HIDEO KOJIMA, NOBORU MATSUMURA, and HIROO INOUE. Can. J. Chem. **70**, 1 (1992).

Quinolines (**2** and **3**) and naphthazepines (**8** and **9**) are prepared in high yields by the reaction of tris(isopropylthio)-cyclopropenylium perchlorate (**1**) with anilines and 1-naphthylamines, respectively, under nitrogen in *N*,*N*-dimethylformamide at 80–85°C. The reactions are proven to proceed through the intermediary formation of iminium salts (**5**, **10**, and **11**) derived from **1** and amines. The reaction of **1** with pyrrole and indole in dimethyl sulfoxide, containing sodium hydride, at 25°C gives 5,6,7-tris(isopropylthio)-1*H*-pyrrolizine (**12**) and 1,2,3-tris(isopropylthio)-9*H*-fluorazene (**14**), respectively, in high yields by intramolecular cyclization of a vinylcarbene intermediate. The possible pathway for the formation of these nitrogen heterocycles is proposed.

Key words: cyclopropenyl cation, aromatic amines, nitrogen heterocycles, three-carbon building block.

HIDEO KOJIMA, NOBORU MATSUMURA et HIROO INOUE. Can. J. Chem. **70**, 1 (1992).

En faisant réagir du perchlorate de tris(isopropylthio)cyclopropénylium (**1**) avec des anilines et des naphtyl-1-amines, sous azote, dans le *N*,*N*-diméthylformamide, à 80–85°C, on a préparé respectivement les quinoléines **2** et **3** et les naphtazépines **8** et **9**, avec d'excellents rendements. On a prouvé que les réactions se produisent par la formation des sels d'iminium **5**, **10** et **11**, dérivés du composé **1** et des amines, comme intermédiaires. Les réactions du composé **1** avec le pyrrole et l'indole, dans le diméthylsulfoxyde contenant de l'hydrure de sodium à 25°C, fournissent respectivement le 5,6,7-tris(isopropylthio)-1*H*-pyrrolizine (**12**) et le 1,2,3-tris(isopropylthio)-9*H*-fluorazène (**14**), avec d'excellents rendements, par la cyclisation intramoléculaire d'un vinylcarbène intermédiaire. On propose une voie éventuelle de formation de ces hétérocycles azotés.

Mots clés : cation cyclopropényle, amines aromatiques, hétérocycles azotés, possibilités d'ajouter trois carbones.

[Traduit par la rédaction]

Introduction

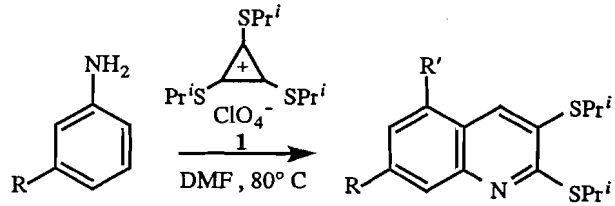
Cyclopropenyl cations have attracted special attention because of their high strain and aromatic character, and their reactions with various nucleophiles such as amines (1), enolates (2), and Grignard reagents (3) have been investigated extensively. Recent studies have shown that the reaction of tris(*tert*-butylthio)cyclopropenyl cation with aliphatic amines, such as 3-aminopropionitrile and 3-aminopropionates, in *N*,*N*-dimethylformamide (DMF) containing sodium hydride gives the corresponding substituted 1,2-dihydropyridines by C_3-ring opening followed by intramolecular cyclization (4). Despite this research, few have investigated the reaction of aromatic amines with this ring system to build nitrogen heterocycles by cyclization at the aromatic ring.

Due to our interest in using the cyclopropenyl cation as a three-carbon building block, we carried out the reaction of tris(isopropylthio)cyclopropenylium perchlorate (**1**) with aniline, *m*-aminophenol, 1-naphthylamine, 5-amino-1-naphthol, pyrrole, and indole. Herein we report experimental details on the preparation of quinolines, naphthazepines, and pyrrolizine and fluorazene derivatives from **1** and the corresponding aromatic amines. Part of the results have been reported in our preliminary papers (refs. 5 and 6).

Results and discussion

Preparation of quinolines from aniline and m-*aminophenol*

The reaction of the cyclopropenyl cation **1** with aniline (2 equiv.) under nitrogen in dry DMF at 80°C gave 2,3-bis(isopropylthio)quinoline (**2**) in a high yield. In this reaction, 3,4-bis(isopropylthio)quinoline was not obtained. The aniline/**1** molar ratio of 2:1 was necessary for raising the yield of **2**; in the molar ratio of 1:1, the yield of **2** after 50 h was 40% (recovery of **1**: 60%). 7-Hydroxy-2,3-bis(isopropylthio)quinoline (**3**) was also prepared under similar conditions from *m*-aminophenol and **1** (molar ratio of 2:1) in 96% yield after 24 h, accompanied by the formation of 5-hydroxy-2,3-bis(isopropylthio)quinoline (**4**) in 4% yield. Thus, the cyclopropenyl cation **1** served as a building block to form quinolines by ring opening followed by intramolecular cyclization.



R = H, OH

2: R = R′ = H
3: R = OH; R′ = H
4: R = H; R′ = OH

Next the reactions were carried out in acetonitrile (MeCN) at 25°C. The reaction with aniline led to the formation of an iminium salt **5** in quantitative yield, although with *m*-aminophenol, quinolines **3** and **4** were isolated in 74 and 3% yields, respectively, after 73 h. The iminium salt **5** was isolated by the evaporation of MeCN after the reaction and its structure was established by measuring the ^1H and ^{13}C nmr spectra. The ^1H nmr spectrum showed a singlet (1H) for the CH=N$^+$ proton at δ 9.08, a broad singlet (2H) for the NH and NH$^+$ protons at δ 8.70–8.90, an unresolved multiplet (10H) for the aromatic ring protons at δ 7.38–7.43, and two doublets (12H, δ 1.18 and 1.26) and two septets (2H, δ 2.98 and 3.19) for the methyl and methine protons of two isopro-

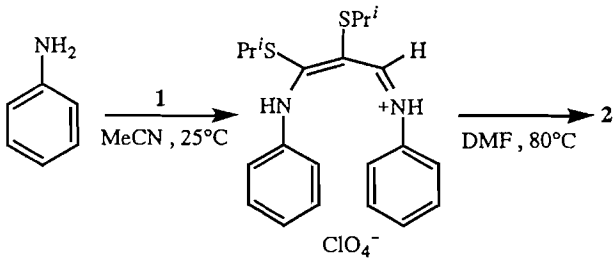
pylthio groups respectively. The ^{13}C nmr spectrum showed a signal due to the $C{=}N^+$ group at δ 175.2. Furthermore, the reaction of **1** with aniline at 25°C was carried out by using DMF instead of MeCN. The yield of **2** after 29 h increased to 14%, but the main product was the iminium salt **5** (84%). Next a solution of **5** in DMF was heated at 80°C for 25 h. It was found that **5** was converted quantitatively into the quinoline **2**. These facts indicate that **2** is produced through the intermediary formation of **5** which undergoes cyclization at 80°C.

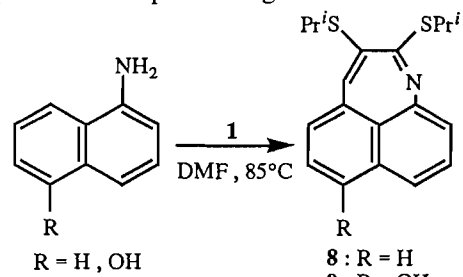


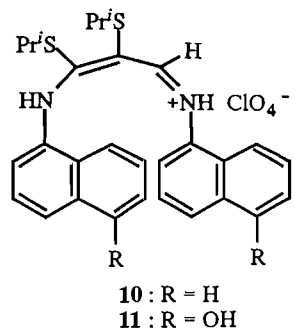
5

The possible pathway for the formation of **5** is proposed in Scheme 1. The nucleophilic attack of aniline on **1** is considered to form vinylcarbene (**6**), which is converted into an intermediate (**7**) by protonation. Formation and protonation of the vinylcarbene intermediate have been suggested in the reactions of 1-(diphenylamino)-2,3-diphenylcyclopropenyl cation with phenylmagnesium bromide (7) and of tris(*tert*-butylthio)cyclopropenyl cation with dimethylamine (8) and *o*-phenylenediamine (4), respectively. The reaction of intermediate **7** with aniline, accompanied by elimination of 2-propanethiol, leads to the formation of **5**. Cyclization of the iminium carbon of **5** at the *o*-position of the anilino group, followed by elimination of aniline, gives quinoline **2**. Quinolines **3** and **4** also are considered to be produced from *m*-aminophenol by this process, although the corresponding iminium salt was not detected.

Preparation of naphthazepines from 1-naphthylamine and 5-amino-1-naphthol

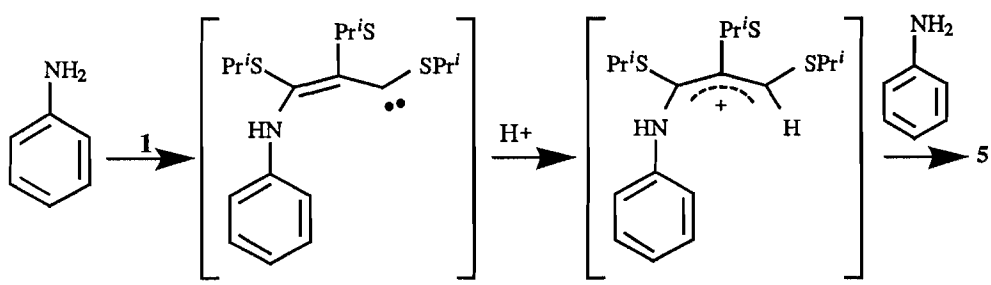
The cyclopropenyl cation **1** reacted under nitrogen with 1-naphthylamine and 5-amino-1-naphthol (2 equiv.) in MeCN under reflux or in DMF at 85°C to give 2,3-bis(isopropylthio)- (**8**) and 7-hydroxy-2,3-bis(isopropylthio)naphth[1,8-*bc*]azepine (**9**), respectively, in high yields. Thus, cyclopropenyl cation **1** undergoes cyclization at the 8-position of the naphthalene nucleus to form the azepine ring, but not at the 2-position to form the pyridine ring. When the reactions were carried out in DMF at 25°C, the yields of **8** and **9** decreased and iminium salts **10** and **11** were obtained as the main products. The iminium salts are considered to be produced by the pathway similar to that in Scheme 1. Furthermore, it was confirmed that iminium salts **10** and **11** were converted into naphthazepines **8** and **9**, respectively, in quantitative yields by heating at 85°C in DMF. From these results, the reaction pathway for the formation of naphthazepines **8** and **9** is considered to be similar to that in the reaction of **1** with anilines described above. Cyclization at the 8-position of the naphthalene ring implies that the carbon at the 8-position and the iminium carbon are favorably situated in positions that permit ring closure.





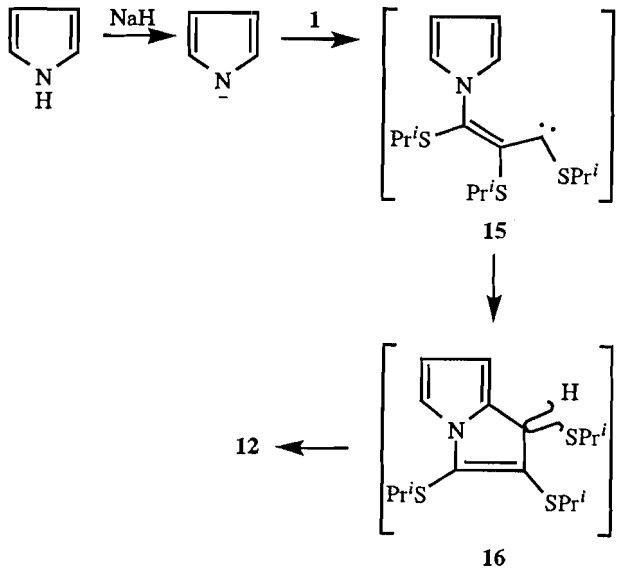
Preparation of pyrrolizine and fluorazene derivatives from pyrrole and indole

To prevent protonation of the vinylcarbene intermediate generated by ring opening, the reaction of cyclopropenyl cation **1** with *N*-anions of pyrrole and indole in dimethyl sulfoxide (DMSO) was conducted. Pyrrole was treated under nitrogen with sodium hydride (1 equiv.) in DMSO at 25°C and **1** (1 equiv.) was added. The reaction proceeded rapidly at 25°C to give 5,6,7-tris(isopropylthio)-1*H*(**12**) and -3*H* (**13**)-pyrrolizine in 53 and 11% yields, respectively, after 1 h. In this reaction, pyrrolizine **13** was found to be derived easily from **12** under irradiation with solar light. Therefore, reaction of **1** with the pyrrolyl *N*-anion was carried out in the dark, affording only **12** in 98% yield. Potassium *tert*-butoxide and potassium hydroxide also were useful, as a base, in this re-



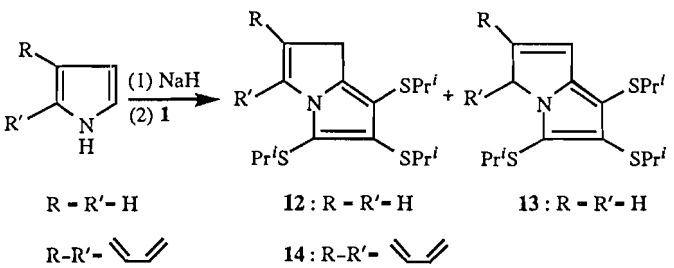
6 **7**

SCHEME 1



SCHEME 2

action. In the absence of a base, **12** and **13** were not produced, but a mixture of unidentified compounds was obtained.



The reaction of **1** with the indole/NaH system (molar ratio of 1:1:1) was carried out under similar conditions. At 85°C, 1,2,3-tris(isopropylthio)-9*H*-fluorazene (**14**) was obtained in 84% yield after 1 h. Cyclization at the 7-position of indole did not occur. Thus, the cyclopropenyl cation **1** was proven to undergo cyclization at the 1,2 positions of pyrrole and indole to form pyrrolizine and fluorazene derivatives respectively.

Reaction with the pyrrolyl *N*-anion is rationalized to proceed through formation of the vinylcarbene intermediate **15** by nucleophilic attack of the pyrrolyl *N*-anion on the cyclopropenyl cation **1**, followed by intramolecular insertion of the carbene into the C—H bond in the 2-position of pyrrole to give **16**, as shown in Scheme 2. Intermediate **16** is converted into **12** by the migration of hydrogen. Fluorazene **14** also is considered to be produced from indole by this process.

Experimental

Melting points were determined on a Yanagimoto MP-S3 melting point apparatus and are uncorrected. The ir spectra of solids (KBr) and oil (neat) were recorded on a Hitachi 215 spectrometer. The ^{1}H nmr (270 MHz) and ^{13}C nmr (68 MHz) spectra were measured on a Jeol JNM-GX 270 FT nmr spectrometer with $CDCl_3$ as solvent and tetramethylsilane as an internal standard. Mass spectra were obtained at 70 eV with a Shimadzu LKB-9000 spectrometer. Elemental analyses of quinolines **2–4**, naphthazepines **8** and **9**, pyrrolizines **12** and **13**, and fluorazene **14** agreed within ±0.3% with the calculated values. Column chromatography was performed on silica gel (Wakogel C-300).

General procedure for the preparation of quinolines, iminium salts, and naphthazepines

Compound **1** (181 mg, 0.5 mmol) was added under nitrogen to a solution of amines (1.0 mmol) in dry DMF or MeCN (20 mL) in one portion and the mixture was stirred at the indicated reaction temperature for 24–73 h. Iminium salts **5**, **10**, and **11** were isolated by removal of the solvent *in vacuo*. The residue was subjected to the measurement of the ^{1}H and ^{13}C nmr spectra without further purification, because structural changes occurred on purification. For the isolation of quinolines **2–4** and naphthazepines **8** and **9**, the reaction mixture with DMF was poured into water (100 mL) and extracted with CH_2Cl_2 (2 × 50 mL). The organic layer was washed with water (3 × 50 mL), dried (Na_2SO_4), and concentrated *in vacuo*. The reaction mixture with MeCN was evaporated *in vacuo*. The residue was purified by silica gel chromatography using the eluent shown below.

2,3-Bis(isopropylthio)quinoline (2) (DMF, 80°C, 29 h): 80% yield; purified by column chromatography (hexane/CH_2Cl_2, 3:1); a colorless oil; ir (neat) ν: 3050, 2960, 2925, 2865, 1620, 1575, 1550, 1490, 1465, 1385, 1360, 1330, 1240, 1155, 1140, 1120, 1055, 990, 780, 750 cm^{-1}; ^{1}H nmr δ: 1.34 (d, J = 6.9 Hz, 6H, CH(CH_3)$_2$), 1.48 (d, J = 6.9 Hz, 6H, CH(CH_3)$_2$), 3.54 (sept, J = 6.9 Hz, 1H, CH(CH$_3$)$_2$), 4.23 (sept, J = 6.9 Hz, 1H, CH(CH$_3$)$_2$), 7.41 (m, 1H, arom), 7.61 (m, 1H, arom), 7.66 (m, 1H, arom), 7.91 (m, 1H, arom), 7.96 (s, 1H, H-4); ^{13}C nmr δ: 23.0 (2C), 35.6, 38.2, 125.3, 125.9, 127.0, 127.9, 128.3, 129.5, 138.5, 147.0, 162.2; ms m/z: 277 (M^+).

7-Hydroxy-2,3-bis(isopropylthio)quinoline (3) and 5-hydroxy-2,3-bis(isopropylthio)quinoline (4) (DMF, 80°C, 24 h): 96 and 4% yields; purified by column chromatography (hexane/CH_2Cl_2, 1:2); a colorless oil. **3**; ir (neat) ν: 3375, 1620, 1580, 1560, 1495, 1450, 1335, 1200, 1130, 1050, 995, 860, 810 cm^{-1}; ^{1}H nmr δ: 1.30 (d, J = 6.7 Hz, 6H, CH(CH_3)$_2$), 1.45 (d, J = 6.7 Hz, 6H, CH(CH_3)$_2$), 3.47 (sept, J = 6.7 Hz, 1H, CH(CH$_3$)$_2$), 4.17 (sept, J = 6.7 Hz, 1H, CH(CH$_3$)$_2$), 5.69 (br s, 1H, OH-7), 7.03 (dd, J = 8.6 and 2.7 Hz, 1H, arom), 7.25 (d, J = 2.7 Hz, 1H, arom), 7.56 (d, J = 8.6 Hz, 1H, arom), 7.93 (s, 1H, H-4); ^{13}C nmr δ: 22.9, 23.0, 35.6, 38.5, 110.0, 117.2, 120.9, 125.0, 128.8, 140.2, 148.4, 157.4, 163.5; ms m/z: 293 (M^+). **4**; ir (neat) ν: 3400, 1620, 1580, 1555, 1465, 1335, 1275, 1200, 1130, 1080, 1050, 805 cm^{-1}; ^{1}H nmr δ: 1.35 (d, J = 6.7 Hz, 6H, CH(CH_3)$_2$), 1.48 (d, J = 6.7 Hz, 6H, CH(CH_3)$_2$), 3.56 (sept, J = 6.7 Hz, 1H, CH(CH$_3$)$_2$), 4.21 (sept, J = 6.7 Hz, 1H, CH(CH$_3$)$_2$), 5.44 (br s, 1H, OH-5), 6.73 (m, 1H, arom), 7.39–7.51 (m, 2H, arom), 8.34 (s, 1H, H-4); ms m/z: 293 (M^+).

Iminium salt (5) (MeCN, 25°C, 25 h): 100% yield; a reddish oil; ^{1}H nmr δ: 1.18 (d, J = 6.7 Hz, 6H, CH(CH_3)$_2$), 1.26 (d, J = 6.7 Hz, 6H, CH(CH_3)$_2$), 2.98 (sept, J = 6.7 Hz, 1H, CH(CH$_3$)$_2$), 3.19 (sept, J = 6.7 Hz, 1H, CH(CH$_3$)$_2$), 7.38–7.43 (m, 10H, arom), 8.70–8.90 (br s, 2H, NH and N$^+$H), 9.08 (s, 1H, CH=N$^+$); ^{13}C nmr δ: 22.19, 22.49, 39.58, 40.15, 103.0, 115.2, 118.3, 118.7, 123.5, 126.8, 127.9, 128.8, 129.5, 129.6, 129.7, 137.3, 145.6, 154.5, 175.2 (CH=N$^+$).

2,3-Bis(isopropylthio)naphth[1,8-bc]azepine (8) (MeCN, reflux, 25 h and DMF, 85°C, 25 h): 91 and 92% yields; purified by column chromatography (hexane/CH_2Cl_2, 2:1); colorless solids, mp 86–87°C; ir (KBr) ν: 3040, 2950, 2915, 2850, 1620, 1600, 1570, 1550, 1495, 1470, 1435, 1385, 1360, 1240, 1150, 1130, 1050, 935, 810 cm^{-1}; ^{1}H nmr δ: 1.36 (d, J = 6.7 Hz, 6H, CH(CH_3)$_2$), 1.61 (d, J = 6.7 Hz, 6H, CH(CH_3)$_2$), 3.59 (sept, J = 6.7 Hz, 1H, CH(CH$_3$)$_2$), 4.41 (sept, J = 6.7 Hz, 1H, CH(CH$_3$)$_2$), 7.58 (m, 1H, arom), 7.65–7.72 (m, 3H, arom), 7.87 (m, 1H, arom), 8.02 (s, 1H, H-3), 9.19 (m, 1H, arom); ^{13}C nmr δ: 22.9, 23.1, 35.9, 38.2, 123.3, 124.4, 124.8, 126.4, 126.9, 127.8, 128.1, 128.3, 130.9, 133.9, 139.0, 144.8, 161.3; ms m/z: 327 (M^+).

(MeCN, reflux, 30 h and DMF, 85°C, 25 h): 96 and 90% yields; purified by column chromatography (hexane/CH_2Cl_2, 1:2); colorless solids, mp 159–160°C; ir (KBr) ν: 3325, 1610, 1575, 1425, 1390, 1355, 1255, 1135, 910, 755 cm^{-1}; ^1H nmr δ: 1.37 (d, J = 6.7 Hz, 6H, $CH(CH_3)_2$), 1.59 (d, J = 6.7 Hz, 6H, $CH(CH_3)_2$), 3.59 (sept, J = 6.7 Hz, 1H, $CH(CH_3)_2$), 4.38 (sept, J = 6.7 Hz, 1H, $CH(CH_3)_2$), 5.76 (br s, 1H, OH-7), 7.03 (m, 1H, arom), 7.51 (m, 1H, arom), 7.57 (d, J = 9.2 Hz, 1H, arom), 8.01 (s, 1H, H-3), 8.09 (d, J = 9.2 Hz, 1H, arom), 8.77 (m, 1H, arom); ^{13}C nmr δ: 22.9, 23.1, 35.9, 38.1, 111.9, 117.1, 119.8, 123.5, 123.9, 124.0, 126.9, 128.6, 132.4, 138.8, 144.6, 151.5, 161.2; ms m/z: 343 (M^+).

*Iminium salt (**10**)* (DMF, 25°C, 26 h): 73% yield with **8** in 26% yield; a reddish oil; ^1H nmr δ: 1.12 (d, J = 6.7 Hz, 6H, $CH(CH_3)_2$), 1.35 (d, J = 6.7 Hz, 6H, $CH(CH_3)_2$), 3.11 (sept, J = 6.7 Hz, 1H, $CH(CH_3)_2$), 3.30 (sept, J = 6.7 Hz, 1H, $CH(CH_3)_2$), 7.45–8.02 (m, 14H, arom), 8.54–8.62 (br s, 2H, NH and N^+H), 9.15 (s, 1H, $CH=N^+$); ^{13}C nmr δ: 22.4, 23.0, 40.1, 40.9, 103.1, 117.8, 119.6 (2C), 121.3, 122.7, 125.3, 125.5, 125.6, 126.8, 126.9, 127.4, 127.6, 127.9, 128.0, 128.5, 128.6, 129.2, 133.1, 133.7, 133.9, 157.4, 178.3 ($CH=N^+$).

*Iminium salt (**11**) (DMF, 25°C, 25 h): 65% yield with **9*** in 35% yield; a reddish oil; ^1H nmr (CD_3CN) δ: 1.06 (d, J = 6.7 Hz, 6H, $CH(CH_3)_2$), 1.42 (d, J = 6.7 Hz, 6H, $CH(CH_3)_2$), 2.97 (sept, J = 6.7 Hz, 1H, $CH(CH_3)_2$), 3.44 (sept, J = 6.7 Hz, 1H, $CH(CH_3)_2$), 5.70–5.80 (br s, 2H, OH), 7.06 (m, 2H, arom), 7.46–7.60 (m, 8H, arom), 8.25–8.35 (m, 2H, NH and N^+H), 9.19 (s, 1H, $CH=N^+$).

General procedure for the preparation of pyrrolizine and fluorazene derivatives

Pyrrole (34 mg, 0.5 mmol) or indole (59 mg, 0.5 mmol) was added to a suspended solution of NaH (50% in mineral oil), Bu^{t}OK, and KOH (0.5 mmol) in dry DMSO (10 mL) and the mixture was stirred under nitrogen at 25°C for 1.5–2 h. To the resulting solution, a solution of cyclopropenyl cation **1** (181 mg, 0.5 mmol) in dry DMSO (10 mL) was added in one portion. After stirring at 25 or 85°C for 1–2 h, the mixture was poured into water (100 mL) and extracted with ether (3 × 50 mL). The organic layer was dried (Na_2SO_4) and evaporated *in vacuo*. The residue was purified by silica gel chromatography using the eluent shown below.

*5,6,7-Tris(isopropylthio)-1H-pyrrolizine (**12**) and 5,6,7-tris(isopropylthio)-3H-pyrrolizine (**13**):* Yield, %: 53 and 11 (NaH, 1 h), 49 and 9 (Bu^{t}OK, 1 h), and 41 and 8 (KOH, 2 h). Irradiation of **12** (0.5 mmol) in deuteriochloroform (1 mL) (nmr sample tube) with solar light for 6 h: 50% yield of **13** and 50% recovery of **12**. Oxidation of *n*-butane was investigated on vanadyl phosphate (VP) prepared in the presence of titania (anatase) and silica as supports. In the case of silica, α-$VOPO_4$ was synthesized with no sign of interaction between the silica surface and vanadium phosphate. On the contrary, titania was coated with amorphous VP (P/V = 1), preventing the crystallization of $VOPO_4$ at least up to the VP content of 21%. *n*-Butane was completely converted into CO_2 for the VP/TiO_2 catalytic system. Upon impregnation with metal sulfates, maleic anhydride (MA) was produced with selectivities depending on the nature of the added metallic species, the best effect being observed with Fe^{2+} (V/Fe = 3). Selectivities to MA were influenced by the P/V ratio, with a maximum at P/V = 1.2.

Key words: vanadyl phosphate, maleic anhydride, butane oxidation, anatase, rutile.

On a étudié l'oxydation du butane sur de phosphate de vanadyle (PV) préparé en présence de titania (anatase) et de silica comme supports. Dans le cas de la silice, on a synthétisé du α-$VOPO_4$ sans signes d'interactions entre la surface de la silice et le phosphate de vanadium. Au contraire, le titania était couvert de PV (P/V = 1) et cette situation empêche la cristallisation du $VOPO_4$, au moins jusqu'à un contenu en PV de 21%. Avec le système catalytique PV/TiO_2, le butane est complètement transformé en CO_2. Après imprégnation sur des sulfates métalliques, il y a formation d'anhydride maléique (AM) avec des sélectivités qui dépendent de la nature des espèces métalliques ajoutées; les meilleurs résultats sont obtenus avec le Fe^{2+} (V/Fe = 3). Les sélectivités en AM sont influencées par le rapport P/V; le maximum se situe à P/V = 1, 2.

Mots clés : phosphate de vanadyle, anhydride maléique, oxydation du butane, anastase, rutile.

[Traduit par la rédaction]

Introduction

Two catalytic processes of industrial importance, namely, the production of maleic anhydride (MA) from C_4 hydrocarbons and phthalic anhydride from *o*-xylene, rely widely on vanadium-based catalysts. In the first process, C_4 hydrocarbons are oxidized into MA using vanadium phosphate catalytic systems (VPO catalysts), while in the second, titania-supported V_2O_5 catalysts are preferred. These two types of catalysts generally contain modifiers, promoters, etc. There has been significant evidence that TiO_2 imparts special properties to V_2O_5, which other more classical supports do not, or do so to a lesser extent. Several authors proposed that a solid solution forms between V^{4+} and TiO_2 (1, 2), though this question still remains debatable.

The VPO catalysts, in spite of the large number of studies on these compounds and the progress made in recent years, remain complex systems that are not yet understood. Three main aspects are still subject to some disagreement: the exact nature of the active phase (is it a crystalline phase and, if so, which one (3), or is it rather an amorphous phase (4)); the oxidation state of V and its control (5); the influence of the P/V ratio on the selectivity to MA (6, 7). These questions have been considered in reviews by Hodnett *et al.* (8) and Centi *et al.* (9).

One way to improve the performance of a catalyst is to increase the number of the active sites exposed to the reacting molecules. High surface area catalysts may be obtained from precursors prepared in nonaqueous solutions (10, 11) or, alternatively, by supporting the catalytic phase. This latter approach was preferred.

Up to now, very little work has been concerned with the study of supported VP catalytic systems. Chinchen *et al.* (12) mention patents to BASF wherein it is "suggested" that a titania/steatite is probably used to support VPO. The same authors also refer to patents to Mitsubishi quoting silica and alumina as supports for these catalysts. Cavani *et al.* (5) prepared a coprecipitated VPO–TiO_2 catalyst with 10% V_2O_5, but have not yet provided results showing how these systems compare with pure VPO catalysts. SiO_2 was taken as support for VPO by Varma and Saraf (13) for the oxidation of butenes, whereas Nakamura *et al.* (14) investigated VPO/α-Al_2O_3 systems.

In spite of the already complex nature of vanadium phosphate catalysts, it was challenging, due to the particular interaction between vanadium compounds and titania, to investigate the catalytic performance of supported VP in the oxidation of *n*-butane. TiO_2 (anatase) and a microfibrilous silica were chosen as supports, the VPO phase being prepared using a procedure that, in absence of support, yielded crystalline α-$VOPO_4 \cdot 2H_2O$ (15, 16). This paper summarizes the preliminary results obtained with these systems.

Experimental

Preparation of the catalysts

Crystalline α-$VOPO_4$ was synthesized according to the method described earlier (15). The supported "$VOPO_4$" (hereafter VP) systems were prepared using the standard method, the only difference being the addition of the support to the reaction mixture. Two supports were chosen: TiO_2 (Eurotitania from Tioxide, batch 1143; So = 61 m^2/g) and a microfibrous SiO_2 (from Redco; So = 550 m^2/g). After refluxing, the slurries were washed and freeze-dried. The amounts of the different reagents in the reaction mixture corresponded to $V_2O_5/(V_2O_5 + TiO_2)$ weight ratios of 5, 10, 15, and 22% (named T5, T10, T15, and T22 in Table 1) and $V_2O_5/(V_2O_5 + SiO_2)$ of 6.6, 12.6, 20, and 31%.

Metals (Me) supported on VP/TiO_2 were obtained by the wet impregnation (H_2O or MeOH) method, using the sulfates of Fe^{2+}, Co^{2+}, Cr^{3+}, and Mn^{2+}. Molybdenum-impregnated systems were prepared with ammonium heptamolybdate. In all cases the V/Me atomic ratio was 3. Impregnation and drying were carried out in a rotavapor.

Systems with different P/V ratios were obtained by impregnation of the (Me)VP/TiO_2 material with the amounts of H_3PO_4 necessary to achieve P/V ratios of 1.1, 1.2, 1.3, and 1.5.

All the solids prepared were pelleted, crushed, and sieved. The catalytic tests were performed on the 0.2–0.315 mm fraction.

Characterization methods

To determine the chemical composition of the solids, they were dissolved by melting with NaOH. Vanadium was determined by atomic absorption spectrometry and the content of phosphorus was obtained by colorimetric analysis as the blue molybdophosphate complex; previous precipitation of titanium and vanadium was with cupferron.

The catalytic systems were also characterized using various techniques: differential thermal and thermogravimetric analyses (Rigaku Thermoflex), infrared spectroscopy (IFS 88 Brucker), X-ray diffraction (Cu Kα radiation, Siemens D500 equipment with DACO-MP setup), scanning electron microscopy (Jeol Temscan 100CX), and electron microprobe analysis EDS (Kevex SC 100).

Catalytic measurements

The catalytic oxidation of *n*-butane (*n*-C_4) was carried out in a flow reactor operated at atmospheric pressure. A detailed description of the apparatus and measurement procedure has been given elsewhere (7). The tests were done on a constant catalyst volume basis (height of catalyst bed: 14 cm; internal diameter of the tubular reactor: 3.5 mm). In these conditions, the sample weight was between 1.2 and 1.8 g.

The reaction was performed in temperature-programmed mode with *n*-C_4 flowing at 0.5 mL/min and air at 35 mL/min. These conditions define a molar concentration of *n*-C_4 of 1.4%. The tubing and valves beyond the reactor were heated to prevent condensation of the reaction products. The analyses were performed by gas chromatography.

Results

Catalyst characterization

Chemical analyses

The chemical analysis data of solids before catalytic performances given in Table 1 indicate that, in the VP/TiO_2 systems, the molar ratio V/P is near 1. The total vanadium content of these catalysts represents 80% of the amount of V introduced in the synthesis mixture. For the VP/SiO_2 catalysts, only 60% of the starting vanadium is found in the final product.

X-ray diffraction and SE microscopy

The X-ray diagrams of the VP/TiO_2 series with different VP contents and of the pure α-$VOPO_4 \cdot 2H_2O$ phase are shown in Fig. 1. The 001 (7.4 Å), 002 (3.7 Å), 102 (3.16

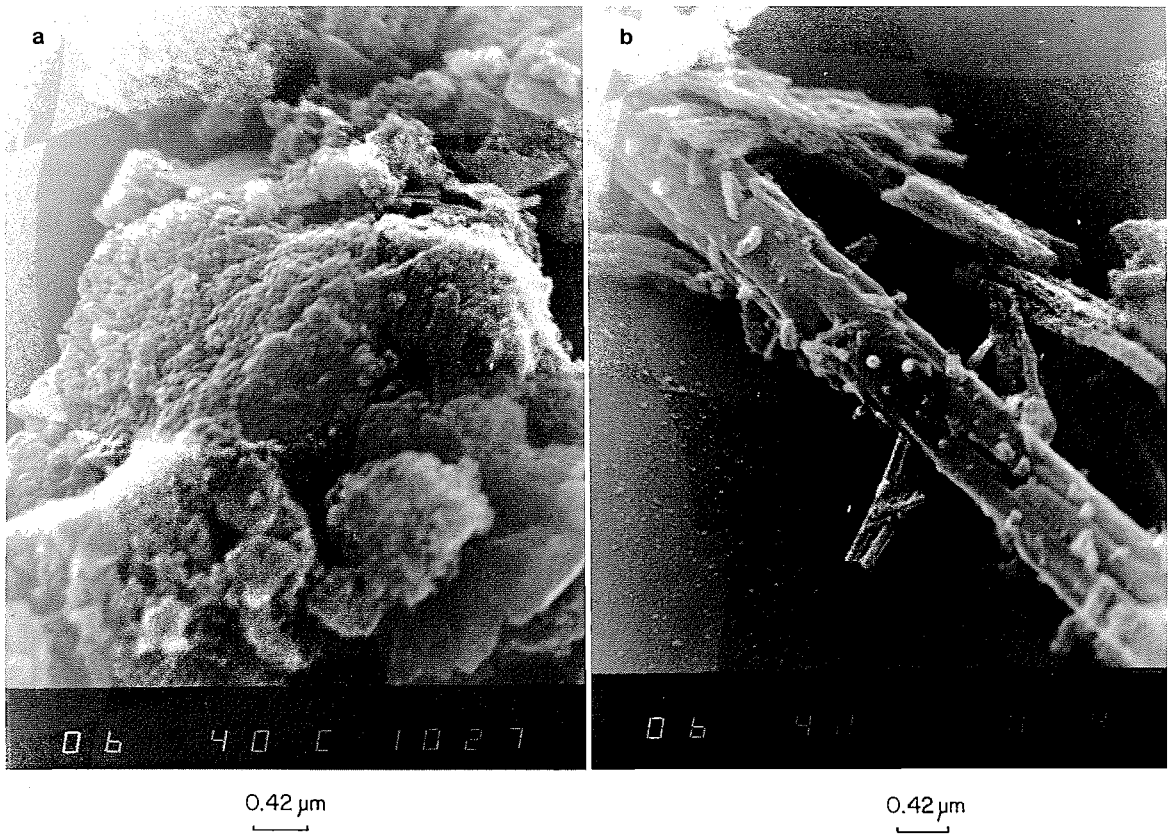

FIG 2. SEM photomicrograph of: (a) VP/TiO_2 and (b) VP/SiO_2. The bar in the lower right corresponds to 0.42 μm.

Å), and 200 (3.09 Å) reflections were taken to identify the crystalline α-$VOPO_4 \cdot 2H_2O$ phase. As can be seen, these diffraction lines are absent in the systems containing less than 21% VP. On the SE micrographs the anatase particles appear as homogeneously coated with VP (Fig. 2(a)). EDX studies verified this situation. Both analyses of aggregates and at various positions on individual particles show similar composition of Ti, V, and P. Only the samples with 31.9% VP contain, in addition, segregated particles of α-$VOPO_4$, thus in agreement with the X-ray diffraction analysis.

This situation was also observed by Fierro *et al.* (17) in the V_2O_5/TiO_2 system; X-ray diffraction data and Raman spectra showed that V_2O_5 was highly dispersed over TiO_2 in $V/(V + Ti) \leq 0.11$ catalyst; in more vanadium-rich systems the presence of tridimensional V_2O_5 crystallites was observed.

The picture is very different for the VP phases prepared in the presence of silica. Indeed, the X-ray diffraction spectra, given in Fig. 3, clearly show that crystalline α-$VOPO_4$ is present in all the samples, with peak intensities increasing with the VP content. Trace b in Fig. 3 indicates that the starting silica contains a small amount of residual quartz. The VP/SiO_2 with 4.1 and 14.6% VP contain, in addition to α-$VOPO_4$, small amounts of another phase characterized by reflections near 15°(2θ). This phase has not yet been identified. Examining these samples with SE microscopy confirms the existence of segregated α-$VOPO_4$, particles, the SiO_2 fibrils being uncoated. This fact is deduced from the microprobe analysis on the fibrous and lamellar materials in Fig. 2(b). Summarizing, the type of support plays an important role in the formation of the VPO phase. Anatase prevents the crystallization of α-$VOPO_4$, at least for VP contents up to 21.0%, and the TiO_2 particles are completely covered with VP. On the contrary, the silica used as support has no effect on the crystallization of the VPO phase, and there is no evidence of vanadium phosphate interacting with the surface of silica.

When V_2O_5 is supported on TiO_2 (anatase) a simultaneous reduction of V_2O_5 and transformation of TiO_2 (anatase) into TiO_2 (rutile) has been observed (1, 2). This polymorphic transformation is catalyzed by V^{5+} and is strongly dependent upon the calcination temperature, specially above 800 K. Taking into account that our VP/TiO_2 systems were air-dried and that the catalytic reactions were carried out up to 673 K, the catalysts will not undergo substantial phase transformation. The aforementioned authors (17) have not found any differences in the percentages of anatase and rutile in the supported catalysts after calcination at 773 K with respect to the unsupported anatase.

The addition of reducing metal ions (like Fe^{2+}, Mn^{2+}) provokes a gradual diminution of the 001 reflections of α-$VOPO_4 \cdot 2H_2O$, while a new peak appears at 13.4°(2θ) (6.6 Å) whose intensity increases with the amount of the reducing species. Such a change of the X-ray diagram had already been reported by Martinez *et al.* (15) in the case of redox intercalation in vanadyl phosphate for which the coexistence of a vanadium (4+) phosphate phase containing interlamellar cations and vanadium (5+) phosphate was proposed.

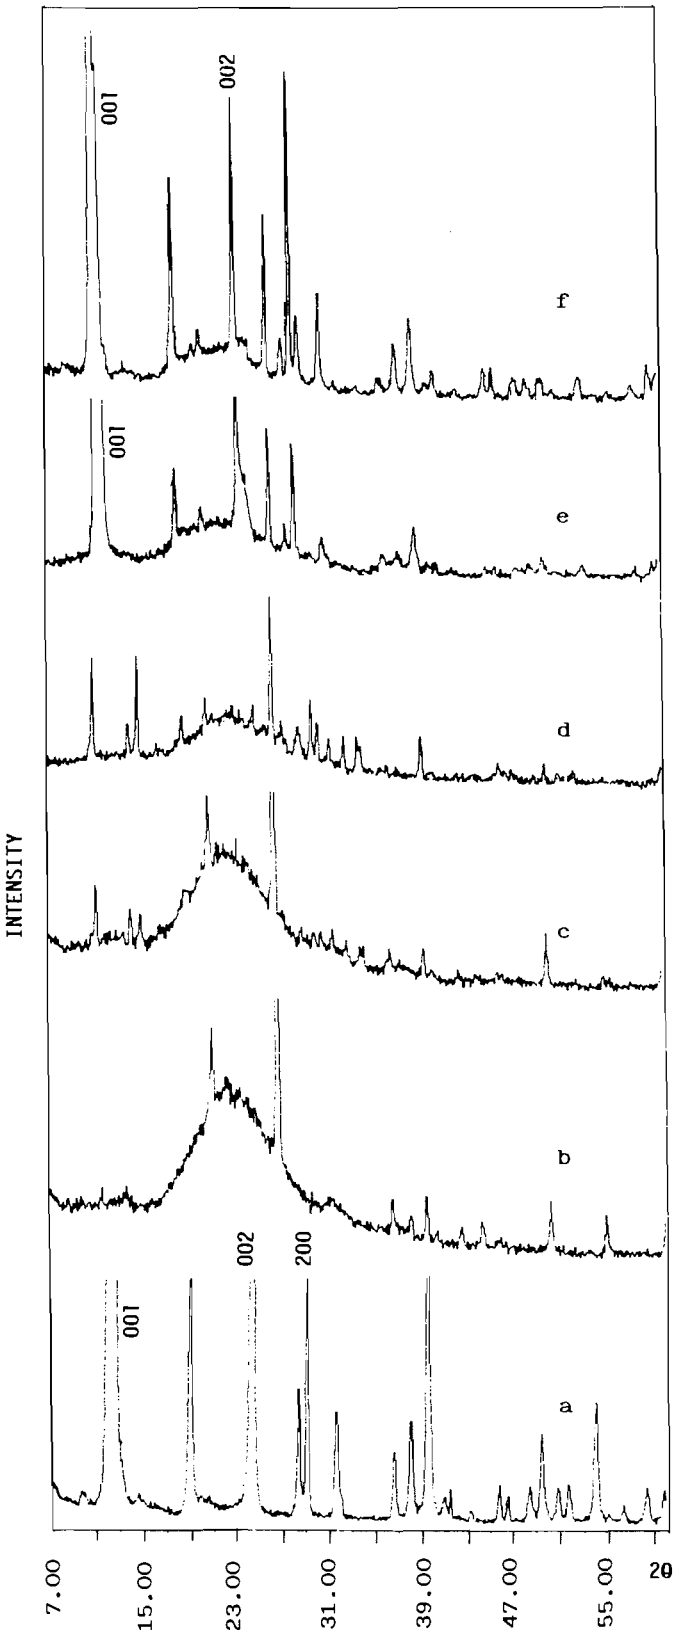

FIG 3. X-ray powder diagrams of unsupported α-$VOPO_4$ (a), SiO_2 showing the reflections of residual quartz (b), and with different amounts of VP: (c) 4.1%; (d) 14.6%; (e) 21.8%, and (f) 33.0%.

Infrared spectroscopy

The IR spectra of the VP/SiO_2 and VP/TiO_2 systems exhibit, without important modifications, the absorption band characteristic of the support and of the active phase. The spectral region between 900 and 1200 cm^{-1} is most sensitive to the modifications of the catalyst. Indeed, this is the frequency domain of the vibrations of PO_4^{3-} (1170, 1080, 1030 cm^{-1}) and V—O groups (1010, 990, 964 cm^{-1}) (15, 16). The spectrum of VP/TiO_2 impregnated with Fe^{2+} (Fig. 4B) clearly shows a band at 990 cm^{-1}, which is assigned to the V^{IV}—O vibration as a consequence of a partial reduction of V^V by Fe^{2+}. As compared to the spectrum of the iron-free sample (Fig. 4A), the intensity of the band at 964 cm^{-1} of the Fe^{2+}-containing catalyst is markedly diminished. This band may be attributed to the P—O stretching vibration of the PO_4^{3-} group within an asymmetrical environment, although Pulvin *et al.* (18) proposed to assign it to the pseudo-symmetrical vibration of O—V=O.

The IR spectrum of the Fe^{2+}-containing VP/TiO_2 sample impregnated with phosphoric acid (Fig. 4C) shows a broad absorption band centered at around 1050 cm^{-1}, which envelopes all the other bands due to the phosphate groups.

EPR measurements

The EPR spectra of the VP/TiO_2 samples (not shown here) are characteristic of vanadyl phosphate, with the signal of trace amounts of V(4+) centers diluted magnetically (19). The sample of VP/TiO_2 partially reduced with Fe^{2+} gives rise to EPR signals that denote the presence of V(4+) and Fe(3+) species, with a broad signal due to large amounts of paramagnetic centers.

Catalytic activity of the VP/TiO_2 systems

Influence of the "$VOPO_4$" content on the reaction of n-*butane*

The conversion of n-C_4 for the catalysts containing 7.5, 13.9, 21.0, and 31.9% VP depends upon the temperature. Thus, total conversion (C) of n-C_4 is achieved at around 380°C for the two catalysts containing the highest amounts of vanadium, and at temperatures above 400°C for those with lesser VP contents. For the four systems, there is a steep increase in activity between 250 and 350°C. In these runs, total oxidation of n-C_4 occurred, CO_2 being the sole reaction product. No maleic anhydride could be detected.

For the four catalysts, the relationship between ln C and $1/T$ does not yield a single straight line but, rather, two linear portions with different slopes. The corresponding activation energies calculated from Arrhenius' equation are 88 kJ/mol between 200 and 300°C, and 15 kJ/mol between 300 and 400°C, respectively. This last value is, of course, typical of a reaction limited by the diffusional process.

Influence of different metal species on the selectivity to maleic anhydride

The oxidizing power of VP/TiO_2 being too strong, it was necessary to temper it by adjoining another metal. This was done, as indicated above, by wet impregnations of VP/TiO_2 catalyst with the sulfates of different metals. The impregnations were carried out on the system containing 31.9% VP.

In a first series of preparations, the base catalyst was impregnated with $FeSO_4$ in order to deposit 2, 4, and 8 wt.% Fe^{2+}. The catalytic tests were performed under the same conditions as those in the preceding section.

Figure 5 compares the course of the conversion vs. reaction temperature obtained for the Fe^{2+}-loaded catalysts with

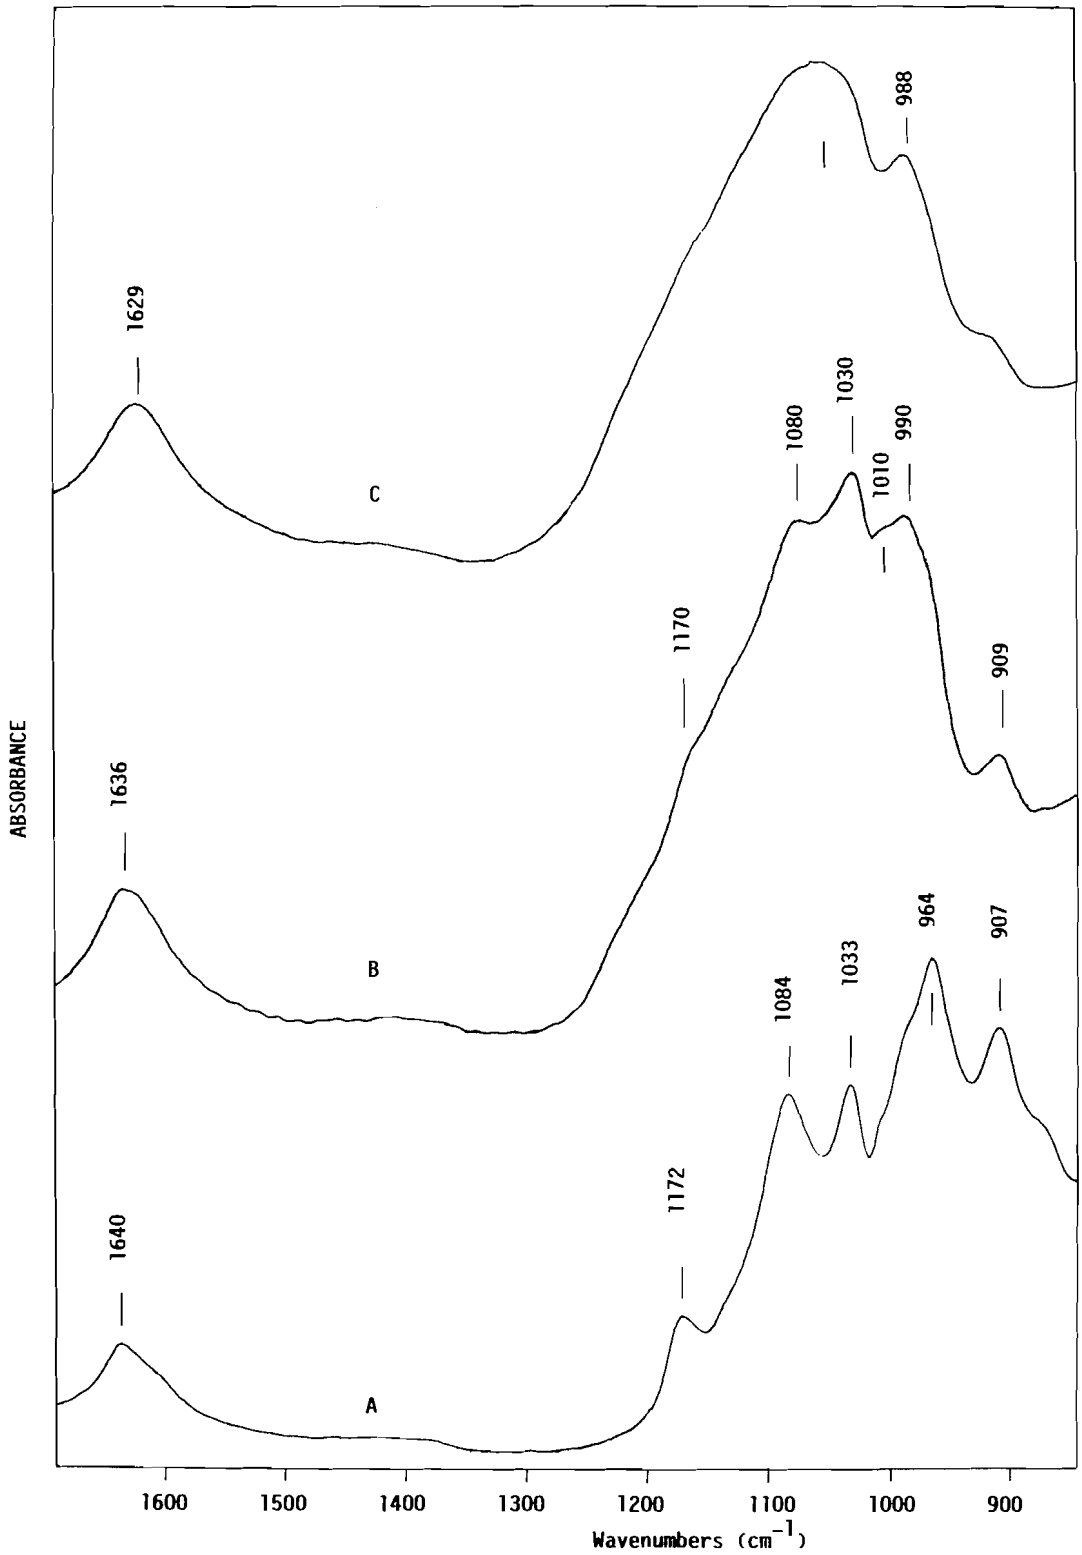

FIG 4. Infrared spectra of VP/TiO_2 (A); VP/TiO_2 impregnated with $FeSO_4$ (B), and the same as (B) with a P/V ratio of 1.2 (C).

that of the base VP/TiO_2 catalyst. Obviously, the addition of $FeSO_4$ lowers markedly the catalytic performance as compared with the reference catalyst. The catalysts containing 4 and 8% Fe^{2+} exhibit almost similar activities, slightly lower than that of the 2% Fe^{2+}-impregnated catalyst.

The effect of adding Fe^{2+} on the production of maleic anhydride is important. Whereas the base VP/TiO_2 produces only CO_2, upon addition of Fe^{2+} maleic anhydride is obtained, in addition to CO_2 as the main reaction product. In accordance with the IR and EPR results for the Fe^{2+}-impregnated catalysts, these systems have V(4+) and V(5+) centers. The selectivity to MA can be related to the pres-

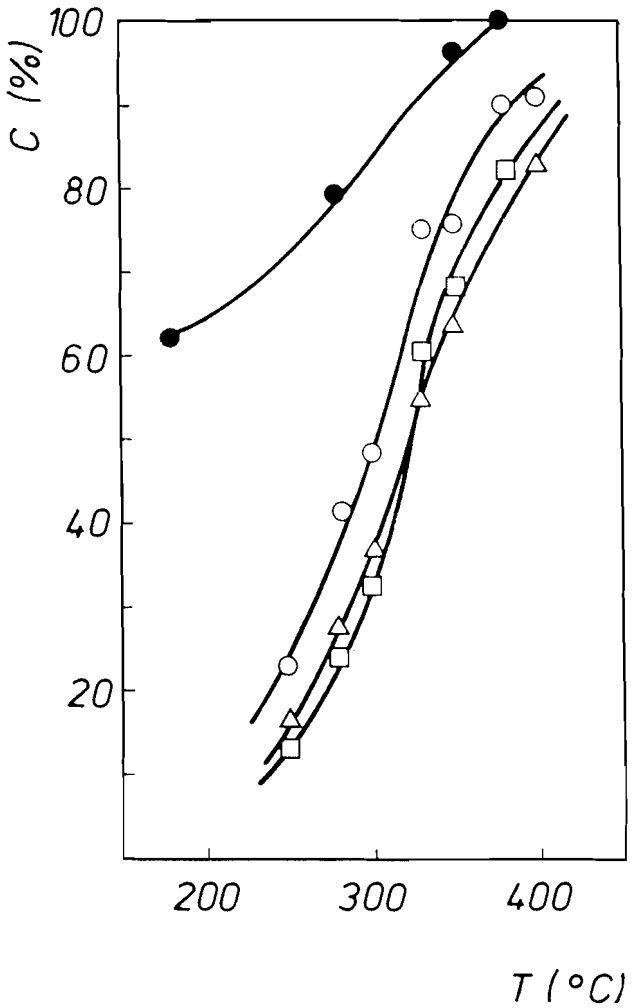

FIG. 5. Conversion of *n*-butane vs. temperature for: ● VP/TiO_2 (31.9% VP) and for the same catalyst impregnated with, respectively, 2% (○), 4% (△), and 8% (□) $FeSO_4$.

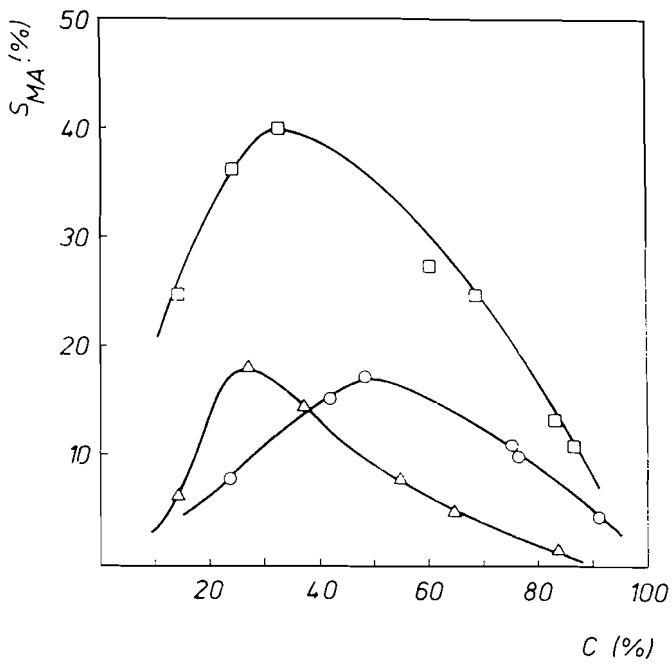

FIG. 6. Evolution of the selectivity to MA vs. conversion for the $FeSO_4$-impregnated VP/TiO_2: ○, □, △: 2, 4, and 8% Fe respectively.

ence of both oxidation states as has been established from EXAFS by other authors (20). A similar conclusion has been proposed by Batis *et al.* (21) with a catalyst based on $(VO)_2P_2O_7$ and V^{+5}, where high selectivity to MA was found when specific $VOPO_4$ phases (α_I, α_{II}, β, γ, etc) are simultaneously present with $(VO)_2P_2O_7$. Figure 6 compares, for the three iron-impregnated catalysts, the selectivities to MA as a function of the conversions obtained at the temperatures indicated in Fig. 5. At 50% conversion, the system containing 4% Fe^{2+} is twice as selective as the one with 2% Fe^{2+} and almost four times as selective as that for 8% Fe^{2+}. For the three catalysts, the maximum selectivity is attained at around 300°C.

In another series of preparations, VP/TiO_2 (31.9% VP) was impregnated with the sulfates of different metals in order to see the influence of the nature of the metal on the selectivity to MA. Except for Mo, which was introduced as ammonium molybdate, the sulfates were used in the amounts required to load the parent catalyst with 4% Me. This amount corresponds to a V/Me atomic ratio of 3.

Figure 7 compares the course of the conversion vs. temperature for the different systems investigated. Although the activity of these catalysts is lower than that of the metal-free catalyst, Co^{2+} and Mn^{2+} appear, among the different metals, to have the most effect on the activity, whereas the Mo^{6+}-impregnated system is the least active. The Co^{2+} and Mn^{2+}-modified catalysts transform approximately twice as much *n*-C_4 as the Mo^{+6}-loaded catalyst, at any temperature between 250 and 350°C. The Cr^{3+} system exhibits intermediate behaviour.

Considering the selectivities to maleic anhydride, for some of the conversion values obtained from Fig. 7 (Fig. 8), three systems are not very selective, namely those containing Mn^{2+}, Cr^{3+}, and Mo^{6+}. The other, the Co^{2+}-impregnated catalyst, appears with a higher selectivity to MA although slightly lower than those developed by the Fe^{2+}-impregnated catalyst. As observed for the system containing Fe^{2+}, the maximum selectivity is reached near 30% conversion, which occurs at around 280–300°C.

Influence of the P/V ratio on the selectivity to MA

The influence of the P/V ratio of unsupported VPO catalysts on the selectivity to MA is still debated. According to different authors (6, 7), the optimal ratio may vary significantly. It was interesting to consider this parameter in our systems, inasmuch as, as mentioned previously, TiO_2-supported VP catalysts are X-ray amorphous. VP/TiO_2 catalysts containing 4% Fe^{2+} were thus prepared with P/V ratios between 1 and 1.5, additional P being supplied by impregnation with the required amounts of phosphoric acid.

Figure 9 shows the evolution of the total conversion of *n*-C_4 as a function of reaction temperature. Obviously, P/V ratios higher than unity depress the catalytic activity as compared with the catalyst where P/V = 1. The catalyst with the highest P/V (1.5) is the least active.

Considering the selectivities to MA, on increasing the P/V ratio there is an influence on the production of MA at least for conversions that do not exceed 40%. This is in accordance with the suggestion of some authors (20) who report that an excess of phosphorus prevents the complete oxida-

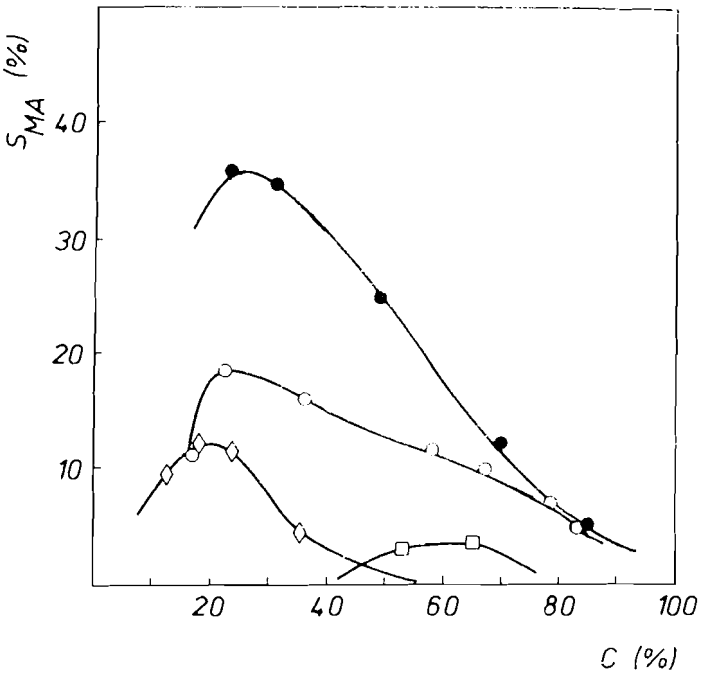

FIG. 8. Evolution of the selectivity to MA vs. conversion for the same catalysts as in Fig. 6: □ Mo^{6+}; ◇ Cr^{3+}; ○ Mn^{2+}; ● Co^{2+}.

tion of vanadium (V^{4+} to V^{5+}) by calcination in air. Beyond this value (40%), the effect is much less obvious (see Fig. 10). The system with P/V = 1.5 that is the least active is also the least selective and that with P/V = 1.2 is the most selective. At higher conversions, i.e., at higher temperatures, this effect vanishes. As for the other catalytic systems investigated, the maximum selectivity is obtained near 25% conversion.

Catalytic activity of unsupported crystalline α-$VOPO_4$

Oxidation tests of *n*-C_4 were performed, as well, under similar experimental conditions on bulk, well-crystallized α-$VOPO_4$ synthesized according to the method described in ref. 15.

These solids were found to be completely inactive in the temperature range investigated.

Catalytic activity of α-$VOPO_4/SiO_2$ systems

As shown previously, these systems always exhibit segregated crystalline α-$VOPO_4$ adjacent to silica whatever the VP content introduced in the preparation.

The catalytic runs carried out on these solids showed only partial conversion, which in no case was higher than 25% at 450°C. No maleic anhydride was produced.

VP/SiO_2 (21.8% VP) was then impregnated, first with $FeSO_4$ (4% Fe^{2+}) and subsequently with H_3PO_4, to realize a P/V ratio of 1.2, and tested. The conversion of *n*-C_4 increased slightly, to yield 30% at 450°C, 53% of the reaction product being maleic anhydride. The activity could be further improved when silica was precalcined at 700°C. Indeed, at 450°C, 55% of the hydrocarbon was converted, but lower selectivities to MA (11%) were obtained (with a maximum of 22% at 400°C).

These results agree with those found by Do *et al.* (22) for V_2O_5 supported on TiO_2 and Al_2O_3, where the TiO_2-supported catalyst was found to exhibit better selectivities for MA than the Al_2O_3-supported catalysts. Although the source of the support effect on the selectivity to MA of V_2O_5/P_2O_5 catalysts is not clear, Do *et al.* (23) related selectivity to MA to the presence of OH groups on the surface. Lopez Nieto *et al.* (24), in studies of the selective oxidation of propene on Al_2O_3, SiO_2, and TiO_2 (anatase)-supported V_2O_5 catalysts, found that V_2O_5/TiO_2 was the most active and selective phase because the V_2O_5 is highly dispersed on non-porous TiO_2, whereas for SiO_2 and Al_2O_3 part of the V_2O_5 species was deposited within the catalyst pores.

Discussion

The use of titania as support to VPO compounds makes difficult the comparison between the data in literature and the present results. Indeed, unsupported VPO catalysts used as starting materials are often, if not generally, well-defined crystalline phases. Nevertheless, as seen in this work, the presence of titania in the synthesis medium prevents the formation of a crystalline phase, up to VP contents near 21%. For this reason, this discussion will be restricted to the comparison of some of the main tendencies observed in this study with the results already published.

First of all, crystalline α-$VOPO_4$ is a much less active catalyst for the oxidation of *n*-butane (in the presence of SiO_2 as well as unsupported) than is its amorphous counterpart. This difference might possibly be only a surface effect, the fraction of the catalyst surface available to the reagents being

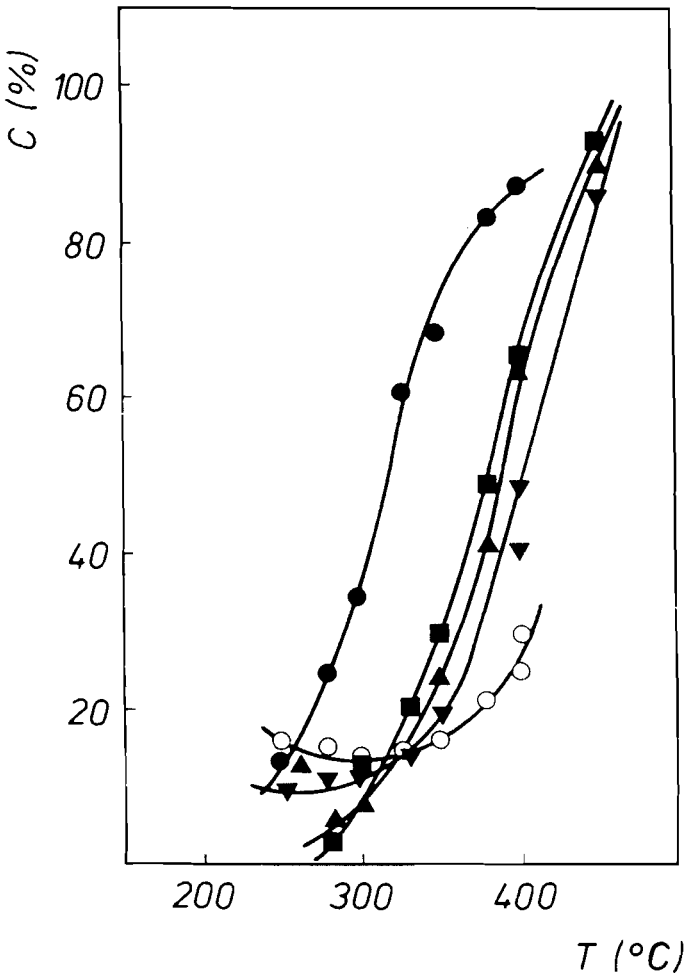

FIG. 9. Evolution of the conversion of *n*-butane vs. temperature for the Fe^{2+}-impregnated VP/TiO_2 with different P/V ratios: ●: 1.0; ■: 1.1; ▲: 1.2; ▼: 1.3; and ○: 1.5.

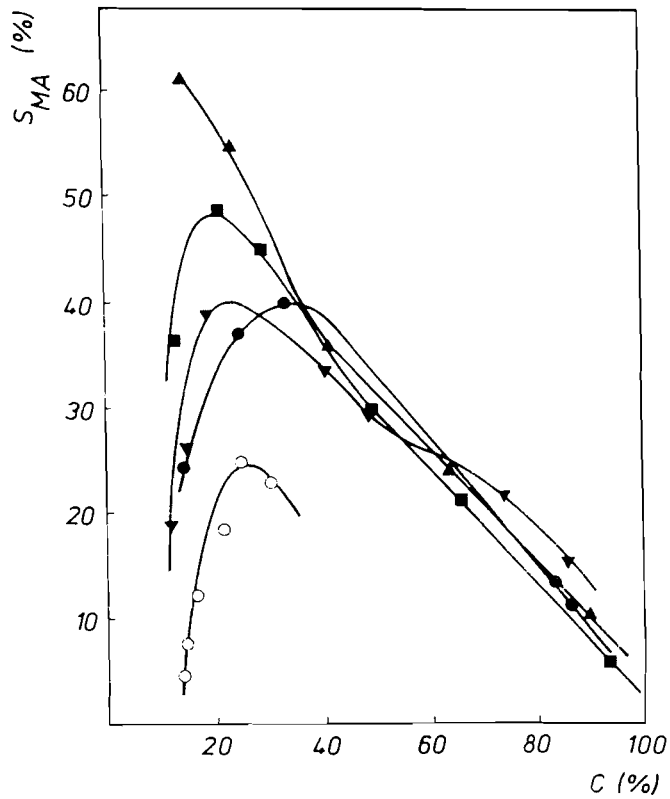

FIG. 10. Effect of the P/V ratio on the selectivity to MA (same symbols as in Fig. 9).

higher for the VP/TiO_2 systems. Nevertheless, independent of the crystalline or amorphous character of the VP phase, both systems yield only CO_2 as reaction product. These observations are consistent with the results reported by Bergeret *et al.* (4), Hodnett (8), and Védrine *et al.* (25), as well as the linear relationship between *n*-butane conversion and VP content (26). The results obtained with such catalytic systems are a clear illustration that it is not enough to reach high conversions if the oxidizing power of these catalysts is not under control in agreement with Cavani *et al.* (5).

In bulk VPO catalysts, the nature of the phase responsible for the formation of MA is not well identified. $(VO)_2P_2O_7$ has been advocated by Cavani *et al.* (27), Contractor *et al.* (3), and Védrine *et al.* (25), among other authors, as being the active phase, while no quantitative correlation between catalytic activity and selectivity and the content of vanadium pyrophosphate could be found by Van Geem *et al.* (6) and Hodnett *et al.* (7, 28). To other authors, it turns out rather that the best catalysts appear to be poorly crystallized or even amorphous VPO phases (25), while for Bordes and Courtine (29) and Morselli *et al.* (30) activity and selectivity are associated with the simultaneous presence of β-$VOPO_4$ and $(VO)_2P_2O_7$. Bergeret *et al.* (4) obtained the best results with a mixture of $(VO)_2P_2O_7$ and an amorphous phase produced upon activation. In this respect, our data show that completely amorphous supported VP with a P/V = 1 does not lead to MA. Maleic anhydride was formed only when the supported VP's were impregnated with a metal sulfate. The promotional effect of a series of elements on the selectivity to MA was investigated by Brutovsky and Gerej (31) and Brutovsky *et al.* (32) in the case of $(VO)_2P_2O_7$, the beneficial effect being in the following sequence: Mn > Co ≈ Sn > Fe > Cu > Li > Zn > Ce > Ni. Patent literature mentions catalysts containing promoters such as alkalis or alkaline earths (33) and Zn (34), which appear to prolong the life of the catalysts by diminishing the loss of phosphorus.

In our catalytic systems prepared by impregnation with metal sulfates, the improvement of the selectivity to MA was in the following order: $Fe^{2+} > Co^{2+} > Mn^{2+} > Cr^{3+} > Mo^{6+}$. It was established for the Fe^{2+}-impregnated VP/TiO_2 that the best selectivities to MA were obtained when the V/Fe atomic ratio was 3. If this sequence is different from the one previously reported, the catalysts are also not similar. These different elements do not simply improve the yield of MA, but in their absence no MA is formed. Their effect is merely to buffer the oxidizing power of VP. Since data on the oxidation state of V and on a possible change in that of the co-metal are not yet available, the way these catalytic systems act and favor the formation of MA cannot be discussed in more detail, although, as has been seen in the IR and EPR discussion of the Fe^{2+}-impregnated system, the higher value for selectivity may be related to the presence in the VP of V^{4+}/V^{5+} ions.

The influence of the P/V ratio on the reaction of *n*-butane has also been extensively investigated. If there seems to be a general consensus (from literature) that excess P with respect to a P/V ratio of 1 improves the selectivity to MA

with a parallel decrease in activity (35), the results reported by some authors are, at the very least, somewhat confusing. For instance, Van Geem and Nobel (6) observe a decrease in activity as the P/V ratio increases but with a maximum selectivity for P/V ratios between 0.58 and 1.06. These authors conclude, however, that selectivity to MA is only determined by the degree of conversion of the hydrocarbon. Nevertheless, it has been shown that low P/V ratios favor VPO phases (β-$VOPO_4$) with a vanadium oxidation number close to 5+, whereas higher P/V ratios stabilize vanadium as V^{4+}, in β or B phases (3), or $(VO)_2P_2O_7$ (5, 7, 14, 28, 29, 36, 37) yielding higher selectivities to MA. The influence of the P/V ratio on the selectivities to MA obtained for the $Fe/VP/TiO_2$ with a maximum at a value of 1.2 is hence consistent with the results of others. Further investigation is needed to characterize the oxidation state of vanadium in those systems, with particular attention to the effect of adding a co-metal on the oxidation state of vanadium, and to its distribution on the solid surface.

Reçu le 18 avril 1991

ABDESSELAM ABOUELFIDA, JEAN PAUL PRADERE, MICHEL JUBAULT et ANDRÉ TALLEC. Can J. Chem. **70**, 14 (1992).

La réduction électrochimique à potentiel contrôlé, sur cathode de mercure et en milieu protique, des 2-éthoxy- et 2-phényl-4*H*-1,3-thiazines diversement substitutées en position 4 conduit aux 6*H*-1,3-thiazines et (ou) aux pyrroles substitués. La sélectivité observée dépend du pH du milieu et de la nature de la substitution : l'orientation de la réduction vers la formation de pyrroles est favorisée en milieu acide (H_2SO_4 à 0,5 mol L^{-1}) et par la présence d'un substituant phényle en position 2 et alkoxycarbonyle en position 4. L'orientation vers la formation de 6*H*-1,3-thiazines et leurs produits de réduction (thiobenzamides, carbamates et 2-thiazolines substitués) est favorisée par l'utilisation d'un milieu faiblement acide (tampon acétique) ou basique (tampon ammoniacal).

Mots clés : réductions electrochimiques, 4*H*- et 6*H*-1,3-thiazines, pyrroles, 2-thiazoline, régression cyclique.

ABDESSELAM ABOUELFIDA, JEAN PAUL PRADÈRE, MICHEL JUBAULT, and ANDRÉ TALLEC. Can. J. Chem. **70**, 14 (1992).

Controlled potential electroreduction (protic medium, mercury cathode) of substituted 2-ethoxy and 2-phenyl-4*H*-1,3-thiazines leads to 6*H*-1,3-thiazines and (or) pyrroles. The nature of the isolated products appears strongly dependent on pH of the medium and type of substitution: pyrrole formation takes place in acidic medium (0.5 mol L^{-1} H_2SO_4) and is favoured by phenyl and alkoxycarbonyl groups at positions 2 and 4, respectively; formation of 6*H*-1,3-thiazines and their reduction products (substituted thiobenzamides, carbamates and 2-thiazoline) occurs in weakly acidic (acetate buffer) or basic (ammoniacal buffer) medium.

Key words: electrochemical reductions, substituted 4*H*- and 6*H*-1,3-thiazines, pyrroles, 2-thiazoline, cyclic regression.

Introduction

L'intérêt d'utiliser les 6*H*-1,3-thiazines comme intermédiaires réactionnels ou comme précurseurs de céphèmes a été mentionné de nombreuses fois ces dernières années (1–6). Cependant, peu de méthodes permettent d'accéder directement aux dérivés 6*H*-1,3-thiaziniques polyfonctionnalisés **A**. En effet, l'introduction de groupements fonctionnels est généralement réalisée par cycloaddition 4+2 en utilisant des méthodes d'activation : catalyse acide (2, 3) ou hautes pressions (7). Nous avons envisagé d'accéder aux composés **A** par réduction de 4*H*-1,3-thiazines substituées **B** dont le mode de préparation a été précédemment décrit (8). La réduction chimique des 4,5,6-alkoxycarbonyl-4*H*-1,3-thiazines **B** (**1***c* et **2***c*) par l'aluminium amalgamé, utilisé dans le cas des dérivés 1,3-thiaziniques (9, 10), ne permet pas d'isoler les 6*H*-1,3-thiazines correspondantes **A**; l'hydrogénation conduit aux thiobenzamide ($R^2 = C_6H_5$) et carbamate ($R^2 = C_2H_5O$) substitués **C** résultant de l'hydrogénolyse du cycle thiazinique intermédiairement formé.[2] La diversité des composés obtenus par réduction chimique nous a conduit à mettre en oeuvre une méthode a priori plus sélective : la réduction électrochimique à potentiel contrôlé, appliquée précédemment au cas des 6*H*-1,3-thiazines (11, 12). Ce mémoire concerne l'extension de cette méthode aux 4*H*-1,3-thiazines substituées **B** (**1***a*–**1***c* et **2***a*–**2***c*), pour lesquelles une sélectivité satisfaisante a été observée lors des premiers essais d'électroréduction (8). Nous décrirons d'abord le comportement polarographique des composés étudiés puis nous exposerons successivement les résultats obtenus par réduction des 2-éthoxy-4*H*-1,3-thiazines **1***a*–**1***c* et des 2-phényl-4*H*-1,3-thiazines **2***a*–**2***c* substituées.

Résultats

Les résultats des études polarographiques effectuées sur les 4*H*-1,3-thiazines substituées **1** et **2**, rassemblés dans le tableau 1, permettent d'effectuer les remarques suivantes :

Les 2-éthoxyl-4*H*-1,3-thiazines **1***a*–**1***c* présentent une première vague de réduction à 4 électrons en milieu très acide alors que cette vague correspond à un transfert biélectronique dans les autres milieux envisagés.

Les 2-phényl-4*H*-1,3-thiazines **2***a*–**2***c* présentent une première vague à 4 électrons, quelle que soit l'acidité du milieu.

La réduction globale des composés étudiés correspond généralement à 4 électrons; l'exception concerne les substrats **1***c* et **2***c* (R = $CO_2C_2H_5$) pour lesquels la réduction globale est à 6 électrons.

*Comportement électrochimique des 2-éthoxy-4*H*-1,3-thiazines substituées* ***1***

*(i) 2-Éthoxy-4*H*-1,3-thiazine* **1**a *(R = H)*

Les électrolyses préparatives ont été réalisées à la température de la glace fondante, compte-tenu de la stabilité limitée de ce composé en milieu protique. En milieu tampon ammoniacal, la réduction effectuée au palier de la première vague polarographique (potentiel de travail E_T = −1,1 V ECS, figure 1, courbe 3) fournit uniquement la 6*H*-1,3-thiazine **3***a* (Rdt = 90%). Dans cette réaction la réduction de la double liaison diactivée C5=C6 est suivie de l'élimination de diméthylamine (mécanisme EC). L'électrolyse, réalisée directement à potentiel très négatif (E_T = −1,6 V ECS) consomme 4 moles d'électron et permet d'isoler le thiocarbamate insaturé **7***a* (Rdt = 60%) (schéma 1). En milieu tampon acétique, les deux vagues successives sont trop peu séparées pour que l'on puisse obtenir une réduction sélective (cf. figure 1, courbe 2). L'électrolyse réalisée au palier de la seconde vague fournit comme précédemment le composé **7***a* (Rdt = 90%). Nous avons verifié que la réduction à −1,1 V ECS de la 6*H*-1,3-thiazine **3***a*, obtenue en tampon ammoniacal,conduit quantitativement au produit d'hydrogénolyse **7***a*. En milieu acide sulfurique, l'électrolyse effectuée à −0,75 V ECS, correspondant au palier de la vague de réduction à 4 électrons (figure 1, courbe 1), conduit à un mélange de carbamate **7***a* (Rdt = 20%) et de pyrrole **5***a* (Rdt = 40%) (schéma 1). Le composé **5***a* résulte d'une contraction du cycle thiazinique avec élimination de sulfure d'hydrogène. En effet, nous avons vérifié que ce pyrrole ne provient, ni de l'évolution du carbamate **7***a* retrouvé inchangé après un séjour de 24 h dans le milieu d'électrolyse, ni de la régression de la 4*H*-1,3-thiazine précurseur **1***a* en milieu acide (13). Par ailleurs, il ne semble pas que la 6*H*-1,3-thiazine **3***a* soit un intermédiaire de la transformation de **1***a* en **5***a* car nous avons constaté que le composé **3***a* est instable en milieu acide sulfurique dans les conditions de la réduction.

*(ii) 2-Éthoxy-4-méthyl-4*H*-1,3-thiazine* **1**b *(R = CH_3)*

Les électrolyses n'ont pu être réalisées qu'en milieu tampon ammoniacal compte-tenu de l'instabilité de ce substrat en milieu acide. À potentiel peu négatif (E_T = −1,1 V ECS), au palier de la première vague, la réduction de **1***b* fournit la 6*H*-1,3-thiazine **3***b* (Rdt = 83%); un polarogramme, enregistré en fin d'électrolyse, montre que la seconde vague de réduction du composé **1***b* est conservée. À potentiel directement très négatif (E_T = −1,4 V ECS), on isole le carbamate **7***b* (Rdt = 44%) (schéma 1).

*(iii) 2-Éthoxy-4-éthoxycarbonyl-4*H*-1,3-thiazine* **1**c *(R = $CO_2C_2H_5$)*

En milieu tampon ammoniacal, les trois vagues observées (figure 2, courbe 3) ne sont pas suffisamment séparées pour obtenir des réductions sélectives. L'électrolyse, réalisée directement à potentiel très négatif (E_T = −1,2 V ECS), consomme entre 5 et 6 moles d'électron et fournit un mélange de 2-éthoxypyrrole substitué **5***c* (Rdt = 50%) et de carbamates diastéréoisomères **9***c* et **9***c'* (Rdt = 38%).

En milieu tampon acétique, la séparation des vagues est encore insuffisante pour atteindre la sélectivité (figure 2, courbe 2) : À E_T = −0,75 V ECS (potentiel correspondant au potentiel de demi-vague), la réduction est très lente. Au bout de 48 h, le résultat coulométrique est de 2,2 moles

SCHÉMA 1. Réduction électrochimique des 2-éthoxy-4*H*-1,3-thiazines **1***a*–**1***c*.

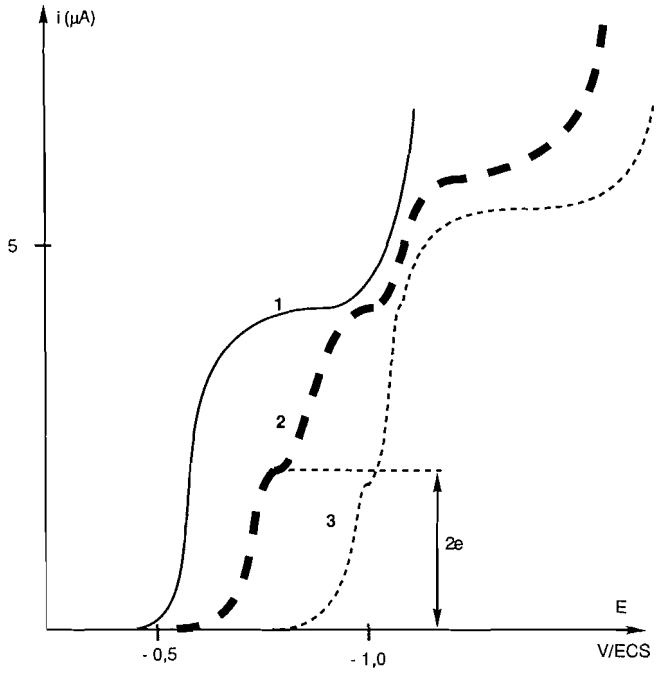

FIG. 2. Polarogrammes de **1***c* (solution à 10^{-3} mol L^{-1}); courbe **1** : H_2SO_4 à 0,5 mol L^{-1} + éthanol (1 : 1); courbe **2** : tampon acétique + éthanol (1 : 1); courbe **3** : tampon ammoniacal + éthanol (1 : 1).

d'électron alors qu'il reste 20% du substrat **1***c* non réduit; le traitement de la solution permet d'isoler la 6*H*-1,3-thiazine **3***c* (Rdt = 45%) et le pyrrole **5***c* (Rdt = 15%) (schéma 1). À E_T = −1,0 V ECS, les deux premières vagues de **1***c* ont disparu après passage de 3,8 moles d'électron; en outre, il apparaît une vague de réduction biélectronique dont le potentiel de demi-vague ($E_{1/2}$ = −1,22 V ECS) est différent de celui de la troisième vague de **1***c* ($E_{1/2}$ = −1,12 V ECS). Le traitement de la solution fournit un mélange de 6*H*-1,3-thiazine **3***c* (Rdt = 11%), de pyrrole **5***c* (Rdt = 18%) et de carbamate insaturé **7***c* (Rdt = 52%) auquel on peut attribuer la nouvelle vague de réduction.[3] Enfin, à E_T = −1,35 V ECS la réduction consomme 6 moles d'électron et conduit directement au mélange des carbamates diastéréoisomères **9***c* et **9***c'* (Rdt = 80%) (schéma 1).

En milieu acide sulfurique, la réduction effectuée au palier de la vague unique (E_T = −0,8 V ECS, figure 2, courbe 1) permet d'isoler un mélange de pyrrole **5***c* (Rdt = 46%) et de carbamates **9***c*, **9***c'* (Rdt = 40%); la formation de ces derniers apparaît surprenante puisque la vague polarographique correspond au transfert de 4 électrons. Par ailleurs, la réduction, dans ce milieu, de la 6*H*-1,3-thiazine **3***c* conduit uniquement au dérivé insaturé **7***c*; on peut en déduire que les composés **3***c* et **7***c* ne sont pas des intermédiaires formés lors de la réduction de la 6*H*-1,3-thiazine **1***c* en carbamates **9**. Cette observation permet de supposer que l'élimination de la diméthylamine à partir des composés de réduction est relativement lente en milieu acide sulfurique.

*Comportement électrochimique des 2-phényl-4*H*-1,3-thiazines substituées* **2**

*(i) 2-Phényl-4*H*-1,3-thiazine* **2**a *(R = H)*

Rappelons que le polarogramme présente, quel que soit le milieu, une vague de réduction unique à 4 électrons (figure 3). En tampon ammoniacal (E_T = −1,0 V ECS), la réduction fournit sélectivement le thiobenzamide insaturé **8***a* (Rdt = 89%) (schéma 2). En tampon acétique (E_T = −0,85 V ECS) on obtient un mélange de thiobenzamide **8***a* (Rdt = 55%) et de pyrrole **6***a* (Rdt = 35%). En milieu acide sulfurique (E_T = −0,7 V ECS) on isole le pyrrole **6***a* avec un excellent rendement (88%). La formation du composé **8***a* (Rdt = 7%) apparaît dans ce cas très minoritaire. On peut observer que dans ces réactions la 2-phényl-4*H*-1,3-thiazine **4***a*, vraisemblablement précurseur du composé **8***a*, n'est jamais isolée contrairement à ses homologues issus de la réduction des 2-éthoxy-4*H*-1,3-thiazines étudiées précédemment. Par ailleurs, le changement d'acidité du milieu d'électrolyse permet d'orienter la réduction, de façon quasi-sélective, soit vers la formation du thiobenzamide **8***a* (milieu basique) soit vers celle du pyrrole **6***a* (milieu très acide).

*(ii) 4-Méthyl-2-phényl-4*H*-1,3-thiazine* **2**b

Les électrolyses du composé **2***b* n'ont été réalisées que dans les deux milieux de pH extrême compte-tenu des résultats obtenus pour la 4*H*-1,3-thiazine précédente **2***a*. En tampon

[3]L'électroactivité du carbamate **7***c* est liée à l'activation de la double liaison par les deux groupements alcoxycarbonyles par comparaison aux carbamates **7***a* et **7***b*. L'obtention de diastéréoisomères dépendant de l'acidité du milieu a déja été observée lors de la réduction de diesters éthyléniques (14).

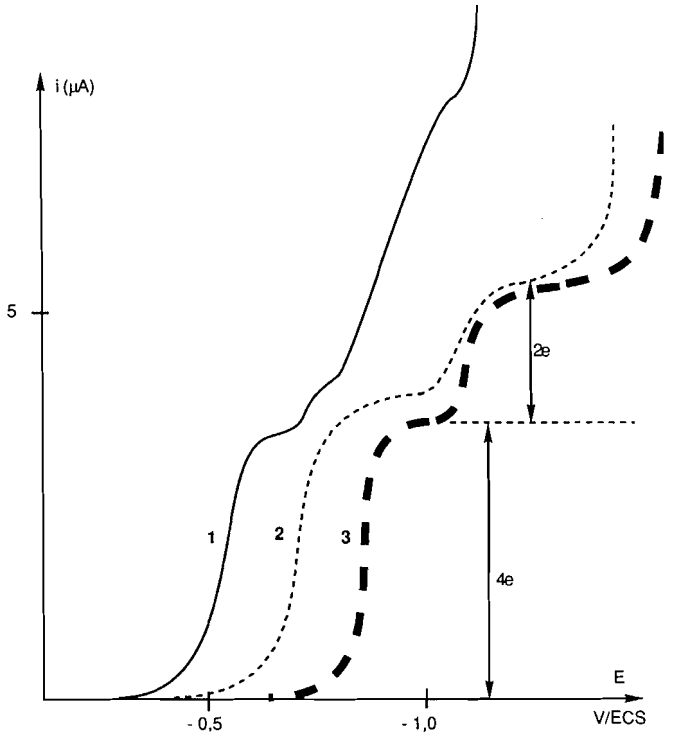

FIG. 3. Polarogrammes de **2***c* (solution à 10^{-3} mol L^{-1}); courbe **1** : H_2SO_4 à 0,5 mol L^{-1} + éthanol (1 : 1); courbe **2** : tampon acétique + éthanol (1 : 1); courbe **3** : tampon ammoniacal + éthanol (1 : 1).

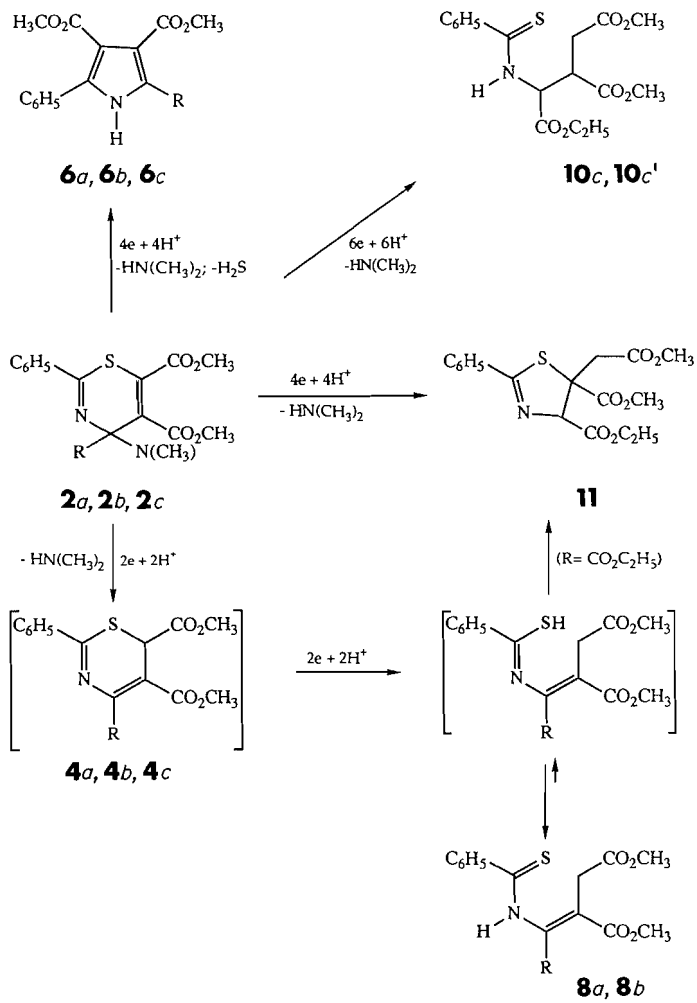

SCHÉMA 2. Réduction électrochimique des 2-phényl-4*H*-1,3-thiazines **2***a*–**2***c*.

ammoniacal (E_T = −1,1 V ECS), le résultat coulométrique est déficitaire par rapport aux 4 moles d'électron attendues. On isole, avec des rendements limités, le pyrrole **6***b* (Rdt = 18%) et le thiobenzamide *N*-substitué **8***b* (Rdt = 42%). En milieu acide sulfurique (E_T = −0,7 V ECS), la réduction n'est pas sélective, mais conduit majoritairement au pyrrole **6***b* (Rdt = 55%). La formation de celui-ci s'accompagne de celle du composé **8***b* (Rdt = 33%) (schéma 2).

*(iii) 4-Éthoxycarbonyl-2-phényl-4*H*-1,3-thiazine* **2***c*

Pour ce composé **2***c*, rappelons que la première vague à 4 électrons est suivie, à potentiel plus cathodique, d'une vague de réduction biélectronique (figure 3, courbes 2 et 3). En tampon ammoniacal, au potentiel de la première vague (E_T = −0,9 V ECS, figure 3, courbe 3) la réduction conduit à un mélange de pyrrole **6***c* (Rdt = 30%) et de 2-thiazoline **11** (Rdt = 52%). La formation de cette 2-thiazoline résulte probablement de la cyclisation intramoléculaire du thioamide insaturé **8***c*, issu lui-même de l'hydrogénolyse de la 6*H*-1,3-thiazine **4***c*, intermédiairement formée. En fin d'électrolyse, on observe, en polarographie, la présence d'une vague biélectronique ($E_{1/2}$ = −1,2 V ECS) que nous avons pu attribuer, par comparaison, à la réduction de l'hétérocycle **11**. Au potentiel de la seconde vague (E_T = −1,3 V ECS), l'électrolyse permet d'isoler minoritairement le pyrrole **6***c* (15%) et majoritairement les thiobenzamides diastéréoisomères **10***c* (Rdt = 32%) et **10***c'* (Rdt = 41%) (schéma 2). Ceux-ci peuvent résulter soit de la réduction du composé insaturé **8***c* dont la double liaison diactivée est électroactive au potentiel utilisé, soit de l'hydrogénolyse de la 2-thiazoline **11** intermédiairement formée.

En milieu tampon acétique, on obtient des résultats comparables. On isole soit le mélange de pyrrole **6***c* et de 2-thiazoline **11** à potentiel peu négatif (E_T = −1,0 V ECS, figure 3, courbe 2), soit le mélange de pyrrole **6***c* (Rdt = 30%) et de thiobenzamides diastéréoisomères **10***c* (Rdt = 30%) et **10***c'* (Rdt = 27%) au potentiel E_T = −1,3 V ECS). En milieu acide sulfurique la réduction de la 4*H*-1,3-thiazine **2***c* effectuée au potentiel E_T = −0,75 V ECS (figure 3, courbe 1) conduit à la formation du pyrrole **6***c* (Rdt = 76%) (schéma 2). Par comparaison au cas du substrat **2***a*, on remarquera que l'utilisation d'un milieu très acide oriente de la même façon la réduction vers la formation de dérivés pyrroliques.

Discussion

Les réductions, effectuées au potentiel de la première vague polarographique, conduisent soit à des 6*H*-1,3-thiazines ou à des produits issus de l'hydrogénolyse de ces dernières, soit à des pyrroles résultant d'une régression cyclique.

(*i*) La formation de 6*H*-1,3-thiazines implique une hydrogénation de la double liaison C5=C6, diactivée par les deux groupements alcoxycarbonyles, suivie d'une élimination de diméthylamine au niveau de la dihydrothiazine intermédiairement formée. La réduction peut s'arrêter à ce stade pour R^2 = C_2H_5O. Les 6*H*-1,3-thiazines obtenues (com-

posés **3**) sont réductibles avec hydrogénolyse de la liaison S—C6. L'affaiblissement de cette liaison serait lié à la présence d'un substituant électroattracteur en position 6. Ce comportement apparaît tout à fait différent de celui des 6*H*-1,3-thiazines monoactivées (R^5 attracteur : la réduction biélectronique porte sur la liaison imine) et diactivées (R^4 et R^5 attracteurs : la dihydrogénation concerne la double liaison C4=C5) précédemment étudiées (11). Il faut noter que toute modification de la substitution sur le cycle thiazinique entraîne un changement du site de réduction. Dans cette étude, les 6*H*-1,3-thiazines ne sont pas isolables pour R^2 = C_6H_5 (composés **4**). Leur réduction, qui s'accompagne de l'hydrogénolyse de la liaison S—C6, s'effectue au même potentiel que la réduction des 4*H*-1,3-thiazines précurseurs. Le groupement phényle, par rapport au groupement éthoxy en position 2, exerce probablement un effet attracteur qui rend plus fragile la liaison S—C6. La réduction s'arrête à la formation des carbamates **7** ou thiobenzamides **8** insaturés lorsque R = H ou CH_3. Par contre, pour R = $CO_2C_2H_5$, l'électroréduction conduit selon la nature du substituant en position 2, soit aux carbamates **9***c*, **9***c*′ ou thiobenzamides **10***c*, **10***c*′ saturés, soit à la 2-thiazoline **11** par une cyclisation intramoléculaire analogue à celle observée lors de la régression cyclique de la 4-éthoxycarbonyl-2-phényl-6*H*-1,3-thiazine-6-one (15).

(*ii*) L'obtention par électroréduction de pyrroles substitués (composés **5** et **6**) semble liée à l'existence d'une première vague de réduction à 4 électrons; par ailleurs, elle est favorisée par l'utilisation d'un milieu très acide, la présence d'un groupement phényle en position 2 et d'un substituant attracteur éthoxycarbonyle en position 4. Deux hypothèses ont été envisagées pour expliquer la formation de ces pyrroles. En effet, ces composés pourraient provenir de la réduction des 6*H*-1,3-thiazines (**3** ou **4**); cette hypothèse ne paraît pas devoir être retenue puisque, d'une part, ces hétérocycles n'ont pas été isolés lorsque R^2 = C_6H_5, d'autre part, ils apparaissent soit instables (composé **3***a*) soit réductibles en milieu acide (composé **3***c*), dans le cas de R^2 = C_2H_5O. Plus vraisemblablement, le cycle pyrrolique résulte de la réduction de la forme protonée de l'imine (schéma 3); un premier transfert biélectronique conduirait à un thiirane, lui-même réductible à 2 électrons avec élimination de sulfure d'hydrogène et de diméthylamine. Les effets de la substitution interviendraient d'une part sur la basicité de l'azote du cycle, d'autre part, sur le caractère électrophile du carbone en position 6. Ce mécanisme de régression cyclique est à rapprocher de celui mentionné pour expliquer la formation de pyrroles par réduction de 6*H*-1,3-thiazines-6-ones comportant un substituant électroattracteur en position 4 (16, 17).

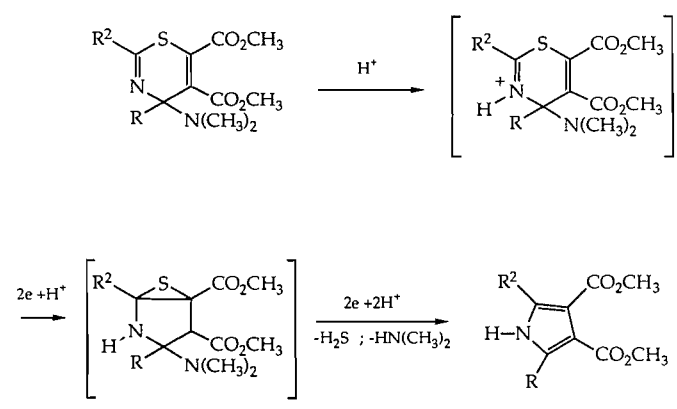

SCHÉMA 3. Mécanisme de formation de pyrroles en milieu acide.

(*iii*) L'obtention par voie chimique de pyrroles substitués peut être réalisée à partir des 6*H*-1,3-thiazines issues des électroréductions. Ainsi la transformation de **3***c* en **5***c* peut être effectuée avec 87% de rendement en traitant la 4-éthoxycarbonyl-6*H*-1,3-thiazine **3***c* par la triéthylamine (8). Le mécanisme de cette réaction est à rapprocher de ceux précédemment mentionnés pour la régression cyclique de 6*H*-1,3-thiazines en milieu fortement basique (18, 19). Dans notre cas, la présence d'un groupement alcoxycarbonylé en position 4 sur les dérivés thiaziniques permet d'effectuer la régression cyclique dans des conditions plus douces (20).

Conclusion

La réduction électrochimique à potentiel contrôlé, sur cathode de mercure et en milieu protique, des 4*H*-1,3-thiazines substituées permet d'accéder aux pyrroles et (ou) aux 6*H*-1,3-thiazines substituées ainsi qu'à leurs produits d'hydrogénolyse. La formation sélective de pyrroles peut être réalisée, soit directement par voie électrochimique, soit indirectement par traitement basique de 6*H*-1,3-thiazines préparées par électroréduction. La régression cyclique apparaît alors comme une méthode de choix pour accéder aux pyrroles substitués, si l'on se réfère à la diversité des dérivés thiaziniques fonctionnalisés mentionnés dans la littérature (2).

Partie expérimentale

Les spectres de RMN ^1H et ^{13}C ont été enregistrés au moyen d'un spectromètre Jeol JNM FX90 respectivement à 90 MHz et 20 115 MHz. Les déplacements chimiques δ sont exprimés en ppm/TMS et les constantes de couplage *J* en hertz. Les spectres ont été obtenus à partir de solutions dans $CDCl_3$. Un spectrophotomètre à transformée de Fourier Bruker IFS 85 est utilisé pour les déterminations infrarouges; les fréquences de vibration caractéristiques sont exprimées en cm^{-1}. Les spectres de masse sont enregistrés à l'aide d'un appareil Varian MAT 112 (énergie de faisceau électronique : 70 eV; intensité dans le filament : 1,5 mA). Les produits réactionnels ont été purifiés par chromatographie sur gel de silice (Merck Kieselgel 60, 70–230 ASTM). Les points de fusion ont été déterminés à l'aide d'un microscope RCH (C. Reichert) à platine chauffante Kofler. Les analyses centésimales ont été effectuées par les services de microanalyse du C.N.R.S. de Vernaison (France).

Réduction par l'aluminium amalgamé (Al/Hg)

L'aluminium amalgamé est préparé en traitant l'aluminium finement divisé (6–25 mmol) par une solution aqueuse contenant 5% de chlorure mercurique. Après quelques minutes, l'amalgame formé est lavé successivement par de l'eau (2 × 20 cm^3) et de l'éthanol (20 cm^3) puis recouvert par une solution éthanolique (20 cm^3) de 4*H*-1,3-thiazine (1 mmol). L'agitation magnétique est maintenue 1 h à température ambiante. L'hydroxyde d'aluminium formé est éliminé par filtration puis lavé par 20 cm^3 d'éthanol. Le filtrat est concentré et chromatographié sur gel de silice.

Polarographie

Les polarogrammes des composés **1***a*–**1***c* et **2***a*–**2***c* (tableau 1 et figures 1–3) ont été enregistrés à l'aide d'un polarographe Tacussel PRG3. Les solutions polarographiques sont constituées d'un mélange, volume à volume, d'une solution d'électrolyte-support et d'une solution à 2 × 10^{-3} mol L^{-1} du composé dans l'éthanol. Les trois solutions d'électrolyte-support utilisées ont la composition suivante : milieu acide, H_2SO_4 à 0,5 mol L^{-1}; milieu faiblement acide, tampon acétique (CH_3CO_2H à 0,5 mol L^{-1} + CH_3CO_2Na à 0,5 mol L^{-1}); milieu faiblement basique, tampon ammoniacal (NH_4Cl à 0,5 mol L^{-1} + NH_3 à 0,5 mol L^{-1}).

Électroréductions préparatives

Elles ont toutes été réalisées, à potentiel controlé, sur cathode de mercure, dans la cellule d'électrolyse à épuisement précédemment décrite (21). Le potentiel de la cathode est maintenu constant à l'aide d'un potentiostat Tacussel PRT et la quantité d'électricité consommée est mesurée à l'aide d'un coulomètre IG5. Le déroulement d'une expérience-type d'électroréduction est le suivant : On introduit, dans la cellule d'électrolyse éventuellement refroidie à 2°C, 130 cm^3 d'un mélange électrolyte-support + éthanol (identique à celui utilisé en polarographie). Après désaération à l'aide d'azote et préélectrolyse de la solution, le composé électroactif ($(1–2) \times 10^{-3}$ mol), dissous dans 20 cm^3 d'éthanol, est ajouté dans la cellule. L'électrolyse est alors effectuée sous courant continu d'azote. Des polarogrammes, enregistés sur des prélèvements de la solution d'électrolyse effectués en cours de réduction, permettent de contrôler l'avancement de la réaction et de détecter la formation éventuelle d'intermédiaires ou de produits d'évolution électroactifs. Après électrolyse complète, le mercure est décanté puis l'éthanol est évaporé sous vide partiel et la solution aqueuse neutralisée par du bicarbonate de sodium. Après extraction au dichlorométhane, la solution organique est séchée sur sulfate de magnésium puis concentrée. Le mélange réactionnel est ensuite chromatographié sur gel de silice (éluant : hexane/éther diéthylique). Les résultats des électroréductions préparatives sont rassemblés dans le tableau 2.

4H-1,3-Thiazines substituées **1**a–c *et* **2**a–c

L'acétylène dicarboxylate de méthyle (5 mmol) est additionné, à température ambiante, à une solution de 3-aza-4-diméthylamino-1-thiabutadiène substitué (5 mmol) (22) dans 20 cm^3 de dichlorométhane. L'évolution de la réaction est suivie par chromatographie sur couche mince jusqu'à disparition de l'hétérodiène correspondant. Après évaporation du solvant, le mélange réactionnel est chromatographié sur gel de silice. (Elution : éther de pétrole/acétate d'éthyle 50 : 50.) Les 4*H*-1,3-thiazines purifiées sont cristallisées dans l'éther diéthylique. Les constantes physiques et les analyses spectroscopiques sont en accord avec les données de la littérature (8).

On the role of the parent cation in the dynamics of formation of laser-induced hydrated electrons

ERNÖ KESZEI[1] AND JEAN-PAUL JAY-GERIN

Groupe du Conseil de recherches médicales du Canada en sciences des radiations, Département de médecine nucléaire et de radiobiologie, Faculté de médecine, Université de Sherbrooke, Sherbrooke (Québec), Canada J1H 5N4

Received June 5, 1991

ERNÖ KESZEI and JEAN-PAUL JAY-GERIN. Can. J. Chem. **70**, 21 (1992).

A short account is given of the continuum and molecular descriptions of the formation of hydrated electrons. Starting with a scheme of hydration dynamics of laser-induced electrons that accounts for the formation of hydrated electrons without invoking the "direct" ionization of water, a new model explaining the dynamics of electron hydration in terms of a molecular description is proposed. According to this model, the parent cation plays an active role in the trapping of electrons, deepening electron traps that preexist in the liquid before excitation. Consequences of this description to the transient absorption spectra are briefly discussed.

Key words: laser-induced electron – cation pairs, hydrated electron formation, liquid water.

ERNÖ KESZEI et JEAN-PAUL JAY-GERIN. Can J. Chem. **70**, 21 (1992).

On présente un court rapport sur les descriptions continue et moléculaire de la formation des électrons hydratés. Utilisant comme point de départ un schéma de la dynamique d'hydratation d'électrons induits par un laser qui tient compte de la formation d'électrons hydratés sans impliquer l'ionisation «directe» de l'eau, on propose un nouveau modèle qui explique la dynamique de l'hydratation des électrons en fonction d'une description moléculaire. D'après ce modèle, le cation parent joue un rôle actif dans le piégeage des électrons en abaissant les pièges d'électrons qui existent déjà dans le liquide avant l'excitation. On discute brièvement des conséquences de cette description sur les spectres d'absorption des espèces transitoires.

Mots clés : photolyse laser femtoseconde, piégeage et hydratation de l'électron, eau liquide.

[Traduit par la rédaction]

Since the discovery and identification of the hydrated electron (1–3), many models have been proposed for the structure of this species as well as for the mechanism and dynamics of its formation. Recent experimental results (4–11) using ultrafast laser spectroscopy techniques have revealed new evidence, which has given rise to new hypotheses for the dynamics of electron trapping and for the subsequent early events in water.[2]

Referring to a recent critical review summarizing current theories of the dynamics of solvation in dipolar liquids (13), continuum models are based on a frequency-dependent dielectric continuum picture of the solvent, where the solute is replaced by a cavity containing the charge. Molecular theories represent a different approach which is promising, but a consistent treatment of solvent structure should be included along with a nonlinear theory of polar solvent dynamics in order to get reliable theoretical results. In a recent paper, Long *et al.* (11) also conclude that the dielectric-relaxation picture of solvation is fundamentally inconsistent with their experimental results on electron hydration in pure water. The important role of molecular interactions in solvation dynamics is also supported from studies of femtosecond laser fluorescence spectroscopy of electronically excited molecules (14), and of femtosecond, laser-driven nonlinear optical responses of liquids (15).

Beside theoretical models, computer simulations (16–20) also provide an insight into the details of electron hydration dynamics, with the great advantage that they treat water as consisting of individual molecules. These simulations use a quantum-mechanical representation of the electron (through, for example, the Feynman path-integral technique), but a classical representation of water molecules and a pseudopotential approach for describing the electron–water interaction. The simulation results largely support an important role of molecular and structural effects of the solvent, but, while there is good qualitative agreement with experiment, quantitative discrepancies are still serious (17; for a review, see ref. 17*b*).

None of the current theories or simulations can explain the dynamical characteristics of electron hydration. Based on the most recent experimental and simulation results, we propose here a model of the dynamics of formation of laser-induced hydrated electrons that differs from the mechanism of hydrated electron formation via high-energy ionizing radiations. We think that a major shortcoming of current theories is that they do not take into account the active role of the positive parent ion in the early events during which localization of laser-induced electrons occurs.

Let us consider the following schematic representation of electron hydration:

$$H_2O \xrightarrow{2\,h\nu} H_2O^*$$

$$H_2O^* \rightarrow \begin{cases} H_2O^+ \xrightarrow{+\,H_2O} H_3O^+ + OH^\cdot \\ e^- \xrightarrow[\tau_1\ (\text{trapping})]{} e_{ir}^- \end{cases}$$

$$e_{ir}^- \xrightarrow[\tau_2]{} e_{aq}^- \text{ (“hydrated” electron)}$$

In this scheme, excitation of a water molecule can be regarded as instantaneous. Electron trapping is a complex

event, where a transient absorption, attributed to the water cation H_2O^+, appears and disappears within 50 fs (i.e., within the time resolution of the femtosecond laser apparatus), during the formation of the e_{ir}^- species. The characteristic time τ_1 for the formation of the latter species has been found to vary from ~110 fs (5) to ~180 fs (11).

As indicated in the above scheme, we think that the precursor of the e_{ir}^- species is *not* a "dry" or quasi-free electron, but rather the excited water molecule itself. The energetics of photoionization of water, recently reviewed by Goulet *et al.* (21), suggests that the energy band gap of liquid water is 8.9 ± 0.2 eV. This is the minimum energy necessary to produce a "dry" electron, or, in other words, to promote an electron into the conduction band of liquid water, while the threshold energy to produce a fully relaxed hydrated electron (along with $H_3O^+_{aq}$ and $OH^{\cdot}_{aq}$) is found to be 6.5 ± 0.5 eV from both single (22–24) and two-photon (25) ionization experiments. Now, the usual excitation energy, supposing a two-photon ionization process, is about 8 eV in all published femtosecond electron hydration experiments (4–11). This energy is sufficient to allow a valence electron to be promoted into one of the localized states of the Urbach tail, which lies below the conduction-band edge of water (21, 26). This obviously means that the actual production of laser-induced hydrated electrons does not proceed via the initial formation of quasi-free (dry) electrons, but that electrons get trapped directly from excitonic states of the liquid. (An interesting and inspiring continuum-model treatment of this process was recently proposed by Schiller (27).)

According to our proposition, these (Mott–Wannier-type) excitonic states can be viewed as Rydberg states with a largely extended outer electron and a localized positively charged core at the center. As the region over which this outer electron extends comprises many water molecules, the electronic charge density at the site of the parent ion is likely to be very small. (It is hard to give an estimate of the spatial range of this exciton; as a reasonable approximation, its radius can be estimated from the initial separation of e_{aq}^- and its parent cation (H_3O^+) after the formation of the e_{aq}^- species, which is about 1 nm (8, 28). Thus, the exciton would extend over a distance of some six water molecules, that is, over a hundred water molecules within a spherical range.) Consequently, the water molecules surrounding the parent ion site experience mainly the Coulombic field of this central (localized) positive charge, and, immediately after excitation, they begin to orientate and be polarized according to this field. The development of such a first hydration shell around the cation has important consequences. In fact, the potential of the central positive core at distances where the charge density of the outer electron is concentrated will be weakened as a result of this "screening." At the same time, the preexisting trap states (of the Urbach tail) that are located in the outer regions of the exciton and are coupled to the excitonic state will be deepened, due to the orientation of the positive poles of the aligned water dipoles towards these outer regions. Now, the screening by the water molecules will tend to diminish the interactions between the outer electron and the parent ion, while the trapping probability of the electron increases with the deepening of the available electron traps. Thus, the presence of the localized positive core of the initial exciton largely facilitates electron trapping in its immediate neighborhood. Once localized in one of these traps, the electron also begins to form its own hydration shell, and the e_{ir}^- species is formed, with a more or less relaxed microenvironment, with a characteristic time τ_1. During this formation time, irrespective of the degree of polarization of the surrounding water molecules, the central H_2O^+ can react with H_2O, with a high proton transfer rate, to give rise to H_3O^+ and $OH^{\cdot}$ (28, 29). This very fast event correlates with the rise and decay of an ultrashort transient absorbance at 625 nm (11). Once the e_{ir}^- species has been formed, it then transforms, with a characteristic time τ_2, into the fully relaxed e_{aq}^- state. (τ_2 has been found to vary from ~240 fs (5) to ~540 fs (11).) The resulting charged species $H_3O^+_{aq}$ and e_{aq}^- can be considered as a kind of solvent-separated ion pair (30). Due to this close proximity, e_{aq}^- can recombine easily with H_3O^+ and $OH^{\cdot}$. Indeed, it has been found that about 50% of the initially formed hydrated electrons undergo recombination within the first 100 ps, and the remaining e_{aq}^- population stabilizes after this time (6, 8, 31). This is in contrast with pulse radiolysis results where the estimated total ionization yield in water, G_{tot}, is about 6 molecules/100 eV (32–34), which stabilizes at about 4.8 molecules/100 eV after 30–100 ps (35, 36), i.e., only some 25% of the initially formed e_{aq}^- recombine. To our opinion, this difference is the direct consequence of the formation of quasi-free (or dry) electrons with large excess kinetic energy in the case of pulse radiolysis.

Summing up the proposed model for laser-induced electron trapping in liquid water, we suggest that the localized central positive core of the Rydberg-like excitonic state, formed upon photoexcitation, polarizes its environment, thus "deepening" preexisting electron traps (of the Urbach conduction-band tail) in the range of the exciton, largely facilitating the trapping of the extended outer electron. Dipolar relaxation around the positive parent site and the trapped electron takes up the excess energy of the exciton, thus giving rise to the formation of the reactive species $H_3O^+_{aq}$, e_{aq}^-, and $OH^{\cdot}_{aq}$ within a 1-nm radius (8, 28), and the subsequent recombination products. It is clear from the proposed model that an ultrafast initial Stokes shift should precede the build-up of the characteristic infrared band of the e_{ir}^- species. However, this Stokes shift should be located in the far infrared region from wavelengths of a few microns down to about 1 μm, the location of the e_{ir}^- infrared band. The large wavelength and the short time scale (probably less than ~100 fs) make the detection of this blue shift very difficult.

The proposed localization dynamics supposes ultrafast solvent relaxation times. The detection of a ~30-fs early configurational relaxation in computer simulations (20) provides support for this interpretation. Moreover, we think that, in water, proton jumps play an important role even in the orientation of the water molecules via an exchange of protons shared in hydrogen bonds. In our opinion, satisfactory simulation results could be obtained only with water molecules whose protons are considered as quantum particles, taking properly into account the role of the (classical) parent cation in the trapping of an electron.

Étude thermodynamique de l'acridone et de la thioxanthone

RAPHAËL SABBAH ET LAHCEN EL WATIK

Centre de thermodynamique et de microcalorimétrie du Centre national de la recherche scientifique, 26, rue du 14 lème RIA, 13003 Marseille, France

Reçu le 2 août 1991

RAPHAËL SABBAH et LAHCEN EL WATIK. Can. J. Chem. **70**, 24 (1992).

Dans le présent travail, nous avons étudié l'acridone et la thioxanthone par calorimétrie de combustion de faibles quantités de substance, de sublimation, par analyse thermique différentielle et par mesures de capacités calorifiques. Les fonctions thermodynamiques obtenues sont les suivantes : Pour l'acridone : $\Delta_{sub}H^0_m(298{,}15\ K) = (136{,}15 \pm 0{,}45)$ kJ mol^{-1}, $\Delta_cH^0_m(s, 298{,}15\ K) = -(6300{,}3 \pm 2{,}5)$ kJ mol^{-1}, $\Delta_fH^0_m(s, 298{,}15\ K) = -(101{,}6 \pm 2{,}6)$ kJ mol^{-1}, $\Delta_fH^0_m(g, 298{,}15\ K) = (34{,}6 \pm 2{,}6)$ kJ mol^{-1}. Pour la thioxanthone : $\Delta_{sub}H^0_m(298{,}15\ K) = (114{,}81 \pm 0{,}41)$ kJ mol^{-1}, $\Delta_cH^0_m(s, 298{,}15\ K) = -(6840{,}5 \pm 3{,}5)$ kJ mol^{-1}, $\Delta_fH^0_m(s, 298{,}15\ K) = -(20{,}5 \pm 3{,}6)$ kJ mol^{-1}, $\Delta_fH^0_m(g, 298{,}15\ K) = (94{,}3 \pm 3{,}6)$ kJ mol^{-1}, $\Delta_{fus}H_m = (35{,}50 \pm 0{,}28)$ kJ mol^{-1}, $T_{pt} = (487{,}88 \pm 0{,}02)$ K. Elles nous ont permis de déterminer l'énergie de conjugaison expérimentale des deux molécules qui nous intéressent et de les comparer aux valeurs théoriques. La molécule d'acridone étant plane, cette comparaison est tout à fait satisfaisante. La différence observée entre la valeur théorique et expérimentale dans le cas de la thioxanthone confirme les résultats expérimentaux sur la structure non plane de cette molécule. À partir de l'enthalpie d'atomisation expérimentale de l'acridone, nous avons pu déterminer une valeur enthalpique pour la liaison C_b-N. Enfin, en utilisant les contributions enthalpiques précédemment déterminées au laboratoire, nous avons pu retrouver par le calcul l'enthalpie d'atomisation de la molécule de thioxanthone.

Mots clés : thermodynamique; calorimétrie; analyse thermique différentielle; acridone; thioxanthone; enthalpies de combustion, de sublimation, de fusion; énergie de conjugaison; enthalpies d'atomisation, de liaisons intramoléculaires; température du point triple.

RAPHAËL SABBAH and LAHCEN EL WATIK. Can. J. Chem. **70**, 24 (1992).

In the present work we studied acridone and thioxanthone by combustion calorimetry of small amounts of substance, by sublimation calorimetry, by differential thermal analysis, and by heat capacity measurements. The thermodynamic quantities derived are as follows: For acridone: $\Delta_{sub}H^0_m(298.15\ K) = (136.15 \pm 0.45)$ kJ mol^{-1}, $\Delta_cH^0_m(s, 298.15\ K) = -(6300.3 \pm 2.5)$ kJ mol^{-1}, $\Delta_fH^0_m(s, 298.15\ K) = -(101.6 \pm 2.6)$ kJ mol^{-1}, $\Delta_fH^0_m(g, 298.15\ K) = (34.6 \pm 2.6)$ kJ mol^{-1}. For thioxanthone: $\Delta_{sub}H^0_m(298.15\ K) = (114.81 \pm 0.41)$ kJ mol^{-1}, $\Delta_cH^0_m(s, 298.15\ K) = -(6840.5 \pm 3.5)$ kJ mol^{-1}, $\Delta_fH^0_m(s, 298.15\ K) = -(20.5 \pm 3.6)$ kJ mol^{-1}, $\Delta_fH^0_m(g, 298.15\ K) = (94.3 \pm 3.6)$ kJ mol^{-1}, $\Delta_{fus}H_m = (35.50 \pm 0.28)$ kJ mol^{-1}, $T_{tp} = (487.88 \pm 0.02)$ K. The experimental results permitted us to determine for each molecule its resonance energy and to compare it with the theoretical value. This comparison fits well for acridone, which is planar. The difference observed in the case of thioxanthone shows that this molecule is not planar, in accord with literature structural results. From the experimental enthalpy of atomization of acridone, we determined an enthalpy value for the C_b—N bond. Using the enthalpy contributions previously determined in our laboratory, we found a value for the enthalpy of atomization of thioxanthone in accord with the experimental result.

Key words: thermodynamics; calorimetry; differential thermal analysis; acridone; thioxanthone; enthalpies of combustion, of sublimation, of fusion; resonance energy; enthalpies of atomization, of intramolecular bonds; triple point temperature.

Introduction

Dans le cadre de l'étude thermodynamique des hétérocycles se trouvant dans les coupes lourdes du pétrole ou dans les produits issus de la pyrolyse du charbon, entreprise au laboratoire depuis quelques années, nous nous sommes intéressés aux deux molécules d'acridone et de thioxanthone.

Comme on le sait, diverses actions programmées depuis plus de dix ans ont eu pour but la valorisation de ces matériaux. Parmi elles, il faut citer les deux opérations d'hydrodésulfuration et de désazotation. Leur but est de convertir les molécules renfermant du soufre ou de l'azote en hydrocarbures afin d'obtenir des combustibles non polluants. La difficulté de pouvoir déterminer directement les enthalpies des différentes réactions liées à ces opérations nécessite le recours à des valeurs précises des enthalpies de formation des réactifs et produits. Malheureusement, pour ces deux substances, il n'existe aucune grandeur thermodynamique dans la littérature.

Possédant au laboratoire les moyens de déterminer avec une exactitude suffisamment bonne, tout en n'utilisant que peu de substance (une étude complète nécessite 200 mg environ de substance pure), certaines grandeurs thermodynamiques : enthalpie de formation aux états condensé et gazeux à partir des enthalpies de combustion et de sublimation, enthalpie de fusion, température du point triple . . . (1–3), nous les avons utilisés pour étudier les deux molécules d'acridone et de thioxanthone.

Partie expérimentale

1. Produits

L'acridone est un produit Fluka (purum, pureté initiale >99%) et la thioxanthone est un produit Aldrich, pureté initiale 98%. Nous les avons repurifiés par recristallisation, le premier dans l'éthanol absolu et le second dans le tétrachlorure de carbone, puis sublimés sous une pression résiduelle de 10^{-2} Torr à 180°C dans le cas de l'acridone et à 120°C dans celui de la thioxanthone (1 Torr = 133,322 Pa).

Il ne nous a pas été possible de déterminer par ATD le degré de pureté de l'acridone car cette substance se décompose à la fusion. Par contre, dans le cas de la thioxanthone, nos expériences d'ATD nous ont permis de déterminer le degré de pureté de l'échantillon repurifié; celui-ci est égal à (99,94 ± 0,01) mol%.

TABLEAU 1. Grandeurs physiques des molécules étudiées à 298,15 K

Substance	Formule	M/g mol^{-1} [a]	ρ/g cm^{-3}	$-(\delta U/\delta P)_T$/J g^{-1} atm^{-1} [b]
Acridone $C_{13}H_9ON$		195,2206	1,201	(0,013)
Thioxanthone $C_{13}H_8OS$		212,2719	1,422	(0,013)

[a] Calculée à partir du tableau des masses atomiques de 1987 (22).
[b] 1 atm = 101,325 kPa.
Les valeurs placées entre parenthèses ont été estimées.

2. Appareillage, techniques et mode opératoire

Pour mener à bien cette étude, nous avons utilisé la calorimétrie de combustion de faibles quantités de substance, la calorimétrie de sublimation, l'analyse thermique différentielle et la mesure des capacités calorifiques.

2.1. Calorimétrie de combustion

Pour réaliser les expériences par calorimétrie de combustion, nous avons utilisé l'appareillage décrit dans la référence 4*a*. Précisons ici que dans le cas de l'acridone, la microbombe qui lui est associée a été décrite dans un précédent mémoire (5). Avec la thioxanthone, nous avons utilisé une microbombe à revêtement de platine décrite dans la référence 4*a*. La sensibilité de la pile du calorimètre CRMT est de 62,4 μV mW^{-1} à 298,15 K; celle de l'amplificateur est de 30 mV. L'oxygène N45, utilisé dans nos expériences, provient de l'Air Liquide; son degré de pureté est égal à 99,995%.

2.2. Calorimétrie de sublimation

Pour mesurer diretement la quantité de chaleur mise en jeu par la sublimation des substances étudiées, nous avons utilisé un calorimètre Tian–Calvet, dont la sensibilité de la pile est de 16,87 μV mW^{-1} à 380 K et de 13,81 μV mW^{-1} à 432 K, associé à une cellule d'effusion de Knudsen. L'appareillage et le mode opératoire ont été décrits dans la référence 2. Toutefois, il y a lieu de préciser ici que le signal issu du calorimètre est amplifié par un nonovoltmètre Keithley modèle 147 (sensibilité utilisée : 30 μV (acridone) et 100 μV (thioxanthone)), puis digitalisé à l'aide d'un voltmètre numérique Keithley modèle 175. L'acquisition et le traitement des données ont été réalisés à l'aide d'un programme écrit par nos soins et traité par un ordinateur Zenith modèle 159.

La très faible pression de vapeur saturante des deux substances étudiées ne nous a pas permis de les sublimer à 298,15 K. En conséquence, la thioxanthone a été étudiée à 380 K et l'acridone à 432 K en utilisant un trou d'effusion respectivement de 1,5 et de 2 mm.

2.3. Analyse thermique différentielle

En utilisant l'appareillage et le mode opératoire décrits dans la référence 3, cette technique nous a permis de mesurer la température du point triple ainsi que l'enthalpie de fusion de la thioxanthone.

Résultats

Nous avons consigné dans le tableau 1 les grandeurs physiques à 298,15 K concernant les substances étudiées qui interviennent dans les calculs menant aux résultats expérimentaux.

1. Calorimétrie de combustion

L'équivalent énergétique du calorimètre (U_{calor}) a été obtenu à partir d'une série de combustions d'acide benzoïque, échantillon 39i du NBS, pour lequel $\Delta_c u^0$ (s, 298,15 K) = $-(26\ 414 \pm 3)$ J g^{-1}. Dans ces expériences, nous avons utilisé environ 5 mg d'acide et 0,2 mg de coton (dont l'énergie de combustion, préalablement déterminée au laboratoire, a pour valeur $\Delta_c u^0$(s, 298,15 K) = $-(16399 \pm 23)$ J g^{-1} (6)). Nous trouvons pour U_{calor}(298,15 K) la valeur (16,025 ± 0,007) J V^{-1} s^{-1} (acridone) et (15,957 ± 0,009) J V^{-1} s^{-1} (thioxanthone).

Les résultats expérimentaux obtenus par calorimétrie de combustion sont consignés dans les tableaux 2 et 3.

2. Calorimétrie de sublimation

L'étalonnage de notre système calorimétrique a été réalisé par effet Joule avant et après les expériences.

À cause de la très faible pression de vapeur saturante des substances étudiées, nous avons admis l'identité $\Delta_{sub}H_m(T) \equiv \Delta_{sub}H^0_m(T)$. Par ailleurs, pour calculer $\Delta_{sub}H^0_m$(298,15 K) à partir de $\Delta_{sub}H^0_m(T\ \text{K})$ (T = 432 K (acridone) et 380 K (thioxanthone)), nous avons utilisé la relation suivante :

$$\Delta_{sub}H^0_m(298{,}15\ \text{K}) = \Delta_{sub}H^0_m(T\ \text{K}) + \int_{T\text{K}}^{298{,}15\ \text{K}} [C^0_{p,m}(\text{g}) - C^0_{p,m}(\text{s})]\mathrm{d}T$$

après nous être assurés par ATD que la substance ne présente aucun changement de phase entre 298,15 et T K. En ce qui concerne l'intégrale $\int_{T\text{K}}^{298{,}15\ \text{K}}[C^0_{p,m}(\text{s})]\mathrm{d}T$, elle a été obtenue par la méthode de chute en utilisant un calorimètre Tian–Calvet et un four maintenus respectivement à 298,15 et T K. Quant à l'intégrale $\int_{T\text{K}}^{298{,}15\ \text{K}}[C^0_{p,m}(\text{g})]\mathrm{d}T$, elle a été déterminée à l'aide d'une méthode de contributions de groupes (7).

Nous avons consigné dans les tableaux 4 et 5 les résultats expérimentaux obtenus par calorimétrie de sublimation.

3. Enthalpie de formation de l'acridone et de la thioxanthone à l'état gazeux

Il est possible, à partir des résultats consignés dans les tableaux 2–5, de déterminer l'enthalpie de formation des substances étudiées à l'état gazeux et à 298,15 K. Celle-ci est égale à (34,6 ± 2,6) kJ mol^{-1} dans le cas de l'acridone et à (94,3 ± 3,6) kJ mol^{-1} dans celui de la thioxanthone.

$\Delta_c U^0_m$(s, 298,15 K) = $-$(6833,0 ± 3,5) kJ mol^{-1}
$\Delta_c H^0_m$(s, 298,15 K) = $-$(6840,5 ± 3,5) kJ mol^{-1}
$\Delta_f H^0_m$(s, 298,15 K) = $-$(20,5 ± 3,6) kJ mol^{-1}

Ces résultats correspondent à la réaction suivante :
$C_{13}H_8OS$ (s) + $16O_2$ (g) + 112 H_2O (l) → $13CO_2$ (g) + $H_2SO_4.115H_2O$ (l)

S = aire des thermogrammes; ΔU = variation de l'énergie interne de la bombe et de son contenu; w_1 = énergie de combustion du coton; w_2 = corrections pour passer à l'état standard.

4. Pression de vapeur saturante de l'acridone et de la thioxanthone

Comme indiqué dans les références 8 et 9, il nous est possible, à partir de nos essais, d'évaluer la pression de vapeur saturante des substances étudiées en utilisant la relation suivante :

$$P(T) \approx \Delta P = \mathrm{d}m/\mathrm{d}t(2\pi RT/M)^{1/2}1/aF$$

dans laquelle ΔP est la pression de part et d'autre du trou d'effusion; $P(T)$, la pression mesurée par effusion à la température T; $\mathrm{d}m/\mathrm{d}t$, la masse effusée par unité de temps; R, la constante des gaz parfaits; M, la masse molaire de la substance; F, le facteur de Clausing et a, l'aire de l'orifice d'effusion.

Nous trouvons respectivement 4×10^{-4} et 2×10^{-3} Torr comme pression de vapeur saturante de l'acridone à 432 K et de la thioxanthone à 380 K.

5. Enthalpie de fusion et température du point triple

Comme précisé dans le paragraphe 2.3, il nous a été possible de déterminer par ATD l'enthalpie de fusion ainsi que la température du point triple de la thioxanthone. Nous avons trouvé $\Delta_{fus}H_m$ = (35,50 ± 0,28) kJ mol^{-1} et T_{pt} = (487,88 ± 0,02) K (définie par rapport à l'EIPT-68).

Le manque de valeurs thermodynamiques consignées dans la littérature pour les deux molécules qui nous intéressent ne nous a pas permis de les comparer à nos résultats expérimentaux.

L'incertitude qui accompagne nos résultats expérimentaux représente l'écart moyen, σ_m, et tient compte des erreurs sur les termes et facteurs de l'expression conduisant au calcul de ces résultats.

Discussion

L'ensemble des fonctions thermodynamiques obtenues et consignées dans la partie Résultats permet la détermination de plusieurs grandeurs énergétiques liées à la structure des molécules étudiées.

1. Energie de conjugaison

Comme on le sait, cette grandeur renseigne sur la stabilité d'une molécule et est étroitement liée à sa structure.

$$\int_{298,15\,K}^{380\,K} C^0_{p,m}(g)dT = (13,91 \pm 0,09) \text{ kJ mol}^{-1}$$

$\Delta_{sub}H^0_m(298,15\ K) = (114,81 \pm 0,41)$ kJ mol^{-1}

S = aire des thermogrammes.

Construite à partir des modèles moléculaires, la molécule d'acridone est plane. Malheureusement nous n'avons trouvé dans la littérature aucune étude sur la structure cristalline ou (et) gazeuse de cette molécule permettant de confirmer cette observation. Il n'en est pas de même pour la thioxanthone qui présente un défaut de planéité confirmé par une étude structurale réalisée par diffraction électronique en phase gazeuse (10).

Dans l'une de nos précédentes publications (11), nous avions indiqué le procédé utilisé pour déterminer l'énergie de conjugaison expérimentale et théorique d'une molécule. Sur le plan pratique, on détermine la valeur expérimentale à partir des enthalpies de combustion à l'état gazeux de la molécule réelle et de la molécule fictive non conjuguée. La première de ces deux grandeurs s'obtient expérimentalement. Quant à la seconde, elle nécessite le recours aux systématiques. Pour notre part, nous avons utilisé celle de Klages qui est consignée par Wheland dans la référence 12.

En ce qui concerne la molécule d'acridone, compte tenu de sa structure plane, l'énergie de conjugaison expérimentale est égale à 390,1 kJ mol^{-1} et est tout à fait compatible avec la valeur théorique 386,7 kJ mol^{-1} obtenue en utilisant les paramètres suivants :

Pour la liaison C_b=0 :

$$\alpha(C) = \alpha + 0,250\beta_0$$
$$\alpha(O) = \alpha + 0,875\beta_0$$
$$\beta(C{=}O) = 1,375\beta_0$$

Pour la liaison C_b—N :

$$\alpha(C) = \alpha$$
$$\alpha(N) = \alpha + 1,750\beta_0$$
$$\beta(C{-}N) = 0,950\beta_0$$

La valeur de β(C—N) a été ajustée sur la molécule de pyrrole et a déjà été utilisée dans le calcul de l'énergie de conjugaison théorique de la molécule de carbazole (*4a*). β_0 représente, dans tous les calculs effectués dans la présente étude, l'intégrale de recouvrement dans la molécule de benzène et a pour valeur absolue 131,7 kJ mol^{-1}.

En ce qui concerne la molécule de thioxanthone, l'énergie de conjugaison expérimentale est égale à 353,2 kJ mol^{-1}. À partir des paramètres ci-dessus indiqués pour la liaison C_b=O et du même jeu de paramètres précédemment utilisés dans le cas du thiophène et de quelques-uns de ses dérivés (13) pour la liaison C_b—S ($\alpha(C) = \alpha$, $\alpha(S) = \alpha + 2,000\beta_0$ et $\beta(C{-}S) = 1,100\beta_0$), nous avons pu déterminer l'énergie de conjugaison théorique; celle-ci est égale à 409,5 kJ mol^{-1}. Étant supérieure à la valeur expérimentale, elle confirme bien le défaut de planéité de la molécule de thioxanthone.

Dans leur publication sur l'étude structurale de la molécule de thioxanthone en phase gazeuse, Iijima *et al.* (10) concluent à partir de leurs résultats et ceux de Gallaher et Bauer sur la molécule de thianthrène (14) que l'angle dièdre formé par les deux noyaux benzéniques est plus important dans le cas de la thioxanthone, ce qui voudrait dire que cette molécule serait plus plane que la molécule de thianthrène. Comme cette molécule a été précédemment étudiée au laboratoire (15), pour confirmer ce résultat, il suffisait de comparer la différence Δ entre les valeurs théorique et expérimentale de l'énergie de conjugaison pour chacune des deux molécules qui nous intéressent. Dans le cas présent, cette différence doit être plus grande dans le cas de la molécule de thianthrène. En utilisant le jeu de paramètres signalé ci-dessus, nous avons pu calculer la valeur théorique de l'énergie de conjugaison du thianthrène, ce qui nous a permis, connaissant $E_{conj,exp}$ = 364 kJ mol^{-1} (15), de déterminer Δ. Nous trouvons Δ = 72,7 kJ mol^{-1} dans le cas du thianthrène et 59,3 kJ mol^{-1} dans celui de la thioxanthone. Le même raisonnement peut être appliqué pour montrer que la molécule de xanthone, précédemment étudiée au laboratoire (1), est plus plane que celle de thioxanthone, confirmant ainsi les résultats expérimentaux d'études sur la structure de ces deux molécules (10, 16, 17) (Δ = 24,3 kJ mol^{-1} dans le cas de la molécule de xanthone).

Comme nous l'avons dit dans l'introduction, nous nous sommes intéressés à l'acridone et à la thioxanthone dans un cadre plus général visant l'étude de molécules polycycliques. De ce fait, il nous a paru intéressant de comparer entre elles les valeurs théoriques de l'énergie de conjugaison consignées dans le tableau 6. On constate que ces valeurs vont en ordre décroissant en passant de la molécule de

TABLEAU 6. Énergie de conjugaison expérimentale et théorique

Molécule	$E_{conj,exp.}$/kJ mol^{-1}	$E_{conj,théor.}$/kJ mol^{-1}
Thioxanthone	350,2	409,5
Xanthone	345,8 (l)	370,1 (l)
Acridone	390,1	386,7
Anthrone	325,6 (23)	336,7

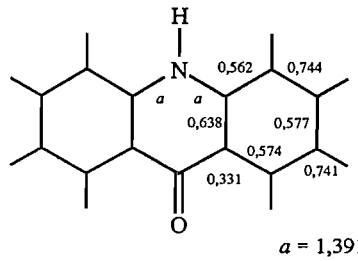

FIG. 1. Indices de liaison dans la molécule d'acridone.

thioxanthone, à celle d'acridone, à celle de xanthone. Ceci peut s'expliquer puisque la délocalisation, fonction de l'électronégativité, est plus grande dans le cas de la molécule de la thioxanthone qu'elle ne l'est dans les deux autres cas et dans l'ordre indiqué. Nous rejoignons ici la même conclusion tirée au moment de l'étude des molécules de dibenzothiophène, de carbazole et de dibenzofuranne (4). Quant à l'anthrone dont l'énergie de conjugaison théorique est égale à celle de la molécule de benzophénone (18), la valeur de celle-ci est inférieure aux trois autres car la conjugaison est incomplète (existence d'un chaînon -CH_2-). Par ailleurs, tout ce qui vient d'être dit trouve sa confirmation en comparant aussi entre elles les valeurs expérimentales de l'énergie de conjugaison. En effet, seule la molécule d'acridone est plane et sa conjugaison complète, ce qui explique la valeur élevée de l'énergie correspondante comparée à toutes les autres. L'énergie de conjugaison de la molécule de thioxanthone est plus élevée que celle de xanthone. Elle le serait encore plus si la molécule de thioxanthone était plane. Enfin, la faible valeur trouvée pour la molécule d'anthrone s'explique du fait que la conjugaison dans cette molécule est incomplète.

2. Enthalpie d'atomisation

L'enthalpie d'atomisation est liée à la transformation suivante : molécule (considérée comme gaz idéal, état fondamental, *T*) → atomes (chacun d'eux considéré comme gaz idéal, état fondamental, *T*).

À partir de l'enthalpie de formation d'une molécule à l'état gazeux et de celle des différents constituants C,H,O,N et S que l'on emprunte aux tables (19) et dont les valeurs sont respectivement égales à : (716,67 ± 0,44), (217,997 ± 0,006), (249,17 ± 0,10), (472,68 ± 0,40) et (276,98 ± 0,25) kJ mol^{-1}, il est possible de calculer son enthalpie d'atomisation expérimentale. Nous trouvons pour les molécules d'acridone et de la thioxanthone respectivement les valeurs : (11965,9 ± 3,9) et (11492,5 ± 4,6) kJ mol^{-1}.

Comme l'enthalpie d'atomisation est égale à la somme des enthalpies des liaisons intramoléculaires, compte tenu des facteurs de stabilisation et destabilisation, il nous a été possible de déterminer l'enthalpie de la liaison C_b—N dans le cas de la molécule d'acridone. Cela revient à retrancher de $\Delta_{a,exp}H(298,15\ K)$ la part enthalpique de toutes les autres liaisons intramoléculaires. Pour déterminer les contributions enthalpiques relatives aux différentes liaisons carbone–carbone, nous avons utilisé le procédé de calcul consigné dans la référence 4*a*. Celui-ci fait intervenir un paramètre lié à la géométrie de la molécule (l'indice de liaison l_{rs} entre deux atomes directement liés r et s), obtenu à partir du calcul théorique de l'énergie de conjugaison (cf. fig. 1). La relation reliant H_{rs} à l_{rs} s'écrit H_{rs}/kJ mol^{-1} = 246,0 l_{rs} + 342,6.

Quant aux enthalpies des liaisons C_b—H, C_b=O et N—H, nous avons respectivement utilisé les valeurs 415,88 758,19 (20) et 384,72 kJ mol^{-1} (21).

Nous trouvons $H(C_b—N)$ = 324,7 kJ mol^{-1} pour une distance interatomique de 1,391 Å. Ce résultat est tout à fait compatible avec le couple de valeurs $H(C_b—N)$ = 348,3 kJ mol^{-1} et $d(C_b—N)$ = 1,389 Å trouvée précédemment dans le cas de la molécule de carbazole (4*a*).

En ce qui concerne la molécule de thioxanthone, en utilisant les valeurs enthalpiques des différentes liaisons précédemment déterminées (15, 18), nous avons pu retrouver son enthalpie d'atomisation expérimentale à 2,4% près.

Remerciements

L'un de nous (L. El Watik) tient à remercier le gouvernement marocain pour l'octroi d'une bourse lui ayant permis de préparer une thèse de doctorat dont ce travail fait partie.

Reactions of dimethyl polysulfides[1] with organomagnesium reagents

PETER D. CLARK,[2] RUSSELL S. MANN, AND KEVIN L. LESAGE
Department of Chemistry, The University of Calgary, 2500 University Drive N.W., Calgary, Alta., Canada T2N 1N4

Received April 11, 1991

PETER D. CLARK, RUSSELL S. MANN, and KEVIN L. LESAGE. Can. J. Chem. **70**, 29 (1992).

Reactions of a mixture of dimethyl polysulfides (DMPS, $CH_3S_xCH_3$, $x = 3 - 8$) with methyl- and phenylmagnesium halides are described. The type of product obtained was dependent on the molar ratio of DMPS to Grignard reagent. When a 6:1 methyl-Grignard to DMPS ratio was used, methanethiol and dimethyl sulfide were the major products obtained after acidification of the reaction mixture. Lesser quantities of methyl-Grignard favored the formation of dimethyl sulfide, dimethyl disulfide, and H_2S. Experiments with a 6:1 phenylmagnesium bromide to DMPS ratio produced benzenethiol and phenylmethyl sulfide as major products after acidification. No methanethiol was observed in these experiments. Mixtures of phenylmethyl mono-, di-, and trisulfides and H_2S were obtained with a 3:1 Grignard/DMPS molar ratio. From a mechanistic viewpoint, product distributions obtained from reaction of Grignard reagents with DMPS can be explained by the formation of magnesium thiolates that are most readily stabilized by adjacent structures. Experiments using phenyl Grignard reagent in limited supply suggested that the internal sulfur atoms of the polysulfide chains were most reactive.

Key words: organic polysulfides, Grignard reagents.

PETER D. CLARK, RUSSELL S. MANN et KEVIN L. LESAGE. Can. J. Chem. **70**, 29 (1992).

On décrit les réactions d'un mélange de polysulfures de diméthyle (PSDM, $CH_3S_xCH_3$, $x = 3 - 8$) avec les halogénures de méthyl- et de phénylmagnésium. Le type de produit obtenu dépend du rapport molaire entre le PSDM et le réactif de Grignard. Lorsqu'on a utilisé un rapport de 6 : 1 entre l'halogénure de méthyle magnésium et le PSDM, l'extraction du mélange réactionnel obtenu après acidification fournit du méthanethiol et du sulfure de diméthyle comme produits principaux. Lorsqu'on utilise des rapports plus faibles de ces réactifs, la formation de sulfure de diméthyle, de disulfure de diméthyle et de H_2S est favorisée. Des expériences avec un rapport de 6 : 1 entre le bromure de phénylmagnésium et le PSDM a conduit, après acidification, à la formation du benzènethiol et du sulfure de phényle et de méthyle comme produits principaux. On n'a pas observé la formation de méthanethiol dans ces expériences. On a obtenu des mélanges de mono-, di- et trisulfures de phényle et de méthyle et H_2S lorsqu'on a utilisé un rapport molaire de 3 : 1 de Grignard/PSDM. D'un point de vue mécanistique, les distributions de produits obtenus par réactions des réactifs de Grignard avec le PSDM peuvent être expliquées par la formation de thiolates de magnésium qui sont facilement stabilisées par des structures adjacentes. Des expériences réalisées avec des quantités limitées de réactif de Grignard suggèrent que les atomes internes de soufre des chaines polysulfurées sont les plus réactives.

Mots clés : polysulfures organiques, réactifs de Grignard.

[Traduit par la rédaction]

Introduction

Under the influence of basic catalysis, sulfur reacts with organic disulfides to form mixtures of organic polysulfides (for a review of polysulfide chemistry, see ref. 1). One industrial use of such chemistry is to inject suitably catalysed dimethyl disulfide into the tubulars of sour gas wells to remove deposited elemental sulfur (2–5):

$$CH_3SSCH_3 + S_8 \xrightarrow{\text{Base}} CH_3S_xCH_3 \qquad x = 3 - 17$$

The value of x depends on the amount of sulfur available and the temperature of reaction but, at 20°C, averages 5 when an amount of sulfur equal to the weight of disulfide is used (5). Organic polysulfides are unstable due to weak S—S bonds (6–12) but they can be shown to be present using NMR spectroscopy (13, 14) (for up to $x = 6$) and by reverse phase HPLC (see ref. 3 for general method) (for up to $x = 17$). In general, it is difficult to isolate organic polysulfides with $x > 3$ since they readily undergo equilibration to smaller polysulfides and sulfur.

Our interest stems from the industrial desire to convert organic polysulfides back to the disulfides and sulfur or to useful sulfur chemicals. This report describes the chemistry that occurs when methyl- and phenylmagnesium halides are contacted with dimethyl polysulfides (DMPS). To our knowledge, no studies on this type of chemistry have been reported. However, it is known that organic disulfides react with organomagnesium compounds to yield sulfides and magnesium thiolates (15–18):

$$R'MgX + RSSR \rightarrow RSR' + RSMgX$$

In similar chemistry, it was reported that organolithium and Grignard reagents cleave the S—S bond of μ-dithiobis-(tricarbonyl)iron (19). Consequently, it was expected that organomagnesium compounds would react readily with DMPS to yield mixtures of sulfides and disulfides and metal thiolates and that the amount of each product type should be dependent on relative reagent stoichiometries.

Experimental

Reagents

With the exception of sulfur, chemicals and solvents were obtained from the Aldrich Chemical Co. Sulfur was obtained from the Shell Canada Ltd. Jumping Pound, Alberta sour gas processing facility and had a purity >99.9%. Tetrahydrofuran (THF) was dried over $LiAlH_4$ and was distilled prior to use.

[1]According to IUPAC nomenclature rules, organic polysulfides are named as polysulfanes. Polysulfides are used throughout this article in keeping with common usage and to be consistent with the organic sulfides described herein.

Dimethyl polysulfide preparation

Sulfur (100 g, 0.391 mol) was added to dimethyl disulfide (100 g, 1.042 mol) containing a trace of triethylamine and which had been saturated with H_2S. The mixture was stirred for 1 h or until all of the sulfur had dissolved. By calculation, this procedure gives a mixture of DMPS with an average value of approximately $x = 5$. HPLC analysis (see ref. 3) reveals a mixture of polysulfides with $x = 3 - 8$ as principal components and with $x = 5$ as the most abundant species.

Reactions with methylmagnesium iodide

All operations were conducted under a nitrogen atmosphere. A solution of DMPS (10.4 g, 0.0556 mol) in THF (50 mL) was added dropwise to a stirred solution of methylmagnesium iodide (prepared from iodomethane (24.1 g, 0.169 mol) and magnesium (4.0 g, 0.164 mol) in the usual way) in THF (200 mL) at 20°C. The mixture was stirred for 2 h and was acidified by dropwise addition of 6 M aqueous HCl. Evolved gases were collected in a calibrated gas syringe and were analysed for H_2S and methanethiol using standard gas chromatographic techniques (see below). Organic products were isolated by extraction with *m*-xylene (4 × 50 mL) and the organic extracts were dried ($MgSO_4$) and filtered. *m*-Xylene was chosen to simplify analysis of the volatile products formed in these reactions. Standard analytical transfer techniques were used to ensure that loss of solution was minimized and the final filtrate was diluted with *m*-xylene to a total volume of 250 mL. This solution was analysed for dimethyl sulfide and dimethyl di- and trisulfides (see below).

Gas analysis

Gases evolved during the acidification procedure were quantified using a HP 5890a gas chromatograph equipped with a 3.3 m Poropak N column linked in series to a 3 m Poropak QS column and a thermal conductivity detector. Analyses were carried out isothermally at 80°C.

Solution analyses

Xylene solutions were analysed using a HP 5890 gas chromatograph fitted with a Supelco SPB-5 fused silica capillary column and linked to an HP 5970 mass detector. The initial column temperature was 50°C; this was increased to 250°C at 10°C/min and was held at 250°C for 20 min. Compounds of interest elute before *m*-xylene. Analyses of solutions obtained from experiments with phenylmagnesium bromide (see below) required that the column temperature be raised to a final value of 300°C.

Compound response factors were obtained for both gas and solution analyses by calibration with pure compounds. Results of the analyses for the above experiment and experiments using 0.0417 and 0.0278 mol of DMPS (other reagent quantities were kept constant) are summarized in Table 1. These data are the average results of three experiments conducted for each of the initial quantities of DMPS; variations of ±5 mol% were observed for the data quoted in Tables 1 and 2.

Reactions with phenylmagnesium bromide

These experiments were conducted using procedures very similar to those described for methylmagnesium iodide. Four experiments (performed in triplicate each using 0.0556, 0.0417, 0.0278, and 0.0927 mol of DMPS) were carried out. Organic products were extracted into dichloromethane instead of *m*-xylene and were analysed for dimethyl di- and trisulfide, benzenethiol, methylphenyl sulfide, diphenyl sulfide, methylphenyl disulfide, diphenyl disulfide, and methylphenyl trisulfide. The average data of these experiments are compiled in Table 2. One series of experiments was performed in which the Grignard was added to the polysulfide (Table 2).

Results and discussion

Reactions of DMPS with methyl magnesium iodide

Planning and interpretation of experiments involving the reaction of DMPS with Grignard reagents is complicated by the fact that DMPS containing over three sulfur atoms can be used only as a mixture of compounds. The DMPS used in this study has the average formula $CH_3S_5CH_3$, although, as pointed out in the experimental section, it consists mostly of a range of compounds with three to eight sulfur atoms. It is probable that sulfur atoms other than those bonded to carbon will be the sites of reaction with Grignard reagents. Thus, a 3 mole excess of Grignard reagent should be sufficient to react with the three internal sulfur atoms in a DMPS mixture of average composition $CH_3S_5CH_3$, and produce dimethyl disulfide as the predominant product. Experiments with Grignard to DMPS ratios greater than 3:1 should promote further reaction with the disulfide to produce smaller compounds.

Data from the reaction of DMPS with methylmagnesium iodide at the 3:1 ratio (Table 1) show that after acidification of the reaction mixture H_2S, dimethyl sulfide, and dimethyl disulfide are the major products, along with lesser amounts of methanethiol and the trisulfide. When the relative amount of Grignard reagent was increased (the 4:1 and 6:1 data in Table 1), the quantities of H_2S and dimethyl disulfide formed decreased and methanethiol and dimethyl sulfide became the major products. No dimethyl trisulfide was observed in the 6:1 ratio experiments. These results can be explained by examination of the possible reactions outlined in Scheme 1.

Because DMPS exists as a mixture of compounds, the number of possible reactions is quite large. Scheme 1 only considers reactions up to and with the pentasulfide; reactions with larger polysulfides should follow similar pathways but need not be considered to explain the observations

[a]As percentage of total number of moles of products.
[b]This experiment was conducted by adding the Grignard solution to the polysulfide.
[c]Includes $CH_3S_4CH_3$. This compound was not detected in the other experiments.
[d]Does not include S_8, which could not be measured accurately.
ND: not detected.

Primary reactions

[1] $CH_3S_5CH_3 + CH_3MgI \longrightarrow CH_3S_xCH_3 + CH_3S_{5-x}MgI$ ($x = 1 - 4$)

[2] $CH_3S_4CH_3 + CH_3MgI \longrightarrow CH_3S_xCH_3 + CH_3S_{4-x}MgI$ ($x = 1 - 3$)

[3] $CH_3S_3CH_3 + CH_3MgI \longrightarrow CH_3S_xCH_3 + CH_3S_{3-x}MgI$ ($x = 1 - 2$)

[4] $CH_3S_2CH_3 + CH_3MgI \longrightarrow CH_3SCH_3 + CH_3SMgI$

Secondary reactions

[5] $CH_3S_4MgI + CH_3MgI \longrightarrow CH_3S_{4-x}CH_3 + (MgI)_2S_x$ ($x = 1 - 3$)

[6] $CH_3S_3MgI + CH_3MgI \longrightarrow CH_3S_{3-x}CH_3 + (MgI)_2S_x$ ($x = 1 - 2$)

[7] $CH_3S_2MgI + CH_3MgI \longrightarrow CH_3SCH_3 + (MgI)_2S$

SCHEME 1. Possible reactions of methylmagnesium iodide with dimethylpolysulfides.

presented in Table 1. Three basic reactions with the pentasulfide are possible (eq. [1] in Scheme 1). Attack of the Grignard reagent at the sulfur adjacent to carbon would lead to dimethyl sulfide and a tetrathiolate. Attack at the next sulfur atom can lead to either a di- or a tetrasulfide and mono- or trithiolates depending on which S—S bond is cleaved. Attack at the central sulfur atom of the pentasulfide leads to the trisulfide and a dithiolate. Similar series of eqs. [2]–[4] can be written for reaction with the tetra-, tri-, and disulfides. Besides these primary reactions, secondary reactions between the produced thiolates and methylmagnesium iodide may occur (eq. [5]–[7] in Scheme 1). In writing these equations, the assumption was made that electron density in the Mg—S bond is polarized to the sulfur atom, thus promoting further reaction of the Grignard reagent with the other sulfur atoms of the thiolates.[3] As can be seen, reactions [5]–[7] produce magnesium sulfides, which on contact with acid would yield H_2S. In addition, these secondary reactions are likely to produce dimethyl sulfide as a final product when excess Grignard reagent is present.

In the initial phases of reaction of methylmagnesium iodide with DMPS, most reaction should be with larger polysulfides (e.g., the pentasulfide) simply because these species are present in the largest concentration. However, based on analysis of final products, it is difficult to decide which sulfur atom of the polysulfides is most susceptible to attack by the Grignard reagent. Regardless of this consideration, all reactions lead to smaller polysulfides, and, if enough Grignard reagent is present, continued reaction should lead to methanethiol (initially as a magnesium thiolate before acidification) and dimethyl sulfide as the major products. In general, this suggestion was confirmed by the observation of increased methanethiol production when high ratios of Grignard reagent to DMPS were used.

Overall, reactions detailed in Scheme 1 explain the type of products observed and the effect of varying the reactant molar ratios. It should be noted that only 90–94% of the sulfur in the reagents could be accounted for in the products (Table 1). Not all of this loss can be accounted for by experimental losses and errors since visual inspection of a typical experiment showed that some elemental sulfur was formed during the acidification stage. Although it was not possible to quantify this elemental sulfur (mostly because of difficulties in recovering it), its formation can be explained by acidification of $(MgI)_2S_x$ ($x > 1$) type species.

Reactions of DMPS with excess phenylmagnesium bromide

Table 2 summarizes the results of experiments in which DMPS was reacted with excess amounts of phenylmagnesium bromide. Other experiments using a deficit of the Grignard and reverse order of reagent addition are described in the following section. A 3:1 molar ratio of Grignard reagent to DMPS gave, after acidification of the

[3]It is assumed that the Mg—S bonds in these compounds are predominantly covalent as is the case for MgS and related compounds.

[19] $CH_3S_3MgBr + C_6H_5MgBr \longrightarrow C_6H_5S_{3-x}CH_3 + (MgBr)_2S_x$ ($x = 1 - 2$)

[20] $CH_3S_2MgBr + C_6H_5MgBr \longrightarrow C_6H_5SCH_3 + (MgBr)_2S$

[21] $CH_3S_xMgBr + C_6H_5S_yCH_3 \longrightarrow CH_3S_nCH_3 + C_6H_5S_mMgBr$ ($x + y = n + m$)

SCHEME 2. Possible reactions of phenylmagnesium bromide with dimethylpolysulfides.

reaction mixture, phenylmethyl sulfide as the major product along with phenylmethyl di- and trisulfides, benzenethiol, and H_2S in lesser quantities. Smaller amounts of diphenyl disulfide, phenylmethyl disulfide, and dimethyl di- and trisulfide were also detected. Higher ratios of Grignard reagent to DMPS (4:1 and 6:1) resulted in benzenethiol and phenylmethyl sulfide as the major products (50.7 and 40.5 mol% respectively). Other products such as H_2S were observed only in minor quantities when a 6:1 Grignard/DMPS ratio was used. As in reactions between DMPS and methylmagnesium iodide, small amounts of elemental sulfur were detected but we could not quantify this product accurately. However, since most of the sulfur added as DMPS was recovered in the organic products (88–93%, see Table 2), it is clear that elemental sulfur was a minor product. Interestingly, no methanethiol was produced in the reactions of DMPS with phenylmagnesium bromide.

Scheme 2 summarizes the possible reactions of phenylmagnesium bromide with polysulfides containing up to five sulfur atoms. Again, it should be remembered that the DMPS mixtures used in these experiments contained polysulfides with more than five sulfur atoms, but their reactions are not considered in detail because they should lead to the same products as the smaller polysulfides. As was the case in reactions with methylmagnesium iodide, it is conceivable that phenylmagnesium bromide may react with the pentasulfide at three different sulfur atoms (reaction [8] in Scheme 2) and that one of these reactions could yield phenylmethyl di- or tetrasulfide depending on which S—S bond is cleaved. However, since methanethiol was not observed in any of the reactions with phenylmagnesium bromide, it can be argued that reaction at the second sulfur atom always results in cleavage of the internal S—S bond to yield phenylmethyl disulfide and a methyl trithiolate species. It is not certain why internal S—S bond cleavage is favored although the disulfide formed in this reaction should be more stable than the tetrasulfide that would be formed from cleavage of the other S—S bond. One possibility is that methanethiolate product is formed but is consumed in subsequent reactions. Although this possibility cannot be discounted for reactions using a 3:1 Grignard to DMPS ratio, it seems probable that some methanethiol should have been formed in experiments using greater quantities of Grignard reagent. However, this was not the case.

Other primary reactions with smaller polysulfides, [9]–[11], should follow similar pathways (Scheme 2). However, once again it can be argued that reactions that would produce methanethiolate product did not occur because methanethiol was not observed on acidification of the reaction mixtures. In addition, reaction [11] is unlikely because only a trace of the disulfide was present in the initial DMPS mixture. Overall, reactions that produced phenylmethyl sulfide must have predominated as this was the major product observed at all Grignard to DMPS ratios (Table 2).

Because the primary reactions produce phenylmethyl polysulfides, more secondary processes (see Scheme 2) are possible with the phenyl-Grignard than was possible with the methyl-Grignard. Each of the sulfur atoms in these mixed polysulfides is chemically distinct. Thus, phenylmethyl tetrasulfide can react with phenylmagnesium bromide in six reactions, summarized by [12] and [13], which can yield different products depending on which S—S bond is broken. Similar reactions, [14]–[17], for the phenylmethyl tri- and disulfide can be written (Scheme 2), and explain the array of products noted in these reactions. As before, reactions leading to magnesium methylthiolate and hence methanethiol likely do not occur. Another series of secondary reactions with magnesium methyl polythiolates, CH_3S_xMgBr ($x = 2 - 4$), are also possible ([18]–[20] in Scheme 2). These reactions produce sulfides, which on acidification yield H_2S. Other reactions, not shown in Scheme 2, involving magnesium phenyl polythiolates formed in the secondary reactions of phenylmethyl polysulfides, are also possible.

Some of the secondary reactions can be used to explain why benzenethiol becomes a major product when excess phenylmagnesium bromide is present. In this regard, reactions [16] and [17] are of particular interest although related reactions occur in the series of reactions represented by [13] and [15]. Reaction [16] results in the formation of magnesium methylthiolate and reaction [17] produces magnesium phenylthiolate (which yields benzenethiol on acidification). The fact that benzenethiol was the predominant product suggests that the phenylthiolate species is more stable than the methyl counterpart. Presumably, this stabilization is based on the ability of the aromatic ring to delocalize electron density. The same arguments can be applied to the series

of reactions [13] and [15] and explain why phenylmethyl sulfide is formed in much greater amounts than diphenyl sulfide. In general, it is probable that attack of a phenyl Grignard reagent on a polysulfide will occur to produce the thiolates that can be stabilized by the aromatic ring.

Reactions of DMPS with a limited supply of phenylmagnesium bromide[4]

Experiments described above were designed to consume all of the polysulfide sulfur and so produce small organosulfur compounds. However, by using a limited amount of Grignard reagent, it should be possible to determine which sulfur atoms of the polysulfides are most reactive. Consequently, some experiments were conducted using a 1:1 molar ratio of DMPS to phenylmagnesium bromide (Table 2). Thus, remembering that the DMPS used in this study has the average molecular formula $CH_3S_5CH_3$ and that the three internal sulfur atoms are likely to be the most reactive, the actual ratio of "reactive sulfur" to Grignard is 3:1. In addition, the Grignard reagent was added dropwise to the polysulfide to ensure that it was present as the limiting reagent.

Data from these experiments show (Table 2) that methylphenyl di- and trisulfide were the major products (formed in almost equimolar amounts), along with lesser quantities of methylphenyl sulfide and benzenethiol. Unchanged DMPS was also detected in the reaction products. If we consider reaction of the phenyl Grignard with dimethyl pentasulfide (reaction [8] in Scheme 2) from a purely statistical viewpoint, twice as much phenylmethyl sulfide and disulfide should be produced in comparison to the trisulfide. Consequently, the data obtained infer that the central sulfur atom of the pentasulfide is the most reactive towards phenylmagnesium bromide and that the two sulfur atoms adjacent to the central one are the next most reactive. Clearly, attack of the sulfur atoms bonded to carbon is least favored. The observation of some benzenethiol and H_2S indicates that reactions were not limited entirely to primary reactions. In addition, reactions of type [21] could alter the distribution of the products observed. Overall, it is difficult to make a definitive statement on the relative reactivity of the polysulfide sulfur atoms, but the results obtained do suggest that the central and internal sulfur atoms are most reactive towards Grignard reagents.

Lastly, it should be noted that in the reaction of DMPS with either methyl- or phenyl-Grignard reagents, no evidence for attack of the Grignard at the carbon atoms of polysulfides or product organic sulfides was found. This in accord with other work that has shown that aliphatic sulfides are inert to Grignard reagents (20). The only exception to these findings appears to be the production of allylbenzene and phenylthiomagnesium bromide from the reaction of phenylallyl sulfide with phenylmagnesium bromide (21).

[4]We are indebted to a reviewer for suggesting these experiments.

Molecular dynamics simulation of interhalogen compounds. 1. Liquid chlorine trifluoride (ClF_3): structure and thermodynamics

RAMESH K. WADI[1] AND VIVEK SAXENA
Department of Chemistry, University of Delhi, Delhi-110 007, India

Received June 5, 1991

RAMESH K. WADI and VIVEK SAXENA. Can. J. Chem. **70**, 34 (1992).

The results of a molecular dynamics (MD) simulation study of liquid chlorine trifluoride (ClF_3) at 217, 260, and 287 K are reported. The cubic simulation cell consists of 108 ClF_3 molecules assumed to be interacting via site–site Lennard–Jones 12–6 pair potential. The parameters for F–F and Cl–Cl interaction are the same as used for the simulation of F_2 and Cl_2, respectively, and those for the Cl–F cross interaction are calculated using Lorentz–Berthelot rules. These results are then used to calculate various radial distribution functions characteristic of the liquid structure. Thermodynamic properties, namely, configurational energy, constant volume specific heat, and internal pressure are also reported. The time-dependent properties, mean square force and torque, self diffusion coefficient, and the quantum corrections to the free energy, were also obtained. The dimer configuration drawn based on the observed contact distances was found to be in good agreement with the results of matrix isolation infrared and laser Raman spectroscopic studies.

Key words: MD simulation, interhalogens, liquid structure, thermodynamic properties.

RAMESH K. WADI et VIVEK SAXENA. Can. J. Chem. **70**, 34 (1992).

On a effectué une simulation par dynamique moléculaire du trifluorure de chlore liquide (ClF_3) à 217, 260 et 287 K. La cellule cubique de simulation comporte 108 molécules de ClF_3 qui interagiraient par potentiel de paires site–site 12–6 de Lennard–Jones. Les paramètres pour l'interaction F–F et Cl–Cl sont les mémes que ceux utilisés respectivement pour F_2 et Cl_2 alors que ceux pour l'interaction croisée Cl–F a été calculée à l'aide des règles de Lorentz–Berthelot. On utilise alors ces résultats pour calculer diverses fonctions de distributions radiales caractéristiques de la structure liquide. On rapporte aussi les propriétés thermodynamiques, soit l'énergie de configuration, la chaleur spécifique à volume constant et la pression interne. On a aussi déterminé les propriétés qui varient avec le temps, soit la force et le moment de torsion quadratique moyen, le coefficient d'autodiffusion et les corrections quantiques à l'énergie libre. On a trouvé que la configuration du dimère tracée en se basant sur les distances de contact observées est en bon accord avec les résultats des études par spectroscopie infrarouge et Raman réalisées avec des matrices isolées.

Mots clés : simulation par dynamique moléculaire, interhalogènes, structure liquide, propriétés thermodynamiques.

Introduction

The list of molecular liquids studied by molecular dynamics (MD) computer simulation is fairly large (1). The major aim of such studies has been to test the adequacy of the proposed potentials and (or) the algorithms used and to obtain the thermodynamic and time-dependent properties, which may be experimentally determinable or even inaccessible. The studies have contributed significantly to the development of the theories of molecular interaction in the condensed state. MD simulations of the relatively simple liquid halogens have been reported by Singer *et al.* (2) using a "2-Lennard–Jones centers" pair potential and were found to reproduce their thermodynamic properties quite well. Further, Rodger, Stone, and Tildesley (3, 4) suggested an anisotropic atom–atom pair potential for molecular chlorine and studied its predictions for a wide range of properties of the crystalline and liquid states. Simulation of liquid hydrogen chloride, quite a complicated system due to H-bonding, required modifications of the usual Lennard–Jones 12–6 parameters. Interhalogens (viz., ClF, ClF_3, ClF_5, BrF_3, BrF_5, etc.) also form an interesting class of compounds as these are not as simple as halogens and not as complex as hydrogen chloride. The price to be paid to simulate with more sophisticated models is heavy computational cost. It is therefore natural that simple models should be fully exploited before they are abandoned in favour of more complicated ones. As most of these compounds are very reactive, hence difficult to purify and manipulate in the pure state, few experimental data are available for comparison purposes. We have started a systematic computer simulation study of the interhalogens with two aims: (*i*) to determine whether the potentials used for the simulation of halogens in the liquid state can also be used for the simulation of the interhalogens and (*ii*) to motivate experimentalists to further study this important class of liquids to determine their diffraction properties, equation of state, self-diffusion coefficients, etc.

In this paper we report the results of MD simulation of liquid ClF_3 at three average temperatures, 217 K, 260 K, and 287 K, so as to have an idea about the temperature variation of its properties in the liquid state. Gas phase microwave (5) and solid state X-ray diffraction studies (6) show that the ClF_3 molecule has a planar distorted "T" structure of C_{2v} symmetry, with the bond lengths and angles depicted in Fig. 1. On the basis of the results from the laser Raman spectroscopic study of ClF_3, Drifford *et al.* (7) suggested the presence of dimers in the liquid state. Evidence of dimers existing in the liquid state has also come from the IR spectra of ClF_3 in argon matrix (8). Though among the theoretical studies, quantum mechanical calculations have been reported for some of the interhalogens, the present work appears to be the first report of their computer simulation study.

Method

All calculations were carried out using the MDPOLY (9) program developed by Thompson, for a microcanonical ensemble of a system of 108 ClF_3 molecules in a cubic box satisfying the densities ρ given in Table 1 and using periodic boundary conditions to avoid surface effects. These

[a]1 bar = 100 kPa.;

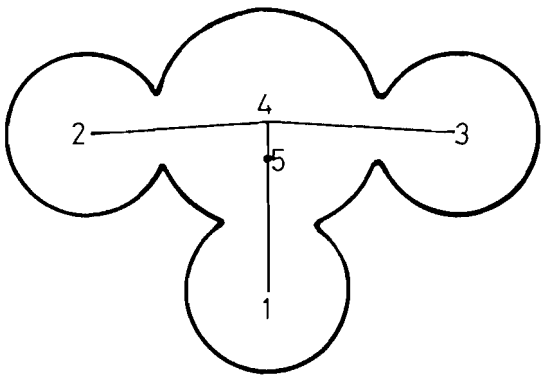

FIG. 1. Chlorine trifluoride molecule; sites 1, 2, and 3 represent fluorine; 4, chlorine, and 5, the centre of mass. Various distances and angles are $r_{24} = r_{34} = 1.698$ Å, $r_{14} = 1.598$ Å, $r_{45} = 0.36$ Å, and ∠ 142 = ∠ 143 = 87° 28′.

molecules were assumed to interact via a Lennard–Jones 12–6 site–site pair potential. The structure of the ClF_3 molecule as given in Fig. 1 was used and kept rigid during the simulation. The equations of motion were integrated by the predictor–corrector scheme of the second order; orientations of the molecules were expressed in terms of quaternions. At least 1000–1500 time steps, each corresponding to 7.5 fs, were required for the equilibration until the fluctuations in the total energy were reduced to about 0.001%. The statistics were then collected over 4000 steps of the production phase. The algorithm of the simulation has been well described by Allen and Tildesley (10).

The potential energy U of the system, assumed to be the sum of the pairwise interactions $u_{ab}(r_{ab})$ from the site a in molecule i at position r_{ia} and the site b in the molecule j at the position r_{jb}, can be represented as

$$[1a] \quad U = \sum_{i<j}\sum \sum_a \sum_b u_{ab}(r_{ab}) \qquad \text{for} \quad r_{ab} \le r_c$$

$$[1b] \quad = 0 \qquad \text{for} \quad r_{ab} > r_c$$

where r_c is the potential truncation distance and, in the present case, half of the box length,

$$r_{ab} = |r_{ia} - r_{jb}|$$

and

$$u_{ab}(r_{ab}) = 4\epsilon_{ab}\{(\sigma_{ab}/r_{ab})^{12} - (\sigma_{ab}/r_{ab})^{8}\}$$

σ_{ab} and ϵ_{ab} are obtained according to Lorentz–Berthelot rules: $\sigma_{ab} = (\sigma_{aa} + \sigma_{bb})/2$ and $\epsilon_{ab} = \sqrt{\epsilon_{aa}\epsilon_{bb}}$. The Lennard–Jones site–site potential parameters used in the simulation are $\sigma_{F-F} = 2.83$ Å, $\epsilon_{F-F} = 52.8$ K, $\sigma_{Cl-Cl} = 3.35$ Å, and $\epsilon_{Cl-Cl} = 173.5$ K (2).

The long-range corrections made to the virial sum v and the potential energy U assuming $g(r) = 1$ for $r_{ab} > r_c$ are

$$[2] \quad T_v = -(2/3)\pi N\, d \int_r^\infty r^2 v(r)\, dr$$

and

$$[3] \quad T_u = 2\pi N\, d \int_r^\infty r^2 u(r)\, dr$$

where d is the number density, N is the number of molecules in the system, and $v(r)$ is the virial function.

The schemes for the calculation of thermodynamic and other properties are described elsewhere (10). The self-diffusion coefficient D is calculated from the mean square displacement MSD(t), as it is linearly related to the diffusion coefficient by the corresponding Einstein equation

$$[4] \quad 2\,t\,D = (1/3)\,\mathrm{MSD}(t)$$

valid at sufficiently long times. D is then calculated as 1/6th of the slope of the MSD(t) line.

Results and discussion

The molecular trajectories obtained during the simulation run were simultaneously used to calculate the com–com (center of mass) and the various site–site radial distribution functions (rdf's) describing the gross structural features of liquid chlorine trifluoride at the three temperatures studied (Fig. 2). With rise in temperature the heights of these peaks can in general be seen to be reduced, and at longer r values the curves tend to flatten to $g(r) = 1$. The coordination number n_0 of the first shell around a moiety (a molecule or a site) was obtained by integration of the function $r^2g(r)$ up to the first minimum in the $g(r)$. The position r_{max} of the first maximum in the $g(r)$ was taken to be the most probable distance between the two moieties. These r_{max} and n_0 are collected in Table 2. Further examination of these rdf curves reveals the closest contact distances. The distance of closest approach of the sites is obtained as the intercept on the abcissa. These distances were 2.5 and 2.8 Å for F–F and Cl–F as compared to 2.8 and 3.06 Å, respectively, found in the crystals (6). Using these distances it is possible to visualize geometrically the positions in which a pair of molecules is likely to be found. Two such dimer configurations are shown in Fig. 3. The configuration of Fig. 3(a) matches well with the one derived from the IR spectral study of ClF_3 in argon matrix (6). In these dimers the molecules are assumed to lie in the molecular plane. As derived in the microwave study

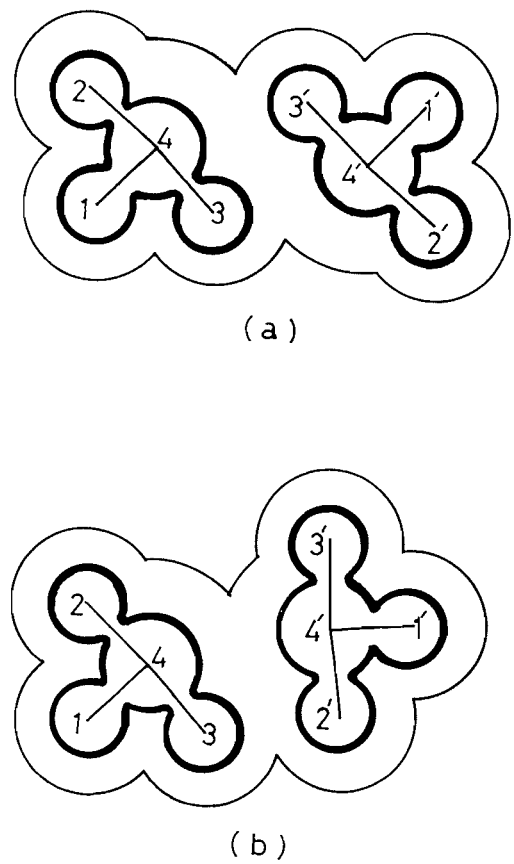

FIG. 3. Two possibilities of the closest approach of a pair of ClF_3 molecules derived from the rdf curves.

(3), the two lone pairs of electrons in the ClF_3 molecule lie above and below the plane of the molecule, thus reducing the chances of association from the two sides of the molecular plane in order to have the least interaction between the lone pairs.

Due to the fact that the nonbonded interactions among the halogens, except fluorine, show a characteristic feature of strong exchange interaction, anomalously shortened contact distances have been observed (11), indicating the existence of specific molecular interactions. The specific interaction described above results in shortened closest contact r_{ij} between the atoms of different molecules if $r_{ij} < (R_i + R_j - \delta)$ or $r_{ij} < 2\sqrt{R_i \cdot R_j} - \delta$, where R_i are the van der Waals radii and δ is the overlap of these spheres of atoms i and j. For a

For personal use only.

normal contact δ is 0.15 Å for contacts between nonhydrogen atoms and 0.30 Å where one of the two atoms is hydrogen (11). Considering R_F = 1.35 Å and R_{Cl} = 1.8 Å, $R_i + r_j - \delta$ values are 2.55, 3.45, and 3.0 Å for F–F, Cl–Cl, and Cl–F, respectively. The corresponding r_{ij}(obs) values are 2.4, 3.2, and 2.8 Å, well in agreement with the above results.

The thermodynamic averages of the configurational energy U, the virial ν, the compressibilities $P/\rho KT$, constant volume specific heat C_v, and the thermal pressure coefficient γ, calculated over 4000 time steps for three average temperatures 217 K, 260 K, and 287 K, are listed in Table 1. Values for the mean squared force $\langle F^2 \rangle$ and torque $\langle \Gamma_i \rangle$ about the axis i, quantum corrections Q_c to the Helmholtz free energy, and the self-diffusion coefficients D are summarized in Table 3. The experimental data are unfortunately not available for comparison.

Kinetics of electron-transfer reactions of the $Co(bpyO_2)_3^{2+/3+}$ couple in acetonitrile

DONAL H. MACARTNEY[1] AND SAMUEL MAK
Department of Chemistry, Queen's University, Kingston, Ont., Canada K7L 3N6

Received June 25, 1991

DONAL H. MACARTNEY and SAMUEL MAK. Can. J. Chem. **70**, 39 (1992).

The kinetics of the outer-sphere electron transfer reactions of tris(1,1′-dioxo-2,2′-bipyridine)cobalt(II) and (III) with a series of nickel polyaza macrocycles, FeL_3^{n+} and OsL_3^{2+} complexes (L is 2,2′-bipyridine or 1,10-phenanthroline, and substituted derivatives), and $Rh_2(O_2CCH_3)_4(CH_3CN)_2^+$ have been investigated in acetonitrile at 25.0°C. An application of the Marcus theory relationship to the cross-reaction rate constants yielded apparent $Co(bpyO_2)_3^{2+/3+}$ self-exchange rate constants of 10^2 M^{-1} s^{-1} from the nickel macrocycle cross-reactions and 10^{-1} M^{-1} s^{-1} from the cross-reactions with the metal polypyridine complexes. The latter cross-reactions are considered to be non-adiabatic due to a mismatch in the donor/acceptor orbital symmetries. The electron exchange rate constant is compared with the exchange rate constants for other Co(II)/Co(III) complex couples and $M(bpyO_2)_3^{2+/3+}$ couples of other first-row transition metals, and discussed in terms of inner-sphere and solvent reorganization barriers.

Key words: electron transfer, Marcus theory relationship, cobalt(II)/(III) couples, 1,1′-dioxo-2,2′-bipyridine.

DONAL H. MACARTNEY et SAMUEL MAK. Can. J. Chem. **70**, 39 (1992).

Opérant en solution dans l'acétonitrile, à une température de 25°C, on a étudié la cinétique des réactions de transferts d'électrons de la sphère extérieure des tris(1,1′-dioxo-2,2′-biypridine)cobalt(II) ou (III) avec une série de macrocycles polyazotés de nickel, de complexes FeL_3^{n+} et OsL_3^{2+} (L = 2,2′-bipyridine ou 1,10-phénanthroline ainsi que leurs dérivés substitués) et du $Rh(O_2CCH_3)_4(CH_3CN)_2^+$. Une application de la relation de la théorie de Marcus aux sections efficaces des constantes de vitesse a permis d'évaluer les constantes de vitesse d'auto-échange apparentes du $Co(bpyO_2)_3^{2+/3+}$; en se basant sur les sections efficaces du nickel impliqué avec le macrocycle, cette valeur est égale à 10^2 M^{-1} s^{-1} alors qu'elle serait égale à 10^1 M^{-1} s^{-1} sur la base des sections efficaces des complexes métalliques de la polypyridine. On considère que ces dernières sections efficaces sont non-adiabatiques à cause du manque de similitude entre les symétries des orbitales donneur/accepteur. On a comparé la constante de vitesse de la réaction d'échange d'électrons avec celles d'autres couples de complexes Co(II)/Co(III) et d'autres couples $M(bpyO_2)_2^{2+/3+}$ d'autres métaux de transition de la première rangée et on en discute en fonction de la couche interne et des barrières à la réorganisation du solvant.

Mots clés : transfert d'électron, relation de la théorie de Marcus, couples cobalt (II)/cobalt (III), 1,1′-dioxo-2,2′-bipyridine.

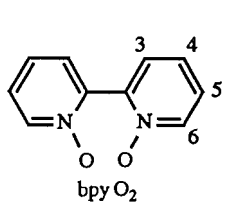
[Traduit par la rédaction]

Introduction

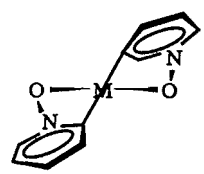
The relationship between the bimolecular electron self-exchange rate constants (k_{11}) for transition metal complex couples and the nature of the donor–acceptor orbitals ($d\pi$ or $d\sigma^*$) has been demonstrated through both experimental and theoretical investigations (1, 2). Relatively slow electron exchange rate constants are found for couples in which the transferring electron resides in an antibonding $d\sigma^*$ (e_g in octahedral symmetry), and substantial reorganization of the metal–ligand bond distances is required prior to electron exchange. Electron exchange in the majority of Co(II)/Co(III) complex couples involves a transfer of an electron between a high-spin $t_{2g}^5 e_g^{*2}$ Co(II) state and a low-spin $t_{2g}^6 e_g^{*0}$ Co(III) state (3). The self-exchange rate constants for the couples $Co(NH_3)_6^{2+/3+}$, $Co(en)_3^{2+/3+}$ (en = 1,2-diaminoethane), $Co(sep)^{2+/3+}$ (sep = 1,3,6,8,10,13,16,19-octaazabicyclo[6.6.6]eicosane), $Co(phen)_3^{2+/3+}$ (phen = 1,10-phenanthroline) are $\geq 10^{-7}$ M^{-1} s^{-1} (25°C) (4), 7.7×10^{-5} (25°C, I = 0.98 M) (5), 5.0 (25.0°C, I = 0.2 M) (6), and 12 M^{-1} s^{-1} (25°C, I = 0.10 M) (7), respectively.

With strong-field cyclic polythiaether ligands the cobalt(II) center is found in a low-spin $t_{2g}^6 e_g^{*1}$ electronic configuration and the reduction in the inner-sphere reorganization barrier results in a more rapid electron exchange. The electron self-exchange rate constant for the $Co([9]aneS_3)_2^{2+/3+}$ couple ([9]aneS$_3$ = 1,4,7-trithiacyclononane), for example, is 9.5×10^4 M^{-1} s^{-1} (25.0°C, I = 0.1 M) (5), while for the analogous $Co([9]aneN_3)_2^{2+/3+}$ couple ([9]aneN$_3$ = 1,4,7-triazacyclononane), involving a high-spin $Co([9]aneN_3)_2^{2+}$ species, $k_{11} = 8 \times 10^{-2}$ M^{-1} s^{-1} (25.0°C, I = 1.0 M) (8). Self-exchange rate constants in the range of 45–640 M^{-1} s^{-1} have also been determined for a series of low-spin $Co\{(dioxime)_3(BF)_2\}^{0/+}$ couples in acetonitrile (9).

The ligand 1,1′-dioxo-2,2′-bipyridine ($bpyO_2$) complexes a variety of transition metal ions (10–14), including cobalt(II) and cobalt(III) (10, 11, 13). This bidentate oxygen donor ligand forms a puckered seven-membered ring when coordinated to metal ion.



bpy O_2



For the past several years, investigations concerning the kinetics of electron transfer reactions of $M(bpyO_2)_3^{2+/3+}$ complex couples of cobalt, nickel, manganese, and iron have been carried out in our laboratory (15, 16). One aim of this work has been to compare the electron transfer behaviour of these complexes with that the analogous tris(2,2′-bipyridine) couples of these first-row transition metals. The *N*-oxidation of the 2,2′-bipyridine ligand results in a change of the donor atom, a weakening of the ligand field, and changes in the ligand π^*-metal t_{2g} overlap interactions.

In this paper we report the results of a kinetic study of the electron transfer reactions of $Co(bpyO_2)_3^{2+}$ and $Co(bpyO_2)_3^{3+}$ with a series of well-characterized nickel(III) polyaza macrocyclic complexes, FeL_3^{n+} and OsL_3^{2+} complexes (L is 2,2′-bipyridine or 1,10-phenanthroline, or substituted derivatives), and $Rh_2(O_2CCH_3)_4(CH_3CN)_2^+$, in acetonitrile containing 0.10 M tetraethylammonium perchlorate. The cross-reaction kinetic data are correlated in terms of the relationship from the Marcus theory (17), and the apparent self-exchange rate constant for the $Co(bpyO_2)_3^{2+/3+}$ couple in this medium has been estimated. The electron exchange rate constant for this couple is compared with those of other Co(II)/Co(III) complex couples and analogous $M(bpyO_2)_3^{2+/3+}$ couples, and discussed in terms of the inner- and outer-sphere barriers to electron exchange.

Experimental

Materials

Acetonitrile (BDH, OmniSolv) was used as received or dried with anhydrous sodium sulphate, filtered, and distilled from calcium hydride. The ligand 1,1′-dioxo-2,2′-bipyridine ($bpyO_2$) was prepared by a published method (11). ^1H NMR (CD_3CN) δ: 7.66 (d of d, 2H, H6), 7.02 (d of d, 2H, H3), 6.88 (t of d, 2H, H4), 6.85 (t of d, 2H, H5) with $J_{3,4}$ = 6.9 Hz, $J_{3,5}$ = 2.8 Hz, $J_{3,6}$ = 0.8 Hz, $J_{4,5}$ = 7.7 Hz, $J_{4,6}$ = 1.7 Hz, and $J_{5,6}$ = 5.9 Hz. Tris(1,1′-dioxo-2,2′-bipyridine)cobalt(II) perchlorate, $[Co(bpyO_2)_3](ClO_4)_2 \cdot 2H_2O$, was prepared from $Co(ClO_4)_2 \cdot 6H_2O$ (Alfa) and $bpyO_2$ in hot aqueous solution (11) and recrystallized from water. Anal. calcd. for $CoC_{30}H_{24}N_6O_{14}Cl_2 \cdot 2H_2O$: C 41.97, H 3.28, N 9.79; found: C 42.42, H 3.06, N 9.82.

The $[Co(bpyO_2)_3](ClO_4)_3$ complex was prepared by the electrochemical oxidation of $Co(bpyO_2)_3^{2+}$ in acetonitrile (containing 0.10 M tetraethylammonium perchlorate) at 0°C. The electrolysis was carried out in a H-shaped three-compartment cell containing platinum electrodes. A green solid, precipitated by concentration of acetonitrile solution, was washed with cold acetonitrile and dried under vacuum. Anal. calcd. for $CoC_{30}H_{24}N_6O_{18}Cl_3$: C 39.09, H 2.62, N 9.19; found: C 37.68, H 2.83, N 8.58. Elemental analyses were performed by Canadian Microanalytical Service, Delta, B.C. **Caution: Perchlorate salts of metal complexes with organic ligands are potentially explosive and should be prepared in small quantities and handled with care.**

The nickel(II) polyaza macrocycles: $Ni([14]aneN_4)^{2+}$ ([14]$aneN_4$ = 1,4,8,11-tetraazacyclotetradecane) (18), $Ni(rac\text{-}Me_6[14]aneN_4)^{2+}$ (*rac*-Me_6[14]$aneN_4$ = *rac*-5,7,7,12,12,14-hexamethyl-1,4,8,11-tetraazacyclotetradecane) (19), $Ni(Me_6[14]dieneN_4)^{2+}$ (Me_6[14]-$dieneN_4$ = 5,7,7,12,14,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene) (20), and $Ni([9]aneN_3)_2^{2+}$ ([9]$aneN_3$ = 1,4,7-triazacyclononane) (21) were prepared as perchlorate salts as described previously. The FeL_3^{2+} and OsL_3^{2+} (L is 2,2′-bipyridine or 1,10-phenanthroline, or substituted derivatives) complexes were prepared by reported synthetic procedures (22) and isolated as perchlorate salts. The analogous iron(III) complexes were prepared by an electrochemical oxidation of corresponding iron(II) species in acetonitrile as described above for $Co(bpyO_2)_3^{3+}$. Dirhodium(II) tetraacetate was prepared by a reported method (23).

Tetraethylammonium perchlorate (TEAP) was prepared by the metathesis of the tetraethylammonium bromide (BDH) with perchloric acid, recrystallized from water several times, and dried at 100°C for 24 h. Tetraethylammonium tetrafluoroborate was prepared and purified in a similar manner, using fluoroboric acid. Tetraethylammonium *p*-toluenesulphonate (Aldrich) was recrystallized twice from ethyl acetate and dried.

Kinetic experiments

The kinetic measurements were made using a TDI model IIA stopped-flow apparatus (Cantech Scientific) and data acquisition system interfaced to a Zenith ZF-151 microcomputer. Pseudo-first-order conditions of excess $Co(bpyO_2)_3^{n+}$ reductant or oxidant were employed and plots of $\ln(A_\infty - A_t)$ or $\ln(A_t - A_\infty)$ against time were linear for at least 3 half-lives. The first-order rate constants were determined from the average of four to six replicate experiments (Supplementary Material[2]). The reactions were conducted in acetonitrile, usually containing 0.10 M TEAP, at a temperature maintained at 25.0 ± 0.1°C by means of an external circulating water bath.

Physical and spectroscopic measurements

The cyclic voltammetric measurements were carried out in acetonitrile (0.10 M TEAP) with a BAS CV-1B cyclic voltammograph (Bioanalytical Systems) attached to a Houston Instruments 100 X–Y recorder. The working (Pt button) and auxilliary (Pt wire) electrodes in the sample solution were separated from the reference electrode (Ag/AgCl) by a glass frit. The ferricinium/ferrocene couple, $Fe(Cp)_2^{+/0}$, (+0.400 V vs. NHE 24)) was used as an internal reference. UV–visible spectra were measured on a Hewlett–Packard 8452A diode-array spectrophotometer. The ^1H NMR spectra were recorded on a Bruker AM-400 instrument operating at 400 MHz, and ^1H–^1H COSY spectra were obtained using Bruker software.

Results

^1H NMR and electronic spectra

The trischelate complex $Co(bpyO_2)_2^{3+}$ would theoretically exist in four diastereomers, each of which has a pair of enantiomers: Λ(δδδ) (= Δ(λλλ)), Λ(δδλ) (= Δ(λλδ)), Λ(δλλ) (= Δ(λδδ)), and Λ(λλλ) (= Δ(δδδ)). An examination of space-filling models of each of the diastereomers (considering only the Λ isomers) reveals that from a consideration of non-bonding interactions a stability order of Λ(δδδ) > Λ(δδλ) >> Λ(δλλ) >> Λ(λλλ) would be expected. The repulsive interactions that emerge upon conversions of δ to λ $bpyO_2$ ligand skew conformations take the form of a H6 proton on one $bpyO_2$ ligand interacting with the plane of a pyridine on another $bpyO_2$ ligand.

The ^1H NMR spectrum of the $Co(bpyO_2)_3^{3+}$ ion in CD_3CN revealed the presence of two of the four potential stereoisomers, which have been identified as Λ(δδδ) and Λ(δδλ) (along with the corresponding enantiomorphs) from one-dimensional ^1H and two-dimensional ^1H–^1H COSY NMR experiments (Fig. 1). The integration of the assigned peaks indicates that the Λ(δδλ) isomer is found in a slightly greater amount than the Λ(δδδ) isomer in acetonitrile at 25°C. A statistical entropy factor would favour the formation of Λ(δδλ) over Λ(δδδ) and this likely compensates for the greater steric instability of the Λ(δδλ) isomer (25).

In the Λ(δδδ) isomer the respective protons on the three $bpyO_2$ rings are equivalent, while on the Λ(δδλ) isomer there are three different pyridine ring types. The first set of protons (H′) are found on the unique λ $bpyO_2$ ligand. By converting a $bpyO_2$ ring from the δ to λ skew, the H6′ protons on the λ ligand are now placed over one of the pyridine rings on each of the other two δ $bpyO_2$ ligands, which form the second set (H″). The protons on the other pyridine ring on the δ $bpyO_2$ ligands form the third set (H‴). The H6′ and H5′ proton resonances are found at 6.48 and 7.67 ppm, respectively, shifted considerably upfield from H6 (9.40) and H5 (8.07) in the Λ(δδδ) isomer, due to the shielding of the aromatic ring (26). The shifts calculated by using the Johnson–

[2]Tables of kinetic data may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2.

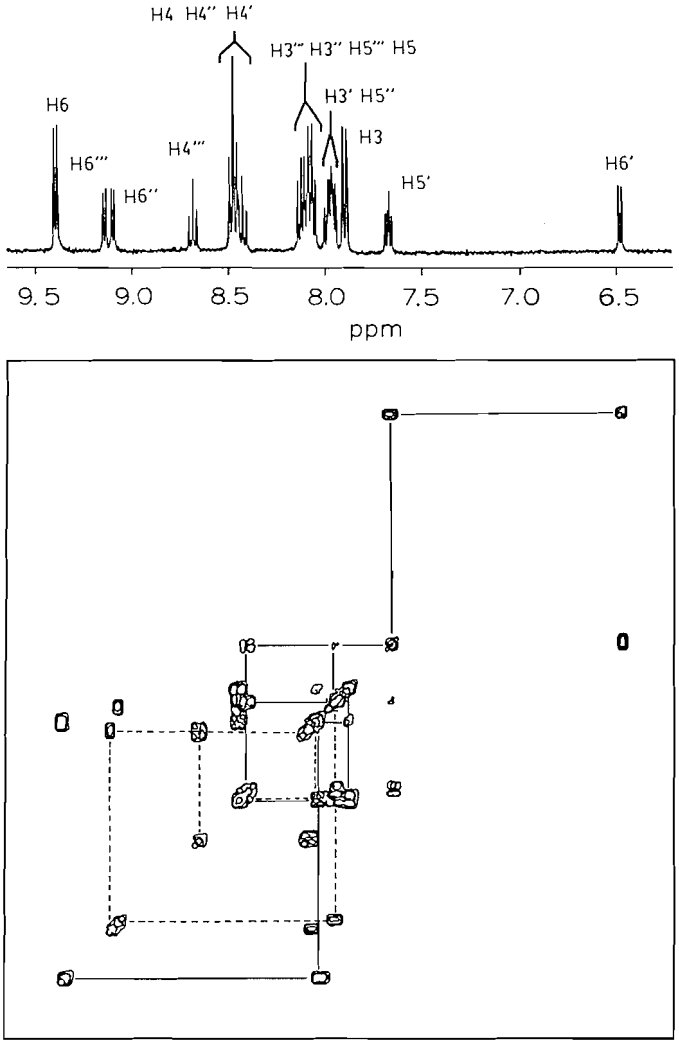

FIG. 1. ^1H–^1H COSY NMR spectrum of $Co(bpyO_2)_3^{3+}$ in CD_3CN. The connections between protons are indicated below the diagonal for the H (——) and H'' (– – –) protons and above the diagonal for the H' (——) and H''' (– – –) protons.

Bovey equation (26, 27) for the H5' (z = 3.50 and ρ = 0.8) and H6' (z = 1.75 and ρ = 0.0) protons on the basis of shielding contributions from the aromatic ring currents, by using the positions of the protons in the space-filling models, are in excellent agreement with the observed values.

The visible spectra of the $Co(bpyO_2)_3^{2+}$ and $Co(bpyO_2)_3^{3+}$ ions in acetonitrile are presented in Fig. 2. For the $Co(bpyO_2)_3^{2+}$ the maxima are found at 509 nm (ϵ = 140 M^{-1} cm^{-1}) and 552 nm (ϵ = 200 M^{-1} cm^{-1}), similar to the spectrum reported for the ion in nitromethane (12). The bands have been assigned to $^4T_{1g}(F) \rightarrow {}^4A_{2g}(F)$ and $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transitions, respectively, and a D_q value of 1004 cm^{-1} has been reported (14). For the $Co(bpyO_2)_3^{3+}$ ion the visible maxima are found at 498 nm (ϵ = 225 M^{-1} cm^{-1}) and 676 nm (ϵ = 230 M^{-1} cm^{-1}, shoulder at 740 nm) and have been assigned to $^1A_{1g} \rightarrow {}^1T_{2g}$ and $^1A_{1g} \rightarrow {}^1T_{1g}$ transitions, respectively. From the asymmetric shapes of the peaks it is likely that the spectrum contains transitions for both the δδδ and δδλ isomers. A similar spectrum has been reported for the $Co(bpyO_2)_3^{3+}$ ion in aqueous media, with maxima at 466 and 671 nm, and D_q calculated to be 1560 cm^{-1} (13).

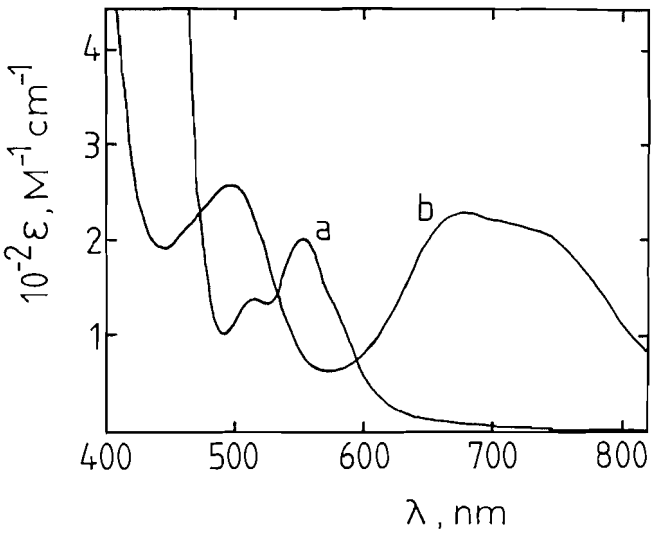

FIG. 2. Visible spectra of the (a) $Co(bpyO_2)_3^{2+}$ and (b) $Co(bpyO_2)_3^{3+}$ complexes in acetonitrile.

The reduction potential of the $Co(bpyO_2)_3^{3+}/Co(bpyO_2)_3^{2+}$ couple in acetonitrile containing 0.10 M TEAP was determined by cyclic voltammetry measurements. A quasi-reversible couple (ΔE_p = 80 mV) was observed with $E_{1/2}$ = 0.53 V vs. the $FeCp^+/FeCp$ internal reference. The reduction potentials of the cross-reactants used in this study were measured in the same medium and were found to be in good agreement with previously reported values in acetonitrile and (or) aqueous solution (28–31).

Kinetics studies

The electron transfer cross-reactions of $Co(bpyO_2)_3^{2+}$ and $Co(bpyO_2)_3^{3+}$ were carried out at 25.0°C in acetonitrile containing 0.10 M tetraethylammonium perchlorate (TEAP).

$$[1] \quad Co(bpyO_2)_3^{2+} + \text{oxidant} \overset{k_{12}}{\rightleftharpoons} Co(bpyO_2)_3^{3+} + \text{reductant}$$

The kinetics of the oxidations of the $Co(bpyO_2)_3^{2+}$ ion with a series of FeL_3^{3+} complexes (L = 2,2'-bipyridine or 1,10-phenanthroline or substituted derivatives) were monitored at the visible maximum of the FeL_3^{2+} species in the range of 510–530 nm. Using a pseudo-first-order excess of the reductant ((1–10) × 10^{-4} M) the kinetics followed the expression in eq. [2],

$$[2] \quad \frac{d[FeL_3^{2+}]}{dt} = k_{obs}[FeL_3^{3+}]$$

where $k_{obs} = k_{12}[Co(bpyO_2)_3^{2+}]$. Likewise for the reductions of $Co(bpyO_2)_3^{3+}$ by FeL_3^{2+} and OsL_3^{2+}, first-order dependences of k_{obs} on the pseudo-first-order excess concentrations of the $Co(bpyO_2)_3^{3+}$ were found. The reactions between $Co(bpyO_2)_3^{2+}$ and the nickel(III) polyaza macrocycles were followed by monitoring the disappearance of the oxidant at its maximum in the region of 300–400 nm, employing pseudo-first-order excess concentrations of the reductant. The kinetics of the oxidation of $Co(bpyO_2)_3^{2+}$ by $Rh_2(O_2CCH_3)_4(CH_3CN)_2^+$ were carried out under pseudo-first-order conditions of excess concentrations of the dirhodium cation, following the disappearance of the reductant at 410 nm. First-order plots for representatives of each group of cross-reaction are presented in Fig. 3. The second-order

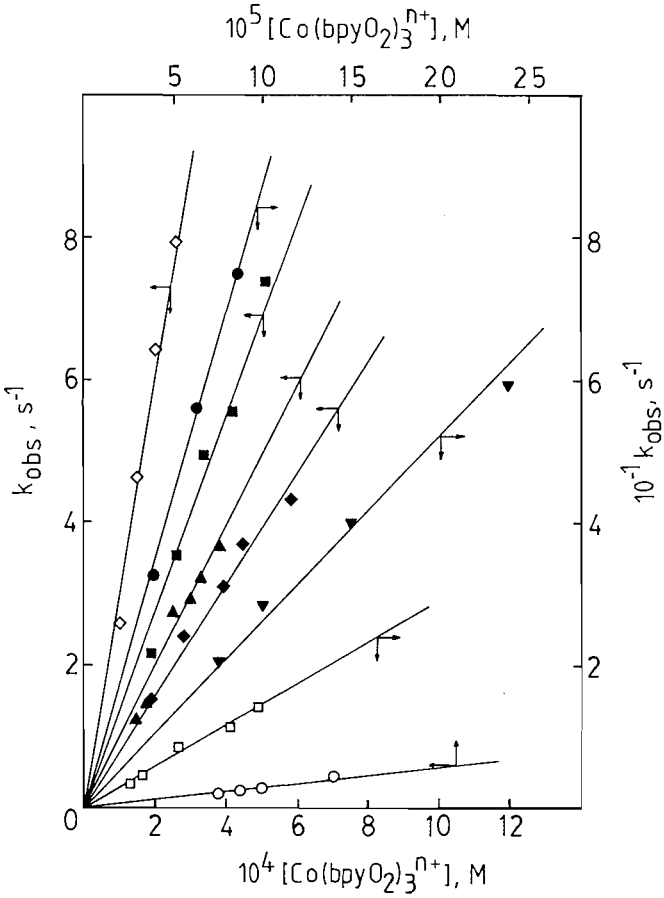

FIG. 3. Dependences of k_{obs} on $[Co(bpyO_2)_3^{n+}]$ for the oxidations of $Co(bpyO_2)_3^{2+}$ by $Fe(Cl\text{-}phen)_3^{3+}$ (●), $Fe(bpy)_3^{3+}$ (■), $Fe(5,6\text{-}Me_2phen)_3^{3+}$ (▲), $Ni(Me_6[14]dieneN_4)^{3+}$ (◆), and $Rh_2(O_2CCH_3)_4(CH_3CN)_2^{+}$ (▼, abscissa is $10^4[Rh_2^{+}]$), and the reductions of $Co(bpyO_2)_3^{3+}$ by $Os(5\text{-}Clphen)_3^{2+}$ (◇), $Os(phen)_3^{2+}$ (□), and $Fe(4,4'\text{-}Me_2bpy)_3^{2+}$ (○) in acetonitrile (0.10 M TEAP) at 25.0°C.

rate constants, k_{12}, for the cross-reactions in this study at 25.0°C are presented in Table 1.

For the $Co(bpyO_2)_3^{2+}/Fe(phen)_2^{3+}$ cross-reaction, determinations of the rate constant as a function of electrolyte concentration and the nature of the anion, using tetraethylammonium salts of ClO_4^-, BF_4^-, and *p*-tosylate (TEAX) as the electrolyte, were undertaken (Supplementary Material[2]). The rate constant increased with increasing concentration of electrolyte, with curvature towards a limiting value above 0.05 M TEAX. The rate constants at 0.01 and 0.10 M TEAX were 1.2×10^4 and 1.7×10^4 M^{-1} s^{-1} for $X^- = ClO_4^-$, 0.65×10^4 and 2.3×10^4 M^{-1} s^{-1} for $X^- = BF_4^-$, and 1.8×10^5 and 3.5×10^5 M^{-1} s^{-1} for X^- = *p*-tosylate, respectively.

An attempt was made to measure the electron self-exchange rate constant k_{11} for the $Co(bpyO_2)_3^{2+/3+}$ by using ^1H NMR line-broadening experiments.

[3] $Co(bpyO_2)_3^{2+} + Co(bpyO_2)_3^{3+} \overset{k_{11}}{\rightleftharpoons} Co(bpyO_2)_3^{3+} + Co(bpyO_2)_3^{2+}$

The addition of the paramagnetic $Co(bpyO_2)_3^{2+}$ ion ($\approx 1 \times 10^{-3}$ M, limited by its solubility) to a solution of the diamagnetic $Co(bpyO_2)_3^{3+}$ ion in CD_3CN at 25°C resulted in no discernible increase in the linewidths of the proton resonances. Using the equation for electron exchange in the slow-exchange domain (33): $k_{11}[Co(II)] = \pi(W_{DP} - W_D)$, where $W_{DP} - W_D$ is the difference in the linewidths of the diamagnetic resonances in the presence and the absence of the paramagnetic species, an upper limit of $k_{11} < 600$ M^{-1} s^{-1} is estimated, using $W_{DP} - W_D < 0.2$ Hz.

Discussion

The electron self-exchange rate constant for the $Co(bpyO_2)_3^{2+/3+}$ couple in acetonitrile is anticipated to be moderately small because the transfer involves changes in the population of the antibonding e_g^* orbitals and a change in the spin configuration from high-spin Co(II) (t_{2g}^5 e_g^{*2}) to low-spin Co(III) (t_{2g}^6 e_g^{*0}). The electron self-exchange rate constants for a number of transition metal complex couples have been predicted with reasonable success by using the semiclassical model for bimolecular electron exchange (1). The rate constant k_{11} may be expressed as the product of a preequilibrium constant K_A, an effective nuclear frequency ν_n, and electronic factor κ_{el}, and a nuclear factor that contains terms for both inner-sphere (ΔG_{in}^*) and solvent reorganizations (ΔG_{out}^*) as well as an inner-sphere nuclear tunneling factor Γ_n:

[4] $$k_{11} = K_A \nu_n \kappa_{el} \Gamma_n \exp[-(\Delta G_{in}^* + \Delta G_{out}^*)/RT]$$

The inner-sphere term, ΔG_{in}^*, corresponds to the reorganization of bond distances and angles required prior to electron transfer, and the outer-sphere term, ΔG_{out}^*, is the energy needed to change the orientations of the solvent molecules surrounding the reactants. The ΔG_{in}^* may be calculated with a knowledge of the bond distances and angles and vibrational frequencies and force constants for the two redox partners:

[5] $$\Delta G_{in}^* = \frac{1}{2} \sum f_i [\Delta d_0)_i/2]^2$$

While crystal structure determinations have not been reported for complexes containing either the $Co(bpyO_2)_3^{2+}$ or $Co(bpyO_2)_2^{3+}$ ion, the difference in the Co—O bond lengths between the two oxidation states is likely to fall in the range of 0.17–0.21 Å observed for other high-spin Co(II)/low-spin Co(III) complex couples, such as those mentioned in the Introduction. If it is assumed that f_i (34)[3] and Δd_0 for the $Co(bpyO_2)_3^{2+/3+}$ couple are similar to those for the $Co(bpy)_3^{2+/3+}$ couple ($\Delta d_0 = 0.19$ Å (2)), the difference in the electron exchange rate constants between the two couples would primarily reside in ΔG_{out}^* and K_A. With these two terms, it is calculated that the self-exchange rate constant for the $Co(bpyO_2)_3^{2+/3+}$ couple in acetonitrile would be about two or three times greater that the value for the $Co(bpy)_3^{2+/3+}$ exchange (20 M^{-1} s^{-1} (I = 0.1 M) (35)) in aqueous solution.

The cross-reaction kinetic data from this study may be correlated in terms of the Marcus equation (17), which relates the rate constant for a cross-reaction, k_{12}, to the rate constants for the component self-exchange reactions, k_{11} and

[3] A value of f_i = 169–176 N m^{-1} has been calculated for the $Co(bpy)_2^{2+/3+}$ couple (2, 34*a* (footnote 50)), and a value of 180 N m^{-1} is estimated for the $Co(bpyO_2)_3^{2+/3+}$ couple on the basis of Co—O stretching frequency for $Co(pyrO)_6^{2+}$ (34*b*).

k_{22}, and the equilibrium constant for the cross reaction K_{12} by eq. [6] (1*a*),

$$[6] \quad k_{12} = (k_{11}k_{22}K_{12}f_{12})^{1/2}W_{12}$$

where

$$[7] \quad \ln(f_{12}) = \frac{[\ln K_{12} + (w_{12} - w_{21})/RT]^2}{4\left[\ln\left(\frac{k_{11}k_{22}}{A_{11}A_{22}}\right) + \frac{w_{11} + w_{22}}{RT}\right]}$$

$$[8] \quad W_{12} = \exp[-(w_{12} + w_{21} - w_{11} - w_{22})/2RT]$$

$$[9] \quad w_{ij} = \frac{z_i z_j e^2}{D_s\sigma_{ij}(1 + \beta\sigma_{ij}I^{1/2})}$$

In the above expressions w_{ij} is the work required to bring ions i and j (charges z_i and z_j) to the separation distance σ_{ij} (taken equal to the sum of the radii of the ions), D_s is the static dielectric constant of the medium, $\beta = (8\pi Ne^2/1000D_skT)^{1/2}$, and $A_{ii} = (4\pi N\sigma_{ii}^2\nu_n(\delta r)/1000)_{ii}$, where δr is the thickness of the reaction shell ($\approx$ 0.8 Å). The values of D_s and β are 37.5 and 0.476 $M^{-1/2}$ $Å^{-1}$, respectively, for acetonitrile at 25°C. In the calculations of the work terms, radii of 8 Å for $Co(bpyO_2)_3^{n+}$, 7–8 Å for the iron and osmium complexes, 5.5 Å for $Rh_2(O_2CCH_3)_4(CH_3CN)_2^+$, and 5–7 Å for the nickel polyaza macrocycles, were employed.

The self-exchange rate constants of the nickel polyaaza macrocycle complexes used in the cross-reactions were determined by an application of the Marcus relationship to the kinetic data from reactions with other nickel complexes and iron or ruthenium tris(polypyridine) complexes in a previous study (16, 31). The self-exchange rate constants for the remainder of cross-reactants (in acetonitrile) were also determined previously from direct measurements or by the application of the Marcus relationship (31, 32).

From the results of several recent kinetic investigations of electron-exchange (9, 31, 36–40) and electron-transfer reactions of metal complexes in acetonitrile, it is becoming evident that ion pairing (and perhaps ion triplets) plays a major role in the rates of outer-sphere processes and their dependence on ionic strength in this medium. At an ionic strength of 0.10 M, ion pairing of the ClO_4^- ion with the cationic metal complexes used in this study is expected to be extensive. Conductivity measurements on the ion pairing between the ClO_4^- ion and ML_3^{2+}, ML_3^{3+} (L = polypyridine ligand) (40), and $Ni([14]aneN_4)^{2+}$ (41), in acetonitrile have yielded ion-pair association constants of <100, 170–900, and 190 M^{-1}, respectively. The observed dependence of k_{12} on the ionic strength and the nature of the anion in the reaction of $Co(bpyO_2)_3^{2+}$ with $Fe(phen)_3^{3+}$ is consistent with previous kinetic studies of electron transfer reactions between cationic complexes in acetonitrile (31, 32, 37). The analysis of these electrolyte dependences in terms of definitive ion-pair association constants and specific rate constants for free and ion-paired species is not simple (38, 40), and is beyond the scope of the present study. For the purposes of calculating the work-term parameters the trivalent metal oxidants are considered to be fully ion-paired (e.g., $\{ML_3,ClO_4\}^{2+}$). With the majority of the cross-reactions involving formally 2+/"2+" charge types, the terms w_{ij} in eq. [8] tend to cancel each other, such that W_{12} is not far from unity.

The electron transfer kinetic data in Table 1 have been correlated with the thermodynamic driving forces for the cross-reactions and presented in Fig. 4 as a plot of $\ln(k_{12}/k_{22}^{1/2}W_{12})$ against $\ln(K_{12}f_{12})^{1/2}$. From eq. [6], the slope and intercept of the plot are expected to be unity and $\frac{1}{2}\ln(k_{11})$, respectively. The points in Fig. 4 fall primarily on two lines, with the cross-reactions involving the nickel macrocycles forming one group and the remainder of the cross-reactants, primarily tris(polypyridine)metal complexes, the other group. The k_{11} values obtained from the cross-reactions involving the nickel macrocycles have a mean value of about 10^2 M^{-1} s^{-1}, while k_{11} calculated from the metal

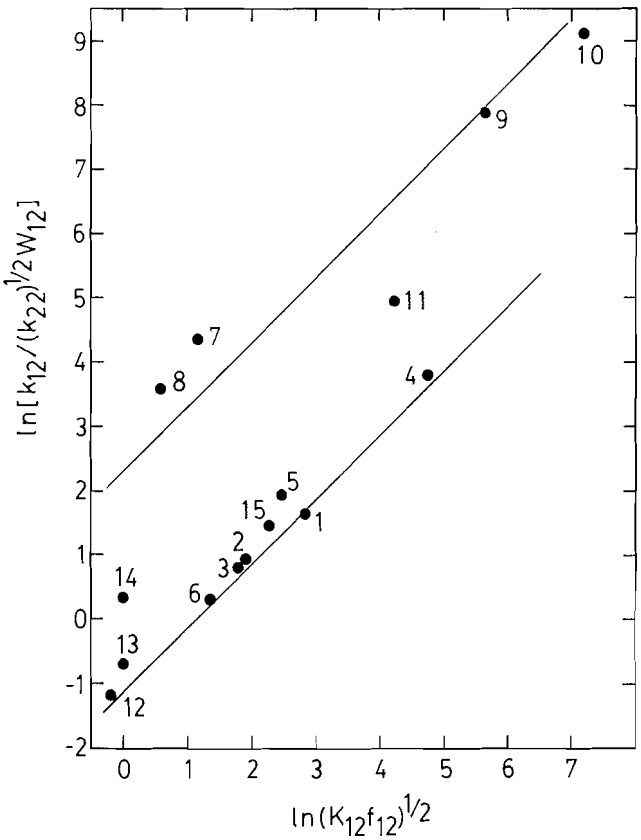

FIG. 4. Marcus correlation of $\ln[k_{12}/(k_{22})^{1/2}W_{12}]$ against $\ln(K_{12}f_{12})^{1/2}$ for the cross-reactions of the $Co(bpyO_2)_3^{2+/3+}$ couple in acetonitrile (I = 0.10 M). The reactions are numbered as in Table 1. The upper line corresponds to a value of k_{11} for the $Co(bpyO_2)_3^{2+/3+}$ couple of 10^2 M^{-1} s^{-1}, while the lower line corresponds to k_{11} = 10^{-1} M^{-1} s^{-1}.

tris(polypyridine) cross-reaction data are close to 10^{-1} M^{-1} s^{-1}. The k_{11} value obtained from the reaction with $Rh_2(O_2CCH_3)_4(CH_3CN)_2^+$, 4 M^{-1} s^{-1}, falls between these two groups. The ^1H NMR line-broadening experiment places k_{11} at less than 600 M^{-1} s^{-1}.

It has recently been suggested that cross-reactions of tris(polypyridine) complexes of Co(III) with Ru(II) amines are non-adiabatic (42), while those with tris(polypyridine)chromium(II) complexes are marginally non-adiabatic (43). From the present study it appears that the cross-reactions of the $Co(bpyO_2)_3^{2+/3+}$ couple with the tris(polypyridine) complexes of iron and osmium are non-adiabatic. We previously observed that significantly lower self-exchange rate constants are derived for high-spin Mn(II)/Mn(III) complex couples when metal tris(polypyridine) cross-reactants are employed, compared to the values obtained from reactions with the nickel macrocycles. These couples have included $Mn(H_2O)_6^{2+/3+}$ (44) and $Mn(edta)^{2-/-}$ ($edta^{4-}$ = ethylenediaminetetraacetate) (45) in aqueous solution and $Mn(urea)_6^{2+/3+}$ (46) in acetonitrile. The electron exchange pathway in the $M(bpy)_3^{2+/3+}$ complexes of Fe, Ru, and Os involves the t_{2g} orbitals and overlap with the π^* ligand orbitals. The exchange pathway of the Mn(II)/Mn(III), Co(II)/Co(III), and Ni(II)/Ni(III) couples involves the antibonding e_g^* orbitals. The incompatibility of the donor and acceptor orbital symmetries in the $Co(bpyO_2)_3/M(bpy)_3$ cross-reactions may account for the lower self-exchange rate constants derived for the $Co(bpyO_2)_3^{2+/3+}$ couple from these cross-reactions rather than from the reactions involving the nickel(II) macrocycles. Electron exchange and electron transfer reactions of the $Rh_2(O_2CCH_3)_4(CH_3CN)_2^{0/+}$ couple involve a weakly antibonding Rh—Rh π^* orbital and exhibit similar cross-reaction behaviour towards both nickel macrocycles and metal polypyridine complexes (31). It is perhaps not surprising, therefore, that the cross-reaction with $Co(bpyO_2)_3^{2+}$ yields a k_{11} value between those of the other two sets of reactants.

The self-exchange rate constant derived in this study for the $Co(bpyO_2)_3^{2+}/Co(bpyO_2)_3^{3+}$ couple may be compared with the value of 10^2 M^{-1} s^{-1} determined for the $Mn(bpyO_2)_3^{2+}/Mn(bpyO_2)_3^{3+}$ couple in acetonitrile (ref. 15, manuscript in preparation). The exchange process for this high-spin d^5/d^4 couple also involves the transfer of an antibonding e_g^* electron, as does exchange in the d^8/d^7 $Ni(bpyO_2)_3^{2+/3+}$ couple, for which an estimate of $k_{11} \approx 10^3$ M^{-1} s^{-1} (16) has been made from cross-reactions with tris(polypyridine)nickel(III) complexes in acetonitrile (16). Kinetic studies of the cross-reactions of the high-spin d^6/d^5 $Fe(bpyO_2)_3^{2+/3+}$ couple with tris(polypyridine)cobalt(II) and (III) complexes in acetonitrile are in progress and preliminary results (16) suggest an exchange rate constant of 10^6–10^7 M^{-1} s^{-1}, consistent with the lower inner-sphere reorganization barrier associated with the transfer of a nonbonding t_{2g} electron.

SUDHINDRA N. MISRA and SHAUN O. SOMMERER, Can. J. Chem. **70**, 46 (1992).

The absorption difference, comparative absorption spectrophotometry, and quantitative analysis of 4*f*–4*f* spectra of praseodymium(III) complexes with ligands possessing varying structural features and binding capabilities have clearly indicated that the $^3H_4 \rightarrow {}^3P_2$, $^3H_4 \rightarrow {}^3P_1$, $^3H_4 \rightarrow {}^3P_0$, and $^3H_4 \rightarrow {}^1D_2$ transitions exhibit substantial intensification as well as a wide variation of oscillator strength. Since these transitions do not follow the selection rules they cannot be considered hypersensitive. Ligands such as β-diketones, Schiff bases, amino acids, diols, nucleic bases, nucleosides, nucleotides, alkoxides, and haloacetates with widely differing binding features in terms of coordinating ability, denticity, and normalized bite appear to induce, to varying degrees, high sensitivity in these non-hypersensitive transitions. The present article reports the high sensitivity of the $^3H_4 \rightarrow {}^3P_2$, $^3P_1$, $^3P_0$, and $^1D_2$ transitions of Pr(III) by considering the solution spectra of 173 species. This unique sensitivity is termed Ligand Mediated Pseudohypersensitivity.

Key words: praseodymium(III), 4*f*–4*f* transitions, hypersensitive transitions.

SUDHINDRA N. MISRA et SHAUN O. SOMMERER. Can. J. Chem. **70**, 46 (1992).

Les différences d'absorption, la spectrométrie d'absorption comparative et des analyses quantitatives des spectres 4*f*–4*f* de complexes du praséodyme(III) avec des ligands possédant diverses caractéristiques spectrales et diverses capacités de liaison indiquent clairement que les transitions $^3H_4 \rightarrow {}^3P_2$, $^3H_4 \rightarrow {}^3P_1$, $^3H_4 \rightarrow {}^3P_0$ et $^3H_4 \rightarrow {}^1D_2$ présentent une intensification importante ainsi que de grandes variations de la force de leur oscillateur. Puisque ces transitions ne suivent pas les règles de sélection, on ne peut les considérer comme hypersensibles. Des coordinats, comme des β-dicétones, des bases de Schiff, des acides aminés, des diols, des bases nucléiques, des nucléosides, des nucléotides, des alcoolates et des halogénoacétates qui possèdent des caractéristiques de liaison très différentes en termes de facilité de coordination, de «denticité» et de «prise» normalisée, semblent induire des sensibilités variables dans ces transitions non-hypertensives. Dans le présent travail, on a examiné la grande sensibilité des transitions $^3H_4 \rightarrow {}^3P_2$, $^3P_1$, $^3P_0$ et $^1D_2$ du Pr(III) en considérant les spectres en solution de 173 espèces. Cette sensibilité unique est appelée «pseudohypersensibilité obtenue par l'intermédiaire des coordinats».

Mots clés : praséodyme(III), transitions 4*f*–4*f*, transitions hypersensibles.

[Traduit par la rédaction]

Introduction

The intensity of hypersensitive transitions (1–3) has been used extensively to distinguish between outer and inner sphere coordination, in identifying the coordinating sites of ligands (4), in determining the immediate coordination environment, and in predicting the coordination number of lanthanides (5–10). Hypersensitivity has attracted much attention even though theories proposed to explain the phenomenon are far from quantitative. The majority of the quantitative work on these intensities has been done in the solid state (11–16) though a few of the studies have involved solution spectra (5–10). Due to phenomenon such as isomerization, dissociation, association, solvolysis, etc., the solution spectra can become quite complex, which in turn causes the data to become only approximate and the reproducibility of the experiment to become questionable. A new dimension to lanthanide coordination chemistry in solution has come of age with the increased use of lanthanides as probes in the exploration of the structural functions of biomolecular reactions (17–20). Moreover, the use of lanthanide hypersensitive bands as marker bands has increased the importance of solution spectra.

The quantitative analysis of the spectral data for Pr(III) complexes with a wide variety of ligands has clearly shown that hypersensitivity cannot be restricted to specific transitions only, but may under certain chemical conditions be extended to non-hypersensitive transitions as well. On the basis of 173 spectra of Pr(III) complexes, the high sensitivity of the $^3H_4 \rightarrow {}^3P_2$, $^3H_4 \rightarrow {}^3P_1$, $^3H_4 \rightarrow {}^3P_0$, and $^3H_4 \rightarrow {}^1D_2$ transitions (all pseudohypersensitive (21)) is reported and termed Ligand Mediated Pseudohypersensitivity.

Experimental

The spectral absorption studies were recorded on Shimadzu 260FS and Perkin Elmer Lambda-2 spectrophotometers. The regions of the pseudohypersensitive transitions were resolved and recorded in an expanded scale mode. All solutions were prepared from reagent grade materials.

The linear curve analysis of the absorption spectra followed by a Gaussian curve analysis of the individual bands led to the computation of the absorption spectral parameters: Slater–Condon F_k — Racah E^k — Coulombic interaction, Lande's ξ 4*f* spin-orbit interaction, nephelauxetic β bonding (*b*), and covalency parameters. The intensity parameter *P* (oscillator strength) and the Judd–

Ofelt T_λ parameters were computed by partial and multiple regression methods on a HP-1000/45 computer (17, 21).

Results and discussion

Pr(III) (f^2) is the simplest tervalent lanthanide ion, yet it has not been extensively investigated when compared to Nd(III) (f^3) and Eu(III) (f^6). One possible reason may be that Judd–Ofelt (22, 23) theory does not work very well for Pr(III) nor does the calculation of oscillator strengths evidenced by the high RMS deviations. The $^3P_2 \leftarrow {}^3H_4$ transition of Pr(III) is hypersensitive, occurring at 5200 cm^{-1}, and is not generally studied in solution spectral investigations. Peacock (24) found that the $^3P_2 \leftarrow {}^3H_4$ and $^1D_2 \leftarrow {}^3H_2$ transitions of Pr(III) showed significant sensitivity and referred to them as pseudohypersensitive transitions. Siddall and Stewart (25) reported the hypersensitivity of the $^1I_6 \leftarrow {}^3H_4$ transition, which was contested by Peacock (24). To explain the anomalous behavior of Pr(III), Carnall *et al.* (26) together with Weber (27) put forward a theory in which certain assumptions made in Judd–Ofelt theory were considered to be invalid, in particular the assumption that the perturbation configurations are degenerate and lie at a higher energy level than $4f - 4f$ transitions. They also found that inclusion of the odd parts of the intensity expression improves the interpretation of Pr(III) absorption spectral intensities slightly. Using this method one finds that the $^3P_{2,1,0} \leftarrow {}^3H_4$ multiplets have $\lambda = 5$ reduced matrix values of 0.283, 0.502, and 0.0 respectively. If this is correct, the discrepancies in the oscillator strength would be more pronounced in the $^3P_1 \leftarrow {}^3H_4$ transition as the reduced matrix element has a higher value than that for $^3P_2 \leftarrow {}^3H_4$. Since this is not observed, the hypersensitivity of the $^3P_2 \leftarrow {}^3H_4$ transition observed by Peacock (24) cannot be explained by this argument.

The T_2 parameter, which is considered to be extremely sensitive towards even minor changes in the immediate coordination environment, is found generally to be negative in value (17, 21, 24). This is reasonable as only the $^3F_2 \leftarrow {}^3H_4$ transition has a significant **U** (2) matrix element but this has not been included in the data set of any of the compounds studied in solution (28, 29, 31). In Pr(III) the variation of the T_6 parameter appears to be related to changes in the immediate coordination sphere around Pr (Table 1).

There has been some difficulty in obtaining a good fit between the observed and calculated oscillator strength of the f–f transitions. Our method, however, of using partial and multiple regression has yielded quite satisfactory results for the $^3P_2 \leftarrow {}^3H_4$ and $^1D_2 \leftarrow {}^3H_4$ transitions while it marginally overestimates values for $^3P_1 \leftarrow {}^3H_4$ and underestimates the values for $^3P_0 \leftarrow {}^3H_4$ transitions (17, 21, 33). The RMS deviations in the oscillator strength values computed by our method were much smaller than those observed by Peacock (24).

An examination of Carnall's coefficients for **U** (2) shows that these are nearly the same for the $^3P_0$ and $^3P_1$ bands; consequently these bands should show the same strengths. One observes, however, that the intensity of the $^3P_1$ band is higher than that of $^3P_0$. There are two possible ways of making the oscillator strengths of $^3P_0$ and $^3P_1$ equal; the first is to use a positive correction factor by setting $T_7 = (^3P_1 - {}^3P_0)$ and the second is to use a negative correction factor $T_8 = (^3P_0 - {}^3P_1)$. At present it is not clear which one of these approaches is the correct one. As expected, however, the introduction of these correction factors does eliminate some of the discrepancy in the oscillator strengths of Pr(III). We are currently working on the detail and feasibility of these correction parameters (17, 21).

Values of the T_λ parameters consist of both vibronic and static components. The variation of T_λ with changes in the chemical environment can be determined by crystal field parameters A_{tP}, which depend upon the position (angular and radial) and the charges of the surrounding ligands. In lanthanide species other than Pr(III), T_2 varies significantly with minor changes in the immediate coordination sphere around the ion while T_4 and T_6 are relatively insensitive. This makes the intensities of non-hypersensitive transitions of little use in solving structural problems. In practice both the oscillator strengths of the transitions and the T_λ parameters have provided significant structural information about lanthanide coordination, especially in solution. In complexes of sufficiently low symmetry the oscillator strength of the hypersensitive transitions is of such magnitude that their description in terms of a forced electric dipole mechanism becomes meaningless.

The f–f transitions are weakly allowed if the energy of the excited state is lowered due to some mixing of the excited states with opposite parity into the ground state as a result of configuration interaction. Substantial intensification of the hypersensitive transitions may be gained by the mixing of metal $4f$ and ligand wave functions due to the increased probability of orbital overlap. With the introduction of covalency in the metal–ligand bond the possibility for a mixing of states with opposite parity improves and relaxes the rules for $4f$–$4f$ transitions leading to the intensification of the f–f bands. Iftikar *et al.* (31) have observed remarkably high intensification of the hypersensitive bands of Nd(III) and Er(III), which they ascribed to eigen perturbation.

During the course of our work with Pr(III) complexes (21) we noted that none of the observed transitions in the 350–1100 nm range (i.e., $^3P_2$, $^3P_1$, $^3P_0$, and $^1D_2 \leftarrow {}^3H_4$) can be considered hypersensitive in an orthodox sense. However, these transitions exhibit very high intensification and a wide variation of their oscillator strengths. The complexes investigated contain ligands with quite different binding features (e.g., haloacetate, amino acid derivatives, mixed ligand, diols (forming chelate rings of varying sizes 5–9-membered), β-diketonates, phenanthroline, nucleic bases, nucleosides, nucleotides, fluorinated nucleic bases, fluorinated nucleosides, Schiff bases, and alkoxides). These complexes have been well characterized by elemental analysis, IR spectroscopy, molecular weight determination, magnetic susceptibilities, conductivities, and thermal analysis.

Complexes with similar types of ligands have been tabulated together with the data on oscillator strengths and T_λ parameters and can be found in Table 1.

Pr(III) alkoxides

The alkoxides of Pr(III) of the general formula $Pr(OR)_3$ and $Pr[Al(OR)_4]_3$ where R = $C_3H_7^i$, $C_4H_9^n$, $C_4H_9^s$, $C_4H_9^t$, $C_5H_{11}^n$, $C_5H_{11}^{neo}$, $C_5H_{11}^t$ gave strong $4f$–$4f$ bands with very high oscillator strengths. These compounds also exhibit substantially high nephelauxetic, bonding, and covalency parameters, which is supported by their solubility in non-

polar organic solvents and the volatility of the *tert*-butoxide, neopentyl oxide, and *tert*-pentyl oxides. The bimetallic alkoxides are much more volatile as evidenced by the easy ability to either distil or sublime the compounds. These characteristics suggest that these compounds contain a substantial amount of covalency in hitherto predominantly ionic Pr–ligand bonds. The oscillator strengths (P) of the four pseudohypersensitive transitions are as follows:

$$^3P_2 \leftarrow {}^3H_4 \quad (16.44\text{–}50.45) \times 10^{-6}$$
$$^3P_1 \leftarrow {}^3H_4 \quad (4.74\text{–}30.30) \times 10^{-6}$$
$$^3P_0 \leftarrow {}^3H_4 \quad (2.84\text{–}17.53) \times 10^{-6}$$
$$^1D_2 \leftarrow {}^3H_4 \quad (5.37\text{–}15.39) \times 10^{-6}$$

The variation of oscillator strength is up to 600% though none of these transitions follow the selection rules for quadrapole transitions and thus cannot be considered to be hypersensitive. We regard these transitions as pseudohypersensitive in nature.

β-Diketonates and diol derivatives

Comprising bifunctional bidentate ligands such as acetylacetone, butane-1,4-, butene-1,4-, and butyne-1, 4-diols, these complexes were investigated at pH = 2.0 and 5.0 in water and DMF by following absorption difference and comparative absorption spectrophotometry. All show a significant variation of intensities for the pseudohypersensitive transitions. The diols are all related, differing only in the bond order (1–3) between the 2nd and 3rd carbon atoms of the diol function. Table 1 shows that the oscillator strength of the transition increases in the order: butane-1,4 < butene-1,4 < butyne-1,4. This ordering suggests that the π-electron density of the butene-1,4 and butyne-1,4 is having some effect of the Pr(III) diol binding.

$$^3P_2 \leftarrow {}^3H_4 \quad (5.206\text{–}12.088) \times 10^{-6}$$
$$^3P_1 \leftarrow {}^3H_4 \quad (1.627\text{–}6.516) \times 10^{-6}$$
$$^3P_0 \leftarrow {}^3H_4 \quad (1.158\text{–}4.363) \times 10^{-6}$$
$$^1D_2 \leftarrow {}^3H_4 \quad (1.138\text{–}3.568) \times 10^{-6}$$

The high sensitivity of these nonhypersensitive transitions is evidenced by the 350% variation in oscillator strengths.

Complexes of nucleic bases, nucleosides, and nucleotides including fluorinated nucleic bases and fluorinated nucleosides

The nucleic bases and nucleosides including their fluorinated analogues possess several potential donor sites yet these ligands form predominantly outer sphere complexes in aqueous medium. The complexes with nucleotides, on the contrary, are essentially ionic and show strong complexation in the solid state with an octa-coordinated environment around the Pr cation. These nucleic bases, nucleosides, and their fluorinated analogues behave differently in aqueous and semi-nonaqueous (equimolar mixture of DMSO and water) media. In water these biomolecules become highly hydrated by weakening the water structure while in semi-nonaqueous media they appear to strengthen the three-dimensional water structure and thus are less hydrated, behaving as better ligands. The presence of an electron-withdrawing fluorine on the biomolecules appears to make them a better ligand, as indicated by the higher oscillator strengths of the pseudohypersensitive transitions.

$$^3P_2 \leftarrow {}^3H_4 \quad (3.141\text{–}16.093) \times 10^{-6}$$
$$^3P_1 \leftarrow {}^3H_4 \quad (0.925\text{–}6.488) \times 10^{-6}$$
$$^3P_0 \leftarrow {}^3H_4 \quad (0.801\text{–}4.70) \times 10^{-6}$$
$$^1D_2 \leftarrow {}^3H_4 \quad (0.528\text{–}4.868) \times 10^{-6}$$

The variation in oscillator strengths observed here is up to 750%. Again all transitions are non-hypersensitive.

Haloacetates

These compounds are highly ionic in nature and soluble in water, ethanol, and polar organic solvents. They behave as 1:2 electrolytes and produce highly conducting aqueous solutions. In the solid state bidentate and dimeric haloacetate attachment is observed, which provides a noncoordinated Pr(III) with three additional water molecules of coordination. These compounds show small magnitudes for the nephelauxetic, covalency, and bonding parameters as well as weak $4f$–$4f$ bands

$$^3P_2 \leftarrow {}^3H_4 \quad (10.70\text{–}15.80) \times 10^{-6}$$
$$^3P_1 \leftarrow {}^3H_4 \quad (3.10\text{–}7.10) \times 10^{-6}$$
$$^3P_0 \leftarrow {}^3H_4 \quad (1.80\text{–}3.40) \times 10^{-6}$$
$$^1D_2 \leftarrow {}^3H_4 \quad (2.0\text{–}3.30) \times 10^{-6}$$

The variation of the observed oscillator strengths for the pseudohypersensitive transitions is of a much smaller magnitude, which is understandable in view of the highly ionic nature of these compounds. However, when the haloacetates are dissolved in methanol, DMF, DMSO, and equimolar binary mixtures the oscillator strengths of the pseudohypersensitive transitions show wide variations. This is most probably the result of a change in the immediate coordination environment around the Pr(III) cation when the coordinated solvent molecule changes from water (32) to polar nonaqueous (30).

$$^3P_2 \leftarrow {}^3H_4 \quad (13.46\text{–}87.01) \times 10^{-6}$$
$$^3P_1 \leftarrow {}^3H_4 \quad (2.68\text{–}45.37) \times 10^{-6}$$
$$^3P_0 \leftarrow {}^3H_4 \quad (0.596\text{–}22.71) \times 10^{-6}$$
$$^1D_2 \leftarrow {}^3H_4 \quad (2.614\text{–}18.07) \times 10^{-6}$$

The extremely wide range of oscillator strengths of the pseudohypersensitive transitions appears to be abnormally high. This evidence suggests that the immediate Pr(III)–haloacetate coordination environment normally consisting of three bidentate haloacetates and three water molecules changes to an environment consisting of eight DMF, DMSO, or MeOH molecules in some combination. This brings about a drastic change in the immediate coordination sphere of the Pr cation when contrasted to the other studies where only partial changes in the immediate coordination sphere were observed.

Mixed ligand complexes

These complexes comprise an aminoacid cysteine/histidine as the primary ligand (A) and various diols as secondary ligands (B) and are of the type MAB, MAB_2, and MA_2B. The size of the ring formed by the aminoacid is fixed but the diols form chelate rings numbering 5, 6, 7, and 8 members and in consequence have varying stability (as shown by the stability constants of the different complexes (33)).

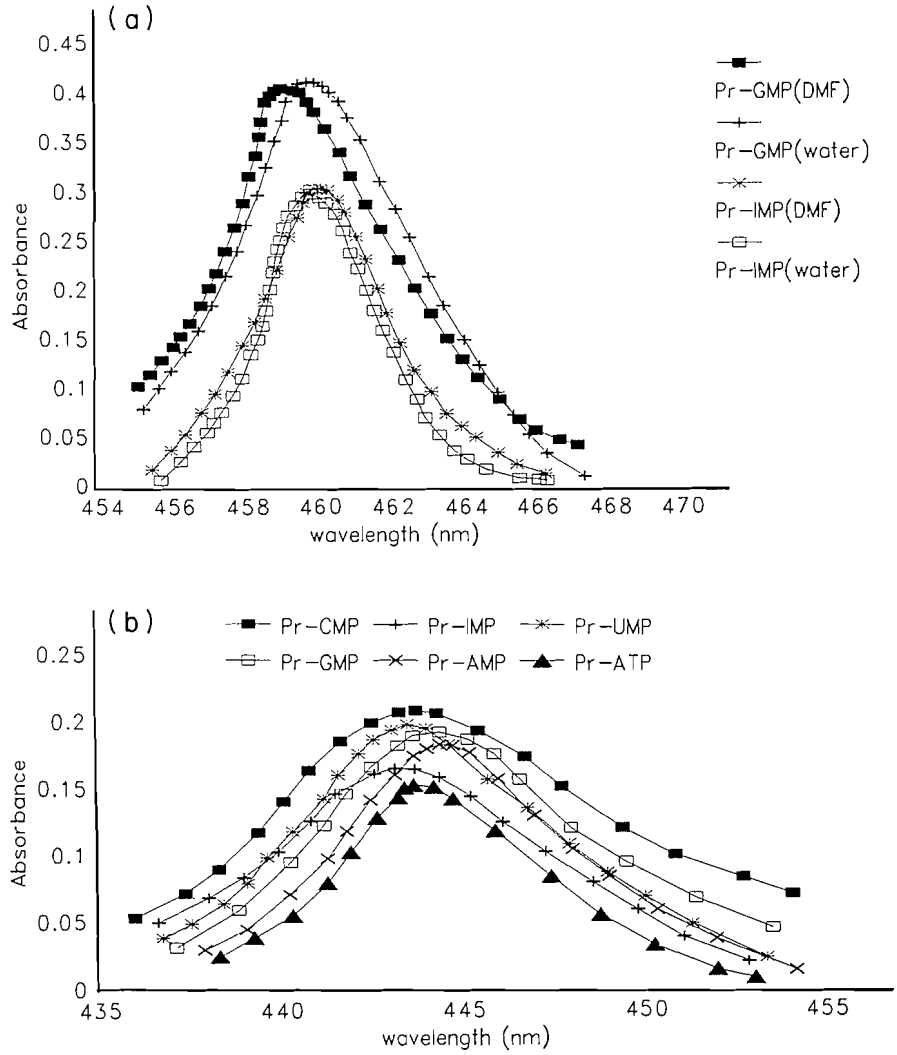

FIG. 3 (a) The pseudohypersensitive $^3H_4 \rightarrow {}^3P_2$ transition of Pr–GMP/IMP in H_2O and DMF. (b) The pseudohypersensitive $^3H_4 \rightarrow {}^3P_2$ transition of Pr(III) with various nucleotides.

$$^3P_2 \leftarrow {}^3H_4 \quad (13.301\text{–}18.5070) \times 10^{-6}$$
$$^3P_1 \leftarrow {}^3H_4 \quad (2.472\text{–}9.926) \times 10^{-6}$$
$$^3P_0 \leftarrow {}^3H_4 \quad (1.197\text{–}6.029) \times 10^{-6}$$
$$^1D_2 \leftarrow {}^3H_4 \quad (1.7172\text{–}8.5285) \times 10^{-6}$$

The values of the oscillator strengths are much lower than expected for such complexes with significant inner sphere complexation. The presence of the oxygen donor diol ligand enhances the overall stability of the complex and will naturally induce some intensification of the bands. The plots of the stability constants versus oscillator strengths of these pseudohypersensitive transitions, especially $^3P_2 \leftarrow {}^3H_4$ and $^1D_2 \leftarrow {}^3H_4$, give a linear correlation with a positive slope, which indicates that the stability of the species contributed towards the intensification of the $4f$–$4f$ bands (33). At the same time the nephelauxetic effect brings the metal closer to the ligand and thus enhances the probability of orbital overlap. The increased stability of the complexes appears to be due to the better participation of the metal $4f$ orbitals in bonding with the ligands (33).

Schiff base complexes

The Schiff bases derived from vanillin and propylene diamine, *o*-phenylene diamine, *oc*-naphthylamine, *o*-phenetidine, *p*-phenetidine, and thiosemicarbazide offer coordinating centers such as O, N, and S and can be either bidentate or tetradentate, which provides several different coordinating environments for Pr(III). These complexes are predominantly inner sphere complexes and have one chlorine and three water molecules in the inner sphere of coordination yielding an octacoordinated Pr(III) (34).

$$^3P_2 \leftarrow {}^3H_4 \quad (10.98\text{–}18.43) \times 10^{-6}$$
$$^3P_1 \leftarrow {}^3H_4 \quad (4.51\text{–}18.43) \times 10^{-6}$$
$$^3P_0 \leftarrow {}^3H_4 \quad (3.10\text{–}7.10) \times 10^{-6}$$
$$^1D_2 \leftarrow {}^3H_4 \quad (3.71\text{–}6.38) \times 10^{-6}$$

The comparatively low magnitude of the oscillator strengths for these pseudohypersensitive transitions in spite of the attached Schiff base is most probably due to the presence of a chloride anion in the inner sphere, which induces sufficient ionicity in these chelates to lower the observed intensities.

Comparative absorption spectral studies

The comparative absorption spectra of Pr–uridine, –thymine, –fluorouridine, and –fluorothymidine are shown in Fig. 1. The spectra show clearly that all four nonhypersensitive bands are varying in shape, energy, and oscillator strengths. These ligands coordinate to Pr(III) through the ribose hydroxyl group with weak participation of the carbonyl oxygen. Thus, nearly identical immediate coordination spheres are present around the Pr(III); however, the presence of fluorine in the fluorinated nucleosides induced substantial intensification of the pseudohypersensitive transitions.

Figures 2(a) and 2(b) show that even when Pr(III) is coordinated with the same ligand, changes in the solvent significantly influence the oscillator strengths of the $4f$–$4f$ bands.

Figure 3 shows the different affinities of various nucleotides towards Pr(III). Even though each of the nucleotides binds predominantly through the phosphate oxygen, clear differences in the band shape, energy, and oscillator strength are evident, which suggests that there is also involvement of the nucleic base.

These spectra taken together clearly show that minor changes in the immediate coordination environment of Pr(III) indeed cause significant intensification of these pseudohypersensitive bands.

Conclusion

Since the values of the T_2 parameters in most of the complexes are negative it becomes meaningless. The T_6 parameter, however, appears to show a definite trend with the changes in the coordination environment. The wide variation of oscillator strengths for the $4f$–$4f$ transitions in all the complexes described in the work are as follows:

$$^3P_2 \leftarrow {}^3H_4 \quad (3.410\text{–}87.01) \times 10^{-6}$$

$$^3P_1 \leftarrow {}^3H_4 \quad (0.925\text{–}45.37) \times 10^{-6}$$

$$^3P_0 \leftarrow {}^3H_4 \quad (0.596\text{–}22.71) \times 10^{-6}$$

$$^1D_2 \leftarrow {}^3H_4 \quad (0.528\text{–}18.07) \times 10^{-6}$$

In summary, one observes that the percentage variation in the oscillator strength of these pseudohypersensitive transitions is very high and they appear to behave much like hypersensitive transitions. The binding characteristics of the ligand, geometry of the complex formed, and the introduction of some covalency appear to relax the selection rules by lowering the energy of the excited state of these transitions. Other factors may also contribute to the enhancement and sensitivity of these transitions:

(*i*) The second-order interactions, which are two orders of magnitude less than the coulombic interactions (generally ignored), may become prominent by the ligating characteristics of the coordinating molecule. This may lower the excited state of these pseudohypersensitive transitions and in consequence their transition probability is enhanced.

(*ii*) The nephelauxetic effect may induce some broadening of the bands and hence may contribute to the intensification of the bands.

(*iii*) These transitions may be borrowing intensities from neighboring transitions.

Partial molar volumes of acidic gases in physical solvents and prediction of solubilities at high pressures

YUMING XU, LILI LI, AND LOREN G. HEPLER[1]

Department of Chemistry and Department of Chemical Engineering, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received March 22, 1991

YUMING XU, LILI LI, and LOREN G. HEPLER. Can. J. Chem. **70**, 55 (1992).

Partial molar volumes at infinite dilution for three acidic gases (carbon dioxide, hydrogen sulfide, and sulfur dioxide) in four physical solvents (propylene carbonate, methyl cyanoacetate, *N*-formyl morpholine, and Selexol) have been obtained using our new dilatometer. These partial molar volumes, in combination with the Henry's law constants obtained previously, have been used in the Krichevsky–Kasarnovsky equation for predicting the solubilities of acidic gases in physical solvents at high pressures.

Key words: partial molar volume, solubility, physical solvents.

YUMING XU, LILI LI et LOREN G. HEPLER. Can. J. Chem. **70**, 55 (1992).

Utilisant un nouveau dilatomètre, on a déterminé les volumes molaires partiels à dilution infinie de trois gaz acides (dioxyde de carbone, sulfure d'hydrogène et dioxyde de soufre) dans quatre solvants physiques (carbonate de propylène, cyanoacétate de méthyle, *N*-formyl morpholine et Séléxol). Dans le but de prédire les solubilités de ces gaz acides dans des solvants physiques à des pressions élevées, on a introduit ces volumes molaires partiels ainsi que les constantes de la loi de Henry obtenues antérieurement dans l'équation de Krichevsky–Kasarnovsky.

Mots clés : volume molaire partiel, solubilité, solvants physiques.

Introduction

We have made measurements leading to the partial molar volumes of acidic gases (SO_2, H_2S, and CO_2) in "physical" solvents for two reasons. (1) One specific reason for making these measurements has been our interest in the use of physical solvents (called "physical" because there is no clear chemical reaction of acid–base type between solvent and solute) for the removal of acidic gases from industrial gas streams. (2) In addition to the specific reason mentioned above, we have a general interest in the use of results of low pressure measurements (partial molar volumes and Henry's law constants) for predicting the solubilities of gases at high pressures.

The simplest relationship between the pressure of a gas and its equilibrium solubility in a liquid solvent is Henry's law that we write as

$$[1] \quad f_2/X_2 = K_H \quad \text{or} \quad P_2/X_2 = K_H$$

in which f_2 and P_2 refer to the fugacity and pressure of the gas, and X_2 is the equilibrium mole fraction of the dissolved gas in the liquid phase. Because Henry's law is applicable only at low pressures, $f_2 \approx P_2$, it is proper to use either version of eq. [1].

Long ago Krichevsky and Kasarnovsky (1) considered the effects of high pressure on the solubilities of slightly soluble gases and derived the equation that is now known by their names:

$$[2] \quad \ln(f_2/X_2) = \ln K_H + [\bar{V}_2^0(P - P_1^0)]/RT$$

Symbols in this equation have the following meanings: f_2 is the fugacity of the gas at some specified total pressure P, X_2 is the equilibrium mole fraction of dissolved gas, K_H is the Henry's law constant, $\bar{V}_2^0$ is the low concentration partial molar volume of the dissolved gas, and P_1^0 is the equilibrium vapour pressure of the solvent at the specified temperature T. Prausnitz *et al.* (2) have provided a contemporary review of the thermodynamic basis of the Krichevsky–Kasarnovsky equation.

The Krichevsky–Kasarnovsky equation has been used most often as the basis of a method for convenient graphical presentation of gas solubility data and sometimes also as a method for screening such data for likely errors. Many of these applications refer to systems in which the vapour pressure of the pure solvent (P_1^0) is much smaller than the applied pressure so that eq. [2] can be simplified to

$$[3] \quad \ln(f_2/X_2) = \ln K_H + \bar{V}_2^0 P_2/RT$$

in which the total pressure and the partial pressure of gas are nearly identical as indicated by the use of P_2. In these common applications of the Krichevsky–Kasarnovsky equation [2] or [3], the fugacities are calculated for each pressure from the equation of state for the gas and then values of $\ln(f_2/X_2)$ are plotted against P_2, with the expectation of observing a (nearly) straight line. Points that fall far from an average smooth or straight line are often considered to be in error and are excluded from further consideration. One useful example of this kind of application has been provided recently by Lu *et al.* (3), who have screened reported solubilities of gases in bitumen.

Our principal interest has been in using the Krichevsky–Kasarnovsky equation in a different way; that is, we use values of K_H and $\bar{V}_2^0$ obtained from results of measurements at low pressures in eqs. [2] or [3] for prediction of the gas solubilities (X_2) at high pressures (P or P_2) and corresponding fugacities (f_2).

Because the Krichevsky–Kasarnovsky equation was derived specifically for gases that are very slightly soluble (such as H_2 in water), there has been considerable interest in modifying the original equation to allow for the kind of non-ideal solution effects that occur in less dilute solutions and that are represented by non-unity activity coefficients. The

most commonly used equation of this type is the Krichevsky–Ilinskaya (4) equation that we write as

$$[4] \quad \ln (f_2/X_2) = \ln K_H + A(X_1^2 - 1)/RT + \bar{V}_2^0 P_2/RT$$

in which A is known as the Margules parameter and X_1 represents the equilibrium mole fraction of solvent in the solution that is saturated at pressure P_2. For slightly soluble gases (X_2 is very small and $X_1 \approx 1$), the middle term on the right side is negligible, and eq. [4] reduces to eq. [3].

There are several excellent reviews (5–8) of methods for measuring the partial molar volumes of gases in liquids. Most of these earlier methods are modifications of the method developed by Horiuti (9). Although these methods work well, we have chosen to use a simpler dilatometric and direct weighing method (10, 11) that is well suited to the present investigation of gases that are moderately soluble at ordinary atmospheric pressure.

Experimental

Our dilatometer consists of a Pyrex glass bulb (68 cm^3), fitted with a calibrated straight capillary tube (3 mm bore). To serve as a reference mark, a thin copper wire was attached halfway up the 100 mm long capillary. The open end of the capillary can be closed with a Nylon cap.

The solvent to be used is degassed with a vacuum pump and then loaded into the dilatometer with a hypodermic syringe until the solvent meniscus is about 10 mm up the capillary tube. The dilatometer is then closed with the Nylon cap and allowed to equilibrate in a constant temperature (±0.005 K) water bath. After thermal equilibrium has been achieved, the height (relative to the reference mark) of the meniscus is measured to ±0.2 mm with a cathetometer. The dilatometer is then removed from the water bath, dried, and weighed to ±0.0002 g.

The solute gas is introduced to the dilatometer under pressure slightly above atmospheric pressure, by way of Tygon tubing connecting the top of the capillary to a gas cylinder. The bulb is then placed in ice-water, causing the solvent to contract and a gas space of ≈1 cm^3 to be formed. This space is large enough to permit good mixing as a result of gentle shaking and rocking of the dilatometer. The intention is *not* necessarily to reach saturation as in most other methods, but merely to dissolve enough gas to permit determination of the amount of dissolved gas by accurate weighing.

The dilatometer is disconnected from the Tygon tubing, closed with the Nylon stopper, returned to the constant temperature bath, and left to equilibrate for 20–30 min. The final level of the meniscus (relative to the reference mark) and the final mass of the dilatometer plus contents are then measured.

The difference between the initial and final heights of the meniscus is combined with the cross-sectional area of the capillary to obtain the volume increase accompanying solution of the gas. Division of this volume by the number of moles of gas dissolved (calculated from masses) yields the apparent molar volume of the dissolved gas.

More information about construction and operation of the dilatometer is presented elsewhere (10, 11).

Propylene carbonate (99.0%) and methyl cyanoacetate (99.0%) were from Aldrich Chemicals. *N*-Formyl morpholine (99.0%) was from BASF. Selexol (a dimethyl ether of polyethylene glycol) from Harrisons and Crosfield Ltd. was examined in the Microanalytical Laboratory of the Department of Chemistry, University of Alberta, and found to contain 0.87% water and to have average molecular weight equal to 266 g/mol. High purity solute gases were from Matheson Gas Products Canada.

TABLE 1. Partial molar volumes ($cm^3\ mol^{-1}$)[a] of acidic gases in physical solvents at 25°C

Solvent	CO_2	H_2S	SO_2
Propylene carbonate	42.2	40.4	43.7
Methyl cyanoacetate	39.6	40.6	44.1
Selexol	42.2	38.5	39.8
N-Formyl morpholine	33.5	37.8[b]	33.1

[a]The standard deviations are all about 0.3 $cm^3\ mol^{-1}$ and total uncertainties are estimated to be ±0.5 $cm^3\ mol^{-1}$.

[b]The color of the solvent *N*-formyl morpholine changed from nearly colorless to light green to dark green as hydrogen sulfide dissolved.

Results

The apparent molar volumes ($V_{\phi,2}$) of solute gases that we have obtained directly from our measurements of volumes and masses are defined by

$$[5] \quad V_{\phi,2} = (V - n_1 v_1^0)/n_2$$

in which V is the total volume of solution, $n_1 v_1^0$ is the total volume of the pure solvent, and n_2 is the number of moles of dissolved gas. The partial molar volume ($\bar{V}_2$) of the dissolved gas is defined by

$$[6] \quad \bar{V}_2 = (\partial V/\partial n_2)_{T,P,n}$$

Combination of eqs. [5] and [6] leads to

$$[7] \quad \bar{V}_2 = V_{\phi,2} + n_2(\partial V_{\phi,2}/\partial n_2)_{T,P,n}$$

For sufficiently dilute solutions, the second term on the right of eq. [7] is negligible and we have the limiting equation

$$[8] \quad \bar{V}_2^0 = V_{\phi,2}^0$$

Typical mole fractions of dissolved gas in our experiments were in the range from 0.005 to 0.04. For these dilute solutions, as in previous investigations (10, 11), the second term on the right of eq. [7] is negligible so that eq. [8] permits evaluation of the desired limiting partial molar volumes from our experimental results, as summarized in Table 1. As discussed previously (10, 11), these partial molar volumes are accurate to about ±1% (≈ ±0.5 $cm^3\ mol^{-1}$).

We do not know of any volumetric measurements leading to partial molar volumes of CO_2, H_2S, or SO_2 in the solvents that we have investigated, so we are unable to make any direct comparisons of our results with those of prior investigations. We can, however, relate our present results to those from some other investigations as follows.

Previous investigations (7, 11) have shown that the partial molar volumes of SO_2 in "inert" solvents are all close to 55 $cm^3\ mol^{-1}$, while volumes of SO_2 in other solvents in which complexes are known or expected to form are distinctly smaller than 55 $cm^3\ mol^{-1}$. Although the "physical" solvents that we have investigated are not strongly basic (as are amines), it is still reasonable to expect that they are good solvents for acidic gases because of solvent–acidic gas interactions, which might be described as complex formation. Our partial molar volumes for SO_2 are all in the <55 $cm^3\ mol^{-1}$ range that has been identified (11) as characteristic of complex formation. Similar comparisons (7, 8) can be made for partial molar volumes of CO_2 in various solvents, again

with the conclusion that there are specific interactions between CO_2 and the solvents that we have investigated.

Jou *et al.* (12) have measured solubilities of CO_2 and H_2S in *N*-formyl morpholine and have analyzed their experimental results in terms of the Krichevsky–Ilinskaya equation [4] and thence calculated $\bar{V}_2^0 = 35.6$ cm^3 mol^{-1} for CO_2 and $\bar{V}_2^0 = 35.1$ cm^3 mol^{-1} for H_2S in this solvent. Considering the uncertainties in our experimental values (33.5 and 37.8 cm^3 mol^{-1}, respectively) for these same gases in the same solvent and the uncertainties that result from calculating (12) values of three parameters (K_H, A, and $\bar{V}_2^0$) from one set of experimental results, the agreement is satisfactory.

Because of our interest in using information (K_H and $\bar{V}_2^0$) obtained from results of measurements made conveniently at low pressures for calculations of solubilities at higher pressures, we now proceed to use the Krichevsky–Kasarnovsky equation [3] as follows. Fugacities of CO_2 at several pressures have been calculated from the virial coefficients (13). These fugacities and corresponding pressures have been combined with our previous values[2] for Henry's law constants (obtained by low-pressure GLC measurements) and the present partial molar volumes to calculate equilibrium solubilities of CO_2 in *N*-formyl morpholine and in propylene carbonate. Results can be summarized and compared with experimental solubilities as follows.

For CO_2 in *N*-formyl morpholine at $T = 298.15$ K, we calculate (as described above) that $X_2 = 0.37$ at $P_2 = 2950$ kPa, as compared to the directly measured (12) $X_2 = 0.34$. Agreement of calculated with experimental solubilities is better at lower pressures, worse at higher pressures. In similar fashion we have calculated that $X_2 = 0.23$ for CO_2 in propylene carbonate at $P_2 = 2104$ kPa, as compared to the directly measured (14) $X_2 = 0.21$ at this same pressure.

It is possible to obtain better agreement between calculated and experimental solubilities, especially at higher pressures, by using the Krichevsky–Ilinskaya equation [4]. Such improvement, however, is less likely to be useful for predictive purposes because the only reliable method at present for obtaining the needed values of the Margules parameter (A) is from additional solubility data.

Still another approach to solubilities of acidic gases in physical solvents where it is probable that moderately stable complexes are formed can involve explicit recognition of the complex by way of an appropriate equilibrium constant, as done previously for volumes of SO_2 in various solvents (11) and for solubilities of NH_3 in $HCCl_3$ (15).

[2]Y. Xu and L. G. Hepler. To be published.

Acknowledgements

We thank Dr. John F. Smith for helpful advice concerning measurements leading to our partial molar volumes and Professor Alan E. Mather for donating some solvents and for his helpful discussions about calculations with our results. We are also grateful to the Natural Sciences and Engineering Research Council of Canada and the Alberta Oil Sands Technology and Research Authority for financial support of this and related research on thermodynamic properties of gases in liquids.

BOUALEM OUSSAID, MOHAMED AYAD, BERNARD GARRIGUES, JEAN-PIERRE FAYET et LE TRANG TRAN. Can. J. Chem. **70**, 58 (1992).

La conformation de 2-iminométhylthiophènes et du 2,5-bis(méthyliminométhyl)thiophène a été étudiée à partir de calculs théoriques, de mesures de moments dipolaires, de l'utilisation du couplage stéréospécifique à travers cinq liaisons et des expériences d'effets Overhauser. Une seule conformation a été mise en évidence : (2*c trans*) pour les 2-iminométhylthiophènes et (2*c* 5*c trans*) pour le 2,-5-bis(méthyliminométhyl)thiophène.

Mots clés : thiophène, imine, conformation.

BOUALEM OUSSAID, MOHAMED AYAD, BERNARD GARRIGUES, JEAN PIERRE FAYET, and LE TRANG TRAN. Can. J. Chem. **70**, 58 (1992).

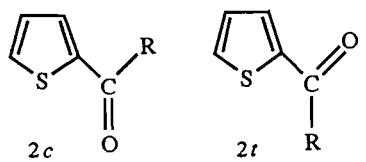
Conformation of 2-iminomethylthiophenes and of the 2,5-bis(methyliminomethyl)thiophene has been elucidated from theoretical investigations, dipole moment measurements, use of stereospecific coupling through five bonds, as well as Overhauser effect experiments. Only one conformation has been found: (2*c trans*) for the 2-iminomethyl thiophenes and (2*c* 5*c trans*) for the 2,5-bis(methyliminomethyl)thiophene.

Key words: thiophene, imine, conformation.

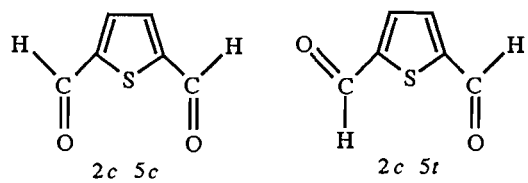
Introduction

Dans la mesure où les répulsions d'origine stérique le permettent, l'effet de conjugaison des cycles thiophéniques avec le groupement carbonyle tend à imposer aux molécules une structure plane susceptible de présenter les conformations 2*c* ou 2*t*. Si la planéité des systèmes conjugués est admise, la nature de la conformation privilégiée fait l'objet d'une controverse entre différents auteurs (1–3). Des études spectrographiques par absorption dans l'infrarouge lointain et micro-ondes concluent à une prépondérance de la structure O—S *trans* (2*t*) pour les 2-formyl thiophènes (4).

Par contre, l'examen des moments dipolaires indique dans de nombreux systèmes thiényle-carbonyle une structure essentiellement O—S *cis* (2*c*), et il en est de même des mesures de l'intensité de la bande de vibration de valence du carbonyle (5–7). La stéréospécificité des couplages à longue distance est en faveur de la structure 2*c* (8, 9).



Le dédoublement des bandes d'absorption ν(C=O) et ν(CH) des 2,5-diformylthiophène est expliqué par l'existence de deux conformères 2*c* 5*c* et 2*c* 5*t* en équilibre à température ordinaire. On estime l'abondance relative de la forme 2*c* 5*t* à 40% (10). Des mesures de moments dipolaires concluent à l'existence d'un mélange de 74% de forme 2*c* 5*c* (7). Enfin, des études par RMN ^{1}H concluent à la présence des conformations 2*c* 5*c* et 2*c* 5*t* dans des pourcentages respectifs de 70–80% et 20–30% (11).



Nous nous proposons pour la première fois d'étudier la conformation de 2-iminomethylthiophène et du 2,5-bis-(methyliminométhyl)thiophène par calcul, mesure du moment dipolaire, utilisation du couplage stéréospécifique Zig-Zag (12) et effet Overhauser.

Partie expérimentale

Généralités

Points de fusion, non corrigés, en capillaires (appareil Tottoli, Büchi). Spectres IR : en suspension dans le Nujol ou sous forme de film, entre lames CaF_2, enregistrés sur un spectromètre Perkin–Elmer 257. Spectres de RMN ^{1}H : déplacements chimiques en ppm par rapport au TMS; constantes de couplage en Hz; appareil Bruker AC 250.

Les spectres ^{1}H ont été enregistrés avec une résolution digitale de 0,15 Hz/point. Celle des spectres ^{13}C est de 0,46 Hz/point.

Les expériences 2D-NOESY ont été réalisées dans des conditions tout à fait classiques, avec un temps de mélange $t_m \cong T_1$. Il est à remarquer que les molécules étudiées présentent un temps de relaxation assez important (jusqu'à 16 s pour H5 du produit **2***c*). D'autre part, pour permettre une relaxation optimum, nous avons

choisi dans tous les cas un délai entre deux accumulations légèrement supérieur à $5 \times T_1$ (ex. : 90 s dans le cas du produit **2***c*).

Les analyses élémentaires ont été effectuées par le service de microanalyse de l'École Nationale Supérieure de Chimie de Toulouse. En outre, les chromatographies analytiques sont effectuées sur plaque de silice Merck réf. 5549.

Synthèse des dérivés **1**, **2**, **3**, **4**

Seuls les dérivés **1**, **2**, **3** sont signalés sans mode opératoire ni paramètres de RMN dans un travail précédent (13).

On mélange à la température ordinaire 0,01 mol de 2-formylthiophène ou de 2,5-diformylthiophène (14) et 0,05 mol d'amine en solution dans 30 mL de méthanol. Le milieu réactionnel est laissé sous agitation 48 h puis évaporé à sec. Après purification sur colonne de silice (éluant acétate d'éthyle) ou recristallisation dans le pentane on obtient le produit recherché analytiquement pur.

2-Méthyliminométhyl thiophène (**1**) : IR (Nujol) : 1637 (C=N) cm^{-1}. Rdt = 75%. RMN ^{13}C ($CDCl_3$) : 155,6 (s, CN), 142,5 (s, C2), 130,0 (s, C3), 128,5 (s, C5), 127,3 (s, C4), 47,7 (s, CH_3).

2-Isopropyliminométhyl thiophène (**2**) : IR (Nujol) : 1631 (C=N) cm^{-1}. Rdt = 83%. RMN ^{13}C ($CDCl_3$) : 151,5 (s, CN), 142,7 (s, C2), 129,9 (s, C3), 128,4 (s, C5), 127,2 (s, C4), 61,3 (s, CH), 24,1 (s, CH_3).

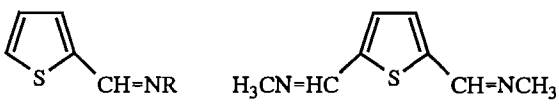
2-Tertiobutyliminométhyl thiophène (**3**) : IR (Nujol) : 1632 (C=N) cm^{-1}. Rdt = 71%. RMN ^{13}C ($CDCl_3$) : 148,7 (s, CN), 144,1 (s, C2), 129,6 (s, C3), 128,1 (s, C5), 127,2 (s, C4), 57,3 (s, C), 29,7 (s, CH_3).

2,5-Bis(methyliminomethyl)thiophène (**4**) : IR (KBr) : 1628 (C=N) cm^{-1}. Rdt = 90%. *F* = 78°C. RMN ^{13}C ($CDCl_3$) : 155,5 (s, CH), 144,6 (s, C2), 129,6 (s, C3), 48,0 (s, CH_3).

Les moments dipolaires des quatre imines thiophéniques (**1**, **2**, **3**, **4**) sont mesurés dans le dioxanne à 25°C (tableau 1). La formule de Debye est utilisée ainsi que la méthode d'extrapolation d'Halverstadt et Kumler (15) pour calculer la polarisation totale avec $\alpha = [d\epsilon/d\omega_2]\omega_2 \rightarrow 0$, $\beta = [dv/d\omega_2]\omega_2 \rightarrow 0$ et $0{,}001 < \omega_2 < 0{,}05$. ϵ est la constante diélectrique, ω_2 la fraction massique de l'échantillon et v le volume massique. Les polarisations électroniques sont assimilées aux refractions moléculaires R_{MD}.

Résultats et discussion

Nous avons pour notre part étudié la conformation des 2-iminométhylthiophènes **1–3** (**1** : R = Me, **2** : R = *i*Pr, **3** : R = *t*Bu) et du 2,5-bis(méthyliminométhyl)thiophène **4**.



4

1 R = CH_3
2 R = *i* Pr
3 R = *t* Bu

Nous avons tout d'abord effectué un calcul théorique MNDO (16) pour les quatre conformations planes possibles 2*t cis*, 2*t trans*, 2*c trans* et 2*c cis*. Ce calcul montre, quelle que soit la nature du substituant R, que la structure la plus stable est la conformation 2*c trans* : −1309,713 eV (**1**), −1621,993 eV (**2**) et −1777,946 eV (**3**) (cf. tableau 2). Il est à noter que la conformation 2*c cis* n'a pas pu être calculée, à cause de l'encombrement stérique.

TABLEAU 1. Grandeurs intermédiaires pour la détermination des moments dipolaires expérimentaux

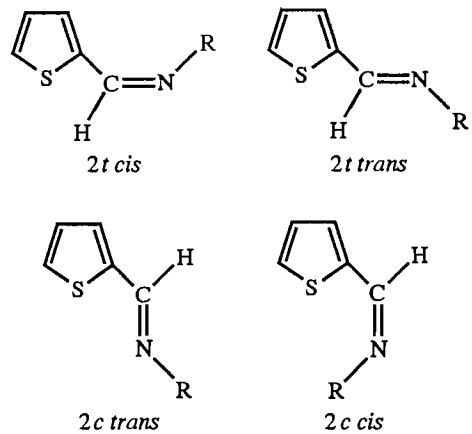
N°	α	β	R_{MD}	$P_{2\infty}$	$\mu_{(D)}$
1	5,09	−0,19	37,21	133,26	2,17
2	3,41	−0,18	42,35	121,03	1,96
3	3,34	−0,16	46,99	131,14	2,03
4	9,77	−0,25	48,87	302,41	3,52

TABLEAU 2. Valeur des énergies (eV) pour les conformations des composés **1–3** (la conformation 2*c cis* n'a pas pu être calculée)

R	N°	2*t cis*	2*t trans*	2*c trans*
Me	**1**	−1308,002	−1309,696	−1309,713
*i*Pr	**2**	−1613,519	−1621,976	−1621,993
*t*Bu	**3**	−1769,468	−1777,927	−1777,946

TABLEAU 3. Moments dipolaires calculés et mesurés (D) pour les composés **1–3**

R	N°	2*t cis*	2*t trans*	2*c trans*	μ_{exp}
Me	**1**	2,44	0,71	2,19	2,17
*i*Pr	**2**	2,55	0,66	2,14	1,96
*t*Bu	**3**	2,42	0,60	2,05	2,03



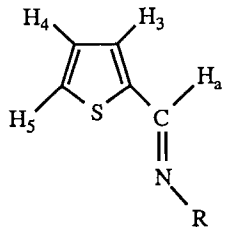
Le moment dipolaire théorique, calculé pour les trois conformations 2*t cis*, 2*t trans* et 2*c trans*, a été comparé à la mesure du moment dipolaire expérimental, effectué dans le dioxanne à 25°C. Les valeurs mesurées sont en faveur de la prépondérance de la conformation 2*c trans* dans le dioxanne : **1** : 2,17 (2,19); **2** : 1,96 (2,14); **3** : 2,03 (2,05) (tableau 3).

La stéréospécificité des couplages entre protons séparés par cinq liaisons dans une disposition Zig-Zag coplanaire ou *trans-trans* a été clairement établie dans de nombreux exemples et notamment en série thiophénique (12, 17, 18). Son existence a été démontrée par des expériences d'effets Overhauser (19), par rayons X dans des 4-bromo 2-formyl thiophènes (9) et enfin par des calculs théoriques de déplacements chimiques (9).

Nous avons pour notre part examiné les spectres des iminométhylthiophènes **1–3** (cf. tableau 4).

Un couplage spécifique Zig-Zag entre le proton imino et le proton H5 du cycle thiophénique a été observé. Sa valeur est comprise entre 0,7 et 0,9 Hz suivant la nature du substituant sur l'azote et confirme l'existence de la conformation 2*c trans*. Aucun dédoublement ni élargissement important n'apparaissent pour une solution refroidie dans le chloroforme à −60°C. La valeur nulle du couplage stéréospécifique $^5J(HCNH_4) = 0$ (**1–3**) qui résulterait des conformations 2*t trans* ou 2*t cis* permet d'éliminer ces deux dernières.

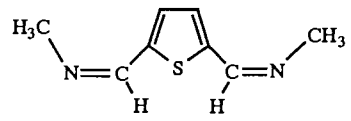
TABLEAU 4. Déplacements chimiques en ppm et constantes de couplages en Hz de 2-iminométhyl thiophène **1–3**



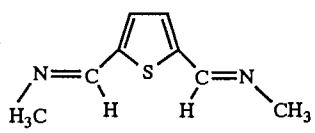
R	N°	H5	H4	H3	J_{45}	J_{35}	J_{34}	J(HaH5)	J(HaH4)
Me	**1**	7,22	6,88	7,15	4,3	1,2	3,7	0,7	0
*i*Pr	**2**	7,34	7,03	7,25	5,0	1,2	3,6	0,8	0
*t*Bu	**3**	7,32	7,02	7,27	4,8	1,2	3,7	0,9	0

Enfin, nous avons pu confirmer nos résultats par des expériences d'effets Overhauser. Dans le cas de **2**, nous avons observé une augmentation de l'intensité du signal du proton H3 de 8% lorsque l'on irradie le proton de la fonction imine; l'intensité des autres protons du cycle thiophénique n'est pas affecté par cette irradiation. Le spectre de RMN ^{2}D NOESY montre une très nette tache de corrélation entre le proton de la fonction imine et H3.

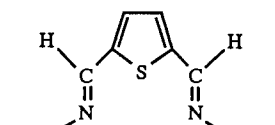
Nous avons étudié la conformation du 2,5-bis-(méthyliminométhyl)thiophène **4**. La simplicité du spectre de RMN ^{1}H dans un domaine de température de −60°C à +60°C ne peut s'expliquer que par la présence d'une conformation présentant un plan de symétrie qui rend équivalent les protons du cycle de la fonction imine et les groupements méthyle. Le composé **4** existe sous l'une des quatre conformations 2*t* 5*t cis*, 2*t* 5*t trans*, 2*c* 5*c trans* et 2*c* 5*c cis*.



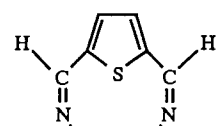
2*t* 5*t cis*



2*t* 5*t trans*



2*c* 5*c trans*



2*c* 5*c cis*

La conformation 2*c* 5*c cis*, trop encombrée stériquement, n'a pas pu être calculée. L'examen du calcul des énergies montre que la conformation 2*c* 5*c trans* est la plus basse en énergie (−1814,703 eV).

La mesure du moment dipolaire expérimental (3,52 D) est en accord avec cette conformation privilégiée (μ_{calc} = 3,39 D, cf. tableau 5). Enfin, dans cette conformation préférentielle, 2*c* 5*t trans*, aucun couplage stéréospécifique entre le proton de la fonction imine et le cycle ne doit exister : c'est ce qui est observé.

TABLEAU 5. Valeur des énergies (eV) et des moments dipolaires (D) pour les conformations de **4**

	2*t* 5*t cis*	2*t* 5*t trans*	2*c* 5*c trans*	μ_{exp}
E_T	−1811,276	−1814,665	−1814,703	
$\mu_{calc.}$	0,92	2,02	3,39	3,52

Conclusion

Alors que la conformation de formylthiophène a fait l'objet de controverses, les premières études que nous avons effectuées à partir de calculs théoriques, de mesures de moments dipolaires, de l'utilisation du couplage stéréospécifique à travers cinq liaisons et des expériences d'effets Overhauser montrent une convergence des résultats.

Dans le cas des iminométhyl thiophènes **1–3**, une seule conformation a été mise en évidence (2*c trans*). Le 2,5-bis(méthyliminométhyl)thiophène existe, lui, sous la conformation 2*c* 5*c trans*.

La conformation des imines hétérocycliques est sous la dépendance d'un certain nombre de facteurs : (*i*) l'attraction entre le soufre et l'azote; (*ii*) la différence de stabilité entre la conformation *cis* et *trans* dans l'enchaînement C=C—C=N, la forme *trans* étant thermodynamiquement la plus stable.

Nous remarquons que ces deux facteurs jouent dans le même sens pour conduire à une conformation *trans* de la fonction imine comme cela a déjà été observé pour les benzylidènes anilines (20).

ROBERT S. MCDONALD, PATRICIA PATTERSON, JUNE RODWELL, and ANN WHALLEY. Can J. Chem. **70**, 62 (1992).

Catalysis by imidazole and *N*-methylimidazole buffers of the intramolecular thiolysis of *N*-*n*-propyl 2-mercaptomethylbenzamide (forming 2-thiophthalide) has been studied in aqueous solution at 40.0°C, μ = 1.0. Unlike other buffers previously studied, imidazole and *N*-methylimidazole are able to catalyze, by a general base route, formation of neutral tetrahedral intermediate; this pathway is rate limiting at pH $\leq$ 7.5. At higher pH, the previously reported general acid-catalyzed breakdown of this intermediate is rate limiting. The relevance of these observations to the currently accepted pathway for the acylation of papain by amide substrates is discussed.

Key words: amide hydrolysis, intramolecular, thiol participation, imidazole, papain model.

ROBERT S. MCDONALD, PATRICIA PATTERSON, JUNE RODWELL et ANN WHALLEY. Can. J. Chem. **70**, 62 (1992).

Opérant à 40.0°C, dans des solutions aqueuses à μ = 1,0, on a étudié l'effet de la catalyse par des tampons d'imidazole et de *N*-méthylimidazole sur la thiolyse intramoléculaire du *N*-propyl-2-mercaptométhylbenzamide (conduisant à la formation de 2-thiophtalides). Contrairement à ce qui a été observé antérieurement avec d'autres tampons, l'imidazole et le *N*-méthylimidazole peuvent catalyser, par le biais d'une catalyse générale basique, la formation d'un intermédiaire tétraédrique neutre; cette voie limite la vitesse à un pH $\leq$ 7,5. À des pH plus élevés, la décomposition de cet intermédiaire assistée par une catalyse générale acide est l'étape qui détermine la vitesse. On discute de l'importance de ces observations pour le mécanisme généralement accepté pour l'acylation de la papaïne par des substrats amides.

Mots clés : hydrolyse d'amides, intramoléculaire, participation d'un thiol, imidazole, modèle de la papaïne.

[Traduit par la rédaction]

A thiol group of a cysteine residue (Cys-25) has been been assigned a nucleophilic role in the acylation of papain by carboxylic ester and amide substrates (1). The acyl enzyme, a thiol ester, has been observed spectroscopically (2) and in certain cases can be isolated and its deacylation studied independently (3). Located within hydrogen bonding distance of the thiol group lies an imidazole residue (of His-159) (4), which has been assigned a general acid–base role on both acylation and deacylation pathways (1, 5, 6).

The key steps involving nucleophilic and general acid–base assistance on the catalytic pathways of several proteases have been modelled in simpler chemical systems that react by an intramolecular pathway (7). However, although the intramolecular thiolysis of an ester has been reported (8) and the corresponding intermolecular reaction is well known (9), there have been few previous reports of nucleophilic involvement by a thiol group during amide hydrolysis. A kinetic study of the reaction of 2-mercaptoethanol with the very reactive amide, acetylimidazole, allowed Jencks and Carriuolo (10) to conclude that the reaction proceeded by way of thiolate attack on the N-protonated substrate. Dafforn and Koshland (11) studied the intramolecular thiolactonization of one acyclic and two bicyclic thiol amides in anhydrous or slightly wet sulfolane solution. Although both an acid-catalyzed and a spontaneous pathway were observed, these authors proposed the intermediacy of both protonated and diprotonated intermediates, which may reflect the particular choice of solvent.

Thus our previous kinetic study (12) of the thiolactonization of amide **1** provided the first direct observation of nucleophilic thiol group participation in the hydrolysis of an unactivated amide in aqueous solution (Scheme 1).

The pH–rate profile and the influence of buffers on the reaction rate allowed the following conclusions to be made concerning the reaction pathway. At low pH ($\leq$2.5) or high buffer concentration, the rate-limiting step is the uncatalyzed formation of neutral tetrahedral intermediate, $\mathbf{I}_0$ (k_1 in Scheme 1 is 9.8×10^{-4} s^{-1} at 40.0°C, μ = 1.0). At higher pH, the (apparent) general acid-catalyzed breakdown of $\mathbf{I}_0$ becomes rate limiting. Actually, on the basis of the Brønsted catalysis plot, we proposed that the rate-limiting step involves the kinetically equivalent general base-catalyzed breakdown of N-protonated tetrahedral intermediate ($\mathbf{I}_+$) to form **2**.

Although imidazole was one of the buffers investigated in this previous study (12), kinetic results in this buffer were significantly different in several respects from those observed in the other buffers examined over the same pH range and were not reported there. Certainly it is most intriguing that it is catalysis by imidazole which is anomalous since it is catalysis by this buffer of the **1** → **2** transformation that provides the closest analogue to the acylation of papain by a substrate amide.

This paper then reports the kinetic results for the catalysis of the thiolactonization of **1** in a series of imidazole and *N*-methylimidazole buffers over the pH range 6–8 and provides a rationale for the "imidazole catalysis dilemma" that may be relevant to the mechanism of action of papain.

Experimental

General information, purification of materials, substrate preparation, product work, and a description of the kinetic methods have been previously described (12). Preparation of buffer solutions has also been described elsewhere (13).

Results and discussion

The identification of thiolactone **2** as the product of the reaction of **1** in imidazole buffers has been confirmed by uv

[a]Quoted k_{obs} values are the average of at least duplicate runs; agreement between replicate runs was always within 10% and normally within 5–6%.

spectra of the reaction mixtures and by product isolation. In each case the final spectrum corresponded to an 80–95% yield of **2**. Although the oxidation of **1** to disulfide could be suppressed, it could not be completely eliminated (see experimental section of ref. 12). However, as long as disulfide formation was minimal and it remained in solution, this side reaction did not interfere appreciably with the thiolactonization kinetics.

Pseudo-first-order rate constants (k_{obs}) for the formation of **2** from **1** in a series of imidazole and *N*-methylimidazole buffers over the pH range 6–8.3 at 40.0°C, μ = 1.0 (with KCl), are collected in Table 1 and those in imidazole buffers are presented graphically in Figs. 1–3.

Several features of these data are strikingly different from those obtained in other buffers (phosphate, MES, Tris) previously reported over this pH range. Two of these are evident in Fig. 1 where the k_{obs} values in imidazole buffer at pH 7.11 are compared with those calculated assuming that imidazole conforms to the mechanistic pathway in Scheme 1 and obeys the Brønsted relationship in ref. 12 (i.e., $k_{HA}' = 2.51 \times 10^{-3}$ M^{-1} s^{-1} and $k_1 = 9.8 \times 10^{-4}$ s^{-1}). Clearly imidazole is a much more efficient catalyst than anticipated (in 2.0 M buffer, k_{obs} is 9-fold larger than predicted) and the buffer plot is essentially linear above 0.20 M, there being no apparent upper limit to k_{obs} at least up to 2.0 M. Previous buffer plots exhibited saturation-type behavior with an upper limit to k_{obs} in the range (0.9–1.6) $\times$ 10^{-3} s^{-1}. In this previous work, linear buffer plots were observed only where catalysis was very weak at high pH (see Table 1 and Fig. 2 of ref. 12). Similar behavior is observed for the other im-

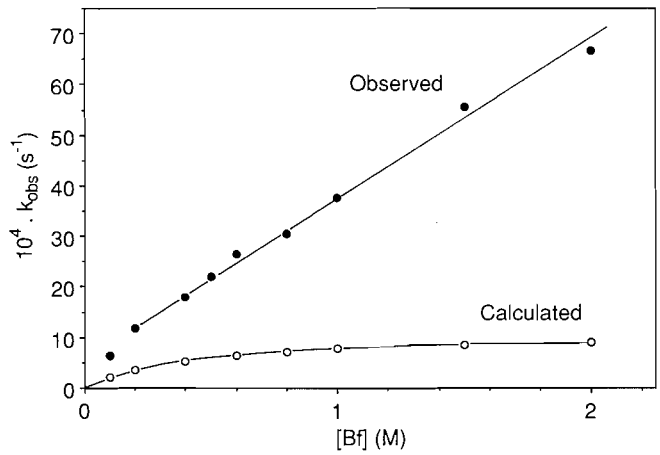

FIG. 1. Comparison of observed and calculated pseudo-first-order rate constants for the thiolactonization of **1** in imidazole buffer, pH 7.11, t = 40.0°C, μ = 1.0.

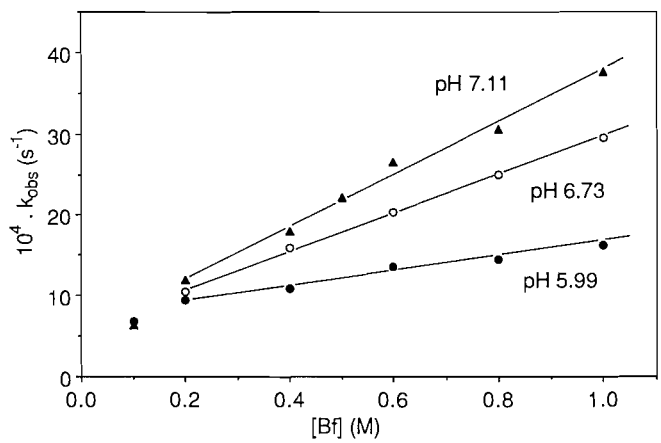

FIG. 2. Pseudo-first-order rate constants for the thiolactonization of **1** in imidazole buffers: pH 5.99, 6.73, and 7.11.

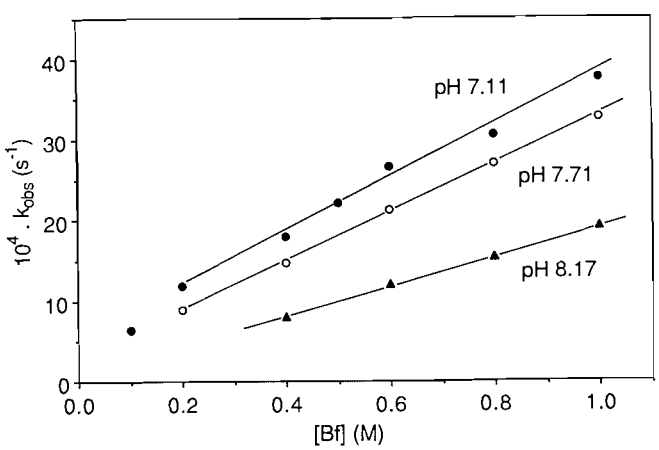

FIG. 3. Pseudo-first-order rate constants for the thiolactonization of **1** in imidazole buffers: pH 7.11, 7.71, and 8.17.

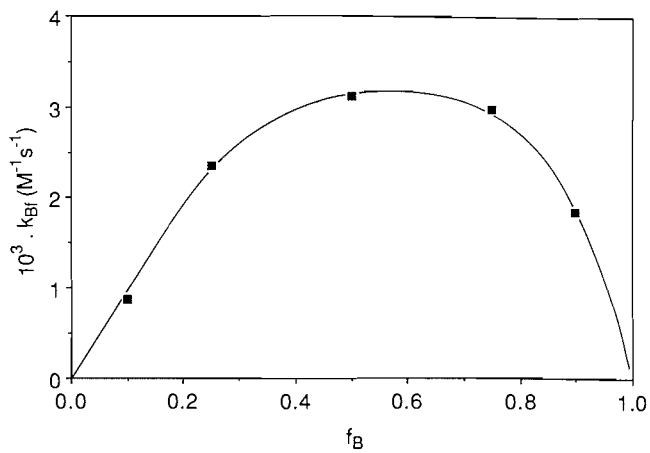

FIG. 4. Second-order buffer-catalyzed rate constants for the thiolactonization of **1** in imidazole buffers vs. f_B, the fraction of imidazole in its basic (neutral) form.

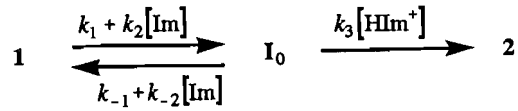
idazole buffers at higher and lower pH (although catalysis appears to be less efficient; see Figs. 2 and 3) and also for the series of *N*-methylimidazole buffers (not illustrated). The slopes, intercepts, and correlation coefficients for the linear portions of all these plots (at [Bf] $\geq$ 0.20 M) are also collected in Table 1.

The intercepts of these buffer catalysis plots are all larger than those that can be calculated from the known rate constants for the water- and hydronium ion-catalyzed terms (i.e., all k_0 values should be $\leq 1.3 \times 10^{-5}$ s^{-1}). Thus, there must be curvature in the buffer plots at *low* concentration, more pronounced at lower pH, which we take as evidence that the general acid-catalyzed (GAC) breakdown of $\mathbf{I}_0$ is still operative (*vide infra*).

Another noteworthy feature of these kinetic results is that catalysis is most efficient in the half-neutralized imidazole (or *N*-methylimidazole) buffer. This is illustrated in Fig. 4 where the apparent imidazole buffer-catalyzed rate constants (the slopes in Table 1) are plotted vs. the fraction of buffer in its basic form. This bell-shaped plot is certainly inconsistent with either GA or GBC (or both) on a single reaction step. Simultaneous cooperative GA–GBC can also be ruled out since this would require termolecular kinetics, which are not observed. Plots of k_{obs} vs. [Im][HIm^+] (not illustrated) are distinctly curved. Further, Breslow and Labelle (14) could detect no association between imidazole and its conjugate acid up to 1.0 M buffer concentration by nmr and cryoscopic measurements. The fact that *N*-methylimidazole buffers also show these characteristics allows us to eliminate the possibility of concerted bifunctional acid–base catalysis although this would be an unprecedented observation for this catalyst. It is also clear that our results are characteristic of the imidazole buffers and not simply due to a change in rate-limiting step of the reaction since other buffers over the same pH range exhibit GAC only.

A plot of the type illustrated in Fig. 4 has been obtained by Schmir and Cunningham (15) in the hydrolysis of an iminolactone catalyzed by acetate buffers. However, their substrate was undergoing significant changes in its state of protonation over the pH range examined. This cannot account for our results since we estimate the pK_a of the thiol



SCHEME 2

TABLE 2. Optimized rate constants and rate constant ratios for the thiolactonization of **1** in imidazole and *N*-methylimidazole buffers (40.0°C, μ = 1.0)

	Imidazole	*N*-Methylimidazole
$10^4 \cdot k_1$ (s^{-1})	11.0 ± 0.6	10.2 ± 0.9
$10^3 \cdot k_2$ (M^{-1} s^{-1})	7.74 ± 0.19	8.32 ± 0.51
k_{-2}/k_3	0.245 ± 0.021	0.516 ± 0.057
k_{-1}/k_3 (M)	0.040 ± 0.009	0.035 ± 0.017

group of **1** to be 9.0 ± 0.2 (12) and, again, other buffers over the same pH range do not show this effect.

One obvious conclusion that can be drawn from the lack of an upper limit to k_{obs} in imidazole buffers is that these buffers must also catalyze *formation* of I_0 (or provide an alternate route to **2**). Keeping in mind that the half-neutralized buffer provides the most efficient catalysis and assuming that breakdown of I_0 remains subject to GAC only, the minimum modification required to the pathway in Scheme 1 is the addition of a kinetic term involving imidazole for the formation of I_0 from **1** (and the reverse reaction). The revised pathway is represented in Scheme 2.

Making the steady-state assumption for I_0 leads to the following expression for k_{obs}:

$$[1] \quad k_{obs} = \frac{(k_1 + k_2[Im])[HIm^+]}{k_{-1}/k_3 + k_{-2}[Im]/k_3 + [HIm^+]}$$

Values of k_1, k_2, and the partitioning ratios k_{-1}/k_3 and k_{-2}/k_3 were adjusted iteratively using the Simplex algorithm (16) in order to minimize the least-squares difference between calculated and experimental k_{obs} values. The optimized values for these rate constants and rate constant ratios for imidazole and *N*-methylimidazole are given in Table 2. When these values are inserted into eq.[1], the k_{obs} values can be reproduced with an average deviation of 6–7%.

Worth noting here is the fact that Breslow and Labelle (14) also accounted for the observation of a bell-shaped buffer catalysis vs. pH profile in the imidazole-catalyzed hydrolysis of RNA by proposing sequential GA–GBC on successive steps of the reaction pathway.

It is reassuring that the optimized values for k_1 are in good agreement with one another and the value previously reported ($(9.8 \pm 1.1) \times 10^{-4}$ s^{-1}) (12). The fact that k_2 for *N*-methylimidazole is slightly larger than that for imidazole may reflect its slightly greater basicity.

The question remains as to how imidazole catalyzes the cyclization of **1** to I_0. We are unable to detect any specific interaction between a typical thiol (2-mercaptoethanol) and a 0.50 M imidazole buffer (pH 7.1) by uv measurements. Imidazole catalyzes the hydrolysis of activated esters and thiolesters (17); both nucleophilic and GBC pathways have been observed. As a general base, imidazole usually behaves normally, having a catalytic rate constant similar to that of hydrogen phosphate dianion, which has similar basicity. However, imidazole often exhibits enhanced nucleophilic reactivity as it does in the hydrolysis of *p*-nitrophenylacetate (18) and thiolesters (19). Intramolecular examples of both nucleophilic (20) and general base catalysis (21) by imidazole in thiolester hydrolysis have been found. There are, however, no reports of the catalysis of the hydrolysis of unactivated amides by imidazole buffers and we have been unable to detect any catalysis of the hydrolysis of *N*-*n*-propylbenzamide or the more reactive *p*-nitroacetanilide in 1.0 M imidazole (pH 7.1) over a period of 24 h.

It is interesting to note that the intramolecular thiolysis of both carboxylate (8) and carbamate (22) esters is not subject to GA–GBC. The sole kinetic pathway involves thiolate attack on the ester carbonyl.

Perhaps the closest analogue to our work is the kinetic study of acetyl group transfer from acetylimidazole to 2-mercaptoethanol catalyzed by imidazole carried out by Jencks and Carriuolo (10). The kinetic term involving [AcIm][RSH][Im] was proposed to correspond to true GBC of thiol attack at the amide carbonyl concerted with loss of imidazole. We also propose a general base role for imidazole in the ring closure of **1** to form I_0. Two kinetically equivalent pathways can be envisioned as outlined in Scheme 3.

Either imidazole provides true GB assistance to thiol attack on the amide carbonyl thus generating I_-, which rapidly becomes protonated (path a), or the thermodynamically unfavorable proton transfer between thiol group and imidazole to form the ion pair is followed by acid-assisted thiolate attack on the amide (path b). Analysis of the observed and estimated rate and equilibrium constants does not allow us to distinguish between these pathways.

This analysis implies that, in the presence of imidazole buffers, the reaction undergoes a change in rate-limiting step from the GBC formation of I_0 at pH $\leq$ 7.5 to its GAC breakdown at pH $\geq$ 7.5. The general base pathway becomes significant only for imidazole buffers for reasons which are as yet unclear.

What is most intriguing is that both pathways in Scheme 3 are analogous to those proposed for the acylation of papain by amide substrates. In his review, Lowe (23) proposed a mechanistic pathway for acylation analogous to path a, i.e., true GBC by imidazole. However, the position of the proton in the thiol–imidazole couple in the active enzyme has been debated for 20 years. The weight of recent evidence from uv (24), solvent isotope effects (25), potentiometric titration (26), and nmr (27) techniques reveals that this couple is from 50–100% in the form of the zwitterionic pair ($-S^-$ HIm^+-) such that imidazolinium might provide general acid assistance to thiolate attack. Unfortunately our results do not shine any light on the ambiguity but they do provide the first evidence that imidazole can catalyze acyl transfer from N to S in an unactivated amide.

There have been numerous previous attempts to observe cooperativity between proximate thiol and imidazole groups in a variety of 2- and 4-substituted imidazoles and appropriately functionalized peptides. Although the substrate chosen for this work was almost invariably the very reactive *p*-nitrophenyl acetate, only very modest rate enhancements (of 2–3 fold) have been observed. Brown and co-workers (21*b*, 30) have reasoned that the lack of success of these studies was due to the fact that the imidazole–thiol pair was not in the proper protonation state. Through a study of the

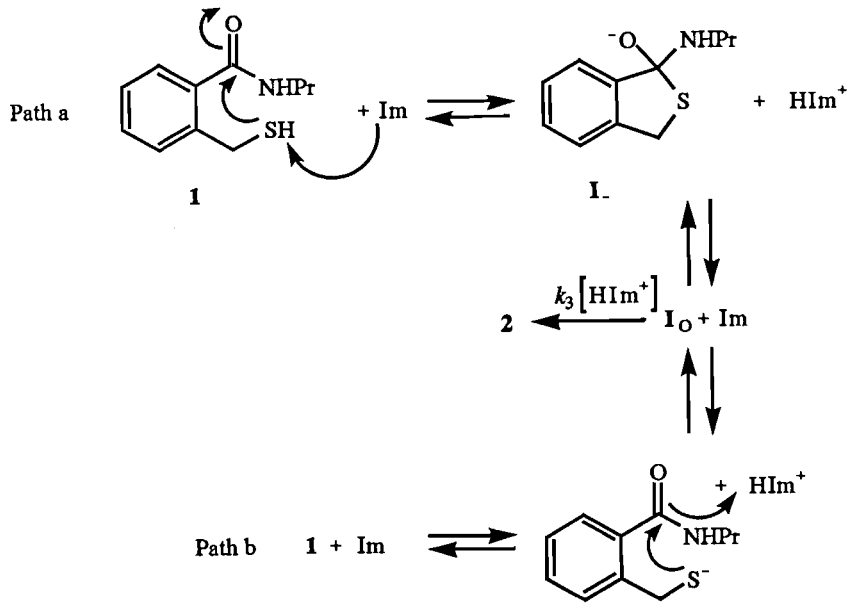

SCHEME 3

catalysis of PNPA hydrolysis by 2-mercaptomethylimidazole and its *N*-methyl derivative, in which the pK_a of the thiol group is lower than that of the imidazole group, they were able to observe significant attack on the ester carbonyl by the thiolate group of the zwitterionic form of the catalyst.

Turning back to our work, the question arises as to why imidazole can catalyze formation of $\mathbf{I}_0$ but other bases of similar or greater basicity cannot. In our previous work (12) we did notice that there was a systematic, if somewhat erratic, trend in k_1 from $(0.9–1.0) \times 10^{-3}$ s^{-1} (pH 0–6) up to 1.6×10^{-3} s^{-1} at pH 7.8. We ascribed this behavior to a modest medium or pH effect but, in retrospect, this may be due to a small general base contribution to the formation of $\mathbf{I}_0$. In any case, the contribution of this term by phosphate (pK 6.48) and Tris (pK 8.25) must be very small since in both of these cases the buffer-catalyzed rate constants decrease with increasing pH consistent with exclusive GAC. In an attempt to determine whether enhanced GBC by imidazole is a pK_a or a geometric effect, we are planning to study the catalytic effect of other substituted imidazoles, some of which have quite different pK_a and steric effects to those reported here.

The involvement of excited configurations in Mulliken charge analyses is examined for ethylene and acetylene, using an optimized 4-31G basis. The net charges of carbon, -346.4×10^{-3} (C_2H_4) and -335.3×10^{-3} e (C_2H_2) at the SCF level, are reduced to -269.9×10^{-3} and -271.2×10^{-3} e, respectively. Double excitations appear to contribute little to these corrections. In acetylene, three single $\sigma \rightarrow \sigma^*$ type excitations are responsible for ~83% of the charge correction whereas, as expected, the role of $\pi \rightarrow \pi^*$ type excitations is small. Similarly, four $\sigma \rightarrow \sigma^*$ configurations account for ~76% of the correction in ethylene. These effects are particularly important in comparisons with alkanes, whose charges are relatively little affected by CI corrections. Theoretical charges obtained from CI calculations appear to converge toward their empirical counterparts in a generalization of Mulliken's scheme, which allows for an uneven partitioning of CH overlap populations.

Key words: charge density, configuration interaction.

CLAUDE MIJOULE, JEAN-MARIE LECLERCQ, MICHEL COMEAU, SÁNDOR FLISZÁR et MAUD PICARD. Can. J. Chem. **70**, 68 (1992).

Utilisant une base 4-31G optimisée, on a étudié l'implication des configurations excitées dans les analyses de charge de Mulliken pour l'éthylène et l'acétylène. Les charges nettes du carbone calculées au niveau auto-cohérent, $-346{,}4 \times 10^{-3}$ (C_2H_4) et $-335{,}3 \times 10^{-3}$ e (C_2H_2), sont réduites respectivement à $-269{,}9 \times 10^{-3}$ (C_2H_4) et à $-271{,}2 \times 10^{-3}$ e (C_2H_2). Il semble que les doubles excitations n'apportent qu'une faible contribution à ces corrections. Dans l'acétylène, trois mono-excitations $\sigma \rightarrow \sigma^*$ sont responsables d'environ 83% de la correction de la charge alors que, comme on pouvait s'y attendre, le rôle des excitations du type $\pi \rightarrow \pi^*$ est faible. De la même manière, quatre configurations $\sigma \rightarrow \sigma^*$ sont la cause d'environ 76% de la correction dans l'éthylène. Ces effets sont particulièrement importants lorsqu'on les compare à ceux des alcanes pour lesquels les charges ne sont pratiquement pas affectées par des corrections d'IC. Les charges théoriques obtenues à l'aide de calculs d'IC semblent converger vers leurs contreparties empiriques, dans une généralisation du schéma de Mulliken.

Mots clés : densité électronique, interaction de configuration.

[Traduit par la rédaction]

Introduction

The theoretical energies of ground state molecules are only slightly improved by the inclusion of single excitations in configuration interaction (CI) calculations. In the case of H_2O, for example, single excitations improve the correlation energy associated with double excitations (DCI) by only 0.6%, in a situation where single and double excitations (SDCI) account for ~92% of the basis set correlation energy (full CI) (1). In contrast, the important role of single excitations is revealed (2) by the erroneous dipole moment predicted for CO when only multiple excitations are retained; inclusion of single excitations restores the correct sign and order of magnitude for μ_{CO}.

This study examines the role of single excitations in CI calculations, attention being focused on charge distributions. Our results thus differ from all the presently known population analyses that were obtained at the SCF level. Here we investigate in detail the atomic charges of ground state ethylene and acetylene and offer comparisons with methane and ethane. With the help of these results, we examine the validity of population analyses carried out with CI wave functions and learn that the charges obtained in this way do, indeed, converge toward those predicted earlier (3) from energy formulas featuring atomic charges in an explicit manner, in sharp contrast with what can be achieved at the SCF level.

Outline of Calculations

The SCF reference state

Using the double-zeta 4-31G basis, all scale factors and structural parameters were optimized following Davidson's optimally conditioned minimization technique (4) (Tables 1 and 2). This optimization, resulting in nearly theoretical virial ratios (as opposed to results deduced with standard exponents, giving $V/T \approx -1.98$), significantly improves the quality of the basis. The calculations of ethylene and acetylene were carried out under the appropriate D_{2h} and

	$H(s')$	1.20	1.18754
	$H(s'')$	1.15	1.128814

[a]Following the original recipe given by R. Ditchfield *et al.* (15).

$D_{\infty h}$ symmetry constraints, respectively. The corresponding ground state electron configurations are

$$1a_g^2\ 1b_{1u}^2\ 2a_g^2\ 2b_{1u}^2\ 1b_{2u}^2\ 3a_g^2\ 1b_{3g}^2\ 1b_{3u}^2$$

for the ^1A_g state of ethylene and

$$1\sigma_g^2\ 1\sigma_u^2\ 2\sigma_g^2\ 2\sigma_u^2\ 3\sigma_g^2\ 1\pi_u^4$$

for the $^1\Sigma_g^+$ state of acetylene.

Configuration interaction

Improvement of the wave functions was achieved by means of SDCI and DCI calculations, the many-electron wave functions being expanded as

$$[1]\qquad |\phi_0\rangle = c_0\,|\Psi_0\rangle + \sum_{k,v} c_k^v\,|\Psi_k^v\rangle + \sum_{k\geq l,v\geq t} c_{kl}^{vt}\,|\Psi_{kl}^{vt}\rangle$$

where $|\Psi_0\rangle$ stands for the appropriate SCF reference state; $|\Psi_k^v\rangle$ represents the single $k \rightarrow v$ and $|\Psi_{kl}^{vt}\rangle$ the double $k,l \rightarrow v,t$ type configurations. The summation indices in eq. [1] prevent double-counting of excited configurations. The $|\Psi_k^v\rangle$'s and $|\Psi_{kl}^{vt}\rangle$'s are space- and spin-adapted in a basis of eigenfunctions of S^2, as described earlier in detail (*5a*). Inclusion of the singly excited configurations is obviously needed for a proper description of one-electron properties such as charge densities and, hence, for properties that are sensitive to this quantity (dipole, quadrupole moments, . . .). The doubly excited configurations are required for two reasons. First, they allow us to indirectly introduce the single excitations by a coupling with the SCF reference state, the direct coupling being forbidden by the Brillouin theorem. Second, they can lead to non-negligible contributions to charge density corrections through a direct coupling with the reference state.

In the present CI developments, a core of two MO's was kept doubly occupied, i.e., the $1\sigma_g$, $1\sigma_u$ orbitals of C_2H_2 and the $1a_g$, $1b_{1u}$ orbitals of C_2H_4 corresponding to carbon *K* shells. The remaining 10 or 12 electrons of C_2H_2 or C_2H_4, respectively, were left available for fractional occupation of the corresponding 20 or 24 MO's.

Charge analysis

The following theoretical evaluation of atomic charges in an *N*-electron molecule involves the calculation of its charge density

$$[2]\qquad \rho(\boldsymbol{r}) = \langle\phi_0\,|\,\hat{\rho}(\boldsymbol{r})\,|\,\phi_0\rangle$$

i.e., the mean value of the density operator

$$\hat{\rho}(\boldsymbol{r}) = \sum_{i=1}^{N} \delta(\boldsymbol{r}_i - \boldsymbol{r})$$

where δ is the Dirac function.

Each molecular orbital $\varphi_a(\boldsymbol{r})$ is developed using the atomic basis set $\chi_\mu(\boldsymbol{r})$, giving

$$[3]\qquad \varphi_a(\boldsymbol{r}) = \sum_{\mu} d_{\mu a}\chi_\mu(\boldsymbol{r})$$

In this manner, inserting eqs. [1] and [3] into eq. [2], $\rho(\boldsymbol{r})$ can be expressed as follows:

$$[4]\qquad \rho(\boldsymbol{r}) = \rho_0(\boldsymbol{r}) + \rho_S(\boldsymbol{r}) + \rho_{SD}(\boldsymbol{r})$$

where $\rho_0(\boldsymbol{r})$ is the charge density involving the contribution of the SCF reference state to $\rho(\boldsymbol{r})$: $\rho_S(\boldsymbol{r})$ is the contribution to the density matrix including all non-diagonal elements of $\hat{\rho}(\boldsymbol{r})$ between the reference state and the singly excited configurations, and all diagonal and non-diagonal elements between the single excited configurations themselves; $\rho_{SD}(\boldsymbol{r})$ is the contribution to the charge density, which includes all the other terms (not contained in $\rho_0(\boldsymbol{r}) + \rho_S(\boldsymbol{r})$) coupling single with double excitations, and double excitations between themselves.

The appropriate expressions are (we assume real $\chi_\mu(\boldsymbol{r})$ and $d_{\mu a}$)

$$\rho_0(\boldsymbol{r}) = c_0^2 \sum_{\mu\nu} P_{d,\mu\nu}(0)\,\chi_\mu(\boldsymbol{r})\,\chi_\nu(\boldsymbol{r})$$

$$\rho_S(\boldsymbol{r}) = \sum_{K\equiv k\rightarrow v} \Bigg[c_k^{v2} \sum_{\mu\nu} P_{d,\mu\nu}(K)\chi_\mu(\boldsymbol{r})\chi_\nu(\boldsymbol{r}) + 2\,(-1)_K^0 c_0 c_k^v \sum_{\mu\nu} P_{n-d,\mu\nu}(0,K)\,\chi_\mu(\boldsymbol{r})\chi_\nu(\boldsymbol{r}) + 2 \sum_{K'\equiv k\rightarrow v'} (-1)_K^{K'} c_k^v c_k^{v'} \sum_{\mu\nu} P_{n-d,\mu\nu}(K,K')\,\chi_\mu(\boldsymbol{r})\chi_\nu(\boldsymbol{r}) + 2 \sum_{K''\equiv k'\rightarrow v} (-1)_K^{K''} c_k^v c_{k'}^v \sum_{\mu\nu} P_{n-d,\mu\nu}(K,K'')\,\chi_\mu(\boldsymbol{r})\chi_\nu(\boldsymbol{r}) \Bigg]$$

$$\rho_{SD}(\boldsymbol{r}) = \sum_{K\equiv k,l\rightarrow v,t} \Bigg[c_{kl}^{vt2} \sum_{\mu\nu} P_{d,\mu\nu}(K)\,\chi_\mu(\boldsymbol{r})\chi_\nu(\boldsymbol{r})$$

$$+ 2 \sum_{K' \in \{\{1/0\} \cap \{1/K\}\}} (-1)_K^{K'} c_{kl}^{vt} c_{k'}^{v'} \sum_{\mu\nu} P_{n-d,\mu\nu}(K,K') \times \chi_\mu(\boldsymbol{r})\chi_\nu(\boldsymbol{r})$$

$$+ 2 \sum_{K'' \in \{\{2/0\} \cap \{1/K\}\}} (-1)_K^{K''} c_{kl}^{vt} c_{k''l''}^{v''t''} \sum_{\mu\nu} P_{n-d,\mu\nu}(K,K'') \chi_\mu(\boldsymbol{r})\chi_\nu(\boldsymbol{r}) \Bigg]$$

with

$$P_{d,\mu\nu}(K) = \sum_a n_{Ka} d_{\mu,Ka} d_{\nu,Ka}$$

$$P_{n-d,\mu\nu}(K,L) = d_{\mu,Ki} d_{\nu,Lj}$$

The summations on k, l, and k', l', k'', l'', run over the MO's occupied in $|\Psi_0\rangle$, while the summations on v, t, and v', t', v'', t'', run over the MO's unfilled in $|\Psi_0\rangle$. The pair of indices K, L, with $L \equiv K'$ or K'', refer to the configurations $|\Psi_K\rangle$ and $|\Psi_L\rangle$, coupled through $\hat{\rho}(\boldsymbol{r})$, and which only differ by the φ_{Ki} and φ_{Lj} MO's. $(-1)_K^L = \pm 1$ following the parity of the permutation that locates at the same place the spin-orbitals present in K and L. n_{Ka} represents the occupancy (0, 1, or 2) of the ath molecular orbital in $|\Psi_K\rangle$. The subscript combination Ka stands for the absolute index of this molecular orbital (i.e., its index in the set defined by eq. [3]). The summation parameter $K' \in \{\{1/0\} \cap \{1/K\}\}$ ($K'' \in \{\{(2/0\} \cap \{1/K\}\}$ stands for the configurations K' (K''), which are, at once, a single-excited (double-excited) configuration with respect to the reference state $|\Psi_0\rangle$, and a single-excited configuration with respect to $|\Psi_K\rangle$.

Finally, using the **P** matrix, defined by

$$\rho(\boldsymbol{r}) = \rho_0(\boldsymbol{r}) + \rho_S(\boldsymbol{r}) + \rho_{SD}(\boldsymbol{r}) \equiv \sum_{\mu\nu} P_{\mu\nu}\chi_\mu(\boldsymbol{r})\chi_\nu(\boldsymbol{r})$$

Mulliken's net atomic charge q_A of atom A is deduced in the usual way (6),

$$[5] \qquad q_A^{\text{Mulliken}} = Z_A - \sum_{\mu \in A} (\mathbf{PS})_{\mu\mu}$$

where Z_A is the nuclear charge of atom A and **S** the effective overlap matrix of the atomic basis set. Charge normalization is ensured by $\Sigma_\mu (\mathbf{PS})_{\mu\mu} \equiv \text{tr}(\mathbf{PS}) = N$, i.e., $\Sigma_A q_A = 0$. In a more general partitioning scheme (3, 7), lifting the constraint of halving all overlap population terms, it is

$$N_A = \sum_{\mu \in A} \left(P_{\mu\mu} + \sum_{\nu \neq \mu} P_{\mu\nu} S_{\mu\nu} \lambda_{\mu\nu} \right)$$

$$q_A = Z_A - N_A$$

i.e.,

$$[6] \qquad q_A = q_A^{\text{Mulliken}} + \sum_{\mu \in A} \sum_{\nu \neq \mu} P_{\mu\nu} S_{\mu\nu} (1 - \lambda_{\mu\nu})$$

The inadequacy of Mulliken's charge analysis at the SCF level has been known for some time (8). Here, both Mulliken's scheme ($\lambda_{\mu\nu} = 1$), eq. [5], and its generalization, eq. [6], are instrumental in assessments regarding CI contributions in charge analyses and the physical validity of results deduced in this manner.

Selection of the relevant configurations

As we are interested in the mean value of a one-electron operator, the contribution of singly excited configurations in the full CI wave function requires attention. Using the Rayleigh–Schrödinger perturbation theory, with the partition of the Hamiltonian written as $\hat{H} = \hat{H}^{(0)} + \hat{V}$, expansion of the wave function up to the second order gives

$$[7] \qquad |\Psi_0\rangle = |\Psi_0^{(0)}\rangle + |\Psi_0^{(1)}\rangle + |\Psi_0^{(2)}\rangle$$

where the following expressions hold for $|\Psi_0^{(1)}\rangle$ and $|\Psi_0^{(2)}\rangle$:

$$[8] \qquad |\Psi_0^{(1)}\rangle = \sum_{K \neq 0} c_{0K}^{(1)} |\Psi_K^{(0)}\rangle \qquad \text{with } c_{0K}^{(1)} = \frac{V_{K0}}{E_0^{(0)} - E_K^{(0)}}$$

$$[8'] \qquad |\Psi_0^{(2)}\rangle = \left\{ -\frac{1}{2} \sum_{I \neq 0} \left\{ \frac{V_{I0}}{E_0^{(0)} - E_I^{(0)}} \right\}^2 \right\} |\Psi_0^{(0)}\rangle + \sum_{K \neq 0} c_{0K}^{(2)} |\Psi_K^{(0)}\rangle$$

with

$$c_{0K}^{(2)} = \left\{ \sum_{I \neq 0} \frac{V_{KI} V_{I0}}{(E_0^{(0)} - E_K^{(0)})(E_0^{(0)} - E_I^{(0)})} \right\} - \frac{V_{00} V_{K0}}{(E_0^{(0)} - E_K^{(0)})^2}$$

where $|\Psi_K^{(0)}\rangle$ is the Kth eigenfunction of $\hat{H}^{(0)}$, $E_K^{(0)} \equiv \langle \Psi_K^{(0)} | \hat{H}^{(0)} | \Psi_K^{(0)} \rangle$ is the associated eigenvalue, $V_{KI} \equiv \langle \Psi_K^{(0)} | \hat{V} | \Psi_I^{(0)} \rangle$ for $K = 0, 1, \ldots$ and $I = 0, 1, \ldots$ (the first term on the right-hand side of eq. [8′] has its origin in the normalization to second order of eq. [7]).

The first-order correction $|\Psi_0^{(1)}\rangle$ allows only the doubly excited configurations (hereafter, {2/0}) to mix with the SCF reference state $|\Psi_0\rangle$, all other excitations making a zero contribution at this stage because of the Brillouin theorem (as concerns single excitations) or the Slater rules otherwise. On the other hand, the second-order correction $|\Psi_0^{(2)}\rangle$ allows single excitations (hereafter, {1/0}) to mix indirectly with $|\Psi_0\rangle$ through the doubly excited configurations.

The first-order correction to $\rho_{SCF}(\boldsymbol{r})$ is

$$\rho^{(1)}(\boldsymbol{r}) = 2 \langle \Psi_0^{(0)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_0^{(1)}(\boldsymbol{r}) \rangle = 2 \sum_{K \neq 0} \frac{V_{K0}}{E_0^{(0)} - E_K^{(0)}} \langle \Psi_0^{(0)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_K^{(0)}(\boldsymbol{r}) \rangle = 0$$

($V_{K0} = 0$ if $K \notin \{2/0\}$, while $\langle \Psi_0^{(0)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_K^{(0)}(\boldsymbol{r}) \rangle = 0$ if $K \notin \{1/0\}$).

The second-order correction to $\rho_{SCF}(\boldsymbol{r})$ is

$$\rho^{(2)}(\boldsymbol{r}) = \langle \Psi_0^{(1)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_0^{(1)}(\boldsymbol{r}) \rangle + 2 \langle \Psi_0^{(0)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_0^{(2)}(\boldsymbol{r}) \rangle$$

$$= -\left\{ \sum_{I \in \{2/0\}} \left\{ \frac{V_{I0}}{E_0^{(0)} - E_I^{(0)}} \right\}^2 \right\} \langle \Psi_0^{(0)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_0^{(0)}(\boldsymbol{r}) \rangle$$

$$+ 2 \sum_{K \in \{1/0\}} \left\{ \sum_{I \in \{\{2/0\} \cap \{\{1/K\} \cup \{2/K\}\}} \frac{V_{KI} V_{I0}}{(E_0^{(0)} - E_I^{(0)})(E_0^{(0)} - E_K^{(0)})} \right\} \langle \Psi_0^{(0)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_K^{(0)}(\boldsymbol{r}) \rangle$$

$$+ \sum_{K \in \{2/0\}} \left\{ \frac{V_{K0}}{E_0^{(0)} - E_K^{(0)}} \right\}^2 \langle \Psi_K^{(0)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_K^{(0)}(\boldsymbol{r}) \rangle$$

$$+ \sum_{K \in \{2/0\}} \sum_{L \in \{\{2/0\} \cap \{1/K\}\}} \left\{ \frac{V_{K0}}{E_0^{(0)} - E_K^{(0)}} \right\} \left\{ \frac{V_{L0}}{E_0^{(0)} - E_L^{(0)}} \right\} \times \langle \Psi_K^{(0)}(\boldsymbol{r}) | \hat{\rho}(\boldsymbol{r}) | \Psi_L^{(0)}(\boldsymbol{r}) \rangle$$

	Single contribution		−0.00172	69.8	
Acetylene	SCF	1.0	0	0.0	−335.3
	DCI	0.92472	−0.13468	2.0	−333.3
	SDCI	0.92084	−0.13678	64.1	−271.2
	Single contribution		−0.00209	62.1	

[a]The results for methane and ethane, deduced from optimized 4-31G calculations, are taken from ref. 8.

where the summation parameter $I \in \{\{2/0\} \cap \{\{1/K\} \cup \{2/K\}\}\}$ stands for the configurations I that are, at once, a double-excited configuration with respect to $|\Psi_0\rangle$, and a single- or a double-excited configuration with respect to $|\Psi_K\rangle$.

It follows immediately that the contribution of a single excitation $K \equiv k \rightarrow v$ to the second-order correction $P^{(2)}_{\mu\nu}$ of the element $P_{\mu\nu}$ of the density matrix is

$$[9] \quad 2\left\{\sum_{I\in\{\{2/0\}\cap\{\{1/K\}\cup\{2/K\}\}\}} \frac{V_{KI}V_{I0}}{(E_0^{(0)} - E_K^{(0)})(E_0^{(0)} - E_I^{(0)})}\right\} \times \{d_{\mu,k}d_{\nu,v}\}$$

To obtain the best possible wave function, eq. [1], while keeping the required computer space at an acceptable level, the configurations were selected (*i*) by retaining all singly excited symmetry- and spin-adapted configurations in the CI process and (*ii*) by picking in order of preference those double excitations that mix more efficiently with single excitations and the SCF reference state. The latter rule introduces a new constraint: one-electron properties are thus expected to converge more rapidly than the correlation energy, subject only to the constraint embodied in the construction of c_k. Hence, a selection of configurations that may be appropriate in charge calculations does not necessarily represent the best choice in problems of correlation energies. Briefly, we approach convergence of the charge results well before achieving that of the energy, as indicated by the results given below. Our calculations involve 20 single plus 283 double excitations for ethylene and 17 single plus 340 double excitations for acetylene, a selection that ensures convergence of the charge results.

Results

The 4-31G optimized geometries and scale factors of ethylene and acetylene are indicated in Tables 1 and 2. The structural parameters are in good agreement with their experimental counterparts though, as usual, the CC bond lengths appear to be somewhat underestimated. Slight uncertainties of this sort, however, do not result in significant errors in charge calculations. In both ethylene and acetylene, the s_L'' and p'' outer shells are those that are most perturbed by optimizations of the scale factors. As described elsewhere (3, 8), the use of well-adapted optimized basis sets is important in calculations of consistent charge distributions.

Table 3 reports the contributions of the excited configurations to the correlation energies and electronic charges of selected hydrocarbons. For ethylene and acetylene, inspection of the corrections contributed by the single and double excitations clearly indicates that the improvements of the energy, on the one hand, and charge distribution, on the other, follow distinct patterns. The modest contribution of the doubly excited configurations to the charges, in pure DCI calculations, suggests that the main correction to $\rho(r)$ primarily arises from interaction between single and double excitations and between single excitations themselves, which reflects in essence the one-electron nature of the operator $\hat{\rho}(r)$. Hence, the contribution of the single excitations can be understood by considering the second-order term $|\Psi_0^{(2)}\rangle$ of the Rayleigh–Schrödinger perturbation development eq. [7], as shown in eq. [9].

In addition, considering now the contribution, eq. [9], of each single excitation to the second-order correction $\rho_0^{(2)}(r)$ of the density matrix, it is clear that the singly excited configurations do not mix among themselves at this order of the perturbation expansion. It is thus straightforward to estimate the individual contributions of the various single excitations that are independently involved in the CI wave function. This results clearly from our numerical investigations (Tables 4 and 5). Indeed, the improvement of the CI wave function obtained by adding the single excitations one by one does not appreciably contaminate the weight of those already included in $|\phi_0\rangle$. The individual contributions of the $k \rightarrow v$ type configurations to the net charge corrections given in Tables 4 and 5 for ethylene and acetylene are vividly illustrated in Figs. 1 and 2. For acetylene, three singly excited configurations lead to ~83% of the net charge correction and are all of the $\sigma \rightarrow \sigma^*$ type, while the $\pi \rightarrow \pi^*$ excitation contributions are weak. The conclusions for ethylene are similar: four configurations are responsible for ~76% of the charge correction and the improvement due to $\pi \rightarrow \pi^*$ excitations is minor.

Convergence appears to be reached when all the single excitations are included in the configuration interaction and when the CI dimension reaches 400 determinants (i.e., nearly

160 spin-adapted configurations). Indeed, a treatment of the excited states that effectively perturb the $k \rightarrow v$ type configurations (i.e., the single and the double excitations with respect to $k \rightarrow v$ that give non-zero CI matrix elements) may be regarded satisfactory with the inclusion of less than 300 spin-adapted configurations in the CI calculation. Present results suggest that a good description of charges in highly symmetric molecules does not necessarily involve very large CI calculations. It is also clear, however, that atomic charges would be plagued by serious errors if CI corrections were left out.

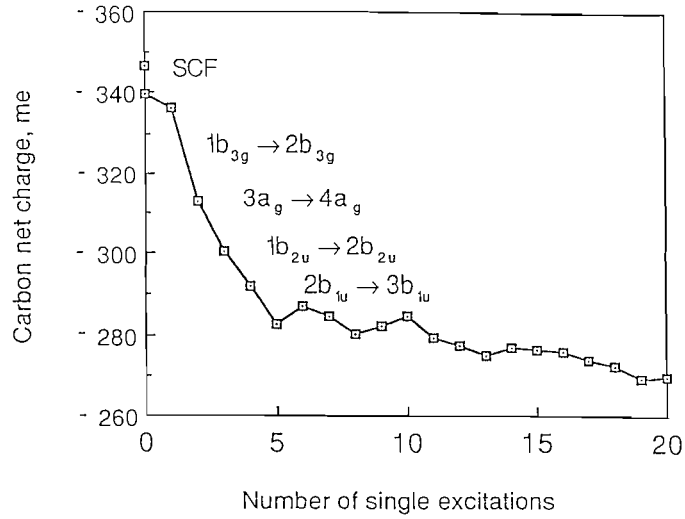

FIG. 1. Contribution of single excitations, in decreasing order of their weight in the CI wave function, to the carbon net charge of ethylene.

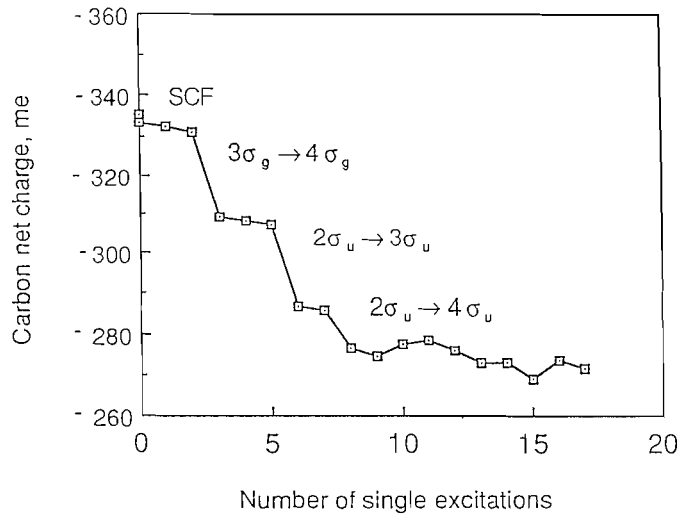

FIG. 2. Contribution of single excitations, in decreasing order of their weight in the CI wave function, to the carbon net charge of acetylene.

Charge analyses following eq. [6] have proven most appropriate in the study of physical properties, namely molecular energies (3), bond dissociation energies (9), and correlations with ^{13}C NMR shifts (10), explicitly involving atomic charges. For alkanes, eq. [6] gives (3, 7)

$$[10] \quad q_C = q_C^{\text{Mulliken}} + N_{CH}p$$

where p measures, for one CH bond, the departure from Mulliken's equipartitioning of overlap populations and N_{CH} counts the H atoms attached to C. The key is in the remarkable properties associated with a particular p value, that rendering all alkane carbons as similar to one another as possible, in a picture describing charge variations as events occurring most reluctantly. This p value is conveniently

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

deduced[3] from Mulliken net charges calculated for the ethane and methane carbons (3, 8), i.e.,

$$[11] \quad p = 3.412 q_C^{\text{Mulliken}}(C_2H_6)/3 - 4.412\, q_C^{\text{Mulliken}}(CH_4)/4$$

From our SDCI charges (Table 3) it follows that p = 138.68 me, a result which applies both to sp^3 and sp^2 carbons (3). The carbon net charges given by eq. [6] are thus 37.8 (C_2H_6) and 7.5 me (C_2H_4). These results compare favorably with their empirical counterparts (3) deduced from energy calculations, i.e., 35.1 (C_2H_6) (ref. 3, p. 107; ref. 11) and 7.7 me (C_2H_4) (ref. 3, p. 145; ref. 12). Clearly, realistic charge analyses require careful consideration of CI corrections. Configuration interaction removes the major inconsistencies plaguing the reference charges of ethane and ethylene at the SCF level and leads to the physically meaningful results that are suggested by energy calculations of alkanes and alkenes based on the electrostatic potentials at the nuclei.

L. are indebted to the Ministère de la Recherche et de la Technologie de France for the financial support offered by the Département de Chimie and the Département de Physique.

[3]Earlier studies (3, 7) indicated that the atomic charges of alkanes can be satisfactorily described in terms of a parameter, n, which determines their relative ordering. In particular, we have $q_C(CH_4)/q_C(C_2H_6) = 4(n + 1)/3n$. This parameter depends on the basis set (e.g., n = 1.3325 for optimized STO-3G Mulliken charges (7) or n = 39.454 for the SCF 4-31G Mulliken results of Table 3). The relative ordering of atomic charges, i.e., n, can be easily modified with the use of charges defined by eq. [10]. With the constraint that all alkane carbons should be as similar to one another as possible, a constraint whose validity is clearly revealed by the study of molecular energies (3, 11) and by correlations between ^{13}C nuclear magnetic resonance shifts and atomic charges (7, 10), it is $n = -4.412$. In this case, $q_C(CH_4)$ and $q_C(C_2H_6)$ represent corrected charges, suited for use in physical problems, namely $q_C(CH_4) = q_C^{\text{Mulliken}}(CH_4) + 4p$ and $q_C(C_2H_6) = q_C^{\text{Mulliken}}(C_2H_6) + 3p$ (from eq. [10]), i.e., $4(-3.412)/3(-4.412) = [q_C^{\text{Mulliken}}(CH_4) + 4p]/[q_C^{\text{Mulliken}}(C_2H_6) + 3p]$. The latter equation gives eq. [11] permitting the numerical evaluation of p for use in eq. [10]. The p correction for the sp^2 carbons of ethylenic hydrocarbons is the same as that determined for the sp^3 carbons, at least to a very good approximation (10*b*).

M. A. ARAMENDIA, V. BORAU, C. JIMENEZ, J. M. MARINAS, M. E. SEMPERE, and F. J. URBANO. Can. J. Chem. **70**, 74 (1992).

This paper deals with the optimization of the variables involved in the synthesis of Pd/sepiolite catalysts used in the individual and competitive reduction of acrylamide and methacrylamide with molecular hydrogen and by hydrogen transfer with cyclohexene as donor. From the reaction profiles of the acrylamide/methacrylamide pair were determined the relative reactivities and relative coefficients of adsorption corresponding to the competitive liquid-phase reductions with molecular hydrogen obtained for different catalysts, solvents, and temperatures. A similar study on the competitive hydrogen transfer reduction of both amides was rendered unfeasible by the fact that acrylamide was strongly adsorbed on the same types of sites as cyclohexene. This completely hindered cyclohexene adsorption and, as a result, inhibited the reaction altogether.

Key words: reduction, acrylamide, methacrylamide, Pd/sepiolite, hydrogen transfer

M. A. ARAMENDIA, V. BORAU, C. JIMENEZ, J. M. MARINAS, M. E. SEMPERE et F. J. URBANO. Can. J. Chem. **70**, 74 (1992).

Dans ce travail on a optimisé les variables impliquées dans la synthèse de catalyseurs Pd/sépiolite utilisés dans la réduction individuelle et compétitive de l'acrylamide et du méthacrylamide à l'aide d'hydrogène et par transfert d'hydrogène à partir du cyclohexène agissant comme donneur. Sur la base des profils réactionnels de la paire acrylamide/méthacrylamide, on a déterminé les quantités relatives et les coefficients relatifs d'adsorption correspondants aux réductions compétitives en phase liquide avec de l'hydrogène moléculaire, obtenues avec divers catalyseurs ou solvants et à diverses températures. Une étude semblable sur les réductions compétitives par transfert d'hydrogène des deux amides n'est pas possible à cause du fait que l'acrylamide est fortement adsorbé sur les mêmes types de sites que le cyclohexène. Cette propriété a complètement empêché l'adsorption du cyclohexène et en conséquence a complètement inhibé la réaction.

Mots clés : réduction, acrylamide, méthacrylamide, Pd/sépiolite, transfert d'hydrogène.

[Traduit par la rédaction]

Introduction

Catalytic hydrogenations by transfer with a variety of hydrogen donors (1, 2) have been widely used in organic syntheses in the last few years, so much so that in many cases they have become viable alternatives to conventional catalytic hydrogenations with gaseous hydrogen.

For a few years now, our research team has investigated the application of aluminium orthophosphates and SiO_2–$AlPO_4$ and Al_2O_3–$AlPO_4$ systems as metals supports in the preparation of heterogeneous reduction catalysts. By supporting Pd on such systems we have prepared excellent catalysts (3–6) suitable for transfer reduction processes involving organic functions.

Sepiolites, namely hydrated magnesium silicates structurally consisting of internal channels capable of accommodating water and other molecules, are highly adsorptive to a number of gases and vapors (7–9) and have been used in chromatography and as catalysts or catalyst supports. Spain abounds with large deposits of this mineral, which is commercialized by TOLSA S.A., hence the great interest in the development of potential applications of this silicate. In this respect, our team has used sepiolites both as acid–base catalysts (10) and as supports for metals such as Pd, Pt, and Ni in order to obtain catalysts active in the reduction of aromatic nitro compounds (11) and in the deprotection of N-protected amino acids (12).

This work aims at comparing the catalytic selectivity of Pd/sepiolite systems in the competitive hydrogenation of acrylamide and methacrylamide, both with molecular hydrogen at a low pressure in a Parr system and by hydrogen transfer with cyclohexene as donor. It also studies the effect of the introduction of a methyl group into the double bond of acrylamide in both reduction processes. In the light of the theory of competitive hydrogenations (13–15), an explanation is provided for the hindered reduction of acrylamide, which, unlike methacrylamide, does not undergo hydrogen transfer with cyclohexene as donor.

Experimental

Supports

The Pd supports used were a sepiolite of the Pansil variety (PS) supplied by TOLSA S.A. and extracted from their ores in Vallecas (Spain), and a mixed SiO_2–$AlPO_4$ system named P2, gelled in propylene oxide, and prepared in our laboratory as described elsewhere (16).

The textural properties of both supports, determined by nitrogen adsorption at liquid-nitrogen temperature, were as follows: surface area (determined by the BET method), 410 and 280 $m^2\ g^{-1}$; pore volume, 0.54 and 0.48 mL g^{-1}; average pore diameter, 35 and 35 Å for support P2 and the sepiolite calcined at 673 K, respectively.

Supported palladium systems

Supported Pd catalysts were prepared by impregnation of the support with an aqueous solution of Na_2PdCl_4 (A), $(NH_3)_4PdCl_2$ (B), or $Pd(NO_3)_2 \cdot 2H_2O$ (C) by the incipient wetness technique.

The slurry was stirred for 24 h, after which the water was evaporated on a rotary vacuum evaporator and dried at 393 K for 24 h,

followed by calcination (by increasing the temperature up to 493 K at a rate of 1 K min^{-1}) and subsequent reduction in a hydrogen stream (99.999% H_2, H_2O < 3 ppm) flowing at a rate of 60 mL min^{-1} and under the same thermal regime followed in the calcination.

One of the catalysts was doped with NaOH. It was labelled Pd_3-PS-A(4), the subscript denoting the Pd content (3%), PS the type of support, A the precursor salt used (Na_2PdCl_4), and (4) that the catalyst was doped with sodium hydroxide at a mole ratio of Na^+ to Pd of 4:1.

Chemicals

The Pd salts, hydrogen donor, acrylamide, methacrylamide, and solvents were commercially available reagents purchased from Merck and Fluka.

Product analysis

The reaction products were analysed by gas chromatography by using high-purity standards. Analyses were carried out on a Hewlett–Packard 5790A gas chromatograph fitted with an HP 18850GC terminal and furnished with a column packed with 10% diethyleneglycol succinate in Chromosorb PAW-60/80 mesh.

Experimental setup and conditions

Hydrogen transfer reductions

Hydrogen transfer reductions were carried out in a Berghof Heiz reactor by using 5×10^{-3} mol of the substrate to be reduced, 0.05 g of Pd catalyst (3% by weight), 5.9×10^{-3} mol of hydrogen donor (cyclohexene), and enough solvent to make up a volume of 6 mL. The reaction temperature varied from experiment to experiment as indicated below. The shaking rate was 1700 rpm, at which external diffusion was under control.

Reductions with gaseous hydrogen

According to a procedure described elsewhere (14), individual and competitive hydrogenation runs were carried out under vigorous shaking in a conventional low-pressure hydrogenator (Parr Instruments Co., model 3911) furnished with a manometer that continuously monitored the hydrogen pressure within the isolated reaction vessel (capacity, 500 mL). The reaction temperature was controlled by pumping water from a thermostatic bath through the vessel jacket, with an accuracy of ±0.5 K.

Individual reactions were carried out under essentially constant-volume conditions in 20 mL of a 0.5 M methanol solution of the substrate, under an initial hydrogen pressure of 0.276–0.414 MPa and at temperatures between 293 and 308 K. The apparent activation energies were calculated over the range 293–318 K. The amount of catalyst employed throughout was 0.045 g (3% Pd by weight).

The initial reaction rates for the individual hydrogenations were obtained from the variation of the hydrogen uptake (calculated from the decrease in the hydrogen pressure at the manometer) as a function of time. As the plots of the decrease in the hydrogen pressure with time were always linear up to 90% conversion, the determination of the initial slope was straightforward and reproducible to within about 6%.

As to the competitive hydrogenations, 20 mL of equimolar mixtures of acrylamide (AC) and methacrylamide (MAC), 0.25 M of each, in methanol were hydrogenated under experimental conditions identical to those used in the individual hydrogenations. The reactions were followed by GLC by analysing the reaction mixtures at appropriate intervals of hydrogen uptake.

Results and discussion

Individual hydrogenations

Hydrogen diffusion control in the reactions was examined. The effect of external diffusion was checked by decreasing the shaking rate from 300 to 100 strokes min^{-1}. The reaction rates were found to be independent of the shaking rate above 200 strokes min^{-1}. Internal diffusion was excluded by using catalysts with a grain diameter less than 0.149 mm.

TABLE 1. Application of the Koros–Nowak criterion

Catalyst	Surface[a] (m^2 g_{Pd}^{-1})	Turnover frequency (s^{-1}) 293 K	300 K	308 K	323 K
Pd_5-PS_{400}-A(4)	62	18.71	27.64	38.73	61.39
Pd_2-PS_{400}-A(4)	64	19.08	26.30	33.38	57.24

Reaction conditions: 20 mL of 0.5 M methacrylamide in 20 mL of MeOH. Initial H_2 pressure: 0.414 MPa. Reaction T: 300 K. Amount of catalyst: just as much as required to obtain 1.359 mg of Pd.

[a]The metal surface area was calculated from $S = 6/\rho d$, where ρ is the metal density and d is the average particle diameter, calculated by transmission electron microscopy (TEM) on a Phillips EM-300 instrument working at 100 kV and an IBAS II KONTRON image analyser, by counting between 600 and 900 particles per sample.

In addition, the hydrogen uptake, r, was found to vary linearly with the weight of catalyst, w. The plot of $1/r$ versus $1/w$ was also linear, and from the reciprocal of the intercept (17), a hydrogen transfer rate of 0.26×10^{-3} mol s^{-1} was obtained. As the hydrogen uptake rate of the fastest reaction was 9.13×10^{-5} mol s^{-1}, the kinetic data obtained must be free from any influence of transport phenomena throughout the variable operational ranges used. The absence of both internal and external heat and mass transfer constraints is apparent from the turnover frequencies listed in Table 1. Also, the absence of any significant changes in turnover between two catalysts that differed in their metal loading by a factor of 2.5 but had similar dispersion confirms that the reaction rates were correctly measured (18).

Table 2 reflects the influence of the type of precursor salt, doping with NaOH, type of support (sepiolite, PS, or mixed SiO_2–$AlPO_4$ system, P2), and calcination temperature of the support in the case of sepiolite, on the catalyst activity in the liquid-phase reduction of the double bond in acrylamide with molecular hydrogen. The reactivity per square meter of Pd of the catalysts supported on sepiolite is not significantly influenced by the calcination temperature. Yet, the doping with NaOH modifies the catalyst specific activity, which is maximum for an Na^+/Pd ratio of 4:1. The type of precursor salt and the solvent in which this is used significantly influence the catalyst specific activity of the resultant system, the best results being obtained with Na_2PdCl_4 in water.

The hydrogenation rate for all substrates, namely acrylamide (AC), methacrylamide (MAC), and cyclohexene (CHE), was zero order in the substrate concentration (0.25–2 M), while the order in the hydrogen pressure (0.414–0.551 MPa) was 0.5.

According to Horiuti–Polanyi (24), the addition of hydrogen to an olefin takes place via the following elementary process:

$$[1] \quad R + 2^* \underset{k_{-1}}{\overset{k_1}{=}} {}^*R^*$$

$$[2] \quad H_2 + 2^* \underset{k_{-2}}{\overset{k_2}{=}} 2H^*$$

$$[3] \quad {}^*R^* + H^* \underset{k_{-3}}{\overset{k_3}{=}} RH^* + 2^*$$

$$[4] \quad RH^* + H^* \overset{k_4}{\rightarrow} RH_2 + 2^*$$

Amount of catalyst: 0.0453 g. Total volume: 20 mL. T: 300 K. Initial pressure: 0.414 MPa. Substrate: AC in 0.5 M MeOH.
[a]Average metal particle diameter as calculated by TEM.

We shall now assume that the chemisorption of hydrogen (step [2]) is in equilibrium, with a constant k_2, and that the most abundant surface intermediate is the semihydrogenated state, RH*, covering almost entirely the available surface; both assumptions are compatible with a zero reaction order in the hydrocarbon. We shall also assume that chemisorbed hydrogen covers only a small fraction of the free sites. Thus:

$$[L] \simeq [RH^*]$$

$$[RH^*] >> [^*] >> [H^*]$$

where [L] is the number of active sites per unit metal area, and [RH*], [*], and [H*] are the concentrations of the semihydrogenated state, free active sites, and adsorbed atomic hydrogen, respectively.

Under these conditions, the overall reaction rate will be given by that of step [4], namely:

$$[5] \quad r = r_4 = [L]k_4k_2^{1/2}[H_2]^{1/2}$$

which is consistent with the kinetic results.

On the other hand, when the hydrogenation of AC or MAC was carried out to completion, the plot of the converted fraction of MAC or AC as a function of time deviated from linearity at a given conversion. This phenomenon cannot be attributed to catalyst poisoning and deactivation because a second introduction of reactant after the first sample had been completely converted gave the same reaction rate obtained for the first AC (or MAC) sample. This behavior is consistent with that found in the liquid-phase hydrogenation of 1-hexene, styrene, α-methylstyrene, acrolein, and methyl vinyl ketone on $Ni/AlPO_4$ catalysts (19–22) and in the liquid-phase hydrogenation of cyclohexene on Pt/Al_2O_3 and Pt/SiO_2 (23), where the reaction order in the olefin changes from zero to unity as a result of the catalyst "starvation" of olefin molecules at very low concentrations. Thus, our work was only concerned with the linear portion of the plot of the decrease in the hydrogen pressure as a function of the reaction time, where the reaction rate was zero order in AC, MAC, and CHE.

The hydrogenation rate is affected by the solvent. The best solvent was found to be methanol, which resulted in the highest reaction rates. We tried to correlate (Table 3) the logarithm of the hydrogenation rate of acrylamide in different solvents (log r) with typical parameters of some of their properties (25), according to the generic equation [6]

$$[6] \quad \log r = A_0 + A_1X$$

As can be seen, all the parameters for which the regression coefficient (r_{xy}) was equal to or greater than 0.94 were a function of the dielectric constant, so the solvent probably influences the bond energies of the activated complex through dielectric properties during the surface reaction.

On the other hand, we applied the multiple regression method to the Taft equation (26):

$$[7] \quad \log r = A_0 + A_1\Pi^* + A_2\beta + A_3\alpha$$

It is obviously correct to say that, with the inclusion of each new adjustable parameter (exploratory variable), the goodness of the fit, as judged by the multiple correlation constant, must either improve or at least remain the same. There are statistical procedures based either on the t test or on F statistics to demonstrate whether or not the inclusion of a new exploratory variable is statistically justified and, where appropriate, we applied such statistical tests. We found a correlation coefficient of 0.99 for a confidence limit of 98% by excluding the Π* term; such a limit dropped to 87% if this term was included. This seems to indicate that the acid–base character of the solvents, like their dielectric constant, plays a major role in the hydrogenation of AC.

The rates of reduction of MAC and AC at the same temperature and hydrogen pressure were rather different (7.5 and 32.7 mmol s^{-1} g_{Pd}^{-1}, respectively, at 308 K). This can be ascribed to steric hindrance in the adsorption of methacrylamide and (or) to the variation of the electron density of the double bond by the +I effect of the methyl group.

On the other hand, the apparent activation energies for AC and MAC were 29.8 ± 1.4 and 29.6 ± 0.8 kJ mol^{-1}, respectively, between 293 and 318 K.

Competitive hydrogenation

drogenation for the couples MAC/AC, AC/CHE, and MAC/CHE, respectively.

The theory of competitive reactions on solid catalysts (13) states that the simultaneous reaction of two reducible molecules, 1 and 2, is a competitive process when the plot of log (C_A^0/C_A) vs. log (C_B^0/C_B) is linear. (C^0 is the initial concentration and C denotes the concentration at time t.) In our case, such a plot (Fig. 2) is linear for the couples AC/MAC (Fig. 2*a*) and MAC/CHE (Fig. 2*c*), so we can state that the simultaneous hydrogenation of A and B for these couples is a competitive process.

The slope of the plot provided the relative reactivity of A to B ($R_{A,B}$). We also calculated the relative equilibrium adsorption constant ($D_{A,B}$) from the expression

$$[8] \quad R_{A,B} = (r_A/r_B)D_{A,B}$$

where r_A and r_B are the individual reaction rates of A and B, respectively. This is only valid provided that the concentrations of A and B are high enough for r_A and r_B to be independent of the concentrations as previously confirmed.

On the other hand, as regards the couple AC/CHE (Fig. 2*b*), the double bond of cyclohexene is not reduced at AC concentrations above 0.025 M because both substrates are adsorbed on the same type of site and AC is retained much more strongly, which hinders cyclohexene adsorption and hence its reactivity. A comparison between the relative adsorption coefficients of the MAC/CHE and AC/CHE pairs (Table 4) reveals that the latter is about 15 times larger than the former, and that the incorporation of CH_3 (MAC) substantially modifies the adsorption.

We studied the variation of $R_{AC,MAC}$, $D_{AC,MAC}$, and the selectivities (S), defined as the ratio between reduced AC and reduced AC plus reduced MAC at half the hydrogen uptake required for the complete reduction of the double bond in both compounds, with the type of catalyst, solvent, and temperature used in the reaction (Table 5).

As can be seen for catalyst Pd_3-PS_{400}-A(4), the relative reactivity ($R_{A,B}$) is independent of the reaction temperature, which, according to Marinas and co-workers (27), by applying the equation

$$[9] \quad R\, \mathrm{d}(\ln R_{AC,MAC})/\mathrm{d}(1/T) = -(E_{a_{AC}} + W_{AC}) + (E_{a_{MAC}} + W_{MAC}) = -(\Delta E_{true})_{AC,MAC}$$

where E_a is the apparent activation energy, W the adsorption heat, and ΔE_{true} the real activation energy, reveals that the real activation energies of the two compounds are identical ($(\Delta E_{true})_{AC,MAC} = 0$). Since, as noted earlier, the apparent activation energies are also identical, the adsorption heats (W) will also be identical.

Since the rates of reduction of acrylamide and methacrylamide are different, there must be a difference in their activation entropies insofar as

$$[10] \quad k_v = (kT/h) \exp[n + \Delta S^{\neq}/R] \exp(E_a^{\neq}/RT)$$

where $\Delta S^{\neq}$ is the entropy increment and $E_a^{\neq}$ the activation

energy (equal for the two substrates), k Boltzman's constant, and h Planck's constant.

Insofar as the entropy factor can be ascribed to the steric hindrance of the adsorption, the decreased rate of reduction of methacrylamide must be attributed to a more negative value of the activation entropy of this process compared to the reduction of acrylamide. We can thus state that the steric effect of the methyl group plays a major role in the process.

On the other hand, Marinas and co-workers (27) derived the following equation:

[11] $$R \ln D_{AC,MAC} = \Delta S_{AC,MAC} - \Delta W_{AC,MAC}/T$$

As shown above, $\Delta W_{AC,MAC} = 0$. Therefore:

[12] $$\Delta S_{AC,MAC} = R \ln D_{AC,MAC}$$

In these cases, the relative adsorption coefficient can be exclusively determined by the entropy factor, which, as stated above, can be ascribed to steric effects on the adsorption.

The inductive effects of the substituents, reflected in changes in the strength of adsorption on the catalyst surface (by alteration of the electron density of the double bond), are directly related to the differential adsorption heat; as this last was virtually zero in our case, the inductive effects involved were clearly negligible.

On analysing the influence of the solvents used (tetrahydrofuran, ethyl acetate, dioxane, and methanol), methanol was found to yield the highest reaction rates and lowest selectivities and relative reactivities in the competitive hydrogenations. The selectivity order found was:

THF > dioxane > ethyl acetate > methanol

Regarding the influence of the catalyst, the order found for the relative reactivities was as follows: Pd_3-PS_{500}-B = Pd_3-PS_{600}-B > Pd_3-PS_{400}-C > Pd_3-PS_{400}-B = Pd/Al_2O_3 > Pd_3-P2-A > Pd/C > Pd_3-PS_{400}-A(4).

We should emphasize the major role played by the precursor Pd salt for a given support. In the case of sepiolite, the greatest selectivity is achieved by using $(NH_3)_4PdCl_2$ and calcining the support at 773 or 873 K prior to the impregnation. This catalyst is much more selective than the Pd/C (Merck) and Pd/Al_2O_3(Fluka) catalysts.

As can be seen, the selectivities are rather high: up to 93% under the optimum conditions, namely by using Na_2PdCl_4 doped with NaOH ($Na^+/Pd = 4$) as precursor, THF as solvent, and a temperature of 293 K.

In view of the above results (Table 4), those obtained in the hydrogen transfer reduction of acrylamide and methacrylamide with the same catalysts are quite logical. Only methacrylamide reduction is feasible under these conditions, as those of acrylamide reduction and cyclohexene disproportionation are inhibited. This shows the signifi-

cance of the adsorption coefficients of the substrate and the donor in hydrogen transfer reactions, as well as the influence of small structural modifications (presence of a methyl group or a proton) in the substrate to be adsorbed on such coefficients. On the other hand, the competitive reduction of AC and MAC by hydrogen transfer with cyclohexene as donor is also unfeasible as the latter cannot be adsorbed on the support to be converted to benzene and release the hydrogen required for the reduction of AC and (or) MAC. Both results confirm that cyclohexene, acrylamide, and methacrylamide are adsorbed on the same type of site, while hydrogen is adsorbed on different free sites, and that the type of donor used plays a significant role in hydrogen transfer processes.

Experiments under way are aimed at comparing the influence of the introduction of a methyl group in the double bond of acrolein, methyl acrylate, and styrene on both types of reduction process: with molecular hydrogen and by hydrogen transfer with cyclohexene as donor.

Pressure dependences of the electrode potentials of some iron(III/II) and cobalt(III/II) couples in aqueous solution

HIDEO DOINE, TODD W. WHITCOMBE, AND THOMAS W. SWADDLE[1]

Department of Chemistry, The University of Calgary, Calgary, Alta., Canada T2N 1N4

Received May 10, 1991

HIDEO DOINE, TODD W. WHITCOMBE, and THOMAS W. SWADDLE. Can. J. Chem. **70**, 81 (1992).

The dependences of the electrode potentials E of aqueous $Fe(H_2O)_6^{3+/2+}$, $Fe(phen)_3^{3+/2+}$, $Fe(CN)_6^{3-/4-}$, and $Co(sep)^{3+/2+}$ upon pressure P (up to ca. 200 MPa) have been measured at 25.0°C relative to an AgCl/Ag(satd. KCl) electrode by cyclic voltammetry. For $Co(sep)^{3+/2+}$ at ionic strength I = 0.28 and 1.00 mol kg^{-1}, $(\partial E/\partial P)_T$ is independent of P as well as I, giving a volume of reaction $\Delta V = +13.7 \pm 0.4$ cm^3 mol^{-1} relative to AgCl/Ag; similarly, for $Fe(H_2O)_6^{3+/2+}$ at I = 0.28 mol kg^{-1} (CF_3SO_3H), $\Delta V = +5.0 \pm 0.3$ cm^3 mol^{-1}. For $Fe(CN)_6^{3-/4-}$ in KCl media, $(\partial E/\partial P)_T$ is independent of P and I at I = 0.28 and 0.51 mol kg^{-1}, giving $\Delta V = -36.1 \pm 1.0$ cm^3 mol^{-1}, but shows some slight dependence on P at I = 1.00 mol kg^{-1} (low-pressure limit $\Delta V_0 = -38 \pm 1$ cm^3 mol^{-1}; $(\partial \Delta V/\partial P)_T \approx +0.030$ cm^3 mol^{-1} MPa^{-1}). For $Fe(phen)_3^{3+/2+}$, $(\partial E/\partial P)_T$ is markedly pressure and medium dependent, with $\Delta V_0 = +14.2 \pm 0.5$ and $+6.2 \pm 0.5$ cm^3 mol^{-1} in KNO_3 media at I = 0.25 and 1.00 mol kg^{-1}, respectively. The peak-to-peak separation of the cyclic voltammograms increases with increasing P for $Fe(CN)_6^{3-/4-}$, but decreases slightly for the cationic couples; these trends can be accounted for in terms of the volumes of activation for the corresponding self-exchange reactions.

Key words: high pressures, electrode potentials, volume of reaction, iron complexes, cobalt complexes.

HIDEO DOINE, TODD W. WHITCOMBE et THOMAS W. SWADDLE. Can. J. Chem. **70**, 81 (1992).

Utilisant la voltampérométrie cyclique et opérant à 25°C, on a déterminé la relation entre la pression P (jusqu'à 200 MPa) et les potentiels à l'électrode E, mesurés par rapport à une électrode de AgCl/Ag (saturé en KCl), de solutions aqueuses de $Fe(H_2O)_6^{3+/2+}$, $Fe(phen)_3^{3+/2+}$, $Fe(CN)_6^{2-/4-}$ et de $Co(sep)^{3+/2+}$. Pour le $Co(sep)^{3+/2+}$, à des forces ioniques I = 0,28 et 1,00 mol kg^{-1}, $(\partial E/\partial P)_T$ est indépendant de la P ainsi que de I, conduisant à un volume de réaction $\Delta V = +13,7 \pm 0,4$ cm^3 mol^{-1} relatif à AgCl/Ag; de la même manière, pour le $Fe(H_2O)_6^{3+/2+}$ à I = 0,28 mol kg^{-1} (CF_3SO_3H), $\Delta V = +5,0 \pm 0,3$ cm^3 mol^{-1}. Pour le $Fe(CN)_6^{3-/4-}$ dans un milieu de KCl, alors que I = 0,28 et 0,51 mol kg^{-1}, $(\partial E/\partial P)_T$ est indépendant de la P et de I, donnant $\Delta V = -36,1 \pm 1,0$ cm^3 mol^{-1} qui est toutefois légèrement dépendant de P lorsque I = 1,00 mol kg^{-1} (la limite à basse pression est $\Delta V_0 = -38 \pm 1$ cm^3 mol^{-1}; $(\partial \Delta V/\partial P)_T \approx$ 0,30 cm^3 mol^{-1} MPa^{-1}). Pour le $Fe(phen)_3^{3+/2+}$, la valeur du $(\partial E/\partial P)_T$ varie beaucoup avec la pression et le milieu; ΔV_0 $= +1,42 \pm 0,5$ et $+6,2 \pm 0,5$ cm^3 mol^{-1} respectivement dans un milieu de KNO_3 avec I = 0,25 et 1,00 mol kg^{-1}. Avec le $Fe(CN)_6^{3-/4-}$, la séparation entre les pics des voltampérogrammes cycliques augmente avec un accroissement de la P, mais elle diminue légèrement pour les couples cationiques; on peut expliquer ces tendances en fonction des volumes d'activation des réactions correspondantes d'auto-échanges.

Mots clès : haute pression, potentiels à l'électrode, volume de réaction, complexes de fer, complexes de cobalt.

Introduction

In connection with our continuing studies of the effects of pressure on the kinetics of electron transfer reactions in the context of Marcus-Hush theory (1–4), we have measured the pressure dependence of the electrode potentials of some typical metal complex couples in aqueous solution, viz., $Fe(H_2O)_6^{3+/2+}$, $Fe(phen)_3^{3+/2+}$, $Fe(CN)_6^{3-/4-}$, and $Co(sep)^{3+/2+}$ (phen = 1,10-phenanthroline; sep = sepulchrate (1,3,6,8,10,13,16,19-octaazabicyclo[6.6.6]eicosane)). The iron couples were chosen with the expectation that they would yield information on the influence of ionic size, charge, and spin state on the pressure response of the electrode potentials, while the cobalt(III/II) sepulchrate couple was included as an ideal example of an obligate outer-sphere low-spin/high-spin electrode transfer system, since neither the cobalt(III) nor the normally labile cobalt(II) ion can escape from the robust encapsulating ligand. For our present purposes, however, the most important consideration is that the pressure dependences of the *kinetics* of the self-exchange reactions of all four couples have been reported (1–6) and the use of those data together with the present results in testing the applicability of the Marcus "cross relation" (7) at high pressure will be described in a forthcoming article.

A variety of approaches to measurements of electrode phenomena at high pressures have been reported (5, 6, 8–15). We have found cyclic voltammetry to be well suited for the measurement of electrode potentials E_P as functions of the pressure P (12, 13); however, our attempts to obtain *kinetic* information from a combination of cyclic and AC voltammetry (16) gave inconsistent results under pressure, and are reported only in outline here.

Our potential measurements were made with reference to an AgCl/Ag electrode in saturated KCl solution. The standard free energy change ΔG^0 for a half-cell with a standard electrode potential E^0 is $-nFE^0$, where n is the number of (moles of) electrons transferred and F is the Faraday constant, and the associated standard volume change ΔV^0 is given by $(\partial \Delta G^0/\partial P)_T$. Thus, the pressure dependence of the potentials E of the single-electron redox half-cells relative to AgCl/Ag can be expressed as a reaction volume ΔV:

$$[1] \quad F(\partial E/\partial P)_T = -\Delta V$$

There is no reason to suppose, however, that ΔV is necessarily constant over pressure ranges of several hundred MPa. Theoretical analysis of the *kinetics* of electron transfer (1) suggests that volumes of activation for homogeneous

self-exchange reactions might be markedly pressure dependent; thus, since the equilibrium electrode processes to which ΔV refers are dynamic, some pressure dependence of ΔV might also be anticipated. In any event, any significant differences between the partial molar compressibilities of the oxidized and reduced species would lead to a pressure-dependent ΔV. Accordingly, a further objective of this study was to assess the constancy of ΔV for some representative electrode reactions over a commonly used range of pressures (200 MPa). Finally, in view of the fact that substantial concentrations of inert electrolyte (at least 0.2 mol kg^{-1}) were necessary to obtain cyclic voltammograms of good quality, the effects of ionic strength I on ΔV were also investigated; however, most of the measurements were made at $I \simeq 0.28$ mol kg^{-1}, to correspond with kinetic studies to be reported later.

Experimental

Equipment

The pressure vessel (13.0 mm o.d., 4.4 mm i.d.) shown in Fig. 1 was machined from 17-4PH stainless steel, and heat-treated at 480°C for 1 h followed by air cooling (Rockwell hardness C44). The calculated ceiling pressure was 515 MPa (safety factor of 2), although the vessel was not tested or used beyond 300 MPa because the electrical lead-throughs (Fig. 2) may not be reliable beyond this pressure. The sample cell (Figs. 1 and 3; 3.85 mm o.d., 2.4 mm minimum i.d.) was machined from virgin Teflon. The electrode tips protruding from the sample cell cap were soldered to the electrical lead-through terminals as required. The helical counter electrode and straight working electrode were of Pt wire; trials with electrodes of other material (e.g., gold) or geometries gave results indistinguishable from those reported below. The reference electrode consisted of a silver rod, diameter 2 mm, enclosed in a 4 mm i.d. heat-shrink Teflon tube which was shrink-fitted at the top over a leak-tight adapter fitting into the cell gap and at the bottom over a 4 mm diameter Vycor porous plug (E. G. & G. Instruments Division, Markham, Ontario). The tube was filled with saturated KCl solution, and that part of the electrode that was exposed to this solution was coated beforehand with AgCl.

Materials

Potassium hexacyanoferrate(III) (BDH Analar reagent) was used as received. Iron(III) perchlorate hydrate (Aldrich, low chloride) was converted to the trifluoromethanesulfonate salt in aqueous CF_3SO_3H by addition of CF_3SO_3K to precipitate $KClO_4$; the iron concentration was determined spectrophotometrically with 1,10-phenanthroline after reduction to iron(II) with hydroxylamine, and the hydrogen ion concentration by titration with alkali. Cobalt(III) sepulchrate chloride monohydrate and tris(1,10-phenanthroline)-iron(II) sulfate 9-hydrate were made and checked for purity as described elsewhere (2, 4). All other reagents were of analytical reagent quality, and distilled water was passed through a Barnstead NANOpure purification train before use.

Measurements

Solutions were prepared by weight, deoxygenated with a nitrogen stream for at least 1 h, brought to 25°C, and injected with a syringe into the sample cell through the filling port in the free piston, leaving no air bubbles inside the cell. The filling port was then

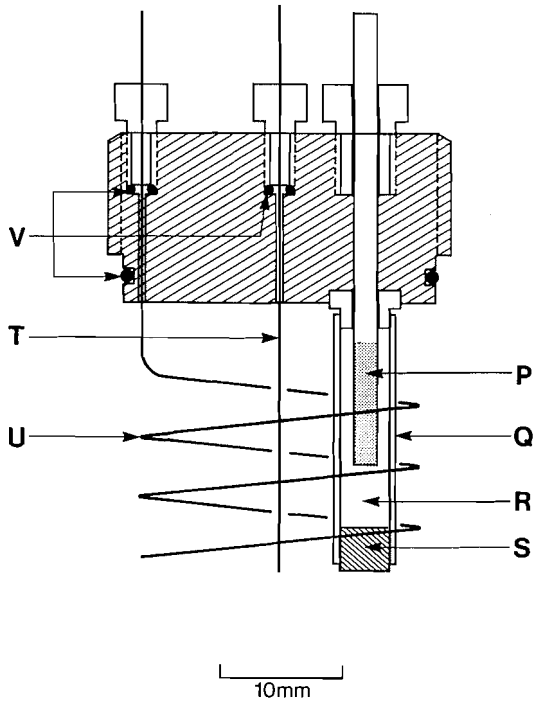

FIG. 3. Electrode assembly. P: Reference electrode (silver rod, 2.0 mm diameter, with AgCl coating over bottom 2 cm). Q: Heat-shrink Teflon tubing. R: Saturated KCl solution. S: Vycor porous disk. T: Working electrode (Pt wire). U: Helical counter-electrode (Pt wire). V: Neoprene O-rings.

sealed with a small O-ring and the threaded plug, and the assembly was lowered into the previously thermostated pressure vessel, which contained pure hexanes as the pressurizing fluid; excess fluid escaped through a weep hole in the pressure vessel at the level of the top of the conical surface (not shown in Fig. 1) or through the high pressure connection in the pressure vessel cap. The vessel was pressurized with a hand-pump and intensifier (capacity: 400 MPa); the hydraulic oil was prevented from mixing with the pressurizing hexanes by use of a large cylindrical separator with a free piston. The pressure was measured with a Heise Bourdon gauge, calibrated against a Pressurements T3800/4 deadweight pressure balance.

Since the assembly was to be operated close to room temperature, and because the number of high-pressure electrical leads had to be kept to a minimum, no provision was made to monitor the temperature of the sample cell *internally* during the electrochemical measurements. Rather, it was established, in a series of experiments in which the Pt electrodes were replaced with a Pt resistance sensor, that any temperature perturbation produced within the sample by (de)pressurization, 0–300 MPa, decayed to within 0.05°C of the temperature (25.0 ± 0.1°C) of the thermostat bath surrounding the pressure vessel within 50 min at worst, and that the temperature of the thermally equilibrated sample was within 0.05°C of that of the bath.

In the electrochemical experiments, measurements were made with a Princeton Applied Research Corporation model 173 potentiostat/galvanostat, model 178 electrometer, model 175 universal programmer, model 117 differential preamplifier, and model RE0074 X–Y recorder. The scan rate v was 50 mV s^{-1} except as noted below, and the scan ranges relative to the AgCl/Ag(satd. KCl) reference electrode were −750 to −200 mV for $Co(sep)^{3+/2+}$, 0 (or, in a few cases, −100) to 600 mV for $Fe(CN)_6^{3-/4-}$, 250 to 850 mV for $Fe(H_2O)_6^{3+/2+}$, and 500 to 1100 mV for $Fe(phen)_3^{3+/2+}$. Prior to making a measurement, a period of 90 min was allowed for complete thermal re-equilibration following set-up or pressure change.

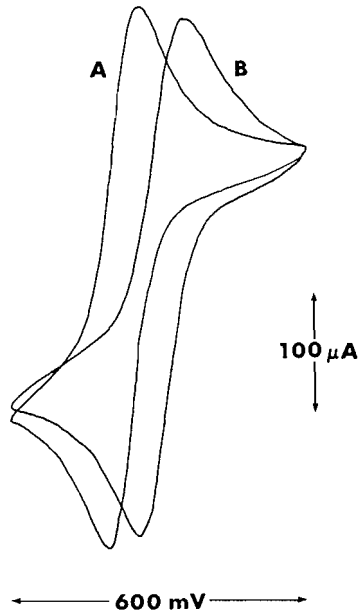

FIG. 4. Effect of pressure on the cyclic voltammogram of $Fe(CN)_6^{3-/4-}$ ([Fe] = 1.46 mmol kg^{-1}) in aqueous KCl (0.498 mol kg^{-1}) at 25.0°C. Cycle A: 4.6 MPa. Cycle B: 204.4 MPa.

Results

Figure 4 illustrates the typical effects of pressure on the cyclic voltammograms — in this case, two cycles for $Fe(CN)_6^{3-/4-}$ at ionic strength I = 0.5 mol kg^{-1}, taken 200 MPa apart. The average of the potentials E_{ox} and E_{red} corresponding to the peak oxidative and reductive currents, respectively, was identified with the reversible electrode potential E relative to that of the AgCl/Ag reference electrode at the prevailing pressure and ionic strength. The peak-to-peak potential separation $\delta E = (E_{ox} - E_{red})$ in this example varied monotonically with rising P from 80 mV at 4 MPa to 105 mV at 204 MPa; as explained below, this can be accounted for accurately in terms of the effect of pressure on the heterogeneous self-exchange rate constant k^{el} for $Fe(CN)_6^{3-/4-}$.

Complete listings of E and δE values as functions of P and I are given in the supplementary tables.[2] Here, values E_P of E for representative systems are presented as graphs (Figs. 5–11) which incorporate normalization of the results of replicate experiments to a common zero-pressure value E_0. This normalization was necessary because, although E values were reproducibly measurable to ±0.8 mV, drifts of some 5 mV in E typically developed from one day to the next for a given solution *in situ,* while still larger discrepancies could occur between experiments some days apart with different samples. Within a 6–8 h series of measurements on a given day, however, drift was negligible; this was demonstrated for each system by comparing series of measurements taken with rising pressure with ones taken with decreasing pres-

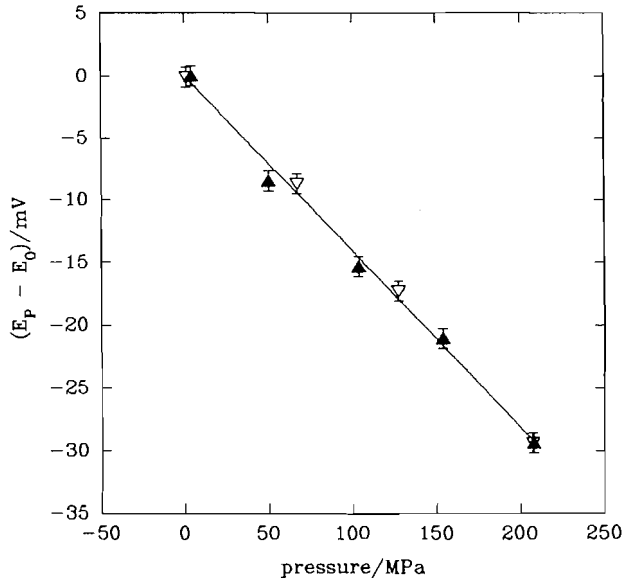

FIG. 5. Pressure dependence of E for $[Co(sep)]Cl_3$ (2.04 mmol kg^{-1}) in aqueous KCl solution (I = 1.02 mol kg^{-1}) at 25°C. Filled triangles: measurements with increasing pressure. Open triangles: measurements taken 1 day later with decreasing P and drift correction of 5.0 mV. Error bars are ±0.8 mV. Solid line: linear regression of all data.

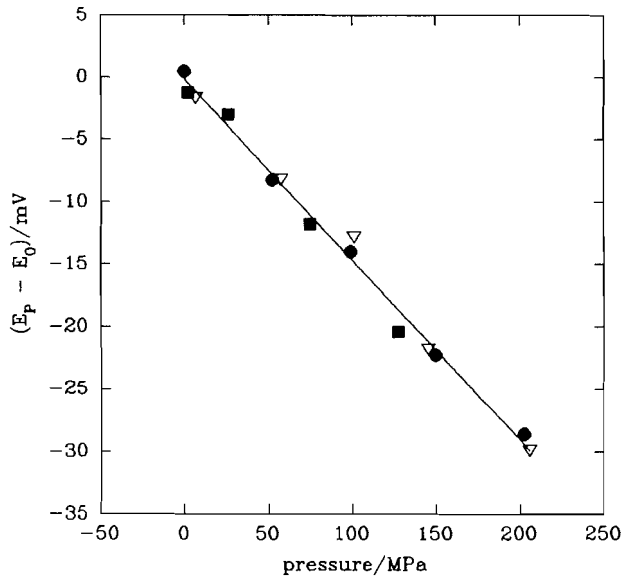

FIG. 6. Pressure dependence of E for $[Co(sep)]Cl_3$ (5.01 mmol kg^{-1}) in aqueous KCl (I = 0.26 mol kg^{-1}) at 25.0°C. Circles and triangles: pressure was first increased, then decreased. Squares: pressure decreasing from an initial 200 MPa.

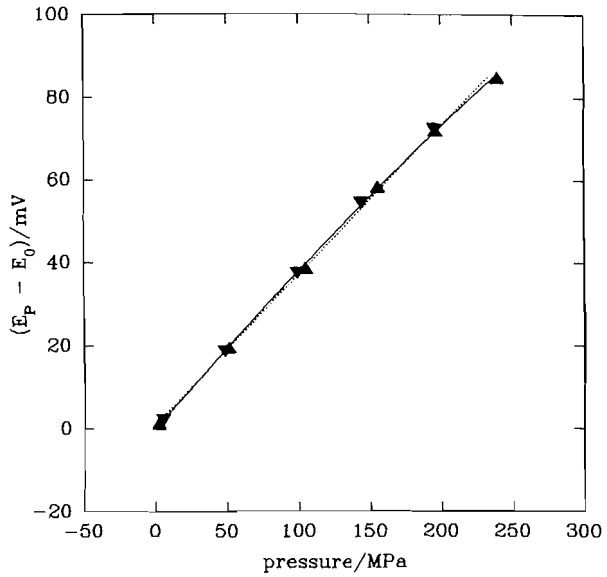

FIG. 7. Pressure dependence of E for $K_3[Fe(CN)_6]$ (4.78 mmol kg^{-1}) in aqueous KCl (I = 0.989 mol kg^{-1}) at 25.0°C. Up triangles: increasing pressure. Down triangles: decreasing pressure (separate experiment). Solid line: quadratic regression. Dotted line: linear regression.

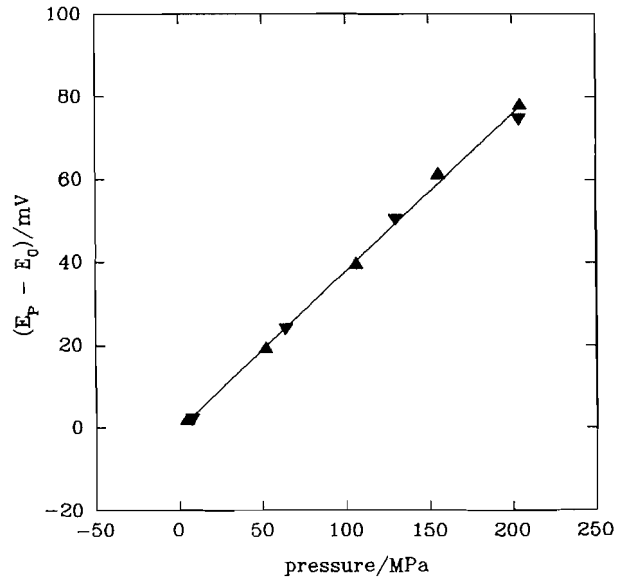

FIG. 8. Pressure dependence of E for $K_3[Fe(CN)_6]$ (1.46 mmol kg^{-1}) in aqueous KCl (I = 0.507 mol kg^{-1}) at 25.0°C. Up triangles: increasing pressure. Down triangles: decreasing pressure (separate experiment). Solid line: linear regression.

sure — in every case, the superposed plots of $(E_P - E_0)$ vs. P coincided within the experimental uncertainty. In other words, the absolute value of E at a given P could vary by several mV from one series of measurements to another, but the value of $(\partial E/\partial P)_T$ was typically reproducible to ±6 μV MPa^{-1}, corresponding to an uncertainty of ±0.6 cm^3 mol^{-1} in ΔV. For example, Fig. 5 shows that the slope of $(E_P - E_0)$ vs. P plots for a particular $Co(sep)^{3+}$ solution at I = 1.0 mol kg^{-1}, taken with ascending pressure on one day and with descending pressure the next, are indistinguishable within the natural scatter of the data, following application of a measured drift correction of −5.0 mV to the latter data set.

Drift in E seemed to be associated with the reference electrode. After several cycles, the Vycor porous plug tended to crack, leading to voltage changes of up to 30 mV, greater peak-to-peak separations, and the appearance of anomalous "spikes" in the CVs. The plug was therefore replaced periodically. No correction for the effect of pressure on junction potentials was applied; since the ultimate objective of this work was to evaluate the pressure effects on homoge-

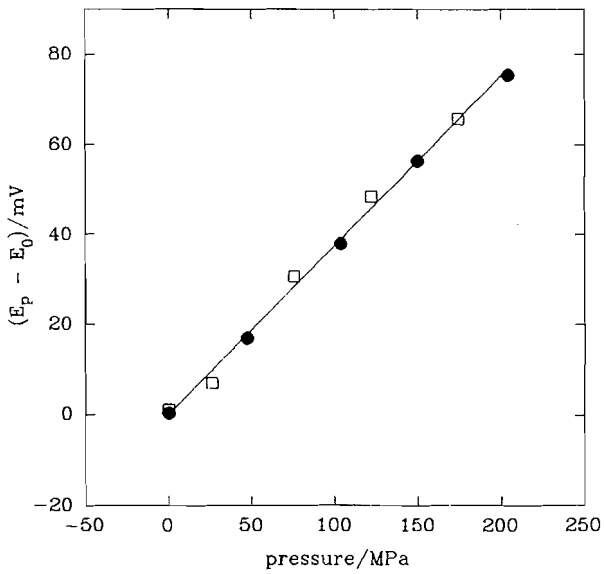

FIG. 9. Pressure dependence of E for $K_3[Fe(CN)_6]$ (4.80 mmol kg^{-1}) in aqueous KCl (I = 0.279 mol kg^{-1}) at 25.0°C. Circles and squares denote different experiments. Solid line: linear regression.

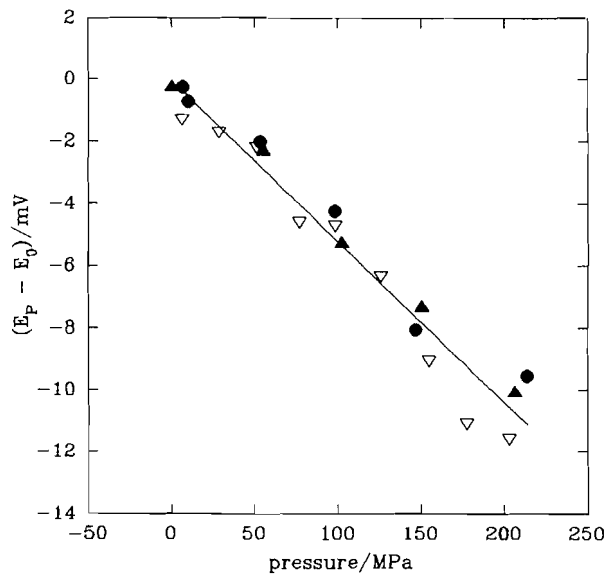

FIG. 10. Pressure dependence of E for $[Fe(H_2O)_6](CF_3SO_3)_3$ (5.00 mmol kg^{-1}) in aqueous CF_3SO_3H (0.250 mol kg^{-1}; I = 0.280 mol kg^{-1}) at 25°C. Different symbols indicate independent experiments. Solid line: linear regression.

neous redox equilibria from E values for the corresponding half-cells relative to the AgCl/Ag electrode, junction potential effects could be ignored.

Equation [1] implies that E will be a linear function of P if ΔV is constant, within the limits of detection, over the operational pressure range:

$$[2] \quad E_P = E_0 - P\Delta V/F$$

In certain of the cases described below, however, plots of E vs. P were distinctly curved. In the absence of a theoretical framework to account for this curvature, it was assumed that

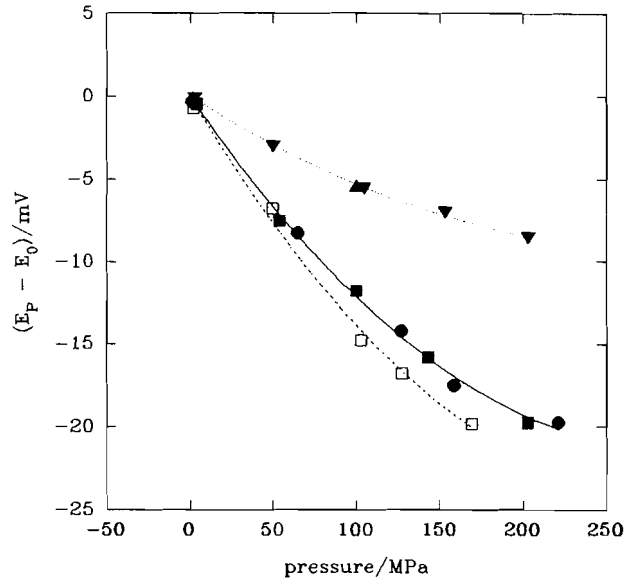

FIG. 11. Pressure dependence of E for $[Fe(phen)_3]SO_4$ in various aqueous media at 25°C. Curved lines are quadratic least-squares regressions; different symbols indicate independent experiments. Open squares and dashed curve: [Fe] = 2.53 mmol kg^{-1}, $[H_2SO_4]$ = 0.0506 mol kg^{-1}, $[Na_2SO_4]$ = 0.0739 mol kg^{-1}, $[phen]_{free}$ = 8.9 mmol kg^{-1}, I = 0.272 mol kg^{-1}. Filled circles: [Fe] = 0.946 mmol kg^{-1}, $[KNO_3]$ = 0.251 mol kg^{-1} $[phen]_{free}$ = 0.020 mol kg^{-1}, I = 0.254 mol kg^{-1}. Filled squares: [Fe] = 0.959 mmol kg^{-1}, $[KNO_3]$ = 0.249 mol kg^{-1}, no added phen, I = 0.253 mol kg^{-1}. Solid curve: I = 0.25 mol kg^{-1} (KNO_3). Triangles and dotted curve: [Fe] = 0.979 mmol kg^{-1}, $[KNO_3]$ = 1.001 mol kg^{-1}, no added phen, I = 1.005 mol kg^{-1}.

E was a quadratic function of pressure, i.e., that $(\partial\Delta V/\partial P)_T$ was sensibly constant over the experimental pressure range:

$$[3] \quad E_P = E_0 + AP + BP^2$$

where $A = -\Delta V_0/F$ and $B = -(\partial\Delta V/\partial P)_T/2F$. In practice, eq. [2] was adopted whenever nonlinear least-squares regression according to eq. [3] gave a standard error in B that was larger than B itself; interestingly, in all such cases, eq. [3] also gave a poorer fit of the data (larger mean square error) than did the simple linear eq. [2] despite the flexibility afforded by the additional parameter, since the quadratic regressions created outliers with relatively large residuals. Replicate data sets were normalized by calculating E_0 for each set according to the appropriate equation ([2] or [3]) and then combining values of $(E_P - E_0)$ to form a single data set for the particular couple and medium composition (Figs. 5–11, in each of which the various symbols indicate different data sets). The values of ΔV or ΔV_0 derived from the combined data sets, as explained below, are collected in Table 1. The sign of ΔV is correct for redox couples written in the standard IUPAC convention, i.e., as reduction potentials, but are relative to the AgCl/Ag(satd. KCl) electrode at ionic strength I rather than to the standard hydrogen electrode at infinite dilution.

For all but the $Fe(CN)_6^{3-/4-}$ couple, values of the peak-to-peak separation δE were typically 65–80 mV, and thus close to the "reversible" range (ref. 16, pp. 230, 231), but occasionally larger values were recorded. Increasing pressure appeared to cause a slight decrease in δE for the cat-

ionic couples, but the δE values were insufficiently accurately reproducible from one run to the next to warrant detailed consideration (see supplementary tables).[2] For the $Fe(CN)_6^{3-/4-}$ couple, δE was relatively large (80 mV and more) and clearly *increased* with increasing pressure (cf. Fig. 4), but again reproducibility between runs was poor — generally, δE became large (up to 230 mV) after several repeated pressure cycles, possibly because of degradation of the Vycor porous plug in the reference electrode.

Cobalt(III/II) sepulchrate

The voltammograms exhibited good reversibility (δE typically 68–70 mV), with $E_0 \simeq -540$ mV vs. AgCl/Ag. The plots of E_P vs. P were accurately linear for $I = 1.0$ and 0.28 mol kg^{-1} (Figs. 5 and 6) and gave $\Delta V = +13.5 \pm 0.4$ cm^3 mol^{-1} and $+13.9 \pm 0.4$ cm^3 mol^{-1}, respectively.

Hexacyanoferrate(III/II)

The peak-to-peak separations δE in KCl media were typically 80–110 mV and *increased* with increasing pressure; thus, they departed further from the reversible range (18) than did δE for the other couples considered here. For $I = 1.0$ mol kg^{-1} (KCl), a slight curvature of the E vs. P plots was clearly discernable in two independent sets of data (Fig. 7) and was accurately represented by the quadratic eq. [3]. The combined data of Fig. 9 give $\Delta V_0 = -38.3 \pm 1.0$ cm^3 mol^{-1} and $(\partial\Delta V/\partial P)_T = 0.030 \pm 0.008$ cm^3 mol^{-1} MPa^{-1}; $E_0 \simeq +270$ mV. Linear regression gave $\Delta V = -34.8 \pm 0.4$ cm^3 mol^{-1}, but with a 2.4-fold increase in the mean standard error. For experiments in aqueous KCl with $I = 0.51$ (Fig. 8) and 0.28 mol kg^{-1} (Fig. 9), however, the data were statistically better represented by a linear regression (eq. [2]), giving $\Delta V = -36.6 \pm 0.7$ and -36.2 ± 0.8 cm^3 mol^{-1} with $E_0 \simeq 235$ and 243 mV, respectively. Cyclic voltammograms obtained at $I = 0.10$ mol kg^{-1} (KCl) were poorly reproducible, with anomalously large δE values, but gave an average ΔV of -34 ± 3 cm^3 mol^{-1}.

An experiment with LiCl rather than KCl as the supporting electrolyte ($I = 0.28$ mol kg^{-1}) gave a linear E_P vs. P plot with $\Delta V = -37.1 \pm 1.3$ cm^3 mol^{-1}, which is similar to the value obtained for the comparable KCl solutions, but the relatively large uncertainty in ΔV, a low E_0 (+214 mV), and a very large δE (194–227 mV) imply the need for caution in making this comparison. In another experiment, K_2SO_4 rather than KCl was used to bring the ionic strength to 0.28 mol kg^{-1}, so that the K^+ ion concentration was reduced from 0.264 to 0.181 mol kg^{-1} at constant I; E_0 (+233 mV), δE (83–141 mV) and ΔV (-34.4 ± 0.6 cm^3 mol^{-1}) were sufficiently close to the analogous data for the KCl medium to imply that changing the K^+ concentration or the nature of the supporting anion has no significant effect in this concentration regime.

Hexaaquairon(III/II)

It was necessary to maintain strongly acidic conditions ($[CF_3SO_3H] = 0.25$ mol kg^{-1}) to suppress hydrolysis of $Fe(H_2O)_6^{3+}$. Trifluoromethanesulfonate was chosen as the non-complexing anion because perchlorate, the logical choice, would have caused precipitation of $KClO_4$ in the reference electrode. The cyclic voltammograms came close to reversible behavior ($\delta E = 71$–79 mV) at a scan rate $v = 20$ mV s^{-1}. The results of three independent experiments are shown in Fig. 10; the vertical scale is expanded, relative to Figs. 6–9, because the pressure effect was small, so that the apparent scatter in the data is no worse than for the other couples. At $I = 0.28$ mol kg^{-1}, $E_0 \simeq +490$ mV, and linear regression of the combined E_P data gave $\Delta V = +5.0 \pm 0.3$ cm^3 mol^{-1}.

Tris(1,10-phenanthroline)iron(III/II)

Because of the insolubility of (for example) the perchlorate salt in perchlorate media, the sulfate salt of $Fe(phen)_3^{2+}$ was used in KNO_3 or $NaHSO_4$ media. Experience with $Fe(phen)_3^{3+}$ in solution (4) suggested a need to maintain high acidity and free phen (added as a 0.3% aqueous solution or as a 5% solution in ethanol), but, because the iron(III) complex is present only transiently in the course of a voltammetric cycle, these turned out to be unnecessary precautions (cf. filled squares and circles in Fig. 11). The salient features shown in Fig. 11 are (*i*) that E_P is clearly a nonlinear function of P, but is well represented by a quadratic regression (eq. [3]), and (*ii*) that E_P is very sensitive to medium effects.

In 1.0 mol kg^{-1} KNO_3, the voltammograms showed excellent reversibility ($\delta E = 61$–70 mV), with $E_0 \simeq +830$ mV, $\Delta V_0 = +6.2 \pm 0.5$ cm^3 mol^{-1}, and $(\partial\Delta V/\partial P)_T = -0.022 \pm 0.003$ cm^3 mol^{-1} MPa^{-1}. At $I = 0.254$ mol kg^{-1} (KNO_3), $\delta E \simeq 65$–76 mV, $E_0 \simeq +890$ mV, $\Delta V_0 = +14.2 \pm 0.5$ cm^3 mol^{-1}, and $(\partial\Delta V/\partial P)_T = -0.049 \pm 0.005$ cm^3 mol^{-1} MPa^{-1}. For the $NaHSO_4$ medium at $I = 0.272$ mol kg^{-1}, $\delta E = 73$–83 mV, $E_0 \simeq +910$ mV, $\Delta V_0 = +16.3 \pm 2.0$ cm^3 mol^{-1}, and $(\partial\Delta V/\partial P)_T = -0.057 \pm 0.024$ cm^3 mol^{-1} MPa^{-1}.

Discussion

The most obvious feature of Table 1 is that ΔV is a moderately positive number for the three cationic couples, but strongly negative for $Fe(CN)_6^{3-/4-}$, relative to AgCl/Ag. This phenomenon might be attributed, at least in part, to the *increase* in solvent electrostriction (17) expected for the effective net reaction [4]

[4] $Fe(CN)_6^{3-} + Ag(s) + Cl^- \rightarrow Fe(CN)_6^{4-} + AgCl(s)$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

as compared with the *decrease* in electrostriction expected for the charge-dissipating reaction [5].

[5] $Fe(H_2O)_6^{3+} + Ag(s) + Cl^- \rightarrow Fe(H_2O)_6^{2+} + AgCl(s)$

This argument alone cannot, however, explain the fact that ΔV values for the corresponding electrode reactions of the larger (and so presumably less electrostrictive) $Fe(phen)_3^{3+}$ and $Co(sep)^{3+}$ ions are *more positive* than for reaction [5] at $I = 0.28$ mol kg^{-1}. The picture is further complicated by the marked pressure dependence of ΔV for the $Fe(phen)_3^{3+/2+}$ case; this is not due to some phenomenon involving ligand dissociation, since added phen had no effect, but the sensitivity of the pressure effect to the nature and concentration of the supporting electrolyte (Fig. 11) suggests the involvement of ion association or other medium effect.

Absolute molar volumes are available, or can be calculated, for all the reactants and products of reactions [4] and [5] (17–19),[3] so that the corresponding volumes of reaction ΔV^0 at infinite dilution, 25.0°C, and 0.1 MPa can be derived: $\Delta V^0 = -49.1$ cm^3 mol^{-1} for reaction [4] and $+12.8$ cm^3 mol^{-1} for reaction [5]. An approximate correction of these to ionic strength 0.28 mol kg^{-1} can be made as described elsewhere (19), but the results ($\Delta V = -47.1$ cm^3 mol^{-1} for $Fe(CN)_6^{3-/4-}$–Ag/AgCl, and $+10.1$ cm^3 mol^{-1} for $Fe(H_2O)_6^{3+/2+}$–Ag/AgCl) are in only slightly better agreement with the electrochemically measured values (-36.2 and $+5.0$ cm^3 mol^{-1}, respectively). It should be borne in mind that the values of ΔV measured electrochemically are in effect averages over the pressure range taken, so that, if an assumed linear dependence of E_P on P conceals a nonlinearity such as is observed for reaction [4] at $I = 1.0$ mol kg^{-1}, ΔV at 0.1 MPa could be numerically larger than the high pressure value, but no statistically significant nonlinearity could be detected for the cases in point, and besides the results for reaction [4] at $I = 1.0$ mol kg^{-1} indicate that no more than about 2–3 cm^3 mol^{-1} could be accounted for in this way.

As with the anomalous behavior of $Fe(phen)_3^{3+/2+}$ noted above, it is likely that a medium effect such as ion association is responsible (but in a different manner) for these discrepancies between calculation and experiment for reactions [4] and [5] — certainly, both the electrochemistry (20–23) and the high-pressure solution chemistry (6) of the highly charged cyanoferrates are well known to be sensitive to counterion effects, while $Fe(H_2O)_6^{3+}$ and $Co(sep)^{3+}$ can be expected to be more prone to association with anions than is the larger $Fe(phen)_3^{3+}$. One may surmise that 1:1 ion association may be largely complete in the cyanoferrate systems at $I = 0.2$–0.5 mol kg^{-1}, so that the electrochemical measurements refer to species such as $\{Fe(CN)_6^{n-}, K^+\}$ rather than the free ions to which the infinite-dilution molar volumes apply. Ion pairs are broken up by increasing pressure, which may explain the curved E_P vs. P plots for the $Fe(phen)_3^{3+/2+}$ case, but such breakup effects will be negligible if pairing is virtually complete at 0.1 MPa, so that the linearity of the E_P vs. P plots for the hexacyanoferrate system (except at the higher electrolyte concentrations, where ion triples could form) could be explained. Such speculation apart, it is reassuring that the signs and orders of magnitude of ΔV values calculated from molar volume data for reactions [4] and [5] are in qualitative agreement with the electrochemical observations. Molar volumes are not available for $Fe(phen)_3^{3+}$ or $Co(sep)^{2+}$, but the fact that ΔV is some 9 cm^3 mol^{-1} more positive for $Co(sep)^{3+/2+}$ than for $Fe(H_2O)_6^{3+/2+}$, despite expectations of similar contributions from electrostriction, may be qualitatively attributed to reorganization (expansion) associated with the spin change on going from Co^{III} to Co^{II}.

As noted above, AC and cyclic voltammetry gave insufficiently accurately reproducible kinetic information to warrant detailed discussion. It is worth noting, however, that the response of the peak-to-peak separation δE to increasing pressure (a marked increase for $Fe(CN)_6^{3-/4-}$, slight decreases for the other couples) is in accordance with the measured volumes of activation ΔV_{ex}^* for the corresponding self-exchange reactions (Table 1). The electrochemical kinetic parameter ψ (16) can be defined in terms of the standard heterogeneous electrochemical rate constant k^{el}, the diffusion coefficient D (assumed here to be the same for both the oxidized and the reduced species), and the scan rate v:

[6] $$\psi = k^{el}/(\pi D v n F/RT)^{1/2}$$

and ψ in turn can be correlated with δE (ref. 16, pp. 230, 231). Thus, the shift $\Delta\delta E_{200}$ in δE on going from atmospheric ("zero") pressure to 200 MPa can be estimated if we know the *relative* values of k^{el} and D at 0 and 200 MPa — it is not necessary to know their absolute values. Furthermore, application of Walden's rule allows use of the solvent viscosity η rather than D:

[7] $$\psi_{200}/\psi_0 = (k^{el}_{200}/k^{el}_0)(D_0/D_{200})^{1/2} = (k^{el}_{200}/k^{el}_0)(\eta_{200}/\eta_0)^{1/2}$$

For water at 25°C, η_{200}/η_0 is only 1.0406 (24), and for the $Fe(CN)_6^{3-/4-}$ electrode reaction ΔV_{ex}^* is $+13$ cm^3 mol^{-1} in 1.0 mol kg^{-1} KCl (6), so that $k^{el}_{200}/k^{el}_0 = 0.350$ and $\psi_{200}/\psi_0 = 0.357$. This means that, if $\delta E = 80$ mV at atmospheric pressure, δE at 200 MPa can be predicted to be about 105 mV — and this is exactly what was found in typical hexacyanoferrate experiments in aqueous KCl (see, for example, Fig. 4). Consideration of eq. [6] also explains the large (194 mV, rising to 227 mV at 194 MPa) δE values found for LiCl solutions, since k^{el} for $Fe(CN)_6^{3-/4-}$ in such solutions is only one-tenth that in aqueous KCl (20).

For the three cationic couples of Table 1, the ΔV_{ex}^* values refer to electron exchange in *homogeneous* solution (rate constants k^{ex}); adapting the theory of Marcus (25, 26), we can write

[8] $$k^{el}_{200}/k^{el}_0 = (k^{ex}_{200}/k^{ex}_0)^{1/2}$$

whence $\psi_{200}/\psi_0 = 1.38$, 1.67, and 1.16 for $Co(sep)^{3+/2+}$, $Fe(H_2O)_6^{3+/2+}$, and $Fe(phen)_3^{3+/2+}$, respectively. Taking typical observed atmospheric-pressure δE values,[4] these calculations predict that, on going to 200 MPa, δE will *decrease* from 70 to 67 mV for $Co(sep)^{3+/2+}$, from 79 to 72 mV for $Fe(H_2O)_6^{3+/2+}$, and from 65 to 64 mV for $Fe(phen)_3^{3+/2+}$. In short, negative activation volumes for the electrode reaction or for the corresponding homogeneous self-

[3]Following Millero (17), absolute molar volumes of aqueous ions may be calculated on the basis that the corresponding quantity for $H^+(aq)$ is -5.4 cm^3 mol^{-1}.

[4]The experimental δE values at 0.1 MPa for the cationic couples correlate with the square roots of the corresponding k_0^{ex} (2–4) in the manner predicted by eq. [6] and Marcus' theory of electrode kinetics (25, 26).

exchange mean that the cyclic voltammogram becomes "more nearly reversible" as the pressure is increased, but the limited accuracy of δE measurements at high pressures militates against extracting reliable volumes of activation from cyclic voltammograms.

Reçu le 28 novembre 1990[2]

DENISE MATTE, BERNARD SOLASTIOUK, ANDRÉ MERLIN et XAVIER DEGLISE. Can. J. Chem. **70**, 89 (1992).

Nous présentons une étude des mécanismes de la *N*-chloration de la succinimide en phase aqueuse en milieu acide (pH < 5) et en milieu basique (pH > 9). Nous avons déterminé les constantes de vitesse et les énergies d'activation des processus mis en cause. Les cinétiques rapides ont été étudiées par spectrophotométrie à écoulement bloqué. En absence d'ions chlorures et dans les domaines de pH étudiés, nos résultats sont en accord avec un modèle cinétique comprenant la contribution de deux processus indiscernables :

$$SH + ClO^- \xrightarrow{k_2} \text{produits}$$

ou

$$S^- + HOCl \xrightarrow{k_3} \text{produits}$$

Les valeurs limites des constantes de vitesse dans le cas où un seul des processus participe à la cinétique de chloration ont été évaluées : $k_2^0 = 1{,}6 \times 10^5\ M^{-1}\ s^{-1}$ à 293 K; $k_3^0 = 2{,}2 \times 10^7\ M^{-1}\ s^{-1}$ à 293 K.

En présence d'ions chlorures et en milieu acide, l'attaque nucléophile de S^- sur le chlore moléculaire Cl_2 s'ajoute à ces deux processus indiscernables.

Mots clés : cinétique, *N*-chloration, succinimide, phase aqueuse, spectrophotométrie à écoulement bloqué.

DENISE MATTE, BERNARD SOLASTIOUK, ANDRÉ MERLIN, and XAVIER DEGLISE. Can. J. Chem. **70**, 89 (1992).

A kinetic study of the *N*-chlorination, in aqueous medium, of succinimide (SH) at low pH (<5) and at high pH (>9) is presented. We have derived the rate constants and activation energies of the processes involved. A stopped-flow spectrophotometric technique was used to study the kinetics. Without chloride ions, our experimental results can be interpreted by two kinetically indistinguishable mechanisms:

$$SH + ClO^- \xrightarrow{k_2} \text{products}$$

$$S^- + HClO \xrightarrow{k_3} \text{products}$$

The limiting values of the rate constants for the case in which only one process is involved in the kinetics of chlorination were evaluated: $k_2^0 = 1.6 \times 10^5\ M\ s^{-1}$ at 293 K; $k_3^0 = 2.2 \times 10^7\ M^{-1}\ s^{-1}$ at 293 K.

In acid medium, in the presence of chloride ions, we observe a nucleophilic attack of the S^- ion on molecular chlorine Cl_2. This process is added to the two former processes.

Key words: kinetics, *N*-chlorination, succinimide, aqueous medium, stopped flow.

Introduction

En solution aqueuse, la succinimide réagit avec l'hypochlorite de sodium pour former la *N*-chlorosuccinimide. La succinimide est un acide faible; la forme acide notée SH et sa base conjuguée S^- peuvent exister sous différentes formes tautomères (figure 1).

La cinétique de cette réaction de *N*-chloration a été étudiée par Hussain et Higuchi (1) dans un domaine étroit de pH allant de 2 à 5 et en absence d'ions chlorures.

Dans ces conditions expérimentales, la réaction est assez lente pour être suivie par des techniques spectroscopiques classiques. Grâce à la spectroscopie à écoulement bloqué, nous avons pu étendre cette étude à toute la gamme de pH couverte par les solutions aqueuses et déterminer l'influence de la température et des ions chlorures sur la cinétique de cette réaction de chloration.

Techniques expérimentales

Les paramètres cinétiques de cette réaction de *N*-chloration ont été déterminés par spectrophotométrie à écoulement bloqué sur un appareil Applied Photophysics modèle 1705 couplé à un microordinateur. Cet appareillage est adapté à l'étude des cinétiques rapides en phase liquide à condition que l'on puisse détecter par absorption ultraviolette ou visible l'un des produits formés ou consommés durant la réaction (2).

En milieu basique (pH > 8), le chlore en solution existe principalement sous forme d'ions hypochlorites ClO^- (figure 2). Le maximum d'absorption de ClO^- se situant à 290 nm et la succinimide et son dérivé *N*-chloré absorbant à des longueurs d'onde plus faibles (figure 3), nous avons suivi la disparition de ClO^- à cette longueur d'onde. En opérant en large excès de succinimide par rapport au chlore, nous nous sommes placés dans les conditions d'une réaction du pseudo-premier ordre. Nous avons pu mesurer une constante de vitesse expérimentale du pseudo-premier ordre k_{obs}, pente de la droite $\ln(A - A_\infty)$ en fonction du temps, A étant la densité optique de la solution à 290 nm à un instant donné et A_∞ la densité optique à cette même longueur d'onde de la solution après réaction. La détermination expérimentale de cette constante de vitesse k_{obs} est détaillée dans l'annexe 1.

En milieu acide, le chlore est presque exclusivement sous forme d'acide hypochloreux HOCl (figure 2). Il n'est pas possible de suivre directement la disparition de ce composé à 235 nm, longueur d'onde de son maximum d'absorption, car la *N*-chlorosuccinimide absorbe également dans cette zone spectrale (figure 4). Toutefois, à cette longueur d'onde, le coefficient d'extinction molaire de la *N*-chlorosuccinimide étant beaucoup plus important que celui de la succinimide, nous pouvons étudier la cinétique de la *N*-chloration de la succinimide en suivant à 235 nm la formation de

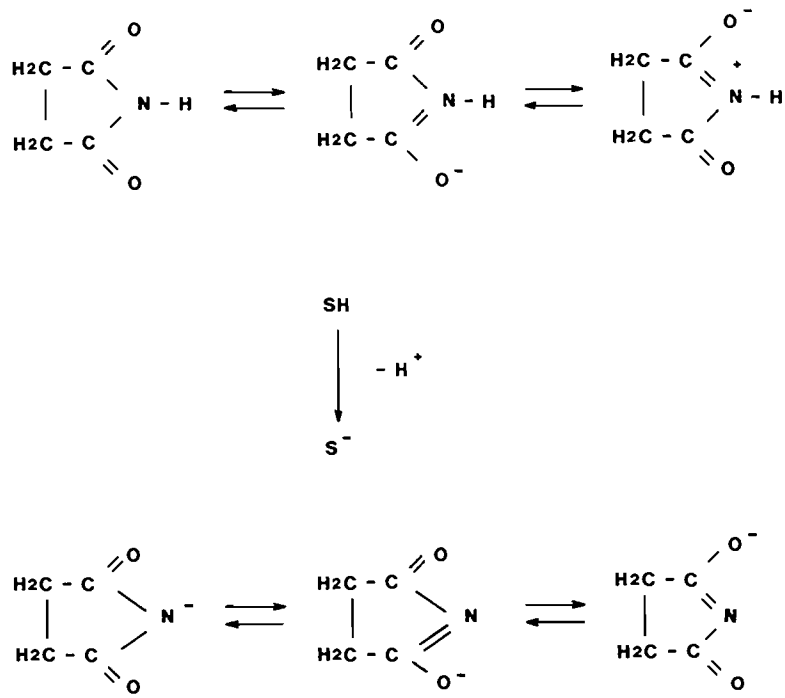

FIG. 1. Structures moléculaires de la succinimide SH et de sa base conjuguée S^-.

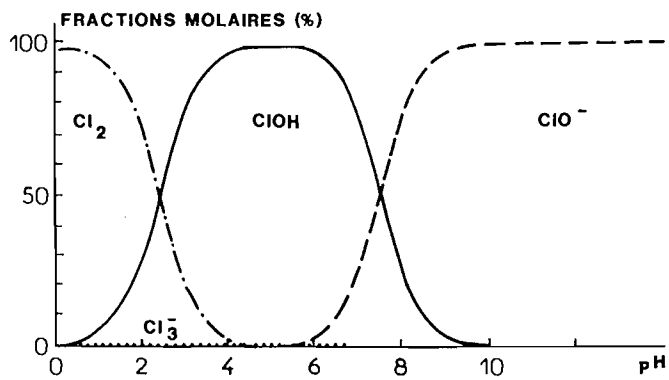

FIG. 2. Zone de prédominance des dérivés du chlore en solution aqueuse; $[Cl]_t = 10^{-3}$ M; $[Cl^-] = 0{,}1$ M.

la *N*-chlorosuccinimide au cours du temps. Dans le cas où la concentration initiale de succinimide est supérieure à la concentration initiale de chlore, la vitesse initiale de réaction v_0 est donnée par la relation :

$$[1] \qquad v_0 = \left(\frac{d}{dt}[SCl]_{t=0}\right) = \frac{(dA/dt)_{t=0}}{[A_\infty - A(0)]}[Cl]_T$$

$A(0)$ et A_∞ sont respectivement les densités optiques de la solution à 235 nm à l'instant initial et après réaction. $(dA/dt)_{t=0}$ est la pente à l'instant initial de la courbe donnant la variation de la densite optique de la solution avec le temps. $[Cl]_T$ représente la concentration totale de chlore. L'établissement de la relation [1] est donné en annexe 1.

La succinimide, de marque Fluka et de qualité Purum, contient moins de 2% d'impuretés. Les sels utilisés pour la fabrication des solutions tampon sont des produits Prolabo de qualité Normapur. Les solutions d'acide hypochloreux sont obtenues en faisant barboter du chlore gazeux dans de l'eau distillée. La solution et ensuite laissée pendant une journée en présence d'oxyde de mercure puis distillée sous pression réduite avant d'être titrée par du thiosulfate de sodium.

Résultats expérimentaux

Dans un premier temps, nous avons vérifié que les résultats expérimentaux, obtenus en milieu basique avec un excès de succinimide, étaient correctement représentés par un modèle d'une cinétique du pseudo-premier ordre. La réaction liant $\ln(A - A_\infty)$ avec le temps étant linéaire, la réaction est du premier ordre par rapport à la concentration en chlore «libre» total $[Cl]_t$ (on appelle chlore «libre» le chlore non lié à un atome d'azote).

La vitesse globale de réaction en milieu basique s'exprime donc par la relation :

$$[2] \qquad v = -\frac{d[Cl]_t}{dt} = k_{obs}[Cl]_t$$

À pH constant, nous avons observé que la constante k_{obs} en milieu basique et la vitesse initiale v_0 en milieu acide sont proportionnelles à la concentration totale de succinimide (figure 5). La réaction est donc globalement du second ordre et d'ordre 1 par rapport à chacun des deux réactifs :

$$[3] \qquad v = k_{exp}[S]_t[Cl]_t$$

avec k_{exp} : constante de vitesse globale du second ordre; $[Cl]_t$: concentration en chlore libre total; $[S]_t$: concentration totale de succinimide chlorée ou non (la succinimide étant en excès par rapport au chlore, sa concentration peut être considérée constante au cours de la réaction).

L'influence du pH sur la constante de vitesse k_{exp} a été étudiée à 293 K en milieu acide (pH < 5) et en milieu basique (pH > 9) (tableau 1 et figure 9). Nous avons aussi suivi l'influence de la température sur ce paramètre à pH fixé (pH = 9,25 dans le cas de la figure 6). La pente de la droite ln (k_{exp}) en fonction de $1/T$ permet de calculer l'énergie d'ac-

2 : Succinimide 2×10^{-3} M pH = 4,45
3 : HOCl $1,25 \times 10^{-3}$ M + succinimide 2×10^{-3} M pH = 4,45 } après réaction

tivation globale avec une précision de l'ordre de 20% : E = 48,8 kJ mol^{-1}.

En milieu acide (pH = 3), nous avons étudié l'augmentation de la vitesse de réaction avec la concentration en ions chlorures. On observe un accroissement linéaire de la constante de vitesse k_{exp} (figure 7) dans le domaine de concentration en ions chlorures étudié (10^{-2} M à 4×10^{-2} M).

Interprétation

Une solution aqueuse de succinimide contient les deux espèces SH et S^- en équilibre :

$$[I] \quad SH \leftrightarrows S^- + H^+ \qquad pK_I = 9,71 \text{ à } 293 \text{ K} \qquad (3)$$

En milieu acide ou neutre (pH < 8), la succinimide existe presque uniquement sous la forme SH. En milieu basique (pH > 11), l'ion S^- est prépondérant (figure 8). De même, le chlore en solution aqueuse peut exister sous quatre formes en équilibre dans des proportions qui dépendent du pH (figure 2).

$$[II] \quad HOCl \leftrightarrows ClO^- + H^+$$

$$pK_{II} = 7,58 \text{ à } 293 \text{ K} \qquad (4)$$

$$[III] \quad Cl_2 + H_2O \leftrightarrows HOCl + H^+ + Cl^-$$

$$pK_{III} = 3,48 \text{ à } 293 \text{ K} \qquad (5)$$

$$[IV] \quad Cl_2 + Cl^- \leftrightarrows Cl_3^-$$

$$pK_{IV} = 0,74 \text{ à } 298 \text{ K} \qquad (6)$$

Ces équilibres sont rapides devant la cinétique de la réaction de chloration et compte tenu de la mise en évidence expérimentale d'un ordre 1 par rapport à chacun des réactifs, nous pouvons envisager huit processus élémentaires différents de formation de SCl susceptibles de limiter la vitesse globale de réaction :

$$(P_1) \quad SH + HOCl \xrightarrow{k_1} SCl + H_2O$$

$$(P_2) \quad SH + ClO^- \xrightarrow{k_2} SCl + OH^-$$

$$(P_3) \quad S^- + HOCl \xrightarrow{k_3} SCl + OH^-$$

$$(P_4) \quad S^- + ClO^- + H_2O \xrightarrow{k_4} SCl + 2OH^-$$

$$(P_5) \quad SH + Cl_2 \xrightarrow{k_5} SCl + H^+ + Cl^-$$

$$(P_6) \quad SH + Cl_3^- \xrightarrow{k_6} SCl + H^+ + 2Cl^-$$

TABLEAU 1. Influence du pH sur les constantes de vitesse k_{exp}

pH	k_{exp} (10^3 M^{-1} s^{-1})	Conditions opératoires
10,90	8,59	T = 293 K
10,75	10,80	$[S]_t = 2,5 \times 10^{-3}$ M
10,70	13,00	$[Cl]_t = 3,35 \times 10^{-4}$ M
10,35	24,80	$\lambda_{analyse}$ = 290 nm
10,00	42,80	
9,75	60,70	
9,25	74,00	
4,45	153,00	T = 293 K
4,00	60,20	$[S]_t = 10^{-3}$ M
3,75	31,70	$[Cl]_t = 6 \times 10^{-4}$ M
3,35	18,10	$\lambda_{analyse}$ = 235 nm
3,00	15,10	

$$(P_7) \quad S^- + Cl_2 \xrightarrow{k_7} SCl + Cl^-$$

$$(P_8) \quad S^- + Cl_3^- \xrightarrow{k_8} SCl + 2Cl^-$$

Chloration en absence d'ions chlorures

Seuls les équilibres [I] et [II] et les processus (P_1), (P_2), (P_3), (P_4) qui ne font pas intervenir d'ions chlorures sont à considérer. Les concentrations courantes globales des réactifs sont donc données par les relations :

$$[4] \quad [Cl]_t = [ClO^-] + [HOCl]$$

et

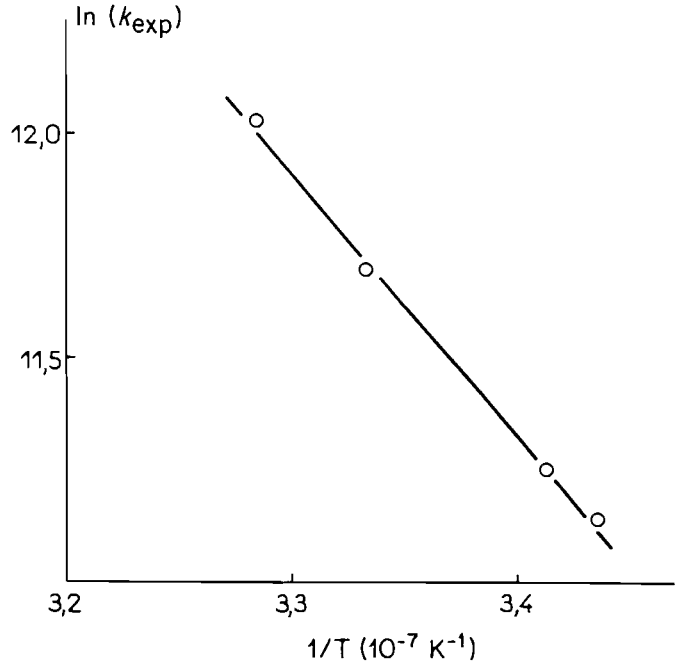

FIG. 6. Influence de la température : variation de $\ln(k_{exp})$ en fonction de $1/T$; pH = 9,25; $[S]_t = 2,5 \times 10^{-3}$ M; $[Cl]_t = 3,35 \times 10^{-4}$ M.

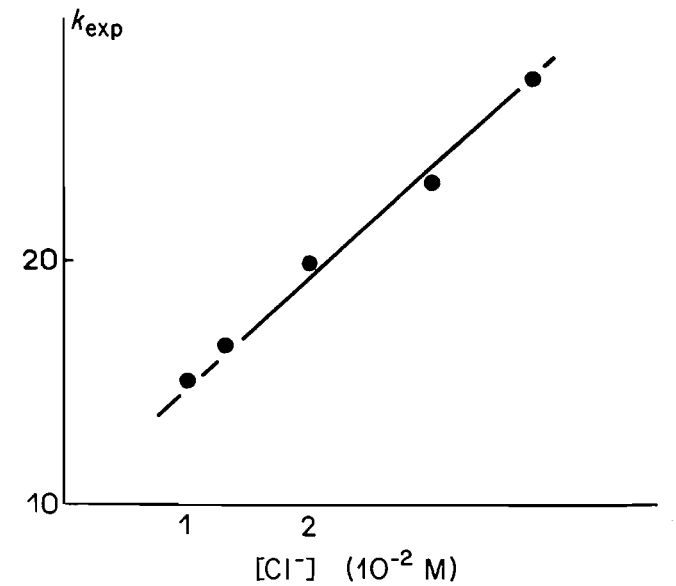

FIG. 7. Influence de la concentration en ions chlorures; T = 293 K; pH = 3,0; $[S]_t = 10^{-3}$ M; $[Cl]_t = 6 \times 10^{-4}$ M.

$$[S]_t = [SH] + [S^-] + [SCl]$$

Dans les conditions expérimentales du pseudo-premier ordre où nous nous sommes placés, la succinimide est en large excès par rapport au chlore et nous pouvons donc négliger la concentration en *N*-chlorosuccinimide [SCl] devant la concentration en succinimide totale :

$$[5] \quad [S]_t = [SH] + [S^-]$$

Les concentrations de ces différentes espèces peuvent être exprimées en fonction des constantes d'équilibre K_I et K_{II}, de leur coefficient d'activité γ_i, du pH, de $[Cl]_t$ et $[S]_t$.

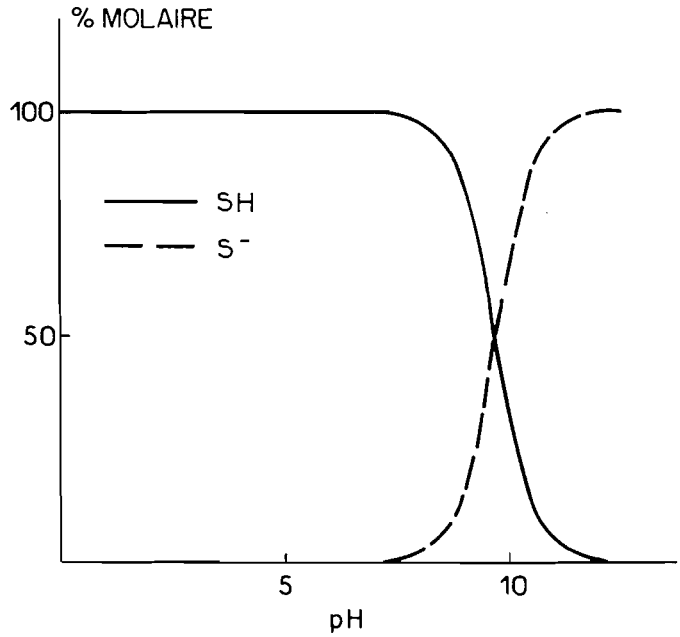

FIG. 8. Pourcentage molaire de succinimide sous forme de SH et S^- en fonction du pH à 293 K.

$$[6] \quad [SH] = \frac{\gamma_{S^-}(H^+)}{\mathcal{A}}[S]_t$$

$$[7] \quad [S^-] = \frac{\gamma_{SH}K_I}{\mathcal{A}}[S]_t$$

$$[8] \quad [HOCl] = \frac{\gamma_{ClO^-}(H^+)}{\mathcal{B}}[Cl]_t$$

$$[9] \quad [ClO^-] = \frac{\gamma_{HOCl}K_{II}}{\mathcal{B}}[Cl]_t$$

avec $\mathcal{A} = \gamma_{S^-}(H^+) + K_I\gamma_{SH}$ et $\mathcal{B} = \gamma_{ClO^-}(H^+) + K_{II}\gamma_{HOCl}$. Le détail du calcul qui conduit aux relations [6]–[9] est donné en annexe 2.

Si $v(P_i)$ est la participation de chacun des processus P_1–P_4 à la cinétique globale de la réaction de *N*-chloration, la vitesse peut s'exprimer par la relation :

$$[10] \quad v = \frac{d[SCl]}{dt} = \sum_{i=1}^{4} v(P_i)$$

Pour un processus bimoléculaire en solution réelle ($A + B \leftrightarrows C^{\neq} \rightarrow C$) où $C^{\neq}$ est le complexe activé du processus :

$$v(P_i) = k_i^0 \frac{\gamma_A\gamma_B}{\gamma_{C^{\neq}}}[A][B]$$

avec k_i^0 : constante de vitesse à dilution infinie.

Nous obtenons alors pour chacun des processus :

$$v(P_1) = k_1^0 \frac{\gamma_{SH}\gamma_{HOCl}}{\gamma_{1^{\neq}}}[SH][HOCl]$$

$$v(P_2) = k_2^0 \frac{\gamma_{SH}\gamma_{ClO^-}}{\gamma_{2^{\neq}}}[SH][ClO^-]$$

$$v(P_3) = k_3^0 \frac{\gamma_{S^-}\gamma_{HOCl}}{\gamma_{3^{\neq}}}[S^-][HOCl]$$

$$v(P_4) = k_4^0 \frac{\gamma_{S^-}\gamma_{ClO^-}}{\gamma_{4^{\neq}}}[S^-][ClO^-]$$

Soit en remplaçant les concentrations des espèces réagissantes par les expressions données par les relations [6]–[9] :

$$[11] \quad v(P_1) = \frac{k_1^0}{\gamma_{1^{\neq}}}(H^+)W[Cl]_t[S]_t$$

$$[12] \quad v(P_2) = \frac{k_2^0}{\gamma_{2^{\neq}}}K_{II}W[Cl]_t[S]_t$$

$$[13] \quad v(P_3) = \frac{k_3^0}{\gamma_{3^{\neq}}}K_IW[Cl]_t[S]_t$$

$$[14] \quad v(P_4) = \frac{k_4^0}{\gamma_{4^{\neq}}}\frac{K_IK_{II}}{(H^+)}W[Cl]_t[S]_t$$

avec

$$W = \frac{\gamma_{S^-}\gamma_{ClO^-}\gamma_{SH}\gamma_{HOCl}}{\mathcal{A}\mathcal{B}}(H^+)$$

En admettant une forme approchée par la loi de Debye–Hückel pour les coefficients des espèces ioniques, *W* prend la forme :

$$[15] \quad W = \gamma^2\frac{(H^+)}{[I_I + \gamma(H^+)][K_{II} + \gamma(H^+)]}$$

(avec $\gamma_{SH} = \gamma_{HOCl} = 1$ et $\gamma = \gamma_{S^-} = \gamma_{ClO^-} = 10^{-0,5\sqrt{I}}$), *I* étant la force ionique du milieu.

En milieu acide (pH < 5), K_I et K_{II} sont négligeables devant (H^+) et l'expression de *W* se simplifie : $W = 1/(H^+)$. La vitesse globale de la réaction s'exprime sous la forme :

$$v = \sum_{i=1}^{4} v(P_i) = \left[\frac{k_1^0}{\gamma_{1^{\neq}}} + \left(\frac{k_2^0K_{II}}{\gamma_{2^{\neq}}} + \frac{k_3^0K_I}{\gamma_{3^{\neq}}}\right)\frac{1}{(H^+)} + \frac{k_4^0K_IK_{II}}{\gamma_{4^{\neq}}}\frac{1}{(H^+)^2}\right][S]_t[Cl]_t$$

soit, d'après la relation [3] :

$$[16] \quad k_{exp} = \left[\frac{k_1^0}{\gamma_{1^{\neq}}} + \left(\frac{k_2^0K_{II}}{\gamma_{2^{\neq}}} + \frac{k_3^0K_I}{\gamma_{3^{\neq}}}\right)\frac{1}{(H^+)} + \frac{k_4^0K_IK_{II}}{\gamma_{4^{\neq}}}\frac{1}{(H^+)^2}\right]$$

Dans cette expression, nous avons regroupé les termes correspondants aux processus en fonction de leur dépendance vis-à-vis de l'activité du proton hydraté : P_1; (P_2,P_3); P_4. À l'intérieur du couple (P_2,P_3), les deux complexes activés ont même charge et même composition, leurs coefficients d'activité $\gamma_{2^{\neq}}$ et $\gamma_{3^{\neq}}$ varient donc de façon identique avec la force ionique. Comme le pH influence de la même manière leur contribution à la vitesse globale de réaction, ces deux processus sont indiscernables. Nous avons déjà rencontré ce phénomène d'indiscernabilité des processus pour la *N*-chloration d'amines secondaires (7) et de l'acide cyanurique (8).

En milieu basique (pH > 11), (H^+) devient négligeable devant les constantes K_{II} et K_I et *W* prend la forme :

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

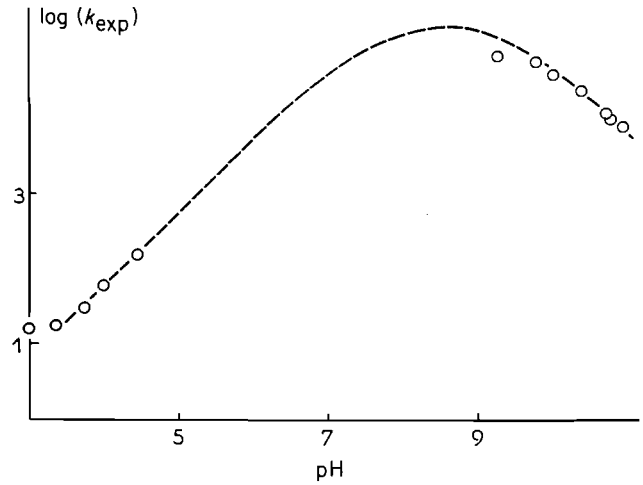

FIG. 9. Influence du pH sur k_{exp}; T = 293 K; pH < 5 : $[S]_t = 10^{-3}$ M, $[Cl]_t = 6 \times 10^{-4}$ M; pH > 8 : $[S]_t = 2{,}5 \times 10^{-3}$ M, $[Cl]_t = 3{,}35 \times 10^{-4}$ M.

$$W = \gamma^2 \frac{(H^+)}{K_I K_{II}}$$

soit :

$$[17] \quad k_{exp} = \left[\frac{k_1^0 \gamma^2}{\gamma_{1^\neq} K_I K_{II}} (H^+)^2 + \left(\frac{k_2^0 \gamma^2}{\gamma_{2^\neq} K_I} + \frac{k_3^0 \gamma^2}{\gamma_{3^\neq} K_{II}} \right)(H^+) + \frac{k_4^0 \gamma^2}{\gamma_{4^\neq}} \right]$$

Nous obtenons la même partition des processus P_1; (P_2,P_3); P_4 vis-à-vis de l'influence de l'activité du proton hydraté qu'en milieu acide et l'indiscernabilité des processus P_2, P_3 est conservée.

En étudiant la variation de la constante de vitesse k_{exp} déterminée à partir des points expérimentaux (tableau 1) en fonction du pH, nous observons, pour les pH inférieurs à 5 et supérieurs à 10, une variation linéaire de log(k_{exp}) avec le pH avec une pente voisine de +1 (±0,1) en milieu acide et de −1 (±0,1) en milieu basique (figure 9).

Ce résultat indique, d'après les relations [16] et [17], que seuls les processus P_2 ou P_3 interviennent dans la chloration de la succinimide en absence d'ions chlorures :

$$P_2 \quad SH + ClO^- \rightarrow SCl + OH^-$$

$$P_3 \quad S^- + HOCl \rightarrow SCl + OH^-$$

D'après les relations [12] et [13], la vitesse globale de la réaction est alors donnée par la relation :

$$v = v(P_2) + v(P_3) = \left[\frac{k_2^0 K_{II}}{\gamma_{2^\neq}} + \frac{k_3^0 K_I}{\gamma_{3^\neq}} \right] W [Cl]_t [S]_t$$

soit

$$k_{exp} = \left[\frac{k_2^0 K_{II}}{\gamma_{2^\neq}} + \frac{k_3^0 K_I}{\gamma_{3^\neq}} \right] W$$

Les deux complexes activés ayant une charge globale de −1, les coefficients d'activité $\gamma_{2^\neq}$ et $\gamma_{3^\neq}$ sont égaux à γ et l'expression de k_{exp} se simplifie :

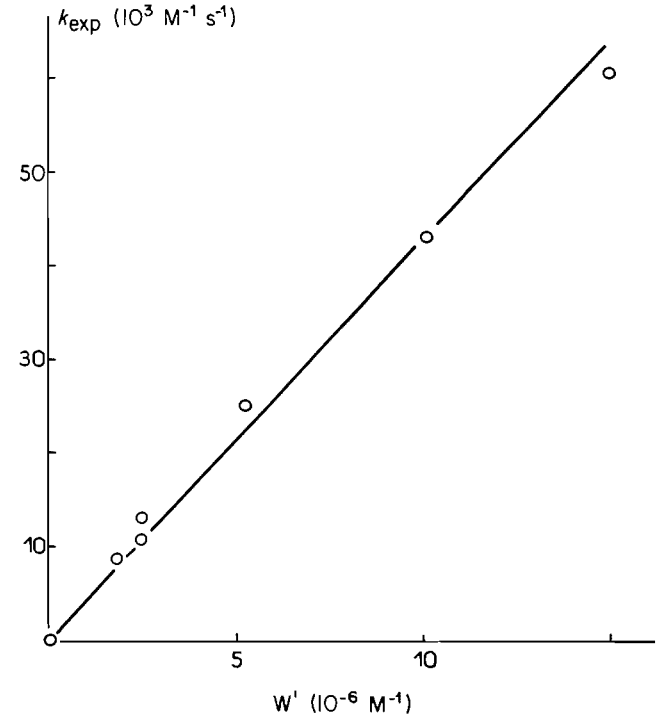

FIG. 10. k_{exp} en fonction de W'.

$$W' = \frac{\gamma(H^+)}{[K_I + \gamma(H^+)][K_{II} + \gamma(H^+)]}$$

$$[18] \quad k_{exp} = [k_2^0 K_{II} + k_3^0 K_I] W'$$

avec

$$W' = \frac{W}{\gamma} = \frac{\gamma(H^+)}{[K_I + \gamma(H^+)][K_{II} + \gamma(H^+)]}$$

La pente de la droite obtenue en portant les valeurs expérimentales des constantes de vitesse k_{exp} en fonction de W' (figure 10) nous permet de calculer, dans le cas limite où l'un des processus devient prépondérant, la valeur théorique maximale des constantes de vitesse k_2^0 et k_3^0 : si $k_2^0 K_{II} > k_3^0 K_I$, $k_2^0 = (1{,}6 \pm 0{,}3) \times 10^5$ M^{-1} s^{-1} à 293 K; si $k_2^0 K_{II} < k_3^0 K_I$, $k_3^0 = (2{,}2 \pm 0{,}4) \times 10^7$ M^{-1} s^{-1} à 293 K. Cette valeur de la constante de vitesse de la chloration de S^- par HOCl est en accord avec celle déterminée en milieu acide par Hussain et Higuchi : $k = 2{,}14 \times 10^7$ M^{-1} s^{-1} à 298 K (1).

La détermination des constantes de vitesse expérimentales obtenues à pH constant (pH = 9,25) à différentes températures (figure 6) a permis l'étude de l'influence de ce paramétre sur les constantes de vitesse k_2^0 et k_3^0 des deux processus P_2 et P_3. Le calcul du coefficient W dans la gamme de température étudiée a été fait en utilisant pour expression des constantes d'équilibre K_I et K_{II} les relations :

$$pK_I = \left(\frac{3000}{T} \right) - 10{,}0686 + 0{,}0253\, T \qquad (3)$$

$$pK_{II} = 36{,}92 - 0{,}167\, T + (2{,}53 \times 10^{-4}) T^2 \qquad (4)$$

Le logarithme des constantes de vitesse k_2^0 et k_3^0 en fonction de $1/T$ est porté par des droites (figure 11) dont les pentes

TABLEAU 2. Constante de vitesse, énergie d'activation, $\Delta H^{\neq}$ et $\Delta S^{\neq}$ des processus de chloration de la succinimide

	Processus	k^0_{293K} ($M^{-1}\,s^{-1}$)	$E^{\neq}$ (kJ mol^{-1})	$\Delta H^{\neq}$ (kJ mol^{-1})	$\Delta S^{\neq}$ (J K^{-1} mol^{-1})
P_2	$SH + ClO^- \rightarrow$	$1{,}6 \times 10^5$	62,7	60,2	61
P_3	$S^- + HOCl \rightarrow$	$2{,}2 \times 10^7$	48,0	45,5	51

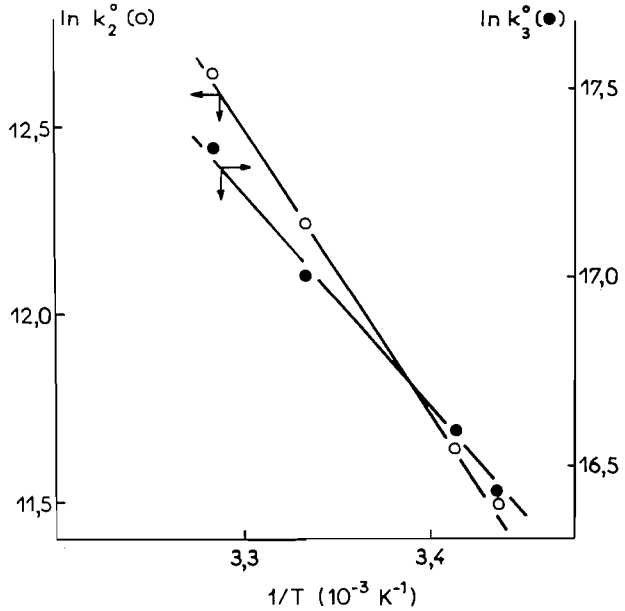

FIG. 11. Influence de la température; (○) ln k_2^0 en fonction de $1/T$; (●) ln k_3^0 en fonction de $1/T$.

donnent les énergies d'activation des processus P_2 et P_3 avec une précision de l'ordre de 20% :

$$\ln k_2^0 = -\frac{7528}{T} + 37{,}76 \qquad E_{2^{\neq}} = 62{,}7 \text{ kJ/mol}$$

$$\ln k_3^0 = -\frac{5770}{T} + 36{,}55 \qquad E_{3^{\neq}} = 48{,}0 \text{ kJ/mol}$$

Le tableau 2 résume les résultats obtenus pour les deux processus possibles de la *N*-chloration de la succinimide en absence d'ions chlorures. Les valeurs des enthalpies et des entropies d'activation des deux processus ont été calculées à partir des constantes de vitesse et des énergies d'activation déterminées précédemment.

Chloration en milieu acide en présence d'ions chlorures

En milieu acide et en présence d'ions chlorures, les concentrations en ions trichlorures Cl_3^- et surtout en chlore moléculaire Cl_2 ne sont plus négligeables (figure 2). En plus des processus P_2 et P_3 indiscernables qui limitent la vitesse de réaction globale en absence d'ions chlorures, nous devons considérer les quatre processus P_5–P_8 qui font intervenir les espèces Cl_3^- et Cl_2.

Les équilibres [I]–[IV] nous permettent d'exprimer la concentration de chaque espèce réagissante en fonction de la concentration en chlorure $[Cl^-]$, des concentrations totales en succinimide $[S]_t$ et en chlore libre $[Cl]_t$, du pH et du coefficient d'activité γ d'un ion de charge ± 1.

En tenant compte des approximations possibles en milieu acide (K_I et K_{II} négligeables devant $\gamma(H^+)$), nous obtenons :

$$[19] \quad [SH] = \frac{\gamma(H^+)}{K_I + \gamma(H^+)}[S]_t \approx [S]_t$$

$$[20] \quad [S^-] = \frac{K_I}{K_I + \gamma(H^+)}[S]_t \approx \frac{K_I}{\gamma(H^+)}[S]_t$$

$$[21] \quad [HOCl] \approx \frac{K_{III}}{\mathcal{D}}[Cl]_t$$

$$[22] \quad [ClO^-] \approx \frac{K_{II}K_{III}}{\mathcal{D}\gamma(H^+)}[Cl]_t$$

$$[23] \quad [Cl_2] \approx \frac{\gamma(H^+)[Cl^-]}{\mathcal{D}}[Cl]_t$$

$$[24] \quad [Cl_3^-] \approx \frac{K_{IV}\gamma(H^+)[Cl^-]^2}{\mathcal{D}}[Cl]_t$$

avec $\mathcal{D} = K_{III} + \gamma(H^+)[Cl^-]$. Le détail du calcul conduisant à ces expressions des concentrations est donné en annexe 3.

À partir des relations [19]–[24] et en utilisant la loi limite de Debye–Hückel pour expliciter les coefficients d'activité, nous pouvons exprimer la participation de chacun des processus P_1, P_2 et P_5–P_8 à la cinétique globale de la réaction :

$$v(P_2) = k_2^0 \frac{\gamma_{SH}\gamma_{ClO^-}}{\gamma_{2^{\neq}}}[SH][ClO^-] = k_2^0 \frac{K_{II}K_{III}}{\gamma(H^+)\mathcal{D}}[S]_t[Cl]_t$$

$$v(P_3) = k_3^0 \frac{\gamma_{S^-}\gamma_{HOCl}}{\gamma_{3^{\neq}}}[S^-][HOCl] = k_3^0 \frac{K_I K_{III}}{\gamma(H^+)\mathcal{D}}[S]_t[Cl]_t$$

$$v(P_5) = k_5^0 \frac{\gamma_{SH}\gamma_{Cl_2}}{\gamma_{5^{\neq}}}[SH][Cl_2] = k_5^0 \frac{\gamma(H^+)[Cl^-]}{\mathcal{D}}[S]_t[Cl]_t$$

$$v(P_6) = k_6^0 \frac{\gamma_{SH}\gamma_{Cl_3^-}}{\gamma_{6^{\neq}}}[SH][Cl_3^-] = k_6^0 \frac{K_{IV}\gamma(H^+)[Cl^-]^2}{\mathcal{D}}[S]_t[Cl]_t$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

$$v(P_7) = k_7^0 \frac{\gamma_S - \gamma_{Cl_3^-}}{\gamma_{7^\neq}} [S^-][Cl_2] = k_7^0 \frac{K_I[Cl^-]}{\mathcal{D}} [S]_t[Cl]_t$$

$$v(P_8) = k_8^0 \frac{\gamma_S - \gamma_{Cl_3^-}}{\gamma_{8^\neq}} [S^-][Cl_3^-] = k_8^0 \frac{1}{\gamma^2} \frac{K_I K_{IV}[Cl^-]^2}{\mathcal{D}} [S]_t[Cl]_t$$

L'expression de la vitesse globale en présence d'ions chlorures devient alors :

$$v = v(P_2) + v(P_3) + \sum_{i=5}^{8} v(P_i)$$

avec

$$v(P_2) + v(P_3) = \frac{k_2^0 K_{II} K_{III} + k_3^0 K_I K_{III}}{\gamma(H^+)\mathcal{D}} [S]_t[Cl]_t$$

Soit d'après la relation [3] :

$$[25] \quad k_{exp} = \frac{1}{\mathcal{D}\gamma(H^+)} \left[k_2^0 K_{II} K_{III} + k_3^0 K_I K_{III} + k_5^0 \gamma^2(H^+)^2[Cl^-] + k_6^0 K_{IV} \gamma^2(H^+)^2[Cl^-]^2 + k_7^0 K_I \gamma(H^+)[Cl^-] + k_8^0 K_I K_{IV} \frac{[Cl^-]^2(H^+)}{\gamma} \right]$$

Si nous nous plaçons dans le cas où le processus P_3 est prépondérant devant P_2 (ce choix arbitraire ne limite pas la généralité du résultat puisque nous n'avons pu évaluer que la valeur théorique maximale des constantes de vitesse k_2^0 et k_3^0 dans le cas où le processus P_2 ou P_3 est exclusif), nous aurons $k_3^0 K_I >> k_2^0 K_{II}$ et $k_3^0 K_I K_{III}$ vaut alors $1{,}44 \times 10^{-6}$ M^2 s^{-1}.

La réaction [25] peut s'écrire :

$$[26] \quad Y - 1{,}44 \times 10^{-6} = k_5^0 \gamma^2(H^+)^2[Cl^-] + k_7^0 K_I \gamma(H^+)[Cl^-] + k_6^0 K_{IV} \gamma^2(H^+)^2[Cl^-]^2 + k_8^0 K_I K_{IV} \frac{[Cl^-]^2(H^+)}{\gamma}$$

avec $Y = k_{exp}\mathcal{D}\gamma(H^+)$. Cette quantité Y peut être calculée à partir des points expérimentaux obtenus à pH constant (pH = 3) et pour des concentrations en chlorure variables. Nous constatons (figure 12) que c'est la proportionnalité qui rend le mieux compte des variations de $(Y - 1{,}44 \times 10^{-6})$ avec $\gamma[Cl^-]$ ou $\gamma^2[Cl^-]$ ce qui élimine les processus P_6 ou P_8. Ceci est d'autant plus vrai que $[Cl^-]$ est grand.

La variation linéaire de Y en fonction de $\gamma(H^+)[Cl^-]$ (figure 13) montre qu'en milieu acide et en présence d'ions chlorures, le processus P_7 semble prépondérant et intervient parallèlement au couple de processus (P_2, P_3) indiscernables. Le processus P_7 correspond à la chloration par le chlore moléculaire Cl_2 de l'ion S^- qui se trouve en très faible quantité dans ces conditions de pH. En admettant une variation linéaire de Y en fonction de $\gamma(H^+)[Cl^-]$, nous pouvons estimer la valeur de la constante de vitesse k_7^0 du processus P_7 : $k_7^0 = 1{,}1 \times 10^9$ M^{-1} s^{-1} à 293 K.

Nous notons également que l'ordonnée à l'origine de cette droite qui représente la quantité $k_3^0 K_{II} K_{III}$ conduit à une valeur expérimentale voisine de la valeur calculée à partir de la constante de vitesse k_3^0 déterminée par l'étude en absence d'ions chlorures et justifie l'interprétation de la courbe de la figure 13.

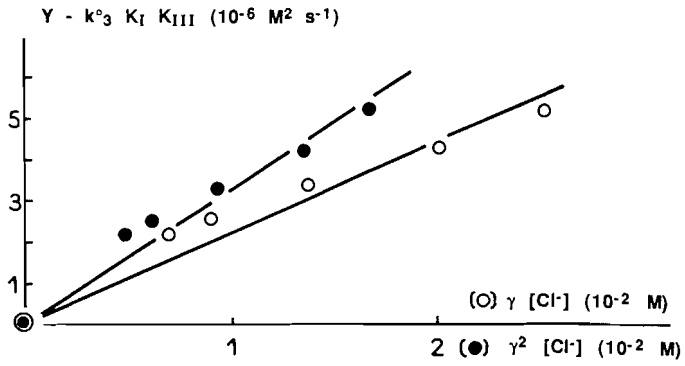

FIG. 12. Variation de $Y - k_3^0 K_I K_{III}$ en fonction de $\gamma[Cl^-]$ (○) et $\gamma^2[Cl^-]$ (●); pH = 3,0; T = 293 K.

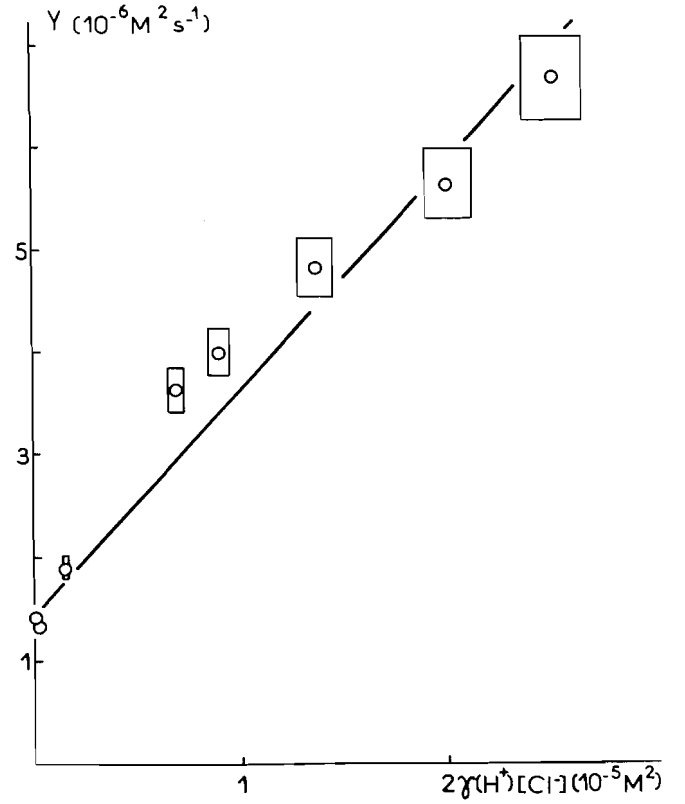

FIG. 13. Variation de Y en fonction de $\gamma(H^+)[Cl^-]$. Ces rectangles d'erreur sont calculés en ne tenant compte que de l'incertitude sur le pH (±0,025).

Conclusion

Cette étude par spectrophotométrie à écoulement bloqué nous a permis de mettre en évidence que, en milieu acide comme en milieu basique, la succinimide pouvait être chlorée soit sous sa forme acide SH par l'ion hypochlorite ClO^- soit sous sa forme basique S^- par l'acide hypochloreux HOCl.

Comme aucun paramètre cinétique ne permet de distin-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

guer ces deux processus, la chloration de S^- par HOCl pourrait être la plus probable en supposant une attaque nucléophile de S^- sur HOCl en tout point semblable au mécanisme cinétiquement démontré en milieu acide : la chloration de S^- par Cl_2 :

$$S^- + HOCl \rightarrow SCl + OH^-$$

$$k_3^0 = 2{,}2 \times 10^7\ M^{-1}\ s^{-1} \text{ à } 293\ K$$

$$S^- + Cl\text{-}Cl \rightarrow SCl + Cl^-$$

$$k_7^0 = 1{,}1 \times 10^9\ M^{-1}\ s^{-1} \text{ à } 293\ K$$

Le facteur 50 entre les valeurs de k_3^0 et k_7^0 laisse penser que la cinétique de chloration par HOCl n'est pas totalement limitée par la diffusion. Les valeurs proches des coefficients de diffusion de HOCl et Cl_2 dans l'eau (D_{Cl_2} = 1,83 $m^2\ s^{-1}$ et D_{ClOH} = 1,28 $m^2\ s^{-1}$ à 298 K (8)) ne permettent pas d'expliquer l'écart entre les constantes de vitesse dans l'hypothèse de cinétiques limitées uniquement par la diffusion. La même observation a été faite pour la *N*-chloration des amines en phase aqueuse (9).

Annexe 1 : Spectrophotométrie à écoulement bloqué. Exploitation des courbes cinétiques

La cinétique de la *N*-chloration de la succinimide en phase aqueuse peut être suivie en temps réel par spectrophotométrie à écoulement bloqué en mesurant, en fonction du temps, la tension V sortant du photomultiplicateur, qui est directement proportionnelle à l'intensité I de la lumière transmise par la solution. La densité optique A est obtenue en utilisant la loi de Beer–Lambert : $A = \log I_0/I$, soit $A = \log V_0/V$, I_0 et V_0 étant respectivement l'intensité de la lumière transmise et la tension à la sortie du photomultiplicateur.

1^er^ cas : Réaction du pseudo-premier ordre. On suit au cours du temps la concentration de l'ion ClO^-

Soit la réaction de chloration d'un substrat S par l'ion ClO^- d'ordre 1 par rapport à ClO^- et d'ordre α par rapport à S :

$$\alpha S + ClO^- \rightarrow P$$

L'ion hypochlorite est de plus en équilibre avec l'acide hypochloreux HOCl $\leftrightarrows$ $ClO^- + H^+$ avec la constante d'équilibre $K = [ClO^-](H^+)/[HClO]$. Cet équilibre est très rapide devant la réaction de chloration de telle sorte que les espèces HOCl et ClO^- restent toujours en équilibre entre elles. Si, à la longueur d'onde d'analyse, seules les espèces ClO^- et P absorbent la lumière, la densité optique est donnée par la relation : $A = \epsilon_1\,[ClO^-] + \epsilon_2\,[P]$, ϵ_1 et ϵ_2 étant respectivement les coefficients molaires d'extinction à cette longueur d'onde de ClO^- et de P.

En désignant par $[Cl]_t$ la concentration en chlore libre total (chlore non lié à un atome d'azote), $[Cl]_t = [HOCl] + [ClO^-] = [ClO^-](K + (H^+))/K$, la concentration totale de chlore $[Cl]_T$ devient :

$$[Cl]_T = [Cl]_t + P = [ClO^-]\frac{K + (H^+)}{K} + [P]$$

La densité optique de la solution prend alors la forme :

$$A = \epsilon[ClO^-] + \epsilon_2[Cl]_T$$

$\epsilon = \epsilon_1 - \epsilon_2 - \epsilon_2(H^+)/K$ reste constant au cours de la réaction, les solutions étant tamponnées.

La concentration du réactif S étant en large excès par rapport à l'hypochlorite, ce dernier sera entièrement consommé à la fin de la réaction et la densité optique à la longueur d'onde d'analyse de la solution après réaction devient :

$$A_\infty = \epsilon_2[Cl]_T$$

et

$$A = A_\infty + \epsilon[ClO^-] \text{ soit : } [ClO^-] = \frac{A - A_\infty}{\epsilon}$$

La réaction étant d'ordre 1 par rapport à $[ClO^-]$ et le réactif S étant en large excès par rapport à l'hypochlorite, on obtient $-\,d[ClO^-]/dt = k[ClO^-]$ avec k constante de vitesse du pseudo-premier ordre exprimée en s^{-1}. On en déduit donc :

$$-\frac{d(A - A_\infty)}{dt} = -\epsilon\frac{d[ClO^-]}{dt} = k(A - A_\infty)$$

soit, après intégration :

$$\ln\frac{A - A_\infty}{A(0) - A_\infty} = -kt$$

Ainsi, si la concentration de départ du réactif S est en large excès par rapport à la concentration d'hypochlorite et que les résultats expérimentaux vérifient la relation $\ln(A - A_\infty) = kt$ + constante, on peut en déduire que la réaction étudiée est du pseudo-premier ordre et déterminer la constante de vitesse apparente k.

2^e^ case : Réaction du deuxième ordre. On suit au cours du temps l'apparition du produit formé

Dans ce cas, on fixe la longueur d'onde de détection au maximum d'absorption de P. À cette longueur d'onde, les espèces HOCl, ClO^-, S ainsi que la solution tampon absorbent partiellement. La densité optique s'exprime alors par la relation :

$$A = \epsilon_1[P] + \epsilon_2[Cl]_t + \epsilon_3[S] + A_t$$

ϵ_1 et ϵ_3 sont respectivement les coefficients d'extinction molaire de P et S à la longueur d'onde d'analyse, ϵ_2 est un coefficient d'extinction molaire qui dépend du pH et A_t la densité optique due à la solution tampon. Ces deux derniers paramètres restent constants au cours de l'expérience. Comme

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

$[Cl]_T = [Cl]_t + [P]$ et $[S]_t = [S] + [P]$, $[S]_t$ étant la concentration totale du réactif chloré ou non, on en déduit :

$$[A] = (\epsilon_1 - \epsilon_2 - \epsilon_3)[P] + \epsilon_2[Cl]_T + \epsilon_3[S]_t + A_t$$

et

$$\frac{d[A]}{dt} = (\epsilon_1 - \epsilon_2 - \epsilon_3)\frac{d[P]}{dt}$$

La densité optique à l'instant initial est donnée par :

$$A(0) = \epsilon_2[Cl]_T + \epsilon_3[S]_t + A_t$$

Dans le cas où la concentration initiale de réactif $[S]_t$ est supérieure à la concentration initiale de chlore $[Cl]_T$, la densité optique de la solution à la fin de la réaction A_∞ est donnée par la relation :

$$A_\infty = (\epsilon_1 - \epsilon_3)[Cl]_T + \epsilon_3[S]_t + A_t$$

et

$$A_\infty - A(0) = (\epsilon_1 - \epsilon_2 - \epsilon_3)[Cl]_T$$

donc

$$\frac{dA}{dt} = \frac{[A_\infty - A(0)]}{[Cl]_T}\frac{dP}{dt}$$

soit

$$\left(\frac{dP}{dt}\right)_{t=0} = \frac{(dA/dt)_{t=0}}{[A_\infty - A(0)}[Cl]_T$$

Précision des résultats

Pour les réactions du pseudo-premier ordre, les constantes de vitesse sont déterminées en mesurant la pente de la droite $\ln(A - A_\infty)$ en fonction du temps par la méthode des moindres carrés. On peut estimer l'incertitude relative sur la constante de vitesse à environ 10%.

Pour les réactions du deuxième ordre, la constante de vitesse est calculée à partir de la pente dA/dt au début de la réaction et des densités optiques $A(0)$ et A_∞ au début et à la fin de la réaction. La précision sur les constantes de vitesse ainsi déterminée est d'environ 20%.

Annexe 2

Les expressions des concentrations des différentes espèces réagissantes sont établies à partir d'une part des bilans en succinimide et en chlore libre total :

[A1] $[Cl]_t = [ClO^-] + [HOCl]$

[A2] $[S]_t = [S^-] + [SH]$

et d'autre part des constantes des équilibres [I] et [II] :

[A3] $$K_I = \frac{(H^+)(S^-)}{(SH)} = \frac{(H^+)[S^-]}{[SH]}\frac{\gamma_{S^-}}{\gamma_{SH}}$$

[A4] $$K_{II} = \frac{(H^+)(ClO^-)}{(HOCl)} = \frac{(H^+)[ClO^-]}{[HOCl]}\frac{\gamma_{ClO^-}}{\gamma_{HOCl}}$$

Ces deux relations [A2] et [A3] forment un système de deux équations à deux inconnues [SH] et $[S^-]$ qui peut être résolu par exemple en exprimant $[S^-]$ en fonction de [SH] à partir de la relation [A3].

$$[S^-] = \frac{K_I[SH]\gamma_{SH}}{(H^+)\gamma_{S^-}}$$

En remplaçant $[S^-]$ par cette expression dans l'équation [A2], nous obtenons directement les relations [6] et [7]. De la même façon, les deux relations [8] et [9] sont déduites du système des deux équations [A1] et [A4] avec comme inconnues $[ClO^-]$ et [HOCl].

Annexe 3

En présence d'ions chlorures et dans les conditions d'une cinétique du pseudo-premier ordre (succinimide en large excès par rapport au chlore), les bilans en succinimide et en chlore libre total deviennent :

[A5] $[S]_t = [SH] + [S^-]$

[A6] $[Cl]_t = [ClO^-] + [HOCl] + [Cl_2] + [Cl_3^-]$

Ces concentrations sont liées entre elles par les lois d'action de masse des équilibres [I]–[IV] :

[A7] $$K_I = \frac{(H^+)[S^-]}{[SH]}\gamma \qquad \text{avec } pK_I = 9{,}71 \text{ à } 293 \text{ K}$$

[A8] $$K_{II} = \frac{(H^+)[ClO^-]}{[HOCl]}\gamma \qquad \text{avec } pK_{II} = 7{,}58 \text{ à } 293 \text{ K}$$

[A9] $$K_{III} = \frac{(H^+)[Cl^-][HOCl]}{[Cl_2]}\gamma$$

avec $pK_{III} = 3{,}48$ à 293 K

[A10] $$K_{IV} = \frac{[Cl_3^-]}{[Cl_2][Cl^-]}\gamma \qquad \text{avec } pK_{IV} = 0{,}74 \text{ à } 298 \text{ K}$$

Les deux équations [A5] et [A7] permettent facilement d'exprimer [SH] et $[S^-]$ en fonction de $[S]_t$. D'après [A5] : $[S^-] = [S]_t - [SH^-]$. En reportant cette expression dans [A7], nous obtenons :

$$[SH] = \frac{\gamma(H^+)}{K_I + \gamma(H^+)}[S]_t$$

et

$$[S^-] = [S]_t - \frac{\gamma(H^+)}{K_I + \gamma(H^+)}[S]_t = \frac{K_I}{K_I + \gamma(H^+)}[S]_t$$

En milieu acide (pH < 3), K_I devient négligeable devant $\gamma(H^+)$ et [SH] ≈ [S]t, $[S^-] \approx K_I/\gamma(H^+)[S]_t$.

À partir des trois lois d'action de masse [A8], [A9], [A10] correspondant aux équilibres [II]–[IV], nous pouvons obtenir par substitutions successives l'expression des concentrations des espèces chlorées en fonction de [HOCl] :

$$[ClO^-] = \frac{K_{II}[HOCl]}{\gamma(H^+)}$$

$$[Cl_2] = \frac{\gamma(H^+)[Cl^-][HOCl]}{K_{III}}$$

$$[Cl_3^-] = \frac{K_{IV}}{K_{III}}\gamma(H^+)[Cl^-]^2[HOCl]$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

Le bilan en chlore libre total [A6] s'écrit alors :

$$[Cl]_t = [HOCl]\left[1 + \frac{K_{II}}{\gamma(H^+)} + \frac{\gamma(H^+)[Cl^-]}{K_{III}} + \frac{K_{IV}}{K_{III}}\gamma(H^+)[Cl^-]^2\right]$$

En milieu acide pH < 3 et dans le domaine de concentration en ions chlorures étudié, $[K_{II}/\gamma(H^+)]$ et $(K_{IV}/K_{III})\gamma(H^+)[Cl^-]^2$ sont négligeables devant $1 + \gamma(H^+)[Cl^-]/K_{III}$.

$$[Cl]t \approx [HOCl]\left[\frac{K_{III} + \gamma(H^+)[Cl^-]}{K_{III}}\right]$$

En posant $\mathcal{D} = K_{III} + \gamma(H^+)[Cl^-]$, nous retrouvons l'équation [21] et par déductions successives, les relations [22]–[24].

The role of coupling in intramolecular proton transfer reactions. The hydrogen oxalate anion as an example

ENRIC BOSCH, MIQUEL MORENO, AND JOSÉ MARÍA LLUCH[1]

Departament de Química, Universitat Autònoma de Barcelona, 08193 Bellaterra, Barcelona, Spain

Received June 11, 1991

ENRIC BOSCH, MIQUEL MORENO, and JOSÉ MARÍA LLUCH. Can. J. Chem. **70,** 100 (1992).

Coupling between the proton motion and the internal degrees of freedom for intramolecular proton transfer in the hydrogen oxalate anion has been studied. A normal mode analysis at a sequence of points along the Intrinsic Reaction Coordinate (IRC) has been performed and the coupling functions $B_{k,F}$ have been obtained. It is shown that, although for the reactant the IRC direction essentially consists of the motion of oxygen atoms, the coupling changes this IRC direction towards the motion corresponding to proton transfer itself. From a quantum point of view, the curvature that appears as a consequence allows corner-cutting tunneling. Finally, the effect of isotope substitution is considered.

Key words: intramolecular proton transfer, coupling functions, IRC curvature, tunneling splitting, isotope substitution.

ENRIC BOSCH, MIQUEL MORENO et JOSÉ MARÍA LLUCH. Can. J. Chem. **70,** 100 (1992).

On a étudié le couplage entre le mouvement du proton et les degrés de liberté interne du transfert protonique intramoléculaire dans l'anion hydrogénoxalate. On a fait un analyse des modes propres de vibration sur une séquence de points de la coordonnée réactionnelle (CRI) et on a pu en tiré les fonctions de couplage $B_{k,F}$. On a démontré que, bien que la direction de la CRI dans le réactif peut être décrite principalement par le mouvement des atomes d'oxygène, le couplage change cette direction de la CRI vers le mouvement correspondant au transfert protonique lui-même. D'un point de vue quantique, la courbure qui apparait rend possible un effet tunnel qui coupe les coins. Enfin, on a considéré l'effet de la substitution isotopique.

Mots clés : transfert protonique intramoléculaire, fonctions de couplage, courbure de la CRI, dédoublement provoqué par l'effet tunnel, substitution isotopique.

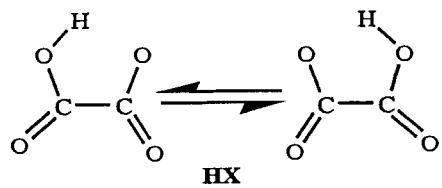
[Traduit par la rédaction]

Introduction

It is generally accepted that proton transfer reactions are among the simplest and most common reactions in chemistry (1,2). Given that these processes primarily involve the motion of the transferring hydrogen, some calculations have frozen the other geometrical parameters (3, 4). In other studies this important restriction has been partially lifted so that the distance between H-donor and H-acceptor atoms is fixed, all other geometrical parameters being fully optimized at each stage of the proton transfer (5–7).

Over the past few years several authors have claimed that the proton motion is strongly coupled to intramolecular vibrational modes in the reaction system (8–18). In particular, we have shown that to have a reliable evaluation of the tunneling dynamics for intramolecular proton transfer in the hydrogen oxalate anion (HX), a bidimensional surface that takes into account the coupling between the proton transfer motion and the vibrations of the heavy atoms through a quadratic term must be considered. This quadratic term acts as a bath, which averages the effect of all the vibrational modes coupled to the system (proton transfer) motion (18).

The purpose of the present paper is to take the intramolecular proton transfer of HX as an example for discussing the importance and the nature of the coupling between the proton motion and the internal degrees of freedom. To this aim we will perform a quantitative analysis of the coupling that explicitly characterizes the interaction between the proton transfer motion and each of the vibrational modes. This study will be done in the full potential hypersurface by calculating the coupling functions $B_{k,F}$.



HX

SCHEME 1

Methodology

Ab initio self-consistent field (SCF) calculations were carried out with the Gaussian 86 series of programs (19), using the triply split valence basis set 3-21 + G (20, 21), which contains a diffuse *sp* shell on atoms other than hydrogen.

All geometrical parameters were completely optimized. Geometry optimization and direct location of minima and the transition state were carried out with the Schlegel gradient optimization algorithm (22).

We have constructed the Intrinsic Reaction Coordinate (IRC) (23–25). The IRC is a line in mass-weighted configuration space whose coordinates $\boldsymbol{x}$ are given parametrically in terms of the arc length s defined by

$$[1] \qquad ds = \left(\sum_{j=1}^{3N} dx_j^2 \right)^{1/2}$$

where $\boldsymbol{x}$ is a column vector whose components are the $3N$ mass-weighted Cartesian coordinates. The IRC is the solution of the differential equation:

$$[2] \qquad \frac{d\boldsymbol{x}}{ds} = -\frac{\nabla V}{|\nabla V|}$$

where ∇ is the N-dimensional gradient operator in mass-weighted coordinates and V is the Born–Oppenheimer potential energy.

A normal mode analysis at a sequence of points along the IRC has been performed. Second energy derivatives with respect to the Cartesian coordinates were computed analytically (26). At a given point of the reaction coordinate we evaluate:

$$[3] \quad K^p = (1 - P) \cdot K \cdot (1 - P)$$

where K is the $3N \times 3N$ Hessian matrix and P is a projector, a $3N \times 3N$ matrix, whose elements are given by

$$[4] \quad P_{i,\gamma,i',\gamma'} = \sum_{k=3N-6}^{3N} L_{i,\gamma,k} \cdot L_{i',\gamma',k}$$

Here $i = 1, \ldots N$ labels the atoms and $\gamma = x, y, z$ the Cartesian coordinates. The quantities $\{L_{i,\gamma,k}\}$; $k = 3N - 6, \ldots, 3N - 1$ are the six $3N$-dimensional unit vectors that correspond to infinitesimal rotation and translations of the N-atom system, and $L_{i,\gamma,3N}$ is the unit vector along the reaction coordinate defined in eq. [2]. Thus, not only the direction of the reaction path but the direction corresponding to infinitesimal rotations and translations is projected out. An explicit expression of the $\boldsymbol{L}$ vectors has been given by Miller *et al.* (27).

Diagonalization of the projected Hessian matrix K^p was finally done in order to obtain the normal modes along the IRC. Note that for stationary points projections are not required.

In symmetrical double-well potentials the stationary states with energies less than the barrier height occur in nearly degenerate pairs consisting of a symmetric state and a higher energy antisymmetric state. The tunneling rate k is directly related to the energy splitting ΔE by (28)

$$[5] \quad k = \frac{2\Delta E}{h}$$

For a unidimensional path this tunneling splitting is given in the semiclassical WKB (29) approximation by

$$[6] \quad \Delta E = \frac{h\nu}{\pi} e^{-\theta}$$

where ν is the vibrational frequency in the well and θ is the classical action integral through the barrier defined by

$$[7] \quad \theta = \frac{1}{\hbar} \mathrm{Im} \int_{\text{barrier}} p(x)dx = \frac{1}{\hbar} \int_{s<}^{s>} (2m(V(x) - E))^{1/2} dx$$

where $s<$ and $s>$ are the initial and end points of the tunneling path. We note that since we use mass-weighted Cartesian coordinates, the mass m in eq. [1] must be a unit mass. To evaluate the tunneling feasibility the θ values at selected points along the IRC have been calculated using eq. [7].

Finally the isotope effect coming from the substitution of the transferring proton by a deuterium has been studied using a basis set method (30). In particular we have taken a basis set χ_i where the basis functions χ_i are localized Gaussian functions:

$$[8] \quad \chi_i(s) = \left(\frac{\alpha}{\pi}\right)^{1/4} \exp\left[\frac{-\alpha}{2}(s - s_i)^2\right]$$

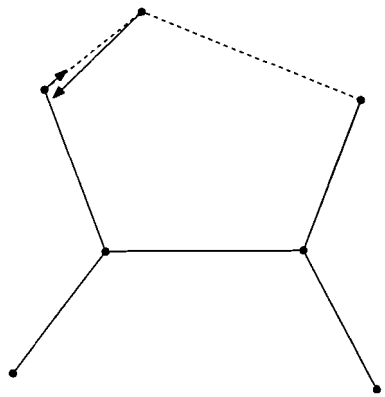

FIG. 1. Normal mode ν_1 of A' symmetry at the hydrogen oxalate minimum in mass-weighted Cartesian coordinates.

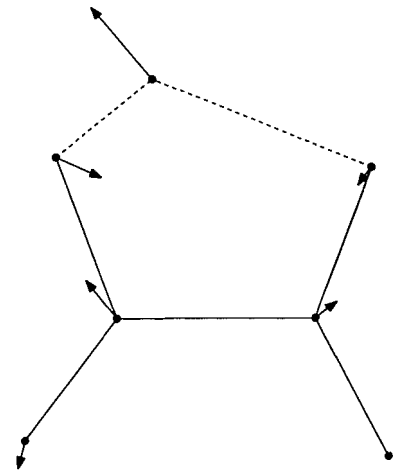

FIG. 2. Normal mode ν_4 of A' symmetry at the hydrogen oxalate minimum in mass-weighted Cartesian coordinates.

where α is an adjustable parameter and s_i values are equally spaced points along the s coordinate. A variational calculation using n localized Gaussian functions provides the lowest n eigenvalues and eigenfunctions of the one-dimensional system. The tunneling splitting ΔE can thereby be obtained. The adjustable parameter α is chosen to provide a balance of linear independence and completeness of the basis set. We have used 41 Gaussian functions for all the calculations.

Results and discussion

A chemical reaction involves a nuclear reorganization in going from reactants to products. In fact, only motions that strictly come from the geometric difference between reactant and product should be required. These motions would lead from reactants to products through the shortest path, a straight path known as the Linear Reaction Path (LRP) (11). For the proton transfer reaction in HX, the dominant component of this coordinate is the displacement of the transferring H.

A normal mode analysis of the reactant (HX) shows that the LRP arises mainly from the superposition of two modes displayed in Figs. 1 and 2. Note that the arrows indicate the direction of the atomic motion in mass-weighted Cartesian coordinates. Taking into account only the normal modes

corresponding to the C_s symmetry we can classify these modes in decreasing order of frequencies as the first and fourth.

Nevertheless the high values of the frequencies associated with these two modes $\nu_1 = 3639$ and $\nu_4 = 1418$ cm^{-1} suggest that motion along the LRP should require passage over a sizeable barrier. In fact an *ab initio* calculation provides a value of 21.24 kcal mol^{-1} for this barrier.

Therefore from a classical point of view it is clear that the reaction cannot proceed along the LRP. Instead, a structure of lower energy has to exist that fulfills the four conditions of a transition state as stated by McIver and Komornicki (31). In fact, when this transition state is located it is seen that an energy barrier of only 8.34 kcal mol^{-1} is imposed (17). From this transition state the IRC can be built as the steepest descent path that can go either way, to reactants or products. Its initial direction at the transition state is given by the normal mode of the imaginary frequency. Assuming the harmonic approximation, we choose the initial step size Δs that produces the appropriate energy lowering $k(\Delta s)^2/2$, where k is the negative force constant associated with the imaginary frequency. Then the IRC is followed, taking very small steps in the direction of the negative gradient, which is equivalent to the Euler method. An initial energy lowering of 0.0005 hartrees and successive steps of $\Delta s = 0.0265$ amu$^{1/2}$ Å have been used (17). The IRC ends up at the normal mode of the lower frequency (of the appropriate symmetry) (32).

Therefore, in contrast with the LRP, going from reactants to products through the transition state by following the IRC implies a distortion of the geometry of the reactant so that an approach to the geometry of the product is not initially provided, but a path with the lowest energy barrier is allowed.

Figure 3 shows the IRC direction for selected points along the IRC. In the reactant well ($s = -1.08$ amu$^{1/2}$ Å) the IRC follows the direction of the lowest normal mode at the geometry of the minimum whose frequency is $\nu_{10} = 320$ cm^{-1}. This low value clearly indicates a slow energy climbing. At this point the IRC essentially consists of the motion of oxygen atoms, the transferring hydrogen remaining attached to the donor oxygen.

In Fig. 4 we display the direction of the straight paths that depart from selected points along the IRC. Each straight path joins two points of the IRC with arc length values of $-s$ and $+s$ respectively. The path is defined by linear interpolation between both extremes in mass-weighted Cartesian coordinates. That is:

$$[9] \quad \mathbf{y}(v) = \frac{1}{2}(\mathbf{y}_s + \mathbf{y}_{-s}) + (\mathbf{y}_s - \mathbf{y}_{-s}) \cdot \frac{v}{\Delta v}$$

where:

$$[10] \quad \Delta v = |\mathbf{y}_s - \mathbf{y}_{-s}|$$

where $\mathbf{y}_{-s}$ and $\mathbf{y}_s$ are the $3N$ mass-weighted Cartesian coordinates of the atoms for the geometries corresponding to $-s$ and $+s$ values of the IRC respectively, v is the distance along the straight path, and $\mathbf{y}(v)$ the corresponding Cartesian coordinates along this path. Note that v varies from $-\Delta v/2$ to $+\Delta v/2$. When the straight path links reactant and product the LRP is obtained.

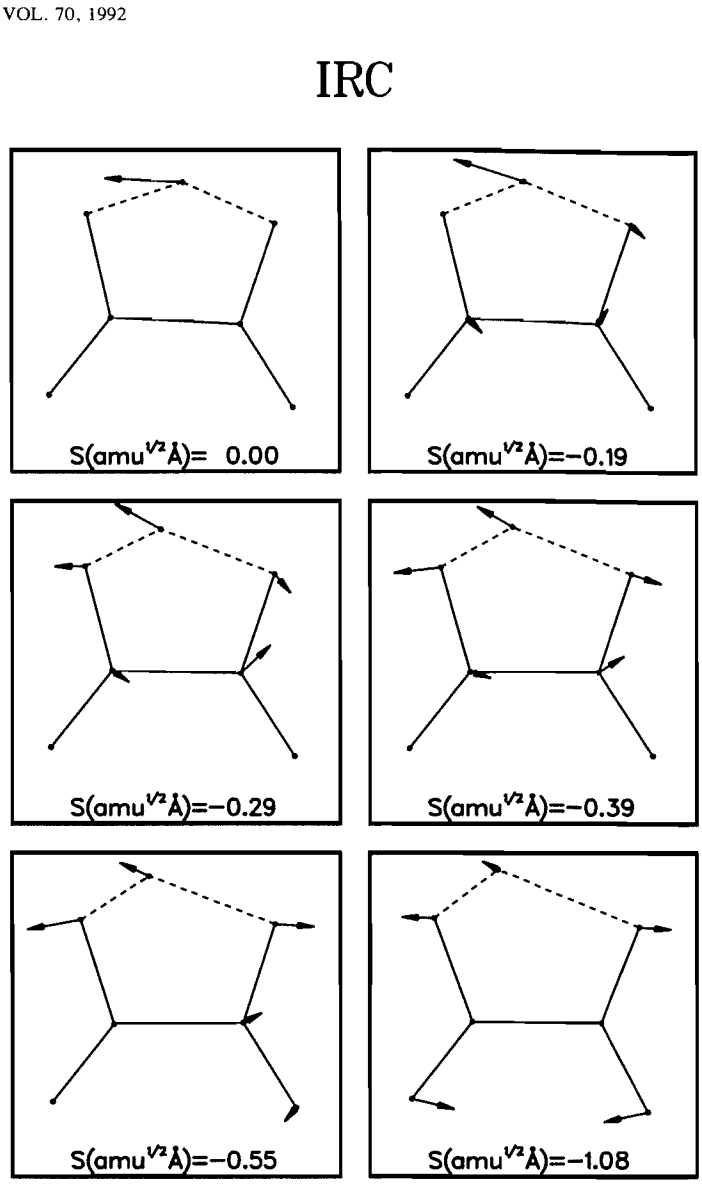

FIG. 3. Snapshots showing the direction in mass-weighted Cartesian coordinates of the IRC for hydrogen oxalate proton transfer at selected points.

To fulfill the requirement that any straight path have no linear nor angular momentum, the following conditions along this path $\boldsymbol{R}_i$ are imposed:

$$[11] \quad \sum_i m_i \cdot \boldsymbol{R}_i'(v) = 0$$

$$[12] \quad \sum_i m_i \cdot \boldsymbol{R}_i(v) \times \boldsymbol{R}_i'(v) = 0$$

where the prime denotes (d/dv). The first condition is satisfied by imposing the condition that the center of mass is always at the origin. The condition that angular momentum remain zero is satisfied by orienting the product axis system in precisely the correct way with respect to that of the reactant.

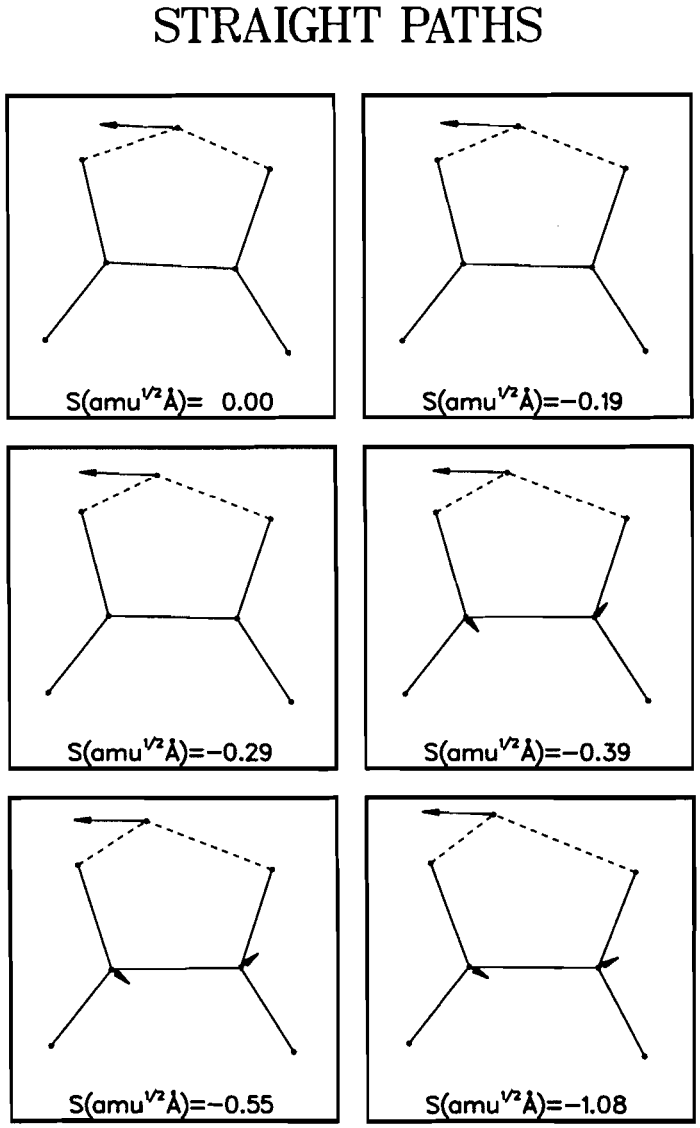

FIG. 4. Snapshots showing the direction in mass-weighted Cartesian coordinates of the straight paths that depart from selected points of the IRC.

In Fig. 4 it is shown that, as the reaction proceeds, the direction of the IRC changes, so that it progressively becomes the direction corresponding to the straight path. This point becomes clear when the snapshots depicted in Figs. 3 and 4 are compared. This way the transition vector entirely corresponds to the proton transfer, the other atoms remaining fixed.

The evolution of the IRC direction is the result of the coupling with the rest of the normal modes and, in particular, with modes 1 and 4. Quantitatively this coupling can be analyzed using the coupling functions $B_{k,F}$ that characterize the interaction between the kth vibrational generalized normal mode and the reaction coordinate F. The $B_{k,F}$ terms are given by

$$[13] \quad B_{k,F}(s) = \sum_{i=1}^{3N} (\delta L_{i,k}(s)/\delta s) \cdot L_{i,F}(s)$$

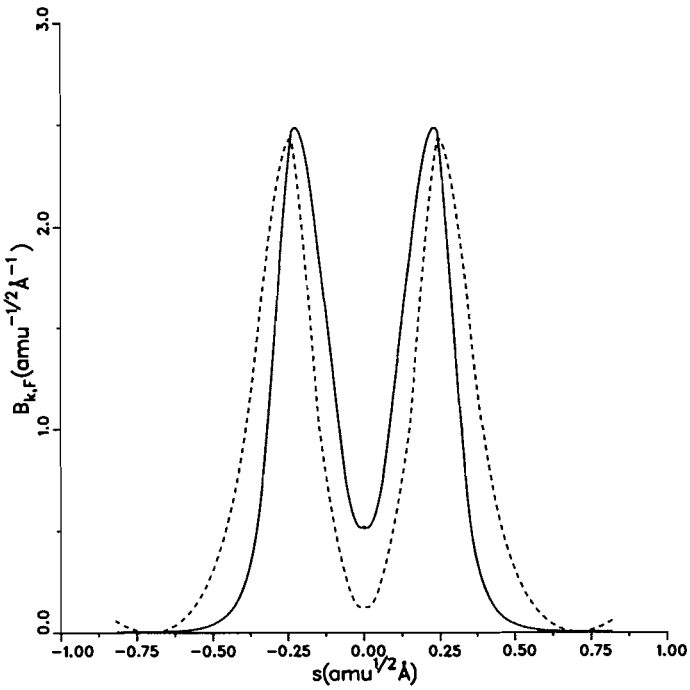

FIG. 5. Absolute value of coupling functions $B_{1,F}$ (solid line) and $B_{4,F}$ (dashed line) along the IRC.

where $L_{i,k}$ and $L_{i,F}$ are, respectively, the ith Cartesian component of the kth eigenvector of the projected force constant matrix and that of the reaction coordinate direction as a function of s. In practice the coupling elements are obtained via a finite difference approximation:

$$[14] \quad B_{k,F}\left(\frac{s_j + s_{j-1}}{2}\right) \approx \frac{\sum_{i=1}^{3N} [L_{i,k}(s_j) \cdot L_{i,F}(s_{j-1}) - L_{i,k}(s_{j-1}) \cdot L_{i,F}(s_j)]}{2(s_j - s_{j-1})}$$

The coupling functions $B_{1,F}$ and $B_{4,F}$ are shown in Fig. 5. Both display two significant peaks at about $s = \pm 0.25$ amu$^{1/2}$ Å. The variation of the adiabatic projected harmonic frequencies corresponding to the A' symmetry along the IRC is shown in Fig. 6. The important change of the 1 and 4 frequencies around $s = \pm 0.25$ amu$^{1/2}$ Å reflects the significant coupling of the corresponding modes with the reaction path.

This coupling is required to cause deviation of the IRC direction towards the motion corresponding to proton transfer itself. An important curvature appears as a consequence. This curvature of the reaction path is defined as

$$[15] \quad \kappa(s) = \left[\sum_{k=1}^{F-1} B_{k,F}(s)^2\right]^{1/2}$$

and has been represented by a solid line in Fig. 7.

It can be observed that two sharp peaks symmetrically appear, one before and one after the saddle point (s =

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12

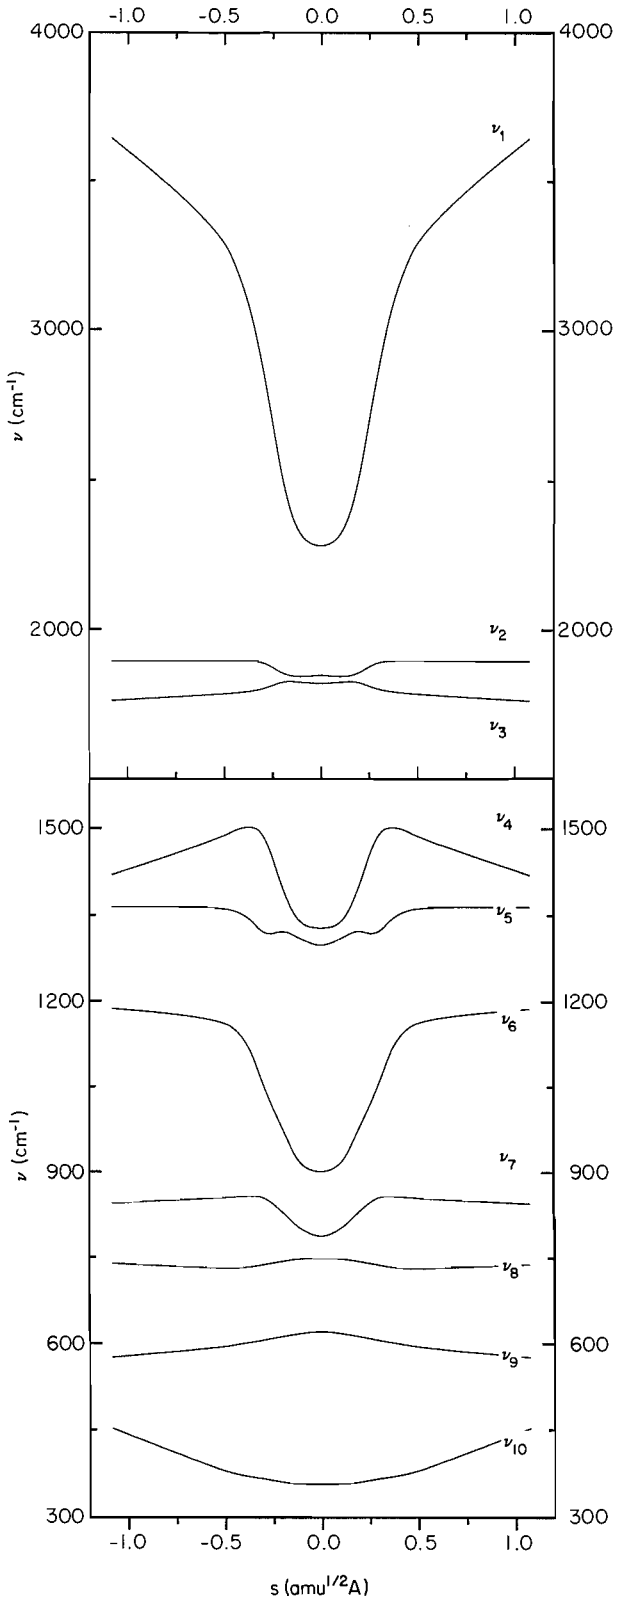

FIG. 6. Projected harmonic frequencies (in cm^{-1}) of the A' symmetry along the IRC.

0 $amu^{1/2}$ Å). These peaks are mostly due to the contribution of the coupling with modes 1 and 4.

From a quantum point of view the IRC curvature has the effect of allowing corner-cutting tunneling, thereby increasing the probability of tunneling. If only the height of the barrier is considered, the more appropriate tunneling path would be the IRC as this path implies the lowest value for such a barrier. However, when the curvature is large a straight line involves a shorter path that can compensate for the energy factor. To analyze this point, we have calculated several parameters at selected points along the IRC. We present these parameters in Table 1.

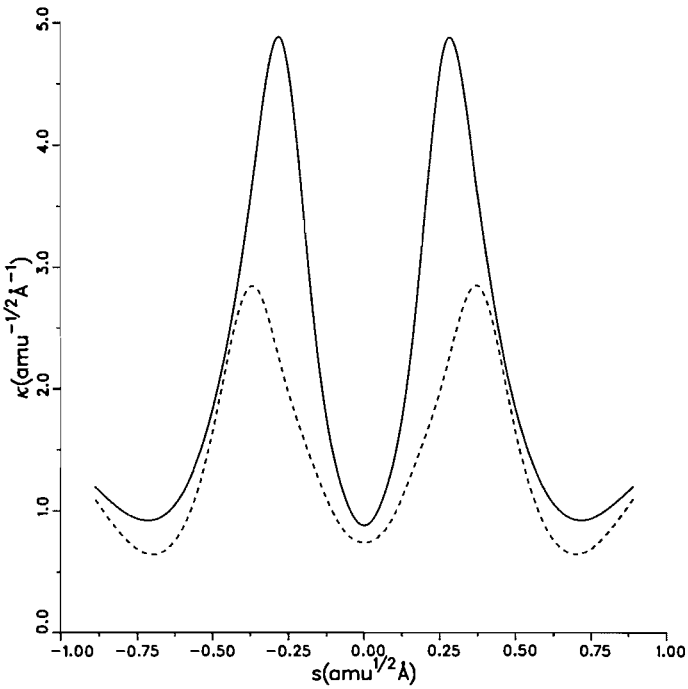

FIG. 7. Total curvature $\kappa(s)$ for hydrogen oxalate HX (solid line) and deuterated hydrogen oxalate DX (dashed line) anions along the IRC.

TABLE 1. Parameters that control the tunneling at selected points of the IRC (see text for details)

s^a	α^b	Δl^a	ΔB^c	$\Delta\theta$
−0.19	19.6	0.004	−0.05	0.004
−0.29	65.6	0.044	−0.43	0.103
−0.39	55.0	0.108	−1.39	0.198
−0.55	62.5	0.266	−3.40	0.643
−1.08	78.7	0.972	−12.91	2.416

[a] In $amu^{1/2}$ Å.
[b] In degrees.
[c] In kcal mol^{-1}.

In this table α stands for the angle obtained from the scalar product between the unitary vectors that define the IRC and the straight paths, respectively. As the IRC deviates more with respect to the straight paths, a higher value of α is obtained. Δl measures at each point the length difference between the IRC and its corresponding straight path. ΔB accounts for the difference of energy barriers between both paths. Finally, following eq. [7], these last two factors determine the value of $\Delta\theta$, the difference between the classical action integral through the barriers.

TABLE 2. Tunneling splittings[a] along the IRC and LRP for HX and DX

Path	ΔE^b
IRC	HX 2.72(−3)
	DX 2.75(−4)
LRP	HX 7.27(−3)
	DX 2.58(−4)

[a]Power of 10 in parentheses.
[b]In cm^{-1}.

In going from the transition state down to reactants the curvature tends to increase the value of the angle α. Then as the IRC deviates from the straight path, its length becomes progressively longer than the corresponding straight path. Table 1 shows that this last factor favors the tunneling through the straight path more and more, in spite of the fact that the barrier differences ΔB evolve unfavorably. Therefore, the LRP is a more feasible way to reach the product than the IRC when the quantum tunneling effect is accounted for.

The above-mentioned considerations can be useful in interpreting certain chemical phenomena. In particular it seems that in enzyme catalysis and protein chemistry the reduction of the distance between the proton-donor and the proton-acceptor atoms facilitates the proton transfer (33, 34). In fact, the effect of this "close packing" is equivalent to pushing the reactant system along the initial stage of the IRC, which, as mentioned above, essentially consists of the motion of the donor and acceptor atoms. Therefore from a classical point of view the energy barrier is lowered. In addition, from a quantum point of view the lengths of both the IRC and the straight paths are shortened in such a way that the proton tunneling is favored.

Another interesting problem is the isotope effect. When the transferring proton is substituted by a deuterium the IRC curvature is noticeably reduced as shown in the dashed curve in Fig. 7. This effect is reflected in Table 2 where the tunneling splittings for HX and DX (deuterated hydrogen oxalate anion) along the IRC and the LRP are shown.

A clear difference comes to light when looking at Table 2: whereas in the HX the splitting is clearly higher along the LRP (18), in the DX both paths lead to almost the same splitting values. On the other hand it is interesting to note that this unidimensional approach, although it underestimates the splitting, already shows that the tunneling frequency for HX is an order of magnitude greater than for DX.

Concluding remarks

From the results obtained in this work the following picture can be developed for intramolecular proton transfer in the hydrogen oxalate anion.

To achieve the minimum energy path the IRC is initiated with a direction in which the contribution of the hydrogen motion is very small. The coupling between the reaction path and the normal modes orthogonal to this path produces a progressive change in the direction of the IRC, the proton transfer itself taking place at the end of this path. This coupling leads to a curvature, so that from a quantum point of view the tunneling dynamics do not follow the IRC, allowing the tunneling path to cut the corner. When the transferring hydrogen is substituted by deuterium the curvature decreases so that this corner-cutting effect is diminished.

A final remark is that any feasible tunneling path not only involves the proton motion but other atom motions that come from the geometric difference of reactant and product. As a consequence the path in mass-weighted Cartesian coordinates becomes longer and the tunneling rate decreases.

We believe these features are general for a wide range of intramolecular proton transfers in chemical and biochemical systems.

Copper(I)-catalyzed cross-dehydrocoupling reactions of silanes and amines

H. Q. Liu and J. F. Harrod
Chemistry Department, McGill University, Montreal, P.Q., Canada H3A 2K6

Received June 18, 1991

H. Q. Liu and J. F. Harrod. Can. J. Chem. **70**, 107 (1992).

In the presence of cuprous chloride, hydrosilanes and primary amines react to give silazanes. Methylphenylsilane reacts with (R)-(+)-α-methylbenzylamine to give the two diastereomeric monosilazanes as the only products. Aniline and benzylamine react with methylphenyl- and diphenylsilanes to give primarily the monosilazane, disilazane, or diazasilane as the main product, depending on the reactant ratios. Phenylsilane gives higher oligomers with aniline, mainly the trisilatriazane and trisiladiazanes, but no high molecular weight material.

Key words: silanes, amines, silazanes, cuprous chloride, dehydrocoupling, catalysis.

H. Q. Liu et J. F. Harrod. Can. J. Chem. **70**, 107 (1992).

En présence de chlorure cuivreux, les hydrosilanes et les amines primaires réagissent pour donner des silazanes. Le méthylphénylsilane réagit avec la (R)-(+)-α-méthylbenzylamine pour donner uniquement les deux monosilazanes diastéréoisomères. L'aniline et la benzylamine réagissent avec les méthylphényl- et diphénylsilanes et, suivant les rapport des réactifs, il se forme surtout des monosilazanes, des disilazanes ou des diazasilanes comme produits principaux. La réaction du phénylsilane avec l'aniline conduit à la formation d'oligomères, principalement le trisilatriazane et les trisiladiazanes; toutefois, il ne se forme pas de produits de poids moléculaires élevés.

Mots clés : silanes, amines, silazanes, chlorure cuivreux, couplage déshydrogénant, catalyse.

[Traduit par la rédaction]

Introduction

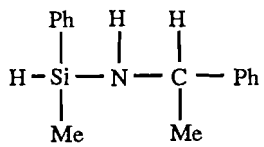
The potential use of polysilazanes as precursors to Si_3N_4 has stimulated the search for new methods for their synthesis (for general reviews, see ref. 1). Dehydrocoupling of silanes with amines is an attractive reaction, producing a relatively benign and light by-product, hydrogen. In general, the uncatalyzed reaction is too slow to be useful under any reasonable reaction conditions and hence requires catalysis. Strong bases are effective catalysts in certain cases (2, 3). In addition, a few transition metal catalysts have been found to work for the catalytic dehydrocoupling of silanes and primary or secondary amines. The most reactive catalysts are $Ru_3(CO)_{12}$, developed by Laine and co-workers (4–8), and $PdCl_2$, studied by Kinsley (9).

During our investigation of the dehydrocoupling reaction between silanes and acetylenic compounds, in the presence of an amine/copper(I) chloride catalyst (10), it was found that, besides the dehydrocoupling reaction of the silane with the acetylene, a dehydrocoupling reaction between silane and amine could also take place. This was particularly apparent when we tried to influence the stereochemical outcome of certain acetylene reactions through the use of a chiral secondary amine. We report here our ensuing investigation of copper(I) as a catalyst for the coupling of a variety of organosilanes and amines.

Results and discussion

In the presence of copper(I) chloride, the reaction of phenylmethylsilane and (R)-(+)-α-methylbenzylamine leads to the formation of the silazane in very good yield. In a typical reaction (mole ratio of silane:amine:CuCl = 1:1:0.067) after 21 h at 100°C an 84% conversion to a mixture of the two diastereoisomers, **1** and **2** was obtained (roughly 1:1 ratio by NMR integration of Si-H resonances at δ = 4.96 and 5.01). In the absence of catalyst, there was no detectable reaction under these conditions.

The reaction of phenylmethylsilane with benzylamine proceeds in essentially the same way as α-methylbenzylamine and leads to the formation of HPhMeSiNHBz, **3**, PhMeHSiN(Bz)SiHPhMe, **4**, and BzNHSi(PhMe)NHBz, **5**, in ratios depending on the initial molar ratio of silane to amine. With an equimolar ratio, the major product is **3**; with a molar ratio of 2:1, after extended reaction time, **4** is the only product, and with a molar ratio 1:2, and long reaction time, **5** is obtained in high yield (Table 1). The results from the reactions of equimolar amine and silane clearly show that the residual NH of **3** has a higher reactivity with methylphenylsilane than does the residual SiH of **3** with benzylamine. This effect allows the production of **4** in near quantitative yields if the reaction is run in the presence of a considerable excess of silane. On the other hand, the low reactivity of the residual SiH of **3** allows the clear demonstration of a stepwise passage from silazane to diazasilane when the reaction is run in the presence of excess amine. Again, there is essentially no reaction in the absence of catalyst.



1, R,R; **2**, S,R

From Table 1, for the reactions with equimolar silane and amine, changes in reaction temperature or catalyst ratio do not have a significant effect on the formation of **5**. In addition, with a molar ratio of silane to amine of 1:2, the reaction took 3 days for complete conversion to **5**, while under otherwise similar conditions, the 2:1 molar ratio reaction, which yields mostly **4**, was complete in 21 h. It thus appears that the very low reactivity of the trisubstituted SiH intermediate with another NH bond is the major rate limiting factor, and the one which accounts for the failure of this combination of reactants to give polymers, or higher oligomers.

The reaction of diphenylsilane and benzylamine is similar to that of phenylmethylsilane and benzylamine. In toluene at reflux, the product is mainly $Ph_2HSiNHBz$, **6**, in the

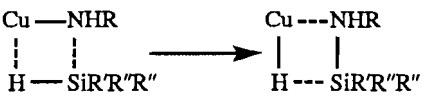
[a]$[Ph_2SiH_2]$ = $[PhCH_2NH_2]$ = 1.94 M; [CuCl] = [TMEDA] = 0.43 M; solvent: toluene; T: reflux.

first stage. Subsequently, the remaining monomers react with **6** to form $Ph_2HSiN(Bz)SiHPh_2$, **7**, and $BzHNSiPh_2NHBz$, **8**, (see Table 2). From the evolution of these reactions, it is again evident that the secondary silanes are much more reactive than the tertiary ones resulting from the coupling reaction, and the reactant primary amine is more reactive than the secondary one produced by the coupling reaction.

The above results indicate that high coupling reactivity requires a minimum of substitution on both the silane and the amine. This expectation is to some degree borne out by the results for reactions of phenylsilane with benzylamine and aniline. These reactions lead, in addition to the silazanes and disilazanes, to oligomers of somewhat higher molecular weight than are achievable with the secondary silanes. As is evident from the results listed in Table 3, the trisilatriazane, **9**, and trisiladiazane, **10**, can be the major products under appropriate reaction conditions. It should be noted, however, that very high CuCl concentrations are needed to produce higher oligomers. Using an equimolar mixture of reactants at 110°C, a near quantitative conversion of phenylsilane and aniline to 1,2-diphenylsilazane was achieved in 1 h, a rate that is not significantly different from the rates of silazane formation from the secondary silanes. One can therefore conclude that there is not a significant difference in reactivity between primary and secondary silanes, with respect to formation of the first SiN bond (see Table 4). However, the $RSiH_2$-N species retain sufficient reactivity to couple further with amine, while the R_2SiH-N species do not.

The reaction mechanism

The most probable mechanism for the CuCl-catalyzed cross-coupling of Si-H and N-H is a σ-bond metathesis involving a four center intermediate of the type:



This type of intermediate is highly congested and analogous σ-bond metatheses also exhibit the kind of sensitivity to steric effects manifest in the present reactions (11). Although the above reaction is believed to be the productive step in dehydrocoupling, a number of other metatheses are probably occurring in the system as well, those shown in reactions [1]–[4] being of some possible importance.

[1] $R_1R_2R_3SiH + CuCl \rightarrow R_1R_2R_3SiCl + CuH$

[2] $RNH_2 + CuH \rightarrow RNHCu + H_2$

[3] $R_1R_2R_3SiH + CuH \rightarrow R_1R_2R_3SiCu + H_2$

[4] $R_1R_2R_3SiCu + RNH_2 \rightarrow CuH + R_1R_2R_3SiNHR$

Reaction [1] is known (12). We have established that preprepared CuH functions identically to CuCl as a catalyst and liberates hydrogen when heated with amines. We presently prefer [2] as the H_2-releasing step, although [3] cannot be excluded on the basis of presently available data. Silyl complexes of Cu(I) are known (13), but thermodynamics would appear to favour [2] over [4].

Conclusions

The CuCl-catalyzed coupling of silanes and amines provides a useful new route to the formation of Si-N bonds. Although this method works well for the synthesis of simple molecules, the activity is not high enough to permit the synthesis of high molecular weight polysilazanes. Given the reactivity patterns observed in the present study, it seems unlikely that copper-based catalysts will prove useful for polymer synthesis. However, the cost factor, relative to noble metal catalysts, certainly favours their use for the synthesis of simple silazanes.

Experimental

Materials and analytical methods

Phenylsilane, phenylmethylsilane, and diphenylsilane were prepared using a literature method (14). Benzylamine, aniline, butylamine, TMED, tributylamine, and (R)-(+)-α-methylbenzylamine (Aldrich Chemical Co.) were distilled from dry NaOH pellets immediately prior to use. CuCl (Anachemia) was used as received. CuH was prepared using a literature method (15). Tetrahydrofuran, toluene, and xylene were distilled from sodium.

^1H NMR spectra were recorded on a Varian XL-200FT spectrometer. Mass spectra were measured on a HP-5980A mass spectrometer using chemical ionization (NH_3). The molecular weights of polymers were measured on a Varian 5000 gel permeation chromatograph, equipped with a Waters Ultrastyragel 1000 Å column at 35°C. The carrier solvent was chloroform for the oligomers of phenylsilane with aniline, or benzylamine, and tetrahydrofuran for the products of the diphenyl- and phenylmethylsilane reactions. Polystyrene standards were used for calibration.

Reactions of diphenyl- and phenylmethylsilane with (R)-(+)-α-methylbenzylamine, aniline, and benzylamine

The reactions reported in Tables 1 and 2 were run by mixing reactants, catalyst, and (in the case of Table 2) solvent in a round bottomed flask and heating for the required length of time under an atmosphere of argon. On completion of the reactions, catalyst was removed by precipitation on cooling to room temperature, followed by filtration. Volatiles were removed by pumping and the residues were analyzed by a combination of GC/MS, ^1H NMR, and GPC. The products **4** and **5** were separated by vacuum distillation (135–140°C and 155–160°C at 0.01 Torr (133.3 Pa)). Some NMR and MS data for the products are listed in Table 5.

Copolymerization of phenylsilane and aniline

Phenylsilane (1 mL), aniline (0.73 mL), CuCl (400 mg), and xylene (4 mL) were introduced into an evacuated flask, equipped with a condenser and a gas inlet. The mixture was heated at reflux under nitrogen for 20 h. After cooling to room temperature to precipitate the catalyst, the liquid layer was decanted into a Schlenk tube and the volatiles were distilled off under vacuum at 100°C to give a very viscous yellow–orange gum (1.2 g, yield: 70%). The progress of the reaction was monitored by periodic sampling and

A MNDO study of planar thioacyl-substituted carbocations

JACK LEON GINSBURG
Department of Chemistry, Saint Mary's University, Halifax, N.S., Canada B3H 3C3

RICHARD FRANCIS LANGLER[1] AND RAJ KUMAR RAHEJA
Department of Chemistry, Mount Allison University, Sackville, N.B., Canada E0A 3C0

AND

LAURA PRECEDO
Department of Chemistry, Florida Institute of Technology, Melbourne, FL 32901, U.S.A.

Received July 19, 1990[2]

JACK LEON GINSBURG, RICHARD FRANCIS LANGLER, RAJ KUMAR RAHEJA, and LAURA PRECEDO. Can. J. Chem, **70**, 111 (1992).

Relative gas phase stabilities of pairs of planar regioisomeric thioacyl-substituted carbocations have been calculated using the MNDO method. These systems are stabilized by good π donors. The role of S π-electron population as a gauge of substituent effects is examined. Similar results were obtained using isodesmic reactions to gauge substituent effects. Results of this and earlier studies are consistent with the resonance saturation effect.

Key words: semiempirical calculations, carbonium ions.

JACK LEON GINSBURG, RICHARD FRANCIS LANGLER, RAJ KUMAR RAHEJA et LAURA PRECEDO. Can. J. Chem. **70**, 111 (1992).

Utilisant la méthode MNDO, on a calculé les stabilités relatives en phase gazeuse de paires de carbocations thioacyles substitués, régio-isomères et plans. Ces systèmes sont stabilisés par de bons donneurs d'électrons π. On a évalué le rôle de la population S d'électrons π comme mesure des effets de substituants. On a obtenu des résultats semblables lorsqu'on a utilisé des réactions isodesmiques comme mesure des effets de substituants. Ces résultats et ceux obtenus au cours d'études antérieures sont en accord avec un effet de saturation par résonance.

Mots clès : calculs semi-empiriques, carbocations.

[Traduit par la rédaction]

Introduction

The last decade has seen a burgeoning interest in the structures of carbocations which have strongly electron-withdrawing groups directly attached to the cationic center (**1***a–f*) (e.g., NO_2, CF_3, CN, and CO). Of course, stabilized carbocations have also been examined in detail (**1***g–o*).

We have undertaken a computational study of thioacyl-substituted carbonium ions **1** (Z = H) in order to (*i*) explore the relationship between the carbonyl and thiocarbonyl systems and (*ii*) to examine substituent effects in structures which are related to the thionium ions we have described previously (2).

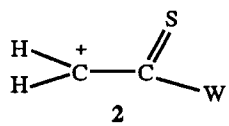
While this study was in progress, Lien and Hopkinson (3) reported computational studies that included thioacyl-substituted carbonium ions **2** (W = H or NH_2).



2

Their results permitted a convenient comparison of our MNDO results with high level *ab initio* calculations (6-31G*) and induced us to focus more on our second objective to avoid redundancy.

An examination of the isodesmic reaction [1] by MNDO furnished a $\Delta\Delta H_r$ of 21 kcal/mol, indicating more facile formation of the thioaldehyde cation.

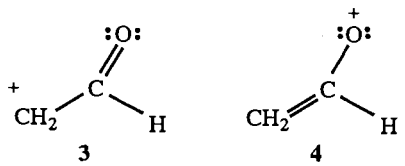
[1] $CH_2CHS^+ + CH_3CHO \longrightarrow CH_2CHO^+ + CH_3CHS$

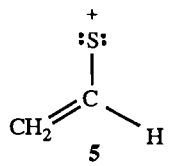
Lien and Hopkinson (3) found a $\Delta\Delta H_f$ of 26 kcal/mol at the 6-31G* level.

Furthermore, the MNDO description of the oxycation **3** shows it to have a modest negative charge on oxygen, suggesting that **4** is not a significant resonance contributor.



3 **4**

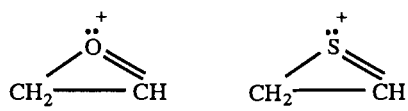
However, the MNDO picture of **2** (W = H) indicates substantial positive charge on sulfur, suggesting that **5** is an important contributor for **2** (W = H).



5

MNDO calculated CC bond lengths and π bond orders are in accord with these conclusions. Given the agreement between our MNDO results and the *ab initio* results on these acyl and thioacyl systems, we concluded that MNDO computations would be useful for a study of thioacyl-substituted carbocations **1**.

Lien and Hopkinson (3) have considered the question of open versus bridged cations, viz: **3** vs. **6** and **2** (W = H) vs. **7**.



6 **7**

They conclude that sulfur bridges more readily than oxygen and that more heavily substituted structures tend to remain open. Examples of both structural types are known (3) for oxygen and sulfur systems. To confirm that planar thioacyl carbocations are local energy minima, we have examined the energy profile of the unsubstituted cation **2** (W = CH_3), for rotation of the thioacetyl group as depicted in reaction [2].

[2] 
Results for the structure that has the geometry restricted to be planar at C^+ demonstrate that the eclipsed planar cation is at a minimum. Lifting the planarity restriction furnished the results presented in Table 1, which support the same conclusion. Consequently, we have examined acyclic thiocarbonyl-substituted carbocations using the MNDO method.

Method

MNDO computations were done on structures **1** using the improved set of *S* parameters (4). For each cation studied, the WXCCSC framework was constrained to be planar and all other geometric parameters were fully optimized. To permit a direct comparison with our earlier studies, calculations on **1** were also done using the original MNDO *S* parameters (5).

1*w*	CF_3	118.8	+12 (+13)
1*x*		106.9	
1*y*	H	245.1	—

[a]Numbers in parentheses are $\Delta\Delta H_f$ values obtained using the original set of *S* parameters (see Methods section).

As can be seen from Table 2, results obtained using the improved parameters are not significantly different from those obtained by using the original set. The same conclusion was reached for our recent study of S-substituted carbon radicals (6).

Results and Discussion

Relative regioisomeric stabilities

Table 2 presents relative gas phase stabilities, $\Delta\Delta H_f$, of regioisomeric pairs of thioacyl-substituted carbocations. $\Delta\Delta H_f$ is a measure of the stabilizing ability of a substituent relative to that of H. As is the case for thionium ions (2) and for

carbocations (7), there is no correlation between $\Delta\Delta H_f$ values and substituent electronegativities.

Examination of Table 3 indicates that stabilization is strongly related to the substituent's π-bonding ability as determined by substituent—C_1 π bond orders and by the differences between regioisomeric C_1—C_2 π bond orders. Thus, NH_2, the most strongly stabilizing substituent, has the largest substituent—C_1 π-bond order and the greatest weakening effect on the C_1—C_2 bond as measured by the difference between C_1—C_2 π-bond orders in the regioisomers. In general, the more strongly stabilizing substituents have relatively large substituent—C_1 π-bond orders while the destabilizing substituents have negligible substituent—C_1 π-bond orders. Also, stabilizing substituents weaken the C_1—C_2 π bond but destabilizing substituents have the opposite effect. There is a good inverse correlation between the stabilizing ability of the substituent and the weakening of the C_1—C_2 π bond. These results are consistent with those obtained for thionium ions (2) and carbocations (7).

Also consistent with thionium ion results is the fact that the π-electron population at S in the sp^2-substituted regioisomer is a much better indicator of the order and relative magnitudes of the $\Delta\Delta H_f$ values than is the π-electron population at C_1 (see Table 4).

Substituent stabilization of thioacyl carbocations

In order to verify our premise that $\Delta\Delta H_f$ is a measure of the stabilizing ability of a substituent, we have computed substituent stabilization effects directly by means of the following reaction.

[3] $XCH_2C(S)CH_3 + {}^+CH_2C(S)CH_3 \rightarrow {}^+CHXC(S)CH_3 + CH_3C(S)CH_3$

TABLE 4. Selected π-electron populations for thioacyl substituted carbocations **1**

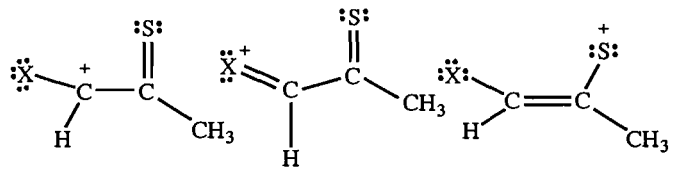
1*x*	CF_3	−0.026	−0.024	+0.070	+0.020

[a]Ionic bond orders p^1 are defined (8, 9) as $P^1_{AB} = -q_Aq_B/R_{AB}$ where q_A = atomic charge on A, q_B = atomic charge on B, and R_{AB} = AB bond length.



8 **9** **10**

As X becomes a better π donor, the relative importance of **10** is diminished leading to reduced charge on sulfur. For very poor π donors, X, contributor **10** becomes important and **9** is deemphasized. Thus the π-electron population at S is a useful measure of the stabilizing ability of X. It has the not inconsiderable advantage that it does not require a quantitative assessment of the significance of $2p$–$3p$ π bonding (e.g., Cl—C_1) versus $2p$–$2p$ π bonding (e.g., NH_2—C_1) in order to gauge substituent effects. Such an assessment would be required, for example, were one to attempt to use C_1—X π-bond orders to anticipate substituent stabilization effects (see Table 3).

Polarization destabilization

In accordance with our earlier carbocation study (7), we find that the destabilizing effects of CHO, CO_2CH_3, and CF_3 are not related to inductive effects. When positioned at C_1, CHO, CO_2CH_3, and CF_3 donate 0.18, 0.08, and 0.07 net electrons, respectively, to the CSC^+ moiety. Neither are their destabilizing effects related to the π-electron population at C_1. Each of the destabilizing substituents leads to π-electron populations at C_1 similar to those for CH_3 and BH_2 (see Table 4).

Our study of S-substituted radicals (6) led to the conclusion that the CF_3 group is a polarization stabilizer when attached to radical carbon but a polarization destabilizer when attached to positively charged carbon. CF_3 was also found to be a polarization destabilizer for carbocations (7).

Table 6 presents ionic bond orders (8, 9*a*), involving C_1 for the destabilizing substituents. A consideration of the differences in total ionic bond order at C_1 for pairs of regioisomers e.g., **1***w*, **1***x* indicates that polarization effects are dominant in the absence of strong π-bonding effects.

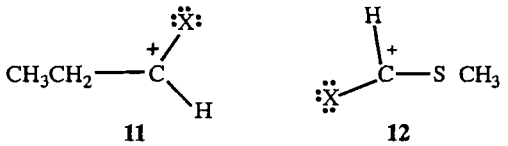
Hyperconjugation in **1**m *and* **1**i

As expected, hyperconjugation is an important stabilizing mechanism for the CH_3 group. The optimized geometry for **1***i* has the BH_2 unit perpendicular to the plane containing the BC_1C_2 unit. This geometry is calculated to be 15 kcal/mol more stable than the geometry having the BH_2 unit coplanar with the BC_1C_2 unit. We conclude that the BH_2 group stabilizes the thioacyl-substituted cations by a hyperconjugative effect. This is in accord with the *ab initio* results on simpler systems (9*b*). Comparison of $\Delta\Delta H_f$'s, π-bond orders, and π-electron populations at S leads to the conclusion that the hyperconjugative effects of BH_2 and CH_3 have the same order of magnitude.

Substituent effects in propyl carbocations (7), thionium ions (2), and thioacyl carbocations

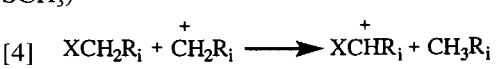
Comparison of $\Delta\Delta H_f$ values and other relevant parameters for common sets of substituents shows that substituent effects are qualitatively similar for all three systems. For example, NH_2 is by far the best stabilizer of the thioacyl carbocations and of the propyl carbocation systems and is also the best π bonder in each system. CF_3 is the most destabilizing substituent in all three systems. The regioisomer in which CF_3 is positioned at the sp^2 carbon has the most negative π-bond order at that carbon. In general, the order of $\Delta\Delta H_f$ values and π-bonding parameters is similar for those substituents which are common to all three of our studies.

We can now present an overview of our MNDO studies on carbocations. For good π bonders there is a decrease in their stabilizing abilities as one goes from propyl carbocations **11** to thioacyl carbocations **8** to thionium ions **12**.



11 **12**

For example, $\Delta\Delta H_f$ for OH increases from −37 kcal/mol to −32 kcal/mol to −20 kcal/mol.[3] In terms of the isodesmic reaction shown in reaction [4] (R_i = C_2H_5 or $C(S)CH_3$ or SCH_3)

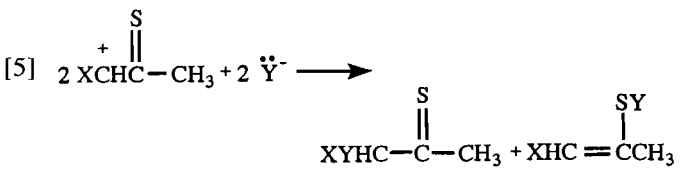


[4]

the stabilizing ability of X decreases as the stabilizing ability of R_i increases. This trend exemplifies the resonance saturation effect (10).

Frontier orbital analysis

The present study has created an opportunity to explore the possibility that some thioacyl carbocations might be expected to develop significant electrophilicity at sulfur. Such cations might serve as precursors in new preparations of vinyl sulfides. Both this novel potential behaviour and the "usual" expected outcome for thioacyl-substituted carbocations reacting with nucleophiles are shown below:



[5]

In order to explore the balance expected for these processes, we have calculated population numbers for the cation LUMO's, which are presented in Table 7. These population numbers indicate the preferred site for nucleophilic attack in accord with frontier orbital arguments (11).

The results in Table 7 permit two generalizations: (*i*) introduction of good electron donors (W or X in **1**), e.g., OH

[3]These numbers were obtained with the original *S* parameters.

[b]Terminal methylene of the vinyl group.
[c]O doubly bonded to C_1.

and NH_2, suppresses electrophilicity at sulfur and (*ii*) strong electron withdrawers (W or X in **1**), e.g., CO_2CH_3 and CF_3, maintain pronounced electrophilicity at sulfur.

Conclusions

1. Thioacyl-substituted carbocations are stabilized by good π donors.

2. Substituent stabilizing ability correlates well with electron population at S. Resonance contributor **10** is especially important for thioacyl systems in which the C^+ bears a poor π donor.

3. Inductive effects do not correlate with the destabilization of carbocationic species in which the C^+ bears -CHO or $-CO_2CH_3$ or CF_3. In these cases polarization effects dominate.

4. Both $-BH_2$ and $-CH_3$ stabilize carbocations through a hyperconjugative effect.

5. There is pronounced electrophilicity at thiocarbonyl sulfur in those cations in which the C^+ bears a strongly electron-withdrawing group.

Electron paramagnetic resonance study of the reactions of the spin trap 2,4,6-tribromonitrosobenzene in benzene solutions

PETER SMITH,[1] KIRK RANDALL MAPLES, AND RAMONA LILLIAN LAU
Paul M. Gross Chemical Laboratory, Department of Chemistry, Duke University, Durham, NC 27706, U.S.A.

Received July 24, 1991

PETER SMITH, KIRK RANDALL MAPLES, and RAMONA LILLIAN LAU. Can. J. Chem. **70**, 116 (1992).

By means of static-sample studies involving the thermal decomposition of symmetric azo compounds and the oxidation of substrates with nickel peroxide, we have characterized by electron paramagnetic resonance 12 spin adducts of 2,4,6-tribromonitrosobenzene, **1**, in benzene at 25°C. In addition, we have used electron paramagnetic resonance spectroscopy to investigate benzene solutions of **1** both by itself and in the presence of olefins, and both in the presence and absence of light. Although **1** by itself did not give evidence for any free radical formation, when **1** was mixed with any one of the 11 olefins tested we could detect nitroxide formation. The presence of light did not affect our results. These observations support the "ene" reaction mechanism of nitroxide formation.

Key words: 2,4,6-tribromonitrosobenzene, spin trapping, nickel peroxide.

PETER SMITH, KIRK RANDALL MAPLES et RAMONA LILLIAN LAU. Can. J. Chem. **70**, 116 (1992).

Faisant appel à des études de résonance paramagnétique électronique (rpe) sur des échantillons statiques impliquant la décomposition thermique des composés azo symétriques et l'oxydation de substrats avec le peroxyde de nickel, on a caractérisé 12 adduits de spin du 2,4,6-tribromonitrobenzène, **1**, dans le benzène, à 25°C. De plus, on a utilisé la rpe pour étudier des solutions benzéniques du composé **1** soit seul ou en présence d'oléfines, tant en présence qu'en absence de lumière. Même si le composé **1** seul ne semble pas donner naissance à la formation de radicaux libres, on a pu détecter la présence de nitroxydes à chaque fois que le composé **1** a été mélangé avec l'une des 11 oléfines étudiées. La présence de lumière ne modifie pas nos résultats. Ces résultats sont en accord avec un mécanisme de réaction «ène» pour la formation du nitroxyde.

Mots clés : 2,4,6-tribromonitrobenzène, piégeage de radicaux, peroxyde de nickel.

[Traduit par la rédaction]

Introduction

The electron paramagnetic resonance, epr, technique of spin trapping has become a useful tool for studying a highly reactive radical, R•, in solution where the steady-state concentration is below the usual epr detection limit (1–6). This technique involves including in the reaction system a low concentration of a diamagnetic substance (the spin trap, ST) that reacts readily with R• to form R(ST)•, the spin adduct,

[1] $R^{\bullet} + ST \rightarrow R(ST)^{\bullet}$

The spin adduct must be an especially persistent (7) radical so that its concentration builds to a readily detectable value.

The most frequently used spin traps have been either nitrones or nitroso compounds, the latter generally providing more informative spin-adduct epr spectra than the former. Also, it is well known (1–5) to be advantageous to employ more than one spin trap to attempt to trap a radical of interest. This conclusion follows from the minimal variation of epr splitting constants for adducts of any one spin trap whereas there is greater variation of these constants for adducts of a particular radical with different spin traps. Thus, the introduction of new spin traps whose characteristics will aid in identifying which radical was indeed trapped provides a broader foundation for this technique. To that end, we have investigated the easily synthesized, inexpensive nitroso compound 2,4,6-tribromonitrosobenzene, $Br_3C_6H_2NO$ (which we denote as *Z*-N=O or **1**), in two reaction systems to discover its utility as a spin trap,

[2] $R^{\bullet} + Z\text{-}N{=}O \rightarrow Z\text{-}N(O^{\bullet})\text{-}R$

Employment of this compound as a spin trap has received relatively little attention in the literature (8–10), yet, based on its structure, **1** seems potentially useful. As **1** proved insufficiently soluble in aqueous solution for our use, we have generated radicals in the presence of **1** in benzene and characterized the resultant spin adducts by epr at 25°C. These studies involved using two radical sources, the oxidation of substrates by nickel peroxide (11, 12), and the thermal decomposition of symmetric aliphatic azo compounds (13–15). Also, we studied the reaction of **1** with several olefins. Our results show **1** forms very persistent (7) spin adducts and displays a quite useful variation of epr splitting constants with respect to the radicals trapped. However, **1**, like many nitroso compounds (16–26), reacts on contact with many olefins both in the light and in the dark to yield persistent radicals that could interfere with the analysis of spin adducts.

Experimental

The epr spectrometer, its accessories, and the general experimental arrangements and procedures were essentially as before (27, 28). However, in contrast to the earlier work (27, 28), we examined all solutions at 25.0 ± 1.0°C as static samples. If nonaqueous, these were contained in thin-walled 4 mm i.d. cylindrical Pyrex tubes, whereas, for aqueous solutions, we employed a Varian V-4548 aqueous-solution sample cell. All spectra were recorded as the first derivative with a field-modulation amplitude of 2.0×10^{-1} G. Unless specified otherwise, all water used was deionized tap water (27).

We synthesized 2,4,6-tribromonitrosobenzene, **1**, from 2,4,6-tribromoaniline (Aldrich, used as received) by a standard procedure (29), recrystallized the crystals so prepared from acetone (Reagent, ACS)/doubly distilled water (27) mixtures, mp 122–124°C (lit. (29*b*) mp 122–123°C), and stored the final product in the dark at room temperature until used. Benzene (Fisher, Certified ACS) was purified using H_2SO_4 (Reagent, ACS) by a standard method (30) and then distilled. Nickel peroxide, NiO_2, prepared by standard techniques (11, 12) from nickel sulfate (Mallinckrodt, ACS), contained $4.4_5 \times 10^{-3}$ g-atoms of available oxygen per gram of NiO_2.

[a]All protons of a given designation are magnetically equivalent.

[b]Unless stated otherwise, present work: at 25.0 ± 1.0°C; ΔH_{pp}, ca. 2.0 G; half-life, ca. 1.0–8.0 h.

[c]Each number in parentheses is the standard deviation of the mean, σ_{n-1}, times 10^2. The maximum error limits of the *a*-values are ca. ± $2\sigma_{n-1}$.

[d]See Experimental.

[e]Δg = (*g*-value − 2.00600) times 10^5. For each *g*-value, σ_{n-1} is ±0.00001 and the maximum error limit, ±0.00006, based on the reported error limits for the standard, potassium peroxylamine disulfonate in an aqueous solution saturated at room temperature with respect to potassium carbonate (27, 28, 31, 32).

[f]Spectrum observed during the photolysis at 25°C of anthraquinone in ethyl benzene in the presence of **1** and with oxygen excluded (8, 9).

[g]At room temperature; solvent, benzene; the method of generation of **30** was similar to that of the present work except that the reaction mixture was first freed of oxygen (10).

The substrates examined were diethylamine (**2**), (±)-α-methylbenzylamine (**3**), phenylacetonitrile (**4**), ethylbenzene (**5**), benzyl acetate (**6**), 2,2′-azobis-(2-methylpropanonitrile) (**7**), 2,2′-azobis-(2-methylbutanonitrile) (**8**), 2,2′-azobis-(2,4-dimethylpentanonitrile) (**9**), 2,2′-azobis-(2-ethylbutanonitrile) (**10**), 4,4′-azobis-(4-cyanopentanoic acid) (**11**), 2,2′-azobis-(2-methylpropane) (**12**), dimethyl 2,2′-azobis-(2-methylpropanoate) (**13**), methacrylic acid (**14**), methyl methacrylate (**15**), ethyl methacrylate (**16**), *n*-butyl methacrylate (**17**), isodecyl methacrylate (**18**), methacrylonitrile (**19**), methacrylamide (**20**), isopropenyl acetate (**21**), allyl chloride (**22**), allyl alcohol (**23**), and allyl benzoate (**24**). All substrates were either samples available in our laboratory (13), synthesized and purified by standard methods (**8–10**, **13**), or were used as received from Alfa (**12**), Aldrich (**3–5**, **11**, **21**), Fisher (**23**), Kodak (**2**, **7**, **19**, **20**, **22**, **24**), Pfaltz and Bauer (**6**), or Rohm and Haas (**14–18**).

NiO_2 redox studies

The reaction conditions were as follows: to a benzene solution 0.10 M in both **1** and the substrate at 25.0°C, we added 1.0 g of NiO_2 and mechanically stirred the mixture; mixtures reacted for ca. 2.0 min before supernatant samples were transferred into epr tubes for analysis. Control mixtures that did not include either **1** or the substrate were also examined in a like manner, these giving no evidence for adduct formation or any other epr radical signals. We examined each of **2–6** in this way.

Azo-compound thermal decomposition studies

The reaction conditions were as follows: we heated at 60°C for 3 min with stirring benzene solutions 0.025 M in both the azo compound and **1**, then cooled these solutions quickly (ca. 2.0 min) to 25.0°C in a constant temperature bath and analyzed samples by epr. Samples that did not contain either **1** or the azo compound were also examined, these not yielding evidence of adduct formation or any other epr radical signals. All azo compounds, **7–13**, received this treatment.

Direct reaction of **1** *with olefins*

The usual reaction conditions were as follows: we stirred benzene solutions 0.050–0.10 M in **1** and 0.050–0.20 M in olefin at 25.0°C, then removed samples for examination by epr at varying time intervals for each olefin/**1** mixture. These experiments were performed in the presence of normal laboratory light and again under photographic dark-room conditions. Finally, the experiments were initiated under photographic dark-room conditions and then the reaction mixtures were exposed to normal laboratory light. We followed this procedure for each of the olefins, **14–24**.

Photolysis studies

While keeping the temperature at 25.0 ± 1.0°C, we exposed 0.10 M solutions of **1** in benzene for 1–3 h to radiation from either normal laboratory lights, a tungsten filament lamp (Westinghouse, 60 W, 110–125 V) 12 cm from the sample, or by a sun lamp (Kenmore, 275 W, 110–125 V) positioned 10 cm from the sample, and then analyzed samples by epr.

Aqueous-system studies

Although **1** was not noticeably soluble in water, we made attempts to employ **1** as a spin trap in stirred aqueous slurries containing **7**. We heated these at 60°C for 3 min with stirring, cooled them quickly (ca. 2.0 min) to 25.0 ± 1.0°C in a constant temperature bath, and analyzed samples by epr. No evidence for **1** spin-adduct formation was obtained from such experiments.

Results

Table 1 summarizes the epr spectroscopic data obtained for all spin adducts of **1** successfully characterized and includes any comparable results in the literature (8–10).

NiO_2 redox studies

The reaction of NiO_2 with **2–6** yielded epr spectra consistent with the presence of only one spin adduct per sub-

strate. We reasonably attributed the spectra obtained to the **1** spin adducts of the radicals that might be produced from NiO_2 oxidation of **2–6** via hydrogen-atom abstraction (11, 12).

Of the **1** spin adducts characterized in our NiO_2-based work, **28** is the only one previously reported in the literature (8, 9). The earlier reported *a*-values, from studies of the photolysis of anthraquinone at 25°C in ethylbenzene in the presence of **1** (8, 9), and our present results are in good agreement.

Azo-compound thermal decomposition studies

The azo compounds decomposed in the presence of **1** to yield the expected radical spin adducts (14). The only corresponding literature report available for **1** spin adducts observed in this section of our studies is for **30** (10) at room temperature in benzene as solvent. The literature value for a_N, 12.28 G (10), is appreciably larger than our result, 12.12 G, and does not fit the trend in a_N with respect to the size of the alkyl groups of the trapped dialkylcyanomethyl radicals shown by our results; i.e., comparison of the epr data for **30–33** suggests that larger alkyl groups induce a larger a_N value for the **1** spin adduct and an a_N value of 12.28 G seems too large for **30**. We are unable to account for this discrepancy.

We obtained no evidence for the formation and trapping of >Ċ—C≡N radicals in the >C=C=N˙ form (33–35). A similar failure to trap 1-cyano radicals in the ketenimine form has been noted before (15, 26) and is perhaps not surprising as spin traps have not been routinely successful at trapping nitrogen-centered radicals (4).

Direct reaction of 1 with olefins

Previous work has shown that **1** reacted directly with unsubstituted long-chain alkenes in benzene at room temperature to produce persistent nitroxide radicals (36). In accordance with this report, we found that **1** reacted directly with all the substituted-ethylene substrates studied, **14–24**, to yield persistent radicals either in the presence or absence of light, their epr spectra consisting of a (1:1:1) triplet of (1:2:1) triplets, the characteristics of which were independent of room lighting conditions. For reactions of **1** with allyl compounds of structure CH_2=C(R′)CH_2R″, e.g., **14–24**, these radicals probably arise from the "ene" reaction sequence

[3] Z—N=O + CH_2=C(R′)—CH_2R″ → Z—N(OH)—CH_2—C(R′)=CHR″

[4] Z—N(OH)—CH_2—C(R′)=CHR″ $\xrightarrow{[O]}$ Z—N(Ȯ)—CH_2—C(R′)=CHR″

These reactions are analogous to those established (16–26) for the reaction of other nitroso spin traps with similar olefins. To detect a radical from a given allyl compound/**1** mixture, time delays varying from 1 to 30 min between mixing and epr examination were required. In addition, raising the concentration of both reactants above those usually employed produced a more intense epr signal in less time. All olefins examined gave evidence for reaction with **1**, and Table 2 lists the epr spectroscopic data for all radicals obtained.

Photolysis studies

We found no epr-detectable spin adducts in **1**/benzene solutions that were photolysed by either normal laboratory lights, a tungsten filament lamp, or a sun lamp.

Discussion

Although it has been stated that the reactivity of arylnitroso spin traps with olefins is probably not important for the hindered aliphatic and aromatic C-nitroso spin traps usually employed (3), our results show that **1** reacted with many alkenes to produce persistent radicals that could easily interfere with the detection and characterization of concurrently generated spin adducts. This radical formation, coupled with the relative insolubility of **1** in aqueous systems, tends to limit the usefulness of **1** as a spin trap.

However, for studies in nonaqueous solutions, **1**, like other arylnitroso spin traps (1–5, 12, 26), shows nice variation

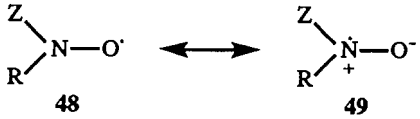
in splitting constants with respect to the radical trapped. For instance, the results given in Table 1 show that the a_N values for the spin adducts from radicals of structure R′(R″)ĊCN, e.g., **27** and **30**, were consistently smaller than those for the analogous R′(R″)ĊCH$_3$ spin-adduct radicals, **28** and **35**, respectively. In addition, the a_N values for the spin adducts of R′(R″)ĊCN radicals where R′ and R″ are relatively small alkyl groups, **30–33**, showed noticeable increases upon extension of the alkyl chains, indicating that the epr spectroscopic data for **1** spin adducts appeared to be quite sensitive to the structure of the radical trapped. These phenomena are a reflection of how readily the nitroxide function responds to the substituents on the nitrogen (38), as illustrated by resonance structures



48 **49**

where structure **48** is favored when the R group is electron withdrawing, either −M or −I (39) and will have a lower a_N value than structure **49**, which is favored when the R group is electron donating, +M or +I. Thus, the differences between the a_N values in the spin adducts **27** and **30** and those in **28** and **35**, respectively, arise because the −CN group is electron withdrawing whereas the −CH$_3$ group is electron donating; and the a_N values for the spin adducts **30–33** vary as a consequence of the expected increase in the electron-donating power of the alkyl chains with increase in extension. In addition to the observed dependence of a_N values of Z-N(O·)-R radicals on the electrical properties of the R group, simple steric considerations predict that the $a_{\beta\text{-H}}$(CH) values tend to decrease as the bulkiness of the R group increases (40). All the $a_{\beta\text{-H}}$(CH) data in Table 1, i.e., for the addition radicals **25–29**, appear to follow this trend.

The radicals in Table 2 consist of two types, namely, **37–44**, for which -R′ varies with -R″ remaining the same, and **45–47**, for which the reverse holds. In the case of **37–44**, a_N is approximately constant except for **37** and **43**, in which the a_N values are noticeably larger than for the others. This fits in with the fact that, in all these radicals, -R′ is attached to the γ-C and so might not be expected to strongly affect a_N, in general. This follows because, although the -R′ groups are fairly strongly electron withdrawing (39, 41, 42), their electrical effects on the nitroxide group would be attenuated by the intervening β-CH$_2$ group. The two exceptions to this conclusion, **37** and **43**, have the only -R′ groups that might interact via intramolecular hydrogen bonding with the nitroxide group, thereby causing both a_N and $a_{\beta\text{-H}}$(CH) to increase (43). Inspection of the data shows that the $a_{\beta\text{-H}}$(CH) values for **37** and **43** are indeed relatively large. Simple steric considerations appear to be sufficient to account for the variation in the other $a_{\beta\text{-H}}$(CH) values, e.g., the fact that the $a_{\beta\text{-H}}$(CH) values for **42** and **44** are larger than those of **37** and **43**, and the variation of the $a_{\beta\text{-H}}$(CH) values in the series **37–41**. We would expect the results for **45–47** to be simply relatable to those for **37–44** as in each radical -R″ is attached to the δ-C and so should not have much influence on a_N. Accordingly, as -R′ in **45–47** is −H, which is much less electron withdrawing and bulky than the -R′ groups in **37–41**, it is not surprising that, in general, the a_N and $a_{\beta\text{-H}}$(CH) values in **45–47** are noticeably larger than those in **37–44**. It should be noted that **46** is not of the same structural type as the other radicals in Table 2, this doubtless being the reason its a values are somewhat out of line with those of **45** and **47**.

Chatgilialoglu and Ingold (44) have cautioned that reactions between nitroso compounds and olefins could appear to be spontaneous, when in fact they are photolytic in nature. In their reaction sequence, the aromatic nitroso spin trap, ArNO, is photolysed to yield aryl radicals, which then attack the solvent, benzene, to yield addition radicals, which finally react with the spin trap to give the detected spin adduct

[5] ArNO + visible light → Ar· + NO

[6] 
[7] 
This spin-adduct epr spectrum would be characterized as a (1:1:1) triplet of (1:1) doublets. Our ability to detect nitroxide formation from mixtures of **1** with alkenes under darkroom conditions suggests that the reactions involved in this study are not photolytic, but are due to the "ene" addition reaction. This point is buttressed by our finding no spin adducts in **1**/benzene solutions that were directly photolysed. In addition, our **1** spin adducts generated using the alkenes all exhibited epr spectra characterized as a (1:1:1) triplet of (1:2:1) triplets, which is a different spin adduct epr pattern than that predicted via the photolytic reaction sequence.

In summary, **1** appears not to be light sensitive, can be synthesized easily and inexpensively, and demonstrates a quite useful variation in the spin-adduct splitting constants with respect to the radical trapped. However, in any reaction system that includes alkenes, **1** may react via the "ene" addition reaction to yield nitroxides that could interfere with the interpretation of the resultant epr spectra. Thus, **1** would seem to be an acceptable spin trap for selected systems.

Received May 22, 1991

PAUL H. MILNE, DANIAL D. M. WAYNER, DAYAL P. DECOSTA, and JAMES A. PINCOCK. Can. J. Chem. **70**, 121 (1992).

The electrochemical oxidation and reduction potentials of a number of substituted 1-methylnaphthalenes (**1***a-l*) and 1-naphthylmethyl radicals (**2***a-l*˙) as well as 2-methylnaphthalene (**3**) and the 2-naphthylmethyl radical (**4**˙) have been measured by cyclic voltammetry and photomodulation voltammetry. The oxidation potentials correlate with σ^+ ($\rho^+ = -7.1$ and -8.4 for **1** and **2**˙ respectively) while the reduction potentials correlate with σ^- ($\rho^- = 10.1$ and 13.0 for **1** and **2**˙ respectively). The relative magnitude of the ρ values can be rationalized when the charge density distribution in these systems is considered. This leads to the interesting conclusion that even though a full charge is placed in the π-system of **1** when it is oxidized or reduced, the fraction of the charge that accumulates at C_4 is actually less than in $\mathbf{2}^+$ or $\mathbf{2}^-$ where only 50–70% of the charge is delocalized into the ring. A correlation between ρ for the redox reactions of **1**, **2**˙, benzyl, diphenylmethyl, and cumyl and the calculated (AM1) charge density at C_4 is established, implying that the sensitivity of the corresponding ions to substituent effects increases as the fraction of charge at that site increases. The redox data have been used in thermochemical cycles in order to estimate the substituent effect on the homolytic, mesolytic, and heterolytic cleavage reactions of **1** and its corresponding radical ions. The implication of these results on the C—C cleavage versus deprotonation of radical cations and on the photochemical homolysis versus heterolysis of naphthylmethyl halides and acetates is discussed.

Key words: electrochemistry, homolysis, heterolysis, naphthylmethyl, substituent effect.

PAUL H. MILNE, DANIAL D. M. WAYNER, DAYAL P. DECOSTA et JAMES A. PINCOCK. Can. J. Chem. **70**, 121 (1992).

Faisant appel à la voltampérométrie cyclique et à la voltampérométrie de photomodulation, on a mesuré les potentiels d'oxydation et de réduction électrochimique d'un certain nombre de 1-méthylnaphtalènes substitués (**1***a-l*) et de radicaux 1-naphtylméthyles (**2***a-l*˙) ainsi que du 2-méthylnaphtalène (**3**) et du radical 2-naphtylméthyle (**4**˙). On peut établir une corrélation entre les potentiels d'oxydation et les α^+ ($\rho^+ = -7{,}1$ et $-8{,}4$ respectivement pour **1** et **2**˙). On peut rationaliser l'amplitude relative des valeurs de ρ en considérant la distribution de la densité de charge dans ces systèmes. Ceci conduit à la conclusion intéressante que, même si une charge complète est placée dans le système π du composé **1** (qu'il soit oxydé ou réduit), la fraction de la charge qui s'accumule en C_4 est en fait moindre que dans les entités $\mathbf{2}^+$ et **2**˙ dans lesquelles seulement 50–70% de la charge est délocalisée dans le cycle. On a établi une corrélation entre les valeurs de ρ des réactions rédox des entités **1**, **2**˙, benzyle, diphénylméthyle et cumyle et la densité de charge calculée (AM1) pour la position C_4; elle implique que la sensibilité des ions corespondants aux effets des substituants croit avec une augmentation de la fraction de la charge dans cette position. Les données rédox ont été utilisées dans des cycles thermodynamiques dans le but d'évaluer l'effet de substituant sur les réactions de clivage homolytique, mésolytique et hétérolytique du composé **1** et des ions radicaux correspondants. On discute de l'implication de ces résultats sur le clivage des liaisons C—C versus la déprotonation des cations radicaux et sur l'homolyse photochimique versus l'hétérolyse des halogénures et des acétates de naphtylméthyle.

Mots clés : électrochimie, homolyse, hétérolyse, naphtylméthyle, effet de substituant.

Introduction

There has been continually growing interest in the use of electrochemical data in thermochemical cycles since Breslow and co-workers used this method to estimate the pK_a of a number of weak carbon acids (1–5). Recently, Arnold and co-workers (6–8) and Bordwell *et al.* (9–12) used this approach for the determination of pK_a's of radical cations and (or) the energies for the homolytic cleavage of C—H bonds. More recently, Arnett *et al.* (13–15) combined calorimetric and electrochemical measurements to obtain data for the heterolytic C—C cleavage reactions.

In essentially all of these cases the electrochemical measurements were made in solutions of very long-lived molecules or ions. We have shown that reliable electrochemical measurements can actually be made in solutions of transient radicals using the photomodulation voltammetry technique (16). We also have recently pointed out that all of the thermochemical cycles describing the homolytic and heterolytic cleavage reactions of molecules and their radical ions can be conveniently represented in a thermochemical mnemonic (Scheme 1, eqs. [1]–[7]) (17). In this mnemonic the vertical arrows represent the loss of R′ as a radical (i.e., the homolytic bond dissociation energy). The horizontal arrows represent the addition or removal of an electron while the diagonal arrows represent the loss of R'^+ (up to the right) or R'^- (up to the left). For the case where R′ = H, the reactions along the diagonals are representations of more familiar thermodynamic parameters; reactions [9] and [11] are

deprotonation reactions (pK_a's) while reactions [10] and [12] are hydride affinities. The latter two reactions are of particular importance to the chemistry of NADH/NAD^+ and its analogs (18–20).

[1] $R - R' \rightarrow R^{\bullet} + R'^{\bullet}$

[2] $R^{\bullet} \rightarrow R^+$

[3] $R^- \rightarrow R^{\bullet}$

[4] $R - R' \rightarrow R - R'^{+\bullet}$

[5] $R - R'^{-\bullet} \rightarrow R - R'$

[6] $R'^{\bullet} \rightarrow R'^+$

[7] $R'^- \rightarrow R'^{\bullet}$

The thermochemistry for all of the possible homolytic and heterolytic cleavage reactions can then be written simply as the sum of the homolytic bond dissociation energy (eq. [1]) with the difference between two potentials (eqs. [2]–[7]). It is important to keep in mind that an entropy correction must be applied to the bond dissociation enthalpies that are usually reported in the literature since the redox potentials are actually *free energy* differences. For R' = H, this correction is ca. −8 kcal mol^{-1} (16). These free energy relationships are given in eqs. [8]–[13].

[13] $R - R'^{-\bullet} \rightarrow R^- + R'^{\bullet}$

$$\Delta G^0_{13} = \Delta G^0_1 + F(E^0_5 - E^0_3)$$

We have now applied this thermochemical approach to the naphthylmethyl system. This system has an advantage over the benzyl system that has been reported (21), as the relative ease of oxidation and reduction makes the electrochemical characterization of the parent methylnaphthalenes more straightforward than it is for the toluenes. Recent results on the photochemical bond cleavage reactions of 1-naphthylmethyl derivatives (N-CH_2-X where N is a substituted naphthalene ring) (22–24) have indicated the importance of the 1-naphthylmethyl radical as an intermediate. Moreover, the rate of oxidation of this radical to the corresponding 1-naphthylmethyl cation seems to be critical in controlling the final product composition of these photoreactions (22). To understand these results in a quantitative sense, values for the oxidation potentials of the 1-naphthylmethyl radicals are needed. In this paper we report redox potential measurements for 12 substituted 1-methylnaphthalenes (**1***a-l*) and the corresponding 1-naphthylmethyl radicals (**2***a-l*') as well as similar values for 2-methylnaphthalene (**3**) and the 2-naphthylmethyl radical (**4**'). The implication of these results on the thermodynamic parameters in Scheme 1 and on the photochemistry of the 1-naphthylmethyl derivatives will be discussed.

Results and discussion

Substituent effects on redox properties

The oxidation and reduction potentials of the substituted **1** (measured by cyclic voltammetry) and the **2**• (measured by photomodulation voltammetry) are given in Table 1. Not surprisingly the series follow the trends expected; electron-donating groups make the oxidation of either **1** or **2**• easier and electron-withdrawing groups make the reduction of either easier. This can be put on a more quantitative basis by using Hammett correlations. Only data for the 4-substituted derivatives of **1** and the 3- and 4-substituted derivatives of **2** were included in this analysis to avoid the complication of adding σ values for the disubstituted cases. The usual benzene ring σ^+ and σ^- values were used since only a limited number of these parameters are available for naphthalene rings (25). The Hammett plots for oxidation of **1** ($\rho^+ = -8.4 \pm 0.9$) and **2**• ($\rho^+ = -7.1 \pm 0.7$) are shown in Fig. 1 and for the reduction of **1** ($\rho^- = 13.0 \pm 1.2$) and **2**• ($\rho^- = 10.1 \pm 0.9$) in Figure 2. Good fits ($r > 0.95$) were obtained in

[a]Measured by cyclic voltammetry at a glassy carbon electrode in acetonitrile with 0.1 M TBAP as supporting electrolyte at a scan rate of 200 mV/s. All potentials are irreversible and potentials are reported as E_p − 30 mV.

[b]Measured by photomodulation voltammetry at a gold minigrid in acetonitrile/di-*tert*-butyl peroxide (9:1 v/v) with 0.1 M TBAP as supporting electrolyte.

[c]Measured by cyclic voltammetry at a glassy carbon electrode in acetonitrile with 0.1 M TBAP as supporting electrolyte at a scan rate of 200 mV/s. All potentials are reversible and potentials are reported as the mid-point between the cathodic and anodic peak.

[d]The reduction wave was not observed due to high background.

[e]Quasireversible wave.

[f]Reversible wave.

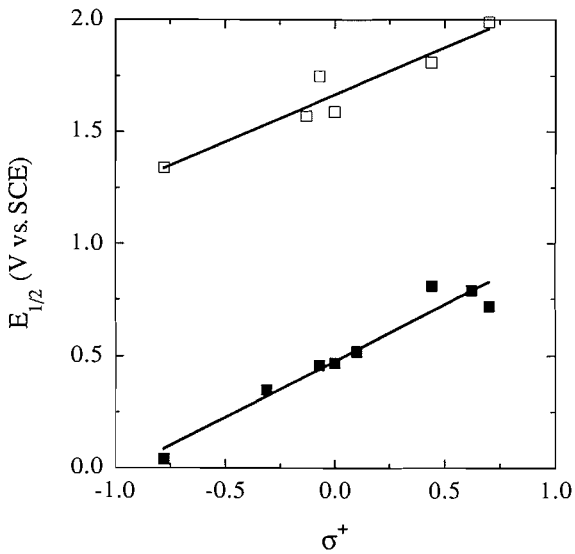

FIG. 1. Hammett plot for the oxidation of **1** (□, $\rho^+ = -7.1$, $r = 0.95$) and **2**$^{\bullet}$ (■, $\rho^+ = -8.4$, $r = 0.97$).

all cases. While most of these redox reactions are irreversible (Table 1), Bordwell *et al.* (9–12) have shown that for a series of structurally related species, the changes in redox properties closely approximate thermodynamic changes; i.e., ΔE_p from cyclic voltammetry $\approx \Delta E^0$, the thermodynamically significant potential. The oxidation and reduction potentials of the radicals (measured by photomodulation voltammetry) also have been shown to be close to E^0 (16, 17, 21).

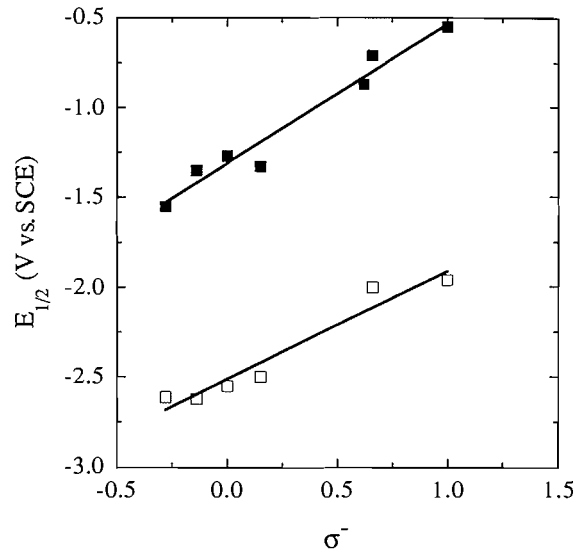

FIG. 2. Hammett plot for the reduction of **1** (□, $\rho^- = 10.1$, $r = 0.97$) and **2**$^{\bullet}$ (■, $\rho^- = 13.0$, $r = 0.98$).

It is interesting to note that for both the oxidations and the reductions, the Hammett ρ value was larger for the redox reaction of the radical than it was for the methylnaphthalene derivative (although the uncertainties in the ρ^+ are large enough that the difference between these values may not be significant). Intuitively one might expect this order to be reversed since a full charge is delocalized in the naphthalene ring in the radical ions ($\mathbf{1}^{+\bullet}$ and $\mathbf{1}^{-\bullet}$) whereas only a fraction (ca. 0.5) of the charge is expected to be delocalized into the ring for the naphthylmethyl ions ($\mathbf{2}^+$ and $\mathbf{2}^-$). It seemed reasonable to expect the sensitivity to substituent effects to be related to the extent of charge delocalization into the ring system.

To investigate this possibility, the charge distributions in these ions were calculated using the AM1 molecular orbital theory (26). The $2p_z$ charge densities for the parent ions $\mathbf{1}e^{+\bullet}$, $\mathbf{1}e^{-\bullet}$, $\mathbf{2}e^+$, and $\mathbf{2}e^{-\bullet}$ as well as the related benzyl ions are shown in Fig. 3 (the total atomic charges give an essentially identical distribution when the charge on the neighboring hydrogens is included). These data show some interesting parallels with the experimental results. Firstly, the charge distribution in the benzyl and the 1-naphthylmethyl systems is similar. This fits with the observation that the Hammett ρ values for the redox potentials of these systems also are the same within the experimental error (27). Secondly, the difference between the 1-naphthylmethyl and the 1-methylnaphthalene systems becomes clear. Because of the odd alternate nature of the arylmethyl ions ($\mathbf{2}^+$ or $\mathbf{2}^-$), more of the charge density accumulates at C_4 and C_2 while very little accumulates at C_3 or in the fused benzo ring. For the even alternate radical ions ($\mathbf{1}^{+\bullet}$ or $\mathbf{1}^{-\bullet}$) the charge is distributed more evenly since there are no nodes in the SOMO.

This result leads to the interesting conclusion that even though essentially a full charge is placed in the π-system of the naphthalene ring in the radical ions, the amount of that charge that ends up near the substituent is actually less than in those systems where only 50–70% of the charge in delocalized. This effect of charge distribution is clearly

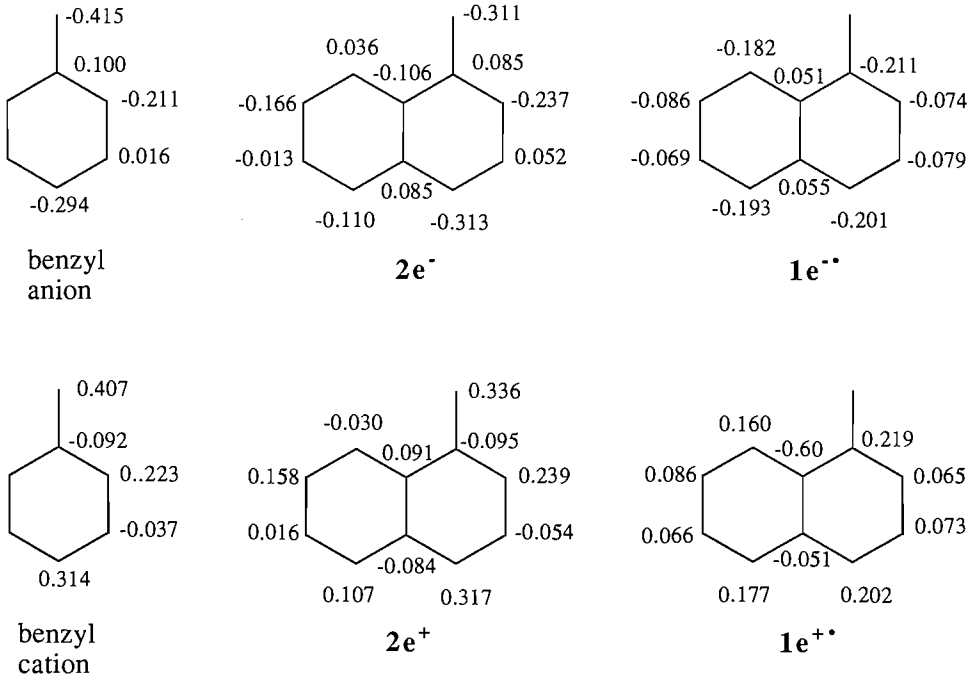

FIG. 3. Calculated (AM1) $2p_z$ charge densities for the cations and anions generated by the one-electron oxidation or reduction of the benzyl radical, **2**$^{\bullet}$ and **1***e*.

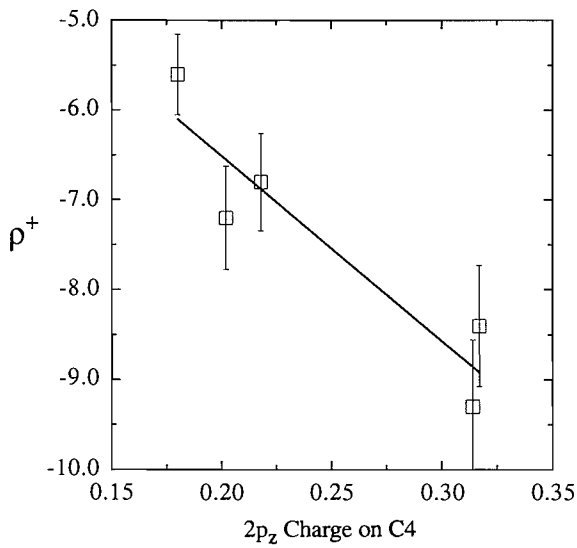

FIG. 4. Plot of ρ^+ for the oxidation of **1**, **2**$^{\bullet}$, benzyl, diphenylmethyl, and cumyl versus the calculated (AM1) $2p_z$ charge density at C_4 in the parent ion.

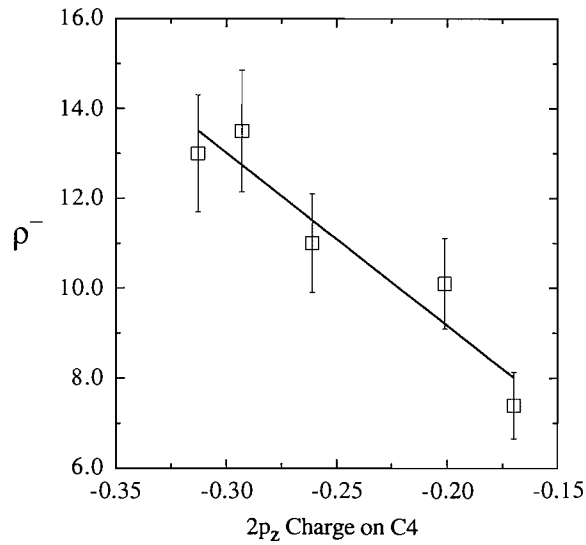

FIG. 5. Plot of ρ^- for the reduction of **1**, **2**$^{\bullet}$, benzyl, diphenylmethyl, and cumyl versus the calculated (AM1) $2p_z$ charge density at C_4 in the parent ion.

seen when the Hammett ρ values for the oxidation and reduction of substituted benzyl, diphenylmethyl, and cumyl (27) radicals along with those for **1** and **2**$^{\bullet}$ are plotted versus the calculated (AM1) $2p_z$ charge density at C_4 (Figs. 4, 5). Although there is some scatter in the plot (which contains electrochemical data for about 40 radicals), the trend is clear.

These observations are important inasmuch as they reinforce the idea that substituent effects in ionic species should not be additive. This issue has been addressed in detail by Dubois and co-workers (28, 29) and is supported by work on substituent effects on the redox properties of α,*p*-disubstituted benzyl radicals (30). In the latter work it was concluded that the effect of two "destabilizing" substituents on an ion is additive while the effect of two "stabilizing" substituents should be less than additive. The lack of additivity is usually rationalized as a saturation effect. However, it is equally well understood in terms of the effect that one substituent will have on the charge density at the site of the second. It is interesting to note that, in this case, the effect of two methoxy substituents on the redox potentials of **1** is essentially additive while the effect on **2** is less than addi-

tive. The configuration of the SOMO in the even alternate and odd alternate ions is consistent with this effect (Fig. 3).

Substituent effects on derived thermochemical parameters

The substituent effects on the C—H cleavage reactions of 1-methylnaphthalene and its radical ions (eqs. [8]–[13]) are given in Table 2. We have assumed that the bond energy for 1-methylnaphthalene derivatives is not dependent on ring substitution (ΔH^0_1 = 85 kcal mol^{-1}; ΔG^0_1 = 77 kcal mol^{-1} (31)). This assumption seems reasonable since there appears to be little effect of substitution on the C—H bond energy in toluenes (32, 33). The values of ΔG^0_6 and ΔG^0_7 have been estimated as −1.87 V and −0.36 V vs. SCE, respectively (17).

The substituent effect on ΔG^0_9 to ΔG^0_{12} depends only on the redox properties of one of the substituted species. For example, changes in ΔG^0_9 are determined only by changes in ΔG^0_4. Similarly ΔG^0_{10} is determined by ΔG^0_2, ΔG^0_{11} by ΔG^0_3, and ΔG^0_{12} by ΔG^0_5. On the other hand, ΔG^0_8 is determined by the difference between the oxidation potential of the naphthylmethyl radical (ΔG^0_2) and the oxidation potential of the methylnaphthalene (ΔG^0_4). In this case, since the Hammett slopes for these two processes are similar, the substituent effects partially cancel so the net effect is quite small. Although this cleavage reaction is not considered to be an important pathway for the substituted naphthalenes (**1**), the result has some important implications.

Arnold and co-workers (7, 8) and Maslak *et al.* (34, 35) have studied the C—C cleavage reactions of radical cations in solution. Maslak has suggested that the term "mesolytic" cleavage (34) be used to distinguish these reactions, which involve the cleavage of a formal one-electron bond, from those reactions that are truly homolytic or heterolytic. For reactions of symmetrical 1,2-diarylethanes the loss of proton (R′ = H, ΔG^0_9; eq. [14]) is expected to have a strong substituent effect while the competing pathway, C—C cleavage (R′ = R, ΔG^0_8; eq. [15]), will have a significantly smaller effect. Although Arnold *et al.* (36) and Tolbert *et al.* (37) have pointed out that kinetics of these competing pathways is strongly influenced by stereoelectronic factors, the relative thermochemistry for these pathways will have a significant impact on the interpretation of these data. Proton loss is usually more exoergonic than C—C cleavage. However, it may be possible to design a reaction, by using the appropriate substitution, in which the thermochemistry of these two pathways is reversed.

[14] $ArCH_2\text{-}CH_2Ar^{+\bullet} \rightarrow ArCHCH_2Ar + H^+$

[15] $ArCH_2\text{-}CH_2Ar^{+\bullet} \rightarrow ArCH_2^{\bullet} + ArCH_2^+$

Photoinduced homolytic and heterolytic cleavage reactions

The photocleavage of benzylic substrates with leaving groups (Ar-LG) is well known to give products that arise from both arylmethyl cations and radicals (38). However, the pathway for the formation of these critical intermediates is not well understood so that reliable predictions about product yields are still impossible. Early mechanisms proposed that the relative yield of cation and radical was controlled by the initial cleavage of the excited state and that the substituents on the aromatic ring could alter the ratio; i.e., the meta effect (39, 40). More recently, it has become obvious that electron transfer, converting the initially formed radical pair ($Ar^{\bullet}/LG^{\bullet}$) to an ion pair ($Ar^+/LG^-$), will be an important factor in determining these yields. Obviously, the data in Table 1 for the oxidation potentials of the substituted naphthylmethyl radicals as well as previous data for the substituted benzyl, cumyl, and diphenylmethyl radicals (16) are critical for understanding this electron transfer process. To this end, we have determined the free energy change (in acetonitrile) for the conversion of the radical pair $NpCH_2^{\bullet}/LG^{\bullet}$) to the ion pair ($NpCH_2^+/LG^-$) for LG = Cl (**5**), Br (**6**), I (**7**), and MeC(O)O (**8**) (Table 3).

[c]Free energy change for the conversion of a radical pair into an ion pair: $NpCH_2^{\bullet} + LG^{\bullet} \rightarrow NpCH_2^+ + LG^-$. $(\Delta G^0_{ET})_{MeCN} = (\Delta G^0_{10})_{MeCN} - (\Delta G^0_1)_g$

The redox data for $Cl^{\bullet}$ $Br^{\bullet}$, $I^{\bullet}$, and $MeC(O)O^{\bullet}$ in acetonitrile are easily derived from thermodynamic data in the literature (41). For acetate, a thermochemical cycle was used (based on eq. [11]) assuming a bond dissociation enthalpy (O—H) of 105 kcal mol^{-1} (30) and literature values for the free energy change associated with the transfer of the relevant ions from water into acetonitrile (42). The values in Table 3 are only for the unsubstituted naphthalene ring. Changes in these values for the substituted cases will parallel the oxidation potential of the 1-naphthylmethyl radicals (Scheme 1) so they have been omitted. Note also, that now LG refers to R′ in Scheme 1.

It is interesting to point out that (except for H, which is not photochemically labile) the ion pair is always more stable than the radical pair in solution. This is in contrast to the relative stability in the gas phase where the ions are not solvated (Table 3), clearly demonstrating that solvation of the product ions is the driving force for all of these reactions. The reasonable assumption that $(\Delta G^0_1)_g = (\Delta G^0_1)_{MeCN}$ is being used. The exoergonicity of these reactions spans a very wide range, from −9 kcal mol^{-1} for the reaction of 4-carboethoxy-1-naphthylmethyl iodide to −50 kcal mol^{-1} for 4-methoxy-1-naphthylmethyl chloride. Because of this fact, it is perhaps intitially surprising that products derived from the radical pair are ever observed. However, the Marcus theory of electron transfer (43) gives an explanation, since an activation barrier is provided by the reorganization energy that is necessary to convert the radical pair to an ion pair. These ideas have been confirmed (22) by results for the photolysis of 1-naphthylmethyl esters ($NpCH_2$-O_2CR). The product analysis leads to the conclusion that the excited state cleaves exclusively to the radical pair ($NpCH_2^{\bullet}/{}^{\bullet}O_2CR$) and the radical pair partitions between electron transfer (to form the ion pair) and decarboxylation of the acyloxy radical. The rates of the electron transfer process were shown to be rationalized by the Marcus equation even into the inverted region. A reorganization energy of ca. 9 kcal mol^{-1} was estimated. Obviously application of these ideas to other cleavage reactions must be considered.

Conclusions

The sensitivity of oxidation and reduction potentials of arylmethyl radicals to ring substitution is related not only to the extent of delocalization of the charge in the corresponding ions, but also to the charge distribution. Thus ρ^+ and ρ^- for the oxidation and reduction of 1-naphthylmethyl radicals are greater than those for the oxidation and reduction of the 1-methylnaphthalenes since the odd alternate nature of the former allows a greater fraction of the charge in the ions to accumulate at C_2 and C_4 even though only 50–70% of the charge is in the aryl ring (as calculated by AM1 molecular orbital theory).The SOMO of even alternate 1-methylnaphthalene radical ions leads to a more even distribution of the charge density at all of the sites. A correlation between the experimental ρ value and the fraction of charge in the $2p_z$ orbital at C_4 has been established.

The redox data lead to estimates of differences in bond energies for homolysis versus heterolysis of 1-naphthylmethyl halides and acetates. In all cases the heterolysis is the energetically favourable process. The electrochemical data complement observed photochemistry of these compounds in which electron transfer of an initially formed radical pair (to generate an ion pair) is found to compete with the intersystem crossing process.

Experimental

Methylnaphthalenes

1-Methyl, 2-methyl, and 1,4-dimethylnaphthalene were purchased from the Aldrich Chemical Company and purified by bulb-to-bulb distillation before use. 3-Cyano and 4-cyanomethyl naphthalene were prepared previously in our laboratory (23). All others were prepared as described below.

3-Methoxy-1-methylnaphthalene: prepared by the method of Bartoli and co-workers (44) and recrystallized from ethanol to give colourless crystals: mp 47–48°C (lit. (44) mp 48–49°C).

4.8-Dimethoxy-1-methylnaphthalene: prepared by the method of Buu-Hoi and Lavit (45). Recrystallization from ethanol gave colourless plates: mp 104–105°C (lit. (45) mp 105°C); ^1H nmr ($CDCl_3$) δ: 8.0 (d, 1H, J = 8.5 Hz), 7.4 (t, 1H, J = 7.8 Hz), 7.15 (d, 1H, J = 8.2 Hz), 6.8 (d, 1H, J = 8.0 Hz), 6.6 (d, 1H, J = 8.0 Hz), 3.9 (s, 3H), 3.8 (s, 3H), 2.8 (s, 3H).

4.7-Dimethoxy-1-methylnaphthalene: prepared by the method of Buu-Hoi and Lavit (46). Recrystallization from ethanol gave colourless plates: mp 54–55°C (lit. (46) mp 54°C); ^1H nmr ($CDCl_3$) δ: 8.2 (d, 1H, J = 8.5 Hz), 7.2–7.0 (m, 3H), 6.7 (d, 1H, J = 8.0 Hz), 3.95 (s, 3H), 3.9 (s, 3H), 3.9 (s, 3H), 2.7 (s, 3H).

4.5-Dimethoxy-1-methylnaphthalene: prepared by the method of Buu-Hoi and Lavit (47). Recrystallization from ethanol gave colourless plates: mp 64–65°C (lit (47) mp 65°C); ^1H nmr ($CDCl_3$) δ: 7.44–7.2 (m, 2H), 7.1 (d, 1H, J = 8.0 Hz), 6.8 (d, 1H, J = 8.0 Hz), 6.7 (d, 1H, J = 8.0 Hz), 3.9 (s, 3H), 3.85 (s, 3H), 2.6 (s, 3H).

4-fluoro-1-methylnaphthalene: prepared by the method of Sauer *et al.* (48): bp 64–66°C at 1 Torr (133.3 Pa) (lit. (48) bp 107.5–109.5°C at 12 Torr).

2-Methoxy-1-methylnaphthalene: prepared by the method of Buu-Hoi and Lavit (49). Recrystallization from ethanol gave colourless plates: mp 41–42°C (lit. (50) mp 39°C); ^1H nmr ($CDCl_3$)

δ: 8.1–7.5 (m, 3H), 7.4–7.2 (m, 2H), 7.1 (d, 1H, J = 8.0 Hz), 3.9 (s, 3H), 2.6 (s, 3H).

4-Carbomethoxy-1-methylnaphthalene: prepared by esterification of the acid with methanol: bp 80–82°C at 0.05 Torr. Crystallization from hexane gave colourless plates: mp 30–31°C (lit. (51) bp 192–194°C at 12 Torr); ^{1}H nmr ($CDCl_3$); δ: 9.1–8.9 (m, 1H), 8.0 (d, 1H, J = 8.0 Hz), 7.9–7.8 (m, 1H), 7.60 (t, 1H, J = 8.0 Hz), 7.50 (t, 1H, J = 8.0 Hz), 7.22 (d, 1H, J = 8.0 Hz), 3.91 (s, 3H), 2.60 (s, 3H).

The acid, 4-methylnaphthoic acid, was prepared by hydrolysis of 4-cyano-1-methylnaphthalene (23) with sodium hydroxide in ethanol/water. Recrystallization of the crude acid from ethanol–water gave colourless needles: mp 178–179°C (lit. (52) mp 180°C).

Electrochemical measurements

Solvents and electrolyte were purified as described previously (16). Radicals for photomodulation voltammetric measurements were generated by photolysis of a solution of acetonitrile/di-*tert*-butyl peroxide (9:1 v/v; 0.1 M tetrabutylammonium perchlorate as the supporting electrolyte) in the presence of the appropriate methylnaphthalene using a 1000-W Hg/Xe arc lamp (Oriel Corp). The output of the lamp was modulated as a sine wave with a mechanical light chopper that operated at frequencies between 20 and 250 Hz. The reference signal for the lock-in amplifier (PAR model 124A) was taken from the output of the light chopper. In electrochemical experiments the ac component of the electrolysis current was demodulated with the lock-in amplifier (Ithaco model 391A) interfaced to a microcomputer. The electrochemical cell was constructed from Teflon® and had a volume of 0.5 mL. The electrode, a gold minigrid (1000 wires/in.; Buckbee–Mears) was placed in the cell so that the exposed surface area was a circle with a radius of 2.5 mm. Currents in the range of 0–500 nA were measured with a PAR model 174A polarograph.

Cyclic voltammetric measurements were performed in acetonitrile/0.1 M tetrabutylammonium perchlorate at a glassy carbon electrode using an EG&G model 173 potentiostat and an EG&G model 175 universal cell programmer. All potentials are reported with respect to the saturated calomel electrode (SCE).

Synthetic applications of glycidic thiolesters. Regioselective reduction to 1,3-diols and 2,3-epoxy alcohols

HSING-JANG LIU[1] AND WEIDE LUO

Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received July 10, 1991

HSING-JANG LIU and WEIDE LUO. Can. J. Chem. **70**, 128 (1992).

Glycidic thiolesters were shown to undergo regioselective reduction with Raney nickel to give 1,3-diols. With sodium borohydride at room temperature and lithium aluminum hydride at −78°C, the reduction of glycidic thiolesters was found to proceed chemoselectively to furnish 2,3-epoxy alcohols.

Key words: glycidic thiolesters, reduction, 1,3-diols, 2,3-epoxy alcohols.

HSING-JANG LIU et WEIDE LUO. Can. J. Chem. **70**, 128 (1992).

On montre que, en présence de nickel de Raney, les thiolesters glycidiques subissent une réduction régiosélective conduisant aux 1,3-diols. Avec le borohydrure de sodium à la température ambiante et avec l'hydrure double de lithium et d'aluminium à −78°C, la réduction de ces esters se produit d'une façon chimiosélective pour fournir des 2,3-époxy alcools.

Mots clés : thiolesters glycidiques, réduction, 1,3-diols, 2,3-époxy alcools.

Introduction

It is well known that simple thiolesters are reduced to primary alcohols by Raney nickel (1–3). However, under the influence of other functionalities present in the molecule, the thiolester group may exert some unusual chemical properties. For example, β-keto thiolesters (4, 5) and derivatives of *S*,*S*′-diethyl dithiomalonate (6, 7) have been shown to undergo fragmentation reaction upon treatment with Raney nickel. In light of these previous findings in our laboratories, it became of interest to investigate the course of reduction of glycidic thiolesters with Raney nickel. Herein we wish to report the experimental results of this investigation as well as those obtained from the reduction of glycidic thiolesters with sodium borohydride and lithium aluminum hydride. Thiolesters have been shown to be more susceptible to reduction with metal hydride reducing agents than the corresponding oxygen analogues and could be reduced to the alcohol level under mild conditions with sodium borohydride in protic solvents (8) and tetrabutylammonium borohydride in aprotic solvents (9). It has also been shown that a clear differentiation of the thiolester group from other frequently encountered acid derivatives, namely ester, amide, and nitrile, could be achieved using sodium borohydride (8). The study on metal hydride reduction of glycidic thiolesters was undertaken in order to examine the viability of selectively reducing the thiolester group, with the intention of developing a new procedure for the preparation of 2,3-epoxy alcohols.

Results and Discussion

Synthesis of glycidic thiolesters

Glycidic thiolesters were first prepared by Wemple and co-workers from α-halo thiolesters and carbonyl compounds (10, 11) using a variant of Darzens condensation (12). In Darzens synthesis of glycidic esters, an alkoxide or sodium amide is generally used as a base. However, it is deemed necessary to use a non-nucleophilic base in the synthesis of glycidic thiolesters in order to avoid nucleophilic attack on the thiolester carbonyl group by the reagent. It has also been shown (11) that α-bromo thiolesters possessing a tertiary *S*-alkyl group are preferred over those with a primary or secondary *S*-alkyl group. One reason could be that the primary and secondary alkyl groups may undergo deprotonation under strongly basic conditions, as the hydrogen atom adjacent to the sulfur atom is quite acidic (13). Another possible reason is that a thiolester derived from a tertiary mercaptan is less prone to elimination reaction leading to ketene formation (14). In Wemple's synthesis (10, 11), lithium bis(trimethylsilyl)amide and sodium hydride were used as the base, and *S*-*tert*-butyl α-bromothiolesters were used as the main starting substrate. For our investigation, a number of glycidic thiolesters were prepared from *S*-*tert*-butyl 2-bromoethanethiolate (**1**) using lithium diisopropylamide as a base. This base was found to be more convenient to use and the results were more reproducible. In an early experiment, compound **1** was deprotonated with 1 equivalent of lithium diisopropylamide in tetrahydrofuran at −78°C. After addition of 1 equivalent of dihydrocinnamaldehyde, the reaction solution was stirred at −78°C for 2 h and then warmed up to room temperature. Under these conditions, a diastereomeric mixture of glycidic thiolesters **2** (1 : 1) was obtained in 25% yield.

To improve the yield, several runs of the reaction were carried out using increasing amounts of thiolester **1** and lithium diisopropylamide. With 2.5 equivalents each of **1** and the base, a 62% yield (based on the aldehyde) of glycidic thiolesters **2** was obtained. This yield could not be further improved by the use of an even greater amount of thiolester **1**.

It appears that the excess amount of thiolester **1** was required in order to cover its rapid consumption due to side reactions such as self-condensation. In a control experiment, thiolester **1** was treated with lithium diisopropylamide (1 equivalent) at −78°C in tetrahydrofuran for 2 h. The mixture was then allowed to warm up to room temperature (ca. 0.5 h). A substantial loss of material occurred and less than 60% of the starting thiolester **1** was recovered.

In the subsequent preparation of glycidic thiolesters, the

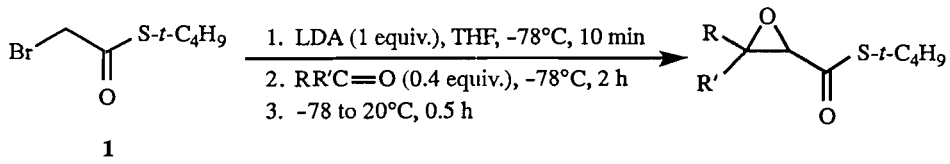
TABLE 1. Preparation of glycidic thiolesters



Glycidic thiolester(s)	% Yield	Glycidic thiolester(s)	% Yield
 **2**	62 (*cis*:*trans* = 1:1)	 **3**	85 (*cis*:*trans* = 1:1)
 **4** (11)	83	 **5**	81
 **6**	66	 **7**	78 (*cis*:*trans* = 2:1)[a]
 **8**[b]	70		

[a]The stereochemistry of these isomers follows from the subsequent reduction with Raney nickel (see Table 2). The terms *cis* and *trans* denote the relationship between the *tert*-butyl group and the oxygen atom of the epoxy ring.
[b]A single stereoisomer was obtained. Its stereochemistry remains to be determined.

following standard procedure was adopted. The enolate ion of thiolester **1** was preformed by treatment with lithium diisopropylamide (1 equivalent) in tetrahydrofuran at −78°C for 10 min. The carbonyl compound (0.4 equivalent) was then introduced. After 2 h at −78°C, the reaction mixture was warmed to room temperature (ca. 0.5 h). Under these conditions, several glycidic thiolesters were prepared in reproducible yields of 62–85%. The results are summarized in Table 1.

Similar to Darzens synthesis of glycidic esters, the formation of glycidic thiolesters is expected to proceed via the following three steps: deprotonation of an α-halo thiolester, nucleophilic addition of the enolate ion thus formed to a carbonyl compound, and cyclization to form the oxirane ring (Scheme 1). It was observed during the preparation of compound **2** that an intermediate was produced immediately following the addition of dihydrocinnamaldehyde at −78°C. This intermediate was slowly (ca. 5 h) converted to the desired product at low temperature (−78°C). This observation also indicated that the final cyclization was much slower than the addition of the enolate anion to the carbonyl compound.

We have also examined the condensation of *S*-*tert*-butyl 2-chloroethanethioate with carbonyl compounds. This reagent was found to be inferior to the corresponding bromo compound **1**. At −78°C over a period of 5 h, the reaction of its enolate ion with cyclohexanone gave rise to chloro alcohol **9** as the only product in 81% yield. When the reaction was carried out by slowly warming the reaction mixture to room temperature over a 2.5 h period, the desired product **4** was formed but only in poor yield (19%). Similarly, the condensation of *S*-*tert*-butyl 2-chloroethanethioate with dihydrocinnamaldehyde at −78°C gave chloro alcohol **10** as the only product (38% yield). In this case, the formation of the desired product **2** was not detected even after the reaction temperature was raised to 20°C.

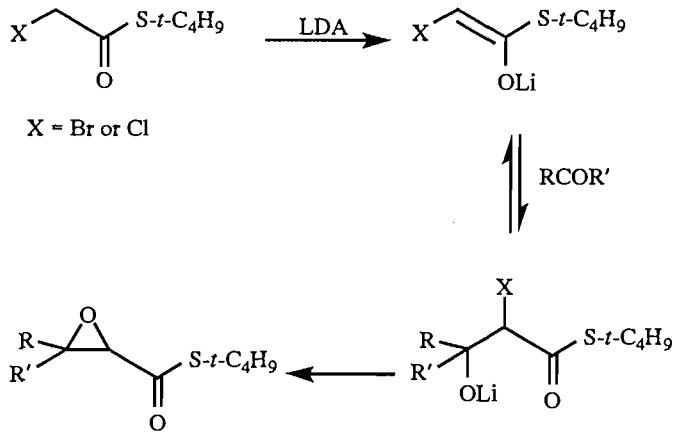

SCHEME 1

Treatment of compounds **9** or **10** with a base such as sodium hydride in tetrahydrofuran or 1,2-dimethoxyethane at room temperature did not yield any detectable amount of the desired glycidic thiolester. Instead, complete decomposition to give the original components, α-chloro thiolester and the carbonyl compound, occurred.

The above results clearly indicate that α-chloro thiolester is not an adequate reagent for the preparation of glycidic thiolesters via Darzens condensation. This is in agreement with the previous findings made by Wemple and co-workers (11). The isolation of intermediate chloro alcohols **9** and **10** and the observed reverse reaction of these intermediates lend support to the proposed mechanistic pathway depicted in Scheme 1.

Reduction of glycidic thiolesters with Raney nickel

Glycidic thiolester *cis*-**2** was treated with W-2 Raney nickel in 95% ethanol at room temperature for 1 h. After filtration and concentration of the filtrate, diol **11** (15) was obtained. The mass spectrum revealed its molecular formula of $C_{11}H_{16}O_2$. The ir spectrum indicated the presence of a hydroxy group showing a strong absorption at 3343 cm^{-1}. This was also confirmed by the signal at δ 2.3 for two D_2O exchangeable hydrogens in the ^1H nmr spectrum. However, at this stage the relationship (i.e., 1,2- or 1,3-) of the two hydroxy groups could not be determined by the ^1H nmr spectrum due to the complexity of the signals at δ 3.8–4.0 for the three hydrogens adjacent to the hydroxy groups.

To solve this problem, the diol was converted to the corresponding diacetate by treatment with excess acetic anhydride and pyridine in methylene chloride. The ^1H nmr spectrum clearly indicated that the product was a 1,3-diacetate derived from 1,3-diol **11**, displaying two low-field signals, a triplet at δ 4.10 (J = 6.5 Hz) for two hydrogen atoms, and a triplet of triplets at δ 5.04 (J = 7, 5.5 Hz) integrating to one hydrogen.

Similar treatment of glycidic thiolesters **3**, **4**, **7**, and **8** with Raney nickel gave rise to 1,3-diols **12** (16), **13** (17), **14** (18), and **15**, respectively. An examination of the results compiled in Table 2 reveals that the reduction in each case proceeded in a completely regioselective manner with preferential cleavage of the carbon–oxygen bond neighboring the thiolester group. As such, this bond is expected to be activated by the thiolester group. Furthermore, in compounds **4**, **7**, and **8**, this bond happens also to be sterically less congested than the other carbon–oxygen bond of the oxirane ring. Most likely, it is the combination of these electronic and steric effects that induced the observed high degree of regioselectivity.

Reduction of glycidic thiolesters with sodium borohydride and lithium aluminum hydride

In this part of the study, several glycidic thiolesters were subjected to sodium borohydride reduction in order to investigate the feasibility of reducing the thiolester group selectively without affecting the adjacent epoxy ring. Thus, compound **4** was treated with 4 molar equivalents of sodium borohydride in 98% ethanol at 20°C. The reduction was found to be completed within 5 h, giving rise to epoxy alcohol **16** (19) in 82% yield.

This procedure is apparently general for the selective reduction of glycidic thiolesters. Under similar conditions, compounds *cis*-**2**, *trans*-**2**, *cis*-**3**, and **8** were also smoothly reduced to their corresponding epoxy alcohols in good yields (80–95%). Results are compiled in Table 3.

It should be noted that up to 4 molar equivalents of the reducing agent were required for completion of the reaction, presumably because of partial consumption of the reagent by the solvent. The amount could be reduced to 2.5 molar equivalents by addition of the reagent in portions (0.5 molar equivalent over every 0.5 h period) during the reaction.

The formation of epoxy alcohols from glycidic thiolesters can also be achieved by the use of lithium aluminum hydride at low temperature. For example, when *trans*-**3** was treated with 3 molar equivalents of the reducing agent in ether at −78°C for 1 h, epoxy alcohol *trans*-**18** (16) was obtained in 89% yield.

The reduction was also attempted using 1 molar equivalent of lithium aluminum hydride. At −78°C, the reaction was found to be slow and incomplete after a long time of reaction (>5 h). When the reaction was carried out at room temperature, a complex mixture was produced, from which hydroxy aldehyde **21** was isolated in 5% yield. This compound was obviously produced as a result of the epoxy ring opening with *tert*-butyl mercaptide generated during the reduction.

Several other glycidic thiolesters were subjected to reduction with a large excess (3 molar equivalents) of lithium aluminum hydride at low temperature (−78°C). As indicated by the results outlined in Table 3, these conditions are generally effective for the selective reduction of the thiolester group.

Conclusion

Several new synthetic aspects of glycidic thiolesters, readily prepared by an α-bromo thiolester version of the Darzens condensation, were successfully explored. Reduction of glycidic thiolesters with Raney nickel was shown to give consistently the corresponding 1,3-diols as a result of the completely regioselective cleavage of the epoxy ring. On the other hand, with sodium borohydride at room temperature or lithium aluminum hydride at −78°C, glycidic thiolesters were readily reduced to give 2,3-epoxy alcohols resulting from the chemoselective reduction of the thiolester moiety. In conjunction with the Darzens glycidic thiolester condensation, these facile and apparently general reductions provide convenient access to 1,3-diols and 2,3-epoxy

[a]The stereochemistry of these isomers was tentatively assigned on the basis of the relative polarities (18) of the corresponding monoacetates (see Experimental). By inference the stereochemistry of the starting glycidic thiolesters 7 was deduced.
[b]The stereochemistry of this compound remains to be determined.

alcohols[2] that cannot be effectively prepared by similar transformations involving glycidic esters.

Experimental

General

Melting points (mp) were determined on a Köfler hot stage apparatus and are uncorrected. Elemental analyses were performed by the microanalytical laboratory of this department. Infrared (ir) spectra were recorded on a Perkin–Elmer model 457 or Nicolet 7-199 FT-IR spectrophotometer. Unless otherwise stated, ir samples were run as thin films. Proton nuclear magnetic resonance (^{1}H nmr) spectra were recorded on a Bruker WH-200 spectrometer and, except where otherwise stated, were obtained on solutions in deuterochloroform with tetramethylsilane as internal reference. The following abbreviations are used: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, and br = broad. Carbon-13 nuclear magnetic resonance (^{13}C nmr) spectra were recorded on a Bruker WH-300 (75 MHz) spectrometer. The multiplicity of ^{13}C nmr signals was derived from off-resonance or Carr–Purcel–Meiboom–Gill spin echo *J*-modulated experiments (APT or Attached Proton Test). Peaks in antiphase (a) with deuteriochloroform were assigned as methyls or methines, while peaks in phase (p) correspond to methylenes or quarternary carbons. High resolution mass spectra (HRMS) were recorded using a Kratos A.E.I. model MS50 high-resolution mass spectrometer. Chemical ionization mass spectra (CIMS) were obtained using an A.E.I. MS12 mass spectrometer, with ammonia as the reagent gas. Concentrations of solvent systems used for column chromatography are given by volumes.

Materials

S-tert-Butyl 2-bromoethanethioate (**1**) was prepared by trapping, with *tert*-butyl mercaptan, of α-bromoacetyl bromide prepared by the Hell–Volhard–Zelinsky reaction (21). Methylene chloride was distilled from anhydrous magnesium sulfate. Ether, 1,2-dimethoxyethane, and tetrahydrofuran were distilled from so-

dium metal and benzophenone under an argon atmosphere. Ethyl acetate, hexane, ether, and methylene chloride used for chromatography and extraction were purified by distillation. Argon was passed through a purification train of Fieser's solution, concentrated sulfuric acid, and potassium hydroxide pellets. Silica gel, 230–400 mesh ASTM, was used as absorbent for flash chromatography. Thin-layer chromatography was carried out using Merck TLC aluminum sheets silica gel 60 F_{254}. Unless otherwise stated, anhydrous magnesium sulfate was used for drying organic solutions.

Preparation of glycidic thiolesters

A number of glycidic thiolesters were synthesized from α-bromo thiolester **1** and the carbonyl compounds. A typical experimental procedure is given below with compounds **2**. Yields of products are shown in Table 1.

S-tert-*Butyl 3-(2-phenylethyl)oxirane-2-carbothioates* (**2**)

Under an argon atmosphere, diisopropylamine (1.11 g, 11.0 mmol) and tetrahydrofuran (30 mL) were placed in a flask and cooled to −78°C by a Dry Ice – acetone bath. A 2.0 M butyllithium solution in hexane (5.0 mL, 10.0 mmol) was slowly added with a syringe. After stirring for 10 min, a solution of compound **1** (2.11 g, 10.0 mmol) in tetrahydrofuran (5 mL) was added dropwise over a period of 10 min. Then a solution of dihydrocinnamaldehyde (0.536 g, 4.00 mmol) in tetrahydrofuran (5 mL) was added dropwise. The resulting mixture was stirred at −78°C for 2 h and the cooling bath was removed. After the mixture was warmed up to room temperature, it was poured into an aqueous

Reduction of glycidic thiolesters with Raney nickel

The reactions were carried out using the general procedure described below. Yields of products are shown in Table 2.

To Raney nickel (W-2, ca. 4 g/mmol of substrate, 50% slurry in water), in a flask, was added water (5 mL). After stirring for 0.5 min, the liquid was carefully removed with a pipet. The residue was washed three times with 95% ethanol (5 mL each). Then a solution of glycidic thiolester (0.5–1.0 mmol) in 5 mL of 95% ethanol was added. After stirring at room temperature for 1 h, the reaction mixture was filtered through a layer of Celite 545. The residue was washed with 30 mL of ethanol. The filtrates were combined and concentrated to give the crude product, which was subjected to either flash chromatography (3% methanol and 30% ether in hexane) giving a pure diol, or direct acetylation as follows.

A pure or crude diol yielded from the reduction reaction was stirred with excess acetic anhydride and pyridine in methylene chloride at room temperature overnight. Then the mixture was poured into an ice-cold aqueous 1 N sodium hydroxide solution and extracted with methylene chloride. The extracts were washed with 1 N hydrochloric acid and aqueous saturated sodium chloride solution, combined, dried, filtered, and concentrated. The residue was chromatographed (10–40% ethyl acetate in hexane) to give mono- and (or) diacetate in good yield.

The diols and their corresponding mono- and (or) diacetates were shown to have the following spectral data.

5-Phenyl-1,3-pentanediol (11): ir: 3343 (br, -OH) cm^{-1}; ^{1}H nmr δ: 1.7–1.8 (complex, 4H), 2.3 (br s, 2H, D_2O exchangeable, -O*H*), 2.74 (ddd, 1H, *J* = 14, 7.5, 8.5 Hz, -C*H*HPh), 2.82 (ddd, 1H, *J* = 14, 7, 9 Hz, -CH*H*Ph), 3.8–4.0 (complex, 3H, -C*H*OH-$CH_2$$CH_2$OH), and 7.2–7.4 (complex, 5H, Ar*H*); CIMS (M + NH_4)$^+$: 198 (calcd. for $C_{11}H_{20}NO_2$: 198). Diacetate of **11**: ir: 1730 (C=O), 1500 and 1450 (Ph) cm^{-1}; ^{1}H nmr δ: 1.8–2.0 (complex, 4H), 2.05 (s, 6H, -COCH_3), 2.64 (td, 2H, *J* = 7, 2 Hz, -CH_2Ph), 4.10 (t, 2H, *J* = 6.5 Hz, -CH_2OAc), 5.04 (tt, 1H, *J* = 7, 5.5 Hz, -C*H*(OAc)-), and 7.15–7.40 (complex, 5H, Ar*H*); HRMS *m/z*: 204.1148 (M$^+$ − CH_3CO_2H, calcd. for $C_{13}H_{16}O_2$: 204.1150).

1-Cyclohexyl-1,3-propanediol (12): ir: 3342 (OH) cm^{-1}; ^{1}H nmr δ: 0.9–1.5 (complex, 6H), 1.5–2.0 (complex, 7H), 2.30 (br s, 1H, D_2O exchangeable, -O*H*), 2.46 (br s, 1H, D_2O exchangeable, -O*H*), 3.68 (dt, 1H, *J* = 7.5, 5.5 Hz, -C*H*(OH)-), 3.90 (dt, 1H, *J* = 11, 5.5 Hz, -C*H*HOH), and 3.95 (dt, 1H, *J* = 11, 5 Hz, -CH*H*OH); CIMS (M + NH_4)$^+$: 176 (calcd. for $C_9H_{22}NO_3$: 176). Reduction of glycidic thiolesters with sodium borohydride

The reactions were carried out using the general procedure described below. Yields of products are shown in Table 3.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

To a solution of a glycidic thiolester (0.5–1.0 mmol) in 98% ethanol (1–2 mL) cooled by an ice bath, was added sodium borohydride (4.0 molar equivalents) with stirring. After 10 min, the ice bath was removed and the reaction mixture was stirred at room temperature for 4–8 h. After the glycidic thiolester was completely consumed as shown by thin-layer chromatography, 1 N hydrochloric acid (5 mL) was carefully added to the mixture. The resulting mixture was poured into 1 N aqueous sodium hydroxide solution (50 mL) and extracted with methylene chloride (3 × 15 mL). The extracts were washed with aqueous saturated sodium chloride solution, combined, dried, filtered, and concentrated. The residue was chromatographed (30–60% ethyl acetate in hexane) to afford the epoxy alcohol.

Reduction of glycidic thiolesters with lithium aluminum hydride

The reactions were carried out using the general procedure described below. Yields of products are shown in Table 3.

At −78°C, to a solution of a glycidic thiolester (0.5–1.0 mmol) in ether (3–6 mL) under an atmosphere of argon was carefully added lithium aluminum hydride (3.0 molar equivalents). The reaction mixture was stirred at −78°C for 1 h, then quenched by addition of water (1 mL). The resulting mixture was acidified with 1 N hydrochloric acid and extracted with methylene chloride (3 × 10 mL). The extracts were washed with aqueous saturated sodium chloride solution, combined, dried, filtered, and concentrated. The residue was chromatographed (30–60% ethyl acetate in hexane) to give the corresponding epoxy alcohol.

The epoxy alcohols obtained from metal hydride reduction of glycidic thiolesters showed the following spectral data.

*2-Hydroxymethyl-1-oxaspiro[2.5]octane (**16**)*: ir: 3400 (OH) cm^{-1}; ^1H nmr δ: 1.4–1.9 (complex, 11H), 3.00 (dd, 1H, J = 7, 4.5 Hz, -C*H*CH_2OH), 3.70 (ddd, 1H, J = 12, 7, 4.5 Hz, -C*H*HOH), and 3.81 (ddd, 1H, J = 12, 8, 4.5 Hz, -CH*H*OH); CIMS $(M + NH_4)^+$: 160 (calcd. for $C_8H_{18}NO_2$: 160). Anal. calcd. for $C_8H_{14}O_2$: C 67.57, H 9.92, found: C 67.57, H 10.11.

*2-Hydroxymethyl-3-(2-phenylethyl)oxiranes (**17**)*:

cis-**17**: ir: 3417 and 3409 (OH) cm^{-1}; ^1H nmr δ: 1.57 (br s, 1H, D_2O exchangeable, -O*H*), 1.81 (dddd, 1H, J = 14, 8.5, 8, 6 Hz, -CH_2C*H*H-), 1.95 (dddd, 1H, J = 14, 9, 8, 6.5 Hz, -CH_2CH*H*-), 2.78 (dt, 1H, J = 13, 8 Hz, PhC*H*H-), 2.91 (ddd, 1H, J = 13, 9, 6. Kinetics of the photochemical reactions of the croconate dianion in aqueous solution

B. ZHAO AND M. H. BACK
Ottawa–Carleton Chemical Institute, University of Ottawa, Ottawa, Ont., Canada K1N 6N5

Received July 5, 1991

B. ZHAO and M. H. BACK. Can. J. Chem. **70**, 135 (1992).

The kinetics of the photochemical reactions of the dianion of croconic acid (1,2-dihydroxycyclopentenetrione) have been studied in aqueous solution in the presence of electron acceptors. In neutral solutions the quantum yield for disappearance of croconate dianion was small ($<10^{-3}$) but was substantially increased in basic solution and in the presence of electron acceptors. At pH 12 in the presence of 4-nitrobenzylbromide and biacetyl a quantum yield of 1 was obtained. The kinetics of the rate of disappearance of croconate dianion as a function of pH and concentration of acceptor showed that the excited dianion is oxidized by acceptors and reacts with hydroxyl ion. A mechanism is proposed that, by assuming reasonable values for the rate constants involved, is shown to be consistent with the results.

Key words: photolysis, kinetics, croconate dianion, electron transfer.

B. ZHAO et M. H. BACK. Can J. Chem. **70**, 135 (1992).

Opérant en solution aqueuse, en présence d'accepteurs d'électrons, on a étudié la cinétique des réactions photochimiques du dianion de l'acide croconique (1,2-dihydroxycyclopentènetrione). Dans des solutions neutres, le rendement quantique pour la disparition du dianion croconate est faible ($<10^{-3}$); toutefois, il augmente considérablement en solution basique et en présence d'accepteurs d'électrons. À un pH de 12, en présence de bromure de 4-nitrobenzyle et de biacêtyl, on a obtenu un rendement quantique de 1. La cinétique de la vitesse de disparition du dianion croconate en fonction du pH et de la concentration d'accepteur montre que le dianion excité est oxydé par les accepteurs et qu'il réagit avec l'ion hydroxyle. On propose un mécanisme qui, en utilisant des valeurs raisonnables pour les constantes de vitesses impliquées, est en accord avec les résultats.

Mots clés : photolyse, cinétique, dianion croconate, transfert d'électrons.

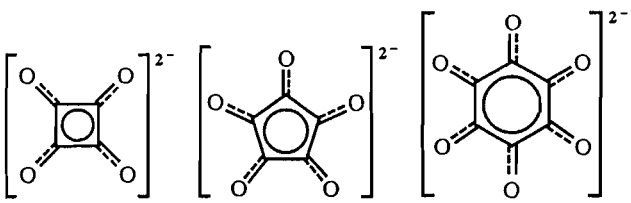
The cyclic dibasic acids, squaric, croconic, and rhodizonic, form symmetrical, resonance-stabilized structures when completely ionized.



Squarate Croconate Rhodizonate

These dianions were named "oxocarbons" by West and Powell (1) and were recognized as members of an aromatic series containing only carbon and oxygen atoms (2, 3). These symmetrical structures have intrigued theoretical chemists who have discussed the structure and bonding, the properties of the molecular orbitals, and the excited electronic states (4–6). The dianions all show strong absorption in the first $\pi \rightarrow \pi^*$ electronic transition. The maximum in the absorption shifts from the visible, 483 nm (3.3×10^4 L mol^{-1} cm^{-1}), for rhodizonate to the near ultraviolet, 363 nm (3.9×10^4 L mol^{-1} cm^{-1}), for croconate, to the ultraviolet, 268 nm (2.4×10^4 L mol^{-1} cm^{-1}), for squarate. This property has led to several useful applications. Rhodizonic acid is an analytical reagent for metal ions, especially iron, lead, and barium (7–9). Squaric acid and croconic acid form condensation products with aminophenols and various types of pyrroles; these are intensely coloured and have found extensive use as photoreceptors in laser recording materials and other photoresponsive devices (10, 11). In spite of the importance of these anions and their derivatives, little is known about the chemical reactions occurring following absorption of light. Rhodizonic acid was known to be unstable when exposed to visible light but no study of the effect has been reported and no mechanism for the reaction proposed. We therefore began a systematic study of the kinetics of the photochemical reactions of these dianions, beginning with rhodizonate (12, 13).

The photochemical reaction of the rhodizonate dianion was shown to be inefficient, with quantum yields $<10^{-3}$ in neutral or weakly basic solutions (13). The rate of disappearance was significantly increased in the presence of electron acceptors, and quantum yields up to about 0.04 were obtained. The results were interpreted in terms of an initial electron transfer from the excited dianion to the acceptor, but a rapid reversal to ground state species prevented an efficient photodissociation. A similar mechanism was suggested to account for the slow thermal reaction.

In the present paper these studies have been extended to the croconate dianion in which the increased energy of the absorbed photon leads to a more efficient photodissociation process. Quantum yields of 1 have been observed in basic solution in the presence of certain additives. Two types of additives have been used to detect intermediates in the reaction: electron acceptors to oxidize the excited dianion of croconic acid, and diphenylpicrylhydrazyl (DPPH) and acrylamide to trap radicals that escaped from the solvent cage. A mechanism is proposed in which the excited dianion undergoes electron transfer to an acceptor molecule as well as direct reaction with hydroxyl ions.

Experimental

Disodium croconate, $Na_2C_5O_5$, was prepared by the thermal oxidation of sodium rhodizonate with hydrogen peroxide in basic solution, according to the procedure described by Schwartz, Gelb, and Yardley (14). The precipitate of sodium croconate was recrystallized from ethanol–water solution and dried at 120°C for 90 min. The ^{13}C NMR spectrum showed only one peak at 188 ppm and the extinction coefficient at the maximum of the strong $\pi \rightarrow \pi^*$ absorption, 363 nm, was 3.9×10^4 M^{-1} cm^{-1}, assuming the

salt was the monohydrate. Neutral solutions of sodium croconate were stable for several months when kept in the dark. Solutions for reaction were prepared daily from the stock solution using distilled and deionized water.

The light source was a medium-pressure mercury arc (Hanovia S-500) used with a Corning filter no. 7-37, which has a maximum transmission at 360 nm and a band pass of 35 nm. Thus the irradiating light was only the group of mercury emission lines in the range 365.0–366.3 nm (15). The intensity of light incident on the reaction cell was measured using a uranyl oxalate actinometer (16). During most of the experiments the incident intensity was in the neighbourhood of 1.1×10^{15} quanta cm^{-2} s^{-1}.

Solutions were irradiated in a spectrophotometer cell (1 cm × 1 cm) that was connected to a reservoir where solutions of croconate dianion and of additives were degassed, using five freeze–pump–thaw cycles, followed by mixing of the solutions in the spectrophotometer cell while under vacuum. The pH of the solutions ranged from 6 to 12, where the acid is fully ionized (pK_1 = 0.80; pK_2 = 2.25 (ref. 3, Chap 3)). The absorption spectra of the solutions were recorded using a Unicam SP-1800 spectrophotometer equipped with a thermostatted cell holder. The rate of disappearance of croconate was monitored at the maximum of its absorption, 363 nm. In all cases the initial rate was well defined and reproducible, with an uncertainty less than ±5%. Any effect of the presence of buffers was checked by irradiation at pH 12 using a trisodiumphosphate buffer or 0.01 M sodium hydroxide. Rates were the same in both solutions, showing that the ions associated with the buffer had no effect on the reaction. In the presence of acrylamide polymerization was measured by precipitating the polymer in methanol, followed by drying to constant weight at 60°C.

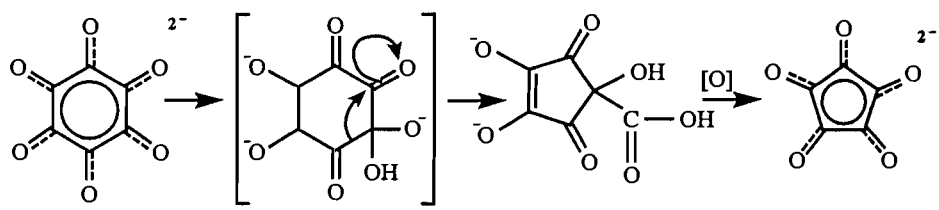
The additives used as electron acceptors were potassium ferricyanide, methyl viologen, 4-nitrobenzylbromide, and biacetyl. They were chosen to represent a range of compounds that easily accept electrons, subject to the restrictions imposed by solubility in water and little absorbance at 366 nm. Except for ferricyanide, where corrections for absorbance were made, the absorbance of the acceptors at 366 nm was <0.1% of that of croconate. The additive least soluble in water was 4-nitrobenzylbromide. Nevertheless at the highest concentration of this additive, 5×10^{-4} M, the absorbance was still linear with concentration. Hydrolysis of 4-nitrobenzylbromide is slow compared to the rate of disappearance of croconate even in strongly basic solutions. The absorption spectrum was unchanged in solutions of pH 12 for more than one-half hour.

All chemicals were reagent grade. Potassium ferricyanide was recrystallized from water–ethanol solutions and 4-nitrobenzyl bromide and acrylamide were recrystallized from methanol–water solution.

Results

Under all conditions croconic acid was more stable thermally than rhodizonic acid. The rhodizonate dianion was oxidized in the dark in aerated solutions, the rate increasing with increasing pH of the solution, and becoming too fast to allow photochemical measurements. Croconate dianion was stable in aerated neutral solutions for several months but the same trend of increasing instability in basic solution was observed. At pH 12, however, solutions of croconate were still stable for several hours. Photolysis in neutral or weakly basic aerated solutions was inefficient because of rapid quenching of the excited dianion by oxygen, but the rate of photolysis increased in basic solution. At pH 12 croconate dianion was converted to the squarate dianion, identified by the λ_{max} of its absorption spectrum, which showed the double maximum characteristic of all the oxocarbon dianions (Fig. 1). In degassed solutions about 30% of the croconate dianion was converted to squarate while in the presence of oxygen the conversion was 100%. Squarate dianion was the only product of the photolysis of croconate dianion identified by absorption over the wavelength range 200–700 nm, although minor absorption by other products at lower wavelength was observed in degassed solutions. Similar observations were made in the photolysis of rhodizonate dianion where croconate dianion was the only product that absorbed in the visible or the ultraviolet regions. Products that have lost the pseudo-aromatic structure of the oxocarbons would be too weakly absorbing to be detected at the concentrations used in the present experiments. The quantities produced were too small to be easily measured by other methods.

The conversion of croconate to squarate probably proceeds by an α-oxo alcohol rearrangement, by analogy with the mechanism discussed by West (3) for the conversion of rhodizonate to croconate, which occurs in the dark in basic solution in the presence of oxygen and some other oxidizing agents.



So efficient is this conversion that no other method has been developed for preparation of croconic acid. Formation of squarate from croconate has not previously been reported and it appears that photolysis under these conditions could provide a useful method for preparation of squaric acid.

In the presence of additives the characteristic spectrum of squarate was not as clear, since all of the additives themselves absorb in the neighbourhood of 270 nm. With ferricyanide a product was formed with λ_{max} 268 nm but the double maximum of squarate was obscured by the absorption due to ferrocyanide formed during the reaction. The product, if squarate, accounted for not more than 50% of the initial concentration of croconate and was observed both in the presence and absence of oxygen. The additive methyl viologen appeared not to be consumed in the reaction and when an equal concentration was used as reference the characteristic absorption spectrum of squarate was clearly seen. The amount corresponded to about 60% conversion of croconate. The absorption spectrum of 4-nitrobenzylbromide has a narrow band with a maximum at 280 nm. In

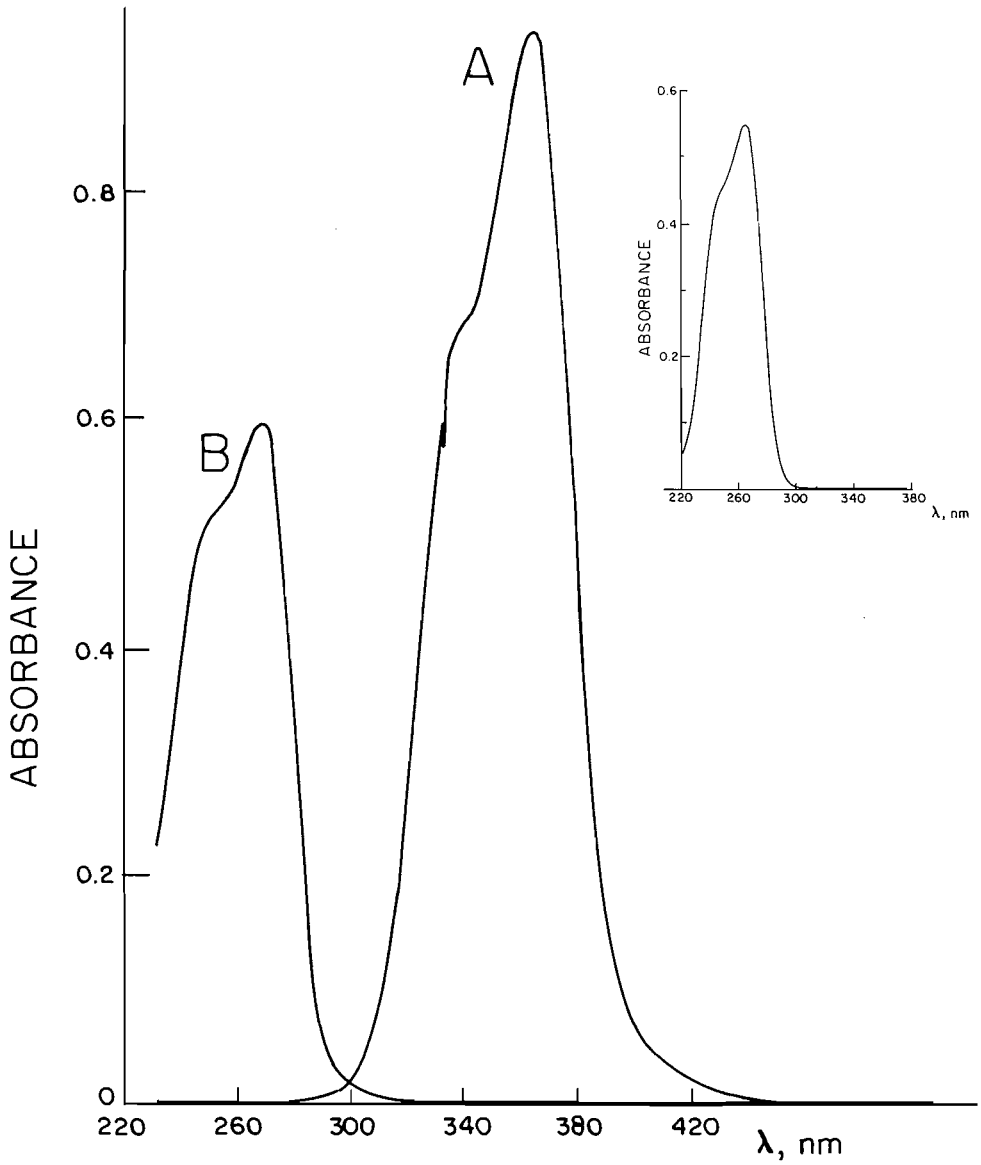

FIG. 1. Absorption spectra of a solution of croconate dianion before and after irradiation in the presence of oxygen, showing formation of squarate dianion. A. 2.4×10^{-5} M croconate dianion in 0.01 M sodium hydroxide before irradiation. B. Same solution after complete consumption of croconate dianion. The absorbance of the squarate dianion indicates quantitative conversion of croconate to squarate. Inset: absorption spectrum of 2.2×10^{-5} M squarate dianion in 0.01 M sodium hydroxide.

neutral solution, where formation of squarate from croconate alone was negligible, the absorbance at 280 nm decreased on photolysis, indicating that 4-nitrobenzylbromide was consumed in the reaction. In degassed basic solution the absorption maximum shifted to 268 nm and increased slightly. In the presence of oxygen the maximum also shifted to 268 nm and the absorbance increased substantially. Assuming that the molar loss of croconate is equal to the molar loss of 4-nitrobenzylbromide (unsubstantiated but reasonable) we estimate that conversion to squarate is 70% in the absence of oxygen and 100% in the presence of oxygen. With biacetyl, formation of squarate was not evident, possibly because of the strong absorption of biacetyl in this region. Hydration of biacetyl was observed at pH 12 and changes in the absorption spectrum were evident after about 10 min. The rate of photolysis of croconate was still much faster under these conditions and the rate was measured within 1 or 2 min of photolysis time. Further thermal reactions were observed after about 30 min.

Measurement of quantum yield

Deaerated solutions were photolyzed in the range of pH 6–12 in the presence and absence of the additives. In both the presence and absence of additives the quantum yield for disappearance of croconate dianion in acid solution was $<10^{-3}$ but increased in basic solution, approaching unity at pH 12 in the presence of biacetyl and 4-nitrobenzylbromide. These results are shown in Fig. 2 and summarized in Table 1.

The presence of an electron acceptor had a considerable effect on the quantum yield. As an illustration, the quantum yield for disappearance of croconate dianion is shown in Fig.

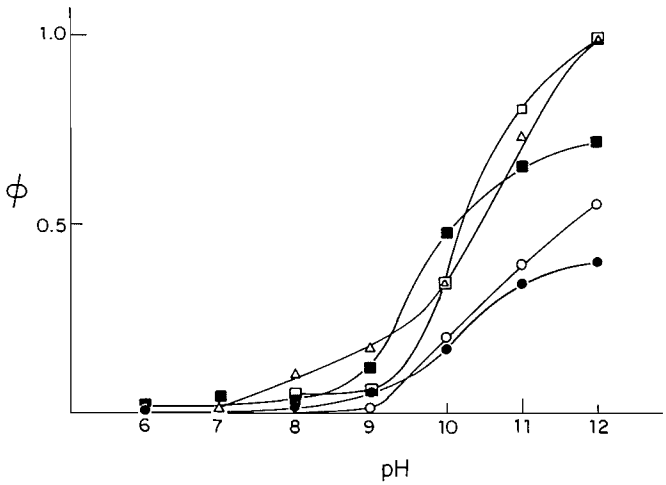

FIG. 2. The quantum yield for disappearance of croconate as a function of pH in the presence and absence of acceptors. The concentration of acceptor is given in Table 1. $[C_5O_5^{2-}] = 2.3 \times 10^5$ M. ●: no acceptor; ○: ferricyanide; ■: methylviologen; △: 4-nitrobenzylbromide; □: biacetyl.

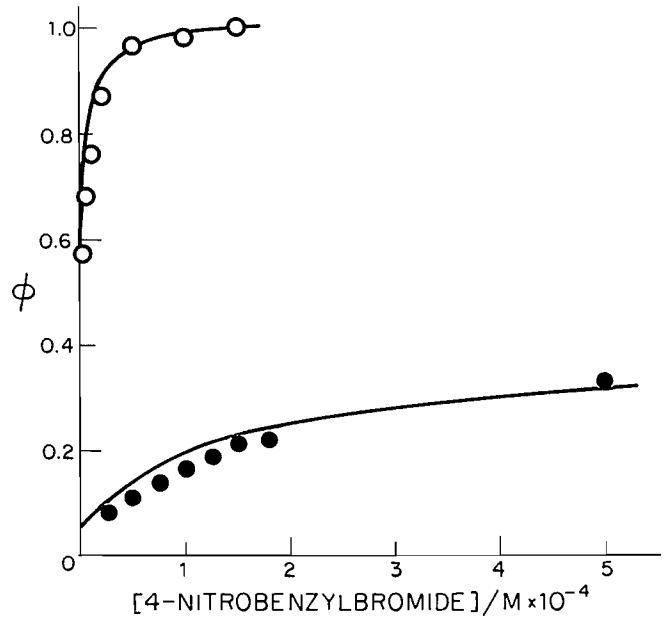

FIG. 3. The quantum yield for disappearance of croconate as a function of the concentration of 4-nitrobenzylbromide. The solid lines are calculated values (see text). $[C_5O_5^{2-}] = 2.3 \times 10^{-5}$ M. ●: pH 9; ○: pH 12.

3 as a function of the concentration of 4-nitrobenzylbromide at pH 9 and 12. The quantum yields as a function of concentration of each additive are given in Table 2. The dependence of the quantum yield on the concentration of croconate was measured with croconate alone at pH 12 and in the presence of 4-nitrobenzylbromide at pH 9. In both cases the quantum yield was independent of the concentration of croconate over the range $(1.3–3.3) \times 10^{-5}$ M.

Photolysis in the presence of radical traps

Photolyses in the presence of DPPH were performed in methanol solutions degassed under vacuum in the usual way. The spectrum and absorption maximum of croconate were not changed in methanol solution. Photolysis of mixtures of croconate and DPPH caused a loss of DPPH as measured by the absorbance of DPPH at 540 nm. Although DPPH has a strong absorbance at 366 nm, no measurable loss of DPPH occurred on photolysis in the absence of croconate. The rate of loss of DPPH was increased when biacetyl, 4-nitrobenzylbromide, and methyl viologen were added to the system but was not affected by the presence of potassium ferricyanide. The relative loss of DPPH as a function of time in the presence and absence of additives is shown in Fig. 4. The quantum yield for loss of DPPH, with respect to photons absorbed by croconate only at 366 nm, is given in Table 3.

Polymerization of acrylamide was observed on photolysis of croconate alone in aqueous solution and the rate was greatly increased in the presence of 4-nitrobenzylbromide and biacetyl. No increase in rate was observed with the additives ferricyanide or methyl viologen. The initial quantum yield for polymerization in aqueous solution at an initial pH of 4.1 is shown in Fig. 5 as a function of concentration of the additive 4-nitrobenzylbromide. Further measurements in buffered solutions showed that the quantum yield for polymerization increased to a maximum value of 2×10^3 at pH 8 and then declined in more basic solution. One experiment using an incident light intensity 14% of the original intensity showed that the rate was proportional to the square root of the light intensity. The results are summarized in Table 4.

The results of a more detailed study of the photopolymerization of acrylamide sensitized by croconate will be reported separately; the present limited results suggest that the photopolymerization follows the general mechanism involving mutual termination of radicals. The rate of polymerization may therefore be expressed by the general equation

$$[1] \quad R_p = k_p[M](\Phi_R I_{abs}/k_t)^{1/2}$$

where k_p and k_t are the rate constants for propagation and termination, respectively, for the acrylamide polymerization, [M] is the concentration of monomer, Φ_R is the quantum yield for production of radicals, and I_{abs} is the intensity of light absorbed by the initiator. Using the value for $k_p/k_t^{1/2}$ of 4.2 $M^{-1/2}$ $s^{-1/2}$ measured by Dainton and Tordoff (17), the quantum yield for production of radicals in the photolysis of croconate was obtained and is given in Table 4.

Discussion

The effect of all four additives on the quantum yield for reaction of croconate dianion is convincing evidence that an initial electron transfer occurs from the excited dianion. The fact that radical reactions (disappearance of DPPH and polymerization of acrylamide) are observed following photolysis indicates that the radical, or radicals, formed as a result of the electron transfer have sufficient lifetime to undergo reactions in the bulk solution. The increase in quantum yield observed in basic solutions (in the presence or absence of additive) suggests that the hydroxyl ion reacts directly with the excited croconate dianion. Excitation provides the energy required for this addition, which does not occur thermally at room temperature. By comparison, reaction of hydroxyl ion with rhodizonate dianion was observed in basic solution without photoexcitation.

A further interesting observation is an apparently synergistic effect of the additive and hydroxyl ions. For exam-

ple, the increase in quantum yield observed on addition of 4-nitrobenzylbromide depends greatly on the pH of the solution. This is illustrated in Fig. 3 where the change in quantum yield is shown as a function of concentration of 4-nitrobenzylbromide at pH 9 and 12. If the effects of both reactants, hydroxyl ion and acceptor, were additive the rate of change of quantum yield with concentration of acceptor would not change with pH; only the quantum yield without additive would change. The limiting quantum yield at high concentration of additive is also quite different at pH 9 and pH 12. Such an effect requires an interaction of one of the reactants with an intermediate formed by the other reactant.

A mechanism for the reaction incorporating these features and allowing for deactivation of the excited state by both acceptor and hydroxyl ion is summarized below (Scheme 1), where A is an acceptor molecule and $(C_5O_5^{2-}...A^-)$ and $(C_5O_5^{2-}...OH^-)^*$ represent the transient intermediates formed between the excited state of the dianion and the reactant, which in each case may re-form the ground state reactants, proceed to products, or react with the other reactant.

Assuming a steady-state concentration of all intermediates the quantum yield may be expressed as

$$[2] \quad \Phi = \frac{k_1[A]}{k_D + k_1[A] + k_6[OH^-]}\left[\frac{k_3 + k_4[OH^-]}{k_2 + k_3 + k_4[OH^-]}\right] + \frac{k_6[OH^-]}{k_D + k_1[A] + k_6[OH^-]}\left[\frac{k_8 + k_9[A]}{k_7 + k_8 + k_9[A]}\right]$$

Photolysis in the absence of acceptors

In the absence of acceptor, eq. [2] may be simplified as follows:

$$[3] \quad \Phi = \frac{k_6[OH^-]}{k_D + k_6[OH^-]}\left[\frac{k_8}{k_7 + k_8}\right]$$

A plot of Φ^{-1} against $[OH^-]^{-1}$ is shown in Fig. 6. Values of $k_8/(k_7 + k_8)$ and k_D/k_6 obtained from the intercept and slope are given in Table 5*a*. Efficient reaction at these concentrations of reactant and hydroxyl ion requires a lifetime for the excited croconate in the microsecond range and preliminary measurements of the time constant for re-formation of the ground state croconate dianion following flash photolysis (18) indicated a value for k_D of 1.3×10^4 s^{-1}. The excited state of the dianion is undoubtedly the triplet. With this value for k_D, $k_6 = 10^8$ M^{-1} s^{-1}. The fact that the ratio $k_8/(k_7 + k_8)$ is smaller than 1 indicates that deactivation by the hydroxyl ion occurs concurrently with reaction.

Photolysis in the presence of acceptors

The addition of electron acceptors in every case increased the quantum yield of disappearance of croconate dianion. Thus energy transfer quenching of the excited croconate dianion by the additives appears of little importance, particularly in basic solution where the quantum yield was high and with biacetyl and 4-nitrobenzylbromide reached a value of 1. It follows that the quantum yield for intersystem crossing is unity and for these additives energy transfer

quenching must be negligible. For the additives where the quantum yield was less than unity, energy transfer quenching cannot be unequivocally ruled out, although the lower quantum yields can be accounted for by other reactions, as will be shown later.

At lower pH where the reaction with hydroxyl ion becomes negligible, eq. [2] may be written as

$$[4] \quad \Phi = \frac{k_1[A]}{k_D + k_1[A] + k_6[OH^-]} \left[\frac{k_3 + k_4[OH^-]}{k_2 + k_3 + k_4[OH^-]}\right]$$

k_D	1.3×10^4 s^{-1}

Evaluation of eq. [2]

With these guides to the values of the rate constants the quantum yield may be calculated from eq. [2] as a function of concentration of additive and of hydroxyl ion. If the rate constants for reactions 1 and 6 (Scheme 1) are similar, the fraction $k_6[OH^-]/(k_D + k_1[A] + k_6[OH^-])$ will be practically unity at pH 12 where $[OH^-] \gg [A]$, the fraction $k_1[A]/(k_D + k_1[A] + k_6[OH^-])$ will be negligible, and the increase in quantum yield as the concentration of additive increases to 10^{-4} M must be caused by the increasing contribution of reaction 9 through the fraction $(k_8 + k_9[A])/k_7 + k_8 + k_9[A])$. Both reactions 4 and 9 may also be diffusion controlled with rate constants close to 10^9 M^{-1} s^{-1}. At a concentration of 4-nitrobenzylbromide of 1×10^{-4} M, $k_9[A]$ must be much greater than $k_7 + k_8$ and therefore the maximum value for $k_7 + k_8$ will be approximately 1×10^3.

Minor modifications to these rate constants were made to maximize the agreement of the calculated quantum yields with the experimental measurements for the additive 4-nitrobenzylbromide at both pH 12 and pH 9. The final values for the rate constants are given in Table 6 and the calculated values for the quantum yield are shown as the solid lines in Fig. 3. At pH 12, as predicted, the first term in eq. [2] contributes a maximum of 1% to the quantum yield even at the highest concentration of 4-nitrobenzylbromide. At pH 9 both terms contribute to the reaction at lower concentrations of additive but at high concentrations the first term predominates. Examples of the values for the fractions in eq. [2] are given in Table 7.

With the additive biacetyl the approach of the quantum yield to the limiting value of 1 at pH 12 was slower over a comparable range of concentration, suggesting that reaction 9 was substantially slower than the corresponding reaction with 4-nitrobenzylbromide. The best agreement was obtained with $k_9 = 10^8$ M^{-1} s^{-1} and $k_1 = 10^{10}$ M^{-1} s^{-1}, the other constants remaining the same. The results for the measurements at pH 12 and pH 11 are shown in Fig. 8. Agreement is only qualitative, suggesting that additional reactions with this additive may be important, but the general pattern of the reaction and the change of quantum yield with pH are consistent with the mechanism.

The quantum yield in the presence of potassium ferricyanide and methyl viologen reached a limiting value less than 1 at pH 12, which suggests deactivation by the additive. To be effective at pH 12, deactivation must take place at the $(C_5O_5^{2-}...OH^-)^*$ complex rather than at the excited croconic dianion.

10. $(C_5O_5^{2-}...OH^-)^* + A \rightarrow C_5O_5^{2-} + OH^- + A$

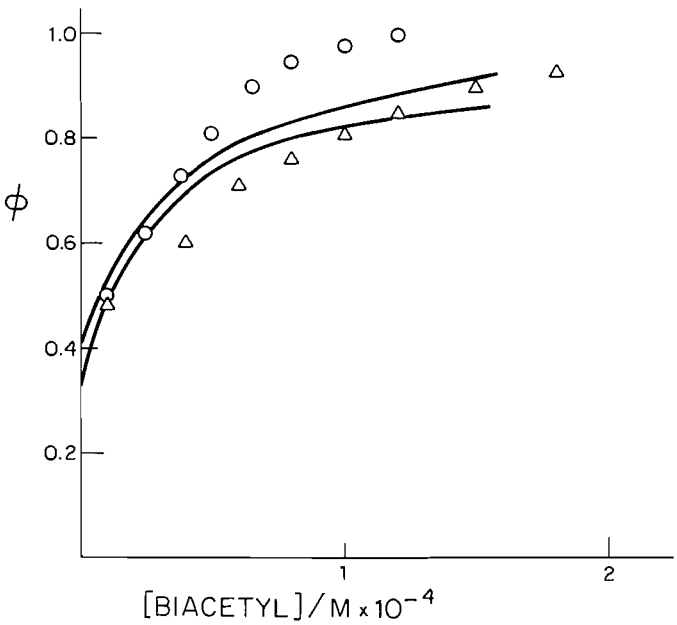

FIG. 8. The quantum yield for disappearance of croconate as a function of the concentration of biacetyl. $[C_5O_5^{2-}] = 2.3 \times 10^{-5}$ M. The solid lines are calculated values (see text). ○: pH 12; △: pH 11.

The fraction $(k_8 + k_9[A])/(k_7 + k_8 + k_9[A])$ in the second term in eq. [2] becomes $(k_8 + k_9[A])/(k_7 + k_8 + k_9[A] + k_{10}[A])$ and approaches the limit $k_9/(k_9 + k_{10})$ as the concentration of additive increases. The limit for potassium ferricyanide was 0.56 and was obtained at a concentration of 5×10^{-5} M^{-1} s^{-1}. For this additive the rate of reaction 9 is therefore slightly greater than for 4-nitrobenzylbromide. With methyl viologen the limiting quantum yield was observed at a concentration 10 times lower, 5×10^{-6} M, and the rate constant for reaction 9 would therefore be of the order of 5×10^{10} M^{-1} s^{-1}. Reaction 1 would likely be very fast as well but still would not make a significant contribution at pH 12. Such a large value for k_9 (or k_1) is reasonable considering the attraction of the positive ion towards the excited dianion and the excited hydroxyl ion complex.

The structure of the hydroxyl ion complex and the type of interaction involved in its formation are, of course, quite unknown. The spectrum of the dianion showed no change in basic solution, and interaction of the dianion and the hydroxyl ion in the ground state is probably unimportant. From studies of NMR spectra it was shown that the dianion was not hydrated in aqueous solution; only the undissociated acid gave evidence of hydration (19). The kinetic evidence clearly indicates reaction 6 is important but identification of the intermediate will require time-resolved experiments.

Further adjustment of rate constants or addition of new reactions to the mechanism was not attempted at this stage. The test of eq. [2] is sufficient to show that the mechanism, although oversimplified, gives a consistent picture of the type of reactions occurring on photolysis.

Polymerization of acrylamide

The rate of initiation of the polymerization of acrylamide is a measure of the rate of production of radicals in the solution. Polymerization occurred in slightly acid solutions and even in an aqueous solution of the monomer (pH 4.1) where the quantum yield for disappearance of croconate was not measurable, even in the presence of 4-nitrobenzylbromide. Polymerization is thus a very sensitive test for the presence of radicals. The rate of polymerization increased with increasing pH, achieved a maximum rate at pH 8, and then decreased in more basic solution. It may be concluded that reactions of the hydroxyl ion with the excited dianion or the intermediate complex do not lead to the formation of radicals. Reaction of the dianion with the additive, on the other hand, should produce radicals through electron transfer, reaction 3, and the quantum yield for this reaction is given by the following expression:

$$[5] \quad \Phi_3 = 2 \cdot \frac{k_1[A]}{(k_D + k_1[A] + k_6[OH^-])} \left[\frac{k_3}{(k_2 + k_3 + k_4[OH^-])}\right]$$

The product of these ratios, calculated using the rate constants in Table 6, is given in the last column in Table 4, where it may be compared with the quantum yield for initiation of radicals calculated from the quantum yield for polymerization and the rate constants for propagation and termination for the acrylamide polymerization. Taking into account the uncertainties in both calculation and measurement, the agreement between these two rates of initiation of radicals is reasonable and is convincing evidence that the electron transfer reaction produces radicals that have sufficient lifetime to diffuse into the solution. It is worth noting that one half of the value for the rate of formation of radicals by reaction 3 is very close to the initiation rate obtained for the rate of polymerization, particularly in the range of pH 7–10, suggesting that only one radical produced in reaction 3 may initiate polymerization. If only the radical formed by electron transfer to the acceptor, and not the croconate monoan-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

ion, were effective in polymerization, the lack of initiation of polymerization in the presence of ferricyanide and methyl viologen would be more readily explained.

Comparison with the photochemical reaction of rhodizonate dianion

Several similarities and differences are evident in the photochemical behaviour of these two oxocarbon anions. Both excited dianions undergo oxidation by electron transfer to a suitable acceptor. The efficiency of the process appears much larger for croconate where a primary quantum yield of 1 for disappearance of the dianion was obtained for certain additives, whereas the quantum yield for disappearance of rhodizonate in the presence of additives did not exceed 4×10^{-2}. The large quantum yield for loss of croconate, however, was observed only in basic solution and was the result of the synergistic effect of the additive and the hydroxyl ion. The photochemical reaction of rhodizonate was measured only in neutral solution because the thermal reaction in basic solution was too fast to allow concurrent photochemical measurements. The similarity in these observations is the loss of the dianion through reactions with hydroxyl ion. In the case of rhodizonate the reaction occurs in the dark, whereas with croconate photochemical excitation of the dianion is required to induce reaction.

The product of the thermal reaction of rhodizonate dianion in basic solution in the presence of oxygen was croconate dianion. Conversion of croconate to squarate occurred photochemically in strongly basic solution in the presence of oxygen. This reaction is a possible easy route to the formation of squaric acid.

Summary and conclusions

The main conclusions from the results of this kinetic study of the photochemical reactions of croconate dianion are (1) both electron acceptors and hydroxyl ion react directly with the excited croconate dianion; (2) both electron acceptors and hydroxyl ion react further with the intermediates formed in the primary interaction of each reactant; (3) radicals are produced and diffuse into the solution following the electron transfer and not following the reactions with hydroxyl ion.

M. P. MERRIN, D. L. HOOPER. R. J. LAFRANCE, R. SNOOKS, and K. VAUGHAN. Can. J. Chem. **70**, 144 (1992).

The synthesis of a new series of 1-aryl-3-aryloxymethyl-3-methyltriazenes (**2**) has been achieved by the reaction of the acetoxymethyltriazene (Ar-N=N-NMe-CH_2OAc) with the appropriate phenol in dry chloroform solution. Triazenes of type **2** are also formed by reaction of the acetoxymethyltriazene with the sodium phenolate, generated by reaction of the phenol with sodium hydride in dry chloroform, but under these conditions a second product is formed, which has been identified as an isomer of **2**. The structure of the second product has been elucidated by spectroscopic analysis to be the 1-aryl-3-(hydroxyaryl)methyl-3-methyltriazene (**3**). The formation of these two isomeric products is accounted for by the ambident nature of the nucleophilic phenolate ion in the displacement of the acetoxy leaving group. The mass spectra of all the triazenes of type **2** exhibit a fairly intense peak at M − 102, which is suggested to arise from a novel intramolecular rearrangement. Two examples of the triazenes of type **2** have been tested for antitumour activity on the NCI tumour panel and have shown statistically significant differential sensitivity in several cell lines. Preliminary investigation of the stability of these triazenes in physiological-pH buffer suggests that they may have the appropriate chemical stability for pro-drug application in therapy.

Key words: triazene, synthesis, antitumour, phenol, spectroscopy, aryloxymethyltriazene, prodrugs.

M. P. MERRIN, D. L. HOOPER, R. J. LAFRANCE, R. SNOOKS et K. VAUGHAN. Can. J. Chem. **70**, 144 (1992).

On a effectué la synthèse d'une nouvelle série de 1-aryl-3-aryloxyméthyl-3-méthyltriazènes (**2**) par la réaction, en solution dans du chloroforme sec, de l'acétoxyméthyltriazène (Ar-N=N-NMe-CH_2OAc) avec le phénol approprié. Le réaction de l'acétoxyméthyltriazène avec le phénolate de sodium, généré par une réaction du phénol avec l'hydrure de sodium dans du chloroforme sec, conduit aussi à la formation des triazènes du type **2**; toutefois, dans ces conditions, il y a formation concomitante d'un autre produit que l'on a identifié comme un isomère du produit **2**. Sur la base d'analyse spectroscopiques, on a établi que le second produit est le 1-aryl-3-(hydroxyaryl)méthyl-3-méthyltriazène (**3**). On explique la formation de ces deux produits isomèriques par la nature ambidente de l'ion phénolate nucléophile dans la réaction de substitution du groupement acétoxyle nucléofuge. Les spectres de masse des triazènes de type **2** présentent tous un pic assez intense à M − 102 qui proviendrait d'un nouvel exemple de réarrangement intramoléculaire. On a évalué deux des triazènes de type **2** pour leur activité antitumorale sur un ensemble de tumeurs NCI; ces produits présentent des sensibilités différentielles statistiquement significatives dans plusieurs lignées de cellules. Une étude préliminaire de la stabilité de ces triazènes dans des tampons à pH physiologique suggère qu'ils ont peut-être la stabilité chimique appropriée pour être utilisés comme pré-médicaments.

Mots clés : triazène, synthèse, antitumorale, phénol, spectroscopie, aryloxyméthyltriazène, pré-médicament.

[Traduit par la rédaction]

Introduction

1-Aryl-3,3-dimethyltriazenes (**1***a*) are an important class of antitumour agents (1), which have been shown to undergo metabolic activation to the short-lived 3-hydroxymethyltriazene (**1***b*) (2). Although the hydroxymethyltriazene (HMT) is inherently unstable under physiological conditions, it has been suggested (3) that a stable derivative of the HMT might be a suitable pro-drug for the active metabolite of the dimethyltriazene, the monomethyltriazene (Ar-N=N-NHMe), formed by loss of formaldehyde from **1***b*. Several derivatives of the HMT have been reported and some do indeed

have antitumour activity in animal models. Examples of such derivatives are the chemically reactive 3-acetoxymethyltriazenes (**1***c*; "acetates") and the relatively inert 3-methoxymethyltriazenes (**1***d*) (4).

The chemical reactivity of the acetates (**1***c*) has been employed in the synthesis of a variety of other derivatives. The acetates react smoothly with methanol to afford the methoxymethyltriazenes (**1***d*) (5) and with azide ion in aqueous acetone to afford the 3-azidomethyltriazenes (**1***e*) (6). Although the acetates do not react with neat thiols (5), we have recently shown that they react with a sodium thiophenolate in anhydrous dimethylformamide to afford a series of 1-aryl-3-arylthiomethyl-3-methyltriazenes (**1***f*) (7). In this paper we report an extension of this synthetic approach to the oxygen analogues, the 3-aryloxymethyltriazenes (**2**), which may represent a significant development in the search for a suitable pro-drug for the active metabolite of the anti-tumour dimethyltriazene.

Experimental

All solvents were purchased from BDH Chemicals Ltd. and were dried over molecular sieves type 4A except for acetone, which was dried over anhydrous sodium sulphate. In some instances the solvents were distilled prior to use. For some reactions chloroform was washed repeatedly with distilled water, dried overnight over anhydrous sodium sulphate, distilled, and stored in the dark.

Melting points were determined using a Reichert hot-stage microscope and are uncorrected.

Infrared spectra were obtained using a Perkin–Elmer 299 infrared spectrophotometer, calibrated against polystyrene film. Samples were prepared in $CHCl_3$ solution and the IR's run using matched KBr cells (Perkin–Elmer) with a $CHCl_3$ reference.

UV maxima were determined in a 2:1 mixture of 0.1 M phosphate buffer (pH 7.5) and isopropanol.

^{13}C (at 90 MHz) and ^1H NMR (at 361 MHz) spectra were acquired on the Nicolet 360 NB spectrometer of the Atlantic Region Magnetic Resonance Centre at Dalhousie University. Sweep widths for ^{13}C were 20 000 Hz and, for ^1H, 4000 Hz. The spectra were obtained at 20°C in deuterochloroform. Chemical shifts in ppm were measured relative to tetramethylsilane (1% internal standard).

Positive ion mass spectra were obtained from the MS service facility of Dalhousie University using a Consolidated Electrodynamics Corporation CEC 21-104 mass spectrometer. The operating parameters were as follows: source temperature 130–145°C; direct probe temperature 75–130°C; accelerating voltage 800 V; ionization voltage 70 eV; scan rate 6 dec s^{-1}.

1-Aryl-3-aryloxymethyl-3-methyltriazenes (2a–h)

Method A

The appropriate 1-aryl-3-acetoxymethyl-3-methyltriazene (**1***c*) (1.3 mmol) prepared by the method of Hemens *et al.* (4) was dissolved in dry chloroform (10 mL). A 50% excess of the phenol (1.9 mmol) was added and the mixture refluxed for 2–18 h depending on the desired product. With phenol itself, the mixture was not heated, but stirred for 24 h. The chloroform was removed under vacuum and the resulting oil washed with anhydrous ether. This usually resulted in the precipitation of the product, which was filtered off, dried, and recrystallized from a suitable solvent. Where

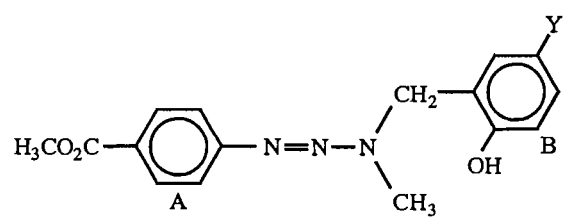
the product was an oil, it was chromatographed on silica gel with hexane/ether prior to recrystallization.

Method B

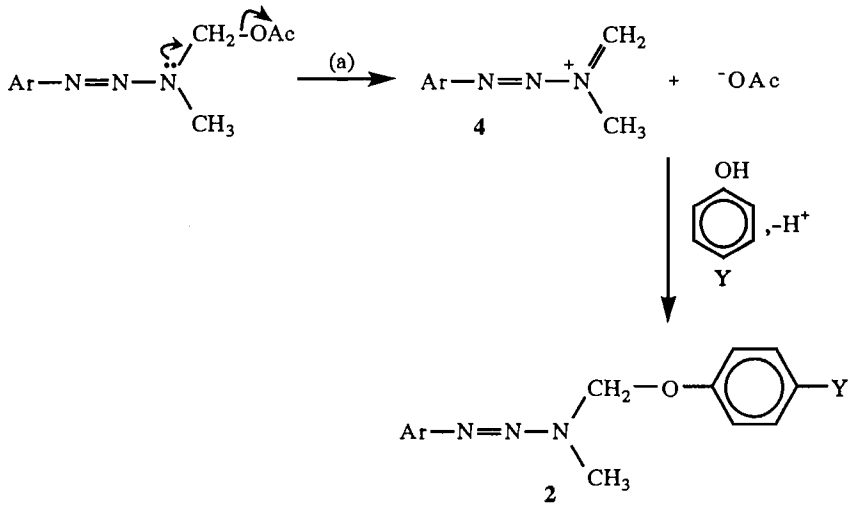
As in method A the 1-aryl-3-acetoxymethyl-3-methyltriazene was dissolved in chloroform. Sodium hydride 60% oily suspension (0.08 g) was placed in a round-bottomed flask fitted with a rubber septum and washed with dry petroleum ether (3 × 10 mL) to remove the oil, affording clean sodium hydride (2.0 mmol). The appropriate phenol (1.9 mmol) was dissolved in anhydrous chloroform and added carefully to the sodium hydride, provision being made for the safe egress of the hydrogen generated by the reaction. The resulting sodium phenolate solution was filtered to remove unreacted sodium hydride and added to the acetoxy methyltriazene solution and refluxed for 2–2½ h. Subsequent work-up was the same as for method A. Column chromatography of the reaction products of method B yielded a second product, identified as **3***a–c*, in addition to the main product (**2***c*, *b*, and *e*).



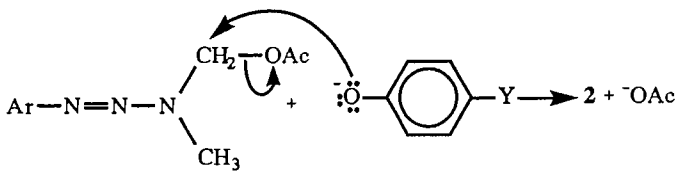
3*a* Y = H
3*b* CH_3
3*c* Br

In both methods the progress of the reaction was followed by TLC using 3:3:1 petroleum ether/ether/chloroform as solvent.

The physical data and yields for the compounds **2***a–h* are shown in Table 1, and those for compounds **3***a–c* in Table 2.[13]C and [1]H NMR shifts are presented in Tables 3–6. The relative intensities



SCHEME 1



SCHEME 2

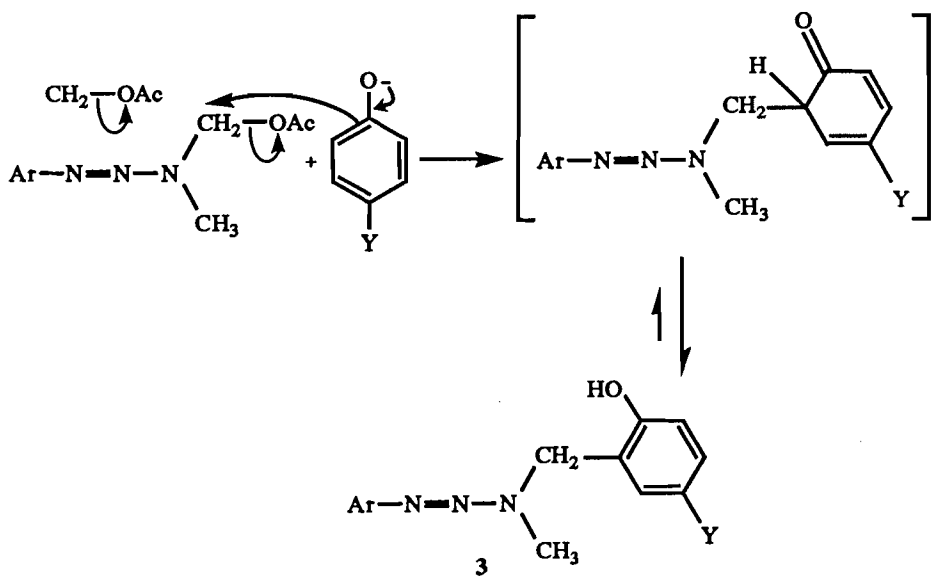
of the mass spectral peaks for compounds **2***a–h* are shown in Table 7, and for compounds **3***a* and **3***c* in Table 8.

Elemental analyses were performed on three of the aryloxymethyltriazenes by Canadian Microanalytical Service Ltd., Delta, British Columbia, and these assays are shown in Table 9.

Results and discussion

After the successful synthesis of the 3-arylthiomethyltriazenes (**1***f*) (7), it was regarded as important to prepare the *O*-aryl analogues (**2**), the objective being to develop a triazene pro-drug with the therapeutic advantages of the hydroxymethyltriazene but with a more useful half-life. The *S*-aryl derivatives (**1***f*) were found to be less reactive than the hydroxymethyltriazenes (**1***b*) under similar conditions. If the stability of these compounds depended to some extent on the leaving-group ability of -S-Ar, then comparison of the pK_a's of substituted phenols (pK_a = 7.15 for *p*-NO_2, 10.21 for *p*-OMe, and 9.98 for phenol itself) and thiophenol (7.8) suggests that an -O-Ar substituent should afford triazenes with hydrolysis profiles ranging from slightly faster to substantially slower than that of the *S*-aryl compounds. The appropriate substituted phenols are more readily available than the corresponding thiophenols, enabling us to examine a wider range of compounds to determine how leaving-group ability affects the hydrolysis rates. A further consideration was to eliminate the unpleasantness of the thiophenol, both as a reagent for synthesis and as a possible by-product of clinical treatment.

Simple replacement of a thiophenol with a phenol, using



SCHEME 3

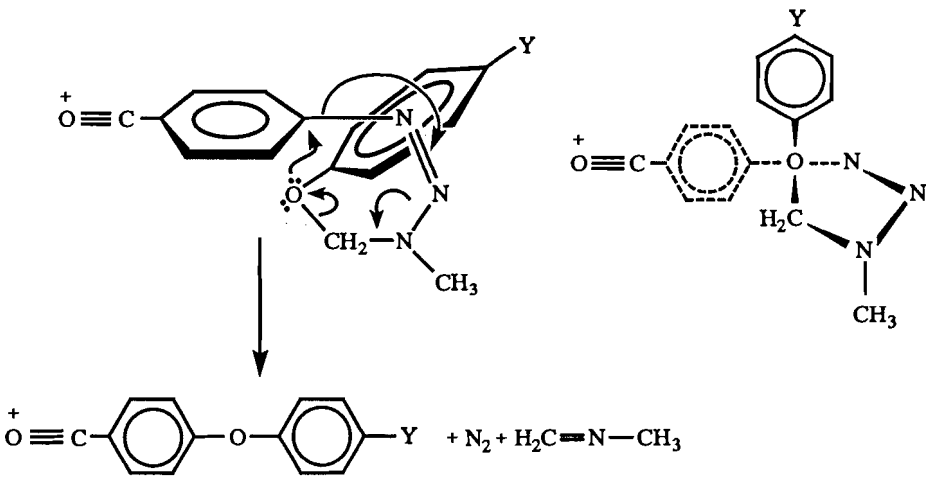

SCHEME 4

the methodology outlined in our previous report (7), was unsuccessful, the desired product being undetectable in the reaction mixtures. It turned out that a change of solvent was required to effect the desired substitution and, in some cases, the initial generation of a phenolate ion with sodium hydride was found to be unnecessary.

Using chloroform as solvent instead of dimethyl formamide enabled us to prepare the desired compounds in yields ranging from 8.5 to 78%. In two cases the generation of the phenolate ion with sodium hydride prior to reaction with the acetoxymethyltriazene (**1***c*) gave the best yields of the 1-aryl-3-aryloxymethyl-3-methyltriazenes (**2***b* and **2***h*).

It is noteworthy that in the reactions using sodium hydride, where the reaction time was extended from 2 to 18 h, a second product, the 1-aryl-3-(hydroxyaryl)methyl-3-methyltriazene (**3***a–c*), was formed. The low yields obtained by this method may be due to the formation of dichlorocarbene generated by refluxing chloroform in the presence of the base phenoxide ion, but there is no direct evidence to support this hypothesis.

The formation of **3** under these conditions could be due to a rearrangement of **2**, but so far we have been unable to produce **3** from pure **2** under the conditions of the reaction. A more likely explanation for the formation of the isomers **2** and **3** is as follows: The formation of the 3-aryloxymethyltriazenes (**2**) by method A is presumed to arise by an S_N1 mechanism as set out in Scheme 1. The initial step (a), in which the iminium ion (**4**) arises by dissociation of the acetate, is analogous to previously reported reactions (5, 6) and is more likely to occur in reaction with the neutral nucleophile, the phenol itself. Reaction of the phenol with the iminium ion and loss of a proton affords the product **2**.

However, in method B, the phenolate ion is generated prior to reaction with the acetate and it is possible that the alternative S_N2 pathway, Scheme 2, is preferred in this case. The formation of the 3-(hydroxyaryl)methyltriazenes (**3**), the isomers of **2**, lends support to this hypothesis and follows logically from the ambident nature of the nucleophilic phenolate ion. A suggested mechanism for the formation of **3** is shown in Scheme 3.

The identification of the 3-aryloxymethyltriazenes **2** and the isomeric 3-(hydroxyaryl)methyltriazenes **3** is based on elemental analyses, mass spectra, and IR and NMR spectroscopic data. The IR spectra of the ethers **2** show that the ester group attached to ring A is retained in the product; those of the isomers **3** also show the OH band at ca. 3400 cm^{-1} due to the phenolic substituent. In the NMR spectra, the triazene *N*-methyl resonance exhibits slightly different shifts for **2** (at ca. 3.30 ppm) than for **3** (at ca. 3.68 ppm). The N-CH_2 signals are distinctly different at ca. 4.80 ppm in **3** and in the range 5.66–5.84 ppm in **2**; the downfield shift is consistent with the deshielding effect of the O atom adjacent to the N-CH_2 group in **2**. Other features of the ^1H NMR spectra are entirely unpredictable.

The structures of **2** and **3** are also supported by the ^{13}C NMR data in Tables 5 and 6. The most significant difference is in the N-CH_2 signal at ca. 83 ppm in **2** and ca. 50 ppm in **3**. The ^{13}C aromatic peaks were assigned by consideration of their coupled multiplicities, peak heights, and additive substituent shift correlation calculations (8).

The mass spectra of all the 1-aryl-3-aryloxymethyl-3-methyltriazenes (**2**) exhibited a fairly intense peak at M − 102, which caused some puzzlement. Comparison with the mass spectra of the *S*-aryl analogues (**1***f*) indicated that the structural requirement for this feature was an ester function on the 1-aryl end of the molecule. Re-examination of the accurate-mass measurements for the *S*-aryl analogues showed that the mass lost in this reaction was 102.0668, corresponding to the empirical formula $C_3H_8N_3O$ for the methyl ester, and 116.0825 corresponding to $C_4H_{10}N_3O$ for the ethyl ester. These cannot be lost as single fragments, and the remaining charged species must arise from some kind of intramolecular rearrangement. One possibility is shown in Scheme 4.

Conclusions

Any further development of these new aryloxymethyltriazenes **2** as potential antitumour agents depends on two factors: (a) the antitumour activity; and (b) appropriate chemical stability. Two compounds of this series **2***e* and **2***h* have been subjected to screening on the investigational in vitro disease-oriented primary antitumour screen of the National Cancer Institute, Bethesda, Maryland. This screen consists of over 60 tumour cultures and each tumour type is tested with five tenfold dilutions of the drug candidate. Both com-

pounds tested have shown statistically significant differential sensitivity in the following cell lines: leukemia subpanel, renal subpanels, colon subpanels, and non-small lung panel. These results will be reported in more detail in an appropriate journal at a later date.

The 3-aryloxymethyltriazenes show a wide range of chemical stability depending on the nature of the substituent Y in the aryloxy moiety. The *p*-nitrophenyloxymethyltriazene (**2***h*) decomposed rapidly in phosphate buffer solution at pH 7.5. Measurement of the rate of this relatively fast reaction was made possible by following the growth of the absorbance at 400 nm in the UV spectrum arising from the *p*-nitrophenolate ion leaving group released into the buffer, to give a half-life of ca. 1 min for the initial decomposition to the hydroxymethyltriazene. In contrast, the *p*-bromophenyloxymethyltriazene (**2***e*) appeared not to decompose at all under identical conditions, but instead this triazene precipitated out of solution before any decomposition occurred. A more detailed study of the pH-dependent hydrolysis of these 3-aryloxymethyltriazenes (**2**) in various buffer media will be described in the next paper in this series.

Charge transfer and electron transfer processes in biologically significant systems. 1. Charge transfer complex formation between 1,3,5-trinitrobenzene and *N,N*-dimethyl-3,4-di-*O*-methyldopamine, a dopamine analogue

JULIAN M. DUST

Department of Chemistry, Sir Wilfred Grenfell College, Corner Brook, Nfld., Canada A2H 6P9

Received June 20, 1991

JULIAN M. DUST. Can. J. Chem. **70**, 151 (1992).

The interactions of *N,N*-dimethyl-3,4-di-*O*-methyldopamine, **1**, a structural analogue of the important neurochemical, dopamine, with 1,3,5-trinitrobenzene (TNB) were studied primarily by ^{1}H nuclear magnetic resonance (nmr). The dopamine analogue, a donor, forms a charge transfer complex with TNB, a model acceptor, in $CDCl_3$ and CD_3CN. Equilibrium constants were determined from the ^{1}H nmr charge transfer induced chemical shift changes. The results are discussed in terms of the probable type of donation from the amine, **1**, to TNB ($n \rightarrow \pi^*$ versus $\pi \rightarrow \pi^*$), comparison with dopamine, and with regard to possible charge transfer interactions in molecular receptors.

Key words: *N,N*-dimethyl-3,4-di-*O*-methyldopamine, charge transfer complex, equilibrium constant.

JULIAN M. DUST. Can. J. Chem. **70**, 151 (1992).

Utilisant principalement la RMN du ^{1}H, on a étudié les interactions entre le 1,3,5-trinitrobenzène (TNB) et la *N,N*-diméthyl-3,4-di-*O*-méthyldopamine (**1**), un analogue de la dopamine, un produit neurochimique important. En solution dans le $CDCl_3$ et dans le CD_3CN, l'analogue de la dopamine, un donneur, forme un complexe de transfert de charge avec le TNB, un accepteur modèle. On a déterminé les constantes d'équilibre à partir des changements dans les déplacements chimiques induits par le transfert de charge. On discute des résultats en termes du type probable de don d'électrons de l'amine **1** vers le TNB ($n \rightarrow \pi^*$ vs. $\pi \rightarrow \pi^*$), par comparaison avec la dopamine et en fonction des interactions possibles de transfert de charge dans les récepteurs moléculaires.

Mots clés : N,N-diméthyl-3,4-di-*O*-méthyldopamine, complexe de transfert de charge, constante d'équilibre.

[Traduit par la rédaction]

Introduction

A unifying concept in pharmacological studies is that of the receptor (1), a site on a muscle, nerve-ending, etc. at which specific bioactive agents can bind. If the bioactive agent or drug initiates a physiological response, such as the contraction of a muscle, either directly or via a transducer molecule (2), then the original bioactive agent is termed an agonist, whereas an antagonist binds with the receptor (or with an adjacent site that affects the conformation of the receptor) without producing the biological response.

Overall, the process can be visualized as an equilibrium (eq. [1]) between the agonist/antagonist (A) and the receptor site (R) to produce an equilibrium concentration of the bound bioactive agent (R–A):

[1] $\quad R + A \rightleftharpoons R\text{–}A$

The equilibrium may then be characterized by a binding constant, $K_{binding}$. Considerable progress has been made in quantifying the number, locations, and kinds of different receptors through binding constant measurements (3–5).

More importantly, the specific interactions involved in the binding of a given bioactive agent with a receptor have not always been fully elucidated. One approach to the problem has been that of "mapping" the receptor site, through the combination of computer modelling and series of binding studies using bioactive agents of similar structure, notably those that contain the functions associated with biological activity and, so, constitute the pharmacophore. These receptor mapping studies have emphasized the importance of the steric fit of the bioactive compound into the receptor site (6).

A somewhat different approach has come from the correlation of the bioactivity with the structure of series of structurally related drugs, using extended Hammett (Hansch) treatments (7, 8). Ariens (9), among others, has generalized such quantitative structure–activity relationships (QSAR's) as follows:

[2] $\quad \log(\text{biological response}) = a + b + c + d + \text{constant}$

where a is a lipophilic (hydrophobic) parameter, b is an electronic (substituent) parameter, c is a steric parameter, and d is a term that encompasses any other physically meaningful parameter, such as the ability to form hydrogen bonds (10). The most commonly used parameters for a, b, and c are $\log P_{oct}$, $\sigma(\sigma^+,\sigma^-)$, and E_s, respectively. P_{oct} is the partition constant between octanol and water for each member of the series of structurally related drugs (i.e., members of the pharmacophoric constellation). To give only a few examples of the efficacy of the approach, the binding of bioactive compounds with proteins (11) and cells (12) has been correlated and correlations between biological response and these parameters for antimalaria drugs (13) and anaesthetics (14) have been demonstrated.

Interestingly, among the interactions possible between the pharmacophore and the receptor, charge transfer (CT) complexation (15) has received relatively little attention (16). This is all the more striking in that CT complexation has been a well-known interaction since the early discoveries of Benesi and Hildebrand (15*a*), through the pioneering work of Briegleb (15*b*), and the valence-bond and molecular orbital descriptions of Mulliken (15*c*) and Dewar and Lepley (15*d*), respectively. For a pharmacophore that has begun the process of "docking" at the receptor site, CT complexation may represent an important binding interaction, a possible d-term interaction (eq. [2]).

The importance of CT interactions to biological systems has been reviewed recently (17). Among the recent literature, however, can be found examples that illustrate the

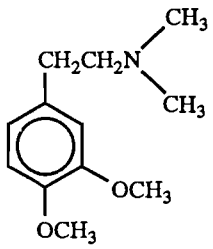
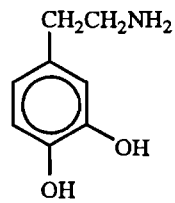
range and significance of CT complex (CTC) formation, including the correlation of carcinogenicity of 5-methylchrysene (as compared to isomeric methylchrysenes) with the disorder in the stacking of the 5-methylchrysene–1,3,5-trinitrobenzene (TNB) complexes, as shown by X-ray crystallography and molecular orbital (MO) calculations (18). CT complexation provides the basis for spectrophotometric assays for a variety of penicillins (19) and other drugs (20). CT complexation has also been found for amino acids and dimethoxybenzenes interacting with a highly electron-deficient synthetic molecular receptor (21). Evidence has recently been reported for the CT complexation of indoles with the acceptor 1-(2,4,6-trinitrophenyl)propan-2-one (22).



1



2

In the present article, we present evidence for the formation of CTC between *N*,*N*-dimethyl-3,4-di-*O*-methyldopamine (*N*,*N*-dimethyl-3,4-dimethoxyphenylethylamine, **1**), a dopamine analogue, and TNB, as a biophysical probe. Dopamine, **2**, is an important neurochemical, a precursor of noradrenaline; its absence in the neurosystem is implicated in Parkinson's disease (23) and cocaine addiction (23*c*). The information derived from the present in vitro study will be discussed in terms of the probable type of donation that occurs from donor, **1**, to acceptor, TNB ($n \rightarrow \pi^*$ versus $\pi \rightarrow \pi^*$), the possible bearing the results have on drug–receptor interactions, and, particularly, the extension of the conclusions to dopamine, itself.

Results

^{1}H nuclear magnetic resonance (nmr) studies

The three equivalent aromatic protons of TNB appear as a singlet at ca. 9 ppm in $CDCl_3$, CD_3CN, or $(CD_3)_2SO$. Addition of an excess of the amine, **1**, to a solution of TNB (in $CDCl_3$ or CD_3CN) causes the TNB singlet to shift to higher field. In $(CD_3)_2SO$ no detectable change in peak position or line shape could be seen. No new peaks are observed. The 8.6–5.0 ppm region of the spectra, where the protons of a trinitrocyclohexadienate moiety of anionic σ-adducts (Meisenheimer adducts) typically resonate (24), is clear of signals. Further, the TNB singlet is relatively sharp, as are the upfield peaks assignable to **1** (even in $(CD_3)_2SO$), indicating that electron transfer, to yield paramagnetic species like radical anions and cations, has not occurred (Fig. 1).

The change in chemical shift of the TNB singlet may be defined as Δ, that is, the difference in chemical shift between free TNB (δ_{TNB-f}) and the averaged shift of free and complexed TNB (δ_{TNB-av}). Hence,

$$[3] \quad \Delta = \delta_{TNB\text{-}f} - \delta_{TNB\text{-}av}$$

The chemical shift averaging is a result of a fast equilibrium

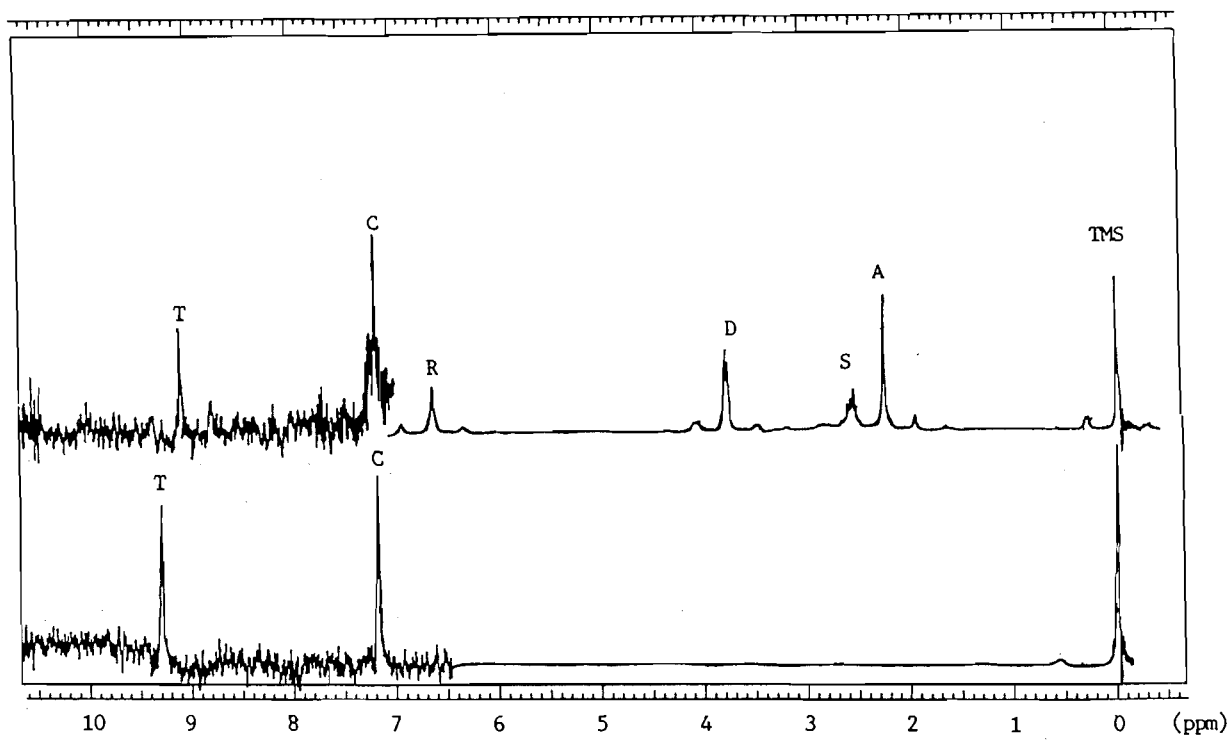


FIG. 1. Typical ^{1}H nmr spectra ($CDCl_3$ solvent). The region from 10.5 to ca. 7 ppm was scanned at a higher amplitude (factor of 100 greater) than that used for the upfield region. The lower spectrum shows the signals for TNB (T), $CHCl_3$(C), and tetramethylsilane (TMS). The top spectrum is that recorded after the addition of a 60-fold excess of **1**. The signals for **1** are labelled as follows: ring H's (R), 3,4-CH_3O's (D), -CH_2CH_2- (S), and -$N(CH_3)_2$ (A).

[a]Defined by eq. [3].
[b]The regression equation for the line is $\Delta/[\mathbf{1}]_0 = -1.18\,\Delta + 0.564$; $K_{CT} = 1.18$ L mol^{-1}, $\Delta_0 = 0.480$ ppm. $r = 0.996$.

(on the nmr time scale) between the free TNB and that bound in the CTC:

[4] $\mathbf{1} + TNB \rightleftharpoons \mathbf{1}$–TNB

Consequently, the upfield shift of the TNB singlet upon introduction of **1** into the system is diagnostic of formation of a CTC in which TNB accepts electron density from **1** (eq. [4]). In this context, the lack of detectable change in peak position with increasing concentration ratio of **1** to TNB in $(CD_3)_2SO$ (DMSO) as solvent suggests that the CTC, if formed, is formed in a concentration lower than the detection limit imposed by the nmr study. An alternative possibility is that either donor or acceptor or both interact more strongly with DMSO than with one another; this specific interaction (*vide infra*) may obscure any CTC formation between **1** and TNB in DMSO.

The change in chemical shift, as a function of the concentration of added **1** (Tables 1–6), was plotted according to the Scatchard equation for nmr data (25):

[5] $\Delta/[\mathbf{1}]_0 = -K_{CT}\Delta + K_{CT}\Delta_0$

where Δ refers to the change in chemical shift in the probe molecule, TNB, as defined above, $[\mathbf{1}]_0$ is the initial added concentration of *N*,*N*-dimethyl-3,4-di-*O*-methyldopamine, which is always present in excess, and K_{CT} is the equilibrium constant for CTC formation. Δ_0 represents the chemical shift change for the TNB probe at that point at which TNB is totally complexed.

A representative plot of the data for each solvent, $CDCl_3$ and CD_3CN, is shown in Fig. 2. All plots gave linear regression lines with satisfactory to good correlation coefficients (0.94–0.99). The regression equation for each separate experiment is given along with each table of data (Tables 1–6). The mean values for K_{CT} obtained from the K_{CT} values determined in the individual experiments are 1.06 ± 0.1 L mol^{-1} in $CDCl_3$ and 0.66 ± 0.24 L mol^{-1} in CD_3CN.

Solvents may interact preferentially with either the donor or the acceptor (26). No attempt has been made in the present study to correct for specific interactions between the

solvent and either of the interactants. It should be recognized, however, that such specific interactions have previously made comparison of gas-phase and solution data on CTC difficult (27). Consequently, the equilibrium constants measured in this study, K_{CT}, should be viewed as apparent equilibrium constants.

Ultraviolent–visible (uv–vis) spectroscopic study

When the ^{1}H nmr sample that contained the highest concentration ratio of **1** to TNB (200:1) was transferred, without dilution, to a semi-micro 0.1-cm-pathlength cuvette and the uv–vis spectrum was obtained (in either solvent) the orange-yellow solution did not contain the characteristic two-band spectrum found for anionic (1:1) Meisenheimer adducts of TNB (24). Instead the spectrum consisted of a single diffuse absorbance at 350–400 nm in $CDCl_3$ and 370–420 nm in CD_3CN. Such broad spectral bands, which are not attributable to either separate interactant, are consistent with CTC formation (eq. [4]) (15, 17).

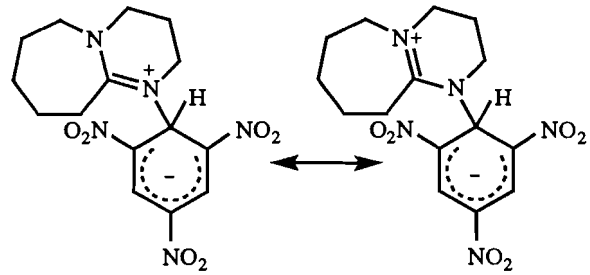
Discussion

1. The nature of the interaction

(a) Nucleophilic versus CT behaviour

Charge transfer complexes occupy one extreme in a continuum of interactions that may occur between electron-rich species and electron-poor aromatic and heteroaromatic systems, exemplified by TNB. In charge transfer complexes, partial electron density is transferred from the HOMO of the donor to the LUMO of the acceptor. If a full electron is transferred, discrete species, namely the radical (D·) or the radical cation of the donor ($D^{+\cdot}$) and the radical anion of the acceptor ($TNB^{-\cdot}$), may form, giving rise to a radical ion pair. Transfer of a pair of electrons, however, with concomitant bonding of the donor to the acceptor produces an anionic Meisenheimer complex (24).

Interestingly, recent molecular orbital calculations (MNDO) have suggested that CT complexation precedes Meisenheimer adduct formation in nucleophilic aromatic substitution (S_NAr) reactions (28), in agreement with kinetic results involving nitrogen-centred nucleophiles in nonpolar solvents (29). Extensive work has also been done on polynitroaromatic systems with OH^- ion (30) in which CTC, radical anion – radical pairs, and Meisenheimer complexes have all been invoked as necessary intermediates. A previous study of the interactions of dopamine and 3,4-di-*O*-methyldopamine, **3**, with TNB in dimethyl sulfoxide (DMSO) demonstrated the presence of Meisenheimer complexes in these related reaction systems (*vide infra*) (31). Finally, Forlani and Cimarelli reported the observation and *isolation* of a zwitterionic adduct, **4**, formed in the reaction of the tertiary amine, 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU), with TNB in toluene (32).



4

Clearly, in the present system only a CTC forms. There is no evidence from either the ^{1}H nmr or uv–vis spectroscopic studies for formation of radical ions or of a Meisenheimer adduct from **1** and TNB. The difference in reactivity between simple, tertiary amines like triethylamine (33) or **1** in contrast to DBU appears to lie, at least partially, in the ability of the DBU moiety of **4** to delocalize the positive charge of the ammonium ion centre, just as the trinitrocyclohexadienate portion of the complex delocalizes the negative charge. Steric hindrance to bond formation between **1** and TNB (as compared to DBU and TNB) may also account for the difference in reactivity between these two systems.

(b) Stoichiometry of the CTC

In the present study the Scatchard plots (eq. [5], Fig. 2) were found to be linear over the range of concentration ratios studied (200:1–25:1). Linearity of such plots has been taken as indicative of the presence of 1:1 CTC alone (34). Concave (upwards) plots have been found in some systems and these results were attributed either to the presence of CTC of higher stoichiometry (2:1, 3:1 etc.) (34) or to an Additional Unspecified Shielding (AUS) effect on the ^{1}H nmr spectra (35). The latter interpretation presumes that the chemical shift of free acceptor (TNB) and of totally complexed acceptor (**1**–TNB) could be different in the presence of donor, **1**, as compared to pure solvent, i.e., Δ would be incorrectly represented in the plot.

Further, in a recent article, Foster and co-workers demonstrated a Scatchard plot that increased to a maximum and then levelled off (22). This anomalous behaviour was attributed to self-association of the indoles used in that study.

It should be emphasized that for those plots that demonstrated only satisfactory correlation coefficients (r ca. 0.94), the points showed only scatter and no regular curvature could be seen. On these grounds, the CTC formed between **1** and TNB appears to have a 1:1 stoichiometry and the interaction is free from termolecular complexation or self-association of the donor, **1**.

(c) Classification of the type of partial electron donation

N,N-Dimethyl-3,4-di-*O*-methyldopamine can act as a partial electron donor in two ways: as an $n \rightarrow \pi^*$ donor via the amine function and as a $\pi \rightarrow \pi^*$ donor via the aromatic ring. This distinction between types of interaction in CT complexation was advanced previously (36), although assignment of one particular mode of donation from a given donor species has been problematic (37).

It should be noted that K_{CT} for *N,N*-dimethylaniline in chloroform (19.7°C) was ascribed a value of 1.3 L mol^{-1} (36), which is in reasonable agreement with the value found for the complex formed by **1** and TNB, i.e., **1**–TNB. There is a declining trend in the values of equilibrium constants for CT complexation between TNB and the following anilines: *N,N*-dimethyl-2,6-dimethylaniline, *N,N*-dimethylaniline, and *N,N*-dimethyl-2-methylaniline. The trend was explained on the basis of the varying ability of the aromatic ring to transfer electron density to TNB. Thus, the equilibrium constants decrease in magnitude in going from *N,N*-dimethylaniline to *N,N*-dimethyl-2-methylaniline, as would be anticipated if the introduction of the *ortho* methyl group leads to steric inhibition of delocalization of electron density from the amino nitrogen into the aniline ring and, thence, to the TNB ring in the complex. However, the steric inhibition of delocalization that would also be expected to apply to *N,N*-dimethyl-2,6-dimethylaniline is overwhelmed by the methyl inductive effect on the donor ability of the aromatic ring. Consequently, the equilibrium constant associated with CT complexation of *N,N*-dimethyl-2,6-dimethylaniline is larger than that found for *N,N*-dimethylaniline and larger still than that found for *N,N*-dimethyl-2-methylaniline (36). Consistent with the similarity in the magnitude of K_{CT} for *N,N*-dimethylaniline and **1** in complexation with TNB, the interaction of **1** with TNB may be $\pi \rightarrow \pi^*$, as found for *N,N*-dimethylaniline.

Some further support for this analysis can be found in the comparison of the magnitude of K_{CT} for **1**–TNB with the equilibrium constants for the complexation of TNB with a series of methyl-substituted benzenes, namely, mesitylene, durene, and pentamethylbenzene. In CCl_4 at 33.5°C the values of K_{CT} were determined to be 0.797 (mesitylene–TNB), 1.32 (durene—TNB), and 1.93 (pentamethylbenzene–TNB) L mol^{-1}. The values of K_{CT}, for these aromatic donors which are clearly unable to act in the $n \rightarrow \pi^*$ fashion, are again notably similar to that found for K_{CT} for CTC formation with **1** in $CDCl_3$ at 33.5°C (i.e., 1.06 L mol^{-1}) (25*c*). It should be noted that K_{CT} values are generally larger in CCl_4 than in $CDCl_3$ (15, 37).

Based upon these comparisons, the CT interaction between **1** and TNB is tentatively assigned as $\pi \rightarrow \pi^*$. However, we cannot rule out the possibility that both forms of interaction (i.e., $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$) are operating in concert. Further evidence, including solid state nmr studies of the isolated complex and enthalpies and entropies of CTC formation, would be required for a more definitive assessment to be made.

A comment should be made concerning the trend found for the various solvents. The magnitude of K_{CT} declined from $CDCl_3$ to CD_3CN and, finally, to $(CD_3)_2SO$ where K_{CT} could not be measured, possibly due to specific interactions with the solvent. These results are in qualitative agreement with the generalization that CTC are essentially nonpolar in the ground state and are, therefore, stabilized in nonpolar solvents (15) or microenvironments.

2. Comparison with dopamine

The interactions of dopamine with TNB in DMSO solution were reported previously (31). Depending upon the degree of ionization of the hydroxyl groups (as a function of concentration and type of added base) a variety of Meisenheimer adducts were observed. In sequence, a nitrogen-bonded adduct was the first to be seen, followed by formation of a carbon-centred adduct, via attack of a ring carbon on TNB. Transient oxygen-centered adducts were postulated, but not observed.

Importantly, no CTC were found in the dopamine–TNB system in DMSO. This is in accord with the present study, where the CT interaction between the dopamine analogue, **1**, and TNB may be overwhelmed by specific interactions of the components with the $(CD_3)_3SO$ solvent.

However, the microenvironment of the receptor site may be relatively nonpolar. Hydrophobic interactions between a bioactive compound and the aqueous biological solution could force the bioactive compound into closer contact with a more nonpolar receptor site. In such a case, dopamine and other members of the series would be expected to bind to acceptor portions of the receptor much as **1** complexes with TNB.

We clearly recognize the importance of other interactions for dopamine, as compared to **1**, including hydrogen bonding of the phenolic OH groups of **2** with the receptor. In fact, 3,4-di-*O*-methyldopamine, **3**, which lacks these OH groups, is biologically active, although it does not affect the central nervous system as dopamine does (38). Nevertheless, CT complexation could be a general binding interaction for **2** and **3**, as well as **1**, and a suitable *d*-term in eq. [2].

In summary, *N,N*-dimethyl-3,4-di-*O*-methyldopamine, **1**, forms CTC with TNB, as a probe of biophysical interaction, in $CDCl_3$ and CD_3CN with K_{CT} values of 1.06 and 0.66 L mol^{-1}, respectively. Based upon comparison of the K_{CT} values with those found in related systems, the CT complexation is *probably* $\pi \rightarrow \pi^*$ in nature. Cooperative $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ interactions cannot be ruled out, however. The amine does not apparently form a CTC with TNB in $(CD_3)_2SO$. However, it is reasonable to conclude that dopamine, as well as **1**, could form CTC with suitable electron-deficient molecules (or moieties), particularly in low polarity solvents (or low polarity microenvironments, which may include receptor sites).

Experimental

General

3,4-Di-*O*-methyldopamine (3,4-dimethoxyphenylethylamine, Aldrich) was distilled; the fraction that boiled at 150–151°C at 9.0 Torr (1 Torr = 133.3 Pa) was collected and stored under N_2 at 10°C. *N,N*-Dimethyl-3,4-di-*O*-methyldopamine, **1**, was prepared by the Eschweiler–Clarke method (39). The purified yield was 46%; bp 120–130°C at 2.3–3.0 Torr (lit. (40)bp 85–90°C at 0.05 Torr). The colourless product, **1**, was stored under N_2 over 4Å molecular sieves at 10°C. In general, it was found necessary to redistill **1** immediately prior to use to obtain consistent results. 1,3,5-Trinitrobenzene (TNB, Eastman) was recrystallized thrice from benzene and once from ethanol, mp 124.5–125°C. $CDCl_3$, CD_3CN, and $(CD_3)_2SO$ (MSD) were allowed to stand over 4Å molecular sieves for 24 h and then used without further purification. The ^1H nmr

spectra were measured using a Varian EM-360 spectrometer operating at 60 MHz with a probe temperature of 33.5°C. Standard Wilmad PP-507 nmr tubes were used for all nmr experiments. The uv–vis spectra were recorded on a Beckman DU-8 spectrophotometer at ambient temperature (24 ± 3°C). Melting points were determined with a Fisher-Johns hotstage and the values reported are uncorrected.

The ^1H nmr experiments: preparation of solutions

Stock solutions of **1** in all solvents were prepared from weighed quantities of **1** in 1 mL volumetrics. Typically, **1** (376 mg, 1.80 mmol) was placed in a 1 mL volumetric flask and the flask then septum-capped, followed by flushing with dry N_2. Addition of $CDCl_3$ to the mark, via syringe, gave an initial stock solution (1.80 mol L^{-1}). A second stock solution was similarly prepared from **1** (451 mg, 2.16 mmol, 2.16 mol L^{-1}). Sequential dilution of the stock solution (0.5 mL in 1 mL volumetrics) gave concentration ratios of **1**:TNB ranging from 25:1 to 120:1. The same procedure was followed for CD_3CN and $(CD_3)_2SO$. The TNB stock solution (1.80×10^{-2} mol L^{-1}) consisted of TNB (19.2 mg, 4.50×10^{-5} mol) dissolved in N_2-purged solvent (5 mL).

A representative experiment

A sample tube contained 0.3 mL of the standard TNB solution in $CDCl_3$ and a drop of tetramethylsilane (TMS) as the internal shift standard. The initial spectrum of free TNB was recorded (0–10 ppm) and the chemical shift of the TNB singlet relative to TMS noted. A small quantity of the appropriate solution of **1** (0.3 mL) was injected into the septum-capped nmr tube via syringe and the spectrum rerecorded. The chemical shift of the averaged signal for free and complexed TNB were measured relative to TMS ($\delta_{TNB\text{-}av}$) (Fig. 1). The experimental data were plotted (Fig. 2) according to the Scatchard equation (25) (eq. [5]) to give the results reported above.

In an analogous fashion to the preparation of ergosterol peroxide from singlet oxygen, the preparation of its sulfur analog was attempted via the Diels–Alder addition of diatomic sulfur to ergosterol. Two of the recently reported methods for generating and trapping diatomic sulfur were employed as well as "activated" sulfur. Although the desired target was not obtained, several interesting steroidal products were isolated including 3,5-cyclo-6,8(14),22-ergostatriene (**12**), ergosta-5,7,22-trien-3-thiol (**13**), and ergosta-4,6,8(14),22-tetraen-3-one (**16**). Mechanistic aspects are discussed.

Key words: diatomic sulfur, ergosterol, sulfur analog of ergosterol peroxide, ergosta-6,22-dien-5a,8a-epidisulfide-3-ol, ergosterol peroxide, 3,5-cyclo-6,8(14),22-ergostatriene, ergosta-5,7,22-trien-3-thiol, ergosta-4,6,8(14),22-tetraen-3-one.

YOULA S. TSANTRIZOS, PATRICIA L. FOLKINS, JAMES F. BRITTEN, DAVID N. HARPP et KELVIN K. OGILVIE. Can. J. Chem. **70**, 158 (1992).

Faisant appel à une méthode similaire à celle utilisée pour la préparation du peroxyde de l'ergostérol à partir de l'oxygène singulet, on a essayé de préparer l'analogue sulfuré via une addition de Diels–Alder du soufre diatomique sur l'ergostérol. On a utilisé du soufre «activé» ainsi que deux des méthodes décrites récemment pour générer et pour piéger le soufre diatomique. Même si l'on n'a pas obtenu la molécule désirée, on a pu isoler de nombreux produits stéroïdaux intéressants, dont du 3,5-cyclo-ergosta-6,8(14),24-triène (**12**), de l'ergosta-5,7,22-triène-3-thiol (**13**) et de l'ergosta-4,6,8(14),22-tétraèn-3-one (**16**). On discute des aspects mécanistiques.

Mots clés : soufre diatomique, ergostérol, analogue sulfuré du peroxyde de l'ergostérol, ergosta-6,22-diène-5a,8a-épidisulfure-3-ol, peroxyde de l'ergostérol, 3,5-cyclo-ergosta-6,8(14),22-triène, ergosta-5,7,22-tyriène-3-thiol, ergosta-4,6,8(14),22-tétraèn-3-one.

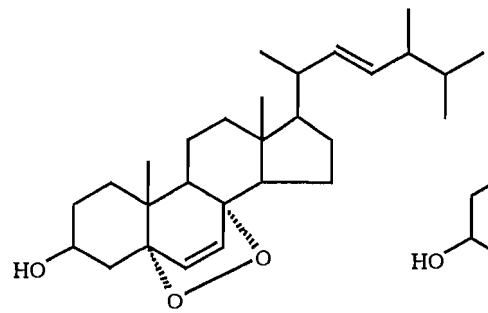
[Traduit par la rédaction]

Introduction

Ergosta-6,22-dien-5a,8a-epidioxy-3-ol (**1**), better known as ergosterol peroxide, was first isolated from the mycelium of *Aspergillus fumigatus* (1) and since then it has been found in several other fungi (2), lichens (3), and marine organisms (4). It exhibits a variety of biological effects including platelet aggregation (2*d*) and toxicity to plant tissues (5).

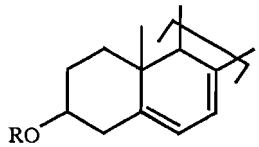
Recently, ergosterol peroxide was isolated from the liquid culture of *Phomopsis convolvulus* (6), a host-specific pathogen of the perennial plant *Convolvulus arvensis* (field bindweed) (7). This weed is classified as one of the most serious agricultural pests worldwide (8) that is hard to control at the present time. Ergosterol peroxide is a weakly phytotoxic compound that was found to be involved in the disease symptoms induced by *P. convolvulus* on field bindweed (6).

Sulfur analogs of biomolecules have been shown in the past to often mimic or even enhance the physiological effects of natural products. Most noteworthy are the examples of prostaglandin (9–11) and leukotriene (12) analogs, although several other sulfur derivatives of biologically important metabolites have been investigated (13). Hence, in hope of enhancing the herbicidal activity of ergosterol peroxide against field bindweed, studies towards the synthesis of ergosta-6,22-dien-5a,8a-epidisulfide-3-ol (**2**) were initiated.



1 **2**

Ergosterol peroxide (**1**) has been synthesized from ergosterol (**3***a*) both enzymatically (2*c*, 14) and chemically (15). The Diels–Alder addition of singlet $O_2(^1\Delta_g)$ to the ergosterol diene is believed to be involved in the photochemical synthesis of the peroxide (15*a*, 16). Hence, it was considered appropriate to attempt the same reaction with diatomic sulfur precursors in an effort to synthesize its sulfur analog (**2**).



3*a* R = H

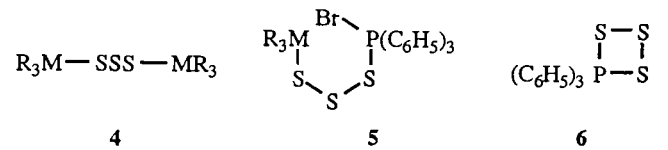
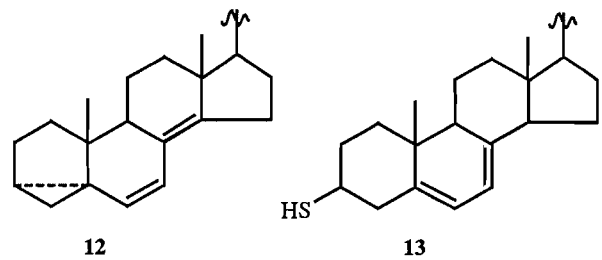
Results and discussion

A number of synthetically useful reagents for the generation of S_2 have been reported by Steliou *et al.* (17), Schmidt and Görl (18), and Harpp and MacDonald (19). In 1984, Steliou found that, in the presence of triphenyldibromophosphorane, organometallic trisulfides of general structure **4** deliver diatomic sulfur to a diene. The reaction mechanism could involve intermediate **5** or the formation of the four-membered ring intermediate **6**, analogous to that proposed in the phosphite-ozone generation of singlet oxygen (20). In 1987, the thermal rearrangement of the aromatic thioketone **7** was shown by Steliou *et al.* (17*b*) to generate S_2, which could be trapped by a number of dienes in high yield. Thioketone **7** is formed *in situ* from 2,2′-dibenzoylbiphenyl **8** (21), thiane **9**, and BCl_3. It has been proposed that a rearrangement takes place via intermediate **10**, which delivers S_2 to dienes (Scheme 1) (15*b*).[3]



When the synthesis of the thioketone (**7**) was carried out in the presence of ergosterol (**3***a*) the main compounds isolated were 3,5-cyclo-6,8 (14),22-ergostatriene (**12**) and ergosta-5,7,22-trien-3-thiol (**13**) (in 41 and 19% yield respectively).



It was evident that these compounds were formed via OH elimination assisted by the Lewis acid even though the diene was not added until after the sulfurating agent was formed (as monitored by TLC) and conditions were kept such that the sulfurating reagent was the limiting reagent. When thiane **9** was added to ergosterol (**3***a*), a rapid silylation occurred to form the derivatives depicted in Scheme 2. In support of the proposed reactions, nearly 85% of unreacted 2,2′-dibenzoylbiphenyl was recovered. In addition, reaction of ergosterol with BCl_3 and **9** alone led to the isolation of the same two products (**12**, **13**) where omission of BCl_3 gave silylated ergosterol.

Structure determination for compound **12** was achieved by the combined NMR data from ^1H, ^{13}C, COSY, DEPT, APT, and HETCOR experiments. A literature search of the proposed structure revealed it to be a known compound (22); its UV and mp characteristics were in agreement with those previously reported (22). Compound **13** has nearly identical ^{13}C and ^1H NMR spectra to those of ergosterol (**3***a*) with appropriate deviations consistent with an -SH group at C-3. Further, an X-ray structure determination was carried out; the ORTEP diagram is shown in Fig. 1. The stereochemistry of the -SH group is identical to that of the -OH functionality in ergosterol (**3***a*), thus the mechanism of formation likely involves the attack of H_2S on the β face of the A ring of **12** (Scheme 2).

To inhibit the elimination reaction initiated by BCl_3 (Scheme 2), ergosterol (**3**) was protected with a *tert*-butyl diphenylsilyl group (**3***b*) and added to the reaction mixture long after it was estimated that thioketone **7** had formed in significant amounts while all of the BCl_3 had been consumed. However, even after refluxing in toluene for 72 h, there was no major product formed and most (70%) of the starting diene was recovered. Although 57% of starting dione **8** was also recovered, proof that some of the diatomic sulfur

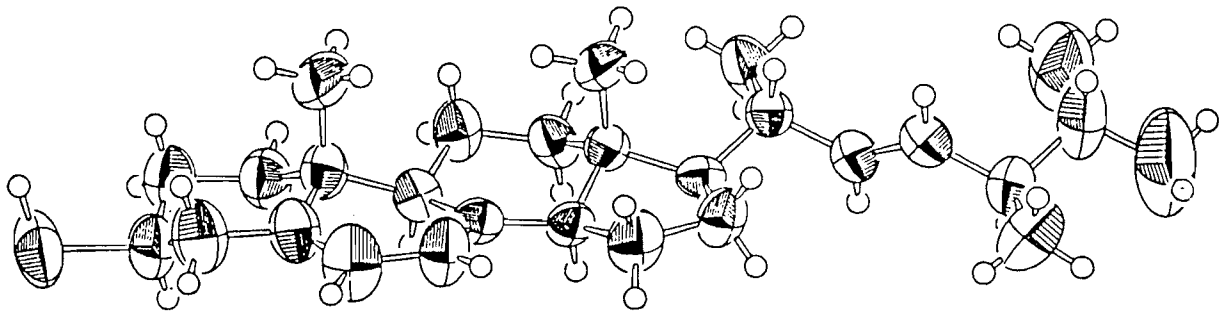

FIG. 1. ORTEP drawing of compound **13**.

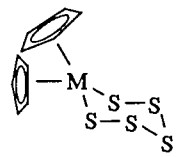
precursor had actually been produced was evidenced by the formation of 21% of 9,10-diphenyl phenanthrene (**11**).

More recently, Harpp and MacDonald (19) reported the generation of diatomic sulfur from organometallic pentasulfides of titanium and zirconium complexes **14**. These reagents are analogous to the organometallic trisulfides **4** in that they undergo S_2 extrusion in the presence of triphenyldibromophosphorane.

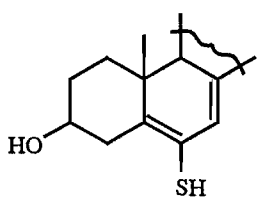


14*a* M = Ti
14*b* M = Zr

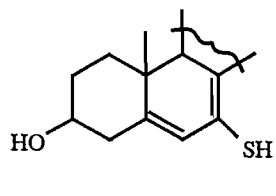
Several attempts to induce a Diels–Alder reaction between S_2 and ergosterol (**3***a*) using Ph_3PBr_2 and bis(*n*-cyclopentadienyl)titana(IV)cyclohexasulfane (**14***a*)[4] produced elemental sulfur (S_8); in addition, two minor products were isolated in low yield.[5]

[4]We are grateful to C. R. Williams for the preparation of this reagent. It was first prepared by McCall and Shaver (23).

[5]The ^1H NMR spectrum of the main steroidal product showed loss of the C-7 proton and a downfield shift of both the 18- and 19-CH_3 signals. The ^{13}C NMR spectrum showed a peak (170.74 ppm) at the characteristic shift of quaternary sp^2 carbons attached to sulfur, a downfield shift of the C-5 signal (139.78 to 150.85 ppm), and upfield shift of the C-8 signal (141.38 to 123.14 ppm). The ^1H NMR spectrum of the minor product showed a loss of the C-6 proton signal and a downfield shift of the C-3 proton signal to 3.90 ppm (from 3.63 ppm in ergosterol (**3***a*)) and the 19-CH_3 signal to 1.11 ppm (from 0.93 ppm in **3***a*). These data suggest that the major compound isolated was the C-7 mercapto ergosterol (ergosta-5,7,22-trien-7-mercapto-3-ol, **15***b*) and the minor, the C-6 mercaptan (ergosta-5,7,22-trien-6-mercapto-3-ol, **15***a*). These compounds do not give a parent ion in the ammonia CI mass spectrum and, due to their low yields, there was an insufficient amount of pure material available for elemental analysis. However, this class of compound is not unusual (24).



15*a*



15*b*

In an attempt to understand the suggested addition of sulfur to ergosterol (compounds **15***a*, **15***b*) in the absence of any detectable Diels–Alder products, the behavior of ergosterol in the presence of elemental sulfur (S_8) (25)[6] was further investigated. S_8 alone failed to react with ergosterol in refluxing toluene over a period of several hours, thus an "activated" form of sulfur was employed. Triethylamine, which is widely used as an activating agent in reactions of elemental sulfur with organic compounds (25,26), was added to the reaction mixture. However, this combination of reagents gave several products, only one of which could be separated and identified. The unidentified products were the likely victims of aromatization as evidenced by the isolation of elemental sulfur (S_8) during flash column chromatography (27).[7]

The main product, isolated from the reaction of "activated" elemental sulfur with ergosterol, showed a downfield shift of the H6 and H7 olefinic protons and loss of the long-range coupling observed in the starting material and thus appeared consistent with anticipated structure **2** inasmuch as the spectrum closely resembled that of the ergosterol peroxide (**1**). However, the APT and DEPT NMR spectra and MS and IR data indicated that ergosta-4,6,8(14),22-tetraen-3-one (**16**) was in fact the correct structure. In addition, the mp and UV were consistent with earlier reports on this compound (28). The details of its structure were obtained by an X-ray structure analysis. The ORTEP diagram is displayed in Fig. 2. Compound **16** is an interesting fungal metabolite of *Penicillium rubrum* (29) and has been shown to be an important biosynthetic intermediate in the metabolism of ergosterol (29).

The mechanism (Scheme 3) that we believe led to the formation of **16** involves first the oxidation of the C-3 OH, by participation of the sulfur (26), followed by a temporary nucleophilic addition of the sulfur to the C-4 carbon and elimination of H-14 to give a conjugated carbonyl derivative.

Attempts to minimize side products of the above reaction by first converting the C-3 OH to its acetate were unsuccessful, leading to an even greater amount of unidentifiable products.

[6]It has been widely observed that sulfur reacts with olefinic carbons in ionic or radical type mechanisms (25).

[7]The formation of aromatic compounds produced by dehydration and dehydrogenation of six-membered ring secondary alcohols was observed previously in similar reactions of elemental sulfur under even milder experimental conditions (27).

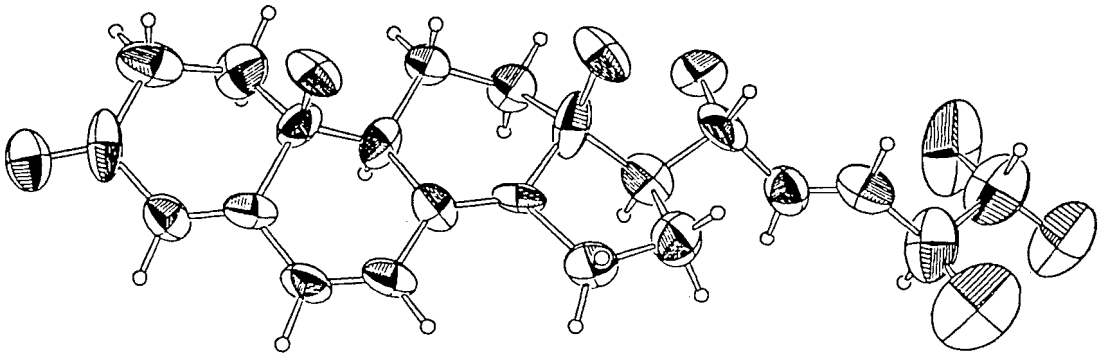

FIG. 2. ORTEP drawing of compound **16**.

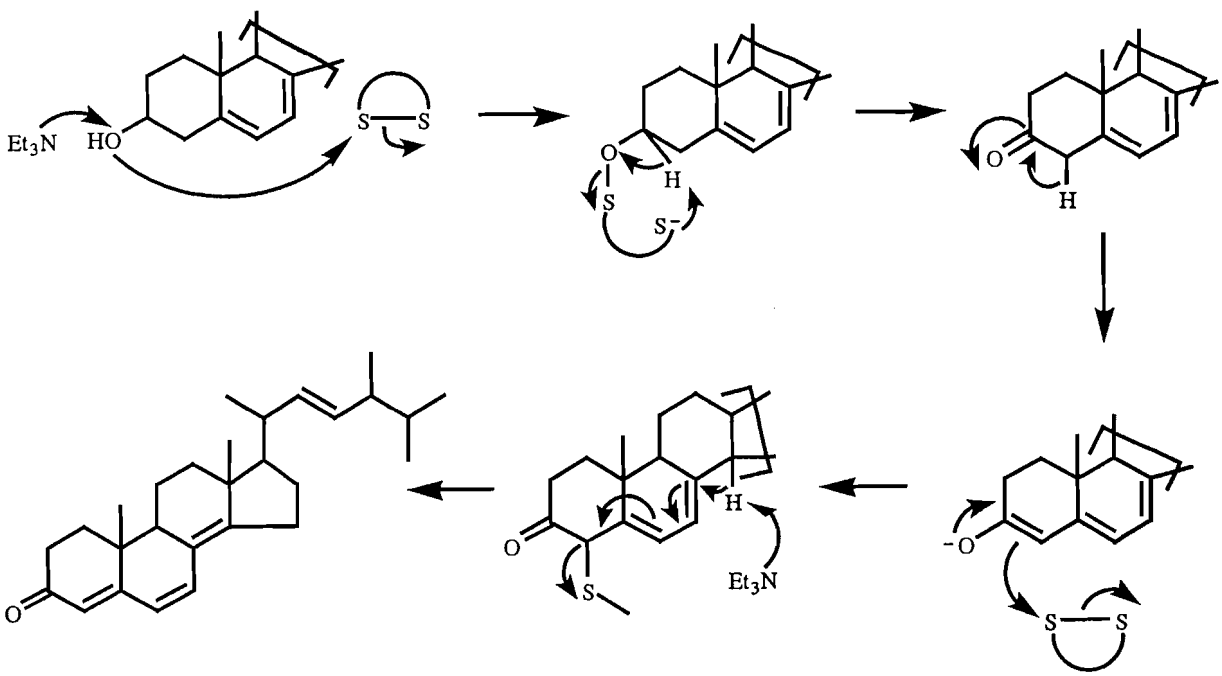
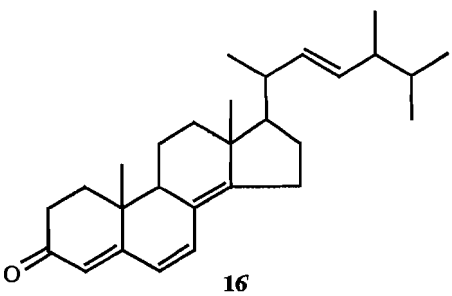


SCHEME 3



16

The fact that the main products isolated in the reaction of ergosterol and activated sulfur were not at all similar to those isolated in the reaction of ergosterol with bis(*n*-cyclopentadienyl)titana(IV)cyclohexasulfane (**14***a*) indicates that these two reactions must proceed by different routes. The products isolated from the reaction of ergosterol with **14***a* can be rationalized by insertion of diatomic sulfur into the double bonds of **3***a*; however, several closely related schemes can be envisaged which cannot be differentiated at this time.

Experimental

General methods

Nuclear Magnetic Resonance spectra were obtained at 20–22°C using Varian XL-200 and XL-300 MHz instruments. ^{1}H and ^{13}C NMR chemical shifts are quoted in ppm and are referenced to the internal deuterated solvent downfield from tetramethylsilane (TMS). Chemical shift assignments of all steroid products were based on the HETCOR and COSY NMR data of each compound and the literature chemical shifts of equivalent carbons in ergosterol and ergosterol peroxide (6). All mass spectra were measured at the Biomedical Mass Spectrometry Unit, McGill University, unless otherwise indicated. The low resolution chemical ionization (NH_3) spectra were obtained using a HP 5980A spectrometer. FAB and high resolution chemical ionization spectra (NH_3) were obtained using a ZAB 2F HS instrument. Ultraviolet spectra were recorded on a Hewlett Packard 8451A diode array spectrophotometer. Infrared spectra were recorded on an Analect ASQ-18 FTIR spectrophotometer calibrated to the 1602 cm^{-1} line of polystyrene. Sulfur analyses were performed on an Antek 771 pyroreactor and 714 sulfur detector system. Melting points were measured using a Gallenkamp capillary apparatus and are uncorrected.

Commercially available compounds were obtained from Aldrich Chemical Co. (Milwaukee, Wis.). Silica gel chromatography was performed on Merck Kieselgel 60 (230–400 mesh, no. 9385) using flash chromatography (30). Chromatographic solvents were fractionally distilled prior to use. All reactions were monitored by thin-layer chromatography carried out on 0.25 mm Merck silica gel plates (60F–254) using UV light and a 10% sulfuric acid ethanolic solution of ammonium molybdate-cerium sulfate developing dip.

*Preparation of 2,2′-dibenzoylbiphenyl (**8**)*

Prepared via oxidation of 2,2′-di(1-phenylmethanol)biphenyl. *o*-Dibromobenzene (4.00 g, 16.9 mmol) was dissolved in dry THF (100 mL) and cooled to −78°C under an atmosphere of nitrogen. *n*-Butyllithium (17 mL of a 2.5 M solution in hexanes, 42.4 mmol) was added (dropwise) and the mixture was allowed to stir at −78°C for 4 h and at room temperature for an additional 0.5 h. A solution of benzaldehyde (5.306 g, 50 mmol) in THF (25 mL) was added subsequently (dropwise) and the reaction was allowed to proceed for another 0.5 h before it was quenched with water (200 mL). The organic layer was then separated, washed with brine (2 × 200 mL), dried over $MgSO_4$, and evaporated under reduced pressure to a yellow oil. The excess benzaldehyde was removed by Kugelrohr distillation, and the remaining oil was allowed to crystallize from hexanes (in a freezer) to give 0.8785 g (28%) of 2,2′-di(1-phenylmethanol)biphenyl, mp 186–192°C. IR (KBr): 3500 (OH) cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$) δ: 2.1 (s, 2H, 2 × CHOH), 2.6 (s, 2O*H*), and 7.1–7.6 (m, 18H, aromatic protons) ppm. ^{13}C NMR (300 MHz, $CDCl_3$) δ: 71.7 (2 × COH), 126.1, 126.9, 127.4, 128.1, 128.2, 128.3, 129.5, 140,0, 142.4 and 143.2 ppm.

Aqueous CrO_3 (0.25 g in 20 mL H_2O) was added dropwise to an acidic solution of 2,2′-di(1-phenylmethanol)biphenyl (0.217 g, 0.594 mmol, in 10 mL glacial acetic acid) at 65°C. The reaction was allowed to stir at 65°C for 0.5 h, then cooled to room temperature, neutralized with a saturated solution of Na_2CO_3, and extracted with ether (3 × 100 mL). The ether layer was dried over $MgSO_4$, evaporated to dryness, and recrystallized from ethanol to obtain 0.157 g (74% yield) of pure crystalline product (**8**). TLC: hexane/ethyl acetate (9:1), R_f 0.21; mp decomposes above 150°C. IR (KBr): 1654 (C=O) cm^{-1}. ^1H NMR (200 MHz, $CDCl_3$) δ: 7.20–7.40 (m, 14H) and 7.67–7.71 (m, 4H) ppm. ^{13}C NMR (300 MHz, $CDCl_3$) δ: 126.7 (C4 and C4′), 127.9 (C6 and C6′), 129.3 (C3″, C3‴), 130.1 (C3 and C3′), 130.3 (C1′, C1‴), 131.4 (C4″ and C4‴), 132.7 (C5 and C5′), 137.3 (C2 and C2′), 138.2 (C8 and C8′), 140.2 (C1 and C1′), and 197.5 (*C*=O) ppm.

*The formation of 3,5-cyclo-6,8(**14**),22-ergostatriene (**12**) and ergosta-5,7,22-trien-3-thiol (**13**)*[8]

To a solution of 2,2′-dibenzoylbiphenyl (0.169 g, 0.467 mmol) and ergosterol (0.185 g, 0.467 mmol) in dry toluene (30 mL), 1,1,1,3,3,3-hexamethyldisilylathiane (0.166 g, 0.933 mmol) was added via a syringe under an atmosphere of nitrogen. The resulting mixture was cooled to 0°C and boron trichloride (0.623 mL of a 1 M solution in CH_2Cl_2, 0.623 mmol) was added slowly via a syringe. The reaction was warmed to room temperature and then allowed to reflux for 9.5 h. Evaporation of the solvent, followed by flash column chromatography of the resulting crude with petroleum ether, led to the isolation of two compounds, 3,5-cyclo-6,8(14),22-ergostatriene (**12**) (fractions 3–6, 72.3 mg, 41% yield) and the ergosterol thiol **13** (fractions 8–13, 36.8 mg, 19% yield). Further elution with petroleum ether/ethyl acetate (3:1) led to the recovery of unreacted 2,2′dibenzoylbiphenyl (140 mg, 83%).

*3,5-Cyclo-6,8(14),22-ergostatriene (**12**):* TLC: Petroleum ether, R_f 0.57; mp 98.5–100°C (lit. (22) mp 102–102.5°C). IR ($CDCl_3$): 1458, 1600 (C=C), 2869 and 2961 (C—C) cm^{-1}. UV (EtOH): max 262 nm. ^1H NMR (200 MHz, $CDCl_3$) δ: 0.46 (dd, J = 5.0 and 8.2 Hz, 1H, H3), 0.76 (s, 3H, 18-CH_3), 0.79–0.84 (2d, J = 6.8 Hz, 6H, 26-CH_3 and 27-CH_3), 0.90 (s, 3H, 19-CH_3), 0.91 (d, J = 6.8 Hz, 3H, 28-CH_3), 1.02 (d, J = 6.7 Hz, 3H, 21-CH_3), 1.2–2.4 (m, 19H, steroid skeleton), 5.2 (m, 3H, H6, H22 and H23), and 6.19 (d, J = 9.5 Hz, 1H, H7) ppm. ^{13}C NMR (300 MHz, $CDCl_3$) δ: 15.56, 17.02, 17.65, 19.30, 19.65, 19.99, 20.39, 21.22, 25.18, 25.33, 26.52, 27.98, 30.79, 33.10, 37.37, 37.58, 39.44, 40.83, 42.86, 43.52, 43.86, 56.14, 124.06, 124.63, 130.57, 132.02, 135.49, and 147.04 ppm. APT (D2 = 4 ms) NMR (300 MHz, $CDCl_3$) δ: 37.58 (C10), 43.52 and 43.86 (C5 and C13), 124.63 (C14), and 147.04 (C8) ppm. DEPT NMR (300 MHz, $CDCl_3$) δ: $6CH_3$ (17.02 and 19.30 (C18 and C19), 17.66 (C28), 19.65 (C26), 19.99 (C27) and 21.22(C2) ppm); $7CH_2$ (15.56 (C4), 20.39 (C11), 25.18 and 25.33 (C2 and C15), 27.98 (C16), 30.79 (C1) and 37.37 (C12) ppm); 10CH (26.52 (C3), 33.10 (C25), 39.44 (C9), 40.83 (C20), 42.86 (C24), 56.14 (C17), 124.06 (C7), 130.57 (C6), 132.02 (C23) and 135.49 C22 ppm). MS (E.I., direct inlet, 65°C), m/z (% relative intensity, assignment): 378 (16, M^+).

*Ergosta-5,7,22-trien-3-thiol (**13**):* TLC: petroleum ether, R_f 0.42; mp 121.5–123°C. $[\alpha]_D^{20}$ −150 (*c* 0.02, CH_2Cl_2). IR ($CDCl_3$): 1458 (C=C), 2873 and 2960 (C—C) cm^{-1}. UV (EtOH): max 274, 284; min 296 nm. ^1H NMR (200 MHz, $CDCl_3$) δ: 0.61 (s, 3H, 18-CH_3), 0.79–0.83 (2d, J = 6.8 Hz, 6H, 26-CH_3 and 27-CH_3), 0.90 (d, J = 6.8 Hz, 3H, 28-CH_3), 0.94 (s, 3H, 19-CH_3), 1.02 (d, J = 6.6 Hz, 3H, 21-CH_3), 1.22–2.08 (m, 19H, steroid skeleton), 2.59–2.63 (m, 2H, 2 × H4), 3.80–3.86 (m, 1H, H3), 5.15–5.20 (m, 2H, H22 and H23), 5.37 (dd, 1H, H7), and 5.55 (bd, J = 5.62 Hz, 1H, H6) ppm. ^{13}C NMR (300 MHz, $CDCl_3$) δ: 12.06 (C18), 16.15 (C19), 17.60 (C28), 19.64 (C26), 19.95 (C27), 20.98 (C11), 21.10 (C21), 22.96 (C15), 28.26 (C16), 33.07 (C25), 33.63 (C2), 36.76 (C10), 38.98 (C12), 40.02 (C1), 40.41 (C20), 41.92 (C4), 42.82 (C13 and C24), 46.19 (C9), 54.55 (C14), 55.70 (C17), 59.09 (C3), 116.14 (C7), 119.84 (C6), 132.01 (C23), 135.50 (C22), 139.24 (C5), and 141.94 (C8) ppm. Chemical shift assignments were consistent with DEPT, APT, and COSY NMR experiments. MS (E.I., direct inlet, 95°C) m/z (% relative intensity, assignment): 378 ($M^+ - H_2S$). Sample analysis using the Antek analyzer confirmed the presence of sulfur in this compound. In addition, a nitroprusside (31) test for thiol was positive.

Protection of ergosterol with tert*-butylchlorodiphenylsilane (**3**b)*

Ergosterol (1.00 g, 2.50 mmol) and imidazole (0.85 g, 12.5 mmol) were dissolved in dry DMF (50 mL) under nitrogen and *tert*-butylchlorodiphenylsilane (1.39 g, 5.00 mmol) was added via syringe. The white precipitate formed was allowed to stir for 12 h at room temperature. The mixture was then extracted with ethyl acetate, the organic layer was washed with 1 M HCl (3 × 50 mL) and water (3 × 50 mL), dried over $MgSO_4$, and evaporated to dryness. The desired product (0.6824 g, 57% yield) and unreacted starting material were purified via flash column chromatography (24:1 hexanes:ethyl acetate). TLC: hexanes/ethyl acetate (4:1), R_f 0.55. ^1H NMR (200 MHz, $CDCl_3$) δ: 0.59 (s, 3H, Si-CH_3), 0.79–0.84 (2d, J = 6.7 Hz, 6H, 26-CH_3 and 27-CH_3), 0.88–0.91 (m, 6H), 1.02–1.05 (m, 12H), 1.2–1.9 (m, 18H, steroid skeleton), 2.31 (m, 2H, 2H4), 3.6 (m, 1H, H3), 5.15–5.20 (dd, 2H, H22 and H23), 5.29–5.34 (m, 1H, H7), and 5.36–5.43 (bd, J = 5.7 Hz, 1H, H6), 7.34–7.40 and 7.64–7.69 (2m, 6H and 4H respectively, phenyl) ppm. MS (C.I.(NH_3), direct inlet, 99°C) m/z (% relative intensity, assignment): 635 (5 M^+ +1), 379 (100, M^+ + 1 − $SiPh_2(C_4H_9)$).

*Reaction of ergosterol with bis(*n*-cyclopentadienyl)titana-(IV)cyclohexasulfane (**15**a,b)*

A solution of Br_2 (50 mL, 1.0 mmol) in dry CH_2Cl_2 (5.0 mL) was added dropwise to a solution of triphenylphosphine (275 mg, ~1.1 mmol in 5.0 mL dry CH_2Cl_2) at 0°C. The suspension of triphenyldibromophosphorane formed was allowed to warm up

[8]X-ray data for compounds **13** (22 pages) and **16** (10 pages), listing of structure factors for **13** (28 pages) and **16** (22 pages), and spectral data for compounds **3***b*, **13**, **15***a*, **15***b* have been deposited as supplementary material and may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2.

to room temperature and then it was added, dropwise, to a solution of ergosterol (800 mg, 1.0 mmol) and bis(*n*-cyclopentadienyl)titana(IV)cyclohexasulfane (340 mg, 1.0 mmol) in 15 mL dry CH_2Cl_2. The reaction mixture was stirred at room temperature for 4 h, evaporated to dryness, and purified by chromatography. Flash column chromatography of the crude mixture, using CH_2Cl_2 as the eluting solvent, led to separation of the isomeric mixture of thiols **15***a* and **15***b* from the remaining crude. Further thin-layer chromatography was carried out on preparative silica gel plates developed five times with petroleum ether/ethyl acetate (5:1) in order to achieve partial separation of the two compounds. The major product **15***b* was isolated in ~15% yield (~250 mg) and the minor product **15***a* in ~5% yield (~20 mg).

*Ergosta-5,7,22 trien-6-mercapto-3-ol (***15***a):* TLC: CH_2Cl_2/ethyl acetate (2:1), R_f 0.59. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 0.80–0.85 (2d, J = 6.8 Hz, 6H, 26-CH_3 and 27-CH_3), 0.84 (s, 3H, 18-CH_3), 0.92 (d, J = 6.8 Hz, 3H, 28-CH_3), 1.03 (d, J = 6.6 Hz, 3H, 21-CH_3), 1.11 (s, 3H, 19-CH_3), 1.2–2.3 (m, 21H, steroid skeleton), 3.90 (m, 1H, H3), 5.20–5.25 (m, 2H, H22 and H23), and 5.36 (m, 1H, H7) ppm. There was a positive nitroprusside test indicating a thiol (31).

*Ergosta-5,7,22-trien-7-mercapto-3-ol (***15***b):* TLC: CH_2Cl_2/ethyl acetate (2:1), R_f 0.59; mp 133.5–135°C. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 0.80–0.85 (2d, J = 6.8 Hz, 6H, 26-CH_3 and 27-CH_3), 0.82 (s, 3H, 18-CH_3), 0.92 (d, J = 6.8 Hz, 3H, 28-CH_3), 0.98 (s, 3H, 19-CH_3), 1.03 (d, J = 6.5 Hz), 1.2–2.4 (m, 21H, steroid skeleton), 3.63 (m, 1H, H3), 5.20–5.25 (m, 2H, H22 and H23), and 5.33 (m, 1H, H6) ppm. ^{13}C NMR (300 MHz, $CDCl_3$) δ: 15.83, 17.67, 18.39, 19.65, 19.98, 21.00, 21.87, 25.31, 26.60, 31.72, 33.10, 35.35, 36.57, 36.69, 36.95, 38.33, 38.91, 40.96, 42.83, 44.82, 57.10, 71.01, 117.79, 123.14, 132.07, 135.52, 140.74, and 150.85 ppm. MS (C.I. (NH_3), direct inlet, 250°C), m/z (% relative intensity, assignment): 397 (61, $M^+ + 1 - S$), 270 (17, $M^+ - S - 125$), 125 (100, side chain). Sample analysis using a "Sulfur analyzer" instrument confirmed the presence of sulfur in this compound; a nitroprusside (31) test was also positive.

*Reaction of ergosterol with elemental sulfur (***16***)*

Ergosterol (5.0 g, 12.6 mmol) and S_8 (3.00 g, 11.7 mmol = ~4 equiv. of S_2) were refluxed in dry toluene (~200 mL) in the presence of 1 equivalent of triethylamine (1.5 mL, ~12 mmol). After a period of 24 h the crude mixture was filtered, washed with water (3 × 100 mL), and evaporated to dryness. Flash column chromatography (2×) of the product mixture with petroleum ether/ethyl acetate (4:1) (2nd chromatography was performed on fractions 13–17 of the 1st column) led to the isolation of compound **16** (ergosta-4,6,8(14),22-tetraen-3-one) as an orange-yellow solid. Preparative thin-layer chromatography on silica gel plates, developed twice with hexane/ethyl acetate (9:1), followed by recrystallization from ethanol, gave crystalline compound **16** in approximately 5% yield (30 mg). TLC: pet. ether/ethyl acetate (3:1), R_f 0.45 (fluorescent spot under UV); mp 112.5–113°C (lit. (29) mp 114–115°C). IR ($CDCl_3$): 1646 (C=O), 1636, 1584 (C=C) cm^{-1}. UV (CH_3CH_2OH, nm): max 350. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 0.78–0.83 (2d, J = 6.7 Hz, 6H, 26-CH_3 and 27-CH_3), 0.90 (d, J = 6.8 Hz, 3H, 28-CH_3), 0.93 and 0.96 (2s, 2 × 3H, 18-CH_3 and 19-CH_3), 1.03 (d, J = 6.7 Hz, 3H, 21-CH_3), 1.15–2.55 (m, 18H, steroid skeleton), 5.17–5.22 (m, 2H, H22 and H23), 5.70 (s, 1H, H2), 6.00 (d, J = 9.5 Hz, 1H, H6), and 6.57 (d, J = 9.5 Hz, 1H, H7) ppm. ^{13}C NMR (300 MHz, $CDCl_3$) δ: 16.62 (C18), 17.61 (C28), 2 × 18.95 (C19 and C2), 19.63 (C26), 19.96 (C27), 21.19 (C21), 25.33 (C11), 27.69 (C16), 33.05 (C25), 2× 34.09 (C1 and C12), 35.55 (C15), 36.71 (C10), 39.25 (C20), 42.83 (C24), 43.95 (C13), 44.28 (C9), 55.66 (C17), 122.95 (C4), 124.38 (C6), 124.42 (C8), 132.49 (C23), 133.97 (C7), 134.96 (C22), 156.04 (C14), 164.32 (C5), and 199.43 (C3) ppm. APT (D2 = 4 ms) NMR (300 MHz, $CDCl_3$) δ: 36.75 (C10), 43.96 (C13), 124.26 (C8), 155.89 (C9), 164.17 (C5), and 199.20 (C3) ppm. DEPT NMR (300 MHz, $CDCl_3$) δ: 6CH_3 (16.61, 17.61, 18.95, 19.63, 19.96, 21.19 ppm), 6CH_2 (18.95, 25.33, 27.69, 2 × 34.09, 35.55 ppm), 10CH (33.05, 39.25, 42.83, 44.28, 55.66, 122.95, 124.42, 132.49, 133.97, 134.96 ppm). MS (C.I. (NH_3), direct inlet, 150°C), m/z (% relative intensity, assignment): 394 (31, $M^+ + 1$), 393 (100, M^+).

Received April 26, 1991

WESLEY G. TAYLOR, TSE WAI HALL, and CARL E. SCHRECK. Can. J. Chem. **70**, 165 (1992).

The 15 2,2-dimethyloxazolidines described here were found to exist in solution predominantly as a single rotational isomer, unlike *N*-acetyloxazolidine (**1**), *N*-acetyl-2-methyloxazolidine (**2**), *N*-acetyl-2-(*n*-octyl)oxazolidine (**3**), and other known 2-substituted *N*-acyloxazolidines. Using ^{13}C NMR spectroscopy, activation energies for interconversion of the *E* (minor) and *Z* (major) rotational isomers of **1–3** were determined from coalescence temperature measurements in pyridine-d_5. A sample of *N*-acetyl-2,2-dimethyloxazolidine (**4**) was isolated for comparison. The rotational isomer of **4** was found by two-dimensional nuclear Overhauser effect spectroscopy (NOESY) to possess the *Z* (or *trans*) stereochemistry. Molecular mechanics (MMX) calculations on the *E* and *Z* isomers of **1–4** helped to account for these findings. The conformation of the energy-minimized structures resembled a C-5 envelope. Samples of *N*-aroyl-2,2-dimethyloxazolidines (**5***a*–**5***n*) were isolated and the rotational isomers were assigned the *Z* stereochemistry by NOESY and ^{13}C NMR experiments. Most of these 2,2-dimethyloxazolidines were ineffective in a bioassay for mosquito repellent activity.

Key words: *N*-acyloxazolidines, *N*-aroyloxazolidines, NMR spectroscopy, rotational isomerism, molecular mechanics.

WESLEY G. TAYLOR, TSE WAI HALL et CARL E. SCHRECK. Can. J. Chem. **70**, 165 (1992).

On a trouvé que, en solution, les 15 2,2-diméthyloxazolidines décrites dans ce travail existent principalement sous la forme d'un seul isomère rotationnel; ce comportement diffère de celui des *N*-acétyl- (**1**), *N*-acétyl-2-méthyl- (**2**), *N*-acétyl-2-octyl- (**3**) oxazolidines et d'autres *N*-acétyloxazolidines substituées en position 2. Faisant appel à la RMN du ^{13}C et se basant sur des mesures des températures de coalescence dans la pyridine-d_5, on a déterminé les énergies d'activation d'interconversion des isomères rotationnels *E* (mineur) et *Z* (majeur) des composés **1–3**. Pour fins de comparison, on a isolé un échantillon de la *N*-acétyl-2,2-diméthyloxazolidine (**4**). En se basant sur l'effet Overhauser nucléaire bidimensionnel (NEOSY), on a démontré que l'isomère rotationnel du composé **4** possède la stéréochimie *Z* (ou *trans*). Des calculs de mécanique moléculaire (MMX) sur les isomères *E* et *Z* des composés **1-4** ont permis d'expliquer ces résultats. Les conformations des structures dont l'energie a été minimisée ressemblent à une enveloppe C-5. On a isolé des échantillons des *N*-aroyl-2,2-diméthyloxazolidines (**5***a*–**5***n*) et, sur la base d'expériences de RMN du ^{13}C et de NEOSY, on a attribué la stéréochimie *Z* à leurs isomères rotationnels. La plupart de ces 2,2-diméthyloxazolidines ne se sont pas avérées efficaces lors d'essais biologiques destinés à mesurer leur activité comme agent de répulsion des moustiques.

Mots clés : *N*-acetyloxazolidines, *N*-aroyloxazolidines, spectroscopie RMN, isomérie rotationnelle, mécanique moléculaire.

[Traduit par la rédaction]

Introduction

During studies on the insect repellent properties of oxazolidine heterocycles (1–3), various *N*-acetyl and *N*-alkylcarbonyl derivatives with alkyl or alkenyl groups at C-2 were found to exist in deuterochloroform solution as binary mixtures of rotational isomers (Fig. 1). The *Z* (or *trans*) rotational isomer was usually found in slight excess over the *E* (or *cis*) isomer. Rotational isomerism in five-membered cyclic nitrosamines, including *N*-nitrosooxazolidine and 2-methyl-*N*-nitrosooxazolidine, also has been studied by ^{13}C NMR spectroscopy (4).

The promising mosquito repellent activity of some of the *N*-acetyloxazolidines prompted us to investigate the rotational isomers of these and related compounds in detail, using high resolution NMR and computational chemistry techniques. We rationalized that comparative information on the conformational preferences of these highly mobile molecules might help in the design of better insect repellents. Thus, *N*-acetyloxazolidine (**1**), *N*-acetyl-2-methyloxazolidine (**2**), and *N*-acetyl-2-(*n*-octyl)oxazolidine (**3**) were selected as representative examples from our previous work (3)

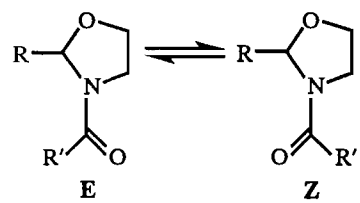

FIG. 1. Rotational isomers of 2-substituted *N*-acetyl- and *N*-alkylcarbonyloxazolidines. In refs. 1–3, these isomers were designated by *cis* and *trans* nomenclature, indicating relative orientation of the R and R′ groups. *E* and *Z* are used here, which means that the *cis* isomers of our earlier work are equivalent to *E* isomers and *trans* is equivalent to *Z*.

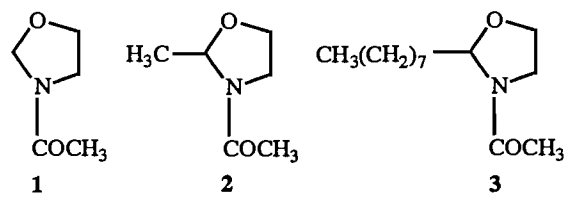
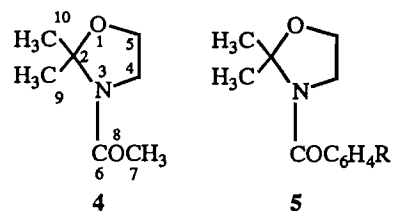
for comparison here with *N*-acetyl-2,2-dimethyloxazolidine (**4**). The synthesis, ^{13}C NMR spectra, and mosquito repellent properties of 14 novel *N*-aroyl-2,2-dimethyloxazolidines (**5**), isolated as single rotational isomers, are also reported.





Results and discussion

N-*Acetyloxazolidines* ***1–4***

Rotational isomers of tertiary amides are capable of existing in solution as equilibrium mixtures because of the energy barrier to rotation about the N—CO bond. This barrier or free energy of activation is relatively high compared with other dynamic processes and has been estimated at 17.4 kcal mol^{-1} for **1** (5).

At room temperature, interconversion of the rotational isomers of *N*-acetyl and *N*-alkylcarbonyloxazolidines was sufficiently slow on the NMR time scale to allow the detection of the *E* and *Z* isomers by ^{13}C NMR spectroscopy (1–3). The major isomers were assigned the *Z* stereochemistry on the basis of ^{13}C chemical shift comparisons with the other isomer in the mixture.

The occurrence of unequal equilibrium isomer populations suggests that a higher free energy of activation is required for the *Z* to *E* conversion than that from *E* to *Z*. Activation energies were determined for **1–3** by measuring the coalescence temperatures of ^{13}C signals from isomeric mixtures of these representative *N*-acetyloxazolidines over a temperature range of 298–363 K in pyridine-d_5 (Table 1). Free energies of activation were calculated with the equations from Shanan-Atidi and Bar-Eli (6), which take into account the effect of unequal isomer populations and of course the frequency difference between the resolved signals. The same approach was used by Haky *et al.* (4) in their NMR study of rotational isomerism of *N*-nitrosooxazolidines in DMSO-d_6.

At 298 K, the *Z* isomer of **1** represented about 60% of the mixture, and the thermodynamic equations (6) confirmed that the activation energy for *Z* to *E* conversion (17.4 kcal mol^{-1}) was slightly greater than for the reverse process. This dif-

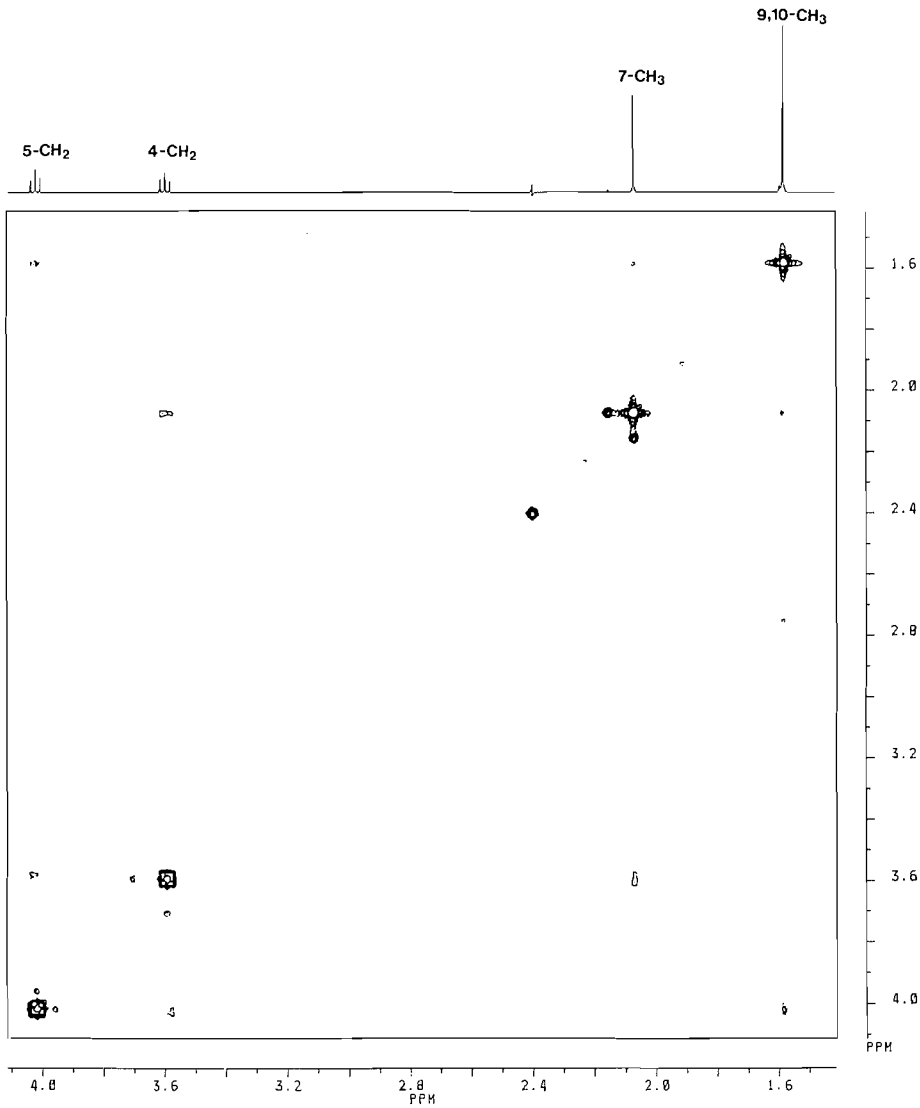

FIG. 3. Contour plot from a NOESY experiment on **4** recorded in $CDCl_3$ at 298 K. A conventional proton spectrum (1.47–4.12 ppm) is shown at the top. The signal at 2.42 ppm is due to folding of the TMS signal.

ference (0.3 kcal mol^{-1}) increased to about 1 kcal mol^{-1} for **2** and **3**, in accord with an increase to 80–85% in the *Z* isomer population. It seemed that unfavorable steric interactions between the C-2 alkyl and C-7 methyl groups in the *E* isomers of **2** and **3** were responsible for the shift in isomer populations. Equilibrium isomer populations of *N*-nitrosooxazolidines also were influenced by the steric crowding effect of a 2-methyl group.

The ^{13}C NMR spectra of **4** showed that one rotational isomer predominated in deuterochloroform and pyridine-d_5 solutions. In fact, the presence of any of the other rotational isomer could not be determined with certainty, implying that C-2 dimethyl substitution created an even greater difference in activation energies than was determined for **2** and **3**. In **4**, minor signals resonating upfield from the main signals for C-2, C-4, and C-5 were apparent (Fig. 2). Their chemical shifts were consistent with those expected from C-2, C-4, and C-5 of *E* **4** since, in the *E* isomers of **1**–**3**, the corresponding carbons resonated upfield compared to the signals of the *Z* isomers. Thus, ^{13}C chemical shift arguments as well as steric considerations suggested that *Z* **4** predominated but experimental evidence to confirm this assignment was sought.

To study the stereochemistry of the major component, proton–proton nuclear Overhauser enhancement (NOE) experiments were attempted on **4** using the two-dimensional NOESY pulse sequence (7). The recent literature illustrates several applications of these techniques to small organic molecules (8–11), sometimes in the phase-sensitive mode to distinguish NOE from intramolecular chemical exchange.

On the assumption that the main isomer of **4** had a favorable rotational correlation time, a potential dipolar interaction leading to an NOE cross-peak should occur between the protons at C-4 and C-7 in the *Z* isomer. Greater C-4 to C-7 interproton distances in the *E* isomer would result in a weaker cross-peak, or none at all, whereas the shorter distance between the methyl protons at C-7 and C-9,10 would be expected to give a stronger cross-peak. The contour plot (Fig. 3) showed a relatively intense cross-peak for the protons at C-4 and C-7 plus a relatively weak cross-peak for the methyl proton (C-7 and C-9,10) interactions. This indicated the *Z* stereochemistry. Although not of value for the stereochemical assignment, a relatively strong cross-peak also was ob-

[a]*R* enantiomer.

served for the C-5 methylene to C-9,10 methyl proton interactions. The cross-peak for the C-4,5 methylene proton interaction may be due to a combination of dipolar and scalar coupling effects.

It was of interest to attempt to account for the rotameric preferences of **1–4** by molecular mechanics, so the relative steric energies of the *E* and *Z* isomers of **1–4** were determined with the MMX force field of PCMODEL (see experimental section). During energy minimizations, the oxazolidine ring adopted a favorable conformation (*vide infra*) while retaining the essentially planar *E* or *Z* geometry of the acetamide group.

Equilibrium isomer populations derived from ^{13}C NMR spectroscopy showed that the *Z* isomer populations increased in a logical manner (**4** > **3** ≃ **2** > **1**), paralleling the steric bulk at C-2. Molecular mechanics calculations predicted that the *Z* isomers of these four oxazolidines also were preferred (Table 2). Differences in ground state steric energies of the minimized structures for the isomers of **1** were small (<0.5 kcal mol^{-1}) and may not be significant, but this increased to 2.5 kcal mol^{-1} on comparing the isomers of **4**. Quantitatively, the molecular mechanics calculations predicted more of the *Z* isomer than was found experimentally, especially for **3**.

It should be emphasized that the molecular mechanics calculations, furnishing total steric energies of isolated molecules in the gas phase, need not agree with the equilibrium populations found in solution. Indeed, solvent effects were evident as illustrated by the higher *Z* isomer populations in pyridine-d_5 than in deuterochloroform. Furthermore, some of the force field parameters for *N*-acetyloxazolidines have not been finalized. Despite these precautions, the agreement between experimental and theoretical results seen in this work was interesting. In a recent study on 2-ethynyl-*N*-acetylpyrrolidine (12), molecular mechanics calculations also predicted that the *Z* isomer would prevail, in agreement with the NMR data.

Minimum energy conformations from molecular me-

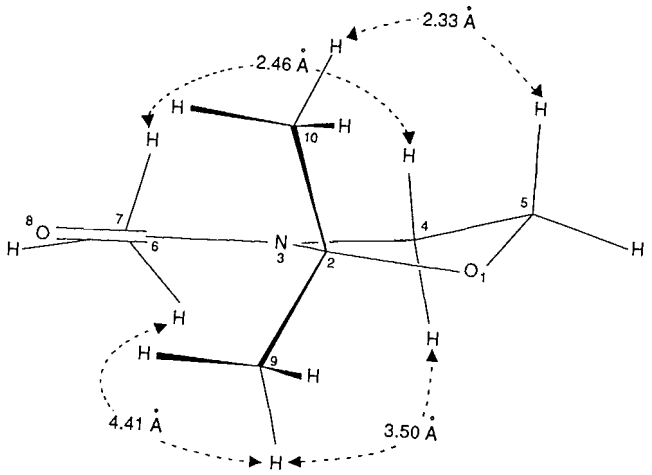

FIG. 4. The lowest energy conformation of the *Z* isomer of **4** found by molecular mechanics calculations and selected interproton distances.

chanics calculations gave ring-puckered structures resembling a C-5 envelope. This geometry has been reported before in molecular mechanics calculations on substituted oxazolidines (13) and was indicated here, for example, by the relatively large endocyclic torsional angles (−39 to −42°) for C(4) − C(5) − O(1) − C(2) and relatively small angles (−5 to −15°) for O(1) − C(2) − N(3) − C(4). Comparison of several torsional angles in *Z* **1–4** and in *E* **1–4** indicated only small differences in the conformations of the energy-minimized structures (Table 3).

The lowest energy conformation found for the *Z* isomer of **4** was of interest (Fig. 4). The interproton distances of 2.33 Å (C-5,10) and 2.46 Å (C-4,7) were consistent with the strong cross-peaks of the NOESY experiment. In fact, the weak NOE cross-peaks observed for C-4 methylene and C-7 methyl interactions to the C-9 methyl protons could be rationalized because the spatial proximity was less than 5 Å, which is approximately the maximum distance for which to expect a response in NOESY experiments (14).

N-*Aroyloxazolidines* **5**a–**5**n

These oxazolidines **5***a*–**5***n* (Table 4) were synthesized by reacting acetone with ethanolamine followed by acylation with various benzoyl chlorides.

The ^{13}C NMR spectra of **5***a*–**5***n* gave single resonances for each carbon of the oxazolidine ring. Chemical shift assignments to the unsubstituted **5***a* were made by reference to ^{13}C chemical shifts of **4** and of *N*,*N*-dimethylbenzamide. The ^{13}C signals for **5***b*–**5***n* could be assigned completely (Table 5) by spectral editing with DEPT and by use of substituent increments for monosubstituted benzenes (15) in conjunction with chemical shifts of the aromatic carbons from **5***a*. In the fluoro-substituted compounds **5***h*–**5***k*, ^{13}C–^{19}F couplings helped to confirm the assignments.

In the ^{13}C NMR spectrum of the *ortho*-trifluoromethyl compound **5***j*, the methyl carbons of the *gem*-dimethyl group were nonequivalent, appearing as two broad signals at 298 K. This observation might be related to slow rotation around the CO-aryl bond, as demonstrated with *ortho*-monosubstituted *N*,*N*-dialkylbenzamides (16). However, the *ortho*-methyl (**5***d*) and *ortho*-methoxy (**5***g*) compounds gave a sharp signal for the *gem*-dimethyl carbons.

The ^{13}C chemical shifts of C-2, C-4, and C-5 in **5***a*–**5***n* were very similar (Table 5), which indicated the same geometry about the amide bond. It was likely *Z* because the phenyl group would be expected to sterically favor that isomer, probably to even a greater extent than with the C-7 methyl group of **4**. To discount the possibility that the coalescence temperatures were less than ambient, the ^{13}C NMR spectrum of **5***b* was obtained at 218 K. That spectrum gave the same signals as those recorded at 298 K.

To assign the stereochemistry of **5***a*–**5***n*, it was anticipated that an NOE should be observed between a C-4 methylene proton and an *ortho* proton of the phenyl ring. This was demonstrated by a NOESY experiment on a sample of the 4′-methyl compound **5***b*. The ^{1}H NMR spectrum of **5***b* gave well-resolved doublets for the *ortho* (2′) and *meta* (3′) protons, and their chemical shifts were first assigned by a $^{1}H/^{13}C$ shift correlation experiment. The contour plot (Fig. 5) showed the anticipated cross-peak between the protons at C-2′ and C-4, which confirmed the *Z* stereochemistry. A strong NOE cross-peak was also observed for the *meta* protons and the protons of the 4′-methyl group.

Mosquito bioassays

Samples of **4** and **5***a*–**5***n* were applied to cloth and evaluated as potential insect repellents using two species of laboratory-reared mosquitoes and a published bioassay procedure (17). Against *Anopheles albimanus* Wiedeman, the compounds offered less than 1 day of protection from three or more mosquitoes biting through the cloth. With *Aedes aegypti* (Linn.), **5***a* and **5***c* showed repellency (6 days of protection) greater than that of the standard *N*,*N*-diethyl-*m*-toluamide (2–3 days) but less than that of other oxazolidine chemicals (2, 3).

Since marked differences in the bioactivity of rotational isomers of amides have recently been indicated, for example with antihypertensive dipeptides (18), it is possible that the relatively weak repellent activity of these 2,2-dimethyloxazolidines is related to an unfavorable *Z* stereochemistry. This hypothesis could be examined by studying conformationally restricted analogues that exist predominantly or exclusively as the *E* isomer. Further work in this direction is in progress.

Experimental

The acid chlorides were purchased from Aldrich Chemical Company (Milwaukee, Wis.) or from Pfaltz and Bauer (Stamford, Conn.), except for *m*-chlorobenzoyl chloride, which was prepared from *m*-chlorobenzoic acid using thionyl chloride. Ethanolamine and triethylamine were obtained from Aldrich. HPLC was performed with a Waters Prep LC/System 500 A instrument equipped with Prep PAK Silica cartridges (Waters Associates, Inc.) and a refractive index detector. GC was performed on a Hewlett–Packard 5838A instrument using a fused silica capillary column (30 m × 0.26 mm i.d.) of DB-1 (J and W Scientific) and splitless injections. A Hewlett–Packard 5985B mass spectrometer equipped with a capillary GC column of DB-1 or CP-Wax 57 CB (Chrompack) was used for GC–MS. Infrared spectra were recorded as liquid films on a Perkin–Elmer 137 instrument. Melting points, taken on a Fisher hot-stage or Büchi 530 apparatus, and boiling points, recorded during vacuum distillations, are uncorrected. Elemental analyses were obtained from C. Daessle, Montréal, Québec.

Synthesis

The preparation and characterization of **1–3** have been described (3). The sample of **4** was prepared from acetone (0.2 mol), ethanolamine (0.44 mol), and acetic anhydride (0.44 mol) by method B (19) and isolated in 21% yield as a colorless oil by HPLC with methylene chloride – ethyl acetate (3:1 v/v) followed by

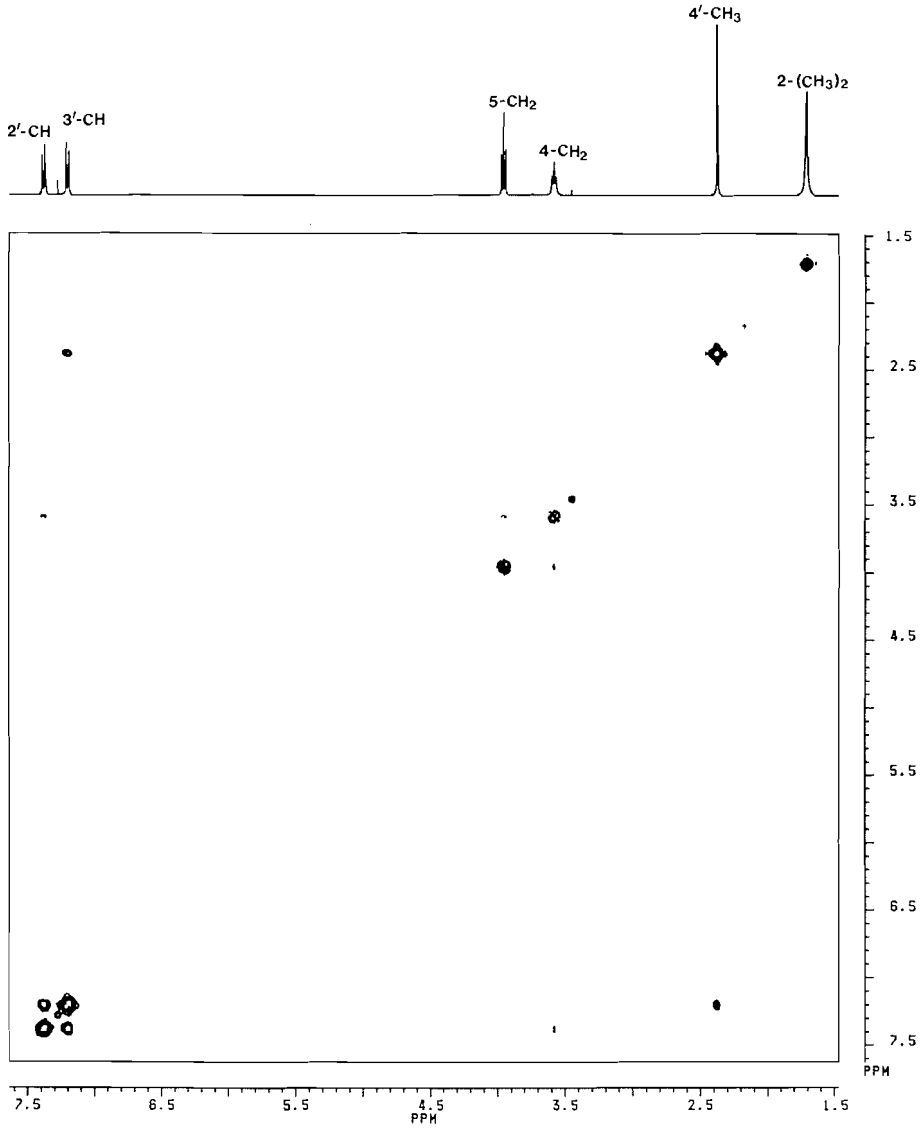

FIG. 5. Contour plot from a NOESY experiment on 2,2-dimethyl-*N*-(4'-methylbenzoyl)oxazolidine (**5***b*) recorded in $CDCl_3$ at 298 K. A conventional proton spectrum (1.47–7.63 ppm) is shown at the top.

distillation: bp 50–53°C (0.05 Torr; 1 Torr = 133.3 Pa) (lit. (20) bp 89–90°C (6 Torr)); IR: 1650 cm^{-1} (C=O); NMR (see Figs. 2 and 3); EI-MS (70 eV) *m/z* (% relative abundance): 143 (M^+, 0), 128 (40), 86 (100), 44 (31), 43 (27); CI-MS (isobutane): 144 (MH^+, 100). Anal. calcd. for $C_7H_{13}NO_2$: C 58.72, H 9.15, N 9.78; found: C 58.96, H 9.24, N 9.79.

Samples of **5***a*–**5***n* were prepared from acetone (0.1 mol), ethanolamine (0.22 mol), and a benzoyl chloride (0.1 mol) essentially following method B of ref. 19 except that triethylamine (0.11 mol) was added to the ice-cold reaction mixture prior to the dropwise addition of the acid chloride. The reaction solvent was dry benzene or toluene. After washing with brine (adjusted to pH 6), the organic layer was dried ($MgSO_4$) and concentrated on a rotary evaporator. Pure samples of **5***a*–**5***h* and **5***j*–**5***k* were obtained by distillation. Crude samples of **5***i* and **5***l* were purified by HPLC with methylene chloride – ethyl acetate – methanol (97: 2.5: 0.5 v/v/v) before distillation. The remaining samples were purified by silica gel (silicAR cc-7) column chromatography (**5***m*) and HPLC (**5***n*) before recrystallization. These samples were of high purity by capillary GC and silica gel TLC (methylene chloride – ethyl acetate, 1:1 v/v). IR spectra showed the amide carbonyl absorption at 1630–1650 cm^{-1}.

NMR spectroscopy

All NMR spectra were acquired in the Fourier transform mode with a Bruker AM-400 spectrometer and Bruker Aspect 3000 software. The ^1H (400.1 MHz) and ^{13}C (100.6 MHz) spectra and the $^1H/^{13}C$ chemical shift correlated two-dimensional spectra (XH-DEPT) were obtained in $CDCl_3$ (0.2 M sample concentrations unless otherwise specified) at 298 K essentially as described before (2).

Coalescence temperatures were determined on 2.0 M solutions of **1–3** in pyridine-d_5 (MSD Isotopes, Dorval, Québec) by variable temperature ^{13}C NMR spectroscopy with a Bruker BVT-1000 temperature control unit. Rotamer populations were derived from peak heights of the paired signals at 298 K.[3]

NOESY spectra were obtained in $CDCl_3$ at 298 K by the standard pulse sequence (recycle delay – 90° – t_1 – 90° – τ – 90° – acquisition) using a 5-mm selective probe with a ^1H 90° pulse length

[3]The following data (one table) may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2: ^{13}C chemical shifts recorded in pyridine-d_5 at 298 K for the rotational isomers of **1–4**.

of 4.9 μs. There were 256 values of t_1 with 16 scans per t_1 increment. These spectra were weighted with a standard sine bell function and zero-filled to 1K × 1K prior to transformation. The contour plots were displayed symmetrized with respect to the diagonal. Mixing times (τ) were chosen that corresponded to the longest spin-lattice relaxation time (T_1) for the protons of interest (8). This corresponded to 3.05 s for the C-7 methyl (acetyl) protons of **4** and to 4.29 s for the *ortho* protons at C-2′,6′ of **5***b*. The T_1 values were measured by the inversion–recovery method with standard Bruker software using NMR solutions previously bubbled with argon for 10 min. To suppress cross-peaks from scalar coupled protons in NOESY experiments (7), random variations to the mixing times were set at 10% of the mixing time.

Molecular mechanics

The molecular mechanics calculations were carried out using the MMX force field of the molecular modelling program PCMODEL (version 3.2), obtained from Serena Software (Bloomington, Ind.). This force field, purchased without the π routines, is similar to the Allinger force field of MM2 (QCPE-395). The program used generalized force field parameters for O-C-N-C (MM2 atom types 6-1-9-1), O-C-C-N (6-1-1-9), N-C-O-C (9-1-6-1), N-C-O-lone pair (9-3-7-20), and C-N-C-C (1-9-3-1). The starting geometry of the oxazolidine ring was flat and separate energy minimizations were performed with torsional angles of 0° and 180° for the C-C-N-C atoms of the acetamide group and C-2 or C-4. Use of the dihedral driver did not uncover more stable conformations than those reported. Calculations were performed using Coulombic (charge–charge) interactions and a value of 1.5 was chosen for the dielectric constant.

The reduction of α-bromocamphor by tertiary amines[1]

JIAN JEFFREY CHEN[2] AND DENNIS D. TANNER
Department of Chemistry, The University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received May 30, 1991

JIAN JEFFREY CHEN and DENNIS D. TANNER. Can. J. Chem. **70**, 173 (1992).

The reduction of α-bromocamphor to camphor by *N,N*-dimethylaniline (DMA) at high temperatures (>200°C) proceeds via a free radical chain sequence. The reduction can be effected with DMA or triethylamine (TEA) in acetonitrile at much lower temperatures in the presence of di-*tert*-butylperoxide. The chain termination step is the dimerization of the camphor radical. These reductions presumably constitute an example of an electron transfer chain mechanism involving a tertiary amine as the chain propagating species.

Key words: reduction, tertiary amines, α-bromocamphor, chain reaction.

JIAN JEFFREY CHEN et DENNIS D. TANNER. Can. J. Chem. **70**, 173 (1992).

La réduction de l'α-bromocamphre en camphre par la *N,N*-diméthylaniline (DMA), à des températures élevées (>200°C), se produit par un mécanisme radicalaire en chaîne. En présence de peroxyde de di-*tert*-butyle, la réduction par de la DMA ou de la triéthylamine (TEA) dans de l'acétonitrile peut être réalisée à des températures beaucoup plus basses. L'étape de terminaison de la chaîne est la dimérisation du radical camphre. Ces réductions constituent probablement un autre exemple d'un mécanisme en chaîne de transfert d'électron impliquant une amine tertiaire comme espèce propageant la chaîne.

Mots clés : réduction, amines tertiaires, α-bromocamphre, réaction en chaîne.

[Traduit par la rédaction]

The reduction of α-bromocamphor (eq. [1]) has been reported to yield camphor (eq. [2]) in the presence of *N,N*-dimethylaniline (DMA) at 200°C (2). Scheme 1 was suggested as the mechanism for reductive debromination. The mechanism assumes that in a primary step the thermal cleavage of the carbon–bromine bond occurs readily at 200°C (eq. [1]). Since the bond dissociation energy (BDE) for the carbon–bromine bond in **1** is expected to be approximately 64 kcal/mol (the carbon–bromine bond dissociation energy for α-bromoacetone) (3), it does not appear to be reasonable,[3] even at these high temperatures, that a nonchain mechanism involving homolytic cleavage of the C—Br bond will lead to an efficient reductive debromination. In accord with this conclusion, the thermal decomposition of **1**, itself, at 200°C yields only a small amount of camphor and no other detectable products (2). The pathway leading to the oxidation product of DMA (eq. [4]) is likewise not clearly defined (2). Utilizing the thermolysis of **1** as an initiation step (eq. [1], Scheme 1) a chain sequence can be proposed that involves a halophilic abstraction of a bromine atom from **1** (eq. [6], Scheme 2). No direct evidence for this pathway is available, with the exception that the dehalogenation proceeds by a chain reaction.

Since the dehalogenation of a number of α-haloketones by 1,3-dimethyl-2-phenylbenzimidazoline (DMBI) (5) and *N*-benzyl-1,4-dihydronicotinamide (BNAH) (6) proceeds via an electron transfer hydrogen abstraction chain sequence (Scheme 3), a more likely mechanistic rationalization for the reported debromination of **1**, in the presence of an amine, is a similar chain sequence where ZH is *N,N*-dimethylaniline (DMA).

[1]Taken in part from ref. 1.

[2]Killam predoctoral fellow. University of Alberta. 1987–1990.

[3]If the preexponential constant reported for the homolysis of several alkyl bromides ($A = 2 \times 10^{13}$) (4) and a BDE of 64 kcal/mol is used for the calculation of the rate constant for the homolysis of α-bromocamphor (**1**) at 200°C (eq. [1]), a value of 1.3×10^{-16} s^{-1} was obtained for k_1. The half-life for **1** is 6×10^{10} days.

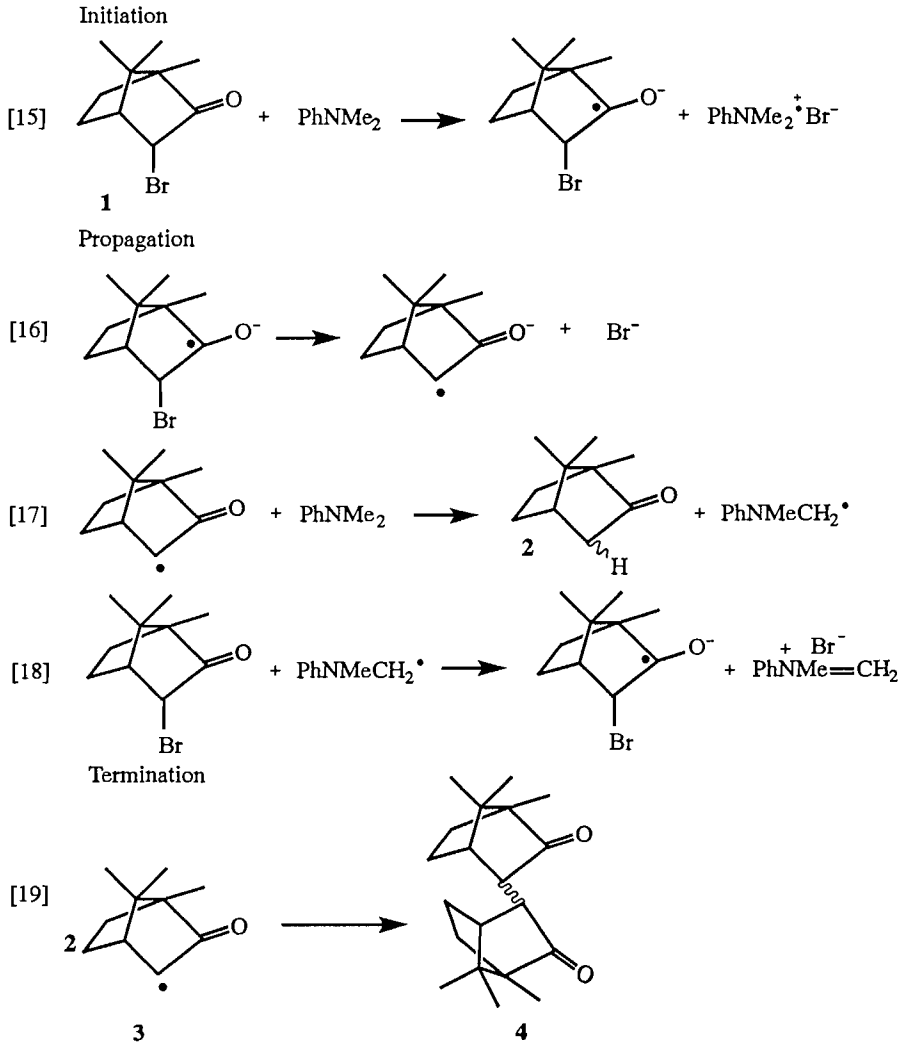

SCHEME 4

Amine radicals as chain carriers have previously been proposed (7).

By analogy to the mechanism established for the reduction of α-haloketones by DMBI (5) and BNAH (6), the reduction α-3-bromocamphor by DMA is likely to follow the radical chain process depicted in Scheme 4.

Initiation of the chain reaction is either thermal (200°C, reaction 1, Table 1), or peroxide initiated at a lower temperature (120°C, di-*tert*-butyl peroxide (BPO), reaction 4, Table 1). The chain was inhibited by the addition of *p*-dinitrobenzene (DMP), reaction 2, Table 1. When triethyl amine (TEA) was used as the reducing agent at the lower temperature (120°C) initiation by BPO is observed, see Table 1. The ability of amines to act as electron donors is well documented. The EPR spectra of quinone radical anions are observed in the reaction of amines with quinones at room temperature (8). EPR spectra were also recorded in the reaction of methylglyoxal with several amines (9). The observation

TABLE 1. The reduction of α-bromocamphor (**1**) to camphor (**2**) by *N*,*N*-dimethylaniline (DMA) and triethylamine (TEA)

Reaction	Amine	Conditions	Product Yield (%) **2**	**1**
1	DMA	Neat,[a] 200°C, 47 h	41.6 ± 0.6	63.4 ± 3.0
2		Neat,[a] 200°C, 47 h, 4% DNB	1.3 ± 0.4	103.5 ± 3.0
3		AN,[b] 120°C, 47 h	1.9 ± 0.2	98.0 ± 2.7
4		AN,[b] 120°C, 47 h, 9% BPO	10.4 ± 0.9	92.4 ± 2.0
5	TEA	AN,[b] 120°C, 47 h	2.2 ± 0.2	101.0 ± 2.2
6		AN,[b] 120°C, 47 h, 11% BPO	101.5 ± 5.5	4.0 ± 0.7
7		Neat,[a] 120°C, 49 h	1.8 ± 0.1	93.4 ± 2.0
8		Neat,[a] 120°C, 49 h, 9% BPO	33.6 ± 4.3	61.4 ± 6.5

[a][**1**] = 0.2 M.
[b][**1**] = 0.1 M, [amine] = 1.0 M.

of the EPR spectra is attributed to direct electron transfer from the amine to the carbonyl compound. In the BPO-initiated reaction the *tert*-butoxy radical reacts quite efficiently with an amine bearing an α-hydrogen to produce an α-aminoalkyl radical (eq. [20]) (10). The α-aminoalkyl radical has been proposed as an intermediate whose function is to act as an electron transfer agent in a radical chain reaction (7, 11).

[20] 
In further support of this proposal, the reduction of **1** by TEA proceeds more slowly in the less polar solvent, neat TEA (reactions 5–8, Table I) (dielectric constant, ε: TEA, 2.42; AN, 37.5) (12). Although this observation may be equivocal, it is consistent with a mechanism that involves an electron transfer process.

A termination step in the initiated free radical chain reduction of α-bromocamphor by amines is the dimerization of the camphor radical (eq. [19], Scheme 4). Three isomeric dimers of the camphor radical (**4**, approximately 0.02% of the starting **1**) were observed in the reaction of **1** with TEA. When the initiated reaction with TEA was carried out in CD_3CN, the product, camphor, was found to have a very low deuterium content (2.8%). The majority of the hydrogen transfer by the camphor radical takes place with TEA.

The reductive debromination of α-bromocamphor by tertiary amines proceeds via a free radical chain mechanism, Scheme 2 or 4. Although no definitive choice can be made between the two mechanisms, reduction by electron transfer – hydrogen atom abstraction appears to be the most attractive pathway, Scheme 4. This mechanistic scheme is also no doubt involved in the dehalogenation of other α-haloketones by DMA at high temperatures (13).

Experimental

Materials

The purification of (+)-α-bromocamphor, camphor, *p*-dinitrobenzene, *p*-di-*tert*-butylbenzene, and acetonitrile (AN) has been previously described (6). Di-*tert*-butylperoxide (BPO) (Aldrich, 98%) was used as supplied. Triethylamine (TEA) was distilled from calcium hydride before use. *N*,*N*-Dimethylaniline (DMA) (Fisher Scientific, reagent grade) was distilled from a small amount of acetic anhydride (14).

General procedure

An aliquot sample of a stock solution of α-bromocamphor (0.1 M or 0.2 M), *p*-di-*tert*-butylbenzene (0.05 M), and the additive in either neat amine or in AN containing the amine was placed in a reaction ampule. The ampule was degassed, sealed, and thermostated at the desired temperature (200°C or 120°C) for the time specified (see Table 1). After the reaction, the ampule was cooled, opened, and analyzed by GC (4,5) using a stainless steel column (20 ft × 1/8 in.) packed with 5% SE-30 on Chromo WAW DMCS 80/100 mesh. Products were identified by a comparison of their GC retention times, GC/IR spectra (using a 50 m Ultra-2 capillary column), and GC/MS spectra (using a 25-m DB-5 capillary column) with those of authentic samples. All reactions were carried out in duplicate.

The three dimers of camphor were detected by GC/MS in the reactions of **1** with TEA. The MS spectra of the three dimers were nearly identical; *m/e*: 302 (M^+), 287, 274, 259, 246, 203, 193, 177, 151, 121, 108, 95, 83, 81, 79, 55, and 41. Their GC/IR spectra were similar to that of camphor. The total yield of the dimers was estimated using their IR intensities relative to camphor. In the reaction of **1** with TEA the yield of the dimers accounted for 0.02% of the starting ketobromide, **1**.

Although no authentic samples of the dimers of camphor were available for comparison, the assignment of the dimers was supported by an indirect observation. A degassed hexane solution of **1** and hexaphenylditin ($Ph_3SnSnPh_3$) was irradiated with a 275-W sunlamp for 17 h. The product mixture was analyzed by GC/IR under the same conditions used for the analysis of the reduction mixture of **1**. Three compounds were detected that had the same GC retention times and GC/MS (*m/e*, 302, M^+) and GC/IR spectra as those observed in the reduction of **1**. These compounds were assigned the structures of the three dimers of camphor.

When the reactions were carried out in CD_3CN the same procedure was followed. The deuterium content of camphor (MW 152) was estimated from the GC/MS measurement of the reaction mixture. The ratio of the intensities of the camphor-d_1 molecular ion (*m/e*, 153, M^+) and camphor-d_0 molecular ion (*m/e*, 152, M^+) was used to determine the deuterium content of camphor.

Binding of water in aqua 18-crown-6 dichloropicric acid complexes in the solid state and its reversible thermal removal

IZAAK M. KOLTHOFF AND MIRAN K. CHANTOONI, JR.[1]
Department of Chemistry, University of Minnesota, Minneapolis, MN 55455-0431, U.S.A.

Received April 8, 1991

IZAAK M. KOLTHOFF and MIRAN K. CHANTOONI, JR. Can. J. Chem. **70**, 177 (1992).

Thermogravimetry, differential scanning calorimetry, and FT-IR vibrational spectral studies on the 1:1:1 18-crown-6:dichloropicric acid:water complex reveal that it remains unaltered when heated to melting. On the other hand, one molecule of water is expelled from the 1:2:2 complex by heating prior to melting. This results in an ionic microcrystalline product of undetermined crystal structure, in which the conformation of the crown is lower than D_{3d} in symmetry. The enthalpy accompanying this process, which involves rupturing of two water–crown hydrogen bonds, is −44 to −55 kJ mol^{-1}. The original 1:2:2 complex is regenerated by exposure of the heated adduct to water vapor. It was found that H_2O in the structure of the solid 1:2:2 adduct was partially replaced by D_2O at room temperature upon exposure to D_2O vapor. The crown–H_2O OH stretch in the IR exhibits a small or negligible positive isotope effect on deuteration.

Key words: crown ether, hydrogen bonding, water, dichloropicric acid.

IZAAK M. KOLTHOFF et MIRAN K. CHANTOONI, JR. Can. J. Chem. **70**, 177 (1992).

Des études de thermogravimétrie, de calorimétrie à balayage différentiel et de spectroscopie vibrationelle IR par TF, effectuées sur le complexe 1 : 1 : 1 18-couronne-6 : acide dichloropicrique : eau, révèlent que ce complexe n'est pas modifié lorsqu'on le chauffe jusqu'à son point de fusion. Par ailleurs, lorsque le complexe 1 : 2 : 2 est soumis à l'action de la chaleur, une molécule d'eau est expulsée avant la fusion. Cette expulsion conduit à la formation d'un produit ionique microcristallin de structure cristalline indéterminée, dans lequel la symétrie de la conformation de la couronne est inférieure à D_{3d}. L'enthalpie qui accompagne ce processus, qui implique le bris de deux liaisons hydrogènes reliant l'eau et l'éther couronne, se situe entre −44 et −55 kJ mol^{-1}. Lorsqu'on soumet le produit obtenu par chauffage à l'action de la vapeur d'eau, le complexe original 1 : 2 : 2 est régénéré. On a trouvé que le H_2O présent dans la structure de l'adduit 1 : 2 : 2 solide est partiellement remplacé par du D_2O lorsqu'on le laisse en présence de D_2O, à la température ambiante. Dans l'IR, la bande d'élongation OH de la couronne–H_2O présente un effet isotopique faiblement positif ou négligeable.

Mots clés : éther couronne, liaison hydrogène, eau, acide dichloropicrique.

[Traduit par la rédaction]

Introduction

The ability of the macrocyclic polyether $(-CH_2CH_2O-)_6$, denoted as 18-cr-6, to form crystalline binary 1:1 and 1:2 host:guest complexes with a large number of neutral organic guest molecules possessing -NH, $-NH_2$, or "acidic" -CH hydrogen bond donating groups has been well documented (1, 2). Water, acting in a dual role as hydrogen bond acceptor to the acidic functional group of the guest molecule, HX, and hydrogen bond donor to the crown heteroatoms, tends to bridge the crown (in its D_{3d} conformation) and monoprotic acid in the uncharged ternary complex 18-cr-6 $(HX \cdot H_2O)_2$ (2). The stereochemistry of the two inversion-related water molecules in this complex is *IA* in the classification scheme of Jeffrey and Maluszynska (3). An attempt to isolate the crystalline binary complex 18-cr-6 · 3,5-dichlorophenol in the absence of water has not been successful (4).

A number of crystalline 1:1:1, 1:1:2, and 1:2:2 18-cr-6:phenol:water adducts (2, 5–10) have been precipitated from organic solvents of intermediate or low polarity (e.g., ethyl acetate, toluene) and their crystal structures determined by X-ray diffraction. To our knowledge, the only neutral aqua 18-cr-6-phenol adduct crystallized from *water* is that of dichloropicric acid, 18-cr-6 $(HPiCl_2 \cdot H_2O)_2$ (**2** in Scheme 1). Crystal structures of both of the polymorphs have been determined (11). Dichloropicric acid, $HPiCl_2$, by far the most acidic of the phenols taken ($pK = -0.7$ in water (12)) participates in a very strong hydrogen bond to water in **2** (O . . . O distance = 2.462 Å).

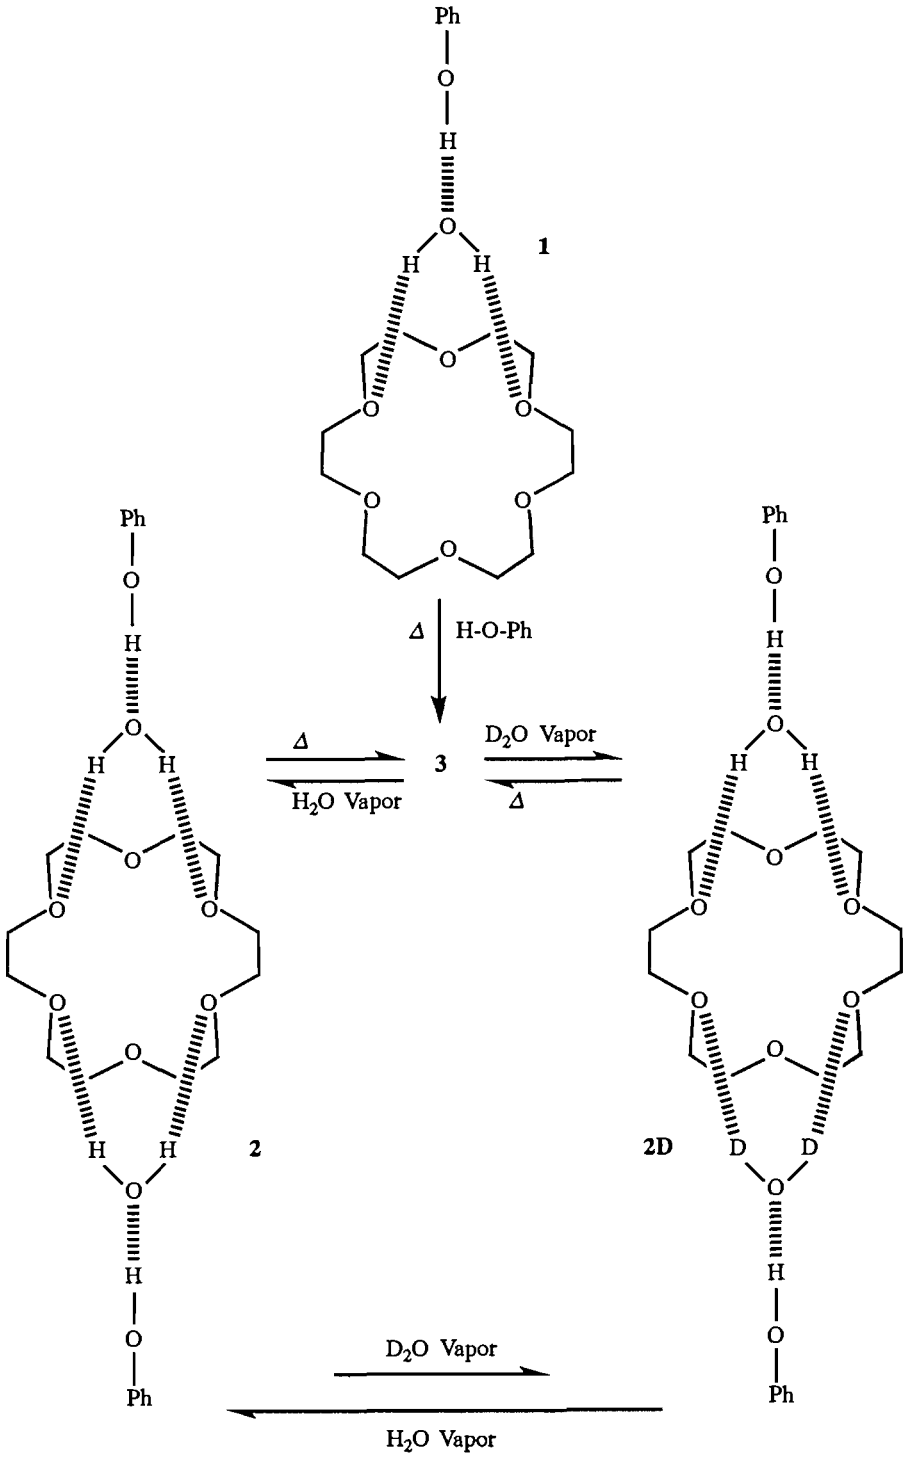
Thermal studies on the crown–acid–water adducts, which can yield information on the strength of binding of the water molecule(s), have not been reported in the literature, largely because of the low melting points of these adducts. In the present paper, results of a thermal analysis of **2** are presented. When heated, **2** is transformed without melting into **3**, which subsequently melts at 123°C (Scheme 1). The following techniques were employed: thermogravimetry (TGA), differential scanning calorimetry (DSC), FT-IR, and assay of the unheated and heated adduct. To establish that changes occur in the crystal structure of **2** upon heating, X-ray powder patterns were run. Using the above techniques, it has been demonstrated that **3** can be reversibly rehydrated on exposure to water vapor at 25°C (Results). Scheme 1 relates the various adducts composed of 18-cr-6, $HPiCl_2$, and water (or D_2O). At present, we are not able to



Ph = 2,4,6-trinitro-3,5-dichorophenyl

decide unambiguously whether **3** has a phenoxide-hydronium (**3***a*) or a phenol-phenoxide-hydronium structure (**3***b*). Although depicted in Scheme 1 as unionized, **1** may in fact be 18-cr-6 ($H_3O^+ \cdot PiCl_2^-$).

To gain insight into the nature of the potential well of the hydrogen bond of the crown oxygens to water, the OD and OH stretching frequencies were compared in the IR spectrum of **2D**. In addition, semiquantitative deuterium isotope exchange studies, which probe the labile character of H_2O in **2**, were

[1] **2** + $D_2O(g) \rightleftarrows$ **2D** + $H_2O(g)$

carried out at 25°C. Finally, the uptakes of D_2O and H_2O vapor by **3** have been compared (Scheme 1).

Experimental

Chemicals

Dichloropicric acid, 18-crown-6, and pentaethyleneglycol dimethylether, GLYME-6, were products used previously (13), while 4,4′-biphenol, 3,5-dichlorophenol, 3-nitrophenol, and 2,4-dinitrophenol (Aldrich Chemical Co.) were used as received. Preparation and purification of the 1:1:1, 1:1:2, and 1:2:2 adducts of the phenols, excepting that of $HPiCl_2$, were carried out by refluxing stoichiometric amounts in toluene and evaporating to crystallization (4). Adduct **1** was prepared by a phase transfer technique, in which 1.32 g (5.0 mmol) 18-cr-6 in 50 mL CH_2ClCH_2Cl (DCE) and 0.30 g (1.0 mmol) $HPiCl_2$ in 50 mL H_2O were stirred for 0.5 h. The organic phase was separated and slowly evaporated at atmospheric pressure (1.0×10^5 Pa) until crystallization. The crystals were washed with 1 mL DCE. Assay: 1:0.95:0.81 (18-cr-6:$HPiCl_2$:H_2O),[2] mp 97.6–99.3°C. The 1:2:1 adduct, **3**, prepared by reacting **1** with $HPiCl_2$ (Results, Scheme 1) softened at 116°C. Its mp, 121.0–122.0°C, was slightly lower than that of **2** when heated, 123–124°C (Table 1). Polymorph II of **2** was precipitated from H_2O at 25°C (11) by slowly adding 0.02 M 18-cr-6 to an equal volume of 0.04 M $HPiCl_2$ and stirring for 10 h. It was recrystallized at 25°C from H_2O by slow evaporation, without stirring, or from $CHCl_3$, DCE, DCE saturated with H_2O, or from DCE:cyclohexane 1:7 (also from the latter at 65°C and cooling). A layering technique between DCE and cyclohexane was also employed for crystallization. Assay: 1:1.96:1.71 from H_2O and 1:(1.975 ± 0.020):(2.035 ± 0.0125) from the organic solvents. Crystals of polymorph I of **2** were separated by hand under a microscope from a mixture of the two polymorphs (11).

The open-chain polyether adduct, GLYME-6 ($HPiCl_2 \cdot H_2O)_2$, was prepared in the same way as polymorph II of **2** and was recrystallized from H_2O at 25°C (mixture of polymorphs). Assay of mixture: 1:2.14:2.28, mp 66.0–67.0°C (square plates), 62.7–63.7°C (needles). All adducts were dried at 25°C over dry N_2 (or over P_2O_5 at 1.3×10^4 Pa pressure for 2 days in the case of GLYME-6 ($HPiCl_2 \cdot H_2O)_2$). Adducts **2** and GLYME-6 ($HPiCl_2 \cdot H_2O)_2$ were not hygroscopic, while **3**, **1**, and **2D** were. Almost completely deuterated 18-cr-6 ($DPiCl_2 \cdot D_2O)_2$ was prepared as described for **2** by precipitating and recrystallizing from D_2O.

Assay procedures

Dichloropicrate in the adducts was determined spectrophotometrically in aqueous 0.001 M NaOH at λ_{max} 380 nm (ε 4.18×10^3). This was checked by alkalimetric titration in H_2O using a glass electrode and was found to agree to within 0.91% of the spectrophotometric value.

[2]A detailed summary of the assays of the various adducts has been deposited as supplementary material and may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada, K1A 052.

18-Crown-6 was determined by first neutralizing $HPiCl_2$ in the adduct in H_2O with KOH and then extracted exhaustively with 0.01 M $KPiCl_2$ (instead of picrate (14)) into CH_2Cl_2 as 18-cr-6 $KPiCl_2$. The latter was found spectrophotometrically at λ_{max} 398 nm (ε = (5.44–5.00) $\times 10^3$, the concentration range being (0–1.5) $\times 10^{-4}$ M). A calibration curve was run with known amounts of $KPiCl_2$ ((0–1) $\times 10^{-4}$ M) in presence of 0.005 M 18-cr-6. In the case of GLYME-6 ($HPiCl_2 \cdot H_2O)_2$, which is poorly extracted into CH_2Cl_2 by the above procedure, the ligand (0.05 M), was determined by ^1H NMR in $CDCl_3$, using 0.264 M *n*-decane as external proton concentration standard. The integrated signals per mol H of *n*-decane (δ 0.879, 1.264 ppm vs. TMS) were averaged and then compared with the integral per mol H of GLYME-6 from the following groups: terminal CH_3O- (6 3.374 ppm), -CH_2- adjacent to CH_3O- (4 3.553, 3.561, 3.571 ppm), and -CH_2-($CH_2CH_2O)_3OCH_2$- (16 3.653, 3.658 ppm). This yielded 1.037, 1.005, and 1.070 mmol GLYME-6/mg adduct, respectively.

The water content of all adducts was estimated from the integral of the ^1H NMR H^+, H_2O signal at δ 7.87–9.68 ppm for **1**, **2**, **3** and 6.597 ppm for GLYME-6 ($HPiCl_2 \cdot H_2O)_2$. The contribution of H^+ was taken equal to the dichloropicrate content. Assays of the partially or totally deuterated adducts were not performed in this study.

Instrumentation

Photomicrographs using either transmitted or reflected light were produced with a Nikon SMZ-10 stereomicroscope equipped with a photographic attachment. DSC scans were performed with a Mettler FP84TA microscopy cell in conjunction with a Mettler FD80 central processor. Aluminum sample cups were used. TGA consisted simply of keeping the sample in a stoppered weighing bottle at a given temperature for 20 min in a mineral oil bath (to constant weight), cooling in a desiccator, and weighing. **Caution**: *Although no detonation occurred in any of the experiments in which dichloropicric acid adducts were heated in 1 g quantities, care must be exercised.* X-ray powder patterns were scanned with a Siemens-D-500 automated diffractometer with CuKα radiation. The powder pattern of **3** exhibited peaks at 2θ = 21.35, 23.30, 19.70, 25.40, and 21.35°, in order of decreasing intensity, as compared to those of **2** at 8.50, 22.95, 21.40, 19.15, 11.40, and 29.40°. When **3** was exposed to H_2O vapor for 12 days at 25°C, peaks were found at 2θ = 23.00, 19.20, 29.50, 28.10, 8.60, 21.40, 23.75, 25.40, and 29.85°. Second harmonic generation capability of the adducts was probed using a homemade Kurtz and Dougherty device (15). Samples were dispersed with Flurolube on a glass slide. Melting points (corrected) were determined with a Thomas Hoover capillary device. UV–VIS absorbances at a single wavelength were taken on a GCA McPherson EU-700 spectrophotometer using 10 mm stoppered silica cells. ^1H NMR one-pulse sequence spectra were scanned by a Nicolet X-300 spectrometer. IR spectra were scanned by means of a Nicolet 5 DXB FT-IR spectrometer and were plotted by an HP 74470A plotter. NaCl discs were used for all samples. All experiments excepting those of DSC and TGA were performed at 20–25°C.

Results

Crystal morphology and X-ray powder pattern of adducts

Photomicrographs of the light yellow monoclinic crystals of polymorphs I and II of 18-cr-6 ($HPiCl_2 \cdot H_2O)_2$ are presented in Fig. 1.

These crystals become opaque, turn golden yellow, and soften when heated to ~75°C and ~87°C, respectively, presumably as a result of microcrystal formation (16). When cooled to 25°C in a dry atmosphere, they remain golden yellow, but again turn light yellow when exposed to water or D_2O vapor. It appears therefore, that **3** is ionic in character, as deduced from its IR spectrum (*vide infra*). Also in

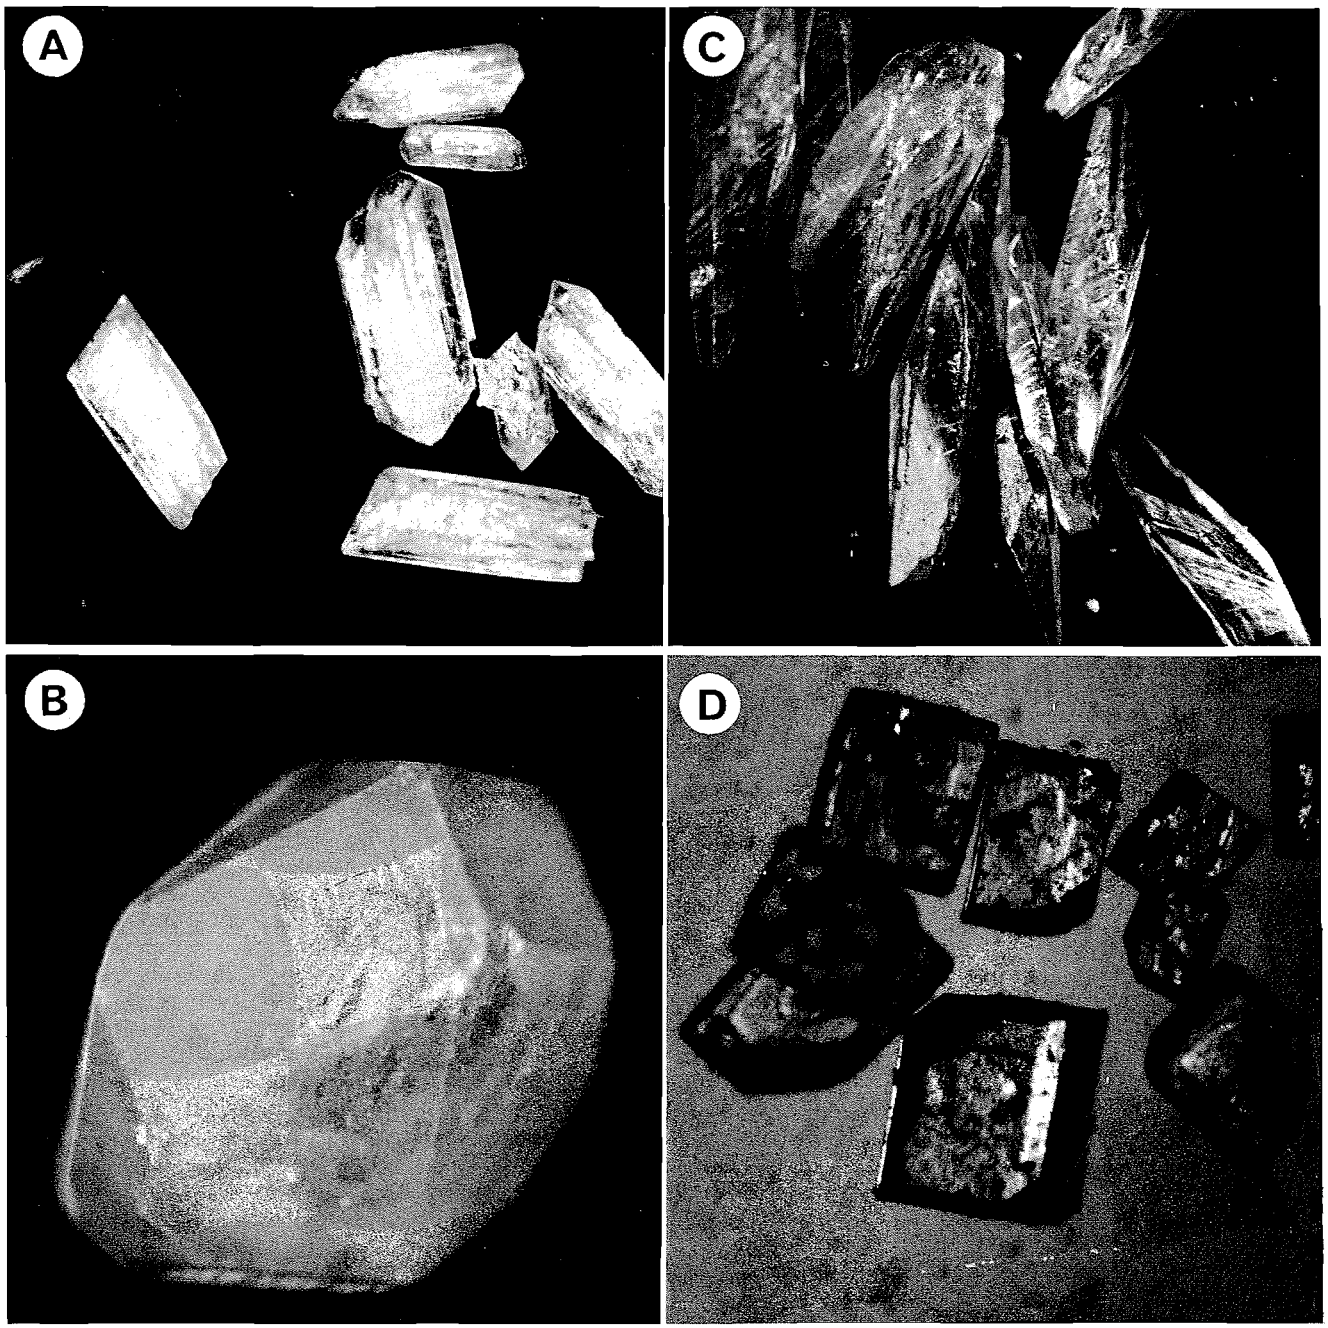

FIG. 1. Photomicrographs of unheated 18-crown-6 $(HPiCl_2 \cdot H_2O)_2$, **2**, and GLYME-6$(HPiCl_2 \cdot H_2O)_2$. A. Polymorph I of **2**. B. Polymorph II of **2** from layering of **2** dissolved in 1,2-dichloroethane with cyclohexane. C. Polymorph II of **2** from water by slow evaporation at 25°C. D. GLYME-6 $(HPiCl_2 \cdot H_2O)_2$ recrystallized in same way as C.

Fig. 1 is a photomicrograph of the very light yellow triclinic rectangular plates of a polymorph of GLYME-6 $(HPiCl_2 \cdot H_2O)_2$.[3] The other polymorph, as needles, is not shown.

The X-ray powder patterns of unheated **2** (polymorph II) and **3** (polymorph II of **2** heated to 113°C and cooled) are compared in Fig. 2. It is evident that **2** and **3** have different crystal structures. Not shown is that of **3** exposed to water vapor, which resembles that of **2** (Experimental).

Differential scanning calorimetry (DSC) and thermogravimetry (TGA) of dichloropicric acid adducts

A DSC scan of **1** (not shown) consists of only the baseline up to 80°C and a small endotherm (~4 kJ mol^{-1}) that merges into that of fusion at ~97°C. This indicates no significant phase change until fusion. A gradual loss in weight, ~2%, from 80 to 100°C is attributed to volatilization of **1** and

[3]D. Britton, J. M. Kolthoff, and M. K. Chantooni, Jr.; crystal structure determination to be published.

For personal use only.

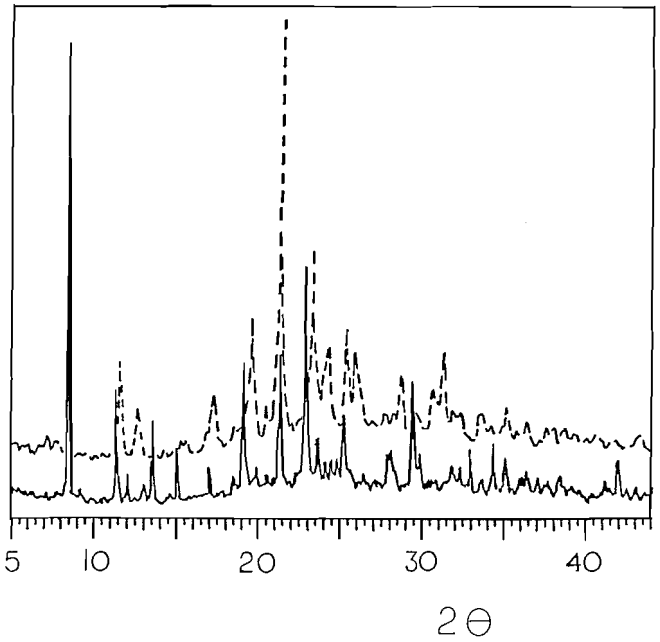

FIG. 2. X-ray powder patterns of unheated and heated **2**, polymorph II: (———) unheated; (— — —) heated to 113°C and cooled. Values of 2θ from 5.0 to 44.0°. λ = 1.541 Å.

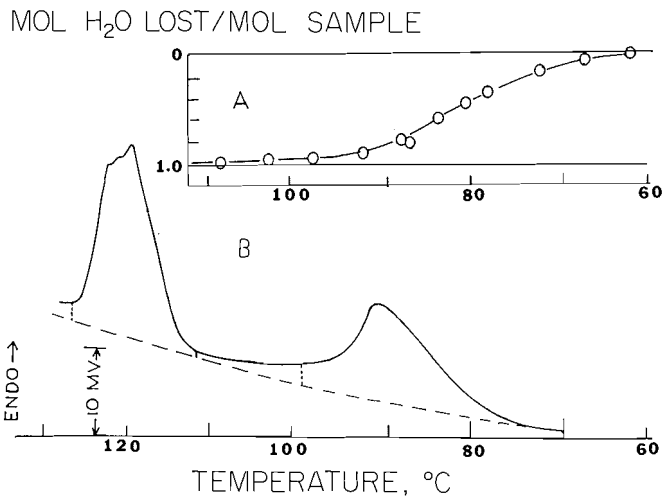

FIG. 3. Thermal studies on 18-crown-6 $(HPiCl_2 \cdot H_2O)_2$, polymorph II. A. TGA on 1618.3 mg 18-cr-6 · 1.96 $HPiCl_2$ · 1.71 H_2O, 10°/min; B. DSC on 5.4 mg 18-cr-6 · 2.00 $HPiCl_2$ · 2.23 H_2O, 3°/min. Vertical dashed lines indicates limits of endotherms.

(or) free $HPiCl_2$. A glass wool plug placed over the bottle containing the sample turned yellow. This does not occur when **2** is heated to 113°C. Both the TGA and DSC[4] of **2**, recrystallized from H_2O at 25°C, are presented in Fig. 3. The onset of loss of weight occurs at ~66°C, some 7°C lower than that of the beginning of the DSC endotherm. This currently is not explained. At higher temperatures a gradual increase in the endotherm is observed, followed by a maximum and subsequent steep decline. Uncertainty in ΔH due to uncertainty in locating the high-temperature limit of the endotherm is ~1.5 kJ mol^{-1}. Constant weight is attained at ~110°C. The loss in weight is linearly correlated with the DSC enthalpy change when the entire DSC is shifted to lower temperatures by 7°C.[5] DSC data of the various adducts are summarized in Table 1.

The loss in weight of **2** at 113°C corresponds to 0.96 mol H_2O/mol adduct, which is confirmed by assay of **3**, 1:2:00:1.16. When **3** is exposed to water vapor for 3 days at 25°C, constant weight is attained, to within 0.04% that of the original unheated sample, **2**. A DSC scan of the rehydrated adduct resembles that of **2** in Fig. 3. It consists of an endotherm at 95°C with $\Delta H = -51.8$ kJ mol^{-1} H_2O and a fusion endotherm of −60.1 kJ mol^{-1}. However, when **3** is rescanned without rehydration, only the baseline is obtained until fusion.

It may be added that exposure of **3** to MeOH vapor results in its superficial uptake, which is lost upon standing for 4 h at 25°C.

Nonlinear harmonic generation in adducts

Considering the dipolar nature of **3***a* or **3***b* and possible acentricity in the crystal structure, the second harmonic generation of **3** was probed, but not found. As expected GLYME-6 $(HPiCl_2 \cdot H_2O)_2$ (space group $P\bar{1}$)[3] and **2** (space group $C2/c$) lacked this capability.

IR spectra of adducts

In Table 2, frequencies of ν(OH) stretching vibrations of water to crown ether oxygens (3350–3550 cm^{-1}) and water to acid (1700–3200 cm^{-1}) in adducts (17–19) of 18-cr-6, water, and various phenols or aliphatic carboxylic acids are entered along with O . . . O distances, d(O . . . O), and O . . . H—O bond angles from X-ray diffraction data. In this study, FT-IR spectra of GLYME-6 $(HPiCl_2 \cdot H_2O)_2$ and aqua complexes of 18-cr-6 with 4,4′-biphenol, 3,5-dichlorophenol, 3-nitrophenol, 2,4-dintrophenol, and $HPiCl_2$ were run, since those of the first five are not available in the literature. FT-IR spectra of **2** and **2D** in the region 1700–3700 cm^{-1} are presented in Fig. 4. The spectrum of **1** (not shown) resembles that of **2**, with the exception of lack of absorption from 2100 to 2600 cm^{-1}. Fermi resonance (19) gives rise to a weak, but persistent, absorption at 1968, 1982, and 1982 cm^{-1} in spectra of unheated **1**, **2**, and **2D**, respectively (Fig. 4). When the crown possesses D_{3d}, or approximately D_{3d}, symmetry, as in unheated 1:1:1 and 1:2:2 aqua complexes of 18-cr-6 with phenols or carboxylic acids, the C-O-C, C-C stretching, and CH_2-CH_2 rocking mode bands occurring at ~1110, ~835, and ~960 cm^{-1} are not, or only slightly, split (19–21). This is found with adducts **1**, **2**, and **2D** in this study (Table 3). On the other hand, these bands are split extensively in the spectrum of unheated GLYME-6 $(HPiCl_2 \cdot H_2O)_2$ (not shown) as a result of the low symmetry of the polyether.[3]

The effects on their IR spectra of heating adducts **1** and **2** at 1.0×10^5 Pa pressure are described next. The entire spectrum of **1** from 400 to 4000 cm^{-1} is practically unchanged when heated to 103°C (Table 3), which is in ac-

[4]In some cases two distinct endotherms have been observed prior to fusion (Table 1). The sum of the ΔH values is the same as that when a single endotherm is encountered. The transition temperature of the first endotherm is not reproducible.

[5]A table of weight loss as ΔH has been deposited as supplementary material in the Depository of Unpublished Data, CISTI, National Research Council of Canada (see footnote 2). The slope of the linear plot is −53.0 kJ mol^{-1}.

TABLE 1. DSC results of 18-crown-6-dichloropicric acid–water adducts

Adduct composition[a]	$T_{transition}$[f] (°C)	$-\Delta H_{transition}$[g] (kJ/mol sample)	$-\Delta H_{fusion}$ (kJ/mol)	Melting point (°C)

cord with DSC results. When **2** is heated to 113°C and cooled in a dry atmosphere, however, the water–crown and water–phenol stretching bands at 3379/3445 and 1771 cm^{-1} disappear, as well as the Fermi-resonance absorption at 1982 cm^{-1}, even though only one water molecule is expelled. These bands are replaced by a broad, moderately strong ν_1/ν_3 absorption of **3** in Fig. 4 (dashed line) from 2400 to 3100 cm^{-1} (centered at ~2650 cm^{-1}), which resembles that of H_3O^+ in 18-cr-6 $H_3O^+ \cdot BF_4^-$ (22) or in *cis-syn-cis*-dicyclohexano-18-cr-6 $H_3O^+ \cdot ClO_4^-$ (23). The pseudo hydronium ion in **3***a* is essentially that found in dicyclohexano-18-cr-6 $(H_3O^+ \cdot PiCl_2^-)_2$ by Peiju *et al.* (24) from X-ray diffraction.

In addition, the $2\nu_2$ symmetrical OH bending and ν_4(OH) asymmetrical bending modes characteristic of H_3O^+ (23) are observed at 2193 and ~1701 cm^{-1}, respectively, in the spectrum of **3**. Moreover, the symmetry of 18-cr-6 has been lowered from practically D_{3d} in **1** and **2** to possibly C_i in **3**, as extensive splitting is found in the C-O-C, C-C stretching, and CH_2CH_2 rocking modes.[6] Results are in Table 3. The presence of a strong absorption from <600 to 1000 cm^{-1} in the IR spectrum of **3** could be ascribed to either $PiCl_2^- \cdots H^+OH_2$ in **3***a* or to $H(PiCl_2)_2^-$ in **3***b*. A spectrum similar to that of **3** (produced when **2** is heated) is obtained when 1 mol $HPiCl_2$ is dissolved in 1 mol melted **1** at 98°C and the solidified mass, which forms after 3 min, remelted at 124°C and cooled (Fig. 4, open circles). This suggests that a mixed adduct, 18-cr-6 · $HPiCl_2$ · HA $(H_2O)_2$ (HA possibly being 2,4-dinitrophenol) could be prepared by reacting HA with melted **1** and hydrating over H_2O vapor.

[6]FT-IR spectra of **2** and **3** in the region 500–1700 cm^{-1} have also been deposited as supplementary material. See footnote 2.

Isotopic deuterium–hydrogen exchange study

In all experiments below the phenol in adducts **3**, **2**, **2D**, and 18-cr-6 $(HPiCl_2)_2$ $H_2O \cdot HDO$ (**3** · HDO) was in the OH form. These adducts were kept at ~25°C and 1.0×10^5 Pa pressure over nitrogen saturated with either H_2O or D_2O, or both, and their IR spectra recorded. When **3** (**2** heated to 117°C) was kept over D_2O for 11 days in a sealed container, **2D** was produced (Scheme 1, Table 3). The D_2O–crown and H_2O–crown doublets at 2502/2573 and 3395/3458 cm^{-1}, respectively, in Fig. 4 are about the same in intensity; the ratio of their integrated areas, $A(OD)/A(OH)$, being 0.92. Exposing **2D** or **3** to H_2O vapor for 4 days resulted in almost complete reversion to **2**. Incomplete exchange ($A(OD)/A(OH) = 0.42$) occurred when **2** was exposed to D_2O for 12 days (Scheme 1). Under these conditions equilibrium [1], the constant of which had not been determined, is displaced to the right. Incorporation of HDO into these adducts, is negligible, as the equilibrium

[2] $H_2O(g) + D_2O(g) \rightleftarrows 2\ HDO(g)$

must lie far to the left. From the above it is surmised that the O—H ··· O water–crown hydrogen bond is somewhat stronger than that of the deuterium analogue, even though a small positive isotope effect was deduced from the infrared (Discussion).

When **2D** was heated to 117°C, cooled, and exposed to D_2O vapor as above, and the procedure repeated three times, the IR spectrum of **2D** was observed ($A(OD)/A(OH) = 0.73$). From this it is inferred that one molecule of D_2O is lost when **2D** is heated and that H_3O^+ or possibly pseudohydronium ion (17) is favored in the structure of **3** over that of D_2OH^+ in the analogous D_2OH^+ compound. The high C_{3v} symmetry of H_3O^+ in **3***b* could be a factor. Replacing one H_2O molecule in **2** by HDO apparently is effected by keeping **3** over *both* H_2O and D_2O for 10 days. A single OD stretching band occurs at 2503 cm^{-1}. The ratio $A(OH)/A(OH)$ was found equal to 0.270, as compared to 0.306 expected for **3** · HDO.

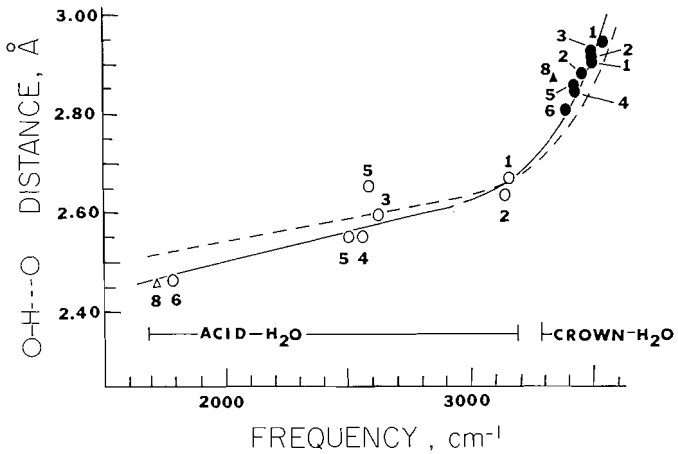

FIG. 5. Relation between O-H ··· O distance and OH stretching frequency of molecular adducts of 18-crown-6 (L) or GLYME-6, with carboxylic acids (or phenols) and water. 1. L·4,4′-biphenol·$2H_2O$. 2. L(3-nitrophenol·$H_2O)_2$. 5. L $(-COOH)_2(H_2O)_2$. 6. L (dichloropicric acid·$H_2O)_2$. 8. GLYME-6 (dichloropicric acid·$H_2O)_2$. Dashed curve is from ref. 25.

Discussion

Correlation between O ··· O distance and IR OH stretching frequency in adducts. Deuterium isotope effects

A plot of the O ··· O distances, d(O ··· O), in various 18-crown-6 aqua complexes vs. OH stretching frequency, ν(OH), in Fig. 5 has been constructed from the data in Table 2. Entries in which the O ··· H—O angle is ≤160° were excluded.

The water-to-crown points, which exhibit a weak dependence of ν(OH) on the acid in the adduct, lie slightly above a similar plot by Novack (25) (dashed line) of O—H ··· O hydrogen-bonded systems not containing crown ethers. Chênevert *et al.* (17) reported ν(OH) to be practically independent of d(O ··· O). It has been suggested (18) that poorly resolved ν(OH) doublets in this high-frequency range could be ascribed to the small difference in water–crown O ··· O distance, Δd(O ··· O). *Approximate* values of Δd(O ··· O) read off the d(O ··· O) vs. ν(OH) plot of Novak using experimental values of ν(OH) in Table 2 are ~0.041 and ~0.036 Å for the 4,4′-biphenol and 3-nitrophenol adducts, respectively, as compared to 0.045 and 0.038 Å from X-ray diffraction studies (Table 2). The presence of a D_2O–crown doublet in addition to a H_2O–crown doublet in the IR spectrum of **2D** in Fig. 4 stipulates that each water molecule in **2** has two different O—H ··· O (crown) distances as required by symmetry. Corresponding values of the ratio ν(OH)/ν(OD) equal to 1.344, 1.354 in the aqua dichloropicric acid 18-cr-6 complex and 1.35 reported in the aqua oxalic acid 18-cr-6 complex (18) characterize a small or negligible positive isotope effect. This is indicative of a single minimum potential well (25) with the proton situated near to the water oxygen.

For the phenolic or carboxylic acid-OH ··· OH_2 stretching band in the above adducts, the plot in Fig. 5 is linear from 1650 to 2700 cm^{-1}, conforming to the relation

$$[3] \quad d(\mathrm{O}\cdots\mathrm{O})(\text{Å}) = 2.21 + 1.40 \times 10^{-4}\nu(\mathrm{OH})(\mathrm{cm}^{-1})$$

The slope is somewhat greater than that of the linear portion of the plot by Novak, 0.8×10^{-4} (dashed line in Fig. 5). The phenolic ν(OD) band in the spectrum of the fully deuterated adduct, 18-cr-6 $(DPiCl_2 \cdot D_2O)_2$ (not shown) occurs at ≤1600 cm^{-1} (ν(OH)/ν(OD) ≥ 1.2), as expected for d(O ··· O) = 2.46 Å (25).

Thermal study on the 1:2:2 18-cr-6 aqua-dichloropicric acid adduct. Postulated mechanism of release of water

From comparison of the DSC and TGA plots of **2** in Fig. 3 it is evident that there is no enthalpy change prior to liberation of water. It is found from a single crystal X-ray diffraction study of **2** at 25°C (11) that there are large thermal vibrations of the proton in the (phenol) OH ··· OH_2 hydrogen bond (B_{eq} = 11 $Å^2$, isotropically refined) and in the H_2O to crown ether hydrogen bonds (B_{eq} 9, 16, $Å^2$). For comparison, the average value of B_{eq} of the methylene crown ring protons is 6.8 ± 1.3 $Å^2$. Apparently, the two hydrogen bonds of one H_2O molecule to the crown ether in **2** break upon heating, releasing $HPiCl_2 \cdot H_2O$, which is unstable ($HPiCl_2$ kept over H_2O vapor was found in this work to be $HPiCl_2 \cdot 0.071\ H_2O$). Picric acid is known not to form a hydrate (26). It is presumed that the remaining water molecule in structures **3***a* or **3***b* meanwhile becomes polarized, as a result of at least a partial proton transfer to it from the phenol. Polarizable hydrogen bonds are encountered in ionization and dissociation of strong acids in water (pK_a = 0–4) as described by Leuchs and Zundel (27). In solution, the critical O ··· O distance for proton transfer to occur is ~2.50 Å (28). This is slightly greater than d(O ··· O) of the 1:2:2 adduct. In this region the shallow double minimum potential well is very sensitive to the environment of the hydrogen-bonded system. The latter can readily be altered thermally.

$$[4] \quad \mathrm{AH}\cdots\mathrm{OH_2} \rightleftarrows \mathrm{A^-} + \mathrm{H^+OH_2}$$

Synthesis, C-13 NMR, and X-ray crystal structure of N6,N9-octamethylenepurinecyclophane

R. A. BELL,[1] R. FAGGIANI, H. N. HUNTER, AND C. J. L. LOCK[1]

Department of Chemistry, McMaster University, Hamilton, Ont., Canada L8S 4M1

Received June 14, 1990[2]

R. A. BELL, R. FAGGIANI, H. N. HUNTER, and C. J. L. LOCK. Can. J. Chem. **70**, 186 (1992).

The synthesis and structure determination of N6,N9-octamethylenepurine cyclophane by single crystal X-ray diffraction is reported. The cyclophane was prepared from 6-chloropurine and 8-aminooctanoic acid as starting materials. The aminooctyl fragment was first attached to N9 of 6-chloropurine by means of the Mitsunobu reaction and cyclization to the cyclophane effected by nucleophilic attack of the amino group at the C6 position and displacement of chloride ion. Reversing the reaction strategy did not result in formation of the cyclophane. Crystals of the cyclophane were monoclinic, $P2_1/n$, a = 9.620(3), b = 12.266(3), c = 11.994(2), Å, β = 111.25(2)°, Z = 4. Intensities were measured with a Nicolet P3 diffractometer and MoKα radiation at room temperature. The structure was solved by direct methods and refined to R = 0.0683, R_w = 0.0493 based on 1730 reflections. The molecule shows some strain, but bond lengths and angles are normal. Attempts to relieve the strain are made by a small distortion of the purine rings and bending of the N6 and C8′ atoms out of the planes to which they are attached (0.314(4), 0.459(5) Å). Further, the N6,H6,C1′ group is twisted by 30° from the pyrimidine plane and the torsion angles in the aliphatic chain are distorted from the idealized 60, 120, 180° (average, 13.6°; range 5.1–24.9°). These distortions result in some weakening of the π-bonding in the adenine moiety.

Key words: purinophane synthesis, nucleophilic aromatic substitution, conformational analysis, crystal structure.

R. A. BELL, R. FAGGIANI, H. N. HUNTER et C. J. L. LOCK. Can. J. Chem. **70**, 186 (1992).

On a réalisé la synthèse du cyclophane N6,N9-octaméthylène purine et on déterminé sa structure par diffraction des rayons-X par un cristal unique. On a préparé ce cyclophane en utilisant la 6-chloropurine et l'acide 8-amino-octanoïque comme produits de départ. On a d'abord relié la fragment amino-octyle à l'azote N9 de la 6-chloropurine à l'aide de la réaction de Mitsunobu et on a ensuite effectué la cyclisation en cyclophane en faisant appel à une attaque nucléophile du groupe aminé sur la position C6 qui provoque un déplacement de l'ion chlorure. Lorsque la stratégie des réactions est inversée, il n'y a pas de formation de cyclophane. Les cristaux du cyclophane sont monocliniques, $P2_1/n$, avec a = 9,620(3), b = 12,266(3) et c = 11.994(2) Å, β = 111,25(2)° et Z = 4. On a mesuré les intensité à l'aide d'un diffractomètre P3 de Nicolet et en utilisant la radiation MoKα, à la température ambiante. On a résolu la structure par des méthodes directes et on l'a affinée jusqu'à des valeurs de R = 0,683 et R_w = 0,0493 pour 1730 réflexions. La molécule présente des tensions, toutefois les longeurs des liaisons et les angles sont normaux. Une partie de la tension est éliminée par une faible distorsion des noyaux purines et un déplacement des atomes N6 et C8′ hors des plans auxquels ils sont attachés (0,314(4) et 0,459(5) Å respectivement). De plus, le groupe N6,H6,C1′ fait un angle de 30° avec le plan de la pyrimidine et les angles de torsions dans la chaîne aliphatique sont déformés par rapport aux valeurs idéales de 60, 120 et 180° (moyenne de 13,6° et écarts allant de 5,1, à 24,9°). Ces distorsions provoquent une diminution de la force de la liaison π dans la portion adénine.

Mots clés : synthèse du purinophane, substitution nucléophile aromatique, analyse conformationnelle, structure de cristaux.

Introduction

Accounting for the chemical effects of the aromatic purine and pyrimidine rings found in ribo- and deoxyribonucleic acids has been the subject of intense study for some time (1).[3] The sequence-dependent arrangement of single (2) and double (3) stranded polynucleotides results in a variety of chemical shift values for neighbouring exchangeable and nonexchangeable heterobase protons. The ability to predetermine the diamagnetic shielding about these aromatic systems would be beneficial for the study of detailed conformational information for a specific sequence.

The two general methods of determining the anisotropy of the molecular diamagnetic susceptibility have involved the use of semi-empirical and quantum mechanics procedures. Originally, the semi-empirical investigations concentrated on calculating the contributions from ring currents (4), local atomic magnetic anisotropy (5), and polarization effects caused by protonation or hydrogen bonding (6). More recently, modifications have come by the comparison of ring current and ^{1}H shifts through correlation with crystal structure coordinates (7). A slightly different approach, which showed good agreement between theoretical and experimental results, was provided through a quantum mechanics study of the total shielding (8).

Despite the level of refinement obtained from the two theoretical approaches, a method of experimentally determining the diamagnetic shielding anisotropy is needed. A previous method of complementing and assessing the shielding anisotropy calculations for benzene involved the examination of the proton chemical shifts of a cyclophane molecule ([10]-paracyclophane) (9). The methylene proton chemical shifts furnished values for the spatial definition of the diamagnetic susceptibility anisotropy around the aromatic system and supplied a viable means of appraising the theoretical calculations.

In the work described here, the synthesis and crystal structure of a purine cyclophane (10) potentially suitable for

the study of the diamagnetic shielding anisotropy about adenine is reported. Our approach to the shielding study necessitated the complete assignment of the ^{1}H NMR spectrum of the purine cyclophane **1** accompanied by the spatial location of the methylene protons relative to the purine system. Also described are the syntheses of two alkylated adenine derivatives used for comparison with the nuclear magnetic resonance (NMR) and ultraviolet (UV) spectroscopic properties of the cyclophane.

Considerations that must be taken into account when designing a cyclophane molecule derived from adenine are the location of the fusion sites on adenine and the length of the methylene chain. The methylene chain should be linked at opposite sides of adenine to enable the bridge to cross directly over the center of the aromatic plane. Purine reactivity and molecular models indicated that favourable fusion sites would be N6 and N9. The resulting methylene proton chemical shifts should provide a variety of shielding values representative of the different regions around the aromatic system. In considering the length of the methylene chain, the number of methylene units must be sufficient so that distortion of the aromatic plane resulting from strain imposed by the bridge is minimized. On the other hand, the chain should be relatively taut in order to restrict the movement of the methylene protons relative to the plane of the purine system. Again, inspection of molecular models revealed that an eight-carbon chain best satisfied these requirements.

Discussion and results

Synthesis

The route chosen for the synthesis of N6,N9-octamethylenepurine cyclophane, **1**, is shown in Scheme 1 and is the combination of two fragments, a purine ring system and a C8-methylene chain. The synthons were selected so that the purine ring was nucleophilic at N9 and electrophilic at C6 and the C8-methylene chain contained the nitrogen atom that was to become N6 in **1**. 6-Chloropurine, **10**, satisfied the first requirement and 8-aminooctanol, **5**, the second, with the hydroxyl group in the presence of the Mitsunobu reagent (11*a*) generating the electrophilic site.[4]

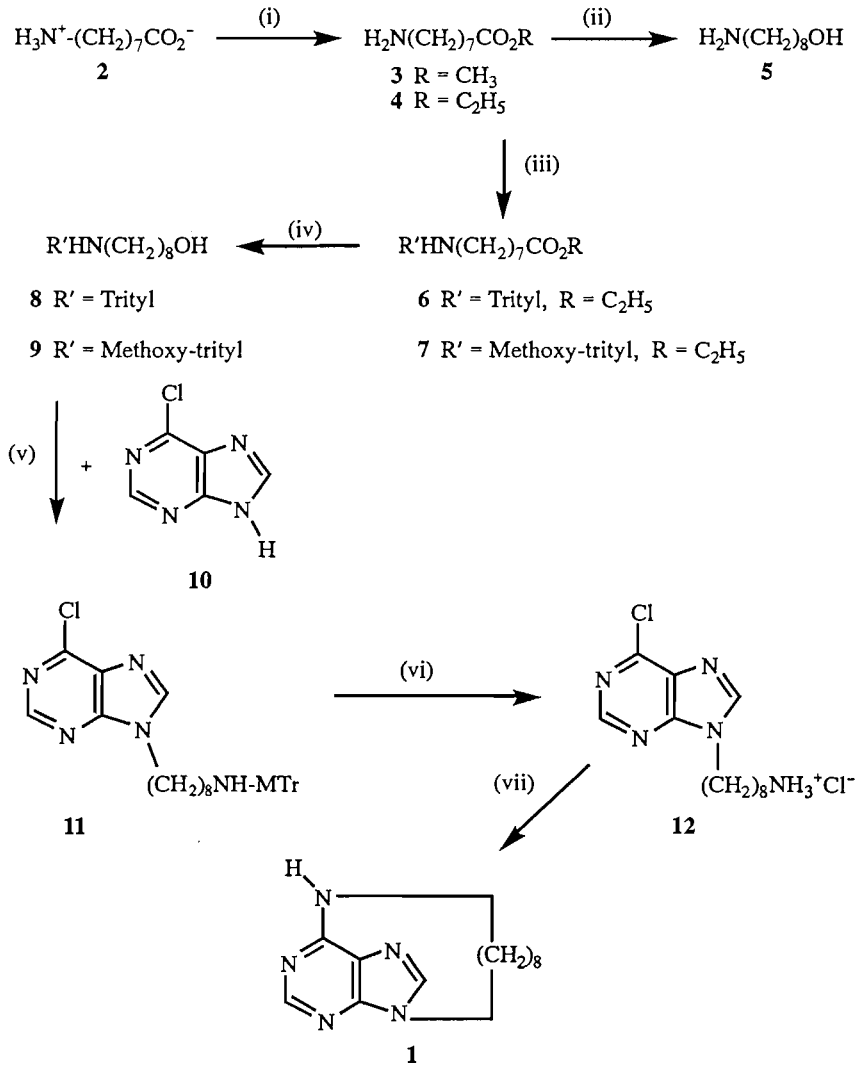
The initial synthetic work was directed towards developing a method of converting 8-aminooctanoic acid, **2**, into 8-aminooctanol. Although **2** is available commercially, it was convenient in the present instance to prepare the amino acid from cyclooctanone via the Beckmann rearrangement by standard procedures (12). Purification of **2** was achieved by adsorption on an ion exchange resin (13).

Initial attempts to reduce amino acid **2** to the amino alcohol with lithium aluminum hydride (LAH) proved fruitless because of the insolubility of the amino acid in suitable aprotic solvents. To overcome this problem, **2** was converted to the methyl ester, **3**, by use of thionyl chloride in methanol (14) and, although the ester could be isolated, it was prone to polyamide formation and difficult to handle. Reduction of freshly prepared samples of **3** with LAH, however, gave very poor yields (<10%) of 8-aminooctanol **5**, presumably because of the formation of insoluble poly(*N*-alkyliminoalane) complexes (15) that were immune to reduction by excess LAH. Reduction with the borane-methyl sulphide reagent (16) likewise led to poor yields of the amino alcohol, even where the potassium salt/18-crown-6 ether modification of Yoon and Cho (17) was used. During these trial reductions the remarkably stable borane-8-aminooctanol adduct was isolated and characterized (18). Fair yields (ca. 30%) of **5** could be obtained by reduction of the ethyl ester by use of the Bouvealt–Blanc procedure with excess sodium in ethanol (19). The ethyl ester **4** was synthesized in order to reduce the rate of polymerization and improve handling characteristics and, in the event, the ethyl group did prove to be of sufficient steric bulk to allow isolation of the amino ethyl ester **4** for brief periods at room temperature.

Since the synthetic scheme required a protected nitrogen atom for the Mitsunobu reaction (11), it was practical to improve the reduction procedure by first blocking the nitrogen atom of amino acid **2** (20). Two blocking groups were tried, the triphenylmethyl (trityl, Tr) group and the monomethoxytriphenylmethyl (methoxytrityl, MTr) group. Szammer (21) has reported the conversion of α-amino acids to the corresponding amino alcohol by reduction of the *N*-trityl ester. Thus, starting with the amino acid ethyl ester **4**, the trityl ester **6** was formed as shown in Scheme **1**. The reaction product was confirmed by the change in chemical shift of the methylene protons adjacent to the amine (from 1.53 to 2.15 ppm) together with the appearance of the expected aromatic protons at 7–7.4 ppm. Electron impact mass spectrometry failed to provide satisfactory molecular ion peaks for **6**, presumably because of thermal decomposition of the sample before ionization. Lithium aluminum hydride reduction of the *N*-trityl ester **6** then resulted in the formation of the *N*-trityl amino alcohol **8** in 87% yield. The ^{1}H NMR spectrum of this compound indicated the loss of ethoxy protons as well as the appearance of a triplet at 3.52 ppm for the methylene protons adjacent to the hydroxyl group. Preliminary trials were carried out on **8** to develop conditions for removal of the trityl group that would not affect the 6-chloropurine moiety. Reductive cleavage under mild conditions with Pd/C in ethyl acetate or ethanol proved unsatisfactory and, as more acidic conditions will remove the chlorine atom from 6-chloropurine, this avenue was not further explored. The trityl group could be successfully removed by acid hydrolysis (HCl–methanol), but these conditions again resulted in the solvolytic loss of the chlorine from 6-chloropurine, and it was concluded that the trityl group alone was not a useful protecting unit. Clearly a group with slightly greater acid lability, but similar steric bulk was required. Smith *et al.* (22) had suggested that the lability of the trityl group should increase as the number of *p*-methoxy substituents increased. With this in mind, the *N*-methoxytrityl ester **7** was prepared and reduced to the *N*-methoxytrityl amino alcohol **9** with LAH in greater than 97% yield from amino acid **2**. The C-13 NMR spectra for both the methoxytrityl ester and the methoxytrityl amino alcohol could be assigned by comparison with C-13 chemical shifts recorded for *n*-octanol, *n*-octylamine, ethyl octanoate, *p*-methoxybenzylamine, and triphenylcarbinol (23). Trial hydrolyses of compound **9** indicated that trifluoroacetic acid in methylene chloride followed by a methanol quench successfully cleaved the methoxytrityl group (24), and similar exposure of 6-chloropurine, **10**, to these mild reaction conditions showed that **10** was recovered completely unchanged.

Reaction of *N*-methoxytrityl amino alcohol **9** with 6-chloropurine, **10**, with use of the method of Mitsunobu (11*a*), afforded the N9-alkylated adduct **11** in 56% isolated yield.

[4]For an example of the use of this reaction using 6-chloropurine see ref. 11*b*.



Reagents: (i) $SOCl_2$, MeOH or EtOH, 0°C. (ii) Sodium, ethanol, reflux. (iii) TrCl or MTrCl, Py, 0°C. (iv) $LiAlH_4$, ether, reflux. (v) DEAD, triphenylphosphine, THF, RT, 8 h. (vi) TFA, MeOH, 1 h. (vii) Acetonitrile, -20°C, 2 h; reflux, 24 h.

SCHEME 1

The proton NMR spectrum of **11** showed purine H-8 and H-2 absorptions at 8.74 and 8.08 ppm and the appearance of a triplet at 4.26 ppm arising from the methylene protons adjacent to N9 of the purine. The ^{13}C NMR spectrum was readily assigned by comparison with chemical shift data recorded for 6-chloropurine, *n*-octylamine, triphenylcarbinol, and *p*-methoxybenzyl-amine (23). Removal of the methoxytrityl group by the trifluoroacetic acid/methylene chloride/methanol procedure noted above yielded compound **12**, which was isolated as the hydrochloride salt and characterized by its proton NMR spectrum. Compound **12** appeared stable when stored as the hydrochloride salt.

The C8 methylene chain was chosen because, from the inspection of molecular models, it was expected to be reasonably taut across the purine ring, but not so strained as to cause extensive distortion of the purine. Intramolecular ring closure at the C6 site was expected to be less influenced by steric strain because of the geometry of nucleophilic attack at the C-6 site of a purine. Figure 1 shows the probable steps involved in the conversion of a substituted 6-chloropurine into an adenine cyclophane. The tetrahedral intermediate, **16**, arises from attack of the primary amine nitrogen of **12** on the *p* orbital at C6 (i.e., perpendicular to the plane of the purine). Thus, during the formation of **16**, there would be only a small constraint placed upon the conformation of the alkyl chain in order to allow the intermediate to be formed. The main imposition of the strain on the alkyl chain would be encountered in the subsequent collapse of the tetrahedral intermediate, when loss of chloride occurs causing the N6 nitrogen to move into the plane of the purine system and thus allows the C6 carbon to again become sp^2 hybridized.

The final ring closure was accomplished by taking into account observations from model experiments (see Scheme 2). These had indicated that primary amines reacted quickly with 6-chloropurine in polar, aprotic solvents such as dimethyl sulphoxide (DMSO), but it was undesirable to use DMSO in the large volumes required to ensure proper solute dilution for intramolecular reaction. Therefore, aceto-

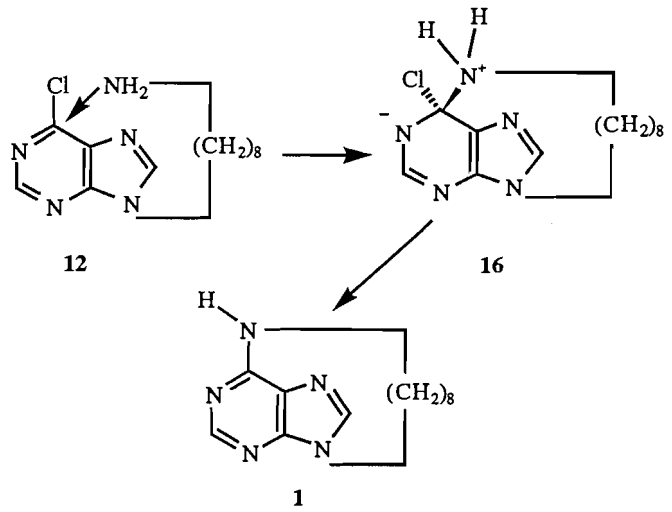

FIG. 1. Diagramatic view of the attack of the NH_2 nucleophile on the site of the 6-chlorine atom proceeding to the tetrahedral transition state **16**.

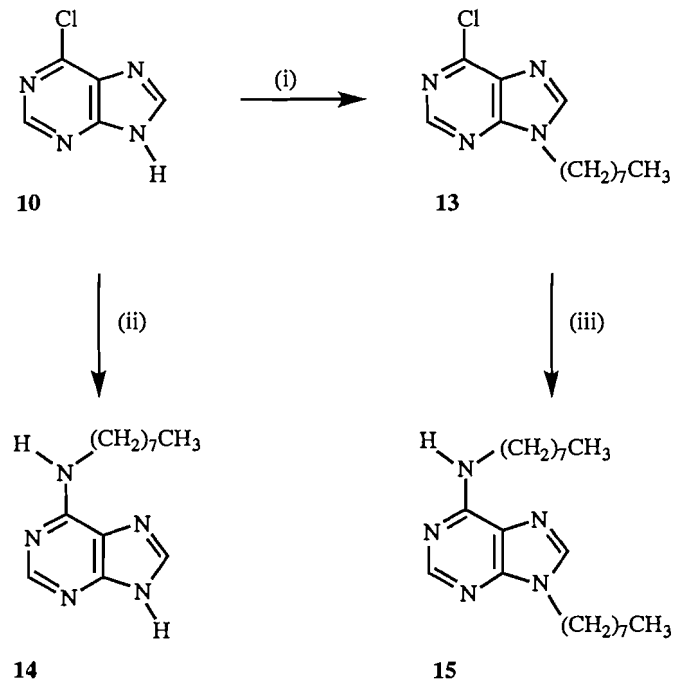

Reagents: (i) *n*-Octanol, triphenylphosphine, DEAD, THF, RT, 8 h; (ii) *n*-Octylamine, acetonitrile, 60°C, 24 h; (iii) *n*-Octylamine, acetonitrile, 60° C, 24 h.

SCHEME 2

nitrile was chosen as the solvent since it possessed similar solvent characteristics to DMSO (25) but was easier to remove upon completion of the reaction. The free amine was best generated from the hydrochloride salt **12** *in situ* and this was accomplished by combining the hindered non-nucleophilic base *N,N*-diisopropylethylamine with the **12** at low temperature (−23°C) and in relatively high concentration. The mixture was then diluted to 10^{-3} M with dry acetonitrile and heated. These reaction conditions gave the octamethylenepurine cyclophane **1** in 30% yield after chromatographic purification. The proton NMR spectrum of **1** was remarkable in showing all 16 methylene protons as diastereotopic and ranging in chemical shift from −0.6 to 4.8 ppm. Assignments were made initially from a two-dimensional COSY spectrum in conjunction with energy-minimized, computer-generated molecular models (26). Further confirmation came from two-dimensional $^{13}C-^{1}H$ heteronuclear shift correlated spectra together with the solid state conformation of the molecule demonstrated by the X-ray crystallographic study reported herein.

N6-Octylpurine, **14**, N9-octylpurine, **13**, and N6,N9-dioctylpurine, **15**, were prepared in model experiments (see Scheme **2**) to assist in refining experimental conditions for the preparation of **1** and also to act as models for the NMR and UV spectrum of **1**. The dialkyl compound **15** showed a UV maximum at λ 268 nm and **1** showed a maximum at λ 278 nm, indicating that some distortion of the purine ring has occurred (see discussion below).

It is of interest to note that during the synthetic work an attempt was made to prepare **1** by first forming the C6–N6 bond and then using the Mitsunobu reaction to carry out the intramolecular cyclization. 6-Chloropurine was readily *N*-alkylated at C6 with amino alcohol **5** by use of the method of Sutherland and Christensen (27), yielding 85% of **17**. The *N*-alkylation was confirmed by high resolution mass spectral data and comparison of the methylene CH_2NH chemical shift differences in the proton spectra of the product **17** (3.35 ppm) and amino alcohol **5** (1.53 ppm). In the final cyclization the electrostatic attraction within the intermediate **18** was expected to assist the ring closure (28). However, after prolonged reaction times and under a variety of reaction conditions, the cyclophane failed to form in detectable yields. This result could have arisen from two possible sources: (*i*) The Mitsunobu reaction proceeds by a number of bimolecular steps but, because intermolecular reaction must be minimized, the starting reactants are present at low concentration. Thus, the rate of these intermediate bimolecular steps would be extremely slow and other reaction pathways may occur before the Mitsunobu zwitterion could form. (*ii*) If the intermediate **18** was formed, reaction may not have taken place if the electron density in the highest occupied molecular orbital (HOMO) on N9 was not correctly oriented. If the HOMO at N9 is *perpendicular* to the ring then there will be minimal steric strain in the approach of the end $CH_2OP^+(Ph)_3$ unit, and an S_N2 transition state should be attainable with a normal activation barrier. If, however, the HOMO at N9 is *in the plane* of the purine ring, then to attain an S_N2 transition state would require severe stretching of the end methylene beyond N9 and **in the plane of the ring**. Molecular models suggest that such a transition state would be very difficult to attain without excessive strain on the alkyl chain and bending of the purine, and therefore make the intramolecular reaction inaccessible. Unfortunately our experiments did not distinguish between these two possibilities. It was noted that for prolonged reaction times there was incomplete recovery of **17**.

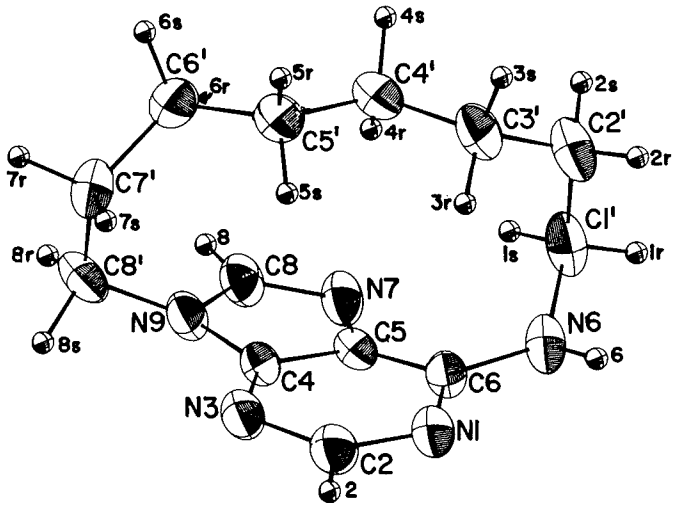

FIG. 2. The molecule of **1** showing the atom numbering. Hydrogen atoms are labelled by affix only in smaller print.

Diffraction studies and conformational analysis

The molecule is shown in Fig. 2 and bond lengths and angles are given in Table 3. One assumes that the structure has at least a small amount of strain present since there are a number of non-bonding distances that are shorter than the accepted van der Waals distances of 2.90–3.10 Å, C...H; 2.75–3.00 Å, N...H; 3.30 Å, C...C; 3.20–3.25 Å, C...N (29). These are C7′...C4, 3.154(4); C6′...N9, 2.941(4); H6r...C8, 2.72; H5s...C4, 1.94; H5s...N3, 2.66; H5s...C5, 2.44; H4s...N7, 2.52; H4s...C5, 2.80; H4s...C8, 2.84; C3′...C6, 3.134(4); H3r...C6, 2.57; H1s...C5, 2.64; H1s...C6, 2.63 (all in Å). Therefore, one looks for distortions in the structure that might indicate attempts to relieve the strain.

One can get an impression of the magnitude of the strain energies, which we pointed out above should be relatively small, from the nature of the distortions of the structure. Bond lengthening or shortening is energetically difficult and it is not surprising that the bond lengths within the adenine moiety agree very well with average values published previously (30). All values for the bond lengths lie within 0.51σ ($\sigma = (\sigma_1^2 + \sigma_2^2)^{1/2}$) of the average values, except C2—N3, which differs by 1.90σ. Similar agreement is obtained between the C—C and C—N distances in the aliphatic chain and published average values (31).

Angular distortions are energetically easier, but although variation is somewhat larger, all angles in the adenine moiety, except C8—N9—C8′ (2.86σ) lie within 2σ of the average values. Similarly C—C—C angles in the aliphatic chain (average value 115.1°, see Table 3) agree well with average values found in long-chain structures in which strain should be absent (114.9° (32), 114.3°, 114.6° (33), 114.9° (34)).

Twisting motions are energetically easiest and are observed. The adenine moiety shows small but significant distortions from planarity, whether one considers the molecule as a whole or the separate pyrimidine and imidazole rings. The dihedral angle between the pyrimidine and imidazole rings is 5.45(9)°, which is not excessive, but at the higher end of the normal range (30), and is not derived from bending about the C4—C5 bond like the pages of a book, but twisting of the imidazole ring relative to the pyrimidine ring about the C8-(centre of C4,C5) axis. The pyrimidine ring can be considered as a distorted boat with C2 and C5 forming the bow and stern. Both these distortions are to allow N6 and C8′ to move towards the aliphatic chain. This is reinforced by both N6 and C8′ being out of the planes of the rings to which they are attached (N6, 0.314(4) Å, C8′, 0.459(5) Å), again in the direction of the aliphatic chain. Further strain relief is achieved by the twist of the N6,H6,C1′ group from the pyrimidine plane by about 30° (C1′—N6—C6—C5, 30.6(3)°; C1′—N6—C6—N1, 147.4(3)°). All these distortions will tend to weaken the π-bonding within the adenine moiety, as can be seen in the bathochromic shift of the long wavelength UV absorption noted for **1** above. Further small distortions occur in the aliphatic chain. The chain is trying to lie as close as possible to the adenine ring system and this causes deviation of the N—C—C—C and C—C—C—C torsional angles from the idealized 60, 120, 180° values (average, 13.6°; range 5.1–24.9°). In particular the C2′—C3′—C4′—C5′, C3′—C4′—C5′—C6′, and C4′—C5′—C6′—C7′ angles (−158.0, 169.1, 139.0°) differ from the 180° found in unstrained aliphatic chains (32–34).

The packing is shown in Fig. 3. The molecules are arranged so that they lie in a layer centred on the 1 0 1 planes. The diagram shows the view normal to these planes. Surprisingly, the molecules are arranged so that there can be none of the expected π–π interaction between adenine moieties in adjacent molecules, perhaps also suggesting some weakening of the π-bonding. Thus both between layers and within layers only intermolecular van der Waals forces are present.

Experimental methods

Melting points were recorded on a Gallencamp capillary tube melting point apparatus and are uncorrected. Proton magnetic resonance (^{1}H NMR) spectra were recorded on a Varian EM-390 or Bruker WM-250 and AM-500 spectrometers with chloroform-*d* as the solvent unless otherwise noted. Unless specified, the usual internal references were tetramethylsilane (TMS) or chloroform. The abbreviations s = singlet, d = doublet, t = triplet, q = quartet, and m = multipet are used in the description of the spin–spin splitting pattern present in the spectra. The natural abundance carbon-13 magnetic resonances (^{13}C NMR) were recorded on Bruker WP-80 (at 20.115 MHz), WM-250 (at 62.896 MHz), and AM-500 (at 125.776 MHz) instruments using chloroform-*d* as the solvent and internal reference unless otherwise noted. All ^{13}C spectra were broad band decoupled. The ^{13}C NMR assignments based upon the literature were obtained from the following sources: *n*-octanol from the Bruker ^{13}C Data Bank (23); triphenylcarbinol from Olah *et al.* (35); 6-chloropurine from Szarek *et al.* (36); and *n*-octylamine and *p*-methoxybenzylamine from Sadtler Standard ^{13}C NMR spectra (23). Low resolution mass spectra (MS) and high resolution mass spectra (HRMS) were obtained at 70 eV on a VG Micromass 7070F double focussing mass spectrometer with the samples being introduced through a direct inlet system. Mass spectra obtained by the Fast Atom Bombardment (FAB) technique were recorded on a VG ZAB-E mass spectrometer. Infrared spectra (IR) were recorded on a Perkin Elmer 283 spectrometer. IR samples were run as neat liquids. The symbols s = strong, m = medium, w = weak, and sh = shoulder were used in the recording of the IR data to indicate the intensity of the recorded bands.

Dry ethanol was obtained by the method of Smith (37). *n*-Butanol, triethylamine, and pyridine were distilled over calcium hydride and stored over 4 Å molecular sieves until needed. Tetrahydrofuran (THF) was dried by refluxing and distilling from sodium and benzophenone under dry nitrogen. THF was collected from the distillation apparatus as required. Methanol was dried by

refluxing over magnesium, distilled, and stored over molecular sieves. NMR solvents chloroform-*d*, methylene chloride-d_2, and dimethyl sulphoxide-d_6 were stored over molecular sieves before use.

Unless alternately specified, column chromatography was performed by the "flash" method of Still, Kahn, and Mitra (38). The silica gel used for column chromatography (5.0% of 100 mesh up, 47.6% of 100–200 mesh, and 47.4% of 200 mesh down) was purchased from Terochem. Silica gel 60 F254 (E. Merck Co.) plates of 0.2 mm thickness were used for analytical thin-layer chromatography. Reversed phase Sep-Pak C18 cartridges were obtained from Waters Associates. Reversed phase KC18F glass-backed thin-layer analytical plates (layer thickness 0.2 mm) were purchased from Whatman Co.

Cyclooctanone oxime

The procedure used was similar to the method of Coffman *et al.* (12). To a stirred solution of cyclooctanone (10 g, 0.079 mol) in dry absolute ethanol (50 mL), was added hydroxylamine hydrochloride (8.81 g, 0.127 mol). An aqueous solution of 50 mL of 1.3 M potassium carbonate was added dropwise and the solution was warmed to 50°C for 2 h. The ethanol solvent was evaporated under reduced pressure in a rotary evaporator and the remaining aqueous solution was extracted three times with 50-mL portions of chloroform. The chloroform extracts were combined, dried over anhydrous sodium sulphate, and the chloroform evaporated under reduced pressure in a rotary evaporator. This yielded 9.4 g (84%) cyclooctanone oxime (bp 87–88°C at 2.5 Torr (lit. (12) bp 123–124°C at 14 Torr; 1 Torr = 133.3 Pa). The oxime showed IR, ν_{max}: 1655 (m)(C=N) cm^{-1}. ^1H NMR (EM 390) δ: 1.47 (s, 6H, carbons 4,5,6 CH_2), 1.73 (s, 4H, carbons 3,7 CH_2), 2.40 (m, 4H, carbons 2.8 CH_2), 10.13 (s, 1H, OH). MS, *m/z* (RI%): 141 (21) [M^+], 124 (12) [M^+ − OH], 113 (100), 98 (32) [M^+ − CHNO], 73 (82), 55(50). HRMS, for $C_8H_{15}NO$, calcd.: 141.1154; found: 141.1130.

Cyclooctanone isooxime (2-azacyclononanone)

The procedure followed was similar to the method of Coffman *et al.* (12). To a stirred solution of sulphuric acid (4 mL of 96%) with distilled water (0.1 mL) at 110°C was added cyclooctanone oxime (951 mg, 6.74 mmol) dropwise. The solution was cooled to room temperature, poured onto ice (90 g), and neutralized with small portions of solid sodium hydroxide. The solution was extracted three times with 100-mL portions of chloroform. The combined extracts were dried over sodium sulphate (anhydrous) and evaporated under reduced pressure in a rotary evaporator, yielding 666.6 (70.0%) of a light brown solid, (mp 74.5–76.5°C (lit. (12) mp 77–79°C). The isooxime showed IR, ν_{max}: 3300 (s)[N-H], and 1650 (s)[CO] cm^{-1}. ^1H NMR (EM 390) δ: 1.6 (m, 10H, carbons 4,5,6,7,8 CH_2), 2.45 (*t*, *J* = 6 Hz, 2H, CH_2−CO), 3.35 (m, 2H, N-CH_2), 6.33 (br s, 1H, N-H). MS, *m/z* (RI%); 141 (35) [M^+], 124 (88) [M^+ − OH], 112 (24), 98 (62) [M^+ − CHNO], 56 (100). HRMS, for $C_8H_{16}NO$ [M + 1]$^+$, calcd.: 142.1232; found: 142.1243.

8-Aminooctanoic acid, 2

The method used was similar to that of Eck (39) or Takagi and Hayashi (13). To a stirred solution of 2-azacyclononanone (0.54 g, 3.8 mmol) dissolved in 5.2 mL of distilled water was added 1.5 mL of concentrated hydrochloric acid and the solution heated to reflux for 2 h. Amberlite IR-120 resin (40 mL) was washed three times with 20-mL portions of methanol and then washed five times with 20-mL portions of distilled water followed by 5 mL of 0.25 M hydrochloric acid. After cooling to room temperature, the hydrolysis solution was added to the resin and allowed to stir for 12 h. The solution was decanted and the resin was washed with distilled water until the washings were neutral. Distilled water (15 mL) and 1 M ammonium hydroxide were added to the resin until the solution was pH 9 and this mixture was stirred for 1 h. After decanting, more distilled water and ammonium hydride were added and the cycle repeated until four decantations were performed. These four solutions were combined and evaporated by use of a rotary evaporator under high vacuum. At the conclusion, benzene was used to form an azeotrope and remove remaining traces of water. Compound **2** was isolated as a cream-coloured solid (0.554 g, 98%) and it showed ^1H NMR (EM 390) D_2O solvent, δ:1.37 (m, 10H, carbons 3,4,5,6,7 CH_2), 2.17 (t, *J* = 6 Hz, 2H, CH_2COO), and 2.97 (t, *J* = 6 Hz, 2H, CH_2NH_2).

Ethyl 8-aminooctanoate, 4

The procedure described was similar to that of Huber and Brenner (14). To obtain the methyl ester, the same procedure was followed with methanol as the solvent. To 10 mL of ethanol stirred under nitrogen atmosphere at −5°C (ice/acetone bath) was added thionyl chloride (0.50 mL, 6.9 mmol) dropwise. After 5 min, 8-aminooctanoic acid, **2** (1.0 g, 6.3 mmol), was added and the solution stirred for 1 h at −5°C followed by 2 h at 40°C. The solvent was then evaporated under reduced pressure in a rotary evaporator and the residue was redissolved in 25 mL chloroform. Distilled water (25 mL) was added and the aqueous layer was adjusted to pH 8–9 with 1 M sodium hydroxide. The chloroform layer was removed and the aqueous layer was extracted twice with 25-mL portions of chloroform. The chloroform extracts were combined, dried over anhydrous sodium sulphate, and evaporated under reduced pressure in a rotary evaporator yielding 1.117 g (95%) ethyl 8-aminooctanoate which showed IR, ν_{max}: 3400 (m)[NH_2] and 1735 (s)[C=O] cm^{-1}. ^1H NMR (EM 390) δ: 1.23 (m, 15H, NH_2 and carbons 3,4,5,6,7 CH_2 and CH_3), 2.18 (t, *J* = 6 Hz, 2H, CH_2CO), 2.58 (t, *J* = 6 Hz, 2H, CH_2N), and 4.03 (q, *J* = 6 Hz, 2H, OCH_2). ^{13}C NMR (WP 80) δ: 173.6 (s, 1C, COO),

60 (s, 1C, OCH_2), 41.9 (s,1C,NCH_2), 34.2 (s,1C,CH_2CO), 33.2(s,1C,C7), 28.9 (s,2C,C4 and C5), 26.5 (s,1C,C6), 24.8 (s,1C,C3), and 14.1 (s,1C,CH_3). (Assignments based upon values for ethyl octanoate and *n*-octylamine (23).) HRMS, for $C_{10}H_{21}NO_2$ $(M + 1)^+$, calcd.: 187.1572; found: 187.1540. MS, *m/z* (RI%); 188 (33)$[M + 1]^+$, 158 (2)$[M^+ - CH_2CH_3]$, 142 (63)$[M^+ - OCH_2CH_3]$, 114 (4)$[M^+ - COOCH_2CH_3]$, and 100 (100)$[M^+ - CH_2COOCH_2CH_3]$.

8-Aminooctanol, 5

The procedure used was similar to that of Manske (19). Ethyl 8-aminooctanoate, **4** (97.5 mg, 0.518 mmol) was dissolved in anhydrous ethanol (5 mL). Without heating or stirring, sodium metal (145 mg, 6.3 mmol) was added as one piece. After the reaction was complete, distilled water (5 mL) was added dropwise. The ethanol was evaporated under reduced pressure in a rotary evaporator and the remaining aqueous solution was extracted three times with 10-ml portions of chloroform. The chloroform was evaporated under reduced pressure leaving the amino alcohol (22.5 mg, 30%) as a white solid. The aqueous extracts contained amino acid and were recovered for reuse. Amino alcohol **5** showed: ^1H NMR (EM 390) δ: 1.27 (s, 12H,carbons 2,3,4,5,6,7 CH_2), 1.53 (s,3H,OH and NH_2), 2.60 (t, J = 6 Hz,2H,CH_2N), and 3.53 (t, J = 6 Hz,2H,CH_2O). ^{13}C NMR (WP 80) δ: 62.22(s,1C,$HOCH_2$), 42.0 (s,1C,CH_2N), 33.5 (s,1C,C7), 32.7 (s,1C,C2), 29.2 (s,2C,C4 and C5), 26.6 (s,1C,C3), and 25.6 (s,1C,C6). (Assignments based upon values for *n*-octanol and *n*-octylamine (23).) MS, *m/z* (RI%): 144 (9)$[M^+ - 1]$, 128 (8)$[M^+ - NH_2]$, 115 (40)$[M^+ - CH_2NH_2]$, and 55 (100). HRMS, for $C_8H_{19}NO$ $(M^+ - 1)$, calcd.: 144.1388; found: 144.1343.

6-(8'-Hydroxy)octylaminopurine, 16

The procedure used was similar to that of Sutherland and Christensen (27). 9-Aminooctanol, **5** (45 mg, 0.3098 mmol) was dissolved in 2 mL of *n*-butanol. The solution was stirred at 80°C under nitrogen atmosphere and 6-chloropurine (43.2 mg, 0.28 mmol) was added. The solution was then heated to 110°C and stirred for 1.25 h. Potassium carbonate (23 mg, 0.166 mmol) was added and the solution stirred for 0.5 h. The solution was then evaporated under reduced pressure in a rotary evaporator. The crude product was recrystallized from hot water yielding 62.5 mg (85%). Compound **16** showed mp 164–166°C (dec.); ^1H NMR (WM-250) DMSO-d_6 solvent, δ: 1.256 (m, 10H, carbons 3',4',5',6',7' CH_2), 1.390 (m, 2H, CH_2), 3.355 (t, 2H, CH_2), 3.432 (t, 2H, CH_2), 7.495 (s, 1H, C2H), and 7.884 (s, 1H, C8H). MS, *m/z* (RI%): 263 (12)$[M^+]$, 246 (5)$[M^+ - OH]$, 232 (5)$[M^+ - CH_2OH]$, 218 (7)$[M^+ - (CH_2)_2OH]$, 204 (11)$[M^+ - (CH_2)_3OH]$, 190 (17)$[M^+ - (CH_2)_4OH]$, 176 (13)$[M^+ - (CH_2)_5OH]$, 162 (39)$[M^+ - (CH_2)_6OH]$, and 148 (100)$[M^+ - (CH_2)_7OH]$. HRMS, for $C_{13}H_{21}N_5O$, calcd.: 263.1745; found: 263.1741.

N-Trityl ethyl 8-aminooctanoate, 6

The method used was a modified version of the method described by Zervas and Theodoropoulos (40). To a stirred solution of ethyl 8-aminooctanoate (190.9 mg, 1.02 mmol) dissolved in 5 mL of chloroform were added triethylamine (103.7 mg, 1.02 mmol) and trityl chloride (1.05 equiv.). After 12 h, the solution was washed three times with 25-mL portions of distilled water. The organic phase was dried over anhydrous sodium sulphate and then evaporated under reduced pressure in a rotary evaporator. The yield of the trityl derivative **6** was 75%. The methoxy derivative was synthesized (by use of *p*-anisylchlorodiphenylmethane (4-methoxytrityl chloride)) under the same conditions yielding **7** in 95%. Compound **6** showed ^1H NMR (EM 390) δ: 1.39 (m, 13H, $(CH_2)_5$ and CH_3), 2.15 (m, 4H, CH_2N and CH_2CO), 4.02 (m, 2H, CH_2 ethyl), and 7.25 (m, 15H, aromatic). Compound **7** showed: ^1H NMR (AM 500) δ: 1253 (m, 9H, $(CH_2)_3$ and CH_3), 1.455 (m, 2H, CH_2-C-N), 1.584 (m, 2H, CH_2-C-COO), 2.107 (t, 2H, CH_2N), 2.258 (t, 2H, CH_2COO), 3.766 (s, 3H, OCH_3), 4.109 (m, 2H, OCH_2), and 7.448 (m, 14H, aromatic). ^{13}C NMR (AM500) δ: 14.25 (s, 1C, ethoxy CH_3), 24.92 (s, 1C, C3), 27.17 (s, 1C, C6), 29.07 (s, 1C, C4), 29.23 (s, 1C, C5), 30.81 (s, 1C, C7), 34.35 (s, 1C, C2), 43.73 (s, 1C, CC8), 55.15 (s, 1C, CH_3O), 60.12 (s, 1C, CH_2O), 70.26 (s, 1C, Tr-C-N), 113.00 (s, 2C, *meta*-anisyl), 126.04 (s, aromatic), 126.65 (s, aromatic), 127.84 (s, aromatic), 128.38 (s, aromatic), 128.56 (s, aromatic), 129.78 (s, aromatic), 130.52 (s, aromatic), 138.8 (s, 1C, *ipso*-anisyl), 146.74 (s, 2C, *ipso*-phenyl), 157.77 (s, 1C, *para*-anisyl) and 174.04 (s, 1C, COO). Assignments based upon values for ethyl octanoate, *n*-octylamine, triphenylcarbinol, and *p*-methoxybenzylamine (23).)

N-Tritylated ethyl 8-aminooctanols, 8, 9

The method used was similar to that used by Szammer (21). Lithium aluminum hydride (108 mg, 2.5 equiv.) was added to stirred anhydrous diethyl ether (8 mL) at 0°C under nitrogen atmosphere. To this solution was added an ethereal solution of *N*-trityl ethyl 8-aminooctanoate, **6** (1.09 mmol in 2 mL ether). The mixture was stirred at 0°C for 1 h and at reflux for 2 h. The reaction was quenched with 2 mL of methanol followed by 2 mL of distilled water. The mixture was filtered and the precipitate washed with 50 mL of ether and 25 mL of chloroform. The filtrate was concentrated (by rotary evaporation under reduced pressure) until only the water was remaining. This aqueous solution was extracted three times with 10-mL portions of chloroform. The combined chloroform extracts were dried over anhydrous sodium sulphate and evaporated under reduced pressure in a rotary evaporator. The yield of the trityl derivative **8** was 87%. The methoxytrityl compound was synthesized under the same conditions yielding 97% of the alcohol **9**. Compound **8** showed: ^1H NMR (EM 390) δ: 1.22 (m, 12H, $(CH_2)_6$), 2.10 (t, 2H, CH_2N), 3.52 (t, 2H, CH_2O), and 7.30 (m, 15H, aromatic). Compound **9** showed ^1H NMR (AM 500) δ: 1.274 (m, 8H, $(CH_2)_4$), 1.459 (m, 2H, CH_2-C-N), 1.529 (m, 2H, CH_2COH), 2.109 (m, 2H, CH_2N), 3.603 (t, 2H, CH_2O), 3.760 (s, 3H, CH_3O), and 7.230 (m, 15H, aromatic). ^{13}C NMR (WP 80) δ: 25.6 (s, 1C, C6), 27.2 (s, 1C, C3), 29.3 (s, 1C, C4), 29.4 (s, 1C, C5), 30.8 (s, 1C, C7), 32.7 (s, 1C, C2), 43.5 (s, 1C, C8), 55.0 (s, 1C, CH_3O), 62.8 (s, 1C, CH_2OH), 70.3 (s, 1C, Tr-C-N), 113.0 (s, 2C, *meta*-anisyl), 126.0 (s, aromatic), 127.6 (s, aromatic), 128.5 (s, aromatic), 129.8 (s, aromatic), 138.5 (s, 1C, *ipso*-anisyl), 146.6 (s, 2C, *ipso*-phenyl), and 157.8 (s, 1C, *para*-anisyl). (Assignments based upon values for *n*-octanol, *n*-octylamine, triphenylcarbinol and *p*-methoxybenzylamine (23).) MS, *m/z* (RI%): 340 (5)$[M^+ - C_6H_5]$, 318 (12), 288 (2)$[M^+ - (CH_2)_8OH]$, and 273 (100)$[M^+ - NH(CH_2)_8OH]$.

6-Chloro,9-(8'-N-methoxytritylaminooctyl)purine, 11

The procedure used was similar to that of Mitsunobu (11*a*), or Iwakawa *et al.* (11*b*). *N*-Methoxytrityl-8-aminooctanol (500 mg, 1.197 mmol) was dissolved in 5 mL of THF. To this stirred solution (under nitrogen atmosphere) was added a solution of triphenylphosphine (316 mg, 1.20 mmol) dissolved in 3 mL of THF. A solution of 6-chloropurine (185 mg, 1.197 mmol) together with diethyl azodicarboxylate (208.5 mg, 1.197 mmol) in 2 mL of THF was then added all at once. The mixture was stirred for 72 h at room temperature and the solvent then evaporated under reduced pressure in a rotary evaporator. The residue was washed three times with 10-mL portions of a solution consisting of 20% chloroform in hexanes. The combined washings were rotary evaporated under reduced pressure and redissolved in a volume of 40% acetonitrile in distilled water that was sufficient to effect dissolution (30–40 mL). A 2-mL portion of this solution was applied to a reversed phase Sep-Pak. The Sep-Pak was washed with 5 mL of fresh acetonitrile/water solution (40:60), followed by elution with 10 mL of acetonitrile. The Sep-Pak was then regenerated by washing with 5 mL of methanol followed by 5 mL of distilled water and the separation procedure was repeated with a fresh aliquot of the crude reaction product. The combined acetonitrile eluates were collected and evaporated under reduced pressure in a rotary evaporator. The yield of the partially purified product was 56% as indicated by ^1H NMR. TLC of **11** with acetonitrile on RP KC18F TLC

plates gave R_f 0.51. Compound **11** showed ^{1}H NMR (WM 250) δ:1.283 (m, 8H, $(CH_2)_4$), 1.457 (m, 2H, $NCCH_2$), 1.921 (m, 2H, $N9CCH_2$), 2.102 (t, 2H, CH_2NH), 3.771 (s, 3H, OCH_3), 4.264 (t, 2H, $N9CH_2$), 6.810 (m, 4H, H_2OH2), 7.252 (m, 14H, Ph), 8.083 (s, 1H, C2H), 8.738 (s, 1H, C8H). ^{13}C NMR (WP 80) δ: 26.5 (s, 1C, C6′), 27.1 (s, 1C, C3′), 28.8 (s, 1C, C2′), 29.2 (s, 1C, C4′), 29.7 (s, 1C, C5′), 30.7 (s, 1C, C7′), 43.4 (s, 1C, C8′), 44.2 (s, 1C, C1′), 55.1 (s, 1C, CH_3O), 70.3 (s, 1C, Tr-C-N), 113.0 (s, 2C, *meta*-anisyl), 126.0 (s, aromatic), 127.6 (s, aromatic), 128.5 (s, aromatic), 129.8 (s, aromatic), 131.8 (s, 1C, C5), 138.5 (s, 1C, *ipso*-anisyl), 145.0 (s, 1C, C8), 146.6 (s, 2C, *ipso*-phenyl), 151.1 (s, 1C, C2), 151.9 (s, 2C, C4 and C6), and 157.8 (s, 1C, *para*-anisyl). (Assignments based upon values for *n*-octylamine, triphenylcarbinol, *p*-methoxybenzylamine, and 6-chloropurine (23).)

6-Chloro,9-(8′-aminooctyl)purine hydrochloride, 12

6-Chloro-9-(8′-*N*-methoxytritylaminooctyl)purine (46 mg, 0.083 mmol) was dissolved in 2 mL of methylene chloride. To this stirred solution was added 12 μL of trifluoroacetic acid and 20 μL of methanol. After 0.5 h more methanol (0.1 mL) and 8 mL of methylene chloride were added. The solution was extracted with twice with 10-mL portions of 0.01 M hydrochloric acid. The combined aqueous layers were evaporated under high vacuum in a rotary evaporator to dryness yielding 12 mg (50%) of **12** as a green solid. Compound **12** (HCl salt) showed ^{1}H NMR (EM 390) D_2O solvent, δ: 1.35 (m, 12H, $(CH_2)_6$), 3.07 (t, 2H, CH_2-N^+), 4.43 (m, 2H, CH_2-N9), and 8.86 (s, 1H, C2H). The free amine, isolated by methylene chloride extraction of a basic solution of the hydrochloride salt in water, was stable and showed ^{1}H NMR (EM 390) δ: 1.33 (br m, 12H, CH_2 on carbons 2′,3′,4′,5′,6′,7′), 3.63 (m, 2H, CH_2NH_2), 4.18 (t, J = 6 Hz, 2H, CH_2N9), 5.95 (s, 2H, NH_2), 7.77 (s, 1H, C2H), and 8.43 (s, 1H, C8H). MS, *m/z* (RI%): 281 (3)[M^+], 279 (14), 167 (32)[$M^+ - C_7NH_2$], 149 (84), and 92 (100).

N6,N9-Octamethylenepurine cyclophane, 1

6-Chloro-9-(8′-aminooctyl)purine hydrochloride (12 mg, 0.0378 mmol) was added to 1 mL of acetonitrile. The mixture was cooled to 0°C and *N*,*N*-diisopropylethylamine (10 mg, 0.080 mmol) was added dropwise. After 0.5 h, the mixture was added to 50 mL of acetonitrile. The solution was stirred at 60°C for 24 h followed by evaporation under reduced pressure in a rotary evaporator. The residue was redissolved in 10 mL of chloroform and extracted three times with 10-mL portions of 0.01 M hydrochloric acid. The organic layer was dried over anhydrous sodium sulphate and evaporated under reduced pressure in a rotary evaporator to dryness yielding 2.8 mg (0.0114 mmol, 30.2%) of crude **1**. The cyclophane was purified by medium pressure chromatography on silica gel using a Lobar column and elution with 1% methanol in chloroform. TLC with 5% methanol in chloroform gave R_f 0.198. The purified cyclophane showed: UV: λ_{max} 278 nm (ε = 10 557, ethanol). ^{1}H NMR (AM500) δ: −0.0636 (C5′*R*), 0.18 (C4′*S*), 0.18 (C3′*S*), 0.517 (C6′*S*), 0.606 (C4′*R*), 0.892 (C5′*S*), 1.030 (C3′*R*), 1.259 (C6′*R*), 1.377 (C2′*S*), 1.470 (C2′*R*), 1.644 (C7′*S*), 1.797 (C7′*R*), 3.350 (C1′*R*), 3.920 (C8′*S*), 4.546 (C8′*R*), 4.687 (C1′*S*). ^{13}C NMR (AM 500) δ: 23.146 (s, 1C, C6′), 25.213 (s, 1C, C3′), 26.128 (s, 1C, C4′), 28.722 (s, 1C, C7′), 30.924 (s, 1C, C2′), 31.322 (s, 1C, C5′), 43.030 (s, 1C, C1′), 45.032 (s, 1C, C8′), 121.313 (s, 1C, C5), 143.106 (s, 1C, C8), 152.417 (s, 1C, C4), 154.141 (s, 1C, C2), and 159.937 (s, 1C, C6). MS, *m/z* (RI%); 245 (79)[M^+], 216 (15)[$M^+ - NHCH_2$], 202 (19)[$M^+ - NH(CH_2)_2$], 188 (21)[$M^+ - NH(CH_2)_3$], 174 (21)[$M^+ - NH(CH_2)_4$], 160 (18)[$M^+ - NH(CH_2)_5$], 134

(11)[$M^+ - (CH_2)_7CH$], 148 (51), 83 (90), and 55 (100). HRMS, for $C_{13}H_{19}N_5$, calcd.: 245.1640; found: 245.1669.

6-Chloro-9-octylpurine, ***13***

The same procedure was followed as for the synthesis of 6-chloro-9-(8′-*N*-methoxytritylaminooctyl)purine. The compound was purified by column chromatography with silica gel (5% methanol in chloroform) yielding 79% of **13**. Compound **13** showed ^{1}H NMR (EM 390) δ: 0.080 (m, 3H, CH_3), 1.23 (m, 10H, $(CH_2)_5$), 1.90 (m, 2H, CH_2-C-N), 4.27 (t, 2H, CH_2N), 8.10 (s, 1H, C2H) and 8.77 (s, 1H, C8H). ^{13}C NMR (AM 500) δ: 14.130 (s, 1C, CH_3), 22.466 (s, 1C, C7′), 26.520 (s, 1C, C3′), 28.833 (s, 1C, C5′), 28.919 (s, 1C, C4′), 29.774 (s, 1C, C6′), 31.574 (s, 1C, C2′), 44.477 (s, 1C, C1′), 131.550 (s, 1C, C5), 145.114 (s, 1C, C8), 150.934 (s, 1C, C2), and 151.815 (s, 2C, C4 and C6) (assigned by comparison with *n*-octylamine (23)). MS, *m/z* (RI%): 266 (10)[M^+], 237 (3)[$M^+ - CH_2CH_3$], 223 (4)[$M^+ - (CH_2)_2CH_3$], 209 (10)[$M^+ - (CH_2)_3CH_3$], 195 (7)[$M^+ - (CH_2)_4CH_3$], 181 (6)[$M^+ - (CH_2)_5CH_3$], 167 (11)[$M^+ - (CH_2)_6CH_3$], 104 (82), and 59 (100). HRMS, for $C_{13}H_{19}N_4Cl$, calcd.: 266.1298; found: 266.1285.

6-Aminooctylpurine and 6-aminooctyl-9-octylpurine, ***14, 15***

6-Chloropurine or 6-chloro-9-octylpurine was dissolved in 2.6 mL of acetonitrile. To this stirred solution were added octylamine (68 μL, 0.41 mmol) and *N,N*-diisopropylethylamine (71 μL, 0.41 mmol). After 24 h at 65°C, the solution was evaporated to dryness under reduced pressure in a rotary evaporator. The crude product was purified by column chromatography using 5% methanol in chloroform. The yield of the 6-amino compound **14** was 73%. The yield of the 6,9-dialkyl compound **15** was 50%. Compound **14** showed mp 169–170°C (lit.(41) mp 165–167°C). ^{1}H NMR (AM 500) δ: 0.855 (t, 3H, CH_3), 1.25 (m, 8H, $(CH_2)_4$), 1.416 (m, 2H, N-C-C-CH_2), 1.693 (m, 2H, N-C-CH_2), 3.600 (m, 2H, CH_2N), 6.068 (br s, 1H, NH), 7.240 (s, 1H, C2H), and 7.962 (s, 1H, C8H). ^{13}C NMR (AM 500) δ: 14.052 (s, 1C, CH_3), 22.614 (s, 1C, C7′), 26.937 (s, 1C, C3′), 29.208 (s, 1C, C5′), 29.321 (s, 1C, C4′), 29.723 (s, 1C, C6′), 31.779 (s, 1C, C2′), and 40.719 (s, 1C, C1′) (assigned by comparison with *n*-octylamine (23)). MS, *m/z* (RI%): 247 (10)[M^+], 204 (8)[$M^+ - (CH_2)_2CH_3$], 190 (14)[$M^+ - (CH_2)_3CH_3$], 176 (6)[$M^+ - (CH_2)_4CH_3$], 162 (25)[$M^+ - (CH_2)_5CH_3$], 148 (100)[$M^+ - (CH_2)_6CH_3$], and 119 (71)[$M^+ - NH(CH_2)_7CH_3$]. HRMS, for $C_{13}H_{21}N_5$, calcd.: 247.1797; found: 247.1784.

Compound **15** showed: UV: λ_{max} 268 (ε = 11 779, ethanol). ^{1}H NMR (EM 390) δ: 0.88 (m, 6H, $2CH_3$), 1.28 (m, 20H, $2(CH_2)_5$), 1.70 (m, 4H, $2CH_2$-C-N), 3.68 (m, 2H, CH_2N6), 4.17 (t, 2H, CH_2N9), 5.90 (br s, 1H, NH), 7.74 (s, 1H, C2H), and 8.45 (s, 1H, C8H). MS, *m/z* (RI%): 359 (41)[M^+], 343 (37), 330 (23)[$M^+ - CH_2CH_3$], 302 (57)[$M^+ - (CH_2)_3$], 288 (23)[$M^+ - (CH_2)_4CH_3$], 260 (92)[$M^+ - (CH_2)_6CH_3$], 247 (37)[$M^+ - CH(CH_2)_7CH_3$], 204 (23)[$M^+ - (CH_2)_8CH_3$], 176 (34)[$M^+ - (CH_2)_{10}CH_3$], 148 (100)[$M^+ - (CH_2)_{12}CH_3$], 104 (73), and 59(80). HRMS, for $C_{21}H_{37}N_5$, calcd.: 359.3049; found: 359.3036.

X-ray studies

A crystal of **1**, suitable for X-ray studies, was chosen after examination with a polarizing microscope. The acicular crystal was sealed in a Lindemann capillary and the space group determined with precession photographs. The cell parameters were determined by a least-squares refinement of the angular parameters of 15 automatically centred reflections in the range $19.1° < 2\theta < 26.5°$. Intensities were measured at 22° on a Nicolet P3 diffractometer with use of graphite-monochromated MoKα radiation (λ 0.71069 Å) and the θ(crystal)–2θ(counter) scan mode. Crystal data

and other numbers related to data collection are given in Table 1. Corrections were made for Lorentz polarization effects but not for absorption. This will introduce a maximum error in F_o of <0.3%. The structure was solved by direct methods. The phases were determined with the use of 321 reflections with $E > 1.2$ and 12 sets of starting phases. All non-hydrogen atoms were found in the subsequent E map. Hydrogen atoms were found from subsequent difference maps and the coordinates of all atoms (C and N with anisotropic temperature factors) were then refined, with minimization of the function $\Sigma w(|F_o| - |F_c|)^2$ until the final shift/error was less than 0.1. Reflections with $3\sigma_I > I > 3\sigma_I$ were treated by the method of French and Wilson (42). Scattering factors were those of Cromer and Waber (43). Secondary extinction was made by the method of SHELX (44).[5] Atomic positional parameters and U_{eq} for non-hydrogen atoms are given in Table 2.[6]

The structure of 2,2-dibutyl-1,3,2-dioxastannane in the solid state and in solution

T. Bruce Grindley,[1] Rasiah Thangarasa, Pradip K. Bakshi, and T. Stanley Cameron[1]
Department of Chemistry, Dalhousie University, Halifax, N.S., Canada B3H 4J3

Received June 19, 1991

T. Bruce Grindley, Rasiah Thangarasa, Pradip K. Bakshi, and T. Stanley Cameron. Can. J. Chem. **70**, 197 (1992).

Crystals of 2,2-dibutyl-1,3,2-dioxastannane (**1**) are orthorhombic, of space group *Pnma*, with $a = 7.663(3)$, $b = 18.437(2)$, $c = 9.277(4)$ Å, $Z = 4$, $R = 0.0568$ ($R_w = 0.0551$) for 1183 independent reflections with $I > 3\sigma(I)$. Compound **1** is a polymer in which each monomer unit is joined to the next by a four-membered $(SnO)_2$ ring. The Sn—O bond lengths inside the monomer units average 2.04 Å while those between monomers average 2.57 Å. The mirror plane of the crystal contains the atoms in the four-membered rings and the other oxygen atoms. Two of the three remaining carbon atoms in the six-membered rings of the monomer units are close to the mirror plane. The other carbon atom is disordered above and below the plane. It was shown by ^{119}Sn NMR spectroscopy that solutions of **1** contain mixtures of oligomers that consist mainly of dimers, trimers, and tetramers in chloroform-*d*. ΔG^0 values for dimer–trimer equilibria and dimer–tetramer equilibria of -2.5 and -1.5 kcal mol^{-1} were obtained from integration of low temperature ^{119}Sn NMR spectra. These values favour the higher oligomers slightly less than those for 2,2-dibutyl-1,3,2-dioxastannolane.

Key words: 1,3,2-dioxastannanes, stannylene acetals, X-ray crystallography, ^{119}Sn NMR spectroscopy.

T. Bruce Grindley, Rasiah Thangarasa, Pradip K. Bakshi et T. Stanley Cameron. Can. J. Chem. **70**, 197 (1992).

Les cristaux de 2,2-dibutyl-1,3,2-dioxastannane (**1**) sont orthorhombiques, groupe d'espace *Pnma*, avec $a = 7,663(3)$, $b = 18,437(2)$, $c = 9,277(4)$ Å, $Z = 4$ et $R = 0,056$ ($R_w = 0,0551$) pour 1183 réflexions indépendantes avec $I \geq 3\sigma(I)$. Le composé **1** est un polymère dans lequel chaque unité de monomère est liée à la suivante par un cycle à quatre chaînons $(SnO)_2$. La longueur moyenne des liaisons Sn—O à l'intérieur des unités de monomère est égale à 2,04 Å alors que celle observée entre les monomères est de 2,57 Å. Le plan miroir du cristal contient les atomes des cycles à quatre chaînons ainsi que les autres atomes d'oxygène. Deux des trois autres atomes de carbone des cycles à six chaînons des unités de monomère se trouvent près du plan miroir. L'autre atome de carbone est désordonné au-dessus et au-dessous du plan. On a montré par RMN du ^{119}Sn que des solutions du composé **1** dans le chloroforme-*d* contiennent des mélanges d'oligomères formés principalement de dimères, de trimères et de tétramères. En se basant sur une intégration des spectres RMN du ^{119}Sn mesurés à basse température, on a pu déterminer que les valeurs de ΔG^0 des équilibres dimère/trimère et dimère/tétramère sont respectivement $-2,5$ et $-1,5$ kcal mol^{-1}. Ces valeurs sont un peu moins favorables aux oligomères plus élevés que celles mesurées pour le 2,2-dibutyl-1,3,2-dioxastannolane.

Mots clés : 1,3,2-dioxastannanes, acétals de stannylène, cristallographie par rayons-X, spectroscopie RMN du ^{119}Sn.
[Traduit par la rédaction]

Introduction

The reactions of 1,2-diols and 1,3-diols with dialkyltin oxides under conditions where water is removed azeotropically yield 1,3,2-dioxastannolanes and 1,3,2-dioxastannanes, respectively. These compounds, often termed stannylene acetals, have become widely used as intermediates for the regioselective monosubstitution of diols (1–3). Most of the reactions studied have involved 1,3,2-dioxastannolanes but those in which 1,3,2-dioxastannanes are intermediates also work efficiently (4, 5).

Structures of 1,3,2-dioxastannolanes in the solid state as determined by X-ray crystallography have ranged from dimers (6, 7), to a pentamer (8), to polymers (9). Derivatives with a few non-bulky substituents, e.g., 2,2-dibutyl-1,3,2-dioxastannolane (9, 10), or 2,2-dibutyl-4-methyl-1,3,2-dioxastannolane (10), are polymers in the solid. In solution, these compounds are less associated and the species present at concentrations observable by ^{119}Sn nmr spectroscopy range from dimers to mixtures of oligomers up to the pentamer (11). 1,3,2-Dioxastannolanes having large substituents on tin, e.g., *tert*-butyl groups (7), or many small substituents (11, 12) can exist solely as dimers both in solution and in the solid state. We have recently shown that highly substituted 1,3,2-dioxastannolanes, such as the 2,2-di-*tert*-butyl-4,4,5,5-tetramethyl derivative, exist as the monomer or as dimer–monomer mixtures (13).

The structure of 2,2-dibutyl-1,3,2-dioxastannane (**1**) has attracted considerable attention. A preliminary X-ray diffraction study published in 1973 suggested that solid **1** was a polymer but no details other than the Sn—O bond lengths were supplied (14). Recently, ^{119}Sn nmr spectra of **1** in the solid state have been measured and the results support the assignment of the structure of **1** as a polymer (10). Molecular weight measurements in pyridine by boiling point elevation gave values of 333 (14) and, for a higher concentration (4.2%), 550 (15). The molecular weight of the monomer is 307.

The most reliable technique for obtaining information about the structures of tin-containing compounds in solution is ^{119}Sn nmr spectroscopy (16). Smith *et al.* (17) and Kennedy (18) demonstrated that for dialkoxydialkyltin derivatives, tetracoordinate tin nuclei absorb between 0 and -40 ppm while pentacoordinate tin nuclei absorb between -150 and -170 ppm. Tetracoordinate tin atoms are present only in monomers. A dimer contains only pentacoordinate tin while higher oligomers contain both pentacoordinate and hexacoordinate tin atoms.

The ^{119}Sn nmr chemical shifts of cyclic derivatives are somewhat different. For 2,2-dibutyl-1,3,2-dioxastannolane (**2**) in solution, pentacoordinate tin nuclei in dimers and oligomers absorb between -126 and -132 ppm while hexacoordinate tin nuclei absorb between -260 and -285 ppm in trimers, tetramers, and pentamers (11). We have recently shown that tetracoordinate tin nuclei in mo-

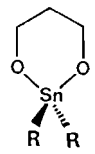
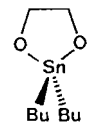
For personal use only.

nomeric 2,2-dibutyl-1,3,2-dioxastannolanes absorb at about +80 ppm (13).



1



2

Smith *et al.* observed ^{119}Sn nmr chemical shifts for **1** of −228 and −288 ppm in saturated chloroform-*d* solution at room temperature and neat at 96°C, respectively. These workers concluded that **1** was probably present in solution as mixtures of oligomers based on their measurement of the chemical shift for a saturated solution of **2** in chloroform-*d* at room temperature of −189 ppm (17). Compound **2** was considered to be a dimer (17) although it has since been shown that a mixture of oligomers was present (11).

In this publication, we report an X-ray diffraction study of **1** at low temperature and variable temperature ^{119}Sn and ^{13}C nmr studies of **1** in solution in order to fully define the species present in both phases. These results will provide a basis for interpreting the spectra and reactions of substituted 1,3,2-dioxastannanes.

Experimental

Commercial 1,3-propanediol was dried over molecular sieves (4 Å) and converted to 2,2-dibutyl-1,3,2-dioxastannane (**1**) by refluxing with an equivalent amount of dibutyltin oxide in benzene in an apparatus for the azeotropic removal of water. Evaporation of the solvent on a vacuum line yielded a white powder. Distillation of dried hexane and toluene onto the sample, followed by heating and cooling cycles conducted in a vacuum, gave colourless crystals suitable for study by X-ray diffraction. The crystals were transferred into capillaries in a dry box and the capillaries were sealed. Crystal data and other experimental details are summarized in Table 1. The data were collected on an Enraf-Nonius CAD4 diffractometer using graphite monochromated MoK_α radiation (λ = 0.70926 Å) at 203 K. Cell dimensions were calculated from 25 reflections with 2θ angles in the range 26–30°. No correction was made for extinction but an absorption correction was applied (20). Atomic scattering factors and corrections for anomalous dispersion for Sn, C, O, and H were taken from the International tables for X-ray crystallography, Vol. IV (21).[2]

The structure was solved by the direct (SHELXS) method (19). All non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atoms were placed geometrically and refined riding on the attached carbon atoms with individual isotropic thermal parameters. C(5) and its attached hydrogens were found to be disordered above and below the mirror plane. C(4) and C(6) were also found to be slightly disordered (see Discussion).

Carbon-13 and tin-119 nmr spectra were measured on a Nicolet NT-360 NB spectrometer at 90.8 and 134.6 MHz, respectively. Chemical shifts are reported with respect to internal tetramethylsilane and external neat tetramethyltin at 20°C, respectively. The samples studied were prepared and sealed under vacuum as previously (11).

[2]Supplementary tables containing more experimental details, anisotropic thermal parameters, hydrogen atom positions, torsional angles, and observed and calculated structure factors may be purchased from the Depository of Unpublished Data, CISTI, National Research Council of Canada, Ottawa, Ont., Canada K2A 0S2.

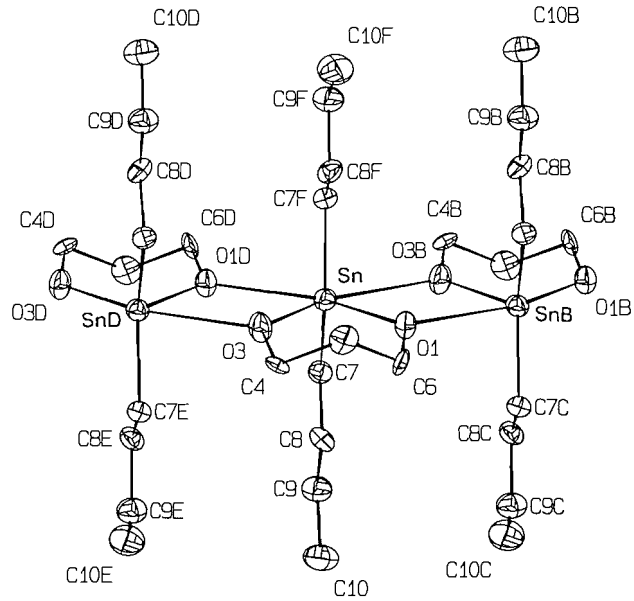


FIG. 1. A segment of the structure of polymeric 2,2-dibutyl-1,3,2-dioxastannane (**1**). The relationships between the labels here and the symmetry labels used in Table 3 and in the table of torsional angles (supplementary Table 4) are as follows: $B = iii = x + 0.5, -y + 0.5, -z + 0.5$; $C = iv = x + 0.5, y, -z + 0.5$; $D = ii = x - 0.5, -y + 0.5, -z + 0.5$; $E = v = x - 0.5, y, -z + 0.5$; $F = i = x, -y + 0.5, z$. Note that C(5), the atom between C(4) and C(6) in the figure, and also C(4) and C(6) have 1 : 1 disorders above and below the plane defined by O(3), Sn, O(1) and only one of the two locations for each are shown for each monomer unit.

Results and discussion

X-ray crystallography

The structure and numbering of the compound is shown in Fig. 1; the crystal data, atomic coordinates, bond lengths, and interbond angles are listed in Tables 1–3.

The individual 2,2-dibutyl-1,3,2-dioxastannane units are linked together through planar four-membered Sn—O—Sn—O rings to form an infinite ribbon polymer. The tin and oxygen atoms are all located on the mirror plane of space group *Pnma*. In initial refinements, the carbon atoms that are bonded to the oxygen atoms, C(4) and C(6), were also found to lie on the mirror plane but the third carbon atom, C(5), was disordered, occupying equally populated sites 0.52 Å above and below the plane. The thermal parameters for C(4) and C(6), particularly U_{22}, were found to be significantly larger than those of the other atoms. It appeared that C(4) and C(6) were slightly disordered as well, lying above the mirror plane when C(5) is below and vice versa. To define the extent of this disorder, several refinements were performed where C(4) and C(6) were fixed at varying distances away from the mirror plane. U_{22} was plotted against the distance away from the plane (see Fig. 2). The final distance away from the plane was that which minimized U_{22}. The two butyl groups are related by the mirror plane. Because the plane of the four-membered ring is the mirror plane of the crystal, all four-membered rings in a particular polymer lie in this plane. The conformation of each 1,3,2-dioxastannane ring is close to a half-chair with five atoms lying close to the plane defined by the two fused planar four-membered rings. All torsional angles involving O(1), Sn, O(3) and their symmetry-related atoms have values

[a]Fixed.
[b]Fixed by a procedure outlined in the text.

of 0 or 180° (supplementary Table 4). The torsional angles O—Sn—O—C have absolute values of 12.1(6)° with signs depending on the orientation of C(5).

The O—Sn—O bond angle inside the 1,3,2-dioxastannane ring is 93.2(2)° while the two O—Sn—O bond angles about a particular tin atom in its two attached four-membered rings are 65.7(2) and 67.3(2)°. The *trans*-O—Sn—O angles are 159.5(2) and 157.9(2)°. The exocyclic C—Sn—C bond angle is 138.4(3)°. Thus, the overall structure about tin is a severely distorted octahedron.

It is interesting to compare the structural features of **1** in the crystal with those of the 1,3,2-dioxastannolanes studied by X-ray crystallography (6–9). A comparison of bond angles and bond lengths is shown in Table 4. Because the *R* value for methyl 4,6-*O*-benzylidene-2,3-*O*-dibutylstannylene-α-D-glucopyranoside (**4**) was rather large (10.9%) and some carbon atoms in the butyl groups were not located (6*a*), we have recently reexamined this molecule by X-ray diffraction at low temperature and the data in Table 4 for **4** are from our study (6*b*).

[e]Reference 21.

O—Sn—O bond angle in the six-membered ring is 14.2° larger and, as a result, the *trans*-O—Sn—O bond angle is also larger by 9.7°. These differences in the O—Sn—O bond angles in the two rings arise from the constraints imposed by closure of rings containing two long Sn—O bonds.

More extensive differences can be noted between the bond angles and lengths for five-coordinate tin centres when compared with those of six-coordinate centres. The magnitudes of exocyclic C—Sn—C bond angles at pentacoordinate tin centres in more highly substituted 1,3,2-dioxastannolanes, ranging from 124.2 to 133.1° (6, 8, 9), are about 10° smaller than those at hexacoordinate tin centres, which range from 134.7 to 142.7° (7, 8). This difference reflects the fact that the butyl groups are equatorial in the distorted trigonal bipyramid of five-coordinate tin and should be separated by 120° whereas the ideal separation for six-coordinate tin is 180°. The other major difference lies in the intermonomer Sn—O bond lengths, 2.23–2.27 Å for pentacoordinate tin (6, 8, 9) and 2.43–2.60 Å for hexacoordinate tin (7, 8). The larger bond lengths for hexacoordinate tin may be a response to the greater crowding about the more substituted centre.

[d] Polymer.

Solution nuclear magnetic resonance spectral results

The 134.6 MHz ^{119}Sn nmr spectra of **1** at 20°C consisted of one broad peak with a chemical shift of −193.5 ppm for a 0.41 M solution in chloroform-*d* and −234.1 ppm for a 0.38 M solution in toluene-d_8. The peak had a half-height linewidth of 1340 Hz in the chloroform-*d* solution at 20°C and it gradually narrowed to 810 Hz as the temperature was raised to 80°C but did not change position much (−199.4 ppm at 80°C). The peak in the spectrum from the toluene-d_8 solution shifted to −214.8 ppm on warming to 80°C and also narrowed (1200 to 375 Hz). When the temperature was lowered to about 10°C, the single peak in the chloroform-*d* spectrum divided into two, one with a shift close to the 20°C chemical shift and a second near −340 ppm that was smaller and broader. Further decrease in temperature caused the small peak to sharpen but the larger peak split again at about −45°C into two peaks having unequal intensities, with the less intense one being less shielded. The low temperature shifts are listed in Table 5. All three peaks sharpened as the temperature was lowered further but the smallest peak, at −187.8 ppm, remained broad, with a linewidth of 630 Hz and at a temperature of −65°C, at which the adjacent peak, at −195.1 ppm, had a linewidth of 72 Hz. Integrations of the two major peaks at −195 and −346 ppm at temperatures below −55°C where both were reasonably sharp showed that the intensity of the former was twice that of the latter (±10%). Of possible species, only a trimer contains two pentacoordinate tin atoms related by C_2 symmetry and one hexacoordinate tin atom. Therefore, it was concluded that the major species present at low temperature was a trimer.

The broad peak at −187.8 ppm lies in the region of the ^{119}Sn nmr spectrum where pentacoordinate tin atoms absorb and it can be assigned to a dimer. The dimer peak is broad at −65°C mainly because the dimer is still exchanging with a third species at this temperature as discussed below.

A 0.3 M sample of **1** in a 2:1 mixture of chloroform-*d* and dichloromethane-d_2 was prepared, to extend the study to lower temperatures. The ^{119}Sn spectra of this sample were very similar to those of the chloroform-*d* solutions at temperatures from 20 to −65°C (see Fig. 3). In spectra recorded at −75 to −95°C, the peak assigned to the dimer was sharper and two additional equal intensity peaks appeared at −200.9 and −333.1 ppm (chemical shifts at −85°C). A tetramer of **1** has C_2 symmetry and would give a ^{119}Sn nmr spectrum having this combination of two equal intensity peaks with the chemical shifts observed. Therefore, it is concluded that the tetramer is the species whose signals appear at temperatures lower than −65°C and exchange of a low concentration of the tetramer with the dimer causes the dimer signal to be broad at the lowest temperature accessible for chloroform-*d* solutions of **1** (see Fig. 4).

The ^{13}C nmr spectra of **1** are consistent with the conclusions drawn above. The spectra at room temperature and above are simple, having the number of signals expected for a monomer. Three signals show marked changes with variation in temperature which are similar in both chloroform-*d* and the mixed solvent system. The butyl C-α signal at 21.8 ppm in the mixed solvent spectra broadened as the temperature was lowered and split at about −20°C into two peaks, one at 19.8 ppm at −85°C, the other obscured by the butyl C-β and C-γ signals between 26.6 and 27.7 ppm. The average signal from the spectrum at 20°C had a $^1J_{Sn,C}$ value of 641 Hz and the signal at 19.8 ppm at −85°C had a $^1J_{Sn,C}$ value of 613 Hz. The magnitude of $^1J_{Sn,C}$ has been related to the size of the C—Sn—C bond angle, increasing with increasing angle size for both butyltin(IV) (23) and methyltin(IV) derivatives (24). C—Sn—C bond angles are larger about hexacoordinate tin than pentacoordinate tin in crystal structures containing dialkoxydialkyltin derivatives (6–9). Because the $^1J_{Sn,C}$ value for the room temperature peak, which is an average of values for pentacoordinate and hexacoordinate tin nuclei, was larger than the value for the peak at 19.8 ppm at −85°C, the peak at 19.8 ppm can be assigned to C-α for butyl groups on pentacoordinate tin.

The relationship obtained for butyltin(IV) derivatives, $^1J_{Sn,C} = 9.99\theta - 746$ Hz, was derived from a relatively small number of points (23). For a J value of 613 Hz, it gives a value of the C—Sn—C bond angle of 136.0°. The relationship obtained for methyltin(IV) derivatives, $^1J_{Sn,C} = 10.7\theta - 778$ Hz, was derived from an extensive set of data (24). It yields a value for the C—Sn—C bond angle of 130.4°. The

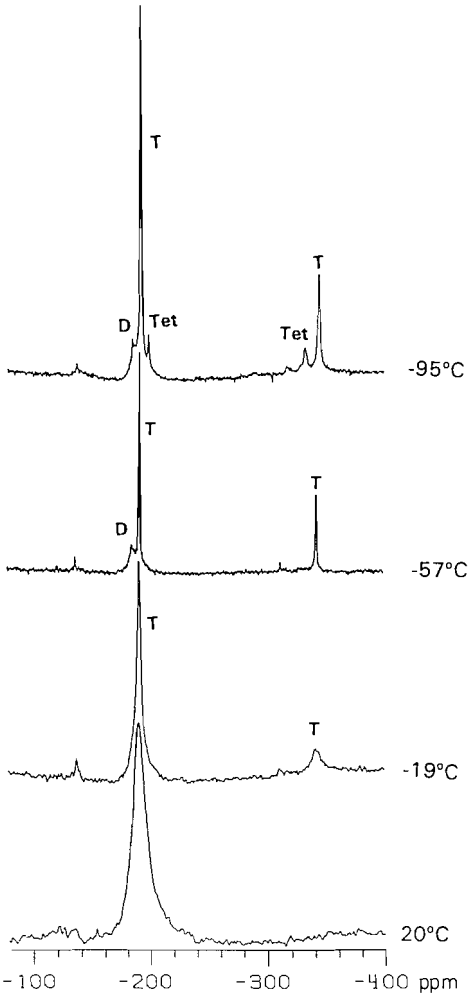

FIG 3. ^{119}Sn nmr spectra (134.6 MHz) of a 0.30 M solution of 2,2-dibutyl-1,3,2-dioxastannane (**1**) in a 2:1 mixture of chloroform-*d* and dichloromethane-d_2 at various temperatures. Labels: D, dimer peak; T, trimer peak; Tet, tetramer peak.

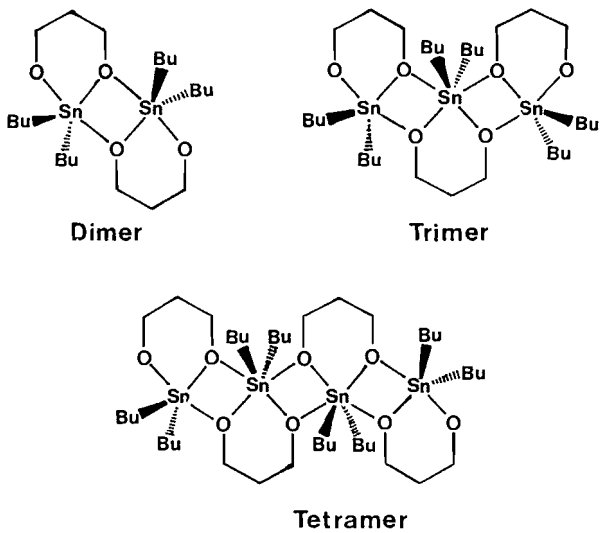

FIG. 4. Structures of those oligomeric species of 2,2-dibutyl-1,3,2-dioxastannane (**1**) observed in solution

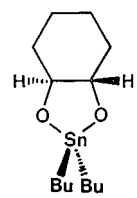
X-ray C—Sn—C bond angle for **1** in which the tin atom is hexacoordinate in a polymer is 138.3(3)°, close to the average of C—Sn—C bond angles at hexacoordinate tin atoms in 1,3,2-dioxastannolanes (138.1 ± 3.0°) (7, 8). The average of C—Sn—C bond angles at pentacoordinate tin atoms in 1,3,2-dioxastannolanes is 127.8 ± 5.1° (6*b*, 8, 9). All structural features of analogous polymeric 1,3,2-dioxastannolanes and 1,3,2-dioxastannanes, i.e., **2** and **1**, are almost identical except for O—Sn—O bond angles in the five- and six-membered rings and directly related angles. Thus, the magnitude of the C—Sn—C bond angle for pentacoordinate tin atoms in the trimer of **1** is probably close to that of the same angle in the 1,3,2-dioxastannolanes, 127.8°. The relationship between $^1J_{Sn,C}$ and C—Sn—C bond angle derived for methyltin(IV) derivatives (24) appears to give an answer for **1** closer to this value than does the equation derived from a limited number of butyltin derivatives (23), suggesting that these relationships are independent of the nature of the alkyl group.

The peak at 36.7 ppm at 20°C in the mixed solvent splits at about −50°C into two major peaks at 36.1 and 34.7 ppm at −85°C with intensities in the ratio of about 2:1, respectively. Similarly, the peak at 66.5 ppm from the spectrum from the mixed solvent solution at 20°C splits at about −57°C into two peaks with chemical shifts of 66.5 and 65.8 ppm at −85°C having intensity ratios of about 2:1. It was concluded from the ^{119}Sn nmr spectra that the trimer was the major species present in solution at −85°C. The observation of two sets of signals present in 2:1 intensity ratios is consistent with a trimer, which consists of a central monomer unit containing hexacoordinate tin flanked by two equivalent monomer units containing pentacoordinate tin.

The coalescence temperatures for the signals at 36.7 ppm and 66.5 ppm at −50 ± 5°C and −57 ± 5°C and chemical shift differences of 56.1 and 126.9 Hz, respectively, were used to calculate rate constants at coalescence of 191.1 and 84.5 s^{-1}, respectively, by means of the method of Shanan-Atidi and Bar-Eli for unequally populated sites (25). Fractional populations for the two sites of 0.67 and 0.33 were used. Free energies of activation of 10.6 ± 0.2 and 10.6 ± 0.3 kcal mol^{-1} were obtained for coalescence at the two sites. The coalescence at 10 ± 5°C of the trimer hexacoordinate peak and its pentacoordinate peak, which have shifts of −344.0 and −194.6 ppm at −20°C, respectively, can be calculated in exactly the same way to have an activation energy of 10.8 ± 0.3 kcal mol^{-1}. These activation energies are slightly smaller than the comparable values of 12.1 ± 0.1 kcal mol^{-1} obtained for the dimer ⇄ trimer barrier for the 2,2-dibutyl-1,3,2-dioxastannolane derivative obtained from (*S*,*S*)-1,2-cyclohexanediol, (1*S*,6*S*)-8,8-dibutyl-7,9,8-dioxastannabicyclo[4.3.0]nonane (**6**) (11).



6

The activation barrier for the dimer ⇄ tetramer interchange appears to be considerably smaller for **1** than for the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

1,3,2-dioxastannolanes, such as **2**, where coalescence for this process occurs simultaneously with that for the dimer ⇄ trimer process. The rate constant for a particular process is directly related to the chemical shift difference between the exchanging sites. Therefore, a rough estimate of the activation barrier for the dimer ⇄ tetramer interchange for **1** can be made from the ratio of the coalescence temperatures for the two processes occurring for **1** since the chemical shift differences are about the same for both. A value of 7.7 kcal mol^{-1} is obtained.

Integration of the trimer and dimer signals in the ^{119}Sn nmr spectra in chloroform-*d* allowed evaluation of the free energy difference for the dimer ⇄ trimer equilibrium. An equilibrium constant $K = [trimer]^2/[dimer]^3$ can be defined for the following equilibrium:

[1] 3Dimer ⇄ 2Trimer

Integrations of the spectra were performed at 208 and 213 K. The equilibrium constants, $K = [trimer]^2/[dimer]^3$, of 310 and 485, gave values of ΔG^0 of −2.4 and −2.6 kcal mol^{-1}, respectively, which yielded an average value of ΔG^0 of -2.5 ± 0.2 kcal mol^{-1} at 210 K. This value is somewhat smaller than that obtained for the same equilibrium for the dimers and trimers of **2**, -3.3 ± 0.1 kcal mol^{-1} at 200 K, obtained by the integration of spectra from a wide range of temperatures (11) for a 0.072 M solution in a 3:2 mixture of chloroform-*d* and dichlorofluoromethane. If the entropy term is the same as obtained earlier (11) for **2**, −27.6 cal mol^{-1} deg^{-1}, ΔH^0 for the equilibrium for **1** is −8.3 kcal mol^{-1}, very similar to the value of -8.8 ± 1.8 kcal mol^{-1} obtained for **2**.

The same procedure was performed on the mixed solvent spectra at 198 and 188 K, except that two equilibria could now be evaluated:

[1] 3Dimer ⇄ 2Trimer

[2] 2Dimer ⇄ Tetramer

For equilibria [1] and [2], ΔG^0 values at 193 K obtained by averaging the values at 198 and 188 K were −2.4 and −1.5 kcal mol^{-1}, respectively. For compounds **2** and **6**, the ΔG^0 values for equilibrium [2] at 200 K were 0.8 and 0.6 kcal mol^{-1}, respectively, algebraically greater than that measured for equilibrium [1] but similar to the difference in values for the two equilibria measured for **1** here.

The average chemical shifts observed by Smith *et al.* in a saturated chloroform-*d* solution at room temperature and neat at 96°C of −228 and −288 ppm, respectively, suggest that extensive oligomerization occurs under these conditions (17). If the chemical shifts from −65°C are used and it is assumed that only dimer and trimer are present, it can be calculated that the mole fraction of trimer is 0.70 for the chloroform-*d* solution. Probably the mixture present contained significant amounts of tetramer and perhaps higher oligomers. The chemical shift of −234 ppm observed for a 0.38 M solution of **1** at 20°C in toluene-d_8 here suggests more extensive oligomerization. The tendency of 1,3,2-dioxastannolanes to favour higher oligomers in less polar solvents had been noted previously (12). The shift to a less shielded position on heating is due to the expected (11) shift in the equilibria towards lower oligomers.

The mixture of species present in the neat liquid at 96°C (17) probably includes still higher oligomers. The average

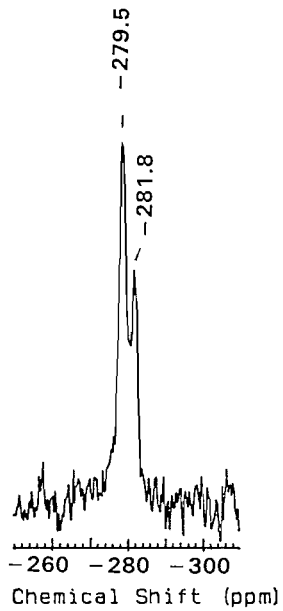


FIG. 5. Expansion of the isotropic peaks in the 74.6 MHz CP/MAS ^{119}Sn nmr spectrum of solid, 2,2-dibutyl-1,3,2-dioxastannane (**1**) spun at 4 kHz.

chemical shifts for the trimer and tetramer are −244.4 and −267.0 ppm from the mixed solvent data, both considerably less shielded than the signal from the neat liquid at −288 ppm. In the solid state, the average chemical shift for the polymer is −280 ppm and solution and solid-state ^{119}Sn chemical shifts are normally very similar (±5 ppm) (10, 26). Large variations in ^{119}Sn nmr chemical shifts with temperature preclude precise definition of the species present but average values more negative than −280 ppm would be expected for higher oligomers than the pentamer.

The ^{119}Sn nmr chemical shifts of **1** are 60–70 ppm more shielded than those for comparable species of its five-membered ring analogue, **2** (11) and 20–30 ppm more shielded than those for acyclic dibutyltin dialkoxide derivatives (17). Similar trends have been observed for tetraalkyltin and lead derivatives (16*d*).

Nuclear magnetic resonance spectral results for the solid

Static and CP/MAS ^{119}Sn nmr spectra of crystalline **1** were measured (10). An expansion of the region of the CP/MAS spectrum containing the isotropic peaks is shown in Fig. 5. Two isotropic peaks were observed close together at −279.5 and −281.8 ppm. These chemical shifts are in the region of the ^{119}Sn chemical shift range expected for hexacoordinate tin but are considerably less shielded than the hexacoordinate tin nuclei of **1** in trimers or tetramers in solution. Similar deshielding of hexacoordinate tin nuclei on moving from low oligomers to higher oligomers and polymers have been noted for tin atoms in 1,3,2-dioxastannolanes (10).

The observation of two peaks is probably due to the 1:1 disorder of C-5 in the crystal. Slightly different environments for tin atoms will arise depending on the orientations of the C-5 atoms in the neighbouring rings. If a particular tin nucleus in a 1,3,2-dioxastannane ring is considered, the C-5 atoms in adjacent rings can both be above the mirror plane of the molecule, both below, or one above and one below in a statistical ratio of 1:1:2, respectively. Three peaks are predicted with intensities in that ratio. The observation of only

two peaks indicates that the magnitude of the effect is small probably because the structural differences are five atoms away from the affected tin atom.

Conclusions

2,2-Dibutyl-1,3,2-dioxastannane (**1**) exists in the crystal as a polymer in which the individual monomer units are joined together by Sn—O bonds which are about 25% longer than those inside the monomer units. The tin atoms are present in highly distorted octahedral coordination. In liquid phases, compound **1** is present as mixtures of oligomers ranging from the dimer to high oligomers with compositions that vary widely depending on temperature and concentration. The tendency to form oligomers containing hexacoordinate tin for **1** is slightly less than that for 2,2-dibutyl-1,3,2-dioxastannolane (**2**) probably because the Sn—O—Sn bond angle inside the monomer ring for **1** is 93.2°, whereas that for **2** is 79.0°. The ^{119}Sn nmr chemical shifts of **1** are about 60–70 ppm more shielded than the five-membered ring analogue **2**, and 20–30 ppm more shielded than acyclic derivatives.

The cross-polarized static and high-resolution magic angle spinning ^{119}Sn NMR spectra of a number of 2,2-dialkyl-1,3,2-dioxastannolanes and one 1,3,2-dioxastannane have been measured in the solid state. For the four compounds on which X-ray studies had been performed, the numbers and positions of the isotropic peaks in the high-resolution spectra were related to the number of tin sites present and the state of oligomerization of the compounds. The chemical shifts of hexacoordinate Sn nuclei are 35–80 ppm larger in polymeric solids than for the same compounds in solution where the compounds exist as trimers and tetramers. States of oligomerization for solids that had not been previously studied by X-ray crystallography were determined using CP/MAS ^{119}Sn NMR spectroscopy. The principal components of the ^{119}Sn chemical shift tensors were obtained from the static spectra and used to calculate chemical shift anisotropies and asymmetry parameters. The values of the chemical shift anisotropies ranged from 600 to 800 ppm for 1,3,2-dioxastannolanes but the value for a 1,3,2-dioxastannane was larger, 919 ppm. The chemical shift anisotropies measured directly from the solid-state powder patterns are in excellent agreement with the values derived from previous variable temperature spin-lattice relaxation measurements in solution when the same oligomer was present in both states. Our results support our previous conclusion that the antisymmetric terms of the chemical shift tensor make a small or negligible contribution to the rate of ^{119}Sn spin-lattice relaxation in these compounds.

Key words: 1,3,2-dioxastannolanes, stannylene acetals, ^{119}Sn NMR, ^{119}Sn NMR of solids, ^{119}Sn chemical shift anisotropy.

Opérant à l'état solide, on a mesuré les spectres RMN du ^{119}Sn, statiques avec polarisation croisée et tournant, à haute résolution, à l'angle magique, d'un certain nombre de 2,2-dialkyl-1,3,2-dioxastannolanes et d'un 1,3,2-dioxastannane. Pour les quatre composés pour lesquels on a déterminé des structures par diffraction des rayons-X, on a pu relié les nombres et les positions des pics isotropes dans les spectres à haute résolution avec le nombre des sites d'étain présents et l'état d'oligomérisation des composés. Les déplacements chimiques des noyaux de Sn hexacoordonnés sont de 35 à 80 ppm plus grands dans les polymères solides que dans les mêmes composés en solution alors que les composés existent sous la forme de trimères ou de tétramères. Faisant appel à la RMN du ^{119}Sn par CP/MAS, on a déterminé les états d'oligomérisation des solides que l'on n'avait pas étudiés antérieurement par diffraction des rayons-X. En se basant sur les spectres statiques, on a obtenu les principales composantes des tenseurs des déplacements chimiques du ^{119}Sn et on les a utilisées pour calculer les anisotropies des déplacements chimiques et les paramètres d'asymétrie. Pour les 1,3,2-dioxastannolanes, les valeurs des anisotropies des déplacements chimiques varient de 600 à 800 ppm; toutefois, pour un 1,3,2-dioxastannane, cette anisotropie est plus élevée, soit 919 ppm. Lorsque le même oligomère est présent dans les deux états, les anisotropies des déplacements chimiques mesurés directement à partir des patrons de poudres à l'état solide sont en très bon accord avec les valeurs obtenues à partir de mesures antérieures de relaxation spin-réseau à températures variables, en solution. Nos résultats supportent notre conclusion antérieure à l'effet que les contributions des termes antisymétriques du tenseur du déplacement chimique à la vitesse de relaxation spin-réseau du ^{119}Sn dans ces composés ne sont que faibles ou négligeables.

Mots clés : 1,3,2-dioxastannolanes, acétals de stannylène, RMN du ^{119}Sn, RMN du ^{119}Sn dans des solides, anisotropie du déplacement chimique du ^{119} Sn.

[Traduit par la rédaction]

Introduction

Tin-119 NMR spectroscopy has become established as a standard technique for evaluating the structures, reactions, and bonding of tin-containing compounds (1). There is now increasing interest in solid-state ^{119}Sn NMR spectroscopy to evaluate bonding at tin and also to provide a bridge between X-ray crystallographic results and solution NMR studies (2–10). A variety of compounds have been examined, including inorganic tin compounds (2), tetraalkyl or aryl tin compounds (3–5), organotin halides (3–6), organotin oxides, hydroxides, and sulfides (3, 4, 7), esters (3, 4, 8), and others (9, 10). Most investigators have only reported the isotropic chemical shift, δ_{iso}, obtained from CP/MAS measurements, even though it is possible to obtain the three principal components of the chemical shift tensor from solid-state NMR studies.

The compounds examined in this publication are 1,3,2-dioxastannolanes and 1,3,2-dioxastannanes, typical examples of the tin-containing intermediates employed in the widely used stannylene reaction (11). We have shown that these compounds are present in solution as dimers and (or) higher oligomers in which the tin atoms are pentacoordinate or hexacoordinate (12, 13). Tin-119 chemical shift ranges have been established for tin nuclei in 2,2-dibutyl-1,3,2-dioxastannolanes; pentacoordinate tin nuclei absorb in the region from −100 to −150 ppm with respect to tetramethyltin, while hexacoordinate tin nuclei absorb between −230 and −300 ppm in solution (12, 13).

We recently measured the ^{119}Sn NMR spin-lattice relax-

ation rates in solution for a number of 1,3,2-dioxastannolanes in which the tin atoms were in either pentacoordinate or hexacoordinate environments (14). The relaxation times in these compounds were short and the major mechanism of spin-lattice relaxation at 8.48 T was due to chemical shift anisotropy. The magnitudes of the chemical shift anisotropies were obtained from variable temperature solution spin-lattice relaxation data at 4.70 and 8.48 T. For one compound, methyl 4,6-*O*-benzylidene-2,3-*O*-dibutylstannylene-α-D-glucopyranoside (**1**), the principal components of the ^{119}Sn chemical shift tensor for the pentacoordinate site in its dimeric structure were determined directly from the static ^{119}Sn NMR spectrum of a powdered sample. The chemical shift anisotropy (CSA) determined from the solid-state experiments, 748 ± 20 ppm, was in good agreement with the value obtained from the solution T_1 data, 720 ± 50 ppm. This result is significant in that it suggests that the antisymmetric components of the ^{119}Sn chemical shielding tensor of **1** make a small or negligible contribution to the rate of spin-lattice relaxation. For compounds containing both pentacoordinate and hexacoordinate tin atoms, the solution ^{119}Sn spin-lattice relaxation data indicate that the tin chemical shift anisotropies for the hexacoordinate sites are approximately 1.5 times those of the pentacoordinate sites. This was a rather surprising result in view of the fact that the pseudo-octahedral environment of a hexacoordinate tin site has potentially high local symmetry. We decided to examine the solid-state ^{119}Sn NMR spectra of a number of other compounds containing five- or six-coordinate tin atoms in order to test the generality of the above conclusion. Furthermore, we were interested in comparing the ^{119}Sn chemical shift anisotropies measured directly in the solid state with those determined from earlier solution spin-lattice relaxation measurements. If these values are similar, the antisymmetric elements of the chemical shift tensors are probably insignificant.

Theory

The complete magnetic shielding tensor in the principal axis system (PAS) can be expressed as a sum of symmetric and antisymmetric tensors (15):

$$\sigma^{s}_{PAS} = \begin{pmatrix} \sigma_{11} & 0 & 0 \\ 0 & \sigma_{22} & 0 \\ 0 & 0 & \sigma_{33} \end{pmatrix} \text{ and}$$

$$\sigma^{a}_{PAS} = \begin{pmatrix} 0 & \sigma_{12} & \sigma_{13} \\ -\sigma_{12} & 0 & \sigma_{23} \\ -\sigma_{13} & -\sigma_{23} & 0 \end{pmatrix}$$

NMR measurements of a static powder sample in the solid state yield information concerning the principal components of the chemical shielding tensor (σ_{ii}, i = 1–3). To first order the antisymmetric tensor does not contribute to the NMR lineshape (16, 17). Any contribution that the antisymmetric terms make to the overall lineshape is expected to be small and would probably escape detection except possibly in careful single-crystal NMR studies of heavy nuclei that have enormous chemical shift ranges (17). The reader is referred to a recent paper by Ding and Ye for a complete discussion (18).

The contribution that the antisymmetric terms make to the rate of CSA relaxation in solution NMR studies is expected to be more profound. Blicharski (19) and other workers (17, 20) have shown that for relaxation by the CSA mechanism

$$[1] \quad \frac{1}{T_1} = \omega_0^2\left(\frac{2}{3}A^2\frac{\tau_1}{1+\omega_0^2\tau_1^2} + \frac{2}{15}S^2\frac{\tau_2}{1+\omega_0^2\tau_2^2}\right)$$

and

$$[2] \quad \frac{1}{T_2} = \omega_0^2\left(\frac{1}{3}A^2\frac{\tau_1}{1+\omega_0^2\tau_1^2} + \frac{1}{15}S^2\left(\frac{4}{3}\tau_2 + \frac{\tau_2}{1+\omega_0^2\tau_2^2}\right)\right)$$

where

$$A^2 = (\sigma^a_{12})^2 + (\sigma^a_{13})^2 + (\sigma^a_{23})^2 \text{ and}$$

$$S^2 = (\Delta\sigma)^2\left(1 + \frac{1}{3}\eta^2\right)$$

Here, $\Delta\sigma = (\sigma_{11} + \sigma_{22})/2 - \sigma_{33}$ and $\eta = (\sigma_{22} - \sigma_{11})/(\sigma_{33} - \sigma_{iso})$, where $\sigma_{iso} = (\sigma_{11} + \sigma_{22} + \sigma_{33})/3$.

For molecules that undergo small-step isotropic rotational diffusion, $\tau_1 = 3\,\tau_2$, and eqs. [1] and [2] become

$$[3] \quad \frac{1}{T_1} = \omega_0^2\left(2A^2\frac{\tau_2}{1+\omega_0^2(3\tau_2)^2} + \frac{2}{15}S^2\frac{\tau_2}{1+\omega_0^2\tau_2^2}\right)$$

$$[4] \quad \frac{1}{T_2} = \omega_0^2\left(A^2\frac{\tau_2}{1+\omega_0^2 9\tau_2^2} + \frac{1}{15}S^2\left(\frac{4}{3}\tau_2 + \frac{\tau_2}{1+\omega_0^2\tau_2^2}\right)\right)$$

The first point of interest is that eqs. [3] and [4] predict that T_2 can exceed T_1. In fact, in the limit where the antisymmetric terms dominate, $T_2 = 2T_1$. In contrast, if the antisymmetric terms do not contribute to CSA relaxation, then eqs. [3] and [4] indicate that $T_2 = (6/7)T_1$.

In ^{59}Co NMR studies of a series of pseudo-octahedral Co(III) complexes, Eaton and co-workers found that $T_2 > (6/7)T_1$ and implicated the antisymmetric terms as being responsible (21). More recently, Anet *et al.* (22) found that the ^{13}C T_2 value in tetrachlorocyclopropene is greater than T_1 and argued that the antisymmetric terms of σ must be responsible. The importance of the antisymmetric terms in this compound was predicted by *ab initio* IGLO calculations (23).

First, we would like to point out that compounds **1**, **2**, and **5** are excellent candidates to use to evaluate the importance of the antisymmetric terms. The mechanism for relaxation is the CSA mechanism (14) and the tin sites in these compounds lack any symmetry. Note that if a site has symmetry greater than C_{2v}, the antisymmetric terms disappear (24). Very similar chemical shifts in solution and from the solid state suggest that the structures of compounds **1**, **2**, and **5** are similar in both media.

The approach that we have taken here is to first assume that the antisymmetric terms do not contribute to T_1, i.e.,

$$[5] \quad \frac{1}{T_1} = \frac{2}{15}\omega_0^2 S^2\frac{\tau_2}{1+\omega_0^2\tau_2^2}$$

and evaluate S^2 from the T_1 minimum (14). We then compare this $\Delta\sigma$ (or S^2) with that measured directly in the solid state. If the two values are the same within experimental error, we suggest that the antisymmetric terms make a negligible contribution to the rate of relaxation. Note that on the basis of eq. [3], the antisymmetric term is much more heav-

ily weighted than the symmetric term (a factor of 15 under conditions of extreme narrowing).

Experimental

Solution ^{119}Sn and ^{13}C NMR spectra were recorded on a Nicolet NT-360 NB NMR spectrometer at 8.48 T (134.62 MHz). Solution data were referenced with respect to external tetramethyltin or tetramethylsilane, respectively. The 1,3,2-dioxastannolanes were prepared from the appropriate diols and a dialkyltin oxide as described previously (12, 13). The diols used for preparation of the 2,2-dibutyl-1,3,2-dioxastannolane derivatives were prepared as described elsewhere (diols for compounds **1–5**, refs. 12, 13, and 25) or were commercial compounds (diols for compounds **6–9**).

Crystalline samples of compounds **2–5** and **8** and **9** were obtained by recrystallization of samples prepared on a vacuum line as outlined elsewhere (12, 13). Sufficiently crystalline samples of **6** and **7** were obtained by evaporation of benzene solutions on the vacuum line. Recrystallization was also performed on the vacuum line so that the samples were never exposed to the atmosphere. The process started with the distillation of anhydrous solvents through the vacuum line onto the solid samples. Closed containers were taken off the vacuum line for cooling and heating during recrystallization and for transfer of crystals to a dry box where the samples were ground and packed in MAS rotors. The rotors were sealed with press-fitting caps, which limited exposure to atmospheric moisture sufficiently that these moisture-sensitive compounds showed no signs of hydrolysis after exposure of the spinners to the atmosphere for up to 2 weeks.

Solid-state MAS ^{119}Sn NMR spectra were recorded on a Bruker MSL-200 NMR spectrometer using a standard Bruker double air-bearing MAS probe. The rotors (7 mm o.d.) were spun at rates of 2.5–4.5 kHz. Conditions for the Hartmann–Hahn match were optimized using a sample of tetracyclohexyltin (26). All spectra were acquired with high-power proton decoupling and 90° pulse lengths of 3–4 μs. Contact times of 1.5–3 ms and recycle times of 5–10 s were used. Some of the static ^{119}Sn NMR spectra were acquired with the addition of a tin 180° pulse after the cross-polarization period in order to generate a Hahn echo before acquisition (27). This pulse sequence was found to be helpful in minimizing the spectral distortion present in experimental static spectra. Solid-state NMR spectra were referenced with respect to tetramethyltin at 0.0 ppm using as a secondary reference tetracyclohexyltin, which has a ^{119}Sn chemical shift of −97.35 ppm (26). The chemical shift of −97.35 ppm was erroneously identified as that of hexamethylditin in our previous paper (14). However, all chemical shifts in our previous study have correct values with respect to tetramethyltin.

Results and discussion

The molecules chosen for study were benzyl 4,6-*O*-benzylidene-2,3-*O*-dibutylstannylene-β-D-glucopyranoside (**2**), methyl 4,6-*O*-benzylidene-2,3-*O*-dibutylstannylene-α-D-mannopyranoside (**3**), methyl 4,6-*O*-benzylidene-2,3-*O*-di-*tert*-butylstannylene-α-D-mannopyranoside (**4**), benzyl 4,6-*O*-benzylidene-2,3-*O*-dibutylstannylene-β-D-galactopyranoside (**5**), 2,2-dibutyl-1,3,2-dioxastannolane (**6**), (4*R*, 5*R*)-2,2-dibutyl-4,5-dimethyl-1,3,2-dioxastannolane (**7**), 2,2-di-*tert*-butyl-1,3,2-dioxastannolane (**8**), and 2,2-dibutyl-1,3,2-dioxastannane (**9**). Compounds **3**, **6**, **8**, and **9** were chosen because information was available about their solid-state structures from X-ray crystallography. The other compounds provided complementary information about a range of environments for tin. Tin-119 CP/MAS NMR spectra of compounds **2–9** were obtained at various spinning rates and the static spectra of all compounds except **3** were also obtained. Typical CP NMR spectra are shown in Figs. 2–7.

Comparison of CP/MAS spectra at two or more spin rates yields values for the isotropic chemical shift, σ_{iso}. The isotropic chemical shift is $(\delta_{11} + \delta_{22} + \delta_{33})/3$, where δ_{ii} (i = 1–3) are the three principal components of the chemical shift tensor. We use the convention $\delta_{11} \geq \delta_{22} \geq \delta_{33}$, i.e., δ_{33} is the principal component of the chemical shift tensor with the smallest chemical shift (i.e., the most shielded component). Tin-119 cross-polarized NMR spectra of static samples allow direct and unambiguous measurement of the principal components of the chemical shift tensor when the signal-to-noise ratios are sufficient. Principal components were measured directly from the static spectra for all compounds except **3**. The magnitude of the chemical shift anisotropy, $\Delta\delta$, is defined according to the convention of Haeberlen (17):

$$[6] \quad \Delta\delta = (\delta_{11} + \delta_{22})/2 - \delta_{33}$$

The asymmetry parameter, η, is defined by eq. [7]:

$$[7] \quad \eta = (\delta_{11} - \delta_{22})/(\delta_{iso} - \delta_{33})$$

as, in all cases, $|\delta_{33} - \delta_{iso}| > |\delta_{11} - \delta_{iso}|$. The experimental chemical shift parameters are summarized in Table 1.

In the carbohydrate derivatives **1–5**, the oxygen atoms are diastereotopic; hence, three dimers are possible for each of these compounds. The different dimers will be designated using conventional carbohydrate nomenclature by means of

the numbers of the two oxygen atoms that are tricoordinate (see Fig. 1). The formation of a dimer from two monomer molecules requires that one oxygen atom from each monomer becomes tricoordinate and that the two tin atoms become pentacoordinate.

A. Comparison of ^{119}Sn NMR spectra from the solid state and solution

In the discussion that follows, the ^{119}Sn NMR spectral data from solid-state (Table 1) and solution spectra (Table 2) will be compared and discussed in relation to what is known or

can be deduced about the structures of the compounds and the nature of the species present in the different phases.

The principal components of the chemical shift tensor for methyl 4,6-*O*-benzylidene-2,3-*O*-dibutylstannylene-α-D-glucopyranoside (**1**) are included for comparison purposes (14). Compound **1** has been studied by X-ray crystallography (28). Because of the large *R*-factor previously obtained (10.8%) and because some carbon atoms were not located, the solid-state structure was recently reevaluated from low temperature X-ray data (29). It is present as a 3,3-dimer in the solid state and in solution in chloroform-*d*, benzene-d_6, and toluene-d_8 (13, 28–30).

Compound **2** is a mixture of two dimers in solution (13); of the two dimers, the symmetrical 3,3-dimer constitutes the majority of the mixture in chloroform-*d*, benzene-d_6, and toluene-d_8. The sample studied here was recrystallized from a mixture of anhydrous toluene and anhydrous hexane. It gave a CP/MAS spectrum containing a single isotropic peak at −128 ppm, consistent with the symmetrical 3,3-dimer (Fig. 2). However, in solution, the chemical shifts of all three peaks, the major one from the 3,3-dimer and the two minor peaks from the unsymmetrical 2,3-dimer, were close together; the largest differences ranged from 0.4 ppm in chloroform-*d* to 4.2 ppm in toluene-d_8. Close inspection of peaks of **2** indicated that the major peak was accompanied by at least two other peaks present at low intensity and at slightly larger frequencies than that of the major peak, consistent with the presence of a small amount of the unsymmetrical dimer. Apparently, the crystalline material studied was a mixture in which the major 3,3-dimer was accompanied by a small proportion of the 2,3-dimer.

The principal components of the chemical shift tensor for tin in **2** are almost identical to those for **1**, suggesting that the bonding environment at tin is similar for these two compounds. In both, the tin atoms are in 1,3,2-dioxastannolane rings *trans*-fused to pyranose rings. It is therefore likely that the different regiochemistry observed in reactions of **1** and **2** (13) arises from factors other than the bonding of the tin atoms. The chemical shift anisotropy of the tin nuclei in the 3,3-dimer of **2**, obtained from spin-lattice relaxation measurements in a toluene-d_8 solution, was 810 ± 60 ppm (14), identical within experimental error to that measured here in the solid state.

Compound **3** is present as complicated mixtures in solution. The composition of the mixtures present depends on solvent and temperature. In chloroform-*d*, dimers and trimers are dominant; in toluene-d_8, the species observable by ^{119}Sn NMR includes tetramers and pentamers and their populations increase as the temperature is lowered. Below −50°C, the latter species are the major species present in toluene-d_8 (25). For the α-benzyl analog of **3** (**3***b*), oligomerization in toluene-d_8 only proceeds as far as the tetramer that becomes dominant below −40°C. Chemical shifts for a 0.22 M solution of **3***b* in toluene-d_8 at −40°C were as follows: trimer (~10%), −117.1, −124.1, and −291.2 ppm, and tetramer, −124.1 and −243.4 ppm.

Crystals of **3** obtained from hexane were found to be pentameric by X-ray crystallography (31). The solid-state ^{119}Sn NMR spectra were obtained on crystals also recrystallized from hexane. Tin-119 CP/MAS NMR spectra were obtained at three different spin rates, 2500, 3200, and 3730 Hz, to make the assignments of the isotropic peaks certain. Despite extensive overlap in the NMR spectra of **3**, it was possible to confirm the presence of two isotropic peaks in the hexacoordinate region and two in the pentacoordinate region. This observation is consistent with a pentameric structure in the solid state if one of the peaks assigned to hexacoordinate tin corresponds to two tin sites. As in the spectra of the solid sample, the spectra of the pentamer in toluene-d_8 solution also contained only four signals, two instead of the three expected in the hexacoordinate region of the spectra. There is no ambiguity in assignment of solution

spectra because the peaks due to trimers, tetramers, and pentamers are all present with relative intensities that vary in a predictable manner with temperature, concentration, and solvent. The relative intensities of the four peaks in the CP/MAS spectra were considerably different; also, there was some evidence for an additional small peak present at −270 ppm, perhaps due to the hexacoordinate site of a trimer contaminant in the sample studied. The relative intensity of the isotropic peak at −119 ppm was greater than those of the other peaks in all solid-state CP/MAS spectra of **3**.

The isotropic chemical shifts of hexacoordinate tin nuclei move to considerably higher frequencies as the size of the oligomer increases (12–14). For **3**, the isotropic ^{119}Sn chemical shifts obtained for hexacoordinate tin nuclei from solution spectra are −267.8 ppm for the trimer, −245.9 ppm for the tetramer, and −213.5 and −236.6 ppm for the pentamer. The corresponding solid-state shifts are −223 and −234 ppm for the pentamer. Differences between solution and solid-state chemical shifts for all compounds are given in Table 3.

The complex spectra of **3** precluded calculation of chemical shift tensor elements by graphical (32) or computer simulation methods (33). The δ_{11}, δ_{22}, and δ_{33} values for **3** given in Table 1 were estimated very approximately by examining the variation in intensity with frequency for the spinning side bands in the CP/MAS spectra and selecting shifts at positions in the spinning side-band patterns that matched those in other 1,3,2-dioxastannolane spectra that could be calibrated against static spectra. Although uncertainties in these δ_{ii} values may be as large as ±50 ppm, it is clear that the chemical shift anisotropies for the pentacoordinate sites are less than those in the hexacoordinate sites. The values of the chemical shift anisotropies measured here for the pentacoordinate sites in the solid-state pentamer are almost identical to those obtained for the two different pentacoordinate sites in the trimer of ***3b*** from T_1 minima in solution, 658 ± 33 ppm and 686 ± 34 ppm (14). The chemical shifts for these sites are also very similar and the total range in chemical shifts for pentacoordinate tin nuclei in **3** and ***3b*** is <10 ppm.

In marked contrast, the value of the chemical shift anisotropy for the hexacoordinate site in the trimer of ***3b*** in solution, 1080 ± 55 ppm (14), is significantly larger than the values obtained for the hexacoordinate sites in the solid-state pentamer of **3**, 806 ± 60 and 864 ± 60 ppm. As noted above, there are also significant chemical shift differences between the hexacoordinate sites of the trimer and tetramer in solution and those of the pentamer in the solid state or solution (see Table 3). These results suggest that both the chemical shifts and the chemical shift anisotropies reflect differences in bonding between the hexacoordinate tin nuclei in trimers and tetramers and those in pentamers and polymers. The principal components of the chemical shift tensor show much more variation with structure than do the isotropic averages. Unfortunately, no 1,3,2-dioxastannolane that has been studied by X-ray crystallography exists as either a trimer or tetramer.

Compound **4**, the first 2,2-di-*tert*-butyl-1,3,2-dioxastannolane derivative to be discussed here, is considered to be a single dimer in solution because the single peak observed in the ^{119}Sn NMR spectrum has a chemical shift of −217.7 ppm, similar to the chemical shifts observed for the parent di-*tert*-butyl derivative **8** from both solution and CP/MAS NMR spectra (34). Compound **8** was shown to be dimeric by X-ray crystallography (ref. 34 and discussion to follow). The CP/MAS ^{119}Sn NMR spectra of **4** contain two isotropic peaks at −213.0 and −225.7 ppm, chemical shifts consistent with pentacoordinate tin sites in dimeric structures (see Fig. 3).

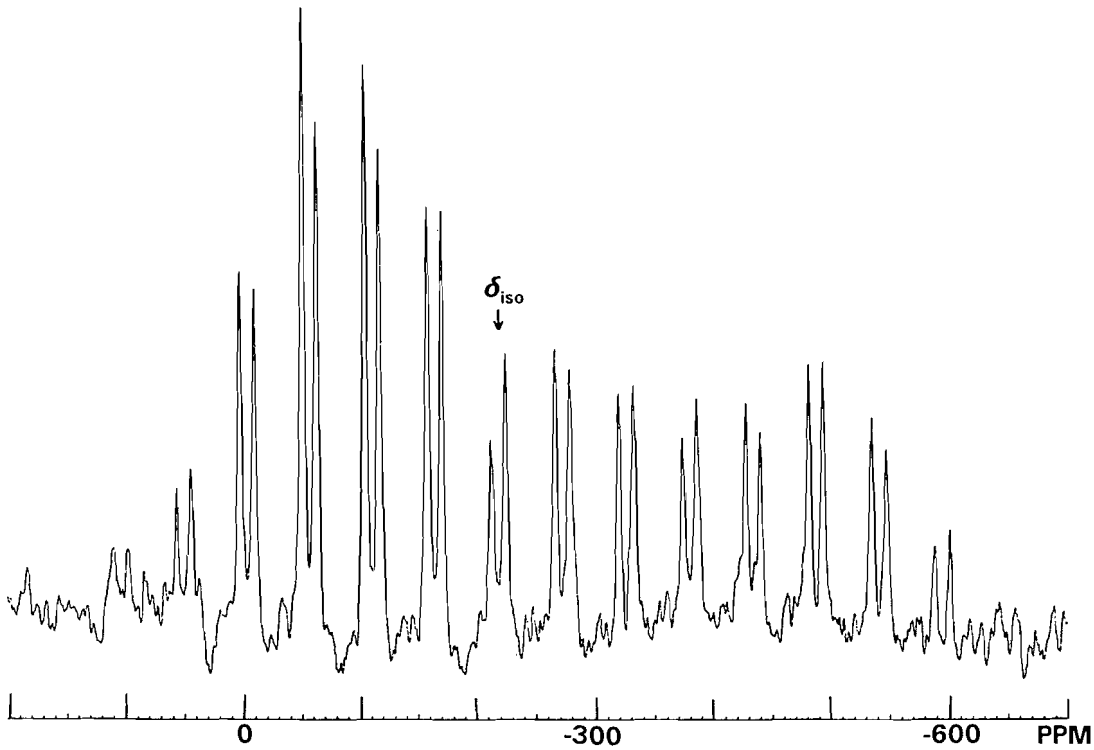

FIG. 3. Tin-119 solid-state CP/MAS NMR spectrum with magic angle spinning at 4.00 kHz for compound **4**.

The peak doubling observed in the solid-state spectra but not in those from solution could be caused by either one of two effects. The species present in the solid state could be one of the C_2-symmetric dimers whose intramolecular symmetry is lost due to crystal forces. Compound **1** was observed to deviate slightly from C_2 symmetry in the solid-state by X-ray diffraction (28, 29) and two peaks separated by 2.2 ppm were observed in its CP/MAS spectra (14). The two sites could also arise because symmetric dimers are present at two locations in the unit cell that are not related by symmetry as for **8** (ref. 34 and *vide infra*). Other possible explanations for the peak doubling could invoke dimers that are not populated in solution. However, there is no reason to expect that these species would form on crystallization.

The intensities and positions of the peaks in the spinning side-band pattern of the CP/MAS ^{119}Sn spectrum of **4** were analysed by an iterative version of the Herzfeld–Berger approach (32) to yield magnitudes of the principal components of the two chemical shift tensors. These values are listed in Table 1. The static spectrum of **4** gave averaged values of these components that, in each case, were intermediate between the values obtained by simulation of the CP/MAS NMR spectra.

The sample of compound **5** was obtained by recrystallization from a mixture of toluene and hexane. The isotropic chemical shift observed for **5** in the CP/MAS spectrum was −141 ppm, similar to the values obtained for the dimer of **5** in solutions in chloroform-*d* and toluene-d_8, −143.8 and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

−138.4 ppm, respectively (Fig. 4). Thus, compound **5** was present as a dimer in the solid. The ^{119}Sn nuclei of **5** are about 13 ppm more shielded than those of the other two carbohydrate dibutylstannylene derivates that exist as dimers, compounds **1** and **2**. All three principal components of the chemical shift tensor contribute significantly to the difference, with δ_{33} showing the largest difference.

The chemical shift anisotropy calculated from solution T_1 data in chloroform-*d* at both 134.62 and 74.62 MHz for **5** was 773 ppm (14), almost identical to the value of 776 ppm obtained from the static spectrum. In calculating the solution value, it was necessary to assume a value for the asymmetry parameter, η. It was assumed that η had the same value as that for compound **1**, 0.49 (14). Substituting the value for η obtained from the static spectrum of the solid, 0.54, changes the solution chemical shift anisotropy slightly to 767 ppm, still very similar to the value from the solid.

Compound **6** has been shown by X-ray crystallography to exist as an infinite ribbon polymer in the crystalline state (35). The sample studied here was obtained by evaporation of a benzene solution. The observed δ_{iso} value, −231 ppm, is somewhat to higher frequency of those of the hexacoordinate tin nuclei of the trimers to pentamers present in solution (ref. 12, see Table 3). This result is consistent with a hexacoordinate tin atom in a highly oligomeric species, such as a polymer. The absence of isotropic peaks in the pentacoordinate region of the CP/MAS ^{119}Sn NMR spectrum confirms that the sample studied here was a polymer (see Fig. 5).

The individual principal components of the chemical shift tensor of **6** are all 100 ± 20 ppm more shielded than those of the pentacoordinate tin sites in the dimers of **1** and **2**. However, both the chemical shift anisotropies and asymmetry parameters for **6** are similar to those of **1** and **2**.

The crystalline sample of compound **7** was obtained by evaporation of a benzene solution. The only possible interpretation of its ^{119}Sn NMR spectra in the solid state is that **7** is an infinite ribbon polymer as observed for **6** although, as for **6**, it was present as a mixture of oligomers in solution (12). The isotropic chemical shifts in the solid-state spectrum were 80 and 61 ppm to higher frequency of those observed for hexacoordinate tin nuclei in spectra from solution, where **7** is present in the trimer and tetramer, respectively. These differences are of the same order of magnitude as noted above but are the largest observed. The actual chemical shift for **7** in the solid state, −205 ppm, is almost the same as that observed for the dimer of **9** in solution, −195 ppm. It is clear that caution must be used in deducing the coordination status of tin from ^{119}Sn NMR chemical shifts of this class of compound, particularly if shifts from compounds having different ring sizes are compared.

Compound **8** was considered to be a single dimer in the solid state based on X-ray crystallography and solid-state NMR spectroscopy (34). The solid powder sample examined here was prepared from large colourless cubically shaped crystals that were obtained by recrystallization from anhydrous toluene, the same solvent previously employed (34). Our high-resolution CP/MAS spectra indicate that the isotropic peak of **8**, earlier observed to be a singlet (34), actually contained four closely spaced peaks, three of which were intense and one that was small but reproducible (see Fig. 6). A single crystal of **8** was assigned to the space group *Pbam* and the unit cell contained two independent but chemically equivalent molecules. Although the structures of

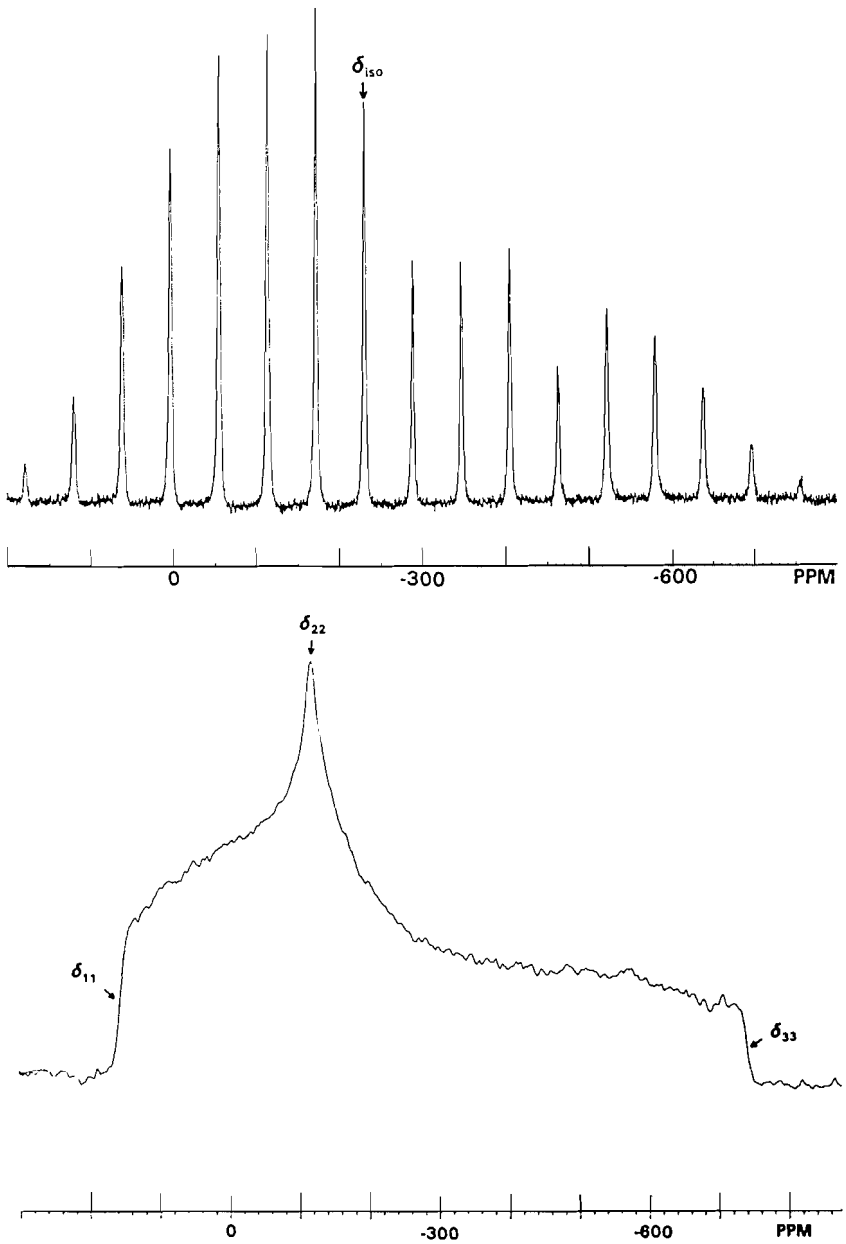

FIG. 5. Tin-119 solid-state NMR spectra for compound **6**; top, CP/MAS spectrum with magic angle spinning at 4.36 kHz; bottom, static spectrum.

the two independent molecules were nearly identical, small differences were observed; two of the 10 bond lengths involving heavy atoms and 8 of the 19 bond angles differed by more than the standard deviations in their respective values. The largest difference was 3.4 times the standard deviation. The X-ray crystallographic study (34) also indicated that the carbon atoms in the two 1,3,2-dioxastannolane rings in the dimeric structure were disordered. Each five-membered ring adopted twist conformations with the OSnO atoms in the mirror plane of the molecule. Each carbon atom in a 1,3,2-dioxastannolane ring was 50% disordered above and below the mirror plane containing the two oxygen atoms. In any one ring, one carbon atom is above the mirror plane and the other below. The crystal structure also had a C_2 axis through the centre of the four-membered SnOSnO ring (34).

If any motion in the 1,3,2-dioxastannolane rings occurs at a rate slower than the NMR chemical-shift time scale for this experiment (i.e., static disorder), two conformers that have C_2 and S_2 symmetry are possible, assuming that the four *tert*-butyl groups in each conformer assume static or averaged positions consistent with the symmetry. For discussion, the carbon atoms attached to the O atoms in the central SnOSnO ring will be designated α and α′ atoms. In the C_2 conformer, the α and α′ atoms are *syn* relative to the plane defined by the SnOSnO ring, while in the S_2 conformer they are *anti*. Each conformer should give rise to one ^{119}Sn NMR peak for a total of two peaks. Four peaks arise because each of the two independent molecules in the unit cell can be present as C_2 or S_2 conformers.

The principal components of the ^{119}Sn NMR chemical shift tensor reported earlier for **8** (34) are very different than those measured here directly from the static spectrum, presum-

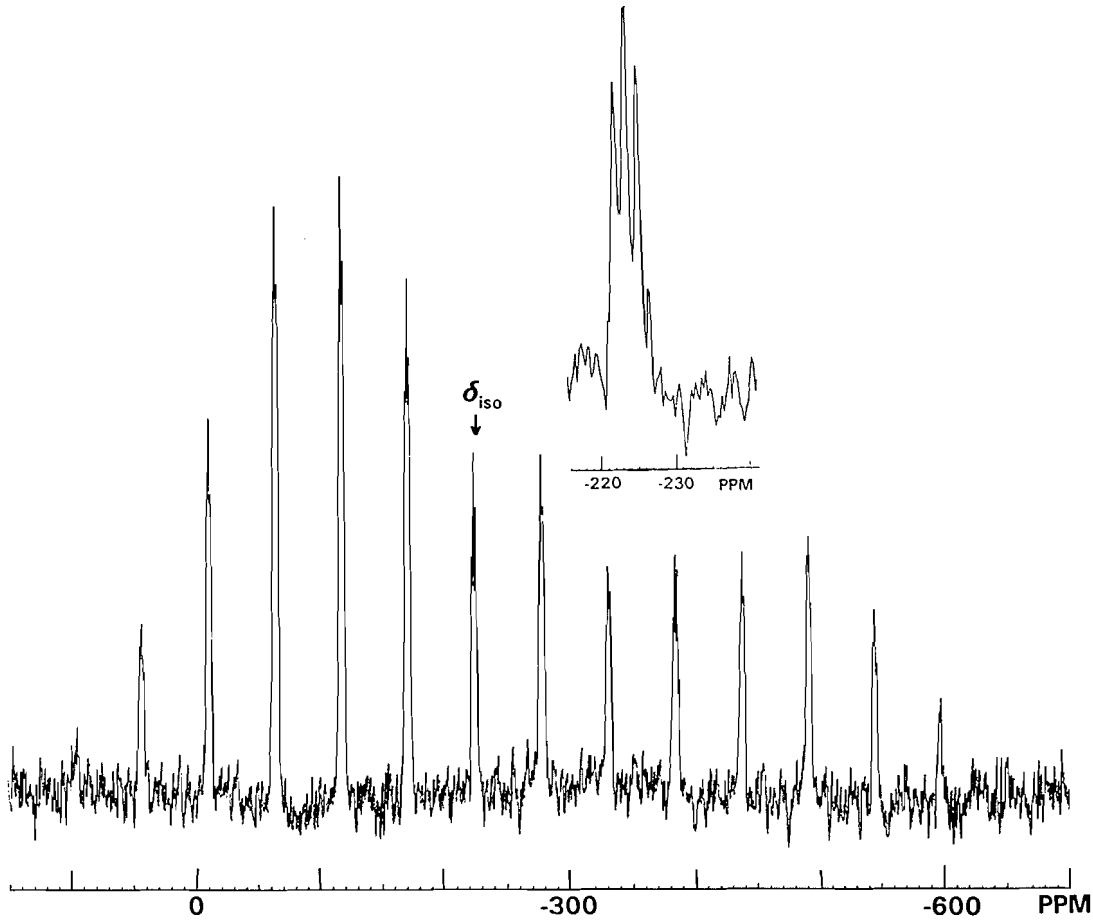

FIG. 6. Tin-119 solid-state NMR spectrum for compound **8** obtained with magic angle sample spinning at 3.99 kHz. The inset shows an expansion of the part of the spectrum containing the isotropic signals.

ably because of the difficulty of estimating these values from slow-spinning CP/MAS spectra.

A preliminary crystal structure of compound **9** has been published in which it was suggested that the structure contained monomer units linked together by long Sn—O bonds (36), which has been interpreted as **9** being a polymer (11). Since no details were published, it was not possible to compare conditions for recrystallization. The sample studied here consisted of needles that were obtained by recrystallization from hexane and toluene. A crystal from the same recrystallization has also been examined by X-ray crystallography (37). The CP/MAS ^{119}Sn NMR spectra of **9** contained two isotropic peaks at −278.5 and −281.6 ppm (Fig. 7). These peaks are on average 66 ppm less shielded than the peak assigned to the hexacoordinate tin atom in a trimer, consistent with the differences in shifts between polymers and trimers observed for **6** and **7** (see Table 3). Thus, these results support the earlier assignment of a polymeric structure to the crystals of **9** (11, 36). The new crystal structure confirmed the assignment of a polymeric structure to solid **9** (37).

Average bond angles at the six pentacoordinate (28–31, 34) and four hexacoordinate (31, 35) tin sites in 1,3,2-dioxastannolanes whose geometries are available from X-ray studies are shown in Fig. 8. An idealized octahedral environment at a dialkyltetraalkoxytin(IV) nucleus might be expected to be more symmetric than a pentacoordinate environment at a dialkyltrialkoxytin(IV) nucleus. However, it can be seen from Fig. 8 that the geometries are far from ideal and, thus, it is not surprising that large chemical shift anisotropies are observed for tin nuclei occupying six-coordinate sites. Where the distortions from octahedral geometry are much smaller, the chemical shift anisotropy is relatively small. For instance, SnO_2, cassiterite, crystallizes with the rutile structure in which each tin atom is surrounded by six oxygen atoms at equal distances, but with O—Sn—O angles of 78, 102, and 90° (38). The ^{119}Sn chemical shift anisotropy for SnO_2, calculated from the data in ref. 2, is 125 ppm, much less than the values observed in the 1,3,2-dioxastannolanes investigated here.

B. General observations

The total range in chemical shift anisotropy for the nine compounds studied here was 600–920 ppm, and some trends were observed within this range. The chemical shift anisotropy for 2,2-dibutyl-1,3,2-dioxastannolanes in pentacoordinate sites varied by over 120 ppm, much more than the range in isotropic chemical shifts (10 ppm).

Replacement of the *n*-butyl groups by *tert*-butyl groups, present in compounds **4** and **8**, results in marked decreases in the isotropic chemical shifts, −98 and −97 ppm for the changes from the dimer of **6** to that of **8** in solution and for the dimer of **3** to that of **4**, respectively. Direct comparisons of $\Delta\delta$ values of *n*-butyl and *tert*-butyl derivatives are not as readily made because values for comparable compounds in the same oligomeric form are not available. However, the $\Delta\delta$ values of **4**, which is dimeric, and those of the pentacoordinate sites of the pentamer **3** are almost identical. Each of the three δ_{ii} values of **4** are about 100 ppm smaller than

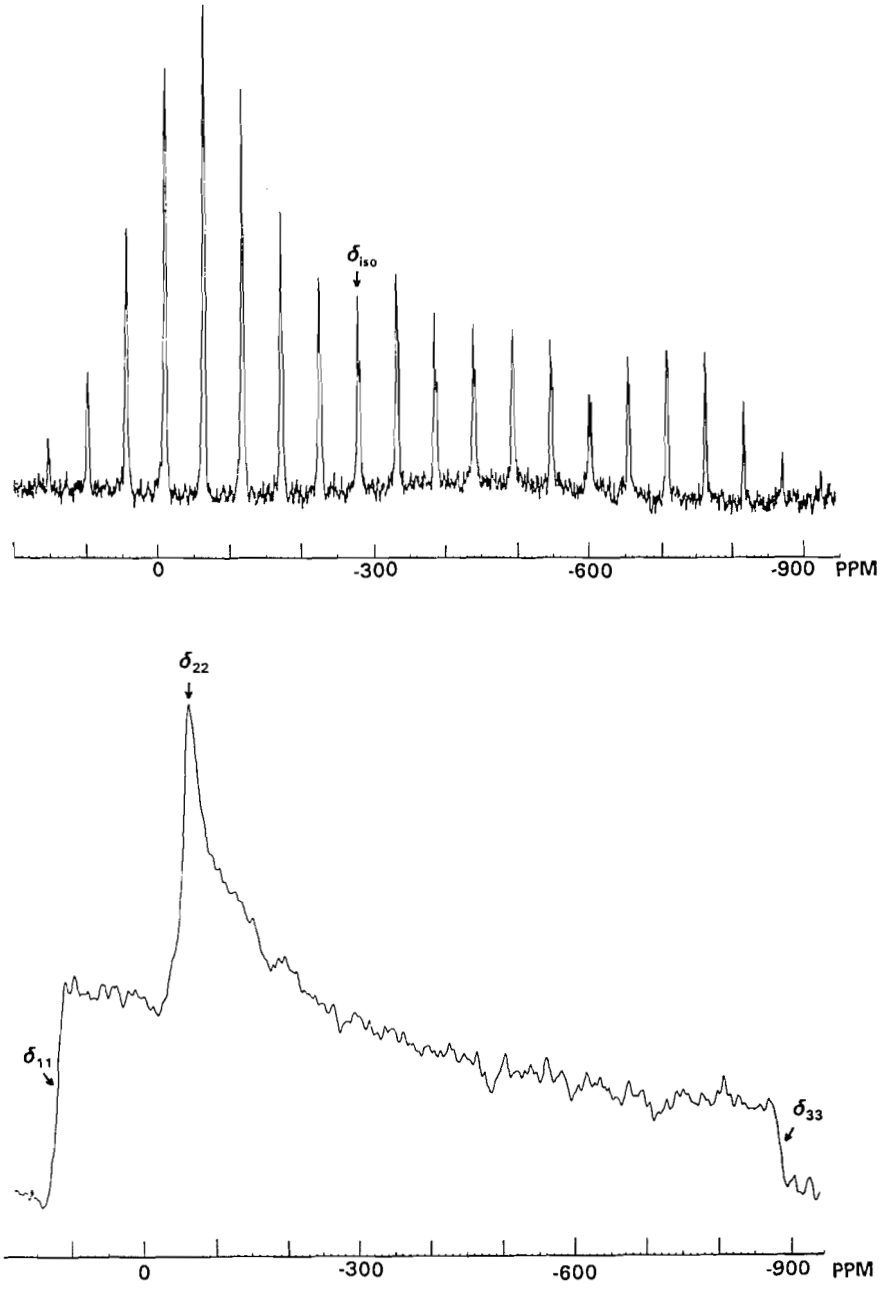

FIG. 7. Tin-119 solid state NMR spectra for compound **9**; top, CP/MAS spectrum with magic angle spinning at 4.00 kHz; bottom, static spectrum.

TABLE 4. Comparison of ^{119}Sn NMR chemical shift anisotropies and isotropic chemical shifts from solution and solid-state data

Compound	Oligomer present	Chemical shift anisotropies		Isotropic chemical shifts	
		Solution (14)	Solid state	Solution (13)	Solid state
1	Dimer	762 ± 50[a]	748 ± 30	−125,[a] −132[b]	−127, −128
2	Dimer	810 ± 60[b]	743 ± 30	−133,[a] −132[b]	−128
5	Dimer	767 ± 40[a,c]	776 ± 30	−144,[a] −138[b]	−141

[a]In chloroform-*d*.
[b]In toluene-d_8.
[c]The value from ref. 14 (773 ppm) was modified because the η value assumed (0.49) for its calculation was slightly different than that measured here (0.54) for solid **5**.

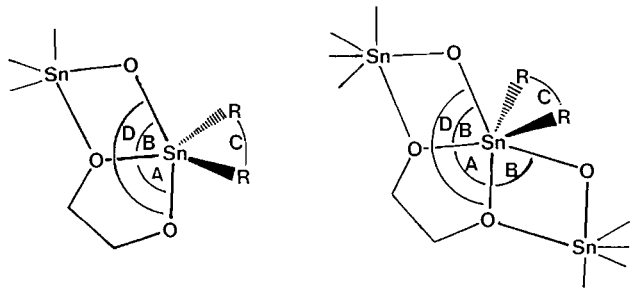

FIG. 8. Average bond angles around tin atoms in 1,3,2-dioxastannolanes obtained from X-ray crystallographic results where the tin atoms are in (a) pentacoordinate sites (28–31, 34) and (b) hexacoordinate sites (31, 35).

those of the pentacoordinate sites of **3**, resulting in the change in δ_{iso} observed.

The different bonding arrangements in the 1,3,2-dioxastannane **9** have a marked effect on the chemical shift anisotropy, which increases by 157 ppm with respect to that for 2,2-dibutyl-1,3,2-dioxastannolane **6**. The major cause of this marked increase in $\Delta\delta$ is the change in the δ_{33} value by −154 ppm. In view of the differences in δ_{33} between **9** and **6**, it is not surprising that the ^{119}Sn isotropic peaks of **9** are considerably more shielded (by about 50 ppm) than that of **6**. The asymmetry parameter is also considerably different for **9** compared to those of all sites in all 2,2-dibutyl-1,3,2-dioxastannolanes.

It was previously concluded from T_1 measurements in solution on compounds that were present as mixtures of oligomers, mainly trimers and tetramers, that $\Delta\delta$ values for hexacoordinate tin sites were approximately 1.5 times those from pentacoordinate sites (14). The $\Delta\delta$ values from ^{119}Sn NMR spectra of solids for hexacoordinate sites in polymers (compounds **6** and **7**) are about the same as those for pentacoordinate sites (compounds **1**, **2**, and **5**). Only one compound (**3**) is present in the solid in an oligomeric form that contains both hexacoordinate and pentacoordinate sites, a pentamer. For compound **3**, the ratios $\Delta\delta_{hexacoordinate}/\Delta\delta_{pentacoordinate}$ were 1.29 and 1.38 for the two hexacoordinate sites. Thus, the previous conclusion appears to apply to hexacoordinate sites in trimers and, perhaps, tetramers only. As the state of oligomerization increases, both the isotropic chemical shifts and the $\Delta\delta$ values for hexacoordinate sites decrease in absolute magnitude and, for the latter, the limiting value for the polymer appears to be of about the same size as those for pentacoordinate sites. Too few X-ray studies are available as yet to identify the factors causing these changes.

C. Do the antisymmetric terms of the shielding tensor contribute to the chemical shift anisotropy of tin in 1,3,2-dioxastannolanes?

Our results for the three compounds for which both solution (14) and solid-state data are available are summarized in Table 4. The similarity in the $\Delta\delta$ values derived from solution T_1 results and measured directly from the solid-state NMR powder spectra imply that the antisymmetric terms do not make a significant contribution to the rate of spin-lattice relaxation (eq. [3]). One could, of course, argue that there is no reason why the shielding tensors in solution and in the solid state should be identical. However, on the basis of the similar isotropic chemical shifts measured in solution and in the solid state, it is reasonable to assume similar values for the principal components in the two different phases. Also, given the extreme sensitivity of ^{119}Sn chemical shifts to subtle changes in molecular structure, this assumption is probably valid.

Conclusions

The ^{119}Sn isotropic chemical shifts of 1,3,2-dioxastannolanes from solid-state spectra and solution spectra are identical (±10 ppm) provided that the same oligomeric species is present in both media. Similarly, chemical shift anisotropies from solution T_1 measurements (14) are identical within experimental error to those from sites of the same species in the static solid-state spectra. This observation supports the previous conclusion (14) that the antisymmetric terms in the ^{119}Sn chemical shift tensor have negligible effects on spin-lattice relaxation rates in these compounds.

The marked and distinctive differences in isotropic chemical shifts of pentacoordinate and hexacoordinate tin sites are not mirrored by distinctive differences in the chemical shift anisotropies. It appears that other factors, such as bond angle variation, type of substituents, and local symmetry, have effects that are of a similar magnitude to that of coordination state on the chemical shift anisotropies and the latter factor is no longer dominant. One trend that is reflected in both the isotropic chemical shifts and the chemical shift anisotropies occurs for hexacoordinate tin sites for compounds for which data can be obtained for trimers, tetramers, pentamers, and polymers; as oligomerization proceeds to higher oligomers, the isotropic chemical shift is deshielded and the chemical shift anisotropy decreases. These changes probably are caused by subtle differences in geometry about the tin atoms.

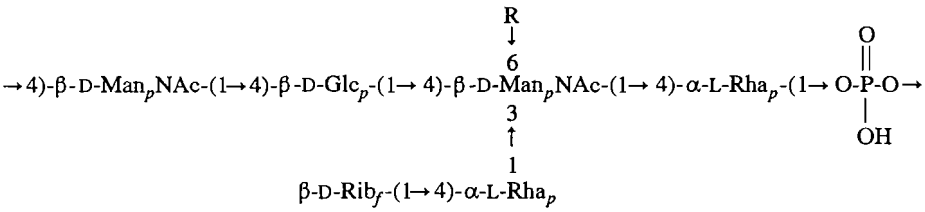
Received April 23, 1991

LINDA M. BEYNON, JAMES C. RICHARDS, MALCOLM B. PERRY, and PETER J. KNISKERN. Can. J. Chem. **70**, 218 (1992).

The specific capsular polysaccharides of *Streptococcus pneumoniae* types 19B and 19C (American types 58 and 59) were investigated by a combination of ^{1}H, ^{13}C, and ^{31}P nuclear magnetic resonance spectroscopy and analytical methods based on mass spectrometry. The two polysaccharides were found to be high molecular weight polymers composed of L-rhamnose, 2-amino-2-deoxy-D-mannose, D-ribose, D-glucose, and phosphate. Homo- and heteronuclear chemical shift correlation techniques and nuclear Overhauser enhancement experiments led to the unambiguous assignment of the ^{1}H and ^{13}C resonances from the glycose residues and established their sequence within repeating oligosaccharide units. The oligosaccharide units are polymerized through phosphate diester linkages.



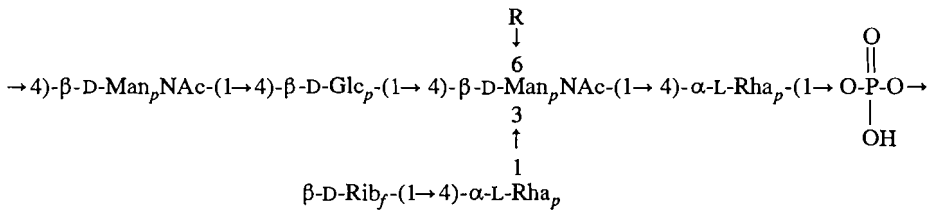
19B polysaccharide R = H
19C polysaccharide R = β-D-Glc$_p$-(1→

Both polysaccharides share a common hexasaccharide structural unit and they differ only in the degree of substitution at the branched 2-acetamido-2-deoxy-β-D-mannopyranosyl residue: the 19C polysaccharide is O-6 linked by β-D-glucopyranosyl end groups to form a heptasaccharide repeating unit, while the 19B polysaccharide is unsubstituted at that position. The serologic cross-reactivity between *S. pneumoniae* serotypes 19B and 19C can now be related to the structural similarity of the antigenic capsular polysaccharides.

Key words: *Streptococcus pneumoniae*, capsular polysaccharide, immuno chemistry.

LINDA M. BEYNON, JAMES C. RICHARDS, MALCOLM B. PERRY et PETER J. KNISKERN. Can. J. Chem. **70**, 218 (1992).

Faisant appel à une combinaison de spectroscopie en résonance magnétique nucléaire du ^{1}H, du ^{13}C et du ^{31}P et de méthodes analytiques basées sur la spectrométrie de masse, on a étudié les polysaccharides capsulaires spécifiques du *Streptococcus pneumoniae* des types 19B et 19C (types américains 58 et 59). On a trouvé que les deux polysaccharides sont des polymères de poids moléculaires élevés, composés de L-rhamnose, de 2-amino-2-désoxy-D-mannone, de D-ribose, de D-glucose et de phosphate. Les techniques de corrélations de déplacements chimiques homo- et hétéronucléaires et d'expériences d'effet Overhauser nucléaire ont permis de faire une attribution non-ambigüe des résonances ^{1}H et ^{13}C des résidus de sucre et d'établir leur séquence dans les unités d'oligosaccharides qui se répètent. Les unités d'oligosaccharides sont polymérisées par des liaisons diesters de l'acide phosphorique.



polysaccharide 19B R = H
polysaccharide 19C R = β-D-Glc$_p$-(1→

Les deux polysaccharides se partagent une unité structurale hexasaccharidique et ils ne diffèrent que par le degré de substitution au niveau de la ramification du résidu 2-acétamido-2-désoxy-β-D-mannopyranosyle : le polysaccharide 19C est lié par l'oxygène 6 aux groupes terminaux β-D-glucopyransoyle pour former une unité heptasaccharidique qui se répète

alors que le polysaccharide 19B n'est pas substitué dans cette position. On peut maintenant établir une corrélation entre l'activité sérologique croisée des *S. pneumoniae* des sérotypes 19B et 19C et la similarité structurelle des polysaccharides capsulaires antigéniques.

Mots clés : *Streptococcus pneumoniae*, polysaccharide capsulaire, immunochimie.

[Traduit par la rédaction]

Introduction

Streptococcus pneumoniae are gram-positive bacteria that are associated with lower respiratory tract infections in adults and otitis media (middle ear infections) in children (1). In addition to a common group antigen (C-substance) (2), 85 type-specific capsular pneumococcal polysaccharide antigens are recognized that show serologic reactivity (3). The Danish serotyping system (4) places the cross-reactive types within groups designated by a number and a capital letter. The origin of serological cross-reactivity can be related to structural homologies among the pneumococcal polysaccharides within a group (3).

Group 19 *S. pneumoniae* is composed of four cross-reacting serotypes; 19A, 19F, 19B, and 19C. The chemical structures of the 19A and 19F specific capsular polysaccharides have been reported by Jennings and co-workers (5,6) and Ohno *et al.* (7). These polymers are composed of similar trisaccharide units,

$\rightarrow$4)-β-D-Man$_p$NAc-(1$\rightarrow$4)-α-D-Glc$_p$-(1$\rightarrow$3/2)-α-L-Rha$_p$-(1$\rightarrow$

polymerized through phosphate diester groups, and only differ in the position of the linkage to the α-L-Rha$_p$ residue. Both the 19A and 19F polysaccharides are included in the 23-valent pneumococcal vaccine currently in use in North America. To establish the molecular basis for the immunobiological activities and serological cross-reactivities among the group 19 pneumococci, we now report the results of the structural analysis of the serotypes 19B and 19C capsular polysaccharides.

Results

Type-specific capsular polysaccharide was obtained from the spent growth medium of *S. pneumoniae* serotype 19B and serotype 19C (8). The two polysaccharides eluted as the void volume fractions on a Sephadex G-50 gel filtration system, indicating each to be a high molecular weight polymer. These materials were further purified by DEAE–Sephacel ion exchange chromatography where the respective polysaccharides eluted as discrete homogeneous fractions in a sodium chloride salt gradient. The 19B and 19C polysaccharides so obtained had $[\alpha]_D$ −54.1 (*c* 1.7, water) and $[\alpha]$ −37.1 (*c* 1.4, water), respectively, and were homogeneous for neutral glycoses, aminodeoxy glycoses, and phosphate. Anal. found for 19B: C 37.7, H 5.4, N 3.1, and ash 15.5%, and for 19C: C 37.3, H 5.6, N 2.7, and ash 11.5%. The phosphate content of the 19B and 19C polymers was determined colorimetrically (9) to be 7.7 and 6.6% (PO_4), respectively.

Complete acid hydrolysis of 19B and 19C polysaccharides and GLC–MS of the derived alditol acetates showed both samples to contain L-Rha, D-Glc, D-ManN, and D-Rib. The relative increase in the amount of glucose released from the 19C polysaccharide after hydrolysis (Glc:Rha, 1.0:1.0), in comparison with that released from the 19B polysaccharide (Glc:Rha, 0.5:1.0), suggested that this polysaccharide contained an additional glucose residue. The absolute configurations of the residues were established by GLC of the

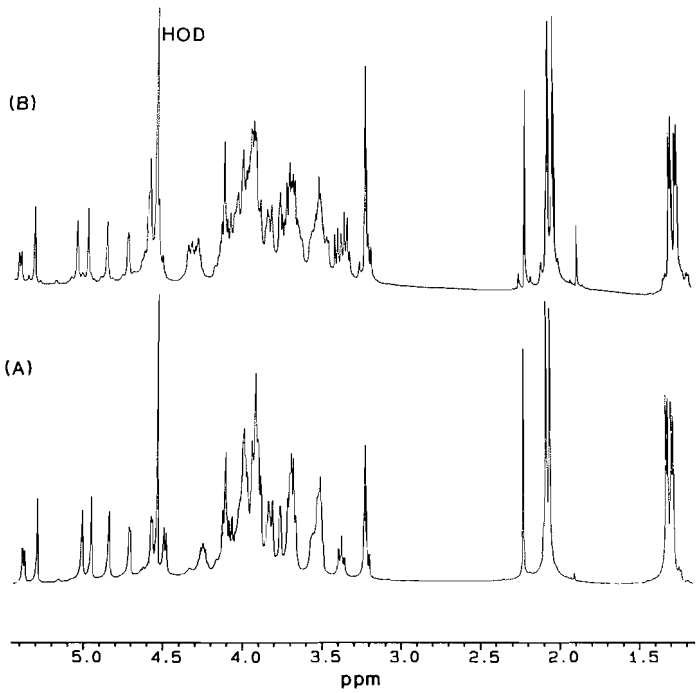

FIG. 1. Proton NMR spectra of the *S. pneumoniae* capsular polysaccharides recorded at 320 K; (A) serotype 19B, (B) serotype 19C.

corresponding (*R*)-2-octyl glycosides (10) and the identity of the D-ManN residues was confirmed by analysis of the nitrous acid-deaminated, reduced ($NaBH_4$), and acetylated products of hydrolysis (11).

The ^{1}H NMR spectra of the 19B and 19C polysaccharides were very similar (Fig. 1). Both spectra contained high-field doublets (J ~6 Hz) at 1.32 and 1.28 ppm for the methyl groups of two 6-deoxyhexoses and a pair of singlets of equal signal area at 2.10 and 2.07 ppm, which could be attributed to the methyl groups of two *N*-acetyl substituents. These findings, in conjunction with the analytical data, would suggest that the two polymers contain L-Rha and D-ManNAc in equal molar amounts. In the ^{13}C NMR spectra (Fig. 2), characteristic resonances at 18.2 and 17.9 ppm were indicative of the C-6 from two 6-deoxyhexoses, while the signals at 54.1 and 50.8 ppm were diagnostic of the C-2 from the 2-acetamido-2-deoxyhexopyranose residues. Resonances at 176.3, 176.0 ppm (C=O) and 23.6 and 22.9 ppm (CH_3) could be attributed to the two acetamido functions. A minor resonance at 55.2 ppm, together with the corresponding ^{1}H resonance at 3.22 ppm, could be attributed to the choline methyl groups from the pneumococcal group antigen, C-substance (2), which is often found as a contaminant of the specific capsular polysaccharide preparations. These resonances were absent from the spectra of the polysaccharides purified by ion exchange chromatography on DEAE–Sephacel.

The ^{13}C NMR spectrum of the 19B polysaccharide (Fig. 2A) exhibited six discrete anomeric carbon resonances at

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

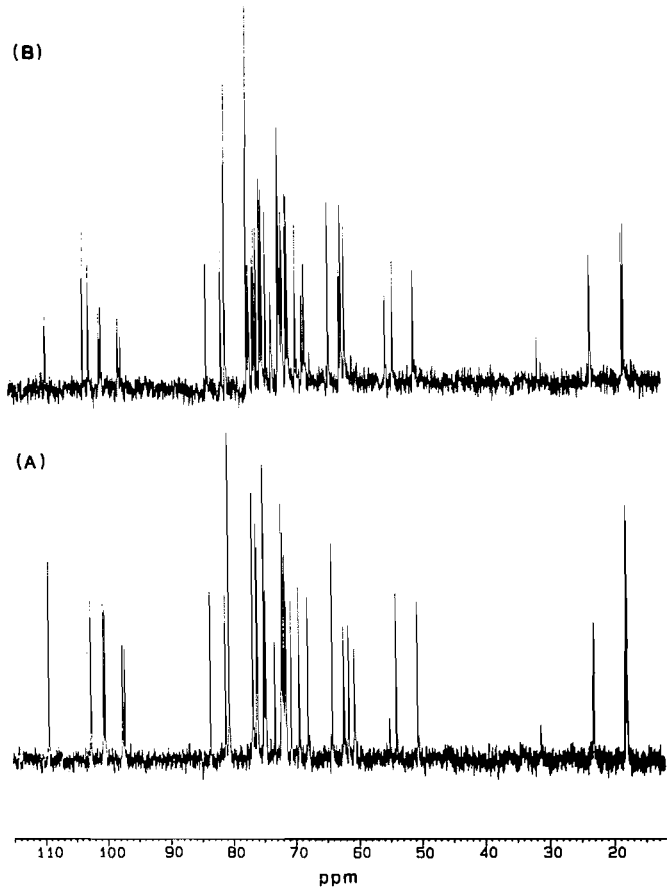

FIG 2. Partial ^{13}C NMR spectra of the *S. pneumoniae* capsular polysaccharides recorded at 310 K; (A) serotype 19B, (B) serotype 19C.

109.4, 102.5, 100.8, 100.5, 97.7, and 97.3 ppm, indicating the polymer to be composed of regular hexasaccharide repeating units. An additional resonance for an anomeric carbon was observed at 103.4 ppm in the ^{13}C NMR spectrum of the 19C polysaccharide (Fig. 2B) suggesting it to be composed of heptasaccharide units. The presence of an anomeric signal at 109.4 ppm in both spectra indicates that the polymers each contain residues having the β-furanosidic ring form (12).

Methylation analysis of the 19B and 19C polysaccharides gave the results recorded in Table 1. The data were consistent with the two polysaccharides being composed of branched repeating oligosaccharide units containing terminal D-Rib$_f$, 4-linked L-Rha$_p$, and 4-linked D-Glc$_p$ residues. The occurrence of the 6-*O*-methyl derivative of *N*-methyl-D-Man$_p$N in the acid hydrolysis products of the 19B polysaccharide indicated that one of the amino sugars was present as a di-*O*-substituted branch point linked through O-3 and O-4 (Table 1, column I). Although the corresponding partially methylated derivative was not detectable in the acid hydrolysate of the 19C polysaccharide, (Table 1, column VI), the presence of 2,3,4,6-tetra-*O*-methyl-D-glucose in addition to the 2,3,5-tri-*O*-methyl-D-ribose suggested that the repeating unit of this polymer contained two branch points. Aqueous hydrofluoric acid treatment of the 19C polysaccharide followed by methylation of the dephosphorylated product and hydrolysis gave approximately equal amounts of *N*-methyl-D-Man$_p$N and *N*-methyl-3,4,6-tri-*O*-methyl-D-ManN$_p$ (Table 1, column VII), indicating the presence of a tri-*O*-substituted 2-acetamido-2-deoxy-sugar residue in the repeating unit. The highly branched nature of the ManNAc residues may account for the low yield or absence of the corresponding derivatives obtained from the methylation analysis procedure.

The structures of the 19B and 19C polysaccharides were determined from an analysis of the fully assigned ^1H and ^{13}C NMR spectra by employing a combination of homo- and heteronuclear chemical shift correlation techniques and nuclear Overhauser enhancement experiments.

Examination of the *J*-connectivities observed in the 2D homonuclear chemical shift correlation (COSY) and relayed coherence transfer (relayed COSY) spectra led to the identification of the coupled spin networks that were representative of the individual glycose residues in the respective oligosaccharide repeating units. The ^1H chemical shift data and ^1H–^1H coupling constants, determined from the appropriate cross-peaks in these spectra, are recorded in Table 2. Assignments of the ^{13}C resonances were then made by direct correlation with the assigned ^1H resonances by heteronuclear ^{13}C–^1H chemical shift correlation (via $^1J_{C,H}$) and by comparison with ^{13}C data from the literature (13) (Table 3).

The COSY spectrum of the ring proton region of the 19C polysaccharide is shown in Fig. 3. In the low-field region of this spectrum (5.4–4.5 ppm), seven resonances for anomeric protons were readily identified from their single vicinal proton couplings. These resonances provided the starting point for spectral analysis and were labelled H-1**a** to H-1**g** according to their decreasing chemical shift values. Delineation of the connectivity pathways defined by the cross-peaks led to the identification of the subspectra associated with each of the component monosaccharide residues (**a**–**g**).

Subspectra corresponding to four of the component monosaccharide residues (**a**, **c**, **d**, and **e**) could readily be attributed to pyranosyl units having the *manno* configuration from the observed small magnitude (≤3 Hz) of the vicinal couplings $J_{1,2}$ and $J_{2,3}$ (14). Residues **a** and **d** were identified as the L-Rha$_p$ residues since the two high-field methyl doublets at 1.32 ($J_{5,6}$ 5.7 Hz) and 1.29 ppm ($J_{5,6}$ 5.6 Hz) could be mapped into the respective connectivity pathways via cross-peaks to H-5**a** (3.91 ppm) and H-5**d** (4.29 ppm) in the full-scale COSY, and to H-4**a** (3.70 ppm) and H-4**d** (3.51 ppm) in the relayed COSY. The resonances for H-2 of residues **c** and **e** occurred at relatively low field (4.5–4.7 ppm). Direct correlation of these resonances to the corresponding ^{13}C resonances for C-2 at 50.8 and 54.1 ppm, respectively, permitted the two residues to be identified as the D-Man$_p$NAc indicated by chemical analysis. The resonance for H-4**e** (4.07 ppm) showed additional heteronuclear coupling (*J* 9.8 Hz), which was apparent from the COSY cross-peak 3,4**e** indicating C-4 as the site of phosphate substitution. Phosphorus-31 coupling to the corresponding ^{13}C resonance, C-4**e** ($^2J_{C,P}$ 5.6 Hz), and the adjacent carbon, C-3**e** ($^3J_{C,P}$ 6.7 Hz), is consistent with phosphate substitution at C-4 of the D-Man$_p$NAc residue. The presence of phosphate at the O-4 position of one of the D-Man$_p$NAc residues may account for the low amount of the ManNAc derivatives detected by glycose and methylation analysis due to incomplete cleavage of the phosphate esters under the hydrolysis conditions employed. It is noteworthy that the COSY cross-peaks relating H-4 and H-5 of this D-

[a]Observed first-order chemical shifts and coupling constants (±0.5 Hz).
[b]Data are for the native 19C polysaccharide in D_2O at 310 K. Chemical shift values in square brackets are for proton resonances shifted (>±0.01 ppm) in the spectrum of the 19B polysaccharide.
[c]$^3J_{H,P}$ value (Hz).
[d]H-5′ value; $J_{4,5'}$ = 7.2 Hz, $J_{5,5'}$ = 12.0 Hz.
[e]The β-D-Man$_p$NAc residues **c** are not substituted by β-D-Glc$_p$ end groups **g** at the O-6 position in the 19B polysaccharide.

Man$_p$NAc residue (4,5**e**) were of relatively low intensity (Fig. 3). A proton NOE experiment provided unambiguous assignment of the H-5**e** resonance.

Due to the axial disposition of the hydroxyl group at C-2 of the *manno*pyranosyl residues, the anomeric configurations were not evident from the $J_{1,2}$ values (≤3 Hz) (14). However, the configurations could be determined from the corresponding one-bond ^{13}C–^1H coupling constants (15). Values for $^1J_{C,H}$ of ca. 173 Hz indicated the α-configuration for the two L-Rha$_p$ residues (**a** and **d**), while $^1J_{C,H}$ values of 162–165 Hz were consistent with the β-configuration for the two D-Man$_p$NAc residues (**c** and **e**). The latter assignments were confirmed by intraresidue ^1H–^1H NOE experiments.

A ^1H–^{13}C connectivity between the H-1**b** resonance (5.29 ppm) and the anomeric carbon at lowest field (109.4 ppm) identified residue **b** as a β-furanoside moiety. The ^1H subspectrum corresponding to residue **b** comprised six ^1H resonances, for which the chemical shifts and ^3J-values (Table 2) were consistent with the residue being a β-D-Rib$_f$ (16). In addition, the residue **b** ^{13}C chemical shifts (Table

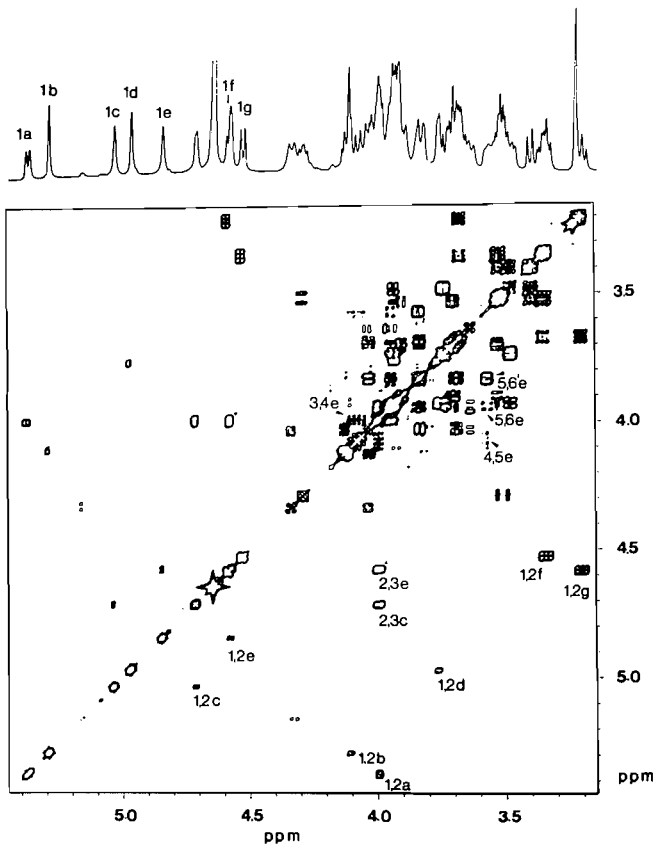

FIG. 3. The COSY contour plot of the ring proton region (5.45–3.15 ppm) of the *S. pneumoniae* serotype 19C capsular polysaccharide recorded at 310 K. Cross-peaks in the low-field region of the spectrum and from the residue **c** spin system are indicated.

3) were similar to those reported (17) for methyl β-D-ribofuranoside, indicating the residue to be present as a nonreducing end group.

Residues **f** and **g** each gave spin-systems comprising seven ^1H resonances. Based on the chemical shift data and the observed large values (8–10 Hz) for the ring proton coupling constants (Table 2), both residues could be identified as β-D-glucopyranose units (18).

The ^{13}C-decoupled ^1H-detected heteronuclear multiple quantum coherence spectrum (Fig. 4) of the 19C polysaccharide shows well-resolved cross-peaks for most of the $^{13}C-^1H$ single bond connectivities. Cross-peaks relating resonances at the 5-position of the β-pyranosyl residues **e**, **f**, and **g**, as well as the H-3**g**/C-3**g** contour, showed considerable overlapping, but a distinction between these residues could be made by comparison with data from the 19B polysaccharide in which the latter residue (**g**) is absent. The ^1H and ^{13}C NMR spectra of the 19B polysaccharide (Figs. 1B and 2B) were assigned similarly using COSY, relayed COSY, and $^{13}C-^1H$ correlation (CHORTLE) techniques (Tables 2 and 3).

For the 19C polysaccharide, the methylene carbon resonance at 68.4 ppm (identified by a DEPT experiment) was mapped into the residue **c** ^1H spin-system from connectivities to the proton resonances at 4.33 (H-6**c**) and 4.04 (H-6'**c**) ppm (Fig. 4), the downfield position of C-6**c** being indicative (19) of substitution at the corresponding position. This resonance is significantly upfield shifted in the spectrum of the 19B polysaccharide. The relatively deshielded values for C-3 (75.1 ppm) and C-4 (ca. 72.0 ppm) of this residue in the spectra of both the 19C and the 19B polysaccharides (Table 3) indicate **c** to be the branching D-Man_pNAc residue identified by methylation analysis. Indeed, from a comparison of the chemical shift data (Tables 2 and 3), it would appear that the only difference between the two serologically re-

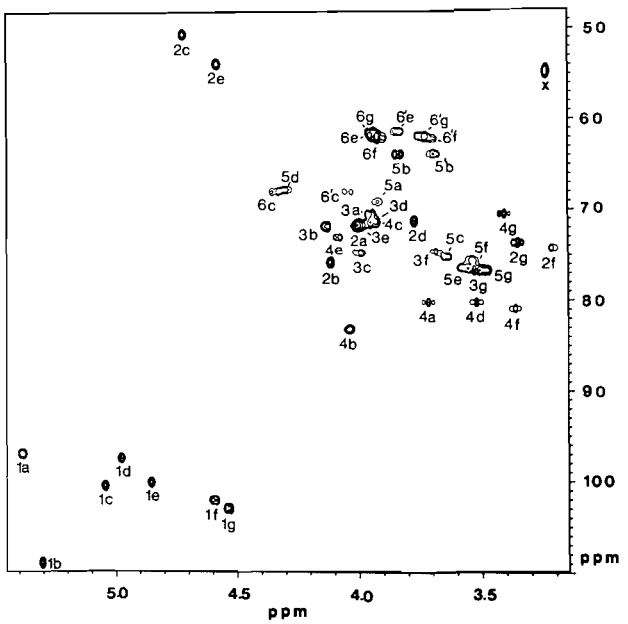

FIG. 4. The ^{13}C-decoupled ^{1}H-detected heteronuclear multiple quantum coherence spectrum of the ring proton region (5.45–3.15 ppm) of the *S. pneumoniae* serotype 19C capsular polysaccharide recorded at 310 K. The contour indicated by "X" is due to the choline methyl resonances from the pneumococcal C-substance.

TABLE 4. Proton NOE data for the *S. pneumoniae* types 19B and 19C polysaccharides[a]

Anomeric proton	Observed proton: Intraresidue NOE	Observed proton: Transglycosidic NOE	Partial sequence
1a	**2a**	—[b]	
1b	—[b]	**4d**	**b→d**
1c	**2c**, **3c**, **5c**	**4a**	**c→a**
1d	**2d**	**2c**, **3c**	**d→c**
1e	**2e**, **3e**, **5e**	**4f**	**e→f**
1f	**3f**, **5f**	**4c**	**f→c**
1g	**3g**, **5g**	**6′c**, **6c**[c]	**g→c**

[a]Measured from 2D NOESY spectra of the native polysaccharides at 310 K in D_2O.
[b]No detectable NOE.
[c]NOE of low intensity.

lated polysaccharides is the presence or absence of the β-D-Glc_p end groups **g** at the O-6 position of the β-D-Man_pNAc residues **c**.

The resonance for H-1**a** ($J_{1,2}$ ~1 Hz)) showed additional splitting (~7 Hz), which could be attributed to phosphorus-31 coupling, indicating that this α-L-Rha_p residue (residue **a**) is glycosidically linked to phosphate. This linkage was confirmed by $^{31}P-^{1}H$ chemical shift correlation, which established a connectivity (via $^{3}J_{H,P}$) between the phosphorus (δ_P −2.1 ppm) and proton (δ_H 5.37 ppm) resonances. In addition, the occurrence of a connectivity between the ^{31}P nucleus and H-4**e** (4.07 ppm) unequivocally established the position of the phosphate diester between residues **a** and **e**:

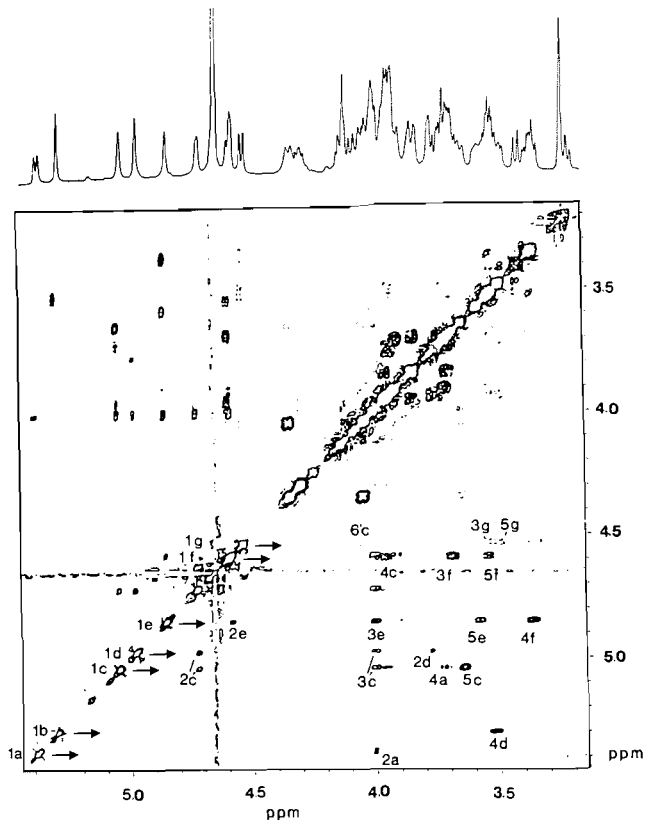

FIG. 5. Contour plot of the ^{1}H spectral region (5.45–3.15 ppm) of the NOESY spectrum for the *S. pneumoniae* serotype 19C capsular polysaccharide recorded at 310 K. Cross-peaks arising from NOE involving the anomeric protons are indicated.

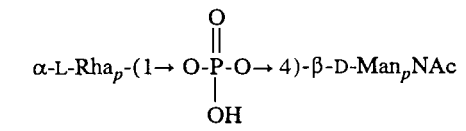

The sequences of the glycoses within the repeating units of the 19B and 19C polysaccharides were determined from NOE measurements that served to establish connectivities between the anomeric and aglyconic protons on adjacent glycosyl residues (Table 4). Two-dimensional experiments (NOESY) were employed and a contour plot of the spectrum obtained on the 19C polysaccharide is shown in Fig. 5.

Nuclear Overhauser effects relating the anomeric proton resonances with other protons within the same ring system provided confirmation of the configurations at the anomeric centres of the glycopyranosyl residues. The occurrence of intraresidue NOE between H-1 and H-3 and between H-1 and H-5 was diagnostic of the β-linked D-Man_pNAc (**c** and **e**) and D-Glc_p (**f** and **g**) residues, while intraresidue effects were observed between only H-1 and H-2 of the L-Rha_p residues (**a** and **d**) indicating the assigned α-configurations.

Transglycosidic NOE were observed between H-1**e**/H-4**f**, H-1**f**/H-4**c**, and H-1**c**/H-4**a**, which established the linear partial sequence, **e→f→c→a**. The anomeric proton reso-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

nance of the α-L-Rha$_p$ residue **a** showed a strong NOE within the pyranosyl ring system to H-2**a** but none to adjacent glycosyl residues. The lack of any interresidue NOE is in accordance with the residue **a** being glycosidically linked to the phosphate moiety. It follows that the main chain of the polymer is composed of the repeating tetrasaccharide unit,

$$\rightarrow 4)\text{-}\beta\text{-D-Man}_p\text{NAc-}(1\rightarrow 4)\text{-}\beta\text{-D-Glc}_p\text{-}(1\rightarrow 4)\text{-}\beta\text{-D-Man}_p\text{NAc-}(1\rightarrow 4)\text{-}\alpha\text{-L-Rha}_p\text{-}(1\rightarrow$$
$$\quad\ \mathbf{e}\qquad\qquad\ \mathbf{f}\qquad\qquad\ \mathbf{c}\qquad\qquad\ \mathbf{a}$$

in which the β-D-Man$_p$NAc **c** provides the point for further substitution.

The occurrence of a transglycosidic NOE between H-1**b** and H-4**d** identifies the disaccharide side chain, **b**→**d**, which is in turn 1,3-linked to the branching β-D-Man$_p$NAc residue **c**, as evidenced from interresidue effects between H-1**d** and H-3**c**/H-2**c**. These effects were observed in the NOESY spectra of both the 19C and the 19B polysaccharides (Table 4), and thereby established the arrangement of the residues within the hexasaccharide unit of the 19B polymer (Fig. 6).

A transglycosidic connectivity between H-1**g** and the methylene proton pair (H-6**c** and H-6′**c**) in the NOESY of the 19C polysaccharide allows the terminal β-D-Glc$_p$ end group **g** to be positioned at O-6 of the trisubstituted β-D-Man$_p$NAc residue in the heptasaccharide unit. This is in accord with the conclusions arrived at from consideration of the ^{13}C chemical shift data. The accumulated evidence therefore establishes that the 19C *S. pneumoniae* capsular polysaccharide is composed of the heptasaccharide units,

$$\begin{array}{l}\qquad\qquad\qquad\qquad\qquad\qquad\beta\text{-D-Glc}_p\\ \qquad\qquad\qquad\qquad\qquad\qquad\ \ 1\\ \qquad\qquad\qquad\qquad\qquad\qquad\ \ \downarrow\\ \qquad\qquad\qquad\qquad\qquad\qquad\ \ 6\\ \rightarrow 4)\text{-}\beta\text{-D-Man}_p\text{NAc-}(1\rightarrow 4)\text{-}\beta\text{-D-Glc}_p\text{-}(1\rightarrow 4)\text{-}\beta\text{-D-Man}_p\text{NAc-}(1\rightarrow 4)\text{-}\alpha\text{-L-Rha}_p\text{-}(1\rightarrow\\ \qquad\qquad\qquad\qquad\qquad\qquad\ \ 3\\ \qquad\qquad\qquad\qquad\qquad\qquad\ \ \uparrow\\ \qquad\qquad\qquad\qquad\qquad\qquad\ \ 1\\ \qquad\qquad\qquad\qquad\qquad\qquad\beta\text{-D-Rib}_f\text{-}(1\rightarrow 4)\text{-}\alpha\text{-L-Rha}_p\end{array}$$

polymerized through phosphate diester groups. The repeating unit of the 19B polysaccharide has the same structure but lacks the β-D-Glc$_p$ end groups.

The positions of the glycosyl linkages and the sequence of the residues within the repeating units were confirmed by NMR and MS-based analyses of the oligosaccharide fragments obtained by partial acid hydrolysis of the 19B and 19C polysaccharides (Scheme 1).

Depolymerization of the 19B polysaccharide with 48% aqueous hydrofluoric acid, followed by fractionation of the products on Bio-gel P2, afforded two major phosphate-free products: a tetrasaccharide **1** (K_{av} 0.55,) and a pentasaccharide **2** (K_{av} 0.48).

The low-field region of the ^{1}H NMR spectrum of reduced **1** contained two singlets at 4.92 and 4.87 ppm for the anomeric protons of two β-D-Man$_p$NAc residues, two doublets (J ~4.6 Hz) at 4.62 and 4.55 ppm for their corresponding H-2 resonances, and a doublet ($J_{1,2}$ 8.4 Hz) at 4.52 ppm for

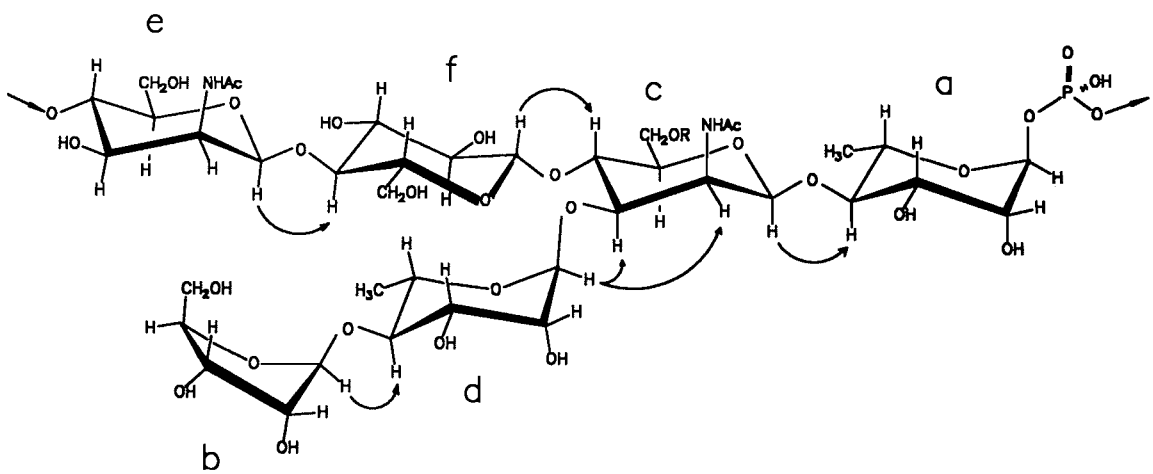

FIG. 6. Structure of the hexasaccharide repeating unit of *S. pneumoniae* serotype 19B capsular polysaccharide (R = H) showing through space connectivities identified by ^{1}H–^{1}H NOE analysis. For the heptasaccharide unit of the serotype 19C polysaccharide R = β-D-Glc$_p$.

SCHEME 1. Oligosaccharides obtained from the capsular polysaccharides of *S. pneumoniae* types 19B and 19C.

the anomeric proton of a β-D-Glc$_p$ residue (Table 5). Other characteristic signals were observed at 2.06 (s, 3H) and 2.08 (s, 3H) ppm and at 1.26 (d, 3H, $J_{5,6}$ 7.5 Hz) ppm for the methyl protons of two acetamido functions and a L-rhamnitol residue, respectively.

The ^{13}C NMR spectrum contained three signals in the anomeric region (Table 5), signals at 54.1 and 53.8 ppm for the C-2 resonances of the 2-amino-2-deoxyhexose residues, and one resonance at 19.2 ppm for the methyl carbon of a reduced rhamnose residue. A resonance at 63.7 ppm was assigned to C-1 of the reducing end residue of **1**.

The FAB mass spectrum of reduced, methylated **1** showed molecular ions at m/z 953 and 931, which correspond to $[M+Na]^+$ and $[M+H]^+$, respectively. The EI mass spectrum showed A-series fragment ions (20) at m/z 709, 464, and 260 produced by sequential cleavage of the glycosidic linkages from the reducing end of the tetrasaccharide, and a fragment ion at m/z 205 that was indicative of the terminal 6-deoxy-hexitol moiety (Fig. 7).

The downfield region of the ^{1}H NMR spectrum of reduced pentasaccharide **2** was similar to that of **1** (Table 5) except for the presence of an additional singlet at 4.96 ppm for the anomeric proton of an α-L-Rha$_p$ residue. Correspondingly, the ^{13}C NMR spectrum showed four signals in the anomeric carbon region (Table 5) and the presence of signals at 17.2 and 19.3 ppm indicated the presence of L-Rha$_p$ and reduced L-Rha residues, respectively.

The FAB mass spectrum of reduced, methylated **2** showed molecular ions at m/z 1105 $[M+H]^+$ and 1127 $[M+Na]^+$. Abundant fragment ions derived from the protonated molecular ion (m/z 1105) were observed at m/z 883, 677, and 196 in the collision-induced dissociation (CID) FAB mass spectrum obtained using linked scans at constant B/E (Fig. 8). The fragment ion at m/z 883 arises from a characteristic A-type cleavage (20), and subsequent loss of the terminal

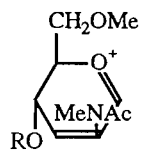
	4.54	1–2	H-2 of ManNAc	63.7	α-L-Rha-ol
	4.53	7.6	β-D-Glc		

[a]Measured in ppm from acetone as an internal standard (δ_H 2.225 ppm; δ_C 31.07 ppm)
[b]For example, β-D-Glc refers to the anomeric proton of a β-D-glucopyranosyl residue unless otherwise specified.
[c]As for *b*, but for the anomeric ^{13}C nuclei.

L-Rha$_p$ residue results in the formation of a fragment ion at *m/z* 677 having the possible structure



R = β-D-Man$_p$NAc-(1→4)-β-D-Glc$_p$-(1→

In conjunction with the data from methylation analysis (Table 1) of the two oligosaccharides, the foregoing results establish that the pentasaccharide **2** is representative of the 19B oligosaccharide repeating unit minus the terminal β-D-Rib$_f$ residue, and that the oligosaccharide **1** depicts the linear tetrasaccharide backbone (Scheme 1).

Partial hydrolysis of the 19B polysaccharide using 0.05 M trifluoroacetic acid (100°C, 3 h) afforded as the major products analogues of oligosaccharide **1** and **2** that were lacking the terminal nonreducing β-D-Man$_p$NAc residue. Gel filtration on Bio-gel P2 gave the trisaccharide **3** (K_{av} 0.57) and the tetrasaccharide **4** (K_{av} 0.47).

Reduced **3** showed ^{1}H NMR resonances at 4.90 (s) and 4.60 (d, $J_{1,2}$ 1–2 Hz) ppm for H-1 and H-2, respectively, of a β-D-Man$_p$NAc residue, and at 4.51 (d, $J_{1,2}$ 8.4 Hz) ppm for H-1 of a β-D-Glc$_p$ residue (Table 5). A singlet at 2.10 (3H) ppm and a doublet (3H, $J_{5,6}$ 7.5 Hz) at 1.27 ppm were indicative of the presence of a single acetamido function and an L-Rha residue, respectively. The ^{13}C NMR data (Table 5) showed two signals in the anomeric region, at 103.5 and 100.5 ppm, indicating **3** to be a trisaccharide. Resonances at 53.7 and 19.2 ppm confirmed the presence of a single amino sugar and a reduced L-Rha residue, respectively.

GLC–EI-MS analysis of reduced, methylated **3** gave a single peak (R_T 13.0 min, program *D*) that showed characteristic fragment ions at *m/z* 187, 205, 219, and 265. Identification of the partially methylated alditol acetates derived after hydrolysis of the reduced, methylated **3** allowed the trisaccharide to be characterized as β-D-Glc$_p$-(1→4)-β-D-Man$_p$NAc-(1→4)-L-Rha.

Examination of the ^{1}H and ^{13}C NMR data from **4** (Table 5) indicated it to be a tetrasaccharide (Scheme 1). Thus, the ^{13}C NMR spectrum of the reduced tetrasaccharide showed three signals in the anomeric region at 102.9, 100.5, and 97.8 ppm, while a single resonance at 50.5 ppm and two resonances at 19.2 and 17.1 ppm indicated the presence of one amino sugar, one reduced L-Rha, and one L-Rha$_p$, respectively.

The FAB mass spectrum of reduced, methylated **4** showed a molecular ion at *m/z* 860 $[M+H]^+$ and EI analysis gave fragment ions at *m/z* 189, 205, 219, 654, and 624 (Fig. 9). That the tetrasaccharide was branched at the D-Man$_p$NAc residue was verified by methylation analysis (Table 1, column IV).

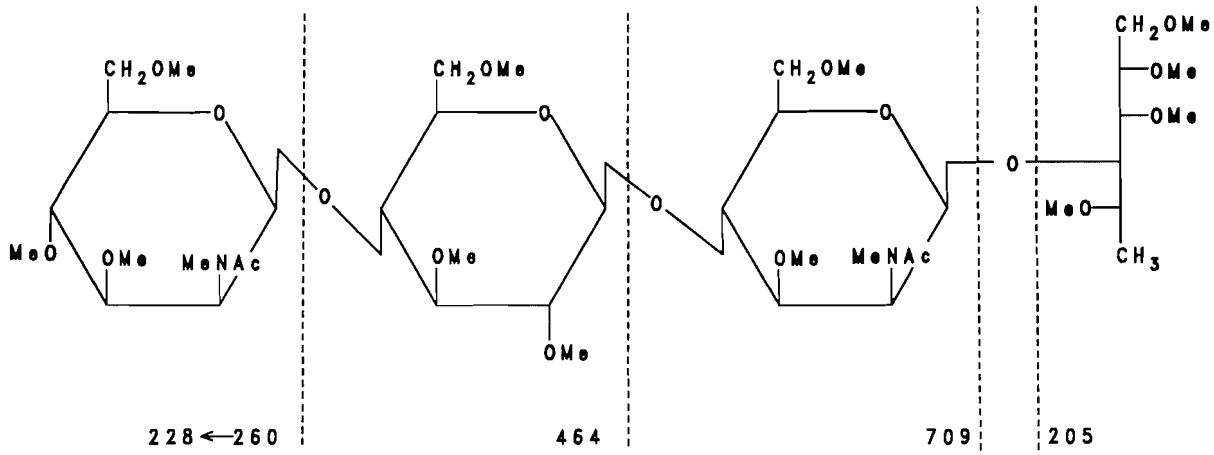

FIG. 7. EI-MS fragment ions of reduced, methylated oligosaccharide **1**.

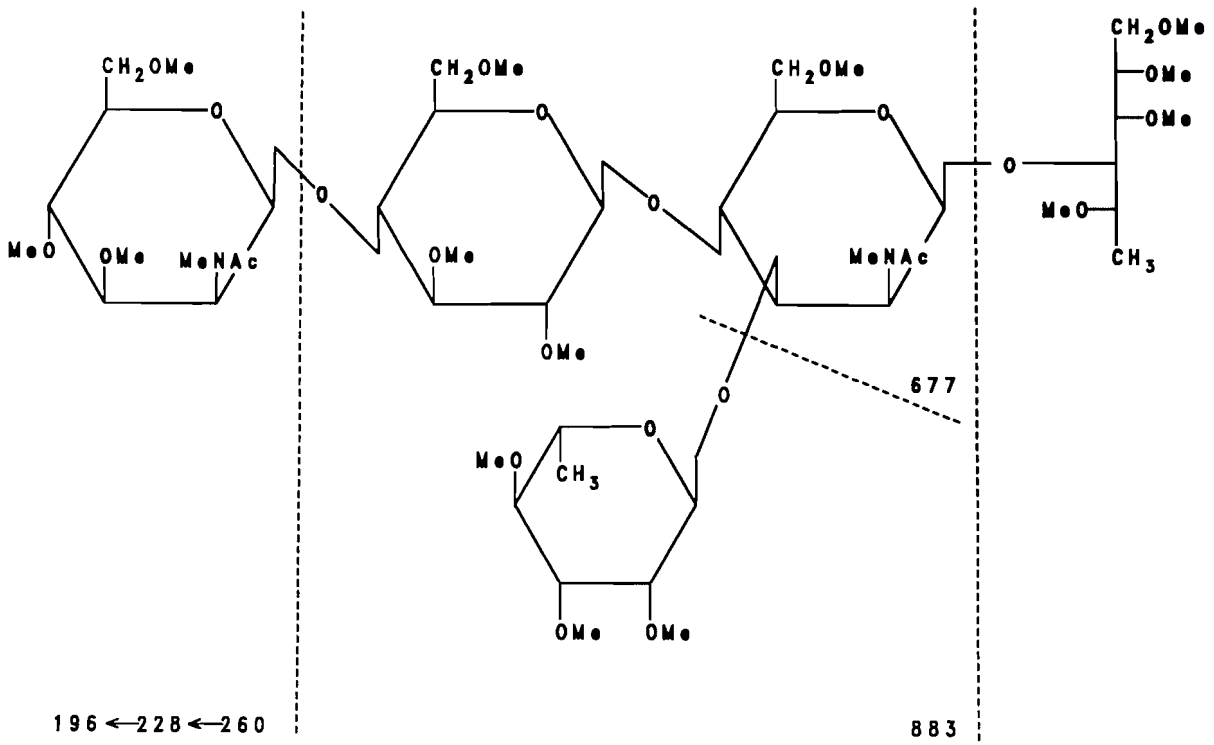

FIG. 8. FAB-MS fragment ions of reduced, methylated oligosaccharide **2**.

Depolymerization of 19C polysaccharide with 48% aqueous hydrofluoric acid, followed by fractionation of the products on Bio-gel P2, afforded a single major product, the phosphate-free hexasaccharide **5** (K_{av} 0.40).

The anomeric region of the ^{1}H NMR spectrum of reduced **5** showed two singlets (4.95 and 4.86 ppm) and two doublets (J ~1–2 Hz, 4.78 and 4.54 ppm) for the respective H-1 and H-2 resonances of two β-D-Man$_p$NAc residues, a singlet (4.92 ppm) from H-1 of an α-L-Rha$_p$ residue, and a pair of doublets ($J_{1,2}$ ~8 Hz, 4.56 and 4.53 ppm) from the H-1 resonances of two β-D-Glc$_p$ residues. The upfield region of the spectrum contained a singlet at 2.07 ppm (6H) and two doublets ($J_{5,6}$ 6.8 Hz) at 1.24 and 1.27 ppm from the methyl protons of two acetamido functions and two rhamnose residues, respectively.

The ^{13}C NMR spectrum of reduced **5** contained five signals in the anomeric region (Table 5), and several high-field resonances that confirmed the presence of the two 2-acetamido-2-deoxy sugars and L-Rha$_p$ residues.

The FAB mass spectrum of reduced, methylated **5** showed molecular ions at m/z 1347 $[M+K]^+$, 1331 $[M+Na]^+$, and 1309 $[M+H]^+$, and a major fragment ion at m/z 1087. The sequence of the glycoses was indicated from the FAB-MS by CID of the protonated molecular ion (m/z 1309) by linked scanning, and from the fragmentation pattern produced in the EI mass spectrum. In the EI mass spectrum characteristic A-

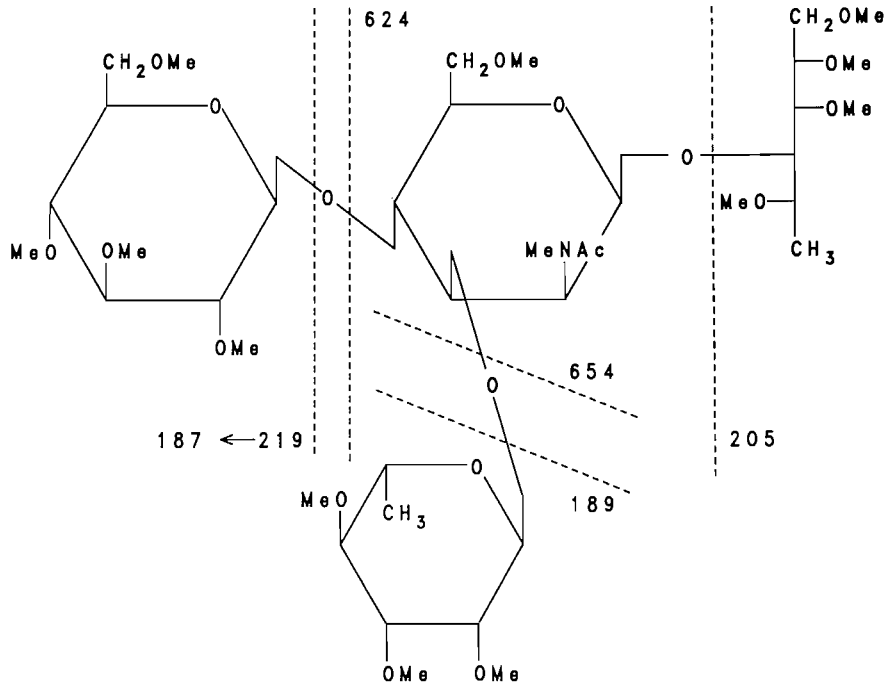

FIG. 9. EI-MS fragment ions of reduced, methylated oligosaccharide **4**.

type fragments at *m/e* 260, 219, 189, and 205 were indicative of ManNAc, Glc, and Rha nonreducing end groups and a terminal rhamnitol residue, respectively. A significant fragment ion at *m/z* 464 established the partial sequence ManNAc-O-Glc, while the ions at *m/z* 1087 and 828 in the CID-FAB-MS defined the position of the branching tri-*O*-substituted ManNAc residue (Fig. 10). Analysis by GLC–MS of hydrolysed, reduced, methylated **5**, after conversion of the partially methylated glycoses to their alditol acetates, identified the linkage positions (Table 1, column VII).

Treatment of the hexasaccharide **5** with trifluoracetic acid (0.5 M, 100°C, 1 h) and fractionation of the hydrolysis products on Bio-gel P2 afforded two oligosaccharides, **6** (K_{av} 0.34) and **7** (K_{av} 0.55).

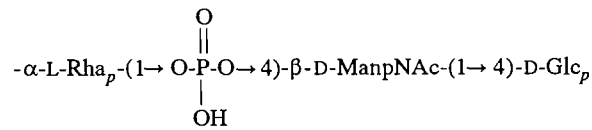
The CI mass spectrum of methylated, reduced ($NaBH_4$) **6** showed a $[M+NH_4]^+$ ion at *m/z* 907, a $[M+H]^+$ ion at *m/z* 890, and fragment ions at *m/z* 654, 205, 187, and 155 (Fig. 11), which were indicative of a branched tetrasaccharide. On the other hand, the CI mass spectrum of the methylated derivative of reduced **7** contained molecular ions at *m/z* 733 $[M+NH_4]^+$ and 716 $[M+H]^+$, indicating it to be a related trisaccharide that was lacking the reducing L-Rha residue. The GLC–EI mass spectrum (R_T 13.6 min, program *D*) of **7** had fragment ions at *m/z* 219, 187, 174, 155, and 130. Hydrolysis of reduced, methylated **7** and analysis by GLC–MS of the partially methylated glycoses as their alditol acetates gave the results shown in Table 1, column VIII.

Thus the above results identify **5** as a β-D-Glc_p-containing analogue of **1**, which corresponds to the oligosaccharide repeating unit of the 19C polysaccharide minus the β-D-Rib_f end group (Scheme 1).

Comparison of the methylation analysis data for the 19B and 19C polysaccharides with those of the derived oligosaccharides (Table 1) confirmed the positions of the glycosyl linkages and the location of the side chains in the native polysaccharides.

Discussion

The structures of the *S. pneumoniae* group 19 capsular antigens are shown in Table 6. A number of common features can be identified that may be responsible for cross-serological activity within the group: (1) the trisaccharide units of the types 19A and 19F have almost identical structures, differing only in the substitution site of the α-L-Rha_p residues; (2) the 19C and 19B polysaccharides share a common hexasaccharide unit. However, the only common structural feature shared by all the four types is the region about the phosphate diester bridge, i.e., the trisaccharide fragment



These structural aspects concur with serologically determined antigenic similarities.

Seven antigenic factors have been identified (21) within the group 19 of S. *pneumoniae* by the use of factor antisera (Table 6). The 19F and 19A pneumococcal types have two antigenic components in common (*19a* and *19d*). In addition, the type 19A expresses an antigenic determinant, *19c*, which, along with the *19a* determinant, is also a component of type 19B and 19C polysaccharides. The antigenic factor, *19b*, is unique to type 19F pneumococci and this factor may

TABLE 6. Structures[a] and antigenic formulae[b] of the group 19 *S. pneumoniae* specific capsular plolysaccharides

Serotype	Repeating unit	Antigenic factors
19F		*19a*, *19b*, *19d*
19A		*19a*, *19c*, *19d*
19B		*19a*, *19c*, *19e*, **7h**
19C		*19a*, *19c*, *19f*, *7h*

[a]Structures of the 19F and 19A polysaccharides are from refs. 5–7.
[b]Antigenic factors are from ref. 21.

reflect the difference between the linkage to the α-L-Rha_p residues in the type 19F and 19A specific polysaccharides. *Streptococcus pneumoniae* types 19B and 19C have three antigenic factors in common, *19a*, *19c*, and *7h*; the latter determinant, which most probably resides in the β-D-Rib_f-(1→4)-α-L-Rha_p-(1→ disaccharide side chains, is also a component of the pneumococcal type 7B and 7C polysaccharides. Expression of the antigenic determinants *19f* and *19e* can be correlated to the presence or absence of the β-D-Glc_p end groups in the type 19C and 19B polysaccharides, respectively.

Rabbit antisera to either the 19F or 19A polysaccharide (22) react strongly with the heterologous polysaccharide, but only poorly with the 19B and 19C polysaccharides. On the other hand, the 19B and 19C polysaccharides and their antisera cross-react extensively with each other (22). It is noteworthy in this context that results in humans indicated much less cross-reactivity between types 19F and 19A and, as a consequence, both polysaccharide antigens are included in a 23-valent vaccine.

Experimental

Streptococcus pneumoniae *type 19B and 19C polysaccharides*

Types 19B and 19C polysaccharides were obtained from the respective bacterial growth media after digestion with trypsin, ribonuclease, and deoxyribonuclease by fractional precipitation with 2-propanol with serological probing (8). The polysaccharides were each eluted as single discrete peaks in a 0→1 M NaCl gradient on DEAE–Sephacel.

Analytical methods

Ion exchange chromatography on DEAE–Sephacel was carried out as described previously (23). Quantitative colorimetric methods used were (*i*) phenol – sulphuric acid for neutral glycoses (24), (*ii*) the method of Chen *et al.* for phosphate (9), and (*iii*) the modified Elson–Morgan for aminoglycoses (25).

Analytical GLC–MS was done with a Hewlett–Packard 5885B system and an OV-17 fused silica column (Quadrex Corp.) using an ionization potential of 70 eV (EI) or with ammonia as reagent gas (CI). The following programs were employed: *A* (for alditol acetates), 180°C for 2 min then 4°C/min to 240°C; *B* (for partially methylated alditol acetates), 180°C for 2 min then 2°C/min to 240°C; *C* (for acetylated (*R*)-2-octyl glycoside derivatives), 180°C for 2 min then 6°C/min to 240°C; *D* (for methylated oligosaccharide alditols), 180°C for 2 min then 10°C/min to 350°C.

For analysis of constituent sugars, samples (1 mg) of polysaccharide were hydrolysed with 4 M trifluoroacetic acid for 1 h at 125°C, and the excess acid was removed by evaporation under a stream of nitrogen gas. Glycoses were determined by GLC–MS of their derived alditol acetates (26).

Methylation of samples (1–2 mg) was carried out using a modification of the method of Hakomori (27,28) and the products isolated by partition between dichloromethane and water. Methylated oligosaccharides were analysed directly by FAB- and (or) CI- and EI-MS. The methylated products were subsequently hydrolysed as above and, after conversion of the partially methylated glycoses to their alditol acetates, analysed by GLC–EI-MS.

FAB-MS analyses were carried out in the positive ion mode using a JEOL AX505H or a VG 70-VS (VG Analytical Ltd., Manchester U.K.) mass spectrometer. An accelerating voltage of 3 kV and a mass resolution of 1500 was employed with the JEOL

AX505H instrument. Samples were dissolved in methylene chloride and dried onto the stainless steel probe tip. *m*-Nitrobenzyl alcohol was applied to the probe tip prior to FAB analysis, and a Xe atom beam of 6 kV was used to sputter and ionize the sample. Spectra were calibrated with Ultramark 1621. CID FAB-MS/MS experiments on M+H ions were performed using helium as the collision gas. Linked scans at constant B/E were generated by a JEOL DA-50,000 data system.

TLC was performed on silica gel (Merck) with 6:3:1 (v/v) *n*-propanol–conc. NH_3–water.

NMR spectroscopy

All measurements were made on solutions in D_2O using a Bruker AM-500 or AMX-500 spectrometer.

Proton spectra recorded at 500 MHz were obtained using a spectral width of 2.6 kHz, a 16-K data block, and a 90° pulse. Chemical shifts are expressed relative to internal acetone (δ_H, 2.225 ppm).

Broad-band proton decoupled ^{13}C NMR spectra were obtained at 125 MHz using a spectral width of 25 kHz, a 32-K data block, and a 90° pulse employing WALTZ decoupling (29). Heteronuclear $^1J_{C,H}$ values were measured using gated decoupling and DEPT spectra (30) were obtained with broad-band decoupling, a 135° proton pulse, and a 3.3-ms delay between pulses. Chemical shifts are referenced to internal acetone (δ_C, 31.07 ppm).

Two-dimensional homonuclear COSY, relayed COSY, and NOESY experiments were carried out as previously described (31) for sweep widths of 2600 or 1250 Hz, and the data were processed to give either magnitude (32) or phase-sensitive (33, 34) spectra.

Heteronuclear ^{13}C–^1H chemical shift correlations were measured using the CHORTLE pulse sequence (35), or in the ^1H-detected mode via multiple quantum coherence ($^1H\{^{13}C\}$HMQC) with a Bruker 5-mm inverse broad-band probe using reverse electronics. The HMQC experiment employed the pulse sequence described by Bax *et al.* (36, 37), and ^{13}C decoupling during ^1H acquisition was achieved using the GARP-1 composite pulse sequence (38). A data matrix of ($t_1 \times t_2$) 256 × 1024 complex points was employed over the full ^{13}C and ^1H spectral regions and 32 scans were acquired for each t_1 value. A squared sine-bell window function shifted over 60° was applied in both dimensions and the data are presented in the absorption mode in f_1 (^{13}C) and the absolute value mode in f_2 (^1H).

Phosphorus-31 spectra were recorded at 202 MHz by employing a spectral width of 10 kHz, a 16-K data set, and a 90° pulse. Chemical shifts are referenced to that of an external sample of aqueous 25% phosphoric acid (δ_P, 0.0 ppm). Two-dimensional ^{31}P–^1H chemical shift correlations were made by ^1H-detected multiple quantum coherence ($^1H\{^{31}P\}$HMQC) (36) for a 64 × 1024 data matrix, 64 scans per t_1 value and a 60-ms delay.

Dephosphorylation of the polysaccharides 19B and 19C

The 19B polysaccharide (42 mg) was dissolved in 48% aqueous hydrofluoric acid (2 mL) and kept at 4°C for 24 h. The reaction was quenched by pouring the mixture into a slurry of solid CO_2–calcium carbonate–dichloromethane (39) and the precipitate and dichloromethane were removed by centrifugation. The hydrolysis products were chromatographed on a column (1.5 × 95 cm) of Bio-Gel P2 with water as the eluant to give the phosphate-free products **1** (K_{av} 0.55, 9.7 mg) and **2** (K_{av} 0.48, 1.4 mg), which were pure by TLC (R_f 0.24 and 0.26, respectively). The oligosaccharides in water (0.5 mL) were each treated with $NaBH_4$ (~30 mg) at 20°C for 3 h, followed by decomposition of excess borohydride with acetic acid and repeated concentration of the solutions from methanol (5 × 1 mL). A sample of each reduced oligosaccharide was methylated, analysed by FAB- and EI-MS, hydrolysed, and the partially methylated glycoses analysed as their alditol acetates by GLC–EI-MS.

The 19C polysaccharide (20 mg) was dissolved in 48% aqueous hydrofluoric acid (1 mL) and kept at 4°C for 22 h. The reaction mixture was worked up as above to afford a single phosphate-free product **5** (K_{av} 0.40, R_f 0.11), which was reduced, methylated, and analysed as previously described for oligosaccharides **1** and **2**.

A sample of oligosaccharide **5** (10 mg) was treated with 0.5 M trifluoroacetic acid for 1 h at 100°C. The excess acid was removed by rotary evaporation and the remaining traces were neutralized with 5% NH_4OH. Separation of the products on Bio-gel P2 gave a tetrasaccharide **6** (K_{av} 0.34, R_f 0.12) and a trisaccharide **7** (K_{av} 0.55, R_f 0.08), which were reduced, methylated, analysed by CI- and EI-MS, and, following hydrolysis, the derived alditol acetates were analysed by GLC–MS.

Partial acid hydrolysis of 19B polysaccharide

The 19B polysaccharide (70 mg) dissolved in 0.05 M trifluoroacetic acid was heated on a boiling water bath for 3 h. The excess acid was removed by rotary evaporation and the remaining traces of acid neutralized with 5% NH_4OH. Separation of the products on Bio-gel P2 gave a trisaccharide **3** (K_{av} 0.57, R_f 0.30, yield 2.9 mg) and a tetrasaccharide **4** (K_{av} 0.47, R_f 0.27, yield 8.7 mg), which were reduced, methylated, and analysed by FAB- and EI-MS (**4**) or GLC–EI-MS (**3**). Each reduced, methylated oligosaccharide was then hydrolysed and analysed as described above.

General methods

Concentrations were made under reduced pressure at <40°C and optical rotations measure at 20°C in 10-cm microtubes, using a Perkin Elmer 243 polarimeter.

Acknowledgments

Fred Cooper provided expert FAB– and GLC–MS analyses and we thank VG Analytical Ltd., Manchester, UK, for mass spectra of oligosaccharides **1** and **2**.

Molecular recognition IX.[1] The synthesis of the H-type 2 human blood group determinant and congeners modified at the 6-position of the *N*-acetylglucosamine unit

EVA PETRAKOVA,[2] ULRIKE SPOHR,[3] AND RAYMOND U. LEMIEUX[4]
Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received July 26, 1991

EVA PETRAKOVA, ULRIKE SPOHR, and RAYMOND U. LEMIEUX. Can. J. Chem. **70**, 233 (1992).

The synthesis of the methyl glycosides of the H-type 2 human blood group determinant (α-L-Fuc-(1c → 2b)-β-D-Gal-(1b → 4a)-β-D-GlcNAc-OMe) and its 6a-deoxy, 6a-*O*-methyl, 6a-chloro-6a-deoxy, 6a-deoxy-6a-fluoro, 6a-amino-6a-deoxy, 6a-acetamido-6a-deoxy, and 6a-deoxy-6a-pivalamido congeners is reported. The compounds were prepared to test the hypothesis that the binding of the H-type 2 trisaccharide by the lectin I of *Ulex europaeus* requires OH-6a to become intramolecularly hydrogen bonded to the neighboring O-5a ring atom. The results obtained in the binding studies are reported in an accompanying publication (Spohr, Paszkiewicz-Hnatiw, Morishima, and Lemieux) where it is demonstrated that the formation of the intramolecular hydrogen bond is not required for effective binding. In view of the results reported in another accompanying paper (Nikrad, Beierbeck, and Lemieux), OH-6a most likely remains in contact with the aqueous phase near the periphery of the combining site.

Key words: *N*-acetylglucosamine derivatives, H-type 2 blood group determinant and congeners, oligosaccharide synthesis.

EVA PETRAKOVA, ULRIKE SPOHR et RAYMOND U. LEMIEUX. Can. J. Chem. **70**, 233 (1992).

On a réalisé les synthèses des glycosides de méthyle du déterminant du groupe sanguin humain H de type 2 (α-L-Fuc-(1c → 2b)-β-D-Gal-(1b → 4a)-β-D-GlcNAc-OMe) et de ses congénères 6a-désoxy, 6a-*O*-méthyl, 6a-chloro-6a-désoxy, 6a-désoxy-6a-fluoro, 6a-amino-6a-désoxy, 6a-acétamido-6a-désoxy et 6a-désoxy-6a-pivalamido. On a préparé ces composés pour vérifier que l'hypothèse selon laquelle il est nécessaire, pour que la liaison du trisaccharide du H de type 2 par la lectine I de l'*Ulex europaeus* puisse se produire, que le groupe OH en 6a soit impliqué dans une liaison hydrogène intramoléculaire avec l'atome d'oxygène en 5a du cycle voisin. Les résultats obtenus lors des études de liaisons font l'objet d'une publication parallèle (Spohr, Paszkiewicz-Hnatiw, Morishima et Lemieux) dans laquelle il est démontré que la formation d'une liaison hydrogène intramoléculaire n'est pas nécessaire pour conduire à une liaison efficace. À la lumière des résultats rapportés dans une autre publication parallèle (Nikrad, Beierbeck et Lemieux), il semble que le groupe OH en 6a demeure en contact avec la phase aqueuse près de la périphérie du site qui se combine.

Mots clés : dérivés du *N*-acétylglucosamine, déterminant du groupe sanguin H de type 2 et ses congénères, synthèse d'oligosaccharides.

[Traduit par la rédaction]

Introduction

The X-ray crystal structure of the complex formed between the lectin IV of *Griffonia simplicifolia* (GS-IV) and the Lewis b tetrasaccharide (α-L-Fuc-(1 → 2)-β-D-Gal-(1 → 3)-[α-L-Fuc-(1 → 4)]-β-D-GlcNAc-OMe) (Le^b-OMe) has revealed that 6 of the 10 hydroxyl groups of the tetrasaccharide reside near or at the periphery of the combining site (1, 2). Chemical modifications of the parent Lewis b-OMe compound have shown that 5 of these 6 hydroxyl groups may be replaced, one at a time, by hydrogen, halogen, or methoxy with only a small effect on the stability (ΔG^0) of the complex. Evidently, these interactions at the periphery of the combining site are weak and in competition with the solvation of the interacting groupings by water.

A similar situation appears to exist for the binding of the H-type 2 trisaccharide in the form of its β-methyl glycoside (H-type 2-OMe), namely, α-L-Fuc-(1c → 2b)-β-D-Gal-(1b → 4a)-β-D-GlcNAc-OMe (**23**), by the lectin I of *Ulex europaeus* in that the 2a-acetamido, OH-3a, OH-6a, and OH-6b proved not essential for productive binding (3–5). Therefore, these substituents appear to reside in the complex at the edge of the combining site and accessible for interaction with the bulk water. It was of particular interest to further examine the involvement of the OH-6a group since deoxygenation at this position increased the stability of the complex by near 0.5 kcal/mol. This paper reports the synthesis of compounds required for a study (5) of the effect on binding of substituting the OH-6a group by smaller, larger, more hydrophobic, and more hydrophilic groups.

Discussion

The synthesis of the 6a-deoxy-6a-fluoro H-type 2 trisaccharide **13** (Scheme 1) started from the *N*-acetylglucosamine derivative **1** (6), which was hydrolyzed in 80% acetic acid to give diol **2** (6). The primary position of **2** was selectively mesylated at −20°C to provide the mesylate **3** (77% yield). Replacement of the mesyloxy group of **3** by fluorine was achieved with tetraethylammonium fluoride in refluxing acetonitrile. Crystalline **4** was isolated in 62% yield. Galactosylation of **4** with bromide **5** (3) was promoted with silver trifluoromethanesulfonate and provided the β-linked disaccharide **8** in 65% yield. Compound **9** was obtained by Zemplen debenzoylation of **8** (98%) and was reacted with fucosyl bromide **10** (7) under halide-ion catalyzed conditions (8) to give trisaccharide **12** (82%). The benzyl groups of **12** were removed by hydrogenolysis to provide the trisaccharide **13** (93%). The ^{19}F nmr data supported the position of the F-atom. The ^1H and ^{13}C nmr data are reported in

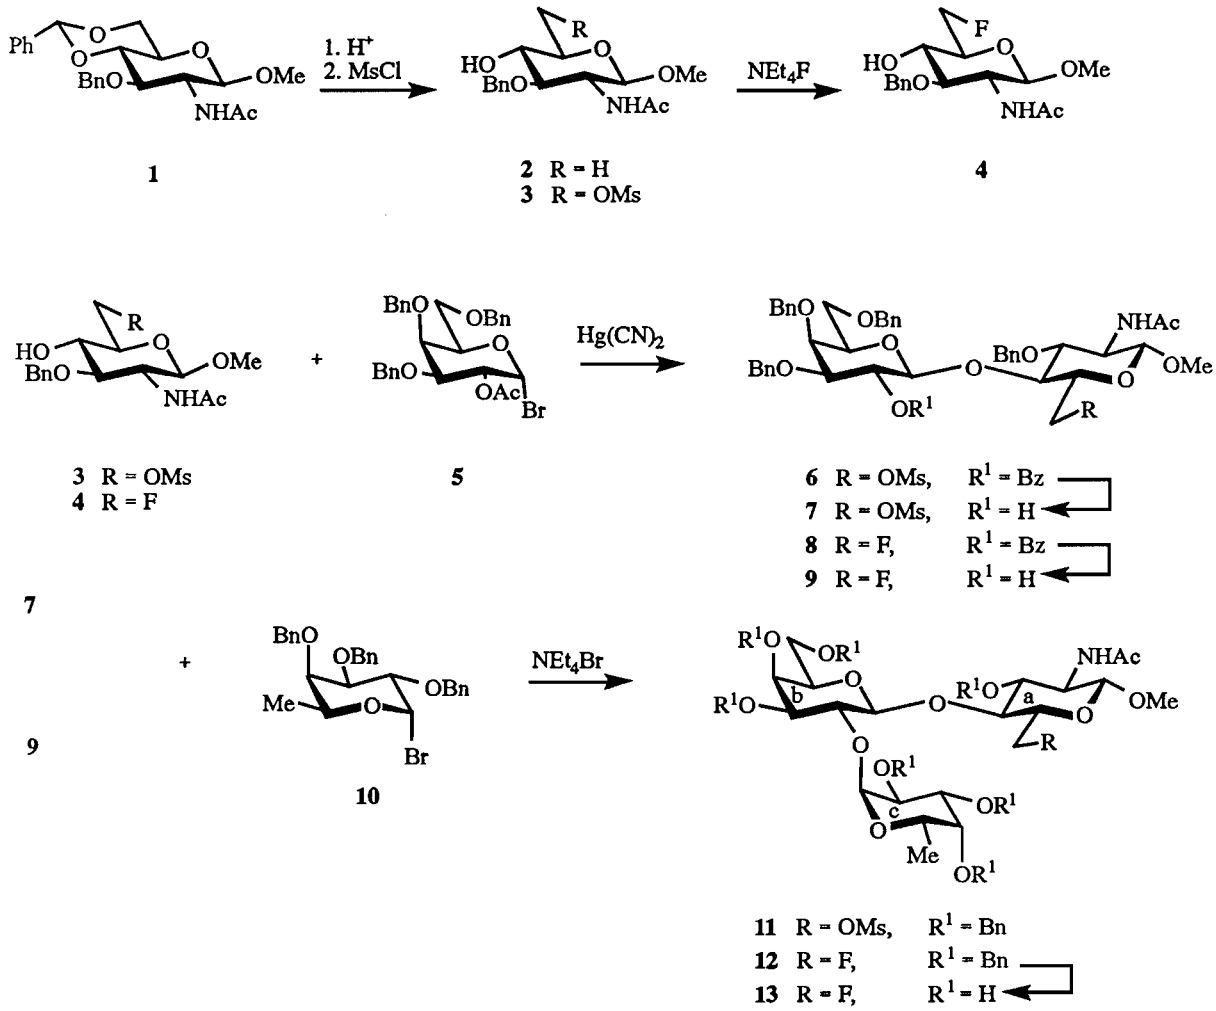

SCHEME 1

Tables 1 and 2 and confirmed the purity and structural assignment.

The blocked 6a-*O*-mesyl derivative **11** (Scheme 1) was prepared analogously. Coupling of galactosyl bromide **5** with alcohol **3** under Helferich conditions (9) furnished the β-linked disaccharide **6** (74%), which was debenzoylated with sodium methoxide to give **7** (75%). Reaction of **7** with the fucosyl bromide **10** in the presence of bromide ion then led to trisaccharide **11**, which was used as the intermediate for the preparation of the H-type 2 derivatives **23**–**29** (Scheme 2).

Mesylate **11** was converted into the benzoyl derivative **14** (84% yield) by replacement of the mesyloxy group by benzoate in *N*,*N*-dimethylformamide at 100°C. Debenzoylation then provided **15** in 98% yield. Hydrogenolysis of **15** in the presence of 5% palladium-on-carbon led to the H-type 2-OMe trisaccharide (**23**), which was to be used as the reference inhibitor.

Methylation of OH-6a of **15** (Scheme 2) using methyl iodide in the presence of barium oxide/barium hydroxide to avoid *N*-methylation of the acetamido group provided the methyl ether **16** in 79% yield. Debenzylation of **16** by catalytic hydrogenolysis then produced the desired 6a-*O*-methyl-H type 2-OMe (**24**).

Reduction of the 6a-mesylate (**11**) (Scheme 1) with sodium borohydride in dimethyl sulfoxide (10) provided the 6a-deoxy derivative **17** in 87% yield. Debenzylation then produced the desired 6a-deoxy H-type 2-OMe (**25**).

The blocked 6a-chloro-6a-deoxy compound **18** (Scheme 2) was prepared in 90% yield by treating the mesyl compound **11** with tetra-*n*-butylammonium chloride in benzene. Hydrogenolysis over palladium then provided **25** in 96% yield.

Reaction of the mesylate **11** with azide ion produced the 6a-azido-6a-deoxy compound (**19**), which was then reduced with zinc in acetic acid to form the amine **20** (Scheme 2) in 53% yield. Debenzylation by catalytic hydrogenolysis in acetic acid provided the desired 6a-amino-6a-deoxy H-type 2-OMe as its acetate salt (**27**). On the other hand, reduction of **19** in the presence of acetic anhydride produced the *N*-acetyl derivative **21** in 60% yield, which, in turn, was deblocked to produce the desired 6a-acetamido-6a-deoxy H-type 2-OMe (**28**). The amine (**20**) was treated with pivaloyl chloride in the presence of pyridine to form **22** in 84% yield. Hydrogenolysis then produced the desired 6a-deoxy-6a-pivalamido H-type 2-OMe (**29**) in 98% yield.

The ^{1}H and ^{13}C nmr data for H-type 2-OMe (**23**) and 6a-substituted derivatives reported in Tables 1 and 2 are seen to be in agreement with the structural assignments. The characteristic interunit deshielding of H-1c and H-5c of

[a]Measured at 360 MHz and 295 K using 0.04 M solutions in D_2O with acetone at 2.225 ppm as internal reference. The assignments were based on homonuclear shift-correlated 2-D experiments (COSY) and expected to be within ±0.01 ppm except for those marked with *g*, which are within ±0.03 ppm.
[b]CH_3O, δ = 3.43 ppm.
[c]$J_{F,6}$ = 47.5 Hz, $J_{F,6'}$ = 46.5 Hz.
[d]CH_3COOH, δ = 1.91 ppm.
[e]6a-CH_3CONH, δ = 2.04 ppm.
[f]$(CH_3)_3C$, δ = 1.20 ppm.
[g]Expected to be within ±0.03 ppm.
*Could not be assigned.

the fucose unit in the ^{1}H nmr spectrum of **23** by 0.54 and 0.19 ppm relative to α-L-Fuc-OMe (**11**) is similarly observed for the other derivatives. Since these deshieldings are interpreted as originating from the proximity of H-1c to O-3b of the β-D-Gal unit and H-5c to O-4a of the β-D-GlcNAc unit, the interglycosidic conformational preferences are not affected by changes in the 6a-substituent.

The immunochemical data are reported in an accompanying paper (5).

Experimental

General methods

The ^{1}H nmr spectra were measured at 360 and 400 MHz (Bruker WM 360 and WH 400) with tetramethylsilane as internal standard for $CDCl_3$ solutions. Reference standard for D_2O solutions was acetone (2.225 ppm). The ^{13}C nmr spectra were recorded at 100 and 75 MHz (Bruker WH 400 and AM 300) using D_2O as solvent and 1,4-dioxane (67.4 ppm) as internal standard. Optical rotations were measured at room temperature (23 ± 1°C) in a 1-dm cell on a Perkin–Elmer 241 polarimeter. Thin-layer chromatograms were performed on precoated plates of silica gel (60-F 254, E. Merck, Darmstadt) and visualized by spraying with 10% sulfuric acid in ethanol followed by heating. For column chromatography, silica gel 60 (230–400 mesh, E. Merck, Darmstadt) and distilled solvents were used. Solvents and reagents were purified and dried according to standard procedures. Melting points are uncorrected.

*Methyl 2-acetamido-3-O-benzyl-4,6-O-benzylidene-2-deoxy-β-D-glucopyranoside (**1**)*

Methyl 2-acetamido-4,6-*O*-benzylidene-2-deoxy-β-D-glucopyranoside (**12**) (30 g, 0.09 mol), barium oxide (42 g, 0.27 mol), barium hydroxide octahydrate (12 g, 0.04 mol), and benzyl bromide (15.3 mL, 0.13 mol) in *N*,*N*-dimethylformamide (360 mL) were stirred for 2 h. The reaction mixture was diluted with dichloromethane, filtered through a pad of Celite, and washed with cold aqueous 1 N hydrochloric acid, saturated aqueous sodium hydrogen carbonate, and water. The solution was concentrated, followed by the addition of diethyl ether. The precipitate was filtered to provide compound **1** (31.4 g, 82%). The analytical sample was recrystallized from ethanol, mp > 300°C, $[\alpha]_D$ −59.4 (*c* 0.8, di-

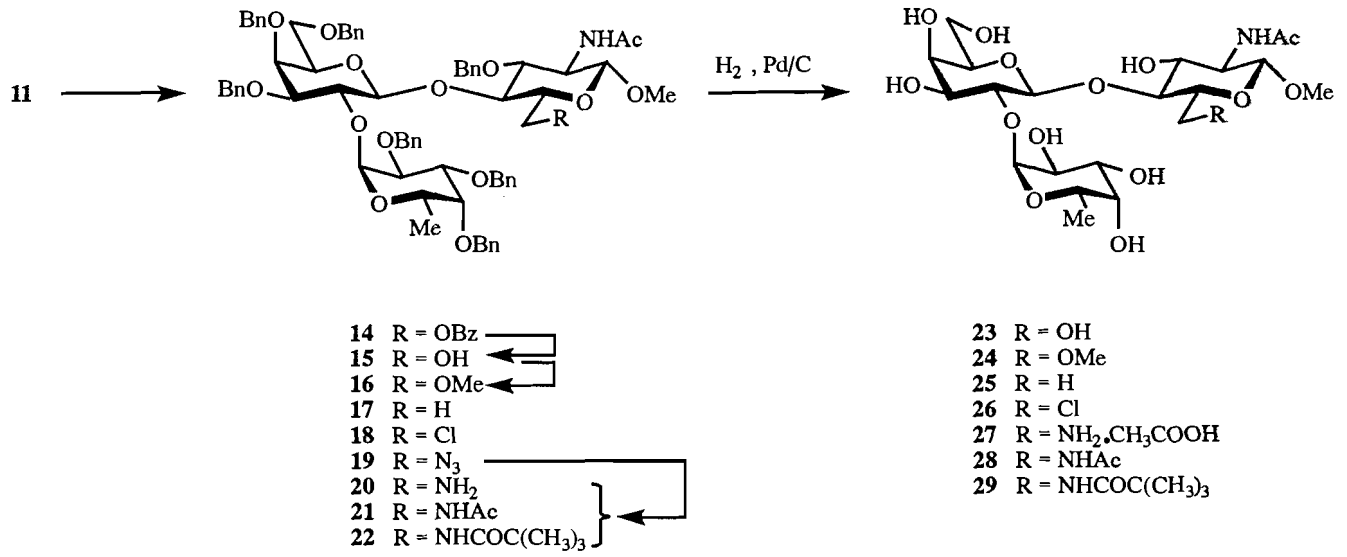
*Methyl 2-acetamido-3-*O*-benzyl-2,6-dideoxy-6-fluoro-*β*-*D*-glucopyranoside (4)*

To a solution of mesylate **3** (2.5 g, 6.2 mmol) in acetonitrile (12 mL) was added a solution of tetraethylammonium fluoride



SCHEME 2

trihydrate (7 g, 34.4 mmol) in acetonitrile (12 mL) and the mixture was heated under reflux for 3 h. After evaporation of the solvent, the residue was applied to a column of silica gel (dichloromethane–methanol 30:1) and the resulting material crystallized from methanol–ether to provide **3** (1.25 g, 62%), mp 245–246°C, $[\alpha]_D$ −15.5 (*c* 0.6, methanol); ^{1}H nmr ($CDCl_3$) δ: 7.45–7.28 (m, 5H, Ph), 5.62 (d, 1H, $J_{NH,2}$ 7.5 Hz, NH), 4.87 (d, 1H, $J_{1,2}$ 8.5 Hz, H-1), 4.78 and 4.67 (ABq, 2H, *J* 11.5 Hz, CH_2Ph), 4.68 and 4.62 (m, 2H, $J_{6,6'}$ 10.5 Hz, $J_{5,6}$ 2.5 Hz, $J_{5,6'}$ 4.5 Hz, $J_{6,F} = J_{6',F}$ 47 Hz, H-6, H-6'), 4.13 (m, 1H, $J_{2,3}$ 10.0 Hz, $J_{3,4}$ 8.5 Hz, H-3), 3.58 (overlapped by H-5, 1H, H-4), 3.54 (m, overlapped by H-4 and CH_3O, H-5), 3.50 (s, 3H, CH_3O), 3.21 (dt, 1H, H-2), 1.98 (s, 3H, CH_3CO); ^{13}C nmr (CD_3CN, CD_3CN set at 118.9) δ: 171.35 (CH_3CO), 129.82, 129.47, 129.06 (Ph), 103.72 (C-1), 84.11 (C-3), 84.07 (d, $J_{C6,F}$ 169.8 Hz, C-6), 76.19 (d, $J_{C5,F}$ 17.4 Hz, C-5), 75.64 (CH_2Ph), 70.97 (d, $J_{C4,F}$ 7.6 Hz, C-4), 57.54, 56.02 (CH_3O, C-2), 24.03 (CH_3CO); ^{19}F nmr (376 MHz, $CDCl_3$, external standard C_6F_6 set at δ 0) δ: −72.31 (dt, $J_{F,H6} = J_{F,H6'}$ = 47 Hz, $J_{F,H5}$ 22.5 Hz, F-6). Anal. calcd. for $C_{16}H_{22}FNO_5$: C 58.71, H 6.77, N 4.28; found: C 58.62, H 6.75, N 4.10.

*Methyl 2-acetamido-4-*O*-(2-*O*-benzoyl-3,4,6-tri-*O*-benzyl-*β*-*D*-galactopyranosyl)-3-*O*-benzyl-2-deoxy-6-*O*-methanesulfonyl-*β*-*D*-glucopyranoside (6)*

A solution of 2-*O*-benzoyl-3,4,6-tri-*O*-benzyl-α-D-galactopyranosyl bromide (**5**, 15 mmol) (4) in toluene (25 mL) was added during a period of 1 h to a stirred solution of the alcohol **3** (4.0 g, 9.9 mmol) in nitromethane–toluene 1:1 (80 mL) containing mercuric cyanide (4.4 g, 17.4 mmol) at 40°C. After stirring for 1 h at 40°C, the solvent was evaporated, and the mixture was diluted with dichloromethane and washed successively with aqueous sodium hydrogen carbonate and water. The syrup obtained on evaporation was chromatographed on a column of silica gel (toluene – ethyl acetate 1:1, dichloromethane – ethyl acetate 2:1). The main component **6** was obtained as a foam in a yield of 74% (6.9 g), mp 68–69°C, $[\alpha]_D$ −4.5 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 8.05–7.15 (m, 25H, 5Ph), 6.24 (d, 1H, $J_{NH,2a}$ 9.0 Hz, NH), 5.62 (dd, 1H, $J_{1b,2b}$ 7.5 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.54 (d, 1H, H-1b), 4.43 (dd, overlapped by CH_2Ph, 1H, $J_{5a,6a}$ 4.5 Hz, H-6a), 4.33 (dd, 1H, $J_{6a,6a'}$ 11.0 Hz, $J_{5a,6a'}$ 5.5 Hz, H-6a'), 4.26 (d, 1H, $J_{1a,2a}$ 5.5 Hz, H-1a), 4.05 (m, 1H, $J_{2a,3a}$ 4.5 Hz, H-2a), 4.02 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.90 (t, 1H, $J_{3a,4a} \sim J_{4a,5a} \sim$ 4.5 Hz, H-4a), 3.80 (t, 1H, H-3a), 3.75 (m, H-5a), 3.71 (dd, 1H, H-3b), 3.66–3.50 (m, 3H, H-5b, H_2-6b), 3.14 (s, 3H, CH_3O), 2.75 (s, 3H, CH_3SO_2), 2.03 (s, 3H, CH_3CO). Anal. calcd. for $C_{51}H_{57}NO_{14}S$: C 65.16, H 6.11, N 1.49, S 3.41; found: C 65.36, H 6.12, N 1.45, S 3.53.

*Methyl 2-acetamido-3-*O*-benzyl-2-deoxy-6-*O*-methanesulfonyl-4-*O*-(3,4,6-tri-*O*-benzyl-*β*-*D*-galactopyranosyl)-*β*-*D*-glucopyranoside (7)*

Compound **6** (3.0 g, 3.2 mmol) was treated with methanolic 0.22 N sodium methoxide solution (35 mL) until *O*-debenzoylation was complete. The solution was made neutral with ion exchange resin Amberlite IR 120 H^+ and evaporated to a syrupy residue that was purified on a column of silica gel (carbon tetrachloride – methanol 15:1). Evaporation of the major fraction left a syrup that was crystallized from ethanol (2.0 g, 75%), mp 68–69°C, $[\alpha]_D$ +5.5 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.5–7.2 (m, 20H, 4Ph), 5.71 (d, 1H, $J_{NH,2a}$ 8.3 Hz, NH), 4.86, 4.81, 4.72, 4.60, 4.55, 4.54 (3ABq, 6H, *J* 11.5 Hz, 3CH_2Ph), 4.71 (d, 1H, overlapped by CH_2Ph, $J_{1a,2a}$ 7.0 Hz, H-1a), 4.65 (dd, 1H, overlapped by CH_2Ph, $J_{5a,6a}$ 2.0 Hz, $J_{6a,6a'}$ 13.0 Hz, H-6a), 4.45 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.38 and 4.32 (ABq, 2H, *J* 11.5 Hz, CH_2Ph), 4.02 (m, 1H, H-3a), 3.96 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.91 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), ~3.81 (m, 2H, H-4a, H-5a), 3.57 (m, overlapped, H-2a), 3.46 (s, 3H, CH_3O), 3.40 (dd, overlapped, H-3b), 2.96 (s, 3H, CH_3SO_2), 1.85 (s, 3H, CH_3CO). Anal. calcd. for $C_{44}H_{53}NO_{13}S$: C 63.22, H 6.39, N 1.68, S 3.84; found: C 62.81, H 6.39, N 1.67, S 3.85.

*Methyl 2-acetamido-4-*O*-(2-*O*-benzoyl-3,4,6-tri-*O*-benzyl-*β*-*D*-galactopyranosyl)-3-*O*-benzyl-2,6-dideoxy-6-fluoro-*β*-*D*-glucopyranoside (8)*

A mixture of the alcohol **4** (0.5 g, 1.5 mmol), silver trifluoromethanesulfonate (1 g, 3.89 mmol), *sym*-collidine (0.2 mL, 1.5 mmol), and 4 Å molecular sieves (1 g) in dichloromethane (15 mL) was stirred at −30°C. A solution of bromide **5** (2 mmol) in dichloromethane (12 mL) was then added dropwise within 20 min. After 45 min at −30°C, tlc (ethyl acetate – methanol 10:1) indicated almost complete reaction. More *sym*-collidine (0.15 mL, 1.1 mmol) was added and after 15 min the reaction mixture was diluted with dichloromethane and filtered. The filtrate was washed with 3% hydrochloric acid, saturated sodium hydrogen carbonate, and water. The organic solution was dried and evaporated and the crude product purified on a column of silica gel (toluene – ethyl acetate 1:1, dichloromethane – ethyl acetate 2:1) to provide the title compound as a solid (0.85 g, 65%). The ana-

lytical sample was recrystallized from ethyl acetate – ether, mp 137–137.5°C, $[\alpha]_D$ −16.2 (*c* 0.6, chloroform); ^{1}H nmr ($CDCl_3$) δ: 8.05–7.1 (m, 25H, 5Ph), 6.07 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH), 5.64 (dd, 1H, $J_{1b,2b}$ 7.5 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.53 (d, 1H, H-1b), 4.39 (d, overlapped by CH_2Ph, H-1a), 4.04 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.83 (m, H-2a), 3.65 (dd, 1H, H-3b), 3.21 (s, 3H, CH_3O), 1.97 (s, 3H, CH_3CO).

*Methyl 2-acetamido-3-*O*-benzyl-2,6-dideoxy-6-fluoro-4-*O*-(3,4,6-tri-*O*-benzyl-*β*-*D*-galactopyranosyl)-*β*-*D*-glucopyranoside (**9**)*

Compound **8** (0.3 g, 0.34 mmol) was debenzoylated in methanolic 0.5 N sodium methoxide solution (20 mL) at room temperature for 20 h. Deionization with Amberlite IR 120 H^+ followed by column chromatography on silica gel (dichloromethane–methanol 30:1) of the resulting material provided the title compound **9** (0.26 g, 98%). The analytical sample was obtained by recrystallization from ethyl acetate – ether, mp 157–158°C, $[\alpha]_D$ +7 (*c* 0.4 chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.4–7.15 (m, 20H, 4Ph), 5.80 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 4.88, 4.84, 4.72, 4.59, 4.56 (3ABq, 6H, *J* 11.5 Hz, 3CH_2Ph), 4.87 (ddd, 1H, $J_{5a,6a}$ 3.5 Hz, $J_{6a,6a'}$ 10.5 Hz, $J_{6a,F}$ 46 Hz, H-6a), 4.75 (d, overlapped by CH_2Ph, H-1a), 4.71 (dd, overlapped by CH_2Ph, $J_{5a,6a'}$ 2.5 Hz, $J_{6a',F}$ 47 Hz, H-6a′), 4.43 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.38 and 4.31 (ABq, 2H, *J* 11.5 Hz, CH_2Ph), 4.08 (t, 1H, $J_{2a,3a} \sim J_{3a,4a} \sim$ 8.5 Hz, H-3a), 3.97 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.94 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 3.88 (t, 1H, $J_{4a,5a}$ 7.5 Hz, H-4a), 3.68 (m, 1H, $J_{5a,F}$ 26.5 Hz, H-5a), ~3.51 (H-2a), 3.47 (s, CH_3O), 3.40 (dd, overlapped, H-3b), 1.85 (s, 3H, CH_3CO). Anal. calcd. for $C_{43}H_{50}FNO_{10}$: C 67.96, H 6.63, N 1.84; found: C 68.02, H 6.63, N 1.90.

*Methyl 2-acetamido-3-*O*-benzyl-2-deoxy-6-*O*-methanesulfonyl-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (**11**)*

A solution of 2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl bromide (**10**, 2 mmol) (7) in dichloromethane (1 mL) was added to a mixture of compound **7** (0.6 g, 0.71 mmol), tetraethylammonium bromide (0.38 g, 1.8 mmol), and 4 Å molecular sieves (4.5 g) in *N*,*N*-dimethylformamide (0.5 mL) and dichloromethane (2 mL). After stirring for 20 h at room temperature, methanol (0.5 mL) was added and stirring continued for 2 h. The mixture was diluted with dichloromethane and filtered through Celite. The filtrate was extracted with saturated aqueous sodium hydrogen carbonate and water, followed by drying and evaporation. The residual solid was crystallized from hexane – ethyl acetate to give **11** (0.4 g, 45%). The mother liquor was evaporated and chromatographed on a column of silica gel with hexane – ethyl acetate 2:1 and then carbon tetrachloride – ethyl acetate 1:1 as eluent to provide an additional amount of compound **11** (0.40 g, total yield 90%), mp 68–69°C, $[\alpha]_D$ −60.8 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.45–7.05 (m, 35H, 7Ph), 6.12 (d, 1H, $J_{2a,NH}$ 8.5 Hz, NH), 5.70 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.52 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.26 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H_3-6c), 4.16 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.03 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.94 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.71 (dd, 1H, H-3b), 3.47 (s, 3H, CH_3O), 2.84 (s, 3H, CH_3SO_2), 1.78 (s, 3H, CH_3CO), 1.19 (d, 3H, H_3-6c). Anal. calcd. for $C_{71}H_{81}NO_{17}S$: C 68.09, H 6.52, N 1.12, S 2.56; found: C 68.01, H 6.42, N 1.10, S 2.58.

*Methyl 2-acetamido-3-*O*-benzyl-2,6-dideoxy-6-fluoro-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (**12**)*

A solution of fucosyl bromide **10** (0.40 mmol) in dichloromethane (2 mL) was added to a stirring mixture of the alcohol **9** (0.16 g, 0.21 mmol) and tetraethylammonium bromide (0.084 g, 0.4 mmol) in dry dichloromethane (2 mL) and *N*,*N*-dimethylformamide (0.5 mL) containing 4 Å molecular sieves (1.2 g). After 20 h at room temperature, methanol (2 mL) was added and the mixture was stirred for 2 h. The reaction mixture was worked up in the usual manner and purified on a column of silica gel (hexane – ethyl acetate 2:1, carbon tetrachloride – ethyl acetate 1:1) to provide compound **12** (0.204 g, 82%), $[\alpha]_D$ −46.4 (*c* 0.3, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.00 (m, 35H, 7Ph), 5.89 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.71 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.74 (d, overlapped by CH_2Ph, $J_{1a,2a}$ 7.5 Hz, H-1a), 4.47 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.28 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.21 (dd, 1H, $J_{2b,3b}$ 9.0 Hz, H-2b), 4.03 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 4.02 (t, overlapped by H-3c, $J_{2a,3a} \sim J_{3a,4a} \sim$ 7.5 Hz, H-3a), 3.99 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.83 (dd, 1H, $J_{3c,4c}$ 3.0 Hz, H-3c), 3.78 (t, 1H, $J_{4a,5a}$ 7.0 Hz, H-4a), 3.71 (dd, 1H, H-3b), 3.69 (d, overlapped by H-3b, H-4c), 3.60–3.39 (m, 7H, H-5a, H-5b, H-6b, H-6b′ and CH_3O at 3.47), 1.83 (s, 3H, CH_3CO), 1.21 (d, 3H, H_3-6c). Anal. calcd. for $C_{70}H_{78}FNO_{14}$: C 71.47, H 6.68, N 1.19; found: C 71.23, H 6.43, N 1.30.

*Methyl 2-acetamido-2,6-dideoxy-6-fluoro-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (**13**)*

A mixture of compound **12** (0.058 g, 0.049 mmol) and 5% palladium-on-carbon (0.058 g) in 95% ethanol (2 mL) was hydrogenated at 100 psi (1 psi = 6.89 kPa) for 24 h. The catalyst was removed by filtration, the solvent evaporated, and the resulting material passed through a column of Sephadex LH 20 using ethanol–water 1:1 as eluant. Freeze-drying an aqueous solution provided compound **13** (0.025 g, 93%) as a light white powder; $[\alpha]_D$ −103.5 (*c* 0.5, water). The ^{1}H and ^{13}C nmr data are presented in Tables 1 and 2; ^{19}F nmr (376.5 MHz, D_2O, $CFCl_3$ as external standard set at 0) δ: −232.4 (dt, $J_{F,6a} = J_{F,6a'} = 47.0$ Hz, $J_{F,5a}$ 26.4 Hz, F-6a).

*Methyl 2-acetamido-6-*O*-benzoyl-3-*O*-benzyl-2-deoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (**14**)*

A mixture of mesylate **11** (0.5 g, 0.4 mmol) and sodium benzoate (0.3 g, 2.1 mmol) in *N*,*N*-dimethylformamide (5 mL) was heated for 4.5 h at 100°C with stirring. The reaction mixture was diluted with dichloromethane and washed twice with water, dried with sodium sulfate, and evaporated. After purification of the crude product on a column of silica gel (ethyl acetate – carbon tetrachloride 2:1), the main fraction left, on evaporation, the benzoate **14** (0.43 g, 84%), $[\alpha]_D$ −38.7 (*c* 0.6, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 8.05–6.95 (m, 40H, 8Ph), 5.89 (d, 1H, $J_{2a,NH}$ 8.0 Hz, NH), 5.68 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.22 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 9.5 Hz, H-2b), 3.42 (s, 3H, CH_3O), 1.84 (s, 3H, CH_3CO), 1.24 (d, 3H, $J_{5c,6c}$ 6.0 Hz, H_3-6c). Anal. calcd. for $C_{77}H_{83}NO_{16}$: C 72.34, H 6.54, N 1.10; found: C 71.96, H 6.52, N 1.14.

*Methyl 2-acetamido-3-*O*-benzyl-2-deoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (**15**)*

Compound **14** (0.15 g, 0.12 mmol) was debenzoylated in methanolic 0.5 M sodium methoxide (2 mL) for 20 h at room temperature. The product was isolated in the usual manner, purified on a column of silica gel (ethyl acetate – carbon tetrachloride 2:1), and obtained as a white foam (0.135 g, 98%), $[\alpha]_D$ −55 (*c* 0.5, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.4–7.0 (m, 35H, 7Ph), 5.69 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 5.59 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 4.79 (d, overlapped by CH_2Ph, $J_{1a,2a}$ 7.5 Hz, H-1a), 4.22 (dd, 1H, $J_{1b,2b}$ 7.5 Hz, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.03 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.48 (s, 3H, CH_3O), 1.90 (s, 3H, CH_3CO), 1.22 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{70}H_{79}NO_{15}$: C 71.59, H 6.78, N 1.19; found: C 71.87, H 6.79, N 1.14.

*Methyl 2-acetamido-3-*O*-benzyl-2-deoxy-6-*O*-methyl-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (**16**)*

A solution of methyl iodide (0.06 mL, 0.96 mmol) in *N*,*N*-dimethylformamide (3 mL) was added to a mixture of compound **15** (0.1 g, 0.085 mmol), barium oxide (0.08 g, 0.52 mmol), and barium hydroxide octahydrate (0.08 g, 0.25 mmol) in *N*,*N*-dimethylformamide (1.0 mL). After stirring for 20 h at room temperature,

*Methyl 2-acetamido-3-*O*-benzyl-2,6-dideoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-*α*-*L*-fucopyranosyl)-*β*-*D*-galactopyranosyl]-*β*-*D*-glucopyranoside (17)*

A mixture of **11** (0.5 g, 0.40 mmol), sodium borohydride (0.06 g, 1.6 mmol), and dimethyl sulfoxide (2 mL) was heated with stirring for 12 h at 85° C in an atmosphere of nitrogen. After cooling, the reaction mixture was poured into ice water, and the precipitate was filtered off and dissolved in dichloromethane. The solution was extracted twice with water, dried, and evaporated. After purification of the crude product by column chromatography on silica gel (carbon tetrachloride – ethyl acetate 1:1) pure **17** (0.4 g, 87%) was obtained as a syrup. Recrystallization from hexane – ethyl acetate 2:1 provided the analytical sample as white needles, mp 118–119°C, $[\alpha]_D$ −60.8 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.00 (m, 35H, 7Ph), 5.69 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 5.54 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 4.75 (d, overlapped by CH_2Ph, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.58 (d, overlapped by CH_2Ph, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.35 (q, overlapped by CH_2Ph, H-5c), 4.24 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.02 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 4.00 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.92 (t, 1H, $J_{2a,3a} \sim J_{3a,4a} \sim$ 9.0 Hz, H-3a), 3.87 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.71 (dd, 1H, H-3b), 3.66 (d, 1H, H-4c), ~3.5 (H-4a), 3.48 (s, 3H, CH_3O), 3.29 (m, H-5a), 3.20 (m, H-2a), 1.80 (s, 3H, CH_3CO), 1.32 (d, 3H, $J_{5a,6a}$ 6.5 Hz, H_3-6a), 1.22 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{70}H_{79}NO_{14}$: C 72.58, H 6.87, N 1.21; found: C 72.47, H 6.88, N 1.19.

*Methyl 2-acetamido-3-*O*-benzyl-6-chloro-2,6-dideoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-*α*-*L*-fucopyranosyl)-*β*-*D*-galactopyranosyl]-*β*-*D*-glucopyranoside (18)*

A solution of **11** (0.5 g, 0.40 mmol) and tetra-*n*-butylammonium chloride (0.15 g, 0.54 mmol) in dry benzene (10 mL) was heated at 70°C for 20 h. After evaporation, the crude product was chromatographed on a column of silica gel (dichloromethane – ethyl acetate 2:1) to provide compound **18** (0.43 g, 90%) as a solid. Recrystallization from ethanol provided the analytical sample, mp 123–124°C, $[\alpha]_D$ − 56 (*c* 1.0, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.45–7.00 (m, 35H, 7Ph), 5.95 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH), 5.70 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.70 (d, overlapped by CH_2Ph, 1H, $J_{1a,2a}$ 7.5 Hz, H-1a), 4.50 (d, overlapped by CH_2Ph, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.29 (q, overlapped by CH_2Ph, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.18 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.02 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), ~3.98 (H-4a), 3.96 (d, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.89 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.82 (t, 1H, $J_{2a,3a} \sim J_{3a,4a} \sim$ 6.5 Hz, H-3a), 3.73 (H-4c), 3.70 (dd, overlapped, H-3b), 3.60 (m, H-2a), 3.47 (s, 3H, CH_3O), 1.80 (s, 3H, CH_3CO), 1.20 (d, 3H, H_3-6c). Anal. calcd. for $C_{70}H_{78}ClNO_{14}$: C 70.49, H 6.59, Cl 2.97, N 1.17; found: C 70.34, H 6.51, Cl 3.24, N 1.20.

*Methyl 2-acetamido-6-azido-3-*O*-benzyl-2,6-dideoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-*α*-*L*-fucopyranosyl)-*β*-*D*-galactopyranosyl]-*β*-*D*-glucopyranoside (19)*

A mixture of **11** (0.8 g, 0.64 mmol) and sodium azide (0.24 g, 3.7 mmol) in *N*,*N*-dimethylformamide (9 mL) was heated with stirring for 4 h at 70°C. It was diluted with dichloromethane, washed with water, and followed by drying and evaporation. The resulting product was purified on a column of silica gel (ethyl acetate – carbon tetrachloride 2:1) to give the title compound **19** (0.70 g, 91%) as a foam; $[\alpha]_D$ −62.7 (*c* 1.0, dichloromethane); IR ($CHCl_3$) *ν*: 3280 (NH), 2098 (N_3) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.40–7.00 (m, 35H, 7Ph), 5.70 (d, 1H, overlapped by NH, $J_{1c,2c}$ 3.5 Hz, H-1c), 5.68 (d, overlapped by H-1c, NH), 4.79 (d, overlapped by CH_2Ph, $J_{1a,2a}$ 7.5 Hz, H-1a), 4.42 (d, overlapped by CH_2Ph, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.22 (q, overlapped by H-2b, H-5c), 4.21 (dd, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.03 (dd, overlapped, H-2c), 4.00 (overlapped, H-3a), 3.99 (overlapped, H-4b), 3.81 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, $J_{3c,4c}$ 2.8 Hz, H-3c), 3.75 (d, H-4c), 3.71 (dd, 1H, $J_{3b,4b}$ 2.5 Hz, H-3b), 3.49 (overlapped, CH_3O), 3.36 (dt, H-2a), 1.85 (s, 3H, CH_3CO), 1.23 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{70}H_{78}N_4O_{14}$: C 70.10, H 6.56, N 4.67; found: C 70.26, H 6.54, N 4.67.

*Methyl 2-acetamido-6-amino-3-*O*-benzyl-2,6-dideoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-*α*-*L*-fucopyranosyl)-*β*-*D*-galactopyranosyl]-*β*-*D*-glucopyranoside (20)*

Zinc dust (0.40 g) and activated zinc–copper couple (0.20 g) (13) were added to a solution of azido compound **19** (0.40 g, 0.33 mmol) in glacial acetic acid (2 mL) with stirring at 18°C. After 1 h, the mixture was filtered, and the filtrate evaporated and coevaporated three times with toluene. The resulting syrup was dissolved in dichloromethane and the solution washed with water, sodium hydrogen carbonate, and water. Purification of the crude product by column chromatography (silica gel, dichloromethane–methanol 30:1) provided **20** as a foam (0.206 g, 53%), $[\alpha]_D$ −31.5 (*c* 0.6, dichloromethane); IR ($CHCl_3$) *ν*: 3280 (NH_2) cm^{-1}; ^{1}H nmr ($CDCl_3$) δ: 7.40–7.00 (m, 35H, 7Ph), 5.69 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 5.55 (d, 1H, $J_{NH,2a}$ 7.5 Hz, NH), 4.75 (d, overlapped by CH_2Ph, H-1a), 4.54 (d, overlapped by CH_2Ph, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.34 (q, overlapped by CH_2Ph, H-5c), 4.24 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.03 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 4.00 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.93 (t, 1H, $J_{3a,4a} \sim J_{4a,5a} \sim$ 9.0 Hz, H-3a), 3.87 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.78 (d, 1H, H-4c), 3.76 (overlapped by H-4c and H-3b, H-4a), 3.72 (dd, 1H, H-3b), 3.60–3.43 (m, 6H, H-5b, H-6b, H-6b′, and CH_3O at 3.48), ~3.31 (m, 2H, H-2a, H-5a), 3.08 (dd, 1H, $J_{6a,6a'}$ 12.0 Hz, $J_{5a,6a}$ 2.5 Hz, H-6a), 2.91 (dd, 1H, $J_{5a,6a'}$ 6.5 Hz, H-6a′), 1.89 (s, 3H, CH_3CO), 1.25 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c). Anal. calcd. for $C_{70}H_{80}N_2O_{14}$: C 71.65, H 6.87, N 2.38; found: C 70.88, H 6.67, N 2.32.

*Methyl 2,6-diacetamido-3-*O*-benzyl-2,6-dideoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-*α*-*L*-fucopyranosyl)-*β*-*D*-galactopyranosyl]-*β*-*D*-glucopyranoside (21)*

To a solution of azido compound **19** (0.20 g, 0.17 mmol) in glacial acetic acid (2 mL) and acetic anhydride (0.5 mL) were added zinc dust (200 mg) and activated zinc–copper (100 mg) couple. The mixture was stirred for 45 min at 18°C, filtered, evaporated, and coevaporated with toluene. The resulting syrup was dissolved in dichloromethane and the solution was washed with water, saturated sodium hydrogen carbonate, and water, followed by drying and evaporation. Column chromatography on silica gel (dichloromethane–methanol 30:1) provided in the main fraction compound **21** (0.124 g, 60%) as a foam, $[\alpha]_D$ −47 (*c* 0.5, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.40–7.00 (m, 35H, 7Ph), 5.83 (t, 1H, $J_{NH,6a} \sim J_{NH,6a'} \sim$ 5.0 Hz, NH-6a), 5.70 (d, 1H, $J_{NH,2a}$ 8.5 Hz, NH-2a), 5.62 (d, 1H, $J_{1c,2c}$ 3.0 Hz, H-1c), 4.59 (d, overlapped by CH_2Ph, $J_{1a,2a} \sim J_{1b,2b}$ 7.5 Hz, H-1a, H-1b), 4.34 (q, overlapped by CH_2Ph, H-5c), 4.16 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.02 (s and d, 2H, H-2c, H-3c), 3.92 (d, overlapped by H-3a, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.91 (t, 1H, overlapped by H-4b, H-3a), 3.85 (s, 1H, H-4c), 3.71 (2H, H-4a and H-3b), 3.62 (2H, H-2a and H-6a), 3.45 (s, overlapped, CH_3O), 1.82 (s, 3H, CH_3CO), 1.21 (s, 3H, H_3-6c). Anal. calcd. for $C_{72}H_{82}N_2O_{15}$: C 71.15, H 6.80, N 2.30; found: C 70.90, H 6.74, N 2.25

*Methyl 2-acetamido-3-*O*-benzyl-2,6-dideoxy-6-pivalamido-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-*α*-*L*-fucopyranosyl)-*β*-*D*-galactopyranosyl]-*β*-*D*-glucopyranoside (22)*

To a solution of **20** (0.15 g, 0.13 mmol) in dichloromethane (5 mL) were added dry pyridine (0.04 mL) and, dropwise, pival-

oyl chloride (0.03 mL, 0.24 mmol). After stirring at room temperature for 30 min, the reaction mixture was worked up conventionally and the product purified on a column of silica gel (dichloromethane–methanol 25:1). The main fraction gave **22** as a foam (0.143 g, 89%), $[\alpha]_D$ −39 (*c* 1.8, dichloromethane); ^{1}H nmr ($CDCl_3$) δ: 7.45–7.00 (m, 35H, 7Ph), 5.99 (6, 1H, $J_{NH,6a} \sim J_{NH,6a'} \sim 5$ Hz, NH-6a), 5.65 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 5.60 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH-2a), 4.65 (d, overlapped by CH_2Ph, $J_{1a,2a}$ 7.5 Hz, H-1a), 4.56 (d, overlapped by CH_2Ph, H-1b), 4.40 (q, overlapped by CH_2Ph, H-5c), 4.20 (dd, overlapped by H-2b, H-3c), 4.19 (dd, overlapped by H-3c, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.02 (dd, overlapped by H-4c, H-2c), 4.00 (d, overlapped by H-2c, H-4c), 3.95 (d, overlapped by H-3a, H-4b), 3.93 (t, 1H, $J_{2a,3a} \sim J_{3a,4a} \sim 7.5$ Hz, H-3a), 3.85 (m, 1H, $J_{6a,6a'}$ 13.5 Hz, $J_{6a,5a}$ 2.5 Hz, H-6a), 3.74 (dd, 1H, $J_{3b,4b}$ 3.0 Hz, H-3b), 3.64 (t, 1H, $J_{4a,5a}$ 7.5 Hz, H-4a), 3.59–3.39 (m, 8H, H-5a, H-5b, H-6b, H-6b′, H-2a, and CH_3O at 3.46), 3.20 (m, 1H, H-6a′), 1.85 (s, 3H, CH_3CO), 1.22 (d, 3H, $J_{5c,6c}$ 6.5 Hz, H_3-6c), 1.14 (s, 9H, $(CH_3)_3C$). Anal. calcd. for $C_{75}H_{88}N_2O_{15}$: C 71.63, H 7.05, N 2.23; found: C 71.86, H 7.06, N 2.20

*Methyl 2-acetamido-2-deoxy-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (23)*

Compound **15** (0.05 g, 0.04 mmol) in 95% ethanol (2 mL) was hydrogenated over 5% palladium-on-carbon (0.1 g) for 24 h at 100 psi. Subsequent gel filtration of the hydrogenation product on a column of Bio-Gel P-2 (10% ethanol) followed by freeze-drying an aqueous solution provided compound **23** (0.022 g, 95%) as a light white powder, $[\alpha]_D$ −94.8 (*c* 0.4, water). The ^{1}H and ^{13}C nmr data are presented in Tables 1 and 2.

*Methyl 2-acetamido-2-deoxy-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-6-*O*-methyl-β-*D*-glucopyranoside (24)*

A solution of **16** (0.1 g, 0.084 mmol) in 95% ethanol (2 mL) containing 5% palladium-on-carbon (0.2 g) was hydrogenated for 24 h at 100 psi. Chromatography on a column of Bio-Gel P-2 (10% ethanol) provided **24** (45 mg, 96%) after lyophilization as a light white powder, $[\alpha]_D$ −62.5 (*c* 1.0, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

*Methyl 2-acetamido-2,6-dideoxy-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (25)*

Compound **17** (0.1 g, 0.086 mmol) in 95% ethanol (2 mL) was hydrogenated over 5% palladium-on-carbon (0.1 g) for 20 h at 100 psi. After purification of the hydrogenation product on a column of Bio-Gel P-2 (10% ethanol) and lyophilization of an aqueous solution, **25** (0.044 g, 96%) was obtained as a light white powder, $[\alpha]_D$ −78.5 (*c* 1.0, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

*Methyl 2-acetamido-6-chloro-2,6-dideoxy-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (26)*

Compound **18** (0.068 g, 0.057 mmol) was hydrogenated and the hydrogenation product purified as described for the preparation of **25** to provide trisaccharide **26** (0.03 g, 95%), $[\alpha]_D$ −57.5 (*c* 1.0, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

*Methyl 2-acetamido-6-amino-2,6-dideoxy-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-gluocpyranoside acetate (27)*

Compound **20** (0.06 g, 0.051 mmol) and 5% palladium-on-carbon (0.06 g) were hydrogenated in glacial acetic acid (1 mL) at 20 psi. After 20 h, the mixture was filtered and evaporated at room temperature to provide, after freeze-drying an aqueous solution, compound **27** (0.027 g, 88%) as a white powder, $[\alpha]_D$ −56.5 (*c* 1.0, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

*Methyl 2,6-diacetamido-2,6-dideoxy-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-β-*D*-glucopyranoside (28)*

Compound **21** (0.1 g, 0.082 mmol) was hydrogenated over 5% palladium-on-carbon as described for the preparation of **25** with subsequent gel filtration to provide **28** (0.047 g, 97%), $[\alpha]_D$ −77.5 (*c* 1.0, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

*Methyl 2-acetamido-2,6-dideoxy-4-*O*-[2-*O*-(α-*L*-fucopyranosyl)-β-*D*-galactopyranosyl]-6-pivalamido-β-*D*-glucopyranoside (29)*

Compound **22** (0.130 g, 0.1 mmol) was hydrogenated in the presence of 5% palladium-on-carbon (0.13 g) as usual and the resulting product purified on a column of Bio-Gel P-2 (10% ethanol) to provide the title compound **29** (0.064 g, 98%), $[\alpha]_D$ −83.8 (*c* 1.0, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

Molecular recognition X. A novel procedure for the detection of the intermolecular hydrogen bonds present in a protein·oligosaccharide complex[1]

P. V. NIKRAD,[2] H. BEIERBECK,[3] AND R. U. LEMIEUX[4]

Department of Chemistry, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received July 26, 1991

P. V. NIKRAD, H. BEIERBECK, and R. U. LEMIEUX. Can. J. Chem. **70**, 241 (1992).

The relative potencies of both the monodeoxy and mono-*O*-methyl derivatives of the Le^b-OMe tetrasaccharide (α-L-Fuc-(1 → 2)-β-D-Gal-(1 → 3)-[α-L-Fuc-(1 → 4)]-β-D-GlcNAc-OMe) as inhibitors of the complexation of a Le^b artificial antigen by the lectin IV of *Griffonia simplicifolia* are interpreted in terms of the X-ray crystal structure at 2.5 Å resolution of the GS-IV · Le^b-OMe complex. Both kinds of derivatives maintain high potencies when the hydroxyl groups involved appear, in the crystal structure, to be in contact with the aqueous phase. Hydroxyl groups situated at the periphery of the combining site and hydrogen bonded to the protein can also be deoxygenated without important loss in potency. However, their methylation leads to a strong decrease in the stability of the complex, because the steric bulk of the introduced methyl group causes loss of complementarity. In contrast, the hydroxyl groups that form hydrogen bonds with the protein along the base of the shallow amphiphilic cleft of the combining site can neither be deoxygenated nor methylated without virtually complete loss of binding activity. Thus, the procedure can provide an appreciation of the various kinds of hydrogen bonds that are present in a protein · oligosaccharide complex. Hard-sphere calculations supported these contentions since an energetically favorable orientation was indicated for a methoxy group at any one of the five positions that were expected to remain in contact with the aqueous phase. However, the calculations, as expected, showed the introduction of strong destabilizing nonbonded interactions when the methylation involved hydroxyl groups that are hydrogen bonded to the protein in the complex. The results are in accord with the previously made rationalization of the near linear enthalpy–entropy compensation found for the active deoxy congeners.

Key words: molecular recognition, lectin IV of *Griffonia simplicifolia*, *O*-methyl derivatives of the Lewis b-OMe tetrasaccharide, detection of intermolecular hydrogen bonds, hard-sphere calculations.

P. V. NIKRAD, H. BEIERBECK et R. U. LEMIEUX. Can. J. Chem. **70**, 241 (1992).

On a déterminé les efficacités relatives des dérivés monodésoxy- et mono-*O*-méthyle du tétrasaccharide Le^b-OMe (α-L-Fuc-(1 → 2)-β-D-Gal-(1 → 3)-[α-L-Fuc-(1 → 4)]-β-D-GlcNAc-OMe) comme inhibiteurs de la complexation d'un antigène artificiel du Le^b par la lectine IV du *Griffonia simplicifolia;* on interprète les résultats en fonction de la structure cristalline d'un complexe GS-IV · Le^b-OMe, déterminée par diffraction des rayons-X, à une résolution de 2,5 Å. Les deux types de dérivés maintiennent des efficacités élevées lorsqu'il semble que, dans la structure cristalline, les groupes hydroxyles sont en contact avec la phase aqueuse. Lorsqu'on désoxygène les groupes hydroxyles qui sont situés à la périphérie du site qui se combine et qui sont liés à la protéine par des liaisons hydrogènes, il n'y a pas de perte importante de l'efficacité. Toutefois, leur méthylation conduit à une perte de complémentarité et à une baisse importante de la stabilité du complexe qui sont le résultat de l'encombrement stérique introduit par les groupes méthyles. Par ailleurs, pour ce qui est des groupes hydroxyles qui forment des liaisons hydrogènes avec la protéine le long de la base de l'interstice amphiphile peu profond du site de combinaison, on ne peut ni les déoxygéner ni les méthyler sans perdre presque complètement l'activité de liaison. Cette procédure permet donc d'apprécier les divers types de liaisons hydrogènes qui sont présents dans un complexe protéine · oligosaccharide. Des calculs de sphères dures corroborent ces conclusions; en effet, les calculs indiquent que les groupements méthoxyles présents dans les cinq positions qui devraient rester en contact avec la phase aqueuse seraient tous dans une orientation qui serait favorable d'un point de vue énergétique. Toutefois, les calculs ont démontré, comme on pouvait s'y attendre, qu'il y a introduction de fortes interactions déstabilisantes et non-liées lorsqu'on effectue la méthylation des groupes hydroxyles qui sont reliés à la protéine du complexe par des liaisons hydrogènes. Les résultats sont en accord avec la rationalisation faite antérieurement au sujet de la compensation pratiquement linéaire enthalpie–entropie détectée avec des congénères actifs déoxygénés.

Mots clés : reconnaissance moléculaire, lectins IV du *Griffonia simplicifolia*, dérivés *O*-méthyles du tétrasaccharide Le^b-OMe, détection des liaisons hydrogènes intermoléculaires, calculs de sphères dures.

[Traduit par la rédaction]

Introduction

The thermodynamic parameters for the association of the methyl glycoside (**1**) of the tetrasaccharide, known as the Lewis b human blood group determinant, with the lectin IV of *Griffonia simplicifolia* established the reaction to be enthalpy driven with an association constant of 4.4×10^4 [L/μmol] at 298 K (1). The thermodynamic studies were extended to include all 10 monodeoxy derivatives of **1** (2). The results, reported in Table 1, showed that three hydroxyl groups provide key polar interactions with the protein since their replacement by hydrogen provided virtually inactive structures. The seven other monodeoxy-Le^b-OMe were active inhibitors and, as previously commented upon (2), changes in the thermodynamic parameters showed virtual linear enthalpy–entropy compensation. Subsequently, the X-ray crystal structure at 2.5 Å resolution[5] indicated that,

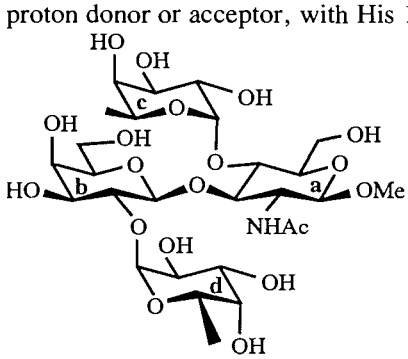
[d]See Table 2.

except for the OH-6a group of the β-D-GlcNAc unit, which is remote from the combining site, the six other non-key hydroxyl groups all reside at or near the periphery of the combining site (see Fig. 1). Indeed, four of these hydroxyl groups, namely those at positions 6b, 2c, 3d, and 4d, appear to remain in contact with the aqueous phase. The three-dimensional geometry of the complex appeared acceptable for favorable hydrogen bonding of O-3c with proton donation from Arg 48 and of O-2d with proton donation from Asn 135, as projected in Fig. 1. The crystal structure at 2.5 Å resolution was not favorable for hydrogen bonding of OH-3d, either as a proton donor or acceptor, with His 114.



a-L-Fuc-(1→2b)-b-D-Gal-(1→3a)-[a-L-Fuc-(1→4a)]-β-D-GlcNAc-OMe (Le^b-OMe)

1

Discussion of results

Binding studies

In view of the above-mentioned indications for hydrogen bond formation, it became of interest to examine the effect on binding of introducing a methyl group at each of the hydroxyl positions of **1**. It was expected that the substitution of any one of the three key hydroxyl groups at positions 3b, 4b, and 4c would lead to loss of stereoelectronic complementarity. Consequently, the *O*-methyl derivatives at these positions were not prepared. Monomethyl derivatives of **1** were synthesized by substitutions at OH-6b, OH-2c, OH-3d, and OH-4d. In the case of OH-6a, it was to be expected that the substitution would not result in significant change in activity since the replacement of this hydroxyl group either by an iodine atom or *O*-mesylation, as previously reported (1), had no appreciable effect on the potency as an inhibitor of the binding of a Le^b-active artificial antigen in a competitive solid-phase radioimmunoassay. Consequently, the 6a-*O*-methyl derivative of **1** was not prepared. Instead, the thermodynamic parameters of the 6a-*O*-mesyl derivative of **1**, reported in Table 2, are accepted as representative of those for the 6a-*O*-methyl congener of **1**. Neither the 3c- nor the 3d-*O*-methyl derivatives of **1** were prepared since the potencies of these structures could be surmised from the potencies of the more readily synthesized 2c,3c- and 2d,3d-di-*O*-methyl derivatives. That is, since the 2c-*O*-

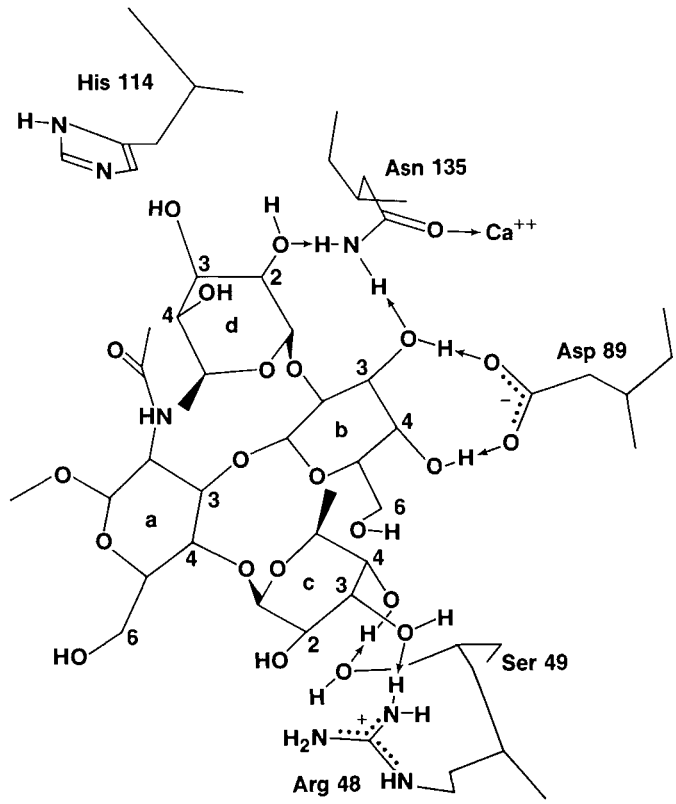


FIG. 1. Fragment of the X-ray crystal structure at 2.5 Å resolution of the complex formed by Le^b-OMe (**1**) and the lectin IV of *Griffonia simplicifolia* to show the intermolecular hydrogen bonds. The ϕ/φ torsion angles about the three intersugar glycosidic bonds are 46.3°/31.1° for α-L-Fuc-(1c → 4a), 55.7°/12.7° for β-D-Gal-(1b → 3a), and 45.6°/15.0° for α-L-Fuc-(1d → 2b), in good agreement with those estimated by HSEA calculation; namely, 55°/25°, 55°/10°, and 45°/15°, respectively. The OH-3b, OH-4b, and OH-4c groups provide the key polar interaction by donating protons to accepting groups located toward the bottom of the cleft that forms the combining site. The OH-3c and OH-2d groups act as proton acceptors from amino acids at the periphery of the combining site to form hydrogen bonds that are not essential to the stability of the complex. Although OH-6b, OH-2c, OH-3d, and OH-4d reside near the periphery of the combining site, these, together with OH-6a, remain in hydrogen bonding interactions with water molecules (see Fig. 3).

[c]In view of the low potency of the 2c,3c-di-*O*-methyl derivative.

[d]In view of the high potencies of the 3d,4d-di-*O*-methyl and the 6b,2c,3d,4d-tetra-*O*-methyl derivatives.

[e]Unpublished.

methyl congener is highly potent but the 2c,3c-di-*O*-methyl derivative is not, evidently methylation at the 3c position strongly hinders complex formation. Also, since the 2d-mono-*O*-methyl and 2d,3d-di-*O*-methyl derivatives of **1** both had almost equally poor potencies, the indication was that methylation at the 3d position is compatible with complex formation. This conclusion was confirmed by preparation of the 6b,2c,3d,4d-tetra-*O*-methyl derivative, which proved to be, as expected, a highly active inhibitor (Table 2).

Semi-empirical energy calculations support the data presented in Table 2. These were accomplished by calculating the energy barriers to rotation about the C-OMe bond of the various GS-IV · mono-*O*-methyl-Le^b-OMe complexes in order to test whether or not there exists an orientation of the methyl group wherein no appreciable nonbonded interaction, either intra- or intermolecular, is present. These assessments were made using the same Kitaygorodsky expression for hard-sphere calculations that is employed in the HSEA method for estimating the conformational preferences about glycosidic linkages (4). In the present situation, coordinates were generated for the six mono-*O*-methyl derivatives of Le^b-OMe noncovalently bound to GS-IV that are presented in Table 1. The energy of interaction of the methyl group with the rest of the Le^b-OMe structure, as well as those with the amino acid residues of the combining site, were then calculated as a function of the Me/C_γ torsion angle defined by the CH_3-O bond and the vicinal C-C bond of the lowest numbered carbon atom of the pyranose ring and always proceeding clockwise for the rotation. These interaction energies were then added to provide the total energy changes with changes in torsion angle displayed in Fig. 2. Thus, with reference to the 6b-methoxy group, the energy of interaction over the range of torsion angles of near 180° to 270° is near zero or slightly negative and, therefore, the *O*-methylation was expected to have no adverse effect on complex formation, as was indeed observed. Similarly for the 2c, 3d, and 4d-*O*-methyl compounds, an orientation exists in which the methyl group has virtually no repulsive interaction, either intramolecularly or with the protein. Indeed, in accord with these observations, the inhibition data show that the addition of a methyl group at these positions does not interfere with com-

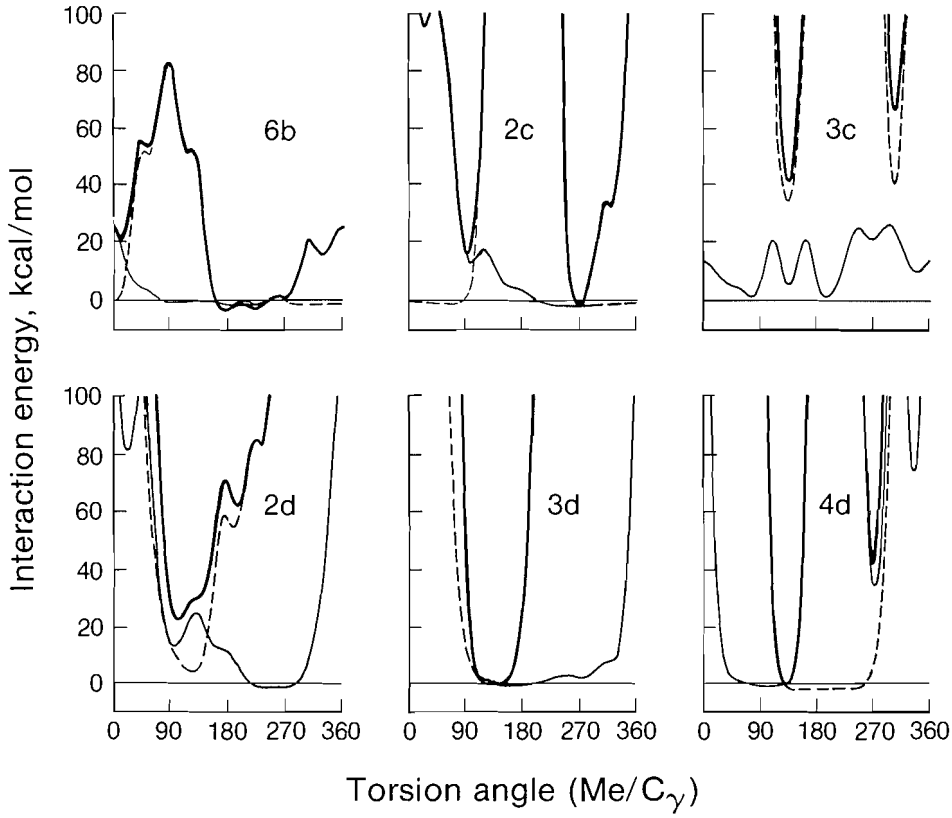

FIG. 2. Potential energy plots provided by hard-sphere calculation of the barriers to rotation about the C-OMe bond to assess whether or not *O*-methylation of hydroxyl groups of Le^b-OMe complexed with GS-IV is compatible with the structure of the complex. The heavy solid plot represents the total of the interaction of the methoxy group within the tetrasaccharide (light solid plot) and the interaction with the protein (dotted plot). Orientations that produce no repulsive interactions are possible only when a methyl group is introduced at either the 6b, 2c, 3d, or 4d positions since, as seen in Table 1, these congeners are highly active whereas the others are not.

plex formation. This is particularly interesting in the case of the 3d-*O*-methyl derivative since it requires that only a weak, if any, hydrogen bond exists between OH-3d and the imidazole group of His 114. It was to be expected, however, that *O*-methylation at either position 3c or 2d would lead to an inactive compound since the crystal structure, as displayed in Fig. 1, is in accord with hydrogen bond formation between the hydroxyl groups at these positions and the protein, and important loss in stereoelectronic complementarity would result. The calculations fully substantiated these expectations. However, the calculations did not anticipate the residual activities for compounds **38** and **42** (Table 2). It is apparent that these situations involve flexible peripheral groups that can offer some adjustment to steric demands for complexation, which our rigid hard-sphere model does not take into account.

It is of interest to note that the *O*-methylation at either position 6b or 4d causes an enhancement of the binding and that these results may be related to the fact that the methyl groups come into contact with hydrophobic residues at the periphery of the combining site: the indolyl group of Trp-133 in the case of CH_3O-6b and both Phe-108 and His 114 in the case of CH_3O-4d. In contrast, CH_3O-2c comes into contact with the strongly hydrophilic guanidine group of Arg 48 and the substitution causes a 23% loss in potency. These stereochemical relationships can be appreciated by examination of the partial CPK model for the complex formed between

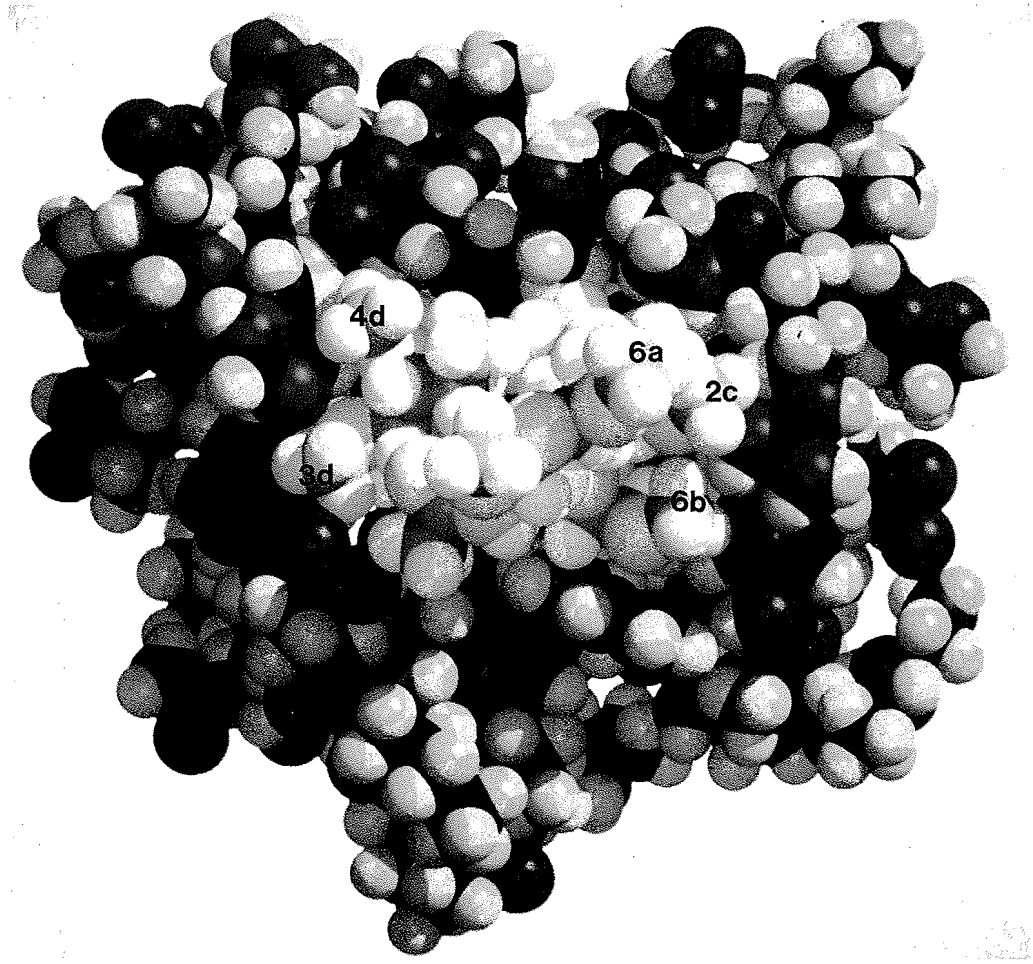

FIG. 3. CPK molecular model of the 6a,6b,2c,3d,4d-penta-*O*-methyl derivative of Le^b-OMe occupying the combining site of the lectin GS-IV, which is represented by the 62 amino acid residues that provide the combining site and the structure about its periphery. Note that both the methyl aglycon and the 6a-methyl groups are both well removed from the combining site. The methyl groups at positions 6b, 2c, 3d, and 4d are in favored orientations according to calculations reported in Fig. 2.

GS-IV and Le^b-OMe, which has positions 6a, 6b, 2c, 3d and 4d *O*-methylated with the methyl groups placed in the favorable orientations identified by the hard-sphere calculations and presented in Fig. 3.

The results achieved in this study thoroughly confirm the indications as to the disposition of the 10 hydroxyl groups present in Le^b-OMe after association with the lectin GS-IV. They also support our proposal (2) that the near-linear enthalpy–entropy compensation that is observed for the binding of Le^b-OMe congeners results from changes in water structure about both the position of structural change prior to complexation and about this position in close proximity to the periphery of the combining site in the complex. An important new insight gained from this research is the recognition that hydroxyl groups of an oligosaccharide that do not come into a hydrogen bonding interaction with the receptor site, but which come into close proximity to amino acid residues at the periphery of the site, may be substituted with little effect on the stability of the complex. In fact, substantial stability may be gained when the substitution leads to new energetically favorable interactions.

In conclusion, it is to be noted that a comparison of the activities of the monodeoxy derivatives of an oligosaccharide with those of the mono-*O*-methyl derivatives provides a powerful novel method for the probing of receptor sites that can yield information that, otherwise, can only be achieved in special cases by high-resolution X-ray crystallography. Thus, such findings may prove useful in efforts aimed at reducing the toxicities of medicinals where it is required to maintain strong recognition by the receptor sites of interest while depressing the interactions responsible for the undesirable side effects.

Chemical synthesis

The procedures used to synthesize the partially *O*-methylated derivatives of Le^b-OMe (**37–44**) followed closely those previously employed (U. Spohr and R. U. Lemieux, unpublished) to synthesize 4d-*O*-methyl-Le^b-OMe and to determine the potency reported in Tables 1 and 2.

The synthesis of the various *O*-alkylated derivatives of Le^b-OMe (**37–44**) required in the first instance the preparation of the substituted fucosyl bromides **15**, **17**, **19**, and **21** (Scheme 1) and the galactosyl bromide **47** (Scheme 2). In the case of the fucosyl bromides, the reactions used and outlined in Scheme 1 are all well-established procedures except for the opening of the stannylene ring (5) of compounds **8** and **9** using fluoride ion. David *et al.* (6) recommended iodide ion for this purpose. However, under the aprotic conditions, the much more strongly nucleophilic

2,3,4-Tri-*O*-benzyl-α-L-fucopyranosyl bromide (**55**) was prepared according to ref. 1.

fluoride ion could be expected to greatly accelerate the overall reaction. Indeed, a reaction that requires refluxing in benzene for up to 24 h using iodide was found to be finished within minutes with the yield of **12** increasing from 10 to 75% (R. U. Lemieux and N. Morishima, unpublished data).

The preparation of the appropriately protected core disaccharides **22** and **49** followed well-established procedures (7) and does not warrant comment further than reported in Scheme 2. The fucosylations of these compounds all resulted in good to excellent yield under the conditions for bromide-ion catalysis (8), which simply employ 4 Å molecular sieve (9) to absorb the liberated hydrogen bromide and *N,N*-dimethylformamide (DMF) in the dichloromethane solvent to accelerate, if need be, the reaction (10).

The various partially *O*-methylated derivatives of Le^b-OMe (**37–44**) are well characterized by the high resolution nmr spectral data reported in Tables 3 and 4. The ^1H nmr data presented in Table 3 confirm the structures and indicate that the introduction of the *O*-methyl groups causes little, if any, change in the conformational preference. These conclusions are further supported by the ^{13}C nmr data presented in Table 4. It is to be noted that the chemical shift assignments are based only on a comparison with those previously assigned to Le^b-OMe (1) and are strictly provisional.

Experimental

General methods

The ^1H nmr spectra were recorded at 300 MHz (Bruker AM 300 spectrometer) with tetramethylsilane as internal standard for $CDCl_3$ solutions. The reference standard for D_2O solutions was acetone (2.225 ppm). The ^{13}C nmr spectra were recorded at 75 MHz (Bruker AM 300 spectrometer), using D_2O as solvent and 1,4-dioxane (67.4 ppm) as internal standard. Optical rotations were measured at room temperature (23 ± 1°C) in a 1-dm cell with a Perkin–Elmer 241 polarimeter. Thin-layer chromatography was performed on a precoated plate of Silica Gel 60 F_{254} (Merck) with detection by spraying with 10% sulfuric acid in ethanol followed by heating. For column chromatography, Silica Gel 60 (230–400 mesh, Merck) and distilled solvents were used. Solvents and reagents were purified and dried according to standard procedures (11). Melting points are uncorrected.

The inhibition studies employed the previously reported competitive solid-phase radioimmunoassay (3) and the relative potencies were calculated from the relative molar amounts that provided 50% inhibition.

O-Benzylations

The benzylations of compounds **4** and **10** of Scheme 1 were performed essentially as follows. The alcohol (20 mmol) was dissolved in DMF (50 mL) and the solution cooled to 0°C. Sodium hydride (100 mmol) was added slowly and the mixture was stirred under nitrogen until the evolution of gas had stopped (about 1 h at 0°C). Benzyl bromide (85 mmol) was then added dropwise with efficient stirring. The mixture was allowed to reach room temperature while stirring for 16 h. The excess sodium hydride was decomposed with methanol (10 mL), and dichloromethane (200 mL) was added. The solids were removed by filtration and the filtrate was evaporated *in vacuo* to a syrup that was chromatographed on a silica gel column using toluene/ethyl acetate as eluent.

O-Methylations

These were conducted under essentially the same conditions as described above for the benzylations except that methyl iodide was substituted for the benzyl bromide.

*Methyl 3,4-di-O-benzyl-2-O-methyl-α-L-fucopyranoside (**6**)*

The syrupy product of the benzylation of **4** (Scheme 1) with $[\alpha]_D$ −90 (*c* 1.1, chloroform) was obtained in 79% yield; ^1H nmr data ($CDCl_3$) δ: 7.43–7.21 (m, 10H, 2Ph), 4.92 (d, 1H, *J* 12.0 Hz, CH_2Ph), 4.87 (d, 1H, $J_{1,2}$ 3.0 Hz, H-1, partly overlapped by CH_2Ph), 4.84 (d, 1H, *J* 12.0 Hz, CH_2Ph), 4.7 (d, 1H, *J* 12.0 Hz, CH_2Ph), 4.65 (d, 1H, *J* 12.0 Hz, CH_2Ph), 3.88–3.78 (m, 3H, H-5 overlapped by H-2 and H-3), 3.62 (dd, 1H, $J_{3,4}$ 2.5 Hz, $J_{5,6}$ 1.0 Hz, H-4), 3.57 (s, 3H, CH_3O), 3.39 (s, 3H, CH_3O), 1.15 (d, 3H, $J_{5,6}$ 6.5 Hz, 3H-6). Anal. calcd. for $C_{22}H_{28}O_5$: C 70.94, H 7.58; found: C 70.15, H 7.51.

*Methyl 2-O-benzyl-3,4-di-O-methyl-α-L-fucopyranoside (**7**)*

The syrupy product of the methylation of **5** (Scheme 1) with $[\alpha]_D$ −72 (*c* 0.34, chloroform) was obtained in 89% yield; ^1H nmr data ($CDCl_3$) δ: 7.22–7.45 (m, 5H, Ph), 4.55 (d, 1H, $J_{1,2}$ 3.5 Hz, H-1), 4.3 and 4.1 (2d, 2H, *J* 12.0 Hz, CH_2Ph), 3.86 (m, 1H, H-5), 3.82 (dd, 1H, $J_{2,3}$ 9.0 Hz, H-2), 3.62 (dd, 1H, $J_{3,4}$ 3.0 Hz, H-3), 3.59 and 3.55 (s, 3H, $2CH_3O$), 3.43 (dd, 1H, $J_{4,5}$ 1.0 Hz, H-4), 3.34 (s, 3H, CH_3O), 1.24 (d, 3H, $J_{5,6}$ 6.5 Hz, 3H-6). Anal. calcd. for $C_{16}H_{24}O_5$: C 64.84, H 8.16; found: C 64.22, H 7.94.

*Methyl 2,3-di-O-methyl-α-L-fucopyranoside (**10**)*

Compound **4** (5.16 g, 26.84 mmol) was dissolved in benzene (250 mL) and di-*n*-butyl tin oxide (7.1 g, 28.5 mmol) was added. The mixture was refluxed for 16 h with azeotropic removal of water formed during stannylation. After 16 h it was concentrated to 100 mL for addition of tetrabutylammonium fluoride (10 g, 38.24 mmol), molecular sieves 4 Å (25 g), and methyl iodide (10 mL, 160.5 mmol). The mixture was stirred at room temperature under nitrogen overnight. The progress of the reaction was monitored by tlc (methanol/dichloromethane 1:9). The solids were removed by filtration and the filtrate was concentrated to a syrup that was chromatographed on a silica gel column (methanol/dichloromethane, 1:19) to provide a highly volatile oily product (5.15 g, 79%) with $[\alpha]_D$ −110 (*c* 3.0, chloroform); ^1H nmr data ($CDCl_3$) δ: 4.75 (d, 1H, $J_{1,2}$ 3.0 Hz, H-1), 3.9 (m, 2H, H-5 overlapped by H-4), 3.55 (dd, 2H, H-2 overlapped by H-3 and CH_3O), 3.49 (s, 6H, $2CH_3O$), 3.4 (s, 3H, CH_3O), 2.38 (d, 1H, OH-4, D_2O exchanged), 1.32 (d, 3H, $J_{5,6}$ 6.5 Hz, 3H-6).

*Methyl 4-O-benzyl-2,3-di-O-methyl-α-L-fucopyranoside (**11**)*

The syrupy product of the benzylation of **10** (Scheme 1) with $[\alpha]_D$ −41 (*c* 1.1, chloroform) was obtained in 88% yield; ^1H nmr data

($CDCl_3$) δ: 7.42–7.25 (m, 5H, Ph), 4.95 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.87 (d, 1H, $J_{1,2}$ 3.5 Hz, H-1), 4.63 (d, 1H, *J* 11.5 Hz, CH_2Ph), 3.85 (m, 1H, H-5), 3.75 (dd, 1H, $J_{2,3}$ 10.0 Hz, H-2), 3.69 (dd, 1H, $J_{3,4}$ 2.5 Hz, $J_{4,5}$ 1.0 Hz, H-4), 3.57 (dd, 1H, H-3), 3.52, 3.51, 3.40 (3s, each 3H, $3CH_3O$), 1.19 (d, 3H, $J_{5,6}$ 6.5 Hz, 3H-6). Anal. calcd. for $C_{16}H_{24}O_5$: C 64.84, H 8.16; found: C 64.88, H 8.44.

Methyl 2,3-di-O-benzyl-α-L-fucopyranoside (12)

As already stated, this compound was prepared from **5** (Scheme 1) in a separate project under conditions similar to those described above for the synthesis of **10** except that benzyl bromide was used as the alkylating agent.

Methyl 2,3-di-O-benzyl-4-O-methyl-α-L-fucopyranoside (13)

As mentioned above, this compound was prepared in a separate project under conditions similar to those used for **4–10** by way of **8** (Scheme 1).

Hydrolysis of the substituted methyl fucosides

The compound, either **6**, **7**, or **11** (Scheme 1) (15 mmol), was dissolved in a mixture of acetic acid (100 mL) and 6 N hydrochloric acid (3 mL) and the solution heated at 65°C. The course of the reaction could be monitored by tlc (ethyl acetate–toluene) and found to be complete within 1 h. The mixture was concentrated *in vacuo* and coevaporated with toluene (200 mL × 5). The residue was chromatographed on silica gel with the solvent mixture used for the tlc. Compound **20** was prepared under similar conditions.

3,4-Di-O-benzyl-2-O-methyl-α/β-L-fucopyranose (14)

The syrupy product from the hydrolysis of **6** (Scheme 1) (86% yield) with $[\alpha]_D$ −100 (*c* 2.6, chloroform) was a 61:39 mixture of the α and β anomers; ^1H nmr data ($CDCl_3$), α isomer, δ: 7.5–7.15 (m, 10H, 2Ph), 5.4 (dd, $J_{1,2}$ 3.0 Hz, $J_{1,OH}$ 2.0 Hz, H-1), 4.57 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.71 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.1 (m, 1H, H-5), 3.81 (m, 2H, H-2α overlapped by H-3β), 3.65 (m, 1H, H-4), 3.55 (s, 3H, CH_3O), 3.46 (dd, 1H, $J_{2,3}$ 9.5 Hz, $J_{3,4}$ 3.0 Hz, H-3 overlapped by H-4β), 2.86 (d, 1H, $J_{1,OH}$ 2.0 Hz, OH-1, D_2O exchanged), 1.13 (d, 3H, $J_{5,6}$ 6.5 Hz, 3H-6). β-Isomer, δ: 7.5–7.15 (m, 10H, 2Ph), 4.79 (d, 1H, *J* 12.0 Hz, CH_2Ph), 4.67 (d, 1H, *J* 12.0 Hz, CH_2Ph), 4.67 (t, 1H, $J_{1,2}$ 7.5 Hz, $J_{1,OH}$ 7.0 Hz, H-1), 4.10 (m, 1H, H-5), 3.81 (m, 2H, H-3β overlapped by H-2α), 3.69 (s, 3H, CH_3O), 3.51 (dd, 1H, $J_{2,3}$ 9.0 Hz, H-2), 3.46 (dd, 1H, $J_{3,4}$ 3.0 Hz, $J_{4,5}$ 1.0 Hz, H-4), 3.1 (d, 1H, $J_{1,OH}$ 7.0 Hz, OH, D_2O exchanged), 1.18 (d, 1H, $J_{5,6}$ 6.0 Hz, 3H-6). Anal. calcd. for $C_{21}H_{26}O_5$: C 70.37, H 7.3; found: C 69.4, H 7.24.

2-O-Benzyl-3,4-di-O-methyl-α/β-L-fucofuranose (16)

The syrupy product from the hydrolysis of **7** (Scheme 1) (89% yield) with $[\alpha]_D$ −31 (*c* 0.51, chloroform) was a 64:36 mixture of the α and β anomers; ^1H nmr ($CDCl_3$), α-isomer, δ: 7.45–7.25 (m, 5H, Ph), 5.2 (dd, 1H, $J_{1,2}$ 3.5 Hz, $J_{1,OH}$ 2.0 Hz, H-1), 4.85 (d, 1H, *J* 11.5 Hz, CH_2Ph, overlapped by CH_2 β signal), 4.66 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.12 (m, 1H, H-5), 3.83 (dd, 1H, $J_{2,3}$ 9.5 Hz, H-2), 3.61 (2s, 6H, $2CH_3O$), 3.55 (s, 3H, CH_3O), 3.6 (dd, 1H, H-3 overlapped by CH_3O signal), 3.48 (dd, H-1, $J_{3,4}$ 3.0 Hz, $J_{4,5}$ 1.0 Hz, H-4), 2.885 (d, 1H, $J_{1,2}$ 2.0 Hz, OH-α, D_2O exchanged), 1.27 (d, 3H, $J_{5,6}$ 6.5 Hz, 3H-6). β-Isomer, δ: 7.45–7.25 (m, 5H, Ph), 4.89 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.6 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.60 (dd, 1H, $J_{1,2}$ 7.5 Hz, $J_{1,OH}$ 7.0 Hz, H-1), 4.12 (m, 1H, H-5), 3.61 (2s, 6H, $2CH_3O$), 3.55 (dd, 1H, H-2 overlapped by CH_3O signal), 3.415 (dd, 1H, $J_{3,4}$ 3.0 Hz, $J_{4,5}$ 1.0 Hz, H-4), 3.28 (dd, 1H, $J_{2,3}$ 9.5 Hz, H-3), 2.96 (d, 1H, $J_{1,OH}$ 7.0 Hz, OH-1, exchanged with D_2O), 1.34 (d, 3H, $J_{5,6}$ 6.0 Hz, 3H-6). Anal. calcd. for $C_{15}H_{22}O_5$: C 63.81, H 7.85; found: C 64.12, H 7.69.

4-O-Benzyl-2,3-di-O-methyl-α/β-L-fucopyranose (18)

The syrupy product from the hydrolysis of **11** (Scheme 1) (89% yield) with $[\alpha]_D$ −39 (*c* 0.63, chloroform) was a 59:41 mixture of the α and β anomers; ^1H nmr data ($CDCl_3$), α-isomer, δ: 7.4–7.15 (m, 5H, Ph), 5.4 (dd, 1H, $J_{1,2}$ 3.5 Hz, $J_{1,OH}$ 2.0 Hz, H-1α), 4.94 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.64 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.1 (m, 1H, H-5), 3.72 (dd, 2H, $J_{2,3}$ 10.0 Hz, H-3 partly overlapped by H-4α), 3.51, 3.53 (2s, each 3H, $2CH_3O$), 2.95 (d, 1H, $J_{1,OH}$ 2.0 Hz, OH-α, D_2O exchanged), 1.17 (d, 3H, $J_{5,6}$ 6.5 Hz, 3H-6). β-isomer, δ: 7.4–7.15 (m, 5H, Ph), 4.94 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.66 (d, 1H, *J* 11.5 Hz, CH_2Ph), 4.53 (t, 1H, $J_{1,2}$ 7.5 Hz, $J_{1,OH}$ 7.0 Hz, H-1), 4.1 (m, 1H, H-5), 3.62 (dd, 1H, $J_{3,4}$ 3.0 Hz, $J_{4,5}$ 1.5 Hz, H-4), 3.53, 3.51 (2s, each 3H, $2CH_3O$), 3.25 (d, 1H, $J_{1,OH}$ 7.0 Hz, OH-β, D_2O exchanged), 1.21 (d, 1H, $J_{5,6}$ 6.0 Hz, 3H-6). Anal. calcd. for $C_{15}H_{22}O_5$: C 63.81, H 7.85; found: C 63.91, H 7.70.

Substituted L-fucopyranosyl bromides

The compounds **15**, **17**, and **19** were prepared under the following conditions from compounds **14**, **16**, and **18** (Scheme 1). Compound **21** was prepared from **20** in a separate project under similar conditions. A solution of oxalyl bromide (8 mmol) in dichloromethane (5 mL) was added to the protected fucose (5 mmol) in a mixture of dichloromethane (5 mL) and DMF (0.5 mL). After stirring at room temperature for 30 min, the mixture was poured into ice-water. The organic layer was twice washed with cold water, and dried over sodium sulfate and 3 Å molecular sieves prior to concentration to a syrup that was used directly in the halide-ion catalyzed fucosylation reactions to be described below.

Bromide-ion catalyzed fucosylations

The protected fucopyranosyl bromide (**15**, **17**, **19**, or **55**) (5 mmol) in dichloromethane (4 mL) was added to a stirred solution of the alcohol (1 mmol), tetraethylammonium bromide (3 mmol), dichloromethane (8.5 mL), DMF (3.3 mL), and 4 Å molecular sieves under scrupulously anhydrous conditions. After stirring under nitrogen for 2 days, methanol (1.4 mL) was added and the stirring continued for a further 2 h. The mixture was freed of solids by filtration and washing with methylene chloride. After washing with aqueous sodium bicarbonate and water, the solution was dried over sodium sulfate and the solvent then removed *in vacuo*.

Methyl 2-acetamido-3-O-(2-O-acetyl-3,4,6-tri-O-benzyl-β-D-galactopyranosyl)-6-O-benzyl-2-deoxy-β-D-glucopyranoside (22)

This compound was prepared following the procedure previously described by Spohr and Lemieux (1).

Methyl 2-acetamido-3-O-(2-O-acetyl-3,4,6-tri-O-benzyl-β-D-galactopyranosyl)-6-O-benzyl-2-deoxy-4-O-(3,4-di-O-benzyl-2-O-methyl-α-L-fucopyranosyl)-β-D-glucopyranoside (23)

Alcohol **22** was reacted with bromide **15** under the conditions for bromide-ion catalyzed glycosylation. The product was chromatographed on a column of silica gel (ethyl acetate/toluene, 4:1) to provide a 79% yield of a white solid, $[\alpha]_D$ −66.3 (*c* 0.37, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.4–7.2 (m, 30H, 6 Ph), 6.43 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.31 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 5.12 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.91 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.38 (s, 2H, CH_2Ph), 4.31 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 3.73 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.50 (dd, 1H, $J_{3c,2c}$ 10.0 Hz, $J_{3c,4c}$ 3.0 Hz, H-3c), 3.43, 3.41 (2s, each 3H, $2CH_3O$), 2.05 (s, 3H, CH_3COO), 1.93 (s, 3H, $NHCOCH_3$), 1.09 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{66}H_{77}NO_{16}$: C 69.52, H 6.81, N 1.23; found: C 69.09, H 6.85, N 1.25.

Methyl 2-acetamido-3-O-(2-O-acetyl-3,4,6-tri-O-benzyl-β-D-galactopyranosyl)-6-O-benzyl-4-O-(2-O-benzyl-3,4-di-O-methyl-α-L-fucopyranosyl)-2-deoxy-β-D-glucopyranoside (24)

Alcohol **22** was reacted with bromide **17** under the conditions for bromide-ion catalyzed glycosylation. Chromatographic purification as described for the isolation of **23** provided a white foam (82% yield), $[\alpha]_D$ −61 (*c* 0.5, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.4–7.15 (m, 25H, 5Ph), 6.48 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.31 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 5.15 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.95 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.69 (t, 2H,

For personal use only.

$J_{A,B}$ 11.5 Hz for both, CH_2Ph), 3.82 (dd, 1H, $J_{1c,2c}$ 3.5 Hz, $J_{2c,3c}$ 10.0 Hz, H-2c overlapped by H-5c), 3.52 (dd, 1H, $J_{3c,4c}$ 3.0 Hz, H-3c), 3.42, 3.41, and 3.37 (3s, each 3H, $3CH_3O$), 2.03 (s, 3H, CH_3COO), 1.17 (s, 3H, $NHCOCH_3$), 1.09 (d, 1H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{60}H_{73}NO_{16}$: C 67.71, H 6.91, N 1.32; found: C 67.36, H 6.94, N 1.29.

*Methyl 2-acetamido-3-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-6-*O*-benzyl-4-*O*-(4-*O*-benzyl-2,3-di-*O*-methyl-α-L-fucopyranosyl)-2-deoxy-β-D-glucopyranoside (25)*

Compound **22** was reacted with bromide **19** under the conditions for bromide-ion catalyzed glycosylation. Chromatographic purification as described for the isolation of **23** provided a white foam (78% yield), $[\alpha]_D$ −59 (*c* 0.3, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.41–7.25 (m, 25H, 5Ph) 6.49 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.30 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 5.11 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.92 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.69 (2d, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.44 (ABq, 2H, $J_{A,B}$ 11.5 Hz and $J_{A,B'}$ 11.5 Hz, CH_2Ph), 4.28 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 3.91 (m, H-5c overlapped), 3.5 (dd, 1H, $J_{3c,2c}$ 10.0 Hz, $J_{3c,4c}$ 3.0 Hz, H-3c), 3.41 (2s, 6H, $2CH_3O$), 3.34 (s, 3H, CH_3O), 2.1 (s, 3H, CH_3COO), 1.9 (s, 3H, $NHCOCH_3$), 1.06 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{60}H_{73}NO_{16}$: C 67.71, H 6.91, N 1.32; found: C 67.07, H 6.94, N 1.33.

*Methyl 2-acetamido-3-*O*-(2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-6-*O*-benzyl-2-deoxy-4-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-glucopyranoside (26)*

The previously described (1) tri-O-benzyl-α-L-fucopyranosyl bromide (**55**, Scheme 1) was reacted with **22** under the conditions for bromide-ion catalyzed focusylation and provided crystalline white needles from ethyl acetate (90% yield) with mp 148–149°C, $[\alpha]_D$ −66.4 (*c* 0.81, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.4–7.10 (m, 35H, 7Ph), 6.57 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.2 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 5.18 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 4.92 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.79 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.05 (dd, overlapped, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.72 (dd, 1H, $J_{3c,4c}$ 3.0 Hz, H-3c), 3.42 (s, 3H, CH_3O), 2.05 (s, 3H, CH_3CONH), 1.57 (s, 3H, CH_3COO), 1.07 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{72}H_{81}NO_{16}$: C 71.11, H 6.67, N 1.15; found: C 70.02, H 6.59, N 1.15.

*Methyl 2-acetamido-6-*O*-benzyl-2-deoxy-4-*O*-(3,4-di-*O*-benzyl-2-*O*-methyl-α-L-fucopyranosyl)-3-*O*-(3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-β-D-gluocopyranoside (27)*

Compound **23** (500 mg, 0.44 mmol) was dissolved in methanolic 0.2 M sodium methoxide and kept overnight at room temperature. After neutralization with Amberlite IRC-50 (H^+) resin, the solution was evaporated to a white solid (405 mg, 85%), mp 90°C, $[\alpha]_D$ −64.4 (*c* 0.263, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.45–7.2 (m, 30H, 6Ph), 7.03 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.14 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.9 (H-2b overlapped by CH_2Ph signals), 4.54 (s, 2H, CH_2Ph), 4.41 (s, 2H, CH_2Ph), 4.38 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.25 (bm, 1H, OH-2b), 4.18 (m, 1H, H-5c), 4.39, 3.45 (2s, each 3H, $2OCH_3$), 1.83 (s, 3H, $NHCOCH_3$), 1.10 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{64}H_{75}NO_{15}$: C 69.99, H 6.88, N 1.28; found: C 69.74, H 6.87, N 1.28.

*Methyl 2-acetamido-6-*O*-benzyl-4-*O*-(2-*O*-benzyl-3,4-di-*O*-methyl-α-L-fucopyranosyl)-2-deoxy-3-*O*-(3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-β-D-glucopyranoside (28)*

Compound **24** was de-*O*-acetylated as described above for **23** to yield a white powder (91% yield), mp 87°C, $[\alpha]_D$ − 63.2 (*c* 0.43, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.45–7.2 (m, 25H, 5Ph), 7.04 (d, 1H, $J_{2a,NH}$ 8.0 Hz, NH), 5.14 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.9 (dd, 3H, H-2b overlapped by CH_2Ph), 4.44 (s, 2H, CH_2Ph), 4.39 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 3.52, 3.5, 3.48 (3s, each 3H, $3CH_3O$ overlapped), 3.26 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, $J_{4c,5c}$ 1.0 Hz, H-4c), 1.53 (s, 3H, $NHCOCH_3$), 1.16 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{58}H_{71}NO_{15}$: C 68.15, H 7.00, N 1.37; found: C 67.95, H 7.04, N 1.39.

*Methyl 2-acetamido-6-*O*-benzyl-4-*O*-(4-*O*-benzyl-2,3-di-*O*-methyl-α-L-fucopyranosyl)-2-deoxy-3-*O*-(3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-β-D-glucopyranoside (29)*

Compound **25** was de-*O*-acetylated as described above for **23** to yield a white powder (93% yield), $[\alpha]_D$ −66.2 (*c* 0.22, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.5–7.2 (m, 25H, 5Ph), 7.05 (d, 1H, $J_{2a,NH}$ 8.0 Hz, NH), 5.14 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.92 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.62 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.54 (s, 2H, CH_2Ph), 4.43 (s, 2H, CH_2Ph), 4.39 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.23 (bm, 1H, OH-2b), 4.17 (m, 1H, H-5c), 3.69 (dd, 1H, $J_{1c,2c}$ 3.5 Hz, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.49 (s, 3H, CH_3O), 3.43 (s, 6H, $2CH_3O$), 1.88 (s, 3H, $NHCOCH_3$), 1.10 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{58}H_{71}NO_{15}$: C 68.15, H 7.00, N 1.37; found: C 67.97, H 7.00, N 1.39.

*Methyl 2-acetamido-6-*O*-benzyl-2-deoxy-4-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-3-*O*-(3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl)-β-D-glucopyranoside (30)*

Compound **26** was de-*O*-acetylated as described for the preparation of **27**. The yield was 92% of crystalline product, which was recrystallized from methanol and had mp 140–142°C, $[\alpha]_D$ −68.4 (*c* 0.6, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.45–7.2 (m, 35H, 7Ph), 7.04 (d, 1H, $J_{2a,NH}$ 6.5 Hz, NH), 5.2 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 4.9 (dd, 3H, H-2b overlapped by CH_2Ph), 4.21 (bm, 1H, OH-2b exchanged with D_2O), 4.05 (dd, 2H, $J_{3c,2c}$ 10.0 Hz, H-2c overlapped by H-5c), 3.79 (dd, 1H, $J_{3c,4c}$ 3.0 Hz, H-3c overlapped by H-4c), 3.52 (s, 3H, CH_3O), 1.5 (s, 3H, CH_3CONH), 1.09 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{70}H_{79}NO_{15}$: C 71.6, H 6.75, N 1.19; found: C 71.40, H 6.59, N 1.33.

*Methyl 2-acetamido-6-*O*-benzyl-2-deoxy-4-*O*-(3,4-di-*O*-benzyl-2-*O*-methyl-α-L-fucopyranosyl)-3-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (31)*

Alcohol **27** was reacted with the bromide **55** (Scheme 1) under the conditions for bromide-ion catalyzed glycosylation. The product was purified by chromatography as described for **23** to provide a white foam (81% yield) with $[\alpha]_D$ −81 (*c* 0.43, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.4–7.0 (m, 45H, 9Ph), 5.7 (d, 1H, $J_{1d,2d}$ 3.5 Hz, H-1d), 5.66 (d, 1H, $J_{2a,NH}$ 8.0 Hz, NH), 4.99 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.92 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.11 (m, 1H, H-5d overlapped by H-2c), 3.41, 3.36 (2s, each 3H, $2CH_3O$), 3.2 (dd, 1H, $J_{3c,4c}$ 3.0 Hz, $J_{4c,5c}$ 1.0 Hz, H-4c), 1.78 (s, 3H, $NHCOCH_3$), 1.2, 1.117 (2s, each 3H, $J_{5c,6c}$ = $J_{5d,6d}$ = 6.5 Hz, 3H-6c, 3H-6d). Anal. calcd. for $C_{91}H_{103}NO_{19}$: C 72.15 H 6.85, N 0.93; found: C 71.66, H 6.99, N 1.01.

*Methyl 2-acetamido-6-*O*-benzyl-4-*O*-(4-*O*-benzyl-2,3-di-*O*-methyl-α-L-fucopyranosyl)-2-deoxy-3-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (32)*

Alcohol **29** was reacted with the bromide **55** (Scheme 1) under the conditions for bromide-ion catalyzed glycosylation. Purification of the product as described for **23** provided a white solid (70% yield) with $[\alpha]_D$ −67.3 (*c* 0.32, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.4–7.0 (m, 40H, 8Ph), 5.69 (2d, 2H, $J_{2a,NH}$ 8.0 Hz, $J_{1d,2d}$ 3.5 Hz, NH partly overlapped by H-1d), 4.96 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c overlapped by CH_2Ph signal), 3.38, 3.34, 3.25 (3s, each 3H, $3CH_3O$), 3.11 (dd, 1H, $J_{3c,4c}$ 3.0 Hz, $J_{4c,5c}$ 1.0 Hz, H-4c), 1.90 (s, 3H, $NHCOCH_3$), 1.18, 1.07 (2d, each 3H, $J_{5c,6c}$ = $J_{5d,6d}$ = 6.5 Hz, 3H-6c, 3H-6d). Anal. calcd. for $C_{85}H_{99}NO_{19}$: C 70.96, H 6.94, N 0.97; found: C 70.70, H 6.93, N 0.97.

*Methyl 2-acetamido-6-*O*-benzyl-2-deoxy-4-*O*-(2-*O*-benzyl-3,4-di-*O*-methyl-α-L-fucopyranosyl)-3-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (33)*

Alcohol **28** was reacted with the bromide **55** (Scheme 1) under the conditions for bromide-ion catalyzed glycosylation. The product was purified by chromatography as described for **23** to provide a white powder (74.4% yield) with $[\alpha]_D$ −62 (*c* 0.3, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.45–7.05 (m, 40H, 8Ph), 5.71 (d,

1H, $J_{2a,NH}$ 8.5 Hz, NH), 5.7 (d, 1H, $J_{1d,2d}$ 3.7 Hz, H-1d), 4.93 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c overlapped by CH_2Ph signal), 4.67 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 3.76 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.44 (dd, 1H, $J_{3c,4c}$ 3.0 Hz, H-3c), 3.32, 3.29, and 3.15 (3s, each 3H, $3CH_3O$), 2.88 (dd, 1H, $J_{4c,5c}$ 1.0 Hz, H-4c), 1.85 (s, 3H, $NHCOCH_3$), 1.17, 1.04 (2d, each 3H, $J_{5c,6c} = J_{5d,6d} = 6.5$ Hz, 3H-6c, 3H-6d). Anal. calcd. for $C_{85}H_{99}NO_{19}$: C 70.96, H 6.94, N 0.97; found: C 70.49, H 7.01, N 1.01.

Methyl 2-acetamido-6-O-benzyl-2-deoxy-3-O-[3,4,6-tri-O-benzyl-2-O-(3,4-di-O-benzyl-2-O-methyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-4-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-β-D-glucopyranoside (34)

Reaction of the bromide (**15**) (Scheme 1) with the alcohol **30** under the conditions for bromide-ion catalysis provided, after the chromatographic purification, a white foam (77.6% yield) with $[\alpha]_D$ −130.0 (*c* 0.32, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.45–7.12 (m, 45H, 9Ph), 5.68 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.62 (d, 1H, $J_{1d,2d}$ 3.5 Hz, H-1d), 4.97 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.92 (d, 1H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.67 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 3.56, 3.3 (2s, each 3H, $2CH_3O$), 1.88 (s, 3H, $NHCOCH_3$), 1.18, 1.12 (2d, each 3H, $J_{5c,6c} = J_{5d,6d} = 6.5$ Hz, 3H-6c, 3H-6d). Anal. calcd. for $C_{91}H_{103}NO_{19}$: C 72.15, H 6.85, N 0.93; found: C 71.64, H 6.83, N 0.91.

Methyl 2-acetamido-6-O-benzyl-2-deoxy-4-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-3-O-[3,4,6-tri-O-benzyl-2-O-(2-O-benzyl-3,4-di-O-methyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (35)

Reaction of the alcohol **30** with the bromide **17** (Scheme 1) under the conditions for bromide-ion catalyzed glycosylation, followed by purification of the product by chromatography, provided a white solid (84% yield), $[\alpha]_D$ −78.6 (*c* 0.41, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.4–7.05 (m, 40H, 8Ph), 5.81 (d, 1H, $J_{2a,NH}$ 8.5 Hz, NH), 5.65 (d, 1H, $J_{1d,2d}$ 3.5 Hz, H-1d), 5.03 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 3.57, 3.54 (2s, each 3H, $2CH_3O$ overlapped), 3.41 (s, 3H, CH_3O), 1.89 (s, 3H, $NHCOCH_3$), 1.28, 1.13 (2d, each 3H, $J_{5c,6c} = J_{5d,6d} = 6.5$ Hz, 3H-6c, 3H-6d). Anal. calcd. for $C_{85}H_{99}NO_{19}$: C 70.96, H 6.94, N 0.97; found: C 70.74, H 6.92, N 0.95.

Methyl 2-acetamido-6-O-benzyl-2-deoxy-3-O-[3,4,6-tri-O-benzyl-2-O-(4-O-benzyl-2,3-di-O-methyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-4-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-β-D-glucopyranoside (36)

The alcohol **30** was reacted with the bromide **19** (Scheme 1) under the conditions for bromide-ion catalyzed glycosylation, followed by purification of the product by chromatography, and provided a white foam (79% yield) with $[\alpha]_D$ −145 (*c* 0.32, chloroform); ^1H nmr data ($CDCl_3$) δ: 7.45–7.25 (m, 40H, 8Ph), 5.83 (d, 1H, $J_{2a,NH}$ 8.0 Hz, NH), 5.60 (d, 1H, $J_{1d,2d}$ 3.5 Hz, H-1d), 5.01 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 3.5 (s, 3H, CH_3O), 3.343, 3.306 (2s, each 3H, $2CH_3O$), 1.91 (s, 3H, $NHCOCH_3$), 1.18, 1.12 (2d, each 3H, $J_{5c,6c} = J_{5d,6d} = 6.5$ Hz, 3H-6c, 3H-6d). Anal. calcd. for $C_{85}H_{99}NO_{19}$: C 70.96, H 6.94, N 0.97; found: C 70.33, H 6.96, N 0.96.

Deblocking by hydrogenolysis to remove the O-*benzyl groups*

Typical experiments involved dissolving the compound (**31**–**36**) (100 mg) in 95% ethanol (4.5 mL) and stirring the solution efficiently over the palladium-on-charcoal catalyst for 16 h under hydrogen at atmospheric pressure. After catalyst removal, the solution was taken to dryness and the resulting residue dissolved in 10% ethanol for passing through a column of Biogel-P2. The appropriate fraction was taken to dryness and then dissolved in water for freeze-drying.

Methyl 2-acetamido-2-deoxy-3-O-[2-O-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-4-O-(2-O-methyl-α-L-fucopyranosyl)-β-D-glucopyranoside (37)

The hydrogenolysis of **31** produced a white powder, in 89% yield, $[\alpha]_D$ −102.2 (*c* 0.78, water). The ^1H and ^{13}C nmr data are reported in Tables 3 and 4.

Methyl 2-acetamido-2-deoxy-4-O-(2,3-di-O-methyl-α-L-fucopyranosyl)-3-O-[2-O-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (38)

The hydrogenolysis of **32** provided a white powder in 74% yield, $[\alpha]_D$ −90 (*c* 0.72, water). The ^1H and ^{13}C nmr data are reported in Tables 3 and 4.

Methyl 2-acetamido-2-deoxy-4-O-(3,4-di-O-methyl-α-L-fucopyranosyl)-3-O-[2-O-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (39)

The hydrogenolysis of **33** provided a white powder in 73% yield, $[\alpha]_D$ −69.4 (*c* 0.8, water). The ^1H and ^{13}C nmr data are reported in Tables 3 and 4..

Methyl 2-acetamido-2-deoxy-4-O-(α-L-fucopyranosyl)-3-O-[2-O-(2-O-methyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (40)

The hydrogenolysis of **34** led to a white powder in 83% yield, $[\alpha]_D$ −127 (*c* 0.7, water). The ^1H and ^{13}C nmr data are reported in Tables 3 and 4.

Methyl 2-acetamido-2-deoxy-4-O-(α-L-fucopyranosyl)-3-O-[2-O-(3,4-di-O-methyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (41)

The hydrogenolysis of **35** provided a white powder in 89% yield, $[\alpha]_D$ −134.5 (*c* 0.73, water). The ^1H and ^{13}C nmr data are reported in Tables 3 and 4.

Methyl 2-acetamido-2-deoxy-4-O-(α-L-fucopyranosyl)-3-O-[2-O-(2,3-di-O-methyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (42)

The hydrogenolysis of **36** provided a white powder in 76% yield, $[\alpha]_D$ −98.5 (*c* 0.63, water). The ^1H and ^{13}C nmr data are reported in Tables 3 and 4.

3,4-Di-O-acetyl-1,2-O-(1-methoxyethylidene)-6-O-methyl-α-D-galactopyranose (45)

The known 6-*O*-methyl-α/β-D-galactopyranose (12) (7.8 g, 21.5 mmol) was acetylated for conversion to the acetobromo derivative in the usual manner using hydrogen bromide in acetic acid. The syrupy product was dissolved in *sym*-collidine (40 mL) and tetraethylammonium bromide. Methanol (10 mL) was then added and the mixture was heated at 60°C for 24 h. The product was isolated in the usual manner (13) and purified by chromatography on a silica gel column (58% yield); ^1H nmr data ($CDCl_3$), *exo* and *endo* isomers δ: 5.82 (d, 1H, $J_{1,2}$ 5.0 Hz, H-1), 5.43 (m, 2H, H-4 overlapped by H-6a), 5.05 (dd, 1H, $J_{2,3}$ 7.0 Hz, $J_{3,4}$ 4.5 Hz, H-3), 4.36–4.1 (m, 3H, H-2, H-5, and H-6b), 3.38 and 3.35 (2s, each 3H, 2MeO), 2.12 (s, 6H, 2OAc), 1.68 (s, 3H, CH_3).

3,4-Di-O-benzyl-1,2-O-(1-methoxyethylidene)-6-O-methyl-α-D-galactopyranose (46)

The orthoester (**45**) (4.0 g, 12 mmol) was deacetylated in the usual manner using sodium methoxide in methanol and, without purification, was subjected to *O*-benzylation under the standard conditions described above. Chromatography on silica gel provided a syrupy product (3.3 g, 65% yield), $[\alpha]_D$ +111 (*c* 0.46, chloroform); ^1H nmr data ($CDCl_3$), *exo* and *endo* isomers, δ: 7.5–7.2 (m, 10H, 2Ph), 5.75 (d, 1H, $J_{1,2}$ 4.5 Hz, H-1), 4.93 and 4.64 (ABq, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.81 and 4.68 (ABq, 2H, $J_{A,B}$ 12 Hz, CH_2Ph), 4.49 (dd, 1H, $J_{1,2}$ 4.5 Hz, $J_{2,3}$ 7 Hz, H-2), 4.09–3.95 (m, 2H, H-6a and H-4), 3.65 (dd, 1H, $J_{3,4}$ 2.5 Hz, H-3), 3.57–3.48 (m, 2H, H-5 and H-6b), 3.31 and 3.28 (2s, each 3H, 2MeO), 1.58 (s, 3H, CH_3). Anal. calcd. for $C_{24}H_{30}O_7$: C 66.96, H 7.02; found: C 66.32, H 6.95.

2-O-Acetyl-3,4-di-O-benzyl-6-O-methyl-α-D-galactopyranosyl bromide (47)

Acetyl bromide (0.9 mL, 12.2 mmol) was added to a stirred mixture of **46** (2.5 g, 5.8 mmol), tetraethylammonium bromide (0.62 g, 3 mmol), 4 Å molecular sieves (1.0 g), and dichloromethane (23 mL). After 1 h, the solids were removed and the solution poured into a stirred mixture of aqueous sodium bicarbonate and ice. Work-up in the usual manner (1) provided a syrup (2.2 g, 79% yield).

*Methyl 2-acetamido-3-O-(2-O-acetyl-3,4-di-O-benzyl-6-O-methyl-β-D-galactopyranosyl)-4,6-O-benzylidene-2-deoxy-β-D-glucopyranoside (**48**)*

A mixture of methyl 2-acetamido-4,6-benzylidene-2-deoxy-β-D-glucopyranoside (7, 14) (1.16 g, 3.6 mmol), mercuric cyanide (1.86 g, 7.4 mmol), powdered calcium sulfate (1.16 g), and 4 Å molecular sieves (2 g) in toluene/nitromethane (1:1, 116 mL) was stirred under nitrogen and the bromide (**47**) (2.1 g, 4.4 mmol) in toluene/nitromethane (14 mL) was added over a 20 min period at room temperature. After 2 h, the solids were removed by filtration and the solution poured into a mixture of aqueous sodium bicarbonate and dichloromethane. The organic layer was washed with water, dried, and evaporated to leave a solid residue. The yield was 1.94 g (76%) of a crystalline solid, which was recrystallized from methanol, mp 145°C, $[\alpha]_D$ −44 (*c* 0.6, chloroform); ^{1}H nmr data ($CDCl_3$) δ: 7.5–7.2 (m, 15H, 3Ph), 5.76 (d, 1H, $J_{NH,2a}$ 6.5 Hz, NH), 5.50 (s, 1H, CHPh), 5.26 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 5.16 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.88 and 4.42 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.61 (m, 3H, CH_2Ph overlapped by H-1b), 4.32 (dd, 1H, $J_{6Aa,6Ba}$ 10.0 Hz, $J_{6Aa,5a}$ 5.0 Hz, H-6Aa), 3.84 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.76 (t, 1H, $J_{5a,6Ba}$ 10.0 Hz, H-6Ba), 3.67 (t, 1H, $J_{4a,5a}$ 9.0 Hz, H-4a), 3.50 (s, 3H, MeO), 3.41 (dd, 1H, H-3b), 3.20 (bt, 1H, $J_{5b,6Ab}$ 5.5 Hz, $J_{5b,6Bb}$ 7.0 Hz, H-5b), 3.10 (s, 3H, OMe), 2.96 (m, 1H, H-2a), 1.96 and 1.98 (s, 3H each, NHAc and OAc). Anal. calcd. for $C_{39}H_{47}NO_{12}$: C 64.89, H 6.56, N 1.94; found: C 64.82, H 6.36, N 1.89.

*Methyl 2-acetamido-3-O-(2-O-acetyl-3,4-di-O-benzyl-6-O-methyl-β-D-galactopyranosyl)-6-O-benzyl-2-deoxy-β-D-glucopyranoside (**49**)*

Compound **48** (1.8 g, 2.5 mmol) was reduced with sodium cyanoborohydride (3.3 g) under the conditions described for the preparation of **22** (1). The yield was 1.3 g (72%) of a solid, which was recrystallized from methanol, mp 222°C, $[\alpha]_D$ +16.9 (*c* 0.64, chloroform); ^{1}H nmr data ($CDCl_3$) δ: 7.4–7.2 (m, 15H, 3Ph), 5.66 (d, 1H, $J_{NH,2a}$ 7.0 Hz, NH), 5.34 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.92 and 4.61 (ABq, 2H, J_{AB} 12 Hz, CH_2Ph), 4.90 (d, 1H, $J_{1a,2a}$ 8.0 Hz, H-1a), 4.69 and 4.5 (ABq, 2H, CH_2Ph), 4.60 (s, 2H, CH_2Ph), 4.41 (d, 1H, H-1b), 4.33 (dd, 1H, $J_{2a,3a}$ 10.0 Hz, $J_{3a,4a}$ 8.0 Hz, H-3a), 4.26 (bs, 1H, OH exchanged with D_2O), 3.86 (d, overlapped, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.54 (dd, overlapped; H-3b), 3.49 (s, 3H, OMe) 3.46 (t, overlapped; $J_{4a,5a}$ 9.5 Hz, H-4a), 3.28 (s, 3H, OMe), 2.94 (m, 1H, H-2a), 2.05 and 1.98 (s, 3H each, NHAc and OAc). Anal. calcd. for $C_{39}H_{49}NO_{12}$: C 64.72, H 6.82, N 1.94; found: C 64.26, H 6.76, N 2.02.

*Methyl 2-acetamido-3-O-(3,4-di-O-benzyl-6-O-methyl-β-D-galactopyranosyl)-6-O-benzyl-2-deoxy-β-D-glucopyranoside (**50**)*

Compound **49** was de-*O*-acetylated under the standard conditions to provide a crystalline product, in 97% yield, which decomposed at >235°C; $[\alpha]_D$ −2.1 (*c* 0.7, chloroform); ^{1}H nmr data ($CDCL_3$) δ: 7.4–7.2 (m, 15H, 3Ph), 6.20 (d, 1H, NH), 4.87 and 4.55 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.76 (d, 1H, $J_{1a,2a}$ 8.5 Hz, H-1a), 4.60 and 4.70 (ABq, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.59 (s, 2H, CH_2Ph), 4.26 (bs, 1H, OH), 4.23 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.16 (dd, 1H, $J_{2a,3a}$ 10.0 Hz, $J_{3a,4a}$ 8.0 Hz, H-3a), 3.96 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 3.80 (d, 1H, $J_{3b,4b}$ 2.0 Hz, H-4b), 3.50 (s, 3H, MeO), 3.39 (dd, 1H, H-3b), 3.26 (s, 3H, MeO), 3.2 (bs, 1H, OH), 3.26 (m, 1H overlapped by MeO signal H-2a), 1.96 (s, 3H, NHAc). Anal. calcd. for $C_{32}H_{47}NO_{11}$: C 65.18, H 6.95, N 2.05; found: C 64.91, H 6.84, N 2.02.

*Methyl 2-acetamido-6-O-benzyl-2-deoxy-4-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl-3-O-[3,4-di-O-benzyl-6-O-methyl-2-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (**51**)*

Reaction of **50** (230 mg, 0.34 mmol) with the fucosyl bromide (**55**) (2.42 mmol) under the conditions for bromide-ion catalyzed glycosylation, followed by purification of the product by chromatography over silica gel, provided a white powder (325 mg, 65% yield), mp 84°C, $[\alpha]_D$ −67.0 (*c* 0.5, chloroform); ^{1}H nmr data ($CDCL_3$) δ: 7.4–7.0 (m, 45H, 9Ph), 5.72 (d, 1H, $J_{2a,NH}$ 8.5 Hz, NH), 5.7 (d, 1H, $J_{1d,2d}$ 3.8 Hz, H-1d), 4.98 (d, 1H, $J_{1c,2c}$ 4.0 Hz, H-1c), 3.31 and 3.26 (2s, each 3H, $2CH_3O$), 1.85 (s, 3H, $NHCOCH_3$), 1.19, 1.13 (2d, each 3H, $J_{5c,6c}$ = $J_{5d,6d}$ = 6.5 Hz, 3H-6c, 3H-6d). Anal. calcd. for $C_{91}H_{103}NO_{19}$: C 72.15, H 6.86, N 0.93; found: C 71.59, H 6.76, N 0.99.

*Methyl 2-acetamido-2-deoxy-4-O-(α-L-fucopyranosyl)-3-O-[6-O-methyl-2-O-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (**43**)*

Hydrogenolysis of compound **51** and purification under the standard conditions described above provided a white amorphous solid (82 mg, 86% yield), $[\alpha]_D$ −104 (*c* 0.26, water). The ^{1}H and ^{13}C nmr data are reported in Tables 3 and 4.

*Methyl 2-acetamido-6-O-benzyl-2-deoxy-4-O-(3,4-di-O-benzyl-2-O-methyl-α-L-fucopyranosyl)-3-O-(2-O-acetyl-3,4-di-O-benzyl-6-O-methyl-β-D-galactopyranosyl)-β-D-glucopyranoside (**52**)*

Alcohol **49** (500 mg, 0.69 mmol) was reacted with the fucosyl bromide (**15**) (2 mmol) under the conditions for halide-ion catalyzed glycosylation. Purification of the product on a column of silica gel (ethyl acetate/methanol, 96:4) gave a white solid (529 mg, 72% yield), mp 177°C, $[\alpha]_D$ −64.0 (*c* 0.38, chloroform); ^{1}H nmr data ($CDCl_3$) δ: 7.4–7.2 (m, 25H, 5Ph), 6.38 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.3 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 5.14 (d, 1H, $J_{1c,2c}$ 3.8 Hz, H-1c), 4.91 and 4.34 (ABq, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 3.45, 3.41, and 3.23 (3s, each 3H, 3MeO), 2.05 and 1.91 (2s, each 3H, $NHCOCH_3$ and OAc), 1.14 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{60}H_{73}NO_{16}$: C 67.71, H 6.91, N 1.32; found: C 67.61, H 6.80, N 1.20.

*Methyl 2-acetamido-6-O-benzyl-2-deoxy-4-O-(3,4-di-O-benzyl-2-O-methyl-α-L-fucopyranosyl)-3-O-(3,4-di-O-benzyl-6-O-methyl-β-D-galactopyranosyl)-β-D-glucopyranoside (**53**)*

Compound **52** (450 mg, 0.45 mmol) was de-*O*-acetylated to produce a white solid (378 mg, 86% yield), mp 92°C, $[\alpha]_D$ −60.5 (*c* 0.4, chloroform); ^{1}H nmr data ($CDCl_3$) δ: 7.45–7.2 (m, 25H, 5Ph), 7.02 (d, 1H, $J_{NH,2a}$ 8.0 Hz, NH), 5.15 (d, 1H, $J_{1c,2c}$ 3.0 Hz, H-1c), 4.9 (H-2b overlapped by CH_2Ph signal), 4.55 (s, 2H, CH_2Ph), 4.37 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.2 (bs, 1H, OH-2b), 4.18 (m, 1H, H-5c), 3.48, 3.46 (2s, each 3H, 2MeO), 3.26 (s, 3H, MeO), 1.93 (s, 3H, NHAc), 1.12 (d, 3H, $J_{5c,6c}$ 6.5 Hz, 3H-6c). Anal. calcd. for $C_{58}H_{71}NO_{15}$: C 68.15, H 7.0, N 1.37; found: C 68.0, H 7.02, N 1.31.

*Methyl 2-acetamido-6-O-benzyl-2-deoxy-4-O-(3,4-di-O-benzyl-2-O-methyl-α-L-fucopyranosyl)-3-O-[3,4-di-O-benzyl-6-O-methyl-2-O-(2-O-benzyl-3,4-di-O-methyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (**54**)*

Compound **53** (300 mg, 0.3 mmol) was reacted with the fucosyl bromide (**17**) (2.10 mmol) under the conditions for halide-ion catalyzed glycosylation. Chromatographic purification of the product on a column of silica gel (ethyl acetate/methanol 96:4) gave **54** as a white foam (311 mg, 81%), mp 96°C, $[\alpha]_D$ −73.1 (*c* 0.35, chloroform); ^{1}H nmr data ($CDCl_3$) δ: 7.4–7.0 (m, 30H, 6Ph), 5.79 (d, 1H, $J_{2a,NH}$ 8.5 Hz, NH), 5.65 (d, 1H, $J_{1d,2d}$ 4.0 Hz, H-1d), 5.15 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 3.82 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.58, 3.55, 3.45, 3.40, and 3.25 (5s, each 3H, 5MeO), 1.97 (s, 3H, NHAc), 1.31 and 1.17 (2d, each 3H, $J_{5c,6c}$ = $J_{5d,6d}$ = 6.5 Hz, 3H-6c, 3H-6d). Anal. calcd. for $C_{73}H_{91}NO_{19}$: C 68.15, H 7.13, N 1.1; found: C 68.44, H 6.94, N 1.08.

*Methyl 2-acetamido-2-deoxy-4-O-(2-O-methyl-α-L-fucopyranosyl)-3-O-[6-O-methyl-2-O-(3,4-di-O-methyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-glucopyranoside (**44**)*

Hydrogenolysis of **54** and purification of the product by passing it twice through a Biogel-P-2 column gave a white powder

TABLE 5. The r_0 values[a] used in the hard-sphere calculations

	H	C	N	O
H	2.66	3.22	3.06	3.00
C	—	3.78	3.61	3.56
N				3.37

[a] $r_0 = 1.11 \times$ (the sum of the van der Waals radii).

(32 mg, 65% yield), $[\alpha]_D$ −110 (*c* 0.14, water). The ^1H and ^{13}C nmr data are reported in Table 3 and 4.

Hard-sphere calculations

Using the X-ray diffraction-derived coordinates for the GS-IV · Le^b-OMe complex at 2.5 Å resolution,[5] methyl groups were substituted for the hydroxyl hydrogens at positions 6a, 6b, 2c, 2d, 3c, 3d, and 4d. In each case, a valency angle of 117° was adopted for CH_3-O-C_α with a CH_3-O_α bond length of 1.43 Å. The orientation of a methyl group (as CH_3, not as a pseudo atom), relative to the sugar unit to which it is attached, is described by the torsion angle defined by the CH_3 group and the lower-numbered vicinal carbon atom, Cγ, of a Me-O_α-C_β-C_γ fragment of the sugar unit. Thus, in Fig. 2, the zero torsion angles refer to the eclipsed conformations for Me/C-5b, Me/C-1c, Me/C-2c, Me/1d, Me/C-2d, and Me/C-3d, respectively.

The results reported in Fig. 2 were obtained using mono-*O*-methyl derivatives of Le^b-OMe only. Starting with the eclipsed conformation described above, the methoxy group was rotated through 360° in 5° steps. After each rotational step, the energy of the interaction of the methyl group with the rest of the Le^b-OMe molecule (except for the adjacent O_α and C_β atoms) was calculated and the results presented in Fig. 2 by the light solid line plot. At each step, the energy of interaction of the CH_3 group with all the amino acid atoms of the receptor GS-IV within 10 Å of the methoxy group oxygen (O_α) was calculated. The plots of these interaction energies versus torsion angles are presented as broken lines in Fig. 2. The heavy solid lines in Fig. 2 represent the sum of the two interaction energies. These nonbonded, hard-sphere interactions were calculated using the Kitaygorodsky expression that we have employed in HSEA calculations (4), namely, $E = 0.14z^{-6} + e^{10.31228-13z}$, when $z = r_{ij}/r_0$ and for which r_{ij} = internuclear distance and r_0, which is known as the equilibrium atomic radius, depends on the atoms involved in the interaction. The values used are reported in Table 5. The orientations displayed in Fig. 3 correspond to the methoxy group torsion angles at the midpoints of the energy minima in Fig. 2.

Acknowledgements

The research was supported by a Natural Sciences and Engineering Research Council of Canada operating grant (A-172) to R.U.L. The authors also wish to acknowledge and thank Dr. Ulrike Spohr for technical guidance and Chembiomed Ltd. for generous assistance. The chemical and immunochemical studies were performed by P.V.N. H.B. did the hard-sphere calculations and generated the computer graphics.

Molecular recognition XI. The synthesis of extensively deoxygenated derivatives of the H-type 2 human blood group determinant and their binding by an anti-H-type 2 monoclonal antibody and the lectin 1 of *Ulex europaeus*[1]

ULRIKE SPOHR,[2] EUGENIA PASZKIEWICZ-HNATIW,[3] NAOHIKO MORISHIMA,[4] AND RAYMOND U. LEMIEUX[5]

Received July 26, 1991

ULRIKE SPOHR, EUGENIA PASZKIEWICZ-HNATIW, NAOHIKO MORISHIMA, and RAYMOND U. LEMIEUX. Can. J. Chem. **70**, 254 (1992).

The relative potencies of a wide variety of deoxygenated derivatives of the methyl glycoside of α-L-Fuc-(1 → 2)-β-D-Gal-(1 → 4)-β-D-GlcNAc (the H-type 2 human blood group related trisaccharide) for the inhibition of the binding of an artificial H-type 2 antigen by the lectin I of *Ulex europaeus* confirmed the previous evidence that the key and productive interaction involves only the three hydroxyl groups of the α-L-fucose unit, the hydroxyl at the 3-position of the β-D-galactose residue, and the nonpolar groups in their immediate environment. Except for the acetamido group and the hydroxymethyl of the β-D-Gal unit, which stay in the aqueous phase, on complex formation the remaining three hydroxyl groups appear to come to reside at or near the periphery of the combining site since their replacement by hydrogen causes relatively small changes ($<\pm 1$ kcal/mol) in the stability of the complex (ΔG^0). Relatively much larger but compensating changes occur for the enthalpy and entropy terms, and these may arise primarily from the differences in the water structure about the periphery of the combining site and the oligosaccharide both prior to and after complexation. It is proposed that steric constraints lead to an ordered state of the water molecules hydrogen-bonded to the polar groups within the cleft formed by the key region of the amphiphilic combining site. Their release to form less ordered clusters of more strongly hydrogen-bonded water molecules in bulk solution would contribute importantly to the driving force for complexation. It is demonstrated that the surface used for the binding of H-type 2-OMe by a monoclonal anti-H antibody is virtually identical to that used by the *Ulex* lectin.

Key words: molecular recognition, H-type 2 blood group determinant and deoxygenated derivatives, lectin I of *Ulex europaeus*, anti-H-type 2 monoclonal antibody, enthalpy–entropy compensation.

ULRIKE SPOHR, EUGENIA PASZKIEWICZ-HNATIW, NAOHIKO MORISHIMA et RAYMOND U. LEMIEUX. Can. J. Chem. **70**, 254 (1992).

Les efficacités relatives d'un grand nombre de dérivés désoxygénés du glycoside de méthyle de l'α-L-Fuc-(1 → 2)-β-D-Gal-(1 → 4)-β-D-GlcNAc (trisaccharide relié au groupe sanguin H de type 2 de l'homme) comme inhibiteurs de la fixation d'un antigène artificiel du H de type 2 par la lectine I de l'*Ulex europaeus* ont confirmé les données antérieures suggérant que cette interaction importante et productive n'implique que les trois groupes hydroxyles de l'unité α-L-fucose, le groupe hydroxyle en position 3 du résidu β-D-galactose et les groupes non-polaires qui se trouvent dans leur environnement immédiat. À l'exception du groupe acétamido et de l'hydroxyméthyle de l'unité β-D-Gal qui restent dans la phase aqueuse lors de la formation du complexe, il semble que les trois autres groupes hydroxyles se retrouvent à, ou près de, la périphérie du site qui effectue la combinaison; en effet, leur remplacement par de l'hydrogène ne provoque que de faibles changements ($<\pm 1$ kcal/mol) dans la stabilité du complexe (ΔG^0). Des changements relativement plus importants se font sentir dans les termes enthalpiques et entropiques; toutefois, ces derniers se compensent et il est possible qu'ils soient principalement le résultat de différences dans la structure de l'eau autour de la périphérie de l'oligosaccharide et du site qui se combine, tant avant qu'après la complexation. On suggère que des contraintes stériques conduisent à un état ordonné des molécules d'eau réunies par des liaisons hydrogènes aux groupes polaires contenues dans l'interstice formé par la région clé du site amphiphile qui se combine. Leur libération, conduisant à la formation d'agrégats moins ordonnés de molécules d'eau réunies par des liaisons hydrogènes plus fortes dans la masse de la solution, pourrait contribuer d'une façon importante à la force aidant à la complexation.

Mots clés : reconnaissance moléculaire, déterminant du groupe sanguin H de type 2 et dérivés désoxygénés, lectine I de l'*Ulex europaeus*, anticorps monoclonal d'anti-H de type 2, compensation enthalpie–entropie.

[Traduit par la rédaction]

Introduction

The specific, non-covalent binding of oligosaccharides by acceptor proteins has received much attention during the last decade. This laboratory has studied the combining sites of various monoclonal antibodies and lectins that specifically bind blood group determinants (1). The strategy was to slightly chemically alter the natural oligosaccharide substrate mainly by replacing hydroxyl, hydroxymethylene, methyl, and *N*-acetyl groups by hydrogen, one group at a time, and to study the effect on the binding. The relative potencies of the modified haptens, as inhibitors of artificial ^{125}I-labelled antigens, were determined using a solid-phase radioimmunoassay (2). Also, the changes in ultraviolet absorption accompanying complex formations were used to determine association constants at various temperatures in order to derive the changes in enthalpy and entropy (2). The striking finding of these binding studies was that only one to four, but mostly two to three, of the hydroxyl groups of a di-, tri-, or tetrasaccharide were indispensable for complex formation. Replacement of only one of these "essen-

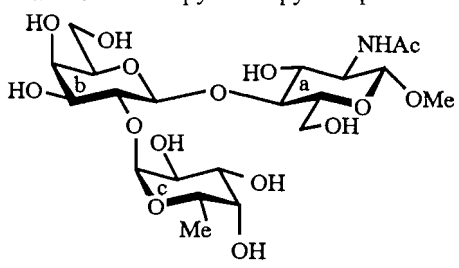
tial" hydroxyl groups virtually abolished complex formation. Usually, these hydroxyl groups, termed the "key polar grouping," occur as a tight cluster flanked by lipophilic surfaces of the oligosaccharide (3) and normally originate from different sugar units of the oligosaccharide. Less often observed, the key hydroxyl groups are provided by only one sugar unit.

The previous binding studies have shown that a particular oligosaccharide may be recognized differently by different acceptor proteins, though the general features recognized are similar in kind. For example, lectin IV of *Griffonia simplicifolia* recognizes a different topography of the Lewis b tetrasaccharide (2) than does a monoclonal anti-Lewis b antibody (4), and two monoclonal anti-Lewis a antibodies have different ways to accommodate the Lewis a trisaccharide (5). In contrast, two monoclonal anti-B antibodies appear to form very similar complexes with the B-trisaccharide (6). In this study, the binding of a monoclonal anti-H type 2 antibody is compared to that of the H-type 2-specific lectin I of *Ulex europaeus*.

That key polar groupings become involved in hydrogen-bond networks with polar groups of the acceptor protein, some of which may be negatively charged, was confirmed by the X-ray crystal structure of the complex formed by the lectin IV of *Griffonia simplicifolia* (GS-IV) and the Lewis b tetrasaccharide (α-L-Fuc-(1 → 2)-β-D-Gal-(1 → 3)-[α-L-Fuc-(1 → 4)]-β-D-GlcNAcOMe) (7, 8). The combining site proved to be a rather small shallow depression at the surface of the protein. The key polar interaction between protein and ligand occurs at the bottom of the cleft where conformational rigidity of the polypeptide chain is greatest. These polar groups are surrounded by aromatic amino acid side chains that may contribute to the stability of the complex by the exclusion of water molecules.

Whereas the hydroxyl groups of a key polar grouping are indispensable to complex formation, the replacement of other hydroxyl groups by hydrogen, halogen, amino, or methoxy groups has a relatively minor effect on the binding. The result may be either an increase or a decrease in the activity normally involving a differential change in free energy of less than 1 kcal/mol. In the case of the lectin GS-IV, these "nonessential" hydroxyl groups were found (8, 9) to be involved in interactions at or near the periphery of the combining site where the protein structure may be conformationally more flexible and interaction with water is more readily possible. Although the replacement of a "nonessential" peripheral hydroxyl group by hydrogen does not importantly affect the change in free energy, the structural change causes a substantial change in the thermodynamic parameters, which takes the form of a linear enthalpy–entropy compensation (9, 10).



1

Probing of the combining site of the H-type 2 (α-L-Fuc-(1c → 2b)-β-D-Gal-(1b → 4a)-β-D-GlcNAc, **1**) specific lectin I of *Ulex europaeus* revealed the key polar grouping to comprise OH-2c, OH-3c, and OH-4c of the α-L-Fuc unit and OH-3b of the β-D-Gal unit (11, 12). Although all four hydroxyl groups provide important polar interactions, the effect on the stability of the complex of replacing either OH-2c or OH-3b by hydrogen was substantially less than for OH-3c and OH-4c. These four hydroxyl groups provide a cluster that is flanked by lipophilic regions of the β-side of the GlcNAc unit, and the α-sides of the Gal and Fuc units, thereby presenting the assortment of amphiphilic surfaces displayed in Fig. 1 (center). The inhibition data (12) indicated that the CH_3O-1a, NHAc-2a, OH-3a, and CH_2OH-6b groups remain in contact with the aqueous phase. As is indicated in the side projections of Fig. 1, OH-3a, OH-6a, and OH-4b are now considered to also interact with the lectin at or near the periphery of its combining site.

In view of the slightly higher activity of the 6a-deoxy H-type 2 congener (11, 12), the OH-6a group appeared to become involved in an interaction within a hydrophobic environment. For this reason, it was suggested that this hydroxyl group may be accepted into the complex by forming an intramolecular bond with O-5a (11, 12). However, this view must now be modified since the X-ray crystal structure of the complex formed by the Lewis b tetrasaccharide and the lectin GS-IV has shown (8), in a very similar situation, that, although the hydroxymethyl group of the β-D-Gal unit is near the indolyl group of a tryptophane unit, the hydroxyl group remains in the aqueous phase (9). In the case of the *Ulex* lectin, the steric complementarity provided for the CH_3-6c and H-5c atoms of the fucose unit contributes importantly to the stability of the complex (12) and infers an important hydrophobic component to the binding reaction.

We now wish to report that these conclusions, largely drawn from the immunochemical properties of monodeoxy derivatives of **1**, are supported by the inhibition data provided by polydeoxygenated congeners. The syntheses of several 6a-substituted derivatives of **1** are reported in a separate communication (13). It is demonstrated that major changes in the structural features that are not directly involved in the binding reaction may be made without causing substantial change in the thermodynamic stability of the complex although major but compensating changes occur for the changes in enthalpy and entropy.

Discussion

A. Synthesis

Scheme 1 outlines the synthesis leading to the H-type 2 derivative (**13**) that has the NHAc-2a, OH-3a, OH-6a, and CH_2OH-6b groups of the H-type 2 trisaccharide (**1**) replaced by hydrogen. To synthesize the starting alcohol (**6**), the enopyranoside (**2**) (14, 15) was hydrogenated in the presence of 5% palladium-on-carbon and triethylamine (16) to crystalline dideoxypyranoside (**3**) (17) in 94% yield. Oxidative cleavage of the benzylidene ring of **3** with *N*-bromosuccinimide (18) provided the 6-bromo compound **4** in 99% yield. Catalytic reduction of **4** to give **5** (98% yield) followed by debenzoylation with sodium methoxide provided the previously reported (19) trideoxy compound (**6**) as an oil in 86% yield. Glycosylation of **6** with acetobromoarabinose (**7**) (20, 21) in boiling toluene was promoted with mercuric cyanide under the conditions developed by Tanaka and co-workers (22) to provide, after deacetylation, the disaccharide (**9**) in 43% isolated yield. Protection of the 3b-

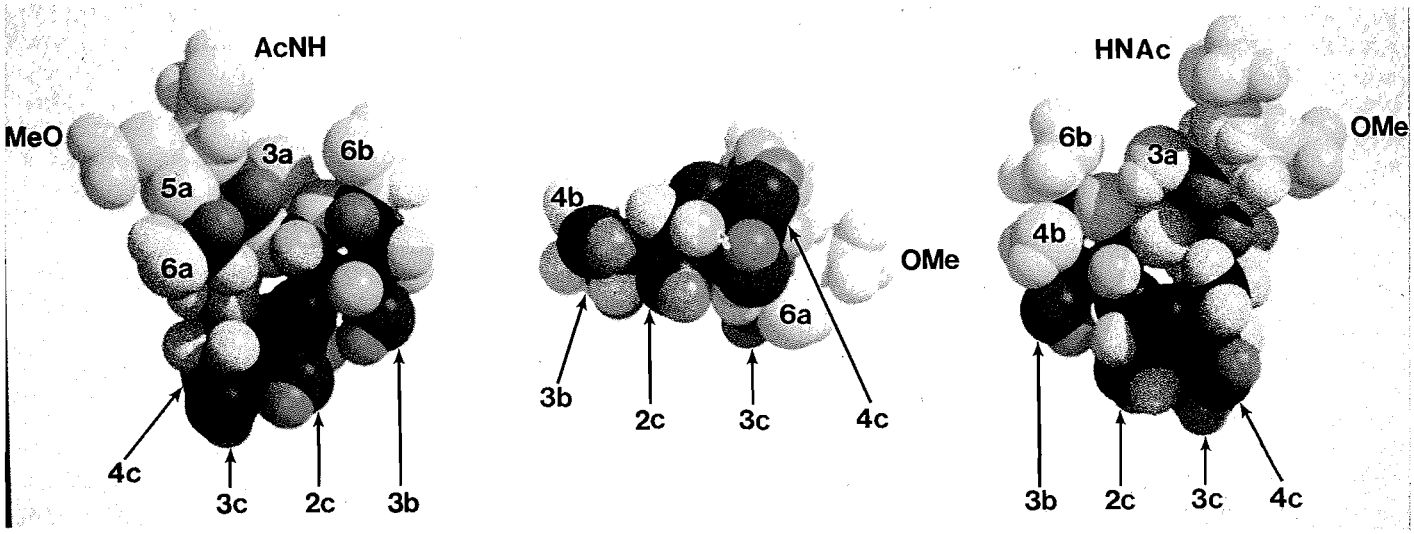


FIG. 1. CPK molecular model for H-type 2-OMe (α-L-Fuc(1c → 2b)-β-D-Gal(1b → 4a)-β-D-GlcNAc-OMe, **1**). Hydroxyl groups in the region for productive binding with the *Ulex* lectin are designated by dark red oxygen and green hydrogen atoms. The aliphatic hydrogen atoms are yellow. Oxygen atoms that come to reside in the complex at or near the periphery of the combining site are presented in light pink. Those groups which come into contact with the aqueous phase near the periphery of the combining site are presented in grey. The rest of the molecule, which is depicted in an off-white and which is derived from the GlcNAc residue, remains in the aqueous phase. The various projections allow an appreciation of the "polyamphiphilic" surface that becomes bound within the stereoelectronically complementary cleft that forms the combining site.

and 4b-positions of **9** was then achieved by benzylidenation with α,α-dimethoxytoluene in the presence of *p*-toluenesulfonic acid (23). The crystalline alcohol (**10**) was obtained in 63% yield and reacted, under halide-ion catalyzed conditions (24), with tri-*O*-benzyl-L-fucosyl bromide (**11**) prepared as previously reported (25). The trisaccharide derivative (**12**) was isolated in 81% yield and hydrogenolyzed over 5% palladium-on-carbon to provide crystalline **13** in 87% yield. The identities and high purities of the above products were all confirmed by appropriate nmr studies. The ^{1}H and ^{13}C nmr data for the H-type 2 related compounds are reported in Tables 1 and 2.

To examine the involvement of the aglyconic MeO-1a group in the binding of **13**, structure **20** was synthesized as described in Scheme 2. The starting alcohol (**14**) was prepared as previously reported (26). Glycosylation of **14** with acetobromoarabinose (**7**) under Helferich conditions produced **15**, which on deacetylation provided the β-linked disaccharide (**16**) in 54% yield. Reaction of **16** with 2,2-dimethoxypropane in the presence of *p*-toluenesulfonic acid led to the alcohol (**17**) (91% yield), which in turn was reacted with **11** under halide-ion catalyzed conditions. Chromatographic separation of the reaction products provided, besides the fully protected trisaccharide **18** (44% yield), the de-*O*-isopropylidinated derivative (**19**) (43% yield). Mild acid hydrolysis of **18** in aqueous acetic acid yielded **19**, which was hydrogenolyzed to the crystalline trisaccharide (**20**) in near quantitative yield.

The syntheses of the polydeoxygenated H-type 2 derivatives (**30** and **31**) (outlined in Scheme 3) started from the enopyranoside (**2**) (Scheme 1). Hydrogenation over 20% palladium hydroxide-on-carbon provided the known highly acid-labile product (**21**) (19), which had to be isolated in the presence of pyridine. The primary hydroxyl group of **21** was preferentially tosylated to form **22** (19) in 54% crystalline yield. The ditosylate **22***a* (19) (10%) was also isolated. Reaction of **22** with the galactosyl bromide (**23**) (27) under Helferich conditions provided the β-linked disaccharide (**24**) in 61% yield. Zemplen deacetylation of **24** furnished the alcohol (**25**) (90% yield) from which the trisaccharide (**26**) was prepared by using **11** under halide-ion catalysis (65% yield). Compound **26** was converted into the benzoate (**27**) by replacement of the tosylate group (68% yield). Debenzoylation with sodium methoxide then provided the alcohol (**28**) (89% yield). The tosylate (**26**) was also used to prepare the 6a-deoxy compound (**29**) (75% yield) by reduction with

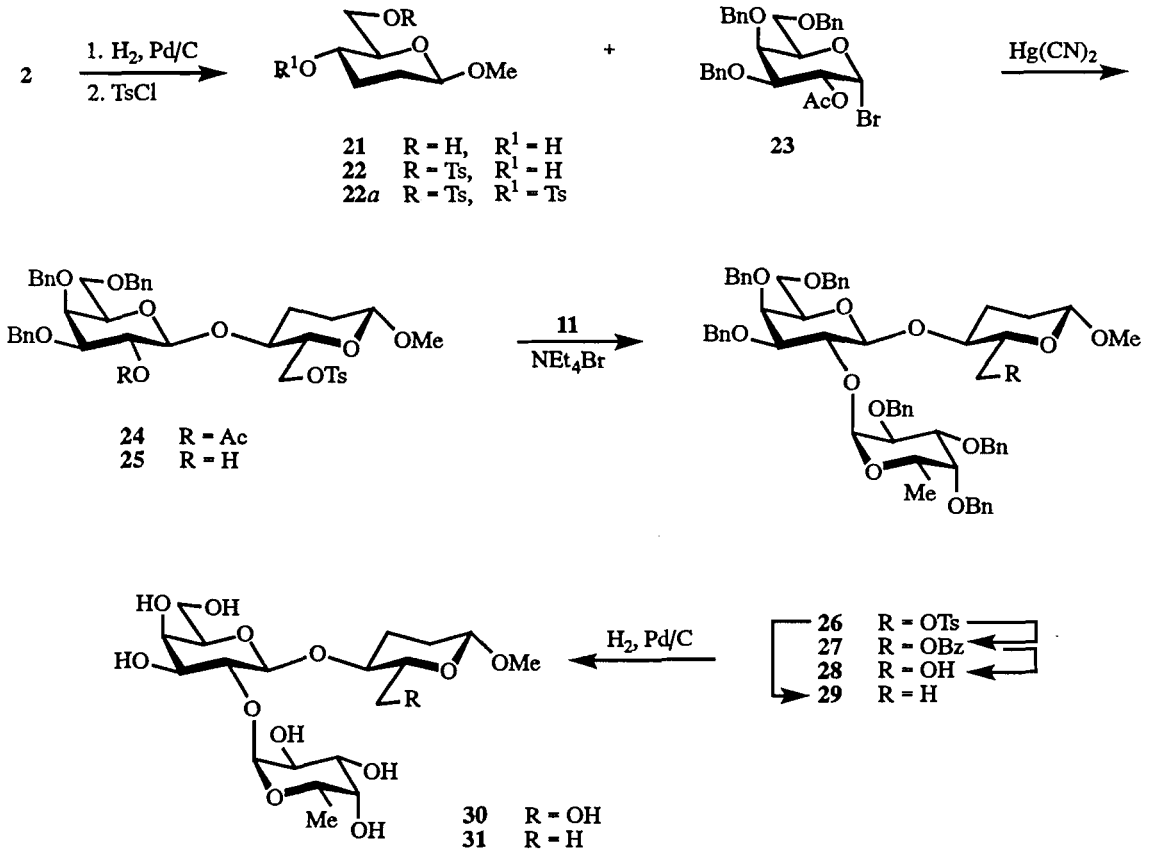

SCHEME 3

lithium aluminium hydride in refluxing tetrahydrofuran (28). Hydrogenolysis of **28** and **29** to remove the benzyl groups then furnished the trisaccharides **30** and **31**. The ^1H and ^{13}C nmr spectra are in complete agreement with the structural assignments (Tables 1 and 2).

The *pseudo*-trisaccharides **50** and **51** (Scheme 5) were prepared starting with racemic (1,5/4)-1-*O*-methyl-5-*C*-hydroxymethyl-1,4-cyclohexanediol (**37**) (Scheme 4), which was synthesized as follows. The known bicyclo carboxylic acid (**32**) (29) was obtained by catalytic hydrogenation of the Diels–Alder adduct of furan and acrylic acid (30). Acetolysis (31) of **32** occurred with about 80% regioselectivity at the 4-position to produce the all-equatorial cyclohexane derivative **33**. However, **33** was isolated by crystallization in only 35% yield. The structural assignment followed from the downfield shifts of the H-2 and H-5 signals and the large coupling constants for $J_{1,2}$, $J_{2,3ax}$, $J_{5,4ax}$, and $J_{5,6ax}$. Reduction with diborane–tetrahydrofuran complex (32) provided the triol (**34**), which was converted directly into the crystalline benzylidene derivative **35** (85%) with α,α-dimethoxytoluene in the presence of *p*-toluenesulfonic acid. The *O*-methyl derivative (**36**) (84% yield) was hydrogenolyzed to the diol

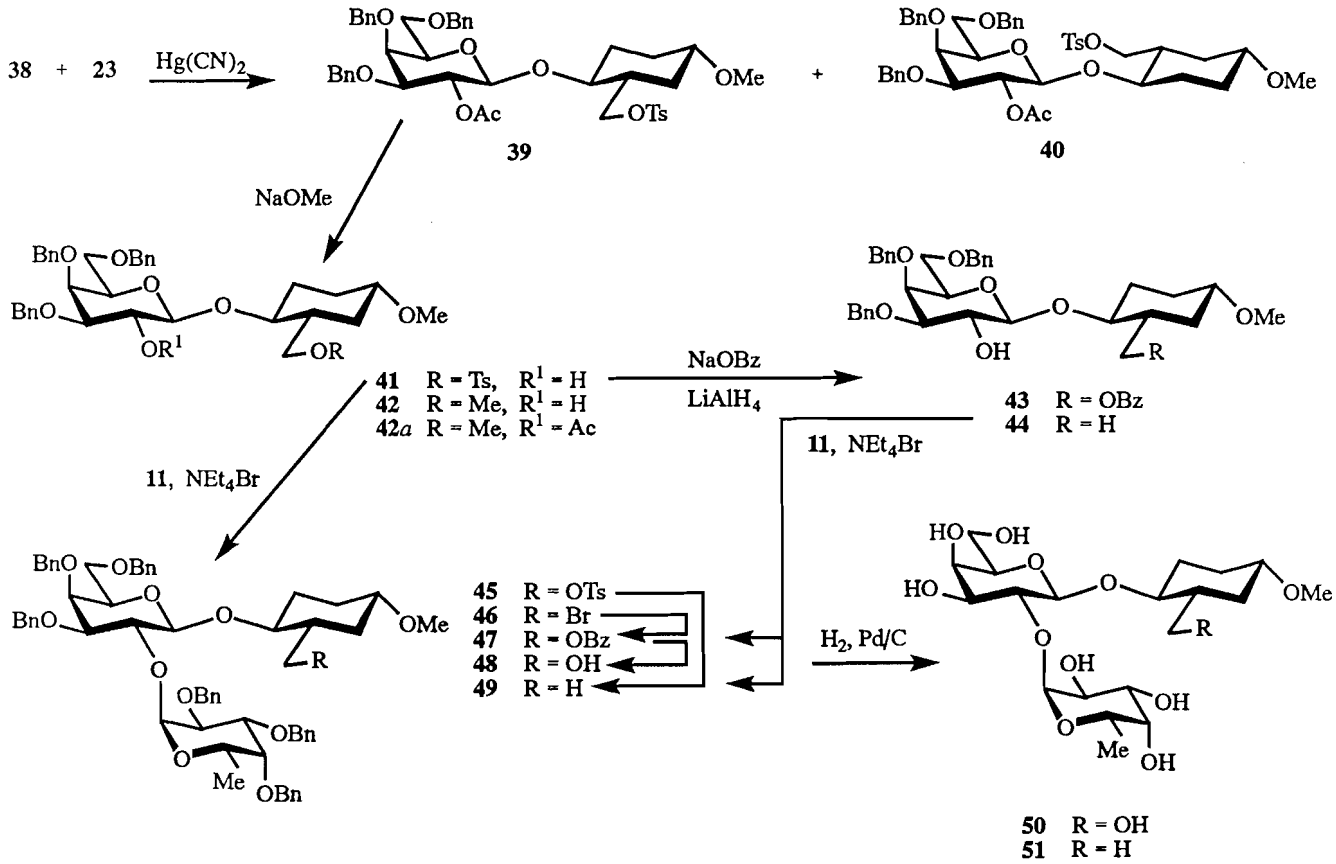
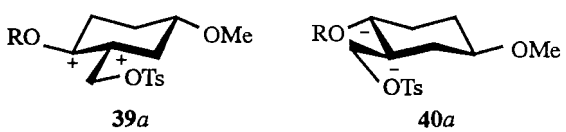


SCHEME 5

(**37**) (99% yield). Monotosylation of **37** provided both the mono- and ditosylates (**38** and **38***a*, respectively) in 72 and 16% yields, respectively.

As outlined in Scheme 5, the racemic tosylate (**38**) was coupled with galactosyl bromide (**23**) under Helferich conditions at room temperature. The two diastereoisomeric disaccharides (**39** and **40**) were separated by chromatography in yields of 22 and 18%, respectively. Their absolute configurations were anticipated from their optical rotations. The aglycon assigned to **39** is expected to reside largely in the conformation depicted by **39***a* wherein the tosyloxy group defines a positive screw pattern of asymmetry with CH_2-6 and, similarly, CH_2-7 with O-4. For the diastereoisomer **40**, these torsion angles are negative, as displayed in **40***a*. Therefore, following the notions introduced by Whiffen (33) and elaborated by Brewster (34) it could be expected that the aglycon of **39** would make a positive contribution to its molecular rotation ($[M]_D = +162°$) and that the molecular rotation would be more negative for **40**, that is, the isomer with $[M]_D = +63°$. Consequently, **39** was chosen for the preparation of the H-type 2 congeners **50** and **51**. Indeed, these products possessed activities for the inhibition of the binding of the H-type 2 trisaccharide compatible with expectation (Table 3).



39*a* **40***a*

R = 2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranosyl

Deacetylation of **39** with sodium methoxide provided the alcohol (**41**) in 62% yield. Some replacement of the tosyl group by methoxide occurred and gave rise to the 7a-O-methyl compound (**42**) (15%), which was also characterized as its 2-O-acetate (**42***a*). This replacement was not observed when the O-5a analog (**24**) (Scheme 3), which has a more electronegative neighboring group, was deacetylated under similar conditions.

Reaction of **41** with **11** in the presence of bromide ion provided the trisaccharide (**45**) in only 20% yield. The main reaction product (52% yield) was identified as the 7a-bromo-7a-deoxy substitution product (**46**). Its structural assignment followed from the upfield shift of C-7a in the ^{13}C nmr spectrum. In contrast, the similar fucosylation of the O-5a analog **25** produced only ~4% yield of the bromo substitution product. The tosylate (**45**) was reduced with lithium aluminium hydride to produce the 7a-deoxy derivative **49** in 53% yield. The 6-O-benzoate (**47**) was obtained in 66% yield by reaction of the bromide (**46**) with sodium benzoate. De-*O*-benzoylation then provided the alcohol **48**. An alternate route to **48** involved replacing the tosyloxy group of **41** by benzoate to form **43** in 65% yield. Compound **43** was used to prepare the trisaccharide (**47**) (64% yield) in the usual way. Reduction of **41** with lithium aluminium hydride provided the 7a-deoxy compound **44**, which was converted to the trisaccharide (**49**) (65% yield). Hydrogenolysis of **48** and **49** provided the target compounds **50** and **51**.

B. Structural and conformational assignments

The ^1H and ^{13}C nmr parameters for H-type 2-OMe (**1**) and the various modified structures are reported in Tables 1 and

2. These are considered to be in full agreement with the structural assignments.

The conformational preference with minimum energy at ϕ/ψ = 50°/15°, and 55°/0° about the glycosidic linkages α-L-Fuc(1 → 2) and β-D-Gal(1 → 4) of the H-type 2 trisaccharide, provided by HSEA calculations (35) is supported by ^1H and ^{13}C nmr data (11). The minimum energy conformer places H-1c of the α-L-Fuc c-unit in near van der Waals contact with O-3b of the β-D-Gal b-unit, and this conformational preference is supported by the interunit deshielding of H-1c by 0.54 ppm (Table 1) relative to α-L-Fuc-OMe (35). Examination of the chemical shifts reported in Table 1 for H-1c of the various derivatives of **1** shows that this interunit deshielding occurs for compounds **30**, **31**, **50**, and **51** and is only slightly less for the L-arabino derivatives **13** and **20**. Therefore, the orientation of the α-L-Fuc c-unit with respect to the β-D-Gal b-unit appears to be essentially the same for all these H-type 2 congeners. The H-5c of **1** is deshielded 0.19 ppm relative to H-5 of α-L-Fuc-OMe and this has been attributed to its proximity to O-4a (35). This interunit deshielding is slightly higher for derivatives **13**, **20**, **30**, **31**, and **50** and even higher (0.37 ppm) for pseudo oligosaccharide **51**. Therefore, it appears that the conformational preferences about the interglycosidic linkages of H-type 2-OMe (**1**) are essentially preserved and the immunochemical data will be interpreted accordingly.

C. Immunochemical studies

The inhibitions by the H-type 2-OMe compound and the various congeners of the binding of a ^{125}I-labelled H-type 2-bovine-serum-albumin artifical antigen by either the lectin or the antibody were determined using a solid phase, competitive radioimmunoassay, which has been reported in detail (2). Whenever possible, 50% inhibitions were determined in order to establish the relative potencies. Although the discussion of the results will be in terms of the effects of structural changes on relative potency, the differential changes in free energy, calculated from the relative potencies, are included in Table 3 to indicate the change in the strength of the driving force for the complexation relative to that of the reference inhibitor (**1**).

It is known that the binding of the H-type 2 structure by

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12

For personal use only.

the *Ulex* lectin is unaffected by replacement of the acetamido group (R^1 in Table 3) either by a hydroxyl or an amino group (11). As seen in Table 3, replacement of OH-3a of **1** by hydrogen to provide **52** leads to a 54% loss in potency. Therefore, the low potency of 25 found for compound **30** can be attributed, in large part, to the deoxygenation at position 3a.

The 6a-deoxy derivative of **1** (**53**) was found to be 2.5 times more potent than **1**. Therefore, it may have been expected that the 6a-deoxy derivative of **30** (**31**) would be about 2.5 times more potent an inhibitor than **30**. Indeed, **31** was found to be 2.7 times more potent than **30**. Remarkably, the 6a-deoxy derivative of **50** (**51**), wherein the a-unit is a *pseudo*-sugar, is also 2.5 times more potent than **50**. That changes at the 2a and 3a positions do not influence the effect of changes at the 6a position is not necessarily surprising since these reside on opposite sides of the pyranose ring.

It was suggested (11, 12) that the increase in the strength of the binding of about 0.5 kcal/mol, which results from the deoxygenation of position 6a of **1**, is related to a requirement for the CH_2OH-6a group to penetrate a hydrophobic region of the combining site for the complex to form. On this basis, it seemed reasonable to expect that OH-6a would become intramolecularly hydrogen-bonded to the vicinal O-5a. A very similar situation was discovered for the CH_2OH-6b group of the Le^b-OMe tetrasaccharide when bound by the lectin IV of *Griffonia simplicifolia* (GS-IV) (2). In this case, deoxygenation led to a slight (31%) decrease in potency. However, the 6b-chloro-6b-deoxy-Le^b-OMe was 1.9 times more potent (36), thereby suggesting that, on being bound, the CH_2OH-6b group penetrates a hydrophobic region. Indeed, the X-ray crystal structure has now shown the CH_2OH-6b to be in van der Waals contact with the indolyl group of the tryptophane-133 unit (9). An accompanying publication (37) provides unequivocal evidence that, in fact, OH-6b remains in contact with the aqueous phase on complex formation. Nevertheless, it is important to note that, as previously pointed out (36), improved binding resulting from the deoxygenation of a hydroxyl group is observed only when the hydroxyl group is sterically well disposed for intramolecular hydrogen bonding with a nearby proton-accepting atom. It seems likely, therefore, as was found for the GS-IV complex, that these hydroxyl groups occur near hydrophobic groups of the protein. Thus, under thermal agitation, the formation of the intramolecular bond may lead to as favorable a contribution to the stability of the complex as when the interaction is with a water molecule. Presumably, the intramolecular hydrogen bonding effect would be most extensively imposed when the hydroxyl group must become engulfed within the combining site.

The data presented in Table 3 show that, in fact, intramolecular hydrogen bonding is not required for the binding of the CH_2OH-6a group of **1** by the *Ulex* lectin. First of all, replacement of the ring oxygen (O-5a) of **30** by a methylene group to provide **50** has negligible effect on the potency. Therefore, O-5a of **1** does not participate directly in the binding reaction with the *Ulex* lectin and, certainly, the intramolecular hydrogen-bond hypothesis does not apply. That OH-6a remains in the aqueous phase is further indicated by the high potency of the 6a-*O*-methyl derivative **56** (37). On the other hand, the replacement of OH-6a by groups such as amino (**57**), ammonium (**58**), and acetamido (**59**), which strongly interact with water, importantly reduced the potency. These results indicate that, in the complex, although the OH-6a group remains hydrogen-bonded to water, it resides near protein structure. This latter conclusion is supported by the low potency of the pivalamide (**60**) as compared to the acetamide (**59**). In the case of Le^b-OMe, the CH_2-6b group interacts with the indolyl group of a tryptophane unit of the *Griffonia* lectin and proved essential to binding (36). Likely, therefore, the *Ulex* lectin comes into nonbonded nonpolar interaction with the CH_2-6a group of the β-D-GlcNAc unit. This conclusion is supported by the inhibition data observed for compounds **53**–**55** since, as seen in Table 3, the replacement of the OH-6a of **1** by either a fluorine or a chlorine atom importantly enhances the stability of the complex (0.90 and 0.75 kcal/mol, respectively).

It was previously established (12) that OH-3b provides part of the key polar interaction for the binding of **1** by the *Ulex* lectin. Therefore, in the complex, the neighboring *cis*-OH-4b must be in close proximity to the combining site if not actually in a direct interaction with the protein at the periphery of the combining site. Indeed, substitution of OH-4b by hydrogen to yield **61** reduced the potency to 37% of that of **1**. In the event that the involvement of OH-4b is at or near the periphery, CH_2OH-6b would not likely be importantly involved since it is even more remote from the combining site. The replacement of OH-6b by hydrogen to form **62** in fact caused only a weak loss in potency. Also, the replacement of the CH_2OH-6b group of **31** by hydrogen to form **13** had no significant effect on potency.

As mentioned above, the CH_2OH-6a group of **1** must be at the periphery of the combining site. Therefore, the protein structure on complex formation comes close to the aglyconic R group (Table 3). This is consistent with the observation that **63** is more potent than **1** and that **13** is more potent than **20**.

How structure **1** is bound by the *Ulex* lectin is depicted in Fig. 1. Since peripheral interactions are relatively weak, it was possible to establish the effects of some of the structural changes in this region on the thermodynamic parameters. These are presented in Fig. 2 where it is seen that, as found for the binding of Le^b-OMe by GS-IV (2, 9), structural changes near the periphery of the combining site have only a minor effect on the change in free energy as compared to the major but near-compensating changes in the enthalpy and entropy. This enthalpy–entropy compensation phenomenon appears related to changes in the structure of the water about the periphery of the combining site (9). It is especially remarkable that the compensation extended to include compound **13**.

The same conclusion was reached by Belleau and Lavoie (38, 39) over 20 years ago in a study of the thermodynamic parameters for the binding of acetylcholine by acetylcholinesterase. A wide range of congeners were prepared, varying only in the structure of the 2-acetoxyethyl group of acetylcholine. As presently found for congeners of H-type 2-OMe and previously reported for derivatives of Le^b-OMe (9), the various structural analogs of acetylcholine that remained *productive* as inhibitors were bound with little differential change in free energy but with a high degree of compensation for the relatively high changes in enthalpy and entropy. It was concluded (38) that in all cases the binding was essentially restricted to the recognition of the trimethylammonium group and that the driving force was derived from the disordering (melting) of water molecules *within* the

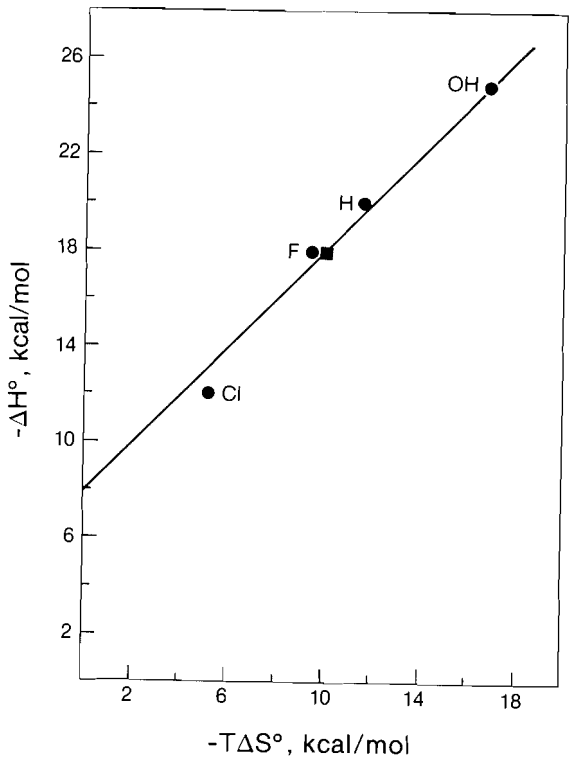

FIG. 2. The effect on the thermodynamic parameters at 298 K for the binding of H-type 2-OMe (**1**) by the lectin I of *Ulex europaeus* of changing the substituent at the 6a-position of the β-D-GlcNAc unit from OH (**1**) to H (**53**), to F (**54**), and to Cl (**55**). The data presented by a square are those for compound **13**, a structure that corresponds to **53** with the NHAc-2a, OH-3a, and CH_2OH-6b groups replaced by hydrogen atoms. The slope of 1 provided by the plot demonstrates the enthalpy–entropy compensation.

combining site. Since stereoelectronic complementarity was found to be the controlling parameter, it was further concluded that productive bindings depend uniquely on specific interactions within the combining site. On this basis, the enthalpy–entropy compensation phenomenon was attributed to changes in the peripheral involvements of water molecules.

The inhibition data presented in Table 3 show that wide variations in the structural features of H-type 2-OMe can be made without causing differential changes in free energy ($\Delta\Delta G^0$) that are greater than 1 kcal/mol. This has been found only when the changes do not involve the key polar grouping and its immediate surrounding. In view of data presented in Fig. 2, these small changes likely result from relatively large but compensating changes in enthalpy and entropy.

In contrast to the positively charged trimethylammonium ion of acetylcholine, the productive surface presented by H-type 2-OMe, as can be appreciated from Fig. 1 (center), is "polyamphiphilic" in the sense that it is made up of a variety of small amphiphilic parts. This surface, together with the stereoelectronically complementary combining site of the lectin, is hydrated prior to complex formation and these water molecules become replaced by the complementary ligand–protein structures, whereas the water molecules at the periphery achieve different states of organization (9). Thus, whereas the latter condition, being related to water only, can be expected to provide an enthalpy–entropy compensation, the productive binding within the combining site is expected to lead to a one-way release of water molecules to bulk.

In an attempt to assess the role of water in these binding reactions, Monte Carlo simulations were made of the hydration of the amphiphilic Le^b-OMe tetrasaccharide (40). It was concluded that the hydration of a polyamphiphilic surface leads to a host of water molecules that are less ordered and less strongly bound than in bulk water. In contrast, the steric constraints for binding water molecules to strongly polar groups within the potential combining site may immobilize water molecules to a greater extent than is present in the bulk condition. If so, the increase in entropy that would result from their release to bulk would contribute to the driving force for complexation. Indeed, Delbaere and Brayer (41) were able to locate water molecules within the active site of native *Streptomyces griseus* protease A. It was noted that this network of "immobilized" solvent molecules resembles the placement of the inhibitor in the complex with chymostatin. The proposed increase in entropy from the release to bulk of strongly bound water molecules from within the combining site would provide compensation for the demands in entropy required for specific organization and immobilization of the reacting species. Monte Carlo simulations of the hydration of the combining site of GS-IV and of its complex with Le^b-OMe may provide a useful test of this proposal and are being pursued.

In the course of this investigation, a monoclonal anti H-type 2 antibody became available and the relative potencies for its binding of H-type 2-OMe (**1**) and several of its congeners are reported in Table 4 where a comparison is made with those found for the *Ulex* lectin. It is readily appreciated that the two proteins recognize very similar regions of the trisaccharide and, therefore, regions about the key polar grouping presented in Fig. 1. It is seen that the 2c-deoxy derivative **66** (R^7 = H) is slightly more strongly bound by the lectin but that the reverse is strongly the case for the 4c-deoxy **68** (R^9 = H) compound. The high relative potency of this compound in inhibiting the antibody indicates that OH-4c is not part of the key polar grouping. The low potencies found for 3b-deoxy **65** (R^4 = H) are very similar and suggest involvement in both cases of OH-3b in a relatively strong polar interaction. The only other significant difference in the affinities is for the Y tetrasaccharide (**64**). In the case of the lectin, the introduction of the fucose unit at the 3a-position of **1** caused a slight decrease in potency relative to the 3a-deoxy compound (**52**, Table 3) (26 vs. 46). On the other hand, the introduction of the second fucose unit provided superior binding by the antibody. This result may arise from this fucose residue providing some additional attractive interactions at the periphery of the antibody combining site. The higher potencies displayed by **63** (R = $(CH_2)_8CO_2Me$) likely have a similar origin. The results presented in Table 4 indicate that the key polar grouping for the binding of the H-type 2 determinant by the *Ulex* lectin was the immunodominant surface of this antigenic determinant in the immune response that led to the production of the monoclonal antibody.

Experimental

Methods

The radioimmunoassays were performed following the procedure recently described (2) using an ^{125}I-labelled [α-L-Fuc-(1→

2)-β-D-Gal-(1→4)-β-D-GlcNAcO-$(CH_2)_8CONH]_{16}$-BSA antigen provided by Chembiomed Ltd., Edmonton, Alberta. The solution provided near 290 000 cpm/100 μL. In the absence of inhibitor, the coated tubes acquired about 40–50% of these counts in the case of the antibody and about 63–78% in the case of the lectin. The monoclonal anti-H-type 2 antibody (IgM, clone 92 FR A2) was available from Chembiomed Ltd. The lectin 1 of *Ulex europaeus* was purchased from Sigma Chemical Company.

The thermodynamic parameters presented in Fig. 2 were determined by difference ultraviolet absorption spectroscopy as previously described (2).

The ^1H nmr spectra were measured at 300, 360, and 400 MHz (Bruker AM300, WM360, and WH400) with tetramethylsilane as internal standard for $CDCl_3$ solutions. The reference standard for D_2O solutioins was acetone (2.225 ppm). The ^{13}C nmr spectra were recorded at 100 and 75 MHz using as a solvent either $CDCl_3$ (77.06 ppm) or D_2O with 1,4-dioxane (67.4 ppm) as internal standard. Optical rotations were measured at room temperature (23 ± 1°C) in a 1-dm cell on a Perkin–Elmer 241 polarimeter. Thin-layer chromatograms were performed on precoated plates of silica gel (60F254, E. Merck, Darmstadt) and visualized by spraying with 10% sulfuric acid in ethanol followed by heating. For column chromatography, silica gel 60 (230–400 mesh, E. Merck, Darmstadt) and distilled solvents were used. Solvents and reagents were purified and dried according to standard procedures. Melting points are uncorrected.

Methyl 4,6-O-benzylidene-2,3-dideoxy-β-D-erythro-*hexopyranoside (3)*

Methyl 4,6-*O*-benzylidene-β-D-*erythro*-hex-2-enopyranoside **2** (14) (1.68 g, 6.77 mmol) was hydrogenated in the presence of 5% palladium-on-carbon (0.85 g) in methanol (85 mL) containing 17 mL of triethylamine at 50 psi (1 psi = 6.89 kPa). Filtration and evaporation left a syrup, which was partitioned between benzene and water. The benzene layer was dried and evaporated to give crystalline **3** (1.59 g, 94%); mp 104–105°C, $[\alpha]_D$ −57 (*c* 0.6, chloroform) (lit. (14) mp 106–107°C; $[\alpha]_D$ −58.8 (*c* 2.55, chloroform)); ^1H nmr ($CDCl_3$) δ: 7.51–7.33 (m, 5H,Ph), 5.56 (s, 1H, PhC*H*), 4.51 (dd, 1H, $J_{1,2ax}$ 9.5 Hz, $J_{1,2eq}$ 2.4 Hz, H-1), 4.30 (dd, 1H, $J_{5,6eq}$ 5.0 Hz, $J_{6ax,6eq}$ 10.4 Hz, H-6eq), 3.80 (t, 1H, $J_{5,6ax}$ 10.0 Hz, H-6ax), 3.57 (ddd, 1H, $J_{3ax,4}$ 10.8 Hz, $J_{3eq,4}$ 4.5 Hz, $J_{4,5}$ 9.2 Hz, H-4), 3.53 (s, 3H, OCH_3), 3.45 (ddd, 1H, H-5), 2.15 (dt, 1H, $J_{2ax,3eq}$ 4.2 Hz, $J_{2eq,3eq}$ < 1.0 Hz, $J_{3ax,3eq}$ 12.0 Hz, H-3eq), 2.02 (ddd, 1H, $J_{2ax,2eq}$ 12.6 Hz, $J_{2eq,3ax}$ 3.5 Hz, H-2eq), 1.76 (dddd, 1H, $J_{2ax,3ax}$ 13.1 Hz, H-3ax), 1.68 (dddd, 1H, H-2ax). Anal. calcd. for $C_{14}H_{18}O_4$: C 67.18, H 7.25; found: C 66.71, H 6.99.

Methyl 4-O-benzoyl-6-bromo-2,3,6-trideoxy-β-D-erythro-*hexopyranoside (4)*

A mixture of compound **3** (1.59 g, 6.36 mmol), *N*-bromosuccinimide (1.38 g, 7.63 mmol), and barium carbonate (1.90 g, 9.54 mmol) in carbon tetrachloride (48 mL) (18) was boiled under reflux for 30 min. The solvent was evaporated and the remainder dissolved in dichloromethane (200 mL). The solution was washed with aqueous sodium bicarbonate and water, followed by drying and evaporation, to leave a crystalline residue (2.08 g, 99%) that was crystallized from a small quantity of methanol to yield pure **4**; mp 107–108°C, $[\alpha]_D$ +12 (*c* 0.8, chloroform); ^1H nmr ($CDCl_3$) δ: 8.05–7.44 (m, 5H, Ph), 4.92 (ddd, 1H, $J_{3ax,4}$ 9.7 Hz, $J_{3eq,4}$ 4.8 Hz, $J_{4,5}$ 8.7 Hz, H-4), 4.54 (dd, 1H, $J_{1,2ax}$ 8.4 Hz, $J_{1,2eq}$ 2.4 Hz, H-1), 3.87 (ddd, 1H, $J_{5,6A}$ 3.2 Hz, $J_{5,6B}$ 7.8 Hz, H-5), 3.63 (dd, 1H, $J_{6A,6B}$ 10.8, H-6A), 3.57 (s, 3H, OCH_3), 3.50 (dd, 1H, H-6B), 2.37 (dddd, 1H, $J_{2eq,3eq}$ 1.0 Hz, $J_{2ax,3eq}$ 3.4 Hz, $J_{3ax,3eq}$ 11.6 Hz, H-3eq), 2.01 (dddd, 1H, $J_{2ax,2eq}$ 12.0 Hz, $J_{2eq,3ax}$ 3.9 Hz, H-2eq), 1.76 (dddd,

$J_{2ax,3ax}$ 12.8 Hz, H-2ax), 1.70 (dddd, 1H, H-3ax). Anal. calcd. for $C_{14}H_{17}BrO_4$: C 51.08, H 5.21, Br 24.27; found: C 51.23, H 5.15, Br 24.62.

Methyl 4-O-benzoyl-2,3,6-trideoxy-β-D-erythro-*hexopyranoside (5)*

The bromo compound **4** (1.35 g, 4.10 mmol) was hydrogenated in the presence of 5% palladium-on-carbon (0.70 g) in methanol (100 mL) containing triethylamine (0.70 mL, 4.92 mmol) at 80 psi for 8 h. Filtration and evaporation left a syrup, which was dissolved in dichloromethane (50 mL). Washing with water and evaporation gave a syrupy product **5** (1.01 g, 98%); $[\alpha]_D$ +7 (*c* 0.8, chloroform); ^{1}H nmr ($CDCl_3$) δ: 8.04–7.44 (m, 5H, Ph), 4.72 (ddd, 1H, $J_{3ax,4}$ 10.3 Hz, $J_{3eq,4}$ 4.9 Hz, $J_{4,5}$ 9.0 Hz, H-4), 4.47 (dd, 1H, $J_{1,2a}$ 8.8 Hz, $J_{1,2eq}$ 2.2 Hz, H-1), 3.71 (dq, 1H, $J_{5,6}$ 6.3 Hz, H-5), 3.53 (s, 3H, OCH_3), 2.32 (dddd, 1H, $J_{2ax,3eq}$ 4.0 Hz, $J_{2eq,3eq}$ 1.5 Hz, $J_{3ax,3eq}$ 12.5 Hz, H-3eq), 1.98 (dddd, 1H, $J_{2eq,3ax}$ 3.9 Hz, $J_{2ax,2eq}$ 12.4 Hz, H-2eq), 1.74 (dddd, 1H, $J_{2ax,3ax}$ 13.1 Hz, H-2ax), 1.64 (dddd, 1H, H-3ax), 1.31 (d, 3H, 3H-6). Anal. calcd. for $C_{14}H_{18}O_4$: C 67.18, H 7.25; found: C 67.13, H 7.23.

Methyl 2,3,6-trideoxy-β-D-erythro-*hexopyranoside (6)*

Compound **6** (1.0 g, 4.0 mmol) was debenzoylated in the usual manner using methanolic sodium methoxide. After evaporation, the crude material was purified by chromatography on a column of silica gel (dichloromethane-10% methanol) to provide **6** (0.52 g, 89%) as an oil; $[\alpha]_D$ −50 (*c* 0.5, water) (lit. (19) $[\alpha]_D$ −21.9 (*c* 0.82, chloroform)); ^{1}H nmr ($CDCl_3$) δ: 4.38 (dd, 1H, $J_{1,2ax}$ 9.2 Hz, $J_{1,2eq}$ 2.2 Hz, H-1), 3.52 (s, 3H, OCH_3), 3.32 (dq, 1H, $J_{4,5}$ 8.5 Hz, $J_{5,6}$ 6.1 Hz, H-5), 3.29 (ddd, 1H, $J_{3ax,4}$ 10.6 Hz, $J_{3eq,4}$ 3.7 Hz, H-4), 2.08 (dddd, 1H, $J_{2ax,3eq}$ 4.1 Hz, $J_{2eq,3eq}$ 2.0 Hz, $J_{3ax,3eq}$ 12.3 Hz, H-3eq), 1.90 (dddd, 1H, $J_{2ax,2eq}$ 12.9 Hz, $J_{2eq,3ax}$ 4.0 Hz, H-2eq), ~1.60 (br, 1H, OH), 1.59 (dddd, 1H, $J_{2ax,3ax}$ 13.3 Hz, H-2ax), 1.49 (dddd, 1H, H-3ax), 1.36 (d, 3H, 3H-6).

*Methyl 4-O-(*α-L-*arabinopyranosyl)-2,3,6-trideoxy*-β-D-erythro-*hexopyranoside (9)*

A mixture of **6** (185 mg, 1.26 mmol), mercuric cyanide (446 mg, 1.76 mmol) and 2,3,4-tri-*O*-acetyl-β-L-arabinopyranosyl bromide (1.76 mmol) (20, 21) in dry toluene (18 mL) was kept under reflux for 2 h. Filtration and evaporation left a syrup, which was deacetylated with 5% potassium hydroxide in methanol (13 mL) for 30 min at room temperature. The precipitate was filtered off and the filtrate was treated with Amberlite MB-3, followed by filtration and evaporation of the solvent. Column chromatography on silica gel eluting with a gradient solvent system of dichloromethane and methanol gave syrupy **9** (151 mg, 43%); $[\alpha]_D$ +7 (*c* 1.0, water); ^{1}H nmr (D_2O) δ: 4.56 (dd, 1H, $J_{1a,2aax}$ 9.2 Hz, $J_{1a,2aeq}$ 2.2 Hz, H-1a), 4.44 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 3.94 (ddd, 1H, $J_{3b,4b}$ 3.7 Hz, $J_{4b,5bax}$ 1.2 Hz, $J_{4b,5beq}$ 2.1 Hz, H-4b), 3.89 (dd, 1H, $J_{5bax,5beq}$ 13.1 Hz, H-5beq), 3.65 (dd, 1H, H-5bax), 3.65 (dd, 1H, H-3b), 3.59 (dq, 1H, $J_{4a,5a}$ 9.0 Hz, $J_{5a,6a}$ 6.3 Hz, H-5a), 3.51 (dd, 1H, $J_{2b,3b}$ 9.6 Hz, H-2b), 3.48 (s, 3H, OCH_3), 3.40 (ddd, 1H, $J_{3aax,4a}$ 10.2 Hz, $J_{3aeq,4a}$ 3.8 Hz, H-4a), 2.20 (dddd, 1H, $J_{2aax,3aeq}$ 4.0 Hz, $J_{2aeq,3aeq}$ 3.3 Hz, $J_{3aax,3aeq}$ 12.6 Hz, H-3aeq), 1.93 (dddd, 1H, $J_{2aax,2aeq}$ 12.8 Hz, $J_{2aeq,3aax}$ 3.8 Hz, H-2aeq), 1.63 (dddd, 1H, $J_{2aax,3aax}$ 13.1 Hz, H-3aax), 1.50 (dddd, 1H, H-2aax), 1.33 (d, 3H, 3H-6a); ^{13}C nmr (D_2O) δ: 104.95 (C-1b), 103.29 (C-1a), 81.17 (C-4a), 75.22 (C-5a), 73.08 (C-3b), 71.76 (C-2b), 69.01 (C-4b), 66.84 (C-5b), 56.93 (CH_3O), 30.37, 29.47 (C-2a, C-3a), 18.02 (C-6a). Anal. calcd. for $C_{12}H_{22}O_7$: C 51.79, H 7.97; found: C 51.09, H 7.87.

*Methyl 4-O-(3,4-O-benzylidene-*α-L-*arabinopyranosyl)-2,3,6-trideoxy*-β-D-erythro-*hexopyranoside (10)*

A mixture of **9** (136 mg, 0.49 mmol), α,α-dimethoxytoluene (0.38 mL), *p*-toluenesulfonic acid monohydrate (5 mg), and *N,N*-dimethylformamide (1.1 mL) was heated at 50°C for 20 min. Neutralization with sodium methoxide, followed by evaporation, left a syrup, which was chromatographed on a column of silica gel (dichloromethane–ethyl acetate, 7:1) to give crystalline **10** (113 mg, 63%); mp 128–129°C, $[\alpha]_D$ −4 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.56–7.38 (m, 5H, Ph), 5.97 (s, 1H, *CH*Ph), 4.39 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.38 (dd, 1H, $J_{1a,2aax}$ 8.9 Hz, $J_{1a,2aeq}$ 2.3 Hz, H-1a), 4.34 (dt, 1H, $J_{3b,4b}$ 6.3 Hz, $J_{4b,5bax} = J_{4b,5beq}$ 3.6 Hz, H-4b), 4.29 (dd, 1H, $J_{5bax,5beq}$ 13.2 Hz, H-5eq), 4.23 (dd, 1H, $J_{2b,3b}$ 7.5 Hz, H-3b), 3.90 (dd, 1H, H-5bax), 3.72 (dt, 1H, $J_{2b,OH}$ 2.2 Hz, H-2b), 3.51 (s, 3H, OCH_3), 3.46 (dq, 1H, $J_{4a,5a}$ 8.9 Hz, $J_{5a,6a}$ 6.2 Hz, H-5a), 3.26 (ddd, 1H, $J_{3aax,4a}$ 10.4 Hz, $J_{3aeq,4a}$ 4.5 Hz, H-4a), 2.36 (d, 1H, OH), 2.22 (m, 1H, H-3aeq), 1.91 (m, 1H, H-2aeq), 1.69–1.54 (m, 2H, H-2aax and H-3aax), 1.36 (d, 3H, 3H-6a). Anal. calcd. for $C_{19}H_{26}O_7$: C 62.28, H 7.15; found: C 61.52, H 7.11.

*Methyl 4-O-[3,4-O-benzylidene-2-O-(2,3,4-tri-O-benzyl-*α-L-*fucopyranosyl)-*α-L-*arabinopyranosyl]-2,3,6-trideoxy*-β-D-erythro-*hexopyranoside (12)*

A solution of bromide **11** (0.44 mmol) in dichloromethane (0.4 mL) was added to a mixture of **10** (64 mg, 0.17 mmol), tetraethylammonium bromide (55 mg, 0.26 mmol), diisopropylethylamine (76 μL, 0.44 mmol), powdered 4 Å molecular sieves (300 mg), *N,N*-dimethylformamide (0.15 mL), and dichloromethane (0.40 mL). After stirring for 20 h at room temperature, the mixture was diluted with dichloromethane and filtered through Celite. The filtrate was washed with aqueous sodium bicarbonate and water, followed by drying and evaporation. Column chromatography of the crude product on silica gel (toluene–ethyl acetate, 50:1 to 3:1, gradient) provided syrupy **12** (109 mg, 81%), $[\alpha]_D$ −53° (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.53–7.24 (m, 20H, 4Ph), 5.88 (s, 1H, *CH*Ph), 5.50 (d, 1H, $J_{1c,2c}$ 3.7 Hz, H-1c), 4.98 and 4.68 (AB, 2H, $J_{A,B}$ 11.2 Hz, CH_2Ph), 4.88 and 4.73 (AB, 2H, J_{AB} 11.7 Hz, CH_2Ph), 4.79 and 4.75 (AB, 2H, J_{AB} 13.0 Hz, CH_2Ph), 4.58 (d, 1H, $J_{1b,2b}$ 6.8 Hz, H-1b), 4.38 (t, 1H, $J_{2b,3b} = J_{3b,4b}$ 6.8 Hz, H-3b), 4.33 (ddd, 1H, $J_{4b,5bax}$ 4.6 Hz, $J_{4b,5beq}$ 4.2 Hz, H-4b), 4.30 (dd, 1H, $J_{1a,2aax}$ 8.9 Hz, $J_{1a,2aeq}$ 2.1 Hz, H-1), 4.11 (q, 1H, $J_{4c,5c}$ < 1.0 Hz, $J_{5c,6c}$ 6.3 Hz, H-5c), 4.09 (dd, 1H, $J_{5bax,5beq}$ 13.0 Hz, H-5beq), 4.05 (dd, 1H, $J_{2c,3c}$ 10.3 Hz, H-2c), 3.93 (t, 1H, H-2b), 3.91 (dd, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.84 (dd, 1H, H-5bax), 3.62 (d, 1H, H-4c), 3.47 (s, 3H, OCH_3), 3.28 (dq, 1H, $J_{4a,5a}$ 8.9 Hz, $J_{5a,6a}$ 6.1 Hz, H-5a), 3.20 (ddd, 1H, $J_{3aax,4a}$ 10.0 Hz, $J_{3aeq,4a}$ 4.5 Hz, H-4), 2.12 (m, 1H, H-3aeq), 1.85 (m, 1H, H-2aeq), 1.58–1.45 (m, 2H, H-2aax, H-3aax), 1.22 (d, 3H, 3H-6a), 1.10 (d, 3H, 3H-6c). Anal. calcd. for $C_{46}H_{54}O_{11}$: C 70.57, H 6.95; found: C 71.03, H 7.04.

*Methyl 2,3,6-trideoxy-4-O-[2-O-(*α-L-*fucopyranosyl)-*α-L-*arabinopyranosyl]-*β-D-erythro-*hexopyranoside (13)*

Compound **12** (51 mg, 0.065 mmol) was hydrogenated in the presence of 5% palladium-on-carbon (25 mg) in 95% ethanol (2.5 mL) at 125 psi for 5 h. Filtration and evaporation left a crystalline residue that was purified by column chromatography on silica gel (dichloromethane–methanol, 5:1). Evaporation of chromatographically pure fractions gave **13** (24 mg, 87%), which was crystallized from methanol–ethyl acetate; mp 230–232°C, $[\alpha]_D$ −106 (*c* 0.5, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2. Anal. calcd. for $C_{18}H_{32}O_{11}$: C 50.94, H 7.60; found: C 50.43, H 7.64.

*4-O-(*α-L-*Arabinopyranosyl)-1,2,3,6-tetradeoxy*-D-erythro-hexopyranose *(16)*

A mixture of 1,2,3,6-tetradeoxy-D-*erythro*-hexopyranose (**14**, 232 mg, 2.0 mmol) (26), 2,3,4-tri-*O*-acetyl-β-L-arabinopyranosyl bromide (**7**, 2.8 mmol), and mercuric cyanide (700 mg, 2.8 mmol) in dry toluene (23 mL) was boiled under reflux for 2 h. After filtration and evaporation, the residue was treated with methanolic 5% potassium hydroxide (21 mL) for 30 min. Filtration, neutralization with acetic acid, and evaporation followed by column chromatography on silica gel (dichloromethane–methanol, gradient) provided crystalline **16** (266 mg, 54%) as the main product; mp 145.5–146°C, $[\alpha]_D$ +63 (*c* 0.7, water); ^{1}H nmr (D_2O) δ: 4.43 (d, 1H, $J_{1b,2b}$ 7.6 Hz, H-1b), 3.93 (ddd, 1H, $J_{3b,4b}$ 3.7 Hz, $J_{4b,5bax}$ 1.3 Hz, $J_{4b,5beq}$ 2.2 Hz, H-4b), 3.90 (dd, 1H, $J_{5bax,5beq}$ 12.8 Hz, H-5beq), 3.86 (m, 1H, H-1aeq), 3.65 (dd, 1H, H-5bax),

*1,2,3,6-Tetradeoxy-4-*O*-(3,4-*O*-isopropylidene-α-L-arabinopyranosyl)-D-*erythro*-hexopyranose (17)*

To a solution of **16** (191 mg, 0.77 mmol) in 2,2-dimethoxypropane (0.4 mL, 3.0 mmol) and *N*,*N*-dimethylformamide (1.9 mL), 5% trifluoromethanesulfonic acid in *N*,*N*-dimethylformamide (50 μL) was added. After stirring for 20 min at room temperature, the solution was neutralized with sodium methoxide and evaporated to leave a syrup. Chromatography on a column of silica gel (dichloromethane–ethyl acetate, 3:1) afforded compound **17** (200 mg, 91%) as a syrup, $[\alpha]_D$ +53 (*c* 1.2, chloroform); ^{1}H nmr ($CDCl_3$) δ: 4.27 (d, 1H, $J_{1b,2b}$ 6.8 Hz, H-1b), 4.23 (ddd, 1H, $J_{3b,4b}$ 5.8 Hz, $J_{4b,5bax}$ 3.3 Hz, $J_{4b,5beq}$ 2.8 Hz, H-4b), 4.17 (dd, 1H, $J_{5bax,5beq}$ 13.2 Hz, H-5beq), 4.06 (dd, 1H, $J_{2b,3b}$ 7.6 Hz, H-3b), 3.86 (m, 1H, $J_{1aax,1aeq}$ 11.3 Hz, H-1aeq), 3.78 (dd, 1H, H-5bax), 3.60 (dt, 1H, $J_{2b,OH}$ 2.8 Hz, H-2b), 3.35 (m, 1H, $J_{1aax,2aax}$ 10.0 Hz, $J_{1aax,2aeq}$ 4.8 Hz, H-1aax), 3.28 (dq, 1H, $J_{4a,5a}$ 9.0 Hz, $J_{5a,6a}$ 6.1 Hz, H-5a), 3.20 (ddd, 1H, $J_{3aax,4a}$ 10.8 Hz, $J_{3aeq,4a}$ 4.7 Hz, H-4a), 2.37 (d, 1H, OH), 2.22 (m, 1H, H-3aeq), 1.75–1.64 (m, 2H, H-2aax and H-2aeq), 1.55 and 1.38 (2s, each 3H, Me_2C), 1.53 (m, 1H, H-3aax), 1.28 (d, 3H, 3H-6a). Anal. calcd. for $C_{14}H_{24}O_6$: C 58.32, H 8.39; found: C 58.23, H 8.38.

*1,2,3,6-Tetradeoxy-4-*O*-[3,4-*O*-isopropylidene-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-α-L-arabinopyranosyl]-D-*erythro*-hexopyranose (18)*

A solution of freshly prepared 2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl bromide **11** (1.73 mmol) in dichloromethane (1 mL) was added to a mixture of **17** (200 mg, 0.69 mmol), tetraethylammonium bromide (292 mg, 1.39 mmol), powdered 4 Å molecular sieves (2.4 g), dichloromethane (1.6 mL), and *N*,*N*-dimethylformamide (0.6 mL). After stirring for 6 h at room temperature, the mixture was diluted with dichloromethane, filtered through Celite, and washed with aqueous sodium bicarbonate and water successively, followed by drying and evaporation. Chromatography on a column of silica gel (benzene–ethyl acetate, 50:1 to 3:1, gradient) afforded two major fractions. Evaporation of the first fraction left a syrup (215 mg, 44%) that was identified as the fully protected trisaccharide **18**, $[\alpha]_D$ −34 (*c* 1, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.44–7.25 (m, 15H, 3Ph), 5.52 (d, 1H, $J_{1c,2c}$ 3.8 Hz, H-1c), 5.00 and 4.68 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.88 and 4.74 (AB, 2H, J_{AB} 12.0 Hz, CH_2Ph), 4.79 (s, 2H, CH_2Ph), 4.47 (d, 1H, $J_{1b,2b}$ 7.0 Hz, H-1b), 4.29 (dd, 1H, $J_{2b,3b}$ 7.0 Hz, $J_{3b,4b}$ 6.5 Hz, H-3b), 4.25 (ddd, 1H, $J_{4b,5bax}$ 3.8 Hz, $J_{4b,5beq}$ 3.3 Hz, H-4b), 4.13 (q, 1H, $J_{4c,5c}$ < 1 Hz, $J_{5c,6c}$ 6.8 Hz, H-5c), 4.07 (dd, 1H, $J_{2c,3c}$ 10.2 Hz, H-2c), 4.06 (dd, 1H, $J_{5bax,5beq}$ 12.8 Hz, H-5beq), 3.88 (dd, 1H, $J_{3c,4c}$ 2.8 Hz, H-3c), 3.85 (m, 1H, H-1aeq), 3.80 (t, 1H, H-2b), 3.75 (dd, 1H, H-5bax), 3.60 (d, 1H, H-4c), 3.29 (ddd, 1H, $J_{1aax,1aeq}$ 11.3 Hz, $J_{1aax,2aax}$ 10.0 Hz, $J_{1aax,2aeq}$ 4.8 Hz, H-1aax), 3.15 (ddd, 1H, $J_{3aax,4a}$ 10.5 Hz, $J_{3aeq,4a}$ 4.8 Hz, $J_{4a,5a}$ 9.0 Hz, H-4a), 3.07 (dq, 1H, $J_{5a,6a}$ 6.0 Hz, H-5a), 2.16 (m, 1H, H-3aeq), 1.70–1.60 (m, 2H, H-2aax, H-2aeq), 1.46 (m, 1H, H-3aax), 1.49 and 1.36 (2s, each 3H, Me_2C), 1.15 (d, 3H, 3H-6a), 1.08 (d, 3H, 3H-6c). Anal. calcd. for $C_{41}H_{52}O_{10}$: C 69.87, H 7.44; found: C 69.97, H 7.38.

The ^{1}H nmr spectrum of the product (199 mg, 43%) of the second fraction was superimposable with that of 1,2,3,6-tetradeoxy-4-*O*-[2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-α-L-arabinopyranosyl]-D-*erythro*-hexopyranose (**19**) formed by heating of **18** in aqueous acetic acid.

*1,2,3,6-Tetradeoxy-4-*O*-[2-*O*-(α-L-fucopyranosyl)-α-L-arabinopyranosyl]-D-*erythro*-hexopyranose (20)*

A solution of **18** (55 mg, 0.078 mmol) in 80% aqueous acetic acid (0.6 mL) was heated at 65°C for 2.5 h. Evaporation and coevaporation with toluene left a syrup, which was hydrogenated in 95% ethanol (2.5 mL) in the presence of 5% palladium-on-carbon (20 mg) at 128 psi for 7 h, when tlc (2-propanol/water, 9:1) indicated completion of the reaction. Filtration and evaporation left a clear syrup of **20** (31 mg, 100%), which was crystallized from ethyl acetate; mp 181–182°C, $[\alpha]_D$ −92 (*c* 0.7, water). The ^{1}H and ^{13}C nmr data are presented in Tables 1 and 2. Anal. calcd. for $C_{17}H_{30}O_{10}$: C 51.77, H 7.67; found: C 51.31, H 7.70.

*Methyl 2,3-dideoxy-*β*-D-*erythro*-hexopyranoside (21) (ref. 19)*

Compound **2** (35 mg, 0.14 mmol) (15) was hydrogenated over 20% palladium hydroxide-on-carbon (9 mg) in ethanol (3.5 mL) for 6 h at 20 psi. After removal of the catalyst and evaporation, pure diol **21** (18.5 mg, 81%) was obtained as a colourless syrup; ^{1}H nmr ($CDCl_3$) δ: 4.42 (dd, 1H, $J_{1,2eq}$ 2.0 Hz, $J_{1,2ax}$ 9.0 Hz, H-1), 3.87 (dd, 1H, $J_{5,6A}$ 4.0 Hz, $J_{6A,6B}$ 11.5 Hz, H-6A), 3.85 (dd, 1H, $J_{5,6B}$ 4.5 Hz, H-6B), 3.64 (m, 1H, H-4), 3.49 (s, 3H, OCH_3), 3.32 (m, 1H, $J_{4,5}$ 9.0 Hz, H-5), 2.32 (bs, 2H, 2OH), 2.10 (m, 1H, H-3eq), 1.90 (m, 1H, H-2eq), 1.62–1.47 (m, 2H, H-2ax, H-3ax); ^{13}C nmr ($CDCl_3$) δ: 102.93 (C-1), 78.99 (C-4), 66.35 (C-5), 63.25 (C-6), 56.54 (OCH_3), 30.68, 30.21 (C-2, C-3).

For larger scale preparations, after removal of the catalyst, the solution was treated with pyridine prior to evaporation to dryness.

*Methyl 2,3-dideoxy-6-*O*-p-toluenesulfonyl-*β*-D-*erythro*-hexopyranoside (22)*

Compound **21** (1.242 g, 5 mmol) was hydrogenated over 20% palladium hydroxide-on-carbon (311 mg) in ethanol (90 mL) at 20 psi for 3 h. The catalyst was removed by filtration and pyridine (10 mL) was added to the solution. It was evaporated to dryness. The residue was left overnight in an oil pump vacuum. The oily product (0.821 g) was dissolved in dry pyridine (12.5 mL), cooled to 0°C, and *p*-toluenesulfonyl chloride (1.012 g, 5.3 mmol) was added. The mixture was stirred at 0°C for 1 h, then more chloride (0.482 g, 2.5 mmol) was added. After 2.5 h, water (1 mL) was added and the mixture was kept stirring for 2 h at room temperature, then poured into ice-water. A precipitate was filtered off and the filtrate was extracted with chloroform. The combined extracts were washed with water, dried, and evaporated to provide compound **22** as a crystallizing syrup (0.72 g, 46%). The precipitate, which was a mixture of two compounds, was chromatographed on a column of silica gel (chloroform–ethyl acetate, 4:1) to provide crystalline methyl 2,3-dideoxy-4,6-di-*O*-*p*-toluenesulfonyl-β-D-*erythro*-hexopyranoside (**22***a*, 0.222 g, 10%) and compound **22** 0.6 g, 38%). Both samples of compound **22** were combined and recrystallized from ether–hexane (0.857 g, 54%); mp 87.5–88.5°C, $[\alpha]_D$ −53.5 (c 0.5, chloroform) (lit. (19) mp 95–96°C (chloroform–petroleum ether), $[\alpha]_D$ −43.8 (*c* 1.1, chloroform)); ^{1}H nmr ($CDCl_3$) δ: 7.82 and 7.35 (2d, 4H, C_6H_4), 4.38–4.32 (2dd overlapped, 2H, $J_{1,2eq}$ ~ 2.5 Hz, $J_{1,2ax}$ 8.5 Hz, H-1, $J_{5,6A}$ 4.5 Hz, $J_{6A,6B}$ 11.0 Hz, H-6A), 4.25 (dd, 1H, $J_{5,6B}$ 2.5 Hz, H-6B), 3.60 (m, 1H, H-4), 3.42 (s and m, 3H, OCH_3 and 1H, $J_{4,5}$ 9.5 Hz, H-5), 2.47 (s, 3H, CH_3 of Ts), 2.10 (m, 1H, H-3eq), 2.05 (d, 1H, $J_{4,OH}$ 5.5 Hz, OH), 1.88 (m, 1H, H-2eq), 1.62–1.44 (m, 2H, H-3ax, H-2ax); ^{13}C nmr ($CDCl_3$) δ: 144.98, 132.66, 129.68, 128.01 (C_6H_4), 102.67 (C-1), 77.48 (C-4), 69.60 (C-6), 65.48 (C-5), 56.36 (OCH_3), 30.36, 29.94 (C-2, C-3), 21.66 (CH_3 of Ts). Anal. calcd. for $C_{14}H_{20}O_6S$: C 53.15, H 6.37, S 10.13; found: C 53.32, H 6.41, S 10.12.

Ditosylate **22***a* melted at 124–125°C (ethyl acetate–hexane); $[\alpha]_D$ −9 (*c* 0.53, chloroform) (Lit. (19) mp 136–138°C (chloroform/petroleum ether)); ^{1}H nmr ($CDCl_3$) δ: 7.80–7.32 (m, 8H, $2C_6H_4$), 4.33 (dd, 1H, $J_{1,2eq}$ 2.0 Hz, $J_{1,2ax}$ 8.0 Hz, H-1), 4.25 (ddd, 1H, $J_{3eq,4}$ 4.5 Hz, $J_{4,5}$ 8.0 Hz, $J_{3ax,4}$ 9.5 Hz, H-4), 4.07 (dd, 1H, $J_{5,6A}$ 3.5 Hz, $J_{6A,6B}$ 11.0 Hz, H-6A), 3.83 (dd, 1H, $J_{5,6B}$ 6.0 Hz, H-6B),

*Methyl 4-O-(2-O-acetyl-3,4,6-tri-O-benzyl-β-D-galactopyranosyl)-2,3-dideoxy-6-O-p-toluenesulfonyl-β-D-*erythro*-hexopyranoside (24)*

A mixture of compound **22** (0.19 g, 0.6 mmol), mercuric cyanide (0.304 g, 1.2 mmol), powdered calcium sulfate (0.1 g), and 4 Å molecular sieves (0.2 g) in toluene–nitromethane (1:1, 4 mL) was stirred under nitrogen for 1 h. Then a solution of bromide **23** (0.487 g, 0.887 mmol) in nitromethane–toluene (1:1, 2 mL) was added dropwise within 15 min. After stirring at room temperature for 1.5 h, the reaction mixture was filtered and poured into a mixture of aqueous sodium bicarbonate and dichloromethane. The organic solution was washed with water, dried, and evaporated. The crude product was chromatographed on a column of silica gel (toluene–ethyl acetate, 4:1) to provide pure disaccharide **24** as a white foam (0.289 g, 61%) and 20 mg (11%) of starting alcohol **22**. The analytical sample of compound **24** was recrystallized from ether–hexane and had mp 110–111°C, $[\alpha]_D$ +1.5 (*c* 0.6, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.80 (d, 2H) and 7.37–7.23 (m, 17H, 3Ph, C_6H_4), 5.31 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.91 and 4.59 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.66 and 4.51 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.41 (s, 2H, CH_2Ph), 4.36 (d, 1H, H-1b), 4.22 (dd, 1H, $J_{1a,2aeq}$ 2.0 Hz, $J_{1a,2aax}$ 9.0 Hz, H-1a), 4.17 (dd, 1H, $J_{6aA,6aB}$ 11.0 Hz, $J_{5a,6aA}$ 2.0 Hz, H-6aA), 4.15 (dd, 1H, $J_{5a,6aB}$ 3.5 Hz, H-6aB), 3.91 (d, 1H, $J_{3b,4b}$ 2.7 Hz, H-4b), 3.58–3.53 (m, 3H, H-5b, 2H-6b), 3.49 (dd, 1H, H-3b), 3.46–3.33 (m, 2H, H-4a, H-5a), 3.30 (s, 3H, OCH_3), 2.42 (s, 3H, CH_3 of Ts), 2.19 (m, 1H, H-3aeq), 2.08 (s, 3H, CH_3CO), 1.77 (m, 1H, H-2aeq), 1.57 (m, 1H, H-3aax), 1.40 (m, 1H, H-2aax). Anal. calcd. for $C_{43}H_{50}O_{12}S$: C 65.30, H 6.37, S 4.04; found: C 65.68, H 6.50, S 3.90.

*Methyl 2,3-dideoxy-6-O-p-toluenesulfonyl-4-O-(3,4,6-tri-O-benzyl-β-D-galactopyranosyl)-β-D-*erythro*-hexopyranoside (25)*

A solution of acetate **24** (82 mg, 0.104 mmol) in methanolic 0.1 M sodium methoxide (4.4 mL) and dichloromethane (0.7 mL) was kept overnight at room temperature. It was neutralized with Amberlite IRC-50 (H^+) and evaporated. The crude product was purified on a column of silica gel (toluene–ethyl acetate, 4:1) to provide pure alcohol **25** (70 mg, 90%) as a white foam; $[\alpha]_D$ −14 (*c* 0.5, chloroform); ^{1}H nmr ($CDCL_3$) δ: 7.80 (d, 2H) and 7.36–7.24 (m, 17H, 3Ph, C_6H_4), 4.87 and 4.62 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.72 and 4.69 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.43 (s, 2H, CH_2Ph), 4.37 (dd, $J_{5a,6aA}$ 4.0 Hz, $J_{6aA,6aB}$ 10.5 Hz, H-6aA), 4.31–4.26 (2dd, d, 3H, $J_{5a,6aB}$ 2.0 Hz, H-6aB, $J_{1a,2aeq}$ 2.0 Hz, $J_{1a,2aax}$ 7.0 Hz, H-1a, $J_{1b,2b}$ 7.5 Hz, H-1b), 3.88 (d overlapped by ddd, 2H, $J_{3b,4b}$ 2.5 Hz, H-4b, $J_{2b,3b}$ 10.0 Hz, $J_{2b,OH}$ 3.0 Hz, H-2b), 3.57 (bs, 3H, H-5b, 2H-6b), 3.52 (m, 1H, H-5a), 3.50 (m, 1H, H-4a), 3.40 (dd, 1H, H-3b), 3.39 (s, 3H, OCH_3), 2.67 (d, 1H, OH), 2.42 (s, 3H, CH_3 of Ts), 2.22 (m, 1H, H-3aeq), 1.81 (m, 1H, H-2aeq), 1.69–1.57 (m, 1H, H-3aax), 1.46 (m, 1H, H-2aax). Anal. calcd. for $C_{41}H_{48}O_{11}S$: C 65.76, H 6.46, S 4.28; found: C 65.55, H 6.59, S 4.33.

*Methyl 2,3-dideoxy-6-O-p-toluenesulfonyl-4-O-[3,4,6-tri-O-benzyl-2-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-*erythro*-hexopyranoside (26)*

A solution of bromide **11** (0.981 mmol) in dichloromethane (1 mL) was added to a stirred mixture of alcohol **25** 0.245 g, 0.327 mmol), tetraethylammonium bromide (0.069 g, 0.327 mmol), dichloromethane (1 mL), *N*,*N*-dimethylformamide (0.4 mL), and 4Å molecular sieves (1 g, powdered). Stirring under nitrogen was continued for 27 h. Then methanol (1 mL) was added and the mixture was stirred for another 2 h. It was diluted with dichloromethane, filtered through Celite, washed with aqueous sodium bicarbonate, water, then dried and evaporated. The residue was chromatographed on a column of silica gel (hexane–ethyl acetate, 3:1, 3:2) to provide in the main fraction pure compound **26** (0.248 g, 65%) as a white foam; $[\alpha]_D$ −34.5 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.78 (d, 2H) and 7.36–7.00 (m, 32H, 6Ph, C_6H_4), 5.69 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.95–4.42 (m, 12H, $6CH_2$Ph), 4.39 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.33 (dd, 1H, $J_{5a,6aA}$ 3.5 Hz, $J_{6aA,6aB}$ 10.0 Hz, H-6aA), 4.30 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.28 (dd, 1H, $J_{1a,2aeq}$ 2.0 Hz, $J_{1a,2aax}$ 7.0 Hz, H-1a), 4.17 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.11 (dd, 1H, $J_{5a,6aB}$ 6.5 Hz, H-6aB), 4.01 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.97 (dd, 1H, $J_{3c,4c}$ 2.0 Hz, H-3c), 3.88 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.81 (d, 1H, H-4c), 3.67 (dd, 1H, H-3b), 3.62–3.50 (m, 4H, H-5a, H-5b, 2H-6b), 3.42 (m, 1H, H-4a), 3.31 (s, 3H, OCH_3), 2.37 (s, 3H, CH_3 of Ts), 2.12 (m, 1H, H-3aeq), 1.84 (m, 1H, H-2aeq), 1.62 (m, 1H, H-3aax), 1.44 (m, 1H, H-2aax), 1.13 (d, 3H, 3H-6c). Anal. calcd. for $C_{68}H_{76}O_{15}S$: C 70.08, H 6.57, S 2.75; found: C 69.94, H 6.77, S 2.81.

From the minor fractions starting alcohol **25** (15 mg, 6%) was isolated, as well as methyl 6-bromo-2,3,6-trideoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-*erythro*-hexopyranoside (15 mg, 4%); ^{1}H nmr ($CDCl_3$) δ: 7.35–6.95 (m, 30H, 6Ph), 5.17 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.96–4.42 (m, 13H, $6CH_2$Ph, at 4.45 d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 4.37 (dd, 1H, $J_{1a,2aeq}$ 2.0 Hz, $J_{1a,2aax}$ 8.0 Hz, H-1a), 4.26 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.21 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.03 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.95 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.91 (d, 1H, $J_{3b,4b}$ 2.8 Hz, H-4b), 3.86 (d, 1H, H-4c), 3.73 (dd, 1H, $J_{6aA,6aB}$ 9.5 Hz, $J_{5a,6aA}$ 2.0 Hz, H-6aA), 3.70 (dd, 1H, H-3b), 3.60–3.52 (m, 3H, H-5b, 2H-6b), 3.50 (s, 3H, OCH_3), 3.47–3.36 (m, 3H, H-6aB, H-5a, H-4a), 2.21 (m, 1H, H-3aeq), 1.87 (m, 1H, H-2aeq), 1.69–1.49 (m, 2H, H-3aax, H-2aax), 1.16 (d, 3H, 3H-6c).

*Methyl 6-O-benzoyl-2,3-dideoxy-4-O-[3,4,6-tri-O-benzyl-2-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-*erythro*-hexopyranoside (27)*

A mixture of tosylate **26** (0.175 g, 0.15 mmol), sodium benzoate (0.108 g, 0.75 mmol), and *N*,*N*-dimethylformamide (2 mL) was heated at 100°C with stirring for 4.5 h. After cooling, it was diluted with dichloromethane, the solution was washed twice with water, dried, and evaporated. The crude product was chromatographed on a column of silica gel (hexane–ethyl acetate, 3:1) to provide pure **27** (0.112 g, 68%) as a white foam; $[\alpha]_D$ −49 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 8.02–6.96 (m, 35H, 7Ph), 5.70 (d, 1H, $J_{1c,2c}$ 2.5 Hz, H-1c), 4.85–4.43 (m, 12H, $6CH_2$Ph), 4.69 (dd, 1H, $J_{6aA,6aB}$ 11.0 Hz, $J_{6aA,5a}$ 3.0 Hz, H-6aA), 4.51 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.41 (q, 1H, overlapped, $J_{5c,6c}$ 6.0 Hz, H-5c), 4.36 (dd, 1H, overlapped, $J_{5a,6aB}$ 7.5 Hz, H-6aB), 4.40 (dd, 1H, overlapped, $J_{1a,2aax}$ ~ 7.0 Hz, $J_{1a,2aeq}$ ~ 2.5 Hz, H-1a), 4.22 (dd, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.02–3.95 (m, 2H, H-2c, H-3c), 3.90 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.74 (dt, $J_{5a,6aA}$ ~ $J_{4a,5a}$ ~ 7.5 Hz, H-5a), 3.71 (d, 1H, $J_{3c,4c}$ 1.5 Hz, H-4c), 3.69 (dd, 1H, H-3b), 3.61–3.52 (m, 4H, H-4a, H-5b, 2H-6b), 3.43 (s, 3H, OCH_3), 2.28 (m, 1H, H-3aeq), 1.89 (m, 1H, H-2aeq), 1.69 (m, 1H, H-3aax), ~1.55 (m, 1H, H-2aax), 1.15 (d, 3H, 3H-6c). Anal. calcd. for $C_{68}H_{74}O_{14}$: C 73.23, H 6.69; found: 72.97, H 6.81.

*Methyl 2,3-dideoxy-4-O-[3,4,6-tri-O-benzyl-2-O-(2,3,4-tri-O-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-*erythro*-hexopyranoside (28)*

Compound **27** (75 mg, 0.067 mmol) was debenzoylated in methanolic 0.5 M sodium methoxide (1.3 mL) at room temperature for 21 h. Then it was diluted with methanol, neutralized with Amberlite IRC-50 (H^+), filtered, and evaporated. Purification was achieved by column chromatography on silica gel (hexane–ethyl acetate, 3:2) to afford pure **28** (60 mg, 89%) as a colourless syrup; $[\alpha]_D$ −50 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.38–6.99 (m, 30H, 6Ph), 5.70 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.97–4.43 (m, 12H, $6CH_2$Ph, 4.45 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.37 (dd, 1H, $J_{1a,2aax}$ 8.0 Hz, $J_{1a,2aeq}$ 2.0 Hz, H-1a), 4.29 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c),

*Methyl 2,3,6-trideoxy-4-*O*-[3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-*erythro*-hexopyranoside (29)*

A mixture of tosylate **26** (122 mg, 0.105 mmol), lithium aluminium hydride (10 mg, 0.26 mmol), and tetrahydrofuran (1.2 mL) was boiled under reflux for 2 h. After cooling, ethyl acetate (0.5 mL) was added and the mixture was poured into ice-water. The precipitate formed was filtered off and dissolved in dichloromethane. The organic solution was washed twice with water, dried, and evaporated. The crude product was purified on a column of silica gel (hexane–ethyl acetate, 3:1) to provide pure **29** (78 mg, 75%) as a white foam; $[\alpha]_D$ −60 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.36–7.00 (m, 30H, 6Ph), 5.72 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.97–4.41 (m, 12H, 6CH_2Ph), 4.49 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.34 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.29 (dd, 1H, $J_{1a,2aeq}$ 2.0 Hz, $J_{1a,2aax}$ 8.0 Hz, H-1a), 4.20 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.01 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.73 (dd, d, 2H, $J_{3c,4c}$ 2.5 Hz, H-3c, overlapped by d, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.70 (dd, 1H, H-3b), 3.62 (d, 1H, H-4c), 3.61–3.43 (m, 3H, H-5b, 2H-6b), 3.46 (s, 3H, OCH_3), 3.28–3.17 (m, 2H, H-4a, H-5a), 2.18 (m, 1H, H-3aeq), 1.83 (m, 1H, H-2aeq), 1.52 (m, 2H, H-3aax, H-2aax), 1.24 (d, 3H, $J_{5a,6a}$ 5.5 Hz, 3H-6a), 1.12 (d, 3H, 3H-6c). Anal. calcd. for $C_{61}H_{70}O_{12}$: C 73.62, H 7.09; found: C 73.43, H 7.31.

*Methyl 2,3-dideoxy-4-*O*-[2-*O*-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-*erythro*-hexopyranoside (30)*

Compound **28** (102 mg, ~0.1 mmol) was hydrogenated in ethanol (6 mL) over 5% palladium-on-carbon (102 mg) at 20 psi for 3 h. The catalyst was removed by filtration. A drop of triethylamine was added to the filtrate and the solvent was evaporated. The product was applied to a column of Bio-Gel P-2 and eluted with 10% ethanol in water. Freeze-drying an aqueous solution provided pure **30** (42 mg, 88%) as a white powder; $[\alpha]_D$ −82.5 (c 0.6, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

*Methyl 2,3,6-trideoxy-4-*O*-[2-*O*-(α-L-fucopyranosyl)-β-D-galactopyranosyl]-β-D-*erythro*-hexopyranoside (31)*

Compound **29** (97 mg, 0.097 mmol) was hydrogenated in ethanol (5.2 mL) over 5% palladium-on-carbon (97 mg) and then purified as described for the preparation of **30**. Pure **31** was obtained as a white powder (33 mg, 75%) after freeze-drying an aqueous solution; $[\alpha]_D$ −96.5 (*c* 0.5, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

DL-(1,5/2)-2,5-Diacetoxycyclohexane carboxylic acid (33)

(±) *endo*-7-Oxabicyclo[2,2,1]-heptane-2-carboxylic acid (**32**, 13.6 g, 0.1 mol) (29) was heated in a mixture of 85% acetic acid (225 mL), acetic anhydride (113 mL), and sulfuric acid (9 mL) for 20 h at 80°C (28). Then sodium acetate trihydrate (18 g) was added and the slightly brown mixture was evaporated. The remainder was taken up in dichloromethane, the mixture washed with water, and the organic solution evaporated to leave a crystalline residue. The material was treated with charcoal in ethanol, followed by filtration, evaporation, and recrystallization from dichloromethane/ether to provide pure **33** (8.2 g, 35%), mp 154–155°C; ^{1}H nmr ($CDCl_3$) δ: 5.03 (dt, 1H, $J_{1,2}$ 10.0 Hz, $J_{2,3ax}$ 10.0 Hz, $J_{2,3eq}$ 4.5 Hz, H-2), 4.79 (m, 1H, H-5), 2.68 (ddd, 1H, $J_{1,6ax}$ 11.5 Hz, $J_{1,6eq}$ 4.5 Hz, H-1), 2.28 (m, 1H, $J_{6eq,6ax}$ 13.5 Hz, H-6eq), 2.18 (m, 1H, H-3eq), 2.04, 2.03 (2s, each 3H, 2CH_3CO), ~2.01 (overlapped, H-4eq), 1.81 (q, 1H, $J_{6ax,5}$ 11.0 Hz, H-6ax), 1.56 (m, 1H, $J_{4ax,5}$ ~11 Hz, H-4ax), 1.47 (m, 1H, H-3ax). Anal. calcd. for $C_{11}H_{16}O_6$: C 54.09, H 6.60; found: C 53.76, H 6.59.

*DL-(1,5/4)-4,7-*O*-Benzylidene-5-*C*-hydroxymethyl-1,4-cyclohexanediol (35)*

A 1 M borane solution in tetrahydrofuran (65 mL, 65 mmol) was added to a stirring solution of the diacetate **33** (4.9 g, 20.1 mmol) in tetrahydrofuran (15 mL) under argon at ice-bath temperature. After the gas evolution ceased, the mixture was kept at room temperature for 48 h. Then methanol (5 mL) was added, followed by evaporation and codistillation with methanol–acetic acid 1:1. The residue, diol **34**, was dried for 2 h at 70°C in an oil pump vacuum and was then taken up in acetonitrile (120 mL). *p*-Toluenesulfonic acid (700 mg) and α,α-dimethoxytoluene (3.8 mL, 25.3 mmol) were added to the turbid suspension. After 15 min, it was neutralized with triethylamine, evaporated, and the residue dissolved in dichloromethane. Washing with water, evaporation of the organic solution, and co-distillation with water and ethanol left a white solid, which was recrystallized from dichloromethane–ether–hexane to provide pure **35** (4.0 g, 85%), mp 126–126.5°C; ^{1}H nmr ($CDCl_3$) δ: 7.5–7.3 (m, 5H, Ph), 5.54 (s, 1H, C*H*Ph), 4.08 (dd, 1H, $J_{7eq,7ax}$ 11.0 Hz, $J_{7eq,5}$ 4.3 Hz, H-7eq), 3.77 (tt, 1H, $J_{1,2ax} \sim J_{1,6ax} \sim$ 11.5 Hz, $J_{1,2eq} \sim J_{1,6eq} \sim$ 4.5 Hz, H-1), 3.62 (t, 1H, $J_{7ax,5}$ 11.0 Hz, H-7ax), 3.47 (dt, 1H, $J_{4,3ax} \sim J_{4,5} \sim$ 11 Hz, $J_{4,3eq}$ 4.0 Hz, H-4), 2.09 (m, 1H, overlapped by H-3eq, H-2eq), 2.04 (m, 1H, H-3eq), 1.82 (m, 2H, H-5, H-6eq), 1.58 (m, 2H, H-3ax, OH), 1.41 (m, 1H, H-2ax), 1.04 (q, 1H, $J_{6ax,6eq} \sim J_{6ax,5} \sim J_{6ax,1} \sim$ 12 Hz, H-6ax). Anal. calcd. for $C_{14}H_{18}O_3$: C 71.77, H 7.74; found: C 71.39, H 7.78.

*DL-(1,5/4)-4,7-*O*-Benzylidene-1-*O*-methyl-5-*C*-hydroxymethyl-1,4-cyclohexanediol (36)*

Sodium hydride (1.5 g, ~50% oily suspension, 31.3 mmol) was added to a stirring solution of compound **35** (4.7 g, 20.1 mmol) in *N*,*N*-dimethylformamide (40 mL) at 0°C. After 30 min, methyliodide (2 mL, 32.1 mmol) was added and stirring continued for 1 h. After the addition of methanol (1 mL), the mixture was evaporated, the residue taken up in dichloromethane, and the solution washed with water and evaporated. The crystalline material was filtered through a column of silica gel (hexane–ethyl acetate, 3:1) to provide pure **36** (4.2 g, 84%). The analytical sample was recrystallized from ether–hexane, mp 63.5°C; ^{1}H nmr ($CDCl_3$) δ: 7.53–7.30 (m, 5H, Ph), 5.56 (s, 1H, C*H*Ph), 4.12 (dd, 1H, $J_{7eq,7ax}$ 11.3 Hz, $J_{5,7eq}$ 4.5 Hz, H-7eq), 3.63 (t, 1H, $J_{5,7ax}$ 11.3 Hz, H-7ax), 3.47 (dt, 1H, $J_{4,5} \sim J_{3ax,4} \sim$ 11 Hz, $J_{3eq,4}$ 4.3 Hz, H-4), 3.36 (s, 3H, OCH_3), 3.28 (tt, 1H, $J_{1,2ax} \sim J_{1,6ax} \sim$ 11 Hz, $J_{1,2eq} \sim J_{1,6eq} \sim$ 4.3 Hz, H-1), 2.19 (m, 1H, $J_{2eq,2ax}$ 13.0 Hz, H-2eq), 2.06 (ddd, 1H, $J_{3eq,3ax}$ 12.5 Hz, $J_{2ax,3eq}$ 7.5 Hz, H-3eq), 1.92 (m, $J_{6eq,6ax}$ 12.0 Hz, H-6eq), 1.77 (m, 1H, H-5), 1.56 (ddd, 1H, $J_{3ax,2ax} \sim$ 12 Hz, $J_{3ax,2eq}$ 3.8 Hz, H-3ax), 1.32 (ddd, 1H, H-2ax), 0.94 (q, 1H, $J_{6ax,5} \sim$ 11.5 Hz, H-6ax). Anal. calcd. for $C_{15}H_{20}O_3$: C 72.55, H 8.12; found: C 72.37, H 8.23.

*DL-(1,5/4)-1-*O*-Methyl-5-*C*-hydroxymethyl-1,4-cyclohexanediol (37)*

A mixture of compound **36** (3.83 g, 15.4 mmol) and 20% palladium-on-carbon (0.95 g) in 95% ethanol (100 mL) was hydrogenated in the hydrogen stream at 15 psi for 4 h. The catalyst was removed by filtration and the solvent evaporated to provide pure diol **37** (2.45 g, 99%) as a colourless syrup; ^{1}H nmr ($CDCl_3$) δ: 4.35 (bs, 1H, OH), 4.13 (bs, 1H, OH), 3.72 (dd, 1H, $J_{7eq,7ax}$ 11.0 Hz, $J_{5,7eq}$ 4.3 Hz, H-7eq), 3.67 (t, 1H, $J_{7ax,5}$ 10.0 Hz, H-7ax), 3.55 (dt, 1H, $J_{3ax,4}$ 11.0 Hz, $J_{4,5}$ 11.0 Hz, $J_{3eq,4}$ 4.5 Hz, H-4), 3.34 (s, 3H, OCH_3), 3.22 (tt, 1H, $J_{1,2ax} \sim J_{1,6ax} \sim$ 11 Hz, $J_{1,2eq} \sim J_{1,6eq} \sim$ 4.3 Hz, H-1), 2.08 (m, 1H, $J_{2eq,2ax}$ 12.5 Hz, H-2eq), 1.99 (m, 1H, overlapped by H-6eq, H-3eq), 1.92 (m, 1H, H-6eq), 1.38 (ddd, 1H, $J_{3ax,3eq} \sim$ 13 Hz, $J_{2ax,3ax} \sim$ 11.5 Hz, H-3ax), 1.20 (ddd, 1H, H-2ax), 0.92 (q, 1H, $J_{6ax,6eq} \sim J_{6ax,5} \sim$ 12 Hz, H-6ax). Anal. calcd. for $C_{18}H_{16}O_3$: C 59.98, H 10.07; found: C 59.98, H 10.11.

*DL-(1,5/4)-1-*O*-Methyl-5-*C*-(p-toluenesulfonyloxy)methyl-1,4-cyclohexanediol (38)*

p-Toluenesulfonyl chloride (1.221 g, 6.4 mmol) was added to a solution of diol **37** (0.933 g, 5.82 mmol) in dry pyridine (12 mL) at 0°C. The mixture was stirred at 0°C for 1.5 h. Then more chlo-

*(1S,4S,5R)-1-Methoxy-5-*C*-(*p*-toluenesulfonyloxy)methylcyclohex-4-yl- and (1R,4R,5S)-1-methoxy-5-*C*-(*p*-toluenesulfonyloxy)methylcyclohex-4-yl 2-*O*-acetyl-3,4,6-tri-*O*-benzyl-β-D-galactopyranoside (39 and 40)*

A mixture of alcohol **38** (0.218 g, 0.69 mmol), mercuric cyanide (0.354 g, 1.4 mmol), powdered calcium sulfate (0.16 g), and 4 Å molecular sieves (0.32 g) in nitromethane–toluene (1:1, 4.5 mL) was stirred under nitrogen for 1 h. Then a solution of bromide **23** (0.719 g, 1.29 mmol) in nitromethane–toluene (1:1, 4 mL) was added dropwise within 20 min. After 2 h, the reaction mixture was filtered and poured into a stirred mixture of aqueous sodium bicarbonate and dichloromethane. The organic solution was washed with water, dried, and evaporated. The resulting material was chromatographed on a column of silica gel (toluene–ethyl acetate, 4:1) to provide two pure compounds: **39** (0.121 g, 22%; R_f 0.34, toluene–ethyl acetate, 4:1) and **40** (0.096 g, 18%; R_f 0.29) as white foams, and a mixture of both (0.039 g). The analytical sample of compound **39** was recrystallized from ether–hexane to provide white needles, mp 97–98°C, $[\alpha]_D$ +20.5 (*c* 0.6, chloroform); ^{1}H-nmr ($CDCl_3$) δ: 7.78–7.22 (m, 19H, 3Ph, C_6H_4), 5.31 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.91 and 4.59 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.66 and 4.51 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.42 (s, 2H, CH_2Ph), 4.35 (d, 1H, H-1b), 4.10 (dd, 1H, $J_{7aA,7aB}$ 9.5 Hz, $J_{5a,7aA}$ 5.5 Hz, H-7aA), 3.98 (dd, 1H, $J_{5a,7aB}$ 3.0 Hz, H-7aB), 3.91 (d, 1H, $J_{3b,4b}$ 2.7 Hz, H-4b), 3.60–3.51 (m, 3H, H-5b, 2H-6b), 3.48 (dd, 1H, H-3b), 3.31 (dt, 1H, overlapped, $J_{4a,5a} \sim J_{4a,3aax} \sim$ 9.5 Hz, $J_{4a,3aeq}$ 4.5 Hz, H-4a), 3.26 (s, 3H, overlapped, OCH_3), 3.03 (m, 1H, H-1a), 2.42 (s, 3H, CH_3 of Ts), 2.17 (m, 1H, H-3aeq), 2.08–1.83 (m, 2H, H-6aeq, H-2aeq overlapped by s, 3H at 2.05, CH_3CO), 1.70 (m, 1H, H-5a), 1.38 (m, 1H, H-3aax), 1.19–0.98 (m, 2H, H-2aax, H-6aax). Anal. calcd. for $C_{44}H_{52}O_{11}S$: C 66.99, H 6.64, S 4.06; found: C 67.23, H 6.50, S 4.21.

Compound **40** had $[\alpha]_D$ +8 (*c* 0.78, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.74–7.17 (m, 19H, 3Ph, C_6H_4), 5.18 (dd, 1H, $J_{1b,2b}$ 8.0 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.92 and 4.60 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.65 and 4.48 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.51 and 4.45 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.29 (d, 1H, H-1b), 4.13 (dd, 1H, $J_{7aA,7aB}$ 9.5 Hz, $J_{5a,7aA}$ 3.5 Hz, H-7aA), 4.03 (dd, 1H, $J_{5a,7aB}$ 6.5 Hz, H-7aB), 3.97 (d, 1H, $J_{3b,4b}$ 2.7 Hz, H-4b), 3.70 (dd, 1H, $J_{6bA,6bB} \sim J_{6bA,5b}$ 8.5 Hz, H-6bA), 3.65 (dd, 1H, $J_{6bB,5b}$ 5.0 Hz, H-6bB), 3.53 (m, 1H, H-5b), 3.48 (dd, 1H, H-3b), 3.38 (dt, 1H, $J_{4a,3aeq} \sim$ 4.0 Hz, $J_{4a,5a} \sim J_{4a,3aax} \sim$ 10 Hz, H-4a), 3.28 (s, 3H, OCH_3), 3.08 (m, 1H, H-1a), 2.31 (s, 3H, CH_3 of Ts), 2.12–1.89 (m, 3H, H-3aeq, H-2aeq, H-6aeq, overlapped by s, 3H at 1.98, CH_3CO), 1.65 (m, 1H, H-5a), 1.20–1.02 (m, 3H, H-2aax, H-3aax, H-6aax).

*(1S,4S,5R)-1-Methoxy-5-*C*-(p-toluenesulfonyloxy)methylcyclohex-4-yl 3,4,6-tri-*O*-benzyl-β-D-galactopyranoside (41)*

Acetate **39** (137 mg, 0.174 mmol) was deacetylated in methanolic 0.11 M sodium methoxide (4.5 mL) at room temperature for 26 h. The solution was neutralized with Amberlite IRC-50 (H^+), filtered, and evaporated. The resulting material was chromatographed on a column of silica gel (toluene–ethyl acetate, 4:1) to provide pure **41** as a white foam (80 mg, 62%); $[\alpha]_D$ +1 (*c* 0,5 chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.78 (d, 2H) and 7.39–7.22 (m, 17H, 3Ph and C_6H_4), 4.87 and 4.61 (AB,2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.73 and 4.69 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.43 (s, 2H, CH_2Ph), 4.41 (dd, 1H, $J_{7aA,5a}$ 5.0 Hz, $J_{7aA,7aB}$ 9.5 Hz, H-7aA), 4.27 (d, 1H, $J_{1b,2b}$ 8.0 Hz, H-1b), 3.97 (dd, 1H, $J_{7aB,5a}$ 3.0 Hz, H-7aB), 3.98 (ddd overlapped by d, 2H, $J_{2b,OH}$ 3.0 Hz, $J_{2b,3b}$ 9.5 Hz, H-2b, $J_{3b,4b}$ 3.0 Hz, H-4b), 3.57 (bs, 3H, H-5b, 2H-6b), 3.45 (dt, 1H, $J_{4a,5a} \sim J_{4a,3aax}$ 10.0 Hz, $J_{4a,3aeq}$ 4.0 Hz, H-4a), 3.40 (dd, 1H, H-3b), 3.29 (s, 3H, OCH_3), 3.10 (m, 1H, H-1a), 2.63 (d, 1H, OH), 2.42 (s, 3H, CH_3 of Ts), 2.19 (m, 1H, H-2aeq), 2.04–1.94 (m, 2H, H-2aeq, H-6aeq), 1.78 (m, 1H, H-5a), 1.41 (m, 1H, H-3aax), 1.27–1.08 (m, 2H, H-2aax, H-6aax). Anal. calcd. for $C_{42}H_{50}O_{10}S$: C 67.54, H 6.75, S 4.29; found: C 67.28, H 6.96, S 4.21.

A minor compound eluted from the column after **41** was found to be (1*S*,4*S*,5*R*)-1-methoxy-5-*C*-methoxymethylcyclohex-4-yl 3,4,6-tri-*O*-benzyl-β-D-galactopyranoside (**42**, 16 mg, 15%). It had $[\alpha]_D$ −7.5 (*c* 0.35, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.42–7.22 (m, 15H, 3Ph), 4.88 and 4.60 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.76 and 4.72 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.45 and 4.43 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.25 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 3.93 (ddd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{2b,OH}$ 1.0 Hz, H-2b), 3.88 (d, 1H, $J_{3b,4b}$ 3.0 Hz, H-4b), 3.63 (d, 1H, OH), 3.59 (bs, 3H, H-5b, 2H-6b), 3.52 (dd, 1H, $J_{7aA,7aB}$ 10.0 Hz, $J_{7aA,5a}$ 4.0 Hz, H-7aA), 3.44 (2dd, overlapped, $J_{7aB,5a}$ 5.0 Hz, H-7aB and H-3b), 3.40 (dt, overlapped, $J_{4a,5a} \sim J_{4a,3aax}$ 10.5 Hz, $J_{4a,3aeq}$ 4.0 Hz, H-4a), 3.34 and 3.33 (2s, each 3H, CH_3O and CH_2OCH_3), 3.61 (m, 1H, H-1a), 2.20 (m, 1H, H-3aeq), 2.19 (m, 2H, H-2aeq, H-6aeq), 1.80 (m, 1H, H-5a), 1.45 (m, 1H, H-3aax), 1.22–1.03 (m, 2H, H-2aax, H-6aax). The compound was acetylated (pyridine, acetic anhydride) and then recrystallized from ether–hexane. **42***a* had mp 91–92°C, $[\alpha]_D$ +22 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.37–7.23 (m, 15H, 3Ph), 5.35 (dd, 1H, $J_{1b,2b}$ 7.8 Hz, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.91 and 4.60 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.66 and 4.49 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.43 (s, 2H, CH_2Ph), 4.35 (d, 1H, H-1b), 3.92 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.61–3.52 (m, 3H, H-5b, 2H-6b), 3.48 (dd, 1H, H-3b), 3.39 (dd, 1H, $J_{5a,7aA}$ 6.0 Hz, $J_{7aA,7aB}$ 9.0 Hz, H-7aA), 3.31 and 3.29 (2s, each 3H, $2OCH_3$, overlapped by H-7aB and H-4a), 3.11 (m, 1H, H-1a), 2.20–1.93 (m, 6H, H-2aeq, H-3aeq, H-6aeq, and $COCH_3$ at 2.04), 1.64 (m, 1H, H-5a), 1.42 (m, 1H, H-3aax), 1.23–1.09 (m, 2H, H-2aax, H-6aax). Anal. calcd. for $C_{38}H_{48}O_9$: C 70.35, H 7.46; found: C 69.91, H 7.42.

*(1S,4S,5R)-5-*C*-Benzoyloxymethyl-1-methoxycyclohex-4-yl 3,4,6-tri-*O*-benzyl-β-D-galactopyranoside (43)*

A mixture of tosylate **41** (100 mg, 0.134 mmol) and sodium benzoate (100 mg, 0.694 mmol) in *N*,*N*-dimethylformamide (1.5 mL) was stirred at 80°C for 4 h. Then the mixture was diluted with dichloromethane, and the organic solution washed twice with water, dried, and evaporated. Chromatographic purification on a column of silica gel (hexane–ethyl acetate, 3:2) afforded pure **43**

For personal use only.

(61 mg, 65%) as a white foam. It had $[\alpha]_D$ +8 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 8.10–7.20 (m, 20H, 4Ph), 4.87 and 4.60 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.71 (s, overlapped by dd, 3H, $J_{A,B}$ 10.5 Hz, CH_2Ph, $J_{5a,7aA}$ 4.5 Hz, $J_{7aA,7aB}$ 11.0 Hz, H-7aA), 4.43 and 4.42 (AB, 2H, $J_{A,B}$ 12.0 Hz, CH_2Ph), 4.37 (dd, 1H, $J_{5a,7aB}$ 2.5 Hz, H-7aB), 4.28 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 3.97 (ddd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{2b,OH}$ 2.0 Hz, H-2b), 3.86 (d, 1H, $J_{3b,4b}$ 3.0 Hz, H-4b), 3.62–3.51 (m, 3H, H-5b, 2H-6b), 3.45 (dt, 1H, $J_{4a,3aeq}$ 4.0 Hz, $J_{4a,3aax} \sim J_{4a,5a}$ 10.0 Hz, H-4a), 3.40 (dd, 1H, H-3b), 3.35 (s, 3H, OCH_3), 3.20 (m, 1H, H-1a), 2.91 (d, 1H, OH), 2.29–2.17 (m, 2H, H-3aeq, H-6aeq), 2.06 (m, 1H, H-2aeq), 1.93 (m, 1H, H-5a), 1.49 (m, 1H, H-3aax), 1.39–1.15 (m, 2H, H-2aax, H-6aax).

*(1S,4S,5S)-1-Methoxy-5-*C*-methylcyclohex-4-yl 3,4,6-tri-*O*-benzyl-*β*-*D*-galactopyranoside (**44**)*

A mixture of tosylate **41** (67 mg, 0.09 mmol) and lithium aluminium hydride (10 mg, 0.27 mmol) in tetrahydrofuran (1.3 mL) was stirred under nitrogen at room temperature for 2 h. Then it was poured into ice-water and extracted with chloroform. The organic solution was washed twice with water, dried, and evaporated. Chromatography of the residue on a column of silica gel (hexane–ethyl acetate, 3:2) gave pure **44** (34 mg, 66%) as a colourless syrup; $[\alpha]_D$ +7 (*c* 0.5 chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.38–7.24 (m, 15H, 3Ph), 4.88 and 4.61 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.72 and 4.67 (AB, 2H, $J_{A,B}$ 11.5 Hz, CH_2Ph), 4.45 (s, 2H, CH_2Ph), 4.29 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 3.95 (ddd, 1H, $J_{2b,3b}$ 10.0 Hz, $J_{2b,OH}$ 2.0 Hz, H-2b), 3.90 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.62–3.54 (m, 3H, H-5b, 2H-6b), 3.43 (dd, 1H, H-3b), 3.32 (s, 3H, OCH_3), 3.13 (m, 1H, overlapped, H-1a), 3.09 (dt, 1H, overlapped, $J_{4a,5a} \sim J_{4a,3aax} \sim$ 10.5 Hz, $J_{4a,3aeq}$ 4.5 Hz, H-4a), 2.34 (d, 1H, OH), 2.17 (m, 1H, H-3aeq), 2.07–1.97 (m, 2H, H-5aeq, H-6aeq), 1.59 (m, 1H, H-5a), 1.40 (m, 1H, H-3aax), 1.17 (m, 1H, H-2aax), 1.05 (d, 3H, $J_{5a,7a}$ 6.5 Hz, 3H-7), 0.98 (q, 1H, $J_{5a,6aax} \sim J_{6aax,6aeq} \sim J_{6aax,1a} \sim$ 12.0 Hz, H-6aax).

*(1S,4S-5R)-1-Methoxy-5-*C*-(p-toluenesulfonyloxy)methylcyclohex-4-yl- and (1S,4S,5S)-5-*C*-bromomethyl-1-methoxycyclohex-4-yl 3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranoside (**45** and **46**)*

A solution of freshly prepared bromide **11** (0.38 mmol) in dichloromethane (0.5 mL) was added to a stirred mixture of alcohol **41** (79 mg, 0.106 mmol), tetraethylammonium bromide (23 mg, 0.109 mmol), dichloromethane (0.3 mL), *N*,*N*-dimethylformamide (0.12 mL), and powdered 4 Å molecular sieves. Stirring under nitrogen was continued for 21 h. Then methanol (0.5 mL) was added. After 2.5 h, the mixture was diluted with dichloromethane and filtered through a pad of Celite. The filtrate was washed with saturated aqueous sodium bicarbonate and water, dried, and evaporated. Subsequent chromatography on a column of silica gel (hexane–ethyl acetate, 3:1) afforded in the first main fraction compound **46** (59 mg, 52%) as a white foam; $[\alpha]_D$ −31.5 (*c* 0.6, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.37–6.94 (m, 30H, 6Ph), 5.71 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.96–4.41 (m, 13H, 6CH_2Ph, at 4.47 d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.30 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.22 (dd, 1H, $J_{2b,3b}$ 10.5 Hz, H-2b), 4.03 (dd, 1H, $J_{2c,3c}$ 10.5 Hz, H-2c), 3.95 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.90 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.83 (d, 1H, H-4c), 3.70 (2dd, 2H, H-3b, $J_{5a,7aA}$ 3.0 Hz, $J_{7aA,7aB}$ 9.5 Hz, H-7aA), 3.60–3.51 (m, 3H, H-5b, 2H-6b), 3.35 (s, 3H, OCH_3), 3.29 (dt, 1H, $J_{4a,5a} \sim J_{4a,3aax}$ 10.0 Hz, $J_{4a,3aeq}$ 4.0 Hz, H-4a), 3.22 (dd, 1H, $J_{5a,7aB}$ 7.0 Hz, H-7aB), 3.15 (m, 1H, H-1a), 2.36 (m, 1H, H-3aeq), 2.20 (m, 1H, H-6aeq), 2.06 (m, 1H, H-2aeq), 1.62 (m, 1H, H-5a), 1.40 (m, 1H, H-3aax), 1.21 (m, 1H, H-2aax), 1.14 (d, 3H, 3H-6c), 1.04 (m, 1H, H-6aax); ^{13}C nmr ($CDCl_3$) δ: 102.92 (C-1b), 97.74 (C-1c), 69.13 (C-6b), 56.11 (CH_3O), 44.92 (C-5a), 36.67, 34.88, 31.59, 29.98 (C-2a, C-3a, C-6a, C-7a), 16.56 (CH_3-6c). Anal. calcd. for $C_{62}H_{71}BrO_{11}$: C 69.20, H 7.02; found: C 69.69, H 6.82.

Continued elution provided compound **45** (24 mg, 20%) as a colourless syrup; $[\alpha]_D$ −33 (*c* 0.45, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.77–7.03 (m, 34H, 6Ph and C_6H_4), 5.70 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.97–4.42 (m, 12H, 6CH_2Ph), 4.30 (d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.28 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.18 (dd, 1H, $J_{7aA,5a}$ 3.5 Hz, $J_{7aA,7aB}$ 9.5 Hz, H-7aA), 4.14 (dd, 1H, $J_{2b,3b}$ 10.0 Hz, H-2b), 4.08 (dd, 1H, $J_{5a,7aB}$ 6.5 Hz, H-7aB), 4.03 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.96 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.88 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.77 (d, 1H, H-4c), 3.60 (dd, 1H, H-3b), 3.56–3.44 (m, 3H, H-5b, 2H-6b), 3.38 (dt, 1H, $J_{4a,3aeq}$ 4.5 Hz, $J_{4a,5a} \sim J_{4a,3aax} \sim$ 9.0 Hz, H-4a), 3.25 (s, 3H, OCH_3), 3.06 (m, 1H, H-1a), 2.34 (s, 3H, CH_3 of Ts), 2.07 (m, 1H, H-3aeq), 1.99–1.86 (m, 2H, H-2aeq, H-6aeq), 1.68 (m, 1H, H-5a), 1.37 (m, 1H, H-3aax), 1.25–1.11 (m, 4H, H-2aax, overlapped by d at 1.12, 3H-6c), 1.01 (q, $J_{5a,6aax} \sim J_{6aeq,6aax} \sim J_{6aax,1a}$ 12.0 Hz, H-6aax); ^{13}C nmr ($CDCl_3$) δ: 102.13 (C-1b), 97.65 (C-1c), 71.37, 71.19 (*C*H_2Ph, C-7a), 69.02 (C-6b), 55.96 (CH_3O), 41.45 (C-5a), 32.24, 30.31, 29.06 (C-2a, C-3a, C-6a), 21.62 (CH_3 of Ts), 16.62 (CH_3-6c).

*(1S,4S,5R)-5-*C*-Benzoyloxymethyl-1-methoxycyclohex-4-yl 3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranoside (**47**)*

*(a) By fucosylation of compound **43***

A solution of bromide **11** (0.297 mmol) in dichloromethane (0.4 mL) was added to a stirred mixture of alcohol **43** (62 mg, 0.089 mmol), tetraethylammonium bromide (19 mg, 0.09 mmol), dichloromethane (0.3 mL), *N*,*N*-dimethylformamide (0.1 mL), and powdered 4 Å molecular sieves (0.4 g). Stirring under nitrogen was continued for 24 h. Then methanol (0.1 mL) was added to the reaction mixture and after 2 h it was worked up as described for the preparation of **45**. Chromatographic purification on a column of silica gel (hexane–ethyl acetate, 3:1), provided **47** (63 mg, 64%) as a white foam, $[\alpha]_D$ −36.5 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 8.01–6.94 (m, 35H, 7Ph), 5.70 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.86–4.42 (m, 15H, 6CH_2Ph, at 4.66, dd, 1H, $J_{7aA,7aB}$ 11.0 Hz, $J_{7aA,5a}$ 4.0 Hz, H-7A, at 4.53, d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b, ~4.44, m, H-5c, overlapped), 4.22 (dd, 1H, $J_{2b,3b}$ 10.5 Hz, H-2b), 4.19 (dd, 1H, $J_{5a,7aB}$ 8.0 Hz, H-7aB), 4.00 (dd, 1H, $J_{2c,3c}$ 10.5 Hz, H-2c), 3.98 (dd, 1H, $J_{3c,4c}$ 2.0 Hz, H-3c), 3.89 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.73 (d, 1H, H-4c), 3.69 (dd, 1H, H-3b), 3.63–3.52 (m, 3H, H-5b, 2H-6b), 3.47 (dt, 1H, $J_{4a,5a} \sim J_{4a,3aax}$ 9.5 Hz, $J_{4a,3aeq}$ 4.5 Hz, H-4a), 3.32 (s, 3H, OCH_3), 3.17 (m, 1H, H-1a), 2.26 (m, 1H, H-3aeq), 2.19 (m, 1H, H-6aeq), 2.05 (m, 1H, H-2aeq), 1.90 (m, 1H, H-5a), 1.46 (m, 1H, H-3aax), 1.28–1.10 (m, 5H, H-2aax, H-6aax, overlapped by d at 1.15, $J_{5c,6c}$ 6.5 Hz, 3H-6c).

*(b) By benzoate substitution of compound **46***

A mixture of compound **46** (35 mg, 0.033 mmol) and sodium benzoate (23 mg, 0.162 mmol) in *N*,*N*-dimethylformamide (0.5 mL) was heated at 120°C for 4.5 h with stirring. Then it was diluted with dichloromethane, washed twice with water, dried, and evaporated. Purification was achieved by column chromatography on silica gel (hexane–ethyl acetate, 3:1) to provide the pure title compound **47** (24 mg, 66%).

*(1S,4S,5R)-5-*C*-Hydroxymethyl-1-methoxycyclohex-4-yl 3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-*L*-fucopyranosyl)-β-*D*-galactopyranoside (**48**)*

Compound **47** (63 mg, 0.057 mmol) was debenzoylated in methanolic 0.5 M sodium methoxide (1.1 mL) at room temperature for 24 h. The reaction mixture was evaporated to dryness and the remainder was taken up in chloroform. The solution was washed twice with water, dried, and evaporated. The crude product was purified on a column of silica gel (hexane–ethyl acetate, 3:1) to provide the pure title compound **48** (43 mg, 76%) as a colourless syrup; $[\alpha]_D$ −43.5 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ:7.38–7.01 (m, 30H, 6Ph), 5.68 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.97–4.44 (m, 13H, 6CH_2Ph, at 4.45 d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b), 4.32 (q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.20 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.02 (dd, 1H, $J_{3c,2c}$ 10.5 Hz, H-2c), 3.94 (dd, 1H, $J_{3c,4c}$ 2.5 Hz, H-3c), 3.90 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.67 (dd, 1H, H-3b), 3.64 (d, 1H, H-4c), 3.64–3.47 (m, 5H, H-5b, 2H-6b, 2H-7a), 3.40 (ddd, 1H, $J_{4a,5a} \sim J_{4a,3aax}$ 10.0 Hz, $J_{4a,3aeq}$ 4.0 Hz, H-4a), 3.33 (s, 3H, CH_3O), 3.14 (m, 1H, H-1a), 2.19–1.95 (m, 3H, H-2aeq, H-3aeq, H-6aeq), 1.77 (t, 1H, OH), 1.53–1.33 (m, 2H, H-5a, H-3aax), 1.28–1.02

(m, 4H, H-2aax, overlapped by d at 1.13, 3H-6c), 1.08 (q, $J_{5a,6ax} \sim J_{6aax,6aeq} \sim J_{6aax,1a} \sim 12$ Hz, H-6aax).

*(1S,4S,5S)-1-Methoxy-5-*C*-methylcyclohex-4-yl 3,4,6-tri-*O*-benzyl-2-*O*-(2,3,4-tri-*O*-benzyl-α-L-fucopyranosyl)-β-D-galactopyranoside (**49**)*

*(a) By fucosylation of compound **44***

A solution of freshly prepared bromide **11** (0.266 mmol) in dichloromethane (0.2 mL) was added to a stirred mixture of alcohol **44** (43 mg, 0.075 mmol), tetraethylammonium bromide (16 mg, 0.076 mmol), dichloromethane (0.3 mL), *N*,*N*-dimethylformamide (0.1 mL), and powdered 4 Å molecular sieves (0.4 g). After stirring for 24 h, the mixture was processed conventionally and separated on a column of silica gel (hexane–ethyl acetate, 3:1) to provide pure **49** (48 mg, 65%) as a colourless syrup; $[\alpha]_D$ −50.5 (*c* 0.5, chloroform); ^{1}H nmr ($CDCl_3$) δ: 7.35–6.95 (m, 30H, 6Ph), 5.69 (d, 1H, $J_{1c,2c}$ 3.5 Hz, H-1c), 4.96–4.40 (m, 14H, 6CH_2Ph, at 4.50 d, 1H, $J_{1b,2b}$ 7.5 Hz, H-1b, at 4.46 q, 1H, $J_{5c,6c}$ 6.5 Hz, H-5c), 4.22 (dd, 1H, $J_{2b,3b}$ 9.5 Hz, H-2b), 4.02 (dd, 1H, $J_{2c,3c}$ 10.0 Hz, H-2c), 3.95 (dd, 1H, $J_{3c,4c}$ 2.0 Hz, H-3c), 3.92 (d, 1H, $J_{3b,4b}$ 2.5 Hz, H-4b), 3.70 (dd, 1H, H-3b), 3.61 (d, 1H, H-4c), 3.59–3.52 (m, 3H, H-5b, 2H-6b), 3.32 (s, 3H, OCH_3), 3.10 (m, 2H, H-1a, H-4a), 2.15 (m, 1H, H-3aeq), 2.00 (m, 2H, H-2aeq, H-6aeq), 1.39–1.24 (m, 2H, H-5a, H-3aax), 1.23–1.09 (m, 4H, H-2aax, overlapped by d at 1.12, 3H-6c), 0.98 (d, 3H, $J_{5a,7a}$ 6.5 Hz, 3H-7a), 0.95 (q, overlapped, 1H, $J_{5a,6aax} = J_{6aax,6aeq} = J_{6aax,1a}$ 12.0 Hz, H-6aax).

*(b) By reduction of tosylate **45***

Lithium aluminium hydride (5 mg, 0.13 mmol) was added to a solution of compound **45** (20 mg, 0.017 mmol) in tetrahydrofuran (0.3 mL). After stirring for 1 h at room temperature, the mixture was poured into ice-water and extracted with chloroform. The organic solution was washed with water, dried, and evaporated. The crude product was purified on a column of silica gel (hexane–ethyl acetate, 3:1) to provide pure **49** (9 mg, 53%).

*(1S,4S,5R)-5-*C*-Hydroxymethyl-1-methoxycyclohex-4-yl 2-*O*-(α-L-fucopyranosyl)-β-D-galactopyranoside (**50**)*

Compound **48** (58 mg, 0.058 mmol) was hydrogenated in ethanol (3.7 mL) over 5% palladium-on-carbon (58 mg) for 2.5 h at 20 psi. After removal of the catalyst, the solution was evaporated to dryness. The residue was applied to a column of Bio-Gel P-2 (10% ethanol-water) to provide pure **50** (22 mg, 82%) as a white powder after freeze-drying an aqueous solution; $[\alpha]_D$ −85 (*c* 0.55, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

*(1S,4S,5S)-1-Methoxy-5-*C*-methylcyclohex-4-yl 2-O-(α-L-fucopyranosyl)-β-D-galactopyranoside (**51**)*

Compound **49** (52 mg, 0.052 mmol) in ethanol (3.3 mL) was hydrogenated and purified as described for the preparation of **50**. Freeze-drying an aqueous solution provided pure **51** (18 mg, 76%) as a white powder; $[\alpha]_D$ −90 (*c* 0.53, water). The ^{1}H and ^{13}C nmr data are reported in Tables 1 and 2.

Received May 3, 1991

ALLYSON L. PERROTT and DONALD R. ARNOLD. Can. J. Chem. **70**, 272 (1992).

Irradiation of an acetonitrile solution of *cis* 1-methyl-2-phenylcyclopentane (**1***b cis*); 1,4-dicyanobenzene (**2**), an electron-accepting photosensitizer; and 2,4,6-collidine (**3**), a nonnucleophilic base, leads to configurational isomerization of the cyclopentane; the photostationary state lies >99% in favour of the *trans* isomer. The mechanism proposed for this reaction involves formation of the radical cation of **1***b cis* by photoinduced electron transfer to the singlet excited state of **2**, deprotonation of the radical cation assisted by the base **3**, reduction of the resulting benzylic radical by the radical anion $\mathbf{2}^{\cdot-}$, and reprotonation of the benzylic anion to give both the *cis* and the *trans* isomers of **1***b*. The photostationary state is controlled by the relative rates of deprotonation of the radical cations of **1***b cis* and *trans*; these rates are dependent upon the extent of overlap of the SOMO of the radical cation, which is largely associated with the phenyl ring, and the benzylic carbon–hydrogen bond. Molecular mechanics calculations (MM3 and MMP2) are used to calculate the preferred conformations of the isomers. The required orbital overlap is 31% effective with the global minimum conformation of the *cis* isomer and essentially ineffective for the low-lying conformations of the *trans* isomer. This proposed mechanism is supported by Stern–Volmer quenching studies, which indicate that both isomers quench the singlet excited state of **2** at the diffusion-controlled rate, and by deuterium incorporation studies. When irradiation of the *cis* isomer is carried out in acetonitrile–methanol-*O-d* as solvent, isomerization is accompanied by deuterium exchange at the benzylic position; the *trans* isomer is stable under these conditions.

Key words: photosensitized electron transfer, radical cation, deprotonation, configurational isomerization, conformation, molecular mechanics (MM3).

ALLYSON L. PERROTT et DONALD R. ARNOLD. Can. J. Chem. **70**, 272 (1992).

L'irradiation d'un mélange de *cis*-1-méthyl-2-phénylcyclopentane (**1***b cis*), de 1,4-dicyanobenzène (**2**, un sensibilisateur accepteur d'électrons) et de 2,4,6-collidine (**3**, une base qui n'est pas nucléophile) en solution dans l'acétonitrile conduit à une isomérisation configurationnelle du cyclopentane; l'état photostationnaire favorise l'isomère *trans* à plus de 99%. Le mécanisme proposé pour cette réaction implique la formation du cation radicalaire du produit **1***b cis* par le biais d'un transfert d'électron photo-induit vers l'état excité singulet du produit **2**, une déprotonation du cation radicalaire assistée par la base **3**, la réduction, par l'anion radicalaire $\mathbf{2}^{\cdot-}$; du radical benzylique qui en résulte et un reprotonation de l'anion benzylique qui fournit les isomères *cis* et *trans* du produit **1***b*. L'état photostationnaire est contrôlé par les vitesses relatives de déprotonation des cations radicalaires des produits **1***b cis* et *trans*; ces vitesses dépendent du degré de recouvrement de la liaison carbone–hydrogène benzylique et des orbitales moléculaires SO du cation radicalaire qui sont très associées au noyau phényle. On a fait appel à des calculs de mécanique moléculaire (MM3 et MMP2) pour calculer les conformations privilégiés des isomères. Le recouvrement orbitalaire requis est efficace à 31% dans la conformation globale minimale de l'isomère *cis* et est essentiellement inefficace pour les conformères les plus stables de l'isomère *trans*. Le mécanisme proposé est en accord avec les résultats d'études d'incorporation de deutérium et d'études de désactivation de Stern–Volmer qui indiquent que les deux isomères désactivent l'état excité singulet du produit **2** à une vitesse contrôlée par la diffusion. Lorsqu'on effectue l'irradiation de l'isomère *cis* dans un mélange d'acétonitrile et de méthanol-*O-d*, l'isomérisation s'accompagne d'un échange de deutérium dans la position benzylique; dans ces conditions, l'isomère *trans* est stable.

Mots clés : transfert d'électrons photosensibilité, cation radicalaire, déprotonation, isomérisation configurationnelle, conformation, mécanique moléculaire (MM3).

[Traduit par la rédaction]

Introduction

Removal of an electron from a neutral molecule weakens bonding interactions, making cleavage more likely. There are several recent reports of photosensitized (electron transfer) carbon–carbon bond cleavage and deprotonation from radical cations generated in this way, and progress has been made toward an understanding of the scope and mechanism of these reactions (1–4). Particularly relevant to this study is the report of contrasting behaviour of the radical cations of *trans* and *cis* methyl 2-phenylcyclopentyl ethers (**1***a*) (2). Irradiation of an acetonitrile–methanol (3:1) solution of *trans* methyl 2-phenylcyclopentyl ether (**1***a trans*) and 1,4-dicyanobenzene (**2**), an electron-accepting photosensitizer, leads to formation of the radical cation $\mathbf{1}a\ trans^{\cdot+}$, which undergoes carbon–carbon bond cleavage and ultimately forms acyclic products, mainly 5-phenylpentanal dimethyl acetal (**4**) (reaction [1]). In marked contrast, the radical cation of the *cis* isomer ($\mathbf{1}a\ cis^{\cdot+}$) does not undergo carbon–carbon bond cleavage; deprotonation resulting ultimately in formation of the *trans* isomer occurs instead (reaction [2]). Evidence for the deprotonation mechanism was provided by the observation that deuterium was incorporated at the benzylic position when the irradiation was carried out in acetonitrile–methanol-*O-d*. The mechanisms for the carbon–carbon bond cleavage and the deprotonation reactions are summarized in Scheme 1.

The key step in the mechanism leading to carbon–carbon bond cleavage (step 7) requires that the dissociation energy

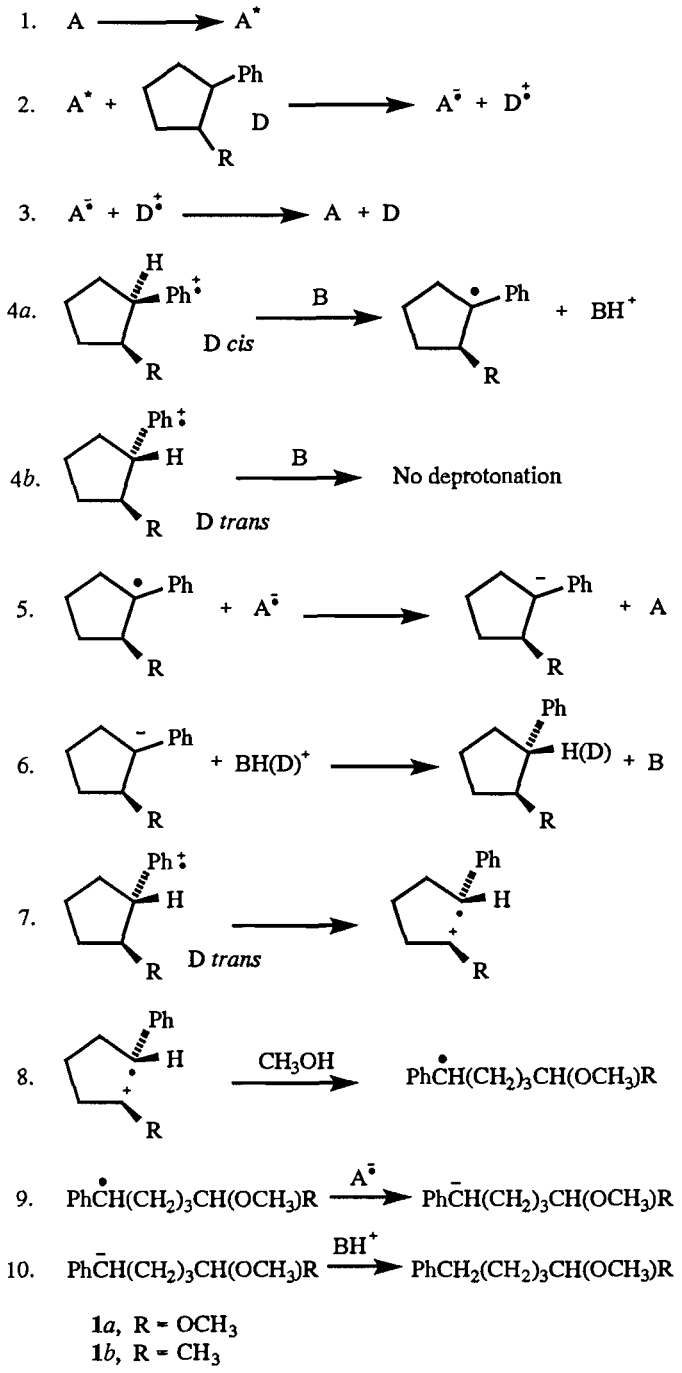
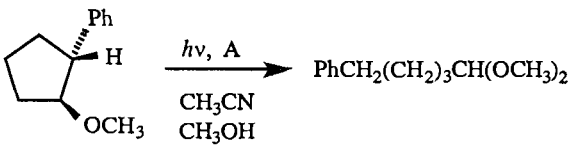


SCHEME 1

of the vulnerable bond of the radical cation be less than ca. 55 kJ mol^{-1}, that the conformation of the methoxy group allow interaction of a nonbonding electron pair on the oxygen with the σ* orbital of the vulnerable bond, and that the singly occupied molecular orbital (SOMO) of the radical cation overlap with this bond (2, 3*a*). These requirements are obviously met in the radical cation **1***a trans*$^{+\cdot}$; cleavage occurs. The lack of carbon–carbon bond cleavage of the radical cation **1***a cis*$^{+\cdot}$ was explained on the basis of an unfavourable conformation of the radical cation: insufficient overlap of a nonbonding pair of electrons on the oxygen with the σ* orbital of the vulnerable benzylic carbon–carbon bond. The preferred conformation of **1***a cis*$^{+\cdot}$ does, however, have the SOMO favourably orientated for overlap with the benzylic carbon–hydrogen bond and deprotonation occurs (step 4*a*) (2).

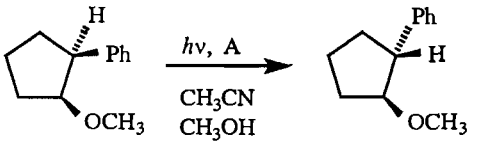
Reaction [1] (ref. 2)



1*a trans*

A = 1,4-dicyanobenzene (2)

Reaction [2] (ref. 2)



1*a cis* **1***a trans*

A = 1,4-dicyanobenzene (2)

It is well established that the thermodynamic acidity of radical cations is greatly increased relative to the neutral molecules (5). The pK_a of the benzylic hydrogen of the radical cation of toluene has been estimated to be in the range −11 to −13 (5*a*). This large increase in acidity is realized only when the SOMO and the benzylic carbon–hydrogen bond overlap. The interaction falls off in a $\cos^2$ relationship with this dihedral angle. Molecular mechanics calculations (MMP2) identify global minimum conformations of **1***a trans* and **1***a cis* that are consistent with this explanation for the difference in reactivity of these radical cations. Similar dependence of the rate of deprotonation on dihedral angle has been reported for other systems (4*b*, 6).

This study focuses on the configurational isomerization reaction exemplified by the conversion of **1***a cis* to **1***a trans*. The behaviour of the radical cations of the analogous 1-methyl-2-phenylcyclopentane isomers, **1***b cis* and **1***b trans*, has been studied. These compounds were chosen because the benzylic carbon–hydrogen bond of these radical cations should be acidic enough for the deprotonation reaction, but the carbon–carbon bond dissociation energy should be above the threshold for cleavage. Therefore, *cis–trans* isomerization should occur without competition from carbon–carbon bond cleavage.

This isomerization reaction involves changing the configuration at a saturated carbon. Such a procedure for the interconversion of diastereomers could prove to be of considerable synthetic utility.[3]

Results

Both *cis* and *trans* 1-methyl-2-phenylcyclopentane (**1***b cis*, *trans*) are known compounds (7). The stereospecific synthesis of the *cis* isomer began with a Grignard reaction, adding phenylmagnesium bromide to 2-methylcyclopentanone. The resulting alcohol was dehydrated with acid, and

[3]The diastereomeric relationship could also result from interaction of a racemic substrate (radical cation) with a chiral base. Differences in the rate of deprotonation of the diastereomeric pairs would then provide a new mechanism for chiral induction.

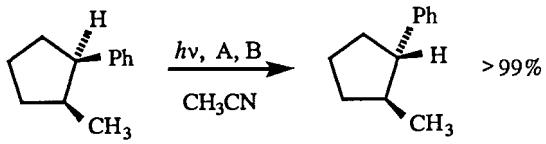
the conjugated alkene was reduced by catalytic hydrogenation. The *trans* isomer was synthesized via a two-step procedure. First, 6-phenyl-1-hexene was prepared by coupling 3-phenylpropylmagnesium bromide and allyl bromide. Then the 6-phenyl-1-hexene was cyclized to a mixture of the isomers, *trans* predominating (85%), by treatment with potassium. Pure *trans* isomer was isolated by preparative gas chromatography (gc).

The irradiation procedure was similar to that used in earlier studies (2). Solutions of the 1-methyl-2-phenylcyclopentane (**1***b*); 1,4-dicyanobenzene (**2**), an electron-accepting photosensitizer; and 2,4,6-collidine (**3**), a nonnucleophilic base, in acetonitrile or in a mixture of acetonitrile–methanol-*O*-*d* (3:1), were degassed by nitrogen ebullition and then irradiated through a Pyrex filter using a medium-pressure mercury vapour lamp. Progress of the reaction was followed by capillary column gas chromatography with a flame ionization detector (gc/fid). The results of the irradiations are illustrated in reactions [3]–[6].

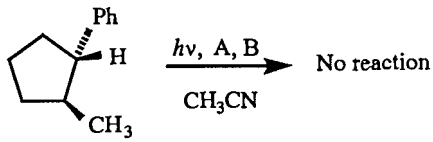
Reaction [3]



1*b cis* **1***b trans*

A = 1,4-dicyanobenzene (**2**)
B = 2,4,6-collidine (**3**)

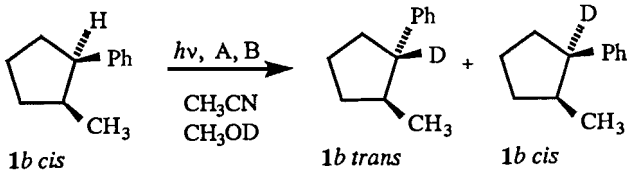
Reaction [4]



1*b trans*

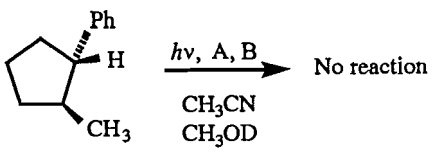
A = 1,4-dicyanobenzene (**2**)
B = 2,4,6-collidine (**3**)

Reaction [5]



1*b cis* **1***b trans* **1***b cis*

Reaction [6]



1*b trans*

Irradiation of the *cis* isomer resulted in isomerization to the *trans* isomer (reaction [3]). Starting with pure *cis* isomer, the ratio of *cis*:*trans* isomers was 79:21 after 4 days irradiation; continued progress of the reaction was impeded, presumably as a result of competitive light absorption by side products. When the irradiation was begun on a mixture of *cis* and *trans* isomers (14:86), the ratio of *cis* to *trans* isomers decreased further (3:97). When the irradiation was begun on the pure *trans* isomer (>99%), no *cis* isomer was detected (reaction [4]). A side product, formed after prolonged irradiation starting with the *cis* isomer, has been isolated and identified: 1-(4-cyanophenyl)-2-methyl-1-phenylcyclopentane (**4**). Only one of the diastereomers was detected (gc/fid, gc/ms). The stereochemical assignment (4-cyanophenyl- and methyl- *trans*) is based upon ^{1}H nmr evidence. This product was not detected when solutions of the *trans* isomer were similarly irradiated.

The deuterium incorporation studies involved similar irradiations of solutions of the cyclopentane (**1***b*), photosensitizer (**2**), and base (**3**) in acetonitrile–methanol-*O*-*d* (3:1). The extent of isomerization and deuterium incorporation was determined by capillary column gas chromatography coupled to a mass selective detector (gc/ms). Analysis of the photolysate following irradiation of the *cis* isomer indicated that all of the *trans* isomer formed had incorporated one atom of deuterium. Prolonged irradiation led to detectable amounts of deuterium incorporated in the *cis* isomer as well (reaction [5]). Analysis (^{1}H and ^{2}H nmr) of the resulting mixture of *cis* and *trans* isomers confirmed that deuterium was incorporated at the benzylic positions. Irradiation of the *trans* isomer in the acetonitrile–methanol-*O*-*d* solvent mixture did not produce the *cis* isomer and, furthermore, no deuterium was incorporated in the recovered *trans* isomer (reaction [6]).

Oxidation potentials of *cis* and *trans* 1-methyl-2-phenylcyclopentane (**1***b cis* and *trans*), required for the discussion of the initial electron transfer step, were determined by cyclic voltammetry. The voltammograms were typical of irreversible oxidation; the oxidation potentials were taken as 0.03 V preceding the anodic peak potentials (8). These values are summarized in Table 1.

Fluorescence quenching studies were carried out to confirm the initial electron transfer from the 1-methyl-2-phenylcyclopentanes (**1***b cis* and *trans*) to the singlet excited state of 1,4-dicyanobenzene (**2**). Stern–Volmer analysis of the fluorescence intensity from **2** as a function of concentration of **1***b cis* and *trans* confirms that both isomers quench the fluorescence of **2** with a rate constant 2.8×10^{10} M^{-1} s^{-1}: electron transfer takes place at the diffusion-controlled rate (Fig. 1).[4]

Molecular mechanics calculations can provide an accurate description of molecular structure (9). Since the introduction of the MMP2 program, additional experimental data have become available. Furthermore, some users have pointed out systematic errors in this program (9*d*): MMP2 underestimates the length of eclipsed single bonds. This is a particularly important deficiency in the case of cyclopentane derivatives. The development of the MM3 program (9*c*) has alleviated this problem by including a torsion-stretch interaction in the force field, and by giving cyclopentane rings distinct parameters, different from open-chain alkanes. Both MM3 and MMP2 molecular mechanics calculations were used to describe the conformers of *cis* and *trans* 1-methyl-2-phenylcyclopentane (**1***b cis* and **1***b trans*). The search for

[4]The slopes of the Stern–Volmer plots (Fig. 1) were $k_q\tau$ = 249.9 for **1***b trans* and 245.4 for **1***b cis*. The measured fluorescence lifetime of 1,4-dicyanobenzene (**2**) in acetonitrile is 8.8×10^{-9} s (10).

TABLE 1. Oxidation potentials of some of the compounds of interest

	E_p (V)[a]	$E_{p/2}$ (mV)
cis Methyl 2-phenylcyclopentyl ether (**1***a cis*)	2.05[b]	117
trans Methyl 2-phenylcyclopentyl ether (**1***a trans*)	2.05[b]	162
cis 1-Methyl-2-phenylcyclopentane (**1***b cis*)	2.30	197
trans 1-Methyl-2-phenylcyclopentane (**1***b trans*)	2.35	228

[a]Anodic peak potential taken from the cyclic voltammogram at a 100 mV/s sweep rate. The reference electrode was saturated calomel (sce). The oxidation potential can be estimated from the peak potential by subtraction 0.028 V (ref. 8).

conformers began with all permutations of structures having the phenyl or the methyl group on either side of the flap of the envelope cyclopentane structure. Four energy minima were identified for each isomer. These results are summarized in Table 2. The global minimum conformations of **1***b cis* and **1***b trans* are illustrated in Figs. 2 and 3.

Discussion

The first three steps in the proposed mechanism for both the carbon–carbon bond cleavage and the deprotonation reactions (Scheme 1) are the same. The first step involves excitation of the photosensitizer, 1,4-dicyanobenzene (**2**). The ultraviolet absorption spectrum of **2** extends out to 290 nm, beyond the short wavelength cutoff of the Pyrex filter. The other components of the irradiation mixture are transparent in this region.

The singlet excited state of **2** can accept an electron from either **1***b cis* or *trans*. The free-energy change (ΔG_{et}) associated with this electron transfer can be calculated from the oxidation potential of the donor, the reduction potential of the acceptor, and the singlet excited state energy by using the Weller equation (eq. [7]) (11). For both *cis* and *trans* **1***b*, electron transfer is exergonic by at least 30 kJ mol^{-1}. Under these conditions electron transfer is expected to occur at the diffusion-controlled rate and the observed fluorescence quenching rate constants, ca. 2.8×10^{10} M^{-1} s^{-1} for both isomers, are in agreement.

$$[7] \quad \Delta G_{et} = F[E^{ox}_{1/2}(D) - E^{red}_{1/2}(A) - e/\epsilon\alpha] - E_{0,0}(A)$$

$$[8] \quad \Delta G_{-et} = F(E^{red}_{1/2}(A) - E^{ox}_{1/2}(D))$$

The third step in the mechanism is back electron transfer, an energy-wasting step that regenerates the ground state starting materials. Back electron transfer, following photoinduced electron transfer, is always exergonic (eq. [8]). However, when the process is as favourable as it is in this case, $\Delta G_{-et} = -4$ eV, the rate falls within the Marcus inverted region and the process becomes relatively slow (12). Estimates based upon study of similar systems place the rate of back electron transfer within the radical ion pair in the range 10^6–10^8 s^{-1} (12*b*). That is, back electron transfer is slow enough to allow a rapid bimolecular reaction of the radical cation within the radical ion pair.

Rapid deprotonation (step 4) requires overlap of the SOMO with the benzylic carbon–hydrogen bond. Maximum interaction occurs when the SOMO and the benzylic bond are at an angle of 0°; there will be no increase in acidity when the benzylic hydrogen is in the same plane as the phenyl ring. The magnitude of the interaction follows a $\cos^2$ relationship with the angle between the SOMO and the benzylic bond (13).[5] Molecular mechanics calculations, both MM3 and MMP2, indicate that the angle (θ) between the plane of the phenyl ring and the benzylic carbon–hydrogen bond is ca. 1° in the global minimum conformation of **1***b trans* (Fig. 3). Furthermore, there is no reactive conformer readily accessible by thermal equilibration. The only potentially reactive conformer ($\theta = 32.5°$) is 15 kJ mol^{-1} above the global minimum (Table 2). It is therefore not surprising that the radical cation of this isomer is stable under these conditions. In marked contrast, this angle is 34° (31% effective overlap) according to the MM3 calculations (51°, or 60% maximum overlap according to the MMP2 calculations) in the global minimum of the *cis* isomer (Fig. 2). While this interaction

[5]Since the molecular mechanics calculations provide an angle (θ) between the plane of the phenyl ring and the benzylic bond, the orbital overlap is assessed with the 1-$\cos^2\theta$ relationship.

TABLE 2. Conformers of *cis* and *trans* 1-methyl-2-phenylcyclopentane (**1***b cis*, *trans*)

Initial conformation[a]	Angle[b]	Energy above the global minimum (kJ/mol)
1*b cis*		
Phenyl (flap-eq), methyl (ax)	34° (51°)	Global minimum (Global minimum)
Methyl (flap-eq), phenyl (ax)	c (8.6°)	c (1.6)
Phenyl (flap-ax), methyl (eq)	24.7° (26.8°)	0.5 (2.3)
Methyl (flap-ax), phenyl (eq)	d (28.3°)	d (6.5)
1*b trans*		
Phenyl (flap-eq), methyl (eq)	1° (1°)	Global minimum (Global minimum)
Methyl (flap-eq), phenyl (eq)	d (9.3°)	d (1.4)
Phenyl (flap-ax), methyl (ax)	32.5° (27.9°)	14.9 (10.0)
Methyl (flap-ax), phenyl (ax)	4.1° (d)	21.1 (d)

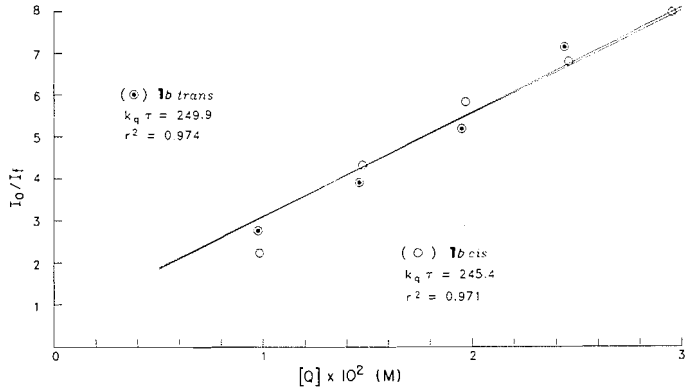

FIG. 1. Stern–Volmer plots of the fluorescence intensity from 1,4-dicyanobenzene (**2**) as a function of the concentration of *cis* and *trans* 1-methyl-2-phenylcyclopentane (**1***b cis* and **1***b trans*).

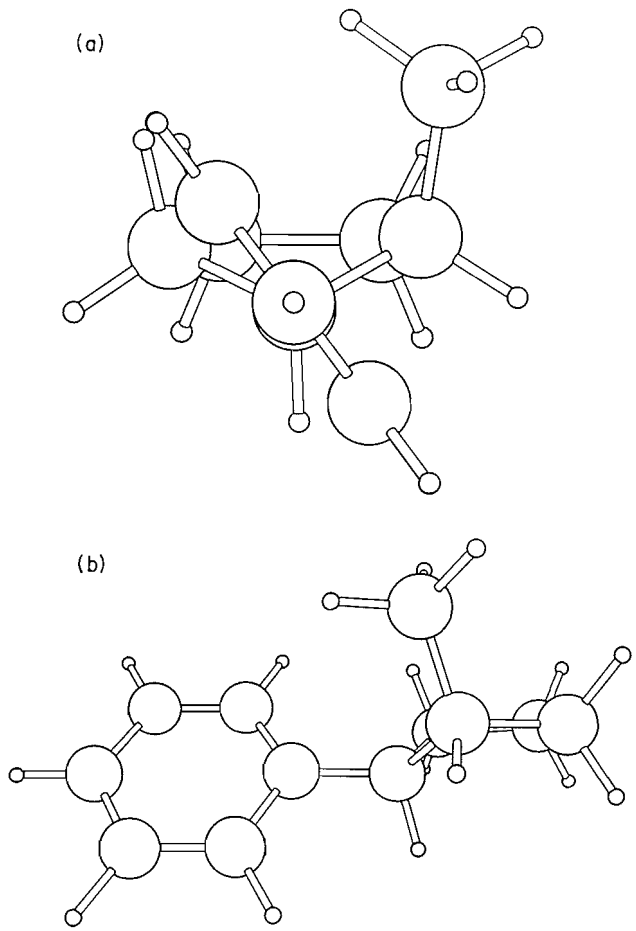

FIG. 2. The global minimum conformer (MM3) of *cis* 1-methyl-2-phenylcyclopentane (**1***b cis*): (a) looking down the plane of the phenyl ring, (b) with the plane of the phenyl ring nearly in the *x*,*y*-plane.

is less than optimal, the radical cation of **1***b cis* does deprotonate: exchange of deuterium for hydrogen at the benzylic position and isomerization to the *trans* isomer are observed.

Two obvious assumptions must be justified: the molecular mechanics calculations were performed on the neutral molecules while the reactive species are the radical cations,

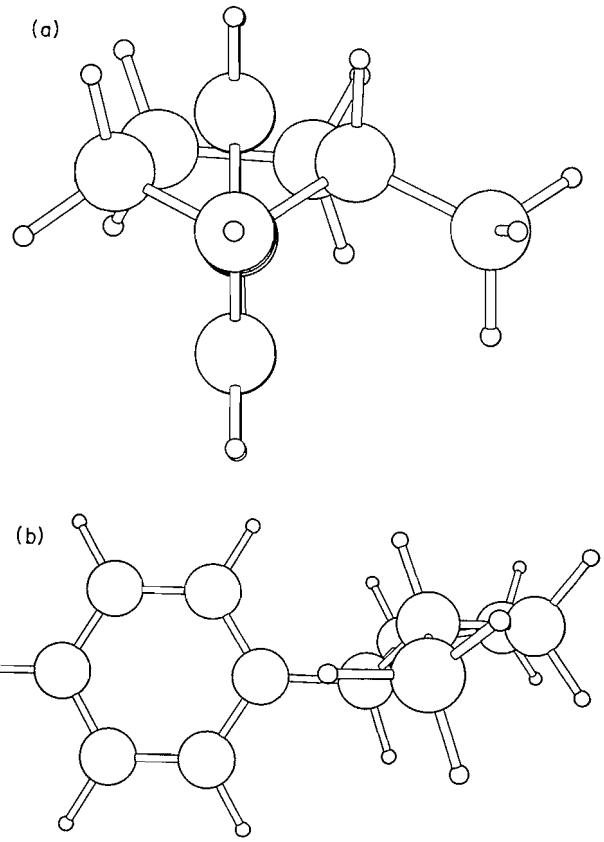

FIG. 3. The global minimum conformer (MM3) of *trans* 1-methyl-2-phenylcyclopentane (**1***b trans*): (a) looking down the plane of the phenyl ring, (b) with the plane of the phenyl ring nearly in the *x*,*y*-plane.

and even though the global minimum conformation does not have favourable orbital overlap, other conformers with the required overlap may be accessible by thermal equilibration. With these hydrocarbons, it is likely that the SOMO is largely associated with the phenyl ring, the preferred conformation of the neutral molecule and the radical cation will be similar, and the molecular mechanics calculations carried out on the neutral molecules can be extended to the radical cations. The lifetime of the radical cation is short, and competitive deactivation by back electron transfer is rapid; therefore, deprotonation will be inefficient if the global minimum conformer does not have favourable overlap.

The acidity of the benzylic hydrogen of the radical cations **1***b cis*$^{\ddagger\cdot}$ and **1***b trans*$^{\ddagger\cdot}$, estimated from a thermochemical cycle (eq. [9] (5*a*)), is pK_a = −15.[6] This high

[6]The acidity of the benzylic hydrogen of the radical cation **1***b trans*$^{\ddagger\cdot}$ can be estimated from the bond dissociation free-energy ($\Delta G^0_{BDE(RH)}$, using cumene as a model) and the standard oxidation potential (E^0_{RH}) using Method 1 (eq. [9]) described in ref. 5*a*. The required data are $\Delta H_{BDE(RH)}$ = 353 ± 6 kJ mol^{-1} (14*a*); $\Delta S_{BDE(RH)}$ = 110 ± 4 J mol^{-1} (14*b*); so, $\Delta G^0_{BDE(RH)}$ = 322 ± 25 kJ mol^{-1}; $E^{ox}_{1/2}$ (**1***b trans*$^{\ddagger\cdot}$) = 2.32 V (vs. sce) (Table 1), accepting this value as an estimate of the standard oxidation potential, E^0_{RH} = 2.56 V (vs. standard hydrogen electrode); $\Delta G^0_{tr(H^+)CH_3CN}$ = 46.0 kJ mol^{-1} (14*c*); $\Delta G^0_{f(H)g}$ = 203.2 kJ mol^{-1} (14*d*). The pK_a (**1***b trans*$^{\ddagger\cdot}$) = −15. The K_a (toluene$^{\ddagger\cdot}$) = −13 by this method.

thermodynamic acidity of the radical cation means that even the solvent, i.e., acetonitrile, might serve as the base.

$$[9]\quad pK_{a(RH^{+})sol} = \frac{1}{2.303\,RT}(-FE^{0}_{RH} + \Delta G^{0}_{tr(H^{+})sol} + \Delta G^{0}_{BDE(RH)g} - \Delta G^{0}_{f(H)g})$$

However, the reaction is significantly more efficient when the stronger base, 2,4,6-collidine (**3**), has been added. The effect of added base, assisting in the deprotonation of strongly acidic radical cations, has been observed before (15).

The final steps in the mechanism for isomerization (Scheme 1, steps 5 and 6), reduction of the radical by the radical anion of the photosensitizer followed by protonation (deuteration), are well understood. The reduction potential of the benzylic radical will be similar to that of the cumyl radical (−1.73 V vs. sce (16)), which is close to that of 1,4-dicyanobenzene (**2**) (−1.66 V). Equilibrium electron transfer is possible and protonation of the carbanion will be rapid. Competitive formation of the 1:1 adduct (1-(4-cyanophenyl)-2-methyl-1-phenylcyclopentane (**4**) results from coupling of the benzylic radical, on the least hindered side, and the radical anion of 1,4-dicyanobenzene, at the *ipso* position, followed by rearomatization of the resulting cyclohexadienyl anion by loss of cyanide ion.

We found no evidence, in any case, for carbon–carbon bond cleavage of either **1***b cis* or **1***b trans*. The global minimum conformer of **1***b trans* has the required overlap of the SOMO with the vulnerable bond; the angle between the plane of the phenyl ring and the benzylic carbon–carbon bond is 57° (70% effective overlap). Nevertheless, cleavage does not occur. This lack of reactivity is readily explained on energetic grounds. Thermochemical cycles used for estimating the bond dissociation energy of the vulnerable benzylic carbon–carbon bond of the radical cations (Scheme 1, step 7) are shown in Fig. 4.[7] Cleavage of the radical cation to the distonic radical cation is well below the threshold energy (ca. 55 kJ mol^{-1} (3*a*)) for the ethers (**1***a*) but is significantly above the maximum for the hydrocarbons (**1***b*). The major difference in the two systems is the lower oxidation potential of the α-oxy radical, relative to that of a secondary benzylic radical (16).

The photostationary state lies well in favour (>99%) of the *trans* isomer (reaction 3). This observation is consistent with the fact that no deuterium was incorporated in **1***b trans*, even after prolonged irradiation is acetonitrile–methanol-*O*-*d* (3:1) (reaction 6). The reported synthesis of **1***b* by the alkali metal catalyzed cyclization of 6-phenyl-1-hexene in refluxing butylcyclohexane gave a mixture of isomers, *trans*:*cis* = 5:1, which was presumed to be a thermodynamic equilibrium corresponding to a difference in energy ΔG = 6 kJ mol^{-1} at 185° (7). We repeated this synthesis, using decalin as solvent, and an 8:1 ratio of isomers (ΔG = 8 kJ mol^{-1} at 190°C) was obtained. The difference in the heat of formation of the isomers calculated with MM3 is 11 kJ mol^{-1} (5 kJ mol^{-1} by MMP2). Despite the lack of quantitative agreement among these estimates, it is evident that the photostationary state lies further in favour of the *trans* isomer than would be obtained at thermodynamic equilibrium.

In this case both the photostationary state and the thermodynamic equilibrium favour the *trans* isomer. In general, the conformational criterion controlling the photostationary state is unrelated to thermodynamic considerations. It will be possible to use this photosensitized (electron transfer) isomerization reaction to convert a more stable isomer to the less stable isomer. The ability to change configuration at a saturated carbon should prove to have signif-

[7]The data for Fig. 4 were taken from refs. 14*a*, *b*, 16, and 17.

icant synthetic utility; our efforts to define the scope of the reaction and to improve the efficiency continue.

Experimental

General information

The ^1H and ^{13}C nmr spectra were recorded on a Nicolet Instruments Corp. narrow bore 360-MHz spectrometer and are reported in parts per million relative to tetramethylsilane. Infrared spectra were recorded on a Perkin–Elmer 180 spectrometer. Frequencies are reported in wavenumbers, relative to polystyrene film (1601.8 cm^{-1}). Gas chromatography with mass selective detection (gc/ms) was carried out on a Hewlett–Packard 5890 gc/5970 mass selective detector interfaced with a Hewlett–Packard 9816 microcomputer. The column used was 25 m × 0.2 mm 5% phenyl methyl silicone on fused silica with a film thickness of 0.25 μm. Gas chromatography with flame ionization detection (gc/fid) was carried out on a Hewlett–Packard 5890. The column used was 25 m × 0.25 mm OV-1701 fused silica. Preparative gas chromatography was carried out on an Aerograph A-700 gc fitted with a thermal conductivity detector, using a 6 ft × $\frac{1}{4}$ in. 20% SE-30 on Chromosorb 60/80 W column.

Electrochemical measurements

Oxidation potentials were obtained by cyclic voltammetry using a three-electrode cell, which has been described previously (18). The working electrode was a platinum sphere (1 mm diameter) and the counter electrode was a platinum wire. The reference electrode was saturated calomel (sce). The electrolyte was 0.1 M tetraethylammonium perchlorate (TEAP) in acetonitrile. Substrate concentrations were approximately 1 mM.

The peak potentials were measured with a 100 mV/s sweep rate. No cathodic wave was detected following the anodic sweep. The half-wave potentials were taken as 0.03 V before the anodic peak potentials (8).

Irradiations

Irradiations were carried out in Pyrex tubes using a Canadian General Electric Co. 1-kW medium-pressure mercury vapour lamp with a Pyrex cooling jacket immersed in a constant temperature bath held at 10°C. Samples were degassed by nitrogen ebullition for 5 min prior to irradiation.

Fluorescence quenching studies

Fluorescence quenching experiments were performed by using a Perkin–Elmer MPF-66 fluorescence spectrophotometer with a Perkin–Elmer MPF-66 xenon lamp power supply interfaced to a Perkin–Elmer 7500 computer. Solutions were 0.01 M in 1,4-dicyanobenzene (**2**). The quencher concentrations ranged from 0.01 to 0.03 M. Solutions were degassed on a vacuum line by three freeze–pump–thaw cycles. The excitation wavelength was 293 nm; the emission was monitored at 309.4 nm. From the previously measured singlet lifetime of **2**, 8.8 × 10^{-9} s (10), both isomers quench the fluorescence with a rate constant of 2.8 × 10^{10} s^{-1}.

Calculations

Molecular mechanics calculations were carried out on a VAX 8800 mainframe computer. The 1989 force field of MM3 and the 1987 force field of MMP2 were used. The dihedral driver option was used to rotate the phenyl group.

Materials

Solvents were distilled prior to use. Acetonitrile and 1,4-dicyanobenzene (**2**) (Aldrich Chem. Co.) were purified as previously described (19). Bromobenzene, 2-methylcyclopentanone, and 1-bromo-3-phenylpropane were obtained from the Aldrich Chemical Company. Decalin and 2,4,6-collidine were obtained from BDH, *o*-chlorotoluene was obtained from Matheson Coleman and Bell, allyl bromide was obtained from Fisher, and cyclododecane was obtained from K & K Laboratories.

Preparation of compounds

Preparation of cis *1-methyl-2-phenylcyclopentane (***1**b cis*)*

2-Methyl-1-phenylcyclopentanol was prepared by a Grignard reaction (7*a*). Bromobenzene (43 mL, 64 g, 0.41 mol) was added to magnesium turnings (10 g, 0.41 mol) in anhydrous diethyl ether. When reaction was complete, the flask was cooled in ice, and 2-methylcyclopentanone (15 mL, 14 g, 0.14 mol) was added dropwise. The reaction mixture was poured into a mixture of concentrated HCl and ice, and then extracted with ether. The combined organic layer was washed with 5% $NaHCO_3$ and with distilled water. Finally, the organic layer was dried over $MgSO_4$ and the solvent was evaporated.

The alcohol was refluxed with *p*-toluenesulfonic acid in benzene. Water was removed by using a Dean–Stark trap. The crude 1-methyl-2-phenylcyclopentene was chromatographed with hexanes on silica gel.

The cyclopentene was hydrogenated over 10% Pd on carbon in ethanol. Chromatography of the product on silica gel with hexanes gave 1-methyl-2-phenylcyclopentane in 88% purity, 30% yield. Preparative gas chromatography was used to prepare samples of 99% purity; ^1H nmr (360 MHz) in $CDCl_3$: 7.1–7.3 (m, 5H), 3.1 (m, 1H), 2.3 (m, 1H), 1.8–2.0 (m, 4H), 1.7 (m, 1H), 1.4 (m, 1H), 0.6 (d, 3H, J = 7.1 Hz).

Preparation of trans *1-methyl-2-phenylcyclopentane (***1**b trans*)*

The synthesis of the *trans* isomer followed the procedure of Pines and co-workers (7*b*, *c*). The first step involves the synthesis of 6-phenyl-1-hexene. 1-Bromo-3-phenylpropane (24 mL, 31 g, 0.16 mol) was added to magnesium turnings (3.8 g, 0.16 mol) in anhydrous diethyl ether. When reaction was complete, allyl bromide (14 mL, 20 g, 0.16 mol) was added dropwise. After the addition was complete, the reaction mixture was refluxed for 16 h. The mixture was cooled and poured into a slurry of concentrated HCl and ice. The aqueous layer was extracted with ether, and the combined organic extracts were washed with 5% $NaHCO_3$ and then with distilled water. The organic extract was dried over $MgSO_4$ and the solvent was evaporated. The crude product was chromatographed on silica gel with hexanes. 6-Phenyl-1-hexene was obtained in 68% yield.

Potassium (0.94 g, 0.024 mol) and *o*-chlorotoluene (0.40 mL, 0.43 g, 0.0034 mol) were refluxed in decalin (25 mL) for 15 min. 6-Phenyl-1-hexene (7.43 g, 0.046 mol) was added dropwise, and the mixture was refluxed for 25.5 h. The black, sludgy reaction mixture was chilled in ice, and isopropanol was added to decompose any remaining potassium. The mixture was diluted with hexanes (100 mL) and filtered to remove the sediment. The filtrate was washed with distilled water until neutral. The organic layer was dried over $CaCl_2$, and the hexanes were evaporated. The remaining solution was distilled under reduced pressure to remove most of the decalin. The residue was chromatographed on silica gel with hexanes as the eluent to give 85% pure *trans* in 34% yield from 6-phenyl-1-hexene. Small quantities of pure *trans* were obtained by preparative gas chromatography; ^1H nmr (360 MHz) in $CDCl_3$: 7.1–7.3 (m, 5H), 2.4 (m, 1H), 1.9–2.1 (m, 3H), 1.7–1.8 (m, 3H), 1.3 (m, 1H), 0.9 (d, 3H, J = 6.4 Hz).

Irradiations

Irradiations of cis *1-methyl-2-phenylcyclopentane (***1**b cis*)*

A solution of 99% pure *cis* isomer (14 mg, 8.7 × 10^{-5} mol), 1,4-dicyanobenzene (**2**) (7.2 mg, 5.6 × 10^{-5} mol), 2,4,6-collidine (**3**) (17 mg, 1.4 × 10^{-4} mol), and cyclododecane (5.2 mg, 3.1 × 10^{-5} mol) in acetonitrile (3 mL) was irradiated for 4 days. Progress of the reaction was followed by gc/fid, using the peak due to cyclododecane as an internal standard. The yield of *trans* isomer was 24% at 50% conversion.

A solution of 99% pure *cis* isomer (15 mg, 9.5 × 10^{-5} mol), (**2**) (8.8 mg, 6.9 × 10^{-5} mol), (**3**) (20 mg, 1.6 × 10^{-4} mol), and cyclododecane (6.3 mg, 3.7 × 10^{-5} mol) was irradiated in acetonitrile–methanol-*O*-*d* (3 mL, 3:1) for 4 days. The *trans* isomer was formed in 17% yield at 46% conversion (gc/fid). Some of the *cis*

isomer and all of the *trans* isomer had incorporated one atom deuterium (gc/ms). Analysis of the ^1H and ^2H nmr spectra indicate exchange occurred at the benzylic position.

A solution of 95% pure *cis* isomer (9.2 mg, 5.7×10^{-5} mol), (**2**) (6.4 mg, 5.0×10^{-5} mol), and cyclododecane (4.4 mg, 2.6×10^{-5} mol) in acetonitrile (2 mL) was irradiated for 1 day. At 74% conversion, the yield of the *trans* isomer was 7% (gc/fid).

A stirred solution of 99% pure *cis* isomer (0.18 g, 1.1×10^{-3} mol), (**2**) (0.56 g, 4.4×10^{-3} mol), and (**3**) (0.28 g, 2.3×10^{-3} mol) in acetonitrile (60 mL) was irradiated for 1 day. The photolysate was chromatographed on silica gel using 1:1 hexanes–CH_2Cl_2 as the eluent. 1-(4-Cyanophenyl)-2-methyl-1-phenylcyclopentane (**4**) was isolated in 36% yield (72% conversion); ir: 3065 (w), 3040 (w), 3010 (w), 2940 (s), 2860 (s), 2215 (s), 1730 (w), 1600 (s), 1500 (m), 1490 (s), 1455 (m), 1445 (m), 1400 (w), 1375 (w), 1015 (w), 885 (w), 815 (s), 740 (m), 715 (m), 685 (s). ^1H nmr (360 MHz) in $CDCl_3$: 7.0–7.5 (m, 9H), 2.8 (m, 1H), 2.6 (m, 1H), 1.8–2.1 (m, 3H), 1.6 (m, 1H), 1.4 (m, 1H), 0.8 (d, 3H); ^{13}C nmr (90 MHz) in $CDCl_3$: 155.4 (s), 145.0 (s), 131.8 (d), 128.8 (d), 128.0 (d), 127.8 (d), 126.0 (d), 119.1 (s), 109 (s), 58.8 (s), 39.3 (d), 38.8 (t), 32.1 (t), 21.4 (t), 17.6 (q). Exact Mass calcd. for $C_{19}H_{19}N$: 261.1517; found: 261.1517.

Irradiations of trans *1-methyl-2-phenylcyclopentane (***1**b trans*)*

A solution of a mixture of isomers, 86% *trans*:14% *cis* (12 mg, 7.8×10^{-5} mol), 1,4-dicyanobenzene (**2**) (11 mg, 8.7×10^{-5} mol), and 2,4,6-collidine (**3**) (15 mg, 1.2×10^{-4} mol) in acetonitrile (3 mL) was irradiated for 7 days. The ratio of isomers in the irradiated mixture was 97:3 *trans*:*cis*.

A solution of 99% pure *trans* isomer (10 mg, 6.2×10^{-5} mol), (**2**) (6.1 mg, 4.8×10^{-5} mol), (**3**) (14 mg, 1.2×10^{-4} mol), and cyclododecane (4.3 mg, 2.6×10^{-5} mol) in acetonitrile (3 mL) was irradiated for 6 days. No volatile products were detected by gc/fid.

A solution of 99% pure *trans* isomer (10 mg, 6.5×10^{-5} mol), (**2**) (5.4 mg, 4.2×10^{-5} mol), (**3**) (14 mg, 1.2×10^{-4} mol), and cyclododecane (4.2 mg, 2.5×10^{-5} mol) in acetonitrile-methanol-*O*-*d* (3 mL, 3:1) was irradiated for 6 days. No volatile products were detected by gc/fid. No deuterium incorporation was detected in the *trans* isomer (gc/ms).

Characterization of the triplet excited state of the phenylxanthenium carbocation[1]

L. J. JOHNSTON[2] AND D. F. WONG

Steacie Institute for Molecular Sciences, National Research Council Canada, Ottawa, Ont., Canada K1A 0R6

Received August 16, 1991

L. J. JOHNSTON and D. F. WONG. Can. J. Chem. **70**, 280 (1992).

The triplet excited state of the 9-phenylxanthenium cation has been observed directly by both luminescence and transient absorption techniques. The triplet–triplet absorption shows $\lambda_{max} \leq 300$ nm and decays over a period of several microseconds in the absence of easily oxidized donors. The triplet cation reacts with 9-phenylxanthydrol and biphenyl via electron transfer to give the corresponding radical and radical cation and also reacts rapidly with both oxygen and 1,3-cyclohexadiene.

Key words: carbocations, triplets, electron transfer, laser flash photolysis.

L. J. JOHNSTON et D. F. WONG. Can. J. Chem. **70**, 280 (1992).

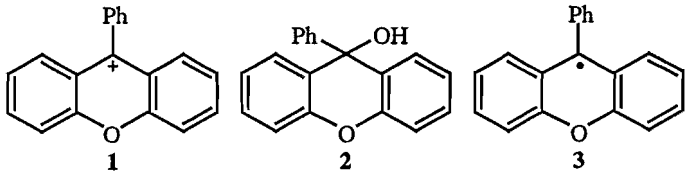
Utilisant des techniques de luminescence et d'absorption d'espèces transitoires, on a observé l'état excité triplet du cation 9-phénylxanthénium directement. L'absorption triplet–triplet présente un λ_{max} à $\leq$300 nm et, en l'absence de donneurs facilement oxydables, elle décroit sur une période de plusieurs microsecondes. Le cation triplet réagit avec le 9-phénylxanthydrol et le biphényle par le biais d'un transfert d'électrons qui conduit au radical et au cation radical correspondant et il réagit aussi rapidement avec l'oxygène ainsi que le cyclohexa-1,3-diène.

Mots clés : carbocations, triplets, transfert d'électrons, photolyse éclair au laser.

[Traduit par la rédaction]

Despite the large volume of data on the reactivities of photogenerated ground state carbocations (1), there have been relatively few investigations of the excited state behavior of these intermediates (2–12). Most of the available information deals with intramolecular rearrangements such as the photo-cyclization of the triphenylmethyl cation (2) and valence isomerizations of protonated unsaturated carbonyl compounds (3, 5, 6) and a variety of aromatics (7). Until recently the excited states involved in these reactions were not characterized. We recently reported a detailed study of the fluorescent properties of a variety of arylmethyl carbocations and demonstrated that excited singlet xanthenyl and dibenzosuberenyl carbocations undergo efficient intermolecular reaction with aromatic donors via an electron transfer mechanism (8). Similar results have also been reported by Das and co-workers for the 9-phenylxanthenium system (9, 10). Further, reaction of triplet 1-methoxynaphthalene with bis(4-methoxyphenyl)methyl cation results in products derived from electron transfer (13). Herein we describe the first direct observation of the excited triplet state of the 9-phenylxanthenium carbocation using both transient absorption and luminescence techniques.

Stable solutions of the 9-phenylxanthenium carbocation (**1**) can be readily generated by protonation and subsequent dehydration of the parent alcohol (9-phenylxanthydrol, **2**) using moderate concentrations (1–10 mM) of trifluoroacetic acid in 2,2,2-trifluoroethanol (TFE). Laser excitation of **1** in TFE[3] using the third harmonic (355 nm) from a Nd:YAG laser results in a complex transient absorption spectrum (Fig. 1) that changes with both time and concentration of the precursor alcohol. Spectrum A in Fig. 1 shows both bleaching of the cation absorption in the 350–450 nm region and a transient (X) at shorter wavelengths ($\lambda_{max} < 300$ nm). This spectrum was recorded 0.5 μs after the laser pulse for a 10^{-4} M solution of **2**. At later times transient X has almost completely decayed, some of the initial cation bleaching has recovered, and an additional long-lived species is observed at 340 nm. These changes are more apparent at higher initial concentrations of alcohol **2**, as shown in Fig. 1, spectrum B; note that the same cation concentration was obtained for both alcohol concentrations by adjusting the amount of acid to give matched optical densities at 355 nm. The long-lived signal at 340 nm can be readily assigned to the 9-phenylxanthenyl radical (**3**) based on its similarity to the known spectrum for this species (9). Radical **3** has a lifetime in excess of 0.5 ms under our experimental conditions. Examination of kinetic traces at 300 and 340 nm on several different time scales demonstrates that X decays within 5–10 μs at low concentrations of alcohol **2** and that its lifetime decreases with increasing concentrations of **2**. The 340 nm signal assigned to the phenylxanthenyl radical shows a growth that is concomitant with the decay at 300 nm, as shown in Fig. 1, and its yield increases with increasing alcohol concentrations. At low alcohol concentrations very little radical is produced and most of the cation bleaching recovers, with kinetics that are identical to the decay of X at 300 nm. Under conditions where the lifetime of X has been shortened by the addition of **2** only a small amount of the cation bleaching recovers on the maximum time scale that we have examined (400 μs).



1 **2** **3**

The above observations are consistent with transient X

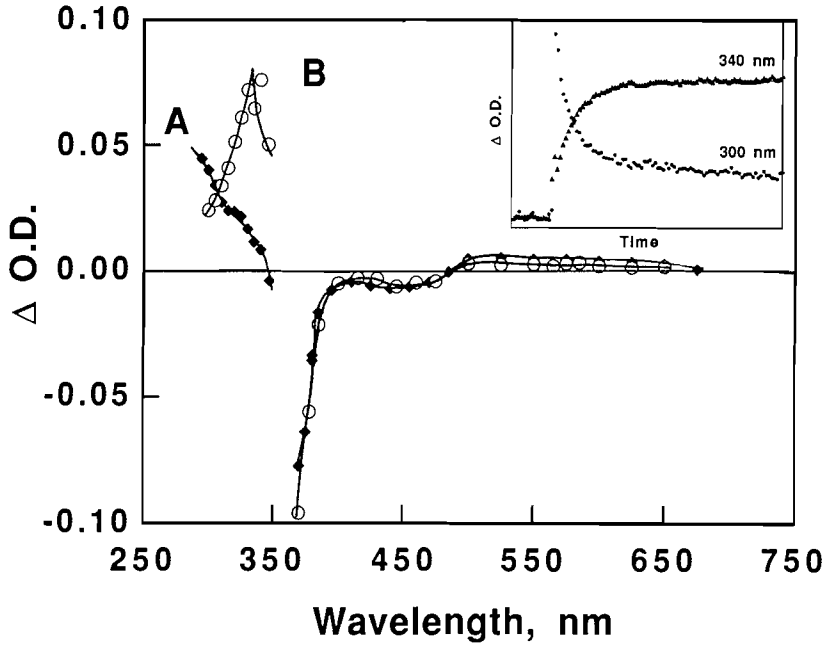

FIG. 1. Transient absorption spectra produced by 355 nm excitation of cation **1** in TFE/H^+: A, 0.13 mM **2**, 0.5 μs delay; B, 0.63 mM **2**, 5 μs delay. Insert: Decay and growth of the transient absorptions at 300 and 340 nm, respectively, following 355 nm excitation of cation **1** in TFE with 0.1 mM initial concentration of alcohol **2**.

reacting with alcohol **2** to generate radical **3**. The rate constants for decay of X at several alcohol concentrations (after correction for the amount of alcohol converted to cation) can be used to calculate an approximate rate constant of 5×10^9 M^{-1} s^{-1} for this reaction. Several additional experiments were carried out in an attempt to identify X. Firstly, the lifetime of X decreased in the presence of air or oxygen (k_q (O_2) ~ 8×10^9 M^{-1} s^{-1}); samples deaerated with oxygen showed no evidence for either X or radical **3**. This is not due to reaction of the singlet cation with oxygen since it was previously demonstrated that the fluorescence lifetime of **1** is the same within experimental error in either oxygen or nitrogen-purged TFE (8). However, addition of sufficient aromatic donor (e.g., anisole) to quench >90% of the excited singlet cations does prevent the formation of both species X and the radical. Secondly, the lifetime of X decreased in the presence of 1,3-cyclohexadiene, with $k_q = 3.5 \times 10^9$ M^{-1} s^{-1}. In this case radical **3** was still formed, again with kinetics that agreed with the decay of the 300 nm transient. Thirdly, excitation of cation **1** in TFE or in ethanol/H^+ glasses at 77 K in a fluorimeter gave weak phosphorescence at 600 nm; the excitation spectrum matched the ground state spectrum of the cation, indicating that the parent alcohol is not the emitting species.

These results suggest that transient X is the triplet excited state of cation **3**. In the absence of quenchers this species decays back to ground state cation with a rate constant that under our conditions is probably limited by traces of oxygen in the sample. The observed oxygen quenching and phosphorescence are consistent with the triplet assignment. The phosphorescence spectrum indicates a triplet energy of approximately 48 kcal, which is reasonable based on the singlet energy of 57 kcal. The triplet reacts with excess alcohol **2** to yield radical **3**, presumably via electron transfer as shown in reaction [1]. Based on the triplet energy and the redox potentials of 0.02 and 0.9 V for radical **3** (15) and alcohol **2** (9), respectively, calculation using the Rehm–Weller equation indicates that reaction [1] is exothermic by ~28 kcal (16). Radical cations in xanthenyl systems have strong absorptions at long wavelength (λ_{max} 900 nm) with a weaker band between 330 and 380 nm (17). The latter would not be readily detectable in our experiments due to overlap with the strong radical signal and cation bleaching. However, there are small differences between the spectrum of **1** and the bleaching observed in the transient experiment, which may indicate some additional absorption in the 350–450 nm region. Further, triplet **2** can be ruled out as a possible candidate for transient X since the latter is not formed by excitation of **2** alone and since the triplet–triplet absorption of **2** has been observed at 440 nm (9).

[1] $\mathbf{1}^* + \mathbf{2} \rightarrow \mathbf{3} + \mathbf{2}^{+\cdot}$

The triplet energy calculated from the phosphorescence spectrum suggests that energy transfer from triplet **1** to 1,3-cyclohexadiene is endothermic by 5–6 kcal/mol. This and the fact that radical **3** is formed efficiently when triplet **1** reacts with diene indicates that this reaction also occurs via electron transfer, which is exothermic by ~7 kcal in this case. The fact that triplet **1** undergoes an efficient electron transfer reaction is confirmed by its rapid reaction with electron donors such as biphenyl. In this case, triplet **1** is quenched with a rate constant of 4.0×10^9 M^{-1} s^{-1}, with the concomitant production of radical **3** and the biphenyl radical cation with its characteristic absorption at 650 nm (17). The efficient electron transfer quenching of triplet **1** is in good agreement with recent reports of efficient electron transfer reactions ($k_q \sim 5 \times 10^9$ M^{-1} s^{-1}) of singlet excited xanthenyl (8, 10) and dibenzosuberenyl (8) cations.

In conclusion, the present results provide direct luminescence and transient absorption evidence for the first excited triplet state of the phenylxanthenium carbocation. The triplet is formed by intersystem crossing from the first excited singlet state,[4] and has a lifetime on the order of 5–10 μs in TFE in the absence of easily oxidized additives. In accord with our earlier results on the behavior of singlet excited diarylmethyl cations, the triplet excited cation readily undergoes electron transfer reactions with various donors. To our knowledge, this represents the first direct observation and characterization of a triplet excited state arylmethyl carbocation, although protonated triplet benzophenones and xanthones have been reported (18) and triplet ground state aryl cations have been observed in glasses at 77 K (11, 12). In this regard it should also be noted that a triplet state has been postulated as an intermediate in some of the photochemistry of the triphenylmethyl cation, although this was not based on any direct spectroscopic evidence (2, 7). Work aimed at generating other diarylmethyl cations by either direct excitation or sensitization and examining their reactivity is currently in progress.

Correlation of the effects of alkyl substituents on the basicities of indoles

PETER A. COHEN AND LOUIS A. COHEN[1]

Laboratory of Bioorganic Chemistry, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD 20892, U.S.A.

Received April 29, 1991

PETER A. COHEN and LOUIS A. COHEN. Can. J. Chem. **70**, 282 (1992).

Alkyl groups at C-2 of indole increase basicity at the site of protonation, C-3, while alkyl groups at C-3 decrease basicity. These opposing effects can be incorporated, for both the isomeric mono- and 2,3-dialkylindoles, into a single linear free energy correlation, $pK_a = -10.05\Sigma\sigma - 3.94$, in which $\Sigma\sigma = \sigma_p^+(\text{C-2}) + 0.60[\sigma_m^+(\text{C-3}) + 0.08D_s - 0.084]$ and D_s is the double bond stabilization parameter at C-3. An analogous correlation for *N*-methylindoles, $pK_a = -8.64\Sigma\sigma - 2.80$, reveals that the effect of *N*-alkylation on basicity is predictable but not additive.

Key words: alkylindoles, carbon basicity, free energy correlation, substituent effects, *N*-alkyl effect.

PETER A. COHEN et LOUIS A. COHEN. Can. J. Chem. **70**, 282 (1992).

Alors que la présence de groupes alkyles en C-2 des indoles augmente leur basicité, celle de groupes alkyles en C-3 provoque une diminution de cette basicité. Il est possible d'incorporer ces effets opposés, tant pour des dérivés mono- ou 2,3-dialkylindoles, dans une seule corrélation linéaire d'énergie libre, $pK_a = -10{,}05\Sigma\sigma - 3{,}94$, dans laquelle $\Sigma\sigma = \sigma_p^+(\text{C-2}) + 0{,}60[\sigma_m^+(\text{C-3}) + 0{,}08D_s - 0{,}084]$ et D_s est le paramètre de stabilisation de la liaison double en C-3. Une corrélation analogue pour les *N*-méthylindoles, $pK_a = -8{,}64\Sigma\sigma - 2{,}80$, révèle qu'il est possible de prédire l'effet de la *N*-alkylation sur la basicité, mais que cet effet n'est pas additif.

Mots clés : alkylindoles, la basicité de carbone, corrélation d'énergie libre, effets de substituant, effet de la *N*-alkylation.

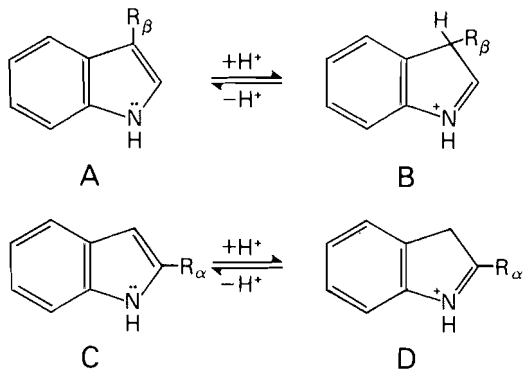


SCHEME 1

relationships, we have attempted to establish such relationships based on the series of pK_a values determined by Hinman and Lang (3) for alkylindoles. These investigators discovered an unexpected property of the pyrrole ring of indole: while an alkyl group at C-2 increases basicity at C-3, an alkyl group at C-3 *decreases* basicity. Quite appropriately, Hinman and Lang argued that an electron-releasing group at C-3 should stabilize the neutral indole (A in Scheme 1) at the expense of its protonated form (B); conversely, the same group at C-2 should stabilize D more effectively than C.

A useful but limited analogy is encountered in the acid-catalyzed hydration of substituted alkenes (4): while protonation of the alkene is consistently the rate-determining step in the hydration process (Scheme 2), we have found (1) that C-3 protonation of indoles is rate determining under conditions of intramolecular proton transfer, but is a rapid equilibrium process in the presence of stronger external acid. For the protonation of alkenes, Knittel and Tidwell (4) achieved a linear correlation of log *k* with a complex parameter, eq. [1], in which σ_p^+ is the electrophilic substituent constant (5)

$$[1]\quad \Sigma\sigma = \sigma_p^+(R_\alpha) + 0.60[\sigma_m^+(R_\beta) + 0.08D_s - 0.084]$$

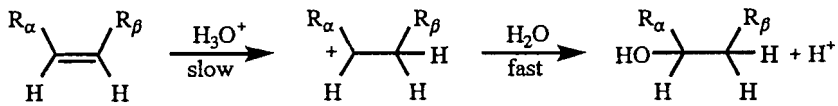
for the group (R_α in Scheme 2) at the olefinic carbon which becomes the carbocation, σ_m^+ is the analogous constant for the substituent (R_β) on the adjacent carbon, and D_s is the double bond stabilization parameter (6) for the β substituent. Since there is a degree of parallelism between the electronic effects expected of substituents on the protonation of alkenes (Scheme 2) and of alkylindoles (Scheme 1), we applied Tidwell's analysis to the indole series (Table 1), taking C-2 as the α carbon and C-3 as β. We were indeed gratified to observe the correlations shown in Fig. 1 and summarized in eqs. [2] and [3]. The only deviant member

$$[2]\quad \text{NH Series(a)}\quad pK_a = -10.05\Sigma\sigma - 3.94 \quad (r = 0.9990)$$

$$[3]\quad \text{N-Me Series(b)}\quad pK_a = -8.64\Sigma\sigma - 2.80 \quad (r = 0.9997)$$

of the set is 3-*tert*-butylindole (**6***a*), which is almost one p*K* unit *more* basic than predicted. Indeed, space-filling models reveal that steric crowding between the *tert*-butyl group and H-4 in the neutral indole is markedly relieved by conversion of C-3 to a tetrahedral carbon, as would occur in protonation.

Of course, it would be desirable to test the validity of eqs.



SCHEME 2

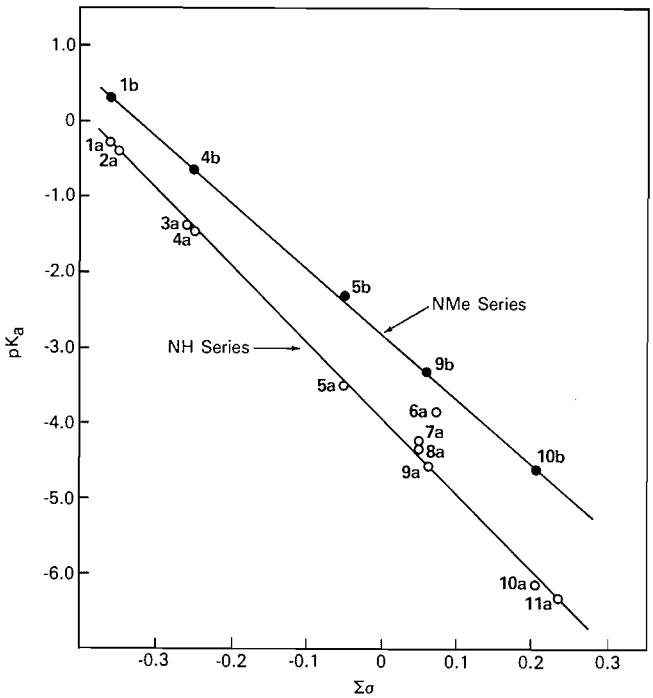

FIG. 1. Plots of the dependence of observed pK_a values for indoles (open circles) and for *N*-methylindoles (closed circles) on $\Sigma\sigma$ (see eq. [1] and Table 1); regression lines and correlation coefficients are given in eqs. [2] and [3], respectively.

[2] and [3] with other substituents. While 2- and 3-alkylindoles exist overwhelmingly as their indole tautomers (7), indoles with stronger electron-releasing groups at C-2 may have to be excluded from analysis because of their partial or total preference for the indolenine tautomer (8). Furthermore, strong electron-withdrawing groups should reduce indole basicity to a level at which measurement of protonation equilibria would become difficult. For example, pK_a values of -8.9 for 3-nitroindole and -12.8 for 2-nitroindole are predicted from eq. [2].

Figure 1 also reveals that the effect of *N*-methylation on pK_a is not constant, a phenomenon we have already observed in the imidazole series (9). While *N*-methylation generally increases basicity at C-3 (Table 1), extrapolation of the slopes of Fig. 1 beyond the point of intersection requires a reversal in order, in that *N*-methylation should result in a decrease in basicity for indoles containing stronger electron-releasing groups at C-2.

Even within the limited range of alkyl substituents, our method of correlation is probably not applicable to pyrroles, for which α-protonation is preferred but is often redirected by other substituents (10). On the other hand, there may be additional indole-like heterocyclic systems (e.g., carbolines) for which this treatment of substituent effects is applicable.

Molecular orbital calculation using spectral representation technique

SHINICHI KATSUKI

Department of Physics, College of General Education, Kyushu University, Fukuoka 810, Japan

Received June 25, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

SHINICHI KATSUKI. Can. J. Chem. **70**, 285 (1992).

The spectral representation technique as a tool for molecular orbital calculation is introduced. The procedure for getting a potential in spectral representation is simple and straightforward. The technique is also shown to be versatile to apply to the so-called effective core-potential case, to the relativistic case, to the non-spherical frozen-area case, to the case of approximate estimation of the electronic structures of molecules without the self-consistent-field process, and to the case of incorporating external effect into the cluster by environment potential.

Key words: spectral representation, molecular orbital calculation, electronic structure, relativistic potential, environment potential.

SHINICHI KATSUKI. Can. J. Chem. **70**, 285 (1992).

On introduit la technique de la représentation spectrale comme outil pour calculer des orbitales moléculaires. La méthode permettant d'obtenir un potentiel dans la représentation spectrale est simple et directe. On a aussi démontré que la méthode est versatile et qu'on peut l'appliquer au soit-disant cas du potentiel efficace du noyau, au cas relativiste, au cas de la surface définie non-sphérique, au cas de l'évaluation approximative des structures électroniques de molécules sans processus de champ auto-cohérent et au cas de l'incorporation, grâce au potentiel de l'environnement, de l'effet externe dans l'agglomération.

Mots clés : représentation spectrale, calculs d'orbitales moléculaires, structure électronique, potentiel relativiste, potentiel de l'environnement.

Introduction

Recently an *ab initio* effective Hamiltonian method was introduced for valence-electron molecular calculations (1, 2). In this method the mathematical technique of spectral representation was used to replace the core-valence interactions with a so-called effective core potential. The method has some characteristic features. First, once the reference all-electron Hartree–Fock–Roothaan calculations for constituent atoms are done, a practical effective Hamiltonian for active electrons of a molecule is obtained in a straightforward manner without any parameter fitting or adjustment procedure. Second, the relativistic effects can be included properly in the effective Hamiltonian (3, 4). Third, the method can handle cases in which the frozen area has a non-spherical shape.

The natural extension of the effective Hamiltonian formalism leads to the linear combination of atomic operator (LCAOP) method or the *ab initio* Hückel (abiHück) method (5), where the potential due not only to the core electrons but all electrons is expressed in the spectral representation.

The effective Hamiltonian method will be briefly reviewed with some newly obtained results in the next section and a description of the LCAOP method will follow. The last section summarizes our approach.

Effective Hamiltonian method and some applications

The molecular orbital theory within the Hartree–Fock approximation has been well established. According to the theory, the energy and many properties of a stationary state of a molecule can be obtained by solving the Schrödinger equation

$$[1] \quad H\Psi = E\Psi$$

where the eigenfunction Ψ is expressed in terms of molecular orbitals ψ_i that satisfy the Hartree–Fock equation

$$[2] \quad F\psi_i = \epsilon_i\psi_i$$

with the Fock operator F (in the case of closed-shell electron configuration)

$$[3] \quad F = -\frac{1}{2}\Delta - \sum_{\mathrm{A}} \frac{Z_{\mathrm{A}}}{r_{\mathrm{A}}} + \sum_{j}^{n} (2J_j - K_j)$$

where

$$[4] \quad J_j f(1) = \int d\upsilon_2 \psi_j^*(2)\psi_j(2) \frac{1}{r_{12}} f(1)$$

$$[5] \quad K_j f(1) = \int d\upsilon_2 \psi_j^*(2) f(2) \frac{1}{r_{12}} \psi_j(1)$$

We may rewrite the Fock operator, by introducing a *complete* set $\{\chi_a\}$ which is not necessarily an orthogonal set, as

$$[6] \quad F = -\frac{1}{2}\Delta + \left[-\sum_{\mathrm{A}} \frac{Z_{\mathrm{A}} - Z_{\mathrm{A}}^{\mathrm{C}}}{r_{\mathrm{A}}} + \sum_{j}^{n-m} (2J_j - K_j) \right] + \Omega \left[-\sum_{\mathrm{A}} \frac{Z_{\mathrm{A}}^{\mathrm{C}}}{r_{\mathrm{A}}} + \sum_{j}^{m} (2J_j - K_j) \right] \Omega$$

where

$$[7] \quad \Omega = \sum_{ab} |\chi_a\rangle (S^{-1})_{ab} \langle\chi_b|$$

$$[8] \quad S_{ab} = \langle\chi_a|\chi_b\rangle$$

$$[9] \quad \sum_{\mathrm{A}} Z_{\mathrm{A}}^{\mathrm{C}} = 2m$$

Printed in Canada

For personal use only.

The operator

$$[10]\quad \Omega O \Omega = \sum_{abcd} |\chi_a\rangle (S^{-1})_{ab} \langle\chi_b| O |\chi_c\rangle (S^{-1})_{cd} \langle\chi_d|$$

is called a spectral representation of an operator O. The potential operator in the rewritten Fock operator (eq. [6]) is expressed partially in spectral representation. The division of $2n$ electrons into $2m$ and $2(n - m)$ electrons is optional as long as the self-consistent-field (SCF) is guaranteed. Z_A^C is a number of electrons which are assumed to belong to the nucleus A among $2m$ electrons. The total energy E_T is calculated as

$$[11]\quad E_T = \sum_i \left(\epsilon_i + \left\langle \psi_i \middle| -\frac{\Delta}{2} - \sum_A \frac{Z_A}{r_A} \middle| \psi_i \right\rangle\right) + \sum_{A>B} \frac{Z_A Z_B}{R_{AB}}$$

(a) Spectral representation of the potential due to core electrons

Core electrons of atoms remain nearly frozen in forming molecules. If a potential due to core electrons (V_{core}) is expressed in the spectral representation in eq. [6], it will change little in the SCF process of a molecular orbital calculation. We may consider only the active valence electrons on the stage, leaving the dormant core electrons behind the scenes. In this case V_{core} may be expressed as a linear combination of atomic core potentials

$$[12]\quad V_{core} = \sum_A V_{core}^A$$

$$[13]\quad V_{core}^A = \Omega_A \left[-\frac{Z_A^C}{r} + \sum_i (2J_i^A - K_i^A) \right] \Omega_A + P_A$$

$$[14]\quad P_A = \Omega_A \left[-\sum_i 2\epsilon_i^A |\psi_i^A\rangle\langle\psi_i^A| \right] \Omega_A$$

The operator P_A, which is called the energy shift operator, is included in eq. [13] for the sake of the lowest *valence* orbital energy (not the lowest *core* orbital energy) being obtained as the lowest eigenvalue of the Fock operator. In eq. [11], in this case, $-Z_A/r_A$ and Z_AZ_B/R_{AB} should be replaced by $-(Z_A - Z_A^C)/r_A + V_{core}^A$ and $(Z_A - Z_A^C)(Z_B - Z_B^C)/R_{AB}$, respectively, and Σ_i should run over just the valence orbitals. A practical choice of the representation basis function set $\{\chi_a\}$ is the atomic basis set used in the reference Hartree–Fock–Roothaan calculation, decontracted to the primitive form. The results of the preliminary applications to N_2, P_2, and As_2 show the usefulness of this method (2).

(b) Spectral representation of relativistic effects

The present approach based on the spectral representation of operator is very suitable to incorporate the relativistic effects in the Fock operator. The mass-velocity term V_{mv} and the Darwin term V_D in the Cowan–Griffin (6) – Wood–Boring (7) formalism are expressed in the spectral representation

$$[15]\quad V_{rel} = \sum_l \Omega^l [V_{mv}^l + V_D^l] \Omega^l$$

$$[16]\quad V_{mv}^l = -\frac{\alpha^2}{4} (\epsilon^l - V^l)^2$$

$$[17]\quad V_D = -\frac{\alpha^2}{4} \left\{ 1 + \frac{\alpha^2}{4} (\epsilon^l - V^l) \right\}^{-1} \frac{dV^l}{dr} \left(\frac{1}{G^l} \frac{dG^l}{dr} - \frac{1}{r} \right)$$

where ϵ^l and G^l are the eigenvalue and the large component radial function of l symmetry ($l = s, p, \ldots$), respectively. V^l is the potential acting on G^l and $\alpha = 1/137.037$. We note that no more than one valence orbital for each symmetry l should be included, because the relativistic effects are orbital index dependent. The method has been shown to work well at the level of one-component approximation (4); it may also work at the level of two- and four-component approximation (15).

(c) Spectral representation of non-spherical frozen area

The idea of active and dormant electrons in atoms can be extended to electrons in molecules. For instance, consider the $NH_3 + H^+$ interaction. Among the molecular orbitals of NH_3, $1a_1$, $1e_x$, and $1e_y$ will not interact with the $1s$ orbital of H^+ when H^+ approaches along the z axis. The effect of the six electrons occupying $1a_1$, $1e_x$, and $1e_y$ may be replaced with a static potential. Our approach is flexible to construct the static potential in spectral representation,

$$[18]\quad V_{eff} = \Omega \left[-\sum_A \frac{Z_A^{eff}}{r_A} + \sum_i (2J_i - K_i) - \sum_i 2\epsilon_i |\psi_i\rangle\langle\psi_i| \right] \Omega$$

where A = N, H_1, H_2, H_3; $i = 1a_1, 1e_x, 1e_y$. The expansion basis set for Ω are the primitive-Gaussian-type orbitals (PGTO) recovered by decontracting the atomic basis functions of N and H, and the spectral representation is a four-center representation. Z_A^{eff} may be calculated as

$$[19]\quad Z_A^{eff} = \sum_{ijk} 2c_{ij}^A c_{ik}^A \langle \phi_j^A \mid \phi_k^A \rangle$$

where c_{ij}^A is the renormalized coefficient for the jth atomic orbital ϕ_j^A of the ith molecular orbital ψ_i to satisfy $\Sigma_A \Sigma_{jk} c_{ij}^A c_{ik}^A \langle \phi_j^A \mid \phi_k^A \rangle = 1$ (8). Equation [19] is not unique to calculate Z_A^{eff}, because there is no definite way to calculate occupation numbers from the molecular orbitals that are not spherically symmetric. The molecular orbital $3a_1$ calculated by this method is listed in Table 1 along with those obtained by the ordinary Hartree–Fock SCF method and the effective Hamiltonian method with the N1s core potential. The results may be improved by using more sophisticated Z_A^{eff} values.

Linear combination of atomic operator method and some applications

If an intuitive "chemical building block" picture for a molecular structure is accepted, the potential field in the Fock operator for the molecule may be approximated by a linear

combination of potential fields of the constituent atoms (in the spectral representation in our case).

$$[20] \quad F = -\frac{1}{2}\Delta + \sum_{A} G_A$$

$$[21] \quad G_A = \Omega_A\left[-\frac{Z_A}{r_A} + \sum_i n_i(J_i^A - \lambda K_i^A)\right]\Omega_A$$

The approach, thus, might be termed as the linear combination of atomic operator (LCAOP) method (5). We can shift up some of the orbitals ψ_i^A in energy, when we are not interested in these orbital states, by adding to eq. [21] the energy shift operator P_A (eq. [14]) which includes the corresponding orbitals ψ_i^A.

In this method molecular orbitals and orbital energies are obtained by non-iterative diagonalization of the one-electron operator (eq. [20]), just as is done in the Hückel method. This method might therefore be called the *ab initio* Hückel (abiHück) method (5, 9).

We introduced the parameter λ in eq. [21] to avoid a complication in the restricted Hartree–Fock formalism for the open-shell electron configuration (many atoms have the open-shell electron configuration) and to prepare a single Fock operator for all the orbitals (closed-shell and open-shell). A naive choice of the parameter is $\lambda = 1/2$ for each occupation number n_i. This choice was supported by calculations for Li_2 and F_2 molecules with several λ values.

Some of the results of test calculations by the abiHück method, such as those for H_2, Li_2, N_2, F_2, CH_4, were more or less acceptable but some other results, such as those for CO, LiF, H_2O, were not acceptable (5). A linear H_2O was obtained probably due to the neglect of multicenter energy integrals. An acceptable result for CO was obtained (Table 2) when one iteration was done, namely, the density matrix in the abiHück method was recalculated from the molecular orbitals that were the eigenfunctions of eq. [20].

Although the method is surely a crude approximation to the electronic structure calculation from the viewpoint of the sophisticated theory of modern quantum chemistry, the results obtained so far suggest several interesting applications.

(a) Starting potential field for the standard SCF process

The results introduced above suggest that the linear combination of potential fields of the constituent atoms is a good starting potential field for a molecular orbital SCF calculation. As shown in Table 3, our approach stabilized the SCF process for F_2 with use of the (321111/21111) basis set. The exponents of the additional three diffuse functions for s and p orbitals are (0.18, 0.09, 0.045) and (0.24, 0.12.0.06), respectively, and the other CGTO are taken from the (33/3) basis set of Huzinaga *et al.* (10).

(b) Environment potential

The potential in the spectral representation generated from the electron distribution in an atom (or a molecule) may serve as an environment potential. The environment potential is necessary to get reliable results for the electronic structure of the cluster which simulates a part of crystal (11, 12). Ficticious surface atoms which appear as a result of cutting out the cluster from the crystal undergo a significantly different field from that in the bulk of the material. Even in the center region of the cluster the potential field may be different from that in the original crystal, owing to the limitation

of the size of the cluster. The environment potential could remedy the situation.

In the environment potential, the shift operator (eq. [14]) including all the occupied orbitals should be added to eq. [21] to prevent the molecular orbitals of the cluster from collapsing into the environment region.

We apply this approach to the interaction between three ammonia molecules $(NH_3)_A$ + $(NH_3)_B$ + $(NH_3)_C$ (cf. Fig. 1), replacing $(NH_3)_A$ with the environment potential. A similar arrangement was used by Ohta *et al.* (13). The environment potential embodying the effect of $(NH_3)_A$ is obtained by eq. [18], but this time Σ_i runs over all the occupied molecular orbitals, $1a_1$, $2a_1$, $1e_x$, $1e_y$, and $3a_1$. Z_A^{eff} is estimated by eq. [19]. We used this model because we can check the usefulness of the idea of the environment potential by comparing the result obtained by the environment potential (EP) method with that of the full SCF molecular orbital calculation. The agreement of the two results is quite good as shown in Table 4, indicating that the environment potential approach is very promising.

(c) Modified atomic orbital

Atomic orbitals used as basis functions for molecular orbital calculation are necessarily modified (or polarized) in a molecule. To cope with the modification, the split-valence (SV) basis set is usually used. If we prepare modified atomic orbitals in advance of the calculation, we can get results at the desired level of accuracy for a smaller size of the basis set (14). As a preliminary test of the idea, a carbon atom in CH_4 is chosen as a working example. The pure atomic orbital (PAO) basis set used for carbon is a (73/6) basis set of Huzinaga *et al.* (10), and a (721/51) SV basis set ψ_i is generated from the (73/6) basis set by decontracting the most diffuse PGTO. Wave functions ψ_i which are composed of the SV basis set and satisfy the following equation

$$[22] \quad \left(-\frac{\Delta}{2} + V(r) + \sum_k V_{env}^H(r - R_k^H)\right)\psi_i(r) = \epsilon_i\psi_i(r)$$

are modified by the environment potential of hydrogen atoms V_{env}^H placed at R_k^H = (1.2, 1.2, 1.2), (1.2, −1.2, −1.2), (−1.2, 1.2, −1.2), and (−1.2, −1.2, 1.2). Contracting the most diffuse PGTO again we get the modified atomic orbitals (MAO) for carbon. The contraction coefficients for MAO are given in Table 5 and the results are listed in Table 6. Better values are obtained by MAO than by PAO.

Summary

The spectral representation technique as a tool for the molecular orbital calculation is introduced. The process to get the potential operator in the spectral representation is simple and straightforward. *No special skill is needed.* One should only calculate one- and two-electron integrals, which

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

are at most two-center integrals and familiar to users of the Hartree–Fock–Roothaan method. Once the potentials in the spectral representation are calculated and stored in a file of a computer, one can incorporate them into calculations only by reading them from the file and evaluating them through overlap integrals. The spectral representation technique thus reduces computation cost by changing multicenter energy integral computations to the simple evaluation of one- and two-center overlap integrals.

This technique is versatile enough to apply to many interesting cases. Although the spectral representation technique as a tool for molecular orbital calculation is just underway and there is room for further improvement, such as a proper simulation of non-spherical distribution of frozen electrons, we hope it is established as one of the useful methods for the quantum mechanical calculations of electronic structures.

Acknowledgements

The approach introduced here originated with Professor Huzinaga's gifted idea. We are very grateful to Professor Huzinaga not only for his invaluable discussions, without which most of the results presented here would not have been obtained, but also for his hospitality while we were in Edmonton. We are also grateful to Professor Mariusz Klobukowski for his kind help in computer processing. The numerical calculations were done using the computer facilities at the University of Alberta and Kyushu University.

On the accuracy of the algebraic approximation in electronic structure calculations for the ground states of H_3^{2+} and H_4^{3+} using basis sets of atom-centred Gaussian-type functions

S. WILSON

Rutherford Appleton Laboratory, Chilton, Oxfordshire, OX11 0QX, England

Received July 25, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

S. WILSON. Can. J. Chem. **70**, 290 (1992).

Sequences of even-tempered basis sets of atom-centered Gaussian-type functions are employed to explore the accuracy that can be achieved for the ground state energies of the H_3^{2+} and H_4^{3+} species in calculations using finite basis sets. These systems are considered as prototypes for the treatment of polyatomic molecules of arbitrary symmetry within the algebraic approximation.

Key words: algebraic approximation, basis sets, even-tempered, universal.

S. WILSON. Can. J. Chem. **70**, 290 (1992).

On utilise des séquences d'ensembles de base équilibrés de fonctions gaussiennes centrées sur les atomes pour examiner la précision que l'on peut atteindre lors du calcul des énergies de l'état fondamental des espèces H_3^{2+} et H_4^{3+}, en utilisant des ensembles de base finis. On considére ces systèmes comme des prototypes pour le traitement de molécules polyatomiques de symétrie arbitraire dans l'approximation algébrique.

Mots clés : approximation algébrique, ensembles de base, équilibrés, universal.

[Traduit par la rédaction]

1. Introduction

Huzinaga (1) has emphasized the "*quasi-empirical*" nature of the vast majority of contemporary *ab initio* electronic structure calculations associated with the error arising from basis set truncation. A similar point of view has been expressed in a review by Davidson and Feller (2) who comment that "the smaller the basis the more *ab initio* calculations assume an empirical flavor." Clementi and co-workers (3) observe that, because of the failure to address the problem of basis set construction in the 1970s, "the chemical literature . . . was flooded with computations which essentially compared experiments with basis set superposition error data." Even today, basis set truncation errors are a major and frequently dominant source of error in molecular electronic structure calculations. However, as long ago as 1963, Schwartz (4) emphasized the need to devise systematic schemes for extending basis sets employed in atomic and molecular electronic structure calculations and developing "an orderly plan of attack" which "is . . . essential for any mathematical analysis of the convergence rate. The old habit of picking the "best" (chosen by art) choice of a fixed number of terms is to be discarded if one wants to see how the problem converges." In more recent years, this point of view has been underlined by Ruedenberg and co-workers and by Wilson and co-workers. Following early work by Reeves (5), Ruedenberg and his colleagues (6–12) introduced the even-tempered basis sets that virtually eliminated at a stroke the tedious exponent optimization that had been the most time-consuming ingredient of many of the pioneering electronic structure calculations carried out in the 1960s. With the introduction of the algebraic approximation into powerful techniques based on many-body perturbation theory (13, 14) for handling the electron correlation problem in atoms and molecules, the basis set truncation error was seen to be the major source of error (15). (A similar conclusion has been reached from more recently reported full configuration interaction calculations (16).) The need to use a large flexible basis set in order to obtain high accuracy became apparent and the concept of the universal basis set was introduced (17–22). These large and flexible basis sets are not only capable of yielding high accuracy but are also transferable from system to system without regard to the nuclear charges or molecular environment involved. The investigation of the convergence of calculated properties of atoms and molecules with increasing size of basis set was realized in practice in the work of Feller and Ruedenberg (23) and Schmidt and Ruedenberg (24), and ultimately led to the concept of a universal systematic sequence of even-tempered basis sets (25, 26). Clementi *et al.* (27, 28) emphasized the simplifications that arise in evaluation of the two-electron integrals when universal even-tempered (or geometric) basis sets are employed. Wilson (29) presented a scheme based on the Cholesky decomposition of the two-electron integral matrix that allows the effective generation, storage, and processing of the integrals associated with a universal even-tempered basis set. The scheme becomes increasingly efficient as the size of the basis set is increased. Huzinaga (1) has stated that "these remarkable universal geometric basis sets . . . will certainly usher us to a new plateau of computational chemistry." More detailed reviews have been provided by the present author (30–32).

There appears to be a widely held belief (see, for example, Schaefer (33)) that finite difference approximations to atomic and molecular wave functions are superior to their finite basis set counterparts. Finite difference methods have, until recently, been the method of choice in atomic structure calculations (34, 35). Furthermore, the finite difference approach has been applied to a range of diatomic molecules containing light atoms (36–40). Numerical Hartree–Fock calculations for atoms and for diatomic molecules have been shown to afford a sub-μhartree level of accuracy for total electronic energies. Over the past decade, it has also been demonstrated that finite basis set expansions can provide equivalent or superior approximations for Hartree–Fock wave functions for atoms and diatomic molecules. By using systematic sequences of even-tempered basis

sets of either Gaussian-type functions (23, 24) or exponential-type functions (41–43), atomic self-consistent field energies, that are, in fact, often more accurate than those obtained by finite difference techniques can be obtained. For diatomic molecules, the accuracy achieved in fully numerical self-consistent field calculations can be matched by calculations performed within the algebraic approximation when elliptical basis functions are employed (44–46). Basis set expansions provide a compact representation of self-consistent field wave functions. Quiney *et al.* (47) point out that "The underlying reason for the success of the finite difference methods lies in the choice of coordinate system for the special cases in which they have found favour."

Systematically constructed sequences of basis sets can also be employed with advantage in studies of the effects of electron correlation in atomic and molecular systems. Use of basis sets yields a square-integrable representation of the complete spectrum and affords an effective quadrature over the continuum. Studies of a simple model problem (a hydrogenic atom perturbed by increasing the nuclear charge) using the techniques of many-body perturbation theory have established that integration over the continuum states can be carried out more accurately using systematically extended basis sets than by the numerical approach traditionally employed in atomic structure calculations (48). In relativistic electronic structure studies the use of the algebraic approximation has not only opened up the possibility of applications to molecules but has also provided representation of the negative energy branch of the spectrum, which is required if one is to go beyond the so-called "no virtual pair" approximation that has been employed even in atomic structure calculations carried out by employing finite differences (49). Finally, the computational advantages of the algebraic approximation should be emphasized since it leads to algorithms with basic linear algebra kernels, which can be executed with great efficiency on vector processing machines and parallel processing computers (50).

For molecular systems without special symmetry properties, the use of atomic basis functions transfers a local coordinate system to the region where the wave function is most rapidly changing, whereas the finite difference approach must, in practice, employ a Cartesian grid, which is a manifestly unsuitable coordinate system especially in the region of the nuclei. However, there appears to have been little systematic study of the accuracy that can be achieved in electronic structure studies of very simple polyatomic systems. In this work, we investigate the convergence of the total energies of the simplest polyatomic one-electron systems, H_3^{2+} and H_4^{3+}, obtained when a systematic sequence of even-tempered basis sets of Gaussian-type functions with *s* symmetry are employed. The convergence is compared with that observed for the H atom and the H_2 molecule. In Sect. 2, a brief description of systematic sequences of even-tempered basis sets, their completeness properties, and applications is given. The results of calculations on the H_3^{2+} and H_4^{3+} systems are presented in Sect. 3 and discussed in Sect. 4 where conclusions are also given.

2. Systematic sequences of even-tempered basis sets

The orbital exponents, $\zeta_k(N)$ in an even-tempered basis set are taken to form a geometric progression, thus

$$[1] \quad \ln \zeta_k(N) = \ln \alpha(N) + k \ln \beta(N) \qquad k = 1, 2, \ldots, N$$

where both $\alpha(N)$ and $\beta(N)$ depend on N, the number of functions in the basis set, as, therefore, do the orbital exponents. For the basis set to approach completeness as $N \rightarrow \infty$, α and β must be functions of N such that

$$[2] \quad \begin{aligned} &\alpha(N) \rightarrow 0 \\ &\beta(N) \rightarrow 1 \\ &\beta(N)^N \rightarrow \infty \end{aligned}$$

Ruedenberg and co-workers (23, 24) suggested empirical functional forms that ensure that these limits are satisfied. In particular, they suggested the forms

$$[3] \quad \ln \alpha(N) = a_0 \ln(\beta(N) - 1) + a_1$$

and

$$[4] \quad \ln \ln \beta(N) = b_0 \ln N + b_1$$

where a_0, a_1, b_0, and b_1 are constant for a given sequence. Basis sets generated according to eqs. [1], [3], and [4] are termed systematic sequences of even-tempered basis sets. Ruedenberg and co-workers take these constants to be different for different atomic species. If, however, they are taken to be independent of the particular system then this is termed a universal systematic sequence of even-tempered basis sets (26).

The set of Gaussian-type basis functions $\exp(-\zeta_k(N)r^2)$ generated in this fashion can be shown to be asymptotically total in $L^2(R^+)$ in the limit of large N since the generalized Muntz–Szasz theorem (51)

$$[5] \quad \lim_{N\rightarrow\infty} \sum_{k=1}^{N} \zeta_k(N)/(1 + (\zeta_k(N))^2) = \infty$$

holds. Note that for fixed α and β, the series of partial sums

$$[6] \quad \mathcal{S}(N) = \sum_{k=1}^{N} \zeta_k(N)/(1 + (\zeta_k(N))^2)$$

converge to a finite limit.

Schmidt and Ruedenberg (24) demonstrated that by employing a systematic sequence of even-tempered basis sets of Gaussian-type functions for the ground state of the hydrogen atom, the calculated energy is found to smoothly approach the exact energy as the basis set is extended. The convergence of the energies obtained by Schmidt and Ruedenberg, using a sequence containing 3, 4, 5, . . ., 10 Gaussian-type functions of *s* symmetry, is displayed in Fig. 1, where the change in the energies $\Delta E(N) = E(N) - E(N - 1)$ ($E(N)$ denoting the energy resulting from a calculation using N basis functions) is shown as a function of the size of the basis set. Results obtained by optimizing the orbital exponents for each basis set (designated "optimal") are compared with those obtained by using the relations [1], [3], and [4], which, following Schmidt and Ruedenberg, are designated "regular." It should be noted that although the variation principle ensures that $\Delta E(N)$ is negative for the "optimal" basis sets this is not necessarily the case for the "regular" basis sets. However, for the hydrogen atom ground state $\Delta E(N) < 0$ and $|\Delta E(N)|$ decreases monotonically as N is increased.

Wells and Wilson (52) demonstrated that sub-μhartree accuracy could be achieved in Hartree–Fock calculations for small diatomic molecules by using systematically constructed basis sets of atom-centered Gaussian-type func-

tions. Using a basis set consisting of 23s, 9p, 4d, 4f, 2g, and 1h Gaussian-type functions on each atom, these authors obtain a total ground state energy for the H_2 molecule with an internuclear separation of 1.400 bohr of −1133629.366 μhartree, which differs by only 0.21 μhartree from the energy obtained by employing basis sets of elliptical functions (44), −1133629.57 μhartree, and that obtained in fully numerical Hartree–Fock calculations (38), −1133629.57 μhartree.

The convergence of calculations of the ground state energy of H_2 obtained from a sequence of atom-centred even-tempered basis sets of Gaussian-type functions of s symmetry is displayed in Fig. 2, where the change in the calculated energy values on extending the basis set by two additional basis functions is displayed as a function of the number of basis functions. The internuclear distance is again 1.400 bohr. Satisfactory convergence of the calculated energy values with increasing size of basis set of functions with s symmetry is, of course, a necessary first step in any accurate calculation. The orbital exponents were generated from eqs. [1], [3], and [4] using the parameters given by Schmidt and Ruedenberg for the H atom. The energies obtained for basis sets containing 10, 12, 14, . . ., 20 are given in ref. 52. The energies resulting from calculations employing 22, 24, 26, . . . 36 basis functions are displayed in Table 1. It can be seen that the convergence pattern shows some oscillation but that sub-μhartree accuracy can be achieved by employing a sufficiently extended basis set. Obviously, these oscillations could be removed by optimizing the exponents for each of the basis sets in the sequence since this would ensure that the energy would decrease monotonically. However, such an optimization of the exponents is not usually practiced in molecular calculations. For the basis set of 26 s functions the smallest eigenvalue of the overlap matrix, a measure of computational linear dependence, was found to be 0.0000285 whilst for the largest basis set considered, the set of 36 s functions, this was found to decrease to 0.0000033.

3. Results of calculations for H_3^{2+} and H_4^{3+}

Calculations were carried out to investigate the convergence of the ground state electronic energy of the prototype triatomic system, the H_3^{2+} molecular ion, in an equilateral triangle configuration and internuclear separation R. Two internuclear separations were considered: R = 1.0 bohr and R = 2.0 bohr. A systematic sequence of even-tempered basis sets of Gaussian-type functions of s symmetry centred on each of the three nuclei was employed. The parameters given by Schmidt and Ruedenberg for the H atom and employed by Wells and Wilson (52) in their study of the H_2 ground state were again used.

The calculated electronic energies for the H_3^{2+} molecular ion are given in Table 2 for R = 1.0 and R = 2.0 bohr for a sequence of even-tempered basis sets containing 10, 11, 12, . . ., 32 functions. For each basis set, the smallest eigenvalue of the overlap matrix, ε_s, is given for the R = 1.0 bohr configuration. This provides a measure of computational linear dependence in the basis set. Values of ε_s for the R = 2.0 bohr configuration were found to be greater than or equal to those for R = 1.0 bohr.

For the H_3^{2+} ion the energy difference $\Delta E(N) = E(N) - E(N-1)$, where $E(N)$ denotes the energy obtained by using a basis set of N functions, is displayed in Figs. 3 and 4 for

the $R = 1.0$ bohr and $R = 2.0$ bohr equilateral triangle configurations, respectively.

Calculations were also performed for the ground state electronic energy of the prototype tetra-atomic system, the H_4^{3+} ion, for a square planar arrangement of the nuclei with side 1.0 bohr. Again, a systematic sequence of even-tempered basis sets of Gaussian-type functions of s symmetry centred on each of the nuclei was employed together with the parameters given by Schmidt and Ruedenberg for the H atom. The results are displayed in Table 3. For each basis set in the sequence 10, 11, 12, . . ., 32 s functions we give the electronic energy together with the smallest eigenvalue of the overlap matrix, ε_s.

The energy difference $\Delta E(N)$ observed for the H_4^{3+} ion is plotted in Fig. 5 as a function of the number of basis functions.

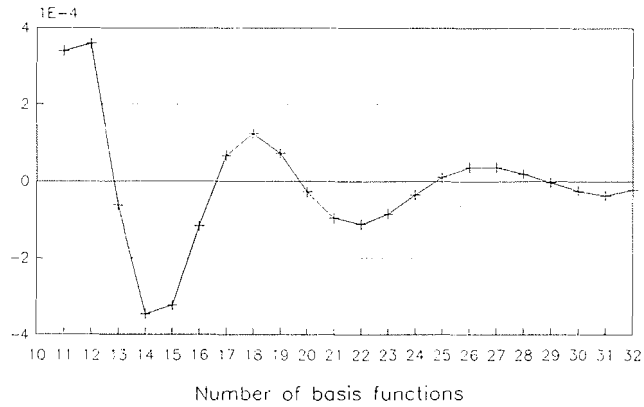

FIG. 5. Convergence of the ground state energy of the H_4^{3+} ion in a square planar configuration with side of 1.0 atomic units using a systematic sequence of even-tempered basis sets of Gaussian-type functions of *s* symmetry.

4. Discussion

The one-electron ions H_3^{2+} and H_4^{3+} afford the simplest prototypes for the study of the accuracy that can be achieved in electronic structure calculations for polyatomic molecules when systematically constructed sequences of even-tempered basis sets are employed. The results can be compared with previous studies of simple atomic and diatomic systems. In the present study, attention has been focused on the convergence patterns observed when Gaussian-type functions of *s* symmetry are centred on each of the nuclei in the system, which is, of course, a necessary first step in any accurate calculation.

Whilst smooth convergence of the calculated energies is observed for the hydrogen atom ground state shown in Fig. 1, there is some oscillation in the convergence pattern for the hydrogen molecule displayed in Fig. 2. For the hydrogen molecule the oscillations are of the order of 5 μhartrees. Convergence to sub-μhartree accuracy is ultimately achieved with a sufficiently large basis set.

For the prototype triatomic system, H_3^{2+}, the convergence with increasing size of basis set is also oscillatory. The oscillations are more pronounced than those observed for the H_2 ground state, being of the order of 200 μhartree in the $R = 1.0$ bohr case for the smaller basis sets considered diminishing, to about 5 μhartree for the larger sets employed. Somewhat improved convergence characteristics are observed for the $R = 2.0$ bohr geometry. It should be noted again that these oscillations could obviously be removed by optimization of the exponents for each of the basis sets in a sequence but in this work we have followed the usual practice of employing basis sets designed for atomic systems in a molecular environment. From the calculations reported in Table 2 it must be concluded that, as the basis set is systematically extended, sub-μhartree accuracy cannot be achieved before computational linear dependence renders the calculations unreliable. It would appear that an absolute accuracy of ~10 μhartree can be achieved for the ground state electronic energy of the H_3^{2+} ion at the nuclear geometries considered.

The convergence with increasing size of basis set is also oscillatory for the prototype tetra-atomic system, the H_4^{3+} ion. The oscillations are more pronounced than those observed for both the H_2 ground state and the H_3^{2+} ion, being of the order of 400 μhartree for the smaller basis sets considered, diminishing to about 40 μhartree for the larger sets. Again we have followed the usual practice of using atomic basis sets in a molecular system. From the calculations reported in Table 3 it must be concluded that, again, as the basis set is systematically extended, sub-μhartree accuracy cannot be achieved before computational linear dependence renders the calculations unreliable. An absolute accuracy of ~50 μhartree can be achieved for the ground state electronic energy of the H_4^{3+} ion at the nuclear geometry considered.

In the present study, we have restricted our attention to one-electron systems using basis functions of *s* symmetry. Certainly, functions of *p*, *d*, *f*, . . . and higher symmetries will be required to approach the exact electronic energies. It is also possible that for many-electron systems there could be some degree of cancellation of errors in the one- and two-electron components of the electronic energy. However, the accurate description of polyatomic, one-electron systems using basis sets of *s* symmetry must be regarded as a necessary first step in any high-precision treatment of polyatomic molecules.

In conclusion, it is useful to recall some empirical advice given by Schwartz (4) in 1963: "it seems quite general, working with computing machines of finite numerical accuracy, a poor choice of basis functions (implying a slow convergence rate) will be signaled by large and rapidly growing roundoff errors. The best cure for this disease will lie not in any improvement in the numerical capability of the machine, but requires the selection of a basis more appropriate to the problem in hand. Thus it appears that the two problems of getting an accurate (numerical) answer at each step, and having these successive answers converge rapidly, are strongly interwoven."

New scheme for large-scale eigenvalue problems of the RPA-type matrix equation

SUSUMU NARITA AND TAI-ICHI SHIBUYA

Department of Chemistry, Faculty of Textile Science and Technology, Shinshu University, Ueda, Nagano-ken 386, Japan

Received July 25, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

SUSUMU NARITA and TAI-ICHI SHIBUYA. Can. J. Chem. **70**, 296 (1992).

A new method is proposed for obtaining a few eigenvalues and eigenvectors of a large-scale RPA-type equation. Some numerical tests are carried out to study the convergence behaviors of this method. It is found that the convergence rate is very fast and quite satisfactory. It depends strongly on the way of estimating the deviation vectors. Our proposed scheme gives a better estimation for the deviation vectors than Davidson's scheme. This scheme is applicable to the eigenvalue problems of nondiagonally dominant matrices as well.

Key words: large-scale eigenvalue problem, RPA-type equation, fast convergence.

SUSUMU NARITA et TAI-ICHI SHIBUYA. Can. J. Chem. **70**, 296 (1992).

On propose une nouvelle méthode d'obtention des valeurs propres et des vecteurs propres d'une équation importante de type RPA. On a effectué quelques évaluations numériques dans le but de déterminer les comportements de convergence de cette méthode. On a trouvé que la vitesse de convergence est très rapide et assez satisfaisante. La vitesse de convergence dépend beaucoup de la façon d'évaluer les vecteurs de déviation. Notre méthode donne une meilleure évaluation des vecteurs de déviation que celle de Davidson. On peut aussi appliquer cette méthode aux problèmes de valeurs propres de matrices principalement non-diagonales.

Mots clés : problème de valeurs propres, équation de type RPA, convergence rapide.

[Traduit par la rédaction]

1. Introduction

In computing quantities such as the transition energies and the transition properties related to electronic states of atoms and molecules, the equations-of-motion (EOM) method has various advantages over the traditional configuration interaction (CI) method. The EOM is set up directly for the electronic transition, taking into account the electron correlation at various levels of approximation, while the CI method deals with the ground and the excited states, separately. The first-level approximation to the EOM is known to be the random phase approximation (RPA), which is equivalent to the time-dependent Hartree–Fock method. At higher levels of approximation such as the higher RPA (1) and the second higher RPA (2), one often ends up with similar RPA-type equations.

The RPA-type equation is written

$$[1] \qquad \begin{bmatrix} \boldsymbol{A} & \boldsymbol{B} \\ -\boldsymbol{B} & -\boldsymbol{A} \end{bmatrix} \begin{bmatrix} \boldsymbol{Y}(k) \\ \boldsymbol{Z}(k) \end{bmatrix} = \omega_k \begin{bmatrix} \boldsymbol{Y}(k) \\ \boldsymbol{Z}(k) \end{bmatrix}$$

where $\boldsymbol{A}$ and $\boldsymbol{B}$ are symmetric $N \times N$ square matrices assumed to be real, $\boldsymbol{Y}(k)$ and $\boldsymbol{Z}(k)$ column vectors with N components, and ω_k the transition energy to the kth state. Because of the special structure of the RPA-type matrix, its eigenvectors show various interesting properties. Some of them were discussed in the monograph by Thouless (3). Mathematical solutions for negative ω are easily obtained from the solutions for positive ω (3). If

$$\begin{bmatrix} \boldsymbol{Y}(k) \\ \boldsymbol{Z}(k) \end{bmatrix}$$

is the eigenvector associated with the positive eigenvalue ω_k, then

$$\begin{bmatrix} \boldsymbol{Y}(-\boldsymbol{k}) \\ \boldsymbol{Z}(-\boldsymbol{k}) \end{bmatrix} \equiv \begin{bmatrix} \boldsymbol{Z}(k) \\ \boldsymbol{Y}(k) \end{bmatrix}$$

is the eigenvector associated with the negative eigenvalue $\omega_{-k} \equiv -\omega_k$.

Equation [1] may be solved by the direct diagonalization of the $2N \times 2N$ unsymmetric matrix unless N gets large. For large N, however, the direct diagonalization becomes formidable. Usually one is only interested in a few solutions of the lowest transition energies. Various iterative algorithms have been developed for this purpose (4–6). Although these methods are applicable to the RPA-type equations, they do not take advantage of the special paired structure of the RPA-type matrix. Recently, Olsen *et al.* (7) proposed iterative algorithms that utilize this structure. In their algorithms, however, computations with $2N$-component vectors are involved.

Alternatively, eq. [1] may be equivalently written as

$$[2a] \qquad \boldsymbol{A}\,\boldsymbol{Y}(k) + \boldsymbol{B}\,\boldsymbol{Z}(k) = \omega_k \boldsymbol{Y}(k)$$

$$[2b] \qquad -\boldsymbol{B}\,\boldsymbol{Y}(k) - \boldsymbol{A}\,\boldsymbol{Z}(k) = \omega_k \boldsymbol{Z}(k)$$

and the subtraction and addition of these equations give

$$[3a] \qquad (\boldsymbol{A} + \boldsymbol{B})\,\boldsymbol{P}(k) = \omega_k \boldsymbol{Q}(k)$$

$$[3b] \qquad (\boldsymbol{A} - \boldsymbol{B})\,\boldsymbol{Q}(k) = \omega_k \boldsymbol{P}(k)$$

where

$$[4] \qquad \boldsymbol{P}(k) = \boldsymbol{Y}(k) + \boldsymbol{Z}(k)$$
$$\boldsymbol{Q}(k) = \boldsymbol{Y}(k) - \boldsymbol{Z}(k)$$

The multiplication of eq. [3a] by $(\boldsymbol{A} - \boldsymbol{B})$ and eq. [3b] by $(\boldsymbol{A} + \boldsymbol{B})$, from the left on both sides, gives

$$[5a] \qquad \boldsymbol{G}\,\boldsymbol{P}(k) = W_k \boldsymbol{P}(k)$$

$$[5b] \qquad \boldsymbol{H}\,\boldsymbol{Q}(k) = W_k \boldsymbol{Q}(k)$$

where

$$[6] \qquad \boldsymbol{G} = (\boldsymbol{A} - \boldsymbol{B})(\boldsymbol{A} + \boldsymbol{B})$$
$$\boldsymbol{H} = (\boldsymbol{A} + \boldsymbol{B})(\boldsymbol{A} - \boldsymbol{B}) = \boldsymbol{G}^T$$

and

$$[7] \qquad W_k \equiv \omega_k^2$$

The associated eigenvectors $\boldsymbol{P}(k)$ and $\boldsymbol{Q}(m)$ must satisfy the orthonormality condition

$$[8] \qquad \boldsymbol{P}(k)^T \boldsymbol{Q}(m) = \delta_{km}$$

Many years ago, Tamura and Udagawa (8) proposed to solve eqs. [5*a*] or [5*b*] instead of solving eq. [1] directly. They proposed to obtain W_k and its associated eigenvector $\boldsymbol{P}(k)$ or $\boldsymbol{Q}(k)$ and then to obtain the other as a solution of the simultaneous equation. To obtain the properly normalized eigenvectors, however, one needs careful treatment of these equations.[1] In the following sections, we will propose a new scheme to solve the Tamura–Udagawa equations, eqs. [5*a*] and [5*b*] or eqs. [3*a*] and [3*b*], of large-N components, and will discuss its efficiency in actual applications.

2. Algorithms

2.1. The Newton–Raphson equation

First we define the Rayleigh quotient $f(\boldsymbol{P},\boldsymbol{Q})$ as

$$[9] \qquad f(\boldsymbol{P},\boldsymbol{Q}) = \frac{\boldsymbol{Q}^T\boldsymbol{G}\boldsymbol{P}}{\boldsymbol{Q}^T\boldsymbol{P}}$$

where $\boldsymbol{P}$ and $\boldsymbol{Q}$ are column vectors of N components and $\boldsymbol{G}$ is given by eq. [6]. The differentiation of eq. [9] with respect to the kth components P_k and Q_k gives

$$[10a] \qquad \left(\frac{\partial f}{\partial P_k}\right)(\boldsymbol{Q}^T\boldsymbol{P}) = \sum_j Q_j G_{jk} - fQ_k$$

and

$$[10b] \qquad \left(\frac{\partial f}{\partial Q_k}\right)(\boldsymbol{Q}^T\boldsymbol{P}) = \sum_j G_{kj} P_j - fP_k$$

It is then clear from eqs. [10*a*] and [10*b*] that the extremum conditions for f readily give eqs. [5*b*] and [5*a*], respectively.

The second derivatives of f are obtained by differentiating eqs. [10*a*] and [10*b*] with respect to the mth components P_m and Q_m:

$$[11a] \qquad \left(\frac{\partial^2 f}{\partial P_m\,\partial P_k}\right)(\boldsymbol{Q}^T\boldsymbol{P}) = -\left(\frac{\partial f}{\partial P_m}\right)Q_k - \left(\frac{\partial f}{\partial P_k}\right)Q_m$$

$$[11b] \qquad \left(\frac{\partial^2 f}{\partial Q_m\,\partial P_k}\right)(\boldsymbol{Q}^T\boldsymbol{P}) = G_{mk} - f\delta_{km} - \left(\frac{\partial f}{\partial P_k}\right)P_m$$

$$[11c] \qquad \left(\frac{\partial^2 f}{\partial P_m\,\partial Q_k}\right)(\boldsymbol{Q}^T\boldsymbol{P}) = G_{km} - f\delta_{km} - \left(\frac{\partial f}{\partial Q_k}\right)Q_m$$

$$[11d] \qquad \left(\frac{\partial^2 f}{\partial Q_m\,\partial Q_k}\right)(\boldsymbol{Q}^T\boldsymbol{P}) = -\left(\frac{\partial f}{\partial Q_m}\right)P_k - \left(\frac{\partial f}{\partial Q_k}\right)P_m$$

The higher order derivatives of f can be obtained similarly. Then, using eqs. [10*a*]–[11*d*], we obtain the Taylor expansion of eq. [9]:

$$[12] \qquad f = f^0 + \sum_j \left[\left(\frac{\partial f}{\partial P_j}\right)^0 \delta P_j + \left(\frac{\partial f}{\partial Q_j}\right)^0 \delta Q_j\right] + \frac{1}{2}\sum_{jk}\left[\left(\frac{\partial^2 f}{\partial P_j\,\partial P_k}\right)^0 \delta P_j\delta P_k + \left(\frac{\partial^2 f}{\partial P_j\,\partial Q_k}\right)^0 \delta P_j\delta Q_k\right] + \frac{1}{2}\sum_{jk}\left[\left(\frac{\partial^2 f}{\partial Q_j\,\partial P_k}\right)^0 \delta Q_j\delta P_k + \left(\frac{\partial^2 f}{\partial Q_j\,\partial Q_k}\right)^0 \delta Q_j\delta Q_k\right] + \ldots$$

where f^0 is equal to $f(\boldsymbol{P}_0,\boldsymbol{Q}_0)$. The derivative coefficients with superscript 0 are all evaluated at $\boldsymbol{P}_0$ and $\boldsymbol{Q}_0$.

The deviation vectors $\delta\boldsymbol{P}$ and $\delta\boldsymbol{Q}$ can be estimated from the Newton–Raphson equation

$$[13] \qquad \begin{bmatrix} f^0_{PP} & f^0_{PQ} \\ f^0_{QP} & f^0_{QQ} \end{bmatrix}\begin{bmatrix} \delta\boldsymbol{P} \\ \delta\boldsymbol{Q} \end{bmatrix} = -\begin{bmatrix} f^0_P \\ f^0_Q \end{bmatrix}$$

where subscripts P and Q denote the differentiation and, for instance,

$$(f^0_P)_k = \left(\frac{\partial f}{\partial P_k}\right)^0$$

and

$$(f^0_{PP})_{mk} = \left(\frac{\partial^2 f}{\partial P_m \partial P_k}\right)^0$$

The kth components of the first derivative coefficient vectors, f^0_P and f^0_Q can be evaluated from eqs. [10*a*] and [10*b*], respectively. Similarly, the (m,k) components of the Hessians, f^0_{PP}, f^0_{QP}, f^0_{PQ}, and f^0_{QQ}, can be evaluated from eqs. [11*a*]–[11*d*], respectively.

In the vicinity of the extremum, the first-order derivative coefficients $(f^0_P)_k$ and $(f^0_Q)_k$ in eqs. [11*a*]–[11*d*] become negligible, and eq. [13] becomes

$$[14a] \qquad (\boldsymbol{G} - f^0\boldsymbol{1})\delta\boldsymbol{P} = -f^0_Q$$

$$[14b] \qquad (\boldsymbol{H} - f^0\boldsymbol{1})\delta\boldsymbol{Q} = -f^0_P$$

Note that the matrix size here is reduced to $N \times N$ from $2N \times 2N$. When the f^0 value approaches the extremum, the Hessian matrices of eqs. [14*a*] and [14*b*] become nearly singular. However, the deviation vectors $\delta\boldsymbol{P}$ and $\delta\boldsymbol{Q}$ would then contain the dominant components of the eigenvectors whose eigenvalues are near to the f^0 value. This is the reason why the Newton–Raphson method shows fast convergence when the initial guess is close to the final solution.

Note that if all the off-diagonal elements of the Hessian matrices are ignored in eqs. [14*a*] and [14*b*], then we have

$$[15a] \qquad \delta P_k = \frac{-\left[\sum_j (G_{kj}P_j - f^0P_k)\right]}{(G_{kk} - f^0)}$$

$$[15b] \qquad \delta Q_k = \frac{-\left[\sum_j (H_{kj}Q_j - f^0Q_k)\right]}{(H_{kk} - f^0)}$$

which are the approximations employed in the Davidson algorithm (10). These approximations may be good when the matrix $\boldsymbol{G}$ is diagonally dominant (i.e., $\varepsilon' << 1$, where $\varepsilon' =$

[1] S. Narita, S. Kumei, and T. Shibuya. Unpublished results.

$|G_{ij}/(G_{ii} - G_{jj})|$) (11). If $\boldsymbol{G}$ is not diagonally dominant, however, they will give only poor deviation vectors.

2.2. The shifted inverse-power method

Now, let us consider the properties of $\boldsymbol{x}^{(1)}$ which is the solution of the equation

$$[16] \quad (\boldsymbol{G} - f\boldsymbol{1})\,\boldsymbol{x}^{(1)} = \boldsymbol{b}$$

f being a scalar and $\boldsymbol{b}$ an arbitrary column vector with a constant norm other than zero. This equation looks very much like eqs. [14]. If all the eigenvalues W_i's and associated eigenvectors $\boldsymbol{P}_i$'s and $\boldsymbol{Q}_i$'s of the matrix $\boldsymbol{G}$ are known, then the vector $\boldsymbol{x}^{(1)}$ of eq. [16] can be written as

$$[17] \quad \boldsymbol{x}^{(1)} = (\boldsymbol{G} - f\boldsymbol{1})^{-1}\boldsymbol{b} = \sum_i \boldsymbol{Q}_i^T\,\boldsymbol{b}(W_i - f)^{-1}\boldsymbol{P}_i$$

Note in this equation that $\boldsymbol{Q}_i^T\,\boldsymbol{b}(W_i - f)^{-1}$ is a coefficient of vector $\boldsymbol{P}_i$. When f is close to an eigenvalue, say W_i, the absolute value of the corresponding coefficient becomes very large compared with the rest, and then $\boldsymbol{x}^{(1)}$ becomes a very good approximation to the exact eigenvector $\boldsymbol{P}_i$ as all other terms in eq. [17] become negligible compared with this particular term of $\boldsymbol{P}_i$.

We obtain a more accurate vector $\boldsymbol{x}^{(2)}$ by replacing a vector $\boldsymbol{b}$ in eq. [17] by the vector $\boldsymbol{x}^{(1)}$:

$$[18] \quad \boldsymbol{x}^{(2)} = (\boldsymbol{G} - f\boldsymbol{1})^{-1}\boldsymbol{x}^{(1)} = \sum_i \boldsymbol{Q}_i^T\,\boldsymbol{b}(W_i - f)^{-2}\boldsymbol{P}_i$$

Note that the magnitude of the corresponding coefficient of $\boldsymbol{P}_i$ in eq. [18] becomes much larger than that in eq. [17]. In general, the result in the kth step of the iteration, $\boldsymbol{x}^{(k)}$, is related to that in the previous step, $\boldsymbol{x}^{(k-1)}$, as

$$[19] \quad \boldsymbol{x}^{(k)} = (\boldsymbol{G} - f\boldsymbol{1})^{-1}\boldsymbol{x}^{(k-1)}$$

The vector $\boldsymbol{x}^{(k)}$ approaches the exact eigenvector as k increases. We call this the inverse iteration effect. By repeating the above procedure we can improve an arbitrary vector $\boldsymbol{b}$ so as to give the exact eigenvalues around the value of f and their associated eigenvectors. This iterative method is well known as the shifted inverse-power method (9).

For small N, it is easy to solve eq. [16] and obtain the vector $\boldsymbol{x}^{(1)}$. For large N, however, it becomes formidable to handle the inverse matrix $(\boldsymbol{G} - f\boldsymbol{1})^{-1}$. This is the major drawback of the shifted inverse-power method. However it gives a more accurate estimation for the deviation vectors than the Davidson algorithm, and therefore is free from the problem of diagonal dominance. With this method, the convergence rate is also drastically improved.

2.3. A compromised method

The method we propose here is a compromise of the Newton–Raphson method, the shifted inverse-power method, and the variational method. Although $\boldsymbol{x}^{(n)}$ in the previous section may be a good approximation to the eigenvector, we can construct an even better vector by taking a linear combination of $\boldsymbol{x}^{(1)}, \boldsymbol{x}^{(2)}, \ldots, \boldsymbol{x}^{(n)}$. Let $\{\boldsymbol{x}^{(k)}\}$ be the set of the results obtained in sequence by eq. [19] and $\{\boldsymbol{y}^{(k)}\}$ be a set of vectors that satisfy the orthonormality conditions

$$[\boldsymbol{y}^{(i)T}\,\boldsymbol{x}^{(j)} = \delta_{ij}, \qquad i, j = 1 \ldots n]$$

n being the number of vectors in each set, and the dimension of vector $\boldsymbol{x}^{(j)}$ is N. The set $\{\boldsymbol{y}^{(k)}\}$ may form an $N \times n$ matrix

$$[20] \quad \boldsymbol{Y} = \boldsymbol{X}(\boldsymbol{X}^T\boldsymbol{X})^{-1}$$

where

$$\boldsymbol{X} = [\boldsymbol{x}^{(1)}, \boldsymbol{x}^{(2)}, \ldots, \boldsymbol{x}^{(n)}]$$

and

$$\boldsymbol{Y} = [\boldsymbol{y}^{(1)}, \boldsymbol{y}^{(2)}, \ldots, \boldsymbol{y}^{(n)}]$$

The coefficients of the linear combination of $\boldsymbol{x}^{(k)}$ may be determined so as to give the minimum value of f by the variational method. Given the basis sets $\boldsymbol{X}$ and $\boldsymbol{Y}$, approximate eigenvectors $\boldsymbol{P}'$ and $\boldsymbol{Q}'$ are represented as

$$[21a] \quad \boldsymbol{P}' = \boldsymbol{X}\,\boldsymbol{p}$$

$$[21b] \quad \boldsymbol{Q}' = \boldsymbol{Y}\,\boldsymbol{q}$$

where the coefficient vectors $\boldsymbol{p}$ and $\boldsymbol{q}$ consist of n elements. Then, eqs. [20] and [9] give

$$[22] \quad f(\boldsymbol{P}',\boldsymbol{Q}')\boldsymbol{q}^T\boldsymbol{p} = \boldsymbol{q}^T\boldsymbol{Y}^T\boldsymbol{G}\boldsymbol{X}\boldsymbol{p} = \boldsymbol{q}^T\boldsymbol{g}\boldsymbol{p}$$

where the matrix elements of the $n \times n$ matrix $\boldsymbol{g}$ are given by

$$[23] \quad g_{km} = \boldsymbol{y}^{(k)T}\,\boldsymbol{G}\,\boldsymbol{x}^{(m)}$$

The differentiation of eq. [22] with respect to the kth component q_k, together with the extremum conditions, give

$$[24] \quad \boldsymbol{g}\boldsymbol{p} = f\boldsymbol{p}$$

This equation can easily be solved by diagonalizing the matrix $\boldsymbol{g}$ giving n solutions. Using the ith eigenvectors $\boldsymbol{p}_i$ in eq. [24] and the basis-set $\boldsymbol{x}^{(j)}$'s, we can compute the corresponding approximate eigenvectors $\boldsymbol{P}_i'$ of $\boldsymbol{G}$ as

$$[25] \quad \boldsymbol{P}_i' = \sum_{j=1}^{n} (\boldsymbol{p}_i)_j\,\boldsymbol{x}^{(j)}$$

where $(\boldsymbol{p}_i)_j$ is the jth component of the eigenvector $\boldsymbol{p}_i$.

Suppose that we are looking for the lowest eigenvalue f_1 and its associated eigenvector $\boldsymbol{P}_1$. Let $\boldsymbol{x}^{(n)}$ be an approximate eigenvector obtained by the shifted inverse-power method, and $\boldsymbol{P}_1'$ be the approximate vector constructed by $\boldsymbol{x}^{(j)}$'s and coefficient vector $\boldsymbol{p}_1$, which belongs to the lowest eigenvalue in eq. [24]. As $\boldsymbol{P}_1'$ contains $\boldsymbol{x}^{(n)}$ as a basis, the f value corresponding to the vector $\boldsymbol{P}_1'$ becomes always less than or equal to that of $\boldsymbol{x}^{(n)}$ itself by virtue of the variational principle. Therefore $\boldsymbol{P}_1'$ becomes a more accurate eigenvector than $\boldsymbol{x}^{(n)}$ itself.

In calculating the basis set $\boldsymbol{X}$, we adopted $-\boldsymbol{f}_Q^0$ instead of $\boldsymbol{b}$ in eq. [16] as in eq. [14a]. The first result is then the same as $\delta\boldsymbol{P}$, the solution of the Newton–Raphson equation [14a]. After having obtained two sets $\{\boldsymbol{x}^{(k)}\}$ and $\{\boldsymbol{y}^{(k)}\}$, we solve the variational equation [24].

We now summarize our computational scheme. Here for simplicity, we look for the solution of the lowest excitation energy only. The extension to obtaining a few eigenvalues and eigenvectors is quite straightforward.

2.3.1. Initialization

Select a set of trial vectors $\boldsymbol{P}$ and $\boldsymbol{Q}$, which satisfy $\boldsymbol{P}^T\boldsymbol{Q} = 1$. As an initial guess, we choose $P_i = Q_i = 1$ and all the other elements of these vectors are set to be 0's, where i is the number corresponding to the smallest diagonal element in the matrix $\boldsymbol{G}$. Probably this choice of the initial guess is the simplest one.

2.3.2. Iteration

(*i*) Calculate f by eq. [9], the first derivative vector $\boldsymbol{f}_Q$ by

eq. [10*b*], and the approximated Hessian matrix $(\boldsymbol{G} - f\mathbf{1})$ by eq. [14*a*].

(*ii*) Compute the residual norm of f_Q.

If it becomes smaller than ε(a tolerance value for convergence), stop the calculation. Then the computed value of f in step (*i*) is the eigenvalue to be obtained.

(*iii*) If the norm is greater than ε, then obtain a sequence of $\boldsymbol{x}^{(k)}$ in the shifted inverse iteration by eqs. [14*a*] and [19] to construct matrix $\boldsymbol{X}$, which consists of n column vectors. In our test calculations shown below, n will be 3. The larger n becomes, the faster is the convergence rate. There is no general rule for the determination of n and it should be chosen case by case.

If the Hessian matrix becomes singular, add a small number to all the diagonal elements and recalculate $\boldsymbol{X}$. Obtain $\boldsymbol{Y}$ from eq. [20]. After having obtained the basis sets $\boldsymbol{X}$ and $\boldsymbol{Y}$, calculate the matrix $\boldsymbol{g}$ in eq. [23].

(*iv*) Solve eq. [24] and choose the lowest eigenvalue f_1 and its associated eigenvector $\boldsymbol{p}_1$.

(*v*) Obtain a renewed trial vector $\boldsymbol{P}$ by eq. [25]. Compute the corresponding vector $\boldsymbol{Q}$ by eq. [3*a*] for the proper normalization, and normalize them by using eq. [8]. Note that ω_1 is equal to the square root of f_1. Jump back to step (*i*).

Needless to say, this scheme is also applicable to the eigenvalue problems of symmetric matrices.

3. Results and discussion

To illustrate the efficiency of the proposed algorithms we calculate the transition energies to 1^1B_u and 2^1A_g states of decapentaene and dodecahexaene by the parametrized EOM method at the $(1p–1h) + (2p–2h)$ level (12). These results are shown in Tables 1–3. In these test calculations, the $\sigma \rightarrow \sigma^*$ mixings are omitted for simplicity.

As is seen in these tables, the convergence rates are very

[c]A tolerance value for convergence is $N \times 10^{-8}$.

fast and quite satisfactory except for the case of the 2^1A_g state of dodecahexaene in Table 2. It appears that the convergence rate does not depend on the matrix size. For the 2^1A_g state of dodecahexaene, a drastic improvement is attained when we set n to be 6, as is shown in Table 3.

The rapid convergence demonstrated in these examples is all due to the combined use of the shifted inverse power method and the variational method. The former extracts the dominant terms of the eigenvectors whose eigenvalues are close to f, and the latter determines the step length of the extracted vectors so as to give the optimum energy. To accelerate the convergence rate, the deviation vector must be properly evaluated. The numerical examples presented here indicate that the shifted inverse-power method is quite effective in evaluating these deviation vectors. It does not make any crude approximation in evaluating the deviation vectors as does the Davidson algorithm, so that it is applicable to the eigenvalue problems of nondiagonally dominant matrices.

It is well known that the Newton–Raphson method becomes very poor when the initial guess is far from the exact solution. However, the inverse sequence, $\boldsymbol{x}^{(k)}$ in eq. [19], obtained by the Newton–Raphson-type equation, provides a good approximation for the exact eigenvector. The reason is quite natural because of the inverse iteration effect discussed in Sect. 2.2. It is very interesting that the matrix in the shifted inverse-power method just corresponds to the Hessian matrix.

By virtue of the shifted inverse-power method, the set $\{\boldsymbol{P}_i\}$ obtained from eq. [25] contains not only the component of the wanted eigenvector but also those of the other eigenvectors whose eigenvalues are near to f. Therefore, once one solution is obtained, we have a good starting vector for the next solution.

Although the present method has good characteristics as mentioned above, the computation of the inverse matrix $(\mathbf{G} - f\mathbf{1})^{-1}$ is a time–memory consuming job particularly when N becomes large. As the matrices in our test calculations, which are shown in Tables 1–3, are not very large, we were able to calculate the inverse matrices of the Hessian and obtain the sequence $\{\boldsymbol{x}^{(k)}\}$ without any difficulty. If the sequence $\{\boldsymbol{x}^{(k)}\}$ is obtained directly without calculating the inverse matrix, then the eigenvalue problems for larger-scale matrices can be solved without consuming computer memory. To confirm this idea, we performed a "direct RPA" calculation on the highly fused ring system as shown in Fig. 1. In this calculation, we obtained the MO's by the PPP (Pariser–Parr–Pople) method and the sequence $\{\boldsymbol{x}^{(k)}\}$ by the Lanczos method (13). As we did not distinguish the symmetries, the RPA matrix size became 2304. The result is shown in Table 4. As expected from the previous results, the convergence rate is quite satisfactory. The fast convergence shows the efficiency of extracting the dominant terms of the eigenvectors whose eigenvalues are close to f.

Orbital reorganization and its energies in the interaction of CO with Sc, Fe, and Cu

KAZUO HIRAI AND NOBUHIRO KOSUGI[1]

Division of Molecular Engineering, Kyoto University, Yoshida, Kyoto 606, Japan

Received June 24, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

KAZUO HIRAI and NOBUHIRO KOSUGI. Can. J. Chem. **70**, 301 (1992).

The interaction of CO with transition metals (M = Cu, Fe, and Sc) is analyzed using a newly developed method within the framework of the Hartree–Fock approximation. This method reveals reorganization of each orbital by the interaction and its energy contribution. To avoid the basis-set dependence in the energy partitioning, the orbital reorganization energy includes both polarization and charge-transfer effects; however, these effects are clearly distinguished by using orbital contours. The interaction in M–CO is discussed not only in terms of widely accepted components, such as metal $4s$–$4p\sigma$ polarization, CO 5σ – metal $3d\sigma$ donation, and metal $3d\pi$ – CO $2\pi^*$ backdonation, but also by using newly found components, metal $3d\sigma$–$4s$ and $4s$–$3d\sigma$ polarization, CO 5σ – metal $4p\sigma$ donation, metal $3d\sigma$ – CO $6\sigma^*$ backdonation, and CO 1π – $2\pi^*$ polarization.

Key words: metal carbonyl, interaction energy, orbital reorganization.

KAZUO HIRAI et NOBUHIRO KOSUGI. Can. J. Chem. **70**, 301 (1992).

On a analysé l'interaction du CO avec les métaux de transition (M = Cu, Fe et Sc) en utilisant une méthode développée récemment dans le cadre de l'approximation de Hartree–Fock. Cette méthode révèle la réorganisation de chaque orbitale sous l'influence de l'interaction ainsi que sa contribution à l'énergie. Afin d'éviter le problème d'une dépendance sur l'ensemble de base dans la répartition de l'énergie, l'énergie de réorganisation orbitalaire inclut les effets de polarisation ainsi que ceux du transfert de charge; toutefois, on fait une distinction claire entre ces effets en utilisant des contours orbitalaires. On ne discute pas de l'interaction M–CO seulement en fonction de composantes bien acceptées comme la polarisation métallique $4s$–$4p\sigma$, la donation CO 5σ – métal $3d\sigma$ et la rétrodonation métal $3d\pi$ – CO $2\pi^*$, mais aussi en utilisant les quatre nouvelles composantes suivantes : polarisation métal $3d\sigma$–$4s$ et $4s$–$3d\sigma$, la donation CO 5σ – métal $4p\sigma$, la rétrodonation métal $3d\sigma$ – CO $6\sigma^*$ et la polarisation CO 1π–$2\pi^*$.

Mots clés : métal carbonyle, énergie d'interaction, réorganisation orbitalaire.

[Traduit par la rédaction]

Introduction

In classical physics the molecular interaction is discussed in terms of the electrostatic forces among dipoles and induced dipoles. These correspond to the electrostatic (ES), polarization (PL), and dispersion terms. In quantum mechanics the exchange (EX) term is taken into account to satisfy the Pauli exclusion principle, and the charge-transfer (CT) term is very important. Several approaches to divide molecular interaction into the ES, EX, PL, and CT terms are proposed within the Hartree–Fock approximation and are applied to various interacting systems.

The interaction of CO with metals in adsorbed surfaces and in carbonyl compounds is an interesting issue for both experimental and theoretical chemists (1–9). It is widely accepted (1) that the interaction can be described as two major CT interactions: σ donation from CO 5σ to metal $3d\sigma$ and π backdonation from metal $3d\pi$ to CO $2\pi^*$, where the donation leads to a concentration of electron density on the metal and the backdonation reduces this charge. Some experiments indicated that the increase of $d\pi$ backdonation makes the M—C bond stronger and the C—O bond weaker (1). However, Bagus and co-workers (2, 4, 5) showed, in various systems involving CO and transition metals, that metal polarization (PL) and $d\pi$ backdonation are much more important than σ donation. In their theoretical work, they used the constrained space orbital variation (CSOV) method (6) to sequentially partition the interaction energy into contributions from intra-unit (PL) and inter-unit (CT) charge redistribution.

Recently, Frey and Davidson (3) investigated the SCF interaction energies for the $^2\Pi$, $^2\Delta$, $^2\Sigma^+$, $^4\Sigma^-$ states of ScCO by modifying the Kitaura–Morokuma (KM) analysis (10). They pointed out that the definition of polarization by Kitaura and Morokuma does not satisfy the Pauli exclusion principle. The concepts of PL and CT begin to lose their meanings as the distance between the fragments decreases or as the basis set becomes rather complete. Even if not complete, the distinction between PL and CT would depend on the basis set used. Furthermore, the concepts of ES and EX lose their meanings in strong interaction regions. To overcome these problems Frey and Davidson (3) redefined the polarization energy including the exchange repulsion, and showed that after the modification the results became reasonable even when the distance between the fragments was short or extended basis sets were used.

In the present work, based on a newly developed method, the features of σ donation, $d\pi$ backdonation, and metal polarization and other components are systematically clarified in the interaction of CO with different transition metals (M = Fe, Cu, and Sc). The total interaction energy is partitioned into the electrostatic plus exchange (ES + EX) term and the polarization plus charge transfer (PL + CT) term. The orbital reorganization through the PL + CT interaction is described as the change of the occupied orbital space from an isolated system to a combined system, and the PL + CT interaction energy is divided into each orbital reorganization. Orbital contours are used to see whether the interaction is PL, CT, or their mixture.

Method and computation

In the present work, the interaction is divided into two steps. In the first step, infinitely isolated fragments approach each other with no change in their wavefunctions. To

satisfy the Pauli exclusion principle, the total wave function $\Phi(P)$ should be constructed by orthogonalization (or antisymmetrization, A) between the fragment wavefunctions, $\Phi(P_A)$ and $\Phi(P_B)$, as follows:

$$[1] \quad P = P_A \cup P_B \neq P_A + P_B$$

$$[2] \quad \Phi(P) = A\{\Phi(P_A) \cdot \Phi(P_B)\} \neq \Phi(P_A) \cdot \Phi(P_B)$$

where P, and P_A and P_B, are the occupied orbital spaces for the total and fragment systems, respectively. The first-step interaction arises from the interaction within the occupied orbital spaces of the fragments and includes only ES and EX terms. The ES + EX interaction energy E_{ES+EX} is obtained as the difference between the energy of the infinitely isolated system and the energy using the orbitals orthogonalized among all the occupied fragment orbitals. In the second step, the total wave function is reorganized from P to Q to satisfy the Hartree–Fock (HF) self-consistent field of the combined system, where Q denotes the HF occupied orbital space. The second-step interaction arises from stabilization through mixing with the vacant orbital space $(1 - P)$ and includes only PL and CT terms. The PL + CT interaction energy E_{PL+CT} is obtained by the difference between the energies for P and Q.

In addition to partitioning of the interaction energy, we have tried to see the change from P to Q by reorganization of each orbital. The first-step interaction is not to be divided into orbital components, but the second-step interaction within the HF approximation can be divided into orbital components as follows:

$$[3] \quad \Phi(P) = \|\phi_{o,1}\phi_{o,2} \cdots \phi_{o,N}\|$$

$$[4] \quad \Psi(Q) = \|\psi_{o,1}\psi_{o,2} \cdots \psi_{o,N}\|$$

where $P = \{\phi_{o,i} | i = 1, 2, \ldots, N\}$ and $Q = \{\psi_{o,i} | i = 1, 2, \ldots, N\}$ are the total occupied orbital spaces spanned by orthonormalized spin orbitals, $\phi_{o,i}$ and $\psi_{o,j}$, respectively, and Ψ denotes the HF wave function after the second-step interaction. The total vacant orbital space after the first-step interaction is $1 - P = \{\phi_{v,j} | j = 1, 2, \ldots, M\}$, where $\langle\phi_{o,i}|\phi_{v,j}\rangle = 0$. Then, $\psi_{o,i}$ can be uniquely described by mixing $\phi_{o,i}$ with $\phi_{v,i}$ as follows:

$$[5] \quad \psi_{o,i} = c_{o,i}\phi_{o,i} + c_{v,i}\phi_{v,i}$$

where

$$[6] \quad \langle\psi_{o,i}|\phi_{o,j}\rangle = c_{o,i}\delta_{ij}$$

$$[7] \quad \langle\psi_{o,i}|\phi_{v,j}\rangle = c_{v,i}\delta_{ij}$$

We can determine these spin orbitals by unitary transformation for the α-spin occupied orbitals and for the β-spin occupied orbitals of $\Phi(P)$ and $\Psi(Q)$ so that the overlap matrix between $\phi_{o,i}$ and $\psi_{o,j}$ is diagonalized as given by eq. [6] and the total energies remain unchanged. Such unitary transformation is achieved by the corresponding orbital transformation (11). Using the resulting relation [6], we obtain $\phi_{v,i}$ by normalizing the difference, $\psi_{o,i} - c_{o,i}\phi_{o,i}$. The orthogonal relation [7] $\langle\psi_{o,i}|\phi_{v,j}\rangle = 0$ $(i \neq j)$ is derived from the relations $\langle\psi_{o,i}|\psi_{o,j}\rangle = 0$ and $\langle\psi_{o,i}|\phi_{o,j}\rangle = 0$. When $M > N$, the orbitals $\phi_{v,i}$ $(i = 1, 2, \ldots, N)$ are uniquely defined to satisfy eqs. [5] and [7] but the remainder $(i = N + 1, \ldots, M)$ is not defined. When $M < N$, $\psi_{o,i} = \phi_{o,i}$ $(i = M + 1, \ldots, N)$. Thus, the change of $\phi_{o,i}(P)$ to $\psi_{o,i}(Q)$ by the inclusion of some part of $\phi_{v,i}(1 - P)$ is uniquely described by the mixture of the particular pair of orbitals.

TABLE 1. Interaction energies in Fe–CO and Cu–CO[a]

	FeCO $^5\Sigma^-(3d\sigma^1 3d\pi^4 3d\delta^2 4s^1)$			CuCO $^2\Sigma^+(3d\sigma^2 3d\pi^4 3d\delta^4 4s^1)$		
	α	β	Total	α	β	Total
E_{ES+EX}	–	–	−2.811	–	–	−1.755
E_{PL+CT}	1.363	1.006	2.369	0.800	0.369	1.169

[a]The values are given in eV, and positive value means stabilization. The SCF energies of CuCO and FeCO are −1751.1699 and −1374.6876 au, respectively.

Next, let us divide the second-step interaction energy E_{PL+CT} into each spin orbital component E_i as follows:

$$[8] \quad E_i = (Ea_i + Eb_i)/2$$

$$[9] \quad Ea_i = E\{\|\psi_{o,1}\psi_{o,2} \cdots \phi_{o,i} \cdots \psi_{o,N}\|\} - E\{\Psi(Q)\}$$

$$[10] \quad Eb_i = E\{\Phi(P)\} - E\{\|\phi_{o,1}\phi_{o,2} \cdots \psi_{o,i} \cdots \phi_{o,N}\|\}$$

$$[11] \quad E_{PL+CT} = \Sigma E_i = E\{\Phi(P)\} - E\{\Psi(Q)\}$$

where the first term in Ea_i is the energy when only the ith spin orbital $\psi_{o,i}$ of Q is substituted by the ith spin orbital $\phi_{o,i}$ of P, that is, $\psi_{o,i} \rightarrow \phi_{o,i}$ in Q; the second term in Eb_i is the energy when only the ith spin orbital of P is substituted by the ith spin orbital of Q, that is, $\phi_{o,i} \rightarrow \psi_{o,i}$ in P. Then, the total stabilization energy in the second-step interaction E_{PL+CT} is equal to a sum of contributions for each spin orbital. Let us call E_i the orbital reorganization energy.

The Cu, Fe, and Sc primitive functions used in the present work were taken from (5333/53/5) contracted Gaussian-type functions of Huzinaga *et al.* (12), and were augmented with three p functions: ζ_p(Cu) = 0.318, 0.142, 0.044, ζ_p(Fe) = 0.255, 0.118, 0.038, ζ_p(Sc) = 0.073, 0.042, 0.024, to describe the 4p orbital, and with a diffuse d function: ζ_d(Cu) = 0.15, ζ_d(Fe) = 0.11, and ζ_d(Sc) = 0.05, according to Hay's suggestion (13). The contraction scheme used was (532121/521111/3111). The C and O basis sets for CuCO and FeCO were of double ζ quality (621/311) from (63/5) of Huzinaga *et al.* (12). The C and O basis sets for ScCO were (73/7) augmented with polarization functions: ζ_d(C) = 0.600 and ζ_d(O) = 1.154, resulting in (721/511/1). The bond lengths R(M—C) and R(C—O) were 1.98 and 1.14 Å for CuCO (2), 1.84 and 1.15 Å for FeCO (2), and 2.12 and 1.183 Å for ScCO (3), respectively. The electronic states calculated were $^2\Sigma^+(3d\sigma^2 3d\pi^4 3d\delta^4 4s^1)$ for CuCO, $^5\Sigma^-(3d\sigma^1 3d\pi^4 3d\delta^2 4s^1)$ for FeCO, and $^2\Pi(3d\pi^1 4s^2)$ and $^4\Sigma^-(3d\pi^2 4s^1)$ for ScCO. The counterpoise method (14) was applied to the isolated systems. The correction energies were very small as follows: 0.0220 eV for Cu($d^{10}s^1$) and 0.0810 eV for CO; 0.0153 eV for Fe($d_{z^2}{}^1 d_{xz}{}^2 d_{yz}{}^2 d_{xy}{}^1 d_{x^2-y^2}{}^1 4s^1$) and 0.1023 eV for CO; 0.0075 eV for Sc($d_{xz}{}^1 4s^2$), 0.0063 eV for Sc($d_{xz}{}^1 d_{yz}{}^1 4s^1$), and 0.0432 eV for CO, where the single-configuration atomic SCF calculations were performed for Cu, Fe, and Sc($d_{xz}{}^1 d_{yz}{}^1 4s^1$) in the $C_{\infty v}$ symmetry and for Sc($d_{xz}{}^1 4s^2$) in the C_{2v} symmetry. The program GSCF3 (15, 16) was used for SCF calculations. All the computations were performed on the workstations DG AViiON 310 and SONY PWS 1550.

Results and discussion

FeCO($^5\Sigma^-$) and CuCO ($^2\Sigma^+$)

Table 1 shows the first-step and second-step energies, E_{ES+EX} and E_{PL+CT}, in the interaction of CO with Fe and Cu in the $^5\Sigma^-(3d\sigma^1 3d\pi^4 3d\delta^2 4s^1)$ FeCO and $^2\Sigma^+(3d\sigma^2 3d\pi^4 3d\delta^4 4s^1)$ CuCO states, respectively. The positive value means stabilization. E_{ES+EX} for FeCO and CuCO are both negative, indicating repulsive interaction. The absolute values of E_{ES+EX} and E_{PL+CT} for FeCO are larger than for CuCO; the interaction between Fe and CO is stronger than between Cu and CO. This is because the metal–CO distance for FeCO (1.85 Å) is smaller than for CuCO (1.98 Å) and is partly because the $4s$ and $3d$ orbitals of Fe have larger radial extent than those of Cu (2).

Tables 2 and 3 show results of the orbital reorganization energies in the second-step interaction. Figures 1 and 2 show contour maps of the orbitals, $\phi_{o,i}$, $\phi_{v,i}$, and $\psi_{o,i}$ together with $c_{o,i}$ and $c_{v,i}$. Figure 1a shows the most contributive σ orbital reorganization in Fe–CO ($\alpha 1$, 35% of E_{PL+CT}, see Table 2). This reorganization demonstrates reduction of the repulsive ES + EX interaction between Fe and CO, which is achieved mainly by the Fe $4s$ orbital polarizing away from CO through $4s$–$4p\sigma$ hybridization and slightly by CO reorganization. The Cu $\alpha 1(\sigma)$ reorganization in Cu–CO shows very similar $4s$–$4p\sigma$ polarization away from CO, which is the most contributive of E_{PL+CT} (50%, see Table 3). Figure 2a shows the $\beta 3$ orbital reorganization in the $^2\Sigma^+(3d\sigma^2 3d\pi^4 3d\sigma^4 4s^1)$ CuCO state (0.136 eV, 12% of E_{PL+CT}), which corresponds to Cu σ polarization from $3d\sigma$ to $4s$ due to repulsive interaction between the doubly occupied CO 5σ and Cu $3d\sigma$ orbitals. This type of polarization is not found in the $^5\Sigma^-(3d\sigma^1 3d\pi^4 3d\delta^2 4s^1)$ FeCO state.

Figure 1b shows contour maps of π orbital reorganization in Fe–CO. The orbitals for α and β spins are exactly the same, because the restricted SCF wavefunctions are used and the α-spin and β-spin π electrons occupy the same orbitals. Figure 1b shows that the Fe $3d\pi$ electron moves towards the CO $2\pi^*$ orbital; that is, the $\beta 1,2$ and $\alpha 2,3$ reorganization of FeCO is typical $d\pi$ backdonation. The $\beta 1,2$ and $\alpha 2,3$ orbital contours of CuCO are nearly the same as those of FeCO. The sums of energy contributions from the π orbital reorganization $\beta 1,2$ and $\alpha 2,3$ are 50 and 22% of E_{PL+CT} in FeCO and CuCO, respectively.

Figures 1c and 1d show the $\beta 3$ and $\alpha 4$ orbital reorganization in the $^5\Sigma^-(3d\sigma^1 3d\pi^4 3d\delta^2 4s^1)$ FeCO state, respectively, both of which correspond to CO 5σ donation to Fe. The $\beta 3$ reorganization shown in Fig. 1c is typical σ donation from CO 5σ to Fe $3d\sigma$. On the other hand, the $\alpha 4$ reorganization shown in Fig. 1d corresponds to σ donation from CO 5σ to Fe $4p\sigma$ ($4sp\sigma$ hybrid directed to CO). Figure 2b shows the $\alpha 4$ orbital reorganization in CuCO, and the $\beta 4$ orbital reorganization in CuCO is almost the same as $\alpha 4$ in Fig. 2b. The $\alpha 4$ and $\beta 4$ reorganization is σ donation from CO 5σ to Cu $4p\sigma$ ($4sp\sigma$ hybrid directed to CO), which is similar to $\alpha 4$ of Fe–CO but is more contributive in energy (17% of E_{PL+CT}) than FeCO $\alpha 4$ (4% of E_{PL+CT}). In the $^2\Sigma^+(3d\sigma^2 3d\pi^4 3d\delta^4 4s^1)$ CuCO state, there is no σ donation from CO 5σ to Cu $3d\sigma$, because the $3d\sigma$ orbital is doubly occupied.

Figure 1e shows the $\alpha 5$ orbital reorganization in FeCO. Interestingly, this clearly indicates σ backdonation from Fe $3d\sigma$ to CO $6\sigma^*$. Other orbital reorganizations in FeCO and CuCO are complicated, but are energetically unimportant.

Bauschlicher *et al.* investigated the same systems based on the CSOV method (2). The FO interaction energies, which

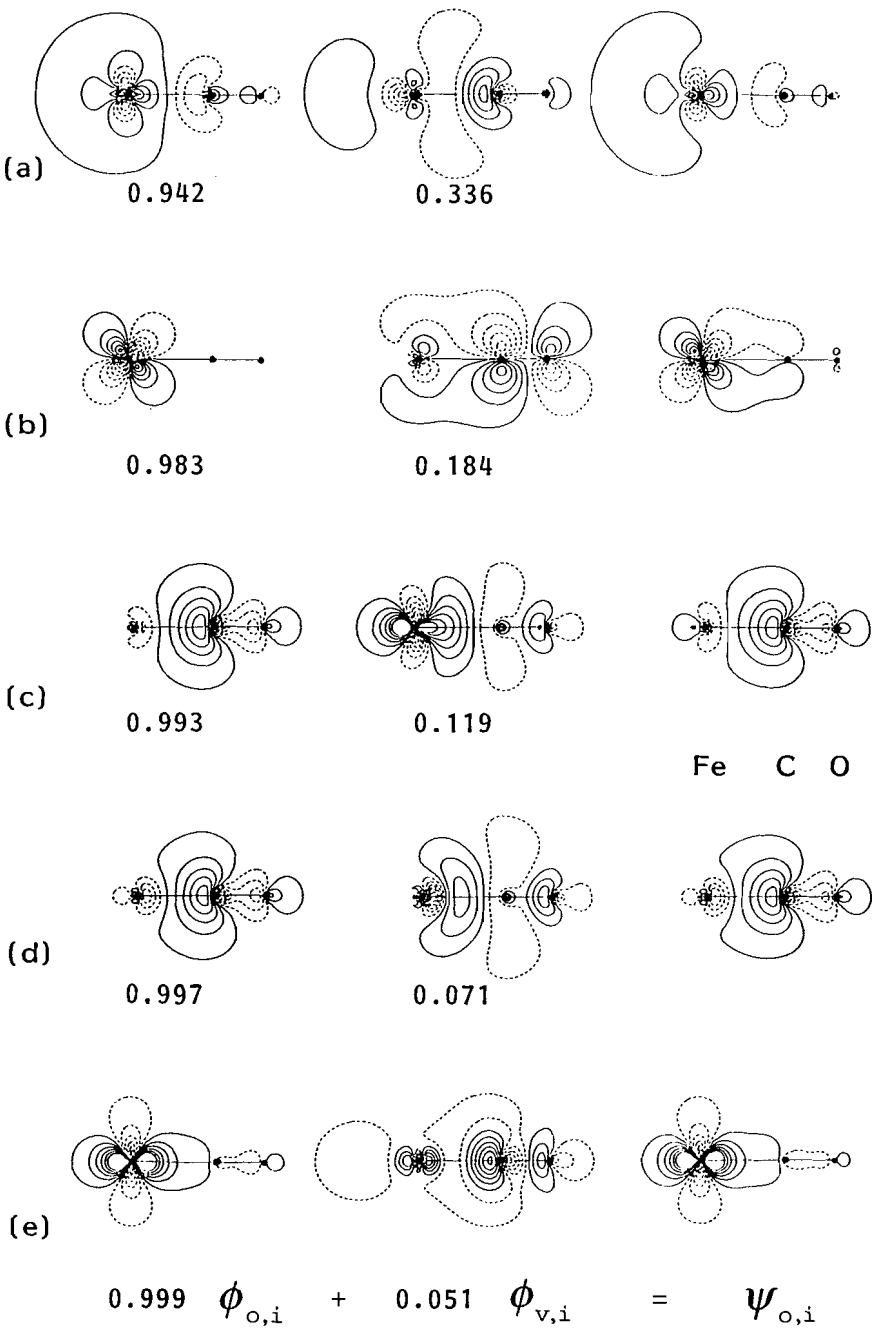

FIG. 1. Contour maps of the orbitals, $\phi_{o,i}$, $\phi_{v,i}$, and $\psi_{o,i}$ together with $c_{o,i}$ and $c_{v,i}$, where $c_{o,i}\phi_{o,i} + c_{v,i}\phi_{v,i} = \psi_{o,i}$, for the $^5\Sigma^-$ FeCO state. (a) $\alpha 1(\sigma)$, (b) $\beta 1,2(\pi)$ and $\alpha 2,3(\pi)$, (c) $\beta 3(\sigma)$, (d) $\alpha 4(\sigma)$, and (e) $\alpha 5(\sigma)$.

are defined with the frozen-orbital (FO) wavefunctions formed by superimposing (and antisymmetrizing) the wavefunctions of the isolated fragments, are -2.80 and -1.82 eV for FeCO and CuCO, respectively, and are nearly the same as the present results ($E_{ES+EX} = -2.811$ and -1.755 eV as shown in Table 1), though the basis functions used are different (but of the same quality) and in the present work the counterpoise method (14) is used. The PL + CT energies evaluated as the difference between their FO and SCF energies are 2.43 and 1.27 eV for FeCO and CuCO, respectively (2). Those are slightly larger than the present results ($E_{PL+CT} = 2.369$ and 1.169 eV). The CSOV stabilization energies within the π orbital space evaluated as [V(M;full basis) $-$ V(M;full σ basis)] + [V(CO;full basis) $-$ V(CO;full σ basis)] are 0.93 and 0.22 eV for FeCO and CuCO, respectively (2). Those are smaller than the present results for the sum of $\beta 1,2$ and $\alpha 2,3$ (1.173 and 0.258 eV). The present result shown in Fig. 1b demonstrates only $d\pi$ backdonation but no polarization at all; therefore, it is probable that the CSOV result underestimates the π orbital stabilization energies. The deficiency may be recovered by taking into account the unidentified (residual) interaction energies in the CSOV analysis, 0.21 and 0.05 eV for FeCO and CuCO, respectively (2). The sums of the metal and CO polarization energies of CSOV, V(M;M) and

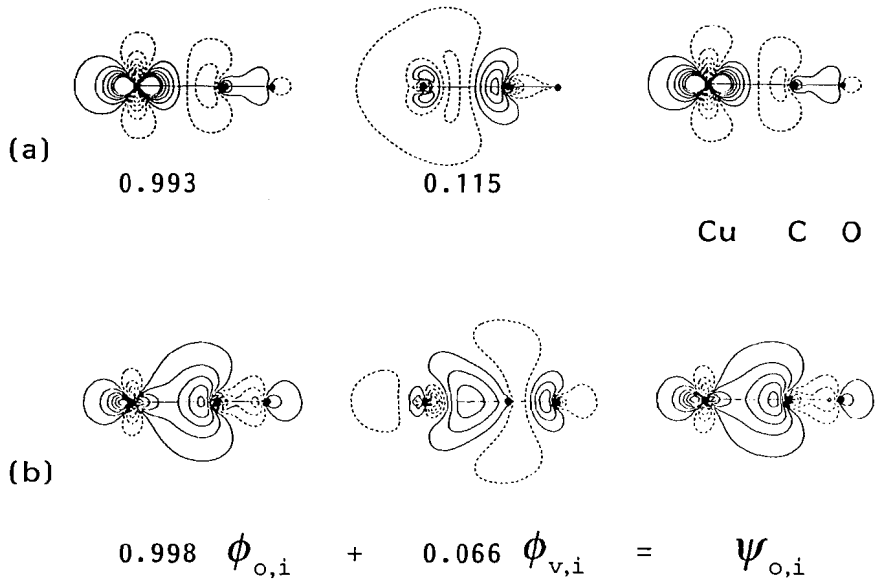

FIG. 2. Contour maps of the orbitals, $\phi_{o,i}$, $\phi_{v,i}$, and $\psi_{o,i}$ together with $c_{o,i}$ and $c_{v,i}$, where $c_{o,i}\phi_{o,i} + c_{v,i}\phi_{v,i} = \psi_{o,i}$, for the $^2\Sigma^+$ CuCO state. (a) β3(σ) and (b) α4(σ).

TABLE 4. Interaction energies in Sc–CO[a]

	ScCO $^2\Pi$ ($3d\pi^1 4s^2$)			ScCO $^4\Sigma^-$($3d\pi^2 4s^1$)		
	α	β	Total	α	β	Total
E_{ES+EX}	–	–	−3.096	–	–	−1.765
E_{PL+CT}	1.208	0.815	2.024	2.233	0.218	2.450

[a]The values are given in eV, and positive value means stabilization. The SCF energies of $^2\Pi$ and $^4\Sigma$ of ScCO are −872.2384 and −872.2570 au, respectively.

V(CO;CO), are 1.15 and 0.86 eV in FeCO and CuCO, respectively. The polarization energy coming from the α1 orbital reorganization in FeCO reaches 72% (0.824 eV) of the CSOV polarization energy, and the polarization energy from α1 and β3 in CuCO reaches 83% (0.717 eV).

ScCO($^2\Pi$, $^4\Sigma^-$)

Table 4 shows the first-step and second-step energies, E_{ES+EX} and E_{PL+CT}, of the interaction between Sc and CO in the $^2\Pi(3d\pi^1 4s^2)$ and $^4\Sigma^-(3d\pi^2 4s^1)$ states of ScCO. E_{ES+EX} for both the $^2\Pi$ and $^4\Sigma^-$ states are negative, indicating repulsive interaction. E_{ES+EX} for the $^2\Pi(3d\pi^1 4s^2)$ state is much larger than that of the $^4\Sigma^-(3d\pi^2 4s^1)$ state. This is consistent with the expectation that the repulsive interaction arises between the CO 5σ and Sc 4s electrons. The $^4\Sigma^-(3d\pi^2 4s^1)$ state is more favorable than the $^2\Pi(3d\pi^1 4s^2)$ state, and the E_{PL+CT} value for $^4\Sigma^-$ is larger than that for $^2\Pi$.

Tables 5 and 6 show results of the orbital reorganization energies in the second-step interaction. The orbital reorganization of the doubly occupied orbitals α1 and β1 for the $^2\Pi(3d\pi^1 4s^2)$ state (62% of E_{PL+CT}) seems to be large Sc polarization from 4s to 3$d\sigma$, or from d^1s^2 to d^2s^1, with small contribution of CO reorganization, resulting in reduction of the axial repulsive interaction, as is shown in Fig. 3a. This type of polarization is very unique. On the other hand, for the $^4\Sigma^-(3d\pi^2 4s^1)$ state, the singly occupied α3 orbital reorganization (19% of E_{PL+CT}) shown in Fig. 4b corresponds mainly to Sc σ polarization through 4s–4$p\sigma$ hybridization, which resembles the singly occupied α1 orbital reorganization of FeCO (Fig. 1a) and CuCO.

Figure 4a shows very large orbital reorganization of half-occupied α1,2 of the $^4\Sigma^-(3d\pi^2 4s^1)$ state (65% of E_{PL+CT}) which corresponds to $d\pi$ backdonation. This is similar to $d\pi$ backdonation of FeCO (Fig. 1b) and CuCO, but shows an increase of the density between Sc and C. This is consistent with the fact that the Sc 3$d\pi$ orbital has a relatively large radial extent. The orbital reorganization for quarterly occupied α2 in the $^2\Pi(3d\pi^1 4s^2)$ state (20% of E_{PL+CT}) corresponds to very similar $d\pi$ backdonation to α1,2 of the $^4\Sigma^-(3d\pi^2 4s^1)$ state.

The α4 and β1 orbital reorganization of the $^4\Sigma^-(3d\pi^2 4s^1)$ state corresponds to σ donation from CO 5σ to Sc 3$d\sigma$, which is very similar to the β3 orbital reorganization in the $^5\Sigma^-(3d\sigma^1 3d\pi^4 3d\delta^2 4s^1)$ FeCO state (Fig. 1c). Figure 3b shows β2 and α3 of the $^2\Pi(3d\pi^1 4s^2)$ state (14% of E_{PL+CT}) and is similar to Fig. 2b showing α4 and β4 of the $^2\Sigma^+(3d\sigma^2 3d\pi^4 3d\delta^4 4s^1)$ CuCO state; contribution of CO 5σ donation to Sc 4$p\sigma$ (not to 3$d\sigma$) is dominant. This is because the 4s orbital is doubly occupied in the $^2\Pi(3d\pi^1 4s^2)$ state and the Sc 4s–3$d\sigma$ polarization is very contributive, as is shown in Fig. 3a.

Figure 3c shows the α4 and β3 orbital reorganization of the $^2\Pi(3d\pi^1 4s^2)$ state. This reorganization contributes little in energy, but shows CO 1π–2π* polarization with very small π donation from CO 1π to Sc 3$d\pi$. It is interesting that this type of polarization is clearly found to be independent of the $d\pi$ backdonation α2.

Frey and Davidson (3) investigated the same states of ScCO based on the original and modified Kitaura–Morokuma (KM) methods. Their ES + EX energies (E_{el} + E_{ex}) based on the original KM method are 2.95 and 1.73 eV for the $^2\Pi$ and $^4\Sigma^-$ states, respectively. These are comparable with the present results (E_{ES+EX} = 3.096 and 1.765 eV). On the other hand, their total PL + CT energies evaluated as $E_{int} - E_{el} - E_{ex}$ with the original KM method, which they call the distortion term, are 1.74 and 2.30 eV for the $^2\Pi$ and $^4\Sigma^-$ states,

α4(π)	0.036	Fig. 3c	CO $1\pi-2\pi^*$ polarization
β3(π)	0.033	(Fig. 3c)	
Others	0.017		
Sum(E_{PL+CT})	2.024		

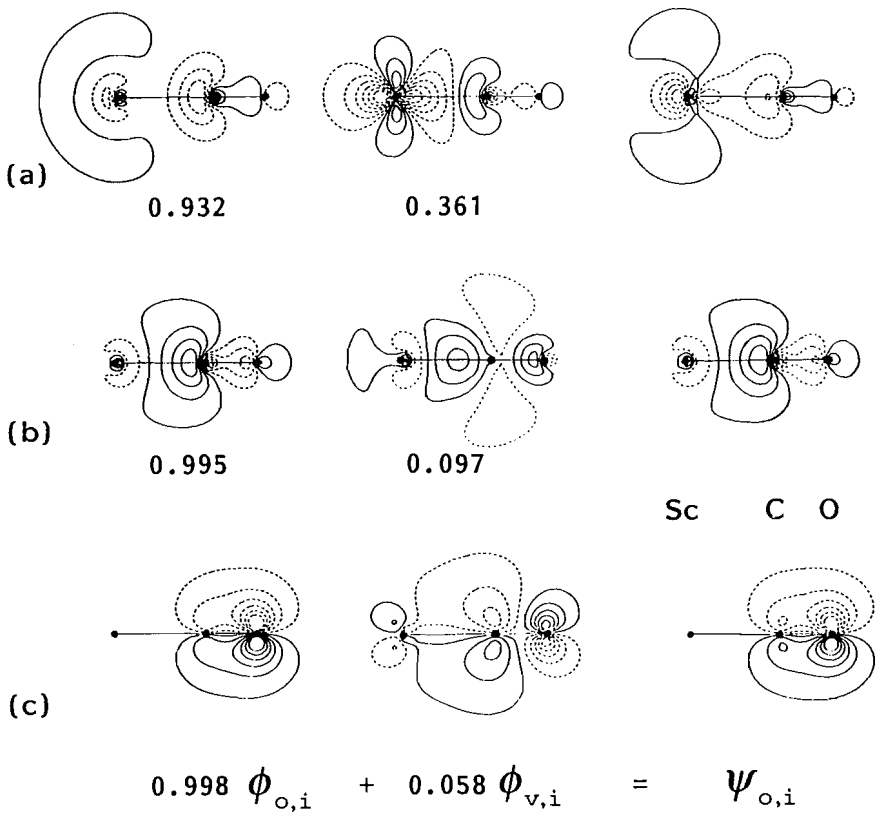

FIG. 3. Contour maps of the orbitals, $\phi_{o,i}$, $\phi_{v,i}$, and $\psi_{o,i}$ together with $c_{o,i}$ and $c_{v,i}$, where $c_{o,i}\phi_{o,i} + c_{v,i}\phi_{v,i} = \psi_{o,i}$, for the $^2\Pi$ ScCO state. (a) β1(σ) and α1(σ), (b) β2(σ) and α3(σ), and (c) α4(π).

respectively, and those evaluated as $E_{plctx}(Sc) + E_{plctx}(CO)$ with the modified KM method, which should be equal to the distortion term, are 1.73 and 2.09 eV, respectively. These discrepancies are attributed to coupling terms (3). The present results (E_{PL+CT} = 2.024 and 2.450 eV) are larger than their results. These discrepancies may arise from differences in the basis functions used; their basis functions for Sc seem to be better than the present ones, lowering the energies of the isolated systems. Furthermore, they divided the PL + CT energies E_{plctx} into the σ and π parts. The σ PL + CT energies $E_{plctx}(\sigma)$ are 1.28 and 0.76 eV and the π PL+CT energies $E_{plctx}(\pi)$ are 0.33 and 1.10 eV for the $^2\Pi$ and $^4\Sigma^-$ states, respectively. The present results ($E_{PL+CT}(\sigma)$ = 1.614 and 0.867 eV, $E_{PL+CT}(\pi)$ = 0.410 and 1.583 eV, respectively) are in qualitative agreement with those.

Conclusions

The present method is able to uniquely partition the interaction into the orbital reorganization. To avoid the basis-set dependence in the energy partitioning, the polarization and charge transfer are not separated within the algorithm; however, the orbital contours make it clear whether the reorganization is polarization or charge transfer in most cases. Centers of gravity of the reorganization orbitals may also be useful for the distinction. Even if polarization and charge transfer appear in the same orbital reorganization, it only

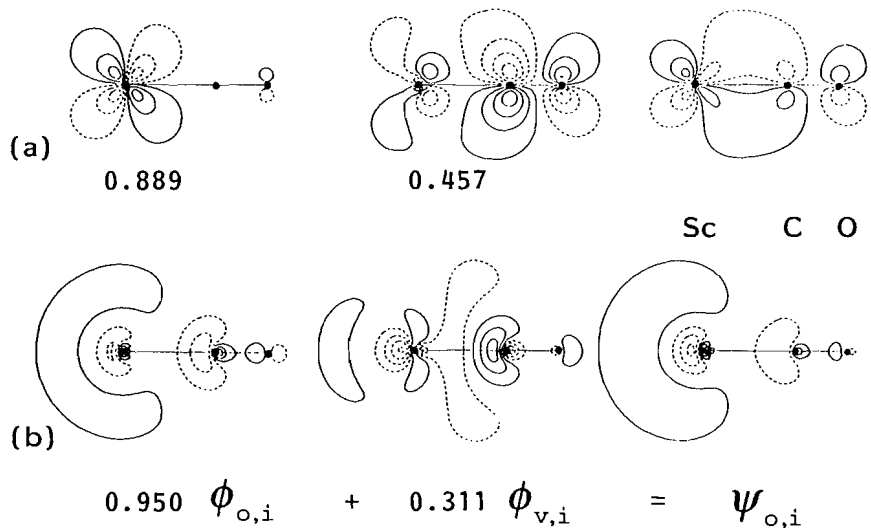

FIG. 4. Contour maps of the orbitals, $\phi_{o,i}$, $\phi_{v,i}$, and $\psi_{o,i}$ together with $c_{o,i}$ and $c_{v,i}$, where $c_{o,i}\phi_{o,i} + c_{v,i}\phi_{v,i} = \psi_{o,i}$, for the $^4\Sigma^-$ ScCO state. (a) $\alpha 1,2(\pi)$ and (b) $\alpha 3(\sigma)$.

suggests that the reorganization cannot be divided definitely into polarization and charge transfer. If we wish to develop a method to distinguish between polarization and charge transfer, it will fall into basis-set dependence. Although the present method is defined within the HF level, it may be extended beyond the HF level by using $\{\phi_{o,i}\}$ and $\{\phi_{v,i}\}$ defined within the HF level.

The interaction of CO with transition metals was analyzed in the high-spin states of the linear model carbonyls, FeCO, CuCO, and ScCO. The orbital reorganization contours were consistent with the conventional concepts of donation, backdonation, and polarization, though the polarization and charge transfer effects cannot be methodologically distinguished. For the $^5\Sigma^-(3d\sigma^1 3d\pi^4 3d\delta^2 4s^1)$ FeCO and $^2\Sigma^+(3d\sigma^2 3d\pi^4 3d\delta^4 4s^1)$ CuCO states, the metal $4s$–$4p\sigma$ polarization and the metal $3d\pi$ – CO $2\pi^*$ backdonation were dominant, where $E_{PL}(4s$–$4p\sigma) \sim 35$ and 50%, and $E_{CT}(3d\pi$–$2\pi^*) \sim 50$ and 22% of E_{PL+CT}, respectively. For the $^2\Pi(3d\pi^1 4s^2)$ and $^4\Sigma^-(3d\pi^2 4s^1)$ states of ScCO, the metal polarization and the metal $3d\pi$ – CO $2\pi^*$ backdonation were dominant, where E_{PL}(metal) ~ 62 and 19%, and $E_{CT}(3d\pi$–$2\pi^*) \sim 20$ and 65% of E_{PL+CT}, respectively. The reorganization orbital contours for the $d\pi$ backdonation (Figs. 1b and 4a) were almost independent of the metals and the electronic configurations, but the energy contributions were dependent on the number of $d\pi$ electrons and the radial extent of $d\pi$ orbitals. On the other hand, the orbital reorganization by the metal polarization was dependent on the electronic configurations. In the $^5\Sigma^-(3d\sigma^1 4s^1)$ FeCO, $^2\Sigma^+(3d\sigma^2 4s^1)$ CuCO, and $^4\Sigma^-(3d\sigma^0 4s^1)$ ScCO states, the dominant metal polarization corresponded to the $4s$–$4p\sigma$ rehybridization away from CO to reduce the repulsive interaction with CO (Figs. 1a and 4b). In the $^2\Pi(3d\sigma^0 4s^2)$ ScCO state, there was no $4s$–$4p\sigma$ polarization but the metal polarization corresponded to the de-excitation from $4s$ to $3d\sigma$, or from d^1s^2 to d^2s^1, to reduce the axially repulsive interaction with CO (Fig. 3a).

Other polarization and backdonation effects were found. In the $^2\Sigma^+(3d\sigma^2 4s^1)$ CuCO state the metal $3d\sigma$–$4s$ polarization was contributive (12% of E_{PL+CT}), indicating the rehybridization between $d\sigma^2 s^1$ and $d\sigma^1 s^2$ to reduce the axially repulsive interaction with CO 5σ (Fig. 2a). The CO 1π–$2\pi^*$ polarization (Fig. 3c) and Fe $3d\sigma$ – CO $6\sigma^*$ backdonation (Fig. 1e) were clearly found in the $^2\Pi(3d\sigma^0 4s^2)$ ScCO and $^5\Sigma^-(3d\sigma^1 4s^1)$ FeCO states, respectively, though less contributive (3.4 and 2.3% of E_{PL+CT}).

The CO 5σ donation to the metals was more complicated. There were two types of donation found in the $^5\Sigma^-(3d\sigma^1 4s^1)$ FeCO state: the donations to Fe $3d\sigma$ and to Fe $4p\sigma$ ($4sp$ hybrid directed to CO). The former corresponded to the well-accepted donation (Fig. 1c) and was more contributive (11% of E_{PL+CT}) than the latter (Fig. 1d, 3.6% of E_{PL+CT}). In the $^2\Sigma^+(3d\sigma^2 4s^1)$ CuCO and $^2\Pi(3d\sigma^0 4s^2)$ ScCO states with the $3d\sigma$ and $4s$ orbitals doubly occupied, respec-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

tively, only the latter type of donation was contributive (17% of E_{PL+CT}, Fig. 2b; 14% of E_{PL+CT}, Fig. 3b). In the $^4\Sigma^-(3d\sigma^0 4s^1)$ ScCO state with the $3d\sigma$ orbital unoccupied, only the former type of donation was contributive (15% of E_{PL+CT}).

Multireference singly and doubly excited CI (MRSDCI) calculations are performed on the NaI molecule by using a model potential method. The potential energy curves of the ground and first excited $^1\Sigma^+$ states are generated over a wide range of internuclear distance R. The curves yield the avoided crossing, which is expected to arise by the mixing of the ionic and covalent configurations, and thus the curve of the first excited state shows a shallow minimum. The geometrical parameters, dipole moment, and dissociation energy are calculated. The agreement of those with the experimental results is satisfactory.

Key words: NaI, MRSDCI calculation, model potential method, potential curve, excited state.

YOSHIKO SAKAI, EISAKU MIYOSHI et TOSINOBU ANNO. Can. J. Chem. **70**, 309 (1992).

Utilisant une méthode avec potentiel modèle, on a effectué des calculs d'IC avec multi-références simplement ou doublement excitées (MRSDCI) sur la molécule de NaI. On a généré les courbes d'énergie potentielle de l'état fondamental et du premier état excité $^1\Sigma^+$ pour un grand ensemble de distances internucléaires R. Les courbes conduisent au croisement évité qui devrait augmenter par le mélange des configurations ionique et covalente; la courbe du premier état excité présente donc un minimum peu profond. On a calculé les paramètres géométriques, le moment dipolaire et l'énergie de dissociation. L'accord entre ces valeurs et les résultats expérimentaux est correct.

Mots clés : NaI, calculs MRSDCI, méthode du potentiel modèle, courbe de potentiel, état excité.

Introduction

Over the last six decades, a number of spectroscopic studies have been done on diatomic alkali halides (1, 2). Although the ground state of these molecules has been well established, only a little knowledge has been gained for the excited states. The alkali halide dissociation reaction is influenced by the interaction between the ionic ground state and the lowest excited covalent state. The crossing (or avoided crossing) of the potential surfaces of these two states arises from the fact that the energy required to separate into ions ($M^+ + X^-$) is larger than the energy required to separate into neutral atoms (M + X), where M and X represent the alkali metal and halogen, respectively. This characteristic of alkali halides leads to interesting effects in the dynamics.

Schaefer *et al.* (3, 4) were the first to provide an analysis of the discrete ultraviolet (UV) spectrum obtained for NaI, and deduced the molecular parameters for the first excited state as well as for the ground state. Bluhm *et al.* (5) and Bower *et al.* (6) found a new bound state that leads to one of the Na(3*p*) asymptotes. Rose *et al.* (7, 8) performed femtosecond transition state spectra (FTS) measurements on the reaction of NaI, LiI, and NaBr. Their work focused particularly on NaI. The data showed that some NaI molecules were being trapped in a well formed by the avoided crossing of the covalent and ionic potential energy surfaces, indicating the presence of the excited bound state. Grice and Herschbach (9) calculated the splitting $\Delta V(R_x)$ between the pair of adiabatic potential energy curves that arise from pseudo-crossing of ionic and covalent states, where R_x is the crossing point of the diabatic potential curves. They pointed out that only when $R_x < 15$ au is $\Delta V(R_x)$ large enough to enable the adiabatic potential curves to govern the nuclear motion; otherwise the dissociation proceeds nonadiabatically, as if there were no mixing of the ionic and covalent configurations. The FTS measurements by Rose *et al.* (8) indicated that the fragments from the LiI dissociation were trapped similarly to the case of NaI, but then the dissociation of NaBr did not exhibit strong trapping. (R_x = 11.9 au for LiI, 13.3 au for NaI, and 15.4 au for NaBr (9).)

It is interesting to represent the potential energy curves of the alkali halides by theoretical calculations using the approach based on first principles. In the present work, we examine the potential energy curves of the ground state ($X^1\Sigma^+$) and the first excited state ($A^1\Sigma^+$) of the NaI molecule over a wide range of internuclear distance R. Careful configuration interaction (CI) calculations are required to describe properly the intermediate part of the potential curves, where the avoided crossing is expected to arise by the mixing of the ionic and covalent configurations. Multireference singly and doubly excited CI (MRSDCI) calculations are performed with extended Gaussian-type basis sets. The core electrons of the atoms are replaced by the model potentials (10–17). Our results include the potential energy curves, dipole moment curves, geometrical parameters, dissociation energy, and the values of R_x and $\Delta V(R_x)$.

Details of calculation

Basis sets and the scheme of calculation

Hartree–Fock–Roothaan (HFR) and MRSDCI calculations were performed on the ground and first excited $^1\Sigma^+$ states of the NaI molecule by using a model potential method (10–17). Nine electrons ($2s^22p^63s$) for the Na atom and seven electrons ($5s^25p^5$) for the I atom were treated explicitly and the remaining (core) electrons were replaced by the model potentials. Model potential parameters and basis sets were determined in the same way as in previous work (15). Major relativistic effects (mass–velocity and Darwin terms) were incorporated for the model potential of the I atom at the level

of Cowan and Griffin's quasirelativistic HF method (13, 18). The valence basis set consists of six s- and four p-type Gaussian-type functions (GTF's) ($6s/4p$) for Na, and of ($6s/5p$) for I. In the molecular calculations, these basis sets were increased by one or two diffuse s- and p-type GTF's and three d-type GTF's, as shown in Table 1, in order to describe the Na^+ and I^- characters in the NaI molecule properly, and they were contracted as (21111/21111/111) for Na and (31111/21111/111) for I.

Following the SCF calculations, the MRSDCI calculations were performed to obtain the potential energy curves for the ground and first excited $^1\Sigma^+$ states. The calculations were done at 18 different distances of R = 4.0–20.0 au and at the dissociation limit ($R = 10^4$ au).

Computer programs JAMOL4 (19) and MICA3[2] were used for the SCF and MRSDCI calculations, respectively. A detailed description of the MRSDCI procedure will be given in the following section.

MRSDCI calculations

At the SCF-MO calculation, the configuration of the ionic state is $(4a_1^2)$, which is an abbreviation of $(1a_1^2 2a_1^2 3a_1^2 1b_1^2 2b_1^2 1b_2^2 2b_2^2 4a_1^2)$ in C_{2v} symmetry, and it turns into $(5a_1^2)$ at the dissociation limit. The highest occupied MO in the ionic state is of the I($6p$) character. The configuration of the covalent state is $(4a_1 5a_1)$, in which the $4a_1$ and $5a_1$ MO's are of the I($6p$) and Na($3s$) characters, respectively. We chose three configurations, $(4a_1^2)$, $(4a_1 5a_1)$, and $(5a_1^2)$, as the references in the MRSDCI calculations. All single and double excitations from these three reference configurations were considered without any orbital being kept frozen. To save configurational space, the configuration state functions (CSF's) were limited to first-order interaction space (20). The number of CSF's thus obtained is 89 252. Because the SCF-MO's of the ionic state are significantly different from those of the covalent state, the choice of the MO's in the CI is critical. We, therefore, adopted the procedure that consists of the following two steps.

1. The MRSDCI calculations with a small dimension were performed first, in which the SCF-MO's up to $10a_1$, $1a_2$, $5b_1$, and $5b_2$ in each representation were considered. Here, the SCF-MO's for the ionic state were used. The CI dimension was 3929.

2. Next, the MRSDCI calculations with full space were performed for the ionic and covalent states separately, using the natural orbitals for each of the states obtained by the above calculation. The dimension of CI was reduced to 3000–6000 (the smaller number of CSF's for the larger R values) by the second-order perturbation selection (21, 22) with an energy threshold of 5 μhartree. Weights of the reference space in the calculated ground and first excited states were 92–93% for all distances. The results of the CI calculations were modified by adding the energy lowering from the rejected CSF's, estimated by a second-order perturbation technique (21, 22), and also by a Davidson-like correction for multireference (23).

Results and discussion

The potential energy curves for the lowest two $^1\Sigma^+$ states obtained by the MRSDCI calculations are shown in Fig. 1. The ionic state produces an avoided crossing with the dissociation asymptote to the neutral atoms, and the curve of the excited state has a shallow minimum. Geometrical parameters (equilibrium Na—I distance R_e, vibrational constant ω_e, rotational constant B_e, and force constant k_e) were obtained by a third-degree polynomial fit to the total energies around the minimum shown in Table 2.

We shall discuss the properties of the ground state first. The results are given in Table 3 with the results of SCF calculation and the experimental data (24). The SCF values agree well with the experimental ones. The MRSDCI calculation improves the results further. The difference in R_e between the MRSDCI and experimental values is 0.02 Å (0.7%). Agreement of the calculated ω_e (256 cm^{-1}) and B_e

(0.116 cm^{-1}) with the experimental values, 258 and 0.1178 cm^{-1}, respectively, is excellent.

To calculate the dissociation energy (D_e) of NaI, two methods were examined, the formulas of which are given as follows:

$$[1] \quad D_e = E(Na^+) + E(I^-) - E(NaI,R_e) - IP(Na) + EA(I)$$

and

$$[2] \quad D_e = E(Na) + E(I) - E(NaI,R_e)$$

where IP(Na) and EA(I) are the experimental ionization potential for Na and electron affinity for I, respectively. It has been confirmed that formula [1] gives more accurate D_e's than formula [2] for diatomic alkali halides (MX) (25), because the electronic structure of MX in the ionic ground $^1\Sigma^+$ state resembles that of the ion pair ($M^+ + X^-$) (25–28). When D_e is calculated by formula [1], most of the differential correlation and relativistic effects between MX and M + X are embedded in the experimental IP and EA (25–28). In the present work, the experimental values of IP(Na) = 5.138 eV and EA(I) = 3.063 eV (9) were used, and the total energy of the (Na^+I^-) system calculated at $R = 10^4$ au, given in Table 2, was used instead of the sum of the energy of the separated ions. By the use of formula [1], the MRSDCI and SCF calculations yielded D_e's of 3.09 and 3.00 eV, respectively. A number of experimental studies on the dissociation energy of the NaI molecule have been reported (29–34). As shown in Table 3, the experimental values of D_0 are in the range 3.00–3.26 eV. After a zero point correction of one-half ω_e on the calculated D_e's, we obtained D_0 = 3.07 and 2.98 eV for the MRSDCI and SCF calculations, respectively. The D_0's thus obtained are included in Table 3. Agreement of the MRSDCI D_0 value with the experimental values is satisfactory.

We also examined formula [2] to obtain D_e. D_e's of 3.08 and 2.50 eV were obtained for the MRSDCI and SCF calculations using the total energies given in Table 2. These D_e's, however, cannot be compared directly with the experimental values. The NaI molecule dissociates into the neutral Na($^2S_{1/2}$) and I($^2P_{3/2}$) atoms. Because of neglect of the spin-orbit interactions (13), our calculations yield the weighted average of the Na($^2S_{1/2}$) + I($^2P_{3/2}$) and Na($^2S_{1/2}$) + I($^2P_{1/2}$) asymptotes. The energy difference between the two atomic states, I($^2P_{3/2}$) and I($^2P_{1/2}$), is 0.94 eV, which is not negligible. Since the averaged energy of I(^2P,av) is higher by 0.31 eV than the energy of I($^2P_{3/2}$), the total energy of the supermolecule (Na + I) shown in Table 3 should be corrected by this amount. After this correction, formula [2] yielded D_e's of 2.77 and 2.19 eV for the MRSDCI and SCF calculations. These results are worse than those obtained by formula [1]. The difference in MRSDCI D_e's obtained by the

two methods is 0.32 eV. Bauschlicher *et al.* (28) have performed *ab initio* CI calculations on MgO (a^3II) and its component atoms and ions, and discussed which of the two methods gives a more accurate D_e value. They concluded that formula [1] gives a more accurate D_e than formula [2] and that the difference in the D_e's obtained by these two methods is very nearly the sum of errors in the calculated IP and EA. Their CI calculation has given an error of 0.21 eV for the IP(Mg) − EA(O) using large STO and GTO basis sets. The same is true of the present case. The experimental value for IP(Na) − EA(I) is 2.08 eV (9). After correcting the value of $\Delta E(\mathrm{I}(^2P,\mathrm{av}) - \mathrm{I}(^2P_{3/2}))$ by the amount 0.31 eV, the difference in the total energies of the systems, Na + I and $Na^+ + I^-$, calculated at $R = 10^4$ au is 2.40 eV, which corresponds to the calculated value of the IP(Na) − EA(I). Thus, the error of IP(Na) − EA(I) amounts to 0.32 eV. This is mainly caused by the difficulty in evaluating electron affinities of atoms (35, 36).

The true potential curves should provide their total energy difference at $R = \infty$, being equal to the experimental value of IP(Na) − EA(I). From this point of view, it is required that the $\mathrm{Na}(^2S_{1/2}) + \mathrm{I}(^2P_{3/2})$ asymptote lies lower, by 2.08 eV, than that of $Na^+(^1S_0) + I^-(^1S_0)$. Our potential curves shown in Fig. 1 yield an energy separation of 2.09 eV at $R = 10^4$ au. This agreement is a result of cancellation of the error caused by omitting the spin-orbit interaction and the above-mentioned error in IP(Na) − EA(I). The spin-orbit interaction will have little effect on the ionic system of $Na^+(^1S_0) + I^-(^2S_0)$ character over the whole range of R. The interaction affects significantly the covalent system of $\mathrm{Na}(^2S_{1/2}) + \mathrm{I}(^2P_{3/2})$ character, as discussed above. The effect will remain, however, nearly constant for a wide range of R, because the electronic structure of the covalent system changes little. Under these assumptions, we consider that the potential curves shown in Fig. 1 should be close to the true curves for the adiabatic ground ($X0^+$) and first excited ($A0^+$) states. We calculated the geometrical parameters for the first excited state by fitting a third-degree polynomial to the total energies around the minimum shown in Table 2. The results, which are given in Table 4, are R_e = 6.49 Å, ω_e = 39 cm^{-1}, and B_e = 0.0206 cm^{-1}. Schaefer *et al.* (3, 4) derived the potential curve of the first excited $^1\Sigma^+$ state ($A0^+$) of NaI, as well as the ground state, by analyzing the UV absorption spectrum. However, the intermediate part of the curve of the excited state is still unclear because of the assumption made to obtain the absolute v' numbering (4). They reported in their first paper (3) that vibrational spacing ω = 39.3 cm^{-1}, averaged rotational constant B = 744 MHz (=0.0248 cm^{-1}), and R = 5.90 Å for the adiabatic $A0^+$ state. These values agree qualitatively with our results. In the refined paper (4), however, they gave the values of Y_{10} ($\approx\omega$) = 27.3 cm^{-1} and Y_{01} ($\approx B$) = 0.0482 cm^{-1} for the adiabatic state ($A0^+$). This B value yields R = 4.24 Å, which is too

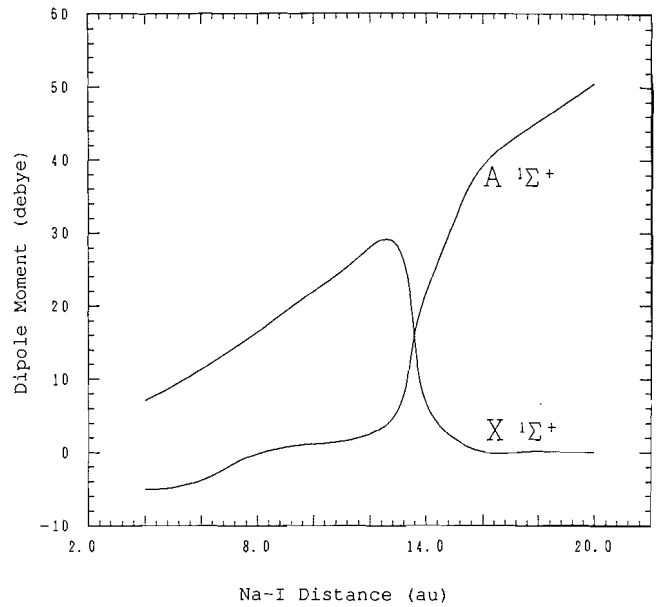

FIG. 2. Dipole moment curves of the ground state ($X^1\Sigma^+$) and the first excited state ($A^1\Sigma^+$) obtained by the MRSDCI calculations as a function of the Na—I distance.

short compared to our R_e of 6.49 Å. From the experimental potential curves of the excited state, we could not obtain quantitative geometrical parameters, because the intermediate part of the potential curve derived from an extrapolation is still questionable (4).

The crossing point of the diabatic potential curves, R_x, is estimated to be 13.3 au (7.04 Å) by a simple formula, IP(Na) − EA(I) = $1/R_x + \alpha/2R_x^4$ (9), where α is the sum of the polarizabilities of the positive and negative ions. From our adiabatic potential curves in Fig. 1, R_x is likely to be 13.5 au (7.14 Å), which is close to the estimated R_x value. The R_e given in Table 4 is shorter than the R_x, by 0.65 Å. We obtained a value of 0.13 eV for the energy splitting $\Delta V(R_x)$ between the adiabatic potential curves at the crossing point (R_x = 13.5 au), which is in good agreement with the result (0.10 ± 0.02 eV) derived from the chemical ionization process $Na + I \rightarrow Na^+ + I^-$ given by Los and coworkers (37). Grice and Herschbach have also obtained a splitting of 0.1 eV by semiempirical calculation (9). These facts give additional support to the reliability of the potential curve of the excited state in Fig. 1.

In Fig. 2 the dipole moment curves given by the MRSDCI calculation are plotted against R. The electronic structures of the two states change dramatically around R_x. The curve of the ground state goes down to zero at $R \simeq 15$ au. The gross populations on the atoms are 8.42 (Na) and 7.58 (I) at R_e, and 7.93 (Na) and 8.07 (I) at 12.5 au. They turn to 9.00 (Na) and 8.00 (I) for $R > 16$ au. On the contrary, the curve of the excited state goes up to the dissociation asymptote for the Na^+ and I^- ions at $R \simeq 16$ au. For $R < 8$ au, dipole moments are of $Na^{\delta-}I^{\delta+}$ character. For example, the gross populations are 9.16 (Na) and 6.83 (I) at 5.0 au. The polarity changes into $Na^{\delta+}I^{\delta-}$ at $R \simeq 8$ au. The gross populations are 8.00 for both atoms, (Na^+I^-), for $R > 16$ au. The dipole moment calculated at R_e is given in Table 3. The value of 9.41 debye agrees very well with the experimental value of 9.21 debye (38).

Acknowledgements

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday. The authors would like to thank Professor Huzinaga for his kind guidance in their research activities over many years. One of the authors (Y.S.) also would like to thank Professor Keiji Morokuma for his helpful suggestions for the present work. The calculations were done at the computer center of the Institute for Molecular Science.

Ab initio study on radical anions of nitro compounds

FABIO RAMONDO

Dipartimento di Chimica, Università degli Studi di Roma, P.le A. Moro 5, 00185 Roma, Italy

Received June 10, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

FABIO RAMONDO. Can. J. Chem. **70**, 314 (1992).

The results of *ab initio* molecular orbital calculations on some nitro compounds, RNO_2 (R = CH_3, CF_3, CH_2F, BH_2, BF_2, BHF, C_6H_5) and on the corresponding radical anions are reported. The geometries of the neutral and charged species were optimized at the SCF and MP2 levels of theory employing the 6-31G* and the 6-31+G* basis sets. The rotation about the CN and BN bonds reveals distinct conformations for each molecule and vibrational frequencies were determined for such structures. All the employed levels of theory predict structural differences between neutral and charged molecules. The major geometrical changes occurring by electron adding to RNO_2 consist in the lengthening of the NO bonds and in the shortening of the CN and BN bonds. The radical anions are calculated to be pyramidal at nitrogen in the stable conformers of $CH_3NO_2^-$, $CF_3NO_2^-$, $CH_2FNO_2^-$, while, for the π-electron-accepting substituents (BH_2, BHF, BF_2, C_6H_5), the anion is planar. Electron correlation energy corrections in the framework of Møller–Plesset perturbation theory were included to determine relative stabilities between different conformations. At the MP4/6-31G*//MP2/6-31G* level, an easy rotation of the NO_2 group is predicted for all the radical anions and neutral molecules with the exception of $BH_2NO_2^-$, $BF_2NO_2^-$, and $BHFNO_2^-$, which show high torsional barriers about the BN bond.

Key words: nitro compounds, radical anions, *ab initio* calculations, molecular structure.

FABIO RAMONDO. Can. J. Chem. **70**, 314 (1992).

On a effectué des calculs d'orbitales moléculaires *ab initio* sur quelques composés nitrés, RNO_2 (R = CH_3, CF_3, CH_2F, BH_2, BF_2, BHF et C_6H_5) et sur les anions radicaux correspondants. On a optimisé les géométries des espèces neutres et chargées aux niveaux auto-cohérent et MP2 de la théorie, en employant des ensembles de base 6-31G* et 6-31+G*. La rotation autour des liaisons CN et BN indique l'existence de conformations distinctes pour chaque molécule et on a déterminé les fréquences de vibration de chaque structure. Tous les niveaux de la théorie qui ont été utilisés permettent de prédire des différences structurales entre les molécules neutres et chargées. Les changements principaux de géométrie se produisent par l'addition d'un électron au RNO_2 et ils consistent en un allongement des liaisons NO et un raccourcissement des liaisons CN et BN. On a calculé que, dans les conformères stables du $CH_3NO_2^-$, $CF_3NO_2^-$ et $CH_2FNO_2^-$, les anions radicaux sont pyramidaux au niveau de l'azote alors que, avec des substituants qui acceptent les électrons π (BH_2, BHF, BF_2 et C_6H_5), l'anion est plan. Afin de déterminer les stabilités relatives des diverses conformations, on a introduit des corrections pour l'énergie de corrélation électronique dans le contexte de la théorie des perturbations de Møller–Plesset. Aux niveaux MP4/6-31G*//MP2/6-31G*, on prédit l'existence d'une rotation facile du groupe NO_2 pour tous les anions radicaux et les molécules neutres, à l'exception des anions $BH_2NO_2^-$, $BF_2NO_2^-$ et $BHFNO_2^-$ pour lesquels il existerait des barrières torsionnelles élevées autour de la liaison BN.

Mots clés : composés nitrés, anions radicaux, calculs *ab initio*, structure moléculaire.

Introduction

Molecules containing the nitro group are involved in many electron-transfer processes both in the gas phase and in solution. Ion–molecule equilibria measurements in the gas phase were applied to determine electron affinities and ion thermochemical data (1, 2). Electron affinities were obtained for a wide variety of organic molecules and have been summarized in a recent review (3). Because of the high electron affinity of the NO_2 group, the formation of stable radical anions via electron attachment occurs easily. The lowest unoccupied molecular (π^*) orbital (LUMO) accepts an extra electron to become a singly occupied molecular orbital (SOMO) of the radical anion. The possibility of conjugation between NO_2 and other groups of the molecule and the presence of electronegative atoms or electron-withdrawing groups leads to the lowering of the LUMO energy and thus to higher electron affinities and to higher stability of the resulting radical anions. Accurate electron affinities were alternatively determined by photodetachment studies (4) but, when polyatomic molecules are investigated, knowledge of the geometry for both the neutral molecule and the anion is required to resolve the photoelectron spectrum. Geometrical changes and normal modes displacements are predicted as a consequence of electron attachment. However, any accurate experimental determination of the geometry and vibrational spectra of stable gas-phase radical anions represents a particularly difficult target. A general structural feature of nitro radical anions can be obtained from electron spin resonance investigations providing information about conformational preference of the nitro group in different organic radical anions (5). On the basis of ^{14}N anisotropic hyperfine splittings (5) and from experimental and theoretical studies of splitting constants (6), aliphatic anions show a tendency for pyramidal nitrogen, while nitroaromatic anions appear to be planar at nitrogen. Likewise, structural changes due to the negative charge are suggested by entropy variations derived from electron attachment measurements in the gas phase (1, 2). Negative entropy changes were determined for the nitrobenzene radical anion and substituted derivatives and this indicates a stiffening of the internal rotation of the NO_2 group moving from neutral to charged species (7, 8).

Detailed structures, relative energies between different isomers, and vibrational spectra of radical anions may be determined by *ab initio* molecular orbital calculations (9, 10). In general, it is desirable to employ extended basis sets including diffuse atomic orbitals for obtaining a correct de-

scription of diffuse charge densities. Self-consistent field (SCF) calculations frequently suffice for the determination of geometries and vibrational frequencies of anions and neutral precursors, and reproduce structural reorganization reliably upon electron attachment; this is valuable when molecular size renders post-SCF treatments non-feasible. The main aim of this work is to determine and compare structural features and stabilities of some radical anions containing the nitro group bonded to substituents with different electron properties, using uniform levels of *ab initio* theory. In particular, a comparative study of molecular parameters calculated for neutral and negatively charged species might provide indications about the change in molecular geometry upon adding an extra electron to the neutral compound and on the character of the molecular orbitals involved. The mutual influence between NO_2 and the substituent bonded to the nitro group can rationalize different conformational behaviours observed moving from a neutral molecule to an anion. The effect of the substituent on the geometry of nitro radical anions and the rotational barriers of the NO_2 framework are investigated with an aliphatic group, such as methyl, and with a π-electron-accepting group, such as BH_2. The influence of electronegative groups on such parameters is investigated by substitution of fluorine atoms in the CH_3 and BH_2 groups. An example of expansion of π conjugation, the radical anion of nitrobenzene, $C_6H_5NO_2^-$, is also included.

Method

Geometry optimizations of neutral and negatively charged molecules were accomplished at the SCF level of theory by analytical gradient-based techniques (11). Split-valence basis sets including polarization, 6-31G*(6D) (12), and (or) diffuse functions, 6-31+G* (12), were employed. The spin-unrestricted Hartree–Fock (UHF) formalism was used for the radical anions and calculated $\langle S^2 \rangle$ values are 0.75 for open-shell systems with the exception of the planar structure of $C_6H_5NO_2^-$, which gives $\langle S^2 \rangle$ values indicating contamination from higher spin states. Vibrational frequencies were calculated at the 6-31G* basis set level to characterize each stationary point on the corresponding potential energy surface and to determine the zero-point corrections (ZPE) to the total energies of the stable structures.

With the exceptions of CF_3NO_2 and $C_6H_5NO_2$, for which the sizes of the molecules render post-SCF calculations prohibitively expensive, geometries were optimized with the second-order Møller–Plesset theory (13) with all orbitals active, using the 6-31G* basis set. The geometries obtained in this way are indicated as MP2/6-31G*. Single-point calculations were carried out using the frozen core approximation (fc), with the Møller–Plesset perturbation theory up to the fourth order, by including single, double, triple, and quadruple excitations. The designation of these calculations is MP4(SDTQ)(fc)/6-31G*//MP2/6-31G* where // means "at the geometry of." Henceforth the term SDTQ(fc) will be omitted. All the energy differences between the different conformations are calculated as ΔHF, ΔMP2, and ΔMP4 for the neutral molecules or as ΔUHF, ΔPMP2, and ΔPMP4 for the radical anions where "P" indicates that the largest spin contamination has been projected out of the UHF correlation energies and will be generically represented by ΔMP2 and ΔMP4. All calculations were carried out using the IBM-VM/CMS version of the GAUSSIAN-88 (14) program on an IBM 3090-600J computer at the University of Rome.

Tables 1 and 2 show the total energies of the most stable molecules calculated at various levels of theory, the ZPE corrections, and the energy differences between conformers. Optimized geometries and vibrational frequencies of the less stable structures as well as the results of additional computations are available from the author upon request.

Results and discussion

Molecular structures

The geometry of the NO_2 group was determined by gas-phase electron diffraction and microwave spectroscopy starting from the simplest aliphatic compound, CH_3NO_2 (15, 16). Both techniques indicate that CH_3NO_2 has staggered conformation. Previous *ab initio* calculations on the staggered and eclipsed conformers of nitromethane were carried out at the SCF level (17, 18) and a slight preference (lower than 0.1 kJ/mol) was found for the staggered orientation at the MP2/6-31G*//HF/6-31G* level (18). To recalculate the equilibrium geometry of CH_3NO_2, the eclipsed and staggered conformations were optimized at the HF/6-31G** and MP2/6-31G* levels. The effect of electron correlation was estimated for both conformers with single point MP4/6-31G*//MP2/6-31G* calculations. The total energies indicate that the staggered conformer is more stable than the eclipsed one but the energy difference between them is extremely small, about 0.04 kJ/mol (MP4/6-31G*//MP2/6-31G*). HF/6-31G* frequency calculations indicate that the eclipsed conformation is a rotational transition state, as suggested by the imaginary frequency (53i cm^{-1}). The height of the rotational barrier is comparable to the small value, 0.025 kJ/mol, determined from microwave spectroscopy (19). Most of the geometrical parameters determined by HF/6-31G** calculations (Fig. 1) agree with the experimental ones, with the exception of the NO bond length, usually underestimated at this level of theory (20). The inclusion of electron correlation provides a better description of the molecular geometry. The bond angles are quite independent of the level of theory adopted but, as expected, the MP2 optimized bond lengths are longer than those obtained from the HF/6-31G** level and this effect is more considerable for the NO bond distances (see Fig. 1). The MP2 optimized geometry of the $-CNO_2$ moiety (r_{CN} = 1.485 Å; r_{NO} = 1.240 Å; $\angle$ONO = 125.7°) agrees with the experimental r_z geometry (16) (r_{CN} = 1.488 ± 0.005 Å; r_{NO} = 1.230 ± 0.004 Å; $\angle$ONO = 124.9 ± 0.5°). Based on these considerations and on previous calculations (18), a single electron configuration with inclusion of electron correlation by perturbation theory appears sufficient to predict satisfactorily the geometry of CH_3NO_2.

CF_3NO_2, as ascertained from gas-phase electron diffraction (21), has a staggered ethane-type conformation with one position missing and the $-CNO_2$ group is found to prefer a nonplanar arrangement. On the contrary, a planar conformation of the $-CNO_2$ moiety seems to be preferred at the HF/6-31G* level. In particular, the C_s eclipsed form of CF_3NO_2 with the O, C, N, and F atoms lying in the same plane and shown in Fig. 1 was calculated to be a minimum on the HF/6-31G* potential energy surface. Vibrational frequencies show that the C_s staggered conformation is a first-order saddle point with imaginary vibrational frequency of 31 cm^{-1}. The relative normal coordinate corresponds to the torsion mode about the CN bond. As a matter of fact, a small variation from planarity of the $-CNO_2$ group is observed in the staggered form of CF_3NO_2 but relaxation of the planarity constraint results in a very small stabilization (0.3 kJ/mol). The negligible energy change and the value of the dihedral angle between the CN bond and the NO_2 plane (177.3°) suggest that the $-CNO_2$ moiety is nearly planar at the HF/6-31G* level. By including these deviations from planarity, the

barrier separating the staggered and eclipsed conformations of CF_3NO_2 is extremely small (0.4 kJ/mol) at the HF/6-31G* and MP2/6-31G*//HF/6-31G* levels. Based upon these results, the rotation about the CN bond in CF_3NO_2 as well as in CH_3NO_2 is virtually free. More accurate previsions of the torsional barrier of CF_3NO_2 might be provided by higher levels of theory but this would increase computational time prohibitively. The CH_2FNO_2 molecule is more suitable than the trifluorine derivative to investigate the effects of electron correlation at higher levels on the height of the rotational barrier of the nitro group. Geometry optimizations were carried out at the SCF and MP2 levels for two distinct orientations of the CH_2F group with respect to the NO_2 framework within the C_s symmetry constraint. The conformation where the CF bond is perpendicular to the NO_2 plane is designated as staggered and that where the fluorine atom is lying on the ONC plane and shown in Fig. 1 is indicated as eclipsed. Due to the asymmetry of the CH_2F group, intermediate orientations of the CF bond with respect to the NO_2 framework might correspond to other critical points. The SCF and MP2 results are consistent with those predicted for CF_3NO_2. In fact, the eclipsed conformer of CH_2FNO_2 is a minimum structure on the HF/6-31G* energy surface, while the staggered form corresponds to a first-order saddle point with CN torsional frequency of 82i cm^{-1}. Likewise, a slight nonplanarity of the -CNO_2 group is inferred from the HF/6-31G* (178.5°) and MP2/6-31G* (176.7°) optimized geometries of staggered CH_2FNO_2. The eclipsed structure is more stable than the staggered conformer at both MP2/6-31G* (10.6 kJ/mol) and MP4/6-31G*//MP2/6-31G* (12.0 kJ/mol) levels.

The most noticeable differences between the theoretical and experimental geometry of CF_3NO_2 (16, 21) are in the CN and NO bond lengths. The HF/6-31G* level predicts the CN bond distance (1.508 Å) shorter than the electron diffraction (1.56 ± 0.02 Å) (21) and microwave (1.534 ± 0.005 Å) (16) values. The r_z structure (16) shows the NO and CF bond distances equal to 1.217 ± 0.004 and 1.314 ± 0.003 Å, respectively, while the HF/6-31G* mean value for the NO bond length in both conformations of CF_3NO_2 is 1.184 Å and that for the CF bond is 1.295 Å. It is clear that the SCF method is not suitable to determine very accurately the molecular geometry of CF_3NO_2. However, as shown by the geometry optimizations of CH_2FNO_2 carried out at the MP2/6-31G* level (Fig. 1), the inclusion of electron correlation appreciably lengthens the CF and NO bonds with

respect to the HF/6-31G* values but has a negligible effect on the CN bond. Indeed, it is known that for compounds containing the nitrosyl and nitro groups, such as CH_3NO and CH_3NO_2 (22, 23), the $\pi \rightarrow \pi^*$ configuration contributes significantly to the ground state wave function, but the molecular geometry is well described also by a single-determinant wave function. Instead, a previous MCSCF study on CF_3NO (24) showed that the largest contributions to the ground state wave function, other than the SCF and $\pi \rightarrow \pi^*$ configurations, come from the $\sigma_{CN} \rightarrow \sigma_{CN}^*$ and $\sigma_{NO} \rightarrow \sigma_{NO}^*$ configurations, and that the CN bond length can be satisfactorily reproduced by theoretical calculations by employing only a two-configuration (TCSCF) wave function by pairing the bonding and the antibonding CN orbitals ($\sigma_{CN} \rightarrow \sigma_{CN}^*$). Based on these results, a better description of the CN bond length in CF_3NO_2 would probably require a multideterminant wave function including the $\sigma_{CN} \rightarrow \sigma_{CN}^*$ configuration as a starting point. The radical anions $CH_3NO_2^-$, $CH_2FNO_2^-$, and $CF_3NO_2^-$ were studied at the UHF level employing the 6-31G* basis set. For a more reliable description of charge density, diffuse functions were added to the heavy atoms and the UHF/6-31+G* optimized geometries of staggered conformers are shown in Fig. 1. By analogy with the neutral molecule, $CH_2FNO_2^-$ was investigated assuming the C_s staggered and eclipsed conformers described above. Mulliken population analysis reveals that the π^* molecular orbital of the NO_2 fragment accepts the extra electron becoming the single occupied molecular orbital (SOMO) of the radical anion. It has a significant coefficient on nitrogen and, at the SCF level, this suggests that the unpaired electron is delocalized onto each atom of the NO_2 group but with a prevalent contribution at nitrogen. The highest values of atomic spin density were calculated on nitrogen for all the radical anions. The staggered conformations of the three anions are energy minima at the UHF/6-31G* level. Frequency calculations show that the eclipsed forms of $CH_3NO_2^-$, $CH_2FNO_2^-$, and $CF_3NO_2^-$ correspond to first-order saddle points. Geometry optimizations at the MP2/6-31G* level were performed for both conformers of $CH_3NO_2^-$ and $CH_2FNO_2^-$ and molecular parameters of the staggered conformation are reported in parentheses in Fig. 1. An MP2/6-31G*//UHF/6-31G* energy calculation predicts that staggered $CF_3NO_2^-$ is 9.5 kJ/mol lower than the eclipsed ion. Higher barriers are calculated at the MP4/6-31G*//MP2/6-31G* level for $CH_3NO_2^-$ (16.7 kJ/mol) and $CH_2FNO_2^-$ (24.2 kJ/mol).

Comparisons of the optimized geometries for the stable conformation of each neutral and negatively charged molecule reveal substantial structural differences at all levels employed. Addition of an electron into the π-antibonding orbital weakens and lengthens the NO bond. The lengthening is in fact 0.075 Å (MP2/6-31G*) for nitromethane, 0.078 Å (MP2/6-31G*) for $CH_2FNO_2^-$, and 0.092 Å (HF/6-31G*) for $CF_3NO_2^-$. Simultaneously, the CN bond short-

ens in these radical anions. The HF/6-31G* level predicts the CN bond length to be 1.478 Å for CH_2NO_2, 1.508 Å for CF_3NO_2, and 1.489 Å for CH_2FNO_2 while 1.446, 1.430, and 1.416 Å are the predicted values for the corresponding anions. The increment in overlap population between the carbon and nitrogen atoms occurring upon electron attachment rationalizes this observation. As a consequence of the weakening of the NO bond, the ONO angle narrows in the radical anions by 4.5° in $CH_3NO_2^-$ and 3.0° in $CF_3NO_2^-$. These remarkable differences in the NO and CN bond lengths are followed by appreciable changes in the geometry of the substituent bonded to NO_2. The CH and CF bond lengths of the charged molecules are longer than in the neutral systems and the lengthening is larger for the CF (0.03 Å) than for the CH bond distances (0.01 Å).

Different conformational aspects are found for the radical anions with respect to their neutral precursors. From the previous arguments it emerges that the calculations reproduce the experimental geometries of CH_3NO_2 and CF_3NO_2 with different accuracy. However, it is known that the differences in length between similar bonds in different conformations of the same molecule are reliable (25). For instance, the variation of geometry of the neutral molecules associated with a change in conformation might reveal conformationally dependent interactions between the substituent and the NO_2 group. A previous study on nitromethane (18) showed that geometric variations from the staggered to the eclipsed conformer could be rationalized by HOMO–LUMO interactions. In particular, the occupied orbital of the methyl group is expected to interact with the unoccupied orbital on the nitrogen of the NO_2 fragment. It was suggested that CH_3 donation into the vacant nitrogen orbital in the LUMO causes a methyl group tilt with respect to NO_2. Indicating H′ as the unique hydrogen and H as one of the two equivalent hydrogen atoms, the tilt angle of CH_3 with respect to the CN bond ($\Delta\alpha$), defined as the difference between the H′CN and HCN bond angles, is negative in the staggered conformer and positive in the eclipsed structure. In addition, the CH bonds involved in the donation into the LUMO are longer than those that cannot interact. These effects of hyperconjugation, previously shown at the HF/6-31G* level (18), are confirmed at the HF/6-31G** and MP2/6-31G* levels. A similar hyperconjugative interaction also can be predicted for the trifluorine derivative. Small geometric changes of the CF_3 group are observed in the rotation about the CN bond. The HF/6-31G* value of the CF′ bond distance perpendicular to NO_2 is 0.007 Å longer than that of the two equivalent CF bonds in the staggered conformer. The CF′ bond lying in the same plane of NO_2 in the eclipsed arrangement is 0.006_5 Å shorter than the out-of-plane CF bond. Moreover, a reversed tilt of the CF_3 group with respect to the CN bond in the two conformations appears. From the value of the difference ($\Delta\beta$) between the F′CN and FCN bond angles there emerges a trifluoromethyl tilt away from the nitro group ($\Delta\beta = 2.0°$) in the eclipsed conformer while CF_3 is tilted towards the NO_2 group ($\Delta\beta = -2.2°$) in the staggered arrangement. Except for these small geometric variations of the methyl and trifluoromethyl groups, the structural parameters of CH_3NO_2 and CF_3NO_2 do not change significantly during this internal motion.

On the contrary, more appreciable variations in the geometry of each charged molecule are observed upon torsion about the CN bond. The eclipsed conformations of $CH_3NO_2^-$, $CF_3NO_2^-$, and $CH_2FNO_2^-$ have a nearly planar configuration at nitrogen. UHF/6-31G* frequency calculations indicate that these structures are transition states with imaginary vibrational frequencies of 339i ($CH_3NO_2^-$), 216i ($CF_3NO_2^-$), and 381i ($CH_2FNO_2^-$) cm^{-1}. An analysis of the components of the eigenvector reveals that the rotation of the R group relative to NO_2 is accompanied by a simultaneous departure from planarity of the nitrogen. As evidence of this tendency, the minimum structure is calculated to be pyramidal at nitrogen and to prefer a conformation in which the NO bonds are placed on the same side of the orthogonal CH and CF bonds, as shown in Fig. 1.

Based on these results, the $-CNO_2$ group is markedly nonplanar in the staggered form of the radical anions and the dihedral angle between the CN bond and the NO_2 plane is 148.5° for $CH_3NO_2^-$, 147.8° for $CF_3NO_2^-$, and 161.6° for $CH_2FNO_2^-$ (UHF/6-31+G*). The tendency towards nonplanarity at nitrogen is also confirmed from the MP2 optimized structures of $CH_3NO_2^-$ and $CH_2FNO_2^-$ with dihedral angles equal to 139.1° and 154.9°, respectively. Additional information on the nonplanar character of the $-CNO_2$ moiety was obtained by forcing the radical anions into an artificially constrained geometry. UHF/6-31G* geometry optimizations were performed on $CH_3NO_2^-$ and $CF_3NO_2^-$ assuming the $-CNO_2$ group to be planar. Such calculations show that both these structures are about 9 kJ/mol above the respective stable isomer. The optimized molecular parameters are comparable with those calculated for the $-CNO_2$ nonplanar isomer with the exception of the CN bond lengths, which are close to the optimized values for the eclipsed conformer at the same computational level (1.437 Å for $CH_3NO_2^-$ and 1.417 Å for $CF_3NO_2^-$). Furthermore, inversion at nitrogen in the staggered $CH_3NO_2^-$ was studied at the UHF/6-31G* level. This stationary point was characterized as a second-order saddle point through its vibrational frequencies. The imaginary frequencies, 196i cm^{-1} and 188i cm^{-1}, can be assigned to the inversion motion of the NO_2 group through a plane containing the CN bond and to the rotation of CH_3 relative to the NO_2 framework. These observations suggest that the rotation about the CN bond is associated with the simultaneous flattening of nitrogen and this internal motion can be regarded as a rotation–inversion process.

Pyramidal nitrogen also is predicted for the simple radical species HNO_2^-. A nonplanar C_s structure and a C_{2v} planar arrangement were studied at different levels of theory. The optimized geometries of the two conformations are reported in Table 3. The C_{2v} structure lies about 11.1 kJ/mol (MP4/6-31G*//MP2/6-31G*) above the C_s structure. Frequency calculations indicate that the C_s structure is a minimum on the UHF/6-31G* and MP2/6-31G* potential energy surfaces while the C_{2v} isomer corresponds to a transition state connecting two equivalent C_s structures with pyramidal nitrogen. From the comparison between the energies of occupied molecular orbitals it emerges that the stabilization of the nonplanar form is substantially the result of the lowering of the SOMO energy on moving from a C_{2v} to a C_s structure. Additional *s*-character of nitrogen in the SOMO is observed in the C_s conformation with respect to the pure π character of this orbital in the planar molecule. As a consequence, increments of 1.9° (UHF/6-31+G**) and 3.3° (MP2/6-31+G**) are calculated for the ONO bond angle in going from the C_s to planar C_{2v} symmetry structure.

HNO_2^- provides further evidence that R-NO_2^- is appreciably nonplanar at nitrogen if the R substituent is a weak π-electron donor.

An examination of the optimized geometries of the radical anions reveals that conformational changes cause appreciable variations in other geometrical parameters. As observed for the neutral molecules, the orthogonal CH and CF bond lengths of each staggered conformer are calculated to be 0.007 Å longer than the other two equivalent distances, also for the radical anions. Likewise, in the eclipsed conformation, the CH and CF bonds lying in the NO_2 plane are shorter than the nonplanar CH and CF bonds by 0.008 Å (CH) and by 0.014 Å (CF). Moreover, the changes are greater than those predicted for the neutral molecules. The structural features calculated for the radical anions containing the nitro group are similar to those obtained in a series of theoretical studies on $CH_3CH_2^-$, $CF_3CH_2^-$, and $CH_2FCH_2^-$ carbanions (26). These substituted ethyl anions provided the prototype systems for the theoretical investigation of the negative hyperconjugation. On the basis of computational results on $CH_2NO_2^-$, $CF_3NO_2^-$, and $CH_2FNO_2^-$ that predict appreciable electron density on the whole NO_2 fragment, it seems reasonable to attribute the conformational preference, as well as the lengthening of the CH and CF orthogonal distances, to negative hyperconjugation. In fact, a weak and stabilizing interaction between the π* SOMO on nitrogen and the orbitals of the CH_3, CF_3, and CH_2F groups might rationalize the small energetic preference for the staggered conformers of all radical anions studied. To investigate hyperconjugation, the CH_2F group represents a model system both for the neutral molecule and the radical anion. The CF bond of $CH_2FNO_2^-$ oriented for hyperconjugative interaction is calculated to be 0.024 Å (HF/6-31+G*) and 0.036 Å (MP2/6-31G*) longer than the eclipsed CF one. A less marked lengthening of the CF bond distance (0.010 Å) is observed at the HF/6-31G* and MP2/6-31G* levels on moving from the eclipsed to staggered conformation of the neutral molecule. Likewise, the MP2/6-31G* shortening of the CN bond length associated with the rotation of CH_2F from the eclipsed to the staggered conformer of $CH_2FNO_2^-$ (0.024 Å) and CH_2FNO_2 (0.010 Å) is in accord with computational results on $CH_2FCH_2^-$ (26). Moreover, the UHF/6-31+G* spin population shows a small increase of fluorine spin density on moving from the eclipsed to the orthogonal conformer. Thus CH_2F in the staggered orientation acts as a weak π-electron acceptor and the decrease in the pyramidalization angle with respect to $CH_3NO_2^-$ and $CF_3NO_2^-$ can be thought of as a structural consequence of hyperconjugation.

The influence of different substituents on the geometry and stability of the anions is indicated, for example, by the values of some molecular parameters. The HOMO/LUMO energy difference, calculated at the HF/6-31G* level, decreases on going from CH_3NO_2 (15.48 eV) to CF_3NO_2 (15.35 eV). Based on these values, the replacement of CH_3 with an electron-withdrawing group tends to lower the LUMO energy with a subsequent stabilization of the radical anion. Thus a small increase of electron affinity is expected going from nitromethane to trifluoronitromethane. Unfortunately, experimental values of electron affinity are available only for CH_3NO_2 from electron-transfer equilibria measurement (0.48 eV) (7) and from the electron-capture detector (0.45 ± 0.09 eV) (27). On the other hand, calculations of accurate electron affinities have proved to be a very delicate problem (9). Very recently, a general computational procedure to give accurate total energies was developed (28), but its application to moderately large molecules is a prohibitive task. The electron affinity of CH_3NO_2 was estimated by single point Møller–Plesset calculations up to

the fourth order employing the 6-31+G* basis set and including the zero-point contribution, but it was found that $CH_3NO_2^-$ lies energetically below the parent neutral molecule only at the UHF and MP3 levels. To observe a qualitative trend, electron affinities of CH_3NO_2, CH_2FNO_2, and CF_3NO_2 were calculated as the difference between the UHF/6-31+G*//UHF/6-31G* total energy of the radical anion and that of the neutral molecule including the zero-point contribution. These calculations indicate that the stability of the radical anion with respect to the neutral precursor increases in the series CH_3NO_2 (0.01 eV), CH_2FNO_2 (0.5 eV), and CF_3NO_2 (1.3 eV). Based on these qualitative results, the CH_2F and CF_3 groups should stabilize an adjacent NO_2^-, partly delocalizing the unpaired electron from the NO_2 framework. In both cases there is a hyperconjugative component to the stabilization. The smaller hyperconjugative effect of the CF_3 substituent is fully compensated for by a larger inductive effect. Such a stabilizing interaction should be more noticeable with strong π-electron acceptor substituents. As expected, their ability to accept *p*-electrons allows the unpaired electron of the anion to delocalize partially onto the R group, lowering the LUMO energy and changing the NO_2 geometry with respect to that of the unconjugated radical anions. To investigate in detail the effects of these substituents on the properties of the NO_2 group, theoretical calculations were carried out on some systems R-NO_2/R-NO_2^-. The nitroborane $BH_2NO_2/BH_2NO_2^-$ pair was chosen as a simple example where the BH_2 substituent has a very strong tendency to accept π-type electrons as a result of its low-lying empty orbital. The substitution of hydrogen with σ-inductive electron acceptor atoms such as fluorine should further stabilize the anion with respect to the neutral molecule, as predicted for the fluorine derivatives of nitromethane. On the other hand, the π-electron donor property of the fluorine atom should decrease the tendency to delocalize the unpaired electron from NO_2 to the boron atom. Therefore, substituents such as BH_2, BHF, and BF_2 show decreasing π-electron acceptor properties.

BH_2NO_2, $BHFNO_2$, and BF_2NO_2 and their respective radical anions were optimized at the HF and UHF levels employing the 6-31G* and the 6-31+G* basis sets. The optimized geometries of the stable conformations of each molecule are reproduced in Fig. 2. Electron correlation effects on the geometry were estimated at the MP2/6-31G* level. The neutral compounds were studied assuming a planar structure and an orthogonal arrangement with BH_2, BF_2, and BHF groups perpendicular to NO_2. Both the conformers are stationary points and all levels of calculation indicate the orthogonal structure (Fig. 2) as the most stable isomer. Vibrational frequencies were calculated at the HF/6-31G* level and show that this conformer is a minimum on the potential energy surface, while the planar one is a first-order saddle point. It corresponds to the rotational transition state connecting two equivalent orthogonal conformations. Small energy barriers separate the planar and orthogonal structures: the MP4/6-31G* values of the torsional barrier are 26.8 kJ/mol (BH_2NO_2), 8.8 kJ/mol ($BHFNO_2$), and 6.0 kJ/mol (BF_2NO_2). The geometry of the radical anions was optimized at the UHF and MP2 levels assuming a planar structure (Fig. 2). The predicted geometry changes upon electron attachment are consistent with those calculated for CH_3NO_2, CH_2FNO_2, and CF_3NO_2. The NO bond lengths are significantly increased while the ONO bond angles decrease and the BN bond lengths shorten. The NO_2 group was allowed to become nonplanar, but a preference for the planar arrangement was found. The positive values of the vibrational frequencies reveal that the planar isomers are minima and, in addition, the values of the A_2 torsional frequency indicate a greater rigidity of these systems with respect to the neutral precursors. The torsional barriers were investigated by geometry optimizations of structures with BH_2, BF_2, and BHF groups perpendicular to the NO_2 fragment, including the possibility of deviations from planarity at nitrogen within the C_s symmetry constraint.

According to frequency calculations, these stationary points were characterized as second-order saddle points. With regard to $BHFNO_2^-$, the asymmetry of the BHF group permits two C_s orthogonal conformations. The structure in which the NO bonds are placed on the side of hydrogen is found to be 4.0 kJ/mol (UHF/6-31G*) lower than the isomer with the opposite configuration at nitrogen. As a general trend, the UHF/6-31G* energy difference between the C_{2v} planar conformer and the C_s nonplanar structure is higher than the small rotational barriers of the neutral molecule; it decreases from BH_2NO_2 (92.5 kJ/mol), to $BHFNO_2$ (56.7 kJ/mol) and BF_2NO_2 (40.9 kJ/mol). The inclusion of electron correlation at the MP4/6-31G* level provides a similar order of stability: 118.6 kJ/mol for BH_2NO_2, 67.8 kJ/mol for $BHFNO_2$, and 50.4 kJ/mol for BF_2NO_2. By imposing the constraint of planarity of the -BNO_2 moiety in the orthogonal conformer of $BH_2NO_2^-$ and $BF_2NO_2^-$, another C_{2v} critical point was obtained; it was characterized by vibrational analysis as a third-order saddle point. The geometries of both the C_s and C_{2v} orthogonal conformers differ by a few thousandths of an Å and the UHF/6-31G* stability difference between them is about 2.0 kJ/mol for $BH_2NO_2^-$ and 0.5 kJ/mol for $BF_2NO_2^-$. These values are sufficiently small to allow free inversion of nitrogen when it is not involved in π-interaction with boron.

The electronic state of the planar structures of $BH_2NO_2^-$ and $BF_2NO_2^-$ is $^2B_1$ and that of $BHFNO_2^-$ is $^2A''$. An analysis of atomic spin density population predicts decreasing values on boron moving from $BH_2NO_2^-$ to $BF_2NO_2^-$ and, simultaneously, spin density increases on the nitrogen atom. On the contrary, negligible values on boron are calculated for the C_s orthogonal structures that show the nitrogen spin density as constant for all the substituents. Mulliken population analysis indicates that the negative charge on the oxygen atoms is nearly independent of the nature and orientation of the substituent while the distribution of atomic charge in the remaining portion of the molecule is strongly altered with the rotation of the NO_2 group. An appreciable charge transfer from boron to nitrogen is observed on moving from planar to orthogonal anions. Looking at the energy and population data, the torsional barrier is sensitive to the amount of π-delocalization of the unpaired electron from nitrogen to boron. Such a π-interaction is improved by the flattening of the NO_2 pyramid, which should increase the *p*-character of the SOMO, making nitrogen a better donor and allowing more complete spin delocalization onto the boron atom.

The calculation of HOMO/LUMO energy differences predicts noticeably smaller values than those reported for nitromethane and its fluorine derivatives. Moreover, an increase in the HF/6-31G* value is observed on moving from BH_2NO_2 (12.50 eV) to $BHFNO_2$ (13.34 eV) and to BF_2NO_2 (13.90 eV). These progressively increasing values are in

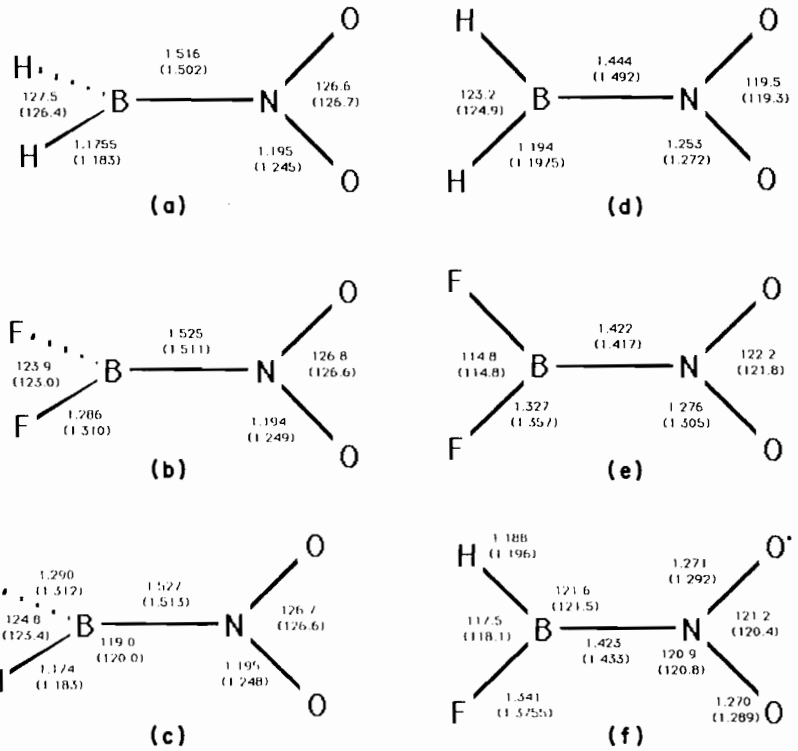

FIG. 2. HF/6-31G* geometries of orthogonal BH_2NO_2 (a), BF_2NO_2 (b), and $BHFNO_2$ (c) and UHF/6-31+G* geometries of planar $BH_2NO_2^-$ (d), $BF_2NO_2^-$ (e), and $BHFNO_2^-$ (f). The MP2/6-31G* parameters are in parentheses (bond lengths in Å and bond angles in deg).

reasonable agreement with the different π-electron acceptor properties of each R group. A higher HOMO/LUMO energy difference is calculated for the orthogonal structure of BH_2NO_2 (14.04 eV), $BHFNO_2$ (15.23 eV), and BF_2NO_2 (15.30 eV) where the π-stabilizing interaction is prevented. Such computational results suggest that the radical anions of nitro compounds with π-electron acceptor groups are appreciably stabilized in that the LUMO energy can be lowered by extension of the π conjugation. As a consequence of the electron-delocalizing property of the substituent, an appreciable lengthening of the NO bond is calculated upon torsion of the NO_2 group. The predicted value of the NO distance is about 1.290 Å for each orthogonal conformer while the UHF/6-31+G* value for the planar arrangement is significantly shorter for each radical anion (see Fig. 2), and this is consistent with the fact that the electron density in the π* orbital of the nitro group is increased when NO_2 is forced out-of-plane.

To extend the study of the structural consequences of electron attachment to molecules containing π-systems, the radical anion $C_6H_5NO_2^-$ was investigated. The molecular structure of nitrobenzene was determined by gas-phase electron diffraction and studied by *ab initio* calculation at the HF/6-31G* level (29). The internal rotation of the nitro group was investigated by including electron correlation effects at the MP2/6-311G**//MP2/6-31G* level (30). The low rotational barrier, 19.04 kJ/mol (30), and the small variations of bond lengths and angles calculated rotating NO_2 from the planar to the orthogonal conformation (29) indicate only a small degree of conjugation between the ring and the nitro group. Similarly, the distribution of net atomic charge remains essentially unaltered by changing conformation. The extent of π-electron transfer from the benzene ring to the nitro group can be investigated by a vibrational frequency study, bearing in mind that the addition of polarization functions is necessary to obtain a reliable description of nitrogen structural features (31). The planar structure was calculated to be at the minimum on the HF/6-31G* potential surface with NO stretchings equal to 1868 cm^{-1} (B_2) and 1640 cm^{-1} (A_1). However, the value of the A_2 torsional frequency about the CN bond (56 cm^{-1}) reveals an easy twist of the NO_2 group with respect to the benzene ring and this is consistent with the small torsional barrier determined for nitrobenzene (30). The previous *ab initio* calculations on the planar structure were repeated by employing a slightly more extended basis set (DZP) (12) or by adding polarization functions also to the hydrogen atoms (6-31G**). The optimized geometry at this latter level shows negligible variations with respect to those reported previously while the dependence of the geometry on the basis set is more appreciable at the DZP level. In particular, a systematic lengthening of NO and CC bond distances by about 0.004 Å is observed. The CN bond length is calculated equal to 1.465 Å while a smaller value (1.458 Å) is calculated at the 6-31G* level (29).

Except for these changes, the basis sets employed describe consistently the effect of the substituent on the ring geometry, predicting differences between CC bond distances and values of internal angles independent of the choice of the basis set. On the grounds of these results, employing only one basis set, 6-31G*, with addition of diffuse functions, 6-31+G*, is a reasonable compromise in investigating the radical anion of nitrobenzene. The planar structure was studied at the UHF level and the 6-31G* and 6-31+G* optimized geometries are reported in Fig. 3. The b_1 π* or-

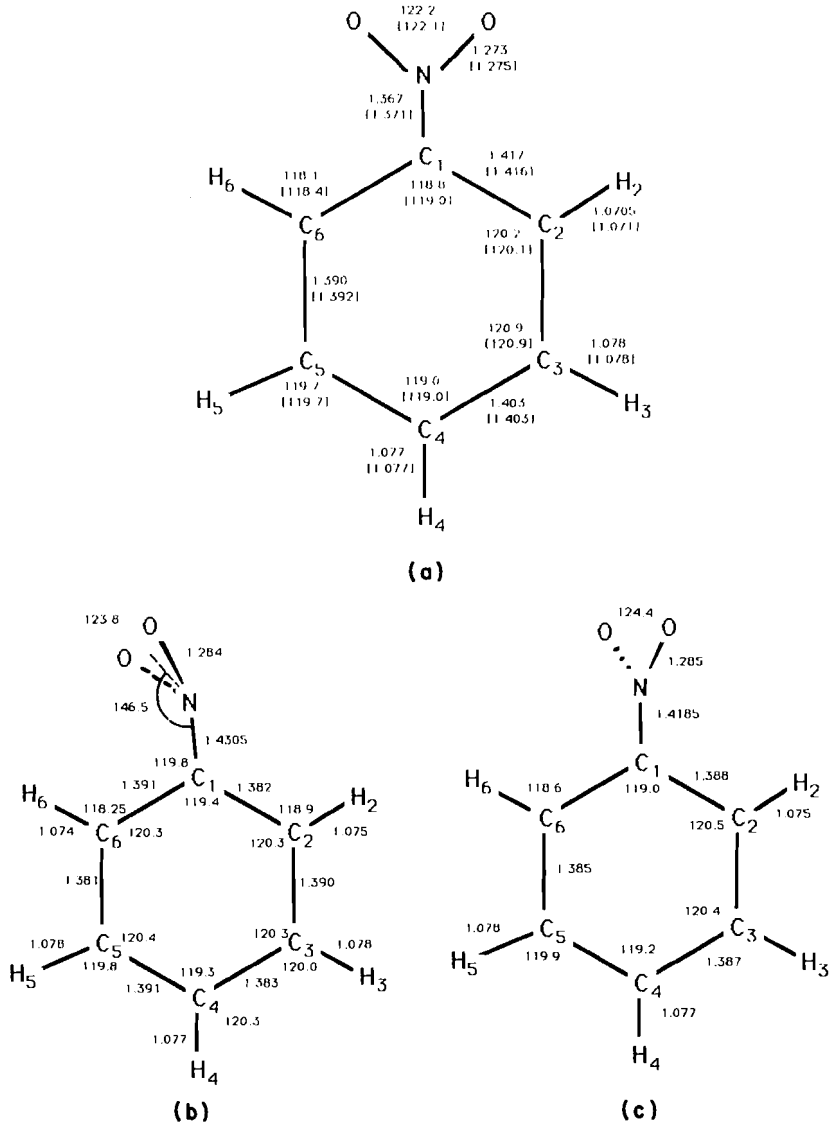

FIG. 3. UHF/6-31G* geometries of the C_{2v} planar (a), C_s (b), and C_{2v} orthogonal (c) structures of $C_6H_5NO_2^-$. The UHF/6-31+G* geometry is in square parentheses (bond lengths in Å and bond angles in deg).

bital is the singly occupied molecular orbital and the electronic state of the radical anion is $^2B_1$, but this conformer suffers spin contamination from higher energy quartet states ($\langle S^2 \rangle = 0.99$) and this is a frequent problem with UHF wave functions when low-lying states of higher spin multiplicity exist (32). However, the quartet state $^4B_1$ is estimated to be about 3.7 eV above the $^2B_1$ ground state by UHF/6-31G* single point calculation at the geometry of the doublet state. In addition, an analysis of atomic spin density for the $^2B_1$ state predicts a spin population on nitrogen and on the C_2, C_4, and C_6 atoms (Fig. 3) in agreement with the electron spin resonance results (33). Additional geometry optimizations carried out in the ROHF formalism provide an unreliable spin density population on the whole molecule, predicting a high value on nitrogen, but a negligible spin density on the benzene ring. Based on these considerations and notwithstanding the high spin contamination emerging from the UHF results, the optimized geometry at this computational level can be discussed.

The geometry of the NO_2 group of $C_6H_5NO_2^-$ reveals a remarkable increase in the value of the NO bond length (0.080 Å) and decrease in the ONO bond angle (2.5°) with respect to the calculated values for the neutral precursor (29). A more marked change is calculated for the CN bond length, which is 0.091 Å shorter in the molecular anion. With regard to the ring geometry, a general lengthening of the CC bond lengths is predicted but the amount is more relevant for the C_1C_2 (0.034Å) and C_3C_4 (0.016 Å) bonds than for the C_2C_3 (0.007 Å) bond. While the differences in the theoretical lengths of the ring CC bonds of the neutral molecule are equal to a few thousands of an angstrom, a noticeable alternation of long/short/long nonequivalent distances is predicted for the radical anion. By employing the 6-31+G* basis set, the C_1C_2 bond length is calculated to be 0.024 Å longer than the C_2C_3 distance while the latter is 0.011 Å shorter than C_3C_4. Concerning the bond angles of the ring, electron charging of nitrobenzene causes decreases of the $C_6C_1C_2$ (3.5°) and $C_3C_4C_5$ (1.4°) bond angles. The remaining ring angles, $C_1C_2C_3$ and $C_2C_3C_4$, increase by about 1.7° and 0.8°, respectively.

Such a comparison shows that the addition of an electron into the b_1 π^* molecular orbital of nitrobenzene simultaneously gives rise both to the expected geometry variations of the nitro group and to marked changes in the ring geometry. According to the Jahn–Teller theorem, the addition of an extra electron to benzene lowers the D_{6h} symmetry of the neutral molecule to D_{2h}. In fact, the $^2E_{2u}$ electronic state is split into ^2A_u and $^2B_{3u}$ components. The molecular geometries of each state were previously calculated at the UHF/STO-3G level (34). Both structures show comparable stability but their optimized geometries are very different. In addition, previous STO-3G calculations performed for a set of singly substituted benzene radical anions (35) reveal that the ^2A state is favoured by π-electron donor substituents while the ^2B state is preferred by π-electron acceptor groups. The expansion of π conjugation or the introduction of electron-withdrawing substituents stabilizes the radical anion, extending the π^*-type SOMO electron density over the aromatic ring and over the substituent. Based upon these arguments, the calculated differences for the ring geometry in going from neutral nitrobenzene to the radical anion should be strongly affected by the degree of conjugation between the aromatic ring and the substituent. In particular, indications of interactions between the nitro group and the ring in the radical anion are suggested by changes in the ring geometry calculated on going from the $C_6H_6^-$ to $C_6H_5NO_2^-$. Geometry optimizations have been carried out on the radical anion of benzene at the same level of theory employed for the nitro-substituted derivative. The ^2A_u and $^2B_{3u}$ electronic states were studied at the UHF level employing the 6-31G* basis set and each electronic state is predicted to have the optimized geometry reported in Fig. 4. The ring bonds and angles of the radical anion of nitrobenzene are close to those calculated for the $^2B_{3u}$ structure of $C_6H_6^-$. However, the shortening of the C_1C_2 and C_3C_4 distances and the increase of the C_2C_3 bond length observed in $C_6H_5NO_2^-$ suggest that the unpaired electron is partly shared between the ring and the substituent. Further evidence of this sharing is given by the values of the ring angles ranging between those of neutral $C_6H_5NO_2$ and those calculated for the $^2B_{3u}$ state of $C_6H_6^-$.

The degree of conjugation between the substituent and the aromatic ring can be alternatively investigated by rotating the nitro group out of the plane of the ring and observing the change in the molecular geometry. By forcing the NO_2 group into an orthogonal conformation, two stationary points are found at the UHF/6-31G* level, as shown in Fig. 3, and the relative $\langle S^2 \rangle$ values are 0.75. The C_s structure with pyramidal nitrogen ($^2A'$) is calculated to be more stable than the C_{2v} orthogonal isomer ($^2B_2$) by about 6.6 kJ/mol. The degree of nonplanarity at nitrogen is indicated by the value of the dihedral angle between the ONO plane and the CN bond (146.5°). In addition, a tilt of the CN bond away from the C_1C_4 axis is predicted for the C_s structure and the difference between the NC_1C_2 and NC_1C_6 angles is 1°. An electron spin resonance study of di-*ortho*-alkylnitrobenzene radical anions (36), in which the NO_2 group is forced out of the aromatic ring, shows a reduction in the spin delocalization from the nitro group into the ring, and a pyramidal nitrogen was proposed as the possible conformation of the NO_2 group. As a matter of fact, the differences in total atomic charges in going from the planar to the orthogonal structures reveal that the NO_2 group gains electronic charge, 0.026 on each oxygen and 0.041 on nitrogen. The largest variation in the ring atomic charge occurs for the C_1 atom, which loses 0.100, while the remaining carbon atoms undergo smaller changes. Simultaneously the atomic spin density on carbon ring atoms decreases down to negligible values in the orthogonal structures.

The reduction of spin density on the ring is reflected significantly in the values of certain parameters. The largest change in the geometry of the anion on going from planar to orthogonal arrangements occurs in the CN bond length, which increases by 0.052 Å in the C_{2v} structure and by 0.064 Å in the C_s conformer. This variation is accompanied by the simultaneous lengthening of the NO bond (0.012 Å) and increase in the ONO angle by 2.2° (C_{2v}) and 1.6° (C_s). The calculated value of the NO bond length (1.285 Å) is close to the value for NO_2 bonded to groups having weak π-electron-donating properties, such as CH_3 (1.286 Å). The considerable short/long/short alternation of the values of the CC ring distances calculated for the planar structure becomes less marked in the orthogonal structures. In particular, the C_{2v} isomer shows C_1C_2, C_2C_3, and C_3C_4 bond lengths equal to 1.388, 1.385, and 1.387 Å, respectively, indicating that the ring geometry is similar to that of the neutral molecule.

[a]The description of the modes is approximate.

Vibrational frequencies

The calculated vibrational frequencies of neutral and negatively charged species are reported in Tables 4 and 5. The comparison between assigned vibrational modes reveals variations that reflect the structural reorganization occurring upon electron attachment. The IR spectrum of the anion NO_2^- produced in low temperature matrix by electron transfer processes (37), shows that the ν_3 stretching mode (1240 cm^{-1}) is appreciably shifted with respect to the frequency of the neutral NO_2 (1617 cm^{-1}) (38). Likewise, the NO_2^- vibrational data gathered from condensed phase studies of nitrite ions (39, 40) (ν_1 = 1332, ν_2 = 821, and ν_3 = 1240 cm^{-1}) are different from the NO_2 vibrational modes (ν_1 = 1320, ν_2 = 750, and ν_3 = 1617 cm^{-1}) (38). A lowering of the NO stretchings as a consequence of the weakening of the NO bond upon electron charging is therefore expected. The values of the NO stretchings for CH_3NO_2 (A'' 1880 cm^{-1} and A' 1688 cm^{-1}) decrease to 1440 cm^{-1} (A'') and 1428 cm^{-1} (A') for $CH_3NO_2^-$; similar decreases are observed passing from CF_3NO_2 (A' 1927 and A' 1639 cm^{-1}) to $CF_3NO_2^-$ (A' 1533 and A'' 1372 cm^{-1}) and from CH_2FNO_2 (A' 1908 and A' 1687 cm^{-1}) to $CH_2FNO_2^-$ (A'' 1505 and A' 1491 cm^{-1}). Comparable lowerings of the NO stretching frequencies are predicted in the anions with NO_2 bonded to boron. The fundamental modes B_1 and A_1 of the orthogonal minimum structure of BH_2NO_2 are calculated to occur at 1818 and 1721 cm^{-1} and those of BF_2NO_2 are at 1833 and 1746 cm^{-1}. The planar structure of the respective radical anions shows the NO stretching modes equal to 1467 and 1366 cm^{-1} in $BH_2NO_2^-$ and 1686 and 1310 cm^{-1} in $BF_2NO_2^-$.

The change in conformation of the neutral molecules does not cause appreciable variations in the vibrational frequencies of the NO_2 group. On the contrary, small variations (ca. 50 cm^{-1}) of the NO stretching modes are calculated upon torsion about the CN bond for the radical anions: the eclipsed conformations have NO stretchings equal to 1478 and 1440 cm^{-1} ($CH_3NO_2^-$), 1577 and 1419 cm^{-1} ($CF_3NO_2^-$). Small changes are also calculated for $BH_2NO_2^-$ and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

$BF_2NO_2^-$: the NO stretching frequencies of the C_s conformations are at 1536 (A') and 1308 (A'') cm^{-1} for $BH_2NO_2^-$ and at 1634 (A') and 1283 (A'') cm^{-1} for $BF_2NO_2^-$.

The minor geometry variations of the groups bonded to NO_2 calculated upon electron adding are reflected in small changes in the vibrational modes of these groups. In particular, the CF, CH, BH, and BF stretching modes for the radical anions are calculated as lowered by about 100 cm^{-1}, with the exception of the CF stretching of CH_2FNO_2, which moves from 1307 cm^{-1} for the neutral molecule to 1091 cm^{-1} for the radical anion. The shortening of the CN and BN bonds occurring by addition of an extra electron is not followed by displacements of the relative stretching modes, which show small lowerings.

As far as the torsional frequency about the CN and BN bonds is concerned, the highest value is calculated for $BH_2NO_2^-$ (394 cm^{-1}), and this is consistent with the high torsional barrier predicted for this anion. A general increase of rigidity of the NO_2 group upon electron attachment is suggested by the values of the NO_2 wagging and rocking modes, which increase for the boron-containing species. This is consistent with the results obtained from measurements of electron-attachment equilibria for the nitrobenzene radical anion and substituted derivatives (7, 8), which predict a stiffening of the NO_2 internal rotation on moving from neutral molecules to radical anions.

Conclusions

The equilibrium geometries and the vibrational frequencies of some radical anions and of the parent neutral molecules containing the nitro group have been studied by *ab initio* molecular orbital calculations at the SCF and MP2 levels. As a general trend, the $-CNO_2$ moiety is characterized by an appreciable structural reorganization upon electron attachment as a consequence of the π^* character of the SOMO. This work shows that both at the SCF and MP2 levels, the $-CNO_2$ framework undergoes major geometry variations in the NO bond, ONO bond angle, and in the CN bond. In fact, the NO and CN bond distances of the radical anions are found to lengthen and shorten, respectively, and the ONO bond angles to decrease. The conjugation between the nitro group and the substituent bonded to NO_2 can delocalize the unpaired electron from the NO_2 onto the remaining atoms of the molecules, influencing thus the structure and the geometry of the NO_2 group. The nonplanar character at nitrogen has been determined for the following substituents: H, CH_3, CH_2F, and CF_3. Planar structures at nitrogen have been predicted for radical anions with strong *p*-electron acceptors such as BH_2, BHF, and BF_2. Nonplanar geometries at nitrogen have been found for the latter substituents oriented perpendicularly with respect to the NO_2 plane. The orthogonal orientation prevents π interactions between the nitrogen and boron atoms of $BH_2NO_2^-$, $BHFNO_2^-$, and $BF_2NO_2^-$, increasing the electron density in the π^* orbital of the NO_2 fragment. The results accomplished from the UHF geometry optimizations of $C_6H_5NO_2^-$ are consistent with those predicted for the boron-containing radical anions.

Barriers to internal rotation of the NO_2 group have been calculated at various levels including Møller–Plesset perturbation theory up to the fourth order, and the barrier heights are consistent with the degree of π conjugation between the NO_2 and the substituent. The rotation about the CN bond is almost free, both for the neutral molecules and for the radical anions of the series CH_3NO_2 and CF_3NO_2; on the contrary, high torsional barriers about the BN bond are calculated for $BH_2NO_2^-$, $BHFNO_2^-$, and $BF_2NO_2^-$ radical anions, and the values of the related torsional frequencies reflect this trend.

Electron thermalization distance distributions and thermal electron mobilities in dense liquid isobutane

TAKEHISA YOSHINARI,[1] NORMAN GEE, AND GORDON R. FREEMAN[2]

Chemistry Department and Radiation Research Centre, University of Alberta, Edmonton, Alta., Canada T6G 2G2

Received May 16, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

TAKEHISA YOSHINARI, NORMAN GEE, and GORDON R. FREEMAN. Can. J. Chem. **70**, 327 (1992).

Free ion yields G_{fi}^{E} were measured at electric field strengths E up to 6.7 MV m^{-1} in liquid isobutane at $556 \leq d$/kg m$^{-3} \leq 739$ (294.4–114.6 K). The yields decreased with decreasing temperature and increasing density up to 677 kg m^{-3}; further increases in density led to little change in G_{fi}^{E}. The thermalization distance distribution $F(y)$ was estimated by fitting the field dependence of G_{fi}^{E} using the extended Onsager model. At lower densities $F(y)$ = YGP (three-dimensional Gaussian body with power tail) provided an adequate fit to the results, while at higher densities $F(y)$ = YE (one-dimensional exponential distribution) was better. Thus the electron-scattering properties of liquid isobutane change somewhat with density. The thermalizing ability of liquid isobutane increased with increasing density up to ~660 kg m^{-3}, then decreased at densities >690 kg m^{-3}. By comparison, the Arrhenius temperature coefficient of mobility of thermal electrons changed in the same density region: $E_{\mu} \approx 7$ kJ mol^{-1} at $d < 660$ kg m^{-3}, and ≈16 kJ mol^{-1} at $d > 690$ kg m^{-3}.

Key words: isobutane, electron thermalization distance, free ion yield, liquid, electron mobility, radiolysis.

TAKEHISA YOSHINARI, NORMAN GEE et GORDON R. FREEMAN. Can. J. Chem. **70**, 327 (1992).

Opérant dans de l'isobutane liquide à $556 \leq d$/kg m$^{-3} \leq 739$ (de 294.4 K à 114.6 K), on a mesuré les rendements en ions libres G_{fi}^{E} à des forces de champ électrique E allant jusqu'à 6.7 MV m^{-1}. Les rendements diminuent lorsque la température diminue et lorsque la densité augmente jusqu'à 677 kg m^{-3}; une augmentation plus poussée de la densité affecte très légèrement la valeur du G_{fi}^{E}. On a évalué la distribution de la distance de thermalisation $F(y)$ en ajustant l'influence du champ sur la valeur du G_{fi}^{E} en faisant appel au modèle étendu de Onsager. Pour des densités plus faibles, l'équation $F(y)$ = YGP (corps gaussien tridimensionnel et queue avec des puissances) permet d'obtenir une concordance adéquate avec les résultats; par ailleurs, pour des densités plus élevées, l'équation $F(y)$ = YE (distribution exponentielle unidimensionnelle) est meilleure. Les propriétés de dispersion des électrons par l'isobutane liquide varient donc un peu avec la densité. Lorsque la densité augmente jusqu'à environ 660 kg m^{-3}, la capacité de thermalisation de l'isobutane liquide augmente d'une façon parallèle; à des densités >690 kg m^{-3}, cette capacité commence à diminuer. Par comparaison, le coefficient de température d'Arrhénius pour la mobilité des électrons thermiques change aussi dans cette même région de densité : $E_{\mu} \approx 7$ kJ mol^{-1} à $d < 660$ kg m^{-3}, et $E_{\mu} \approx 16$ kJ mol^{-1} à $d > 690$ kg/m^{3}.

Mots clés : isobutane, distance de thermalisation de l'électron, rendement en ion libre, liquide, électron mobilité, radiolyse.

[Traduit par la rédaction]

Introduction

When ionizing radiation interacts with a fluid, electrons are ejected from molecules to form ion–electron pairs (1*b*). The ejected electron possesses excess kinetic energy, which it loses by inelastic collisions with molecules as it moves away from its sibling cation. The electron reaches thermal energy at some distance y, which is usually sufficiently small that there is Coulombic attraction between the sibling electron–ion pair that is significant in comparison with the random thermal energy k_BT. The creation of the electron ion pair is represented as

$$[1] \qquad M \rightsquigarrow [M^+ + e^-]$$

where the square brackets around the charged entities represent the significant electrostatic attraction between them. A competition (2) then takes place between recombination of the electron and ion (geminate neutralization),

$$[2] \qquad [M^+ + e^-] \rightarrow M$$

and diffusion apart of the ion and electron until their mutual Coulombic attraction becomes negligible compared to k_BT (free ion formation),

$$[3] \qquad [M^+ + e^-] \rightarrow M^+ + e^-$$

The free ions ultimately encounter other free ions at random and can neutralize each other (random neutralization),

$$[4] \qquad M^+ + e^- \rightarrow M$$

or they can be attracted to electrodes by a sufficiently large applied electric field E, collected, and measured,

$$[5] \qquad \begin{cases} e^- & \xrightarrow{E} \text{ anode} \\ M^+ & \xrightarrow{E} \text{ cathode} \end{cases}$$

The number of free ion pairs formed per 100 eV (16 aJ) of energy absorbed by the fluid, denoted G_{fi}^{E}, is determined by the magnitudes of the thermalization distance y, the dielectric relative permittivity ε of the fluid, the temperature T, and E.

The rate at which G_{fi}^{E} increases with E is strongly affected by the shape of the thermalization distance distribution function $F(y)$ (1*c*). In turn the shape of $F(y)$ and the mean value of y reflect the strength of the electron–molecule interactions in the liquid, mainly for electrons of energies be-

tween about 1 eV (~200 zJ) and 1.5 k_BT (~5 zJ); z = zepto = 10^{-21}.[3]

For most liquids, as the temperature is decreased G_{fi}^E decreases (3, 4). The $F(y)$ distribution function that fits the (E, G_{fi}^E) data in the widest range of systems (1*d*) has a Gaussian body and a power tail, and is designated YGP (1*c*, 4). The Gaussian shape is attributed to randomness of the scattering (1*a*). The yields in liquid carbon disulfide behaved differently (5); as the temperature was decreased from 460 to 168 K (and density increased concomitantly from 1000 to 1444 kg m^{-3}) G_{fi}^E *increased*. Furthermore, the (E, G_{fi}^E) data could not be fitted by $F(y)$ = YGP. A distribution with an exponential body and a power tail, designated YEP, provided a better fit but was also inadequate at the lowest temperatures (densities >1350 kg m^{-3}). At these highest densities a simple power function designated YP (1*c*) gave satisfactory fits (5). These distribution functions indicate a lack of randomness in the scattering.

The behavior in dense liquid CS_2 brought to mind earlier studies of G_{fi}^E in isobutane (2-methylbutane) (6, 7). As the liquid was cooled from 296 to 169 K, with concomitant increase of density from 553 to 688 kg m^3, G_{fi}^E decreased and the variation of G_{fi}^E with E could be fitted by using YGP. However, on further cooling to 148 K (709 kg m^{-3}) the yields stayed about constant and their field dependence was consistent with YP (6).

In the present work G_{fi}^E was measured in isobutane from 294.4 to 114.6 K (556 to 739 kg m^{-3}). Particular attention was given to the behavior at T < 180 K, d > 677 kg m^{-3}. The effects of increasing density on $F(y)$ and on the mean thermalization distance $\langle y \rangle$ were examined by fitting the (E, G_{fi}^E) data.

The mobilities μ of thermal electrons were also measured to check the purity of the liquid and to extend the earlier range of measurements. The Arrhenius temperature dependence of μ changes in the same density region as does $F(y)$.

Experimental

Materials

Matheson research grade isobutane (>99.96 mol%) was further purified in a grease-free vacuum line, by the method used for *n*-butane described in ref. 4.

Apparatus

Low-pressure liquid conductance cells (8) with electrode separations l of 2.51 and 3.26 mm were used. The electron conductance amplifier, charge integrator, voltage supplies, and dosimetry are described or referenced in ref. 4. Temperature control and measurement are described in ref. 9.

The densities are dielectric permittivities were taken from ref. 10.

Results and discussion

Electron mobility

At all temperatures except the lowest (114.6 K, which is 0.9 K above the freezing point) the electron conductance signal decayed linearly, or nearly so (11), with time. This indicated that the liquid was sufficiently free of electron-attaching impurities. The applied field strengths were in the range 0.3–5 MV m^{-1}, and the measured electron drift times

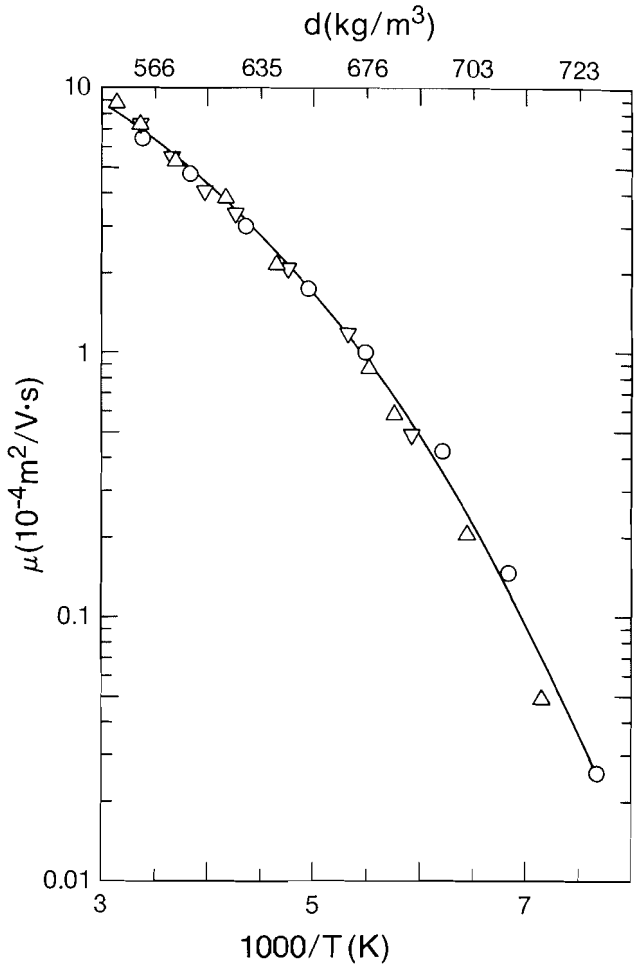

FIG. 1. Arrhenius plot of electron mobility μ in liquid isobutane. ○, present work; ▽, ref. 7; △, ref. 12. The full curve was calculated from eqs. [8]–[13], using the parameter values given in the text.

t_d were in the range 2–700 μs. The conductance signal at 114.6 K was convex toward the time axis and had a long tail, so was not used.

The electron mobilities were calculated from eq. [6],

$$[6] \qquad \mu = l^2/t_d \cdot V$$

where l is the distance between the parallel electrodes and V is the applied voltage. For the conditions of this work the diffusion correction (11) was negligible. At each temperature at least eight measurements, half obtained with positive and half with negative applied voltage, were averaged to give the results in Fig. 1 and Table 1. The present mobilities agree with earlier reports at the higher temperatures (7, 12), but are somewhat higher than those reported for the lower temperatures (12).

The variation of μ with liquid temperature T and density d is interpreted by a two-state model (12), which is summarized as follows. The electrons are in equilibrium between quasifree (qf) and localized (loc) states:

$$[7] \qquad e_{qf}^- + \text{medium} \rightleftharpoons e_{loc}^-$$

A fraction χ of the electrons is in the quasifree state:

$$[8] \qquad \chi = \int_{-\infty}^{\infty} N(E)[1 + \exp(E/k_BT)]^{-1} dE$$

TABLE 1. Thermal electron mobilities in isobutane

T (K)	d (kg m^{-3})	μ (10^{-4} m^2 V^{-1} s^{-1})
130.5	725	0.026
146.6	710	0.143
161.1	696	0.424
182.2	676	1.00
201.5	656	1.72
229.4	627	3.00
261.5	594	4.76
294.5	555	6.51
294.8	555	6.37

where $N(E)dE$ is the fraction of localized states that lie at energies between E and $E + dE$ from the quasifree state, and k_B is Boltzmann's constant.

The distribution function $N(E)$ is taken to be a Gaussian about a mean value E_0 with a dispersion σ,

$$[9] \quad N(E) = \pi^{-1/2}\sigma^{-1} \exp[-(E - E_0)^2/\sigma^2]$$

The parameters E_0 and σ vary with temperature,

$$[10] \quad E_0 = E(0) - aT$$

$$[11] \quad \sigma = \sigma(0) + bT^{1.5}$$

In previous work the power of T in eq. [11] was taken as 1.0, but that value did not provide enough curvature for the data in Fig. 1.

The observed mobility is the sum of the contributions of e^-_{qf} of mobility μ_{qf} and e^-_{loc}:

$$[12] \quad \mu = \chi\mu_{qf} + (1 - \chi)\mu^0_{loc} \exp(-E_{loc}/k_BT)$$

where μ^0_{loc} and E_{loc} are respectively the preexponential factor and activation energy of e^-_{loc} mobility. The value of μ_{qf} is density and temperature dependent, taken as

$$[13] \quad \mu_{qf} = \mu_{ref}(d_{ref}/d)^2(T_{ref}/T)$$

where μ_{ref} is the mobility at the reference density d_{ref} and temperature T_{ref}.

Previously selected values of the parameters for isobutane (12) were used as far as possible: $E(0) = 32$ zJ entity^{-1} (0.20 eV ent^{-1}), $\sigma(0) = 0$, $\mu^0_{loc} = 1 \times 10^{-5}$ m^2 V^{-1} s^{-1}, $E_{loc} = 11$ zJ ent^{-1} (0.07 eV ent^{-1}), $\mu_{ref} = 3 \times 10^{-3}$ m^2 V^{-1} s^{-1} at $T_{ref} = 295$ K and $d_{ref} = 555$ kg m^{-3}. The new values $a = 43$ yJ ent^{-1} K^{-1} (0.27 meV ent^{-1} K^{-1}) and $b = 7.2$ yJ ent^{-1} K$^{-1.5}$ (0.0448 meV ent^{-1} K$^{-1.5}$) provided the full curve in Fig. 1. The contribution of e^-_{loc} is negligible (1% at the lowest T, and less at higher T's), so eq. [12] reduces to [12′] in this case:

$$[12'] \quad \mu = \chi\mu_{qf}$$

While we do not treat mobilities in low density liquids here, to fit data at $d/d_c < 2.5$ (13) using eq. [11], the variation of μ_{qf} with density in the low density liquid regime would have to change to $\mu_{qf} \propto d^{-4}$. Furthermore, near the critical region quasilocalization of the electrons lowers the measured μ (12).

Free-ion yields and thermalization distance distributions

The yields decreased relatively rapidly as the temperature was decreased from 294 to 180 K (density increased from 555 to 677 kg m^{-3}), then decreased more slowly as the temperature was decreased further to 130 K (density increased to 725 kg m^{-3}): see Figs. 2 and 3. At 114.6 K (740 kg m^3), which is 0.9 K above the freezing point, the G^E_{fi} curve lies below that for 130.9 K at low fields and above it at high fields (Fig. 3).

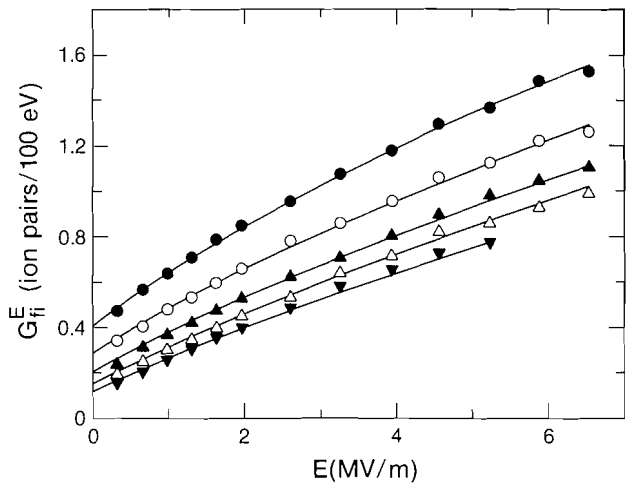

FIG. 2. Electric field strength dependence of free ion yields in liquid isobutane at $T = 294.4$ K (●), 261.9 K (○), 229.4 K (▲), 200.5 K (△), and 180.6 K (▼). The curves were calculated from eqs. [14]–[18] and $F(y) = YP$ (Table 3).

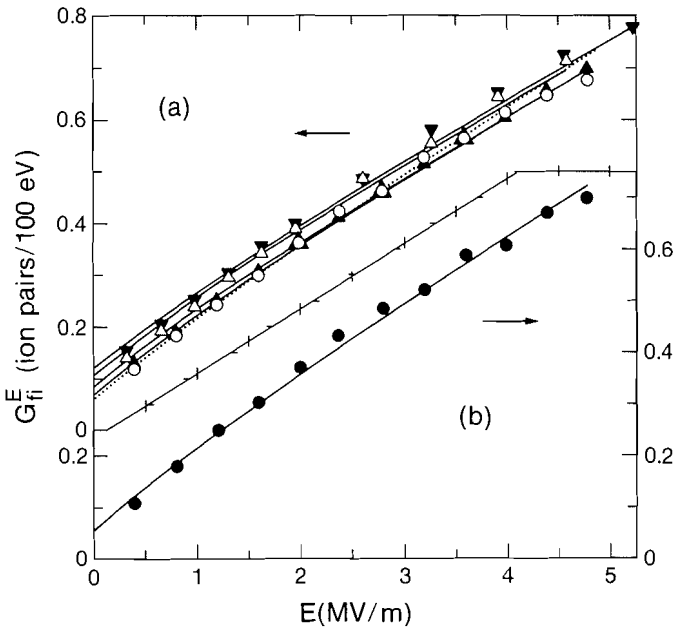

FIG. 3. Field strength dependence of free ion yields in liquid isobutane at (a) $T = 180.6$ K (▼), 169.7 K (△), 149.6 K (▲), 130.9 K (○), and (b) 114.6 K (●). Lines calculated as in Fig. 2. The · · · line in (a) is the line from (b), to show the cross-over.

The free ion yield at a given set of conditions can be calculated from (1*c*)

$$[14] \quad G^E_{fi} = \phi^E_{fi} G_{tot}$$

where G_{tot} is the total yield (ion pairs per 16 aJ) of reaction [1], which is measured chemically by electron capture in the liquid phase, or electrically in the gas phase. The probability ϕ^E_{fi} that an initial ion pair will become a free-ion pair is calculated from

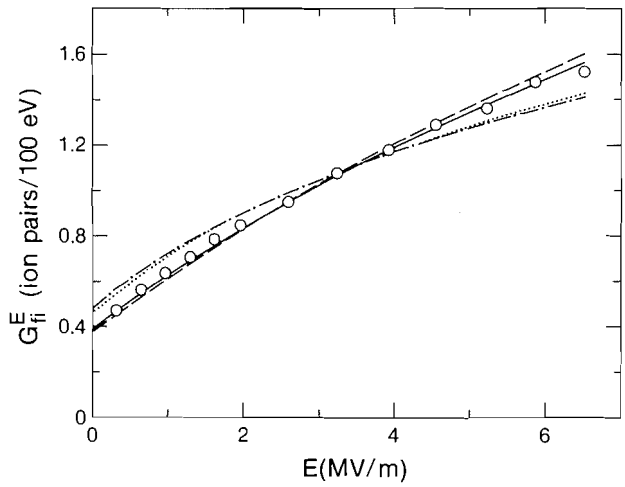

FIG. 4. Free ion yields at 294.4 K (○) compared to those calculated by eqs. [14]–[18] using G_{tot} = 4.2 and $F(y)$ = YGP (——), YG (– – –), YEP (—·—·), and YE (· · ·), with parameter values from Table 2.

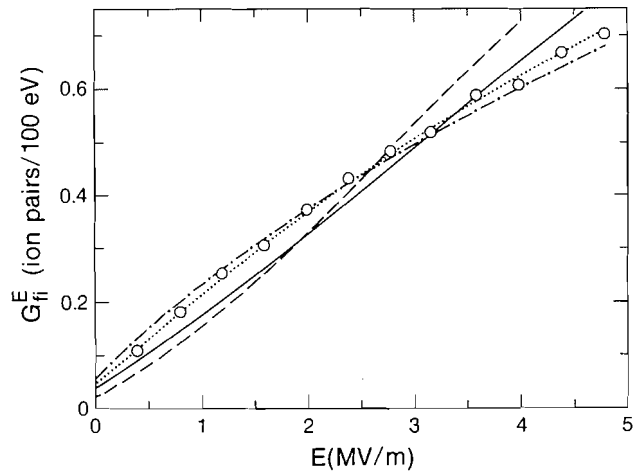

FIG. 5. Free ion yields at 114.6 K (○). Lines calculated as in Fig. 4.

TABLE 2. Parameter values for curves in Figs. 4 and 5[a]

	294.4 K		114.6 K	
Distribution	G_{fi}^{0}	b (nm)	G_{fi}^{0}	b (nm)
YG	0.373	11.4	0.025	9.7
YGP	0.392	10.7	0.040	8.7
YE[b]	0.459	12.7	0.046	8.3
YEP[b]	0.474	11.6	0.059	7.2

[a]Free ion yields in liquid isobutane. Assumed G_{tot} = 4.2. The equations for the distribution functions YG, YGP, YE, and YEP are given in refs. 1*c* and 13.
[b]y_0 = 1 nm.

$$[15] \quad \phi_{fi}^{E} = \int_0^\infty \phi_{fi}^{E}(y)F(y)dy$$

where y is the distance between the electron and ion at the time when the electron reaches thermal energy, $F(y)$ is the distribution function, and

$$[16] \quad \phi_{fi}^{E}(y) = \phi_{fi}^{0}(y)[1 + f(E,\varepsilon,T,y)]$$

The probability at zero field is (2)

$$[17] \quad \phi_{fi}^{0}(y) = \exp(-\xi^2/4\pi\varepsilon_0\varepsilon k_B T y) = \exp(-r_c/y)$$

where $-\xi$ is the electron charge, ε_0 is the permittivity of vacuum, ε is the relative permittivity of the medium between the electron and cation, and r_c is the distance at which the coulombic attraction energy between the electron and ion equals $k_B T$. The field enhancement term in eq. [16] is (1*c*)

$$[18] \quad f(E,\varepsilon,T,y) = e^{-2\beta y}\sum_{m=1}^{\infty}\frac{(2\beta y)^m}{(m+1)!}\sum_{j=0}^{m-1}(m-j)\frac{(r_c/y)^{j+1}}{(j+1)!}$$

where $\beta(m^{-1}) = \xi E/2k_B T = 5800\,E/T$, where E is in V m^{-1}.

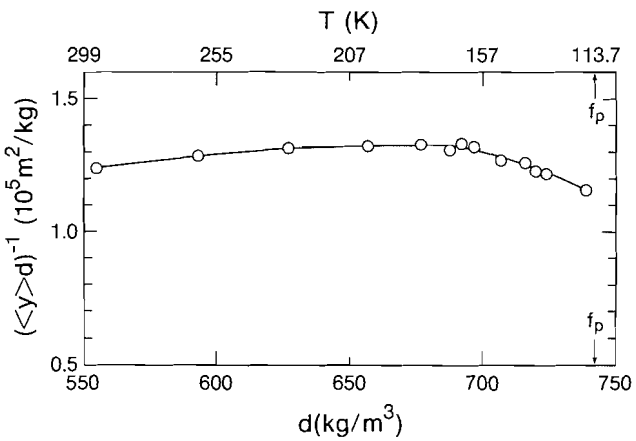

FIG. 8. Thermalizing ability plotted against density; $\langle y \rangle$ obtained using $F(y)$ = YP.

One may obtain information about $F(y)$ by fitting eqs. [14]–[18] to yields measured under a wide range of conditions. Many forms of $F(y)$ have been considered (1*c*, 13–17). The most common are based on Gaussian or exponential forms. A Gaussian-type distribution can arise from nearly random scattering of the thermalizing electrons by the fluid molecules, while an exponential-type might arise from a greater contribution of forward scattering in the more ordered, denser fluid (1*c*). Four example distributions (13) are a three-dimensional Gaussian designated YG, a one-dimensional exponential designated YE, and each with the addition of a y^{-3} power tail for a few percent of the pairs that have the largest y values, and therefore designated YGP and YEP, respectively. The power tail at large y values is an artifact of the model, in which it is assumed that there is only one ionization event per microzone, and is due to the rapid combination of the ions and electrons nearest the center of the few microzones that contain more than one ion–electron pair (1*c*). The explicit forms of these functions are given in refs. 1*c* and 13. In Figs. 4 and 5 yields calculated from these four distributions, with best-fit parameter values given in Table 2, are compared to the measured values at 294.4 K (555 kg m^{-3}) and 114.6 K (740 kg m^{-3}). In the former the best fit was obtained with YGP, while in the latter it was obtained with YE. This unusual change of the distribution function indicates that the scattering properties of the liquid are somewhat different at the lowest and highest densities.

Figure 6 shows that yields calculated with YGP are not unreasonable at densities up to 677 kg m^{-3} (temperatures down to 180.6 K). This is why measurements in isobutane at $d < 555$ kg m^{-3} could be fitted with YGP (18). Figure 7 shows that yields calculated with YE are not unreasonable at densities down to 725 kg m^{-3} (temperatures up to 130.9 K). The parameter values used to obtain the curves in Figs. 6 and 7 are listed in Table 3.

Less than 40% of the initial ionizations produce free ions at the highest field and temperature used in the present work. Therefore the low y value half of the $F(y)$ distribution makes a negligible contribution to the yields displayed in Figs. 6 and 7. We can therefore neglect the shape of the main body of the distribution and focus on the shape of the tail. For that purpose we use a simple power function, designated YP (1*c*, 7):

$$[19] \quad F(y) = \begin{cases} 0 & y < y_{min} \\ x y_{min}^{x} y^{-(x+1)} & y > y_{min} \end{cases}$$

where x and y_{min} are adjustable parameters. A reasonable fit to the yields at all temperatures and densities (Figs. 2 and 3) was obtained with $x = 2.05$, although the curvature of the lines is a bit too small. Parameter values for the curves in Figs. 2 and 3 are listed in Table 3. This compromise function varies as $y^{-3.05}$, compared to the y^{-3} tails in YGP and YEP. The mean values of y, $\langle y \rangle$, in YP are similar to those in YGP over the range of density and temperature where the latter is an adequate distribution (Table 3). However, the values of $\langle y \rangle$ in YE are significantly smaller than those in YP because the former has an unrealistically large number of pairs at the lowest y values.

The values of G_{fi}^0 obtained by extrapolation with YP are

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

slightly higher than those obtained with YGP or YE (Table 3). The preferred values would be the averages of those in the two columns of the table, but we do not list them because they do not have an associated distribution function.

Electron thermalizing ability of the liquid

The inverse of the average thermalization distance, normalized for the density of the liquid, $(\langle y \rangle d)^{-1}$, is a measure of the inherent ability of the liquid to remove excess kinetic energy from hot electrons. This quantity is plotted against isobutane density in Fig. 8. The plot has a slightly positive slope for densities up to about 660 kg m^{-3}, and a negative slope for densities above about 690 kg m^{-3}. In this same density region, 660–690 kg m^{-3}, the temperature dependence of the electron mobility undergoes a significant change (Fig. 1). In the lower density region, $d < 660$ kg m^{-3}, the Arrhenius temperature coefficient is $E_\mu \approx 7$ kJ mol^{-1}, whereas at $d > 690$ kg m^{-3} it is $E_\mu \approx 16$ kJ mol^{-1}. These changes in behavior are attributed to an undetermined change in liquid structure, or molecular packing. Values of the viscosity of the liquid in this low-temperature region are not available in the literature. A large program of studying liquids for their own sake is badly needed to assist programs in many other fields, such as the behavior of electrons in fluids.

A theoretical study on the activation of hydrogen–hydrogen and hydrogen–alkyl bonds by electron-poor early transition metals

E. FOLGA AND T. ZIEGLER[1]

Department of Chemistry, University of Calgary, Calgary, Alta., Canada T2N 1N4

Received May 23, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

E. FOLGA and T. ZIEGLER. Can. J. Chem. **70**, 333 (1992).

A theoretical study has been carried out on four σ-bond metathesis reactions mediated by the electron-poor lutetium metal centre. The four processes include hydrogen exchange, $X_2Lu\text{-}H + D_2 \rightarrow X_2Lu\text{-}D + HD$ (**1**), and hydrogenolysis $X_2Lu\text{-}CH_3 + H_2 \rightarrow Cl_2Lu\text{-}H + CH_4$ (**2**), in which a H—H bond is activated, as well as methane exchange, $X_2Lu\text{-}CH_3 + CH_4 \rightarrow X_2Lu\text{-}CH_3 + CH_4$ (**3**), and methylation, $Cl_2Lu\text{-}H + CH_4 \rightarrow X_2Lu\text{-}CH_3 + H_2$ (**4**), in which a C—H bond is activated. The Cp^*_2Lu fragment employed in a number of experimental studies was modelled by Cl_2Lu and all calculations were based on approximate Density Functional Theory (DFT). The study combined methods from quantum mechanics and statistical mechanics to obtain enthalpies and entropies of activation as well as transition state structures. All four processes were found to have an ordered four-centre transition state with negative entropies of activation given by $\Delta S^{\neq} = -109$ (**1**), -124 (**2**), -131 (**3**), and -134 (**4**) J mol^{-1} K^{-1} at $T = 298.15$ K. The Gibb's free energies of activation, $\Delta G^{\neq}(=\Delta H^{\neq} - T\Delta S^{\neq})$ were calculated as $\Delta G^{\neq} = 81.6$ (**1**), 126.0 (**2**), 136.7 (**3**), and 130.6 (**4**) kJ mol^{-1} at $T = 298.15$ K. The calculated trends in $\Delta G^{\neq}$ are consistent with the observed order of reactivity for σ-bond metathesis reactions between R—H and M—R′ bonds: R = R′ = H >> R = H, R′ = CH_3 > R = R′ = CH_3. The decrease in the reaction rate is related to the diffferent abilities of the 1*s* hydrogen orbital and the σ_{CH_3} methyl orbital to stabilize the four-centre transition state. Thus, the spherical 1*s* hydrogen orbital is better able to overlap fully with orbitals on adjacent centres than the directional σ_{CH_3} orbital. As a consequence, the electronic barrier is seen to increase from the hydrogen exchange reaction towards the hydrogenolysis and methane exchange processes as one or two hydrogens, respectively, are replaced by methyl groups in the four-centre transition state.

Key words: Density Functional Theory, C—H activation, metathesis, hydrogenolysis, H—H activation.

E. FOLGA et T. ZIEGLER. Can. J. Chem. **70**, 333 (1992).

On a effectué une étude théorique sur des réactions de métathèse impliquant quatre liaisons-σ et l'entremise du lutécium comme centre métallique pauvre en électrons. Les quatre processus comprennent : l'échange d'hydrogène, $X_2Lu\text{-}H + D_2 \rightarrow X_2Lu\text{-}D + HG$ (**1**), l'hydrogénolyse, $X_2Lu\text{-}CH, + H_2 \rightarrow Cl_2Lu\text{-}H + CH_4$ (**2**) dans laquelle une liaison H—H est activée, l'échange de méthane, $X_2Lu\text{-}CH_3 + CH_4 \rightarrow X_2Lu\text{-}CH_3 + CH_4$ (**3**) et la méthylation, $Cl_2Lu\text{-}H + CH_4 \rightarrow X_2Lu\text{-}CH_3 + H_2$ (**4**) dans laquelle il y a activation d'une liaison C—H. On a utilisé le Cl_2Lu comme modèle du fragment Cp^*_2Lu qui a été souvent employé dans un certain nombre d'études expérimentales et tous les calculs sont basés sur la théorie de la densité fonctionnelle (TDF) approximative. L'étude a combiné des méthodes de la mécanique quantique et de la mécanique statistique pour obtenir les enthalpies et les entropies d'activation ainsi que les structures des états de transition. On a trouvé que les quatre processus possèdent un état de transition ordonné à quatre centres avec des entropies d'activation calculées qui sont négatives : $\Delta S^{\neq} = -109$ (**1**), -124 (**2**), -131 (**3**) et -134 (**4**) J mol^{-1} K^{-1}, à 298,15 K. Les enthalpies libres d'activation, $\Delta G^{\neq}$ $(=\Delta H^{\neq} - T\Delta S^{\neq})$, calculées sont égales à 81,6 (**1**), 126,0 (**2**), 136,7 (**3**) et 130,4 (**4**) kJ mol^{-1}, à 298,15 K. Les tendances calculées pour les $\Delta G^{\neq}$ sont en accord avec l'ordre de réactivité observé pour les réactions de métathèses des liaisons-σ entre des liaisons R—H et M—R′ : R = R′ − H >> R = H, R′ − CH_3 > R − R′ = CH_3. L'abaissement de la vitesse de la réaction est relié aux pouvoirs différents de l'orbitale 1*s* de l'hydrogène et de l'orbitale σ_{CH_3} du méthyle de stabiliser l'état de transition à quatre centres. L'orbitale 1*s* sphérique de l'hydrogène donne donc lieu à un plus grand recouvrement des orbitales des centres adjacents que l'orbitale σ_{CH_3} orientée. En conséquence, alors qu'on remplace respectivement un ou deux hydrogènes par des groupes méthyles dans l'état de transition à quatre centres, on voit un accroissement de la barrière électronique lorsqu'on passe de la réaction d'échange d'hydrogène vers les processus d'hydrogénolyse et d'échange de méthane.

Mots clés : théorie de la densité fonctionelle, activation d'une liaison C—H, métathèse, hydrogénolyse, activation d'une liaison H—H.

[Traduit par la rédaction]

Introduction

The activation (breaking) of H—H and C—H bonds by transition metal centres has been studied extensively over the last decade by experimental (1–4) as well as theoretical (5, 6–9, 12) techniques. Electron-rich middle to late transition metal complexes are known (1, 5) to add H_2 oxidatively to form dihydride complexes.

[1] $ML_n + H_2 \rightarrow$  $\rightarrow L_nM(H)_2$

1

The process in eq. [1] is facile and proceeds through a three-centre transition state (1, 5) in a concerted manner. Electron-rich metal centres can also activate alkylic C—H bonds (2, 5*i–k*, 6*a–c*) by a concerted oxidative addition

[2] $ML_n + H\text{—}CH_3 \rightarrow$  $\rightarrow L_nM(H)(CH_3)$

2

The reaction is not as facile as H—H addition and has only been realized (2) in a limited number of cases. The H—H and C—H bonds are of roughly the same strength. However, H—H activation is thermodynamically more favourable since M—H bonds of middle to late transition metals are stronger

(2*g*, 6*d*–*e*, 12) than the corresponding M–alkyl bonds. Thus, oxidative addition of H_2 in eq. [1] is in general exothermic (5*i*–*l*, 6*c*) whereas the C—H addition of eq. [2], with some important exceptions (2), is endothermic (5*i*–1, 6*c*). The H—H addition is further kinetically more facile since the spherical $1s_H$ orbital (5*i*–*l*) is better able to stabilize the three-centre transition state, **1**, than the more directional σ_{CH_3} orbital in **2**.

Early transition metals are in general too electron poor to activate H—H and C—H bonds by oxidative addition. They are, nevertheless, able to activate H—H and C—H bonds in the recently discovered σ-bond metathesis reaction (3):

[3] $L_nM—R + H—R^* \rightarrow L_nM—R^* + H—R$

($M = d^0, f^{14}d^0$; R, R* = H, alkyl)

The general formulation of the σ-bond metathesis reaction in eq. [3] includes hydrogen exchange, eq. [4*a*], methane exchange, eq. [4*b*], and hydrogenolysis of metal alkyls, eq. [4*c*].

[4*a*] $L_nM—H + D_2 \leftrightarrow L_nM—D + HD$

[4*b*] $L_nM—CH_3 + {}^*CH_4 \leftrightarrow L_nM—{}^*CH_3 + CH_4$

[4*c*] $L_nM—R + H_2 \rightarrow L_nM—H + RH$

[4*d*] $L_nM—H + CH_4 \rightarrow L_nM—CH_3 + H_2$

(M = Lu, Sc; L = Cp*; *n* = 2)

The σ-bond metatheses by organo-lutetium and organo-scandium methyl complexes were studied experimentally by Watson (3*c*–*e*) and Bercaw and co-workers (3*a*–*b*) in connection with the Ziegler–Natta polymerization process. Both complexes were reported to readily undergo hydrogenolysis, eq. [4*c*], giving up metal hydrides that then rapidly underwent H/D exchange, eq. [4*a*]. Methane exchange, eq. [4*b*], was observed in several instances and kinetic studies were carried out for M = Sc (3*a*,*b*), Y, and Lu (3*c*–*e*). Hydrogenolysis of metal alkyls, eq. [4*c*], is postulated to take place during the chain-termination step in Ziegler–Natta polymerization (3). Electron-poor early *f*-block elements are also known (3*f*,*g*) to activate H—H and C—H bonds according to the reaction given in eq. [3].

The activation of the H—H bond by electron-poor metal centres in the σ-bond metathesis reactions of eqs. [4*a*] and [4*c*] has been postulated (3) to proceed via a four-centre transition state **3***a*.

[5] $L_nM—R + H—H \rightarrow \left[\begin{array}{cc} L_nM & R \\ H & H \end{array}\right]$ (**3***a*) $\rightarrow L_nM—H + R—H$

A similar four-centre transition state **3***b*

[6] $L_nM—R + H—CH_3 \rightarrow \left[\begin{array}{cc} L_nM & R \\ H_3C & H \end{array}\right]$ (**3***b*) $\rightarrow L_nM—CH_3 + R—H$

has been inferred for the activation of the C—H bond in the two reactions of eqs. [4*b*] and [4*d*]. Activation of H—H bonds via the four-centre transition state, **3***a*, might also occur in complexes of middle to late transition metals (9).

Up-to-date theoretical investigations on σ-bond metathesis include a GVB (Generalized Valence Bond) study of the reaction in eq. [4*a*] (M = Sc, Ti; L = Cl) by Steigerwald and Goddard (7*a*) and EHA (Extended Hückel Approximation) calculations of the reactions in eqs. [4*a*] and [4*b*] (M = Lu, L = Cp*) by Hoffmann and co-workers (7*c*). Recently, Rappé (7*b*) discussed σ-bond metathesis between C—H bonds of olefins or acetylenes and the Sc—R (R = H, CH_3) linkage. We (7*d*) have also reported preliminary calculations on the reaction in eq. [4*a*] with $ML_n = LuCl_2$.

The present investigation is concerned with a comparison between the activation of the H—H bond in eqs. [4*a*] and [4*c*], and the activation of the C—H bond in eqs. [4*b*] and [4*d*]. In particular, we shall contrast the degree to which the frontier orbitals on H and CH_3 are able to stabilize the four-centre transition states **3***a* and **3***b* and its implication (3*a*,*b*, 7*a*,*b*) for the activation energies of the processes in eqs. [4*a*]–[4*d*]. We have chosen Cl_2Lu to model the Cp^*_2Lu fragment employed by Watson (3*c*–*e*). The activation of H—H, eq. [1], and C—H bonds, eq. [2], by electron-rich metal centres has been studied previously in our group (6*c*).

Our calculations are based on Approximate Density Functional Theory (10), which over the past decade has emerged as a tangible and versatile computational method. It has been employed successfully to obtain thermochemical data (11, 12), molecular structures (13, 14), force fields and frequencies (15), assignments of NMR (16, 17), photoelectron (18), ESR (19), and UV spectra (15), and transition state structures as well as activation barriers (20), dipole moments (21), and other one-electron properties. Thus, approximate DFT is now applied to many problems previously covered exclusively by *ab initio* Hartree–Fock (HF) and post-HF methods. The recently acquired popularity of approximate DFT stems in large measure from its computational expedience, which makes it amenable even to large-size molecules at a fraction of the time required for HF or post-HF calculations. More important, perhaps, is the fact that expectation values derived from approximate DFT in most cases are better in line with experiment than results obtained from HF calculations. This is in particular the case for systems involving transition metals. An analysis of why approximate DFT affords more reliable results than HF has recently been published by Cook and Karplus (22) as well as by Tschinke and Ziegler (23).

Computational details

The reported calculations were all carried out by utilizing the HFS–LCAO program system developed by Baerends *et al.* (24, 25) and vectorized by Ravenek (25*b*). The numerical integration procedure applied for the calculations was developed by Becke (26). All molecular structures were optimized on the singlet energy surface within the C_s symmetry group. The geometry optimization procedure was based on the method developed by Versluis and Ziegler (13). Vibrational frequencies were evaluated from force constants calculated by numerical differentiation of the energy gradients (15). The transition states were optimized according to the method due to Simons *et al.* (27) in the implementation by Baker (28) that has been adopted to the HFS–LCAO program system by Fan *et al.* (15). The electronic configurations of the molecular systems were described by an uncontracted triple-ζ STO basis set (29) on lutetium for 5*d*, 6*s*, and 6*p* as well as a double-ζ STO basis set (22) on chlorine (3*s*,3*p*) and hydrogen (1*s*,2*p*). The $1s^22s^22p^63s^23p^63d^{10}4s^24p^64f^{14}5s^25p^6$ configuration on Lu and the $1s^22s^22p^2$ configuration on Cl were assigned to the core and treated by the frozen-core approximation (24). A set of auxiliary (30) *s*, *p*, *d*, *f*, and *g* STO functions, centred on all nuclei, was used to fit the molecular density and present Coulomb and exchange poten-

For personal use only.

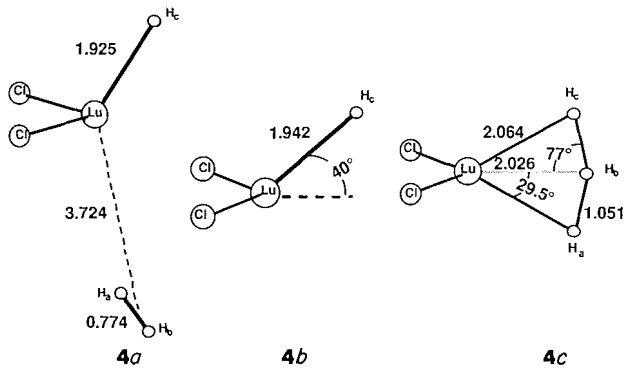
tials accurately in each SCF cycle. Relativistic effects were taken into account according to the approach by Snijders *et al.* (31) in its quasi-relativistic implementation (32).

Energy differences were calculated by including the local correlation potential by Stoll *et al.* (33*a*) and Becke's (33*b*) non-local exchange corrections. Calculations on metal carbonyls (34), binuclear metal complexes (35), alkyl and hydride complexes (6*c*–*f*, 36), as well as complexes containing M—L bonds for a number of different ligands (12, 37), have shown that the Approximate Density Functional method employed here affords metal–ligand and metal–metal bond energies of nearly chemical accuracy (±5 kcal mol^{-1}). More than 50 molecular structures optimized by Approximate Density Functional Theory have been compared with experiment (13). The agreement between experiment and theory is in most cases excellent. The application of Approximate Density Functional Theory to organometallic chemistry has recently been reviewed (36, 38).

H—H bond activation

Transition state structure for the hydrogen exchange reaction: $Cl_2Lu—H + H_2 \rightarrow Cl_2Lu—H + H_2$

A schematic energy profile for the hydrogen exchange reaction of eq. [4*a*] is given in Fig. 1. Our calculations indicate that a weak adduct, **4***a*, is formed in the early stages of the process. The formation energy for **4***a* was calculated to be only 4.9 kJ mol^{-1}. The equilibrium structure **4***a*, optimized under C_s symmetry constraints, reveals only a slight elongation of the H—H bond (by 0.002 Å) and a rather long distance of 3.724 Å from the midpoint of the H—H bond to the lutetium centre.



The Cl_2Lu—H framework in **4***a* resembles the optimized structure of free Cl_2LuH, **4***b*, which was found to have a nonplanar geometry with the hydride bent 40° out of the Cl_2Lu coordination plane. The barrier of inversion for free Cl_2LuH was calculated to be 8.7 kJ mol^{-1}.

There are two electron pairs involved in bond breaking and bond making during the exchange reaction in eq. [4*a*]. The two orbitals holding the electron pairs in the early stages of the reaction are shown to the left of the correlation diagram in Fig. 2. Of lowest energy is 2*a*′, which is made up of the σ_g orbital on the incoming H_2 molecule. This orbital describes the intact H—H bond. The 6*a*′ orbital of higher energy represents the Lu—H linkage. The bonding interaction in 6*a*′ is between a well-directed hybrid on lutetium (0.58 $6s - 0.43\ d_{x^2-y^2} + 0.43\ d_{z^2} + 0.50\ d_{yz}$) and $1s_{H_c}$.

The optimized transition state for the reaction in eq. [4*a*] was found to have a planar structure of C_{2v} symmetry, **4***c*. The two Lu—H distances of 2.064 and 2.026 Å are only slightly longer than the Lu—H hydride bond in **4***b* of 1.941 Å. The symmetrical H—H bond distances of 1.051 Å are substantially longer than the calculated H—H bond in free H_2 at 0.772 Å. The Lu—H_a—H_b—H_c ring structure in **4***c*

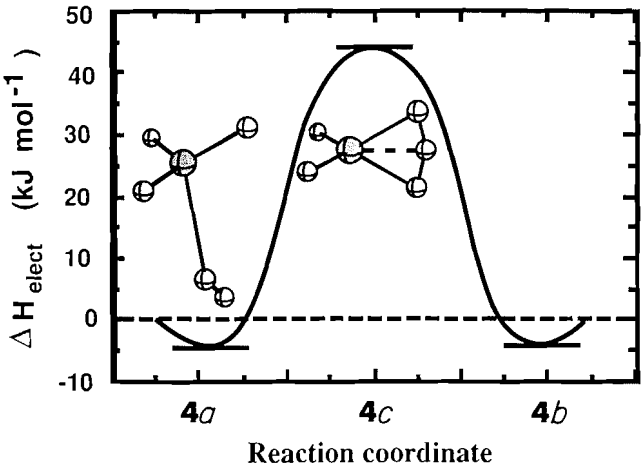


FIG. 1. Profile for the hydrogen exchange reaction $Cl_2LuH_c + H_a—H_b \rightarrow Cl_2LuH_a + H_b—H_c$. The energies are relative to the reactants (products).

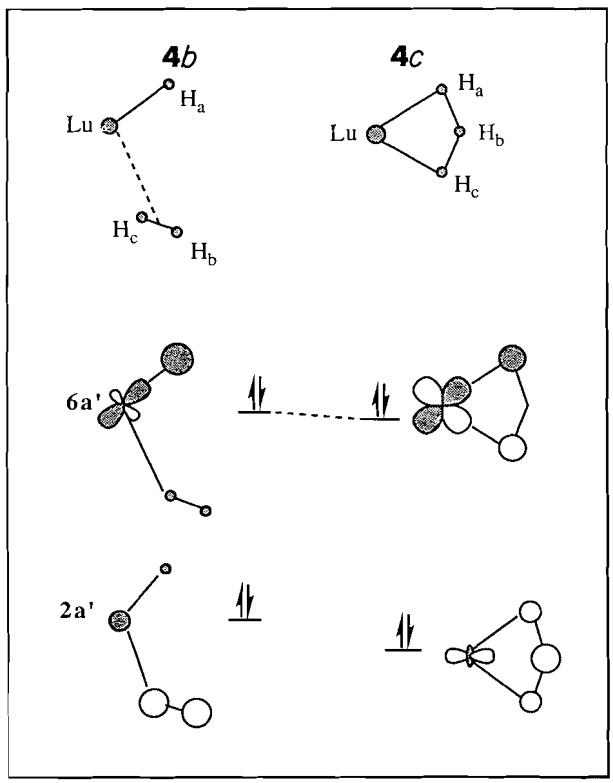

FIG. 2. Correlation diagram for the passage **4***a* → **4***c*.

clearly has the characteristics of a four-centre transition state with substantial bonding interaction between the adjacent atoms in the ring. In addition, there is some stabilizing interaction between Lu and H_b across the ring.

The two occupied orbitals responsible for the stabilizing interaction within the ring structure are shown to the right in Fig. 2. The 2*a*′ orbital represents a four-centre bonding interaction between the metal-based $d_{x^2-y^2}$ orbital on Cl_2Lu^+ and three in-phase 1*s* hydrogen orbitals on H_3^-. The 6*a*′ orbital of higher energy represents a three-centre bonding interaction involving the d_{yz} orbital on lutetium and an out-of-phase combination of 1*s* orbitals on the two equivalent hydrogen atoms.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

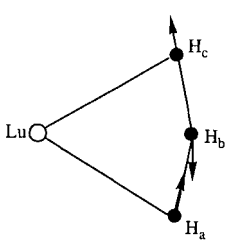
The two electron pairs involved in the bond making and bond breaking through the passage from **4***a* to **4***c*, Fig. 2, remain in orbitals, 2*a*′ and 6*a*′, with strong stabilizing interactions. The electron pair of lowest energy is situated in an orbital 2*a*′, localized largely on the hydrogen atoms. This orbital will experience a loss in the bonding interaction between H_a and H_b as the H_a—H_b bond is stretched in the process **4***a* → **4***c*. The loss is, however, compensated for by an increase in the stabilizing interaction between H_b and H_c.

The electron pair of higher energy remains in a Lu—H bonding orbital, 6*a*′. The metal hybrid in 6*a*′ is able to change its nodal characteristics and directionality during the transit **4***a* → **4***c*, from a hybrid (0.58 6*s* − 0.43 $d_{x^2-y^2}$ + 0.43 d_{z^2} + 0.50 d_{yz}) pointing towards H_c in $\mathbf{4}_a$ to a pure d_{yz} orbital in $\mathbf{4}_c$. This is made possible by drawing on the pool of empty orbitals in the 5*d*, 6*s*, and 6*p* shells (7, 8). It should be noted that the stretch of the incoming H_a—H_b bond from 0.77 Å in $\mathbf{4}_a$ to 1.05 Å in $\mathbf{4}_c$ adds 85.7 kJ mol^{-1} to the calculated electronic barrier. This destabilization is only partially compensated for by the stabilizing interactions in 2*a*′ and 6*a*′ of **4***c*, Fig. 2.

The nodal flexibility distinguishes electron-poor early transition metals and *f*-block elements from hydrogen or alkylic carbon atoms. Thus in σ-bond metathesis involving H—H or C—H bonds neither the hydrogen nor the alkylic carbon have any empty orbitals of the same nodal characteristics as d_{yz} in $\mathbf{4}_c$. As a consequence, the electron pair of highest energy will reside in a two-centre nonbonding orbital rather than in the three-centre bonding orbital, 6*a*′, shown to the right in Fig. 2. The lack of stabilization for the upper electron pair in σ-bond metathesis involving H—H or alkylic C—H bonds will result in high barriers for this type of process. In fact, they are [2*s* + 2*s*] symmetry forbidden reactions. Our explanation for the reason that [2_s + 2_s] exchange reactions between H—H and Lu—H bonds are allowed is based on simple molecular orbital arguments. Similar explanations have been put forward by Steigerwald and Goddard (7*a*), Rappé (7*b*), as well as Jolly and Marynick (8).

The transition state structure **4***c* has a single negative force constant. The corresponding normal mode, **5**, represents the reaction coordinate that, as one might expect, primarily constitutes an asymmetric H–H–H stretch.

Using the GVB gradient program, Steigerwald and Goddard (7*a*) obtained a barrier of 17 kcal mol^{-1} (71.1 kJ mol^{-1}) for a similar isomerization process involving scandium rather than lutetium. The Sc—H_a bond distance in the transition state was optimized to be 1.887 Å, i.e., 0.213 Å shorter than the Lu—H_a bond distance calculated in this work. It is an acceptable difference if one takes into account the size of the ionic radii ($R_{Sc^{3+}}$ = 0.89 Å, $R_{Lu^{3+}}$ = 1.00 Å) (39). Goddard calculated the H_a—H_b distance as 1.014 Å and the



5

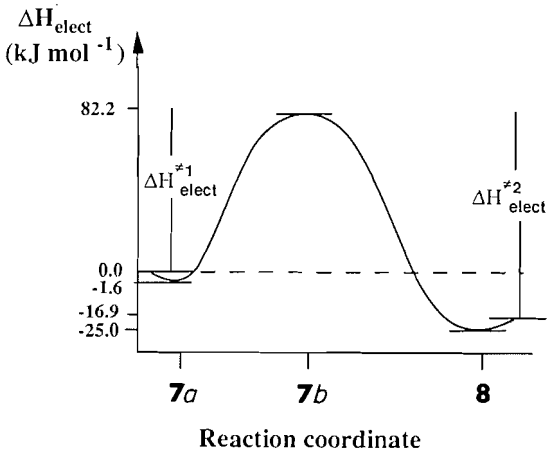


FIG. 3. Profile for the reaction $Cl_2LuCH_3 + H_2 \rightarrow Cl_2LuH + CH_4$. The energies are relative to the reactants.

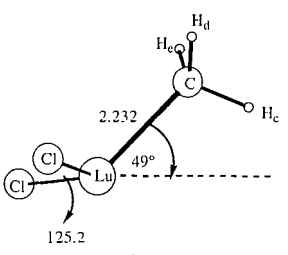
H_a—Lu—H_c angle as 65°, compared to 1.057 Å and 59° reported here. As for the geometry of the scandium hydride, it was assumed to be planar and optimized as such with the Sc—H bond distance of 1.780 Å.

Transition state structure for the hydrogenolysis reaction:
Cl_2Lu—CH_3 + H_2 → Cl_2Lu—H + CH_4

We have discussed the hydrogen exchange reaction in the previous sections. In the following, we shall examine the related hydrogenolysis reaction of eq. [4*c*]. The results from our theoretical study are summarized in Fig. 3 where we present an energy profile for the process. It can be seen from Fig. 3 that the electronic energy of the products (Cl_2LuH and CH_4) is lower than the corresponding energy of the reactants (Cl_2LuCH_3 and H_2) by 16.9 kJ mol^{-1}. It is in fact observed experimentally (3*a*, 3*c*) that the equilibrium in eq. [4*c*] is shifted to the right. The reaction is further seen to have a substantial electronic barrier, $\Delta H^{\neq 1}_{elect}$, of 82.2 kJ mol^{-1}, Fig. 3.

We have optimized the geometry of the reactant Cl_2LuCH_3. The methyl complex has a structure, **6**, with the methyl group bent out of the Cl_2Lu coordination plane. Interestingly, the crystal structure of the related $Cp^*_2ScCH_3$ complex has a planar geometry (3*b*). We have calculated the barrier of inversion for the lutetium methyl to be 13.7 kJ mol^{-1}. In addition, we note that the methyl group can rotate freely about its C_3 axis.

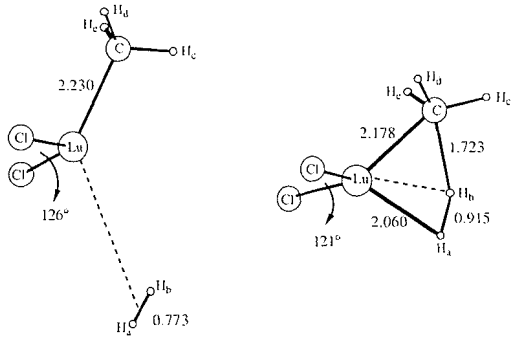


6

The incoming H_2 molecule forms a weak adduct, **7***a*, with Cl_2LuCH_3, **6**, in the early stages of the hydrogenolysis reaction. The adduct is similar to that, $\mathbf{4}_a$, found for the hydrogen exchange process. It has a moderately stretched H_a—H_b bond and the adduct stabilization energy is only 1.6 kJ mol^{-1}.

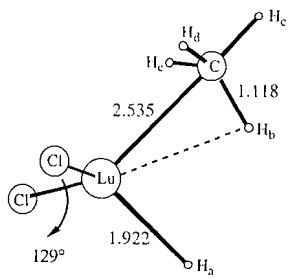
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

The transition state, **7***b*, was optimized without any symmetry constraints. The transition state comprises four centres: Lu, C, H_a, and H_b, arranged in a nearly planar geometry. The structure **7***b* represents an early, reactant-like transition state where the H_a—H_b bond of the dihydrogen is still intact, although stretched from 0.773 to 0.915 Å. On the other hand, the emerging C—H_b bond at 1.723 Å is still much longer than an ordinary aliphatic C—H bond of 1.10 Å. The methyl group in **7***b* can rotate almost freely around its C_3 axis with a relatively modest barrier of 18.2 kJ mol^{-1}.



7*a* **7***b*

The product of the hydrogenolysis reaction is a weak methane adduct, **8**. The Lu—H_a bond distance in **8** is comparable to that of free Cl_2LuH and the methane fragment is only slightly distorted compared to that of free CH_4. The total adduct stabilization for **8** is calculated to be 8.2 kJ mol^{-1}.



8

There are two substantial contributions to the calculated electronic activation barrier of $\Delta H^{\neq}_{elect}$ = 82.2 kJ mol^{-1}. They come from the energy required to deform the two fragments, H_a–H_b and Cl_2Lu–CH_3, to the shapes they take up in the transition state, **7***b*. The energy needed to stretch a hydrogen molecule to coincide with the H_a–H_b fragment of **7***b* is found to be 49.8 kJ mol^{-1}. Clearly, the H_2 molecule undergoes a smaller degree of stretching than in the case of the hydrogen exchange (85.2 kJ mol^{-1}). The energy required to deform the Cl_2LuCH_3 molecule, **6**, to the geometry taken up by the Cl_2Lu—CH_3 framework in **7***b* is calculated to be 35.6 kJ mol^{-1}. The deformation involves an increase in the angle, α, between the C_3 axis of the methyl group and the Lu—CH_3 bond vector by about 40°, Fig. 4. The deformation shown in Fig. 4 redirects the σ-orbital on CH_3 towards the incoming H_b atom at the expense of losing some of the bonding interaction with the d_{xy} orbital on lutetium.

A schematic correlation diagram for the process **7***a* → **7***b* → **8** is presented in Fig. 5. The diagram in Fig. 5 correlates

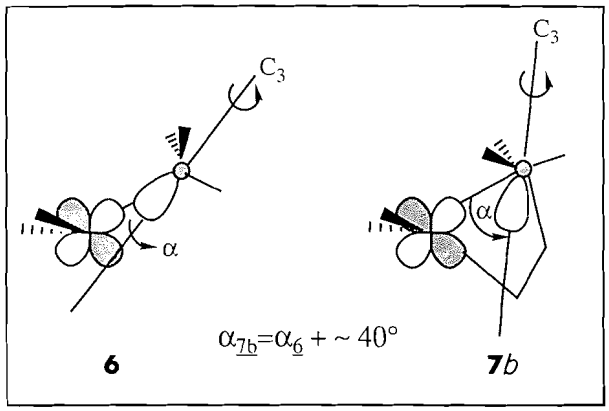


FIG. 4. Deformation of Cl_2LuCH_3 fragment in transition state **7***b*.

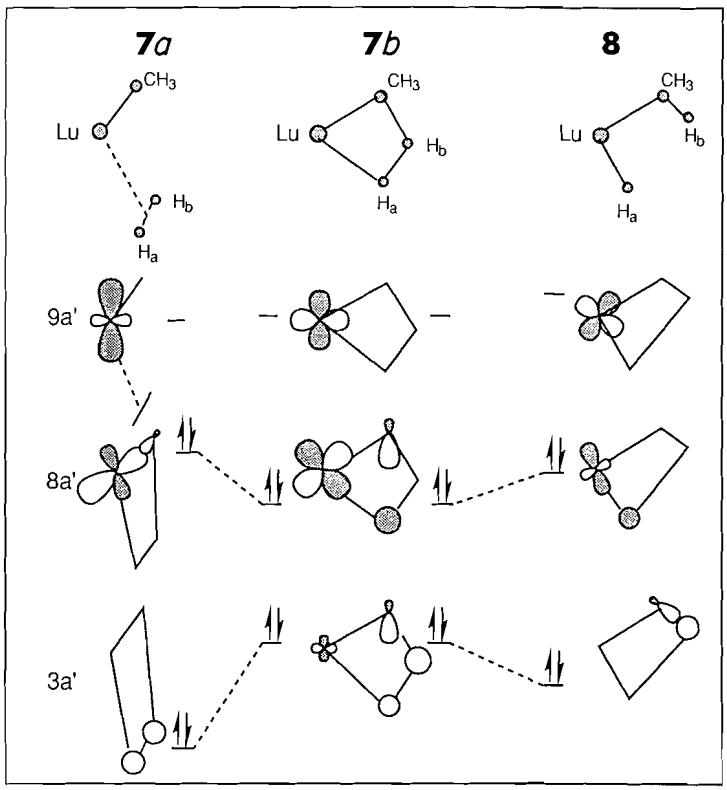

FIG. 5. Correlation diagram for the process $Cl_2LuCH_3(H_2)$ → $Cl_2LuH(CH_4)$. Chlorine and methyl hydrogen atoms are not included.

the two occupied orbitals 3*a*′ and 8*a*′ (HOMO) as well as the 9*a*′ (LUMO) from reactants, **7***a*, to products, **8**. The orbitals 3*a*′ and 8*a*′ hold the two electron pairs involved in bond breaking and bond making during the hydrogenolysis reaction.

The 3*a*′ orbital on the reactants' side represents the H_a—H_b σ-bond of the incoming hydrogen molecule. It correlates smoothly with the C—H_b bond at the product side, **8**, via the virtually ligand-only orbital of the transition state **7***b*. The 3*a*′ orbital is considerably destabilized in the transition state, as the H_a—H_b bond is stretched without any significant bonding interaction between H_b and the methyl carbon. This is in contrast to the previously discussed hydrogen exchange re-

action of eq. [4*a*] where the corresponding 2*a*′ orbital in the transition state **4***c*, see Fig. 2, is characterized by a substantial interaction between H_b and H_c. In that case, the electron pair is residing in a truly three-centre orbital. As already mentioned, it is the lack of a strong three-centre stabilization in 3*a*′ of **7***b* that is primarily responsible for the larger electronic barrier in the hydrogenation reaction compared to the hydrogen exchange process.

The HOMO of the reactant **7***a*, representing the Lu—CH_3 bond, is made up of a $5d_{z^2}/5d_{x^2-y^2}/5d_{xy}/6s$ hybrid on the lutetium centre and σ_{CH_3}. The HOMO of the product **8**, which represents the Lu—H bond, on the other hand comprises another hybrid of different directionality on lutetium, and the 1*s* orbital on the lateral hydrogen atom, H_a. These two HOMOs correlate via the HOMO of the transition state, 8*a*′ (in the middle of Fig. 5).

The presence of several empty orbitals in the 5*d*, 6*s*, and 6*p* shells of lutetium is essential for the change in directionality of the hybrid on the metal. This change is required in order to maintain an optimal overlap with the adjacent ligand orbitals throughout the reaction. As one can easily see from Fig. 5, the $5d_{xy}$ orbital plays an appreciative role in the stabilization of 8*a*′ in the transition state.

Entropies and enthalpies of activation

We have calculated the enthalpies and entropies of activation for the reactions in eqs. [4*a*] and [4*c*]. The kinetic parameters were evaluated in the harmonic oscillator and rigid rotor approximation with the use of standard formulas of statistical mechanics (40). The calculated parameters for the reaction in eqs. [4*a*] and [4*c*] are presented in Tables 1 and 2.

It is clear that $\Delta H^{\neq}$ is dominated by the electronic energy barrier, ΔH_{elect}, of Figs. 1 and 3. The rotational and translational contributions to $\Delta H^{\neq}$ are negative, as one might expect from reactions with a highly ordered transition state, **4***c* and **7***b*. The negative contributions from $\Delta H^{\neq}_{rot}$ and $\Delta H^{\neq}_{trans}$ are simply a consequence of the fact that the reactants have six degrees of translational freedom and five degrees of rotational freedom, whereas the transition states have three of each. It is also consistent with an ordered transition state that the contribution to $\Delta H^{\neq}$ from $\Delta H^{\neq}_{vib}$ is positive. As the transition state is formed from the two reactants, three degrees of translational freedom and two degrees of rotational freedom are transformed into five degrees of vibrational freedom. The additional vibrational degrees of freedom will increase ΔH_{vib} in the transition state.

The vibrational zero-point energy has a positive contribution, $\Delta H^{\neq}_0$, to $\Delta H^{\neq}$. This contribution is given by

$$[7] \qquad \Delta H^{\neq}_0 = \frac{1}{2}\sum_{i=1}^{N(\text{transt.})} hc\omega_i - \frac{1}{2}\sum_{i=1}^{N(\text{reactant.})} hc\omega_i$$

In the two reactions of eqs. [4*a*] and [4*c*] $\Delta H^{\neq}_0$ is positive, Table 2, since

$$[8] \qquad \sum_{i=1}^{N(\text{transt.})} > \sum_{i=1}^{N(\text{reactant.})} \omega_i$$

There are two reasons for this. The first has to do with the fact that the vibrational degrees of freedom in the transition state, N(transt.), exceed the number of vibrational degrees of freedom among the reactants, N(reactant.), by five. The second factor stems from the fact that the weakening of the incoming H_a—H_b bond in the transition states **4***c* and **7***b* is counteracted by the formation of the Lu—H_b bond across the four-centre ring system. We have in addition for **4***c* the formation of an H_c—H_b bond. A transition state for which eq. [8] holds and $\Delta H^{\neq}_0$ is positive could appropriately be termed a bond-making transition state. The total enthalpy of activation at 298.15 K was calculated to be 49.0 kJ mol^{-1}, which is only 4.5 kJ mol^{-1} higher than the calculated electronic barrier, $\Delta H^{\neq}_{elect}$. Thus, the negative contributions from $\Delta H^{\neq}_{rot}$ and $\Delta H^{\neq}_{trans}$ are seen to nearly cancel $\Delta H^{\neq}_{vib}$ and $\Delta H^{\neq}_0$.

The entropies of activation at 298.15 K were calculated to be −109 and −124 J mol^{-1} for the hydrogen exchange and hydrogenolysis reaction respectively. It follows from Table 2 that the negative values for $\Delta S^{\neq}$ are primarily determined by the large negative translational contribution, $\Delta S^{\neq}_{trans}$, and to a lesser extent by the rotational component, $\Delta S^{\neq}_{rot}$. The vibrational term, $\Delta S^{\neq}_{vib}$, is on the other hand positive. The negative values of $\Delta S^{\neq}_{trans}$ and $\Delta S^{\neq}_{rot}$ stem from the decrease in the number of the translational (three) and rotational (two) degrees of freedom of the transition state whereas the posi-

[c]$Cl_2Lu—CH_3 + H_2 \rightarrow Cl_2Lu—H + CH_4$.
[d]$Cl_2Lu—CH_3 + {}^*CH_4 \rightarrow Cl_2Lu—{}^*CH_3 + CH_4$.
[e]$Cl_2Lu—H + CH_4 \rightarrow Cl_2Lu—CH_3 + H_2$.

tive value of $\Delta S^{\neq}_{vib}$ comes from the increase in the number of the vibrational degrees of freedom (five) in the transition state. The relatively large negative entropy of activation once again underlines the highly ordered nature of the transition state. It should be noted that the methyl group in the hydrogenolysis reaction of eq. [4*c*] maintains its free rotation around the C_3 axis from reactant, **7***a*, to the transition state, **7***b*. Thus this degree of freedom does not contribute to either $\Delta H^{\neq}$ or $\Delta S^{\neq}$.

H—C activation

Transition state structures for the methane exchange reaction: $Cl_2Lu—CH_3 + {}^*CH_4 \rightarrow Cl_2Lu—{}^*CH_3 + CH_4$

The methane exchange process in eq. [4*b*] has been studied experimentally for a number of metal centres, including lutetium (3*c–e*), yttrium (3*c–e*), and scandium (3*a,b*). The pioneering steps in this field were taken by Patricia Watson (3*c*), who discovered the methane exchange reaction of eq. [4*b*]. Her discovery was made during an investigation of the reaction between $Cp^*_2Lu—CH_3$ and benzene. Her studies demonstrated that the reaction in eq. [4*b*] has a rate of approximately 4.6 × 10^{-4} M^{-1} s^{-1} at 343 K in the case of Cp^*_2Lu. The reaction is enhanced by the more electrophilic yttrium (k = 2.6 × 10^{-3} M^{-1} s^{-1} at 343 K) and inhibited in the case of the more nucleophilic scandium (k = 1 × 10^{-5} M^{-1} s^{-1} at 353 K).

The results from our calculations are summarized in the reaction profile in Fig. 6. We have located a methane adduct, **9***a*, at the early stages of the methane reaction. The formation enthalpy for **9***a* was calculated to be 19.4 kJ mol^{-1}, which makes **9***a* less stable then the reactants Cl_2LuCH_3 and CH_4.

The methane exchange reaction has a substantial electronic barrier of 108.6 kJ mol^{-1}, Fig. 6. The associative transition state, **9***b*, is of C_{2v} symmetry. It follows from the optimized transition state structure that the $C_1—H_a$ bond of the incoming methane has been stretched almost to the breaking point with a $C_1—H_a$ bond distance of 1.56 Å. This stretch requires 150.3 kJ mol^{-1} and is thus a major contributor to the sizable electronic barrier of $\Delta H^{\neq}_{elect}$ = 108.6 kJ mol^{-1}. Each of the methyl groups in **9***b* has a tilting angle, α, of 38°, which is quite similar to that of 41° calculated for the methyl group in **7***b*. The tilting angle adopted in **9***b* is a compromise between a value of α ~ 5° for the optimal interaction between lutetium and the two methyl groups and a value of α ~ 55° for the optimal interaction between H_a and

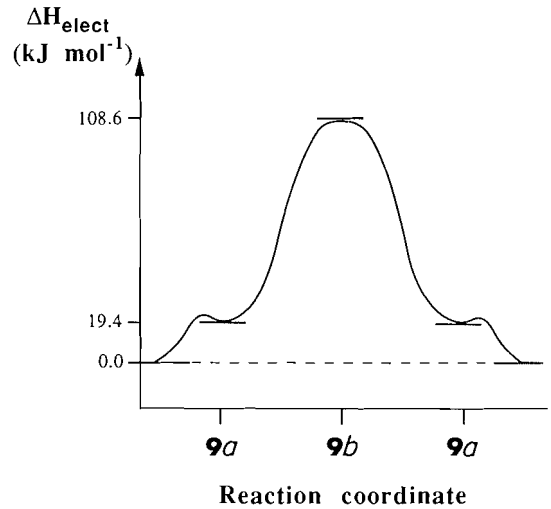

FIG. 6. Profile for the reaction $Cl_2LuCH_3 + {}^*CH_4 \rightarrow Cl_2Lu{}^*CH_3 + CH_4$. The energies are relative to the reactants (products).

the same two methyl groups. This compromise ensures the best simultaneous overlap between the highly directional σ_{CH_3} orbitals on the methyl groups and orbitals on the adjacent lutetium and H_a centres. The price paid for this compromise is a considerable elongation of the Lu—C and C—H_a links in the four-centre transition state, **9***b*. Thus, the Lu—C distance in **9***b* is 0.1 Å longer than the regular Lu—C bond in **6**, whereas the C—H_a distances in **9***b* are nearly 0.4 Å longer than a normal C—H bond. It should also be noted that the two CH_3 groups in **9***b* can rotate freely around their C_3 axis. The central H_a atom has a rather short distance to lutetium of 1.920 Å. The short distance, in conjunction with the spherical nature of the 1*s* orbital on H_a, facilitates a substantial Lu–H interaction in addition to the C—H_a bonds.

Both C—H_a distances are somewhat shorter than the corresponding C—H_b distance of **7***b* (1.723 Å). The $C_1—H_a—C_2$ angle is 167° in **9***b* and differs from the C—$H_b—H_a$ angle of 155° in **7***b* and from the $H_a—H_b—H_c$ angle of 154° in **4***c*. The across-the-ring Lu–H_a distance of 1.92 Å is slightly shorter than the calculated 1.96 Å in **7***b* and the corresponding Lu–H_b separation of 2.03 Å in **4***c*. These trends are facilitated by the wider $C_1—Lu—C_2$ angle of 84° in **9***b* compared to the C—Lu—H_a angle of 75° in **7***b* and the 59° $H_a—Lu—H_c$ angle in **4***c*. A Hückel calculation (5) performed on a comparable transition state with the Cp rings in

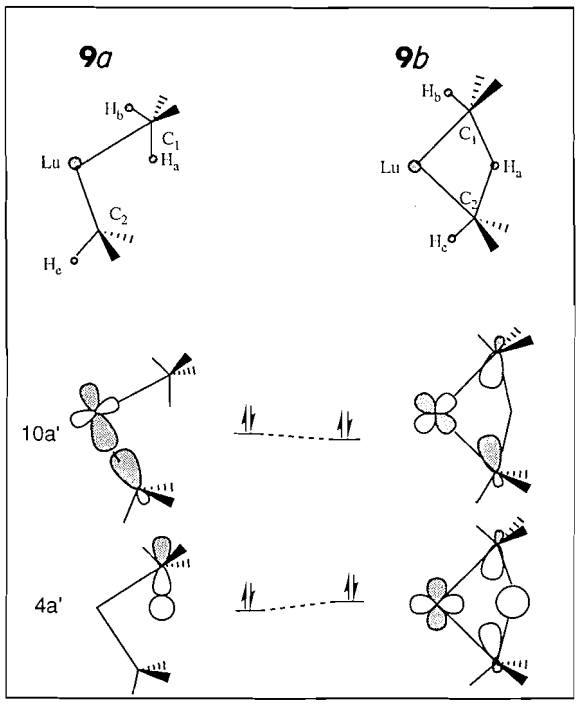

FIG. 7. Correlation diagram for the process $Cl_2Lu—CH_3 + {}^*CH_4 \rightarrow Cl_2LuCH_3({}^*CH_4)$. Chlorine atoms are not included.

place of chlorine atoms revealed a structure quite similar to **9***b*. The tilting angle α between the C_3 axis of each of the equivalent methyl groups and the corresponding Lu—C bond was calculated to be 43.0°. However, the Hückel calculation found a substantially higher electronic barrier, $\Delta H^{\neq}_{elect}$, of about 190 kJ mol^{-1}.

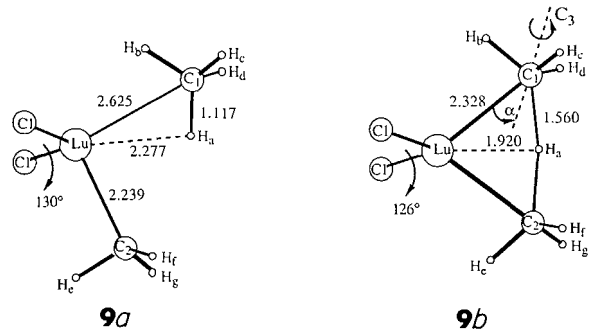

Figure 7 represents a correlation diagram for the passage from **9***a* to **9***b*. The occupied 4*a*′ and 10*a*′ (HOMO) orbitals are shown because of their role in bond breaking and bond formation during the methane exchange reaction. On the reactants' side, the 4*a*′ orbital represents the $C_1—H_a$ σ-bond of the methane molecule. It is composed of σ_{CH_3} on C_1 and the 1*s* orbital on H_a. In the transition state, the 4*a*′ orbital is a three-centre bonding orbital comprising the two σ_{CH_3} hybrids on the methyl groups and the 1*s* orbital on H_a. The orientation of the σ_{CH_3} hybrids is clearly not optimal for the $C_1—H_a—C_2$ interaction. An optimal interaction would have required a tilting angle of α = 55°.

The highest occupied molecular orbital on the reactants' side corresponds to the Lu—C σ-bond of the lutetium methyl molecule. It is made up of a $5d_{xy}/5d_{z^2}/5d_{x^2-y^2}/6s$ hybrid on the metal centre and a σ_{CH_3} orbital on the C_2 atom. It correlates with a three-centre HOMO in the transition state, representing a bonding interaction between the d_{xy} orbital on lutetium and an out-of-phase combination between the σ_{CH_3} orbitals on the two equivalent methyl groups. During the course of the reaction, the metal *d* component in 10*a*′ undergoes a rehybridization, analogous to that seen in the hydrogen exchange or the hydrogenolysis processes. The presence of the empty *d* orbitals, in particular d_{xy} and $d_{x^2-y^2}$, on the metal fragment, makes such a rehybridization possible. We note that the orientation of the σ_{CH_3} lobes is less than optimal for the interaction between σ_{CH_3} and d_{xy}. An optimal interaction would have required a tilting angle of α = 5°.

It follows from our analysis that two main factors contribute to the substantial electronic activation barrier of 108.6 kJ mol^{-1} for the methane exchange reaction. The first is related to the stretch of the $C_1—H_a$ bond in the incoming methane, which amounts to 152 kJ mol^{-1}. The second stems from the inability of the directional σ_{CH_3} orbital to attain at the same time optimal stability in the 4*a*′ and 10*a*′ orbitals of the transition state **9***b* for any orientation of the methyl groups.

Transition state structures for the methylation reaction:

$$Cl_2Lu—H + CH_4 \rightarrow Cl_2Lu—CH_3 + H_2$$

Entropies and enthalpies of activation

We have calculated the contributions to $\Delta H^{\neq}$ and $\Delta S^{\neq}$ for the two C—H activating processes in eqs. [4*b*] and [4*d*]. The results are compared in Tables 1 and 2 to similar calculations involving the two H—H activating processes of eqs. [4*a*] and [4*c*]. It is interesting to note that $\Delta H^{\neq}_0$, from the zero-point correction of eq. [7], is the only contribution to $\Delta H^{\neq}$ that differs qualitatively between the two types of reactions. Thus $\Delta H^{\neq}_0$ is positive for the H—H activating processes and negative for the C—H activating processes, Table 2. Both types of reactions have, as already discussed previously, four-centre transition states encompassing elements of bond making and bond breaking. However, the C—H activating processes involve a transition state in which a C—H bond has been stretched to the breaking point so that:

$$[9] \quad \sum_{i=1}^{N(transt.)} \omega_i < \sum_{i=1}^{N(reactant.)} \omega_i$$

As a consequence, the contribution to $\Delta H^{\neq}$ from the zero point energy, $\Delta H^{\neq}_0$, is negative. The H—H bonds of the incoming hydrogen molecules in the transition states of the H—H activating processes are not stretched to the same extent, with the result that eq. [8] applies and $\Delta H^{\neq}_0$ is positive. One might say, based on the different signs for $\Delta H^{\neq}_0$, that the C—H activating reactions approach the transition state in a process that is net bond breaking whereas the H—H activating reactions approach the transition state in a process that is net bond making.

The entropies of activation at 298.15 K were calculated to be −131.1 and −134.7 J mol^{-1} for the methane exchange and methylation reaction, respectively. Thus $\Delta S^{\neq}$ is somewhat more negative for the C—H activating processes compared to the reactions involving H—H activation, Table 2. The negative activation entropy is largely determined by the loss of three translational degrees of freedom as the incoming H_2 or CH_4 molecules are incorporated into the four-centre transition state. However, the decrease in entropy is

somewhat more pronounced for CH_4 due to its larger mass (40).

Concluding remarks

We have investigated four σ-bond metathesis reactions mediated by the electron-poor lutetium metal centre. The four processes include hydrogen exchange, eq. [4*a*], and hydrogenolysis, in which an H—H bond is activated, as well as methane exchange, eq. [4*b*], and methylation, eq. [4*d*], in which a C—H bond is activated. We find all processes to have a highly ordered transition state with a negative entropy of activation ($\sim$100 J mol^{-1} K^{-1}).

The calculated Gibb's free energy of activation, $\Delta G^{\neq}$ ($=\Delta H^{\neq} - T\Delta S^{\neq}$) increases from 81.6 kJ mol^{-1} for the hydrogen exchange reaction to 126.0 kJ mol^{-1} for the hydrogenolysis process and 136.7 kJ mol^{-1} for the methane exchange reaction, Table 2. This trend is a result of an increasing electronic barrier, which plays a dominating role in the determination of the activation enthalpy. Also, the entropy of activation contributes to this trend by adopting an increasingly negative value. The calculated trends in $\Delta G^{\neq}$ are consistent with the trend observed by Bercaw and coworkers (3) for the organo-scandium species and indicate the following decrease in the reactivity of the R—H bonds with various M—R′ linkages: R = R′ = H >> R = H, R′ = CH_3 > R = R′ = CH_3. The decrease in the reaction rate is related to the different abilities of the 1*s* hydrogen orbital and the σ_{CH_3} methyl orbital to stabilize the four-centre transition state. Thus, the spherical 1*s* hydrogen orbital is better able to overlap fully with orbitals on adjacent centres than the directional σ_{CH_3} orbital. As a consequence, the electronic barrier is seen to increase, Table 2, from the hydrogen exchange reaction towards the hydrogenolysis and methane exchange processes as one or two hydrogens, respectively, are replaced by methyl groups in the four-centre transition state.

The hydrogen exchange process as well as the hydrogenolysis reaction is characterized by a positive zero-point energy correction, $\Delta H_0^{\neq}$, to the total activation, see Table 2. This is understandable since the weakening of the H—H bond in the transition state for the two processes (**4***c* and **7***b*, respectively) is more than compensated for by the formation of strong Lu—H and H—H (**4***c*) bonding interactions. The result is a net bond formation. The methane exchange reaction has, on the other hand, a negative contribution from $\Delta H_0^{\neq}$, Table 2. This can be attributed to the "classical" character of the transition state, **9***b*, for this reaction. Thus, in **9***b* a C—H bond (C_1—H_a) of an incoming methane molecule has been broken, and this bond breaking has not yet been compensated for by the formation of a new C—H bond (C_2—H_a) or a full Lu–C (Lu–C_1) interaction.

On the allowed symmetries of all distorted forms of conformers, molecules, and transition structures

PAUL G. MEZEY

Department of Chemistry and Department of Mathematics, University of Saskatchewan, Saskatoon, Sask., Canada S7N 0W0

Received June 17, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

PAUL G. MEZEY. Can. J. Chem. **70**, 343 (1992).

Based on the catchment region point symmetry theorem, a general framework and some new results are presented on symmetry constraints of deformations preserving chemical identity. The point symmetries of the unique critical point (equilibrium) nuclear arrangement corresponding to a conformer, molecule, or a transition structure and those of a family of nuclear arrangements with an arbitrarily small limit on the allowed distortions provide a complete symmetry characterization of the entire potential surface catchment region of the chemical species. Consequently, the point symmetries of all distorted molecular forms that preserve chemical identity can be deduced by testing symmetry conditions only within an arbitrarily small domain of the potential surface, in the vicinity of the equilibrium arrangement. Additional constraints are deduced on the point symmetries of transition structures obtained directly from the given conformer.

Key words: molecular distortions, symmetry, catchment regions, new symmetry theorems, framework groups, point groups.

PAUL G. MEZEY. Can. J. Chem. **70**, 343 (1992).

En se basant sur le théorème de la symétrie du point dans la région de captation, on présente un cadre général et quelques nouveaux résultats relatifs à la symétrie des contraintes de déformation qui préservent l'identité chimique. Les symétries de point du point critique unique (équilibre) de l'arrangement nucléaire correspondant à un conformère, la molécule ou la structure de transition et celles d'une famille d'arrangements nucléaires, avec une faible tolérance arbitraire pour les distorsions permises, fournissent une caractérisation complète de la symétrie de toute la surface de potentiel de la région de captation des espèces chimiques. En vérifiant les conditions de symétrie uniquement à l'intérieur du faible domaine arbitraire de la surface de potentiel au voisinage de l'arrangement à l'équilibre, on peut alors déduire les symétries de point de toutes les formes moléculaires déformées qui préservent l'identité chimique. On déduit des contraintes additionnelles sur les symétries de point des structures de transition obtenues directement a` partir du conformère donné.

Mots clés : distorsions moléculaires, symétrie, régions de captation, nouveaux théorèmes de la symétrie, cadre général, groupes de point.

Introduction

Point symmetries of equilibrium nuclear arrangements, of stable configurations and transition structures, have been recognized as important tools for the analysis of molecular properties and reaction processes (e.g., refs. 1–9). Whereas the early studies focussed on individual nuclear configurations or on specific reaction paths, in a recent study some new results have been derived using a global approach and a symmetry domain partitioning of the nuclear configuration space (10). In this note we shall extend this approach in order to derive some new results on the available symmetries of distorted nuclear configurations that preserve the chemical identity of the molecular species.

The range and type of distortions that preserve the chemical identity of molecular conformations, individual molecules, or transition structures are dependent on the potential energy hypersurface belonging to the given stoichiometry (and to the given electronic state, usually the electronic ground state). Even small distortions may lead to changes in conformational classification, and if the disortions are large enough then a molecule cannot preserve its identity; a chemical reaction occurs. Some of these distortions may preserve the point symmetry of nuclear configurations while some others do not, and, in fact, these distortions may lead to major symmetry changes. However, not all point symmetries are available for each chemical species of the given stoichiometry, even if the given stoichiometric family of nuclei does have possible arrangements with these symmetries. For example, any planar arrangement of an NH_3 system (of no coincident nuclei) belongs to the transition structure catchment region of the pyramidal inversion process of ammonia, or to the catchment region of another non-ammonia species, and no planar symmetry may occur within the family of distorted ammonia configurations that preserve chemical identity. Fortunately, the deformations leading to specified symmetry changes and those leading to chemical identity changes are interrelated. These interrelations can be studied by taking a global configuration space approach (11). A recent result on the global symmetry analysis of nuclear configuration spaces is the *catchment region point symmetry theorem* (10): *within each catchment region the critical point nuclear configuration has the highest point symmetry*. In addition, point symmetry groups occurring within a catchment region of a stable conformer or a molecule have an algebraic structure: they form an algebraic lattice (12). Although this result provides some constraints on the point symmetry groups, by itself it is insufficient to decide which actual point symmetry groups are available for distorted configurations. Based on these results, we shall provide here a general framework and a new rule for the study of symmetries of chemical identity preserving deformations.

We shall use the terminology and basic concepts re-

viewed recently in ref. 10; further background and more detail on the global properties of potential energy hypersurfaces may be found in ref. 11. Here only a brief summary of the background will be given.

A *stoichiometric family* of chemical species is defined by specifying N nuclei as well as an overall charge and electronic state. The stoichiometric family includes all conformers and isomers of all stable molecules, transition structures, reaction intermediates, decomposition products, as well as all their distorted conformations that have the given overall atomic composition. All possible internal (relative) nuclear arrangements (nuclear configurations) for $N \geq 3$ nuclei can be described by $3N - 6$ internal coordinates; the collection of all possible nuclear arrangements forms a $(3N - 6)$-dimensional *nuclear configuration space*. This space may be chosen as a *metric* space M with a global metric (11), that is, with a global distance function, where the distance between any two points K and K' of M is a measure of dissimilarity between the corresponding two nuclear configurations. For a given electronic state a potential energy value can be assigned to each configuration K; this assignment generates a *potential energy hypersurface* $E(K)$ over M. At each *critical point* of a potential energy surface the energy gradient vanishes. The second energy derivatives are the elements of the *Hessian matrix* of the critical point. For an ordinary (non-degenerate) energy minimum, all eigenvalues of the Hessian matrix are positive; for a simple saddle point of a transition structure, precisely one eigenvalue is negative. The *index* λ of the critical point $K(\lambda,i)$ is the number of negative eigenvalues of the Hessian matrix $H(K(\lambda,i))$ and i is a serial index. If the local internal coordinates are derived from the *mass-weighted Cartesian coordinates* of the nuclei, then a *steepest descent path* represents a formal, infinitely slow relaxation of nuclear configurations. A *catchment region* is a subset of M, representing the range of deformations that preserve chemical identity of a chemical species of a given electronic state. By an equivalent definition, a catchment region $C(\lambda,i)$ of a potential energy hypersurface is that subset of nuclear configurations from where the relaxation paths lead to a common critical point $K(\lambda,i)$ of the potential energy hypersurface. The catchment region $C(0,i)$ of the minimum point $K(0,i)$ represents the ith stable molecular species (conformer or molecule) of the given stoichiometry and the electronic state of the given potential energy hypersurface $E(K)$; the steepest descent paths from all points K of the catchment region $C(0,i)$ lead to the minimum point $K(0,i)$. The dimension of $C(0,i)$ is (almost always) $3N - 6$. A transition structure is (almost always) represented by a $(3N - 7)$-dimensional catchment region $C(1,j)$ of a saddle point $K(1,j)$ of critical point index $\lambda = 1$. For sake of simplicity in the terminology, the less important catchment regions of higher critical point indices are also referred to as formal chemical species.

We shall use the following terminology: an n-dimensional hypersurface C_n within a nuclear configuration space M is a *relaxed cross section* of M with respect to a given potential energy hypersurface $E(K)$ if at every point K of C_n the energy gradient is tangential to C_n (10). (Note that alternative definitions are also known; however, as it has been pointed out in ref. 10, these alternative definitions do not always satisfy some coordinate-invariance requirements.) Relaxed cross sections are of importance in potential surface analysis; for example, a typical catchment region of a transition structure is a $(3N - 7)$-dimensional subset of a relaxed cross section C_n of M, with $n = (3N - 7)$. Since neither steepest descent nor steepest ascent paths may leave such a hypersurface C_n, relaxed cross sections have many properties analogous to properties of the complete nuclear configuration space M, even if the dimension n is much lower than the dimension $3N - 6$ of M. In particular, the following catchment region point symmetry theorem is equally applicable within the configuration space M and within its relaxed cross sections C_n (10):

Within each catchment region $C(\lambda,i)$*, the nuclear configuration corresponding to the critical point* $K(\lambda,i)$ *has the highest point symmetry (a proof is given in ref. 10).*

The expression "highest point symmetry" refers to group–subgroup relations: within a catchment region $C(\lambda,i)$, the point symmetry group of the critical point $K(\lambda,i)$ contains as subgroups all other point symmetry groups occurring in $C(\lambda,i)$, where each point symmetry group is considered to be one of its own subgroups. The critical point $K(\lambda,i)$ is not necessarily the only point within the catchment region $C(\lambda,i)$ that has the highest point symmetry. For example, all points of the catchment region $C(\lambda,i)$ may have the same (and by default, the highest) point symmetry.

The simplest proof of this result is based on an earlier result of Pechukas (6): if mass-weighted coordinates are used, then all point symmetry (and all framework group) elements of nuclear configurations are preserved along segments of steepest descent paths between critical point. By limit arguments, the group element occurring along the path must also be present at the critical point at the end of the path, and additional elements may appear only at the critical points.

The catchment region point symmetry theorem provides a link between the point symmetry of the nuclear arrangement (a purely geometrical property) and molecular stability (an energy-dependent property). The theorem is applicable for the potential energy surfaces and catchment regions of all electronic states of all neutral and ionic species of the given stoichiometric family (10).

In what follows below, we shall apply a similar approach for deriving symmetry conditions on all chemical identity preserving deformations of molecules, testing only an arbitrarily small neighborhood of the critical points of catchment regions.

A symmetry theorem on neighborhoods of critical points

We shall consider a small limit r for distortions of an equilibrium nuclear configuration $K(\lambda,i)$. This limit r is given in terms of the configuration space distance function (metric) $d(K,K')$, expressing the dissimilarity of two nuclear configurations K and K'.

Take an n-dimensional catchment region $C(\lambda,i)$ of the nuclear configuration space M, where $n = 3N - 6 - \lambda$, the typical case. (Note that for a minimum point $K(\lambda,i)$ the index $\lambda = 0$ and the dimension of the corresponding catchment region $C(\lambda,i)$ is usually $n = 3N - 6$, whereas for saddle points of transition structures the typical case corresponds to $\lambda = 1$ and $n = 3N - 7$.) The catchment region $C(\lambda,i)$ is a subset of an n-dimensional relaxed cross section C_n of the nuclear configuration space M. Consider a radius $r > 0$, and the n-dimensional ball $B(C(\lambda,i), r)$ containing all those points K of the relaxed cross section C_n that are at distance r or less from the critical point $K(\lambda,i)$,

$$[1] \quad B(C(\lambda,i), r) = \{K : K \in C_n, d(K(\lambda,i), K) \leq r\}$$

The $(n - 1)$-dimensional boundary sphere of this ball $B(C(\lambda,i), r)$ is denoted by $S(C(\lambda,i), r)$,

[2] $S(C(\lambda,i), r) = \{K : K \in C_n, d(K(\lambda,i), K) = r\}$

If this radius r is a small enough positive value then the ball $B(C(\lambda,i), r)$ and, hence, its boundary sphere $S(C(\lambda,i), r)$ fall within the catchment region $C(\lambda,i)$:

[3] $B(C(\lambda,i), r) \subset C(\lambda,i)$

and

[4] $S(C(\lambda,i), r) \subset C(\lambda,i)$

Choose any configuration K from catchment region $C(\lambda,i)$, different from the critical point $K(\lambda,i)$,

[5] $K \in C(\lambda,i)$

[6] $K \neq K(\lambda,i)$

If K is not within $B(C(\lambda,i), r)$, that is, if

[7] $K \in C(\lambda,i) \backslash B(C(\lambda,i), r)$

then the steepest descent path from K must pass through $S(C(\lambda,i), r)$ at some point K' as it leads to $K(\lambda,i)$. Note that $C(\lambda,i)$ and $B(C(\lambda,i), r)$ are within the same relaxed cross section C_n of the nuclear configuration space M. Consequently, a path of steepest descent from K must stay within C_n, and hence it cannot avoid passing through the sphere $S(C(\lambda,i), r)$. Also note that, due to condition [4] and to the positivity of r, point K' of the boundary sphere $S(C(\lambda,i), r)$ cannot be a critical point. Consequently, by the preservation of point symmetry elements along steepest descent paths, sphere $S(C(\lambda,i), r)$ must have a point K' with precisely the same point symmetry elements as K.

Alternatively, if K is within $B(C(\lambda,i), r)$,

[8] $K \in B(C(\lambda,i), r)$

then the steepest ascent path from K must contain a point K' common with sphere $S(C(\lambda,i), r)$. Consequently, by the preservation of point symmetry elements along steepest ascent paths, sphere $S(C(\lambda,i), r)$ must have a point K' with precisely the same point symmetry elements as K. This proves the following theorem.

Theorem 1

Each point symmetry group $g(K)$ present for any distorted nuclear configuration K of a $(3N - 6 - \lambda)$-dimensional catchment region $C(\lambda,i)$ is also present at some configuration K' on a $(3N - 6 - \lambda - 1)$-dimensional sphere $S(C(\lambda,i), r)$ of center $K(\lambda,i)$ and of an arbitrarily small positive radius r, where r is small enough so that $S(C(\lambda,i), r)$ falls within the catchment region $C(\lambda,i)$.

Comment 1: Distortions are considered with reference to the equilibrium (critical point) nuclear configuration $K(\lambda,i)$, which is not regarded distorted. Of course, the point symmetry group $g(K(\lambda,i))$ (the group of highest symmetry within $C(\lambda,i)$) does not have to occur along the sphere $S(C(\lambda,i), r)$, but it does occur if for some other point K, $g(K) = g(K(\lambda,i))$ holds.

Comment 2: It is computationally much simpler to find a critical point on a potential surface than to find the boundaries of its catchment region. The above theorem allows one to obtain information on the extent of a catchment region by finding out all point symmetry groups that occur within the catchment region. This can be accomplished by testing the point symmetries only along a small sphere of distorted configurations around the critical point.

Comment 3: The above theorem provides more information than the catchment region point symmetry theorem. By knowing the point symmetry group $g(K(\lambda,i))$, and knowing that it is the largest point symmetry group within the catchment region $C(\lambda,i)$, there is often ambiguity concerning the actual point symmetry groups occurring within $C(\lambda,i)$. Note that it is not necessary for a catchment region to contain configurations having point symmetries corresponding to each subgroup of $g(K(\lambda,i))$. The same group $g(K(\lambda,i))$ may be obtained as a result of combining a different collection of its subgroups. A trivial example is the case where all configurations K of $C(\lambda,i)$ have the same point symmetry group $g(K(\lambda,i))$ and no configuration K of $C(\lambda,i)$ has any one of the nontrivial subgroups g of $g(K(\lambda,i))$ as its point symmetry group.

Spherical maps of point symmetries of catchment regions and their boundaries

We shall use the above theorem to compare point symmetry groups of a catchment region $C(\lambda,i)$ with those occurring on its boundary $B(\lambda,i)$. We have seen above that the point symmetry group $g(K)$ of any (non-critical) point K of a catchment region $C(\lambda,i)$ is present at some point K' of a small sphere $S(C(\lambda,i), r)$ around the critical point $K(\lambda,i)$. This generates a symmetry-preserving $K \rightarrow K'$ assignment of all points of $C(\lambda,i) \backslash K(\lambda,i)$ to points of the sphere $S(C(\lambda,i), r)$.

Let us denote by G_i the collection of all those points K' of the sphere $S(C(\lambda,i), r)$ where the three-dimensional point symmetry group of nuclear configurations is g_i:

[9] $G_i = \{K' : K' \in S(C(\lambda,i), r), g(K') = g_i\}$

Each set G_i may be disconnected and we shall consider their maximum connected components G_{ik}.

These sets G_{ik} provide a symmetry-domain partitioning of the sphere $S(C(\lambda,i), r)$ that reflects all possible point symmetries of distorted configurations of $C(\lambda,i)$. The pattern and neighbor relations of these symmetry domains G_{ik} on the sphere $S(C(\lambda,i), r)$ provide a detailed symmetry characterization of the catchment region.

Consider now another map on the sphere $S(C(\lambda,i), r)$ that describes the point symmetry groups occurring along the boundary $B(\lambda,i)$ of the catchment region $C(\lambda,i)$. If the catchment region $C(\lambda,i)$ is that of an energy minimum, $\lambda = 0$, then most of the nuclear configurations along the boundary $B(\lambda,i)$ are those of transition structure catchment regions. Hence, the results we shall describe below are of relevance to transition structures, which are the easiest to visualize in the two-dimensional case. However, we shall not rely on (often misleading) visualization and the derivation will be general for the multidimensional case of any catchment region $C(\lambda,i)$ of arbitrary index λ.

The $(3N - 6 - \lambda - 1)$-dimensional boundary $B(\lambda,i)$ divides the relaxed cross section C_n into two subsets: to the catchment region $C(\lambda,i)$ and the remainder $C_n \backslash C(\lambda,i)$ of the cross section C_n (we regard $B(\lambda,i)$ as a part of this second subset).

Each point K of the boundary $B(\lambda,i)$ has some point symmetry $g(K)$. In addition, to each point K of $B(\lambda,i)$ we assign a point symmetry $g'(K)$, which is one of point symmetries occurring within the catchment region $C(\lambda,i)$. To generate this assignment, we first note that the boundary surface $B(\lambda,i)$ is topologically equivalent to a $(3N - 6 - \lambda - 1)$-dimen-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

sional smooth surface $S(\lambda,i,w)$ placed within $C(\lambda,i)$, where the homeomorphism

$$[10] \quad h(K) = K'', K \in B(\lambda,i), K'' \in S(\lambda,i,w)$$

establishing the topological equivalence between $B(\lambda,i)$ and $S(\lambda,i,w)$ is chosen so that

$$[11] \quad d(K,K'') < w$$

for some small positive value w. As $w \to 0$, $K'' \to K$ follows. By limit arguments, for an infinitesimal w, all the point symmetry elements of K'' must also be present for configuration K at the boundary $B(\lambda,i)$:

$$[12] \quad g(K'') \subset g(K)$$

However, K is not on any steepest descent path leading to the critical point $K(\lambda,i)$ of the catchment region $C(\lambda,i)$; consequently, the group $g(K)$ at point K may have some additional point symmetry elements besides those present in $g(K'')$. Hence the two groups, $g(K)$ and $g'(K) = g(K'')$ are not necessarily the same.

By the composition of the above $K \to K''$ assignment and the $K'' \to K'$ assignment generated by the paths of steepest descent from each point K'' of the $S(\lambda,i,w)$ surface to a point K' on the sphere $S(C(\lambda,i), r)$, one obtains a $K \to K'$ assignment of the boundary points K of $B(\lambda,i)$ to points K' on the sphere $S(C(\lambda,i), r)$. Take now the point symmetry $g(K)$ and assign it to the corresponding point K' on the sphere $S(C(\lambda,i), r)$. This assignment is denoted by

$$[13] \quad g_a(K') = g(K)$$

generating a new point symmetry map on sphere $S(C(\lambda,i), r)$.

The range of the $K \to K'$ assignment is denoted by $S'(C(\lambda,i), r)$. If the boundary surface $B(\lambda,i)$ is closed, then the $K \to K'$ assignment is onto $S'(C(\lambda,i), r) = S(C(\lambda,i), r)$, hence the new symmetry map of the $g_a(K')$ point symmetry groups covers the entire sphere $S(C(\lambda,i), r)$. Otherwise we obtain a new symmetry map only on a subset $S'(C(\lambda,i), r)$ of the sphere $S(C(\lambda,i), r)$, $S'(C(\lambda,i), r) \neq S(C(\lambda,i), r)$. This map represents the $g(K)$ point symmetry group distribution along the boundary $B(\lambda,i)$ of catchment region $C(\lambda,i)$.

Let us denote by G'_i the collection of all those points K' of the sphere $S(C(\lambda,i), r)$ where the assigned three-dimensional point symmetry group $g_a(K')$ is g'_i:

$$[14] \quad G'_i = \{K': K' \in S(C(\lambda,i), r), g_a(K') = g_i\}$$

As in the case of the previous partitioning, each set G'_i may be disconnected and we shall consider their maximum connected components G'_{ik}.

The symmetry domains G'_{ik} generate a partitioning of the sphere $S(C(\lambda,i), r)$ reflecting all the point symmetries of configurations along the boundary $B(\lambda,i)$ of catchment region $C(\lambda,i)$. *These are the configurations that are distorted to a critical extent, sufficient to change their chemical identity,* as compared to the chemical species represented by the catchment region $C(\lambda,i)$. The pattern and neighbor relations of the symmetry domains G'_{ik} on the sphere $S(C(\lambda,i), r)$ provide a detailed symmetry characterization of the boundary $B(\lambda,i)$ of the catchment region $C(\lambda,i)$.

The two maps on sphere $S(C(\lambda,i), r)$ are not independent. By taking into account the range of assignment $K \to K'$, a simple substitution of eq. [13] into relation [12] proves the following theorem.

Theorem 2

For any point $K' \in S'(C(\lambda,i), r)$, the actual point symmetry group $g(K')$ is a subgroup of the corresponding boundary point symmetry group $g_a(K')$:

$$[15] \quad g(K') \subset g_a(K'), \qquad K' \in S'(C(\lambda,i), r)$$

Comment 1: This result can be rephrased as follows. Consider the pattern of point symmetry group distribution along the boundary $B(\lambda,i)$ of a catchment region $C(\lambda,i)$, and the pattern of point symmetry groups along a sphere around the critical point $K(\lambda,i)$. These patterns can be interrelated so that the boundary pattern is "superior" to the pattern present along the sphere, where term "superior" indicates a pointwise group/subgroup relation.

Comment 2: Combining this result with the catchment region point symmetry theorem leads to an interesting observation. Ordinary points K' of a catchment region $C(\lambda,i)$ are "symmetry-dominated from both inside and outside" of the catchment region: both the critical point $K(\lambda,i)$ (dominance from the "inside") and the corresponding boundary point K (dominance from the "outside") have point symmetry groups that are never proper subgroups, but are possibly supergroups of the point symmetry group of K':

$$[16] \quad g(K(\lambda,i)) \supset g(K') \subset g(K)$$

Symmetry-wise, ordinary points K' of a catchment region are "squeezed" in between the critical point $K(\lambda,i)$ and the boundary $B(\lambda,i)$ of the catchment region $C(\lambda,i)$.

Two generalizations

For each symmetry operator R of a nuclear configuration K, one may assign a permutation operator P by the following rule: the rearrangement of identical nuclei caused by the symmetry operator R is undone by the permutation P of identical nuclei. For two different nuclear configurations, K_1 and K_2 of the same set of nuclei, both having a given symmetry operator R, the assigned permutation operators P_1 and P_2 may be different. That is, the point symmetry operator R does not determine the permutation operator P in general. For each configuration K the pairs (R,P) of associated operators form a group, often referred to as the framework group of configuration K. Framework groups provide more information than point symmetry groups.

As a consequence of framework group invariance along noncritical segments of steepest descent paths (6) and the catchment region framework group theorem (10), all results of this study remain valid if one replaces point symmetry groups and their elements with framework groups and their elements, respectively. This generalizes the two theorems of this study to framework groups and their maps.

Another generalization is provided by noting that point symmetry and framework group conservation are equally valid along steepest descent and steepest ascent paths. Hence the results derived in this study are also valid for the "upside down" energy hypersurface $-E(K)$. Note that the catchment regions of $E(K)$ and the formal catchment regions of $-E(K)$ are in general different, hence applying the theorems to $-E(K)$ does provide new information.

Conclusions

All the point symmetries available to the distorted nuclear configurations of a conformer, molecule, or transition structure can be accounted for by considering a small family of nuclear configurations along a sphere of arbitrarily small positive radius, centered on the equilibrium configuration of the species. The distortions are restricted to those preserving the chemical identity of the species, that is, to configurations within a catchment region. Distances (expressing dissimilarity of configurations), radii, and the corresponding spheres are taken within a metric configuration space M. By testing point symmetries within a small sphere around the equilibrium configuration, these results allow one to calculate and account for all possible symmetries actually present within the entire catchment region even if the extent and shape of the catchment region is not known. The pattern of point symmetry group distribution along the sphere shows an interesting relation with the pattern of point symmetry groups along the boundary of the catchment region, that is, along the hypersurface of configurations representing borderline distortions with respect to the preservation of chemical identity. An assignment between configurations of the sphere and those of the boundary surface implies a "symmetry dominance" of the ordinary interior configurations of the catchment region by the boundary configurations. Hence, ordinary configurations are symmetry-dominated both from the "inside," by the critical point, and from the "outside," by the boundary of the catchment region.

Analogous results are valid for framework groups and for the catchment regions of "upside down" energy hypersurfaces $-E(K)$.

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

LEIF J. SAETHRE and ODD GROPEN. Can. J. Chem. **70**, 348 (1992).

The molecular structures of square-planar X_4^{2+}, X_4^{+}, and X_4 (X = S, Se, Te) have been calculated using the effective core potential model. For X_4^{2+} the agreement between experimental and calculated values is excellent provided that *d* orbitals are included in the basis set. For the hypothetical molecules X_4^{+} and X_4 the bond lengths are found to increase dramatically as one and, subsequently, two electrons are added to the systems. Extensive population analysis shows that this increase is almost exclusively due to loss of bonding in the π system, whereas the bonding in the σ system remains relatively unaltered. These results make it possible to predict covalent single bond radii for S, Se, and Te for which the influence of π repulsion is removed. From the calculated variation of bond lengths with atomic charge, bond lengths are predicted for a series of planar disulphide rings.

Key words: structure, bonding, chalcogen, theoretical, ECP.

LEIF J. SAETHRE et ODD GROPEN. Can. J. Chem. **70**, 348 (1992).

Utilisant le modèle du potentiel de coeur effectif, on a calculé les structures moléculaires des ions plans carrés X_4^{2+}, X_4^{+} et X_4 (X = S, Se et Te). Pour le X_4^{2+}, à la condition d'y inclure les orbitales *d* dans la base, l'accord est excellent entre les valeurs calculées et expérimentales. On a trouvé que, pour les molécules hypothétiques X_4^{+} et X_4, les longueurs des liaisons augmentent d'une façon dramatique lorsqu'on ajoute un, puis un deuxième, électron aux systèmes. Une analyse extensive de la population montre que cette augmentation est pratiquement complètement due à une perte de liaison dans le système π alors que la liaison par le système σ demeure pratiquement inchangée. Grâce à ces résultats, il est possible de prédire les rayons des liaisons covalentes simples du S, du Se et du Te desquelles on a éliminé la répulsion π. En se basant sur la variation des longueurs de liaisons avec les charges atomiques, on peut prédire les longueurs de liaison d'une série de cycles disulfurès plans.

Mots clés : structure, liaison, chalcogène, théorique, ECP.

[Traduit par la rédaction]

Introduction

The molecular structures of S_4^{2+}, Se_4^{2+}, and Te_4^{2+} have been determined by X-ray crystallography and found to possess square-planar symmetry (D_{4h}) or very nearly so (1–6). The slight variation in symmetry and bond lengths is attributed to the nature of the counterions and to differences in the crystallographic packing (5–7). The average S—S, Se—Se, and Te—Te bond lengths are found to be 2.00, 2.27, and 2.68 Å, respectively (5, 6). These bonds are all shorter than the corresponding single bonds (8), and the stability has been explained as due to an aromatic 6π-electron system.

Figure 1 shows a schematic drawing of the valence molecular orbitals of π symmetry. These orbitals represent the highest occupied and the lowest unoccupied orbitals for these systems. The six electrons occupy one bonding and two degenerate, essentially non-bonding, molecular orbitals. According to simple Hückel theory this results in a cyclic 2-electron 4-center bond with a π-bond order of 0.5, which accounts for the observed bond lengths. As can be seen from the figure, additional electrons are forced to enter into the antibonding b_{2u} orbital if the molecular symmetry is kept the same. This would remove the π stabilization and with two electrons in the b_{2u} orbital one would, to a first approximation, expect the bond lengths to be close to pure single bonds. The purpose of this investigation is to calculate the bond length increase and describe the bonding properties as one and, subsequently, two electrons are added to the molecular systems (Scheme 1).

The hypothetical neutral molecules may in fact serve as models for the study of structure and bonding in *cis*-planar

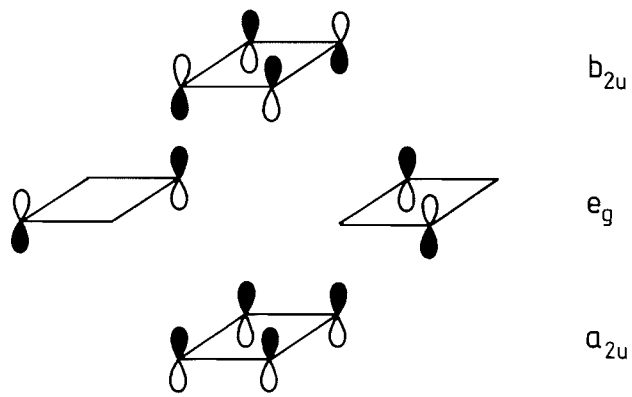

FIG. 1. Schematic representation of the valence molecular orbitals of π symmetry.

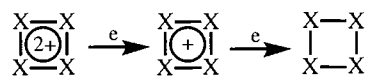

SCHEME 1

dichalcogen molecules. For example, from a survey of experimental S—S bond lengths between divalent sulphur atoms, Hordvik proposed that the bond length varies with the dihedral angle, being smallest (about 2.03 Å) at 90° and increasing to a maximum value (about 2.10 Å) for the *cis*-planar structure (9):

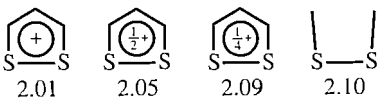
This relationship has been verified both experimentally and theoretically, and is believed to be due to the p_π lone-pair repulsion at 0° dihedral angle, and to π bonding, which is most pronounced at 90°(10).

In other classes of compounds the S—S bond is part of planar five-member rings of different π-electron population. For the dithiolium cation (Scheme 2) the ring is stabilized by a 6π-electron system (11). This results in a relatively short S—S bond of about 2.01 Å (12), which is close to the S—S bonds in S_4^{2+}. For the next two rings in Scheme 2 it is assumed that the positive charge is shared between two (13) and four (14) disulphide rings, respectively. The last compound represents a neutral *cis*-planar disulphide (9).



SCHEME 2

From the above it seems that the bonding in disulphides and related molecules is closely connected to the population of the π orbitals. In the present study we will therefore focus on the relationship between bond distances and the π-electron population of the bond. We believe that the square-planar chalcogens are ideally suited model compounds for this purpose, since the structures are homo-atomic, with bonding angles of 90°, and have no additional substituents or dihedral angles to complicate the analysis.

As expected for such an interesting class of compounds, several theoretical investigations have been performed. These include both *ab initio* (S_4^{2+}, S_4, S_4^{2-}) (15–17), effective core potential (Te_4^{2+}, Te_4) (18), and semiempirical methods (S_4^{2+}, Se_4^{2+}, and Te_4^{2+}) (19, 20). We earlier carried out preliminary calculations on X_4^{2+} and X_4 (X = S, Se, Te) using effective core potentials (21). In that paper "technical" details on basis sets, choice of parameters, as well as comparison with full *ab initio* calculations on S_4^{2+} and S_4 are discussed. In the present work we will emphasize the chemical bonding in these compounds and have for this reason also included results for the X_4^+ cations, which were not discussed earlier.

Method and computational details

The possibility of dividing the electrons into subshells and treating the valence electrons in the frozen sea of the core electrons was first proposed by Fock, Vesselow, and Petraschen (22). Today several groups have developed different schemes for simulating the valence-core interaction by Effective Core Potentials, ECP (23). Most of the schemes are the same, based on a projection operator and a local potential, but differing in the way the parameters are determined. There have been, basically, two different approaches. One was suggested by Goddard and Melius (24), who used an angular dependent projection operator. The other approach was suggested by Bonifacic and Huzinaga (25), who expressed the projection operator explicitly through the core orbitals. This latter approach has successfully been pursued by Huzinaga and co-workers (26). We have in our laboratory (27) developed an ECP scheme based on the ideas put forward by Huzinaga *et al.* This scheme, without the frozen orbitals, is applied in the present calculations. The one-electron operator then takes the following form:

$$F = h + \Sigma_i^c |f_i^c> B_i^c <f_i^c| + \Sigma_k A_k e^{-\alpha_k r^2}/r + \Sigma_j (J_j^v - K_j^v)$$

Here the first and the last terms are the well-known one-electron operator with reduced nuclear charge and the valence Coulomb and exchange operators. The second term is the projection operator where B_i^c's are taken equal to the core orbital energies with opposite sign. The third term is the local potential, which corrects for the incomplete screening, exchange interactions between core and valence, and effects of basis set reduction through the ECP operator. The parameters A_k and α_k are optimized so that the orbital energies of a selected atomic state are reproduced.

The *ab initio* reference calculations were carried out with double-ζ quality basis sets for S, Se, and Te, respectively (28). In the ECP calculations these were truncated to six *s* and five *p* functions and augmented with one *d* function with exponent values equal to 0.48, 0.33, and 0.22 respectively for S, Se, and Te. For further details see ref. 21.

Results and discussion

Bond lengths

The optimized bond lengths of square-planar X_4^{2+}, X_4^+, and X_4 are shown in Table 1. Also shown is the calculated bond length increase for X_4^+ and X_4 relative to those in X_4^{2+}. The calculations were performed both with and without valence *d*-orbitals. We will first focus on the results for X_4^{2+} where experimental results are available.

Table 1 shows that the agreement between experimental and calculated values is excellent when *d*-orbitals are included in the basis set. The calculations give bond lengths well within the range of the experimental values. Electron correlation was not included in these calculations. Such a correction would probably lead to an elongation of the bonds (17). On the other hand, a more complete basis set, such as inclusion of a second set of *d*-orbitals, would probably have decreased the bonds (17). It seems that in this study the effects of electron correlation and a somewhat limited basis set are mutually cancelling, and that the chosen basis set is able to reproduce the experimental values satisfactorily at the HF level. As mentioned in the introduction, the main object of the calculations is to calculate the relative increase in bond length as π electrons are added to the systems. The good agreement for the dications gives confidence that the predicted bond lengths for the monocations and neutral molecules are reasonably accurate.

When valence *d*-orbitals are excluded from the basis set, the calculated bond lengths are systematically overestimated. For S_4^{2+} they are about 11%, and for Se_4^{2+} and Te_4^{2+} about 7% too long. This *d*-orbital effect was noted earlier, and is well known for sulphur compounds (21, 29). The effect has generally been attributed to the ability of the *d* functions to act as polarization functions. In this study they are also active participants in the bonding by virtue of their symmetry, as will be shown below.

The calculated increase in bond lengths as additional electrons are added to the molecules is quite dramatic. When *d*-orbitals are included the increase is about 0.05 Å for one electron and about 0.12 Å when the b_{2u} orbital is com-

pletely filled. This lengthening is remarkably constant for all chalcogens, even though the atomic radii increase appreciably down the periodic table. The results when *d*-orbitals are omitted are essentially the same, although the increase is somewhat less. Both sets of results may be understood from an increase in the p_π repulsion, which is less dramatic as the atomic separation becomes larger.

Electron population

Extensive Mulliken population analyses have been performed for all molecules, both with and without valence *d*-orbitals. It is well known that this type of analysis is basis-set dependent, and should be used with caution (30). In this study, however, the analysis is simplified by the homogeneity of the rings, and the use of similar valence basis sets for all molecules. The populations are calculated for bond lengths corresponding to the optimized geometries in Table 1, and are shown in Tables 2, 3, and 4. In each case the X—X bond is along the Cartesian *x*-axis with the *z*-axis perpendicular to the molecular plane.

We will first discuss the results in the simple case when *d*-orbitals are omitted. Table 2 shows the orbital and overlap populations for the three sets of molecules, X_4^{2+}, X_4^{+}, and X_4. The table reveals a number of interesting features. We see first that the orbital *s* and p_x populations are remarkably constant both for all sets and for each chalcogen within the set. In all cases the molecules use p_x for bonding, leaving the *s* electrons essentially as *s* lone pairs. This is clearly seen from the overlap populations where the *s*–*s* and *s*–p_x interactions are antibonding and the p_x–p_x the strongest bonding. Second, the p_z (or π) populations and also the π bonding are essentially constant within each set of molecules, but as the π population increases to 1.75 the π bonding becomes very small. When the π system incorporates all 8 electrons, i.e., when p_π lone pairs are formed, the π interaction becomes antibonding. Thus, it is the π-population which is responsible for the variation in bonding properties; the σ-bonding remains constants.

Turning now to the results when *d*-orbitals are included in the basis set, Tables 3 and 4 show that the general features of the electron population are much the same as for the simple case without *d*-orbitals. Table 3 shows that the pop-

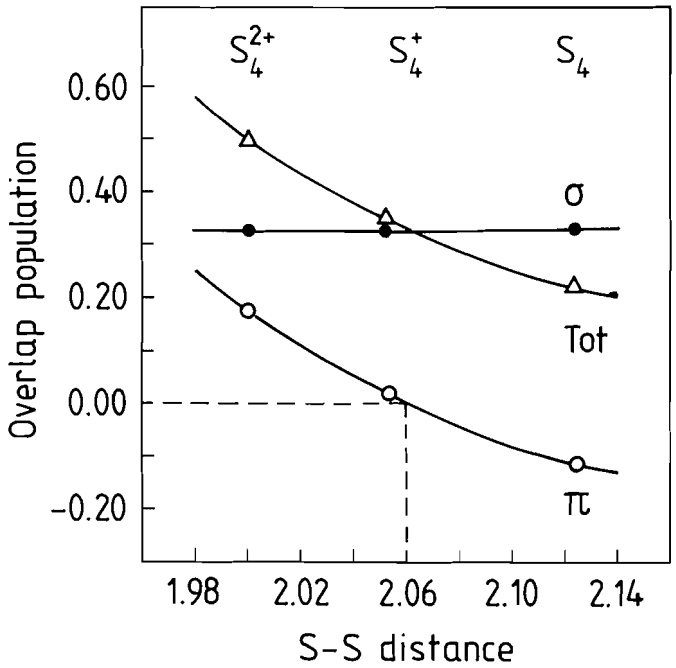

FIG. 2. Variation of σ, π, and total overlap population with S—S bond length in S_4^{2+}, S_4^{+}, and S_4.

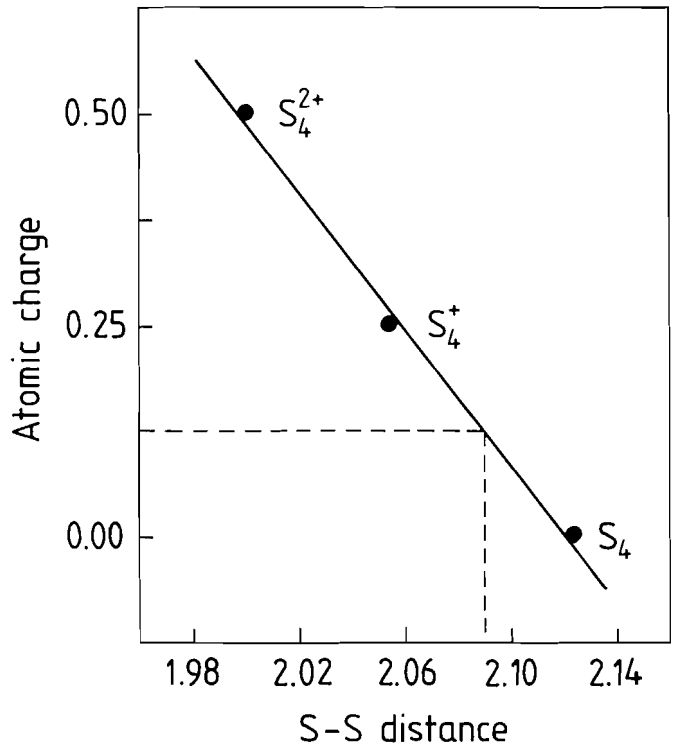

FIG. 3. Atomic charge on sulphur as a function of S—S bond length in S_4^{2+}, S_4^{+}, and S_4.

ulations of the most important d-orbitals are quite modest and that charge density is transferred from the s and p_z orbitals to the $d_{x^2-y^2}$ and d_{xz} orbitals, respectively. This polarization leads to a significant increase in both the σ(s–d_σ and p_x–d_σ) and the π (p_z–d_{xz}) bonding. The increase in π bonding is relatively large and may be explained from the fact that the d_{xz} (or d_π) orbital has the proper symmetry to bind to a neighbouring p_z orbital in the molecular orbital of e_g symmetry (see Fig. 1). For further discussion on the importance of adding d-orbitals to symmetry-deficient basis sets, see ref. 31. In the present case, the shorter bond lengths obtained with d-orbitals lead to stronger π bonds for X_4^{2+} and more antibonding π bonds for X_4.

Table 4 also shows the σ, π, and total overlap population. It is seen that for each chalcogen the total population decreases as more electrons are added to the molecular system. However, as found without d-orbitals, but even more pronounced here, the variation is almost exclusively due to the increase in π bonding. This remarkable result is illustrated for sulphur in Fig. 2, where the overlap population is plotted as a function of calculated bond lengths. Similar figures may be drawn for Se and Te.

Prediction of single bond radii for S, Se, and Te

The variation of X—X bond lengths with overlap population, such as depicted for S—S in Fig. 2, enables us to estimate the bond lengths for which the π population is zero. These distances should then correspond to pure covalent single bonds. Table 4 shows that this occurs for bond lengths slightly longer than those calculated for X_4^{+}. Simple interpolation on a smooth curve through the three points as shown in Fig. 2 gives the following bond distances: S—S = 2.06 Å, Se—Se = 2.32 Å, and Te—Te = 2.76 Å. These correspond to single bond radii of 1.03, 1.16, and 1.38 Å respectively for S, Se, and Te, which are very close to those proposed by Pauling, 1.04, 1.17, and 1.37 Å, respectively (8). As mentioned above, Hordvik arrived at 2.10 Å for S—S bonds in *cis*-planar disulphides, which corresponds to a sin-

gle bond radius of 1.05 Å (9). The two systems are of course not directly comparable, but it appears from this study that appreciable $\pi-\pi$ repulsion is present in both compounds.

Variation of bond lengths with atomic charge

Figure 3 shows how the calculated S—S bond lengths vary with the atom charge on sulphur. For simplicity the best straight line is drawn through the three points. This dependence is of course directly related to the overlap population in Fig. 2. As mentioned in the introduction, there seems to be a relationship between the S—S bond lengths and the ring charge (13). If we assume that the charge is mainly located on the sulphur atoms, we may use Fig. 3 to predict S—S bond lengths in these planar systems. We have already mentioned the resemblance between the S—S bonds in S_4^{2+} (2.00 Å) and those in the dithiolium cations (2.01 Å) for which a sulphur charge of 0.50 may be assumed. Similarly, S—S bond lengths of 2.05 and 2.09 Å are predicted for the charges 0.25 and 0.125. The latter value is obtained from interpolation, as shown in Fig. 3. Both of these S—S bonds correspond exactly to those found experimentally (13, 14). On the other hand, the predicted value of 2.12 Å for a neutral planar system is somewhat longer than the 2.10 Å value suggested by Hordvik.

AO integral evaluation using Cartesian exponential type orbitals (CETOs)[1]

RAMON CARBÓ[2] and EMILI BESALÚ
Laboratori de Química Computacional, Estudi de Ciències, Estudi General de Girona, 17071 Girona, Spain

Received July 15, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

RAMON CARBÓ and EMILI BESALÚ. Can J. Chem. **70**, 353 (1992).

CETO functions and their properties are defined and described, to provide a means of obtaining general expressions for many-center many-electron integral formulae. Compact integral expressions are written by means of nested summation symbols, a new concept developed in this paper. Integrals over CETO functions are computed by means of a set of several auxiliary integral forms. No transformations other than frame rotations are needed to compute the usual integral terms. The formulae obtained are immediately programmable in any high level language and the parallelizable terms are obtained with a simple rule. Results can be considered an encouraging alternative way to solve the STO integral problem.

Key words: many-center AO integrals, molecular basis sets, ETO, STO, CETO.

RAMON CARBÓ et EMILI BESALÚ. Can. J. Chem. **70**, 353 (1992).

On définit et décrit des fonctions d'orbitales de type cartésien exponentiel (CETO) et leurs propriétés; ces fonctions pourraient ouvrir la voie pour obtenir des expressions générales pour des formules d'intégrales à plusieurs électrons et à plusieurs centres. On dérive des expressions intégrales compactes en utilisant des symboles de sommation emboîtés les uns dans les autres, un nouveau concept développé dans ce travail. Pour calculer les intégrales sur les CETO, on utilise un ensemble de quelques formes d'intégrales auxiliaires. Il n'est pas nécessaire de faire appel à d'autres transformations que des rotations du repère de référence pour calculer les termes des intégrales usuelles. Les formules qui sont obtenues peuvent immédiatement être programmées dans n'importe lequel language de haut niveau et on obtient des termes parallélisables avec une règle simple. On peut considérer que les résultats sont une alternative encourageante pour la solution du problème des intégrales du type de Slater.

Mots clés : intégrales d'orbitales atomiques à plusieurs centres, bases moléculaires, orbitales de type exponentiel, orbitales de type Slater, orbitales de type cartésien exponentiel.

[Traduit par la rédaction]

Introduction

Although defined in 1960 by Boys and Cook (1), Cartesian Exponential Type Orbital (CETO) functions did not attract notice until a GTO integral review made by Saunders (2), where they were cautiously manipulated as a subproduct.

As integrals over Exponential Type Orbitals (ETO) are raising interest among various research groups (3–8), we tried to open anew the CETO functions study as a way to approach the ETO integral problem from another point of view.

This paper approaches the computation of CETO integrals by using a notation where all the necessary elements, integrals plus coordinate transformations, are compactly expressed. We prove in this way how CETO integrals are expressible in terms of accessible concepts and auxiliary functions well known in the literature. Care has been taken to provide the simplest formulation possible, suited to easy translation to any high level programming language and well adapted to parallelization.

To fulfill this primary goal, the present paper will be roughly divided into four parts. The first one will introduce the concepts of CETO functions and their transformation properties. The second discusses one- and two-center one-electron integrals. The third is devoted to obtaining two-center Coulomb repulsion integrals and in the fourth part many-center integrals are analyzed.

1. CETO

1.1 Definition 1: CETO functions

Let us define a real normalized Cartesian Exponential Type Orbital (CETO) with the screening parameter α and centered at the point $\boldsymbol{A}$ as

$$[1.1] \quad \chi(\boldsymbol{A},\boldsymbol{a},n,\alpha) = N_n(\boldsymbol{a},\alpha)\, H_a(\boldsymbol{A},\boldsymbol{a})\, P_n(\mathbf{A},\alpha)$$

where the following conditions hold:

1 $\boldsymbol{a} = (a_1,a_2,a_3)$, a_i integer ≥ 0 $\forall i$
2 n integer ≥ 0
3 α real >0
4 $r_A = |\boldsymbol{r} - \boldsymbol{A}|$, $\boldsymbol{r} = (x_1,x_2,x_3)$, $\boldsymbol{A} = (A_1,A_2,A_3)$

and where one can distinguish the following terms:

(i) The normalization factor

$$[1.2] \quad N_n(\boldsymbol{a},\alpha) = \alpha(2\alpha)^{a+n+1/2} \cdot [(2a+1)!!\,(\pi\, p\,(2(a+n+1))!)^{-1}]^{1/2}$$

with $a = \Sigma_i a_i$ and $p = \Pi_i(2a_i - 1)!!$.

(ii) The angular part

$$[1.3] \quad H_a(\boldsymbol{A},\boldsymbol{a}) = \prod_i (x_i - A_i)^{a_i}$$

where a is defined in eq. [1.2].

(iii) The radial part

$$[1.4] \quad P_n(\boldsymbol{A},\alpha) = r_A^n \exp(-\alpha r_A)$$

In some cases condition 2 above can be relaxed, allowing negative values, and condition 3 may be extended with $\alpha =$

1.2. Relationship of CETO with STO functions

Slater Type Orbital (STO) (2, 9*a*) functions have been well known since their description by Slater ca. 60 years ago (10). STO have been massively studied and used as atomic basis sets (11). In the convenient definition by Wahl *et al.* (12), normalized STO are constructed over spherical coordinates. After some elementary manipulations one can see that it is possible to write any STO in terms of CETO functions (9, 13*a*).

The interesting pattern here is the appearance of the structure of Cartesian STO functions, expressible as finite linear combinations of CETO functions. This property can be also used in similar contexts where spherical harmonic functions are present. Take also as an example the atomic spinor functions, see ref. 13. It will be easy to design relativistic one-electron orbitals as formed by four-dimensional vectors whose components are CETO linear combinations. CETO functions can be considered the building blocks of Cartesian STO. In this sense, solving the integral evaluation problem over CETO functions will be the same as solving the integral STO problem.

1.3. Practical details on CETO products

As is well known, basis functions when used in a LCAO framework appear in product pairs at the moment of computing molecular integrals. Analysis of the structure of these CETO products will permit easy definition of canonical integral forms.

1.3.1 Orientation of CETOs over the line joining a pair of centers

(*i*) To be useful for integral computation a product of two CETO functions must be *well-oriented,* in such a way that the x_3-axis (z-axis) coincides with the line joining the two centers involved.

(*ii*) Here we analyze how to perform an effective rotation over the coordinates $\boldsymbol{x}^0 = (x_1^0,x_2^0,x_3^0)$ using the Eulerian angles $\omega = (\varphi,\theta,\delta)$ and the rotation matrix $\boldsymbol{R}(\omega)$ (14). The rotation $\boldsymbol{R}(\omega)$ is chosen in order to express the coordinates $\boldsymbol{x}^0$ in terms of the coordinate system $\boldsymbol{x} = (x_1,x_2,x_3)$ having the same origin as $\boldsymbol{x}^0$, say $\boldsymbol{A}$, and which is well oriented with respect to another center, $\boldsymbol{B}$.

(*iii*) Thus, the rotations in the present paper will be used to orient well two CETO functions, centered at different sites. The rotation angles involved for this kind of manipulation will be constructed by the vector: $\omega_s = (\varphi,\theta,0)$. This is because of the cylindrical symmetry that the prolate spherical coordinates system (see Definition A1 in Appendix A) possesses with respect to a rotation around the axis line joining both centers.

(*iv*) Cartesian coordinate power products such as those forming the CETO angular part, $H_a^0(\boldsymbol{A},\boldsymbol{a})$, are of special interest when dealing with this kind of AO functions.

Using the result of the rotation matrix product over coordinate vectors, the following relationship can be found:

$$[1.5]\quad H_a^0(\boldsymbol{A},\boldsymbol{a}) = \Sigma\,(\boldsymbol{i} = \boldsymbol{0},\boldsymbol{a}) \cdot \Sigma(\boldsymbol{j} = \boldsymbol{0},\boldsymbol{i})\, \boldsymbol{M}(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a}) f(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a},\varphi,\theta)\, H_a(\boldsymbol{A},\boldsymbol{g})$$

where $a = \Sigma_i g_i = \Sigma_i a_i$. Certain definitions should be taken into account in order to interpet eq. [1.5]. They are written as follows:

1. We will call $\Sigma(\boldsymbol{i} = \boldsymbol{0},\boldsymbol{a})$, $\Sigma(\boldsymbol{j} = \boldsymbol{0},\boldsymbol{i})$ *nested summation symbols*. A general description of these is given in Appendix A, Definition A2.

2. The M coefficients correspond to the binomial coefficient product:

$$[1.6]\quad M(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a}) = (-1)^{a_1-i_1+i_3}\binom{a_1}{i_1}\binom{a_2}{i_2}\binom{a_3}{i_3}\binom{i_1}{j_1}\binom{i_2}{j_2}$$

3. The f function is defined as

$$[1.7]\quad f(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a},\varphi,\theta) = (\sin\theta)^{b_1}(\cos\theta)^{b_2}(\sin\varphi)^{b_3}(\cos\varphi)^{b_4}$$

where the four-dimensional vector $\boldsymbol{b}$ is built up in terms of vectors $\boldsymbol{a}$, $\boldsymbol{i}$, and $\boldsymbol{j}$ elements using the rules:

$$[1.8]\quad \boldsymbol{b} = \boldsymbol{b}(\boldsymbol{a},\boldsymbol{i},\boldsymbol{j}) = (i_1 + i_2 + i_3 - (j_1 + j_2), a_3 + j_1 + j_2 - i_3, a_1 + i_2 - i_1, a_2 + i_1 - i_2)$$

4. The three-dimensional vector $\boldsymbol{g}$ components are constructed by the rules:

$$[1.9]\quad \boldsymbol{g} = \boldsymbol{g}(\boldsymbol{a},\boldsymbol{i},\boldsymbol{j}) = (j_1 + j_2 + i_3, a_1 + a_2 - (i_1 + i_2), a_3 + i_1 + i_2 - g_1)$$

5. In the present framework the index j_3 must be considered constant and equal to zero.

1.3.2 General CETO products and their properties

(*i*) Using CETO Definition 1 one can easily find that if two CETO functions share the same center, that is, if $\boldsymbol{A} = \boldsymbol{B}$ and $R = 0$, their product is but a new CETO within the same center, or:

$$[1.10]\quad \Omega_{AA'} = \chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\,\chi(\boldsymbol{A},\boldsymbol{a}',n',\alpha') = \chi(\boldsymbol{A},\boldsymbol{a}+\boldsymbol{a}',n+n',\alpha+\alpha')$$

(*ii*) The product of two CETO functions placed at centers $\boldsymbol{A}$ and $\boldsymbol{B}$ respectively, separated by a distance R, giving a charge distribution Ω_{AB} when rotated, can be written as

$$\begin{aligned}[1.11]\quad \Omega_{AB} &= \chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\,\chi(\boldsymbol{B},\boldsymbol{b},m,\beta)\\ &= \Sigma(\boldsymbol{i} = \boldsymbol{0},\boldsymbol{a})\,\Sigma(\boldsymbol{j} = \boldsymbol{0},\boldsymbol{i})\,\Sigma(\boldsymbol{i}' = \boldsymbol{0},\boldsymbol{b})\\ &\quad\cdot \Sigma(\boldsymbol{j}' = \boldsymbol{0},\boldsymbol{i}')\,\boldsymbol{M}(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a})\,\boldsymbol{M}(\boldsymbol{i}',\boldsymbol{j}',\boldsymbol{b})\\ &\quad\cdot f(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a},\varphi_A,\theta_A)\,f(\boldsymbol{i}',\boldsymbol{j}',\boldsymbol{b},\varphi_B,\theta_B)\\ &\quad\cdot W(A,\boldsymbol{g},n,\alpha)\,W(B,\boldsymbol{g}',m,\beta)\end{aligned}$$

where the f and M coefficients and the $\boldsymbol{g}$ and $\boldsymbol{g}'$ vectors arise from the rotations that put each CETO in a well-oriented form with respect to the other. The W functions are a particular form of CETO functions, which are defined below in the next section.

1.3.3. Well-oriented CETO form

When observing eq. [1.5] it is easy to consider how the general CETO structure changes. The CETO functions, once transformed, become linear combinations of unnormalized Well-Oriented CETO (WO-CETO) functions, which can be defined as follows:

Definition 2: WO-CETO functions

Using the conventions:

1. $\boldsymbol{n} = (n_1,n_2,n_3)$
2. $m \in \{0,1\}$
3. $\alpha \geq 0$ and real
4. $R \geq 0$ and real
5. $s \in \{-1,0,+1\}$

6. $z(s) = sR/2$
7. $r(s) = (x_1^2 + x_2^2 + (x_3 - z(s))^2)^{1/2}$

an unnormalized WO-CETO function is written as

$$[1.12] \quad W(z(s),\boldsymbol{n},m,\alpha) = x_1^{n_1} x_2^{n_2} (x_3 - z(s))^{n_3} r(s)^m \exp\{-\alpha r(s)\}$$

One can represent unnormalized WO-CETO functions as a product of the following terms, when the convention $z(s) = (0,0,z(s))$ and the definitions [1.3] and [1.4] apply:

(*i*) An *angular part*:

$$[1.13] \quad H_n(z(s),\boldsymbol{n}) = x_1^{n_1} x_2^{n_2} (x_2 - z(s))^{n_3}$$

where $n = \Sigma_i n_i$.

(*ii*) A *radial part*:

$$[1.14] \quad P_m(z(s),\alpha) = r(s)^m \exp\{-\alpha r(s)\}$$

In this way $r_A = r(-1)$, so one can also use the symbol $W(A,\boldsymbol{n},m,\alpha)$ for $W(z(-1),\boldsymbol{n},m,\alpha)$; moreover, one can write $r_B = r(+1)$ and, consequently, $W(B,\boldsymbol{n},m,\alpha) = W(z(+1),\boldsymbol{n},m,\alpha)$.■

A still simpler expression, having the form of some sort of elementary CETO building block, can be also described:

Definition 3: E-CETO functions

Taking into account the same conventions as in Definition 2, an Elementary CETO (E-CETO) function is:

$$[1.15] \quad E(\boldsymbol{n},m,\alpha) = W(z(0),\boldsymbol{n},m,\alpha).■$$

1.3.4. WO-CETO products. Cartesian form in terms of E-CETOs

The product of two WO-CETO functions can be written in terms of the third axis components, so:

$$[1.16] \quad \Omega_{AB}^W = W(A,\boldsymbol{a},n,\alpha)\, W(B,\boldsymbol{b},m,\beta) = \Sigma(\boldsymbol{i} = \boldsymbol{0},\boldsymbol{p})\, \Gamma(\boldsymbol{i},\boldsymbol{a},\boldsymbol{b},R) \cdot x_1^{a_1+b_1} x_2^{a_2+b_2} x_3^{i_1+i_2} P_{nm}(\boldsymbol{A},\alpha,\boldsymbol{B},\beta)$$

with

$$\Gamma(\boldsymbol{i},\boldsymbol{a},\boldsymbol{b},R) = (-1)^{a_3-i_1}\binom{a_3}{i_1}\binom{b_2}{i_2}(R/2)^{a_3+b_3-(i_1+i_2)}$$

The two-dimensional vector $\boldsymbol{p}$ is defined as (a_3,b_3) and

$$[1.17] \quad P_{nm}(\boldsymbol{A},\alpha,\boldsymbol{B},\beta) = P_n(\boldsymbol{A},\alpha)\, P_m(\boldsymbol{B},\beta)$$

2. Integrals over one-electron operators

Although already described by Saunders (2), overlap and kinetic energy integrals over a CETO framework will be briefly discussed for the sake of completeness. One- and two-center nuclear attraction integrals will also be studied here.

The notation presented previously in the above discussion is used in all integral cases, leading in this way to a compact description of every integral form, usually needed in quantum chemical problems.

All one-electron integrals studied here can be written in terms of overlap integrals.

2.1. Overlap integrals

(*i*) *One center*

The one-center overlap integrals can be easily obtained considering the structure of eq. [1.10]:

$$[2.1] \quad S_{AA} = \langle\chi(\boldsymbol{A},\boldsymbol{a}',n',\alpha')|\chi(\boldsymbol{A},\boldsymbol{a}'',n'',\alpha'')\rangle = \langle\chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\rangle$$

where $\boldsymbol{a} = \boldsymbol{a}' + \boldsymbol{a}''$, $n = n' + n''$, $\alpha = \alpha' + \alpha''$, and

$$[2.2] \quad \langle\chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\rangle = \int \chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\, dV = \delta(\wedge_i(a_i = \dot{2}))\, F_t(a_1 + a_2 + 1, a_3) \cdot F_2(a_2,a_1)\, t!\, \alpha^{-(t+1)}$$

with $t = 2 + n + \Sigma_i a_i$.

The integral [2.2] vanishes unless $a_i = \dot{2}$, $\forall i$, as signaled by the logical Kronecker delta function, described in Appendix A, Definition A3, appearing as a first factor. The functions F_k, coming from the integration of the angular part of the CETO function, are defined in Appendix B, Definition B5.

(*ii*) *Two center*

Taking into account the rotations outlined in section 1.3.1, the two-center overlap integral can be expressed as

$$[2.3] \quad S_{AB} = \langle\chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)|\chi(\boldsymbol{B},\boldsymbol{b},m,\beta)\rangle = \Sigma(\boldsymbol{i} = \boldsymbol{0},\boldsymbol{a})\, \Sigma(\boldsymbol{j} = \boldsymbol{0},\boldsymbol{i})\, \Sigma(\boldsymbol{i}' = \boldsymbol{0},\boldsymbol{b}) \cdot \Sigma(\boldsymbol{j}' = \boldsymbol{0},\boldsymbol{i}')\, M(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a})\, M(\boldsymbol{i}',\boldsymbol{j}',\boldsymbol{b}) \cdot f(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a},\varphi_A,\theta_A) f(\boldsymbol{i}',\boldsymbol{j}',\boldsymbol{b},\varphi_B,\theta_B) \cdot \langle W(A,\boldsymbol{g},n,\alpha)|W(B,\boldsymbol{g}',m,\beta)\rangle$$

where it is necessary to compute overlap integrals over WO-CETO functions, as

$$[2.4] \quad S_{AB}^W = \langle W(A,\boldsymbol{a},n,\alpha)|W(B,\boldsymbol{b},m,\beta)\rangle = \delta(a_1 + b_1 = \dot{2} \wedge a_2 + b_2 = \dot{2})\, (R/2)^{t+1} \cdot F_2(a_2 + b_2,\, a_1 + b_1) \cdot \Sigma(\boldsymbol{r} = \boldsymbol{0},\boldsymbol{t})\, \Gamma(\boldsymbol{r},\boldsymbol{c})\, A_{r_1}(\sigma)\, B_{r_2}(\tau)$$

with $\boldsymbol{t} = (t,t)$, $t = 2 + m + n + \Sigma_i(a_i + b_i)$, and having $\sigma = R(\alpha + \beta)/2$ and $\tau = R(\alpha - \beta)/2$. The coefficients $\Gamma(\boldsymbol{r},\boldsymbol{c})$ arise from the development of the prolate coordinates function $P(\boldsymbol{c},u,v)$, with the definition of the six-dimensional vector $\boldsymbol{c} = (n + 1, m + 1, a_3, b_3, k, k)$, as explained in Appendix A, Definition A4. The $A_k(x)$ and $B_k(x)$ integrals are defined in Appendix B, Definitions B1 and B2.

The sum $a_1 + b_1 + a_2 + b_2$ is even for nonvanishing integrals, due to the properties of the F_k functions, defined in Appendix B, Definition B5. Thus, the index $k = (a_1 + b_1 + a_2 + b_2)/2$, appearing in the expression of the vector $\boldsymbol{c}$, has always an integer value.

2.2. Kinetic energy integrals

Kinetic energy integrals may be computed using overlap integrals and the symmetric form of the associated kinetic energy operator derived from Green's first identity (15):

$$[2.5] \quad T_{AB} = \langle\chi_A|-1/2\, \nabla^2|\chi_B\rangle = 1/2\, \langle\nabla\chi_A|\nabla\chi_B\rangle$$

Furthermore, one obtains:

$$[2.6] \quad \partial W(A,\boldsymbol{a},n,\alpha)/\partial x_i = a_i\, W(A,\, \boldsymbol{a} - \boldsymbol{e}_i,\, n,\, \alpha) + n\, W(A,\, \boldsymbol{a} + \boldsymbol{e}_i,\, n - 2,\, \alpha) - \alpha\, W(A,\, \boldsymbol{a} + \boldsymbol{e}_i,\, n - 1,\, \alpha)$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

where $\{e_i\}$ are the rows of the (3×3) unit matrix.

The fact must be noted here that if a_i or n is zero in the original WO-CETO, the first or the second term on the right side of eq. [2.6] will vanish.

Once the rotations described in paragraph 1.3.1 are performed over the CETO functions appearing in eq. [2.5], this integral can be expressed as a sum involving overlap integrals of type [2.4] as

$$[2.7] \quad T_{AB} = 1/2 \sum_i T_{ABi}$$

employing the auxiliary definition:

$$\begin{aligned}[2.8] \quad K_i(s,p) = b_i \langle & W(A, \boldsymbol{a} + s\boldsymbol{e}_i, n - p, \alpha) \\ & \cdot |W(B, \boldsymbol{b} - \boldsymbol{e}_i, m, \beta)\rangle \\ & + m \langle W(A, \boldsymbol{a} + s\boldsymbol{e}_i, n - p, \alpha) \\ & \cdot |W(B, \boldsymbol{b} + \boldsymbol{e}_i, m - 2, \beta)\rangle \\ & - \beta \langle W(A, \boldsymbol{a} + s\boldsymbol{e}_i, n - p, \alpha) \\ & \cdot |W(B, \boldsymbol{b} + \mathbf{e}_i, m - 1, \beta)\rangle\end{aligned}$$

where $s \in \{-1,+1\}$ is a sign and $p \in \{0,1,2\}$ an integer, one obtains:

$$[2.9] \quad T_{ABi} = a_i K_i(-1,0) + n K_i(+1,2) - \alpha K_i(+1,1)$$

In one-center kinetic energy integrals, the term [2.9] can be written using the following combination:

$$\begin{aligned}[2.10] \quad U_{AAi} = & -a_i(a_i - 1) && \chi(\boldsymbol{A}, \boldsymbol{a} - 2\boldsymbol{e}_i, n, \alpha) \\ & -n(2a_i + 1) && \chi(\boldsymbol{A}, \boldsymbol{a}, n - 2, \alpha) \\ & +\alpha(2a_i + 1) && \chi(\boldsymbol{A}, \boldsymbol{a}, n - 1, \alpha) \\ & -\delta(n > 2)\, n(n - 2) && \chi(\boldsymbol{A}, \boldsymbol{a} + 2\boldsymbol{e}_i, n - 4, \alpha) \\ & +\alpha(n + (n - 1)\delta(n > 1)) && \chi(\boldsymbol{A}, \boldsymbol{a} + 2\boldsymbol{e}_i, n - 3, \alpha) \\ & -\alpha^2 && \chi(\boldsymbol{A}, \boldsymbol{a} + 2\boldsymbol{e}_i, n - 2, \alpha)\end{aligned}$$

then:

$$[2.11] \quad T_{AAi} = \langle U_{AAi} \rangle$$

where the symbol $\langle U_{AAi} \rangle$ stands for an integral like the one-center overlap including all the CETO functions present in eq. [2.10].

2.3. Nuclear attraction integrals

(i) One-center integrals of the form $\langle$AA:A$\rangle$

This type of integral can be computed by integrating within a spherical coordinates framework. They can be associated with a one-center overlap integral [2.2] as follows:

$$\begin{aligned}[2.12] \quad \langle AA':A \rangle &= \int \chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\, r_A^{-1}\, \chi(\boldsymbol{A},\boldsymbol{a}',n',\alpha')\, dV \\ &= \langle \chi(\boldsymbol{A}, \boldsymbol{a} + \boldsymbol{a}', n + n' - 1, \alpha + \alpha') \rangle\end{aligned}$$

(ii) Two-center integrals of the form $\langle$AA:B$\rangle$

This type of integral, and the following case, can be obtained by integrating in a prolate spherical coordinates framework.

One can see that the nuclear attraction integral is a linear combination of two-center overlap integrals:

$$\begin{aligned}[2.13] \quad \langle AA':B \rangle &= \int \chi(\boldsymbol{A},\boldsymbol{a}',n',\alpha')\, r_B^{-1}\, \chi(\boldsymbol{A},\boldsymbol{a}'',n'',\alpha'')\, dV \\ &= \int \chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\, r_B^{-1}\, dV \\ &= \Sigma(\boldsymbol{i} = \mathbf{0},\boldsymbol{a})\, \Sigma(\boldsymbol{j} = \mathbf{0},\boldsymbol{i})\, M(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a}) \\ &\quad \cdot f(\boldsymbol{i},\boldsymbol{j},\boldsymbol{a},\varphi,\theta)\, \langle W(A,\boldsymbol{g},n,\alpha) | W(B,\mathbf{0},-1,0) \rangle\end{aligned}$$

where $\boldsymbol{a} = \boldsymbol{a}' + \boldsymbol{a}''$, $n = n' + n''$, and $\alpha = \alpha' + \alpha''$. The M and f coefficients and the vectors $\boldsymbol{g} = \boldsymbol{g}(\boldsymbol{a},\boldsymbol{i},\boldsymbol{j})$, constructed as in eq. [1.9], arise from the rotations transforming the CETO centered at $\boldsymbol{A}$ into a well-oriented form with respect to the CETO centered at $\boldsymbol{B}$.

Also the term $r_B^{-1} = \chi(\boldsymbol{B},\mathbf{O},-1,0) = W(B,\mathbf{O},-1,0)$ can be expressed either as a CETO or a WO-CETO, relaxing conditions 2 and 3 of CETO Definition 1.

The overlap-like integrals appearing in eq. [2.13], which involve the operator $W(B,\mathbf{0},-1,0)$, can be taken as a particular case of the two-center overlap integrals described in eq. [2.4].

(iii) Two-center integrals of the form $\langle$AB:A$\rangle$ *or* $\langle$AB:B$\rangle$

In this case, one has

$$\begin{aligned}[2.14] \quad \langle AB:A \rangle &= \int \chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\, r_A^{-1}\, \chi(\boldsymbol{B},\boldsymbol{b},m,\beta)\, dV \\ &= \langle \chi(\boldsymbol{A}, \boldsymbol{a}, n - 1, \alpha) | \chi(\boldsymbol{B},\boldsymbol{b},m,\beta) \rangle\end{aligned}$$

Thus, a finite linear combination of WO-CETO overlap integrals suffices to compute the two-center $\langle AB:A \rangle$ integrals.

3. Coulomb repulsion integrals

Coulomb repulsion integrals over CETO functions, conserving the important role already obtained in GTO and STO choices, are discussed here.

The one- and two-center Coulomb integral computation is set as was done in earlier classical work, see for example refs. 12 and 16. We use the structure of the nuclear attraction monoelectronic integrals to solve the integration over the coordinates of the first electron for the one-center problem, in the same way as Wahl *et al.* (12) proposed when dealing with STO functions in general. However, we reverse this integration scheme for the two-center case, as did O-ohata and Ruedenberg, also within the STO functions framework, in an interesting paper published in 1966 (16).

This twofold integration scheme was adopted after realizing that, when considering the two-center case, the potential first integration drives towards a second integration step with plenty of difficulties, if general analytical formulae are sought. In fact, Wahl *et al.* (12) proposed to perform the second integration numerically. The integral analytical evaluation over the coordinates of the second electron, in the two-center CETO function case, corresponds to a calculation of integrals, involving in the worst situation an infinite series if the O-ohata and Ruedenberg (16) scheme is used.

It must be said now, taking into account the property outlined in eq. [1.10], that all the Coulomb repulsion integrals will transform into integral forms, which we have called *reduced Coulomb integrals*. For example, a Coulomb integral written schematically in the form $\langle AA|r_{12}^{-1}|BB \rangle$ will be reduced to $\langle A|r_{12}^{-1}|B \rangle$. Only this kind of integral is discussed in the present paper, due to the fact that the coordinate rotations and the use of property [1.10] will transform

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

Coulomb integrals into this last form, $|A\rangle$ and $|B\rangle$ being WO-CETO functions. Moreover, as will be shown in Sect. 4, when following the approach outlined there, the many-center integrals require only reduced Coulomb integrals in order to be evaluated. Two kinds of reduced Coulomb integrals over WO-CETO functions will be studied here: one- and two-center.

3.1. Potential functions

The general integration structure adopted in order to obtain analytical formulae in the one-center case is based on the first integration, associated with a nuclear attraction integral like those appearing in eq. [2.14]. In fact, writing the following general reduced Coulomb integral:

$$[3.1]\quad R_{AB} = \langle A|r_{12}^{-1}|B\rangle = \iint [W(A,\boldsymbol{a},n,\alpha)\{1\}]\, r_{12}^{-1} \cdot [W(B,\boldsymbol{b},m,\beta)\{2\}]\, dV_1\, dV_2$$

integration with respect to the electron {2} is equivalent to computing a nuclear attraction integral such as:

$$[3.2]\quad \vartheta(1) = [\langle B|r_{12}^{-1}\rangle\{1\}] = [\langle W(B,\boldsymbol{b},m,\beta)|r_{12}^{-1}\rangle\{1\}]$$

which in turn is a function of electron {1} coordinates. Thus, in general, a reduced repulsion integral may be written:

$$[3.3]\quad R_{AB} = \int [W(A,\boldsymbol{a},n,\alpha)\{1\}]\, \vartheta(1)\, dV_1$$

The integration over the coordinates of the electron number {2} must be done over a prolate spherical coordinate system $\{r_{B2},r_{12},r_{B1}\}$ defined in Appendix A, Definition A1, and the obtained analytic expression of the nuclear attraction integral shown in eq. [3.2]. The intercenter distance, r_{B1}, will act here as a variable and it has to be integrated when considering the electron {1} coordinates. To have electron {2} in a well-oriented system with respect to electron {1}, it is necessary to perform a rotation, for each position of electron {1}, from the original system to the prolate spherical system.

Let the WO-CETO attached to electron {2} coordinates be symbolized by $W(B,\boldsymbol{b},m,\beta)$.

Electrons {1} and {2} are described by means of typical spherical coordinate systems $\{r_{A1},\theta_1,\varphi_1\}$ and $\{r_{B2},\theta_2,\varphi_2\}$, respectively.

After performing the needed rotations outlined in Sect. 1.3.1, one can express the $\vartheta(1)$ potential function [3.2] as

$$[3.4]\quad \vartheta(1) = \Sigma(\boldsymbol{i} = \boldsymbol{0},\boldsymbol{b})\, \Sigma(\boldsymbol{j} = \boldsymbol{0},\boldsymbol{i})\, M(\boldsymbol{i},\boldsymbol{j},\boldsymbol{b})\, f(\boldsymbol{i},\boldsymbol{j},\boldsymbol{b},\varphi_1,\theta_{B1})\langle W(B,\boldsymbol{g},m,\beta)|W(\{1\},\boldsymbol{0},-1,0)\rangle$$

where $\Sigma(\boldsymbol{i} = \boldsymbol{0},\boldsymbol{b})$ and $\Sigma(\boldsymbol{j} = \boldsymbol{0},\boldsymbol{i})$ are nested summation symbols and the coefficients $M(\boldsymbol{i},\boldsymbol{j},\boldsymbol{b})$ and $f(\boldsymbol{i},\boldsymbol{j},\boldsymbol{b},\varphi_1,\theta_{B1})$ are defined in Sect. 1.3.1. Note that the angle θ_{B1} is measured from the center $\boldsymbol{B}$. The $W(\{1\},\boldsymbol{0},-1,0)$ notation stands for a WO-CETO centered on the position of the electron {1}.

The vector $\boldsymbol{g}$, according to eq. [1.9], is defined here as $\boldsymbol{g}(\boldsymbol{b},\boldsymbol{i},\boldsymbol{j})$.

Using eq. [2.4], eq. [3.4] can be written:

$$[3.5]\quad \langle W(B,\boldsymbol{g},m,\beta)|W(\{1\},\boldsymbol{0},-1,0)\rangle = F_2(g_2,g_1)\, N(T_b,\beta)\Sigma(\boldsymbol{p} = \boldsymbol{0},\boldsymbol{q})\, A(\boldsymbol{p},\boldsymbol{h},\beta)\, r_{B1}^{T_b-s}\, \{(-1)^{p_4} - \exp(-\beta r_{B1})\}$$

where:

(*i*) $T_b = m + \Sigma_i b_i$

(*ii*) The function N is defined by

$$[3.6]\quad N(t,\beta) = 2^{-t}\, \beta^{-2}$$

(*iii*) The coefficients A are constructed by means of

$$[3.7]\quad A(\boldsymbol{p},\boldsymbol{h},\beta) = \Gamma(\boldsymbol{p},\boldsymbol{h})\, \Lambda(\boldsymbol{p})\, (2/\beta)^s$$

where Γ appears as in eq. [2.4] with $\boldsymbol{t} = (p_1,p_2)$. The Λ coefficient is defined as $\Lambda(\boldsymbol{p}) = (p_1!p_2!)/(p_3!p_4!)$ and $s = p_1 + p_2 - (p_3 + p_4)$.

(*iv*) The six components of the vector $\boldsymbol{h}$ are

$$[3.8]\quad \boldsymbol{h} = (m + 1,\, 0,\, g_3,\, 0,\, k,\, k)$$

with $k = (g_1 + g_2)/2$.

(*v*) Finally,

$$[3.9]\quad \boldsymbol{q} = (m + 1,\, m + 1,\, p_1,\, p_2)$$

Although the previous scheme seems very promising for both one- and two-center cases, we faced the same difficulties as Wahl *et al.* (12) have surely met, when integration over the second electron was to be performed. In consequence, we use this approach only for the one-center integrals, discussed next.

3.2. One-center reduced Coulomb integrals

Let be $W(1) = W(A,\boldsymbol{a},n,\alpha)$ and $W(2) = W(B,\boldsymbol{b},m,\beta)$ two WO-CETOs centered at the origin, that is, $\boldsymbol{A} = \boldsymbol{B} = \boldsymbol{0}$.

One can define the following quantities:

(*i*) $T_a = n + \Sigma_i a_i$ and $T_b = m + \Sigma_i b_i$ as the total order of each WO-CETO.

(*ii*) $T = T_a + T_b$ as the total order of the integral.

The integral to be calculated is

$$[3.10]\quad R_{AA} = \langle A|r_{12}^{-1}|A\rangle = \iint W(1)\, r_{12}^{-1}\, W(2)\, dV_1\, dV_2$$

which can be written using the potential integral described in eq. [3.2].

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

One can obtain the expression for $\vartheta(1)$ using eq. [3.5] where the prolate spherical system needed is configured by means of the parameters $\{r_2, r_{12}, r_1\}$.

Integration over the electron $\{1\}$ is carried out in a spherical coordinates framework $\{r_1, \theta_1, \varphi_1\}$ and leads to the final result:

$$[3.11] \quad R_{AA} = \delta(\wedge_i(a_i + b_i = \dot{2}))\, N(T_b - 1, \beta)\, \Sigma(\boldsymbol{i} = \boldsymbol{0}, \boldsymbol{b})\, \Sigma(\boldsymbol{j} = \boldsymbol{0}, \boldsymbol{i}) C(\boldsymbol{i}, \boldsymbol{a}, \boldsymbol{b})\, \Sigma(\boldsymbol{p} = \boldsymbol{0}, \boldsymbol{q})\, A(\boldsymbol{p}, \boldsymbol{h}, \beta)\, D(\boldsymbol{p}, n, \alpha, \beta)$$

where the following definitions hold.

(*i*) The C coefficients are defined as

$$[3.12] \quad C(\boldsymbol{i}, \boldsymbol{a}, \boldsymbol{b}) = B(\boldsymbol{i}, \boldsymbol{a}, \boldsymbol{b}) F_1(a_1 + a_2 + i_1 + i_2 + i_3 - (j_1 + j_2) + 1, a_3 + b_3 + j_1 + j_2 - i_3)$$

with the B coefficients being defined in turn by means of

$$[3.13] \quad B(\boldsymbol{i}, \boldsymbol{a}, \boldsymbol{b}) = M(\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{b})\, F_2(b_1 + b_2 - (i_1 + i_2), j_1 + j_2 + i_3) F_2(a_2 + b_1 - i_1 + i_2, a_1 + b_2 + i_1 - i_2)$$

where $M(\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{b})$ are the transformation coefficients constructed as in eq. [1.6].

(*ii*) N and A are the same as the coefficients defined in eqs. [3.6] and [3.7] respectively, and the functions F_k are described in Appendix B, Definition B5.

(*iii*) The six components of the vector $\boldsymbol{h}$ are the same as these defined in eq. [3.8], with the same definition of index g_3.

(*iv*) The vector $\boldsymbol{q}$ has its components constructed as: $(T_b + 1, T_b + 1, p_1, p_2)$.

(*v*) The coefficients D are defined as:

$$[3.14] \quad D(\boldsymbol{p}, n, \alpha, \beta) = (t - 1)!\, \{(-1)^{p_4} \alpha^{-t} - (\alpha + \beta)^{-t}\}$$

with $t = 3 + n - (p_1 + p_2) + p_3 + p_4$.

(*vi*) From the parity restrictions associated with the F_k functions, it is easy to determine that the following conditions necessarily hold: $\{\wedge_i(a_i + b_i = \dot{2})\}$, in order to have non-vanishing integrals. This generates the logical Kronecker delta appearing in eq. [3.11].

(*vii*) To avoid integration divergence when obtaining $\vartheta(1)$, before carrying out any calculation as described in this section, it is necessary to ensure that $T_a \geq T_b$.

3.3 Two-center reduced Coulomb integrals

Let W_A, W_B be two WO-CETO functions placed at the centers $\boldsymbol{A}$ and $\boldsymbol{B}$ respectively, with $\boldsymbol{A} \neq \boldsymbol{B}$ and R being the inter-center distance.

Due to the problems discussed at the end of Sect. 3.1, the integration in the two-center case has been done using the methodology outlined by O-ohata and Ruedenberg (16). The integral to be computed now is a reduced Coulomb integral written as

$$[3.15] \quad R_{AB} = \int\int W_A(\boldsymbol{r}_1 - \boldsymbol{r}_A)\, |\boldsymbol{r}_1 - \boldsymbol{r}_2|^{-1} W_B(\boldsymbol{r}_2 - \boldsymbol{r}_B)\, d\boldsymbol{r}_1\, d\boldsymbol{r}_2$$

Making a change of variable:

$$[3.16] \quad \boldsymbol{r}_2 - \boldsymbol{r}_B = \boldsymbol{r}_1 - \boldsymbol{r}_C$$

one must evaluate integral [3.15] in the form:

$$[3.17] \quad R_{AB} = \int\int W_A(\boldsymbol{r}_1 - \boldsymbol{r}_A)\, |\boldsymbol{r}_C - \boldsymbol{r}_B|^{-1} W_B(\boldsymbol{r}_1 - \boldsymbol{r}_C)\, d\boldsymbol{r}_1\, d\boldsymbol{r}_C = \int |\boldsymbol{r}_C - \boldsymbol{r}_B|^{-1}\, S(\boldsymbol{r}_C - \boldsymbol{r}_A)\, d\boldsymbol{r}_C$$

To obtain this final result an overlap integral has to be calculated between the CETO functions χ_A, χ_C, resulting from the translation of W_A, W_B to the new frame defined in eq. [3.16]:

$$[3.18] \quad S(\boldsymbol{r}_C - \boldsymbol{r}_A) = \int \chi_A(\boldsymbol{r}_1 - \boldsymbol{r}_A)\, \chi_C(\boldsymbol{r}_1 - \boldsymbol{r}_C)\, d\boldsymbol{r}_1 = \Sigma(\boldsymbol{i} = \boldsymbol{0}, \boldsymbol{a})\, \Sigma(\boldsymbol{j} = \boldsymbol{0}, \boldsymbol{i})\, \Sigma(\boldsymbol{i}' = \boldsymbol{0}, \boldsymbol{b})\, \Sigma(\boldsymbol{j}' = \boldsymbol{0}, \boldsymbol{i}')$$
$$\cdot M(\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{a})\, M(\boldsymbol{i}', \boldsymbol{j}', \boldsymbol{b}) f(\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{a}, \varphi_A, \theta_A)\, f(\boldsymbol{i}', \boldsymbol{j}', \boldsymbol{b}, \varphi_A, \theta_B) \langle W(A, \boldsymbol{g}, n, \alpha) | W(C, \boldsymbol{g}', m, \beta) \rangle$$

with $\boldsymbol{g} = \boldsymbol{g}(\boldsymbol{a}, \boldsymbol{i}, \boldsymbol{j})$ and $\boldsymbol{g}' = \boldsymbol{g}(\boldsymbol{b}, \boldsymbol{i}', \boldsymbol{j}')$ following the convention outlined in eq. [1.9].

Using the expression [3.18] in eq. [3.17] and the Laplace expansion of $|\boldsymbol{r}_C - \boldsymbol{r}_B|^{-1}$, one arrives at the final result:

$$[3.19] \quad R_{AB} = \delta(a_1 + b_1 = \dot{2} \wedge a_2 + b_2 = \dot{2}) R^2\, (R/2)^{t+1}\, \Sigma(\boldsymbol{i} = \boldsymbol{0}, \boldsymbol{a})\, \Sigma(\boldsymbol{j} = \boldsymbol{0}, \boldsymbol{i})\, \Sigma(\boldsymbol{i}' = \boldsymbol{0}, \boldsymbol{b})\, \Sigma(\boldsymbol{j}' = \boldsymbol{0}, \boldsymbol{i}')$$
$$\cdot M(\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{a})\, M(\boldsymbol{i}', \boldsymbol{j}', \boldsymbol{b})\, F_2(g_2 + g_2', g_1 + g_1')\, F_2(c_1 + c_1', c_2 + c_2')$$
$$\cdot \sum(\boldsymbol{r} = \boldsymbol{0}, \boldsymbol{t})\, \Gamma(\boldsymbol{r}, \boldsymbol{d}) \sum_{s=0}^{\infty} P(s, c_3 + c_3', c_4 + c_4')\, J(\boldsymbol{u}, \sigma, \tau)$$

where:

(*i*) The $\boldsymbol{c}$ and $\boldsymbol{c}'$ vectors are defined by means of the general vector structure:

$$[3.20] \quad \boldsymbol{c} = \boldsymbol{c}(\boldsymbol{a}, \boldsymbol{i}, \boldsymbol{j}) = (a_1 - i_1 + i_2, a_2 + i_1 - i_2, i_1 + i_2 + i_3 - (j_1 + j_2), a_3 + j_1 + j_2 - i_3)$$

$\boldsymbol{c}' = \boldsymbol{c}(\boldsymbol{b}, \boldsymbol{i}', \boldsymbol{j}')$ being defined in a similar manner.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

(*ii*) The function P is

$$[3.21]\quad P(k,m,n) = \int_0^{\pi} P_k(\cos\theta)(\sin\theta)^m(\cos\theta)^n\,d\theta = 2^{-k}\sum_{p=0}^{q}\frac{(-1)^p(2(k-p))!}{p!(k-p)!(k-2p)!}F_1(m,k+n-2p)$$

where $q = [k/2]$ is the largest integer in the quotient $k/2$, the function F_1 is defined in Appendix B, Definition B5, and $P_k(x)$ are Legendre polynomials of order k.

$$[3.22]\quad (iii)\ J(\boldsymbol{u},\sigma,\tau) = K(\boldsymbol{u},\sigma,\tau) + L(\boldsymbol{u},\sigma,\tau)$$

where $\boldsymbol{u} = (\boldsymbol{r},s,t)$, $\boldsymbol{r} = (r_1,r_2)$, and

$$[3.23]\quad K(\boldsymbol{u},\sigma,\tau) = \int_1^{\infty} x^{(t-s+2)}A_{r_1}(\sigma x)B_{r_2}(\tau x)\,dx$$

$$[3.24]\quad L(\boldsymbol{u},\sigma,\tau) = \int_0^{1} x^{(t+s+3)}A_{r_1}(\sigma x)B_{r_2}(\tau x)\,dx$$

One can use a product $A_k(x)B_l(y)$ expansion form avoiding negative powers of x in the expression of $L(\boldsymbol{u},\sigma,\tau)$. In this manner, the K and L integrals lead to computing the $C_k(x)$ and $D_k(x)$ auxiliary functions, defined in Appendix B, Definitions B3 and B4.

(*iv*) In this formulation $\boldsymbol{t} = (t,t)$, $t = 2 + m + n + \Sigma(a_i + b_i)$, the vector $\boldsymbol{d} = (n+1, m+1, g_3, g_3', h, h)$ with $h = (g_1 + g_1' + g_2 + g_2')/2$, as well as the parameters σ and τ, which are defined as in eq. [2.4].

(*vi*) The parity restrictions associated with the F_k functions have their origin in the logical Kronecker delta appearing in eq. [3.19].

4. Many-center integrals

To compute many-center integrals, two choices can be proposed in a first instance.

The first is based on optimally expressing a two-center CETO product in terms of a linear combination of CETOs, centered at each of the sites belonging to the product functions. This approach will be discussed here and then used to describe in the following sections how to compute three- and four-center integrals. More details will be given elsewhere.

The second option can be based on trivially expressing the 1*s* exponential part of the CETO functions in terms of a linear combination of primitive GTO, as did Fernández Rico (4*e*) when dealing with STO. This approach, which possesses an extreme simplicity and is well adapted to the same form as the Cartesian angular part of the CETO and GTO functions, seems very promising because the exponential part of the CETO functions only has to be expanded.

In fact, when using a Gaussian expansion, a unique fixed primitive GTO linear combination is needed, as a consequence of the scaling theorem demonstrated by O-ohata, Taketa, and Huzinaga (17) when dealing with a similar problem. In this easy numerical environment, integrals over CETO functions become transformations of primitive cartesian GTO integrals. This second approach will be studied in depth elsewhere.

4.1. Two-center expansion of a CETO function product

Let there be two CETO functions centered at points $\{\boldsymbol{A},\boldsymbol{B}\}$ at a distance R: $\{\chi_A,\chi_B\}$. In the present approach the product of both functions Ω_{AB} will be expanded, using a more general structure than the one proposed by Ruedenberg (18), consisting of the sum of two bilinear forms:

$$[4.1]\quad \Omega_{AB} \approx \sum_{\alpha\epsilon A}\sum_{\alpha'\epsilon A}\Gamma_\alpha\Gamma_{\alpha'}\Omega_{\alpha\alpha'} + \sum_{\beta\epsilon B}\sum_{\beta'\epsilon B}\Gamma_\beta\Gamma_{\beta'}\Omega_{\beta\beta'}$$

But, as has been shown before in eq. [1.10], the CETO products $\Omega_{\alpha\alpha'}$ and $\Omega_{\beta\beta'}$ can be substituted by unique CETO functions χ_a and χ_b, respectively. Thus the product Ω_{AB} can also be expressed in terms of WO-CETO functions $\{\Psi_\alpha^A,\Psi_\beta^B\}$ centered separately on $\boldsymbol{A}$ and $\boldsymbol{B}$. Connecting the present approach with earlier ideas of Harris and Rein (19*a*), Newton (19*b*), and Okninski (19*c*), one can also write eq. [4.1] as

$$[4.2]\quad \Omega_{AB} \approx \sum_{\alpha\epsilon A} c_\alpha^A\Psi_\alpha^A + \sum_{\beta\epsilon B} c_\beta^B\Psi_\beta^B$$

In fact, after obtaining this simplified result, it is crucial to prove the product Ω_{AB} can be expanded at the centers $\boldsymbol{A}$ and $\boldsymbol{B}$ with sufficient accuracy. A general theoretical discussion on the way these linear combinations can be calculated follows.

Optimal linear coefficients can be computed using the compact matrix form of eq. [4.2], supposing both sides equal:

$$[4.3]\quad \Omega_{AB} = \boldsymbol{\Psi}^A\boldsymbol{c}^A + \boldsymbol{\Psi}^B\boldsymbol{c}^B$$

then $\{\boldsymbol{c}^A,\boldsymbol{c}^B\}$, the column vectors of the expansion coefficients, can be obtained by multiplying equation [4.3] on the left by the WO-CETO basis set column vectors $(\boldsymbol{\Psi}^A)^+$ and $(\boldsymbol{\Psi}^B)^+$ where both basis sets are stored respectively, and integrating. The following linear system can be built up:

$$[4.4]\quad \boldsymbol{s}_A = \boldsymbol{S}_{AA}\,\boldsymbol{c}^A + \boldsymbol{S}_{AB}\,\boldsymbol{c}^B$$
$$\boldsymbol{s}_B = \boldsymbol{S}_{BA}\,\boldsymbol{c}^A + \boldsymbol{S}_{BB}\,\boldsymbol{c}^B$$

where $\boldsymbol{s}_A = \langle\boldsymbol{\Psi}^A|\Omega_{AB}\rangle$ and $\boldsymbol{S}_{AA} = \langle\boldsymbol{\Psi}^A|\boldsymbol{\Psi}^A\rangle$ is the metric matrix of the WO-CETO basis set centered on $\boldsymbol{A}$. The same definitions apply but with respect to center $\boldsymbol{B}$ for $\boldsymbol{s}_B$ and $\boldsymbol{S}_{BB}$.

Collecting $\{\boldsymbol{s}_A,\boldsymbol{s}_B\}$ and the other matrices in [4.4] in a hypermatrix system one can easily write:

$$[4.5]\quad \boldsymbol{s} = \boldsymbol{S}\,\boldsymbol{c}$$

with obvious definitions for the organization of the matrices in eq. [4.4] as hypermatrices in eq. [4.5]. As $\boldsymbol{S}$ is the metric matrix of the union of the basis sets $\{\boldsymbol{\Psi}^A,\boldsymbol{\Psi}^B\}$, and consequently $\boldsymbol{S} > 0$, then an inverse will always exist: $\boldsymbol{S}^{-1}$, which can be used to solve eq. [4.5].

After some tests, we recommend Cholesky's decomposition (20) in order to compute $\boldsymbol{S}^{-1}$, due to the numerical stability of the method and to the possibility of performing iterative computations when new functions are added to the linear combination [4.3]. When adding functions to the expansion [4.3] it is mandatory to choose them so as to achieve a good fitting between the expansion [4.3] and Ω_{AB}. The parameter taken as an indicator of the degree of fitting is the norm:

$$[4.6]\quad q^{(2)} = |\Omega_{AB} - (\boldsymbol{\Psi}^A\boldsymbol{c}^A + \boldsymbol{\Psi}^B\boldsymbol{c}^B)|^2$$

Supposing all the involved functions are normalized, then the measure:

$$[4.7]\quad \xi = \int \Omega_{AB}\,(\boldsymbol{\Psi}^A\boldsymbol{c}^A + \boldsymbol{\Psi}^B\boldsymbol{c}^B)\,dV$$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

is nothing more than the degree of fitting of the linear combination [4.3] of the WO-CETO charge distribution Ω_{AB}: as $\xi \rightarrow 1$, Ω_{AB} is better covered by the two-center expansion and $q^{(2)} \rightarrow 0$. Numerical experience shows how the measure ξ tends to one with sufficient accuracy ($\approx 10^{-8}$) using a reasonable number of terms (≈ 20) in the combination [4.2].

4.2. Reduction of three- and four-center integrals to mono and bicentric terms

Using the CETO expansion method outlined in the preceding section, it can be seen that molecular integrals may be constructed as linear combinations of other integrals within a reduced number of centers. Three important cases can be considered:

(*i*) Three-center nuclear attraction integrals $\langle AB{:}C\rangle$ will reduce to an expression involving two-center integrals of the $\langle AA{:}C\rangle$ and $\langle BB{:}C\rangle$ type. Here, the expansion expressed in eq. [4.2] is used in order to compute the $\langle AB{:}C\rangle$ integral, and one can write:

$$[4.8]\quad \langle AB{:}C\rangle = \int \chi(\boldsymbol{A},\boldsymbol{a},n,\alpha)\, r_C^{-1}\, \chi(\boldsymbol{B},\boldsymbol{b},m,\beta)\, dV = \langle \Omega_{AB}|r_C^{-1}\rangle = \sum_{\alpha\epsilon A} c_\alpha^A \langle \Psi_\alpha^A|r_C^{-1}\rangle + \sum_{\beta\epsilon B} c_\beta^B \langle \Psi_\beta^B|r_C^{-1}\rangle$$

(*ii*) In general, it can be considered as the evaluation of a two-electron four-center integral of any kind: $\langle AB|\boldsymbol{T}|CD\rangle$. Expanding both charge distributions involved as described in expression [4.2], the integral will be a sum of four bilinear terms that will depend on the four kinds of integral $\{\langle A|\boldsymbol{T}|C\rangle, \langle A|\boldsymbol{T}|D\rangle, \langle B|\boldsymbol{T}|C\rangle, \langle B|\boldsymbol{T}|D\rangle\}$, reduced to bicentric forms:

$$[4.9]\quad \langle AB|\boldsymbol{T}|CD\rangle \approx \sum_a \sum_c C_a^{AC}\, C_c^{CA}\, \langle a|\boldsymbol{T}|c\rangle + \sum_a \sum_d C_a^{AD}\, C_d^{DA}\, \langle a|\boldsymbol{T}|d\rangle + \sum_b \sum_c C_b^{BC}\, C_c^{CB}\, \langle b|\boldsymbol{T}|c\rangle + \sum_b \sum_d C_b^{BC}\, C_d^{DB}\, \langle b|\boldsymbol{T}|d\rangle$$

Thus, three- and four-center Coulomb integrals will be expressed in terms of the reduced Coulomb integrals as defined in eq. [3.1].

(*iii*) An interesting situation, which can easily be solved within the present approach, corresponds to two-center integrals of the "exchange" type: $\langle AB|\boldsymbol{T}|AB\rangle$, which have not been previously discussed. It is well known that in the STO framework and with the Coulomb operator substituting the operator $\boldsymbol{T}$, they are not so trivially computed as the two-center "Coulomb" type integrals: $\langle AA|\boldsymbol{T}|BB\rangle$, as the papers by Ruedenberg (21) or Wahl *et al.* (12) prove. But, using eq. [4.9], they are simply expressed in terms of one-center $\langle A|\boldsymbol{T}|A'\rangle$, $\langle B|\boldsymbol{T}|B'\rangle$, and two-center $\langle A|\boldsymbol{T}|B\rangle$ integrals. The same can be said for the "hybrid" type integrals $\langle AA|\boldsymbol{T}|AB\rangle$.

Conclusions

A general but simple framework has been described in order to compute integrals over CETO functions. The proposed formulation has been written in such a way as to permit: (*a*) construction of a procedure to compute basic two-center and many-center integrals; (*b*) easy buildup of a program structure in any high level language for any integral; (*c*) parallelization of the terms lying inside nested summation symbols.

Appendix A: Definitions

Definition A1: Prolate spherical system

When we refer to the *prolate spherical parameter system* $\{r_A,r_B,R\}$ we mean to use the coordinates:

$$[A.1] \quad u = (r_A + r_B)/R, \qquad v = (r_A - r_B)/R, \qquad \varphi = \varphi_A = \varphi_B$$

the volume element being $dV = (R/2)^3(u^2 - v^2)\,du\,dv\,d\varphi$ and the integration limits: $u\epsilon\{1,\infty\}$, $v\epsilon\{-1,+1\}$, $\varphi\epsilon\{0,2\pi\}$.■

Definition A2: Nested summation symbols

Let us use a *nested summation symbol* as a general expression like $\Sigma(\boldsymbol{k} = \boldsymbol{r},\boldsymbol{s})$ describing a sequence of summation symbols.

The meaning of such a convention corresponds to performing all the sums involved in the generation of all possible forms of vector $\boldsymbol{k}$, whose elements are defined by the limits $k_i = r_i,s_i;\forall i$.

Nested summation symbolism is very convenient because successive generation of $\boldsymbol{k}$ vector elements can be programmed in a general way under any high level language, using a unique **do** or **for** loop irrespective of the number of sums involved. These symbols are well suited for programming in a parallel hardware environment. Inside a nested sum, all operations attached to each vector $\boldsymbol{k}$ can be run into a separate CPU. More details about nested summation symbology can be found in ref. 22.

Definition A3: Logical Kronecker delta

A logical Kronecker delta, $\delta(\{L\})$, is a symbolic factor that is unity when the logical expression $\{L\}$ is true and zero otherwise.■

An initial and crude form of this symbol was given some years ago by one of us within the context of the development of a MCSCF (23). More details concerning Logical Kronecker and related topics can be found in ref. 22.

Definition A4: $P(\boldsymbol{a},u,v)$ function and $\Gamma(\boldsymbol{r},\boldsymbol{a})$ coefficients

For some of the integrals appearing in this paper, it is helpful to obtain an expression for the expansion of the binomial products, which can be written as

$$[A.2] \quad P(\boldsymbol{a},u,v) = (u + v)^{a_1}(u - v)^{a_2}(1 + uv)^{a_3} \cdot (1 - uv)^{a_4}(u^2 - 1)^{a_5}(1 - v^2)^{a_6}$$

One can easily deduce the equivalent compact form:

$$[A.3] \quad P(\boldsymbol{a},u,v) = \Sigma(\boldsymbol{r} = \boldsymbol{0},\boldsymbol{p})\,\Gamma(\boldsymbol{r},\boldsymbol{a})\,u^{r_1}v^{r_2}$$

where $\boldsymbol{p} = (t + 2a_5, t + 2a_6)$ with $t = a_1 + a_2 + a_3 + a_4$.

The coefficients in eq. [A.3] are defined as

$$[A.4] \quad \Gamma(\boldsymbol{r},\boldsymbol{a}) = \Sigma(\boldsymbol{k} = \boldsymbol{0},\boldsymbol{a})\,\delta(k_1 + k_2 + k_3 + k_4 + 2k_5 = r_1)\delta(a_1 + a_2 - (k_1 + k_2) + k_3 + k_4 + 2k_6 = r_2)\,C(\boldsymbol{k},\boldsymbol{a})$$

where

$$[A.5] \quad C(\boldsymbol{k},\boldsymbol{a}) = (-1)^t \prod_{i=1}^{6} \binom{a_i}{k_i}$$

with the index definition: $t = a_2 + a_5 + k_2 + k_4 + k_5 + k_6$.

Appendix B: Auxiliary integrals

Definition B1: $A_k(x)$ integrals

$$[B.1] \quad A_k(x) = \int_1^\infty t^k\,e^{-xt}\,dt.■$$

Definition B2: $B_k(x)$ integrals

$$[B.2] \quad B_k(x) = \int_{-1}^{+1} t^k\,e^{-xt}\,dt.■$$

Definition B3: $C_k(x)$ integrals

$$[B.3] \quad C_k(x) = \int_1^\infty t^{-k}\,e^{-xt}\,dt.■$$

Definition B4: $D_k(x)$ integrals

$$[B.4] \quad D_k(x) = \int_0^1 t^k\,e^{-xt}\,dt.■$$

The evaluation and extensive computational properties of these integrals can be found in the handbook of Abramowitz and Stegun (24).

Definition B5: $F_k(m,n)$ functions

$$[B.5] \quad F_k(m,n) = \int_0^{k\pi} (\sin x)^m (\cos x)^n\,dx$$
$$= \delta(n = \dot{2})\{k\delta(m = \dot{2})(\Gamma(p)\Gamma(q)/\Gamma(p + q)) + \delta(k = 1 \wedge m \neq \dot{2})(2^{m+1}\,m! \prod_{r=0}^{m} [2(n + r) + 1])\}$$

with $k\epsilon\{1,2\}$, $p = (m + 1)/2$, $q = (n + 1)/2$, and $\Gamma(x)$ is the gamma function.■

Partial information on this definition can be found in ref. 25.

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

TOSHIKATSU KOGA and AJIT J. THAKKAR. Can. J. Chem. **70**, 362 (1992).

It is suggested that atomic orbitals with improved long-range behavior can be obtained by using energy-optimized Gaussian basis sets to which Gaussians have been added to satisfy a subset of some recently derived constraints that must be satisfied by the exact Hartree–Fock orbitals. This procedure is demonstrated by illustrative calculations for helium. This method is found to be superior to the *ad hoc* method of adding diffuse Gaussians in an even-tempered fashion.

Key words: Gaussian basis sets, long-range behavior, asymptotic constraints.

TOSHIKATSU KOGA et AJIT J. THAKKAR. Can. J. Chem. **70**, 362 (1992).

On suggère que l'on peut obtenir des orbitales atomiques avec un meilleur comportement à longue distance en utilisant des bases gaussiennes optimisées pour l'énergie auxquelles on a ajouté des gaussiennes dans le but de satisfaire un sous-ensemble de contraintes dérivées récemment et qui doivent être satisfaites par des orbitales de Hartree–Fock exactes. On fait une démonstration de cette procédure par des calculs de l'hélium. On a trouvé que cette méthode est supérieure à la méthode *ad hoc* impliquant l'addition bien tempérée de gaussiennes diffuses.

Mots clés : bases gausiennes, comportement à longue distance, contraintes asymptotiques.

Introduction

The long-range behavior of atomic orbitals is important in the calculation of many physically important properties. Examples of such properties include electric properties such as multipole moments, polarizabilities, and hyperpolarizabilities (1, 2), and momentum space properties such as the Compton profile peak height (3–5). Standard variationally optimized basis sets (for reviews, see refs. 6–10) are usually not sufficiently flexible at long range unless they are very large. Hence, it is common practice to augment standard basis sets with diffuse basis functions whenever properties such as those discussed above are to be computed.

There is no single standard method for choosing diffuse basis functions. If the basis set consists of Slater-type functions (STF), then the known asymptotic behavior of Hartree–Fock atomic orbitals (11–13) can be used to add diffuse STF whose exponents match the asymptotic behavior (4, 13). If the basis set consists of Gaussian-type functions (GTF), then one may add diffuse GTF with exponents chosen such that the augmented basis set produces a good fit to the asymptotic behavior in the physically important region (14). A common *ad hoc* prescription, followed in refs. 15–19 and in many other papers, is to choose diffuse GTF with exponents that form a geometric sequence with the exponents of the two most diffuse GTF in the variationally optimal basis set. We shall refer to the diffuse functions chosen by this *ad hoc* procedure as even-tempered diffuse functions.

The purpose of this paper is to demonstrate that self-consistent-field (SCF) orbitals with improved long-range behavior can be obtained by using energy-optimized GTF basis sets supplemented by GTF chosen to ensure that the SCF orbitals satisfy some of the linearly averaged position moment (LAPM) constraints that we recently derived (20).

The LAPM constraints

The LAPM relationships (20) that must be satisfied by the exact solutions of the closed shell Hartree–Fock equations are given by

$$[1] \quad e_i(K,L,M) = \epsilon_i$$

in which ϵ_i is the orbital energy corresponding to the ith orbital ψ_i and

$$[2] \quad e_i(K,L,M) = e_{1,i}(K,L,M) + e_{2,i}(K,L,M)$$

The one-electron component in eq. [2] is given by

$$[3] \quad e_{1,i}(K,L,M) = \{-K(2K+2L+1)[r^{2K+L-2}Y^*_{LM}(\Omega)]_i + [r^{2K+L}v(\boldsymbol{r})Y^*_{LM}(\Omega)]_i\}/[r^{2K+L}Y^*_{LM}(\Omega)]_i$$

and the two-electron component by

$$[4] \quad e_{2,i}(K,L,M) = \sum_{j=1}^{N} \{2[r^{2K+L}w_{jj}(\boldsymbol{r})Y^*_{LM}(\Omega)]_i - [r^{2K+L}w_{ji}(\boldsymbol{r})Y^*_{LM}(\Omega)]_j\}/[r^{2K+L}Y^*_{LM}(\Omega)]_i$$

In the above equations, $v(\boldsymbol{r})$ is the one-electron potential,

$$[5] \quad w_{ij}(\boldsymbol{r}) = \int [\psi_i^*(\boldsymbol{r}')\psi_j(\boldsymbol{r}')]\,|\boldsymbol{r}-\boldsymbol{r}'|^{-1}\,d\boldsymbol{r}'$$

Y_{LM} are spherical harmonics, and square brackets are used to denote *linear* averages as follows:

$$[6] \quad [f(\boldsymbol{r})]_i = \int f(\boldsymbol{r})\psi_i(\boldsymbol{r})\,d\boldsymbol{r}$$

in which ψ_i is a Hartree–Fock orbital. Equation [1] is valid for all $K \geqq 0$, but, in atoms, only for some L and M deter-

mined by the angular momentum symmetry of ψ_i. The acronym LAPM for the set of relationships embodied in eq. [1] arises from the occurrence of *l*inear *a*verages over *p*osition *m*oments (20–23). The special case $K = L = M = 0$ is the Hartree–Fock counterpart of the original zero-momentum energy expression (24–26), and the full set of LAPM equations is a Hartree–Fock analog of the modified zero-momentum expression (27).

Since the LAPM relationships place emphasis on the outer reaches of the electron density (20), it is plausible that they can somehow be used to determine diffuse basis functions. We found that attempting to satisfy a subset of the LAPM equations by modifying exponents of basis functions that are present in variationally optimized basis sets does not work well. A more suitable procedure is to begin with a variationally optimized basis set, add m basis functions to it, and vary the exponents of the added functions until the augmented basis set satisfies m constraints given by the LAPM eq. [1]. Note that this requires an additional layer of iterations to ensure that the orbital energies used in the constraints coincide with those obtained from the SCF procedure in that basis set.

Results for atomic helium

A large number of calculations based on the above procedure were performed for the helium atom. In this case, symmetry dictates that $L = M = 0$ in eq. [1]. To construct GTF basis sets of dimension N, we began with variationally optimal basis sets containing $(N - m)$ GTF, added m GTF, and varied the exponents of the m added functions to ensure that self-consistent-field (SCF) solutions of the Hartree–Fock (HF) equations in the full N-GTF basis set satisfied the LAPM eq. [1] with $L = M = 0$ and $0 \leqq K \leqq m - 1$. This was done with $N = 4, 6, 8, 10, 12, 14$ and with $m = 0, 1, 2$. In some cases no satisfactory solutions were obtained for $m = 2$. The variationally optimal basis sets with 6 GTF or less were refined versions of the basis sets of van Duijneveldt (28), and those with 7 or more GTF were taken from the work of Partridge (29). For the sake of comparison, N-GTF basis sets constructed by the *ad hoc* addition of an even-tempered diffuse GTF to a variationally optimal basis set with $N - 1$ GTF were also considered.

A summary of the results is presented in Table 1, which lists the total and orbital energies, and the average percent error Δ in the moments $\langle r^k \rangle$ ($-2 \leqq k \leqq 10$ excluding $k = 0$) with respect to the numerically determined Hartree–Fock values (13, 30). The standard energy-optimal basis sets appear as the $m = 0$ cases, the basis sets constructed by the *ad hoc* procedure are denoted by a d after the number of constraints, and those constructed via the LAPM constraints are denoted by an L after the number of constraints.

We found that it is not always possible to apply two or more LAPM constraints. No solutions were found for $N = 10, 12, 14$ with $m = 2$L. Moreover, in the $N = 4$ and 6 cases, the $m = 2$L solutions are not satisfactory because the exponent of one of the two added GTF is larger than an exponent in the underlying $(N - 2)$ GTF energy-optimal basis set. We think the constraint procedure must be considered unsuccessful for atomic helium if it does not produce diffuse functions. Furthermore, in the $N = 8$, $m = 2$L case, even though the two added GTF are more diffuse than any functions in the substrate, their exponents (0.11 and 0.16) are rather close to each other and this leads to near-linear dependence. In view of the above results, we believe that the LAPM procedure should be restricted to one constraint per orbital.

TABLE 1. Overall performance of Gaussian basis sets for helium. N is the number of basis functions. m is the number of constraints; d indicates that the geometric sequence method is used for the diffuse functions whereas L indicates that LAPM constraints (see text) have been used. E and ϵ are the total and orbital energies respectively. Δ is the mean percent error for the moments $\langle r^k \rangle$ with $k = -2, -1, 1, \ldots, 10$

N	m	E	ϵ	Δ

Hartree–Fock limit		−2.861680	−0.917956	0

Next, we turn to a comparison of standard basis sets ($m = 0$), one-LAPM constraint basis sets ($m = 1$L), and basis sets containing one diffuse function added in an even-tempered fashion ($m = 1$d). Table 1 shows clearly that, for a fixed basis set size N, the $m = 1$L sets yield a substantially lower Δ than either the $m = 0$ or $m = 1$d sets. It is rather surprising that the *ad hoc* $m = 1$d sets do *not* have a smaller Δ than the $m = 0$ sets except for $N = 6, 8$. Table 2 contains a detailed comparison of the moments for $N = 8$. Evidently, the $m = 1$L set has a much smaller Δ because it produces high moments $\langle r^k \rangle$ ($k \geqq 5$) that are in much better agreement with the HF limit values than the $m = 0$ and $m = 1$d sets. Since the high moments weight the outer reaches of the electron density, we can conclude that the SCF orbital in the $m = 1$L basis set has much more accurate long-range behavior than the SCF orbitals in the $m = 0$ and $m = 1$d basis sets.

Moreover, Table 1 shows that the $m = 1$L sets lead to better orbital energies than the $m = 1$d and $m = 0$ sets, except for $N = 4$. The relatively poor behavior of the $N = 4$, $m = 1$L basis set leads us to suggest that the LAPM constraints are not suitable for very small basis sets. Table 2 shows that the price for the better long-range behavior and orbital energies of the $m = 1$L set is a slightly worse disagreement with the HF limit values of the lower moments. Not unexpectedly, the $m = 1$L sets predict a somewhat worse energy than the energy-optimized $m = 0$ basis sets. However, the $m = 1$L energies are generally better than the $m =$

TABLE 2. Comparison of moments $\langle r^k \rangle$ for some basis sets. N and m are defined in Table 1. Quantities in parentheses are percent errors relative to the Hartree–Fock (HF) limit[a]

k	$N = 8, m = 0$	$N = 8, m = 1d$	$N = 8, m = 1L$	HF limit [a]
−2	5.99112 (−0.07)	5.98552 (−0.17)	5.98546 (−0.17)	5.99550

1d ones. In fact, the $m = 1L$ sets are better than the $m = 1d$ sets on almost all counts. The exponents α and the linear coefficients c for the $m = 1L$ basis sets for helium are listed in Table 3.

Conclusions

We have demonstrated that, for atomic helium, basis sets with improved asymptotic behavior can be obtained from standard energy-optimized GTF basis sets by adding one GTF with an exponent chosen such that the augmented basis set satisfies one LAPM constraint. The resulting basis sets are superior to those produced by the commonly used *ad hoc* procedure of adding a diffuse GTF in an even-tempered fashion. We are performing tests to see whether the LAPM basis sets in Table 3 lead to less basis set superposition error in interatomic potential energy calculations, and whether they offer any advantages in polarizability calculations.

It remains to be seen whether this procedure can be successfully used for heavier atoms, and whether it can be extended to open-shell atoms. Such extensions are being explored in our laboratories. If both of these objectives can be met, then the LAPM procedure will become a generally useful method for adding a diffuse function to a GTF basis set.

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

HARTMUT BUECKERT, STUART M. ROTHSTEIN, and JAN VRBIK. Can. J. Chem. **70**, 366 (1992).

We show how to optimize many-parameter wavefunctions for use in quantum Monte Carlo by deriving and utilizing formulas for analytical rather than numerical evaluation of the required derivatives. We present these in a form which is easily vectorizable for use on a supercomputer. We also discuss several technical issues of variational Monte Carlo to ensure both an unbiased and efficient optimization. Finally, we illustrate our optimization scheme's numerical performance by optimizing ground-state wavefunctions for LiH and H_2O, each with more than 100 variational parameters.

Key words: quantum Monte Carlo, optimization, electron correlation, LiH, H_2O.

HARTMUT BUECKERT, STUART M. ROTHSTEIN et JAN VRBIK. Can J. Chem. **70**, 366 (1992).

On démontre comment optimiser des fonctions d'onde à plusieurs paramètres, utilisables en mécanique quantique selon Monte Carlo; pour réaliser cette optimisation, on met au point et on utilise des formules permettant de faire une évaluation analytique plutôt que numérique des dérivées requises. On les présente sous une forme que l'on peut facilement vectoriser en vue d'une utilisation à l'aide d'un super-ordinateur. On discute aussi de plusieurs points techniques de la méthode de Monte Carlo variationnelle qui permettent d'effectuer une optimisation à la fois impartiale et efficace. Enfin, on donne une démonstration de la performance de notre schéma d'optimisation à l'aide des fonctions d'onde de l'état fondamental du LiH et du H_2O qui contiennent chacun plus de 100 paramètres variationnels.

Mots clés : mécanique quantique de Monte Carlo, optimisation, corrélation électronique, LiH, H_2O.

[Traduit par la rédaction]

Introduction

Our objective is to optimize wavefunctions for use in quantum Monte Carlo which involve a large number of variational parameters. Our optimization scheme shares features of that reported by Umrigar, Wilson, and Wilkins (1) (U.W.W.), who propose minimizing the *variance* of the local energy, and that of Huang, Sun, and Lester, Jr. (2) (H.S.L.), who update the parameters stochastically to avoid ensemble dependency (unlike U.W.W. who use a fixed Monte Carlo sample). Another related paper is Schmidt and Moskowitz (3). They did optimization using analytical derivatives only for the electron correlation parameters. Our emphasis will be on optimizing all the remaining, yet primary parameters (basis set orbital exponents and the molecular orbital coefficients). (Others may also have used analytical derivatives, but even in that event, the relevant formulas are lacking.)

It is absolutely essential for efficient optimization of a large number of parameters to use analytical (as opposed to numerical) evaluation of the required derivatives. The improvement in efficiency (over numerical differentiation) is proportional to the number of parameters to be optimized, and can thus easily reach a factor of 100 or more. (Numerical differentiation takes two extra evaluations of the local energy for each variational parameter, whereas our technique does all these derivatives as a byproduct of a single evaluation, with only a small extra cost.)

We will present the relevant formulas, which are in a form readily vectorizable for use on supercomputers. We also discuss several technical issues to ensure both an unbiased and efficient optimization. We then illustrate our optimization scheme's numerical performance with applications to the ground states of LiH and H_2O molecules, using wavefunctions having more than 100 variational parameters.

Quantum Monte Carlo has virtually unlimited flexibility in its choice of atomic orbitals and correlation functions; the optimization technique represented here provides a useful tool for an in-depth study of the efficiency (in terms of speed of convergence to a complete set) of these. Work in this direction is reported here with the ultimate objective to design a procedure capable of reducing (almost arbitrarily, we hope) the trial function's error for any given molecule.

Analytical derivatives

In this section we report the formulas for the first and second derivatives of the wavefunction (ψ) and the corresponding local energy (E_L), with respect to the parameters of ψ. We assume a trial function of the form $\psi^\uparrow\psi^\downarrow\psi^c$, where $\psi^\uparrow$ is a Slater determinant of molecular orbitals (LCAO in our case) for the spin up electrons, $\psi^\downarrow$ the analog for spin down electrons, and ψ^c is the correlation function. Extension to linear combinations of such functions, as in multiconfiguration Hartree–Fock, is straightforward.

The local energy is conveniently computed as follows:

$$[1] \quad E_L = -\frac{1}{2}(g^\uparrow + g^\downarrow + 2(\mathbf{F}_\alpha^\uparrow \cdot \mathbf{F}_\alpha^{c\uparrow} + \mathbf{F}_\beta^\downarrow \cdot \mathbf{F}_\beta^{c\downarrow}) + g^c) + U$$

where $E_L = H\psi/\psi$, $g^\uparrow = \nabla_N^2\psi^\uparrow/\psi^\uparrow$, $\mathbf{F}_i^\uparrow = \nabla_i\psi^\uparrow/\psi^\uparrow$, etc, and U is the potential energy function. Also, ∇_i is the 3-di-

mensional gradient operator corresponding to the ith electron, and ∇_N is its $3N$-dimensional analog, where N is the number of spin up ($\uparrow$) or down ($\downarrow$) electrons. (In general $N^\uparrow \neq N^\downarrow$, but we omit the superscript on N.) Here, and throughout this paper, two *or more* repeated Greek indices α, β, ... imply summation over all the N electrons. Repeated Roman do *not* imply summation.

It is now necessary to introduce some additional notation. Let $\mathbf{A}^\uparrow$ be the $J \times N$ matrix of values of J atomic orbitals, each evaluated N times, corresponding to the location of the individual electrons. Each atomic orbital is a function of an electron's location $\boldsymbol{r}$, and a single orbital exponent ζ. Extension to two or more non-linear parameters is possible.

Let $\mathbf{B}^\uparrow$ and $\mathbf{D}^\uparrow$ be the matrix of the corresponding gradients and ∇_i^2 values of the atomic orbitals, respectively. ($\mathbf{B}$ has three components for each entry; *i.e.*, it is a $J \times N \times 3$ matrix.) Let $\mathbf{A}^{\uparrow\zeta}$ be the matrix of elements of $\mathbf{A}^\uparrow$, differentiated with respect to the individual (*one for each row*) orbital exponents ζ. We stress this non-standard definition of a matrix of derivatives by using a matrix with superscript ζ rather than with a simple prime. Similarly for $\mathbf{B}^{\uparrow\zeta}$ and $\mathbf{D}^{\uparrow\zeta}$. Finally, let $\mathbf{C}$ be the $N \times J$ matrix of MO coefficients. Thus $\mathbf{CA}^\uparrow$ is the Slater matrix of N molecular orbitals evaluated at each electron's position, and $\psi^\uparrow = \det(\mathbf{CA}^\uparrow)$. The parameters of $\psi^\uparrow$ are the ζ's and the elements of $\mathbf{C}$.

One can easily compute the quantities appearing in eq. [1] by calculating the inverse of the Slater matrix $(\mathbf{CA}^\uparrow)^{-1}$, and some simple matrix algebra (4). In particular,

$$[2] \qquad g^\uparrow = (\mathbf{CD}^\uparrow)_{\alpha\beta}(\mathbf{CA}^\uparrow)^{-1}_{\beta\alpha}$$

and

$$[3] \qquad \mathbf{F}_i^\uparrow = (\mathbf{CB}^\uparrow)_{\alpha i}(\mathbf{CA}^\uparrow)^{-1}_{i\alpha}$$

Here we again stress that $\mathbf{B}$ has the extra dimension of 3, corresponding to the x, y, z components of the gradient. Thus, in effect we are taking the ith diagonal component (3 dimensional) from each of three $N \times N$ matrices.

We can also show that

$$[4] \qquad \frac{\partial \psi^\uparrow}{\partial c_{ij}} = \psi^\uparrow \mathbf{A}^\uparrow_{j\alpha}(\mathbf{CA}^\uparrow)^{-1}_{\alpha i}$$

and

$$[5] \qquad \frac{\partial g^\uparrow}{\partial c_{ij}} = \mathbf{D}^\uparrow_{j\alpha}(\mathbf{CA}^\uparrow)^{-1}_{\alpha i} - \mathbf{A}^\uparrow_{j\alpha}(\mathbf{CA}^\uparrow)^{-1}_{\alpha\beta}(\mathbf{CD}^\uparrow)_{\beta\gamma}(\mathbf{CA}^\uparrow)^{-1}_{\gamma i}$$

where $i = 1, \ldots, N$, and $j = 1, \ldots, J$.

Similarly, for the drift contribution to E_L:

$$[6] \qquad \mathbf{F}^\uparrow_\alpha \cdot \mathbf{F}^{c\uparrow}_\alpha = (\mathbf{CA}^\uparrow)^{-1}_{\beta\alpha}(\mathbf{CB}^\uparrow)_{\alpha\beta} \cdot \mathbf{F}^{c\uparrow}_\beta$$

we obtain

$$[7] \qquad \frac{\partial \mathbf{F}^\uparrow_\alpha \cdot \mathbf{F}^{c\uparrow}_\alpha}{\partial c_{ij}} = (\mathbf{B}^\uparrow_{j\gamma} - \mathbf{A}^\uparrow_{j\alpha}(\mathbf{CA}^\uparrow)^{-1}_{\alpha\beta}(\mathbf{CB}^\uparrow)_{\beta\gamma}) \cdot \mathbf{F}^{c\uparrow}_\gamma(\mathbf{CA}^\uparrow)^{-1}_{\gamma i}$$

where the scalar product (the standard 3-component operation) is between $\mathbf{F}_\gamma^{c\uparrow}$ and the extra third dimension of $\mathbf{B}^\uparrow$.

Now let us turn to the derivatives with respect to ζ_i, the orbital exponents:

$$[8] \qquad \frac{\partial \psi^\uparrow}{\partial \zeta_i} = \psi^\uparrow \mathbf{A}^{\uparrow\zeta}_{i\alpha}(\mathbf{CA}^\uparrow)^{-1}_{\alpha\beta}\mathbf{C}_{\beta i}$$

$$[9] \qquad \frac{\partial g^\uparrow}{\partial \zeta_i} = (\mathbf{D}^{\uparrow\zeta}_{i\alpha} - \mathbf{A}^{\uparrow\zeta}_{i\gamma}(\mathbf{CA}^\uparrow)^{-1}_{\gamma\delta}(\mathbf{CD}^\uparrow)_{\delta\alpha})(\mathbf{CA}^\uparrow)^{-1}_{\alpha\beta}\mathbf{C}_{\beta i}$$

and

$$[10] \qquad \frac{\partial \mathbf{F}^\uparrow_\alpha \cdot \mathbf{F}^{c\uparrow}_\alpha}{\partial \zeta_i} = (\mathbf{B}^{\uparrow\zeta}_{i\gamma} - \mathbf{A}^{\uparrow\zeta}_{i\alpha}(\mathbf{CA}^\uparrow)^{-1}_{\alpha\beta}(\mathbf{CB}^\uparrow)_{\beta\gamma}) \cdot \mathbf{F}^{c\uparrow}_\gamma(\mathbf{CA}^\uparrow)^{-1}_{\gamma\delta}\mathbf{C}_{\delta i}$$

Derivatives of g^c and of $\mathbf{F}^\uparrow_\alpha \cdot \mathbf{F}^{c\uparrow}_\alpha$ with respect to the parameters appearing in ψ^c are also required. For our applications we chose the usual Jastrow factor which contains two parameters. (The same function for all electron pairs was used in our trial functions.) In this case the derivative formulas are too straightforward to be presented here.

Design of the computer program

Following the approach of U.W.W., we seek the parameters of ψ which minimize the variance of the local energy:

$$[11] \qquad V = \frac{\sum_i (E_L(i) - E_g)^2 w(i)}{\sum_i w(i)}$$

Here $w(i) = (\psi(i)/\psi^0(i))^2$, where ψ_0 is the trial function computed with the "current" values of the optimized parameters, and ψ reflects any possible change of these. Now E_g is an estimate of the energy of the state of interest; our optimization proved fairly robust to the actual choice of E_g, and will perform well given just about any reasonable estimate. The sum is taken over a large number (a "block") of configurations drawn from ψ_0^2. (To use weights in this manner is the only proper way to estimate the variance, and to ignore them may (in our experience) adversely affect the performance of the algorithm.)

When attempting to optimize V with a fixed collection of configurations one immediately encounters a very serious obstacle: as the nodes of ψ change, it is very common for only a few (often just one) configurations to acquire an enormous weight $w(i)$, effectively disabling the other configurations and rendering the results of any further optimization of V virtually useless. We follow H.S.L.'s recommendations for dealing with this: ψ_0^2 is reset and a new block of configurations generated correspondingly after each update of the parameters, where the previous block averages of the analytical derivatives of V with respect to the individual variational parameters are used for this update. (A block is typically 20 Metropolis-sampling type of iterations (5) of a few hundred configurations (an ensemble).) However, we do not necessarily accept each such parameter update, as some moves may lead to variance deoptimization (backtracking being a standard feature of almost all optimizations). Our criteria for accepting/rejecting an update are described below.

We now discuss some important features of the procedure in detail:

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 123.30.183.119 on 09/08/12
For personal use only.

Equilibration

The parameters in ψ are modified at the end of each block of Monte Carlo iterations. At that point the ensemble is distributed according to the previous ψ_0. Then we want to simulate a new block according to the updated ψ (to be called ψ_0 now), but we know that it will take several iterations just to re-equilibrate the ensemble. To do so, special care must be taken to remove the "locked-in" configurations which, under Metropolis sampling, would effectively never move (or only after extremely many attempts). They arise because the probability of moving a configuration goes to zero when a node of the new (updated) ψ gets into its immediate vicinity (6). Each such configuration is a remnant of ψ_0 and not at all representative of the current ψ. Keeping it and its likes would significantly bias the averaging process. (This problem, even though not well publicized, applies to any quantum Monte Carlo algorithm which employs an acceptance/rejection step.)

We deal with this problem by monitoring the "staleness" of each configuration — the number of times its move has been consecutively rejected. (A configuration which moves is assigned a staleness of zero.) When the staleness reaches a fixed value (such as 8), the corresponding configuration is replaced by another one, randomly selected from those whose staleness is zero. With this feature near-equilibration is achieved relatively quickly; we usually discard the first 2–8 iterations of each block to allow the ensemble to adjust to the new values of the parameters. Thereafter we start averaging: the local energies, their derivatives with respect to individual variational parameters, the derivatives of ψ, and the values of $(E_L - E_g)^2$ (whose average defines the block variance).

The variance

Since the block variance is subject to statistical fluctuation (unlike in standard optimization), it is important not to reject all changes which result in its increase. For this purpose we use the following scheme:

The average block variance is computed as follows:

$$[12] \quad M^{-1} \sum_{i=1}^{M} (E_L(i) - E_g)^2 \equiv \overline{(E_L(i) - E_g)^2}$$

(This is effectively a double summation, where the implied sum is over all configurations of the contributing part of the block. Thus, M equals the number of configurations times the number of contributing iterations.)

If the current block variance is higher than 1.5 times the "best" variance, the move is rejected — the procedure backtracks to the "best" results (wavefunction and ensemble) so far. At the same time the value of the "best" variance is increased by a factor of 1.5 to prevent the procedure from being "cornered" by statistical fluctuations. (These factors were determined empirically.) Also, the value of the optimization parameter λ (to be described shortly) is doubled, which results in a more conservative parameter "move" for the next block. Otherwise, the parameter update is accepted. But should the current variance actually be smaller than the "best" variance, this too is updated, and the value of λ modified to $\sqrt{(5\lambda)}$ (so that the next move can be more "daring").

To estimate the derivatives of the variance [11], it is important to realize that both ψ and E_L will vary with the parameters, but ψ_0 is fixed (defining the distribution of configurations in the current block). Then the first derivative of the variance with respect to a variational parameter (say, p_j) is obtained from the first derivatives of E_L and ψ as follows:

$$[13] \quad \frac{1}{2}\frac{\partial V}{\partial p_j} = \overline{(E_L - E_g)\frac{\partial E_L}{\partial p_j}} + \overline{(E_L - E_g)^2\left(\frac{1}{\psi}\frac{\partial \psi}{\partial p_j}\right)} - \overline{(E_L - E_g)^2} \cdot \overline{\frac{1}{\psi}\frac{\partial \psi}{\partial p_j}}$$

For the second derivative, to a good approximation:

$$[14] \quad \frac{1}{2}\frac{\partial^2 V}{\partial p_j^2} \approx \sum_{i=1}^{M} \left\{ \frac{\partial}{\partial p_j} \left[\frac{(E_L(i) - E_g)w(i)}{\left(\sum_{i=1}^{N} w(i)^2\right)^{1/2}} \right] \right\}^2$$

$$= \overline{\left(\frac{\partial E_L}{\partial p_j}\right)^2} + \overline{2(E_L - E_g)\left(\frac{\partial E_L}{\partial p_j}\right)\left(\frac{1}{\psi}\frac{\partial \psi}{\partial p_j}\right)} + \overline{(E_L - E_g)^2\left(\frac{1}{\psi}\frac{\partial \psi}{\partial p_j}\right)^2} - 2\left[\overline{(E_L - E_g)\frac{\partial E_L}{\partial p_j}} + \overline{(E_L - E_g)^2\left(\frac{\partial \psi}{\psi \partial p_j}\right)}\right] \cdot \overline{\left(\frac{1}{\psi}\frac{\partial \psi}{\partial p_j}\right)} + \overline{((E_L - E_g)^2)} \cdot \left[\overline{\left(\frac{1}{\psi}\frac{\partial \psi}{\partial p_j}\right)}\right]^2$$

This approximation is standard with least-squares fits used by statisticians and applies equally well here (7).

Updating quantities

Using the variance derivatives eq. [13] the variational parameters are updated by the steepest-descent technique:

$$[15] \quad p_j \rightarrow p_j - \frac{\overline{\frac{\partial V}{\partial p_j}}}{\overline{\frac{\partial^2 V}{\partial p_j^2}}} \cdot \lambda^{-1}$$

Typically λ assumes values between 5 and 10, starting with an initial value of 10.

Estimating the variational parameters

This procedure will optimize ψ even from very rough initial estimates of the variational parameters and a randomly generated ensemble. However, scores of blocks are required to reach a good variance minimum (to achieve "stabilization"), so for increased efficiency this is done in two stages:

First we perform a coarse optimization with a very small block size (we used 5 iterations) with only one or two iterations discarded to allow for equilibration within a block. The parameters very quickly assume quite reasonable values, and these are then used as improved initial values to perform one or more fine optimizations. This consists of several much larger blocks (we used 20 iterations) and more allowance made for equilibration (8 iterations were discarded). Upon stabilization one can still observe small changes in the variational parameters (essentially random fluctuations), and we

[b]Equation [17] with $b = c = 0$.

choose to simply average these over several dozen extra blocks.

It is important to stress that some components of our sampling technique will bias the variance estimate: random replacement of stale configurations; use of a relatively small number of iterations to near-equilibrate within each block; rejection of blocks with large variances; etc. All this will usually slightly exaggerate the quality of the achieved results, both in terms of the variance and ground-state energy. (See Table 1.) This will be more pronounced in the coarse optimizations, but still visible in fine-tuning runs as well. Thus it is necessary to subsequently perform a standard Metropolis-sampling verification to get proper estimates of these quantities. For this purpose we significantly increase the ensemble size as well.

Applications

We apply our scheme to optimize wavefunctions for the ground state of the LiH and H_2O molecules, taken at the experimental geometry. Initially we consider wavefunctions as expressed as a single product of two determinants (one for each spin possibility) multiplied by a Jastrow-type electron correlation function:

$$[16] \quad \psi^c = \exp\left(\sum_{i>j} \frac{ar_{ij}}{1 + br_{ij}}\right)$$

For the sake of programming convenience the basis set was created from Cartesian-like STO's:

$$[17] \quad [a,b,c,d] \equiv \zeta^m r^a x^b y^c z^d \exp(-\zeta r)$$

where $m = a + \ldots + d + 3$. (The non-standard "normalization" constant was intentional.)

For the c_{ij} matrix we start with an $N \times N$ unit matrix for the anticipated "dominant" N basis functions, and zero otherwise. (Without any loss of generality, for our choice of wavefunction the unit matrix can and should be kept fixed throughout the optimization.) For LiH the initial ζ's for all orbitals were equal to the corresponding atomic number. The initial (200) configurations were distributed randomly. The Metropolis iterations were done using a time-step value of 0.05 au. For the "fine" optimizations we used 500 blocks, discarding 300 to allow for stabilization. For the verification of our results, we used 1000 configurations; after equilibration we averaged the energy and variance over 10 blocks of 500 iterations each.

For H_2O the oxygen 1s orbital exponent was initially set at 8; for the second shell orbitals we used the value of 3. The initial random ensemble was distributed randomly as well. The Metropolis time-step was 0.005 au. The optimization was done in stages: first using only a few orbitals (10), then reoptimizing with more oxygen orbitals (initial orbital exponent equal to 6.)

The verified energy and variance, and the corresponding optimized parameters for both molecules appear in Tables 1–3, respectively.

It is obvious that our trial function is not general enough to give us the exact answer even in the limit of using infinitely many atomic orbitals. In fact, we reach this limit with

9 orbitals for LiH and 42 for H_2O. For LiH the single configuration wavefunction recovers roughly 77% of the correlation energy, for H_2O it is 46%.

Our initial choices of ζ (described above) were purposely made rather arbitrarily. In practice one may elect to use known well-studied basis sets originally designed for Hartree–Fock calculations to speed up the optimization.

The derivatives of the wavefunction and of the local energy of a single-product trial function can be easily extended to a multiconfiguration wavefunction augmented by the electron-correlation Jastrow (8):

$$[18] \quad \psi = (\psi_0^{\uparrow}\psi_0^{\downarrow} + C_1\psi_1^{\uparrow}\psi_1^{\downarrow} + \ldots)\psi^c$$

where the ψ_i's are several different Slater determinants, and the C's are additional optimization parameters. Here the leading term corresponds to the already optimized single-configuration wavefunction, so only the c_{ij}'s, ζ's, and the C's of the additional components need be optimized. We suggest doing this in stages: first optimize C_1 and $\psi_1^{\uparrow(\downarrow)}$, then C_2 and $\psi_2^{\uparrow(\downarrow)}$ (with fixed $\psi_0^{\uparrow(\downarrow)}$, C_1 and $\psi_1^{\uparrow(\downarrow)}$), etc.

To illustrate that this is indeed easily done, we optimized trial function [18] with up to four configurations for the case of LiH. Also, primarily for the sake of curiosity, we changed the basis set to one of "exact" hydrogen-like orbitals:

$$[19] \quad \chi = \rho^l L_n^l(\rho) P_l(\cos(\theta)) \exp(-\rho/2)$$

where $\rho = \zeta r$, P is the standard Legendre polynomial, and L is a Laguerre polynomial, scaled such that the constant term is equal to one:

$$[20]\quad L_\alpha^\beta = 1 - \frac{\alpha-\beta}{\beta+1}\rho + \frac{(\alpha-\beta)(\alpha-\beta-1)}{(\beta+1)(\beta+2)2!}\rho^2 - \frac{(\alpha-\beta)(\alpha-\beta-1)(\alpha-\beta-2)}{(\beta+1)(\beta+2)(\beta+3)3!}\rho^3 + \ldots$$

The energy and variance results for each of four stages of optimization are shown in Table 1. (Note that the single-configuration result was not an improvement over the previous one using the Cartesian Slater orbital basis.) As we continued the optimization, the variance improved at each stage, with the net improvement of about 40%. The energy improved in tandem with the variance. Our optimized four-component wavefunction (Table 4) recovered roughly 85% of the correlation energy. (In our final optimization stage we kept fixed only the parameters for dominant (first) configuration.)

In our applications to LiH and H_2O we used the common choice of both the electron correlation function and the molecular orbitals. Our derivative formulas will also apply (with only minor changes) to other choices, such as the one made by Sun *et al.* (9), who allow the basis function orbital exponents to be different for each molecular orbital. For the sake of curiosity, we extended their wavefunction to 42 orbitals, but this resulted in no significant improvement over the 42 orbital wavefunction we reported above.

Our paper has focused on the technicalities of wavefunction optimization by the Monte Carlo technique. Having concentrated on the technical aspects, we tried to identify the basic ingredients needed for any successful future development, the use of analytical derivatives in particular. We hope to have provided a valuable tool for further research into the electron correlation problem.

In this paper, we use the semi-empirical Hartree–Fock method introduced within the finite electric field perturbation approach, to calculate the molecular and π-system polarizabilities of *trans* and *cis* polyene H(-CH=CH-)$_n$H (n = 3, 4, 5, ..., 18). The result is that for a given n, the order of both molecular and π-system polarizabilities of polyene is *trans* > *cis*. This result is consistent with the order of experimental values of *trans* and *cis* hexatriene. When the n increases from 3 to 18, the contribution of π-system polarizability to the molecular polarizability increases from 45 to 70%. Using these results, we have extrapolated the polarizabilities of both *trans* and *cis* polyacetylene. The order is *trans* > *cis*. These results and crystal parameters lead to an estimate of the dispersion energies among polyacetylene chains. The result is also $E_{disp}(trans) > E_{disp}(cis)$.

Key words: polarizability, polyacetylene, *cis*/*trans*, CNDO, dispersion energy.

ZHONGHAO HUANG, DANIEL A. JELSKI, RONGSHUN WANG, DEMIN XIE, CHENDA ZHAO, XINFU XIA et THOMAS F. GEORGE. Can. J. Chem. **70**, 372 (1992).

Dans ce travail, on utilise la méthode semi-empirique de Hartree–Fock introduite dans une approche de perturbation d'un champ électrique défini pour calculer les polarisabilités moléculaires et des systèmes-π des polyènes *cis* et *trans* H(-CH=CH-)$_n$H (n = 3, 4, 5, ..., 18). Le résultat est que, pour une valeur donnée de n, l'ordre des polarisabilités moléculaires et des systèmes-π du polyène est *trans* > *cis*. Ce résultat est en accord avec les valeurs expérimentales de l'ordre des *trans*- et *cis*-hexatriènes. Lorsque la valeur de n augmente de 3 à 18, la contribution de la polarisabilité du système-π à la polarisabilité moléculaire augmente de 45 à 70%. Utilisant ces résultats, on a extrapolé les polarisabilités des *cis*- et *trans*-polyacétylènes. L'ordre est *trans* > *cis*. Ces résultats et les paramètres cristallins conduisent à une évaluation des énergies de dispersion entre les chaînes de polyacétylène. On en déduit que $E_{disp}(trans) > E_{disp}(cis)$.

Mots clés : polarisabilité, polyacétylène, *cis*/*trans*, CNDO, énergie de dispersion.

[Traduit par la rédaction]

Introduction

Polyacetylene (PA) is an important conductive polymer that has two isomers, *trans* and *cis* (see Fig. 1). Since PA was synthesized (1,2) and it was found that the conductivity of doped PA rapidly increases from 10^{-6} $(\Omega\ cm)^{-1}$ to as high as 10^3 $(\Omega\ cm)^{-1}$ with increasing dopant concentration (3), much experimental and theoretical research (4,5) has been reported, including differences between *trans* and *cis* PA (6–8). Polarizability is an important property of a material and closely related to interactions among molecules and the dielectric coefficient of the material. Because PA is relatively insoluble and decomposes before melting (9), these experimental difficulties have so far precluded the measurement of the polarizability of either *trans* or *cis* PA.

Davies (10) studied the π-system polarizabilities of the *trans* polyene series, using the perturbed HMO method. He found that the α^{π}_{xx}, which is the component of π-system polarizability along the carbon chain, is proportional to L^3, where L is the length of carbon chain. Recently, Hurst *et al.* (11) calculated the polarizabilities of *trans* polyene series, H(-CH=CH-)$_n$H (n = 2, 3, ..., 11), using the *ab initio* coupled–perturbed Hartree–Fock method, and the extrapolated polarizability of *trans* PA is 60.3 au/C_2H_2. To our knowledge, no study of the polarizability of *cis* PA and the contribution of the π-system polarizability to molecular polarizability has yet been reported. It is therefore interesting to calculate and compare the π system and the molecular polarizabilities of both *cis* and *trans* PA, and to discuss their differences, which is the purpose of this article.

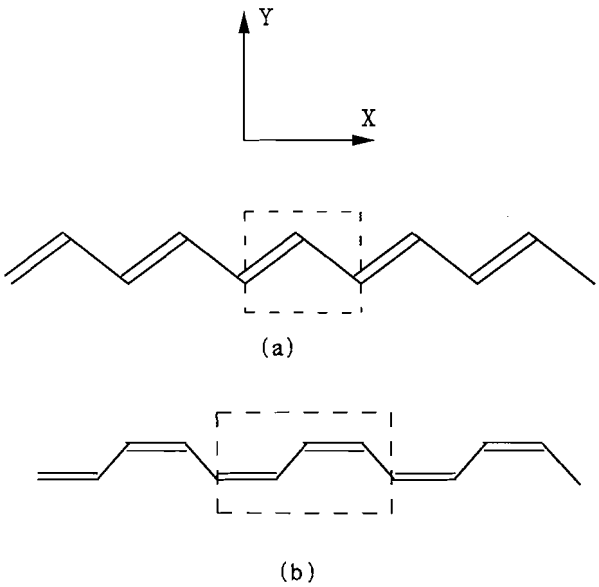

FIG. 1. Diagram of the geometry of *trans* (*a*) and *cis* (*b*) polyacetylene. The polyacetylene unit cell is indicated by the dashed lines. The coordinates used in this calculation are illustrated, with the *z*-axis taken as perpendicular to the page. The origin is chosen as the center of mass for each member of the polyene series.

Method

Because PA can be considered an infinite polyene, and given the difficulty of directly calculating the polarizability of an infinite polymer, the best method available is to calculate the polarizabilities of a series of polyenes with finite chain length, and then extrapolate to the infinite limit, i.e., PA. Hence the longer the polyene chain, the more reliable the extrapolated result for PA may be expected to be. We therefore choose a method for which chain length is not a severe limitation.

Zyss *et al.* (12,13) calculated the polarizabilities of many conjugated molecules using the semi-empirical Hartree–Fock method introducing a finite electric field perturbation, and obtaining good results. This method can be briefly described as follows. If $\hat{H}_0$ is the single-electron Hamiltonian operator of an unperturbed system and **F** is a finite external electric field, the single-electron Hamiltonian of the perturbed system is

$$[1] \quad \hat{H} = \hat{H}_0 + \mathbf{r} \cdot \mathbf{F}$$

where **r** is the coordinate vector of the electron, and where we have used $F = 10^{-4}$ au (13). Substituting eq. [1] into the Hamiltonian operator in the Roothaan equations (14), one obtains the molecular polarizability as

$$[2] \quad \alpha_{ii} = [\mu_i(F = F_i) - \mu_i(F = 0)]/F_i$$

$$[3] \quad \alpha = \frac{1}{3}\sum_i \alpha_{ii} \qquad (i = x, y, z)$$

where μ_i is the component of the molecular dipole moment along the *i*-axis.

Given the desirability of performing the calculation on as large a polyene molecule as possible, we choose a semi-empirical method (CNDO/2) (15) instead of an *ab initio* technique. Considering the importance of the π system in polyene and PA, we are especially interested in the contributions of the $2p_z$ (π) electron to the molecular polarizability, and these are reported separately as α^π.

TABLE 1. Polarizabilities (au) of *trans* and *cis* hexatriene

	Present work α	Experimental data (ref. 16)		
		Refractivity	Density (g/cm^3)	α
trans	73.1920	1.5135	0.7369	87.4565
cis	71.1604	1.4577	0.7175	81.4466

In Table 1, we list the relative experimental values (16) and our calculated results for the polarizabilities of *trans* and *cis* hexatriene. The structure parameters of hexatriene come from experimental values (17,18). Our results are consistent with experiment and demonstrate the reliability of this method.

Only a few structure parameters of polyene molecules have been determined, and these all approach the standard values: L(C=C) = 1.35 Å, L(C—C) = 1.45 Å, $\measuredangle$CCC = 120°, the same as the case for the determined and optimized PA parameters (19,20). Therefore we take the standard parameters as the structure parameters of both *trans* and *cis* polyene. The coordinate system is as shown in Fig. 1. It is possible to distinguish between *trans* and *cis* forms only for $n \geq 3$, and hence our calculation starts with $n = 3$.

Results

In Table 2 we list π-system and molecular polarizabilities and the contributions of the π system to molecular polarizability. Some of these data are illustrated in Fig. 2. From these results, we derive the following conclusions:

1. When *n* is the same, the order of both molecular and π-system polarizabilities of *trans* and *cis* polyene is *trans* > *cis*, also shown in Fig. 2. This order is consistent with the order of experimental polarizabilities of *trans* and *cis* hexatriene.

2. The molecular polarizability of polyene mainly comes from the contribution of the π system. The longer the carbon chain, the larger the contribution of the π system. When *n* increases from 3 to 18, the contribution of the π system increases from 45 to 70%.

3. A value for $\alpha^\sigma/n = \alpha/n - \alpha^\pi/n$ is easily calculated. This difference is nearly constant over the entire range of *n*, as shown in Fig. 2. This means that the polarizability of the σ system in a -CH=CH- unit for various polyenes is the same, which obviously differs from the π system. The σ polarizability is essentially independent of chain length. This differs from the π polarizability because of the delocalized nature of the π system.

To generalize the polyene results to PA, we require a function that accounts for the fact that $d(\alpha/n)/dn \rightarrow 0$ for large *n*. The proposed function (11) is

$$[4] \quad \log(\alpha/n) = a + b/n + c/n^2$$

This implies that $\lim_{n\rightarrow\infty} \alpha/n = 10^a$ for PA. Our values and Hurst's are compared in Table 3. The relative polarizabilities of the *cis* and *trans* PA are in the same order as for the polyene series. However, the π-electron contribution for PA is larger than for polyene, as shown in Table 3.

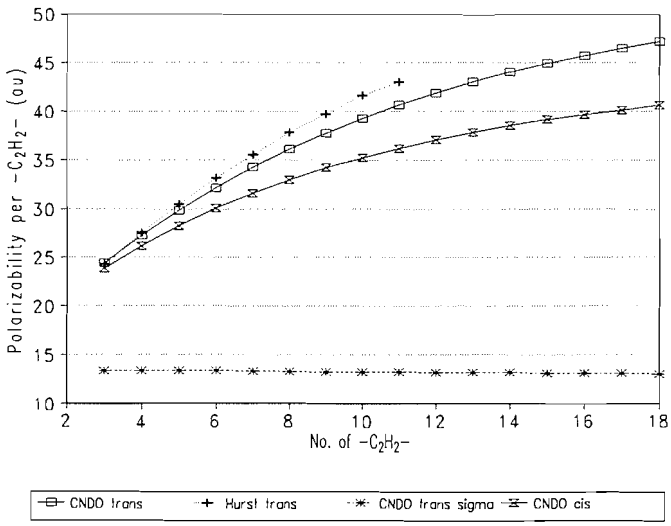

FIG. 2. Polarizability of polyene as a function of chain length, comparing the *trans* and *cis* isomers. Also shown are the *ab initio* (11) results and the σ-electron polarizability for the *trans* species. The σ-electron polarizability for the *cis* isomer is almost identical.

Discussion

We begin by considering the reasons why the *trans* isomer polarizability is larger than the *cis*. First are geometric considerations. If L is the length of the carbon chain, $L = n \times l$, then l is the length of the projection of a unit cell (-CH=CH-) (including both a C=C and a C—C bond) on the x-axis. In our calculation, l is equal to 2.425 Å and 2.125 Å for *trans* and *cis* polyene, respectively. The projection of *trans* is larger than *cis* by 0.3 Å. This makes the conjugation length of the *trans* polyene π system longer than that of *cis* polyene by $n \times 0.3$ Å, when n is the same. This is the main reason that both π-system and molecular polarizabilities of *trans* polyene are larger than those of *cis* polyene.

Besides the difference in x-axis projection length between the *trans* and *cis* unit structures, we consider another factor affecting polarizability magnitude. The unit cell of *trans* PA consists only of one -CH=CH- segment, whereas a unit cell of *cis* PA consists of two -CH=CH- segments, as shown in Fig. 1. This demonstrates that the translational symmetry of *trans* PA is higher than that of *cis* PA. Clearly, the higher the translational symmetry, the larger the delocalizability, and the larger the polarizability. Thus one would expect the *trans* and *cis* isomers to differ in subtle chemical respects in addition to geometrical effects. We expect similar effects for finite polyenes as well.

Two functional forms to describe the polarizability of *trans* polyene have been given in the literature. Hurst *et al.* (11) suggest that $\alpha \approx N^{\gamma}$, where they find $\gamma \approx 1.6$ for small polymers. However, if the delocalization length is finite, then γ must also be a function of n and must eventually tend toward 1, i.e., the polarizability is proportional to n. We specify the proportionality constant as

$$[5] \quad \alpha = Cn^{\gamma}$$

where two parameters, C and γ, are to be fitted to the data.

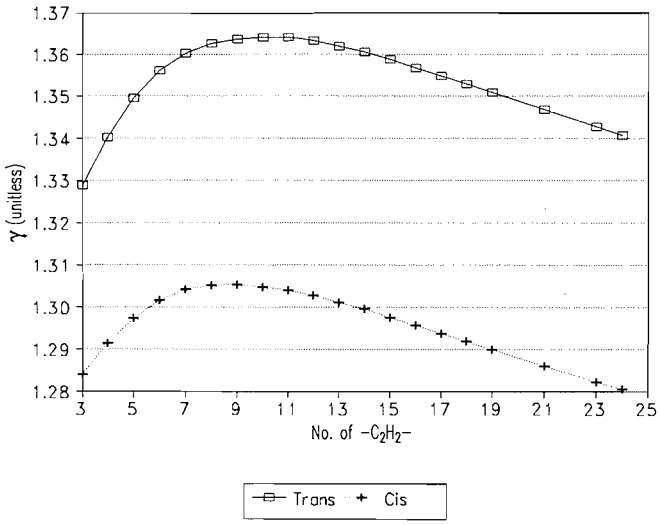

FIG. 3. Parameter γ versus polyene length.

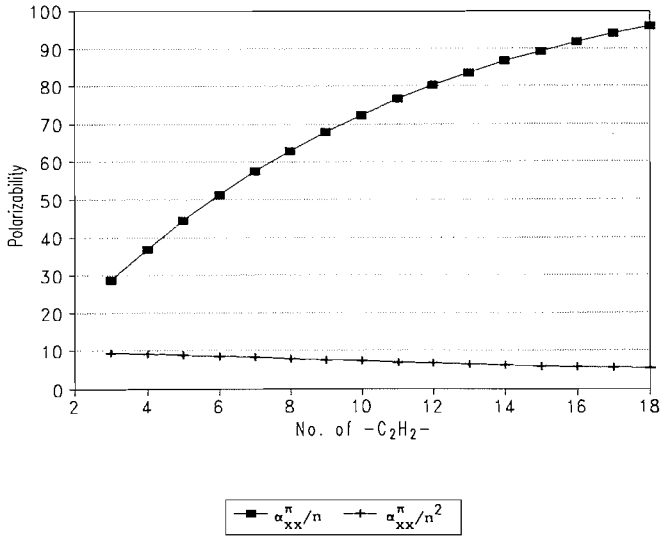

FIG. 4. α^{π}_{xx}/n and α^{π}_{xx}/n^2 for *trans*-polyene.

Equation [5] will provide some significant physical insight in what follows.

Hurst *et al.* (11) have proposed yet another function, given by eq. [4]. Parameter a has clear physical significance, already mentioned. Parameters b and c only influence the behavior at small n, and from physical arguments (i.e., a less conjugated system), we know that $b < 0$. We have fitted our data to the Hurst function for *trans* PA, with the results shown in Table 3. It is seen that our value for a corresponds very closely with that of Hurst, and thus our value for the PA polarizability is close to that obtained by Hurst. This implies that as the chain becomes longer, the values obtained for the polarizability will more closely match the *ab initio* results. Since Hurst used polyenes with $n = 2, 3, \ldots, 11$, and we use $n = 3, 4, \ldots, 18$ from which to extrapolate the polarizability of PA, this implies that the semi-empirical method with minimal Slater type basis can closely match the *ab initio* result. However, parameters b and c, which affect short-chain behavior, are less reliable.

The physical significance of the power law (eq. [5]) depends on how C is defined. If C is defined as C_∞, the limiting value of α/n as $n \rightarrow \infty$, then $C_\infty = 10^a$, identical to the limiting value in eq. [4], and eq. [5] is valid for large n when $\gamma = 1$. On the other hand, if C is defined as C_0, the polarizability of the $-C_2H_2-$, i.e., α for $n = 1$, the form can be fitted to small n but will be incorrect in the large n limit if γ is assumed to be constant. Further, in this case it is apparent that γ cannot converge to unity since then the polarizability of the infinite chain would equal that for $n = 1$. Finally, C_0 must be equal for both *cis* and *trans* polymers, and therefore has a very definite physical meaning. It is clear that γ has a different physical interpretation depending on how C is chosen.

A least-squares fit to determine C_0 in the *trans* and *cis* cases reveals 17 au ± 1 au. Given $C_0 = 17$, it is then possible to plot the necessary value of γ from the CNDO and Hurst data. This is shown in Fig. 3, and several points can be made. First, we note that values for γ are larger in the *trans* case than in the *cis*. This is consistent with the value of a, and with the notion that the *trans* form has a larger polarizability. Secondly, it is apparent that γ goes through a maximum at approximately $n = 9$ for the *cis* isomer, and $n = 10$–11 for the *trans* isomer. This probably reflects a distance related to the delocalization effect in polyene, indicating that electrons are delocalized over a larger region in the *trans* isomer than in the *cis*.

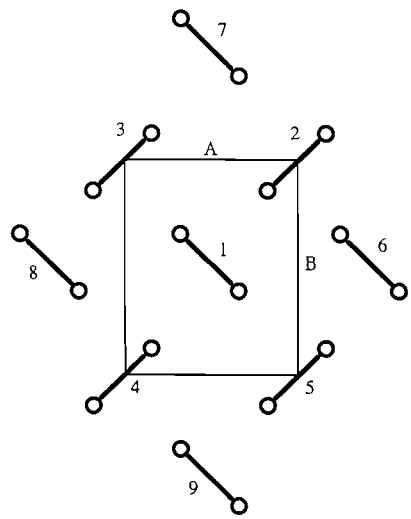

FIG. 5. The (001)-plane for the crystal unit cell of *trans* and *cis* polyacetylene.

Figure 4 illustrates the α^{π}_{xx}/n and the α^{π}_{xx}/n^2 for *trans* polyene. Using HMO theory (infinite delocalization length), Davies (10) showed that this ratio should increase proportionally to n^2 for *trans* PA. If the delocalization length were infinite, then one would expect the HMO theory to be accurate, but Fig. 4 indicates that it is not valid. Therefore, the existence of a typical delocalization length is further indicated.

The dispersion energy of crystalline PA

The crystal structure parameters of both *trans* and *cis* PA have been determined (20,21) and are similar to each other (see Fig. 5 and Table 4). Because PA is a nonpolar mate-

TABLE 4. The E_{disp} among chains and relevant parameters of *trans* and *cis* PA

	trans PA	*cis* PA
Cell parameter (refs. 20, 21)		
A (Å)	4.24	7.61
B (Å)	7.32	4.39
C^a (Å)	2.46	4.47
α (deg)	90.	90.
β (deg)	91.5	90.
γ (deg)	90.	90.
Ionization energy (au)	0.243	0.246 (ref. 22)
E_{disp}(kcal/mol)	9.873	5.194

[a]The C-axis is along the carbon chain, and the repeat unit along the C-axis is $-C_2H_2-$ for *trans* PA and $-C_4H_4-$ for *cis* PA.

rial, we can estimate the dispersion energy among PA chains in crystals as

$$[6] \quad E_{disp} = -\frac{3}{4} \times \frac{\alpha^2 I}{R^6}$$

where I is the ionization energy of PA (22), and R is the distance between centers of two chains. The calculated results and relevant parameters are listed in Table 4, and E_{disp} is the sum of the dispersion energies between chain 1 and chains 2, 3, 4, 5, 6, 7, 8, and 9, respectively. We use the extrapolated α/n for PA, as calculated above, and all the centers of nine PA units are on the same plane. Consistent with our previous results, E_{disp} for the *trans* PA is larger than for the *cis*. These are shown in Table 4.

Conclusion

We have calculated the polarizability of a series of *trans* and *cis* polyene molecules. Our results compare favorably with those of Hurst (10). The data have been fitted to an appropriate function, and it is found that our data and Hurst's have the same limiting behavior. We therefore conclude that the polyene data may be extrapolated to provide information about polyacetylene.

Further, we have considered the relative polarizability of *trans* and *cis* polyene, and we show that *trans* has a larger polarizability than *cis*. An inquiry into the reasons for this phenomenon indicates that it is a function of geometry and of symmetry.

Finally, we have presented data on the crystal dispersion energy. We find dramatic differences between the *trans* and *cis* forms, which should in principle be measurable, thereby allowing experimental confirmation of our results.

Institute for Fundamental Chemistry, 34-4, Takano-Nishihiraki-cho, Sakyo-ku, Kyoto 606 Japan

Received July 5, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

MASATAKA NAGAOKA, YOSHISHIGE OKUNO, TOKIO YAMABE, and KENICHI FUKUI. Can. J. Chem. **70**, 377 (1992).

To clarify the mechanism of chemical reactions in solution, each solvent molecule was classified as either a reactive-solvent molecule or a medium-solvent molecule in accordance with its role in the reaction. The proton transfer reaction of formamidine in water was treated as a model reaction. *Ab initio* molecular orbital calculations were performed for the complex made up of a formamidine, a reactive-water molecule, and a medium-water molecule. The optimized geometries and the solvation energies were obtained and the orbital interaction analysis carried out along the intrinsic reaction coordinate (IRC). It was found that the medium-water molecule influences the reaction dynamically rather than energetically. There was no energy change in the potential barrier under the influence of the medium-water molecule, in contrast to the remarkable barrier-reducing effect of the reactive-water molecule. The situation is different from that in chemical reactions involving ionic states. Chemical reaction molecular dynamics (CRMD) simulation for this system was performed in order to investigate the energy relaxation mechanism. It was found that just after the reaction finishes, a relative translational motion is first induced between the supermolecule, which consists of a formamidine and a reactive-water molecule, and the medium-water molecule, and is then followed by a rotational motion of the medium-water molecule.

Key words: formamidine, chemical reaction molecular dynamics method, reactive-solvent molecule, medium-solvent molecule, energy relaxation mechanism.

MASATAKA NAGAOKA, YOSHISHIGE OKUNO, TOKIO YAMABE et KENICHI FUKUI. Can. J. Chem. **70**, 377 (1992).

Dans le but de clarifier les mécanismes de réactions chimiques en solution, on a classifié chaque molécule de solvant, suivant son rôle dans la réaction, soit comme une molécule de solvant réactive soit comme une molécule de solvant agissant comme milieu réactionnel. On a utilisé la réaction de transfert de proton de la formamidine dans l'eau comme modèle. On a effectué des calculs d'orbitales moléculaires *ab initio* sur le complexe formé d'une formamidine, d'une molécule d'eau réactive et d'une molécule d'eau agissant comme milieu réactionnel. On a obtenu les géométries optimisées et les énergies de solvatation et on a réalisé une analyse des interactions orbitalaires le long des coordonnées intrinsèques de la réactions (CIR). On a trouvé que l'eau agissant comme milieu réactionnel n'a pas d'influence sur l'énergie de la réaction; elle agit toutefois sur la dynamique de la réaction. Sous l'influence de la molécule d'eau agissant comme milieu réactionnel, il n'y a pas de changement d'énergie dans la barrière de potentiel; ce comportement diffère d'une façon notable avec l'effet remarquable de réduction de la barrière de la molécule d'eau réactive. La situation est différente de celle qui prévaut dans les réactions chimiques impliquant des états ioniques. Afin d'évaluer le mécanisme de relaxation moléculaire, on a effectué une simulation de la dynamique moléculaire de la réaction chimique (DMRC). On a trouvé que, immédiatement après la fin de la réaction, il se produit d'abord un mouvement relatif de translation entre la supermolécule, qui consist d'une formamidine et d'une molécule d'eau réactive, et la molécule d'eau agissant comme milieu réactionnel qui est suivi d'un mouvement de rotation de la molécule d'eau agissant comme milieu réactionnel.

Mots clés : formamidine, méthode de la dynamique moléculaire de la réaction chimique, molécule de solvant réactive, molécule de solvant agissant comme milieu réactionnel, mécanisme de relaxation d'énergie.

[Traduit par la rédaction]

Introduction

Based on extensive gas phase research using molecular orbital (MO) theories, theoretical chemists have recently been challenged to resolve problems in solution chemistry in terms of molecular language (1–4). It is true that most treatments were developed in combination with techniques that were originally invented in the field of condensed phase physics. Hence the chemical and physical quantities of their concern are closely related to equilibrium properties of solution and ensemble-averaged properties. However, as far as solvent effects are concerned, not only *long-range interactions* but also *short-range interactions* should be taken into consideration. In particular, a chemical reaction in solution, with accompanying recombination and reorientation of constituent atoms, is essentially a nonequilibrium process, with both energy concentration and dissipation. Thus, we must inevitably deal with such short-range interactions as *exchange-exclusion* and *electron transfer interactions* between a solute molecule and certain solvent molecules, in addition to long-range interactions, i.e., *electrostatic*, *polarization*, and *dispersion interactions*.

Under the circumstances, one can be led naturally to the notion that solvent molecules in solution should be classified in two categories; the *reactive-solvent* molecule and the *medium-solvent* molecule. The former is defined as a solvent molecule that interacts with a solute molecule through short-range interaction, while the latter interacts through long-range interaction. A reactive-solvent molecule might be included in a reactant in addition to the solute molecules themselves, if the short-range interaction were regarded as part of the chemical bonding interaction. Although the simulation that deals with both a solute and a number of medium-solvent molecules at the same time must represent a good approach to the study of the medium-solvent effect, it

cannot be denied that the reactive-solvent effect might play a dominant role in solving the mechanism of chemical reaction dynamics in solution.

We have therefore investigated the proton transfer reaction of formamidine in water as one model of chemical reactions in solution (5, 6). The proton transfer reaction is worthwhile investigating because its study contributes in general to a deeper understanding of chemical reactivity, and is of special importance to biochemical systems. In fact, extensive theoretical studies for solvation in biological systems have been examined by several researchers (7). Moreover, much attention has been paid to studies of formamidine on the relation between molecular conformation and biological activity (8–11).

Previously, we determined that the potential energy barrier, 59.11 kcal/mol, of the intramolecular proton transfer process of formamidine is reduced to 21.56 kcal/mol, with the assistance of only a water molecule, which corresponds to the energy difference between the stable state (I) and the transition state (II) for the intrasupermolecular proton transfer reaction process of the formamidine–water (FW) system (Fig. 1) (5, 6). On the other hand, the potential energy barrier calculated recently by MP4/6-311G(*d*,*p*) wave functions was reported by Truhlar and co-workers (12) to be 24.6 kcal/mol for the FW system. Although it was also reported that the potential energy barrier is 6.8 kcal/mol and is significantly lower than the value 21.56 kcal/mol, Truhlar and co-workers must have misunderstood the definition of the "potential energy barrier" adopted in ref. 6. Therefore, the value that should have been compared with 21.56 kcal/mol is 24.6 kcal/mol for the reaction E → F in their Table II(B). The difference between their value (24.6 kcal/mol) and ours is just 3.0 kcal/mol and, moreover, no striking difference in the geometries can be recognized. Hence, it is expected that the energetics for the proton transfer reaction process of the FW system can be described sufficiently by the basis set used in our study.

On the basis of these static studies for the proton transfer reaction of formamidine in water, the dynamic investigation for the FW system was performed by chemical reaction molecular dynamics (CRMD) simulation and the existence of the dynamic transition state (DTS) was postulated (13, 14). The water molecule in the FW system can be recognized as a reactive-water molecule because it plays a central role in proton rearrangement. However, after taking the *reactive solvent* effect into consideration, the next step for understanding solution chemistry is to clarify the role of the medium-solvent molecule in the chemical reaction mechanism.

The aim in the present article, therefore, is to show the *medium-solvent* effect not only from the static, but also from the dynamic, viewpoint. For the purpose, another water molecule (i.e., a medium-solvent molecule) is added to the original FW system and the static medium-solvent effect is investigated first by an *ab initio* MO method. On the basis of the supermolecular treatment of the formamidine–water–water (FWW) complex, *ab initio* MO calculations are performed and then the transition state (TS) obtained as a saddle point on the potential energy surface is compared with that of the FW system. The interaction between the FW system and the medium-water molecule is certified to be the long-range interaction, by analysis of optimized geometries, solvation energies, and orbital interactions. The intrinsic reaction coordinate (IRC) is carefully traced and then the potential energy barrier is estimated. It is clear that the medium-water molecule does not influence both the original FW geometry and then the potential energy barrier and, as a result, the solvation energy is small, as well as the orbital interaction between the FW system and the medium-water molecule.

After constructing the intermolecular potential function between the FW system and a medium-water molecule, the CRMD simulation for the FWW complex is performed in the constant-temperature scheme (CTS) (13) and hence the energy relaxation mechanism can be investigated precisely. (The CRMD studies in the constant-energy scheme (CES) will be discussed in another publication (15).) It is understood that the medium-solvent effect in the energy relaxation/supply is observed after/before the reaction finishes/starts. The relative translational kinetic energy between the FW system and the medium-water molecule first increases. Then it transfers to the rotational kinetic energy of the medium-water molecule.

In the following section, the method utilized in the present article is precisely explained and, in the Results and discussion, the calculational results are presented, with discussion in terms of *ab initio* MO theory and CRMD treatment. Finally, a concise summary is drawn in the Conclusions.

Method

Ab initio *MO calculations and IRC analysis*

Ab initio MO calculations (16) were carried out by using the GAUSSIAN86 program (17) with the minimal STO-3G basis set (18) at the Hartree–Fock level of theory (19). All the geometries of the complexes were optimized with the analytical energy gradient method (20). All optimizations were accomplished under the tight convergence criterion.

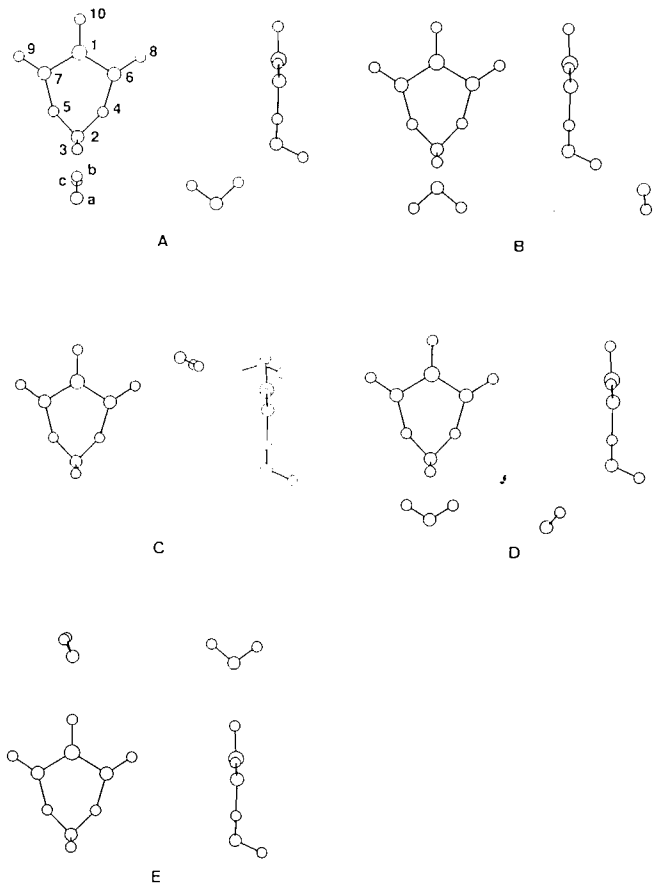

FIG. 2. Optimized geometries of the FW(TS)–W(SS) complex.

In the supermolecular treatment where another water molecule (i.e., a medium-solvent molecule) is added to the FW system, the geometry optimization of TS should be performed straightforwardly for the total FWW complex and may then be denoted as FWW(TS). It is, however, easily understood that the direct optimization of FWW(TS) should be difficult because of its high dimensionality. Therefore, the TS-optimization was first executed for the complex that consists of the TS structure of the FW system (i.e., FW(TS)) and the stable state (SS) structure of a water molecule (i.e., W(SS)), namely, for the FW(TS)–W(SS) complex. From the viewpoint of chemical reaction dynamics, it is expected that, for the reaction to occur, the medium-water molecule should take the favorable position and orientation to the TS geometry of FW, and the optimized geometry of the FW(TS)–W(SS) complex cannot be very different from the optimized geometry of the FWW(TS) complex.

As a matter of fact, such a large complex as the FW(TS)–W(SS) system can possess several stable structures. Thus, before the optimization calculation, we examine some possibilities by carrying out orbital interaction analysis for MOs of each isolated molecule and can select certain orientations as candidates for stable structures. After obtaining optimized stable geometries, for the sake of completeness we execute the random search procedure for other possible stable geometries that might exist, by choosing 2000 orientations between the FW(TS) and W(SS) systems within the cubic box (22 Å each side). The total energies for these orientations can be used later for the fitting of the intermolecular potential function between them, which is employed for the CRMD studies of the FWW complex together with the previous intrasupermolecular potential function of the FW supermolecule (13, 21).

TABLE 1. Total potential energy of the optimized geometries

	Total energy (hartree)
W(SS)	−74.96590
F(SS)	−147.15328
FW(TS)	−222.10898
FW(SS)	−222.13399
FW(TS)–W(SS)	
A	−297.08422
B	−297.08415
C	−297.08121
D	−297.07966
E	−297.07826
FWW(TS)	−297.08503
FWW(SS)	−297.10995

To obtain the FWW(TS) structures and information about their electronic states, full optimization is also performed on the basis of those optimized geometries obtained above for the FW(TS)–W(SS) complex. The solvation energy of a medium-water molecule is estimated from the difference between an optimized total energy of FWW(TS) and the sum of the energies of two isolated systems, FW(TS) and W(SS). The IRC of the FWW complex is analyzed by using the GAUSSIAN86 program equipped with the IRC algorithm (22) and comparing with that of the FW system (6, 13, 14). To explain the medium-solvent effect in terms of MO language, Mulliken population analysis (23) is utilized as a supplement for the FW(TS) system, the SS of the FW system (i.e., FW(SS)), W(SS), and the SS of formamidine (i.e., F(SS)). Hence, the energetics for a chemical reaction in solution can be analyzed, and how many varieties of approach a medium-solvent takes can also be understood.

Potential function

Intramolecular motions, i.e., vibrations and librations, are usually related to much higher frequencies than intermolecular motions. This fact allows us to utilize the rigid-body approximation of the medium-water molecule. Thus, during the CRMD simulation for the FWW complex, three internal degrees of freedom of a medium-water molecule are restricted to correspond to the SS structure. Other degrees of freedom, which correspond to the translation and the rotation at a distance, are included in order to express the intermolecular potential energy surface.

The intrasupermolecular potential function for the FW system:

$$[1] \quad V_{FW} = \sum \left\{ \frac{a_{1ij}}{r_{ij}} + \frac{a_{2ij}}{r_{ij}^2} + \frac{a_{3ij}}{r_{ij}^3} + \frac{a_{4ij}}{r_{ij}^4} + \frac{a_{6ij}}{r_{ij}^6} \right\}$$

was fitted to reproduce the potential energy surface along the IRC by our newly developed heuristic potential function (HPF) method (21, 24). On the contrary, the intermolecular potential energy function between the FW system and a medium-water molecule was constructed similarly by the least-

mean-squares method (25). Although the intermolecular potential function for the CRMD simulation should be fitted in the neighborhood of the true IRC of the FWW complex, the present potential energy function was prepared to reproduce relative energies of various orientations between the FW(TS) system and the W(SS) molecule. The functional form is assumed to be as follows:

$$[2] \quad V_{\text{FW-W}} = \sum \left\{ \frac{b_{3ij}}{r_{ij}^{3}} + \frac{b_{6ij}}{r_{ij}^{6}} + \frac{b_{12ij}}{r_{ij}^{12}} \right\}$$

where

$$[3] \quad b_{12ij} > 0$$

Although 2000 randomly selected configurations within the cubic box explained previously were used for the electronic energy calculation and were stored as the data base for fitting to the above potential functional form, those configurations with energies higher than the energy threshold of the sum of the isolated FW(TS) and W(SS) energies plus 2 kcal/mol were excluded from the first because the preferential sampling by the bath mode partition function (21) gives them small weightings. Finally, including 5 optimized stable geometries, 1912 configurations between the FW(TS) system and the W(SS) as a whole form the data base. The parameter optimization of eq. [2] was performed by the modified Levenberg–Marquardt method (26–28). Optimized parameters were checked by another test data base than the above initial data base and were found to represent the potential energy surface.

CRMD simulation

The Hamiltonian equations of motion for the atoms in the FWW complex were solved numerically by using the Verlet algorithm (29). For the sake of comparing the dynamical difference between the FW system and the FWW complex, the constant-temperature scheme (CTS) simulation was re-

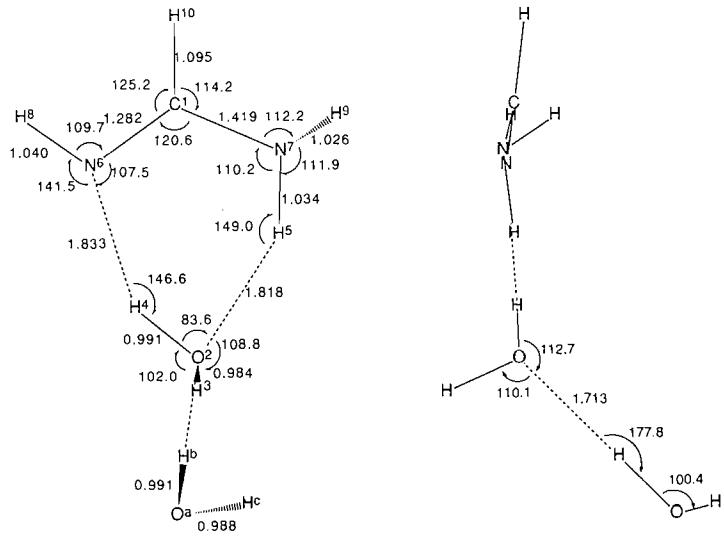

FIG. 5. Bond distances and bond angles in the optimized structure of the FWW(SS) complex. Numerical values are given in angstrom for bond length and in degrees for bond angle.

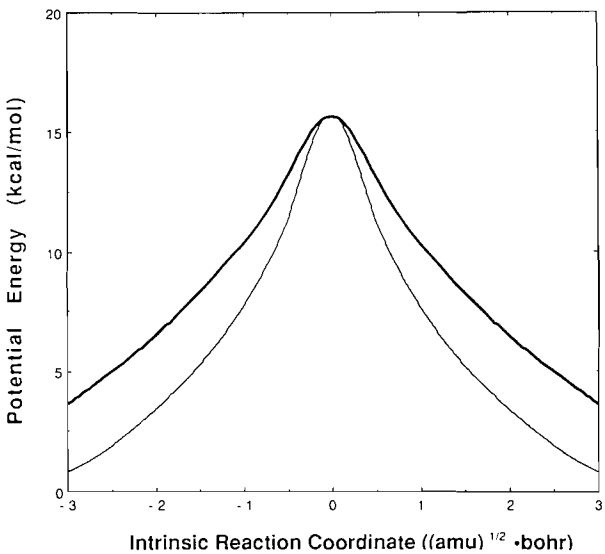

FIG. 6. Potential energy profiles along the intrinsic reaction coordinate (IRC) of the FW system (thin solid line) and the FW–W system (thick solid line).

alized for the FW part of the FWW complex in the CRMD simulation (13), where each atom in the FW part of the FWW complex was assigned the same initial configuration and velocity as those in the CRMD simulation for the isolated FW system. In other words, those trajectories were initiated at the saddle-point (i.e., TS) geometry of the isolated FW system with initial internal temperature $T_0 = 1$ K;

$$[4] \quad T_0 = \sum \frac{m_i v_i^2}{3Nk_B}$$

where m_i and v_i denote the mass and the velocity of the ith atom in the FW system, respectively, and N is the total number of atoms.

Two initial conditions were employed: the randomly directed initial velocity (R-D IV) condition and the IRC-directed initial velocity (IRC-D IV) condition. So that the velocity distribution can reproduce the Maxwell–Boltzmann distribution at a given initial internal temperature T_0, a random number generator was used for determining a set of R-D IVs. Using an optimized conformation for the total of the FW(TS) and W(SS) systems, after 10 ps equilibration with the FW(TS) geometry fixed (i.e., the dynamic equilibration), the CRMD simulation was started for the FWW complex as a whole. As explained before, the two O—H bond lengths and the angle between them of the medium-water molecule are constrained to hold the SS geometry during the whole simulation. This constrained dynamics was realized by using a set of Lagrangian multipliers, which adjust the magnitudes of the forces of constraint involving two hydrogen and one oxygen atoms (29, 30). This treatment is called the SHAKE algorithm.

Results and discussion

TS-optimization of the FW(TS)–W(SS) complex

Five optimized geometries (A–E in Fig. 2) were found by geometry optimization of the complex that consists of the FW(TS) supermolecule and the W(SS) molecule. Those potential energies calculated for them can be compared with the sum of energies for the isolated FW(TS) and W(SS) (Table 1). As explained in the Introduction, since our present attention is being paid to chemical reaction dynamics in solution, it is necessary to select the most influential medium-water molecule for the reaction, and to investigate the effect of the medium-water molecule on the original FW reaction system. The optimized geometry A is, for that reason, chosen because it is the most energetically stable among these optimized geometries (Table 1), and the distance between the transferring proton, the H4 atom or the H5 atom, and the medium-water molecule, is the shortest among them (Fig. 2). Still more important is that the medium-water molecule of geometry A is supposed to play an effective role for energy relaxation because its orientation is the most favorable for energy transfer from the vibrational energy between the transferring proton and the O2 atom to the ro-

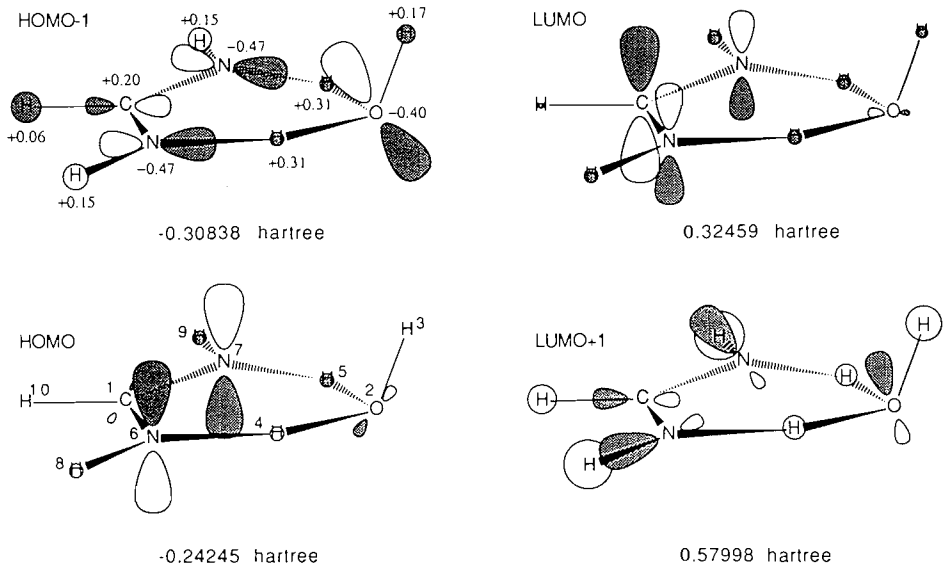

FIG. 7. Molecular orbitals and total atomic charges of the FW(TS) system. Orbital energies are also given in hartree.

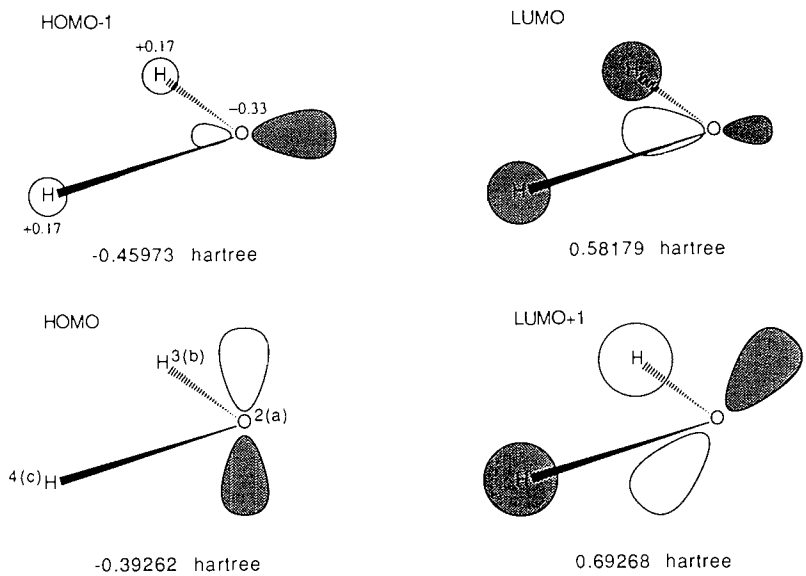

FIG. 8. Molecular orbitals and total atomic charges of the W(SS). Orbital energies are also given in hartree.

tational kinetic energy of the medium-water molecule (31). This conjecture is also supported by the remarkable H3 motion in the CRMD simulation in the previous studies (13). Thus, we recognize the character of the optimized geometry A and, hereafter, denote it solely as that of the FW(TS)–W(SS) system. The bond distances and bond angles of the optimized FW(TS)–W(SS) geometry are shown in Fig. 3. This optimized geometry is also classified as the C_s symmetry group.

Full TS-optimization of the FWW complex

Full TS-optimization of the FWW(TS) complex was carried out on the basis of the optimized FW(TS)–W(SS) geometry and the vibrational analysis confirmed that the geometry obtained corresponds to the TS structure of FWW. It can be recognized that there is no striking geometric difference between the FWW(TS) complex and the FW(TS)–W(SS) one, although the distance of the hydrogen bond r_{2b} and the r_{46} and r_{57} of the FWW(TS) system is a little shorter and the bond length of r_{24} and r_{25} is a little longer (Fig. 4). Thus it is concluded that the geometric effect of the medium-water molecule on the original FW(TS) supermolecule is almost negligible. The energy of the FWW(TS) complex is −297.08503 hartree and the energy difference from the FW(TS)–W(SS) complex is just 0.5 kcal/mol (Table 1). Consequently, the fully optimized geometry, i.e., the FWW(TS) complex, can be approximated sufficiently by the optimized geometry between the original FW(TS) system and the W(SS).

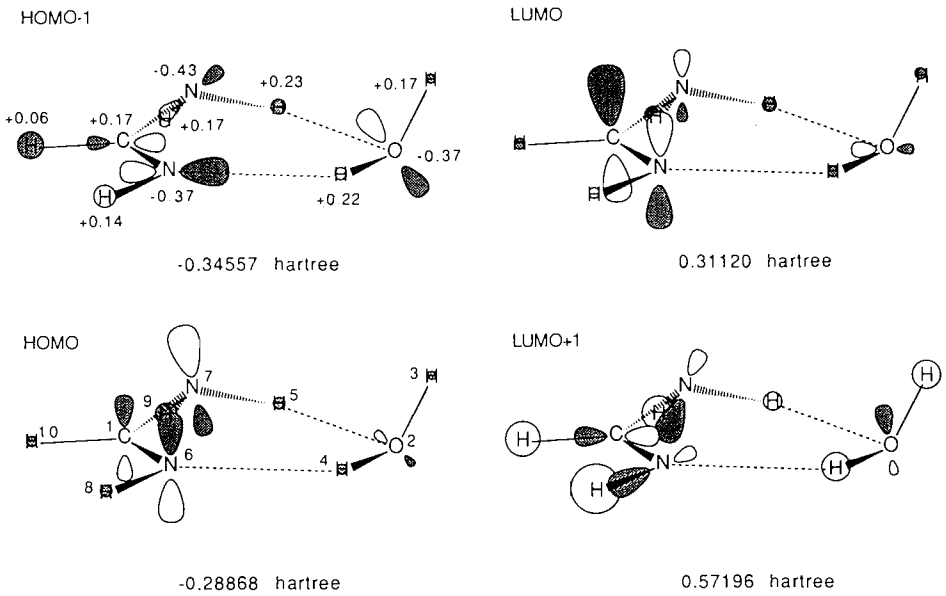

FIG. 9. Molecular orbitals and total atomic charges of the FW(SS) system. Orbital energies are also given in hartree.

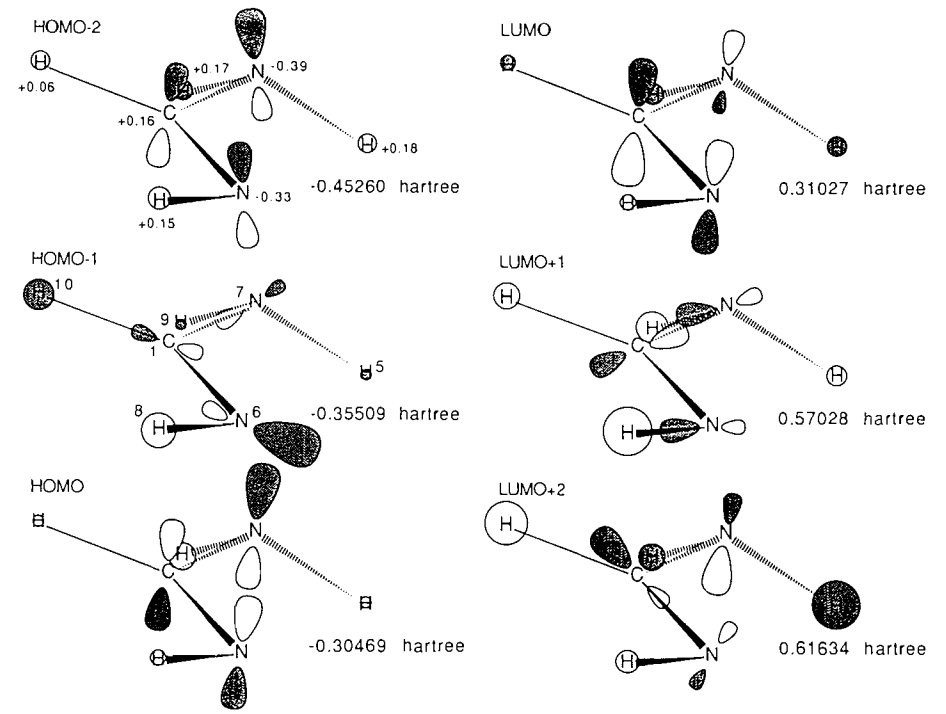

FIG. 10. Molecular orbitals and total atomic charges of the formamidine. Orbital energies are also given in hartree.

The solvation energies of the medium-water and the reactive-water molecule are 6.95 and 58.23 kcal/mol, respectively. The solvation energy of the medium-water molecule is almost one eighth that of the reactive-water molecule and it confirms that the medium-water molecule should be distinguished from the reactive-water one.

IRC analysis of the FWW complex and the stable states

The IRC analysis was performed for the supermolecular model of the total FWW complex and compared with that of the FW system. The SS of the FWW complex (i.e., FWW(SS)) can be found by IRC analysis (Fig. 5) and it was observed that the optimized SS geometry is not influenced by a water molecule so much as the previously optimized geometry of the FW(SS) system (6). The medium-water solvation energy, 6.91 kcal/mol, was almost the same as that in the FW(TS) system. This is clearly in contrast to the fact that the reactive-water solvation energy of the SS, 9.32 kcal/mol, was much less than that of the TS, 58.23 kcal/mol,

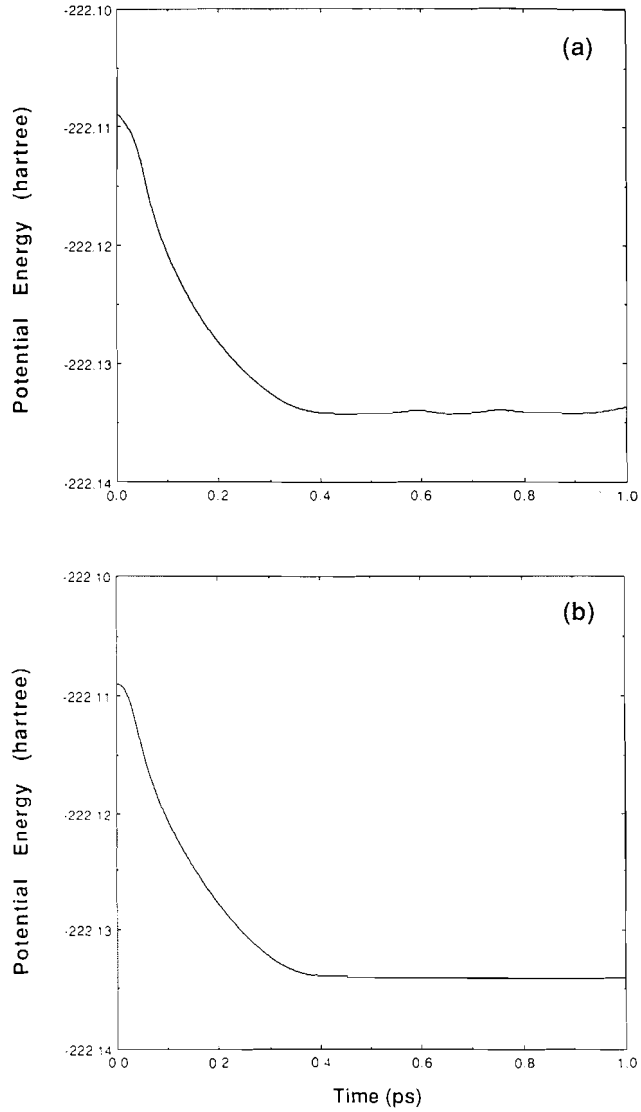

FIG. 11. Potential energy curve of the CRMD simulation in the case of IRC-directed initial velocity for (*a*) the FW system and (*b*) the FW–W system.

which was attributed to the potential energy reducing effect through the short-range interactions.

The potential energy profile along the IRC shows that the potential energy barrier of the FWW complex, 15.65 kcal/mol (Fig. 6), is almost the same as that of the FW system, 15.69 kcal/mol (13). This is also because a medium-water molecule solvates energetically both the FW(SS) and the FW(TS) system to the same extent.

Molecular orbital analysis

The schematic picture of the frontier orbitals and the total atomic charges for the FW(TS) system and the W(SS) molecule are shown in Figs. 7 and 8, respectively. There exist two kinds of electron lone pair, one in the FW system and the other in the W molecule. As explained later, the orbital interaction between FW and W is found less charge-transfer-interactive. However, if we use a term, *the donor and acceptor interaction*, the HOMO–LUMO interaction may be explained by the interaction between a lone pair orbital of W/FW and an unoccupied orbital of FW/W. Taking the second-order perturbation theory into consideration, the larger the magnitude of overlapping and the smaller the energy difference between the orbitals involved, the larger is the stabilization energy associated with the interaction between them. Accordingly, it can be found that the following orbital combinations are important for the effective orbital interaction for each structure of the FW(TS)–W(SS) complex.

	FW(TS)	W(SS)
A	HOMO−1	← LUMO
B	LUMO+1	→ HOMO
C	LUMO+1	→ HOMO
D	HOMO−1	← LUMO
E	LUMO+1	→ HOMO

As is easily understood from Table 1, the solvation energy for each orientation is equal to ~6.0 kcal/mol and is known as the stabilization energy of hydrogen bonding. According to the energy decomposition analysis developed by Yamabe and Morokuma (32, 33), it is concluded that the stabilization energy of a hydrogen bond originates mainly from the electrostatic energy. Although it was reported also that the contribution of the charge transfer energy turns out to be equally large by using the minimal STO-3G basis set,

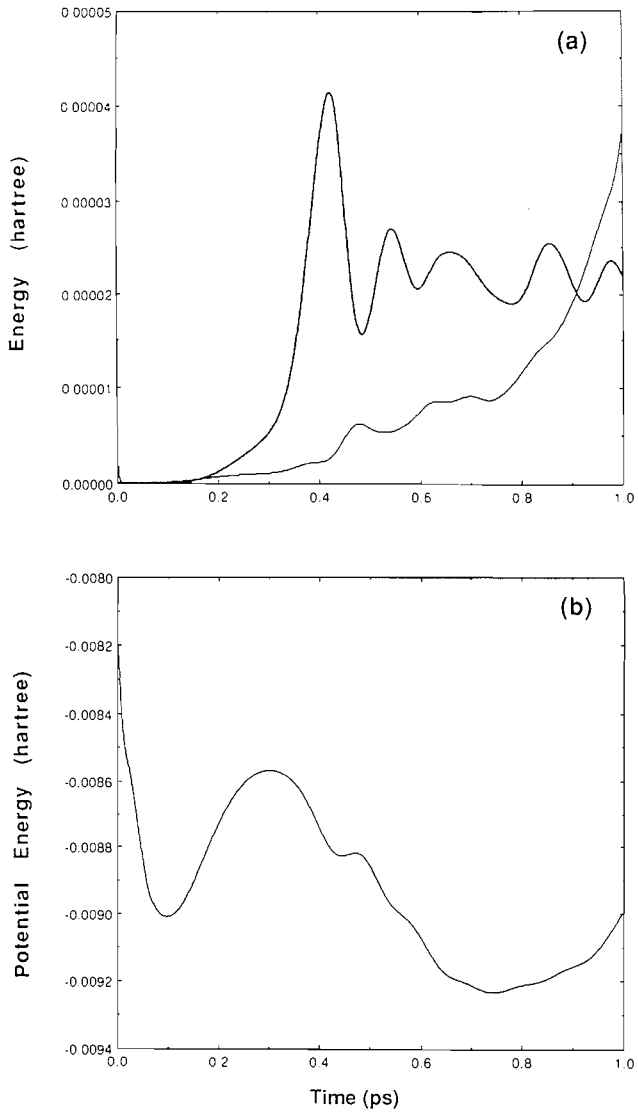

FIG. 12. Energy flows for the FW–W system in the case of IRC-directed initial velocity: (*a*) the rotational kinetic energy of W (thin solid line) and the relative translational one between FW and W (thick solid line), and (*b*) the potential energy between FW and W.

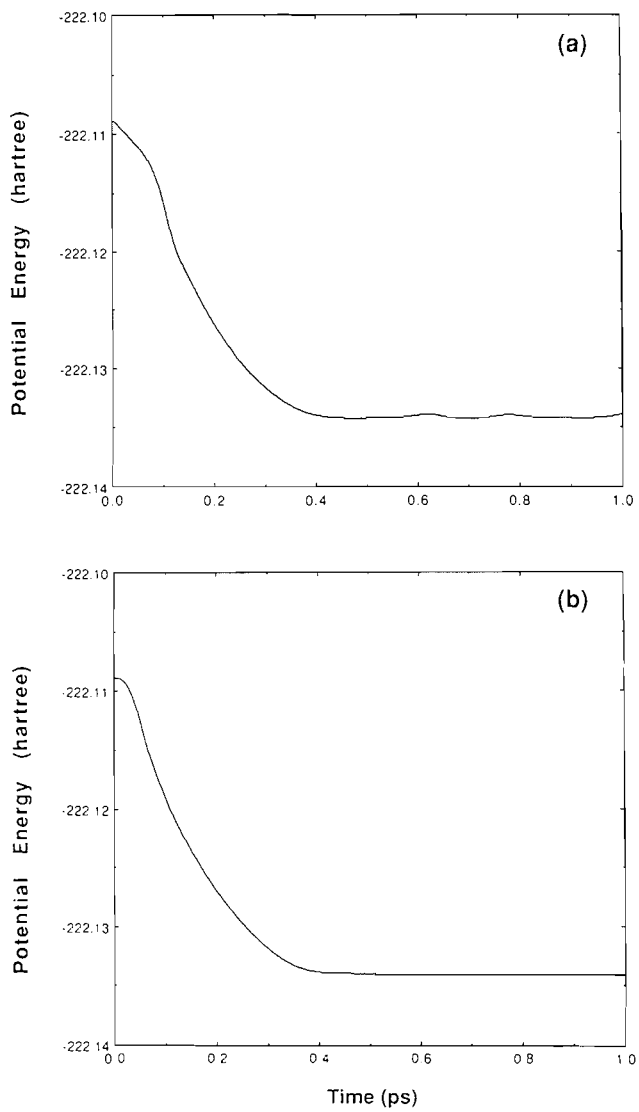

FIG. 13. Potential energy curve of the CRMD simulation in the case of randomly directed initial velocity for (*a*) the FW system and (*b*) the FW–W system.

it is due to the superposition error of the basis set. The present calculation has been executed by the minimal STO-3G basis set and, therefore, the present stabilization energy, i.e., the solvation energy by hydrogen bond creation, arises mainly by the electrostatic interaction between the FW system and the W molecule.

The energetic order and phases of the orbitals for the FW(SS) system (Fig. 9) are similar to those of the FW(TS) system (Fig. 7). Furthermore, no striking differences are observed with respect to the charge distribution between the FW(TS) and FW(SS) systems. These facts suggest that not only the orbital symmetry but also electrostatic interaction does not change along the IRC in the present reaction system. The barrier-reducing effect of a medium-water molecule does not appear because nearly the same stabilization is accomplished for TS and SS, respectively. Thus the circumstances contrast with chemical reactions involving ionic states. For example, Bohme and Mackay reported that the hydration in S_N2 reactions in solution gives rise to smaller rate constants than those in the gas phase (34). Several theoretical studies have concluded that the energy barrier increases with the assistance of water (2, 35–37). On the other hand, Warshel reported that in a heterolytic bond cleavage reaction, the specific orientation of surrounding solvent molecules or a protein cage reduces the energy barrier on the free energy surface (38). These results are attributed to the fact that the electrostatic coupling between the solute charge distribution and that of the solvent determines the energetics of chemical reaction systems (36, 39, 40). It is true that the entropy factor also depends on the long-range interaction between the solute and solvent. However, it is expected that its contribution to the factor is equivalent for both FW(TS) and FW(SS) and, therefore, the dynamic effect caused by the medium-water should become more important for understanding the proton transfer reaction in the FW system.

On the contrary, the situation is in clear contrast to that of a formamidine and a water molecule (i.e., a reactive-solvent molecule), where "stabilization" of a few hundred kcal/mol is observed and the orbital symmetry between the SS and TS structures is quite different. This is why the water mol-

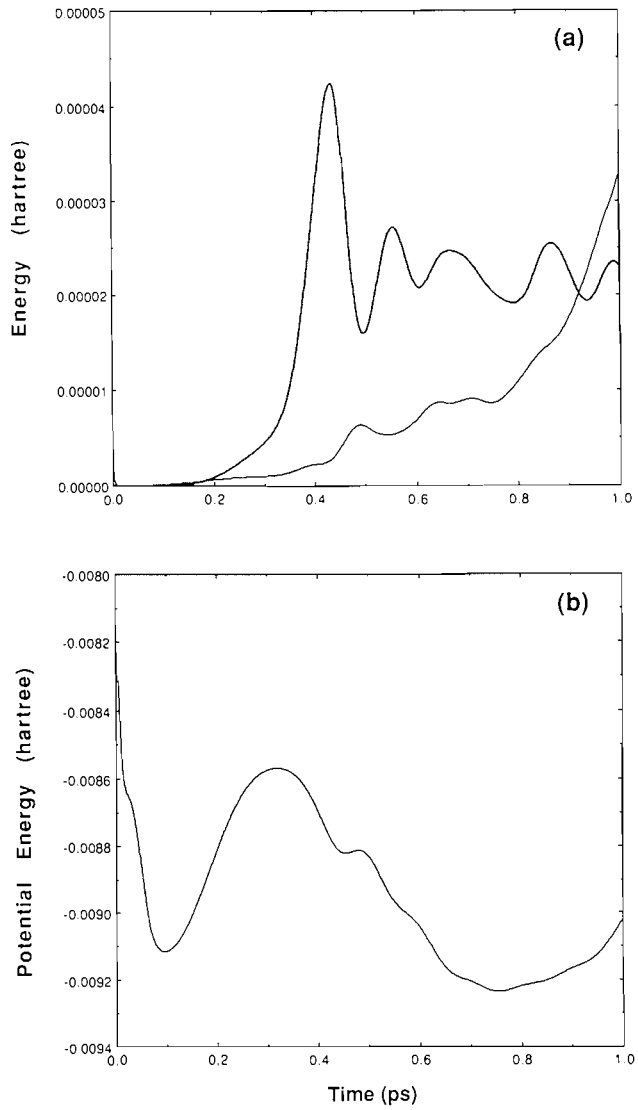

FIG. 14. Energy flows for the FW–W system in the case of randomly directed initial velocity: (*a*) the rotational kinetic energy of W (thin solid line) and the relative translational one between FW and W (thick solid line), and (b) the potential energy between FW and W.

ecule should be treated as a reactive-solvent molecule in this article. While electrostatic interaction can be also expected between the N6 and the H4 and between the H5 and the O2 (see, Figs. 8 and 10), the charge transfer interaction, which may be considered as one of the donor–acceptor interactions between the HOMO − 1 of the formamidine and the LUMO of the W(SS) and that between the LUMO + 2 of the formamidine and the HOMO of the W(SS), should play the more dominant role in this system.

Intermolecular potential function

The intermolecular potential function between the FW system and the W molecule was fitted by using the configurations and their total energies between the FW(TS) and the W(SS) structures. Although the fitted potential function was approximated for the FW(TS)–W(SS) intermolecular potential energies in the neighborhood of the IRC on the potential energy surface, this approximation can be allowed because interaction energies between FW(TS) and W(SS) are found to be small. The fitting of parameters, shown in Table 2, was accomplished with a standard deviation of 1.40×10^{-4} hartrees. Further, the standard deviation, 2.03×10^{-4} hartrees, for the test data base suggests that the present fitting is satisfactory enough to be in good agreement with *ab initio* MO energies.

CRMD simulation and the energy relaxation mechanism

In simulations with IRC-D IV, except for the slight oscillation in the SS region for the FW system in the time-dependent potential energy profile, there is little difference between the FW system and the FW part of the FWW system (Fig. 11). As shown in Fig. 12, the change in internal vibrational kinetic energy shows that the medium-water molecule has little movement with respect to the FW supermolecule around the saddle-point region. The relative translational kinetic energy between the FW system and the W molecule increases at the entrance of the SS region, followed by the increase of the rotational kinetic energy of the W molecule.

In simulations with R-D IV, the slow decrease of the potential energy over the starting 0.2 ps for the FW system disappears for the case of the FWW system as shown in Fig. 13. This fact can be observed for each of the 10 trajectories calculated and is considered the most important result brought about by the participation of the medium-water molecule. It is explained by the IRC stabilization effect, which can result in the rate constant increase (14). On the other hand, the kinetic energy flow is similar to that in the IRC-D IV case (Fig. 14); that is, the internal vibrational kinetic energy of FW transfers, by way of relative translational kinetic energy, to the rotational kinetic energy of W. Since the 10 trajectories show also the same characteristic, it can be concluded that there is a temporal order in the energy relaxation mechanism for the FWW(TS) complex.

Conclusion

The solvent effect for chemical reactions in solution was investigated by classifying solvent molecules as reactive-solvent or medium-solvent. The proton transfer reaction of formamidine in the solvent water was treated in this study as a model for the biological system. The FW(TS) system can be largely stabilized in comparison to the TS structure of isolated formamidine and the corresponding stabilization between the SS structures is not found. This phenomenon explains the remarkable potential energy barrier-reducing effect of the reactive-water molecule. On the other hand, the solvation energy of a medium-water molecule for the FW supermolecule is quite small. Therefore, the potential energy barrier does not change in the presence of a medium-water molecule in comparison with reactions involving ionic states. The solvation energy of the medium-water molecule in the FWW complex consists mainly of the electrostatic interaction and was discussed by *ab initio* MO analysis according to frontier orbital theory based on second-order perturbation theory.

The energy relaxation mechanism was clarified by the CRMD simulation. The averaged position of the center of mass of the medium-water molecule does not change during the reaction process. After the decrease of the internal vibrational kinetic energy occurs, the relative translational kinetic energy between the FW system and the medium-water molecule first increases and is then followed by the increase

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

of the rotational kinetic energy of the medium-water molecule. The IRC stabilization effect was found by comparing the CRMD simulations for the FW and the FWW systems. This effect is important and will be discussed in detail in a future publication (15).

Molecular integrals over Laguerre Gaussian-type functions of real spherical harmonics

OSAMU MATSUOKA

Department of Physics, The University of Electro-Communications, Chofu, Tokyo 182, Japan

Received May 9, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

OSAMU MATSUOKA. Can. J. Chem. **70**, 388 (1992).

Molecular integrals are formulated over the Laguerre Gaussian-type functions (LGTF) of *real* spherical harmonics. They include the overlap integrals and the energy integrals of kinetic, nuclear attraction, and electron repulsion. For the nuclear-attraction integrals the formulations based on the point as well as the Gaussian nuclear charge distribution models are presented. Integral formulas over the LGTFs of *real* spherical harmonics are found a little more complicated than those of the LGTFs of *complex* spherical harmonics due to the summations over magnetic quantum numbers.

Key words: molecular integral, Gaussian-type function, spherical harmonic, solid harmonic, Sonine polynomial.

OSAMU MATSUOKA. Can. J. Chem. **70**, 388 (1992).

On formule des intégrales moléculaires pour les fonctions de Laguerre de type gaussien (FLTG) des harmoniques sphériques *réelles*. Elles comprennent les intégrales de recouvrement et les intégrales d'énergie cinétique, d'attraction nucléaire et de répulsion électronique. Pour les intégrales d'attraction nucléaire on présente les formulations basées sur des modèles de distributions de charges ponctuelles ainsi que gaussiennes. On a trouvé que, à cause des sommations sur les nombres quantiques magnétiques, les formules intégrales pour les FLTG des harmoniques sphériques *réelles* sont un peu plus compliquées que les FLTG des harmoniques sphériques *complexes*.

Mots clés : intégrale moléculaire, fonction de type gaussien, harmonique sphérique, harmonique solide, polynôme de Sonine.

1. Introduction

The Laguerre Gaussian-type function (LGTF) is a spherical harmonic Gaussian and is defined as

$$L_n^{(l+1/2)}(\alpha r^2)\exp(-\alpha r^2)r^l Y_{lm}(\theta,\phi)$$

where $L_n^{(l+1/2)}$ is the generalized Laguerre (or Sonine) polynomial, Y_{lm} is the spherical harmonic, α is the exponent parameter, n, l, and m are quantum numbers, and (r,θ,ϕ) denotes the spherical coordinates. The LGTF shares with other spherical harmonic Gaussians a common desirable feature that all members with the same angular quantum number l but with different magnetic quantum numbers $m = -l, \ldots, +l$ are independent of each other in contrast to those of the Cartesian Gaussians of higher angular quantum numbers than of d types. Furthermore, the molecular integral of electron repulsion over the LGTFs is of particularly simple form to facilitate fast computation.

In a previous paper (1) (which will be referred to as I hereafter) by the present author, Fieck's (2) analysis of molecular integrals over the LGTFs was reformulated so that it is suitable for computation and his analysis was generalized to include such various kinds of molecular properties as the multipole moments and transitions, the electric field and gradient, the quasi-relativistic interactions, etc. Recently, it was further generalized (3) to include the molecular integrals of Breit interaction for relativistic calculation.

In previous works (1–3), the formulations were done over the LGTFs of *complex* spherical harmonics (CSH) (or the complex LGTFs). The complex LGTFs could be appropriately adopted for *linear* molecules. However, for general *polyatomic* molecules the LGTFs of *real* spherical harmonics (RSH) (or the real LGTFs) are more suitable. Thus, in the present paper the real LGTFs have been employed for the analysis. The formulas of molecular integrals over the real LGTFs have been found a little more complicated than those over the complex LGTFs but their analysis has been done almost parallel to the one on the complex LGTFs. In I, the analysis was done on various molecular properties and the formulas of the energy integrals (i.e., the overlap, the kinetic energy, the nuclear attraction, and the electron-repulsion integrals) were derived indirectly as special cases of integral formulas of more general properties. In the present paper, analysis has been limited to the one on the energy integrals but their formulas have been derived directly through the definitions and properties of the real LGTFs so that their derivations might be more transparent. For nuclear-attraction integrals the formulas based on the point as well as the Gaussian nuclear charge distribution models are presented.

In Sect. 2 the real LGTFs are defined and the Talmi transformation among them is described. In Sect. 3 the formulas of the energy integrals are derived directly using the definitions and the properties of the real LGTFs. Section 4 gives some concluding remarks. In the appendices some of the formulas and properties used in Sects. 2 and 3 are derived and discussed.

2. Laguerre Gaussian-type functions and Talmi transformation

2.1. Laguerre Gaussian-type functions

The unnormalized LGTF of *real* spherical harmonic is defined by

$$[2.1]\qquad \chi_{\alpha N}(\boldsymbol{r}) = (-1)^l \hat{Y}_N(\nabla)\exp(-\alpha r^2),$$

where N is a set of integers (quantum numbers):

$$[2.2]\qquad N = (n, l, m)$$

n and l being nonnegative and $|m| \leq l$. The operator $\hat{Y}_N(\nabla)$ is obtained by substituting the differential operators $\partial/\partial x$, $\partial/\partial y$, and $\partial/\partial z$ into the Cartesian coordinates x, y, and z in the homogeneous solid harmonic $Y_{nlm}(\boldsymbol{r}) = r^{2n+l}Y_{lm}(\theta,\phi)$. In

For personal use only.

the present paper the RSHs $Y_{nl}(\theta,\phi)$ are defined through the CSHs $\bar{Y}_{lm}(\theta,\phi)$ of Condon–Shortley as:

[2.3]
$$Y_{l,0}(\theta,\phi) = \bar{Y}_{l,0}(\theta,\phi)$$
$$Y_{l,|m|}(\theta,\phi) = (1/\sqrt{2})[\bar{Y}_{l,-|m|}(\theta,\phi) + (-1)^m \bar{Y}_{l,|m|}(\theta,\phi)]$$
$$Y_{l,-|m|}(\theta,\phi) = (i/\sqrt{2})[\bar{Y}_{l,-|m|}(\theta,\phi) - (-1)^m \bar{Y}_{l,|m|}(\theta,\phi)]$$

where i is the imaginary unit. The real LGTF defined by [2.1] is written explicitly as

[2.4]
$$\chi_{\alpha N}(\boldsymbol{r}) = N_{\alpha nl} L_n^{(l+1/2)}(\alpha r^2) \exp(-\alpha r^2) Y_{0lm}(\boldsymbol{r})$$

where

[2.5]
$$N_{\alpha nl} = (-1)^n 2^{2n+l} n! \alpha^{n+l}$$

and the generalized Laguerre (or Sonine) polynomial is defined by

[2.6]
$$L_n^{(s)}(x) = \sum_{m=0}^{n} \frac{\Gamma(n+s+1)}{m!(n-m)!\Gamma(m+s+1)} (-x)^m$$

$\Gamma(x)$ being the Gamma function. A derivation of [2.4] is given in Appendix 1.

The real LGTF located at position $\boldsymbol{A}$ is thus written as

[2.7]
$$\chi_{\alpha_A N_A}(\boldsymbol{r}_{\mu A}) = \hat{Y}_{N_A}(\nabla_A) \exp(-\alpha_A r_{\mu A}^2)$$

where $\boldsymbol{r}_{\mu A} = \boldsymbol{r}_\mu - \boldsymbol{A}$, $\boldsymbol{r}_\mu$ being position of the electron μ and ∇_A is the differential operator with respect to the position vector $\boldsymbol{A}$. Here we have used the fact that $\hat{Y}_{N_A}(\nabla_{\mu A}) = (-1)^{l_A} \hat{Y}_{N_A}(\nabla_A)$ when operating on a function of argument $r_{\mu A}$.

For analysis of nuclear-attraction and electron-repulsion integrals, it is convenient to generalize the definition of the real LGTF, [2.1], to include the case when $n = -1$:

[2.8]
$$\chi_{\alpha(-1)lm}(\boldsymbol{r}) = -(2\alpha)^{l-1} F_l(\alpha r^2) Y_{0lm}(\boldsymbol{r})$$

where the incomplete Gamma function is defined by

[2.9]
$$F_l(t) = \int_0^1 du u^{2l} \exp(-tu^2)$$

2.2. *Talmi transformation*

A product of two real LGTFs $\chi_{\alpha_1 N_1}(\boldsymbol{r}_1)$ and $\chi_{\alpha_2 N_2}(\boldsymbol{r}_2)$ can be written as a finite sum over the products of two real LGTFs $\chi_{\alpha_3 N_3}(\boldsymbol{r}_3)$ and $\chi_{\alpha_4 N_4}(\boldsymbol{r}_4)$ of coordinates $\boldsymbol{r}_3 = \boldsymbol{r}_1 - \boldsymbol{r}_2$ and $\boldsymbol{r}_4 = (\alpha_1 \boldsymbol{r}_1 + \alpha_2 \boldsymbol{r}_2)/(\alpha_1 + \alpha_2)$ with $\alpha_3 = \alpha_1\alpha_2/(\alpha_1 + \alpha_2)$ and $\alpha_4 = \alpha_1 + \alpha_2$:

[2.10]
$$\chi_{\alpha_1 N_1}(\boldsymbol{r}_1)\chi_{\alpha_2 N_2}(\boldsymbol{r}_2) = \sum_{N_3 N_4} \chi_{\alpha_3 N_3}(\boldsymbol{r}_3)\chi_{\alpha_4 N_4}(\boldsymbol{r}_4) T(\alpha_3 N_3, \alpha_4 N_4 \mid \alpha_1 N_1, \alpha_2 N_2)$$

The indices N_1, N_2, N_3, and N_4 have to satisfy the relation

[2.11]
$$2n_1 + l_1 + 2n_2 + l_2 = 2n_3 + l_3 + 2n_4 + l_4$$

Relation among magnetic quantum numbers m_1, m_2, m_3, and m_4 is a little more complicated than the one for the complex LGTFs ([2.14] of I) and is discussed in Appendix 2. The relation [2.10] is known as Talmi transformation (4) and the coefficients T are called Talmi coefficients which are expressed in terms of the Moshinsky–Smirnov coefficients (5, 6) and Niukkanen coefficients (7) (see also [2.16] and [2.24] of I).

Using [2.10] a product of two real LGTFs located at $\boldsymbol{A}$ and $\boldsymbol{B}$ with exponent parameters α_A and α_B respectively, can be expressed again in terms of real LGTFs located at $\boldsymbol{P} = (\alpha_A \boldsymbol{A} + \alpha_B \boldsymbol{B})/(\alpha_A + \alpha_B)$:

[2.12]
$$\chi_{\alpha_A N_A}(\boldsymbol{r}_{\mu A})\chi_{\alpha_B N_B}(\boldsymbol{r}_{\mu B}) = \sum_{N_P} \chi_{\alpha_P N_P}(\boldsymbol{r}_{\mu P}) W(N_P; \alpha_A N_A, \alpha_B N_B \mid \boldsymbol{BA})$$

where

[2.13]
$$W = \sum_{N_R} \chi_{\alpha_R N_R}(\boldsymbol{BA}) T(\alpha_R N_R, \alpha_P N_P \mid \alpha_A N_A, \alpha_B N_B)$$

In [2.12] and [2.13] $\alpha_P = \alpha_A + \alpha_B$, $\alpha_R = \alpha_A\alpha_B/(\alpha_A + \alpha_B)$, and $\boldsymbol{BA} = \boldsymbol{B} - \boldsymbol{A}$ and the indices N_P and N_R have to satisfy the relation

[2.14]
$$2n_A + l_A + 2n_B + l_B = 2n_P + l_P + 2n_R + l_R.$$

3. Molecular integrals

In this section the formulas of the energy integrals are derived. For the analysis an operator identity will be used:

[3.1]
$$\hat{Y}_{N_1}(\nabla)\hat{Y}_{N_2}(\nabla) = \sum_N \hat{Y}_N(\nabla)\, \Xi(lm \mid l_1 m_1, l_2 m_2)$$

Here the summations over n and l are done under the restriction

[3.2]
$$2n + l = 2n_1 + l_1 + 2n_2 + l_2$$

and m takes two values m_+ and m_- given by (8, 9)

[3.3]
$$m_\pm = \text{sign}(m_1)\,\text{sign}(m_2)\,|\,(|m_1| \pm |m_2|)\,|$$

where

[3.4]
$$\text{sign}(x) = +1 \text{ for } x \geq 0 \quad \text{and sign}(x) = -1 \text{ for } x < 0$$

In Appendix 2 the Gaunt coefficients Ξ of RSHs are related to those of CSHs.

3.1. *Overlap integral*

Using [2.12] the overlap integral is reduced to

[3.5]
$$\langle \alpha_A N_A \mid \alpha_B N_B \rangle = \int d^3 \boldsymbol{r}_1 \chi_{\alpha_A N_A}(\boldsymbol{r}_{1A})\chi_{\alpha_B N_B}(\boldsymbol{r}_{1B}) = \sum_{N_P} W(N_P; \alpha_A N_A, \alpha_B N_B \mid \boldsymbol{BA})[\alpha_P N_P \mid 1]$$

Using the orthogonality properties of the Sonine polynomials and the RSHs the basic integral in [3.5] reads

[3.6]
$$[\alpha_P N_P \mid 1] = \int d^3 \boldsymbol{r}_1 \chi_{\alpha_P N_P}(\boldsymbol{r}_{1P}) = \delta_{n_P 0}\delta_{l_P 0}\delta_{m_P 0}\sigma(\alpha_P)$$

where

[3.7]
$$\sigma(\alpha) = \pi/2\alpha^{2/3}$$

Hence the overlap integral, [3.5], is further reduced to

[3.8]
$$\langle \alpha_A N_A \mid \alpha_B N_B \rangle = \sigma(\alpha_P) W(000; \alpha_A N_A, \alpha_B N_B \mid \boldsymbol{BA})$$

The formula [3.8] can be adopted in practice for the computation. However, using a formula of the Talmi coeffi-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 92.62.229.171 on 09/08/12
For personal use only.

cient in [2.10] when $N_3 = (0, 0, 0)$, the W function of [3.8] is further reduced to

$$[3.9] \quad W = (-1)^{l_B}(4\pi)^{1/2} \times \sum_{N_R} \chi_{\alpha_R N_R}(\boldsymbol{BA})\Xi(l_R m_R) \mid l_A m_A, l_B m_B)$$

where, due to the properties of the Gaunt coefficients Ξ (eqs. [3.2] and [3.3]), the summations over n_R and l_R are done under the restriction

$$[3.10] \quad 2n_R + l_R = 2n_A + l_A + 2n_B + l_B$$

and m_R takes two values

$$[3.11] \quad m_R = \text{sign } (m_A) \text{ sign } (m_B) \mid (|m_A| \pm |m_B|) \mid$$

The derivation of the expression [3.9] is very much analogous to the one for the complex LGTFs (eq. [3.15] of I). The formulas [3.8] and [3.9] can also be adopted in the computation.

3.2 Kinetic-energy integral

Using the definition of the LGTFs, [2.1], the kinetic-energy integral in nonrelativistic calculations is reduced to an overlap integral:

$$[3.12] \quad \langle \alpha_A N_A \mid \nabla^2 \mid \alpha_B N_B \rangle = \int \mathrm{d}^3 \boldsymbol{r}_1 \chi_{\alpha_A N_A}(\boldsymbol{r}_{1A}) \nabla_1^2 \chi_{\alpha_B N_B}(\boldsymbol{r}_{1B}) = \langle \alpha_A N_A \mid \alpha_B, (n_B + 1), l_B, m_B \rangle$$

In relativistic (Dirac–Fock) calculations the kinetic-energy operator is $\boldsymbol{\sigma}\cdot\boldsymbol{p}$, where $\boldsymbol{\sigma} = (\sigma_x, \sigma_y, \sigma_z)$ are Pauli 2×2 matrices and $\boldsymbol{p} = -i\nabla$ is the momentum operator. Thus the integral appearing in the calculation is

$$[3.13] \quad \langle \alpha_A N_A \mid \hat{Y}_{01m}(\nabla) \mid \alpha_B N_B \rangle = \int \mathrm{d}^3 \boldsymbol{r}_1 \chi_{\alpha_A N_A}(\boldsymbol{r}_{1A}) \hat{Y}_{01m}(\nabla_1) \chi_{\alpha_B N_B}(\boldsymbol{r}_{1B})$$

where $m = 0, \pm 1$. Using [2.7] and [3.1] it can be shown that

$$[3.14] \quad \hat{Y}_{01m}(\nabla_1)\chi_{\alpha_B N_B}(\boldsymbol{r}_{1B}) = -\sum_{l'm'} \Xi\,(l'm' \mid 1m, l_B m_B)\chi_{\alpha_B n_B l'm'}(\boldsymbol{r}_{1B})$$

Here, due to the Gaunt coefficient Ξ, $l' = l_B \pm 1$ and $m' = m_B$, $m_B \pm 1$ and it has been used that $\hat{Y}_{01m}(\nabla_1) = -\hat{Y}_{01m}(\nabla_B)$ when operating on a function of argument $\boldsymbol{r}_{1B}$. Then integral [3.13] is also reduced to the overlap integrals:

$$[3.15] \quad \langle \alpha_A N_A \mid \hat{Y}_{01m}(\nabla) \mid \alpha_B N_B \rangle = -\sum_{l'm'} \Xi(l'm' \mid 1m, l_B m_B) < \alpha_A N_A \mid \alpha_B n_B l'm' \rangle$$

3.3. Nuclear-attraction integral

Using [2.12] the nuclear-attraction integral is reduced to

$$[3.16] \quad \langle \alpha_A N_A \mid V(r_C) \mid \alpha_B N_B \rangle = \int \mathrm{d}^3 \boldsymbol{r}_1 \chi_{\alpha_A N_A}(\boldsymbol{r}_{1A}) V(r_{1C}) \chi_{\alpha_B N_B}(\boldsymbol{r}_{1B}) = \sum_{N_P} W(N_P; \alpha_A N_A, \alpha_B N_B \mid \boldsymbol{BA})[\alpha_P N_P \mid V(r_C)]$$

where the attractive center of nuclear potential $V(r_C)$ is assumed on location (atom) $\boldsymbol{C}$ and the basic integral is defined as

$$[3.17] \quad [\alpha_P N_P \mid V(r_C)] = \int \mathrm{d}^3 \boldsymbol{r}_1 \chi_{\alpha_P N_P}(\boldsymbol{r}_{1P}) V(r_{1C})$$

If the *point-charge* model for the atomic nucleus is adopted, $V(r_{1C}) = 1/r_{1C}$. Then using the definition of the LGTFs, [2.7], we obtain

$$[3.18] \quad [\alpha_P N_P \mid 1/r_{1C}] = \hat{Y}_{N_P}(\nabla_P) \int \mathrm{d}^3 \boldsymbol{r}_1 \exp(-\alpha_P r_{1P}^2)(1/r_{1C})$$

For the integral in [3.18] Boys (10) gives a formula

$$[3.19] \quad \int \mathrm{d}^3 \boldsymbol{r}_1 \exp(-\alpha_P r_{1P}^2)(1/r_{1C}) = (2\pi/\alpha_P) F_0(\alpha_P \overline{CP}^2)$$

After differentiation of [3.19] by $\hat{Y}_{N_P}(\nabla_P)$, we get

$$[3.20] \quad [\alpha_P N_P \mid 1/r_{1C}] = -4\pi \chi_{\alpha_P (n_P - 1) l_P m_P}(\boldsymbol{CP})$$

where $\boldsymbol{CP} = \boldsymbol{C} - \boldsymbol{P}$. Fieck (2) gives a proof of [3.20] using the Poisson equation. A more direct and straightforward derivation is given in Appendix 1.

If the *Gaussian nuclear charge distribution* model (11) for the atomic nucleus is adopted,

$$[3.21] \quad V(r_{1C}) = \int \mathrm{d}^3 \boldsymbol{r}_2 \exp(-\alpha_C r_{2C}^2)(1/r_{12})$$

where α_C is a nuclear parameter. Then noting that $\exp(-\alpha r^2) = \chi_{\alpha 000}(\boldsymbol{r})$, the basic integral [3.19] is shown to be written as

$$[3.22] \quad [\alpha_P N_P \mid V(r_C)] = \int \mathrm{d}^3 \boldsymbol{r}_1 \int \mathrm{d}^3 \boldsymbol{r}_2 \chi_{\alpha_P N_P}(\boldsymbol{r}_{1P}) \chi_{\alpha_C 000}(\boldsymbol{r}_{2C})(1/r_{12})$$

This is a basic integral for the electron-repulsion integral and is written (see [3.28] of next subsection)

$$[3.23] \quad [\alpha_P N_P \mid V(r_C)] = -4\pi\sigma(\alpha_P + \alpha_C)\chi_{\alpha_T (n_P - 1) l_P m_P}(\boldsymbol{CP})$$

where σ is defined by [3.7] and $\alpha_T = \alpha_P \alpha_C/(\alpha_P + \alpha_C)$.

Both of the basic integrals, [3.20] and [3.23], are expressed in terms of the generalized LGTFs, [2.1] and [2.8].

3.4 Electron-repulsion integral

Using [2.12] separately for the two charge distributions of electrons 1 and 2, the electron-repulsion integral is reduced to

$$[3.24] \quad \langle \alpha_A N_A, \alpha_B N_B \mid 1/r_{12} \mid \alpha_C N_C, \alpha_D N_D \rangle = \int \mathrm{d}^3 \boldsymbol{r}_1 \int \mathrm{d}^3 \boldsymbol{r}_2 \chi_{\alpha_A N_A}(\boldsymbol{r}_{1A}) \chi_{\alpha_B N_B}(\boldsymbol{r}_{1B}) \chi_{\alpha_C N_C}(\boldsymbol{r}_{2C}) \times \chi_{\alpha_D N_D}(\boldsymbol{r}_{2D})(1/r_{12}) = \sum_{N_P N_Q} W(N_P; \alpha_A N_A, \alpha_B N_B \mid \boldsymbol{BA}) \times W(N_Q; \alpha_C N_C, \alpha_D N_D \mid \boldsymbol{DC})[\alpha_P N_P \mid 1/r_{12} \mid \alpha_Q N_Q]$$

where $\alpha_Q = \alpha_C + \alpha_D$. Using the definition of LGTFs, [2.7], for $\chi_{\alpha_P N_P}(\boldsymbol{r}_{1P})$ and $\chi_{\alpha_Q N_Q}(\boldsymbol{r}_{2Q})$, where $\boldsymbol{Q} = (\alpha_C \boldsymbol{C} + \alpha_C \boldsymbol{D})/(\alpha_C + \alpha_D)$, the basic integral in [3.24] is written as

$$[3.25] \quad [\alpha_P N_P \mid \alpha_Q N_Q] = \int \mathrm{d}^3 \boldsymbol{r}_1 \int \mathrm{d}^3 \boldsymbol{r}_2 \times \chi_{\alpha_P N_P}(\boldsymbol{r}_{1P}) \chi_{\alpha_Q N_Q}(\boldsymbol{r}_{2Q})(1/r_{12}) = \hat{Y}_{N_P}(\nabla_P) \hat{Y}_{N_Q}(\nabla_Q) \int \mathrm{d}^3 \boldsymbol{r}_1 \int \mathrm{d}^3 \boldsymbol{r}_2 \times \exp(-\alpha_P r_{1P}^2 - \alpha_Q r_{2Q}^2)(1/r_{12})$$

For the integral in [3.25] Boys (10) gives a formula

$$[3.26] \quad \int \mathrm{d}^3 \boldsymbol{r}_1 \int \mathrm{d}^3 \boldsymbol{r}_2 \exp(-\alpha_P r_{1P}^2 - \alpha_Q r_{2Q}^2)(1/r_{12}) = [2\pi^{5/2}/\alpha_P \alpha_Q (\alpha_P + \alpha_Q)^{1/2}] F_0(\alpha_T \overline{QP}^2)$$

where $\alpha_T = \alpha_P\alpha_Q/(\alpha_P + \alpha_Q)$. As [3.26] shows the integral in [3.25] depends on $\boldsymbol{QP} = \boldsymbol{Q} - \boldsymbol{P}$ so that $\hat{Y}_{N_Q}(\nabla_Q)$ in [3.25] can be replaced by $(-1)^{l_Q}\hat{Y}_{N_Q}(\nabla_P)$. Then using [3.1] for the product $\hat{Y}_{N_P}(\nabla_P)\hat{Y}_{N_Q}(\nabla_Q)$ and noting

$$[3.27] \quad \hat{Y}_N(\nabla_P)F_0(\alpha_T\overline{QP}^2) = -2\alpha_T\chi_{\alpha_T(n-1)lm}(\boldsymbol{QP})$$

we obtain for the basic integral of [3.25]

$$[3.28] \quad [\alpha_P N_P|1/r_{12}|\alpha_Q N_Q] = (-1)^{l_Q+1}(4\pi)^{3/2}\sigma(\alpha_P + \alpha_Q) \times \sum_{N_T} \Xi(l_T m_T \mid l_p m_p, l_Q m_Q)\chi_{\alpha_T(n_T-1)l_T m_T}(\boldsymbol{QP})$$

where σ is defined by [3.7] and the summations over $N_T = (n_T, l_T, m_T)$ are done under the restrictions

$$[3.29] \quad 2n_T + l_T = 2n_P + l_P + 2n_Q + l_Q$$

and

$$[3.30] \quad m_T = \text{sign}\,(m_P)\,\text{sign}\,(m_Q)\,|\,(|m_P| \pm |m_Q|)\,|$$

A derivation of [3.27] is given in Appendix 1.

4. Concluding remarks

In previous works (1–3), the formulations of molecular integrals were done over the *complex* LGTFs so that they are suitable for the calculations of *linear* molecules. In the present work the formulation has been done over the *real* LGTFs so that it is expected to be useful for general *polyatomic* molecules.

The formulas of molecular integrals over the real LGTFs are a little more complicated than those over the complex LGTFs. The complications in the case of real LGTFs are due to two reasons: (*1*) The total magnetic quantum number m in the Gaunt coefficient Ξ defined for the RSHs takes two values, [3.3], while the corresponding quantum number for the CSHs takes only one value such that $m = m_1 + m_2$ ([3.3] of I). (*2*) In the Talmi coefficients $\tilde{T}$ defined for the complex LGTFs there is a simple relation [A2.6], while in the T for the real LGTFs the relation among the magnetic quantum numbers is a little more complicated. Thus except for these complications the formulas over the real LGTFs are almost the same as those over the complex LGTFs.

In nonrelativistic calculations the LGTFs, [2.1], with quantum number $n = 0$ are usually employed and in relativistic calculations the LGTFs with quantum number $n = 0$ and 1 are needed. Thus if we restrict ourselves to adopt only the LGTFs with quantum number $n = 0$ (and 1), we should get some simplifications for the integral formulas.

Appendix 1. Explicit expressions of Laguerre Gaussian-type function and of basic integrals for nuclear-attraction and electron-repulsion integrals.

Fieck (2) suggested a derivation of the expression [2.4] via recursion formula and sketched the proof of the expression [3.20] and [3.27] via Poisson equation. In this appendix other direct derivations of these expressions will be presented using a generalized gradient formula (3).

Fujimura and Matsuoka (3) generalized Bayman's gradient formula (12) of solid harmonic to include the *homogeneous* solid harmonic. For an arbitrary radial function $f(r)$ the generalized gradient formula (3) reads

$$[A1.1] \quad \hat{Y}_{n_1l_1m_1}(\nabla)[f(r)Y_{l_2m_2}(\theta,\phi)] = \sum_{lm} \Xi(lm \mid l_1m_1, l_2m_2)g_{2n_1+l_1,l_2,l}(r)Y_{lm}(\theta,\phi)$$

where the summation over l extends from $|l_1 - l_2|$ to $l_1 + l_2$ in step of 2, Ξ is the Gaunt coefficient defined by [3.1], and

$$[A1.2] \quad g = \sum_k \frac{(2n_1 + l_1 + l_2 + l + 1)!!}{(2l + 2k + 1)!!} \times \binom{(2n_1 + l_1 + l_2 - l)/2}{k} \times r^{l+2k}\left(\frac{1}{r}\frac{d}{dr}\right)^{(l+2n_1+l_1-l_2)/2+k} [f(r)/r^{l_2}]$$

the summation over k being done in the range $[0, (2n_1 + l_1 + l_2 - l)/2]$.

Using [A1.1] for $\exp(-\alpha r^2)$ and noting the definition of Sonine polynomial, [2.6], it is straightforward to get an explicit expression of the real LGTF:

$$[A1.3] \quad \hat{Y}_{nlm}(\nabla)\exp(-\alpha r^2) = (-1)^l\chi_{\alpha nlm}(\boldsymbol{r}).$$

If one notes that

$$[A1.4] \quad (r^{-1}d/dr)^lF_0(\alpha r^2) = (-2\alpha)^lF_l(\alpha r^2)$$

and using [A1.1] for $F_0(\alpha r^2)$ it is also straightforward to derive

$$[A1.5] \quad \hat{Y}_{0lm}(\nabla)F_0(\alpha r^2) = (-2\alpha)^lF_l(\alpha r^2)Y_{0lm}(\boldsymbol{r}) = -2\alpha(-1)^l\chi_{\alpha(-1)lm}(\boldsymbol{r})$$

where on the second line the generalized definition of the LGTF, [2.8], has been used.

In order to prove [3.20] and [3.27] for $n = 1, 2, 3, \ldots$, we use [A1.1] for $F_0(\alpha r^2)$ and also use the recursion relation:

$$[A1.6] \quad (2m + 1)F_m(t) - 2tF_{m+1}(t) = \exp(-t)$$

Then we get

$$[A1.7] \quad \hat{Y}_{100}(\nabla)F_0(\alpha r^2) = -2\alpha\exp(-\alpha r^2)/(4\pi)^{1/2}$$

If we note that

$$[A1.8] \quad \hat{Y}_{nlm}(\nabla) = \hat{Y}_{n-1,lm}(\nabla)\hat{Y}_{100}(\nabla)/Y_{00}(\theta,\phi)$$

and use [A.13] in this equality, then we get

$$[A1.9] \quad \hat{Y}_{nlm}(\nabla)F_0(\alpha r^2) = -2\alpha(-1)^l\chi_{\alpha(n-1)lm}(\boldsymbol{r}) \quad (n = 1, 2, 3, \ldots)$$

Equations [A1.5] and [A1.9] prove [3.20] and [3.27].

Appendix 2. Talmi and Gaunt coefficients of real spherical harmonics

The RSHs $Y_{lm}(\theta, \phi)$ are obtained from the CSHs $\tilde{Y}_{lm}(\theta, \phi)$ by a unitary transformation:

$$[A2.1] \quad Y_{lm} = \sum_{m'=-l}^{l} U_{mm'} \tilde{Y}_{lm'}$$

From [2.3] it is seen that only the following elements of the unitary matrix **U** are nonvanishing:

$$[A2.2] \quad U_{00} = 1$$

$$U_{|m|,-|m|} = 1/\sqrt{2}, \qquad U_{|m|,|m|} = (-1)^m/\sqrt{2}$$

$$U_{-|m|,-|m|} = i/\sqrt{2}, \qquad U_{-|m|,|m|} = i(-1)^{m+1}/\sqrt{2}$$

Thus the inverse transformation is written as

$$[A2.3] \quad \tilde{Y}_{lm} = \sum_{m'=-l}^{l} Y_{lm'} U^*_{m'm}$$

Hence, using [A2.1]–[A2.3], all the quantities defined for the CSHs in I can be transformed to those for the RSHs.

The Talmi transformation for the complex LGTFs $\tilde{\chi}_{\alpha N}(\boldsymbol{r})$ is defined as (eqs. [2.12]–[2.14] of I)

$$[A2.4] \quad \tilde{\chi}_{\alpha_1 N_1}(\boldsymbol{r}_1)\tilde{\chi}_{\alpha_2 N_2}(\boldsymbol{r}_2) = \sum_{N_3 N_4} \tilde{\chi}_{\alpha_3 N_3}(\boldsymbol{r}_3)\tilde{\chi}_{\alpha_4 N_4}(\boldsymbol{r}_4)\tilde{T}(\alpha_3 N_3, \alpha_4 N_4 \mid \alpha_1 N_1, \alpha_2 N_2)$$

Using [A2.1] and [A2.3] in [A2.4] the Talmi coefficients T of real LGTFs, eq. [2.10], are written by those of the CSHs, $\tilde{T}$, as

$$[A2.5] \quad T(\alpha_3 n_3 l_3 m_3, \alpha_4 n_4 l_4 m_4 \mid \alpha_1 n_1 l_1 m_1, \alpha_2 n_2 l_2 m_2) = \sum_{\mu_1\mu_2\mu_3\mu_4} \tilde{T}(\alpha_3 n_3 l_3 \mu_3, \alpha_4 n_4 l_4 \mu_4 \mid \alpha_1 n_1 l_1 \mu_1, \alpha_2 n_2 l_2 \mu_2) \times U^*_{m_3\mu_3} U^*_{m_4\mu_4} U_{m_1\mu_1} U_{m_2\mu_2}$$

Among the indices the relations [2.11] and

$$[A2.6] \quad \mu_1 + \mu_2 = \mu_3 + \mu_4$$

hold. Among the indices m_1, m_2, m_3, and m_4, relations like [A2.6] hold but their explicit expressions would not be necessary for writing the computer program for the coefficients. It should be noted that the coefficients T as well as $\tilde{T}$ are real.

The Gaunt coefficients $\tilde{\Xi}$ for complex homogeneous solid harmonics $\tilde{Y}_{nlm}(\boldsymbol{r})$ are defined by (eq. [3.1] of I)

$$[A2.7] \quad \tilde{Y}_{N_1}(\boldsymbol{r})\tilde{Y}_{N_2}(\boldsymbol{r}) = \sum_{N} \tilde{Y}_N(\boldsymbol{r})\tilde{\Xi}(lm \mid l_1 m_1, l_2 m_2)$$

where relations [3.2] and

$$[A2.8] \quad m_1 + m_2 = m$$

hold. Thus, using [A2.1] and [A2.3] in [A2.7], the Gaunt coefficients Ξ for real homogeneous solid harmonics are written as

$$[A2.9] \quad \Xi(lm \mid l_1 m_1, l_2 m_2) = \sum_{\mu_1\mu_2} \Xi(l\mu \mid l_1\mu_1, l_2\mu_2) U^*_{m\mu} U_{m_1\mu_1} U_{m_2\mu_2},$$

where $\mu = \mu_1 + \mu_2$ and index m takes two values given by [3.3]. O-ohata and Ruedenberg (8, 9) give more explicit expressions for [A2.9]. It should be noted that the coefficients Ξ as well as $\tilde{\Xi}$ are real.

Electronic structure of lower singlet states of binuclear copper acetate monohydrate

KATSUYUKI OGASAWARA,[1] YUJI MOCHIZUKI,[2] TAKESHI NORO, AND KIYOSHI TANAKA[3]
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo, 060, Japan

Received June 10, 1991

This paper is dedicated to Professor Sigeru Huzinaga on the occasion of his 65th birthday

KATSUYUKI OGASAWARA, YUJI MOCHIZUKI, TAKESHI NORO, and KIYOSHI TANAKA. Can. J. Chem. **70**, 393 (1992).

The electronic structures of the ground state and the excited states due to the $3d$–$3d$ transition of copper acetate monohydrate are investigated by *ab initio* calculations. No direct bond is obtained between the two Cu ions, but they are bonded by bridges of the four acetates. The excited states represented by the one-electron excitation of an occupied $3d$ electron to an unoccupied $3d$ orbital in either of the two Cu's are located around 1.6–1.8 eV, which corresponds to the energy region of band I. Those of the simultaneous one-electron $3d$–$3d$ excitation in both Cu's (i.e., two-electron excitation) are located around 3.2–3.4 eV. They correspond to the energy region of band II.

Key words: copper acetate monohydrate, binuclear compound, bridged bond, $3d \rightarrow 3d$ excited states.

KATSUYUKI OGASAWARA, YUJI MOCHIZUKI, TAKESHI NORO et KIYOSHI TANAKA. Can. J. Chem. **70**, 393 (1992).

Faisant appel à des calculs *ab initio*, on a étudié la structure électronique de l'état fondamental et des états excités résultant de la transition $3d$–$3d$ du monohydrate de l'acétate de cuivre. On n'a pas observé de liaison directe entre les deux ions de Cu; ils sont toutefois reliés aux quatre acétates par des ponts. Les états excités, représentés par l'excitation d'un électron de l'orbitale $3d$ occupée vers l'orbitale $3d$ inoccupée de l'un ou l'autre des deux Cu, sont situés autour de 1,6–1,8 eV et ceci correspond à la région d'énergie de la bande I. Ceux de l'excitation simultanée d'un électron $3d$–$3d$ des deux Cu (c'est-à-dire une excitation à deux électrons) sont situés autour de 3,2–3,4 eV. Ils correspondent à la région d'énergie de la bande II.

Mots clés : monohydrate de l'acétate de cuivre, composé binucléaire, liaison pontée, états excités $3d \rightarrow 3d$.
[Traduit par la rédaction]

1. Introduction

Many dimeric copper(II) compounds exhibit subnormal magnetic moments and have long been studied extensively (1). Binuclear copper acetate monohydrate is a typical example of this type and has been investigated by experiments on its geometrical structure, magnetic properties, and electronic spectra (2). The two copper ions are bridged symmetrically by four acetates, and two waters coordinate along the Cu–Cu axis (3, 4). The Cu–Cu distance is about 2.62 Å, which is a little larger than that in the Cu metal (2.56 Å). There is some controversy on the bonding character (δ-bond (5) or σ-bond (6)) between the Cu unpaired $3d$ electrons, and no direct bond between two Cu's (1, 2).

Measurements of the magnetic succeptibility of the system indicated that the ground state of the complex is singlet (1, 2); the magnetic moment of this system is lower than the values usually found for copper(II) compounds and the magnetic susceptibility decreases as the temperature declines.

Copper acetate monohydrate is known to have three broad-band systems in its electronic transition spectra: band I (1.6–1.8 eV), band II (3.2–3.4 eV), and band III (3.7–6.2 eV). Since the experimental work by Tsuchida *et al.* (7), the origin of these bands has been a topic of great discussion (2*b*). The bands that correspond energetically to bands I and III have been observed in mononuclear Cu complexes such as $CuSO_4(OH_2)_5$ (1). The assignment of band I has been established to be $3d$–$3d$ single-electron excitation in a Cu ion (8) and band III has been assigned as a ligands-to-metal charge transfer (CT) band (9). Band II is a weak shoulder on band III, which is much broader and stronger. The origin of band II has not yet been established. It has been tentatively assigned by various researchers: single $3d$ electron excitation (9, 10), double excitation of $3d$ electrons (11), and CT transition from ligands to copper (12, 13). Recently, Ross *et al.* (14) performed a detailed investigation of band I by the use of magnetic circular dichroism (MCD) and considered the spin–spin coupling between the two coppers in the excited states making up band I. They also discussed the assignment of band II (they called it the dimer band) and tentatively concluded that the band is due to CT from the ligands to the copper ion.

Several simple theoretical studies (9–11, 13, 15, 16) were carried out on the spin coupling between the coppers and the electronic structure of the ground and excited states. Otherwise, only one *ab initio* calculation has been carried out, by de Loth *et al.* (17). They used a split valence basis set and calculated the energy separation between the lowest singlet and triplet states. They discussed the exchange mechanism of the two Cu's in the ground state.

In this work, we carry out *ab initio* calculations on this system and discuss the electronic structure of the ground state and the lower singlet excited states. We focus our attention especially on the character of bonding between the two Cu's and the classification of the excited states corresponding to bands I and II.

2. Method of calculation

The geometrical structure of a copper acetate monohydrate is shown in Fig. 1. The molecular plane of the two waters (axial ligands) is assumed to bisect the two bridging acetate planes. The CH_3 group in each acetate ion is replaced by a hydrogen. This may help to reduce computing

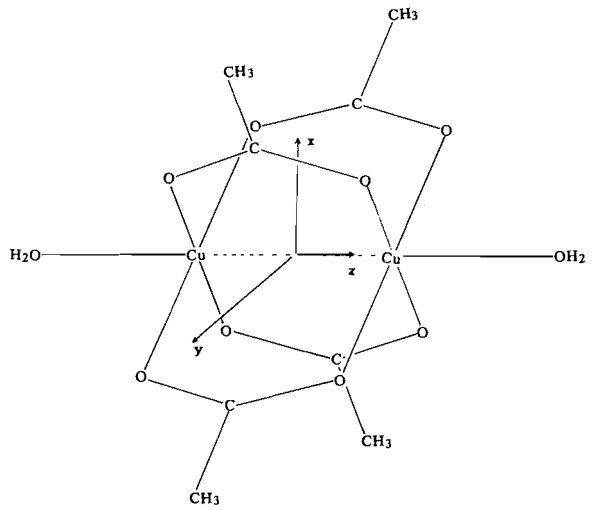

FIG. 1. Schematic geometrical structure of copper acetate monohydrate.

effort without sacrificing the reliability of the calculated results. The structure belongs to the D_{2h} symmetry point group. The geometrical parameters are taken from the neutron diffraction data obtained by Brown and Chidambaram (3) and they are shown as follows:

R(Cu—Cu)	= 2.614 Å	R(Cu—OH_2)	= 2.162 Å
R(Cu—O)	= 1.967 Å	R(Cu—Cu)	= 1.260 Å
∠Cu—O—C	= 122.8°	∠O—C—O	= 124.9°

The basis set used is composed of the MIDI4, split valence type, given by Huzinaga and Tatewaki (18), (3,3,3,2, 1/3,3/4,1) for Cu, (4,2,1/3,1) for O and C, and (3,1) for H. A diffuse p-type primitive Gaussian function (exponent = 0.117) is augmented to the Cu basis set. The total number of basic orbitals is 190. In calculating molecular integrals, we employ the integral approximation based on the semi-orthogonalized orbitals by Osanai and Kashiwagi (19).

We carry out a self-consistent field (SCF) calculation on the lowest $^3B_{1u}$ state. The wave function may be represented by the use of a component of $3d_8$ ($3d_{xy}$) as follows

[1] (Closed shell structure)$[3d_{xy}(8b_{1g})^1 3d_{xy}(6a_u)^1]$

where $3d_{xy}$ is directed toward the four oxygens of the equilateral ligands around each copper and the MO's $3d_{xy}(8b_{1g})$ and $3d_{xy}(6a_u)$ are primarily represented by bonding and antibonding of the two $3d_{xy}$'s, respectively. The closed-shell part of the wave function is expressed by the following electronic configuration

$$[2]\quad (1\text{-}17a_g)^{34}\cdot(1\text{-}7b_{1g})^{14}\cdot(1\text{-}9b_{2g})^{18}\cdot(1\text{-}9b_{3g})^{18}\cdot(1\text{-}5a_u)^{10}\cdot(1\text{-}15b_{1u})^{30}\cdot(1\text{-}11b_{2u})^{22}\cdot(1\text{-}11b_{3u})^{22}$$

This wave function ensures possible diradical form where two parallel spins are localized primarily on the $3d_{xy}$ atomic orbitals (AO's) of the two coppers. Starting from the molecular orbitals (MO's) thus obtained, we carry out a two-configuration self-consistent field (TCSCF) calculation where the two configurations are as follows:

[3] (Closed shell structure)$[3d_{xy}(8b_{1g})^2]$

[4] (Closed shell structure)$[3d_{xy}(6a_u)^2]$

The mixing of these two configurations is also possible, to describe the diradical form of the singlet coupling of the two unpaired electrons localized on $3d_{xy}$ AO's of the two coppers.

FVCI (full valence configuration interaction) calculations for the singlet ground state and excited states are carried out by the use of the resultant TCSCF MO's. As the predominant configurations are not well known for the lower excited states, especially for the doubly excited states, the FVCI scheme may help to avoid generating an inappropriate set of configuration state functions (CSF). In the FVCI calculation, the following orbitals are taken as frozen core orbitals:

$$1\text{-}14a_g,\ 1\text{-}6b_{1g},\ 1\text{-}7b_{2g},\ 1\text{-}7b_{3g},$$
$$1\text{-}4a_u,\ 1\text{-}12b_{1u},\ 1\text{-}9b_{2u},\ 1\text{-}9b_{3u}.$$

They are mainly composed of the core orbitals of Cu($1s$, $2s$, $3s$, $2p$, and $3p$), the occupied orbitals of C and H, and the occupied orbitals of O except for the $2p_\sigma$ orbitals, which belong to the equilateral oxygen ligands. In generating CSF's, we take all possible distributions of the 34 valence electrons on the 20 valence orbitals, which are mainly represented by $3d$, $4s$ orbitals of the coppers and oxygen $2p_\sigma$ orbitals of acetic acids. These $2p_\sigma$ orbitals are directed toward the copper. Those orbitals are shown in Table 1 in connection with the irreducible representations. As the resulting occupied MO's of the TCSCF wave function are not eigenfunctions of a Fock-like operator, it is easy to partition those MO's of the closed-shell part into core orbitals and valence orbitals. This is because any unitary transformation among the closed-shell MO's does not change the total wave function. The valence MO's, mostly representing $3d$ and $2p_\sigma$, are projected out from the TCSCF wave function by the corresponding orbital technique (20). In projecting out the valence MO's, we prepare the MO's of the SCF wave functions on the fragments, $(Cu^{2+})_2$ and $(HCOO^-)_4(H_2O)_2$, separately. By the use of the $3d$ dominant MO's of the $(Cu^{2+})_2$ triplet wavefunction of the configuration

[5] (Closed shell structure)$[3d_{xyg}{}^1 3d_{xyu}{}^1]$

the $3d$ type valence MO's are projected out from the occupied orbitals of the TCSCF wave function of the complex. The $2p_\sigma$(O) MO's of the ground state SCF wavefunction of $(HCOO^-)_4(H_2O)_2$ are used to project out those $2p_\sigma$-type valence MO's of the compound system. The unoccupied $4s$-type MO's are projected out from the unoccupied orbital space so as to maximize the overlap with the $4s$ dominant MO's of $(Cu^{2+})_2$ obtained from the SCF MO's of the septed wavefunction of

[6] (Closed shell structure)$[3d_{z^2g}{}^1 3d_{z^2u}{}^1 3d_{xyg}{}^1 3d_{xyu}{}^1 4s_g{}^1 4s_u{}^1]$

The number of CSF's of the FVCI are of the order of 47 300–47 900 for the states under consideration (^1A_g, $^1B_{1g}$, $^1B_{2g}$, $^1B_{3g}$, ^1A_u, $^1B_{1u}$, $^1B_{2u}$, and $^1B_{3u}$).

[a]The numbers for population are the same within the given digits for the two states: TCSCF for ^1A_g, and SCF for $^3B_{1u}$.
[b]Belonging to the acetic acid.
[c]Belonging to water.

3. Results and discussion

3.1. (TC)SCF results: character of the lowest ^1A_g and $^2B_{1u}$ states

The TCSCF energy of the lowest ^1A_g state is −4169.11130 hartree. This is slightly lower than the SCF energy of the lowest $^3B_{1u}$ state by about 0.0005 eV. By experiment, the ground state of the system is singlet and its energy is lower than the lowest triplet state by about 0.035 eV (2). The energetical order of the two states is in accord with experiment, but this energy separation is very small. As was pointed out by de Loth *et al.* (17), we should employ a much more extensive computational method than the TCSCF or SCF scheme to obtain energy separation comparable to experiment.

The Mulliken-type population analysis is performed for the ^1A_g and $^3B_{1u}$ states by the use of the (TC)SCF wave functions. The results are summarized in Table 2. In both states, each Cu is populated by about 28 electrons, i.e., Cu^+ rather than Cu^{2+}. If one sees the results in more detail, one notes that the $3d$ shell is occupied by about 9 electrons and the electron population of the $4s$ and $4p$ shell is about 0.8. The population of the $3d_\delta$ orbitals in the two states is about 3 for each copper. The two unpaired electrons are localized on the $3d_{xy}$ of the coppers. All oxygens are occupied by about 8.6–8.7 electrons, which means that oxygens are nearly O^-. The overlap population between the two coppers is about −0.02, whereas that of Cu—O (acetic acid) is about 0.29.[4]

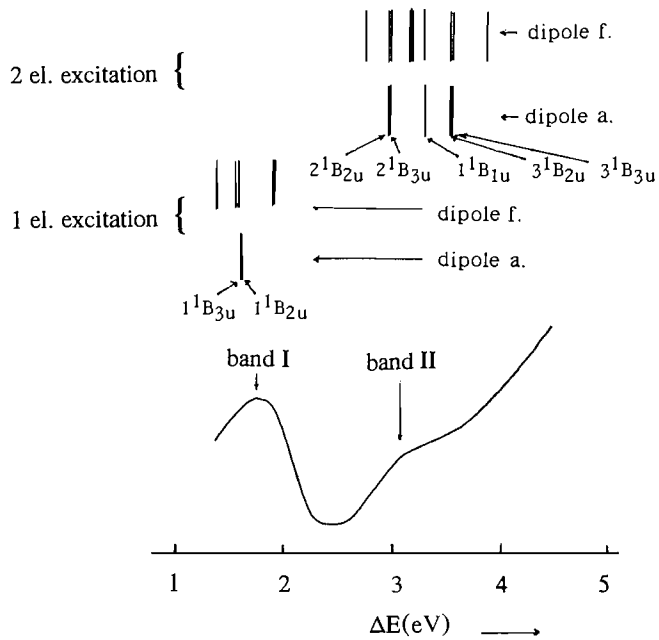

FIG. 2. Calculated vertical excitation energies in comparison with bands I and II. Note: The term "dipole f." means dipole-forbidden transition and "dipole a." represents dipole-allowed transition.

[4]The overlap population of Cu—O(water) is 0.17.

This indicates that the two coppers are not bonded directly but bridged by the four acetic acids.

3.2 The FVCI results: the d–d *singlet excited states*

Using the results of the FVCI, we are going to discuss the lower excited states. The total energy of the ground state (^1A_g) is −4169.46775 hartree. The calculated excitation energies are also compared with the observed excitation spectra in Fig. 2. Table 3 shows excitation energies, leading configurations, and their coefficients for the excited states below 4 eV relative to the ground state. The configurations A and B that are shown in the table correspond to those given by eqs. [3] and [4], respectively. They contribute primarily to the ground state wave functions. The lower 3*d* to 3*d* excited states are described by excitation to the $3d_{xy}(a_u)$ MO, which is empty in configuration A, or by excitation to an empty MO of $3d_{xy}(b_{1g})$ in configuration B.

The wave function of the ground state is expressed by the out-of-phase combination of the two configurations with almost the same weight. This may be schematically expressed by

$$[7]\quad \{3d_{xy}(1) + 3d_{xy}(2)\}^2 - \{3d_{xy}(1) - 3d_{xy}(2)\}^2 \propto [3d_{xy}(1)^1 3d_{xy}(2)^1]^{[1]}$$

where $3d_{xy}(1)$ is an AO of a copper and $3d_{xy}(2)$ is that of another copper and $[3d_{xy}(1)^1 3d_{xy}(2)^1]^{[1]}$ represents the singlet coupling of two electrons occupying the two AO's.

Every excited state given in the table is also expressed by two primary configurations and they mix with almost equal weight. The excited states are described as essentially intra-3*d* excitations. All the excited states that lie below 2.0 eV are represented mainly by single electron excitations from A or B. They are primarily described as 3*d* to 3*d* single electron excitation in either of the two coppers. As an example, we show a schematic form of the wave function of the 1^1B_{2u} state in terms of AO's in a form similar to eq. [6]:

$$[8]\quad [\{3d_{zx}(1) + 3d_{zx}(2)\}^1\{3d_{zx}(1) - 3d_{zx}(2)\}^2\{3d_{xy}(1) + 3d_{xy}(2)\}^2\{3d_{xy}(1) - 3d_{xy}(2)\}^1]^{[1]} - [\{3d_{zx}(1) + 3d_{zx}(2)\}^2 \times \{3d_{zx}(1) - 3d_{zx}(2)\}^1\{3d_{xy}(1) + 3d_{xy}(2)\}^1\{3d_{xy}(1) - 3d_{xy}(2)\}^2]^{[1]} \propto [3d_{zx}(1)^2 3d_{zx}(2)^1 3d_{xy}(1)^1 3d_{xy}(2)^2]^{[1]} - [3d_{zx}(1)^1 3d_{zx}(2)^2 3d_{xy}(1)^2 3d_{xy}(2)^1]^{[1]}$$

This wave function represents the single electron excitation ($3d_{zx} \rightarrow 3d_{xy}$) in either of the Cu's.

Our interest has been drawn to the ordering of the 3*d* levels. By the present calculation, the first two excited states are $3d_{x^2-y^2}(d_\delta')$ to $3d_{xy}(d_\delta)$ excitation and the excitation energy is about 1.4 eV. The lobe of $3d_{x^2-y^2}$ bisects the O—Cu—O angle where the O's are equilateral ligands. The next four levels are d_π ($3d_{yz}$ and $3d_{zx}$) to $3d_{xy}$ excited levels. They are located around 1.6 eV. The $3d_{z^2}$ (d_σ) level is the most stable and $3d_{z^2}$ to $3d_{xy}$ excitation is found at about 1.9 eV. It is interesting to compare the excitation energies of these excited states with band I. Dipole-allowed transitions of the 1^1B_{3u} and 1^1B_{2u} states (1.58 and 1.61 eV) are in especially good agreement with the center of the peak of band I (1.8 eV). The present results indicate that band I is composed of 3*d* to 3*d* single electron excitation in either of the two coppers. All 3*d* to 3*d* singly excited states lie below 2 eV and the assignment of 3*d* to 3*d* single electron excitation (9, 10) to band II is not supported.

The excited states higher than 2.7 eV are led by doubly excited configurations, double electron excitation to the empty $3d_{xy}(a_u)$ MO in configuration A or, in other words, excitation to the empty $3d_{xy}(b_{1g})$ MO in configuration B. They are essentially described as simultaneous single electron 3*d*–3*d* excitation in both coppers. As an example, the wave function of the 1^1B_{1u} state is given in terms of AO's as follows:

$$[9]\quad [\{3d_{x^2-y^2}(1) + 3d_{x^2-y^2}(2)\}^1\{3d_{x^2-y^2}(1) - 3d_{x^2-y^2}(2)\}^2\{3d_{z^2}(1) + 3d_{z^2}(2)\}^2\{3d_{z^2}(1) - 3d_{z^2}(2)\}^1\{3d_{xy}(1) + 3d_{xy}(2)\}^2 \times \{3d_{xy}(1) - 3d_{xy}(2)\}^2]^{[1]} - [\{3d_{x^2-y^2}(1) + 3d_{x^2-y^2}(2)\}^2\{3d_{x^2-y^2}(1) - 3d_{x^2-y^2}(2)\}^1\{3d_{z^2}(1) + 3d_{z^2}(2)\}^1\{3d_{z^2}(1) - 3d_{z^2}(2)\}^2 \times \{3d_{xy}(1) + 3d_{xy}(2)\}^2\{3d_{xy}(1) - 3d_{xy}(2)\}^2]^{[1]} \propto [3d_{x^2-y^2}(1)^2 3d_{x^2-y^2}(2)^1 3d_{z^2}(1)^1 3d_{z^2}(2)^2 3d_{xy}(1)^2 3d_{xy}(2)^2]^{[1]} - [3d_{x^2-y^2}(1)^1 3d_{x^2-y^2}(2)^2 3d_{z^2}(1)^2 3d_{z^2}(2)^1 3d_{xy}(1)^2 3d_{xy}(2)^2]^{[1]}$$

This wave function represents two-electron excitation ($3d_{x^2-y^2} \rightarrow 3d_{xy}$ in one Cu and $3d_{z^2} \rightarrow 3d_{xy}$ in another Cu).

Although the transition probability to these doubly excited states should be small even in the dipole-allowed $^1B_{1u}$, $^1B_{2u}$, and $^1B_{3u}$ states, it is interesting to note that the five dipole-allowed excited states, $^1B_{2u}$ (2.96 eV, 3.52 eV), $^1B_{3u}$ (2.99 eV, 3.55 eV), and $^1B_{1u}$ (3.30 eV), are located at comparable transition energies of band II, which is centered around 3.3 eV. As band II is a very weak shoulder of band III, it is highly possible that band II originated from one-electron 3*d* to 3*d* transitions in both coppers simultaneously. Hansen and Ballhausen (11) assigned band II as doubly excited ($(d_\sigma)^2$ to $(d_\delta)^2$) transition. This excited state is the 6^1A_g state by the present calculation. This state is represented by singlet coupling of the unpaired d_σ electrons in both Cu's and is unstable relative to the ground state by about 3.9 eV.

Apart from these states, we also calculated the energies of the CT states. The excitation energies for the CT states are about 10 eV or more. They are much higher than those for the broad peak of band III, which are supposed to have originated from CT excitation. The variational space selected in this calculation is limited to the one that is appropriate to describe only *d*–*d* transitions, and CT states would not be predicted well by the present calculation. In this context, possible contribution of CT to band II (12–14) is not denied by the present calculation. More extensive calculation is desired for this purpose.

4. Summary

By using a split valence basis set and employing the limited FVCI scheme, we have investigated the electronic structure of the ground and lower Cu $3d$–$3d$ excited states of the binuclear copper acetate monohydrate. Each copper has almost nine $3d$ electrons, but it is formally not Cu^{2+} but Cu^{+}. About 0.8 electron is back-donated to $4s$ and $4p$ shells.

The excited states due to $3d$ to $3d$ single electron transition in either Cu contributes to band I, as is well established. The excited states distributed between 3.0 and 3.6 eV are primarily led by $3d$ to $3d$ single electron excitation in both coppers simultaneously. The present result suggests that these states contribute to band II, which is a weak shoulder of the strong absorption band III.

5. Acknowledgements

The authors are grateful to Professors K. Ohno and F. Sasaki for their discussions on this problem. This work has been supported by a grant-in-aid of the Japanese Ministry of Education. All calculations were carried out using the computer codes JAMOL4 (21) and JASON2 (22), on systems HITAC M-680H, M-682H, and S-820/20 at the Institute for Molecular Science and the Computing Center of Hokkaido University.

The authors feel it a great honor to contribute this paper to the special issue of the Canadian Journal of Chemistry dedicated to Professor Huzinaga. They are indebted to Professor Huzinaga for his leadership, over a long period, in the field of theoretical molecular physics and quantum chemistry. They express their deep gratitude for his enlightening them through his papers and books.
