amount of the expected acetylated *aldehydrol* derivatives (20). The Vorbrüggen coupling (21) of **7** and bis-(trimethylsilyl)thymine (22) in refluxing dichloroethane, using trimethylsilyl triflate as catalyst, proceeded smoothly to give nucleoside **8** in 91% yield. Subsequent deacetylation using methanolic ammonia afforded diol **9** in a quantitative manner that was selectively monosilylated to give the 5′-TBDMSi ether **10** in 86% yield. Having served its function (when acetylated) of directing the stereochemistry of the nucleosidation reaction, the 2′-OH was removed by forming the 2′-*O*-phenoxythiocarbonate **11** followed by treatment with tributyltin hydride (AIBN initiation) in hot toluene (23). The 2′-deoxy compound **12** was thus obtained in 81% yield for the two steps. The stereo- and regioselectivity of nucleoside formation was conclusively verified by comparing this product with the *p*-methoxyphenyl ether prepared from alcohol **3** obtained via the 3′-radical allylation route. The two samples of nucleoside **12** were identical in all respects. The product was also identical to material prepared by a completely different asymmetric synthesis (24) commencing from 4-*O*-benzyl-3,4-dihydroxybutyne.

The thymidine "middle unit" **13** was prepared from either compounds **9** or **12**. The Mitsunobu coupling (25) of alcohol **9** and thiolacetic acid employing diisopropyl azodicarboxylate and triphenylphosphine proceeded regioselectively to afford thiolester **14** in 85% yield. However, the subsequent removal of the remaining 2′-hydroxyl, again via the tributyltin hydride reduction of the phenoxythiocarbonate **15**, gave only fair yields of **16**, presumably due to interference with the radical reaction by the 5′-thiolester functionality. The target nucleoside was much more efficiently obtained by the desilylation, using tetra-*n*-butylammonium fluoride in THF, of the 2′-deoxynucleoside **12** to give alcohol **17**, followed by Mitsunobu coupling with thiolacetic acid, which afforded the thiolester **16** in 87% yield for the two steps. The deprotection of the *S*-acetate was carried out in methanolic sodium hydroxide followed by neutralization with acidic resin. Careful deoxygenation of all of the solutions proved necessary to prevent the rapid oxidation of the resultant thiolate to the symmetrical disulfide. The reaction could also be performed using methanolic ammonia, again carefully removing and excluding any oxygen. The thiol **13** was thus obtained in 98% yield.

The thymidine "3-end unit" was prepared in three steps from thymidine (Scheme 3). The Mitsunobu coupling of the free nucleoside and thiolacetic acid in a mixture of THF and DMF gave the 5′-monothiolester **18** in 52% yield that was converted to the 3′-silyl ether **19** in 92% yield. The deacetylation was again performed using methanolic hydroxide, being careful to exclude oxygen from the reaction, which

(a) AcSH/DIAD/PPh_3/DMF/THF; (b) TBDMSiCl/imidazole/DMF; (c) NaOH/MeOH

SCHEME 3

gave the thiol **20** in quantitative yield. It should be pointed out that, unlike 5′-deoxy-5′-thiouridine derivatives that exist as Michael adducts with the pyrimidine base (26), the analogous derivatives of thymidine are stable as the free thiol.

In summary, the thiothymidine and 3′-deoxy-3′-*C*-(2″-hydroxyethyl)thymidine derivatives **4**, **13**, and **20** required for the preparation of a sulfide-linked DNA analogue have been efficiently synthesized by two routes. One of these ap-

proaches is applicable to all four bases and work in this regard is ongoing. The coupling of the units has been successfully carried out and, in the case of the dimer, the molecule has been deprotected and activated for incorporation into DNA. The details of this work will be described shortly.

Experimental

General methods

Melting points (mp) were determined using an Electrothermal MP apparatus and are uncorrected. Low-resolution chemical ionization mass spectra (CI) were obtained on an HP 5980A quadrapole mass spectrometer in the direct-inlet mode. High-resolution CI and fast-atom bombardment (FAB) mass spectra (HRMS) were obtained on a VG ZAB-HS sector mass spectrometer, again, in the direct-inlet mode. The measurements were carried out at a resolving power of 10 000. Elemental analyses were performed by Guelph Chemical Laboratories Ltd., Guelph, Ontario. All compounds were shown to be homogeneous by thin-layer chromatography (tlc) and high-field NMR and (or) to have a purity of >95% by elemental analysis.

^{1}H NMR spectra were recorded on either Varian XL200 or Varian XL300 spectrometers and the assignments are based on homonuclear decoupling and (or) COSY experiments. When deuteriochloroform was employed as solvent, internal tetramethylsilane (TMS) was used as the reference. The residual proton signal or methanol, assigned a value of 3.30 ppm, was used as the reference in this case. The multiplicities are recorded using the following abbreviations: s, singlet; d, doublet; t, triplet; q, quartet; h[7], heptet; m, multiplet; m″, symmetical signal of *n* lines; br, broad. ^{13}C NMR spectra were all obtained at 75.4 MHz using a Varian XL300 spectrometer. The $^{13}CDCl_3$ and $^{13}CD_3OD$ signals, assigned values of 77.00 and 49.00 ppm, respectively, were used as references in these solvents. Peak assignments were, in some cases, made with the aid of APT or HETCOR experiments.

Tetrahydrofuran was distilled from sodium benzophenone ketyl. Dichloromethane and 1,2-dichloroethane were distilled from P_2O_5. Toluene was dried over sodium wire. Pyridine was distilled from calcium hydride. *N,N*-Dimethylformamide was dried by shaking with KOH followed by distillation, at reduced pressure, from BaO. Thin-layer chromatography (tlc) was performed using Kieselgel 60 F_{254} aluminium-backed plates (0.2 mm thickness) and visualized by UV and (or) dipping in a solution of ammonium molybdate (2.5 g) and ceric sulfate (1 g) in 10% v/v aqueous sulphuric acid (100 mL), followed by heating. Kieselgel 60 (Merck 230–400 mesh) silica gel was employed for column chromatography.

*Aldehyde (**2**)*

Osmium tetroxide (100 mg, 0.393 mmol) was added to a two-phase system comprising ethyl ether (8 mL) and water (8 mL) containing nucleoside **1** (1.00 g, 2.63 mmol). To the resulting brown mixture was then added sodium metaperiodate (1.24 g, 5.80 mmol) in small portions over 0.5 h. The reaction was stirred at ambient temperature under nitrogen in the dark. After an additional 1 h the mixture was extracted with dichloromethane (2 × 200 mL) and washed with aqueous sodium bicarbonate (5% w/v, 300 mL) and water (300 mL). The combined organic phases were then dried (Na_2SO_4), filtered, and the solvent removed *in vacuo* yielding a colorless glass. Chromatography over silica gel (2:1 to 4:1 ethyl acetate/hexanes, v/v) afforded aldehyde **2** as a white solid (740 mg, 74% yield); ^{1}H NMR ($CDCl_3$, 200 MHz) δ: 0.120 and 0.122 (two s, 6H, Si*Me*$_2$), 0.93 (s, 9H, *t*-Bu), 1.94 (fine d, 3H, J = 1.2 Hz, 5-Me), 2.08 (A of ABXY, 1H, H2′$_A$), 2.32 (B of ABXY, 1H, H2′$_B$), 2.50–2.84 (m, 3H, H1″$_{AB}$ and H3′), 3.73–3.84 (m, 2H, H5′$_A$, and H4′), 3.97 (dd, 1H, H5′$_B$), 6.14 (dd, 1H, H1′), 7.54 (fine q, 1H, J = 1.2 Hz, H6), 8.72 (br s, 1H, NH), 9.80 (s, 1H, C*H*O), $J_{H1'-H2'A}$ = 6.7 Hz, $J_{H1'-H2'B}$ = 5.2, $^2J_{H2'A-H2'B}$ = −13.5, $J_{H2'A-H3'}$ = 6.8, $J_{H2'B-H3'}$ = 7.8; ^{13}C NMR ($CDCl_3$): 12.58 ppm (5-Me), 18.40 (*C*Me$_3$), 25.90 (C*Me*$_3$ and Si*Me*$_2$), 32.24 (C3′), 38.57 (C2′), 46.72 (C1″), 63.25 (C5′), 84.65 and 85.36 (C1′ and C4′), 110.58 (C5), 135.40 (C6), 150.50 (C2), 164.04 (C4), 199.80 (*C*HO); MS (CI–NH_3) *m/e*: 383 ([MH^+], 100%), 274 ([M + NH_4^+ − ThyH], 17), 257 ([MH^+ − ThyH], 68), 127 ([ThyH + H^+], 10); HRMS (CI–NH_3) *m/e* calcd. for $C_{18}H_{31}N_2O_5Si$: 383.20022; found: 383.220018.

*5′-O-tert-Butyldimethylsilyl-3′-deoxy-3′-C-(2″-hydroxyethyl)thymidine (**3**)*

Sodium borohydride (34 mg, 0.90 mmol) was added to a stirred solution of aldehyde **2** (690 mg, 1.80 mmol) in methanol (16 mL) and the reaction was stirred at ambient temperature. After 1.5 h glacial acetic acid (200 mL) was added to the solution and the solvent evaporated *in vacuo* affording a colorless syrup that was extracted with dichloromethane (150 + 100 mL) and washed with aqueous sodium bicarbonate (saturated, 300 mL) and brine (300 mL). The combined organic phases were then dried (Na_2SO_4), filtered, and the solvent removed *in vacuo* affording essentially pure alcohol **3** as a colorless glass (593 mg, 85% yield), which was used in the next step without further purification: ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 0.12 and 0.13 (two s, 6H, Si*Me*$_2$), 0.94 (s, 9H, *t*-Bu), 1.51–1.62 (m, 1H, H1″$_A$), 1.74–1.85 (m, 1H, H1″$_B$), 1.92 (fine d, 3H, J = 1.3 Hz, 5-Me), 2.14 (A of ABXY, 1H, H2″$_A$), 2.25 (B of ABXY, 1H, H2″$_B$), 2.37–2.49 (m, 1H, H3′), 3.65–3.81 (m, 5H, H5′$_A$; H4′; H2″$_{AB}$ and -O*H*), 4.01 (dd, 1H, H5′$_B$), 6.08 (dd, 1H, H1′), 7.57 (fine q, 1H, J = 1.3 Hz, H6), 8.34 (br s, 1H, N*H*), $J_{H1'-H2'A}$ = 6.8 Hz, $J_{H1'-H2'B}$ = 3.9, $^2J_{H2'A-H2'B}$ = −13.5, $J_{H2'A-H3'}$ = 9.2, $J_{H2'B-H3'}$ = 7.6; ^{13}C NMR ($CDCl_3$): 12.84 (5-Me), 1942 (Si*C*Me$_3$), 26.53 (SiC*Me*$_3$ and Si*Me*$_2$), 35.57 (C3′), 35.88 (C1″), 39.76 (C2′), 61.31 (C5′), 64.02 (C2″), 86.32 and 87.94 (C1′ and C4′), 110.78 (C5), 137.80 (C6), 152.29 (C2), 166.42 (C4); MS (CI–NH_3), *m/e*: 385 ([MH^+], 17%), 276 ([M + NH_4^+ − ThyH], 21), 259 ([MH^+ − ThyH], 100), 127 ([ThyH + H^+], 10); HRMS (CI–NH_3) *m/e* calcd. for $C_{18}H_{33}N_2O_5Si$: 385.21588; found: 385.21593.

*5′-O-tert-Butyldimethylsilyl-3′-deoxy-3′-C-(2″-hydroxyethyl)-2″-O-(methanesulfonyl)thymidine (**4**)*

Methanesulfonyl chloride (201 μL, 2.60 mmol) was added dropwise to a stirred solution of alcohol **3** (500 mg, 1.30 mmol) in dry dichloromethane (5 mL) containing pyridine (946 μL, 11.7 mmol) and the resulting solution was stirred at room temperature under a nitrogen atmosphere. After 5 h the reaction was extracted with dichloromethane (2 × 100 mL) and washed with dilute sulphuric acid (2.5% w/v, 200 mL), aqueous sodium bicarbonate (saturated, 200 mL) and water (200 mL). The combined organic phases were then dried (Na_2SO_4), filtered, and the solvent removed *in vacuo*. The resulting syrup was chromatographed over silica gel (8:1 ethyl acetate/hexanes, v/v) to afford mesylate **4** as a crystalline solid (556 mg, 92% yield): mp 72–76°C (dec.); ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 0.12 (s, 6H, Si*Me*$_2$), 0.93 (s, 9H, *t*-Bu), 1.74 (m[10], 1H, H1″$_A$), 1.93 (fine d, 3H, J = 1.2 Hz, 5-Me), 1.97–2.06 (m, 1H, H1″$_B$), 2.16 (A of ABXY, 1H, H2′$_A$). 2.27 (B of ABXY, 1H, H2′$_B$), 2.40–2.52 (m, 1H, H3′), 3.03 (s, 3H, OMs), 3.74–3.81 (m, 2H, H4′ and H5′$_A$), 4.00 (dd, 1H, H5′$_B$), 4.23–4.35 (m, 2H, H2″AB), 6.12 (dd, 1H, H1′), 7.53 (fine q, 1H, J = 1.2 Hz, H6), 8.73 (br s, 1H, N*H*), $J_{H1'-H2'A}$ = 6.8 Hz, $J_{H1'-H2'B}$ = 4.4, $^2J_{H2'A-H2'B}$ = −13.5, $J_{H2'A-H3'}$ = 8.3, $J_{H2'B-H3'}$ = 8.0; ^{13}C NMR ($CDCl_3$): 12.54 ppm (5-Me), 18.36 (Si*C*Me$_3$), 25.86 (SiC*Me*$_3$ and Si*Me*$_2$), 31.72 (C1″), 34.39 (C3′), 37.42 (O*Ms*), 38.46 (C2′), 62.81 (C5′), 67.67 (C2″), 84.70 and 85.60 (C1′ and C4′), 110.40 (C5), 135.40 (C6), 150.51 (C2), 164.04 (C4); MS (CI–NH_3) *m/e*: 480 ([M + NH_4^+], 2.3%), 463 ([MH^+], 87%), 354 ([M + NH_4^+ − ThyH], 51), 337 ([MH^+ − ThyH], 100); HRMS (CI–NH_3) *m/e* calcd. for $C_{19}H_{35}N_2O_7SSi$: 463.19342; found: 463.19343.

*3-Deoxy-3-C-(2′-hydroxyethyl)-1,2-O-isopropylidene-2′-O-para-methoxyphenyl-5-trityl-α-D-ribofuranose (**6**)*

A solution of alcohol **5** (2.96 g, 6.43 mmol), *para*-methoxyphenol (2.39 g, 19.29 mmol), triphenylphosphine (2.19 g, 8.36 mmol), and diethyl azodicarboxylate (1.32 mL, 8.36 mmol)

in dry tetrahydrofuran was refluxed for 20 min. The solvent was then removed *in vacuo* yielding a violet syrup. Chromatography over silica gel (3:1 hexanes/ethyl acetate, v/v) afforded ether **6** as a white solid (3.30 g, 91% yield). Recrystallization from dichloromethane gave white crystals: mp 117–118°C; ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.34 and 1.51 (two s, 6H, C*Me*$_2$), 1.69–1.95 (m, 2H, H1′$_{AB}$), 2.39 (h^7, 1H, H3), 3.10 (A of ABX, 1H, H5$_A$), 3.40 (B of ABX, 1H, H5$_B$), 3.76 (s, 3H, O*Me*), 3.91–3.98 (m, 3H, H4 and H2′$_{AB}$), 4.70 (t, 1H, H2), 5.90 (d, 1H, H1), 6.76 (apparent d, 4H, MeO*Ph*O-), 7.21–7.47 (two m, 15H, C*Ph*$_3$), J_{H1-H2} = 3.8, J_{H2-H3} = 4.2, J_{H4-H5A} = 3.9, J_{H4-H5B} = 3.0, $^2J_{H5A-H5B}$ = −10.6; ^{13}C NMR ($CDCl_3$): 24.64 ppm (C1′), 26.42 and 26.76 (C*Me*$_2$), 41.87 (C3), 55.69 (O*Me*), 63.15 (C5), 66.34 (C2′), 80.90 and 81.03 (C2 and C4), 86.45 (*C*Ph$_3$), 104.99 (C1), 111.42 (*C*Me$_2$), 114.55 and 115.27 (*C*H of MeO*Ph*O-), 126.90; 127.76; 128.70 (*C*H of Tr), 143.92 (4° of Tr), 152.83 and 153.69 (4° of MeO*Ph*O-), MS (CI–NH$_3$), *m/e*: 567 ([MH$^+$], 4.9%), 243 ([CPh$_3^+$], 100), HRMS (CI–NH$_3$) *m/e* calcd. for $C_{36}H_{39}O_6$: 567.27466; found: 567.27489; Anal. calcd. for $C_{36}H_{38}O_6$: C 76.30, H 6.76; found: C 76.04, H 7.14.

1,2,5-Tri-O-*acetyl-3-deoxy-3*-C-*(2′-hydroxyethyl)-2′*-O-para-*methoxyphenyl-α-D-ribofuranose (7)*

Acetonide **6** (576 mg, 1.00 mmol) was dissolved in glacial acetic acid (15 mL) containing acetic anhydride (2.37 mL, 25.0 mmol) and the solution was heated to 70°C and stirred for 15 min. Camphorsulfonic acid (464 mg, 2.00 mmol) was then added and the resulting solution was stirred under nitrogen for 12 min. The solution was then cooled to 0°C and carefully poured into a solution of sodium carbonate (27.2 g) in water (170 mL) and the resulting suspension swirled occasionally over 30 min. The product was extracted with ethyl ether (2 × 200 mL) and washed with aqueous sodium bicarbonate (saturated, 200 mL) and water 200 mL). The combined ether extracts were then dried ($MgSO_4$), filtered, and the solvent evaporated *in vacuo* affording a colorless syrup that was chromatographed over silica gel (3:1 hexanes/ethyl acetate, v/v) to give triacetate **7** as a colorless syrup (282 mg, 69% yield): ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.72–2.16 (m, 2H, H1′$_{AB}$), 2.06; 2.07, and 2.09 (three s, 9H, OAc), 2.49 (h^7, 1H, H3), 3.76 (s, 3H, O*Me*), 3.86–4.05 (m, 2H, H2′$_{AB}$), 4.05–4.34 (m, 3H, H4, and H5$_{AB}$), 5.30 (d, 1H, H2), 6.09 (s, 1H, H1), 6.81 (s, 4H, MeO*Ph*O-), J_{H1-H2} ~ 0, J_{H2-H3} = 4.8; ^{13}C NMR ($CDCl_3$): 20.16; 20.26, and 20.64 ppm (OC*OMe*), 24.46 (C1′), 38.98 (C3), 55.15 (O*Me*), 64.98 (C5), 66.13 (C2′), 76.68 (C2), 82.36 (C4), 98.42 (C1), 114.22 and 114.76 (*C*H of MeO*Ph*O-), 152.14 and 153.52 (4° of MeO*Ph*O-), 168.62; 169.42, and 170.17 (*C*OMe); MS (CI–NH$_3$) *m/e*: 428 ([M + NH$_4^+$], 16%), 411 ([MH$_4^+$], 1.2), 351 ([MH$^+$ − AcOH], 100); HRMS (CI–NH$_3$) *m/e* calcd. for $C_{20}H_{27}O_9$: 411.1655; found: 411.1657.

2′,5′-Di-O-*acetyl-3′-deoxy-3′*-C-*(2″-hydroxyethyl)-2″*-O-para-*methoxyphenyl-(β-D-ribofuranosyl)thymine (8)*

Trimethylsilyl trifluoromethanesulfonate (0.75 mL, 1.56 mmol) was added dropwise to a stirred solution of triacetate **7** (6.41 g, 15.64 mmol) and bis-(trimethylsilyl)thymine (4.10 g, 17.20 mmol) in dry 1,2-dichloroethane (120 mL) and the resulting solution was heated to reflux under a nitrogen atmosphere. After 6 h the solution was cooled in an ice bath and poured into ice-cold aqueous sodium bicarbonate (5% w/v, 500 mL) and extracted with dichloromethane (500 mL). The organic phase was dried (Na_2SO_4), filtered, and the solvent removed *in vacuo* yielding a brown foam that was chromatographed over silica gel (2:1 ethyl acetate/hexanes, v/v) to give **8** as a white foam (6.78 g, 91% yield): ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.93 (fine d, 3H, 5-Me, J = 0.7), 2.11 and 2.13 (two s, 6H, OAc), 2.55 (h^7, 1H, H3′), 3.76 (s, 3H, O*Me*), 3.89–4.00 (m, 2H, H2″$_{AB}$), 4.20 (ddd, 1H, H4′), 4.38 (A of ABX, 1H, H5′$_A$), 4.45 (B of ABX, 1H, H5′$_B$), 5.51 (dd, 1H, H2′), 5.72 (d, 1H, H1′), 6.80 (s, 4H, MeO*Ph*O-), 7.26 (fine q, 1H, J = 0.8 Hz, H6), 8.74 (br s, 1H, NH), $J_{H1'-H2'}$ = 1.3, $J_{H2'-H3'}$ = 6.1, $J_{H3'-H4'}$ = 10.2, $J_{H4'-H5'A}$ = 4.8, $J_{H4'-H5'B}$ = 2.2, $^2J_{H5'A-H5'B}$ = −12.6; ^{13}C NMR ($CDCl_3$): 12.48 ppm (5-Me), 20.57 and 20.64 (CO*Me*), 24.48 (C1″), 39.00 (C3′), 55.53 (O*Me*), 63.20 (C5′), 66.06 (C2″), 77.31 (C2′), 82.00 (C4′), 91.23 (C1′), 110.63 (C5), 114.52 and 115.08 (*C*H of MeO*Ph*O-), 135.64 (C6), 149.95; 152.35 and 153.80 (C2 and 4° of MeO*Ph*O-), 163.85 (C4), 169.50 and 170.30 (*C*OMe); MS (CI–NH$_3$), *m/e*: 477 ([MH$^+$], 100%), 417 ([MH$^+$ − AcOH], 4.6), 351 ([MH$^+$ − ThyH], 86); HRMS (CI–NH$_3$) *m/e* calcd. for $C_{23}H_{29}N_2O_9$: 477.18730; found: 477.18742. Anal. calcd. for $C_{23}H_{28}N_2O_9$: C 57.98, H 5.92, H 5.88; found: C 57.99, H 6.27, N 5.75.

3′-Deoxy-3′-C-*(2″-hydroxyethyl)-2″*-O-para-*methoxyphenyl-(β-D-ribofuranosyl)thymine (9)*

Nucleoside **8** (107 mg, 0.20 mmol) was dissolved in methanol (1.00 mL), cooled to 0°C, and a steady stream of NH_3 gas bubbled through the solution for 10 min. The solution was then allowed to warm to ambient temperature and was stirred for 10 h. The solvent was removed *in vacuo* and the residue was chromatographed over silica gel (20:1 dichloromethane/methanol, v/v) yielding the diol **9** as a white foam (92 mg, 100% yield): ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.88 (s, 3H, 5-Me), 1.76–1.92 (m, 1H, H1″$_A$), 2.08–2.23 (m, 1H, H1″$_B$), 2.33–2.41 (m, 1H, H3′), 3.75 (s, 3H, O*Me*), 3.82 (br d, 1H, H4′), 4.04 (br t, 2H, H2″$_{AB}$), 4.16 (br t, 2H, H5′$_{AB}$), 4.39 (d, 1H, H2′), 5.55 (br s, 2H, -O*H*), 5.77 (s, 1H, H1′), 6.81 (s, 4H, MeO*Ph*O-), 7.89 (s, 1H, H6), 10.03 (s, 1H, N*H*), $J_{H1'-H2'}$ ~ 0, $J_{H2'-H3'}$ = 4.16; ^{13}C NMR ($CDCl_3$): 12.38 ppm (5-Me), 24.01 (C1″), 37.73 (C3′), 55.60 (O*Me*), 60.74 (C5′), 67.05 (C2″), 76.85 (C2′), 85.41 (C4′), 92.59 (C1′), 109.85 (C5), 114.58 and 115.32 (*C*H of MeO*Ph*O-), 136.50 (C6), 150.88; 152.49 and 153.85 (C2 and 4° of MeO*Ph*O-), 164.70 (C4); MS (CI–NH$_3$) *m/e*: 410 ([M + NH$_4^+$], 1.1%), 393 ([MH$^+$], 100), 284 ([M + NH$_4^+$ − ThyH], 4.0), 267 ([MH$^+$ − ThyH], 9.4), 127 ([ThyH + H$^+$], 0.8); HRMS (CI–NH$_3$) *m/e* calcd. for $C_{19}H_{25}N_2O_7$: 393.16618; found: 393.16625.

5′-O-tert-*Butyldimethylsilyl-3′-deoxy-3′*-C-*(2″-hydroxyethyl)-2″*-O-para-*methoxyphenyl-(β-D-ribofuranosyl)thymine (10)*

To a solution of alcohol **9** (1.91 g, 4.00 mmol) in freshly distilled *N,N*-dimethyformamide (4 mL) was added *tert*-butyldimethylsilyl chloride (0.63 g, 4.20 mmol) and imidazole (598 mg, 8.80 mmol) and the reaction was stirred at room temperature under a nitrogen atmosphere. After 18 h the solvent was removed *in vacuo* and the residue was extracted with ethyl acetate (2 × 300 mL) and washed with water (300 mL). The combined organic layers were then dried (Na_2SO_4), filtered, and evaporated *in vacuo* yielding a white foam that was chromatographed over silica gel (2:1 ethyl acetate/hexanes) to give silyl ether **10** as a white solid (2.12 g, 86% yield): ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.12 and 0.14 (two s, 6H, Si*Me*$_2$), 0.95 (s, 9H, C*Me*$_3$), 1.91 (s, 3H, 5-Me), 1.71–1.81 (m, 1H, H1″$_A$), 2.05–2.18 (m, 1H, H1″$_B$), 2.37 (h7, 1H, H3′), 3.74–3.80 (overlapping s and m, 4H, H5′$_A$ and O*Me*), 4.01 (br t, 2H, H2″$_{AB}$), 4.14–4.20 (m, 2H, H4′ and H5′$_B$), 4.36 (apparent t, 1H, H2′), 4.81 (s, 1H, -O*H*), 5.75 (s, 1H, H1′), 6.80 (s, 4H, MeO*Ph*O-), 7.81 (s, 1H, H6), 10.08 (s, 1H, N*H*), $J_{H1'-H2'}$ ~ 0; ^{13}C NMR ($CDCl_3$): 12.72 ppm (5-Me), 18.64 (*C*Me$_3$), 23.76 (C1″), 26.03 (*CMe*$_3$ and Si*Me*$_2$), 36.71 (C3′), 55.69 (O*Me*), 61.47 (C5′), 66.33 (C2″), 76.58 (C2′), 85.61 (C4′), 92.97 (C1′), 109.82 (C5), 114.59 and 115.61 (*C*H of MeO*Ph*O-), 135.89 (C6), 150.74; 152.88 and 153.73 (C2 and 4° of MeO*Ph*O-), 164.77 (C4); MS (FAB–glycerol) *m/e*: 507 ([MH$^+$], 1.8%), 171 (22), 127 ([ThyH + H$^+$], 3.6); HRMS (FAB–glycerol) *m/e* calcd. for $C_{25}H_{39}O_7N_2Si$: 507.25265; found 507.25277. Anal. calcd. for $C_{25}H_{38}O_7N_2Si$: C 59.26, H 7.56, N 5.53; found: C 58.87, H 7.83, N 5.30.

5′-O-tert-*Butyldimethylsilyl-3′-deoxy-3′*-C-*(2″-hydroxyethyl)-2″*-O-para-*methoxyphenyl-2′*-O-*phenoxythiocarbonyl-(β-D-ribofuranosyl)thymine (11)*

Phenyl chlorothionoformate (595 μL, 4.30 mmol) was added dropwise to a stirred solution of nucleoside **10** (1.98 g, 3.91 mmol) in dry dichloromethane (10 mL), containing dry pyridine (2.5 mL) and the reaction was stirred under a nitrogen atmosphere at 0.°C.

5′-S-*Acetyl-3′,5′-dideoxy-3′*-C-*(2″-hydroxyethyl)-2″*-O-para-*methoxyphenyl-5′-thiothymidine (16)*

Diisopropyl azodicarboxylate (1.05 mL, 5.32 mmol) was added dropwise to a stirred solution of triphenylphosphine (1.39 g, 5.32 mmol) in dry tetrahydrofuran (10 mL) cooled to 0°C under nitrogen, resulting in a milky suspension. After 0.5 h a solution of nucleoside **17** (1.00 g, 2.66 mmol) and thiolacetic acid (0.38 mL, 5.32 mmol) in dry tetrahydrofuran (20 mL) was slowly added and the stirring at 0°C continued for 0.5 h after which time the reaction was allowed to warm to room temperature. After 40 min the solvent was removed *in vacuo* and the resulting yellow syrup was chromatographed over silica (25:1 dichloromethane/methanol, v/v) affording thiolester **16** as a white solid (1.00 g, 87% yield): ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.96 (s, 3H, 5-Me), 1.69–1.80 (m, 1H, H1″$_A$), 2.02–2.12 (m, 1H, H1″$_B$), 2.16–2.31 (m, 3H, H3′ and H2″$_{AB}$), 2.38 (s, 3H, SAc), 3.26 (A of ABX, 1H, H5′$_A$), 3.36 (B of ABX, 1H, H5′$_B$), 3.76 (s, 3H, O*Me*), 3.88 (m[6], 1H, H4′), 3.96 (apparent t, 2H, H2″$_{AB}$, J = 5.9), 6.08 (dd, 1H, H1′), 6.82 (s, 4H, MeO*Ph*O-), 7.36 (s, 1H, H6), 9.16 (br s, 1H, N*H*), $J_{H1'-H2'}$ = 4.2 and 6.0, $J_{H4'-H5'A}$ = 6.5, $J_{H4'-H5'B}$ = 3.5, $^2J_{H5'A-H5'B}$ = −14.4; ^{13}C NMR ($CDCl_3$): 12.62 ppm (5-Me), 30.52 (SCO*Me*), 31.56 and 31.67 (C1″ and C2′), 38.96 and 39.06 (C3′ and C5′), 55.66 (O*Me*), 66.50 (C2″), 83.74 and 84.75 (C1′ and C4′), 110.67 (C5), 114.63 and 115.22 (*C*H of MeO*Ph*O-), 135.40 (C6), 150.31; 152.54 and 153.89 (C2 and 4° of MeO*Ph*O-), 163.85 (C4), 194.71 (S*C*OMe); MS (CI–NH$_3$), *m/e*: 452 ([M + NH$_4^+$], 8.3%), 435 ([MH$^+$], 100), 326 ([M + NH$_4^+$ – ThyH], 3.6), 309 ([MH$^+$ – ThyH], 53), 127 ([ThyH + H$^+$], 2.8); HRMS (CI–NH$_3$) *m/e* calcd. for $C_{21}H_{27}N_2O_6S$: 435.15898; found: 435.15889.

3′-Deoxy-3′-C-*(2″-hydroxyethyl)-2″*-O-(para-*methoxyphenyl)thymidine (17)*

A stock solution of tetra-*n*-butylammonium fluoride (1 N in THF, 7.9 mL, 7.9 mmol) was added to stirred solution of nucleoside **12** (1.29 g, 2.64 mmol) in dry tetrahydrofuran (5 mL) and the resulting solution was stirred at room temperature under a nitrogen atmosphere. After 1.5 h the solvent was evaporated *in vacuo* and the residue chromatographed over silica (20:1 dichloromethane/methanol, v/v) affording nucleoside **17** as a white solid (0.99 g, quantitative): ^{1}H NMR (200 MHz, CD_3OD) δ: 1.86 (s, 3H, 5-Me), 1.63–1.80 (m, 1H, H1″$_A$), 1.91–2.07 (m, 1H, H1″$_B$), 2.14–2.35 (m, 2H, H2′$_{AB}$), 2.38–2.53 (m, 1H, H3′), 3.69–3.81 and 3.89–4.00 (two m, 5H and 3H, -O*Me*; H5′$_{AB}$; H4′; and H2″$_{AB}$), 6.04 (dd, 1H, H1′), 6.81 (s, 4H, MeO*Ph*O-), 8.00 (s, 1H, H6), $J_{H1'-H2'}$ = 3.2 and 6.7; ^{13}C NMR ($CDCl_3$): 12.40 ppm (5-Me), 31.45 (C1″), 34.53 (C3′), 39.09 (C2′), 55.59 (O*Me*), 61.50 (C5′), 66.74 (C2″), 84.95 and 86.41 (C1′ and C4′), 110.19 (C5), 114.57 and 115.23 (CH of MeOPhO-), 136.37 (C6), 150.45; 152.48 and 153.80 (C2 and 4° of MeOPhO-), 164.22 (C4); MS (CI–NH$_3$) *m/e*: 394 ([M + NH$_4^+$], 2.5%), 377 ([MH$_4^+$], 87), 268 ([M + NH$_4^+$ – ThyH], 23), 251 ([MH$^+$ – ThyH], 100), 127 ([ThyH + H$^+$], 16); HRMS (CI–NH$_3$) *m/e* calcd. for $C_{19}H_{25}N_2O_6$: 377.17126; found: 377.17114. Anal. calcd. for $C_{19}H_{25}N_2O_6$: C 60.63, H 6.43, N 7.44; found: C 60.23, H 6.77, N 7.30.

5′-S-*Acetyl-5′-deoxy-5′-thiothymidine (18)*

Diisopropyl azodicarboxylate (1.62 mL, 8.26 mmol) was added dropwise to a stirred solution of triphenylphosphine (2.16 g, 8.26 mmol) in dry tetrahydrofuran (18 mL) cooled to 0°C under

nitrogen resulting in a milky suspension. After 0.5 h a solution of thymidine (1.00 g, 4.13 mmol) and thiolacetic acid (0.59 mL, 8.26 mmol) in dry *N,N*-dimethylformamide (15 mL) was slowly added and the stirring at 0°C continued for 0.5 h after which time the reaction was allowed to warm to room temperature. After 0.5 h the solvent was removed *in vacuo* and the resulting brown syrup pumped for 2 h. The resulting glass was chromatographed over silica (25:1 to 15:1 dichloromethane/methanol, v/v) affording thiolester **16** as a white solid (650 mg, 52% yield): ^{1}H NMR (300 MHz, CD_3OD) δ: 1.90 (fine d, 3H, J = 1.2 Hz, 5-Me), 2.25 (dd, 2H, H2′$_{AB}$), 2.35 (s, 3H, SAc), 3.23 (d, 2H, H5′$_{AB}$), 3.93 (td, 1H, H4′), 4.20 (td, 1H, H3′), 6.19 (t, 1H, H1′), 7.44 (fine q^4, 1H, J = 1.2 Hz, H6), $J_{H1'-H2'AB}$ = 6.8 Hz, $J_{H2'AB-H3'}$ = 5.0, $J_{H3'-H4'}$ = 3.5, $J_{H4'-H5'AB}$ = 6.2; ^{13}C NMR (CD_3OD): 12.38 ppm (5-Me), 30.43 (CO*Me*), 32.30 (C5′), 40.09 (C2′), 74.37 (C3′), 86.46 (2C, C1′ and C4′), 111.83 (C5), 137.66 (C6), 152.25 (C2), 166.26 (C4), 196.46 (*C*OMe); MS (CI–NH_3) m/e: 318 ([M + NH_4^+], 14%), 301 ([MH^+], 100), 175 ([MH^+ − ThyH], 1.1), 127 ([ThyH + H^+], 17); HRMS (CI–NH_3) m/e calcd. for $C_{12}H_{17}N_2O_5S$: 301.08582; found: 301.08574.

*5′-S-Acetyl-3′-*O*-tert-butyldimethylsilyl-5′-deoxy-5′-thiothymidine (19)*

tert-Butylchlorodimethylsilane (309 mg, 2.05 mmol) and imidazole (280 mg, 4.10 mmol) were successively added to a stirred solution of nucleoside **18** (560 mg, 1.86 mmol) in dry *N,N*-dimethylformamide (5 mL) and the reaction was stirred at ambient temperature under a nitrogen atmosphere. After 18 h the solution was poured into water (300 mL) and the product was extracted with dichloromethane (2 × 200 mL) and washed with water (2 × 300 mL). The combined organic extracts were then dried (Na_2SO_4), filtered, and the solvent removed *in vacuo* yielding a yellow syrup. Chromatography over silica gel (25:1 dichloromethane/methanol, v/v) afforded the silyl ether **19** as a colorless solid (709 mg, 92% yield): ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.08 and 0.10 (two s, 6H, Si*Me*$_2$), 0.90 (s, 9H, *t*-Bu), 1.96 (fine d, J = 1.2 Hz, 5-Me), 2.10 (A of ABXY, 1H, H2′$_A$), 2.28 (B of ABXY, 1H, H2′$_B$), 2.40 (s, 3H, SAc), 3.21 (d, 2H, H5′$_{AB}$), 3.99 (td, 1H, H4′), 4.17 (dt, 1H, H3′), 6.21 (dd, 1H, H1′), 7.23 (find q^4, 1H, J = 1.2 Hz, H6), 8.62 (br s, 1H, N*H*), $J_{H1'-H2'A}$ = 7.5 Hz, $J_{H1'-H2'B}$ = 6.1, $^2J_{H2'A-H2'B}$ = −13.8, $J_{H2'A-H3'}$ = 6.5, $J_{H2'B-H3'}$ = 3.2, $J_{H3'-H4'}$ = 3.5, $J_{H4'-H5'AB}$ = 5.8; ^{13}C NMR ($CDCl_3$): 12.60 ppm (5-Me), 17.87 (Si*C*Me$_3$), 25.64 (Si*Me*$_2$ and Si*C*Me$_3$), 30.56 (CO*Me*), 31.13 (C5′), 40.44 (C2′), 73.84 (C3′), 85.13 and 85.17 (C1′ and C4′), 111.10 (C5), 135.32 (C6), 150.16 (C2), 163.74 (C4), 194.48 (*C*OMe); MS (CI–NH_3), m/e: 432 ([M + NH_4^+], 4.9%), 415 ([MH^+], 100), 306 ([M + NH_4^+ − ThyH], 1.8), 289 ([MH^+ − ThyH], 11), 127 ([ThyH + H^+], 13); HRMS (CI–NH_3) m/e calcd. for $C_{18}H_{31}N_2O_5SSi$: 415.17230; found: 415.17213.

*3′-*O*-tert-Butyldimethylsilyl-5′-deoxy-5′-thiothymidine (20)*

Methanolic sodium hydroxide solution (0.50 N, 7.7 mL, 3.86 mmol), previously saturated with N_2 gas, was slowly added to a stirred solution of thiolester **19** (800 mg, 1.93 mmol) in methanol (30 mL, deoxygenated) and the reaction allowed to stir at ambient temperature under nitrogen. After 1 h, the base was neutralized with Amberlite H^+ resin, which was filtered and washed thoroughly with methanol. Evaporation of the alcohol *in vacuo* afforded the thiol **20**, a colorless glass that crystallized upon standing (738 mg, quantitative): mp 116–119°C (dec.); ^{1}H NMR (300 Mhz, $CDCl_3$) δ: 0.098 and 0.10 (two s, 6H, Si*Me*$_2$), 0.90 (s, 9H, *t*-Bu), 1.95 (fine d, 3H, J = 1.2 Hz, 5-Me), 1.53 (t, exchangeable, 1H, S*H*), 2.16 (A of ABXY, 1H, H2′$_A$), 2.30 (B of ABXY, 1H, H2′$_B$), 2.78 (A of ABXY, 1H, H5′$_A$), 2.89 (B of ABXY, 1H, H5′$_B$), 3.95 (apparent q^4, 1H, H4′), 4.36 (dt, 1H, H3′), 6.25 (t, 1H, H1′), 7.34 (fine q^4, 1H, J = 1.2 Hz, H5), 8.41 (br s, 1H, N*H*), $J_{H1'-H2'A}$ = $J_{H1'-H2'B}$ = 6.7 Hz, $J_{H2'A-H3'}$ = 7.1, $J_{H2'B-H3'}$ = 4.3, $^2J_{H2'A-H2'B}$ = −13.7, $J_{H3'-H4'}$ = 4.6, $J_{H4'-H5'A}$ = $J_{H4'-H5'B}$ = 4.6, $^2J_{H5'A-H5'B}$ = −14.2, $J_{SH-H5'AB}$ = 8.3; ^{13}C NMR ($CDCl_3$): 12.65 ppm (5-Me), 17.87 (Si*C*Me$_3$), 25.66 (Si*Me*$_2$ and Si*C*Me$_3$), 26.41 (C5′), 40.54 (C2′), 72.50 (C3′), 84.46 and 85.97 (C1′ and C4′), 111.24 (C5), 135.51 (C6), 150.20 (C2), 163.65 (C4); MS (CI–NH_3) m/e: 390 ([M + NH_4^+], 1.4%), 373 ([MH^+], 100), 247 ([MH^+ − ThyH], 2.7), 127 ([ThyH + H^+], 28); HRMS (CI–NH_3) m/e calcd. for $C_{16}H_{29}N_2O_4SSi$: 373.161733; found: 373.161730. Anal. calcd. for $C_{16}H_{27}N_2O_4SSi$: C 51.58, H 7.58, N 7.52, S 8.60; found: C 51.19, H 7.59, N 7.36, S 8.32.

It was found that chromatography of the thiol over silica immediately after the reaction (1:1 hexanes/ethyl acetate, v/v) removes a small amount of impurity that accelerates the oxidation of the product to the symmetrical disulfide: ^{1}H NMR (300 MHz, CD_3OD) δ: 0.096 and 0.101 (two s, 6H, Si*Me*$_2$), 0.90 (s, 9H, *t*-Bu), 1.94 (fine d, 3H, J = 1.2 Hz, 5-Me), 2.16 (A of ABXY, 1H, H2′$_A$), 2.30 (B of ABXY, 1H, H2′$_B$), 3.02 (A of ABX, 1H, H5′$_A$), 3.07 (B of ABX, 1H, H5′$_B$), 4.10 (td, 1H, H4′), 4.35 (dt, 1H, H3′), 6.19 (apparent t, 1H, H1′), 7.23 (fine q, 1H, J = 1.2 Hz, H6), 8.95 (br s, 1H, nH), $J_{H1'-H2'A}$ = 7.1, $J_{H1'-H2'B}$ = 6.3, $^2J_{H2'A-H2'B}$ = −13.6, $J_{H2'A-H3'}$ = 6.7, $J_{H2'B-H3'}$ = 3.5, $J_{H3'-H4'}$ = 3.8, $J_{H4'-H5'A}$ = 6.0, $J_{H4'-H5'B}$ = 5.4, $^2J_{H5'A-H5'B}$ = −14.0; ^{13}C NMR ($CDCl_3$): 12.59 ppm (5-Me), 17.85 (Si*C*Me$_3$), 25.64 (Si*Me*$_2$ and Si*C*Me$_3$), 40.21 and 41.88 (C2′ and C5′), 73.56 (C3′), 85.01 and 85.54 (C1′ and C4′), 111.11 (C5), 135.59 (C6), 150.26 (C2), 163.95 (C4); MS (FAB–glycerol) m/e: 743 ([MH^+], 8.4%), 437 (46).

Micellar rate enhancement studies in mixed sodium fluorocarbon/hydrocarbon surfactant solutions

TERRENCE J. CONNOLLY AND VINCENT C. REINSBOROUGH[1]
Department of Chemistry, Mount Allison University, Sackville, N.B., Canada E0A 3C0

Received August 7, 1991

TERRENCE J. CONNOLLY and VINCENT C. REINSBOROUGH. Can. J. Chem. **70**, 1581 (1992).

Stopped-flow kinetic studies were conducted in mixed micellar solutions of fluorocarbon and hydrocarbon anionic surfactants to determine the prevalent micellar form. The probe reaction was the Ni_{aq}^{2+}/pyridine-2-azo-*p*-dimethylaniline (PADA) complexation, which is many times accelerated in the presence of anionic micelles. Binding constants for Ni_{aq}^{2+} and PADA partitioning between bulk solution and micelles were determined through the murexide technique and solubility measurements respectively and the molar reaction volume was obtained from the Robinson equation. The three binary surfactant systems investigated had sodium perfluoroheptanoate as the fluorocarbon surfactant while the hydrocarbon surfactants were sodium decylsulfate, sodium nonanesulfonate, and sodium octanesulfonate. The kinetic results were consistent with unimicellar composition in all three systems which was not the behaviour previously found with the sodium octane sulfonate / sodium perfluoroctanoate system. The difference was attributed to closer similarity in the surfactant pair hydrophobicities as revealed through their critical micelle concentrations. Another finding was that mixed micelles synergistically can lead to a much greater solubilization of PADA than is possible through either of the pure surfactants.

TERRENCE J. CONNOLLY et VINCENT C. REINSBOROUGH. Can. J. Chem. **70**, 1581 (1992).

Dans le but de déterminer la forme micellaire prévalante, on a réalisé des études cinétiques à flux stoppé sur des solutions micellaires d'agents de surface anioniques fluoro- et hydro-carbonés. La réaction indicatrice utilisée est la complexation Ni_{aq}^{2+}/pyridine-2-azo-*p*-diméthylaniline (PADA) qui est fortement accélérée en présence de micelles anioniques. Les constantes de fixation du Ni_{aq}^{2+} et de partition du PADA entre la masse de la solution et les micelles ont été déterminées respectivement à l'aide de la technique du murexide et de mesures de solubilité et on a évalué le volume molaire de la réaction grâce à l'équation de Robinson. Les trois systèmes binaires d'agents de surface étudiés contenaient du perfluoroheptanoate de sodium comme agent de surface fluorocarboné alors que les agents de surface hydrocarbonés étaient le décylsulfate de sodium, nonanesulfonate de sodium et octanesulfonate de sodium. Dans les trois systèmes, les résultats cinétiques sont en accord avec la composition unimicellaire; ce comportement est différent de celui observé antérieurement avec le système octanesulfonate de sodium / perfluorooctanoate de sodium. On attribue la différence à la plus grande similarité dans les hydrophobicités des paires d'agents de surface qui sont révélées par leurs concentrations micellaires critiques. Une autre observation a trait au fait que les micelles mixtes peuvent agir par synergie pour conduire à une solubilisation beaucoup plus grande du PADA que celle possible par chacun des agents de surface agissant seuls.

[Traduit par la rédaction]

Introduction

Mixing hydrocarbon and fluorocarbon surfactants is commonplace in industry to achieve better wash results but the constitution and structure of the micelles responsible for this enhanced detergency are still not well understood. Models for binary surfactant mixes range from the extremes of two one-component micelles and a single two-component micelle to intermediate scenarios of two micelles with one richer than the other in one surfactant (refs. 1–4 and references cited therein). Impinging lately upon the situation is the growing realization that fluorocarbon micelles differ quite markedly from hydrocarbon micelles (5, 6). Recently, we investigated the rate enhancements that the complexation reaction between Ni_{aq}^{2+} and the bidentate ligand pyridine-2-azo-*p*-dimethylaniline (PADA) experienced in the presence of mixed sodium perfluorooctanoate (SPFO) / sodium octanesulfonate (SOS) micellar solutions (4). The kinetic results we obtained were consistent with there being two separate micelles of pure or almost pure composition present in solution. In this surfactant mixture, the fluorocarbon surfactant had the greater hydrophobicity, the lower critical micelle concentration (CMC), and presumably the greater influence in determining properties of the mixed solutions. In the first phase of the present study, the roles of the surfactant types were switched by conducting the same kinetic studies in sodium perfluoroheptanoate (SPFH) / sodium decylsulfate (SDeS) micellar solutions. SPFH and SDeS have CMC values of 0.068 mol dm^{-3} and 0.024 mol dm^{-3} respectively in millimolar nickel ion solutions. In this micellization situation, the hydrocarbon surfactant is dominant and any differences in micellar structure between the two mixed surfactant situations should be clear from the kinetic behaviour. Rate enhancements in micellar solution of the Ni_{aq}^{2+}/PADA complexation reaction find a ready explanation in the model of Robinson and co-workers (7–11) which is sufficiently refined to reveal major micellar structural differences. In the second part of this work, the system sodium perfluoroheptanoate (SFPH) / sodium octanesulfonate(SOS) was investigated kinetically. This combination of short-chained surfactants reverts to having the fluorocarbon dominant (CMC = 0.070 mol dm^{-3}) with the hydrocarbon surfactant having a CMC of 0.15 mol dm^{-3}. This second system is similar to the SPFO/SOS system investigated previously (4) except that the CMC values of the pure surfactants are closer together. The data from this second system suggested that a third hydrocarbon/fluorocarbon surfactant combination where the CMC values were almost coincident should be examined. The system chosen in the third section was sodium perfluoroheptanoate / sodium nonanesulfonate (SPFH/SNS).

Experimental

A Cantech stopped-flow apparatus (deadtime 3 ms) with spectrophotometric detection was used to obtain rate constants under

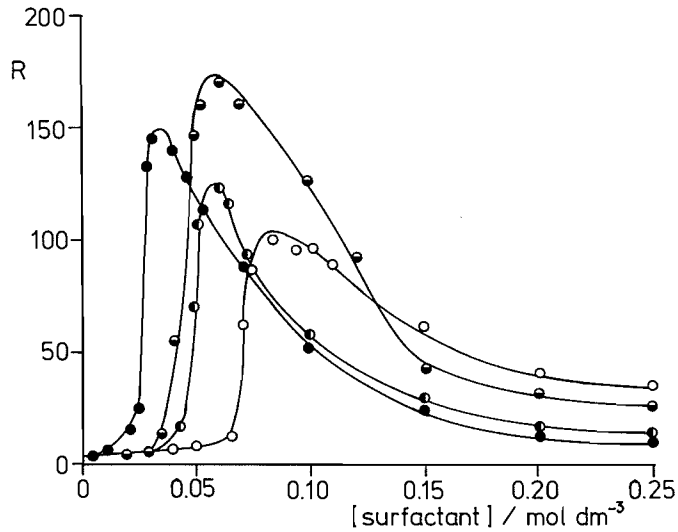

FIG. 1. Rate enhancements R of of the Ni_{aq}^{2+}/PADA complexation reaction in SDeS/SPFH solutions: (●) pure SDeS, (◐) 1:1 SDeS/SPFH, (◒) 1:3 SDeS/SPFH, (○) pure SPFH. [surfactant] = total surfactant concentration.

pseudo-first-order conditions for the formation of the Ni_{aq}^{2+}/PADA complex and the Ni_{aq}^{2+}/murexide complex in the mixed micellar solutions. The dye and Ni_{aq}^{2+} reactant solutions were adjusted to pH 7.2 ± 0.1 before mixing in the PADA runs and to pH 6.0 ± 0.1 in the murexide runs. Equal concentrations of surfactant were used in both reactant syringes to avoid surfactant concentration jumps. Solubility measurements of PADA (Sigma) in surfactant solutions were carried out spectrophotometrically as described previously (8, 9). Solutions of the fluorocarbon surfactants were prepared *in situ* by neutralizing the acids (Aldrich and Fluka) with the highest quality sodium hydroxide (Aldrich). Sodium decylsulfate or SDeS (Lancaster), sodium nonanesulfonate or SNS (Sigma), and sodium octanesulfonate or SOS (Sigma) were dried at room temperature in vacuum and used without further purification. All solutions were made from triply distilled water.

Results and discussion

SDeS/SPFH system

In Fig. 1 the observed rate constants (k_{obs}) for the complexation of Ni_{aq}^{2+} with the dye ligand PADA in pure SDeS, pure SPFH, in 1:3 SDeS/SPFH, and in 1:1 SDeS/SPFH solutions at 25.0°C at various surfactant concentrations are given as R, the ratio of k_{obs} in solution to k_{obs} in pure water (9), which is (1.2 ± 0.1) × 10^3 dm^3 mol^{-1} s^{-1} (11). In addition to the 1:3 and 1:1 SDeS/SPFH systems, three other mixed systems were studied kinetically: the 3:1, 1:2, and 1:6 mole ratios. The general concentration dependence of R was similar to that observed previously in other micellar systems, i.e., little change from unity until close to the CMC and then a more or less sharp rise to a maximum just beyond the CMC followed in turn by a more gradual decline to a plateau in concentrated micellar solution. The increase in rate is a concentrative effect brought about when both reactants, metal cation and hydrophobic dye, are attracted strongly into the micellar surface region (7). Properly speaking, the micelles are not acting as catalysts since no new path is being provided for the reaction with the activation energy for the complexation reaction remaining the same with or without surfactant (7, 8). The values of R_{max} for all six systems investigated are listed in Table 1.

R values for pure SDeS solutions agreed with previously published results with an R_{max} of 150 ± 20 and a CMC of 24 mmol dm^{-3} as determined from the beginning of the steeply rising slope (9). Pure SPFH had not been investigated before in this context but its R_{max} value of 115 was consistent with the R_{max} value of 400 reported for the longer chained sodium perfluorooctanoate or SPFO (4). The reported CMC values for SPFH lie in the range 80–85 mmol dm^{-3} (5, 13) and the value obtained in this work, of 70 mmol dm^{-3}, undoubtedly reflects a slight lowering of the CMC due to the background 10^{-3} mol dm^{-3} Ni_{aq}^{2+} in solution (increasing the ionic strength of surfactant solutions generally lowers the CMC).

For the first mixed system, 3:1 SDeS/SPFH, substituting each fourth SDeS with a SPFH molecule made little difference to the observed rate enhancements. Even though pure SPFH has a higher CMC than does pure SDeS, R_{max} for the 3:1 SDeS/SPFH system was the same as for pure SDeS and the combined CMC was 28 mmol dm^{-3} in total surfactant. The 1:1 SDeS/SPFH system showed more the effect of adding the "weaker" surfactant as the R_{max} declined to 130 and the mixed CMC rose to 43 mmol dm^{-3}. The 1:3 SDeS/SPFH system dramatically reversed this trend with R_{max} rising to 170 and the mixed CMC remaining unchanged. The R_{max} value for the 1:6 SDeS/SPFH system declined slightly to 152 but still was large in view of the 115 reading for pure SPFH. The mixed CMC for the 1:6 system of 62 mmol dm^{-3} total surfactant also was low in view of the CMC of pure SPFH. It is clear that the 1:3 and the 1:6 systems demonstrate synergistic effects (14). Minor synergistic effects have been reported for some mixed anionic hydrocarbon micellar systems (12) but these were not found in the previously studied mixed fluorocarbon/hydrocarbon surfactant system (4).

The Robinson model accounts quantitatively for micellar rate enhancements by the expression (8, 9, 11)

$$k^s_{obs} = k^s_f [Ni^{2+}]/\{CV[1 + (CK_{Ni})^{-1}][1 + (CK_{PADA})^{-1}]\}$$

where k^s_{obs} is the observed rate constant in surfactant solution, k^s_f is the second-order forward rate constant for the complexation in surfactant solution, C is the concentration of the surfactant in the form of micelles, i.e., the total concentration less the CMC, and V is the molar reaction volume of the surfactant. The parameter V is a measure of the tightness or density of the micellar surface region in which the probe reaction occurs. K_{Ni} and K_{PADA} represent partitioning coeficients for each reactant going on and coming off the micelles, e.g., $K_{Ni} = [Ni^{2+}]_s/C[Ni^{2+}]_b$ where subscripts s and b denote the micellar surface and bulk solution pseudophases respectively. K_{PADA} is defined analogously. The value of k^s_f is assumed equal to the rate constant in pure water (1. 2 × 10^3 dm^3 mol^{-1} s^{-1}) (8). Values of K_{Ni} and K_{PADA} are obtained independently by the murexide technique (4, 15) and by solubility measurements respectively (8, 9). Curve-fitting of the kinetic data yields parameter V and (or) K_{Ni}. The values of K_{Ni} (experimental and fitted), K_{PADA}, and V are found in Table 1.

First of all, the fitted binding constants of nickel ion to the micelles in all the pure and mixed surfactant systems agreed reasonably well with those obtained through the murexide technique, which speaks well for the kinetic model. Secondly, K_{Ni} for pure SPFH of 55 was reasonable since K_{Ni} for sodium perfluorooctanoate was 250 (4). Rather surpris-

[a]Fitted values.
[b]Experimental values.

ingly, the binding of the dye PADA to pure SPFH micelles (K_{PADA}) was equally as strong as it was to the presumably larger pure SPFO micelles (4). This may be related to the anomalous nature of perfluorinated surfactants (5). A consistency with sodium perfluorooctanoate did develop, however, in the remarkably low value of the reaction volume of 0.15 $dm^3\ mol^{-1}$ for pure SPFH. The value of V for sodium heptanesulfonate of the same chain length is 0.89 $dm^3\ mol^{-1}$ (10) and, even allowing for the 1.5 factor Shinoda *et al.* (16) found should be used when comparing the properties of fluorocarbon surfactants with their hydrocarbon counterparts, values of reaction volumes of 0.15 $dm^3\ mol^{-1}$ or 0.16 $dm^3\ mol^{-1}$ as found with sodium perfluorooctanoate micelles seem grossly out of line (V for sodium dodecylsulfate is 0.40 $dm^3\ mol^{-1}$ for the same reaction (11)). However, the reaction volume should approximate the molar volume of the surfactant according to theory (17) and for SPFO this should be slightly less than the reported value of 0.22 $dm^3\ mol^{-1}$ for sodium perfluorononanoate at 30°C (18). With short-chained hydrocarbon surfactants, V values often exceed the molar volume of the surfactant many times, suggesting that such micelles are loosely held together and (or) the reaction zone extends considerably into the solution from the micelle surface (10). Fluorinated surfactants on the other hand appear to maintain the tightness of micellar surface region even with a seven-membered tail. Guo *et al.* (5) have noted that the so-called Stern layer of the perfluoroheptanoic micelle is very compact as compared with ordinary or hydrocarbon surfactants, which is in agreement with our results. The better than expected micellar "catalysis" effected by fluorocarbon surfactants on the Ni_{aq}^{2+}/PADA complexation reaction thus is not a result of any greater attraction of either of the reactants Ni_{aq}^{2+} or PADA into the micellar surface region but rather of a pronounced constriction of this part of the micelle.

Remarkably, this contraction of the micellar surface region persists when SDeS is added to pure SPFH micelles to at least 25 mol% SDeS where V is 0.17 $dm^3\ mol^{-1}$ (Table 1). At this concentation, both K_{Ni} and K_{PADA} have increased in keeping with the presence of 25 mol% SDeS for which these partitioning constants are higher. Thus, with increased K values and V remaining the same, the rate enhancement increases overall as compared with the pure SPFH situation. At 50 mol% SDeS, the partitioning constants and the V values both increase, thus negating any overall increase in R as compared with the 25 mol% SDeS system. Thus, a maximum in R_{max} occurs around 25 mol% SDeS in the SDeS/SPFH system. R_{max} values should be a practical indicator of the efficiency of anionic detergents because according to the kinetic analysis the value of R is decided by the effectiveness with which the micellar surfactant is able to attract metallic ions and organic material, and these constitute two important types of materials good detergents should remove from solution. In applications where this is desired, a mixed SDeS/SPFH soap with 25 mol% SDeS should be a more effective dirt remover than either of the pure surfactants.

When SPFO was added to micellar SOS solutions to constitute a 10 mol% SPFO system, the rate enhancements increased dramatically, despite a countering decrease in K_{PADA}. This increase resulted because the reaction volume underwent an eightfold decrease (4). This together with other evidence such as the common occurrence of two CMC's in many of the mixed systems was interpreted to indicate that relatively pure perfluorooctanoate micelles were formed, perhaps together with pure or almost pure octylsulfate micelles, and that the former micelles were almost entirely responsible for the observed rate enhancements. On the other hand, in the mixed system reported here, the kinetic parameters of even the 25 mol% SPFH system seem simply to reflect more or less proportionately the mole ratios of each surfactant. Moreover, no systems gave evidence of having more than one CMC. Thus, it would appear that in the SDeS/SPFH system one mixed-micelle was responsible for the observed rate enhancements. Perfluoroheptanoate monomers are apparently adsorbed and absorbed into decylsul-

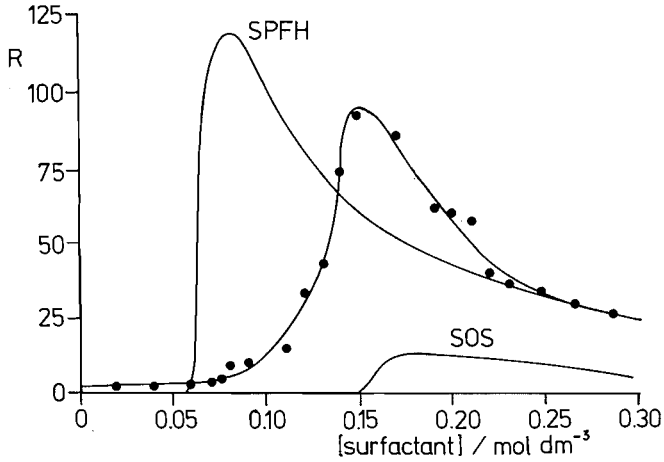

FIG. 2. Rate enhancements R of the Ni_{aq}^{2+}/PADA complexation reaction in 1:1 SOS/SPFH solutions. Fitted curves for R are also shown for the pure surfactants. [surfactant] = total surfactant concentration.

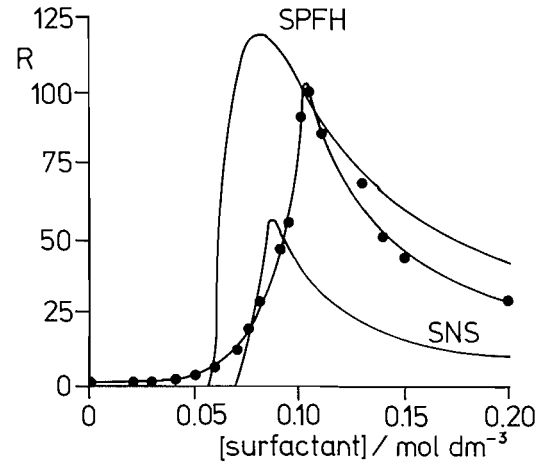

FIG. 3. Rate enhancements R of the Ni_{aq}^{2+}/PADA complexation reaction in 1:1 SNS/SPFH solutions. Fitted curves for R for the pure surfactants are also shown. [surfactant] = total surfactant concentration.

fate micelles where they bring about a roughly proportional diminution in the attraction experienced by each reactant into the micelle but cause an inordinately large shrinking of the micellar surface region in respect to the Ni_{aq}^{2+}/PADA complexation reaction.

SOS/SPFH system

The rate enhancement plots for the 1:1 SPFH/SOS system as compared with the curves for pure SPFH and pure SOS are displayed in Fig. 2. The kinetic parameters for the system as obtained through stopped-flow murexide runs (K_{Ni}), solubility measurements (K_{PADA}), and computer curve-fitting (V) are listed in Table 1. Three features especially are notable and these cause this sytem to resemble more closely the SPFH/SDeS system than the SPFO/SOS system. First of all, R_{max} for the 1:1 combination is 75% of the R_{max} value for pure SPFH or about nine times that for pure SOS. Secondly, the reaction volume of the equimolar mixture in solution is remarkedly close to the reaction volume for pure SPFH. The fluorocarbon surfactant monomer controls this parameter, reducing it to a value four times lower than in pure SOS. Thirdly, the K_{PADA} values indicate that the mixed system is a much more efficient PADA scavenger than either of the pure components, an observation not noted before in mixed surfactant systems. The solubility and the murexide curves gave no sign either of any second CMC's so that all indicators point to a one-micelle system as with the SDeS/SPFH situation.

SNS/SPFH system

From the results with the foregoing perfluorocarbon/hydrocarbon surfactant combinations, whether one or two micelles were formed in these mixed systems seemed to depend on how close were the CMC values for the two pure surfactants. The CMC values for SOS and SPFO in 10^{-3} mol dm^{-3} Ni_{aq}^{2+} were 0.15 mol dm^{-3} and around 0.02 mol dm^{-3} respectively (4) and two micelles were apparently formed in the micellar solutions of the mixtures. SDeS and SPFH had CMC's of 0.024 mol dm^{-3} and 0.070 mol dm^{-3} respectively and their mixtures indicated only one micellar form was prevalent in solution. In the first case, the CMC's differed by a factor of seven while in the second case the factor was three. With the SOS/SPFH system, the CMC ratio was two and simply one micelle formed. To test this closeness-of-CMC hypothesis further, a hydrocarbon surfactant was mixed equimolarly with a fluorocarbon surfactant where the CMC values of the two pure components were even closer and rate enhancements for the probe reaction were obtained in these solutions. The selected two were sodium nonanesulfonate (SNS) and sodium perfluoroheptanoate (SPFH) with CMC's of 0.081 mol dm^{-3} (10) and 0.070 mol dm^{-3}, respectively, or a CMC ratio of 1.2. The data (Fig. 3) and the kinetic parameters from the Robinson analysis (Table 1) for the 1:1 SNS/SPFH system are best consistent with unimicellar composition. The molar reaction volume, in its intermediate position between those of the pure surfactants, reflects a more equal input by each surfactant into its determination. Apparently, as the hydrocarbon and the fluorocarbon surfactant approach each other in their CMC's and hence hydrophobicities (the actual value of the CMC is usually viewed as a trade-off between the polarity of the ionic head of the surfactant and its hydrophobicity (19); changing ionic heads from sulfate to sulfonate or carboxylate is not as influential in modifying the CMC as changing the tail length), the two are more compatible in the micellar assembly. Our results indicate that a ratio in CMC values of the two pure short-chained surfactants of about five or greater is required for two types of micelles to be formed, whereas below five one mixed micelle is to be expected. Shinoda and Nomura state that micellar incompatibility or two micelles will be the case when the chain lengths of both surfactants are sufficiently long (20). For short-chained surfactant mixtures such as we are concerned with here, our work shows that a further condition for a single micellar form in solution is that the CMC's of the pure surfactants be close together.

This mixed micelle formed in sufficiently concentrated hydrocarbon/fluorocarbon surfactant solutions has interesting properties born of synergism that may recommend its use for various applications. For example, in a 1:1 SNS/SPFH micellar solution, the organic dye PADA is solubilized much more effectively than in either of the pure micellar solutions and this increase in solubilization is more dramatic as the CMC values of the pure surfactant components approach each

other. Also curious is the dominant role often played by the fluorocabon surfactant in mixtures in compressing the micellar surface region to a value differing little from that of the pure fluorocarbon surfactant. On the other hand, it is somewhat difficult to picture fluorocarbon and hydrocarbon chains with their different sizes and electron-withdrawing powers lining up amicably in a mixed micelle. Therefore, it may not be surprising that these differences are reconciled by the fluorocarbon having principal control over the forces at work in the micellar surface region.

Enthalpies of solution of naphthalene, *N*,*N*-dimethyl-1-naphthylamine, and 1,8-bis(dimethylamino)naphthalene in 16 organic solvents

DANIEL FIGEYS,[1] MAŁGORZATA KOSCHMIDDER,[2] AND ROBERT L. BENOIT[3]

Département de chimie, Université de Montréal, C.P. 6128, Succ. "A", Montréal (Qué.), Canada H3C 3J7

Received May 8, 1991[4]

DANIEL FIGEYS, MAŁGORZATA KOSCHMIDDER, and ROBERT L. BENOIT. Can. J. Chem. **70**, 1586 (1992).

The enthalpies of solution of naphthalene, *N*,*N*-dimethyl-1-naphthylamine, and 1,8-bis(dimethylamino)naphthalene (proton sponge) were determined at 298.15 K in 16 organic solvents (*n*-hexane, cyclohexane, carbon tetrachloride, chloroform, 1,2-dichloroethane, benzene, chlorobenzene, dimethyl sulfoxide, *N*,*N*-dimethylformamide, ethyl acetate, 1,4-dioxane, anisole, nitrobenzene, benzonitrile, methanol, ethanol). Additional determinations were made with benzene. Useful linear relationships are observed between the molar enthalpies of solution of the four compounds in the solvents. The molar enthalpies of solution were correlated with the solvatochromic parameters of the solvents. The presence of $N(CH_3)_2$ groups on naphthalene does not significantly contribute to the solute–solvent interactions.

DANIEL FIGEYS, MAŁGORZATA KOSCHMIDDER et ROBERT L. BENOIT. Can. J. Chem. **70**, 1586 (1992).

Opérant à 298.15 K, on a déterminé les enthalpies de solution du naphtalène, de la *N*,*N*-diméthyl-1-naphtylamine et du 1,8-bis(diméthylamino)naphtalène (éponge à protons) dans 16 solvants organiques (*n*-hexane, cyclohexane, tétrachlorure de carbone, chloroforme, 1,2-dichloroéthane, benzène, chlorobenzène, diméthylsulfoxyde, *N*,*N*-diméthylformamide, acétate d'éthyle, 1,4-dioxane, anisole, nitrobenzène, benzonitrile, méthanol et éthanol). On a effectué des mesures supplémentaires dans le benzène. On a observé des relations linéaires utiles entre les enthalpies molaires de solution des quatre composés dans les solvants. Il existe une corrélation entre les enthalpies molaires et les paramètres solvatochromiques des solvants. La présence de groupes $N(CH_3)_2$ sur le naphtalène ne contribue pas d'une façon significative aux interactions solutés–solvants.

[Traduit par la rédaction]

Introduction

The unusual structure of the aromatic diamine 1,8-bis-(dimethylamino)naphthalene (proton sponge, PS) confers to its conjugated cation, PSH^+, a nonspecific solvation. This property has been used to formulate an extrathermodynamic assumption leading to valuable single-ion enthalpies of transfer between solvents (1). To assess the validity of the assumption, we had to ascertain the absence of specific interactions between PS as a solute and the solvents, such as H-bonding between protogenic solvents and the $-NMe_2$ group of PS. We therefore determined the standard molar enthalpy of solution of PS in a wide range of organic solvents. We present here the corresponding calorimetric data and their analysis in terms of solute–solvent interactions. To this effect we looked for correlations between the molar enthalpy of solution of PS and the solvatochromic parameters of the solvents (2). We also considered another approach related to that of Fuchs and Rodewald (3), who studied the difference between the molar enthalpy of solution of substituted aromatic solutes and that of the parent compound. Thus we also determined the standard molar enthalpy of solution of *N*,*N*-dimethyl-1-naphthylamine (DMNA) and that of naphthalene (NA) in the same series of solvents. The solvents used were selected so that their solvatochromic parameters would cover a wide range of values. The poor solubility of NA and PS, however, imposed some restrictions on our choice of solvents.

Experimental

Proton sponge (Aldrich, 99%) was purified according to the procedure of de Groot and Sikkema (4). *N*,*N*-Dimethyl-1-naphthylamine (Aldrich, 99%) was used as received and naphthalene (Aldrich, 99%) was recrystallized from ethanol. Benzene (99.9%+), chlorobenzene (99.9%+), nitrobenzene (99%), benzonitrile (99%), ethyl acetate (99.9%+), 1,2-dichloroethane (99.8%), 1,4-dioxane (99.8%), anisol (99%), *n*-hexane (99%+), and carbon tetrachloride (Spectrograde) were supplied by Aldrich. Dimethyl sulfoxide (99.9%) was obtained from BDH, ethanol (anhydrous) from Anachemia. *N*,*N*-Dimethylformamide (reagent grade), cyclohexane (Spectrograde), and chloroform (spectrograde) were from ACP and methanol (spectrograde) from American Chemicals. Chloroform was treated with 4A molecular sieves and distilled.

The enthalpies of solution were measured at 298.15 ± 0.01 K with an LKB model 8721-1 isoperibol calorimeter as previously described (1); the nul detector was connected to a digital–analog circuit and a Zenith computer. The amounts of compounds dissolved in 0.100 dm^3 of solvent were obtained from the weights of the 0.001 dm^3 reaction ampoules. Two different types of ampoules were used, either a glass one whose neck was closed with Parafilm for unreactive solvents, or a small Teflon cylinder tightly closed with thin glass caps at both ends (5). The calorimetric measurements were made at different final solute concentrations, 0.001–0.02 mol dm^{-3}.

Results and discussion

The molar enthalpies of solution were calculated from a linear regression correlation of the heat change against solute concentration. The uncertainties quoted are the standard deviations of the slopes. The enthalpy values obtained for each of the compounds are taken to be equal to the infinite dilution values $\Delta_{sol}H^0_m$ because no concentration dependence was observed in the low concentration range studied, 0.001–0.02 mol dm^{-3}. The standard molar enthalpies of solution at 298.15 K are listed in Table 1 for naphthalene, *N*,*N*-dimethyl-1-naphthylamine, and proton sponge. Our results for the solution of NA in dimethylformamide and methanol are in good agreement with previous values (3).

We note that the three sets of $\Delta_{sol}H^0_m$ values for NA, DMNA, and PS in Table 1 vary within a narrow range of

approximately 7 kJ mol^{-1} (excluding the $CHCl_3$ values) in spite of the widely different properties of the solvents as can be assessed from their solvatochromic parameters (2). The solvents' parameters of interest for our set of solutes are: δ_H, the Hildebrand solubility parameter, Π^*, a measure of the solvents dipolarity/polarizability, and α, the hydrogen-bond donor ability. The values of δ_H and Π^* are listed in Table 1; the values of α are 0 except for chloroform (0.44), methanol (0.93), and ethanol (0.83), and the values of δ_{cor} (a polarizability correction) are 1 for the aromatic solvents, 0.5 for the chloro solvents, and 0 for the other solvents. The $\Delta_{sol}H^0_m$ values for DMNA are consistently some 15–20 kJ mol^{-1} more exothermic than those for NA and PS. This is because at 298.15 K DMNA is a liquid while NA and PS are both solids. As a matter of fact, if we subtract the enthalpy of fusion of NA (+18.0 kJ mol^{-1}) (6), the calculated values of the enthalpy of solution of supercooled liquid NA in the various solvents are now within a few kJ mol^{-1} of the corresponding values for liquid DMNA.

Correlation between enthalpies of solution

The plot of the molar enthalpies of solution of DMNA in the 16 solvents against those of NA in the same solvents shows some interesting features. If we attempt to use all the data the correlation is rather poor (r = 0.85, s.d. = 1.5) but if we divide the solvents into two groups we obtain two essentially parallel lines:

Line a:

$$[1]\quad \Delta_{sol}H^0_m\,(\text{DMNA, l}) = (1.21 \pm 0.09)\,\Delta_{sol}H^0_m\,(\text{NA}) - (21 \pm 1.5)$$

with N = 9, r = 0.982, s.d. = 0.5, where N is the number of solvents in the correlation; r denotes the correlation coefficient; s.d. is the standard deviation of the estimate. The nine solvents include *n*-hexane and cyclohexane, and the aromatic and chlorosolvents (excluding $CHCl_3$). For the remaining six solvents we have

Line b:

$$[2]\quad \Delta_{sol}H^0_m\,(\text{DMNA,l}) = (1.24 \pm 0.07)\,\Delta_{sol}H^0_m\,(\text{NA}) - (19 \pm 1.3)$$

with N = 6, r = 0.994, s.d. = 0.22.

The correlations between the molar enthalpies of solution of PS and NA are not as good. We find

Line a:

$$[3]\quad \Delta_{sol}H^0_m\,(\text{PS}) = (1.2 \pm 0.2)\,\Delta_{sol}H^0_m\,(\text{NA}) - (5 \pm 4)$$

with N = 9, r = 0.866, s.d. = 1.5.

Line b:

$$[4]\quad \Delta_{sol}H^0_m\,(\text{PS}) = (1.0 \pm 0.3)\,\Delta_{sol}H^0_m\,(\text{NA}) + (2 \pm 5)$$

with N = 6, r = 0.889, s.d. = 0.85.

Finally, for benzene we obtain

Line a:

$$[5]\quad \Delta_{sol}H^0_m\,(\text{Bz,l}) = (0.78 \pm 0.07)\,\Delta_{sol}H^0_m\,(\text{NA}) - (14 \pm 1)$$

with N = 9, r = 0.972, s.d. = 0.37.

These correlations are clearly of practical interest. For example, for the solvent water, from a value of $\Delta_{sol}H^0_m$ (NA) = + 29.9 kJ mol^{-1} (6) and eq. [4] we calculate $\Delta_{sol}H^0_m$ (PS) = + 32 kJ mol^{-1} to be compared with the experimental 30 ± 5 kJ mol^{-1} (1). However, the significance of these correlations is unclear since the two groups of solvents do not form well-defined families. Furthermore, the experimental uncertainties on the enthalpies do not account for the scatter of the points.

Correlations between enthalpies of solution and solvent parameters

The enthalpy of solvation of a solute, i.e., its transfer from the gas phase to the solvent, can be taken to include a number of additive enthalpy contributions that correspond to the creation of a cavity in the solvent, the solute–solvent dis-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

persion and polar interactions, the structural changes produced by the solute in the solvent, and specific interactions, such as H-bonding, between the solute and the solvent. Clearly, isolating the different contributions will lead to a better understanding of solute–solvent interactions and various approaches have been tried to solve the problem (7). Recently, considerable success has been achieved in correlating a large number of physicochemical properties and reactivity parameters to solute and solvent properties through linear relationships (2). We have applied multiple linear regression analysis to correlate our molar enthalpies of solution, and other derived enthalpies, to the solvatochromic parameters of the solvents listed in Table 1.

We obtained for solid NA and PS, and liquid DMNA the following equations where all the coefficients are statistically significant at the confidence level of 95% according to Student's *t*-test.

$$[6] \quad \Delta_{sol}H^0_m\,(NA) = (1.28 \pm 0.05)\,\delta_H - (14 \pm 2)\,(\Pi^* - 0.21\,\delta_{cor}) - (9 \pm 2)\,\alpha$$

where $N = 16$, $R^2 = 0.9950$, s.d. = 1.5.

$$[7] \quad \Delta_{sol}H^0_m\,(PS) = (1.19 \pm 0.06)\,\delta_H - (10 \pm 2)\,\Pi^* - (8 \pm 1)\,\alpha$$

where $N = 16$, $R^2 = 0.9946$, s.d. = 1.5.

$$[8] \quad \Delta_{sol}H^0_m\,(DMNA,l) = (0.26 \pm 0.04)\delta_H - (4 \pm 1.5)\,(\Pi^* + 0.44\,\delta_{cor})$$

where $N = 15$ ($CHCl_3$ excluded), $R^2 = 0.847$, s.d. = 1.3.

For benzene there is no satisfactory correlation since R^2 is only 0.65.

The coefficients of the parameters δ_H, Π^*, and α of the equations make chemical sense in that the cavity term adds a positive contribution to $\Delta_{sol}H^0_m$ while the expected negative contributions come from both polar interactions and H-bond interactions between the solutes and the H-bond donor solvents. Somewhat unexpectedly, the equations have no constant term; when the multiple regression program was run with a constant the R^2 value dropped to ~0.3. Using δ_H^2, which may be preferable to δ_H (7), also gave poorer correlations. The equations do not include a term to account for possible electron donor–acceptor (EDA) interactions of the solutes with the chloro and aromatic solvents, in part because there is no simple way to account for such interactions (8). At any rate the linear relationships between the $\Delta_{sol}H^0_m$ values of naphthalene and those of PS and DMNA would suggest that EDA interactions would only involve the solute's Π electrons and not the nitrogen lone pair. It may be that EDA interactions are accounted for, at least in part, in the Π^* term. It is somewhat difficult to compare the values of the coefficients of the parameters for the three solutes. For NA and PS, which are both solids and with similar enthalpies of sublimation, the coefficients of δ_H and α are nearly the same while those of Π^* are somewhat different, but there is a δ_{cor} term that is significant for NA but not for PS. If we omit δ_{cor} from the NA correlation we obtain:

$$[9] \quad \Delta_{sol}H^0_m\,(NA) = (1.28 \pm 0.07)\,\delta_H - (12 \pm 2)\,\Pi^* - (10 \pm 2)\,\alpha$$

where $N = 16$, $R^2 = 0.991$, s.d. = 1.9.

This time the Π^* coefficients are the same within error for NA and PS. The closeness of the α coefficients for NA and PS would imply that H-bonding between the solvents and the $-NMe_2$ groups plays only a minor role, if any, and that Π electron – hydrogen bond interactions are more important. To obtain a comparable equation for solid DMNA we added 18 kJ mol^{-1}, an estimated value of the molar enthalpy of fusion of DMNA, to the values of $\Delta_{sol}H^0_m$ (DMNA,l) and we found

$$[10] \quad \Delta_{sol}H^0_m\,(DMNA) = (1.40 \pm 0.05)\,\delta_H - (14 \pm 2)\,\Pi^* - (10 \pm 1.5)\,\alpha$$

where $N = 15$, $R^2 = 0.996$, s.d. = 1.5.

The coefficients of δ_H, Π^*, and α are now near those for solid NA and PS. It is puzzling that eq. [10] has no constant term, particularly in view of the fact that current work on the solution of pyridines leads to equations with constant terms whose values are related to the physical state of pyridines, whether gaseous, liquid, or solid. At any rate the terms in eq. [6], [7], [9], and [10] should be regarded as measuring the differences between the solute–solvent interactions formed and the solute–solute interactions disrupted (9). Within these limitations the correlations between the molar enthalpies of solution and the solvatochromic parameters of the solvents permit us to estimate the respective contributions of cavity, polar, and H-bonding terms. For example, for naphthalene the positive cavity contribution would vary between 20 and 40 kJ mol^{-1} and would be counterbalanced by the negative contributions of 0–10 kJ mol^{-1} each for polar and H-bonding terms. The correlations have also a good predictive value. Thus for the solution of NA in the solvent water, we calculate from the solvatochromic parameters and eq. [6] $\Delta_{sol}H^0_m = +34$ kJ mol^{-1}, to be compared with a +29.9 kJ mol^{-1} experimental value (6). For the solution of PS in pyridine we calculate +19 kJ mol^{-1} while a recent experiment gave +17.35 kJ mol^{-1}.

We also looked at correlations between the enthalpy of solvation (gas to solvent) and the solvatochromic parameters of the solvents, but the standard deviations were too high for good predictive value. Similarly, the correlations between the heats of transfer of the solutes (taking cyclohexane as reference solvent) and the differences between the solvatochromic parameters were not satisfactory. Taking naphthalene as the parent compound for PS and correlating the differenes between the heats of transfer of both solutes (3) also lead to no meaningful results. Finally the comparison of correlation, eqs. [7], [9], between $\Delta_{sol}H^0_m$ (NA) and $\Delta_{sol}H^0_m$ (PS), and the solvatochromic parameters on the one hand, and the direct linear relation between $\Delta_{sol}H^0_m$ (PS) and $\Delta_{sol}H^0_m$ (NA), eqs. [3], [4], on the other hand shows that these relations are not strictly compatible and this may account for the fact that the linear relation between $\Delta_{sol}H^0_m$ (PS) and $\Delta_{sol}H^0_m$ (NA) is only approximate.

Atrazine in mineral soil: the analytical chemistry of speciation[1]

DONALD S. GAMBLE[2] AND L. ALI ISMAILY
Land Resource Research Centre, Research Branch Agriculture Canada, Ottawa, Ont., Canada K1A 0C6

Received December 2, 1991

DONALD S. GAMBLE and L. ALI ISMAILY. Can. J. Chem. **70**, 1590 (1992).

The HPLC–microfiltration method previously described for determining atrazine and hydroxyatrazine species in organic soil has been adapted to a mineral soil. The method was able to monitor atrazine concentrations of less than 1.0×10^{-6} M, which is over 40 times lower than the atrazine concentrations measured in the earlier organic soil experiments. During kinetics experiments, it also monitored four free and sorbed chemical species instead of only one. Measurements were obtained with much better accuracy and productivity than can be obtained by conventional methods. The atrazine sorption capacity of the mineral soil was also measured. The analytical chemical data produced can support heterogeneous chemical kinetics calculations.

DONALD S. GAMBLE et L. ALI ISMAILY. Can. J. Chem. **70**, 1590 (1992).

Dans le but de déterminer des espèces atrazine et hydroxyatrazine dans des sols organiques, on a adapté à une huile minérale la méthode de CLHP/microfiltration décrite antérieurement. La méthode permet d'évaluer des concentrations d'atrazine de moins de $1{,}0 \times 10^{-6}$ M, soit 40 fois moins que les concentrations d'atrazine mesurées lors des expériences antérieures avec des sols organiques. Au cours d'expériences cinétiques, on peut aussi déterminer quatre espèces chimiques libres et sorbées au lieu d'une seule. Des mesures ont été réalisées avec une meilleure précision et une meilleure productivité que celle possible avec des méthodes conventionnelles. On a aussi measuré la capacité de sorption de l'atrazine à partir de l'huile minérale. Les données analytiques chimiques ainsi produites peuvent supporter des calculs de cinétique chimique.

[Traduit par la rédaction]

Introduction

The herbicide atrazine, used extensively to control weeds in corn, has become associated with a number of environmental problems. Contamination of soil and groundwater is an example (2–4), and its plant toxicity is influenced by the extent to which it is free in solution or sorbed (5, 6). Mathematical models for its persistence and mobility in soils must account for sorption–desorption kinetics and equilibria, and chemical degradation (7, 8). Hydrology models, which seek to predict movement and concentrations of contaminants in groundwater and soil, will consequently require analytical chemical data. The first requirement is that the chemical properties, including speciation, of the atrazine must be quantitatively known. A number of authors have already contributed information on the chemical reactions and speciation of atrazine (9–17). The next requirement is that the relevant physical chemistry properties of particular soils must be measured. They include numbers and acid strengths of carboxyl groups, and atrazine sorption capacities. These physical chemical properties must then be monitored over the course of experiments with a particular soil and atrazine. Variables needed for the supporting calculations should be measured experimentally. It is not sufficient to measure total atrazine in an experimental sample because the calculations of parameters for hydrology models can only be done with measurements of free and bound forms. The physical nature and chemical reactivity of the soil will make a large contribution to the manner and rate of pesticide–soil interactions. In light of this, it is not practical to attempt to solve pesticide–soil interaction problems using only information about the chemistry of the pesticide, without information about the chemistry of the soils. To avoid experimental artifacts the analytical chemical method for measuring the distribution of atrazine between a solution and the suspended solids must not disturb the distribution being measured. This is equally true for both equilibrium and nonequilibrium distributions.

A combination of acid–base titrations and HPLC with microfiltration has been designed to meet such requirements. The basic HPLC–microfiltration method for chemical kinetics speciation experiments was reported previously by us for organic soil (1). The analytical chemical methods must next be adapted to monitor the chemical speciation of atrazine as a function of time when mineral soils are used, because of their greater economic and environmental importance. With mineral soils two experimental problems are encountered that are not encountered with organic soils (1). The soil particles are harder to slurry properly because they are somewhat more dense than organic soil particles. In addition it was anticipated that their sorption capacities and chemical reactivities would be substantially smaller than those of organic soil, because of smaller carboxyl group contents. Preliminary experiments have confirmed this.

A conventional sorption experiment typically uses several samples, each of which has to be separately filtered or centrifuged and extracted for analysis. Each extraction commonly uses only 50–100 mL of extractant for each gram of soil. The preparation for HPLC or GC injection requires 2 days for shaking, separation, volume reduction with a rotary evaporator, and adjustment of the residue to a known volume. This produces only about a dozen low-precision data points for the whole experiment, and the small-volume batch extractions would tend to disturb the solution–solid distributions of pesticide that they were supposed to measure. Such a method is not only labour intensive, but it also produces data that do not support detailed chemical kinetics calculations very well.

The objective of this work was to adapt the analytical chemical methods developed for atrazine interactions with an organic soil to the investigation of its interactions with a mineral soil.

							Total	0.0565

[a]See Wang and McKeague (19).

Theory

The extraction method used in this study involves injection of an aqueous slurry of soil into an HPLC fitted with inline microfilters. The inline filters trap the soil particles and the flow of the mobile phase results in extraction of atrazine. Analysis of the chromatogram shows the total concentration of a pesticide that was distributed between the solution and quickly accessible sorption sites on the suspended particles. In a typical atrazine – mineral soil experiment, a 20.0 μL injection of slurry contains approximately 4×10^{-4} g of particles, which are trapped on the inline filters. With a mobile phase flow rate of 1.0 mL/min, a typical peak retention time of 6.0 min would give a ratio of extractant to sample approximately equal to 15.0 L/g of soil. The subtraction of solution concentrations determines concentrations of labile sorbed pesticide. The inline extraction distinguishes between desorption that is fast, relative to the extraction time, and desorption that is slow. This distinction should be directly relevant to bioavailability, since very slow desorption rates could limit plant uptake.

Experimental section

Equipment

Titrations

The automatic titrator used has been previously described (18).

Chemical kinetics and speciation

A Varian high-pressure liquid chromatograph was used. It consisted of a Star 9010 variable wavelength UV–visible detector, and a model 4400 Beckman integrator. The column was a Beckman C-18 Ultrasphere ODS, 5 μm particle size, 4.6 mm × 25.0 cm. They were protected with Altech Guard Column Cartridges, C-18 Adsorbosphere. Hamilton microliter syringes ranged in size from 50 to 250 μL. A B-D 1-cm^3 26G 3/7 Tuberculin syringe and precision glide needle, and a B-D Yale 20 needle were also used. Preinjection filtration was done with MSI Cameo Nylon filters, 3 mm diameter, 0.45 μm pore size. Samples were thermostated at 25.00°C in water-jacketed reaction vessels.

Materials and reagents

Mineral soil

The location and properties of the B horizon mineral soil from Central New Brunswick were similar to the Sunbury soil documented by Wang and McKeague (19). Some additional properties are listed in Table 1.

Reagents and standard solutions

Atrazine and hydroxyatrazine reagents and standard stock solutions were the same as previously described (1). Analytical chemical standards contained either 1.000×10^{-6} M or 1.000×10^{-5} M atrazine.

Procedures

Titrations

About 1.0 g of mineral soil weighed to four decimal places was added to 10 mL of 1.0 N NaCl, and titrated with 0.1 N standard NaOH, at 25.0°C. The titrator was programmed to deliver 0.1 mL every 3.0 mins. Titrations using 0.1 N HCl were done in a similar way. Standard buffers were used.

Kinetics chemical speciation experiments

A 0.5 g portion of mineral soil was suspended with stirring in approximately 15 mL of redistilled H_2O for about 2 days. This wetted all of the surfaces and sorbed H_2O into soil particles. The hydrolysis reaction was started by the addition of atrazine standard stock solution, with the total sample volume being adjusted to 25.0 mL. Some sorption experiments were done with high initial concentration of atrazine (5.0×10^{-5} M) in order to saturate the sorption sites and yield a measure of the atrazine sorption capacity of the soil. Subsaturation experiments had an initial atrazine concentration of 1.0×10^{-6} M. From these experiments the rate of the sorption process was examined. Vigorous stirring maintained a uniform suspension of soil particles throughout the whole solution and thermostated water jackets maintained the slurry temperature at 25.0°C. Microfiltrate (0.45 μm) and whole slurry analyses were done as functions of time, essentially as previously described (1). The detector wavelength was set at 220 nm for atrazine, and 240 nm for hydroxyatrazine. An additional inline filter, a 2-μm stainless steel frit, ahead of the guard column was used to prevent excess system pressures by catching some of the soil particles. The system of inline microfilters and guard column was cleaned at the end of each work day. A methanol/H_2O mobile phase, 80:20, with 1.58×10^{-3} M HCl was used with a flow rate of 1.0 mL/min. Microcomputer spreadsheets were used for converting raw analytical chemical measurements and clock and calendar readings into chemical kinetics data for free and reversibly sorbed forms of atrazine and hydroxyatrazine. Table 2 summarizes the experimental conditions for the two types of kinetics–speciation experiments with atrazine and mineral soil.

The determination of parameters

Solution phase concentrations were determined by measuring filtrates obtained with 0.45 μm Nylon 66 disposable filters. Sorption was determined by injecting first the 0.45 μm filtrate and next the whole slurries, and then calculation of the differences. Site saturation gave the sorption capacity, measured on the plateau of the sorption vs. solution concentration curve. Sorption equilibrium functions were calculated from subsaturation experiments and the measured capacity. The early approach to sorption equilibrium was used for the calculation of sorption and desorption rate constants.

Results and discussion

The high organic carbon content of the New Brunswick soil implies a relatively high total content of carboxyl and carboxylate groups. Several authors have demonstrated the central importance of humic carboxyl groups to pesticide –

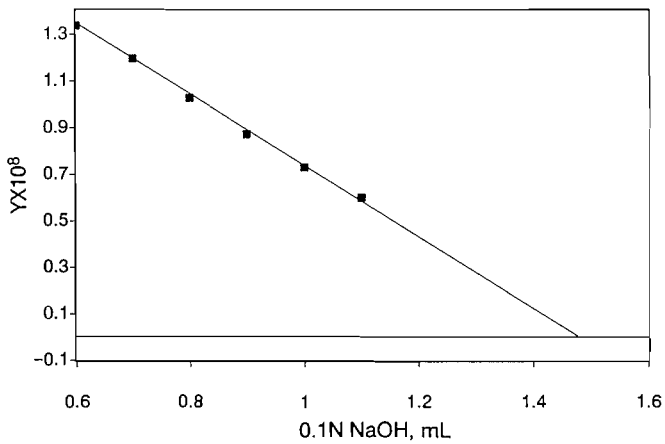

FIG. 1. $M_H V_B$, Gran's function plot for the New Brunswick mineral soil, 1.0 N NaCl. $Y = (V_{sl} - V_B)\text{antilog}(-16.9 \times E_{obs})$ where V_{sl} and V_B are the volumes of the slurry and the base, respectively, and E_{obs} is the observed potential.

soil interactions (1, 20–31). The extent to which the extractable iron and aluminum of this New Brunswick soil might be blocking carboxyl or clay sorption sites is unknown. The best analytical chemical option available for this question is direct titration of the whole soil by standard base. The significance of the exchangeable metal ions is that the portion of them not held by inorganic cation exchange sites equals the number of carboxylate anions. The relative amounts of them held by carboxylate and clay sites were unknown, however, and the upper limit to the number of possible carboxylate anions corresponds to the case in which none of the exchangeable metal ions was held by clay or hydrous metal oxide ion exchange sites.

The conventional appearance of the Gran's plot for titration with standard base shown in Fig. 1 is important evidence indicating that the analytical chemical method is not susceptible to serious interference from the complicated mixture of components in a natural mineral soil. For example, it did not suffer from the type of weak acid polyelectrolyte buffering that makes sharp equivalence points impossible in fulvic acid titrations (32). The purpose of the 1.0 N NaCl was to prevent the Donnan potential restriction of proton movement from particles into the external solution. If an

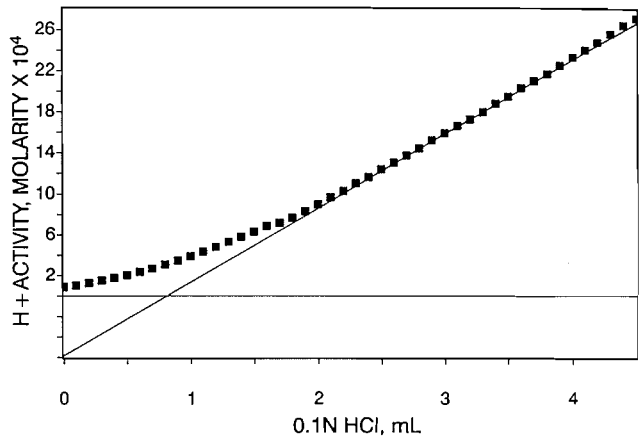

FIG. 2. HCl titration curve for the New Brunswick mineral soil, 1.0 N NaCl.

equivalence point can also be obtained for the titration of the soil with standard acid, it should be a measure of all of the sites that can be protonated. This might include carboxylate anions and such inorganic bases as carbonates, bicarbonates, and hydrous metal oxides. A comparison of this equivalence point with the total ion exchangeable metal ions in Table 1 should be a useful clue to the nature of the sites being titrated. A satisfactory Gran's plot was not obtained for the titration with a standard acid. However, titration with standard HCl produced a clearly defined equivalence point as shown in Fig. 2. The limiting slope of the curve after the early proton binding phase represents a simple dilution of the added H^+. The equivalence point is the boundary between the H^+ binding and H^+ dilution regions of the curve. This is essentially the same type of dilution curve used previously (33, 34) for the titration of fulvic acid with atrazine. In the absence of CO_2 evolution from carbonate or bicarbonate decomposition, the equivalence point should represent a total for carboxylates and hydrous metal oxides. It gives an upper limit for the number of carboxylate anions, for the particular case in which no hydrous metal oxides are being titrated.

A plot of the weighted average equilibrium function for the acid dissociation of acidic sites (35, 36), $\bar{K}_A$ vs. α, is shown in Fig. 3. The use of 1.0 N NaCl ensured that a_{H^+} was approximately the same in and on the soil particles as it was in the external solution (37, 38). Any experimental error in the determination of the number of protonated acid sites will be reflected in the numerical values of $\bar{K}_A$. In the present case, it cannot be assumed that the nonlinear regions of the two ends of the plot have real chemical meaning. Only the linear middle region was used for subsequent calculations.

If a mixture of carboxyl groups has a wide range of weak acid K_A values, the $\bar{K}_A$ determined macroscopically for the whole mixture can sometimes differ by one or two orders of magnitude from the K_A values of individual components (39). This could confuse any attempt at molecular level interpretations of such phenomena as hydrogen-bonded sorption and Brönsted acid catalysis. This problem may be resolved by using the differential equilibrium function, calculated with the equation

$$K_A = -\frac{d(\alpha M_{H^+})}{d\alpha}$$

M_{H^+} and α are the H^+ molarity and the degree of ionization.

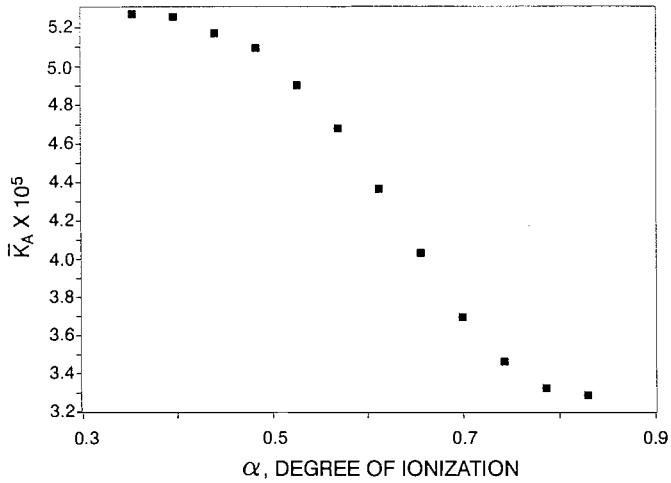

FIG. 3. The weighted average equilibrium function ($\bar{K}_A$) vs. degree of ionization (α), for the acidic sites of the New Brunswick mineral soil.

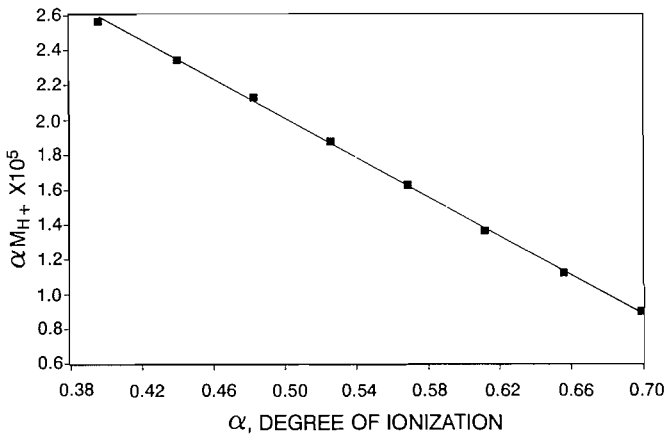

FIG. 4. The calculation of the differential equilibrium function for acid dissociation of the acidic sites in the New Brunswick mineral soil. $\bar{K}_A = -[d(\alpha M_{H^+})/d\alpha]$.

In the present case, this is simply the slope of the straight line for which the least-squares fit is illustrated in Fig. 4. Although the K_A cannot be identified with individual components of the mixture, it is much more directly related to them than is the $\bar{K}_A$ (39). In particular, the numerical values of K_A will not be wrong by one or two orders of magnitude. They may therefore be used for the molecular level interpretations of hydrogen-bonding and acid catalysis effects without major numerical errors. This is expected to remove some causes of data scatter and to improve the effectiveness of predictive calculations.

The data from the acid and base titrations that are directly related to some of the causes of pesticide interactions with soil are listed in Table 2. For example, the K_A, α, and base titration equivalence point govern hydrogen-bonded sorption and Brönsted acid catalysis of atrazine. The acid titration endpoint indicates the expected carboxylate contribution to the cation exchange capacity. The apparent ion exchange capacity from Table 1 and the HCl titration equivalence point from Table 2 are consistent with each other. At present there is no direct evidence that the apparent ion exchange capacity corresponds exactly to the number of carboxylate anions, and the most general case is that clays and hydrous

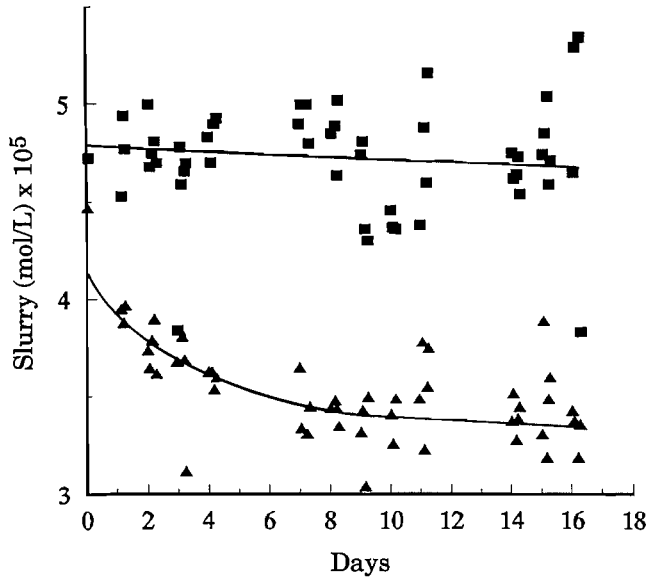

FIG. 5. Chemical analysis of the slurry, using the HPLC–microfiltration method, for a site saturation experiment. Concentration of atrazine vs. time for —■—, whole slurry, $\sigma = 2.0 \times 10^{-6}$; and —▲—, microfiltrate, 0.45 μm, $\sigma = 1.1 \times 10^{-6}$.

metal oxides might contribute to the observed cation exchange capacity. It is therefore only an upper limit for the number of free carboxylate anions. Carboxylate ligands in very stable transition metal chelates would not be free. Within the limits of experimental uncertainty, the apparent cation exchange capacity and the HCl titration equivalence point cannot be assumed to differ significantly. While the HCl equivalence point would be relevant to the ion exchange uptake of cationic pesticides such as Paraquat (20, 21, 40), it is the NaOH equivalence point that is appropriately used for the calculation of $\bar{K}_A$ and K_A. Because the plot in Fig. 4 is linear, it produced the single numerical value for K_A that is recorded in Table 2. There are two indications that the range of K_A values in the New Brunswick mineral soil must be quite narrow. One is that only the single numerical value was obtainable from the data presented in Fig. 4. The other is that K_A is only 1.1–1.7 times larger than the $\bar{K}_A$ value for K_A values in Fig. 3. There are at least two possible reasons for this in the natural, chemically unprocessed, mineral soil. One is that humic acids tend to have a narrower range of K_A values than fulvic acids. Another is that a substantial fraction of the more strongly acidic carboxyl groups may be blocked by chelated Fe(III) and Al(III). Assuming the typical values of 50% organic carbon in humic materials and approximately 3 mequiv./g of carboxyl groups in humic acid, the organic carbon analysis indicates that it would be reasonable to expect about 0.5 mequiv./g total carboxyl groups in the New Brunswick mineral soil. According to the Gran's equivalence point, no more than 30% of that amount was found to be protonated. If only a portion of the total carboxyl groups were protonated, it would have been the most weakly acidic portion.

The results of this atrazine analyses for a site saturation experiment obtained directly by the HPLC–microfiltration method are presented in Fig. 5. The raw data were fitted to polynomials by the method of least squares. The standard deviation for the slurry curve was 2.0×10^{-6}, and for the filtrate curve it was 1.1×10^{-6}. Atrazine recoverable from

the whole slurry decreased slowly as a linear function of time, within the limits of experimental error. The solution phase concentration of atrazine decreased substantially during the first 8 days, after which there was a linear decrease. An apparent early drop in solution concentration was too fast to be monitored. Subtraction of the two fitted curves shown in Fig. 5 gives the atrazine sorption curve shown in Fig. 6. It reveals two important pieces of information. The first is that not all of the sorption was instantaneous. Several authors have reported that sorption and desorption of pesticides by soils can be slow, so that sorption–desorption kinetics should be accounted for (7, 27, 41–43). The data presented in Fig. 6 clearly show an equilibration time of approximately 8 days. The other important information is that the plateau showed no net decrease. The total atrazine in the whole experimental sample was somewhat greater than the amount required for maintaining site saturation. The results of the determination of atrazine sorption capacity in this way for the New Brunswick mineral soil are summarized in Table 3. Its numerical value is critically important for the subsequent calculations of sorption equilibrium, sorption kinetics, and catalysed chemical reaction kinetics.

The results of chemical analyses for hydroxyatrazine in a site saturation experiment shown in Figs. 7 and 8 are quite different from the corresponding atrazine curves. The standard deviations for the slurry and filtrate curves are 1.8×10^{-7} and 4.9×10^{-8} respectively. The hydroxyatrazine analyses are more difficult than the atrazine analyses, and consequently less useful for subsequent calculations. Significant information is obtained from them, however. In contrast to the atrazine, which must initially be sorbed from the solution onto sorption sites, the hydroxyatrazine, from the hydrolysis of atrazine, initially appears on the catalytic sorption sites. Some of it then desorbs to appear in solution for the first time. At least 4 days were required for the es-

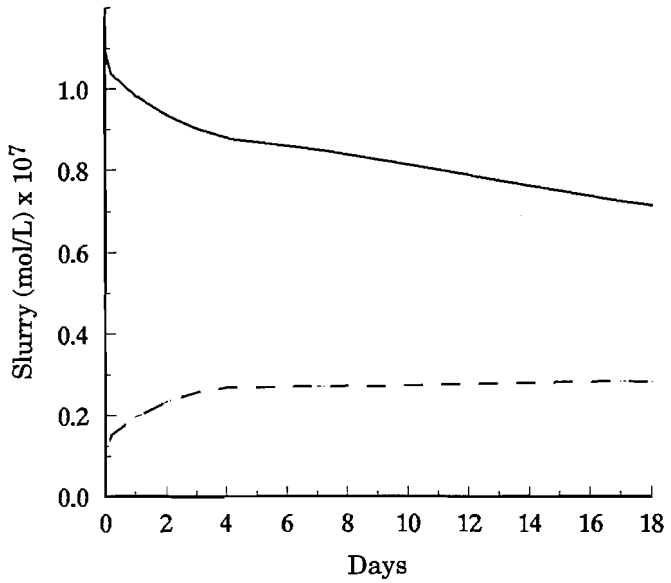

FIG. 9. Concentration of free and reversibly sorbed atrazine vs. time for a subsaturation experiment: ——, in solution; and – – – –, reversibly sorbed.

tablishment of sorption equilibrium. All three curves clearly reflect the continuous production of hydroxyatrazine; however, not enough hydroxatrazine was produced to saturate its sorption sites. The site saturation experiments (Figs. 5–8) revealed four chemical species plus a material balance loss, all of which were monitored simultaneously during the kinetics experiments. The material balance loss increased continuously with time and at 14 days it was equal to 1.3 mol% of the initial atrazine concentration for a site saturation experiment.

A test of the experimental method with an initial atrazine concentration more than 40 times lower than the site saturation experiment gave slurry and filtrate analyses for atrazine similar to those in Fig. 5. The standard deviations for the slurry and filtrate curves were 5.7×10^{-8} and 2.8×10^{-8} respectively. The solution phase and reversibly sorbed atrazine determined as before are shown in Fig. 9. In these experiments, only 1–2 mol% of sorption sites were covered by atrazine. While sorption was clearly observed, no evidence was found for the production of hydroxyatrazine. This does not prove, however, that none was produced. If, as expected, hydroxyatrazine was present, then its total amount must have been quite small. Some of it may have been irreversibly sorbed, and the concentrations of the remainder may simply have been below the detection limits of the analytical chemical method. The material balance loss for this experiment is 16.3 mol% after 14 days reaction time. This material balance loss is an order of magnitude larger than that for the site saturation experiment. The mol% of the material balance loss is evidently not proportional to the amount of reversibly sorbed atrazine; the processes governing the material balance loss warrant further investigation.

Conclusions

The experimental results presented here prove that the analytical chemical method with HPLC and microfiltration previously demonstrated for free and sorbed chemical species in an atrazine organic soil system (1) can be successfully adapted to the environmentally more important case of atrazine in mineral soil systems.

It is also concluded from these results that the method has a number of important advantages. Instead of only one free chemical species being monitored during kinetics experiment, as is common in heterogeneous catalysis research, all four of the free and reversibly sorbed chemical species were monitored simultaneously (1). In addition, the usual material balance loss was monitored. This simultaneous monitoring of five directly relevant experimental variables should substantially improve the subsequent chemical kinetics calculations. Each slurry injection completes an extraction with chemical analysis in only a matter of minutes, using approximately 15 litres of mobile phase as extractant per gram of soil sample. Each kinetics experiment typically has 30–50 such extractions with analyses during its course. Sorption equilibration is monitored as it happens, using only one experimental sample.

Atrazine in mineral soil: chemical species and catalysed hydrolysis[1]

DONALD S. GAMBLE[2] AND SHAHAMAT U. KHAN
Land Resource Research Centre, Research Branch, Agriculture Canada, Ottawa, Ont., Canada K1A 0C6

Revised December 2, 1991

DONALD S. GAMBLE and SHAHAMAT U. KHAN. Can. J. Chem. **70**, 1597 (1992).

Equilibrium and kinetics parameters have been evaluated at 25.0°C for the heterogeneous catalysis of atrazine hydrolysis in slurries of a chemically characterized mineral soil. The fraction of acidic sites that accounts for sorption capacity, and the sorption equilibrium function resemble those for humic acid and organic soil. Sorption and desorption half-lives increased with increasing coverage of sorption sites. The sorption half-lives ranged from 3.6 to 735 days. The desorption half-lives ranged from 1 to 11 days. The hydrolysis half-lives ranged from 9.6 to 168 days and are consistent with Brönsted acid catalysis theory. The relationship of independent variables to data scatter has been analyzed. The information obtained should be useful for water and solute transport models.

DONALD S. GAMBLE et SHAHAMAT U. KHAN. Can. J. Chem. **70**, 1597 (1992).

Opérant à 25°C, on a évalué l'équilibre et les paramètres cinétiques de la catalyse hétérogène de l'hydrolyse de l'atrazine, délayée dans une huile minérale de composition chimique définie. La fraction des sites acides qui explique la capacité de sorption anisi que la fonction d'équilibre de la sorption ressemblent à celles de l'acide humique et des sols organiques. Les temps de demi-vies de la sorption et de la désorption augmentent avec une augmentation de la couverture des sites de sorption. Les demi-vies de sorption varient de 3,6 à 735 jours. La demi-vies de désorption varient de 1 à 11 jours. Les temps de demi-vies d'hydrolyse varient de 9,6 à 168 jours et ils sont en accord avec la théorie de la catalyse acide de Brønsted. On a analysé la relation entre les variables indépendantes et l'éparpillement des données. L'information obtenue devrait être utile pour des modèles de transport par de l'eau et des solutés.

Introduction

Villeneuve *et al.* (1) have observed that the increasing use of deterministic hydrology models for the persistence and leaching of pesticides in soils has increased the requirement for knowledge of pesticide sorption and degradation rate constants. Analysis of the sensitivity of the computed pesticide concentrations and distributions to the empirical parameters used in computation (sensitivity analysis) has been reported by Villeneuve *et al.* (1). This sensitivity analysis (1) indicates that errors of 15–24% in the degradation constant or an error of 24% in the adsorption constant can cause a 100% error in model predictions. A contributing cause to these large errors is the use of oversimplified theories for sorption and degradation. The physical and chemical phenomena responsible for sorption and degradation of pesticides need to be identified, measured, and accounted for in interpretive and predictive calculations.

In a review of sorption theory for dilute solutions, Jaroniec and Madey (4) described both a distribution coefficient and an isotherm equation based on the law of mass action. However, the distribution coefficient does not account for the number of unoccupied sorption sites or for sorption capacity and the isotherm did not account for site heterogeneity.

The literature reviewed by Jaroniec and Madey (4) does not describes a theory that uses both the weighted average concept to account for sorption site heterogeneity, and sorption capacity with the law of mass action to account for the effect of empty sorption sites. The present work seeks to develop such a theory with a single mathematical description. The type of theoretical description being used determines the types and amounts of experimental data that are required. An analytical chemical method similar to that described earlier for an organic soil has been developed for this purpose (2, 3). It has been shown that organic matter dominates pesticide interactions with soils, and carboxyl groups have been identified as being important in these interactions (3, 5, 6).

The objective of this work was to obtain separate numerical values for these sorption and chemical reaction parameters that are required by hydrology models, such as PRZM. Villeneuve *et al.* (1) for example, have discussed its application to the pesticide aldecarb. Atrazine interactions with the aqueous slurry of a mineral soil were used as a case study for the present work. In this study parameters for the persistence and leaching of atrazine in mineral soil were obtained which include the sorption equilibrium function, sorption and desorption rate constants, and a pseudo-first-order reaction rate constant for catalysed hydrolysis. Over the last 30 years atrazine has been the most heavily used herbicide in Canada and in the U.S.A. Residues of atrazine have been found in 4,123 of 10,942 surface water samples and in 343 of 3,208 ground water samples analysed (STORET, 1988, STORET water quality file, Office of Water, U.S. Environmental Protection Agency).

Theory

Atrazine sorption equilibrium

When reversible sorption equilibrium has been established in an aqueous slurry of soil particles, the law of mass action may be applied to give the weighted average equilibrium constant, $\bar{K}_1$, as described previously (3).

$$[1] \qquad \bar{K}_1 = \frac{C_{At}}{C_0 M_{At}} = \frac{\theta_{At}}{\theta_0 M_{At}}$$

M_{At} is atrazine molarity. C_{At} and θ_{At} are sorption sites on soil occupied by atrazine, in mol/L of slurry and mol/g of soil, respectively. C_0 and θ_0 are unoccupied sorption sites, in the

[1]LRRC Contribution No. 91-17.
[2]Author to whom correspondence may be addressed.

same units as those of C_{At} and θ_{At}. The numerical values of empty site variables C_0 and θ_0 depend on the definitions of sorption capacity:

$$[2] \quad C_c = C_{At} + C_0$$

$$[3] \quad \theta_c = \theta_{At} + \theta_0$$

In the previous work with organic soil (3), C_c and θ_c were defined in terms of the number of protonated carboxyl groups in the soil. It has since been found, however, that generally only about 1 mol % or less of the protonated carboxyl groups act at any instant as sorption sites (7, 8). In the present mineral soil study, C_c and θ_c are therefore defined in terms of experimentally measured apparent sorption capacities. This causes corresponding changes in the definitions and numerical values of $\bar{K}_l$ and χ_l, the mole fraction of sorption sites covered, according to eqs. [4] and [5].

$$[4] \quad C_0 = C_c - C_{At}$$

$$[5] \quad \chi_l = C_{At}/C_c$$

To provide a valid comparison of organic soil results to those for the mineral soil used in the present study, $\bar{K}_l$ and χ_l values must be translated to the revised definition of C_c (or θ_c). Otherwise, the numerical values would differ by about two orders of magnitude.

The distribution coefficient K_D that is in general use for pesticide sorption by soils and sediments may be defined in terms of moles of pesticide by eq. [6].

$$[6] \quad K_D = (\theta_{At}/M_{At})$$

This is commonly used as an empirical constant. The correct meaning and real properties of K_D can be deduced, however, by the use of eqs. [1] and [3] with its definition, eq. [6]. Eq. [7] gives the simple relationship

$$[7] \quad K_D = \bar{K}_l(\theta_c - \theta_{At})$$

It should be noted that under certain conditions $\bar{K}_l$ might be approximately constant. If for example, hydrogen bonding sites had a narrow range of weak acid strengths, it might be difficult to observe changes in $\bar{K}_l$. Even if $\bar{K}_l$ is approximately constant, however, K_D must decrease when the site coverage θ_{At} increases. Since the sorption capacity θ_c is now known to be a quite small portion of the protonated carboxyl groups, this effect is somewhat more important than previously expected. Not only will different soils have different sorption capacities θ_c, but also a given soil can have different θ_c values if different amounts of its carboxyl sites are neutralized. Lime applications, for example, could affect the amount of carboxyl groups neutralized. The practical consequence is that the empirical use of K_D without any consideration of sorption capacity or site loading will cause unnecessary data scatter. Brouwer *et al.* (9) have demonstrated that K_D values can be scattered by factors of 20–50. It is important to note that this is not made necessary by the properties of soils. It is instead caused by the incorrect use of the parameter K_D. Published correlations that work roughly with K_D to give data scattered by factors of 20–50 (9) should work somewhat better if $\bar{K}_l$ is used. Even the K_{om} coefficient which has been normalized to constant amounts of soil organic matter has data scattered by factors of 2–6 (200–600%) (9).

Atrazine sorption–desorption kinetics

The sorption–desorption rate law described by eqs. [8]–[10] has been previously used for atrazine–organic soil experiments (3).

$$[8] \quad \frac{dM_{At}}{dt} = -k_{S1}M_{At} + k_{S1}C_{At}$$

$$[9] \quad k_{S1} = k_{B1}C_0$$

$$[10] \quad k_{S2} = k_{B1}/\bar{K}_l$$

k_{S1} is the pseudo-first-order rate constant for atrazine sorption and k_{B1} is the corresponding second-order rate constant. k_{S2} is the first-order rate constant for atrazine desorption. It is evident that k_{S1} depends on the extent of site loading as shown below:

$$[11] \quad k_{S1} = k_{B1}(C_c - C_{At})$$

In addition it cannot be assumed that k_{B1} is a constant. Instead, it might very well have a distribution of values that represents sorption site heterogeneity. To account for these effects, especially when sorption site coverage is extensive, the integral rate law has been used in the form of eqs. [12] and [13].

$$[12] \quad F(t) = k_{B1}(t_2 - t_1)$$

$$[13] \quad F(t) = \int_{M_1}^{M_2} \{1/[(C_{At}/\bar{K}_l) - C_0M_{At}]\}dM_{At}$$

M_1 and M_2 are the integration limits for the atrazine molarity, M_{At}. A spreadsheet and a curve-fitting program readily yield a value for k_{B1}. k_{S1} and k_{S2} are then obtained from eqs. [9] and [10].

Atrazine hydrolysis kinetics

The integral rate law in equations [14] and [15] has been used previously for atrazine hydrolysis in slurries of organic soil (3).

$$[14] \quad \int_{c_1}^{c_2} (1/M_{At})dC_{Tl} = -k_{rl}(t_2 - t_1)$$

$$[15] \quad k_{r2} = \left(\frac{V_S}{W_S\bar{K}_l\theta_0}\right) k_{rl}$$

C_{Tl} is the total measurable atrazine as described by eq. [16],

$$[16] \quad C_{Tl} = M_{At} + C_{At}$$

V_S and W_S are solution volume and weight of soil sample. k_{r2} is the first-order rate constant for the hydrolysis of atrazine on the catalytic sorption sites. It is important to note that C_{Tl}, M_{At}, V_S, and W_S are all direct experimental measurements. $\bar{K}_l$ and θ_0 are determined from direct measurements of the capacity C_c and reversibly sorbed atrazine C_{At}. The practical significance of this is that k_{r2} must be used for correlations and predictive calculations, because k_{rl} is only an artifact of the experimental method. One can obtain any arbitrary value of k_{rl} by manipulating the experimental ratio (V_S/W_S). Karickhoff and Morris (10) have stated that apparent rate constants depend on experimental methodology. Perdue and Wolfe (11, 12) pointed out that humic carboxyl groups are Brönsted acid catalysts. Therefore, k_{r2} is expected to depend on the weak acid constants, K_A, of those

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 217.78.4.112 on 09/08/12
For personal use only.

carboxyl groups. The relationship could be obscured or lost in plots with k_{r1}.

According to eq. [15], the numerical value of k_{r2} will depend on the definitions used in $\bar{K}_1\theta_0 = (\theta_{At}/M_{At})$. The comparison of the humic acid and organic soil results (3, 6) with present mineral soil results therefore requires that they be translated accordingly.

Hydroxyatrazine appearance kinetics

The apparent rate constant k_{p3} for the appearance of hydroxyatrazine may be calculated with eq. [17] which has been used for organic soil experiments (3).

$$[17] \quad \int_{C_1}^{C_2} (1/C_{AT})dC_{T2} = k_{p3}(t_2 - t_1)$$

C_{T2} is the total measurable hydroxyatrazine. The molecular level interpretation of k_{p3} and its relationship to k_{p2} cannot be determined until the capacity and equilibrium function for hydroxyatrazine are known. According to Wang *et al.* (7), the structure, sorption capacity, and the sorption equilibrium function $\bar{K}_2$ for hydroxyatrazine should be different from those for atrazine. If this were the case, then the conversion of atrazine to hydroxyatrazine on the sorption sites would change the structure and properties of the sites. An implication of this is that it cannot be assumed that monitoring atrazine disappearance and monitoring hydroxyatrazine appearance will give the same information. Separate hydroxyatrazine sorption–desorption experiments might therefore be useful.

Categories of variables

Three categories of variables should be clearly distinguished from each other for the conduct, calculations, and molecular level interpretation of experiments with these environmental chemistry systems. They are described below.

Inner variables

Inner variables are those identified by theory as being required for totally specifying the state of a chemical system. They should be used for correlations, molecular level interpretive calculations, and predictive calculations. Typical examples include the numbers or concentrations of protonated carboxyl groups, and the mole fraction of sorption sites occupied by a sorbed pesticide.

Outer variables

Outer variables are the type that are manipulated operationally for the conduct of an experiment. Typical examples include pH, total moles of pesticide or metal ion added to a sample, and the ratio of weight of solid sample to volume of experimental solution. They are more practical than inner variables for running many types of experiments, and frequently inner variables cannot be used for that purpose.

Background description variables

These variables are useful as general background information, for developing qualitative insight or for making practical decisions. They are not used in chemical calculations, and do not appear in the mathematical descriptions of the system. Typical examples include elemental analysis, and percent organic matter in a mineral soil.
