A photo-oxidation of croconic acid into oxalic acid

Paul-Louis Fabre, Paule Castan, Diane Deguenon, and Nicole Paillous

Abstract: Croconic acid, $H_2C_5O_5$, is readily oxidized. This may be attested by decolorization of the solutions and by observation of oxalic acid complexes. The oxidation products are identified by ^{13}C NMR spectroscopy as oxalic and mesoxalic acids, and experimental conditions are specified. The oxidation process requires dioxygen and photons. In parallel, the electrochemical oxidation of croconic acid is studied in aqueous media and in acetonitrile. A potential–pH diagram is drawn.

Key words: croconic acid, oxalic acid, oxidation, electrochemistry, photochemistry.

Résumé : L'acide croconique $H_2C_5O_5$ est facilement oxydé, ceci est attesté par la décoloration de ses solutions et l'obtention de complexes de l'acide oxalique. Les produits d'oxydation ont été identifiés par spectroscopie RMN du ^{13}C, ce sont les acides oxalique et mesoxalique. Les conditions expérimentales requises par cette oxydation sont spécifiées, ce sont la présence de dioxygène et de lumière. Parallèlement, l'oxydation électrochimique de l'acide croconique a été étudiée dans l'eau et l'acétonitrile. Le diagramme potentiel–pH est décrit.

Mots clés : acide croconique, acide oxalique, oxydation, électrochimie, photochimie.

Introduction

4,5-Dihydroxycyclopentenetrione **1,** commonly known as "croconic" acid, $H_2C_5O_5$, and the croconate anion $[C_5O_5]^{2-}$ have received considerable attention from both a theoretical and an experimental point of view (1–6). Croconate, like squarate or rhodizonate ions, is a member of the oxocarbon ring system, $[C_nO_n]^{2-}$, a new class of aromatic substances with planar structure containing only carbon and oxygen atoms. Both croconic and squaric acids are strong acids in aqueous solution, having pK_{A1} values of 0.80 (7) and 0.54 (8), respectively.

During the course of our investigations concerning transition metal complexes of croconic acid we attempted to prepare a manganese croconate complex. In the presence of croconic acid, 2,2′-bipyridine, and Mn(II) salt, the complex $[Mn(C_{10}H_8N_2)(C_2O_4)]_n$ was unexpectedly obtained, and was structurally identified (9). This synthesis requires the oxidation of croconic acid into oxalic acid.

Oxidation of croconic acid and of other polyketo compounds by molybdenum(VI) in acidic media has already been described by Verchere and Fleury (10–12); a transient 1/1 complex between Mo(VI) and the ionized acid was shown. Oxalic and mesoxalic acids were identified among the oxidation products. In the same way, Zubieta and co-workers described a Mo(V)–oxalate cluster obtained from polyoxomolybdate(VI) and rhodizonic acid (13). The mechanism proposed in these studies always requires electron transfer steps implying reduction of the metal. Rhodizonic acid ($H_2C_6O_6$) is known to be unstable when exposed to visible light but no study has been reported.

More recently, Zhao and Back have studied the photochemical reactions of the dianions of rhodizonic and croconic acids (14–16). In basic media, the photochemical oxidation of the croconate dianion leads to formation of the squarate dianion. Taking into account these last results and those we obtained, it seems evident that the photochemical dissociation process of croconic acid itself (acidic media) is quite different from that of its dianion (neutral or basic media). The oxalate complex we obtained during the course of our complexation process has prompted us to examine the oxidation process of croconic acid, leading to oxalic acid, in the presence or absence of manganese salts.

Experimental

Materials

Croconic acid and its potassium salt were prepared according to the procedure described by Fatiadi et al. (17).

Synthesis of tetraphenylphosphonium croconate

To an aqueous solution of $P(C_6H_5)_4Cl$ (2 mmol in 10 mL), an aqueous solution of potassium croconate (1 mmol in 10 mL) is added under stirring. The solution is kept overnight on cooling and yields yellow crystals that are isolated by filtration, washed with ether, and dried under vacuo (yield 95%).

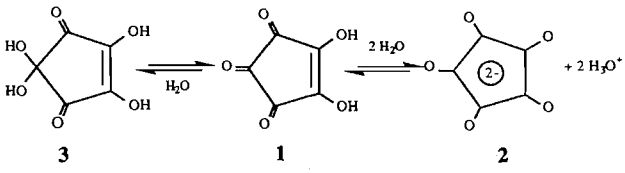
Scheme 1.



Physical measurements

IR spectra were recorded on a Perkin–Elmer 983 spectrophotometer coupled with a Perkin–Elmer infrared data station; samples were run as Nujol mulls. NMR spectra were recorded on a Brucker WM 250 Fourier transform spectrometer. UV–visible spectra were measured on a Cary 2390 spectrophotometer. Electrochemical measurements were carried out with a homemade potentiostat controlled by an Apple IIe microcomputer (18). The electrochemical cell was a conventional one with three electrodes: a working disk electrode, Cv (vitreous graphite, diameter 3 mm) or Pt (diameter 2 mm); an auxiliary electrode, Pt wire; and a reference electrode, Ag/AgCl, KCl 0.1 mol L^{-1}. EPR spectra of frozen solutions were obtained on a Bruker 200 TT spectrometer with a Bruker cryostat.

Irradiations were performed with a Muller reactor device equipped with a 200 W high-pressure mercury lamp (Osram) and an interference water cooling filter (Oriel 365FS 10–50, 25% transmission at 365 nm). The solutions of croconic acid (varying from 10^{-3} to 10^{-4} mol L^{-1}) were irradiated from 10 to 60 s in a UV quartz cell. The thickness of the cell was adjusted to obtain similar absorptions whatever the concentration. The effect of scavengers was tested under irradiation at 365 nm. NaN_3 (12 mmol L^{-1} final concentration) or DABCO (1,4-diazabicyclo[2,2,2] octane) (10 mmol L^{-1} final concentration) were added to a croconic acid solution (9×10^{-4} mol L^{-1}). We verified that the changes observed by using NaN_3 are essentially due to a pH variation.

Results and discussion

In the presence of croconic acid, 2,2′-bipyridyl, and Mn(II) salt, the complex $[Mn(C_{10}H_8N_2)(C_2O_4)]_n$ was unexpectedly obtained, and was structurally identified (9). This system requires oxidation of croconic acid into oxalic acid. At first we presumed a catalytic oxidation of croconic acid by Mn(III) traces, of which are always present in Mn(II) salts. However, it can be established that oxidation occurs even without manganese salts. Indeed, a yellow solution of croconic acid rapidly decolorized under exposure to light. The croconic acid degradation is an oxidation process. So, as a first step, the electrochemical behaviour of croconic acid was studied.

Electrochemical oxidation

According to the acidity constants of croconic acid (pK_{A1} = 0.80 and pK_{A2} = 2.24) and to hydration, the predominant forms are **1**, **2**, and **3** and depend on pH. The monoanion is not predominant.

In acid media, the oxidation process has already been reviewed (19), but the products were not isolated. Then, the electrochemical oxidation was studied in aqueous media as a function of pH. At a glassy carbon electrode, the voltammograms show, by cyclic voltammetry, the oxidation peak of croconic acid (Fig. 1). The oxidation process appears irreversible;

Fig. 1. Cyclic voltammograms at a Cv electrode in aqueous media of croconic acid 1 mol L^{-1}, potential scan speed 0.1 V s^{-1}: A: pH = 1.53; B: pH = 7.0.

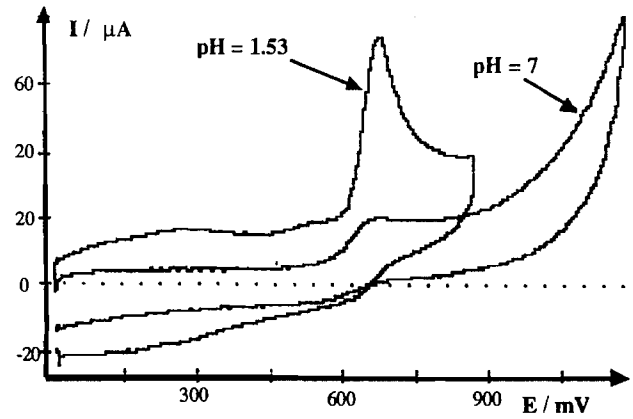


Fig. 2. Voltammograms at a rotating Cv electrode in aqueous media of croconic acid, rotation speed 1000 rpm: A: pH = 0.6, $[C_5O_5H_2]$ = 1 mmol L^{-1}; B: pH = 7.0, $[C_5O_5H_2]$ = 0.7 mmol L^{-1}.

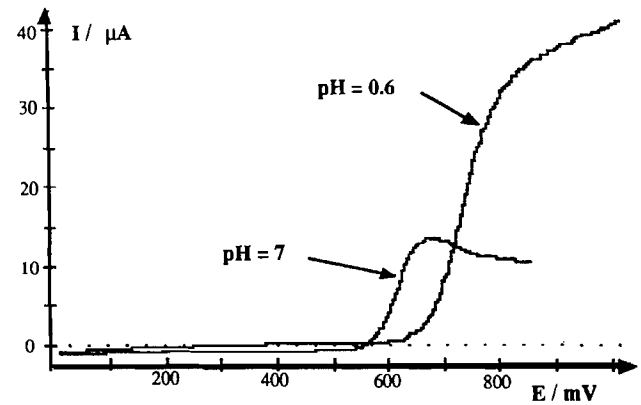

no reduction peak is observed on the backward scan. The peak current is linearly related to the square root of the potential scan speed and to the croconic acid concentration. At pH higher than 4, passivation of the electrode which disturbs the voltammetric recordings, is observed (Fig. 2); the diffusion decreases on the plateau.

Also in acid media, the diffusion wave is observed under stationary conditions at a rotating electrode, while at higher pH the wave does not present the plateau due to passivation of the electrode. Moreover, the current is lower than the current observed in acid media. This can be attributed to electrode passivation but also to a kinetic effect on the oxidation process. Effectively, by exhaustive electrolysis, coulometric integration is in agreement with a two-electron transfer whatever the pH. But in acid media electrolysis is carried out within 10 min while the basic media it requires more than an hour to be complete. The global oxidation process is expressed by the following equation:

$$H_2C_5O_5 \rightarrow C_5O_5 + 2\,H^+ + 2\,e^-$$

which gives the pentaketone **4** that exists under various hydrated forms (**4***b*, **4***c*).

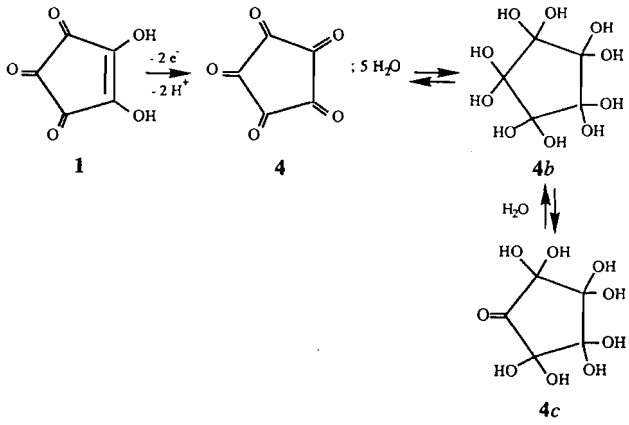
Scheme 2.



The ^{13}C NMR spectra of the resulting solution obtained by electrolysis in buffered D_2O–H_2O mixtures confirm this equation. The spectra show the hydrated form (**4***c*), which is characterized by signals at 94.8, 97.7, and 98.7 ppm ($CH(OH)_2$) and at 209.6 ppm (C=O). These are in agreement with the previously reported values: 93.0, 95.9, 96.9, and 208.0 ppm (2, 20).

According to Levich's equation for the diffusion current under stationary conditions, the diffusion coefficient of croconic acid is calculated in acid media to be $D = 5.6 \times 10^{-6}$ cm^2 s^{-1}. It is the same order of magnitude as the value reported by Sazou and Kokkinidis (19), $D = 5.5 \times 10^{-6}$ cm^2 s^{-1}.

Taking into account the half-wave potential $E_{1/2}$ measured under stationary conditions at a Cv electrode, the *E*–pH diagram is obtained (Fig. 3). This diagram is consistent with the oxidation equation where the apparent potential ($E^{\circ\prime}$) is related to the standard potential E° and to the acidity constants of croconic acid by

$$E^{\circ\prime} = E^\circ - 0.059\ \text{pH} + 0.029 \log (1 + K_{A1}/[H_3O^+] + K_{A1}K_{A2}/[H_3O^+]^2)$$

According to this equation, the potential is linearly related to −0.059 pH in acid media as observed and it should be independent of pH in basic media. In fact, at pH > 12 the potential appears to decrease with pH, which means that H^+ is involved in the oxidation process of croconate anions. It may be attributed to the formation of leuconate anions from the hydration of the pentaketone **4**:

$$C_5O_5^{2-} + 4\ H_2O \rightarrow C_5H_6O_9^{2-} + 2\ H^+ + 2\ e^-$$

or to the formation of squarate dianion according to Zhao and Back (15):

$$C_5O_5^{2-} + H_2O \rightarrow C_4O_4^{2-} + CO_2 + 2\ H^+ + e^-$$

In organic solvents (acetonitrile CH_3CN), the electrochemical behaviour of croconate dianion $[P(C_6H_5)_4]_2C_5O_5$ was studied at a platinum electrode. Under nonstationary conditions, the voltammograms show two oxidation processes (Fig. 4) that appear monoelectronic and reversible. When the potential sweep scans the two redox couples the peak ratio RI_p (reduction peak current/oxidation peak current) of the first step is slightly lower than 1 whereas it equals 1 when the potential sweep scans only the first redox couple. The peak currents are linearly related to the square root of the potential scan speed and to the croconate concentration. The oxidation process of croconate is expressed by the two successive electron transfers:

$$C_5O_5^{2-} \rightleftharpoons C_5O_5^- + e^-$$
$$C_5O_5^- \rightleftharpoons C_5O_5 + e^-$$

Under stationary conditions at a rotating Pt electrode, the voltammograms present two monoelectronic waves whose half-wave potentials are 0.28 and 0.81 V. The limiting currents are linearly related to the square root of the electrodes rotation speed and to the corconate concentration. The oxidation process is diffusion controlled as evidenced by cyclic voltammetry. According to the Levich's equation on the diffusion current under stationary conditions, the diffusion coefficient of croconate dianion is calculated to be $D = 8.0 \times 10^{-6}$ cm^2 s^{-1}. By electrolysis at a potential on the first plateau, the yellow solutions turn orange after a one-electron exchange per dianion and yield a stable radical whose EPR spectra give a *g* value of 2.0065 (6). Electrolysis of croconate dianion on the second plateau gives a two-electron exchange per dianion and yields the pentaketone **4**.

The electrochemical behaviour of croconic acid depends on the nature of the solvent. In an organic solvent, the oxidation proceeds through two monoelectronic exchanges and a long-lived radical $C_5O_5^-$ can be formed, since the EPR signal is still observed after several hours at ambient temperature. In aqueous media, the electrochemical oxidation becomes bielectronic (the radical is unstable) and yields the pentaketone more or less hydrated. So, a photoexcitation of croconic acid into radical species may activate the degradation of croconic acid. Moreover, the oxidation process depends on the acidity level.

Photochemical oxidation

Identification of products

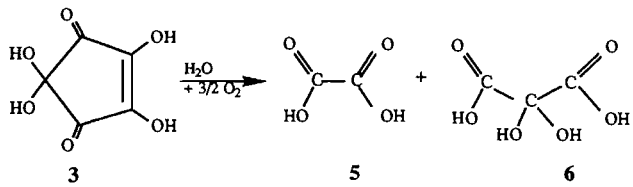
Analysis of the resulting products in solution is achieved by ^{13}C NMR spectroscopy. ^{13}C NMR spectra of croconic acid have long been studied (2). In aqueous solution some of the carbonyl groups become hydrated and an equilibrium can be observed between the various hydrated forms.

Before light exposure, in D_2O (1.5 mL) with 0.1 mL of concentrated sulfuric acid (the oxidation process is faster in acidic medium, vide infra), we observed by NMR spectroscopy an equilibrium between the triketone form (**1**) and its monohydrate (**3**) that leads to a four-signal spectrum. The signal at 183.2 ppm is attributed to the triketone **1**, which exhibits fast exchange of the carbon sites. The croconic monohydrate **3** shows a low-frequency signal at 89.2 ppm corresponding to $C(OH)_2$ and signals at 151.6 ppm (COH) and 194.3 (C=O) ppm.

After 2 days under daylight, the yellow solution of croconic acid becomes colorless. The ^{13}C NMR spectra reveal the disappearance of croconic acid. Weak signals within the 80–100 ppm range are attributed to $C(OH)_2$ of the hydrated forms. These signals decrease with time. Moreover, two peaks at 162.9 and 173.2 are observed and related to carbonyl carbons. The ^{13}C NMR spectra of oxalic and mesoxalic acids have been recorded under the same experimental conditions. The ^{13}C NMR spectra of oxalic acid (**5**) present a single peak at 162.9 ppm while those of mesoxalic acid (**6**) present two types of signals: at 94.0 ppm the peak of the $C(OH)_2$ carbons and at 173.5 ppm the peak of the COOH carbons. Our results indicate that croconic acid oxidation leads to oxalic and mesoxalic acids through hydroxylated oxocarbons that are detected by ^{13}C NMR spectroscopy in the 80–100 ppm range. Oxalic acid is also characterized by precipitation with $CaCl_2$ (the precipitate is identified by elemental analysis and IR spectrum). By contrast, under the same conditions mesoxalic and oxalic acid solutions are stable even under irradiation. Moreover, it may be emphasized that the oxidation process of croconic acid, which is small in neutral solutions, is enhanced in acidic media and is not observed in pure D_2O.

Similarly Zhao and Back (15) observed that in neutral solutions the quantum yield for disappearance of croconate dianion was small but was substantially increased in basic solution. At pH = 12, these authors observed conversion of the croconate dianion to the squarate dianion, analogous to the conversion of rhodizonate to croconate that occurs in strong basic media and is so efficient that no other method has been developed for the preparation of croconic acid. Moreover, Stadeli et al. (2) observed in the spectra of leuconic acid (**4***b*), which is the fully hydrated form of oxidized croconic acid, a signal at ca. 195 ppm, which increases with time and was attributed to squaric acid.

Scheme 3.



By comparison with our results, the oxidation of croconic acid in basic media is different from that in acid media. This is confirmed by the E–pH diagram of croconic acid.

Redox process

Assuming the formation of oxalic and mesoxalic acids from the oxidation of croconic acid, the redox system may be expressed as follows:

$$\underset{\mathbf{3}}{C_5H_4O_6} + 4\,H_2O \rightarrow \underset{\mathbf{5}}{C_2H_2O_4} + \underset{\mathbf{6}}{C_3H_4O_6} + 6\,H^+ + 6\,e$$

with the dioxygen system:

$$O_2 + 4\,H^+ + 4\,e^- \rightarrow 2\,H_2O$$

The overall system may be written as

$$2\,H_2C_5O_5 + 3\,O_2 + 4\,H_2O \rightarrow 2\,C_2H_2O_4 + 2\,C_3H_4O_6$$

To check this chemical balance, redox titrations by permanganate solutions were undertaken. Solutions of croconic acid exposed to dioxygen and light were titrated by $KMnO_4$ solutions. According to the oxidation of oxalic and mesoxalic acids:

$$C_2H_2O_4 \rightarrow 2\,CO_2 + 2\,H^+ + 2\,e^-$$
$$C_3H_4O_6 \rightarrow 3\,CO_2 + 4\,H^+ + 4\,e^-$$

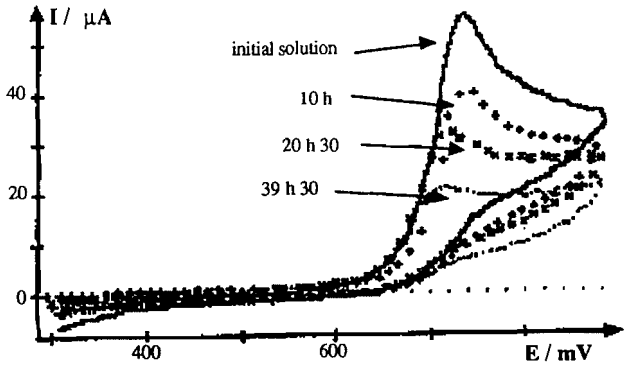
The redox titration requires 6 electron-equivalents per croconic acid. Experimentally we found always around 6.5 (higher than 6) electrons, owing to the incomplete decomposition of the initial solution of croconic acid.

Preliminary kinetic analysis

To get more information about the oxidation pathway, we undertook preliminary kinetic studies. The croconic acid concentration can be easily monitored by electroanalytical methods or UV–visible spectroscopy. In this case, we used cyclic voltammetry at a Pt electrode.

In acid aqueous media (HCl or H_2SO_4), croconic acid solutions are electroactive at a Pt electrode. As oxalic and mesoxalic acid solutions are not electroactive at a Pt electrode in this solvent, the diffusion current is related to the croconic acid concentration and provides a monitor for kinetic studies. Moreover, the voltammograms do not show the appearance of squaric acid, which presents an oxidation peak around 0.85 V. Then, by recording the voltammograms as a function of time (Fig. 5), we observed that the peak current of croconic acid

Fig. 5. Cyclic voltammograms at a Pt electrode in H_2SO_4 0.1 mol L^{-1} of croconic acid as a function of time, potential scan speed 0.1 V s^{-1}: t = 0 h (—); t = 10 h (+++); t = 20 h 30 (×××), and t = 39 h 30 (···).



decreases with time. Kinetic determinations were then carried out under various conditions. Assuming a first-order rate, the rate constants were calculated by linear regression of $\log(I_{t=0}/I_t) = kt$.

From Fig. 6 we can point out that Mn(II) salt does not affect the oxidation speed of croconic acid; there is no catalytic effect. Croconic acid appears to be oxidized by dioxygen in acid medium and the process is photochemically activated. Under an Ar atmosphere, we did not observe any significant oxidation of the acid. Moreover, the oxidation rate increases when the acidity level increases.

From these preliminary results there are two requirements for the oxidation of croconic acid in acid media: dioxygen and photons (light). To obtain more information, the kinetics of the photo-oxidation process was followed by UV spectroscopy.

Photochemistry

Croconic acid H_2Cr presents two bands at λ = 230 nm and λ = 295 nm. These bands are displaced according to acid–base equilibria (21). The croconate dianion is characterized by a typical band at λ 363 nm (Fig. 7). This band enables us to follow the croconate concentration and the ratio $(A_0 - A_t)/A_0$ represents the degree of oxidation as a function of time. When irradiation is performed, at first the absorption at 363 nm of the solution increases. Formation of transient radical species is suggested to explain this increase. Then the whole absorption spectrum decreases as a function of time. The value of A_0 is recorded when the irradiation is stopped. In the following section we use v_0 as the initial speed of oxidation

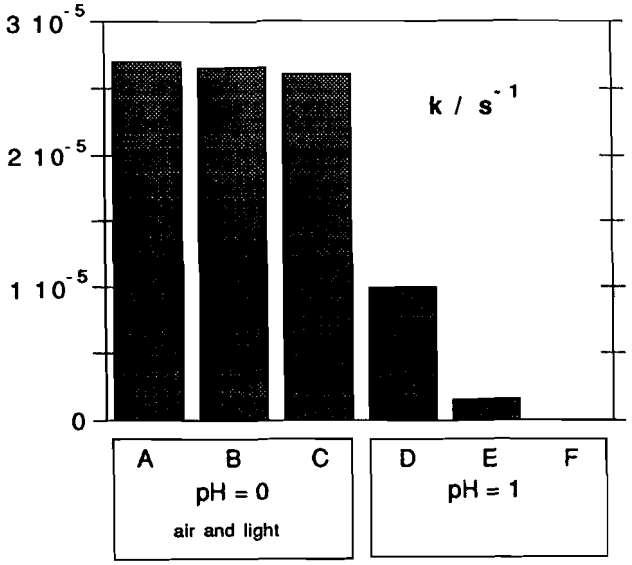
$$v_0 = -d[H_2Cr]/dt(t = 0) = k[H_2Cr]_0^p \text{ with } \rho_0 = v_0/[H_2Cr]_0(ms^{-1})$$

The superscript p is the order rate related to croconic acid (equal to one for a first-order rate) and ρ_0 should be constant for a first-order rate.

The variation of ρ_0 as a function of croconic acid concentration shows that ρ_0 is not a constant as for a first-order rate but that it is linearly related to the concentration. Moreover, Fig. 8 shows the variation of ρ_0 with pH. It appears that ρ_0 decreases rapidly when acidity decreases.

In this way EPR spectroscopy was carried out under irradiation in order to observe the occurrence of radicals. When the solution of croconic acid was irradiated, we observed radical

Fig. 6. Pseudo-first-order rate constant of croconic oxidation measured by cyclic voltammetry at a Pt electrode: $[C_5O_5H_2]_{(t=0)}$ = 1 mmol L^{-1}; pH = 0: A, croconic acid alone; B, with 2,2 bipyridyl 0,1 mmol L^{-1}; C, with 2,2 bipyridyl, $MnCl_2$ 0,1 mmol L^{-1}; pH = 1: crononic acid alone; D, air and light; E, air and dark; F, under Ar.



signals on the EPR spectra at g_1 = 2.0055, g_2 = 2.0045, and g_3 = 2.0038 with intensities of 1.75, 1, and 8.5, respectively. These signals are related to the presence of three different organic radicals according to the different shape of the signals. In organic aprotic solvents the electrochemical oxidation of croconate dianion leads to a stable radical whose EPR spectra gives a g value of 2.0065.

According to all these results, three major parameters appear in the oxidation process of croconic acid:

1. pH. Oxidation occurs in acidic media. From Fig. 8, ρ_0 appears linearly related to pH and reaches 0 in neutral medium. The slope of the ρ_0 variations in acid media gives a crossing point at pH 4.7. This value has the same order of magnitude as the pK_A of the HO_2, radical (22), which can yield singlet dioxygen by deprotonation (23). However, in this case the kinetic parameter should be higher at high pH values and this pathway cannot be retained. Alternatively, the variation of ρ_0 may be related to the acidity constants of croconic acid, that is, to the relative domains of the species. At low pH, the protonated form (**1**) or its hydrated form (**3**) are predominant and easily oxidized. At pH > 4, the croconate dianion (**2**) is predominant and, due to is high delocalization, is too stable to undergo an oxidation process (solutions of $K_2C_5O_5$ do not turn colorless).

2. Dioxygen is necessary according to the overall process. The involvement of singlet dioxygen is not indicated since the reaction rate is not significantly modified by classical scavengers of singlet dioxygen such as sodium azide or DABCO. The reaction is inhibited in D_2O while it would be accelerated as in the case of a singlet dioxygen oxidation.

3. Light enhances the croconic acid oxidation. The EPR signals observed under irradiation suggest that reaction is due to a radical pathway. As shown by isobestic points in the UV spectra, the decomposition of form **3** is achieved via an intermediate product. Moreover, the increase of absorbance under

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

Fig. 7. UV–vis spectra of croconic acid solution after irradiation sequences (5 s).

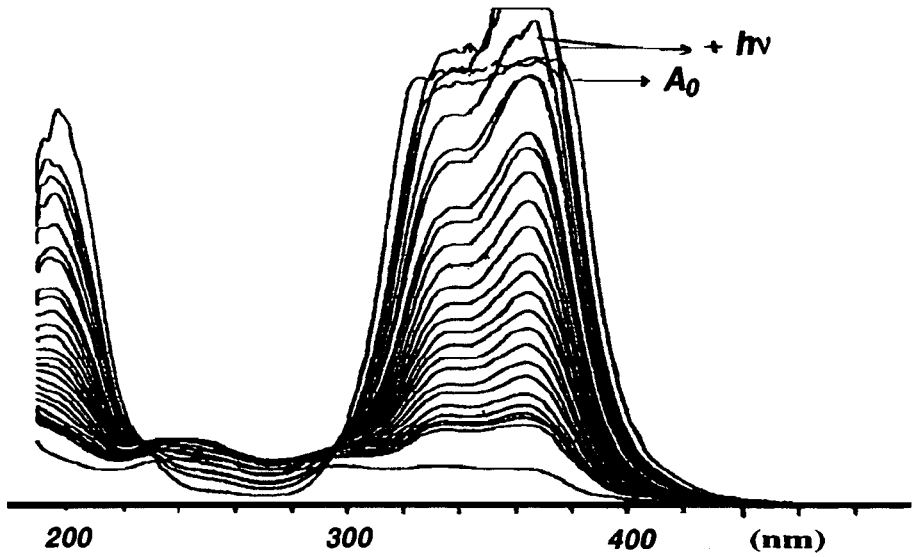

Fig. 8. Variation of the kinetics parameter ρ_0 versus pH.

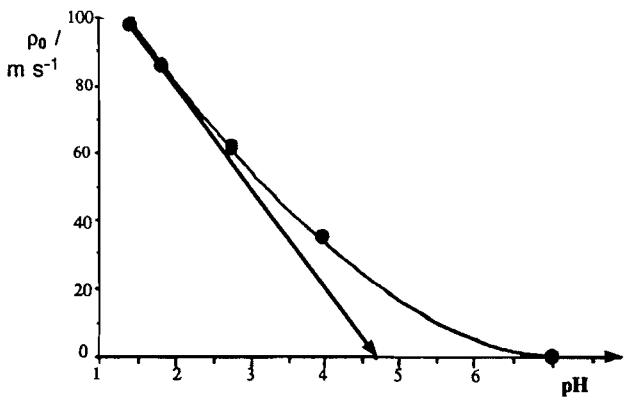


irradiation may be attributed to the transient formation of a radical. In basic media where the dianion $C_5O_5^{2-}$ is the predominant form, excited $C_5O_5^{2-*}$ (**3***) can yield the radical anion $C_5O_5^{-}$ (15, 16) or be deactivated by dioxygen (16).

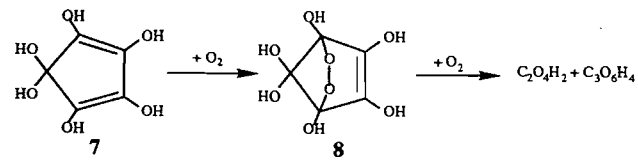
Transposition of croconate dianion oxidation (15, 16) in acid medium would lead to the following sequence:

$$C_5O_6H_4 + h\nu \rightarrow C_5O_6H_4^*$$

$$\underset{\mathbf{3}^*}{C_5O_6H_4^*} + \underset{\mathbf{3}}{C_5O_6H_4} + 3\,H_2O \rightarrow \underset{\mathbf{4}c}{C_5O_9H_8} + \underset{\mathbf{7}}{C_5O_6H_6}$$

The formation of compound **7** requires the preliminary reduction of croconic acid. On the basis of the EPR signals observed, it is suggested that this reduced product may occur from an electron transfer between a molecule of croconic acid in the excited state and another molecule in the ground state, leading to the subsequent formation of the croconic radical anion (this assumption is in agreement with the bimolecular character of the reaction). The oxidation of the diene **7** may be

Scheme 4.



expressed either by a 1,4 addition as proposed in Scheme 4 or by two 1,2 additions of oxygen (24).

Conclusion

Oxocarbon compounds are reported to present interesting properties as ligands. They also undergo redox processes that enable $[C_nO_n]^{2-}$ conversions. Moreover, in this work croconic acid has been shown to be oxidized into oxalic and mesoxalic acids in acid media. These results are in agreement with those of Verchere and Fleury (10–12) on the oxidation of croconic acid and other polyketo compounds with metal salts in acidic media. The main difference in the oxidation products in acidic and basic media arises from the acido-basic properties of croconic acid; this is supported by the potential–pH data for croconic acid. Similarly, the electrochemical oxidation and the photooxidation are different in acidic and basic media.

The acidity and tautomerism of β-diketones in aqueous solution

John W. Bunting, James P. Kanter, Raymond Nelander, and Zhennan Wu

Abstract: The acidity and keto–enol tautomerism of a series of symmetrical β-diketones ($RCOCH_2COR$ (**1**): R = methyl (*a*), phenyl (*b*), 3-pyridinyl (*c*), 4-pyridinyl (*d*), 3-(*N*-methyl)pyridinio (*e*), and 4-(*N*-methyl)pyridinio (*f*)) and two series of unsymmetrical β-diketones ($RCOCH_2COCH_3$ (**7***a*–**7***f*) and $RCOCH_2COC_6H_5$ (**8***a*–**8***f*)) have been investigated in aqueous solution at 25°C and ionic strength 0.1. Values of pK_a^{eq} were measured spectrophotometrically, and the acidities of the enols (pK_a^E) were obtained from the analysis of the pH dependence of the buffer catalysis for the general acid-catalyzed protonation of the enolate conjugate bases. These data in turn allowed the calculation of the acidities of the keto tautomers (pK_a^K) and the equilibrium constants for enolization (K_E = [Enol]/[Keto]). In general, K_E is greater for the symmetrical ketones (**1**) than for the corresponding R-substituted unsymmetrical ketones (**7** and **8**). K_E is much more sensitive to the nature of the R substituent in these three series of β-diketones than in the corresponding series of β-keto esters and amides. Correlations between pK_a^K for **8** and **7** combined with the known acidities of the corresponding β-keto esters and amides provide the first accurate estimates of the acidities of dimethyl malonate (pK_a = 13.0) and malonamide (pK_a = 12.5) in aqueous solution.

Key words: acidity, tautomerism, β-diketones.

Résumé : Opérant en solutions aqueuses, à 25°C et à une force ionique de 0,1, on a étudié l'acidité et l'isomérie céto–énolique d'une série de β-dicétones symétriques ($RCOCH_2COR$ (**1**) : R = méthyl (*a*), phényl (*b*), 3-pyridyle (*c*), 4-pyridyle (*d*), 3-(*N*-méthyl)pyridinio (*e*) et 4-(*N*-méthyl)pyridinio (*f*)) et de deux séries de β-dicétones non symétriques ($RCOCH_2CORCH_3$ (**7***a*–**7***f*) et $RCOCH_2COC_6H_5$ (**8***a*–**8***f*)). On a mesuré les pK_a^{eq} spectrophotométriquement et on a déterminé les acidités des énols (pK_a^E) par une analyse de la relation entre la dépendance sur le pH de la catalyse du tampon sur la protonation par catalyse acide générale des bases conjuguées énolates. Ces données permettent ensuite de calculer les acidités des céto-tautomères (pK_a^K) et les constantes d'équilibre de l'énolisation (K_E = [Énol]/[Cétone]). En général, la valeur de K_E est plus grande pour les cétones symétriques (**1**) que pour les cétones non symétriques correspondantes substituées par des groupes R (**7** et **8**). La valeur de K_E est beaucoup plus sensible à la nature du substituant R dans ces trois séries de β-dicétones que dans les séries correspondantes de β-cétoamides. Des corrélations entre les valeurs des pK_a^K des composés **7** et **8** combinées avec les acidités connues des β-cétoesters et β-cétoamides correspondants fournissent les premières évaluations précises des acidités du malonate de diméthyle (pK_a = 13,0) et du malonamide (pK_a = 12,5) en solution aqueuse.

Mots clés : acidité, tautomérie, β-dicétones.

[Traduit par la rédaction]

Introduction

In aqueous solution, β-diketones (**1** = KH) exist in equilibrium with their keto–enol isomers (**2** = EH) and the corresponding enolate anion (**3** = E^-) as described in Scheme 1. Titration of the equilibrium mixture of KH and EH gives an apparent acid ionization constant, K_a^{eq} (eq. [1]), which may be described by the ionization constant of either tautomer and the equilibrium ratio of the enol and keto tautomers, K_E = [EH]/[KH], as shown in eqs. [2] and [3].

$$[1] \quad K_a^{eq} = [H^+][E^-]/([KH] + [EH])$$

$$[2] \quad pK_a^{eq} = pK_a^K + \log (1 + K_E)$$

$$[3] \quad pK_a^{eq} = pK_a^E + \log (1 + 1/K_E)$$

pK_a^{eq} is usually readily determined by spectrophotomeric titration in aqueous solutions buffered at various pH values. In principle, the measurement of any one of pK_a^K, pK_a^E, or K_E then allows the evaluation of all equilibrium constants in Scheme 1 using eqs. [2] and [3]. Aqueous solutions of acetylacetone (**1**: R = CH_3) have been examined a number of times (1–10), and there is general agreement that at equilibrium approximately 20% of this diketone exists in the form of the enol (**2**: R = CH_3) near room temperature. However, there have been relatively few studies of other β-diketones in aqueous solution (4, 7, 11–13), and thus there is little information

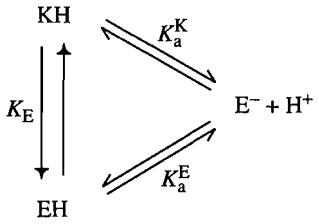
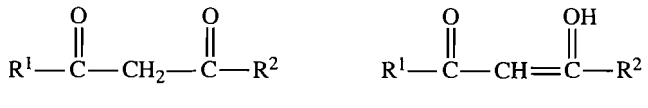
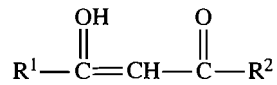
Scheme 1.



available on the dependence of each of the three equilibrium constants of Scheme 1 upon the nature of the R substituents in **1**, which represents symmetrical β-diketones, or upon R^1 and R^2 in **4**, which represents unsymmetrical species ($R^1 \neq R^2$).



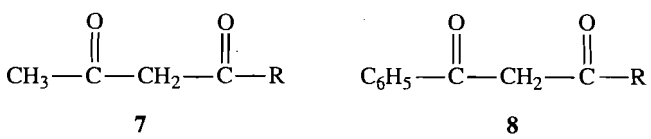
4 5



6

The study of unsymmetrical β-diketones introduces an additional complication, which is not relevant for symmetrical β-diketones, and is of no significance for β-keto esters or amides that we have recently examined (14). Unsymmetrical β-diketones (**4**) can enolize to give a pair of enol structural isomers (**5** and **6**). Thus the generation of enols by O-protonation of the enolate ion derived from **4** will in general give a mixture of these two enol species, and so the pK_a^E and K_E defined in terms of Scheme 1 will contain a contribution from the equilibrium ratio of **5**: **6**. This limitation will complicate the interpretation of the structural dependences of pK_a^E and K_E and also relationships between pK_a^K and pK_a^E such as those which were developed (14) for β-keto esters and amides.

The current work reports an investigation of the equilibria for the deprotonation and tautomerism of 15 β-diketones in aqueous solution. These species include six symmetrical ketones (**1***a*–**1***f*; see Table 1), six β-keto methyl ketones (**7***a*–**7***f*; see Tables 1 and 2; note that **1***a* = **7***a*), and six β-keto phenyl ketones (**8***a*–**8***f*; note that **8***a* = **7***b* and **8***b* = **1***b*). Useful linear free energy relationships are established between pK_a^K values for the various classes of β-diketones and the corresponding β-keto esters and amides (14). We have also found that the enol contents of β-keto esters and amides are not, in general, a reasonable basis for the confident prediction of the enol contents of similarly substituted β-diketones.



7 8

Experimental

2,4-Pentanedione (acetylacetone **1***a*), 1-phenyl-1,3-butanedione (benzoylacetone **7***b*), and 1,3-diphenyl-1,3-propanedione (dibenzoylmethane **1***b*) are commercially available. All other neutral β-diketones were prepared by the condensation of the enolate anion of 3- or 4-acetylpyridine with the appropriate methyl ester. A detailed synthesis of **1***c* is described below. Each pyridyl β-diketone was methylated by treatment with methyl bromide in acetone solution in a pressure bottle at room temperature for 24 h. All products were characterized by ^1H NMR spectroscopy in CD_3SOCD_3; in general these spectra indicated the presence of a mixture of the keto and enol tautomers in this solvent (13).

1,3-Di-3-pyridinyl-1,3-propanedione (1*c*)

Methyl nicotinate (2.5 g) was dissolved in 3-acetylpyridine (10 mL). An 80% dispersion of sodium hydride in mineral oil (0.6 g) was added to this solution, with constant stirring, over a period of 30 min. The mixture was stirred and refluxed for a further 2.5 h during which time the solution became bright yellow. The product solution was cooled to room temperature, diluted with diethyl ether (40 mL), and neutralized with a few drops of concentrated HCl. A saturated aqueous solution of sodium chloride (20 mL) was added, and the product was collected by exhaustive extraction with methylene chloride. These extracts were dried over magnesium sulfate, and the solvent was removed on the rotary evaporatory. The resulting oil was treated with a 1:1 mixture of diethyl ether and hexane (10 mL). After refrigeration overnight, large pale-yellow crystals of **1***c* were obtained, and recrystallized from 2-propanol in 78% overall yield; mp 198–200°C (lit. (15) mp 199–201°C; (16) mp 198°C).

The following β-diketones were similarly prepared: **1***d*, mp 152–154°C; **7***c*, mp 81–83°C (lit. (17) 81–82°C); **7***d*, mp 66–67°C (lit. (18) mp 66–67°C); **8***c*, mp 119–121°C; **8***d*, mp 83–84°C (lit. (18) mp 83–84°C).

The following bromide salts were also obtained: **1***e*·$(Br^-)_2$, mp 243°C (dec.); **1***f*·$(Br^-)_2$, mp 248°C (dec.); **7***e*·Br^-, mp 142°C (dec.); **7***f*·Br^-, mp 152°C (dec.); **8***e*·Br^-, mp 210–212°C; **8***f*·Br^-, mp 255–257°C.

pK_a measurements

The spectrophotometric measurements of pK_a^{eq} and the evaluation of pK_a^K in pH-jump experiments by stopped-flow spectrophotometry closely followed the methods described in detail in our recent work (14). All experimental data are for aqueous solutions of ionic strength of 0.1 (KCl + buffer) at 25°C, with the exception of data for dibenzoylmethane (**1***b*) for which limited aqueous solubility required the addition of 10% acetonitrile to all aqueous solutions.

Fig. 1. The pH dependence of the absorption spectrum of **7***e* (0.101 mM) in aqueous solution. Spectra are at pH 4.00 (spectrum 1), 6.03, 6.23, 7.02, and 8.50 (spectrum 5).

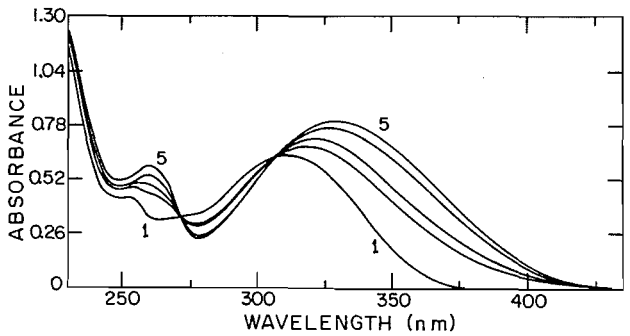

Fig. 2. The pH dependence of the absorption spectrum of **1***e* (0.0454 mM) in aqueous solution. Spectra are at pH 2.08 (spectrum 1), 3.47, 4.00, 4.51, 5.04, 5.52, and 7.04 (spectrum 7).

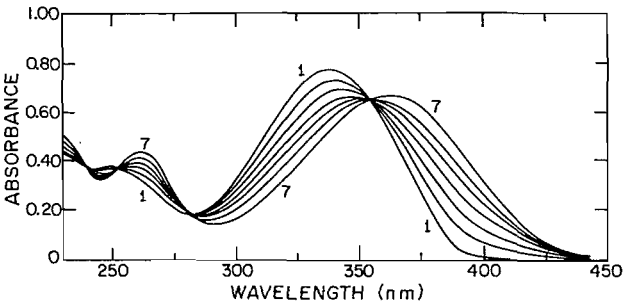

Results

Figures 1 and 2 display the pH-dependence of the electronic absorption spectra of two of the ketones examined in this study. These two examples, which are typical of the spectral observations for all diketones in the current study, are chosen to demonstrate pH-dependent spectra for a β-diketone (**7***e*) that predominates over its enol tautomer, and a diketone (**1***e*) that exists mainly as the enol isomer. In basic solution, each enolate conjugate base displays an intense long-wavelength absorption maximum. These λ_{max} are listed in Tables 1 and 2, and vary systematically in the order: methyl < phenyl < 3-pyridyl < 4-pyridyl < 3-(*N*-methyl pyridinio) < 4-(*N*-methyl pyridinio) for the enolates; i.e., systematically from *a*–*f* for the conjugate bases from each of **1**, **7**, and **8**. The same ordering of λ_{max} values was also observed (14) for the enolate conjugate bases of the corresponding β-keto esters and amides. All symmetrical enolate ions (**3**) have longer wavelength absorption maxima (Table 1) than do the corresponding unsymmetrical enolate ions from each of **7** and **8** (Table 2). The corresponding enol (**2***f*) has λ_{max} = 353 nm.

The pH dependence of the absorbance at constant wavelength in the vicinity of λ_{max} of the enolate was used to evaluate pK_a^{eq} for the equilibrated tautomeric mixtures from each of **1**, **7**, and **8**. Values of pK_a^{eq} are listed in Tables 1 and 2.

The acidities of the enols (pK_a^E) were calculated form the pH dependence of buffer catalysis of the ketonization reactions in pH-jump experiments in which a solution of the enolate conjugate base was rapidly acidified in the stopped-flow spectrophotometer. This technique, and the algebraic treatment of the kinetic data that allows the calculation of pK_a^E, have recently been described (14) in some detail. Values of pK_a^E are included in Tables 1 and 2. These tables also include K_E calculated from eq. [3], and pK_a^K, which was subsequently calculated from eq. [2].

For **1***e* and **1***f* there was no observable time-dependent absorbance change upon acidification of the enolate species. This implies that the conjugate acid species is predominantly the enol tautomer in these two cases and that $pK_a^{eq} = pK_a^E$. For **8***d* and **8***f*, the time-dependent absorbance changes upon acidification of the enolate were quite small. In these two cases, values of pK_a^E were still measurable; however, these enol acidities are within experimental error of pK_a^{eq}, and so accurate values of K_E and pK_a^K are not directly accessible by the current experimental method. The estimates of pK_a^K in Tables 1 and 2 for these two species are based upon the linear free energy relationships that are developed below.

Discussion

The data in Tables 1 and 2 represent the most extensive set of data that are currently available for the structural dependence of the equilibrium constants defined in Scheme 1 for β-diketones in aqueous solution. Before discussing the trends in these data it is important to appreciate a limitation that is inherent in the current experimental method for the evaluation of K_E and pK_a^K. The calculation of these two parameters requires a significant difference between pK_a^{eq} and pK_a^K. If K_E (= [Enol]/[Keto]) < 1, this difference is large and accurate values of K_E and pK_a^K are obtained. However, $pK_a^E \approx pK_a^{eq}$ for those species for which the tautomeric ratio lies heavily in favour of the enol tautomer, and accurate numerical values of K_E are not accessible. Our experience from both the current study and our earlier work (14) is that K_E should be less than 5 for the quantitative analysis of structural effects upon K_E and pK_a^K. This limit will be adopted in the correlation analyses of equilibrium constants that are presented below, although we will also show that the linear free energy relationships that we have developed do allow an alternative route to the estimation of pK_a^K (and consequently K_E) when this equilibrium constant is not directly accessible experimentally.

Acidities of keto and enol tautomers

A well-defined relationship between the acidities of the β-keto methyl ketones (**7**) and the structurally related β-keto phenyl ketones (**8**) is shown in Fig. 3. This figure includes data points for the methyl esters and amides of acetoacetic and benzoylacetic acids in addition to the β-diketones of the current study. The correlation line in Fig. 3 is defined by eq. [4], which in turn allows the estimation of pK_a^K for **8***d* and **8***f* (Table 2).

$$[4]\quad pK_a^K(\mathbf{8}) = 0.98(\pm 0.05)pK_a^K(\mathbf{7}) - 0.2(\pm 0.2) \qquad (r = 0.995;\ n = 6)$$

Similar linear correlations can be demonstrated between pK_a^K values for β-keto methyl ketones (**7**) and β-keto methyl esters (**9**) (eq. [5]), β-keto phenyl ketones (**8**) and β-keto methyl esters (**9**) (eq. [6]), β-keto methyl ketones (**7**) and β-keto amides (**10**) (eq. [7]), and β-keto phenyl ketones (**8**) and β-keto amides (**10**) (eq. [7]). The slope parameters in eqs. [5]–

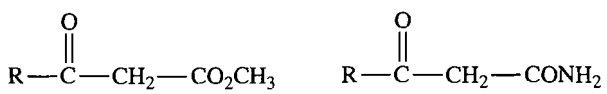
[8] demonstrate that β-diketones are somewhat less sensitive to variation in the R substituent of the acyl functional group than are the less acidic β-keto esters and amides



9 **10**

[5] $pK_a^K(\mathbf{7}) = 0.80(\pm0.08)pK_a^K(\mathbf{9}) + 0.4(\pm0.3)$ $(r = 0.982; n = 6)$

[6] $pK_a^K(\mathbf{8}) = 0.77(\pm0.09)pK_a^K(\mathbf{9}) + 0.2(\pm0.3)$ $(r = 0.975; n = 6)$

[7] $pK_a^K(\mathbf{7}) = 0.78(\pm0.07)pK_a^K(\mathbf{10}) + 0.7(\pm0.3)$ $(r = 0.984; n = 6)$

[8] $pK_a^K(\mathbf{8}) = 0.75(\pm0.08)pK_a^K(\mathbf{10}) + 0.6(\pm0.3)$ $(r = 0.977; n = 6)$

Interpolation in these correlation equations can be used to predict pK_a^K for some related species. Equation [5] and pK_a^K= 10.60 for methyl acetoacetate (**7**: R = OCH_3) (14) predicts pK_a^K = 12.9 for dimethyl malonate (**9**: R = OCH_3). Equation [6] and pK_a^K = 10.28 for methyl benzoylacetate (**8**: R = OCH_3) (14) lead to pK_a^K = 13.0 for this same malonate diester. These predictions are similar to the pK_a = 13.3 for diethyl malonate (19) that is the only experimental value we have been able to locate for the acidity of a malonate diester in aqueous solution, although the experimental basis of this value is unclear.

A similar analysis using pK_a^K = 10.41 for acetoacetamide and pK_a^K = 10.04 for benzoylacetamide (14) leads to pK_a^K = 12.5 for malonamide (**10**: R = NH_2) from both eqs. [7] and [8]. We have been unable to find a literature value for the acidity of this diamide in aqueous solution. Williams and Xia (20) have recently estimated $K_E = 4 \times 10^{-10}$ for the enolization of malonamide. These values of pK_a^K and K_E then allow the cal-

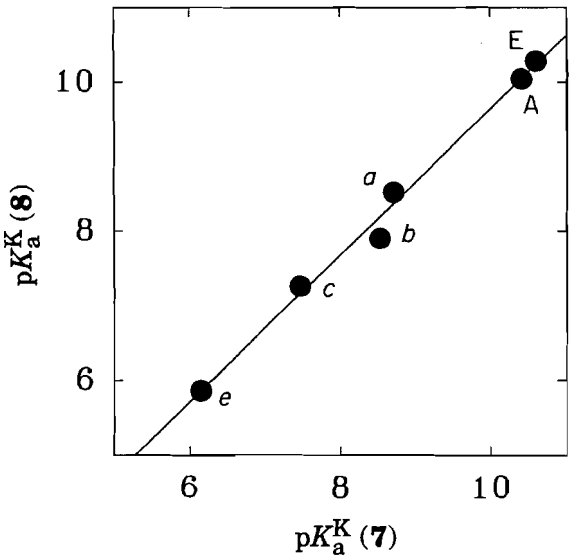
For personal use only.

Fig. 3. Correlation between pK_a^K for **8** and pK_a^K for **7** (*a–e* as defined in Table 2), including data for methyl esters (**9** = E) and amides (**10** = A) of acetoacetic and benzoylacetic acids. The correlation line is defined by eq. [4].



culation of pK_a^E = 3.1 for the enol of malonamide using Scheme 1.

Figure 4 shows a linear relationship (eq. [9]) between pK_a^K for symmetrical β-diketones (**1**) and pK_a^K for the corresponding unsymmetrical β-keto methyl ketones (**7**). A similar linear relationship (eq. [10]) also exists between pK_a^K for **1** and pK_a^K for the unsymmetrical β-keto phenyl ketones (**8**). The pK_a^K data estimated above for the diester and diamide of malonic acid appear to be consistent with these relationships. Equations [9] and [10] can be used to estimate for **1***e* and **1***f* (see Table 1) for which we have been unable to demonstrate any β-diketone tautomer upon acidification of solutions of the enolate conjugate bases in pH-jump experiments. The calculated K_E ratios then confirm the predominance of the enol tautomers in these two cases.

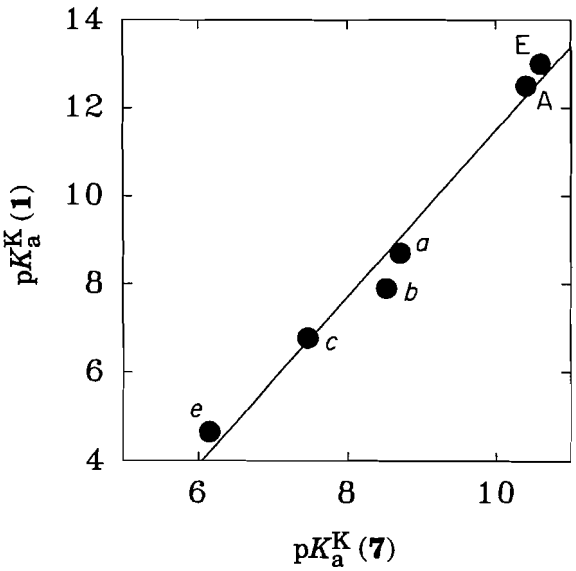
[9] $pK_a^K(\mathbf{1}) = 2.22(\pm0.15)pK_a^K(\mathbf{7}) - 10.6(\pm0.5)$ $(r = 0.990; n = 6)$

[10] $pK_a^K(\mathbf{1}) = 2.16(\pm0.12)pK_a^K(\mathbf{8}) + 9.4(\pm0.4)$ $(r = 0.993; n = 6)$

[11] $pK_a^K(\mathbf{8}) = 1.05(\pm0.06)pK_a^E(\mathbf{7}) - 0.1(\pm0.1)$ $(r = 0.993; n = 6)$

Since the experimentally measured pK_a^E values contain contributions from more than one enol tautomer of **7** and **8**, we did not expect to find simple relationships for pK_a^E that are analogous to those reported above for pK_a^E. However, Figs. 5 and 6 show that some approximate relationships involving pK_a^E do exist. Thus, there appears to be a linear relationship between the pK_a^E values for the enols of **7** and **8** (Fig. 5 and eq. [11]) although β-keto esters and amides, which give a single enol, deviate somewhat from the relationship for the β-diketones. Figure 6

Fig. 4. Correlations between pK_a^K for **1** and **7** (*a–e* as defined in Tables 1 and 2), including data for dimethyl malonate (A) and malonamide (E) evaluated from eq. [4] as examples of **1**. The correlation line is defined by eq. [9].



demonstrates the dependence of pK_a^E upon pK_a^K for **1**, **7**, and **8**. The correlation line in Fig. 6 corresponds to eq. [12], which is defined for the symmetrical β-diketones (**1**). The data for the unsymmetrical ketones, apart from the 3-(*N*-methyl pyridinio) derivatives (**7***e* and **8***e*), are also consistent with eq. [12].

[12] $pK_a^E(\mathbf{2}) = 0.68(\pm0.07)pK_a^K(\mathbf{1}) + 2.6(\pm0.5)$ $(r = 0.981; n = 6)$

Structural effects upon K_E

It is apparent from Table 2 that K_E is smaller for β-keto methyl ketones (**7**) than for the corresponding β-keto phenyl ketones (**8**) bearing the same R substituent. This enhanced enol content for phenyl ketones over methyl ketones is dramatized by the 30-fold greater K_E for dibenzoylmethane (**1***b*) than for acetylacetone (**1***a*); this is presumably attributable to the styrene-like conjugation that is present in the enols of phenyl ketones. For the symmetrical β-diketones (**1**) enol content increases in the order: methyl < 3-pyridyl < phenyl ≈ 4-pyridyl << 3- and 4-(*N*-methyl puridinio). With the exception of R = 3-(*N*-methyl pyridinio), this same order is essentially preserved for **7** and **8**, although the enol content is clearly smaller for R = phenyl than for R = 4-pyridyl in these two series of unsymmetrical ketones. For **7***e* and **8***e*, the enol content is unusually small in comparison with the high enol content of the symmetrical 3-(*N*-methyl pyridinio) diketone (**1***e*). For both **7***e* and **8***e*, K_E is of similar magnitude to that found for **7***a* and **8***a* and more than 10-fold smaller than for the isomeric 4-(*N*-methyl pyridinio) species (**7***f* and **8***f*). We have no simple explanation for the unique effects from the 3-(*N*-methyl pyridinio) substituents in symmetrical and unsymmetrical β-diketones, other than to suggest that the predominant enol, for reasons unknown, may be that which enolizes on the side of the acetyl and benzoyl groups, respectively (i.e., **5**: $R^2 = CH_3$ or C_6H_5), rather than

Fig. 5. Correlation between pK_a^K for the enols of **8** and **7** (*a–e* as defined in Table 2). The correlation line is defined by eq. [11]. The data for methyl esters (**9** = E) and amides (**10** = A) of acetoacetic and benzoylacetic acids are not included in this relationship.

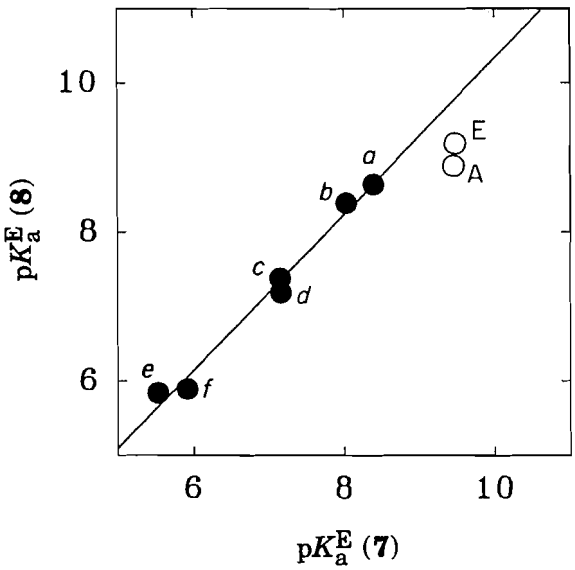


Fig. 6. The relationship between pK_a^E and pK_a^K for **1** (filled circles), **7** (empty circles), and **8** (filled triangles). The correlation line is eq. [12] defined for symmetrical ketones (**1**) only.

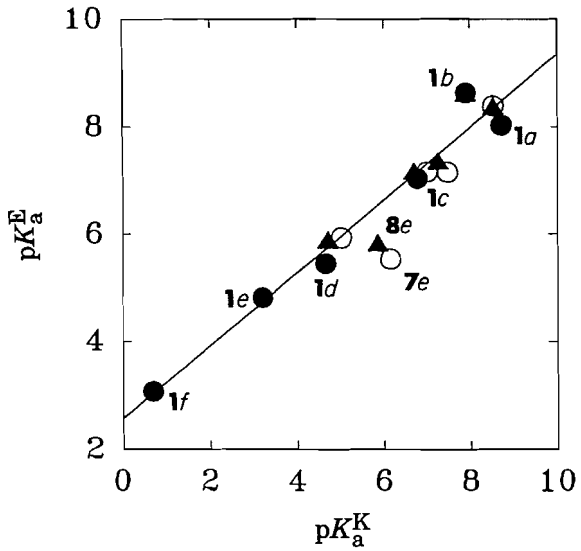

rather than towards the 3-pyridinio carbonyl group (i.e., **6**: R^1 = 3-($C_5H_4NCH_3^+$)).

The strong dependence of K_E upon R for β-diketones in Tables 1 and 2 is in marked contrast with the relative insensitivity of K_E to the same six R substituents in β-keto esters and amides (**9** and **10** with R substituents *a–f* as defined in Tables 1 and 2) (14). All of these β-keto esters and amides predominate over their enol tautomers (enol contents in the range 6–22%) in aqueous solution, with K_E for each of **9** and **10** being smaller than for the corresponding R-substituted diketone in Table 2. For each of **9** and **10**, K_E varies less than 4-fold, with little difference between the enol contents for R = methyl and R = phenyl. For both **9** and **10**, K_E is largest for R = 4-pyridyl, with approximately a 2-fold decrease in enol content upon N-methylation of either the 3- or 4-pyridyl derivatives. This latter observation is in marked contrast to the dramatic increase in K_E that is indicated in Tables 1 and 2 upon methylation of **1***c*, **1***d*, **7***d*, and **8***d*.

The foregoing comparisons make it clear that, in general, substituent effects upon K_E from the acyl groups in β-keto esters and amides cannot be used as a general guide to the effects of these same acyl groups upon the enol contents of β-diketones. While this result may initially appear somewhat surprising, in fact there should be significant differences between the roles of substituent effects upon enol stability for β-keto esters (and amides), symmetrical β-diketones, and unsymmetrical β-diketones. For **9** and **10**, enolization is only expected towards the ketone, and not towards the formal carbonyl group of the ester or amide unit. In these cases, the dependence of K_E upon R gives a direct indication of the influence of R upon the relative stabilities of ketones and their isomeric enols. For symmetrical diketones, two R groups are changed simultaneously and, while there is only one enol species, the effects of the two R groups upon the stability of **2** will probably be quite different. For unsymmetrical β-diketones, there is the additional problem that the experimentally determined K_E contains contributions from two structurally isomeric enols (**5** and **6**) and the likelihood that the equilibrium ratio of [**5**]/[**6**] will also be dependent upon R^1 and R^2.

A multinuclear NMR study of the cycloaddition reaction of $SNSAsF_6$ with *tert*-butylphosphaacetyline $(CH_3)_3CCP$ leading to the 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3C\overline{CPSNS}^+$ cation; a preliminary account of the novel exchange of a cyclic phosphorus by nitrogen in the reaction of $(CH_3)_3C\overline{CPSNS}^+$ with azide N_3^- leading to 5-*tert*-butyl-1,3,2,4-dithiadiazolyl $(CH_3)_3C\overline{CNSNS}^{\cdot}$

Simon Parsons, Jack Passmore, Xiaoping Sun, and Manfred Regitz

Abstract: The cycloaddition reaction of SNS^+ (as the AsF_6^- salt) with 5-*tert*-butylphosphaacetyline $(CH_3)_3CCP$ in sulfur dioxide solution at −60°C gave $(CH_3)_3C\overline{CPSNS}^+$, the first identified example of a 1,3,2,4-dithiazaphospholium heterocycle $R\overline{CPSNS}^+$. The cycloadduct was characterized by multinuclear NMR (^1H, ^{13}C, ^{14}N, ^{15}N, ^{31}P) spectroscopy at low temperature. Reduction of 6π $(CH_3)_3C\overline{CPSNS}^+$ in situ with $SbPh_3$ in the presence of Me_4NCl led to a radical, which may be the 7π *tert*-butyl-1,3,2,4-dithiazaphospholyl $(CH_3)_3C\overline{CPSNS}^{\cdot}$. The reaction of 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3C\overline{CPSNS}^+$ with azide N_3^- surprisingly gave the previously known 5-*tert*-butyl-1,3,2,4-dithiadiazolyl $(CH_3)_3C\overline{CNSNS}^{\cdot}$. The conversion of $(CH_3)_3C\overline{CPSNS}^+$ to $(CH_3)_3C\overline{CNSNS}^{\cdot}$ by the net replacement of a cyclic phosphorus with nitrogen is unprecedented.

Key words: dithiazaphospholium, dithiazaphospholyl, cycloaddition, multinuclear NMR, ESR.

Résumé : La réaction de cycloaddition du SNS^+ (sous forme de sel de AsF_6^-) avec le *tert*-butylphosphaacétyline $(CH_3)_3CCP$ en solution dans le bioxyde de soufre à −60°C donne le $(CH_3)_3C\overline{CPSNS}^+$, qui est le premier exemple identifié d'un 1,3,2,4-dithiazaphospholium hétérocyclique $R\overline{CPSNS}^+$. On a caractérisé l'adduit

Introduction

Previous investigations showed that SNS^+ (as the AsF_6^- salt) undergoes quantitative symmetry-allowed cycloaddition reactions with a variety of nitriles, alkynes, and SN^+ (1) to give five-membered rings. The kinetics of the cycloadditions with C≡N, C≡C, and C=C bonds show (1*e*) that the rate of reaction is inversely proportional to the ionization energy of the latter, implying that the cycloaddition proceeds via the interaction of the LUMO of SNS^+ (acceptor) with the HOMO of the multiple bond (donor). Thus, the cycloadditions of SNS^+ are the simplest of any of the 1,3-dipole-type species. We predicted that a number of other unsaturated molecules, including the phosphaalkynes RC≡P, should undergo thermodynamically favourable cycloadditions based on a bonds formed/bonds broken model (2). On the basis that the rate of these cycloadditions should be inversely proportional to ionization energy (IP = 9.70 eV for $(CH_3)_3CCP$, a low IP relative to other molecules that cycloadd to SNS^+ (1*e*)), we expected that $(CH_3)_3CCP$ would undergo a fast thermodynamically allowed concerted cycloaddition reaction with SNS^+. These predictions (2) are confirmed by this work. Reference has been made (3) to the cycloadditions of SNS^+ with the doubly bonded C=N, P=N, P=P, and N=N bonds[3] as we had previously predicted (2), but no experimental evidence was provided. However, reactions of SNS^+ with double bonds may be expected to be more complex than those with triple bonds, as the reactions of SNS^+ with olefins form a mixture of 1:1 and 2:1 olefin–SNS^+ cycloadducts in liquid SO_2 at room temperature or lower (1*c*, 2). In addition, the claim has been made (4) for the preparation of $(CH_3)_3CCPSNSAsF_6$ on the basis that a radical was produced on the reduction of the isolated salt, which was attributed to $(CH_3)_3CCPSNS^{\cdot}$. However, no direct evidence was given for the $(CH_3)_3CCPSNS^+$ cation, and the radical is very unlikely $(CH_3)_3CCPSNS^{\cdot}$ (see below). In this paper, a multinuclear NMR study of the cycloaddition reaction of $SNSAsF_6$ with *tert*-butylphosphaacetyline $(CH_3)_3CCP$ in sulfur dioxide solution at −60°C is described. This gives 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3CCPSNS^+$, the first identified example of any 1,3,2,4-dithiazaphospholium heterocycle $RCPSNS^+$. We show in this work that $(CH_3)_3CCPSNSAsF_6$ readily decomposed on attempted isolation at room temperature. The ESR spectral parameters (1:1:1 triplet with g = 2.0045, a^N = 1.467 mT, a^P not observed) for the radical, said to be $(CH_3)_3CCPSNS^{\cdot}$ (4) given on reduction of the isolated product $(CH_3)_3CCPSNSAsF_6$, do not fit a SNS·-containing radical in which the SNS moiety is connected to a conjugated system as would be expected for $(CH_3)_3CCPSNS^{\cdot}$. The ESR data are, however, consistent with a radical in which the $SNS^{\cdot}$ moiety is connected to a nonconjugated fragment. Previous investigations have shown (1*f*, 2, 5) that a variety of such conjugated $SNS^{\cdot}$-containing radicals have very similar g (2.005–2.008) and a^N (1.10 ± 0.03 mT) values that are substantially different from the a^N values (1.28 ± 0.03 mT) of the nonconjugated radicals in which the two sulfurs are bonded to a saturated moiety (Table 1). Therefore, the identity of this radical is very likely not $(CH_3)_3CCPSNS^{\cdot}$ as proposed (4). In this work, an attempted generation of the 5-*tert*-butyl-1,3,2,4-dithiazaphospholyl $(CH_3)_3CCPSNS^{\cdot}$ radical was carried out by in situ reduction of $(CH_3)_3CCPSNS^+$ (as the AsF_6^- salt) at low temperature with $SbPh_3$ in the presence of Me_4NCl. In addition, reaction of $(CH_3)_3CCPSNS^+$ with cesium azide CsN_3 in liquid SO_2 was performed, which surprisingly gave the previously known 7π 5-*tert*-butyl-1,3,2,4-dithiadiazolyl $(CH_3)_3CCNSNS^{\cdot}$ radical. The conversion of $(CH_3)_3CCPSNS^+$ to $(CH_3)_3CCNSNS^{\cdot}$ by the net replacement of a cyclic phosphorus with nitrogen is unprecedented, although baffling rearrangements are not unusual in sulfur nitrogen chemistry (6, 7*a*, 19). A preliminary account of this work has been briefly described in a conference presentation (7*b*).

Experimental section

Instrumentation and reagents

Multinuclear NMR spectra were recorded with Varian Associates XL-200 MHz (as described (8) for ^1H and ^{13}C spectra) and UNITY 400 MHz spectrometers. For the UNITY 400 MHz spectrometer, the spectra were accumulated in 72K (^{13}C), 12K (^{14}N), 128K (^{15}N), or 115K (^{31}P) data points, and obtained unlocked. ^{13}C spectra were run at 100.58 MHz with a spectral width of 30.0 kHz (0.46 Hz/data point, acquisition time 1.200 s, pulse width 12.0 μs) with ^1H decoupling. ^{14}N spectra were run at 28.90 MHz with a spectral width of 12.0 kHz (1.47 Hz/data point, acquisition time 0.501 s, pulse width 40 μs, 1000 scans). ^{15}N spectra were run at 40.54 MHz with a spectral width of

Table 1. ESR parameters[a] of various SNS•-containing radicals.

[a]All the SNS•-containing radicals have very similar g values (2.005–2.008), characteristic of the unpaired electron delocalized along the SNS moiety. All the SNS•-containing radicals for which the SNS moiety is bonded to a conjugated system have very close a^N values (1.10 ± 0.03 mT); however, the radicals for which the SNS moiety is bonded to a saturated system have greater a^N values (ca. 1.3 mT).

[b]The g and a^N values are taken from ref. 5 (for Bu^{t}CPSNS• by Sutcliffe, the values are taken from ref. 4); the g and a^N values by Schriver are taken from ref. 2.

[c]For Bu^{t}CPSNS• (g = 2.0059, a^N = 1.14 mT) (this work), the g value fits the SNS•-containing radicals, and the a^N value fits the radicals for which the SNS• moiety is connected to a conjugated system.

20.0 kHz (0.31 Hz/data point, acquisition time 3.198 s, pulse width 20 μs, 2000 scans). ^{31}P spectra were run at 161.93 MHz with a spectral width of 90.0 kHz (0.69 Hz/data point, acquisition time 0.640 s, pulse width 10 μs). The pulse widths quoted correspond to tip angles of 58° (^{13}C), 60° (^{14}N), and 55° (^{15}N, ^{31}P). Spectra were referenced externally to a solution of TMS in SO_2 (^{1}H and ^{13}C), neat CH_3NO_2 (^{14}N and ^{15}N), and 3 M H_3PO_4 in D_2O (^{31}P). ESR spectra were recorded as the first derivative

[a]Singlet and doublet are represented by s and d, respectively. The ^1H and ^{31}P spectral data of $(CH_3)_3CCP$ in SO_2 solution were obtained using a Varian XL-200 MHz NMR spectrometer at room temperature. The ^{13}C spectral data of $(CH_3)_3CCP$ (TMS in C_6D_6 as reference) are taken from ref. 7. The spectral data of $(CH_3)_3\overline{CCPSNS}^{+}$ (1.4 M) were obtained using a Varian UNITY-400 MHz NMR spectrometer at −60°C (AsF_6^- anion, SO_2 solvent). The spectral data for $(CH_3)_3\overline{CCNSNS}^{+}$ and $H_3\overline{CCSNSCH}^{+}$ were previously obtained (1*e*) using a Varian XL-200 MHz NMR spectrometer at room temperature.

[b]The integration in the ^{14}N spectrum implied that ca. 20% SNS^+ ($\delta(^{14}N) = -90.8$ ppm, $\Delta\nu_{1/2} = 6$ Hz) remained unreacted at the time the spectrum was obtained, indicating that the reaction was likely incomplete at this point. No SNS^+ was detected in the weaker ^{15}N spectrum, possibly because of the much lower signal-to-noise ratio and (or) differences in the ^{15}N relaxation times.

[c]^{31}P chemical shift calculated by eq. [2].

[d]^{31}P chemical shift calculated by eq. [3].

of the absorption curve in the X-band with a locally modified Varian E-4 spectrometer using DPPH as a field marker.

$SNSAsF_6$ was prepared as described (9). *tert*-Butylphosphaacetyline $(CH_3)_3CCP$ was used as received (10) from Professor M. Regitz. The NMR (^1H, ^{31}P) spectra of $(CH_3)_3CCP$ in liquid SO_2 were recorded at room temperature using a Varian XL-200 MHz spectrometer. See Table 2 for data obtained in this work and from the literature (11). The NMR studies established that $(CH_3)_3CCP$ did not react with SO_2 under ambient conditions, therefore SO_2 is a suitable solvent for $(CH_3)_3CCP$.

Multinuclear NMR (^{14}N, ^{15}N, ^{31}P, ^{13}C, ^1H) spectroscopic studies on the cycloaddition reaction of $SNSAsF_6$ with *tert*-butylphosphaacetyline $(CH_3)_3CCP$

The reaction was performed in a 10 mm NMR tube (fitted with a J. Young "O-Ringette" type valve) in situ. SO_2 (2.82 g) and $(CH_3)_3CCP$ (0.281 g, 2.81 mmol) were successively condensed onto $SNSAsF_6$ (0.764 g, 2.86 mmol) at −196°C. The contents were warmed to −60°C, immediately giving a bright yellow solution. The solution was kept at this temperature for 4 h. The multinuclear NMR (in the time sequence of ^{15}N, ^{14}N, ^{13}C, ^{31}P, and ^1H) spectra[4] were recorded using a Varian UNITY 400 MHz spectrometer at −60°C. The ^1H spectrum was taken on the decoupling coil. The cycloadduct $(CH_3)_3\overline{CCPSNS}AsF_6$ was shown to decompose in liquid SO_2 at room temperature after 4 h, giving a complex mixture in solution and a black precipitate (^1H NMR: a group of peaks at 1.0–1.5 ppm) with almost all the detectable phosphorus in solution converted to PF_6^- anion (^{31}P NMR: $\delta = -143.6$ ppm (int 100%), septet, $^1J_{PF} = 712.5$ Hz and four unassigned peaks between −20 and −110 ppm (int less than 8%)). NMR data of the reaction product $(CH_3)_3\overline{CCPSNS}^{+}$ are shown in Table 2. The data for the starting material $(CH_3)_3CCP$ and for the related heterocycles $(CH_3)_3\overline{CCNSNS}^{+}$ and $H\overline{CSNSCCH_3}^{+}$ are also included for comparison.

Reduction of the 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3CCPSNS^+$ cation with $SbPh_3$ in the presence of Me_4NCl

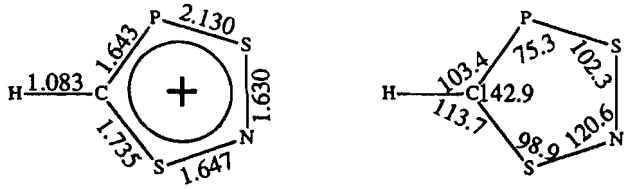
The reactions were performed in situ in a two-bulbed (ca. 15 cm^3) vessel incorporating a 4 mm quartz ESR tube and a medium frit.[5] SO_2 (1.55 g) and $(CH_3)_3CCP$ (0.0299 g, 0.299 mmol) were successively condensed onto $SNSAsF_6$ (0.0148 g, 0.0554 mmol) at −196°C. The contents were warmed to −60°C, immediately giving a bright yellow $(CH_3)_3CCPSNSAsF_6$ solution. The solution was kept at this temperature for 2 h and then quickly poured through a precooled (ca. −40°C) glass frit (to avoid possible decomposition of the cycloadduct) onto the solid mixture of $SbPh_3$ (0.020 g, 0.0566 mmol) and Me_4NCl (0.014 g, 0.128 mmol) in the second bulb at −40°C, immediately giving an orange solution. This solution was then diluted with preweighed $CFCl_3$ (7.38 g) and part of it transferred into the attached ESR tube, which was subsequently flame sealed at −196°C. The ESR spectrum was recorded at room temperature, showing a 1:1:1 triplet with g = 2.0059(3) and a^N = 1.14(2) mT.[4] The ESR signal completely disappeared on exposure of this sample to room light for one day at room temperature. A low-temperature (−60°C) ESR spectrum was recorded on another similarly prepared sample, showing an essentially identical 1:1:1 triplet (g = 2.0057, a^N = 1.13 mT, and a^P not observed),[4] which disappeared on exposure to light at room temperature.

Reaction of the 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3CCPSNS^+$ cation with azide N_3^- leading to 5-*tert*-butyl-1,3,2,4-dithiadiazolyl $(CH_3)_3CCNSNS^{\cdot}$

The reactions were performed similarly to the reduction of $(CH_3)_3CCPSNS^+$ as described above. The mixture of $SNSAsF_6$ (0.0160 g, 0.0599 mmol) and $(CH_3)_3CCP$ (0.0584 g, 0.583 mmol) in liquid SO_2 (1.48 g) gave a bright yellow $(CH_3)_3CCPSNSAsF_6$ solution, which was then quickly poured onto an excess CsN_3 (0.039 g, 0.224 mmol) at −40°C, immediately giving an orange solution. This orange solution was diluted with $CFCl_3$ (7.30 g), and part of it was transferred into the attached ESR tube, which was subsequently flame sealed at −196°C. The ESR spectrum[4] was recorded on this sample at −60°C, showing hyperfine 1:1:1 triplets of a 1:1:1 triplet due to two nonequivalent ^{14}N (I = 1); g = 2.0060, $a^{N'}$ = 1.08 mT, $a^{N''}$ = 0.06 mT. The pattern and g and a^N values of the spectrum are characteristic of those of 1,3,2,4-dithiadiazolyl $RCN''SN'S^{\cdot}$ radicals (g = 2.005–2.007, $a^{N'}$ = 1.08–1.11 mT) (1*f*, 2, 5, 7*a*) and almost identical to an authentic sample of $(CH_3)_3CCN''SN'S^{\cdot}$ (g = 2.0071, $a^{N'}$ = 1.09 mT, $a^{N''}$ = 0.06 mT) (13). On exposure to room light for 2 weeks at room temperature, the ESR spectrum[4] exhibited a weaker signal of a 1:2:3:2:1 quintet (g = 2.011, a^N = 0.53 mT) (cf. $(CH_3)_3CCNSSN^{\cdot}$: g = 2.012, a^N = 0.52 mT) (13) coincident with disappearance of the three-line pattern, indicating that the $(CH_3)_3CCN''SN'S^{\cdot}$ had photochemically rearranged to $(CH_3)_3CCNSSN^{\cdot}$ as we have previously demonstrated (7*a*, 13). The ESR studies of another similarly prepared sample also showed the formation of $(CH_3)_3CCNSNS^{\cdot}$ and its subsequent partial rearrangement to $(CH_3)_3CCNSSN^{\cdot}$.

[5] The experimental techniques have been described in ref. 12.

Fig. 1. The optimized (RHF, STO-3G) geometries of the 6π 1,3,2,4-dithiazaphospholium $HCPSNS^+$ cation.



Molecular orbital calculations

The geometries of the hydrogen derivative of 6π 1,3,2,4-dithiazaphospholium $HCPSNS^+$ were optimized, and its electronic structure was then examined by molecular orbital calculations on the basis of the optimized geometries. The geometry optimization (Fig.1) and the subsequent MO calculations were performed with the Gaussian 92 program at the STO-3G (RHF) level.

Results and discussion

Multinuclear NMR spectroscopic studies of the cycloaddition reaction of $SNSAsF_6$ with *tert*-butylphosphaacetyline $(CH_3)_3CCP$

When $SNSAsF_6$ was mixed with an excess of $(CH_3)_3CCP$ in liquid SO_2 at −60°C, the colour of the solution immediately turned to bright yellow (different from the yellow colour of $SNSAsF_6$). The rapid colour change and subsequent NMR studies indicated that the cycloaddition of SNS^+ with $(CH_3)_3CP$ (eq. [1]) was likely relatively fast[6]

[1] $(CH_3)CCP + SNSAsF_6 \rightarrow (CH_3)_3CCPSNSAsF_6$

The initial reaction product underwent decomposition at room temperature to give a complex mixture (^1H and ^{31}P NMR), which hindered its isolation. The attempted isolation of $(CH_3)_3CCPSNS^+$ as the $AlCl_4^-$ salt was unsuccessful, probably as a consequence of the decomposition of the cation during the anion exchange[7] and (or) subsequent work-up. Therefore,

[6] On the basis of the correlation of the rate of SNS^+ cycloaddition to the ionization potential of the multiple bonds C≡N (IP 12–14 eV), C≡C (IP 11–13 eV), and C=C (IP = 10.5 for C_2H_4) bonds (1*e*, *g*)), the cycloaddition reaction of $(CH_3)_3CCP$ (IP=9.70 eV) would be expected to be fast.

[7] The attempted isolation of $(CH_3)_3CCPSNSAlCl_4$ was performed by reacting CsCl with $(CH_3)_3CCPSNSAsF_6$ in situ in liquid SO_2 followed by the evacuation of SO_2 and in situ reaction of the product (expected to be the covalent $(CH_3)_3CCPSNSCl$) with $AlCl_3$ in CH_2Cl_2 (expected to give $(CH_3)_3CCPSNSAlCl_4$). The recovered solid product was characterized by ^1H NMR, showing, however, a group of unassignable resonances (spectrum deposited), indicating that a complex mixture was formed.

the cycloadduct was characterized in situ at −60°C by multinuclear NMR (^{1}H, ^{13}C, ^{14}N, ^{15}N, ^{31}P) spectroscopy.

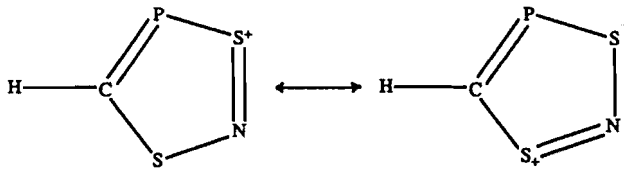
The NMR (^{1}H, ^{13}C, ^{31}P) resonances of the cycloadduct $(CH_3)_3C\overline{CPSNS}^+$ appeared at lower field relative to those of $(CH_3)_3CCP$ (see Table 2), characteristic of the formation of the deshielded cation (cf. the cycloadditions of nitriles (1*e*, *f*)). The ^{14}N spectrum of $(CH_3)_3C\overline{CPSNS}^+$ exhibited a broader signal (δ = 37.5 ppm, $\Delta\nu_{1/2}$ = 790 Hz) than that (δ = −28 ppm, $\Delta\nu_{1/2}$ = 580 Hz) of the corresponding N′ in the nitrogen analogue $(CH_3)_3C\overline{CN''SN'S}^+$ (1*e*)), consistent with the replacement of N″ by the larger P. The magnitude of $^1J(^{31}P, ^{13}C)$ of $(CH_3)_3C\overline{CPSNS}^+$ (104 Hz) is surprisingly greater than that of $(CH_3)_3CCP$ (38.5 Hz). However, this is characteristic of a decrease in the CP bond order,[8] and indicates the presence of a C=P double bond. Neilson and co-workers showed (15) that for various acyclic phosphaalkenes (C=P), the ^{31}P chemical shifts are directly proportional to the $^1J_{PC}$ coupling constants. Using Neilson's plot of $\delta(^{31}P)$ versus $^1J_{PC}$ for various C=P containing molecules (Fig. 1 in ref. 15), $\delta(^{31}P)$ = 389 ppm (observed for $(CH_3)_3C\overline{CPSNS}^+$) corresponds to $^1J_{PC}$ = 99 Hz (observed 104 Hz for $(CH_3)_3C\overline{CPSNS}^+$). Alternatively, $^1J_{PC}$ = 104 Hz (observed for $(CH_3)_3C\overline{CPSNS}^+$) corresponds to $\delta(^{31}P)$ = 402 ppm (observed 389 ppm for $(CH_3)_3C\overline{CPSNS}^+$). This further supports the presence of a C=P double bond in the heterocyclic $(CH_3)_3C\overline{CPSNS}^+$. The ^{15}N spectrum of $(CH_3)_3C\overline{CPSNS}^+$ exhibited a singlet (δ = 30.8 ppm, $\Delta\nu_{1/2}$ = 4.8 Hz), and the $^2J(^{31}P, ^{15}N)$ coupling was not observable (estimated from the ^{15}N linewidth to be smaller than 4 Hz). This is in the range found for $^2J(^{31}P, ^{15}N)$ for heterophospholes $-\overline{NCPCC}$ (typically 0–9 Hz), while $^1J(^{31}P, ^{15}N)$ for heterophospholes $-\overline{NPCCC}$ are typically 80–90 Hz (16), which further supports the identity of the $\overline{CPSNS}^+$ ring. Our NMR results (refer to Table 1) also quantitatively fit eqs. [2] and [3], which were previously established for the correlations of the ^{31}P chemical shift ($\delta(^{31}P)$) of various =P- moiety containing acyclic and heterocyclic compounds to the ^{14}N (14,16) and ^{13}C (14,17) chemical shifts ($\delta(^{14}N)$ and $\delta(^{13}C)$, respectively) of the corresponding =N- (replacement of P by N) and =CH- (replacement of P by CH) moieties in analogous acyclic and heterocyclic compounds.

[2] $\delta(^{31}P) = 1.33\delta(^{14}N) + 279$

[3] $\delta(^{31}P) = 4.88\delta(^{13}C) - 422$

In addition, the difference (59 ppm) between the $\delta(^{15}N)$ of $(CH_3)_3C\overline{CPSNS}^+$ (30.8 ppm) and $\delta(^{14}N)$ of N′ in $(CH_3)_3C\overline{CN''SN'S}^+$ (−28 ppm) (1*e*, 2) is comparable to those for $CH_3\overline{NCPCN}'$ and the nitrogen analogue $CH_3\overline{NCNCN}'$ (the difference in $\delta(^{14}N)$ for N′ is ca. 50 ppm) (16) and for $CH_3-\overline{CCPN(CH_3)N}'$ and the nitrogen analogue $H\overline{CCNN(CH_3)N}'$ (the difference in $\delta(^{14}N)$ for N′ is ca. 40 ppm) (16). Thus, the formation of the new type of 6π heterocyclic 1,3,2,4-dithiazaphospholium $-\overline{CPSNS}^+$ is further evidenced by a careful examination of its ^{31}P and ^{14}N (^{15}N) chemical shifts. The multinuclear NMR spectroscopic studies establish the presence of 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3-\overline{CCPSNS}^+$, reasonably formed by the symmetry-allowed cycloaddition reaction of SNS^+ with *tert*-butylphosphaacetyline $(CH_3)_3CCP$. This is the first example of any 1,3,2,4-dithiazaphospholium heterocycle.

The ab initio calculations showed that the frontier molecular orbitals of 6π $H\overline{CPSNS}^+$ (HOMO and LUMO) consist of conjugated p_π orbitals (p_π coefficients on $H\overline{CPS'NS}^+$ (HOMO, LUMO): C (0.50, 0.08), P (0.63, 0.28), S′(0.18, −0.57), N (−0.35, 0.80), and S (−0.39, −0.47)) similar to the previous known nitrogen analogue $H\overline{CNSNS}^+$ (p_π coefficients on $H\overline{CN'S'NS}^+$ (HOMO, LUMO): C (−0.26, 0.12), N′(0.04, 0.17), S′(0.73, −0.54), N (0.09, 0.83), and S (−0.65, −0.51)). The CP bond order[9] obtained from the calculated CP bond distance of 1.643 Å (Fig. 1) is ca. two, supporting the proposed C=P double bond in the cycloadduct by NMR studies. In addition, the sum of the bond orders in the SNS moiety is ca. three (each SN bond possesses bond order 1.4), and the sum of bond orders for all the bonds in the cationic heterocycle is estimated to be ca. seven and can represented by valence bond structures **1** and **2**.



1 **2**

All these results support the proposed identity of the heterocyclic $\overline{CPSNS}^+$ cation.

Reduction of the 6π 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3C\overline{CPSNS}^+$ cation to a radical that may be the 7π 5-*tert*-butyl-1,3,2,4-dithiazaphospholyl $(CH_3)_3C\overline{CPSNS}^{\cdot}$

$SNSAsF_6$ cycloadds to $(CH_3)_3CCP$ in liquid SO_2 to give the 6π $(CH_3)_3C\overline{CPSNS}AsF_6$. Since $(CH_3)_3C\overline{CPSNS}AsF_6$ under-

[8] The $^1J(^{31}P, ^{13}C)$ of phosphaalkenes (C=P) (30–112 Hz) are generally larger than those of phosphaalkynes (C≡P) (14–56 Hz) (14).

[9] The bond orders are calculated by Pauling's equation (18):

bond order = 10 exp [−(D_b − D_1)/0.711]

where D_b is the bond length (optimized or observed), and D_1 is the sum of the radii of the two atoms the bond order between which is one. The covalent radii used are as follows (12): r_C = 0.772 Å, r_P = 1.10 Å, r_S = 1.04 Å, and r_N = 0.70 Å.

goes decomposition to a complex mixture at room temperature, instead of reducing a recovered $SNSAsF_6/(CH_3)_3CCP$ reaction product as was performed in previous work (4), in this work the $(CH_3)_3CCPSNS^+$ cation was prepared and reduced in situ at −40°C using excess $SbPh_3$ in the presence of Me_4NCl (eq. [4]),

[4] $(CH_3)_3CCPSNSAsF_6 + 1/2\ SbPh_3 + Me_4NCl \rightarrow (CH_3)_3CCPSNS^{\cdot} + 1/2\ SbPh_3Cl_2 + Me_4NAsF_6$

immediately giving a radical species the ESR spectrum of which exhibited a 1:1:1 triplet (due to the coupling to ^{14}N (I = 1)) with g = 2.0059 and a^N = 1.14 mT. This is reasonably attributed to a new type of heterocyclic 7π 5-*tert*-butyl-1,3,2,4-dithiazaphospholyl $(CH_3)_3CCPSNS^{\cdot}$ (cf. the previously known $(CH_3)_3CCNSNS^{\cdot}$ (13)) by comparison with various conjugated SNS· moiety containing heterocyclic radicals (g = 2.005 − 2.007, a^N = 1.10 ± 0.03) (Table 1). The a^P coupling was not observable even at −60°C.[10] The a^N values for the proposed $(CH_3)_3CCPSNS^{\cdot}$ radical obtained in this work (a^N = 1.10 mT) and the radical previously obtained (a^N = 1.467 mT) (4) are substantially different. The reason for this difference (ca. 0.33 mT) is not clear but, most likely, the previous attempted generation of $(CH_3)_3CCPSNS^{\cdot}$ (4) was not successful because of decomposition of the original $(CH_3)_3CCPSNSAsF_6$ at room temperature (as demonstrated earlier in this paper) prior to the reduction.

The novel exchange of a cyclic phosphorus by nitrogen in the reaction of $(CH_3)_3CCPSNS^+$ with azide N_3^- leading to 5-*tert*-butyl-1,3,2,4-dithiadiazolyl $(CH_3)_3CCNSNS^{\cdot}$

In contrast to the possible formation of 5-*tert*-butyl-1,3,2,4-dithiazaphospholyl $(CH_3)_3CCPSNS^{\cdot}$ by reduction of the 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3CCPSNS^+$ cation according to eq. [2], reaction of $(CH_3)_3CCPSNS^+$ with cesium azide CsN_3 in liquid SO_2 gave another radical species the ESR spectrum of which at −60°C surprisingly exhibited hyperfine 1:1:1 triplets of a 1:1:1 triplet (g = 2.0060, $a^{N'}$ = 1.08 mT, $a^{N''}$ = 0.06 mT), characteristic of the previously known 7π 5-*tert*-butyl-1,3,2,4-dithiadiazolyl $(CH_3)_3CCNSNS^{\cdot}$. Consistently, as expected, this radical on photolysis rearranged to 5-*tert*-butyl-1,2,3,5-dithiadiazolyl $(CH_3)_3CCNSSN^{\cdot}$ identified by ESR (1:2:3:2:1 quintet) (7*a*, 13). It is noteworthy that the reduction of $(CH_3)_3CCPSNS^+$ by $SbPh_3$ in the presence of Me_4NCl gave a radical the low-temperature ESR spectrum of which only gave a 1:1:1 triplet reasonably attributable to $(CH_3)_3CCPSNS^{\cdot}$, but did not give a hyperfine structure. In addition, this sample did not undergo a photochemical rearrangement as in the case for $(CH_3)_3CCNSNS^{\cdot}$ under similar conditions, but instead decomposed to diamagnetic species in room light. All the results unambiguously show that the reaction of 5-*tert*-butyl-1,3,2,4-dithiazaphospholium $(CH_3)_3CCPSNS^+$ with azide N_3^- gave the previously known 5-*tert*-butyl-1,3,2,4-dithiadiazolyl $(CH_3)_3CCNSNS^{\cdot}$ radical. The conversion of $(CH_3)_3CCPSNS^+$ to $(CH_3)_3CCNSNS^{\cdot}$ by the net replacement of a cyclic phosphorus with nitrogen is unprecedented.

The following two possible mechanisms (Schemes 1 and 2) are proposed[11] to account for the reaction of $(CH_3)_3CCPSNS^+$ with N_3^- leading to $(CH_3)_3CCPSNS^{\cdot}$. The initial step of this reaction may involve a cycloaddition of N_3^- ($^-N{=}N^+{=}N^-$) to the C=P bond leading to **2** (Scheme 1). Alternatively, it may also involve an attack of terminal nitrogen on N_3^- on the carbon of **1** leading to **6** (Scheme 2). On elimination of N_2 **2** and **6** give fused bicyclic molecules **3** and **7**, respectively. The potential molecular strain in the three-membered CNP ring in **3** may induce a ring opening, giving **4**. The phosphorus on both **4** and **7** may possibly be abstracted on reaction with the solvent SO_2 ($P_xS_yO_z$) and, as a result, the final product **5** (identified by ESR) is formed.

The previous investigations showed (6, 7*a*) that sulfur-nitrogen-containing compounds often undergo complex structural rearrangements, e.g., the isomerization of 1,3,2,4-dithiadiazolyl radicals (7*a*) and scrambling reactions of sulfur diimides (6). This preliminary work shows another example of the baffling features involved in the chemistry of sulfur nitrogen compounds.

Conclusions

The previous investigations showed that the SNS^+ cation (as the AsF_6^- salt) undergoes general extensive cycloaddition reactions with various nitriles, alkynes, alkenes, and SN^+ (1). In this work, the generality of this type of pseudo 1,3-dipolar cycloaddition has been extended to the phosphaalkyne $(CH_3)_3CCP$ to lead to the first example of a new class of heterocyclic compound 1,3,2,4-dithiazophospholium $(CH_3)_3CCPSNS^+$ (eq. [1]). This cationic cycloadduct was character-

[10] An explanation for the coupling constant $a^P \simeq 0$ was sought by a comparison of the coefficients of p_π SOMO of $HCPSNS^{\cdot}$ (ROHF, STO-3G) on N (0.97) and P (0.08), and total spin densities of $HCPSNS^{\cdot}$ (UHF, STO-3G)) in the *s*-orbitals for N (0.042) and P (0.001) (cf. optimized $HCN'SNS^{\cdot}$: p_π coefficients N (0.95) and N′ (0.08); *s*-orbital spin density N (0.048) and N′ (0.001)). The optimized geometries (bond lengths (Å) and angles (°)) for $HCPSNS^{\cdot}$ (ROHF, STO-3G) are given below: H—C (1.080), C—P (1.621), P—S′(2.115), S′—N (1.742), N—S (1.749), C—S (1.751); ∠SCP (146.4), ∠CPS′(75.2), ∠PS′N (103.2), ∠S′NS (115.0), ∠NSC (100.1), ∠S′CH (113.7), ∠HCP (100.5). These low-level calculations imply that the value of a^P may indeed be very small. Much higher level calculations are needed before the point can be viewed as settled. However, the calculation of the molecular isotropic and anisotropic hyperfine tensors (coupling constants) has been said to be one of the most challenging tasks in computational chemistry (19).

[11] The reaction mechanisms were proposed by Professor Z. Valenta of this Department.

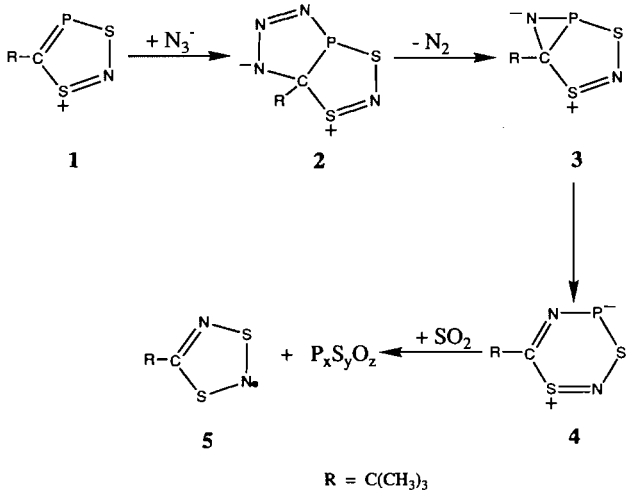
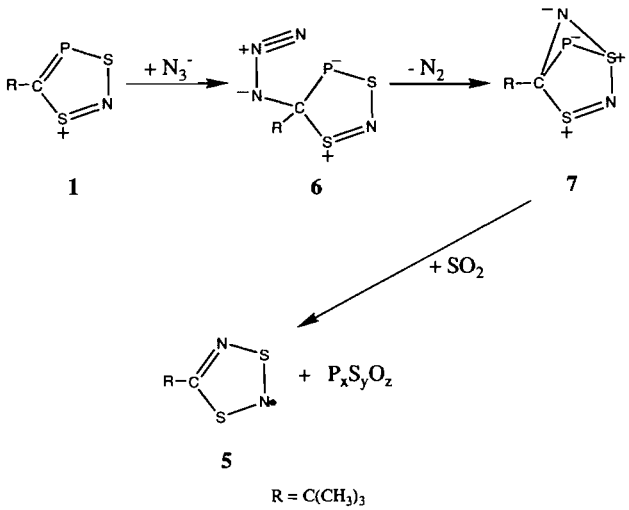
Scheme 1.



Scheme 2.



ized by multinuclear NMR (^{1}H, ^{13}C, ^{14}N, ^{15}N, ^{31}P) spectroscopy. The ^{31}P chemical shift of $(CH_3)_3C\overline{CPSNS}^+$ fits well with eqs. [2] and [3] for correlations of a variety of =P- containing compounds to the corresponding nitrogen =N- and hydrocarbon =CH- containing analogues, supporting the identity of this new class of five-membered ring $\overline{CPSNS}^+$, and it is further supported by *ab initio* calculations. This work suggests that other triply bonded species X≡Y containing one or more heavier atoms of groups 14 and 15[12] may also cycloadd to SNS^+ in the readily prepared $SNSAsF_6$ (9) in the convenient solvent SO_2 at low temperatures, leading to the formation of new classes of five-membered rings readily characterizable by multinuclear NMR spectroscopy. In addition, our results imply that isolation of the salts of these cations in the solid state will necessitate exchange of AsF_6^- by other anions, e.g., $AlCl_4^-$.

[12] SNS^+ also cycloadds to the XS≡N (X = F, Cl, Br) (1*e*, 2) triple bond containing a heavier atom (of group 16) to give $X\overline{SNSNS}^+$, although the reaction is not likely a symmetry-allowed concerted cycloaddition.

Reduction of the 6π $(CH_3)_3C\overline{CPSNS}^+$ cation with $SbPh_3$ in the presence of Me_4NCl may have given $(CH_3)_3C\overline{CPSNS}^{\cdot}$, the first member of a new class of 7π 1,3,2,4-dithiazophospholyl radicals, supported by ESR spectroscopy, showing a 1:1:1 triplet with $g = 2.0059$ and $a^N = 1.14$ mT. However, splitting from ^{31}P was not observed, possibly because the a^P value is very small.

Reaction of 5-*tert*-butyl-1,3,2,4-dithiazaphospholyl $(CH_3)_3C\overline{CPSNS}^+$ (as the AsF_6^- salt) with azide N_3^- in liquid SO_2 surprisingly gave the previously known 7π 5-*tert*-butyl-1,3,2,4-dithiadiazolyl $(CH_3)_3C\overline{CNSNS}^{\cdot}$ radical. The conversion of $(CH_3)_3C\overline{CPSNS}^+$ to $(CH_3)_3C\overline{CNSNS}^{\cdot}$ by the net replacement of a cyclic phosphorus with nitrogen is unprecedented.

The synthesis of a new radical, possibly $(CH_3)_3C\overline{CPSNS}^{\cdot}$, and $(CH_3)_3C\overline{CNSNS}^{\cdot}$ from $(CH_3)_3C\overline{CPSNS}^+$ suggests that this cation, and those like it, are likely to open up even more unusual chemistry.

Acknowledgements

We thank Dr. P. Penner for obtaining NMR spectra using a Varian UNITY 400 MHz spectrometer, Dr. S. Mattar and Mr. R. McGregor for recording low-temperature ESR spectra of $(CH_3)_3C\overline{CNSNS}^{\cdot}$ (S.M.) and $(CH_3)_3C\overline{CPSNS}^{\cdot}$ (R.M.), respectively, and Professor Z. Valenta for suggesting the reaction mechanisms. We also thank the Natural Sciences and Engineering Research Council of Canada (NSERC) and the University of New Brunswick (X.S.) for financial support, and the Canadian Commonwealth Scholarship and Fellowship Committee for a graduate scholarship (S.P.).

A study of the negative ion FABMS of tris(perfluorophenyl)phosphine and related compounds: matrix effects

Mandapati Saraswathi, Jack M. Miller, and Tim R.B. Jones

Abstract: The mass spectra of tris(perfluorophenyl)phosphine obtained under negative ion Fast Atom Bombardment conditions showed formation of an unusual ion at *m/z* 397 attributed to $((C_6F_5)_2PO_2)^-$. The matrix effects involved in this reaction are discussed. Negative ion FAB spectra of tris(perfluorophenyl)arsine and tris(perfluorophenyl)stibine are also reported.

Key words: pentafluorophenylphosphine, -arsine, -stibine; negative ion FABMS; matrix effects.

Résumé : Les spectres de masse d'ions négatifs du tris(perfluorophényl)phosphine obtenus par bombardement à l'aide d'atomes rapides montrent la formation d'un ion inhabituel à *m/z* 397 que l'on attribue à l'espèce $((C_6F_5)_2PO_2)^-$. On discute de l'effet de matrice impliqué dans cette réaction. On rapporte également les spectres d'ions négatifs FAB du tris(perflurophényl)arsine et du tris(perfluorophényl)stibine.

Mots clés : pentafluorophénylphosphine, pentafluorophénylarsine, pentafluorophénylstibine, ions négatifs FABMS, effet de matrice.

Introduction

Liquid matrices used in FABMS can produce adverse effects in analysis of organic and organometallic compounds. For example, low surface activity of analytes may result in poor response in the spectra. Since extensive chemical noise or background may be produced by the matrices, this can interfere in characterization of analytes (1). Therefore, the selection of matrix plays a vital role in FABMS.

In addition, many groups have reported (2–11) both expected and unexpected reactions of FAB matrices with analytes. Protonation in the FAB matrix of organic analytes such as nucleosides (2), chlorin (3), organic dyes (4), and peptides (5) is common. Reductive dehalogenation reactions have also been observed during FABMS analysis of halogenated compounds including nucleotides (6), nucleosides (7), phenylalanine (8), and phenothiazine drugs (9). In other work, an impurity of ammonium chloride in a thioglycerol FAB matrix yielded $(M + NH_4)^+$ ions from valinomycin with almost complete exclusion of the $(M + H)^+$ ion (10), and the formation of adduct ions with analytes in radical reactions induced by glycerol as a FAB matrix has been reported (11).

Chemical reactions, more complicated than simple protonation and adduct formation, can also occur in the FAB source. For example, Schiff-base product formation with formaldehyde generated from glycerol matrix was observed during the analysis of angiotensin (12). In addition to the FAB matrix giving unexpected and (or) unwanted reactions in FAB mass spectra, other side reactions with the metal probe tips have also been reported (13, 14). Copper cluster formation with fomblin oil (13) and exchange reactions of copper metal with metal in organometallic samples (14) occurred when copper probe tips were used. Stainless steel tips eliminated most but not all of these effects (15).[2]

The undesirable reactions of liquid matrices may provide valuable information or insights into the chemical reactivity of analytes (16). As one part of a study of these reactions, we wish to report the formation of an unusual ion at *m/z* 397 from tris(perfluorophenyl)phosphine with a 3-nitrobenzyl alcohol (NBA) matrix under negative ion FAB.

Results and discussion

The negative ion FAB mass spectrum of tris(perflurophenyl)phosphine (**1**) obtained using NBA as matrix is given in Fig. 1, with the corresponding positive ion spectrum for comparison. The most abundant ions observed in the negative ion spectrum are at *m/z* 167(100%) and 397(81%). Other important ions are at *m/z* 148, 249, 315, 365, 381, 513, 529, and 532 (molecular ion), though the latter is very weak compared to that of the positive ion spectrum. The electron capture ability of this compound is surprisingly poor. The perfluorophenyl anion (*m/z* 167) is the base peak in the spectrum. The same ion is more abundant in the spectra of tris(perfluorophenyl)arsine (**2**) and tris(perfluorophenyl)stibine (**3**) (Table 1). The negative ion FAB spectrum of **1** has entirely different ion intensities than its positive ion electron impact spectrum (17). This is in sharp contrast to related Group V perfluoro-triptycene ana-

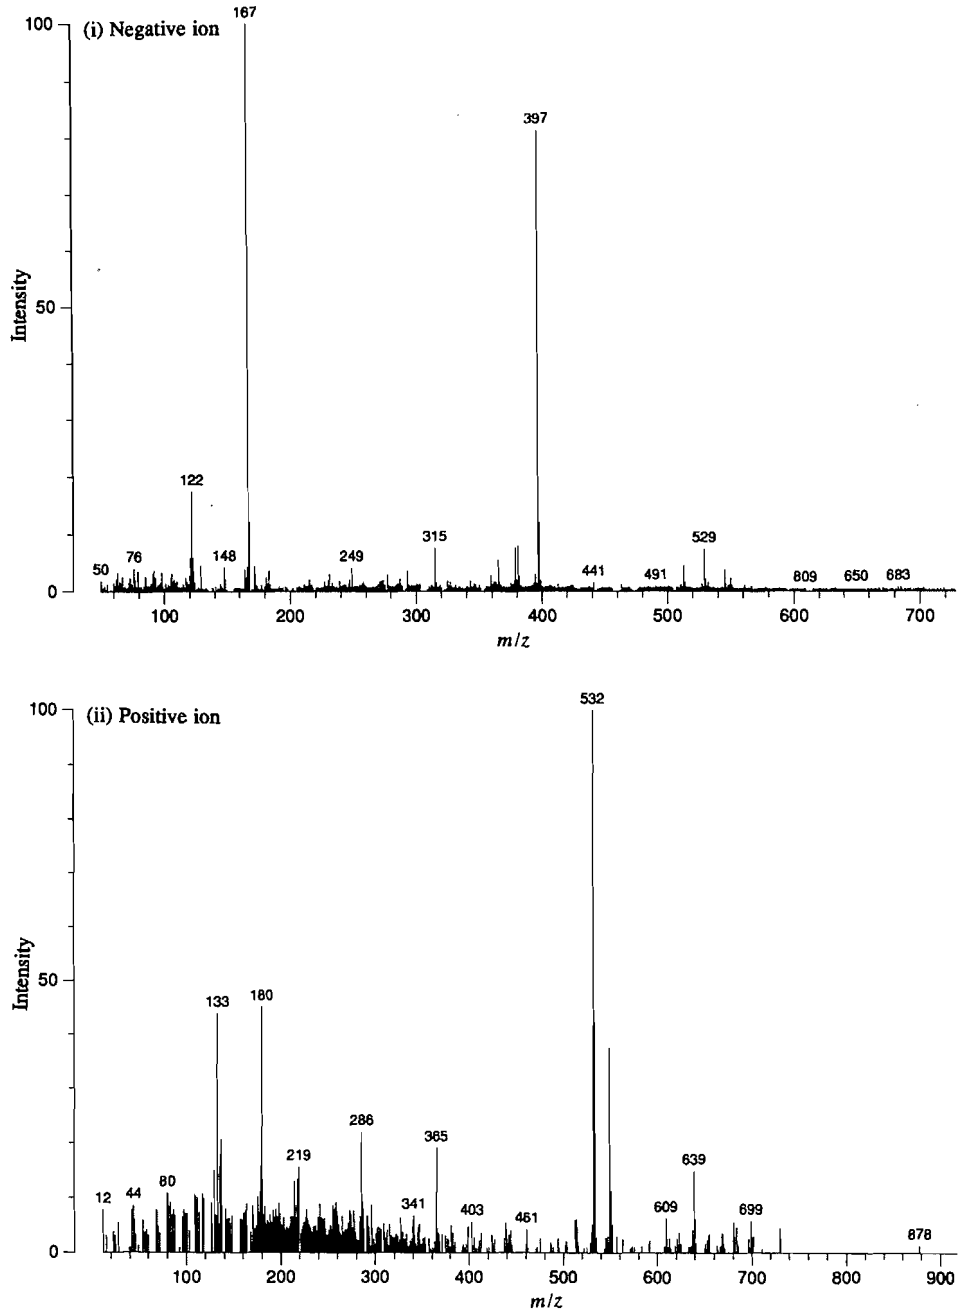
Fig. 1. FAB spectra of $(C_6F_5)_3P$–NBA: (i) negative ion; (ii) positive ion.



logs described previously (18) where the negative ion FAB spectra closely resembled the positive ion EI spectra. The high oxidation potentials of the Group V elements may cause the parent negative ions to be very weak, though the fluoroaromatic rings might be considered as good electron acceptors. Thus, tris(perfluorophenyl)amine (**4**) did not give good spectra under negative ion FAB conditions. The clearly delineated fragmentation of **1** obtained under negative ion FAB conditions using NBA as a matrix is given in Scheme 1. Collision-induced dissociation techniques were used to probe the ion structures, especially that of the ion at *m/z* 397.

We also see, in the spectrum of **1**, other ions at *m/z* 549, 578, and 685 that do not arise directly by simple ionization of the analyte. These additional ions are $(M + 17)^-$, $(M + 46)^-$, and $(M + 153 \text{ or NBA})^-$, respectively. The metastable and collision-induced dissociation spectra of the molecular ion of **1** (*m/z* 532) show that loss of perfluorophenyl from the molecular ion is a facile process. Loss of PF_2 from the $(C_{12}F_{10}P)^-$ ion (*m/z* 365) produces another abundant ion at *m/z* 296 and $(M - F)^-$, $(C_{12}F_{10}P - F_2)^-$, $(C_{12}F_{10}P - C_6F_4)^-$, and $(C_{12}F_{10}P - PF_3)^-$ are the other minor ions. However, the ion at *m/z* 397 is not produced in the unimolecular decomposition of the molecular ion of **1**. This suggests the involvement of the FAB matrix in the formation of the *m/z* 397 ion. Precursors are not detected

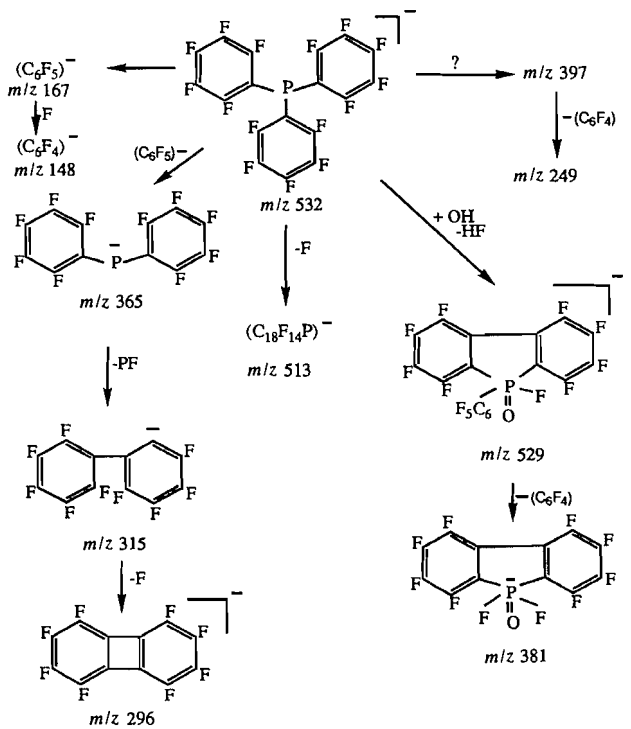
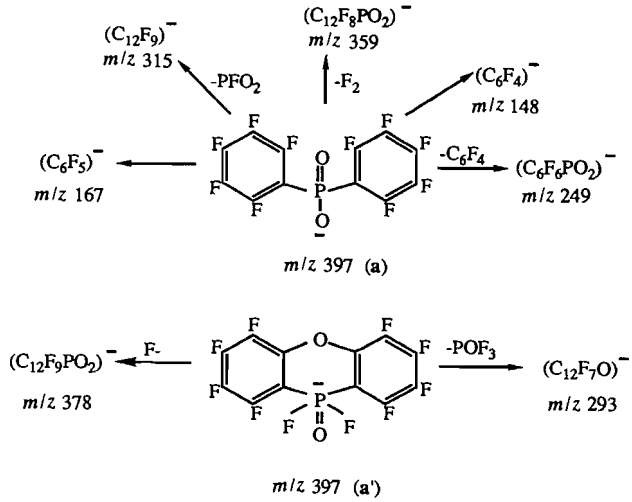
Scheme 1. Fragmentation of molecular ion (*m/z* 532) of **1** under negative ion FAB.



in B^2/E linked scan studies of the 397 ion. However, the metastable spectrum of the adduct ion of **1** with NBA (i.e., *m/z* 685) produced three abundant ions at *m/z* 397, 532 [$M^{-\bullet}$ of $P(C_6F_5)_3$], and 684 (Fig. 2).

The fragmentation in the first field-free region of the other ions with masses above that of the molecular ion, i.e., at *m/z* 549 and 578 (Fig. 2), also produced an ion at *m/z* 397 as a major fragment. The ion at *m/z* 529, obtained in the negative ion FAB spectrum of **1**, may be generated by the addition of an OH group and subsequent loss of HF from the molecular ion in an NBA matrix, which is a source of hydroxy radicals (19). The metastable ion spectrum of *m/z* 529 showed loss of oxygen as a major process, to produce an ion at *m/z* 513 (Fig. 2). The *B/E* spectrum of the 578 ion also showed the formation of

Scheme 2. Metastable ion fragmentation of *m/z* 397.

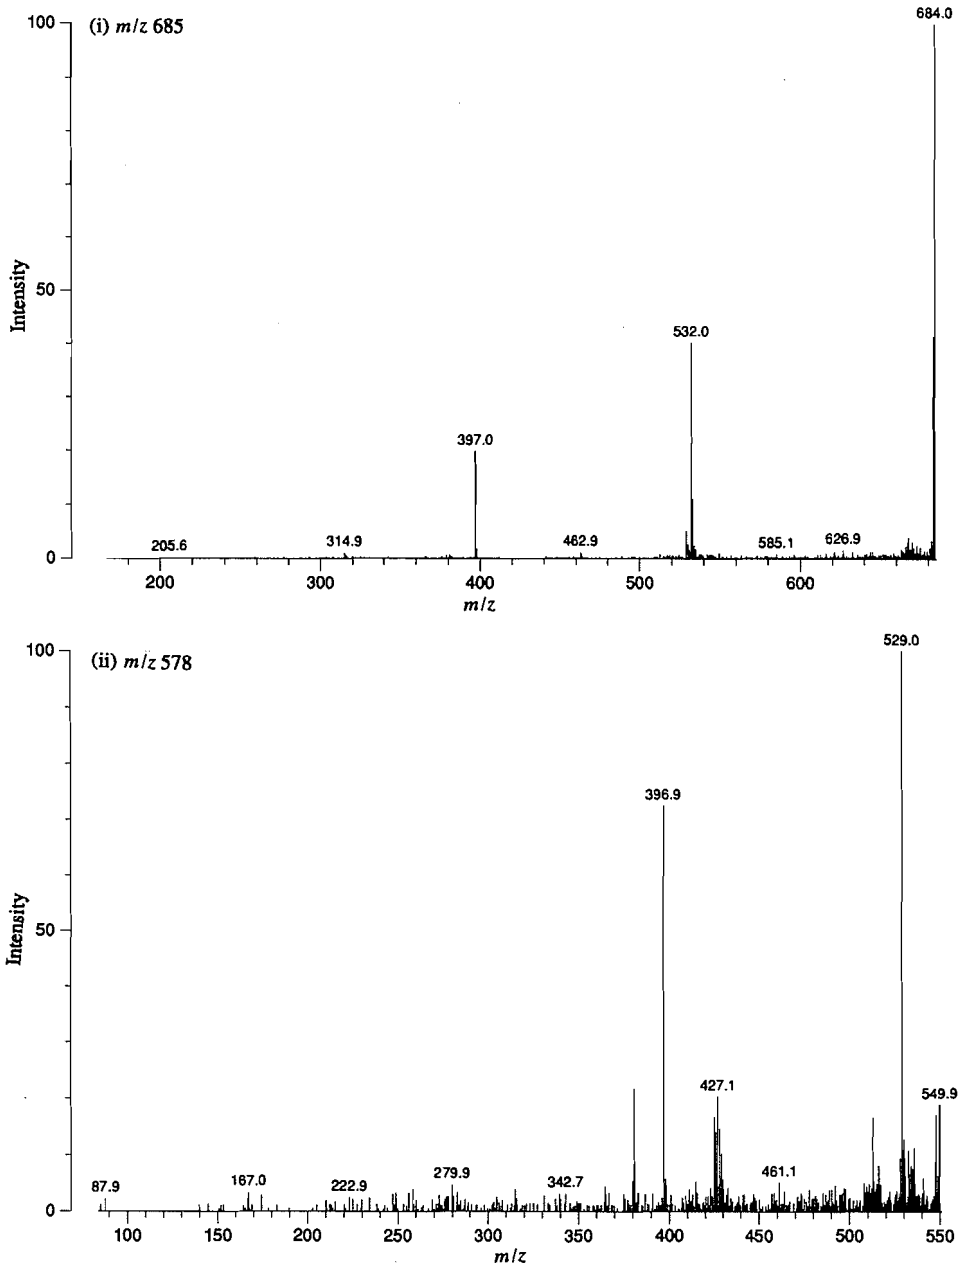


a 529 ion. The ion at *m/z* 578 could be made up of a mass 532 species bound to NO_2. This would account for the formation of *m/z* 397, but not of 529. Surprisingly, the *B/E* linked scan study of the 549 ion did not produce the 529 ion, suggesting that it may not be the hydroxyl adduct. The formulation of *m/z* 549 thus remains elusive, though it may be related to an NBA adduct of the 397 species.

The positive ion FAB of **1** in an NBA matrix did give the molecular ion as the base peak and other ions at *m/z* 365, 549, and 639 (Fig. 1). Formation of the unexpected 397 ion was not observed. The negative ion FAB spectra of **1** and tris(perfluorophenyl)phosphine oxide recorded with matrices containing hydroxy groups such as NBA, glycerol, 3-mercapto-1,2-propanediol, and 2,2′-thiodiethanol also showed the formation of an *m/z* 397 ion. However, this ion is not produced from a 2-nitrophenyloctylether matrix. The mestastable ion spectra of the 397 ion obtained from **1** and tris(perfluorophenyl)phosphine oxide using NBA and glycerol are found to be similar (Fig. 3). The position of the 397 ion was not shifted when the spectra were recorded with the addition of deuterium oxide to NBA or glycerol matrices. These experiments further establish that hydrogen radicals produced from selvedge are not directly involved in the formation of the 397 ion, though hydroxilic matrices are necessary. The origin of the 397 ion could not be established from B^2/E linked scan studies. This can be attributed to either the rapid decomposition of precursor ions and (or) to the formation of this species in the selvedge itself through the oxidation of the phosphine. The ion at *m/z* 549 might have also formed in the matrix. On unimolecular decomposition this yields primarily the 397 ion by the loss of 152 mass units. This suggests that the ion at *m/z* 549 could be the (NBA − H) adduct of the 397 species.

Multiple high-resolution mass measurements of the 397 ion obtained from **1** with an NBA matrix fit the elemental composition of $C_{12}F_{10}PO_2$ (calcd: 396.94859; theoretical: 396.94763; Δ = 2.4 ppm). Chemical ionization experiments carried out with tris(perfluorophenyl)phosphine and tris(perfluorophenyl)phosphine oxide failed to form a 397 ion. These experiments, together with the requirement for a hydroxilic matrix, clearly suggest that formation of the 397 ion must involve the matrix in a vital role. Based on these results, two structures for the *m/z* 397 ion are proposed, **a** and **a′** (Scheme 2). Formation

Fig. 2. Metastable negative ion FAB spectra of $(C_6F_5)_3P$–NBA: (i) *m/z* 685; (ii) *m/z* 578; (iii) *m/z* 549; and (iv) *m/z* 529.



of mestastable ions at *m/z* 148, 167, 249, 315, and 359 from the 397 ion can be explained using structure **a**, and the remaining ions at *m/z* 293 and 378 can arise more readily from structure **a′**. Both structural types are consistent with species previously identified in the EI and positive ion FAB spectra of various Group V derivatives. The ion at *m/z* 397 thus is likely to be a mixture of **a** and **a′**, with the same empirical formulae. This ion formation is analogous to the solution chemistry oxidation of phosphine.

Conclusions

The matrices possessing hydroxy groups used for recording FABMS tris(perfluorophenyl)phosphine resulted in the formation of an unusual ion at *m/z* 397 by the oxidation of phosphorus(III) to phosphorus(V). The radical differences between the positive and negative ion FAB spectra and the EI spectrum serve as a warning that interpretation of mass spectra based solely on a single ionization technique can lead to

errors unless that technique is well understood for a particular compound class. For these compounds, the EI spectra are probably the best. In the negative ion FAB spectrum the *m/z* 397 species appears to be a reaction product involving the matrix rather than something involving preferential ionization of impurities.

Experimental

Compounds **1–3** utilized in this study were prepared according to procedures described in the literature: **1** (20), **2** and **3** (21); compound **4** was obtained from Fluorochem Limited. Compounds 2-nitrophenyl octyl ether (Fluka), 3-nitrobenzyl alcohol, 3-mercapto-1,2-propanediol, 2,2′-thiodiethanol, glycerol, and deuterium oxide (Aldrich) were used without further purification.

FAB mass spectra were recorded on a Kratos concept 1S mass spectrometer, interfaced to a Kratos DART/MACH3 data system. The standard concept FAB source was used with an Ion Tech Fast Atom Gun. Ionization was achieved using

Fig. 3. Metastable negative ion FAB spectra of *m/z* 397: (i) $(C_6F_5)_3P$–NBA; (ii) $(C_6F_5)_3P$–glycerol; (iii) $(C_6F_5)_3PO$–NBA; and (iv) $(C_6F_5)_3PO$–glycerol.

xenon fast atoms generated with 6–8 kV and 1 mA emission current. The pressure in the source was (1–2) × 10^{-5} Torr (1 Torr = 133.3 Pa). The source was operated at room temperature. Samples dissolved in the matrix were placed on 1 mm diameter stainless steel probe tips. A 8 kV accelerating potential was used at a resolving power of 1000 for recording low-resolution spectra and 10 000 for Exact Mass measurement. The data system was calibrated with a mixture of sodium iodide, rubidium iodide, and cesium iodide (1:1:1 molar ratio); spectra were acquired, averaged, and the matrix background was subtracted using the data system. Helium was used as the collision gas for recording Collisionally Activated Dissociation (CAD) spectra and the pressure of helium was adjusted to reduce the main beam intensity by 30–35% of its original value. Daughter ion and precursor ion scans were recorded by keeping B/E and B^2/E, respectively, constant.

1-Deoxy-D-xylulose

Isaac A. Kennedy, Thomas Hemscheidt, James F. Britten, and Ian D. Spenser

Abstract: 1-Deoxy-D-xylulose (= 1-deoxy-D-*threo*pentulose) is a precursor of thiamin (Vitamin B_1) and of pyridoxine (Vitamin B_6) in bacteria. The synthesis of a [2,3-$^{13}C_2$] bond-labeled sample of the compound, to be used for investigations of the biosynthesis of the two vitamins, is described. In aqueous solution 1-deoxy-D-xylulose exists mainly as the open chain ketone. In methanol solution the compound exists as a mixture of the open chain ketone and the two corresponding epimeric furanoses. In acid solution the compound yields a dimeric anhydride, di-β-1-deoxy-D-xylulofuranose 2,3′:3,2′-dianhydride, whose structure was established by X-ray crystallography.

Key words: [2,3-$^{13}C_2$]-1-deoxy-D-xylulose, di-β-1-deoxy-D-xylulofuranose 2,3′:3,2′-dianhydride, 5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose, 4-*O*-benzyl-2,3-*O*-isoproylidene-D-threose.

Résumé : Dans les bactéries, le 1-désoxy-D-xylulose (= 1-désoxy-D-*thréo*pentulose) est un précurseur de la thiamine (vitamine B_1) et de la pyridoxine (vitamine B_6). On décrit la synthèse d'un échantillon de ce composé marqué sur les liaisons [2,3-$^{13}C_2$] qui sera utilisé dans des études de la biosynthèse des deux vitamines. En solution aqueuse, le 1-désoxy-D-xylulose existe principalement sous la forme d'une chaîne cétonique ouverte. En solution dans le méthanol, le composé existe sous la forme d'un mélange de la chaîne cétonique ouverte et des deux furanoses épimères correspondants. En solution acide, le composé fournit un anhydride dimère, le 2,3′:3,2′-dianhydride du di-β-1-désoxy-D-xylulofuranose, dont on a déterminé la structure par diffraction des rayons X.

Mots clés : [2,3-$^{13}C_2$]-1-désoxy-D-xylulose, 2,3′:3,2′-dianhydride du di-β-1-désoxy-D-xylulofuranose, 5-*O*-benzyle-3,4-*O*-isopropylidène-1-désoxy-D-xylulose, 4-*O*-benzyle-2,3-*O*-isoproylidène-D-thrèose.

[Traduit par la rédaction]

Introduction

The natural occurrence of 1-deoxy-D-xylulose (= 1-deoxy-D-*threo*pentulose) was first reported in 1976 (1). The compound was obtained from an isolate of *Streptomyces hygroscopicus*, and its structure and stereochemistry were deduced from its mass spectrum and on the basis of the identification of its reduction product as a mixture of 1-deoxy-D-xylitol and 1-deoxy-D-lyxitol, by comparison of their ^{1}H NMR spectra, GLC retention times, and optical rotation values with those of authentic specimens prepared from D-xylose and D-lyxose, respectively (2).

It was subsequently found that a wide range of microorganisms show enzymic activity leading to the formation of 1-deoxy-D-xylulose as well as of 1-deoxy-L-xylulose, by acyloin type condensation of pyruvic acid with D-glyceraldehyde or L-glyceraldehyde, respectively (3), a reaction that is catalysed by pyruvate dehydrogenase (E.C. 1.2.4.1) (4) and is accompanied by decarboxylation. Another enzyme, acetoin dehydrogenase (E.C. 1.1.1.5), found in the same microorganisms, generates 1-deoxy-D-xylulose or its enantiomer by reaction of D- or L-glyceraldehyde, respectively, with acetoin or methylacetoin instead of with pyruvic acid, yielding acetaldehyde or acetone, respectively, as the second product (4).

Received February 15, 1995.

1-Deoxy-D-xylulose is described as a crystalline compound, $C_5H_{10}O_4$, mp 61–63°C (1), 62–63°C (3), $[\alpha]_D$ +46 (*c* 1, H_2O)(1), +33.6 (*c* 1, H_2O)(3). Since the crystalline compound shows strong carbonyl absorption at 1710 cm^{-1} (2, 4), it follows that it exists as the open chain ketone (2). 1-Deoxy-L-xylulose, mp 63–65°C, $[\alpha]_D$ −33 (*c* 1, H_2O) (3) showed similar characteristics.

The appearance of three methyl singlets in the ^{1}H NMR spectrum ((D_2O or [D_6]DMSO) δ: 2.15 (80%), 1.31, 1.23 ppm (together 20%, signal at 1.31 more intense than signal at 1.23)) (2), ((D_2O) δ: 2.50 (72%), 1.69 (20%), 1.64 (6%); 3.75–4.70 (4H, m) ppm) (3) leads to the conclusion that in solution the compound exists as a mixture in which the open chain ketone predominates over the two anomeric furanoses, one of which is more abundant than the other.

Several chemical syntheses of 1-deoxyxylulose have been reported. Derivatives of the L-enantiomer, prepared from threonamide (5, 6), had been reported long before the compound had been isolated from natural sources. Two syntheses of 1-deoxy-D-xylulose ($[\alpha]_D^{21}$ +34 (*c* 1, H_2O)) were devised in connection with investigations of thiamin biosynthesis, one starting with derivatives of D-glyceraldehyde and acetaldehyde, the other from D-arabinose (7). The former method was employed to prepare a sample of 1-deoxy-D-[1,1,1-$^2H_3$]xylulose, the latter to generate a sample of the [1,1,1,(*RS*)-5-$^2H_4$]derivative. Both of these labeled compounds were shown to be incorporated into the thiazole nucleus of thiamin in *Escherichia coli* (7). The latter compound served as a precursor also of pyridoxine in *E. coli* (8). Another synthesis (9), leading to racemic 1-deoxyxylulose, starts from xylitol, a *meso* compound.

None of these syntheses were suitable for the preparation of the ^{13}C-labeled sample we required for our investigation of pyridoxine biosynthesis. What was needed was a sample of 1-deoxy-D-xylulose bond-labeled with ^{13}C at C-2,3, in order to test the direct incorporation of the substrate into pyridoxol without cleavage of the C-2,C-3 bond. This bond is one of only two bonds that are formed *de novo* when pyridoxine is derived from [1,2,3,4,5,6-$^{13}C_6$]glucose (10). To prove that 1-deoxy-D-xylulose is a late intermediate on the route from glucose into pyridoxine, it must be shown that the intact C-2,3 bond of the deoxypentulose is incorporated into pyridoxine.

Results and discussion

The major determinant in the design of the synthesis of ^{13}C-labeled compounds is the availability of ^{13}C-labeled starting materials that are not exorbitantly expensive. This factor becomes overriding when two contiguous carbon atoms in the target compound are to be enriched with ^{13}C.

This paper describes a synthesis of [2,3-$^{13}C_2$]-1-deoxy-D-xylulose (**14**) that starts with triethyl phosphono[1,2-$^{13}C_2$]acetate (**2**), or from ethyl bromo[1,2-$^{13}C_2$]acetate. Ethyl bromoacetate is a convenient starting material for preparation of triethyl phosphonoacetate (11). Both doubly labeled compounds are commercially available. The key intermediate of the route is [1,2-$^{13}C_2$]-4-*O*-benzyl-2,3-*O*-isopropylidene-D-threose (**10**), from which the target compound, [2,3-$^{13}C_2$]-1-deoxy-D-xylulose (**14**), is obtainable in four steps. The route to **10** proceeds by a sequence that has been well explored in the preparation of the corresponding unlabeled compounds, employing the Sharpless titanium-catalyzed asymmetric epoxidation procedure, followed by Payne and Pummerer rearrangement (12, 13). Unlabeled 4-*O*-benzyl-2,3-*O*-isopropylidene-D-threose (**18**) is accessible (14–16) in two steps from (−)-2,3-*O*-isopropylidene-D-threitol ([4*R*,5*R*]-4,5-di(hydroxymethyl)-2,2-dimethyl-1,3-dioxolane) (**15**), a compound that is commercially available.

Condensation of *O*-benzylglycolaldehyde (**1**) with triethyl phosphono[1,2-$^{13}C_2$]acetate (**2**) (cf. refs. 17–19) under conditions known to yield the *E* isomer exclusively (ref. 20, and footnote 9 of ref. 12) gave ethyl [1,2-$^{13}C_2$]-4-benzyloxy-*E*-but-2-enoate (**3**) in 79% yield. Reduction with diisobutyl aluminium hydride (cf. refs. 19, 21) gave [1,2-$^{13}C_2$]-4-benzyloxy-*E*-but-2-en-1-ol (**4**) in quantitative yield. This compound was subjected to the Sharpless asymmetric epoxidation procedure (cf. refs. 12, 13, 19, and 22), using D-(−)-diisopropyl tartrate in the presence of titanium tetraisopropropoxide, giving [1,2-$^{13}C_2$]-(2*R*,3*R*)-4-benzyloxy-2,3-epoxybutan-1-ol (**5**) in 86% yield. Payne and Pummerer rearrangements (12, 13) then yielded, in sequence, [1,2-$^{13}C_2$]-(2*R*,3*R*)-4-benzyloxy-1-phenylthiobutane-2,3-diol (**6**), then the corresponding 2,3-isopropylidene derivative, [1,2-$^{13}C_2$]-(2*R*,3*R*)-4-benzyloxy-2,3-*O*-isopropylidene-1-phenylthiobutane-2,3-diol (**7**), followed by the corresponding sulfoxide (**8**) and the *gem*-acetoxy sulfide (**9**). In basic solution the latter undergoes hydrolysis accompanied by inversion (13, 23), to yield the labeled key intermediate, [1,2-$^{13}C_2$]-4-*O*-benzyl-2,3-*O*-isopropylidene-D-threose ([4,4′-$^{13}C_2$]-(4*S*,5*R*)-5-benzyloxymethyl-4-formyl-2,2-dimethyl-1,3-dioxolane)(**10**). The overall yield of **10** from **6** was 71%.

Grignard reaction of **10** with methyl magnesium chloride gave a 2.5:1 diastereomeric mixture of the corresponding methyl carbinols, [2,3-$^{13}C_2$]-5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylitol and -lyxitol (**11**) in 90% yield. The mixture was oxidized with pyridinium dichromate (24) to yield [2,3-$^{13}C_2$]-5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**12**) in 88% yield. Acid hydrolysis removed the isopropylidene protecting group to give [2,3-$^{13}C_2$]-5-*O*-benzyl-1-deoxy-D-xylulose (**13**) (yield 88%), which, on hydrogenolysis in the presence of 10% palladium/carbon gave the desired product, [2,3-$^{13}C_2$]-1-deoxy-D-xylulose (**14**) in quantitative yield. Overall, 10 g bond labeled starting material (**2**) furnished 0.95 g bond labeled 1-deoxy-D-xylulose (**14**) (16% yield).

In preparation for the labeled synthesis, the new steps of the above reaction sequence, from the key intermediate (**10**) to the final product (**14**), were explored with unlabeled material. Unlabeled 4-*O*-benzyl-2,3-*O*-isopropylidene-D-threose (**18**) was obtained in two steps from (−)-2,3-*O*-isopropylidene-D-threitol [(4*R*,5*R*)-4,5-di(hydroxymethyl)-2,2-dimethyl-1,3-dioxolane] (**15**) (Aldrich), by oxidation (15, 16) of the monobenzyl derivative, (4*R*,5*R*)-5-benzyloxymethyl-4-hydroxymethyl-2,2-dimethyl-1,3-dioxolane (**16**) (14). The utility of the *tert*-butyldimethylsilyl protecting group was also investigated. 4-*O*-(*tert*-butyldimethylsilyl)-2,3-*O*-isopropylidene-D-threose (**19**) was obtained from **15** via **17** in two analogous steps (25).

Nonstereospecific Grignard methylation of the aldehyde group of **18** or of **19** with methyl magnesium chloride yielded a diastereomeric mixture (5:2 and 3:2, respectively, for **20** and **21**) of 5-protected-3,4-*O*-isopropylidene-1-deoxy-D-xylitol and -lyxitol. Oxidation of each of the two diastereomeric mixtures, **20** or **21**, either with pyridinium dichromate (24) or with oxalyl chloride – DMSO (26) gave the corresponding 5-protected-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**22**, **23**) in 90% and 78% yield, respectively.

Conversion of the 5-*tert*-butyldimethylsilyl derivative (**23**) into free 1-deoxy-D-xylulose (**27**), either stepwise, using tetrabutylammonium fluoride to yield 3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**26**), followed by hydrolysis with dilute acid, or directly, with sodium fluoride in HCl solution, gave the final product in very poor (ca. 25%) yield. Silyl protection was therefore abandoned in favour of benzyl protection.

Simultaneous removal of both the benzyl (27) and the isopropylidene (27, 28) protecting groups from 5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**22**) using boron trichloride gave the deoxypentulose (**27**) in poorer yield (26%) than stepwise removal of the two groups. Presumably side reactions occur and the reagent and the product form a complex that resists separation even after repeated addition of methanol, followed by flash chromatography. Hydrogenolytic debenzylation of 5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**22**) gave 3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**26**) in 95% yield, from which 1-deoxy-D-xylulose (**27**) was obtained in 75% yield by acid hydrolysis. Conversely, acid hydrolysis of 5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**22**) gave 5-*O*-benzyl-1-deoxy-D-xylulose (**24**) in 88% yield. Hydrogenolysis in the presence of Pd/C then gave the free 1-deoxy-D-xylulose (**27**) in 95% yield. The latter deprotection sequence was chosen for the labeled synthesis.

When 1-deoxy-D-xylulose (**27**) was prepared from 3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**26**) by acid hydrolysis, and the solution was concentrated without complete removal of acid, a crystalline compound was obtained whose physical

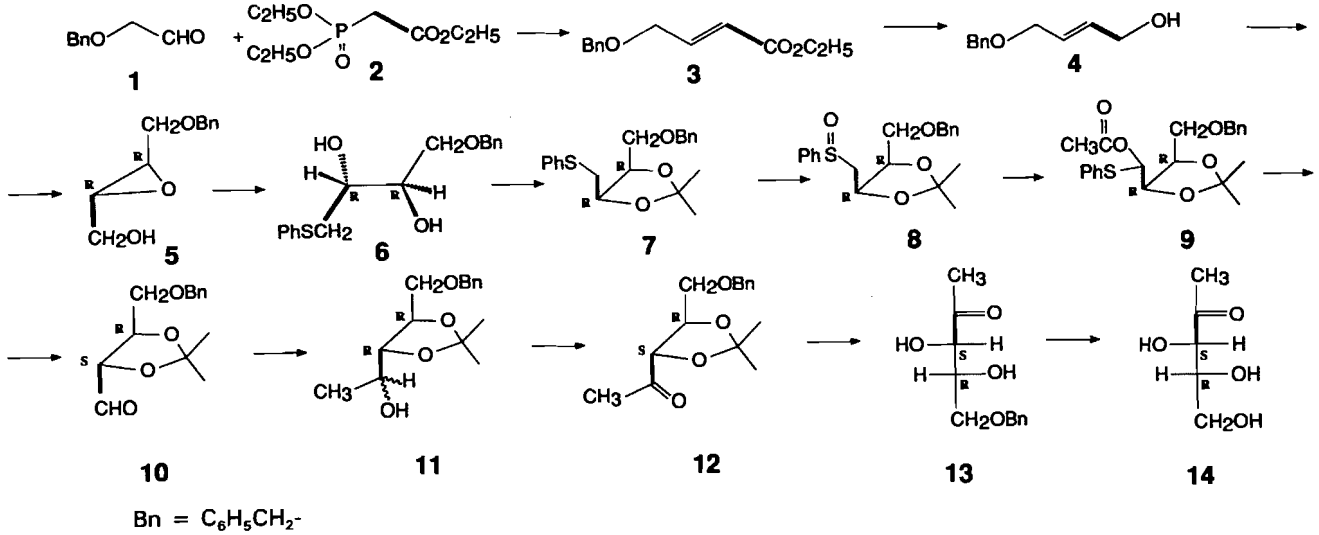
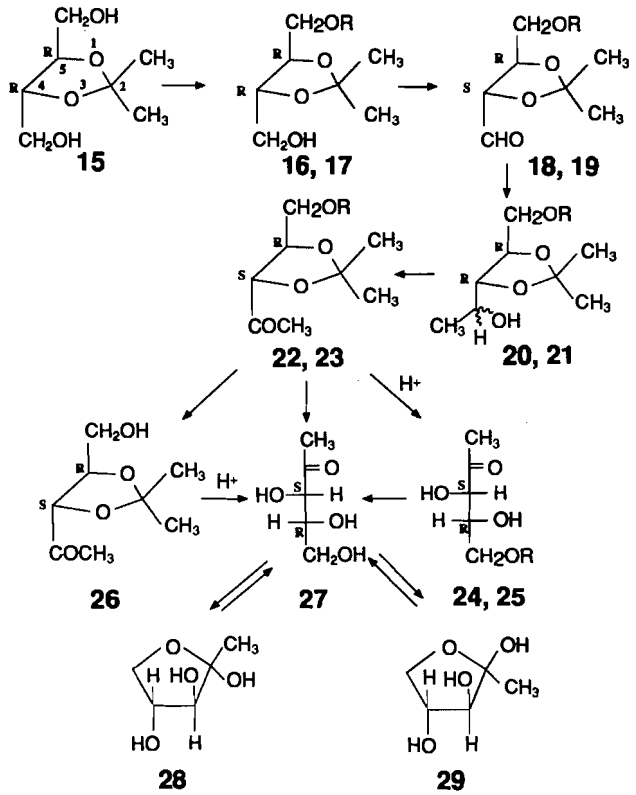
Scheme 1. Synthesis of [2,3-$^{13}C_2$]-1-deoxy-D-xylulose (**14**) from *O*-benzylglycolaldehyde (**1**) and triethyl [1,2-$^{13}C_2$]phosphonoacetate (**2**). ▬ = ^{13}C–^{13}C.



Bn = $C_6H_5CH_2$-

Scheme 2. Synthesis of 1-deoxy-D-xylulose (**27**) from (−)-2,3-*O*-isopropylidene-D-threitol (**15**).



16, 18, 20, 22, 24 R = $C_6H_5CH_2$-
17, 19, 21, 23, 25 R = *tert*-butyldimethylsilyl-

constants (mp 145–146°C, $[\alpha]_D^{20}$ −55.2 (*c* 1, CH_3OH)) were different from those reported (1,3) for 1-deoxy-D-xylulose (**27**).

The structure of this compound was determined by X-ray crystallography. The compound was found to be di-β-1-deoxy-D-xylulofuranose 2,3′:3,2′-dianhydride (**30**), a dimer of β-1-deoxy-D-xylulofuranose (**29**). X-ray structure analysis of **30** (Fig. 1) showed it to contain a non-crystallographic twofold axis relating the two furanose rings, which adopt puckered conformations, with the two methylene groups, C(5) and C(5′), out of plane towards the same side of the molecule. Intramolecular bonding is normal. The OH groups at C(4) and C(4′) are strongly hydrogen bonded: The oxygen atom O(4) forms a hydrogen bond to HO(4′) of one of the neighbouring dimers (at $x+1, y-1, z$: 2.888(1) Å) and the H of O(4) interacts with the furanose ring oxygen, O(5′), of another (at $x, y-1, z$: 2.957(1) Å). This results in a two-dimensional sheet perpendicular to the crystallographic *c*-axis, with the methyl groups (C(1) and C(1′)) on one face and the methylene groups (C(5) and C(5′)) on the other. The crystallographic screw axes (2_1) stack these sheets in the *c*-direction, with methylenes facing methylenes, and methyls intertwined with methyls. The atomic coordinates and equivalent isotropic temperature factors are listed in Table 1.

Experimental

The starting material for the synthesis of 1-deoxy-D-xylulose (**27**) was a commercial product, (−)-2,3-*O*-isopropylidene-D-threitol ((4*R*,5*R*)-4,5-di(hydroxymethyl)-2,2-dimethyl-1,3-dioxolane) (**15**) (Aldrich). This was converted into 4-*O*-benzyl-2,3-*O*-isopropylidene-D-threose (**18**) as well as into 4-*O*-(*tert*-butyldimethylsilyl)-2,3-*O*-isopropylidene-D-threose (**19**) in analogy with published procedures that were employed to synthesize the L-enantiomers. Monobenzylation of (**15**) (14) gave 4-*O*-benzyl-2,3-*O*-isopropylidene-D-threitol (**16**) from which **18** was obtained (15, 16) by Swern oxidation (26). Monosilylation of **15** (25) gave 4-*O*-(*tert*-butyldimethylsilyl)-2,3-*O*-isopropylidene-D-threitol (**17**), Swern oxidation of which gave **19** (25).

(4*R*,5*R*)-5-Benzyloxymethyl-4-(2′-(*RS*)-hydroxyethyl)-2,2-dimethyl-1,3-dioxolane (5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylitol plus 5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-lyxitol) (20)

Methyl magnesium chloride (3 M in THF, Aldrich, 2 equivalents) was added dropwise to a stirred solution of **18** ($[\alpha]_D^{20}$ −19.4 (*c* 1.30, $CHCl_3$); lit. (16) $[\alpha]_D^{21}$ of enantiomer +16.8 (*c*

(s, 2H, OCH_2), 4.63 (s, 2H, $CH_2C_6H_5$), 7.22–7.38 (m, 5 H, C_6H_5). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 208, 137.6, 128.1 (2×), 127.3 (3×), 110.7, 81.6, 77.0, 73.2, 69.9, 26.6, 26.1, 26.0. Anal. calcd. for $C_{15}H_{20}O_4$: C 68.16, H 7.63; found: C 68.06, H 7.71.

5-*O*-Benzyl-1-deoxy-D-xylulose (24)

5-*O*-Benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**22**) (1.0 g, 3.8 mmol) was dissolved in 50 mL of a solution prepared by mixing CH_3CN, H_2O, and 2 M HCl in the ratio 90:6:3 (29). The mixture was stirred for 24 h and was then concentrated, and CH_2Cl_2 (30 mL) was added.

The solution was washed with saturated Na_2CO_3 (2 × 5 mL) and brine. The organic layer was concentrated after drying over Na_2SO_4 and chromatographed on silica gel (230–400 mesh) using the following solvents: 50% ether – petroleum ether until a yellowish fraction came off, then CH_2Cl_2, and finally 5% methanol – CH_2Cl_2 to afford 0.75 g (87%) **24** as a colourless oil. $[\alpha]_D^{20}$ +51.6 (*c* 1.32, CH_2Cl_2). ^1H NMR (200 MHz, $CDCl_3$) δ: 2.22 (s, CH_3), 2.34 (d, 1H, *J* = 7.7 Hz, OH), 3.55 (m, 1H, CH), 3.58 (s, 1H, OH), 3.65 (d, 1H, *J* = 4.5 Hz, COCH), 4.13–4.19 (m, 2H, CH_2O), 4.51 (s, 2H, $OCH_2C_6H_5$), 7.28 (m, 5H, C_6H_5). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 208.1, 137.6, 128.4 (2×), 127.9, 127.8 (2×), 76.3, 73.6, 71.0, 70.4, 25.5. HRMS calcd. for $C_{12}H_{17}O_4$ (M^+ + 1): 225.1127; found: 225.1123. Anal. calcd. for $C_{12}H_{16}O_4 \cdot 0.25\ H_2O$: C 63.00, H 7.27; found: C 62.65, 62.95; H 7.18, 7.08.

(4*R*,5*R*)-5-*O*-(*tert*-Butyldimethylsilyl)oxymethyl-4-(2′-(*RS*)-hydroxyethyl)-2,2-dimethyl-1,3-dioxolane (5-*O*-(*tert*-butyldimethylsilyl)-3,4-*O*-isopropylidene-1-deoxy-D-xylitol plus 5-*O*-(*tert*-butyldimethylsilyl)-3,4-*O*-isopropylidene-1-deoxy-D-lyxitol) (21)

Methyl magnesium chloride (1 M in THF, Aldrich, 3 equivalents) was added dropwise to a stirred solution of **19** (1.4 g) in dry THF (25 mL) at 0°C and the mixture was stirred overnight and allowed to reach room temperature. It was then refluxed for 1 h, cooled, diluted with cold ether (40 mL), and was then added dropwise to an ice-cold saturated aqueous solution of ammonium chloride (75 mL). The phases were separated and the aqueous phase was extracted with ether (3 × 50 mL). The organic extracts were combined, washed with water (2 × 40 mL) and saline (2 × 40 mL), dried over anhydrous $MgSO_4$, filtered, and evaporated. The residual oil was purified by flash chromatography (10% ethyl acetate – hexane 1:3), followed by bulb-to-bulb distillation (oven temp. 140°C, 0.2 Torr; 1 Torr = 133.3 Pa). Yield 1.0 g, (70%) with respect to **19**, mixture of two diastereomers ca. 3:2.

Major, less polar diastereomer: $[\alpha]_D^{20}$ −23.0 (*c* 2.89, $CHCl_3$). ^1H NMR: (500 MHz, $CDCl_3$) δ: 0.1 (s, 6H, $SiMe_2$), 0.9 (s, 9H, Si-*t*Bu), 1.25 (d, 3H, *J* = 6.2 Hz, CH_3CHOH), 1.38, 1.39 (2 × s, 6H, $C(CH_3)_2$), 3.65 (m, 2H, $SiOCH_2$), 3.8 (m, 1H, OCH), 3.89 (m, 2H, OCH, *C*HOH). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 108.9, 84.3, 79.6, 68.3, 64.4, 27.1, 27.0, 26.0, 19.5, 18.2, −5.4. MS(EI) *m/z*: 275 ($M^+ - CH_3$, 10%), 175 (25), 157 (14), 133 (14), 131 (93), 117 (57), 89 (11), 83 (21), 75 (100). HRMS calcd. for $C_{13}H_{27}O_4Si$ ($M^+ - CH_3$): 275.1679; found: 275.1672.

Minor, more polar diastereomer: $[\alpha]_D^{20}$ −7.9 (*c* 1.58, $CHCl_3$). ^1H NMR: (500 MHz, $CDCl_3$) δ: 0.065 (s, 6H, $SiMe_2$), 0.89 (s, 9H, Si-*t*Bu), 1.21 (d, 3H, *J* = 6.2 Hz, CH_3CHOH), 1.39, 1.40 (2 × s, 6H, $C(CH_3)_2$), 3.73 (m, 2H, $SiOCH_2$), 3.8 (m, 2H, 2 OCH), 3.94 (m, 1H, *C*HOH). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 109.2, 82.7, 77.6, 67.5, 63.8, 27.3, 27.2, 25.9, 19.7, 18.3, −5.5. MS(EI) *m/z*: 275 ($M^+ - CH_3$, 12%), 245 (5), 187 (8), 175 (35), 157 (14), 131 (92), 117 (58), 99 (27), 83 (21), 75 (100). HRMS calcd. for $C_{13}H_{27}O_4Si$ ($M^+ - CH_3$): 275.1679; found: 275.1692.

(4*S*,5*R*)-4-Acetyl-5-(*tert*-butyldimethylsilyl)oxymethyl-2,2-dimethyl-1,3-dioxolane (5-*O*-(*tert*-butyldimethylsilyl)-3,4-*O*-isopropylidene-1-deoxy-D-xylulose) (23)

To a stirred solution of oxalyl chloride (0.31 mL, 3.6 mmol, 1.2 equiv.) in dry CH_2Cl_2 (6 mL) at −78°C was added dropwise a solution of DMSO (0.5 mL, 7.2 mmol, 2.4 equiv.) in CH_2Cl_2 (3 mL) over 5 min. After stirring for 15 min, a solution of **21** (0.9 g, 3.1 mmol) in dry CH_2Cl_2 (6 mL) was added over 5 min. and stirring was continued for 2 h at −78°C. Triethylamine (1.7 mL, 12 mmol, 4 equiv.) in CH_2Cl_2 (5 mL) was then added to the reaction mixture and the temperature was allowed to rise to room temperature over 1.5 h. The mixture was diluted with 5 volumes anhydrous ether, the solution was filtered through a Celite pad, and the filtrate was concentrated in vacuo. The residual oil was diluted with ether and washed with water (2 × 5 mL) and salt solution (5 mL). The ether layer was dried over $MgSO_4$, filtered, and evaporated. The 5-*O*-(*tert*-butyldimethylsilyl)-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**23**) so obtained was purified by flash chromatography with 10% ethyl acetate in hexane (Yield 0.7 g). $[\alpha]_D^{20}$ −20.0 (c 2.23, $CHCl_3$). ^1H NMR (500 MHz, $CDCl_3$) δ: 0.09 (s, 6H, $SiMe_2$), 0.9 (s, 9H, Si-*t*Bu), 1.43, 1.46 (2 × s, 6H, $C(CH_3)_2$), 2.29 (s, 3H, $COCH_3$), 3.76 (dd, 1H, *J* = 3.9, 11.3 Hz, CH_2O), 3.88 (dd, 1H, *J* = 3.5, 11.3 Hz, CH_2O), 4.06 (m, 1H, $CHCH_2$), 4.32 (d, 1H, *J* = 7.5 Hz, *C*HCO). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 109.2, 82.7, 77.6, 67.5, 63.8, 27.3, 27.2, 25.9, 19.7, 18.3, −5.5. MS(EI) *m/z*: 288 (M^+, 0.3%), 273 ($M^+ - CH_3$, 3.2) 245 (14),231 (26), 187 (22), 173 (31), 145 (35), 143 (23), 131 (31), 117 (100), 101 (33), 89 (14), 86 (40), 84 (63), 75 (66), 73 (80). HRMS calcd. for $C_{14}H_{28}O_4Si$: 288.1757; found: 288.1784.

(4*S*,5*R*)-4-Acetyl-5-hydroxymethyl-2,2-dimethyl-1,3-dioxolane (3,4-*O*-isopropylidene-1-deoxy-D-xylulose) (26)

*A. By debenzylation of 5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (22)*

A mixture of the benzyl ether **22** (0.16 g, 0.61 mmol) and pre-equilibrated 10% palladium/carbon (Aldrich, wet Degussa type) (0.1 g) in 95% ethanol (6 mL) was hydrogenated (30, 31) for 3 h at room temperature and atmospheric pressure. The mixture was filtered through Celite, and the filtrate evaporated at reduced pressure to afford a white solid. The solid residue was redissolved in a small amount of MeOH and applied to a column of alumina (neutral, Brockmann, Activity 1), equilibrated with CH_2Cl_2. The column was washed with 5% MeOH in CH_2Cl_2. The product (0.10 g, 95%) slowly formed a semisolid mass upon evaporation of the solvent. $[\alpha]_D^{20}$ −19.2 (*c* 1.83, CH_3OH). ^1H NMR (200 MHz, $CDCl_3$) δ: 1.37 (s, 3H, CH_3), 1.41 (s, 3H, CH_3), 2.25 (s, 3H, CH_3CO), 2.22 – 2.36 (br s, 1H, OH), 3.66 (dd, 1H, *J* = 12.0, 4.1 Hz, O-C*H*H), 3.84 (dd, 1H, *J* = 12.0, 3.4 Hz, O-C*H*H), 4.04 (ddd, 1H, *J* = 7.9, 4.1, 3.4 Hz, O-C*H*-CH_2), 4.20 (d, 1H, *J* = 7.9 Hz, O-C*H*-CO). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 209.1, 110.7, 81.6, 78.0, 62.2, 26.7, 26.5, 26.0.

B. By desilylation of 5-O-(tert-*butyldimethylsilyl*)-*3,4*-O-*isopropylidene-1-deoxy-*D*-xylulose (**23**)*

A 0.4 M solution of **23** (0.1 g) in THF was reacted with a 1 M solution of tetrabutylammonium fluoride (2 equiv.) in THF at 0°C with stirring under nitrogen. The progress of the reaction was monitored by TLC (silica gel, pet. ether – ethyl acetate 7:3). When reaction appeared complete (ca. 1 h) the mixture was concentrated in vacuo and the residue applied to a column of alumina (neutral, Brockmann, Activity III), equilibrated with CH_2Cl_2. The column was washed with two bed volumes of CH_2Cl_2 and was then eluted with two bed volumes each of 1% MeOH in CH_2Cl_2, 2% MeOH in CH_2Cl_2 and 3% MeOH in CH_2Cl_2. The product, obtained in poor yield (20–25%) upon evaporation of the solvent, elutes in the 2% and 3% fractions.

A similarly poor yield of 1-deoxy-D-xylulose (**27**) wa obtained when **23** was simultaneously desilylated and hydrolyzed with aqueous HF.

1-Deoxy-D-xylulose (27)

Method A

Acid hydrolysis of 3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**26**) (100 mg, 0.57 mmol) with 2 M HCl in acetonitrile, following the procedure for the conversion of **22** into **24**, gave 1-deoxy-D-xylulose (**27**) (58 mg, 75%), together with a number of unidentified byproducts that gave discrete spots on TLC. One of these by-products, which was obtained in 10% yield (13 mg), was isolated as a crystalline compound and identified as **30** (see below).

Method B

Hydrogenolysis of 5-*O*-benzyl-1-deoxy-D-xylulose (**24**) (0.50 g, 2.2 mmol) in the presence of Pd/C (see conversion of **22** into **26**) gave 1-deoxy-D-xylulose (**27**) (0.29 g, 97%).

Method C

Boron trichloride (1 M in CH_2Cl_2, Aldrich, 2.4 mL, 2.4 mmol) (27, 28) was added dropwise to a solution of 5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**22**) (0.13 g, 0.49 mmol) in CH_2Cl_2 (2 mL) at −78°C. The reaction mixture was warmed to 0°C for 30 min. and then to room temperature for an additional 30 min. Excess BCl_3 was removed under vacuum and 95% aqueous methanol (10 mL) was added and the mixture concentrated. This process was repeated and the crude concentrate chromatographed on neutral alumina (1% MeOH – CH_2Cl_2) to afford a mixture of the cyclized products (**28** and **29**) as an oil (17 mg, 26%).

In aqueous solution, the product exists mainly as the open chain deoxypentulose **27** (66%), together with a 1:1 mixture of the anomeric α and β furanoses **28** and **29** (33%). $[\alpha]_D^{20}$ +22.4 (*c* 1.10, H_2O);[2] (lit. (7) $[\alpha]_D^{21}$ +34 (*c* 1, H_2O)). ^{1}H NMR (200 MHz, D_2O) δ: 1.35, 1.39 (anomers), 2.21 (open chain)(total 3H, 3 s, in the ratio 16:15:67, CH_3), 3.52–3.78 (m, 2H, OCH_2), 4.07–4.33 (m, 2H, CHCH). ^{13}C NMR (50.3 MHz, H_2O) δ: 216.7,79.7, 74.0, 64.7, 28.2.

In methanol solution the product exists mainly as a 1:1 mixture of the two oily cyclized products **28** and **29** (17 mg, 26%). ^{1}H NMR (200 MHz, CD_3OD) δ: 1.27 (s, CH_3), 1.32 (s, CH_3)(anomeric ratio ca. 1:1), 3.19–3.23 (m, 2H, 2(OH)), 3.29–3.33 (m, 4H, 2 × 2(OH)), 3.45–3.74 (m, 4H, 2 × CH_2O), 3.90–4.20 (m, 4H, 2 × (CH, CH)). ^{13}C NMR (50.3 MHz, CD_3OD) δ: 110.4, 105.9; 85.1, 83.8; 79.2. 77.8; 72.8, 71.6; 19.1, 16.9 (ratio of anomers 1:1).

Di-β-1-Deoxy-D-xylulofuranose 2,3′:3,2′-dianhydride (30)

The dimeric compound (**30**) was obtained as colourless crystals in 10% yield as a by-product in the preparation of **27** from **26** by acid hydrolysis (method A). It was recrystallized from methanol/CH_2Cl_2. Melting point: 145–146°C. $[\alpha]_D^{25}$ −55.2 (*c* 1, CH_3OH). ^{1}H NMR (200 MHz, CD_3OD) δ: 1.41 (s, 6H 2×CH_3), 3.60 – 3.70 (m, 4H, 2 × CH_2O), 4.02 (m, 2H, 2 × C*H*OH), 4.12 (d, 2H, *J* = 2.7 Hz, 2 × CH), 4.78 (s, 2H, 2 × OH). ^{13}C NMR (50.3 MHz, CD_3OD) δ: 105.0, 83.0, 77.9, 74.3, 21.6. Anal. calcd. for $C_{10}H_{16}O_6$: C 51.72, H 6.95; found: C 51.09, H 6.84.

Crystal data:

$C_{10}H_{16}O_6$ fw = 232.23

Monoclinic, $a = 6.2580(10)$, $b = 7.999(2)$, $c = 10.547(2)$ Å, β = 90.52(3)°, $V = 527.9(2)$ Å^3, $Z = 2$, $\rho_c = 1.461$ g cm^{-3}, $\mu = 0.121$ mm^{-1} (296(2)° K, MoKα$_1$, λ = 0.71073 Å).

A single crystal of **30** (0.40 × 0.25 × 0.08 mm^3) was glued to a glass fibre. X-ray diffraction data were collected on a Siemens P4 diffractometer with a Mo rotating anode. Variable speed scans (4° – 60°/min in ω, 0.37° in ω on either side of the Kα split) were used for θ–2θ scans of the full sphere of reflections in the range $3.5° < 2\theta < 60.0°$. Three standard reflections were measured after every 97 measurements. No decay was observed. 3386 reflections were collected, and 186 low-angle reflections were recollected at lower power to determine the intensities of several reflections that had overflowed the counter (scale factor = 6.5). Merging of the data resulted in 2953 independent reflections ($R_{int} = 0.019$). Absorption and extinction corrections were not required.

The SHELXTL programs (32) were used for structure solution, refinement, and preparation of diagrams and tables. Direct methods provided a model of all non-hydrogen atoms in the polar space group $P2_1$. Anisotropic refinement and a difference Fourier synthesis revealed all hydrogen atoms, which were subsequently refined isotropically. Full-matrix weighted least-squares refinement on F^2 of 209 parameters using 2953 reflections with $F^2 > -3\sigma$ gave a goodness of fit $S = 1.043$ and a $wR2 = 0.088$, where $S = [\Sigma[w(F_o^2 - F_c^2)^2]/(m-n)]^{1/2}$ for *m* reflections and *n* parameters; $wR2 = [\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]]^{1/2}$; and $w = 1/[\Sigma^2(F_o^2) + (0.0597P)^2]$, $P = [\max(0,F_o^2)/3] + [2F_c^2/3]$.

The traditional *R* equals 0.035, for all values of *F*. The largest difference peak and hole were 0.226 and −0.192 e/Å^3. The absolute configuration of **30** follows from that of its precursor (**27**) whose synthesis from starting materials of known absolute configuration is here described. Scattering factors (33) and anomalous scattering corrections (34) were taken from International Tables for Crystallography, Vol. C.[3]

[2] The value of $[\alpha]_D$ was found to vary from preparation to preparation, due to variation in the proportions of the open chain (**27**) and furanose (**28, 29**) forms that were present.

[3] Tables of bond lengths and angles, of anisotropic temperature factors, of hydrogen atom parameters, of torsion angles, and of least-squares planes may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2.

Tables of bond lengths, bond angles, and hydrogen atom parameters have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

Synthesis of [2,3-$^{13}C_2$]-1-deoxy-D-xylulose (14)

The starting materials, ethyl [1,2-$^{13}C_2$]bromoacetate (Cambridge Isotopes), triethyl [1,2-$^{13}C_2$]phosphonoacetate (**2**) (Aldrich), and *O*-benzylglycolaldehyde (benzyloxyacetaldehyde (Aldrich)) (**1**), were commercial products. Ethyl [1,2-$^{13}C_2$]bromoacetate was converted into triethyl [1,2-$^{13}C_2$]phosphonoacetate (**2**) in 95% yield by a published method (11).[4] Each step in the synthetic sequence leading to the labeled end product was performed repeatedly on a small scale. The products of individual preparations of a given intermediate were combined for the next step, when necessary. A total of 10 g **2** was converted into 0.95 g **14**, a net yield of 16%.

Triethyl [1,2-$^{13}C_2$]phosphonoacetate (2): bp 100–102°C at 0.6 torr (lit. (11) bp 109–109.5°C at 0.8 torr). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.25 (t, 3H, J = 7.1 Hz, ester CH_2CH_3), 1.31 (t, 6H, J = 7.1 Hz, 2(PO-CH_2CH_3)), 2.92 (ddd, 2H, $^1J_{^{13}C,H}$ = 128.9 Hz, $J_{P,H}$ = 21.6 Hz, $^2J_{^{13}C,H}$ = 7.4 Hz, $^{13}CH_2{}^{13}CO$), 4.06 – 4.23 (m, 6H, 3(OCH_2CH_3)). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 165.8 (dd, $J_{^{13}C,^{13}C}$ = 58.4 Hz, $J_{^{13}C,P}$ = 7.0 Hz), 62.7, 62.6, 61.5, 34.3 (dd, $J_{^{13}C,P}$ = 134.5 Hz, $J_{^{13}C,^{13}C}$ = 58.4 Hz), 16.3, 16.2, 14.0.

*Ethyl [1,2-$^{13}C_2$]-4-benzyloxy-*E*-but-2-enoate (3) (17–19)*

Triethyl [1,2-$^{13}C_2$]phosphonoacetate (**2**) (2.0 g, 8.9 mmol, Aldrich) in benzene (6 mL) was added dropwise over 20 min to a suspension of NaH (220 mg, 9 mmol) in benzene (30 mL) at 22°C. The mixture was stirred for 1.5 h at 22°C and *O*-benzylglycolaldehyde (**1**) (1.35 g, 9.0 mmol, Aldrich) in benzene (5 mL) was added dropwise over 10 min. A gelatinous precipitate began to form as the aldehyde was added. The mixture was stirred for 3 h, water was added, and the layers separated. The aqueous layer was washed with ether (3×) and the combined organic extracts were dried over $MgSO_4$. Concentration followed by chromatography (5% ether – hexanes) on silica gel (230–400 mesh) gave **3** (1.5 g, 78%) as a colourless oil. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.25 (t, 3H, J = 7.1 Hz, O-CH_2CH_3), 4.10–4.23 (m, 4H, CH_2-CH=, O-CH_2CH_3), 4.52 (s, 2H, CH_2-C_6H_5), 6.11 (tddd, 1H, $J_{^{13}C,H}$ = 164.0 Hz, $^3J_{H,H}$ = 15.8 Hz, $^2J_{^{13}C,H}$ = 3.3, $^2J_{H,H}$ = 2.0 Hz, ^{13}C-H), 6.88–7.05 (m, 1H, C-H), 7.27–7.34 (m, 5 H, C_6H_5). ^{13}C NMR (50.3 Hz, $CDCl_3$) δ: 166.2 (d, J = 75.49 Hz), 144.1 (d, J = 70.5 Hz), 137.6, 128.4 (2×), 127.7, 127.5 (2×), 121.3 (d, J = 75.5 Hz), 72.6, 68.5 (d, J = 6.0 Hz), 60.3, 14.2. MS (EI) *m/z*: 222 (M^+, 1%), 193 (2), 110 (10), 91 (100); (CI) *m/z*: 240 ($M^+ + NH_3$, 100%), 223 ($M^+ + 1$, 16). HRMS calcd. for $^{13}C_2C_{11}H_{16}O_3$: 222.1166; found: 222.1166.

*[1,2-$^{13}C_2$]-4-Benzyloxy-*E*-but-2-en-1-ol (4) (19)*

Diisobutyl aluminium hydride (21) (1.5 M solution in toluene, Aldrich, 9.4 mL, 14.1 mmol) was added dropwise over 10 min to a solution of **3** (1.25 g, 5.6 mmol) in methylene chloride (30 mL) at 0°C (cf. ref. 21). After stirring for 6 h, excess methanol was added while the temperature was maintained between 0 and 5°C. The resulting white gelatinous precipitate was filtered through celite, washed with hot methanol, and the filtrate was concentrated. Chromatography (20% ethyl acetate – petroleum ether) on silica gel (230–400 mesh) gave **4** (1.0 g, 99%) as a colourless oil. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.38 (br s, 1H, OH), 4.12 (dm, 2H, J = 148.4 Hz, $^{13}CH_2$-O), 5.89 (dm, 1H, J = 148.9 Hz, =^{13}CH), 5.74–5.90 (m, 1H, =CH), 7.26–7.39 (m, 5 H, C_6H_5). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 138.1, 132.2 (d, J = 45.9 Hz), 128.4 (2×), 127.7 (2×), 127.6, 72.3, 70.1, 62.9 (d, J = 46.0 Hz). MS (CI) *m/z*: 198 ($M^+ + NH_3$, 100%), 163 ($M^+ + H - H_2O$, 11).

[1,2-$^{13}C_2$]-(2R,3R)-4-Benzyloxy-2,3-epoxybutan-1-ol ([1,2-$^{13}C_2$]-(2R,3R)-4-benzyloxymethyl-2-hydroxymethyl-2,3-oxirane) (5) (12, 19, 22)

To a solution of methylene chloride (80 mL) at −20°C was added sequentially titanium tetraisopropropoxide (2.8 mL, 9.35 mmol) and D-(−)-diisopropyl tartrate (2.5 mL, 11.7 mmol) in methylene chloride (5 mL) and the mixture stirred for 10 min. [1,2-$^{13}C_2$]-4-Benzyloxy-*E*-but-2-en-1-ol (**4**) (1.5 g, 8.3 mmol) in methylene chloride (5 mL) was added and the mixture stirred for 2 h at −20°C and then stored overnight at −18°C. After 18 h, aqueous saturated Na_2SO_4 solution (8 mL) and ether (8 mL) were added to the reaction mixture, which was stirred for 1 h at 22°C. After filtration through Celite, the filtrate was concentrated and diluted with ether (63 mL). 1 N NaOH solution (14 mL) was added to the ethereal solution and the resulting mixture stirred 30 min at 0°C. The ether layer was separated and the aqueous layer washed with ether (2×). The combined ether extracts were washed with brine, dried, and concentrated. Chromatography (20% ethyl acetate – petroleum ether) on silica gel (230–400 mesh) gave **5** as a colourless oil (1.4 g, 86%). $[\alpha]_D^{20}$ +28.8 (*c* 1.68, CH_2Cl_2) (lit. (14) $[\alpha]_D^{22}$ of enantiomer: −21 (*c* 0.97, $CHCl_3$)). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.13 (br s, 1H, OH), 2.60–3.37 (m, 2H, O-CH, O-CH*H*), 3.43–3.79 (m, 3H, $^{13}CH_2$-OH, O-C*H*H), 3.90–4.41 (m, 1H, O-^{13}CH), 4.57 (AB q, 2H, J = 12.1 Hz, O-CH_2), 7.32–7.38 (m, 5H, C_6H_5). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 137.7, 128.4 (2×), 127.7 (2×), 73.3, 69.6, 61.1 (d, J = 46.2 Hz), 55.7 (d, J = 46.2 Hz), 54.4. MS (EI) *m/z*: 195 (M^+ − H, 5%), 177 (3), 107 (92), 91 (100); (CI) *m/z*: 214 ($M^+ + NH_3$, 100%). HRMS calcd. for $^{13}C_2C_9H_{13}O_3$ (M^+ − H): 195.0932; found: 195.0962.

[1,2-$^{13}C_2$]-(2R,3R)-4-Benzyloxy-1-phenylthiobutane-2,3-diol (6) (12)

A solution of the epoxide **5** (580 mg, 3.0 mmol) in *tert*-butanol (15 mL) was mixed with a 0.5 M NaOH solution (15 mL, 7.5 mmol) and nitrogen gas was passed vigorously through the mixture for 40 min. The mixture was then heated to reflux in a nitrogen atmosphere and thiophenol (400 μL, 40 mmol) in *tert*-butanol (3 mL) was added over 3 h by syringe pump. The reaction mixture was cooled to room temperature, the layers were separated, and the aqueous layer was washed with methylene chloride (3 × 5 mL). The combined organic extracts were washed successively with 1 N NaOH solution, water, and brine, dried over $MgSO_4$, and concentrated to afford the crude diol as a solid. Recrystallization from methylene chloride and hexanes affords **6** as white needles, mp 102–103°C (470 mg, 52%). $[\alpha]_D^{20}$ −22.2 (*c* 1.11, CH_2Cl_2) (lit. (12) $[\alpha]_D^{25}$ of enantiomer: +40.3 (*c* 0.77, EtOH)). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.55–3.00 (m, 3H, $^{13}CHHSC_6H_5$, 2(OH)), 3.29–3.36 (m, 1H, CH*H*SC_6H_5), 3.55–4.10 (m, 4H, O-CH_2, 2(O-CH)), 4.53 (s, 2H, O-CH_2-C_6H_5), 7.14–7.39 (m, 10H, 2(C_6H_5)). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 135.0, 129.8 (2×), 129.0 (2×), 128.5 (2×), 127.9 (2×), 127.8 (2×), 126.6, 73.6,

[4] Literature references in this section refer to non-enriched (and in one case (19) singly enriched) compounds.

71.9, 70.3 (d, J = 38.22 Hz), 38.0 (d, J = 38.22 Hz). MS (EI) *m/z*: 306 (M^+, 15%), 167 (20), 124 (43), 91 (100). HRMS calcd. for $^{13}C_2C_{15}H_{20}O_3S$: 306.1200; found: 306.1208.

[4,4′-$^{13}C_2$]-(4R,5R)-5-Benzyloxymethyl-4-phenylthiomethyl-2,2-dimethyl-1,3-dioxolane ([3,4-$^{13}C_2$]-(2R,3R)-2,3-O-isopropylidene-1-benzyloxy-4-phenylthiobutane-2,3-diol, ([3,4-$^{13}C_2$]-(2R,3R)-2,3-O-isopropylidene-1-benzyl-4-phenylthiobutan-1,2,3-triol) (7) (12)

Diol **6** (320 mg, 1.0 mmol) in methylene chloride (10 mL) was treated with 2,2-dimethoxypropane (250 μL, 2.2 mmol) and phosphorus oxychloride (1 drop) was added. The solution was stirred overnight at 22°C. 15% Aqueous NaOH solution (5 drops) was added and the mixture stirred for 30 min. After adding water, the layers were separated and the organic fraction dried and concentrated to afford **7** as a colourless oil (360 mg, 99%). A small amount of the product was chromatographed (5% ether – petroleum ether) on silica gel (230 – 400 mesh) for analysis. Compound **7** slowly reverts to **6** when kept in the refrigerator for several days. $[\alpha]_D^{20}$ −2.27 (c 1.01, CH_2Cl_2). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.34 (s, 3H, CH_3), 1.46 (s, 3H, CH_3), 3.31 (dm, 2H, J = 77.5 Hz, $^{13}CH_2$-S-C_6H_5), 3.53 – 3.64 (m, 2H, O-CH_2), 4.31 (dm, 1H, J = 150.4 Hz, O-^{13}CH), 4.31 – 4.37 (m, 1H, O-CH), 4.56 (AB q, 2H, J = 12.0 Hz, O-$CH_2C_6H_5$), 7.17 – 7.37 (m, 10 H, 2(C_6H_5)). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 137.6, 135.9, 129.4 (2×), 128.9 (2×), 128.4 (2×), 127.8 (2×), 126.2 (2×), 108.8, 76.1, 75.7 (d, J = 40.39), 73.6, 68.4, 39.9 (d, J = 40.39), 28.0, 25.4. MS (EI) *m/z*: 346 (M^+, 7%), 199 (5), 167 (25), 109 (12), 91 (100). HRMS calcd. for $^{13}C_2C_{18}H_{24}O_3S$: 346.1513; found: 346.1523.

[4,4′-$^{13}C_2$]-(4R,5R)-5-Benzyloxymethyl-4-phenylthiomethyl-2,2-dimethyl-1,3-dioxolane sulfoxide ([3,4-$^{13}C_2$]-(2R,3R)-2,3-O-isopropylidene-1-benzyloxy-4-phenylthiobutane-2,3-diol sulfoxide) (8) (12)

m-Chloroperoxybenzoic acid (50–55%, 200 mg, ca. 0.58 mmol) dissolved in methylene chloride (6 mL) was added from a dropping funnel to **7** (200 mg, 0.58 mmol) in methylene chloride (6 mL) at −20°C. After stirring for 1 h, the mixture was washed with 1 N NaOH solution (2×), water (2×), and brine, dried ($MgSO_4$), and concentrated to afford the oily product (206 mg, 99%) as a mixture of diastereomers. This product was used without further purification for the next step. When the preparation of the sulfoxide is carried out on a large scale (>1 g starting material) further oxidation takes place and a significant amount of the sulfone (>5%) is formed as a by-product. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.29, 1.42, 1.43, 1.49 (s, 6H, 2(CH_3)), 2.31 – 3.20 (m, 2H, $^{13}CH_2$-S), 3.24 – 3.75 (m, 2H, O-CH_2), 4.18 – 4.61 (m, 3H, O-^{13}CH, O-$CH_2C_6H_5$), 4.93 – 5.12 (m, 1H, O-CH), 7.14 – 7.71 (m, 10 H, 2(C_6H_5)). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 137.7, 131.2, 131.1, 129.2 (2×), 129.0 (2×), 128.3 (2×), 128.2 (2×), 127.7 (2×), 124.6 (2×), 123.6, 108.7, 108.6, 76.0, 75.4, 75.2, 73.4, 73.2, 71.5 (d, J = 39.9 Hz), 70.5 (d, J = 40.0 Hz), 68.2, 66.7, 66.1, 59.6 (d, J = 40.1 Hz), 57.6 (d, J = 40.0 Hz), 27.7, 25.2. MS (EI) *m/z*: 363 (M^+ + 1, 1%), 237 (16), 125 (52), 91 (100). HRMS calcd. for $^{13}C_2C_{18}H_{25}O_4S$ (M^+ + 1): 363.1550; found: 363.1533.

[4,4′-$^{13}C_2$]-(4R,5R)-5-Benzyloxymethyl-4-(α-RS-α-acetoxy-α-phenylthio)methyl-2,2-dimethyl-1,3-dioxolane ([3,4-$^{13}C_2$]-(2R,3R)-2,3-O-isopropylidene-1-benzyloxy-4-phenylthio-4-acetoxybutane-2,3-diol) (9) (12)

Sodium acetate (2.70 g, 33 mmol) was added to **8** (2.10 g, 5.8 mmol) dissolved in acetic anhydride (50 mL) and the mixture refluxed under nitrogen for 8 h. After cooling to room temperature, the reaction mixture was washed successively with saturated $NaHCO_3$ solution, water, and brine, dried ($MgSO_4$), and concentrated. Chromatography (10% ether – hexanes) afforded the oily product **9** (1.65 g, 73%) as a 5:1 mixture of diastereo-mers. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.32, 1.46, 1.48 (s, 6H, 2(CH_3)), 1.90, 2.06 (1:4.7) (s, 3H, $COCH_3$), 3.52–3.80 (m, 2H, O-CH_2), 4.28 (dm, 1H, J = 143.5 Hz, O-^{13}CH), 4.37 (m, 1H, O-CH), 5.59 (m, 2H, O-$CH_2C_6H_5$), 6.12 (dm, 1H, J = 143.5 Hz, ^{13}CH-S), 7.26–7.50 (m, 10 H, 2(C_6H_5)). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 169.0, 137.5, 134.5, 133.5 (2×), 130.7, 128.2 (3×), 128.6, 128.5 (2×), 128.3 (2×), 128.1, 127.7, 127.5, 109.2, 81.9, 80.6, 79.6, 79.1, 78.2, 77.3, 76.8, 76.6, 75.6, 73.3, 66.1, 27.0, 25.3, 24.8, 20.9. MS (EI) *m/z*: 404 (M^+, 1%), 344 (4), 295 (3), 145 (53), 91 (100); (CI) *m/z*: 422 (M^+ + NH_3, 18%), 354 (100).

[4,4′-$^{13}C_2$]-(4R,5R)-5-Benzyloxymethyl-4-formyl-2,2-dimethyl-1,3-dioxolane ([1,2-$^{13}C_2$]-4-O-benzyl-2,3-O-isopropylidene-D-threose, [1,2-$^{13}C_2$]-(2S,3R)-4-O-benzyl-2,3-O-isopropylidene-2,3,4-trihydroxybutanal, [4,4′-$^{13}C_2$]-(2S,3R)-5-(phenylmethoxy)methyl]-2,2-dimethyl-1,3-dioxolane-4-carboxaldehyde) (10) (23)

Potassium carbonate (1.30 g, 9.0 mmol) was added to a solution of **9** (1.50 g, 3.8 mmol) in methanol (50 mL) and the mixture stirred overnight at 22°C. Under these conditions hydrolysis of the acetoxy phenylthio function is accompanied by inversion (13, 23). The solvent was removed in vacuo, methylene chloride (15 mL) was added, and the mixture was washed with 0.5 N NaOH solution (2×) and brine. Drying ($MgSO_4$) followed by concentration gave the crude aldehyde **10** (940 mg, 99%), which was used without further purification since it is reported (16) that the intensity of the CHO proton signal drops to one half after 12 h. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.41 (s, 3H, CH_3), 1.48 (s, 3H, CH_3), 3.30–3.90 (m, 3H, O-^{13}CH, O-CH_2), 4.15–4.32 (m, 1H, O-CH), 4.59 (s, 2H, $CH_2C_6H_5$), 7.28–7.34 (m, 5 H, C_6H_5), 9.73 (ddd, 1H, J = 178.0 Hz, 26.0 Hz, 1.40 Hz, ^{13}CHO).

[4,4′-$^{13}C_2$]-(4R,5R)-5-Benzyloxymethyl-4-(2′-(RS)-4-hydroxyethyl-2,2-dimethyl-1,3-dioxolane ([2,3-$^{13}C_2$]-5-O-benzyl-3,4-O-isopropylidene-1-deoxy-D-xylitol plus [2,3-$^{13}C_2$]-5-O-benzyl-3,4-O-isopropylidene-1-deoxy-D-lyxitol) (11)

Grignard methylation of [1,2-$^{13}C_2$]-4-*O*-benzyl-2,3-*O*-isopropylidene-D-threose (**10**) and work-up was carried out, starting with 900 mg (3.6 mmol) **10** as described for the unlabeled compound (**18** → **20**). Yield 870 mg (91%). Ratio of diastereomers 2.5:1. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.20 (m, 6H, 2(CH_3)), 1.33, 1.34 (s, 3H, $^{13}CHCH_3$, 2.5:1), 2.80 (br s, 1H, OH), 3.21–3.72 (m, 3H, O-CH_2, O-CH), 3.91–4.22 (m, 2H, O-^{13}CH, ^{13}CH-OH), 4.53 (s, 2H, $CH_2C_6H_5$), 7.26–7.29 (m, C_6H_5). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 137.7, 137.5, 128.4 (2×), 127.8 (2×), 127.6, 109.1, 109.0, 82.9 (d, J = 42.8), 82.3 (d, J = 40.8), 81.9, 81.2, 73.6, 67.8 (d, J = 42.3), 67.5 (d, J = 40.8), 27.1, 26.9, 19.9, 19.7. MS (EI) *m/z*: 268 (M^+, 0.5%), 269 (M^+ + H, 6), 253 (54), 210 (20), 91 (100); (CI) *m/z*: 286 (M^+ + NH_3, 30%), 268 (9). HRMS calcd. for $^{13}C_2C_{13}H_{23}O_4$ (M^+ + H): 269.1663; found: 269.1664.

[2,3-$^{13}C_2$]-5-O-Benzyl-3,4-O-isopropylidene-1-deoxy-D-xylulose ([4,4'-$^{13}C_2$]-(4S,5R)-4-acetyl-5-benzyloxymethyl-2,2-dimethyl-1,3-dioxolane) (12)

Oxidation of **11** and work-up was carried out, starting with 1.40 g (5.3 mmol) **11**, as described for the unlabeled compound (**20** → **22**). Yield 1.30 g (93%). $[\alpha]_D^{20}$ −17.4 (*c* 1.50, CH_2Cl_2). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.41 (s, 3H, CH_3), 1.45 (s, 3H, CH_3), 2.24 (d, 3H, *J* = 4.0 Hz, $CH_3{}^{13}CO$), 3.59–3.82 (m, 3H, O-CH_2, O-^{13}CH), 4.14–4.21 (m, 1H, O-CH), 4.58 (s, 2H, $CH_2C_6H_5$), 7.29–7.32 (m, 5H, C_6H_5). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 208.2 (d, *J* = 45.9 Hz), 137.7, 128.2 (2×), 127.5 (2×), 110.9, 81.7 (d, *J* = 45.9 Hz), 77.0, 73.4, 70.1, 26.8, 26.1 (2×). MS (EI) *m/z*: 266 (M^+, 3%), 222 (11), 91 (100); (CI) *m/z*: 284 ($M^+ + NH_3$, 94%), 267 (M^+ + H, 70), 209 (100). HRMS calcd. for $^{13}C_2C_{13}H_{20}O_4$: 266.1428; found: 266.1425.

[2,3-$^{13}C_2$]-5-O-Benzyl-1-deoxy-D-xylulose (13)

Hydrolysis of 5-*O*-benzyl-3,4-*O*-isopropylidene-1-deoxy-D-xylulose (**12**) (600 mg, 2.3 mmol) and work-up was carried out as described for the unlabeled compound (**22** → **24**). Yield 460 mg (90%). $[\alpha]_D^{20}$ 50.43 (*c* 1.25, CH_2Cl_2). ^{1}H NMR (200 MHz, $CDCl_3$) δ: 2.23 (dd, 3H, *J* = 6.04 Hz, 1.27 Hz, $CH_3{}^{13}CO$), 2.8 (br s, 1H, OH), 3.39 (s, 1H, OH), 3.57–3.60 (m, 2H, O-CH_2), 3.78–4.22 (m, 2H, O-^{13}CH, O-CH), 4.53 (s, 2H, $CH_2C_6H_5$), 7.24–7.37 (m, 5 H, C_6H_5). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 208.1 (d, *J* = 39.1 Hz), 137.4, 128.2 (2×), 127.6 (3×), 77 (d, *J* = 39.4 Hz), 73.3, 70.7, 70.5, 25.5. MS (EI) *m/z*: 227 (M^+ + H, 2%), 226 (M^+, 0.5), 136 (5), 91 (100); (CI) *m/z*: 244 ($M^+ + NH_3$, 100). HRMS calcd. for $^{13}C_2C_{10}H_{17}O_4$ (M^+ + H): 227.1194; found: 227.1192.

[2,3-$^{13}C_2$]-1-Deoxy-D-xylulose (14)

Hydrogenolysis of the benzyl ether **13** (300 mg, 1.3 mmol) in the presence of 10% palladium/carbon, as described for the unlabeled compound (**24** → **27**), gave [2,3-$^{13}C_2$]-1-deoxy-D-xylulose (**14**) in quantitative yield (180 mg) as a colourless oil. ^{1}H NMR (200 MHz, CD_3OD) δ: 1.23–1.37 (m, 3H, $CH_3{}^{13}$C-OH), 2.16 (dd, 3H, *J* = 6.1 Hz, 4.9 Hz, $CH_3{}^{13}CO$) ($CH_3{}^{13}$C-OH:$^{13}COCH_3$ = 2.1:1), 3.15–3.23 (m, 2H, 2(OH)), 3.24–4.6 (m, 5 H, CH-^{13}CH, O-CH_2, OH). ^{1}H NMR (200 MHz, D_2O) δ: 1.30–1.34 m, 3H, $CH_3{}^{13}$C-OH), 2.17 (d, *J* = 4.66 Hz, $CH_3{}^{13}CO$) ($CH_3{}^{13}$C-OH:$CH_3{}^{13}CO$ = 1:1.5), 3.40–4.41 (m, 4H, O-CH_2, ^{13}CH-CH). ^{13}C NMR (50.3 MHz, CD_3OD) δ: 212.2 (d, *J* = 41.4 Hz), 110.6 (d, *J* = 49.5 Hz), 105.8 (d, *J* = 46.4 Hz), 85.1 (d, *J* = 47.0 Hz), 83.6 (d, *J* = 48.9 Hz), 78.4 (d, *J* = 41.4 Hz), 77.6, 72.6, 71.2, 19.1, 16.8, 16.6. ^{13}C NMR (50.3 MHz, D_2O) δ: 213.1 (d, *J* = 40.6 Hz), 109.4 (d, *J* = 48.5 Hz) 105.5 (d, *J* = 47.1 Hz), 82.7 (d, *J* = 46.9 Hz), 81.3 (d, *J* = 46.5 Hz), 77.2 (d, *J* = 41.2 Hz), 78.3, 72.8, 71.8, 16.9, 14.8. MS (CI) *m/z*: 154 ($M^+ + NH_3$, 90%), 136 (M^+, 100), 119 (70), 101 (36).

Acknowledgment

This investigation was supported by a research grant (GM50778) (to I.D.S) from the National Institute of General Medical Sciences, U.S. Public Health Service, which is gratefully acknowledged.

Comparison of calcium complexation of some carboxylic acids derived from D-glucose and D-fructose

Hélène Bazin, Alain Bouchu, Gérard Descotes, and Michelle Petit-Ramel

Abstract: The aim of this work was to compare calcium sequestering behaviour of 11 carboxylic acids derived from carbohydrates, and to study the influence of molecular structure on the calcium complexation. For this purpose, various carboxylic acids derived from methyl D-glucopyranoside, methyl D-fructopyranoside, and methyl D-fructofuranoside were synthesized and studied using an ion selective electrode to determine calcium complex formation constants. Complexation sites of carbohydrate skeletons were determined using ^{13}C NMR.

Key words: Ca(II) complexation, carboxylic acids, fructofuranosides, fructopyranosides, glucopyranosides.

Résumé : Le but de ce travail est de comparer la complexation des ions calcium de 11 dérivés carboxyliques de sucres, et d'étudier l'influence de leur structure moléculaire sur cette complexation. Pour cela, divers acides carboxyliques dérivés des D-glucopyranoside, D-fructopyranoside et D-fructofuranoside de méthyle ont été synthétisés. Les constantes des équilibres de complexation ont été determinées à l'aide d'une électrode sélective réversible aux ions calcium. Les sites de complexation des squelettes sucres ont été déterminés par rmn ^{13}C.

Mots clés : complexation du Ca(II), acides carboxyliques, fructofuranosides, fructopyranosides, glucopyranosides.

Introduction

It is well known that the use of sodium tripolyphosphate (STP) in detergent formulations as a calcium and magnesium sequestering agent is subject to regulation because it leads to eutrophication of surface waters including lakes and seas (1–5). For this reason, extensive studies have been carried out with the aim of finding an alternative for STP that meets all requirements. The main demands of such substitutes are good sequestration (Ca and Mg), good biodegradability/biocompatibility, low price, good solubility in water, and nontoxicity.

Up to now the intensive search for substitutes for STP has resulted in only a few systems meeting the technical, commercial, and environmental requirements. These substitutes include complexing agents (nitrilotriacetate (NTA) and citrate), a precipitating agent (sodium carbonate), and an inorganic ion exchanger (zeolite NaA).

The now commonly used alternative for STP is zeolite NaA (6–9), an inorganic ion exchanger that has several attractive properties: it is cheap, the calcium binding is satisfactory, and the substance is nontoxic. However, there are also some drawbacks involved in its use, namely, low solubility in water and slow binding of magnesium, especially at lower washing temperatures (6, 9, 10). Moreover, deposits (incrustations) formed on the fabrics during the washing process do not dissolve. In view of these negative aspects, a so-called cobuilder is added, which prevents the formation of incrustation and acts as a carrier, transporting the calcium and the magnesium ions to the zeolite NaA (9).

Polyacrylate and copolymers of acrylate and maleate are widely used for this purpose and they generally show optimal performance for incrustation inhibition. These copolymers are reported to be physiologically safe (11) but they are not biodegradable, which makes their long-term application unattractive.

For this reason, the development of (bio-)degradable detergent additives is of considerable importance. Carbohydrates may serve as an alternative starting material for the preparation of polycarboxylic acids since (*i*) carbohydrates are inexpensive renewable materials and (*ii*) carbohydrate-derived products are expected to be readily (bio-)degradable via hydrolysis of the acid-labile acetal bonds.

In the last decade ether carboxylic acids derived from carbohydrates have been of importance because of their multiple properties. They can be obtained by several reactions (Fig. 1*a*): oxidation of carbohydrate with or without ring opening, carboxymethylation, ethoxylation of carbohydrate with subsequent hydrolysis of hydroxyl to carboxyl groups, graft copolymerization of carbohydrates with acrylic acid (or derivatives), and cyanoethylation followed by subsequent hydrolysis of nitriles to carboxyl groups.

Actually, the most useful and most studied products are oxidized (12–19) and carboxymethylated (13, 20, 21) polysaccha-

rides. The first are obtained by periodic oxidation of polysaccharides with cleavage of vicinal diol, the second by carboxymethylation of polysaccharides. These latter show better calcium sequestering capacity than STP.

Oxidation products of adduct carbohydrate – ethylene oxide present good performance, but the cost of this oxidation method limits its industrial application (22, 23).

Copolymerization of carbohydrate with acrylic acid leads to a graft copolymer, which possesses good anti-incrustation properties (24–27).

Currently, the number of ether carboxylic acids obtained by hydrolysis of cyanoethylated carbohydrates is limited. However, nitriles, which are carboxylic acid precursors, make the cyanoethylation a very attractive way to obtain such compounds.

Consequently we first synthesized carboxylic acids from carbohydrates by cyanoethylation and subsequent hydrolysis of the nitriles to carboxylic acids (Fig. 1*b*). We then determined the calcium complex formation constants of these acids, using a calcium selective electrode.

Study of carboxylic derivatives of methyl D-glucopyranoside **1–8** permits us to particularize the influence of both carboxylic groups and anomeric configuration on calcium sequestering properties. Comparison of percarboxylic derivatives of methyl D-glucopyranoside, **4** and **8**, methyl D-fructopyranoside, **9**, and methyl D-fructofuranoside, **10** and **11**, allows us to compare, on the one hand, the influence of the carbohydrate and, on the other hand, the influence of the pyranic or furanic ring on the calcium complexation.

Experimental

Syntheses of carboxylic acids **1–11** derived from carbohydrates have been described in a previous work (28). These new carboxylic acids were obtained by cyanoethylation of protected or unprotected D-glucose and D-fructose. The acidic alcoholysis of these cyanoethylated carbohydrates leads to the corresponding methyl esters, which were saponified to the carboxylic acids. All new cyanoethylated compounds, methyl esters, and carboxylic acids were fully characterized by ^1H and ^{13}C NMR and microanalysis.

The stability constants of the calcium complexes were determined using a calcium selective electrode. A Corning digital 250 expanded-scale pH-meter, a calcium electrode Tacussel F 2112 Ca, and a single-junction Tacussel XR 100 reference electrode were used to follow the variation in Ca^{2+} activity of an aqueous $CaCl_2$ solution by titration with a sequestering compound. All titrations were carried out under an atmosphere of nitrogen at 25 + 0.5°C.

The calibration curve of the calcium ion selective electrode was obtained by measuring the activity of Tacussel aqueous standard $CaCl_2$ solutions (10^{-2}, 5×10^{-3}, 10^{-3}, 5×10^{-4}, 10^{-4}, and 5×10^{-5} M).

The pH-meter was calibrated and the electrode assembly standardized at pH 3.00, pH 7.00, and pH 10,00 with buffer solutions obtained from Aldrich.

Determination at fixed sequestering compound concentration

Aqueous sodium hydroxide (maintained under nitrogen atmosphere) was added to 100 mL of an aqueous $CaCl_2$ solution (μ = 0.1 M, KCl) and 2 mL of an aqueous sequestering compound solution (0.1 M) to obtain pH variations of 0.1.

Determination at fixed pH

The polycarboxylate compound (2.0 mL of 0.1 M aqueous solution) was added in 20 portions to 100 mL of an aqueous $CaCl_2$ solution (μ = 0.1 M, KCl). The pH was fixed at 10 by adding aqueous NH_3.

The protonation constants of each carboxylic acid were determined by protometric measurements.

^{13}C (50.32 MHz) NMR spectra were recorded on a Bruker AC 200 spectrometer.

Results and discussion

After validation of our measurements and our data processing with α-hydroxyacids, complexation by the carboxylic acids **1–11** was examined.

α-Hydroxyacids

For this group the reference compounds were racemic lactic acid, HOOC-CHOH-CH_3; malic acid, HOOC-CHOH-CH_2COOH; and citric acid, HOOC-COH-$(CH_2COOH)_2$.

Calcium complexation depends on the pH of the solution and, although detergency studies are made at basic pH, we first considered the pH influence on the calcium complexation at a constant [ligand]/[calcium] ratio (Fig. 2*a*) and, second, the calcium ion concentration versus the ligand concentration at a constant alkaline pH (Fig. 2*b*).

Metal and ligand concentrations were fixed, respectively, at 10^{-3} M and 2×10^{-3} M and measurements were carried out between pH 3 and 12 (Fig. 2*a*). In the case of citric acid, the concentration of the uncomplexed calcium remains weak and constant at pH higher than 6.5, when the total deprotonation of the three carboxylic groups is effective. In the case of malic and lactic acids and at pH higher than the latter deprotonation constant, the free calcium concentration is more important and fluctuating. For pH higher than 10.5–11, the observed fast decrease in the free calcium concentration can be explained by calcium carbonate precipitation.

At pH 10, metal concentration was fixed at 10^{-3} M and ligand concentration varied from 0 to 2×10^{-3} M. It can be seen from Fig. 2*b* that citrate is a better complexant than malate and lactate. This major difference in the complexation behaviour of these acids can be explained by the lower acidity constant of the hydroxyl group (K_{OH}) for citric acid. This hydroxyl is easily ionized at basic pH and can take part in the calcium complex in alcoholate form. For concentrations of malic and lactic acids ranging from 0.7 to 1.2×10^{-3} M and 0 to 10^{-3} M, respectively, an irregular decrease in the free calcium concentration is observed. This anomaly can be explained by the coexistence of polynuclear complexes or complexes of variable stoechiometry and their corresponding equilibra.

Complex constants

The stability constants of calcium complexes (Table 1) were calculated using two complementary methods. Under the defined experimental conditions (6.5–11 pH range and a [ligand]/[Ca(II)] ratio of 1:1) and according to Craggs et al. (34), protonated species can be neglected and we can assume that the stoechiometry of the complexes is 1:1, expressed by the complexation equilibrium :

$$[1] \quad Ca^{2+} + L^{n-} \rightleftharpoons CaL^{2-n}$$

$$K = \frac{[CaL^{2-n}]}{[Ca^{2+}][L^{n-}]}$$

The stability constant K of the complex is easily calculated (eqs. [2] and [3]) from the initial and experimental concentra-

tions in calcium and ligand as, $[Ca^{2+}]_0$, $[L^{n-}]_0$, $[Ca^{2+}]$

$$[2] \quad [L^{n-}] : [CaL^{2-n}] = [Ca^{2+}]_0 - [Ca^{2+}]$$
$$[3] \quad [L^{n-}] = [L^{n-}]_0 - [CaL^{2-n}]$$

For a constant [ligand]/[Ca(II)] ratio of 2:1, and in the pH range corresponding to the complex formation, the calculation of the stability constant depends on the average of the concentrations in free calcium (Fig. 2*a*).

At pH 10, the complexation constant can be calculated from each set of experimental points. The stability constant of citric acid is quite invariant (Fig. 2*c*) because of the strong complexation with the three carboxylic groups. As expected, the calculation range can be considered above the 1:1 [ligand]/[Ca(II)] ratio, in good agreement with the assumption of major formation of the 1:1 complex.

Table 2 shows that both experimental approaches are entirely satisfactory and lead to comparable average values. As these calculated constants are in excellent agreement with those reported in the literature, this study shows that the experimental procedures are reliable and perfectly reproducible.

Carboxylic derivatives from methyl D-glucopyranosides

Quantitative information about interactions between protons and functional groups of the ligand may conventionally be given by the general formation equilibria constants Kq of the species HqL. Standard derivations are calculated from the residual variance and the matrix of variances by a pit-mapping method (29).

Protonation constants for **1**–**7** are given in Table 3. This table shows that the first acidity increases with an increasing number of carboxylic groups. For each anomer α and β, these constants are comparable.

Metal and ligand concentrations were fixed, respectively, at 10^{-3} and 2×10^{-3} M and the measurements were carried out between pH 3 and 12. For each compound, the free calcium concentration fluctuates more than those observed for citric, malic, and lactic acids. There is a free calcium concentration level for each compound. This level is smallest with the tetracarboxylic acid.

At pH 10, metal concentration was fixed at 10^{-3} M and

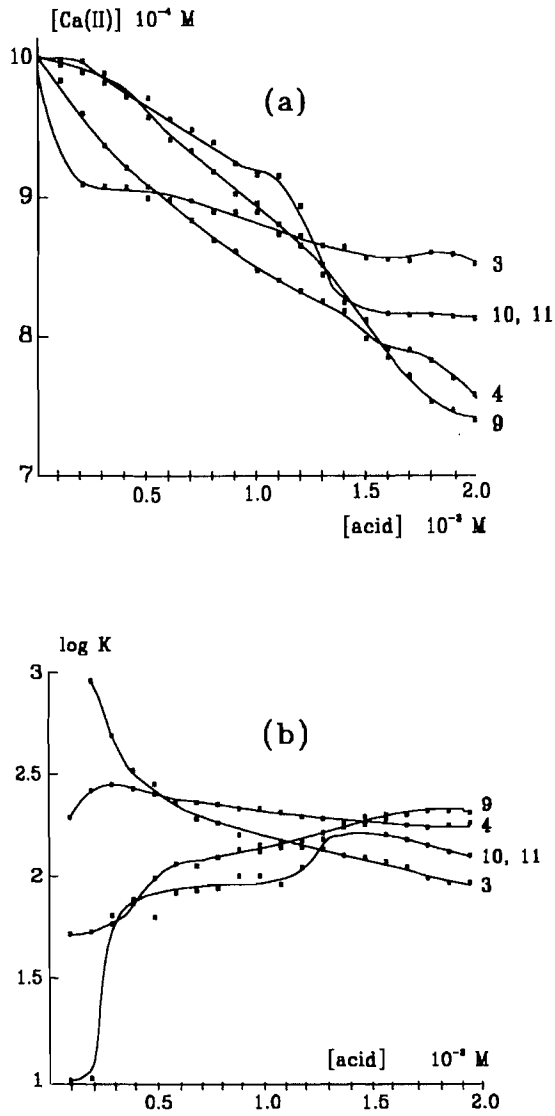
Fig. 4. Carboxylic acids derived from methyl D-fructoside.
(*a*) Calcium complexation according to the ligand concentration.
(*b*) Stability constants according to the ligand concentration.



ligand concentration varied from 0 to 2×10^{-3} M. To demonstrate the influence of the number of carboxylic groups, we have included the methyl α-D-glucopyranoside, which has no carboxylic group. Figure 3*a* shows that an increasing number of carboxylic groups has a favourable effect on the calcium sequestering strength.

To determine whether the behaviour of α anomers differs from that of β anomers, the calcium complexation of mono- and dicarboxylic acids, **1**, **5** and **2**, **6**, have been compared (Fig. 3*b*). In the ligand concentration range from 0 to 0.7×10^{-3} M, Fig. 3*b* shows that β anomer **5** is a better complexant than α anomer **1**, and in the ligand concentration range from 0 to 1.1×10^{-3} M, the α anomer **2** is a better complexant than β anomer **6**. So for low ligand concentrations, the anomeric configuration has a significant influence on the calcium complexation. This effect is more pronounced for ligands having fewer carboxylic groups.

Complex constants

Stability constants for α anomers, calculated from the relation [Ca(II)] = f(ligand), are represented according to the ligand concentration (Fig. 3*c*). **4** shows similar behaviour to citric acid. Its stability constants are almost the same for the region of ligand concentration from 0 to 2×10^{-3} M. For **1**, **2**, and **3**, stability constants are stable over the ligand concentration range 10^{-3} to 2×10^{-3} M. The average values calculated in the previous interval are given in Table 4, with the complex constants calculated from the relation [Ca(II)] = f(pH).

This table shows that the two experimental methods lead to comparable values and, for a [ligand]/[calcium] ratio of 2:1, the α and β anomers have the same complexation strength.

Carboxylic derivatives from methyl D-fructosides

Measurements at pH 10 were the only ones performed. Since the anomeric configuration has no effect on the calcium complexation for tetracarboxylic compounds (see results obtained with methyl D-glucopyranoside derivatives), the tetracarboxylic derivatives from methyl α- and β-D-fructofuranoside **10** and **11** have not been separated.

Results of the calcium complexation at pH 10 obtained for tetracarboxylic derivatives from methyl β-D-fructopyranoside

11

9 and methyl α- and β-D-fructofuranoside **10** and **11** are reported in Fig. 4*a* with the curves previously obtained for tri- and tetracarboxylic derivatives from methyl α-D-glucopyranosides **3** and **4**.

As we have seen, the tetrasubstituted derivatives **4**, **9**, **10**, and **11** are better complexants than the tricarboxylic derivative **3**. For a [ligand]/[calcium] ratio of 2:1 and for the tetracarboxylic compounds **4**, **9**, **10**, and **11**, the derivatives from methyl D-fructofuranoside **10** and **11** are the least active and the derivative from methyl β-D-fructopyranoside **9** is the most active.

Complex constants

Figure 4*b* illustrates the variation of stability constants for **3**, **4**, **9**, **10**, and **11** with ligand concentration. Although at a [ligand]/[Ca(II)] ratio of 2:1 **9** is more active than **4**, its stability constants are less stable than those of **4**.

The stability constants calculated in the ligand concentration range 0 to 2×10^{-3} M illustrate this observation (Table 4).

Determination of the calcium complexation sites for the carbohydrate skeletons

Upon complexation of calcium ions by a ligand, the relaxation times and the chemical shifts of the carbons are perturbed. These perturbations are more important if the carbon in question is near a complexation site (35, 36). The complexation sites for the carbohydrate skeletons of **2**, **3**, **4**, **10**, and **11** have been so determined using ^{13}C NMR, by measurements of chemical shift variation of the carbons of the ligand with increasing calcium concentration, after verification that addition of a salt that is inert towards complexation (sodium chloride, and addition of calcium chloride) to an aqueous solution of methyl α-D-glucopyranoside (which presents no calcium complexation under our experimental conditions) does not lead to great variations of chemical shift for the ring carbons. ^{13}C NMR spectra of the ligands with increasing calcium chloride concentrations, [ligand]/[Ca(II)] ratio from 0 to 1, have been obtained and the variations of chemical shift induced by

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

the calcium complexation are represented according to the ratio [ligand]/[Ca(II)].

Methyl α-D-glucopyranoside derivatives 2, 3, and 4

For the dicarboxylic derivative **2**, the highest chemical shift variations are obtained for the C3 and C4. So the oxygens on C3 and C4 are the privileged complexation sites (Fig. 5*a*).

For tricarboxylic derivative **3**, the more perturbated chemical shifts are obtained for the C5 and C3, showing privileged complexation sites by the ring oxygen and the oxygen on C3 (Fig. 5*b*).

For tetracarboxylic derivative **4**, the highest chemical shift variations are obtained for the C4, C3, and C6. So the oxygens on C4, C3, and C6 are the privileged complexation sites (Fig. 5*c*).

Methyl α- and β-D-fructofuranoside derivatives 10 and 11

Figures 6*a* and 6*b* show that the carbons having the highest chemical shift variations are the carbons C2 and C1 for the α anomer **10** and the carbon C1 for the β anomer **11**.

Conclusion

Calcium sequestering properties of 11 carboxylic derivatives from methyld D-glucopyranoside, methyl D-fructopyranoside, and methyl D-fructofuranoside have been studied using a calcium selective electrode and introducing a precise and reproductible procedure.

Study of the citric, malic, and lactic acids allowed us to set up two experimental approaches for the calcium complexation measurement. The first follows the variations in free calcium concentration with the pH, the second, with the ligand concentration. These two processes lead to the corresponding complex formation constants, which are in excellent agreement with those reported in the literature. If the pH is fixed, as in the case of the detergency studies, the second process, which is moreover more precise, must be used.

Although these carboxylic acids are biodegradable, their calcium sequestering properties are less effective than those of citric acid. In addition, at pH 10 and for a temperature higher than 50°C, a de-etherification of carboxyethyl groups occurs, leading to the free carbohydrate. So the use of such compounds is not appropriate in the case of the usual laundry products.

Moreover, from a fundamental point of view, at the time of the study of calcium complexation for the carboxylic derivatives of methyl D-glucopyranoside, we emphasize that the calcium complexation strength *increases* with increasing number of carboxylic groups. Although the tetracarboxylic derivative **4** is less effective than citric acid, its calcium complexation behaviour being similar, for a [ligand]/[Ca(II)] ratio higher than 1, the anomeric configuration has no effect on the calcium complexation, and for a [ligand]/[Ca(II)] ratio smaller than 1, the anomeric configuration has a significant effect on the calcium complexation, when the compound contains fewer carboxylic groups.

Comparison of the complexing properties of the tetracarboxylic derivatives from methyl D-glucopyranoside, methyl D-fructopyranoside, and methyl D-fructofuranoside shows that (*i*) pyranic derivatives seem more effective than furanic derivatives, and (*ii*) for pyranic rings, the complex stability for derivatives of methyl D-glucopyranoside and methyl D-fructopyranoside is almost identical, but for a [ligand]/[Ca(II)] ratio of 2:1, the first is the more effective.

The ^{13}C NMR study of the calcium complexes, which allows us to easily determine the calcium complexation sites, shows that (*i*) for the derivatives of methyl D-glucopyranoside, in addition to the carboxylic groups, the oxygen on C3 is the only common complexation site, (*ii*) for the derivatives of methyl D-fructofuranoside, complexation sites differ for each anomer.

Synthesis of 3-substituted tetrahydroisoquinolines by acid-catalyzed cyclization of *p*-toluenesulfonamides of *N*-benzyl aminoacetaldehyde derivatives

Viviana L. Ponzo and Teodoro S. Kaufman

Abstract: The acid-catalyzed cyclization of *p*-toluenesulfonamides of *N*-benzyl aminoacetaldehyde, or their acetalic counterparts, usually yields 1,2-dihydroisoquinolines. However, cyclization of intermediates bearing a substituent α to the carbonyl group affords 3-substituted 2-*p*-toluenesulfonyl tetrahydroisoquinolin-4-ol derivatives, capable of further transformation into the related 1,2,3,4-tetrahydroisoquinolines.

Key words: 3-substituted tetrahydroisoquinolines, MY336-a analog, acid-catalyzed cyclization, tetrahydroisoquinolin-4-ol derivatives.

Résumé : La cyclisation, catalysée par un acide, des *p*-toluènesulfonamides du *N*-benzylaminoacétaldéhyde ou de leurs acétals équivalents conduit habituellement aux 1,2-dihydroisoquinoléines. Cependant, la cyclisation des intermédiaires portant un substituant en position α du carbonyle conduit aux dérivés 2-*p*-toluènesulfonyl tétraisoquinolin-4-ol substitués en position 3, pouvant subir des transformation plus poussées en donnant les 1,2,3,4-tétrahydroisoquinoléines apparentées.

Mots clés : tétrahydroisoquinoléines substituées en position 3, analogue du MY336-a, cyclisation catalysée par un acide, dérivés du tétrahydroisoquinolin-4-ol.

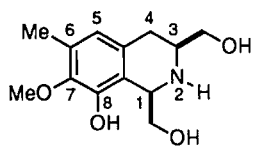
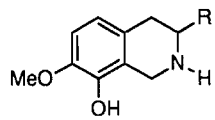
The synthesis of isoquinolines and 2-*p*-toluenesulfonyl-1,2-dihydroisoquinolines by acid-catalyzed cyclization of *p*-toluenesulfonamides of *N*-benzylaminoacetaldehyde acetals was first reported by Jackson and co-workers (1); it is a modification of the Pomeranz–Fritsch process, which has been used as a synthetic tool of importance in the preparation of a variety of isoquinoline systems (2). A salient feature of this sequence is the possibility of synthesizing the relatively uncommon and difficult to obtain heterocycles carrying a 7,8-substitution pattern on the isocyclic ring.

The original strategy was modified by Boger et al. (3) and more recently by Castedo and co-workers (4), enhancing its synthetic power. Additionally, as part of a study on the total synthesis of the novel β-adrenergic receptor antagonist MY336-a (**1**) bearing a 1,3-disubstituted heterocyclic ring, we recently reported the successful obtention of a 1-substituted 1,2,3,4-tetrahydroisoquinoline from the related *p*-toluenesulfonyl 1,2-dihydroisoquinoline precursor (5).

In a further extension of this series of work, we wish to report the applicability of the Jackson sequence to the elaboration of 3-substituted tetrahydroisoquinolines through the syntheses of prototypes **2** and **3**, and the obtention of **4**, which embodies the 3,7,8-oxygenated substituent array present in **1**.



MY336-a, **1**



2 R= Me
3 R= CH_2CH_2OH
4 R= CH_2OH

Although many 3-substituted isoquinolines have been synthesized by alternative routes, it has been reported that the formation of 3-alkylisoquinolines is difficult or fails in the Pomeranz–Fritsch synthesis (6), and it is known that isoquinolines and dihydroisoquinolines having alkyl, aryl, or aralkyl groups in the 3 position have generally been obtained in lower yield than derivatives unsubstituted in that position, by the Bischler–Napieralski procedure (7).

As shown in Scheme 1, for the preparation of the simplest prototype (**2**), the known aldehyde **5** (8) was reductively aminated with alanine ethyl ester to afford the secondary amine **6**, which readily provided intermediate **7** in 76% overall yield upon reaction with *p*-toluenesulfonyl chloride. Functional group interconversion furnished the required substrates for cyclization; thus, **7** in THF–ethanol was reduced with lithium

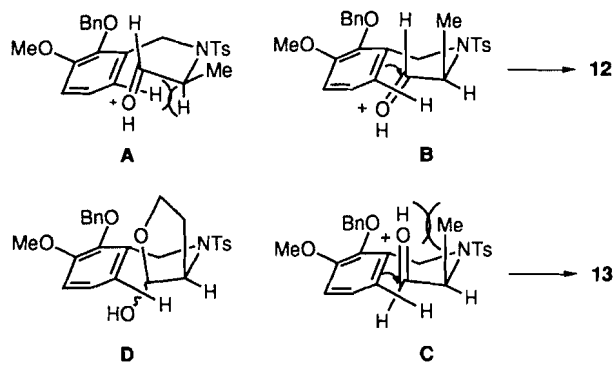
borohydride, generated in situ (9), to alcohol **8**, which was immediately reoxidized to the related aldehyde **9** following the procedure of Swern, and, finally, acetalization of **9** with 2,2-dimethoxypropane in methanol under *p*-toluenesulfonic acid catalysis furnished **10** in 80% yield from **7**.

Heating under reflux a dioxane solution of acetal **10** containing 4 equivalents of 6 N hydrochloric acid smoothly led to a 1:5.8 mixture of cyclized products in combined 82% yield. These were identified as the expected, light-sensitive, 1,2-dihydroisoquinoline derivative **11** and a 3-methyl-1,2,3,4-tetrahydroisoquinolin-4-ol to which structure **12** was assigned based on the small $J_{H\text{-}3,H\text{-}4}$ value observed and the nOe data shown in Fig. 1. The same product distribution was observed upon cyclization of aldehyde **9**.

Scheme 2.



The isolation of **12** as the main cyclization product was puzzling, since this transformation usually provides 1,2-dihydroisoquinolines. The causes of this reaction outcome were studied. Careful inspection of Dreiding models suggested that, due to the steric interaction between the hydrogen atom α to the carbonyl group and the aromatic proton located in the ring closure position (**A**, Scheme 2), cyclization could only be accomplished by an aromatic ring attack on the intermediate carbonium ion, formed by protonation either of the acetalic or (most probably) of the aldehydic moieties, from the same face of the 3-substituent.

In this analysis, the aromatic ring would be capable of attacking either one of two different conformations of the protonated carbonyl, the most favored one being that in which it is antiperiplanar (**B**) with the 3-substituent and gives rise to **12** through a chair-like transition state. On the other hand, attack to the synperiplanar conformation (**C**), producing the diastereoisomeric compound **13**, should be disfavored due to the interaction between the protonated oxygen and the 3-methyl group, resulting in a diminished yield of the latter. Since alcohol **13** could not be isolated, it was supposed that it would

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

easily dehydrate to afford the observed 1,2-dihydroisoquinoline derivative **11**, while the lack of a *trans* β-hydrogen atom would preclude the dehydration of **12** under the acidic reaction conditions.

To test this hypothesis, chromatographically purified **12** was exposed to the same cyclization conditions. However, this attempt to obtain **11** met with failure, since only some decomposition of the alcohol was detected and no evidence of formation of the dehydrated product was found.

Interestingly, it was reported (10) that structurally related 3,4-dihydroisoquinolines, obtained through a Bischler–Napieralski type cyclization and carrying a 3*R**,4*S** substitution pattern, were resistant to dehydration when PCl_5 was employed as cyclodehydration agent, while its substitution by P_2O_5 afforded isoquinolines by a process similar to that of the Pictet–Gams reaction. Resistance to dehydration with PCl_5 was explained as being a result of the disfavored formation of the required intermediate carbocation.

Dehydration of **12** was acceptably accomplished either by treating the alcohol with hexamethylphosphoric triamide (HMPA) as reported by Monson (11), a procedure that does not require a *trans* orientation of the hydroxyl and the β-hydrogen for elimination to occur, or by heating the alcohol in 1,1,2,2-tetrachloroethane with anhydrous copper(II) sulfate adsorbed on silica gel (12). Although the mechanisms of these dehydrations are not clear, the formation of intermediates with carbonium cationic character is invoked in both cases.

The behaviour of epimeric alcohol **13** was also verified. To this end, **12** was submitted to a Mitsunobu reaction as modified by Martin, employing *p*-nitrobenzoic acid as the acidic component to overcome the usually low yields associated with the serious steric hindrance around the reacting group (13). As expected, the reaction was not very clean, but afforded the required *p*-nitrobenzoate **14**, which provided **13** in 50% overall yield from **12** after brief exposure to a methanolic solution of sodium hydroxide. Comparison of $J_{H\text{-}3,H\text{-}4}$ and nOe data of **12** and **13** (Fig. 1) confirmed the proposed configurational assignments for both alcohols.

To our satisfaction, **11** was obtained in 80% yield as the sole isolable product when the epimerized alcohol **13** was subjected to the standard cyclization conditions.

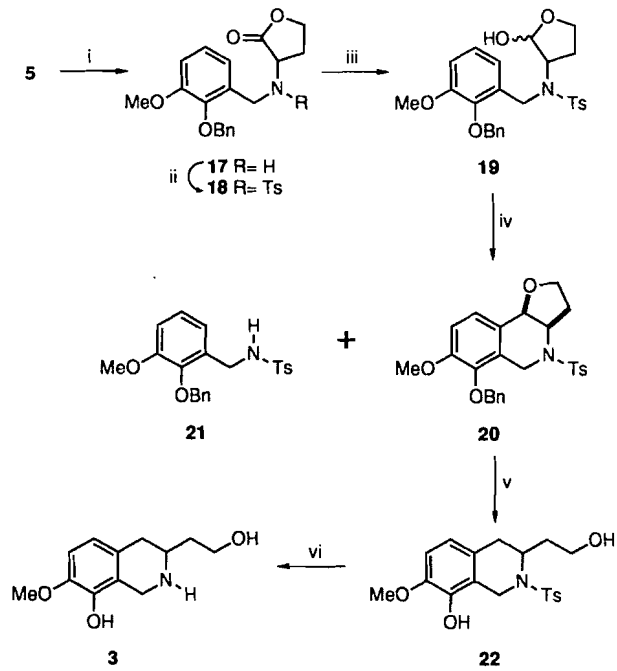
To finish the proposed synthesis, **12** was submitted to a palladium-catalyzed hydrogenolysis in hydrochloric acid – methanol to cleanly afford **15**, which was reductively detosylated to furnish model compound **2** in 37% overall yield from **5**.

Curiously, in spite of precedents on related systems (14), 1,2-dihydroisoquinoline **11** proved to be resistant to catalytic double bond hydrogenation, while its treatment with sodium in liquid ammonia gave a complex mixture of products; thus, the unexpected obtention of **12** provided a short and easy entry into the target 3-substituted tetrahydroisoquinoline.

Tempted with the possibility of obtaining optically active cyclized compounds, the synthetic scheme was repeated employing L-alanine ethyl ester as starting material. Unfortunately, racemization of the chiral center during the cyclization step gave **12** in its racemic form, as evidenced by duplication of the H-5, H-6, and 7-methoxyl signals in its ^1H NMR spectrum when recorded in benzene-d_6 employing (+)-Eu(hfc)$_3$ as chiral shift reagent.

Next, the cyclization of a less flexible model was studied in order to better understand the factors affecting this process and

Scheme 3.



(i) 2-amino-γ-butyrolactone. HBr, (**16**. HBr), TEA, H_2/PtO_2, EtOH; (ii) TsCl, pyridine, CH_2Cl_2; (iii) DIBAH, toluene, -45°C; (iv) 6N HCl, dioxane, 140°C; (v) H_2, 10% Pd/C, H_2SO_4, MeOH; (vi) 1. Na,NH_3, -33°C, 2. NH_4Cl, -33°C to room temp.

to evaluate the possibility of synthesizing 1,2,3,4-tetrahydroisoquinolines carrying functional groups on the C-3 side chain amenable to further elaboration.

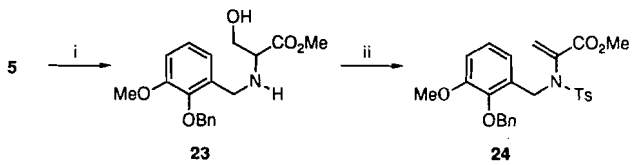
Compound **3** was selected as the synthetic target based on the ready availability of the starting 2-amino-γ-butyrolactone (**16**), capable of being reduced to a masked aldehyde suitable for cyclization in a few steps, and embodying a ring that should restrict the direction of the attack by the aromatic moiety, since the protonated intermediate (**D**, Scheme 2) can only adopt a synperiplanar orientation with regard to the C-3 substituent.

Platinum-catalyzed reductive amination of **5** with amine **16** furnished compound **17**, which was transformed into the related *p*-toluenesulfonamide **18** by reaction with *p*-toluenesulfonyl chloride (Scheme 3). Partial reduction of the latter with diisobutyl aluminium hydride (DIBAH) in toluene at −45°C afforded an unseparable mixture of epimeric lactols **19** ready for cyclization, in an acceptable 50% overall yield from **5**.

When heated in dioxane containing 4 equivalents of 6 N hydrochloric acid, the lactols sluggishly cyclized to give significant decomposition after 75 min and a modest 52% yield of product, to which the expected structure **20** was assigned based on its ^1H NMR signals and nOe data analysis as depicted in Fig. 1. An increase in acid concentration to 6.5 equivalents was detrimental, causing a further decrease in yield to 41%, whereas keeping the heating bath at 140°C shortened the reaction time to 45 min and resulted in 69% recovery of **20**. In addition, 7% of *p*-toluenesulfonamide **21** was isolated; this is known to be produced when cyclization is difficult or impeded (1).

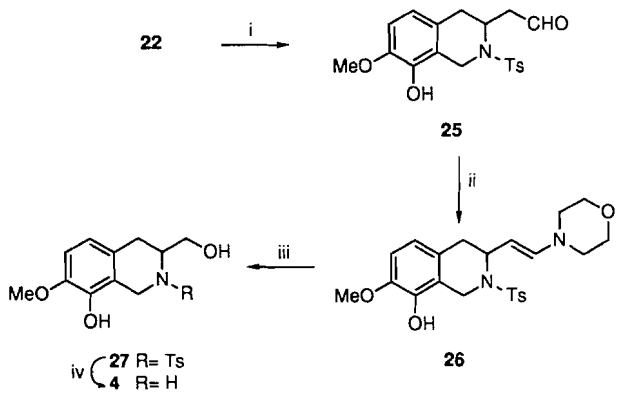
To complete the synthesis, **20** was submitted to a palladium-on-charcoal-catalyzed hydrogenation to give **22** and,

Scheme 4.



(i) SerOMe.HCl, TEA, H_2/PtO_2, EtOH; (ii) TsCl, pyridine, CH_2Cl_2

Scheme 5.



(i) $(F_3CCO)_2O$, DMSO, CH_2Cl_2, -60°C, TEA; (ii) morpholine, 4 Å molecular sieves, benzene; (iii) 1. O_3, Et_2O, -78°C, 2. $NaBH_4$, MeOH; (iv) 1. Na, NH_3, -33°C, 2. NH_4Cl, -33°C to room temp.

finally, this sulfonamide was reductively detosylated, furnishing the 1,2,3,4-tetrahydroisoquinoline **3** in 86% overall yield for both steps.

Having obtained models **2** and **3**, attention was turned to the synthesis of **4**. Unfortunately, the first approach and most direct route to the target proved unsuccessful, as depicted in Scheme 4.

While reductive amination of **5** with serine methyl ester efficiently provided **23**, reaction of this amine with *p*-toluenesulfonyl chloride in pyridine – methylene chloride gave only α,β-unsaturated ester **24** under an ample variety of conditions. This was not surprising, since many serine ester derivatives have shown a tendency towards β-elimination in the presence of base (15, 16).

We then envisaged a second plan, involving a one-carbon degradation of intermediate **22**. As shown in Scheme 5, this was achieved by Swern oxidation of the starting alcohol to **25** in 69% yield, followed by convenient transformation of this aldehyde into its related enamine **26** by reaction with morpholine in benzene under 4Å molecular sieves catalysis (17). Without purification, **26** was ozonized at −78°C (18) employing a sodium borohydride based reductive work-up of the intermediate ozonides, which afforded alcohol **27**. This, in turn, was detosylated with sodium in refluxing liquid ammonia to give **4**, an analog of **1**, in 60% overall yield from **25**.

In conclusion, an effective strategy for the synthesis of 3-substituted tetrahydroisoquinolines by proper modifications of Jackson's sulfonamido acetal cyclization strategy is reported through the elaboration of prototypes **2** and **3**. The first Jackson-type cyclization of a lactol was carried out, leading to a furo[3,4-*b*]isoquinoline derivative, the first such tricyclic structure to be prepared using this route. In addition, as demonstrated by the elaboration of a lower partial analog of MY336-a, the ready availability of the present synthetic scheme seems suitable as a strategy for the first total synthesis of the natural product. This work is underway.

Experimental section

Melting points were measured on an Ernst Leitz hot-stage microscope apparatus and are uncorrected. IR spectra were taken on a Bruker IFS 25 spectrometer with solid samples as KBr pellets and liquid samples as films. ^1H and ^{13}C NMR spectra were recorded in deuteriochloroform unless otherwise stated, on a Bruker AC-200E instrument at 200.13 and 50.32 MHz, respectively, with tetramethylsilane as the internal standard. ^{13}C NMR resonances corresponding to two carbon atoms are designated with an asterisk, while those assigned to three carbons are marked with #. High-resolution mass spectral data were obtained from UMYMFOR (Buenos Aires). All reactions were carried out in a dry nitrogen atmosphere.

General procedure for the reductive amination of 5 and synthesis of *p*-toluenesulfonamides

The amine salt, triethylamine, and pre-reduced platinum oxide in absolute ethanol were successively added to a solution of **5** in absolute ethanol. The reaction was stirred at room temperature under hydrogen at atmospheric pressure until no starting material remained. The catalyst was separated by centrifugation, the volatiles were evaporated under reduced pressure, and the oily residue was dissolved in a 10:1 mixture of methylene chloride – pyridine.

A 0.58 M solution of *p*-toluenesulfonyl chloride in the same solvent was added dropwise to the above solution cooled in an ice-water bath. After stirring overnight, brine (50 mL) was added and the products were extracted with diethyl ether (3 × 50 mL). The combined ethereal extracts were successively washed with 1 N hydrochloric acid (2 × 10 mL), saturated sodium hydrogen carbonate (10 mL), and brine (2 × 10 mL), then dried over sodium sulfate and concentrated under reduced pressure. The residue was flash-chromatographed.

Ethyl-2-[*N*-(2-benzyloxy-3-methoxyphenyl)methyl-*N*-(*p*-toluenesulfonyl)]aminopropanoate (7)

By the general method, reaction of alanine ethyl ester hydrochloride (790 mg, 5.13 mmol), triethylamine (0.714 mL, 5.13 mmol), platinum oxide (70 mg), and **5** (1241 mg, 5.13 mmol) in absolute ethanol (25 mL) provided amine **6** (1619 mg, 92%) as an oil; IR (film): 3750–3100, 2978, 2954, 1730, 1586, 1478, 1274, 1184, 1082, 986, 752, and 698 cm^{-1}; ^1H NMR δ: 1.22 (3H, t, J = 11 Hz, OCH_2CH_3), 1.25 (3H, d, J = 7 Hz, $CHCH_3$), 1.90 (1H, br s, $w_{1/2}$ = 15 Hz, NH), 3.30 (1H, q, J = 7 Hz, $CHCH_3$), 3.70 (2H, q, J = 11 Hz, OCH_2CH_3), 3.88 (3H, s, OCH_3), 4.10 (2H, ABq, J = 7.1 Hz, Δδ = 0.07, $ArCH_2N$), 5.04 (2H, s, OCH_2Ph), 6.86 (1H, dd, J = 1.8, 7.7 Hz, ArH), 6.90 (1H, dd, J = 1.8, 7.7 Hz, ArH), 7.07 (1H, t, J = 7.7 Hz, ArH), and 7.31–7.49 (5H, m, ArH of benzyl); ^{13}C NMR δ : 14.10, 16.82, 46.67, 55.73, 55.93, 60.42, 74.77, 111.51, 121.62, 123.88, 127.78, 128.14*, 128.23*, 133.82, 137.79, 146.09, 152.62, and 175.33.

Following the general method, the reaction of the *p*-toluenesulfonyl chloride solution (7.2 mL, 4.19 mmol) with **6** (1250 mg, 3.64 mmol) in methylene chloride – pyridine (22

mL) gave sulfonamide **7** (1502 mg, 83%) as an oil; IR (film): 2988, 2940, 1736, 1596, 1584, 1478, 1334, 1220, 1160, 1070, 982, 862, 760, 702, and 662 cm^{-1}; ^1H NMR δ: 1.02 (3H, t, J = 7 Hz, CH_2CH_3), 1.18 (3H, d, J = 7.3 Hz, $CHCH_3$), 2.41 (3H, s, $ArCH_3$), 3.80 (3H, s, OCH_3), 3.82 (2H, q, J = 7 Hz, CH_2CH_3), 4.40 (2H, s, $ArCH_2N$), 4.50 (1H, q, J = 7.3 Hz, $CHCH_3$), 5.01 (2H, ABq, J = 18 Hz, Δδ = 0.09, OCH_2Ph), 6.85 (1H, dd, J = 1.8, 7.9 Hz, ArH), 7.04 (1H, t, J = 7.9 Hz, ArH), 7.13 (1H, dd, J = 1.8, 7.9 Hz, ArH), 7.29–7.39 (5H, m, ArH of benzyl), and 7.43 (4H, ABq, J = 8.5 Hz, Δδ = 0.37, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 13.58, 16.30, 21.31, 43.68, 55.42, 55.62, 60.81, 74.46, 111.16, 120.81, 123.79, 127.35*, 127.83, 128.19*, 128.35*, 129.19*, 132.09, 136.92, 137.37, 143.04, 144.51, 152.06, and 170.86; HRMS calcd. for $C_{27}H_{31}NO_6S$: 497.1872; found: 497.1891.

2-[*N*-(2-Benzyloxy-3-methoxyphenyl)methyl-*N*-(*p*-toluenesulfonyl)]amino-γ-butyrolactone (18)

Following the general procedure, reaction of the hydrobromide of **16** (750 mg, 4.13 mmol), triethylamine (0.575 mL, 4.13 mmol), platinum oxide (70 mg), and aldehyde **5** (1000 mg, 4.13 mmol) in absolute ethanol (25 mL) afforded **17** (1230 mg, 91%) as an oil; IR (film): 3600–3100, 2938, 1778, 1584, 1478, 1378, 1274, 1170, 1018, 982, 754, and 700 cm^{-1}; ^1H NMR δ: 1.80–1.90 (1H, br s, $w_{1/2}$ = 10 Hz, NH), 1.91–2.09 (1H, m, $CHCH_2$), 2.22–2.43 (1H, m, $CHCH_2$), 3.32–3.46 (1H, m, $CHC{=}O$), 3.78 (2H, s, $ArCH_2N$), 3.90 (3H, s, OCH_3), 4.07 (1H, dt, J = 6.4, 9.3 Hz, CH_2O), 4.30 (1H, dt, J = 2.4, 9.3 Hz, CH_2O), 5.05 (2H, ABq, J = 11 Hz, Δδ = 0.10, OCH_2Ph), 6.88 (1H, d, J = 7.9 Hz, ArH), 6.95 (1H, dd, J = 2.1, 7.9 Hz, ArH), 6.98 (1H, dd, J = 2.1, 7.9 Hz, ArH), and 7.30–7.48 (5H, m, ArH of benzyl); ^{13}C NMR δ: 29.75, 46.30, 54.62, 55.27, 65.19, 74.46, 111.33, 121.23, 123.64, 127.53, 127.87*, 127.91*, 132.68, 137.22, 145.65, 152.18, and 176.76.

By the general procedure, addition of the *p*-toluenesulfonyl chloride solution (1.4 mL, 0.81 mmol) to **17** (225 mg, 0.69 mmol) dissolved in methylene chloride – pyridine (4 mL) provided **18** (422 mg, 88%) as an oil; IR (film): 2938, 1784, 1598, 1478, 1336, 1274, 1160, 1088, 1020, and 754 cm^{-1}; ^1H NMR δ: 2.12–2.29 (2H, m, $CHCH_2$), 2.43 (3H, s, $ArCH_3$), 3.89 (3H, s, OCH_3), 3.98–4.32 (3H, m, $CHCH_2$), 4.29 (2H, q, J = 10.1 Hz, $ArCH_2N$), 4.99 (2H, ABq, J = 11 Hz, Δδ = 0.08, OCH_2Ph), 6.86 (1H, dd, J = 3, 8 Hz, ArH), 7.00 (1H, d, J = 8 Hz, ArH), 7.02 (1H, dd, J = 3, 8 Hz, ArH), 7.32 (5H, s, ArH of benzyl), and 7.55 (4H, ABq, J = 8.3 Hz, Δδ = 0.53, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 21.13, 27.17, 44.68, 55.38, 56.37, 64.89, 74.29, 111.61, 120.68, 123.93, 127.50*, 127.79, 128.02*, 128.44*, 129.12*, 130.05, 136.24, 136.71, 143.35, 144.56, 152.03, and 172.87; HRMS calcd. for $C_{26}H_{27}NO_6S$: 481.1559; found: 481.1572.

Methyl-2-[*N*-(2-benzyloxy-3-methoxyphenyl)methyl-*N*-(*p*-toluenesulfonyl)]aminopropenoate (24)

Employing the general procedure, serine methyl ester hydrochloride (1098 mg, 7.06 mmol), triethylamine (0.982 mL, 7.06 mmol), platinum oxide (80 mg), and aldehyde **5** (1708 mg, 7.06 mmol) in absolute ethanol (28 mL) afforded **23** (2263 mg, 92%) as an oil; IR (film): 3600–3080, 2950, 1734, 1654, 1586, 1478, 1376, 1274, 1206, 1182, 1080, and 754 cm^{-1}; ^1H NMR δ: 2.10 (2H, br s, $w_{1/2}$ = 17 Hz, NH and OH), 3.35 (1H, dd, J = 4.5, 5.9 Hz, $CHCO_2CH_3$), 3.55 (1H, dd, J = 5.9, 10.8 Hz, CH_2OH), 3.64 (3H, s, CO_2CH_3), 3.70 (2H, d, J = 4.3 Hz, $ArCH_2N$), 3.71 (1H, dd, J = 4.5, 10.8 Hz, CH_2OH), 3.89 (3H, s, OCH_3), 5.04 (2H, s, OCH_2Ph), 6.87 (1H, d, J = 8.4 Hz, ArH), 6.88 (1H, d, J = 7.4 Hz, ArH), 7.04 (1H, dd, J = 7.4, 8.4 Hz, ArH), and 7.31–7.45 (5H, m, ArH of benzyl); ^{13}C NMR δ: 46.28, 51.50, 55.36, 61.52, 61.91, 74.46, 111.36, 121.32, 123.71, 127.56, 127.87*, 127.97*, 132.91, 137.33, 145.70, 152.25, and 172.93.

By the general procedure, reaction of the *p*-toluenesulfonyl chloride solution (0.65 mL, 0.38 mmol) with **23** (50 mg, 0.15 mmol) in methylene chloride – pyridine (1 mL) provided **24** (61 mg, 85%) as a solid, mp 113.5-115°C (hexane – diethyl ether); IR(KBr): 2946, 1728, 1632, 1586, 1480, 1342, 1272, 1162, 1074, 982, 798, and 712 cm^{-1}; ^1H NMR δ: 2.44 (3H, s, $ArCH_3$), 3.52 (3H, s, CO_2CH_3), 3.86 (3H, s, OCH_3), 4.47 (2H, s, $ArCH_2N$), 4.91 (2H, s, OCH_2Ph), 5.41 (1H, s, $C{=}CH_2$), 6.12 (1H, s, $C{=}CH_2$), 6.83 (1H, d, J = 7.5 Hz, ArH), 6.86 (1H, d, J = 7.5 Hz, ArH), 7.04 (1H, t, J = 7.5 Hz, ArH), 7.32 (5H, s, ArH of benzyl), and 7.47 (4H, ABq, J = 8.2 Hz, Δδ = 0.40, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 21.39, 46.47, 51.96, 55.56, 74.74, 111.67, 121.57, 124.01, 127.03, 127.71*, 127.84*, 128.16*, 128.27*, 129.17*, 129.47, 135.51, 135.56, 137.23, 143.36, 152.23, and 164.05; HRMS calcd. for $C_{26}H_{27}NO_6S$: 481.1559; found: 481.1553.

2-[*N*-(2-Benzyloxy-3-methoxyphenyl)methyl-*N*-(*p*-toluenesulfonyl)]aminopropan-1-ol (8)

To a solution of sulfonamide **7** (1120 mg, 2.25 mmol) in a 1:1 THF–EtOH mixture (30 mL) were successively added lithium bromide (392 mg, 4.51 mmol) and sodium borohydride (172 mg, 4.51 mmol). The reaction was stirred overnight at 40°C, then 10% w/v citric acid solution (10 mL) was added, the organic solvents were evaporated under reduced pressure, and the reaction products were extracted with ethyl acetate (3 × 30 mL). The extract was dried, concentrated, and chromatographed, affording **8** as an oil (870 mg, 85%); IR (film): 3490, 3030, 2970, 2942, 1600, 1586, 1478, 1328, 1270, 1154, 1090, 1030, 970, 854, 816, 756, 658, and 622 cm^{-1}; ^1H NMR δ: 0.74 (3H, d, J = 6.9 Hz, $CHCH_3$), 1.78 (1H, dd, J = 6.9, 7.2 Hz, $CHCH_3$), 2.43 (3H, s, $ArCH_3$), 3.16 (2H, t, J = 7.2 Hz, CH_2OH), 3.89 (3H, s, OCH_3), 4.19 (2H, ABq, J = 16 Hz, Δδ = 0.12, $ArCH_2N$), 5.01 (2H, ABq, J = 11.3 Hz, Δδ = 0.15, OCH_2Ph), 6.86 (1H, dd, J = 1.6, 8.1 Hz, ArH), 7.10 (1H, t, J = 8.1 Hz, ArH), 7.23 (1H, dd, J = 1.6, 8.1 Hz, ArH), 7.34 (5H, s, ArH of benzyl), and 7.45 (4H, ABq, J = 8 Hz, Δδ = 0.36, ArH *p*-toluenesulfonamide); ^{13}C NMR δ: 13.45, 21.29, 40.84, 55.56, 55.73, 64.18, 74.95, 111.35, 120.86, 124.33, 126.82, 127.97*, 128.24*, 128.44*, 129.45*, 132.20, 137.09, 137.54, 143.00, 144.43, and 152.17; HRMS calcd. for $C_{25}H_{29}NO_5S$: 455.1766; found: 455.1783.

2-[*N*-(2-Benzyloxy-3-methoxyphenyl)methyl-*N*-(*p*-toluenesulfonyl)]aminopropanal dimethyl acetal (10)

A methylene chloride solution of dimethyl sulfoxide (4.26 mL, 9.32 mmol) was dropwise added in 2 min to a stirred solution of oxalyl chloride (4.66 mmol) in the same solvent (3 mL) cooled to −60°C. After 5 min, a solution of alcohol **8** (707 mg, 1.55 mmol) in methylene chloride (3 mL) was incorporated dropwise. The mixture was stirred for 15 min at −60°C, followed by addition of triethylamine (1.73 mL, 12.43 mmol). Then it was left to react for 15 min at −60°C and 15 min at

room temperature; the reaction was quenched with brine (10 mL) and the product was extracted with diethyl ether (3 × 30 mL). The extracts were combined, dried over sodium sulfate, concentrated under reduced pressure, and chromatographed to furnish aldehyde **9** (672 mg, 95%); IR (film): 3030, 2962, 2898, 1736, 1598, 1482, 1352, 1336, 1274, 1158, 1078, 1012, 976, 814, 750, and 664 cm^{-1}; ^1H NMR δ: 1.03 (3H, d, J = 7 Hz, $CHCH_3$), 2.44 (3H, s, $ArCH_3$), 3.87 (3H, s, OCH_3), 3.94 (1H, q, J = 7 Hz, $CHCH_3$), 4.18 (2H, ABq, J = 15 Hz, Δδ = 0.07, $ArCH_2N$), 4.98 (2H, s, OCH_2Ph), 6.87 (1H, t, J = 5.2 Hz, ArH), 7.05 (2H, d, J = 5.2 Hz, ArH), 7.32 (5H, s, ArH of benzyl), 7.46 (4H, ABq, J = 8.3 Hz, Δδ = 0.40, ArH of *p*-toluenesulfonamide), and 9.32 (1H, s, CHO); ^{13}C NMR δ: 11.06, 21.41, 43.43, 55.68, 61.78, 74.96, 112.07, 121.51, 124.31, 127.22*, 128.07, 128.31*, 128.46*, 129.68#, 128.88, 137.06, 143.59, 145.48, 152.39, and 198.90.

Tosic acid (16 mg, 0.085 mmol) and 2,2-dimethoxypropane (0.30 mL) were successively added to a solution of aldehyde **9** (193 mg, 0.426 mmol) in absolute methanol (8 mL). After stirring overnight at room temperature, saturated sodium hydrogen carbonate (1 mL) and brine (10 mL) were added and the alcohol was removed under reduced pressure. The reaction products were extracted with diethyl ether (3 × 40 mL), dried over sodium sulfate, concentrated, and chromatographed to give acetal **10** (210 mg, 99%) as a solid, mp 107–108.5°C (hexane – diethyl ether); IR (KBr): 3030, 2936, 2836, 1598, 1586, 1478, 1452, 1340, 1272, 1158, 1088, 972, 816, 756, and 658 cm^{-1}; ^1H NMR δ: 0.84 (3H, d, J = 6.9 Hz, $CHCH_3$), 2.41 (3H, s, $ArCH_3$), 3.01 (3H, s, $CHOCH_3$), 3.18 (3H, s, $CHOCH_3$), 3.87 (3H, s, OCH_3), 3.98 (1H, dq, J = 6.9 , 5.2 Hz, $CHCH_3$), 4.07 (1H, d, J = 5.2 Hz, $CH(OCH_3)_2$), 4.30 (2H, s, $ArCH_2N$), 5.01 (2H, ABq, J = 11 Hz, Δδ = 0.05, OCH_2Ph), 6.83 (1H, dd, J = 1.4, 8 Hz, ArH), 7.05 (1H, t, J = 8 Hz, ArH), 7.19 (1H, dd, J = 1.4, 8 Hz, ArH), 7.30–7.43 (5H, m, ArH of benzyl), and 7.45 (4H, ABq, J = 8.4 Hz, Δδ = 0.40, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 12.06, 21.33, 42.22, 54.28, 54.64, 55.05, 55.71, 74.56, 105.96, 110.92, 121.05, 123.74, 127.16*, 127.83, 128.23#, 129.29#, 132.79, 137.62, 137.92, 142.81, 144.68, and 152.10; HRMS calcd. for $C_{27}H_{33}NO_6S$: 499.2028; found: 499.2035.

Cyclization of aldehyde 9 to (3*R**,4*S**)-8-benzyloxy-4-hydroxy-7-methoxy-3-methyl-2-(*p*-toluenesulfonyl)-1,2,3,4-tetrahydrosoquinoline (12) and 8-benzyloxy-1,2-dihydro-7-methoxy-3-methyl-2-(*p*-toluenesulfonyl)isoquinoline (11)

Aldehyde **9** (65 mg, 0.144 mmol) in dioxane (0.7 mL) containing 6 N hydrochloric acid (0.01 mL, 4 equiv.) was heated under reflux for 20 min; the solution was cooled to room temperature, made basic with saturated sodium hydrogen carbonate (0.5 mL), diluted with brine (5 mL), and extracted with ethyl acetate (3 × 30 mL). The combined extracts were washed with brine (5 mL), dried, and concentrated under reduced pressure to give a crude that was chromatographed, yielding 1,2-dihydroisoquinoline **11** as an oil (9 mg, 12%); IR (film): 3032, 2924, 2840, 1598, 1492, 1348, 1272, 1162, 1088, 1038, 812, 708, and 630 cm^{-1}; ^1H NMR δ: 2.21 (3H, s, CH_3-3), 2.25 (3H, s, $ArCH_3$), 3.81 (3H, s, OCH_3), 4.55 (2H, s, H-1), 4.98 (2H, s, OCH_2Ph), 6.02 (1H, s, H-4), 6.47 (2H, ABq, J = 8.2 Hz, Δδ = 0.17, H-5 and H-6), 7.18 (4H, ABq, J = 8.4 Hz, Δδ = 0.46, ArH of *p*-toluenesulfonamide), and 7.30–7.45 (5H, m, ArH of benzyl); ^{13}C NMR δ: 21.14, 22.01, 44.66, 55.78, 74.80, 110.60, 118.96, 119.46, 123.59, 125.04, 126.81*, 128.05, 128.32#, 128.39*, 128.52*, 135.17, 135.26, 137.03, 142.77, and 152.00; HRMS calcd. for $C_{25}H_{25}NO_4S$: 435.1504; found: 435.1511.

Increasing the polarity of the eluent furnished alcohol **12** (52 mg, 70%) as a solid, mp 111–113°C (hexane – diethyl ether); IR (KBr): 3346, 2968, 2886, 1606, 1598, 1492, 1346, 1278, 1166, 1068, 958, 820, 750, and 674 cm^{-1}; ^1H NMR δ: 0.59 (3H, d, J = 6.9 Hz, CH_3-3), 2.30 (1H, br s, $w_{1/2}$ = 15 Hz, OH), 2.43 (3H, s, $ArCH_3$), 3.56 (1H, d, J = 16.8 Hz, H-1_{ax}), 3.90 (3H, s, OCH_3), 4.28 (1H, br s, H-4), 4.33 (1H, dq, J = 6.9, 2.0 Hz, H-3), 4.71 (1H, d, J = 16.8 Hz, H-1_{eq}), 5.13 (2H, ABq, J = 12 Hz, Δδ = 0.11, OCH_2Ph), 6.84 (2H, ABq, J = 8 Hz, Δδ = 0.13, H-5 and H-6), 7.30–7.38 (5H, m, ArH of benzyl), and 7.50 (4H, ABq, J = 8.2 Hz, Δδ = 0.42, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 12.60, 21.42, 38.95, 54.14, 55.74, 70.65, 74.23, 111.75, 125.90, 126.53, 126.71, 127.23*, 128.09, 128.34*, 128.42*, 129.63*, 136.34, 137.23, 143.08, 143.37, and 151.90; HRMS calcd. for $C_{25}H_{27}NO_5S$: 453.1609; found: 453.1590.

(3*aR**,3*bR**)-6-Benzyloxy-7-methoxy-4-(*p*-toluenesulfonyl)-2,3,3*a*,3*b*,4,5-hexahydrofuro[3,4-*b*]isoquinoline (20)

A solution of DIBAH in toluene (1.5 M, 0.63 mL, 0.94 mmol) was added dropwise to a stirred solution of lactone **18** (430 mg, 0.894 mmol) in toluene (10 mL) at −45°C. When no starting material remained (TLC) saturated ammonium chloride was added (5 mL), the reaction was warmed to room temperature, and the products were extracted with diethyl ether (4 × 20 mL). The organic extracts were dried over sodium sulfate, concentrated under reduced pressure, and chromatographed to afford lactols **19** as an inseparable mixture (353 mg, 82%); IR (film): 3534, 2924, 1598, 1478, 1160, and 660 cm^{-1}.

The above mixture of lactols (200 mg, 0.43 mmol) was dissolved in dioxane (10 mL) and 6 N hydrochloric acid (0.25 mL, 1.52 mmol) was added dropwise. After heating the vigorously stirred biphasic system at 140°C for 45 min, it was cooled to room temperature, the acid was carefully neutralized with saturated sodium hydrogen carbonate, brine (7 mL) was added, and the reaction products were extracted with diethyl ether (4 × 25 mL). Drying, concentration, and chromatographic purification of the combined ethereal extracts provided **20** (140 mg, 69%) as a solid, mp 107–108°C (hexane – diethyl ether); IR (KBr): 2928, 1598, 1496, 1330, 1278, 1160, 1088, 920, 814, and 700 cm^{-1}; ^1H NMR δ: 1.70–1.90 (1H, m, $CHCH_2$), 2.09–2.25 (1H, m, $CHCH_2$), 2.42 (3H, s, $ArCH_3$), 3.60–3.75 (2H, m, CH_2O), 3.69 (1H, d, J = 16.2 Hz, H-1_{ax}), 3.86 (3H, s, OCH_3), 4.67 (2H, br s, H-3 and H-4), 4.87 (1H, d, J = 16.2 Hz, H-1_{eq}), 4.98 (2H, s, OCH_2Ph), 6.6 (2H, ABq, J = 8.4 Hz, Δδ = 0.14, H-5 and H-6), 7.28–7.48 (5H, m, ArH of benzyl), and 7.31 (4H, ABq, J = 8 Hz, Δδ = 0.41, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 21.25, 29.53, 38.18, 55.57, 55.71, 65.43, 74.00, 74.73, 111.27, 124.90, 125.97, 126.97*, 127.98, 128.29*, 128.37*, 129.22#, 136.12, 137.19, 142.96, 143.00, and 151.95; HRMS calcd. for $C_{26}H_{27}NO_5S$: 465.1610; found: 465.1602.

An increase in solvent polarity produced the elution of **21** (12 mg, 7%), as a solid, mp 105–106°C (hexane – diethyl ether); IR (KBr): 3260, 2948, 1588, 1482, 1322, 1274, 1160,

1052, 986, and 750 cm^{-1}; ^1H NMR δ: 2.38 (3H, s, $ArCH_3$), 3.85 (3H, s, OCH_3), 3.91 (2H, d, J = 6.5 Hz, $ArCH_2N$), 4.75 (1H, t, J = 6.5 Hz, NH), 4.95 (2H, s, OCH_2Ph), 6.72 (1H, dd, J = 2, 8 Hz, ArH), 6.83 (1H, dd, J = 2, 7.7 Hz, ArH), 6.90 (1H, dd, J = 7.7, 8 Hz, ArH), 7.22–7.33 (5H, m, ArH of benzyl), and 7.38 (4H, ABq, J = 8.3 Hz, Δδ = 0.41, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 21.27, 42.95, 55.57, 74.54, 112.03, 121.29, 123.98, 126.80*, 128.05, 128.28#, 128.31*, 129.24, 130.15, 136.63, 136.86, 142.82, 145.11, and 152.13; HRMS calcd. for $C_{22}H_{23}NO_4S$: 397.1348; found: 397.1350.

Dehydration of alcohol 12 to 1,2-dihydroisoquinoline 11

Anhydrous copper(II) sulfate supported on silica gel (17.7 mg, 1:3 w/w, 1.1 equiv.) was added to a solution of the alcohol (8 mg, 0.018 mmol) in 1,1,2,2-tetrachloroethane (1 mL). The mixture was heated and stirred for 1 h at 100°C. After separation of the catalyst by centrifugation, the supernatant was chromatographed, affording **11** (6 mg, 80%).

(3*S,4*S**)-8-Benzyloxy-4-hydroxy-7-methoxy-3-methyl-2-(*p*-toluenesulfonyl)-1,2,3,4-tetrahydroisoquinoline (13) by Mitsunobu inversion of alcohol 12**

Diethylazodicarboxylate (0.33 mL, 2.1 mmol) was added dropwise to a stirred solution of alcohol **12** (200 mg, 0.43 mmol), triphenylphosphine (550 mg, 2.1 mmol), and *p*-nitrobenzoic acid (320 mg, 1.9 mmol) in dry benzene (20 mL) at room temperature. The solution was stirred for 4 h, whereupon the volatile components were removed under reduced pressure and the residue was chromatographed, yielding the *p*-nitrobenzoate **14** (130 mg, 50%) as a solid, mp 64–65°C (hexane – diethyl ether); IR (KBr): 2942, 1726, 1608, 1526, 1496, 1350, 1266, 1162, 1090, 980, 812, 736, 718, and 670 cm^{-1}; ^1H NMR δ: 0.83 (3H, d, J = 6.8 Hz, CH_3-3), 2.41 (3H, s, $ArCH_3$), 3.87 (1H, d, J = 16.8 Hz, H-1_{ax}), 3.90 (3H, s, OCH_3), 4.68 (1H, dq, J = 5.3, 6.8 Hz, H-3), 4.71 (1H, d, J = 16.8 Hz, H-1_{eq}), 5.10 (2H, ABq, J = 11.2 Hz, Δδ = 0.08, OCH_2Ph), 6.05 (1H, d, J = 5.3 Hz, H-4), 6.90 (2H, ABq, J = 8.6 Hz, Δδ = 0.09, H-5 and H-6), 7.30–7.40 (5H, m, ArH of benzyl), 7.46 (4H, ABq, J = 8.3 Hz, Δδ = 0.42, ArH of *p*-toluenesulfonamide), and 8.27 (4H, ABq, J = 9.1 Hz, Δδ = 0.10, ArH of *p*-nitrobenzoate); ^{13}C NMR δ: 10.92, 21.41, 39.44, 48.38, 55.79, 71.08, 74.33, 111.44, 121.70, 123.62, 123.82*, 126.76, 127.07*, 128.22*, 128.42*, 128.54*, 129.65, 130.75*, 134.96, 136.68, 137.14, 143.04, 143.37, 150.74, 151.63, and 163.84.

Sodium hydroxide (50 mg) was added to a solution of ester **14** (100 mg, 0.16 mmol) in methanol (4 mL). After stirring for 1 h at room temperature, the solution was neutralized with 1 N hydrochloric acid, brine (5 mL) was added, the organic solvent was removed under reduced pressure, and the reaction products were extracted with diethyl ether (3 × 15 mL). Chromatographic purification of the dried and concentrated extract afforded alcohol **13** as an oil (74 mg, 100%); IR (film): 3504, 2920, 2850, 1654, 1598, 1492, 1438, 1324, 1280, 1162, 1074, 1026, 814, 736, and 670 cm^{-1}; ^1H NMR δ: 0.64 (3H, d, J = 6.8 Hz, CH_3-3), 1.65 (1H, br s, $w_{1/2}$ = 13 Hz, OH), 2.41 (3H, s, $ArCH_3$), 3.75 (1H, d, J = 16.9 Hz, H-1_{ax}), 3.89 (3H, s, OCH_3), 4.33 (1H, dq, J = 6.8, 5.6 Hz, H-3), 4.64 (1H, d, J = 16.9 Hz, H-1_{eq}), 4.81 (1H, bd, J = 5.6 Hz, H-4), 5.06 (2H, ABq, J = 11.3 Hz, Δδ = 0.09, OCH_2Ph), 7.07 (2H, ABq, J = 8.6 Hz, Δδ = 0.34, H-5 and H-6), 7.22–7.39 (7H, m, ArH of benzyl and ArH of *p*-toluenesulfonamide), and 7.64 (2H, d, J = 8.3 Hz, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 21.37*, 39.59, 50.99, 55.74, 68.31, 74.16, 111.42, 121.46, 125.97, 127.02*, 128.05, 128.31#, 128.43*, 129.58*, 136.71, 137.27, 142.71, 143.17, and 151.01; HRMS calcd. for $C_{25}H_{27}NO_5S$: 453.1609; found: 453.1595.

Dehydration of alcohol 13 to 1,2-dihydroisoquinoline 11

A solution of alcohol **13** (80 mg, 0.18 mmol) in dioxane (0.7 mL) and 6 N hydrochloric acid (0.12 mL, 4 mol. equiv.) was heated under reflux for 20 min and cooled to room temperature, then saturated sodium hydrogen carbonate (0.5 mL) and brine (5 mL) were added and the products were extracted with ethyl acetate (3 × 30 mL). The extracts were washed with brine (5 mL), dried, and the solvent was removed under reduced pressure to give a crude, chromatography of which furnished 1,2-dihydroisoquinoline **11** as an oil (63 mg, 80%).

General method for the reductive detosylation of 2-(*p*-toluenesulfonyl)-1,2,3,4-tetrahydroisoquinolines

A solution of the sulfonamide in dry THF was added to anhydrous liquid ammonia contained in a three-necked flask, fitted with a Dry Ice – acetone condenser protected with a sodium hydroxide tube and an ammonia inlet. With rapid stirring, sodium metal contained in a graduated glass tube was slowly added to the solution until the characteristic blue color persisted for about 10 min. The reaction was quenched with ammonium chloride (4 mol. equiv.), the solvent was evaporated at room temperature, and the residue was mixed with methanol (2 mL). The methanolic solution was mixed with silica gel, the solvent was removed under reduced pressure, and the adsorbed reaction product was chromatographed.

8-Hydroxy-7-methoxy-3-methyl-1,2,3,4-tetrahydroisoquinoline (2)

To a solution of alcohol **12** (20 mg, 0.044 mmol) in methanol (2 mL) were added 10% Pd/C (3 mg) and 6 N hydrochloric acid (0.5 mL). The reaction was stirred overnight under hydrogen at 3 atm (1 atm = 101.3 kPa), then the catalyst was separated by centrifugation and washed twice with methanol (0.5 mL). Solvent evaporation under reduced pressure and chromatography provided **15** (15 mg, 98%) as an oil; IR (film): 3440, 2922, 2848, 1596, 1498, 1332, 1282, 1158, 1068, 960, 816, 724, and 670 cm^{-1}; ^1H NMR δ: 0.95 (3H, d, J = 6.8 Hz, CH_3-3), 2.38 (3H, s, $ArCH_3$), 2.43 (1H, dd, J = 1.8, 10.8 Hz, H-4_{ax}), 2.97 (1H, dd, J = 5.4, 10.8 Hz, H-4_{eq}), 3.85 (3H, s, OCH_3), 4.06 (1H, d, J = 16.5 Hz, H-1_{ax}), 4.45 (1H, ddd, J = 1.8, 5.4, 6.8 Hz, H-3), 4.80 (1H, d, J = 16.5 Hz, H-1_{eq}), 5.70 (1H, br s, OH), 6.61 (2H, ABq, J = 7.9 Hz, Δδ = 0.16, H-5 and H-6), and 7.48 (4H, ABq, J = 8.3 Hz, δ = 0.49, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 16.43, 21.34, 34.43, 38.38, 47.25, 56.01, 109.21, 117.94, 119.91, 125.20, 127.09*, 129.45*, 137.01, 141.46, 142.91, and 144.14.

Following the general detosylation procedure, a solution of sulfonamide **15** (20 mg, 0.058 mmol) in THF (0.8 mL) was added to anhydrous liquid ammonia (4 mL). After reaction with sodium, ammonium chloride quench, and the usual work-up, tetrahydroisoquinoline **2** (10 mg, 90%) was recovered as a solid, mp 226–230°C (methanol – diethyl ether); IR (KBr): 3700–2500, 2940, 2926, 1588, 1500, 1384, 1288, 1242, and 880 cm^{-1}; ^1H NMR δ (D_2O, HOD at δ_H 4.60): 1.27 (3H, d, J = 6.5 Hz, CH_3-3), 2.63 (1H, dd, J = 10.3, 17.3 Hz, H-4), 2.89

(1H, dd, J = 4.5, 17.3 Hz, H-4), 3.39 (1H, ddt, J = 4.5, 6.5, 10.3 Hz, H-3), 3.67 (3H, s, OCH_3), 4.12 (2H, ABq, J = 16.2 Hz, $\Delta\delta$ = 0.22, H-1), and 6.70 (2H, ABq, J = 8.4 Hz, $\Delta\delta$ = 0.23, H-5 and H-6); ^{13}C NMR δ (D_2O, dioxane at δ_C 66.64): 18.82, 33.06, 41.62, 50.89, 57.67, 113.52, 116.52, 121.20, 125.88, 143.36, and 146.93; HRMS calcd. for $C_{11}H_{15}NO_2$: 193.1103; found: 193.1097.

8-Hydroxy-3-(2-hydroxyethyl)-7-methoxy-1,2,3,4-tetrahydroisoquinoline (3)

To a solution of compound **20** (150 mg, 0.322 mmol) in a 2:1 methanol – diethyl ether mixture (3 mL) were added 10% Pd/C (15 mg) followed by 7.2 N sulfuric acid (0.30 mL), and the reaction was stirred overnight under hydrogen at 4 atm. The catalyst was separated by centrifugation, the solvent was removed under reduced pressure, and the crude product was chromatographed, yielding **22** (119 mg, 98%) as needles, mp 160–160.5°C (hexane – ethyl acetate); IR (KBr): 3750–3300, 2930, 1498, 1328, 1282, 1158, 1062, 954, 874, 722, and 676 cm^{-1}; ^1H NMR δ: 1.53–1.64 (2H, m, $CHCH_2$), 2.36 (3H, s, $ArCH_3$), 2.38 (1H, dd, J = 1.9, 12.9 Hz, H-4_{ax}), 2.63 (1H, dd, J = 5.9, 12.9 Hz, H-4_{eq}), 3.63 (1H, dt, J = 4.3 Hz, 11.9, CH_2OH), 3.78 (1H, dt, J = 6.5, 11.9 Hz, CH_2OH), 3.84 (3H, s, OCH_3), 4.25 (1H, d, J = 17.7 Hz, H-1_{ax}), 4.44 (1H, m, H-3), 4.79 (1H, d, J = 17.7 Hz, H-1_{eq}), 5.80 (2H, br s, $w_{1/2}$ = 13 Hz, ArOH and CH_2OH), 6.57 (2H, ABq, J = 8.3 Hz, $\Delta\delta$ = 0.19, H-5 and H-6), and 7.44 (4H, d, J = 8.2 Hz, $\Delta\delta$ = 0.47, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 21.29, 31.77, 34.28, 38.78, 48.01, 55.93, 58.51, 109.13, 117.35, 119.63, 124.84, 126.65*, 129.51*, 137.11, 141.50, 143.08, and 144.22.

By the general procedure, a solution of sulfonamide **22** (30 mg, 0.080 mmol) in THF (0.9 mL) was added to anhydrous liquid ammonia (7 mL). Reaction with a slight excess of sodium was followed by ammonium chloride quench and the usual work-up to provide tetrahydroisoquinoline **3** (16 mg, 88%) as a yellowish solid, mp 254–257.5°C (methanol – diethyl ether); IR (KBr): 3700–2200, 3400, 2942, 1502, 1438, 1292, 1090, 878, and 618 cm^{-1}; ^1H NMR δ (D_2O, HOD at δ_H 4.60): 1.60–1.90 (2H, m, CH_2CH_2OH), 2.63 (1H, dd, J = 10.5, 17 Hz, H-4_{ax}), 2.84 (1H, dd, J = 4.6, 17 Hz, H-4_{eq}), 3.25–3.40 (1H, m, H-3), 3.54–3.67 (2H, m, CH_2OH), 3.61 (3H, s, OCH_3), 4.04 (2H, ABq, J = 16.3 Hz, $\Delta\delta$ = 0.24, H-1), and 6.63 (2H, ABq, J = 8.4 Hz, $\Delta\delta$ = 0.22, H-5 and H-6); ^{13}C NMR δ (D_2O, dioxane at δ_C 66.64): 32.47, 36.49, 43.19, 54.42, 58.70, 60.37, 114.50, 117.94, 122.25, 126.71, 144.56, and 148.07; HRMS calcd. for $C_{12}H_{17}NO_3$: 223.1208; found: 223.1209.

3-Formylmethyl-8-hydroxy-7-methoxy-2-(*p*-toluenesulfonyl)-1,2,3,4-tetrahydroisoquinoline (25)

A methylene chloride solution of dimethyl sulfoxide (0.695 mL, 1.33 mmol) was added dropwise in 2 min to a stirred solution of trifluoroacetic anhydride (0.67 mmol) in the same solvent (1.5 mL) cooled to −60°C. After stirring for 15 min, a solution of alcohol **22** (125 mg, 0.33 mmol) in methylene chloride (1 mL) was incorporated dropwise. After a 15 min reaction period, triethylamine (0.23 mL, 1.66 mmol) was added and left to react for 15 min at −60°C and 15 min at room temperature; then brine (10 mL) was added and the reaction product was extracted with diethyl ether (3 × 25 mL). The extracts were combined, dried over sodium sulfate, concentrated under reduced pressure, and chromatographed to furnish aldehyde **25** (86 mg, 69%); IR (film): 3444, 2922, 2842, 1720, 1498, 1332, 1284, 1160, 1090, 964, 816, 728, and 676 cm^{-1}; ^1H NMR δ: 2.39 (3H, s, $ArCH_3$), 2.50 (2H, dd, J = 1.5, 6.9 Hz, CH_2CHO), 2.52 (1H, dd, J = 2.5, 15.9 Hz, H-4_{ax}), 2.88 (1H, dd, J = 5.5, 15.9 Hz, H-4_{eq}), 3.85 (3H, s, OCH_3), 4.16 (1H, d, J = 17.1 Hz, H-1_{ax}), 4.77 (1H, d, J = 17.1 Hz, H-1_{eq}), 4.80 (1H, ddd, J = 2.5, 5.5, 6.9 Hz, H-3), 5.74 (1H, s, OH), 6.60 (2H, ABq, J = 8.3 Hz, $\Delta\delta$ = 0.18, ArH), 7.47 (4H, ABq, J = 7.4 Hz, $\Delta\delta$ = 0.43, ArH of *p*-toluenesulfonamide), and 9.67 (1H, t, J = 1.5 Hz, CHO); ^{13}C NMR δ: 21.37, 32.18, 39.09, 45.55, 46.63, 56.00, 109.39, 117.61, 119.89, 124.32, 127.05*, 129.60*, 136.43, 141.56, 143.38, 144.45, and 199.57; HRMS calcd. for $C_{19}H_{21}NO_5S$: 375.1140; found: 375.1149.

8-Hydroxy-3-hydroxymethyl-7-methoxy-2-(*p*-toluenesulfonyl)-1,2,3,4-tetrahydroisoquinoline (27)

To a solution of aldehyde **25** (50 mg, 0.132 mmol) in dry benzene (2 mL) were successively added powdered activated 4Å molecular sieves (150 mg) and morpholine (0.017 mL, 0.198 mmol). After stirring overnight at room temperature, the solids were decanted by centrifugation and washed twice with anhydrous benzene (1 mL). The organic solution was evaporated under reduced pressure to give enamine **26** (56 mg, 95%) as a yellowish oil; IR (film): 2958, 2852, 1650, 1498, 1330, 1284, 1160, 1062, 946, 728, and 664 cm^{-1}; ^1H NMR δ: 2.39 (3H, s, $ArCH_3$), 2.56 (1H, dd, J = 10.5, 15.6 Hz, H-4_{ax}), 2.88 (4H, t, J = 4.7 Hz, CH_2NCH_2), 3.14 (1H, dd, J = 8.3, 15.6 Hz, H-4_{eq}), 3.58 (4H, t, J = 4.7 Hz, CH_2OCH_2), 3.70 (1H, d, J = 16.5 Hz, H-1_{ax}), 3.84 (3H, s, OCH_3), 4.01 (1H, d, J = 13.8 Hz, NCH=C*H*), 4.05 (1H, dd, J = 8.3, 10.5 Hz, H-3), 4.78 (1H, d, J = 16.5 Hz, H-1_{eq}), 4.82 (1H, br s, $w_{1/2}$ = 8 Hz, OH), 5.93 (1H, d, J = 13.8 Hz, N-C*H*=CH), 6.62 (2H, ABq, J = 8.3 Hz, $\Delta\delta$ = 0.15), and 7.48 (4H, ABq, J = 8.2 Hz, $\Delta\delta$ = 0.48, ArH of *p*-toluenesulfonamide); ^{13}C NMR δ: 21.35, 35.11, 39.03, 46.28*, 52.80, 55.92, 67.91*, 95.55, 109.07, 118.24, 119.63, 125.42, 127.57*, 128.19, 129.15*, 136.74, 141.46, 142.47, and 144.13.

A solution of enamine **26** (50 mg, 0.112 mmol) in dry diethyl ether (2 mL) was cooled to −78°C and treated with ozonized oxygen until no starting material was left as determined by TLC. The intermediate ozonides were reacted with excess sodium borohydride in methanol for 1.5 h at −78°C and 30 min at room temperature. Then, 10% citric acid (5 mL) was added, the organic solvents were removed under reduced pressure, and the reaction products were extracted with diethyl ether (3 × 20 mL). The combined extracts were dried and chromatographed to furnish alcohol **27** (30 mg, 73%) as an oil; IR (film): 3500, 2926, 1498, 1336, 1284, 1162, 1090, 968, 814, and 666 cm^{-1}; ^1H NMR δ: 2.39 (1H, br s, $w_{1/2}$ = 16 Hz, CH_2OH), 2.42 (3H, s, $ArCH_3$), 2.70 (1H, dd, J = 3.2, 12.1 Hz, H-4_{ax}), 2.96 (1H, dd, J = 6, 12.1 Hz, H-4_{eq}), 3.71 (1H, dd, J = 5.1, 11.1 Hz, CH_2OH), 3.74 (1H, d, J = 15.7 Hz, H-1_{ax}), 3.83 (1H, dd, J = 3.4, 5.1 Hz, CH_2OH), 3.84 (3H, s, OCH_3), 4.02–4.12 (1H, m, H-3), 4.74 (1H, d, J = 15.7, H-1_{eq}), 5.86 (1H, br s, ArOH), 6.70 (2H, ABq, J = 8.4 Hz, $\Delta\delta$ = 0.08, ArH), and 7.54 (4H, ABq, J = 8.0 Hz, $\Delta\delta$ = 0.43, ArH of toleuensulfonamide); ^{13}C NMR δ: 21.35, 40.49, 43.39, 44.01, 55.98, 64.55, 109.21, 118.73, 119.62, 126.79, 127.40*, 129.63*, 133.49, 141.69, 143.50, and 144.56; HRMS calcd. for $C_{18}H_{21}NO_5S$: 363.1140; found: 363.1133.

8-Hydroxy-3-hydroxymethyl-7-methoxy-1,2,3,4-tetrahydroisoquinoline (3)

Following the general reductive detosylation procedure, a solution of sulfonamide **27** (30 mg, 0.083 mmol) in THF (0.9 mL) was added to anhydrous liquid ammonia (7 mL) and left to react with a slight excess of sodium. Ammonium chloride quench and the usual work-up provided tetrahydroisoquinoline **4** (15 mg, 87%) as a solid, mp 238–241°C (methanol–diethyl ether); IR (KBr): 3418, 3370, 3298, 2934, 1624, 1502, 1438, 1334, 1286, 1116, 1040, 922, and 810 cm^{-1}; ^1H NMR δ (D_2O, HOD at δ_H 4.60): 3.23–3.29 (1H, m, H-3), 3.54 (2H, dd, J = 3.3, 5.4, CH_2OH), 3.85 (3H, s, OCH_3), 3.88 (1H, dd, J = 5.3, 11.3, H-4_{ax}), 4.00 (1H, dd, J = 3.7, H-4_{eq}), 4.05 (2H, ABq, J = 16.1, Δδ = 0.10, H-1), and 6.76 (2H, ABq, J = 8.6, Δδ = 0.13, ArH); ^{13}C NMR δ (D_2O, dioxane at δ_C 66.64): 35.39, 40.74, 44.25, 56.45, 64.89, 112.34, 116.50, 119.85, 125.08, 141.64, and 145.96; HRMS calcd. for $C_{11}H_{15}NO_3$: 209.1052; found: 209.1051.

Abstract: Sulfoxides are valuable chiral auxiliaries because they direct the formation of carbon–carbon bonds. As a route to enantiomerically pure sulfoxides, we examined hydrolase-catalyzed kinetic resolution by hydrolysis of a pendant acetoxy group. Screening hydrolases for the enantioselective hydrolysis of the acetate in 2-(methylsulfinyl)phenyl acetate, **1***b*, identified cholesterol esterase (CE) as the most enantioselective enzyme. The enantiomeric ratio, *E*, ranged from 10 to 25, favoring the (*R*) configuration at sulfur. Competing chemical hydrolysis of **1***b* caused the large range in the measured values of *E*. A small-scale (250 mg) resolution of (±)-**1***b* yielded (*S*)-**1***b* with >99% ee (11% yield) after recrystallization. Changing the methyl substituent to phenyl or *n*-butyl did not significantly change the enantioselectivity (*E* = 10 and 15, respectively), but changing it to a chloromethyl substituent lowered the enantioselectivity slightly (*E* = 5). Changing the phenyl acetate to a naphthyl acetate (2-(phenylsulfinyl)phenyl acetate vs. 1-(phenylsulfinyl)-2-naphthyl acetate) increased the enantioselectivity from 10 to 19. In all cases CE favored the (*R*)-sulfoxide. To aid the design of new resolutions with CE, we propose an empirical rule that accounts for the observed enantiopreference of CE toward these 5 sulfoxides and 15 other chiral aryl acetates. This empirical rule uses both the size of the substituents and their conformational preferences to predict which enantiomer reacts faster.

Key words: kinetic resolution, lipase, cholesterol esterase, sulfoxides, empirical rule.

Résumé : Les sulfoxydes sont des auxiliaires chiraux utiles parce qu'ils orientent la formation de liaisons carbone–carbone. Dans le but d'obtenir des sulfoxydes énantiomériquement purs, on a examiné la possibilité d'utiliser une résolution cinétique catalysée par une hydrolase impliquant l'hydrolyse d'un groupe acétoxy. Une évaluation des hydrolases pour leur capacité à effectuer l'hydrolyse énantiosélective de l'acétate de 2-(méthylsulfinyl)phényle, **1***b*, a permis d'identifier l'estérase de cholestérol (CE) comme l'enzyme le plus énantiosélectif. Le rapport énantiomérique, *E*, varie de 10 à 25 et il favorise la configuration (*R*) au niveau du soufre. L'hydrolyse chimique compétitive du composé **1***b* provoque les grandes variations observées dans les valeurs mesurées de *E*. Une résolution préparative à faible échelle (250 mg) du composé (±)-**1***b* conduit, après recristallisation, au (*S*)-**1***b* avec un ee >99% (rendement de 11%). Lorsqu'on change le substituant de méthyle à phényle ou *n*-butylé, il n'y a pas de changement significatif d'énantiosélectivité (*E* = 10 et 15, respectivement); toutefois, si on le remplace par un chlorométhyle, l'énantiosélectivité est légèrement diminuée (*E* = 5). Si l'on remplace l'acétate de phényle par l'acétate de naphtyle (acétate de 2-(phénylsulfinyl)phényle vs. acétate de 1-(phénylsulfinyl)-2-naphtyle) l'énantiosélectivité passe de 10 à 19. Dans tous les cas, la CE favorise le (*R*)-sulfoxyde. Dans le but d'aider au développement de nouvelles résolutions à l'aide de la CE, on propose une règle empirique qui permet de tenir compte des énantiopréférences observées pour la CE vis-à-vis de ces 5 sulfoxydes et de 15 autres acétates arylés chiraux. Ces règles empiriques font appel à la fois à la grosseur des substituants et à leurs préférences conformationnelles pour prédire quel énantiomère réagira le plus rapidement.

Mots clés : résolution cinétique, lipase, estérase de cholestérol, sulfoxydes, règle empirique.

Introduction

Chiral sulfoxides (1) are useful chiral auxiliaries to direct the formation of carbon–carbon bonds (2). Examples include: electrophilic additions to anions at the α- or β-carbon, nucleophilic addition to the C=C bond of vinyl sulfoxides or a carbonyl β to the sulfoxide, radical reactions at the α-carbon, and Diels–Alder reactions of vinyl sulfoxides.

Two classes of enantioselective syntheses are the best current routes to enantiomerically pure sulfoxides (3): (*1*) stereospecific displacements at sulfites, sulfinates, and related compounds with established chirality at sulfur and (*2*) enantioselective oxidation of sulfides. Stereospecific displacements of menthol from *O*-menthyl *p*-tolylsulfinate remain the most common synthetic methods because the starting sulfite is easily prepared (4). Recent research identified several alternate starting compounds that yield sulfoxides after one (5) or two (6) displacements at the sulfur stereocenter. Examples of enantioselective oxidations of sulfides that yield sulfoxides with >90% ee include oxidations with a modified Sharpless reagent (7), chiral oxaziridines (8), titanium complexes of binaphthol (9), chloroperoxidase (10), and microorganisms (11). Recent comparisons of several of these reagents found that they complement one another (12). A related approach is to introduce carbon stereocenters in the sulfides and then use an achiral reagent for oxidation (for recent examples, see ref. 13).

Another route to enantiomerically pure sulfoxides is resolution. Although some resolutions relied on complexation (14), enantioselective oxidation (15), or reduction (16), the most successful resolutions used hydrolase-catalyzed reactions, Fig. 1. Almost 30 years ago Reid et al. (17) used pepsin to catalyze the enantioselective hydrolysis of sulfites with the structure PhOS(O)OR. Although hydrolysis yielded achiral product, the unreacted sulfite was enriched in one enantiomer. More recently, researchers resolved sulfoxides by hydrolyzing pendant ester groups in sulfoxides. Ohta et al. (18) resolved sulfinylacetates and sulfinylpropanoates by a microbe-catalyzed hydrolysis. Burgess et al. (19) resolved these compounds using the more readily accessible *Pseudomonas* K-10 lipase from Amano. Cardellicchio et al. resolved the related methyl (*Z*)-3-arylsulfinylpropenoates with lipase from *Candida rugosa* (CRL) or α-chymotrypsin (20), while Allenmark and Andersson (21) resolved a series of 2-(alkylsulfinyl)benzoates with CRL. Similarly, Mikolajczyk et al. used hydrolases for the enantioselective synthesis of sulfoxides by hydrolysis of the meso diesters (22). In all but one of these hydrolase-catalyzed reactions, the sulfur stereocenter lay in the acid portion of the ester.

In this paper, we examine the ability of lipases to resolve sulfur stereocenters that lie in the alcohol portion of the ester. We

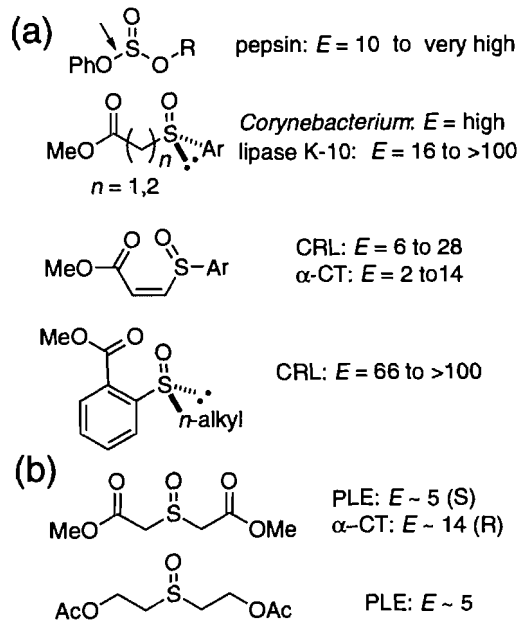
Fig. 1. Enantiomerically enriched sulfoxides and sulfinates prepared by enantioselective hydrolysis. (*a*) Racemic sulfoxides and sulfinates that were resolved by enantioselective hydrolysis. The absolute configuration of the favored enantiomer is shown where known. (*b*) Meso sulfoxides that were desymmetrized by enantioselective hydrolysis. In all but one example, the sulfoxide lies in the acid portion of the ester. Abbreviations: PLE = pig liver esterase; α-CT = α-chymoptrypsin; lipase K 10 = lipase from *Pseudomonas* sp. type K 10 from Amano; CRL = lipase from *Candida rugosa*.



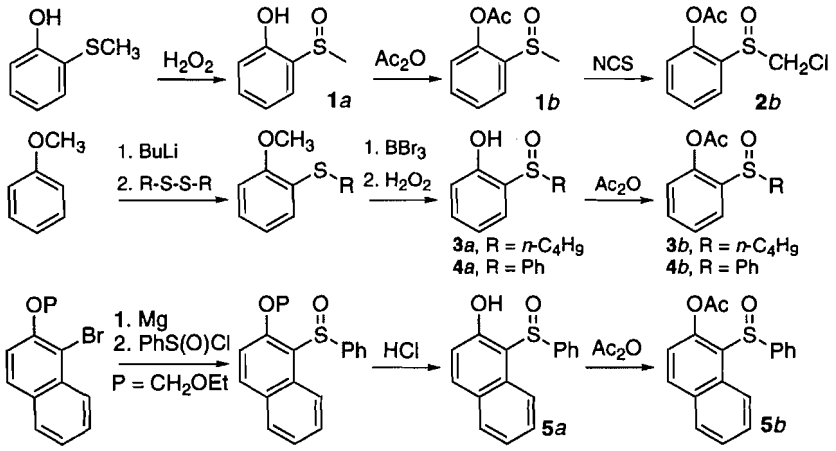
used lipases to resolve 2-(alkylsulfinyl)phenyl acetates, **1*b***–**3*b***, 2-(phenylsulfinyl)phenyl acetate, **4*b***, and 1-(phenylsulfinyl)-2-naphthyl acetate, **5*b***. The enzyme cholesterol esterase showed the highest enantioselectivity for these substrates, but these enantioselectivities were only moderate; enantiomeric ratios ranged from 5 to 25. In addition, we use this data and previous data from similar chiral aryl acetates to propose an empirical rule. The empirical rule accounts for the observed enantiopreference of CE toward these compounds and may be useful for the design of new CE-catalyzed resolutions, especially the resolution of remote stereocenters and non-carbon stereocenters.

Results

Synthesis and resolution of sulfoxides

Sulfoxides **1*b***–**5*b*** were prepared by standard chemical procedures, Scheme 1. Oxidation of 2-(methylthio)phenol followed by acetylation gave 2-(methylsulfinyl)phenyl acetate, **1*b***. Chlorination of **1*b*** using *N*-chlorosuccinimide gave the chloromethylsulfoxide, **2*b***. To prepare **3*b*** and **4*b***, we deprotonated anisole with butyllithium and quenched this anion with the appropriate disulfide. Removal of the methyl group, oxidation at sulfur, and acetylation gave **3*b*** and **4*b***. Preparation of the naphthyl derivative **5*b*** started from 1-bromo-2-naphthol protected as the ethoxymethyl ether. The Grignard reagent prepared from this bromide was quenched with phenylsulfinyl

Scheme 1.



chloride, then deprotected and acetylated to give **5***b*. When we used the benzyl protecting group, the Grignard reagent formed in very low yield; when we used the methyl protecting group, its removal required BBr_3, which also reacted with other parts of the molecule. Previous researchers made **1***a* and **3***a* by reaction of 2-mercaptophenol with an alkyl halide followed by oxidation with hydrogen peroxide (23). Both methods appear comparable.

Using substrate **1***b*, we screened commercial lipases and esterases for their ability to catalyze the enantioselective hydrolysis of the acetoxy group, Table 1, eq [1]. Pancreatic

[1] 
cholesterol esterase (CE) showed the highest enantioselectivity. The enantiomeric ratio, *E* (24), for this reaction ranged from 10 to 25, indicating modest to good enantioselectivity. Two other lipases, lipase from *Candida rugosa* (CRL) and lipase from *Aspergillus niger* (ANL), also showed modest enantioselectivity, $E = 7 \pm 2$ and 9 ± 2, respectively. The enantiomeric ratio for the other enzymes was less than 4.

Competing chemical hydrolysis of **1***b* caused the large range in the measured enantiomeric ratio for the CE-catalyzed reaction. The half-life for nonenzymatic hydrolysis of **1***b* was approximately 40 h under the conditions used for enzymatic reactions: phosphate buffer (10 mM, pH 7.0) stirred with an equal volume of ethyl ether.[2] We measured lower enantiomeric ratios when the reaction times were long, consistent with more chemical hydrolysis. We made no correction for this chemical hydrolysis. For the less enantioselective enzymes, this chemical hydrolysis did not significantly affect the measured enantiomeric ratio.

The facile chemical hydrolysis of **1***b* is consistent with the electron-withdrawing effect of the methylsulfinyl substituent. Indeed, the pK_a of the leaving phenol, **1***a*, is 7.06 (25), similar to that for *p*-nitrophenol, whose pK_a is 7.14 (26). Esters of *p*-nitrophenol also hydrolyze slowly in neutral aqueous solutions. Although competing chemical hydrolysis is a disadvantage of using a reactive ester, the more rapid enzymatic reaction is an advantage. CE catalyzed the hydrolysis of **1***b* 200 times faster than a natural substrate, cholesterol acetate, under the same conditions: 33 vs. 0.17 U/mg, respectively.

A crude preparation of CE, pancreas acetone powder, also showed a similar enantioselectivity toward **1***b*, Table 1. In previous resolutions of binaphthols, we also found that this crude preparation showed the same enantioselectivity as purified CE (27). We used this pancreas acetone powder to resolve 250 mg of **1***b*. At 56% conversion, the remaining substrate, (*S*)-**1***b*, had 77% ee corresponding to an *E* of 9.2. We removed phenol **1***a* as the phenolate by washing with sodium carbonate solution.[3] After recrystallization of (*S*)-**1***b* from toluene–hexane, we isolated 28 mg with >99% ee, 11% yield. The maximum yield is 50% in a resolution.

Cholesterol esterase catalyzed the hydrolysis of similar acetoxysulfoxides **2***b*–**5***b* with similar enantioselectivities: 5–19. Changing the methyl substituent in **1***b* to chloromethyl in **2***b* lowered the enantioselectivity from 10–25 to 5. Changing the methyl substituent in **1***b* to butyl or phenyl in **3***b* or **4***b* had little effect on enantioselectivity: *E* was 14 and 10, respectively. Changing from phenyl acetate **4***b* to naphthyl acetate **5***b* increased the enantioselectivity from 10 to 19. For CRL- and ANL-catalyzed hydrolyses of **5***b*, the enantiomeric ratios were 6 and 3, respectively.

Cholesterol esterase favored the (*R*) enantiomer for all five substrates. We established the absolute configuration of **1***b* and **4***b* by comparing their optical rotations to known rotations in the literature, see Experimental section. We also tentatively assigned (*R*) absolute configurations to the favored enantio-

[2] The rate of nonenzymic hydrolysis of **1***b* decreased at 0°C ($t_{1/2}$ = 600 h). Replacing the ethyl ether phase with chloroform or hexane also decreased the rate of hydrolysis ($t_{1/2}$ > 100 d, 180 h, respectively, at room temperature). We also checked for racemization of **1***a* and **1***b*. When stirred in aqueous solution overnight, we observed partial hydrolysis of **1***b* and partial racemization of both **1***a* and **1***b* at pH 4, partial hydrolysis of **1***b* and complete racemization of both **1***a* and **1***b* at pH 8, and complete hydrolysis of **1***b* and complete racemization of the resulting **1***a* at pH 10. However, when an organic phase was present as in the enzyme reaction, this racemization was completely suppressed. Over 4 d at pH 8.6 or 6.9 we detected no racemization of **1***a* or **1***b* when we added hexane–isopropanol (9:1) as a second phase. We did observe a small amount of hydrolysis of **1***b* under these conditions.

[3] This extraction procedure racemized **1***a*. See footnote 1

[a]CE = cholesterol esterase; PPL = lipase from porcine pancreas; CRL = lipase from *Candida rugosa* (synonym *C. cylindracea*); ANL = lipase from *Aspergillus niger* (Amano AP-6); RML = lipase from *Rhizomucor miehei* (Amano MAP-10); K-10 = lipase from *Pseudomonas* sp. (Amano K-10); PCL = lipase from *Pseudomonas cepacia* (Amano P30); ACE = electric eel acetylcholine esterase.

[b]U/mg = μmol ester hydrolyzed per minute per mg of solid.

[c]The % conversion was determined either from the amount of base consumed during hydrolysis or calculated from the enantiomeric excess of the starting material (ee_s) and product (ee_p) using conv. = $ee_s/(ee_s+ee_p)$.

[d]The enantiomeric purity of **1***a*, **1***b*, **2***a*, and **2***b* were determined by HPLC using a Chiralcel OB column. The enantiomeric purities of **3***b*-**5***b* were determined by ^{1}H NMR in the presence of (+)-Eu(hfc)$_3$. Compounds **3***a*-**5***a* were acetylated and the enantiomeric purities of the acetates were measured by ^{1}H NMR in the presence of (+)-Eu(hfc)$_3$.

[e]E = enantiomeric ratio, which measures the preference of the enzyme for one enantiomer over the other (See ref. 24). The *E* listed is an average of at least two reactions. The values of ee and %conv. are for one of these reactions and may not give exactly the *E* shown. Reference 34 includes experimental details of the enzyme hydrolysis and work-up for similar compounds.

[f]Pancreas acetone powder, a crude preparation of cholesterol esterase, was used as the catalyst.

[g]Tentative assignment of absolute configuration based on the relative chemical shift of the favored enantiomer in the ^{1}H NMR in the presence of Eu(hfc)$_3$.

mers of **2***b*, **3***b*, and **5***b* based on relative positions of the acetyl methyl ^{1}H NMR resonance in the presence of Eu(hfc)$_3$. The resonance for the fast-reacting enantiomer appeared downfield of the resonance for the slow-reacting enantiomer for all five acetoxysulfoxides. The other hydrolases also favored (*R*)-**1***b* except lipase from *Rhizomucor miehei* (RML), which favored (*S*)-**1***b*, but with low enantioselectivity. CRL favored the (*R*) enantiomers of **4***b* and **5***b* with moderate enantioselectivity, but ANL showed low enantioselectivity and favored (*S*)-**4***b* and (*R*)-**5***b*.

Empirical rule to predict the enantiopreference of CE toward chiral aryl esters

An empirical rule that predicts the enantiopreference of CE toward secondary alcohols, Fig. 2*a* (28), does not apply to the sulfoxides resolved in this paper. To include these substrates, we propose an extension of this secondary alcohol rule to chiral aryl esters, Fig. 2*b*. Like the earlier rule, the extension uses the size of the substituents to predict which enantiomer will react faster.

Figure 3 summarizes all reported resolutions of chiral aryl esters with CE. The first group of substrates, Fig. 3*a*, are rigid. They include binaphthols (27) and thiobinaphthol (29), spiro compounds (27), helicene derivatives (30),[4] and α-tocopherols (32, 33). To apply the rule, we simply chose the enantiomer whose shape best matched the schematic in Fig. 2*b*. Of the 11 examples, 10 fit the empirical rule. The exception (spirobiindanol where R = H) showed only a slight enantiopreference for the other enantiomer.

[4] The authors reported a (+) rotation for a quinone derived from oxidation of the favored enantiomer. We tentatively assign this as the (*P*) configuration shown because (+)-[5]-helicene has the (*P*) configuration (31).

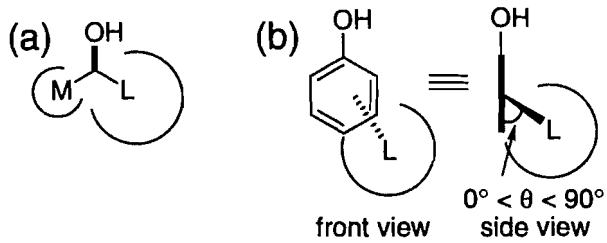
Fig. 2. Empirical rules for the observed enantiopreference of cholesterol esterase. (*a*) Cholesterol esterase favors the enantiomers of secondary alcohols with the shape shown, where M represents a medium substituent such as methyl and L represents a large substituent such as phenyl. For details see ref. 28. (*b*) A proposed extension of this empirical rule to chiral aryl esters. With the aryl ester oriented in the plane of the paper, cholesterol esterase favors the enantiomer with the larger substituent, L, to the lower right and behind the plane of the paper.



The second group of substrates comprises the sulfoxides resolved in this paper and the related phosphines and phosphine oxides resolved previously (34), Fig. 3*b*. These substrates are flexible because a single bond links the stereocenter to the aryl ring. Rotation about this bond allows both enantiomers to adopt conformations that resemble the aryl ester rule. However, these conformations are diastereomeric so one enantiomer adopts this conformation more easily.[5] We suggest that this enantiomer will react faster. Thus, applying the aryl ester rule to flexible substrates requires the researcher to compare the stabilities of the conformations whose shape matches the rule. The fast-reacting enantiomer is the one whose conformation lies lower in energy.

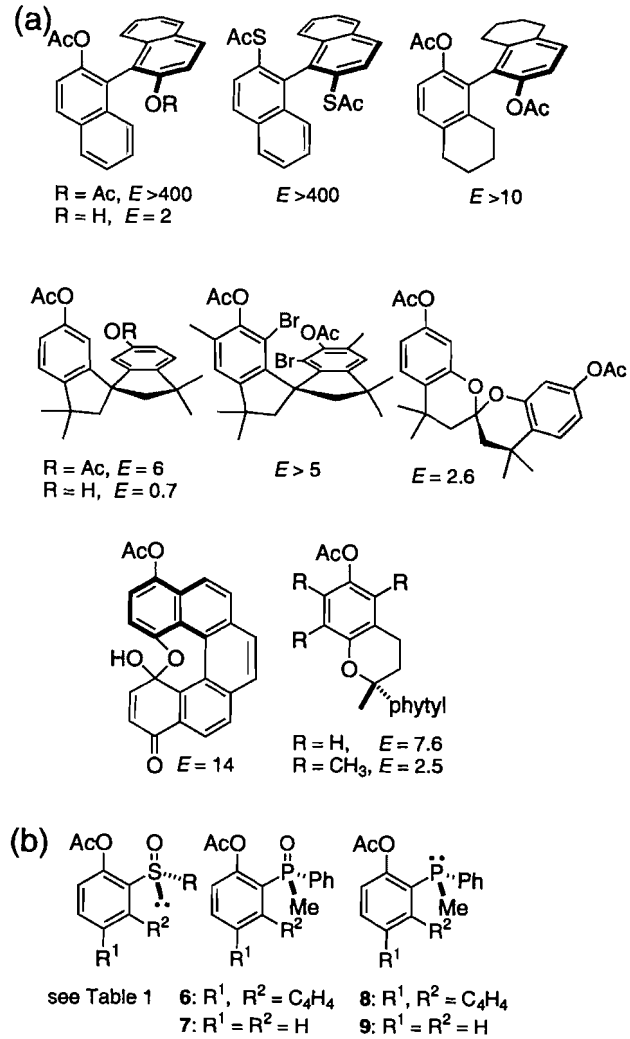
We compared the stabilities of enantiomers of sulfoxides **1***b*–**5***b* in conformations that resemble the rule using molecular mechanics and indeed found that the conformation for the fast-reacting (*R*) enantiomer lay 0.60–1.7 kcal/mol lower in energy, Table 2. Figure 4 compares the conformations for (*R*)- and (*S*)-**5***b*. When (*R*)-**5***b* orients the phenyl substituent as suggested by the rule, it lies 1.7 kcal/mol lower in energy that the corresponding conformation of (*S*)-**5***b*. This difference is probably due to the favorable eclipsed orientation of the sulfoxide oxygen and naphthyl ring for (*R*)-**5***b* and the less favorable *gauche* orientation of these groups in (*S*)-**5***b* (35).

A similar comparison of conformations that resemble the rule, for phosphine oxides **6** and **7**, also found that the fast-reacting (*R*)-enantiomers lay lower in energy, Table 2. For **6**, the energy difference between the local minima was 0.40 kcal/mol. For **7**, only the fast-reacting enantiomer had a local minimum that resembled the rule, so we compared the energies at $\theta = 45°$,[6] the middle of the range suggested in the rule, $0° > \theta > 90°$. The fast-reacting enantiomer lay 0.78 kcal/mol lower at

[5] Enantiomers have identical energies for their global minima and for the ensemble of all conformations, but two particular conformations may be diastereomeric and therefore differ in energy.

[6] θ is the dihedral angle between the aryl ring and the largest substituent as defined in Fig. **2***b*.

Fig. 3. Structures of the fast-reacting enantiomers in CE-catalyzed resolutions of chiral aryl esters. (*a*) Rigid substrates. Ten of the eleven substrates follow the rule; one spirobiindanol (R = H) does not. (*b*) Flexible substrates: sulfoxides, phosphine oxides, and phosphines (ref. 34). Table 2 summarizes the enantioselectivity of CE toward these substrates.



45° and by a similar amount throughout the range, Fig. 5. The conformation for the fast-reacting enantiomer lies lower in energy because the oxygen on phosphorus eclipses the aromatic ring. In the slow-reacting enantiomer the methyl group on phosphorus eclipses the aromatic ring. Both X-ray crystal structures and semi-empirical calculations showed that an oxygen on phosphorus favors a nearly eclipsed orientation to an aromatic ring (36).

The fast-reacting enantiomers of phosphines **8** and **9** also lay at lower energy when we compared conformations that resembled the rule. We found no local minima that resemble the rule, so we again compared the energies at $\theta = 45°$ where the difference was 1.6 kcal/mol for **8**, Fig. 6, and 0.80 kcal/mol for **9**. The conformation for the fast-reacting enantiomer is more stable because the lone pair, not the methyl, eclipses the aromatic ring. Such conformations have been previously identified as low-energy conformations (37).

Fig. 4. Conformations of sulfoxide **5***b* that resemble the aryl ester rule. Both enantiomers have local minima that place the largest group (phenyl) into the orientation required by the rule. However, the conformation for the (*R*)-**5***b* (fast reacting) lies 1.7 kcal/mol lower in energy than the conformation for the (*S*)-**5***b* (slow reacting). In (*R*)-**5***b*, the sulfoxide oxygen eclipses the aryl ring, while in (*S*)-**5***b* the sulfoxide oxygen lies *gauche* to the aryl ring. This difference allows (*R*)-**5***b* to more easily adopt a conformation that resembles the aryl ester rule. Structures and relative energies were calculated using molecular mechanics. Gray indicates carbon atoms, stippling indicate oxygen atoms, diagonal stripes indicate the sulfur atom, and the small light gray ball represents the sulfur lone pair.

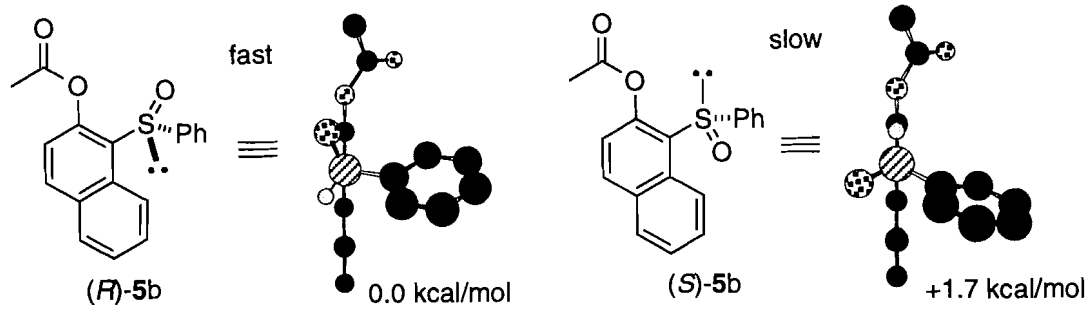


Fig. 5. Conformational energies of the two enantiomers of phosphine oxide **7** in conformations that resemble the chiral aryl ester rule. The fast-reacting enantiomer lies at lower energy throughout the range $0° > \theta > 90°$. The energy difference at $\theta = 45°$ is 0.78 kcal/mol. The fast-reacting enantiomer lies at lower energy because the oxygen, not the methyl, eclipses the aryl ring. Gray indicates carbon atoms, stippling indicates oxygen atoms, and vertical stripes indicate the phosphorus atom.

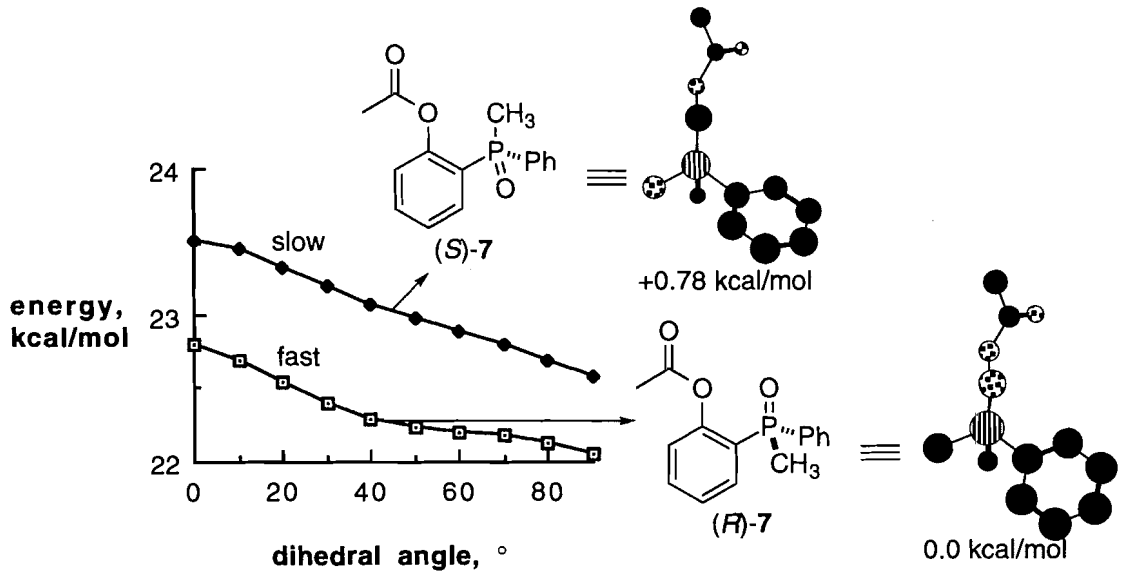

In summary, the aryl ester rule in Fig. 2*b* reliably predicts which enantiomer reacts faster with CE for 16 of the 17 examples. For rigid substrates, one simply choses the enantiomer whose shape best matches the rule. For flexible substrates, one compares the stabilities of the two enantiomers in conformations that resemble the rule and chooses the more stable one.

Discussion

Cholesterol esterase resolved sulfoxide **1***b* with moderate enantioselectivity ranging from 10 to 25. Using this resolution, we prepared (*S*)-**1***b* with >99% ee, but in modest yield. Cholesterol esterase also resolved four other sulfoxides, **2***b*–**5***b*, with similar enantioselectivity, suggesting that this resolution may be useful for a wide range of substrates. Indeed, we recently reported the resolution of several phosphines and phosphine oxides using a similar approach (34).

The degree of enantioselectivity was lower than previous resolutions (20, 21) where the sulfoxide was in the acid portion of the ester. Thus, putting the sulfoxide in the alcohol portion does not seem to be a good general strategy for resolution of sulfoxides. Nevertheless, several synthetic applications of arylsulfoxides require a methoxy or other alkoxy group oriented *ortho* to the sulfinyl group for high enantioselectivity (38). For these applications, our kinetic resolution may be a good route to the enantiomerically pure sulfoxides.

We also proposed an extension of the empirical rule for sec-

Fig. 6. Conformational energies of the two enantiomers of phosphine **8** in conformations that resemble the chiral aryl ester rule. The fast-reacting enantiomer lies at lower energy throughout the range $0° > \theta > 90°$, but both enantiomers have similar energies at $\theta = 90°$. The energy difference at $\theta = 45°$ is 1.6 kcal/mol. The fast-reacting enantiomer lies at lower energy because the lone pair, not the methyl, eclipses the aryl ring. Gray indicates carbon atoms, stippling indicates oxygen atoms, vertical stripes indicate the phosphorus atom, and the small light gray ball represents the phosphine lone pair.

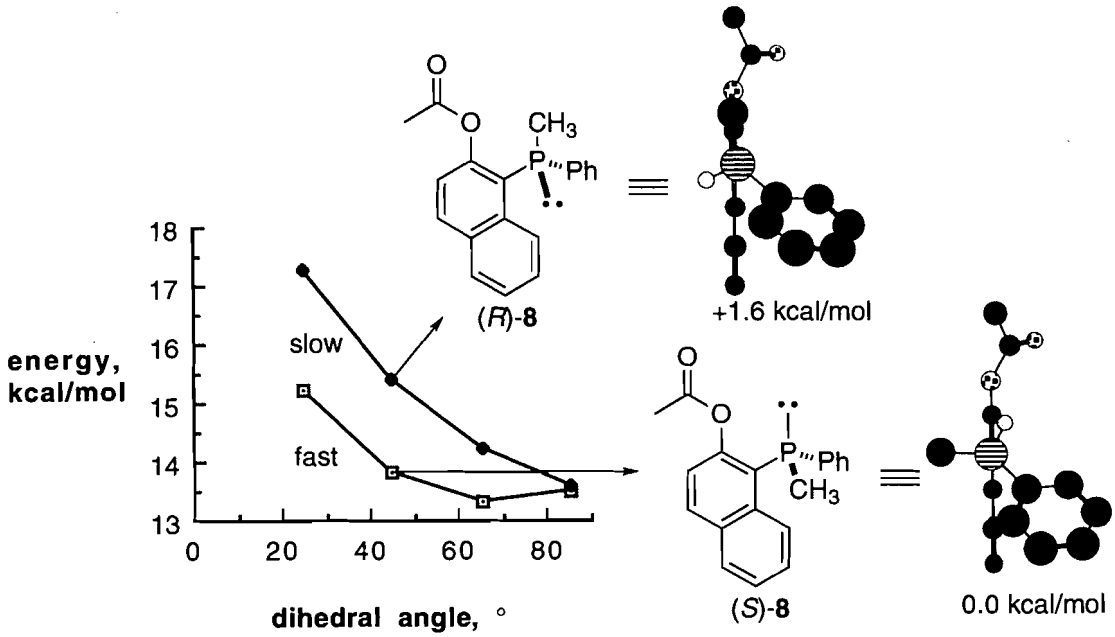

Table 2. Angles and relative energies of conformations that resemble the aryl ester rule.

Substrate	θ(fast)[a]	θ(slow)[b]	ΔEnergy[c]	E[d]
1*b*	88°	53°	1.1	10–25
2*b*[e]	87°	77°	0.60	5
3*b*	83°	81°	1.6	14
4*b*	83°	66°	1.7	10
5*b*	80°	62°	1.7	19
6	52°	63°	0.40	32
7	17°	(45°)[f]	0.78[g]	4
8	(45°)[f]	(45°)[f]	1.6	5
9	(45°)[f]	(45°)[f]	0.80	4

[a]The dihedral angle between the aryl ring and the large group as defined in Fig. 2*b* for the local minimum, which resembles the rule for the fast-reacting enantiomer. Some local minima may also be global minima.

[b]Same as in note *a*, but for the slow-reacting enantiomer.

[c]$\text{Energy}_{\text{slow}} - \text{Energy}_{\text{fast}}$ in kcal/mol. The positive values indicate that the conformation for the fast-reacting enantiomer lies lower in energy.

[d]Enantioselectivity of CE toward these substrates. Data for **6–9** are from ref. 34.

[e]The chlorine atom oriented *anti* to the sulfoxide oxygen.

[f]This enantiomer had no local mimimum where $0° < \theta < 90°$. The energy difference is for the middle of this range, $\theta = 45°$. Unless otherwise noted, the energy differences were similar throughout the entire range.

[g]Difference at 45° for both enantiomers.

ondary alcohols to include chiral aryl esters. For rigid substrates, the enantiomer that resembles the schematic in Fig. 2*b* indeed reacted faster for 10 of the 11 examples. For the flexible substrates, this empirical rule required a comparison of conformational energies. We compared these energies using molecular mechanics and found that in all nine cases the fast-reacting enantiomer was the one that more easily adopted a conformation that resembled the rule. Although the calculated energy differences were small, <2 kcal/mol, we believe most errors cancelled because we compared the conformations of enantiomers. Indeed, the calculated conformational preferences were consistent with the experimentally determined conformational preferences of sulfoxides, phosphine oxides, and phosphines.

Without this empirical rule, CE appeared to have an opposite enantiopreference toward sulfoxides and phosphines. When we compared the 3-D structures of the fast-reacting enantiomers, we found that the lone pair of the phospine overlapped, not the lone pair of the sulfoxide, but the oxygen. (Compare the structures of the fast-reacting sulfoxide in Fig. 4 with the fast-reacting phospine in Fig. 6). However, our empirical rule explains this difference. For the sulfoxide, the oxygen, not the sulfoxide lone pair, favors the eclipsed orientation to the aromatic ring, while for the phosphine the lone pair favors this orientation. In the most stable conformation both the sulfoxide and phosphine have a similar orientation of the large substituent.

The empirical rule currently predicts only which enantiomer reacts faster and not the degree of enantioselectivity. For both the rigid and flexible substrates, most of the enantioselectivities range from moderate to good, with a few excellent enantioselectivities. There is no obvious structural feature that distinguishes the substrates resolved with excellent enantioselectivity from the others. For the flexible substrates, we looked for a correlation between the degree of enantioselectivity and the difference in conformational energies in Table 2,

but found only a moderate correlation. This is consistent with the notion that both differences in conformational energies and interactions in the active site will contribute to enantioselectivity.

Crystallographers have not yet solved the three-dimensional structure of mammalian cholesterol esterase, but they have solved the structure of CRL, a related enzyme. This structure showed that the active site indeed contains large and medium-sized pockets as suggested by the secondary alcohol rule (39). Our extension to chiral aryl esters suggests that within the large pocket, one side is more open than the other and that this difference determines the enantiopreference of CE toward chiral phenols. The structure of CRL indeed shows more space on the side of this large pocket suggested by the empirical rule. Although there are fewer examples, this chiral aryl rule may also apply to CRL. For the sulfoxides **1***b*, **4***b*, and **5***b*, CRL was less enantioselective than CE; however, for the phosphines and phosphine oxides, CRL was more enantioselective (34).

This empirical rule may be useful in the design of new CE-catalyzed resolutions. Up until now most lipase-catalyzed resolutions involve stereocenters close to the ester group. One current goal is to extend the usefulness of lipases by resolving stereocenters distant from the ester and to resolve non-carbon stereocenters. This empirical rule may help identify good examples.

Experimental section

General

Cholesterol esterase (CE) from porcine pancreas was purchased from Genzyme, Boston, Mass. Lipase from *Candida rugosa* (also known as *C. cylindracea* (40)), acetylcholine esterase, porcine pancreas lipase, and bovine pancreas acetone powder were purchased from Sigma Chemical Co., St. Louis, Mo. Lipase from *Pseudomonas cepacia* (lipase P-30), lipase from *Rhizomucor miehei* (MAP-10, synonym *Mucor miehei* (40)), lipase from *Aspergillus niger* (AP-6), and lipase from *Pseudomonas* K10 (lipase-K10) were purchased from Amano International Enzyme Co., Troy, Va. One unit of hydrolase activity, U, corresponds to one μmol of ester group hydrolyzed per minute. Silica gel 70–230 mesh, 60Å (Aldrich, Milwaukee, Wis.) was used for flash chromatography. All other reagents were purchased from Aldrich Chemical Company. Melting points are uncorrected. Tetrahydrofuran and benzene were dried by distillation from sodium under nitrogen with benzophenone as an indicator. Methylene chloride was distilled from sodium hydride and stored over 4Å molecular sieves. Silica gel plates (0.25 mm, Whatman) with G-UV-254 indicator were used for TLC. Mass spectra were acquired using electron ionization conditions (70 eV). ^{1}H NMR spectra were recorded in $CDCl_3$ at 200 MHz using tetramethylsilane as the internal reference. Unless otherwise noted, ^{13}C NMR spectra were recorded in $CDCl_3$ at 75 MHz and were proton decoupled. Either $CDCl_3$ (77.0 ppm) or tetramethylsilane was used as the internal reference. Enzyme assays and reactions were run as described previously for phosphine oxides (34).

(±)-2-(Methylsulfinyl)phenol, ***1****a*

Hydrogen peroxide (24 mL of a 30% soln., 0.21 mol) was added dropwise to a stirred solution of 2-(methylthio)phenol (25 g, 0.18 mol) in acetic acid (100 mL) that was kept at room temperature with a water bath. After addition was complete the reaction mixture was stirred for 45 min. The acetic acid was removed as an azeotrope with toluene by rotary evaporation. The residue dissolved in ethyl acetate (200 mL) and was washed with saturated $NaHCO_3$ solution (2 × 200 mL) and water (200 mL). The organic phase was dried over $MgSO_4$, filtered, and concentrated by rotary evaporation to a solid. Recrystallization from toluene yielded pale yellow crystals, 25.5 g (92%): mp 126–127°C (lit. (23) mp 127–128°C); ^{1}H NMR δ: 7.92–6.89 (m, 4H), 2.95 (s, 3H); ^{13}C NMR δ: 159.1, 133.0, 124.8, 123.4, 119.9, 119.4, 41.7; MS *m/z*: 156 ($M^{+\bullet}$, 93), 141 (100), 113 (49), 109 (11), 65 (22), 63 (11); The mass spectrum and ^{1}H NMR spectrum agree with those reported previously (23).

(±)-2-(Methylsulfinyl)phenyl acetate, ***1****b*

Acetic anhydride (8.5 mL, 90 mmol) was added to a stirred solution of **1***a* (7.2 g, 46 mmol) and pyridine (5.7 mL, 70 mmol) in CH_2Cl_2 (300 mL). The mixture was refluxed for 8 h, when a TLC showed that the reaction was complete. The mixture was cooled, washed with saturated $NaHCO_3$ solution (2 × 500 mL) and with H_2O (500 mL). The organic phase was dried over $MgSO_4$, filtered, and concentrated by rotary evaporation to an oil that solidified on standing. Recrystallization from toluene–hexane yielded white crystals, 7.6 g (82%): mp 85–86°C; R_f = 0.16 (ethyl acetate – hexane, 1:1); ^{1}H NMR δ: 7.98–7.16 (m, 4H), 2.78 (s, 3H), 2.34 (s, 3H); ^{13}C NMR δ: 168.3, 146.0, 137.6, 132.0, 127.2, 124.7, 122.6, 42.2, 20.6; MS *m/z*: 198 ($M^{+\bullet}$, 11), 156 (87), 141 (100), 113 (18), 109 (10), 43 (13); HRMS calcd. for $C_9H_{10}O_3S$: 198.0351; found: 198.0347.

(±)-2-(Chloromethylsulfinyl)phenyl acetate, ***2****b*,

was prepared by chlorination of **1b** as described by Satoh et al. (41) for a similar (methylsulfinyl)benzene. Purification by column chromatography on silica gel eluted with hexane – ethyl acetate (3:1) gave a yellow oil, (22%): R_f = 0.22 (hexane – ethyl acetate, 3:1); ^{1}H NMR δ: 7.98–6.91 (m, 4H), 4.64 (d, 1H, J = 16 Hz), 4.41 (d, 1H, J = 16 Hz), 2.35 (s, 3H); MS *m/z*: 234 ($(M + 2)^{+\bullet}$, 2), 232 ($M^{+\bullet}$,4), 190 (27), 141 (100), 113 (27), HRMS calcd. for $C_9H_9O_3ClS$: 231.9961; found: 231.9960.

1-Methoxy-2-(butylthio)benzene was prepared as described below for 1-methoxy-2-(phenylthio)benzene: yellow oil (82%); R_f = 0.40 (hexane – ethyl acetate, 19:1); ^{1}H NMR δ: 7.45–6.77 (m, 4H), 3.90 (s, 3H, OCH_3), 2.90 (t, 2H, J = 7 Hz), 2.0–1.3 (m, 4H), 0.93 (t, 3H, CH_3, J = 7 Hz). ^{13}C NMR (50 MHz) δ: 156.0, 128.0, 125.9, 124.6, 120.4, 109.9, 55.9, 32.0, 31.5, 22.7, 14.4; MS *m/z*: 196 ($M^{+\bullet}$, 70), 153 (18), 140 (100), 138 (17), 125 (24). Previous researchers reported a similar ^{1}H NMR spectrum, except for the δ3.90 resonance, which they observed at δ3.50 (42).

(±)-2-(Butylsulfinyl)phenol, ***3****a*, was prepared as described below for **4***a*. The methyl group in 1-methoxy-2-(butylthio)benzene was removed with BBr_3 and the resulting 2-(butylthio)phenol was purified by column chromatography on silica gel eluted with hexane to give a yellow oil (40%): R_f = 0.59 (hexane – ethyl acetate, 9:1); ^{1}H NMR δ: 7.8–6.6 (m, 4H), 2.68 (t, 2H, J = 7 Hz), 1.8–1.2 (m, 4H), 0.88 (t, 3H, CH_3, J = 7 Hz). Oxidation with hydrogen peroxide yielded **3***a* as an

For personal use only.

oil (71%): R_f = 0.23 (hexane – ethyl acetate, 3:1); ^{1}H NMR δ: 7.37–6.86 (m, 4H), 3.05 (m, 2H), 1.70 (m, 2H), 1.44 (m, 2H), 0.92 (t, 3H, CH_3, J = 7 Hz); ^{13}C NMR δ: 159.9, 132.8, 125.4, 121.3, 119.6, 119.4, 55.0, 24.4, 21.7, 13.6; MS *m/z*: 198 ($M^{+\bullet}$, 46), 142 (87), 124 (87), 96 (100), 65 (20), 57 (25), 41 (18). Previous researchers reported a similar mass spectrum and ^{1}H NMR spectrum (23).

(±)-2-(Butylsulfinyl)phenyl acetate, ***3***b, was prepared by acetylation of ***3****a* as described below for ***5****a*; yellow oil (62%): R_f = 0.36 (hexane – ethyl acetate, 3:1); ^{1}H NMR δ: 8.0–7.1 (m, 4H), 3.1–2.7 (m, 2H), 2.33 (s, 3H, $COCH_3$), 1.95–1.30 (m, 4H) 0.95 (t, 3H, CH_3, J = 7 Hz); ^{13}C NMR δ: 168.2, 146.2, 135.8, 127.0, 125.5, 122.6, 55.2, 24.1, 21.7, 13.6; MS *m/z*: 240 ($M^{+\bullet}$, 4), 198 (31), 142 (18), 124 (38), 96 (32), 43 (30); HRMS calcd. for $C_{12}H_{16}O_3S$: 240.0820; found: 240.0822.

1-Methoxy-2-(phenylthio)benzene

To a solution of anisole (1.0 mL, 9.2 mmol) in dry THF (7 mL) cooled to −78°C under nitrogen was added butyllithium (3.4 mL of a 2.5 N soln. in hexanes, 1.1 equiv.) and the resulting solution was stirred at 0°C for 1.5 h. Diphenyldisulfide (2.21 g, 10.1 mmol) dissolved in THF (7 mL) was added to the reaction mixture and stirred at room temperature for 2 h. The reaction was quenched by the addition of water (10 mL) and the products were extracted with diethyl ether (3 × 20 mL). The organic phase was washed with 10% NaOH solution (20 mL), H_2O (20 mL), and saturated NaCl solution (20 mL) and dried over $MgSO_4$, filtered, and concentrated by rotary evaporation. Column chromatography on silica gel eluted with hexane – ethyl acetate (99:1) afforded a yellow oil, 1.49 g (75%): R_f = 0.21 (hexane – ethyl acetate, 99:1); ^{1}H NMR δ: 7.38–6.89 (m, 9H), 3.88 (s, 3H); ^{13}C NMR δ: 157.2, 134.4, 131.5, 131.3, 129.0, 128.3, 127.0, 123.9, 121.1, 110.8, 55.8; MS *m/z*: 216 ($M^{+\bullet}$, 100), 210 (17), 183 (10), 168 (11). Previous researchers reported a similar ^{1}H NMR (43).

(±)-2-(Phenylsulfinyl)phenol, ***4***a

Boron tribromide (10 mL of a 1 N solution in CH_2Cl_2, 2.5 equiv.) was added to a solution of 1-methoxy-2-(phenylthio)benzene (0.84 g, 3.9 mmol) in dry CH_2Cl_2 (25 mL) cooled to −23°C under nitrogen. The resulting solution was stirred for 1 h at −23°C, then stirred for 24 h at room temperature. The organic phase was washed with H_2O (30 mL), saturated $NaHCO_3$ solution (30 mL), and H_2O (30 mL), then dried over $MgSO_4$, filtered, and concentrated by rotary evaporation. Column chromatography on silica gel eluted with hexane – ethyl acetate (9:1) afforded 2-(phenylthio)phenol as an oil, 0.63 g (80%): R_f = 0.28 (hexane); IR (neat): 3357 (OH), 3058, 1576, 1471, 1191, 738, 688 cm^{-1}; ^{1}H NMR δ: 7.55–6.91 (m, 9H), 6.52 (s, 1H, OH, exchanges with D_2O); ^{13}C NMR (50 MHz) δ: 156.3, 136.2, 135.1, 131.6, 128.6, 126.2, 125.5, 120.7, 115.7, 115.1; MS *m/z*: 202 ($M^{+\bullet}$, 100), 96 (23). Previous researchers prepared this sulfide in low yield by another route (44). To prepare ***4****a*, hydrogen peroxide (0.25 mL of a 33% solution, 1.1 equiv.) was added to a solution of 2-(phenylthio)phenol (0.48 g, 2.4 mmol) in acetic acid (5 mL) at room temperature and stirred for 1 h. The acetic acid was removed by rotary evaporation to give a yellow solid. Recrystallization from toluene gave white crystals, 0.38 g (74%): mp 163–164°C (lit. (45) mp 164–165 °C); R_f = 0.37 (hexane – ethyl acetate, 3:1); ^{1}H NMR δ: 7.72–6.87 (m); ^{13}C NMR δ: 159.4, 143.6, 133.1, 131.4, 129.5, 126.0, 124.8, 123.1, 119.9, 119.6; MS *m/z*: 218 ($M^{+\bullet}$, 100), 170 (59), 141 (19), 125 (22), 110 (36), 94 (41), 77 (26, C_6H_5+).

(±)-2-(phenylsulfinyl)phenyl acetate, ***4***b, was prepared by acetylation of ***4***a using the procedure described below for ***5***b: yellow oil, 0.18 g (50%); R_f = 0.18 (hexane – ethyl acetate, 3:1); ^{1}H NMR δ: 7.97–7.12 (m, 9H), 2.24 (s, 3H); ^{13}C NMR (50 MHz) δ: 166.9, 146.2, 143.5, 136.3, 131.4, 130.7, 128.6, 126.3, 125.2, 124.8, 122.5, 21.3; MS *m/z*: 260 ($M^{+\bullet}$, 12), 219 (14), 218 (100), 170 (40), 125 (11), 110 (18), 109 (11), 94 (18); HRMS calcd. for $C_{14}H_{12}O_3S$: 260.0507; found: 260.0503.

(±)-2-(Ethoxymethoxy)-1-(phenylsulfinyl)naphthalene

Magnesium turnings (0.24 g, 10 mmol) and 1-bromo-2-(ethoxymethoxy)naphthalene (2.56 g, 9.1 mmol) were added to dry THF (20 mL.). Once the Grignard reaction was initiated, the solution was refluxed for 45 min. Upon cooling to room temperature, benzenesulfinyl chloride (46) (1.46 mL, 9.1 mmol) dissolved in THF (10 mL) was added dropwise. The reaction mixture was refluxed for 15 min, then cooled and poured into 1% HCl (20 mL). The products were extracted with ethyl acetate (3 × 25 mL) and the combined extracts were dried over $MgSO_4$, filtered, and concentrated by rotary evaporation. Column chromatography on silica gel eluted with hexane – ethyl acetate (4:1) afforded an oil, 0.51 g (17%): R_f = 0.12 (hexanes – ethyl acetate, 4:1); ^{1}H NMR δ: 8.67 (d, 1H, J = 10 Hz), 7.95–7.15 (m, 10H), 5.37 (d, 1H, J = 12 Hz), 5.24 (d, 1H, J = 12 Hz), 4.05 (q, 2H, J = 8 Hz), 3.6 (t, 3H, J = 10 Hz).

(±)-2-(Hydroxy)-1-naphthylphenylsulfoxide, ***5***a

Concentrated HCl (3 drops) was added to a solution of (±)-2-(ethoxymethoxy)-1-(phenylsulfinyl)naphthalene (0.50 g, 1.5 mmol) in methanol (10 mL). The solution was refluxed for 45 min, then the solvent was removed by rotary evaporation and the residue dissolved in ethyl acetate (20 mL). The organic phase was washed with saturated $NaHCO_3$ (10 mL), then with saturated NaCl (10 mL), and dried over $MgSO_4$, filtered, and concentrated by rotary evaporation to a yellow oil, 0.35 g (75%): R_f = 0.41 (hexanes – ethyl acetate, 3:1); ^{1}H NMR δ: 8.25–6.82 (m); MS *m/z*: 284 ($M^{+\bullet}$, 6), 268 (31), 252 (100), 220 (34), 191 (23), 146 (36). This material was used in the next step without further purification.

(±)-2-Acetoxy-1-naphthylphenylsulfoxide, ***5***b

Sodium carbonate (0.16 g, 1.5 mmol), *N,N*-dimethyl-4-aminopyridine (14 mg, 0.11 mmol), and acetic anhydride (0.17 g, 1.7 mmol) were added to a solution of ***5****a* (0.35 g, 1.1 mmol) in ethyl acetate (10 mL) and the mixture was stirred for 12 h. The reaction mixture was washed with 1% HCl (10 mL), saturated NaCl (10 mL), and dried over $MgSO_4$, filtered, and concentrated by rotary evaporation. Column chromatography on silica gel eluted with hexane – ethyl acetate (4:1) afforded an oil, 0.29 g (86%): R_f = 0.19 (hexanes – ethyl acetate, 4:1); ^{1}H NMR δ: 8.72–7.15 (m, 11H), 2.35 (s, 3H); MS *m/z*: 310 ($M^{+\bullet}$, 18), 268 (100), 252 (35), 220 (85), 159 (51).

Enantiomeric purity

Enantiomers of **1***a*, **1***b*, **2***a*, and **2***b* were separated by HPLC on a chiral stationary phase (Chiralpak OB – tribenzoylated cellulose on silica gel, Daicel Chemical Industries, Ltd. Fort Lee, N.J.) eluted with hexane–isopropanol (4:1) at 0.5 mL/min. Samples were dissolved in eluting solvent at a concentration of 1 mg/mL. **1***a*: $k'_S = 1.26$, $k'_R = 2.08$, $\alpha = 1.65$; **1***b*: $k'_S = 8.07$, $k'_R = 8.34$, $\alpha = 1.37$; **2***a*: $k'_S = 1.28$, $k'_R = 1.74$, $\alpha = 1.36$; **2***b*: $k'_S = 6.80$, $k'_R = 9.28$, $\alpha = 1.36$. For **3–5**, the acetates and phenols were separated by chromatography on silica gel eluted with toluene – ethyl ether (9:1) for **3** and **4** or hexane – ethyl acetate (4:1) for **5**. Kagan and co-workers recently reported an enantiomeric enrichment of sulfoxides during silica gel chromatography due to dimerization of the sulfoxides (47). We combined all the fractions containing the acetates or the phenols to avoid any such enrichment. The enantiomeric purity of the isolated **3***b*–**5***b* was determined by ^{1}H NMR in the presence of Eu(hfc)$_3$ (approximately 1.5 equiv.). The acetyl methyl resonances were separated by 8 Hz under these conditions. The enantiomeric purity of **3***a*–**5***a* was determined in the same manner after acetylation with acetic anhydride as described above.

Absolute configuration

Phenol **1***a*, isolated from a CE-catalyzed resolution of **1***b* was converted to (*R*)-(+)-1-methoxy-2-(methylsufinyl)benzene and its optical rotation was compared to that reported in the literature. Potassium carbonate (1.5 equiv.) and CH_3I (1.5 equiv.) were added to **1***a* dissolved in acetone (5 mL) and the suspension was stirred for 12 h at room temperature. The acetone was removed by rotary evaporation. The residue was suspended in ethyl acetate (5 mL) and washed with 1% HCl (5 mL), then saturated NaCl (5 mL), dried over $MgSO_4$, filtered, and concentrated under vacuum to an oil: $[\alpha]_D$ (obsd) +65 (*c* 3.2, acetone) (lit. (48) $[\alpha]_D$ −25.8 (*c* 3.2, acetone) for the (*S*) enantiomer with 8% ee). Similarly (*R*)-(+)-1-methoxy-2-(phenylsulfinyl)benzene was prepared from **4***a* isolated from a CE-catalyzed resolution: $[\alpha]_D$ (obsd) +44 (*c* 0.03, MeOH) (lit. (49) (*R*)-(+): $[\alpha]_D$ +275 (*c* 1.03, acetone)). The absolute configurations of the enantiomers of **2***b*, **3***b*, and **5***b*, which reacted faster with CE, were also assigned the (*R*) configuration based on the relative positions of the acetyl methyl ^{1}H NMR resonance in the presence of Eu(hfc)$_3$. The resonance for the fast-reacting enantiomer appeared downfield of the resonance for the slow-reacting enantiomer for all five acetoxysulfoxides.

Resolution of (±)-1*b* with pancreas acetone powder

Bovine pancreas acetone powder (an inexpensive source of CE, 210 mg, Sigma) and crude sodium taurocholate (329 mg, Sigma) were added to a mixture of phosphate buffer (25 mL, 10 mM, pH 7.0 and diethyl ether (25 mL). The pH was readjusted to 7.0 and a solution of (±)-**1***b* (251 mg, 1.27 mmol) in diethyl ether (25 mL) was added. The pH was maintained at 7.0 with a pH stat, which controlled the addition of NaOH (0.505 N). At the 56% conversion, LiCl (1 g) was added to break up the emulsion and the reaction mixture was extracted with ethyl acetate – ethanol (9:1, 3 × 55 mL). The combined extracts were dried over $MgSO_4$, filtered, concentrated by rotary evaporation, and redissolved in toluene (25 mL). This toluene solution was washed with saturated Na_2CO_3 solution (1 × 20 mL) to remove **1***a*.[2] The toluene solution was then washed with H_2O (20 mL), saturated NaCl solution (20 mL), dried over $MgSO_4$, filtered, and concentrated to give (*S*)-**1***b* as an oil, 77% ee. Recrystallization from toluene–hexane yielded white crystals, 28 mg, 0.14 mmol, 11% yield from a maximum 50% in a resolution, >99% ee by HPLC. The TLC and ^{1}H NMR of (*S*)-**1***b* were identical to that for the racemate.

Conformational analysis of 1–9

Local minima and their relative energies were calculated using molecular mechanics using HyperChem revision 3 (Hypercube, Waterloo, Ont.) with default MM+ parameters. Structures were minimized first using a steepest decent algorithm and then with a conjugate gradient to an rms error of <0.005. When we found no local minimum in the range $0° > \theta > 90°$, we compared several fully minimized structures with a fixed θ as shown in Figs. 5 and 6.

Abstract: A new "electron-reversed" method for the functionalization of a seven-membered ring is developed. Cycloheptenyl-η^3-allyltitanocene complexes derived from cycloheptatriene react with aldehydes or carbon dioxide to afford, respectively, the mixture of isomeric 1,4- and 1,3-cycloheptadienyl carbinols **3***a–e* and **2***a–e* or methyl esters **7** and **6**. The **3/2** and **7/6** ratios increase with increasing steric hindrance in the electrophile. Moreover, these may be significantly increased by introducing *tert*-butyl substituents on the Cp rings of the starting titanocene dichloride. The regiochemistry of the reaction was rationalized in terms of the equilibrium between the two envisageable allylic complexes. The reaction constitutes the first direct entry to functionalized 1,4-cycloheptadienes, some of which are related to biologically active compounds.

Key words: η^3-allyltitanium complexes, cycloheptadiene derivatives, regiocontrol, electron reversal.

Résumé : Une nouvelle méthode de type inversion de polarité de fonctionnalisation du cycle à sept atomes de carbone est présentée. Les cycloheptenyl-η^3-allyltitanocenes, obtenus à partir du cycloheptatrième, sont opposés à divers aldéhydes ou au dioxyde de carbone. Il en résulte des mélanges de cyclohepta-1,4 et -1,3-diényl carbinols (respectivement **3** et **2**) ou d'esters méthyliques (**7** et **6**). Les rapports **3/2** et **7/6** augmentent avec la taille de l'éléctrophile utilisé. Par ailleurs, on observe une nette augmentation de ce rapport par l'introduction du groupe *tert*-butyle sur chacun de cycles cyclopentadiényles du dichlorure de titanocène de départ. La régioseléctivité de la réaction est interprétée en terme d'équilibre entre les deux complexes allyliques possibles. La réaction offre une approche directe des dérivés de cyclohepta-1,4-diène d'intérêt biologique.

Mots clés : complexes η^3-allyltitane, dérivés cycloheptadiènes, régiosélectivité, inversion de polarité.

The significant synthetic interest in allyl organometallics lies especially in that they can be used for the stereocontrolled construction of open-chain systems (1). Allylation reactions that involve nucleophilic attack of various allylic metals on electrophiles such as aldehydes, ketones, imines, and Michael acceptors have been extensively studied (2). The allylic organometallic method has been successfully applied for the stereoselective synthesis of a number of segments that are commonly found in biologically active compounds (3).

Besides the ability to control the stereochemical course of the reaction, the transition-metal-based allyl organometallics can lead to reversed polarity equivalents (Umpolung). In this matter, in our recent communication we reported a procedure for the transformation of cycloheptatriene into the cycloheptenyl-η^3-allyltitanocene complexes (4). The latter can be related to simpler η^3-allyltitanocenes, which are efficient allylation agents known to add to aldehydes in a regio- and stereocontrolled fashion (5). To the best of our knowledge, there are no precedents, however, for the use of alkenyl-η^3-allyltitanocenes (6) as nucleophilic allyl reagents. We therefore focused our attention on the synthetic use of the cycloheptenyl-η^3-allyltitanocenes formed. The complex mixtures were reacted in situ with aldehydes **1***a–e* to produce, in good yield, isomeric homoallylic alcohols **2***a–e* and **3***a–e* (Scheme 1).[2] The **3/2** ratio was noted to increase with increasing size of aldehyde.

In seeking to expand the scope of this new methodology concerning the functionalization of seven-membered rings,[3] we decided to explore the reactivity of the complexes **A** and **B** towards other electrophiles. Moreover, we undertook studies of allylation reaction regioselectivity, in particular aimed at improving the **3/2** product ratio. Indeed, the reaction could provide a first straight entry to 1,4-cycloheptadienes substituted at the 6 position (analogous to **3**), closely related to biologically active molecules (8).

Received January 31, 1995.

Results and discussion

Carbon dioxide has been shown to insert into η^3-allyltitanium(III) reagents to afford, after hydrolysis, the corresponding β,γ-unsaturated carboxylic acids (9). We have reacted this small, symmetrical electrophile with the cycloheptenyl-η^3-allyltitanium complexes **A**/**B**, prepared in situ by the reaction of preformed Cp_2TiCl and isopropylmagnesium chloride in the presence of cycloheptatriene. The resulting crude mixture of carboxylic acids **4** and **5** was treated with diazomethane and chromatographed to give corresponding isomeric esters **6** and **7** (Scheme 2). It must be mentioned that the major product **7** is a direct starting material for the preparation of biologically active molecules of marine origin (10). The five-step synthesis of **7**, involving a rearrangement of functionalized vinylcyclopropanes, has been reported in the literature (11).

The ratio of **7**/**6** = 1.22 is not surprising in light of the evolution of the regioselectivity observed for aldehydes (Scheme 1). The overall data indicate that steric effects play a leading part in the control of regioselectivity. The increase of the **3**/**2** product ratio as the size of electrophile increases, may be related to the greater steric hindrance for complex **A** (related to **2**) compared with complex **B** (related to **3**). In fact, two opposing factors can operate here. The electronic factor should favour complex **A**, owing to the conjugation of the vinyl group with the allyl system. However, to gain the maximum resonance energy, the conjugation in **A** involves a planar arrangement of five of the seven carbon atoms of the ring. As a result, increased steric hindrance should exist in **A**, probably due to interaction with the titanocene part.

To obtain additional insight into the regiochemical outcome of the reaction we decided to enhance steric bulk in the complexes by introducing *tert*-butyl substituents into both cyclopentadienyl rings. We assumed that such a supplementary hindrance should alter the regioselectivity of the addition step. Therefore, substituted titanocene dichloride $(^t BuCp)_2TiCl_2$ was prepared and used as a precursor for the formation of cycloheptenyl-η^3-allyltitanium complexes ^{t}**A** and ^{t}**B**. The complexes added in situ with aldehydes **1***a–e* or carbon dioxide to produce, respectively, homoallyl alcohols **2***a–e* and **3***a–e* or acids **4** and **5** (esters **6** and **7** after diazomethane methylation). The reactions were carried out as previously, and overall yields of the products (**2**+**3**) appeared closely similar to those obtained for the reactions using Cp_2TiCl_2. Likewise for the latter, the major regioisomers **3***a–e* were obtained as stereochemically pure products by ^{1}H and ^{13}C NMR as well as by GC-coupled mass spectroscopy. Similarly, minor compounds **2***a*, **2***d*, and **2***e* possess spectral characteristics that are consistent with their single stereoisomer structure. On the other hand, compounds **2***b* and **2***c*, derived from less sterically hindered aldehydes, show evidence (^{13}C NMR and GC–MS) of the presence of two stereoisomers.

The molar ratios relative to the pairs of regioisomers **3**/**2** and **7**/**6** (**5**/**4**) together with the corresponding ratios obtained

previously from the nonsubstituted cyclopentadienyl-ring-bearing complexes **A** and **B** are summarized in Table 1.[4] Comparison of these two series of values shows that the supplementary hindrance introduced into the cycloheptenyl-η^3-allyltitanocenes does affect the regioselectivity of the reaction. Indeed, the **3/2** (**7/6**) ratio increases significantly for all electrophiles used. This phenomenon agrees with the postulate of the steric demands being greater for complex **A** than for complex **B**.

Quenching experiments contributed further to the clarification of the regiochemistry. The complex mixtures **B/A** and **^{t}B/^{t}A** were trapped with gaseous HCl. The ratios of the resulting 1,4- vs. 1,3-cycloheptadiene, determined by ^{1}H NMR and gas chromatography, were 0.82 and 1.15, respectively. We assumed them to approach the **B/A** and **^{t}B/^{t}A** equilibrium levels. Indeed, the ratio was lower for nonsubstituted complexes (**B/A**) (than for the substituted ones (**^{t}B/^{t}A**). On the other hand, both values were significantly lower than any of the corresponding **3/2** ratios from Table 1.

More detailed studies, particularly in kinetics, are needed to elucidate the regiochemistry of the reaction. However, a plausible hypothesis implies an equilibrium between **A** and **B** (Fig. 1), possibly ensured by dehydrometallation followed by a rehydrometallation process. Such an equilibrium, disturbed by the reacting electrophile, can be assumed on account of the variable **3/2** product ratio,which was systematically higher than the corresponding **B/A** (**^{t}B/^{t}A**) values. The regiochemistry of the reaction is thus determined in the kinetically controlled addition of the electrophile to the equilibrated mixture of **A** and **B** (Fig. 1). In this context, the increase of the **3/2** product ratio with size of attacking electrophile suggests that the steric demands are more strict on the path to the transition state starting from **A** than on that starting from **B**. Because of the presumed reactant-like transition state for the allyltitanation reactions (12), the above statement agrees favorably with the thermodynamic postulate of the sterically disfavoured complex **A**. An introduction of the supplementary bulky group into the titanocene unit destabilizes complex **^{t}A** much more than complex **^{t}B**, leading to the higher **B/A** equilibrium level (1.15 = **^{t}B/^{t}A** > **B/A** = 0.82). Indeed, the **3/2** ratio increases for all the electrophiles used. This effect appears to be particularly pronounced when a bulky aldehyde, e.g., isobutyraldehyde (**1***d*), is used (**3/2** ratio change from 3 to 15.7).

The above hypothesis is true only if the complexes **A** and **B** are interconverted at a rate slower than that at which the rapid electrophilic addition occurs. Nevertheless, an opposite trend cannot be completely ruled out at present. If Curtin–Hammett conditions apply, only differences in the kinetics of electrophilic addition will affect the regiochemical outcome of the

[4] The molar ratios of the regioisomers **3/2** and **7/6** (**5/4**) were established by ^{1}H NMR, using crude reaction mixtures.

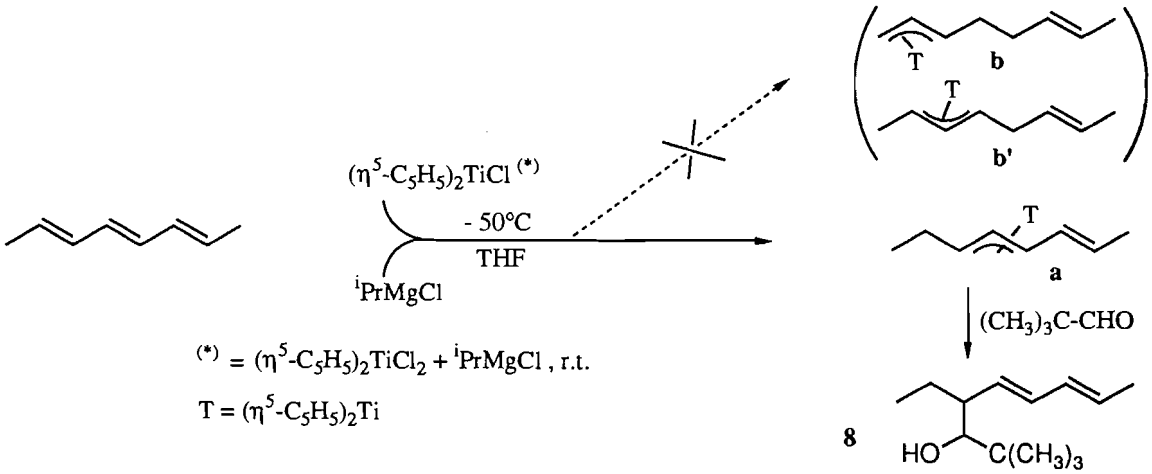
Scheme 3.



reaction. In any case, although steric factors play a major role in determining regioselectivity, the reactivity of the electrophile must still be taken into account. For example, benzaldehyde reacts least selectively with **B/A** but is more sterically hindered than either propionaldehyde or hexanal (Table 1). Furthermore, the less hindered CO_2 reacts more selectively with ^{t}**B**/^{t}**A** than most of the aldehydes examined.

Additional insight into the specific role of the steric factor in the *cyclic* alkenyl-η^3-allyltitanocenes is provided by an experiment in which a *linear* triene, namely 2,4,6-octatriene, was used as substrate (Scheme 3). The preparation of the corresponding allyltitanocene(s) and its(their) reaction with pivalic aldehyde (**1***e*) were carried out according to the usual protocol. The only product obtained in good yield was the conjugated homoallylic alcohol **8**. Such a result indicates a strong preference for the formation of the conjugated complex **a**, to the detriment of the totally absent isolated complexes **b** and **b′**. The absence of the steric factor for acyclic complexes is an especially striking fact, since the most bulky aldehyde was employed here as an electrophile.

Conclusion

The "reversed polarity" approach to the functionalization of a seven-membered ring is of synthetic interest since (*i*) it offers a simple opportunity to introduce electrophile reagents directly into the cycloheptatriene, and (*ii*) it provides a first straight entry to the 6-substituted 1,4-cycloheptadienes. Indeed, the regiochemical trends that are analyzed make possible further improvement of the 1,4 vs. 1,3 product ratio. Due to the high stereoselectivity exhibited for the former, the reaction employing chiral allyltitanium reagent (13) could open a direct way to optically active 1,4 derivatives of biological interest.

Experimental section

General

Organometallic reactions were run under argon atmosphere using vacuum line techniques. The solvents used were distilled under argon from sodium benzophenone ketyl. Aldehydes **1***a–e*, cycloheptatriene, titanocene dichloride, and isopropylmagnesium chloride (2 M solution in THF) were purchased from Aldrich Chemical Co. Aldehydes and cycloheptatriene were distilled under argon prior to use. 2,4,6-Octatriene was prepared by a reported procedure (14). ^{1}H and ^{13}C NMR spectra were recorded at 400 and 100.53 MHz, respectively. Mass spectra were obtained by the EI (70 eV) technique. Gas chromatography (GC) was carried out on 30 m × 0.25 mm copper column packed with methyl silicone with a flow rate of 1.6 mL/min. Column flash chromatography was performed on silica gel 60 (Merck) by using hexane:diethyl ether (8:2 to 95:5 v/v) as eluents.

Representative procedure for the preparation of cycloheptadienyl carbinols 2 and 3

Isopropylmagnesium chloride (1.5 mL, 2 M solution in THF) was added by syringe at room temperature under argon to a stirred suspension of titanocene dichloride[5] (0.75 g, 3.02 mmol) in 20 mL of THF. After stirring for 30 min the resulting green solution of Cp_2TiCl was cooled to −50°C. Freshly distilled cycloheptatriene (0.41 g, 4.5 mmol) and a second portion of isopropylmagnesium chloride (1.5 mL) were simultaneously added, dropwise via syringes. After stirring for 10 min at −50°C, pivalic aldehyde (0.26 g, 3.02 mmol) was added neat by syringe and the mixture was allowed to warm gradually to −20°C over a period of 30 min. The reaction mixture was poured into a separatory funnel containing ether (100 mL), and treated with saturated aqueous $NaHCO_3$ (25 mL). The ether layer was separated and the aqueous layer was extracted with ether. The combined ether layers were dried over $MgSO_4$ and concentrated in vacuo. The residue was diluted with ether/hexane = 2/1 (20 mL) and the titanium derivatives separated by filtration (the major portion of titanocene dichloride can be recovered by acidifying the aqueous layer). The solvent was removed in vacuo. Purification by flash chromatograpy on silica gel column eluting with hexane/ether (5/1) afforded the isomeric homoallylic alcohols **2***e* (0.016 g, 3%) and **3***e* (0.39 g, 73%).

Reaction of cycloheptenyl-η³-allyltitanocene complexes with carbon dioxide: esters 6 and 7

The cycloheptenyl-η³-allyltitanium complex mixture was obtained as described above, in two separated reduction steps: Cp_2TiCl (3 mmol in about 25 mL of THF), formed at first at room temperature, was then allowed to react within 10 min with the second equivalent of iso-C_3H_7MgCl in the presence of cycloheptatriene (0.41 g, 4.5 mmol, 1.5 equiv.) at −50°C. Carbon dioxide was then passed through the reaction mixture at −50°C, with stirring for 10 min, and the temperature was allowed to rise to −20°C over a 0.5 h period. The mixture was treated with 2 M HCl and air was passed, with stirring, through the solution for 5 min. The solution was diluted with 140 mL of ether/hexane = 9/1 and the precipitate of titanocene chloride was recovered by filtration. The organic layer was extracted with two portions of 0.5 M NaOH (2 × 15 mL). The aqueous layer was acidified with 2 M HCl and extracted with ether (3 × 40 mL). The ethereal layer was washed with brine to pH 4−5, and concentrated in vacuo to provide the crude mixture of acids **4** and **5**.[4] The corresponding methyl esters **6** and **7**[4] were prepared by using excess diazomethane in ether and were purified by chromatography on silica gel, eluting with hexane/ether = 95/5.

6 (0.15 g, 33%): ^1H NMR (C_6D_6) δ: 7.12 (br s, 1H), 5.85–5.72 (m, 3H), 3.33 (s, 3H), 2.20 (m, 1H), 2.05–1.96 (m, 2H), 1.52 (pseudoquintet, 2H); ^{13}C NMR{^1H} (CD_3COCD_3) δ: 168.2, 144.5, 132.5, 129.7, 123.8, 52.1, 32.1, 31.4, 29.1; MS *m/z*: 152 (M^+, 22), 137 (8), 121 (10), 93 (44), 91 (100), 77 (58).

7 (0.18 g, 39%): ^1H NMR (C_6D_6) δ: 6.73 (ddd, J = 1.8, 3.6, 11.4 Hz, 1H), 6.02 (dd, J = 4.7, 11.4 Hz, 1H), 5.74–5.65 (m, 2H), 3.42 (s, 3H), 3.20 (m, 1H), 2.1–1.98 (m, 2H); ^{13}C NMR{^1H} (CD_3COCD_3) δ: 174.6, 135.5, 131.2, 126.7, 125.4, 47.9, 31.1, 26.6, 26.5; MS *m/z*: 152 (M^+, 26), 137 (10), 121 (8), 93 (52), 91 (100), 77 (59).

Addition of octenyl η³-allyltitanocene to pivalic aldehyde: dienol 8

Cp_2TiCl was obtained as described above, starting from 4 mmol (1.00 g) of titanocene dichloride. The stirred solution of Cp_2TiCl in 30 mL of THF was cooled to −50°C and the freshly distilled 2,4,6-octatriene (0.43 g, 4 mmol) was added via syringe, simultaneously with a second portion of isopropylmagnesium chloride (2 mL, 2 M solution in THF). After 10 min stirring at −50°C, pivalic aldehyde (0.34 g, 4 mmol) was added slowly via syringe and the temperature was allowed to rise to −20°C over a 0.5 h period. The basic ($NaHCO_3$) work-up was performed as outlined above. The crude homoallylic alcohol **8** was obtained as a sole product

[6] MS identical for both diastereomers.

that was further purified by flash chromatography (hexane/ether = 12/1) (0.54 g, 69%, EE probably; traces of an another stereoisomer (<5%) were observed by ^{1}H and ^{13}C NMR). ^{1}H NMR (C_6D_6) δ: 5.64–5.61 (m, 1H), 5.49–5.33 (m, 3H), 3.32–3.27 (m, 1H), 3.21–3.15 (m, 1H), 1.91 (pseudoquad., J = 6.3 Hz, 1H), 1.60 (br s, 1H, D_2O exchangeable), 1.51 (dd, J = 1.7, 6.7 Hz, 3H), 1.01 (s, 9H), 0.89 (t, J = 5.5 Hz, 3H); ^{13}C NMR{^{1}H} (C_6D_6) δ: 132.8, 132.2, 130.8, 124.9, 81.9, 44.5, 36.5, 27.9, 26.7, 14.7, 13.9; MS *m/z*: 195 (M^+ – H, 31), 179 (27), 151 (50), 110 (65), 95 (42).

Quenching of cycloheptenyl-η^3-allyltitanocene complexes with gazeous HCl

The complex mixture was obtained by the procedure outlined above, in two separate reduction steps at room temperature and then at −50°C. The protonation was performed at −50°C by passing gazeous HCl over a 10 min period. After the conventional basic ($NaHCO_3$) treatment, the ratios of 1,4- to 1,3-cycloheptadiene were established by GC chromatography as well as by ^{1}H NMR. They were equal to 0.82 and 1.15 for the reactions using Cp_2TiCl_2 and Cp'_2TiCl_2, respectively.

A novel PC-based gravimetric autotitrator with a multi-solution delivery system

Mark A. Hetherington, Min Chen, and R. Stephen Reid

Abstract: The development of a novel PC-based gravimetric autotitrator is described. A single electronic balance serves as the weight buret for the delivery of three different solutions. It is therefore possible to add titrand and titrant under automated control. Investigation of the standard nickel(II)–glycinate–proton equilibrium system was used to evaluate performance.

Key words: titrator, titration, potentiometry, automated control.

Résumé : On décrit le développement d'un appareil d'autotitrage gravimétrique basé sur un ordinateur personnel. Une seule balance électronique sert de burette à mesurer pour la distribution de trois solutions différentes. Il est donc possible d'ajouter les substances titrantes et à titrer sous contrôle automatisé. Dans le but d'évaluer la performance de la méthode, on a étudié le système standard en équilibre : nickel(II)–glycinate–proton.

Mots clés : appareil de titrage, titration, potentiométrie, contrôle automatisé.

Introduction

Equilibrium potentiometric studies can yield acid dissociation and complexation constant data of high precision. However, the collection of the necessary data (possibly hundreds of data points per titration) is time-consuming, tedious, and repetitive; automation of this process is thus highly desirable.

A number of PC-based autotitrators with various software design and hardware configurations (1–7) have been reported previously. Delivery control has been accomplished in one of two ways. In volumetric designs (1–3), a digitally controlled buret is employed; electronic pulses from the computer advance a piston of a motor-driven syringe. The volume added at any stage is proportional to the number of pulses sent. While a wide variety of autotitration systems is commercially available, these are both expensive and insufficiently flexible for equilibrium titration work (8).

In gravimetric designs (4–7), a titrant reservoir is placed on an analytical balance. The computer controls an on–off valve set in the delivery tube from the reservoir to a titration vessel. The current reservoir weight is sensed by the computer and hence the weight of any titrant added can be inferred.

Gravimetric delivery systems display several advantages over their volumetric counterparts. The precision and accuracy of weighing is intrinsically higher than that involved in measuring volumes (9). Even a modestly priced electronic analytical balance can yield a resolution of 0.1 mg (i.e., 0.1 μL). Such balances are also readily interfaceable. Further, delivery of titrant by weight eliminates problems due to solution density fluctuations caused by temperature variations.

An ideal autotitration system for speciation studies would require the operator merely to input the titration parameters and supply the titrant, titrand, and, where applicable, solutions for dilution or ionic strength control. The system would then handle sample preparation, introduction, titration, and disposal. The autotitrator described in this paper was developed as another step towards this ideal system. It uses a single electronic balance to serve as the "weight buret" and can currently accommodate up to three separate solution delivery vessels.

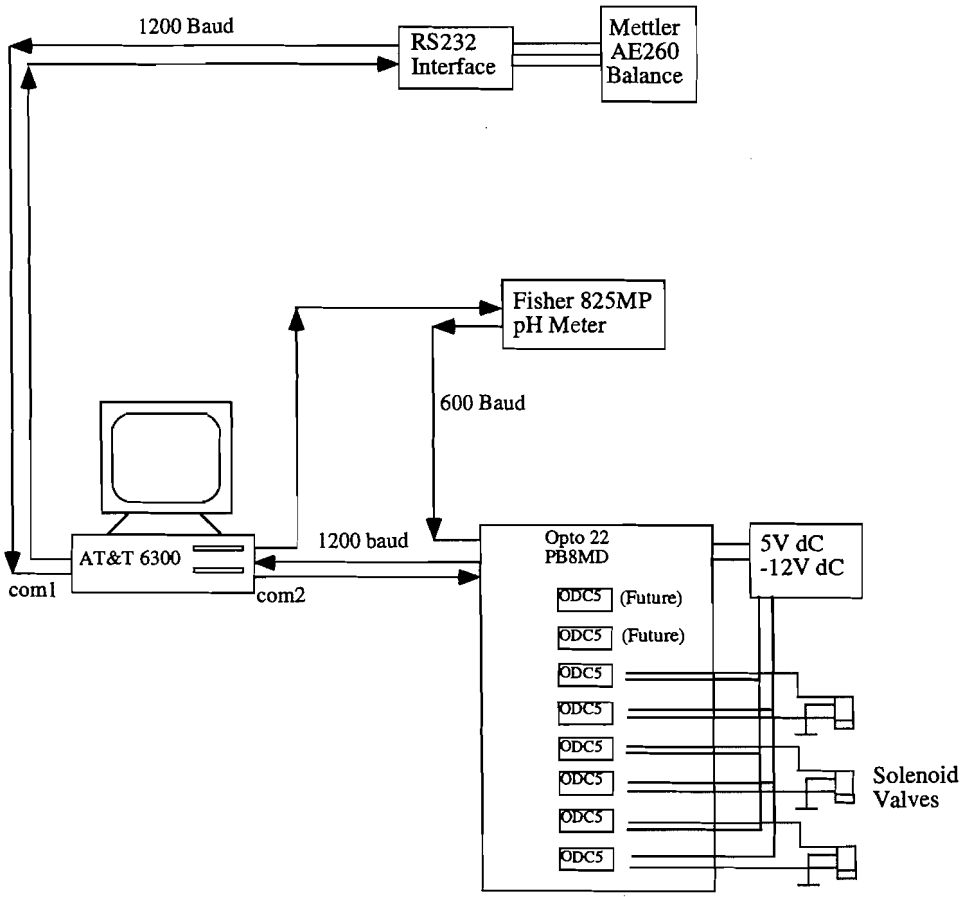
Experimental

pH measurement

All pH measurements were made with a Fisher Accu-pHast standard combination glass body pH electrode (Cat. No. 13-620-296) and a Fisher Accumet pH meter (model 825MP). The electrode was calibrated following the suggested NIST (National Institute of Standards and Technology) method. First, a set of primary standard solutions are prepared, the pH of which have been accurately determined (NIST, ref. 10). The electrode is then calibrated using these primary solutions. Since these NIST solutions are only stable for a few hours, a set of stable commercial buffer solutions are then standardized using the NIST solutions, yielding secondary standards that can then be used for routine recalibration.

A 0.05 molal solution of potassium hydrogen phthalate (KHP), which has been ground and dried, in H_2O at 25°C is assigned a NIST pH of 4.008. A solution that is 0.025 molal in both KH_2PO_4 and Na_2HPO_4 has an NIST pH of 6.865 at the same temperature (10). The electrode was calibrated using these solutions and subsequently the stable commercial buffers (BDH) with nominal pH values of 4.00 and 7.00 were analyzed as unknown solutions and their exact pH values recorded.

Fig. 1. Hardware architecture of the computer-controlled gravimetric autotitrator.



A temperature of 25°C was maintained using a water bath equipped with a Haake D1 circulator and cold water cooling coil.

Preparation of solutions for system validation

Unless otherwise specified, all chemicals were purchased from BDH (British Drug Houses, Toronto, Ont.) and were used as received. Corning Mega-Pure™ water (doubly-distilled, deionized) was used throughout for all solutions. All solutions for this study, with the exception of titrant and KHP solution, were prepared in a solvent containing 0.29 M NaCl and 0.01 M HCl for a total ionic strength of 0.3 M. The acid concentration of this solvent was determined to be 0.01115 ± 0.0010 M′ by titration of samples dispensed from one of the reservoirs on the balance with NaOH titrant from another of the reservoirs. M′ is used to denote "weight molarity," i.e., moles of solute per kilogram of solution. This is a convenient unit to use when titrating gravimetrically.

The NaOH titrant was made, using proper procedures to ensure absence of carbonate (11), by dilution of a saturated solution to volume with water. The NaOH concentration was determined as 0.08651 ± 0.0001 M′ by titration of samples of standard solution of the primary standard KHP prepared as described below.

The standard KHP solution, 0.05305 M′ in 0.14 M KNO_3, was prepared using ground and dried KHP and KNO_3 as supplied. The weight molarity of the solution was calculated by determining the weight of solution as the difference between the weight of a 250 mL volumetric flask before and after being filled and made up to the mark.

A standard solution of 0.2036 ± 0.00026 M′ nickel chloride was made by dissolving $NiCl_2 \cdot 6H_2O$ in solvent and bringing it to volume in a 250 mL volumetric flask. This stock $NiCl_2$ solution was standardized by titration with a standard EDTA solution in ammonia buffer using a Murexide indicator. This EDTA solution was in turn standardized by titration of a 0.03048 M standard nickel solution prepared by dissolving nickel metal in a 1:1 mixture of concentrated HNO_3 and water and quantitatively transferring and bringing to volume in a precalibrated 250 mL volumetric flask. The EDTA solution, prepared by dissolving the disodium salt in water, was found to have a concentration of 0.02096 ± 0.00008 M.

A stock solution of glycine hydrochloride was prepared by dissolving enough glycine hydrochloride in 1 L of solvent to make a ~0.03 M solution. The concentration was found to be 0.0306 ± 0.0002 M′.

Hardware

A Mettler AE160 electronic balance (Mettler Instrument Corp., Princeton, N.J.) equipped with an RS232C interface (commercially available from Mettler) was used as the weight buret for the titrator system. The computer-controlled valves were made by the General Valve Corporation, Fairfield, N.J. (part no. 2-26-900). The titration vessel is stirred magnetically.

An AT&T 6300WGS microcomputer was used to control

the system. The pH meter and analytical balance are interfaced to the computer via proprietary RS232 interfaces.

The computer is equipped with only two serial ports and there are three components to interface. To allow interfacing of several devices to the computer, and also allow for future expansion, an Opto 22 8-point intelligent digital and analog Input/Output (I/O) controller (PB8MD, Opto 22 Inc., Hunting Beach, CA 92649, U.S.A.) was employed. This setup routes the input data from the pH meter, and the control pulses to the valves, through a single computer serial port. Figure 1 shows the hardware architecture. Figure 2 shows the general layout of the whole system.

To enable fine flow rate control a micrometer-controlled needle restriction valve (Fig. 3) was constructed and set in line with the solution delivery tubing. The flow rate can thus be correlated with a setting on the micrometer head, and set reproducibly.

Solution delivery system

The titrant is delivered by gravity (the reservoir is elevated above the titration vessel by a distance of about 30 cm). The flow is controlled by latching on/off solenoid valve(s) that are opened and closed by separate 12 V, 700 mA pulses under computer control via the Opto controller. A siphon tube enters each solution reservoir through a small hole in the cap. The tube is held so that a very small annulus is maintained between the inside edge of the hole and the tube. Thus, the only point of physical contact between the reservoir and the rest of the delivery system is where the tube touches the liquid. Previous studies (5) have shown this to be preferable to systems involving tubulated reservoir bottles, where tension in the delivery tubing inevitably contributes to instability in balance readings. Teflon tubing, 1.48 mm i.d. and 3.00 mm o.d., was chosen for all delivery tubing because it is stiff enough to allow reproducible tubing alignment, flexible enough to work with effec-

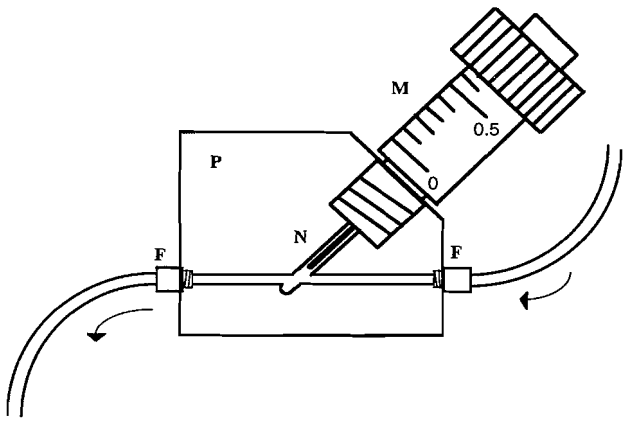
Fig. 3. Micrometer-controlled needle restriction valve. Arrows indicate direction of liquid flow. F: end-fittings; M: micrometer head; N: "needle;" P: Plexi-glas block.



tively, and easy to rinse. The titration vessel is a 10 mL glass vessel placed in the constant temperature bath. A Plexiglas cap is used to locate the pH sensor and solution delivery tubes in position. It also holds a gas delivery tube; titrations are performed under a "blanket" of argon to minimize any effects related to atmospheric carbon dioxide.

Figure 4 shows the electronic balance and "microchamber" constructed to address the issues of evaporation and contamination common to a dip-tube type system. The microchamber was developed to reduce the exchangeable air space above the solution reservoirs. The chamber consists of a clear circular Plexiglas enclosure that can slide up and down on steel supports so solutions may be changed or replenished. An O-ring in the base of the microchamber seals it against the floor of the balance when in the lowered (operating) position. The use of this chamber has reduced the evaporation to around 0.01 mg/min or ~5 mg per 8 h working day and could be reduced further if all fittings and casings of the balance itself were sealed from the room environment. The concentration changes during the course of a series of titrations can be shown to be negligible under these operating conditions. SUPERQUAD (see below) is capable of refining the titrant concentration so corrections can also be made at the point of data analysis if required.

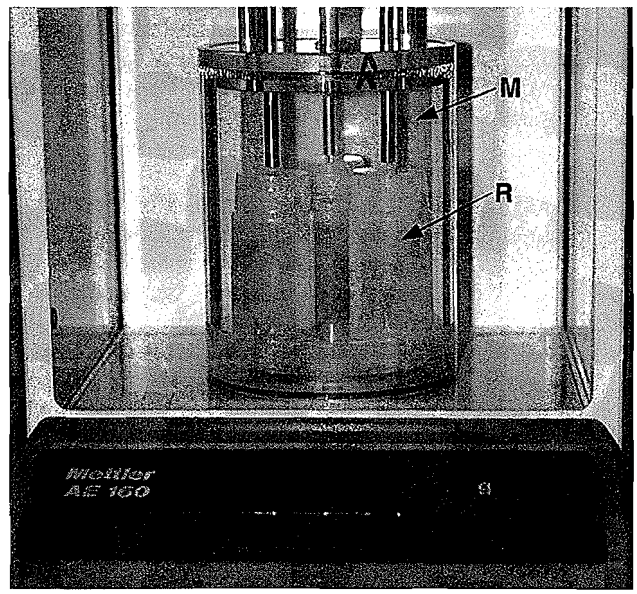
SASKWATCH — software control program

SASKWATCH, from **SASK**atoon **W**eight **A**utotitrator **C**ontrol **H**andler, is the control program for the autotitrator, written in Turbo Pascal version 5.0 (Borland International Inc., Scotts Valley, Calif.).

The operator inputs control parameters and performs various tasks through a series of control menus. Firstly, the parameters for the titration are input. The operator will choose between pH or mV mode for the signal from the pH meter and select initial and final pH or mV values for the titration.

Extensive studies of the relationship between valve open time and the resultant weight of solution delivered showed this to display essentially straight-line behaviour. The slope and intercept of this line for each delivery channel can be entered directly, or determined experimentally by a subroutine. The computer then "knows" how long a given valve must be left open in order for a specified weight of solution to be delivered.

Fig. 4. Electronic balance with microchamber (M) and solution reservoir (R).



Three types of titration can be selected. The simplest involves the delivery of a constant weight of titrant between successive points in the titration. This is suitable for rapid, "survey" titrations, but not for accurate speciation work. (A weight increment small enough to locate points precisely will result in far too many data points in buffer regions.)

More complex to implement, but more useful, is a constant pH (or mV) increment between points. This requires prediction of the future shape of the titration curve. Analytically, this is impossible in the absence of the very information the titration is being performed to elicit; however, a reasonable approximation can be found using the hyperbolic extrapolation routine of Smit and Smit (12). The three most recent data points (pH as a function of weight of titrant added) are mathematically fitted to a hyperbolic model. It is then assumed that the new point also lies on this path; hence, the weight increment required can be calculated by entering the desired "target pH" into the model. In practice, this works well; for instance, if a typical pH increment of 0.20 is selected, actual increment observed are typically within 0.02 of this. (Note that since the actual weight delivered and the actual resultant pH are recorded for every point, the slight inadequacy in prediction capability does *not* represent an error in the actual data recorded.)

The constant pH increment titration has the disadvantage that too many data will be collected in the endpoint regions, and much time will be taken waiting for pH stabilization according to stringent criteria (see below). A *combination type* titration is also implemented, where constant pH increment mode is enabled until the required weight additions become small, when they default to a minimum value (i.e., constant weight increment mode). This mode gives a better distribution of data points, and is the one we normally use.

Since both pH electrode response and complexation reactions can take a finite time, the routine also checks that equilibrium has been reached before "accepting" a pH reading into the stored data-set. A user-selectable number of individual

readings (typically 10) is input, and the slope in the pH versus time response is calculated. If this is significantly different from zero (the stringency test is also user-selectable) then the measurements are rejected, and the cycle repeated after a short wait. This continues until equilibrium is judged to have been reached or a "time out" period is exceeded. The mean of the most recent set of measurements is then stored.

Titrator operation

Firstly, the sample addition routine is used. The operator is asked to select a valve number (2 or 3) corresponding to the desired solution and position on the balance pan. Each vessel has its own delivery tubing and computer-interfaced control valve. By keeping a record of which valve was opened last, the titrator "knows" which solution has been delivered. Next, a prompt for weight of sample to be added appears and the valve is opened for the required time calculated on the basis of a prior flow rate calibration for that valve.

After the desired samples from all reservoirs have been added, titration parameters are input, as above, and titration is performed. Various prompts ensure the readiness of the various hardware components. The first titrant addition is made. On the basis of the recent shape of the titration curve and a flow calibration made prior to the start of titration, the computer predicts the valve open time required to reach the next desired weight or pH value. This cycle continues unattended and finishes when the preset maximum weight or pH range is met or exceeded. At this time an output file, consisting essentially of pH (or mV) and titrant weight data pairs, is created. All data analysis and subsequent presentation were performed on an IBM compatible PC, after data transfer from the titrator computer via floppy diskette.

Experimental approach for the nickel(II)–glycinate–proton study

The study involves the determination of the two acid dissociation constants for glycine, the formation constants for the three Ni–Gly complexes, and various important solution parameters. Since there are at least five equilibria involved in this system, a systematic approach is necessary; the important solution parameters are standardized first and the equilibrium constants are then determined one at a time in "building block" fashion as suggested in a previous study (13). Figure 5 shows the equilibrium scheme for the nickel(II)–glycine system.

The NaOH titrant was standardized by filling one of the solution reservoirs with the KHP standard solution and a second with the titrant. The sample addition routine was used to dispense samples of the KHP, which were then titrated as usual. To determine the apparent molar ionic product of water (pK^c_W) and the acid concentration, samples of solvent, contained in one of the reservoirs, were titrated with the NaOH titrant, contained in a second reservoir. Next the solvent was replaced by the glycine standard solution and the dissociation constants for glycine were obtained by titrating samples of glycine with NaOH. Finally, the third reservoir was filled with the nickel standard solution and the formation constants for Ni(II)–Gly were found by titrating samples of Ni(II)–Gly prepared with Ni:Gly ratios ranging from 1:1 to 1:4. The resulting formation and acid dissociation constants were then compared with those of the interlaboratory study to determine if errors were present in the experimental system.

Fig. 5. Equilibrium scheme and definition of formation constants for the nickel(II)–glycine system.

$$H_2Gly^+ \underset{}{\overset{K_{a1}}{\rightleftharpoons}} HGly \overset{K_{a2}}{\rightleftharpoons} Gly^+ \underset{K_{f1}}{\rightleftharpoons} NiGly^+ \underset{K_{f2}}{\rightleftharpoons} Ni(Gly)_2 \underset{K_{f3}}{\rightleftharpoons} Ni(Gly)_3^-$$

$$K_{f1} = \frac{[NiGly^+]}{[Ni^{2+}]\,[Gly^-]} \qquad K_{f2} = \frac{[Ni(Gly)_2]}{[Gly^-]\,[NiGly^+]}$$

$$K_{f3} = \frac{[Ni(Gly)_3^-]}{[Gly^-]\,[Ni(Gly)_2]}$$

Results and discussion

All titration data was processed using SUPERQUAD (14). Processing times were typically 0.5–5 min, depending on the speed of the PC employed. The NaOH concentration was determined by keeping the number of millimoles of KHP and the value of pK^c_W (set at the value of 13.76 determined previously (7, 13)) constant and refining the NaOH concentration, "electrode parameter" $E^{0\prime}$, and the pK_a values for KHP. The acid concentration and pK^c_W were determined by keeping the NaOH concentration constant and refining $E^{0\prime}$, pK^c_W, and HCl concentration.

Once the solution parameters were determined, the dissociation constants were found by refining the total millimoles of glycine and proton, both pK_a values for glycine, and $E^{0\prime}$ while keeping the NaOH concentration and pK^c_W constant. The acid dissociation constant pK_{a1} was found to be 2.43 ± 0.02 and pK_{a2} was 9.63 ± 0.03. Following published recommendations, only data in the range $2.0 < pH < 9.5$ were used for the determination of these equilibrium constants (7).

The formation constants for the various Ni(II)–Gly complexes were determined by refining the total millimoles of proton and glycine, the logarithm of the formation constants log K_{f1}, log K_{f2}, and log K_{f3}, and $E^{0\prime}$ while keeping pK^c_W, total millimoles of nickel, both dissociation constants, and the NaOH concentration constant.

As previously suggested, data in the range $2.5 < pH < 9$ were input for fitting these constants except for Ni(II):Gly ratios less than 1:2, in which case usable data are only available in the pH range $2.5 < pH < 8$. Above this range, pH readings were erratic, signalling that precipitation of nickel hydroxide had commenced. Below this range, acid error in the electrode led to large residual values that compromised the goodness of fit.

The weighted mean values and associated standard deviations for the formation constants were determined using the values from all titration data. These values are log K_{f1} = 5.65 ± 0.02, log K_{f2} = 4.71 ± 0.03, and log K_{f3} = 3.50 ± 0.02. As

shown in Table 1, these values compare well with those reported in the literature, including previous studies from this laboratory.

The titration system is being used in a variety of metal–ligand speciation studies involving Gd, Hg, Cu, and other metal ions.

Conclusion

A novel PC-based single-buret multi-solution autotitrator has been developed for use in speciation studies. Validation was performed by investigating the well-characterized nickel(II)–glycine complex system. The formation and dissociation constants thus obtained were in good agreement with the accepted literature values. The system as described is capable of collecting the quality, high-precision data required for such speciation studies.

Abstract: The reaction of Li[4-$CH_3C_6H_4C(NSiMe_3)_2$] with PhECl (E = S, Se) in a 1:1 molar ratio produces the monosubstituted derivatives 4-$CH_3C_6H_4C(NEPh)[N(SiMe_3)_2]$ (**3***b*, E = Se; **3***d*, E = S). The thermolysis of **3***b* at 130°C produces $PhSeN(SiMe_3)_2$ and 4-$CH_3C_6H_4CN$. Crystals of **3***b* slowly acquire a purple stain upon prolonged standing at 23°C owing to the formation of 4-$CH_3C_6H_4C(NH_2)(NSePh)$ (**4***c*, λ_{max} = 551 nm). The formamidine derivative $HC(NH_2)(NSePh)$ (**4***a*, λ_{max} = 472 nm) was isolated from the reaction of $HCN_2(SiMe_3)_3$ with PhSeCl (1:3 molar ratio) in dichloromethane. The structure of **4***a* was shown by X-ray crystallography to involve a *syn* configuration at the >C=N- bond and hydrogen bonding between amino nitrogen atoms. The crystals of **4***a* are monoclinic, space group $P2_1$ (No. 4), with *a* = 7.514(1), *b* = 5.575(1), *c* = 8.925(1) Å, β = 100.71(1)°, *V* = 367.40(6) Å^3, and *Z* = 2. The final *R* and R_w values were 0.055 and 0.060, respectively. The ^1H and ^{77}Se NMR spectra indicate that both **4***a* and **4***c* exist as a mixture of tautomers in THF solution. DFT calculations for the model tautomers $HC(NH_2)(NER)$ and HC(NH)(NHER) (E = S, Se; R = H, Ph) show that the former is more stable in all cases, but the difference in total bonding energy is smaller for selenium than for sulfur (17.5 vs. 29 kJ mol^{-1}). The visible absorption band for **4***a* is assigned to the HOMO–LUMO transition (ΔE = 2.90 eV, λ_{max} = 427 nm) of the minor tautomer.

Key words: formamidine, tautomer, selenium, purple chromophore.

Résumé : La réaction du Li[4-$CH_3C_6H_4C(NSiMe_3)_2$] avec le PhECl (E = S, Se), dans un rapport molaire de 1 : 1, conduit à la formation des dérivés monosubstitués 4-$CH_3C_6H_4C(NEPh)[N(SiMe_3)_2]$ (**3***b*, E = Se; **3***d*, E = S). La thermolyse du composé **3***b* à 130°C fournit du $PhSeN(SiMe_3)_2$ et 4-$CH_3C_6H_4CN$. Les cristaux du produit **3***b* acquièrent lentement une couleur violette lorsqu'on les laisse à 23°C pour une période prolongée; cette couleur est due à la formation du 4-$CH_3C_6H_4C(NH_2)(NSePh)$ (**4***c*, λ_{max} = 551 nm). On a isolé le dérivé formamidine $HC(NH_2)(NSePh)$ (**4***a*, λ_{max} = 472 nm) du milieu réactionnel de la $HCN_2(SiMe_3)_3$ avec le PhSeCl (rapport molaire 1 : 3) dans le dichlorométhane. Faisant appel à la diffraction des rayons X, on a montré que la structure du composé **4***a* implique une configuration *syn* au niveau de la liaison >C=N- et des liaisons hydrogènes entres les atomes des azotes aminés. Les cristaux du composé **4***a* sont monocliniques, groupe d'espace $P2_1$ (No. 4), avec *a* = 7,514(1), *b* = 5,575(1), *c* = 8,925(1) Å, β = 100,71(1)°, *V* = 367,40(6) Å^3, and *Z* = 2. Les valeurs finales de *R* et R_w sont respectivement de 0,055 et 0,060. Les spectres RMN du ^1H et du ^{77}Se indiquent que, en solution dans le THF, les deux composés **4***a* et **4***c* existent chacun sous la forme d'un mélange de tautomères. Des calculs DFT sur les tautomères modèles $HC(NH_2)(NER)$ et HC(NH)(NHER) (E = S, Se; R = H, Ph) montrent que, dans tous les cas, le premier est le plus stable; toutefois, la différence en énergie totale de liaison est plus faible pour le sélénium que pour le soufre (17,5 vs. 29 kJ mol^{-1}). La bande d'absorption dans le visible du composé **4***a* est attribuée à la transition des OM HO et BV (ΔE = 2,90 eV, λ_{max} = 427 nm) du tautomère mineur.

Mots clés : formamidine, tautomère, sélénium, chromophore violet.

Introduction

Organoselenium-nitrogen compounds, e.g., *N*-(phenylselenenyl)-*o*-quinone imine (1), have attracted attention recently, partly on account of their applications in organic synthesis (2). Cyclic oligomers of the type $(RSeN)_4$ (R = Me, ^{i}Pr, Ph) have been spectroscopically identified (3) and the structure of $(HSeN_4)$ has been determined by ab initio calculations (4). In an attempt to make related eight-membered rings of the type $(RC)_2N_4(SeR)_2$ we found that the reaction of $PhCN_2(SiMe_3)_2$ with $RSeCl_3$ (R = Me, Ph) unexpectedly produces the intensely coloured diazenes **1***a* (λ_{max} = 502 nm) and **1***b* (λ_{max} = 553 nm) (5). The diazene **1***b* is formed in better yields, via the resonance-stabilized radical $PhC(NSePh)_2^{\bullet}$ (**2**), from the reaction of $PhCN_2(SiMe_3)_2$ with three molar equivalents of PhSeCl (6). The monosubstituted derivative **3***a* was obtained as an oil contaminated with a purple impurity, tentatively assumed to be the diazene **1***b*, when this reaction was con-

ducted with a 1:1 molar ratio (6). We have now prepared pure samples of **3*b*** as white crystals and observed that in the solid state these crystals develop a purple taint after several weeks at room temperature. We report here investigations of the thermolysis and hydrolysis of **3*b*** that have led to the identification of the purple chromophore and theoretical calculations that elucidate the origin of the low-energy electronic transition. The X-ray crystal of structure of $HC(NH_2)(NSePh)$ is also described.

Experimental

Reagents and general procedures

Solvents were dried by treatment with the appropriate drying agent and freshly distilled before use. All reactions and the manipulation of moisture-sensitive products were carried out under an atmosphere of nitrogen by using Schlenk techniques or a Vacuum Atmospheres drybox. Li[4-$CH_3C_6H_4C(NSiMe_3)_2$] (7), $HCN_2(SiMe_3)_3$ (8), and $PhSeN(SiMe_3)_2$ (9) were prepared by literature methods. $LiN(SiMe_3)_2$ was obtained from Aldrich and recrystallized from hexanes – diethyl ether before use. PhSeCl (Aldrich) was used as received. PhSCl was prepared from Ph_2S_2 (Aldrich) and SO_2Cl_2 in CCl_4.

Instrumentation

^1H and ^{77}Se NMR spectra were run on Bruker ACE-200 and Bruker AM-400 spectrometers, respectively, operating at 200.132 and 76.132 MHz. ^{77}Se NMR chemical shifts are reported relative to Me_2Se. UV–visible spectra were determined by using a Cary 5E spectrophotometer. Infrared spectra were recorded as Nujol mulls (KBr plates) on a Mattson 4030 FTIR spectrometer. Elemental analyses were performed within the Chemistry Department at the University of Calgary.

Preparation of 4-$CH_3C_6H_4C(NSePh)[N(SiMe_3)_2]$, 3*b*

A solution of PhSeCl (1.91 g, 10 mmol) in CH_2Cl_2 (20 mL) was added dropwise (20 min) to a solution of Li[4-$CH_3C_6H_4C(NSiMe_3)_2$] (10 mmol) in diethyl ether (60 mL) at −78°C. The yellow reaction mixture was allowed to warm slowly to 23°C to produce a white precipitate of LiCl. Solvent was removed under vacuum to give a yellow oil, which was extracted with hexanes (2 × 50 mL). The hexanes were removed under vacuum to give a yellow solid, which was recrystallized from a *minimum* volume of pentane at −18°C, yielding **3*b*** as an off-white solid (1.1 g, 2.5 mmol, 25%). ^1H NMR ($CDCl_3$) δ: 7.22–7.76 (m, 9H, $CH_3C_6H_4$ and SeC_6H_5), 2.40 (s, 3H, $CH_3C_6H_4$), 0.31 (s, 18H, $Si(CH_3)_3$). ^{77}Se NMR (THF) δ: 779 (s).

Preparation of 4-$CH_3C_6H_4C(NSPh)[N(SiMe_3)_2]$, 3*d*

The compound **3*d*** was obtained in 50% yield from PhSCl and Li[4-$CH_3C_6H_4C(NSiMe_3)_2$] by a procedure similar to that described for the preparation of **3*b***. ^1H NMR ($CDCl_3$) δ: 7.21–7.79 (m, 9H, $CH_3C_6H_4$ and SC_6H_5), 2.41 (s, 3H, $CH_3C_6H_4$), 0.27 (s, 18H, $Si(CH_3)_3$). Anal. calcd. for $C_{19}H_{30}N_2SSi_2$: C 62.12, H 7.82, N 7.24; found: C 62.15, H 7.90, N, 7.88.

Preparation of 4-$CH_3C_6H_4C(NH_2)(NSPh)$, 4*b*

A stoichiometric amount of methanol was added to a solution of **3*d*** (0.36 g, 1.0 mmol) in THF (10 mL). The reaction mixture was heated gently during 10 min and then the volatile materials were removed under vacuum to give 4-$CH_3C_6H_4C(NH_2)(NSPh)$ as a colourless solid (0.22 g, 0.90 mmol, 90%). IR (cm^{-1}): 2723 m, 2674 m, 1627 m, 1304 m, 1153 m, 1086 m, 1022 m, 829 m, 769 m, 735 s, 688 m. ^1H NMR (CD_2Cl_2) δ: 7.75–7.50 (m, 4H, $CH_3C_6H_4$), 7.40–7.10 (m, 5H, SC_6H_5), 5.11 (s, 2H, NH_2), and 2.37 (s, 3H, $CH_3C_6H_4$). Anal. calcd. for $C_{14}H_{14}N_2S$: C 69.39, H 5.82, N 11.56; found: C 70.26, H 6.23, N 11.62.

Preparation of 4-$CH_3C_6H_4C(NH_2)(NSePh)$, 4*c*

4-$CH_3C_6H_4C(NH_2)(NSePh)$ was obtained in 40% yield as dark purple crystals by the treatment of **3*b*** with methanol in a manner similar to that described above for the preparation of **4*b***. IR (cm^{-1}): 2721 m, 2671 m, 1306 m, 1261 m, 1018 m, 966 m, 822 m, 768 m, 733 s, 688 m, 669 m. UV–vis: λ_{max} 551 nm, ε(apparent) 8000 M^{-1} cm^{-1}.[2] ^1H NMR (CD_2Cl_2) δ: 8.35–8.20 (m, 2H, $CH_3C_6H_4$), 7.90–7.75 (m, 2H, $CH_3C_6H_4$), 7.70–7.10 (m, 14H, $CH_3C_6H_4$ and C_6H_5), 5.12 (s, 4H, NH_2), 2.45 (s, 3H, $CH_3C_6H_4$), and 2.38 (s, 3H, $CH_3C_6H_4$). Anal. calcd. for $C_{14}H_{14}N_2Se$: C 58.14, H 4.88, N 9.69; found: C 58.75, H 4.56, N 9.73.

Reaction of $HCN_2(SiMe_3)_3$ with PhSeCl

A solution of PhSeCl (3.16 g, 17 mmol) in CH_2Cl_2 (20 mL) was added dropwise to a solution of $HCN_2(SiMe_3)_3$ (1.49 g, 5.7 mmol) in (20 mL) at −78°C. The reaction mixture was allowed to warm slowly to 23°C with stirring and the colour of the solution changed from yellow to orange-red and, finally, to dark purple. After 16 h solvent was removed under vacuum to give a black solid, which was extracted with hexanes (3 × 15 mL). Removal of hexanes under vacuum yielded PhSeSePh

[2] The apparent molar extinction coefficients of **4*a*** and **4*c*** were calculated as the absorbance at the maximum divided by the total concentration and the optical path length.

Crystal structure determination of $HC(NSePh)(NH_2)$

A dark brown plate-like crystal of **4***a* (0.09 × 0.30 × 0.45 mm) with a metallic lustre was obtained from CH_2Cl_2–heptane (2:10) at 14°C, mounted on a glass fibre, and coated with epoxy. Pertinent crystallographic data are listed in Table 1. The unit cell constants were determined from the setting angles of 22 reflections with $28.57 < 2\theta < 35.56°$. All measurements were made on a Rigaku AFC6S diffractometer with the ω–2θ scan technique. An empirical absorption correction using the program DIFABS (10) was applied. The data were corrected for Lorentz and polarization effects.

The structure was solved by heavy-atom methods and expanded using Fourier techniques (11). The non-hydrogen atoms were refined anisotropically. The C atoms of the benzene ring were constrained to be a regular hexagon; H atoms were located from a difference map and were included in the final rounds of calculations at geometrically idealized positions. Atomic scattering factors (12, 13), corrected for anomalous dispersion (14), were used. Data processing was carried out using TEXSAN (15) and the structure was solved and refined using SHELX76 (16). Positional parameters are given in Table 2 and selected bond distances and bond angles are summarized in Table 3.

Hydrogen atom parameters, anisotropic thermal parameters, torsion angles, and complete tables of bond lengths and bond angles have been deposited.[3]

[3] Supplementary material mentioned in the text may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council of Canada, Ottawa, Canada, K1A OS2.

Tables of hydrogen atom parameters and bond lengths and angles have also been deposited with the Cambridge Crystallographic Data Centre and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 IEZ, U.K.

Calculations

All calculations were based on approximate density functional theory within the local density approximation (17), using the ADF program system developed by Baerends et al. (18, 19), and vectorized by Raveneck (20). The numerical integration was based on a scheme developed by Becke (21). All molecular dimensions were fully optimized, by a procedure based on the method developed by Versluis and Ziegler (22). All bonding energies were evaluated by the generalized transition state method due to Ziegler and Rauk (23). This treatment also allows for a detailed energy decomposition of the total bonding energy into steric and single orbital contributions (24). A double-ζ STO basis (18) was employed for the *ns* and *np* shells of the main group elements. This basis set was augmented by a 3*d* STO function for sulfur, 4*d* STO for selenium, and for hydrogen a 2*p* STO was used as polarization. Electrons in lower shells were treated by the frozen core approximation (18). A set of auxiliary (26) *s*, *p*, *d*, *f*, and *g* STO functions, centered on the different nuclei, was used in order to fit the molecular density and present Coulomb and exchange potentials accurately in each SCF cycle.

Energy differences were calculated by augmenting the local density approximation (LDA) energy expression by Vosko et al. (27) with Becke's exchange corrections (28) and Perdew's nonlocal correlation correction (29).

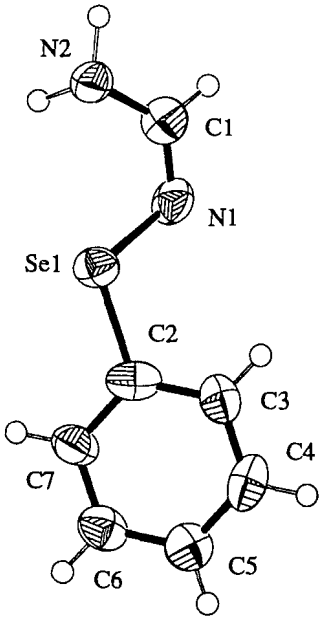
Results and discussion

Synthesis of 4-$CH_3C_6H_4C(NEPh)[N(SiMe_3)_2]$ (*3b*, E = Se; *3d* E = S)

The monosubstituted compounds **3***b* and **3***d* were obtained as

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

Fig. 1. ORTEP diagram for $HC(NH_2)(NSePh)$ showing atom labelling; 50% probability ellipsoids are shown for non-hydrogen atoms.



moisture-sensitive white crystals by the reaction of $Li[4\text{-}CH_3C_6H_4C(NSiMe_3)_2]$ with PhSeCl or PhSCl, respectively. The use of the lithium derivative rather than $4\text{-}CH_3C_6H_4C(NSiMe_3)_3$ (6) yields a cleaner, more easily purified product, particularly in the case of the selenium derivative **3***b*. The ^1H NMR spectrum of **3***b* is almost identical to that of analytically pure **3***d* and the ^{77}Se NMR spectrum exhibits a singlet at δ 779 ppm (cf. δ (^{77}Se) 995 ppm for **1***c* (30)). Nevertheless, satisfactory analytical data could not be obtained for **3***b* even on samples that appeared to be pure on the basis of ^1H and ^{77}Se NMR spectra.

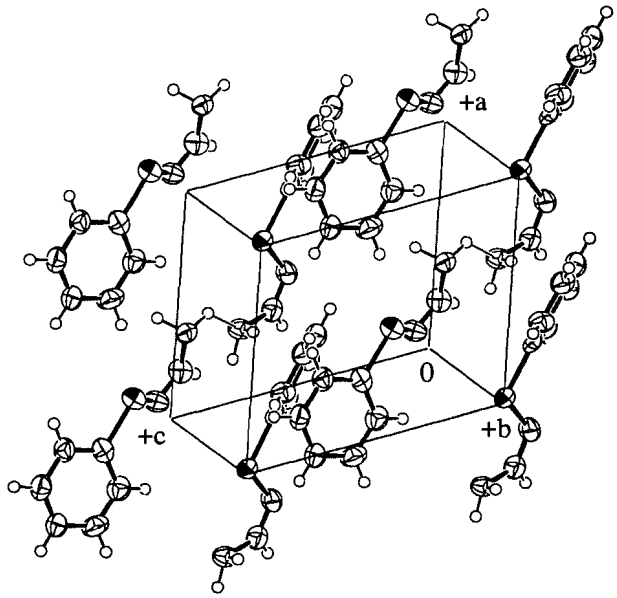
Crystalline samples of **3***b* develop a dark purple taint over a period of several weeks at 23°C even when stored under an argon atmosphere. The thermal decomposition of solid **3***b* at 130°C for 12 h produces $PhSeN(SiMe_3)_2$ (δ (^{77}Se) 682 ppm, cf. lit. δ 684 ppm (9)) and $4\text{-}CH_3C_6H_4CN$, which was identified by IR and ^1H NMR spectroscopy. No evidence for the formation of **1***c* in the solid state decomposition of **3***b* was obtained. Thus it seems unlikely that the purple chromophore that is produced slowly in crystalline samples is **1***c*. The decomposition of **3***b* in THF solution does, however, produce the diazene **1***c*, together with Ph_2Se_2 and $PhSeN(SiMe_3)_2$, all of which were identified by the ^{77}Se NMR spectrum of the purple solution.

Spectroscopic characterization and X-ray structure of $HC(NH_2)(NSePh)$

Although trithiolated benzamidines of the type $ArCN_2(SPh)_3$ are thermally unstable at room temperature (6), the corresponding formamidine derivative $HCN_2(SPh)_3$ can be isolated as colourless crystals.[4] By contrast, the reaction of $HCN_2(SiMe_3)_3$ with three molar equivalents of PhSeCl produced $HC(NH_2)(NSePh)$, **4***a*, presumably as a result of hydrolysis during the work-up procedure. Both the ^1H NMR spectrum and the ^{77}Se NMR spectrum of **4***a*, which shows two resonances at δ 988 and δ 912 ppm, suggest the existence of two tautomeric forms in solution. Compound **4***a* exhibits an intense visible absorption band at 472 nm in CH_2Cl_2 solution.

[4] T. Chivers and I. Vargas-Baca. Unpublished results.

Fig. 2. Packing diagram for $HC(NH_2)(NSePh)$.



The structure of **4***a* was determined by X-ray crystallography. An ORTEP drawing with the atomic numbering scheme is displayed in Fig. 1. Selected bond lengths and bond angles are summarized in Table 3. The molecule **4***a* adopts a *syn* configuration with respect to the C(1)═N(1) double bond, as has been observed for **1***a* (5). The N-C-N-Se unit is nearly planar, with a dihedral angle of −7.5°, and the phenyl ring is twisted by 37.5° with respect to the N-C-N plane. As indicated in Fig. 2, the molecules in the crystal lattice are connected by hydrogen bonds between nitrogen atoms of amino groups (N---N′ separation of 3.00 Å with N2---H′-N2′ angle of 124°; primed atoms at symmetry position: $1\text{-}x, y\text{-}½, \text{-}z$). The C—N bond distances of 1.43(2) and 1.28(2) Å are typical for single and double bonds, respectively (31). The Se—N bond distance of 1.80(1) Å is comparable to the value 1.817(3) Å observed for the selenium-substituted diazene **1***a* (5) and somewhat shorter than the single bond value of 1.87 Å (32).

Hydrolysis of $4\text{-}CH_3C_6H_4C(NEPh)[N(SiMe_3)_2]$ (E = S, Se)

The purple colour of $HC(NH_2)(NSePh)$ suggested that hydrolysis might be an explanation for the purple taint apparent in aged crystals of the monosubstituted compound **3***b*. Consequently **3***b* and, for comparison, **3***d* were deliberately converted to the expected hydrolysis products $4\text{-}CH_3C_6H_4C(NH_2)(NEPh)$ (**4***b*, E = S; **4***c* E = Se) by the addition of methanol. The ^1H NMR spectrum of the pale yellow sulfur derivative, which remains unchanged down to −90°C, is consistent with the sole existence of the tautomer **4***b*′ in solution. By contrast, the ^1H NMR and ^{77}Se NMR spectra of $4\text{-}CH_3C_6H_4C(NH_2)(NSePh)$ (**4***c*) suggest the existence of both tautomers **4***c*′ and **4***c*″ in approximately the same amounts in CD_2Cl_2 solutions at room temperature. Furthermore, the selenium derivative **4***c* is dark purple and exhibits an intense visible absorption band at 551 nm. For comparison the diazene **1***b* exhibits a visible absorption band at 553 nm with a shoulder at 580 nm (6).

DFT calculations for $HC(NH_2)(NSeR)$ and HC(NH)[NH(SeR)]

To compare the relative stabilities of the amino and imino tautomers **4a′–c′** and **4a″–c″**, respectively, and to provide an explanation of the purple colour of the selenium derivatives, approximate density functional theory (DFT) calculations (33) were carried out on the model compounds $HC(NH_2)(NER)$ and HC(NH)[NH(ER)] (E = S, Se; R = H, Ph) (33). The results are summarized in Table 4. The calculated structural parameters for the amino derivative $HC(NH_2)(NSePh)$ are compared with the corresponding experimental values for **4c** in Table 3. Bond distances are reproduced within 0.05 Å for the organic moiety and 0.10 Å for the bonds to the heavy element. Larger differences are observed between calculated and experimental values of the bond angles, probably as a result of the intermolecular hydrogen bonding interactions in the solid state.

The calculations show that the amino tautomers **4a′** are always more stable than the imino tautomers **4a″**, due to the larger π delocalization. Selenium forms a weaker π-bond than sulfur with nitrogen. Consequently, the energy barrier between the tautomers is smaller for the selenium derivatives. This is consistent with the NMR spectroscopic data, which showed the existence of two tautomers in solution for the selenium derivatives **4a** and **4c**, whereas only the amino tautomer is evident in the ^1H NMR spectrum of **4b**. The lowest energy electronic transition for all the model compounds is the HOMO $[n_E] \rightarrow$ LUMO[π*(C═N)] transition. In the amino tautomers mixing of the chalcogen lone pair and π*(C═N) MOs increases the HOMO–LUMO gap so that the electronic transitions are of higher energy than the corresponding transition for the imino tautomer. The replacement of the H substituent on the chalcogen in the model compounds by an aryl group raises the energy of the lone pair so that the predicted value of the electronic transition for the imino tautomer HC(NH)[NH(SePh)] is 427 nm, in reasonable agreement with the experimental value of 472 nm for **4a**. On the other hand, on the basis of NMR spectroscopic evidence, the sulfur derivative **4b** exists only as the amino tautomer and exhibits no absorption in the visible region consistent with the predicted trend of higher transition energies for the sulfur compounds compared to their selenium analogues (see Table 4).

Conclusions

The purple chromophore formed from RC(NSePh)$[N(SiMe_3)_2]$ (R = H, aryl) in solution or, more slowly, in the solid state has been identified as the hydrolysis product RCN_2H_2SePh, which, for R = H, adopts a *syn* conformation in the solid state. In contrast to the corresponding sulfur derivatives, which form only the amino tautomer $RC(NH_2)(NSPh)$ in solution, the selenium compounds exist as a mixture of amino and imino tautomers, $RC(NH_2)(NSePh)$ and RC(NH)(NHSePh), respectively. DFT calculations suggest relatively close values of the total bonding energies for the two tautomers in the case of the selenium derivatives. The calculations also indicate that the purple colour of the Se compounds can be attributed to the HOMO $[n_E] \rightarrow$ LUMO[π*(C═N)] transition of the imino tautomer.

^{1}H, ^{19}F, and ^{13}C nuclear magnetic resonance approaches to the barrier to rotation about the Csp^2—Csp^3 bond in 1,1,1-trifluoro-2-phenylethane. Proximate coupling constants and molecular orbital computations

Ted Schaefer, Paul Hazendonk, and David M. McKinnon

Abstract: The ^{1}H, ^{19}F and $^{13}C\{^{1}H\}$ nuclear magnetic resonance spectra of 1,1,1-trifluoro-2-phenylethane, **1**, in CS_2–C_6D_{12}, acetone-d_6, and benzene-d_6 solutions, on analysis, yield long-range coupling constants from which are derived the apparent twofold barriers to rotation about the Csp^2—Csp^3 bonds. The twofold barrier is 9.0(2) kJ/mol, independent of solvent, 4.0 kJ/mol larger than that of ethylbenzene, also independent of solvent. The theoretical barrier heights for the free molecules at the post-Hartree–Fock level of molecular orbital theory (frozen-core MP2/6-31G*) also differ by 4 kJ/mol, but are about 1 kJ/mol higher than the experimental estimates. The perpendicular conformer is the most stable for both molecules. Comparisons are made with the benzyl halides, in which the internal barriers are remarkably sensitive to solvent. A spin–spin coupling constant over five formal bonds, ^{5}J(H, F), involving the *ortho* protons in **1**, is +0.74(2) Hz and is discussed in some detail in terms of its dependence on internuclear distances (possible through-space interactions). The solvent perturbations of ^{3}J(H, F) and of ^{2}J(C, F) are of opposite sign. Other long-range coupling constants or their absence are also pointed out. For example, those between ^{19}F and ^{13}C nuclei or protons at the *meta* position are effectively zero; at the *para* position they are significant.

Key words: 1,1,1-trifluoro-2-phenylethane; ^{1}H, ^{19}F, and ^{13}C NMR; long-range spin–spin coupling constants; through-space ^{1}H, ^{19}F spin–spin coupling constants; internal rotational potential; molecular orbital computations of internal potential.

Résumé : L'analyse des spectres de résonance magnétique nucléaire du ^{1}H, du ^{19}F et du $^{13}C\{H\}$ du 1,1,1-trifluoro-2-phényléthane, **1**, en solution dans du CS_2–C_6D_{12}, dans de l'acétone-d_6 ou du benzène-d_6, permet d'obtenir les constantes de couplage à longue distance à partir desquelles on peut dériver les barrières binaires apparentes à la rotation autour des liaisons Csp^2—Csp^3. La barrière binaire est de 9,0(2) kJ/mol, elle est indépendante du solvant et elle est 4,0 kJ/mol plus élevée que celle de l'éthylbenzène qui est aussi indépendante du solvant. Les hauteurs des barrières théoriques des molécules libres, évaluées par la théorie des orbitales moléculaires à un niveau post-Hartree–Fock (MP2/6-31G* à référence fixée), diffèrent aussi par 4,0 kJ/mol; elles sont toutefois environ 1 kJ/mol plus élevées que les évaluations expérimentales. Dans les deux molécules, le conformère perpendiculaire est le plus stable. On a fait des comparaisons avec les halogènures de benzyle dans lesquels les barrières internes sont particulièrement sensibles au solvant. La constante de couplage spin–spin à travers cinq liaisons formelles, ^{5}J(H, F), impliquant les protons *ortho* du composé **1** est égale à +0,74(2) Hz; on en discute en détail en fonction de sa dépendance sur les distances internucléaires (interactions possibles à travers l'espace). Les perturbations des solvants sur les ^{3}J(H, F) et ^{2}J(C, F) sont de signes opposés. On spécifie aussi d'autres constantes de couplage à longue distance et, dans les cas appropriés, leur absence. Par exemple, ces constantes entre les noyaux ^{13}C et ^{19}F ou les protons en position *méta* sont effectivement égales à zéro; en position *para*, elles sont significatives.

Mots clés : 1,1,3-trifluoro-2-phényléthane; RMN du ^{1}H, du ^{13}C et du ^{19}F; constantes de couplage spin–spin à longue distance; constantes de couplage spin–spin ^{1}H, ^{19}F à travers l'espace; potentiel de rotation interne; calculs d'orbitales moléculaires du potentiel interne.

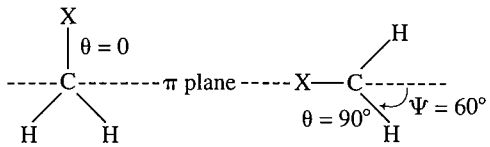
Introduction

This report presents theoretical and experimental assessments of the potential hindering rotation about the Csp^2—Csp^3 bond in 1,1,1-trifluro-2-phenylethane, **1**. Comparisons are made with similar and extensive data for ethylbenzene (1–4) and other benzyl derivatives. A secondary aim of this study concerns the through-space or proximate component of the spin–spin coupling constant over five formal bonds, $^5J(^{19}F, H\text{-}2)$, between the fluorine-19 nuclei and the *ortho* protons in **1**.



A **B**

All theoretical and experimental studies agree that **A** is the conformer of lowest, **B** that of highest, energy for the ethylbenzene (X = CH_3). Disagreement exists as to the difference in energies between **A** and **B**, the twofold component of the internal rotational potential; the numbers lie between 4.2 and 9.2 kJ/mol (3, 4). Molecular orbital calculations imply the presence of a fourfold component, V_4, in the rotational potential, of the same sign as V_2 and probably no larger than one-fifth of the magnitude of the latter (1, 2). If this statement holds, then V_2 is probably less than 6 kJ/mol in solution and also, as indicated by the invariance of the barrier-dependent $^6J(H, CH_2)$ to solvent (1), quite insensitive to the local environment of the molecule. The assumption of a pure twofold potential in solution yield V_2 as 5.0 kJ/mol (1). The rotational spectrum for the vapor (2) is consistent with a V_2 of 4.9(7) and a V_4 of 0.9 kJ/mol, as well as with a vanishing V_4 and a V_2 of 7.8(7) kJ/mol. The presence of a significant magnitude for V_4 has not been shown experimentally.

The origin of the barrier to internal rotation in ethylbenzene has been discussed in terms of steric repulsion (1), which destabilizes **B**, a molecular orbital model invoking four-electron (overlap) repulsion (5), minimized in **A**, as well as in terms of hyperconjugative stabilization of **A** (6, 7). An indirect approach (7) suggests that the hyperconjugative component is 1.2 ± 0.3 kJ/mol, the hyperconjugative ability of the C—C bond being larger than that of the C—H bond in the side chain. While this number must be regarded with circumspection (7), because no other measurements of hyperconjugative contributions to conformational energies appear to exist for neutral molecules, intuition suggests that the electronegative fluorine substituents in **1** may act to reduce the hyperconjugative interaction with the aromatic π system, that is, to destabilize **A**. Turning to **B**, considerations of size suggest that this conformer is more energetic for **1** than for ethylbenzene. Alternatively, attractive forces between the ^+C–F^- and *ortho* ^-C–H^+ dipoles will counteract the steric repulsion and, depending on their relative magnitude, **B** may actually be more stable relative to **A** in **1** than in ethylbenzene.

With these possibilities in hand, it appears sensible to compute the internal rotational potential for free **1**, to predict its geometry at a reliable level of molecular orbital theory (for use by molecular spectroscopists), and to compare these data with measurements of the internal barrier for **1** in solvents of varying polarity. The long-range spin–spin coupling constant between the methylene and *para* ring protons is sensitive, in principle, to the potential opposing the motion about the Csp^2—Csp^3 bond (1).

Experimental

The 1,1,1-trifluoro-2-phenylethane, **1**, was prepared as described (8). Dilute solutions of **1** in CS_2–C_6D_{12}–TMS–C_6F_6, acetone-d_6–TMS–C_6F_6, and benzene-d_6–TMS–C_6F_6 solvent mixtures (see Table 1 for details) were filtered into 5 mm o.d. nmr sample tubes, were degassed by at least four freeze–pump–thaw cycles, and the tubes were then flame-sealed to produce reasonably symmetric tops. The nmr measurements utilized an AM 300 Bruker spectrometer.

As many as 64 free induction decays (200 for ^{13}C), using acquisition times of 40 s (34 s for ^{13}C), were added, and were preceded by extensive shimming, monitored by the decays from internal reference compounds. After zero-filling to four times the size of the data table and the application of small amounts of resolution enhancement, Fourier transformation yielded spectra with a resolution of 0.003, 0.006, and 0.030 Hz/point for ^1H, ^{19}F, and ^{13}C nuclei, respectively.

Molecular orbital computations[2] on **1** and **2** used the computer program GAUSSIAN 92 (10). Bond angles and lengths were optimized but the atoms of the phenyl group were constrained to a plane during the optimizations. INDO MO FPT computations of spin–spin coupling constants (11, 12) utilized various computed geometries. Energies and coupling constants were fit to Fourier series in the conformational angles, θ and ψ (see **A** and **B**).

Results and discussion

Spectral analyses

The spectra were analyzed with the computer program NUMARIT (13), as extensively reworked by R. Sebastian and K. Marat in this laboratory. Tables 1 and 2 present the extracted spectral parameters. Figure 1 displays part of the ^{19}F nmr spectrum of the CF_3 group in **1**, demonstrating that $^5J(H, F)$ is positive. In Fig. 2 one multiplet of the ^1H nmr spectrum of the CH_2 group in **1** shows the agreement attained between theory and experiment of protons coupled to eight other nuclei. The $^{13}C\{^1H\}$ spectra were also subjected to analysis so as to find the precision available from these first-order spectra.

Theoretical internal barriers

Table 3 presents the components of theoretical barriers to internal rotation about the Csp^2—Csp^3 bond in **1**. As expected, **A** lies at the bottom of the potential (θ = 0), which is dominated by the twofold component. For the split-valence basis sets, V_2 is 11.3, 10.8, and 10.5 kJ/mol for the RHF 6-31G, 6-31G*, and 6-31G** bases, respectively. The correlation-gradient, MP2/6-31G*, energies at θ = 0 and θ = 90° differ by 10.04 kJ/mol. In comparison, for ethylbenzene the V_2 values are 6.0 kJ/mol for both RHF 6-31G* bases (1, 2) and a single-point MP2/6-31G*//6-31G* barrier height is 5.8 kJ/mol (2). Theoretically, therefore, the hindering potential in **1** is 4–5 kJ/mol larger than in ethylbenzene.

Figures 3 and 4 present the planar and perpendicular MP2/

[2] For details of the notation for the various basis sets and the MP2 approximation to electron correlation, see ref. 9.

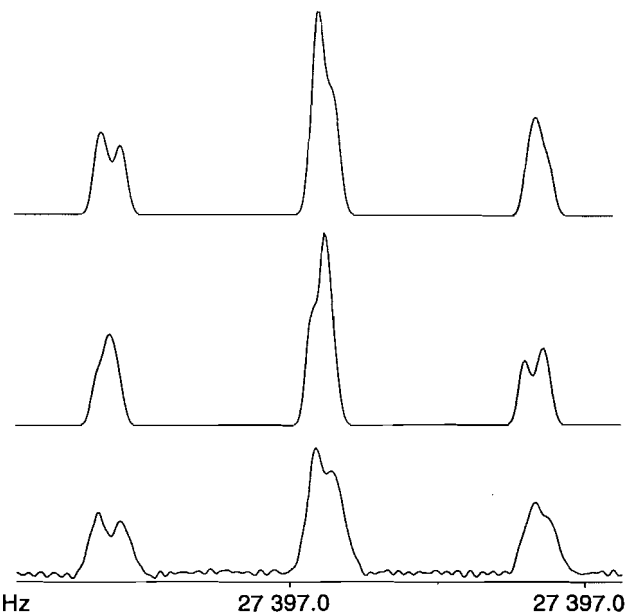
Fig. 1. The ^{19}F nmr spectrum of a 6.3 mol% solution of 1,1,1-trifluoro-2-phenylethane, in benzene-d_6 at 282.36 MHz and at 300 K, is shown at the bottom. The scale is in Hz to high frequency of internal C_6F_6. The computed spectrum at the top uses the spectral parameters in Table 1, with a linewidth of 0.045 Hz and ^5J(H, F) = +0.7 Hz. In the middle, the simulated spectrum has ^5J(H, F) = −0.7 Hz. A ^7J(H, F) of 0.07 Hz is present in all spectra.



6-31G* geometries of **1**, of possible use to molecular spectroscopists. Note the opening of the exocyclic CCC bond angles in the planar form, implying repulsive destabilization of **A**.

Experimental barriers in solution

The long-range coupling constants between the methylene and ring protons are all functions of the angle ψ (see **B**). In particular, ^6J(H, CH_2) = ^6J is proportional to $\sin^2\psi$ (1) which, in turn, has an expectation value dependent on the torsional potential about the Csp^2—Csp^3 bond (14). One may write $^6J = {}^6J_{90}\langle\sin^2\psi\rangle$, where $^6J_{90}$ is the value at $\psi = 90°$. $^6J_{90}$ decreases in magnitude as the electronegativity of the substituent on the

Fig. 2. The ^{1}H nmr spectrum of one of the methylene multiplets of a 4.7 mol% solution of 1,1,1-trifluoro-2-phenylethane in CS_2–C_6D_{12} is compared with the computed spectrum. The scale is in Hz at 300.135 MHz to high frequency of internal TMS, at 300 K.

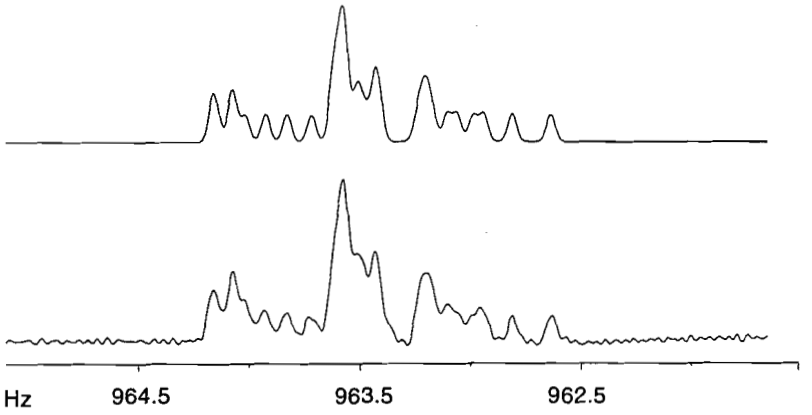

Fig. 3. The MP2/6-31G* geometry of the perpendicular, most stable, structure of 1,1,1-trifluoro-2-phenylethane is shown. The projection of the a C—H bonds onto a plane perpendicular to the phenyl plane illustrates that their torsion angle is 29.8° in the *J* method discussed in the text. The Csp^2-Csp^3-Csp^3 angle is 111.8°.

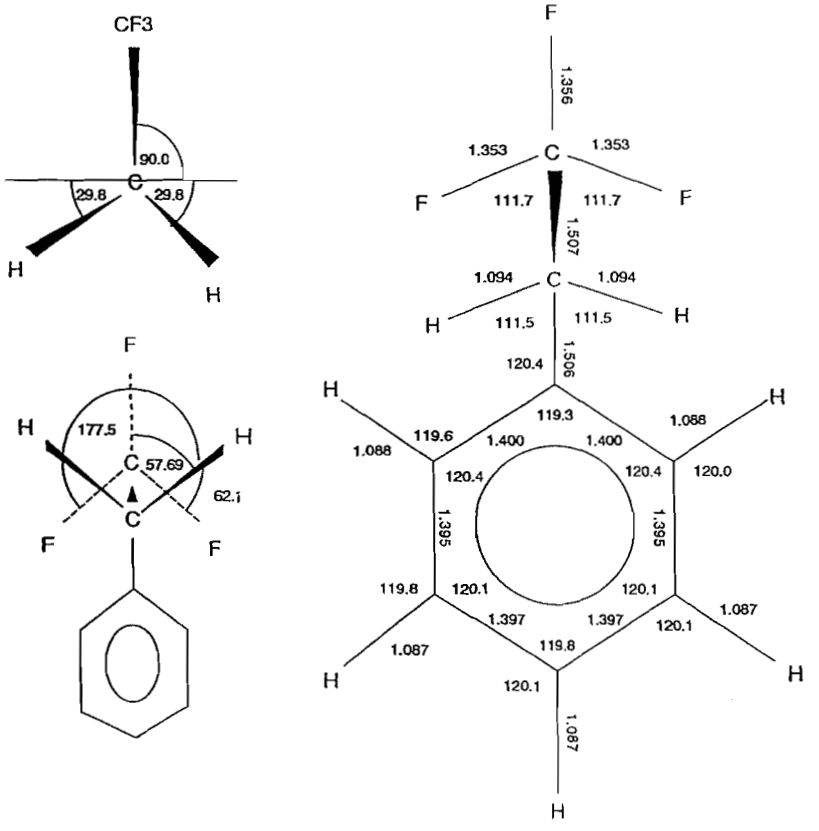

methylene group increases (smaller σ–π hyperconjugative overlap). For example, it is −1.20 Hz for X = H (15) and −0.95 Hz for X = F, as determined (16) experimentally. Other $^6J_{90}$ values are −1.02 Hz for X = OH or OCH_3 (17) and −1.16 Hz for X = CH_3 (1). The electronegativity on the Pauling scale is 3.46 for X = CF_3, leading[3] to $^6J_{90}$ = −1.03 Hz for **1**. It fol-

[3] Our INDO MO FPT computations for X = H, F, and CF_3 yield $^6J_{90}$ as −1.22, −1.07, and −1.14 Hz, respectively, qualitatively in agreement with a reduction in the magnitude of $^6J_{90}$ caused by an electronegative substituent. The experimental value (16) for X = F is 0.12 Hz lower in magnitude than the theoretical; the empirical value of $^6J_{90}$ for X = CF_3, used in the text, is 0.11 Hz lower in magnitude than that given by the INDO parameterization.

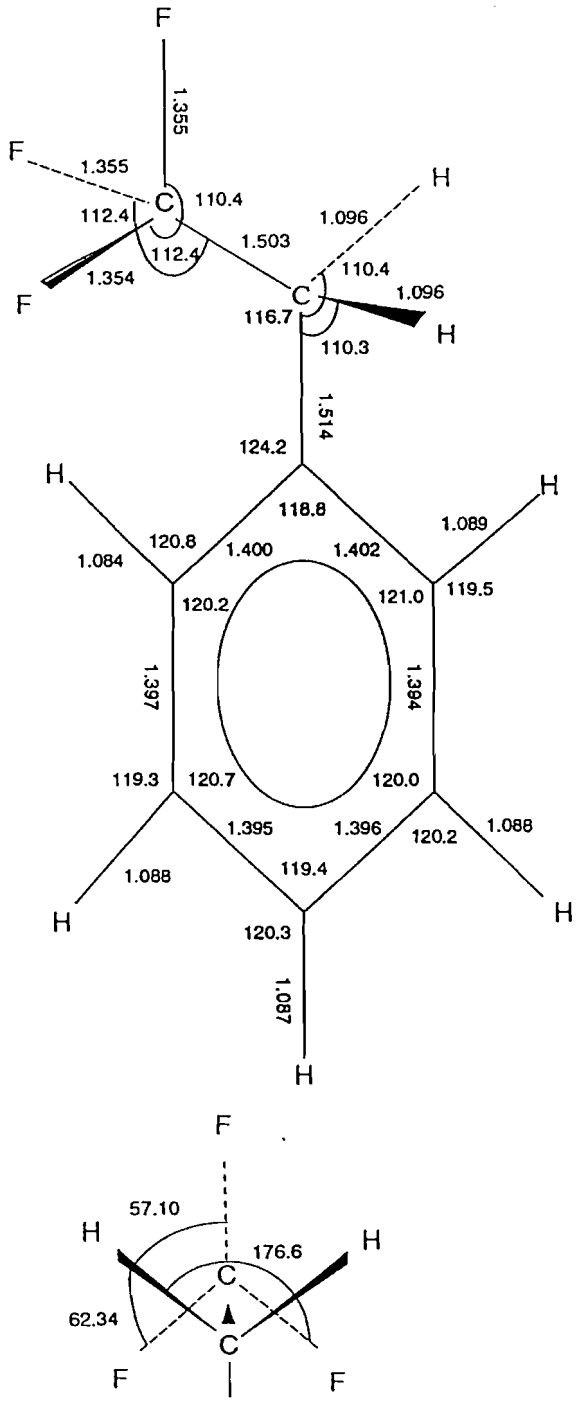
Fig. 4. The MP2/6-31G* geometry of the high-energy conformer of 1,1,1-trifluoro-2-phenylethane illustrates the opening of the bond angles in the side chain, possibly indicative of steric strain.



lows that $\langle \sin^2\psi \rangle = 0.336$, where the average of ^6J for the three solutions (Table 1) is used. From a hindered rotor model (14), the apparent V_2 follows as 9.0 kJ/mol, 4.0 kJ/mol higher than given by the same approach for ethylbenzene in a range of solvents (1, 3). The MP2/6-31G*, correlation-gradient computation for the free molecule has the barrier height as 10.04 kJ/mol, which is 4.2 kJ/mol higher than that from a similar calculation for ethylbenzene (see above). Considering possible errors in theory and experiment, it seems possible to conclude that, for both molecules, the two methods essentially agree about the barrier heights. By implication, the internal rotational potentials in both molecules, one polar, the other not, are insensitive to environment (note the essentially equal $^6J(H, CH_2)$ numbers for **1** in the three solvents in Table 1) or, pushing the evidence, the barrier heights in both molecules are about 1 kJ/mol lower in solution than in the vapor. While the dipole moment of ethylbenzene is only 0.6 D (2), that of **1** is computed as 2.53 D for **A** and 2.42 D for **B** (MP2/6-31G*), which are similar to the 2.32 D measured for CH_3CF_3 (18). To first order in reaction field theory (19), a large solvent perturbation of the internal potential is therefore not anticipated.

[a]In kJ/mol, numbers in parentheses being standard errors.

[b]In the perpendicular form, **A**, defined by $\theta = 0$, the minimum computed energies in a.u. are −597.441 228 (STO-3G), −605.161 984 (6-31G), −605.365 304 (6-31G*), −605.377 477 (6-31G**), and −606.887 011 (MP2/6-31G*). The barrier height for the post-Hartree–Fock calculation is 10.04 kJ/mol.

[c]The expectation value of $\sin^2\theta$ at 300 K, being related to that of $\sin^2\psi$ (see **B**) by $\langle \sin^2\theta \rangle = 1.5 - 2 \langle \sin^2\psi \rangle$ for tetrahedral angles at the methylene carbon atom.

The presence of a hyperconjugative component of the barrier in **1** cannot be established at present. At first sight, the absence of any hyperconjugative interaction between the CH_2CF_3 group and the aromatic π system is indicated by the essential equality of the chemical shifts of H-4 and C-4 in **1** and benzene (20, 21); hence the barrier should have no such component. However, as a referee points out, the equality of shifts could also reflects a combination of C–H hyperconjugation and π-electron polarization by the remote CF_3 group or, indeed, opposing C–H and C–C hyperconjugation.

An intriguing contrast exists between these data and the solvent effects on the internal rotational potentials of the benzyl halides. According to the ^6J method above, for benzyl fluoride **A** is stabilized by 1.7 ± 0.4 kJ/mol when the solvent is changed from CS_2 to acetone-d_6 (16); in the former solvent the twofold potential, with **A** also at the minimum, is only 0.7(2) kJ/mol. Similarly, for benzyl chloride, the apparent twofold barriers are 8.8 ± 0.4 and 11.2 ± 0.4 kJ/mol in the two solvents (22). A different method, based on residual intramolecular dipolar coupling constants, measured for the compounds dispersed in nematic solvents, also yields barriers for X = F, Cl, Br, I that increase in magnitude as the polarity of the medium rises (23, 24). For example, in the least polar solvent the (assumed) V_2 is 8.96 ± 0.06 kJ/mol, when X = Cl, rising to 11.05 ± 0.14 kJ/mol in the most polar nematic medium (24); the dielectric constants of these media are not given.

For personal use only.

The reasons for the contrast between the benzyl halides, X = F to I, and X = CF_3 or CH_3, escape us; **1** is certainly at least as polar as any of the benzyl halides. One possibility (5) for the halides might be that **A** is favored by electrostatic forces between the $^+C–X^-$ and *ortho* $^-C–H^+$ dipoles; these are proportional to the reciprocal of the effective dielectric constant and thus the old question again arises. What is the effective dielectric constant at the site of the interaction of the intramolecular charges on the molecular periphery when the molecule is immersed in a solvent of bulk dielectric constant? The similar magnitudes of the changes in potential, caused by the same solvents, for X = F or Cl, even though the barriers are substantially different, are consistent with this electrostatic origin: the dipole moments of benzyl fluoride and chloride and essentially equal, that is, the $^+C–X^-$ dipoles are very similar. While this rationalization is consistent with the insensitivity to solvent of the barrier in ethylbenzene (1), it appears as inconsistent with the behaviour of **1**. The Mulliken charges (MP2/6-31G*) are $-0.38e$ on fluorine and $+0.21e$ on *ortho* hydrogen atoms. The qualitative difference is that the C—F bonds are staggered about the *ortho* C—H bonds in **B** for **1**, whereas the C—F bond lies in the molecular plane when X = F. Perhaps further discussion should await confirmation by another method of the solvent independence of the internal rotational potential of **1**.

^4J(H, CH_2) and ^5J(H, CH_2) in 1

^4J(H, CH_3) in toluene has been written as $-1.08\sin^2\psi - 0.32\cos^2\psi$, the first term referring to a π-electron contribution, the second to a σ-electron component (25). If the coefficient of the term in $\sin^2\psi$ is multiplied by 1.03/1.20, as indicated from the treatment above the ^6J(H, CH_2) in **1**, then ^4J(H, CH_2) becomes −0.524 Hz because $\langle\sin^2\psi\rangle$ is 0.336. This number happens to agree exactly with the average of the measured numbers in Table 1.

In toluene, ^5J(H, CH_2) apparently (15) obeys the relationships, $0.336\sin^2\psi + 0.322\sin^2(\psi/2)$. Again, reduction of the σ, π maximum by 1.03/1.20 and noting that $\langle\sin^2(\psi/2)\rangle$ is 0.5 for any combination of evenfold terms in the internal rotational potential yields ^5J(H, CH_2) as 0.258 Hz, in reasonable agreement with the average, 0.264(3) Hz, of the values in Table 1. These two calculations assume that the σ-electron terms are independent of X, which may be unwarranted, so that the present agreements between experimental and theoretical numbers for ^4J(H, CH_2) and ^5J(H, CH_2) could be accidental.

^5J(H, CF_3) and proximate coupling mechanisms

The long-range coupling constants between ^{19}F nuclei and ring protons in **1** (Table 1) demonstrate a relatively large ^5J(H, CF_3) of + 0.74(2) Hz. The ^7J(H, CF_3) of magnitude 0.07(1) Hz is most likely a σ,π transmitted coupling constant, whose magnitude is consistent with the undetectable ^6J(H, CF_3). The latter is also expected to have a component transmitted by the π electrons, but smaller than ^7J(H, CF_3), perhaps only about 25% as large, as found for σ,π interactions in toluene. On that basis, ^5J(H, CF_3) may contain a σ,π component of comparable magnitude to ^7J(H, CF_3). The implication, that ^5J(H, CF_3) is dominated by other coupling mechanisms,[4] is assessed as follows.

[4] For a recent, extensive review of the theoretical and physical aspects of spin–spin coupling constants and, in particular, of through-space or proximate modes of the transmission of nuclear spin-state information, see ref. 26.

Fig. 5. ^5J(H-2, CF) is plotted as a function of the dihedral angle of the C(*ortho*)C (*ipso*)CF fragment in **1**. The INDO MO FPT values show that a close approach of H-2 and the fluorine atom leads to a large, negative ^5J. The circles refer to the C—F bond, which remains distant from the *ortho* C—H bond for all conformations. As the C—C(F_3) bond moves out of the phenyl plane, some rotation about this bond occurs, leading to a minimum in one H, F distance at a dihedral angle near 40° (6-31G* geometry). The predicted ^5J, to be compared with measurement, is obtained by averaging two values, equally displaced from 90° (H-2 and H-6 are isochronous).

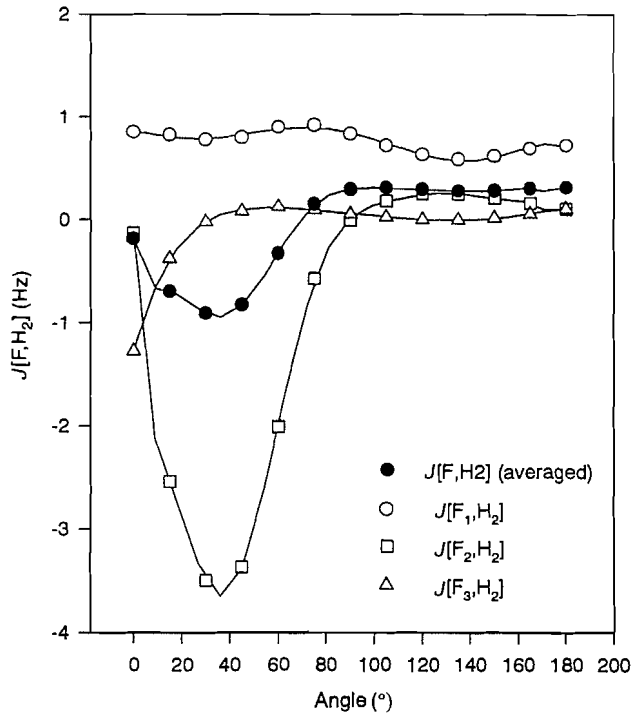

Figure 5 displays the INDO MO FPT values of ^5J(H, CF_3) as a function of the torsion angle between the Csp^3—Csp^3 bond and the aromatic plane (6-31G* geometries). As expected from various computational schemes (26), a close approach of the atoms containing the coupled nuclei leads to a negative, through-space coupling constant (the in-plane conformer has F-1 far from H-2, the CF_3 group being in a nearly staggered conformation about the *ortho* C—H bond). The prediction of a change in sign of ^5J(H, CF_3), from negative to positive, for an out-of-plane angle between 60° and 70° is qualitatively consistent with the 90 ± arc $(\langle\sin^2\theta\rangle)^{1/2}$ of 65.5° or 114.5° derived from the coupling constants in the previous section. A positive shift of about 0.5 Hz in the computed coupling constants would produce semiquantitative agreement with measurement. Another representation of the sensitivity of ^5J(H, CF_3) to nonbonded interatomic distances is developed in Figs. 6 and 7. Figure 6 displays the RHF 6-31G* distances between the ^{19}F nuclei and the *ortho* proton as a function of the torsion angle in Fig. 5 (as the angle increases the CF_3 group also rotates somewhat about the Csp^2—Csp^3 bond in order to relieve steric strain). Figure 7 demonstrates the high sensitivity of ^5J(H, CF_3) to the internuclear distance in regions where it is smaller than the sum of the van der Waals radii of hydrogen and fluorine. The change in sign from positive to negative

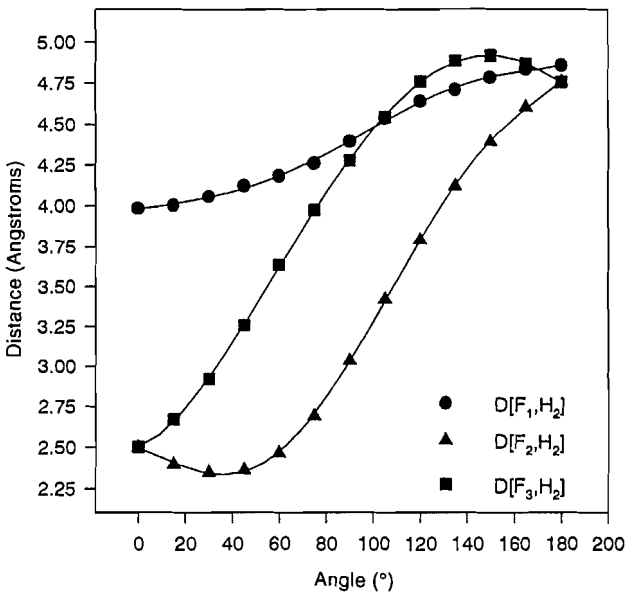
Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

Fig. 6. The distances between the ^{19}F nuclei and the *ortho* proton in **1** are plotted as a function of the angle by which the C—C(F_3) bond twists out of the ring plane. One ^{19}F nucleus remains far from the proton, another approaches it most closely at about 40° because rotation about the C—C(F_3) bond also occurs during the out-of-plane twist, no doubt in order to relieve steric repulsion (6-31G* geometries).



for a given ^{19}F nucleus occurs very near 3.0 Å; the average coupling constant is −0.33 Hz at a 60° torsion from the aromatic plane, +0.15 Hz at 75°.

Although the present computations and measurements of ^5J(H, CF_3) in **1** are not entirely compatible, theory yielding numbers somewhat too small, measurements on a derivative of **1** in which the CF_3 group lies much nearer the aromatic plane, on average, would test the prediction of a negative ^5J(H, CF_3).

In $C_6H_5OCF_3$, ^5J(H, CF_3) is +1.03(1) Hz (27). The magnitude of the barrier to rotation is uncertain, although it appears that the perpendicular conformer is most stable, as indicated by 6-31G computations (27) and by alternative internal rotational potentials derived from residual dipolar coupling constants measured for solutions in nematic solvents (28). In the 4-fluoro derivative, ^5J(H, CF_3) is +0.95Hz (27). Of course, if through-space interactions are important, it is then expected that their magnitudes depend crucially on the details of geometry, small differences in bond angles and lengths leading to significant changes in ^5J(H, CF_3).

The challenge to the theory of proximate coupling constants is emphasized by the following examples. In 2-trifluoromethylbenzaldehyde, in which the C—H bond of the formyl group spends most of its time wedged between two C—F bonds, ^5J(H, CF_3) is +2.2 Hz (29), yet INDO MO FPT calculations find a negative value. In 2-hydroxybenzotrifluoride, a negative ^5J(OH, CF_3) is in qualitative agreement with theory (30). In other words, the sign and magnitude of ^5J(H, CF_3) depend on the site of the CF_3 group as well as that of the proton.

$^3J(CH_2, F)$

In Table 1 it is shown that $^3J(CH_2, F)$ in **1** increases from 10.72 Hz in CS_2–C_6D_{12} to 11.27 Hz in acetone-d_6 solution. For CH_3CF_3, a reaction field model (31) of the solvent dependence of $^3J(CH_2, F)$ predicts an increase of 0.62 Hz, in close agreement with the 0.55 Hz measured for **1**. $^3J(CH_3, F)$ is reported as 12.8 Hz for CH_3CF_3, state not given (32). The value of 10.95 Hz for **1** in benzene-d_6 solution is consistent with an effective dielectric constant rather larger than anticipated in reaction field models (19). Some ^nJ(C, F) values for **1** also display an intrinsic solvent dependence (Table 2), discussed below.

$^nJ(^{13}C, ^{19}F)$ in 1

^1J increases algebraically in going from CS_2 to acetone-d_6 solution, as expected from an electrostatic model (31). In contrast, the positive ^2J(C, F) decreases as polarity of the solvent increases. This striking behaviour is opposite to that of ^2J(H, F) in CHF_3, where decreases[5] are dominated by van der Waals interactions with the solvent (33) molecules and attributed to perturbations of the orbital contributions to the coupling constant. Were ^2J(C, F) negative in **1**, the solvent perturbations could be attributed to an increase in a positive Fermi contact contribution, caused by bond polarizations (31). As it is, the experimental observations remain unexplained; all ^2J(C, F) are thought to be positive (34), and its INDO MO FPT value for **1** is 4 Hz.

^3J(C, F) is computed to be positive and rather insensitive to θ, while ^4J(C, F) can be written as $-0.06 + 0.51\sin^2(\phi/2) - 0.64\sin^2\phi + 0.28\sin^2 2\phi$, where φ is the angle by which the C—C(F_3) bond twists *out* of the phenyl plane. Experimentally, $\langle\sin^2\phi\rangle$ is 0.87, $\langle\sin^2(\phi/2)\rangle$ is 0.5 for an evenfold potential, and $\langle\sin^2 2\phi\rangle$ is estimated as 0.46 so that the theoretical value of ^4J(C, F) follows as −0.22 Hz. It is of interest that the signs of ^4J(C, F) and ^5J(H, F) are predicted to be opposite (in Fig. 5 one must take a rough mean for arc $\sin^2\phi \sim 65°$ or 115° to obtain an estimate of the theoretical ^5J(H, F), and find about 0.2 Hz). Because the experimental value of ^5J(H, F) is +0.74(2) Hz and that of ^4J(C, F) is ± 0.70(2) Hz, the sign of the latter should be determined (not an easy experiment for **1**).[6]

^5J(C, F) in **1** is ≤0.03 Hz in magnitude and, it may be noted, ^6J(H, CF_3) is undetectable (Table 1); both involve the *meta* site in **1**. The *para* position, however, yields a ^6J(C, F) of 0.30(2) Hz in magnitude and a ^7J(H, CF_3) of 0.07 Hz. If these two coupling constants are transmitted through the π-electron system, they should be proportional to Q^CCH and Q^HCH, respectively. The hyperfine parameters are a measure of spin polarization by spin density in the 2*pz* orbital of the *para* C—H bond, causing parallel and antiparallel spin orientations of the proton and ^{13}C nucleus, respectively. Q^CCH/Q^HCH is −1.6 (3) for neutral (diamagnetic) molecules, whereas $|^6J$(C, F)/^7J(H, CF_3)| is 4 in **1**. Therefore another coupling mechanism may be present for ^6J(C, F), its nature unknown.

[5] ^2J(H, F) is 79.14(2), 79.29(2), and 79.47(2) Hz in CS_2, C_6H_6, and $(CH_3)_2C{=}O$ solutions, respectively (33), and is 79.69(2) Hz for the vapor at about 72 atm (1 atm = 101.3 kPa), whereas ^2J(C, F) in **1** is 29.79(1), 29.46(1), and 29.23 Hz for these solvents.

[6] Such an experiment would provide comparisons with theory and experiment (35) for ^5J(H,F) and ^4J(C,F) measured on aromatic compounds in which a ring C—F bond lies near a ^{13}C—H bond of a methyl group on a side chain. In these compounds the ratio, $^4J/^5J$, can change sign as the C—F and C—H bonds move away from a common plane.

Fig. 7. ^5J(H, F) is plotted as a function of the distance between the ^{19}F nuclei and the *ortho* proton in **1**. These distances occur as the C—C(F_3) bond twists away from the plane of the phenyl group (6-31G* geometries). The one outlier (a solid circle) may well be a misleading datum.

The enols of acetic acid and methyl acetate

J. Peter Guthrie and Zhi Liu

Abstract: We have determined the heat of formation of 1,1-dimethoxyethene, $\Delta H_f(l) = -75.56 \pm 0.87$ kcal mol^{-1}, by measuring the heat of hydrolysis. The heat of vaporization, 8.47 ± 0.10 kcal mol^{-1}, was estimated from the boiling points at various pressures. The standard entropy of gaseous 1,1-dimethoxyethene, $82.02 \pm 2.$ cal deg^{-1} mol^{-1}, was calculated using frequencies obtained by MO calculations at the 6-31G** level. The free energy of transfer, 1.02 ± 1, was estimated by additivity with allowance for a distant polar interaction. Thus the free energy of formation in aqueous solution, $\Delta G_f(aq) = -37.07 \pm 1.48$ kcal mol^{-1}, could be calculated. The free energies of hydrolysis for enol ethers appear to be insensitive to structure; we used an average value and so calculated the values of the free energies of formation of the enols of acetic acid and methyl acetate, -67.90 ± 1.67 and -52.48 ± 1.53 kcal mol^{-1}, respectively. These values are in good agreement with other recent evaluations. This method should be applicable to related enols.

Key words: enols, thermodynamics, heat of formation, entropy, ketene acetal.

Résumé : On a déterminé la chaleur de formation du 1,1-diméthoxyéthène, $\Delta H_f(l) = -75,56 \pm 0,87$ kcal mol^{-1}, à partir de la mesure de sa chaleur d'hydrolyse. On a évalué sa chaleur de vaporisation, $8,47 \pm 0,10$ kcal mol^{-1}, à partir de ses points d'ébullition à diverses pressions. Utilisant les fréquences obtenues à partir de calculs d'OM au niveau 6-31G**, on a calculé que l'entropie standard du 1,1-diméthoxyéthène à l'état gazeux est de $82,02 \pm 2.$ cal deg^{-1} mol^{-1}. Utilisant une additivité qui tient compte d'une interaction polaire à distance, on a évalué l'énergie libre de transfert à $1,02 \pm 1$. On a donc pu calculer que l'énergie libre de formation en solution aqueuse est de $\Delta G_f(aq) = -37,07 \pm 1,48$ kcal mol^{-1}. Les énergies libres d'hydrolyse des énols semblent insensibles à la structure; on a utilisé une valeur moyenne et on a pu ainsi calculer les valeurs des énergies libres de formations des énols de l'acide acétique et de l'acétate de méthyle qui seraient respectivement de $-67,90 \pm 1,67$ et $-52,48 \pm 1,53$ kcal mol^{-1}. Ces valeurs sont en bon accord avec d'autres évaluations récentes. Cette méthode devrait être applicable à des énols apparentés.

Mots clés : énols, thermodynamique, chaleur de formation, entropie, acétal du cétène.

Introduction

Kresge, Wirz, and co-workers (1–6) have determined the enol contents of simple aldehydes and ketones and, more recently, of mandelic acid (7). As yet the only routes to the enol content of acetic acid are an indirect thermodynamic argument that we have presented (8), and an indirect kinetic analysis of deuterium exchange kinetics (8). The carbon pK_a values of acetic acid (8) and ethyl acetate (9) have been calculated from kinetics of exchange.

We have now determined the heat of formation of 1,1-dimethoxyethene, and have calculated a value of the free energy of formation in aqueous solution based on this heat of formation. We have examined a possible way to estimate the free energy change for the hypothetical hydrolysis reactions leading to the enol of methyl acetate and the enol of acetic acid. These calculations lead to values in good agreement with those reported earlier, suggesting that the new estimation procedure is valid.

Results

1,1-Dimethoxyethene was prepared by the literature procedure (10) and purified by distillation in vacuum. Despite careful pre-treatment of the glassware with base, to avoid any acid-catalyzed polymerization, we found that the distilled sample invariably contained a few percent of impurity. The impurity increased in amount over time, and precipitated as a white, noncrystalline solid. This material was separated, and its ^{1}H nmr spectrum in $CDCl_3$ was recorded; this spectrum showed the peaks expected for poly (-C(OCH$_3$)$_2$-CH$_2$-). Since a simple ketal will not react in aqueous sodium hydroxide solution, the effect of this impurity on the heat of reaction was assumed to be simply that of dilution of the sample.

The observed heat of reaction for process [1], see Table 1, was -33.30 ± 0.85 kcal mol^{-1} for a sample shown by nmr analysis to be 94% pure. The true heat of reaction was therefore calculated to be -35.43 ± 0.85 kcal mol^{-1}.

[1] $CH_2{=}C(OCH_3)_2(l) + 2\ H_2O\ (soln) \rightleftharpoons CH_3COOH\ (soln) + 2\ CH_3OH\ (soln)$

Correcting to the standard state for all species, using data from Table 1, leads to a heat of reaction for process [2], as -17.79 ± 0.86 kcal mol^{-1}.

$$\rightleftharpoons CH_3COOH(l) + 2\ CH_3OH\ (l)$$

Now it is possible to calculate the heat of formation of liquid 1,1-dimethoxyethene, using heats of formation from the literature: Table 2. The value so calculated is −75.56 ± 0.87 kcal mol^{-1}. To determine the heat of vaporization, we measured the boiling point at reduced pressures, using a small-scale apparatus (11). The boiling point data, Table 3, can be fitted to the equation: $\log p = 8.587 - 2068/T$. At each pressure, the heat of vaporization was calculated from the boiling point, using the empirical relationship that we have reported (12). The average heat of vaporization so determined was 8.47 ± 0.28 kcal mol^{-1}; the error is taken as the weighted average error in the original correlation (12). This allows calculation of the heat of

Table 3. Vapor pressures and heat of vaporization for $CH_2{=}C(OCH_3)_2$.[a]

p (Torr)	t (°C)	ΔH_{vap} (kcal mol^{-1})
760	89	8.30
133	47	8.47

69	30	8.56
	Avg.	8.47 ± 0.10

[a]Calculated as described in the text.

formation of 1,1-dimethoxyethene in the gas phase as −67.09 ± 0.90 kcal mol^{-1}.

The entropy was estimated in several independent ways. First we applied Benson's group additivity method (13). Since no value for the group contribution for an sp^2 carbon bonded to two oxygens, $[C_d(O)_2]$ has been reported, we used $[C_d(C)_2]$ as an approximation; such approximations are generally reasonably close (13, 14). This estimation procedure led to a value of $S°(g) = 87.43$ cal deg^{-1} mol^{-1}. Next we used MM3 to estimate the entropy by way of vibrational frequencies and statistical mechanics; this required using estimated values of two parameters for which no values were available. Although the force constant for O-C_d-O bending is likely to be close to 0.6 md Å rad^{-2}, and the preferred angle to 120° (the values we chose), the torsional parameters are harder to guess. The value of the entropy turned out to be moderately sensitive to the exact values used, varying from 82.9 to 86.3 cal deg^{-1} mol^{-1} depending on the values used for the unknown torsional parameters for the C(sp^2)—O bond of a ketene acetal. Finally we employed molecular orbital methods to estimate the vibrational frequencies that were then used to calculate the entropy by statistical mechanics. AM1 led to a value of 86.05 cal deg^{-1} mol^{-1}; GAUSSIAN 92[3] at the 6-31G* level led to a value of 81.94 cal deg^{-1} mol^{-1}, and at the 6-31G** level to a value of 82.02. These calculations used the default scale factor of 1/1.12 to correct the calculated frequencies. We used the entropy from GAUSSIAN 92 at the 6-31G** level for further calculations, and assign an uncertainty of ± 2 cal deg^{-1} mol^{-1}.

From the enthalpy and entropy we can calculate the free energy of formation in the gas phase as −38.09 ± 1.09 kcal mol^{-1}. Finally, we need to estimate the free energy of transfer from the gas phase to aqueous solution, in order to calculate the free energy of formation in water. The free energy of transfer cannot be measured directly because of the rapid hydrolysis of the ketene acetal, even in aqueous hydroxide solution (15). We estimate the free energy of transfer by making use of the sequence: isobutene: 2-methoxypropene: 1,1-dimethoxyethene, assuming that the effects of replacing CH_3 by OCH_3 are constant except that there will be a distant polar interaction (16, 17) for the two methoxy groups in 1,1-dimethoxyethene.

[3] GAUSSIAN 92, Revision D.2. M.J. Frisch, G.W. Trucks, M. Head-Gordon, P.M.W. Gill, M.W. Wong, J.B. Foresman, B.G. Johnson, H.B. Schlegel, M.A. Robb, E.S. Replogle, R. Gomperts, J.L. Andres, K. Raghavachari, J.S. Binkley, C. Gonzalez, R.L. Martin, D.J. Fox, D.J. Defrees, J. Baker, J.J.P. Stewart, and J.A. Pople, Gaussian, Inc., Pittsburgh, Pa. 1992.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

For lack of information allowing a better correction we will assume that this is the same as the interaction in $CH_2(OCH_3)_2$ (17), namely 1.56 kcal mol^{-1}. Thus we end up with an estimated free energy of transfer of 1.02 kcal mol^{-1} for 1,1-dimethoxyethene, to which we assign an uncertainty of ±1 kcal mol^{-1}. This allows us to calculate the free energy of formation in aqueous solution as −37.07 ± 1.48 kcal mol^{-1}.

As a check we calculated the free energy of transfer using AMSOL 1.0[4] (18); this led to a value of 0.12 kcal mol^{-1} for the standard states that we use. AMSOL seems to give values within 1.5 kcal mol^{-1} of the true value for various compounds that have been tested (18). We will use the value estimated above, but consider AMSOL a confirmation of the approximate correctness of the estimate.

Now we would like to calculate the free energies of formation of the enols of methyl acetate and acetic acid. The problem here is to estimate the effect of substituents on the free energy of hydrolysis of an enol ether. For sp^3 hybridized carbon, the free energy change for process [3] is moderately sensitive to electron withdrawal from the central carbon by R^1, R^2 and R^3 (19).

[3] 
The slope of a plot of ΔG vs. $\Sigma\sigma^*$ for R^1, R^2 and R^3 is 0.63. On the other hand, for esters where OR is attached to an sp^2 hybridized carbon the free energy change is almost totally insensitive to electron withdrawal. For R = CF_3, CH_3, pCH_3O-C_6H_4, C_6H_5, pNO_2-C_6H_4, ΔG = +1.65 (20), +1.70 (21), +1.17 (22), +1.26 (22), +1.21 (22) (all for reaction in water, where the standard state of water is the pure liquid at unit activity). There does appear to be an effect on changing from an aliphatic to an aromatic acyl substituent, but within each series the effect of drastic change in substituents is very small.

[4]

[5] 
We therefore propose, as a speculation to be tested, that for enol ethers as well, the free energy change for the hypothetical hydrolysis [5] will be very insensitive to the nature of R^1, R^2, and R^3. First we will calculate a weighted average value from the data available in the literature. From the data in Table 2 we can calculate free energy changes for these hydrolysis reactions, as shown in Table 4. The weighted average value is −0.86 ± 0.39. Now using this weighted average value for the free energy changes in reactions [6] and [7] we can calculate

[6] $CH_2{=}C(OCH_3)_2$ (aq) + H_2O (l)

$\rightleftharpoons CH_2{=}C(OCH_3)(OH)$ (aq) + CH_3OH (aq)

[4] QCPE606, Quantum Chemical Program Exchange, Indiana University.

Table 4. Free energy of hydrolysis of enol ethers.[a]

Enol ether	ΔG_{hydrol}
$CH_2{=}CH(OCH_2CH_3)$	−1.6 ± 0.57
$CH_2{=}C(CH_3)(OCH_3)$	0.08 ± 1.27
Cyclohexenyl-OCH_3	−0.48 ± 1.38
$CH_2{=}C(Ph)(OCH_3)$	−0.26 ± 0.65
Average	−0.56 ± 0.63
Weighted average	−0.86 ± 0.39

[a]In aqueous solution at 25°C, calculated using the free energies of formation in Table 3. Gibbs free energies are in kcal mol^{-1}.

[7] $CH_2{=}C(OCH_3)(OH)$ (aq) + H_2O (l)

$\rightleftharpoons CH_2{=}C(OH)_2$ (aq) + CH_3OH (aq)

the free energies of formation for the enols of methyl acetate, −52.48 ± 1.53 kcal mol^{-1}, and of acetic acid, −67.90 ± 1.67

[8] CH_3-CO-OCH_3 (aq) $\rightleftharpoons CH_2{=}C(OCH_3)(OH)$ (aq)

[9] CH_3-CO-OH_3 (aq) $\rightleftharpoons CH_2{=}C(OH_3)$ (aq)

kcal mol^{-1}. With these energies in hand we can calculate free energy changes for the enolization processes; ΔG_8 = 26.44 ± 1.64 kcal mol^{-1}, pK_E = 19.4 ± 1.2, ΔG_9 = 26.45 ± 1.71 kcal mol^{-1}, pK_E = 19.4 ± 1.3.

Discussion

These results for acetic acid, pK_E = 19.4 ± 1.3, may be compared with expectations based on disproportionation calculations, where the enol content of acetic acid was predicted to be pK_E = 21 ± 2 (8), or the prediction based on deuterium exchange into acetic acid, pK_E = 19.3 ± 2.2 (8).

For methyl acetate, we predict a pK_E of 19.4 ± 1.2, in agreement with a value based on kinetics of exchange in aqueous solution (9).

The thermochemical approach reported in this paper should have some generality, and could make more pK_E values accessible to indirect determination. The major limitation that we see is the assumption that the free energy change for the hypothetical hydrolysis process leading from an enol ether to an enol will be the same as for simple models. This seems reasonable in the absence of large substituent effects, but cannot be assumed to apply if there are large resonance or field effects from substituents.

Given the markedly different pK_a values of the enols of mandelic acid (7) and simple aldehydes and ketones (23), it is surprising that the assumption of similar free energies of hydrolysis for the enol ethers holds as well as it does. Since the various procedures leading to enol contents for acetic acid or methyl acetate, including the present work, lead to consistent results, it suggests that the assumption is valid. We still feel that extrapolation to compounds with strong electron-withdrawing substituents would require new model compounds.

Experimental

Materials

Bromoacetaldehyde dimethyl acetal, potassium metal, and

terpineol were purchased from Aldrich, and used without further purification. 1,1-Dimethoxyethene was prepared by reaction of bromoacetaldehyde dimethyl acetal with the potassium salt of terpineol, following the literature procedure (10). The nmr spectrum ($CDCl_3$) showed two sharp peaks at d 3.08 and 3.64 in a ratio of 1:3. There were additional peaks at 1.41 and 3.26 that were attributed to polymer. On standing, a sample of 1,1-dimethoxyethene deposited a white solid, the nmr spectrum of which consisted mainly of these two peaks. The sample of 1,1-dimethoxyethene used for calorimetry was 94% monomer and 6% polymer.

Methods

The nmr spectra were recorded on a Varian Gemini 300 instrument. Vapor pressures were determined using a small-scale boiling point apparatus (11). Heats of reaction and solution were determined using a homemade calorimeter, as previously described (24). The reaction solvent was 0.1 N NaOH.

Acknowledgments

We thank the Natural Sciences and Engineering Research Council of Canada for financial support of this work. We thank Dr. T.L. Amyes for communicating results of her studies of exchange in methyl acetate prior to publication.

Synthesis of (*S*)-4-hydroxy-α-lapachone and biotransformation of some 4-chromanones by *Mortierella isabellina* ATCC 42613

Herbert L. Holland, Jia Qi, and T. Samuel Manoharan

Abstract: 1-Methoxy-2-naphthol was converted by MOM ether formation, lithiation at C-3, reaction with 3,3-dimethylacryloyl chloride, cyclization, and oxidation using cerium ammonium nitrate to 4-keto-α-lapachone (2,2-dimethyl-4-keto-1-oxa-1,2,3,4-tetrahydroanthra-5,10-quinone). Reduction by biotransformation using *Mortierella isabellina* ATCC 42613 gave (*S*)-4-hydroxy-α-lapachone in high (>95%) optical purity. Reduction of several 2,2-dimethyl-4-chromanones to the corresponding (*S*)-alcohols by *M. isabellina* is also reported.

Key words: biotransformation, chemoenzymatic, 4-hydroxy-α-lapachone, *Mortierella isabellina*.

Résumé : Faisant appel à la série de réactions suivantes, formation d'éther MOM, lithiation en C-3, réaction avec du chlorure de 3,3-diméthylacryloyle, cyclisation et oxydation à l'aide du nitrate d'ammonium cérique, on a transformé le 1-méthoxynapht-2-ol en 4-céto-α-lapachone (2,2-diméthyl-4-céto-1-oxa-1,2,3,4-tétrahydroanthra-5,10-quinone). Sa réduction par biotransformation utilisant de la *Mortierella isabellina* ATCC 42613 conduit à la (*S*)-4-hydroxy-α-lapachone avec une pureté optique élevée (>95%). On rapporte aussi la réduction de plusieurs 2,2-diméthyl-4-chromanones en alcools-(*S*) correspondants par la *M. isabellina*.

Mots clés : biotransformation, chemoenzymatique, 4-hydroxy-α-lapachone, *Mortierella isabellina*.

Introduction

The biotransformation of 4-chromanone (**1**) by *Mortierella isabellina* ATCC 42613 can be used to prepare (*S*)-4-chromanol (**2**) in high yield and enantiomeric purity (Scheme 1) (1). (*S*)-4-Hydroxy-α-lapachone (**3**), which possesses the (*S*)-4-chromanol functional unit, has been isolated from the Japanese Kisasage tree *Catalpa ocata* (2, 3) and from the heartwood of the Brazilian *Zeyhera tuberculosa* (4), and has been shown to possess antineoplastic properties (4). The racemate of **3** was prepared by Gupta and Khanna in a non-regioselective synthesis (5, 6), and by Tapia's group in a route involving construction of the aromatic ring via Diels–Alder addition to a suitably substituted quinone (7), but preparation of the natural chiral material has not hitherto been reported. To develop a route to (*S*)-**3** based on chiral reduction of an appropriately substituted keto precursor we have examined the biotransformation by *M. isabellina* of a number of substituted 4-chromanones (**4**, **8**, and **13**). The syntheses of these compounds and their biotransformations by *M. isabellina* are presented, together the preparation of (*S*)-4-hydroxy-α-lapachone (**3**) by *M. isabellina*-catalyzed reduction of 2,2-dimethyl-4-keto-1-oxa-1,2,3,4-tetrahydroanthra-5,10-quinone.

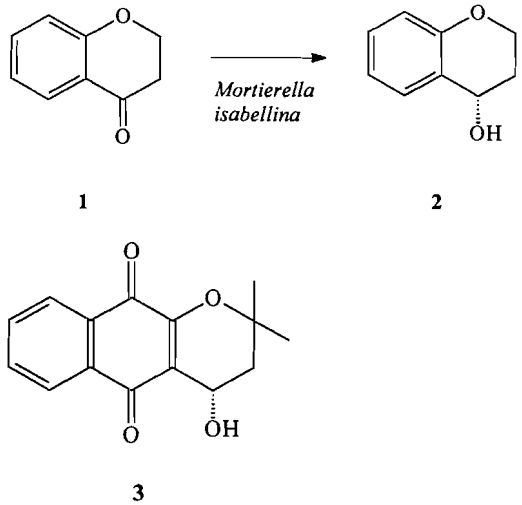
Scheme 1. Preparation of (*S*)-4-chromanol.



Results and discussion

To investigate the effect of methyl substitution at C-2 on the stereochemistry of biotransformation of a chromanone, the 2,2-dimethyl-substituted substrate **4** was prepared by a modification of ApSimon's method (8) and subjected to biotransformation using *M. isabellina* (Scheme 2). The desired (*S*)-alcohol **5** was produced in good yield, but its enantiomeric excess (40%) was low. The absolute stereochemistry of this and other reduction products described below was assigned in two ways: firstly, in accord with the observation that *M. isa-*

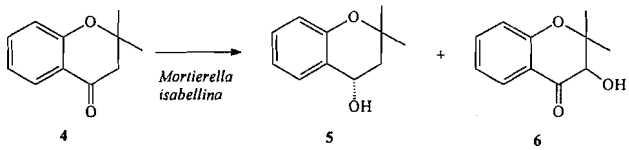
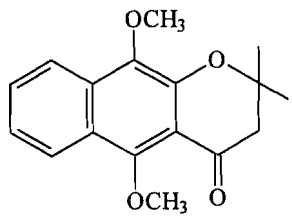
Scheme 2. Biotransformation of 2,2-dimethyl-4-chromanone.



bellina reduces benzylic ketones according to Prelog's rule to give (*S*) benzylic carbinols (1, 9), and secondly by the observation that addition of the chiral ^{1}H nmr shift reagent tris[3-(heptafluoropropylhydroxymethylene)-*d*-camphorato] europium(III) to a non-racemic benzylic alcohol results in a ^{1}H nmr spectrum in which the carbinol hydrogen of the -C*H*(OH)- unit can be resolved into two baseline-separated signals in the 10–20 ppm region. In all cases examined using alcohols of known configuration, the signal attributable to the (*S*) enantiomer is upfield and that of the (*R*) enantiomer downfield (1, 10, 11). In addition to the production of **5**, biotransformation of **4** by *M. isabellina* also resulted in formation of a minor product, hydroxyketone **6**, whose stereochemistry was not examined.

A route to 4-hydroxy-α-lapachone via a precursor such as **7** was first considered. Prior to undertaking synthesis of the latter, we examined reduction of 2,2-dimethyl-5,8-dimethoxychroman-4-one (**8**). Chroman-4-ones with this substitution



7

pattern have not been reported, and we developed the synthesis of **8** from 2,5-dimethoxyphenol as outlined in Scheme 3. Biotransformation of **8** by *M. Isabellina* (Scheme 3) gave the alcohol (*S*)-**9** in high yield (99%) and in an enantiomeric purity exceeding 95%. A ^{1}H nmr analysis in the presence of tris[3-(heptafluoropropylhydroxymethylene)-*d*-camphorato] europium(III) failed to reveal any (*R*) enantiomer; addition of controlled amounts of synthetic (±)-**9** to the biotransformation product followed by nmr analysis confirmed the (*S*) configuration of the latter by the gradual appearance of a C*H*OH signal downfield from that of the original sample.

Biotransformation of the chroman **10** (Scheme 4) also gave **9**, but in racemic form. Additional products were obtained and assigned structures **11** and **12** on the basis of homonuclear nOe experiments. It was clear from mass spectral and ^{1}H nmr analysis that **11** was a mono-O-demethyl derivative of the substrate, and the site of demethylation was shown to be O(5) by the absence of nOe enhancement of the benzylic methylene protons upon irradiation of the remaining O-methyl signal at δ 3.77 ppm. Similarly, **12** was clearly a phenolic derivative of substrate; nOe experiments involving irradiation of the C-5 methoxy signal at δ 3.74 ppm showed an enhancement of only the benzylic methylene protons at δ 2.74, while irradiation of the C-8 methoxy resonance resulted only in enhancement of

Scheme 3. Synthesis and biotransformation of 5,8-dimethoxy-2,2-dimethyl-4-chromanone (**8**).

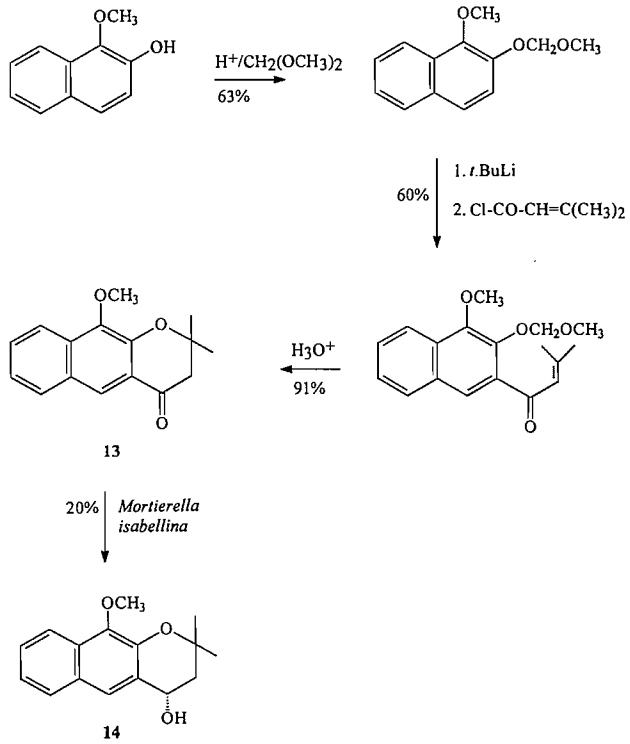
the C-7 aromatic hydrogen signal. During investigation of the synthesis and biotransformation of 6,7-benzo-5,8-dimethoxy-2,2-dimethyl-4-chromanone **7** as a route to **3**, we were unsuccessful in attempts to prepare **7** by a route analogous to that of Scheme 3. Although lithiation of a protected phenol intermediate analogous to that shown in Scheme 3 was achieved (evidenced by incorporation of deuterium label when quenched with D_2O), reaction of this species with dimethylacryolyl chloride did not afford the desired ketone, resulting only in formation of intractable product mixtures. We therefore turned our attention to the monomethoxy analogue **13**, whose synthesis from 1-methoxy-2-naphthol is shown in Scheme 5. In contrast to the THP protection of Scheme 3, we found here that protection of the phenolic group as a MOM ether facilitated purification of intermediates. It was also necessary, again in contrast to the route of Scheme 3, to use *tert*-butyllithium for lithiation of the intermediate protected phenol.

Biotransformation of **13** by *M. isabellina* gave the (*S*) alcohol **14** (Scheme 5), but the enantiomeric purity was low (32%) and phenolic side-products were obtained. However, given that the presence of a substituent *ortho* to the carbonyl group undergoing biocatalytic reduction apparently results in enhancement of the optical purity of the resulting (*S*) alcohol (cf. results from **4** vs. **8**), we examined the quinone **15** (4-ketolapachone), obtained by ceric ion oxidation of **13** (Scheme 6). Biotransformation of **15** by *M. isabellina* resulted in the formation of (+)-4-hydroxy-α-lapachone (**3**) in acceptable yield and high (>95%) enantiomeric purity. The absolute configuration of the (+) (natural) enantiomer of **3** has been assigned as (*S*) by application of the extended dibenzoate chirality rule to the CD spectrum of its benzoate ester (2). The configuration of our product is thus established. Furthermore, under conditions described above where racemic alcohols give cleanly resolved signals in chiral nmr analysis, we were unable to detect any (*R*)-**3** in our product. The reactions of Schemes 5 and 6 therefore represent the first asymmetric synthesis of the natural enantiomer of (*S*)-(+)-4-hydroxy-α-lapachone.

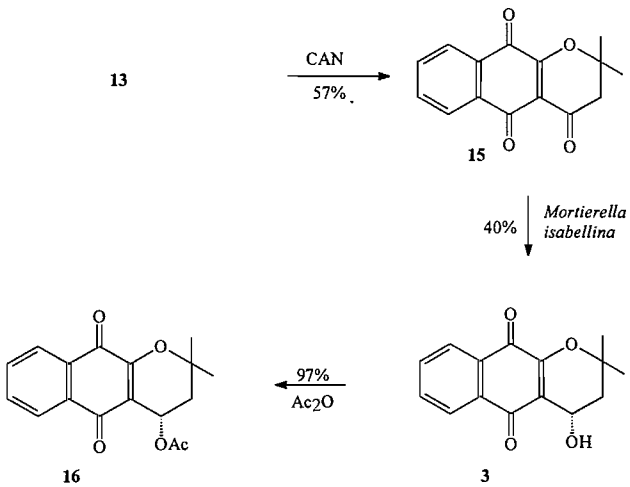
Although spectral data of our synthetic sample matched those reported in the literature for both natural (2–4) and synthetic (5–7) 4-hydroxy-α-lapachone, we observed discrepancies in physical data. This material has been variously reported as a yellow oil (natural (2, 4) and synthetic racemate (7)) and a yellow solid with mp 117–119°C (synthetic racemate (6)), whereas our material melted at 67°C. Furthermore, natural 4-hydroxy-α-lapachone has a reported rotation, $[\alpha]_D$ +27.4, whereas our sample showed $[\alpha]_D$ +39.7 under the same conditions. From this it may be inferred that the natural material is not optically pure, possessing an enantiomeric purity of 69%. To confirm this our sample of **3** was converted to the acetate **16** in order to compare the data obtained therefrom with those reported for synthetic racemic **16** and for **16** obtained by acetylation of natural 4-hydroxy-α-lapachone. Again, although our spectral data for **16** matched those reported (2), the mp and rotation data were disparate, the latter confirming the conclusion that natural 4-hydroxy-α-lapachone is not optically pure as isolated. Our sample of **16** has $[\alpha]_D$ −22.7 whereas the acetate of natural 4-hydroxy-α-lapachone has $[\alpha]_D$ −14.2, corresponding to ee = 63% (2).

We therefore suggest that our synthesis of (*S*)-(+)-4-hydroxy-α-lapachone gives enantiomerically pure material, whereas the natural product is not enantiomerically homogeneous. Whether this results from an aspect of its biosynthesis or the occurrence of partial racemization during the extraction procedure is unknown.

Scheme 5. Synthesis and biotransformation of 6,7-benzo-2,2-dimethyl-8-methoxy-4-chromanone (**13**).



Scheme 6. Preparation of (*S*)-4-hydroxy-α-lapachone (**3**) and the acetate (**16**).



Experimental

Apparatus, materials, and methods

Melting points were determined on a Kofler heating stage. Infrared spectra were recorded with an Analect 6260FX spec-

For personal use only.

trometer. The nmr spectra were recorded at 200 MHz (routine ^1H) or 50 MHz (routine ^{13}C) with a Bruker AC200 spectrometer using $CDCl_3$ as solvent and $CHCl_3$ as internal standard. ^{13}C signals are assigned as primary (p), secondary (s), tertiary (t), or quaternary (q) from analysis of JMOD spectra. Enantiomeric ratios were examined by ^1H nmr analysis in the presence of sufficient tris[3-(heptafluoropropylhydroxymethylene)-*d*-camphorato] europium(III) to cause shifting of the C*H*OH signals under investigation to δ 10–20 ppm. Homonuclear nOe difference spectra were obtained at McMaster University using a Bruker AM500 spectrometer. Optical rotations were obtained in the stated solvent at ambient temperature with a Rudolph Autopol III polarimeter. Mass spectra were obtained with a Kratos 1S instrument operating in EI mode. Thin-layer chromatography (tlc) was performed on Merck silica gel 60F-254 and flash column chromatography used silica gel, 230–400 mesh. Microanalyses were performed by Guelph Chemical Laboratories, Guelph, Ontario.

Maintenance of microorganisms

Mortierella isabellina ATCC 42613 was obtained from the American Type Culture Collection, Rockville, Md., and was maintained on 4% malt agar slopes, grown at 27°C, and stored at 4°C.

Preparation of bicyclic substrates

*2,2-Dimethyl-4-chromanone (**4**)*

Based on a procedure of ApSimon et al. (8), a mixture of *o*-hydroxyacetophenone (13.5 g), pyrrolidine (12.2 g), dry acetone (6 g), and toluene (100 mL) was stirred under argon for 4 days. The mixture was then acidified with 5% HCl, and the organic layer was separated and washed with saturated aqueous NaCl (3 × 50 mL), dried, and evaporated. The residue was dissolved in dichloromethane and passed through a short column of Florisil using dichloromethane as eluent. The effluent was washed with 5% KOH (4 × 50 mL), dried, and evaporated. Crystallization of the residue from ethanol gave the title compound in 65% yield; mp 90°C; ^1H nmr δ: 1.46 (6H, s), 2.72 (2H, s), 6.90–7.01 (2H, m), 7.46 (1H, d of t), and 7.85 (1H, d of d) ppm; ^{13}C nmr δ: 26.6 (2C, p), 48.8 (s), 77.6 (q), 118.3 (t), 120.3 (q), 120.6 (t), 126.5 (t), 136.1 (t), 160.0 (q), and 192.4 (q) ppm.

*5,8-Dimethoxy-2,2-dimethyl-4-chromanone (**8**)*

A mixture of 2,5-dimethoxyphenol (7 g), dihydropyran (16.5 mL), and concentrated HCl (2 drops) was stirred overnight under an argon atmosphere. Dichloromethane (100 mL) was then added, and the resulting solution washed with 10% NaOH (2 × 20 mL). The organic layer was dried and evaporated, and the residue purified by Kugelrohr distillation (120–130°C/0.7 Torr; 1 Torr = 133.3 Pa) to yield 8.7 g (82%) of 2,5-dimethoxyphenol tetrahydropyranyl ether as a colourless oil; ^1H nmr δ: 1.55–1.75 (4H, m), 1.85–2.0 (6H, m), 3.55–4.05 (8H, m and two s), 5.59 (1H, t), 6.45–6.51 (1H, m), and 6.78–6.85 (2H, m) ppm; ms *m/z*(%): 238(1.4), 180(1), 166(1), 154(100), 139(63), 125(9), 111(22), 85(24). This material was dissolved in dry THF (400 mL), and the solution was placed under an argon atmosphere and cooled to 0°C. A solution of *n*-BuLi (14 mL, 2.8 M in hexane) was then added slowly and with stirring at such a rate as to maintain the reaction temperature below 5°C. On completion of addition, the cooling bath was removed and the mixture stirred at room temperature for 2 h. The system was then cooled to −65°C and 3,3-dimethylacryloyl chloride (4.2 mL) was added slowly. The system was left to warm to ambient temperature overnight, then water (100 mL) was added. The resulting mixture was stirred for 15 min and then extracted with chloroform. The organic phase was dried and evaporated to yield a viscous oil (14 g) that was directly dissolved in chloroform (30 mL). To this solution was added dilute HCl (60 mL, 6 M), and the resulting mixture was stirred at room temperature for 2 h. The solution was then extracted with chloroform (3 × 200 mL) and the extract dried and evaporated. The residue was subjected to Kugelrohr distillation at 125–135°C/0.5 Torr to give 5,8-dimethoxy-2,2-dimethyl-4-chromanone (1.27 g). Further product was obtained by chromatography of the residue from the Kugelrohr distillation using 50–60% ethyl acetate – hexane as eluent; mp 143–145°C (from ethyl acetate); ir (KBr) ν_{max}: 1694 cm^{-1}; ^1H nmr δ: 1.50 (6H, s), 2.72 (2H, s), 3.84 and 3.87 (each 3H, s), 6.39 and 7.0 (2H, ABq) ppm; ^{13}C nmr δ: 26.3 (2C, p), 50.2 (s), 56.1 (p), 56.9 (p), 79.2 (q), 101.6 (t), 111.3 (q), 118.4 (t), 143.0 (q), 151.3 (q), 153.8 (q), 191.3 (q) ppm; ms *m/z*(%): 236(64), 221(31), 206(6), 181(58), 180(100), 165(21), 151(31), 137(54), 123(45). Anal. calcd. for $C_{13}H_{16}O_4$: C 66.09, H 6.83%; found: C 65.79, H 6.65%.

*5,8-Dimethoxy-2,2-Dimethylchroman (**10**)*

Lithium aluminum hydride (1.0 g) was added to a stirred solution of 5,8-dimethoxy-2,2-dimethyl-4-chromanone (2.7 g) in dry THF (200 mL), and resulting mixture stirred and heated under reflux for 1 h. The mixture was then cooled, ethyl acetate (5 mL) added, and the reaction mixture stirred for a further 30 min at room temperature. A saturated aqueous solution of sodium sulfate (200 mL) was then added, and the mixture extracted with chloroform (3 × 150 mL). The extract was dried and evaporated and the residue chromatographed on silica gel. Elution with 30–40% ethyl acetate – hexane gave (±)-5,8-dimethoxy-2,2-dimethyl-4-chromanol (**9**, 2.3 g, 85%), obtained as a colourless solid following crystallization from ethyl acetate – hexane; mp 99–101°C; ir (KBr) ν_{max}: 3520 cm^{-1}; ^1H nmr δ: 1.41 and 1.48 (each 3H, s), 1.95–2.15 (2H, m), 3.50 (1H, s, exchanges with D_2O), 3.81 and 3.85 (each 3H, s), 5.0 (1H, t), 6.35 and 6.74 (2H, ABq) ppm; ^{13}C nmr δ: 26.8 (p), 27.2 (p), 40.2 (s), 55.5 (p), 56.7 (p), 60.8 (t), 75.1 (q), 100.1 (t), 111.2 (t), 114.0 (q), 132.1 (q), 143.7 (q), 152.3 (q) ppm; ms m/z(%): 238(66), 205(36), 183(33), 182(100), 167(18), 153(5), 139(19), 107(11). Anal. calcd. for $C_{13}H_{18}O_4$: C 65.53, H 7.61%; found: C 65.56, H 7.80%.

Concentrated HCl (12 mL) was added to a solution of the alcohol **9** (0.44 g) in chloroform (6 mL) and the resulting mixture stirred overnight at room temperature. Water (10 mL) was then added and the mixture was extracted with chloroform (3 × 25 mL). The extract was dried and evaporated, and the residue subjected to chromatography. Elution with 30–40% ethyl acetate – hexane gave 2,2-dimethyl-5,8-dimethoxychromene (0.34 g, 84%); mp 62–64°C; ^1H nmr δ: 1.45 (6H, s), 3.76 and 3.79 (each 3H, s), 5.56 and 6.63 (2H, ABq), and 6.29 and 6.68 (2H, ABq) ppm; ms *m/z*(%): 220(25), 205(100), 190(12), 175(24), 157(6), 91(5), 77(5).

To a solution of the above olefin (0.34 g) in ethyl acetate (6 mL) was added 10% palladium/carbon catalyst (50 mg). Overnight hydrogenation using a Parr apparatus at 19 psig (1

For personal use only.

psi = 6.9 kPa) followed by filtration and evaporation of the filtrate gave 5,8-dimethoxy-2,2-dimethylchroman (**10**, 0.31 g, 91%); mp 56–58°C; ^{1}H nmr δ: 1.38 (6H, s), 1.78 (2H, t), 2.66 (2H, t), 3.78 and 3.81 (each 3H, s), 6.29 and 6.66 (2H, ABq) ppm; ^{13}C nmr δ: 17.4 (s), 26.6 (2C, p), 32.2 (s), 55.5 (p), 56.6 (p), 74.1 (q), 99.5 (t), 109.2 (t), 111.4 (q), 120.5 (q), 143.3 (q), 151.8 (q); ms *m/z*(%): 222(100), 167(84), 166(69), 151(6), 137(21), 123(15). Anal. calcd. for $C_{13}H_{18}O_3$: C 70.24, H 8.16%; found: C 70.62%, H 7.82%.

Biotransformations of bicyclic substrates

General procedures

Two slopes of *Mortierella isabellina* ATCC 42613 were used to inoculate 15 1 L Erlenmeyer flasks each containing 200 mL of an autoclaved medium composed of glucose (40 g), soybean flour (5 g), yeast extract (5 g), sodium chloride (5 g), and dibasic potassium phosphate (5 g) per L of distilled water. The flasks were allowed to stand overnight at 27°C, then were placed on a rotary shaker at 180 rpm, and growth continued for a further 72 h at 27°C. The fungus was then harvested by centrifugation (IEC chemical centrifuge) and resuspended in 15 1 L Erlenmeyer flasks each containing 200 mL of distilled water. Substrate (1 g in 30 mL of 95% ethanol) was then distributed among the flasks, which were replaced on the rotary shaker at 180 rpm, at 27°C, for a further 72 h. The fungus and aqueous medium were then separated by filtration as before, the aqueous medium extracted with dichloromethane (continuous extraction, 72 h), and the fungus discarded. Concentration of the medium extract gave the crude product, which was examined by tlc, using ether or 10% methanol – ether as solvent, and then subjected to flash chromatography. The yields and ee values quoted below refer to purified, homogeneous material, and arise from the combination of (only) homogeneous column fractions without further purification (e.g., crystallization) that could lead to changes in stereochemical enrichment values.

*2,2-Dimethyl-4-chromanone (**4**)*

Biotransformation of **4** (1 g) by the above procedure gave the following products in order of elution. (*S*)-2,2-Dimethylchroman-4-ol (**5**, 0.78 g); ir (KBr) ν_{max}: 3353 cm^{-1}; ^{1}H nmr δ: 1.26 and 1.39 (each 3H, s), 1.71–2.11 (2H, m), 2.90 (1H, br. s, exchanges D_2O), 4.75 (1H, d of t), and 6.73–7.42 (4H, m) ppm; ^{13}C nmr δ: 25.8 (p), 26.4 (p), 42.5 (s), 63.5 (t), 75.1 (q), 117.1 (t), 120.2 (t), 124.3 (q), 127.6 (t), 128.1 (t), and 153.2 (q) ppm; ms *m/z*(%): 178(60), 145(70), 123(57), 122(100), 121(71); $[\alpha]_D$ +8.4 (*c* 2.0, chloroform); ee 40% based on integration of C*H*OH and C-5H nmr signals in the presence of Eu(tfc)$_3$. 2,2-Dimethylchroman-3-ol-4-one (**6**, 42 mg); ir (KBr) ν_{max}: 1694, 3467 cm^{-1}; ^{1}H nmr δ: 1.22 (3H, s), 1.65 (3H, s), 3.78 (1H, br s, exchanges D_2O), 4.43 (1H, s), and 6.92–7.84 (4H, m) ppm; ^{13}C nmr: 17.2 (p), 26.9 (p), 77.0 (s), 83.5 (q), 118.4 (t), 188.9 (q), 121.1 (t), 126.7 (t), 136.6 (t), 159.5 (q), 194.4 (q); ms *m/z*(%): 192(68), 178(12), 163(53), 148(17), 121(100). M$^+$ calcd. for $C_{11}H_{12}O_3$: 192.0786; found: 192.0790.

*5,8-Dimethoxy-2,2-dimethyl-4-chromanone (**8**)*

Biotransformation of **8** (0.25 g) using four 1 L Erlemeyer flasks as described above gave, following extraction and chromatography with 30–50% ethyl acetate – hexane, (*S*)-5,8-dimethoxy-2,2-dimethylchroman-4-ol (**9**, 0.25 g, 99%); mp 67–69°C; nmr and mass spectral data identical with those described above for (±)-**9**; $[\alpha]_D$ +7.5 (*c* 1.5, ethanol); ee >95% based on ^{1}H nmr analysis of the C*H*OH signal in the presence of Eu(tfc)$_3$.

*5,8-Dimethoxy-2,2-dimethylchroman (**10**)*

Exposure of **10** (0.35 g) to *M. isabellina* (2 L of culture in 10 Erlenmeyer flasks) for 72 h followed by extraction as described above gave a crude extract (0.15 g) that was subjected to chromatography using 20–60% ethyl acetate – hexane as eluent and gave, in order of elution, 5,8-dimethoxy-2,2-dimethylchroman (**10**, 50 mg); 2,2-dimethyl-5-hydroxy-8-methoxychroman (**11**, 6 mg), as an oil; ^{1}H nmr δ: 1.37 (6H, s), 1.80 (2H, t, *J* = 7 Hz), 2.65 (2H, t, *J* = 7 Hz), 3.77 (3H, s), and 6.24/6.58 (2H, ABq) ppm; ^{13}C nmr δ: 17.4 (s), 26.6 (2C, p), 32.1 (s), 56.7 (p), 74.1 (q), 104.1 (t), 110.0 (q), 110.1 (t), 143.1 (q), 144.5 (q), 147.8 (q) ppm; ms *m/z*: M$^+$ 208; an oil (33 mg), which was further purified by preparative tlc (alumina) using chloroform as eluent to give 5,8-dimethoxy-2,2-dimethylchroman-4-ol (**9**, 5 mg), identified by spectral comparisons with authentic material; $[\alpha]_D$ 0; and 5,8-dimethoxy-2,2-dimethyl-6-hydroxychroman (**12**, 10 mg), as an oil; ^{1}H nmr δ: 1.35 (6H, s), 1.76 (2H, t, *J* = 7 Hz), 2.74 (2H, t *J* = 7 Hz), 3.74 and 3.77 (each 3H, s), and 6.43 (1H, s) ppm; ^{13}C nmr δ: 17.8 (s), 26.6 (2C, p), 32.2 (s), 56.2 (p), 60.8 (p), 73.6 (q), 98.2 (t), 115.5 (q), 137.0 (q), 137.4 (q), 140.8 (q), and 145.6 (q) ppm; ms *m/z*: M$^+$ 238.

Synthesis of 6,7-benzo-2,2-dimethyl-8-methoxy-4-chromanone (**13**)

A solution of 1-methoxy-2-naphthol (12) (6.26 g) and *p*-toluenesulfonic acid (0.1 g) in dichloromethane (80 mL) containing dimethoxymethane (25 mL) was heated under reflux (argon atmosphere) overnight in an apparatus fitted with a Soxhlet apparatus containing 40 g of activated 3 Å molecular sieves. The mixture was then cooled, triethylamine (1 mL) added, and the resulting solution washed (2 × 10% aqueous sodium hydroxide followed by saturated NaCl), dried, and evaporated. The residue was passed through a column of silica gel using 2% ethyl acetate – hexane as eluent to give 4.85 g (63%) of 1-methoxy-2-(methoxymethoxy)-naphthalene as a pale yellow oil; ^{1}H nmr δ: 3.53 (3H, s), 3.99 (3H, s), 5.27 (2H, s), 7.4–8.1 (6H, m) ppm; ^{13}C nmr δ: 58.2 (p), 61.1 (p), 96.0 (s), 116.7 (t), 121.4 (t), 124.1 (t), 124.5 (t), 126.0 (t), 127.6 (t), 129.0 (q), 130.6 (q), 144.0 (q), 145.0 (q) ppm; ms *m/z*(%): 218(100), 188(24), 173(71), 145(37), 127(33). M$^+$ calcd. for $C_{13}H_{14}O_3$: 218.0943; found: 218.0941.

A solution of *tert*-butyllithium (8.2 mL, 1.4 M in pentane) was added slowly to a stirred solution of 1-methoxy-2-(methoxymethoxy)-naphthalene (2.0 g) in dry THF (30 mL) under an argon atmosphere at −80°C. The resulting green solution was allowed to reach room temperature, stirred at that temperature for 1 h, and then recooled to −80°C. Upon slow addition of 3,3-dimethylacryolyl chloride (1.4 mL), the reaction mixture became pale yellow. The reaction was stirred overnight at room temperature, and then worked up by addition of aqueous THF and extraction with chloroform. The organic extract was washed with 10% aqueous sodium hydroxide, saturated sodium bicarbonate solution, and saturated sodium chloride, and then dried and evaporated. Chromatography (silica gel, 30% ethyl acetate – hexane) afforded 1.7 g (60%) of 3-(3′,3′-

For personal use only.

dimethylacryloyl)-1-methoxy-2-(methoxymethoxy)-naphthalene as a pale yellow oil; ^{1}H nmr δ: 2.01 (3H, s), 2.26 (3H, s), 3.52 (3H, s), 4.04 (3H, s), 5.18 (2H, s), 6.68 (1H, t), and 7.5–8.1 (5H, m) ppm; ms *m/z*(%): 300(21), 285(9), 256(26), 200(34) relative to 83(100). M^+ calcd. for $C_{18}H_{20}O_3$: 300.1362; found: 300.1386.

The above compound (4.32 g) was dissolved in a mixture of THF (90 mL) and 6 M sulfuric acid (10 mL) and the resulting solution refluxed overnight. The solution was then cooled, neutralized by addition of 5% aqueous sodium hydroxide solution, and the resulting mixture extracted with chloroform. The extract was washed with saturated sodium bicarbonate solution, dried, and evaporated to give a residue that, following chromatography, afforded 6,7-benzo-2,2-dimethyl-8-methoxy-4-chromanone (**13**, 3.35 g, 91%); mp 94–95.5°C from ethyl acetate – hexane; ^{1}H nmr δ: 1.55 (6H, s), 2.85 (2H, s), 4.03 (3H, s), 7.36 (1H, t), 7.54 (1H, t), 7.67 (1H, d), 8.08 (1H, d), and 8.28 (1H, s) ppm; ^{13}C nmr δ: 27.0 (2C, p), 49.7 (s), 61.0 (p), 70.0 (q), 121.3 (t), 122.0 (t), 123.0 (t), 124.7 (t), 126.1 (q), 126.6 (t), 130.0 (t), 132.6 (q), 142.5 (q), 146.2 (q), and 193.0 (q) ppm; ms *m/z*(%): 256(100), 241(16), 201(49), 200(64), 185(25), 157(44). M^+ calcd. for $C_{16}H_{16}O_3$: 256.1099; found: 256.1119. Anal. calcd. for $C_{16}H_{16}O_3$: C 74.98, H 6.29%; found: C 74.61, H 6.60%.

Biotransformation of 6,7-benzo-2,2-dimethyl-8-methoxy-4-chromanone (13)

Using a 72 h growth of *M. isabellina* (600 mL of culture in three 1 L Erlenmeyer flasks), the title ketone (0.18 g) was converted to (*S*)-6,7-benzo-2,2-dimethyl-8-methoxychroman-4-ol (**14**, 35 mg), isolated as an oil by chromatography on silica gel using a 2% ether – benzene stepwise gradient elution; ^{1}H nmr δ: 1.36 (3H, s), 1.53 (3H, s), 1.92 and 2.24 (each 1H, dd), 2.4 (1H, br. s, exchanges D_2O), 3.95 (3H, s), 5.02 (1H, t), 7.36 (2H, m), 7.69 (1H, d), 7.73 (1H, s), and 8.04 (1H, d) ppm; ^{13}C nmr δ: 25.9 (p), 29.4 (p), 42.8 (s), 60.7 (p), 64.1 (t), 75.8 (q), 120.9 (t), 121.5 (t), 123.7 (t), 125.9 (t), 127.6 (t), 128.0 (q), 128.4 (q), 128.6 (q), 141.4 (q), and 142.8 (q) ppm; ms *m/z*(%): 258(46), 240(60), 225(100), 210(30), 202(81), 187(55). M^+ calcd. for $C_{16}H_{18}O_3$: 258.1256; found: 258.1270; $[\alpha]_D$ +24.8 (*c* 0.5, ethanol), ee 32% based on ^{1}H nmr analysis of the C*H*OH signal in the presence of Eu(tfc)$_3$. Also obtained from chromatography was a pale green oily material (11 mg) tentatively identified as a phenolic derivative of **14** by the following spectral data: ^{1}H nmr δ: 1.33 (3H, s), 1.51 (3H, s), 1.9 and 2.2 (each 1H, dd), 3.92 (3H, s), 4.95 (1H, t), 6.31 (1H, br. s, exchanges D_2O), 6.94 (1H, s), 7.03 and 7.88 (2H, ABq), and 7.41 (1H, s) ppm; ms *m/z*(%): 274(2), 256(10), 241(9), 226(4) relative to 83(100). Lack of material and instability of the product precluded further analysis.

Synthesis of 4-hydroxy-α-lapachone

4-Keto-α-lapachone (15)

A solution of 6,7-benzo-2,2-dimethyl-8-methoxy-4-chromanone (**13**, 0.2 g) in acetonitrile (2 mL) was cooled to 0°C and then a solution of ceric ammonium nitrate (2.18 g) in water (10 mL) was added at 0°C over a period of 5 min. The mixture was stirred for a further 30 min at 0°C, water (20 mL) was added, and the resulting solution was extracted with chloroform. The extract was dried and concentrated to a volume of 30 mL. The resulting solution was then aerated and refluxed for 24 h. After this period the cooled solution was washed (saturated aqueous sodium bicarbonate), dried, and evaporated. Chromatography of the residue gave 4-keto-α-lapachone (**15**, 0.11 g, 57%) as a yellow solid, mp 161–164°C (from benzene–hexane) (lit. (2) mp 163–165°C); ir ν_{max}: 1689, 1714 cm^{-1}; ^{1}H nmr δ: 1.62 (6H, s), 2.77 (2H, s), 7.76 (2H, m), and 8.10 (2H, m) ppm; ^{13}C nmr δ: 26.1 (2C, p), 48.7 (s), 84.4 (q), 112.9 (q), 126.3 (t), 127.0 (t), 130.8 (q), 132.0 (q), 133.3 (t), 135.4 (t), 162.4 (q), 180.0 (q), 180.6 (q), and 189.7 (q) ppm; ms *m/z*(%): 256 (73), 201 (98), 173(47), 104(100).

(S)-4-Hydroxy-α-lapachone (3)

Biotransformation of the ketone **15** (0.41 g) with a culture of *M. isabellina* in eight 1 L Erlenmeyer flasks as outlined above, followed by chromatography of the extract, gave (*S*)-4-hydroxy-α-lapachone (**3**, 0.2 g, 49%) as a yellow solid, mp 67°C (lit. (2) yellow syrup (*S*); (6) mp 117–119°C (racemate); (7) yellow oil (racemate); (4) yellow oil (*S*);); ir ν_{max}: 1645, 1683, 3505 cm^{-1}; ^{1}H nmr δ: 1.44 (3H, s), 1.55 (3H, s), 2.08 (2H, dd), 3.80 (1H, br s, exchanges D_2O), 4.97 (1H, t), 7.70 (2H, m), and 8.08 (2H, m) ppm; ^{13}C nmr δ: 26.7 (p), 27.1 (p), 39.6 (s), 60.0 (t), 79.8 (q), 120.4 (q), 126.0 (t), 126.6 (t), 131.2 (q), 131.9 (q), 133.4 (t), 134.3 (t), 154.1 (q), 180.1 (q), and 186.1 (q) ppm; ms *m/z*(%): 258(24), 243(10), 203(93), 176(69), 146(87), 105(50), 83(100). M^+ calcd. for $C_{15}H_{14}O_4$: 258.0892; found: 258.0888. $[\alpha]_D$ +39.7 (*c* 1.3, methanol) (lit. (2) $[\alpha]_D$ +27.4 (methanol)), ee >95% by ^{1}H nmr analysis of the C*H*OH signal in the presence of Eu(tfc)$_3$.

(S)-4-Acetoxy-α-lapachone (16)

Acetic anhydride (1 mL) was added to a solution of (*S*)-4-hydroxy-α-lapachone (**3**, 0.071 g) in dry pyridine (2 mL) and the mixture allowed to stand overnight at room temperature. The usual work-up afforded a yellow residue that, on chromatography, afforded (*S*)-4-acetoxy-α-lapachone (**16**, 0.08 g, 97%). Crystallization from ethanol gave a pale yellow solid, mp 145–148.5°C (lit. (6) mp 136–138°C (racemate); (7) mp 138.5–139.5°C (racemate); (4) mp 118–120°C (*S*); (2) mp 139.5–140.5°C (*S*)); ir ν_{max}: 1616, 1651, 1683, 1739, 2931, 2979 cm^{-1}; ^{1}H nmr δ: 1.51 (3H, s), 1.56 (3H, s), 2.15 (5H, s + m), 6.10 (1H, dd), 7.72 (2H, m), and 8.10 (2H, m) ppm; ^{13}C nmr δ: 21.0 (p), 25.4 (p), 28.8 (p), 38.1 (s), 60.6 (t), 78.7 (q), 116.7 (q), 126.3 (t), 131.1 (q), 132.0 (q), 133.2 (t), 134.4 (t), 155.8 (q), 170.0 (q), 179.9 (q), and 182.7 (q) ppm; ms *m/z*(%): 300(0.6), 258(100), 243(12), 225(9), 201(71). M^+ calcd. for $C_{16}H_{16}O_5$: 300.0998; found: 300.1004. $[\alpha]_D$ −22.7 (*c* 1.3, methanol) (lit. (2) $[\alpha]_D$ −14.2 (*c* = 1.03, methanol)).

Association between halothane and oxygenated solvents by ^{1}H NMR spectroscopy

Marcela Tkadlecová, Jaroslav Havlíček, and Vladimír Dohnal

Abstract: Using ^{1}H NMR spectroscopy the complex-formation equilibria between halothane (2-bromo-2-chloro-1,1,1-trifluoroethane) and methyl *tert*-butyl ether or tetrahydrofuran in various inert solvents (hexane, heptane, decane, cyclohexane) were measured as a function of temperature. For two different association models (ideal solution and athermal solution), assuming only the formation of a 1:1 H-bonded complex, the equilibrium constants and the standard enthalpies of the complex-formation reaction were calculated. The ideal solution model provides values of the equilibrium constant that differ for different inert solvents. The athermal solution model makes this false solvent effect much smaller. For the low halothane concentration used, its dimerization was neglected. This assumption was verified experimentally.

Key words: ^{1}H NMR, association, complex formation, halothane.

Résumé : Utilisant la spectroscopie RMN du ^{1}H, on a mesuré l'influence de la température sur l'équilibre de formation de complexes entre l'halothane (2-bromo-2-chloro-1,1,1-trifluoroéthane) et l'oxyde de méthyle et de *tert*-butyle ou le tétrahydrofurane, dans divers solvents inertes (hexane, heptane, décane, cyclohexane). On a calculé les enthalpies standard de la réaction de formation des complexes pour deux modèles différents d'associations (solutions idéales et athermales) ne supposant que la formation de complexes 1 : 1 par liaisons hydrogènes. Les valeurs de la constante d'équilibre obtenues à l'aide du modèle de la solution idéale diffèrent pour chacun des solvants inertes. Le modèle de la solution athermale conduit à un faux effet de solvant qui est beaucoup plus faible. Pour les faibles concentrations d'halothane utilisées, on a négligé sa dimérisation. On a vérifié cette hypothèse expérimentalement.

Mots clés : RMN du ^{1}H, association, formation de complexes, halothane.

[Traduit par la rédaction]

1. Introduction

Due to the highly acidic hydrogen atom in the molecule of 2-bromo-2-chloro-1,1,1-trifluoroethane (halothane) a strong complexation via hydrogen bonding occurs when this bromofreon is mixed with efficient proton acceptors, such as oxygenated solvents. We have studied this interesting class of systems within a broader long-term project on haloalkane-containingmixtures. Recently, we reported extensive thermodynamic data (vapor–liquid equilibria (1), excess enthalpies (2), excess heat capacities (3), excess volumes (3)) for mixtures of halothane with oxygenated solvents, documenting the governing effect of complex formation on thermodynamic solution properties. Using several association models, a detailed analysis of the data has been carried out (4) for halothane + methyl-*tert*-butyl ether, + tetrahydrofuran, + 2-propanone, and + methyl acetate and quantitative information concerning the degree of complexation and stability of the complexes has been obtained. For these systems, a very good simultaneous description of vapor–liquid equilibria and thermal properties has been achieved by simple association models, the resulting solvation enthalpies agreeing well with the results obtained by quantum mechanical calculations.

^{1}H NMR spectroscopy provides an alternative technique for studing complex formation. Since the work on association in the systems of chloroform with acetone or triethylamine (5) appeared, ^{1}H NMR has often been applied to the study of association phenomena. Self-association has been studied in alcohols (6, 7) and simple organic acids (8–11) as well as in complex organic molecules (12, 13). Hetero-association has been investigated in systems of phenol with oxygenated solvents (14, 15), amides (14), fluoroalkanes (16), and in systems of acetonitrile with amides (17, 18). Solvent effects in these measurements have been observed and discussed (10, 14).

In this work, ^{1}H NMR spectroscopy was employed to measure complex formation between halothane and methyl *tert*-butyl ether (MTBE) or tetrahydrofuran (THF) in several inert solvents. The values of the equilibrium constants and the standard enthalpies of complex formation obtained were compared with those derived from thermodynamic measurements.

Experimental

Materials

Halothane (Spofa Praha, >99.9% stabilized with 0.01 mass % of thymol), hexane, heptane, and cyclohexane (all Lachema Brno, p.a.) were used after distillation and drying with molecular sieves. MTBE (Fluka, 99.5%) and THF (Aldrich, HPLC grade, 99.9%) were used without purification. Decane (Aldrich, 99%) was dried with molecular sieves.

Instrumentation

A Varian NMR spectrometer, model Gemini 300 HC, with a variable-temperature accessory was used, the working frequency being 300.075 MHz. The homogeneity of the magnetic field was adjusted on a sample tube with deuterated acetone and then the measurements were performed without lock. Like the acetone sample, all measured samples had similar volumes of about 1 mL to maintain the field homogeneity. Each sample was measured three times with four scans and pulse width 6° after the initial 10 min temperature equilibration.

The ^{1}H NMR signal of halothane is a quartet due to ^{1}H–^{19}F coupling (coupling constant 5.2 Hz). Its chemical shift was referenced to the signal of an inert solvent. To justify such referencing, tetramethylsilane was added to some samples after the difference between the chemical shift of halothane and that of inert solvent was measured. It was observed that the chemical shifts of inert solvent and oxygenated solvent are independent of sample composition; only the chemical shift of halothane changes due to the association. The reproducibility of the measured chemical shift differences was ±0.5 Hz. The temperature of the sample, stable within ±0.1 K, was calibrated by means of methanol or ethylene glycol temperature calibration set.

Sample preparation

For each system (halothane + MTBE or + THF in various inert solvents) 10 samples were prepared directly in the sample tubes by means of weighing, from the following stock solutions: (*a*) mixture of halothane in inert solvent, (*b*) mixture of oxygenated solvent in inert solvent (samples 2–6) or pure oxygenated solvent (samples 7–10), and (*c*) inert solvent (not used for samples 6 and 10). Relatively large sample volumes (1 mL) were used in order to minimize the volume of the vapor phase and to decrease the influence of inaccuracy in weighing.

Let x_A^0 and x_B^0 stand for the analytical mole fractions of halothane and oxygenated solvent, respectively. In all samples prepared, x_A^0 were similar and less than 0.05 to suppress the effect of possible halothane dimerization. For such low concentrations of halothane in our samples the self-association of halothane was neglected (see also discussion). The chemical shift measured for sample 1 (halothane in inert solvent without MTBE or THF) was considered to be the chemical shift of the monomeric halothane. The mole fraction x_B^0 of MTBE or THF in the prepared samples increased approximately in the following sequence: 0, 0.007, 0.015, 0.03, 0.05, 0.07, 0.15, 0.30, 0.50, 0.75, to obtain roughly constant increments in the chemical shift difference measured.

Procedure

Assuming only 1:1 complex formation between halothane and oxygenated solvent (4), the observed chemical shift of halothane δ_{obs} is given as the weighted arithmetic mean of the shift corresponding to the proton in the uncomplexed form δ_A and that corresponding to the proton in the complexed form δ_{AB}

$$\delta_{obs} = \frac{n_A^0 - n_{AB}}{n_A^0}\,\delta_A + \frac{n_{AB}}{n_A^0}\,\delta_{AB}$$

where n_A^0 is the analytical molar amount of halothane and n_{AB} is the molar amount of the complex in equilibrium. The value of δ_A is obtained for sample 1 (mixture of halothane and inert solvent without oxygenated solvent). Then,

$$\Delta\delta_{obs} = \delta_{obs} - \delta_A = \frac{n_{AB}}{n_A^0}\,(\delta_{AB} - \delta_A) = \frac{n_{AB}}{n_A^0}\,D$$

where D is the difference between the chemical shifts δ_{AB} and δ_A. Thus, nine $\Delta\delta_{obs}$ values corresponding to the compositions of samples 2–10 were obtained for each system at a given constant temperature. To analyze these experimental data, i.e., to calculate the equilibrium constant of complex formation, two simple association models were used.

Ideal association model

The simplest model assumes that the mixture of true species (A, B, AB) forms an ideal solution. The equilibrium constant for the complex-formation reaction (A + B → AB) in terms of mole fractions can be expressed as follows

$$K = \frac{x_{AB}}{x_A x_B} = \frac{n_{AB}(n_A^0 + n_B^0 + n_I - n_{AB})}{(n_A^0 - n_{AB})(n_B^0 - n_{AB})}$$

where n_B^0 and n_I are the added molar amounts of the oxygenated and the inert solvent, respectively.

Athermal association model

In this model, the mixture of true species is considered to be nonideal, its nonideality originating solely from differences in species sizes. The Flory–Huggins expression employed to describe the activity coefficients of the species involved (i = A, B, AB) is

$$\gamma_i = \frac{\Phi_i}{x_i}\,\exp\left(1 - \frac{\Phi_i}{x_i}\right)$$

where Φ_i are the volume fractions of true species

$$\Phi_i = \frac{r_i n_i}{\sum_j r_j n_j}$$

r_j being the size parameter of the j-species. The van der Waals volumes normalized by Abrams and Prausnitz (19) were used as the size parameters in this work (halothane 3.5682, MTBE 4.0678, THF 2.9415, hexane 4.4998, heptane 5.1742, decane 7.1974, cyclohexane 4.0464). Under the assumption $r_{AB} = r_A + r_B$, the equilibrium constant can be expressed as follows:

$$K = \frac{x_{AB}}{x_A x_B} \times \frac{\gamma_{AB}}{\gamma_A \gamma_B} = \frac{r_A + r_B}{r_A r_B} \times \frac{n_{AB}(r_A n_A^0 + r_B n_B^0 + r_I n_I)}{(n_A^0 - n_{AB})(n_B^0 - n_{AB})} e^{-1}$$

To estimate the values of parameters K and D for a given model, an objective function must be minimized. The objective function considered here assumes equal standard deviations at all points and is given by the sum of the squares of differences between calculated and experimental values of quantity $\Delta\delta_{obs}$. The best parameters were calculated by means of an optimization procedure based on the method of conjugate gradients (20).

For the ideal association model approximate values of parameters K and D can also be calculated according to Nakano et al. (14). Their linearized formula, derived for the equilibrium constant expressed in terms of molarities, was modified for the equilibrium constant expressed in terms of mole fractions as follows

$$\frac{n_B^0}{n_I \Delta\delta_{obs}} = \frac{K+1}{KD} \times \frac{n_A^0 + n_B^0 - n_{AB}}{n_I} + \frac{1}{KD}$$

The iteration starts with $n_{AB} = 0$ in all points. Using linear regression the values of parameters K and D and then new values of n_{AB} at each point are calculated, until the values of K and D are constant.

Nakano's iterative method converges very quickly, but its estimates are not well justified statistically. They provided, however, a good initial approximation for calculating the best values of parameters by minimizing the objective function mentioned above. For the athermal association model the optimization started with parameters found for the ideal association model.

Results

For all systems, the measurements were carried out at three temperatures: approximately 297, 303, and 310 K. The association in the system of halothane with MTBE was measured in four inert solvents: hexane, decane, heptane (two measurements), and cyclohexane (two measurements). For duplicate measurements newly prepared samples were used. The reproducibility, as judged by the differences in calculated values of K and D for the replicates, is for heptane fully comparable with the uncertainties of the determination, $\sigma(K)$ and $\sigma(D)$, but for cyclohexane is somewhat worse. Therefore, cyclohexane was not used in the measurements on halothane with THF.

The optimized values of K and D with their standard deviations and the standard deviation of fit are given for each system and temperature in Table 1 (ideal association model) and Table 2 (athermal association model). Using the values of K at three different temperatures of each system the value of ΔH with its standard deviation for each system was calculated from the van't Hoff equation.

The van't Hoff plots are shown for the ideal association model and the athermal association model in Figs. 1 and 2, respectively. In both figures, the results inferred previously from thermodynamic measurements (4) are plotted for comparison (solid lines). Dotted lines in Fig. 2 represent the van't Hoff plots, obtained for the system of halothane with MTBE or THF by averaging the $K_{298.15}$, ΔH values from measurements in different inert solvents. The parameters $K_{298.15}$, ΔH of these straight lines are given in Table 3.

Discussion

Comparison of models used

From a comparison of Figs. 1 and 2 it is clear that the ideal association model produces a false solvent effect. The optimized values of K decrease and the values of D increase in the following order of inert solvents: cyclohexane, hexane, heptane, and decane, the pattern being the same for systems with MTBE and THF (cyclohexane was not used for systems with THF). The athermal association model makes the differences between individual inert solvents used significantly smaller and more random, which can easily be seen qualitatively from the comparison of Figs. 1 and 2 and quantitatively from comparison of Tables 1 and 2.

Using the athermal association model, the range of K values obtained for different solvents at a given temperature decreased 5 times for systems with MTBE and 8 times for systems with THF as compared with the ideal association model. The parameter D should be temperature independent; its variation decreased 4 times for MTBE and 5 times for THF. There was also some improvement in the variation of ΔH values: 1.5 times for MTBE and 2 times for THF. The standard deviation of fit did not change significantly with the use of the athermal association model. Also, the differences in values of correlation coefficients for the van't Hoff plots between the two models used were insignificant. These values were mostly greater than 0.999 and never less than 0.993.

Let us stress that the better performance of the athermal association model has not been achieved by increasing the number of fitted parameters. The adjustable parameters are the same as in the ideal association model, i.e., K and D. However, it turns out that the parameters evaluated for the model of athermal association have a better physical significance than those obtained for ideal association model.

Comparison with results from thermodynamics

The aim of this work was to compare the results from ^{1}H NMR measurements with those calculated from thermodynamic measurements. For this purpose, the values of $K_{298.15}$ and ΔH obtained from the NMR measurements in different inert solvents were averaged, and calculated average values are listed in Table 3 together with the results from ref. 4. The comparison is given for the athermal association model, which performed better both on the spectroscopic (better physical significance of the evaluated parameters) and the thermodynamic data (significantly smaller standard deviation of fit).

As can be seen from Table 3 the agreement between the association parameters derived from spectroscopy and from thermodynamics is qualitative rather than quantitative. The qualitative agreement consists in the fact that, for the system halothane + THF, both the spectroscopic and the thermodynamic measurements imply a higher degree of complexation (higher $K_{298.15}$) and a lower stability of the respective com-

plex (less negative ΔH) than for halothane + MTBE. The quantitative agreement is, however, less specific.

For an exact quantitative comparison, it should be considered that the athermal association model in ref. 4 was applied with equal van der Waals volumes of the nominal components ($r_A = r_B$). If the same simplification, such as in ref. 4, is used, the values of $K_{298.15}$ from spectroscopy are about 10% greater for MTBE and 10% smaller for THF as compared to the values in Table 3. Then, the quantitative comparison of $K_{298.15}$ is as follows: the values from spectroscopy are roughly 1.5 times higher than those from thermodynamics both for MTBE and for THF, the relative difference between MTBE and THF being kept the same (15%). The spectroscopic and thermodynamic values of ΔH agree within about 1.5 kJ/mol, the former being more negative.

The lack of quantitative agreement might be caused by different experimental conditions in the two types of measurements; when compared to the thermodynamic measurements, the NMR data were obtained in the presence of an inert solvent and at much lower halothane concentrations.

The observed systematic differences between individual inert solvents and the effort to eliminate this false solvent effect enabled us to choose the better model from the two association models used. Although the chosen athermal association model diminished the solvent effect significantly, it can hardly be considered fully realistic, since it accounts only for molecular size differences while all non-chemical interactions are neglected.

To judge the influence of the different concentration ranges for which the experimental data were obtained (i.e., $x_A^0 < 0.05$ for the NMR measurements and the whole composition range for the thermodynamic measurements), the extent of halothane dimerization was explored.

Dimerization of halothane

In all calculations above, the dimerization of halothane was neglected. This essential assumption was verified as follows:

(*a*) For five dilute solutions of halothane in hexane with x_A^0 uniformly covering a range from 0.01 to 0.05, the chemical shift of halothane was measured and extrapolated to $x_A^0 = 0$. The value of the chemical shift of the monomeric halothane, $\delta_A = 1688.0 \pm 0.3$ Hz (5.6253 ± 0.0010 ppm) obtained in this way at 297.85 K is 1.5 Hz smaller than the chemical shift of halothane measured for sample 1 with hexane as inert solvent. This difference is small and should be suppressed by referencing the measured chemical shift of halothane for the

individual sample to the sample 1. The temperature dependence of the chemical shift of halothane in sample 1 was found to be insignificant. The differences in the measured chemical shifts of halothane in individual inert solvents for sample 1 are also small (within ±1.5 Hz from the signal of halothane in hexane) and comparable to the standard deviations of fit of the complex formation experiments given in Tables 1 and 2.

(*b*) An additional six samples of halothane+hexane with x_A^0 covering the whole composition range were prepared and the chemical shifts of halothane were measured. The changes in chemical shift of halothane due to dimerization are small (about 40 Hz for pure halothane), while the maximal measured values of $\Delta\delta_{obs}$ for the case of association with MTBE or THF were greater than 300 Hz.

Supposing the formation of linear dimer and the athermal solution ($r_{AA} = 2r_A$), the optimal values of the dimerization constant and the difference between chemical shift of dimer and monomer were found by minimizing the sum of squares of differences between experimental and calculated values of chemical shifts of halothane. The calculation was very unstable; the model of ideal solution did not converge.

Solid lines are van't Hoff plots calculated from thermodynamic data.

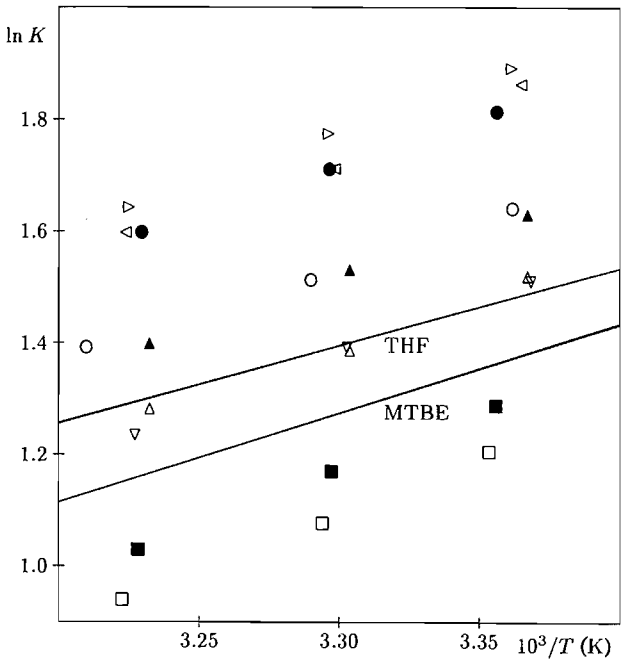

Fig. 2. Athermal association model: experimental van't Hoff plot for systems of halothane with MTBE (hollow symbols) or THF (full figures) as measured in several inert solvents, △ ▽ ▲ heptane, ○ ● hexane, □ ■ decane, ◁ ▷ cyclohexane. Dotted lines average measurements for all the inert solvents used (for parameters of these lines see Table 3), solid lines are calculated from thermodynamic data.

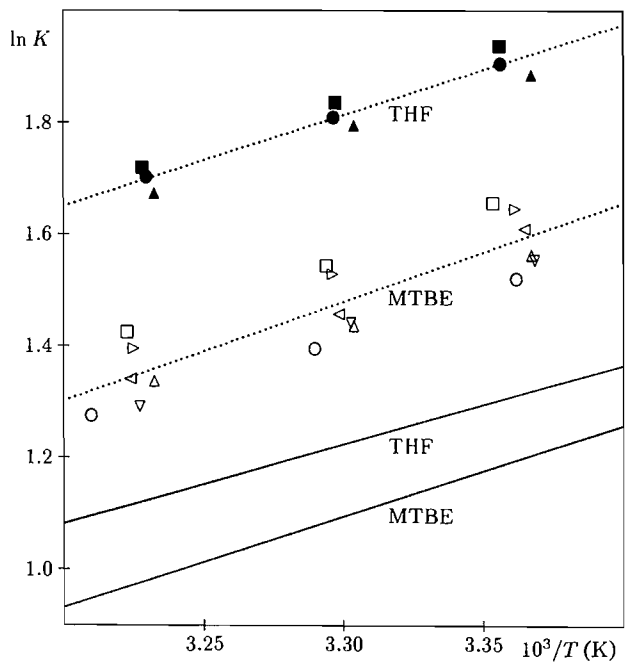

Therefore only the model of athermal association was used. For 297.85 K the following values were estimated: dimerization constant 0.091 ± 0.010 and chemical shift of dimer 2154 ± 41 Hz (7.18 ± 0.14 ppm), standard deviation of fit being 0.4 Hz.

Having determined the value of the self-association constant of halothane, it can be readily found that, for $x_A^0 < 0.05$, less than 1% of halothane is dimerized. Thus, our spectroscopic measurements should be virtually unaffected by the self-association of halothane.

In concentrated halothane solutions, however, the extent of halothane dimerization increases, reaching nearly 15% for pure halothane. Through comparison of the excess Gibbs energy values calculated for the system halothane + MTBE or THF it was found that the values of $K_{298.15}$ from thermodynamics would be about 20% higher if self-association of halothane were accounted for. Thus, the influence of halothane self-association on the results derived from thermodynamics turns out to be significant and its complete neglect can at least partially explain the lack of quantitative agreement between the results from spectroscopy and those from thermodynamics.

Application pratique des réseaux neuro mimétiques aux données spectroscopiques (infrarouge et masse) en vue de l'élucidation structurale

D. Cabrol-Bass, C. Cachet, C. Cleva, A. Eghbaldar et T.P. Forrest

Résumé : Au cours de ces trois dernières années, des recherches intensives menées indépendamment par plusieurs équipes ont montré que les réseaux neuro mimétiques à couches peuvent être utilisés pour analyser les données spectroscopiques en vue de la détermination de structures moléculaires et que leurs performances s'approchent de celles de spécialistes chevronnés. La construction de tels réseaux, leur apprentissage et l'évaluation de leurs performances requièrent des bases de données spectrales et structurales de taille importante, des logiciels spécialisés, des machines performantes et des temps de calculs non négligeables. Cependant, une fois ces réseaux mis au point, leur utilisation pratique peut se faire directement au laboratoire d'analyse, c'est à dire sur des machines de faible coût (type PC), avec un minimum de manipulations et dans un temps très bref. Dans cet article on rappelle la méthodologie de mise au point des réseaux neuro mimétiques pour l'interprétation des données spectroscopiques et on présente un logiciel permettant d'appliquer ces réseaux sur un ordinateur de type PC couplé ou non avec les spectromètres infrarouge et de masse. Ce logiciel accepte comme données d'entrée, d'une part la description des réseaux à appliquer, et d'autre part les spectres à interpréter numérisés, l'un et l'autre sous forme de fichiers ASCII. Cette approche permet d'appliquer les réseaux neuro mimétiques directement au laboratoire d'analyse avec des ressources informatiques limitées.

Mots clés : réseaux neuromimétiques, spectres infrarouge, spectres de masse, détermination de structure.

Abstract: In the last few years, intensive research by several groups has shown that neural networks can be used to analyse spectral data for structural elucidation, and that their performance approaches that of an expert in the field. The construction of such networks, their training and evaluation, requires large structural and spectral databases and significant computational resources and time. However, once the network has been completed it can be used very effectively for practical applications on an ordinary desktop computer. In this article we describe the methodology for creating such a network for infrared and mass spectra, and present a program for use on a personal computer, either connected to a spectrometer or independently. The program accepts data in ASCII format, both for the network description and for the spectral information. This approach permits the use of neural networks in an analytical laboratory with limited computational resources.

Key words: neural networks, infrared spectroscopy, mass spectroscopy, structure determination.

Introduction

Après les premiers travaux de McCulloch et Pitts (1), puis ceux de Rosenblatt sur le perceptron (2), il aura fallu attendre ces dernières années pour voir se développer des applications des réseaux neuro mimétiques en Chimie. Depuis le début des années 90, leur nombre n'a cessé de croître rapidement, en particulier dans les domaines de la classification automatique et de la prévision de propriété. D'excellents articles de synthèse (3–5) et un ouvrage (6) présentant les applications des réseaux neuro mimétiques en Chimie ont été publiés récemment. L'intérêt des réseaux neuro mimétiques pour l'interprétation et la classification des données spectroscopiques résulte de leurs qualités intrinsèques, en particulier, (*i*) la tolérance au bruit de fond : l'information étant délocalisée sur l'ensemble des connexions entre neurones, une perturbation éventuelle de quelques données n'entraîne pas une dégradation irrémédiable des performances des réseaux; (*ii*) l'aptitude à la généralisation : il n'est pas nécessaire d'apprendre exhaustivement tous les cas de figure possibles d'un problème pour pouvoir classer un nouveau jeu de données.

Un réseau neuro mimétique, dans sa forme la plus simple (réseau à couches non-récurrent), est constitué de plusieurs unités élémentaires de traitement appelées cellules (ou neurones) organisées en couches. Chaque cellule i d'une couche est reliée à toutes les cellules j de la couche précédente au travers des connexions affectées d'un poids W_{ij}. La première couche, qui reçoit l'information à traiter, est appelée couche d'entrée (ou rétine), la dernière, qui produit les réponses du réseau, est appelée couche de sortie (ou couche de décision).

Chaque cellule constitue une unité élémentaire de traitement qui effectue la sommation pondérée des valeurs qui lui sont transmises (éq. [1]), puis applique au résultat obtenu net_i, une fonction de transfert, généralement de type sigmoïde (éq. [2]) :

$$[1] \quad net_i = \Sigma_j W_{ij} \cdot out_j + \theta_i$$

$$[2] \quad out_i = \frac{1}{1 + \exp(-k \cdot net_i)}$$

equations dans lesquelles θ_i est une valeur ajustable appelée bias, W_{ij} est le poids de la connexion entre les cellules i et j, net_i est le résultat de la sommation effectuée par éq. [1], out_i est le résultat de l'application de la fonction de transfert [2], il constitue une des entrées des cellules de la couche suivante, et k est un paramètre ajustable de la fonction de transfert.

Le comportement collectif des neurones permet de simuler, de manière rudimentaire, quelques facultés du système nerveux (simulation neuro mimétique), notamment l'apprentissage et la mémorisaiton, et leur confère ainsi une certaine aptitude à la reconnaissance et la généralisation.

La mise en oeuvre d'une application avec un réseau à couches non récurrent s'effectue généralement en trois phases : apprentissage, évaluation, application.

L'apprentissage se fait à partir d'un ensemble d'exemples (ensemble d'apprentissage) qui sont présentés au réseau plusieurs fois. Quand on dit présentés, on entend que les exemples sont appliqués en entrée pour que le réseau modifie au fur et à mesure les poids associés à ses connexions afin d'adapter sa réponse en sortie en fonction des exemples présentés (apprentissage non supervisé) et éventuellement des réponses attendues (apprentissage supervisé). Une présentation complète de l'ensemble d'apprentissage est appelé cycle d'apprentissage ou epoch. Il existe différents algorithmes d'apprentissages (rétropropagation du gradient, gradient conjugué, «line search», etc.); leur description dépasse le cadre de cet article, voir par exemple la référence 4.

L'évaluation consiste à présenter au réseau un ensemble d'exemples (ensemble de test) et à mesurer la qualité de ses réponses. Suivant les objectifs que l'on se fixe on peut chercher à évaluer la capacité du réseau à reconnaître les exemples qu'on lui a soumis lors de l'apprentissage (mémorisation). Dans ce cas, l'ensemble de test sera extrait de l'ensemble d'apprentissage. Mais dans la plupart des applications on s'intéresse à la capacité du réseau à généraliser son aptitude de reconnaissance à des exemples nouveaux (prévision). Dans ce cas, l'ensemble de test doit être constitué d'examples qui ne font pas partie de l'ensemble d'apprentissage. Dans le cas où le nombre d'exemples est limité, on peut employer une procédure dite de «cross-validation» dans laquelle les exemples utilisés en phase d'évaluation sont extraits tour à tour de l'ensemble d'exemples disponibles. Evidemment, il y a une dégradation des performances quand on passe de la mémorisation à la prévision. En particulier, si on pousse l'apprentissage trop loin, le réseau risque de mémoriser des détails non significatifs des exemples de l'ensemble d'apprentisage et ceci au détriment de sa capacité de généralisation. On parle alors de sur-apprentissage. Evidemment si la qualité des réponses n'est pas jugée satisfaisante, il faut modifier l'architecture du réseau et (ou) le codage de l'information présentée en entrée et (ou) la méthode d'apprentissage. Les phases d'apprentissage et d'évaluation sont donc étroitement liées et, pour l'heure, il n'existe pas de méthode qui permette d'aboutir à de bons résultats sans coup férir.

L'application consiste à exploiter un réseau, dont les performances après apprentissage et évaluation sont jugées acceptables, pour classer des exemples dont on ne sait pas s'ils figurent ou non dans les ensembles d'apprentissage ou de test et par conséquent dont les réponses ne sont pas connues a priori. L'hypothèse sous-jacente est que ces nouveaux exemples sont tirés d'une population ayant les mêmes caractéristiques que la population parente dont ont été extraits les ensembles d'apprentissage et de test et que, par conséquent, les performances attendues seront au moins aussi bonnes que celles observées en prévision.

Comme l'ont montré van Est et al. (7), le développement d'applications concrètes des réseaux neuro mimétiques pour l'analyse des données spectroscopiques fait intervenir plusieurs niveaux. En amont se trouve la recherche informatique portant sur les réseaux eux-mêmes (nouvelles architectures, nouveaux modes d'apprentissage, optimisation des paramètres, etc.). Puis, exploitant les résultants précédents, peuvent se développer des travaux de recherche appliquée dont l'objectif est d'aboutir à des réseaux efficaces pour un type de problème donné. Enfin, ces réseaux pourront être incorporés dans des logiciels destinés aux analyses de laboratoire; ces derniers ne doivent avoir à se préoccuper ni de l'architecture des réseaux ni de leurs modes internes de fonctionnement, mais les utiliseront simplement comme des outils destinés à faciliter leur travail d'interprétation. Dans le présent travail, on s'intéresse à ce dernier niveau en proposant un logiciel pouvant être utilisé sur une machine de type PC, couplé ou non avec les spectromètres. Ce logiciel est capable d'appliquer des réseaux, préalablement mis au point, par nous mêmes ou par d'autres, à des spectres de masse et infrarouge pour en tirer des informations structurales.

Réseaux neuro mimétiques et interprétation des données spectroscopiques

Dans l'application qui nous préoccupe, les réseaux neuro mimétiques sont utilisés pour déduire des informations structurales relatives à une molécule inconnue à partir de données spectrales. Le vecteur d'entrée est donc constitué d'une série de valeurs réelles qui décrivent le spectre considéré, tandis que le vecteur de sortie est constitué d'une série d'indicateurs qui caractérisent certains éléments structuraux de la molécule.

Vecteur d'entrée

En ce qui concerne le vecteur d'entrée, il faut distinguer le cas où le spectre à traiter est continu (spectre de bandes) de celui où il est discontinu (spectre de raies). Les spectres infrarouge seront pris comme exemples des spectres continus et les spectres de masse comme exemples des spectres de raies.

Pour les premiers (infrarouge) on peut décomposer la plage de fréquences du spectre en un certain nombre d'intervalles, chacun de ces intervalles constituant un élément du vecteur d'entrée. La plage de fréquences toutes entière peut être divisée en intervalles d'égale largeur (8–12) ou, au contraire, certaines parties plus riches en informations peuvent être découpées plus finement que d'autres (13, 14) ou même on

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

peut ne retenir que certaines parties spécifiques du spectre (15). Récemment, Meyer et al. (16) ont appliqué au spectre infrarouge une analyse en composantes principales pour construire des vecteurs d'entrée de faible dimensionalité (de 4 à 10) représentatifs de l'ensemble du spectre.

Pour chaque intervalle, deux types de codage ont été utilisés jusqu'à présent. Dans le premier (8, 9, 15) chaque élément du vecteur d'entrée reçoit une valeur égale à zéro lorsqu'il n'y a pas de bande dans l'intervalle qui lui est associé et une valeur proportionnelle à l'intensité de la bande, comprise entre zéro et un, dans le cas contraire. Cette manière de coder le spectre revient à le transformer en un spectre de raies et fait perdre l'information relative à la largeur et à la forme des bandes. Dans le second type de codage, on associe à chaque intervalle, la valeur de l'absorption en son milieu (10, 17), ou la valeur moyenne sur l'intervalle (11, 13). Ces valeurs sont généralement normalisées entre zéro et un. Ceci s'apparente à une numérisation du spectre et le vecteur ainsi obtenu conserve plus d'informations. La transformation par analyse en composantes principales (16) réduit considérablement la dimensionalité du vecteur d'entrée tout en conservant la plus grande quantité d'information.

Pour les spectres du second type (spectres de masse) s'il paraît simple d'associer l'intensité de chacune des valeurs du rapport *m/z* à un élément du vecteur d'entrée, cette solution est à écarter pour deux raisons.

1. Les spectres de masse ne sont pas très reproductibles, en particulier au niveau de l'intensité des pics. Pour résoudre ce problème, on utilise des modes de codage de l'intensité des pics qui permettent d'atténuer les variations trop importantes. Deux types de codages se sont révélés les plus efficaces : le codage logarithmique (18) qui permet d'atténuer les variations d'intensité et le codage par seuillage (19, 20) qui consiste à fixer en seuils ordonnés et à affecter à chaque pic le seuil atteint par son intensité. Dans le cas où il n'y a qu'un seul seuil, on parle de codage binaire (21, 22).

2. Les informations structurales contenues dans un spectre de masse sont de nature très variée. La plage utile de valeurs du rapport *m/z* étant comprise entre 40 et 440 environ, on obtiendrait, si on retenait toutes ces valeurs, un vecteur d'entrée dont la dimension serait de l'ordre de 400. En fait, un grand nombre de ces pics ne sont pas pertinents et en pratique on n'en retient qu'un certain nombre considérés comme caractéristiques de certains motifs structuraux. Mais il n'y a pas que les pics eux-mêmes qui puissent être associés à des informations structurales. Il y a également des séries de pics, des pics isotopiques ou des différences clefs (M − 18, M − 28, ...) qui sont caractéristiques d'une ou plusieurs famille(s) de composés. En plus des rapports *m/z* retenus, on ajoute donc au vecteur d'entrée d'autres descripteurs construits par autocorrélation, sommation, moyennisation, etc. (23–25).

Il apparaît donc que, dans un cas comme dans l'autre, le spectre numérisé ne peut pas être utilisé tel quel, mais qu'il faut lui faire subir certaines transformations pour constituer le vecteur d'entrée.

Vecteurs de sortie

En ce qui concerne les vecteurs de sortie, on utilise généralement des indicateurs de la présence (valeur 1) ou de l'absence (valeur 0) de motifs structuraux (sous structures) (8–11, 14, 16), mais d'autres sortes d'informations structurales comme par exemple le type de substitution aromatique (15), le type d'alcool (7) ou la classe de composé (12, 17, 24–26) peuvent également figurer comme éléments additionnels du vecteur de sortie. Dans ce dernier cas, un autre réseau spécifique à chaque classe peut être utilisé pour raffiner la classification, voire identifier spécifiquement chaque composé; on parle alors de réseaux hiérarchiques (13, 24). Une application particulière de ce type a été développée par Tanabe et al. (27) en infrarouge. Un premier réseau effectue une classification en 40 catégories (les éléments du vecteur de sortie sont alors des indicateurs d'appartenance à ces classes). Pour chacune d'entre elles, un deuxième réseau effectue alors la reconnaissance des composés (les éléments du vecteur de sortie étant ici associés individuellement à un composé spécifique). Le vecteur de sortie peut aussi être utilisé pour contruire une clef permettant de retrouver rapidement un spectre particulier dans une collection de spectres (28).

Architecture

La définition des vecteurs d'entrée et de sortie détermine corrélativement le nombre de neurones (cellules) des couches d'entrée (*NE*) et de sortie (*NS*). Il a été montré que les réseaux ayant une couche intermédiaire (couche cachée) ont des performances légèrement supérieures aux réseaux qui n'en possèdent pas (9, 11). Il reste donc à fixer le nombre de (*NC*) cellules dans cette couche et éventuellement le nombre de couches cachées. Ce nombre dépend aussi du nombre d'exemples disponibles pour effectuer l'apprentissage. En effet, il est souhaitable de limiter la taille des réseaux pour éviter le phénomène de sur-apprentissage. Une règle empirique, pas toujours respectée, donne comme valeur indicative $NC = 2NE + NS$, mais la plupart des auteurs fixent ce nombre arbitrairement ou sur la base d'essais plus ou moins systématiques.

Le tableau 1 donne l'architecture des réseaux employés par différents auteurs ainsi que le type de codage du vecteur d'entrée.

Ensembles d'apprentissage et de test

La conduite des phases d'apprentissage et de test requiert la constitution d'ensembles d'exemples formés des spectres et des structures correspondantes, ces spectres et structures étant transformés respectivement en vecteurs d'entrée et de sortie avant leur utilisation. La taille et la composition de ces ensembles sont très importantes. En effet, il faut qu'ils soient représentatifs de la population de molécules dont on cherchera à établir la structure une fois le réseau mis au point. Par ailleurs, le nombre de connexions pouvant être assez élevé, il faut disposer d'un nombre d'exemples suffisamment grand pour réduire l'indétermination portant sur les poids de ces connexions. Les ensembles sont le plus souvent constitués par tirage aléatoire parmi les collections d'exemples disponibles. Il est néanmoins nécessaire de vérifier que les distributions dans ces ensembles des motifs structuraux retenus pour constituer le vecteur de sortie sont bien représentatives de leurs distributions dans la population parente. Cette précaution n'est pas toujours respectée par tous les auteurs. Pour compenser la faible représentation de certains motifs structuraux dans la population parente, Smits et al. (13) introduisent dans l'ensemble d'apprentissage le même exemple plusieurs fois, ou construisent des exemples «synthétiques» par simulation

ou modification d'exemples existants. Dans le même but, et pour sortir des minima locaux dans lesquels le réseau peut se trouver, Klawun et Wilkins (14) proposent de poursuivre l'apprentissage avec une sur-représentation des cas «difficiles». Malgré les réserves de principe que peut susciter cette manière de procéder, il semble que les performances du réseau en soient sensiblement améliorées. La taille des spectrothèques disponibles étant forcément limitée et les temps d'apprentissage augmentant rapidement avec le nombre des exemples retenus, on est toujours contraint de faire un compromis. Le tableau 2 donne les tailles des ensembles d'apprentissage et de test utilisés dans les travaux cités en références. Il est à noter que pour la plupart d'entre eux, les ensembles de test sont de taille inférieure aux ensembles d'apprentissage. Dans ces conditions, il est difficile d'apprécier la capacité des réseaux à généraliser.

PASCAL Programme développé par les auteurs en PASCAL.

Conduite de l'apprentissage

L'algorithme classique de la rétropropagation du gradient est le plus utilisé pour l'apprentissage des réseaux multicouches. Les paramètres de l'apprentissage (vitesse d'apprentissage et inertie) sont souvent ajustés empiriquement de sorte que la convergence du réseau soit rapidement obtenue.

En ce qui concerne le nombre d'épochs, il importe que l'apprentissage soit interrompu avant que le réseau n'entre dans la phase de sur-apprentissage au cours de laquelle il commence à mémoriser des détails non significatifs des spectres, ce qui détériorerait son aptitude à la généralisation. Deux types de critères sont utilisés comme condition d'arrêt. Des critères a priori qui interrompent l'apprentissage dès que l'erreur globale du réseau (somme des carrés des écarts) ou l'erreur globale cumulée sur une sous-population tirée au hasard devient inférieure à un seuil fixé arbitrairement à l'avance. Ces critères conduisent à de bons résultats pour des réseaux mono-sortie mais, pour les réseaux multi-sorties, ils ignorent les disparités qui peuvent exister dans la rapidit de convergence pour chaque motif structural à reconnaître. On peut également utiliser une condition d'arrêt optimisée. Il s'agit en fait de suivre, au fur et à mesure de l'apprentissage, les performances du réseau sur un ensemble de test et ce pour chaque sortie. On peut dès lors mettre fin à l'apprentissage lorsque le niveau de performances ne s'améliore plus et avant que le sur-apprentissage ne commence à le dégrader. Ce critère serait sans doute parfait si les performances optimales étaient toutes obtenues simultanément pour toutes les sorties, ce qui est rarement le cas. Il faut alors trouver un compromis entre les différents optima afin de fixer un nombre de cycles d'apprentissage en tenant compte de la plus ou moins grande rapidité de convergence des sorties. Si les disparités sont trop importantes, il peut être préférable de séparer en deux réseaux distincts les sorties qui convergent rapidement de celles qui demandent un plus grand nombre de cycles d'apprentissage.

Evaluation des performances

Pour évaluer les performances des réseaux, aussi bien en reconnaissance qu'en prévision, on utilise deux catégories d'indicateurs : ceux construits à partir des écarts entre les valeurs de sortie calculées par le réseau et les valeurs attendues, et ceux qui se fondent sur les réposes obtenues après classification. Pour effectuer cette classification, chaque valeur de sortie *So* (valeur réelle généralement comprise entre 0 et 1) doit être convertie en une réponse booléenne $R \in$ [**Vrai**, **Faux**] relative à la présence de l'élément structural qui lui est associé. On adopte souvent une logique trimodale en ajoutant la valeur **Indéfini**. Pour cela il est nécessaire de fixer des seuils : *SA* seuil d'acceptation et *SR* seuil de rejet, tels que $R =$ **Faux** pour *So* inférieur à *SR*; $R =$ **Indéfini** pour *So* compris entre *SR* et *SA* inclusivement et $R =$ **Vrai** pour *So* supérieur à *SA*. Les valeurs des seuils *SA* et *SR* sont le plus souvent fixées arbitrairement mais peuvent aussi être optimisées en fonction du critère de performance retenu (11).

Il est très difficile de comparer rigoureusement les performances des réseaux décrits par les différents auteurs car ils n'utilisent pas tous les même indicateurs. De plus, des indices portant le même nom ne sont pas toujours définis de la même façon. Par exemple, un des indices les plus fréquemment mis en avant : le taux de réponses exactes, est parfois calculé en ajoutant au score la valeur 1 pour les réponses correctes (sans faire la distinction entre réponses positives et négatives) et 0,5 pour les cas douteux, tandis que d'autres auteurs ne comptent que les réponses correctes. De plus, l'ensemble des données nécessaires à la comparaison des résultats obtenus n'est pas toujours publié. Certains indices, en particulier le taux global de réponses exactes, dépendent de la probabilité a priori de trouver le ou les motifs structuraux considérés, donc de leurs proportions dans les populations étudiées, et donnent souvent une image exagérément flatteuse des performances réelles du réseau. La question de la validation et de l'évaluation des réseaux est discutée dans la référence 31; pour une revue critique des indices utilisés voir Sbirrazzuoli et al. (29).

Malgré ces difficultés de comparaison, il ressort clairement des travaux publiés que les réseaux neuro mimétiques à couches atteignent, dans le domaine qui nous intéresse, des niveaux de performances égaux ou supérieurs aux méthodes utilisées classiquement pour la classification des spectres (26, 32). Certains essais, qui demandent à être confirmés, montrent même que leurs performances supportent la comparaison avec celles d'étudiants avancés (15) voire de praticiens expérimentés (13), cependant cette conclusion reste controversée (12).

Application pratique au laboratoire d'analyse

Les logiciels répertoriés dans le tableau 2, col. 5 sont spécifiquement conçus pour faciliter la construction de nouveaux réseaux, la conduite de leur apprentisage et l'évaluation de leurs performances, mais ne sont pas bien adaptés à une utilisation pratique au laboratoire d'analyse. En effet, pour ce type d'utilisation, il est nécessaire de disposer d'un logiciel qui : (*i*) construise automatiquement le vecteur d'entrée à partir du spectre du composé inconnu en fonction des caractéristiques retenues pour le réseau spécifique à appliquer; (*ii*) soumette ce vecteur d'entrée au réseau dont l'architecture et les poids des connexions auront été préalablement déterminés au cours de la phase d'apprentissage; (*iii*) calcule le vecteur de sortie; (*iv*) applique éventuellement la méthode de seuillage retenue pour produire les réponses concernant les différents motifs structuraux à reconnaître; (*v*) permette éventuellement d'appliquer plusieurs réseaux pour une même molécule inconnue et donne une présentation synthétique des résultats obtenus.

Une telle application en spectroscopie infrarouge a été

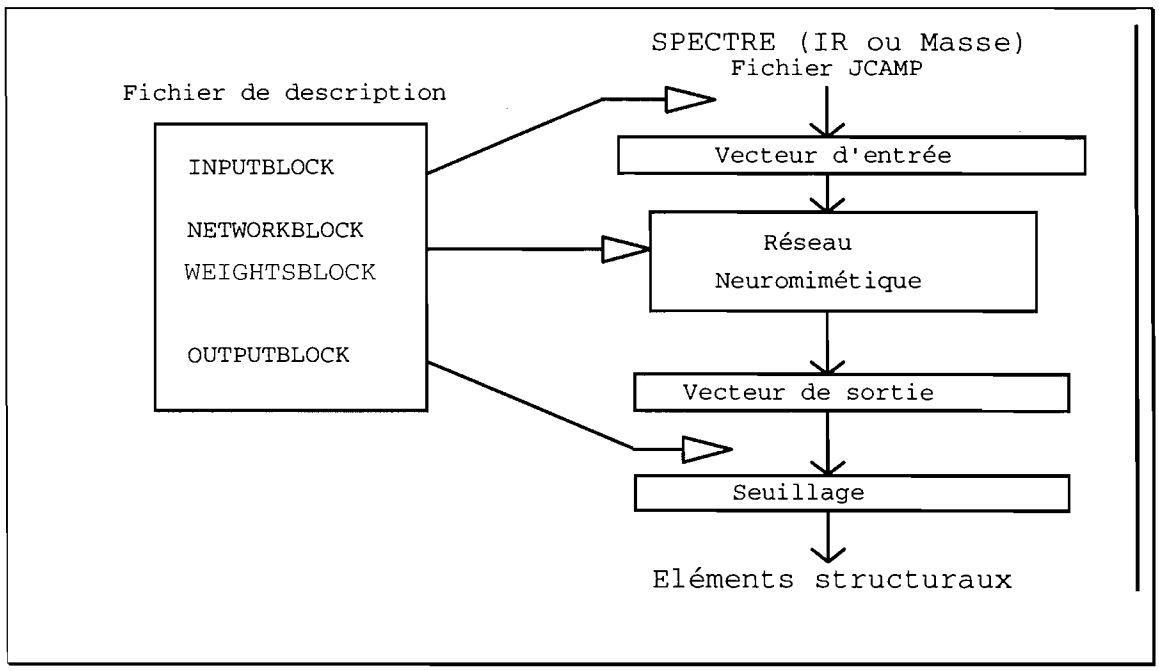
Fig. 1. Schéma fonctionnel du programme ANNE pour le traitement d'un spectre.



développée récemment par van Est et al. (7) sur mini-ordinateur VAX sous VMS. Les fichiers décrivant les réseaux (architecture et poids) qui résultent de la phase d'apprentissage conduite sur une station Sun SPARC sont préalablement chargés sur le VAX. Le spectre infrarouge du composé inconnu au format standard JCAMP-DX (33) est ensuite transmis du spectromètre à un PC par la voie série RS232 suivant le protocole KERMIT, puis du PC au mini-ordinateur VAX par le réseau Ethernet suivant le protocole NFS. Cette solution n'est pas généralisable aux laboratoires d'analyse qui n'ont pas tous accès à un réseau Ethernet ni à un mini-ordinateur VAX, aussi avons-nous préféré développer un programme unique, dénommé ANNE (Artificial Neural Network Executable), qui puisse être exploité entièrement sur un PC standard fonctionnant sous MS-DOS, tel que ceux généralement couplés aux spectromètres et s'appliquant aussi bien à la spectroscopie infrarouge qu'à la spectrométrie de masse. Contrairement aux apprentissages qui peuvent être assez longs, la conversion des spectres et l'application d'un réseau est extrêmement rapide et il n'y a pas d'immobilisation du PC.

Après apprentissage effectué sur station UNIX à l'aide du logiciel ASPIRIN et détermination par optimisation des valeurs des seuils, toutes les informations relatives à un réseau particulier et au mode de codage des spectres sont rassemblées dans un fichier de description ASCII dont le format est inspiré du standard JCAMP.

Ce fichier se compose des sections ou blocs suivants : (*i*) un en-tête qui permet d'identifier le réseau et spécifie le type de spectroscopie utilisée; (*ii*) le bloc de description du réseau (NETWORKBLOCK) qui contient la topologie du réseau (nombre de noeuds dans chaque couche), et qui spécifie la fonction de transfert utilisée (*iii*) le bloc de description du vecteur d'entrée (INPUTBLOCK) qui contient les informations nécessaires au prétraitement du spectre brut pour construire le vecteur d'entrée; (*iv*) le bloc de description des sorties (OUTPUTBLOCK) qui contient pour chaque sortie le nom de l'élément structural correspondant, les valeurs des seuils et éventuellement les degrés de confiances attribués à chaque réponse; (*v*) le bloc des poids (WEIGHTSBLOCK) qui contient les valeurs des bias et des poids des connections entre cellules.

Le début de chaque bloc et chaque champ d'information à l'intérieur d'un bloc est précédé d'un label qui permet de l'identifier. Les dits labels sont placés en début de ligne et commencent par ##. Seul le block de description du vecteur d'entrée a un contenu qui dépend du type de spectroscopie. Les spécifications complètes du fichier de description des réseaux sont données en annexe. Des exemples de fichiers de description sont contenus avec des fichiers spectres et le programme exécutable ANNE dans la disquette de démonstration qui peut être obtenue auprès des auteurs.[2]

Ces fichiers (un par réseau) peuvent être distribués aux utilisateurs du laboratoire d'analyse par tout système de transfert de fichiers, voire sur disquette. En fait, rien n'impose que ces fichiers résultent du logiciel ASPIRIN que nous utilisons. Si on respecte son format (voir annexe) il peut contenir les résultats obtenus avec n'importe quel autre logiciel de simulation de réseaux neuro mimétiques. L'application des réseaux ainsi décrits est prise en charge par le programme ANNE, lequel est écrit en Pascal orienté objet (Turbo Pascal 6.0). L'architecture des réseaux ainsi que les dimensions des vecteurs d'entrée et de sortie étant variables d'une application à l'autre, il a fallu prévoir une allocation dynamique de la mémoire pour les grandes matrices et vecteurs manipulés par le programme. Pour cela, nous avons fait appel aux unités contenues dans «Object Professional» de Turbo Power Software.

Les spectres à interpréter doivent être disponibles au format

[2] Pour obtenir une copie du programme exécutable ainsi que des exemples de fichiers de description des réseaux envoyer une disquette 3,5 HD formatéee à D.C-B.

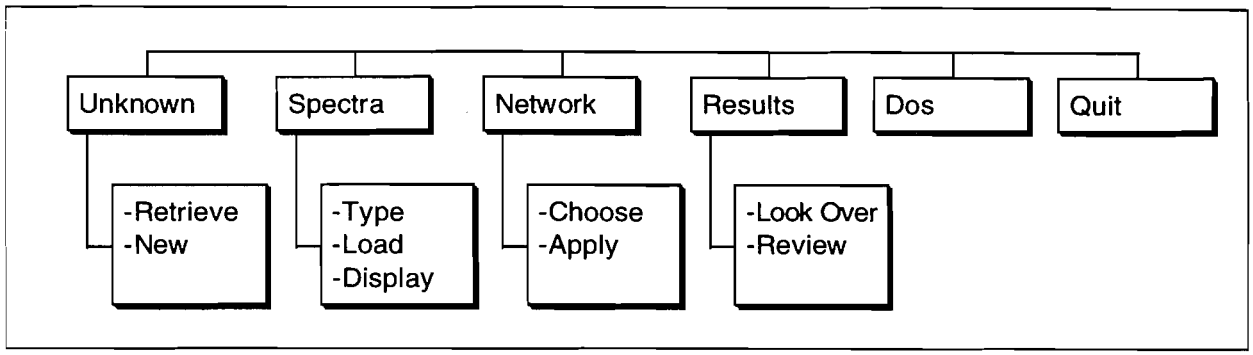
Fig. 2. Système de menu du programme ANNE.



Unknown

Retrieve : Reprise de l'étude d'une structure déjà partiellement élucidée.

New : Initialisation de l'étude d'une nouvelle substance de structure inconnue.

Spectra

Type : Choix du type de spectroscopie.

Load : Chargement du spectre correspondant à la substance en cours d'étude.

Display : Visualisation du spectre à l'écran.

Network

Choose : Choix du réseau neuro mimétique et chargement des poids.

Apply : Application du réseau au spectre sélectionné puis examen des résultats obtenus pour décider de leur rejet ou de leur archivage.

Results

Review : Examen de la synthèse des conclusions relatives à la substance étudiée tirées par tous les réseaux employés précédemment et archivés.

Look over : Examen des résultats du dernier réseau appliqué.

DOS : Accès au système d'exploitation.

standard JCAMP-DX (33). Pour les spectres infrarouge cela ne pose pas de problème; en effet, la plupart des spectromètres disposent de cette facilité. Les données seront enregistrées suivant la spécification ##XYDATA=(X++(Y..Y)). Cela n'est pas aussi simple pour les spectres de masse pour lesquels le standard JCAMP-DX n'est pas aussi répandu. Aussi peut-il être nécessaire d'écrire un programme de conversion pour disposer du spectre de masses au format JCAMP-DX; dans ce cas, les données seront enregistrées suivant la spécification ##XYDATA=(XY..XY).

Le programme ANNE est doté d'une interface utilisateur organisée autour d'un menu hiérarchique dont les options principales sont représentées dans la figure 2. Le système dispose d'un système d'aide contextuelle qui rend inutile la consultation d'un manuel d'utilisation. Les opérations sont logiquement effectuées dans l'ordre des options et sous options proposées par le menu, mais il est possible de revenir en arrière ou de procéder dans un ordre différent.

Le premier traitement effectué lors de l'application d'un réseau par le programme consiste à convertir le spectre expérimental en vecteur d'entrée, conformément aux spécifications contenues dans la partie INPUTBLOCK du fichier de description du dit réseau. Les spécifications pour cette conversion sont différentes suivant le type de spectre, mais le résultat est le même, à savoir : le vecteur d'entrée constitué d'une série de nombres réels. Dans le cas d'un spectre infrarouge, les spécifications de conversion sont simples puisqu'elles consistent seulement à préciser quelles sont les plages de fréquences à prendre en compte et la résolution à retenir pour chacune d'entre elles. Pour les spectres de masse il est bien connu que l'utilisation exclusive des intensités des pics est insuffisante et qu'il faut leur adjoindre des descripteurs supplémentaires construits à partir de ces pics. La syntaxe adoptée pour la partie INPUTBLOCK permet de spécifier la plupart des descripteurs utilisés classiquement (23–25). Si nécessaire, il est facile d'implémenter de nouveaux descripteurs dans l'unité Pascal contenant les routines de conversion des spectres de masse. Le temps total de chargement et de conversion d'un spectre d'une part et de chargement et d'application d'un réseau d'autre part ne dépasse pas 1 s sur un PC 486DX à 33 MHz.

Pour une même spectroscopie, plusieurs réseaux peuvent avoir été mis au point et pourront être appliqués l'un après l'autre aux mêmes données spectrales. Evidemment, les conversions à effectuer peuvent être différentes pour chacun d'eux. Les résultats obtenus par le réseau employé et pour chacune de ses sorties sont présentés immédiatement accompagnés, s'il y a lieu, de l'indication du degré de confiance qui s'y rattache. L'ensemble des résultats obtenus, pour une même substance de structure inconnue, par tous les réseaux qui auront été employés est présenté d'une manière synthétique grâce à l'option Review (voir figure 3). Cette présentation permet de mettre en évidence les convergences, complémentarités et éventuelles divergences dans les conclusions obtenues par les différents réseaux appliqués.

Exemple d'application

À titre d'exemple, nous utiliserons les résultats obtenus avec deux réseaux : l'un traitant les spectres infrarouge (29), l'autre les spectres de masse[3] qui permettent de reconnaître des motifs structuraux assez généraux figurant dans le tableau 3.

Dans ce tableau, nous avons porté les valeurs des seuils de SR et SA utilisées pour décider respectivement de l'absence ou de la présence du motif structural. Figurent également les valeurs de deux indicateurs de performance des réseaux : la qualité globale (GQ) et la qualité extra-statistique (EQ). La qualité globale est définie par le rapport du nombre de réponses exactes au nombre d'exemples traités $GQ = (IPc + IAc)/N_t$, avec IPc = nombre de réposes positives correctes, IAc = nombre de réposes négatives, N_t = nombre total de cas traités. Cette grandeur est souvent la seule donnée par les auteurs; bien qu'ayant une significant simple, elle peut donner une idée exagérément optimiste des performances d'un réseau car elle inclut la probabilité a priori de trouver une réponse exacte. Aussi avons-nous introduit (29) la qualité extra-statistique (EQ) qui ne présente pas cet inconvénient et qui permet une comparaison plus fine des performances de différents réseaux. $EQ = (GQ - S_t)/(1 - S_t)$; avec $S_t = 1 + 2P_i + 2P_i^2$ probabilité a priori de répondre juste lorsque la proportion du motif i dans la population est P_i. La qualité extra statistique représente donc l'amélioration relative apportée par le réseau par rapport à la probabilité a priori de répondre juste.

Les performances atteintes sont très satisfaisantes pour tous les motifs structuraux étudiés. On observe cependant des différences entre les deux types de spectroscopie. En particulier on note que, comme on pouvait s'y attendre, la spectroscopie infrarouge est plus efficace pour reconnaître les groupements fonctionnels, notamment oxygénés. La spectrométrie de masse, de son côté, donne des indications plus variées et plus fiables sur le squelette hydrocarboné.

Pour la très grande majorité des molécules mono ou polyfonctionnelles examinées, tous les motifs structuraux présents sont bien reconnus. Les réponses faussement négatives sont rares et correspondent dans la plupart des cas à des situations particulières (équilibre céto-énoliques, molécules particulièrement encombrées, interactions entre groupes fonctionnels voisins, conjugaison, etc...).

Par exemple, pour l'acide benzoïque tous les motifs structuraux présents ou absents sont correctement identifiés par les deux réseaux à l'exception du groupe acide carboxylique. Celui-ci est détecté sans ambiguïté comme étant présent par le réseau (IRNET.IRN) opérant sur le spectre infrarouge (motif IR3, $So = 0.990$) mais n'est pas reconnu par le réseau (MASSNET.MSN) en spectrométrie de masse (motif SM2, $So = 0.024$) ainsi que cela apparaît dans l'extrait d'écran de la figure 3. Cette apparente contradiction entre les réponses fournies par les deux réseaux s'explique et peut être tournée en avantage. En effet, nous avons observé que les réponses fournies par le réseau en spectrométrie de masse sont fortement influencées par le fait que le motif structural recherché est porté ou non par un système aromatique. En particulier, pour le groupe «Acide carboxylique» le réseau en spectrométrie de masse ne donne de réponses positives que pour les acides aliphatiques alors que le réseau en infrarouge donne des réponses positives pour tous les types d'acides. Dans le cas présent, l'existence du noyau aromatique étant détectée sans ambiguïté par les deux techniques (Motif IR10, $So = 0.997$. Motif SM13, $So = 0.732$), on peut facilement conclure que le groupe acide carboxylique détecté en infrarouge est porté par le noyau aromatique et que c'est pour cette raison qu'il n'est pas détecté en spectrométrie de masse. Dans ce cas particulièrement simple il est donc facile de construire la structure correcte. Evidemment, pour des structures plus complexes on ne peut pas espérer obtenir aussi facilement une solution complète. Cependant l'utilisation combinée des deux spectroscopies, qui se trouve facilitée par le programme ANNE, permet de tels recoupements qui facilitent l'élaboration d'une structure.

Conclusion

Les réseaux neuro mimétiques constituent une technique de classification des données spectrales dont les performances égalent ou dépassent celles des techniques employées plus classiquement.

Si leur mise au point peut être longue et demander des équipement informatiques spécifiques, leur application au laboratoire d'analyse peut se faire avec des matériels largement disponibles. Le logiciel présenté permet d'exploiter très simplement cette technique. Pour chaque substance de structure inconnue dont on dispose des spectres, le programme présente sous la forme d'un tableau synthétique l'ensemble des réponses fournies par les différents réseaux neuro mimétiques mis en oeuvre. Les convergences, complémentarités et divergences éventuelles dans les conclusions sont ainsi clairement mises en évidence. Evidemment, l'utilité de ce programme se trouvera renforcée par la disponibilité de réseaux neuro mimétiques performants permettant de déduire la présence ou l'absence de motifs structuraux plus nombreux et variés que ceux disponibles pour l'instant. La construction et l'apprentissage de tels réseaux est en cours dans notre laboratoire. Le format de description des réseaux que nous proposons permet l'échange des réseaux entre équipes utilisant des matériels et des logiciels différents.

Annexe : Specifications du fichier de description des reseaux

Nom : XXXXX.MSN ou IRN

Les informations figurant en police `Courier Bold` telles que : ##INPUTBLOCK sont des mots réservés (labels) qui doivent apparaître tels quels. Les informations données en police *Times Roman Italique* doivent être remplacées par une donnée.

Le fichier est constitué d'un en-tête et de quatre blocs : le bloc de description de l'architecture du réseau, le bloc de description du vecteur d'entrée, le bloc de descriptions vecteur de sortie et le bloc des poids des connexions.
Chaque bloc et chaque type d'information à l'intérieur d'un bloc est précédé d'un label qui permet de l'identifier.
Les labels sont placés en début de ligne et commencent par ##
Le fichier se termine par une ligne contenant le label ##END

Structure générale

En-tête
##NETWORKBLOCK
Bloc de description de l'architecture du réseau
##INPUTBLOCK
Bloc de description du vecteur d'entrée (dépend du type de spectroscopie)
##OUTPUTBLOCK
Bloc de description du vecteur de sortie
##WEIGHTSBLOCK
Bloc contenant les poids des connexions
##END

##INPUTBLOCK	Label de début du bloc
##CONVTYPE = *ConvType* [1]	*ConvType* = Type de conversion à effectuer sur les données [2] *ConvType* ∈ {0, 1, 2} *ConvType* = 0 : Les données ne sont pas modifiées. 1 : Les données sont codées par seuillage 2 : Les données sont transformées par l'équation [3] Si *ConvType* = 1, les lignes suivantes préciseront le nombre de niveaux et les seuils:
##NBLEVELS = *NbLevels* *Seuil Valeur*	*NbLevels* = Nombre de niveaux de seuillage [4] *NbLevels* Lignes suivantes : *Seuil* = Seuil supérieur de chaque niveau *Valeur* = Valeur attribuée aux signaux entrant dans ce niveau
##DETECTLEVEL = *DetectLevel*	*DetectLevel* = Valeur du seuil de détection d'un pic. [5].
##NBRANGES = *NbRanges* *Li Ls*	*NbRanges* = Nombre de plages à prendre en compte [6] *NbRanges* lignes suivantes : *Li* = Limite inférieure de la plage *Ls* = Limite supérieure de la plage
##NBPEAKS = *NbPeaks* *MZ*	*NbPeaks* = Nombre de pics individuels à prendre en compte [7]. *NbPeaks* Lignes suivantes : *MZ* = Valeur du rapport M/Z de chaque pic à prendre en compte.
##NBDIFFERENCES = *NbDiff* *DX*	*NbDiff* = Nombre de différences clefs à prendre en compte [8] *NbDiff* Lignes suivantes : *DX* = Valeur telle que M/Z = M-DX est à prendre en compte
##NBSETS = *NbSets* *NbPs* $M_1\ M_2\ \ldots\ M_{NbPs}$	*NbSets* = Nombre d'ensembles de pics à prendre en compte [8]. 2x*NbSets* lignes suivantes : *NbPS* = Nombre de pics dans un ensemble $M_1\ M_2\ \ldots\ M_{NbPs}$: Valeurs des rapports M/Z des pics de l'ensemble considéré.
##NBSERIES = *NbSeries* *Raison Début*	*NbSeries* = Nombre de séries de pics à prendre en compte [9]. *NbSeries* lignes suivantes : *Raison* = Raison de la série *Débutt* = Rapport M/Z du premier pic de la série.
##NBPATTERNS = *NbPatterns* *NbPT* $M_i\ I_i$	*NBPatterns* = Nombre de "Patterns" à prendre en compte [10] *NbPattern* Groupes de lignes suivantes *NbPt* = Nombre d'éléments dans le pattern *NbPT* Lignes suivantes : $M_i\ I_i$: valeurs du rapport M/Z et de l'intensité du *i* ième pic du "Pattern".
##NBATCSUMS = *NbAtcSums* *Patc*	*NbAtcSums* = Nombre de sommes d'autocorrélations à prendre en compte [11] *NbAtcSums* lignes suivantes : *Patc* = paramètre d'autocorrélation
##NBCONSTSUMS = *NbCstSums* *PSum*	*NbCstSums* = Nombre de sommes constantes à prendre en compte [12] *NbCstSums* lignes suivantes : *PSum* = Paramètre de somme constante
##NBISOTOPIC = *NbIsotop* *DecIsoptop*	*NbIsotop* = Nombre de pics isotopiques à prendre en compte [13] *NbIsotop* lignes suivantes : *DecIsotop* décalage isotopique

[1] Seul le paramètre ##CONVTYPE = *ConvType* est obligatoire et doit figurer en premier, les autres sont facultatifs et peuvent être donnés dans n'importe quel ordre. Cet ordre détermine l'ordre des éléments dans le vecteur d'entrée.

[2] Les spectres sont normalisés entre 0 et 1 par rapport au pic de base préalablement à tout traitement.

[3] $I_M = (\log_2(1 + L_M/1000))^{1/2}$

[4] Le codage par seuillage permet d'effectuer une transformation non-linéaire sur les signaux.
Exemple :
##NBLEVELS = 4
0.2 0.0
0.6 0.4
0.8 0.8
1.0 1.0

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

Les signaux dont l'intensité I est $0.0 < I <= 0.2$ recevront la valeur 0.0
$0.2 < I <= 0.6$ recevront la valeur 0.4
$0.6 < I <= 0.8$ recevront la valeur 0.8
$0.8 < I <= 1.0$ recevront la valeur 1.0

[5] Les signaux dont la valeur d'intensité après codage est inférieure au seuil indiqué par *DetectLevel* sont affectés de la valeur 0. Cette opération ne s'applique pas aux pics isotopiques.

[6] Toutes les valeurs de *M/Z* dans les plages ($Li <= M/Z <= Ls$) ainsi définies constituent autant d'éléments du vecteur d'entrée.
Exemple :
##NBRANGES = 1
40 220
Retient toutes les valeurs comprises entre 40 et 220 bornes incluses comme autant d'éléments du vecteur d'entrée.

[7] Ajoute les pics énumérés comme éléments du vecteur d'entrée.
Exemple :
##NBPEAKS = 5
112
124
141
156
167
Retient toutes les valeurs correspondantes à *M/Z* = 112, 124, 141, 156, 167 comme éléments du vecteur d'entrée.

[8] Ajoute les pics M – DX comme éléments du vecteur d'entrée
Exemple :
##NBDIFFERENCES = 4
18
28
46
54
Retient toutes les valeurs à M – 18, M – 28, M – 46 et M – 54 comme éléments du vecteur d'entrée.

[9] Ajoute la moyenne des valeurs de chaque ensemble défini comme élément du vecteur d'entrée.
Exemple :
##NBSETS = 2
4
79 81 93 95
6
55 67 81 91 95 107
Ajoute les éléments $\frac{1}{4}(I_{79} + I_{81} + I_{93} + I_{95})$ et $\frac{1}{6}(I_{55} + I_{67} + I_{81} + I_{91} + I_{95} + I_{107})$ au vecteur d'entrée.

[10] Ajoute un indice de similarité avec un schéma prototypique (pattern) défini. Pour chaque schéma défini par un vecteur prototype formé des intensités correspondantes à une série de valeurs de *M/Z*, cet indice est calculé en faisant le produit scalaire de ce vecteur prototype par le vecteur extrait du spectre pour les mêmes valeurs du rapport *M/Z* (25).
Exemple :
##NBPATTERNS = 1
4
41 0.60
55 0.34
67 0.31
79 0.41
Ajoute la valeur du produit scalaire entre le vecteur prototype Vp = [0.60, 0.34, 0.31, 0.41] et le vecteur extrait du spectre pour les mêmes valeurs de *M/Z* Vs = $[I_{41}, I_{55}, I_{67}, I_{79}]$ au vecteur d'entrée.

[11] Ajoute les sommes d'autocorrélations normalisées au vecteur d'entrée (23).
Exemple :
##NBNBATCSUMS = 1
14
Ajoute la valeur de AC(14)/AC(0) au vecteur d'entrée.
$AC(\Delta m) = \sum_{m=1}^{m=L-\Delta m} I_m \cdot I_{m+\Delta m}$ avec Δm paramètre d'autocorrélation et L plus forte masse.

[12] Ajoute des termes *Cps* dits «constant summ» définis par réf. 24 au vecteur d'entrée.
Exemple :
##NBNCONSTSUMS = 1
28
Ajoute la valeur de $Cps = (\sum_m I_m \cdot I_{M+ps-m})/I_B$ pour ps = 28; I_B : intensité du pic de base. *ps* : masse de la partie commune.
Nota : Les pics intervenant dans le produit sont tels que la somme de leur valeur de *M/Z* est égale à la masse moléculaire M + le paramètre choisi ps.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

[13] Ajoute les intensités des pics isotopiques spécifiés au vecteur d'entrée. Noter que cette intensité échappe à l'application du paramètre *DetectLevel.*

Bloc de description du vecteur de sortie

Poly *N*-(2-cyanoethyl)pyrrole as a selective film for the thickness-shear-mode acoustic wave sensor

Zhiping Deng, David C. Stone, and Michael Thompson

Abstract: Poly *N*-(2-cyanoethyl)pyrrole films have been synthesized by electrochemical polymerization and characterized by cyclic voltammetry, scanning electron microscopy, and X-ray photoelectron spectroscopy. Polymeric coatings prepared on the surface of a thickness-shear-mode acoustic wave sensor have been used to examine response selectivity to a number of gas-phase probe molecules. The responses of the poly *N*-(2-cyanoethyl)pyrrole based sensor are compared with the parent polypyrrole device and rationalized in terms of the molecular interactions between probes and polymer films. The polar cyano functionality enhances interactions with analytes such as acetonitrile.

Key words: gas sensor, thickness-shear-mode acoustic wave sensor, poly *N*-(2-cyanoethyl)pyrrole film, polypyrrole film, conducting polymer.

Résumé : On a synthétisé des films de poly *N*-(2-cyanoéthyl)pyrrole par polymérisation électrochimique et on les a caractérisés par voltampérométrie cyclique, microscopie électronique à balayage et par spectroscopie photoélectronique des rayons X. On a utilisé les revêtements polymériques préparés sur la surface d'un senseur d'onde acoustique dans le mode de cisaillement de l'épaisseur pour examiner la sélectivité de la réponse à un certain nombre de molécules sondes en phase gazeuse. On a comparé les réponses du senseur basé sur le poly-*N*-(2-cyanoéthyl)pyrrole avec celles de l'équivalent ne portant que le polypyrrole parent et on a rationalisé les différences en fonction d'interactions moléculaires entre les sondes et les films de polymère. Une fonction polaire cyano augmente les interactions avec les produits à analyser, comme acétonitrile.

Mots clés : senseur de gaz, senseur d'onde acoustique dans le mode cisaillement de l'épaisseur, film de poly-*N*-(2-cyanoéthyl)pyrrole, film de polypyrrole, polymère conducteur.

Introduction

Films or coatings of polypyrrole (PPY) and its derivatives have proven to be extremely useful in the fabrication of gas-phase chemical sensors (1). These materials possess unique electronic, magnetic, and optical properties that allow their molecular recognitive capabilities to be coupled directly with electronic circuits in a sensor configuration (2). The ease of preparation by electrochemical polymerization together with their chemical stability under normal conditions have contributed to the application of polypyrroles in various sensing systems for more than a decade (3, 4).

Polypyrrole films display fast reversible changes in conductivity when exposed to gases or vapours (5). This phenomenon makes them attractive for application as chemical sensors based on conductivity changes. Bartlett and Ling-Chung (6) investigated the behaviour of a sensor with respect to reversible changes in the presence of various saturated organic vapours. They found that the response of a polypyrrole film to a gas depended on both the nature of the analyte and the semiconducting properties of the polymer.

Polypyrrole has also been used as a chemically selective layer on thickness-shear-mode (TSM) acoustic wave devices for gas sensing. Adsorption of gas-phase species into the polypyrrole layer causes a shift in the series resonant frequency of the piezoelectric crystal. The Sauerbrey equation (7) can then be used to describe the resulting relationship between mass change and frequency shift. This sensing process involves sorption of the molecules both on and into the polymer film, and so is dependent on film structure and functionality. For example, using a combination of polypyrrole-coated TSMs with optical spectroscopy and work function measurements, Topart and Josowicz (8) were able to study the interaction between methanol and polypyrrole. The combination of conductivity together with piezoelectric measurements has also been employed to examine the interaction between polypyrrole and different vapours (9). Slater et al. (10), for example, showed that simultaneous recording of mass and conductivity changes could be employed to overcome the problem of moisture interference in piezoelectric response.

The properties of polypyrrole (and its derivatives) can be modified both chemically and electrochemically (11), allowing fine tuning of its capabilities for selective adsorption. In this context, Wallace and co-workers (12, 13) reported the use of polypyrrole film as a stationary phase in liquid chromatography and concluded that subjecting the films to different

Received March 28, 1995.

For personal use only.

potentials affected their selectivity, thus altering the partition coefficients.

Thompson and co-workers (14) have studied the effect of different oxidation states of the polymer film with respect to TSM sensor response to several organic gas-phase probes. Their results demonstrated that changing the oxidation state could lead to an enhancement of selectivity and sensitivity. For instance, the greatest sensitivity for toluene was achieved with the neutral polymer, the oxidized form gave the best results for ammonia, while for methanol either extreme oxidation or reduction was preferable. Elliott and co-workers (15, 16) also investigated the absorption of neutral organic species in aqueous solution to the poly(*N*-methyl)pyrrole film in detail. They observed that the partition of dichloromethane into the reduced form is approximately twice that into the oxidized form of poly(*N*-methyl)pyrrole.

The general selectivity of polypyrrole-based sensors is considered poor, however, somewhat limiting their application for detecting gases and vapours. Strategies used to improve their molecular recognitive capability have included the incorporation of different counterions into the polypyrrole film, since this was found to change the morphology of thin films and the concentration of chemical defects (17, 18). Alternative approaches include chemical derivatization (19) and the use of sensor arrays with pattern recognition techniques (10).

In the present work, we describe the fabrication and study of conducting poly *N*-(2-cyanoethyl)pyrrole (PCPY) films, which are expected to provide improved selectivity for certain gases due to the presence of the cyano group.

Experimental

Materials

Methanol, toluene, acetonitrile, triethylamine (Aldrich), and tetrabutylammonium perchlorate (Fluka) were all of analytical reagent grade and used as received. Pyrrole and 1-(2-cyanoethyl)pyrrole were purchased from Aldrich and vacuum-distilled before use.

Equipment

Electrochemical polymerization was carried out in the TSM cell as described previously (14). 9 MHz Gold-coated piezoelectric crystals (International Crystal Manufacturing Co., Oklahoma) were used as the working electrodes (0.25 cm^2 gold on each side) in the polymerization. A combined platinum–Ag/AgCl electrode (Metrohm) functioned as the counter and reference electrode, respectively. All polymer films were deposited onto the electrode from freshly prepared solutions. Either cyclic potential or step potential deposition was performed using a potentiostat (model RDE4, Pine Instrument Company). Before the electropolymerization, electrolyte solutions containing the monomer were degassed by purging with nitrogen for 20 min.

Scanning electron microscopy (SEM) was performed using a Hitachi S-570 SEM with an accelerating voltage of 18 kV. The samples were coated with a very thin gold film by sputter-coating for 60 s at a current of 20 mA. To measure the thickness of the polymers, the polymer-coated crystals were broken across the centre of the electrode.

X-ray photoelectron spectra (XPS) were obtained with a Leybold Max 200 XPS system using an unmonochromatized Mg Kα X-ray source with an analysis area of 2 mm × 4 mm. The source was run at 15 kV and 20 mA. The survey spectra and quantitative atomic measurements were acquired with a pass energy of 192 eV, while high-resolution spectra were obtained with a pass energy of 48 eV. Features in the resultant spectra due to excitation from weaker X-ray satellite lines were subtracted out using an algorithm supplied by the manufacturer. Relative atomic percentages were derived from spectra run in low-resolution mode, normalized to unit transmission of the spectrometer. The sensitivity factors used for the normalized spectra were empirically derived by Leybold. Deconvolution of the high-resolution spectra was again performed using software provided with the spectrometer.

TSM experiments were performed using the oscillator method described previously (14). The conducting polymers used in the current paper are all in the oxidized state as prepared. The oscillation frequency was measured by a universal frequency counter (Hewlett–Packard model 5334B) interfaced to a Macintosh II computer. Data were collected every 6 s.

Gas generation

A gas sample system was designed and constructed to control the flow rate and concentration of the test vapours (Fig. 1). This system employs three bubblers in series to generate the vapour from the corresponding liquid. This is connected as the "sample loop" of a six-port chromatographic injection valve, which allows the bubbler to be isolated from the rest of the flow system at both ends. Separate lines are incorporated to allow dilution of the sample vapour stream and purging of the cell containing the TSM. Mass flow meters (Cole–Parmer) are used in conjunction with needle valves to set and control the flow rates through the bubbler, bypass, dilution, and purge lines. Check valves are also included in each line to allow further isolation of those parts of the system not in use at any one time. Stainless steel components and PTFE tubing were used in all parts of the system where organic vapours could be present.

In normal operation, helium was passed through the bubbler and purge lines continuously at a flow rate of 30 mL/min, a switching valve being used to switch them to the detector cell as appropriate. The concentration of each sample vapour was determined by passing the sample stream through a cold trap for a specific period of time and then weighing the condensed liquid. The values obtained were 45 ± 5 (methanol), 10 ± 3 (toluene), 34 ± 4 (acetonitrile), 29 ± 3 (triethylamine), and 15 ± 5 (water) mg/L. Relative standard deviation for repeated exposure of a given film to a single analyte was typically 1–4%. For different films, the response to the same analyte showed a relative standard deviation of 2–8%. It was also found that the same film could be successfully reused following exposure to different analyte vapours.

Results and discussion

Electrochemical polymerization

Cyclic voltammetry is widely employed to investigate kinetics of electrode processes for electrochemical polymerization and to characterize the resulting polymer film (20). Figure 2 shows typical cyclic voltammograms of the electrochemical polymerization of 0.1 M 1-(2-cyanoethyl)pyrrole in acetonitrile containing 0.1 M tetrabutylammonium perchlorate as the sup-

Fig. 1. Schematic diagram of the gas generation device.

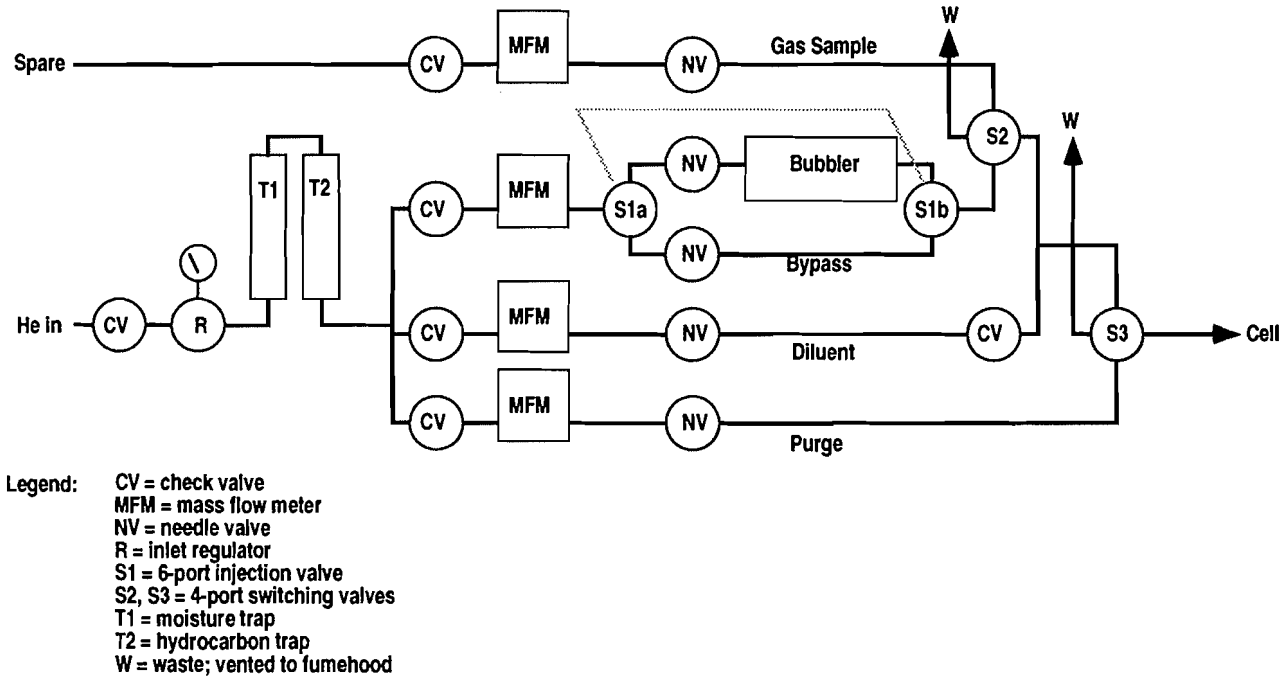

Fig. 2. Cyclic voltammogram of polymerization of 1-(2-cyanoethyl)pyrrole (0.1 M) and 0.1 M tetrabutylammonium perchlorate – acetonitrile at scan rate of 100 mV/s. Scan potential range is from 0.0 to 1.2 V vs. Ag/AgCl (3 M).

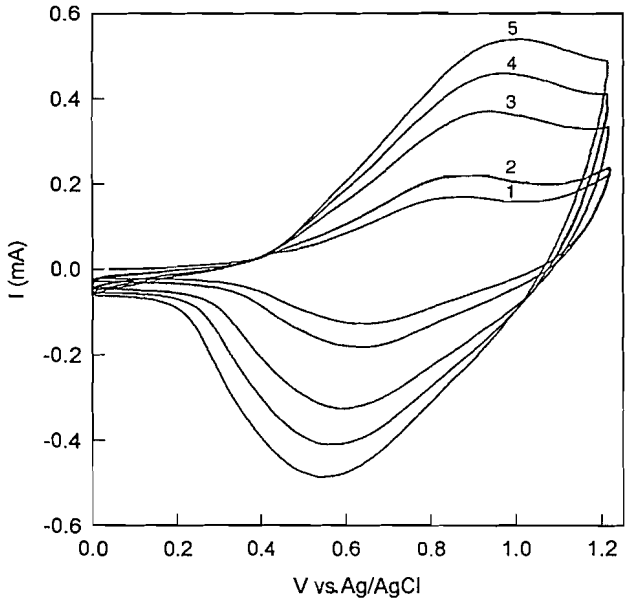
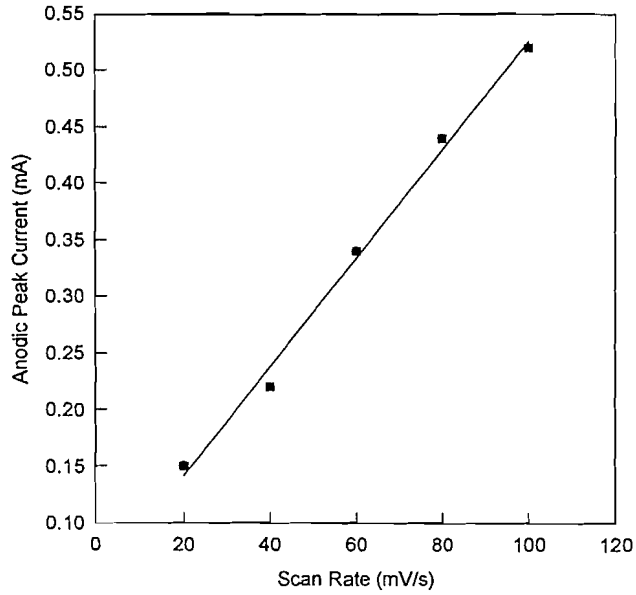
Fig. 3. Cyclic voltammogram of PCPY in 0.1 M tetrabutylammonium perchlorate – acetonitrile without monomer. Scan potential is from 0.0 to 1.2 V. (1) 20; (2) 40; (3) 60; (4) 80; (5) 100 mV/s.



porting electrolyte. The voltammograms were obtained using a cyclic potential from 0.0 to 1.2 V vs. Ag/AgCl (3 M) at a scan rate of 100 mV/s. On the first scan, the current increases sharply upon reaching +1.1 V, indicating the beginning of monomer oxidation. The oxidation potential for 1-(2-cyanoethyl)pyrrole is higher than that for pyrrole because of the steric and electronic effects of the side chain in the 1-(2-cyanoethyl)pyrrole. The inductive effect of this side chain makes oxidation of the monomer more difficult (3). The anodic peak on the second scan is at about +0.7 V, which corresponds to the oxidation of PCPY. As polymerization proceeds, the peak potential moves towards higher potentials, while the corresponding peak current continues to increase until it stops after 22 scans. The rate of current increase is fastest over the initial cycles, then becomes increasingly slower. The anodic peak shift is variously attributed to electrochemical polarization due to a heterogeneous electron transfer, ohmic polarization of film or solution, the mobility of the counterion due to the porosity of the thin film, and a decrease in the film conductivity (21). The cathodic peak for the second cycle is at ca. +0.64 V, which corresponds to the reduction of PCPY. During reduction of the polymer, counteranions (ClO_4^- in this system) diffuse out of the polymer film. It is not surprising that the cathodic peak is much broader than the anodic peak since the counterions diffuse out slowly. The cathodic peak potential also moved to lower potential values with successive scans.

Figure 3 shows the scan rate dependence of the cyclic voltammogram of PCPY in the same electrolyte solution but without the monomer. Well-defined anodic and cathodic peaks were observed. The anodic peak shifts to more positive potential whereas the cathodic peak moves toward lower potential as the scan rate increases, thus increasing the difference between both peaks. The other feature of the cyclic voltammogram is that both anodic and cathodic peaks are very broad, which is characteristic of slow diffusion of the dopant anions in and out of the polymer film (20, 22).

Fig. 4. The dependence of anodic current on the scan rate.



The anodic peak current values in Fig. 3 can be plotted as a function of the scan rate, which helps to determine the mechanism of the electrode process. The graph is shown in Fig. 4. A very linear dependence is obtained, indicating that the electrode process is not controlled by diffusion of electroactive species to the electrode surface. Furthermore, it can be concluded that the electroactive species is effectively localized on the electrode surface (23–25).

Scanning electron microscopy

The morphology of the polymer as electrochemically formed on the electrode of the TSM was examined by SEM. Both normal (microscopically rough) and smooth (optically flat) TSMs were used in order to study the effect of the roughness of the underlying surface. It was found that for very thin films of PCPY deposited using either a step potential (+1.2 V, 40 s) or cyclic voltammetry (10 scans), the polymer film follows the morphology of the electrode very closely. As the film thickness increases, the morphology becomes increasingly different from that of the underlying electrode. Figure 5*a* shows the photomicrograph for a thick film (+1.2 V, 3 min) deposited onto a rough TSM. As the polymer grows on the surface, it assumes a globular form that increasingly fills in the cavities comprising the underlying surface. This results in a "lumpy," non-uniform surface. Figure 5*b* shows the film formed under identical conditions on a smooth TSM. This film was considerably less "lumpy," showing a more consistent film thickness in keeping with the flatness of the underlying electrode. Based on the frequency shifts in air for the deposition process, the same amount of polymer was deposited in each case (~140 μg per side), giving globular films, although the resulting film surface area was greater for the rough than for the smooth TSM. Similar results were obtained for PPY films, and are consistent with results obtained for other polypyrrole derivatives by this group (14). The side view of the same film (Fig. 5*c*) can be used to estimate the film thickness, which was about 2 μm. It is interesting to compare the polymer films pre-

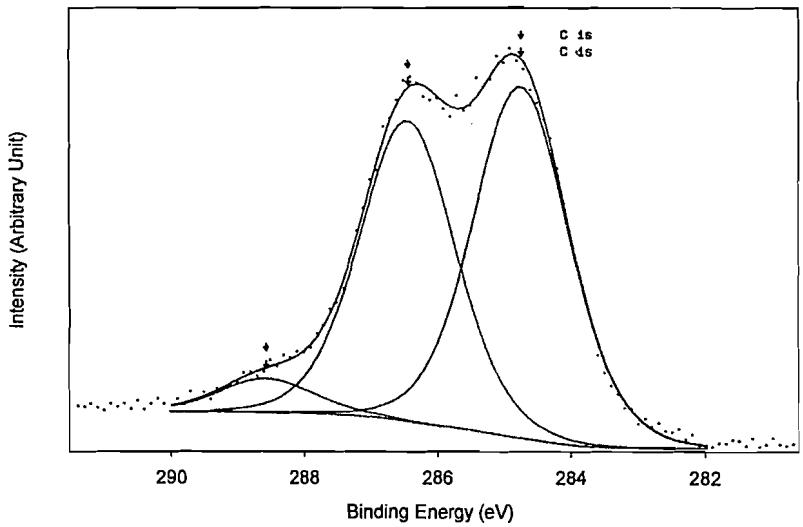
Fig. 6. C(1*s*) X-ray photoelectron spectrum of PCPY.



pared by cyclic voltammetry with those prepared using the step potential method. Although very similar in appearance, the former were found to be more compact, uniform, and less cracked than the latter.

X-ray photoelectron spectra

The C(1*s*) core level spectrum is shown in Fig. 6. The C 1s peak can be deconvoluted into three peaks, corresponding to 284.6, 286.3, and 288.4 eV. The carbon peaks are asymmetric and skewed toward the high-binding-energy side. The peak at 284.6 eV is complex and cannot be assigned to one specific species. It has previously been assigned to the α and β carbons of the pyrrole ring (26). The difference in binding energy between the α and β carbon atoms has been reported as 0.9 eV (27, 28), but the individual lines are difficult to resolve. The peak at 286.3 eV (with intensity almost equal that of the peak at 284.6 eV) is attributed to the carbon atom in the cyano group. This is in disagreement with the assignment previously made with reference to PPY (29), where the peak at 286.2 eV was attributed to carbon bound to the ClO_4^- counterion and the peak at 288.5 eV to the cyano group of trapped acetonitrile solvent. Standard spectra of poly(acrylonitrile) (PAN) and poly(methacrylonitrile) (PMAN), however, have both been used to assign the cyano carbon to 286.7 eV (30). To confirm the assignment, a polypyrrole film was prepared at +1.0 V under identical solution conditions to the PCPY film and XPS analysis performed in the same way. The C 1*s* peak assignments and relative intensities are summarized in Table 1. Comparing the intensities for peaks 1 and 2 shows that the ratio increases from 1:0.30 for PPY to 1:0.90 for PCPY, suggesting that the peak at 286.3 eV arises from both trapped solvent and the inherent cyano group of the PCPY film. As further support for this assignment, it is noted that Barber et al. (31) gave the cyano carbon in pure acetonitrile as 287.3 eV The third peak (288.4 eV) is therefore assigned to a carbonyl group, which could arise from either atmospheric oxidation or interaction with the perchlorate counterion.

The N (1*s*) spectrum contains only one major peak at 400.0 eV and does not yield significant additional information. The Cl (2*p*) spectrum consists of two pairs of overlapped peaks that can be deconvoluted into four peaks at 200.8, 202.3, 207.5, and 209.4 eV representing the $2p_{1/2}$ and $2p_{3/2}$ peaks for two different Cl species. The peak at the lower binding energy can be assigned to Cl^-, which might have leaked from the reference electrode. The peak on the high-binding side is generally attributed to perchlorate ions from the supporting electrolyte.

Interaction with volatile vapours

To elucidate the dominant mechanisms of interaction for different gases with the PCPY film, five probe molecules were employed, each of which is capable of interacting with the surface in different ways. Possible interactions include π–π overlap, dipole–dipole, hydrogen bond formation, and Lewis acid–base combinations. The responses of PCPY to these probes are compared with those of PPY. Table 2 summarizes the solvation parameters for the probe molecules used in the context of a linear solvation energy relationship for solute – stationary phase interactions in GLC (32, 33). Here, the polarizability parameter R_2 is a measure of the ability of a solute to interact through n and π electrons while the polarity parameter π_2^* is a measure of the ability to support dipole–dipole and dipole – induced dipole interactions. Similarly, the parameters α_2^H and β_2^H indicate the relative gas-phase hydrogen bond acidities and basicities, while log L^{16} accounts for dispersion interactions. All these parameters provide a relative scale for comparing different analytes (34) and, since no quantitative data are available to characterize the solubility properties of both PPY and PCPY films, it is difficult to interpret the results only by these parameters.

Assuming that the Sauerbrey equation is valid for the experimental conditions used, the appropriate frequency shifts yield a direct comparison of the mass of each analyte sorbed on or into the film once the dynamic steady-state response has been reached. Consideration of the number of analyte molecules corresponding to this added mass, however, reveals that this will be influenced by film thickness and porosity, and by the relative rates of adsorption and desorption. The latter will in turn depend on the number and strength of analyte–film interactions, the analyte volatility, the temperature, and the gas-phase molar concentration. In addition, different concentrations were obtained for each analyte, and, since each analyte has a different volatility, it is therefore difficult to normalize the results in order to make a valid comparison between analytes without making some further assumptions. The steady-state frequency shifts obtained for each film–analyte combination were therefore recalculated for a constant film thickness. The validity of this approach is ensured by our results, which demonstrate that there is a linearity between the frequency responses and film thickness. The normalized frequency shifts, which were typically calculated from the average of five consecutive measurements, are listed in Table 3.

The mass uptake under static conditions, which corresponds to the plateau on the curve of frequency against time, represents the equilibrium of sorption between gas and solid phases, which is determined by the thermodynamic factor associated with the interactions between vapor and polymer. The equilibrium involved can be described quantitatively by the partition coefficient, which is related to the frequency shifts by the following equation (35, 36):

$$K = \frac{\Delta f_v \rho}{\Delta f_s C_v}$$

where Δf_v is the sensor frequency shift caused by the vapor sorption C_v is the vapor concentration (gm cm^{-3}), and Δf_s the initial frequency shift due to the deposition of coating. ρ is the density of coating material, 1.48 and 1.40 g cm^{-3} for PPY and PCPY, respectively, obtained from the TSM device measurement in this work. The K and log K values calculated are shown in Table 4. More quantitative information about the solubility interaction can be obtained from the log K value, which is a function of the solvation parameters of the solute (33). It is found that the partition coefficient of acetonitrile for PCPY is twice as large as that for PPY, while K of methanol for PCPY is 1.7 times that for PPY. The K values of toluene for PCPY decrease to one tenth, and the magnitude of K of triethylamine for PCPY also drops to half, compared with those for PPY. The partition coefficients of water for both PPY and PCPY films are almost identical. The K value of methanol for PPY in our work is consistent with that reported in literature (36) if the differences in concentration are taken into account.

An alternative approach is to normalize the frequency shifts by the molar concentration in the gas phase to preclude the factor of molecular weight. The frequency responses thus calculated are shown in Fig. 7. Comparing first the responses of each film to the same analyte, it can be seen that there is a marked decrease in response on going from PPY to PCPY for toluene and triethylamine, whereas an increase is observed for acetonitrile, water, and methanol. The results can be explained by considering the nature of the interaction with the polymer film. The main interaction for toluene will presumably be through π–π stacking of the benzene and pyrrole sub-units, as indicated by its large values for R_2 and log L^{16}. The net favorable interactions are the result of π–σ attractions that overcome π–π electron repulsion. These electrostatic forces determine the geometry of the interaction while van der Waals forces contribute to the magnitude of the interaction (37). Toluene can also interact with PPY through either an orthogonal π–HN bonded model or a non-orthogonal orientation π–dipole interaction (38). Geometric orientation is therefore an important factor for the interaction of toluene with PPY. It was reported that PPY has a helical structure (39–42); however, the presence of the cyanoethyl side chain would be expected to block the helical channel, thus preventing toluene from effectively interacting with the pyrrole ring. Hence, the lowest frequency response of PCPY to toluene could be attributed to the steric effect of the pendant side chain. Although triethylamine has one of the lowest polarizability parameters (R_2), it also has a dispersion parameter (log L^{16}) similar to that of toluene. Furthermore, it is capable of forming a hydrogen bond with the pyrrole N-H (in PPY), which is obviously missing in the case of PCPY. Thus a similar effect would be predicted, i.e., a decrease in response on going from a PPY to a PCPY film, as in fact is observed. Although hydrogen-bonding interactions can be expected to be stronger than π-electron or dispersion interactions, the fact that triethylamine has a higher volatility than toluene explains why the relative responses (corrected for

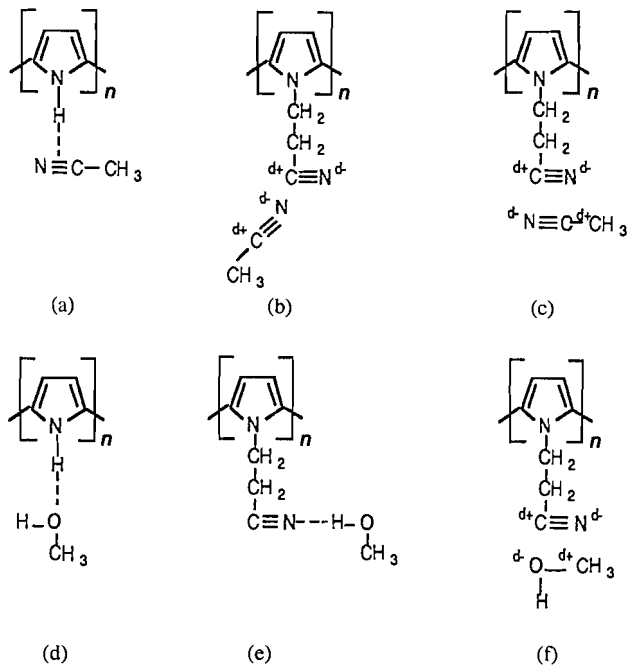
gas-phase molar concentration) should be different in the case of PPY film. The larger response for triethylamine than for toluene for PCPY film is somewhat harder to rationalize, but could well be a function of the shape of the adsorption isotherms for these two analytes, which in turn depends on the volatility of the respective vapours and the strength of the interaction between them and the polymers (43), as well as the assumptions made in the normalization procedure adopted.

Considering the remaining three analytes, acetonitrile is expected to interact with PPY via π–HN (44, 45), but with PCPY principally through dipole–dipole interaction (46) as shown in Figs. 8*a*, *b*, and *c*. Since the cyano group is one of the most polar functionalities, the dipole–dipole interaction between acetonitrile and PCPY is possibly stronger than the π–HN interaction in the case of PPY. Water and methanol are expected to interact through hydrogen bonding, which is through NH—O with PPY (44, 45) and CN—HO with PCPY

Fig. 8. Schematic of the interaction between various analytes and polymer films. (*a*) Acetonitrile interacts with PPY through NH-π; (*b*) and (*c*) acetonitrile interacts with PCPY through dipole–dipole; (*d*) methanol interacts with PPY through hydrogen bonding; (*e*) methanol interacts with PCPY by hydrogen bonding; (*f*) methanol interacts with PCPY through dipole–dipole.



(46) or through π–HO with both polymers (Figs. 8*d* and *e*) (38). Thus the increased response to each analyte on going from PPY to PCPY can be explained by the introduction of the highly polar cyano group, providing an additional dipole–dipole interaction (Fig. 8*f*). Interestingly, the order of responses for the PPY film follows the boiling point order for these three compounds, indicating that at room temperature there is insufficient difference in the relative strengths of specific interactions to overcome simple condensation effects

(this relationship is not observed if the different gas-phase concentrations are not taken into account). If the ratio of the PCPY to PPY responses from Table 3 is calculated for each analyte, values of 2.4, 1.1, and 1.8 are obtained for acetonitrile, water, and methanol, respectively. Comparing the polarizability (R_2), polarity (π_2^*), and dispersion parameters (log L^{16}) for these three analytes suggests that the principal reasons for these differences are the polarizability and polarity (i.e., dipole–dipole interactions) rather than the ability to form hydrogen bonds with the PCPY cyano group through H-bond donation.

Conclusions

PCPY films provide an additional material for forming chemically selective surfaces on TSM acoustic wave sensors. The highly polar nature of the cyano group allows interaction through alternate mechanisms to hydrogen bonding (for example), so PCPY-coated sensors could usefully be incorporated into sensor arrays where it is the pattern of responses, rather than an absolute value from a single device, that provides the sensor signal and allows a degree of selectivity to be obtained. These films may be deposited electrochemically, and have been characterized in terms of their morphology, surface functional groups, and response to different gas-phase probe molecules. The results of these studies can be correlated with solubility parameters and rationalized on the basis of an understanding of the morphology and structure of the PCPY film. Future work will attempt to correlate these findings with conductivity measurements.

The crystal and molecular structure of chlorotriphenyl(isoquinolinium-1-carboxylato)tin(IV)

Frank E. Smith, Lian Ee Khoo, Lian Sai Chia, and Rosemary C. Hynes

Abstract: The synthesis and crystal structure of the 1:1 complex formed between triphenyltin chloride and isoquinoline-1-carboxylic acid ($[Ph_3SnCl:C_{10}H_7NO_2]$) is described. The tin(IV) atom is found to be five coordinate, being bound to three phenyl groups, the chlorine atom, and an oxygen from isoquinoline-1-carboxylic acid. The geometry around the tin atom is that of a trigonal bipyramid, with the three phenyl groups occupying the equatorial positions, and the apical sites taken by the chlorine atom and a carboxyl oxygen from the isoquinoline-1-carboxylic acid. The crystals are triclinic, space group $P\bar{1}$, with $a = 17.932(12)$ Å, $b = 17.935(15)$ Å, $c = 18.686(12)$ Å, $\alpha = 63.16(5)°$, $\beta = 81.70(6)°$, $\gamma = 68.45(6)°$, $V = 4986(6)(10)$ Å^3, $Z = 8$, and $D_{calc} = 1.486$ Mg m^{-3}. The final residual is $R_F = 0.050$, on 8375 reflections with $I_{net} > 2.5\sigma(I_{net})$. Two of the cell dimensions are equivalent and there are four molecular units in the unit cell, so precautions are described for ensuring that correct space-group determination had been made and that some concealed symmetry in the final structure had not been overlooked.

Key words: triorganotin, complex, isoquinoline-1-carboxylic acid, fungicidal activity.

Résumé : On décrit la synthèse et la structure cristalline du complexe 1 : 1 formé entre le chlorure de triphénylétain et l'acide isoquinoléine-1-carboxylique ($[Ph_3SnCl : C_{10}H_7NO_2]$). On a trouvé que l'atome d'étain(IV) est pentacoordiné; il est lié à trois groupes phényles, à un atome de chlore et à un oxygène de l'acide isoquinoléine-1-carboxylique. La géométrie autour de l'atome d'étain est une bipyramide trigonale dans laquelle les trois groupes phényles occupent les positions équatoriales alors que les positions apicales sont occupées par l'atome de chlore et un oxygène carboxylique de l'acide isoquinoléine-1-carboxylique. Les cristaux sont tricliniques, groupe d'espace $P\bar{1}$, avec $a = 17,932(12)$, $b = 17,935(15)$ et $c = 18,686(12)$ Å, $\alpha = 63,16(5)°$, $\beta = 81,70(6)°$ et $\gamma = 68,45(6)°$, $V = 4986(6)(10)$ Å^3, $Z = 8$ et $D_{calc} = 1,486$ Mg m^{-3}. La valeur résiduelle finale, $R_F = 0,050$, pour 8375 réflexions avec $I_{net} > 2,5\sigma(I_{net})$. Deux des dimensions de la cellule sont équivalentes et il y a quatre unités moléculaires par motif cellulaire; on décrit donc les précautions qu'il faut prendre pour s'assurer que le groupe d'espace a bien été déterminé et que certaines symétries cachées de la structure finale n'ont pas été omises.

Mots clés : triorganoétain, complexe, acide isoquinoléine-1-carboxylique, activité fongicide.

[Traduit par la rédaction]

Introduction

In almost all instances, carboxylic acids form tin complexes in their deprotonated (carboxylate) forms, but there are a few cases of coordination to tin by the electrically neutral acids (1). For example, picolinic acid and quinaldic acid have been reported to form complexes with triphenyltin chloride (2, 3) and isothiocyanate (4). In each of these complexes, the structures are similar, with the acid in the form of its zwitterion behaving as a monodentate ligand and bonding to the triphenyltin moiety via a carboxylate oxygen. The resulting five-coordinate organotin species have a trigonal bipyramidal geometry, but are held together in pairs through hydrogen bonding. The hydrogen bonding may be between the heterocyclic N-atoms and uncoordinated carboxylate oxygens of different molecules in the pair (2), or through uncoordinated water molecules positioned between the two units (3, 4).

These compounds, as well as displaying most unusual structures, have also shown promising fungicidal activity (5). The use of triphenyltin compounds as fungicides is well documented (6–11). However, when fungicides are to be used on living vegetation, the phytocidal properties of the compounds are also of great significance. Triphenyltin chloride adducts have been shown to possess a high fungicidal to phytocidal ratio (12) and we have therefore been prompted to commence the synthesis of a series of analogous complexes between

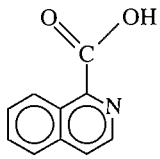
triphenyltin chloride and other protonated carboxylic acids containing heterocyclic nitrogen atoms. We describe here the synthesis and crystal structure of one such complex, that formed between triphenyltin chloride and isoquinoline-1-carboxylic acid.



Isoquinoline-1-carboxylic acid

Experimental

Preparation of chlorotriphenyl(isoquinolinium-1-carboxylato)tin(IV)

The 1:1 adduct, Ph_3SnCl:isoquinoline-1-carboxylic acid, was obtained as a white crystalline solid in good yield (90%) by mixing hot ethanol solutions containing stoichiometric quantities of triphenyltin chloride and isoquinoline-1-carboxylic acid. The complex crystallized in the refrigerator, was filtered off, washed with cold ethanol, and then recrystallized from ethanol (mp 125–127°C (dec.)). Microanalyses were performed at Universiti Sains Malaysia. Analytical data for $Ph_3SnCl:C_{10}H_7NO_2$: Anal. calcd. for $C_{28}H_{22}NO_2ClSn$(%): C 60.19, H 3.92, N 2.51; found(%): C 59.92, H 4.07, N 2.42.

X-ray analysis

Space group and cell dimensions

The crystals are triclinic, space group $P\bar{1}$ with a = 17.932(12) Å, b = 17.935(15) Å, c = 18.686(12) Å, α = 63.16(5)°, β = 81.70(6)°, γ = 68.45(6)°, V = 4986(6)(10) Å^3, Z = 8, and D_{calc} = 1.486 Mg m^{-3}. Crystal dimensions: 0.33 × 0.30 × 0.30 mm. Empirical formula: $C_{28}H_{22}NO_2ClSn$ or $[Ph_3SnCl:C_{10}H_7NO_2]$. FW = 558.62, F(000) = 2226.85, μ = 1.16 mm^{-1}, λ = 0.70930 Å.

Data collection, structure solution and refinement

Cell dimensions were obtained from 25 reflections with 2θ in the range 30°–40°. The intensity data were collected at 293 K on a Rigaku model AFC6S diffractometer run by the TEXRAY[3] diffractometer control program, using the $\theta/2\theta$ scan mode and $Mo_{K\alpha}$ radiation (λ = 0.70930 Å). A total of 13 408 reflections were measured, of which 12 904 were unique. Of these, 8375 had $I_{net} > 2.5\sigma(I_{net})$ and merging R was 4.6% for 504 pairs of symmetry-related reflections. The h, k, and l ranges were −17 to 19, 0 to 19, and −17 to 20, respectively, and $2\theta_{max}$ was 45°. Absorption corrections were made from four ψ-scan curves (13). The minimum and maximum transmission factors are 0.665 and 0.770. The structure was solved by direct methods (SOLVER (14)), followed by a difference Fourier. Refinement was by block-diagonal least-squares cycles. Phenyl rings were refined as rigid groups with carbons anisotropic. All hydrogens were given calculated positions and assigned fixed isotropic thermal parameters equal to 0.01 + U_{eq} of the bonded atom. All other atoms were refined anisotropically. The final least-squares cycle was calculated with 216 atoms and 1045 parameters and 8375 out of 12 904 reflections. Weights based on counting statistics were used. Final residuals are R_F = 0.050, R_W = 0.045 for data with $I_{net} > 2.5\sigma(I_{net})$, R_F = 0.099, R_W = 0.047 for all data. The goodness of fit was 1.67. Maximum shift/error was 0.094. In the last difference Fourier map, the top peak was 0.670 e/Å^3, and the deepest hole was −0.560 e/Å^3. Scattering factors were taken from the literature (15). Structure solution and refinement was performed using the NRCVAX system of crystal structure solving programs (14).

Results and discussion

The tin(IV) atom is found to be five coordinate, being bound to three phenyl groups, the chlorine atom, and an oxygen from isoquinoline-1-carboxylic acid. The geometry around the tin atom is that of a trigonal bipyramid, with the three phenyl groups occupying the equatorial positions, and the apical sites taken by the chlorine atom and a carboxyl oxygen from the isoquinoline-1-carboxylic acid. The molecular structure and crystallographic numbering scheme are shown as an ORTEP

[16] plot in Fig. 1 while Fig. 2 is a drawing illustrating the packing in the very large unit cell, which contains four molecular units designated A, B, C, and D. The final fractional coordinates of non-hydrogen atoms with equivalent isotropic thermal parameters are listed in Table 1, while the bond lengths and bond angles for the complex are in Tables 2 and 3, respectively. Calculated hydrogen atom parameters and anisotropic thermal parameters have been deposited as Tables S-1, S-2, and S-3, respectively.[4]

Once the space group had been determined as $P\bar{1}$ with two of the cell dimensions equivalent and four molecular units in the unit cell, it became essential to ensure that the space-group had been correctly determined and that some concealed symmetry in the final structure had not been overlooked. The crystallographic software used, NRCVAX [14], provides routines for cell reduction (CREDUC) and the identification of missed symmetry (MISSYM), both of which were run to double check this most unusual cell. The cell reduction program did identify a pseudo-monoclinic cell. The transformation:

$$\begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 2 \\ 0 & 1 & 0 \end{bmatrix}$$

gives an A-centred monoclinic cell with dimensions a = 17.932, b = 33.360, c = 17.935 Å, β = 111.55°, but the δ (deviation of α and γ from 90 degrees) is unacceptably high at 2.343°. Further analysis confirmed the original space-group determination to have been correct.

There are two close contacts with an adjacent trigonal bipyramidal molecule and we propose that these dissymmetric trigonal bipyramidal units are linked together by hydrogen bonding into centrosymmetrically related pairs (A–C and B–D). While it proved impossible to locate the acidic protons on the electron density map, it appears that they are situated between the molecules in each dimer in such a position as to facilitate the formation of hydrogen bonds between each of the

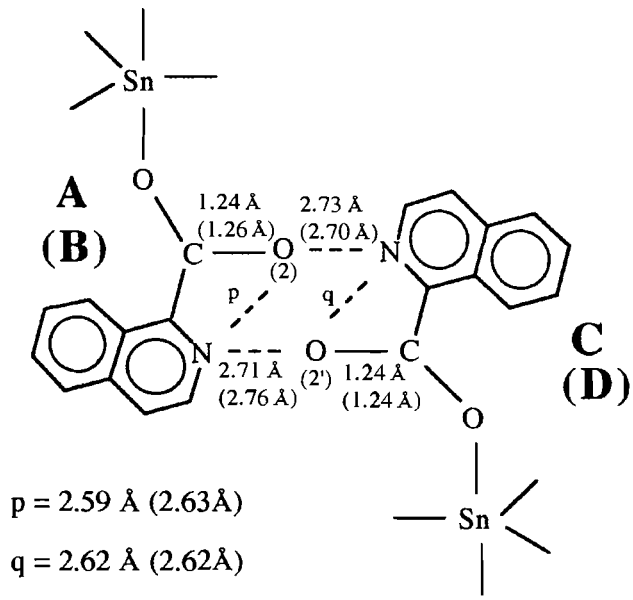
uncoordinated carboxylic acid oxygen atoms and heterocyclic nitrogen atoms of the two molecules in the dimer. A very similar hydrogen bonding scheme was found for the analogous complex of picolinic acid with triphenyltin chloride (2), for which the position of the acidic proton was located precisely. In the picolinic acid complex, the acidic proton is bonded to the nitrogen of the pyridine ring. The acid is thus coordinated in the form of a zwitterion. Each acidic proton is involved in a bifurcated hydrogen bond to the corresponding uncoordinated carboxylate oxygen atoms in each member of the pair of centrosymmetrically related molecules, thus holding the two molecules in close proximity.

We believe the hydrogen bonding scheme present in the title complex to be very similar to that found for the analogous picolinic acid complex, with the acidic protons H-bonding to the symmetry-related O(2) of another molecule. Figure 3 is a schematic drawing the intra- and inter-molecular close N–O contacts in both sets of hydrogen-bonded dimeric pairs. The distances given show that the two pairs have almost identical configurations. Table 4 gives a selection of bond distances and interatomic separations for the title complex (molecule A and dimer A–C) and the picolinic acid complex.

The similarity in the atomic separations listed in Table 4 is consistent with the two related compounds having a similar hydrogen bonding scheme. If the acidic protons are included

Fig. 3. Inter- and intramolecular N—O distances in the dimeric units of the title complex.



in calculated positions for a zwitterionononic structure, with the N—H bond distances set at 0.977 Å, the O–H separations may be calculated. When this is done, the O–H distances, averaged over the four molecular units, are 2.19 Å (same molecule) and 1.88 Å (between molecules). The corresponding distances for the picolinic acid complex are 2.17 and 1.73 Å, respectively.

In a recent review (1) it has been pointed out that the hydrogen bonding schemes of Ph_3SnX complexes with protonated carboxylic acids fall into one of two categories, distinguished by the Sn–O(2) separation. Where the hydrogen bonding between the monomers involves the participation of an uncoordinated water molecule (3, 4), the Sn–O(2) distance is found to be about 3.3 Å, whereas for direct hydrogen bonding as reported for the picolinic acid complex (2) this distance is about 3.8 Å. It is significant to note that the Sn–O(2) distance for the title compound is 3.77 Å, giving further support for the hydrogen bonding model proposed.

The Sn–O(1) distance of 2.359 Å for the title complex is comparable to those found for the quinaldic acid (2.350 Å (3)) and picolinic acid (2.347 Å (2)) complexes. These values are somewhat larger than the Sn—O bond lengths of 2.25 Å in dichlorodimethylbis(pyridine-*N*-oxide)tin(IV) (17), 2.317 Å in aquachlorotriphenyl(2,2′:6′,2″-terpyridyl)tin(IV) (18), or 2.25 Å in aquaisothiocyanatotriphenyl(2,2′:6′,2″-terpyridyl)tin(IV) (19). The elongation of Sn–O distance in the protonated carboxylic acid complexes is probably partially due to the double-bond character of the C—O bonds. The Sn–Cl distance of 2.489 Å is also very similar to that found in the picolinic (2.515 Å (2)), and quinaldic acid (2.526 Å (3)) complexes and within the range of Sn–Cl distances (2.32–2.58 Å) in other chloro complexes (20).

We have found that only those carboxylic acids with a carboxyl group that is α to the heterocyclic nitrogen atom are able to form complexes in the protonated form with triphenyltin chloride. Thus, we were unable to prepare such complexes between nicotinic or isonicotinic acids and Ph_3SnCl.

Sn—Cl	2.489(3)	2.515(1
C(1)—O(1)	1.250(11)	1.256(3)
C(1)—O(2)	1.240(10)	1.232(3)
N---O(2)	2.593(11)	2.661(5)
N---O(2′)	2.726(12)	2.651(5)

As was previously pointed out (3, 4), it would therefore appear that the presence of the α nitrogen is essential for the formation of this type of complex, probably to facilitate the proton transfer process, which is essentially the conversion of the hydrogen bond between the acidic proton and the heterocyclic nitrogen in the free acid into a covalency in the complex (there now being a hydrogen bond in place of the former covalency between the acidic proton and the carboxylate oxygen).

Electrochemistry of methylidyne and 1,2,3,5-dithiadiazole complexes of iron and nickel and a reinterpretation of the composition of "$PhCN_2S_2Fe_2(CO)_6$"[1]

Abstract: The title compounds have been studied in CH_2Cl_2 by cyclic voltammetry. Nonacarbonyldi(μ_3-methylidyne)triiron, $[Fe_3(CO)_9(\mu_3\text{-}CX)_2]$ (X = F, Cl, Br, H), undergo chemically reversible $1e^-$ reduction (−0.72 to −0.88 V vs. SCE) and irreversible oxidation (+1.59 to +1.72 V); the compound for which X = F displays a second, irreversible reduction (−1.96 V). Using reduction potentials of comparable μ_3-E (E = S, Se, NPh, PPh) clusters, μ_3-methylidyne ligands are shown to be strongly basic, comparable to PPh and NPh and more basic than S or Se. The methylidyne clusters are both more difficult to oxidize and reduce than isomeric alkyne clusters $[Fe_3(CO)_9(C_2R_2)]$, indicative of greater thermodynamic stability. The complexes previously formulated as $[Fe_2(CO)_6(S_2N_2CC_6H_4X)]$ (X = H, CF_3, OCH_3) are reversibly reduced (−1.59 to −1.70 V) and irreversibly oxidized (+1.0 to 1.3 V), unlike free dithiadiazole radicals, which are reversibly oxidized around +0.8 V. This behaviour is not consistent with the ring-centered free radical claimed for the case where X = H; instead we find conclusive evidence that these are diamagnetic complexes of the 3-*H*-1,2,3,5-dithiadiazolines, $[Fe_2(CO)_6(S_2N\{NH\}CC_6H_4X)]$ (ν_{NH} = 3376–3381 cm^{-1}; δ_{NH} = 6.55–7.1 ppm). Dicyclopentadienyldithiadiazoledinickel, $[Ni_2Cp_2(S_2N_2CC_6H_5)]$, is both reversibly reduced (–0.79 V) and oxidized (+0.45 V); and irreversibly oxidized at +1.9 V. This is consistent with an unpaired electron, and only the nickel cluster has an ESR signal (g = 2.0410, no resolved hyperfine splitting). Extended Hückel theory locates the free electron in a SOMO restricted to Ni, C, and S atoms.

Key words: electrochemistry, organometallic, methylidyne, dithiadiazole, dithiadiazoline.

Résumé : On a étudié les composés mentionnés dans le titre par voltampérométrie cyclique dans du CH_2Cl_2. Le nonacarbonyldi(μ_3-méthylidyne)fer, $[Fe_3(CO)_9(\mu_3CX)_2]$ (X = Cl, Br, H), subit une réduction à $1é^-$ chimiquement réversible (−0,72 à −0,88 V vs. SCE) et une oxydation irréversible (+1,59 à +1,72 V); le composé dans lequel X = F présente une deuxième réduction irréversible (−1,96 V). Utilisant les potentiels de réduction d'agrégats μ_3E (E = S, Se, NPh, PPh), on montre que les coordinats μ_3-méthylidyne sont fortement basiques, comparables à PPh et NPh et plus basiques que S ou Se. Les agrégats méthylidynes sont à la fois plus difficiles à oxyder et plus difficiles à réduire que les agrégats alcyniques isomères $[Fe_3(CO)_9(C_2R_2)]$; ceci indique une plus grande stabilité thermodynamique. Contrairement aux radicaux dithiadiazoles libres qui sont oxydés d'une façon réversible à environ +0,8 V, les complexes pour lesquels on avait proposé antérieurement la structure $[Fe_2(CO)_6(S_2N_2CC_6H_4X)]$ (X = H, CF_3, OCH_3) sont réduits d'une manière réversible (−1,59 à −1.70 V) et ils sont oxydés d'une manière irréversible (+1,0 à +1,3 V). Ce comportement n'est pas en accord avec l'existence d'un radical libre centré sur un cycle, tel qu'il avait été préconisé pour le cas où X = H; on trouve plutôt des données concluantes indiquant que ceux-ci sont des complexes diamagnétiques des 3-*H*-1,2,3,5-dithiadiazolines, $[Fe_2(CO)_6(S_2N\{NH\}CC_6H_4X)]$ (ν_{NH} = 3376–3381 cm^{-1}; δ_{NH} = 6,55–7,1 ppm). Le dicyclopentadiényldithiadiazoledinickel, $[Ni_2Cp_2(S_2N_2CC_6H_5)]$, est aussi bien réduit (–0.79 V) qu'oxydé (+0,45 V) d'une façon réversible et il est oxydé irréversiblement à +1,9 V. Ce comportement est en accord avec la présence d'un électron non apparié et seul l'agrégat du nickel possède un signal en rpe (g = 2,0410, sans

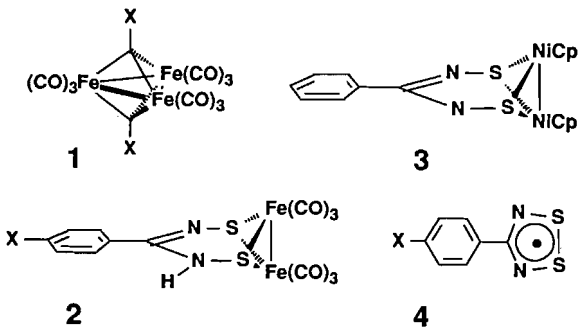
Introduction

Electrochemical studies of organometallic compounds can give useful insights into their behavior and electronic structure. The enhanced chemical reactivity of many low-valent organometallic compounds, compared to classical coordination compounds, requires the use of special handling techniques, including specialized electrochemical cells and the use of nonaqueous solvents. In this work we use cyclic voltammetry to study several organometallic cluster compounds using an original cell design that is equally capable of operating under a vacuum or a carbon monoxide atmosphere (1). The methylidyne complexes $[Fe_3(CO)_9(\mu\text{-}CX)_2]$, **1**, (X = F, Cl, Br, H) (2) and the so-called dithiadiazole complexes $[Fe_2(CO)_6(S_2N_2CPh)]$, **2***a*, and $[Ni_2Cp_2(S_2N_2CPh)]$ **3** (3) were investigated. (Cp stands for η^5-C_5H_5.) The latter two were claimed to be paramagnetic organometallic clusters. In fact we discovered that all the iron carbonyl clusters including **2***a* have a similar electrochemical behavior. However, the nickel cyclopentadienyl complex behaved differently. It was reminiscent of the paramagnetic parent 1,2,3,5-dithiadiazole ring system, **4** (4). This led us to question the validity of the claim that **2***a* contains a ligand-centered unpaired electron.



To further assess this problem we prepared two 4-substituted aryl analogues to **2***a* with better solubility and convenient NMR spectral patterns, $[Fe_2(CO)_6(S_2N_2CC_6H_4X)]$, X = OCH_3, **2***b*, and X = CF_3, **2***c*. A detailed spectroscopic investigation of these complexes using mass spectrometry, ^1H and ^{13}C NMR, ESR, and electronic absorption spectroscopy conclusively demonstrates that **2** should be reformulated as complexes of the 3-*H*-1,2,3,5-dithiadiazolines $[Fe_2(CO)_6(S_2N\{NH\}CC_6H_4X)]$ (X = H, OCH_3, CF_3), and that they are in fact diamagnetic. However, we have also established that **3** is definitely a paramagnetic species with the unpaired electron located mostly on C, S, and Ni atoms. A preliminary account of this work has appeared (5).

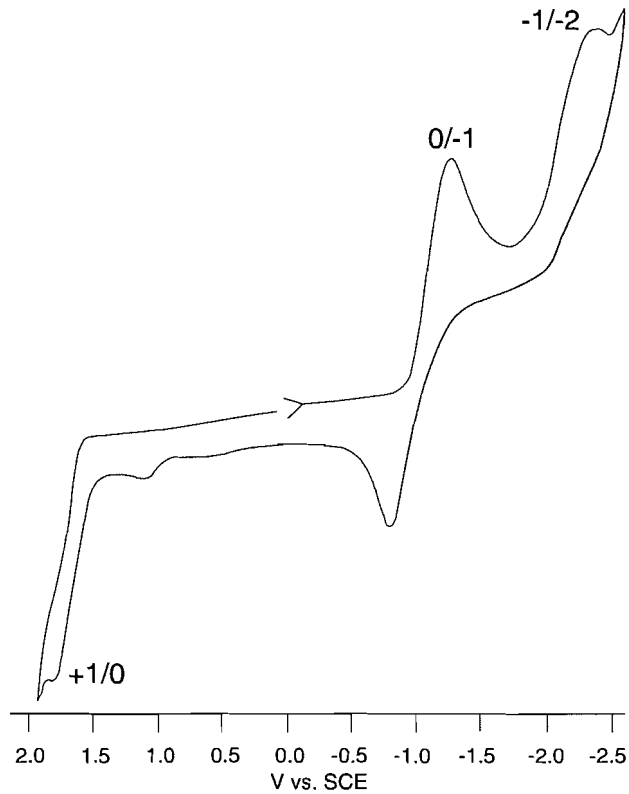
Electrochemistry

$Fe_3(CO)_9(\mu_3\text{-}CX)_2$ ***1***a *X = F,* ***1***b *X = Cl,* ***1***c *X = Br,* ***1***d *X = H*

Figure 1 shows the cyclic voltammogram (cv) of **1***a* in CH_2Cl_2.

Fig. 1. Cyclic voltammogram of $[Fe_3(CO)_9(CF)_2]$, **1***a*, in CH_2Cl_2 containing 0.5 M $^nBu_4NPF_6$ electrolyte.



In the cv, one reversible first reduction wave with $\mathscr{E}_{1/2}$ = −0.88 V vs. SCE and an irreversible second reduction wave at −1.96 V are observed. Under the conditions stated in Table 1, an irreversible oxidation occurs within the range of solvent stability at $\mathscr{E}_a$ = +1.58 V. Experiments with a CO atmosphere in the electrochemical cell show a slight improvement of the reversibility of the oxidation and reduction steps in the cv. This effect has been noted before for structurally similar bicapped clusters $[Fe_3(CO)_8(\mu_3\text{-}E)_2]$ (6).

Reversible reductions were found for the corresponding chloro, bromo, and hydrido clusters with half-wave potentials at −0.72, −0.74, and −0.86 V vs. SCE, respectively. None of these clusters had a second reduction step within the solvent stability field. Irreversible oxidation steps are observed at +1.68, +1.72, and +1.59 V.

$[Fe_2(CO)_6(S_2N\{NH\}C\text{-}C_6H_4\text{-}X)]$, **2**a *X = H,* **2**b *X = OCH_3,* **2**c *X = CF_3*

Figure 2 shows the cv of **2***a* in CH_2Cl_2 at +25°C and a scan rate of 100 mV s^{-1}. Under these conditions a reversible one-electron reduction at $\mathscr{E}_{1/2}$ = −1.70 V and an irreversible oxidation at +1.2 V are observed. The oxidation step remained strictly irreversible even at scan rates of 10 V s^{-1} and temperatures

*$Ni(Cp)_2(S_2N_2CC_6H_5)$, **3**.*

Figure 3 shows the cv of the nickel complex in CH_2Cl_2. Fully reversible reduction and oxidation processes are observed at $\mathscr{E}_{1/2}$ = −0.79 V and $\mathscr{E}_{1/2}$ = +0.45 V, respectively. A second, irreversible oxidation process could also be observed at +1.9 V. Repeated scanning through this second oxidation causes the disappearance of all signals in the voltammogram. However, in contrast to the iron complexes, the complete cv can be recovered by reconditioning the electrode through holding the potential at −2.0 V for about a minute.

We noticed considerable similarity in the redox properties of the iron carbonyl clusters **1** and **2**. First, they all have a reversible first reduction $\mathscr{E}_2$; secondly, they all have an irreversible oxidation process $\mathscr{E}_1$; thirdly, the separation between

$\mathscr{E}_1$ and $\mathscr{E}_2$ is of similar magnitude: 2.40–2.46 V for **1** and 2.69–2.87 V for **2**. In view of the claim that **2***a* contains an unpaired electron centered on the heterocyclic ring (3*a*), we were surprised by the absence of a facile, reversible oxidation process, as invariably observed for 1,2,3,5-dithiadiazole radicals, whose electrochemistry has been exhaustively studied (4). On the other hand, the nickel cluster **3** displays such a process, identified as $\mathscr{E}_2$ in Table 1, where for comparative purposes the potentials of the parent heterocycles are also listed. Complex **3** is reversibly oxidized at a considerably less positive potential compared to S_2N_2CPh (+0.45 vs. +0.78 V). The very different electrochemical behaviour of **2** and **3**, which are otherwise quite similar clusters derived from the same heterocycles, led us to carefully compare their spectroscopic properties.

Solution studies

That the structures of **2***b,c* are similar to the butterfly structure of **2***a*, for which a crystal structure is known (3*a*), is readily proven by IR spectroscopy. In the CO stretching region, in CS_2 solution, all three have virtually identical absorptions both in frequency and relative intensity (Table 2). There is a very small but consistent trend in ν(C≡O) values: each band moves slightly to higher wave number with increasing electron-withdrawing character of the remote substituent. The bands are also strikingly similar to those of related thiolate clusters (for example, $[Fe(CO)_3SC_2H_5]_2$: 2070, 2034, 2000, 1987 cm^{-1}) (7), which also possess the butterfly structure. In contrast to the solution spectra, solid-state spectra recorded either as Nujol mulls or as KBr pellets show each CO band split into two, indicative of substantial symmetry lowering in the crystal.

Clusters **2** provide well-resolved NMR spectra typical for diamagnetic species, i.e., without paramagnetic line broadening or unusual chemical shifts (5), whereas the parent dithiadiazole radicals **4** show broad featureless NMR spectra consistent with their paramagnetism. The ^1H and ^{13}C chemical shifts (Table 3) are within the range observed for a wide variety of aryl-C(NS~)$_2$ compounds that we have previously studied (8). The samples of **4** were sealed under vacuum to prevent the facile reaction with oxygen (8*a*). The ^1H spectra show, in addition to the typical A_2B_2 aromatic peaks, one relatively broad peak with variable chemical shift (range: 6–7 ppm) integrating to 1H. This latter peak disappeared on shaking the solution with a little D_2O (5). Supposing this to be a hydrogen atom attached to one of the nitrogen atoms of the dithiadiazole ligand, we returned to solution IR spectroscopy using much more concentrated solutions in $CHCl_3$, which has an open window above 3000 cm^{-1}. All three complexes showed a weak but relatively sharp peak around 3380 cm^{-1}, assigned to ν(N-H) (9).

ESR spectra

We were unable to obtain an ESR signal even from concentrated solutions of pure samples of **2**, which is consistent with diamagnetism, in agreement with the NMR and electrochemical evidence. Figure 4 shows the isotropic ESR spectrum of **3** in solution. It displays a strong signal without any hyperfine structure. The *g*-value is 2.0410 and the peak-to-trough separation is 0.69 mT. This is very similar to the ESR signal reported for the paramagnetic cobalt cluster $[Co_3Cp_3(\mu_3\text{-}S)_2]I$, which has a broad single line and a *g*-value of 2.05 (10). In extremely dilute solutions in CH_2Cl_2, an additional, weak, five-line pattern is observed, which can be identified as the parent radical **4** by its *g*-value of 2.011 and a_N of 0.49 mT (4*b*, 11). This very small amount of **4** probably results from thermal or photochemical dissociation of the cluster. The absence of the familiar five-line pattern in the ESR spectrum of **3** indicates that the distribution of the unpaired electron in the clus-

ter is quite different than in the parent heterocycle. This conclusion is supported by the EHMO calculations reported below.

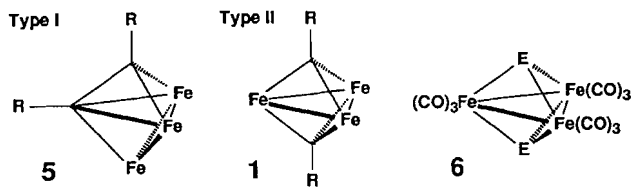
Electronic spectra

We have measured the electronic absorption spectra of **2** and **3** in CH_3CN solution (Table 4). The contrast in their properties seen electrochemically is repeated here. Complexes **2** absorb in the blue (~470 nm) and in the UV (322 and 232 nm). For comparison, the electronic spectrum of diamagnetic $Fe_2S_2(CO)_6$ consists of three bands at 476, 333, and 278 nm. The intensity of the 333 nm band is 11 900 (12). The low-energy band in this cluster is considered to be due to transitions within the metal–metal bonding orbitals, i.e., it is cluster centered. Complex **3** has a visible band considerably higher in energy (399 nm) and three UV bands (346, 326, and 243 nm); in addition there is a weak band at very low energy (876 nm). Apart from the low-energy band, this spectrum is quite similar to that reported (up to 820 nm) for the paramagnetic cluster $[Ni_3Cp_3(\mu_3S)_2]$, which has a visible band at 396 nm and two UV bands (13). These results are in qualitative agreement with the EHMO calculations reported below.

Discussion

Electron counting

Iron–carbon clusters with the analytical formula $Fe_3(CO)_9C_2R_2$ can exist according to Wade's rules (14) in at least two possible stereo isomers. Compounds of type I are well known as trinuclear alkyne clusters, **5** (15). Only recently with the synthesis of the series of methylidyne clusters $Fe_3(CO)_9(\mu_3\text{-}CX)_2$, **1**, (X = F, Cl, Br, H) have examples of type II been found (2). Both are *closo* polyhedra with $n = 5$, where n represents the number of skeletal polyhedron vertices, and with 12 (i.e., $2n+2$) skeletal electrons (14). Each CX ligand acts as a three-electron donor. By this treatment, the C—C bonds in the type I complexes are considered as part of the skeletal framework. Both types are 54e$^-$ clusters and fit the 18-electron rule.



Iron–sulfur clusters of the general formula $Fe_2(CO)_6(SLig)_2$, where Lig refers to any one of a direct S—S bond, terminal σ-bonded groups (Me, Et), or some sort of indirect bridge, i.e., including the ring-opened dithiadiazole ligands in **2**, are all tetrahedral clusters with $(2n+4)$ skeletal bonding electrons.

For personal use only.

They do not fit Wade's rules in any simple way. However, they do fit the $18e^-$ rule precisely, with each S atom acting as a three-electron ligand. According to the evidence presented in this work, we conclude that **2** are electron-precise $36e^-$ clusters formed from a dithiadiazoline ligand, while **3** is a $39e^-$ species formed from the parent dithiadiazole. The precise electron count in the latter is complicated by the question of whether or not it has a Ni—Ni bond.

This leaves only consideration of the formal oxidation states of the metals in these clusters. In both **2***a* and **3** the S—S bonds have opened up considerably on cluster formation (from 2.09 in the dimer to 2.93 and 2.905 Å in the two clusters (3)). If this is considered to be due to oxidative addition to the metals, then formally we are dealing with complexes of the $[S_2N_2CR]^{2\bullet-}$ and $[S_2N_2HCR]^{2-}$ ligands and hence with metals in Fe^+ and Ni^{2+} oxidation states. In much the same way, S_2N_2 forms complexes through oxidative addition that are formally derivatives of $S_2N_2^{2-}$ (16).

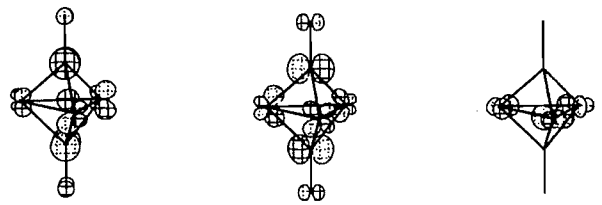
Comparison of redox potentials for 1

The electrochemical behaviour of the parent triiron cluster $[Fe_3(CO)_{12}]$ (17), alkyne clusters $[Fe_3(CO)_9(RCCR)]$, **5**, (15*f*), and bicapped trigonal planar clusters $[Fe_3(CO)_8(\mu_3\text{-}E)_2]$, E = S, Se, NPh, PPh, **6** (6), has been studied in detail. In general, the triiron clusters all undergo a reversible one-electron reduction step. In addition, further electrode processes, such as a second reduction or an oxidation step, are also observed but are usually less well defined.

The type I alkyne complexes **5***a* (R = Me), **5***b* (R = Et), and **5***c* (R = Ph) undergo a first reduction at −0.47, −0.49, and −0.36 V, respectively, and a second reversible reduction at −0.65, −0.60, −0.67 V, as well as irreversible oxidation at +1.29, +1.42, +1.35 (anodic peak potentials), all measured in CH_2Cl_2 (15*f*). There is a small difference in potential between the first and second reductions of these type I complexes. This has been attributed to thermodynamic effects accompanying a structural reorganization from a *closo* to a *nido* geometry, based on solution IR and NMR evidence (15*f*). The much greater separation between the sequential reductions in **1** suggests that such a rearrangement does not readily occur for the type II clusters. Comparison of the redox potentials of type I and II clusters is complicated by differences in substituents at C. However, the closest similarity in properties might be expected between **1***d* (R = H) and **5***a* (R = Me). We see that the μ_3-methylidyne is almost 0.4 V harder to reduce, as well as 0.3 V harder to oxidize, than the dimethylacetylene cluster. Thus the electrochemical stability range, defined as the difference between the potentials at which oxidation and reduction occur, is significantly greater for **1** than for **5**.

The capped trigonal planar type II clusters **6** are of directly comparable structure to **1**. In all cases the initial reduction is reversible with the comparable potentials at −0.61 V (S), −0.56 V (Se), −0.86V (NPh) (6*a*), and −0.79V (PPh) (6*b*) measured in THF solution. The first reductions of **1**, irrespective of the nature of R, are more comparable to these heteroatom capped clusters than to the isomeric type I alkyne clusters. Bond et al. have suggested that, so long as the free energy of solvation for a series of compounds is similar and there are no major structural changes during the reduction process, then the reduction potentials should reflect the energy of the LUMO (17*a*). Since these conditions are likely to apply to the tri-capped clusters, the reduction potentials serve as a measure of their LUMO energies. These therefore provide an insight into the relative basicity of the capping groups, since substitution with a more basic ligand should raise the energy of the LUMO, making reduction more difficult. On this basis μ_3-methylidyne ligands are strongly basic, comparable to PPh and NPh, and more basic than S.

All of these results corroborate earlier conclusions emphasizing the stability of the alkylidyne clusters and in particular the high degree of covalency of the Fe—Fe and Fe—C bonding (18). The electronic structure of **1***a* has been studied by Extended Hückel as well as SCF methods in C_{3h} symmetry (i.e., with one C≡O group on each iron lying in the plane of the iron triangle) (18*a*). In the oxidation process, electrons are removed from the *e″* HOMO **7** and **8**, which are Fe—C_{apical} as well as Fe—Fe bonding. The experimental evidence suggests that removal of electrons from these orbitals leads to cluster fragmentation. Reduction involves occupation of the *a′* LUMO **9**, which is Fe—Fe anti-bonding but does not involve the capping ligands.



7 8 9

Comparison of redox potentials for 2

The reduction potentials may be compared to those of $[Fe_2(CO)_6S_2]$ (19) and $[Fe_2(CO)_6(SR)_2]$ (R = Me, Et, $S(CH_2)_nS$, n = 2,3) (20), which have been studied by cyclic voltammetry. The "naked" disulfide cluster has been shown to undergo a complex redox process in THF solution, in which the radical anion forms in an electrochemically irreversible (but chemically well-defined) process at −1.53 V and dimerizes to give $[Fe_4S_4(CO)_{12}]^{2-}$. The dimer is subsequently reduced to the dianion $[Fe_2S_2(CO)_6]^{2-}$ at −2.46 V. This process can be reversed, with the first reoxidation at −2.2 V and the second at −0.63 V (19). This interesting process is rather difficult to compare with the reversible reduction of **2**.

Under a CO atmosphere, $[Fe_2(CO)_6(SR)_2]$ are reduced quasi-reversibly or reversibly. Bridged systems, i.e. those with $S(CH_2)_nS$ dithiolate ligands, were found to be electrochemically the best behaved. The potentials range from −1.1 to −1.2 V using DMF as the solvent (20). The ~0.5 V difference between these values and the −1.6 to −1.7 V recorded for the reduction of **2** may in part be solvent related, since the strongly coordinating solvent DMF is expected to move reduction potentials to a less negative value compared to the weakly interacting dichloromethane used in our study. Thus, the electrochemical reductions of $[Fe_2(CO)_6(SR)_2]$ and **2** are roughly comparable and the ring-opened dithiadiazoline ligand in **2** may be considered an exotic form of a bridging dithiolate.

Comparison of redox potentials for 3

There is no directly comparable disulfide with the same cluster structure as **3**. Instead $[CpNi(CO)]_2$ reacts with elemental sulfur to yield the paramagnetic cluster $[Ni_3Cp_3(\mu_3\text{-}S)_2]$ (13*a*).

The electrochemistry of this cluster has been studied in benzonitrile (13*c*), acetonitrile, acetone, and methylene chloride (13*b*). The central redox processes are qualitatively similar to those observed for **3**. Reversible oxidation (+0.09 V in CH_2Cl_2) and reversible reduction (−0.81 V) as well as irreversible oxidation (+0.97 V in CH_2Cl_2) are observed. The electrochemical reversibility of this first oxidation of $[Ni_3Cp_3(\mu_3\text{-}S)_2]$ has been substantiated by chemical synthesis of the cation. In CH_3CN and PhCN the second oxidation is reversible and further irreversible oxidation is observed. Thus, $[Ni_3Cp_3(\mu_3\text{-}S)_2]$ is considerably easier to oxidize than **3** (in accord with its greater electron richness), but its reduction is very comparable to that of **3**.

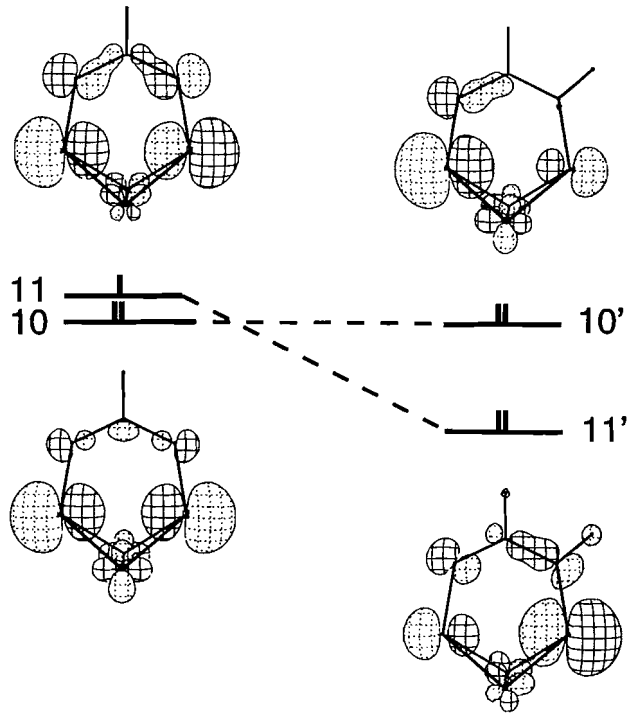
Solid-state structures of 2

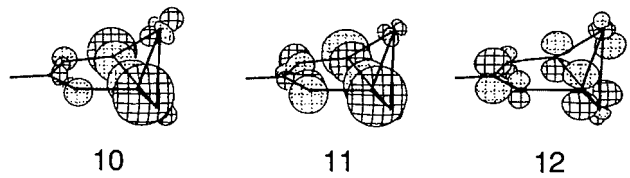
The evidence originally presented for the claim that **2***a* contains a ring-centered unpaired electron consisted of (*i*) magnetic susceptibility measurements, which were not fully discussed, and (*ii*) the presence of short N...N contacts in the single-crystal X-ray crystal structure (3*a*). However, these short contacts fit both in *length* and *direction* for hydrogen bonding between an N—H unit and a nitrogen atom on the adjacent molecule. The short intermolecular distance between N(1) and N(2) is 2.84 Å. If a hydrogen atom is attached to N(2) at the calculated position for an sp^2 hybridized nitrogen atom and with d(N—H) = 0.95 Å, the distance from H to N(1) in the adjacent molecule is 2.03 Å. Similarly, attachment to N(1) with the same bond length gives a distance H to N(2) of 2.12 Å. These values are very similar to the average of 2.20 Å tabulated in ref. 21 for a wide range of N—H...N bonds. If the material prepared by these authors was indeed a dithiadiazoline complex as suggested here, the magnetic results and the five-line ESR signals they obtained may have been due to co-crystallization of uncoordinated **4***a*, which is apparently a common occurence in this chemistry.[4] The splitting of the carbonyl bands in the IR spectra of solid samples of **2** is consistent with the unsymmetrical dithiadiazoline structure we have proposed, as is the inequivalence in the C—N bond lenghts of 1.295(8) and 1.348(7) found in the crystal structure of **2***a*.

MO description of 2 and 3

EHMO descriptions of **2** and **3**, as *radicals*, using S_2N_2CH as a model ligand have been published (3). We have been able to repeat the essential features of these calculations, although in our hands the parameters published in ref. 3 lead to very different results; the parameters we have used are listed in Table 5. The makeup of the highest filled orbitals of **2** turns out to be very sensitive to parameter choice.[5] Using the best choice of parameters, in our judgment, we find for the purported radical that the singly occupied molecular orbital (SOMO) of **2** is indeed **11**, a sulfur and nitrogen lone-pair-type orbital almost entirely localized on the ligand, as previously claimed (3*a*). At slightly lower energy is the first doubly occupied orbital, **10**, derived from the S—S σ bond in the free heterocycle. The LUMO **12** is derived from the ligand π_4 orbital, and has a large contribution from the carbon monoxide carbon atoms. However, as we have demonstrated, **2** is not a free radical, but rather a diamagnetic cluster containing $S_2N\{NH\}CR$. What is the consequence of attaching a hydrogen atom to a ring nitrogen atom? The answer to this question is addressed in Fig. 5. Attachment of a hydrogen atom to one of the ring nitrogen atoms in a reasonable geometry stabilizes **11′** sufficiently so that it falls below **10′**, which then becomes the HOMO of the new cluster.

Fig. 5. Schematic representation of the effect of H coordination to a nitrogen lone pair in a model version of **2** using HCN_2S_2 as the ligand. Stabilization of **11′** (viewed here in the plane of the dithiadiazole ligand) occurs, leaving **10′** as the HOMO of the dithiadiazoline-containing cluster.



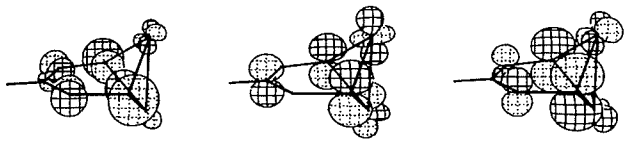


In contrast to **2**, the makeup of the frontier orbitals of model **3** is quite insensitive to parameter choice for sulfur and nitrogen. Essentially the same picture develops using the two H_{ii}

[4] A.J. Banister. Private communication.

[5] Such sensitivity to Hückel parameters also applies to $[Fe_2S_2(CO)_6]$ (22) and $[Fe_2S_2(CO)_6]^{2-}$ (23), which have been intensively studied by a wide variety of computational methods. DeKock et al. have reported HFS calculations on both compounds. We found that the best approximation to the HFS calculation on the neutral cluster (22*d*) using EHMO could be achieved using"standard" H_{ii} for N and S. Yet for the dianion (23*a*) much better agreement was obtained if the H_{ii} of DeKock and Gray were employed (24). Andersen et al. also used these latter parameters in their EHMO calculations (22*c*). Since **2** is geometrically and electronically more closely related to the dianion, we decided to employ the DeKock and Gray H_{ii}. The choice has a profound influence on the frontier orbitals of **2**: with standard H_{ii}, the HOMO is Fe–Fe σ bonding, similar to the a_1 orbital calculated by all methods to be HOMO of $[Fe_2S_2(CO)_6]$. This orbital is HOMO-3 in **2** when using the DeKock and Gray H_{ii}.

choices. The LUMO **15** is a combination of the ligand π_4 orbital and Cp contributions. The SOMO **14** is made up from ligand π_3 (35%), Ni 3*d* (40%), and the Cp (25%). It has a node at the ring nitrogen atoms. This description is similar to that published previously (3*b*), and explains the absence of coupling noted above for the ESR spectrum of **3** since the major isotopes of C, S, and Ni have $I = 0$. The highest doubly occupied orbital, **13**, is a S,N lone-pair orbital very similar to **11**.



13 14 15

Although the discussion here must be regarded as tentative until high-level calculations are performed, we find a satisfying explanation of the fact that **3** is stable as a radical while **2** is not. Due to the two extra valence electrons in the nickel cluster, the unpaired electron donated by **4** is accommodated in an anti-bonding orbital with significant participation by the back-bonding Cp ligands. This orbital has very similar topology to the LUMO of **2**, which is also capable of accepting an additional electron, as demonstrated by the reversible one-electron reduction reported above. On the other hand, the hypothetical radical form of **2** would need to accommodate the unpaired electron in the ring σ orbital **11** (or alternatively in a metal–metal bonding MO, using "standard" parameters.) This configuration is too reactive, resulting in hydrogen abstraction, and the loss of the 37th valence electron to a localized N—H bond. Fundamentally these are not unexpected results. For example, while ferrocene is electron-precise, nickelocene is a $20e^-$ metallocene. The higher effective nuclear charge of nickel over iron accounts for the lowering of the energy of the anti-bonding orbitals. Nickel clusters are simply more likely to be stable when electron-rich than are iron clusters.

Formation of the dithiadiazole and dithiadiazoline complexes

The reaction sequences leading to **2** and **3** are complex. First of all, the dithiadiazole radicals themselves are not capable of reducing $Fe_3(CO)_{12}$ to the radical anion (17). The same is true for $[CpNi(CO)]_2$, which undergoes an irreversible $2e^-$ reduction only at -2.4 V (25). This would seem to rule out the involvement of an ETC mechanism for CO displacement from the parent clusters. Substitution is accompanied, at least formally, by oxidative addition. It may be that the final electron count is controlled more by the cluster electronic structure than by the nature of the dithiadiazole ligand. In the case of **3**, the cluster tolerates electron-richness, but **2** resists deviation from the $18e^-$ count. The "excess" electron may then be dumped out onto the ligand, where H-atom abstraction may then be invoked to explain the formation of the dithiadiazoline. (In this regard, the use of toluene as the solvent may be significant, since this is a well-known source for H abstraction.) Whatever mechanism is proposed to deal with these observations must also account for the low yields of these reactions, which never seem to exceed 50% of theory.

There are clear similarities here with the reaction of S_4N_4 and $Ni(CO)_4$, which results after work-up in the formation of $Ni(S_2N_2H)_2$, i.e., a complex of the protonated form of $S_2N_2^{2-}$, or $S_2N_2H^-$ (26). On the other hand, with $CpCo(CO)_2$ the complex $CpCoS_2N_2$ is obtained, formally derived from $S_2N_2^{2-}$ (16). The reactions of binary thiazenes with organometallic complexes are also not well understood, involve complex redox changes, and may very well involve the intermediacy of free radicals. We believe that the reactions of **4** with transition metals are useful models for the even more complex reactions of the binary compounds, and are therefore worthy of further investigation. Work on the elucidation of the mechanism whereby stable free-radical heterocycles interact with metal clusters is in progress, as are attempts to produce the redox changes identified for **3** by chemical means.

Experimental section

General

$Fe_3(CO)_9(\mu_3\text{-}CX)_2$ (X = F, Cl, Br, H) (2), $[RC_6H_4CN_2S_2]_2$ (R = H, CH_3O, CF_3) (8*a*), $[Fe_2(CO)_6(S_2N\{NH\}CPh)]$ (3*a*), and $[Cp_2Ni_2(S_2N_2CPh)]$ (3*b*) were prepared by published procedures. Solvents were reagent grade, and distilled from sodium wire (toluene) or from P_2O_5 (CH_2Cl_2). Unless otherwise indicated, all procedures were performed under an atmosphere of purified N_2 using a dry-box, Schlenk ware, and vacuum-line techniques. Infrared spectra were recorded on a BOMEM MB102 Fourier transform spectrometer. Electronic absorption spectra were obtained in 1.00 cm quartz cuvettes on a Varian DMS 100S spectrophotometer. ESR spectra were collected using a spectrometer constructed from a Bruker ESP300E console, microwave bridge, signal bridge, field controller, and Hall controller connected to an older electromagnet. NMR spectra were acquired at 250.13 (^1H) and 62.90 (^{13}C) MHz on a Bruker AC250-F spectrometer. Mass spectra were recorded by the Mass Spectrometry Center, University of Alberta, Canada. Elemental analyses were performed by MHW Laboratories, Phoenix, Ariz., U.S.A.

Preparation of $[Fe_2(CO)_6(S_2N\{NH\}CC_6H_4OCH_3)]$, 2*b*

$CH_3OC_6H_4CN_2S_2$ (0.50 g, 2.37 mmol) and $[Fe_3(CO)_{12}]$ (1.23 g, 2.44 mmol) were stirred in 100 mL toluene under N_2. The mixture was slowly heated to 95°C over a period of 3 h until tlc analysis (silica with 1:1 CH_2Cl_2–hexanes eluant) indicated disappearance of $Fe_3(CO)_{12}$. After cooling to room temperature unreacted solid material was removed by filtration and the solvent removed under vacuum. The crude product was recrystallized from hot toluene to give orange crystals, 0.48 g (0.98 mmol, 41% yield), mp 165–169°C (dec). Anal. calcd. for $C_{14}H_8Fe_2N_2O_7S_2$: C 34.17, H 1.64, N 5.69, S 13.03%, found: C 34.12, H 1.59, N 5.47, S 12.94%.

Preparation of $[Fe_2(CO)_6(S_2N\{NH\}CC_6H_4CF_3)]$, 2*c*

$CF_3C_6H_4CN_2S_2$ (0.25 g; 1.0 mmol) and $Fe_3(CO)_{12}$ (0.34 g; 0.67 mmol) in 75 mL toluene were heated for 8 h while the temperature was slowly increased to 70°C, and were stirred until all the $Fe_3(CO)_{12}$ was consumed (tlc). The solution was then filtered hot, and the filtrate reduced to dryness. Recrystallization of the residue from toluene–hexanes gave 0.27 g (0.51 mmol, 51% yield) of fine orange needles (dec. 165°C). In some reactions extraction of the solids from the first filtration with CH_2Cl_2 yielded some additional product. Anal. calcd. for $C_{14}H_5F_3Fe_2N_2O_6S_2$: C 31.73, H 0.95, N 5.29, S 12.10%; found: C 31.90, H 1.16, N 5.53, S 12.00%.

Electrochemistry

Cyclic voltammetric (cv) studies (scan rates v = 20–5000 mV s^{-1}) were made with a PAR 173 potentiostat in combination with a PAR 175 programmer and recorded on a Houston Graphics 2000 XY plotter or a Hewlett Packard 181 storage oscilloscope. Electrochemical experiments were performed on a platinum three-electrode system with the platinum working electrode either a 0.5 mm Pt wire or a 0.5 mm diameter Pt micro-tip. A positive feedback circuitry was employed to minimize *iR* drop losses. The vacuum-tight all-glass electrochemical cell has been described in detail elsewhere (1). The cell was charged with the supporting electrolyte (NBu_4PF_6) at a concentration of 0.05 mol L^{-1}. After heating of the electrolyte at +90°C for 12 h on the vacuum line to remove traces of water, the solvent (dry degassed CH_2Cl_2) was transferred under vacuum. Compounds under investigation and ferrocene acting as an internal reference compound were added to the cell using break-seal techniques. The ferricenium/ferrocene couple was determined in this system at +0.48 V vs. SCE at 25°C. For experiments under a CO atmosphere a slight positive pressure (1.1–1.2 atm; 1 atm = 101.3 kPa) was used to fill the electrochemical cell with the gas on a vacuum line.

Extended Hückel MO calculations

EHMO calculations were performed using CACAO 4.0 running on a 25 MHz 486 Intel-based personal computer (27). Parameters employed are listed in Table 5. Geometries used are based on idealizations of the structures as determined by X-ray crystallography (3).

Supplementary data

Infrared spectroscopic and mass spectral data for **2***b* and **2***c* have been deposited.[6]

[6] The supplementary material can be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2.

Acknowledgments

This work was supported by the Natural Sciences and Engineering Research Council of Canada, the University of Lethbridge research fund (R.T.B.), the Deutsche Forschungsgesellschaft and Fonds der Chemischen Industrie, Germany (D.L. and H.M.S.). Synthesis of acetylenedicarboxylic acid esters and asymmetric Diels–Alder reactions of the bis(methyl (*S*)-lactyl) ester

James L. Charlton, Gaiklean Chee, and Heather McColeman

Abstract: A general method has been developed for the preparation of acetylenedicarboxylic acid esters and applied to the synthesis of both achiral and chiral esters. Diels–Alder reactions of one of the chiral esters, the bis(methyl (*S*)-lactyl) ester, with various types of dienes, such as phenylbutadiene, orthoquinodimethanes, and isobenzofuran, have been investigated. Moderate asymmetric induction was observed in reactions with dienes bearing an α-hydroxyl group. In one case, an unusual solvent-induced reversal of asymmetric induction was observed.

Key words: acetylenedicarboxylic acid esters, phenylbutadiene, orthoquinodimethanes, isobenzofurans, Diels–Alder, asymmetric.

Résumé : On a développé une méthode générale de préparation des esters de l'acide acétylènedicarboxylique et on l'a appliquée à la synthèse d'esters tant achiraux que chiraux. On a étudié les réactions de Diels–Alder de l'un des esters chiraux, l'ester bis((*S*)-lactyle de méthyle), avec divers types de dienes, tels que le phénylbutadiène, les orthoquinodiméthanes et l'isobenzofurane. Avec les dienes portant un groupe α-hydroxyle, on a observé une induction asymétrique modérée. Dans un cas, on a observé une inversion inhabituelle de l'induction asymétrique induite par un solvant.

Mots clés : esters de l'acide acétylènedicarboxylique, phénylbutadiène, orthoquinodiméthanes, isobenzofuranes, Diels–Alder, asymétrique.

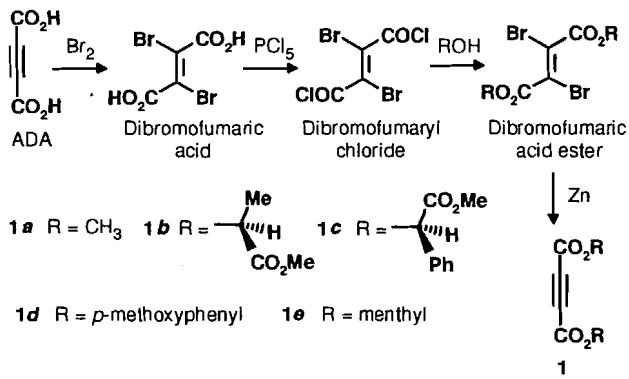
Introduction

The simple dialkyl esters of acetylenedicarboxylic acid (ADA) such as the dimethyl, diethyl, and dimenthyl can be prepared in good yield by direct esterification of the acid, and these esters have been widely used in studies of intermolecular Diels–Alder reactions with numerous types of dienes (see ref. 1 for a few examples). In some cases, direct esterification of ADA is complicated by the addition of the alcohol to the reactive triple bond polarized by the carboxylate groups (2). This side reaction has hindered the preparation of more complicated ADA esters such as the diaryl esters, which can only be prepared in moderate yield (~14%) by direct esterification of either ADA or acetylenedicarbonyl chloride (3). The preparation of complex ADA esters is, in fact, a very difficult task and it is noteworthy that literature reports of ADA ester derivatives, other than the simple dialkyl esters, are infrequent (3). Chiral esters of ADA, except for the menthyl ester, have been neglected as dienophiles in studies of asymmetric Diels–Alder reactions and the disregard of these compounds is attributed to difficulties encountered in their preparation. In addition, esters of alcohols that contain ester groups themselves, such as methyl lactate, cannot be prepared by direct esterification of ADA because the ester groups of the alcohols are susceptible to side reactions such as transesterification and hydrolysis. We would now like to report the full details of a general method for the preparation of ADA esters that is applicable to the synthesis of all types of ADA esters (Scheme 1).

Scheme 1.



Asymmetric induction in Diels–Alder reactions of the fumarate or acrylate of methyl lactate has been the subject of numerous studies (4), and we considered that studies of the analogous ester of ADA might be equally worthwhile. The

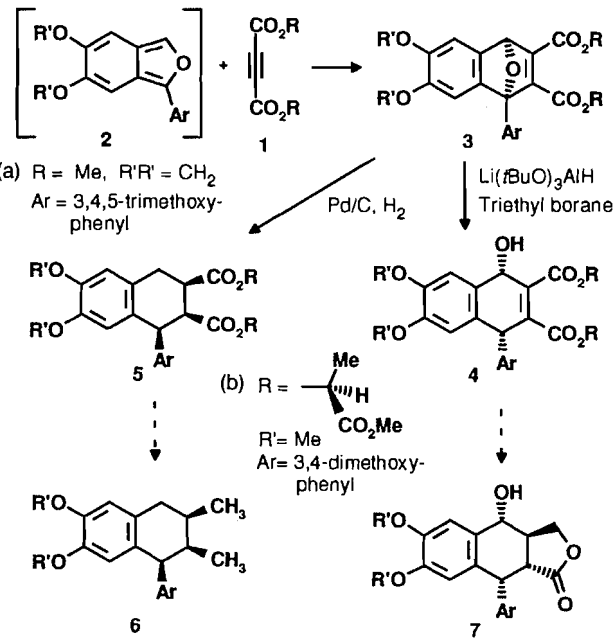
Scheme 2.



approach in Scheme 1 makes possible the preparation of the lactyl ADA ester **1***b*, and a study has been undertaken of its Diels–Alder reactions with various dienes such as phenylbutadiene (5), orthoquinodimethanes (*o*-QDMs) (6), and isobenzofurans (7). These dienes have been used extensively in organic synthesis for the construction of biaryl, aryltetralin, and naphthalene compounds. For instance, Rodrigo and co-workers have previously shown that an isobenzofuran can be trapped by dienophiles such as dimethyl ADA ester **1***a* to give a racemic cycloadduct that can then be hydrogenated with Pd/C to afford the corresponding tetralin **5***a* (see Scheme 2, series (a)) (8). In addition, the oxygen bridge can also be reductively cleaved by lithium tri-*tert*-butoxyaluminumhydride and triethyl borane to afford the corresponding 1,4-*cis*-dihydro naphthol **4***a* (9). The method should be applicable to the asymmetric synthesis of aryltetralin lignans, as proposed in Scheme 2. If cycloadduct **3***b* could be formed from isobenzofuran **2** and lactyl ADA ester **1***b* with the absolute stereochemistry shown, it could then be reduced stereoselectively to an aryltetralin with podophyllotoxin (**7**) or norisoguaiacin (**6**) relative and absolute stereochemistry, compounds that show antitumor and antibacterial activity, respectively (10).

Results and discussion

A. Synthesis of acetylenedicarboxylic acid esters

The ADA esters were prepared according to the procedures shown in Scheme 1 and briefly described in a preliminary communication (11). The general approach involves esterification of dibromofumaryl chloride followed by 2,3-dibromo elimination to afford the acetylenic diester in excellent yield. Dibromofumaryl chloride can be prepared by bromination of ADA followed by treatment with phosphorus pentachloride. Other than the bromination of ADA (80%), every step afforded a yield of >90% with no addition to the triple bond, transesterification, or hydrolysis. Bromination of a neutral aqueous solution of the potassium salt of ADA in the presence of sodium bromide proceeded smoothly. Phosphorus pentachloride rather than thionyl chloride was used for the preparation of dibromofumaryl chloride since the latter caused the liberation of bromine, which led to formation of unidentified by-products. The esterification of the acid chloride was carried out in carbon tetrachloride using pyridine as a catalyst at ice temperature. Of all the steps leading to the acetylenic esters, zinc-promoted debromination of dibromofumarate was the most troublesome due to the necessity to change the reaction conditions as the type of the diester changed. This was especially obvious in the case of bis(methyl (*S*)-lactyl) and bis(methyl (*R*)-mandelyl) esters of dibromofumaric acid. The former could be reduced with granular zinc in refluxing THF in 4 h, while the latter required the much more activated amalgamated zinc. In addition, the preparation of the mandelyl ADA ester **1***c* from the dibromofumarate using amalgamated zinc dust in refluxing THF for 1 h gave rise to the fumarate and maleate of the corresponding ester as by-products (3–4% each). Under the same condition, these products, which result from the reduction of the triple bond, were not observed in the preparation of lactyl ADA ester **1***b*. The reason for this is not known. It was found that the mandelyl ADA ester **1***c* and its fumarate were inseparable by chromatography. However, we discovered that α-hydroxy-*o*-QDM, which is a short-lived intermediate that can be prepared thermally from benzocyclobutenol (12), reacted with the fumarate at a faster rate than with the acetylenic ester. Therefore, treating a mixture of mandelyl ADA ester **1***c* and its fumarate with a trace amount of benzocyclobutenol in refluxing toluene allowed almost complete removal of the 4% fumarate as a cycloadduct after chromatography. The removal of the fumarate can be monitored by the disappearance of the olefinic protons at 7.06 ppm.

Although the approach in Scheme 1 does not offer any superiority over direct esterification methods for simple dialkyl esters of ADA (**1***a* and **1***e*), it does provide a method for the synthesis of complex ADA esters. The previously reported bis(*p*-methoxyphenyl) ester of ADA (**1***d*), which could be prepared only in 14–15% yield by direct esterification of ADA or acetylenedicarbonyl chloride (3), could now be prepared using the approach in Scheme 1 in an overall yield of >70%. Similarly, two new chiral esters of ADA, the lactyl ester **1***b* and mandelyl ester **1***c*, which could not be obtained by any direct esterification method, were also synthesized in excellent yield.

B. Asymmetric Diels–Alder reactions of bis(methyl (*S*)-lactyl) acetylenedicarboxylate (1*b*)

The Diels–Alder reactions of lactyl ADA ester **1***b* with various types of dienes were investigated. The dienes chosen for study were phenylbutadiene, various *o*-QDMs (α-hydroxy, α-phenyl-α′-hydroxy, α-hydroxy-α-phenyl, and α-phenyl), and an aryl isobenzofuran.

(*E*)-1-Phenyl-1,3-butadiene (13) was reacted with lactyl ADA ester **1***b* in refluxing xylenes to give a mixture of two diastereomers (**8**/**9**) in a 1:1.3 ratio,[2] as determined by integration of the four methoxy singlets between 3.5 and 3.8 ppm in

[2] Absolute stereochemistry of the major cycloadduct was not determined.

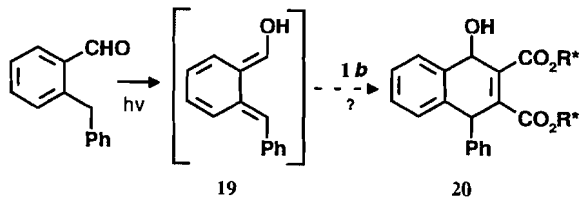
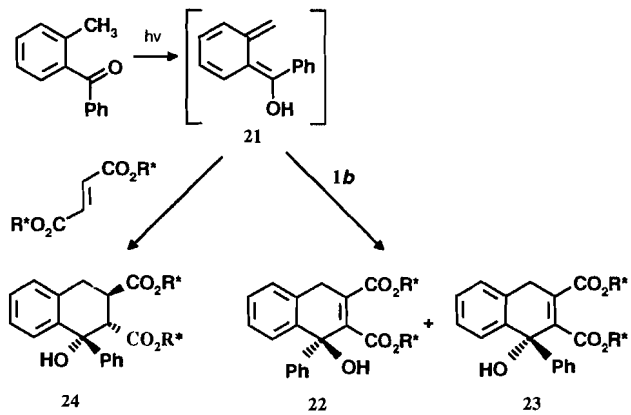


Scheme 7.



the NMR spectrum. Carrying out the reaction in methylene chloride at room temperature using $MeAlCl_2$ as catalyst gave only a slightly improved 1:2 mixture of the two diastereomers. The diastereomers were not separated but were further dehydrogenated to the biaryl **10** using Pd/C in refluxing xylenes, in order to confirm their structures (Scheme 3).

α-Phenyl-*o*-QDM (**11**), prepared thermally from α-phenylbenzocyclobutene (14) in refluxing toluene, reacted nonselectively with ADA ester **1*b*** to give a mixture of two diastereomers (**12/13**) in a 1:1.4 ratio[2] (see Scheme 4). In view of the poor diastereoselectivity, no attempt was made to separate the two diastereomers. The structures were confirmed by aromatization using Pd/C in refluxing xylenes to afford the phenylnaphthalene **14**. This aromatized product showed an interesting ^{13}C NMR feature in that 10 instead of 8 aromatic CH peaks were observed. This indicates that the C-2′ and C-3′ were not identical to C-6′ and C-5′, respectively, on the NMR time scale at room temperature, and the reason for this is attributed to the restricted rotation about the C1—C1′ bond of the molecule. Restricted rotation in arylnaphthalene derivatives giving rise to atropisomers has been studied elsewhere (15) but, to the best of our knowledge, the observed ^{13}C NMR properties of these compounds have not been reported.

α-Hydroxy-*o*-QDM (**15**), formed by the irradiation of 2-methylbenzaldehyde in benzene at room temperature, was reacted with lactyl ADA ester **1*b***. The addition was highly diastereoselective, generating a mixture of two fairly unstable diastereomers **16** and **17** (1:5 ratio),[2] which dehydrated slowly to give naphthol **18** upon standing at room temperature (Scheme 5). When α-hydroxy-*o*-QDM was generated thermally from benzocyclobutenol (12) in refluxing benzene, only the naphthol **18** was isolated.

o-QDM **19** was generated photochemically from *o*-benzylbenzaldehyde since its thermal precursor, *trans*-2-phenylbenzocyclobuten-1-ol, tends to be very difficult to prepare (16). Disappointingly, the aldehyde did not form a trappable *o*-QDM **19** on irradiation in the presence of ADA ester **1*b***, probably due to quenching of the triplet aldehyde by the dienophile (**4*b***)(Scheme 6).

α-Hydroxy-α-phenyl-*o*-QDM (**21**), generated by irradiation of 2-methylbenzophenone, was reacted with lactyl ADA ester **1*b*** to give a mixture of two diastereomers **22** and **23** (1:2.1 ratio),[2] which were characterized by NMR spectroscopy. The structures of the diastereomers were confirmed by dehydration using pTsOH in refluxing benzene to afford the phenylnaphthalene **14**. The reaction is depicted in Scheme 7.

Although the diastereoselectivity of the reaction was synthetically unsatisfactory, an interesting phenomenon was observed during the search for other solvents that might improve diastereoselectivity. When polar solvents such ethyl acetate, acetone, acetonitrile, or methanol were used, the ratio of the two diastereomers was reversed, as shown in Table 1.

To examine if a similar effect would occur with another dienophile carrying the same chiral auxiliary, an experiment was carried out using methyl (*S*)-lactyl fumarate as dienophile. In solvents such as benzene, acetone, and ethyl acetate, the reaction afforded predominantly diastereomer **24** (>90%

Table 1. Solvent effects on the diastereofacial selectivity in the Diels–Alder reaction of α-hydroxy-α-phenyl-*o*-QDM (**21**) with bis(methyl (*S*)-lactyl) acetylenedicarboxylate (**1***b*).

Solvent	Ratio of isomer[a] A : B
Hexane–benzene	1 : 2
Benzene	1 : 2.1
Ethyl acetate	2.2 : 1
Acetone	2.4 : 1
Acetonitrile	2 : 1
Methanol	2 : 1

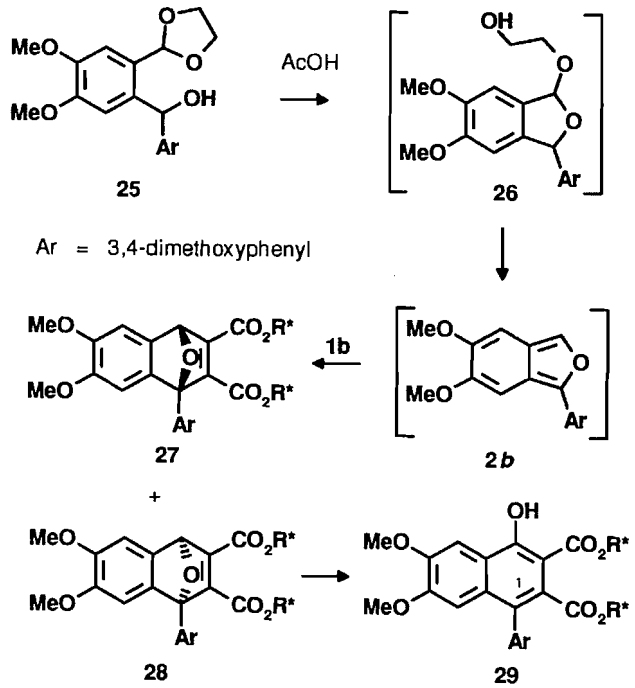
[a]Measured using the integration ratios of two methyl doublets between 1.2 and 1.4 ppm of their ^{1}H NMR ($CDCl_3$) spectra.

de) as given in Scheme 7.[3] In methanol, the diastereoselectivity of the reaction was reduced, affording two diastereomers in a 1:1.4 ratio, with **24** remaining as the major isomer. Solvent effects on Diels–Alder reactions are well known and can result in notable improvement in reaction rates, *endo*/*exo* diastereoselectivity, and diastereofacial selectivity (18). The phenomena have been explained by solvophobicity and electrostatic interactions of the solute and solvent (19). In all cases studied, the enhancement of the *endo*/*exo* or diastereofacial selectivities was observed, but no one has reported the unusual solvent-induced reversal of asymmetric induction in Diels–Alder reactions. A solvent-induced reversal of asymmetric induction has been observed in the photodeconjugation of an α,β-unsaturated lactyl ester (20). As well, the $TiCl_4$-catalysed Diels–Alder reaction of lactyl fumarate with cyclopentadiene yields a preferred product of opposite configuration to that of the uncatalysed reaction (21). A complete understanding of the effect of solvents on the asymmetric control of the Diels–Alder reaction of ADA ester **1***b* and *o*-QDM **21** will require further study.

The last diene used for the study of a Diels–Alder reaction of ADA ester **1***b* was isobenzofuran **2***b*, generated using a modified literature procedure, via phthalan **26** by the acid-catalysed elimination reaction of hydroxyacetal **25** (Scheme 8)(22). Precursor **25** was reacted with ADA ester **1***b* in the presence of a catalytic amount of glacial acetic acid at 95°C for 20 min, giving the aromatized cycloadduct naphthol **29** as a major product (80 ± 5%), and two bridged cycloadducts (**27** and **28**) as minor products (20 ± 5%) in a 1:1.2 ratio,[2] as determined by the integration of two pairs of lactyl doublets between 1.0 and 1.6 ppm. Using $MeAlCl_2$ or Et_2AlCl in place of glacial acetic acid as a catalyst for the formation of isobenzofuran **2***b* and for the Diels–Alder reaction, at either room temperature or at 70°C, failed to afford any cycloadduct from hydroxyacetal **25** and ester **1***b*.

[3] The assignment of the absolute and relative stereochemistry of diastereomer **24** was made on the basis of previous work on a similar compound. Because the chiral auxiliary of the dienophile employed in this study had the opposite stereochemistry to that used previously, a reverse facial selectivity in the Diels–Alder reaction was assumed. (ref. 17).

Scheme 8.



Since the formation of **27** and **28** showed no diastereoselectivity, no attempt was made to isolate the bridged cycloadducts, and the crude product was reacted further in the presence of acid to convert both minor products to the naphthol, which was isolated in 80% yield after chromatography. Its ^{1}H NMR spectrum showed an interesting feature in that most of the characteristic peaks of naphthol **29** were split into doublets. Similar to phenylnaphthalene **14**, the phenomenon is attributed to the restricted rotation about the C1—C1′ bond, which causes naphthol **29** to exist in two diastereomeric forms as observable in the NMR spectrum. Further investigations on the hindered rotation of arylnaphthalene lignans are under progress and will be reported in the near future.

The results for the Diels–Alder reactions of ADA ester **1***b* with various types of diene are summarized in Table 2. The dienes without an α-hydroxy group afforded stable cycloadducts but, disappointingly, gave poor diastereoselectivity. This was only marginally increased in the presence of the Lewis acid $MeAlCl_2$. In reactions with *o*-QDMs, diastereofacial selectivity was poorer than when using the fumarate of methyl lactate, which is known to give de's of >95% (4). Even though reasonable diastereoselectivity was observed in reactions with α-hydroxy-*o*-QDMs, the cycloadducts tended to be fairly unstable due to their ease of dehydration. The reaction of isobenzofuran **2***b* with ADA ester **1***b* appeared nonselective, and was not suitable for use in the preparation of diastereomerically pure aryltetralins. The use of the Lewis acids Et_2AlCl or $MeAlCl_2$ in this reaction entirely stopped cycloadduct formation.

Experimental

A description of general instrumentation, procedures for the irradiation experiments, and identification and characterization of compounds has been provided previously (4).

Table 2. Yields and diastereomer ratios of the Diels–Alder reactions of bis(methyl (*S*)-lactyl) acetylenedicarboxylate (**1***b*) with various dienes.

Type of diene	Cycloadducts (% yield)[a]	Ratio of two diastereomers[b]	Aromatization product (% yield)[c]
Phenylbutadiene	82	1:1.3	92
	75[d]	1:2[d]

A. Synthesis of acetylenedicarboxylic acid esters

Dibromofumaric acid

A modification of a literature procedure was used (23). An aqueous solution of KOH (2 M, ca. 20 mL) was added to the monopotassium salt of acetylenedicarboxylic acid (5.51 g, 36.3 mmol) with stirring until the resulting solution became neutral. Bromine (6.33 g, 39.6 mmol) was added to sodium bromide (18.7 g, 0.18 mol) in water (80 mL), and this solution was then added to the neutral solution of ADA. Water was added to the mixture to give a total volume of 150 mL. The brown color of the solution discharged after 2 h in the dark at room temperature. It was left standing for a further day. The colorless solution was acidified with concentrated HCl to pH 1–2, and extracted with ethyl acetate (4 × 20 mL). The organic layer was washed with saturated sodium bisulfite (3 × 20 mL), dried ($MgSO_4$), and concentrated in vacuo to give a colorless solid (9.44 g). The product was recrystallized from THF–hexanes to give colorless needles (8.0 g, 80%); mp 237–238°C, identical to that reported previously (24); IR (CH_2Cl_2): 1697 cm^{-1}; ^{13}C NMR (H_2O/D_2O) δ: 113.10 (2 × C), 168.61 (2 × CO); mass spectrum *m/e* (rel %): 276 (1.3), 274 (2.4), 272 (1.2), 186 (4), 184 (6), 182 (3), 151 (16), 149 (17), 106 (95), 104 (100).

Dibromofumaryl chloride

The compound was prepared according to Ott's procedure (24). Dibromofumaric acid (4.69 g, 17.1 mmol), petroleum ether (30 mL), and phosphorus pentachloride (7.17 g, 34.4 mmol) were stirred together at room temperature until the precipitate dissolved (ca. 5 h). The solution was poured onto crushed ice and stirred for 15 min. The organic layer was separated, dried ($MgSO_4$), and concentrated in vacuo to give a pale yellow liquid (4.87 g, 92%). IR (CH_2Cl_2): 1779 cm^{-1}. ^{13}C NMR ($CDCl_3$) δ: 114.64 (2 × C), 162.00 (2 × CO); mass spectrum *m/e* (rel %): 312 (4.5), 310 (5.5), 277 (24), 275 (36), 257 (10), 256 (14), 249 (25), 247 (35), 213 (18), 211 (11), 184 (17), 133 (98), 131 (100). Exact Mass calcd. for $C_4{}^{79}Br^{81}Br^{35}Cl_2O_2$: 309.7621; found: 309.7578.

General procedure for the preparation of dibromofumarates (except for the dimethyl ester)

To the alcohol (3.18 mmol) and pyridine (0.255 g, 3.22 mmol) in CCl_4 (20 mL) at 0°C under nitrogen, was added dibromofumaryl chloride (0.497 g, 1.60 mmol) in CCl_4 (10 mL), dropwise, over a period of 10 min. The mixture was stirred for 20 min and then at room temperature for another 40 min. It was washed with water (2 × 20 mL), 5% sodium bicarbonate (4 × 20 mL), and water (2 × 20 mL). The organic layer was dried ($MgSO_4$) and concentrated in vacuo.

Bis(methyl (R)*-lactyl) dibromofumarate*: A yellow liquid (93%); $[\alpha]_D^{20}$ −22.4 (*c* 0.923, $CHCl_3$); IR (CH_2Cl_2): 1748 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.61 (d, 6H, *J* = 7.05), 3.79 (s, 6H), 5.27 (q, 2H, *J* = 7.06); ^{13}C NMR ($CDCl_3$) δ: 16.71 (2 × CH_3), 52.57 (2 × CH_3), 70.84 (2 × CH), 112.66 (2 × C), 161.24 (2 × CO), 169.65 (2 × CO); mass spectrum *m/e* (rel %): 367 (15.0), 365 (15.1), 345 (7), 343 (15), 341 (8), 293 (15), 291 (15), 183 (37), 155 (14), 86 (100). Anal. calcd. for $C_{12}H_{14}Br_2O_8$: C 32.31, H 3.16; found: C 32.43, H 3.21.

Bis(p-*methoxyphenyl) dibromofumarate*: A pale yellow solid (96%); mp 146–148°C; IR (CH_2Cl_2): 1700 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 3.81 (s, 6H), 6.93 (d, 4H, *J* = 9.08), 7.15 (d, 4H, *J* = 9.10); ^{13}C NMR ($CDCl_3$) δ: 55.63 (2 × CH_3), 113.26 (2 × C), 114.64 (4 × CH), 121.75 (4 × CH), 143.42 (2 × C), 157.89 (2 × C), 160.85 (2 × CO); mass spectrum *m/e* (rel %): 486 (M^+, 2.0), 365 (3), 363 (6), 361 (4), 326 (8), 284 (4), 282 (5), 124 (100), 123 (48), 109 (95). Anal. calcd. for $C_{18}H_{14}Br_2O_6$: C 44.47, H 2.90; found: C 44.47, H 2.86.

Bis(methyl (S)*-mandelyl) dibromofumarate*: A colorless liquid that crystallized upon standing (93%); mp 61–63°C; $[\alpha]_D^{20}$ −103.3 (*c* 1.462, $CHCl_3$); IR (CH_2Cl_2): 1749, 1751 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 3.77 (s, 6H), 6.07 (s, 2H), 7.39–7.41 (m, 6H), 7.48–7.51 (m, 4H); ^{13}C NMR ($CDCl_3$) δ: 52.88 (2 × CH_3), 76.36 (2 × CH), 113.09 (2 × C), 127.65 (4 × CH), 128.86 (4 × CH), 129.62 (2 × CH), 132.46 (2 × C), 161.22 (2 × CO), 167.87 (2 × CO); mass spectrum *m/e* (rel %): 407 (2.0), 405 (4.4), 403 (2.3), 189 (14), 150 (31), 149 (100.0) 121 (36), 118 (22), 105 (45). Anal. calcd. for $C_{22}H_{18}Br_2O_8$: C 46.34, H 3.18; found: C 46.58, H 3.18.

Dimenthyl dibromofumarate: A colorless oil that crystallized upon standing (100%); mp 82–85°C; $[\alpha]_D^{20}$ −55 (*c* 0.418,

$CHCl_3$); IR (CH_2Cl_2): 1732 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 0.79 (d, 6H, J = 6.92), 0.84–0.93 (m, 2H), 0.92 (d, 6H, J = 7.11), 0.94 (d, 6H, J = 6.67), 1.11 (m, 4H), 1.50 (m, 4H), 1.71 (br d, 4H), 2.02 (dp, 2H, J = 2.73, 6.96), 2.06 (m, 2H), 4.84 (dt, 2H, J = 4.39, 10.91); ^{13}C NMR ($CDCl_3$) δ: 16.02 (2 × CH_3), 20.72 (2 × CH_3), 21.95 (2 × CH_3), 23.20 (2 × CH_2), 25.95 (2 × CH), 31.45 (2 × CH), 34.06 (2 × CH_2), 40.19 (2 × CH_2), 46.90 (2 × CH), 77.78 (2 × CH), 112.01 (2 × C), 161.84 (2 × CO); mass spectrum *m/e* (rel %): 395 (0.5), 273 (1.7), 271 (3.6), 269 (1.8), 149 (17), 139 (22), 138 (50), 123 (31), 95 (94), 81 (85). Anal. calcd. for $C_{24}H_{38}Br_2O_4$: C 52.38, H 6.96; found: C 52.54, H 7.04.

Dimethyl dibromofumarate

A mixture of dibromofumaryl chloride (0.425 g, 1.38 mmol) and methanol (4 mL) was refluxed under nitrogen for 2 h. The solvent was evaporated and the precipitate was dissolved in dichloromethane (5 mL), then washed with 5% sodium bicarbonate (3 × 10 mL) and water (2 × 10 mL). The dichloromethane layer was dried ($MgSO_4$) and concentrated in vacuo to give a colorless solid (0.393 g, 94%); mp 36–37°C; IR (CH_2Cl_2): 1744 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 3.91 (s, 6H); ^{13}C NMR ($CDCl_3$) δ: 53.68 (2 × OCH_3), 112.70 (2 × C), 162.59 (2 × CO); mass spectrum *m/e* (rel %): 304 (14), 302 (28), 300 (15), 273 (48), 271 (97), 269 (51), 223 (30), 221 (30), 195 (15), 193 (17), 149 (20), 147 (20), 133 (35), 131 (35). Exact Mass calcd. for $C_6H_6Br_2O_4$: 301.8612; found: 301.8606.

General procedure for the preparation of acetylenedicarboxylates (not including the bis(methyl (R)-mandelyl) and dimenthyl esters)

Dibromofumarate (1 mmol), dry THF (10 mL), and granular zinc (0.4 g, 6 mmol) were refluxed under nitrogen for 2–5 h depending on the type of ester (Note: the bis(*p*-methoxyphenyl) ester required a catalytic amount of I_2). The granular zinc was filtered off and THF evaporated. The brown residue was dissolved in dichloromethane (5 mL) and washed with water (4 × 10 mL). The organic phase was dried ($MgSO_4$) and concentrated in vacuo.

*Dimethyl acetylenedicarboxylate (**1**a)*: The reaction was complete after 2 h reflux with granular zinc. A colorless liquid was obtained (93%), ^1H NMR ($CDCl_3$) δ: 3.85 (s, 6H); ^{13}C NMR ($CDCl_3$) δ: 53.42 (2 × CH_3), 74.63 (C≡C), 152.12 (2 × CO), identical to that reported previously.[4]

*Bis(methyl (S)-lactyl) acetylenedicarboxylate (**1**b)*: The reaction was complete after 4 h reflux with granular zinc. A yellow oil that crystallized upon standing was obtained (95%). The solid was recrystallized from ethyl acetate–hexane; mp 78–81°C; $[\alpha]_D^{20}$ +8.0 (*c* 0.365, CHCl3); IR (CH_2Cl_2): 1732, 1760 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.57 (d, 6H, J = 7.05), 3.78 (s, 6H), 5.23 (q, 2H, J = 7.06); ^{13}C NMR ($CDCl_3$) δ: 16.74 (2 × CH_3), 52.70 (2 × CH_3), 70.72 (2 × CH), 74.98 (C≡C), 150.76 (2 × CO), 169.47 (2 × CO); mass spectrum *m/e* (rel %): 255 (2.0), 227 (13), 183 (100), 155 (49), 111 (45.9), 87 (31), 83 (51), 80 (39). Anal. calcd. for $C_{12}H_{14}O_8$: C 50.35, H 4.93; found: C 50.10, H 4.95.

*Bis(p-methoxyphenyl) acetylenedicarboxylate (**1**d)*: This reaction required a 5 h reflux with granular zinc and I_2 (20 mg). A colourless oil that crystallized upon standing was obtained (93%); mp 146–147°C; ^1H NMR ($CDCl_3$) δ: 3.81 (s, 6H), 6.91 (br d, 4H, J = 9.14), 7.09 (br d, 4H, J = 9.15), identical to that previously reported (3); ^{13}C NMR ($CDCl_3$) δ: 55.61 (2 × CH_3), 75.96 (C≡C), 114.66 (4 × CH), 121.82 (4 × CH), 143.00 (2 × C), 150.32 (2 × C), 157.97 (2 × CO).

*Bis(methyl (R)-mandelyl) acetylenedicarboxylate (**1**c)*: Bis-(methyl (*R*)-mandelyl) dibromofumarate (71 mg, 0.12 mmol), dry THF (3 mL), and amalgamated zinc dust (47 mg, 0.72 mmol) were refluxed under nitrogen for 1 h. The solution was worked up as in the general procedure above to give a pale yellow liquid (47 mg, 95%). The ^1H NMR spectrum of the crude product showed the presence of two by-products (3–4% each). One was identified as the fumarate of methyl (*R*)-mandelate by comparison to an authentic sample (25), while the other appeared to be the maleate ester (see below). The fumarate was inseparable from mandelyl ester **1***c* by chromatography. This by-product could be removed by reacting the crude product (40 mg) with a small amount of benzocyclobutenol (12) (6 mg) in refluxing toluene (2 mL) for 30 min, followed by chromatography with 10% ethyl acetate – hexanes, which afforded the pure mandelyl ester **2** (38 mg, 85%); $[\alpha]_D^{20}$ −45.6 (*c* 0.485, $CHCl_3$); IR (CH_2Cl_2): 1761, 1735 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 3.75 (s, 6H), 6.03 (s, 2H), 7.39–7.48 (m, 10H); ^{13}C NMR ($CDCl_3$) δ: 52.96 (2 × CH_3), 75.11 (C≡C), 76.18 (2 × CH), 127.70 (4 × CH), 128.92 (4 × CH), 129.76 (2 × CH), 132.22 (2 × C), 150.64 (2 × CO), 167.64 (2 × CO); mass spectrum *m/e* (rel %): 351 (M−CO_2CH_3, 1.0), 189 (6), 159 (10), 150 (31), 149 (24), 118 (66), 105 (80), 91 (100), 77 (71). Anal. calcd. for $C_{22}H_{18}O_8$: C 64.39, H 4.42; found: C 65.38, H 4.42.[5]

Bis(methyl (R)-mandelyl) maleate: mp 73–74°C; $[\alpha]_D^{20}$ −173 (*c* 0.15, $CHCl_3$); IR (CH_2Cl_2): 1755, 1763 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 3.68 (s, 6H), 5.90 (s, 2H), 6.43 (s, 2H), 7.35 (br s, 10H); ^{13}C NMR ($CDCl_3$) δ: 52.61 (2 × CH_3), 75.07 (2 × CH), 127.62 (4 × CH), 128.71 (4 × CH), 129.23 (2 × CH), 129.78 (2 × CH), 133.18 (2 × C), 163.77 (2 × CO), 168.59 (2 × CO); mass spectrum *m/e* (rel %): 255 (6), 248 (2), 165 (3), 150 (50), 149 (100), 121 (42), 105 (31), 91 (22), 77 (30). Anal. calcd. for $C_{22}H_{20}O_8 \cdot EtOAc$: C 62.39, H 5.64; found: C 62.71, H 5.16.

*Dimenthyl acetylenedicarboxylate (**1**e)*: Dimenthyl dibromofumarate (75 mg, 0.13 mmol), dry THF (3 mL), and amalgamated zinc dust (84 mg, 1.28 mmol) were stirred under nitrogen at room temperature for 16 h. The solution was worked up as in the general procedure described above to give a colorless solid (46 mg, 92%); mp 131–133°C; $[\alpha]_D^{20}$ −79.1 (*c* 0.139, $CHCl_3$); IR (CH_2Cl_2): 1726 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 0.77 (d, 6H, J = 6.93), 0.91 (d, 6H, J = 6.99), 0.92 (d, 6H, J = 6.50), 0.85–0.93 (m, 2H), 1.06 (m, 4H), 1.44 (m, 4H), 1.70 (m, 4H), 1.89 (dp, 2H, J = 2.64, 6.94), 2.03 (m, 2H), 4.84 (dt, 2H, J = 4.44, 10.92); ^{13}C NMR ($CDCl_3$) δ: 16.10 (2 × CH_3), 20.70 (2 ×

[4] Dimethyl acetylenedicarboxylate is commercially available. Its chemical information can be obtained from The Aldrich Catalog Handbook of Fine Chemicals 1994–1995, Aldrich Chemical Company, Inc., Milwaukee, Wis., pp. 548 (1994), and references cited therein.

[5] The unsatisfactory data of the elemental analysis of ADA ester **2** can probably be attributed to the difficulty in complete removal of the trace amount of the corresponding fumarate.

CH_3), 21.91 (2 × CH_3), 23.27 (2 × CH_2), 26.08 (2 × CH), 31.47 (2 × CH), 33.99 (2 × CH_2), 40.45 (2 × CH_2), 46.80 (2 × CH), 74.87 (C≡C), 77.66 (2 × CH), 151.61 (2 × CO); mass spectrum *m/e* (rel %): 139 (24), 138 (49), 129 (16), 123 (30), 95 (100), 83 (90), 81 (82). Anal. calcd. for $C_{24}H_{38}O_4 \cdot 1.5$ EtOAc: C 68.93, H 9.64; found: C 68.95, H 9.62.

B. Diels–Alder reactions of bis(methyl (*S*)-lactyl) acetylenedicarboxylate

(E)-1-Phenyl-1,3-butadiene

A modified literature procedure was used (13). *n*-Butyllithium (2.0 M, 5.6 mL, 11.2 mmol) was added dropwise to a suspension of methyltriphenylphosphonium bromide (3.95 g, 11.0 mmol) in ether (30 mL) under N_2 in an ice bath. The precipitate dissolved and the solution was stirred for 30 min and then cooled to −78°C, followed by dropwise addition of *trans*-cinnamaldehyde (1.39 g, 10.5 mmol) in ether (10 mL). The mixture was gradually warmed to room temperature and stirred for another 2 h. The colorless precipitate was filtered off with the aid of Celite, and the filtrate was concentrated in vacuo. The residue was redissolved in petroleum ether (10 mL) and eluted through a short silica gel column, washed with petroleum ether (ca. 20 mL), and the collected solution concentrated in vacuo to leave a pale yellow liquid (0.75 g, 55 %), which was used in the next reaction without purification.

*Cycloadducts **8** and **9***

A mixture of (*E*)-1-phenyl-1,3-butadiene (0.177 g, 1.36 mmol), **1***b* (0.118 g, 0.41 mmol), and hydroquinone (2 mg) in xylenes (4 mL) was refluxed under N_2 for 6 h. The resulting solution was run through a short silica gel column and rinsed with hexanes to remove xylenes. The product was then eluted with ethyl acetate and concentrated in vacuo to give a pale yellow liquid (0.17 g), containing mainly two diastereomers in a 1:1.3 ratio, as determined by ^{1}H NMR spectroscopy.[2] The product was chromatographed using 25% ethyl acetate – hexanes to give an oil (0.14 g, 82%); IR (CH_2Cl_2): 1745 cm^{-1}; ^{1}H NMR ($CDCl_3$, a mixture of two diastereomers) δ: 1.23 (d, 3H, *J* = 7.01), 1.25 (d, 4H, *J* = 6.95), 1.50 (d, 3H, *J* = 7.06), 1.53 (d, 4H, *J* = 7.05), 3.12 (m, 2.3H), 3.30 (m, 2.3H), 3.59 (s, 3H), 3.60 (s, 4H), 3.74 (s, 3H), 3.76 (s, 4H), 4.44 (m, 2.3H), 4.95 (q, 1H, *J* = 6.99), 5.09 (q, 1.3H, *J* = 6.99), 5.20 (q, 1H, *J* = 7.09), 5.23 (q, 1.3H, *J* = 7.06), 5.80 (m, 4.6H), 7.15–7.30 (m, 11.7H); mass spectrum *m/e* (rel %): 414 (M−H_2, 2.0), 312 (34), 225 (78), 181 (100), 153 (33), 149 (31). Exact Mass (CIMS, NH_4^+) calcd. for $C_{22}H_{24}O_8 \cdot NH_4$: 434.1815; found: 434.1780.

*Lewis acid-catalyzed Diels–Alder reaction of **1**b and phenylbutadiene*

A mixture of phenylbutadiene (55 mg, 0.43 mmol), **1***b* (15.5 mg, 0.054 mmol), and $MeAlCl_2$ (1.0 M in hexanes, 0.22 mL, 0.21 mmol) in CH_2Cl_2 (2 mL) was stirred under nitrogen at room temperature for 20 h. The mixture was diluted with CH_2Cl_2 (10 mL), washed with water (3 × 10 mL), dried ($MgSO_4$), and concentrated to afford a brown residue (60 mg). The ^{1}H NMR spectrum of the crude product showed the presence of two diastereomers in a 1:2 ratio, with the chemical shifts identical to those of cycloadducts **8** and **9**. The product was chromatographed using 25% ethyl acetate – hexanes to give an oil (17 mg, 75%).

*Biaryl **10***

A mixture of diastereomers **8** and **9** (70 mg, 0.17 mmol) was refluxed with Pd/C (0.3 g) in xylenes (4 mL) for 10 h. The mixture was filtered through a short column of silica gel, and rinsed with hexanes to remove xylenes. The product was eluted with ethyl acetate and concentrated to leave a pale yellow oil (65 mg, 92%); $[\alpha]_D^{20}$ −21.8 (*c* 0.625, $CHCl_3$); IR (CH_2Cl_2): 1743 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.26 (d, 3H, *J* = 6.99), 1.61 (d, 3H, *J* = 7.04), 3.62 (s, 3H), 3.8 (s, 3H), 5.25 (q, 1H, *J* = 6.96), 5.33 (q, 1H, *J* = 7.04), 7.37–7.41 (m, 5H), 7.55 (m, 2H), 8.06 (dd, 1H, *J* = 4.80, 7.90); ^{13}C NMR ($CDCl_3$) δ: 16.68 (CH_3), 16.94 (CH_3), 52.12 (CH_3), 52.33 (CH_3), 69.52 (2 × CH), 127.81 (CH), 127.97 (CH), 128.15 (2 × CH), 128.94 (2 × CH), 129.02 (CH), 129.34 (CH), 133.80 (C), 134.55 (CH), 138.90 (C), 141.06 (C), 164.81 (C), 167.19 (C), 170.59 (C), 170.74 (C); mass spectrum *m/e* (rel %): 414 (M^+, 10), 311 (47), 225 (85), 152 (19), 84 (100). Exact Mass calcd. for $C_{22}H_{22}O_8$: 414.1314; found: 414.1293.

*Cycloadducts **12** and **13***

A mixture of **1***b* (0.10 g, 0.35 mmol) and α-phenylbenzocyclobutene (**14**) (95 mg, 0.52 mmol) in toluene (5 mL) was refluxed for 5 h. The solution was concentrated in vacuo to give an oily residue that was chromatographed using 25% ethyl acetate – hexanes to afford a mixture of two diastereomers (**12** and **13**, 0.10 g, 62%) in a 1:1.3 ratio, as determined by ^{1}H NMR spectroscopy;[2] IR (CH_2Cl_2): 1750 cm^{-1}; ^{1}H NMR ($CDCl_3$, a mixture of two diastereomers) δ: 1.35 (d, 4H, *J* = 7.02), 1.36 (d, 3H, *J* = 7.02), 1.52 (d, 4H, *J* = 7.02), 1.57 (d, 3H, *J* = 7.29), 3.64 (s, 4H), 3.67 (s, 3H), 3.77 (s, 3H), 3.78 (s, 4H), 3.84 (dd, 1.3H, *J* = 3.4, 22.2), 3.85 (dd, 1H, *J* = 3.4, 22.2), 4.02 (dd, 1H, *J* = 4.39, 21.9), 4.06 (dd, 1.3H, *J* = 4.4, 22.36), 5.06 (q, 1.3H, *J* = 7.02), 5.18 (m, 2.3H), 5.26 (m due to overlap of two quartets, 2.3H), 7.13–7.25 (m, 21H); mass spectrum *m/e* (rel %): 464 (M−H_2, 6), 362 (19), 275 (30), 231 (54), 202 (32), 119 (66) 116 (63). Exact Mass (CIMS, NH_4^+) calcd. for $C_{26}H_{26}O_8 \cdot NH_4$: 484.1971; found: 484.1937.

*Phenylnaphthalene **14***

A mixture of diastereomers **12** and **13** (50 mg, 0.11 mmol) and Pd/C (0.30 g) in xylenes (5 mL) was refluxed for 20 h. The work-up procedure for biaryl **10** was used to give a yellow oil (45 mg, 90%); $[\alpha]_D^{20}$ +13.7 (*c* 0.54, $CHCl_3$); IR (CH_2Cl_2): 1744 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.21 (d, 3H, *J* = 6.97), 1.66 (d, 3H, *J* = 7.04), 3.63 (s, 3H), 3.77 (s, 3H), 5.18 (q, 1H, *J* = 6.97), 5.39 (q, 1H, *J* = 7.04), 7.13–7.53 (m, 8H), 8.01 (br d, 1H, *J* = 8.02), 8.67 (s, 1H); ^{13}C NMR ($CDCl_3$) δ: 16.71 (CH_3), 17.06 (CH_3), 52.09 (CH_3), 52.36 (CH_3), 69.41 (CH), 69.49 (CH), 124.13 (C), 127.03 (CH), 127.63 (CH), 127.83 (CH), 127.96 (CH), 128.04 (CH), 129.11 (CH), 129.32 (CH), 129.94 (C), 130.41 (CH), 130.53 (CH), 131.72 (CH), 132.39 (C), 134.27 (C), 136.29 (C), 139.16 (C), 164.91 (C), 167.25 (C), 170.66 (C), 170.91 (C); mass spectrum *m/e* (rel %): 464 (M^+, 37), 361 (41), 275 (100), 231 (20), 202 (62). Exact Mass calcd. for $C_{26}H_{24}O_8$: 464.1471; found: 464.1499.

*Cycloadducts **16** and **17**, and naphthol **18***

1*b* (0.145 g, 0.51 mmol) and 2-methylbenzaldehyde (4*a*) (0.303 g, 2.5 mmol) were irradiated in benzene (10 mL) for 2.5

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

h and then concentrated in vacuo. Chromatography of the crude product using 25% ethyl acetate – hexanes afforded two fairly unstable diastereomers (**16** and **17**, 96 mg, 46%) in a 1:5 ratio, as determined by ^{1}H NMR spectroscopy.[2] IR (CH_2Cl_2): 3489 (OH), 1742 cm^{-1}; ^{1}H NMR ($CDCl_3$, major diastereomer) δ: 1.57 (d, 3H, J = 7.08), 1.60 (d, 3H, J = 7.10), 3.69 (dd, 1H, J = 4.64, 23.0), 3.99 (dd, 1H, J = 3.77, 23.05), 3.78 (s, 3H), 3.81 (s, 3H), 5.29 (q, 1H, J = 7.06), 5.45 (q, 1H, J = 7.12), 5.72 (t, 1H, J = 4.16), 7.20–7.38 (m, 3H), 7.79 (dd, 1H, J = 1.89, 6.93). A by-product (81 mg, 39%) was also isolated from the chromatography of the crude diastereomers. It was identified as the naphthol **18**; $[\alpha]_D^{20}$ +24.6 (*c* 0.46, $CHCl_3$); IR (CH_2Cl_2): 1746 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.56 (d, 6H, J = 7.07), 3.73 (s, 6H), 5.33 (q, 2H, J = 7.05), 7.57 (dd, 2H, J = 3.19, 3.24), 7.88 (dd, 2H, J = 3.24, 3.3), 8.30 (s, 2H); ^{13}C NMR ($CDCl_3$) δ: 17.02 (2 × CH_3), 52.39 (2 × CH_3), 69.55 (2 × CH), 127.72 (2 × C), 128.77 (4 × CH), 130.72 (2 × CH), 133.47 (2 × C), 166.54 (2 × C), 171.10 (2 × C); mass spectrum *m/e* (rel %): 388 (M^+, 16), 285 (54), 199 (100), 171 (14), 149 (15). Exact Mass calcd. for $C_{20}H_{20}O_8$: 388.1158; found: 388.1150.

*Cycloadducts **22** and **23***

1*b* (69 mg, 0.24 mmol) and 2-methylbenzophenone (78 mg, 0.40 mmol) were irradiated in benzene for 2 h. The reaction mixture was concentrated in vacuo and chromatographed (ethyl acetate – hexanes) to give a mixture of two diastereomers (**22** and **23**, 95 mg, 82%) in a 1:2.1 ratio, as shown in the ^{1}H NMR spectrum.[2] IR (CH_2Cl_2): 3458 (OH), 1741 cm^{-1}; ^{1}H NMR ($CDCl_3$, mixture of two diastereomers) δ: 1.24 (d, 3H, J = 7.02), 1.34 (d, 6.3H, J = 7.05), 1.56 (d, 3H, J = 7.04), 1.57 (d, 6.3H, J = 7.05), 3.68 (s, 3H), 3.74 (s, 6.3H), 3.76 (s, 6.3H), 3.79 (s, 3H), 3.85 (d, 3.1H, J = 22.58), 4.02 (d, 2.1H, J = 22.57), 4.03 (d, 1H, J = 22.74), 4.43 (s, 2.1H), 4.69 (s, 1H), 5.15 (m due to overlap of four quartets, 6.2H), 7.16–7.59 (m, 27.9H); mass spectrum *m/e* (rel %): 464 ($M-H_2O$, 32), 361 (34), 301 (26), 275 (100), 202 (53). Exact Mass calcd. for $C_{26}H_{24}O_8$: 464.1470; found: 464.1442. A mixture of diastereomers **22** and **23** (20 mg, 0.04 mmol) was refluxed with *p*-TsOH (6 mg) in benzene for 1 h. The solution was filtered through a short silica gel column, and concentrated in vacuo to give an oily residue (16 mg, 80%), that had an NMR spectrum identical to that of phenylnaphthalene **14** (see above).

*Cycloadduct **24***

Methyl (*S*)-lactyl fumarate (4*a*) (140 mg, 0.48 mmol) and 2-methylbenzophenone (93 mg, 0.47 mmol) were irradiated in benzene for 20 h and then concentrated in vacuo. The ^{1}H NMR spectrum of the crude product showed the presence of predominantly one diastereomer (>90% de), and a by-product (ca. 20%) that was identified as the maleate of methyl (*S*)-lactate by comparison to an authentic sample (4*a*). The cycloadduct and the maleate were inseparable by chromatography. The latter could be removed by reacting the crude product (0.233 g) with an excess of benzocyclobutenol (12) (0.15 g) in refluxing toluene for 5 h, followed by chromatography with 15–25% ethyl acetate – hexanes, which afforded the pure cycloadduct **24** (0.10 g, 44%) (17); $[\alpha]_D^{20}$ +48.6 (*c* 0.500, $CHCl_3$); IR (CH_2Cl_2): 3436, 1744 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.13 (d, 3H, J = 7.05), 1.54 (d, 3H, J = 7.02), 3.15 (dd, 1H, J = 11.96, 16.32), 3.43 (dd, 1H, J = 4.32, 16.33), 3.57–3.82 (m, 2H), 3.68 (s, 3H), 3.77 (s, 3H), 4.20 (s, 1H, OH), 4.90 (q, 1H, J = 7.04), 5.12 (q, 1H, J = 7.09), 6.91 (d, 1H, J = 7.13), 7.02–7.42 (m, 8H); ^{13}C NMR ($CDCl_3$) δ: 16.29 (CH_3), 16.84 (CH_3), 32.76 (CH_2), 39.34 (CH), 52.29 (CH_3), 52.55 (CH_3), 55.01 (CH), 68.78 (CH), 68.90 (CH), 76.29 (C), 126.22 (2 × CH), 126.61 (CH), 126.97 (CH), 127.60 (2 × CH), 127.68 (CH), 128.10 (CH), 130.21 (CH), 133.30 (C), 140.36 (C), 146.60 (C), 171.16 (CO), 171.50 (CO), 171.63 (CO), 174.17 (CO); mass spectrum *m/e* (rel %): 466 (0.3, $M-H_2O$), 334 (10), 274 (16), 231 (45.3), 205 (100), 202 (57). Exact Mass calcd. for $C_{26}H_{26}O_8$: 466.1628; found: 466.1657.

*Arylnaphthol **29***

1*b* (0.10 g, 0.35 mmol) and hydroxyacetal **25** (22) (0.16 g, 0.41 mmol) were dissolved in a minimum amount of dichloromethane (ca. 0.5 mL), and then maintained at 95°C in the presence of glacial acetic acid (0.18 mL) for 20 min. The NMR spectrum of the crude product (1 mg in $CDCl_3$) showed the presence of naphthol **29** (80 ± 5%), and two diastereomers (**26** and **27**, 20 ± 5%). The remainder of the crude mixture was reacted for another 20 min, and then chromatographed using 25–35% ethyl acetate – hexanes to give a colorless solid (0.17 g, 80%); mp 69–72°C; $[\alpha]_D^{20}$ +27 (*c* 1.05, $CHCl_3$); IR (CH_2Cl_2): 3350, 1739 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.01 (d, 3H, J = 6.85), 1.07 (d, 3H, J = 6.85), 1.57 (d, 3H, J = 7.02), 1.58 (d, 3H, J = 7.01), 3.65 (d, 6H, J = 4.12), 3.73 (d, 6H, J = 1.99), 3.78 (s, 6H), 3.86 (d, 6H, J = 4.08), 3.94 (d, 6H, J = 0.88), 4.05 (s, 6H), 5.16 (dq, 2H, J = 4.79, 6.84), 5.40 (dq, 2H, J = 2.46, 7.02), 6.73 (d, 2H, J = 5.81), 6.88–6.97 (m, 6H), 7.74 (s, 2H), 12.00 (d, 2H, J = 3.52); ^{13}C NMR ($CDCl_3$) δ: 16.25 (CH_3), 16.30 (CH_3), 16.67 (CH_3), 16.73 (CH_3), 51.93 (2 × OCH_3), 52.30 (2 × OCH_3), 55.57 (2 × OCH_3), 55.75 (2 × OCH_3), 55.78 (2 × OCH_3), 55.89 (2 × OCH_3), 69.18 (OCH), 69.23 (OCH), 69.97 (2 × OCH), 100.47 (2 × C), 102.67 (2 × CH), 105.73 (2 × CH), 110.49 (CH), 110.62 (CH), 114.16 (CH), 114.25 (CH), 119.77 (2 × C), 123.28 (CH), 123.36 (CH), 127.43 (2 × C), 128.30 (C), 128.37 (C), 128.98 (C), 129.00 (C), 132.31 (2 × C), 148.17 (C), 148.24 (C), 148.39 (C), 148.47 (C), 149.69 (2 × C), 152.38 (2 × C), 159.43 (C), 159.50 (C), 167.18 (CO), 167.30 (CO), 168.82 (CO), 168.89 (CO), 170.03 (2 × CO), 170.28 (2 × CO); mass spectrum *m/e* (rel %): 600 (M^+, 11), 496 (17), 410 (100), 84 (14). Exact Mass calcd. for $C_{30}H_{32}O_{13}$: 600.1842; found: 600.1847.

Acknowledgments

We are grateful to the Natural Sciences and Engineering Research Council of Canada for financial support of this project. The financial assistance of the University of Manitoba in the form of a Postgraduate Fellowship is also acknowledged. We acknowledge the assistance of W. Buchannon and T. Foniok in providing mass spectral and NMR spectroscopic services.

Unsymmetrical dienophiles and their reactions with *ortho*-quinodimethanes

James L. Charlton, David Bogucki, and Peng Guo

Abstract: Three unsymmetrical chiral dienophiles have been synthesized and their reactivities with α-hydroxy-*ortho*-quinodimethanes have been assessed. Thus, the methyl (*S*)-lactyl esters of *trans*-4-bromocrotonate and *trans*-4-acetoxycrotonate (**1** and **2**) and mono (methyl (*S*)-lactyl) fumarate **3** were synthesized. Each was reacted with α-hydroxy-*o*-quinodimethane and α-hydroxy-α-phenyl-*o*-quinodimethane. While reaction with α-hydroxy-*o*-quinodimethane gave synthetically useful yields of cycloadducts with high regioselectivity and diastereoselectivity, the corresponding reactions with α-hydroxy-α-phenyl-*o*-quinodimethane were less successful. The reaction of **3** with α-hydroxy-α′-phenyl-*o*-quinodimethane also gave a mixture of cycloadducts.

Key words: *ortho*-quinodimethanes, lignans, Diels–Alder, asymmetric, lactate.

Résumé : On a synthétisé trois diénophiles chiraux non symétriques et on a évalué leurs réactivités avec les α-hydroxy-*ortho*-quinodiméthanes. On a ainsi synthétisé les *trans*-4-bromocrotonoate et *trans*-4-acétoxycrotonoate (**1** et **2**) et le monofumarate (**3**) de ((*S*)-lactyle de méthyle). On a les a tous fait réagir avec l'α-hydroxy-*ortho*-quinodiméthane et l'α-hydroxy-α-phényl-*ortho*-quinodiméthane. Alors que la réaction de l'α-hydroxy-*ortho*-quinodiméthane fournit des rendements synthétiquement utiles de cycloadduits avec de fortes régiosélectivités et diastéréosélectivités, les réactions correspondantes avec l'α-hydroxy-α-phényl-*ortho*-quinodiméthane ne conduisent pas au même succès. La réaction du composé **3** avec l'α-hydroxy-α′-phényl-*ortho*-quinodiméthane conduit aussi à un mélange de cycloadduits.

Mots clés : *ortho*-quinodiméthanes, lignanes, Diels–Alder, asymétrique, lactate.

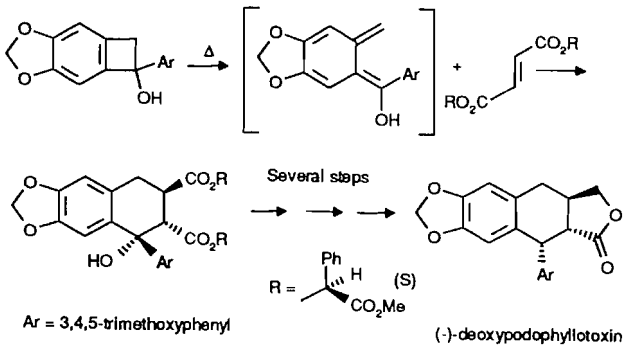
[Traduit par la rédaction]

Introduction

In several publications we have demonstrated the use of both methyl lactyl fumarate and methyl mandelyl fumarate in asymmetric Diels–Alder reactions with *ortho*-quinodimethanes (*o*-QDMs) and the elaboration of the corresponding cycloadducts into naturally occurring lignans (1). An example of the synthesis of (−)-deoxypodophyllotoxin is shown in Scheme 1 (1*a*).

One of the pitfalls in using a symmetrical dienophile such as bis(methyl lactyl) or (methyl mandelyl) fumarate in such reactions is that it is often difficult to later chemically differentiate between the two ester groups in the cycloadduct. A potential solution to this problem is to use an unsymmetrical dienophile. While a number of unsymmetrical chiral dienophiles have been used in Diels–Alder reactions (see the extensive list of references in ref. 2), we were particularly interested in 4-halo or 4-oxy derivatives of crotonic acid esters as these dienophiles would provide a route to the butyrolactone functionality often found in aryl tetralin lignans such as deoxypodophyllotoxin (see Scheme 1). Although these dienophiles should be more useful in later functional group transformations, it remained to be determined if they would show sufficiently high yield, regioselectivity, diastereoselectivity (*endo* vs. *exo*), and asymmetric induction to make them synthetically useful. To this end we have synthesized the methyl (*S*)-lactyl esters of *trans*-4-bromocrotonate and *trans*-4-acetoxycrotonate, **1** and **2**. The mono (methyl (*S*)-lactyl) ester of fumaric acid, **3**, was also prepared. Methyl lactyl esters were chosen as the reactions of methyl lactyl esters of acrylates and fumarates have been very stereoselective in reactions with α-hydroxy-*o*-quinodimethanes. Each ester was reacted with α-hydroxy-*o*-quinodimethane and α-hydroxy-α-phenyl-*o*-quinodimethane. **3** was also reacted with α-hydroxy-α′-phenyl-*o*-quinodimethane.

Scheme 1.



Results and discussion

The crotonate esters **1** and **2** were synthesized[2] from 4-bromo-

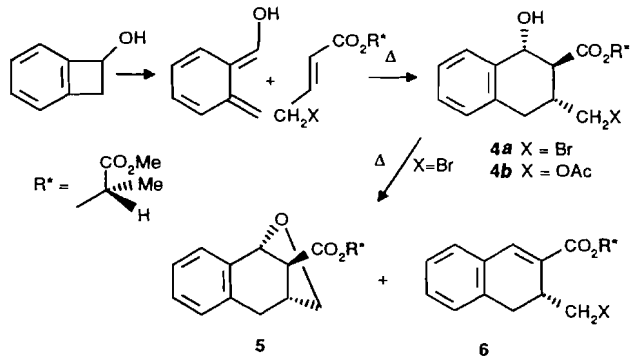
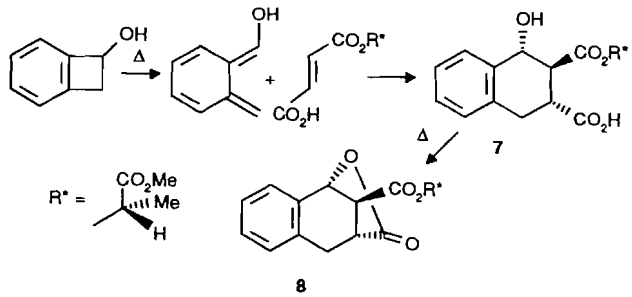


Scheme 5.



crotonic acid, which in turn was prepared using the method of Pinza and Pifferi (3*a*) as shown in Scheme 2. Mono (methyl (*S*)-lactyl) fumarate, **3**, was prepared by two methods as shown in Scheme 3. Using a modified literature procedure (4), methyl (*S*)-lactate was mixed with maleic anhydride (1:1) to give the mono (methyl (*S*)-lactyl) maleate intermediate. Without purification, this intermediate was isomerized to the fumarate in the presence of a catalytic amount of thionyl chloride to give **3** in 42% yield. In the second method, **3** was prepared in 48% yield by heating a 1:1 mixture of methyl (*S*)-lactate and fumaryl chloride.

Thermolysis of benzocyclobutenol (5)[3] was used as the method for generating α-hydroxy-*o*-QDM and assessing its reactivity with **1**, **2**, and **3**. To prepare the cycloadduct with 4-bromocrotonate **1**, 1.8 equivalents of benzocyclobutenol were refluxed with **1** in benzene for 70 h at which time a further 1.6 equivalents of benzocyclobutenol were added and the solution refluxed for a further 95 h. The solution was evaporated and chromatographed (EtOAc–hexanes) to give cycloadduct **4***a* (89%). The structure of the cycloadduct **4***a* was established from its ^{1}H NMR spectrum and by its conversion to the ether **5** on refluxing in toluene (see Scheme 4). Carrying out the cycloaddition reaction itself in refluxing toluene also gave primarily the ether **5** along with the elimination product **6.**

The cycloadduct of 4–acetoxycrotonate **2** with α-hydroxy-*o*-QDM was likewise prepared by refluxing **2** with 2 equivalents of benzocyclobutenol in toluene for 67 h. Evaporation of the toluene and chromatography (EtOAc–hexanes) gave cycloadduct **4***b* in 76% yield. The cycloadduct was assigned the structure **4***b* (see Scheme 4) on the basis of its spectral properties. The absolute stereochemistries of cycloadducts **4***a* and **4***b* were assigned on the basis of our previous experience with methyl lactyl unsaturated esters reacting with hydroxy-*o*-QDMs (1*c*, *d*, *f*, *g*, *h*, and *j*), but the assignment should be regarded as tentative. Although the precise diastereoselectivity and regioselectivity for the formation of **4***a* and **4***b* is unknown, it should be noted that there were only very minor peaks in the ^{1}H NMR spectra of the crude products that could be attributed to isomeric cycloadducts.

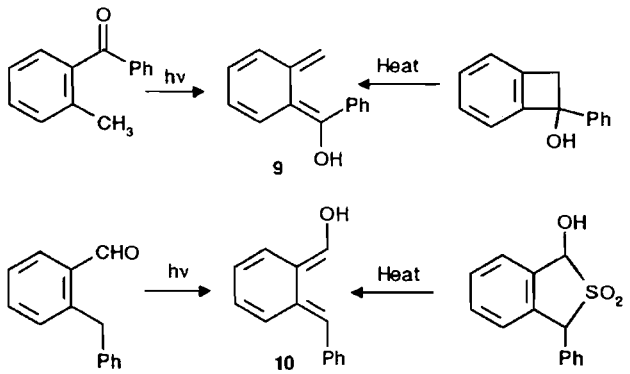
Dienophile **3** was reacted with α-hydroxy-*o*-QDM by adding benzocyclobutenol (2.7 equivalents) to a refluxing solution of **3** in toluene and refluxing for a further 2 h. Passage through a short silica gel column (EtOAc), evaporation, and crystallization from EtOAc–hexane gave cycloadduct **7** in 42% yield (see Scheme 5). Further concentration of the mother liquors gave crystals of the lactone **8** in 5% yield, identified by comparison with an authentic sample whose absolute and relative stereochemistry had been previously assigned (1*j*). The cycloadduct **7** closed readily to the lactone **8** on standing for a few days in methylene chloride solution, thereby providing confirmation of both the absolute and relative stereochemistry assigned to **7**.

From the above encouraging results it appears that the three unsymmetrical dienophiles **1**, **2**, and **3** all react with α-hydroxy-*o*-QDMs giving synthetically useful levels of regioselectivity, diastereoselectivity, and asymmetric induction. In a previous paper we proposed that hydrogen bonding between the lactyl chiral auxiliary and the hydroxyl of the *o*-QDM is very important in the reactions of lactyl substituted dienophiles and α-hydroxy-*o*-QDMs (1*d*). It appears that it is equally important in these reactions, leading to products with the lactyl ester group adjacent to and *trans* (*exo* addition), to the neighboring hydroxyl group.

To investigate the scope of these reactions we have also studied the addition of **1**, **2**, and **3** with α-hydroxy-α-phenyl-*o*-quinodimethane **9** (see Scheme 6). This *o*-QDM is a model for other similar oxygenated *o*-QDMs that we have found useful

[3] For preparation of benzocyclobutenol see ref. 5(*b*).

Scheme 6.



in asymmetric lignan synthesis. Unfortunately none of the three unsymmetrical dienophiles reacted with α-hydroxy-α-phenyl-*o*-quinodimethane **9** to give a cycloadduct with reasonable stereo- or regioselectivity. **1** and **2** did not react at all with the *o*-QDM generated either photochemically from 2–methylbenzophenone, or thermally from -phenylbenzocyclobutenol (1*c*). Dienophile **3** did react with the *o*-QDM **9** generated from benzocyclobutenol, but the ^{1}H NMR spectrum of the crude product indicated that it was a mixture of at least four isomeric cycloadducts. Dienophile **3** was also reacted with *o*-QDM **10**, generated either photochemically or thermally from its corresponding sulfone as shown in Scheme 6. Thermal generations of *o*-QDM **10** from the sulfone in the presence of dienophile **3** gave a mixture of four cycloadducts while the photochemical reaction gave back only starting materials.

Experimental

A description of general instrumentation, procedures for the irradiation experiments, and identification and characterization of compounds have been provided previously (1).

4-Bromo-(methyl (*S*)-lactyl) crotonate, 1

Crotonic acid (5.01 g, 58.2 mmol) was refluxed in a solution of CCl_4 (50 mL) containing NBS (10.53 g, 59.16 mmol) and benzoyl peroxide (210 mg, 0.867 mmol) under a N_2 atmosphere for 4.5 h. The solution was cooled, kept at 5°C for 16 h, and the resulting colorless precipitate (succinimide) filtered off. Thionyl chloride (6.40 ml, 87.7 mmol) was added to the solution, which was then stirred at 60°C in a 100 mL round-bottom flask fitted with a condenser and drying tube ($CaCl_2$) for 4 h. The solution was cooled to room temperature, the solvent evaporated and several small portions of CCl_4 evaporated, from the remaining liquid. The crude acid chloride was refluxed in CCl_4 (20 ml) in the presence of methyl (*S*-lactate (8.30 ml, 86.9 mmol) under a drying tube ($CaCl_2$) for 66.5 h. After cooling the solution to room temperature and evaporating the solvent, the crude product was chromatographed on silica gel (8% EtOAc – hexanes) to give a light yellow liquid (5.83 g, 40%): $[\alpha]_D^{25}$ −12.6 (*c* 0.95, $CHCl_3$); IR ($CHCl_3$): 1719 (CO) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.53 (d, 3H, *J* = 7.1), 3.76 (s, 3H), 4.02 (dd, 2H, *J* = 1.2, 7.2), 5.17 (q, 1H, *J* = 7.1), 6.10 (dd, 1H, *J* = 1.2, 15.4), 7.08 (dt, 1H, *J* = 7.3, 15.4); ^{13}C NMR ($CDCl_3$) δ: 17.0 (CH_3), 28.9 (CH_2), 52.4 (CH_3), 68.8 (CH), 123.7 (CH), 143.0 (CH), 164.6 (C), 171.0 (C); mass spectrum (NH_4^+ CI) *m/z* (relative intensity): 253/251 ([M + H]$^+$, 3), 221/219 (3), 193/191 (12), 171 (15), 166/164 (9), 149/147 (100), 121/119 (8), 113 (13), 68 (70). Anal. calcd. for $C_8H_{11}O_4Br$: C 38.27, H 4.42; found: C 38.49, H 4.34.

4-Acetoxy-(methyl (*S*)-lactyl) crotonate, 2

4-Bromo-(methyl (*S*)-lactyl) crotonate (1.00 g, 3.98 mmol) and silver acetate (731 mg, 4.38 mmol) in acetic acid (26 mL) were stirred at 100°C under a drying tube ($CaCl_2$) for 22 h. The solution was filtered to remove precipitate, which was washed with EtOAc. Water was added to the filtrate and the whole extracted with EtOAc. The EtOAc layers were combined, washed with saturated $NaHCO_{3\ (aq)}$, water, dried ($MgSO_4$), and evaporated. The crude product was chromatographed on silica gel (10% EtOAc – hexanes) giving a colorless liquid (685 mg, 75%): $[\alpha]_D^{25}$ −11.4 (*c* 2.30, $CHCl_3$); IR ($CHCl_3$): 1742 (CO) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.53 (d, 3H, *J* = 7.1), 2.13 (s, 3H), 3.76 (s, 3H), 4.76 (dd, 2H, *J* = 2.0, 4.5), 5.18 (q, 1H, *J* = 7.1), 6.11 (dt, 1H, *J* = 2.0, 15.8), 7.02 (dt, 1H, *J* = 4.5, 15.8); ^{13}C NMR ($CDCl_3$) δ: 17.0 (CH_3), 20.7 (CH_3), 52.4 (CH_3), 62.4 (CH_2), 68.7 (CH), 121.1 (CH), 142.6 (CH), 164.9 (C), 170.2 (C), 171.1 (C); mass spectrum (NH_4^+ CI) *m/z* (relative intensity): 231 ([M + H]$^+$, 1), 171 (22), 127 (21), 85 (100), 55 (24); HRMS calcd. for $C_8H_{11}O_4$ ($M^+ - CH_3CO_2$) 171.0657; found: 171.0657.

Mono (methyl (*S*)-lactyl) fumarate, 3

Method 1

A procedure similar to that used to prepare monomethyl fumarate was used (4). Maleic anhydride (1.02 g, 10.4 mmol) and methyl (*S*)-lactate (1.4 mL, 15 mmol) were mixed until a homogeneous solution was obtained. Thionyl chloride (0.05 mL) was added and the mixture heated on a steam bath for 10 min. After cooling, the solution was made basic with aqueous 5% $NaHCO_3$, washed with CH_2Cl_2, acidified with 10% aqueous HCl, and extracted with CH_2Cl_2. The combined organic extracts were dried ($MgSO_4$) and evaporated to leave a colorless oil (0.85 g, 42%): $[\alpha]_D^{20}$ −8.6 (*c* 0.91, $CHCl_3$); IR (CH_2Cl_2): 1736, 1711 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.55 (d, 3H, *J* = 7.1), 3.76 (s, 3H), 5.21 (q, 1H, *J* = 7.1), 6.90 (d, 1H, *J* = 15.7), 7.08 (d, 1H, *J* = 15.6), 10.6 (br s, 1H); ^{13}C NMR ($CDCl_3$) δ: 16.9 (CH_3), 52.7 (CH_3), 69.6 (CH), 133.9 (CH), 134.4 (CH), 164.0, 169.2, 170.9 (CO); mass spectrum *m/z* (relative intensity): 157 (2), 143 (23), 113 (25), 99 (100), 85 (6). Anal. calcd. for $C_8H_{10}O_6$: C 47.65, H 4.99; found: C 47.30, H 4.99. The proton NMR also exhibited peaks consistent with the presence of a small amount (ca. 6%) of the isomeric maleate ester; ^{1}H NMR ($CDCl_3$) δ: 1.57 (d, 3H, *J* = 7.1), 3.78 (s, 3H), 5.25 (q, 1H, *J* = 7.1), 6.41 (d, 1H, *J* = 12.5), 6.47 (d, 1H, *J* = 12.6).

Method 2

Fumaryl chloride (5 mL, 47.4 mmol) and methyl (*S*)-lactate (5 mL, 52.4 mmol) were heated at 100–110°C under nitrogen for 30 h. Water (30 mL) was added and the aqueous phase was made basic with solid sodium carbonate. The aqueous phase was extracted with CH_2Cl_2, acidified with 10% aqueous HCl, and extracted again with CH_2Cl_2. The latter extract was dried and evaporated to leave a dark oil (5.5 g, 58%). The oil was purified by chromatography on silica gel using 30% EtOAc –

hexanes as eluant to give a colorless oil (4.56 g, 48%). All physical data were identical to those given above.

Cycloadduct 4*a*

Benzocyclobutenol (37.5 mg, 0.312 mmol) and 4–bromo-(methyl-(*S*)-lactyl)-crotonate (42.8 mg, 0.170 mmol) were refluxed in benzene (3.0 mL) under a drying tube ($CaCl_2$) for 70 h. More benzocyclobutenol (33.0 mg, 0.275 mmol) was added and refluxing of the solution continued for 95 h. The solvent was evaporated and the crude product chromatographed on silica gel (8% EtOAc – hexanes) to give a light yellow liquid (56.3 mg, 89%): $[\alpha]_D^{25}$ −65.8 (*c* 0.28, $CHCl_3$); IR ($CHCl_3$): 3504 (OH), 1747 (CO) cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.58 (d, 3H, *J* = 7.2), 2.55 (m, 1H, H-3), 2.80 (dd, 1H, *J* = 9.6, 10.6, H-2), 2.95 (d, 2H, *J* = 8.0), 3.52 (dd, 1H, *J* = 3.4, 10.3, H-4), 3.57 (dd, 1H, *J* = 5.7, 10.3, H-4), 3.83 (s, 3H), 4.04 (br s, 1H), 4.99 (d, 1H, *J* = 9.5, H-1), 5.31 (q, 1H, *J* = 7.2), 7.12 (d, 1H, *J* = 6.8), 7.24 (m, 2H), 7.67 (d, 1H, *J* = 7.1); ^{13}C NMR ($CDCl_3$) δ: 16.7 (CH_3), 32.9 (CH_2), 35.8 (CH), 37.3 (CH_2), 53.0 (CH_3), 53.5 (CH), 69.0 (CH), 71.7 (CH), 126.3 (CH), 126.6 (CH), 127.5 (CH), 128.1 (CH), 133.9 (C), 136.8 (C), 172.5 (C), 173.5 (C); mass spectrum (NH_4^+ CI) *m/z* (relative intensity), 390–388 ([M + NH_4]$^+$, 32), 372–370 (M^+, 90), 355–353 (38), 308 (28), 273 (30), 251–249 (100), 240–238 (31), 187 (88), 158 (36), 141 (61), 128 (52), 115 (27), 91 (28); HRMS calcd. for $C_{16}H_{19}O_5{}^{81}Br$: 372.0395; found: 372.0394; HRMS calcd. for $C_{16}H_{19}O_5{}^{79}Br$: 370.0415; found: 370.0418.

Ether 5 and elimination product 6

Benzocyclobutenol (98.8 mg, 0.822 mmol) and 4–bromo-(methyl-(*S*)-lactyl)-crotonate (99.5 mg, 0.396 mmol) were refluxed in toluene (3.5 mL) with a drying tube ($CaCl_2$) for 71 h and the solvent was evaporated. A ^1H NMR spectrum of the crude product mixture indicated that cycloadduct **4**a, plus elimination and ether products **5** and **6**, were present in a ratio of 4.5:1.0:1.7, respectively. Chromatography on silica gel (5% EtOAc – hexanes) gave samples of compounds **6** and **5** as pale yellow liquids. Elimination product **6**: $[\alpha]_D^{25}$ +35.3 (*c* 0.59, $CHCl_3$); IR ($CHCl_3$): 1713 (CO) cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.60 (d, 3H, *J* = 7.1), 3.04 (m, 2H), 3.29 (m, 2H), 3.55 (m, 1H, H-4), 3.78 (s, 3H), 5.26 (q, 1H, *J* = 7.0), 7.28 (m, 4H), 7.68 (s, 1H, H-1); ^{13}C NMR ($CDCl_3$) δ: 17.0 (CH_3), 30.5 (CH_2), 33.2 (CH_2), 34.8 (CH), 52.4 (CH_3), 68.9 (CH), 127.1 (CH), 128.5 (C), 128.8 (CH), 129.0 (CH), 130.6 (CH), 131.2 (C), 134.4 (C), 139.2 (CH), 165.6 (C), 171.2 (C); mass spectrum *m/z* (relative intensity), 354–352 (M^+, 5), 251–249 (8), 169 (18), 155 (100), 141 (33), 128 (13), 115 (13), 59 (11); HRMS calcd. for $C_{16}H_{17}O_4{}^{81}Br$: 354.0289; found: 354.0300; HRMS calcd. for $C_{16}H_{17}O_4{}^{79}Br$: 352.0310; found: 352.0324. Ether **5**: $[\alpha]_D^{25}$ −32.7 (*c* 0.28, $CHCl_3$); IR ($CHCl_3$): 1744 (CO) cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.36 (d, 3H, *J* = 7.0), 2.81 (d, 1H, *J* = 17.5, H-4), 3.04 (m, 1H, H-3), 3.42 (m, 2H, H-2, H-4), 3.50 (s, 3H), 3.83 (d, 1H, J = 8.3, H-10), 4.16 (m, 1H, H-10), 4.95 (q, 1H, *J* = 7.0), 5.01 (d, 1H, *J* = 5.1, H-1), 7.16 (m, 4H); ^{13}C NMR ($CDCl_3$) δ: 16.7 (CH_3), 33.8 (CH_2), 35.6 (CH), 48.6 (CH), 52.2 (CH_3), 68.7 (CH), 74.3 (CH_2), 76.8 (CH), 126.1 (CH), 127.9 (CH), 128.3 (CH), 129.0 (CH), 133.7 (C), 137.6 (C), 168.9 (C), 170.6 (C); mass spectrum *m/z* (relative intensity), 290 (M^+, 7), 186 (19), 158 (19), 142 (71), 129 (100), 115 (13), 91 (19), 71 (60); HRMS calcd. for $C_{16}H_{18}O_5$: 290.1155; found: 290.1152.

Cycloadduct 4*b*

Benzocyclobutenol (220 mg, 1.83 mmol) and 4–acetoxy-(methyl-(*S*)-lactyl)-crotonate (206 mg, 0.895 mmol) were refluxed in toluene (2.0 mL) with a drying tube ($CaCl_2$) for 67 h and the solvent was evaporated. The crude product was chromatographed on silica gel (5% and 10% EtOAc – hexanes consecutively) to give a light yellow liquid (240 mg, 76%): $[\alpha]_D^{25}$ −45.9 (*c* 0.70, $CHCl_3$); IR (CH_2Cl_2): 3484 (OH), 1736 (CO) cm^{-1}; ^1H NMR ($CDCl_3$) δ: 1.56 (d, 3H, *J* = 7.1), 2.05 (s, 3H), 2.57 (m, 1H, H-3), 2.70 (dd, 1H, *J* = 9.6, 10.9, H-2), 2.80 (m, 1H, H-4), 2.93 (dd, 1H, *J* = 5.7, 16.6, H-4), 3.82 (s, 3H), 3.97 (d, 1H, *J* = 4.1), 4.06 (dd, 1H, *J* = 4.3, 11.1, H-10), 4.16 (dd, 1H, *J* = 5.8, 11.1, H-10), 5.00 (dd, 1H, *J* = 3.3, 9.4, H-1), 5.27 (q, 1H, *J* = 7.2), 7.10 (d, 1H, *J* = 7.1), 7.23 (m, 2H), 7.65 (m, 1H); ^{13}C NMR ($CDCl_3$) δ: 16.6 (CH_3), 20.8 (CH_3), 31.3 (CH_2), 34.3 (CH), 51.8 (CH), 52.9 (CH_3), 66.1 (CH_2), 69.0 (CH), 71.6 (CH), 126.2 (CH), 126.6 (CH), 127.4 (CH), 128.0 (CH), 133.9 (C), 137.0 (C), 170.8 (C), 172.3 (C), 173.9 (C); mass spectrum *m/z* (relative intensity): 350 (M^+, 2), 272 (54), 203 (40), 187 (62), 168 (87), 158 (100), 141 (61), 129 (57), 115 (20), 91 (24), 85 (32), 59 (18); HRMS calcd. for $C_{18}H_{22}O_7$: 350.1365; found: 350.1365.

Cycloadduct 7 and lactone 8

Mono (methyl (*S*)-lactyl) fumarate **3** (0.247 g, 1.2 mmol) and 4 Å molecular sieves (0.2 g) in toluene (6 mL) were heated to reflux. Benzocyclobutenol (0.38 g, 3.2 mmol) in methylene chloride (5 mL) was added portionwise over 20 min, and the solution stirred for another 2 h. After passing through a short silica gel column (EtOAc) the solution was evaporated to leave an oil that crystallized from EtOAc–hexanes (4:1) giving colorless crystals (01.64 g, 42%), mp 152–153°C: $[\alpha]_D^{25}$ −78.4 (*c* 0.90, $CHCl_3$); IR (CH_2Cl_2): 3503, 1738 cm^{-1}; ^1H nmr ($CDCl_3$) δ: 1.60 (t, 3H, *J* = 7.15), 3.05 (m, 2H), 3.25 (m, 2H), 3.82 (s, 3H), 4.96 (d, 1H, *J* = 9.5, H-1), 5.34 (q, 1H, *J* = 7.16), 7.13–7.26 (m, 4H), 7.71 (d, 1H, *J* = 7.4); ^{13}C nmr ($CDCl_3$) δ: 16.6 (CH_3), 31.4 (CH_2), 40.4 (CH), 50.4 (CH), 53.1 (CH_3), 69.1 (CH), 70.9 (CH), 126.8 (CH), 126.9 (CH), 127.6 (CH), 132.8 (C), 136.5 (C), 172.9 (C), 173.9 (C), 179.1 (C); mass spectrum *m/z* (relative intensity): 304 (3), 200 (17), 156 (27), 128 (100), 45 (53). Anal. calcd. for $C_{16}H_{18}O_7$: C 59.62, H 5.63; found: C 59.30, H 5.64. Further concentration of the mother liquors from above gave another colorless crystalline compound (0.019 g, 5%) that proved to be the lactone **8;** properties are identical to those previously reported in the literature (1j).

The thioformamidyl group as an α-substituent in carbocations

M. Bertone, D.L.J. Vuković, A. Cunje, C.F. Rodriquez, E. Lee-Ruff, and A.C. Hopkinson

Abstract: *Ab initio* molecular orbital calculations at MP2(FULL)/6-311G(d,p) or MP2(FULL)/6-31G(d,p) are reported for carbocations $RR'CCHO^+$, $RR'CCHS^+$, $RR'CCONH_2^+$, and $RR'CCSNH_2^+$ where R and R′ are H, CH_3, c-C_3H_5, and C_6H_5. Primary (R = R′ = H), secondary (R = H, R′ = alkyl or phenyl), and tertiary (R = R′ = CH_3) ions prefer the cyclic oxiranyl or thiiranyl structure **9**, with the open structure **8** being a transition structure for ring opening. Tertiary carbocations with R = R′ = phenyl or cyclopropyl and the 9-thioformamidyl-9-fluorenyl cation have the open structure. Isodesmic reactions show $CONH_2$ to be weakly stabilizing in the methyl cation, and $CSNH_2$ has a larger stabilizing effect, roughly equivalent to that of a methyl group. An α-thioamide substituent is less stabilizing in the ethyl cation and even less stabilizing in the isopropyl cation. In $C_6H_5CHCSNH_2^+$ the $CSNH_2$ group is slightly destabilizing and, by extrapolation, is more destabilizing in $Ar_2CCSNH_2^+$. The rearrangement of the α-thioformamidyl-benzyl cation to benzothiophene is calculated to have a low barrier, 15.4 kcal/mol at HF/6-31G(d,p).

Key words: molecular orbitals, destabilized carbocations, rearrangement.

Résumé : On a effectué des calculs d'orbitales moléculaires *ab initio* aux niveaux MP2(FULL)/6-311G(d,p) ou MP2(FULL)/6-31G(d,p) pour les carbocations $RR'CCHO^+$, $RR'CCHS^+$, $RR'CCONH_2^+$ et $RR'CCSNH_2^+$ dans lesquels R et R′ sont égaux à H, CH_3, cyclo-C_3H_5 et C_6H_5. Pour les ions primaires (R = R′ = H), secondaires (R = H et R′ = alkyle ou phényle) et tertiaires (R = R′ = CH_3) les structures préférées sont les oxiranyles et thiiranyles cycliques (**9**) alors que la structure ouverte (**8**) intervient comme structure de transition pour l'ouverture du cycle. Les carbocations tertiaires avec R = R′ = phényle ou cyclopropyle ainsi que le carbocation 9-thioformamidyl-9-fluorényle existent dans la structure ouverte. Les réactions isodesmiques montrent que le $CONH_2$ est faiblement stabilisant dans le cation méthyle alors que le $CSNH_2$ possède un effet stabilisant plus important, approximativement équivalent de celui du groupe méthyle. Un substituant α-thioamide est moins stabilisant dans le cation éthyle et encore moins stabilisant dans le cation isopropyle. Dans le $C_6H_5CHCSNH_2^+$ le groupe $CSNH_2$ est légèrement moins déstabilisant et, par extrapolation, il est plus déstabilisant dans le $Ar_2CCSNH_2^+$. On a calculé que la barrière au réarrangement du cation α-thioformamidyl-benzyle en benzothiophène est relativement faible, 15,4 kcal/mol au niveau HF/6-31G(d,p).

Mots clés : orbitales moléculaires, carbocations déstabilisés, réarrangement.

[Traduit par la rédaction]

Electron-deficient molecules are extremely sensitive to substituent effects and the highest sensitivity ever observed is for the generation of methyl cations CH_2X^+ from methanes CH_3X in the gas phase (1). Carbocations, in general, are electron-deficient species that can be stabilized by π-donating substituents such as NH_2, OCH_3, and F, and that usually are destabilized by electron-withdrawing groups (2–9). However, when electron-withdrawing substituents like CN, COOR, $CONR_2$, COR, $PO(OR)_2$, CF_3, NO_2, SOR, and SO_2R are attached directly to the cationic carbon, the adjacent empty *p*-orbital on carbon induces these substituents to become π donors and, consequently, ions containing these substituents are less destabilized than expected (for reviews, see ref. 10). The chemistries of a wide variety of "destabilized" carbocations have been studied extensively, and some ions are sufficiently stable to be observed directly by UV and NMR spectroscopy (11–14).

Carbocations containing the thioamide group are particularly interesting since this substituent appears to be stabilizing in carbocations containing another destabilizing group, but to be destabilizing in less electron-deficient carbocations (14, 15). Such substituents, which change their electronic character depending upon their molecular environment, are said to be amphielectronic.

Stabilization by $CSNH_2$ may occur through two types of interaction. In the first, π donation leads to delocalization of the positive charge onto the sulfur, i.e., there is a large contribution from resonance structure **1***b* and this implies a shortening of the C—C bond and a lengthening of C—S. This interaction is maximized by the thioamide group being coplanar with $R'RC^+$. Hartree–Fock level *ab initio* molecular orbital calculations have shown structure **1***b* to be an important con-

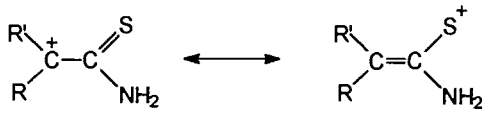
tributor to the parent ion (R = R′ = H) but to be of little importance for the oxygen analogue (16).



1*a* 1*b*

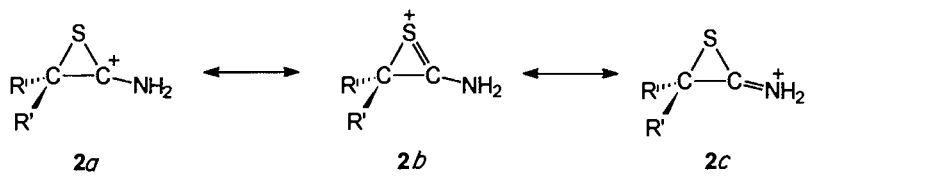
The second possible stabilizing interaction, neighbouring group participation, involves rotation about the C^+–$CSNH_2$ bond to form the sulfur-bridged ion, **2**, in which the charge is delocalized over both heteroatoms and the cationic carbon. Earlier *ab initio* studies have shown the amino group to be strongly stabilizing in both thiiranyl and oxiranyl cations and structure **2***c* is the best representation of this ion (16).

Previously only the parent amino-substituted thiiranyl cation (R = R′ = H) was studied at the MP2(FC)/6-31G(d,p)//HF/6-31G(d) level of theory (16). By extrapolation from the more extensive study on the oxiranyl cations it seemed probable that increased substitution would favour the ring-opened structure, **1**, but sulfur is a better bridging atom than oxygen making it difficult to predict which of the $RR'CCSNH_2^+$ ions would be cyclic. We now present a theoretical study of the relationship between structures **1** and **2** as a function of the stabilizing ability of substituents R and R′, using several combinations of H, CH_3, c-C_3H_5, and C_6H_5. The inclusion of electron correlation systematically favours the cyclic ion **2** over the open ion, **1**, and for this reason, molecular size permitting, electron correlation is included in the optimisation of most structures.

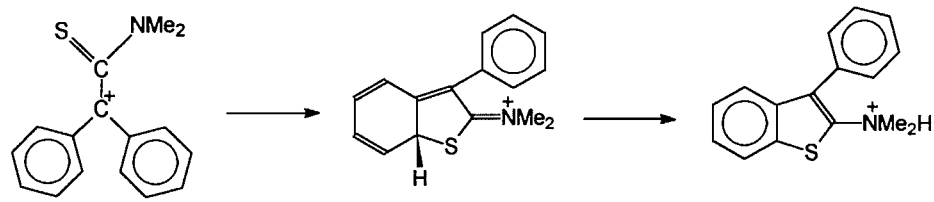
Spectral data on α-(*N*,*N*-dimethylthioformamidyl)-diphenylmethyl cations have been interpreted in terms of the open ion, **3**, a structure similar to that observed for the oxygen analogues (11, 17). Ion **3** rapidly rearranges to benzothiophene **5** at room temperature, with **4** being suggested as an intermediate (14, 17). In intermediate **4**, the aromaticity of one phenyl group has been destroyed and the other phenyl group cannot formally carry the positive charge, but it is possible to draw resonance structures in which the charge is located on the heteroatoms. Intuitively this structure seemed likely to be high on the potential energy surface and we therefore extended our study to include the energy profile for the rearrangement of **3** into **4**.

Computational details

Ab initio molecular orbital calculations were performed using GAUSSIAN 92 (18). For structures **1** and **2** of cations $RR'CSNH_2^+$, for methanes RR′CHCSNH$_2$, and for a limited number of the oxygen analogues of these compounds, structure optimizations using gradient techniques (19) were carried out at the HF/6-31G(d,p) level (20). For some open ions it was necessary to initially fix the two substituents R and R′ to be coplanar with the thioamide group in order to prevent the structures from collapsing into the cyclic ions **2**. Subsequent



2*a* 2*b* 2*c*



3 4 5

optimization, releasing all constraints, followed by harmonic vibrational frequency calculations, determined whether the structures were at minima or were transition structures. All structures were subsequently optimized using correlated wavefunctions, with MP2(FULL)/6-31G(d,p) (21) calculations used for the smaller molecules, and MP2(FC)/3-21G(d) calculations for ions containing two cyclopropyl substituents or one or more phenyl groups. The 9-thioformamidyl substituted fluorenyl cation was optimized at HF/6-31G(d,p) and at MP2(FC)/3-21G(d) (22). Structures **6** and **7**, in which the amino group of the thioamides has been replaced by H (thereby reducing the relative stability of the cyclic ion), have been optimized at HF/6-31G(d,p) and at MP2(FULL)/6-311G(d,p) for R = R′ = H and R = R′ = CH_3. Structures for ion **7** in which R = R′ = c-C_3H_5 and R = R′ = C_6H_5 have been optimized at MP2(FC)/3-21G(d).

Total energies, relative energies, and zero-point energies are given in Table 1, and some key structural details are in Table 2. Data for the thioacetamides are given in Table 3.

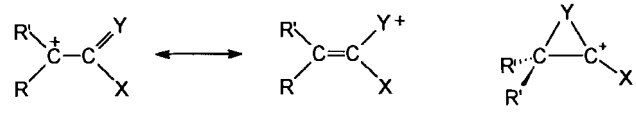
Results and discussion

1. Structural details; factors that determine whether the ion is cyclic or open

a) Open ions 8

Structures **1** and **6** may be generalized as **8**. For aldehydes (**8**, X = H, Y = O or S) when R and R′ are both H, the open ion is higher in energy than the cyclic ion **9** at HF/6-31G(d,p) and inclusion of electron correlation further increases the relative stabilization of the cyclic structure. When both R and R′ are CH_3, the open ions have lower energies than the cyclic isomers, but inclusion of electron correlation results in $(CH_3)_2CCHS^+$ becoming cyclic, while the oxygen analogue remains open but with a very low potential for bending into the cyclic structure.



8*a* **8*b*** **9**

Aldehydes substituted with R = R′ = C_6H_5 and c-C_3H_5 have open structures at HF/3-21G(d). The $(c\text{-}C_3H_5)_2CCHY^+$ ions have the two cyclopropyl groups perpendicular to the plane defined by CCHY and coincident with the formally vacant *p*-orbital on C^+, thereby having the configuration in which the cyclopropyl groups can most effectively donate electron density to the cationic carbon. The $(C_6H_5)_2CCHY^+$ ions have the plane of CHY rotated out of the plane defined by $C_{ipso}C^+C_{ipso}$ (by 17° for Y = O and 45° for Y = S) but large C^+CY angles indicate that there is no tendency for neighbouring group participation. The phenyl groups are prevented from being copla-

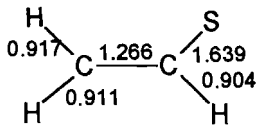
nar by interaction between *ortho* hydrogens, and the angle of twist is ≈22° for Y = O and ≈29° for Y = S.

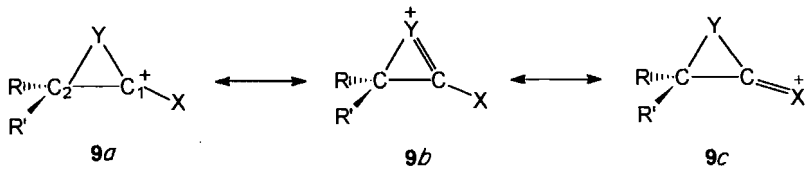
For ions **8** in which R and R′ do not stabilize an adjacent cationic carbon, then valence bond structure **8***b* permits delocalization of charge onto the heteroatom, Y. This structure is of greatest significance when R = R′ = H and, from the structural data on H_2CCHS^+ in Table 2, it is clear from the short C—C distance (1.405 Å) and the long C—S distance (1.661 Å) that structure **8***b* is a major contributor. A Mayer bond order analysis (25) on this structure (at HF/6-31G(d,p)) shown in **8***c* gave bond orders of 1.266 for C—C and 1.639 for C-S, indicating that **8***a* is more important than **8***b*, but that the contribution from the latter is quite large. The structural data on the oxygen analogues H_2CCHO^+, C—C 1.483 Å and C-O 1.226 Å, are much closer to standard single and double bonds, respectively, indicating the valence bond structure **8***b* is less important in the oxygen-containing ions.



8*c*

In carbocations containing an α-amide group (**8**, X = NH_2, Y = S or O) the amino group heavily stabilizes the cyclic structure through contributions from structures **2***c*. For example, for H_2CCHS^+ the cyclic ion **9** is lower in energy than the open ion **8** by 28.3 kcal/mol, while for the thioamide ion $H_2CCSNH_2^+$ the difference is 44.3 kcal/mol. A consequence of this stabilization is that α-amide substituted ions containing R groups that stabilize the open structure do not always prefer the open structure. Thioamide substituted ions with either R = R′ = CH_3 or with one R group C_6H_5 or c-C_3H_5 are then cyclic. Similarly, $(CH_3)_2CCONH_2^+$ is calculated to be cyclic, a result that is contrary to experimental evidence that ion $(CH_3)_2CCON(CH_3)_2^+$, generated under solvolytic conditions, is an open ion (26). Ion $C_6H_5CHCONH_2^+$ has the open structure **8** at HF/6-31G(d,p) with all the atoms almost coplanar (oxygen and phenyl eclipse) but, since inclusion of electron correlation consistently favours the cyclic structure, it is possible that higher level calculations would show the cyclic structure to be preferred. Similar comments apply to tertiary carbocations (R = R′ = C_6H_5 or c-C_3H_5). At HF/3-21G(d) ions $(C_6H_5)_2CCYNH_2^+$ (Y = O or S) have the amide group twisted approximately 90° out of the plane defined by $C_{ipso}C^+C_{ipso}$, in the appropriate conformation for bridging but, as shown by C⁺CY angles of 119.3° (Y = O) and 116.1° (Y = S), there is no evidence of bridging. For ion $(C_6H_5)_2CCSNH_2^+$, however, inclusion of electron correlation at MP2(FC)/3-21G(d) resulted in a decrease in angle C⁺CS to 91.5°.

The 9-thioformamidyl-9-fluorenyl cation has the planar thioamidyl group perpendicular to the fluorenyl ring structure, with angle C⁺CS varying from 114.5° at HF/3-21G(d) to 84.0° at MP2(FC)/3-21G(d) and 113.2° at HF/6-31G(d,p). Clearly, the amount of neighbouring group participation is dependent on the level of calculation, probably indicating a low potential for the ring-opening vibrational mode, and at the levels of theory used here it is not possible to give a definitive answer as to whether these more heavily substituted ions are cyclic or open. Experimentally, solutions of diphenylmethyl and fluorenyl cations containing an α-$CSNMe_2$ group are intensely coloured, with spectra similar to those of unsubstituted ions, providing strong evidence that the ions have the open structure (17).

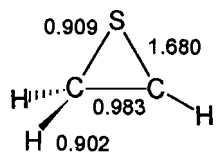


9*a* **9***b* **9***c*

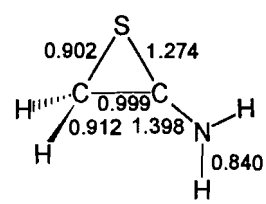
(b) Cyclic ions

It is only possible to optimize cyclic structures **9** for oxiranyl and thiiranyl cations when they are at minima on the potential energy surface. Other ions ring open to form a rotamer of **8** in which the CXY plane is coplanar with the empty *p*-orbital on C⁺. The Y—C2 distance and C2C1Y angle both increase as the electron-donating abilities of R and R′ increase. For all the cyclic aldehydes the C2—Y distances are considerably longer than standard single C—Y bonds (~1.80 Å for C—S and ~1.43 Å for C-O) (2), the C1—Y distances are close to C=Y double bond distance (~1.61 Å for C=S and ~1.22 Å for C=O), and the C1—C2 distances are intermediate between single and double bonds (~1.54 Å for C—C, ~1.34 Å for C=C) (2). For ions that we have classified as cyclic, angle C2C1Y varies between 74° and 82°.

The results of a Mayer bond order analysis (25) on CH_2CHS^+, the ion with the smallest C2C1Y angle, are shown on structure **10**. The C1—S bond order of 1.680 indicates considerable double bonding between these atoms, but both C1—C2 and C2—S have bond orders close to one and must be considered to be single bonds. Clearly then resonance structure **9***b* (X = H, Y = S) is the best way of representing this ion.



10



11

For cyclic ions where X = NH_2, much of the positive charge in **9** is transferred onto the nitrogen and structure **9***c* becomes a major contributor. This requires a double bond between C and N and the average C—N distance for these ions (~1.30 Å) is close to that for a standard C=N distance (C=N is 1.27 Å, C—N is 1.47 Å). The cyclic amide ions have less charge delo-

For personal use only.

calization onto Y than the equivalent aldehyde-containing ions and this is reflected in longer C1—Y distances (by 0.04–0.06 Å). Comparison of the bond orders calculated for the cyclic thioamide **11** (X = NH_2, Y = S, R = R′ = H) with those for the cyclic thioaldehyde **10** show the C1—S bond order to be much smaller (1.274 compared with 1.680), but there is still some double bond character in the ring. In **11** the C—N bond has the highest bond order (1.398). This indicates some double bond character, but less than implied by the short bond length.

The barrier to ring opening of the cyclic ion, the energy difference between structures **9** and **8**, decreases as angle C2C1Y increases. This crude relationship is best illustrated by the thioamide series where, when R = R′ = H the angle is 74.6° and the barrier is 44.3 kcal/mol, when R = R′ = CH_3 the angle is 77.3° and the barrier 29.8 kcal/mol, when R = H, R′ = c-C_3H_5 the angle is 78.7° and the barrier 13.9 kcal/mol, and when R = H, R′ = C_6H_5 the angle is 84.7 and the barrier 8.4 kcal/mol.

2. Stabilization energies of α-substituents in carbocations

(a) Substituents in methyl cations CH_2X^+

The methyl cations are extremely electron deficient and any substituent X in CH_2X^+ ions is a potential source of electron density. The ability of a substituent to stabilize the methyl cation can be assessed from the isodesmic reaction in eq. [1] where a positive energy indicates that R is stabilizing in the cation. This approach has been used extensively to assess the stabilities of cations. In our earlier study of ions

[1] $CH_2R^+ + CH_4 \rightarrow CH_3^+ + CH_3R$

CH_2COX^+ (X = CH_3, NH_2, OH and F), we found that, using the open ions, **8**, in eq. [1], groups CHO, $COCH_3$, and $CONH_2$ were stabilizing, and COOH and COF were destabilizing (16). By contrast, ions CH_2CHS^+ and $CH_2CSNH_2^+$ were found to be strongly stabilized (ΔE for eq. [1] was 30.6 kcal/mol for CH_2CHS^+ and 35.7 kcal/mol for $CH_2CSNH_2^+$). We have now reevaluated ΔE for eq. [1] for $CH_2CONH_2^+$ and $CH_2CSNH_2^+$ using structures optimized at MP2(FULL)/6-31G(d,p), and the resulting ΔE values of 10.3 kcal/mol and 37.4 kcal/mol, respectively (Table 5), are in good agreement with the earlier values obtained with lower level theory (16).

To put the stabilization energies provided by amidyl substituents onto a comparative scale, we have used eq. [1] to calculate ΔE for methyl cations substituted by methyl, vinyl, cyclopropyl, and phenyl substituents. The total energies for these methanes and methyl cations are given in Table 4 and the stabilization energies are in Table 5. For these hydrocarbon substituents, the MP2(FULL)/6-31G(d,p) calculations consistently give higher ΔE values than the HF level calculations, with the difference being in the range 6–12 kcal/mol. For several of these ions accurate experimental enthalpies of formation are available (25) and stabilization energies calculated from these data, shown in the last column of Table 5, are within ±2 kcal/mol of the values calculated at MP2(FULL)/6-31G(d,p). Only for the cyclopropylcarbinyl cation, where the experimental enthalpy is not well established, is there a large difference between experiment and theory. From the stabilization energies in Table 5, then, we conclude that the relative stabilizing abilities of substituents in the methyl cation are $CONH_2$(open) < $CSNH_2$(open) ≈ CH_3 < $CONH_2$(cyclic)≈ $CH{=}CH_2$ < c-C_3H_5≈C_6H_5 < $CSNH_2$(cyclic). In making these comparisons it should be noted that the stabilization energies calculated for the cyclic amide substituted ion, **2**, are not for isodesmic reactions and, for these reactions, inclusion of electron correlation increases the stabilization by larger amounts (>20 kcal/mol).

(b) Thioamide as an α-substituent in cations $RCHX^+$ and $RR'CX^+$

The question as to whether an α-thioamidyl group is destabilizing in a secondary carbocation $RCHCSNH_2^+$, where the other substituent R is stabilizing, can be addressed by using the reaction in eq. [2] (Table 6). Considering the open structure, **1**, the thioamidyl group stabilizes the ethyl cation by 16.5 kcal/mol, compared with 37.4 kcal/mol for the stabilization of

[2] $RCHCSNH_2^+ + RCH_3 \rightarrow RCH_2^+ + RCH_2CSNH_2$

the methyl cation. In the cyclopropylcarbinyl cation, c-$C_3H_5CHCSNH_2^+$, the thioamidyl group is stabilizing by 7.9 kcal/mol, while in the benzyl cation $C_6H_5CHCSNH_2^+$ it is destabilizing by 1.9 kcal/mol. However, neighbouring group participation results in each of these open structures being transition structures that collapse into cyclic structure **2**. Using structure **2** in eq. [2] produces a reaction that is not isodesmic but for which the stabilization energies for all ions are positive.

Replacement of the remaining hydrogen atom attached to the cationic carbon by an electron-donating group creates a tertiary carbocation and it is ions of this type that have been observed and characterized under stable ion conditions (14, 17). The size of these ions, $Ar_2CCSNMe_2^+$, precludes the use of high level *ab initio* calculations at this time, but we have calculated the stabilization energy provided by the thioamidyl group in the isopropyl cation by using eq. [3].

[3]

Based on the open structure, **1**, the thioamidyl group is stabilizing but by only 8.0 kcal/mol. Thus the stabilization energies resulting from an α-$CSNH_2$ group in methyl, ethyl, and isopropyl cations are 37.4, 16.5, and 8.0 kcal/mol, respectively. By comparison, using experimental enthalpies of formation, an α-methyl substituent stabilizes the methyl, ethyl, and isopropyl cations by 43.4, 19.8, and 19.9 kcal/mol (27).

An α-thioamidyl substituent is slightly destabilizing in the open benzyl cation $C_6H_5CHCSNH_2^+$ and, since a second phenyl group contributes additional stabilization, the α-thioamidyl group is expected to be more destabilizing in the diphenylmethyl cation, $(C_6H_5)_2CCSNH_2^+$. Furthermore, our geometry optimizations on $(C_6H_5)_2CCSNH_2^+$ have shown this ion to prefer the open structure, in keeping with the experi-

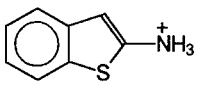
mental observation that ions $Ar_2CCSNMe_2^+$ have the open structure (17). We therefore conclude that an α-thioamidyl group is destabilizing in diarylmethyl cations.

3. Rearrangement of the α-thioformamidyl-benzyl cation

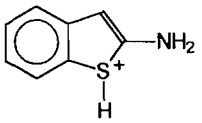
Our interest in the thioformamidyl group as an α-substituent in carbocations was initiated by our discovery that α-(*N*,*N*-dimethylthioformamidyl)-diarylmethyl cations, $Ar_2CCSNMe_2^+$, undergo cyclization to form benzothiophenes, with substitution occurring in the phenyl group containing the more electron-donating substituent (14,17). A plausible mechanism for this reaction involves nucleophilic attack by sulfur on the aryl group that carries the larger fraction of the positive charge. Structure optimization on $Ph_2CCSNH_2^+$ established that both phenyl groups are rotated ~26° relative to the plane defined by the two ipso carbons and the two exocyclic carbons. The thioformamidyl group is rotated ~90° relative to this plane, placing the sulfur atom in a position to attack a phenyl group from above. In an unsymmetrically substituted ion, the aryl group containing the more electron-donating substituents lies more closely in the plane and the other aryl group rotates further out of plane, thereby making the electron-rich aryl group the more accessible for nucleophilic attack. Semi-empirical calculations at the AM1 level showed that for *p*-$CH_3OC_6H_4,C_6H_5CCSNH_2^+$ the transition state for attack on the substituted ring is lower in energy than that for attack on the phenyl.

The α-(*N*,*N*-dimethylthioformamidyl)benzyl cation also rearranges to a benzothiophene and we have modelled this reaction theoretically at HF/6-31G(d,p) by examining the rearrangement of the sulfur-bridged ion **12** (structure **9** with R = C_6H_5, R′ = H, X = NH_2, Y = S) to the initial product of cyclization, the benzothiophene protonated at the bridging carbon, ion **13**. The transition structure for this reaction was located by first mapping the surface, using the *ortho* carbon-sulfur distance as a reaction coordinate, and then optimizing, using the eigenvector-following method (28), the transition structure associated with the highest point on the profile (transition structure **14**). Ion **13** is 14 kcal/mol below **12** and the barrier to its formation, via **14**, is 15.4 kcal/mol above **12**. Ion **15**, the structure through which **12** racemizes, is only 8.4 kcal/mol above **12**. Some of the key geometric parameters for structures **12–15** are given in Fig. 1.

Ion **13**, the intermediate in the ring-closing reaction, is the only protonated 2-aminobenzothiophene that we have examined at HF/6-31G(d,p), but at HF/3-21G(d) the N-protonated isomer **16** is 8.3 kcal/mol lower than **13** while the S-protonated isomer, **17**, is 18.4 kcal/mol higher than **13**.



16



17

In isomer **13**, the phenyl group has been disrupted and the geometric parameters for structure **13** reveal an alternation of bond lengths around the carbon framework. The C—N distance of 1.305 Å, while slightly longer than that in **12** (1.279 Å), clearly indicates a large amount of π-delocalization from nitrogen.

Conclusions

Ab initio molecular orbital calculations show that primary (CH_2X^+) and secondary ($RCHX^+$) carbocations in which X = CHO, CHS, $CONH_2$, and $CSNH_2$ have a cyclic structure **9** involving an oxiranyl or thiiranyl ring. The amino group of the amide substituent stabilizes the cyclic structure by delocalizing the positive charge on to the nitrogen and the amide-substituted ions consequently have a higher barrier to ring opening than the aldehyde-substituted ions. Tertiary ions $RR'CX^+$, where R = R′ = CH_3, are also cyclic, but for ions in which R = R′ = cyclopropyl or phenyl, the cations have the open structure.

In methyl cations all substituents are stabilizing and, by use of isodesmic reactions, we have shown that the amide group, $CONH_2$, has a very small effect while the thioamide $CSNH_2$, is almost as stabilizing as the methyl group. In secondary carbocations, $RCHCSNH_2^+$, the stabilization resulting from $CSNH_2$ is considerably smaller when R = CH_3, and is negative (i.e., destabilizing) when R is C_6H_5. In the only tertiary ion we were able to calculate at MP2(FULL)/6-31G(d,p), ion $(CH_3)_2CCSNH_2^+$, the thioamide group is stabilizing but by only 8.0 kcal/mol. From all these data, it is clear that the $CSNH_2$ group attached to a cationic carbon stabilizes very electron-deficient carbocations even without any involvement from neighbouring group participation. However, in tertiary ions $RR'CCSNH_2^+$, where both R and R′ are powerful electron

donors, the open structure is preferred and, from the result on $C_6H_5CHCSNH_2^+$ and noting the trend in stabilization resulting from substitution by one and two methyl groups, we conclude that $CSNH_2$ will be destabilizing in $(C_6H_5)_2CCSNH_2^+$.

In solution, 2,2-diaryl-2-chloro-*N*,*N*-dimethylthioacetamide and α-*N*,*N*-dimethylthioformamidyl-diarylmethyl cations undergo facile ring closure to form benzothiophenes and the monoaryl derivatives also undergo this reaction, but more slowly. The ease of this reaction implies a low barrier to rearrangement and the calculated barrier of 15.4 kcal/mol for the rearrangement of $C_6H_5CHCSNH_2^+$ to the protonated benzothiophene is consistent with these experimental observations.

^{1}H and ^{13}C nuclear magnetic resonance and molecular orbital studies of the internal rotational potential and of spin–spin coupling transmission in phenylallene

Ted Schaefer, Scott Kroeker, and David M. McKinnon

Abstract: The ^{1}H nuclear magnetic resonance spectra of phenylallene, diluted in acetone-d_6 and benzene-d_6, yield long-range coupling constants over as many as eight formal bonds between the ring and side-chain protons. These are discussed in terms of σ- and π-electron spin–spin coupling mechanisms, which are sensitive to the torsion angle between the allenyl and phenyl fragments. The torsion angle is assessed by means of molecular orbital computations of the internal rotational potential, whose height is calculated as 16.0 kJ/mol at the MP2/6-31G* level of correlation-gradient theory. Comparison with experimental and theoretical internal rotational potentials for styrene suggests that steric repulsions in the planar form of styrene amount to about 4 kJ/mol. In a field of 7.0 T, phenylallene is partially aligned, entailing a positive dipolar coupling constant between the methylene protons, from which absolute signs of the spin–spin coupling constants involving these protons can be inferred. Such coupling constants over seven and eight bonds, to the *meta* and *para* protons, are taken as being mediated by the extended π-electron system, providing a measure of π-electron contributions to coupling constants between *meta* protons and those in side chains (spin correlation). Some coupling constants between protons and ^{13}C nuclei in the side chain, as well as between ring protons and these ^{13}C nuclei, are also discussed in terms of spin coupling mechanisms. Solvent perturbations of one-bond proton–carbon coupling constants in the allenyl group do not follow the usual pattern in which an increase in polarity of the solvent is associated with an increase in the magnitude of the coupling constant.

Key words: ^{1}H NMR, phenylallene; ^{1}H NMR, long-range spin–spin coupling constants in phenylallene; phenylallene, internal rotational potential, molecular orbital computations; molecular orbital calculations, an internal rotational potential in phenylallene.

Résumé : Les spectres RMN du ^{1}H du phénylallène, en solution dans l'acétone-d_6 et le benzène-d_6, permettent de tirer les constantes de couplage sur des distances allant jusqu'à huit liaisons formelles, entre les protons du cycle et ceux de la chaîne latérale. On les discute en fonction des mécanismes de couplage spin–spin des électrons σ et π qui sont sensibles à l'angle de torsion entre les fragments allényle et phényle. On évalue l'angle de torsion par des calculs d'orbitales moléculaires du potentiel de rotation interne dont la hauteur a été évaluée à 16,0 kJ/mol au niveau MP2/6-31G* de la théorie de corrélation du gradient. Une comparaison des potentiels expérimental et théorique de rotation interne du styrène suggère que les répulsions stériques dans la forme planaire du styrène sont de l'ordre de 4 kJ/mol. Dans un champ de 7,0 T, le phénylallène est partiellement aligné impliquant une constante de couplage dipolaire positive entre les protons du méthylène et à partir de laquelle on peut déduire les constantes de couplage spin–spin de ces protons. On considère que ces constantes de couplages s'étendant sur sept et huit liaisons, vers les protons *méta* et *para*, sont rendues possibles par le système étendu d'électrons π et qu'elles fournissent une mesure des contributions des électrons π aux constantes de couplage entre les protons *méta* et ceux de la chaîne latérale (corrélation de spin). On fait appel aux mécanismes de couplage de spin pour discuter aussi de quelques constantes de couplage entre des protons et des noyaux ^{13}C de la chaîne latérale, comme celles entre les protons du cycle et des noyaux ^{13}C. Les perturbations par les solvants des constantes de couplage proton–carbone à travers une liaison dans le groupe allényle ne suivent pas le patron

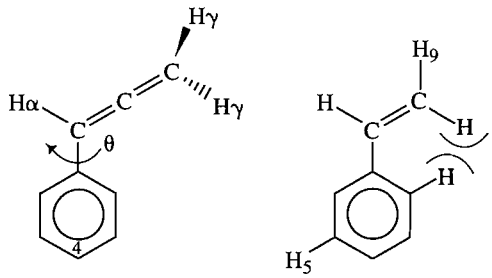
Introduction

One aim of this report is to compare the computed barriers to internal rotation in phenylallene, **1**, and styrene, **2**. In the planar conformer of **2** the indicated repulsions oppose the π-electron conjugation favouring planarity. Whether, in fact, there exists a (small) barrier to planarity in **2** is a matter of disagreement (1–8) between experimental and theoretical data. The β-CH bond is absent in **1**, while ^{13}C nmr chemical shifts indicate (9) rather similar π conjugational energies in the two molecules. Hence the barriers to rotation about the bond between the fragments in **1** and **2** may, by subtraction, represent a first approximation to the steric destabilization of planar **2**. Accordingly, molecular orbital computations of the internal rotational potential in **1** are reported here and are compared with similar computations (5, 6, 10) on styrene.



1 **2**

A second aim of this work is the analysis of the ^{1}H nmr spectra of **1**. In particular, the long-range spin–spin coupling constants over four to eight formal intervening bonds, between the protons on the side chain and those in the phenyl group, are obtained. The dependence of such coupling constants on the conformational angle, θ (see **1**), and hence on the internal rotational potential, has been discussed in detail for styrene and a number of its derivatives (3, 11, 12). A similar discussion for phenylallene does not appear to be available and is given below. It also happens that the spectral pattern for the phenyl group in acetone-d_6 solution is unique and is illustrated.

In addition, some coupling constants between protons and ^{13}C nuclei within the side chain are presented and compared with earlier measurements. Long-range coupling constants of the ring protons with the ^{13}C nuclei in the allenyl fragment are also given and are discussed in terms of coupling mechanisms.

Experimental

Phenylallene, **1**, was prepared from 1,1-dibromo-2-phenylcyclopropane, itself constructed using styrene, bromoform, and potassium hydroxide, exactly as described in the recent literature (13). Dilute solutions of **1** (see Table 1 for details) in benzene-d_6 and acetone-d_6 were filtered into 5 mm o.d. nmr tubes and were then degassed by at least five cycles of the freeze–pump–thaw procedure. The tubes were flame-sealed under vacuum such that reasonably symmetric tops were produced.

The ^{1}H nmr spectra were obtained from an AM 300 Bruker spectrometer at a probe temperature of 300 K. Typically, 32 free induction decays were coadded, using acquisition times of 30 s and a digital resolution of 0.017 Hz/point after zero-filling to twice the original data table. A small amount of resolution enhancement and Fourier transformation produced spectra whose line widths at half-height were about 0.03 Hz. Final shimming procedures used the free induction decays from internal tetramethylsilane (TMS). Similar procedures were used for the ^{13}C nmr spectra, except that acquisition times were 20 s, digital resolution was 0.027 Hz/point, and the number of coadded free induction decays was as large as 1800.

The signs of the coupling constants between the ring and γ protons (see **1**) were determined by partial decoupling (14) experiments in which the transitions of the α protons were irradiated for given spin states of the γ protons, while detecting those of the ring protons. The signs of the coupling constants in Table 1 follow on the basis that $^4J_{\alpha\gamma}$ is negative, as it is if ^3J(H, CH_3) in 1-chloro-1,2-butadiene is positive (15–17). The sign of the dipolar coupling between the γ protons in **1** is consistent with the absolute signs in Table 1 (see below).

Molecular orbital computations on phenylallene employed various basis sets[2] in the program GAUSSIAN 92 (18), as well as the AM1 algorithm (19). The conformational angle, θ, was fixed at 15° intervals between 0° (planar) and 90° (perpendicular) while all other angles and bond lengths were optimized during the SCF cycles, with the constraint, however, that the phenyl moiety remain planar. Some post-Hartree–Fock correlation-gradient calculations, MP2/6-31G* (frozen-core), were done for the planar and perpendicular conformations. The relative energies at various θ values were fit to

$$V(\theta) = \Sigma_n V_n \sin^2 (n\theta/2)$$

where n is the foldedness of the term contributing to the internal rotational potential. Expectation values at 300 K of $\sin^2\theta$ were calculated from these potentials.

Results and discussion

Spectral analyses

Analyses of the ^{1}H nmr spectra employed the program NUMARIT (21), rather extensively reworked by R. Sebastian and renamed NUMMRIT. The spectra were treated as arising from ABB'CC'XY_2 spin systems. A satisfactory fit to the methylene proton (Y_2) region could not be had in the absence of a *positive* dipolar coupling between them. Table 1 presents the spectral parameters. The finite dipolar coupling means that the phenylallene molecules are partially aligned in the field, B_0. In the planar conformation the interproton vector of the methylene group lies perpendicular to the molecular plane. Because of the sign of the diamagnetic anisotropy of the mol-

[2] An explanation of the notation and the meaning of the basis sets, and a description of the MP2 approximation to electron correlation, can be found in ref. 20.

[e]These parameters are correlated by 0.55.
[f]These parameters are correlated by 0.88.
[g]The dipolar coupling is positive.

Fig. 1. The ^{1}H nmr spectrum of the methylene protons at 300 MHz and 300 K for a 5.1 mol% solution of phenylallene benzene-d_6 is shown at the bottom of the figure. At the top the best theoretical spectrum is shown in the absence of a dipolar coupling constant between these protons; the rest of the ^{1}H nmr spectrum, containing transitions from the α and the phenyl protons, agrees well with experiment. The middle spectrum has the dipolar coupling constant for the methylene protons as +0.0150(4) Hz. A negative sign, relative to those of the spin–spin coupling constants involving these protons, did not allow a fit of theory to experiment.

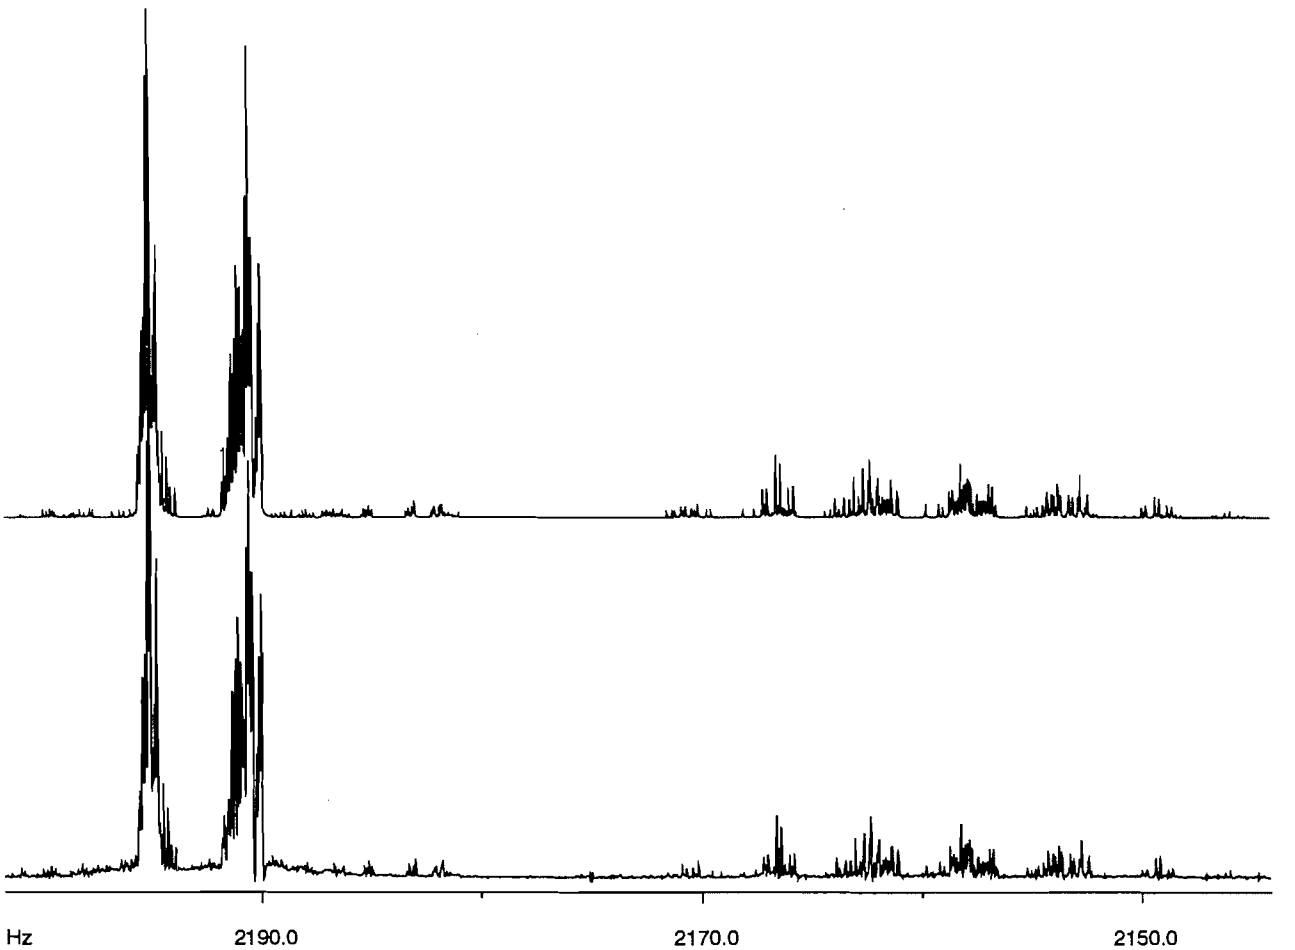
Fig. 2. The ^{1}H nmr spectra, experimental and theoretical, are shown for the phenyl protons of phenylallene as a 5.1 mol% solution in acetone-d_6 (300 MHz and 300 K). The *para* protons resonate at 2158.75 Hz to high frequency of internal TMS. The *ortho* and *meta* protons differ in their chemical shifts by 0.82 Hz (0.0027 ppm). In consequence, their spectrum is dominated by two bands of peaks separated by roughly 4.3 Hz, the average of the coupling constants between the *para* proton and the *ortho* and *meta* protons (in Table 1, $^3J_{34} + {}^4J_{24}$ is 8.68 Hz). Some of the weak peaks in the *para* region are obscured by noise in this spectrum; they do exist.



ecule and because $\langle \sin^2\theta \rangle$ is about 0.1 (see below), a positive dipolar coupling constant is indeed anticipated (22, 23). Figure 1 illustrates the spectral consequences.

The dipolar coupling constant is +0.0124(5) in acetone-d_6 and +0.0150(4) Hz in benzene-d_6 solution. It cannot be concluded that either the alignments or the internal barriers differ in the two solutions.[3] Because the magnitudes of the dipolar coupling constants drop off as the cube of the internuclear distance, one may conclude that the three-bond, or *ortho*, coupling constants in Table 1 are uncertain to within about 0.003 Hz. Similarly, introduction of a dipolar coupling between the α and *ortho* protons did not improve the spectral fits. Because, in addition, proton–proton coupling constants within a phenyl group are solvent dependent,[4] this dependence being rather

[3] At 500 MHz one should have 0.033 and 0.042 Hz for the dipolar coupling constants at 300 K, still rather small. A procedure designed to obtain the alignment factors and the diamagnetic anisotropy, independently of the complications due to internal rotation, would involve deuteration at, say, the *para* position of the phenyl ring (22, 23).

[4] This fact has been documented for a wide variety of benzene derivatives in this laboratory. The pattern of the solvent dependencies in Table 1 is the same as in the other molecules; $^4J_{24}$ *decreases* in the more polar solvent, for example.

Table 2. Some ^nJ(H, ^{13}C) values for phenylallene, **1**

larger (Table 1) than the expected dipolar coupling constants, and because they are not germane to the aims of this paper, this matter was not investigated further.

The chemical shifts of the *ortho* and *meta* protons of phenylallene differ by only 0.82 Hz in the acetone-d_6 solution. In consequence, the spectral pattern of the ring protons is at first confusing and, to our knowledge, of a kind not available in the literature. Figure 2 therefore displays the computed and measured ring proton spectra for the acetone-d_6 solution.

Some ^{13}C nmr data for the allenic group are shown in Table 2. The signs of the coupling constants within the side chain involving the ring protons are based on theory or analogous compounds.

The theoretical internal rotational potential of 1

The theoretical energies, employing various basis sets, are reproduced in Table 3 for various values of the torsion angle, θ. The twofold and fourfold components of the internal rotational potential, derived from these energies, are given in Table 4, in which comparisons are made with similar values for styrene. It has been recommended (24) that AM1 potential heights for styrene and similar molecules be scaled by a factor of 1.9 ± 0.25; the value for phenylallene is then 14.1 ± 1.9 kJ/mol. This value will not be discussed further, except to note that it comes close to 16.0 kJ/mol, as obtained from the MP2/6-31G* (frozen core) approach, a correlation-gradient calculation.

For styrene, **2**, the experimental barrier height is either 12.8(1) kJ/mol, based on supersonic jet fluorescence spectroscopy (1), or 13.8(2) kJ/mol, as obtained from microwave spectroscopy (2). In Table 4 it can be seen that the 6-31G value, at 13.2 kJ/mol, agrees best with these values whereas a larger basis set, 6-31G*, gives a lower barrier.[5] From the viewpoint of the unknown barrier in phenylallene, it is interesting, first, that each basis set yields a barrier higher by very close to 4.0 kJ/mol than for styrene and, second, that the first approximation to electron correlation energies, MP2/6-31G*, does not alter the computed barrier.[6] This difference of 4.0 kJ/mol is here taken as a first estimate of the destabilization of the planar form of styrene due to the steric repulsion between the *ortho* and β-*cis* C—H bonds (see **2**). A trial potential energy curve which included a term in $E_s \cos^{12}\theta$, and used to fit the deuterium quadrupolar splitting of styrene-α-*d*, itself partially oriented in a magnetic field, suggested that E_s, the steric repulsion energy, was probably less than 4.2 kJ/mol (4).

Figures 3 and 4 give the MP2/6-31G* structure of the planar and perpendicular forms of phenylallene, probably of use to molecular spectroscopists. According to the potentials in Table 4, the expectation values of $\langle\cos^2\theta\rangle$ at 300 K are 0.90 and

[5] A post-Hartree–Fock computation (6) for styrene, MP4(SDQ)/6-31G//HG/6-31G, has the barrier height as only 10.4 kJ/mol. For differing views about the basis set dependence of computed barriers in benzene derivatives, and the reliability of various approaches to accounting for electron correlation, see refs. 25 and 26.

[6] For styrene the MP2/6-31G* barrier is 1.1 kJ/mol lower than the 6-31G* barrier (6).

[a]The 6-31G** geometries were used for ^nJ(H,H) and 6-31G geometries for ^nJ(H,C); this will not alter the qualitative functional relationships presented here, while only semiquantitative agreement of the coefficients, *A–D*, with experiment would be anticipated at best.

[b]The factor by which the ^nJ from theory has to be multiplied in order to reproduce experiment; it is assumed that $\langle\sin^2\theta\rangle$ is 0.103 and that the internal rotational potential is evenfold, so that $(\sin^2(\theta/2))$ is 0.5. It is notorious that INDO MO FPT computations overestimate σ-electron contributions, particularly for possible all-*trans* pathways; in such situations the factor will be smaller than in others (compare $^5J_{3\alpha}$ and $^8J_{4\gamma}$, for example).

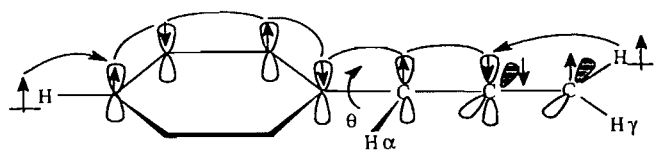
0.83 for **1** and **2**, respectively, at the 6-31G level of theory, implying somewhat lower conjugation in the latter. The chemical shifts of the C-4 nuclei,[7] often taken (9) as indicative of the extent of π-electron transfer, are, respectively, 128.5, 126.6, and 127.6 ppm for benzene, **1**, and **2** (9). As expected from the $\langle\cos^2\theta\rangle$ values, unity corresponding to most effective π overlap, the allenyl group transfers slightly more electron density to the phenyl moiety than does the vinyl fragment. The argument is, not that allenyl is a better intrinsic π donor than vinyl, but that the steric forces, which act conformationally to somewhat inhibit π conjugation in styrene, are absent in phenylallene. The *para* protons in **1** are also somewhat more shielded, by 0.03 ppm, than those in **2**, in acetone-d_6 solution. However, the shift for **2** was measured at a concentration of 16 mol% (28), that for **1** at 5.1 mol%.

Long-range coupling constants, ^nJ(H,H)

INDO MO FPT computations (29–31) yielded ^nJ(H,H) as a function of the torsion angle and were fit to plausible functions of this angle, as summarized in Table 5. In all the functional relationships discussed below, the units of ^nJ are Hz.

(a) The γ protons

Theoretically, $^8J_{4\gamma} = -0.79(1) + 0.73(3)\sin^2\theta$, or, equivalently, $-0.06\sin^2\theta - 0.79\cos^2\theta$ and strongly implies the π-electron-mediated coupling mechanism indicated in **A**. In **A**, the benzene plane lies perpendicular to the page, so that its $2p\pi$ orbitals are oriented in the plane of the page. Therefore, in the planar conformer of **1**, the methylene plane is also parallel to the page. A crossed arrow indicates the spin state of the proton. The usual σ–π spin polarization mechanism, defined by a negative hyperfine interactive parameter, Q^{H}CH, leads to the parallel orientation of the π electron at C-4. The electron spin correlation along the extended π-electron system yields the indicated spin state at C-β. Another σ–π, or hyperconjugative, interaction involving the γ-proton and defined by the positive hyperfine interaction parameter, Q^{H}CCH, then leads to the spin state of the γ proton. Hence the two protons possess parallel spin states, defining a negative $^8J_{4\gamma}$.



A

As θ increases from zero, as in **A**, the π-electron spin correlation decreases and disappears at $\theta = 90°$. The computed θ dependence of ^8J agrees with this model. The semiempirical, INDO MO FPT, computational scheme predicts the qualitative conformational dependence of long-range coupling constants rather well (32), particularly for pure π-electron mechanisms, but is not expected, in general, to provide quantitative results. One approach to a calibration of the computations, for the present molecule, is to compare the measured $^4J_{\alpha\gamma}$, also a π-electron coupling constant (17), with the computed number. These are -6.8_3 and -8.0 Hz, respectively, the ratio being 0.85. Reduction of the computed ^8J values by this factor[8] leads to $^8J_{4\gamma} = -0.67(1) + 0.62(2)\sin^2\theta$. This equation

[7] Reference 9 does not appear to give the ^{13}C nmr chemical shifts for **1**, although they are quoted in ref. 27 as coming from the former.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12

predicts $\langle \sin^2\theta \rangle$ as 0.102(4) at 300 K, based on an $^8J_{4\gamma}$ of −0.607 Hz (Table 1).

It so happens that this expectation value agrees exactly with those computed from the 6-31G* or 6-31G** potentials (Table 4). It is also true that $^8J_{4\gamma}$ is essentially the same in the two solvents. Naturally, it does not follow that the internal rotational potential of phenylallene is independent of solvent. Yet, this certainly appears to be true for ethylbenzene[9] in a variety of solvents (34). The spin–spin coupling constants of styrene and a number of its derivatives have been interpreted (3, 11) on the basis of such an independence, although a contrary conclusion was reached (4) from partially averaged quadrupolar coupling constants in deutero derivatives of styrene. The simplest assumption at present, consistent with the available evidence, is that the internal potential in phenylallene is not affected by the present solvents. The ensuing discussion of other coupling constants makes this assumption.

$^7J_{3\gamma} = {}^7J_{5\gamma} \equiv {}^7J$ is 0.206 Hz. It is unlikely (33) that this coupling constant is transmitted by other than the π-electron mechanism discussed for $^8J_{4\gamma}$. The sign can be understood from the spin orientations in structure **A**, the smaller magnitude than that of $^8J_{4\gamma}$ from the notion that spin correlation for atoms belonging to different classes (starred, unstarred) is larger in magnitude than between atoms of the same class (37, 38). A suggestive set of numbers is the Hückel bond orders, being 0.667 for *ortho*, −0.333 for *para*, and zero for *meta*, carbon atoms in benzene. The INDO MO FPT results for $^7J_{3\gamma}$ do not seem sensible, given by $0.52\cos^2\theta + 0.36\sin^2\theta$ and leading to a value of 0.36 Hz in the perpendicular conformer. One expects $^7J_{3\gamma}$ to become very small, that is, to vanish essentially at $\theta = 90°$. A derivative of **1** with a very large average θ is needed to confirm this expectation.

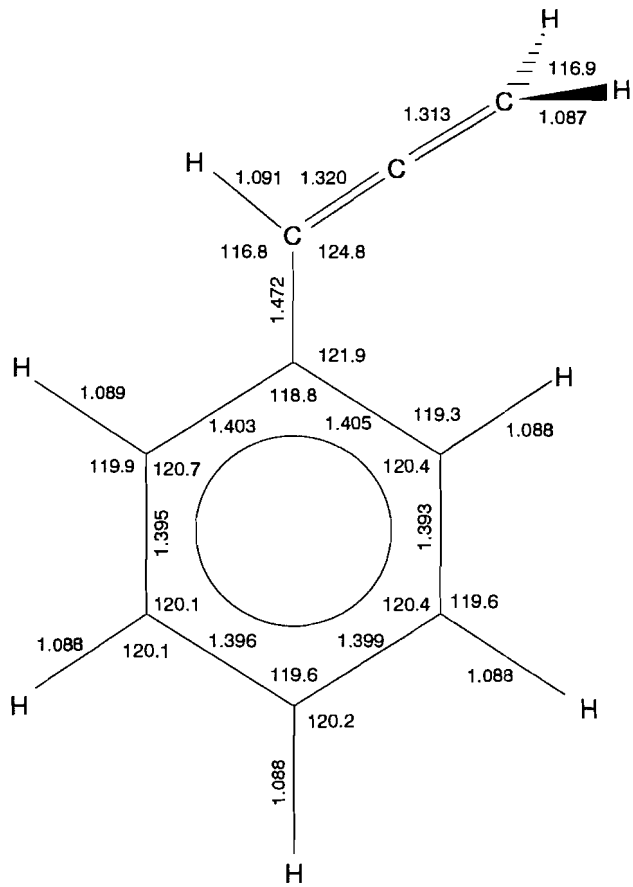
In terms of the present model, $^7J_{3\gamma}/^8J_{4\gamma} = -0.34$ is a measure of the ratio of the π-electron contributions, at *meta* and *para* sites, to coupling constants involving nuclei in the side chain of benzene derivatives. There has been uncertainty about this ratio, for example, in toluene (39) and other alkyl benzene derivatives (40). Because, say, ^5J(H, CH) in such compounds has a stereospecific σ-electron component (39, 41), subtraction of a known π-electron component from the measured value would increase the precision with which conformational populations could be deduced.

As to $^6J_{2\gamma}$, its striking aspect is the near equality with $^8J_{4\gamma}$; the former is −0.581(3) Hz, the latter, −0.607(4) Hz (the numbers are averages for the two solutions). The implication, that the π-electron contributions to these coupling constants are effectively equal, is unexpected from the viewpoint of bond orders available from molecular orbital theory (42–45), where J is proportional to the square of a mobile bond order.

[8] Of course, this approach does not take into account any computational errors at the C-4 site nor the computation of the π-electron spin correlation at the C-1, C-α sites. However, judging by similar computations for $^7J_{4\beta}$ in styrene, also a pure π-electron coupling constant (33), and the rather good agreement with the available experimental data (3, 28, 33), this calibration is reasonable.

[9] The internal rotational potential in the relatively polar molecule, benzyl fluoride, changes by 2 kJ/mol in passing from CS_2 to acetone-d_6 solution (35); its dipole moment is 1.77 D in benzene solution (36). The computed dipole moments for phenylallene are 0.078 D for the planar and 0.076 D for the perpendicular conformers (6-31G**).

Fig. 3. The MP2/6-31G* (frozen-core) structure of the planar conformer of phenylallene may well be of interest to molecular spectroscopists. The computed rotational constants are 4.579 23, 0.993 14, and 0.820 72 GHz at the equilibrium geometry. The height of the internal rotational barrier is calculated as 16.0 kJ/mol, so that this structure is presumably somewhat more to the point than that of the perpendicular structure in Fig. 4. A high-level computed structure for allene is available (63), as is an MP2/6-31G* structure (64). The latter has a C=C length of 1.313 Å (experiment, 1.308 Å). Comparison with the MP2/6-31G* structure above for phenylallene suggests a slight lengthening of the Cα—Cβ bond, implying some delocalization into the C1—Cα bond.

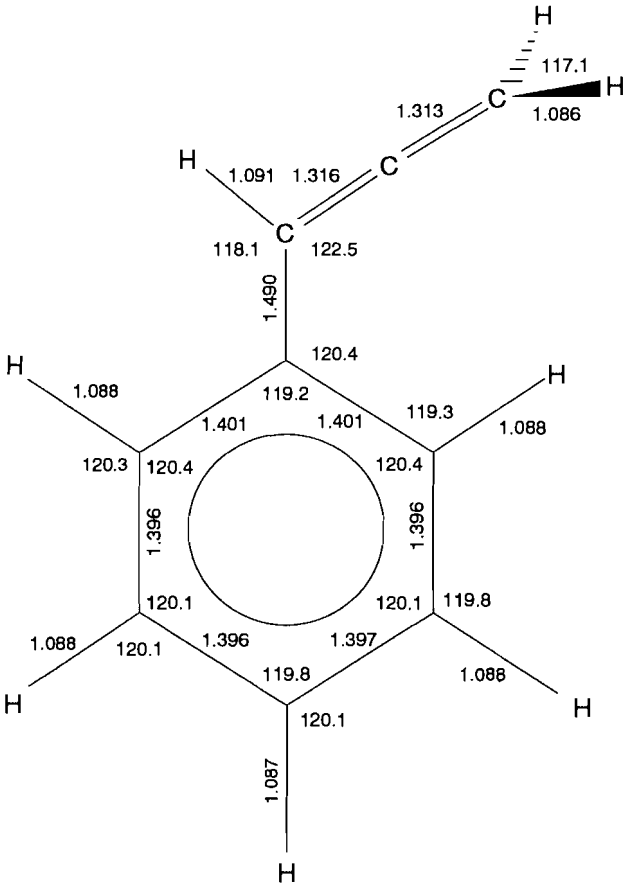


However, in various formulations based on valence bond theory (37, 43), J is proportional to a bond order, variously defined (43, 45). Some formulations (46) yield nearly equal contributions of the π-electrons to the coupling constants between *ortho* and between *para* protons in benzene. While it is perhaps unexpected that spin correlation between *para* sites is comparable to that between *ortho* sites, it may be noted that $^8J_{4\gamma}$ has two coupling pathways via the aromatic π-electron systems, $^6J_{2\gamma}$ only one.[10]

The INDO MO FPT computation yields $^6J_{2\gamma} = -0.96\cos^2\theta - 0.39\sin^2\theta$. After reduction by a factor of 0.85, as for $^8J_{4\gamma}$, this result implies a $^6J_{2\gamma}$ of −0.33 Hz in the perpendicular conformer, inexplicable in the present model in the absence of an

[10] It is amusing that the ratio of the magnitudes of the Coulson (Hückel) bond orders for *para* and *ortho* sites is one-half; there exists no theoretical justification, however, for a proportionality of J^π to the magnitude of the Hückel bond order.

Fig. 4. The MP2/6-31G* structure of the *perpendicular* conformer of phenylallene. There are some significant predicted changes in bond angles at the first exocyclic carbon atom (see Fig. 3). The exocyclic Csp^2–Csp^2 bond length has lengthened by nearly 0.02 Å. The computed rotational constants are 4.182 14, 0.967 747, and 0.867 967 GHz. Note that the side chain is not drawn in projection, it being more convenient to indicate bond parameters in the structure as drawn.



additional mechanism operative at $\theta = 90°$. A similar situation holds for ^5J(H-2, C-γ) below.

(b) The α proton

The coupling constant, $^6J_{4\alpha}$, in styrene consists of two components, one due to a π-electron mechanism analogous to the one in **A** and the other arising from a σ,π mechanism. The former depends on $\cos^2\theta$, the latter on $\sin^2\theta$ (33). One formulation (3) has $^6J_{4\alpha} = -0.149\cos^2\theta - 0.597\sin^2\theta$, another (47) yields $-0.130\cos^2\theta - 0.800\sin^2\theta$. On the assumption that $\langle\sin^2\theta\rangle$ is 0.103 for phenylallene, the first equation would yield $^6J_{4\alpha}$ in this molecule as −0.195 Hz, the second as −0.199 Hz. The experimental value is −0.212(2) Hz (Table 1). The INDO MO FPT//6-31G** computations for phenylallene give $^6J_{4\alpha} = -0.228(1)\cos^2\theta - 1.009(1)\sin^2\theta$, an overestimate of the magnitudes, as also found for styrene (3). Reduction of both terms by a factor of 0.69 would produce agreement with a $\langle\sin^2\theta\rangle$ of 0.103, that is $^6J_{4\alpha} = -0.157(1)\cos^2\theta - 0.696(1)\sin^2\theta$.

Turning to $^5J_{3\alpha}$, one may note that INDO MO FPT methods are notorious for an overestimation of the σ-electron component of such coupling constants, toluene (39, 41) and benzaldehyde (48) being only two examples. Indeed, for phenylallene, the INDO MO FPT//6-31G** expression is $^5J_{3\alpha} = 0.25\cos^2\theta + 0.36\sin^2\theta + 0.81\sin^2(\theta/2)$. For an evenfold potential, $\langle\sin^2(\theta/2)\rangle$ is 0.5, so that $^5J_{3\alpha}$ is computed as 0.67 Hz, in contrast to the measured value of 0.284(2) Hz. For benzaldehyde and toluene derivatives there is evidence (49, 50) that ^5J effectively vanishes at $\theta = 0°$ (not an all-*trans* pathway). An empirical expression for $^5J_{3\alpha}$ can be developed as follows. The π- and σ,π-electron contributions at $\theta = 0°$ are taken as 34% (see the discussion of plain58$J_{4\gamma}$ and $^7J_{3\gamma}$) of those assessed above for $^6J_{4\alpha}$, that is, 0.053 and 0.237 Hz, respectively. Together with the experimental value of $^5J_{3\alpha}$, one then has $^5J_{3\alpha} = 0.05\cos^2\theta + 0.24\sin^2\theta + 0.42\sin^2\theta/2$, an expression more likely to correspond to reality than that found theoretically. One might argue that, because ^5J in benzaldehyde vanishes at $\theta = 0°$, also for an sp^2 carbon atom in the side chain, so should ^5J in phenylallene. However, ^6J in benzaldehyde is undetectable (51), corresponding to the large internal barrier, and implying a negligible π component also of ^5J, that is, at $\theta = 0°$.

Finally $^4J_{2\alpha} = -0.50(8)\cos^2\theta - 1.22(1)\sin^2\theta - 0.19(1)\sin^2(\theta/2)$, theoretically. The experimental value is −0.378(3) Hz. An empirical procedure, based on the behaviour of $^{6,8}J_\gamma$ and $^6J_{4\alpha}$, yields $^4J_{2\alpha} = -0.16\cos^2\theta - 0.70\sin^2\theta - 0.32\sin^2(\theta/2)$.

A test of all these empirical relationships would require a derivative characterized by a large effective torsion angle.

The dipolar coupling constant, $D_{\gamma\gamma}$

At a torsion angle, θ, of zero, $D_{\gamma\gamma}$ must be positive, as follows (22, 23) from the known partial alignment of aromatic molecules in the magnetic field of the spectrometer. If the anisotropy of the diamagnetic susceptibility were known, as well as the proton, proton distance in the methylene group in phenylallene, $D_{\gamma\gamma}$ could be related to the torsional potential: $D_{\gamma\gamma}$ must be negative for the perpendicular conformer ($\theta = 90°$). If the calculated torsional potential is correct and if the molecule orients in the same way as benzene, then the signs of $^{6,7,8}J_\gamma$ given in Table 1 are absolute and independent of the sign determinations described above.

Some $^nJ(^1H, ^{13}C)$ for phenylallene

Table 2 contains the $^nJ(^1H, ^{13}C)$ values accessible by analysis of the ^{13}C nmr spectral of **1**, mainly in benzene-d_6 solution.

(a) $^nJ(H,C)$ within the side chain

One striking fact is the *decrease* in ^1J(H,C) in passing from benzene-d_6 to acetone-d_6 solution.[11] The decrease is 3.9 Hz for ^1J(H,C-α) and 1.0 Hz for ^1J(H,C-γ). In most cases[12] an increase is observed (53, 54) in passing to the more polar environment, as predicted by models in which the electric field from the solvent causes a redistribution of charge in the whole molecule carrying the C—H bond (53). If the charge redistri-

[11] For the neat compound, containing also 10% v/v benzene-d_6 and 5% v/v TMS, ^1J(H,C-α) is 161.5(3) Hz (52). Reference 52 collects all available ^nJ(H,C) values within the allenyl group for numerous allenes and also points out discrepancies of sign and magnitude for earlier data.

[12] For example, for the olefinic protons in 1,3-dioxole, ^1J(H,C) increases when moving from benzene-d_6 to acetone-d_6 solution (55).

bution is confined to the C—H bond, then a decrease is indeed calculated (53). Why this should be true for the allenyl moiety is unknown and needs further study for a number of its derivatives. ^1J(H,C) in such compounds has been correlated with dual substituent parameters (56).

Solvent perturbations of ^2J(H,C) and ^3J(H,C) have not been reported previously; they amount to a few percent in Table 2.

(b) $^nJ(^1H, ^{13}C)$*, ring protons to side chain* ^{13}C *nuclei*

(i) The para *proton coupling constants*: Consider first the coupling constants involving the *para* proton, $^{5,6,7}J$(H-4,C). ^5J(H,C-α) is 0.91 Hz; its computed dependence on θ can be written as $1.23 - 0.33 \sin^2\theta$, and is larger than the +0.65 Hz measured (57) for the corresponding coupling constant in toluene and the 0.5 Hz reported for benzoic acid (58). The coupling constant in toluene has been interpreted as a σ–π interaction, proportional to $Q^{H}CHQ^{C}CC$. Both hyperfine interactions are negative and refer to π-electron spin densities on the contiguous aromatic carbon atoms (57). In **1**, C-α is sp^2 hybridized, so that an additional hyperfine interaction comes from π spin density on C-α (see structure **A**). This contribution can be thought of as involving parameters describing the polarization of orbitals, containing *s* character and centered on C-α, by the π density on C-α (59). The net result is a negative contribution to ^5J(H-4, C-α). As θ increases from 0° to 90°, the INDO computations indicate a decrease of 0.33 Hz, corresponding to cessation of spin correlation between the π-electrons on C-1 and C-α. The INDO MO FPT numbers are again too large, apparently. Taking $\langle\sin^2\theta\rangle$ as 0.103, as in the discussion of the proton–proton coupling constants, together with the requirement that theory fit experiment, leads to $0.94 - 0.25 \sin^2\theta$ for the coupling constant. Of course, this relationship assumes that theory overestimates both contributions by the same factor; this is not known.

As to ^6J(H-4, C-β), the computed numbers are reproduced by $-0.47 \sin^2\theta - 0.66 \cos^2\theta$, written in this way to emphasize the possible π-electron and σ,π-electron (hyperconjugative) components. The demand, as above, that the coefficients lead to agreement with the measurement of (−)0.42 Hz, leads to the expression, $^6J = -0.31 \sin^2\theta - 0.43 \cos^2\theta$. If true, then the σ,π hyperfine parameter, $Q^{C}CCCsp > 0$, and proportional to $\sin^2\theta$, is 0.44 of the magnitude of the σ,π hyperfine parameter, $Q^{H}CCH$, characterizing $^6J_{4\alpha}$ in a previous section. The π-electron contribution, the term in $\cos^2\theta$, should decrease more than the σ,π term as θ takes on large values.

^7J(H-4, C-γ) is 0.28 Hz, which theoretically follows $0.52 \cos^2\theta + 0.05 \sin^2\theta$, indicating a coupling constant transmitted via spin correlation in the extended system and, if the usual reduction in the theoretical parameters is applied, one has $0.31 \cos^2\theta + 0.03 \sin^2\theta$. The π-electron correlation at C-β favours their parallel orientation, as in structure **A** (Hund's rule). Hence the positive coupling constant can be thought of as being a result of the positive product, $Q^{H}CHQ^{C}CC\gamma$, which outweighs the negative contribution proportional to $Q^{H}CHQ^{C\gamma}C\gamma$. Just like ^8J(H-4, H-γ), ^7JH,C) should become very small or vanish when the π-electron conjugation between the aromatic and allenic moieties is removed at θ = 90°.

(ii) The ortho *proton coupling constants*: Turning to $^{3,4,5}J$(H,C) for the *ortho* protons, the theoretical vicinal coupling constant ^3J(H-2, C-α) is given by $4.55 + 0.77 \cos^2\theta + 1.05 \sin^2(\theta/2)$. The theoretical expression suggests a π-electron contribution of about 0.77 Hz and a θ-dependent substituent effect from C-β. For an evenfold potential, $\langle\sin^2(\theta/2)\rangle = 0.5$, and with a $\langle\sin^2\theta\rangle$ of 0.103 one has ^3J(H,C) as 5.76 Hz, whereas the measured value is 5.36 Hz. In toluene, ^3J(H,C) is 4.62 Hz (57). At least part of the higher magnitude in **1** may be attributed to a π-electron contribution via the partial double bond between C-1 and C-α, the term in $\cos^2\theta$, as well as the larger length of the exocyclic Csp^2—Csp^3 bond in toluene.

The INDO numbers for ^4J(H-2, C-β) are represented by $-0.63 \sin^2\theta - 0.76 \cos^2\theta - 0.26 \sin^2(\theta/2)$. Multiplication by a factor of 0.68 produces agreement with the measured −0.63(3) Hz.

For ^5J(H-2, C-γ), the INDO numbers are reproduced by $0.36 \sin^2\theta + 0.66 \cos^2\theta + 0.06 \sin^2(\theta/2)$. The term in $\cos^2\theta$ represents the transmission of spin-state information by the extended π-electron system, most effective in the planar conformation. The term in $\sin^2\theta$ is puzzling because it has a maximum in the perpendicular conformation of **1** but cannot be a β σ,π contribution of the sort involved in ^6J(H-4, C-β). Were this true, ^7J(H-4, C-γ) should also have a substantial value at φ = 90°, yet does not. The measured ^5J(H-2, C-γ) is 0.43 Hz; the theoretical expression, if multiplied by 0.65, would yield that number.

(iii) The meta *proton coupling constants*: ^4J(H-3, C-α) has a theoretical formulation, $0.71 - 0.13 \cos^2\theta - 0.17 \sin^2(\theta/2)$, implying a π-electron contribution of −0.13 Hz in the planar molecule and a negative substituent perturbation with a maximum magnitude when the C-α, C-β bond extends the all-*trans* bond arrangement. The π-electron contribution to ^4J(H,H) in benzene is −0.23(2) Hz (60). The experimental value of 0.80 Hz is larger than the 0.51 Hz predicted by theory, the only example in which this inversion occurs, and suggests that INDO underestimates the σ-electron component of ^4J(H,C) for the famous W configuration of the intervening bonds in an aromatic system.

^5J(H-3, C-β) can be written, theoretically, as $0.42 \cos^2\theta + 0.34 \sin^2\theta + 0.45 \sin^2(\theta/2)$. The first term represents the π-electron component in the extended π system in the planar form, the second term a putative σ,π component, and the last term would then account for a σ-electron contribution. This relationship predicts 0.63 Hz for ^5J(H-3, C-β), while the measured value is less than half as large. The overestimate is similar to that for ^5J(H-3, H-α).

Finally, ^6J(H-3, C-γ) computes as $-0.31 \cos^2\theta - 0.18 \sin^2\theta + 0.10 \sin^2(\theta/2)$. The positive σ-electron term, in $\sin^2(\theta/2)$, has a precedent in one of a similar magnitude predicted (33) for the all-*trans* ^6J(H-5, H-9) in styrene (see **2**) and confirmed in 3-fluorostyrene (61). However, the predicted value of ^6J(H-3, C-γ) in **1** is −0.25 Hz and is measured as ±0.04 ± 0.02 Hz. To assess which term, or perhaps all, are faulty in the theory also requires a phenylallene derivative characterized by a large θ.

^{13}C nuclear magnetic resonance chemical shifts

The ^{13}C nmr chemical shifts of the allenyl moiety in Table 2 display solvent perturbations as large as 0.54 ppm and of varying sign and are also different from those reported for a solution of **1** in $CDCl_3$ (62). Satisfactory computations of these shifts for the free molecule are now possible, judging from the results for allene (63).

Abstract: The electrochemical behavior of 4-trifluoromethylacetophenone (TFMA) has been studied in aqueous ($2 \leq pH \leq 10$), micellar, and ethanolic solutions using polarographic techniques. A slow hydration process of the carbonyl group has been observed by means of polarography and UV–visible spectrophotometry. Besides the well-known pH dependence of the electroreduction of aromatic ketones, C—F bond cleavages concomitant to the ketone reduction occur under electrolysis conditions in alkaline medium (pH = 10) at a very negative potential (−1.7 V), leading to the formation of 4-methylacetophenone, which is reduced at this potential with formation of the carbinol and of symmetrical and dissymmetrical pinacols. Finally, the reduction of TFMA has been performed in the presence of chiral surfactants in order to test their ability to induce an asymmetric induction.

Key words: 4-trifluoromethylacetophenone, 4-methylacetophenone, electroreduction, micellar medium, chiral surfactants, hydration, C—F bond fission.

Résumé : Une étude polarographique de la 4-trifluorométhylacétophénone (TFMA) a été réalisée en milieux aqueux ($2 \leq pH \leq 10$), micellaire et éthanolique. Un phénomène d'hydratation lente de la fonction carbonyle a été mis en évidence en polarographie et en spectroscopie UV–visible. Des électrolyses préparatives ont été menées aux différents pH étudiés. Outre la formation des carbinols et pinacols diastéréoisomères attendus, une coupure des liaisons C—F concomitante à la réduction de la fonction carbonyle se produit lors de l'électrolyse en milieu basique (pH = 10) à un potentiel assez négatif (−1,7 V). La 4-méthylacétophénone est alors formée et est elle-même réductible à ce potentiel pour conduire au carbinol et à des pinacols symétriques et dissymétriques. Nous avons également réalisé la réduction de la TFMA en présence de tensioactifs chiraux afin de tester leur potentialité au niveau de l'induction asymétrique sur les produits de réduction.

Mots clés : 4-trifluorométhylacétophénone, 4-méthylacétophénone, électroréduction, milieu micellaire, agents tensioactifs chiraux, hydratation, coupure d'une liaison C—F.

Introduction

Previous papers from this laboratory have reported on the mechanism of electrochemical reduction of aromatic ketones derived from acetophenone in aqueous or in micellar medium (1, 2) and in the presence of cyclodextrins (3). In particular, the dimerization reaction leading to diastereomeric pinacols has been investigated in these media. The present work extends these studies to trifluoromethylacetophenone (TFMA).

Indeed, the presence of a CF_3 group on the aromatic ring of aromatic ketones causes a significant shift of the corresponding half-wave reduction potentiel ($E_{1/2}$) to less negative values (4), making the electrochemical study in aqueous medium easier. However, in aqueous solutions, numerous carbonyl compounds are known to be subject to complex equilibria involving hydration–dehydration of the carbonyl group and keto–enol and acid–base equilibria; these result in the formation of both geminal-diols and enols or carbanion enolates according to the pH (5–7). Moreover, the reduction of trifluoromethyl compounds in aqueous and nonaqueous solutions may also involve C—F bond fission (8–13).

In this work, both the electrochemical and spectroscopic behavior of TFMA have been investigated in various protic solvents such as aqueous, micellar, and ethanolic solutions.

Results

1. Polarographic study

pH effects

The shape of the polarograms of TFMA changes significantly over the pH range 2–10 (Fig. 1). In acidic medium (pH < 5), two successive polarographic waves (A_1 and A_2) are observed. In the pH range 2–5, the half-wave potential of the first one

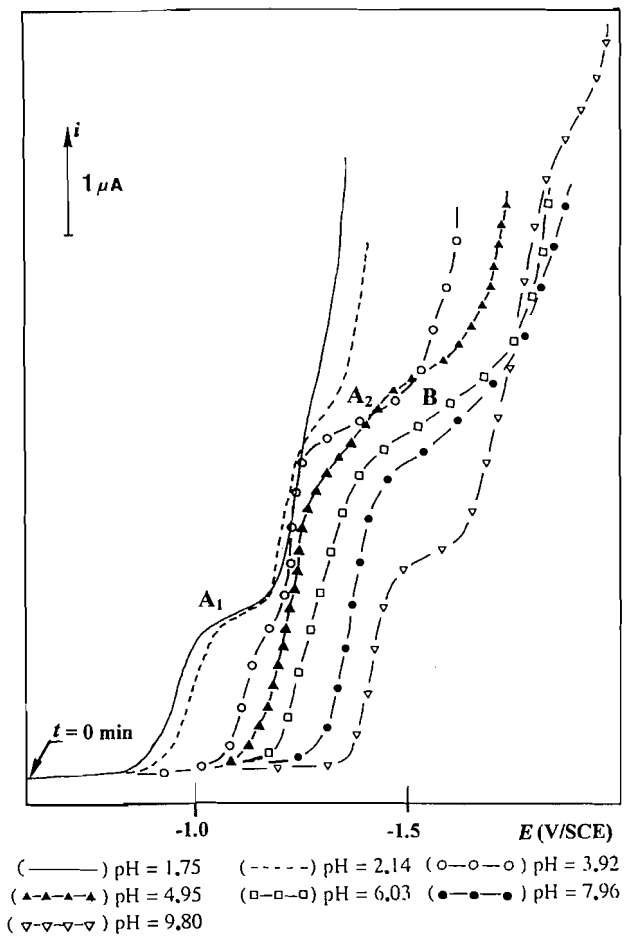
Fig. 1. Polarographic curves of 1×10^{-3} M TFMA recorded in different aqueous buffer solutions ($v = 4$ mV s^{-1}).



(A_1) shows a linear shift to more negative values by about 70 mV per pH unit (Fig. 2*a*). The height of the second wave A_2 is approximately equal to that of the first one and its half-wave potential ($E_{1/2} = -1.2$ V) is independent of pH from the value at which it first becomes discernible (pH 2) to the value at which it merges with the first wave (pH 5) to give a new wave B (Figs. 1, 2*a*). The half-wave potential of this wave B becomes slightly more negative as the pH is increased ($\Delta E_{1/2}$ / ΔpH $\cong$ 40 mV). Finally, in basic medium (pH 10) its limiting current decreases and a fourth wave (C) appears at more negative potential ($E_{1/2} = -1.72$ V), very close to the electrolyte reduction limit.

We have noticed that the wave heights of TFMA (i_{dA} and i_{dB}) decrease slowly with time (Fig. 2*b*) and that, in 50/50 ethanol/water solutions, the wave heights are constant but systematically smaller, even for the first scan, than in aqueous solutions ($0.6 \times i_{dH_2O}$) (Figs. 3, 4). These current variations with time prevent any accurate coulometric determination of the electron number involved in the electroreduction of TFMA at the different pH values.

Micellar medium effects

In the presence of surfactants, polarographic curves of TFMA are modified according to the nature of surfactants added (Figs. 3–5). In the presence of GHU, a surfactant that forms micelles but at a very high critical micellar concentration (CMC) (Table 1), the shape of the polarographic wave is not modified (Fig. 3). However, in weakly acidic solutions, addition of nonionic surfactants such as BRIJ35, OTG, and LS at a concentration superior to their respective CMC (Table 1) causes a shift of the reduction waves toward more negative potentials (Figs. 3, 5). In basic medium (Fig. 4), the addition of BRIJ35 has two major effects: first, wave B is shifted toward more positive potentials (curve 2) and its intensity is higher ($i_{dB} = 3.34$ μA) than in aqueous solution at the same pH ($E_{1/2} =$

Fig. 2. (*a*) Variation of half-wave potentials of waves A_1, A_2 and B as a function of pH. (*b*) Variation of $i_{d\,(A_1 + A_2)}$ as a function of time.

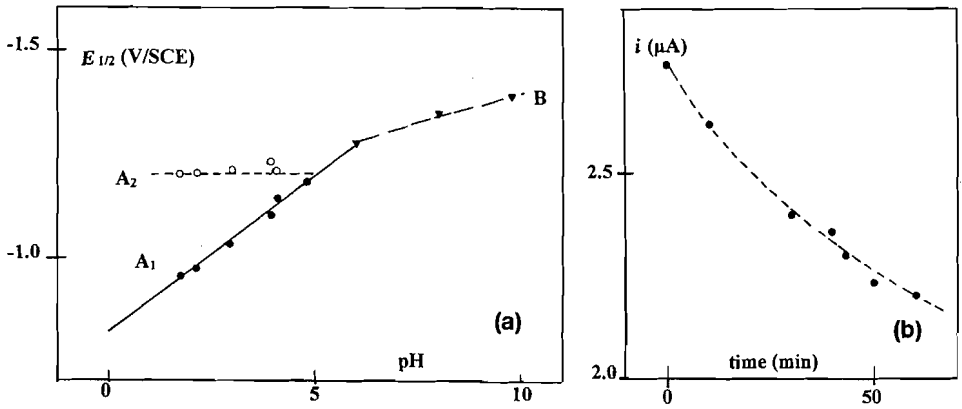


Fig. 3. Polarographic curves of 1×10^{-3} M TFMA at pH = 4: (1) with 1×10^{-3} M GHU; (2) with 1×10^{-3} M BRIJ35; (3) in 50/50 water/ethanol solution.

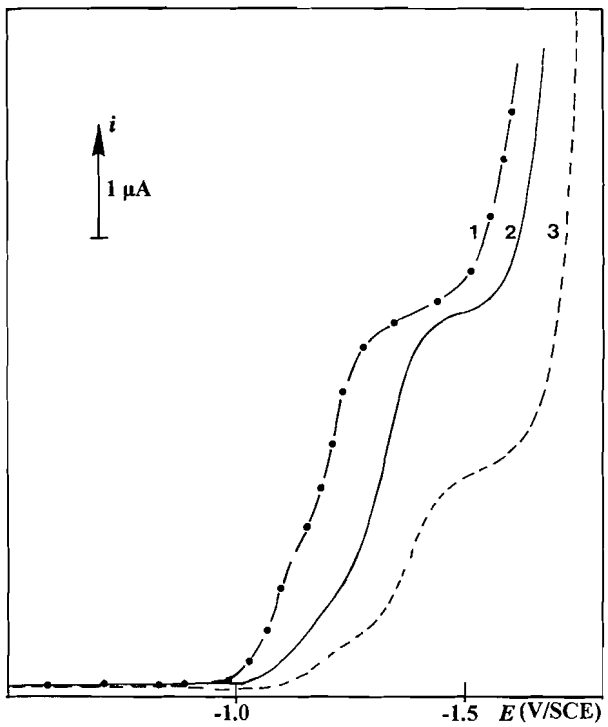

Fig. 4. Polarographic curves of 1×10^{-3} M TFMA at pH = 10: (1) without surfactant; (2) with 1×10^{-3} M BRIJ35; (3) in 50/50 water/ethanol solution.

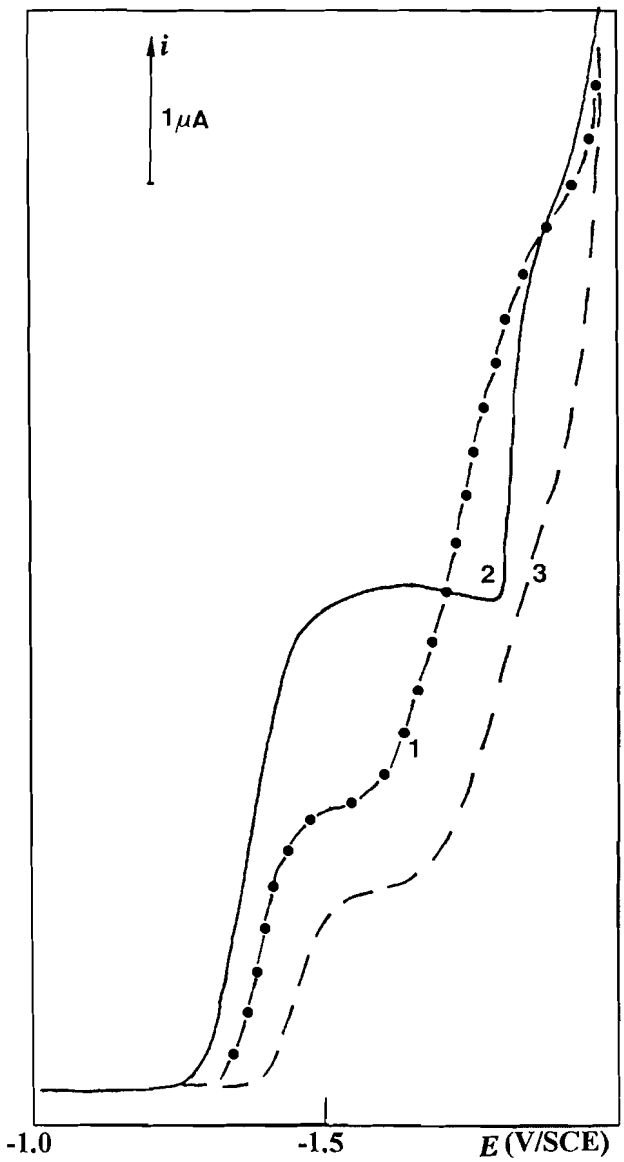

-1.40 V and $i_{dB} = 2.0$ μA, curve 1), and second, wave C is shifted toward negative potentials. Therefore it appears that in the presence of BRIJ35, the reduction of TFMA becomes roughly independent of the pH of the solution from pH 4 to pH 10 and occurs at $E_{1/2} \cong -1.35$ V (Figs. 3 and 4).

2. Preparative controlled-potential electrolyses

In aqueous solutions

Electrolyses of TFMA were performed in the different buffer solutions used, allowing an assignment of the reaction products obtained at a fixed potential corresponding to each of the four waves A_1, A_2, B, and C. The relative quantities of ketone (TFMA), carbinol (C1), and pinacols (P1) were determined

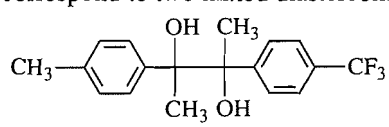
from ^{1}H NMR spectral analysis (Table 2). The values are summarized in Table 3.

In acidic medium (pH 3), a coulometric *n* value of 1 was obtained upon electrolysis at a potential on the diffusion plateau of the first wave (A_1). It corresponds to the formation of pinacols (P_1) as major products. Electrolysis at the potential of the second wave (A_2) gave a coulometric *n* value of 1.3 for which both pinacols (P_1) and carbinol (C_1) were obtained. Reduction of TFMA at a potential situated on the diffusion plateau of the second wave B in the pH 5 solution produced mainly carbinol (C_1). A higher than expected *n* value is obtained (Table 3). It could result from a beginning of C—F bond cleavages even at this pH value (vide infra).

Finally, controlled-potential electrolysis at −1.72 V in a pH 10 buffer solution yielded mainly pinacols (P_1) but also numerous other compounds. At least the different products were separated by GC (DB1 column) and identified by mass spectrometry coupled with gas chromatography (Table 4) and by assignment of their ^{1}H NMR signals, especially in the aromatic region, by comparison with NMR spectra of authentic samples (Table 2). Except for TFMA and its reduction products (the carbinol (C_1) and the pinacols (P_1)), there were methylacetophenone (MA) and its corresponding carbinol (C_2) and pinacols (P_2) (Tables 2 and 4). The chemical and electrochemical reduction of MA gave the authentic samples used for identification. The GC peaks arising at 47.6 and 48.2 min might correspond to two mixed diastereomeric pinacols (P3).



(P_3)

This hypothesis has been confirmed by analysis of the frag-

reduction products estimated, from the GC and NMR data, are the following: TFMA 6%, C_1 14 %, P_1 38 %, MA <2%, C_2 28%, P_2 3%, P3 11%.

In micellar medium

Electrolyses of TFMA were also performed in the presence of chiral surfactants (2.5×10^{-2} M LS and 5×10^{-2} M OTG) at pH 5 ($E_{appl} = -1.43$ V). Carbinol (C_1) obtained as reduction product, after its identification by ^1H NMR, was analyzed by GC on a LIPODEX-E column that allows good separation of the two enantiomers (*R* and *S*). There was no asymmetric induction (enantiomeric excess ≤ 0.05).

3. UV spectroscopic studies

In acetonitrile, TFMA shows a strong π–π* absorption band (K) at 239 nm, a medium-intensity benzenoid band (B) at about 277 nm (ε = 1000), and a weak band corresponding to the *n*–π* transition (λ_{max} = 316 nm, ε = 50) (Fig. 6*a*). The lat-

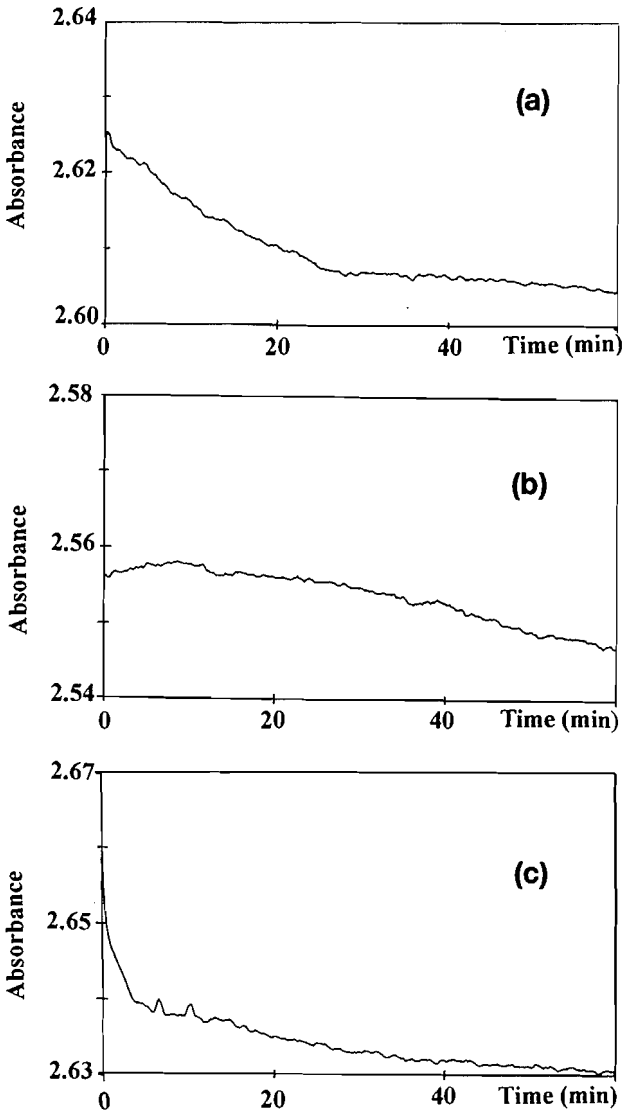
Fig. 7. Variation of absorbance at 284 nm as a function of time in various media: (*a*) aqueous buffer solution (pH = 4); (*b*) aqueous buffer solution (pH = 4) + 1×10^{-3} M BRIJ; (*c*) 50/50 water/ethanol solution.



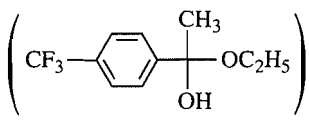
ter disappears in aqueous solution because of the low solubility of TFMA in water. Under these conditions, we observe only two strong bands (λ_{max} (K) = 221 nm, ε = 80 000 and, λ_{max} (B) = 284 nm, ε = 1300) (Fig. 6*b*).

Information on hydration of TFMA can be obtained both from the decrease of the carbonyl absorption band and from the shift of the strong aromatic absorption at 284 nm. Indeed, absorbance of the n–π^* transition is directly proportional to the concentration of free carbonyl compound present in the solution; however, we cannot use it because of the low intensity of the band. On the other hand, hydration of the carbonyl group suppresses delocalization, and the aromatic π–π^* absorption band at 284 nm is progressively replaced by another corresponding to the aromatic hydrocarbon absorption situated at lower wavelength. The kinetics of hydration of TFMA was therefore followed by the decrease of the absorbance at 284 nm as a function of time (Fig. 7).

In aqueous solution (pH 4), we observe that the absorbance at 284 nm decreases regularly with time (Fig. 7*a*). The presence of BRIJ 35 in the solution causes first the stabilization of absorbance with, further, a slower decrease than in water solution (Fig. 7*b*). On the contrary, in hydroalcoholic solution, we observe a rapid decrease of the absorbance (Fig. 7*c*).

Discussion

The substitution of acetophenone with the CF_3 electron- withdrawing group enhances the hydration property of the carbonyl function (5). For example, α,α,α-trifluoroacetophenone has frequently been chosen as a model compound to study hydration–dehydration and acid–base equilibria involving the geminal diol group -$C(OH)_2CF_3$ (6, 7). In the case of TFMA, the evolution of the polarographic curves (Fig. 2*b*) and of the spectrophotometric spectra (Fig. 7*a*) as a function of time in aqueous solution strongly suggests that the carbonyl group is involved in a slow hydration–dehydration equilibrium ($k_h \cong 10^{-4}$ s^{-1}, a value estimated from polarographic and UV spectroscopy data) leading to the non-reducible geminal diol form. The rate of carbonyl hydration is expected to be sensitive to electronic effects occurring in the 4-substituted phenacyl derivatives; for example, a value of $k_h \cong 10^{-6}$ s^{-1} had been calculated for the 4-methylacetophenone (18). In the presence of the neutral surfactant (BRIJ35), the ketone is solubilized in the polyoxyethylene (O-CH_2-CH_2-)$_n$ region of the micelles (19) where the hydration reaction is slightly inhibited. In ethanolic solutions, the hemiacetal is more rapidly formed than the *gem*-diol, leading to an immediate decrease of the absorption wave.



It is generally accepted that aromatic ketones are reduced according to the pH of the solution, with the formation of carbinol or pinacols in various amounts (1, 20, 21). The presence of a CF_3 group in the TFMA causes a shift of half-wave reduction potentials to less negative values ($\Delta E_{1/2} \cong 25$ mV) (4), making the study in aqueous solution easier.

In acidic medium, as previously reported by Stocker et al. (22), electrolysis at the first reduction step A_1 (E_{appl} (A_1) = −1.05 V) yields pinacols (Table 3). The ketyl radical results from the reduction of the protonated ketone (wave A_1 in Fig. 1 and in Scheme 1). It can further be involved either in a dimerization reaction leading to the pinacols (P_1) (see Scheme 1), with little preference in the steric approach (*dl*/*meso* = 0.9) (22), or in a second reduction step (A_2) at more negative potential (E_{appl} (A_2) = −1.20 V) (Fig. 1) leading to the carbinol (C_1) (see wave A_2 in Fig. 1 and in Scheme 1). In the case of acetophenone, this second wave lies in the potential range where the discharging of protons occurs in acidic medium (1). With TFMA, at a potential corresponding to wave A_2, the reduction and the dimerization reactions are in competition and the same percentage of pinacols and carbinol is obtained (Table 3). The half-wave potential of wave A_1 shifts to more negative values as the pH of the solution is increased, and merges with A_2 into a single two-electron wave at pH 5, a value of pH slightly lower than that obtained with benzaldehyde and acetophenone (21) probably due to the presence of the CF_3 group. When the electrolysis potential becomes more negative (on the plateau of wave B), the reduction process prevails as regards the

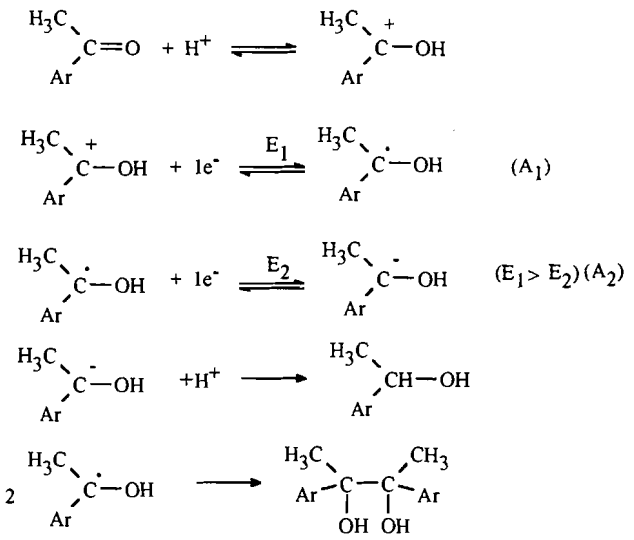
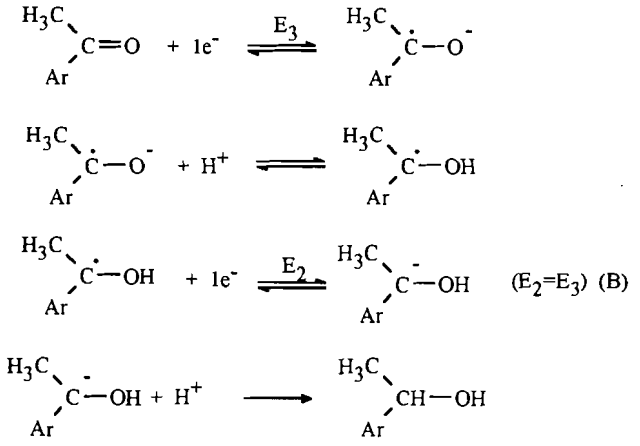
For personal use only.

Scheme 1.



Scheme 2.



dimerization, and all the molecules are reduced to form the carbinol (Table 3).

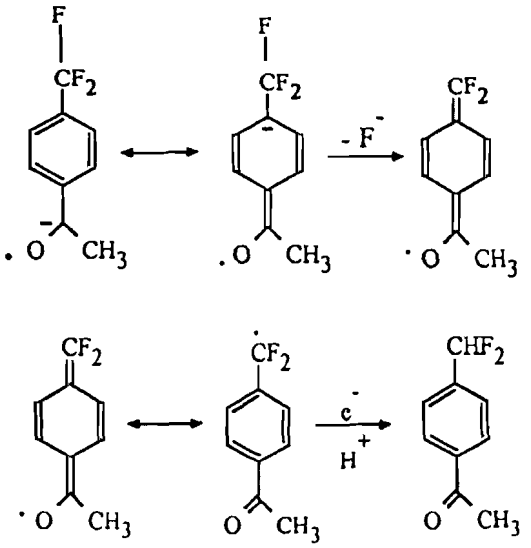
In alkaline medium, the ketone can also be reduced directly to form the anion-radical, which after protonation is reduced to form the carbinol (Scheme 2).

However, when the proton concentration decreases, the electropinacolization involving radical–radical, radical–substrate, or ion–substrate coupling (22, 23) becomes prevalent with, as a consequence, a decrease of the wave height (i_{dB}) (Fig. 1).

Contrary to the results previously published by Stocker et al. (22), we obtained a relatively high yield of pinacols after electrolysis in basic medium at a potential ($E_{appl} = -1.7$ V) corresponding to the fourth reduction step (see wave C of Fig. 1) (Table 2). The ratio *dl/meso* for diastereomeric pinacols is 2, in agreement with the value generally reported for these alkaline media (24). Moreover, under our electrolysis conditions at very negative potential, one may consider a possible C—F. bond cleavage concomitant to the ketone reduction (22). In aqueous solution, it has been reported that the successive reductive removal of the three fluorine atoms of trifluoromethyl compounds can be carried out at a single potential (−1.7 V in the case of TFMA) (8, 9, 13). For such a cleavage the presence of an activating group in the molecule is clearly necessary as demonstrated by the fact that trifluoromethylbenzene itself is non-reducible even at more cathodic potentials than −2.0 V vs. SCE (13), while for aromatic compounds bearing a sulfamyl function, a trifluoromethyl substituent is reduced to the methyl group at −1.76 V in aqueous solution (8).

The protonation of the intermediates is slower in alkaline medium, and a competition between the protonation of the radical-anion (Scheme 2) and the loss of a fluoride anion, as proposed by Coleman et al. (12) in the case of trifluoro-benzylesters, can occur (Scheme 3).

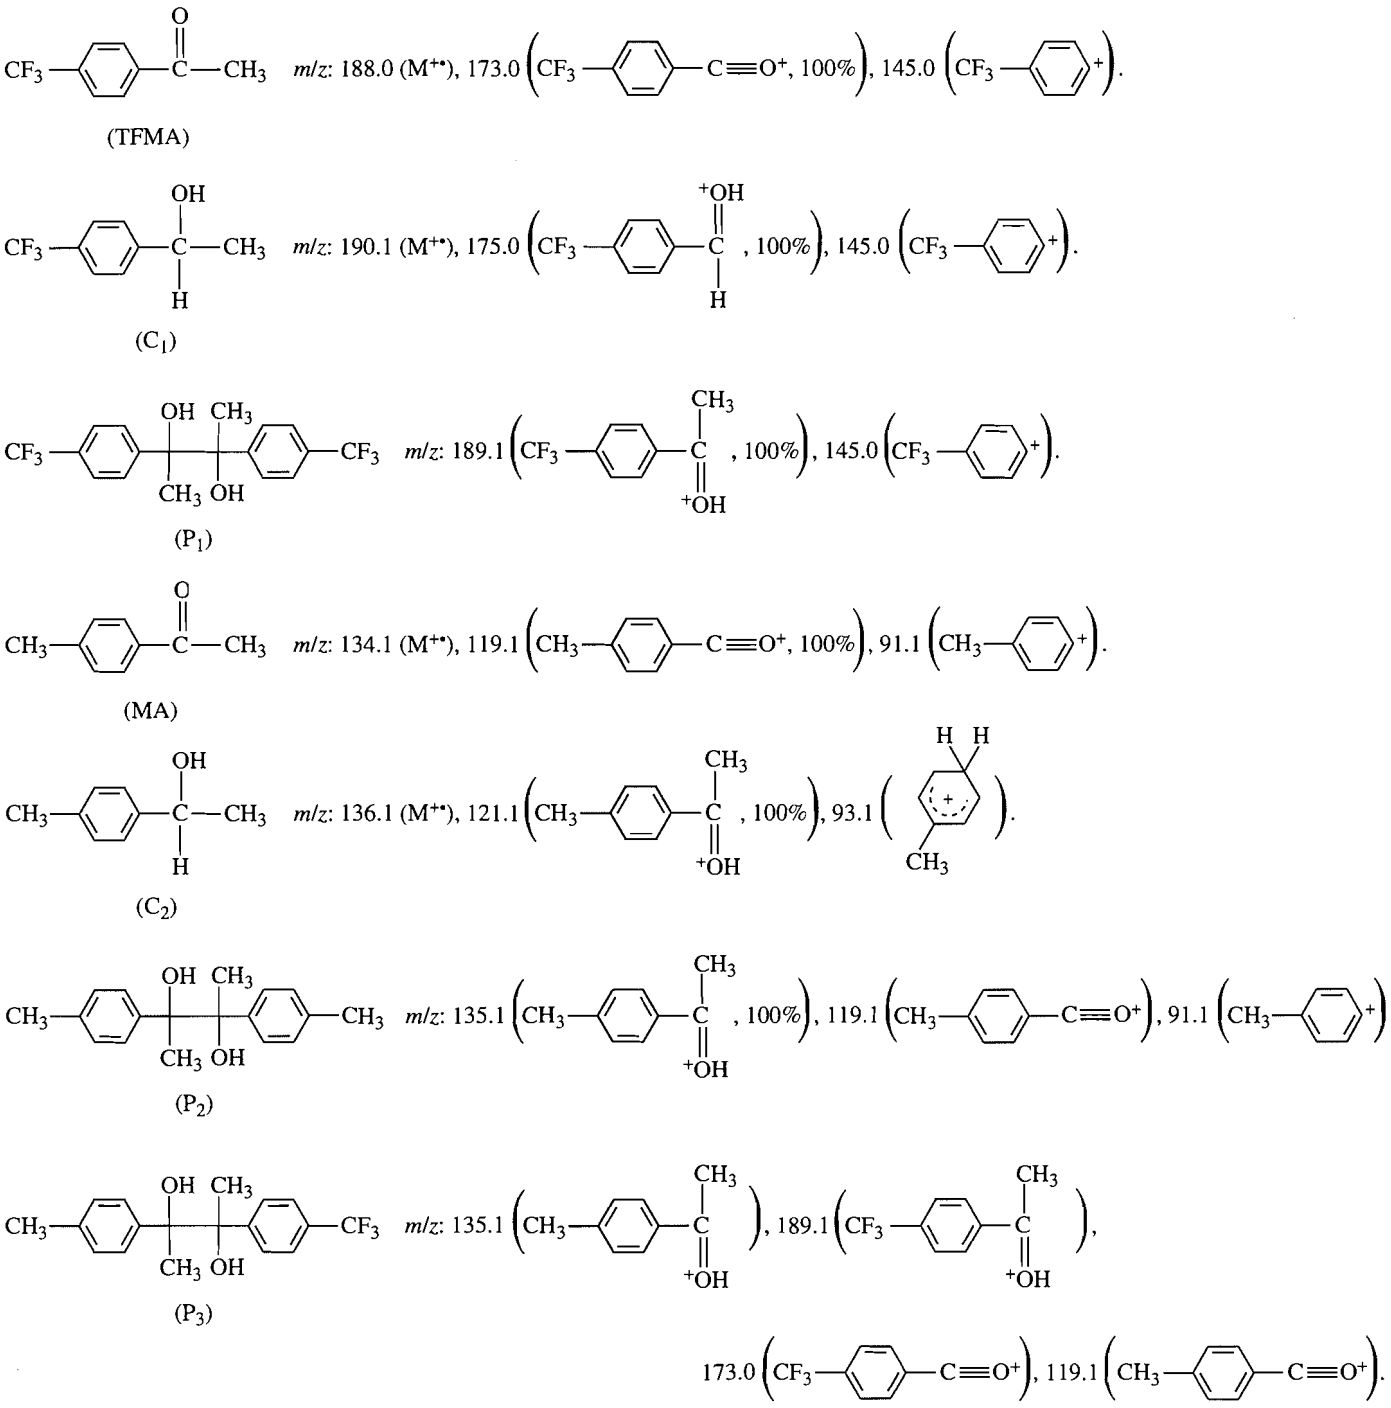
Scheme 3.



Three consecutive cleavages of fluorine bonds from the trifluoromethyl group lead to the formation of methylacetophenone (MA), which bas been found in the reduction products of TFMA at pH 10 (Table 4). This ketone is further reduced under these conditions with the formation of its carbinol (C_2) and pinacols (P_2) as reduction products, characterized in EIGC mass spectrometry and ^{1}H NMR by comparison with authentic samples.

The shape of polarograms depends on the nature of the surfactants present in the solution (Figs. 3–5), more precisely, on their micellar properties (CMC) but also on their adsorption mode at the mercury electrode (2). In the presence of nonionic surfactants such as BRIJ35, LS, and OTG at a concentration higher than their CMC, the electroreduction of TFMA occurs at roughly the same potential ($E_{1/2} \cong -1.35$ V) whatever the buffer solution. In the presence of GHU, a surfactant that does not form micelles at the concentration used (14), the polarograms have the same evolution with pH as in aqueous solutions. Moreover, tensammetric curves have shown that at the same concentration, LS appears to be more strongly adsorbed than OTG and GHU.[2] This fact can explain the small hump observed on the polarogram recorded in the presence of LS. These results strongly suggest that TFMA is solubilized in the hydrophobic core of the micelles of BRIJ35, LS, and OTG, inside which chemical reactions, such as hydration and protonation are inhibited.

[2] C. Mousty, unpublished results.



Chiral micelle systems can be used as a simple analogue to mimic the stereochemistry of enzyme reactions. However, few examples of asymmetric induction for the reduction of prochiral substrates in chiral micelles have been described. In particular, two papers report the reduction, by sodium borohydride, of phenylalkylketones in aqueous micelles of chiral surfactants such as trialkylmethylammonium bromides (25), dodecyl glucopyranoside, and dodecyl glucopyranouranate (26), giving optically active carbinols with enantioselectivities of up to 17.7% (25) and 98% (26), respectively. As a means of comparison, we have performed the electroreduction of TFMA in chiral micelles of OTG and LS. Contrary to the latter results, we do not observe any significant chiral induction. Indeed, hydrophobic interactions play an important role in the enantioselectivity. The bonding of prochiral ketone with chiral micelles is a dynamic process that would certainly be improved by the presence of a long alkyl chain in the ketone molecules. Such investigations are in progress in our group.

Experimental

Aqueous solutions ($2 \leq pH \leq 10$) were prepared with McIlvaine (acidic medium) and Britton Robinson (basic medium) buffer solutions. The ionic strength was adjusted to 0.5 M by

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12

adding KCl. 4-Trifluoromethylacetophenone (TFMA) (Aldrich), 4-methylacetophenone (MA) (Janssen), polyoxyethylene dodecyl ether (BRIJ35) (Fluka), and 1-*S*-octyl β-D-thioglucopyranoside (OTG) (Aldrich) were used as received. The β-*N*-glucosyl-*N*-heptylurea (GHU) and the 2-*O*-lauroyl saccharose (LS) were provided by Professor Plusquellec (14, 15). The critical micellar concentrations (CMC) of these nonionic surfactants are given in Table 1.

Polarographic current voltage curves were recorded by means of a Tacussel PRG5 polarograph. The drop time was kept constant at 1 s with an electromagnetic hammer. The outflow of mercury was 0.64 mg s^{-1} for a mercury height of 50 cm. During all electrochemical measurements, we used a saturated calomel electrode (SCE) as reference; the cell was thermostated at 30°C and maintained under an inert atmosphere by argon previously saturated by flowing through the TFMA solution. The TFMA solutions were obtained by diluting a concentrated DMF stock solution (0.1 M) into the aqueous electrolytic medium.

Preparative controlled-potential electrolyses were carried out in a three-compartment glass cell joined by two sintered glasses. The cathodic compartment contained 100 mL of buffer solution, 400 mg of TFMA, a reference electrode, an Ar tube, and a mercury pool of 13 cm^2 as the working electrode. The anode was a glassy carbon electrode. When the electrolyses were stopped, the solutions were neutralized and extracted twice with 50 mL ethyl ether.

The reduction products were column chromatographed on silica gel (eluent cyclohexane/ethyl acetate 7/3) and finally analyzed by gas chromatography (GC) on a DB1 or a LIPODEX-E column and by NMR spectroscopy (^{1}H, 400 MHz, DMSO-d_6) (Table 2). Authentic samples of the carbinols were obtained by chemical reduction of TFMA with sodium borohydride.

Methylacetophenone (MA) was used as a reference product, its corresponding carbinol was obtained by chemical reduction with $NaBH_4$, and the pinacols were synthesized by a controlled-potential electrolysis at pH 10, $E_{appl} = -1.70$ V. NMR data for these compounds are given in Table 2.

Mass spectra (EIGC) were obtained from the "Service Central d'analyse" of CNRS (see preceding page).

UV absorption spectra were recorded with a Uvikon 941 spectrophotometer using a matched pair of 1 cm fused quartz cells.

Acknowledgment

We acknowledge the contribution of Professor Plusquellec, Laboratoire de Chimie organique et des substances naturelles (URA 1467) from the École Nationale Supérieure de Chimie of Rennes, for supplying the LS and GHU.

On the relationship between the order parameter $\langle P_2(\cos\theta)\rangle$ and the shape of orientation distributions

Claude-Paul Lafrance, Anne Nabet, Robert E. Prud'homme, and Michel Pézolet

Abstract: The molecular orientation is generally expressed by an "order parameter," $\langle P_2\rangle$, which depends on both the angular position and the shape of the orientation distribution. This parameter is an average made over all orientations of the structural units studied in a sample and, consequently, a given $\langle P_2\rangle$ value can correspond to different orientation distributions. In this article, model distributions are used to show the relationship between the shape, width, and angular position of the center of the orientation distribution on the $\langle P_2\rangle$ coefficient, for the case where the distribution of the molecular chains exhibits cylindrical symmetry with respect to the reference direction. A significant difference is observed between the order parameters calculated for distributions of Gaussian and Lorentzian shapes with similar width at half-height. The variation of the $\langle P_2\rangle$ coefficient as a function of the width at half-height, $W_{1/2}$, and of the position of the center of the distribution, θ_C, is analyzed. Figures showing the range of $W_{1/2}$–θ_C coordinates that can correspond to a given $\langle P_2\rangle$ value are presented. As an example, the influence on the order parameter of the disorder between the different domains of phospholipid samples (mosaic spread) and of the conformational disorder in the acyl chains of these molecules is also studied. This example permits the evaluation of the magnitude of the errors that can be introduced in calculations of the tilt angle of the molecular chains in the case of distributions of finite widths or of bimodal character.

Key words: orientation, orientation function, phospholipid bilayers, conformational disorder, mosaic spread.

Résumé : L'orientation moléculaire est généralement exprimée par un paramètre d'ordre, $\langle P_2\rangle$, dont la valeur dépend à la fois de la position angulaire et de la forme de la distribution d'orientation. Ce paramètre d'ordre constitue une moyenne faite sur toutes les orientations des unités structurales étudiées dans un échantillon et, en conséquence, une valeur de $\langle P_2\rangle$ donnée peut correspondre à différentes distributions d'orientation. Des distributions modèles sont utilisées afin de montrer l'influence de la forme, de la largeur et de la position angulaire du centre de la distribution d'orientation sur le coefficient $\langle P_2\rangle$, pour le cas où les chaînes moléculaires possèdent une symétrie cylindrique par rapport à la direction de référence. Une différence significative est observée entre les paramètres d'ordre calculés pour des distributions de formes Gaussienne et Lorentzienne de même largeur à mi-hauteur. La variation du coefficient $\langle P_2\rangle$ en fonction de la largeur à mi-hauteur, $W_{1/2}$, et de la position du centre de la distribution, θ_C, est analysée. Des figures montrant la plage de coordonnées $W_{1/2}$–θ_C pouvant correspondre à une valeur de paramètre d'ordre donnée sont présentées. À titre d'exemple, la variation du coefficient $\langle P_2\rangle$ en fonction du désordre entre les différents domaines d'échantillons de phospholipides et en fonction du désordre conformationnel dans les chaînes acyles de ces molécules est également étudiée. Cet exemple permet d'évaluer l'importance des erreurs pouvant être introduites dans le calcul de l'angle d'inclinaison des chaînes moléculaires dans le cas de distributions de largeur finie ou de caractère bimodal.

Mots clés : orientation, fonction d'orientation, bicouches de phospholipides, désordre conformationnel, désordre entre les différents domaines.

Introduction

The occurrence of orientation at the molecular level has a considerable importance in macromolecular science, since it gives directional properties to materials. In the last two decades, numerous publications have dealt with the characterization of orientation in oriented polymer films and fibers (1–5), in biological membranes (6, 7), and in liquid crystals (3). Measurements of molecular orientation are now commonly conducted in various fields of research, yet the literature gives many examples where conclusions drawn from such measurements seem to overlook limitations related either to the characterization method itself or to the mathematical significance of the order parameter calculated from the experiment.

Recently, Myers and Cooper (8) analyzed some of the errors that can arise in the determination of orientation of polymers by infrared spectroscopy. More specifically, the

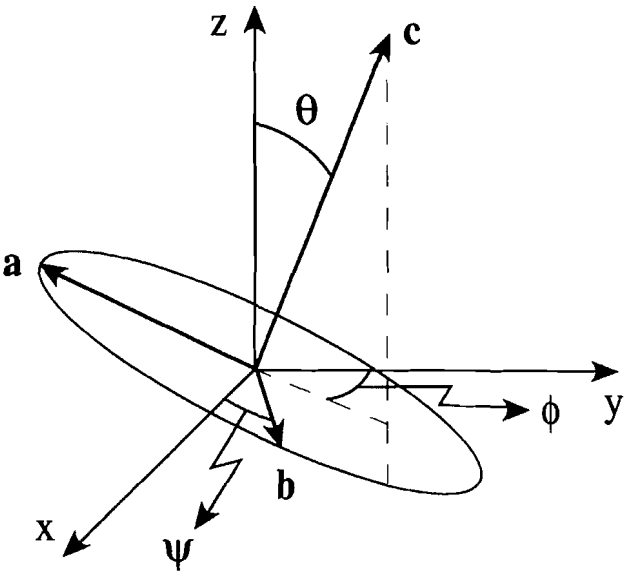
problems caused by the imperfect polarizer behavior, by the improper determination of the chain conformation, and by the assumption of an inaccurate value of the angle between the chain axis and the transition dipole moment were discussed. Furthermore, Ahn and Franses (9) mentioned the possible influence of the width of the orientation distribution on the tilt angle calculated from infrared spectroscopy measurements of Langmuir–Blodgett films. Following this line, the present article focusses on the interpretation of the order parameter, taking into account the fact that orientation distributions at the molecular level are neither necessarily very narrow nor can always be considered as of unimodal character.

Generally, the molecular orientation is expressed by an "order parameter" or "orientation function," $\langle P_2(\cos\theta)\rangle$, or $\langle P_2\rangle$, which is the second-order coefficient of a series expansion of the orientation distribution (1–5). Although all the techniques generally used to study the molecular orientation allow the calculation of the $\langle P_2\rangle$ coefficient, wide-angle X-ray diffraction (WAXD) and infrared spectroscopy (IR) are often preferred over other characterization methods. The main advantage of X-ray diffraction is that the orientation distribution of different crystal planes can be measured directly, giving the width, the shape, and the position of the maximum of the distribution. The orientation of the crystal phase is then completely defined, and all the $\langle P_n\rangle$ coefficients of the series expansion can be determined (1, 10–12). On the other hand, infrared spectroscopy is a simple, fast, and reliable method that can be used to calculate the $\langle P_2\rangle$ coefficient for amorphous or crystalline samples, in either solid, gel, or liquid crystalline phases (4, 6).

The $\langle P_2\rangle$ coefficient depends not only on the angular position of the orientation distribution but also on its shape and width, since it is an average made over all orientations in the sample. Thus, the $\langle P_2\rangle$ value can be used, for example, to discuss the evolution of orientation in a series of polymer samples deformed to different draw ratios. However, the knowledge of this sole coefficient does not allow the unambiguous determination of the inclination of structural units in a sample. The objective of this paper is, first, to emphasize the fact that the $\langle P_2\rangle$ coefficient is an average and to give guidelines on the interpretation of this order parameter. The relationship between the $\langle P_2\rangle$ coefficient and the shape, width, and angular position of the orientation distribution will be discussed. A comparison with the calculation of $\langle P_n\rangle$ coefficients from X-ray diffraction will be made, using model distributions, since WAXD allows the direct measurement of the orientation distribution, and thus offers a practical method to visualize the effect of the shape and position of the distribution on the $\langle P_2\rangle$ value. These simulations will demonstrate that the discrimination between different types of orientation distribution, all having the same $\langle P_2\rangle$ value, can be made when $\langle P_n\rangle$ coefficients of higher orders are known. Yet it will be shown that, even in this case, the possibility of differentiating between certain orientation distributions depends on the precision of the $\langle P_n\rangle$ values obtained from the experiment, and it can still be difficult if only a few coefficients are known ($n \leq 8$).

The final section of this paper presents an evaluation of the errors that can be introduced in angular calculations by assuming a single and narrow orientation distribution model when the actual distribution can exhibit a finite width or possess a bimodal character. For this purpose, the influence on the $\langle P_2\rangle$ coefficient of the disorder that can be present in phospholipid samples will be analyzed. Phospholipids are the main constituents of biological membranes and, since the properties of membranes depend on the molecular orientation of their constituents, several studies have appeared in the literature dealing with the orientation of the acyl chains of these molecular assemblies. This system has been chosen to illustrate the influence of the shape of orientation distribution on the order parameter because different types of disorder occur in phospholipid samples. The "mosaic spread," i.e., the disorientation between different domains of phospholipid samples deposited on a support, gives an example of the broadening of an orientation distribution by the superimposition of a second distribution. Besides, the occurrence of conformational disorder, which can be introduced either thermally or by the interaction of phospholipids with peptides and proteins, can be used as a model to illustrate the discrepancy between interpretations of orientation measurements arising when the distribution is of bimodal character rather than unimodal. Figures will be shown to evaluate the influence of both types of disorder in molecular orientation studies.

Fig. 1. The Euler angles θ, ϕ, and ψ defining the orientation of a set of molecular coordinates **a**, **b**, **c** with respect to a macroscopic reference system x, y, z. θ and ϕ describe the orientation in space of the molecular chain axis **c**, while ψ refers to the rotation of the **a** and **b** molecular axes around **c**.



Theory

Characterization of the molecular orientation by a series of Legendre polynomials

The orientation in space of a set of orthogonal axes (**abc**), for example, the crystal axes of an orthorhombic unit cell, can be completely described with respect to a macroscopic reference frame (xyz) by using the Euler angles θ, ϕ, and ψ (1), as shown in Fig. 1. Defining **c** as the molecular chain axis, the angle θ describes the inclination of the chain with respect to z, ϕ describes the position of its projection in the xy plane, while the angle ψ describes the rotation of the unit cell around its **c** axis. The orientation distribution of structural units in polymer

or biological samples can be characterized by using a variety of mathematical functions, the aim of the procedure being to associate one or several index values to the sample investigated. By reference to the boundaries of the function, these index values are then indicative of the degree and of the type of orientation distribution that is present. With respect to the coordinate system defined in Fig. 1, the orientation distribution of the structural units, $N(\theta, \phi, \psi)$, can be mathematically expressed as a series expansion in spherical harmonics (13–16). However, this mathematical treatment can often be simplified by the presence of transverse isotropy of the distribution of the molecular chain axis in the samples, i.e., isotropy in the *xy* plane. The problem then reduces to the description of the orientation of a unique axis, **c**, with respect to a reference direction, *z*. For distributions of such cylindrical symmetry, the distribution $N(\theta)$ can be characterized by using a series of Legendre polynomials, $P_n(\cos\theta)$ (1, 2, 10, 17):

$$[1] \quad N(\theta) = \sum_{n=0}^{\infty} (n + 1/2)\langle P_n\rangle P_n(\cos\theta)$$

where the normalization term $(n + \frac{1}{2})$ ensures the convergence of the series, while the coefficients $\langle P_n\rangle$ are the values that are determined experimentally. All the odd-order terms in eq. [1] are equal to zero because of the symmetry with respect to the mirror plane perpendicular to the *z* axis. The first even-order Legendre polynomials are given by:

$$P_0(\cos\theta) = 1$$

$$[2] \quad P_2(\cos\theta) = \tfrac{1}{2}(3\cos^2\theta - 1)$$

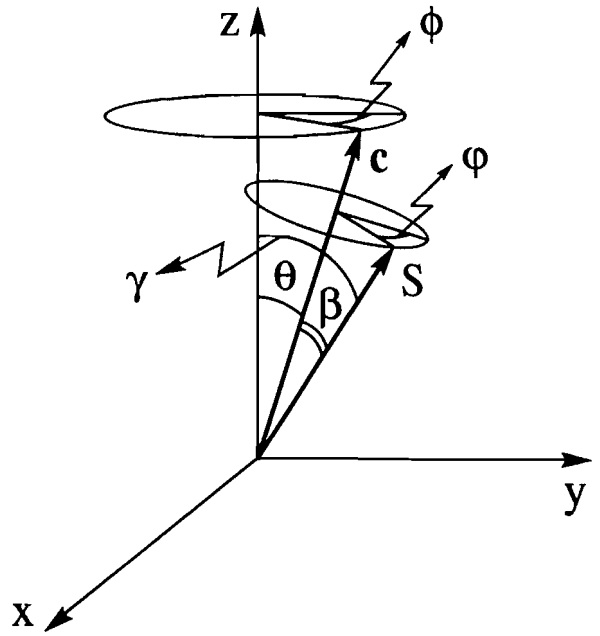
$$P_4(\cos\theta) = \tfrac{1}{8}(35\cos^4\theta - 30\cos^2\theta + 3)$$

The $\langle P_n\rangle$ coefficients of eq. [1] for a given structural unit are obtained by averaging the orientation of all units in the sample. For an isotropic sample, all coefficients are equal to zero, except $\langle P_0\rangle$, which is always equal to unity. For an oriented sample exhibiting an infinitely narrow distribution centered at an angle θ_C, the $\langle P_n\rangle$ coefficients take the value of the corresponding polynomial at this angle. Since all polynomials have their maximum value of unity at $\theta = 0°$, $\langle P_2\rangle = 1$ for structural units oriented perfectly parallel to the reference direction, while $\langle P_2\rangle = 0$ and -0.5 for a perfect orientation at $\theta = 54.7°$ and 90°, respectively.

All characterization methods used for molecular orientation studies allow the calculation of the $\langle P_2\rangle$ coefficient (1, 2). Raman spectroscopy and polarized fluorescence measurements also give the $\langle P_4\rangle$ value, and coefficients up to $\langle P_8\rangle$ can be obtained by NMR spectroscopy. Only wide-angle X-ray diffraction allows the calculation of all $\langle P_n\rangle$ coefficients, because the shape of the orientation distribution of crystal planes is measured directly by this technique.

For a system composed of several nested orientation distributions, each of these showing cylindrical symmetry, for example, *i* about the symmetry axis *z*, *j* about *i*, and *k* about *j*, the Legendre addition theorem can be used to calculate the relation between the global $\langle P_n\rangle$ coefficients obtained from the measurement and the coefficients characterizing each distribution. If, in the above example, γ is defined as the angle between *k* and the reference direction *z*, this theorem states that

Fig. 2. Geometric representation for the study of the orientation of a molecular axis **c** inclined at θ from the reference direction *z*, using measurements made for a structural unit **S** located at β from **c** and at γ from *z*. The distributions of **c** about *z* and of **S** about **c** both exhibit cylindrical symmetry.



the global $\langle P_n\rangle_\gamma$ measured for this system is equal to the product of the $\langle P_n\rangle$ values characterizing each of the distributions:

$$[3] \quad \langle P_n\rangle_\gamma \equiv \langle P_n\rangle_{kz} = \langle P_n\rangle_{kj}\langle P_n\rangle_{ji}\langle P_n\rangle_{iz}$$

This property of the Legendre polynomials can be used to isolate the contributions from nested orientation distributions to the global $\langle P_2\rangle_\gamma$ coefficient calculated from the experiment. Let us consider the determination of the $\langle P_2\rangle_{cz}$ coefficient, which characterizes the orientation of the molecular chain **c** with respect to the reference direction *z*, by taking measurements relative to a structural unit **S**, which is inclined at an angle β from **c**, as is depicted in Fig. 2. The structural units studied could be, for example, the normal to a set of crystal planes studied by WAXD, or the dipole transition moment of a vibration studied by infrared spectroscopy. Since both the distributions of **S** with respect to **c** and of **c** with respect to *z* exhibit cylindrical symmetry, then that of **S** with respect to *z* also possesses this symmetry. Using eq. [3], the measured $\langle P_2\rangle_\gamma$ or $\langle P_2\rangle_{Sz}$ coefficient characterizing the orientation of the units **S** inclined at the angle γ with respect to *z* is related to the $\langle P_2\rangle_{cz}$ coefficient by:

$$[4] \quad \langle P_2\rangle_\gamma \equiv \langle P_2\rangle_{Sz} = \langle P_2\rangle_{Sc}\langle P_2\rangle_{cz}$$

Since the angle β is generally considered as fixed, i.e., the orientation distribution of **S** about **c** is infinitely narrow, then $\langle P_2\rangle_{Sc} = P_2(\cos\beta)$, and the $\langle P_2\rangle_{cz}$ is calculated by the equation:

$$[5] \quad \langle P_2\rangle_{cz} = \frac{\langle P_2\rangle_{Sz}}{P_2(\cos\beta)}$$

Discussion

Relationship between the $\langle P_2 \rangle$ coefficient and the orientation distribution

The relationship between the $\langle P_2 \rangle$ coefficient and the shape and angular position of the orientation distribution can be illustrated through the calculation of the $\langle P_n \rangle$ coefficients from the intensity distribution measured by wide-angle X-ray diffraction, $I(\theta)$. Considering Fig. 2, it can be seen that the fraction of chains **c** oriented at any angle θ is proportional to the circumference of the base of the cone described by the rotation of **c** about *z*, i.e., it is proportional to $N(\theta) \sin \theta$. For a given set of crystal planes, the diffracted intensity measured at an angle θ, $I(\theta)$, is proportional to the number of planes inclined at this angle, and the $\langle P_n \rangle$ coefficients are thus given by (1, 10, 17):

$$[6] \quad \langle P_n \rangle = \frac{\int_0^{\pi/2} I(\theta) \sin \theta \, P_n(\cos \theta) \, d\theta}{\int_0^{\pi/2} I(\theta) \sin \theta \, d\theta}$$

The model orientation distributions $I(\theta)$ used here are obtained by a 50% Gaussian – 50% Lorentzian sum, the functions being defined by:

$$[7] \quad \text{Gaussian: } I_G(\theta) = I_C \exp[-\ln 2((\theta - \theta_C)/\omega_{1/2})^2]$$

$$\text{Lorentzian: } I_L(\theta) = I_C[1 + (\sqrt{2} - 1)((\theta - \theta_C)/\omega_{1/2})^2]^{-2}$$

where I_C, θ_C, and $\omega_{1/2}$ represent, respectively, the maximum intensity, the center, and the half-width at half-height of the distribution. For the Lorentz-type function, the expression in the square brackets is raised to a –2 power instead of –1 for a classical Lorentzian, which causes a faster decrease of the tail of the distribution. The function then becomes equivalent to a Pearson VII function with an adjustable parameter $m = 2$ (11, 12). This shape of Lorentzian function is used here because, for highly oriented polymers, the orientation distribution of the crystal planes measured by wide-angle X-ray diffraction exhibits a mixed Gaussian–Lorentzian character, which is well approximated by a 50%G–50%L sum of the functions given in eq. [7] (10–12). Moreover, as will be discussed further, the analysis of data from the literature indicates that the 50%G–50%L sum also gives a good fit of the shape of the mosaic spread in supported phospholipid samples.

Table 1 gives $\langle P_2 \rangle$ values calculated using a Gaussian, a Lorentzian, and a sum of 50% Gaussian – 50% Lorentzian functions, for distributions centered at $\theta_C = 0°$ with full-widths at half-height ($W_{1/2} = 2\omega_{1/2}$) between 5° and 20°. It is observed that the shape of the orientation distribution has a considerable influence on the order parameter. For example, the $\langle P_2 \rangle$ coefficient calculated for the Lorentzian and the Gaussian–Lorentzian sum shows a significant deviation from unity when $W_{1/2} = 10°$, whereas that obtained for the Gaussian function is still close to the value for perfect parallel orientation. It has been assumed in different studies that the shape of orientation distributions can be well approximated by a Gaussian function (9, 18, 19). However, the exponential form of this type of function produces a rapid decrease of the tail of the curves, and mathematical simulations made using a Gaussian or another function of exponential form generally fall below the experimental distributions in the low-density region of the curves (10, 18, 20, 21). Comparisons made between orientation distributions measured by X-ray diffraction and mathematical simulations have shown that, for oriented polymers, a function of mixed Gaussian and Lorentzian character (Pearson VII function) gives a much better fit than the Gaussian shape (10–12, 21).

Table 1. $\langle P_2 \rangle$ coefficient calculated for orientation distributions generated using the Gaussian and Lorentzian functions defined in eq. [7] and a 50%–50% sum of these functions for different values of the full-width at half-height of the distribution, $W_{1/2}$ (in degrees).

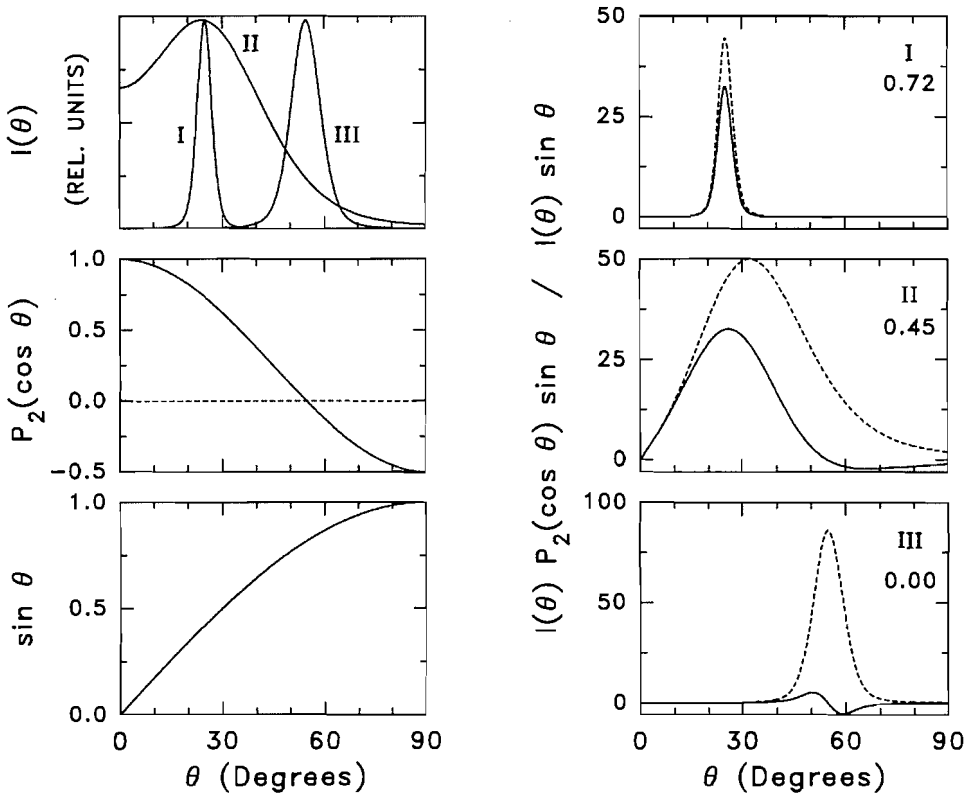
$W_{1/2}$	Gauss	50% G + 50% L	Lorentz
5	1.00	0.98	0.97
10	0.98	0.94	0.91
15	0.96	0.89	0.85
20	0.94	0.85	0.79

Figure 3 illustrates the calculation of the $\langle P_2 \rangle$ coefficient for three different orientation distributions defined by a 50% Gaussian – 50% Lorentzian sum. The distribution curves, $I(\theta)$, are shown on the left-hand side of the figure, together with the curves showing the variation as a function of θ of the second-order Legendre polynomial $P_2(\cos \theta)$ and of the sine function. Distributions I and II are centered at $\theta_C = 25°$, with a full-width at half-height of 5° and 40°, respectively, while distribution III has its maximum at 54.7°, with $W_{1/2} = 10°$. The expressions evaluated in the numerator and denominator integrals of eq. [6] are plotted in the three graphs on the right-hand side of Fig. 3 for the different orientation distributions. The $\langle P_2 \rangle$ value is calculated from the ratio of the area under the full curve divided by that under the dotted curve. For the narrow distribution I, the shape of these two curves is identical, and the value of the $\langle P_2 \rangle$ coefficient, 0.72, is close to the value of the $P_2(\cos \theta)$ function at $\theta = 25°$, which is equal to 0.732. Distribution II multiplies the Legendre polynomial curve over a broader range, showing significant intensity up to angles where $P_2(\cos \theta) < 0$. The full curve corresponding to the numerator of eq. [6] thus takes negative values at $\theta > 54.7°$. Moreover, the dotted curve relative to the normalization term $I(\theta) \sin \theta$ defines a considerable area in comparison with the full curve, and is shifted towards the high angles because the sine function increases with θ. These two factors give a much lower $\langle P_2 \rangle$ value of 0.45 for distribution II as compared to that obtained for the intensity distribution I, even if both exhibit their maximum at $\theta_C = 25°$.

Distribution III is centered at the angle where the $P_2(\cos \theta)$ polynomial is equal to zero. Therefore, the numerator of eq. [6] gives both positive and negative areas in the corresponding graph of the right-hand side of Fig. 3 and the $\langle P_2 \rangle$ coefficient is negligible, even if the $I(\theta)$ curve exhibits a considerable orientation. Thus, an orientation measurement giving $\langle P_2 \rangle = 0$ can be interpreted either as an indication of an ordered system centered around $\theta = 54.7°$, or as a completely isotropic system.

A given $\langle P_2 \rangle$ value can correspond either to a narrow distribution centered at the angle θ_{narrow} where the Legendre polynomial is equal to the calculated coefficient, or to a broad distribution centered at an angle between θ_{narrow} and 0° (positive $\langle P_2 \rangle$ values) or between θ_{narrow} and 90° (negative $\langle P_2 \rangle$

Fig. 3. Calculation of the $\langle P_2 \rangle$ coefficient from eq. [6] for three different model intensity distributions $I(\theta)$. The $\langle P_2 \rangle$ values for distributions I, II, and III are given in the corresponding graphs of the right-hand side of the figure, showing the curves for $[I(\theta)\ P_2(\cos\theta)\ \sin\theta]$ (solid line) and $[I(\theta)\ \sin\theta]$ (dotted line).



values). This is illustrated in Fig. 4, which presents different orientation distributions that were constructed using a 50% Gaussian – 50% Lorentzian sum, or the addition of two such functions. Despite the obvious differences in the position and in the width of the peaks, all distributions give the same $\langle P_2 \rangle$ coefficient. The first distribution is centered at $\theta_C = 24°$ and its $\langle P_2 \rangle$ coefficient takes the value of the polynomial at this angle, 0.750, since it is sufficiently narrow ($W_{1/2} = 2.5°$). The second and third distributions are broader than the first one and are centered at angles $\theta_{narrow} < 24°$. The two distributions at the bottom of the figure show that it is not possible to determine whether this order parameter corresponds to a unimodal or a bimodal distribution. To obtain this information, it is necessary to calculate higher order $\langle P_n \rangle$ coefficients, using X-ray diffraction, NMR, Raman, or polarized fluorescence spectroscopy. The knowledge of the $\langle P_2 \rangle$ and $\langle P_4 \rangle$ coefficients, with sufficient accuracy, can rule out some types of orientation distribution, as it is seen by comparing the $\langle P_4 \rangle$ values in Fig. 4, but the unambiguous discrimination between some distributions requires still higher order coefficients. Since the precision on $\langle P_n \rangle$ coefficients obtained in orientation studies is at best 0.01 (for example, by comparing results from different crystal planes in WAXD (10–12, 22) or from different IR bands), the distinction between the second, fourth, and fifth distributions displayed in Fig. 4 is not possible from their $\langle P_4 \rangle$ values, but could be made on the basis of the $\langle P_8 \rangle$ coefficients.

The interpretation of the type and degree of orientation cannot be made on the sole basis of the $\langle P_2 \rangle$ value unless the coefficient is close to the boundaries of the $P_2(\cos\theta)$ polynomial. $\langle P_2 \rangle$ coefficients close to 1.0 or to −0.5 clearly indicate that the sample studied is highly oriented, with its chains oriented nearly parallel or perpendicular to the reference direction, respectively. However, a $\langle P_2 \rangle$ value close to zero can be obtained for an isotropic sample, or for a highly oriented sample where the molecular chains are oriented around $\theta = 54.7°$, or for a sample possessing a broad orientation distribution at an intermediate angle.

Figure 5*a* shows a three-dimensional representation of the variation of the $\langle P_2 \rangle$ coefficient as a function of the width at half-height $W_{1/2}$ and of the position θ_C of a mixed Gaussian – Lorentzian orientation distribution. As stated above, for a very narrow distribution, the $\langle P_2 \rangle$ coefficient is equal to the value of the second-order Legendre polynomial (eq. [2]) at the angle corresponding to the center of the distribution. Thus, for $W_{1/2} = 0°$, the $P_2(\cos\theta)$ curve is obtained, with a maximum of unity at $\theta = 0°$ and a minimum of −0.50 at $\theta = 90°$. The broadening of the orientation distribution causes a decrease of the absolute value of the $\langle P_2 \rangle$ coefficient, except for distributions centered around $\theta = 54.7°$, which are always characterized by a $\langle P_2 \rangle$ value near zero. Figure 5b gives iso-$\langle P_2 \rangle$ curves obtained by joining the θ_C and $W_{1/2}$ coordinates corresponding to identical $\langle P_2 \rangle$ values, i.e., these curves represent the intersection between horizontal planes and the three-dimensional surface of Fig. 5*a*. It can be observed that the $\langle P_2 \rangle$ values near

Fig. 4. Values of the $\langle P_4 \rangle$ and $\langle P_8 \rangle$ coefficients, for different orientation distributions, all having the same order parameter $\langle P_2 \rangle = 0.750$.

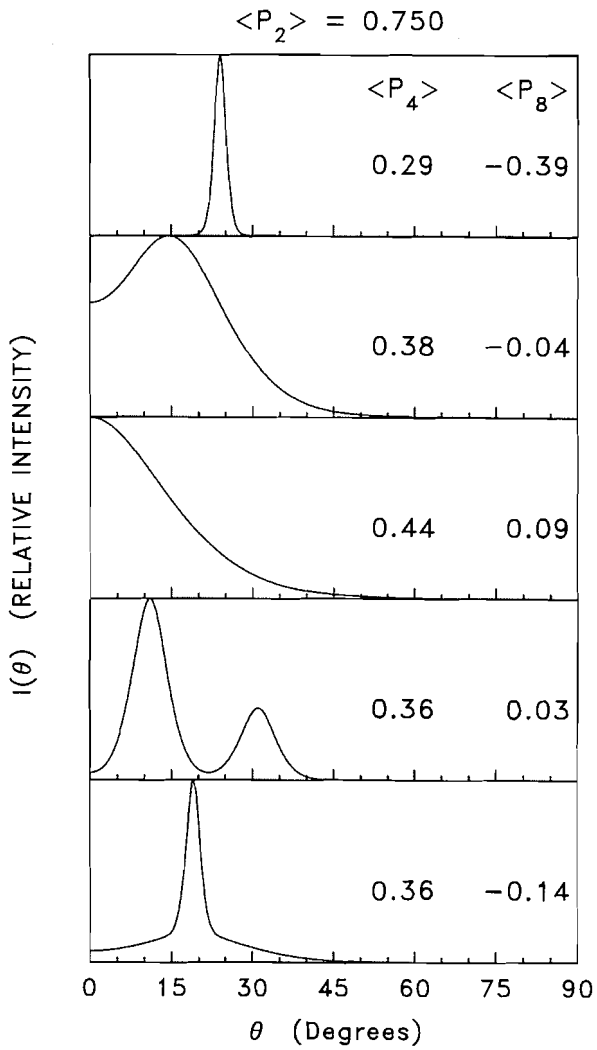

Fig. 5. (*a*) Three-dimensional representation of the variation of the $\langle P_2 \rangle$ coefficient as a function of the full-width at half-height ($W_{1/2}$) and of the position of the maximum (θ_C) of the orientation distribution. (*b*) Iso-$\langle P_2 \rangle$ curves for different values of the coefficient as a function of $W_{1/2}$ and θ_C.

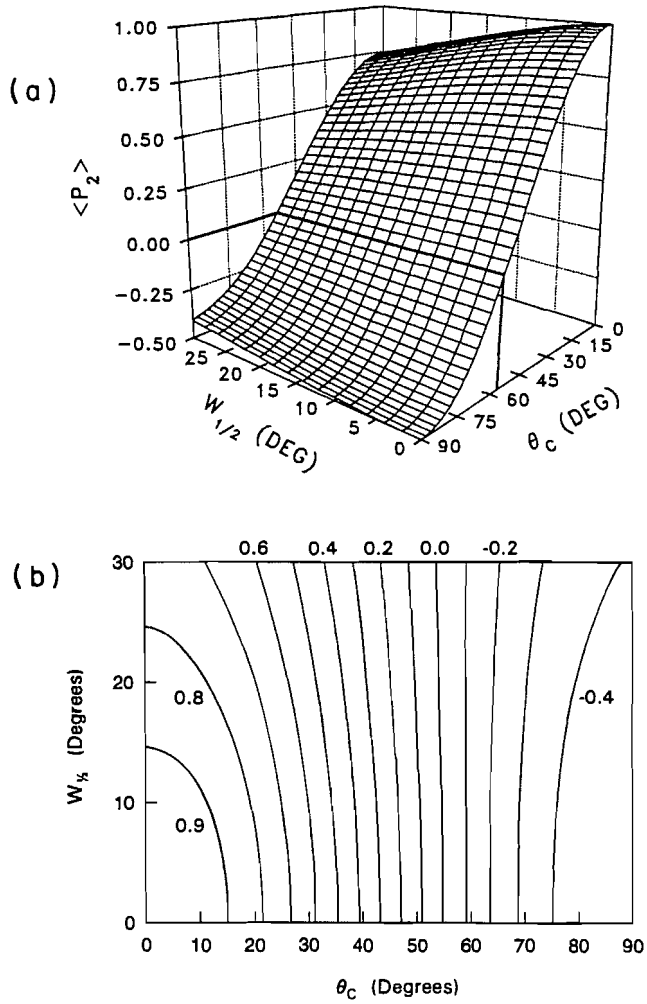


the extremum of the function vary significantly with the width and position of the center of the distribution. For example, a $\langle P_2 \rangle$ coefficient equal to 0.90 can be obtained for a narrow distribution located at $\theta_C = 15°$ as well as for a distribution with $W_{½} = 14.5°$ and centered at $\theta_C = 0°$. In comparison, for the $\langle P_2 \rangle = 0.50$ curve, the θ_C value varies only by 8°, from approximately 35° to 27°, when the width of the distribution increases from nearly zero to $W_{½} = 30°$. For unimodal distributions, Fig. 5*b* can be used to determine the range of $\theta_C - W_{1/2}$ coordinates corresponding to a given value of the $\langle P_2 \rangle$ coefficient.

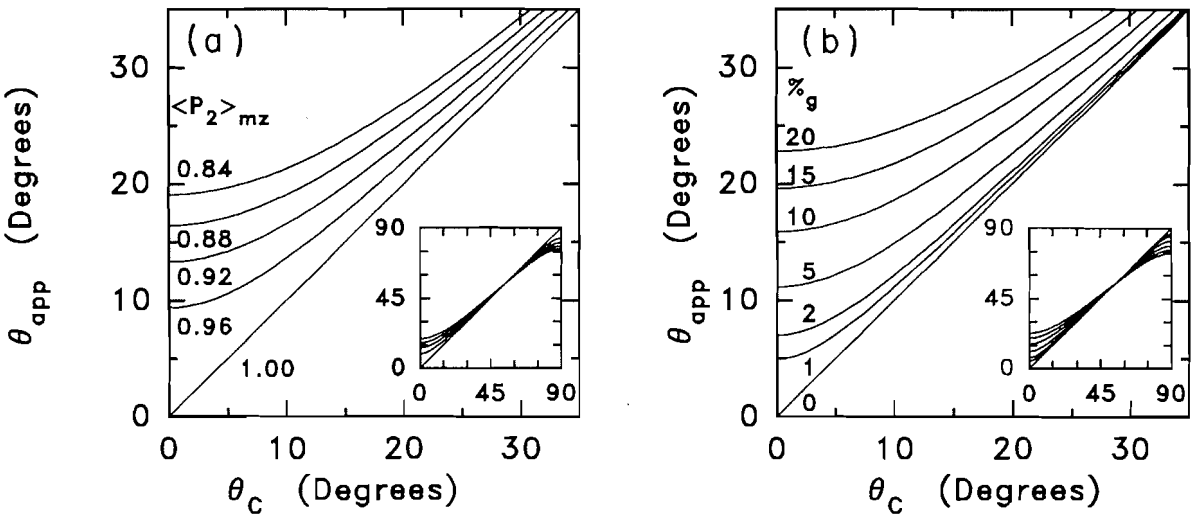
Calculation of angles from the $\langle P_2 \rangle$ coefficient

In many instances, the $\langle P_2 \rangle$ coefficient is used as an orientation index, which indicates the evolution of the molecular orientation in a series of samples. For example, the $\langle P_2 \rangle_c$ value is frequently plotted as a function of the draw ratio, λ, in order to study the variation of the molecular chain orientation occurring during the deformation of polymers. However, the $\langle P_2 \rangle$ coefficient is also sometimes used to calculate the angle between a given structural unit in the sample and the reference direction. For example, infrared measurements of the $\langle P_2 \rangle_\gamma$ coefficient for two different bands can be used to determine the angle β between the dipole transition moment and the molecular chain for the second vibration, provided that this angle is known for the first one and that the orientation distribution of the chains and of both vibrations exhibit cylindrical symmetry. In other cases, the $\langle P_2 \rangle_\gamma$ coefficient is also used to calculate the apparent tilt angle, θ_{app}, of the molecular chains with respect to the reference direction, *z*:

$$[8] \quad \theta_{app} = \arccos\left[\frac{2\langle P_2 \rangle_\gamma}{3P_2(\cos\beta)} + \frac{1}{3}\right]^{1/2}$$

However, such angular calculations are justified only in the case of very narrow orientation distributions, since the $\langle P_2 \rangle_\gamma$ coefficient depends on both the shape and the angular position of the center of the distribution, as was discussed in the preceding section. Therefore, it is important to evaluate the magnitude of the errors that can be introduced when calculations are made using eq. [8], assuming a narrow and unimodal ori-

Fig. 6. Curves describing the apparent angle θ_{app} (eq. [8]) between the phospholipid acyl chain axis and the normal to the surface of the sample as a function of the molecular chain orientation θ_C: (*a*) for different values of the mosaic spread order parameter $\langle P_2 \rangle_{mz}$; (*b*) for different fractions of methylene groups in and between *gauche* conformers x_g (in %).



entation distribution whereas the real shape of this distribution is unknown. To achieve this, it is convenient to analyze results of studies where calculations of this sort are made. Orientation studies of phospholipid bilayers by infrared spectroscopy have been chosen for this purpose, since this characterization method gives the $\langle P_2 \rangle$ coefficient only, whereas the orientation of the lipid acyl chains can be affected by different types of disorder.

Orientation measurements of phospholipid bilayers

Phospholipid molecules, which are the main constituents of biological membranes, are built of two acyl chains linked to a polar head group (6). These molecules form bilayer structures, where the carbon chains form the inner hydrophobic part of the membrane, while the polar heads are exposed to the aqueous media on both sides of the membrane. The properties of these molecular assemblies are temperature dependent, with a phase transition occurring at the so-called "melting temperature," T_m. In the gel phase ($T < T_m$), the conformation of the carbon chains is generally considered as all-*trans*, whereas in the liquid crystalline phase ($T > T_m$), *gauche* bonds are present in the acyl chains. Attenuated total reflectance (ATR) and tilted angle transmission infrared spectroscopy are frequently used to investigate the molecular orientation in phospholipid bilayers (6, 7).

The $\langle P_2 \rangle_\gamma$ coefficient measured for samples deposited on a solid substrate, as it is done in orientation studies of biological membranes by infrared spectroscopy, can be considered as resulting from three different orientation contributions. First, the angle β between the transition dipole moment and the molecular chain introduces a factor equal to $P_2(\cos \theta)$ in the calculation, assuming that the orientation of the dipole with respect to the chain can be represented by a delta function, as is done in eq. [5]. It is noteworthy that Zbinden (23) and, more recently, Myers and Cooper (8) pointed out that there can be inaccurate assumptions regarding the β values for vibrations that are frequently used in orientation studies. In cases where discrepancies are obtained when the molecular chain axis orientation is calculated from different vibrations, this factor should thus be considered. The $\langle P_2 \rangle_\gamma$ coefficient also takes into account two orientation distributions, one resulting from the inclination of the chains with respect to the normal to the surface of the membrane, and the other from the disorder of the different membrane domains on the surface of the support. This latter type of disorder is generally referred to as the mosaic spread. Using the Legendre addition theorem (eq. [3]), the $\langle P_2 \rangle_\gamma$ value measured for such samples can be written as:

$$[9] \quad \langle P_2 \rangle_\gamma = \langle P_2 \rangle_{mz} \langle P_2 \rangle_{cm} P_2(\cos \beta)$$

where the subscripts mz and cm refer to the orientation distributions of the membrane domains with respect to the support and to that of the molecular chains in the membrane, respectively.

Values of $W_{1/2}$ ranging from 5° to 15° are common for the mosaic spread of supported samples measured in studies of biological membranes (18, 24–30). However, knowing the width at half-height of the distribution is not sufficient to assess the effect of this disorder on the measurements, since the shape of the distribution is also important, as is demonstrated in Table 1. $\langle P_2 \rangle_{mz}$ values of 0.92 ± 0.02 were calculated for freeze-fractured multilayered purple membrane samples studied by electron microscopy measurements (18, 31), which showed an orientation distribution curve with $W_{1/2} \approx 12.5°$ (18). A comparison with the results presented in Table 1 indicates that the shape of such a distribution is definitely not Gaussian, and would better be described by a 50% Gaussian – 50% Lorentzian distribution. A curve-fitting analysis of the results of Stamatoff et al. (28), who studied multilayered DPPC samples by X-ray diffraction, also indicates that the mosaic spread distribution in biological membranes is not purely Gaussian. The exponential form of the Gaussian function produces a rapid decrease of the tail of this distribution, which falls below the experimental points. Comparing

the Gaussian, Lorentzian, and the 50%G–50%L curves, the latter showed the best correlation with the experimental data.

It can thus be concluded that the mosaic spread in phospholipid bilayer samples exhibits a shape that can be approximated by a Gaussian – Lorentzian sum. Considering the values given in Table 1 for this type of distribution, it appears that the influence of the $\langle P_2 \rangle_{mz}$ coefficient in orientation studies cannot be neglected. Figure 6*a* shows curves that demonstrate the deviation between the apparent angle θ_{app} calculated by eq. [8] and the actual center θ_C of narrow orientation distributions (delta functions) for different $\langle P_2 \rangle_{mz}$ values. It is observed that the superimposition of the mosaic spread over the molecular chain distribution can cause a significant discrepancy between these two angles, particularly near $\theta_C = 0$ and 90°.

Another factor that could affect the interpretation of orientation measurements of phospholipids is the presence of *gauche* conformers in the acyl chains of the lipids. In the liquid crystalline phase, the presence of *gauche* conformers precludes the definition of a chain axis, and orientation measurements by IR spectroscopy can thus only be considered as indicative of the average orientation of the studied vibrations. For the gel phase, the tilt angle between the acyl chains and the normal to the bilayer could be calculated using eq. [8] in cases where the preparation conditions provide a narrow ($W_{1/2} < 5°$) mosaic spread, or if a good estimate of the $\langle P_2 \rangle_{mz}$ coefficient can be obtained for samples prepared by a given procedure. Nevertheless, provided that this condition is fulfilled, it is still necessary to determine the shape of the orientation distribution.

For phospholipids in the gel phase, it is frequently assumed that the acyl chains of the lipid are in the all-*trans* conformation (32). However, several studies by infrared (6, 33–35), NMR (36, 37), and Raman (38, 39) spectroscopy have shown that approximately a 2–7% fraction of *gauche* conformers is probably already present at temperatures below the transition, accounting for an average of 0.5–1.0 *gauche* bond per chain. The *gauche* rotamers are probably located mostly in kinks (*gtg'*) or jogs (*gttg'*) (34, 40, 41), which are not too disruptive of side-to-side order in the bilayer, or form end-*gauche* methyl groups (38). Moreover, the insertion of peptides or proteins in membranes can also introduce conformational disorder in the phospholipid acyl chains. A simple calculation (40) can be made to evaluate the influence of the nonplanar conformers on the orientation measurements of lipid acyl chains. Let us consider a bimodal distribution of the orientation of the methylene groups, with a first population of *trans* conformers oriented along the molecular chain axis, and a second oriented at 60° from this axis, with respective fractions x_t and x_g. Neglecting the presence of double *gauche* conformers, the x_g population is composed of the CH_2 groups located at the *gauche* bonds and of those between the *g* and *g'* conformers. The global $\langle P_2 \rangle_{CH_2}$ coefficient for this bimodal distribution is given by:

$$[10] \quad \langle P_2 \rangle_{CH_2} = x_t \langle P_2 \rangle_t + x_g \langle P_2 \rangle_g$$

It is assumed again that the orientation distributions of the x_t and x_g populations both exhibit cylindrical symmetry with respect to the reference direction and that the orientation of the CH_2 groups in the x_g fraction can be represented by a delta function inclined at 60° from the acyl chain axis. Then, $\langle P_2 \rangle_t = \langle P_2 \rangle_{cz}$ and the Legendre addition theorem leads to:

$$[11] \quad \langle P_2 \rangle_g = \langle P_2 \rangle_{cz} P_2(\cos 60°)$$

where the subscripts *z* and *c* represent the reference direction and the molecular chain axis, respectively. Using $x_g = (1 - x_t)$ and introducing eq. [11] in eq. [10] gives the equation:

$$[12] \quad \langle P_2 \rangle_{CH_2} = (1.125x_t - 0.125) \langle P_2 \rangle_{cz}$$

Assuming that $\langle P_2 \rangle_{cz} = P_2(\cos \theta_C)$, i.e., the orientation distribution of the acyl chains centered at θ_C is very narrow, the $\langle P_2 \rangle_{CH_2}$ coefficient calculated by eq. [12] can be used to evaluate, through eq. [8], the apparent angle between the chains and the membrane normal, θ_{app}. Figure 6*b* presents curves describing the variation of θ_{app} as a function of the orientation of the molecular chain axis θ_C for different percentages of methylene groups in the x_g population. These curves show that, even for a fraction $x_g \leq 5\%$, the presence of the *gauche* conformers in the phospholipid hydrocarbon chains can result in a significant error in the calculation of the chain tilt in the membrane. As it was observed in Figs. 5 and 6*a*, distributions oriented around $\theta_C = 0°$ are influenced more strongly than those centered at higher angles. However, even for phospholipids with chains oriented at 20°–35° from the reference direction, a range that encompasses the tilt angle values measured for several phospholipids (29, 42–44), *trans–gauche* isomerization could introduce some errors in the determination of the chain tilt angle by IR spectroscopy measurements at temperatures below the transition temperature. For example, for molecular axis orientations θ_C of 20° and 35°, θ_{app} values of 21.1° and 35.5° are calculated, respectively, if $x_g = 2\%$, while values of 22.6° and 36.2° are obtained for $x_g = 5\%$.

Conclusions

This article presents an analysis of the relationship between the order parameter $\langle P_2 \rangle$ and the width, the shape, and the position of the maximum θ_C of the orientation distribution. It is shown that distributions of different widths, shapes, and θ_C can give the same order parameter. Therefore, to determine unambiguously the characteristics of the actual orientation distribution, the $\langle P_2 \rangle$ coefficient is generally not sufficient and higher order coefficients are necessary. In cases where only the $\langle P_2 \rangle$ is known, the tilt angle θ_C between the molecular chain axis and the reference direction can be calculated from the order parameter only if the distribution is unimodal and very narrow because, in this particular case, the $\langle P_2 \rangle$ coefficient is close to the value of the $P_2(\cos \theta_C)$ polynomial. For broad distributions, or for distributions featuring more than one maximum, the $\langle P_2 \rangle$ value has to be considered as an average, which cannot be used to calculate the tilt angle.

The above conclusions have also been applied to the determination of the acyl chain orientation in phospholipid samples, frequently studied by infrared spectroscopy, a method that allows only the calculation of the $\langle P_2 \rangle$ coefficient. The order parameter obtained for supported phospholipid samples contains three different contributions, arising from the mosaic spread, from the orientation of the lipid molecules in the bilayers, and from the orientation of the transition dipole moment of the vibration used for the calculation. Our simulations show that the presence of mosaic spread and that of conformational disorder cannot be neglected in orientation studies. The anal-

ysis of the probable influence of these two parameters indicates that errors of a few degrees can be made in the determination of the tilt angle of the acyl chains of the lipids. The deviations between the apparent tilt angle and the true center of the orientation distribution are larger for distributions centered close to 0 or 90°.

Preparation of *ortho*-hydroxyalkylanilines as *ortho*-quinone methide imine precursors via an aminoborane complex

David Migneault, Michael A. Bernstein, and Cheuk K. Lau

Abstract: A general process for *ortho*-specific hydroxyalkylation of secondary anilines has been developed. *N*-Methylanilinochlorophenylboranes react readily with aryl aldehydes, and with α,β-unsaturated or saturated aliphatic aldehydes to give the corresponding *ortho*-hydroxyalkylanilines in good yield. Thermolysis of the latter generated the corresponding *ortho*-quinone methide imine, which can participate in an electrocyclic or intramolecular [4+2] cycloaddition reaction to give various dihydro- and tetrahydroquinoline derivatives. Application of the method to the syntheses of 5-aza analogs of hexahydrocannabinol is demonstrated.

Key words: quinone methide imine, *ortho*-hydroxyalkylaniline, azacannabinoids.

Résumé : On a mis au point un processus général pour effectuer l'hydroxyalkylation *ortho*-spécifique d'anilines secondaires. Les *N*-méthylanilinochlorophénylboranes réagissent facilement avec les aldéhydes aryliques et aliphatiques saturés ou α,β-insaturés pour fournir les *ortho*-hydroxyalkylanilines correspondantes avec de bons rendements. La thermolyse de ces dernières permet de générer les imines correspondantes de *ortho*-quinométhide qui peuvent participer dans des réactions électrocycliques ou de cycloaddition intramoléculaires [4+2] pour donner divers dérivés de la dihydro- et de la tétrahydroquinoléine. On a démontré l'application de cette méthode à la synthèse d'analogues 5-aza de l'hexahydrocannabinol.

Mots clés : imine de quinométhide, *ortho*-hydroxyalkylaniline, azacannabinoïdes.

[Traduit par la rédaction]

Introduction

ortho-Quinone methide imines **1** are highly reactive and useful synthetic intermediates. A variety of nitrogen-containing heterocycles have been prepared by the reaction of *ortho*-quinone methide imines with an olefin via cycloaddition or electrocyclic reactions (1–10). These highly reactive and unstable intermediates can be generated by flash vacuum pyrolysis of *ortho*-aminobenzyl alcohols or their *tert*-butoxycarbonylamino derivatives (2, 3), pyrolytic decarboxylation of dihydro-1,3-benzoxazin-2-ones (4), photolytic or thermal extrusion of SO_2 from 2,1-benzisothiazoline 2,2-dioxides (5, 6) fluoride-induced 1,4-elimination of [*ortho*-[(trimethylsilyl)alkylamino]-benzyl]trimethyl ammonium iodide (7), photodecarbonylation of oxindol (8), thermal ring cleavage of 2-azidoindole (9), and thermal tautomerization of *N*-phenylbenzoazetine (10).

Recently we reported the preparation of various substituted 2-phenyl-4*H*-1,3,2-benzodioxaborines, stable *ortho*-quinone methide precursors, by treating a phenol with an aldehyde in the presence of dichlorophenylborane (11). Herein we report the extension of this methodology to prepare a variety of *N*-methyl-2-hydroxyalkylanilines and their thermolysis to generate the corresponding *ortho*-quinone methide imines **1** under fairly mild conditions. Trapping of the latter with an olefin via an eletrocyclic or an intramolecular [4+2] cycloaddition reaction led to the syntheses of *N*-methyl-2-alkyl-1,2-dihydroquinolines as well as 5-aza analogs of hexahydrocannabinol (Scheme 1).

Results and discussion

ortho-Hydroxyalkylation of *N*-methylaniline

ortho-Specific hydroxyalkylation of aniline can be achieved quite readily by *ortho*-lithiation of *tert*-butoxycarbonylaniline followed by trapping of the resulting anion with the appropriate aldehyde (3, 12). Reaction of an aldehyde with *N*-methylanilinodichloroborane, prepared from *N*-methylaniline and boron trichloride *in situ*, provided a non-basic alternative. However, the latter reaction works well with benzaldehyde but poorly with aliphatic aldehydes (13). With our recent success in *ortho*-hydroxyalkylation of phenol using dichlorophenylborane as the complexing agent (11), we decided to investigate the use of this reagent to prepare *ortho*-hydroxyalkylanilines.

Using the procedure we reported for *ortho*-hydroxyalkylation of phenol (11), reaction of *N*-methylaniline with dichlorophenylborane and benzaldehyde in the presence of triethylamine in dichloromethane at 0°C gave a very poor yield of the corresponding benzyl alcohol. However, reaction of the preformed *N*-methylanilinochlorophenylborane **7***a* with benzaldehyde, in the presence of diisopropylethylamine at

0°C, gave 90% yield of the desired benzyl alcohol **4***a* (3) (Table 1). The presumed intermediate, 2,4-diphenyl-3,1,2-benzoxazaborine **3***a*, was not isolated. The yield of **4***a* was comparable to that reported by Sugasawa et al. using boron trichloride (13). It was thus of interest to study the scope and limitations of this reaction to determine whether **7** would react readily with aliphatic aldehydes in good yield. Thus, reaction of **7** with a series of α,β-unsaturated aldehydes was first investigated. A stock solution of **7** was prepared in advance according to the procedure of Sugasawa et al. (13). This solution could be stored at 0°C for more than 2 weeks without deterioration. In a typical procedure, a solution of **7** (11 mmol) in dichloroethane was added dropwise to a mixture of the aldehyde (10 mmol) and diisopropylethylamine (20 mmol) in dichloromethane at −20°C. The mixture was stirred at −20°C to 0°C for the appropriate time. The results are summarized in

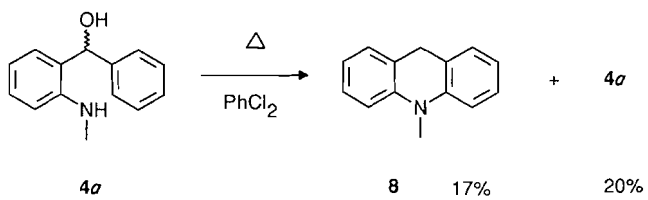
Scheme 2.



4*a* **8** 17% 20%

Table 1. Reaction of **7***a* with cinnamaldehyde gave a 71% yield of the corresponding allylic alcohol **4***b*. Similarly, **7***a* reacts readily with 3-methyl-2-butenal, crotonaldehyde, and acrolein to give **4***c* (55%), **4***d* (75%), and **4***e* (65%), respectively. With citral, the *ortho*-hydroxyalkylated product **4***f* was isolated in 59% yield. (*R*)-(+)-Citronellal, a saturated aliphatic aldehyde, was found to react quite readily with **7***a* to give the corresponding alcohols **4***g* as a 1:1 mixture of diastereomers in 81% yield. Reaction of 3-methoxy-*N*-methylanilinochlorophenylborane **7***b* with (*R*)-(+)-Citronellal gave 66% yield of the corresponding alcohols as a 1:1 mixture of regioisomers **4***h* and **4***i*. Both **4***h* and **4***i* are themselves composed of 1:1 mixtures of diastereomers. The two diastereomers of **4***i* were separable by chromatography while those of **4***h* were not.

Electrocyclic reactions of *ortho*-quinone methide imines

The benzylic and allylic alcohol substituted anilines **4** thus prepared are all well disposed for electrocyclic reactions. Thermolysis of the benzyl alcohol **4***a* in refluxing 1,2-dichlorobenzene (180°C) for 0.75 h gave only a 17% yield of the corresponding 10-methyl-9,10-dihydroacridine **8** (4) (Scheme 2), presumably via the *ortho*-quinone methide imine intermediate **1**. No trace of the corresponding acridine was detected. The yield was not improved by extending the reaction time or by raising the reaction temperature to 250°C. In contrast, flash vacuum thermolysis of **4***a* at 600°C gave a much better yield of the corresponding dihydroacridine derivative (4).

Dehydration and electrocyclization of the allylic alcohol derivatives **4***b*–**4***d* was more successful and the results are summarized in Table 2. Thermolysis of the cinnamyl alcohol derivative **4***b* in refluxing dichlorobenzene (180°C) for 0.75 h gave a 43% yield of the desired 1-methyl-2-phenyl-1,2-dihydroquinoline **5***a* (14). A significant amount of starting material (27%) was also recovered. Extending the reaction time

[b]Isolated yield.

resulted in lower yields due to decomposition. At a lower temperature (refluxing benzene), the reaction took 5 h to complete. More by-products were formed and the yield of **5***a* was significantly lower. In our previous work, it was found that the *ortho*-quinone methides could be generated more readily from 2-phenyl-4*H*-1,3,2-benzodioxaborin than the corresponding *ortho*-hydroxyalkyl phenol (11). It was hoped that the analogous 2-phenyl-4*H*-3,1,2-benzoxazaborin would behave similarly to afford the *ortho*-quinone methide imine more readily. Thus, a mixture of alcohol **4***b*, phenylboronic acid (3 equivalents), and a catalytic amount of propionic acid was refluxed in benzene for 20 h with concomitant removal of water. No trace of the corresponding 2-phenyl-4*H*-1,3,2-benzoxaborin was observed during this reaction, but a slightly better yield of **5***a* (57%) was isolated after chromatography. Electrocyclization of **4***c* was achieved in refluxing xylene (130°C), giving the corresponding *N*-methyl-2,2-dimethyl-1,2-dihydroquinoline **5***b* in 53% yield. Another product, **9**, formed by dehydration of the side chain, was also obtained in 16% yield. Similarly, thermolysis of the crotyl alcohol derivative **4***d* at 130°C gave 51% yield of the cyclized product **5***c* (12) and a 15% yield of the dehydrated product **10**. Attempts to limit the formation of the dehydrated products by using the phenylboronic acid procedures described above for **4***b* resulted in extensive decomposition. Apparently **4***c* and **4***d* are much more acid sensitive than **4***b*. Thermolysis of the unsubstituted allyl alcohol **4***e* at various temperatures and conditions failed to give any electrocyclized product. Either starting material was recovered or decomposition resulted when the reaction was performed at higher temperature. Thermolysis of the allylic alcohol derived from citral **4***f* in refluxing xylene gave mainly the dehydrated product **11** (48%) and only a 21% yield of the cyclized product **5***d*, an aza analog of cannabichromene. None of the product derived from the [2+4] cycloaddition with the terminal olefin, which would have led to the synthesis of a 5-aza analog of tetrahydrocannabinol, was detected. Reducing the temperature by refluxing **4***f* in benzene gave only **11** and none of the desired product **5***d*.

Syntheses of 5-aza tetrahydrocannabinoid analogs

Intramolecular trapping of *ortho*-quinone methide imines by an olefin via flash vacuum pyrolysis of *ortho*-hydroxyalkylaniline at 600°C has been reported (3). Our newly developed methodology of *ortho*-hydroxalkylation of aniline can provide such substrates quite readily. We investigated the application of this methodology for the preparation of 5-*aza* analogs of hexahydrocannabinol. Alcohols **4***g*, **4***h*, and **4***i* described in Table 1 were prepared for this purpose from Citronellal (Scheme 1 and Table 3). Thus, thermolysis of **4***g* in refluxing dichlorobenzene for 0.75 h gave a 69% yield of a 1.4 to 1 mixture of the expected cycloaddition product **6***a* and the dehydrated product **12***a*. However, thermolysis of **4***g* in the presence of phenylboronic acid and a catalytic amount of propionic acid in refluxing toluene for 32 h gave 71% of **6***a* and **12***a* in a ratio of 6.6:1. The two compounds were separated after repeated chromatography. Only a single optically active diastereomer of **6***a* ($[\alpha]_D^{25}$ +43 (*c* 1.2, $CHCl_3$)) was obtained. The stereochemistry of **6***a* is identical to that of the natural hexahydrocannabinol as confirmed by 2D COSY and decoupling NMR experiments. The vicinal coupling constant of the aliphatic signal of H-10a at δ 2.42 (d, t) across the ring junction, *J*(6a,10a), was measured to be 11.1 Hz; this is consistent with a *trans* ring junction. The equatorial orientation of the 9-Me group and boat conformation of the saturated carbonaceous ring was deduced from the analysis of the (highest field) H-10ax (δ 0.86). This proton appeared as an apparent quartet, due to approximately equal geminal and two *trans* diaxial vicinal couplings (11.4 Hz). H-9 is therefore axial, and the methyl substituent is equatorial. The ^{13}C NMR spectrum is consistent with the structure.

Thermolysis of the 3-methoxyaniline derivative **4***h* in dichlorobenzene or xylene gave no trace of the cyclized product **6***b*. Only the dehydration product **12***b* was isolated. However, after refluxing **4***h* with phenylboronic acid and a catalytic amount of propionic acid in 1,2-dichlorobenzene for 1.5 h, a 1:1 mixture of **6***b* and **12***b* was isolated in a 70% yield.

An analytical sample of **6*b*** was obtained after repeated chromatography of the mixture. The compound was found to be optically active, ($[\alpha]_D^{25}$ −51 (*c* 4.2, $CHCl_3$)). The aliphatic region of the ^1H NMR spectrum is virtually identical to that of **6*a***, indicating it has the same stereochemistry. The ^{13}C NMR spectrum is again consistent with the indicated structure.

In contrast, thermolysis of the 5-methoxyaniline derivative **4*i*** in refluxing benzene in the presence of phenylboronic acid and a catalytic amount of propionic acid for 20 h gave 51% of the desired cyclized product **6*c*** and the dehydrated product **12*c*** in the ratio of 10:1. Using the same method but refluxing in 1,2-dichlorobenzene for only 0.25 h, the yield of **6*c*** was increased to 61%. No trace of the dehydrated product **12*c*** was observed. The ^1H NMR and ^{13}C NMR spectra of compound **6*c*** are very similar to those of compounds **6*a*** and **6*b***, and are consistent with the indicated structure.

In summary, we have shown that *ortho*-hydroxyalkylation of *N*-methylaniline via *N*-methylanilinochlorophenylborane is a general and efficient process that works well with aromatic, α,β-unsaturated, and saturated aliphatic aldehydes. The *N*-methyl-*ortho*-hydroxyalkylanilines thus obtained are useful precursors of *o*-quinone methide imines. We have also shown that the latter can be generated pyrolytically from *N*-methyl-*ortho*-hydroxyalkylanilines much more readily in the presence of phenylboronic acid. With the 2-alkyl chain properly substituted with an olefin, the resulting *o*-quinone methide imines can either undergo a facile electrocyclic reaction to give *N*-methyl-2-alkyl-1,2-dihydroquinolines or they may undergo an intramolecular cycloaddition reaction to give polycyclic tetrahydroquinoline derivatives. The method was applied to the synthesis of several analogs of 5-azahexahydrocannabinol.

Experimental

General information

Proton nuclear magnetic resonance spectra were obtained on a Varian 200, Brucker ARX 400 and Brucker ARX 500 spectrometers. Reported boiling points are those observed during distillation with a Kugelrohr apparatus and are uncorrected. Melting points were measured on a Buchi 510 melting point apparatus and are uncorrected. Low-resolution mass spectral analyses were performed by the Oneida Research Services, Inc. of Whitesboro, N.Y. Exact masses were obtained by high-resolution mass spectroscopy performed by Dr. O. Maimer of McGill University, Montreal, Québec. Elemental analyses were performed by Guelph Chemical Laboratories Ltd., Guelph, Ontario. Flash chromatography was performed using Merck silica gel 60, 230–400 mesh and tlc using Merck silica gel 60F 254 sheets.

General procedure A

Preparation of N-*methyl*-ortho-*hydroxyalkylanilines*

A stock solution of *N*-methylanilinochlorophenylborane **7*a*** was prepared by adding dichlorophenylborane (100 mmol) to a solution of *N*-methylaniline (100 mmol) in 1,2-dichloroethane (100 mL) at 0°C. The resulting mixture was refluxed for 2 h under a rapid stream of nitrogen to remove the HCl formed. The mixture was cooled to give a 0.8 M cloudy solution that could be stored at 0°C for more than 6 weeks without deterioration. In a typical procedure, a solution of **7** (11 mmol) in dichloroethane was added dropwise to a mixture of the aldehyde (10 mmol) and diisopropylethylamine (20 mmol) in dichloromethane at −20°C. The mixture was stirred at −20°C to 0°C for the appropriate time, quenched with ammonium hydroxide (not needed for benzaldehyde and saturated aliphatic aldehydes), and then filtered through a short pad of silica gel. The filtrate was concentrated and the residue was chromatographed on silica gel and eluted with EtOAc–hexane (0–20%).

*(2-Methylaminophenyl)-phenylmethanol (**4**a)*

Following the general procedure A, benzaldehyde (1.06 g, 10 mmol) was reacted with **7*a*** to give, after chromatography, 1.95 g (90%) of the title compound **4*a*** (3); mp 122–125°C; ir (film): 3420 (NH), 3250 (OH) cm^{-1}; ^1H nmr (200 MHz, $CDCl_3$), δ: 2.40 (bs, 1H), 2.77 (s, 3H, N-CH_3), 4.55 (bs, 1H), 5.84 (br s, 1H, CHO), 6.70 (m, 2H), 6.90 (m, 1H), 7.25 (m, 6H). Anal. calcd. for $C_{14}H_{14}NO$: C 78.84, H 7.09, N 6.56; found: C 78.71, H 7.10, N 6.43.

*1-(2-Methylaminophenyl)-3-phenylprop-2-en-1-ol (**4**b)*

According to general procedure A, cinnamaldehyde (1.32 g, 10 mmol) was reacted with **7*a*** at −20°C for 1.5 h to give, after chromatography, 1.70 g (71%) of the title compound as a solid; mp 76–78°C; ir (film): 3325 (NH), 3150 (OH) cm^{-1}; ^1H nmr (200 MHz, $CDCl_3$), δ: 2.87 (s, 3H, N-CH_3), 2.16 (br s , 1H), 4.9 (br s, 1H), 5.43(m, 1H), 6.60 (m, 4H), 7.30 (m, 7H). Exact Mass calcd. for $C_{16}H_{18}NO$ (M+1): 240.1388; found: 240.1388. Anal. calcd. for $C_{16}H_{17}NO$: C 80.30, H 7.16, N 5.85; found: C 80.26, H 7.33, N 5.71.

*3-Methyl-1-(2-methylaminophenyl)-but-2-en-1-ol (**4**c)*

According to general procedure A, 3-methyl-2-butenal (841 mg, 10 mmol) was reacted with **7*a*** (11 mmol) at −20°C for 0.5 h to give, after chromatography, 1.05 g (55%) of the title compound; ir (film): 3100–3600 (NH, OH) cm^{-1}; ^1H nmr (200 MHz, CD_3COCD_3), δ: 1.70 (d, 3H, J = 1.2 Hz), 1.72 (d, 3H, J = 1.2 Hz), 2.80 (d, 3H, J = 5.3 Hz, N-CH_3), 4.22 (d, 1H, J = 4.0 Hz, OH), 5.38 (d, 1H, J = 5.38 Hz), 5.40 (d, 1H, J = 5.40 Hz), 5.65 (m, 1H), 6.60 (m, 2H), 7.10 (m, 2H); ms, *m/z*: 192 (M+1), 174.

*(2-Methylaminophenyl)-but-2-1-ol (**4**d)*

According to general procedure A, crotonaldehyde (701 mg, 10 mmol) was reacted with **7*a*** (11 mmol) at −20°C for 0.75 h to afford, after chromatography, 1.33 g (75%) of the title compound as an oil; ir (film): 3100–3600 (NH, OH) cm^{-1}; ^1H nmr (200 MHz, CD_3COCD_3), δ: 1.67 (d, 3H, J = 5.0 Hz), 2.79 (d, 3H, J = 5.3 Hz, N-CH_3), 4.36 (d, 1H, J = 4.0 Hz, OH), 5.10 (m, 1H), 5.25 (bs, 1H), 5.80 (m, 2H), 6.60 (m, 2H), 7.10 (m, 2H); ms, *m/z*: 178 (M+1), 177, 160.

*(2-Methylaminophenyl)-prop-2-en-1-ol (**4**e)*

According to general procedure A, acrolein (200 mg, 3.56 mmol) was reacted with **7*a*** (11 mmol) at 0°C for 0.5 h, then at room temperature for 0.75 h, to afford, after chromatography, 375 g (65%) of the title compound as an oil; ir (film): 3100–3600 (NH, OH) cm^{-1}; ^1H nmr (200 MHz, CD_3COCD_3), δ: 2.80 (d, 3H, J = 5.2 Hz, N-CH_3), 4.52 (d, 1H, J = 4.3 Hz, OH), 5.10 (dt, 1H, J = 10.4, 1.6 Hz), 5.18 (m, 2H), 5.3 (dt, 1H, J = 17.2, 1.8 Hz), 6.18 (m, 1H), 6.56 (m, 2H), 7.10 (m, 2H). Anal. calcd.

for $C_{10}H_{13}NO$: C 73.59, H 8.03, N 8.58; found: C 73.54, H 8.19, N 8.44.

*1-(2-Methylaminophenyl)-3,7dimethylocta-2,6-dien-1-ol (**4**f)*
According to general procedure A, citral (1.522 g, 10 mmol) was reacted with **7***a* (11 mmol) at −20°C for 3 h to afford, after chromatography, 1.522 g (59%) of the title compound as a mixture of 2-(*E*) and 2-(*Z*) isomers, in a ratio of 2.4:1. An analytical pure sample of each isomer was obtained by repeated chromatography. The less polar alcohol (an oil) exhibited: ir (film): 3100–3600 (NH, OH) cm^{-1}; ^1H nmr (200 MHz, CD_3COCD_3), δ: 1.57 (s, 3H), 1.63 (s, 3H), 1.75 (d, 3H, J = 1.3 Hz), 2.15, (m, 4H), 2.82 (s, 3H, N-CH_3), 4.18 (d, 1H, J = 4.0 Hz, OH), 5.10 (m, 1H, NH), 5.42 (m, 2H), 5.68 (dd, 1H, J = 8.9, 1.1 Hz), 6.50 (m, 2H), 7.10 (m, 2H). The more polar alcohol (an oil) exhibited: ^1H nmr (200 MHz, CD_3COCD_3), δ: 1.58 (s, 3H), 1.65 (s, 3H), 1.69 (d, 3H, J = 1.4 Hz), 2.10 (m, 4H), 2.83 (s, 3H, N-CH_3), 4.22 (d, 1H, J = 4.3Hz, OH), 5.10 (m, 1H, NH), 5.35 (m, 2H), 5.63 (dd, 1H, J = 8.6, 1.1 Hz), 6.55 (m, 2H), 7.10 (m, 2H). Exact Mass calcd. for $C_{17}H_{26}NO$ (M+1): 260.2014 ; found: 260.2014.

*(3R)-1-(2-Methylaminophenyl)-3,7-dimethyloct-6-en-1-ol (**4**g)*
According to general procedure A, (*R*)-(+)-Citronellal (Sigma, 85% pure, $[\alpha]_D$ +11.8) (1.54 g, 10 mmol) was reacted with **7***a* (11 mmol) at 0°C for 0.5 h, then at 20°C for 3 h, to afford, after chromatography, 2.12 g of the title compound as a 1:1 mixture of diastereomers (81%); ^1H nmr (400 MHz, CD_3COCD_3), resolved signals of the mixture, δ: 0.93 (d, 3H, J = 6.5 Hz), 0.95 (d, 3H, J = 6.4 Hz), 1.56 (s, 3H), 1.60 (s, 3H), 1.62 (s, 3H), 1.68 (s, 3H), 2.79 (s, 3H, N-CH_3), 2.80 (s, 3H, N-CH_3), 5.05 (m, 1H, CH═C), 5.12 (m, 1H, CH═C), 5.41 (bs, 1H, NH), 5.44 (bs, 1H, NH); other resonances, δ: 1.12 (m, 1H), 1.20 (m, 1H), 1.35 (m), 1.70 (m), 1.90 (m), 4.30 (m, 2H, OH), 4.77 (m, 2H, CHO), 6.56 (m, 4H), 6.98 (m, 2H), 7.07 (m, 2H). Anal. calcd. for $C_{17}H_{27}NO$: C 78.11, H 10.41, N 5.36; found: C 78.23, H 10.48, N 4.92.

*(3R)-1-(2-Methoxy-6-methylaminophenyl)-3,7-dimethyloct-6-en-1-ol (**4**h) and (3R)-1-(4-methoxy-6-methylamino-phenyl)-3,7-dimethyloct-6-en-1-ol (**4**i)*
According to general procedure A, (*R*)-(+)-citronellal (1.54 g, 10 mmol) was reacted with **7***b* (11 mmol) at −20°C for 2 h and at 20°C for 0.5 h to afford, after chromatography, 32% of **4***h* and 34% of **4***i*. Compound **4***h* is an inseparable 1:1 mixture of diastereomers: ^1H nmr (400 MHz, CD_3COCD_3), resolved signals of **4***h*, δ: 0.91 (d, 3H, J = 6.6 Hz), 0.95 (d, 3H, J = 6.6 Hz), 1.56 (s, 3H), 1.60 (s, 3H), 1.63 (s, 3H), 1.66 (s, 3H), 2.76 (s, 3H, N-CH_3), 2.77 (s, 3H, N-CH_3), 3.72 (s, 3H, OCH_3), 3.73 (s, 3H, OCH_3), 4.32 (d, 1H, J = 3.5 Hz, OH), 4.34 (d, 1H, J = 3.6 Hz, OH), 5.05 (bt, 1H, J = 7.1 Hz, CH═C), 5.12 (bt, 1H, J = 7.1 Hz, CH═C), 5.50 (m, 2H, CHO), 6.05 (bs, 2H, NH), 6.23 (d, 2H, J = 8.3 Hz), 6.25 (d, 4H, J = 8.2 Hz), 7.00 (t, 1H, J = 8.2 Hz); other resonances, δ: 1.15 (m, 2H), 1.30 (m, 2H), 1.40 (m, 2H), 1.50 (m, 2H), 1.70 (m, 2H), 2.0 (m, 4H). Exact Mass calcd. for $C_{18}H_{30}NO_2$ (M+1): 292.2276; found: 292.2276. The two diastereomers of compound **4***i* were separated by repeated chromatography. The less polar isomer: ^1H nmr (400 MHz, CD_3COCD_3), δ: 0.91 (d, 3H, J = 6.6 Hz), 1.18 (m, 1H), 1.42 (m, 2H), 1.60 (s, 3H), 1.66 (s, 3H), 1.65 (m, 2H), 1.97 (m, 2H), 2.78 (d, 3H, J = 5.2 Hz, N-CH_3), 3.73 (s, 3H), 4.13 (d, 1H, J = 4 Hz, OH), 4.72 (m, 1H, CHO), 5.12 (bt, 1H, J = 7.2 Hz, CH═C), 5.48 (bs, 1H, NH), 6.11 (m, 2H), 6.88 (d, 1H, J = 8.8 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 17.7, 19.6, 25.9, 26.2, 30.4, 38.5, 43.62, 55.1, 72.1, 97.7, 100.3, 122.5, 125.8, 128.4, 131.3, 150.2, 161.1. The more polar isomer of **4***i* : ^1H nmr (400 MHz, CD_3COCD_3), δ: 0.94 (d, 3H, J = 6.8 Hz), 1.13 (m, 1H), 1.40 (m, 1H), 1.48 (m, 1H), 1.56 (s, 3H), 1.63 (s, 3H), 1.65 (m, 2H), 1.80 (m, 1H), 1.95 (m, 1H), 2.78 (d, 3H, J = 5.2 Hz, N-CH_3), 3.73 (s, 3H), 4.16 (d, 1H, J = 3.9 Hz, OH), 4.70 (m, 1H, CHO), 5.05 (bt, 1H, J = 7.2 Hz, CH═C), 5.48 (bs, 1H, NH), 6.10 (d, 1H, J = 7.4 Hz), 6.12 (s, 1H), 6.86 (d, 1H, J = 7.8 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 17.8, 20.6, 25.9, 26.1, 30.2, 30.4, 37.7, 43.3, 55.1, 72.9, 97.7, 100.3, 121.9, 125.8, 128.7, 131.2, 150.3, 161.2. Exact Mass calcd. for $C_{18}H_{30}NO_2$ (M+1) : 292.2276; found: 292.2276.

*Preparation of 10-methyl 9,10-dihydroacridine (**8**)*
A solution of **4***a* (203 mg, 0.95 mmol) in 1,2-dichlorobenzene (6 mL) was heated to reflux for 40 min. The reaction mixture was poured directly onto a silica gel column and eluted with EtOAc–hexane to give 32 mg (17%) of the title compound **8** (3) and 44 mg (20%) of recovered starting material. The title compound is a solid, mp 91–93°C; ^1H nmr (200 MHz, CD_3COCD_3), δ: 3.39 (s, 3H), 3.85 (s, 2H), 6.90 (m, 4H), 7.20 (m, 4H). Anal. calcd. for $C_{14}H_{13}N$: C 86.12, H 6.71, N 7.17; found: C 86.19, H 6.87, N 7.11.

General procedure B

*Thermolysis 1-(2-methylaminophenyl)-3-phenyl-prop-2-en-1-ol (**4**b)*
A solution of **4***b* (995 mg, 4.16 mmol) in 1,2-dichlorobenzene (30 mL) was heated to reflux for 40 min. The solution was cooled and then poured directly onto a silica gel column and eluted with 0–5% Et_2O–hexane to give 398 mg (43.3%) of 1-methyl-2-phenyl-1,2-dihydroquinoline **5***a* (14) and 270 mg (27%) of recovered starting material. The cyclized product **5***a* is a solid, mp 82–84°C; ir (KBr): 1580, 1490, 735 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$), δ: 2.72 (s, 3H, N-CH_3), 5.15 (dd, 1H, J = 4.8, 1.3 Hz), 5.67 (dd, 1H, J = 9.8, 4.8 Hz), 6.38 (d, 2H, J = 9.8 Hz), 6.43 (d, 2H, J = 7.9 Hz), 6.61 (dt, 1H, J = 7.4, 1.0 Hz), 6.92 (dd, 1H, J = 7.3, 1.5 Hz), 7.1 (dt, 1H, J = 8.1, 1.6 Hz), 7.40 (s, 5H). Exact Mass calcd. for $C_{16}H_{16}N$ (M+1): 222.1283; found: 222.1283.

*Thermolysis of 3-methyl-1-(2-methylaminophenyl)-but-2-en-1-ol (**4**c)*
According to general procedure B, a solution of **4***c* (768 mg, 4.02 mmol) in xylene (21 mL) was heated to reflux for 5 h to give, after chromatography, 53% of 1,2,2-trimethyl-1,2-dihydroquinoline **5***b* and 16% of the elimination product [2-(3-methylbuta-1,3-dienyl)-phenyl]-methylamine **9**. Compound **5***b* : ir (film): 2960, 1595, 1490 cm^{-1}; ^1H nmr (200 MHz, CD_3COCD_3), δ: 1.32 (s, 6H, CH_3), 2.79 (s, 3H), 5.46 (d, 1H, J = 9.8 Hz), 6.24 (d, 1H, J = 9.8 Hz), 6.5 (dt, 2H, J = 8.2, 1.0 Hz), 6.80 (dd, 1H, J = 7.1, 1.7 Hz), 7.01 (dt, 1H, J = 7.8, 1.7 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 27.3, 30.5, 56.6, 110.5, 116.4, 121.6, 123.8, 126.5, 128.5, 132.2, 145.0. Exact Mass calcd. for $C_{12}H_{16}N$ (M+1): 174.1283; found: 174.1283. Compound **9** : ir (film): 3430 (NH), 1600, 1500 cm^{-1}; ^1H nmr

(200 MHz, CD_3COCD_3), δ: 1.95 (s, 3H), 2.82 (d, 3H), 4.95 (bs, 1H, NH), 5.00 (m, 2H), 6.60 (m, 2H), 6.75 (s, 2H), 7.12 (dt, 1H, J = 7.9, 1.4 Hz), 7.32 (dd, 1H, J = 7.5, 1.3 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 18.8, 30.9, 110.3, 117.1, 117.5, 122.9, 124.1, 127.2, 128.9, 133.9, 142.3, 146.6. Exact Mass calcd. for $C_{12}H_{16}N$ (M+1): 174.1283; found: 174.1283.

*Thermolysis of (2-methylaminophenyl)-but-2-en-1-ol (**4**d)*

According to general procedure B, a solution of **4***d* (979 mg) in xylene (29 mL) was heated to reflux for 22 h to give, after multiple chromatography, 446 mg (51%) of 1,2-dimethyl-1,2-dihydroquinoline **5***c* and 86 mg (10%) of [2-(buta-1,3-dienyl)-phenyl]-methylamine **10**. Compound **5***c*: ir (film): 2960, 1595, 1495, 680 cm^{-1}; ^{1}H nmr (200 MHz, CD_3COCD_3), δ: 1.07 (d, 3H, J = 6.3 Hz), 2.84 (s, 3H), 4.11(quintet, 1H, J = 6.2 Hz), 5.68 (dd, 1H, J = 9.7, 5.3 Hz), 6.30 (d, 1H, J = 9.8 Hz), 6.45 (m, 2H), 6.84 (dd, 1H, J = 7.3, 1.6 Hz), 7.01 (dt, 1H, J = 7.8, 1.5 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 18.2, 35.8, 55.3, 110.5, 116.5, 122.5, 124.9, 126.7, 127.0, 129.0, 145.0. Anal. calcd. for $C_{11}H_{13}N$: C 82.97, H 8.23, N 8.80; found: C 82.94, H 8.11, N 9.15. Compound **10**: ir (film): 3300–3500 (NH) cm^{-1}; ^{1}H nmr (200 MHz, CD_3COCD_3), δ: 2.87 (s, 3H), 3.75 (bs, 1H), 5.17 (dd, 1H, J = 9.2, 1.7 Hz), 5.35 (dd, 1H, J = 16.9, 2.0 Hz), 6.30 (m, 2H), 6.70 (m, 3H), 7.11 (dd, 1H, J = 7.5, 1.5 Hz), 7.22 (dt, 1H, J = 7.8, 1.6 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 30.7, 109.6, 116.4, 119.0, 122.6, 126.8, 128.8, 130.0, 132.4, 133.7, 146.7. Exact Mass calcd. for $C_{11}H_{14}N$ (M+1): 160.1126; found: 160.1126.

*Thermolysis of 1-(2-methylaminophenyl)-3,7dimethylocta-2,6-dien-1-ol (**4**f)*

According to general procedure B, a solution of **4***f* (195 mg, mixture of *cis* and *trans* isomers) was heated to reflux in xylene for 1.5 h to give, after multiple chromatography, 39 mg (21%) of 1,2-dimethyl-2-(4-methylpent-3-enyl)-1,2-dihydroquinoline **5***d* and 78 mg (48%) of [2-(3,7-dimethylocta-1,3,6-trienyl)-phenyl]-methylamine **11** as a complex mixture of isomers. Compound **5***d*: ir (film): 2960, 2920, 1600, 1580 780 cm^{-1}; ^{1}H nmr (200 MHz, $CDCl_3$), δ: 1.27 (m, 1H), 1.30 (s, 3H), 1.52 (s, 3H), 1.63 (s, 3H), 2.02 (m, 3H), 2.76 (s, 3H), 5.10 (m, 1H), 5.33 (d, 1H, J = 9. 9 Hz), 6.33 (d, 1H, J = 9.9 Hz), 6.44 (d, 1H, J = 8.2 Hz), 6.54 (dt, 1H, J = 7.3 Hz, 1.0 Hz), 6.77 (dd, 1H, J = 7.7, 1.0 Hz), 6.98 (dt, 1H, J = 9.3, 1.5 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 17.6, 23.9, 25.7, 27.3, 30.2, 41.5, 60.1, 109.3, 115.7, 121.0, 124.3, 125.0, 126.5, 129.0, 130.0, 131.5, 145.5. Exact Mass calcd. for $C_{17}H_{24}N$ (M+1): 242.1909; found: 242.1909.

*Thermolysis of (3*R*)-1-(2-methylaminophenyl)-3,7-dimethyloct-6-en-1-ol (**4**g)*

According to general procedure B, a solution of **4***g* (1.276g, 4.889 mmol) in 1,2-dichlorobenzene (25 mL) was heated to reflux for 0.75 h to afford, after multiple chromatography, 474 mg (40%) of (6a*R*,9*R*,10a*R*)-5,6,6,9-tetramethyl-5,6,6a,7,8,9,10,10a-octahydrophenanthridine **6***a* and 342 mg (29%) of (3*R*)-(1*E*)-[2-(3,7-dimethylocta-1,6-dienyl)-phenyl]-methylamine **12***a*. Compound **6***a*: $[\alpha]_D$ +43 (*c* 1.2, $CHCl_3$); ir (film): 2960, 2930, 1600, 1580, 780 cm^{-1}; ^{1}H nmr (500 MHz, CD_3COCD_3), δ: 0.86 (q, 1H, J = 11.4 Hz, H-10ax), 0.94 (dt, 1H, J = 12.7, 3.5 Hz, H-8ax), 0.97 (d, 3H, J = 6.6 Hz), 0.99 (s, 3H), 1.23 (m, 1H, H-7ax), 1.25 (m, 1H, H-6a), 1.28 (s, 3H), 1.56 (m, 1H, H-9ax), 1.81 (m, 1H, H-8eq), 1.90 (m, 1H, H-7eq), 2.42 (dt, 1H, J = 11.1, 4.0 Hz, H-10a), 2.49 (m, 1H, H-10eq), 2.85 (s, 3H), 6.55 (m, 2H), 7.10 (m, 2H); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 19.1, 22.8, 26.2, 28.2, 32.2, 32.4, 35.0, 35.6, 40.1, 47.6, 57.1, 111.6, 115.5, 124.7, 126.9, 145.9. Exact Mass calcd. for $C_{17}H_{26}N$ (M+1): 244.2065; found: 244.2065. Compound **12***a*: ir (film): 3430 (NH) 2950, 2900, 1600, 1500, 740 cm^{-1}; ^{1}H nmr (500 MHz, $CDCl_3$), δ: 1.14 (d, 3H, J = 6.7 Hz), 1.45 (m, 2H), 1.65 (s, 3H), 1.74 (d, 3H, J = 1.0 Hz), 2.07 (m, 2H), 2.35 (m, 1H), 2.91 (s, 3H), 3.81 (bs, 1H), 5.16 (m, 1H), 5.96 (dd, 1H, J = 15.6, 8.0 Hz), 6.37 (d, 1H, J = 15.6 Hz), 6.67 (d, 1H, J = 8.1 Hz), 6.75 (m, 1H), 7.2 (m, 2H); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 15.9, 17.7, 20.1, 25.7, 25.9, 30.9, 37.1, 37.2, 109.9, 117.3, 123.7, 124.6, 127.3, 128.1, 131.4, 139.5, 145.9. Anal. calcd. for $C_{17}H_{25}N$: C 83.89, H 10.35, N 5.75; found: C 83.86, H 9.88, N 5.72. Exact Mass calcd. for $C_{17}H_{26}N$ (M+1): 244.2065; found: 244.2065.

*Thermolysis of (3*R*)-1-(2-methoxy-6-methylaminophenyl)-3,7-dimethyloct-6-en-1-ol (**4**h)*

According to general procedure B, a solution of **4***h* (161 mg, 0.4 mmol) in xylene (2.5 mL)was heated under reflux for 2 h to afford 111 mg (73%) of (3*R*)-(1*E*)-[2-(3,7-dimethylocta-1,6-dienyl)-3-methoxyphenyl]-methylamine **12***b*; ^{1}H nmr (400 MHz, $CDCl_3$), δ: 1.08 (d, 3H, J = 6.7 Hz), 1.39 (m, 2H), 1.59 (s, 3H), 1.67 (s, 3H), 2.02 (m, 2H), 2.30 (m, 1H), 2.81 (s, 3H), 3.75 (s, 3H), 4.25 (bs, 1H, NH), 5.12 (bt, 1H, J = 6.1 Hz), 5.86 (dd, 1H, J = 16.4, 7.8 Hz), 6.20 (d, 1H, J = 16.4 Hz), 6.29 (s, 1H), 6.31 (s, 1H), 7.07 (t, 1H, J = 8.2 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 17.8, 21.3, 25.9, 26.7, 31.2, 38.0, 38.7, 55.7, 100.7, 104.1, 121.4, 125.6, 128.8, 131.6, 141.0, 148.9, 158.5. Exact Mass calcd. for $C_{18}H_{28}NO$ (M+1): 274.2170; found: 274.2171.

General procedure C

*Thermolysis of 1-(2-methylaminophenyl)-3-phenylprop-2-en-1-ol (**4**b) in the presence of phenylboronic acid*

A mixture of **4***b* (100 mg, 0.42 mmol), phenylboronic acid (153 mg, 1.26 mmol), and propionic acid (9.3 mg, 0.126 mmol) in benzene (6 mL) was refluxed for 20 h with concomitant removal of water. The mixture was concentrated in vacuum and the residue was chromatographed on silica gel, eluting with 2.5% EtOAc–hexane to give 52.8 mg (57%) of **5***a*.

*Thermolysis of (3*R*)-1-(2-methylaminophenyl)-3,7-dimethyloct-6-en-1-ol (**4**g) in the presence of phenylboronic acid*

According to general procedure C, a mixture of **4***g* (200 mg, 0.76 mmol), phenylboronic acid (250 mg, 2.06 mmol), and propionic acid (15 mg, 0.21 mmol) in 5 mL of toluene was refluxed for 32 h to give, after chromatography, 132 mg (71%) of a mixture of **6***a* and **12***a* in the ratio of 6.6:1.

*Thermolysis of (3*R*)-1-(2-methoxy-6-methylaminophenyl)-3,7-dimethyloct-6-en-1-ol (**4**h) in the presence of phenylboronic acid*

According to general procedure C, a mixture of **4***h* (200 mg, 0.69 mmol), phenylboronic acid (250 mg, 2.06 mmol), and propionic acid (15 mg, 0.21 mmol) in 5 mL of 1,2-dichloro-

benzene was refluxed for 1.5 h to give, after chromatography, 132 mg (70%) of a mixture of (6a*R*,9*R*,10a*R*)-1-methoxy-5,6,6,9-tetramethyl-5,6,6a,7,8,9,10,10a-octahydrophenanthridine **6***b* and **12***b* in the ratio of 1:1. An analytical sample of **6***b* was obtained by multiple chromatography. Compound **6***b*: $[\alpha]_D$ −51 (*c* 4.2, $CHCl_3$); ^{1}H nmr (400 MHz, CD_3COCD_3), δ: 0.61 (q, 1H, *J* = 11.4 Hz, H-10ax), 0.77 (s, 3H), 0.91 (d, 3H, *J* = 6.5 Hz), 1.10 (m, 2H), 1.30 (s, 3H), 1.44 (dt, 1H, *J* = 11.3, 2.3 Hz), 1.61 (m, 1H), 1.87 (m, 1H), 1.94 (m, 1H), 2.48 (dt, 1H, *J* = 10.7, 2.2 Hz), 2.79 (s, 3H), 2.95 (m, 1H), 3.76 (s, 3H), 6.31 (d, 1H, *J* = 8.1 Hz), 6.34 (d, 1H, *J* = 8.4 Hz), 6.97 (t, 1H, *J* = 8.3 Hz); ^{13}C nmr (100.6 MHz, $CDCl_3$), δ: 15.9, 22.7, 26.1, 28.8, 33.0, 33.1, 36.1, 37.3, 40.6, 50.2, 55.1, 55.9, 100.4, 107.6, 115.3, 126.8, 148.5, 158.4. Exact Mass calcd. for $C_{18}H_{28}NO$ (M+1): 274.2170; found: 274.2171.

*Thermolysis of (3*R*)-1-(4-methoxy-6-methylaminophenyl)-3,7-dimethyloct-6-en-1-ol (**4***i*) in the presence of phenylboronic acid*

According to general procedure C, a mixture of **4***i* (291 mg, 1 mmol), phenylboronic acid (365 mg, 3 mmol), and propionic acid (22 mg, 0.3 mmol) in benzene (10 mL) was refluxed for 20 h to give, after chromatography, 140 mg (51%) of a mixture of (6a*R*,9*R*,10a*R*)-3-methoxy-5,6,6,9-tetramethyl-5,6,6a,7,8,9,10,10a-octahydrophenanthridine **6***c* and (3*R*)-(1*E*)-[2-(3,7-dimethylocta-1,6-dienyl)-5-methoxyphenyl]methylamine **12***c* in the ratio of 10:1. An analytical sample of **6***c* was obtained by multiple chromatography. Compound **6***c*: $[\alpha]_D$ +37 (*c* 4.5, $CHCl_3$); ^{1}H nmr (400 MHz, CD_3COCD_3), δ: 0.83 (q, 1H, *J* = 11.6 Hz, H-10ax), 0.98 (d, 3H, *J* = 6.5 Hz), 1.0 (s, 3H), 1.20 (m, 2H), 1.22 (m, 1H), 1.29 (s, 3H), 1.54 (m, 1H), 1.82 (m, 1H), 1.89 (m, 1H), 2.37 (dt, 1H, *J* = 10.3, 2.7 Hz), 2.45 (m, 1H), 2.83 (s, 3H), 3.71 (s, 3H), 6.12 (d, 1H, *J* = 2.4 Hz), 6.16 (dd, 1H, *J* = 8.3, 2.4 Hz), 7.0 (d, 1H, *J* = 8.3 Hz); ^{13}C nmr (100.6 MHz, CD_3COCD_3), δ: 19.1, 23.1, 26.5, 28.7, 32.4, 33.0, 35.8, 36.0, 41.3, 48.9, 55.1, 57.7, 99.2, 100.7, 120.2, 125.9, 147.8, 160.0. Exact Mass calcd. for $C_{18}H_{28}NO$ (M+1): 274.2170; found: 274.2172. Insufficient compound **12***c* was available for complete characterization. The reaction was repeated with 225 mg (0.77 mmol) of **4***i* in refluxing 1,2-dichlorobenzene for 0.25 h to give 129 mg (61%) of **6***c* with no trace of **12***c*.

Volumetric properties of (water + diethanolamine) systems

Yadollah Maham, Tjoon T. Teng, Alan E. Mather, and Loren G. Hepler

Abstract: Densities of completely miscible (water + methyldiethanolamine) and (water + ethyldiethanolamine) systems have been measured over the full range of compositions at temperatures from 25 to 80°C. Results of these measurements have been used in calculating excess molar volumes and partial molar volumes of each component. We have also identified different measures of the thermal expansion of these systems and have calculated some of these derivative quantities. The partial molar volumes and their derivatives with respect to temperature provide a basis for extending our understanding of molecular interactions in these (water + organic) systems.

Key words: diethanolamines, excess molar volumes, partial molar volumes, expansivities, aqueous solutions.

Résumé : Opérant à des températures allant de 25 à 80°C, on a mesuré les densités des systèmes complètement miscibles (eau + méthyldiéthanolamine) et (eau + éthyldiéthanolamine) sur l'ensemble des plages de composition. On a utilisé ces résultats pour calculer les volumes molaires en excès et les volumes molaires partiels de chacun des composants. On a aussi identifié différentes mesures de l'expansion thermique de ces systèmes et on a calculé quelques-unes de ces quantités dérivées. Les volumes molaires partiels et leurs dérivées par rapport à la température fournissent une base pour étendre notre compréhension des interactions dans ces systèmes (eau + composé organique).

Mots clés : diéthanolamines, volumes molaires en excès, volumes molaires partiels, expansivité, solutions aqueuses.

[Traduit par la rédaction]

Introduction

Various (water + alkanolamine) systems are used for removal of acidic gases such as carbon dioxide and especially hydrogen sulfide from gas streams in the natural gas and petroleum industries and are of increasing importance in treating acidic gas streams in several chemical production industries. Knowledge of several properties, including densities at several temperatures, is required for engineering design and for subsequent operations, as summarized by Astarita et al. (1).

In addition to the well-established industrial uses of experimental data for these completely miscible (water + alkanolamine) systems, there is interest in using volumetric data in combination with molecular theories or models of solutions to extend our understanding of molecular interactions in (water + organic) systems. Because much of our focus in this paper is on the volumetric properties of an alkanolamine at infinite dilution in water, we cite two theoretical investigations (2, 3) that focussed on the temperature dependence of partial molar volumes of aqueous solutes. We also call attention to subsequent theory by Yoshimura and Nakahara (4), a useful review by Davis (5), and recent theory by Marcus (6). Some of each of these cited works is devoted to volumetric properties of (water + organic) systems, and some of the theoretical work by Marcus (6) is specifically concerned with volumetric properties of (water + alkanolamine) systems.

There have been two recent reports (7, 8) of volumetric properties of (water + alkanolamine) systems. We also call attention to several other reports (7–23) of volumetric properties of (water + organic) systems, which include experimental results or methods of analysis that are related to our work.

Experimental

Methyldiethanolamine [$CH_3N(C_2H_4OH)_2$, MDEA] and ethyldiethanolamine [$C_2H_5N(C_2H_4OH)_2$, EDEA] from Aldrich Chemical Company were stated to be 99% and 98+% pure. Results of titrations with standardized hydrochloric acid were consistent with purities slightly better than 99% for both MDEA and EDEA, which were then used as received. Mixtures of these ethanolamines with doubly distilled water were made by mass, with care being taken to minimize exposure to air (carbon dioxide).

Densities were measured with an Anton Paar DMA 45 density meter, which was calibrated with dry air and distilled water at each temperature, making use of densities of water from Kell (24). Accuracies of most of our densities are about $\pm(3 \times 10^{-5})$ g cm^{-3}, with accuracies of a few densities (especially at the higher temperatures) being about $\pm(8 \times 10^{-5})$ g cm^{-3}. Temper-

[a]Units are g cm^{-3} for densities (d) and are cm^3 mol^{-1} for excess molar volumes (V^E).

atures of the water bath were stable to ±0.001° during the time required to measure a density and were known to ±0.01°C, as measured with a Guildline platinum resistance thermometer.

Results

Experimental results (mole fractions and densities) and one kind of derived result (excess molar volume, V^E) are reported in Table 1 for (water + MDEA) systems and in Table 2 for (water + EDEA systems). The excess molar volume is defined by

$$[1] \quad V^E = V_m - x_1V_1^* - x_2V_2^*$$

in which V_m represents the volume of a mixture containing a total of one mole of (water + alkanolamine), x_1 and x_2 are mole

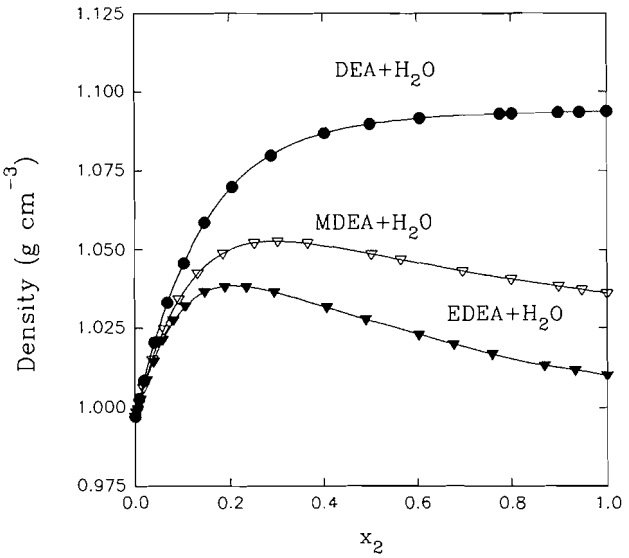
Fig. 1. Densities of (water + alkanolamine) systems at 25°C. DEA (densities from ref. 8) represents diethanolamine. MDEA and EDEA (densities from Tables 1 and 2) represent methyldiethanolamine and ethyldiethanolamine. All of these densities decrease with increasing temperature.



fractions of water and alkanolamine, respectively, and V_1^* and V_2^* are the molar volumes of the corresponding pure liquids. Equation [1] can also be expressed as

$$[2] \quad V^E = [x_1M_1 + x_2M_2)/d] - (x_1M_1/d_1^*) - (x_2M_2/d_2^*)$$

in which M_1 and M_2 represent molar masses of water and alkanolamine, respectively, and d, d_1^*, and d_2^* represent densities of a mixture of specified mole fraction, of pure water, and of pure alkanolamine, respectively. The values of V^E listed in Tables 1 and 2 were calculated from mole fractions, molar masses, and densities by way of eq. [2].

The general trends of density and V^E with increasing mole fraction of alkanolamine are illustrated in Figs. 1 and 2.

Calculations and discussion

The partial molar volume of a component ($\overline{V}_i$) is defined by

$$[3] \quad \overline{V}_i = (\partial V/\partial n_i)_{T,p,n,j}$$

Differentiation of eq. [1] and combination with eq. [3] leads (25, 26) to the following equations for the partial molar volumes of water ($\overline{V}_1$) and of alkanolamine ($\overline{V}_2$):

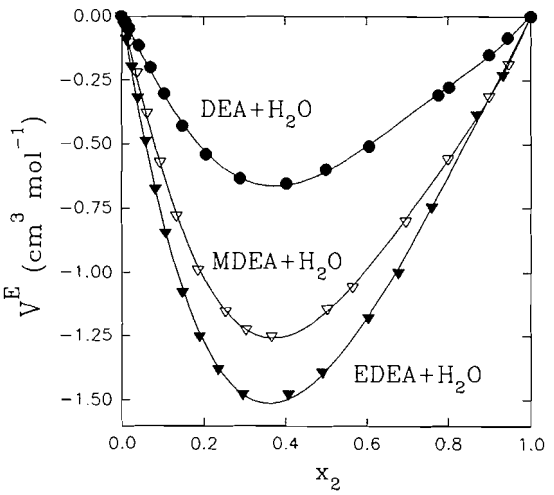
$$[4] \quad \overline{V}_1 = V^E + V_1^* - x_2(\partial V^E/\partial x_2)_{p,T}$$

$$[5] \quad \overline{V}_2 = V^E + V_2^* + (1 - x_2)(\partial V^E/\partial x_2)_{p,T}$$

Equations equivalent to [4] and [5] are presented in the useful review by Davis (5).

A convenient way to carry out the differentiations specified in eq. [4] and eq. [5] can begin with equations that will fit the V^E results that are reported in Tables 1 and 2. For this purpose we use equations of the Redlich–Kister form:

Fig. 2. Excess molar volumes of (water + alkanolamine) systems at 25°C. See legend for Fig. 1.



$$[6] \quad V^E = x_2(1 - x_2)\sum A_n(1 - 2x_2)^{n-1}$$

Redlich–Kister coefficients (A_n) are listed in Table 3 for the (water + MDEA) and (water + EDEA) systems.

Differentiation of eq. [6] with respect to x_2 and combination of the result of differentiation with eqs. [4] and [5] leads to the following equations for the partial molar volumes of water ($\overline{V}_1$) and of alkanolamine ($\overline{V}_2$):

$$[7] \quad \overline{V}_1 = V_1^* + x_2\sum A_n(1 - 2x_2)^{n-1} - 2x_2(1 - x_2)\sum A_n(n - 1)(1 - 2x_2)^{n-2}$$

$$[8] \quad \overline{V}_2 = V_2^* + (1 - x_2)^2\sum A_n(1 - 2x_2)^{n-1} + 2x_2(1 - x_2)^2\sum A_n(n - 1)(1 - 2x_2)^{n-2}$$

Much of our present interest is in the partial molar volume of water at infinite dilution ($\overline{V}_1^\circ$) in an alkanolamine and in the partial molar volume of an alkanolamine at infinite dilution ($\overline{V}_2^\circ$) in water. We therefore set $x_2 = 1$ in eq. [7] and $x_2 = 0$ in eq. [8] to obtain

$$[9] \quad \overline{V}_1^\circ = V_1^* + \sum A_n(-1)^{n-1}$$

and

$$[10] \quad \overline{V}_2^\circ = V_2^* + \sum A_n$$

Equations [7] and [8] permit calculation of the partial molar volumes of each component (not at infinite dilution) conveniently and with the accuracy that is justified by the accuracy of the experimental data; we have used these equations for this purpose as reported later in this paper. But it should be recognized that the Redlich–Kister equation [6] and its derivative equations [7] and [8] are intended to provide the best overall fit of the data in convenient form with a minimum number of adjustable parameters. It is known, however, that the Redlich–Kister equation and especially its derivatives do not always provide the best representation of properties of either component at infinite dilution in the other component. Therefore, we

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

consider two alternatives to eqs. [9] and [10] for evaluation of $\overline{V}_1^\circ$ and $\overline{V}_2^\circ$.

As shown previously (8), the apparent molar volume of water in alkanolamine ($V_{\phi,1}$) and the apparent molar volume of alkanolamine in water ($V_{\phi,2}$) can be calculated as

$$[11] \quad V_{\phi,1} = V_1^* + (V^E/x_1) = V_1^* + [V^E/(1 - x_2)]$$

and

$$[12] \quad V_{\phi,2} = V_2^* + (V^E/x_2)$$

Simple graphical or analytical extrapolation of $V_{\phi,1}$ to $x_1 = 0$ ($x_2 = 1$) leads to the desired value of $\overline{V}_1^\circ$ and similar extrapolation of $V_{\phi,2}$ to $x_2 = 0$ leads to the desired value of $\overline{V}_2^\circ$. Perron et al. (17) have used an equivalent method based on extrapolation of the "reduced volume" represented by V^E/x_1x_2 to $x_2 = 1$ or 0 to obtain equally accurate values of partial molar volumes at infinite dilution.

The methods of obtaining $\overline{V}_2^\circ$ by way of eq. [10], extrapolation of $V_{\phi,2}$, or extrapolation of V^E/x_1x_2 are all satisfactory and lead to similar results having good accuracy. On the other hand, because we have few V^E values for x_2 near unity (small x_1), accuracies of $\overline{V}_1^\circ$ values are less good, especially for those derived from Redlich–Kister coefficients and eq. [9]. The values of $\overline{V}_1^\circ$ that we cite later have all been obtained by extrapolation of $V_{\phi,1}$ values to $x_1 = 0$.

Before using the equations above with our experimental results for calculation of partial molar volumes, we turn to consideration of thermal expansion. The thermal expansion of a pure substance is often expressed in terms of the coefficient of thermal expansion, defined as $\alpha^* = (1/V^*)(\partial V^*/\partial T)_p$. It is more convenient for us to omit the $(1/V^*)$ and to consider the molar expansivity (E_i^*) of a pure substance (i) defined as

$$[13] \quad E_i^* = (\partial V_i^*/\partial T)_p$$

For a mixture the corresponding definition of the molar expansivity in terms of the molar volume represented by V is

$$[14] \quad E = (\partial V/\partial T)_{p,\text{composition}}$$

Similarly, we define a partial molar expansivity ($\overline{E}_i$) as

$$[15] \quad \overline{E}_i = (\partial \overline{V}_i/\partial T)_{p,\text{composition}}$$

Differentiation of a well-known equation for the molar volume of a mixture ($V = x_1\overline{V}_1 + x_2\overline{V}_2$) with respect to temperature and combination with the definitions expressed by eqs. [13]–[15] gives us

$$[16] \quad E = x_1\overline{E}_1 + x_2\overline{E}_2$$

as a relationship between the molar expansivity of the mixture and the partial molar expansivities of the components.

Following earlier investigations (2, 3) of the dependence of $\overline{V}_2^\circ$ on temperature in relation to "structure-making" and "structure-breaking" solutes in water, we will be concerned with

$$[17] \quad (\partial \overline{E}_2^\circ/\partial T) = (\partial^2 \overline{V}_2^\circ/\partial T^2)_p$$

Because we and others have expressed our experimental results in terms of excess molar volumes, it is useful to consider the effect of temperature on the excess volume by differentiating eq. [1] with respect to temperature, defining the excess molar expansivity as

$$[18] \quad E^E = (\partial V^E/\partial T)_{p,\text{composition}}$$

and thence obtaining

$$[19] \quad E^E = E - x_1E_1^* - x_2E_2^*$$

All of our V^E values are negative (Tables 1 and 2 and Fig. 2), as is common for other completely miscible (water + polar organic) systems. These V^E values become less negative with increasing temperature, as is also common.

Partial molar volumes of water ($\overline{V}_1$) and of alkanolamines ($\overline{V}_2$) can be calculated for all compositions by using the Redlich–Kister coefficients (Table 3) in eqs. [7] and [8]. An illustration of the results of such calculations for the partial molar volumes of MDEA over the complete range of compositions and several temperatures is provided in Fig. 3. Several previous investigators (for examples see refs. 7, 8, 12, 14, 21, and 23) have observed similar minima in graphs of $\overline{V}_2$ against mole fraction (as in Fig. 3) for various alcohols and other polar organics in water.

Koga and colleagues (19, 23) have used partial molar vol-

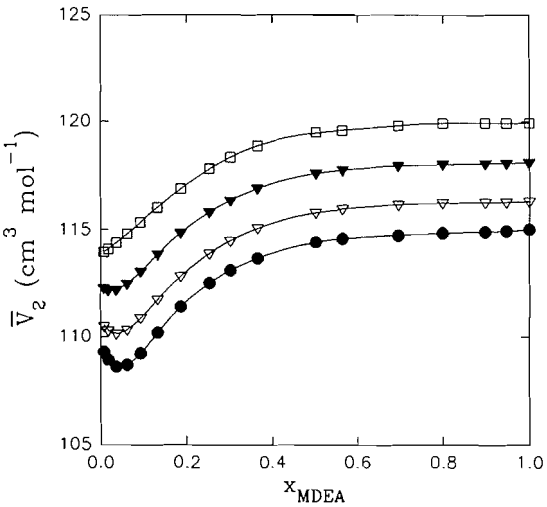
[a]Units of $\overline{V}_1°$ and $\overline{V}_2°$ are $cm^3\ mol^{-1}$.

Fig. 3. Partial molar volumes of MDEA in water at several temperatures. ●, 25°C; ▽, 40°C; ▼, 60°C; □, 80°C.



umes and several other thermodynamic properties as a basis for deducing detailed "pictures" of solute–solute, solute–water, and water–water interactions over ranges of composition for (water + 2-butoxyethanol) and (water + dimethyl sulfoxide) systems. Pagé, Huot, and Jolicoeur (7) have used their collection of thermodynamic properties (volumes, compressibilities, and heat capacities) of the (water + ethanolamine) system as a basis for their picture of molecular interactions. One of the reasons for undertaking the present investigation and also our earlier investigation (8) of the volumetric properties of other (water + alkanolamine) systems was to obtain some of the data needed for forming similar pictures of molecular interactions in these systems; calorimetric measurements are in progress. Because development of credible pictures along the lines described by Koga (19, 23) and Jolicoeur (7) requires an extensive array of thermodynamic data, we turn now to sim pler analyses that can be carried out with only our presently reported results.

Previous investigators of dilute aqueous solutions have used several criteria as a basis for describing some solutes as "structure makers" and other solutes as "structure breakers". One such classification (2, 3) is based on the sign of $d^2\overline{V}_2°/dT^2$; a positive sign corresponds to a structure-making solute while a negative sign corresponds to a structure-breaking solute. In Table 4 we list the values of partial molar volumes of MDEA and of EDEA at several temperatures at infinite dilution in water ($\overline{V}_2°$). Graphs of $\overline{V}_2°$ of MDEA and of EDEA against temperature give straight lines with positive slopes. Values of the slopes $d\overline{V}_2°/dT$ are 0.08 $cm^3\ mol^{-1}\ K^{-1}$ for MDEA and 0.10 $cm^3\ mol^{-1}\ K^{-1}$ for EDEA. Because of the linearity of $\overline{V}_2°$ against temperature, $d^2\overline{V}_2°/dT^2 = 0$ within the accuracies of our results over the temperature range 25–80°C, which means (according to the criterion of temperature dependence of partial molar volumes) that these solutes cause no net or overall structure-making or structure-breaking effects in water. It was observed earlier (8) that values of $d\overline{V}_2°/dT$ are positive and values of $d^2\overline{V}_2°/dT_2 = 0$ for other alkanolamines in water, which led to the same conclusion about these solutes being neither net structure makers nor net structure breakers.

Partial molar volumes of water at infinite dilution in MDEA and in EDEA are listed in Table 4. Accuracies of these values do not justify making any statement about $d^2\overline{V}_1°/dT^2$, but it is clear that the first derivatives $d\overline{V}_1°/dT$ are positive. All of the $\overline{V}_1°$ values are smaller than the corresponding molar volumes of pure water (V_1*) at the same temperature. This observation is consistent with the idea that the molar volume of pure water is a sum of the "actual" molecular volumes plus the "empty" volume that arises from the hydrogen-bonded "open" structure of liquid water. Partial molar volumes (8) of water at infinite dilution in other alkanolamines at several temperatures are also smaller than corresponding values of V_1* and have been interpreted similarly.

Sakurai and Nakagawa (18) have measured densities of dilute solutions of water in benzene and in several *n*-alkanols at several temperatures. They have used these densities and corresponding compositions in evaluating the partial molar volumes of water at infinite dilution (represented here by $\overline{V}_1°$) in each solvent at several temperatures. Their values of $\overline{V}_1°$ for water at infinite dilution in methanol, ethanol, *n*-propanol, and *n*-butanol at each temperature from 5 to 45°C are substantially smaller than corresponding values of V_1* and are consistent with the interpretation above.

We also note that the partial molar volumes of water in alkanols increase with number of atoms of carbon per molecule of alkanol in the sequence ethanol through *n*-octanol and that the difference between V_1* and $\overline{V}_1°$ values decreases with increasing number of atoms of carbon per molecule of alkanol. This effect is sufficiently large that the values of $\overline{V}_1°$ for water in *n*-octanol are *larger* than the corresponding values of V_1* at the higher temperatures (35 and 45°C). This observation leads us to suggest that our earlier (see above) explanation for values of $\overline{V}_1°$ being smaller than corresponding values of V_1* is probably incomplete and might even be largely mistaken.

The values of $\overline{V}_1°$ reported by Sakurai and Nakagawa (18)

for water in alkanols in the sequence ethanol through *n*-octanol and also for water in benzene lead to positive values of $d\overline{V}_1°/dT$, as also reported here and previously (8) for water in alkanolamines. All of these positive values of $d\overline{V}_1°/dT$ are consistent with the general observation that dV/dT is positive for most pure substances and most solutions. But they have also reported that $d\overline{V}_1°/dT$ is negative for water in methanol, for which neither they nor we have any satisfactory explanation.

Sakurai and Nakagawa (18) have also reported values of $V_1°$ for water in benzene that are substantially larger (3–4 cm^3 mol^{-1}) than corresponding values of V_1*. It seems reasonable to suggest that this unusual difference can be explained on the basis of disruption of the "stacked layers structure" of liquid benzene, with a consequent increase in volume. It may also be that a similar explanation involving disruption of reasonably closely packed alkane chains is appropriate for the relatively large values of $\overline{V}_1°$ for water in the larger alkanols.

We (11, 15) and others (9, 10, 13, 16, 17) have used partial molar volumes ($\overline{V}_2°$) of many organics in water to develop additivity schemes that might contribute to our understanding of organic–water interactions and that are certainly useful for predicting partial molar volumes for organic solutes in water. A few of these investigations (especially ref. 16) have led to additivity schemes for partial molar expansivities. Our further developments along these lines, based on our own and other recently reported volumes and expansivities, will be reported later.

Crystal and molecular structure of *Z*- and *E*-1,2-dichloro-1,2-bis(2-chlorophenyl)-ethylene. An X-ray and NMR study

Luciano Antolini, Ugo Folli, Dario Iarossi, Adele Mucci, Silvia Sbardellati, and Ferdinando Taddei

Abstract: The crystal structures of the title compounds were determined by single crystal X-ray diffraction techniques. The molecule of the *Z* isomer, which crystallizes in the monoclinic space group *C2/c* with $Z = 4$ in a cell of dimensions $a = 14.891(2)$, $b = 10.780(2)$, $c = 8.769(1)$ Å, $\beta = 97.47(2)°$, $V = 1395.7(7)$ Å^3, has crystallographic twofold symmetry. The *E* form crystallizes in the orthorhombic space group *Pbca* with $a = 11.730(1)$, $b = 6.932(1)$, $c = 16.841(1)$Å, $V = 1369.4(2)$ Å^3, and $Z = 4$. Its molecules have crystallographically dictated $\bar{1}$ symmetry. In both isomers the phenyl rings are roughly perpendicular to the average ethylene plane. The atoms characterizing this plane show significant deviations from planarity in the *Z* isomer. Marked bond-angle distortions at the ethene carbons of both structures are observed. The ^{1}H and ^{13}C NMR spectra of the compounds were measured and, particularly in the case of the ^{1}H chemical shifts, fall into two quite separate spectral regions. At low temperature, two conformational isomers, those with different relative orientation of the C—Cl bonds of the phenyl rings, are observed in the spectrum of each compound.

Key words: chlorostilbenes, overcrowded molecules, X-ray structure, conformations, NMR spectroscopy.

Résumé : On a déterminé les structures cristallines des composés mentionnés dans le titre à l'aide de techniques de diffraction des rayons X sur des cristaux uniques. La molécule de l'isomère *Z*, qui cristallise dans le groupe d'espace *C2/c*, avec $a = 14,891(2)$, $b = = 10,780(2)$, $c = 8,769(1)$ Å, $\beta = 97,47(2)°$, $V = 1395,7(7)$ Å^3, et $Z = 4$, possède une symétrie cristallographique binaire. La forme *E* cristallise dans le groupe d'espace orthorhombique *Pbca* avec $a = 11,730(1)$, $b = 6,932(1)$ et $c = 16,841(1)$ Å, $V = 1369,4(2)$ Å^3, et $Z = 4$. Ses molécules existent dans une symétrie $\bar{1}$ dictée par sa cristallographie. Dans les deux isomères, les noyaux phényles sont approximativement perpendiculaires au plan moyen de l'éthyléne. Dans l'isomère *Z*, les atomes caractérisant ce plan présentent des déviations significatives par rapport à la planéité. Dans les deux structures, on a observé des distorsions marquées dans les angles de liaison des carbones de l'éthène. On a déterminé les spectres RMN du ^{1}H et du ^{13}C et les déplacements chimiques, particulièrement du ^{1}H, sont divisés en deux régions spectrales bien distinctes. À basse température, dans chacun des composés, on a observé deux isomères conformationnels qui différent par l'orientation relative des liaisons C—Cl par rapport aux noyaux phényles.

Mots clés : chlorostilbènes, molécules encombrées, structure par rayons X, conformations, spectroscopie RMN.

[Traduit par la rédaction]

Introduction

The reductive coupling of benzotrichloride in anaerobic conditions in the presence of metal ions in low states of oxidation yields (1 – 4) tolane tetrachloride, which is partly dehalogenated to a mixture of *Z*- and *E*-1,2-dichloro-1,2-bis(phenyl)ethylene. When iron(II) chloride is employed, dehalogenation does not take place even in boiling acetonitrile solution (5). We have found that, when (2-chloro)benzotrichloride is reacted with iron(II) chloride, extensive dehalogenation occurs at room temperature to yield *Z*- (**1**) and *E*-1,2-dichloro-bis(2-chlorophenyl)ethylene (**2**), the *E*/*Z* isomer ratio being close to unity. The overcrowded character of the coupling product formed from (2-chloro)benzotrichloride probably accounts for the relative ease with which dehalogenation occurs.

Received February 6, 1995.

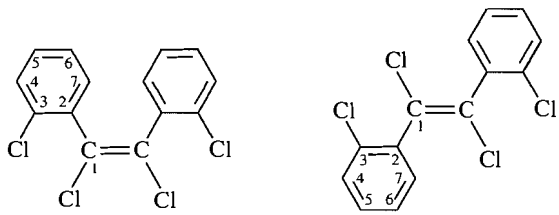
Scheme 1



1 **2**

In view of the presence of *ortho* substituents and of the chlorine atoms in the ethene fragment, compounds **1** and **2** should be conformationally hindered, and the *ortho* chlorine atoms should give rise to additional conformational preferences owing to the relative orientation of the corresponding C—Cl bonds.

Accordingly, these molecules were studied both in the solid state (X-ray spectroscopy) and in solution (NMR spectroscopy), in order to discover the extent of the constraints hindering internal rotation of the rings and the structure of the conformational minima. The results of the NMR analysis

should afford useful insight into the presence and quantity of their *E* and *Z* isomers in reaction mixtures.

Experimental

Compounds

2-Chlorobenzotrichloride (Aldrich) (5.50 g, 19.6 mmol) was dissolved in CH_3CN (80 mL) (previously distilled from P_2O_5 in Ar atmosphere). Ar was bubbled into the solution in order to obtain an inert atmosphere in the reaction apparatus. $FeCl_2 \cdot 4H_2O$ (11.91 g, 59.9 mmol) was then introduced and the mixture stirred for 7 h at 45–50°C. The reaction was quenched by dilution with water (500 mL). The precipitated organic material was filtered, thoroughly washed, first with water and then with cyclohexane (to remove colour), and dried in a vacuum desiccator over P_2O_5. The crude product (2.15 g, 69%) had mp 115–160°C and consisted of only two compounds (*E* and *Z* isomers) as revealed by TLC (SiO_2, petroleum ether bp 30–40°C/ethyl ether 3:1)and GLC (HPS cross-linked 5% PH ME silicon; *E*/*Z* ratio 45:55). Anal. calcd. for $C_{14}H_8Cl_4$: C 52.9, H, 2.5; found: C 53.5, H 2.5%.

Dissolution of the crude in hot acetone, followed by slow cooling at room temperature, yielded a fraction of almost pure *E* isomer, which was further purified by crystallization from isopropyl alcohol; mp 170–172°C (100% purity by TLC and GLC analysis); a crystal was selected for X-ray diffraction. From the acetone mother liquor, by concentration and refrigeration at 0°C, a fraction rich in the *Z* isomer was isolated, and was further purified by crystallization from *n*-hexane and finally from isopropyl alcohol; mp 125–127°C (100% purity by TLC and GLC analysis); a crystal was selected for X-ray analysis. For the high- and low-melting isomer, melting points of 170°C and 139°C, respectively, have been reported (6).

X-ray structure determination

The selected crystals were sealed in a glass capillary and transferred directly to an Enraf-Nonius CAD4 diffractometer. All measurements were carried out at room temperature under the conditions summarized in Table 1, which also contains information relating to data reductions and structure determinations.

Major calculations were carried out on a VAX 6310 computer with the use of the SHELX-86 program (8) for structure solution, SHELX-76 (9) for least-squares refinements and source of scattering factors, and ORTEP (10) for molecular drawings. Final fractional atomic coordinates and equivalent isotropic thermal parameters are given in Tables 2 and 3 for the *Z* and *E* forms, respectively.[2]

[2] Tables of anisotropic thermal parameters for non-hydrogen atoms, complete bond distances and bond angles, torsion angles, selected least-squares planes, and stereoviews of unit cell contents may be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON K1A 0S2, Canada.

Structure factor amplitudes are no longer being deposited and may be obtained directly from the authors.

Tables of bond lengths and angles and stereoviews of unit cells have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from the Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

NMR measurements

The spectra were measured with a Bruker AMX-400 spectrometer operating at 400.13 and 100.61 MHz for ^1H and ^{13}C nuclei, in $CDCl_3$ solution (0.1 M). Chemical shifts are given as δ values referring to TMS. The acquisition time was 5–6 s for ^1H and 1–2 s for ^{13}C spectra. ^{13}C NMR data were obtained from ^1H-detected chemical shift correlation via heteronuclear multiple-quantum coherence (HMQC) (11) and ^1H-detected heteronuclear multiple-bond correlation (HMBC) (12) experiments with standard pulse sequences. The delay Δ_1 = 3.07 ms was employed for the evolution of ^1J(CH) in HMQC and for the low-pass *J*-filter in HMBC, and the delay Δ_2 = 50 ms for the long-range coupling constant evolution in HMBC; AQ = 0.6 s and the resolution in *f*1 before zero-filling was 0.1–0.2 ppm.

Results and discussion

Table 4 lists selected interatomic distances and bond and torsion angles for both structures. The molecule of the *Z* isomer (Fig. 1) lies on a crystallographic twofold axis, whereas that of the *E* form (Fig. 2) has an inversion center at the midpoint of the ethene bond. Hence, in both cases, the asymmetric unit contains one half molecule.

The conformation of the molecules can be described in terms of torsion angles around the C(1)—C(2) bond or by means of the dihedral angle between mean planes through the ethene and phenyl moieties. These torsional (see Table 4) and dihedral angles (80.1° and 82.2° for the *Z* and *E* forms, respectively) show that the phenyl groups have quite similar and roughly normal orientations with respect to the ethene plane. This conformation differs significantly from those observed for the *Z* and *E* isomers of tetrachlorostilbene (1,2-dichloro-1,2-bis(4-chlorophenyl)ethylene) (13, 14), characterized by torsion angles of about 54 and 75°, respectively. It appears that the larger dihedral angles between the phenyl rings and the ethene plane in these compounds can be attributed mainly to the repulsive interaction between the Cl(1) and Cl(2) atoms (Table 4). The dihedral angles become smaller in the 4-chlorophenyl analogues since in their case the repulsive interaction involves the Cl(1) and H atoms. The phenyl rings make a dihedral angle of 69.7° between themselves in the *Z* form, whereas they are exactly parallel, for reasons of symmetry, in the *E* isomer. It should also be pointed out that the six atoms belonging to the ethene fragment of the *Z* isomer display relevant distortions from coplanarity, with atomic deviations ranging from +0.056 to −0.056 Å. Similar, but slightly larger, distortions from planarity were also observed in the ethene moiety of *Z*-dichlorostilbene (13) and, in both cases, could be determined by short, nonbonded intramolecular interactions. A Cl(1)···Cl(1′) separation of 3.07 Å was observed in the above-cited compound, which compares with a value of 3.139(1) Å in our *Z* isomer.

There are no significant differences between corresponding bond distances in compounds **1** and **2** and they compare well with those reported for *E*- and *Z*-dichlorostilbene (13). In both structures, the ethene fragment suffers from considerable strain in the bond angles, which deviate significantly from 120°. An increase in the C(1′)-C(1)-C(2) bond angles (see Table 4) and a parallel decrease in the Cl(1)-C(1)-C(2) angles is observed as well. These angular deformations are more

likely to be due to short, nonbonded intramolecular interactions between atoms of *o*-chlorophenyl substituents and the chlorines attached to the ethene fragment than to electronic effects.

The molecular packing of compounds **1** and **2** is characterized by a lack of short van der Waals contacts. In both cases, only three interatomic distances less than 3.60 Å were observed; the shortest ones are a Cl(2)···Cl(2) contact of 3.421(1) Å in the *Z* isomer, and a Cl(1)···C(4) separation of 3.464(3) Å in the *E* form. Nevertheless, the crystal packing of the *Z* isomer shows evidence of weak π–π interactions between the molecules stacked in the 1 0 −1 direction. The stacking distance between mean planes through phenyl rings is 3.621 Å, and the shortest C···C contact 3.640(4) Å. The molecules of the *E* isomer are stacked along the *b* direction, but at a distance of one axis length (6.932 Å). The closest, albeit weak, ring–ring interactions occur between phenyl groups whose mean planes make a dihedral angle of 61.3°. In both isomers, the ring chlorine atoms are oriented in such a way as to allow the rings to come close together. The ^1H and ^{13}C chemical shifts measured at 300 and 240 K for compounds **1** and **2** are reported in Table 5. The δ values were obtained fom 1D spectra, whereas the assignment was performed through 2D inverse detection: HMQC (11) and HMBC (12) experiments were performed and ^1H chemical shifts were simulated with the DNMR5 program (15). The signal assignment is mostly

based on the fact that only H(7) affords a correlation with C(1) in the HMBC spectrum. The spectral lines of the protons show different widths at half-height, indicating that slow internal rotation(s) occur. The ^{1}H spectrum of compound **1** is closer to first order and the signals of the single protons are at higher field than in compound **2**. The sharpest signals are those at 7.13 ppm and the broadest those at 7.25 ppm. The ^{1}H spectrum of compound **2** is strongly coupled and contains two groups of signals with the same integrated area, one within 7.45–7.52 ppm and the other within 7.32–7.38 ppm. On lowering the sample temperature to 240 K, the spectrum of each compound shows the presence of two chemical species, in the ratio 85/15 for compound **1** and 45/55 for compound **2**. In the ^{13}C spectrum of **2**, the splitting of a number of signals is observed already at 300 K and all the signals are split at 240 K, yet for compound **1** this occurs only at 240 K.

The internal rotation process in these molecules can occur

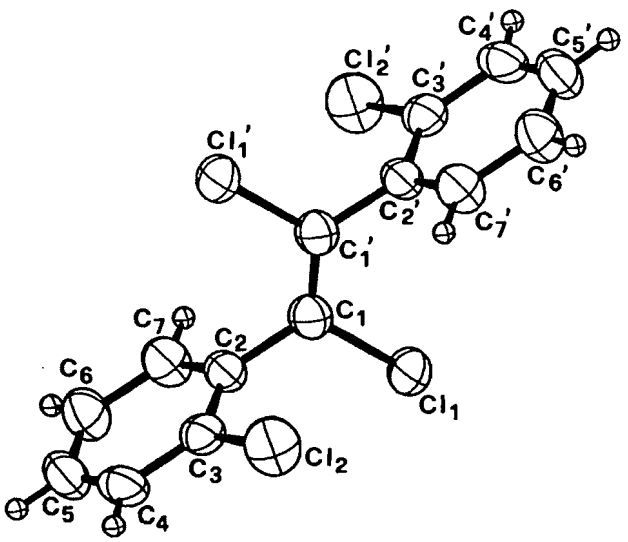
Fig. 2. The structure of *E*-1,2-dichloro-1,2-bis(2-chlorophenyl)-ethylene with atom labelling scheme. Thermal motion ellipsoids enclose 50% probability. Primed atoms are related to unprimed ones by the symmetry transformation $1 - x$, $1 - y$, $1 - z$ of the reference coordinates.



around the hexocyclic C(sp^2)—C(sp^2) bond and the conformational minimum is expected for the phenyl ring almost perpendicular to the plane of the double bond, owing to the presence of the chlorine atom on C(1). Two orientations are nevertheless expected, which we will label *syn* and *anti*, in view of the fact that the C—Cl bonds on the phenyl rings can be located on the same or opposite side with respect to the ethylenic plane. The rotational minima for the phenyl rings almost perpendicular to the double-bond plane are found from semi-empirical AM1/MNDO (16) calculations, and the *anti* are more stable than the *syn* conformations in compounds **1** and **2**. The *anti* form is that found in the solid state structure of these compounds.

The higher field ^1H resonance in compound **1** with respect to compound **2**, for the *syn* and *anti* forms, can probably be attributed to reciprocal screening due to the ring current effect, which should be less efficient in the *E* isomer, **2**. It is trickier to justify the small relative ^1H chemical shifts of the *anti* and *syn* forms in each compound, which would appear to depend mainly on the orientation of the protons with respect to the C—Cl bonds of the phenyl rings and from other effects that are difficult to quantify.

Action of tetrabutylammonium tribromide with *para*-substituted chalcones in protic and aprotic media

Jacques Berthelot, Yamina Benammar, and Bernard Desmazières

Abstract: Bromination of the double bond of *para*-substituted chalcones under mild conditions in aprotic solvents is accomplished with high yields using tetrabutylammonium tribromide ($TBABr_3$). In methanol, the main reaction is (α-β) bromomethoxylation. Stereoselectivity, regioselectivity, and chemioselectivity of this bromomethoxylation reaction are described.

Key words: bromination, bromomethoxylation, tetrabutylammonium tribromide, (α-β) dibromodihydrochalcones, α-bromo,β-methoxydihydrochalcones.

Résumé : La bromation de la double liaison ethylènique de chalcones *para*-substituées a été effectuée en utilisant le tribromure de tétrabutylammonium ($TBABr_3$). Cette réaction, dans les solvants aprotiques, se produit dans des conditions douces et les rendements obtenus sont élevés. Dans le méthanol, le produit majoritaire correspond à une (α-β) bromométhoxylation. Les aspects stéréo, régio et chémiosélectifs de cette réaction de bromométhoxylation sont envisagés.

Mots clés : bromination, bromométhoxylation, tribromure de tétrabutylammonium, (α-β) dibromodihydrochalcones, α-bromo-β-méthoxydihydrochalcones.

(α-β) Dibromodihydrochalcones **I** and α-bromo,β-methoxydihydro chalcones **II** are interesting intermediates in the synthesis of biologically active cyclic compounds such as pyrazolines (1), pyrimidines (2), imidazoles (1), aziridines (2), and quinoxalines (3). Some chalcones are also used as precursors in the synthesis of natural compounds such as flavones (4). Compounds **I** are usually prepared using bromine (alone or with an excess of bromide) or *N*-bromosuccinimide (NBS) in weakly polar, aprotic solvents (CCl_4, $CHCl_3$, CH_2Cl_2). Yields are limited by secondary reactions, e.g., bromination of aromatics (4). The members of group **II** are normally prepared in methanol (after several days of heating) using either bromine, NBS in excess, or methylhypobromite. Yields are limited, and compounds **I** are produced as by-products. Yields for the group **II** compounds improve when an excess of NBS in hot methanol is used in the presence of acids, bromine, or silver salts (5, 6). Group **II** compounds can also be synthesized by high-temperature methanolysis of the dibromo products **I**; however, this reaction is not general, as it depends strongly on the nature of the aromatic substituents (4).

We have used tetrabutylammonium tribromide ($TBABr_3$) to perform regioselective bromination of activated aromatics (phenols and amines) (7) in high yields and without polymerization. $TBABr_3$ (a stable, non-hygroscopic solid) is easy to use under mild conditions and, unlike bromine, it is neither corrosive nor toxic. We hoped that use of this reagent to perform room temperature bromination of chalcones might lead to improved yields in the synthesis of **I** or **II**.

Results

We used *para*-substituted chalcones in the (*E*) configuration as reactants. The products (**I** and **II**) were characterized by physical and spectroscopic methods and were positively identified by comparison with authentic samples.

(a) In aprotic solvents

In $CHCl_3$ one equivalent of $TBABr_3$ was found to nearly quantitatively brominate one equivalent of chalcone (Table 1) at room temperature.

[1] X-PhCOCH=CHPh-Y + $TBABr_3$
1 **2**

→ X-PhCOCHBr-CHBrPh-Y + TBABr
I **3**

Sonication (50 kHz) of the reactant mixture at 20°C greatly reduced reaction times and increased yields of the (α-β) dibromo compounds to more than 95% in all cases (Table1). In order to optimize the experimental conditions, chalcone **1***a* was used as a model reactant with different solvents, $CHCl_3$, CCl_4, CH_2Cl_2, or CH_3CN (Table 2). At 60°C the bromination reaction was faster (3 h), but the yield was lower (50%) due to polymerization of the enone system. As seen in Table 2, the best yields were obtained by sonicating stoichiometric proportions of the reactants, in chloroform at room temperature.

With each chalcone, only the (α-β) dibromo compound **I** was obtained as a racemic mixture of *erythro* isomers. Bromination of double bonds by bromine has been studied in a large number of solvents, and its mechanism is well known (5, 8, 9). However, few studies of bromination by Br_3^- have been reported. Generally, this anion is generated in situ by reaction of bromine with excess Br^- (7). Bellucci et al. have proposed the following mechanism for tribromide in $CHCl_3$ (10) (Scheme 1).

This *trans* addition was confirmed by the reconversion of the dibromides back to the initial chalcones using an excess of iodide (11).

(b) In methanol

Enone bromination with bromine, NBS, or methyl hypobromite in methanol gives three main products, namely, the dibrominated (D.B.) and the (α-β) bromomethoxylated regioisomers whose proportions depend on the experimental conditions (12) (Scheme 2).

Substitution reactions (when alkyl groups are present), electrophilic addition to aryl moieties, enone polymerization, and formation of secondary derivatives (β brominated or β methoxybrominated ketones) can also occur concurrently (13).

The reaction in methanol was performed in the same way as in aprotic solvents. Compound **1***a* was used as a model to study this reaction. The results are summarized in Table 3.

The best yield of the C_α compound was obtained at 20°C with sonication (experiment 3); there was no evidence for the formation of the C_β regioisomer and no secondary products or polymerization (except at 60°C). Yields of the dibrominated compound were small (about 5%) except in the $CHCl_3$–MeOH mixture. After 3 days of stirring in methanol, in the absence or presence of $TBABr_3$, the dibromide can be recov-

ered intact, and there was no noticeable formation of methoxylated derivatives. This result eliminates the possibility that the formation of the dibrominated compound is a first step, followed by partial methanolysis.When an excess of NaBr (or $NaHCO_3$) was added, there was no noticeable modification of the chemioselectivity.

Results obtained with *para*-substituted chalcones

Based on the results obtained with **1***a*, reactions with the *para*-substituted chalcones were carried out using stoichiometric proportions at room temperature in methanol.

Regardless of the mixing conditions (stirring or sonication), the same results were obtained with each chalcone. The only noticeable difference was the accelerated rate of reaction when ultrasound was used. In all cases, global yields were almost quantitative. Polymerization and formation of by-products were inhibited, and bromination was slower than in $CHCl_3$. Only chalcones bearing an electron-withdrawing group (Br or NO_2) on the aromatic ring vicinal to the carbonyl group are transformed into a mixture of the two (α-β) bromomethoxylated regioisomers. Chalcones containing an electron-donating group (**1***b*, **1***c*, **1***f*) give quantitatively the C_α brominated derivative. With regard to chemioselectivity, it appears that the yield of the dibrominated compound increases when the reaction time increases. It is worth noting the essential role that the solvent plays in this reaction (8, 9). The equilibrium constant for the reaction $Br_3^- \leftrightarrows Br_2 + Br^-$ is strongly dependent on the nature of the solvent ($K_D = (7–9) \times 10^{-6}$ in aprotic solvents such as $CHCl_3$ or CH_3CN, but $K_D = 5 \times 10^{-3}$ in methanol) (8) Since the reaction is slow in methanol (from 25 to 72 h depending on the enone), the two brominating reagents (Br_2 and Br_3^-) must be present simultaneously, and bromination by $TBABr_3$ in methanol seems to be a complex process. Presumably the chalcones with electron donors give Markovnikov additions where product arises from normal nucleophilic capture β to the carbon bearing the C(O)Ar unit. Electron withdrawers change the electronic distribution and the relative α/β attack in MeOH. This interpretation is supported by the results obtained by Heasley et al., who studied the reaction of Br-Cl with (α-β) unsaturated esters (14).

[a]Yields for pure, isolated compound.

While the bromination of alkenes by Br_2 is a basic reaction in organic chemistry, the electrophilic addition of Br_3^- to ethylenic compounds is uncommon, except when it occurs indirectly. The use of $TBABr_3$ in synthesis of brominated chalcones is interesting and useful as it allows excellent yields, without polymerization as a side reaction, under mild reaction conditions. The essential role of the solvent is confirmed in these reactions.

Experimental

General remarks

All chalcones, with the exception of **1***a*, which was purchased from Aldrich Chemical Co, were prepared according to the usual method, the Claisen–Schmidt reaction. The appropriate aldehydes and acetophenones were used in equimolecular proportions in ethanol and were treated with an aqueous NaOH solution (20–40%) (15). $TBABr_3$ was obtained from Janssen Chemica. Melting points were measured using a Köfler hot bench. ^1H NMR spectra were recorded using an AC 200 Bruker spectrometer (200 MHz, solution in $CDCl_3$, internal reference TMS, chemical shifts in ppm). Mass spectra (MS) were obtained using a Ribermag R10–10 C quadrupolar mass spectrometer.

The purity of the products was checked by thin-layer chromatography (stationary phase: fluorescent silica gel, mobile phase: diethyl ether – hexane in variable proportions, generally about 20%:80%, respectively). Purification was performed by preparative chromatography on fluorescent silica gel (Merck PF-254, 20 cm × 20 cm plates, thickness 0.1 cm), using diethyl ether and hexane as eluent.

As the dibrominated and bromomethoxylated compounds are thermally unstable, it was not possible to use gas chromatography.

A standard ultrasonic cleaning bath (50 kHz) was used (at room temperature) for reactions requiring sonication.

Reaction conditions

Reactions were generally performed at room temperature, 2×10^{-3} mol of chalcone and 2×10^{-3} mol of $TBABr_3$ were dissolved in 100 cm^3 of solvent. The reactions were carried out using either mechanical stirring or ultrasound. The initially red-colored solution changed gradually to yellowish and finally became colourless, at which point the reaction was

complete, as confirmed by TLC. The solvent was evaporated and the residue, dissolved in diethyl ether, was washed first with aqueous 5% sodium thiosulfate solution and finally with water. After evaporation of the solvent, a colorless oil was obtained.

In the case of bromination reactions performed in aprotic medium, the pure dibrominated compound was readily precipitated by addition of a small amount of ethanol.

For reactions performed in methanol, the putative dibrominated compound was crystallized by adding a few drops of ethanol. After separation of the dibrominated compound, the remaining solution, which contained the bromomethoxylated compound (or the two regioisomers in the case of **1***d* and of **1***e*), was purified using preparative chromatography.

(α-β) Dibromo dihydrochalcones I: APhCOCH$_\alpha$Br-CH$_\beta$BrPhB

All of these compounds were characterized by ^{1}H NMR, the -CHBr-CHBr- system of vicinal *erythro* dibrominated compounds giving two doublets between 5 and 5.9 ppm, with a coupling constant $J_{\alpha\beta} = J_{\beta\alpha}$ of 10–12 Hz (17). These latter values are characteristic of two protons in the *anti* position. The compounds were identified by comparison with samples prepared according to literature data (identical physical constants and spectroscopic properties).

α-Bromo β-methoxy dihydrochalcones II: APhCOCH$_\alpha$Br-CH$_\beta$(OMe)PhB

As previously mentioned, the chalcones **1***a, b, c, f,* and *g* give only one bromomethoxylated regioisomer **II**. The compounds **II***a, b, c, f,* and *g* were purified using preparative chromatography as mentioned above and were identical to compounds prepared according to the literature. ^{1}H NMR spectra display characteristic doublets (between 5 and 5.9 ppm) corresponding to the -CH(Br)-CH(OMe)- system and a singlet between 3.1 and 3.8 ppm (3H) corresponding to the β methoxy.

In the case of **II***d* and **II***e*, a mixture of two bromomethoxylated regioisomers C$_\alpha$ and C$_\beta$ was obtained after purification by preparative chromatography. These two isomers were not separated using GC (because of their thermal instability) or liquid chromatography (TLC or HPLC). They were characterized by ^{1}H NMR and mass spectroscopy. The relative abundances of the two isomers were determined by ^{1}H NMR. The regioisomers **II***e* have not been described previously. Only the **II***d* C$_\alpha$ compound was known previously (16*e*), but a similar preparation resulted in an unstable oil containing the two regioisomers.

II*a*: mp 78°C (lit. (16*h*) mp 77°C); NMR δ_H: 7.25–8.2 (10H, m), 5.15 (1H(α), d, $J_{\alpha\beta}$ 11.7 Hz), 4.75 (1H(β), d, $J_{\beta\alpha}$ 11.7 Hz), 3.1 (3H, s), MS (EI) *m/z*: 287–289 ((M − OCH$_3$)$^+$, 90%), 121 ((PhCHOCH$_3$)$^+$, 100%), 105 ((PhCO)$^+$, 75%).

II*b*: mp 110°C (lit. (16*i*) mp 109°C); NMR δ_H: 7.9 (2H, d), 7.3 (2H, d), 7.0 (4H, d), 5.2 (1H(α), d, $J_{\alpha\beta}$ 10 Hz), 4.8 (1H(β)), d, $J_{\beta\alpha}$ 10 Hz), 3.85 (3H, s), 3.2 (s, 3H); MS (EI) *m/z*: 299 ((M − Br)$^+$, 40%), 151 ((MeOPhCHOCH$_3$)$^+$, 100%), 135 ((CH$_3$OPhCO)$^+$, 95%), ((PhCHOMe)$^+$, 30%).

II*c*: mp 125°C (lit. (16*j*) mp 126°C); NMR δ_H: 7.8–8.0 (2H, m), 7.4–7.2 (5H, m), 7.0 (2H, d), 5.1 (1H(α), d, $J_{\alpha\beta}$ 10 Hz), 4.8 (1H(β), d, $J_{\beta\alpha}$ 10 Hz), 3.8 (3H, s), 3.2 (3H, s); MS (EI) *m/z* : 348–350 (M$^{+\cdot}$, 3%), 238 ((M−(Br + OCH$_3$)$^+$, 28%), 207 ((M − (Br + 2OCH$_3$))$^+$, 20%), 135 ((CH$_3$OPhCO)$^+$, 100%), 121 ((PhCHOCH$_3$)$^+$, 55%), 105 ((PhCO)$^+$, 35%).

II*f*: mp 102°C (lit. (16*k*) mp 102°C); NMR δ_H: 7.7–8.0 (2H, m), 7.4–7.0 (5H, m), 6.9–6.8 (2H, m), 5.1 (1H(α), d, $J_{\alpha\beta}$ 9.8 Hz), 4.7 (1H(β), d, $J_{\beta\alpha}$ 9.8 Hz), 3.75 (3H, s), 3.1 (3H, s), MS (EI) *m/z*: 348–350 (M$^{+\cdot}$, 5%), 238 (M − (Br + OCH$_3$))$^+$, 35%), 207 ((M − (Br + 2OCH$_3$))$^+$, 10%), 151 ((MeOPhCHOCH$_3$)$^+$, 100%), 105 ((PhCO)$^+$, 80%).

II*g*: mp 118°C (lit. (16l) mp 115°C); NMR δ_H: 7.3–8. (9H, m), 5.1 (1H(α), d, $J_{\alpha\beta}$ 12 Hz), 4.7 (1H(β), d, $J_{\beta\alpha}$ 12 Hz), 3.15 (3H, s); MS(EI) *m/z*: 321–323–325 ((M − OCH$_3$)$^+$, 1%), 273–275 ((M − Br)$^+$, 20%), 155–157 ((ClPhCHOCH$_3$))$^+$, 80%), 105 ((PhCO)$^+$, 100%).

The mixture of the two regioisomers of **II***d* was an oil. MS (EI) *m/z*: 365–367–369 ((M − OMe)$^+$, 1%), 317–319 ((M − Br)$^+$, 5%), 227–229 ((BrPhCOCH(OCH$_3$)$^+$, 35%), 183–185 ((BrPhCO)$^+$, 30%), 121 ((PhCHOCH$_3$)$^+$, 100%). The peak at *m/z* 227–229 is characteristic of the presence of C$_\beta$, the peak at 121 indicates the presence of C$_\alpha$.

(α) BrPhCOCH$_\alpha$Br-CH$_\beta$(OMe)Ph: NMR δ_H: 7.1–7.8 (aromatic H, m), 4.9 (1H(α), d, $J_{\alpha\beta}$ 12.5 Hz), 4.6 (1H(β), d, $J_{\beta\alpha}$ 12.5 Hz), 3.1 (3H, s). This is consistent with the *erythro* structure (17).

(β) BrPhCOCH$_\alpha$(OMe)-CH$_\beta$BrPh: NMR δ_H: 7.1–7.8 (aromatic H, m), 5.05 (1H(α), d, $J_{\alpha\beta}$ 12,5 Hz), 4.7 (1H(β), d, $J_{\beta\alpha}$ 12.5 Hz), 3.3 (3H, s). This is consistent with the *erythro* structure (17).

Comparison of the singlet integrations corresponding to the three protons of the methoxy groups of each regioisomer gives the ratio (α)/(β) = 1/3.

Similarly, for the mixture of the regioisomers of **II***e*: MS (EI) *m/z*: 332–334 ($(M-OCH_3)^+$, 5%), 253 ($(M - (Br + OCH_3)^+$, 25%), 194 ($(NO_2PhCOCH(OCH_3)^+$, 35%), 150 ($(NO_2PhCO)^+$, 95%), 121 ($(PhCH(OCH_3)^+$, 100%). The peak at *m/z* 194 indicates the presence of C_β and the peak at 121 the presence of C_α.

(α) $NO_2PhCOCH_\alpha Br\text{-}CH_\beta(OCH_3)Ph$: NMR δ_H: 8.3–7.3 (aromatic H, m), 4.6 (1H(α), d, $J_{\alpha\beta}$ 12.6 Hz), 4.4 (1H(β), d, $J_{\beta\alpha}$ 12.6 Hz), 3.4 (3H, s). This is consistent with the *erythro* structure (17).

(β) $NO_2PhCOCH_\alpha(OMe)\text{-}CH_\beta BrPh$: NMR δ_H: 8.3–7.3 (aromatic H, m), 4.7 (1H(α), d, $J_{\alpha\beta}$ 12.6 Hz), 4.5 (1H(β), d, $J_{\beta\alpha}$ 12.6 Hz), 3.6 (3H, s). This is consistent with the *erythro* structure (17). As described above, we obtained (α)/(β) = 2/3.

Kinetics and mechanism of the oxidation of the sulphite ion by the Mn(III)–cydta complex ion

Uttra Chandrawat, Aditya Prakash, and Raj N. Mehrotra

Abstract : The reinvestigated oxidation of S(IV), HSO_3^-/SO_3^{2-} ions, by $[Mn(cydta)(OH_2)]^-$ confirmed that S(IV) is oxidized in two parallel paths; the order with respect to [S(IV)] is one in one of the paths and two in the other. The nature of the dependence of the rate on $[H^+]$ is also confirmed. However, the rapid scan of the reaction mixture and measurement of the initial absorbance of the reaction mixture at different wavelengths at the beginning of the reaction suggest an outer-sphere mechanism. The rate parameters are of the same order as obtained in known reactions of an outer-sphere mechanism and this mechanism is further supported by the Marcus cross relation.

Key words: kinetics, outer-sphere mechanism, $[Mn(cydta)]^-$, SO_3^{2-}.

Résumé : Un réexamen de la réaction d'oxydation du S(IV), des ions HSO_3^-/SO_3^{2-}, par le $[Mn(cydta)(OH_2)]^-$ a permis de confirmer que le S(IV) est oxydé par deux voies parallèles; l'ordre de la réaction par rapport au [S(IV)] est de un dans l'une des voies et de deux dans l'autre. On a aussi confirmé la nature de la dépendance de la vitesse de réaction sur la $[H^+]$. Toutefois, un balayage rapide du mélange réactionnel et une mesure de l'absorbance initiale du mélange réactionnel à diverses longueurs d'onde au début de la réaction suggèrent l'existence d'un méchanisme de couche externe. Les paramètres de vitesse sont du même ordre que ceux obtenus dans des réactions connues de mécanisme de couche externe et ce dernier est aussi supporté par la relation croisée de Marcus.

Mots clés : cinétique, mécanisme de couche externe, $[Mn(cydta)]^-$, SO_3^{2-}.

[Traduit par la rédaction]

Introduction

The oxidation of S(IV) (HSO_3^-/SO_2^{2-}) by metal ions has the following unusual feature: both one- and two-electron net oxidations occur, and the product may be sulphate, the dithionate ion, or, more often, a mixture (1). The oxidation of the S(IV) ion, a subject of much attention in the past, is of current interest (2). Parallel first- and second-order dependence on [S(IV)] were suggested in an inner-sphere mechanism with the assumption that $cydta^{4-}$ acted as a pentadentate ligand allowing S(IV) to occupy the sixth coordination site of manganese(III) (3). There are, however, both early (4) and recent (5) literature references suggesting that $[Mn(cydta)(OH_2)]^-$ is a seven-coordinated complex in which $cydta^{4-}$ is a hexadentate ligand in aqueous $[Mn(cydta)(OH_2)]^-$ solution and the seventh coordination site is occupied by water. The same is true for the complex solution in methanol (6). Therefore this reinvestigation was considered desirable. The previous results (3), the parallel first- and second-order paths in [S(IV)] and an increase in the rate with pH, are confirmed although the inverse rate dependence on $[H^+]$ is linked to a first-order path in [S(IV)] rather than a path second-order in [S(IV)] (3). Similarly, the reaction path with $S_2O_5^{2-}$ accounts for the second-order path in [S(IV)]. In addition to the spectral evidence, which did not support the formation of an inner-sphere complex (though the formation of a precursor complex is not excluded), other evidence, such as comparison of the estimated rates of electron transfer with other outer-sphere reactions (5) including the oxidation of dithionite ion (7) and the application of the Marcus cross-relation (8), are indicative of an outer-sphere mechanism.

Experimental

Materials

Acetic (Sarabhai-M, GR) and perchloric (E. Merck, GR) acids were standardized against a standard alkali. Sodium acetate (Sarabhai, GR) solution was prepared by weight. An approximate $Mn(ClO_4)_2$ (G.F. Smith) solution, prepared in dilute perchloric acid, was standardized against a standard EDTA solution using PAR (4-(2-pyridylazo)-resorcinol) indicator (9). *trans*-Cyclohexane-1,2-diamine-*N*,*N*,*N*′,*N*′-tetraacetic acid (cydta) was obtained from Baker and Sigma. All chemicals, certified or reagent grade, were used as received.

The Mn(III) complex was prepared by the oxidation of $[Mn(cydta)]^{2-}$ by PbO_2 in dilute sulphuric acid (10). The use of excess PbO_2 was avoided because it causes the oxidation of H_4cydta to formaldehyde. The $PbSO_4$ and PbO_2 were filtered

through a sintered crucible and the pH of the filtrate was adjusted to 4. The stock solution, stored in a refrigerator, was suitably diluted in the desired buffer and standardized spectrophotometrically at 510 nm ($\epsilon = 345$ dm^3 mol^{-1} cm^{-1} at pH <6) (4). The pH was checked with an Agrionic pH meter. Twice-distilled water, purged with nitrogen for at least 1 h, was used for the preparation of solutions.

The freshly prepared sodium sulphite (Baker, Analyzed grade) solution was standardized iodometrically (11). An acetate concentration of 0.06 mol dm^{-3} was present in the buffered solution prepared by mixing sodium acetate and acetic acid solutions in the required ratio (12).

Rate measurements

The rate of the reaction was measured, under pseudo-first-order conditions ($[SO_3^{2-}] \gg [Mn(cydta)(OH_2)^-]$), in terms of the disappearance of $[Mn(cytda)(OH_2)]^-$ at 510 nm using a Union Giken RA-401 stopped-flow spectrophotometer. The temperature of the reactant solutions (±0.1°C) in storage cylinders was maintained at the desired temperature by circulating water from a Haake D8G circulatory water bath. Several measurements were made on a particular run, storing good stopped-flow traces for averaging and calculation of k_{obs}, the pseudo-first-order rate constant. The standard deviation for the k_{obs} values was <5% at low $[SO_3^{2-}]$ and between 5 and 10% at high $[SO_3^{-2}]$.

Test for free radical

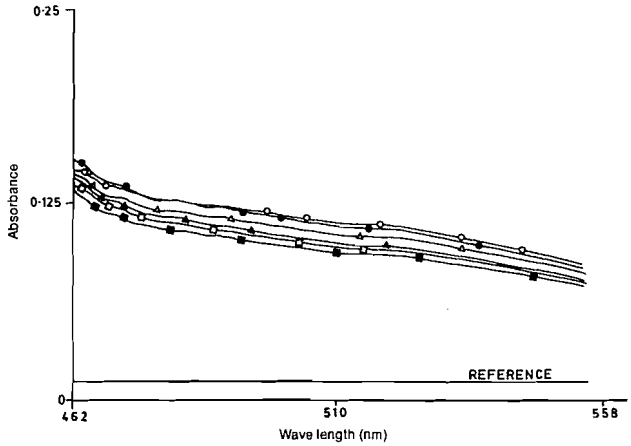
The addition of 1 mL of acrylonitrile to solutions of $[Mn(cytda)(OH_2)]^-$ and SO_3^{2-}, purged with nitrogen, did not show cloudiness even on long standing. However, a curdy precipitate of polyacrylonitrile obtained on mixing these solutions indicated the formation of free radicals during the reaction.

Rapid scanning

A rapid scan of the reaction mixture covering 48 nm on either side of 510 nm, Fig. 1, was recorded on a Union Giken RA-415 stopped-flow spectrophotometer using a 3.5 nm slit and the spent reaction mixture as the reference. This short range, sufficient for the detection of the newly formed species, is recorded over a period of a few milliseconds after mixing. The spectra, top to bottom, were recorded at 3, 5, 9, 13, 15, and 17 ms after mixing. The decreasing absorbance, over a period much less than the period over which the reaction was studied, did not represent the formation of an intermediate because the concentration of such an intermediate, if formed, is likely to increase with time unless its rate of decomposition is faster than its rate of formation. In that case the reaction is unlikely to proceed through an intermediate complex. Hence, the decrease in the absorbance is probably due to the reduction of $[Mn(cydta)(OH_2)]^-$ ion.

In another experiment the initial absorbance of the stopped-flow traces at the time of initiation of the reaction were measured over 470–610 nm at 10 nm intervals. These were compared with the absorbance obtained when S(IV) solution was replaced with water but using the same $[Mn(cydta)(OH_2)]^-$ solution. No significant changes in the absorbance were noted at any of the wavelengths used. Hence it is concluded that no new species was formed on mixing solutions of $[Mn(cydta)(OH_2)]^-$ and S(IV).

Fig. 1. The successive rapid scan spectra of the reaction mixture ($10^4[Mn(cydta)^-] = 4.0$, $10^2[\text{sulphite}]_0 = 1.08$ mol dm^{-3}, pH 4.27 at 25.3°C) recorded at 510 nm with an interval of 0 ms and a gate time 1 ms. The spectrum starting from top to bottom corresponds to the times 3 (●), 5 (○), 9 (△), 13 (△), 15 (□), and 17 (■) ms after mixing.



Results

Stoichiometry

The stoichiometry of the reaction was determined using excess $[Mn(cydta)(OH_2)]^-$ over [S(IV)] at different pH values and ionic strengths. The low pH's, 3.32 and 3.72, were selected particularly because $S_2O_6^{2-}$ is a significant product of sulphite radical recombination at low pH (13). The two solutions were introduced into the stopped-flow apparatus and the final absorbance at 510 nm was read from the stopped-flow trace, and $\Delta[Mn(cydta)(OH_2)^-]$ was calculated for a given [S(IV)]. In the control experiment the initial absorbance of the $[Mn(cydta)(OH_2)]^-$ solution was measured by replacing the sulphite solution with degassed distilled water. A value of $\Delta[Mn(cydta)(OH_2)^-]/\Delta[SO_3^{2-}] = 1.97 \pm 0.03$ indicated a 2:1 stoichiometry consistent with eq. [1].

$$[1]\quad 2[Mn(cydta)(OH_2)]^- + SO_3^{2-} + H_2O \rightarrow 2[Mn(cydta)(OH_2)]^{2-} + SO_4^{2-} + 2H^+$$

The stoichiometry, estimating excess unreacted sulphite by back titrating with iodine, remained inconclusive because of the scattered ratio values and irreproducible results (14). This is attributed to air oxidation of sulphite (15). In a qualitative test, sulphite ion was removed by the addition of formaldehyde, which forms an adduct (2*e*). Product analysis indicated that sulphate ion was the principal product. The dithionate ion was, however, not detected.

Dependence on [S(IV)]

The plot between k_{obs} and [S(IV)], Fig. 2, indicates that k_{obs} increased more rapidly than the increase in [S(IV)]. However, the plots of $k_{obs}/[S(IV)]$ against [S(IV)], Fig. 3, are linear with intercepts at all temperatures.

Dependence on pH

The effects of $[H^+]$ on the observed rate, Table 1, indicates that

For personal use only.

Fig. 2. The concave-up plot of k_{obs} against $[sulphite]_0$ ($10^4[Mn(cydta)^-] = 4.0$, $[CH_3COO^-] = 0.06$, $\mu = 0.16$ mol dm^{-3} at pH 4.27 at 25°C).

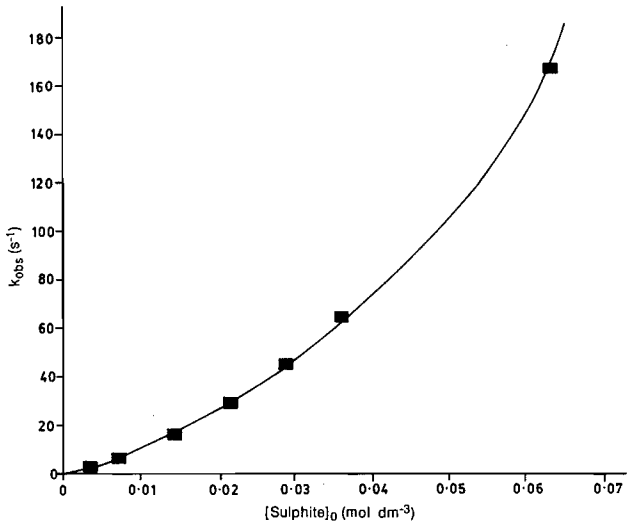

Table 1. The dependence of k_{obs} on pH at 25°C. $10^4[Mn(cydta)^-] = 4.0$, $10^3[SO_3^{2-}] = 7.2$, $\mu = 0.4$ mol dm^{-3}.

pH	3.8	4.08	4.4	4.66	5.05
k_{obs} (s^{-1})	3.12	4.54	7.80	13.0	28.7

the rate increases with pH. A linear plot with an intercept, Fig. 4, is obtained when $k_{obs}/[SO_3^{2-}]$ is plotted against $[H^+]^{-1}$.

Effect of ionic strength

The effect of ionic strength, not studied by previous workers (3), was investigated with $LiClO_4$ (Table 2) because sodium ions, at times, produce medium effects (16). At relatively high ionic strengths (μ), the Davies equation [2] (17) is applicable. The required plot between $\log k_{obs}$ and $\sqrt{\mu}/(1 + \sqrt{\mu})$ was linear with the slope value 1.7, indicating that the reactants are similarly charged and have one and two charges, respectively.

$$[2] \quad \log k_{obs} = \log k_0 + m(\sqrt{\mu}/(1 + \sqrt{\mu}))$$

Effect of $[SO_4^{2-}]$

The addition of Na_2SO_4, at constant ionic strength ($NaClO_4$), had no effect on the rate. The k_{obs} value, measured over $[SO_4^{2-}] = (0.4 - 4.0) \times 10^{-4}$ mol dm^{-3} ($10^4[Mn(cydta)(OH_2)^-] = 4.0$, $10^3[SO_3^{2-}] = 7.2$, $[CH_3CO_2^-] = 0.06$, $\mu = 0.4$ mol dm^{-3}, pH 4.27 at 25°C) was 6.87 ± 0.33 s^{-1}. It indicated the absence of any reversible step involving SO_4^{2-} in the mechanism.

Effect of $[Mn(cydta)^{2-}]$

The effect of the addition of $[Mn(cydta)^{2-}]$ ($0.2–2.0 \times 10^{-4}$ mol dm^{-3}) on the rate ($10^4[Mn(cydta)(OH_2)^-] = 4.0$, $10^3[SO_3^{2-}] = 7.2$, $[CH_3CO_2^-] = 0.06$, $\mu = 0.3$ mol dm^{-3}, pH 4.27 at 25°C) indicated that the k_{obs} value, 4.66 ± 0.06 s^{-1}, was independent of $[Mn(cydta)^{2-}]$. This excluded the possibility of a reversible step during the electron transfer.

Effect of acrylamide

The rates, measured at different concentrations of acrylamide, decreased with increasing acrylamide concentration. This indicates that an equilibrium reaction in which free radicals and the reduced oxidant are generated is not rate determining. If it were so, the removal of the free radicals by a scavenger would have resulted in an increase in the forward rate.

Fig. 3. The plot of $k_{obs}/[sulphite]_0$ against $[sulphite]_0$ at $\mu = 0.16$ mol dm^{-3} and temperature 8.5 (■), 16.5 (+), 25 (□), and 31.6°C (▲).

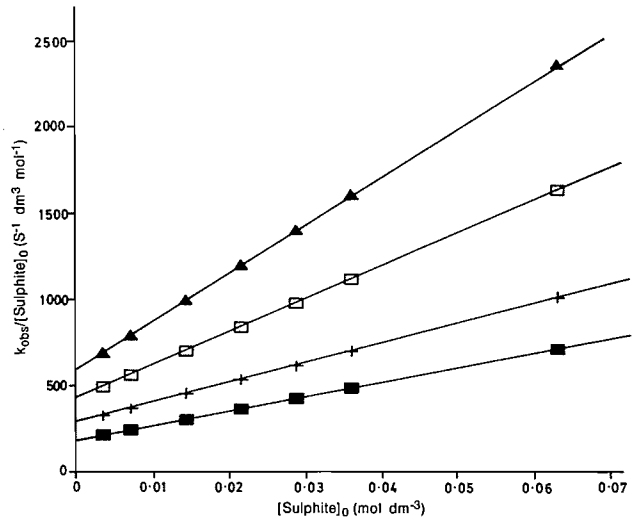

Fig. 4. The plot of $k_{obs}/[sulphite]_0$ against $[H^+]^{-1}$ ($10^4[Mn(cydta)^-] = 4.0$, $10^3[sulphite] = 7.2$ and $\mu = 0.4$ mol dm^{-3} at 25°C).

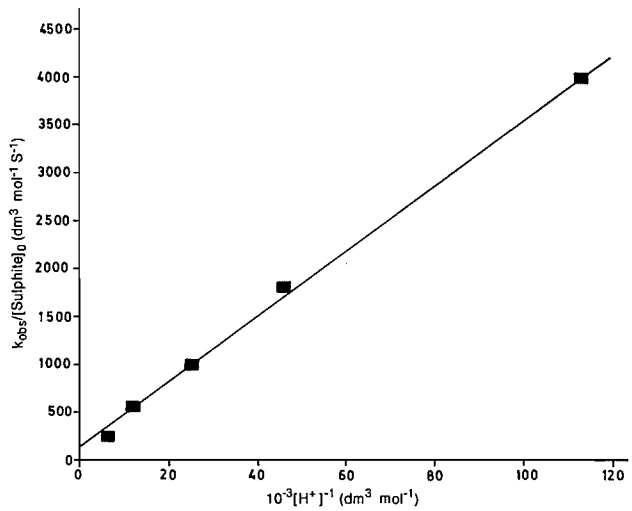

Table 2. Dependence of k_{obs} on the initial ionic strength at 25°C. $10^4[Mn(cydta)^-] = 4.0$. $10^3[SO_3^{2-}] = 10.8$, $[CH_3COO^-] = 0.06$ mol dm^{-3} at pH 4.27.

μ(mol dm^{-3})	0.16	0.40	0.516	1.0
k_{obs} (s^{-1})	5.57	7.97	9.22	12.6

Mechanism and discussion

Mechanism

The retarding effect of H^+ could arise either from the equilib-

rium [3] with $pK_a = 6.79$ (18), or the equilibrium [3*a*] with $pK_h = 8.1$ (4).

$$[3]\quad HSO_3^- \overset{K_a}{\rightleftharpoons} H^+ + SO_3^{2-}$$

$$[3a]\quad [Mn(cydta)(OH_2)]^- \overset{K_h}{\rightleftharpoons} [Mn(cydta)(OH)]^{2-} + H^+$$

Since the difference between the pK_a and pK_h values is more than one unit, the equilibrium [3*a*] is less likely to affect the kinetics rates. Moreover, the deprotonated $[Mn(cydta)(OH)]^{2-}$ ion associated with a reduced potential (19) may prove to be a poor oxidant in comparison to the $[Mn(cydta)(OH_2)]^-$ ion. Thus the retarding effect of H^+ is ascribed to the greater reactivity of SO_3^{2-} ion.

The formation of an intermediate in the proposed mechanism is not emphasized because in a reaction where the observed rate constant is a product of a rate and a preequilibrium constant, such speculation is probably unwarranted (20). This does not mean that the formation of a precursor complex is excluded although the spectrophotometric measurements did not hint at the formation of any newer species.

In view of the stoichiometry and kinetic results and the consideration that SO_4^{2-} ion is the only oxidation product, the following mechanism based on simple reactions is proposed.

$$[3]\quad HSO_3^- \overset{K_a}{\rightleftharpoons} H^+ + SO_3^{2-}$$

$$[4]\quad 2HSO_3^- \overset{Q_d}{\rightleftharpoons} S_2O_5^{2-} + H_2O$$

$$[5]\quad [Mn(cydta)(OH_2)]^- + SO_3^{2-} \overset{k}{\longrightarrow} [Mn(cydta)(OH_2)]^{2-} + SO_3^-$$

$$[6]\quad [Mn(cydta)(OH_2)]^- + S_2O_5^{2-} \overset{k_1}{\longrightarrow} [Mn(cydta)(OH_2)]^{2-} + SO_3^- + SO_2$$

$$[7]\quad [Mn(cydta)(OH_2)]^- + SO_3^- \overset{k_7}{\longrightarrow} [Mn(cydta)(OH_2)]^{2-} + SO_3$$

$$[8]\quad SO_3 + H_2O \overset{\text{fast}}{\longrightarrow} SO_4^{2-} + 2H^+$$

where the product of the ionic charges in the rate-determining steps [5] and [6] is 2, a value in fair agreement with the slope value 1.7 obtained in the Davies plots.

The protonation (21) of HSO_3^- to yield SO_2 is not considered because the pK_a of H_2SO_3 is 1.6 and, therefore, is unlikely to be a significant species under the conditions of the study. The formation of $S_2O_5^{2-}$ in reaction [4], $Q_d = 0.088$ dm^3 mol^{-1} (22), and reducing the complex in the rate-limiting reaction [6] explains the parallel second-order term in [S(IV)] in the rate law.

The existence of SO_3^- radical in aqueous solution is supported by esr (23). The SO_3^- radicals can also decay through reactions [9] and [10] as well as reaction [7]. The recently estimated values of k_9 and k_{10} are 1.8×10^8 and 2.3×10^8 dm^3 mol^{-1} s^{-1}, respectively (24).

$$[9]\quad SO_3^- + SO_3^- \overset{k_9}{\longrightarrow} S_2O_6^{2-}$$

$$[10]\quad SO_3^- + SO_3^- \overset{k_{10}}{\longrightarrow} SO_3 + SO_3^{2-}(SO_4^{2-} + SO_2)$$

Reaction [7] is required both by the stoichiometry and the effect of acrylamide on the rate. Further, its precedence over reactions [9] and [10] is evident from its value, 1×10^9 dm^3 mol^{-1} s^{-1}, estimated in $[Ru(NH_3)_4(phen)]^{2+}$ oxidation of sulphite ion (2*e*). Though the exact value for the present case can not be estimated (beyond our facilities), yet there is no reason to believe that it might be much different. The irreversible hydrolysis of SO_3 in reaction [8] is known to be rapid.

The above sequence of reactions leads to the rate law in eq. [11], which could be expressed as eq. [12] with the proviso that $1 \gg K_a[H^+]^{-1} + Q_d[HSO_3^-]^2$ because of the small values of K_a and Q_d and $[H^+]$ and $[HSO_3^-]$ used.

$$[11]\quad \frac{-d[Mn(cydta)(OH_2)^-]}{dt} = \frac{2(kK_a[H^+]^{-1} + k_1Q_d[HSO_3^-])[Mn(cydta)(OH_2)^-][HSO_3^-]}{1 + K_a[H^+]^{-1} + Q_d[HSO_3^-]}$$

$$[12]\quad \frac{k_{obs}}{[HSO_3^-]} = 2(kK_a[H^+]^{-1} + k_1Q_d[HSO_3^-])$$

Equation [12] is consistent with the linearity of the plots in Figs. 3 and 4. The close agreement in the values of kK_a, 0.0179 (intercept, Fig. 3) and 0.0173 s^{-1} (slope, Fig. 4), and that of $k_1Q_d = 1.57 \times 10^4$ (slope, Fig. 3) and 1.55×10^4 dm^6 mol^{-2} s^{-1} (intercept, Fig. 4) from two different plots supports the rate law and the mechanism.

The values of k and k_1, Table 3, were deduced from the least-squares values of the intercepts ($= kK_a[H^+]^{-1}$) and slopes ($= k_1Q_d$) of the plots in Fig. 3 at various temperatures. The respective activation parameters deduced from these values are also reported there.

Discussion

The results of the stoichiometry and the retarding effect of H^+ of the previous study (3) are confirmed. The inverse H^+ ion dependence is, however, linked with a path first-order in [S(IV)] rather than to a path second-order in [S(IV)] (3). This inversion is due to the proposed reactions of SO_3^{2-} and $S_2O_5^{2-}$; the former is responsible for the inverse H^+ ion dependence whereas the latter is independent of $[H^+]$.

Further, no difficulty is seen in the reaction between $S_2O_5^{2-}$ and $[Mn(cydta)(OH_2)]^-$ because $k_1 \approx 10^5$ dm^3 mol^{-1} s^{-1} is much less than its estimated (3) rate (two orders higher than the rate of diffusion-controlled reactions) for its reaction with $[Mn(cydta)(OH)]^{2-}$ ion. The other area of disagreement is the inner-sphere mechanism (3).

The focal point for the inner-sphere mechanism was that hexadentate $cydta^{4-}$ acted as a pentadentate ligand (3). It is not clear why one carboxylato arm behaved differently from the others in the otherwise seven-coordinated complex (4, 5). The first step in the accommodation of S(IV) in the seven-coordinated manganese ion would involve bond rupture between the carboxylato arm and the metal centre. The rate of such a process is considered to be less rapid than the rate of electron transfer as in the outer-sphere oxidation of dithionite by $[Mn(cydta)(OH_2)]^-$ (7). The present reaction more closely resembles the dithionite reaction. The reactive species SO_3^{2-} and $S_2O_5^{2-}$ are identical with SO_2^- and $S_2O_4^{2-}$ and so is the

equilibrium governing the formation of the dimeric species. The rate-determining constants are also similar. Further, if the predicted (3) association constant ($\approx 10^{-2}$) between the metal and S(IV) is taken into consideration then k and k_1 values are further increased, lending more support to the outer-sphere mechanism. The rate of exchange of water (25), $4.4 \times 10^8\ s^{-1}$, coordinated to the seventh site, prevented its substitution by S(IV).

The other factors negating an inner-sphere mechanism include the recent suggestion (2*f*) that access by S(IV) to the metal centre is needed for the formation of dithionate, which presently is not an oxidation product. The approach of a negatively charged species to the carboxylate side is considered electrostatically unfavourable, and the presence of the cyclohexane substituent on the diamine side prevents adequate donor–acceptor orbital overlap (5).

The outer-sphere nature of the reaction is finally examined in the light of Marcus theory (8) given by the following equations (26).

$$[13]\quad k_{12} = (k_{11}k_{22}K_{12}f_{12})^{1/2}W_{12}$$

$$[14]\quad \ln f_{12} = \frac{(\ln K_{12} + (w_{12} - w_{21})/RT)^2}{4(\ln (k_{11}k_{22}/Z^2) + (w_{11} + w_{22})/RT)}$$

$$[15]\quad W_{12} = \exp((w_{11} + w_{22} - w_{12} - w_{21})/2RT)$$

$$[16]\quad w_{ij} = \frac{z_i z_j e^2}{D\sigma_{ij}(1 + \beta\sigma_{ij}\sqrt{\mu})}$$

where k_{12} is the rate constant for electron transfer from SO_3^{2-} to the oxidant, k_{11} is the self-exchange rate constant for the SO_3^-/SO_3^{2-} couple, k_{22} is the self-exchange rate constant for the various complexes (used as oxidants), K_{12} is the equilibrium constant for the various electron-transfer reactions, W_{12} is the electrostatic work term, w_{ij} is the work required to bring ions i and j (charges z_i and z_j) to the separation distance σ_{ij} (equal to the sum of the radii of the ions), D is the static dielectric constant of the medium, $\beta = (8\pi Ne^2/1000D\mathbf{K}T)^{1/2}$, Z is the collision rate, a value 1×10^{25} is used for Z^2 (27), R is the gas constant (kcal $mol^{-1}\ K^{-1}$), and $\mathbf{K}$ is the Boltzmann constant. The radius of SO_3^- and SO_3^{2-} is taken as 3 Å.

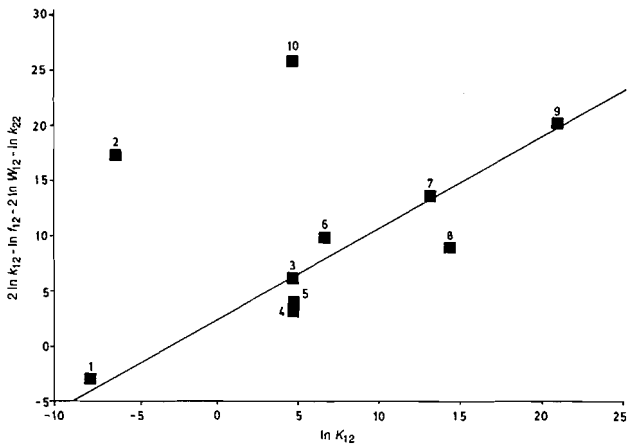
Assuming the adiabatic nature of the self-exchange reactions, eq. [13] could be rearranged to eq. [17].

$$[17]\quad 2\ln k_{12} - \ln f_{12} - 2\ln W_{12} - \ln k_{22} = \ln k_{11} + \ln K_{12}$$

The plot of eq. [17] for the data in Table 4 is linear, Fig. 5, though the points corresponding to MnO_4^- and $[Mn(cydta)(OH_2)]^-$ show considerable deviation. The least-squares value of the slope, excluding the MnO_4^- and $[Mn(cydta)(OH_2)]^-$ points, is 0.83 ± 0.09 ($r^2 = 0.942$), in fair agreement with the expected value of unity. The intercept results in a value of k_{11} equal to 8 $dm^3\ mol^{-1}\ s^{-1}$, which is in fair agreement with the recently estimated value 4 $dm^3\ mol^{-1}\ s^{-1}$ (2*f*).

The deviation corresponding to MnO_4^- is attributed to the formation of an inner-sphere complex (2*f*). The same is not true for $[Mn(cydta)(OH_2)]^-$ for it is felt that this complex is not similar to the complexes listed in Table 4. This observation is based on the fact that inclusion of the rate of oxidation of vanadium(IV) by $[Mn(cydta)(OH_2)]^-$ with those by polyaza macrocycle– (28) and tris(polypyridine)–metal complexes (29) for treatment by the Marcus theory resulted in two separate straight lines, as shown earlier (29), one each for the

Fig. 5. The plot of $2 \ln k_{12} - \ln f_{12} - 2 \ln W_{12} - \ln k_{22}$ against $\ln K_{12}$.



polyaza macrocycle and tris(polypyridine) complexes, with the point corresponding to the Mn complex falling on the straight line of the polyaza macrocycle complexes. Both polyaza macrocycle and tris(polypyridine) complexes oxidize vanadium(IV) by an outer-sphere mechanism (28, 29). Hence, $[Mn(cydta)]^-$ shows greater resemblance to the polyaza macrocycle complexes than to the polypyridine complexes.

In conclusion, the reaction, which not only shows similarities with the rate and mechanism of a similar known outer-sphere reaction (7) but also has rates similar to those of several other outer-sphere reactions (5), cannot be considered as an inner-sphere reaction on the simple assumption that $cydta^{4-}$ is acting as a pentadentate ligand. However, a further study of this interesting reducing agent by polyaza macrocycle complexes, known to be outer-sphere oxidants (28), is needed to test the strict compliance with the Marcus theory (8) because $[Mn(cydta)]^-$ has shown greater resemblance to polyaza macrocycle complexes than polypyridine complexes in V(IV) oxidation. We plan to undertake this study in the near future.

Acknowledgements

We thank the Department of Science and Technology for providing financial assistance for the stopped-flow instrument, and the Council of Scientific and Industrial Research for financing the project and awarding a Junior Research Fellowship to U.C. We sincerely thank Professor D.H. Macartney, Queen's University, for a critical preview of the manuscript and for allowing his program for the calculations presented in Table 4.

Étude thermodynamique des trois isomères de l'acide chlorobenzoïque. Partie II[1]

Raphaël Sabbah et Aaron Rojas Aguilar

Résumé : Notre calorimètre isopéribolique à bombe rotative, précédemment décrit, a été modifié : (*i*) en diminuant et en stabilisant les échanges thermiques entre le système calorimétrique et le milieu extérieur; (*ii*) en modifiant son thermomètre de mesure; (*iii*) en lui associant un système informatisé de robotique, d'acquisition et de traitement des signaux thermiques. Après avoir vérifié la bonne marche de l'appareil ainsi modifié et réalisé l'étalonnage du système calorimétrique, nous avons déterminé à 298,15 K et par calorimétrie de combustion les enthalpies de formation à l'état condensé des trois isomères de l'acide chlorobenzoïque. En associant ces valeurs à celles de leurs enthalpies de sublimation à 298,15 K, nous avons pu déterminer leurs enthalpies de formation à l'état gazeux. Les valeurs expérimentales des fonctions thermodynamiques $-\Delta_c H_m^0$ (s, 298,15 K), $-\Delta_f H_m^0$ (s, 298,15 K), $\Delta_{sub} H_m^0$ (298,15 K) et $-\Delta_f H_m^0$ (g, 298,15 K) sont données pour les acides 2-chloro-benzoïque, 3-chlorobenzoïque et 4-chlorobenzoïque. À partir de l'enthalpie d'atomisation expérimentale de ces trois acides, une valeur enthalpique a été proposée pour la liaison C_b—Cl dans ce type de composés. Les valeurs expérimentale et théorique de l'énergie de conjugaison sont compatibles. Une discussion sur la stabilité relative de quelques dérivés monosubstitués de l'acide benzoïque étudiés au laboratoire est aussi développée.

Mots clés : thermodynamique, calorimétrie de combustion, analyse thermique différentielle; acide 2-chlorobenzoïque, acide 3-chlorobenzoïque, acide 4-chlorobenzoïque, enthalpies de combustion, de formation, énergie de conjugaison, enthalpies d'atomisation, de liaisons intramoléculaires, substance d'intercomparaison.

Abstract: Our isoperibol rocking-bomb calorimeter, previously described, has been modified to: (*i*) reduce and stabilize the heat exchange between the calorimetric system and its surroundings; (*ii*) change its thermometer; (*iii*) associate with it a computer program for the robotics of different steps of an experiment, data acquisition, and determination of the thermodynamic quantities. After testing these modifications and calibrating the calorimetric system, the enthalpies of formation in the condensed state and at 298.15 K of the three isomers of chlorobenzoic acid have been determined by combustion calorimetry. Associating these values with those of their enthalpies of sublimation previously measured, we determined their enthalpies of formation in the gaseous state. The experimental values of the thermodynamic functions $-\Delta_c H_m^0$ (s, 298.15 K), $-\Delta_f H_m^0$ (s, 298.15 K), $\Delta_{sub} H_m^0$ (298.15 K), and $-\Delta_f H_m^0$ (g, 298.15 K) are given for 2-chlorobenzoic acid, 3-chlorobenzoic acid, and 4-chlorobenzoic acid. From the experimental value of the enthalpy of atomization, it has been possible to determine an enthalpy value for the C_b—Cl bond. The experimental and theoretical values of the resonance energy of the three isomers are compatible. The relative stability of some monosubstituted derivatives of benzoic acid studied in our laboratory is also discussed.

Key words: thermodynamics, combustion calorimetry, differential thermal analysis; 2-chlorobenzoic acid, 3-chlorobenzoic acid, 4-chlorobenzoic acid, enthalpies of combustion, of formation, resonance energy, enthalpies of atomization, of intramolecular bonds, reference material.

1. Introduction

Plusieurs travaux ayant pour but la mise en évidence du lien existant entre grandeurs énergétiques et structure dans les composés organiques ont été réalisés au laboratoire depuis quelques années. L'étude thermodynamique des dérivés monosubstitués de l'acide benzoïque en fait partie. Après avoir étudié les acides aminobenzoïques (1, 2) et les acides hydroxybenzoïques (3), nous avons entrepris au début de cette décennie, l'étude partielle des dérivés halogénés (Cl, Br, I) par calorimétrie de sublimation et par analyse thermique différentielle (4–6). Le présent travail se propose de compléter cette étude dans le cas des dérivés chlorés par calorimétrie de combustion. Il permettra d'apporter une contribution au niveau des liaisons intramoléculaires et de la stabilité relative des molécules d'acide benzoïque monosubstituées.

Signalons au passage que les travaux réalisés jusqu'ici sur l'étude des propriétés thermodynamiques des trois isomères

de l'acide chlorobenzoïque sont très peu nombreux. La majeure partie d'entre eux traite de la combustion du dérivé *para* en vue de pouvoir le proposer comme substance d'intercomparaison en calorimétrie de combustion de substances chlorées (7, 8).

2. Partie expérimentale

2.1. Produits

Les acides chlorobenzoïques utilisés dans ce mémoire sont des produits Fluka (pour l'acide 2-chlorobenzoïque, pureté : 98%) et Aldrich (pour les acides 3-chlorobenzoïque, pureté : >99% et 4-chlorobenzoïque, pureté : 99%). Ces trois substances ont été repurifiées par sublimations successives, trois fois dans le cas des acides 2-chloro- et 4-chlorobenzoïques et deux fois dans le cas de l'acide 3-chlorobenzoïque, sous une pression résiduelle de 1,3 Pa à 373 K.

La pureté des échantillons ainsi traités a été déterminée par analyse thermique différentielle; elle est de (99,95 ± 0,01), (99,94 ± 0,01) et (99,92 ± 0,01) mol% respectivement pour les isomères *ortho*, *méta* et *para*.

Les autres substances citées dans ce travail ont été utilisées telles que : anhydrique arsénieux (Merck; 99,5%), permanganate de potassium (Prolabo; 99,5%), nitrate d'argent (Prolabo; 99,8%), iodate de potassium (Prolabo; 99,9%), acide chlorhydrique (Prolabo; R.P. p.a.), brome (Fluka; 99,5%), hexachloroplatinate de sodium (Fluka; >99%).

Toutes les solutions décrites dans ce travail ont été préparées à partir d'une eau distillée et déminéralisée.

L'oxygène utilisé dans nos expériences de combustion est un produit Air Liquide N45; son degré de pureté est égal à 99,995% (fraction molaire d'azote : $<10^{-5}$).

2.2. Appareillage, technique et mode opératoire

Pour réaliser l'étude objet de ce mémoire, nous avons utilisé la calorimétrie de combustion et l'analyse thermique différentielle.

2.2.1. Calorimétrie de combustion

Elle a été réalisée à l'aide d'un calorimètre isopéribolique semblable au modèle mis au point et utilisé à l'Argonne National Laboratory (9), précédemment décrit dans la référence 2 et auquel ont été apportées certaines modifications visant : (*i*) la diminution et la stabilisation des échanges thermiques entre le système calorimétrique et le milieu extérieur; (*ii*) la modification de son thermomètre de mesure; (*iii*) l'association d'un système informatisé de robotique, d'acquisition et de traitement des signaux thermiques.

Ce calorimètre est constitué de deux parties : une enceinte extérieure et un seau intérieur. L'enceinte extérieure est un récipient à double paroi renfermant de l'eau maintenue à (298,15 ± 0,002) K à l'aide d'une régulation électronique conçue, réalisée et mise au point par les services techniques du Centre et dont l'élément sensible est une thermistance (Fenwall GB32) de 2 kΩ à 298,15 K. Afin de lui éviter des fluctuations de température trop brutales, l'enceinte extérieure a été recouverte sur sa périphérie d'un revêtement en mousse de polyuréthane de 50 mm d'épaisseur. Par ailleurs et pour la même raison, ce calorimètre est placé dans une salle thermorégulée dont la variation de température n'excède pas ±0,1 K dans la journée.

L'enceinte extérieure abrite le seau calorimétrique. Il existe entre ces deux parties une couche d'air d'environ 10 mm. Ce seau peut recevoir, outre la bombe rotative et le système d'engrenages qui lui est solidaire, une résistance chauffante de 86 Ω alimentée par trains d'ondes à partir d'une tension alternative de 220 V, un agitateur rotatif ayant la forme d'une hélice et 2880 g d'eau distillée pesée au 1/10 de gramme à l'aide d'une balance (Mettler, modèle P5-11).

La bombe utilisée est de forme cylindrique ($\phi_{ext} = 8$ cm, $h =$ 16,5 cm). Elle est réalisée à partir d'un alliage à haute teneur en nickel (Parr, modèle 1004) et est revêtue d'une épaisseur de 0,5 mm de platine pur. Son volume utile est de 0,347 dm^3. Elle est équipée d'un jeu d'engrenages qui lui permet de se mouvoir selon deux axes perpendiculaires. Elle comporte deux électrodes de mise de feu et deux robinets à pointeaux permettant l'entrée et la sortie des gaz.

La température de l'eau du seau calorimétrique est déterminée à l'aide d'une thermistance linéarisée de 5,6 kΩ à 298,15 K (Betatherm 36K53A3) que nous avons étalonnée entre 293 et 303 K. La valeur de sa résistance en fonction du temps est mesurée à l'aide d'un multimètre numérique Keithley modèle 2001, sensible au millième d'ohm.

Le signal électrique issu de ce multimètre est traité à l'aide d'un ordinateur et d'un programme informatique mis au point au laboratoire. Celui-ci gère l'évolution de la température du seau calorimétrique avant et pendant la période initiale, pendant les périodes principale et finale, et commande (*a*) la mise de feu à la substance étudiée par l'intermédiaire d'un courant redressé fourni par une source de 6 V traversant un fil de platine de 0,05 mm d'épaisseur, de 45 mm de longueur, tendu entre les deux électrodes; (*b*) la rotation de la bombe réalisée 180 s après la mise de feu. Trente rotations s'effectuant en 216 s se sont avérées nécessaires pour assurer l'homogénéité du système réactionnel après combustion.

Avec ce système de détection, nous pouvons déterminer avec fiabilité T'_i et T_f à $\pm 3 \times 10^{-5}$ K ainsi que les pentes des parties rectilignes de la courbe $T = f(t)$ (fig. 1) correspondant aux périodes initiale et finale.

Lorsqu'on travaille avec une substance solide, comme c'est le cas ici, celle-ci est mise sous forme de pastilles à l'aide d'une presse (Parr, modèle 2811). Les expériences préliminaires réalisées avec les trois isomères ayant conduit à des combustions incomplètes lorsque $m \geq 0{,}8$ g, nous avons été contraints, afin de les éviter, d'utiliser une substance auxiliaire favorisant la combustion en plaçant nos pastilles à l'intérieur d'un sachet confectionné par nos soins à partir de film de polythène de 50 μm d'épaisseur. Par ailleurs et afin de travailler dans les meilleures conditions de substitution, on s'arrange pour que la masse de substance brûlée (pastille + sachet de polythène), déterminée au μg près à l'aide d'une balance Mettler, modèle M5, fournisse en brûlant une variation de température ΔT aussi voisine que possible de celle qui est obtenue lors de l'étalonnage du système calorimétrique à partir de la combustion d'acide benzoïque. On place l'ensemble pastille + sachet dans un creuset en platine ayant une capacité de 3 cm^3. Le fil de platine, ci-dessus mentionné, est relié à cet ensemble à l'aide d'un fil de coton d'environ 50 mm de longueur. Les masses de ces deux fils sont, elles aussi, pesées au μg près. À chaque pesée, on associe la valeur de la pression atmosphérique du moment, du degré hygrométique et de la température de l'air ambiant pour pouvoir calculer la masse réelle de la pastille, du sachet de polythène, des fils de coton et de platine et du creuset.

Avant chaque expérience, on introduit 20 cm^3 de solution 0,0589 M d'anhydride arsénieux (As_2O_3) dans la bombe. Ce volume est nécessaire pour réduire le chlore contenu dans la substance à l'état d'ions chlorures (Cl^-). La pression d'oxygène à l'intérieur de la bombe est de 3,04 MPa. Une fois garnie, la bombe est placée dans le seau calorimétrique contenant l'eau distillée. Elle est maintenue verticale à l'aide d'un ressort métallique dont l'autre extrémité est fixée à une borne électrique solidaire et isolée du seau. Ce ressort sert de conducteur du courant électrique nécessaire pour porter au rouge le fil de platine permettant à la combustion de démarrer. Le seau, fermé par un couvercle, est placé à l'intérieur de la jaquette isotherme.

2.2.2. Analyse thermique différentielle

Cette technique nous a permis de déterminer le degré de pureté de nos substances. L'appareillage et le mode opératoire sont consignés dans les références 10 et 11.

2.3. Préparation des solutions titrées

2.3.1. Permanganate de potassium ($KMnO_4$) : 6,5 g de cette substance ont été dissous à chaud dans 2 dm^3 d'eau. Après décantation et filtration, la solution obtenue a été stockée dans un flacon de couleur brune. Sa concentration ($c = 0{,}0202$ M) a été déterminée à partir d'une solution titrée d'acide oxalique 0,05 M.

2.3.2. Anhydride arsénieux (As_2O_3) : 12 g de ce composé ont été dissous à chaud dans 1 dm^3 d'eau. Après décantation et filtration, la concentration de la solution obtenue ($c = 0{,}0589$ M) a été déterminée à partir de la liqueur précédente de permanganate de potassium.

2.3.3. Nitrate d'argent ($AgNO_3$) : 17 g de cette substance ont été dissous dans 1 dm^3 d'eau. La concentration de cette solution ($c = 0{,}1007$ M) a été déterminée par dosage à partir d'une solution titrée de chlorure de sodium 0,1 M.

2.4. Analyse de la phase liquide

La solution issue de la bombe après combustion est étendue à 200 cm^3.

À part le dosage des ions hexachloroplatinates $(PtCl_6)^{2-}$ réalisé par spectrophotométrie dans le visible, tous les autres dosages ont été effectués par potentiométrie en utilisant une électrode de référence au calomel et une électrode de mesure en platine (dans le cas du dosage de la solution de $KMnO_4$ et de As_2O_3) et d'argent (dans le cas du dosage de Cl^-). Généralement deux à trois essais ont été réalisés pour chaque dosage. L'exactitude et la reproductibilité des mesures sont supérieures à 99,5%.

Signalons au passage que nous n'avons pas trouvé dans nos solutions une concentration significative en acides nitrique et nitreux.

Tous les dosages potentiométriques ont été réalisés en utilisant des microburettes de 2 ou (et) 5 cm^3 (protégées de la lumière dans le cas de la solution de permanganate de potassium).

2.4.1. Dosage de As_2O_3

Les analyses sont réalisées à partir de la liqueur titrée de $KMnO_4$ décrite ci-dessus sur 20 cm^3 de solution initiale de As_2O_3 ou issue de la bombe après combustion, additionnées de 10 cm^3 d'acide chlorhydrique 6 M et d'une goutte de solution 0,0025 M d'iodate de potassium. Nous avons pris le soin de vérifier à plusieurs reprises et un mois après l'essai que la concentration des solutions analysées n'avait pas changé.

2.4.2. Dosage de $(PtCl_6)^{2-}$

Une quantité (2 cm^3) de solution issue de la bombe après combustion est additionnée de 2 cm^3 d'eau déminéralisée, d'une goutte de brome liquide et d'une solution saturée de bromure de sodium. Le brome en excès est éliminé en faisant passer un courant d'air comprimé dans la solution ainsi obtenue. On ajoute alors 1 cm^3 d'une solution d'iodure de potassium à 1% et on complète le volume de la solution ainsi préparée à 7 cm^3 par addition d'eau déminéralisée. La détermination spectrophotométrique de la concentration en ions $(PtCl_6)^{2-}$ se fait dans le visible (à 490 μm). L'étalonnage préalable de l'appareil a été réalisé à partir de solutions titrées d'hexachloroplatinate de sodium (Na_2PtCl_6).

2.4.3 Dosage de Cl^-

Afin de vérifier que tout le chlore contenu dans la substance brûlée est bien passé sous la forme de Cl^- et de $(PtCl_6)^{2-}$, des analyses d'ions chlorures ont été réalisées sur 10 cm^3 de solution issue de la bombe après combustion en utilisant la solution titrée de $AgNO_3$ décrite dans le paragraphe 2.3.3. La valeur moyenne du chlore total trouvée est de $(99{,}7 \pm 0{,}3)$%.

Nous avons aussi pris la précaution de vérifier que la solution issue de la bombe après combustion ne contenait pas d'ions Au^{3+} pouvant provenir de l'attaque par l'acide chlorhydrique de l'or éventuellement présent au niveau des soudures des deux électrodes sur le couvercle de la bombe. Cette vérification a été réalisée en utilisant la réaction de Au^{3+} avec I^- (provenant d'une solution de KI) et en dosant, par iodométrie à partir d'une solution titrée de thiosulfate de sodium, l'iode ainsi formé (12).

2.5. Oxydation catalytique de As_2O_3 en As_2O_5 par l'oxygène en présence de platine

Dans le cas de la combustion de dérivés chlorés, la présence de la solution d'anhydride arsénieux dans la bombe est indispensable si l'on veut que tout le chlore contenu dans la substance

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

étudiée passe après combustion à l'état d'ions chlorures (une légère partie du chlore est cependant complexée sous la forme d'ions hexachloroplatinates et dosée par spectrophotométrie).

Il a été montré qu'en présence d'oxygène (sous une pression de 3,04 MPa) le revêtement platiné de la bombe catalysait l'oxydation de As_2O_3 en As_2O_5 (13). Il était donc indispensable de connaître exactement la fraction de As_2O_3 ainsi oxydée entre le moment du garnissage de la bombe et celui de sa rotation.

Deux méthodes peuvent être utilisées pour déterminer la quantité de As_2O_3 ainsi oxydée. L'une d'elles, décrite par Stridh (13), consiste à mesurer le pH d'une solution de As_2O_3 additionnée d'une autre de As_2O_5, la concentration de ces deux solutions étant connue. On établit la courbe pH = [$c(As_2O_5)$] et on l'utilise ensuite pour déterminer, à partir du pH des solutions recueillies après combustion, la concentration en As_2O_5 formé. Une seconde méthode consiste à réaliser l'étalonnage du système calorimétrique en plaçant dans la bombe 20 cm^3 de la solution de As_2O_3 et à déterminer par titrage potentiométrique les quantités de As_2O_3 avant et après expérience. À partir de la courbe pH = [$c(As_2O_5)$] ci-dessus mentionnée, on peut se rendre compte que si la concentration en As_2O_5 dépasse 10^{-3} mol dm^{-3}, la variation du pH en fonction de la concentration de As_2O_5 devient faible, ce qui rend imprécise la détermination de cette concentration dans les solutions issues de la combustion. En conséquence, la seconde méthode donnant, dans ce cas, des résultats plus exacts et plus reproductibles est préférée à la première. Nos expériences ont permis de constater que (2,7 ± 0,3)% de As_2O_3 se trouvant dans la solution initiale s'oxydaient catalytiquement. Nous en avons tenu compte dans le calcul de la concentration initiale de la solution de As_2O_3 utilisée.

À noter que l'oxydation catalytique de As_2O_3 en As_2O_5 est surtout prépondérante entre le moment du garnissage de la bombe et celui de sa rotation. En effet, la formation de HCl entraîne une diminution du pH de la solution initiale, ce qui a pour effet de réduire l'oxydation catalytique de As_2O_3 (12).

2.6. Analyse de la phase gazeuse

Après chaque combustion et détente de la phase gazeuse à 101,3 kPa, nous avons vérifié, à l'aide des tubes de Dräger, l'absence dans celle-ci de chlore et de monoxyde de carbone.

3. Résultats

Nous avons consigné dans le tableau 1 les grandeurs physiques à 298,15 K des substances utilisées qui interviennent dans les calculs menant aux résultats expérimentaux.

L'étalonnage du système calorimétrique, consistant à déterminer son équivalent énergétique (U_{calor}), a été effectué à l'aide de l'acide benzoïque (échantillon 39i du NIST) dans les mêmes conditions que la mesure de l'énergie de combustion des acides chlorobenzoïques. C'est ainsi qu'un gramme d'acide benzoïque, comprimé sous la forme de deux pastilles, a été brûlé en présence de 20 cm^3 de solution 0,0589 M de As_2O_3. Nous trouvons U_{calor} = (14 995,7 ± 1,4) J K^{-1}.

Les résultats expérimentaux obtenus par calorimétrie de combustion et correspondant à la réaction :

$$ClC_6H_4CO_2H(s) + 7\ O_2(g) + 598\ H_2O(l) \rightarrow 7\ CO_2(g) + [HCl{\cdot}600\ H_2O](l)$$

sont consignés dans les tableaux 2–4. Les grandeurs thermodynamiques à l'état standard qui les accompagnent ont été calculées à partir des valeurs expérimentales en utilisant un programme informatique écrit par nos soins, tenant compte des corrections dites de Washburn et des données de la littérature. Dans le calcul de l'enthalpie de formation de nos substances à l'état condensé, nous avons adopté pour $\Delta_f H_m^0$ (g, 298,15 K, CO_2), $\Delta_f H_m^0$ (l, 298,15 K, H_2O) et $\Delta_f H_m^0$ (l, 298,15 K, ($HCl{\cdot}600\ H_2O$)) respectivement les valeurs (−393,51 ± 0,13) kJ mol^{-1} (14), (−285,830 ± 0,042) kJ mol^{-1} (14) et (−166,62 ± 0,08) kJ mol^{-1} (15).

À part l'acide 4-chlorobenzoïque qui a fait l'objet de plusieurs travaux par calorimétrie de combustion dans le but de l'ériger comme substance d'intercomparaison dans l'étude des substances chlorées (7, 8) par cette technique, les deux autres isomères ont été très peu étudiés (16, 17).

Les valeurs de l'enthalpie de combustion de l'isomère *para*, obtenues avec un appareillage comparable au nôtre et consignées dans la littérature, sont comprises entre −3062,8 et −3065,4 kJ mol^{-1} (7, 16–21). En conséquence, notre résultat (−3065,6 ± 0,5) kJ mol^{-1} est tout à fait compatible avec ces valeurs.

En ce qui concerne les deux autres isomères, seules deux valeurs de l'enthalpie de combustion pour chacun d'eux existent dans la littérature (16, 17). L'une d'elles, obtenue avec un appareillage doté de bombe rotative (17), est égale à (−3088,3 ± 0,7) kJ mol^{-1} pour l'isomère *ortho* et à (−3068,5 ± 1,5) kJ mol^{-1} pour l'isomère *méta*. Comme nous pouvons le constater, ces deux valeurs sont en parfait accord avec nos résultats (cf. tableaux 2 et 3).

4. Discussion

L'ensemble des résultats expérimentaux consignés dans le tableau 5 permet la détermination de certaines grandeurs énergétiques liées à la structure des molécules étudiées.

4.1. Energie de conjugaison

Les trois molécules d'acides chlorobenzoïques étudiées dans ce mémoire sont conjuguées. En conséquence, nous avons essayé de déterminer, d'abord, leur énergie de conjugaison expérimentale, puis avons comparé celle-ci à la valeur théorique obtenue en utilisant la méthode de calcul décrite dans la référence 22.

L'énergie de conjugaison est, par définition, égale à la différence entre l'énergie réelle de la molécule et l'énergie qu'elle aurait si les divers systèmes insaturés qu'elle comporte étaient indépendants. Sur le plan pratique, pour la déterminer, nous utilisons les enthalpies standard de combustion à l'état gazeux de la molécule réelle et de la molécule fictive non conjuguée. La première de ces grandeurs s'obtient expérimentalement tandis que la seconde nécessite le recours aux systématiques. En ce qui nous concerne, nous avons utilisé celle de Klages qui est consignée dans la référence 23. Quant au calcul de l'énergie de conjugaison théorique, nous avons utilisé la méthode décrite dans la référence 22 en utilisant le jeu de paramètres suivant :

Pour la liaison C—Cl, $\alpha Cl = \alpha + 2{,}125\ \beta_0$ et $\beta C—Cl = 0{,}750\ \beta_0$ (24), k(C—Cl) = 4 × 10^2 N m^{-1}, d_0(C—Cl) = 1,7.

Pour la fonction acide (2, 22) :

$-\Delta_c U^0_m$ (s, 298,15 K) = (3065,55 ± 0,52) kJ mol^{-1}
$-\Delta_c H^0_m$ (s, 298,15 K) = (3065,55 ± 0,52) kJ mol^{-1}

ΔT : variation exacte de la température du système calorimétrique.
ΔT_{IBP} : variation de l'énergie interne de la bombe et de son contenu.
W_1 : énergie de combustion de la substance auxiliaire et du coton.
W_2 : corrections pour passer à l'état standard.
$n_f(As_2O_3)$: nombre de moles de As_2O_3 à l'état final.

Tableau 5. Grandeurs thermodynamiques des acides chlorobenzoïques à 298,15 K.

Substance	$-\Delta_c H^0_m$ (s, 298,15 K) (kJ mol^{-1})	$-\Delta_f H^0_m$ (s, 298,15 K) (kJ mol^{-1})	$\Delta_{sub} H^0_m$ (298,15 K)[a] (kJ mol^{-1})	$-\Delta_f H^0_m$ (g, 298,15 K) (kJ mol^{-1})
Acide 2-chlorobenzoïque	3087,8 ± 0,2	405,1 ± 0,5	100,9 ± 0,5	304,2 ± 0,7
Acide 3-chlorobenzoïque	3069,7 ± 0,6	423,2 ± 0,8	101,4 ± 0,4	321,8 ± 0,9
Acide 4-chlorobenzoïque	3065,6 ± 0,5	427,3 ± 0,7	102,5 ± 0,4	324,8 ± 0,8

[a]Valeurs empruntées à la référence 4.

αO-(H) = α + 2,500 β_0 $\quad$ βC-O-(H) = 1,080 β_0
αO = α + 0,875 β_0 $\quad$ βC-O = 1,375 β_0
αC = α + 0,250 β_0

(β_0 est l'intégrale de recouvrement dans la molécule de benzène et a, pour valeur absolue, 131,7 kJ mol^{-1}). Les calculs effectués nous ont permis d'obtenir les résultats consignés dans le tableau 6.

Comme nous pouvons le constater, il existe un accord satisfaisant entre les différentes valeurs expérimentales et théoriques de l'énergie de conjugaison.

Tableau 6. Energie de conjugaison des trois acides chlorobenzoïques.

Acide 2-chlorobenzoïque	209	217
Acide 3-chlorobenzoïque	223	216
Acide 4-chlorobenzoïque	226	217

4.2. Enthalpie d'atomisation

Pour déterminer la somme des enthalpies des liaisons intramoléculaires d'une molécule, il est indispensable de connaître son enthalpie d'atomisation. Celle-ci, à l'état standard et à la température T, est liée à la transformation suivante : molécule (considérée comme gaz idéal, état fondamental, T) $\rightarrow$ atomes (chacun d'eux, considéré comme gaz idéal, état fondamental, T).

Sur le plan expérimental, à une température donnée, si l'on considère une molécule de formule générale : $C_aH_bO_cCl_d$, la réaction d'atomisation s'écrit :

$$C_aH_bO_cCl_d(g) \rightarrow aC(g) + bH(g) + cO(g) + dCl(g)$$

L'enthalpie liée à cette réaction s'appelle «enthalpie d'atomisation expérimentale» et est égale à :

$$\Delta_{a,exp}H^0_m = a\Delta_fH^0_mC(g) + b\Delta_fH^0_mH(g) + c\Delta_fH^0_mO(g) + d\Delta_fH^0_mCl(g) - \Delta_fH^0_mC_aH_bO_cCl_d(g).$$

Aussi, à partir de l'enthalpie de formation d'une molécule à l'état gazeux et de celle des différents constituants C, H, O et Cl, que l'on emprunte aux tables (14) et qui, à 298,15 K, valent respectivement : (716,67 ± 0,44), (217,997 ± 0,006), (249,17 ± 0,10) et (121,302 ± 0,008) kJ mol^{-1}, est-il possible de calculer son enthalpie d'atomisation expérimentale. Nous trouvons pour les trois molécules d'acides chlorobenzoïques les valeurs consignées dans le tableau 7.

Pour déterminer l'enthalpie de liaison $H(C_b—Cl)$ dans les molécules d'acides chlorobenzoïques, nous sommes partis de $\Delta_{a,exp}H^0_m$ (298,15 K). En effet, on sait que l'enthalpie d'atomisation est égale à la somme des enthalpies des liaisons intramoléculaires compte tenu des facteurs de stabilisation et de déstabilisation.

Tableau 7. Enthalpie d'atomisation expérimentale des trois acides chlorobenzoïques et de la liaison (C_b—Cl).

Substance	$\Delta_{a,exp}H_m^0$ (298,15 K) (kJ mol^{-1})	H(Cb—Cl) (kJ mol^{-1})
Acide 2-chlorobenzoïque	7031 ± 2	338,7
Acide 3-chlorobenzoïque	7048 ± 2	354,6
Acide 4-chlorobenzoïque	7051 ± 2	358,6

Pour ce qui est des liaisons C_b—C_b du cycle benzénique, nous avons utilisé le procédé de calcul consigné dans la référence 25. Celui-ci fait intervenir un paramètre lié à la géométrie de la molécule (l'indice de liaison l_{rs} entre deux atomes directement liés r et s) obtenu à partir du calcul théorique de l'énergie de conjugaison (fig. 2). La relation reliant H_{rs} à l_{rs} s'écrit : (H_{rs}/kJ mol^{-1}) = 246,0 l_{rs} + 342,6.

Quant à H(C_b—H), H(C_b—C) et H(C_b—COOH), nous avons utilisé les valeurs 415,88; 351,56 et 1657,35 kJ mol^{-1} (26). Ainsi, dans le cas présent, pour calculer H(C_b—Cl), cela revient à retrancher de $\Delta_{a,exp}H_m^0$ (298,15 K) la part énergétique des différentes liaisons ci-dessus mentionnées. Le calcul effectué nous a permis d'obtenir les valeurs consignées dans le tableau 7. Nous avons adopté la valeur moyenne de 356,6 kJ mol^{-1} pour H(C_b—Cl) dans les acides chlorobenzoïques. Le même calcul, réalisé avec la molécule de chlorobenzène, nous a donné H(C_b—Cl) = 348,7 kJ mol^{-1}.

4.3. Stabilité relative de quelques dérivés monosubstitués de l'acide benzoïque

Ayant précédemment étudié au laboratoire les acides aminobenzoïques (2), hydroxybenzoïques (3) et, dans le présent travail, les acides chlorobenzoïques, il nous a paru intéressant de comparer la stabilité relative de ces dérivés monosubstitués de l'acide benzoïque à partir des valeurs de leur enthalpie de formation à l'état gazeux et à 298,15 K consignées dans le tableau 8.

Au sujet des dérivés *ortho* et *para*, cette comparaison fait ressortir que les isomères *ortho* seraient plus stables lorsque X (substituant) = OH ou NH_2. L'inverse est observé lorsque X = Cl. Dans le premier cas, cette stabilité serait vraisemblablement due à la formation d'une liaison hydrogène intramoléculaire entre l'atome d'oxygène du carbonyle et celui d'hydrogène de la fonction hydroxyle ou aminée. À l'effet stérique, qui en est partiellement la cause dans le second cas, vient s'ajouter, à notre avis, un effet de répulsion électrostatique entre l'atome de chlore et celui d'oxygène du carbonyle.

La comparaison des isomères *ortho* dans le cas où X = OH ou NH_2 permet de se rendre compte que la stabilité du dérivé hydroxylé est supérieure à celle du dérivé aminé. La chélation semble s'affaiblir en passant de l'acide hydroxybenzoïque à l'acide aminobenzoïque. Cette observation rejoint celle que nous avions faite à la suite de l'étude de ces mêmes composés par calorimétrie de sublimation et consignée dans un précédent travail (3). Elle trouve une confirmation dans l'ouvrage de Julg (35) à propos de l'énergie mise en jeu par la liaison hydrogène intramoléculaire dans les acides hydroxybenzoïque et aminobenzoïque : O—H···O (25 kJ mol^{-1}), N—H···O (11 kJ mol^{-1}).

Enfin, on note que, quel que soit l'isomère considéré, la stabilité semble croître dans l'ordre X = NH_2, Cl, OH et serait due à une conjugaison qui s'intensifierait en passant des acides amino, aux chloro et aux hydroxybenzoïques (cf. tableau 8).

Signalons, pour terminer, que les conclusions consignées dans ce paragraphe auraient pu être déduites en prenant comme élément de comparaison les valeurs de l'énergie de conjugaison des molécules consignées dans le tableau 8.

Fig. 2. Indices de liaison dans les molécules des trois acides chlorobenzoïques.

4.4. Peut-on ériger l'acide chloro-4 benzoïque au rang de substance d'intercomparaison en calorimétrie de combustion des substances chlorées?

À cette question, des chercheurs (17, 18) avant nous ont répondu par l'affirmative considérant que ce composé possède les propriétés requises dans un tel cas : stable, possédant une faible pression de vapeur saturante, non-hygroscopique, facile

à manipuler et à stocker, ignition aisée. Vis-à-vis de ces propriétés, nous n'avons aucun commentaire à faire. Par contre, comme nous l'avons indiqué dans le paragraphe 2.2.1. et quel que soit l'isomère, à partir d'une certaine masse ($m \geq 0{,}8$ g) de substance et dans nos conditions expérimentales, il nous a été très difficile d'obtenir une combustion complète sans la présence de substance auxiliaire (dans notre cas le polythène dont la part énergétique représente 4,2 % de l'énergie totale dissipée). Signalons au passage que Hu et al. (18) utilisent, dans certaines de leurs expériences avec l'acide 4-chlorobenzoïque, l'huile de paraffine comme substance auxiliaire.

L'incertitude qui accompagne nos valeurs expérimentales représente l'écart moyen, $\sigma_m = \pm\{(x - x_0)^2/n(n-1)\}^{1/2}$, x étant chacune des n valeurs entrant dans le calcul de la moyenne x_0. Lorsque la valeur expérimentale est fonction de plusieurs variables, l'incertitude calculée tient compte de l'erreur sur chacune de ces variables.

Remerciements

Les auteurs tiennent à remercier les services techniques du Centre pour l'aide qu'ils leur ont apportée dans les travaux de modification du calorimètre isopéribolique à bombe rotative ainsi que M. Juan Antonio Guardado Perez pour sa contribution dans la remise en route de cet appareil. L'un de nous (A.R.A.) remercie le Consejo Nacional de Ciencia y Technologia (CONACYT) pour l'octroi d'une bourse lui ayant permis de préparer, au laboratoire, une thèse dont ce travail constitue la première partie.

1-Aminocyclohexene-2,4-dicarbonitrile derivatives. Syntheses and structural study

Antonio Lorente, Carmen Galan, Isabel Fonseca, and Juliana Sanz-Aparicio

Abstract: Substituted 1-aminocyclohexene-2,4-dicarbonitriles were obtained by reaction of α,β-unsaturated nitriles (two equivalents) with benzyl cyanide. By recrystallization from ethanol one diastereomeric racemate was isolated in each case. The cyclohexene structures were established from spectroscopic data (IR, MS, and one- and two-dimensional NMR). Relative stereochemical configurations and conformational preferences in the solid state of cyclohexenes **2** and **3** and propanedicarbonitrile **1** were established from X-ray crystallography. Crystals of **1** ($C_{17}H_{14}N_2$) belong to the orthorhombic space group *Pbca*. Cell dimensions are $a = 17.168(7)$, $b = 21.612(5)$, $c = 7.508(2)$ Å, $V = 2785(7)$ Å^3. Final $R = 0.078$ and $R_w = 0.091$; 1363 reflections were observed. The compound **2** ($C_{26}H_{21}N_3$) crystallizes in the monoclinic space group $P2_1/n$ with $Z = 4$. The crystal data for **2** are $a = 7.743(1)$, $b = 24.420(1)$, $c = 11.164(1)$ Å, $\beta = 102.65(1)°$, $V = 2059.7(3)$ Å^3. Final $R = 0.046$ and $R_w = 0.059$; 2701 reflections were observed. Crystals of **3** ($C_{16}H_{17}N_3$) belong to the triclinic space group $P\bar{1}$. Cell dimensions are $a = 14.582(1)$, $b = 7.283(1)$, $c = 7.116(1)$ Å, $\alpha = 110.84(0)°$, $\beta = 85.92(0)°$, $\gamma = 97.81(1)°$, $V = 696.9(2)$ Å^3. Final $R = 0.047$ and $R_w = 0.052$; 2227 reflections were observed. The cyclohexene ring in **2** and **3** exists as a sofa rather then as a half-chair conformation.

Key words: 1-aminocyclohexenes, α,β-unsaturated nitriles, benzyl cyanide.

Résumé : On a obtenu les 1-aminocyclohex-1-ène-2,4-dicarbonitriles substitués par réaction de nitriles α,β-insaturés (deux équivalents) avec du cyanure de benzyle. Par recristallisation, on a obtenu dans chaque cas un racémique diastéréoisomère. On a déterminé les structures des cyclohexènes par des données spectroscopiques (IR, SM et RMN en une ou deux dimensions). Pour établir les configurations stéréochimiques relatives et les préférences conformationnelles des cyclohexènes **2** et **3** et du propanedicarbonitrile **1** à l'état solide, on a fait appel à la diffraction des rayons X. Les cristaux du composé **1** ($C_{17}H_{14}N_2$) sont orthorhombiques, groupe d'espace *Pbca*, avec $a = 17,168(7)$, $b = 21,612(5)$ et $c = 7,508(2)$ Å, $V = 2785(7)$ Å^3. $R = 0,078$ et $R_w = 0,091$ pour 1363 réflexions observées. Les cristaux du composé **2** ($C_{26}H_{21}N_3$) sont monocliniques, groupe d'espace $P2_1/n$, avec $a = 7,743(1)$, $b = 24,420(1)$ et $c = 11,164(2)$ Å, $\beta = 102,65(1)°$, $V = 2059,3(3)$ Å^3. $R = 0,046$ et $R_w = 0,059$ pour 2701 réflexions observées. Les cristaux du composé **3** ($C_{16}H_{17}N_3$) sont tricliniques, groupe d'espace $P\bar{1}$, avec $a = 14,582(1)$, $b = 7.283(1)$ et $c = 7,116(1)$ Å, $\alpha = 110,84(0),°$ $\beta = 85,92(0)°$ et $\gamma = 97,81(1)°$, $V = 696,9(2)$ Å^3. $R = 0,047$ et $R_w = 0,052$ pour 2227 réflexions observées. Les cycles des cyclohexènes des composés **2** et **3** existent dans la conformation sofa plutôt que dans la conformation demi-chaise.

Mots clés : 1-aminocyclohexènes, nitriles α,β-insaturés, cyanure de benzyle.

Introduction

The base-catalyzed dimerizations of α,β-unsaturated dinitriles allow the synthesis of aminocyclohexenes (1, 2) and amino-1,3-cyclohexadienes (3–8), which can be hydrolyzed to the corresponding cyclohexanones or cyclohexenones, respectively. Conformational analysis of cyclohexenes and their derivatives have been performed by different experimental (9) and theoretical methods (10). In most cases the lowest-energy conformation is the half-chair; however, the presence of substituent or fused rings can lead to conformations that are close to the ideal sofa arrangement. In this paper we describe the synthesis and structural study of 1-aminocyclohexene-2,4-dicarbonitriles **2** and **3**.

3,4,5-triphenylcyclohexene-2,4-dicarbonitrile (**2**) whereas, when the reaction was performed with sodium 2-propoxide in 2-propanol, 1,2-diphenyl-1,3-propanedicarbonitrile (**1**) was obtained. By reaction of **1** with another equivalent of cinnamonitrile in a sodium methoxide – methanol solution the cyclohexene **2** was obtained. Similarly the reaction of crotononitrile with benzyl cyanide, in similar conditions to those employed in the preceding case, afforded 2,4-dimethyl-3-phenyl-1,3,5-pentanetricarbonitrile (**4**) and its cyclization product: 1-amino-3,5-dimethyl-4-phenylcyclohexene-2,4-dicarbonitrile (**3**). The same reaction with NaH as the base in dimethylformamide (DMF) affords **3** as the sole product of the reaction.

Experimental

General

All melting points were taken in open capillary tubes on a Büchi SMP-20 and are uncorrected. IR spectra were measured as KBr pellets on a Perkin–Elmer 883 spectrophotometer. Mass spectra were recorded on a Hewlett–Packard 5988 spectrometer at 70 eV. ^{1}H and ^{13}C NMR spectra were recorded on a Varian UNITY-300 spectrometer at 303 K. The recording conditions were: ^{1}H NMR (299.949 MHz), 2% w/v solutions, acquisition time 3 s, spectral width 4000 Hz, and pulse width 11 μs. Conventional irradiation was used for the double resonance experiments. ^{13}C NMR (75.429 MHz) spectra were recorded using 5% w/v solutions, acquisition time 1 s, delay time 2 s, spectral width 16 500 Hz, and pulse width 3.6 μs. The homonuclear (COSY 45°) and heteronuclear (XHCORD) shift correlation experiments were performed by using standard Varian pulse sequences. Microanalyses were carried out in a Perkin–Elmer Elemental Analyzer model 240B.

X-ray diffraction

The crystals were mounted on an automatic four-circle diffractometer (Enraf–Nonius CAD-4 or Philips PW 1100). Cell parameters were obtained by least-squares refinement and intensity data were collected using graphite monochromatized radiation (MoKα on CAD-4 and CuKα on Philips) and the ω–2θ scan technique; two standard reflections measured every 100 reflections showed no intensity variation. Lorentz and polarization corrections were applied. The structures were determined by direct methods using the programs MITHRIL (11) and MULTAN 80 (12). The H atoms for compounds **1** and **3** were located on a difference map and, for compound **2**, on a difference map and by geometrical calculations. All H atoms were introduced in the refinement. In compound **1** all the parameters of the H atoms were maintained fixed but in compounds **2** and **3** the coordinates were refined, while the thermal parameters were fixed. An empirical weighting scheme (13) was applied in order to give no trends in $\langle w\Delta^2F\rangle$ vs. $\langle|F_o|\rangle$ and $\langle\sin\theta/\lambda\rangle$. The atomic scattering factors and anomalous dispersion were taken from International Tables for X-ray crystallography (14). The computation was made on a VAX 11/750 with XRAY70 (15), PARST (16), and Xtal 3.0 (17) programs. Experimental and X-ray structural data for compounds **1–3** are collected in Table 1.

Synthesis of 1,2-diphenyl-1,3-propanedicarbonitrile (1)

To a solution of sodium (230 mg, 10 mmol) in dry propan-2-ol (30 mL), benzyl cyanide (1.17 g, 10 mmol) and cinnamonitrile (1.29 g, 10 mmol) were added. The reaction mixture was stirred at room temperature for 3 h and then poured into ice-water (200 mL). The solid material thus obtained was filtered and recrystallized from propan-2-ol, 75% yield. Anal. calcd. for $C_{17}H_{14}N_2$: C 82.90, H 5.73, N 11.37; found: C 82.70, H 5.60, N 11.51.

By fractional recrystallization from propan-2-ol diastereomeric racemates α(1*R*,2*S*; 1*S*,2*R*) and β(1*R*,2*R*; 1*S*,2*S*) were individually isolated.

(1R,2S; 1S,2R) isomer: mp 124–125°C (lit. (18) mp 123°C). IR ν: 2242, 1494, 1453, and 1429 cm^{-1}; MS *m/e*: 246 (M^+, 28%), 178 (14), 131 (67), 130 (100), 128 (18), 118 (48), 117 (86), 116 (58), 104 (47), 103 (74), 102 (40), 101 (14), 90 (38), 89 (58), 88 (14), 78 (26), and 77 (64).

(1R,2R; 1S,2S) isomer: mp 132–133°C. IR ν: 2243, 1492, 1454, and 1434 cm^{-1}; MS *m/e*: 247 (M^+ + 1, 11%), 246 (M^+, 35), 178 (20), 131 (66), 130 (100), 118 (40), 117 (84), 116 (58), 90 (28), 89 (56), 88 (11), 78 (19), and 77 (63).

Synthesis of 1-amino-3,4,5-triphenylcyclohexene-2,4-dicarbonitrile (2)

Procedure A

To a solution of sodium (690 mg, 30 mmol) in dry methanol (75 mL), benzyl cyanide (1.76 g, 15 mmol) and cinnamonitrile (3.87 g, 30 mmol) were added. The reaction mixture was stirred at 50°C for 8 h and at room temperature for 12 h and was then concentrated to dryness. The oily residue was dissolved in ethanol (50 mL) and precipitated by addition of diethyl ether. The solid thus obtained was purified by recrystallization from ethanol; 66% yield, mp 271–272°C. IR ν: 3464, 3365, 3230, 2236, 2182, 1636, and 1604 cm^{-1}; ^{13}C NMR (acetone-d_6) δ: 35.78 (C-6), 47.47 (C-5), 54.15 (C-3), 56.60 (C-4), 76.18 (C-2), 119.32 and 119.99 (CN), 128.05, 128.21, 128.42, 128.77, 128.93, 129.25 and 130.66 (Co, m, p, aromatics), 136.73, 138.35 and 140.18 (C_{ipso}), and 158.64 (C-1); MS *m/e*: 375 (M^+, 13%), 227 (30), 226 (42), 205 (13), 204 (14), 171 (33), 170 (100), 169 (93), 155 (13), 150 (21), 143 (19), 142 (17), 130 (22), 115 (21), and 77 (16). Anal. calcd. for $C_{26}H_{21}N_3$: C 83.17, H 5.64, N 11.19; found: C 83.10, H 5.79, N 11.02.

Procedure B

To a solution of sodium (69 mg, 3 mmol) in dry methanol (20 mL), 1,2-diphenyl-1,3-propanedicarbonitrile (**1**) (738 mg, 3 mmol) and cinnamonitrile (387 mg, 3 mmol) were added. The reaction mixture was heated at 50°C for 8 h and then poured into ice-water (200 mL). The precipitate thus obtained was filtered and recrystallized from ethanol; 69% yield.

Synthesis of 2,4-dimethyl-1-phenyl-1,3,5-pentanetricarbonitrile (4) and 1-amino-3,5-dimethyl-4-phenylcyclohexene-2,4-dicarbonitrile (3)

Procedure A

To a solution of sodium (920 mg, 40 mmol) in dry methanol (100 mL), benzyl cyanide (2.34 g, 20 mmol) and crotononitrile (2.68 g, 40 mmol) were added. The reaction mixture was stirred at 50°C for 8 h and then concentrated in vacuo. The oily residue thus obtained was dissolved in diethyl ether (100 mL) and washed with water (3 × 50 mL). The organic phase was

dried ($MgSO_4$) and concentrated under vacuum. The crude product was purified by flash chromatography on a silica gel column (diameter 6 cm) (hexane – ethyl acetate, 3:1) affording first **4**; 6% yield, bp (3 Torr; 1 Torr = 133.3 Pa) 167°C. IR ($CHCl_3$) ν: 2245, 2185, 1494, 1455, and 1422 cm^{-1}; ^{1}H NMR (CD_3CN) δ: 1.11 (d, 3H, CH_3, J = 6.60 Hz), 1.17 (d, 3H, CH_3, J = 6.60 Hz), 2.26–2.56 (m, 5H, aliphatics), 4.04 (d, 1H, H-1, J = 6.60 Hz), and 7.36–7.47 (m, 5H, aromatics); MS *m/e*: 251 (M^+, 15%), 211 (11), 184 (30), 183 (46), 156 (15), 144 (79), 143 (69), 142 (19), 128 (17), 117 (89), 116 (69), 115 (55), 108 (100), 91 (19), 90 (14), 89 (25), and 77 (23). Anal. calcd. for $C_{16}H_{17}N_3$: C 76.46, H 6.82, N 16.72; found: C 76.81, H 6.70, N 17.01.

On continuing elution with the same mixture of solvents a second product **3** was obtained, and was recrystallized from ethanol; 8% yield, mp 203–204°C. IR ν: 3432, 3347, 3243, 2237, 2187, and 1654 cm^{-1}; ^{1}H NMR (acetone-d_6) δ: 0.71 (d, 3H, CH_3-C5, $J_{Me,b}$ = 6.36 Hz), 0.98 (d, 3H, CH_3-C3, $J_{Me,a}$ = 6.79 Hz), 2.39 (ddd, 1H, **Hd**, $J_{c,d}$ = −17.68 Hz, $J_{b,d}$ = 4.95 Hz, $J_{a,d}$ = 0.98 Hz), 2.61 (m, 1H, **Hb**), 2.64 (m, 1H, **Hc**, $J_{b,c}$ = 12.06 Hz, $J_{a,c}$ = 2.20 Hz), 2.96 (m, 1H, **Ha**), 5.62 (br s, 2H, NH_2), and 7.35–7.55 (m, 5H aromatics); ^{13}C NMR (acetone-d_6) δ: 16.85 (CH_3-C3), 17.44 (CH_3-C5), 35.35 (C-6), 36.25 (C-5), 39.85 (C-3), 56.02 (C-4), 76.84 (C-2), 118.76 and 119.45 (CN), 128.29, 128.89 and 129.85 (Co, m, p aromatics), 138.16 (C_{ipso}), and 156.95 (C-1).

Procedure B

To a suspension of 80% sodium hydride (1.2 g, 40 mmol) in anhydrous DMF (50 mL), benzyl cyanide (2.34 g, 20 mmol) and crotononitrile (2.68 g, 40 mmol) were added. The mixture was stirred at room temperature for 48 h and then the solvent was removed in vacuo. The residue thus obtained was treated with diethyl ether to give a solid that was filtered and recrystallized from ethanol; 41% yield.

Results and discussion

Description of the structure of 1,2-diphenyl-1,3-propanedicarbonitrile (1)

The crude product of the reaction is a diastereomeric racemic mixture arbitrarily designated α and β (diastereomeric ratio (^{1}H NMR) α:β ca. 65:35). The assignment of relative configurations to the diastereomeric racemates α (1*R*,2*S*; 1*S*,2*R*) and β (1*R*,2*R*; 1*S*,2*S*) was performed by X-ray diffraction of a monocrystal of the α diastereomer obtained by recrystallization of the crude diastereomeric mixture from propan-2-ol.

X-ray analysis

Figure 1 displays a view of the molecule with atomic numbering. Selected bond lengths, bond angles, and torsion angles are shown in Table 2. See Table 8 for coordinates and thermal parameters. Successive isotropic and anisotropic refinement cycles showed large temperature factor values for atoms C3, N3, N5, C23, and C24, which suggests a certain disorder; this may explain the high values of the *R* factors. All lengths and angles have normal values, except for the distance C24—C25,

Fig. 1. Molecular plot of **1** showing the atom numbering with displacement ellipsoids drawn (17) at the 50% probability level.

C11-C1-C2-C21	178.6(5)	C21-C2-C4-C5	68.2(8)

which is shorter than the expected value. The molecule consists of a central chain with two cyano groups and two phenyl rings attached to it. The torsion angles around C1—C2 are C3-C1-C2-C4 −179.2 (6)° and C11-C1-C2-C21 178.6 (5)°. The phenyl rings, which form an angle of 11.4(2)° between them, are above and below the central chain, C11 being −1.175(6) Å and C21 at 1.183(6) Å out of the plane formed by C3-C1-C2-C4. There are no other intermolecular forces than van der Waals.

Spectral properties

The IR spectrum shows the C≡N stretching frequency at 2242 (α) and 2243 (β) cm^{-1}. The ^1H NMR chemical shifts and splitting patterns are also consistent with the suggested structure. The aliphatic protons appear as a four-spin ABCM system, which was analysed by means of the LAOCOON III program (19). The magnetic parameters deduced from this analysis are shown in Table 3.

Description of the structure of 1-amino-3,4,5-triphenylcyclohexene-2,4-dicarbonitrile (2)

Recrystallizations from ethanol of the crude reaction afforded a single diastereomer whose relative configuration (3*S*,4*S*,5*R*; 3*R*,4*R*,5*S*) was determined by X-ray diffraction.

X-ray analysis

Selected bond lengths, bond angles, and torsion angles are collected in Table 4. See Table 9 for coordinates and thermal parameters. Figure 2 displays a view of the molecule with atomic numbering. The delocalization between the donor N27 and the acceptor cyano group is reflected in the molecular dimensions: the C5—C6 distance of 1.364(3) Å is significantly longer than the C=C bond in ethylene (1.336(2) Å) (20) and in unsubstituted cyclohexene (1.335(3) Å) (21); there is a corresponding shortening of the C5—N27 (1.348(4) Å) bond rela-

(3) $+X - 1/2, -Y + 1/2, +Z + 1/2$

tive to the normal C(sp^2)—N (1.426 Å) bond (22). The lengthening of the C1—C2 and C2—C3 bonds is a consequence of intramolecular interactions (23) between the neighbouring groups attached to the carbon atoms in positions 1, 2, and 3. The steric hindrance is alleviated by the molecule taking up a sofa conformation (see ring torsional angles in Table 4); the phenyl groups at C2 and C3 are in an equatorial position and the one at C1 in a quasi-equatorial orientation while the cyano group at C2 is in an axial orientation. H1 and H41 are in quasi-axial, H3 in axial, and H42 in quasi-equatorial positions. There are two weak N...N hydrogen bonds (Table 5) (24, 25). There are one intramolecular (C14—H14...N20) and two intermolecular (C4—H42...N29, C9—H9...N27) short contacts that can reasonably be described as hydrogen bonds according to Taylor and Kennard (26). The molecules are held together by this network of hydrogen bonds and by van der Waals forces.

Spectroscopic data

The IR spectrum shows the N-H stretching frequency at 3464, 3365, and 3230 cm^{-1}, and the C≡N stretching frequency at 2236 (unconjugated) and 2182 (conjugated) cm^{-1}. The 300 MHz spectrum of compound **2** was analyzed iteratively (19) and the best computed data of chemical shifts and coupling constants are given in Table 6. The values of $^3J_{bc}$ and $^3J_{bd}$ are in agreement with those calculated by application of the empirical equation of Haasnoot et al. (27) for the vicinal torsion angles expected for an axial–quasi-axial and axial–quasi-equatorial relationship between Hb–Hc and Hb–Hd, respectively. The magnitude of the homoallylic coupling constants ($^5J_{ad} < 1$Hz, $^5J_{ac} > 1$Hz) indicate that protons **a** and **c** are in a quasi-axial and **d** in a quasi-equatorial orientation. The assignment of carbon resonances has been made on the basis of the proton–carbon shift correlation spectrum.

Description of the structure of 1-amino-3,5-dimethyl-4-phenylcyclohexene-2,4-dicarbonitrile (3)

The crude product of the reaction is a diastereomeric racemic mixture that affords a single diastereomer on recrystallizing from ethanol. The assignment of the relative configuration (3*R*,4*R*,5*R*; 3*S*,4*S*,5*S*) to this diastereomer was performed by X-ray diffraction.

X-ray analysis

Selected bond lengths, bond angles, and some torsion angles are collected in Table 7. Coordinates and thermal parameters are shown in Table 10. Figure 3 displays a view of the molecule with atomic numbering. As in the cyclohexene **2** there is a delocalization between the amino and the cyano groups: the double bond C5═C6 in the cyclohexene is longer than in ethylene and unsubstituted cyclohexene while C5—N17 and C6—C18 are shorter than standard values but, in both cases, very similar to the values found in **2**. However the distances C1—C2 and C2—C3 have normal values because of the less bulky substituents. The steric hindrance due to the substituents at C2 causes lengthening of the C2—C8 bond. Here also, as a consequence of the steric hindrance, the cyclohexene **3** adopts a sofa conformation (see ring torsional angles in Table 7). The methyl and phenyl groups at C2 and C3 are positioned equatorially and the methyl group at C1 is in a quasi-equatorial orientation. There are two hydrogen bonds between the amino and the cyano groups. The two hydrogen atoms of the amine group are involved in intermolecular hydrogen bonding with the N atoms of the cyano groups. The geometry of these hydrogen bonds is as follows: (*i*) N17...N(19(1) 3.053 (2) Å, H171...N19(1) 2.16(3) Å, N17—H171...N19(1) 161(2)° and (*ii*) N17...N9(2) 3.225(2) Å, H172...N9(2) 2.56(3) Å, N17—

H172...N9(2) 131(2)°. Symmetry code: (1) $-x+1, -y+1, -z+1$; (2) $-x+1, -y, -z$. The molecules are held together by these hydrogen bonds and by van der Waals forces.

Supplementary data for compounds **1–3** are available.[3]

Spectroscopic data

The IR spectrum shows the N-H stretching frequency at 3432, 3347, and 3243 cm^{-1}. The unconjugated and conjugated C≡N stretching appear at 2237(w) and 2187(s) cm^{-1}, respectively.

^1H and ^{13}C NMR

The aliphatic protons appear as a ten-spin complex $ABCDX_3Y_3$ system. The assignment of proton resonances has been made on the basis of the proton–proton shift correlation spectrum and double resonance experiments. In acetone at 300 MHz the signals due to **Ha**, **Hd**, CH_3-C3, and CH_3-C5 appear well differentiated. Overlapping resonances between **Hb** and **Hc** signals were observed. The assignment of all signals was made feasible by a homonuclear 2D COSY 45° experiment ($CDCl_3$). The multiplet at 2.96 ppm (**Ha**) displays a strong correlation with the doublet at 0.98 ppm (CH_3-C3) and a weak correlation (homoallylic coupling) with the signals centered at 2.39 (**Hd**) and 2.64 (**Hc**) ppm. The multiplet at 2.61 ppm (**Hb**)

[3] X-ray data for compounds **1–3** have been deposited as supplementary material and can be purchased from: The Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, Canada K1A 0S2. Tables of atomic coordinates and of bond lengths and angles have also been deposited with the Cambridge Crystallographic Data Centre, and can be obtained on request from The Director, Cambridge Crystallographic Data Centre, University Chemical Laboratory, 12 Union Road, Cambridge, CB2 1EZ, U.K.

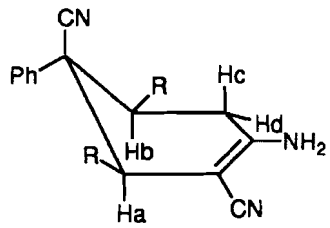
Fig. 4. Notation for aliphatic hydrogens of cyclohexenes **2** and **3**.



correlates strongly with the doublet at 0.71 ppm (CH_3-C5) and, finally, the multiplets at 2.61 (**Hb**) and 2.64 (**Hc**) ppm correlate with the multiplet at 2.39 ppm (**Hd**). To strengthen these assumptions double resonance (DR) experiments were performed in acetone-d_6 at 300 MHz. On saturating the CH_3-C3 signal at 0.98 ppm the multiplet at 2.96 ppm collapses to an apparent double doublet. By irradiation of the CH_3-C5 signal at 0.71 ppm the multiplet at 2.61 collapses to a double doublet. On saturating the **Ha** signal at 2.96 ppm the multiplet at 2.39 collapses to a double doublet and the doublet at 0.98 collapses to a singlet. Finally, by irradiation of the **Hd** signal at 2.39 ppm the multiplet at 2.96 collapses to an apparent quartet and the multiplets centered at 2.61 and 2.64 ppm simplify. As in the cyclohexene **2**, the magnitude of the homoallylic coupling ($^5J_{ad}$ and $^5J_{ac}$) attests that protons **a** and **c** are in a quasi-axial and **d** in a quasi-equatorial orientation.

The assignment of carbon resonances has been made on the basis of APT and proton–carbon shift correlation spectra.

A study of the Reformatsky reaction on formylcoumarins

Lakshmi Narayan Dutta, Manju Bhattacharyya, and Asoke Kumar Sarkar

Abstract: The reactions of bromozinc enolate reagents on formylcoumarins (**1**, **2**) afforded spiro-γ-lactones (**15–18**), furan derivatives (**13**, **14**), and coumarinylcarbinols (**3**, **4**) as highly unusual products along with the expected β-hydroxyesters (**5–12**). Stereochemical features of some of these products turned out to be highly informative and were unambiguously corroborated.

Key words: formylcoumarins, unusual Reformatsky products, stereochemistry.

Résumé : Les énolates bromozinciques réagissent sur les formylcoumarines (**1**, **2**) pour donner les β-hydroxyesters attendus (**5–12**) ainsi que des spiro-γ-lactones (**15–18**), des dérivés furaniques (**13**, **14**) et coumarinylcarbinols (**3**, **4**) dont les caractéristiques stéréochimiques, corroborées dans certains cas sans ambiguïté, fournissent d'importantes informations.

Mots clés : formylcoumarines, produits Reformatsky inattendus, stéréochimie.

The Reformatsky reaction is of enormous research interest (1, 2) though it has found very limited application to coumarin systems (3). We have recently studied (4) this reaction on coumarinyl methyl ketones in order to assess various selectivities of this versatile reagent for the synthesis of naturally occurring coumarins (5). The success of these investigations prompted us to undertake further study of this reaction on formylcoumarins (1, 2). This ultimately uncovered some highly interesting and uncommon findings, which we wish to report in this communication.

Results

4-Formylcoumarin (**1**) and 4-formyl-7-methoxycoumarin (**2**), prepared through SeO_2 oxidation (6) of the respective 4-methylcoumarins on treatment with the Reformatsky reagents generated as bromozinc enolates from α-bromoesters of acetic, propionic, *n*-butyric, and *iso*-butyric acids in benzene, afforded the expected β-hydroxyesters[2] (**5–12**) in 40% yield.[3] In addition to these products, each reaction afforded the corresponding alcohol (**3**, **4**) as a relatively polar component in 20% yield, presumably formed through the simple reduction of the formyl group in **1** and (or) **2**. This observation is highly unusual under Reformatsky conditions and the reaction pathway most likely proceeds via a SET mechanism (7).

19 R = H; R^1 = CH_2OAc
20 R = OMe; R^1 = CH_2OAc

The identity of the above alcohols (**3**, **4**) could be conclusively established through the preparation of authentic samples of **3** and **4** by $NaBH_4$ reduction of **1** and **2**, respectively. These simple monomeric reduction products **3** and **4** could ultimately be converted into their corresponding acetates **19** and **20**, having mp's of 99 and 168°C. Since we failed to detect any pinacol products, viz., CouCH(OH)CH(OH)Cou, in any of the Reformatsky reactions performed, it is reasonable to assume that the initial anion radical produced from **1** and **2** must have free access to a proton source (8), most likely the α-bromoester.

Using the bromozinc enolate generated from ethyl α-bromoacetate, the formylcoumarins (**1**, **2**) afforded the corresponding β-hydroxyesters (**5**, **6**), whose preferred conformation turned out to be **5***a* and **6***a*, respectively, as the β-H of

these β-hydroxyesters appeared in their ^{1}H NMR spectra at about δ 5.54 as a doublet of a doublet (J = 4, 8 Hz) in complete agreement with the Karplus equation (9). Further, these preferred conformers are in full conformity with conformational analysis if due contributions of hydrogen bonding and nonbonded steric interaction in all their plausible conformations are taken into consideration (10). Analogously, the β-hydroxyesters (**11**, **12**) obtained from the bromozinc enolate of α-bromo-iso-butyrate may have their preferred conformation as **11***a* and **12***a*.

Cou = 4-Coumarinyl/7-methoxy-4-coumarinyl

When bromozinc enolates generated from esters of α-bromopropionic acid and α-bromo-*n*-butyric acid were allowed to react with **1** and **2**, a relatively polar semisolid material was eluted in each case from the column chromatogram. ^{1}H NMR spectra of these semisolids revealed them to be the corresponding β-hydroxyesters (**7**, **9** from **1** and **8**, **10** from **2**), but upon more careful scrutiny of each of their spectra the presence of two different signals for the alcohol methine proton was observed at δ 5.4 and δ 5.0, respectively, in a 1:1 ratio. Not surprisingly, this 1:1 mixture was the diastereomeric *erythro* and *threo* β-hydroxyesters, which have been better referred to as "pref" and "parf" (11). However, what was surprising was the fact that the reaction fails to record any diastereoselectivity, contrary to a number of reports (4, 12).

Fortunately, each of the above mixtures of diastereomeric alcohols (**7**–**10**) could be resolved into their pure components (**7***a*–**10***a* and **7***b*–**10***b*) through extensive column, chromatographic separation, where the respective *erythro* alcohols (**7***a*–**10***a*) migrated out earlier than the corresponding *threo* alcohols (**7***b*–**10***b*). The alcoholic methine proton appeared at ~δ 5.4 (1H, d, J = 4 Hz) in the *erythro* alcohols (**7***a*–**10***a*) and at ~δ 5.0 (1H, d, J = 8 Hz) in the *threo* alcohols (**7***b*–**10***b*). Conformational analysis (10) suggests the preferred conformation of the *erythro* alcohols to be **7***a*–**10***a* and the *threo* alcohols to be **7***b*–**10***b*. This prediction was corroborated by the observed coupling constant of the alcoholic methine protons, which had ^3J values of 4 Hz for **7***a*–**10***a* and 8 Hz for **7***b*–**10***b*, and are in excellent agreement with the J values predicted simply from the Karplus equation (9).

It should be mentioned at this stage that the reaction of bromozinc enolate derived from α-bromo-*n*-butyrate with **1** and **2** afforded relatively nonpolar yellow solids having mp's of 119 and 64°C, respectively, in low yield (~8%). From ^{1}H and ^{13}C NMR spectra (Table 1) as well as 2D COSY (^{1}H–^{1}H) studies (13) these compounds were characterized as furan derivatives **13** and **14**. These furans could be formed through cyclization of diaddition adducts **13***a* and **14***a*, respectively, followed by their unusual dehydrogenation. This was further substantiated by the fact that **13***a* could be detected in trace amounts (^{1}H

NMR spectrum fully consistent with its assigned structure). The configuration of the double bond indicated in the α,β-unsaturated ester moiety in **13** and **14** was initially assigned as *E* due to their presumed formation from the respective β-hydroxyesters (4, 14). Finally NOE (13) studies unequivocally confirmed the *E* configuration of the olefinic double bond in **13** and **14**. In **13** an enhancement in the intensity of the 3″-H at δ 8.56 was noticed on irradiation of the 4″-$CO_2CH_2CH_3$ methylene at δ 4.14. This close proximity in space of 3″-H and the methylene group of 4″-$CO_2CH_2CH_3$ further suggests the preferred conformation of this α,β-unsaturated ester moiety as *s-trans*.

To our pleasant surprise the Reformatsky reaction on **1** and **2**, employing α-bromo-iso-butyrate, afforded a few additional minor products e.g., **15** and **16** from **1** and **17** and **18** from **2**. IR spectra of all these minor products indicated the presence of a highly characteristic absorption of a γ-lactone carbonyl stretching (15) at ~1770 cm^{-1}. This tempted us to assign the presence of a spiro-γ-lactone moiety in all these compounds and, upon careful consideration of the mechanistic aspects of their possible genesis, intermediate **21** was seen as the most plausible precursor. The presence of a relatively shielded methylene group at δ 3.91 (2H, q, J = 7 Hz) of one of the two ethoxycarbonyl groupings in **15** and **18** plausibly suggests a configuration of these two as **15***a* and **18***a* wherein one for the ethoxycarbonyl groups falls directly above the σ-plane of the aromatic nucleus in their most populated preferred conformation. This sort of shielding is not expected if the configuration is represented as **15***b* and **18***b*.

substantiated from the reaction of **1** through the isolation of another spiro-γ-lactone (**16**) in which the relative shielding of the protons of the methylene group in one of the ethoxycarbonyl functions is not observed. In addition, both the lactone methine proton and vinylic methine proton in **16** appeared as a doublet with a *J* value of 4 Hz. This is possible only if the two coupled protons assume a W-type orientation (16), thus demanding the configuration as represented in **16***a*. This type of coupling is not found with **15***a* and **18***a*, in agreement with our proposition. It is interesting to point out at this stage that another spiro-γ-lactone (**17**) was isolated from the reaction of **2**, having an ^1H NMR spectrum in agreement with the configuration as depicted in **17***a*, with a close resemblance to **16***a* from a configurational standpoint. It should be emphasized at this stage that the proposed structures **17***a* and **18***a* are in full agreement with their ^{13}C NMR (Table 1) and 2D COSY (^1H–^1H) spectra (13).

The formation of spiro-γ-lactones (**15***a*, **16***a*, **18***a*) delineated above necessitates the consumption of 3 moles of bromozinc enolate per mole of formylcoumarins (**1**, **2**), and involves a 1,4-addition to the conjugated coumarin carbonyl, along with 1,2-additions to the aldehyde and coumarin carbonyls, via **21** as a plausible intermediate, followed by further usual modifications. The genesis of **17***a* is most likely ratio-

nalized by 1,2-addition of a further mole of bromozinc enolate at the C-2 centre of **21**. Moreover, the isolation of the various products suggests that 1,2-addition to the aldehyde most likely involves minimum energy of activation.

Finally, it may be concluded that the Reformatsky reaction of formyl coumarins, using α-bromoacetate and α-bromopropionate, is highly chemoselective. Relatively less chemoselectivity has been observed with the more bulky bromozinc enolates generated from α-bromo-*n*-buryrate and iso-butyrate. Thus the Reformatsky reaction should prove to be an attractive method for the elaboration of different types of side chains in coumarin. It is highly interesting to note that the formation of spiro-γ-lactone and furan derivatives is unique, and there are almost no reports in the literature in which a substrate takes up more than 1 mole of bromozinc enolate reagent to afford such products. The reduction of the aldehyde function to the corresponding alcohol, observed under Reformatsky reaction conditions, also constitutes a highly unusual finding.

Experimental procedure

Boiling points and melting points are uncorrected. UV spectra were taken in aldehyde-free ethanol on a Hitachi U-2000 spectrophotometer. IR spectra were recorded in KBr with a Hitachi 270-30 data processor. The ^{1}H NMR spectra were determined in $CDCl_3$ on JEOL FX100 FT and Hitachi R600 FT spectrometers using TMS as internal standard. Mass spectra were recorded on a Finnigan Mat 1020C spectrometer operating at 70 eV and a Shimadzu model Gems QP 1000DA spectrometer. ^{13}C NMR spectra were run on a Bruker WH 250 spectrometer that was also used for the NOE studies and 2D homounuclear (^{1}H–^{1}H) COSY experiments.

Reformatsky reaction with 1 and 2 employing various ethyl α-bromoesters of acetic, propionic, *n*-butyric, and isobutyric acids

General procedure

The respective Reformatsky reagents were prepared by heating at reflux the corresponding α-bromoesters (17.1 mmol) along with zinc wool (1.11 g, 16.97 mmol) and a pinch of iodine in dry benzene under anhydrous conditions. Formylcoumarin **1** (1 g, 5.75 mmol in 50 mL of dry benzene) or **2** (1 g, 4.90 mmol in 50 mL of dry benzene) was added dropwise after all the zinc wool had dissolved and, after complete addition, refluxing was continued for a further period of 12 h while the nitrogen atmosphere was maintained throughout. The reaction mixture was finally cooled and decomposed by the addition of 20% sulphuric acid (100 mL) in the cold. The benzene layer was removed and the aqueous layer was extracted with $CHCl_3$ (3 × 50 mL). The combined benzene and chloroform extracts were washed with saturated brine solution (3 × 50 mL), followed by washing with aqueous saturated $NaHCO_3$ solution (3 × 30 mL). The solution was finally dried over anhydrous sodium sulphate and evaporation of the solvent afforded the respective crude products from which all of the pure products (**3–18**) were isolated by extensive column chromatography over silica gel (Table 2).

*$NaBH_4$ reduction of **1** and **2**, respectively, to the corresponding alcohols **3** and **4***

Formylcoumarin **1** (500 mg, 2.88 mmol) or **2** (500 mg, 2.45 mmol) was taken up in 50 mL methanol, an solid $NaBH_4$ (4.0 g, 0.11 mol) was added slowly in portions. After stirring overnight the mixture was decomposed with dilute hydrochloric acid until the solution became acidic; it was extracted with ethyl acetate (3 × 50 mL) and finally dried over anhydrous sodium sulphate. Removal of solvent afforded the respective reduction products **3** and **4**, in 95% yield, which were ultimately crystallized from methanol (Table 2).

*Preparation of acetates (**19**, **20**) of the respective reduction products (**3**, **4**)*

The reduction products, **3** (100 mg, 0.57 mmol) and **4** (100 mg, 0.49 mmol) obtained either as Reformatsky reaction product or as $NaBH_4$ reduction product from **1** and **2**, respectively, were separately warmed with 2 mL of acetic anhydride and a catalytic amount of fused sodium acetate under anhydrous condition for 1 h, and decomposed with crushed ice. The resulting mass was neutralized with solid $NaHCO_3$ and finally extracted with $CHCl_3$ (3 × 10 mL). The combined chloroform extracts were washed with brine (3 × 15 mL) and dried over anhydrous sodium sulphate. Evaporation of the solvent afforded the respective acetates (**19**, **20**), which were finally crystallized from a $CHCl_3$ – petroleum ether mixture (Table 2).

*Separation of diastereomeric alcohols, **7–10** into pure diastereomers, **7a** and **7b**, **8a** and **8b**, **9a** and **9b**, **10a** and **10b**, respectively*

The crude mixture of diastereomeric alcohols (**7–10**) was subjected to extensive and careful column chromatography over silica gel using 10% ether – petroleum ether mixture as eluant. In all experiments the *erythro* diastereomers **7***a*, **8***a*, **9***a*, **10***a* eluted first, followed by the polar *threo* diastereomers **7***b*, **8***b*, **9***b*, and **10***b*, respectively.

In a typical experiment 200 mg of alcohol, **8**, was fed into a column of silica gel and was eluted with 10% ether – petroleum ether mixture. The *erythro* diastereomer **8***a* (40 mg) migrated out first, followed by a mixture of *erythro* and *threo* diastereomers (100 mg). After this the nonpolar *threo* diastereomer, **8***b* (50 mg), in pure form, could be eluted from the same chromatogram.

Peptide models XI. Substitution effects on peptide chains. The magnitude of side-chain–backbone interactions in oligopeptides HCO-(NHCHRCO)$_n$-NH$_2$ for R = CH$_3$. An ab initio study

M.A. McAllister, G. Endredi, W. Viviani, A. Perczel, P. Csaszar, J. Ladik, J.-L. Rivail, and I.G. Csizmadia

Abstract: The stabilization effect of the Me group with respect to H has been determined for peptides of the type HCO-(NH-CHR-CO)$_n$-NH$_2$ for $1 \leq n \leq 3$. It was found that for the Me group the stabilization energy was in the vicinity of 5.4 kcal/mol. The site of substitution had no appreciable effect on the stabilization energy. The stabilization energy for monomethyl substitution (R = CH$_3$) ranged from 5.21 to 5.60 kcal/mol. For dimethyl substitution the values were between 10.53 and 10.81 kcal/mol, and for trimethyl substitution it was 15.99 kcal/mol.

Key words: stabilization effects of substituents, oligopeptide conformations, ab initio study on HCO-(NHCHRCO)$_n$-NH$_2$.

Résumé : On a déterminé l'effet de stabilisation du groupe méthyle par rapport à l'hydrogène dans les peptides du type HCO-(NH-CHR-CO)$_n$-NH$_2$ dans lesquels $1 \leq n \leq 3$. On a trouvé que l'énergie de stabilisation du groupe méthode est d'environ 5,4 kcal/mol. Le site de substitution n'a pas d'effet appréciable sur l'énergie de stabilisation. L'énergie de stabilisation pour la monosubstitution (R = CH$_3$) varie de 5,21 à 5,60 kcal/mol. Les énergies de stabilisation provoquées par deux méthyles s'établissent entre 10,53 et 10,81 kcal/mol alors que celle associée à une substitution par trois méthyles est égale à 15,99 kcal/mol.

Mots clés : effets de stabilisation de substituents, conformations des oligopeptides, étude ab initio de HCO-(NHCHRCO)$_n$-NH$_2$.

Introduction

The use of ab initio molecular orbital calculations to investigate substituent effects on chemical reactions has become commonplace (1, 2). Recently Wiberg et al. used this methodology to study the electronic effect of substitution on several classes of organic compounds including hydrocarbons (3, 4), alkenes (5), and carbonyls (6). Similarly, Tidwell et al. have used this technique to investigate substituent effects on highly reactive intermediates, ones which are not easily accessible via experiment. These included ketenes (7), allenes (8), isocyanates (9), diazomethanes (10), fulvenones (11), and diazocyclopolyenes (11). In the field of peptide chemistry, recent studies of single amino acid diamides generated from glycine, alanine, and valine have been subjected to an analogous study (12–15) in order to investigate substituent effects of the various side chains found in amino acids. However, this methodology has not, as yet, been applied to the study of oligopeptides. Recent studies on the polyalanine systems For-Ala-Ala-NH_2 (16–18) and For-Ala-Ala-Ala-NH_2 (19) have made available the necessary data for studying substituent effects on these systems.

The Ramachandran map, $E = E(\phi, \psi)$, associated with single amino acid diamides, HCO-NH-CHR-CO-NH_2, has nine discrete conformations as shown schematically in Fig. 1. These nine conformational centres, which can clearly be identified (13) on the Ramachandran potential energy surface (PES), have been labelled by subscripted Greek letters (α_D, α_L, β_D, β_L, γ_D, γ_L, δ_D, δ_L, ε_D, and ε_L).

Methodology

Ab initio calculated properties of all compounds under study were determined from full geometry optimizations at the HF/3-21G level of theory (20) using the GAUSSIAN 92 program (21). In all cases the geometry optimizations were terminated only when the root-mean-square force (gradient) along the internal coordinates was less then 6.5×10^{-5} au. Previous studies (17, 18) have revealed that a more stringent convergence criterion does not lead to significant changes in either the calculated molecular energy or structure. In particular, dihedral angles (ϕ and ψ) of selected alanine dipeptide triamides were found to change no more than ±0.4° when the gradient convergence criterion was increased 10-fold (16).

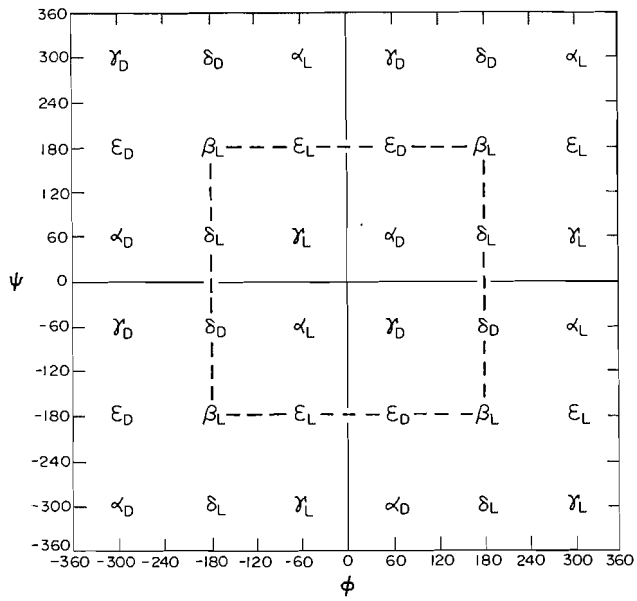
The energy values obtained from the ab initio computations are total energies for the molecule as a whole and therefore no direct comparison is possible when dealing with different compounds. This difficulty has been encountered in the studies of a series of substituted molecules and the problem was solved by considering so-called isodesmic reactions (1–11) where the number of identical bond types is conserved during the reaction. To be able to compare the conformational energy of peptides with different side chains we have proposed the use of similar reasoning (12–15). Thus, the isodesmic reaction can be represented by eq. [1].

[1] For-(NH-CH_2-CO)$_n$-NH_2 + n(R-CH_3)

→ For-(NH-CHR-CO)$_n$-NH_2 + n(CH_4)

Equation [1] is an isodesmic reaction that compares the relative effects of changing a substituent (R) on a peptide backbone (NH-CHR-CO)$_n$ to that of a simple alkane (R-CH_3). Thus, a calculated ΔE that is greater than zero (endothermic) for the above reaction would indicate that the substituent (R) prefers to be on the alkane rather than on the peptide. Similarly, if the ΔE for the reaction is less than zero (i.e., exothermic) then the substituent preferentially stabilizes the peptide relative to the alkane. From previous studies (3), we know that when R = CH_3 there is only a minimal substituent effect on R-CH_3. We can thus assume that the main substituent effect emerging from this analysis is due to stabilizing or destabilizing effects on the peptide backbone itself.

Fig. 1. Idealized PES topology for a single amino acid residue involving two complete cycles of rotation in both ϕ and ψ (the location of the minima are specified by their names in terms of subscripted Greek letters).



The corresponding stabilization energy is defined by eq. [2].

[2] $\Delta E^{R}_{stabil} = E_X$[For-(NH-CHR-CO)$_n$-$NH_2$] + nE(CH_4)

$- \{E_{\gamma_L}$[For-(NH-CH_2-CO)$_n$-NH_2] + nE[R-CH_3]$\}$

In eq. [1], For-(NH-CH_2-CO)$_n$-NH_2 stands for oligo- or poly-glycine, where For- is the N-terminal formyl (HCO-) protecting group and -NH_2 is the C-terminal amide protecting group. For-(NH-CHR-CO)$_n$-NH_2 is a homo-peptide with degree of polymerization n and R stands for the side chain of the amino acid residue. In eq. [2] ΔE^{R}_{stabil} is the stabilization energy, E_X[For-(NH-CHR-CO)$_n$-NH_2] is the energy of any homo oligo-peptide, with degree of polymerization n in conformation X, and E_{γ_L}[For-(NH-CH_2-CO)$_n$-NH_2] is the energy of oligo-glycine diamide in its reference conformation (γ_L)$_n$. Finally, E(CH_4) and E(R-CH_3) are energy values of the appropriate hydrocarbons.

In this calculation the glycine residues (For-(NH-CH_2-CO)$_n$-NH_2) are always in their global minimum energy conformation (poly γ_L); the hydrocarbons R-CH_3 and CH_4 are also considered in their global minimum energy conforma-

ε_L	—	—	—	—	—	—	—	—	—	—

[a]Energy values are in kcal/mol. The definition of ΔE^R_{stabil} is given in eqs. [2] and [3]. The following fully optimized hydrocarbon energy values (HF/321G) were used in eq. [2] to calculate ΔE^R_{stabil}: E(Me-H) = −39.976 877 hartree; E(Me-Me) = −78.793 948 hartree; E(Me-^{i}Pr) = −156.434 471 hartree.

[b]For Gly, b = 0. Thus $\Delta E^R_{stabil} = \Delta E^R_{X-\gamma_L}$.

tion, while the compound studied, i.e., For-(NH-CHR-CO)$_n$-NH$_2$, may be in any desired conformation. ΔE^R_{stabil}, then, is a measure of the change in energy associated with transfering the group R from the hydrocarbon R-CH$_3$ to a glycine residue, plus the change in energy associated with the peptide conformational change when it goes from its global minimum (i.e., poly γ_L) to the chosen conformation (X). For the X = poly γ_L conformations the large negative values of ΔE^R_{stabil} indicate that the R group is more stabilizing for the amino acid backbone than is the hydrocarbon.

In contrast to the above, for a given peptide, the various conformations can be compared in terms of their relative energies with respect to the global minimum, which is defined by eq. [3].

$$[3] \qquad \Delta E^R_{X-\gamma_L} = E(\text{given conformation:X}) - E(\text{global minimum})$$

Scheme 1 below shows the labeling scheme used to define the bonding in the mixed dipeptides and tripeptides. These schemes are used to define the folding parameters "d" and "τ", which have been introduced previously (16–18).

For the mixed dipeptide triamides,

$$d_{model} = {}^2H^d—{}^4H^d$$

$$\tau_{model} = {}^2H^d—C^1\alpha—C^2\alpha—{}^4H^d$$

For the mixed tripeptides,

$$d^1{}_{model} = {}^1H^d—C^1\alpha$$

$$d^2{}_{model} = {}^2H^d—C^3\alpha$$

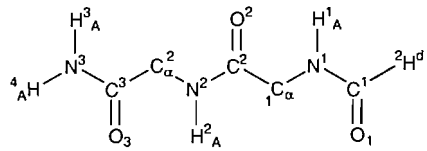
$$\tau^1{}_{model} = {}^1H^d—C^3\alpha—C^2\alpha—C^1\alpha$$

$$\tau^2{}_{model} = {}^2H^d—C^1\alpha—C^2\alpha—C^3\alpha$$

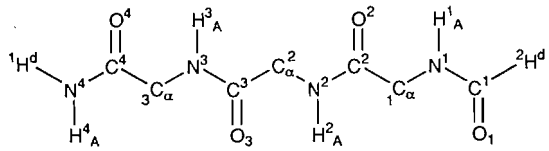
In all cases, the corresponding d_{crit} and τ_{crit} values are obtained by replacing the necessary H—C bond distances with a value of 1.515 Å and the H—N bond distances with a value of 1.462 Å, as was done previously (16–19).

Scheme 1.

Labeling Scheme for Mixed Dipeptides



Labeling Scheme for Mixed Tripeptides



Results

Calculated values of $\Delta E^R_{X-\gamma_L}$ and ΔE^R_{stabil} for monopeptides, that is, diamides of glycine, alanine, and valine, are given in Table 1, and are shown graphically in Fig. 2. Table 2 contains the total energies of the 49 stable conformations of For-Ala-Ala-NH$_2$ dipeptides, as well as the corresponding $\Delta E^R_{X-\gamma_L}$ and ΔE^R_{stabil} values (which are plotted in Fig. 3*a*). Table 3 and Fig. 3*b* show the calculated $\Delta E^R_{X-\gamma_L}$ and ΔE^R_{stabil} values for the tripeptide For-Ala-Ala-Ala-NH$_2$.

Table 4 contains energetic and structural data for the mixed dipeptides. Table 5 contains the corresponding information for the mixed tripeptides.

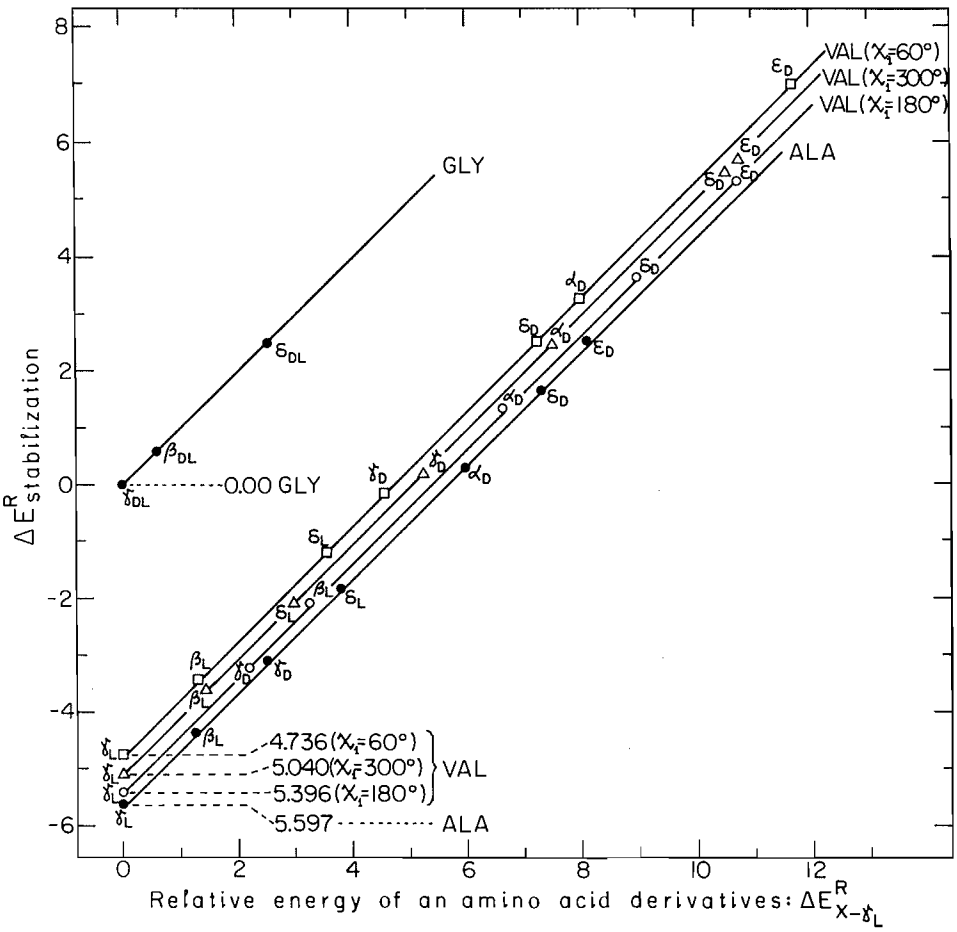
Fig. 2. Variation of stabilization energy (ΔE^{R}_{stabil}) for alanine diamide, as computed for conformer X, with relative energy ($\Delta E^{R}_{X-\gamma_L} = E^{R}_{X} - E^{R}_{\gamma_L}$) with respect to its γ_L conformer (in kcal/mol units). The equivalent information for glycine diamide and valine diamide is also shown for the sake of comparison.



Discussion

It should perhaps be emphasized that Figs. 2 and 3 may be misleading in the sense that the same information is given on both the horizontal and the vertical axes. This is necessarily so, since all that is done is the shifting of the reference state as illustrated by Fig. 4. However, such representations as shown in Figs. 2 and 3 are useful because they show graphically the spread of energy values as well as the continually decreasing y-intercept.

(i) Monopeptides

Methyl substitution (from R = H to R = Me) at the α-carbon of a simple peptide such as HCO-NH-CHR-CO-NH_2 is stabilizing the backbone in its γ_L conformation in excess of 5 kcal/mol. The various ΔE^{Me}_{stabil} values span the following range:

$$-5.60 \text{ kcal/mol} \leq \Delta E^{Me}_{stabil} \leq +2.57 \text{ kcal/mol}$$
$$\gamma_L \qquad\qquad \epsilon_D$$

It is interesting to note that the ^{i}Pr group is a better electron donor than Me; therefore more extensive stabilization is expected from the ^{i}Pr group. However, ^{i}Pr is bulkier than Me and therefore steric hindrance would be somewhat destabilizing. Consequently, the Me and ^{i}Pr stabilization become approximately equivalent (14).

$$\Delta E^{Me}_{stabil} \approx \Delta E^{iPr}_{stabil}$$

This is clearly illustrated in Table 1 and Fig. 2.

(ii) Homodipeptides

A total of 49 conformations for HCO(-NH-CHMe-CO)$_2$-NH_2 have been obtained by geometry optimization (16, 17) and the stabilization energy ($\Delta E^{Me,Me}_{stabil}$) of each of these conformations has now been calculated. The various $\Delta E^{Me,Me}_{stabil}$ values span the following range

$$-10.81 \text{ kcal/mol} \leq \Delta E^{Me,Me}_{stabil} \leq +4.56 \text{ kcal/mol}$$

of stabilization energy values has been found.

$$-15.99\text{kcal/mol} \leq \Delta E^{Me,Me,Me}_{stabil} \leq +6.25\text{kcal/mol}$$
$$(\gamma_L\gamma_L\gamma_L) \qquad (\delta_D\delta_D\delta_D)$$

This is illustrated in Fig. 3*b* and summarized in Table 3.

The results for the alanine homooligopeptide diamides shown in Figs. 2, 3*a*, and 3*b* are summarized in Fig. 5, where b_1, b_2, and b_3 are the intercepts for ΔE_{stabil} with respect to the $\Delta E^{R}_{X-\gamma_L} = E_{rel}$ corresponding to the stabilization energy at the $(\gamma_L)_n$ conformation.

(iv) Mixed dipeptides and tripeptides

The energetics of systematic replacement of α-hydrogens in For-Gly-Gly-NH_2 with Me groups to give the corresponding For-Ala-Gly-NH_2, For-Gly-Ala-NH_2, and For-Ala-Ala-NH_2 are depicted in Fig. 6. The approximately −5.4 kcal/mol stabilization energy per Me substitution is apparent and there is only a negligible difference in stability between For-Gly-Ala-NH_2 and For-Ala-Gly-NH_2.

Fig. 4. The shifting of the reference state for changing from $\Delta E^{R}_{X-(\gamma_L)n}$ to ΔE^{R}_{stabil}.

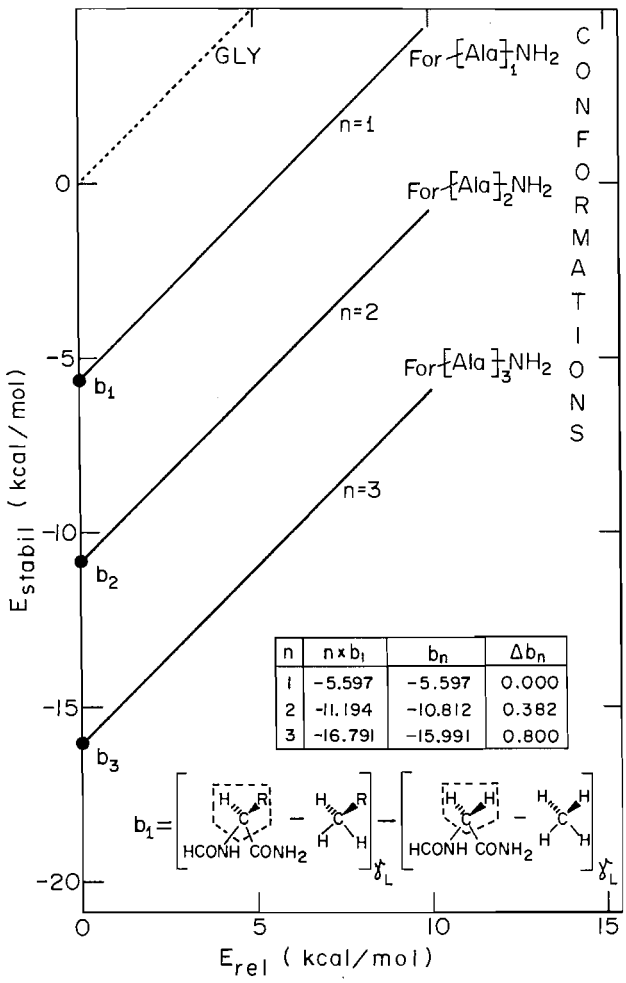
Fig. 5. Variation of stabilization energy (ΔE^{R}_{stabil}) for HCO-(NH-CHR-CO)$_n$-NH$_2$ with $1 \leq n \leq 3$, as computed for conformer X, with relative energy ($\Delta E^{R}_{X-(\gamma_L)n} = E^{R}_{X} - E^{R}_{(\gamma_L)n}$) with respect to its $(\gamma_L)_n$ conformers.



n	n x b_1	b_n	Δb_n
1	-5.597	-5.597	0.000
2	-11.194	-10.812	0.382
3	-16.791	-15.991	0.800

Similar information is presented for tripeptides in Fig. 7. Again, the Me substitution appears to be reasonably constant and the different isomers have practically the same stability.

If the Me stabilization energy were strictly constant then the stabilization could be fit to a straight line:

$$\Delta E_{stabil} = (b_1) \times n$$

where the variable n is the degree of polymerization of the peptide For-(NH-CHMe-CO)$_n$-NH$_2$ and the slope b_1 is the stabilization exerted by a single Me group for a monopeptide ($n = 1$).

Figure 8 indicates that this is only approximately true. As the diagonal broken line shows, there is an ever increasing systematic deviation from such a simple rule. Since this systematic deviation represents a reduction in stabilization energy it seems reasonable to assume that such a destabilizing phenomenon demonstrates steric hindrance due to Me crowding.

Such a phenomenon is also encountered in partially Me-substituted tripeptides. For example: For-Ala-Gly-Ala-NH$_2$ (denoted as Me, H, Me) is more stable than For-Ala-Ala-

Fig. 6. Energetics of systematic Me substitution of Gly-Gly leading to Ala-Ala.

For personal use only.

Gly-NH_2 (denoted as Me, Me, H) and For-Gly-Ala-Ala-NH_2 (denoted as H, Me, Me). Figure 9, presenting the energetics of Me transfer via isodesmic reactions, also underlines this phenomenon.

In summary, it is also clear from Fig. 8, for both $n = 2$ and $n = 3$, that Me substitution in the N-terminal amino acid residue (i.e., near the formyl protecting group) stabilizes the oligopeptide slightly more than substitution at the C-terminal amino acid residue (i.e., near the amide protecting group). Also, substitution at the central amino acid residue in the case of $n = 3$ represents somewhat less effective destabilization than either one of the terminal substitutions in tripeptides.

Concluding remarks

As a result of the present work, the stabilization of all oligopeptide and protein conformations can now be related to the standard conformation $(\gamma_L)_n$ of polyglycine.

$$\begin{array}{l} \text{-Gly-Gly-Gly-} + CH_3\text{-}CH_2\text{-OH} + CH_3\text{-}CH_3 + CH_3\text{-}CH_2\text{-Ph} \\ \quad \gamma_L \ \ \gamma_L \ \ \gamma_L \\ \qquad \Big\downarrow \ \Delta E_{\text{stabil}} = b_{\text{Ser}} + b_{\text{Ala}} + b_{\text{Phe}} < 0 \\ \text{-Ser-Ala-Phe-} \qquad + 3\ CH_4 \\ \quad \gamma_L \ \ \gamma_L \ \ \gamma_L \\ \qquad \Big\downarrow \ \Delta E^{\text{Me}}_{\gamma_L \rightarrow \alpha_D} > 0 \\ \text{-Ser-Ala-Phe-} \qquad + 3\ CH_4 \\ \quad \gamma_L \ \ \alpha_D \ \ \gamma_L \end{array}$$

The value of b_{Ala} is presented here for different degrees of polymerization ($1 \leq n \leq 3$). The value of b_{Ser} has been published recently (22) for various side-chain orientations, and the value of b_{Phe} will be published shortly (23). When stabilization energies are available for all amino acid residues, in every possible side-chain conformation, then the stabilization energy will be available for all backbone folding, and every possible short-range, backbone–side-chain interaction. The only stabilization or destabilization forces that lie outside of such an approach are the long-range side-chain–backbone and side-chain–side-chain interactions.

Application of median filtering to noisy data

David C. Stone

Abstract: The properties and application of the median filter are investigated using both simulated and real data for signals evolving with time. Comparison is made with existing numerical techniques for drift compensation and noise reduction in analytical measurements such as the moving average and Savitzky–Golay digital filters. The median filter provides a means for dealing with "spiky" noise and separating peaks from a slowly changing baseline, even when the exact nature of the drift and noise distribution is not known. Median filtering is a useful and complementary addition to existing digital filtering techniques, being mathematically robust and readily implemented on any computer platform.

Key words: median filtering, signal noise, signal processing, digital filters, chemometrics, data smoothing.

Résumé : Utilisant des données simulées ainsi que réelles de signaux évoluant avec le temps, on a étudié les propriétés et le domaine d'application du filtre médian. On a effectué une comparaison de cette méthode avec les techniques numériques existantes pour la compensation de la dérive et pour la réduction du bruit dans des mesures analytiques telles que la moyenne pondérée et les filtres digitaux de Savitzky–Golay. Le filtre médian fournit une façon de tenir compte du bruit à pointes et de séparer les pics d'une ligne de base qui se modifie lentement, même lorsque la nature exacte de la dérive et de la distribution du bruit n'est pas connue. Le filtrage médian est une addition utile et complémentaire aux techniques existantes de filtrage digital, il est mathématiquement robuste et il peut facilement être mis en place sur toutes sortes d'ordinateurs.

Mots clés : filtrage médian, bruit de signal, étude des signaux, filtres digitaux, chimiométrique, aplanissement des données.

Introduction

Many measurements in analytical chemistry involve recording the evolution of some dependent variable (the signal) with an independent variable increasing in discrete steps. The most obvious examples are the measurement of time-dependent phenomena in kinetic studies, although with the increasing use of computers many wavelength-dependent measurements can be described in the same terms. This has led to the development of various numerical methods for dealing with noisy or drifting signals, ranging from the simple to the complex (1–3). The method of choice for a particular situation will be determined by factors such as the nature of the measurement and noise, the magnitude of the signal-to-noise ratio, the computational and programming resources available, and the time scale for the required calculations. Different methods may also be considered where calculations must be performed in real time as data are collected rather than following completion of the measurement cycle. Thus while sophisticated and powerful procedures are increasingly being applied to analytical situations, there is still a place for simple mathematical procedures that can be accomplished with a minimum of computational expenditure and programming experience. One such method is the technique of median filtering. Originally described by Tukey (4) in the 1970s, median filtering has previously been applied to image (5) and speech processing (6). For example, many image-processing programs that provide "sharpening" or "edge extraction" functions exploit median filtering to achieve this.

It is difficult to say how widely median filtering has been employed in analytical chemistry, although it is likely that averaging techniques and polynomial smoothing are both considerably more prevalent. Papers explicitly on median filters and their properties are rare within the chemical literature (7, 8), while the technique is not as well covered in chemometrics texts as other methods of noise reduction. Median filtering can, however, be usefully applied to problems in analytical chemistry as demonstrated by the recent original work of Moore and Jorgenson (7). They applied this method to the extraction of peaks from chromatograms having strongly drifting baselines, and were able to show that it provided a superior performance to the mathematically more complex Butterworth and Chebyshev digital filters. More recently Camus and Larson (8) applied median filtering to noise reduction in atom probe analysis. This paper is of particular interest because it highlights the implicit assumption often made that the noise distribution is Gaussian. In this case the distribution is binomial (an event with probability q will occur m times out of n trials where m is an integer, $0 \leq m \leq n$), so filters developed for Gaussian noise do not perform well, distorting important features of the data. A more familiar example of this situation might be photon-counting measurements, in which errors are described by the Poisson distribution.

In this paper, the properties of the median filter are explored for situations common in analytical chemistry using synthetic transient response data, and its performance is compared to other, readily implemented digital filters. The transient functions chosen represent both continuous and discontinuous, symmetrical and asymmetrical functions. The baseline correction method of Moore and Jorgenson is also further evaluated in terms of the integrity of the extracted peak profile as well as the recovered peak area. Finally, the median filter is demonstrated using "worse case scenario" data from a surface acoustic wave based chemical sensor system.

Experimental

Instrumentation

The surface acoustic wave – gas chromatographic combination used in this work is a development of a system described previously (9). Briefly, a surface acoustic wave (SAW) device is used as the frequency-controlling element in a radio frequency oscillator circuit, and is situated in a GC detector oven immediately at the outlet of a capillary column. Under these circumstances, the oscillation frequency is perturbed by mass eluting from the column and adsorbing to the SAW surface. The recorded chromatographic peaks are therefore a function of both the evolving eluate concentration and the adsorption kinetics at the sensor surface. In the current system, both channels of a quartz 52 MHz dual delay-line SAW device are electrically connected in parallel and exposed to a single gas stream. A second, external SAW device is used as a signal reference source. Measurements can be made by monitoring either the difference frequency between the two SAWs, or recording the frequency of the detector SAW directly.

The oscillation frequency of the SAW device was monitored continuously using an HP5328A counter (Hewlett Packard) connected to an Apple™ Macintosh® II computer via an IEEE 488 interface bus (National Instruments). Mixtures of up to six components were injected on to a J&W 30 m × 0.53 mm DB-Wax capillary column (Chromatographic Specialities, Inc.). Chemicals used were either analytical grade and used as received or were freshly distilled before use. Confirmation of the chromatogram was obtained using an FID detector in series with the SAW device and an HP3390A recording integrator (Hewlett Packard).

Software

Data collection and analysis were performed using custom software written and compiled using Think C™ 6.0 (Symantec Corp.). The median filtering subroutines were written using methods derived from Press et al. (10). Additional smoothing and filtering were achieved using the generalized Savitzky–Golay method (sliding or initial-point least-squares smoothing) as implemented by Gorry (11). The software also includes routines for peak height, width, and area calculation, baseline subtraction, and curve fitting. Peaks are defined by the user in a special window by drawing a straight line across the base of the peak as identified visually; all peak calculations are then performed within this region.

A second program was written to generate artificial data for more detailed analysis of the filter. This allowed data sets describing a variety of functions to be constructed with or without the addition of specific noise distributions. Comparison of the original and filtered data was achieved by exporting the data to a spreadsheet program for analysis and plotting.

Results and discussion

General description of filter properties

A common technique for improving the signal-to-noise ratio of data evolving with time is the moving average (MA) filter (ref. 2, p. 175). In essence, the kth value is replaced with the arithmetic mean of all the values in the range $(k - r)$ to $(k + r)$ of a moving "window" of rank r and width $(2r + 1)$. It should be noted that the first and last r values are "lost" from the data in the process. An alternative scheme involves bin (or boxcar) averaging, where each kth value is replaced with the mean of j replicate determinations. This latter approach is satisfactory where the rate of data collection is much greater than the rate of any change in the measured signal and the noise is normally distributed. When the sampling rate is low relative to the rate of change of the signal, however, this can result in a significant distortion of the measured profile.

A simple calculation can readily show that a single outlier affects the mean greatly, resulting in a rectangular "step" of width $2r + 1$ in the filtered data. In the same way it can be shown that passing a MA filter over a step function will result in a ramp of width $2r + 1$ centred at the point of the step, since each successive window will contain a greater number of larger values (Fig. 1A). Recognition of this sensitivity of the mean to outliers has resulted in increasing interest in "robust" (nonparametric) statistical methods (12). Such methods are attractive since it is readily demonstrated that the median is considerably less sensitive to outliers than the mean. Furthermore, there are no assumptions concerning the nature of the noise distribution implicit in their use. From a computational

viewpoint, however, the median could be considered as less efficient since calculation requires sorting the data into either ascending or descending order. For a set of n values x_i the median is calculated as

$$[1] \quad m = x_k; \qquad k = \frac{(n+1)}{2} \qquad (n \text{ odd})$$

$$[2] \quad m = \frac{(x_k + x_l)}{2}; \qquad k = n/2;\ l = (n/2) + 1 \qquad (n \text{ even})$$

Since this is a selection process it is possible to speed up the calculation by using a variation of the Quicksort method in which only those subsets containing the required kth value are sorted (10). In this modification a further improvement in speed can be obtained for even $n > 100$ by equating the median to the $(n/2)$th value, avoiding two sorts (for the two centre values). With these considerations in mind, implementation of the median filter (ME) is essentially the same as for the moving average filter: For $r > 0$, the kth point in the filtered data corresponds to the median of the unfiltered values in the window $(k - r)$ to $(k + r)$. As with the moving average filter, the first and last r points are lost. Again, a simple calculation serves to illustrate the properties of this filter. When a median filter (moving average using the median instead of the mean) with $r = 1$ is passed over a single outlier, the outlying value will always be at the extreme end of the ranked data, and so will never become the median value. Similarly, when a median filter is passed over a step function it can readily be appreciated that the median value will become the higher value precisely when the centre of the window is at the step point *provided* that the window is narrower than the step function (Fig. 1B). This clearly demonstrates the importance of careful selection and optimization of filter parameters when applying digital filtering to experimental data.

Figure 2 shows the effects of applying both filters to an artificially generated chromatographic peak, which is essentially a continuous function (Gaussian) with a slight asymmetry introduced by virtue of monitoring the evolving profile at a fixed point over time rather than at a fixed time over distance (13). For the data used here the retention time and variance were 3.00 min and 0.004 min^2, respectively, while the actual peak consisted of ≈40 data points. Both filters caused a decrease in observed peak height with increasing r, although for small r the ME filter showed a smaller reduction. They also gave rise to increased peak widths, although the median filter did so at a slower rate. The two filters showed opposite behaviour with increasing r for other peak properties such as observed area and retention time, however. Thus the MA filter gave constant area and retention time, while the ME filter showed reduced area and a slight increase in retention time (3.00 to 3.08 min for $r = 0$ to $r = 15$). These results can be directly attributed to the difference in mathematical properties of the median and mean, which also explain the flat-topped, truncated peaks produced by the median filter. The latter are produced whenever the data points are symmetrically distributed about a single minimum or maximum, i.e., the values on one side are the mirror image of those on the other. In fact it can be shown (Fig. 3) that there is a relationship between r and the number of identical values about the centre, n_c. For n even, symmetrically distributed points,

[a]Same as Table 1.

[5] $n_c = r + 2$ for r odd, $r > 0$

[6] $n_c = r + 1$ for r even, $r > 0$

The effect of filtering on overall peak shape can be evaluated by calculating the root mean square of the differences between filtered and unfiltered data, i.e.,

[7] $$\text{distortion} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - y_i')^2}$$

Such calculations showed that both filters caused increasing distortion of overall peak shape, the MA filter having the greater effect (Table 1).

A discontinuous, asymmetrical peak shape was generated using exponential functions. This type of transient would be encountered, for example, in flow injection analysis using a well-stirred mixing tank with a step concentration input function. The moving average and median filters were again applied to these data, and their effect evaluated as before (Fig. 4). Both filters caused approximately the same decrease in peak height with increasing rank (97.7% of maximum for r = 15) while the peak width increased slightly. Times for peak maximum were unchanged for the ME filter but decreased markedly for the MA filter (86.0% of original for r = 15). A similar truncation of the peak maximum was observed for the ME filter as before, but the moving average filter caused a much larger distortion of the overall peak shape (Table 2). In particular, the time at which the concentration first increases was masked by the moving average filter. Note also that the severity of all these effects for both filters depends on the number of points sampled during evolution of the profile: the higher the sampling rate and the broader the profile, the lower the relative distortion of the filtered to original signals.

Effect of noise on filter performance

The effect of measurement noise was investigated by superposing known noise functions onto the original data shown in Fig. 1 and repeating the filtering calculations. The noise values were generated using methods outlined in Press et al. (10) to give three different distributions: (*i*) uniform random deviates with zero mean and ranges ±0.02, 0.05, and 0.10; (*ii*) normally distributed deviates with zero mean and standard deviations of 0.02, 0.05, and 0.10; and (*iii*) exponentially distributed deviates with zero mean multiplied by scaling factors of 0.02, 0.05, and 0.10. As expected, the median filter successfully removed the spike from the data while retaining the step function for all three noise types. (Note, however, that when r is greater than or equal to the width of the step function in the data (r = 5 in this case) the step function will be completely removed.) This is to be expected since, as we have seen, the mathematical properties of the median filter favour application to data where edge retention is important (5). In the same way, the moving average filter gave rise to the same features as shown in Fig. 1B. Both filters were successful in reducing baseline noise as measured by the standard deviation, there being a significant difference in s between filtered and unfiltered data as measured by the F-test (p = 0.05). Using the same measure, there was no significant difference between the standard deviations for the two different filters. Similar results were obtained by Camus and Larson for a simulated composition profile with superposed binomially distributed noise (8).

Filter performance for drift compensation

Moore and Jorgenson (7) used median filtering to extract chromatographic peaks from data with a drifting baseline by first using the filter to completely remove the peak of interest and then subtracting the baseline to obtain the peak in the absence of drift. As long as the filter rank was greater than or equal to the number of points in the peak, accurate peak areas and heights were obtained on comparing the filtered and unfiltered data. A similar procedure was carried out using the data of Fig. 2 added to known baseline drift and noise functions. Initial cal-

culations were performed using a filter of rank 40 since there were approximately this many points in the peak. The performance of this method of baseline correction was evaluated in terms of the recovered peak area as a percentage of the starting peak area, and the results are summarized in Table 3.

In general terms, the technique worked well provided that the slope of the baseline within the peak envelope did not change rapidly, although a slight rise of the baseline, after filtering, on the trailing side of the peak was observed in some cases. This is a result of the properties of the median when applied to data having a varying slope, and results in a slight dip below zero in the baseline-subtracted peak. With the data analysed here, 95% or better of the original peak area (based on the area before addition of simulated drift) was recovered using $r = 40$ when the magnitude of the baseline slope under the peak was less than ≈ 0.04 (for comparison, the peak height/width ratio was 2.10). The recovered area could be improved for any degree of baseline drift by increasing the width of the window used in the filter, but this also resulted in a considerable increase in the time taken to perform the filtering operation.

In terms of the other peak parameters, the recovered peak heights and widths (width at half-maximum height) follow the same basic pattern as the areas, although the extent of the variation is lower. For example, when only 67% of the area was recovered, 82% of the height and 87% of the width were recovered. Peak retention times were only shifted relative to the peak of Fig. 2 when artificial noise was added to the signal, typically giving a variation of less than 0.3%.

Comparison with other digital filters

A common approach to filtering noise is the application of Savitzky–Golay (SG) smoothing (14–18). This technique also uses a moving window; however, a polynomial is fitted through the points in the window by the method of least squares. (The MA filter can therefore be considered as a zero-order SG filter.) The success of this technique lies in the fact that fitting can be achieved by simple convolution with a set of integer weights, rendering it computationally fast and simple. An added benefit is that derivatives can easily be obtained during the smoothing process by calculating the appropriate weights, explaining the widespread use and popularity of the method. Although the first and last r points are again lost on smoothing the data, Gorry (11) has developed a refinement that retains these values. In the following discussion, the exact filter will be identified using Savitzky and Golay's notation, *XaYZ*, where *X* is the width ($= 2r + 1$), *Y* the order of the polynomial, and *Z* the order of the differential.

The effect of applying SG smoothing to the data of Fig. 1, both with and without added noise, was investigated using r values of 2, 5, and 7 and both second- and third-order polynomials. The noise distributions used were as follows: normal with mean zero and standard deviation ± 0.05; uniform with mean zero and range ± 0.05; and exponential with mean zero and scale factor 0.05. Some typical results are shown in Fig. 5. Note that at sharp edges the filter produces ripples that widen as the filter rank is increased. This is a result of trying to fit a polynomial function across a discontinuity: similar results would be obtained with filters based on the fast Fourier transform (FFT) algorithm such as the Butterworth and Chebyshev filters (7, 19). Savitzky–Golay smoothing also reduces the height and increases the width of such features as spikes and steps. Note that the smoothing gives rise to a curving baseline in the same way that sharp edges give rise to ripples. A one-tailed *F*-test was used to see if there was a significant improvement between the baseline standard deviations of the filtered

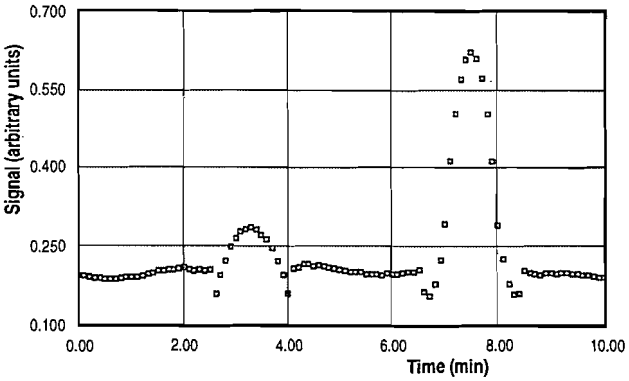
Fig. 5. The effect of a 15a20 Savitzky–Golay smoothing on the data of Fig. 1 with added uniform noise. See text for further details.



and unfiltered data for each noise function over increasing time frames. Generally, it was found that while all the filters used here reduced baseline noise significantly over long time periods, a significant reduction was only obtained over short periods with normally distributed noise. When the moving average and median filters were applied to the same data, the results were the same as in the absence of the noise functions. Camus and Larson report that a MA filter of rank 9 gave a better reduction in noise than a ME filter of equal rank for a sloping function with binomially distributed noise, whereas the median filter showed a significantly better performance for a step function, in keeping with the results obtained here.

Figure 6 shows the performance of the three different filters for three data sets, each containing 1000 points and having a different noise distribution function. A filter rank of zero indicates the unfiltered data. For comparison, Camus and Larson presented similar calculations using a binomial noise distribution and median, moving average, and parabolic filters. As expected, all filters successfully reduce noise as r is increased for flat baselines regardless of the noise distribution, although the magnitude of the reduction in variance decreases exponentially with increasing r. For exponential and normal noise functions, there is little to choose between the ME and MA filters if the sole criterion is reduction in baseline variance. For uniform and binomial noise distributions, the MA filter gives the better performance for the same rank *provided* that the data do not contain a discontinuity, such as a step function. Both the MA and ME filters perform better than the SG filter for exponential and normal noise distributions. This is because (for the same rank) the noise reduction capability of SG filters decreases with order and, as mentioned previously, the MA filter is a SG filter of rank zero. For uniform deviates the SG filter would be preferred to the ME on the basis of computational speed only.

A similar study was performed on the peak of Fig. 2 in order to compare the performance of the different filters with regard to peak shape: different noise functions were added to the original data, and the filters applied prior to peak shape analysis. All SG filters studied were third-order polynomials (i.e., *X*a30 filters). Since the original data set is a continuous function with superposed noise, the SG filter produced increasingly smooth peaks as the window width was increased. The baseline was also flattened out, exhibiting similar features as noted above. In comparison, the ME filter gave rise to increasingly

Fig. 6. Effect of the Savitzky–Golay, median and moving average filters on different baseline noise distributions as a function of filter rank r. (A) Exponential noise with zero mean and scale factor 0.05; (B) Gaussian noise with zero mean and standard deviation 0.05; (C) uniform random noise with zero mean and range ±0.05. Noise is expressed as the standard deviation relative to that of the unfiltered data.

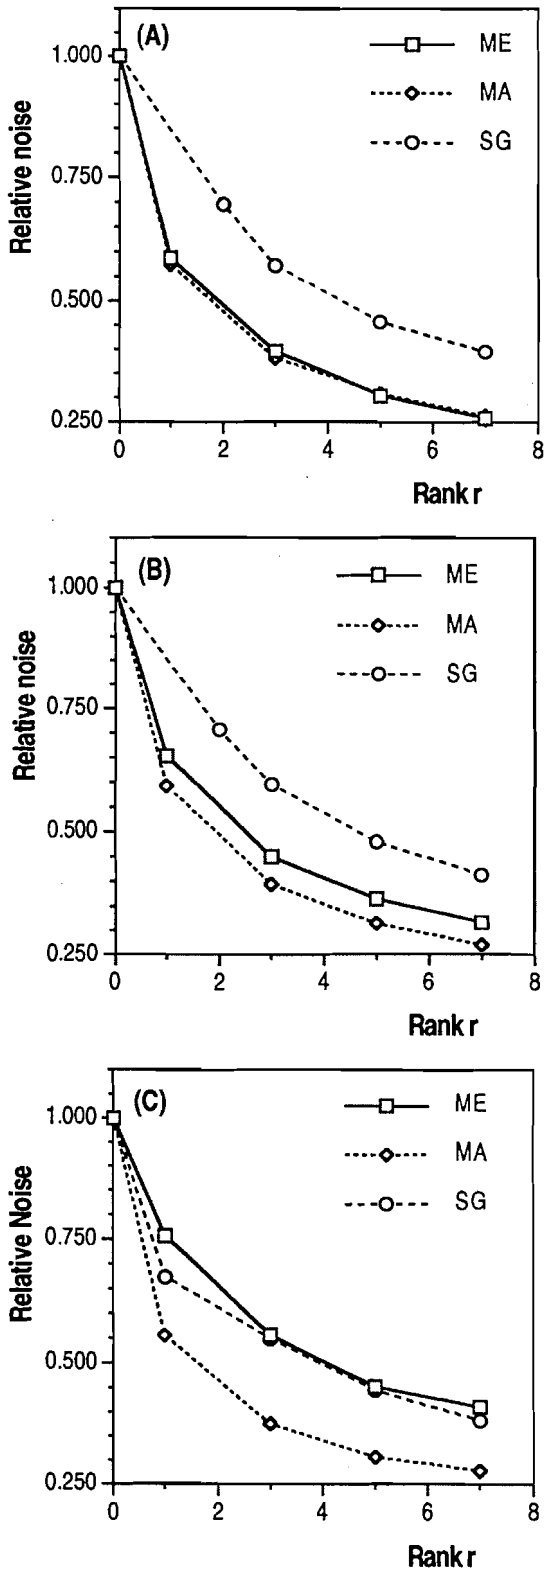


Fig. 7. Distortion produced by different filters on noisy data. Original = data of Fig. 2; exponential = exponential noise with scale factor 0.02; Gaussian = normally distributed noise with zero mean and standard deviation ±0.02; uniform = random distribution with zero mean and range ±0.02; medX = median filter of rank X; aveX = moving average filter of rank X.

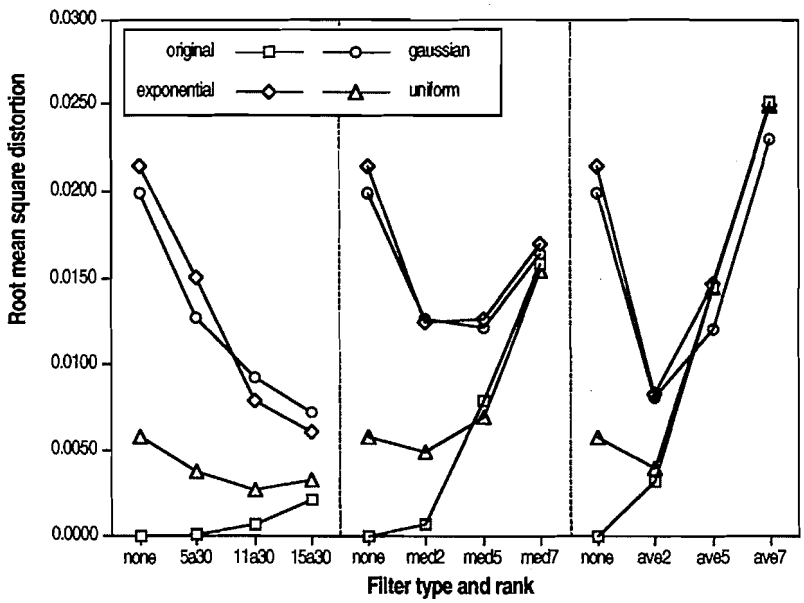

truncated, flat-topped peaks as described earlier. The MA filter again had a similar effect on the baseline, while the peaks were of the expected shape. Analysing the peak parameters showed that both the ME and MA filters gave a decrease in peak height and an increase in width at half height with increasing r as noted above, the ME filter showing the slower rate of change. Results for the SG filter were harder to interpret because of the added noise, but comparing results for the same analysis performed on the original peak showed that the SG filter increased area and decreased height while leaving the width at half height and retention time unaffected. Similar results have been obtained by Enke and Nieman for Gaussian and Lorentzian peaks (16). Results for the ME and MA filters were identical to those noted earlier.

The effect of filtering on overall peak shape was also studied by comparing the noisy peak (filtered and unfiltered) with the original noise-free data by calculating the distortion as described above. The results are summarized in Fig. 7 and show two effects: (*i*) an initial decrease due to noise reduction followed by (*ii*) increasing "true" distortion due to the filter properties. Note that in the absence of any superposed noise all the filters cause increasing distortion with increasing r, the least effect occurring with the SG filter and the greatest with the moving average. With a uniform noise distribution of zero mean and range ±0.02 there appears to be an optimum filter rank for reducing peak distortion for all three filters, corresponding to the balance of the two processes already outlined. The rapid increase in distortion measured for the ME and MA filters can be attributed to the peak truncation and increasing inclusion of the baseline, respectively. For normal (Gaussian) and exponential ("spiky") distributions, the best results were obtained for the SG filter with increasing rank: significant reductions in distortion were also achieved using the ME and MA filters, but this was reversed if the rank was increased beyond an optimal value.

Table 4. Comparison of approximate calculation times for different filters.

	Time[a] (s)		
r	ME	MA	SG
1	0.82	0.10	0.07
7	1.75	0.30	0.33
12	4.55	0.45	0.55
40	16.8	1.30	n/a[b]

[a]Calculations performed on the same 1000 point data set using a Macintosh II with 68020 processor and 68881 co-processor.

[b]The specific implementation of the routine to calculate weight tables for SG filtering was limited to a rank of 25 for practical reasons.

The final comparison between these three filters is concerned with the time taken to perform the necessary computations. Table 4 summarizes the time required to complete filtering of the same 1000 point data set for different filter parameters. These results were obtained using the implementations described in the experimental section, with the exception that median calculations were performed using a full data sort. The reason for this was that the faster median implementation described earlier was found to be faulty whenever the routine was applied to a window containing a sequence of identical values. Clearly, if this error was remedied calculation times could be improved. Although calculation times on different platforms will to some extent be implementation and compiler dependent, generally faster times will be obtained on more recent personal computers.

Other digital filtering techniques that have been applied to

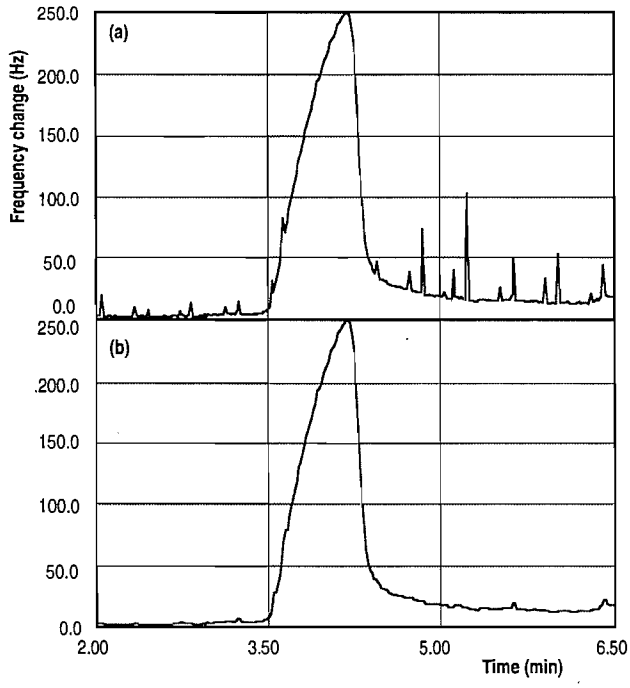
Fig. 8. SAW–GC response for injection of 0.20 μL of 1:1 toluene:2-nitrotoluene (by volume) using T_{inj} = 207°C, T_{col} = 178°C, T_{det} = 72°C, and T_{saw} = 57.6°C. 2-Nitrotoluene peak (*a*) in the presence of electrical noise, and (*b*) after application of the median filter, r = 1. Note: no coating on the quartz SAW device. For other details, see text and ref. 9.



analytical signals are based on either Fourier Transform or Kalman filtering techniques (1–3). Unlike the methods described so far, these techniques require more detailed knowledge of the nature of the signal and any noise or drift associated with it. In addition, they represent a significant increase in mathematical and computational complexity. A good example of this is the recent application of a modified extended Kalman filter incorporating least median of squares (robust) regression to detect and correct drifting calibration in graphite furnace-AAS while minimizing the effect of outliers and the number of recalibration measurements (20). One potential advantage of Kalman filtering is that it is not necessary to know the exact physical relationship describing the evolving signal, as long as a suitable mathematical function can be found that accurately describes the observed behaviour. To obtain good results with this technique, however, it is essential to have good estimates of the system and measurement noise. Another potential problem with FFT-based filters (such as the previously mentioned Butterworth and Chebyshev filters) is that they can introduce features into the data that may constitute an interference from an analytical viewpoint. A more detailed comparison with these filters is beyond the scope of the present article.

Application to transient sensor signals

As described in the experimental section, median filtering has been implemented in the software used to collect and analyse data from a SAW–GC combination. The reason for this was that under certain conditions with the particular configuration used, the SAW response can be subject to noise resulting from the heating circuits of the GC turning on and off. This noise is characteristically a regularly spaced, single-point "spike" in the data and thus ME filtering represents a logical choice for its removal. An example is shown in Fig. 8 both before and after filtering. Since the noise peaks are only a single point, they can be successfully removed using r = 1, ensuring minimal distortion of the analyte peak profiles. Both SG and moving average filters would not be as successful in removing such features.

A hazard in the use of any form of data processing is overprocessing, i.e., applying a sequence of processing techniques that produce a good picture but in the process completely mask the quality of the original measurement. For completeness, an example is given in Fig. 9. This shows results deliberately obtained from the SAW–GC system under a "worst-case" scenario: a badly aged SAW device operating at elevated temperature and close to the edge of the oscillators' stable region combined with an old, contaminated capillary column and injection port septum. Application of ME filtering with subsequent SG smoothing to restore a rounded appearance to the analyte peaks gives a reasonable chromatogram, but in the process has generated one spurious peak and significantly altered peak heights and areas. Multiple filter passes and combinations of techniques can make poor data look good, but they do not make it better. As always, it is the responsibility of the operator to exercise judgement on both the quality of the data and the required level and sophistication of filtering applied to it prior to analysis.

Conclusions

Like any other digital processing technique, median filtering has its advantages and disadvantages. It has been demonstrated that, compared to moving average and Savitzky–Golay filtering, ME filtering is particularly effective at removing noise spikes from experimental data. When applied in this manner, low filter ranks should be used ($1 \leq r \leq 3$) to ensure successful filtering with minimal distortion of the original signal. Likewise, ME filtering is particularly well suited to situations in which retention of sharp edges and discontinuities in the data are important. Median filtering can also be successfully applied to peak measurement in the presence of drifting baselines as previously demonstrated by Moore and Jorgenson (7). In addition to the conditions identified by these authors, it has been demonstrated here that the relative baseline slope is important in determining the accuracy of peak areas and heights obtained by this method.

In more general terms, a moving average or Savitzky–Golay filter may be preferred in situations were large filter ranks are required for successful smoothing of noisy data, but once again careful attention must be paid to the nature of the signal being processed and the information required from it: if peak heights are important, for example, an SG filter may well be preferable to an MA filter. Finally, a simple median filter could be implemented for real-time smoothing of experimental data as an alternative to other techniques, provided that large values of r are not required. Median filtering is thus a useful complement to existing data-processing methods for instrumental measurements.

Dosage comparatif des produits issus de la dégradation alcaline des hexoses

Marie-France Dubois, Luc Rigal et Antoine Gaset

Résumé : L'analyse quantitative du glucose, du fructose, du mannose, du sorbose, du psicose, et parallèlement des acides lactique, glycérique, glycolique, formique et acétique issus du traitement alcalin des hexoses est étudiée par chromatographie liquide haute performance ionique, couplée à un détecteur à ampérométrie pulsée avec deux colonnes Carbopac Dionex en série pour les sucres et à un conductimètre avec une colonne HPICE AS1 Dionex pour les acides. Cette méthode sensible et fiable ne nécessite aucun prétraitement des échantillons. Elle est comparée à la chromatographie liquide haute performance sur colonnes Biorad HPX87C et HPX87P montées en série pour les sucres et sur colonne Interaction ORH 801 pour les acides ainsi qu'au dosage enzymatique. Elle est appliquée à la comparaison du comportement du fructose, du glucose et du mannose en milieu alcalin.

Mots clés : hexoses, acides polyhydroxylés, isomérisation, dégradation alcaline, chromatographie liquide haute performance ionique.

Abstract: The mixture of hexoses and carboxylic acids produced by alkaline degradation of fructose was analyzed quantitatively by high-performance liquid chromatography. A pulsed amperometric detector with two Carbopac Dionex columns in series was employed in the assay of sugars (glucose, fructose, mannose, sorbose, and psicose), while a conductimeter with an HPICE AS1 Dionex column was employed for carboxylic acids (lactic, glyceric, glycolic, formic, and acetic). This sensitive and reproducible method obviated sample pretreatment. The results were compared with those of enzymatic assays and HPLC determinations using Biorad HPX87C and HPX87P columns in series for the sugars, and an Interaction ORH 801 column for the carboxylic acids. The behaviour of fructose, glucose, and mannose in alkaline medium was compared.

Key words: hexoses, polyhydroxylic acids, isomerization, alkaline degradation, high-performance ionic liquid chromatography.

Introduction

La dégradation alcaline des hexoses conduit à un très grand nombre de produits (1). Il se forme essentiellement des sucres isomères de l'hexose de départ (fructose, glucose, mannose, sorbose, psicose...) (2) ainsi que des acides polyhydroxylés (acides lactique, glycolique, glycérique, formique et acétique...) (3).

L'analyse de ces composés de dégradation est très importante dans de nombreux domaines : dans l'alimentaire, car ils influencent la saveur et la couleur des produits (4–6); dans les traitements des liqueur noires issues des procédés papetiers (7–9); et dans l'industrie de transformation des sucres (10–14) et en particulier pour l'optimisation de la production de l'acide lactique (15–20).

Les principales méthodes analytiques utilisées pour le dosage de tels milieux sont : (*i*) la chromatographie liquide haute performance (CLHP) sur colonne, de type silice greffée par des groupements amino propyl ou de type échangeurs d'ions sous forme Ca^{2+} ou Pb^{2+}, pour les sucres (21–28), ou de type silice greffée par des groupements C_8 ou C_{18} ou du type échangeurs d'ions sous forme H^+, pour les acides (6, 29–31).

La détection est alors assurée par réfractométrie dans le cas des sucres et des acides ou par spectrophotométrie UV, plus sensible, dans le cas des acides. Pour les sucres, la spectrophotométrie visible après ajout-post colonne est de moins en moins utilisée (28). Ce type d'analyse impose des prétraitements de neutralisation et déminéralisation du fait de la mise en oeuvre de solvants organiques dans le cas des colonnes type silice greffée, ou de résine échangeuse d'ions dans le cas de la chromatographie d'échange.

(*ii*) les méthodes enzymatiques : ces techniques, du fait même de la spécificité de l'enzyme employée, permettent le dosage sélectif du produit. Cependant, elles nécessitent un essai par produit à doser, et dans certains cas, un prétraitement de décoloration. Enfin, ces enzymes ne sont disponibles que pour quatre de nos produits (32, 33) (glucose, fructose, mannose et acide lactique).

(*iii*) la chromatographie en phase gazeuse, par exemple sur colonne type OV 101, pour les sucres (34–36), CP Sil 5 pour les acides (15, 37–39), couplée à un détecteur à ionisation de flamme : les sucres et les acides doivent subir préalablement une dérivation après neutralisation et lyophilisation (40). Cette dernière est assez délicate dans le cas des mélanges de

sucres et d'acides. Elle risque de provoquer une modification du milieu. De plus, l'acide formique et l'acide acétique ne pourront pas être dosés dans les mêmes conditions d'analyses.

Pour notre part, nous nous sommes intéressés à la mise au point d'une méthode d'analyse fiable et sensible des principaux hexoses et acides polyhydroxylés rencontrés dans les milieux issus du traitement basique du fructose, du glucose ou du mannose.

La chromatographie liquide haute performance ionique (CLHPI) couplée à l'ampérométrie pulsée pour les sucres (41–44) et à la conductimétrie pour les acides (45, 46) élimine les contraintes imposées par les autres méthodes analytiques (prétraitement des milieux, décoloration...). Notre objectif est d'optimiser ces deux méthodes CLHPI en vue de suivre l'évolution en fonction du temps de neuf composés issus de la dégradation alcaline des sucres.

Partie expérimentale

Réactifs et étalons

Tous les produits sont de pureté élevée, pour analyse :

Sucres étalons : D-fructose (Fluka 47 739), D-glucose (Prolabo 24 379-294), D-mannose (Aldrich 11 285-5), D-sorbose (Roquette Frères 80078), D-psicose (Sigma P-1275), D-galactose (Prolabo 24 333 183), Cellobiose (Prolabo 22 558 120), Arabitol (Sigma A 3381).

Acide étalons : acide DL-lactique (sodium salt) (Fluka 71 720), acide acétique (sodium salt) (Merck 6268), acide formique (Fluka 06 440), acide glycérique (calcium salt) (Fluka 50 036), acid glycolique (Fluka 50 590), acid pimelique (Fluka 80 500), acide propionique (Fluka 81 910).

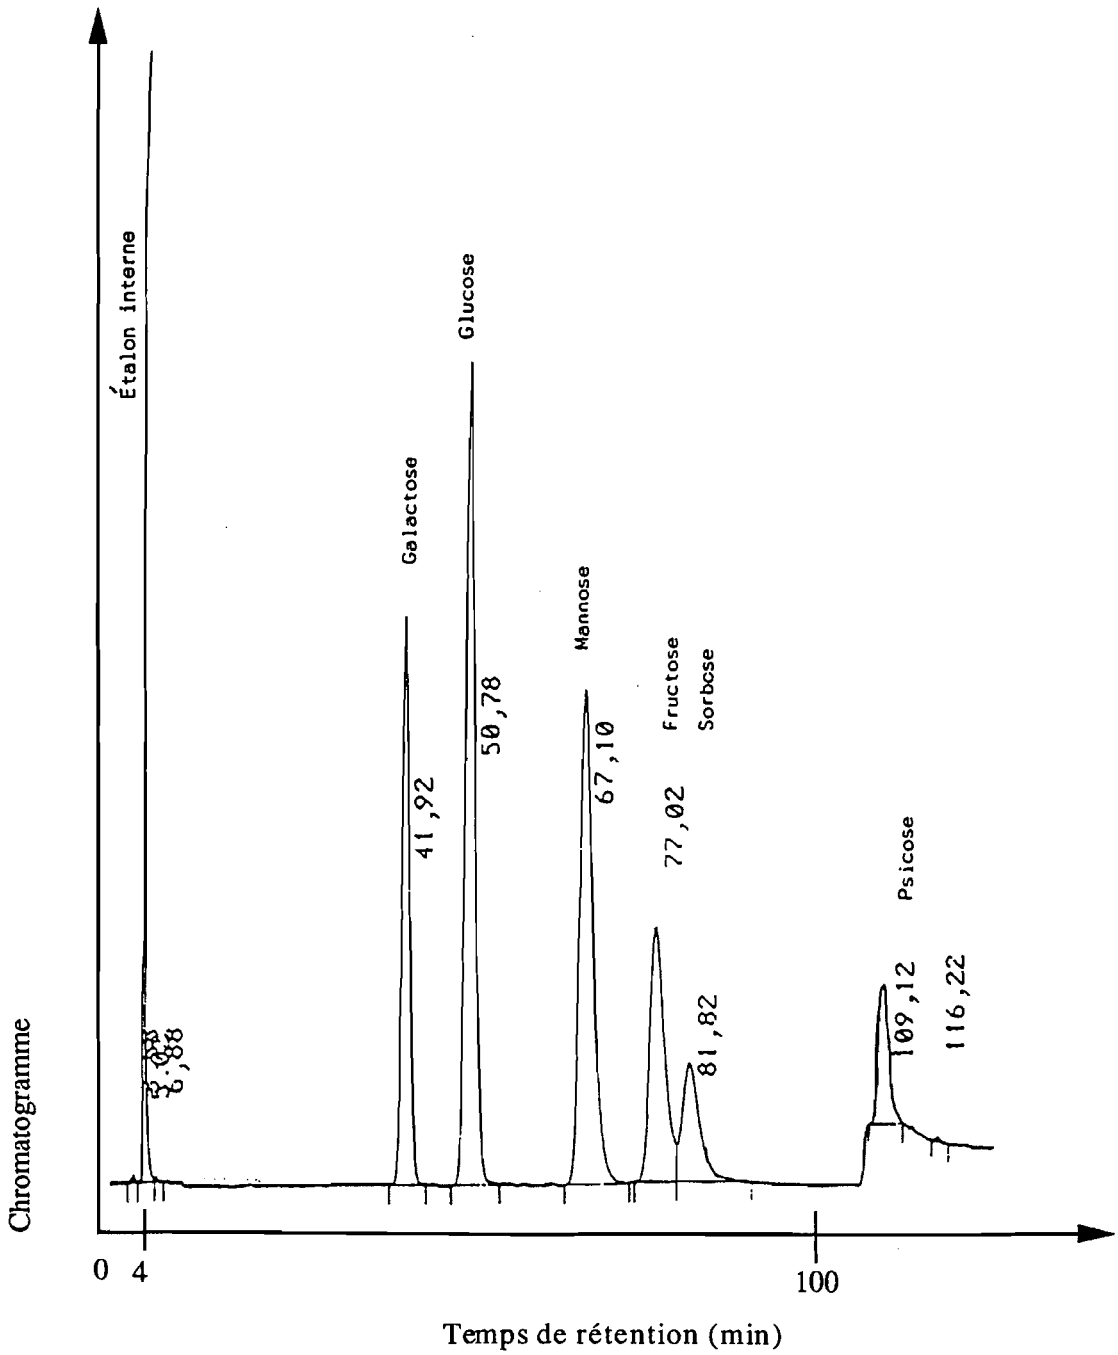
Fig. 2. Séparation CLHPI de glucose, fructose, mannose, sorbose et psicose avec deux colonnes Carbopac montées en série. Température : 20°C. Débit d'éluant : 1 mL/min, éluant E_1 : NaOH 100 mM, E_2 : H_2O, gradient étagé : 0–4 min : 15% E_1; 4–100 min : 100% E_2; 100–125 min : 100% E_1; 125–145 min : 15% E_1. Ajout post-colonne : 300 mM de soude.



Réactifs pour les éluants : soude (Baker 7067), acide octane sulfonique (Dionex 35 362), tétrabutylammonium hydroxyde (Janssen 17 6610), acide sulfurique (Fluka 84 720), propanol-2 (Chromasol SDS).

Méthodes de dosage

Chromatographie liquide haute performance (CLHP)

Un chromatographe liquide équipé avec une pompe Perkin Elmer Isocratique 250, une vanne Rhéodyne 7 125 (boucle d'injection 20 μL), un réfractomètre Perkin Elmer LC25, un chauffe-colonne Croco Cil™ et un intégrateur LDC, Milton Roy CI 10B ont été utilisés.

Pour les sucres, les colonnes sont de type échangeur de cation forte sous forme Ca^{2+} ou Pb^{3+} (Bio-Rad Aminex HPX 87C and HPX 87P; 300 mm × 7,8 mm i.d.) monté avec une précolonne (cartouche Biorad Microguard). L'éluant est l'eau désionisée. L'étalon interne est le cellobiose.

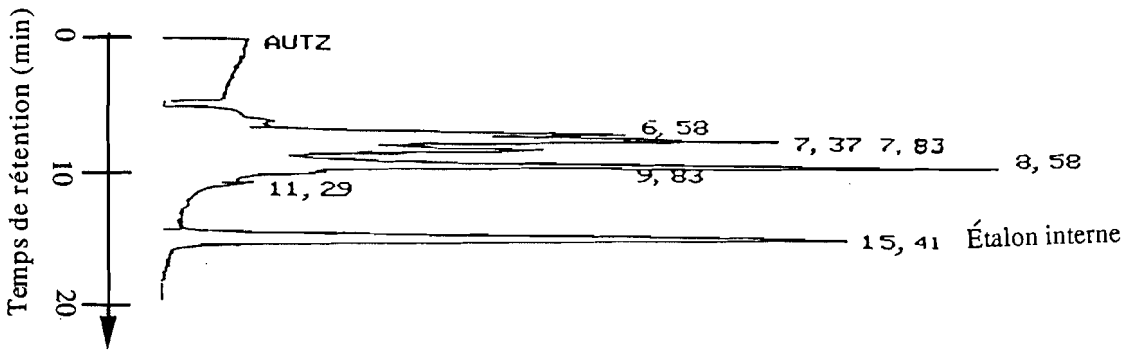
Tableau 1. Comparaison du dosage du glucose, du fructose, du mannose et de l'acide lactique par les méthodes CLHP, enzymatique et CLHPI.

Composé	Dosage CLHP après prétraitement (g/L)	Dosage enzymatique après prétraitement (g/L)	Dosage enzymatique sans prétraitement (g/L)	Dosage CLHPI sans prétraitement (g/L)
Glucose	1,41	1,35	1,66	1,73
Fructose	0,88	0,96	1,03	1,07
Mannose	1,08	1,05	1,18	1,24
Acide lactique	7,24	7,47	7,90	8,00

Fig. 3. Chromatogramme d'un milieu réactionnel de dégradation alcaline du fructose sur la colonne Interaction ORH 801. Température de la colonne : 35°C. Eluant : H_2SO_4 0,01 N. Débit d'éluant : 0,6 mL/min.



Pour les acides, la colonne est de type échangeur de cation forte sous forme H^+ (300 mm × 6,5 mm i.d.) monté avec une précolonne (cartouche Interaction Ionguard). L'éluant est l'acide sulfurique 0,01 N. L'étalon interne est l'acide pimélique.

Chromatographie liquide ionique haute performance (CLHPI)

Le système de chromatographie ionique utilisé est le BioLC Dionex avec une boucle d'injection de 50 µL et équipé de deux manières différentes pour les analyses de sucres et pour celles des acides.

Pour les sucres : Les séparations sont réalisées sur une ou deux colonnes Carbopac (250 mm × 4 mm i.d.) commercialisées par la Société Dionex, montées en série, reliées à une précolonne Carbopac PA1 Dionex. Les deux types d'éluants utilisés sont de l'eau désionisée, avec une résistivité de 18 MΩ et une solution de soude à 150 mM.

Dans le cas de la réalisation d'un gradient ou d'un gradient étagé à l'aide de ces deux éluants, un ajout post-colonne de soude 300 mM juste avant la cellule du détecteur par ampérométrie pulsée (PAD) est nécessaire afin d'éviter de trop grands changements de pH lors de la détection, et de stabiliser ainsi la ligne de base.

L'étalon interne utilisé est l'arabitol. Les caractéristiques du PAD sont : électrode en or; potentiels appliqués : $E_1 = 0{,}05$ V, $E_2 = 0{,}60$ V, $E_3 = -0{,}60$ V; durées d'application : $t_1 = 480$ ms, $t_2 = 120$ ms, $t_3 = 60$ ms.

Pour les acides : Les conditions d'analyse pour les acides sont : colonne HPICE AS1 (250 mm × 8 mm i.d.) de la Société Dionex, éluant solution d'acide octane sulfonique 1 mM et de propanol-2 à 2% dans l'eau désionisée, régénérant tétrabutylammoniumhydroxyl (TBAOM), étalon interne acide propionique, conductimètre sensibilité 30 µS.

Enzymologie

Les dosages sont réalisés suivant les tests de Boehringer et Mannheim (1 112 821, 139 106, 131 229).

Préparation des échantillons

Obtention de mélanges réactionnel type

Dans un ballon de 500 mL muni d'un agitateur mécanique, d'un réfrigérant et d'un thermomètre, le sucre en solution dans l'eau (100 mL) est thermostaté à la température choisie, sous agitation. La base (NaOH) en solution dans 100 mL d'eau est alors additionnée. En fin de réaction (9 h) le milieu réactionnel est refroidi dans un bain d'eau et de glace pilée.

Traitement des milieux réactionnels

Pour l'analyse des échantillons par CLHPI ou enzymologie, les échantillons sont simplement dilué dans l'eau désionisée (dosages enzymatiques et des sucres par CLHPI) ou dans l'éluant (dosages des acides en CLHPI). Dans ce dernier cas le pic négatif qui correspondrait à l'eau injectée, de conductivité plus faible que celle de l'éluant est supprimé.

Dans le cas de l'analyse par CLHP, pour le dosage des acides, les milieux réactionnels sont prétraités sur résines échangeuses d'ions H^+ (Lewatit S100) afin d'éliminer les cations présents dans la solution, puis dilués dans l'eau désionisée. Pour le dosage des sucres, les milieux réactionnels sont neutralisés et déminéralisés par percolation sur résine acide (Lewatit S100 forme H^+) puis basique (Lewatit MP62 forme OH^-). Ils sont ensuite dilués si nécessaire dans l'eau désionisée.

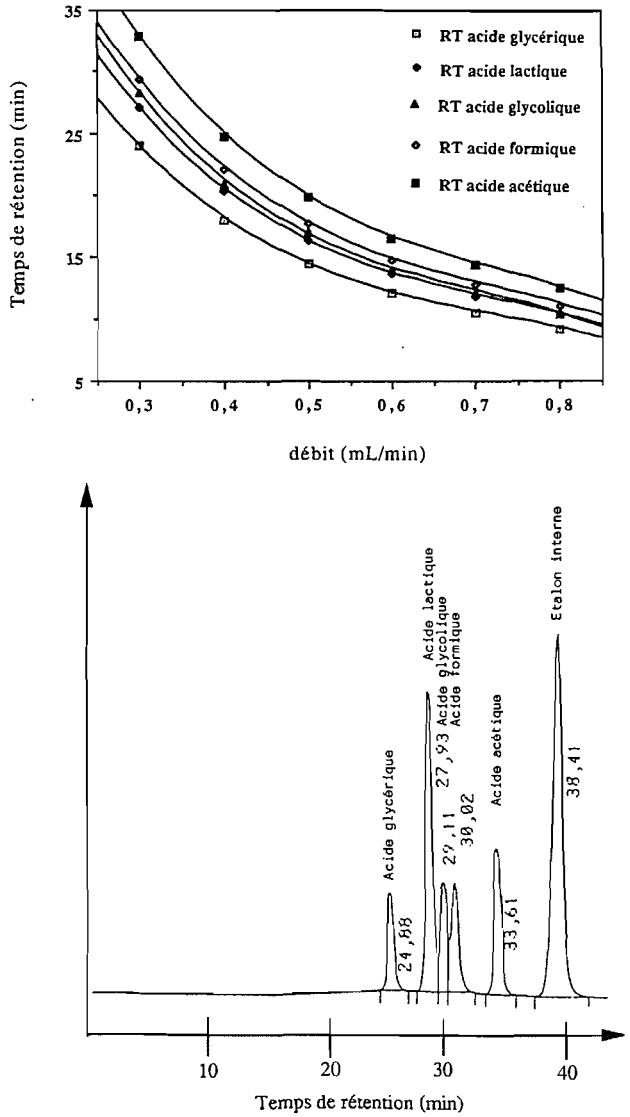
Fig. 4. Séparation CLHPI des acides lactique, glycolique, glycérique, formique et acétique sur la colonne Dionex HPICE AS1. Température : 21°C. Eluant : solution d'acide octane sulfonique 1 mM et de propanol-2 à 2% dans l'eau désionisée. Débit d'éluant : 0,3 mL/min.



Résultats et discussion

1. Analyse des sucres

L'analyse des sucres en CLHP sur colonne calcium ou plomb ne permet pas la séparation satisfaisante du glucose, fructose, mannose, sorbose et psicose. Par contre, avec les deux colonnes Ca^{2+} et Pb^{2+} montées en série, une diminution de la température et du débit de l'éluant améliore la séparation (figure 1). Cependant cette technique nécessite le traitement préalable des milieux réactionnels (neutralisation et déminéralisation).

La chromatographie liquide haute performance ionique par échange d'ion permet de résoudre cette difficulté. Cette technique présente l'avantage de mettre en œuvre des résines stables de pH = 0–14 et de ne nécessiter que des temps d'équilibrage très court. La détection ampérométrique pulsée est spécifique, sensible et compatible avec un gradient d'élution, grâce à l'ajout post-colonne de soude concentrée (41, 42). La sensibilité autorise de grandes dilutions de l'échantillon ce qui élimine de nombreux problèmes d'interférences avec la matrice. Les milieux réactionnels, dans le cas du traitement alcalin des hexoses peuvent donc être injectés sans prétraitement, après simple dilution.

Tableau 2. Comparaison du comportement du fructose, du glucose et du mannose en milieu basique concentré.

	Sucre de départ		
Produit	Fructose[a]	Glucose[a]	Mannose[a]
Fructose	0,001	0,001	0,036

[a]Mole de produit formé/mole de sucre introduit. Conditions opératoires : concentration en sucre = 25 g/L; NaOH = 2 M; 9 h; 40°C.

Dans le cas d'une seule colonne Carbopac, la séparation des différents sucres à doser n'est pas satisfaisante en dépit des changements de force éluante, de gradient et de débit. Afin d'augmenter l'efficacité de séparation, deux colonnes Carbopac ont été montées en série. La réalisation d'un gradient étagé dans le cas de l'utilisation de ces deux colonnes a permis d'obtenir une séparation correcte de l'ensemble des sucres (figure 2). Dans ces conditions, l'analyse quantitative de ces hexoses est obtenue avec une bonne précision ($x \pm 0{,}02\,x$). La gamme de concentration utilisée pour nos essais après ajout de l'étalon interne est de 10 à 200 ppm. Cependant, la limite de détection pour les sucres avec le PAD est largement inférieure puisqu'elle se situe autour de quelques picomoles injectées (42).

La comparaison des résultats obtenus selon les méthodes, CLHP, enzymatique et CLHPI dans le cas du dosage de glucose, fructose et mannose contenus dans un milieu réactionnel (tableau 1) montre que : le prétraitement de neutralisation et de déminéralisation impératif pour l'analyse CLHP conduit à une sous-estimation des sucres; et lorsque le milieu réactionnel est peu coloré, les concentrations en sucre obtenues par la voie enzymatique sans prétraitement et par CLHPI sont voisines. Cependant, dans le cas de milieux réactionnels trop colorés, le dosage enzymatique n'est plus fiable sans prétraitement de décoloration. Celui-ci constitue une source d'erreur.

Cette méthode de dosage par CLHPI permet donc de doser de façon fiable sensible et directe, le glucose, le mannose, le fructose, le sorbose et le psicose. De plus, cette méthode à permis de mettre en évidence la présence de galactose dans les milieux réactionnels issus du traitement alcalin du fructose, du glucose ou du mannose.

Fig. 5. Cinétique d'isomérisation du fructose. Concentration initiale en fructose : 100 g/L; NaOH : 0,3 M; température : 40°C.

For personal use only.

2. Analyses des acides carboxyliques polyhydroxylés

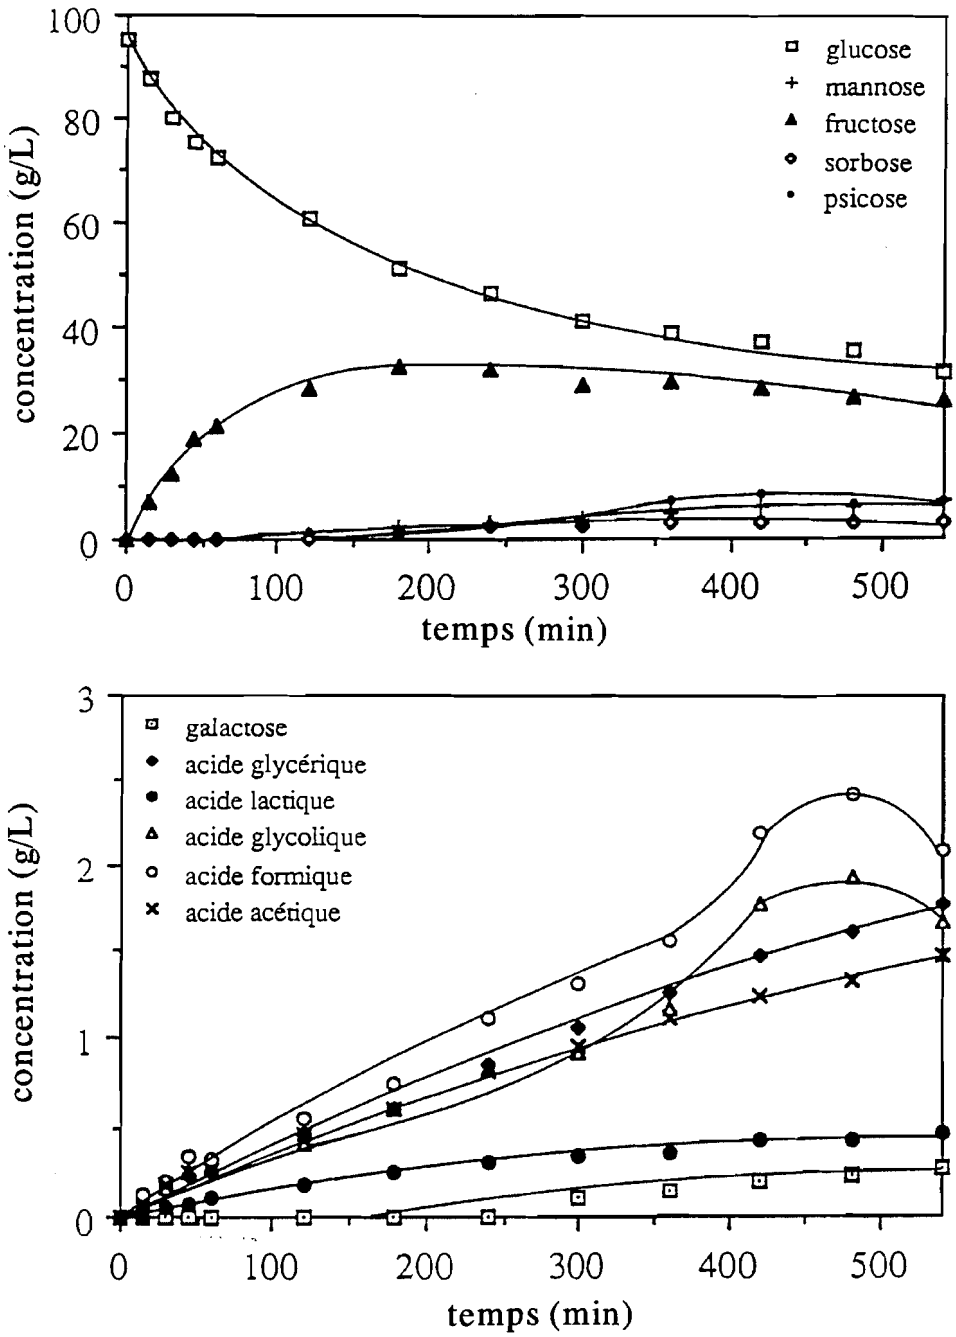
L'analyse des acides en CLHP sur colonne échangeuse sous forme H^+ nécessite le prétraitement des milieux réactionnels afin déliminer les cations présents dans la solution. Sur ce type de colonne on peut détecter les sucres et les acides. Cependant, leurs temps de rétention sont très voisins et l'analyse d'un milieu réactionnel issu de la dégradation alcaline du fructose ne permet pas de les doser de façon satisfaisante dans le mélange (figure 3).

De plus, la comparaison du dosage de l'acide lactique par cette méthode et la méthode enzymatique avant et après prétraitement de décationisation sur résines échangeuses montre que ce dernier est à l'origine d'une sous-estimation des concentrations (tableau 1).

Le dosage par chromatographie liquide ionique haute performance résoud cette difficulté. En effet, comme dans le cas des sucres, le prétraitement n'est plus nécessaire. Dans les conditions d'utilisations standards (débit d'éluant 0,8 mL/min), les acides sont mal séparés. La diminution du débit permet d'améliorer cette séparation (figure 4).

Les résultats obtenus pour les concentrations en acide lactique sont comparables à ceux obtenus par dosage enzyma-

Fig. 6. Cinétique d'isomérisation du glucose. Concentration initiale en glucose : 100 g/L; NaOH : 0,3 M; température : 40°C.



tique sans prétraitement (tableau 1). De plus, cette méthode chromatographique permet de doser les acides glycérique, glycolique, acétique et formique, ce qui n'était pas le cas des autres méthodes. L'analyse quantitative de ces cinq acides est obtenue avec une bonne précision ($x \pm 0{,}025\ x$). Grâce au système de suppression chimique, le bruit de fond est diminué et la sensibilité augmentée. Nous avons travaillé dans une gamme de concentration après dilution de 10 à 20 ppm. Celle-ci pourra être déplacée vers des concentrations plus faibles sans difficulté.

3. Application au cas de mélanges réactionnels

L'évolution des constituants de milieux réactionnels issus de traitements alcalins du fructose, du glucose et du mannose a été suivie grâce à la méthode de dosage par CLHPI. L'étude cinétique de la transformation du fructose en glucose et en mannose, et inversement, en solution alcaline a été menée par de nombreux auteurs (21, 24, 34, 35, 47–52). Cependant, si la formation du psicose a été prise en considération par quelques auteurs (21, 49, 52, 53), celles due sorbose et du galactose ne l'ont été que plus rarement (2, 21, 54–56). Les résultats obtenus par nos soins confirment la différence de comportement des trois hexoses vis-à-vis de l'action de la soude :

(*i*) Dans des conditions opératoires de faible concentration en base, l'isomérisation du fructose en glucose et mannose (figure 5) est plus rapide que celle du glucose (figure 6) et

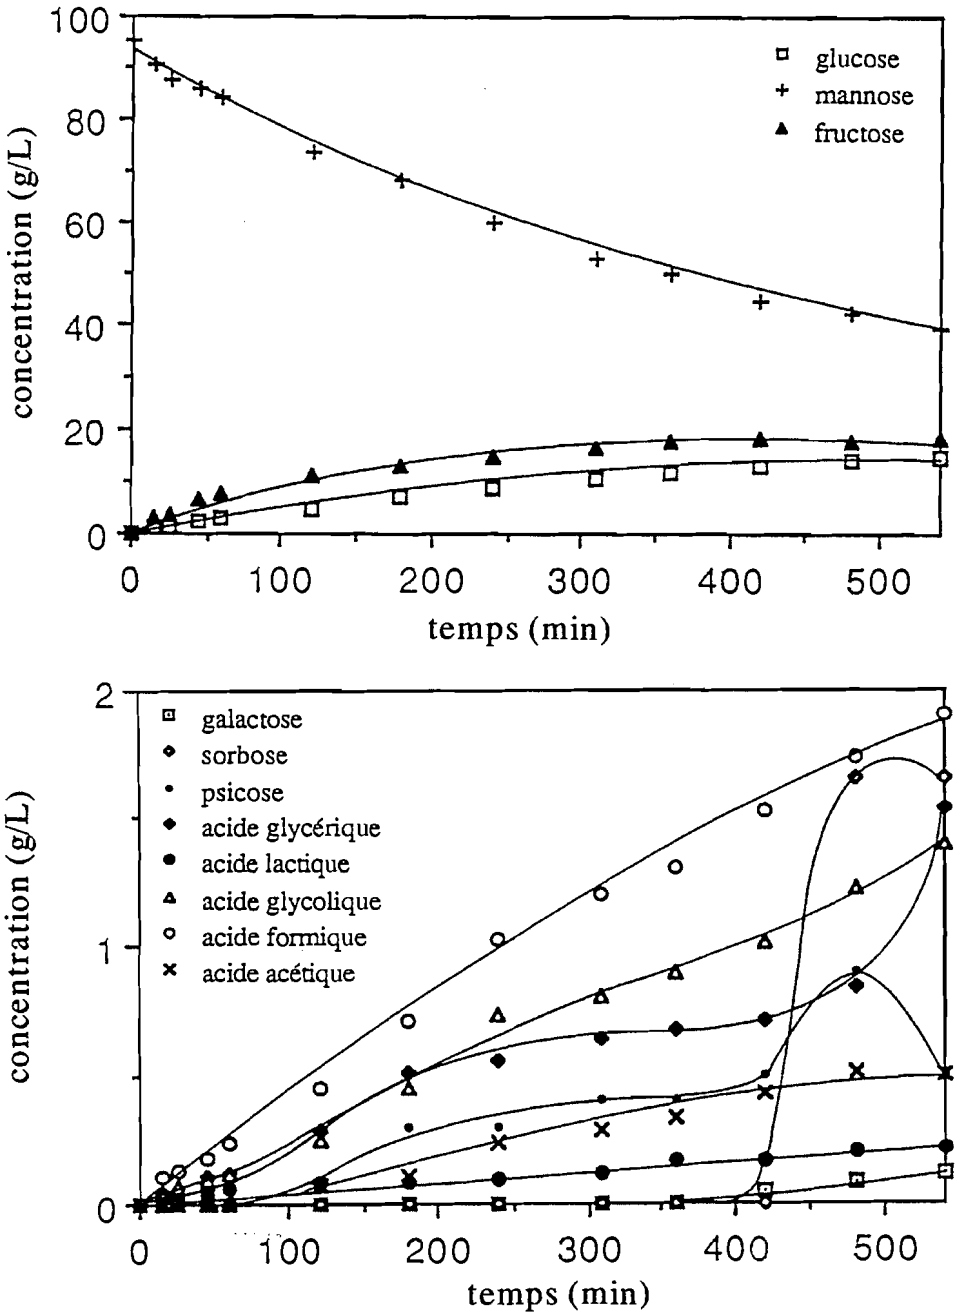
For personal use only.

Fig. 7. Cinétique d'isomérisation du mannose. Concentration initiale en mannose : 100 g/L; NaOH : 0,3 M; température : 40°C.



surtout du mannose (figure 7) (24). L'apparition du sorbose, du psicose et du galactose, qui mettent en jeu des mécanismes plus complexes (2, 21) est nettement plus lente. Cependant, à partir du fructose ou du glucose, le sorbose et le psicose atteignent après quelques heures de réaction, des concentrations à peine plus faibles que celle du mannose. L'apparition du galactose, dans ces deux cas, est retardée et il ne se forme qu'en proportion plus faible que les acides. À partir du mannose, le psicose n'est obtenu qu'en concentration très faible, et les formations du galactose et du sorbose sont très retardées.

(*ii*) Dans ces mêmes conditions de faible concentration en base, la formation de l'acide lactique est nettement défavorisée par rapport à celle des autres acides. Par contre, à forte concentration en soude, et pour une faible concentration initiale en monosaccharide, c'est l'acide lactique qui devient majoritaire (tableau 2). Ici aussi, l'ordre de réactivité vis-à-vis de l'action des bases est fructose > glucose > mannose.

Conclusion

L'analyse quantitative des sucres issus de la dégradation d'un hexose en milieu alcalin est obtenue avec les meilleurs résultats par la méthode chromatographique liquide ionique. Bien que cette séparation soit relativement longue, elle permet de doser exactement glucose, fructose, mannose, surbose, psi-

For personal use only.

cose sans prétraitement. En outre, elle permet de mettre en évidence la présence de galactose. L'augmentation de la capacité des résines utilisées dans les colonnes Carbopac devrait permettre de diminuer les durées d'analyses. La chromatographie liquide haute performance sur les colonnes plomb et calcium en série a confirmé la présence de ces sucres et le dosage enzymatique des trois principaux sucres (glucose, fructose et mannose) a permis une vérification quantitative. Les acides issus de ce même traitement sont également dosés grâce à une seconde analyse par chromatographie liquide ionique et le dosage de l'acide lactique est confirmé par enzymologie. Cette méthode d'analyse permet donc d'envisager l'étude de l'optimisation de l'obtention de l'acide lactique par traitement alcalin des monosaccharides en milieu concentré.

A two-dimensional copper(I) polymer containing both molecular rod and anionic bridges: synthesis and crystal structure of (μ-chloro)-(μ-pyrazine)copper(I)

J.M. Moreno, J. Suarez-Varela, E. Colacio, J.C. Avila-Rosón, M.A. Hidalgo, and D. Martin-Ramos

Abstract: The crystal structure of bright-red crystals of the bidimensional polynuclear diamagnetic (μ-chloro)(μ-pyrazine)copper(I) complex has been analyzed from X-ray diffraction data. The structure was solved by the heavy-atom method. Full-matrix least-squares refinement based on 673 reflections with $F > 4\sigma(F)$ converged to a final $R = 0.043$ and $R_w = 0.048$. Crystals of this complex are monoclinic, space group $P2/c$, $a = 3.814(1)$, $b = 6.356(1)$ and $c = 11.497(5)$ Å; $\beta = 96.04(2)°$, $Z = 2$. The structure consists of planes of copper(I) atoms linked by pyrazine and Cl^- bridges, each Cu(I) being in a distorted tetrahedral environment formed by two chloride ions and two nitrogen atoms belonging to two pyrazine molecules, with bond distances of Cu—Cl = 2.349(1) and Cu—N = 2.038(4) Å. Vibrational and electronic spectroscopy of the title compound is also reported.

Key words: two-dimensional copper(I)–pyrazine complexes.

Résumé : Utilisant les données de la diffraction des rayons X, on a déterminé la structure cristalline des cristaux rouge brillant du complexe diamagnétique polynucléaire bidimensionnel (μ-chloro)(μ-pyrazine)cuivre(I). On a résolu la structure par la méthode des atomes lourds et on l'a affinée par la méthode des moindres carrés (matrice complète) jusqu'à des valeurs finales de $R = 0{,}043$ et $R_w = 0{,}048$ pour 673 réflexions avec $F > 4\sigma(F)$. Les cristaux du complexe sont monocliniques, groupe d'espace $P2/c$, avec $a = 3{,}814(1)$, $b = 6{,}356(1)$ et $c = 11{,}497(5)$ Å; $\beta = 96{,}04(2)°$, $Z = 2$. La structure est formée de plans d'atomes de cuivre(I) liés par des ponts pyrazine et chlore; chaque Cu(I) comporte un environnement tétraédrique déforme formé par deux ions chlores et deux atomes d'azote appartenant à deux molécules de pyrazine et les distances des liaisons sont Cu—Cl = 2,349(1) et Cu—N = 2,038(4) Å. On rapporte aussi les spectres de vibration et électronique du composé mentionné dans le titre.

Mots clés : complexes bidimensionnels cuivre(I)–pyrazine.

Introduction

Numerous examples of pyrazine-bridged derivatives of copper(II) complexes have been prepared and structurally characterized in order to study the ability of the pyrazine bridge to mediate the magnetic exchange interaction in new one- (1–4) and two-dimensional (5–8) materials. However, pyrazine-bridged metal complexes are not only interesting because of their magnetic properties. Thus, Hoskins and Robson proposed (9) that infinite-ordered frameworks may be formed by linking together tetrahedral or octahedral metal centres through rodlike connecting ligands, such as pyrazine. These coordination polymers (9–12) present potential utility in host–guest chemistry, ion exchange, and heterogeneous catalysis. A significant part of the research in this field has concerned systems assembled by using copper(I) salts and *N,N'*-donor bidentate linear ligands with different rod lengths. Despite this, since the copper(I)–pyrazine dimers reported in the early 1960s by Lever et al. (13, 14) nearly three decades passed until Thompson and co-workers described the first one-dimensional structurally described pyrazine-bridged copper(I) complex (15), and, to the best of our knowledge, only a few one- (15–17), two- (17–19), and three-dimensional (19) pyrazine-

bridged copper(I) complexes have been reported so far. Furthermore, it should be stressed that several of these compounds were obtained by serendipitous reduction of copper (II) to copper(I) (15, 18, 19).

In the present work we report on the crystal structure of a new two-dimensional (μ-chloro)(μ-pyrazine)copper(I) polymer obtained by accidental reduction of copper(II) in the presence of *N,N*-3,4-dimethylphenyl(carboxymethyl)glycine.

Experimental

Physical measurements

Microanalyses of C, N, and H, and measurements of electronic and infrared spectra were carried out as already reported (20).

Syntheses

N,N-*3,4-dimethylphenyl(carboxymethyl)glycine*

This compound was synthesized according to the methods described in the literature (21).

(μ-Chloro)(μ-pyrazine)copper(I)

The title compound was obtained by using standard crystal-growing techniques in gels. The procedure was as follows: a solution (5 mL) of silica gel (pH = 5, ρ = 1.059 g cm^{-3}), prepared with sodium metasilicate (Merck) solution (pH = 11.2) and HCl (1 M), containing 0.5 g (2.07 mmol) of $Cu(NO_3)_2 \cdot 3H_2O$ was added to a glass test tube. When the coagulation took place, 3 mL of silica gel without the copper salt were added and also allowed to coagulate. After gelling, 10 mL of an aqueous solution (adjusted to pH = 8 with NaOH 6 M) formed by 0.49 g (2.07 mmol) of *N,N*-3,4-dimethylphenyl(carboxymethyl)glycine and 1 g (12.49 mmol) of pyrazine were poured on the gel. After 2 weeks suitable reddish crystals for single X-ray diffraction were formed, mechanically separated from the gel, and washed with distilled water. Experiments were performed at room temperature (about 20°C). Anal. calcd. for $C_4H_4N_2ClCu$: C 26.83, H 2.25, N, 15.64, Cu 35.48; found: C 26.97, H 2.31, N 15.33, Cu 35.65. Infrared spectrum (v = very, w = weak, m = medium, s = strong), ν(pyrazine) cm^{-1}; 3075, 3020 w (b_{1u}, b_{3u}); 1474 m (b_{1u}); 1408 s (b_{3u}); 1155 s (b_{1u}); 1110 m (b_{2g}); 1046 m (b_{1u}); 800 s (b_{2u}); 594 w (b_{3g}) and 446 s (b_{2u}); 306 vw ν(Cu-Cl).

X-ray data collection and structure determination

Single-crystal data collection was performed at ambient temperature with a Siemens–Stoe AED-2 four-circle diffractometer using monochromatized Mo K_α radiation (λ = 0.710 69 Å). The unit cell parameters for the red crystals were obtained from least-squares refinement of 25 reflections ($25 > 2\theta > 35°$). Crystal data: $C_4H_4N_2ClCu$, M = 179.08, monoclinic, space group $P2/c$, a = 3.814(1), b = 6.356(1), c = 11.497(5) Å, β = 96.04(2)°, U = 277.19(15) $Å^3$, Z = 2, D_c = 2.146 g cm^{-3}, $F(000)$ = 176, μ(Mo K_α) = 4.31 mm^{-1}.

A total of 999 independent reflections (R_{int} = 2.35%) out of 5168 were collected by the ω–2θ scan mode ($3 > 2\theta > 65°$) with variable scan rate from 0.6° to 3.6° min^{-1} depending on the intensity. A total of 673 reflections with $F > 4\sigma(F)$ were considered to have observable intensity and were used in the structure analysis. Intensities of three check reflections measured after every 90 min showed only statistical variation. The data were corrected for Lorentz and polarization effects and for absorption (empirical, based on azimuthal scans for three reflections). Transmission factors ranged from 0.927 to 1.000.

Table 1. Atomic coordinates (×10^4) and equivalent isotropic displacement coefficients ($Å^2 \times 10^4$).

Atom	x	y	z	U_{eq}[a]
Cu	0	2020(1)	2500	38(1)
Cl	5000	−135(2)	2500	39(1)
N(1)	0	3794(4)	1017(3)	30(1)
C(2)	1256(8)	3079(6)	0000	33(2)
C(3)	−1264(9)	5771(5)	0960(4)	31(2)

[a] U_{eq} defined as one third of the trace of the orthogonalized U_{ij} tensor.

The structure was solved by a combination of Patterson and Fourier techniques by using the SHELXTL-PLUS program package (22) on a MicroVAX II computer. In the final refinement, all non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed at their calculated positions and only their thermal parameters were refined. The function minimized was $\Sigma w(\Delta F)^2$ ($w = 1/\sigma_F^2$), resulting in a final $R = \Sigma||F_o| - |F_c||/\Sigma|F_o|$ value of 0.0434 and $R_w = [\Sigma w(|F_o| - |F_c|)^2/\Sigma w|F_o|^2]^{1/2} = 0.0475$. Maximum and minimum peaks in the final Fourier synthesis were 0.48 and −0.50 e $Å^{-3}$. The goodness-of-fit ratio was 0.81 for 40 parameters (data-to-parameter ratio = 16.8/1). Atomic coordinates for the non-hydrogen atoms are listed in Table 1. Hydrogen atom parameters, anisotropic thermal parameters, and structure factors have been deposited.[2]

Results and discussion

The (μ-pyrazine)(μ-chloro)copper(I) complex was obtained by accidental reduction of Cu(II) to Cu(I) in the reaction medium. In this process, the glycine derivative might act as reduction agent, since, as we have previously shown, the 2,6-dimethylphenylglycinato can be easily oxidized to oxalato anion in the presence of Cu(II) (20). Nevertheless, because of reduction of Cu(II) in the presence of 2,3-dimethylpyrazine has been reported (18), a possible mechanism in which the pyrazine derivative acts as reduction agent cannot be disregarded.

The electronic spectrum of the complex shows the presence of a single band at 600 nm. Since no d–d transitions are expected for a d^{10} complex, this band has been assigned to a metal-to-ligand charge transfer transition (MLCT). These MLCT bands appear at slightly higher energies, within the visible region, in most of Cu(I)–pyrazine complexes, affording orange or yellow colours (15–19). The positions of these bands depend upon the pyrazine substituents since methyl groups make pyrazine a poorer π acceptor (16). In our com-

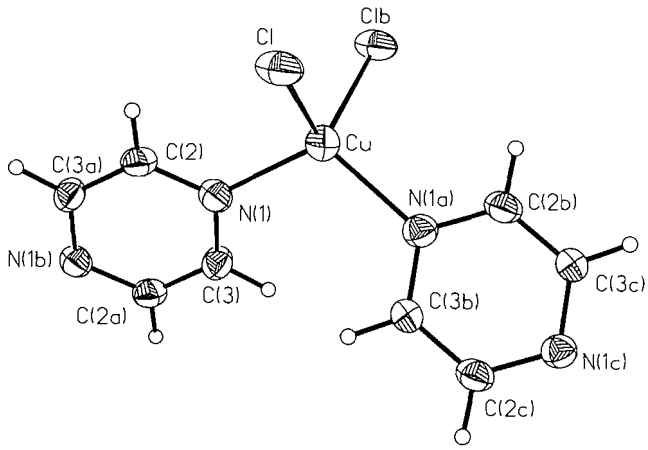
Fig. 1. A view of the coordination about the copper atom; 40% probability thermal ellipsoids are shown for the non-hydrogen atoms.



plex, the shift of the MLCT toward lower energies might be attributed to the substitution of two N-donor ligands by two bridging chloride ions, which would decrase the HOMO–LUMO gap. Nevertheless, a detailled molecular orbital calculation should be carried out in order to obtain a best understanding of this effect.

The IR spectrum of free pyrazine shows two absorption bands at 804 and 417 cm^{-1} in the 900–400 cm^{-1} region. It is this latter band that gives more information about the coordination mode of the pyrazine. Thus, this band is shifted to higher frequencies as a consequence of the pyrazine coordination to the metal ions. Nevertheless, the position of this band, when not split, gives little useful information about the pyrazine coordination mode, as has already been pointed out (6, 15). The IR spectrum of our complex shows, as the most significant feature, a single band centred at 446 cm^{-1}, which corresponds to a symmetrical bridging coordinated pyrazine with not very strong interaction, its value being in the low-frequency range for bridging pyrazines (6, 15, 16). The remaining bands observed (experimental section) correspond to those previously assigned (15, 23). An additional Cu–Cl absorption band appears at 306 cm^{-1}.

Up to now, all the copper(I)–pyrazine complexes described in the literature (15–19) show the pyrazine as the only bridging ligand. It should be noted that this complex is new in the sense that it incorporates two different kinds of bridging ligands in the structure, namely the pyrazine and the chloride ion. The only precedents for this kind of complex are limited to those of composition Cu_2LX_2 (13, 14) and CuLX (14) (where L = pyrazine, methylpyrazine, and dimethylpirazine; and X = Cl^-, Br^-, I^-, or CN), but none were examined by X-ray diffraction.

The most relevant feature of the structure is the disposition of the Cu(I) ions in two-dimensional lattices. Within each layer the metal ions are bridged by two chloride ions and two pyrazine ligands. Thus, each copper ion is tetracoordinated, giving rise to a CuN_2Cl_2 chromophore. A view of the chromophore together with the atomic labelling scheme is given in Fig. 1, while bond lengths and angles are listed in Table 2. This four-coordinate environment is compatible with two idealized geometries: tetrahedral and square-planar. The procedure proposed by Muetterties and Guggenberger (24) locates the coordination polyhedron at 1% of the $T_d \leftrightarrow D_{4h}$ deformation pathway, the geometry being almost that of an idealized tetrahedron. Within the coordination polyhedron both Cu—Cl and Cu—N bond distances of 2.349(1) and 2.038(4) Å, respectively, fall well withinin the range of those previously reported for related compounds (15–19, 25, 26) and do not deserve further comment.

Table 2. Bond lengths (Å) and angles (deg).

Cu—Cl	2.349(1)	Cu-N(1)	2.038(4)
N(1)—C(2)	1.335(6)	N(1)-C(3)	1.344(6)
C(2)—C(3)^{I}	1.373(7)		
Cl-Cu-N(1)	104.8(1)	Cl-Cu-Cl^{II}	108.5(1)

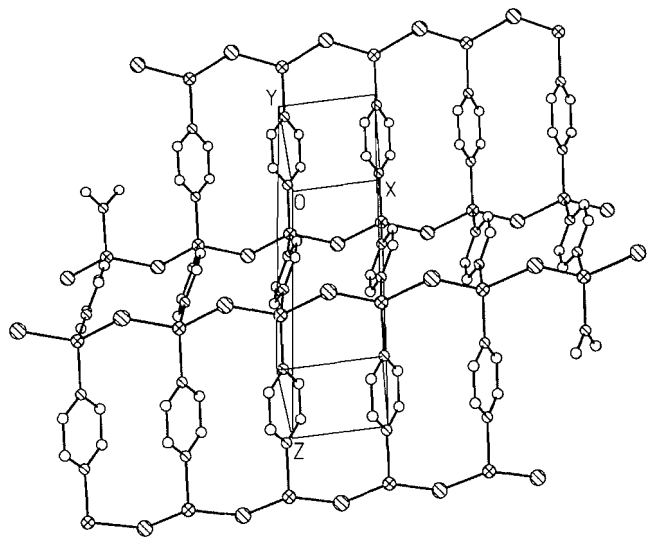
I = $-x$, $1-y$, $-z$; II = $x-1$, y, z; III = $-x$, y, $\frac{1}{2}-z$; IV = $x+1$, y, z

Fig. 2. A perspective view of a two-dimensional layer within the packing.



The layers, see Fig. 2, can be described as formed by two types of perpendicular monodimensional zigzag chains crossing at the copper atoms. Chains of the first type run along the *c* axis and have pyrazine as bridging ligand, while those of the second type extend parallel to the *a* axis containing bridging chloride anions. Then, the three-dimensional crystal structure is achieved by stacking of two-dimensional layers along the *b* axis. Intralayer Cu···Cu distances are 3.814 and 6.883 Å for Cu-Cl-Cu and Cu-pyz-Cu, respectively. In the tridimensional network pyrazine rings stack with a distance of 3.814 Å, which suggests some degree of extensive π–π cloud interactions.

It seems that the presence of bridging chloride anions in the structure prevents the formation of a 3–D scaffold-like material. The inclusion of chloride anions in the structure affords the following effects: Firstly, the value of the metal–chloride–metal angle is in our case (*ca.* 109°) far from the theoretical value of 180° given by Hoskins and Robson (9).

Table 3. Bond lengths and angles for pyrazine derivatives in some copper complexes.

Compound	Reference	C—N (Å)	C—C (Å)	N-C-C (°)	C-N-C (°)

[c]mepyz = methylpyrazine.
[d]2,5-mepyz = 2,5-methylpyrazine.

Secondly, rodlike ligands yield larger metal–metal distances than do chloride ions. While the first effect could be responsible for the difficulty in arranging the atoms geometrically to built up scaffold-like structures (9), the latter might prevent the formation of cavities large enough to allow the formation of interpenetrating frameworks (12).

As for the pyrazine rings, these are located on an inversion centre, being, as usual, planar within the experimental error. Nevertheless, some values of bond lengths and angles are significantly different from those found for free pyrazine (27) and bridging copper-pyrazine complexes (1–8, 15–17). Moreover, comparison of pyrazine bond lengths and angles in our complex with those reported in the literature, Table 3, reveals that the distortions in the former are of different sign. Thus, the distortions in the reported complexes, compared with free pyrazine, show a marked trend towards increasing the C—C and C-N-C values, while the N—C and N-C-C values remain almost constant. However, in our complex the C—C and C-N-C values are significantly lower and the C—N bond distances slightly longer. The increase of the C-N-C angle when pyrazine is coordinated has been justified on the basis of electronic reasons (2), since the involvement of the lone-pair electrons on the nitrogen atom in bonding to the copper atom reduces the repulsion between lone-pair and ring electrons. Taking into account that the above-mentioned electronic reasons support similar distortion in our compound, the observed distortions may be attributed to steric effects arising from the manner in which the copper, μ-pyrazine, and μ-chloro entities are held together to form the bidimensional lattice.

Thermodynamic properties of the $NiCl_2$–$CoCl_2$–KCl system

Peter J. Tumidajski and Christopher A. Pickles

Abstract: The thermodynamic behavior of $NiCl_2$ in $NiCl_2$–$CoCl_2$–KCl ternary solutions was investigated using formation cells of the type, (−)Ni/$NiCl_2$–$CoCl_2$–KCl/C, $Cl_{2\,(gas,\,1\,atm)}$ (+). The values of the $NiCl_2$ activity coefficients indicate a non-ideal system consonant with the formation of complex species. The $NiCl_2$ activity coefficients at 1000 K were fitted to the polynomial equation,

$$\ln \gamma = (-1225 + 363t - 3186t^2 + 8385t^3 - 6369t^4)Y^2 + (6776 - 1639t + 14803t^2 - 41112t^3 + 32405t^4)Y^3 + (-8665 + 1842t - 16964t^2 + 48873t^3 - 39440t^4)Y^4$$

where

$$Y = 1 - X_{KCl} \text{ and } t = \frac{X_{CoCl_2}}{X_{CoCl_2} + X_{NiCl_2}}$$

The experimental data were limited to the ranges $0 \leq t \leq 0.80$ and $0.10 \leq Y \leq 0.5$.

Key words: molten salt, thermodynamic properties, nickel chloride, non-ideal solution, complex species.

Résumé : Utilisant des cellules de formation du type (−) Ni/$NiCl_2$–$CoCl_2$–KCl/C, $Cl_{2(gaz,\,1\,atm)}$(+), on a étudié le comportement thermodynamique du $NiCl_2$ dans des solutions ternaires de $NiCl_2$–$CoCl_2$–KCl. Les valeurs des coefficients d'activité du $NiCl_2$ indiquent que le système n'est pas idéal, ce qui est en accord avec la formation d'espèces complexes. Les coefficients d'activé du $NiCl_2$ à 1000 K peuvent être ajustés à l'équation polynomiale

$$\ln \gamma = (-1225 + 363t - 3186t^2 + 8385t^3 - 6369t^4)Y^2 + (6776 - 1639t + 14803t^2 - 41112t^3 + 32405t^4)Y^3 + (-8665 + 1842t - 16964t^2 + 48873t^3 - 39440t^4)Y^4$$

dans laquelle $Y = 1 - X_{KCl}$ et

$$t = \frac{X_{CoCl_2}}{X_{CoCl_2} + X_{NiCl_2}}$$

Les données expérimentales sont limitées par $0 \leq t \leq 0{,}80$ et $0{,}10 \leq Y \leq 0{,}5$.

Mots clés : sels fondus, propriétés thermodynamiques, chlorure de nickel, solution non idéale, espèces complexes.

Introduction

In previous publications from the authors, the thermodynamic properties of charge asymmetric molten salt solutions of metal chlorides with alkali halide solvents have been investigated by EMF measurements (1–7). The measurements provide valuable and practical information on: the feasibility of new processes for the recovery of metals by fused salt electrolysis, and high-temperature batteries and energy storage devices.

The thermodynamic properties of the charge asymmetric molten salt solutions, such as the exothermic enthalpies and activities with pronounced negative deviations from ideality, indicate the formation of complex species. The concept of complex formation in molten salts has been described in detail elsewhere (1, 6). Briefly, a molten salt complex like $(MCl_{z+r})^{r-}$ is a local configuration where a cation M^{z+} is surrounded by $(z + r)Cl^-$ anions.

[1] $$MCl_z + r \cdot ACl \leftrightarrow (MCl_{z+r})^{r-} + r \cdot A^+$$

Within the complex itself, the M—Cl bond distances and, accordingly, the corresponding bond energies, are different from the M—Cl bond distances in the noncomplexed pure molten MCl_z state. However, because of overall electrical neu-

trality, the anions and cations occupy single anionic and cationic lattice sites within the quasi-lattice structure of the ionic solution. Thus, the $(MCl_{z+r})^{r-}$ entities are not discrete ions on single anionic sites. A perturbation in the cation to anion bond distance within the continuum of the molten ionic phase is regarded as evidence of a complex species.

Previous work has focused on the thermodynamic state of the metal ions (and the complex) by control of the solvent composition with mixed halide solvents. The situation where the thermodynamic behavior of solutions in which two metal cations compete for the available chloride anionic ligands has not heretofore been reported. Accordingly, this paper reports on the thermodynamic behavior of the $NiCl_2$–$CoCl_2$–KCl solutions.

Experimental

The $NiCl_2$, $CoCl_2$, and KCl were spectroscopic grade and anhydrous. They were received in sealed ampoules from APL Engineered Materials (Urbana, Illinois). They were packed under argon gas. The chemicals were used without further purification. Nickel electrodes were polished with fine emery paper, and then washed several times with a 10 volume percent HF solution, distilled water, and acetone. Weighing, handling, and the transfer of all chemicals was conducted inside a glove box filled with anhydrous argon gas where the oxygen and moisture were always kept below 5 ppm.

The cell design was similar to the chloride formation cells described elsewhere (3, 4, 7). The cell consisted of a nickel metal electrode immersed in the $NiCl_2$–$CoCl_2$–KCl molten solution of known composition and a graphite chlorine electrode which also dipped into a molten solution of the same composition. The two cell compartments were separated by an asbestos fiber diaphragm fused into silica glass. The cell reaction is

$$[2] \quad Ni_{(s)} + Cl_{2(g,\,1\,atm)} = \underline{NiCl_2}$$

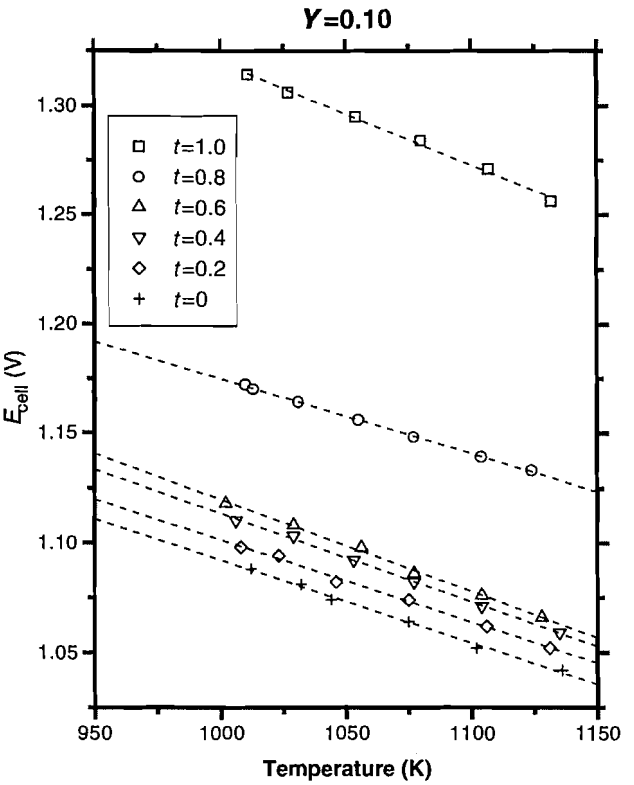
where, $\underline{NiCl_2}$ represents the $NiCl_2$ in the $NiCl_2$–$CoCl_2$–KCl solution. The corresponding Nernst equation is

$$[3] \quad E_{cell} = E^0_{NiCl_2} - \frac{RT}{2F}\ln(\gamma_{NiCl_2}X_{NiCl_2})$$

where F is Faraday's constant of 96 487 J V^{-1} mol^{-1}, R is the universal gas constant given as 8.3144 J K^{-1} mol^{-1}, and T is the absolute temperature in Kelvin. The standard state in all cases is pure liquid $NiCl_2$ at the temperature of the experiments. $E^0_{NiCl_2}$ is the standard potential for the formation of pure liquid $NiCl_2$. Values for $E^0_{NiCl_2}$ were obtained from a previous investigation (8).

Initially, the cell was heated for 24 h in a furnace while anhydrous argon gas passed over the salts to remove any residual moisture. Then, EMFs were measured with a Hewlett Packard model 3468B multimeter. Reversibility was confirmed by temperature cycling and with polarization tests. For a complete description of the temperature cycling procedure and the polarization test refer to previous reports (1, 4). In all cases, the cell EMF returned to within ±2 mV of the original cell EMF. Cell EMFs were also corrected for the thermoelectric potential between the nickel and the graphite electrodes.

Fig. 1. Cell voltage versus temperature for the $Y = 0.10$ composition.



The values ranged from 1 to 5 mV over the range of experimental temperatures. The temperature upper limit was determined by subjective observation of vapor loss from the melt.

Results and discussion

Cell EMFs have been plotted against temperature in Figs. 1–3 for $Y = 0.1$, $Y = 0.25$, and $Y = 0.50$, respectively. The broken lines in Fig. 1–3 indicate the least-squares lines through the experimental data points. Table 1 summarizes the statistical treatment of the least-squares lines, which have been expressed in the form $E = A + BT$, where E is the cell EMF in volts and T is the temperature in Kelvin. Melt compositions have been expressed in terms of the following variables:

$$[4] \quad Y = 1 - X_{KCl}$$

$$[5] \quad t = \frac{X_{CoCl_2}}{X_{CoCl_2} + X_{NiCl_2}}$$

All measured cell potentials are reported with a positive sign as they represent spontaneous overall cell reactions. The correlation coefficients in Table 1 indicate that the relationship between EMF and temperature is linear. The estimate for the standard deviations of cell EMF for the regression of cell EMF on temperature is less than ±2 mV for all points. Further, the measured EMF values were stable and reproducible to within ±1 mV.

Values for $\ln \gamma_{NiCl_2}$ at 1000 K were calculated with eq. [3]. The values are summarized in Table 2. It can be seen that γ_{NiCl_2} deviates markedly from ideal behavior in consonance

Fig. 2. Cell voltage versus temperature for the $Y = 0.25$ composition.

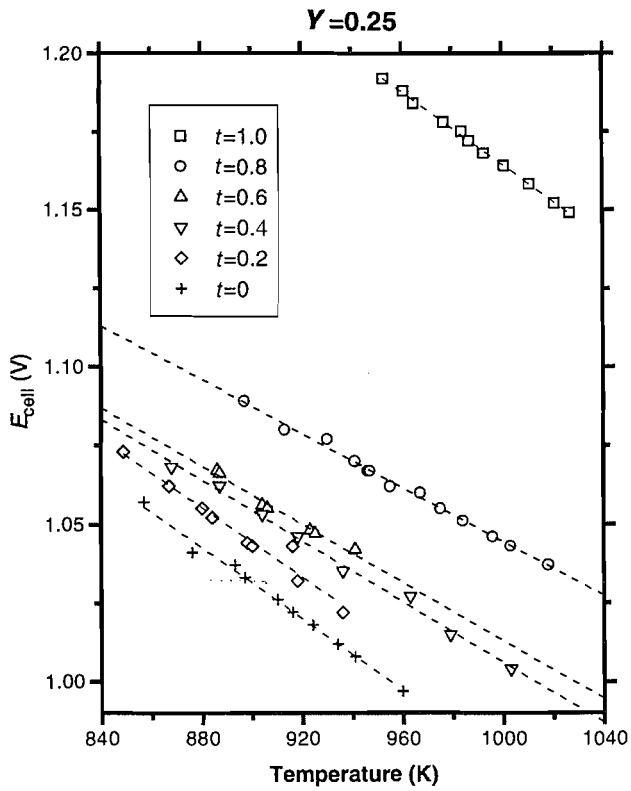

Fig. 3 Cell voltage versus temperature for the $Y = 0.50$ composition.

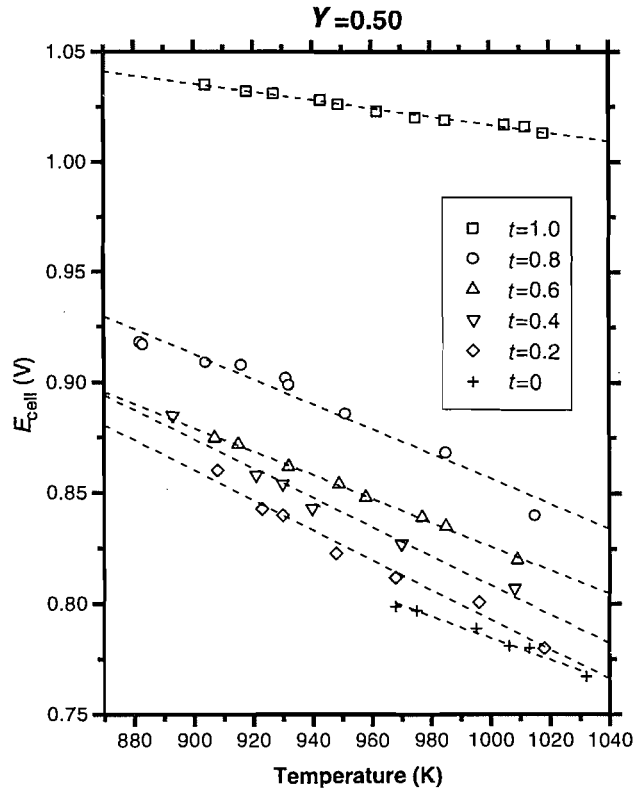

with the thermodynamic behavior commonly associated with complex formation in fused salts. When Y is constant, the values of γ_{NiCl_2} do not vary appreciably with changes in t. It appears that the thermodynamic state of $NiCl_2$ in the ternary solution is mainly defined by the behavior of $NiCl_2$ in the binary $NiCl_2$–KCl solution with only minor influence by the addition of $CoCl_2$. Conversely, when t is constant and Y varies, then there a definite dependence of γ_{NiCl_2} on Y (i.e., with the availability of the chloride anions).

The experimental values of $\ln \gamma_{NiCl_2}$ at 1000 K were fitted to a polynomial function of Y and t in the manner described previously (9). The resultant equation is

$$[6]\quad \ln \gamma = (-1225 + 363t - 3186t^2 + 8385t^3 - 6369t^4)Y^2 + (6776 - 1639t + 14803t^2 - 41112t^3 + 32405t^4)Y^3 + (-8665 + 1842t - 16964t^2 + 48873t^3 - 39440t^4)Y^4$$

Table 2. Values of ln γ_{NiCl_2} for the $NiCl_2$–$CoCl_2$–KCl ternary system at 1000 K.

t	Y	ln γ_{NiCl2}
0	0.10	−6.340
0	0.25	−4.535
0	0.50	−0.815
0.20	0.10	−6.331
0.20	0.25	−4.538
0.20	0.50	−0.785
0.40	0.10	−6.325
0.40	0.25	−4.809
0.40	0.50	−0.858
0.60	0.10	−6.066
0.60	0.25	−4.506
0.60	0.50	−0.860
0.80	0.10	−6.651
0.80	0.25	−4.545
0.80	0.50	−0.875

Therefore, eq. [6] can be used to calculate the $NiCl_2$ thermodynamic properties for any composition in the ternary $NiCl_2$–$CoCl_2$–KCl solution at 1000 K. And, in conjunction with the Gibbs–Duhem equation, the integral thermodynamic properties at 1000 K can be calculated for the ternary solution.

Conclusions

1. The thermodynamic properties of $NiCl_2$ in the $NiCl_2$–$CoCl_2$–KCl ternary solution indicate marked deviations from ideality in consonance with nickel complex formation.
2. The addition of $CoCl_2$ to the $NiCl_2$–KCl solution has a minor influence on the nickel chloride activity.
3. Values of ln γ_{NiCl_2} were fitted to a polynomial equation at 1000 K. The equation can be used to calculate the thermodynamic properties of $NiCl_2$ for any composition in the ternary melt within the composition range $0 \leq t \leq 0.80$ and $0.10 \leq Y \leq 0.5$.

Structural characterization of the O-chain polysaccharide from *Proteus mirabilis* strain 7570

Dušan Uhrín, Vandana Chandan, and Eleonora Altman

Abstract: The O-chain polysaccharide produced by *Proteus mirabilis* strain 7570 was shown by chemical analysis and 1D and 2D NMR spectroscopy to be a high molecular weight acidic linear polymer of tetrasaccharide repeating units, composed of D-galacturonic acid, 2-acetamido-2-deoxy-D-galactose, and 2-acetamido-2-deoxy-D-glucose (2:1:1). In addition, native O-chain was randomly substituted by O-acetyl groups.

Key words: *Proteus*, lipopolysaccharide, O-chain, structure, NMR.

Résumé : L'analyse chimique et la spectroscopie RMN 1D et 2D ont montré que la chaîne O-spécifique produite par la souche 7570 de *Proteus mirabilis* est un polymère linéaire et acide, de haut poids moléculaire, constitué d'un tétrasaccharide répétitif, composé d'acide D-galacturonique, de 2-acétamido-2-désoxy-D-galactose, et de 2-acétamido-2-désoxy-D-glucose (2 : 1 : 1). De plus, la chaîne O-spécifique native est substituée de manière stochastique par des groupements O-acétyles.

Mots clés : *Proteus*, lipopolysaccharide, chaîne O-spécifique, structure, RMN.

Introduction

Proteus mirabilis, a common uropathogen, can cause urinary tract infections in hospitalized hosts and in patients with anatomic abnormalities or with local damage of urinary tract (1). Bladder and kidney stones (2) and bacteraemia (3) are other complications of *P. mirabilis* infection. Postulated virulence factors of *P. mirabilis* include fimbria-mediated adherence to uroepithelial cells via fimbriae, hydrolysis of urea by urease, haemolysin-induced cytotoxicity, swarming motility, IgA protease activity, and destruction of kidney epithelium by invasion (4). The severity of the disease caused by *P. mirabilis* has been attributed to its ability to degrade urea, which may lead to formation of struvite or carbonate-apatite struvite stones (5). In addition, exopolysaccharides of pathogenic strains of *Proteus* have been hypothesized to be potential virulence factors accelerating crystal growth (5). Here we report the structure of the O-antigen of *P. mirabilis* strain 7570 (ATCC 51286) isolated from a patient with struvite urolithiasis and serotyped as 0:23,56 by passive agglutination.

Experimental

LPS isolation and O-polysaccharide (O-PS) preparation

Cells of *P. mirabilis* strain 7570 were grown in brain heart infusion (BHI) broth (Difco) in a 75 L IF-75 fermenter (New Brunswick Scientific) at 37°C over 18 h and harvested in 1% phenol solution. *Proteus mirabilis* LPS was extracted by a modified enzyme – hot aqueous phenol method as described by Johnson and Perry (6). The well-separated aqueous and phenol layers were dialyzed against tap water until phenol free and lyophilized. The lyophilizates were dissolved in 1% saline (w/v) and, following the removal of insoluble material by low-speed centrifugation, the clear solutions were subjected to ultracentrifugation (105 000 × *g*, 4°C, 12 h) to obtain the LPS as precipitated gels. The LPS gels from the aqueous layer were dissolved in distilled water and lyophilized to give purified LPS in ca. 2% yield (based on dry cell weight). To obtain O-PS, aqueous LPS was subjected to mild acid hydrolysis in 1% (v/v) acetic acid at 100°C for 2 h and the insoluble lipid A was removed by centrifugation. The concentrated supernatant was dissolved in pyridinium acetate (0.05 M, pH 4.5) and fractionated by gel filtration on a Sephadex G-50 column (Pharmacia, 2 × 90 cm) with the same buffer as eluent. Fractions of the eluate (10 mL) were collected automatically and analyzed colorimetrically for neutral aldose (7), aminoglycose (8), hexuronic acid (9), phosphate (10), and 3-deoxy-2-octulosonate (11).

Analytical methods

GLC was done with a Hewlett–Packard 5890 series II gas chromatograph fitted with a hydrogen flame detector using a capillary column (0.32 mm × 30 m) containing fused silica DB-17 (J&W Scientific); an initial temperature of 180°C was held for 2 min, followed by an increase to 240°C at 4°C/min.

High-performance anion exchange chromatography (HPAEC) was performed using a Dionex HPLC system fitted with a CarboPac PA1 pellicular anion exchange column (4 × 250 mm) with pulsed amperometric detection (PAD). The flow rate was 1.0 mL/min. The following pulse potentials

were used: $E1$ = 0.05 V; $E2$ = 0.6 V; $E3$ = −0.8 V. The response time of the PAD was set to 360 ms for the pulse duration range of 2. Prior to injection the column was equilibrated with a 85:15 mixture of 150 mM NaOH (eluent A) and 1 M sodium acetate in 150 mM NaOH (eluent B). For the uronic acid determination the O-chain was hydrolyzed with 10 N hydrochloric acid for 15 min at 90°C. The isocratic separation of acidic monosaccharides was achieved with a 1:1 mixture of eluents A and B. The absolute configurations of glycoses were established by GLC–MS of their trimethylsilylated (*R*)-2-butyl glycoside derivatives (12). Neutral monosaccharides were determined by GLC as their alditol acetate derivatives. The O-PS was hydrolysed with 2 M trifluoroacetic acid for 17 h at 100°C. The liberated glycoses were reduced ($NaBH_4$) and acetylated as previously described (13).

O-deacetylation of O-PS

O-PS (20 mg) was treated with 5% ammonium hydroxide (2 mL) at 37°C overnight. The excess of ammonia was removed by flushing with a stream of nitrogen, and the solution was lyophilized.

Carbodiimide reduction of O-PS

O-Deacetylated (O-deAc) O-PS (10 mg) was dissolved in distilled water (3 mL) and the pH adjusted to pH 4.7 with 0.5 N HCl. After addition of 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (30 mg), the stirred mixture was maintained at pH 4.7 with 0.05 N HCl. When the consumption of hydrochloric acid ceased, sodium borodeuteride (60 mg) was added, and the reaction was allowed to proceed for 17 h at room temperature. The mixture was neutralized with dilute acetic acid, dialyzed extensively against distilled water, and lyophilized. The residue was subjected to a repeated carbodiimide reduction following the procedure described above. The final product was purified on Sephadex G-50 gel filtration column eluted with distilled water (yield, 4.6 mg).

Methylation analysis

Samples of the carbodiimide-reduced O-deAc O-PS (2 mg) were methylated according to the Hakomori procedure and the methylated products were extracted into dichloromethane (5 × 0.5 mL). Methylation product was subjected to methanolysis with 3% (w/v) methanolic hydrogen chloride at 80°C for 4 h, followed by neutralization with silver carbonate. The concentrated residue was hydrolyzed with 2 M trifluoroacetic acid (1 mL) for 7 h at 100°C and, following concentration to dryness, reduced with sodium borodeuteride in water over 17 h at room temperature. The solution was acidified with 10% acetic acid and the reaction mixture was evaporated under a stream of N_2, followed by evaporation from methanol containing 10% acetic acid (5 × 0.5 mL) to remove borate. The residual alditols were acetylated by heating with acetic anhydride:pyridine mixture (1:1, 1 mL) at 100°C for 1 h and analyzed by GLC–MS.

SDS-PAGE

LPS preparations were subjected to SDS-PAGE with the Laemmli buffer system (14). The 4% stacking gel and the 12.5% separating gel did not contain SDS (15).

NMR spectroscopy

NMR spectra were obtained on a Bruker AMX 500 spectrometer using standard Bruker software. The observed ^1H chemical shifts are reported relative to internal acetone (2.225 ppm) and the carbon chemical shifts are quoted relative to the methyl group of internal acetone (31.07 ppm). The O-deAc O-PS sample was exchanged twice with D_2O and measured at 35°C using 10 mg dissolved in 0.5 mL of D_2O. Acquisition and processing of respective 2D NMR experiments were done as described previously (16).

General methods

Concentrations were made up under reduced pressure and below 40°C. Optical rotations were determined at 20°C in 10 cm microtubes using a Perkin–Elmer model 243 polarimeter.

Results and discussion

Extraction of *P. mirabilis* strain 7570 cells by the modified lysozyme phenol–water extraction procedure, followed by purification of the LPS by repeated ultracentrifugation afforded an aqueous-phase LPS (yield, 1.13 g). The silver-stained profiles of purified aqueous-phase LPS gave a pattern typical of the smooth type although the bands representing LPS with shorter O-chains were more pronounced than the SDS-PAGE banding pattern of *Salmonella enteritidis* or *Escherichia coli* LPS (Fig. 1). The lack of staining of the upper LPS bands could be due to the inability of the material to enter the gel, possibly because of a high concentration of charged groups in the O-chain PS (see below). Partial hydrolysis of the S-type LPS with hot dilute acetic acid gave an insoluble lipid A, and gel-filtration of the water-soluble products on Sephadex G-50 afforded an O-PS fraction eluting in the void volume of the system (yield, 9.3%). It was homogeneous with respect to hexuronic acid and 2-amino-2-deoxyglycose components and had $[\alpha]_D$ +100 (*c* 1.59, water). Anal. found: C 38.00, H 5.03, N 2.67, ash 6%.

Hydrolysis of the carbodiimide-reduced O-PS ($NaBD_4$), followed by GLC–MS analysis of the $NaBH_4$-reduced and acetylated product, showed it to be composed of 2-amino-2-deoxy-D-glucose, 2-amino-2-deoxy-D-galactose, and D-galactose-6,6-d_2 (1:1:2). The presence of galacturonic acid was further confirmed by high-performance anion-exchange chromatography of the hydrolysis products of the native O-PS. The D configuration of glycoses was established by capillary GLC of the trimethylsilylated derivatives of their (*R*)-2-butyl glycosides. Methanolysis of the methylated carbodiimide-reduced O-PS, followed by hydrolysis, reduction ($NaBD_4$), and acetylation of the resulting alditol methyl ethers (Table 1) showed the O-chain to be composed of a linear repeating tetrasaccharide unit containing the following linked glycoses: [→4)-D-Gal$_p$A-(1→, →2)-D-Gal$_p$A-(1→, →3)-D-Glc$_p$NAc-(1→ and →3)-D-Gal$_p$NAc-(1→].

The ^1H NMR spectrum of the native O-PS exhibited a heterogeneity due to the presence of the *O*-acetyl groups. The complex pattern was simplified after O-deacetylation, and subsequent 2D NMR analysis confirmed that the sample consisted of a single molecular species. The ^1H NMR spectrum of the O-deAc O-PS showed, inter alia, signals for two *N*-acetyl groups at 2.01 (3H) and 2.15 (3H) ppm, together with four anomeric signals at 4.54, 4.835, 4.945, and 5.405 ppm (Table 2), consistent with the proposed tetrasaccharide repeating unit. The anomeric resonances were labelled **a**, **b**, **c**, and **d** according to the descending chemical shifts in the ^1H NMR spec-

trum. The resolution-enhanced ^{1}H NMR spectrum of O-deAc O-PS (see top trace of the 2D NOESY spectrum, Fig. 2) indicated, on the basis of large $J_{1,2}$ values, that residues **c** and **d** had β-D-configuration, while residues **a** and **b** yielded broad singlets precluding an immediate determination of their anomeric configuration.

^{1}H resonances of the O-deAc O-PS were partially assigned using a 2D proton chemical shift correlated spectroscopy (COSY) and a total correlated spectroscopy (TOCSY). A series of 2D TOCSY spectra was acquired using mixing times of 25, 45, and 90 ms. The magnetization transfer from H-1 stopped at H-4 in residue **d**, while it was relayed only as far as H-3 for residues **a** and **b**, possibly due to small $J_{1,2}$ values and (or) fast spin–spin relaxation. The observed transfer from H-4 to H-3 and H-2 in **a** and **b** residues allowed, however, the identification of H-4**a** and H-4**b** signals as overlapping singlets at 4.38 ppm. No transfer to H-5 protons was observed in either **a**, **b**, or **d** residue as expected for a *galacto*-pyranosyl configuration. All the resonances for the residue **c** were identified and its β-D-Glc$_p$ configuration was established.

The sequence and the position of the glycosidic linkages in the O-deAc O-PS were determined by a 2D nuclear Overhauser effect spectroscopy (NOESY), which in addition enabled the ^{1}H assignments of H-5 resonances in residues **a**, **b**, and **d** and those of H-6,6′ in the residue **b**. Four 2D NOESY spectra were acquired using mixing times of 50, 100, 150, and 200 ms, allowing for discrimination between the direct NOE cross peaks and the peaks due to the spin diffusion (Fig. 2). The H-5 resonances of residues **a**, **b**, and **d** were located on the basis of H-4/H-5 and H-3/H-5 NOE cross peaks. However, the NOEs between H-5 and H-6,6′ were established for the residue **b** only, suggesting that residues **a** and **d** are oxidized at C-6. In addition, the NOEs between protons of one of the $NCOCH_3$ groups and H-2**c** and H-4**c** resonances were observed, indicating the presence of the *N*-acetyl group in the residue **c**. No NOEs were observed for the protons of the other *N*-acetyl group. Characteristic intraresidue NOEs were detected between H-1 and H-2 protons in the residues **a** and **b**, indicating their α-D-configuration. The sequence of the glycoses in the repeating unit of the O-PS was established from the following observed interglycosidic NOEs: 1**a** → 2**c** and 3**c**; 1**b** → 4**a**; 1**c** → 2**d**; and 1**d** → 3**b**.

To resolve the ambiguity in the **a** → **c** linkage and also to verify the structure determined via ^{1}H NMR spectroscopy, a ^{13}C NMR spectrum of O-deAc O-PS was analyzed and assigned on the basis of ^{13}C–^{1}H correlated (2D HMQC) and proton-relayed ^{13}C–^{1}H correlated (2D HMQC-TOCSY) experiments (Table 3). In the 2D HMQC spectrum only cross peaks between directly attached protons and carbons are observed, while in the 2D HMQC-TOCSY spectrum additional cross peaks are detected for any given carbon, corresponding to other protons within the same residue. The intensity of these cross peaks depends on the magnitude of coupling constants between the protons involved and on the length of the TOCSY mixing time. For short mixing times only immediate neighbours of a particular proton are

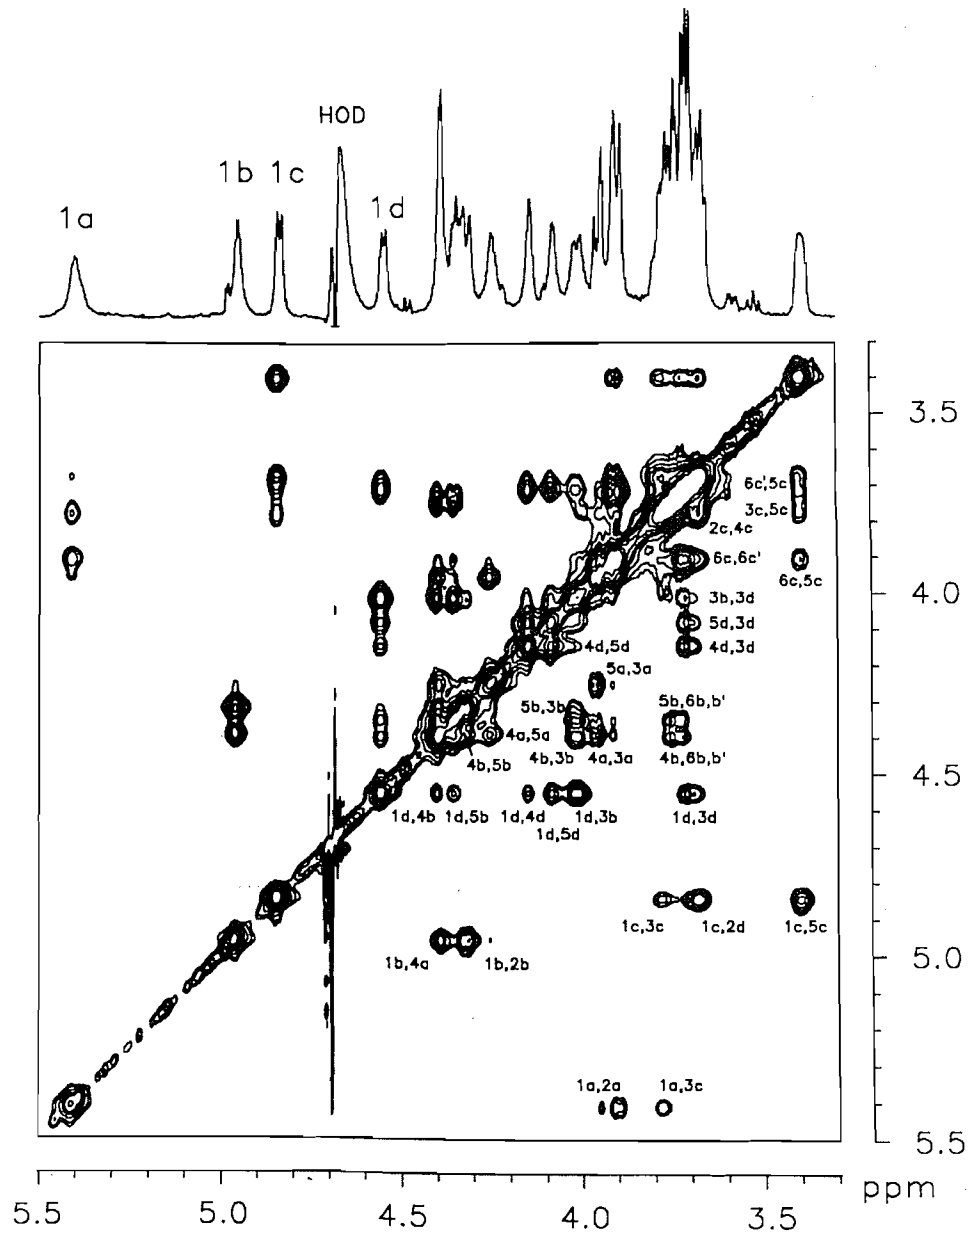
Fig. 2. A 500 MHz 2D NOESY spectrum of O-deAC O-PS acquired using a mixing time of 150 ms. The following cross peaks appeared due to the spin diffusion, as deduced from 2D NOESY spectra acquired with shorter mixing times: 1**d**/4**b**, 1**d**/5**b**, and 3**b**/3**d**.



observed, while for longer mixing periods more remote protons might also appear. Therefore, when two proton resonances are overlapped, while their corresponding carbon resonances are separated, it is possible by a combination of 2D HMQC and 2D HMQC-TOCSY experiments with a short mixing time to establish the neighbouring protons for each carbon and thus deduce the carbon assignment (16).

In the case of O-deAc O-PS, two protons (H-2**c**, 3**c**) reso-

[a]Not observed.
[b]Broad signal.

nating at 3.77 ppm were correlated on the basis of a 2D HMQC experiment with carbon signals at 82.58 and 55.17 ppm. These ^{13}C chemical shifts are characteristic for a carbon involved in glycosidic linkage and a carbon carrying an *N*-acetyl group, respectively. In the subsequent 2D HMQC-TOCSY experiment, acquired using a short mixing time (16 ms), a relay signal at 4.84 ppm (H-1**c**) was observed at 55.17 ppm but not at 82.58 ppm. This implies that the *N*-acetyl group is present at C-2**c**, while the C-3**c** is involved in a glycosidic linkage. In a similar manner, the assignments of the remaining carbons involved in glycosidic linkages were established by a combination of HMQC and HMQC-TOCSY experiments, confirming the results of the homonuclear experiments.

The position of the second *N*-acetyl group was determined from the HMQC spectrum where a cross peak between the H-2**b** proton (4.31 ppm) and a ^{13}C signal at 49.19 ppm, characteristic of the α-linked 2-amino-*galacto*-pyranosyl residue, was observed (17). In addition, the expected cross peaks between the H-5**a** and H-5**d** and their corresponding carbons were not observed in the HMQC spectrum. These ^{13}C signals were also missing in the 1D ^{13}C spectrum of O-deAc O-PS, possibly due to the fast spin–spin relaxation of C-5 signals in the residues **a** and **d**. The ^{13}C resonances of their respective carboxyl groups (C-6) appeared as one very broad signal at 174 ppm.

The combined chemical and NMR evidence permits the structure of the O-antigen to be established as a linear tetrasaccharide repeating unit **1**.

It has been suggested that the acidic nature of the O-polysaccharides of *P. mirabilis* contributes to the formation of stones in the alkaline environment created by the bacterial urease activity. Most of these polysaccharides contain acidic components, such as uronic acids, phosphate groups, and, less frequently, pyruvate ketals and lactic acid (18). Partial O-acetylation has been reported in several O-specific polysaccharides of *P. mirabilis*.

Acknowledgements

We express our appreciation to J.L. Penner, University of Toronto, for serotyping the *P. mirabilis* strain. F. Cooper provided GLC–MS analyses, and large-scale cell production was carried out by D.W. Griffith.

Abstract: In characterizing the UV–visible absorption properties of a series of seven anilino class squaraine dyes in dimethyl sulfoxide (DMSO) – water mixtures, spectral features characteristic of aggregation were observed. These included hypsochromic and hypochromic shifts of the absorption maximum, relative to the nonassociated state of these dyes. Previously aggregation of this class of squaraine dyes had only been reported in studies of Langmuir–Blodgett (LB) films prepared with squaraine dyes. In the present study two distinctly different and novel solution dye aggregates, designated as type A and type B, were identified on the basis of their characteristic absorption properties. The type A aggregate was characterized by an absorption maximum that was hypsochromically and hypochromically shifted, in comparison with that of the nonassociated dyes, and had a secondary absorption occurring at approximately the same wavelength at which nonassociated squaraine dyes absorb. These spectral features are believed to be the result of a "face-to-face" alignment of molecules in the aggregate. The type B aggregate featured a broad absorption typically from 525 to 700 nm. Based on similarities between the spectral features of type B aggregates and LB films of surfactant squaraines, the alignment of molecules in the solution aggregate was believed to be such that the electron-deficient squarylium moieties interacted with the electron-rich dialkylamino phenyl moieties. Certain squaraine dyes that were investigated as part of this study were found to form both type A and type B aggregates, depending upon the composition of the DMSO–water medium. Typically, the type A aggregate formed preferentially in media of intermediate DMSO content (50–70% DMSO) and the type B aggregate in more water-rich media (<20% DMSO). In the intervening region it was possible to monitor spectroscopically a dynamic conversion from the type B aggregate to the type A aggregate. An examination of structure–property relationships indicated that dyes with less hydrophobic N-alkyl substituents formed only type A aggregates. Squaraine dyes with more hydrophobic N-alkyl substituents were found to form type B aggregates in water and type A aggregates in some DMSO–water mixtures. A model of squaraine aggregation was proposed in which the type A squaraine aggregate was "thermodynamically" preferred while the type B aggregate was "kinetically" preferred. The stability of the type B aggregate was proposed to be enhanced by increasing hydrophobicity of the N-alkyl substituents and decreased by increasing amounts of DMSO in the solvent system.

Key words: squaraine dyes, aggregation, crystallochromy, solvent effects.

Résumé : Opérant dans des mélanges diméthylsulfoxyde–eau, on a déterminé les propriétés d'absorption dans l'UV–visible d'une série de sept colorants squaraïne de la classe de anilino; elles permettent d'observer des caractéristiques spectrales typiques d'agrégation. Celles-ci incluent des déplacements hypsochromes et hypochromes des maxima d'absorption par rapport à l'état non associé de ces colorants. Antérieurement, des agrégations de colorants squaraïne de cette classe n'avaient été rapportées que dans des études de films de Langmuir–Blodgett (LB) préparés avec des colorants squaraïne. Dans la présente étude, en se basant sur les propriétés caractéristiques d'absorption, on a identifié deux nouveaux colorants agrégés en solution, distinctement différents et désignés respectivement de type A et de type B. L'agrégat de type A est caractérisé par une absorption maximale qui, par comparaison avec les colorants non associés, est hypsochromatiquement et hypochromiquement déplacé et qui présente une absorption secondaire se produisant approximativement à la même longueur d'onde que celle des colorants squaraïne non associés. On croit que ces caractéristiques spectrales sont le résultat d'un alignement face à face des molécules dans l'agrégat. L'agrégat de type B est caractérisé par une absorption large qui s'étale d'une façon typique entre 525 et 700 nm. En se basant sur des similarités entre les caractéristiques spectrales des agrégats de type B et les films LB des agents de surface squaraïnes, on croit que l'alignement de molécules dans la solution agrégée est telle que les portions

électrodéficientes squarylium interagissent avec les portions dialkylaminophényles riches en électron. On a trouvé que certains colorants squaraïnes utilisés dans cette étude forment des agrégats aussi bien du type A que du type B dépendant de la composition du milieu DMSO–eau. D'une façon typique, les agrégats de type A se forment préférentiellement dans un milieu contenant une quantité intermédiaire (50–70%) de DMSO alors que les agrégats de type B se forment dans des milieux plus riches en eau (<20% de DMSO). Dans la région intermédiaire, il est possible de détecter d'une façon spectroscopique une conversion dynamique des agrégats de type B en agrégats de type A. Un examen des relations structure–propriété indique que les colorants portant des substituants N-alkyles moins hydrophobiques ne forment que des agrégats de type A. On a trouvé que les colorants squaraïne avec des substituants N-alkyles plus hydrophobiques forment des agrégats de type B dans l'eau et des agrégats de type A dans certains mélanges de DMSO–eau. On propose un modèle d'agrégation de la squaraïne dans lequel l'agrégat de type A de la squaraïne est préféré d'un point de vue thermodynamique alors que l'agrégat de type B est cinétiquement préféré. On suggère que la stabilité des agrégats de type B est augmentée avec une augmentation de l'hydrophobicité des substituants N-alkyles et qu'elle diminue avec une augmentation des quantités de DMSO dans le système de solvant.

Mots clés : colorants squaraïne, agrégation, cristallochromie, effets de solvant.

Introduction

Since their initial preparation in 1965 (1), the squaraine dyes have been studied using a wide range of experimental and theoretical methods. These include studies of the solution state properties using UV–visible (2), fluorescence emission (2, 3), and nuclear magnetic resonance (NMR) spectroscopies (4), as well as electrochemical techniques (5). The properties of these dyes in the solid state have been investigated using single crystal (6) and X-ray powder diffraction techniques (5), while a number of workers have prepared Langmuir–Blodgett thin films incorporating squaraine dyes (7).

As part of our studies of the squaraine dyes we recently reported the observation of novel solution aggregates of a squaraine dye in mixtures of dimethyl sulfoxide (DMSO) and water (8).

When squaraine **4** was added to DMSO–water mixtures with greater than 70% DMSO, spectroscopic characterization of the solutions showed an absorption indicative of the nonassociated squaraine, $\lambda_{max} \simeq 664$ nm, $\varepsilon_{664} \simeq 300\,000\ M^{-1}\ cm^{-1}$, Fig. 1.

In media of between 50 and 70 v/v% DMSO–water we reported that the introduction of squaraine **4**, in a trifluoroethanol (TFE) solution, resulted in solutions with an absorption maximum at 530 nm, $\varepsilon_{530} \simeq 80\,000\ M^{-1}\ cm^{-1}$, and a secondary absorption at approximately 650 nm. The solutions had an absorption spectrum identical to Fig. 2 (spectrum 7). The reduced intensity and large hypsochromic shift of the absorption maximum, in comparison with the spectral features of the nonassociated dye observed in more DMSO-rich media, indicated that aggregation had occurred. This was the first reported example of a solution squaraine aggregate and for the purposes of this paper associated squaraines characterized by such a shift of the absorption maximum and a secondary absorption at longer wavelengths will be referred to as *type A aggregates*.

In DMSO–water mixtures with less than 20% DMSO the addition of squaraine **4**, in TFE solution, yielded solutions characterized by a broad absorption maximum from 550 nm to 700 nm, similar to Fig. 2 (spectrum 1). This absorption was also hypochromically shifted, relative to the intensity of the absorption maximum of the nonassociated dye, and squaraine aggregates that feature these absorption characteristics will henceforth be denoted as *type B aggregates*.

Fig. 1. UV–visible absorption spectrum of squaraine **4** in DMSO.

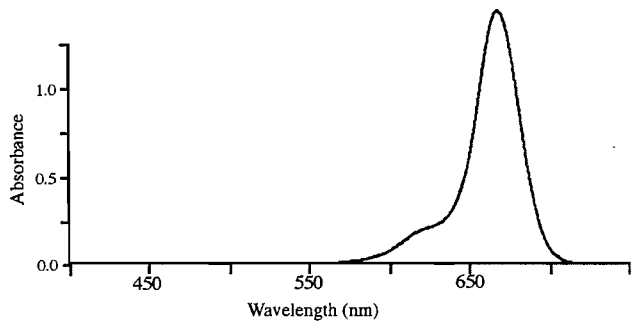

Fig. 2. UV–visible absorption spectra of squaraine **4** in 30 v/v% DMSO–water monitored at 12 min intervals after sample preparation, showing the dynamic conversion from a type B aggregate (spectrum 1) to a type A aggregate (spectrum 7).

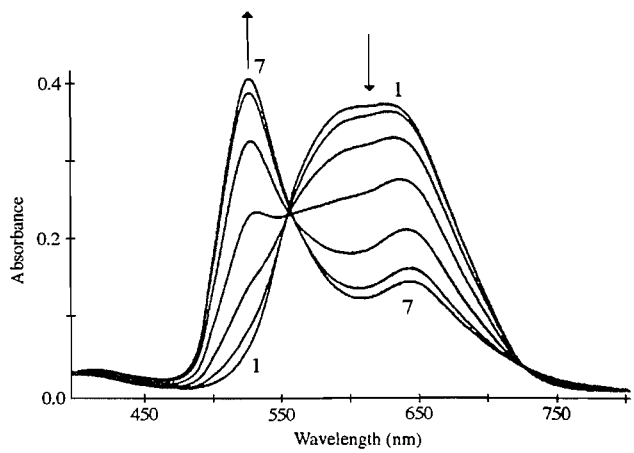

In the intervening region (20–50% DMSO) we reported that the type B aggregate formed initially on addition of the squaraine **4** – TFE solution to the binary solvent system. Over time, *a dynamic conversion from the type B aggregate to the type A aggregate was observed*, see Fig. 2. As the amount of DMSO cosolvent increased, the rate of this dynamic conversion was found to increase.

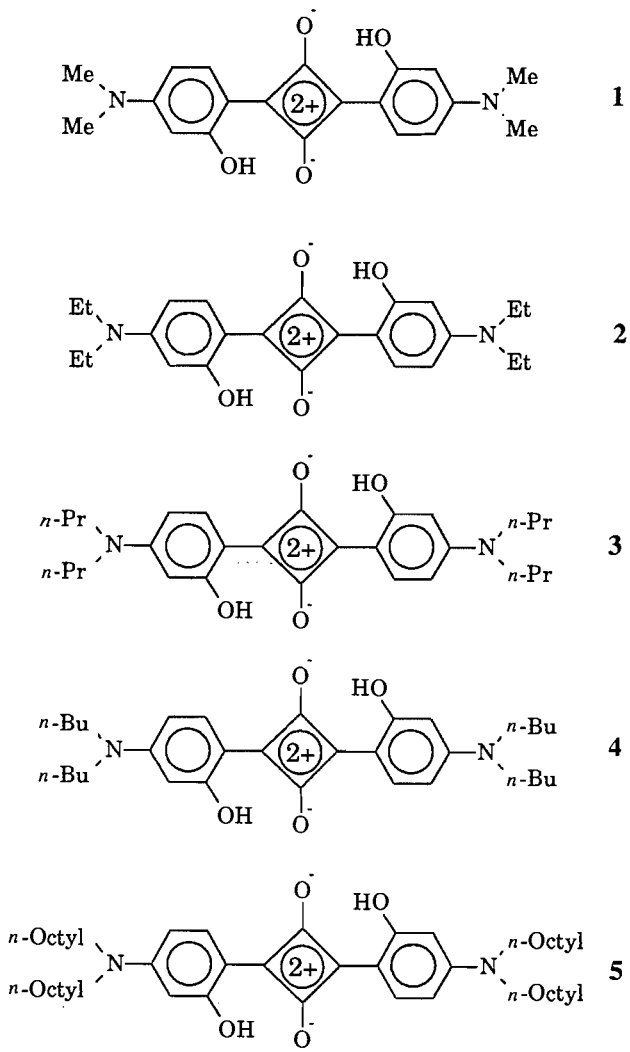
Prior to these observations, the only published reports concerning the aggregation of squaraine dyes dealt with the association of surfactant squaraine dyes in Langmuir–Blodgett thin films (7). In these studies aggregation could be detected by characterizing the thin films using UV–visible absorption spectroscopy. Subsequently other workers have reported the solution state aggregation of squaraine dyes (9).

Through the study of these novel dye aggregates there is the potential to better understand both the intrinsic molecular properties of these dyes, and their intermolecular interactions. Accordingly, a comprehensive investigation of the aggregation properties of this class of squaraine dyes was undertaken. The goals of these studies included gaining an understanding of (*i*) the effect on aggregation of various functional groups in the dye, (*ii*) the nature of the DMSO solvent effect on squaraine aggregation, and (*iii*) the spatial relationship between molecules in the two aggregate types.

Experimental investigations of these aggregation phenomena involved a spectrophotometric study of bis(4-di-*n*-butylamino-2-hydroxyphenyl)squaraine, **4**, and six other squaraine dyes in a series of DMSO–water mixtures. The other dyes included bis(4-dimethylamino-2-hydroxyphenyl)squaraine, **1**, bis(4-diethylamino-2-hydroxyphenyl)squaraine, **2**, bis(4-di-*n*-propylamino-2-hydroxyphenyl)squaraine, **3**, and bis(4-di-*n*-octylamino-2-hydroxyphenyl)squaraine, **5**. Bis(4-di-*n*-butylamino-2-hydroxy-6-methylphenyl)squaraine, **6**, and bis(8-hydroxy-9-julolidinyl)squaraine, **7**, were also included in these studies.



Experimental

Synthesis

Squaraine dyes were prepared using the method of Sprenger and Ziegenbein (10) in which two equivalents of aromatic dialkylamine were reacted with one equivalent of squaric acid in a toluene–1-butanol solvent system. Details concerning the preparation of these dyes will be published elsewhere.

Squaraine aggregation studies

Purification of reagents and preparation of solutions

Considerable care was taken in the purification of reagents and preparation of solutions for these experiments. All glassware was soaked overnight in a bath of Decon-75, washed with copious amounts of distilled water, and oven dried.

Dimethyl sulfoxide was freshly distilled from calcium hydride. Distilled and doubly deionized water was refluxed for 4 h in order to remove CO_2, and cooled under a stream of nitrogen. Binary DMSO–water mixtures were prepared for these studies by accurately determining the mass of each component in the mixtures. Organic solvents used in the preparation of dye stock solutions included 2,2,2-trifluoroethanol, acetone, and *N*,*N*-dimethylacetamide. These solvents were of spectroscopic grade and were purified, when necessary, according to standard procedures (11).

Stock solutions of each dye were freshly prepared in an appropriate solvent and characterized by UV–visible absorption spectroscopy prior to each experiment. The physical properties of the stock solutions of the squaraine dyes included in this study are reported in Table 1. Bis(4-dimethylamino-2-hydroxyphenyl)squaraine, **1**, was found to be highly insoluble and as a result a saturated stock solution was prepared in *N*,*N*-dimethylacetamide and the excess dye was removed by filtration. The concentration of this solution was estimated to be 6×10^{-6} M, based on an estimated extinction coefficient of $\varepsilon_{646} = 350\,000\ M^{-1}\ cm^{-1}$ for the absorption maximum at 646 nm that is typical for dyes of this class (2).

Spectrophotometric method

Reproducible results were obtained in the spectrophotometric studies by preparing samples in a consistent manner. This involved introducing 2 mL of the appropriate DMSO–water mixture into a 10-mL round-bottom flask that was fitted with a stirring bar, a rubber septum, and flushed with nitrogen. An aliquot of the dye stock solution (maximum 1 v/v%, unless otherwise noted) was then added quickly to the mixture and stirring continued for 30 s, followed by sonication for 60 s. The solution was transferred quickly by syringe into a quartz cuvette and placed in a Cary 3 UV–visible spectrophotometer fitted with a thermostated cell compartment at 25°C. The absorption spectrum of the sample was recorded immediately and at intervals of 10–15 min for at least 1 h. These experiments were performed either in duplicate or triplicate. Samples were subsequently stored for later analysis. Due to experimental limitations squaraine **1** could not be studied in

Table 1. Spectroscopic properties of squaraine dyes that were used in the aggregation study.

Squaraine	λ_{max} (nm)	ε (M^{-1} cm^{-1})	Solvent[a]
Bis (4-dimethylamino-2-hydroxyphenyl), **1**	646	350 000	*N,N*-DMA
Bis (4-diethylamino-2-hydroxyphenyl), **2**	638	318 000	TFE

Results and discussion

1. Classification of squaraine aggregates: Classes A, B, and A/B

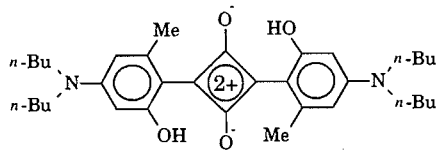
In these studies the aggregation properties of seven squaraine dyes were investigated as a function of solvent composition using a series of DMSO–water mixtures. Characterization of these solutions for several hours after preparation and again after at least 1 day, via UV–visible absorption spectroscopy, delineated the spectroscopic properties of these aggregates over both the short and long term. As a summary, it is useful to group these compounds into three classes based on the impact of solvent composition on aggregation in the short-term experiments.

Class A squaraines formed only *type A aggregates* when self-association occurred. Bis(8-hydroxy-9-julolidinyl)squaraine, **7**, was included in this class, as addition of this dye in an *N,N*-dimethylacetamide stock solution to water and mixtures of between 10 and 50 v/v% DMSO–water resulted in solutions whose spectroscopic properties were similar to those of the previously defined type A aggregates.

When a stock solution of bis(4-dimethylamino-2-hydroxyphenyl)squaraine, **1**, in *N,N*-dimethylacetamide was diluted 10-fold with water the resulting solution was found to feature a broad absorption at 550 nm, $\varepsilon_{550} \simeq 81\ 000\ M^{-1}\ cm^{-1}$, and a secondary absorption at 684 nm, Fig. 3*a*. These spectral features are diagnostic of aggregation phenomena and are similar to that observed when squaraine **4** was introduced into mixtures of between 50 and 70% DMSO. In both cases aggregation resulted in a hypsochromic and hypochromic shift of the absorption maximum and a secondary absorption at longer wavelengths. Based on this similarity, it was concluded that squaraine **1** formed type A aggregates in 10 v/v% *N,N*-dimethylacetamide–water.

In media of less than 50% DMSO, bis(4-diethylamino-2-hydroxyphenyl)squaraine, **2**, was characterized by two absorptions at 566 and 645 nm, Fig. 3*b*. In 10 v/v% DMSO–water these two absorptions were of similar intensity, $\varepsilon_{566} \simeq \varepsilon_{645} \simeq 55\ 000\ M^{-1}\ cm^{-1}$, but as the DMSO content of the medium increased, the intensity of the longer wavelength absorption increased to eventually become the dominant absorption in the 40% DMSO mixture, $\varepsilon_{657} \simeq 71\ 000\ M^{-1}\ cm^{-1}$.

The absorption spectrum of aggregates of squaraine **2** and



6

the typical type A aggregate are similar in that both feature two absorptions that are hypochromically shifted in comparison with nonassociated dyes. In both cases one absorption occurs at approximately the same wavelength at which the nonassociated dye absorbed while the second absorption was hypsochromically shifted by at least 100 nm. For squaraine **4**, as well as other dyes in this study, the longer wavelength absorption of the type A aggregate was the less intense of the two absorptions. For squaraine **2** this was not the case but, based on the similar splitting of the absorption spectrum, this dye is considered to form type A aggregates in media of less than 50% DMSO.

The spectral characteristics of the type A aggregates that formed with squaraine dyes **1**, **2**, and **7** are summarized in Table 2. The range of DMSO–water solvent compositions in which squaraines **2** and **7** formed aggregates or were nonassociated is reported in Table 3.

Class B squaraines were found to form only *type B aggregates* when self-association occurred. In these studies only bis(4-di-*n*-octylamino-2-hydroxyphenyl)squaraine, **5**, was included in this class. Solutions of squaraine **5** that were prepared in water and media of 10–80 v/v% DMSO–water were all characterized by spectral features characteristic of a type B aggregate, i.e., a broad absorption from 550 to 725 nm. These solutions are stable over the 1 h monitoring period. Spectroscopic characterization of these solutions after at least 3 days revealed that the aggregates prepared in 0–60% DMSO did not change, while the type B aggregate in 70% DMSO converted to a type A aggregate.

The third group of dyes are the *Class A/B squaraines* that were found to form type A aggregates in mixtures of intermediate DMSO composition, and type B aggregates in water-rich media. For dyes in this class a dynamic conversion from type B aggregates to type A aggregates was also spectroscopically observed in some solvent media. The previously reported aggregation properties of bis(4-di-*n*-butylamino-2-hydroxyphenyl)squaraine, **4**, are typical of a Class A/B dye (8). Experiments with squaraine **4** that were carried out as part of the present study also demonstrate that the type B aggregate of squaraine 4 that formed in water could be converted to a type A aggregate by altering the solvent composition to 50 v/v% DMSO, a solvent composition in which the type A aggregate was known to be stable. The type A aggregate that forms in 50% DMSO was not affected, however, by changing the solvent composition to 6.25% DMSO–water, a solvent composition in which the type B aggregate was generally observed with squaraine **4**.

The aggregation properties of bis(4-di-*n*-propylamino-2-hydroxyphenyl)squaraine, **3**, were very similar to those of squaraine **4**, although the range of solvent compositions in which the type A and B aggregates formed differed, see Table 3. Spectroscopic characterization of the aggregate solutions of squaraine **3** several days after preparation revealed that the type B aggregates that formed in water had changed to type A aggregates.

Bis(4-di-*n*-butylamino-2-hydroxy-6-methylphenyl)squaraine, **6**, was classified as a Class A/B dye as it formed type A or B aggregates depending upon solvent composition. A dynamic conversion from type B to type A aggregates was observed for squaraine **6** in 40 and 50 v/v% DMSO–water. The dye was initially found to aggregate yielding a type B aggregate, Fig. 3*c* (spectrum 1). Over the 1 h monitoring period this absorption decreased in intensity while an absorption at 575 nm developed. Upon equilibration the squaraine solutions were characterized by absorptions diagnostic of type A aggregates, Fig. 3*c* (spectrum 9). As was observed with squaraines **3** and **4**, the rate of conversion from the type B aggregate to the type A aggregate was found to increase with increasing DMSO content.

The spectroscopic properties of the type A and B aggregates that formed with these three dyes are reported in Table 2 and the solvent compositions in which aggregation occurred are reported in Table 3.

With several of the dyes in this study it was observed that when the dye existed in the nonassociated state the intensity of the characteristic squaraine absorption decreased over time. The rate of loss of the chromophore was also found to decrease as the amount of water in the solvent system decreased. This phenomenon could be the result of a slow precipitation of the dye out of solution and (or) a chemical reaction occurring in the DMSO–water solvent system that results in chromophore loss. Other workers have noted a slow fading of the colour of aqueous squaraine solutions and attributed it to attack of hydroxide on the central squaraine ring (12). Such a situation could certainly occur in these studies and similar problems may also affect the long-term stability of the aggregated squaraine dyes.

2. UV–visible absorption properties of type A and B squaraine aggregates

The optical absorption properties of aggregates that formed with the seven squaraine dyes used in these studies result from electronic transitions to states that are dependent on the relative spatial orientation of molecules (13). Although specific features of the type A and B aggregates varied within this family of dyes, their general spectroscopic properties were similar. Therefore, it may be possible to gain an understanding of the spatial orientation of molecules in the squaraine aggregates by examining the spectral features of the type A and B aggregates.

Squaraines **2**, **3**, and **4** were characterized in DMSO-rich media in the nonassociated state with absorption maxima in the region from 650 to 665 nm. The type A aggregates of this series of dyes featured a major absorbance that was both hypsochromically and hypochromically shifted, relative to the nonassociated dye, and was observed in the region between 523 and 566 nm. Typically these aggregates also featured a secondary absorbance at ca. 650 nm. In DMSO-rich media

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 46.23.64.124 on 09/08/12
For personal use only.

squaraines **6** and **7** were characterized by an absorption maximum at 682 nm. Type A aggregates that formed with these dyes featured absorption maxima that occurred between 572 and 580 nm and a less intense absorbance at the same wavelength as the nonassociated dye.

In terms of the qualitative observations regarding dye aggregation (14) and exciton theory (13), these hypsochromically shifted absorption maxima indicate that the dyes formed aggregates with many molecules whose transition dipoles were parallel. This corresponds to an aggregate with a "face-to-face" packing of dye molecules.

These results are consistent with the results of a study by Law and Chen of surfactant squaraine dyes (*7a*). In their investigation, monolayers of suitable squaraine dyes were prepared using the Langmuir–Blodgett film technique and the absorption properties of these monolayers measured. The unsymmetrical dye 1-(4-dimethylaminophenyl)-3-(4-di-*n*-octadecylaminophenyl) squaraine, **8**, formed a stable monolayer in which Law and Chen concluded that there was a slightly offset face-to-face packing of molecules. The absorption properties of this monolayer were identical to those of the type A aggregate identified in the present study, thus indicating that similar intermolecular interactions were occurring in both instances.

A possible explanation for the characteristic minor absorbance of the type A aggregate involves attributing it to an absorption by nonassociated dye. This suggestion is not supported by the studies of squaraine **4** at dilute concentrations (10^{-7} M), which indicate that in general the minor absorbance in the type A aggregate does not correspond to absorption by nonassociated dye.

Alternatively, this absorption could result from a transition within the face-to-face aggregates that is not accounted for by exciton theory.

The spectroscopic features of the type B aggregates of squaraines **3**, **4**, **5**, and **6** are essentially identical as each was characterized by a broad absorption from 500 to 750 nm. Comparisons of the absorption spectra of these dyes in the nonassociated state and as type B aggregates demonstrate that the absorption intensity of the latter is considerably less than the former, 80 000 versus 300 000 M^{-1} cm^{-1}, respectively. Such a hypochromic shift is diagnostic of aggregation phenomena. Unlike the type A aggregates, however, the type B aggregate lacked a shift in the absorption maximum that can be readily correlated with exciton theory.

On the basis of the width of the absorption of this aggregate, ca. 250 nm, it can be concluded that this peak represents the summation of several optical transitions. These multiple transitions occur at energies above and below the absorption energy of the nonassociated dye. In terms of the exciton model, dimer absorbances that are near the monomer absorbance energy correspond to aggregate geometries for which the angular relationship between chromogens approaches the nodal point at 55°. Such a situation was reported by Fuhrhop et al. in studies of protoporphyrin IX glycosamides in which dimerization resulted in a broadened Soret band that lacked an appreciable exciton shift (15). Accordingly, the spectroscopic features of the type B aggregate could be indicative of multiple absorbances from an aggregate of molecules with varying orientations that are greater and less than 55°.

An alternative explanation of the absorption features of the type B aggregate of these squaraine dyes would involve intermolecular interactions that are not considered by the exciton model. In their study of surfactant squaraine dyes Law and Chen reported that bis(4-(*N*-methyl-*N*-octadecylamino)phenyl) squaraine, **9**, formed monolayers that were stabilized by charge transfer interactions between adjacent molecules (*7a*). These interactions were the result of an alignment of molecules in the monolayer that permitted the electron-deficient squarylium moieties to interact with the electron-rich dialkylamino phenyl moieties. The spectroscopic properties of the monolayer of squaraine **9** were similar to those of the type B aggregate, suggesting that the spatial orientation of molecules in the solution aggregates was similar.

3. Structure-property relationships and the role of the DMSO–water solvent medium in squaraine aggregation

To better understand the aggregation properties of the seven squaraine dyes in this study it is instructive to examine the role that molecular functionality and the DMSO–water solvent system plays in aggregation. One group of dyes that should be compared includes the bis(4-dialkylamino-2-hydroxyphenyl)squaraines with N-alkyl substituents that include methyl, ethyl, *n*-propyl, *n*-butyl, and *n*-octyl groups. To further investigate the role of molecular structure on aggregation phenomena the behaviour of bis(4-di-*n*-butyl-2-hydroxyphenyl)-squaraine and bis(4-di-*n*-butyl-2-hydroxy-6-methylphenyl)-squaraine as well as bis(4-di-*n*-propylamino-2-hydroxyphenyl)squaraine and bis(8-hydroxy-9-julolidinyl)squaraine should be compared.

(a) Comparison of the aggregation properties of squaraine dyes with varying N-alkyl substituents

Comparison of the short-term aggregation properties of the five bis(4-di-*N*-alkylamino-2-hydroxyphenyl)squaraine dyes with varying N-alkyl substituents shows that these compounds were considerably different, Table 3. As the effect of the squaraine ring and the hydroxyl functionality should be the same for all of these dyes, it is reasonable to propose that the difference in their aggregation characteristics is related to particular properties of the N-alkyl substituents. One would expect that the electronic influence of the five different substituents would not vary appreciably with increasing chain length, and this assertion is consistent with the results of electrochemical studies of squaraine dyes (5). However, it would be expected that the influence of *hydrophobic interactions* would be greater for squaraine dyes with longer alkyl chains.

Several workers have reported that alkyl substitution in dye molecules affects their aggregation properties. Iyer and Singh studied the sodium salts of a series of 1-amino-4-alkylaminoanthraquinone-2-sulfonic acids with alkyl substituents including methyl, ethyl, *n*-propyl, and *n*-butyl (16). For this class of compounds self-association proceeded only as far as the dimer state. With alkyl chains of increasing length the critical aggregation concentration, hereafter referred to as the CAC, was found to decrease. Thermodynamic studies of the dimerization of these dyes were consistent with explanations of hydrophobic interactions based on water-structure arguments. In other studies it was noted that dyes with alkyl functionality tended to have lower CACs and form higher order aggregates with increasing alkyl chain length (17).

It is reasonable to assume that van der Waals forces would

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 46.23.64.124 on 09/08/12
For personal use only.

be primarily responsible for the self-association of dye molecules with short alkyl chains. Based on the above discussion, hydrophobic forces would also be expected to contribute significantly to the free energy of association for dyes with moderate to long alkyl chains.

The aggregation properties of the bis(4-dialkylamino-2-hydroxyphenyl)squaraine dyes with methyl, ethyl, *n*-propyl, *n*-butyl, and *n*-octyl chains can be interpreted on the basis of these arguments. The dyes in this series with methyl and ethyl substituents were found to form type A aggregates. *Since shorter alkyl chains are associated with minor hydrophobic effects, it is proposed that the free energy of association for the formation of type A aggregates with these two dyes does not feature a significant additional contribution from hydrophobic interactions.*

The free energy of aggregation for bis(4-di-*n*-octylamino-2-hydroxyphenyl)squaraine, **5**, is expected to include a considerable additional contribution due to hydrophobic interactions, resulting in a decrease in the CAC and an increased degree of aggregation, in comparison with squaraine dyes with shorter alkyl chains. *That this dye with increased hydrophobicity should form an aggregate with a different spatial orientation of chromophores (the type B species) relative to the aggregate formed with the less hydrophobic dyes (the type A species) was not anticipated.*

Bis(4-di-*n*-propylamino-2-hydroxyphenyl)squaraine, **3**, and bis(4-di-*n*-butylamino-2-hydroxyphenyl)squaraine, **4**, both formed type B aggregates in water that were stable over the 1 h monitoring period. Based on a comparison with other dyes in this series, these results indicated that aggregation of these two dyes in this medium was subject to the same influences that resulted in the formation of the type B aggregate of squaraine **5**.

To further probe this phenomenon of squaraine aggregation it is worthwhile to examine the effects of adding these dyes to binary DMSO–water mixtures.

The preparation of aggregated dyes in aqueous media containing organic cosolvents is generally believed to decrease the degree of aggregation and increase the CAC (17). Both of these observations reflect a change in the free energy of aggregation that favours the nonassociated dye and (or) destabilizes the aggregate. Studying a series of dyes in DMSO–water mixtures should therefore provide an estimate of the relative stabilities of their aggregates.

Bis(4-diethylamino-2-hydroxyphenyl)squaraine, **2**, formed stable type A aggregates in DMSO–water mixtures up to and including 40 v/v% DMSO–water. In media of greater than 50% DMSO the dye existed in a nonassociated state. These results indicated that, as expected, with increasing DMSO content there is a shift in the association equilibrium towards the monomeric state. Monitoring these solutions over time revealed no changes in the spectroscopic properties of the aggregate solutions.

Both bis(4-di-*n*-propylamino-2-hydroxyphenyl)squaraine, **3**, and bis(4-di-*n*-butylamino-2-hydroxyphenyl)squaraine, **4**, formed type B aggregates in water and, relative to squaraine **2**, the alkyl substituents on these dyes were more hydrophobic. These dyes, therefore, were expected to be strongly aggregated and were found to aggregate over a similar range of solvent mixtures as squaraine **2**, Table 3.

In addition to the cosolvent "weakening" these dye aggregates, so that the nonassociated state eventually became more favoured in DMSO-rich media, it was also noted that in mixtures of DMSO–water it was possible to observe a conversion from the type B to type A aggregate. The response time of aggregate solutions to perturbations that render them in a non-equilibrium state depends on the strength of their mutual association. Weakly associated dye aggregates will rapidly shift towards the monomeric state upon dilution or elevation of temperature. This change in equilibrium can be detected by a rapid increase in the intensity of the absorption ascribed to the monomer. For strongly aggregated dyes it is found that the time required to reestablish equilibrium after changes in conditions can range from minutes to days (18). The slow change in the properties of strongly aggregated solutions is generally referred to as "aging" and can be readily monitored by absorption spectroscopy.

The type B aggregate that formed with bis(4-di-*n*-propylamino-2-hydroxyphenyl)squaraine, **3**, in water was found to have converted to a type A aggregate when analyzed by UV–visible absorption spectroscopy several days later. This result would indicate that the type A aggregate was thermodynamically preferred and that the type B aggregate should be considered as a thermodynamically less stable aggregate. The slow aging of the type B aggregate solution to a type A species would indicate that the molecules in this ensemble were strongly bound.

By introducing squaraine **3** into mixtures of DMSO–water it was possible to affect the aggregate stability, relative to that in water, and thereby alter this aging process. In the range of solvent compositions from 10 to 20 v/v% DMSO–water the thermodynamics of aggregation were sufficiently different than in water so that conversion from type B to type A aggregates could be monitored over a 1 h period. Given that a similar conversion was observed in water, the cosolvent appears to aid in this process. With increasing DMSO content, 30 and 40 % DMSO, only the type A aggregate was observed and presumably the aggregate stability continued to decrease with increasing DMSO content.

For bis(4-di-*n*-butylamino-2-hydroxyphenyl)squaraine, **4**, a similar solvent-dependent conversion from a type B to type A aggregate was observed and the enhanced stability of its type B aggregate in DMSO–water mixtures, relative to squaraine **3**, could be related to the greater hydrophobicity of this dye.

Bis(4-di-*n*-octylamino-2-hydroxyphenyl)squaraine, **5**, is believed to be the most hydrophobic dye in this study, forming type B aggregates in DMSO–water mixtures up to and including 80% DMSO, and in solvent compositions up to 60% DMSO these aggregates were stable for at least 3 days. In a DMSO-rich medium of 70% DMSO squaraine **5** initially formed a type B aggregate but after several days conversion to a type A aggregate had occurred. This was clearly a similar aging phenomenon as that observed with squaraines **3** and **4**. The fact that this only occurred in DMSO-rich media and after several days is indicative of the ability of the N-alkyl substituents of increasing hydrophobicity to stabilize the type B aggregate, although this was not ultimately the most stable aggregation state.

Unusual effects of DMSO on aggregation of hydrophobic molecules have previously been observed. Uehara et al. studied aggregation of chlorophyll *a* in binary DMSO–water mixtures as a means of modelling the states of aggregation of this compound that are observed in vivo (19). Using UV–visible absorp-

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 46.23.64.124 on 09/08/12
For personal use only.

tion spectroscopy these workers were able to identify three different colloidal forms of chlorophyll *a* and to determine that the solvent composition controlled which aggregate formed.

Langhals and Balli also reported dynamic aggregation effects in DMSO–water mixtures (20). Studying a series of dimethinemerocyanine dyes containing long alkyl chains it was reported that these compounds formed J aggregates, i.e., aggregates that absorbed light at a longer wavelength than the absorption maximum of the nonassociated dye, at concentrations as low as 5×10^{-8} M. Furthermore, upon addition of the dyes to DMSO–water mixtures it was observed by absorption spectroscopy that an initial aggregate formed and converted over time to a second aggregate with a longer wavelength absorption, a J aggregate. These dynamic aggregation effects are similar to the present squaraine aggregation studies.

*(b) Comparison of the aggregation properties of bis(4-di-*n*-butylamino-2-hydroxyphenyl)squaraine, **4**, and bis(4-di-*n*-butylamino-2-hydroxy-6-methylphenyl)squaraine, **6***

The aggregation properties of squaraines **4** and **6** were found to be similar, i.e., they formed type B aggregates in water, a conversion from type B to type A aggregates was observed in some DMSO–water mixtures, while in DMSO-rich media only type A aggregates were observed. Comparison of the structures of these dyes reveals that their only difference is that squaraine **6** has a methyl group substituted *ortho* to the squaraine ring in the C(6) position.

The presence of the methyl group adjacent to the four-membered ring could result in a steric interaction between this alkyl group and the C-O group on the squaraine ring. This would result in a twisting of the phenyl rings out of the plane of the four-membered ring and a bathochromic shift of the absorption maximum (2). The degree of twisting is a function of the magnitude of the repulsive forces and may be counterbalanced by the proposed intramolecular hydrogen bonding involving the phenyl hydroxyl group and a squaraine C-O group (2, 5).

The energies associated with the van der Waals forces all feature a r^{-6} dependence on separation distance and are expected to diminish rapidly at large intermolecular separations. As a result of these distance requirements it is believed that planar molecules, which can closely pack, are the most likely to form stable aggregates. The stability of the aggregates formed with squaraine **6** and squaraine **4** did not differ appreciably. Thus, it may be concluded that distortions in molecular geometry that resulted from steric interactions involving the methyl substituents in squaraine **6** were not sufficient to destabilize aggregates that formed with this dye.

In the preceding discussion of squaraine dyes **1**–**5** it was noted that factors associated with increasing hydrophobicity of the N-alkyl groups were related to the formation of type B aggregates in water. For the squaraines **4** and **6** the hydrophobicity of their N-alkyl substituents was the same. The presence of the methyl group in squaraine **6** could have further affected the hydrophobicity of the dye.

Studies of the free energy of transfer of pure hydrocarbons into water can be shown to provide a quantitative measure of the hydrophobic effect (21). Although predictions concerning hydrophobic interactions between solutes that are based on such thermodynamic studies can be misleading (22), they still serve as a means of estimating the hydrophobicity of solutes. For example, the free energies of transfer of benzene and toluene from their liquid state into water are 4.6 and 5.4 kcal mol^{-1}, respectively (23). This comparison demonstrates that introduction of a methyl group into an aromatic ring increases its hydrophobic effect. A similar substitution in the squaraine dyes should have slightly increased the hydrophobicity of squaraine **6** relative to squaraine **4**.

The DMSO solvent effect on aggregation of these two dyes is similar to that discussed previously for the dyes with varying N-alkyl substituents.

*(c) Comparison of the aggregation properties of bis(4-di-*n*-propylamino-2-hydroxyphenyl)squaraine, **3**, and bis(8-hydroxy-9-julolidinyl)squaraine, **7***

Comparison of the aggregation properties of squaraines **3** and **7** in water can provide a subtle means of probing the role of molecular functionality in influencing self-association. The compounds 8-hydroxyjulolidine, **10**, and 3-di-*n*-propylaminophenol, **11**, are similar in that each consists of a 3-aminophenol moiety and N-alkyl functionality involving a three-carbon chain. For 8-hydroxyjulolidine these propyl chains are bonded to the aromatic ring but no such restriction is present in 3-di-*n*-propylaminophenol. The squaraine dyes that are prepared with these two compounds are anticipated to have differing electronic and hydrophobic properties. For bis(8-hydroxy-9-julolidinyl)squaraine, **7**, the fused alkyl chains should support delocalization of the lone pair of electrons on the nitrogen into the phenyl ring. Experimental evidence in support of this has been garnered from studies of the electrochemical (5) and UV–visible absorption properties of similar squaraines (2). This change in the electronic characteristics of the dye is not expected to significantly alter its aggregation properties.

In terms of hydrophobic interactions it is not necessarily apparent how squaraine **3** and **7** would compare. Once again, although not strictly comparable, it is constructive to look for insights from studies of hydrophobic effects. Thermodynamic studies of hydrophobic solutes have demonstrated that the free energy of transfer, a measure of the hydrophobic effect, increases with increasing internal degrees of freedom (24). For linear and branched alkanes this is believed to be mainly an entropic effect. The increase in hydrophobic effect due to increased internal degrees of freedom is demonstrated by the experimentally measured standard free energies of solution of tetrahydrofuran and 1-butanol that are reported to be 1.72 and 2.35 kcal mol^{-1}, respectively, at 25°C (24). Investigations of aliphatic alcohols and their corresponding ethers have demonstrated that enthalpic factors are also significant (25).

These investigations of hydrophobic effects for alkanes and cyclic hydrocarbons would indicate that bis(8-hydroxy-9-julolidinyl)squaraine, **7**, should be less hydrophobic than bis(4-di-*n*-propylamino-2-hydroxyphenyl)squaraine, **3**. This is consistent with the observation that squaraine **7** forms type A aggregates in water but squaraine **3** forms type B aggregates under the same conditions.

The DMSO solvent effect on the aggregation of squaraines **3** and **7** can be understood on the basis of the previous discussion.

4. A thermodynamic model of squaraine dye aggregation

In the discussion of structure–property relationships it was proposed that the introduction of substituents of increasing

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 46.23.64.124 on 09/08/12
For personal use only.

hydrophobicity into anilino-class squaraine dyes should have increased the degree of aggregation and decreased the CAC. The DMSO–water solvent effect studies provided qualitative support for these changes in the association equilibria. In addition, the thermodynamic relationship between these type A and type B aggregates can be proposed on the basis of the results of these studies.

Both spectroscopic monitoring of aggregate solutions and minimum concentration studies demonstrated that the Class A/B dyes were found to rapidly aggregate upon addition to water, indicating that the nonassociated form of these dyes was not stable in these media. For squaraines **3**, **4**, and **6**, energetically favorable self-association yielded the type B aggregate. Monitoring squaraine **3** in water over time revealed a conversion to the type A aggregate. This dynamic aggregate conversion indicates that the type B aggregate could be considered to be "kinetically" preferred while the type A aggregate was "thermodynamically" preferred.

The results of the DMSO–water solvent effect studies are consistent with this interpretation of the events associated with squaraine aggregation. The addition of organic cosolvent to water is expected to destabilize the aggregates, relative to the nonassociated state (18). With increasing amounts of DMSO the nonassociated form of the dye eventually is stabilized. In intermediate solvent mixtures the type B aggregate was destabilized by DMSO cosolvent, resulting in a more facile conversion to the type A aggregate than was observed in water.

The assignment of the type A aggregate as the thermodynamically preferred aggregate in water and DMSO–water media was supported by the medium effect studies with squaraine **4**. These investigations showed that the type B aggregate of squaraine **4** in water would convert to a type A species by dilution to 50% DMSO. However, the type A aggregate in 50 v/v% DMSO–water did not convert to the type B species by dilution to 6.25% DMSO, a medium in which the type B aggregate formed on initial mixing.

The preceding discussion of structure–property relationships noted that factors associated with the introduction of hydrophobic functionality into these dyes resulted in the formation of type B aggregates. In the case of bis(4-di-*n*-octylamino-2-hydroxyphenyl) squaraine, **5**, the only Class B dye in these studies, its type B aggregates were sufficiently stable in the short-timeframe experiments that they formed in DMSO–water mixtures in which all other squaraines had either converted to the type A aggregate or were nonassociated. The slow conversion of type B aggregates of squaraine **5** to type A aggregates that was observed in 70% DMSO demonstrates that the first aggregate species to form is not the most thermodynamically stable state, although conversion to type A aggregates in more water-rich media did not occur over a period of several weeks.

Conclusions

In this study the aggregation properties of seven squaraine dyes were investigated in a series of DMSO–water mixtures using UV–visible absorption spectroscopy. In general it was found that when aggregation occurred these dyes formed one or both of two novel solution aggregates, designated as type A and type B, depending upon the composition of the mixed solvent system.

The spectroscopic properties of the type A aggregate can be interpreted within the framework of exciton theory as being diagnostic of a face-to-face packing of molecules in the aggregate. This is consistent with the results of a study of monolayers of surfactant squaraine dyes reported by Law and Chen (*7a*). The spectroscopic properties of the type B aggregate cannot readily be interpreted by exciton theory.

The propensity of the squaraine dyes to form one or both types of aggregates can be understood through an examination of structure–property relationships. Specifically, squaraine dyes with less hydrophobic N-alkyl substituents, i.e., methyl and ethyl, formed only the type A aggregates in these studies. Dyes with more hydrophobic substituents, i.e., *n*-butyl or *n*-octyl, formed type B aggregates in water that would convert over time to type A aggregates. The change in the spatial orientation of chromophores that was observed with more hydrophobic squaraines was not anticipated. In these studies the DMSO cosolvent served to destabilize the aggregate, thereby aiding in the conversion of type B aggregates to type A and, in sufficient quantities, leading to complete dissociation of the dyes.

Based on these observations, a thermodynamic model of squaraine dye aggregation has been proposed in which the type B aggregate is kinetically preferred while the type A aggregate is thermodynamically preferred. Increasing hydrophobicity of the dye is believed to stabilize the type B aggregate while increasing amounts of DMSO destabilize the type B aggregate, resulting in a more facile conversion to the type A species.

1,3-Dioxan-5-ones: synthesis, deprotonation, and reactions of their lithium enolates

Marek Majewski, D. Mark Gleave, and Pawel Nowak

Abstract: A general synthetic route to 2-alkyl- and 2,2-dialkyl-1,3-dioxan-5-ones, using tris(hydroxymethyl)-nitromethane as the starting material, is described. Deprotonation of these compounds was studied. It was established that these dioxanones could be deprotonated with LDA; however, the reduction of the carbonyl group via a hydride transfer from LDA, giving the corresponding dioxanols, often competed with deprotonation. The reduction could be minimized by using Corey's internal quench procedure to form silyl enol ethers and was less pronounced in 2,2-dialkyldioxanones (ketals) than in 2-alkyldioxanones (acetals). Self-aldol products were observed when dioxanone lithium enolates were quenched with H_2O. Addition reactions of lithium enolates of dioxanones to aldehydes were *threo*-selective as predicted by the Zimmerman–Traxler model. Dioxanones having two different alkyl groups at the 2-position were deprotonated enantioselectively by chiral lithium amide bases with enantiomeric excess (ee) of up to 70%.

Key words: 1,3-dioxan-5-ones, enantioselective deprotonation, chiral lithium amides.

Résumé : On décrit une méthode générale de synthèse des 2-alkyl- et 2,2-dialkyl-1,3-dioxan-5-ones qui fait appel au tris(hydroxyméthyl)nitrométhane comme produit de départ. On a étudié la déprotonation de ces composés. Il a été établi que ces dioxanones peuvent être déprotonées par le LDA; toutefois, ces déprotonations sont souvent accompagnées par des réductions du groupe carbonyle, via un transfert d'hydrure provenant du LDA, conduisant aux dioxanols correspondants. Il est possible de minimiser la réduction en utilisant la méthode de piégeage interne de Corey conduisant à la formation d'éthers énoliques silylés; la réduction est moins prononcée avec les 2,2-dialkyldioxanones (cétals) qu'avec les 2-alkyldioxanones (acétals). On a observé des produits d'autoaldolisation lorsqu'on piège les énolates lithiés de la dioxanone avec de l'eau. Les réactions d'addition des énolates de lithium des dioxanones sur les aldéhydes sont *threo*-sélectives comme on peut le prédire à l'aide du modèle de Zimmerman–Traxler. Sous l'influence d'amidures de lithium chiraux, les dioxanones possédant deux groupes alkyles différents en position 2 sont déprotonées d'une façon énantiosélective avec un ee allant jusqu'à 70%.

Mots clés : 1,3-dioxan-5-ones, déprotonation énantiosélective, amidures de lithium chiraux.

[Traduit par la rédaction]

Introduction

2-Alkyl- and 2,2-dialkyl-1,3-dioxan-5-ones (**2**) constitute a group of interesting heterocyclic compounds about which relatively little is known. These compounds can be considered simply as acetal and ketal protected forms of 1,3-dihydroxyacetone, a key building block in nature. A common way to synthesize both natural and unnatural carbohydrates and their analogues is to use enzyme-catalyzed aldol reactions of 1,3-dihydroxyacetone phosphate (1, 2). One drawback to this reaction is that it is only suitable for certain aldehydes: nonhindered aliphatic, α-heteroatom-substituted, and differently protected alkoxy aldehydes are common substrates; however, severely hindered aliphatic or α,β-unsaturated aldehydes do not react (2). Furthermore, aromatic aldehydes are either poor substrates or are unreactive.

We became interested in dioxanones during a study of enantioselective deprotonation of C_s symmetrical ketones (3, 4). 1,3-Dioxan-5-ones, which are nonsymmetrically substituted at the 2-position, belong to the C_s symmetry point group and are conformationaly biased and, for these reasons, can be considered promising candidates for enantioselective deprotonation with chiral lithium amide bases. Enolates of these dioxanones can be viewed as synthetic equivalents of the dihydroxyacetone enolate, and it was hoped that the enolates will react readily with both aromatic and hindered aliphatic aldehydes.

The differences in free energy between conformers of dioxanones having equatorial substituents at the 2-position and the corresponding axial conformers (*A* values) are greater than these observed for cyclohexanones (5). This was expected to cause higher selectivity in enantioselective deprotonation experiments with dioxanones than with analogous cyclohexanones, according to Koga's original observations (6). However, this expectaction did not materialize (vide infra).

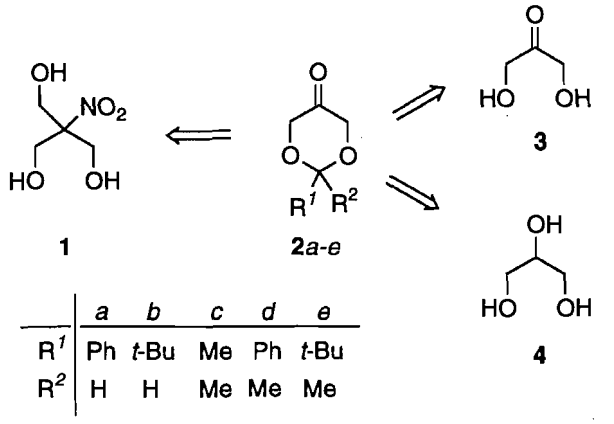
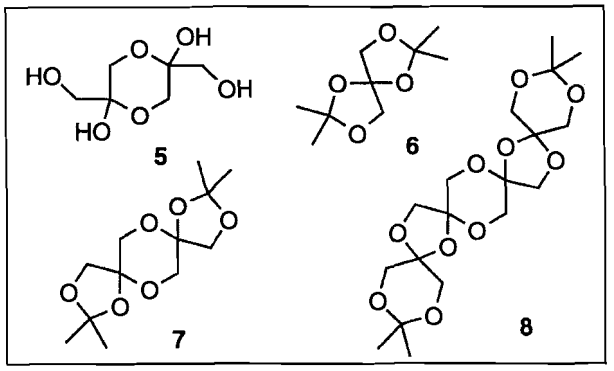
Scheme 1.





Enolate chemistry of dioxanones has not been explored before. To the best of our knowledge enolization of dioxanones has been performed in only two instances and in both cases the reaction constituted part of a multi-step synthesis: (*i*) In 1988 Hirama et al., as part of the Avermectin project, reported the aldol reaction of a derivative of 4-hydroxymethyl-2,2-dimethyldioxan-5-one (7). (*ii*) In 1990 Francl, Swindell, and co-workers described the deprotonation of 2,2-dimethyldioxan-5-one by LDA, followed by reaction of the resulting enolate with MeI (8).

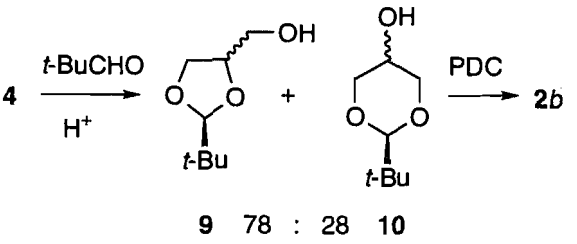
Of special note is the work done by Enders et al. on the enantioselective alkylation of 2,2-dimethyldioxan-5-one using the SAMP/RAMP hydrazone methodology (9).

Results and discussion

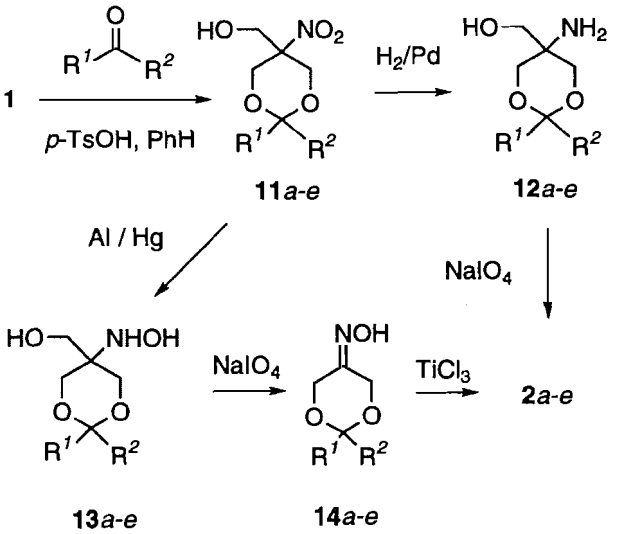
Synthesis of dioxanones

At the onset of this work several 2-alkyl- and 2,2-dialkyl-1,3-dioxa-5-ones were known (10); however, we encountered a number of problems when trying to repeat their syntheses. In an effort to devise a reasonably efficient, reproducible route to dioxanones we first attempted two obvious approaches: starting from dihydroxyacetone (**3**) or 1,2,3-propanetriol (**4**, Scheme 1). Both strategies were unsuccessful. 1,3-Dihydroxyacetone is commercially available in the form of a stable dimer **5**, which can be degraded to dihydroxyacetone at elevated temperatures. Numerous attempts to obtain compound **2***c* via a reaction of either the dimer or the monomer with acetone under acidic conditions produced variable amounts of the compounds **6**, **7** (major product), and **8**. It seems that the dimer reacts faster with ketones than the monomer.

Scheme 2.



Scheme 3.



Condensation of 1,2,3-propanetriol (**4**) with pivalaldehyde yielded predominantly two diastereoisomeric dioxolanes **9** (Scheme 2) (11). All attempts (Swern, Collins, Fetizon's, PDC, and Jones conditions were tried) to oxidize the minor dioxanol (**10**) to the corresponding dioxanone **2***b* either failed or gave low yields, presumably due to instability of the dioxanone product.

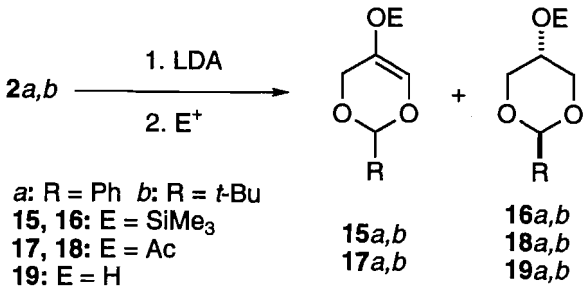
2-Phenyl-1,3-dioxan-5-one (**2***a*) had been synthesized by several groups using tris(hydroxymethyl)nitromethane (**1**) as the starting material (10*a*,*c*,*d*). We were able to refine this strategy and devise two pathways for synthesis of all the dioxanones **2***a–e* used in this study (Scheme 3). Condensation of **1** with aldehydes and ketones proceeded well. The next step, aluminum amalgam reduction of a nitro compound analogous to **11***a–e* (i.e., **11***f*: R^1 = H; R^2 = CH_2CH_2Ph) was previously reported by Trost et al. to give the corresponding amine **12***f* (10*f*). In our hands the hydroxylamines **13***a–e* were always produced, often together with the corresponding amines, which complicated the purification. The last reaction in this pathway, hydrolysis with $TiCl_3$, was capricious and thus, albeit the pathway **1** → **11** → **13** → **2** proved a viable strategy, a better method was sought. In the end, the strategy via a catalytic hydrogenation under high pressure (**1** → **11** → **12** → **2**) gave higher overall yields and was more amenable to scaling up.

With the problem of synthesis of dioxanones **2***a–e* solved, the stage was now set for deprotonation experiments.

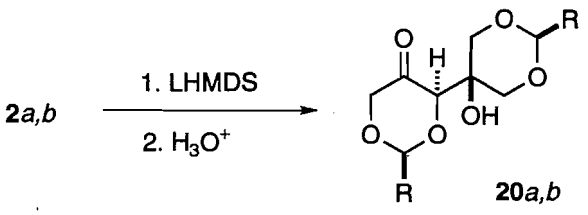
Lithium enolates of 1,3-dioxan-5-ones

Our initial attempts to deprotonate phenyldioxanone **2***a* and

Scheme 4.



Scheme 5.



tert-butyldioxanone **2***b* with LDA were not successful. Treatment of either **2***a* or **2***b* with LDA (THF; −78°C) followed by addition of either acetic anhydride or chlorotrimethylsilane yielded two products in each case. In addition to the expected enol ethers or esters (**15**, **17**; Scheme 4), products arising from LDA behaving as a reducing agent were obtained (compounds **16** and **18**). The amounts of reduction products were substantial (40–65%), and clearly rendered the deprotonation experiments inefficient. In all cases these componds were *trans* and no sign of the *cis* product was observed. This is consistent with the axial attack of the reducing agent.

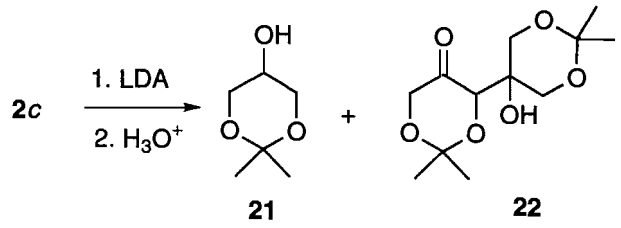
When aldol experiments were attempted on the enolates of both dioxanones (**2***a*, **2***b*) using pivalaldehyde or benzaldehyde as electrophiles, the dioxanols **19***a* and **19***b* were obtained as the major products under a variety of conditions. Isolated yields ranged from 40 to 68%.

Reduction by LDA is well precedented (for a review, see ref. 12). In our case the reduction was an undesirable side reaction, and so various reaction parameters were probed in an effort to control the reaction system. The first variable tested was the solvent: Et_2O, THF, and DME were tried in experiments with compound **2***b*. Formation of the dioxanol **19***b* as, respectively, 81, 63, and 64% of the isolated products was observed. Diethyl ether clearly favors reduction whilst the reaction in DME was much less clean than in other solvents and several unidentified side products were detected.

The observation that the amount of reduction could be increased using ether as the solvent led to a more thorough investigation, with TMS-Cl and Ac_2O used to trap the lithium alkoxide. Dioxanyl ethers **16***a,b* and esters **18***a,b* were obtained in high yields (72–89%). Thus, LDA could be used efficiently for diastereoselective reduction of dioxanones.

We found that the reduction could be minimized by using Corey's internal quench procedure for the formation of silyl enol ethers (13). With LDA as base only 5% reduction was observed with both dioxanones **2***a* and **2***b* under internal quench conditions (cf., the Experimental section, procedure B4*b*). Also, replacing LDA with lithium amides derived from amines that lack any α-hydrogens (i.e., LiTMP or LHMDS) prevented reduction (12). Reaction of dioxanones with lithium amides can thus be successfully controlled and, depending on the conditions, either enolization or reduction might be the major pathway. The procedures to avoid reduction should be applicable to other cases like ours, where reduction with LDA is undesirable.

Scheme 6.



Aldol addition reactions

Attempted aldol addition of the Li enolate of *tert*-butyldioxanone **2***b* (generated with LHMDS or LiTMP to avoid reduction) to benzaldehyde yielded large quantities of recovered starting material. Modifications such as increasing the amount of the base (to two equivalents), prolonging the reaction time (to 90 min), and warming to 0°C had little effect. These results were surprising because both LHMDS and LiTMP had given high yields in the formation of silyl enol ethers using the internal quench procedure.

An experiment whereby the dioxanone was treated with LHMDS at 0°C in ether, and after 2 h quenched with water, was done with the intention of determining whether the enolization was clean. The results with both **2***a* and **2***b* were disappointing. Neither reaction was particularly "clean." A small amount of dioxanone decomposition was thought to have occurred. In the case of phenyldioxanone this was evidenced by the presence of benzaldehyde (approximately 30%). In both cases the major constituent of the crude reaction mixture was the self-aldol product (**20**) (Scheme 5).

Ketones usually do not suffer from self-aldolization unless they are exceptionally reactive (14*a*). Dioxanones belong to the class of α-alkoxyketones, which are known to be very electrophilic with the reactivity approaching that of aldehydes (14*b*). Self-aldol addition of α-alkoxyketones is precedented (15).

Further work on 1,3-dioxan-5-ones revealed that the acetals (**2**, R^1 or R^2 = H) were less stable, and more prone to reduction and to self-aldolization than the ketals (**2**, R^1 and R^2 = alkyl). Accordingly, we decided to investigate enolization reactions of 2,2-dimethyl-1,3-dioxan-5-one (**2***c*). Deprotonation of this compound with LDA followed by aqueous quench (Scheme 6) gave very little of the reduction product **21** (5% in THF and 17% when Et_2O was used as the solvent) and substantial amounts of the self-aldol product **22** (up to 64%).

Somewhat surprisingly, aldol reaction of the lithium enolate of **2***c* with benzaldehyde worked well both under rapid quench (in this method the ketone is added to LDA followed immediately by addition of the aldehyde) (3) and normal conditions and a mixture of two diasteroisomeric aldol products (**23***a* and **24***a*; Scheme 7) was formed in up to 76% yield (the ratio of *threo*:*erythro* isomers was 65:35). Other aldehydes (heptanal, cyclohexanecarbaldehyde, cinnamaldehyde) gave similar results, with cyclohexanecarbaldehyde being the most

Table 1. Enantioselective deprotonation of dioxanone **2e**.

Entry	Lithium amide	LiCl	ee (%)[a]	Yield (%)[b]
1	**25**a	—	10 (–)	43
2		0.5 equiv.	4 (–)	63
3	**25**b	—	13 (+)	32
4		0.5 equiv.	39 (+)	56
5	**25**c	—	60 (–)	32
6		0.5 equiv.	70 (–)	63
7	**26**a	—	18 (–)	58
8		0.5 equiv.	60 (–)	51
9	**26**b	—	50 (–)	41
10		0.5 equiv.	60 (–)	41
11	**27**	—	23 (+)	28
12		0.5 equiv.	20 (+)	51

[a]The symbol (+) or (–) refers to the sign of the $[\alpha]_D$ of the major enantiomer.

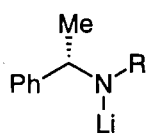
[b]Yields of isolated, purified product **23***c*.

diastereoselective; the ratio of *threo* and *erythro* isomers **23***b* and **24***b* in this case was greater than 90:10. It seems that the self-aldol reaction occurs primarily when the lithium enolate of a dioxanone is quenched with water, while quenching with an aldehyde leads to a reasonably clean aldol product.

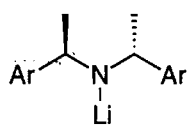
The lithium enolate of dioxanone **2***e* reacted with cyclohexanecarbaldehyde and gave only one diastereoisomer of the corresponding aldol (*cis-threo* **23***c*) to the limit of NMR detection. Thus, the aldol addition of dioxanone lithium enolate was successfully realized and proved *threo*-selective in agreement with the Zimmerman–Traxler model (14*a*).

Enantioselective deprotonation

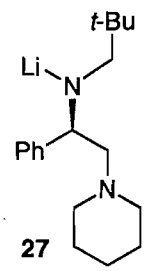
Deprotonation of the dioxanone **2***e* with chiral bases **25–27** was studied. The nonracemic enolates were trapped as the aldol product **23***c* and the enantiomeric excess (ee) was measured by NMR using the chiral shift reagent $Eu(hfc)_3$. The results are presented in Table I. Generally, the enantioselectivities were modest. Addition of LiCl (0.5 equivalents) resulted in a measurable improvement of enantioselectivity in most cases. This effect of LiCl on enantioselective deprotonation is precedented (16), and it is likely that lithium chloride changes the aggregation of chiral lithium amides (17). Aldols derived from dioxanones



25*a*: R = Me
25*b*: R = CH_2Ph
25*c*: R = $CHPh_2$



26*a*: Ar = Ph
26*b*: Ar = 2-naphtyl



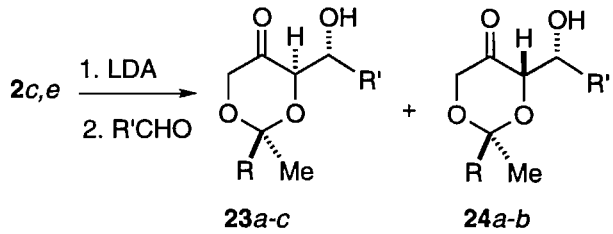
27

proved prone to decomposition during column chromatography and, although the conversion in most cases was high (the starting material was consumed) and the NMR spectra of the crude products appeared reasonably clean, the yields of pure aldols (after column chromatography) were low.

Conclusions

Synthesis and selected reactions of five 2-alkyl- and 2,2-dialkyl-1,3-dioxan-5-ones were studied. A general synthetic route, using tris(hydroxymethyl)nitromethane as the starting material, was developed for dioxanones. It has been established that dioxanones can be successfully deprotonated; however, reduction by LDA, giving the corresponding dioxanols, can compete with deprotonation. Reduction could be maximized by using ether as solvent and could be minimized by using Corey's internal quench procedure to form silyl enol ethers and by use of dioxanones derived from ketones, rather than from aldehydes. Formation of self-aldol products was observed when dioxanone Li enolates were quenched with H_2O.

Scheme 7.



23*a-c* **24***a-b*

a R = Me; R' = Ph
b R = Me; R' = cyclohexyl
c R = *t*-Bu; R' = cyclohexyl

Aldol addition reactions of lithium enolates of 2,2-dimethyl- and 2-*tert*-butyl-2-methyl-1,3-dioxan-5-ones (**2***c* and **2***e*) to various aldehydes were *threo*-selective as predicted by the Zimmerman–Traxler model. Diastereoselectivities in excess of 95:5 were observed.

Dioxanones having two different alkyl groups at the 2-position were deprotonated enantioselectively by chiral lithium amide bases in the presence of LiCl with ee of up to 70%.

Experimental Section

General methods

All air-sensitive reactions were carried out under argon. Diethyl ether, THF, DME, benzene, and hexane were dried with sodium and distilled under nitrogen from sodium benzophenone ketyl. Diisopropylamine, triethylamine, pyridine, and TMEDA were distilled from CaH_2 under argon and stored over 4 Å molecular sieves. Aldehydes were freshly distilled and stored under argon. Chiral amines were distilled under reduced pressure and stored over 4 Å molecular sieves. TMSCl was distilled under argon from CaH_2 and stored over Reillex™ 402 (Aldrich®) (18). Ac_2O was freshly distilled and stored under argon. *n*-BuLi was periodically titrated using 2,5-dimethoxybenzyl alcohol as indicator.

Flash chromatography (19) was carried out using Merck Kieselgel 60 (230–400 mesh), and all TLC was performed on precoated plates (Merck, silica gel 60, F254). The spots were detected using UV light, iodine, or by dipping a plate in an aqueous solution containing phosphomolybdic acid, $Ce(SO_4)_2$ and H_2SO_4 followed by charring on a hot plate. Melting points are uncorrected. NMR spectra were recorded at 300 MHz (^1H) and 75 MHz (^{13}C), $CDCl_3$ was used as solvent unless otherwise stated, and TMS was used as internal standard. The multiplicity of ^{13}C NMR signals was determined by *J*-modulation (20).

Polyacetals 6, 7, and 8

A solution of dihydroxyacetone monomer (5 mmol) was prepared by refluxing the dimer (451 mg, 2.5 mmol) in acetone (15 mL) overnight. Then, *p*-TsOH·H_2O (10 mg) was added and the mixture was stirred at room temperature. Progress of the reaction was monitored by GC. After 46 h the acetone was removed in vacuo and $CHCl_3$ was added. After washing with saturated aqueous $NaHCO_3$ solution (15 mL) and water (2 × 10 mL) the solution was dried ($MgSO_4$) and chloroform was removed to yield a white solid (310 mg) that comprised **6**, **7**, and **8** (19:64:17). The products were separated by flash chromatography (SiO_2, hexane:AcOEt), which yielded pure **6** (30 mg), **7** (152 mg), and **8** (66 mg).

Compound 6

White solid. R_f 0.24 (4:1 hexane:AcOEt); mp 145–146°C. IR: 1294 cm^{-1}. ^1H NMR δ: 4.10 (2H, d, J = 9.1 Hz), 3.96 (2H, d, J = 9.1 Hz), 1.48 (6H, s), 1.39 (6H, s). ^{13}C NMR δ: 110.8, 109.1, 71.5, 26.4, 26.2. MS (CI-NH_3), *m/z* (rel. intensity): 189 ($[M + 1]^+$, 1), 173 (36), 131 (13), 115 (100), 72 (63). A correct elemental analysis could not be obtained.

Compound 7

White solid. R_f 0.39 (4:1 hexane:AcOEt), mp 160-162°C. IR: 1305, cm^{-1}. ^1H NMR δ: 4.18 (2H, d, J = 11.5 Hz), 4.04 (2H, d, J = 9.3 Hz), 3.74 (2H, d, J = 9.3 Hz), 3.63 (2H, d, J = 11.5 Hz), 1.51 (6H, s), 1.45 (6H, s). ^{13}C NMR δ: 112.0, 100.3, 71.8, 65.4, 26.6, 26.3. MS (CI-NH_3), *m/z* (rel. intensity): 278 ($[M + 18]^+$, 9), 261 ($[M + 1]^+$, 100), 245 (21), 220 (60), 203 (19), 185 (26), 172 (22), 131 (32), 127 (31), 114 (33), 72 (38). Anal. calcd. for $C_{12}H_{20}O_6$: C 55.37, H 7.74; found: C 55.24, H 7.51.

Compound 8

White solid. R_f 0.10 (4:1 hexane:AcOET); mp 199–202°C. IR: 1305 cm^{-1}. ^1H NMR δ: 4.00 (4H, dd, J = 11.4, 9.4 Hz), 3.87 (4H, d, J = 11.7 Hz), 3.74 (4H, d, J = 9.4 Hz), 3.60 (4H, dd, J = 11.7, 11.4 Hz), 1.51 (6H, s), 1.45 (6H, s). ^{13}C NMR δ: 112.1, 100.4, 89.2, 71.6, 63.7, 63.4, 26.6, 26.3. MS (CI-NH_3), *m/z* (rel. intensity): 422 ($[M + 18]^+$, 6), 350 (41), 333 (67), 292 (100), 185 (54), 129 (46), 114 (41), 72 (36). Anal. calcd. for $C_{18}H_{28}O_{10}$: C 53.46, H 6.98; found: C 53.60, H 7.15.

Synthesis of 2-alkyl-1,3-dioxan-5-ones and 2,2-dialkyl-1,3-dioxan-5-ones (refs. 10*b–d, f*)

*5-Hydroxymethyl-5-nitro-1,3-dioxanes (**11**)*

General procedure A1: An aldehyde (or ketone) (50 mmol) was added to a solution of tris(hydroxymethyl)nitromethane (7.556 g, 50 mmol) and *p*-TsOH·H_2O (95 mg, 0.5 mmol) in benzene (150 mL). The mixture was refluxed overnight under a Soxhlet filled with 4 Å molecular sieves. The benzene was removed in vacuo, saturated aqueous $NaHCO_3$ solution (50 mL) was added, and the mixture was extracted with ethyl acetate (3 × 50 mL). Drying ($MgSO_4$) and removal of solvent generally afforded the nitrodioxane in a sufficiently high state of purity for the next stage of the synthesis.

*5-Hydroxymethyl-5-hydroxylamino-1,3-dioxanes (**13**)*

General procedure A2: A 2% aqueous solution of $HgCl_2$ (200 mL) was added to the reaction vessel containing aluminum foil (5.395 g) that had been cut into approximately 1 cm^2 squares. The mixture was swirled for 20 s and then decanted. The foil was successively washed (as quickly as possible) with ethanol (200 mL) and diethyl ether (200 mL) before addition of the nitrodioxane (20 mmol) in 10% aqueous THF (250 mL). The reaction vessel was immediately cooled to 0°C and a vigorous reaction ensued with strong evolution of hydrogen gas. The mixture was stirred for 30 min (at which time TLC indicated no starting material remained), then filtered, and the filter cake was washed with acetone (100 mL). The organic solvents were removed in vacuo and the resulting aqueous solution was extracted with ethyl acetate (2 × 50 mL), dried ($MgSO_4$), and concentrated. The crude hydroxylaminodioxane was used without additional purification.

*1,3-Dioxan-5-one oximes (**14**)*

General procedure A3: To a solution of hydroxylamine (10 mmol) in methanol (75 mL) was added KH_2PO_4 (1.361 g, 10 mmol). The solution was cooled to 0°C; then a solution of $NaIO_4$ (2.353 g, 12 mmol) in water (75 mL) was added dropwise over a period of 5 min. The solution generally turned blue, then green, then yellow-orange, and a thick white suspension appeared. After 30 min the mixture was filtered and the filter cake washed with chloroform (50 mL). After removal of organic solvents in vacuo $Na_2S_2O_3$ was added in small portions, with stirring, until the brown colour of iodine disappeared. Extraction with AcOEt (3 × 75 mL) followed by drying ($MgSO_4$) and removal of solvent yielded the oxime; smaller amounts of dioxanone were also typically observed.

*1,3-Dioxan-5-ones (**2**)*

General procedure A4: An aqueous, freshly prepared solution of $TiCl_3$ (15 mmol, 1 M) was added to a solution of oxime (5 mmol) and ammonium acetate (4.625 g, 60 mmol) in dioxane (40 mL) at 0°C. The mixture was stirred vigorously and the progress of the reaction was monitored by TLC. After 45 min the mixture was extracted with diethyl ether (5 × 50 mL) and dried ($MgSO_4$). The crude material was purified by flash chromatography (SiO_2).

*5-Amino-5-hydroxymethyl-1,3-dioxanes (**12**)*

General procedure A5: A solution of **11** (150 mmol) in EtOH (300 mL) was vigorously mixed with Raney nickel (0.5 g), filtered, and fresh Ra-Ni (5 g) was added. The mixture was then hydrogenated, with stirring, in a high-pressure Parr reactor (85°C; 1400 psi of H_2) for 4 h (1 psi = 6.9 kPa). The catalyst was then filtered off and the solvent was removed (roto-vap), affording crude compound **12**, which was generally subjected to oxidative cleavage with $NaIO_4$ (procedure A6) without purification.

*1,3-Dioxan-5-ones (**2**)*

General procedure A6: A cold solution of $NaIO_4$ (120 mmol) in H_2O (300 mL) was added to a solution of **12** (100 mmol) in 1:1 MeOH:H_2O at 0°C. The resulting mixture was stirred at 0°C for 15 min – 1.5 h, filtered, and extracted with CH_2Cl_2 (10 × 50 mL). After drying ($MgSO_4$) and removal of the solvents (rotovap; bath temp. <30°C), the crude dioxanone **2** was purified by short-path distillation (Kugelrohr).

2-Phenyl-1,3-dioxan-5-one (2*a*) (ref. 10*i*)

*Compound 11*a
Procedure A1 afforded white solid in 88% yield. ^{1}H NMR showed that the product contained two isomers in a ratio of 88:12. *Major isomer*: R_f 0.22 (1:1 hexane:AcOEt); mp 120–121°C. IR: 3416 cm^{-1}. ^{1}H NMR δ: 7.53–7.40 (5H, m), 5.65 (1H, s), 4.93 (2H, d, J = 12.9 Hz), 4.71 (1H, t, J = 4.6 Hz), 4.26 (2H, d, J = 12.9 Hz), 3.91 (2H, d, J = 4.6 Hz). ^{13}C NMR (acetone-d_6) δ: 138.4, 129.3, 128.4, 126.6, 101.7, 88.2, 69.0, 63.5. MS (CI-NH_3), *m/z* (rel. intensity): 257 ([M + 18]$^+$, 68), 240 ([M + 1]$^+$, 100), 238 (23), 210 (15), 105 (38). Anal. calcd. for $C_{11}H_{13}NO_5$: C 55.22, H 5.48, N 5.86; found: C 55.15, H 5.52, N 5.92. *Minor isomer*: R_f 0.58 (1:1 hexane:AcOEt); mp 83–85°C. IR: 3481 cm^{-1}. ^{1}H NMR δ: 7.55–7.32 (5H, m), 5.52 (1H, s), 4.60 (2H, d, J = 11.6 Hz), 4.41 (2H, d, J = 6.4 Hz), 4.28 (2H, d, J = 11.6 Hz), 2.05 (1H, t, J = 6.4 Hz). ^{13}C NMR (acetone-d_6) δ: 138.1, 129.6, 128.7, 126.9, 101.9, 83.1, 67.6, 63.2. MS (CI), *m/z* (rel. intensity): 257 ([M + 18]$^+$, 100), 240 ([M + 1]$^+$, 41), 227 (23), 210 (25), 195 (21), 105 (27).

*Hydroxylamine 13*a
Procedure A2 afforded a white solid, in 89% yield, that was a mixture of two isomers (88:12). *Major isomer*: mp 134–135°C, IR: 3392, 3251, 3228 cm^{-1}. ^{1}H NMR δ: 7.50 (2H, m), 7.38 (3H, m), 5.47 (1H, s), 4.31 (2H, d), 3.79 (2H, d), 3.50 (2H, s). ^{13}C NMR (acetone-d_6) δ: 139.4, 129.2, 128.5, 126.8, 102.0, 69.0, 61.8, 58.0. MS (CI-NH_3), *m/z* (rel. intensity): 226 ([M + 1]$^+$, 76), 210 (100), 194 (33), 121 (42), 73 (42). Anal. calcd. for $C_{11}H_{15}NO_4$: C 58.66, H 6.71, N 6.22; found: C 58.44, H 6.67, N 6.13.

*Amine 12*a
Procedure A5 afforded **12***a* in quantitative yield; mp 115–117°C (lit. (10*c*) mp 117–118°C). One isomer. ^{1}H NMR δ: 7.52–7.47 (m, 2H), 7.40–7.32 (m, 3H), 5.40 (s, 1H), 3.90 (d, 2H, J = 11.0 Hz), 3.84 (d, 2H, J = 11.0 Hz) 3.40 (s, 2H), 2.70 (br s, 3H).

*Oxime 14*a
Procedure A3 afforded a yellow oil, comprising 86% oxime **14***a* and 14% ketone **2***a*. The mixture was separated by flash chromatography (SiO_2, 8:1 PhH:AcOEt); the ketone was eluted first, followed by the oxime (white solid, 64%). R_f 0.50 (1:1 hexane:AcOEt); mp 82–85°C; IR: 3367, 1452 cm^{-1}. ^{1}H NMR δ: 8.93 (1H, s), 7.57–7.45 (2H, m), 7.45–7.32 (3H, m), 5.65 (1H, s), 5.30 (1H, d, J = 15.7 Hz), 4.63 (1H, d, J = 14.3 Hz), 4.53 (1H, d, J = 14.3 Hz), 4.44 (1H, d, J = 15.7 Hz). ^{13}C NMR δ: 151.0, 137.1, 129.2, 128.3, 126.0, 100.5, 66.4, 62.1. MS (CI-NH_3), *m/z* (rel. intensity): 194 ([M + 1]$^+$, 59), 179 (100), 105 (24).

*2-Phenyl-1,3-dioxan-5-one (2*a*) (ref. 10*i*)*
Procedure A4 afforded the crude material, which was purified by flash chromatography (8:1 benzene:ethyl acetate) and yielded the ketone **2***a* as a white solid (60%). R_f 0.42 (1:1 hexane:AcOEt). ^{1}H NMR δ: 7.56–7.36 (5H, m), 5.90 (1H, s), 4.51 (2H, d, J = 15 Hz), 4.50 (2H, d, J = 15 Hz). ^{13}C NMR δ: 204.2, 136.7, 129.3, 128.4, 126.1, 98.9, 72.4. Procedure A6 afforded **2***a* in 26% yield (reaction time 20 min).

2-*tert*-Butyl-1,3-dioxan-5-one (2*b*) (ref. 10*h*)

*Compound 11*b
Procedure A1 yielded the crude product (90%), which was a mixture of two isomers (64:36). *Major isomer*: R_f 0.70 (1:1 hexane:AcOEt), mp 102–103 °C. IR: 3523 cm^{-1}. ^{1}H NMR δ: 4.42 (2H, d, J = 11.5 Hz), 4.28 (2H, d, J = 6.7 Hz), 4.11 (1H, s), 4.01 (2H, d, J = 11.5 Hz), 2.02 (1H, t, J = 6.7 Hz), 0.92 (9H, s). ^{13}C NMR δ: 108.1, 62.9, 67.5, 62.4, 34.7, 24.4. MS (CI-NH_3), *m/z* (rel. intensity): 237 ([M + 18]$^+$, 100), 220 ([M + 1]$^+$, 16), 218 (22), 175 (18), 162 (65). *Minor isomer*: R_f 0.37 (1:1 hexane:AcOEt); mp 166–167°C. IR: 3575, 3436 cm^{-1}. ^{1}H NMR δ: 4.86 (2H, dd J = 12.8, 1.4 Hz), 4.14 (1H, s), 3.88–3.77 (4H, m), 1.76 (1H, t, J = 6.1 Hz), 0.88 (9H, s). ^{13}C NMR (acetone-d_6) δ: 107.4, 88.1, 68.6, 63.4, 34.9, 24.2. MS (CI-NH_3), *m/z* (rel. intensity): 237 ([M + 18]$^+$, 100), 220 ([M + 1]$^+$, 4), 190 (14), 175 (21), 162 (20), 86 (16). Anal. calcd. for $C_9H_{17}NO_5$: C 49.31, H 7.82, N 6.39; found: C 49.23, H 7.71, N 6.17.

*Hydroxylamine 13*b
Procedure A2: White solid, 85% yield. Mixture of two isomers (56:44). *Major isomer*: R_f 0.21 (5% MeOH in $CHCl_3$); mp 164–165°C. IR: 3475, 3269, 3214 cm^{-1}. ^{1}H NMR δ: 4.14 (2H, d, J = 11.8 Hz), 4.06 (1H, s), 3.94 (1H, v br s), 3.53 (2H, d, J = 11.8 Hz), 3.46 (2H, s), 0.92 (9H, s). ^{13}C NMR (acetone-d_6) δ: 107.9, 68.8, 62.0, 58.0, 35.2, 24.7. MS (CI-NH_3), *m/z* (rel. intensity): 206 (100), 190 (87), 174 (37), 158 (17), 148 (13), 101 (21). Anal. calcd. for $C_9H_{19}NO_4$: C 52.67, H 9.33, N 6.82; found: C 52.77, H 9.57, N 6.64.

*Amine 12*b
Procedure A5 afforded **12***b* in quantitative yield as a mixture of two isomers in a ratio of 69:31 (by GC; isomers were not separated); mp 154–158°C. IR (KBr): 3343.5, 3307.6, 3187.1, 1046.6 cm^{-1}. ^{1}H NMR (*major isomer*): 4.05 (s, 1H), 3.75 (d, 2H, J = 11.0 Hz), 3.58 (d, 2H, J = 11.0 Hz), 3.30 (m, 1H) 2.60 (br s, 3H), 0.93 (s, 9H); (*minor isomer*): 4.03 (s, 1H), 3.95 (d, 2H, J = 11.0 Hz), 3.75 (d, 2H, J = 11.0 Hz), 3.30 (m,1H), 2.60 (br s, 3H), 0.90 (s, 9H). ^{13}C NMR (*major isomer*): 108.0, 73.8, 64.3, 50.6, 34.7, 24.4; (*minor isomer*): 107.6, 73.0, 64.2, 48.9, 34.5, 24.5. MS (CI-NH_3): 191 (M + 2, 11), 190 (M + 1, 100), 122 (9), 101 (14).

*Oxime 14*b
Procedure A3: Crude material was a yellow solid that comprised 86% oxime (**14***b*) and 14% ketone (**2***b*). Separated by flash chromatography (SiO_2, 3:1 hexane:AcOEt), the oxime was the second component to be eluted (white solid, 69%). R_f 0.28 (3:1 hexane:AcOEt); mp 98–100°C. IR: 3282 cm^{-1}. ^{1}H NMR δ: 7.15 (1H, s), 5.19 (1H, d, J = 15.7 Hz), 4.48 (1H, d, J = 14.2 Hz), 4.31 (1H, d, J = 14.2 Hz), 4.24 (1H, s), 4.21 (1H, d, J = 15.7 Hz), 0.93 (9H, s). ^{13}C NMR δ: 151.9, 107.0, 66.3, 62.2, 35.1, 24.5. MS (CI-NH_3), *m/z* (rel. intensity): 174 ([M + 1]$^+$, 87), 116 (100), 86 (11). Anal. calcd. for $C_8H_{15}NO_3$: C 55.47, H 8.73, N 8.09; found: C 55.40, H 8.87, N 7.99.

*2-tert-Butyl-1,3-dioxan-5-one (2*b*) (ref. 10*h*)*
Procedure A4 yielded the crude material, which was purified by flash chromatography (SiO_2, 3:1 hexane:AcOEt). White solid, 50% yield. R_f 0.39 (3:1 hexane:AcOEt). ^{1}H NMR δ:

4.43 (2H, d, J = 18.0 Hz), 4.43 (1H, s), 4.27 (2H, d, J = 18.0 Hz), 0.97 (9H, s).
Procedure A6 afforded **2***b* in 50% yield (reaction time 20 min).

2,2-Dimethyl-1,3-dioxan-5-one (2*c*) (refs. 8, 9)

Compound ***11***c *(ref. 21)*
Procedure A1: Acetone (25 mL, 340 mmol) was added to a solution of p-TsOH·H_2O (190 mg, 1 mmol) and tris(hydroxymethyl)nitromethane (15.112 g, 100 mmol) in benzene (150 mL). The mixture was refluxed overnight under a Soxhlet extractor containing 4 Å molecular sieves. Solvents were removed in vacuo and saturated aqueous $NaHCO_3$ solution (200 mL) was added. The mixture was extracted with AcOEt (4375 mL), dried ($MgSO_4$), and the solvent was removed to yield an off-white solid (14.651 g, 77%). R_f 0.31 (1:1 hexane:AcOEt); mp 123–125°C. IR: 3426 cm^{-1}. ^1H NMR δ: 4.46 (2H, d, J = 13.0 Hz), 4.14 (2H, d, J = 13.0 Hz), 3.94 (2H, s), 3.78 (1H, s), 1.43 (3H, s), 1.32 (3H, s). ^{13}C NMR (acetone-d_6) δ: 98.6, 87.1, 63.0, 61.2, 25.3, 20.1. MS (CI-NH_3), m/z (rel. intensity): 209 ([M + 18]$^+$, 100), 192 ([M + 1]$^+$, 91), 176 (82), 162 (37), 146 (45), 127 (28). Anal. calcd. for $C_7H_{13}O_5N$: C 43.98, H 6.85, N 7.33; found: C 44.10, H 7.09, N 7.19.

Amine ***12***c
Procedure A5 afforded **12***c* in 93% yield; mp 63–65°C (hexane:Et_2O 1:1) (lit. (10*i*) mp 54.5–55.5°C; (10*j*) 72–73°C). IR (KBr): 3325, 3262, cm^{-1}. ^1H NMR δ: 3.76 (d, 2H, J = 12.0 Hz), 3.52 (d, 2H, = 12.0 Hz), 3.48 (s, 2H), 2.30 (br s, 3H), 1.41 (s, 3H), 1.39 (s, 3H). ^{13}C NMR δ: 98.3, 67.2, 65.1, 50.1, 24.7, 22.2; MS (CI-NH_3), m/z: (rel. intensity): 162 (M + 1, 100%), 146 (15), 104 (52), 73 (97). Anal. calcd. for $C_7H_{15}NO_3$: C 52.17, H 9.32, N 8.69; found: C 52.18, H 9.65, N 8.65.

Oxime ***14***c *and 2,2-dimethyl-1,3-dioxan-5-one (2*c*) (refs. 8, 9)*
Procedures A2, A3: Aluminum amalgam reduction of the nitrodioxane (**11***c*) yielded a complex mixture thought to comprise hydroxylamine, primary amine, and oxime. The mixture was not amenable to separation and was immediately submitted to the oxidative cleavage conditions. The amount of dioxanone in the crude product mixture from oxidative cleavage was maximized by allowing the reaction to proceed for 38 h. The crude material typically comprised 60% dioxanone (**2***c*) and 40% oxime (**14***c*). The mixture was separated by flash chromatography (SiO_2, 4:1 hexane:AcOEt).
14*c*. R_f 0.12 (4:1 hexane:AcOEt). IR: 3360 cm^{-1}. ^1H NMR δ: 4.60 (2H, s), 4.27 (2H, s), 1.41 (6H, s). ^{13}C NMR δ: 155.7, 100.0, 59.1, 57.4, 23.5. MS (CI-NH_3), m/z (rel. intensity): 163 (4), 146 (100), 130 (15), 98 (72), 58 (11).
2*c*. R_f 0.31 (4:1 hexane:AcOEt). IR: 1738 cm^{-1}. ^1H NMR δ: 4.16 (4H, s), 1.46 (6H, s). ^{13}C NMR δ: 207.5, 99.7, 66.3, 23.0. MS (CI-NH_3), m/z (rel. intensity): 131 ([M + 1]$^+$, 100), 72 (11), 58 (10).
Procedure A6 afforded **2***c* in 49% yield (reaction time 15 min).

2-Phenyl-2-methyl-1,3-dioxan-5-one (2*d*)

Compound ***11***d
Modified procedure A1 (1.1 equivalents of tris(hydroxymethyl)nitromethane were used and the reaction mixture was refluxed for 87 h) yielded **11***d* as an off-white solid (76%) that was isomerically pure; mp 129–130°C. IR: 3510, 1548 cm^{-1}. ^1H NMR δ: 7.52–7.34 (5H, m), 4.64 (2H, d, J = 12.5 Hz), 3.85 (2H, d, J = 12.5 Hz), 3.68 (2H, d, J = 6.1 Hz), 1.74 (1H, t, J = 6.1 Hz), 1.53 (3H, s). ^{13}C NMR (acetone-d_6) δ: 139.7, 129.3, 128.6, 126.7, 101.4, 87.8, 63.4, 63.3, 31.4. MS (CI-NH_3), m/z (rel. intensity): 271 ([M + 18]$^+$, 15), 254 ([M + 1]$^+$, 100), 238 (20), 224 (35), 105 (31). Anal. calcd. for $C_{12}H_{15}NO_5$: C 56.91, H 5.97, N 5.53; found: C 56.77, H 6.12, N 5.39.

Hydroxylamine ***13***d *and amine* ***12***d
Procedure A2 yielded a white solid (87%) that comprised 50% primary amine (**12***d*) and 50% hydroxylamine (**13***d*). The mixture could be separated by flash chromatography (SiO_2, methanol:AcOEt); however, oxidative cleavage was generally performed on the mixture.
13*d*. R_f 0.71 (1:1 MeOH:AcOEt); mp 139–140°C. IR: 3397 cm^{-1}. ^1H NMR δ: 7.47–7.28 (5H, m), 3.80 (2H, d, J = 11.6 Hz), 3.66 (2H, d, J = 11.6 Hz), 3.27 (2H, s), 1.44 (3H, s). ^{13}C NMR (acetone-d_6) δ: 141.2, 129.3, 128.4, 127.1, 101.0, 63.3, 61.8, 57.9, 32.0. MS (CI-NH_3), m/z (rel. intensity): 240 ([M + 1] + , 100), 224 (45), 192 (28), 121 (88), 104 (52), 73 (20). Anal. calcd. for $C_{12}H_{17}NO_4$: C 60.24, H 7.16, N 5.85; found: C 60.21, H 6.96, N 5.88.
12*d*. R_f 0.37 (1:1 MeOH:AcOEt); mp 166–168°C. IR: 3345, 3278 cm^{-1}. ^1H NMR δ: 7.45–7.37 (5H, m), 3.67 (2H, d, J = 11.2 Hz), 3.50 (2H, d, J = 11.2 Hz), 3.22 (2H, br s), 3.17 (2H, s), 1.46 (3H, s). ^{13}C NMR (acetone-d_6) δ: 142.7, 129.2, 128.4, 127.1, 100.6, 70.1, 69.6, 64.8, 31.8. MS (CI-NH_3), m/z (rel. intensity): 225 (M + 2, 13), 224 (M + 1, 100), 192 (7), 135 (18), 105 (8), 104 (34), 73 (22). Anal. calcd. for $C_{12}H_{17}NO_3$: C 64.55, H 7.67, N 6.27; found: C 64.56, H 7.84, N 6.22.
Procedure A5 afforded **12***d* in quantitative yield.

Oxime ***14***d *and 2-phenyl-2-methyl-1,3-dioxan-5-one (2*d*)*
Modified procedure A3 (two equivalents of $NaIO_4$ and half an equivalent of KH_2PO_4 were used) yielded a mixture of dioxanone **2***d* and oxime **14***d* (44:56). The mixture was separated by flash chromatography (SiO_2, 6:1 hexane:AcOEt), ketone eluted first (41%), followed by oxime (54%).
14*d*. R_f 0.23 (4:1 hexane:AcOEt). IR: 3350, 1458 cm^{-1}. ^1H NMR δ: 7.56–7.32 (5H, m), 4.79 (1H, d J = 16.5 Hz), 4.37 (1H, d, J = 16.5 Hz), 4.37 (1H, d, J = 13.8 Hz), 4.27 (1H, d, J = 13.8 Hz), 1.61 (3H, s). ^{13}C NMR δ: 155.2, 140.8, 128.4, 128.1, 125.9, 101.3, 60.3, 58.1, 28.4. MS (CI-NH_3), m/z (rel. intensity): 208 ([M + 1]$^+$, 100), 192 (66), 130 (10), 105 (13).
2*d*. R_f 0.44 (4:1 hexane:AcOEt). IR: 1751 cm^{-1}. ^1H NMR δ: 7.59–7.34 (5H, m), 4.27 (2H, d, J = 17.1 Hz), 4.12 (2H, d, J = 17.1 Hz), 1.67 (3H, s). ^{13}C NMR δ: 206.6, 140.7, 128.2, 128.1, 125.5, 100.7, 67.1, 26.7. MS (CI-NH_3), m/z (rel. intensity): 193 ([M + 1]$^+$, 100), 177 (24), 105 (13). Anal. calcd. for $C_{11}H_{12}O_3$: C 68.73, H 6.29; found: C 68.56, H 6.02.
Procedure A6 afforded **2***d* in 92% yield (reaction time 30 min).

2-*tert*-Butyl-2-methyl-1,3-dioxan-5-one (2*e*)

Compound ***11***e
Modified procedure A1 (two equivalents of pinacolone were used and the mixture was refluxed for 48 h) yielded the crude product (83%) as an off-white solid comprising two

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 46.23.64.124 on 09/08/12
For personal use only.

isomers (68:32). *Major isomer*: R_f 0.38 (1:1 hexane:AcOEt), mp 92–94°C. IR: 3429, 3337 cm^{-1}. ^1H NMR δ: 4.63 (2H, d, J = 13.2 Hz), 4.03 (2H, d, J = 13.2 Hz), 3.82 (2H, d, J = 6.1 Hz), 1.80 (1H, t, J = 6.1 Hz), 1.37 (3H, s), 0.91 (9H, s). ^{13}C NMR (acetone-d_6) δ: 102.6, 87.8, 63.3, 62.0, 39.3, 24.2, 11.4. MS (CI-NH_3), m/z (rel. intensity): 235 ([M + 2]$^+$, 13), 234 ([M + 1]$^+$, 100), 218 (9), 176 (21). Anal. calcd. for $C_{10}H_{19}NO_5$: C 51.78, H 8.63, N 5.87; found: C 51.72, H 8.31, N 5.88.

Compound ***13e***
Procedure A2: White solid, 87% yield. Mixture of isomers (64:36). *Major isomer*: mp 159–161°C. IR: 3487, 3273 cm^{-1}. ^1H NMR δ: 3.88 (2H, d, J = 12.0 Hz), 3.75 (2H, d, J = 12.0 Hz), 3.48 (2H, s), 1.35 (3H, s), 0.99 (9H, s). ^{13}C NMR (acetone-d_6) δ: 105.3, 61.9, 61.8, 57.8, 39.9, 24.7, 11.5. MS (CI-NH_3), m/z (rel. intensity): 220 ([M + 1]$^+$, 64), 204 (100), 188 (67), 172 (56), 130 (41), 104 (48), 73 (31). Anal. calcd. for $C_{10}H_{21}NO_4$: C 54.77, H 9.65, N 6.39; found: C 55.04, H 9.82; N 6.32.

Compound ***12e***
Procedure A5: White solid, 98% yield. Mixture of two isomers in a ratio of 77:23 (not separated); mp 82–87°C (hexane). IR (KBr): 3252 cm^{-1}; ^1H NMR δ *(major isomer)*: 3.85 (dtr, 2H, J_1 = 1.5, J_2 = 12.0 Hz), 3.48 (dtr, 2H, J_1 = 1.5, J_2 = 12.0 Hz), 3.28 (s, 2H), 1.70 (brs, 3H), 1.32 (s, 3H), 1.03 (s, 9H), *(minor isomer)*: 3.75 (s, 2H), 3.67 (d, 2H, J = 11.5 Hz), 3.58 (d, 2H, J = 11.5 Hz), 1.70 (br s, 3H), 1.38 (s, 3H), 0.97 (s, 9H); ^{13}C NMR δ *(major isomer)*: 102.5, 67.3, 64.9, 50.5, 39.4, 24.5, 11.2; *(minor isomer)*: 102.0, 66.2, 64.6, 49.0, 39.2, 24.6, 11.3; MS (CI-NH_3), m/z: 204 (M + 1, 100%), 188 (11), 146 (22), 115 (50), 104 (73), 86 (32), 73 (52). Compound ***14e***
Procedure A3: The crude product was a greenish solid that contained an oxime:ketone mixture (80:20). The mixture was separated by flash chromatography (SiO_2, hexane:AcOEt). Oxime (***14e***) eluted first (white solid, 52%). R_f 0.18 (6:1 hexane: AcOEt); mp 64–65°C. IR: 3284, 3162, 1162 cm^{-1}. ^1H NMR δ: 7.50 (1H, br s), 4.77 (1H, d, J = 17 Hz), 4.62 (1H, d, J = 17 Hz), 4.40 (1H, d, J = 14.5 Hz), 4.29 (1H, d, J = 14.5 Hz), 1.34 (3H, s), 1.01 (9H, s). ^{13}C NMR δ: 155.7, 104.1, 61.2, 58.6, 40.3, 25.0, 16.1. MS (CI-NH_3), m/z (rel. intensity): 189 ([M + 2]$^+$, 12), 188 ([M + 1]$^+$, 100), 172 (10), 130 (37). Anal. calcd. for $C_9H_{17}NO_3$: C 57.73, H 9.15, N 7.48; found: C 57.77, H 9.32, N 7.29.

*2-tert-Butyl-2-methyl-1,3-dioxan-5-one (**2e**)*
Procedure A4: $TiCl_3$ hydrolysis was generally performed on the crude oxime:ketone mixture obtained in the preceding step without additional purification.
2e. R_f 0.44 (6:1 hexane:AcOEt); mp 47-49°C. IR: 1736 cm^{-1}. ^1H NMR δ: 4.33 (2H, d, J = 18.5 Hz), 4.25 (2H, d, J = 18.5 Hz), 1.37 (3H, s), 1.04 (9H, s). ^{13}C NMR δ: 207.9, 103.6, 68.8, 40.4, 25.2, 15.9. MS (CI-NH_3), m/z (rel. intensity): 173 ([M + 1]$^+$, 100), 115 (29). Anal. calcd. for $C_9H_{16}O_3$: C 62.76, H 9.36; found: C 62.91, H 9.50.
Procedure A6 (reaction time 5h) afforded ***2e*** in 63%.

Enolization and reactions of dioxanones.
General procedure B
Diisopropylamine (0.08 mL, 0.55 mmol) was dissolved in THF (3 mL) and cooled to 0°C. *n*-BuLi (0.24 mL of a 2.3 M solution in hexanes; 0.55 mmol) was added, dropwise, and the solution was stirred for 15 min before cooling to −78°C. Dioxanone **2** (0.50 mmol) in THF (1.5 mL) was then added dropwise over 5 min. The resulting mixture was stirred for 30 min at −78°C and was then treated with an appropriate electrophile, stirred for a specific length of time, and then quenched with saturated aqueous NH_4Cl solution (2 mL) at −78°C. After warming to room temperature, saturated $NaHCO_3$ solution was added (5 mL) and the mixture was extracted with Et_2O (3 × 5 mL). The combined organic extracts were washed with brine (1 × 10 mL) and dried ($MgSO_4$). Removal of solvents in vacuo yielded the crude product(s).

The above procedure was followed in experiments with chiral lithium amide bases with the following modifications: (*i*) reaction time for deprotonation of the amine with BuLi was 90 min. (*ii*) In experiments with LiCl the chloride was added as 0.56 M solution in THF to the lithium amide, the mixture was stirred for 30 min, cooled to −78°C and the dioxanone was added. The enantiomeric excess was measured by ^1H NMR using $Eu(hfc)_3$ as the chiral shift reagent.

(B1) Enol acetates
Acetic anhydride (0.24 mL, 2.5 mmol) was added, as the electrophile, to the solution of the enolate generated as above. After stirring for between 30 min and 1 h at −78°C the reaction was quenched with water. Standard work-up yielded the crude enol acetate, usually accompanied by the acetate of the product of reduction.

(B2) Aldols
The aldehyde, typically PhCHO (0.50 mmol), was added in one portion to the enolate solution and the solution was stirred at −78°C for 15 min. Standard work-up yielded the crude aldol products.

(B3) Protonation
After the dioxanone (0.50 mmol) had been stirred with LDA (0.55 mmol) for 30 min, the reaction was quenched with saturated aqueous NH_4Cl solution. Work-up in the usual manner yielded a mixture that was typically analysed by GC and (or) ^1H NMR.

(B4) Silylation
(a) External quench: TMSCl (0.32 mL, 2.5 mmol) was added, as the electrophile, immediately followed by Et_3N (1 mL) and the mixture was allowed to warm to room temperature. The excess TMSCl, Et_3N, and THF were removed in vacuo and saturated aqueous $NaHCO_3$ (10 mL) was added. Extraction with ether (3 × 5 mL), drying ($MgSO_4$), and removal of solvent yielded the crude product mixture.
(b) Internal quench: TMSCl (0.32 mL, 2.5 mmol) was added to a solution of LDA (0.55 mmol) in THF (3 mL), followed by the dropwise addition of dioxanone (0.5 mmol) in THF (1.5 mL) over 3 min. After 1 min Et_3N (1 mL) was added and the mixture was allowed to warm up to room temperature. Work-up identical to that for the external quench procedure was performed.

18*a*: R_f 0.30 (4:1 hexane:AcOEt); mp 108–109°C (lit. (10*a*) mp 118°C).

*5-Acetyloxy-2-*tert*-butyl-1,3-diox-4-ene (**17**b) and* trans-*2-*tert*-butyl-1,3-dioxan-5-ol acetate (**18**b)*

Crude product (60%; yellow oil) contained a mixture of **17**b and **18**b (43:57) that was purified by flash chromatography (SiO_2, 10:1 hexane:AcOEt). The components could not be separated and were characterized via independent synthesis.

17*b*. R_f 0.19 (15:1 hexane:AcOEt). IR: 1759 cm^{-1}. ^{1}H NMR δ: 6.67 (1H, s), 4.48 (1H, d, J = 14.3 Hz), 4.45 (1H, s), 4.16 (1H, d, J = 14.3 Hz), 2.14 (3H, s), 0.96 (9H, s). ^{13}C NMR δ: 169.3, 135.8, 130.3, 104.5, 64.3, 34.3, 24.3, 20.5. MS (CI-NH_3), *m/z* (rel. intensity): 218 ([M + 18]$^+$, 100), 200 ([M]$^+$, 9), 157 (15), 132 (50), 129 (20), 115 (16). Anal. calcd. for $C_{10}H_{16}O_4$: C 59.98, H 8.05; found: C 60.22, H 7.99.

18*b*. R_f 0.47 (4:1 hexane:AcOEt). IR: 1750 cm^{-1}. ^{1}H NMR δ: 4.85 (1H, tt, J = 10.4, 5.3 Hz), 4.23 (2H, dd, J = 10.9, 5.3 Hz), 4.03 (1H, s), 3.42 (2H, dd, J = 10.9, 10.4 Hz), 2.04 (3H, s), 0.91 (9H, s). ^{13}C NMR δ: 169.8, 107.6, 68.3, 63.0, 34.7, 24.7, 20.8. MS (CI-NH_3), *m/z* (rel. intensity): 220 (M + 18]$^+$, 18), 203 ([M + 1]$^+$, 47), 145 (85), 117 (100), 86 (29). Anal. calcd. for $C_{10}H_{18}O_4$: C 59.39, H 8.97; found: C 59.47, H 9.12.

trans-*2-Phenyl-1,3-dioxan-5-ol (**19**a)*

Crude product (obtained according to procedure B3) contained 81% **19***a* and 19% starting material **2***a*. Purification by flash chromatography (SiO_2, hexane:AcOEt) gave **19***a* as clear liquid (83%). Spectral properties were in agreement with literature values (10*i*).

trans-*2-*tert*-Butyl-1,3-dioxan-5-ol (**19**b)*

Crude product (obtained according to procedure B3 in Et_2O) contained 89% **19***b* and 11% starting material **2***b*. Purification was by flash chromatography (SiO_2, hexane:AcOEt). White solid. R_f 0.22 (4:1 hexane:AcOEt). IR: 3297 cm^{-1}. ^{1}H NMR δ: 4.18 (2H, dd, J = 11.0, 5.2 Hz), 4.00 (1H, s), 3.85 (1H, m), 3.33 (2H, dd, J = 11.0, 10.0 Hz), 1.43 (1H, d, J = 5.5 Hz), 0.92 (9H, s). ^{13}C NMR δ: 107.5, 71.6, 61.4, 34.5, 24.8. MS (CI-NH_3), *m/z* (rel. intensity): 178 ([M + 18]$^+$, 62), 161 ([M + 1]$^+$, 70), 103 (100).

19*b* via inverse addition: A solution of LDA (0.50 mmol) in ether (2 mL) was added, dropwise, to a solution containing dioxanone **1***b* (72 mg, 0.45 mmol) in ether (3 mL) at −78°C. The mixture was stirred for 1 h before quenching with saturated aqueous NH_4Cl solution. Work-up in the usual manner yielded a mixture (65:35) of alcohol **19***b* and ketone **2***b*.

*4-(1-Hydroxy-4-*tert*-butyl-3,5-dioxanyl)-2-*tert*-butyl-1,3-dioxan-5-one (**20**b)*

To a solution of HMDS (0.15 mL, 0.69 mmol) in diethyl ether (3 mL) at −5°C was added, dropwise, *n*-BuLi (0.37 mL of a 1.88 M solution in hexanes). The solution was stirred for 90 min before cooling to −78°C. A solution of dioxanone **2***b* (53 mg, 0.33 mmol) in ether (1.5 mL) was added dropwise over 5 min. The solution was allowed to warm to 0°C and was stirred for 2 h, after which time the reaction was quenched with saturated aqueous NH_4Cl solution (2 mL). After warming to room temperature, saturated aqueous $NaHCO_3$ solution (10 mL) was added and the mixture was extracted with ether (2 × 8 mL). The organic extracts were combined and washed with brine (2 × 15 mL). Drying and removal of solvents yielded the crude product mixture, which was purified by flash chromatography (SiO_2, 10:1 hexane:AcOEt). Self-aldol **20***b* was isolated as an oil (18 mg, 34%). R_f 0.47 (4:1 hexane:AcOEt). IR: 3571, 1738 cm^{-1}. ^{1}H NMR δ: 5.13 (1H, s), 4.36 (2H, s), 4.14

(1H, dd, J = 11.8, 3.2 Hz), 4.06 (1H, s), 4.01 (1H, dd, J = 11.7, 3.3 Hz), 3.96 (1H, d, J = 2.0 Hz), 3.71 (1H, d, J = 11.7 Hz), 3.64 (1H, d, J = 11.7 Hz), 3.15 (1H, d, J = 2.0 Hz), 0.96 (9H, s), 0.93 (9H, s). ^{13}C NMR δ: 203.9, 107.8, 103.4, 80.5, 74.7, 72.5, 72.3, 71.4, 35.2, 34.8, 24.6, 24.5. MS (CI-NH_3), *m/z* (rel. intensity): 334 ([M + 18]$^+$, 100), 317 ([M + 1]$^+$, 74), 259 (53), 248 (57), 173 (21), 101 (33).

*2,2-Dimethyl-1,3-dioxan-5-ol (**21**) (ref. 22)*

To a solution of $NaBH_4$ (20 mg, 0.53 mmol) in i-PrOH (4 mL) at 0°C was added dioxanone **2***c* (114 mL, 0.96 mmol). The solution was stirred for 30 min before quenching with water (2 mL). The mixture was extracted with ether (2 × 5 mL) and the combined organic extracts washed with saturated aqueous NaCl solution (15 mL), dried ($MgSO_4$), and the solvents removed in vacuo. The crude material was purified by flash chromatography (SiO_2, 1:2 hexane:AcOEt) to afford a clear liquid (77 mg, 61%). R_f 0.27 (1:2 hexane:AcOEt). ^{1}H NMR δ: 4.07 (2H, dd, J = 12.1, 1.1 Hz), 3.75 (2H, dd, J = 12.1, 1.7 Hz), 3.53 (1H, m), 2.84 (1H, d, J = 10.2 Hz), 1.46 (3H, s), 1.43 (3H, s). ^{13}C NMR δ: 98.4, 65.2, 63.5, 27.7, 19.5.

*4-(1-Hydroxy-4,4-dimethyl-3,5-dioxanyl)-2,2-dimethyl-1,3-dioxan-5-one (**22**)*

Procedure B3 (THF; 0.5 equiv. of LDA) yielded a mixture comprising 38% dioxanone **2***c*, 4% alcohol **21**, and 58% **22**. Removal of the more volatile components under high vacuum (0.1 Torr, 16 h; 1 Torr = 133.3 Pa) yielded **22** in a high state of purity (oil, 44%). R_f 0.26 (1:1 hexane:AcOEt). IR: 3460, 1747 cm^{-1}. ^{1}H NMR δ: 4.48 (1H, s), 4.28 (1H, d, J = 17.2 Hz), 4.13 (1H, d, J = 12.1 Hz), 4.03 (1H, d, J = 11.7 Hz), 4.00 (1H, d, J = 17.2 Hz), 3.85 (1H, d, J = 12.1 Hz), 3.67 (1H, d, J = 11.7 Hz), 2.83 (1H, br s), 1.49 (3H, s), 1.47 (3H, s), 1.45 (3H, s), 1.42 (3H, s). ^{13}C NMR δ: 208.2, 101.0, 98.2, 73.8, 68.6, 67.2, 65.1, 64.4, 23.8, 23.5, 23.1, 23.0. MS (CI-NH_3), *m/z* (rel. intensity): 278 ([M + 18]$^+$, 24), 261 ([M + 1]$^+$, 45), 220 (100), 131 (17). Anal. calcd. for $C_{12}H_{20}O_6$: C 55.37, H 7.74; found: C 55.27, H 7.60.

General procedure for rapid quench aldol reactions of 2*c* (ref. 3)

A solution of dioxanone **2***c* (50 μL, 0.42 mmol) in 1.5 mL THF was added, dropwise, to a solution of LDA (0.46 mmol) in THF (3 mL) at −78°C. The aldehyde (0.42 mmol) was then added immediately, in one portion. Stirring was continued for 2 min prior to quenching with saturated aqueous NH_4Cl solution (2 mL). The solution was allowed to warm to room temperature, then was worked up in the usual manner.

*4-(Hydroxyphenylmethyl)-2,2-dimethyl-1,3-dioxan-5-one (**23**a, **24**a)*

Procedure B2 afforded crude product (yellow oil, 86 mg, 92%) containing the *threo* and *erythro* isomers[2] **23***a* and **24***a* (64:36). A pure sample of each compound was obtained by flash chromatography (SiO_2, 4:1 hexane:AcOEt); the *threo* isomer (23) **23***a* (30 mg, 32%) eluted first, followed by the *erythro* compound **24***a* (25 mg, 28%).

23*a*. R_f 0.18 (4:1 hexane: AcOEt). IR: 3494, 1741 cm^{-1}. ^{1}H NMR δ: 7.26–7.45 (5H, m), 4.91 (1H, dd, J = 7.7, 3.1 Hz), 4.35 (1H, dd, J = 7.7, 1.4 Hz), 4.27 (1H, dd, J = 17.5, 1.4 Hz), 4.04 (1H, d, J = 17.5 Hz), 3.62 (1H, d, J = 3.1 Hz), 1.37 (3H, s), 1.25 (3H, s). ^{13}C NMR δ: 211.0, 139.2 128.1, 127.1, 101.2, 76.1, 72.7, 66.7, 23.6, 23.2. MS (CI-NH_3), *m/z* (rel. intensity): 254 ([M + 18]$^+$, 100), 237 ([M + 1]$^+$, 15), 178 (19), 131 (54). Anal. calcd. for $C_{13}H_{16}O_4$: C 66.09, H 6.83; found: C 66.23, H 6.73.

24*a*. R_f 0.13 (4:1 hexane:AcOEt). IR: 3473, 1750 cm^{-1}. ^{1}H NMR δ: 7.45–7.30 (5H, m), 5.24 (1H, dd, J = 8.0, 2.7 Hz), 4.48 (1H, dd, J = 2.7, 1.5 Hz), 4.30 (1H, dd, J = 17.1, 1.5 Hz), 4.06 (1H, d, J = 17.1 Hz), 2.78 (1H, d, J = 8.0 Hz), 1.49 (3H, s), 1.37 (3H, s). ^{13}C NMR δ: 207.4, 140.1, 128.3, 127.9, 126.5, 101.0, 78.0, 71.3, 67.2, 24.3, 23.3. MS (CI-NH_3), *m/z* (rel. intensity): 255 (M + 19, 14), 254 (M + 18, 100), 237 (M + 1, 11), 219 (31), 196 (13), 179 (18), 178 (31), 165 (36), 161 (59), 131 (52), 130 (11), 124 (33), 113 (46), 105 (18), 94 (10), 76 (32), 72 (25). Anal. calcd. for $C_{13}H_{16}O_4$: C 66.09, H 6.83; found: C 66.11, H 6.70.

*4-(Cyclohexylhydroxymethyl)-2,2-dimethyl-1,3-dioxan-5-one (**23**b, **24**b).*

Procedure B2 afforded crude product (oil, 97 mg, 95%) containing the *threo* isomer[2] **23***b* and a small amount of the *erythro* isomer[2] **24***b* (less than 10% by NMR). Purification by flash chromatography (SiO_2; 4:1 hexane:AcOEt; R_f 0.32) afforded **23***b* (70 mg, 69%) as a yellow solid (mp 64–66°C). IR (KBr): 3531, 1737 cm^{-1}. ^{1}H NMR δ: 4.28 (dd, 1H, J_1 = 17.5, J_2 = 1.5 Hz), 4.21 (dd, 1H, J_1 = 7.5, J_2 = 1.5 Hz), 4.03 (d, 1H, J = 17.5 Hz), 3.69 (m, 1H), 3.00 (br s, 1H), 1.92–1.47 (m, 7H), 1.47 (s, 3H), 1.44 (s, 3H), 1.44–1.09 (m, 4H); ^{13}C NMR δ: 212.0, 100.9, 74.1, 73.3, 66.6, 38.3, 29.5, 26.4, 26.3, 26.2, 26.0, 23.7, 23.6; MS (CI); *m/e* (rel. intensity): 260 (M + 18, 100), 243 (M + 1, 65), 95 (11), 72 (16). Anal. calcd. for: $C_{13}H_{22}O_4$: C 64.44, H 9.15; found: C 64.68, H 9.17.

cis-*4-(Cyclohexylhydroxymethyl)-2-*tert*-butyl-2-methyl-1,3-dioxan-5-one (**23**c) (ref. 23)*

Procedure B2, followed by purification by flash chromatography (SiO_2, 8:1 hexane:AcOEt), yielded **23***c* as an oil (53 mg, 61%). R_f 0.38 (4:1 hexane:AcOEt). IR (KBr): 3530, 1731 cm^{-1}. ^{1}H NMR δ: 4.36 (dd, 1H, J = 18.0 Hz, J = 1.5 Hz), 4.30 (d, 1H, J = 5.5 Hz), 4.22 (d, 1H, J = 18.0 Hz), 3.73 (ddd, 1H, J_1 = 3.5, J_2 = 5.5 Hz, J_3 = 5.5 Hz), 2.91 (d, 1H, J = 3.5 Hz), 1.83–1.75 (m, 3H), 1.75–1.60 (m, 4H), 1.45 (s, 3H), 1.35–1.10 (m, 6H), 1.06 (s,9H). ^{13}C NMR δ: 210.2, 103.3, 76.4, 75.7, 69.5, 40.0, 38.7, 29.2, 27.1, 26.3, 26.2, 26.0, 25.0, 15.7. MS (CI-isobutane), *m/z* (rel. intensity): 286 (M + 2, 14), 285 (M + 1, 68), 227 (26), 185 (11), 173 (18), 167 (20), 113 (12), 101 (100), 95 (26). Anal. calcd. for: $C_{16}H_{28}O_4$: C 67.57, H 9.92; found: C 67.82, H 10.15. $[\alpha]_D^{24}$ −34.5 (*c* 0.8, MeOH) for the sample having 67% ee (by ^{1}H NMR).

[2] The aldol stereostructural assignments (*threo* vs. *erythro* isomers; compounds **23***a–c* and **24***a, b*) were made by NMR on the basis of the well-known "rule of thumb" based on the analysis of a large number of coupling constants in ^{1}H NMR spectra and chemical shifts in ^{13}C NMR spectra (cf. ref. 23). All assumptions inherent in this analysis apply. To determine the relative configuration (*cis* or *trans*) in compound **23***c* a crystal structure of a derivative of this compound was obtained (the full crystallographic data will be published elsewhere).

Acknowledgements

We are grateful to Natural Sciences and Engineering Research Council of Canada and to the University of Saskatchewan for financial support of this work. We thank Professor J. W. Quail for help in establishing the relative configuration of compound **23***c*.

Organic nitrates, thionitrates, peroxynitrites, and nitric oxide: a molecular orbital study of the $RXNO_2 \rightleftharpoons RXONO$ (X = O, S) rearrangement, a reaction of potential biological significance

Dale R. Cameron, Alison M.P. Borrajo, Brian M. Bennett, and Gregory R.J. Thatcher

Abstract: The rearrangement of organic thionitrate to sulfenyl nitrite potentially mediates the release of nitric oxide from organic nitrates, such as nitroglycerin, in the presence of thiol. The biological activity of these nitrovasodilators is proposed to result from release of nitric oxide in vivo. The thionitrate rearrangement bears analogy to the rearrangement of peroxynitrous acid to nitric acid, which has been proposed to mediate the biological toxicity of nitric oxide and superoxide. In this paper, the two concerted rearrangement processes and competing homolytic reactions are explored using molecular orbital calculations at levels up to MP4SDQ/6-31G*//MP2/6-31G*. Examination of structure and energy for all conformers and isomers of $RSONO_2$ (R = H, Me), models for organic thionitrates and their isomers, demonstrates that structures corresponding to thionitrates and sulfenyl nitrates are of similar energy. Free energies of reaction for homolysis of these compounds are low ($\Delta G_0 < 19$ kcal/mol), whereas the barrier for concerted rearrangement is large ($\Delta G^{\neq}$(aq.) = 56 kcal/mol). The larger barrier for concerted rearrangement of peroxynitrous acid to nitric acid ($\Delta G^{\neq}$(aq.) = 60 kcal/mol) again compares unfavourably with homolysis ($\Delta G_0 < 11$ kcal/mol for homolysis to NO_2 or $^{\cdot}NO$). The transition state structures, confirmed by normal mode and intrinsic reaction coordinate analysis, indicate that considerable structural reorganization is required for concerted rearrangement of the ground state species. These results suggest that concerted rearrangement is not likely to be a viable step in either biological process. However, rearrangement via homolysis and radical recombination may provide an energetically accessible pathway for peroxynitrous acid rearrangement to nitric acid and rearrangement of thionitrate to sulfenyl nitrite. In this case, NO_2 will be a primary product of both reactions.

Key words: thionitrate, nitric oxide, peroxynitrite, nitrovasodilator, nitrate.

Résumé : Le réarrangement des thionitrates organiques en nitrites de sulfényle pourrait éventuellement permettre de dégager, en présence de thiols, de l'oxyde nitrique à partir de nitrates organiques, comme la nitroglycérine. Il est suggéré que l'activité biologique de ces nitrovasodilatateurs est le résultat d'une expulsion in vivo d'oxyde nitrique. Le réarrangement thionitrate ressemble au réarrangement de l'acide peroxynitreux en acide nitrique qui serait la cause de la toxicité biologique de l'oxyde nitrique et du superoxyde. Dans ce travail, utilisant des calculs d'orbitales moléculaires à des niveaux allant jusqu'à MP4SDQ/6-31G*//MP2/6-31G*, on a examiné les deux processus concertés du réarrangement et les réactions homolytiques qui leur font compétition. Un examen de la structure et de l'énergie de chacun des conformères et des isomères des $RSONO_2$ (R = H, Me), modèles des thionitrates organiques et de leurs isomères, permet de démontrer que les structures correspondant aux thionitrates et aux nitrites de sulfényles sont d'énergies semblables. Les énergies libres de réaction pour l'homolyse de ces composés sont basses ($\Delta G_0 < 19$ kcal/mol) alors que la barrière pour le réarrangement concerté est élevée ($\Delta G^{\neq}$(aq) = 56 kcal/mol). La barrière encore plus élevée observée pour le réarrangement concerté de l'acide peroxynitreux en acide nitrique ($\Delta G^{\neq}$(aq) = 60 kcal/mol) donne à nouveau lieu à une comparaison non favorable avec l'homolyse ($\Delta G_0 < 11$ kcal/mol pour l'homolyse en NO_2 ou en $^{\cdot}NO$). Les structures des états de transition, confirmées par une analyse du mode normal et des coordonnées de la réaction

intrinsèque, indiquent qu'une réorganisation structure importante est requise pour un réarrangement concerté des espèces dans l'état fondamental. Ces résultats suggèrent qu'il est peu probable que le réarrangement concerté soit une étape viable dans l'un ou l'autre des processus biologiques. Toutefois, un réarrangement par le biais d'une homolyse et d'une recombinaison de radicaux peut s'avérer une voie énergétiquement accessible pour le réarrangement de l'acide peroxynitreux en acide nitrique et pour le réarrangement du thionitrate en nitrite de sulfényle. Dans ce cas, le NO_2 sera le produit primaire de chacune de ces réactions.

Mots clés : thionitrate, oxyde nitrique, peroxynitrite, nitrovasodilatateur, nitrate.

[Traduit par la rédaction]

Introduction

Nitric oxide is the subject of substantial, current interest, stimulated by recent evidence suggesting many varied biological roles for NO, extending beyond vasodilation to immune function and neurotransmission (1). Furthermore, there is significant interest in the toxicology and pharmaceutical applications of ·NO and ·NO-releasing agents (2). Interestingly, glyceryl trinitrate (GTN, nitroglycerin), which has been used since 1879 in the treatment of angina pectoris (3), is now widely believed to exert its therapeutic effect through release of nitric oxide (·NO) in vivo (4). Several simple organic nitrates ($RONO_2$) in addition to GTN, including erythrityltetranitrate, isosorbide dinitrate, and isoidide dinitrate, are effective and clinically important vasodilators (5). A substantial body of evidence supports the hypothesis that the vasodilatory activity of these organic nitrates, and indeed of other potent vasodilators such as nitroprusside and molsidomine, is largely the result of activation of guanylate cyclase (GCase) leading to an elevated level of intracellular cGMP, which mediates vascular smooth muscle relaxation. Consideration of pharmacological data has led to the conclusion that activation of GCase by nitrovasodilators is effected by binding of a common proximal ligand to a heme site. There is some consensus in the literature that this ligand is ·NO and that Endothelium Derived Relaxing Factor (EDRF) is in fact ·NO or a nitrosothiol (RSNO) (6). The exact biotransformation mechanism by which GTN is converted to ·NO or nitrosothiol remains unresolved. A sulfhydryl-dependent biotransformation pathway requires mediation by either glutathione-S-transferase (GST) or non-enzymically by a free thiol, possibly cysteine (7). The early, seminal hypothesis of Ignarro et al. (4*a*) proposed that organic nitrates enter the smooth muscle cell where breakdown occurs by an enzymic or non-enzymic process to yield inorganic nitrite. The pathway rests on the intermediacy of inorganic nitrite (NO_2^-), which must be converted to ·NO (eqs. [1]–[3]). Although this pathway was accepted for many years, substantial evidence now exists against the intermediacy of NO_2^- in the biotransformation of GTN (8).

[1] $RONO_2 + R'SH \xrightarrow{R'SH} NO_2^- + R'SSR' + ROH$

[2] $NO_2^- + H^+ \longrightarrow HONO \xrightarrow{-O_2} \cdot NO$

[3] $\cdot NO + R''SH \xrightarrow{-O_2} R''SNO$

The task then is to formulate a chemically reasonable mechanism for the conversion of GTN to ·NO mediated by thiol (RSH). Such a mechanism may be simply drawn as involving the initial formation of a thionitrate ($RSNO_2$), which rearranges to a sulfenyl (RSONO) or sulfinyl nitrite (RS(O)NO) (eqs. [4], [5]). Either of these nitrites may be drawn as forming NO on homolysis. Although a similar mechanism appeared in the pharmacological literature in recent years, no experimental work or computational studies have been reported to support this mechanism (4*c*, 9). Furthermore, it is of interest that this mechanism is analogous to that recently proposed by Koppenol et al. for the rearrangement reaction between peroxynitrous and nitric acids (10). This peroxynitrite rearrangement, itself, is of substantial biological significance, as it is proposed to mediate the biological toxicity of ·NO and superoxide (eqs. [6], [7]).

[4] $RONO_2 + R'SH \rightarrow R'SNO_2 + NO_2^- + H^+$

[5] $R'SNO_2 \rightleftharpoons [R'SONO \rightleftharpoons R'S(O)NO] \rightarrow \cdot NO + R'SO\cdot$

[6] $\cdot NO + \cdot O_2^- \rightarrow OONO^-$

[7] $OONO^- + H^+ \rightarrow HOONO \rightleftharpoons HONO_2$

The molecular orbital calculations reported within examine the thermodynamics, reaction barriers, and reaction profiles for the thionitrate and peroxynitrite rearrangements and the thermodynamics of related competing homolytic processes. The results allow comparison of the two rearrangement processes, examination of the viability of these and competing processes as general reactions of biological significance, and speculation as to modes of catalysis. Activation barriers for the rearrangement processes are calculated at levels up to MP4SDQ/6-31G*//MP2/6-31G* with aqueous solvation energies applied and structures along the reaction coordinate examined by intrinsic reaction coordinate (IRC) and Natural Bond Orbital (NBO) analysis.

Methodology

Isomers of methyl thionitrate and $HSNO_2$ were employed as truncated models of organic thionitrates and their isomers. The energy and structure for each isomer of $MeSNO_2$ was calculated employing full geometry optimization at the following levels: AM1 (11), PM3 (12), HF/6-31G*//HF/6-31G* and MP2/6-31G*//HF/6-31G* using GAUSSIAN 92 (13) on an IBM RISC 6000/355, and SPARTAN 3.0[2] on an SGI Iris Indigo, employing the standard basis sets supplied (14). Energies and structures for the isomers of $HSNO_2$ were calculated employing full geometry optimization at the following levels: PM3,

HF/6-31G*//HF/6-31G*, MP2/6-31G*//HF/6-31G*, MP2/6-31G*//MP2/6-31G*, and MP4SDQ/6-31G*//MP2/6-31G*. Energies and structures for the isomers of $HONO_2$ were calculated employing full geometry optimization at the following levels: PM3, HF/6-31G*//HF/6-31G*, MP2/6-311G**//HF/6-31G*, MP2/6-31G*//MP2/6-31G*, and MP4SDQ/6-31G*//MP2/6-31G*, with the exception of the rearrangement transition state, which was obtained at levels up to MP2/6-311G**//HF/6-31G*. Energies and structures for free radical species were calculated employing full geometry optimization at the levels UMP2/6-31G*//UMP2/6-31G* and UMP4SDQ/6-31G*//UMP2/6-31G*. All MP calculations use the frozen-core approximation. For selected structures, pre-orthogonal NBO overlap matrices were obtained and second-order perturbational analyses and full NBO analyses performed with GAUSSIAN 92 (15). Mulliken charges and charges derived from the electrostatic potential (CHELP) were recorded for each structure (16). The continuum dielectric solvation models employed for aqueous solvation energies were SM3-PM3 (17) as implemented in SPARTAN and the CDM model of Lim and Chan.[3] These models were applied using geometries obtained at the ab initio level. The identity of stationary points was confirmed by calculation of analytical frequencies at the appropriate level. Thermochemical data were obtained by normal mode analysis and calculation of analytical frequencies (using SPARTAN 4.0 for RMP2 structures. Free energies, enthalpies of reaction (ΔG, ΔH), and free energies of activation ($\Delta G^{\ddagger}$) were calculated from various reactants including a PdV term for dissociative processes. Transition state structures for both rearrangement reactions were located by full optimization using linear synchronous transit geometries (obtained using SPARTAN) as starting points. The character of these transition state structures was confirmed by (*i*) analysis of the normal mode associated with the single imaginary frequency, and (*ii*) IRC analysis (at the RHF/6-31G* level, using GAUSSIAN 92) along the reaction coordinate from transition state to ground states (19). The term ground state is used throughout to indicate stationary points on the calculated potential energy surfaces possessing zero imaginary frequencies. The more correct terms, reactant and product, lead to confusion, since the two rearrangement reactions discussed in this paper are considered in forward and reverse directions. Frequencies and zero point energies (E_{ZP}) are scaled by 0.9 (20). A discussion on the suitability of the 6-31G* basis set in calculations at the MP2 level for methyl nitrate and nitric acid has appeared previously (21).

Results

Thorough exploration of the conformational space for nitric acid isomers has been reported by Hehre and co-workers (21*b*), therefore only one isomer of nitric acid (**1**) and the *cis* (**2c**) and *trans* (**2t**) isomers of peroxynitrous acid were studied herein (Scheme 1, Table 1). However, in the absence of previous work, a thorough study of the isomers of the thionitrates, $HSNO_2$ and CH_3SNO_2, was required. Several rotamers were located of structures corresponding to sulfenyl nitrites (RSONO (**3H**, R = H; **3M**, R = Me)), in addition to conformers of sulfinyl nitrites (RS(O)NO (**4H**, R = H; **4M**, R = Me)) and thionitrate ($RSNO_2$ (**5H**, R = H; **5M**, R = Me)) (Scheme 1, Table 1, Table 2, Fig. 1). The identity of these structures as energy minima and first- or second-order saddle points was confirmed by calculation of analytical frequencies (Table 1, Fig. 1). A greater range of conformers was located for the Me series due to the additional S—C bond rotational barriers. Calculations at the HF/6-31G* level show sulfenyl nitrite (**3**) and thionitrate (**5**) isomers to be of similar energy (Table 1, Fig. 1, Fig. 2), in particular in comparison to their oxygen congeners, nitric and peroxynitrous acid, where the latter is considerably the less stable. Estimation of the influence of aqueous solvation through various solvation approximations demonstrates little difference in energy between the thionitrate and sulfenyl nitrite isomers and their conformers (Table 1, Fig. 1). Thus sulfenyl nitrites are predicted to be of similar stability to their thionitrate isomers in the gas phase and solution. Comparison of energies obtained from geometry optimization at the MP2 level of **3H**, **4H**, and **5H** does not significantly change this conclusion, but at this level the structure of the sulfinyl nitrites (**4H**) is lost upon geometry optimization to yield association complexes of NO with HSO (Tables 1, 2, 5). Again at the higher MP4//MP2 level sulfenyl nitrites and thionitrates are seen to be of similar energy (Tables 1, 5). The experimentally observed frequencies in *tert*-butyl thionitrate associated with NO_2 a stretch, NO_2 s stretch, and NO_2 bend are 1301, 1265, and 831 cm^{-1}, compared with 1322, 1226, and 806 cm^{-1} calculated for $HSONO_2$. The N=O stretch in HSONO is calculated at $\approx$1593 cm^{-1} (**3Hcs**, **3Hca**), suggesting the possibility for experimental detection of transient sulfenyl nitrite species.

We previously calculated structures and energies for all conformers of $HSNO_2$ and CH_3SNO_2 by full geometry optimization using the semi-empirical AM1 and PM3 Hamiltonians and ab initio calculation at the lower RHF/3-21G* level (22). At these lower levels of calculation, geometrical parameters for the isomeric thionitrates and sulfenyl nitrite structures are reproduced reasonably consistently when compared to the data at the higher levels of calculation. However, molecular energy is highly dependent on method and basis set (22). This is illustrated for the $HSNO_2$ series, in which molecular energies at the PM3 level show sulfinyl nitrites as the most stable structures, whereas at the HF/6-31G*//HF/6-31G* sulfenyl nitrites are most stable (Fig. 2). Comparison of these data and those at higher levels of calculation suggest that, for these and related molecules, the minimal level of calculation must include MP2/6-31G* energies, although a lower level of geometry optimization may be accommodated.

Fig. 1. Structures, structural labels, and relative molecular energies (kcal/mol) for methyl thionitrate isomers. First- and second-order saddle points (two imaginary frequencies) are indicated by superscripts(‡). Energies are MP2/6-31G*//HF/6-31G* + E_{ZP} with aqueous solvation energies (SM3) indicated in parentheses. The stereochemical labels employed to indicate isomer geometry are applied in an identical fashion to the H series (**3H**, **4H**, **5H**).

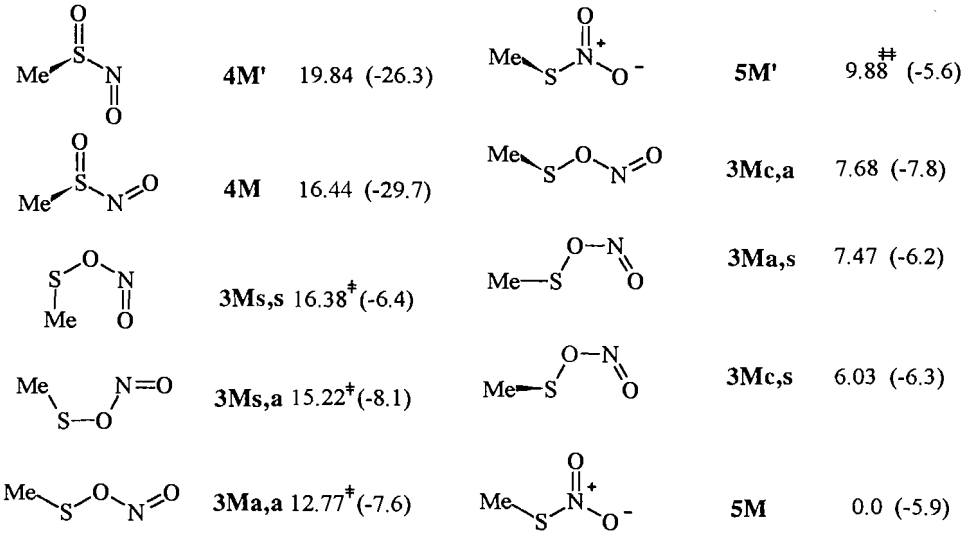

Fig. 2. Relative molecular energies for conformers of **3H**, **4H**, **5H** calculated at semi-empirical and ab initio levels: PM3 + E_{ZP}; HF/6-31G*//HF/6-31G* + E_{ZP}

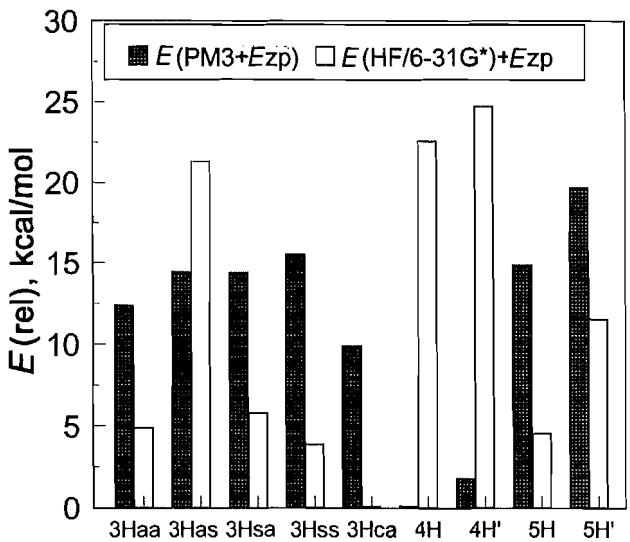

Calculations on NO_2 and other free radical species treated in this present paper have been reported previously (23). The purpose of the calculations reported within is to provide comparative thermodynamic parameters for the homolytic dissociations of the nitric acid and thionitrate isomers. Energies obtained at the UMP4SDQ/6-31G*//UMP2/6-31G* level (Table 1) are used with zero point energy (E_{ZP}) corrections and vibrational data to yield free energy, enthalpy, and entropy of reaction for homolysis (Tables 3–5; Figs. 3, 4, 6, 7). For comparison with these calculations, the experimentally estimated O—O bond energy in peroxynitrous acid is ≈20 kcal/mol (24). Calculated values of $\langle S^2 \rangle$ are in the range 0.76–0.78 (doublets) and reveal little spin contamination. Projected PMP2 energies with annihilation of contaminating spin states deviate from UMP2 energies by 0.8 kcal/mol for thiyl radical to 2.7 kcal/mol for nitric oxide. Extension of electron correlated effects from the MP2 to MP4SDQ level leads to differences in relative molecular energies for radical and other species, modifying quantitative reaction energies but not altering qualitative conclusions made from data calculated at the MP2 level (Tables 1, 4, 5).

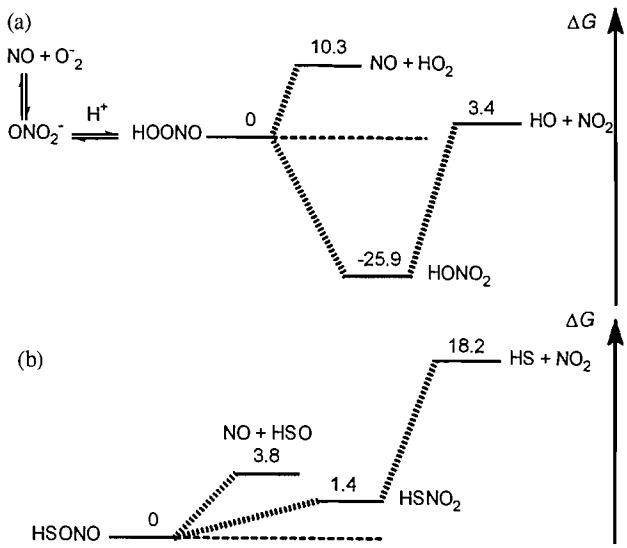
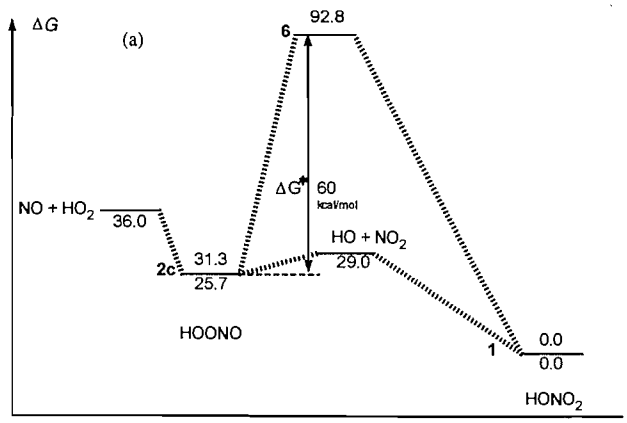
Fig. 3. Thermochemical data for (*a*) peroxynitrous acid, nitric acid, and related free radical species; (*b*) thionitrate, sulfenyl nitrite, and related free radical species. Free energies of reaction shown are at the MP4SDQ/6-31G*//MP2/6-31G* level, in kcal/mol (see Table 3).



oxynitrous acid with nitric acid was explored by varying several bond angles and bond lengths separately and in combination, approximating the reaction coordinate, at various levels of calculation. However, in each case, the "reaction profile" proceeded to plateau approximately 65–100 kcal/mol above peroxynitrous acid, whereupon "dissociation" of the molecule occurred. A transition state for rearrangement was instead located by geometry optimization from the linear synchronous transit structure generated from high-energy conformers of $HONO_2$ and HOONO (Fig. 5). Clearly, destruction of the O-N-O-O plane is essential for transition state location and indeed reaction. To confirm that this structure corresponded to the transition state for rearrangement, the imaginary frequency corresponding to the reaction coordinate and structures along the intrinsic reaction coordinate were examined. One imaginary frequency was located corresponding to the reaction coordinate (-2143 cm^{-1}, RHF frequency) and the reaction profile generated from the IRC did indeed correspond to rearrangement of peroxynitrous acid to nitric acid (Fig. 6). Examination of structures along the IRC from *trans*-peroxynitrous acid (**2t**) to nitric acid demonstrates clearly the initial rotation about the O—O bond to place HO orthogonal to the plane of the nitro moiety (O-N-O) (Fig. 6). Reaction proceeds by lengthening of the O—O distance and migration of HO towards nitrogen and thence relaxation to the planar nitric acid

Fig. 4. Reaction coordinate – free energy profiles for homolysis and rearrangement. (*a*) Free energy profile for peroxynitrite rearrangement. (*b*) Free energy profile for thionitrate rearrangement. Relative free energies below line are at MP4SDQ/6-31G*//MP2/6-31G* and those above line (and $\Delta G^{\neq}$) are MP4SDQ/6-31G*//MP2/6-31G* + *E*(CDM-aq.sol.), in kcal/mol (see Tables 1, 5). *E*(CDM-aq.sol.) is derived from CDM data.



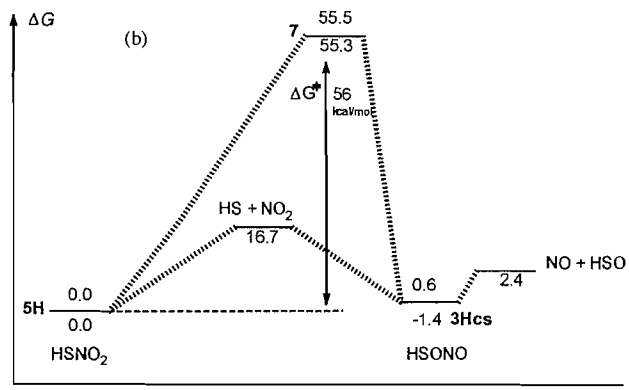


Fig. 5. Structural data for peroxynitrite (**6**) and thionitrate (**7**) rearrangement transition states obtained by optimization at HF/6-31G* and MP2/6-31G*, respectively. See Figs. 6 and 7 for stereochemical representations.

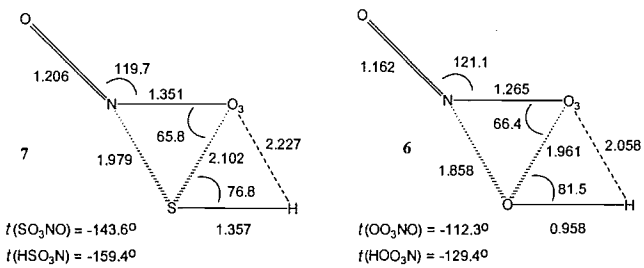

structure. In addition, the proximity of the hydrogen to the oxygen O3 along the entire reaction profile is clear. Although the O3···H distance reaches 2.0 Å and there is likely electrostatic stabilization between these two centres, NBO analysis reveals no significant charge transfer interactions indicative of stronger hydrogen bonding.

The reaction energy profile depicted uses the N— OH distance as the *x*-axis reaction coordinate (Fig. 6). The profile generated using the mass-scaled internal coordinate (not shown) is smooth and more symmetric; however, use of the N—OH distance as the reaction coordinate provides a profile that clearly demonstrates a curious and informative "discontinuity" at d(HO—N) ≈ 2.2 Å. This discontinuity lies at the crossover between the two processes, torsional and scissile. The first process is initial torsional rotation about the bond between the oxygen (O3) and nitrogen in peroxynitrous acid (**2t**), to place HO orthogonal to the O-N-O plane. This structure is close to the transition state for rotation about this O—N bond. The second process, structural deformation of this "rotamer" through O—O bond elongation, migration, and cleavage, is associated with the large energy barrier.

The reaction energy profile for thionitrate rearrangement was located in a similar manner to that for peroxynitrite. IRC energies and structures were calculated at the HF/6-31G*//HF/6-31G* level and reveal a similar reaction pathway to the peroxynitrite rearrangement. However, the dislocation of HS from the nitro plane (O-N-O) is much less marked than that of HO in the related rearrangement. Reaction again proceeds from the *trans* isomer, in this case sulfenyl (**5Hca**), to the planar thionitrate (**3H**). Again the proximity of the hydrogen with the bridging oxygen along the profile is noted and, again, NBO analysis did not provide evidence of a hydrogen bond involving significant charge transfer. Since the energies of the **5Hca** and **5Hcs** conformers are close and dependent on level of calculation, this rearrangement reasonably may proceed equally from either conformer. The structures and energies of the ground and transition state species were reoptimized at the MP4SDQ/6-31G*//MP2/6-31G* level (Fig. 7) with normal mode analysis (Table 1, Table 2, Fig. 5). The imaginary frequency corresponding to the reaction coordinate for **7** is at -886 cm^{-1} (MP2 frequency).

Combination of the thermodynamic data for homolysis with activation energies for rearrangement allows construction of free energy profiles for reactions of peroxynitrite (Fig. 4*a*) and thionitrate (Fig. 4*b*). Relative molecular energies, enthalpies, and free energies have been calculated at a number of different levels with zero point energies (E_{ZP}) and aqueous solvation approximations (Tables 3, 4, and 5). The PM3-SM3, CDM, and other solvation models applied do not yield consistent values for aqueous solvation energies, presumably owing to lack of parameterization for molecules similar to those in this study (Table 1). Cramer and Truhlar state that the PM3-SM3 model may give anomalously positive solvation energy values for nitroaliphatics partly because of unusual atomic charges at N in PM3 level calculations; SM2 performs equally poorly (17). Comparison of PM3 electrostatic charges at atoms with those from MP2 calculations (Table 1) demonstrates the anticipated large positive charges at N in **1H** and **5H** at the PM3 level: +1.81 (HF geometry) and +1.44 (MP2 geometry), respectively. The CDM aqueous solvation model utilizes charges from the ab initio calculations and does indicate PM3-SM3 to yield a relatively positive solvation energy for **1H**, but not for **5H**. In addition, the choice of charge type, electrostatic, Mulliken, or natural, has a significant effect on CDM solvation energies. Clearly, use of the calculated aqueous solvation energies is limited to indication of the magnitude of perturbation of the reaction free energies calculated in the gas phase, on transfer to aqueous solvent (Table 1). For these small neutral molecules this perturbation is small relative to the large activation free energies. At the highest level of calculation employed and with (CDM) solvation energies applied, it can be estimated that the free energy of activation in aqueous solution at 298 K for peroxynitrous acid rearrangement to nitric acid is 60 kcal/mol and that for rearrangement of thionitrate to sulfenyl nitrite is 56 kcal/mol (Fig. 4).

Discussion

GTN biotransformation

Two general pathways for organic nitrate biotransformation may be described, characterized as sulfhydryl dependent and heme dependent (4, 7, 25). There is substantial debate about whether the sulfhydryl-dependent pathway requires glutathione-S-transferase (7*c*). However, it has been conclusively demonstrated that GTN in the presence of specific, simple thiols is capable of activation of guanylate cyclase (7*d*). Therefore, it has been postulated that in the presence of these specific thiols ·NO is a minor product of the reaction of thiol with GTN. The major product of reaction of GTN with all thiols at neutral pH is inorganic nitrite (8). Early hypotheses required generation of ·NO or nitrosothiol from the initial nitrite product (4*a*). In recent years, alternative postulates have appeared widely, involving thionitrate as an intermediate, with further reaction such as (*a*) subsequent reduction to nitrosothiol (for example, ref. 26), or (*b*) concerted rearrangement to sulfinyl and sulfenyl nitrites (4*c*, 9). Indeed, a chemically reasonable mechanism may be drawn, in which thionitrate partitions between thiolysis yielding nitrite ion and concerted rearrangement to the sulfenyl or sulfinyl nitrite (Scheme 2). Support for the subsequent homolytic generation of ·NO may be drawn from (*a*) the reported facile homolytic decomposition of the related sulfenyl and sulfinyl nitrates (27), and (*b*) the relative stability and ease of generation of sulfinyl radicals (28). However, only one paper has appeared, by Oae et al., directed at the reactivity of thionitrates, and this work did not deal with aqueous solution (29). The paper of Oae et al. yields only circumstantial evidence for rearrangement, in that sulfonyl species are observed

as products of thionitrate decomposition, presumably from sulfinyl radical recombination (30) (Scheme 2). However, we have recently demonstrated ·NO generation from *tert*-butyl thionitrate in aqueous solution at neutral pH and ambient temperature using an ·NO selective Clarke-type electrode (ISO-NO, World Precision Instruments) (Thatcher and Lock, unpublished results). The question to be answered is whether this ·NO may derive from sulfenyl nitrite after rearrangement of the initially formed thionitrate (Scheme 2).

Thionitrates, sulfenyl and sulfinyl nitrites

The few thionitrates studied to date are reactive species, only

tertiary alkyl thionitrates having sufficient stability for storage. Sulfinyl and sulfenyl nitrites have not been isolated and similarly can be expected to be high-energy species. Sulfenyl nitrates have been observed to undergo rapid homolysis in aqueous solution to NO_2 and sulfinyl radical, yielding a sulfonothioate product by radical recombination (27). Although the planar thionitrate is the only stable conformer, there are several low-energy sulfenyl nitrite conformers. The calculations on the isomers of $MeSNO_2$ and $HSNO_2$ demonstrate that structures corresponding to thionitrates and sulfenyl nitrites are of similar energy at the highest level of calculation with electron correlation incorporated at the MP2 or MP4SDQ//MP2 levels (Tables 3, 5; Fig. 1). Structures corresponding to sulfinyl nitrites are not stable at the highest level of geometry optimization. The lowest energy sulfenyl nitrite conformers are 1–7 kcal/mol higher in energy than the thionitrate in the H and Me series of compounds, except with inclusion of electron correlation at the MP4SDQ level when the sulfenyl nitrites become marginally more stable (Fig. 1, Table 5). Thus rearrangement of thionitrate to sulfenyl nitrite appears thermodynamically accessible.

Thionitrate rearrangement

The thermodynamic viability of rearrangement of thionitrate to sulfenyl nitrite, in light of competing homolytic fission to NO_2 and thiyl radical, can be judged from the data shown in Figs. 3 and 4 (Tables 2 and 5). Indeed comparison with data for $^{\cdot}NO$ and sulfinyl radical gives information on the homolysis of the sulfenyl nitrite itself. Clearly, rearrangement of thionitrate to sulfenyl nitrite is thermodynamically viable: $\Delta G_0(aq) = 0.6$ kcal/mol. Competitive homolysis to NO_2 and sulfinyl radical reflects a low S—N bond dissociation energy: $\Delta G_0 = 16.7$ kcal/mol (Fig. 4). However, the lower free energy of reaction of sulfenyl nitrite to yield $^{\cdot}NO$ and thiyl radical ($\Delta G_0 = 3.8$ kcal/mol, Fig. 3) suggests that, with a low barrier to rearrangement, this pathway would be viable for $^{\cdot}NO$ generation from the initially formed thionitrate (Scheme 2). It remains to examine the energy barrier of the thionitrate → sulfenyl nitrite rearrangement step.

Inspection of the HOMO and other close-lying occupied orbitals for thionitrate reveals problems in terms of orbital symmetry for a simple concerted reaction via migration of HS along the nitro (ONO) plane. Indeed, the transition state located for the rearrangement reaction has the sulfur dislocated out of the nitro plane, although S, O, N, and O are coplanar in both ground states. If the rearrangement is viewed from the sulfenyl nitrite, reaction is initiated by rotation about the SO—NO and HS—ON bonds followed by S—O bond elongation and migration of sulfur to nitrogen (Fig. 7). The free energy of activation for the rearrangement of thionitrate (**5H**) is 56 kcal/mol in the gas phase at the highest level of calculation. The PM3-SM3 model suggests a small relative stabilization of the transition state from aqueous solvation (Table 1), but the CDM model yields a negligible reduction of the barrier, which remains at 56 kcal/mol at 25°C. This activation barrier is clearly substantial, especially in light of the small bond dissociation energies associated with the S—O and S—N bonds of the ground states. The size of this barrier provoked us to examine the similar peroxynitrite rearrangement. This reaction had been proposed in the literature, supported by MO calculations.

Peroxynitrite rearrangement

The rearrangement mechanism proposed by Koppenol et al. is founded upon comparison of molecular orbital calculations with experimental data (10). A mechanism via homolytic dissociation of peroxynitrous acid and radical recombination of hydroxyl radical and nitrogen dioxide was rejected, partly on the basis of an estimated $\Delta S^{\ddagger}$ of 1–5 cal mol^{-1} K^{-1}, which was argued to be too low for a homolytic reaction. Instead, a concerted rearrangement mechanism was proposed in which peroxynitrous acid undergoes concerted migration of OH from O to N via a high-energy rotamer to yield nitric acid as product. The free energy barrier to rearrangement was presented as 17 kcal/mol (PM3 level). The authors reported location of a "potential transition state" at the PM3 level with ∠OON = 80° and d(O—O) = 1.8 Å (cf. Fig. 5), although no confirmation by normal mode analysis was provided. Subsequent calculations at the RHF/6-31G** level on peroxynitrous acid conformers did not locate any transition states, but a speculative rearrangement mechanism was expounded (31). Previous to this work, the conformational space of peroxynitrous acid had been fully explored at the RHF and MP2/6-31G* levels by Hehre and co-workers (21*b*).

The formation of peroxynitrite species and isomerization in the gas phase are also of interest in atmospheric chemistry. Atkinson et al. proposed that alkyl nitrates formed from reaction of peroxy radicals with nitric oxide might result from rearrangement of the peroxynitrite to the nitrate via a cyclic transition state akin to the transition state located in the present calculations (a flattened analogue of **6** was drawn) (32). However, these workers emphasized a rearrangement proceeding from a vibrationally and chemically excited peroxynitrite, for which a reaction energy profile was drawn. Burkholder et al. suggested a similar rearrangement of peroxynitrous to nitric acid, again via a high-energy form of peroxynitrous acid (24).

The rearrangement pathway mapped by IRC analysis from location of the transition state structure (Figs. 5, 6, and 7) shows similarity to that speculated upon by Koppenol and Klasinc (31). The initial process is rotation about the O—N bond of peroxynitrous acid towards the rotamer with the HO oxygen orthogonal to the nitro (ONO) plane, in simile with the thionitrate rearrangement mechanism. However, in this reaction further dislocation of the oxygen from the nitro plane is required to permit orbital overlap in the transition state (Fig. 6). The underestimation of the barrier for rearrangement in previous work results from the assumption that the initial, simple torsional motion surmounts the barrier to rearrangement. In fact, the very substantial barrier results from the bond lengthening and bending processes associated with migration of oxygen consequent to the initial rotational motion. The free energy of activation for rearrangement of peroxynitrous acid at 25°C with aqueous solvation corrections applied is 60 kcal/mol. The substantial hypothetical barrier for rearrangement of nitric acid to peroxynitrous acid ($\Delta G^{\ddagger}$ (aq.) = 93 kcal/mol) allows comparison with the rearrangement of thionitrate to sulfenyl nitrite ($\Delta G^{\ddagger}$ (aq.) = 56 kcal/mol). The higher barrier is compatible with the more extreme geometrical distortion required to reach the transition state in the peroxynitrite rearrangement.

Rearrangement versus homolysis

It has been clearly demonstrated experimentally that peroxynitrite in aqueous solution isomerizes to nitrate via peroxynitrous acid (33). Equally, it can be simply demonstrated that

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

alkyl thionitrate spontaneously yields ·NO in aqueous solution. However, the substantial barriers to reaction, calculated for the concerted rearrangement processes involved, strongly argue against such concerted rearrangements mediating the observed experimental phenomena. The free energies of reaction associated with the competitive homolytic processes are calculated to be low: ≈17 kcal/mol for dissociation of thionitrate to NO_2 and thiyl radical; and ≈3 kcal/mol for dissociation of peroxynitrous acid to NO_2 and hydroxyl radical. Rearrangement via homolysis and radical recombination appears a more likely pathway for both reactions. Of course, the concerted rearrangement processes may be susceptible to catalysis. Indeed, the limited range of thiols, which in the presence of GTN are able to activate GCase, all possess a β-carboxylate group; for example, thiosalicylic acid (*7a*, *d*). The ability of a β-carboxylate or carboxylic acid group to participate in intramolecular base, nucleophilic, and acid catalysis is well documented. We are currently exploring potential catalytic pathways experimentally and through further MO calculations. The present calculations cannot rule out a nonconcerted ionic or diradical rearrangement. However, the low free energy for homolysis of the S—O bond of thionitrate coupled with that for dissociation of sulfenyl nitrite to ·NO suggests that a homolysis–recombination pathway is more reasonable (eq. [8], Fig. 4). If separation and diffusion of the initial geminate pair competes with recombination, NO_2 may be released before ·NO in both thionitrate and peroxynitrite rearrangements. The question then to be addressed is whether NO_2 may mediate some of the biological activity of organic nitrates and toxicity of ·NO.

[8] $R'SNO_2 \rightarrow \{R'S^{\cdot}\ {}^{\cdot}NO_2\} \rightarrow R'SONO \rightarrow R'SO^{\cdot} + {}^{\cdot}NO$

Conclusions

1. Structures representing thionitrates and conformers of sulfenyl nitrites are of similar energy at the higher levels of calculation employed, including electron correlation at the MP4SDQ//MP2 and MP2 levels. Structures corresponding to sulfinyl nitrites do not represent stable equilibrium geometries at the MP2 level of calculation.
2. Free energies of reaction for homolysis of thionitrates, sulfenyl nitrites, and peroxynitrous acid, at 298 K, all lie below 17 kcal/mol. The free energy for homolysis of nitric acid is 29 kcal/mol.
3. Structural reorganization to reach the transition states for concerted rearrangement of thionitrate to sulfenyl nitrite and peroxynitrous acid to nitric acid requires destruction of the ONOX plane of the ground states (X = S, O).
4. The energy barriers for concerted rearrangement of peroxynitrous acid and thionitrate are substantial: $\Delta G^{\ddagger}$ (aq.) = 60 kcal/mol and 56 kcal/mol, respectively.
5. The small energies of homolysis and the large activation barriers to concerted rearrangement suggest that the most reasonable mechanism for rearrangement involves homolysis followed by radical recombination. In this case, NO_2 is an initial product of reaction.

Structure–sweetness relationships for fructose analogs. Part III. 3-Deoxy-D-*erythro*-hexulose (3-deoxy-D-fructose): composition in solution and evaluation of sweetness

Walter A. Szarek, Robert J. Rafka, Te-Fang Yang, and Olivier R. Martin

Abstract: As part of continuing studies on the structural features responsible for the intense sweetness of D-fructose, 3-deoxy-D-*erythro*-hexulose (3-deoxy-D-fructose, **1**) was prepared, its solution composition was determined, and its taste was evaluated. In aqueous solution, 3-deoxy-D-fructose exists as a complex mixture of five tautomeric forms in which the β-D-pyranose form is preponderant (52.5% at 22°C) and the α-D-pyranose form is the least abundant (5%). Quite remarkable is the behavior of the open-chain *keto* form of **1**: its content increases from 7.5% at 22°C, to 36% at 82°C, and to 47% at 97°C, making this form the preponderant one at high temperatures. 3-Deoxy-D-fructose was found to be sweet, albeit probably not as sweet as D-fructose. The hydroxyl group at C-3 is thus not an essential function of the glycophore of D-fructose. The significance of this result is discussed in relation to the evidence already available and the divergent theories that have been proposed to explain the origin of the sweet taste of D-fructose.

Key words: 3-deoxy-D-*erythro*-hexulose (3-deoxy-D-fructose), sweetness, solution composition.

Résumé : La poursuite d'études sur les attributs structuraux responsables pour la douceur intense du D-fructose nous a conduit à préparer le 3-désoxy-D-*érythro*-hexulose (3-désoxy-D-fructose, **1**), à déterminer sa composition en solution et à évaluer son goût. En solution aqueuse, le 3-désoxy-D-fructose existe sous forme d'un mélange complexe de cinq formes tautomères dans lequel la forme β-D-pyranose est prépondérante (52.5% à 22°C) et la forme α-D-pyranose est la moins abondante (5%). Le comportement de la forme à chaîne ouverte *céto* est tout-à-fait remarquable : présente à 7.5% à 22°C, sa concentration augmente à 36% à 82°C et à 47% à 97°C, ce qui en fait la forme la plus abondante à haute température. Le 3-désoxy-D-fructose est doux, cependant probablement pas aussi doux que le D-fructose. Le groupement hydroxyle en C-3 apparaît ainsi ne pas être une fonction essentielle du glycophore du D-fructose. L'importance de ce résultat est discuté en relation avec les données déjà disponibles et les théories divergentes qui ont été proposées pour expliquer l'origine de la douceur du D-fructose.

Mots clés : 3-désoxy-D-*érythro*-hexulose (3-désoxy-D-fructose), caractère sucré, composition d'une solution.

Introduction

The origin of the intense sweetness of D-fructose, the sweetest of the natural sugars (1), has been the object of much debate (2). While the lipophilic component X of the presumed tripartite AH–B–X glycophore (3) can be attributed to one of the methylene groups (2), the assignment of the hydrogen bond donor (AH) and acceptor (B)-couple remains unresolved. As part of continuing studies on deoxy ketohexoses designed to probe the role of individual hydroxyl groups in the glycophore of D-fructose, we have already shown (4) that the 5-OH group is not essential for the sweet response since 5-deoxy-D-*threo*-hexulose (5-deoxy-D-fructose) is nearly as sweet as D-fructose. We have now completed studies on 3- and 4-deoxy-D-fructose (3-deoxy-D-*erythro*- and 4-deoxy-D-*threo*-hexulose). We report, in this article, the composition of 3-deoxy-D-*erythro*-hexulose (**1**) in solution and an evaluation of its sweet taste. The properties of 4-deoxy-D-*threo*-hexulose will be reported separately.

A brief summary of the attempts to rationalize the sweet taste of D-fructose will serve to place our results in proper perspective. In early studies, Shallenberger (1, 5) had proposed that the anomeric hydroxyl group (HO-2) and the oxygen atom at C-1 (O-1) of β-D-fructopyranose (**2**), the major form of D-fructose in solution (6), constituted the AH–B site of the glycophore. This assignment was supported, in particular, by

the reduced sweetness of analogs **3** (β-D-arabinose) and **4** (1,5-anhydro-D-mannitol) lacking the CH_2OH and the 2-OH groups, respectively (7). This model does not take into consideration the other hydroxyl groups of the molecule and does not explain the considerable difference in sweetness between D-fructose and its C-5 epimer, L-sorbose: as it exists almost exclusively as α-L-sorbopyranose **5** in solution (6), this ketose

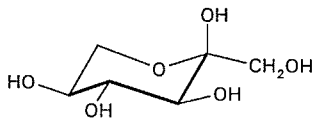
4 $R^1 = H, R^2 = CH_2OH$



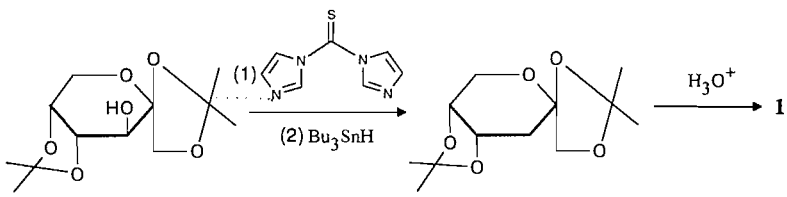
5

is, structurally, very closely related to β-D-fructopyranose; it is, however, nearly devoid of sweet taste. The molecular properties of the two ketoses have been compared using IR spectral data (8) and by means of theoretical calculations (9–11), in attempts to explain this difference of sweetness. In one of these attempts (10), the results have suggested that the assignment of the AH–B couple in β-D-fructopyranose should be reversed, making HO-1 the hydrogen bond donor and O-2 the acceptor. Interestingly, the examination of IR data led Mathlouthi and Portmann (12) to propose the same revised assignment. In 1988, on the basis of intensity–time studies of the sweetness of sugars, Birch et al. (13, 14) suggested that the anomeric center may play no direct role and that the AH–B component of the glycophore was the 3,4-α-glycol system. Very recently, Lichtenthaler and Immel (2) have defined and calculated molecular hydrophobicity potential profiles for sugars, which provide a global description of the hydrophilic and hydrophobic regions in the molecule. This approach seems to lend support to Birch's proposal since it was found that the zone of greatest hydrophilicity in β-D-fructopyranose was centered around the 4-OH group, thus possibly making this group essential for sweetness. This is also consistent with our prediction that the O-4 atom would be the most attractive site for protonation (9). Of relevance are also the observations that both the 6-thio- (15) and the 6-carba- (16) analogs of β-D-fructopyranose are intensely sweet, presumably as a result of the expansion of the hydrophobic region of the molecule (2). Our studies on 3- and 4-deoxy-D-fructose were expected to contribute further evidence towards a better understanding of the origin of the sweetness of D-fructose.

Results and discussion

Synthesis

3-Deoxy-D-fructose (**1**) is not available from natural sources, although its presence has been detected in caramel mixtures by glc analysis (17); an enzyme catalyzing the reduction of 3-deoxyglucosone to **1** has been recently isolated from porcine liver (18). The first synthesis of **1** was reported by Kuhn et al. (19) (multistep synthesis from D-glucosamine). Compound **1** has also been obtained by way of the Perkow reaction of 1,3,4,5,6-penta-*O*-acetyl-*keto*-D-fructose with trimethyl phosphite (20) and by way of isomerization reactions of 3-deoxy-D-*arabino*- or *ribo*-hexoses (21). However, radical deoxygenation procedures make this deoxy ketose readily available: treatment of the 3-*O*-(imidazolylthiocarbonyl) derivative of 1,2:4,5-di-*O*-isopropylidene-D-fructopyranose (**6**) (22) with tributyltin hydride, as described by Rasmussen et al. (23), afforded, after 20 min at reflux temperature in toluene, compound **7** in 87% yield (lit. (23): 65% after a reaction time of several hours). 3-Deoxy-D-fructose (**1**) was obtained by deacetonation of **7** in 2:1 (v/v) acetone–water in the presence of an acidic ion-exchange resin, purification by chromatography, and recrystallization from hot ethanol (overall yield from **6**: 68%). During the course of the present studies, the synthesis of **1** by essentially the same procedure was reported by Dills (24).



6 **7**

Composition of 1 in solution

Upon dissolution of a solid sample in D_2O at room temperature, 3-deoxy-D-fructose (**1**) rapidly equilibrates into a mixture in which five different forms are clearly discernible (^1H NMR, ^{13}C NMR). Integration of the signals of the protons at the deoxy position indicates a composition (Table 1) reminiscent of that of D-fructose: the β-pyranose form is predominant (52.5%), the α- and β-furanose forms are relatively abundant (20% and 15%), and the α-pyranose form is minor (5%). The major difference with D-fructose is a much larger proportion of *keto* form (7.5%): that the removal of a secondary substituent from D-fructose increases the content of acyclic form is consistent with the well-known influence of the number of substituents on the position of the tautomeric equilibrium (25). While the *keto* form is hardly detectable in D-fructose (0.5–0.8%) (26), its highly deoxygenated analogs exist completely (e.g., 6-hydroxy-2-hexanone (27)) or largely (e.g., 1,6-dihydroxy-2-hexanone (28)) in the open-chain form in aqueous solution. It is remarkable that we had not observed the *keto* form in the spectra of the 5-deoxy isomer of **1**, namely 5-deoxy-D-*threo*-hexulose, in our previous studies of this compound (4). This can be explained by the fact that the β-pyranose form of 5-

Table 1. Equilibrium composition of **1** at room temperature (22°C).[a,b]

Solvent	β-Pyranose (%)	α-Pyranose (%)	β-Furanose (%)	α-Furanose (%)	*keto* form (%)
D_2O	52.5	5	15	20	7.5
CD_3OD	41	10	16	24	9

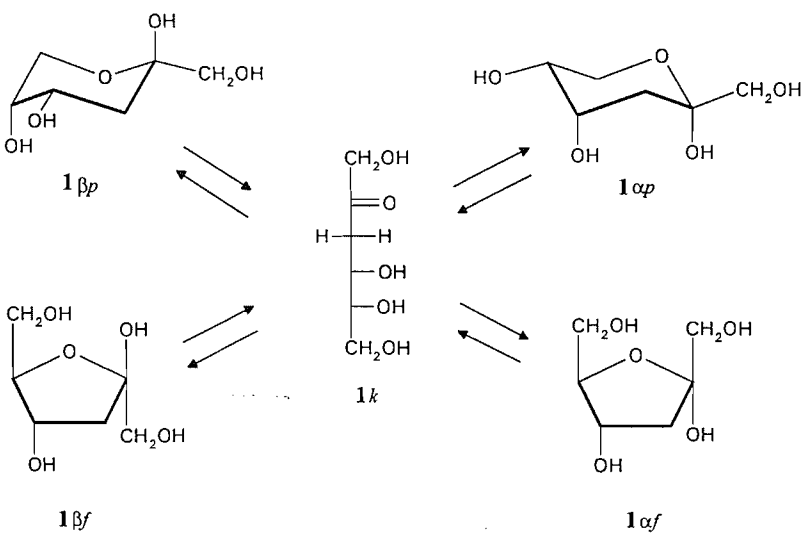
[a]By integration of ^1H NMR signals.

[b]For comparison, the composition of D-fructose at 31°C in D_2O is the following (25): β*p*, 65%; α*p*, 2.5%; β*f*, 25%; α*f*, 6.5%; *k*, 0.8%.

deoxy-D-fructose is especially favorable (no axial substituents) and it is the only one to be actually detected (see also ref. 29). The stability of this tautomeric form is probably also responsible, in part, for the unusual behavior of 5-deoxy-D-fructose and its aldose isomer (5-deoxy-D-glucose) towards glucose isomerase (aldose → ketose isomerization exclusively) (29). The equilibrium composition of **1** in CD_3OD has also been determined and the results are reported in Table 1.

The NMR signals of the two H-3 protons of the different forms of **1** in solution (D_2O as well as CD_3OD) occur in a wide chemical-shift range (1.75–2.75 ppm in D_2O) with relatively little overlap and therefore provide a great deal of structural information. The protons at C-3 of the major, β-pyranose form (**1**β*p*) are nearly equivalent in D_2O and form a higher-order spin system; however, the ^1H NMR parameters of **1**β*p* can be readily obtained from the spectrum of **1** in CD_3OD, in which the equilibration of **1** is slower than in D_2O (~2 h) and the signals of H-3e and H-3a are well separated. The coupling constants for **1**β*p* (Table 2) clearly indicate that H-4 is axial and H-5 equatorial and, therefore, that the β-pyranose form of **1** adopts the same $^2C_5$ conformation as β-D-fructopyranose in solution (6). The ^1H NMR parameters detectable for the minor α-pyranose tautomer (**1**α*p*) suggest that its conformation is the alternate $^5C_2$ chair form. Thus, both anomers adopt the conformation in which the anomeric OH group is axial, a situation that prevails also for most 2-hexuloses (6): these conformations are predicted, on the basis of simple relative free energy calculations (30), to be the more stable ones (**1**β*p*: $^2C_5$, 1.7; $^5C_2$, 5.05. **1**α*p*: $^2C_5$, 3.45; $^5C_2$, 2.75 kcal/mol; note: because of the absence of an OH group at C-3, the contribution of the anomeric effect was taken as 0.85 kcal/mol).

The proportion of furanose forms in an equilibrated solution of **1** is similar to that observed in D-fructose; however, as a result of the absence of a substituent at C-3, which suppresses *gauche* interactions with the substituents at the anomeric carbon, the ratio of anomers is much closer to 1, with the α-anomer being predominant (α/β ratio: ~1.3 in **1**, ~0.25 in D-fructose). The absence of significant differences in the ^{13}C



NMR parameters of **1**α*f* and **1**β*f* (e.g., δ C-2 = 106.14 and 106.47 ppm) and in the H,H-coupling constants makes the assignment of the anomeric configuration of the furanose forms difficult. However, it is noted that the difference in chemical shift between the two protons at C-3 (Δδ (H-3A,3B)) is much larger (0.5 ppm) in one anomer than in the other (0.12 ppm), the average chemical shift being about the same (Table 2). The large difference was attributed to the anomer (α) in which *one* of the two H-3's is *cis* with respect to two oxygen atoms, and the small difference to the anomer (β) in which each H-3 is *cis* with respect to one oxygen atom. This assignment is entirely corroborated by the data reported (31) for the methyl furanosides of 2-deoxy-DL-*erythro*-pentose (Δδ (H-3A,3B): α-anomer, 0.48; β-anomer, 0.12 ppm).

The study of the composition of **1** in aqueous solution at variable temperature revealed an unusual behavior (Table 3): while the proportion of α,β-furanose and α-pyranose forms remained roughly constant as the temperature of the solution was raised, the content of *keto* form increased sharply at the expense of the β-pyranose tautomer. The *keto* form actually became the major tautomeric form at temperatures above 80°C! This behavior is in contrast with that of D-fructose (6,

26, 32) and other ketoses (6) for which the decrease of the β-pyranose form at higher temperatures is usually accompanied by an increase of the furanose forms. As expected on the basis of entropic factors, the *keto* form of D-fructose also increases with temperature (26, 33) (a 12.5-fold increase of its concentration between 30 and 80°C has been recently reported (34)), but, because of the small initial concentration, its content remains below 10%. Interestingly, a similar temperature dependence has been observed by Angyal et al. (35) for 1-deoxy-D-fructose (6% *keto* form at 37°C, 26% at 85°C), the β-pyranose form remaining, however, preponderant, even at 85°C. The presence of a large amount of *keto* form at high temperature in 1- and 3-deoxy-D-fructose is probably attributable primarily to electronic factors that affect the reactivity of that form: the removal of either vicinal hydroxy group indeed decreases the reactivity of the carbonyl function and thus

makes the *keto* form energetically comparable to the other tautomeric forms.

Evaluation of sweetness of 1

The sweetness of 5% and 10% (w/v) aqueous solutions of 3-deoxy-D-fructose was evaluated by three trained panelists[2] who compared, in two sessions, the taste of these two solutions with that of recently prepared (0.5–1 h) 2, 5, and 10% solutions of D-fructose, 5 and 10% solutions of sucrose, and aged tap water. The 5% solution of 3-deoxy-D-fructose was judged to be less sweet than the 5% sucrose solution, with two panelists noting a slightly bitter aftertaste. At higher concentration (10%), the solution was judged to be sweeter than a 5% solution of sucrose, although less sweet than a 10% solution of D-fructose or sucrose with, again, some additional taste sensations.

Thus, 3-deoxy-D-fructose is sweet, although probably not as sweet as D-fructose itself. The comparison is made difficult by the fact that the concentration of the presumed sweet form, i.e., the β-D-pyranose tautomer, is substantially lower for **1** (~45–50%) than it is for D-fructose (~60–65%) at physiological temperature. Furthermore, one cannot exclude the possibility that a minor form also contributes to the sweetness of the ketose. Nevertheless, this result clearly indicates that the 3-OH group is not an essential function of the glycophore of D-fructose, a finding that seems to support the attribution of the primary AH–B site to the hydroxyl functions at C-1 and C-2 of the parent ketose. However, we believe, in agreement with Lichtenthaler and Immel (2), that the hydrophilic component of the D-fructose glycophore is not limited to a single α-glycol group. In view of the evidence currently available and the results presented here, we propose that the hydroxyl groups at C-1 and C-2 form the dominant AH–B system and the hydroxyl groups at C-3 and C-4 form a secondary hydrophilic site, in which the 4-OH is the more important function. This interpretation is supported by our studies on 4-deoxy-D-*threo*-hexulose, which will be the subject of a forthcoming publication.

Experimental

^{1}H NMR spectra were recorded at 360.13 MHz on a Bruker AM-360 spectrometer, and ^{13}C NMR spectra at 90.56 or 100.6 MHz on Bruker AM-360 or AM-400 spectrometers, respectively. Chemical shifts (δ) are given in ppm downfield from Me_4Si. Spectra were recorded in D_2O containing 1,4-dioxane (^{13}C NMR: δ 67.26) or acetonitrile (^{13}C NMR: δ CH_3CN 119.8; ^{1}H NMR: δ 2.05 ppm downfield from $Me_3Si(CH_2)_3SO_3Na$) as the internal standard, or in CD_3OD (δ HCD_2OD 3.31). Coupling constants (Hz) were obtained from first-order analyses of the ^{1}H NMR spectra, with the exception of the signals of H-3A,3B of **1**β*p* in D_2O (see Table 2); the simulation of this spin system was performed using PCPMR (Serena Software) on an IBM-compatible personal computer. For the ^{13}C NMR spectra recorded in the APT-mode, (+) or (−) are used to indicate a positive (quaternary and methylene) or a negative (methine and methyl) amplitude of the signals.

[2] Each panelist distinguished among the basic tastes in the test described by Spencer (36) as well as correctly ranked the sweetness of sucrose solutions in the test described by Cameron (37).

3-Deoxy-D-*erythro*-hexulose (1) ("3-deoxy-D-fructose")

To a solution of 3-deoxy-1,2:4,5-di-*O*-isopropylidene-β-D-*erythro*-hexulopyranose **3** (23) (2.07 g, 8.45 mmol) in a mixture of acetone (25 mL) and water (50 mL) was added Amberlite IR-120(H^+) ion-exchange resin (6 g), and the mixture was stirred for 24 h at room temperature. The liquid was then decanted from the resin, passed through a bed of Amberlite IR-45(OH^-) ion-exchange resin (~6 g), and concentrated. The residual, crude **1**, was purified by column chromatography (2:1:0.1 (v/v/v) dichloromethane–ethanol–water, solvent system *A*) and recrystallization from ethanol; a total mass of 1.15 g (83%) of crystalline **1** was obtained in three crops; mp 111–112°C (lit. (19) mp 112–114°C; lit. (21*a*) mp 113–115°C); R_f 0.33 (solvent *A*); $[\alpha]_D$ −43.8 (2 min) → −40.0 (40 min) (*c* 1.6, H_2O) (lit. (19) $[\alpha]_D$ −69 (4 min) → −43.5 (40 min) (*c* 1.0, H_2O); lit. (21*a*) $[\alpha]_D$ −70.1 (3 min) → −42.5 (40 min) (*c* 1.0, H_2O)); ν_{max} (KBr): 3300 (br, OH), 1450, 1275, 1255, 1210, 1150, 1080, 1055, 1030, 980, 880, 860, 790, 735, and 710 cm^{-1}; ^{13}C NMR: immediately after dissolution in D_2O (100.6 MHz, CH_3CN as internal standard; β-pyranose form almost exclusive), δ: 42.11 ((−) C-3), 64.57, 68.14 ((−) C-1,6), 65.55, 67.83 ((+) C-3,4), 97.96 ((−) C-2); equilibrated solution in D_2O (90.56 MHz, 1,4-dioxane as the internal standard; signals labeled "s" (small) belong to a minor component (α-pyranose or *keto* form)), δ: 35.07 ((−), s), 42.12 (−), 42.17 (−), 42.27 (−), 60.39 ((−), s), 62.23 (−), 63.09 (−), 63.18 (−), 64.65 (−), 65.56, 65.60 (+), 65.91 (−), 66.17 (−), 66.50 ((−), s), 66.80 ((+), s), 67.48 ((+), s), 67.89 (+), 68.22 (−), 68.58 ((+), s), 68.63 ((−), s), 71.69 (+), 72.02 (+), 74.96 ((+), s), 86.40 (+), 86.96 (+), 97.10 ((−), s, C-2 (α-pyranose)), 98.03 ((−), C-2 (β-pyranose)), 106.14 and 106.47 ((−), C-2 (α,β-furanoses)), and 212.51 (s, C-2 (*keto* form)). ^{1}H NMR data: see Table 2. Partial data for an equilibrated solution of **1** in CD_3OD, α-furanose form, δ: 1.845 (dd, $J_{3A,3B}$ = 13.5 Hz, $J_{3A,4}$ = 4.5 Hz, H-3A), 2.43 (dd, $J_{3B,4}$ = 7.5 Hz, H-3B), 4.05 (~q, $J_{4,5}$ ~4.5 Hz, H-5), 4.20 (dt, H-4); β-furanose form, δ: 2.15 (d, $J_{3,4}$ = 6.9 Hz, H-3's), 3.87 (~q, $J_{4,5}$ = 5.2 Hz, H-5), 4.35 (dt, H-4); α-pyranose form, δ: ~1.85 (dd, $J_{3A,3B}$ = 14.3 Hz, H-3A), 1.99 (dd, $J_{3B,4}$ = 4.0 Hz, H-3B); *keto* form, δ: 2.57 (dd, $J_{3A,3B}$ = 15 Hz, $J_{3A,4}$ = 8.9 Hz, H-3A), 2.72 (dd, $J_{3B,4}$ = 3.6 Hz, H-3B).

Investigations of aluminum hydroxyphosphates and activated sludge by ^{27}Al and ^{31}P MAS NMR

Stephen J. Duffy and Gary W. vanLoon

Abstract: High-resolution solid-state ^{27}Al and ^{31}P MAS NMR has been used to investigate the nature of aluminum- and phosphorus-containing solids formed during wastewater treatment. Although difficult to characterize by conventional techniques, these amorphous solids can be characterized by MAS NMR, providing information about their short-range ordering. In the present study, most of the solids were precipitated under conditions of high alkalinity, similar to those encountered during wastewater treatment. The ageing time of the aluminum hydroxide prior to the addition of phosphate (t_1), the ageing time of the aluminum hydroxyphosphates after the addition of phosphate (t_2), and the phosphorus to aluminum molar ratio were controlled while the effects of changing the parameters were examined. It was found that the aluminum MAS NMR chemical shift was related to the amount of phosphate present in the solid, which in turn was related to t_1, t_2, and the P:Al molar ratio. The results also lend support to the hypothesis that phosphate removal occurs through an adsorption process onto amorphous aluminum hydroxide, rather than through direct precipitation of aluminum phosphate. The increased understanding of aluminum and phosphate chemistry and the species formed during wastewater treatment will be useful in optimizing wastewater treatment processes.

Key words: aluminum, phosphate, NMR, activated sludge, wastewater treatment.

Résumé : On a utilisé la RMN MAS du ^{27}Al et du ^{31}P pour étudier la nature de solides, contenant du phosphore et de l'aluminium, formés au cours du traitement des eaux usées. Même s'ils sont difficiles à caractériser par les techniques conventionnelles, ces solides amorphes peuvent facilement être caractérisés par la RMN MAS et on obtient ainsi des informations sur leur arrangement à courte distance. Dans la présente étude, la plupart des solides ont été précipités dans des conditions d'alcalinité élevée semblables à celles utilisées durant le traitement des eaux usées. Le temps de vieillissement de l'hydroxyde d'aluminium avant l'addition du phosphate (t_1), le temps de vieillissement des hydroxyphosphates d'aluminium après l'addition du phosphate (t_2) et les rapports molaires du phosphore à l'aluminium ont été contrôlés alors que les effets d'un changement de ces paramètres ont été examinés. On a trouvé que le déplacement chimique de l'aluminium dans la RMN MAS est relié à la quantité de phosphate présente dans le solide qui, à son tour, est relié à t_1, à t_2 et au rapport molaire P : Al. Les résultats supportent aussi l'hypothèse selon laquelle l'enlèvement du phosphate se produit par un processus de surface sur l'hydroxyde d'aluminium plutôt que par une précipitation directe du phosphate d'aluminium. La meilleure compréhension de la chimie de l'aluminium et des phosphates ainsi que des espèces qui se forment au cours du traitement des eaux usées sera utile pour l'optimisation de ces procédés de traitement.

Mots clés : aluminium, phosphate, RMN, boues activées, traitement des eaux usées.

Introduction

Point-source pollutant discharges from municipal wastewater treatment facilities are recognised as having a major impact on water quality and the surrounding ecosystems. Since the early 1970s, phosphates have been identified as a pollutant of specific concern with regard to eutrophication of water bodies (1). To reduce the amount of this element entering receiving waters from point sources, one cost-effective and efficient phosphorus removal method includes addition of alum to the wastewater stream as part of an integrated treatment system. One such system, the activated sludge process (ASP) is a method of treating wastewater biologically under aerobic conditions in order to reduce the biological oxygen demand (BOD). At many locations, ASP treatment plants have been modified in a simple manner to incorporate the addition of alum as a part of the overall process. Where this has been done, it has usually been possible to reduce the phosphorus content of discharges to less than 1 mg L^{-1}. However, even this level of residual phosphorus is sufficient to cause significant accumulation of phosphate nutrient in sensitive ecosystems and therefore further stringent controls on wastewater effluent quality may be required.

Alum or other aluminum additives serve two interconnected purposes in the wastewater treatment process. The first is to aid in coagulation and flocculation of organic and inor-

ganic colloidal material and the second is to precipitate soluble inorganic phosphate from the wastewater stream. Optimizing effectiveness and efficiency in carrying out these processes requires a knowledge of the behaviour of aluminum throughout its "lifetime" in the treatment system.

Soluble phosphates are effectively precipitated from wastewater by aluminum(III) under conditions of high alkalinity, leaving very low residual concentrations, often lower than 0.2 mg L^{-1}. On the other hand, a portion of the particulate phosphates that are formed does not settle in the clarifier and is subsequently discharged from the treatment system; these fine materials are consequently the principal form of phosphorus released into the receiving water (2).

Often, when the chemistry of phosphorus removal is discussed, a very simple but chemically inadequate description of the reaction of phosphate with alum-derived aluminum ion is given by eq. [1] (3–5).

[1] $Al^{3+} + PO_4^{3-} \longrightarrow AlPO_4$ (s)

In many cases, however, the aluminum (Al^{3+}) is injected at a point in the treatment system where the concentration of soluble phosphate is very low and the simple stoichiometry indicated by eq. [1] could not be correct.

Alum additions during the activated sludge process have been done at various locations; frequently the point chosen is within but near the exit of the aeration chamber. For example, Plant A at Kingston Township Pollution Control Plant (KTPCP) adds alum at this point and measurements show that the soluble phosphorus concentration just upstream from the point of addition is approximately 0.5 mg L^{-1} (2). The coagulant dose is 5 mg L^{-1} aluminum, which corresponds to a 1:11.5 molar ratio of phosphorus to aluminum. The 0.5 mg L^{-1} concentration of soluble phosphorus at this location compares with a concentration of between 2 and 4.5 mg L^{-1} soluble phosphorus in the aerator influent. This indicates that a large fraction of soluble phosphorus has been removed in the aerator itself.

If the formation of aluminum phosphate is not a direct precipitation process as shown in eq. [1], then it is important to know how the phosphorus is subsequently removed from solution. The answer to this question may provide insight into the conditions required to maximize the dephosphorization capability of alum. It is known that when alum, in the form of a hydrated aluminum(III) ion, is added to a high alkalinity wastewater with a typical pH of approximately 7, its principal reactions are a series of rapid successive hydrolysis steps, ultimately resulting in the precipitation of amorphous aluminum hydroxide.

One hypothesis for phosphorus removal involves phosphate adsorbing onto the newly formed amorphous aluminum hydroxide, producing an aluminum phosphate solid. Goldshmid and Rubin addressed a similar issue and reported that the solid phases identified in precipitates were $AlPO_4$, $Al_3(OH)_3(PO_4)_2$, and $Na_3Al_5H_6(PO_4)_8$, depending on the conditions of precipitation (6).

In this paper we examine the nature of the solid aluminum precipitates from both a well-characterized laboratory system and an activated sludge process, using magic angle spinning (MAS) nuclear magnetic resonance (NMR) spectroscopy as well as several other techniques.

High-resolution solid-state MAS NMR has recently become an important tool for providing specific chemical and structural information of a type that has been unattainable by more traditional means (7–13). X-ray diffraction (XRD) analysis is one of the traditional methods and is used to determine the crystalline nature of solid materials. However, when dealing with solids that are not highly ordered on a molecular level, an X-ray diffraction pattern cannot be obtained. It is with such XRD amorphous solids, having a lower level of molecular order, that MAS NMR is particularly useful for interpreting structures (14). Since both aluminum and phosphorus have nuclei, ^{27}Al and ^{31}P, respectively, that are favourable for NMR analysis, this technique is particularly suitable for examining aluminum- and phosphorus-containing solids. While NMR has seen little application in dephosphorization studies, it has been applied to structural analysis of aluminophosphate molecular sieves or zeolites (15–17).

Three parameters from the MAS NMR spectra may be used in interpreting the structures of amorphous aluminum hydroxides, aluminum phosphates, and aluminum hydroxyphosphates: chemical shifts, the relative size of peaks, and the degree of sharpness associated with each signal. Of these, the most important is the ^{27}Al chemical shift; its value depends primarily on the coordination number for the aluminum and on the nature of the neighbouring atoms. Shown in Table 1 are ^{27}Al and ^{31}P MAS NMR chemical shifts for aluminum oxides, aluminum hydroxides, and aluminum phosphates reported in various sources. The octahedral forms of aluminum appear separated from tetrahedral forms by about 50–80 ppm, while smaller differences, up to 25 ppm, are due to the nature of the aluminum neighbours. In the case of tetrahedral aluminum, Muller, Gessner et al. showed that in situations where the nearest neighbours were AlO_4, SiO_4, or PO_4 the chemical shifts ranged between 71 and 87 ppm, 50 and 67 ppm, and 33 and 45 ppm, respectively (11). The size of a peak in a spectrum is generally a reflection of the amount of element in a particular structural environment, while the peak widths can indicate the extent of molecular order. In a qualitative way, the narrower the peak, the more ordered the system. Table 2 summarizes XRD results and NMR peak widths measured at half peak height for a number of the solids investigated in the present study. The ^{27}Al MAS NMR spectra that had peak widths less than 10 ppm were from samples that had been identified as being crystalline, while spectra that had peaks widths greater than 10 ppm were generally associated with XRD amorphous material.

The differences in the ^{31}P MAS NMR chemical shifts are smaller than those for ^{27}Al since a single type of coordination associated with PO_4 tetrahedra is involved in all cases. However, the small change in chemical shifts that are a consequence of changing environments near the phosphate groups can also be used as evidence for particular structures.

In this paper we have synthesized aluminum hydroxide, aluminum phosphate, and aluminum hydroxyphosphate precipitates, using a variety of conditions related to wastewater treatment. We also obtained sludge samples from a local treatment plant and examined the ^{27}Al and ^{31}P MAS NMR spectra of the various solids.

Experimental methods

aqueous solutions of 0.833 mol L^{-1} carbonate species and 0.323 mol L^{-1} phosphate species. These solutions plus commercial grade liquid alum ($Al_2(SO_4)_3 \cdot 14H_2O$ 48% w/v) obtained from KTPCP and distilled deionized water were used to prepare most of the solids precipitated in the laboratory. Other chemicals included Fisher Certified aluminum hydroxide and aluminum chloride hexahydrate, Baker Analyzed Reagent aluminum sulfate 16-hydrate, aluminium phosphate (variscite), and ICN Pharmaceuticals aluminum metaphosphate ($Al(PO_3)_3$).

Laboratory preparation of solid samples

Three types of aluminum solids were prepared in the laboratory: (*i*) aluminum hydroxides precipitated at high alkalinity, (*ii*) aluminum hydroxyphosphates precipitated at high alkalinity, and (*iii*) aluminum phosphates precipitated at low pH. The solids formed at high alkalinity were prepared by one of two methods. The first method involved adding alum alone or prior to the addition of phosphate. The second method involved adding phosphate first, and then alum. In both methods, 25.00 mL of bicarbonate solution and sufficient distilled deionized water (DDW) to bring the final volume to 100 mL were first mixed in a 150 mL beaker. Following this, 0.860 mL of alum and 1.00, 5.00, or 50.00 mL of the phosphate solution were added in the appropriate order. The molar ratios of phosphorus to aluminum in solution used were therefore 0.17, 0.87, or 8.7, respectively. Using an Eppendorf™ micropipet, the alum was added into a solution while it was being smoothly mixed using a single-blade stirrer at 350 rpm. The actual quantity of aluminum added was 50 mg, as determined by atomic absorption spectroscopy (AAS) analysis. The aluminum phosphate solid precipitated at low pH was prepared by mixing aqueous solutions containing equimolar amounts of aluminum and phosphorus without further adjustment of pH; the pH after mixing was near 3.

The time allowed for the aluminum hydroxide to age prior to the filtration or addition of phosphate is referred to as t_1. On the other hand, t_2 refers to the ageing time after the phosphate addition and prior to the solid being filtered. Actual values of t_1 and t_2 were established for each experiment and are documented in the results and discussion section.

Samples were filtered using either a 0.45 μm filter or a porcelain filter crucible and were dried for approximately 2 h at 110°C and then weighed. Further drying at the same temperature effected only small additional weight losses, never larger than 5%. Some whole or partial samples were heated at 800°C for 16 h in a muffle furnace and were reanalyzed by MAS NMR or X-ray diffraction, or digested with hydrochloric acid and analyzed for aluminum by AAS and for phosphorus using a molybdenum blue procedure.

Four aerator sludge samples were obtained from plant A of the KTPCP. The first two samples were retrieved from a loca-

tion just prior to alum addition, the third sample was obtained from a location just downstream from the alum addition point, and the fourth sample was obtained from the sludge being recycled into the aeration chamber.

Sample analyses

A duplicate series of aluminum hydroxyphosphates were analyzed for aluminum, phosphorus, and water in order to determine the molecular formulas. Samples were prepared using the second method described earlier with the P:Al molar ratios of 0.17, 0.87, and 8.7. The t_1 was 0 min and t_2 was 2 h for each sample. After determining the quantity of aluminum and phosphorus (the latter assuming a HPO_4^{2-} species), the amount of hydroxide associated with the solid material was determined by means of a charge balance calculation. The amount of water associated with the solid, previously dried to near constant weight at 110°C, was determined by the weight loss of the solid after heating at 800°C for 16 h, taking into account the water produced from the released hydroxides. A simple example of this process is given in eq. [2].

$$[2] \quad Al(HPO_4)(OH)\cdot H_2O \xrightarrow[16\ h]{800°C} AlPO_4 + 2\ H_2O$$

In the above hypothetical situation the aluminum undergoes a conversion from an octahedral to a tetrahedral arrangement. This is also consistent with the ^{27}Al MAS NMR data, which indicated an octahedral aluminum prior to heating at 800°C and a tetrahedral aluminum after heating, as shown in the results and discussion below.

Guinier–deWolff patterns were obtained by XRD analysis and were compared to patterns for known aluminum and phosphorus compounds.

NMR methods

MAS NMR analyses were conducted on laboratory chemical reagents, on solids precipitated from solutions prepared in the laboratory, and on sludge samples retrieved from plant A at KTPCP. The ^{27}Al MAS NMR spectra were obtained on a Bruker AM-400 solid-state high-resolution NMR spectrometer operating at a field of 9.4 T, using a 5 mm VT multinuclear ultra-high-speed double-tuned MAS probe. The ^{27}Al frequency of 104.2 MHz and sample spinning rates of 6–11 kHz were used. Depending on the sample, between 100 and 3200 free induction decays were performed at a repetition time of 1 s and a pulse length of 2 μs. Samples were packed into zirconia rotors, which contained 0.03% Al or less. The ^{27}Al MAS NMR chemical shifts are referenced to a static signal obtained from a 0.2 M aqueous solution of $Al(NO_3)_3$.

The ^{31}P MAS NMR spectra were obtained on a Bruker CXP-200 solid-state high-resolution NMR spectrometer using a ^{13}C cross-polarization magic angle spinning (CP-MAS) accessory probe and a field of 4.7 T. The ^{31}P frequency of 80.98 MHz and sample spinning rates of 3–5 kHz were used. Depending on the sample, between 16 and 32 000 free induction decays were performed at a repetition time of 5 s and a pulse length of 3 μs. The ^{31}P NMR chemical shifts are referenced to solid $(NH_4)H_2PO_4$.

Results and discussion

Investigations of aluminum hydroxide precipitated in the absence of phosphate

The results of the ^{27}Al MAS NMR analyses on a number of samples of amorphous aluminum hydroxide of various ages, t_1, are reported in Table 3. The dominant peak in all samples appeared near 8 ppm (Fig. 1) in agreement with results for six-coordinate aluminum hydroxide solids as reported by Hayashi (18), Bradley and Hanna (19), and Kunnar et al. (20). When the source of aluminum (aluminum sulfate or aluminum chloride), the method of precipitation (good mixing or none), or age of aluminum (t_1 equal to 2 h or 29 d) was varied, no quantifiable difference was found in the MAS NMR signal. This is unlike previous experimental results using the "Ferron method" where decreasing aluminum reactivity (reflecting increasing crystallinity) was observed as the amorphous aluminum hydroxide aged or when the hydroxide was prepared without good mixing (21). The contrasting results reflect the variation in sensitivity of the two methods with respect to assessing molecular order.

While there was no significant difference between NMR spectra of samples aged up to 29 d, the t_1 = 107 d samples (Al-3 and Al-6) had signals that were broader and with chemical

Fig. 1. ^{27}Al MAS NMR spectrum of amorphous aluminum hydroxide (sample Al-1), $t_1 = 2$ h, prepared by precipitating alum at high alkalinity. Spinning side bands appear on either side of the main signal about 85 ppm away.

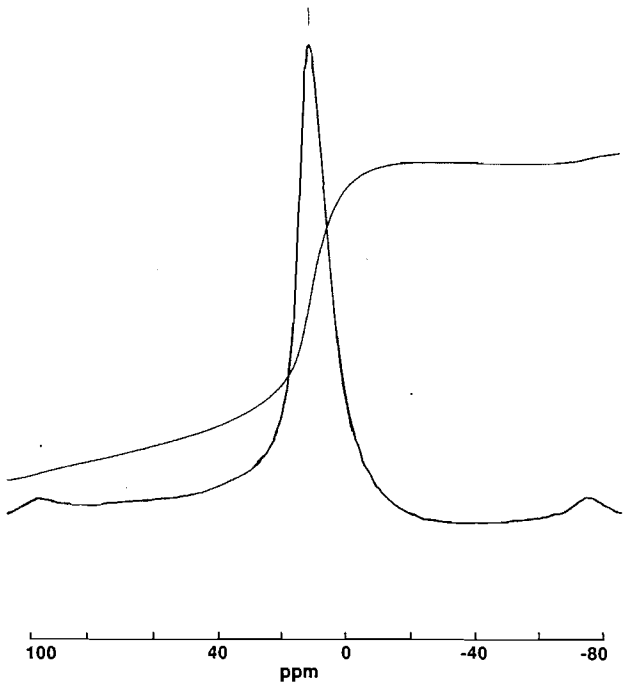

Fig. 2. ^{27}Al MAS NMR spectrum of aluminum hydroxide solid (sample Al-3), $t_1 = 2568$ h, prepared by precipitating alum at high alkalinity. Spinning sides bands are not shown.

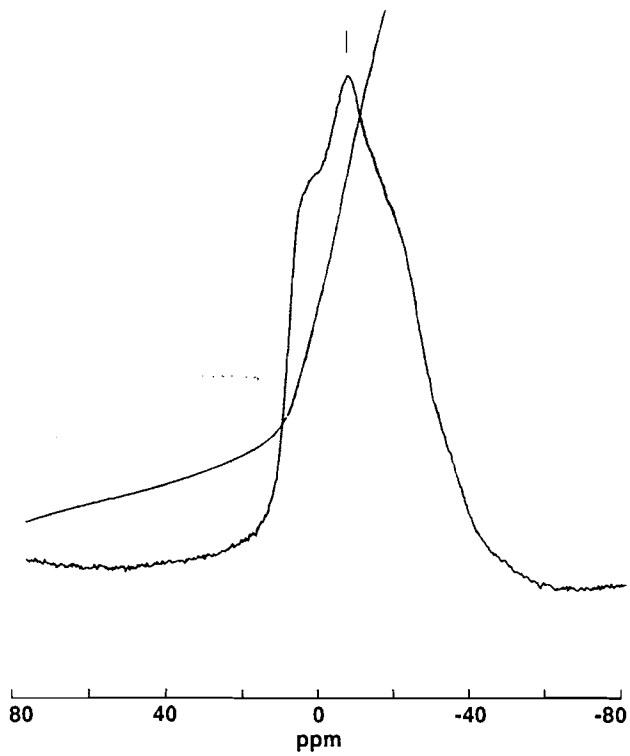

shifts centred at −7 ppm (Fig. 2). During the extended ageing, there was a rise in the solution pH to near 10, as a result of re-equilibration of atmospheric CO_2 and the carbonate species. A high pH is known to favour the formation of bayerite during crystallization and would also cause partial resolubilization of aluminum as $AlOH_4^-$. In highly alkaline solutions the aluminum hydroxide solid is known to have a negatively charged surface (22). This could affect both the structure of the solid in solution and the solid recovered after filtering and cause the observed shift in the NMR chemical signal that was obtained.

Much more significant changes in the NMR spectra were observed when the precipitates were heated. Phase transitions that solid aluminum hydroxides and oxyhydroxides undergo upon heating have been reviewed by Mackenzie and Berggren (23). A simplified sequence involving the major transitions observed for aluminum hydroxide can be represented by eq. [3]:

$$[3]\quad \text{amorphous } Al(OH)_3 \xrightarrow[\approx 300°C]{-H_2O} \gamma\text{-}Al_2O_3 \xrightarrow[>1000°C]{} \alpha\text{-}Al_2O_3$$

where α-Al_2O_3 (corundum) is heat stable up to 1950°C. Dollimore indicated that heating freshly precipitated aluminum hydroxide to a temperature of 800°C or higher eventually produces corundum (24).

Our samples were subjected to heating at 800°C for 16 h (from now on referred to as being calcined) and the MAS NMR results (Table 3) indicate partial conversion of aluminum coordination to a tetrahedral form, consistent with the formation of γ-Al_2O_3. The spectra had two broad peaks, the smaller one centred at 65 ppm characteristic of a tetrahedral signal and the original octahedral signal centred near 8 ppm (Fig. 3). However, samples Al-3 and Al-6, both of which had been aged (t_1) for 107 d, after being calcined gave a single sharp peak at 76 ppm indicating complete conversion of aluminum to a tetrahedral form (Fig. 4). The spectrum was identical to that reported for β-$NaAlO_2$ (sodium aluminate) in Table 2.

Investigation of aluminum phosphate precipitated at low pH

MAS NMR spectra were obtained on solid samples of variscite, $AlPO_4 \cdot 2H_2O$, aluminum metaphosphate, $Al(PO_3)_3$, and the solid prepared by reacting equimolar amounts of phosphorus and aluminum at pH 3 (PAl-1). The peak positions are shown in Table 4. Variscite gave a large sharp peak at −11 ppm that is similar to the octahedral aluminum signal at −13.2 ppm reported by Blackwell and Patton (17). When the sample of variscite was calcined, the ^{27}Al MAS NMR spectrum changed to having a sharp peak at 38 ppm and a second smaller peak at 31 ppm, producing berlinite (determined by XRD), similar again to the results reported by Blackwell and Patton (17).

Since sample PAl-1 had been prepared by precipitating aluminum phosphate under acid (pH 3) conditions, no hydroxide would be formed and the product would be expected to be essentially $AlPO_4$. The ^{27}Al MAS NMR results showed a sharp peak at −11 ppm and a second, smaller, overlapping peak at −9 ppm, similar to the spectrum of variscite (Fig. 5). The XRD measurements on PAl-1 indicated that it was crystalline but of unknown structure; the lines did not match the spectrum for variscite. After sample PAl-1 had been calcined, two distinct forms of aluminum phosphate were identified

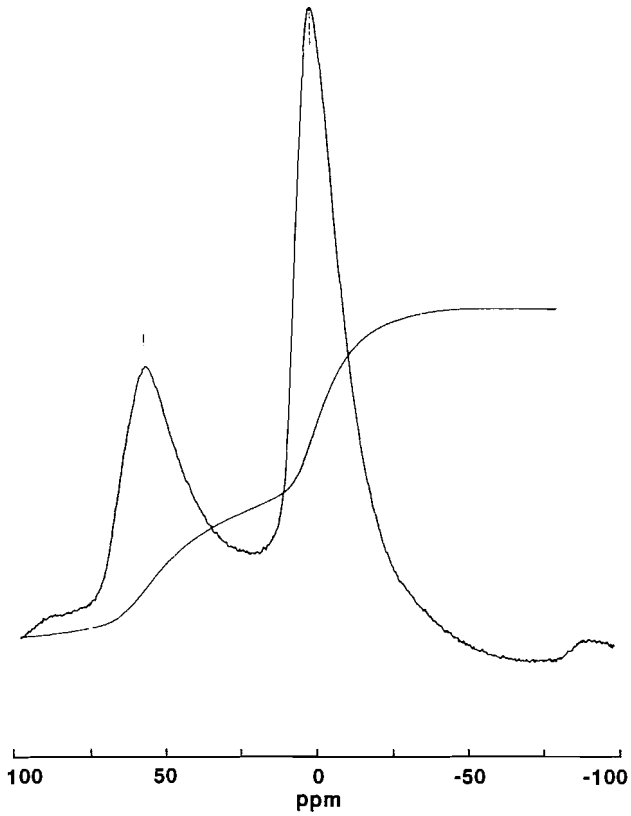
Fig. 3. ^{27}Al MAS NMR spectrum of calcined amorphous aluminum hydroxide (sample Al-5), t_1 = 1 min, prepared by precipitating aluminum (chloride) at high alkalinity. Spinning side bands appear on either side of the main signal about 85 ppm away.



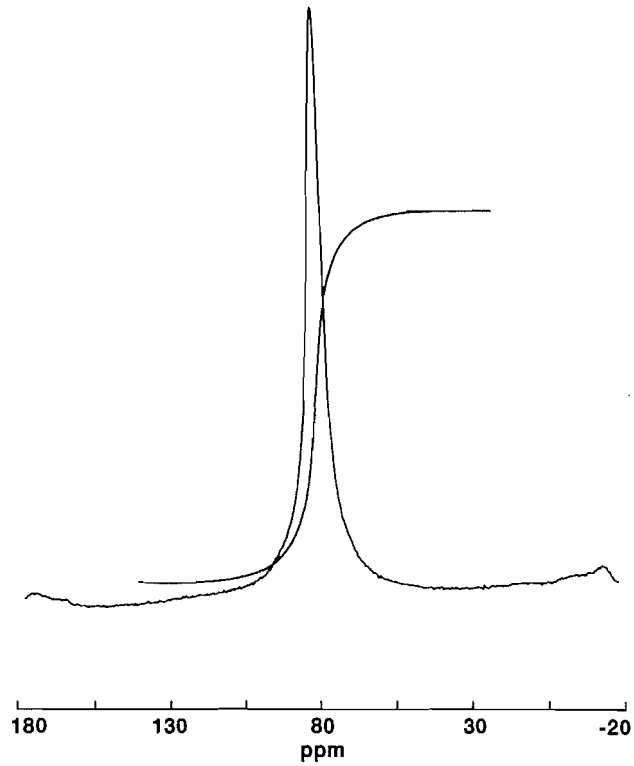
(Fig. 6). The tetrahedral aluminum signal at 38 ppm indicated anhydrous $AlPO_4$, while the octahedral resonance at −16 ppm had been previously described by Muller et al. as characteristic of solid $Al(H_2PO_4)_3$ (25).

The solids mentioned above were also characterized by ^{31}P MAS NMR analyses and the peak positions are shown in Table 4. The spectrum obtained from variscite had a peak at −19 ppm close to the −19.3 ppm reported by Blackwell and Patton (17). PAl-1 had a signal at −18 ppm, again indicating that the solid is similar to variscite. However, the NMR spectrum of the calcined PAl-1 sample indicated the presence of two environments for phosphorus as there were two peaks, one at −22 ppm and the other at −27 ppm, while calcined variscite had only one peak at −23 ppm.

Investigations of aluminum hydroxyphosphates precipitated at high alkalinity

In a wastewater treatment plant, aluminum is precipitated under conditions of high alkalinity in the presence of phosphate, and aluminum hydroxyphosphates are formed. We therefore studied the precipitates formed under similar conditions in the laboratory. Aluminum hydroxyphosphates are solids that may be thought of as intermediate between aluminum hydroxide and aluminum phosphate. We would expect this composition to be reflected in the NMR chemical shifts.

Fig. 4. ^{27}Al MAS NMR spectrum of calcined aluminum hydroxide (sample Al-3), t_1 = 2568 h, prepared by precipitating aluminum (chloride) at high alkalinity. Spinning side bands appear on either side of the main signal about 90 ppm away.



Influence of t_1 on the ^{27}Al MAS NMR spectra

Table 5 summarizes the MAS NMR peak positions for a series of six solids precipitated from solutions with high alkalinity and an equilibrium pH near 7. When investigating the effect of varying t_1, the molar ratio of added P:Al was 0.17; in some typical cases this is near the ratio at the point of alum addition in a treatment plant. Alum was added to solutions without phosphate and the precipitates were aged for times, t_1, ranging from 1 to 9000 min. Phosphate was then added and the precipitate was allowed to equilibrate with the solution for a constant time, t_2, of 2 h. One other solid was formed with phosphate present at the time of alum addition; t_1 was equal to 0 min and t_2 was equal to 2 h for this sample.

Each of the MAS NMR spectra of the precipitates showed a large broad peak (the peak width ranged from 18 to 22 ppm at half peak height) with the maximum located between 4 and 6 ppm, close to the 8 ppm signal obtained for the amorphous aluminum hydroxide samples and far from the variscite signal at −11 ppm. The consistent position of the peak in all cases indicated that, regardless of the age of the aluminum hydroxide, the solid that was formed after being in contact with phosphate still contained aluminum only in octahedral coordination. Samples with t_1 of 0 and 1 min were both clearly amorphous materials as no lines were observed in the XRD spectrum.

It was especially interesting that there was no apparent difference between the NMR results for the precipitate formed when phosphate was present in the solution prior to the addition of alum (t_1 of 0 min) and the precipitates that had been

allowed to age for 1 or 10 min before adding phosphate. Where t_1 was 0 min, it was possible that aluminum could have reacted directly with phosphate, while in the latter cases aluminum hydroxide had precipitated before phosphate addition and the only method of phosphate removal was through post-precipitation adsorption processes. The similar NMR spectra for all samples suggest that, in no case, was there significant evidence for direct coordination between phosphate and aluminum ion.

There are, however, important differences between NMR spectra of aluminum hydroxide alone and aluminum hydroxide that was allowed to react with phosphate. In the latter cases only, ageing of the hydroxide (t_1) caused the ^{27}Al NMR peak maximum to shift downfield. It appeared that the shift was

related to the presence of phosphate in the precipitate. Table 6 shows that the size of the peak, reflecting the amount of phosphate that was adsorbed, decreased with increasing t_1. Maximum uptake of phosphate occurred when t_1 = 0 but the maximum value could never exceed a ratio of 0.17 P:Al in this experiment. Therefore, the presence of phosphate in the precipitate caused the NMR peak to shift toward the position of the peak for variscite but, because the amount of phosphate was small, the final position was still far from the value associated with variscite, where the P:Al ratio is 1. A second feature of NMR spectra of samples with phosphate differing from those of samples without phosphate was the presence of two small broad peaks centred near 30 and 60 ppm, indicating other minor aluminum components of possible tetrahedral coordination (Fig. 7).

Influence of t_1 on the NMR spectra for the calcined aluminum hydroxyphosphate solids

NMR spectra of the calcined aluminum hydroxyphosphate precipitates gave evidence of the heterogeneous composition of the amorphous material. A large, broad, composite peak with maxima occurring at 39, 13, and 53 ppm (Fig. 8) was obtained for the calcined sample PAl-2 prepared with t_1 equal to 0. However, the calcined sample with t_1 equal to 9000 min (PAl-7), gave only a small peak at 40 ppm while broad signals at 7 and 65 ppm were much larger (Fig. 9). It appeared that the broad signal from calcined PAl-2 was a combination of overlapping peaks due to different aluminum components: possibly $AlPO_4$, which has a signal near 40 ppm, Al_2O_3 with a signal near 60 ppm, and $Al(OH)_3$ near 8 ppm. As the phosphate content of the series of six samples decreases, the ^{27}Al MAS NMR spectra began to more closely resemble the two peaks obtained from the calcined aluminum hydroxide samples that were discussed earlier.

Influence of t_1 on the ^{31}P MAS NMR spectra

The ^{31}P MAS NMR peak maxima for samples in the series with t_1 values ranging from 0 to 9000 min, and t_2 constant at 2 h, are also shown in Table 5. The spectra obtained for each of these samples consisted of one broad signal centred near −11

Fig. 7. ^{27}Al MAS NMR spectrum of amorphous aluminum hydroxyphosphate (sample PAl-5), t_1 = 100 min, t_2 = 2 h, P:Al = 0.17, prepared by precipitating alum at high alkalinity followed by the addition of phosphate. Spinning side bands appear on either side of the main signal about 80 ppm away.

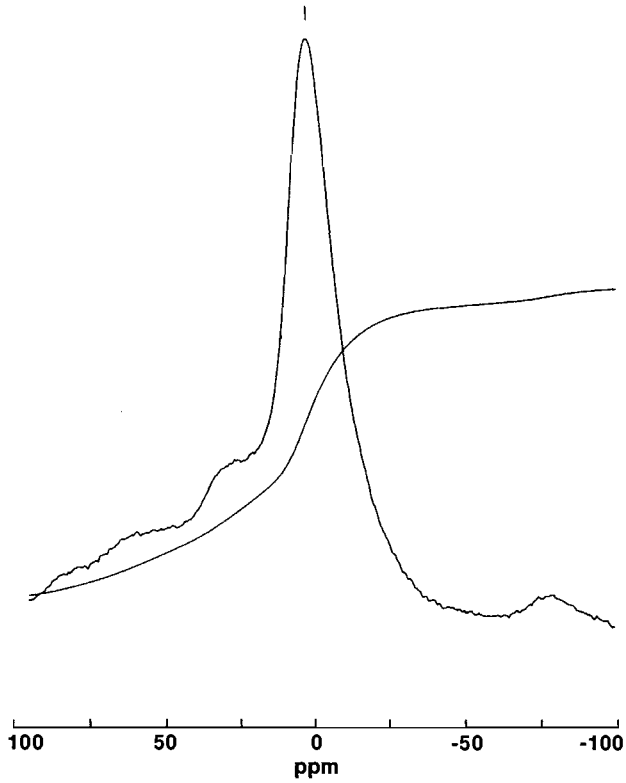

Fig. 8. ^{27}Al MAS NMR spectrum of calcined amorphous aluminum hydroxyphosphate (sample PAl-2), t_1 = 0 min, t_2 = 2 h, P:Al = 0.17, prepared by precipitating alum at high alkalinity in the presence of phosphate.

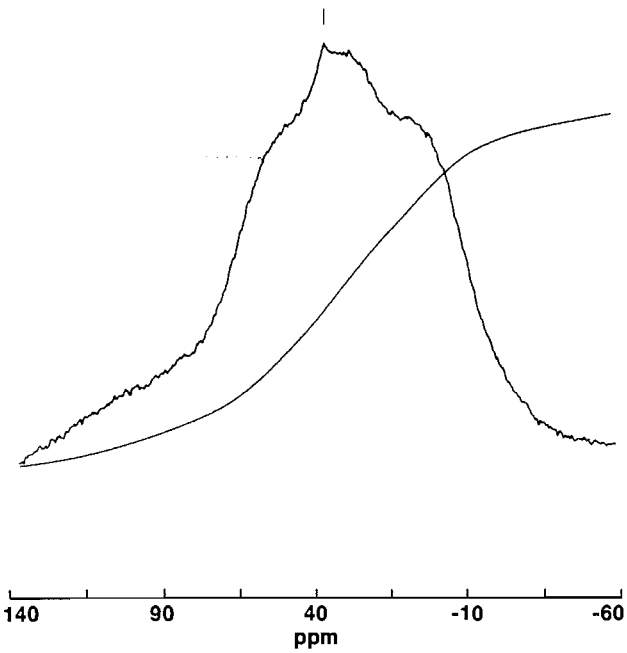

Fig. 9. ^{27}Al MAS NMR spectrum of calcined amorphous aluminum hydroxyphosphate (sample PAl-7), t_1 = 9000 min, t_2 = 2 h, P:Al = 0.17, prepared by precipitating alum at high alkalinity followed by the addition of phosphate.

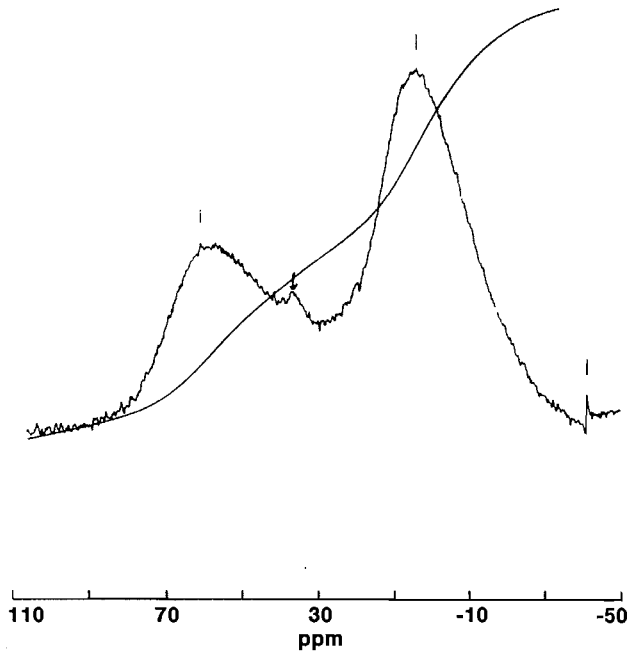

ppm, quite different from the variscite result of −19 ppm. For this set, the instrument parameters (including the number of scans) were held constant so that the integrated signal could be taken as proportional to the amount of phosphate adsorbed by the aluminum hydroxide. Although no calibration was carried out, the integrated peak areas showed that phosphorus content increased with decreasing values of t_1 (Table 6).

Influence of t_2 and the P:Al molar ratio on the nature of solid aluminum hydroxyphosphate

The influence of ageing in the presence of phosphate, t_2, and of the P:Al molar ratio on the structure of the aluminum hydroxyphosphate precipitates was also investigated. To ensure maximum phosphorus removal, a t_1 of 0 was chosen for all samples. Ageing times of 2 h and 3.5 months were chosen for t_2, and P:Al molar ratios of 0.17, 0.87, and 8.7 were used.

The MAS NMR peak maxima are shown in Table 7. As the P:Al molar ratio was increased from 0.17 to 0.87 and then to 8.7, the chemical shift of the main NMR peak moved from 4 to −4 ppm and then to −10 ppm (Figs. 10, 11, and 12). The extent of upfield shift was related to the amount of phosphate coordinated to the aluminum as noted above, except that, in this experiment, the difference was larger because the amount of phosphate was much higher than had been previously used. The larger proportion of phosphate in the precipitate was also reflected in the mass of the solids obtained. After drying at 110°C the masses of precipitates for material prepared using P:Al molar ratios of 0.17, 0.87, and 8.7 were in the ratios 1:1.6:2.3. After analysis for aluminum, phosphorus and water, the formulas of these solids were calculated to be $Al(HPO_4)_{0.16}(OH)_{2.7}\cdot 1.0H_2O$, $Al(HPO_4)_{0.8}(OH)_{1.4}\cdot 0.8H_2O$, and $Al(HPO_4)_{1.2}(OH)_{0.6}0.5H_2O$ for the three molar ratios, respectively. It is interesting that the molar ratio of phosphorus

[a]The aluminum chemical shift is referenced to a 0.2 M static aluminum nitrate solution and the phosphorus chemical shift is referenced to solid ammonium dihydrogen phosphate. Sh = sharp, Sm = small, Br = broad, nd = not determined.

to aluminum in the third solid is 1.2, greater than that of the 1:1 ratio in $AlPO_4$.

The NMR spectra of these samples also showed a small broad signal in the tetrahedral region and another effect of increasing the P:Al molar ratio was to augment this contribution. The presence of a strong broad signal at 45 ppm, near the location for $AlPO_4$, became more pronounced at the P:Al molar ratios of 0.87 and 8.7, such that it was clear that a tetrahedral aluminum was formed as a minor component of the precipitate (Figs. 10–12).

When the precipitate was allowed to remain in contact with the phosphate-containing solution for an extended time (t_2 = 3.5 months) the octahedral peak shifted from 4 to 6 ppm, from −4 to −1 ppm, and from −10 to −7 ppm for the 0.17, 0.87, and 8.7 molar ratio samples, respectively. This indicates that during the long ageing process there had been a loss of adsorbed phosphate that was likely related to the rise in pH noted earlier.

The ^{27}Al MAS NMR spectra of the calcined samples having a t_2 of 2 h and P:Al molar ratios of 0.87 and 8.7 (PAl-9 & PAl-11) are shown in Figs. 13 and 14. There were strong sharp signals at 39 ppm and at 40 and 46 ppm, respectively; both are characteristic of tetrahedral aluminum, which is the expected form after heating. The peak maxima for the ^{31}P MAS NMR spectra are also shown in Table 7.

Alum assisted activated sludge samples

Sludge samples retrieved from plant A of the KTPCP were analyzed by ^{27}Al and ^{31}P MAS NMR and the peak maxima from the resulting spectra are reported in Table 8. Each aluminum NMR spectrum contained a single broad peak near −1 ppm along with a broad shoulder peak centred near 55 ppm (Fig. 15). The chemical shift of the main peak indicates that there was a substantial quantity of phosphate associated with the aluminum in this material, similar to that used for the laboratory-prepared samples with the P:Al molar ratio of 0.87. The calcined sludge samples gave a single sharp NMR peak at 39 ppm (Fig. 16), which also occurred with calcined samples that had been prepared using a P:Al molar ratio of 0.87. The results indicated that the sludge contained aluminum solids that were mostly octahedral and that there was an approximately equal quantity of phosphorus and aluminum in the

[a]The aluminum chemical shift is referenced to a 0.2 M static aluminum nitrate solution and the phosphorus chemical shift is referenced to solid ammonium dihydrogen phosphate. Sh = sharp, Sm = small, Br = broad.

sludge. Chemical analysis of the aerator sludge confirmed this by showing that the particulate aluminum and phosphorus concentrations were 107.9 and 96.5 mg L^{-1}, respectively, corresponding to a molar ratio of 0.78 (2). The small broad peak at 55 ppm is an indication that a portion of aluminum exists in the tetrahedral form and is possibly due to an aluminum oxide.

The peak maxima results of the ^{31}P MAS NMR spectra are also reported in Table 8. Each sample had a broad signal at −8

ppm that was similar to those obtained from samples precipitated at high alkalinity, but different from that of variscite at −19 ppm. The calcined samples had a signal at −28 ppm, again similar to that obtained for the samples prepared with a molar ratio of 0.87, but different from the calcined variscite sample.

Summary

The technique of high-resolution solid-state ^{27}Al MAS NMR provides useful information concerning structures of amorphous aluminum hydroxide and hydroxyphosphate solids. The ^{31}P MAS NMR, while not as informative, provided data that supported the observations from the aluminum NMR results. The ^{27}Al MAS NMR analysis showed that amorphous aluminum hydroxides and aluminum hydroxyphosphates contained mostly octahedral aluminum. In the case of the aluminum hydroxyphosphates, a formula such as $Al(HPO_4)_{0.8}(OH)_{1.4}0.8\ H_2O$, based on both the NMR information and chemical analysis, would best represent the structure of the amorphous material formed in a wastewater treatment process. The ^{27}Al MAS NMR results also showed that when these solids were calcined the aluminum was converted from an octahedral to a tetrahedral coordination.

Other results obtained using MAS NMR were consistent with a process in which aluminum hydrolyzes immediately upon entry into a highly alkaline wastewater stream followed by subsequent removal of phosphate by an adsorption process onto the surface of the hydrous aluminum oxide. The formation of tetrahedral $AlPO_4$ occurred, but only to a small extent and only under conditions of high ratios of soluble phosphate to soluble aluminum (in this case, a molar ratio of 8.7), which are unlikely to exist in the ASP. With increasing phosphorus content of the solids, the aluminum NMR results showed an upfield shift of the NMR signal (from 4 to −10 ppm). A trend related to the age of the aluminum (t_1) was also established; this indicated that with increased age prior to phosphate addition, less phosphorus was adsorbed onto the solid. The trend was again followed by observing the upfield shift of the MAS NMR signal. The degree of mixing at the time of alum addition made no difference in the form of the aluminum solid as observed by MAS NMR.

Acknowledgements

The authors wish to thank Ms. Sue Blake for assistance in performing the MAS NMR measurements, Prof. R.D. Heyding for carrying out XRD measurements on many of the solids, and Prof. B.K. Hunter for helpful discussions. Thanks are also due to David Cybulski for work performed and the Natural Sciences and Engineering Research Council of Canada and the School of Graduate Studies at Queen's University for financial support.

Base-catalyzed ring openings of benzocyclobutenones and -ols

J.C. Bradley and T. Durst

Abstract: The base-catalyzed ring opening of a number of isomeric *E*- and *Z*-benzylidenebenzocyclobutenones and -ols has been studied in both protic and aprotic solvents. Cleavage of the C1—C2 bond results in the formation of stilbenes with mainly, and at times exclusively, retained stereochemistry. For the alcohols, these results point to an oxyanion-induced carbon–carbon bond cleavage leading to a vinyl anion that is protonated with retention of configuration in the protic solvents rather than to an electrocyclic ring opening to an alkoxy *o*-quinodimethane. Reaction of the *Z* isomer of benzylidenebenzocyclobutenol with methyllithium in THF at 20°C causes isomerization to the *E* isomer, cleavage of the C1—C2 bond, and recyclization of the resultant isomerized vinyl anion.

Key words: benzylidenebenzocyclobutenones, base-catalyzed ring opening; benzylidenebenzocyclobutenols, base-catalyzed ring opening.

Résumé : On a étudié l'ouverture de cycle catalysée par les bases, en solvants protiques ainsi qu'aprotiques, d'un certain nombre de *E* et *Z* benzylidènebenzocyclobuténones et -ols. Le clivage de la liaison C1—C2 conduit à la formation de stilbènes qui, d'une façon générale et quelquefois exclusive, conservent la stéréochimie de départ. Pour les alcools, ces résultats suggèrent l'existence d'un clivage de liaison carbone–carbone induit par un oxyanion qui conduit à un anion vinylique qui, dans les solvants protiques, subit plutôt une protonation avec rétention de configuration qu'une ouverture électrocyclique de cycle conduisant à une alkoxy-*o*-diquinométhane. La réaction de l'isomère *Z* du benzylidènebenzocyclobuténol avec le méthyllithium dans le THF, à 20°C, provoque une isomérisation en isomère *E*, un clivage de la liaison C1—C2 et une recyclisation de l'anion vinylique isomérisé qui en résulte.

Mots clés : benzylidènebenzocyclobuténones, benzylidènebenzocyclobuténols, ouverture de cycle catalysée par les bases.

Introduction

The base-catalyzed cleavage of benzocyclobutenones, **1**, and -butenols, **2**, has been studied by a number of authors with the view of determining the selectivity between the cleavage of the aryl CO bond (C1—C7), bond (a), leading to phenylacetic acids and the benzyl CO bond (C1—C2), bond (b), resulting in the formation of *o*-toluic acids (1–5). In the case of benzocyclobutenols, the question of whether the intermediate obtained upon cleavage of bond (b) is best described as a benzylic carbanion, **3**, or, a 1-alkoxy-*o*-quinodimethane, **4**, has also been addressed (6). Factors that alter the ratio of the bond (a) to bond (b) cleavage in benzocyclobutenones are easily rationalized. In the case of **1** (R = H), treatment with hydroxide ion gives approximately equal amounts of phenylacetic and *o*-toluic acids (1). Addition of an anion-stabilizing group either in the aromatic ring or at the 2-position results in predictable changes in the bond (a) to (b) ratio. For example, treatment of 6-methoxybenzocyclobutenone with ethanolic KOH leads almost exclusively to 3-methoxyphenylacetic acid (2, 3), while replacement in **1** of an α-hydrogen by a bromine results only in the rupture of bond (b) (4) (Scheme 1).

Treatment of benzocyclobutenols with strong bases in alcohols or water gives almost exclusive cleavage of the (b) bond, affording *o*-methylbenzaldehydes (1, 5, 6). The rate of ring opening in the oxyanion **5** is considerably accelerated relative to that in **2** and requires only minutes at temperatures as low as −78°C. In contrast, the thermal ring opening in **2** occurs at a synthetically useful rate in refluxing toluene. The rate enhancement has been touted as an example of an oxyanion-accelerated electrocyclic ring opening (6).

Choy and Yang (6*a*) have attempted to determine, by trapping experiments with dimethyl fumarate and dimethyl maleate, whether **3** or **4** is the representation of the ring better opened hybrid. The results were, however, somewhat ambiguous. Approximately 80% of the cycloaddition products obtained from **2** (R = H) upon treatment with NaH in THF at 0°C in the presence of dimethyl maleate had retained the *cis* geometry of the dienophile, but in 20% the stereochemical integrity of the alkene was lost. A similar reaction of **2** (R = Ph) at −78°C gave only the expected Diels–Alder product. These results could be explained by a combination of a concerted cycloaddition beginning with **4** and a competing tandem Michael addition–cyclization pathway commencing with **3** or, more simply, by assuming that the Michael addition

intermediate from **3** and dimethyl maleate is partly isomerized prior to cyclization when R = H at 0°C, but not at −78°C when R = Ph. A study by Swenton et al. (*6b*) with a different substrate also addressed the above question; it too failed to give a definitive answer. A very recent paper by Olofson and coworkers (7) reports that the ring opening of the sodium salts of **5** in the presence of aromatic aldehydes affords excellent yields of δ-lactols. Benzylic anions, e.g. 3, are assumed to be intermediates (8).

Access to both isomeric benzylidenebenzocyclobutenones **6***E* and **6***Z* (*8a*) and a variety of related benzocyclobutenols provided us with a unique opportunity to probe the nature of the intermediates obtained upon cleavage of bond (b) in these compounds under basic conditions. If the ring-opened intermediate is best described as a vinyl carbanion, such cleavage should result in the formation of the acids **7***Z* from **6***E* via **8** and **7***E* from **6***Z* via **9**. These expectations are based on the reasonable assumption that the vinyl anions **8** and **9** maintain their stereochemical integrity and protonate with retention of configuration (9). In contrast, description of the intermediate as an alkoxy-*o*-quinodimethane leads to the allenic derivative **10** from both **6***E* and **6***Z*. Subsequent protonation should lead to the same product mixture from both **6***E* and **6***Z* (Scheme 2).

Discussion and results

(a) Benzylidenebenzocyclobutenones in protic media

Reaction of **6***E* and **6Z** with methanolic KOH at 25°C afforded a 4:1 mixture of (a) to (b) cleavage products in the case of **6***E* and 1:5 for **6***Z*. Importantly, the (b) bond cleavage products were formed exclusively with retention of configuration. No crossover products were detected in the NMR of the crude products obtained from either **6***E* or **6***Z*. The higher (b) to (a) cleavage in **6***Z* vs. **6***E* is likely due to the greater strain in the alkoxide derived from the *Z* isomer compared to that from the *E* isomer, thereby weakening the C1—C2 bond. Similar results were obtained when $CH_3O^-Na^+/CH_3OH$ was used as the basic medium except that somewhat lower (a) to (b) ratios were observed: 2:1 for **6***E* and 1:7 for **6***Z*. These results are consistent with the description of the intermediates in the ring opening of **6***E* and **6***Z* as the vinyl anions **8** and **9**, respectively, rather than the allene alkoxide **10**.

Treatment of the 4,5-methylenedioxybenzylidenebenzocyclobutenones **11** with KOH in methanol gave higher values for the (a) to (b) ratios than those obtained with **6**. Only the bond (a) cleavage product **12** was observed with **11***E* while **11***Z* gave a 1:1 mixture of **13** and **14**. Again, the bond (b) cleavage product **14** was uncontaminated with its geometric isomer, constistent with a vinyl anion intermediate, Scheme 3.

(b) Benzylidenebenzocyclobutenols

Reaction of the tertiary alcohol **15***Z* with 5 N KOH afforded a 13:1 mixture of the (b) vs. (a) cleavage products **16** and **17**, respectively, while **15***E* gave a 1:1 mixture of **17** and **18**. The observed stereochemistry of the (b) cleavage products **16** and **18** is consistent only with a vinyl carbanion intermediate. The product **17** was tentatively identified by NMR and GC–MS. It appeared to be formed as a roughly equal mixture of the two possible geometric isomers from both **15***E* and **15***Z*. Isomerization of this α,β-unsaturated ketone via a hydroxide ion addition-elimination sequence should be quite facile.

Interestingly, the *Z* alcohol **19** afforded a 6:1:1 mixture of

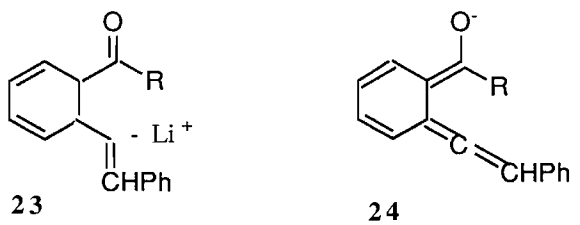
the (b) cleavage products **20***E* and **20***Z* and the (a) cleavage product **21**. Analysis of the results of the reaction of **19***E* in methanolic KOH was complicated by further reaction of the products due to the refluxing methanol reaction conditions required to break the cyclobutene ring. Finally in this series, the secondary alcohols **22***E* and *Z* gave even higher loss of stereochemical integrity in the (b) bond fragmentation products. These results are summarized in Table 1.

Overall, the results obtained in the base-catalyzed fragmentaion of the above benzylidenebenzocyclobutenols are consistent with a vinyl carbanion rather than the allenic alkoxide description for the intermediate, The observed trend: complete stereochemical retention in the (b) cleavage products from **15***E* and *Z*, to some loss in the products obtained from **19***Z* and even more from those derived from **22***E* and **22***Z*, indicates a decreasing barrier to inversion in the vinyl anion **23** on going from R = Ph to CH_3 to H. This suggests an increasing contribution of the allenic alkoxide resonance hybrid **24** as the R group becomes smaller, thereby lowering the barrier to inversion.



23 **24**

R = H, CH_3, Ph

(c) Reactions in aprotic media

The alkoxy anion-induced ring cleavage starting with the alcohols **22***E* and *Z* was also studied under aprotic conditions with the hope of trapping or observing spectroscopically the ring-opened anionic intermediates.

Thus addition of 1 equivalent of CH_3Li to a solution of **22***Z* in THF at −78°C gave a ^{13}C NMR spectrum that corresponded to the alkoxide **27***Z*. No significant changes were observed upon warming to near 0°C, but on further warming to about 20°C for 1 h the spectrum changed and corresponded to one containing **27***E* as the major component. No further changes were observed when the solution was left at 20°C for an additional 16 h. Quenching of the solution gave **22***E* as the major product. Similar treatment of **22***E* resulted in the recovery of the starting material.

Reaction of **22***Z* with 2 equivalents of CH_3Li in THF at room temperature afforded a mixture of products: recovered **22***Z*, isomerization product **22***E*, and the ring-opened products **25** and **26** in a ratio of 0.1:1.1:0.2 as judged by GC analysis. The structures of the alcohols **25** and **26** were assigned on the basis of their spectroscopic properties and via unambiguous synthesis from the corresponding 2-formylstilbenes.

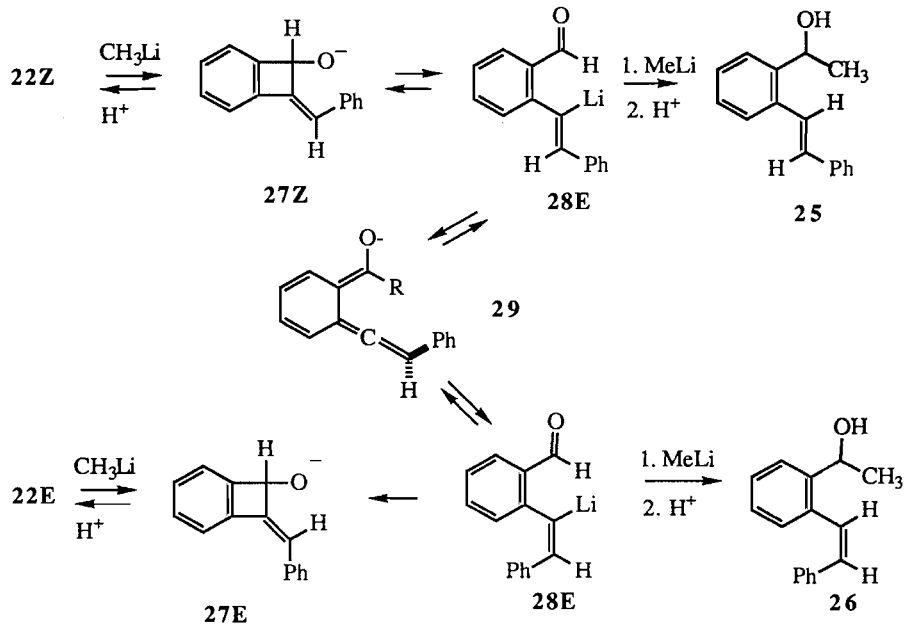
Scheme 4.



These results are interpreted as shown in Scheme 4. The lithio alkoxide **27***Z* is stable to 0°C, but opens to the vinyllithium derivative **28***E* when warmed to 20°C. In the absence of rapid quenching by a protic solvent, this species can isomerize to **28***Z* and then recyclize to **27***E*. Both **28***E* and **28***Z* are trapped by the excess CH_3Li to give the alcohols **25** and **26**, respectively.

Surprisingly, the reaction of **22***Z* with 10 equivalents of CH_3Li at room temperature did not result in a larger percentage of trapping of the aldehydes **28***E* and **28***Z* with CH_3Li. Instead, these conditions retarded considerably the isomerization of **22***Z* to **22***E*, giving ratios of **22***Z*:**22***E*:**25** + **26** of 3:1:0.2 (GC analysis). We initially postulated that "protection" of the alkoxide **27***Z* toward ring opening might be due to a second metallation either at the *ortho* aromatic or a vinyl position and that such a metallation stabilizes the alkoxide, thereby making ring opening more difficult. When this was tested by quenching the reaction mixture with D_2O, no deuterium incorporation was found in the recovered **22***Z* by MS, suggesting possible stabilization of **27***Z* by the excess CH_3Li via aggregation (10).

Conclusions

The anionic ring opening of the C1—C2 bond in benzylidenebenzocyclobutenols and -ones is most readily explained as occurring via carbon–carbon cleavage resulting in vinyl anions rather than an oxyanion-promoted electrocyclic ring opening. This decision is based on the trapping of the aldehyde-vinyllithium intermediates **27***E*/*Z* with CH_3Li, and the observation that the base-catalyzed ring openings in protic media result in the formation of stilbenes with retention of configuration. It is difficult to explain these results assuming that the intermediates have alkoxyallenic (*o*-quinodimethane) structures.

Experimental section

General

Details concerning the purification of solvents and reagents, chromatographic procedures, and the aquisition of spectroscopic data have been described in earlier publications (8).

Reaction of E*-2-benzylidenebenzocyclobutenone,* **6***E, with KOH*

A solution of **6***E* (47 mg) in methanolic KOH (5 N, 3 mL) was warmed to 40°C for 1.5 h and then kept at room temperature for a further 18 h. The solution was acidified with 5 mL of 5 N HCl and extracted thoroughly with ether. The yield of acids, a 4:1 mixture of *E*-2,3-diphenylpropenoic acid (11) (δ: 7.95, s, CHPh) and 2-(*Z*-2-phenylethenyl)-benzoic acid **7***Z* (12) (δ: 6.62, d, J = 12.4 Hz, CHPh), was 50.6 mg (96%). The mixture was esterified with ethereal diazomethane and the resultant esters were separated by radial chromatography (silica gel, 1:1 hexane–CH_2Cl_2).

For methyl *E*-2,3-diphenylpropenate (13): IR: 1709 cm^{-1}; ^1H NMR, δ: 3.77 (3H, s), 6.96–7.04 (2H, m), 7.08–7.23 (5H, m), 7.3–7.4 (3H, m), 7.85 (lH, s); ^{13}C NMR, δ: 52.4, 127.8, 128.2, 128.7, 129.1, 129.7, 130.6, 132.4, 134.6, 135.9, 140.5, 168.4; HRMS, calcd. for $C_{16}H_{14}O_2$: 238.0994; found: 238.0999.

For the methyl ester of **7***Z*: ^1H NMR, δ: 3.87 (3H,s), 6.63 (lH, d, J = 12.4 Hz), 7.0–7.3 (9H, m), 7.96 (lH, m); ^{13}C NMR, δ: 52.0, 126.9, 127.1, 128.0, 129.2, 129.3, 129.6, 130.4, 130.6, 131.1, 131.9, 136.7, 139.6, 167.5; HRMS, calcd. for $C_{16}H_{14}O_2$: 238.0994; found: 238.0998.

Reaction of 2-benzylidenebenzocyclobutenone, **6***Z, (8*a*) with KOH*

The enone **6***Z* (50 mg) was treated as above yielding 49.2 mg of a 5:1 mixture of 2-(*E*-2-phenylethenyl)-benzoic acid (14), **7***E*, (δ = 7.02, J = 16.4 Hz) and *Z*-2,3-diphenylpropenoic acid (11) (δ = 7.08, CHPh). Treatment with diazomethane afforded the corresponding esters .

For methyl *Z*-2,3-diphenylpropenoate: ^1H NMR, δ: 3.76 (3H, s), 7.02 (lH, s), 7.2–7 5 (10H, m); ^{13}C NMR, δ: 52.2, 126.5 (2), 128.2, 128.4, 128.5, 128.7, 131.6, 134..9, 135.7,

136.9, 170.1; HRMS, calcd. for $C_{16}H_{14}O_2$: 238.0994; found: 238.0974.

For the methyl ester of **7*E***: ^{1}H NMR, δ: 3.92 (3H, s), 7.00 (lH, d, J = 16.2 Hz), 7.23–7.39 (4 H, m) 7.50 (lH, t, J = 8 Hz), 7.55 (2H, d, J = 8 Hz), 7.71 (lH, d, J = 8 Hz), 7.92 (lH, dd, J = 8, 1.4 Hz), 7.98 (lH d, J = 16.2 Hz); ^{13}C NMR, δ:52.1, 126.8 (2), 126.9, 127.1 127.4, 128.5, 128.6, 130.6, 131.4, 132.1 137.4, 139.2, 167.8; HRMS, calcd. for $C_{16}H_{14}O_2$: 238.0994; found: 238.0989.

Reaction of E-*2-benzylidene-4,5-methylenedioxybenzocyclobutenone,* ***11****E, (8a) with aqueous KOH*

The enone **11*E***, (8*a*) (59.5 mg) was allowed to react in 3 mL of methanolic KOH for 22 h at room temperature. Work-up, as above, afforded 62.4 mg of **12** as a yellowish solid, insoluble in common organic solvents. IR (KBr): 3500–2700 cm^{-1}; ^{1}H NMR(D_2O/K_2CO_3), δ: 5.93 (2H, s), 6.62 (lH, dd, J = 8.0, 1.7 Hz), 6.66 (lH, dd, J = 1.7, 0.5 Hz), 6.82 (lH, dd, J = 8.0, 0.5 Hz), 7.0–7.2 (6H, m), 7.42(1H, s).

Reaction of Z-*2-benzylidene-4,5-methylenedioxybenzocyclobutenone,* ***11****Z, (7a) with aqueous KOH*

This compound (8*a*) (50.2 mg) when reacted in the same manner as **11*E*** afforded a mixture whose ^{1}H NMR (D_2O/K_2CO_3) was interpreted as a 1:1 mixture of **13** and **14** with the key peaks occurring at δ: 7.0 (d, J = 16 Hz) for **13** and 6.85 (lH, dd, J = 8.0, 1.5 Hz), 7.09 (lH, d, J = 1.5 Hz) for **14**. These compounds were not further characterized.

Cleavage reactions of E- *and* Z-*1-phenyl-2-benzylidenebenzocyclobutenone,* ***15****E and* ***15****Z*

Solutions of these compounds (8*b*) in 5 N methanolic KOH were kept at room temperature for 3 days and then worked up by acidifying the solution and extracting with ether, as above. The products were characterized by ^{1}H NMR. Ratios were determined by GC. See Table 1.

From **15*Z*** the major product was 2′-benzoyl-*trans*-stilbene, **16**. ^{1}H NMR, δ:7.04 (IH, d, J = 16.3 Hz), 7.18 (lH, d, J = 16.2 Hz), 7.1–7.9 (14H, m); MS.: 284 (100, $M^{+\cdot}$), 283 (16), 265 (9), 207 (35), 206 (23), 178 (41), 77 (24); HRMS, calcd. for $C_{21}H_{16}O$: 284.1201; found: 284.1220.

From **15*E***, the major products were separated by silica gel radial chromatography plates using 2:1 hexanes–CH_2Cl_2. 2′-Benzoyl *cis*-stilbene, **18**, had ^{1}H NMR, δ:6.48 (lH, d, J = 12.2 Hz), 6.60 (1H, d, J = 12.2 Hz), 7.06–7.18 (5H, m), 7.28–7.33 (3H, m), 7.36–7.44 (3H, m), 7.53 (lH, t, J = 7.3 Hz), 7.44, (2H, d, J = 7.0 Hz); ^{13}C NMR, δ: 126.7 127.2, 128.1, 128.3 128.5, 128.6, 129.0, 130.1, 130.2, 130.3, 131.4, 133.0, 133.6, 136.9, 137.6, 138.6, 197.8; MS: 284 (100, $M^{+\cdot}$); HRMs, calcd. for $C_{21}H_{16}O$: 284.1201; found: 284.1212.

l-Benzoyl-1,2-diphenylethylene, **17**, was obtained as a 1:1 mixture of isomers. The ^{1}H NMR, spectrum of the mixture showed absorption only in the δ = 7–8 ppm region. The carbonyl carbons of the two isomers occurred at δ = 197.3 and 199.3. The MS of the mixture had peaks at 284 (95, $M^{+\cdot}$), 207 (10, M − C_6H_5), 206 (23, M − C_6H_6), 179 (25, M − PhCO), 105 (100, $PhCO^+$).

Preparation of E-*2-benzylidene-1-methylbenzocyclobutenol,* ***19****E*

To a solution of 96 mg benzocyclobutenone **6*E*** (0.46 mmol) in THF (10 mL) at 78°C was added 0.92 mmol of CH_3Li. The reaction mixture was stirred for 30 min at 78°C, allowed to warm to room temperature, and quenched with saturated NH_4Cl solution. Further work-up followed by chromatography (1:3 hexane:CH_2Cl_2, increasing to pure CH_2Cl_2) afforded 94 mg (91%) of **19*E*** as a colorless solid mp 78–79°C; ^{1}H NMR, δ: 1.74 (3H, s), 2.56 (lH, OH), 6.48 (1H, s), 7.2–7.6 (9H); ^{13}C NMR, δ: 23.5, 82.4, plus 12 peaks from 117–155 ppm; MS: 222 ($M^{+\cdot}$, 100), 221 (M − H, 52), 207 (M − CH_3, 60), 179 (M − CH_3CO, 63), 178 (83); HRMS, calcd. for $C_{16}H_{14}O$: 222.1044; found: 222.1054. Anal. calcd.: C 86.45, H 6.35; found: C 86.32, H 6.56.

Preparation of Z-*2-benzylidene-1-methylbenzocyclobutenol,* ***19****Z*

Using the same procedure as above and on a similar scale, the *Z* isomer **19*Z***, mp 114–116°C was obtained in 43% yield from **6*Z*** (the low yield is due to the instability of **19*Z*** under basic conditions). ^{1}H NMR, δ: 1.74 (3H, s) 2.65 (1 H, OH), 6.56 (1H, s), 7.2–7.5 (7H, m), 7.70 (2H, d, J = 8.2 Hz); ^{13}C NMR, δ: 22.8, 83.7, plus 12 additional resonances between 118 and 154 ppm; MS 222 ($M^{+\cdot}$, 100), 221 (M−H, 48), 207 (M − CH_3), 52), 179 (M − CH_3CO, 53), 178 (68); HRMS, calcd. for $C_{16}H_{14}O$: 222.1044; found: 222.10057. Anal. calcd.: 86.45, H 6.35, found: C 86.28, H 6.51.

Reaction of ***19****Z with KOH*

This reaction was carried out in 5 N methanolic KOH for 45 min at room temperature. A ^{1}H NMR spectrum of the crude product showed four methyl peaks at δ = 2.59, 2.51, and 2.29 (and 2.23) in an approximate 6:1:1 ratio. These peaks were assigned to **20*E***, **20*Z***, and the isomers of **21**, respectively (see below). GC monitoring of a second run showed that these ratios did not change significantly when the reaction was continued for 3 days prior to work-up. Careful silica gel chromatography (radial) with 2:1 hexanes/CH_2Cl_2 afforded almost pure **20*E*** and **20*Z***.

For **20*E***: (11) IR ($CHCl_3$): 1683 cm^{-1}; ^{1}H NMR, δ: 2.60 (3H, s), 6.96 (1H, d, J = 16.3 Hz), 7.2–7.7 (10H, m); ^{13}C NMR, δ: 29.8, 126.8, 127.1, 127.3, 127.4, 127.8, 128.6, 129.0, 131.5, 131.6, 137.2, 137.3 (2×), 202.1; MS 222($M^{+\cdot}$, 100), 221 (17), 207 (M−CH_3, 52), 179 (M − CH_3CO, 63).

For **20*Z***: ^{1}H NMR, δ: 2.52 (3H, s), 6.61 (1H, d, J = 12.1 Hz), 6.89 (1H, d, J = 12.2 Hz), 6.95–7.4 (8H, m), 7.6–7.8 (1H, m); ^{13}C NMR, δ: 41.9, 127.0, 127.2, 128.1, 129.2(2×) 130.1, 130.4, 131.1, 131.6, 136.6, 137.7, 137.8, 201.

These isomers could not be completely separated.

Reaction of ***19****E with KOH*

When **19*E*** was dissolved in 5 N methanolic KOH, no reaction was observed (GC) after 3 days. The reaction mixture was then refluxed for 30 min. The ^{1}H NMR, spectrum of the crude product was very complicated. It revealed one significant peak at δ = 2.53, which was attributed to **20*Z***. The assignment of this peak as indicating the presence of **20*Z*** was verified by comparing GC retention times with those of an authentic sample.

Preparation of Z-*2-benzylidenebenzocyclobutanol,* ***22****Z*

To a solution of **6*Z*** (114 mg, 0.55 mmol) in methanol (5 mL) was added $NaBH_4$ (61 mg). The mixture was stirred for 30 min

at room temperature and then poured into a mixture of ether (10 mL) and 1% HCl (10 mL). Separation, reextraction of the aqueous phase with ether, and evaporation of the combined organic phase afforded a crude product, which was passed through a short silica gel plug. The yield of **22***E* was 114 mg, 99%. IR: 3577 cm^{-1}(OH); ^1H NMR, δ: 2.35 (lH, d, J = 10.9 Hz, OH), 5.78 (lH, d, J = 10.8 Hz), 6.59 (s, lH), 7.20–7.4 (7H, m), 7.62 (2H, d, J = 8 Hz); MS: 208 (100, $M^{+\cdot}$), 207 (43, M−H), 179 (64, M − CHO), 178 (74); HRMS, calcd. for $C_{15}H_{12}O$: 208.0890; found: 208.0888. Anal. calcd. for $C_{15}H_{12}O$: C 86.54, H 5.77; found: C 86.40, H 5.93.

Preparation of Z*-2-benzylidenebenzocyclobutenol,* 22E
The same procedure as for **22***Z* afforded 97% of **22***E*. IR: 3580 cm^{-1}; ^1H NMR, δ: 2.51 (lH, s, OH), 5.49 (s, lH), 6.50 (s, lH), 7.2–7.6 (m, 9H); MS: 208 (100, $M^{+\cdot}$), 207 (45, M − H), 179 (66, M − CHO), 178 (73); HRMS, calcd. for $Cl_{15}H_{12}O$: 208.0888; found: 208.0896. Anal. calcd. for $C_{15}H_{12}O$: C 86.54, H 5.77; found: C 86.35, H 5.83.

Reaction of 22Z *and* 22E *will methanolic KOH*
The alcohol **22***Z* was stirred with 5 N KOH for 3.5 h at room temperature. Work-up afforded a mixture of two aldehydes, which were partially separated by radial chromatography (3:1 hexane/CH_2Cl_2).

2′-Formyl-*trans*-stilbene: mp 79–81°C (lit. (11*b*) mp 80–82°C; ^1H NMR, δ: 7.05 (lH, d, J = 16.3 Hz), 7.26–7.46 (6H, m), 7.54–7.61 (3H, m), 7.71 (lH, d, J = 7.8 Hz), 10.31 (lH, s), ^{13}C NMR, δ: 12 aromatic and alkene signals from 126.4–140.9, 192.0 (CHO); MS: 208 (100, $M^{+\cdot}$), 207(31), 179(40, M − CHO), 178 (50), 165 (25), 105 (35), 89 (22); HRMS, calcd. for $C_{15}H_{12}O$: 208.0888; found: 208.0900.

2′-Formyl-*cis*-stilbene (15): ^1H NMR, δ: 6.82 (lH, d, J = 12.2 Hz), 6.97 (1H, d, J = 12.2 Hz), 7.00–7.04 (2H, m), 7.11–7.1 6 (3H, m), 7.27 (lH, d, J = 7.5 Hz), 7.35–7.5 (2H, m), 7.87 (lH, dd, J = 1.5, 7.7 Hz), 10.23 (lH, s). The MS was almost identical with that of the *trans* isomer. This product was not further characterized since it could not be completely separated from the *trans* isomer.

The cleavage of **22***E* under the above conditions was followed by g.c. The major products had identical retention times with those of the *trans* and *cis* stilbenes, above. The ratio of *cis* to trans isomers was approximately 2.5:1. A small amount of an aldehyde (δ = 9.74) isomeric with the above products (GC–MS) was also detected.

Reaction of 22E *and* 22Z *with methyllithium in THF*
These reactions were carried out by addition of the appropriate amount of CH_3Li to a solution of **22***E* or **22***Z* in THF at −78°C or at room temperature. The room temperature reactions were allowed to proceed for 40 min. Work-up involved quenching with aqueous NH_4Cl and extraction with ether. Product ratios were based on ^1H NMR analysis of the crude reaction mixtures. Authentic samples of the alcohols **25** (characteristic ^1H NMR peaks, δ:1.50 (3H, d, J = 6.4 Hz), 5.27 (lH, q, J = 6.4 Hz), 6.95 (lH, d, J = 16.0 Hz)), and **26** (characteristic ^1H NMR peaks at δ: 1.41 (3H, d, J = 6.4 Hz), 5.12 (lH, q, J = 6.4 Hz), 6.63 (lH, d, J = 12.2 Hz), 6.74 (lH, d, J = 12.3 Hz)). Authentic samples were prepared for comparison by reacting **20***E* and **20***Z*, respectively, with CH_3Li.

On the Baylis–Hillman reaction of acrylate, acrylonitrile, and acrolein with some non-enolizable α-dicarbonyl compounds: synthesis of phytotoxic bipolaroxin models

George M. Strunz, Richard Bethell, Glen Sampson, and Peter White

Abstract: The Baylis–Hillman reaction of acrylonitrile, methyl acrylate, and acrolein with several cyclic α-dicarbonyl compounds was investigated. Whereas acrylonitrile reacted with most of these ketones, giving good yields of the expected 1'-cyanovinyl carbinols, the more sterically demanding methyl acrylate failed to undergo the reaction. Attempted Baylis–Hillman reaction of acrolein with the 1,2-dicarbonyl substrates usually resulted in polymers but, in two cases, the desired α-substituted acroleins were obtained. An alternative route to such compounds was developed, employing a Grignard – allylic oxidation sequence. In bioassays, some of the products, embodying the functionality believed responsible for the phytotoxicity of the sesquiterpene bipolaroxin, inhibited germination of lettuce seeds. This activity diminished with time.

Key words: Baylis–Hillman, acrylonitrile, acrylate, acrolein, α-dicarbonyl, bipolaroxin, phytotoxicity.

Résumé : Nous avons étudié la réaction de Baylis–Hillman sur l'acrylonitrile, l'acrylate de méthyle ainsi que l'acroléine avec plusieurs composés α-dicarbonyliques cycliques. Tandis que l'acrylonitrile réagit avec la plupart de ces cétones, fournissant les carbinols 1'-cyanovinyliques attendus avec de bons rendements, l'acrylate de méthyle, à cause de sa plus grande exigence stérique, ne réagit pas de tout. Quand la réaction de Baylis–Hillman fut essayée avec l'acroléine et les composés α-dicarbonyliques, seulement des polymères furent obtenus à l'exception de deux cas, où les acroléines α-substituées furent obtenues. Utilisant la réaction de Grignard, suivie d'une oxidation allylique, une autre route pour produire ces composés fut developpée. Quelques-uns de ces produits, possédant la structure partielle que l'on croit responsable de la phytotoxicité du sesquiterpène bipolaroxin, ont inhibé la germination des semences de laitue. Cet activité a diminué avec le temps.

Mots clés : Baylis–Hillman, acrylonitrile, acrylate, acroléine, composés α-dicarbonyliques, bipolaroxin, phytotoxicité.

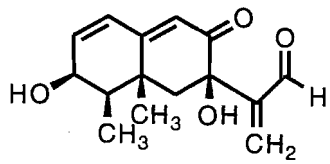
Introduction

The sesquiterpene bipolaroxin, **1**, is a phytotoxic metabolite produced by *Bipolaris cynodontis*, a pathogen of Bermuda grass, *Cynodon dactylon* (L.), which is considered an important weed species in certain agricultural systems (1). The mechanism proposed to account for the phytotoxicity of bipolaroxin (by analogy with the suggested mode of action of 7-hydroxycostal (2)) involves conjugate addition of a nucleophile to the enal system, giving an intermediate such as **II**, followed by a fragmentation resulting in release of the phytotoxic agent acrolein (Scheme 1) (1).



1

The hydroxy enal system, believed to confer phytotoxicity upon bipolaroxin, is reminiscent of functionality **IX** accessible via the Baylis–Hillman reaction (Scheme 2) (3); in fact, bipolaroxin is *formally* derivable by a Baylis–Hillman-type condensation involving one carbonyl group of the diketone **III** (in Scheme 1) and acrolein. As all steps in the Baylis–Hillman sequence appear to be reversible (cf. ref. 4), the release of acrolein in vivo by bipolaroxin may be analogous to a "biologically catalyzed" retro-Baylis–Hillman-type process.

We were intrigued by the possibility that simple Baylis–Hillman products derived from acrolein and suitable α-diketones (or aldehydes) might, like bipolaroxin, release acrolein on interaction with certain (intracellular?) plant con-

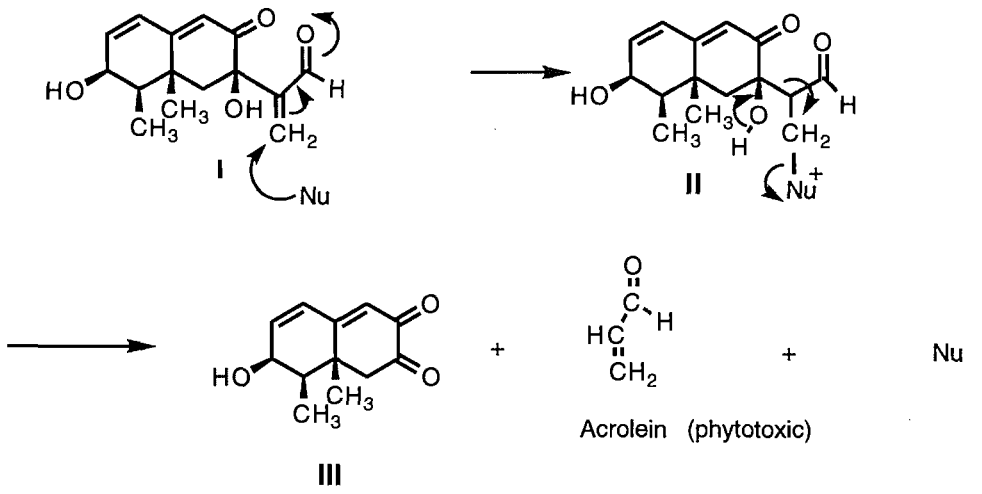
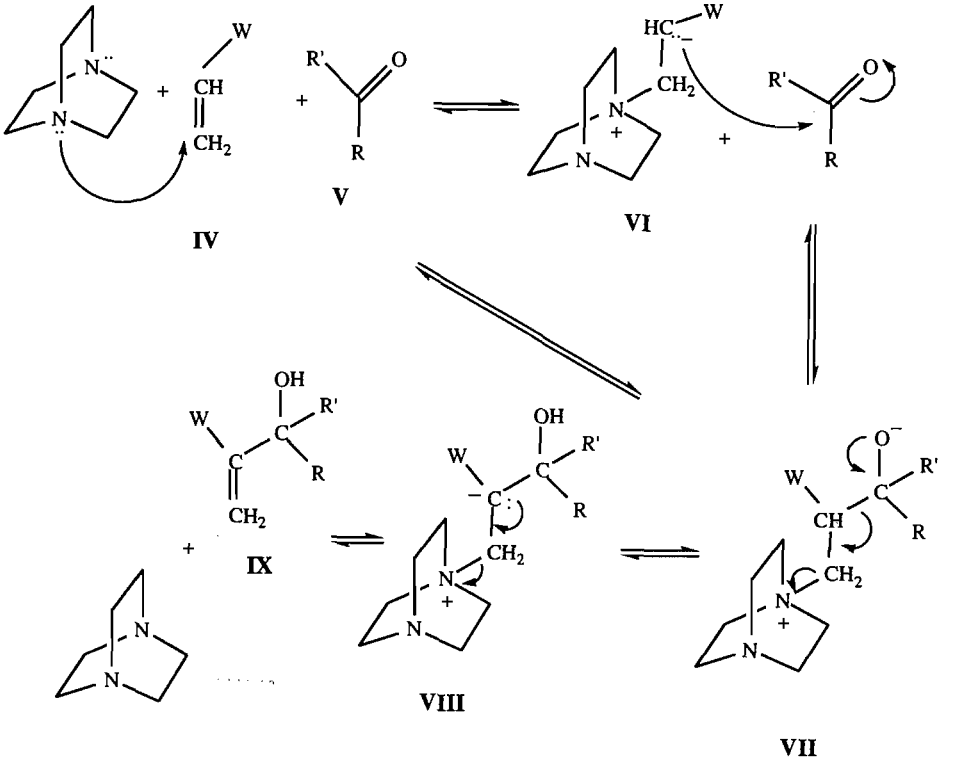
Scheme 1.



Scheme 2. W = electron-withdrawing group, e.g., -CHO, -COR, -COOR, -CN; R = alkyl or aryl; R′ = usually H.



stituents, thus providing support for the proposed mechanism of action of the natural phytotoxin and perhaps even suggesting leads for development of useful, environmentally benign, herbicides.

Acrolein features rarely as the conjugated carbonyl substrate (nucleophilic partner) in Baylis–Hillman-type condensations (with aldehydes), clearly because of its propensity to form oligomers or polymers under the basic catalysis employed. We considered that this hurdle might perhaps be surmounted by selection of appropriate reaction conditions. For example, successful condensations of acrolein with aldehydes have been reported under high (kbar) pressure, which effects a dramatic acceleration in the rates of Baylis–Hillman reactions (5). Alternatively, the desired hydroxy enals might in principle be accessible by selective reduction of the corresponding Baylis–Hillman-derived hydroxy acrylates or acrylonitriles.

In contrast to aldehydes, *ketones* are not generally considered to be reactive carbonyl partners in Baylis–Hillman reactions (again, except under high pressure (5)). It appeared to us that the enhanced reactivity of certain α-diketones towards aldol-type reactions (cf. ref. 6) might perhaps make them suitable partners for reaction with Baylis–Hillman-type vinyl carbanion equivalents. Indeed, α-keto esters have been found to possess the requisite reactivity (7).

This paper reports our investigation into the preparation of

compounds embodying functionality **IX**, via the Baylis–Hillman reaction of non-enolizable α-dicarbonyl precursors (**V**, R′ = COR″) with the "activated olefins" acrolein, methyl acrylate, and acrylonitrile (**IV**, W = CHO, CO_2Me, CN) (Scheme 2). The hydroxy enals obtained from successful reaction with acrolein were tested for phytotoxic activity in bioassays.

Results and discussion

As a prelude to this study, the behavior of acrolein with an aldehyde electrophile under typical Baylis–Hillman conditions was first examined. Reaction of acrolein with a large excess of benzaldehyde, no solvent, and 0.1 equivalent of either 1,4-diazabicyclo[2.2.2]octane (DABCO) or 3-quinuclidinol (3-QDL) as catalyst afforded, after 4 days at ambient temperature, a 12% yield (based on acrolein) of the desired hydroxy enal, **2***a*. In contrast, methyl acrylate and acrylonitrile gave, on 3-QDL catalyzed reaction with benzaldehyde under similar conditions, the Baylis–Hillman products, **2***b* and **2***c*, in yields of 85% and 82%, respectively.

Although this result did not augur well for the proposed use of acrolein in the Baylis–Hillman reaction, we proceeded to explore its feasibility with α-diketones as the electrophilic partners. In the absence of solvent, cyclohexane-1,2-dione exists as a tautomeric mixture containing about 40% of the enol form (8), and it appeared unlikely to be a suitable substrate for Baylis–Hillman reaction, a conjecture attested by the complex mixture resulting from its reaction with acrylonitrile and DABCO.[2] It was clear that any potential α-dicarbonyl substrate must be **non-enolizable**, leading us to the selection, for study purposes, of the readily available[3] 1,2-naphthoquinone, acenaphthenequinone, camphorquinone **3**, homoadamantane-2,3-dione **4** (9), bicyclo[3.3.2]decane-9,10-dione **5**, 3,3,5,5-tetramethylcyclopentane-1,2-dione **6**, dihydro-4,4-dimethyl-2,3-furandione **7**, and 3,3,6,6-tetramethylcyclohexane-1,2-dione **8** (10).

Racemic camphorquinone **3** readily underwent the 3-QDL catalyzed Baylis–Hillman reaction with acrylonitrile, affording, after 15 days at ambient temperature, the keto-hydroxynitrile, **11***c*, in 73% yield. The product was obtained as a single isomer, whose regio- and stereochemistry were tentatively assigned on the basis of the nuclear Overhauser enhancement between the hydroxylic proton and the C-4 bridgehead proton, as well as the protons of one of the two methyl groups on C-7. (*endo* Attack is, of course, expected to be favored for steric reasons.) A minor product, **12** (ca. 12%) , arising either from reaction of acrylonitrile dimer with **3**, or by conjugate addition to **11***c* of the anion derived from a second molecule of acrylonitrile, was obtained in some runs.

In contrast, treatment of camphorquinone **3** with methyl acrylate in the presence of 3-QDL for 17 days afforded unchanged camphorquinone and no trace of Baylis–Hillman product **11***b*. This result may be attributed to the hindered nature of the camphorquinone carbonyl groups, and the difference in steric demand between nitrile and ester. Perhaps not surprisingly, therefore, all attempts to prepare the desired model, **11***a*, directly

[2] R. Bethell and G.M. Strunz. Unpublished results.

[3] 1,2-Naphthoquinone, acenaphthenequinone, and compounds **3**, **6**, and **7** are commercially available. The 1,2-diketones **4**, **8**, and **9** were prepared essentially using literature procedures (9–11) (with some minor experimental modifications). Compound **5** was prepared from bicyclo[3.3.1]nonan-9-one by reduction of the corresponding cyanohydrin silyl ether, Tiffeneau-Demyanov ring expansion (12), and selenium dioxide oxidation of the ring-expanded ketone (cf. ref. 9). Norbornane-2,3-dione **9**, an apparently logical candidate for testing, is reported to be unstable (11), undoubtedly a contributing factor in the unsatisfactory results obtained on attempting the Baylis–Hillman reaction with acrylonitrile (8% yield of product **10**) Accordingly, it was not investigated further (with acrolein) in the present study. Neither of the conjugated aryl diones 1,2-naphthoquinone nor acenaphthenequinone was sufficiently reactive to afford satisfactory yields of Baylis–Hillman products with acrylonitrile,[2] and their reaction with acrolein was not pursued.

by Baylis–Hillman reaction of **3** with acrolein were unsuccessful. Reaction, either in the presence or absence of solvent (THF, benzene) catalyzed by DABCO, triethylamine, 3-hydroxyquinuclidine, 1,5,7-triazabicyclo[4.4.0]dec-5-ene on polystyrene, or triphenylphosphine (3), at temperatures ranging from −78°C to room temperature, or with ultrasonic radiation (13), resulted in polymerization of acrolein and, typically, recovery of unchanged camphorquinone, **3**.

Attempts to reduce **11***c* selectively to the desired aldehyde **11***a* using a wide variety of reagents and conditions (DIBAL, $LiAlH_2(OEt)_2$, $LiAlH_4$,Et_3SiH/Lewis acid, $SnCl_2$/HCl (Stephen reduction), etc.) were unsuccessful, vitiating the hope that interaction of the reducing reagent with the hydroxyl group might produce a complex capable of delivering hydrogen to the unhindered nitrile group. Only in the case of $LiAlH_2(OEt)_2$ was an aldehydic product isolated (albeit in low yield), but here accompanied by conjugate reductive displacement of the hydroxyl group. A possible mechanism for this transformation is depicted in Scheme 3. Results observed on treatment of benzaldehyde and the series of 1,2-dicarbonyl compounds **3–8** with acrylonitrile and acrolein under catalysis by 3-QDL are compiled in Table 1. As mentioned above, methyl acrylate afforded an 85% yield of the hydroxy acrylate **2***b* on reaction with benzaldehyde, but failed to give a Baylis–Hillman product with *any* of the α-dicarbonyl compounds. Of the α-dicarbonyl compounds tested, only 3,3,5,5-tetramethyl-

cyclopentane-1,2-dione **6** and the ketolactone **7** proved to be satisfactory substrates for Baylis–Hillman reaction with acrolein. In contrast to the readiness of 3,3,5,5-tetramethylcyclopentane-1,2-dione **6** to undergo the Baylis–Hillman reaction with acrolein and acrylonitrile, all attempts to effect the process with 3,3,6,6-tetramethylcyclohexane-1,2-dione **8**, under similar conditions, furnished unchanged diketone. This result may be attributed both to greater steric inhibition of nucleophilic attack at the carbonyl groups of **8**, and the lack of enhanced reactivity associated with "eclipsing" the two carbonyl groups (as in **6**).

It has previously been noted that the Baylis–Hillman reaction of acrylate esters, CH_2=CHCOOR, with aldehydes as electrophiles, is significantly influenced by steric and electronic properties of the R group (4). Furthermore, β-substituted acrylates (e.g., crotonyl systems) do not undergo the reaction even under high-pressure conditions (3). The sensitivity of the reaction to steric effects is highlighted in the present study by the dramatic contrast observed between the behavior of acrylonitrile and methyl acrylate, the former reacting readily with most of the 1,2-dicarbonyl compounds and the (more sterically demanding) ester failing to give *any* of the corresponding Baylis–Hillman products.

Notwithstanding the successful preparation of **16** and **18**, the Baylis–Hillman reaction is clearly not a generally useful synthesis of the desired keto hydroxy enal system **IX** (W = CHO, R′ = COR″). An alternative, more versatile approach was therefore briefly explored, using camphorquinone **3** as substrate, in order to augment the number of compounds available for bioassay. Reaction of **3** with the Grignard reagent prepared from 2-bromopropene and allylic oxidation of the product **20** provided a viable, if not wholly satisfactory solution, affording **11***a* in ca. 25% yield. Regioisomer **19**, resulting from *endo* attack of the Grignard reagent at the C-2 carbonyl was also obtained (25% via **21**) by this procedure. The structure and stereochemistry of these compounds were confirmed by nOe experiments.

Five hydroxy enal models, **2***a*, **11***a*, **16**, **18**, and **19** were thus readily accessible by simple methodology for phytotoxicity testing. Compound **16**, prepared in a single step by the Baylis–Hillman reaction, and **11***a* and **19**, accessible via a Grignard – allylic oxidation sequence, feature the keto hydroxy enal functional array present in bipolaroxin. As the liberation of acrolein, believed responsible for the phytotoxicity of bipolaroxin, is triggered by conjugate addition of a nucleophile to the enal system, it was clearly important to ascertain initially the in vitro stability of these compounds in aqueous medium. Accordingly, compound **16**, considered representative of the series, was dissolved in the minimum volume of methanol and stirred for 24 h at ambient temperature with aqueous buffers at pH 3.0, 7.0, and 10. Both TLC analysis and quantitative recovery of unaltered starting material attested to the relative stability of the hydroxy enal system in neutral and acidic aqueous medium (pH 7.0 and 3.0). On the other hand, the treatment at pH 10 predictably resulted in virtually quantitative conversion of **16** back to its diketone precursor **6**.

Bioassay results showing the ability of some of the hydroxyacroleins and acrylonitriles, as well as their precursor carbonyl compounds, to inhibit germination of lettuce seeds during an 8 day period (an indicator of phytotoxic activity) are compiled in Table 2. For seeds placed on agar in wells treated with 100 ppm solutions,[4] the ketolactone **7** did not show significant inhibition after 8 days, whereas the derived hydroxyacrolein **18** strongly inhibited germination (and the corresponding acrylonitrile **17** was also active). On the other hand, neither the α-diketone **6** nor its derivatives **16** or **15** were inhibitory at this concentration. Whereas camphorquinone **3** and the derived hydroxyacrolein **11***a* were essentially devoid of activity, the isomeric hydroxyacrolein **19** showed significant inhibition.

From these data, one can conclude that although the phytotoxicity of bipolaroxin may indeed result from in vivo liberation of acrolein as suggested (1, 2), structural features besides the presence of the implicated keto hydroxy enal functional array are necessary for the bioactivity. Interestingly, *both* benzaldehyde *and* its hydroxyacrolein derivative **2***a* strongly inhibited germination when applied at 100 ppm, indicating a different mode of action, at least in the former case.

When the bioassay period was extended to 16 days, inhibitory effects on germination and seedling growth were dramatically attenuated and were no longer detectable even for the 500 ppm treatments with any of the test compounds other than **17**, benzaldehyde, and **2***a*.

Experimental

General

Melting points were determined on a hot-stage apparatus and are uncorrected. Infrared spectra were recorded on a Philips Pye Unicam PU9516 infrared spectrophotometer. Accurate mass measurements were made on a Kratos MS-50 instrument. NMR spectra were recorded in $CDCl_3$ on a Varian XL-200 spectrometer operating at a frequency of 200.068 MHz for ^1H, and on a Varian Unity 400 operating at a frequency of 399.946 MHz for ^1H and100.564 MHz for ^{13}C.

2-[1′-(1′-Hydroxy-2′-oxo-3′,3′,5′,5′-tetramethylcyclopentyl)]-propenal 16

Acrolein (0.17 mL, 2.5 mmol) was added to a solution of 3,3,5,5-tetramethyl-1,2-cyclopentanedione **6** (382 mg, 2.5 mmol) in dry THF (5 mL) containing 3-quinuclidinol (3-QDL) (70 mg, 0.25 mmol). The reaction mixture was stirred at ambient temperature in a closed vessel for 3 days, when additional acrolein (0.17 mL, 2.5 mmol) was added. Stirring was continued for a further 2 days until TLC analysis indicated that reaction was complete. Water was then added and the mixture was extracted with ether (4 × 10 mL). The extracts were dried over $MgSO_4$ and removal of solvent on a rotary vacuum evaporator afforded the crude product (601 mg) as an orange-colored oil. Flash chromatography on silica gel (eluent: hexane-EtOAc, 5:1) furnished 379 mg (72%) of pure keto hydroxy enal **16** as an almost colorless oil; IR ($CHCl_3$): 3550 (sharp), 3500–3200, 3000–2800, 1740, 1690, 1455, 1370, 1300 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 0.82 (3H, s), 1.05 (3H, s), 1.23 (3H, s), 1.23 (3H, s), 1.84 (2H, ABq, J_{AB} = 13.0 Hz, $\Delta\nu$ = 76.1 Hz), 3.65 (1H, s), 6.35 (1H, s), 6.50 (1H, s), 9.52 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 210.1251 (5) (M^+) (calcd. for $C_{12}H_{18}O_3$: 210.1256), 195 (3) ($M-CH_3$), 182 (6) (M − CO),

[4] All of the compounds tested inhibited germination of lettuce seeds when the concentration was increased to 10 000 ppm.

2-[1′-(1′-Hydroxy-2′-oxo-3′,3′,5′,5′-tetramethylcyclopentyl)]-acrylonitrile 15

3,3,5,5-Tetramethyl-1,2-cyclopentanedione **6** (301 mg, 1.95 mmol) and 3-QDL (50 mg, 0.195 mmol) were dissolved in acrylonitrile (5.0 mL). The solution was stirred at ambient temperature in a closed vessel for 3 days. Ether was added and the mixture was washed with water and brine and dried over $MgSO_4$. Removal of solvent on a rotary vacuum evaporator afforded 402 mg (100%) of chromatographically pure **15** as a pale brown solid, mp 104°C; IR ($CHCl_3$): 3550 (sharp), 3400–3200, 3000–2850, 2240, 1740, 1460 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.05 (3H, s), 1.09 (3H, s), 1.22 (3H, s), 1.25 (3H, s), 1.92 (2H, ABq, J_{AB} = 13.2 Hz, $\Delta\nu$ 69.6 Hz), 2.77 (1H, br s), 6.18 (1H, s), 6.25 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 207.1259 (14) M^+) (calcd. for $C_{12}H_{17}NO_2$: 207.1260), 123 (100) ($M - C_5H_8O$), 108 (7) ($M - C_5H_8O - CH_3$).

Baylis–Hillman reaction of acrylonitrile and camphorquinone

Racemic camphorquinone **3** (2.530 g, 22 mmol) and 3-QDL (280 mg, 2.2 mmol) were dissolved in acrylonitrile (15.0 mL). The solution was stirred in a closed vessel at ambient temperature for 18 days, during which time the color changed from yellow to dark red. After addition of water, the mixture was extracted thoroughly with ether and the extracts were washed with brine and dried over $MgSO_4$. The crude amorphous product obtained on removal of solvent on a rotary vacuum evaporator was purified by flash chromatography on silica gel. Elution with hexane–EtOAc (5:1) afforded pure **11***c* (3.517 g; 73%) as a white solid, mp 73°C; IR ($CHCl_3$): 3550 (sharp), 3100–2850, 2220, 1750 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 0.87 (3H, s), 1.00 (3H, s), 1.01 (3H, s), 1.24–1.40 (2H, m), 1.59–1.66 (1H, m), 1.86–1.96 (1H, m), 2.21 (1H, d, J = 4.8 Hz), 3.49 (1H, br s), 5.68 (1H, s), 5.87 (1H, s); ^{13}C NMR ($CDCl_3$) δ: 9.2 (q), 20.3 (q), 21.9 (q), 22.6 (t), 27.8 (t), 45.5 (s), 51.2 (d), 58.9 (s), 79.1 (s), 116.5 (s), 124.9 (s), 130.0 (t), 215.8 (s); FABMS (NOBA matrix): 220 (19) ($M^+ + H$), 219 (23) (M^+), 204 (6) ($M - CH_3$), 202 (13) ($M - OH$), 174 (100).

A minor by-product **12** (718 mg; 12%) eluted after **11***c*; IR $CHCl_3$): 3550, 3000–2850, 2275, 2240, 1740 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 0.92 (3H, s), 1.00 (3H, s), 1.05 (3H, s), 1.21–1.28 (1H, m), 1.38–1.45 (1H, m), 1.63–1.70 (1H, m), 1.89–1.99 (1H, m), 2.29 (1H, d, J = 4.4 Hz), 2.50–2.53 (2H, ~t), 3.62–3.66 (1H, m), 3.80–3.84 (1H, m), 5.86 (1H, s), 6.18 (1H, s); ^{13}C NMR ($CDCl_3$) δ: 9.4 (q),19.1 (d), 20.3 (q), 22.3, 22.3 (t/q), 28.7 (t), 45.7 (s), 52.4 (d), 59.9, 60.0 (t/s), 83.2 (s), 116.0 (s), 117.3 (s), 121.6 (s), 133.8 (t), 212.9 (s); HREIMS, *m/z* (relative intensity) (ion): 272.1521 (1) (M^+) (calcd. for $C_{16}H_{20}N_2O_2$: 272.1525), 244 (11) ($M - CO$), 243 (10) ($M - CHO$), 229 (5) ($M - CO - CH_3$), 189 (3) ($C_{11}H_{13}N_2O$), 188 (6) ($C_{11}H_{12}N_2O$), 83 (100) (C_6H_{11}).

3-Phenyl-3-hydroxy-2-methylenepropanonitrile 2*c*

Standard procedure as above: acrylonitrile (0.66 mL, 10 mmol), benzaldehyde (5 mL), DABCO (112 mg, 1 mmol), ambient temperature, 8 days. The crude product obtained on work-up was purified by flash chromatography on silica gel. Elution with hexane–EtOAc (2:1) furnished 1.3 g (82% from acrylonitrile) of chromatographically pure **2***c* as a clear colorless oil; IR ($CHCl_3$): 3600 (sharp), 3550–3200, 3150–2800, 2240, 1490, 1455, 1395 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 3.98 (2H, ABq, J_{AB} = 3.9 Hz, $\Delta\nu$ = 514 Hz), 6.01 (1H, d, J = 1.2 Hz), 6.09 (1H, d, J = 1.6 Hz), 7.38 (5H, s); HREIMS, *m/z* (relative intensity) (ion): 159.0687 (36) (M^+) (calcd. for $C_{10}H_9NO$: 159.0684), 107 (100) (C_7H_7O), 79 (52) (C_6H_7), 77 (48) (C_6H_5).

Methyl 3-phenyl-3-hydroxy-2-methylenepropanoate 2*b*

Standard procedure: methyl acrylate (1.15 mL, 12.8 mmol), benzaldehyde (10 mL), DABCO (143 mg, 1.28 mmol), ambient temperature, 8 days. The crude product obtained after work-up was purified by flash chromatography on silica gel. Elution with hexane–EtOAc (2:1) furnished 2.09 g (85% from methyl acrylate) of chromatographically pure **2***b* as a clear colorless oil; IR ($CHCl_3$): 3600 (sharp), 3550–3300, 3100–2850, 1720, 1630 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 3.00 (1H, br), 3.73 (3H, s), 5.57 (1H, br), 5.83 (1H, t, J = 1.2 Hz), 6.34 (1H, d, J = 0.8 Hz), 7.26–7.40 (5H, m); HREIMS, *m/z* (relative intensity) (ion): 192.0798 (41) (M^+) (calcd. for $C_{11}H_{12}O_3$: 192.0786), 105 (100) (C_7H_5O),191 (38) ($C_{11}H_{11}O_3$), 160 (49) ($C_{10}H_8O_2$), 159 (11) ($C_{10}H_7O_2$), 132 (47)(C_9H_8O).

3-Phenyl-3-hydroxy-2-methylenepropanal 2*a*

Standard procedure: acrolein (1.00 mL, 15.0 mmol), benzaldehyde (10 mL), DABCO (141 mg, 1.3 mmol), ambient temperature, 8 days. The crude product, obtained after work-up, was purified by flash chromatography on silica gel. Elution with hexane–EtOAc (3:1) furnished 292 mg (12% from acrolein) of chromatographically pure **2***a* as a clear colorless oil; IR ($CHCl_3$): 3600 (sharp), 3550–3300, 3150–2700, 1685 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 4.20 (2H, ABq, J_{AB} = 4.3 Hz, $\Delta\nu$ 571 Hz), 6.16 (1H, s), 6.44 (1H, s), 7.26–7.38 (5H, m), 9.58 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 162.0666 (34) (M^+) (calcd. for $C_{10}H_{10}O_2$: 162.0681), 161 (100) ($C_{10}H_9O_2$),107 (14) (C_7H_7O), 105 (19) (C_7H_5O), 79 (28) (C_6H_7).

Dihydro-4,4-dimethyl-3-hydroxy-3-(1′-cyanovinyl)-2-furanone 17

Standard procedure: dihydro-4,4-dimethyl-2,3-furandione (**7**) (499 mg, 3.9 mmol), 3-QDL (100 mg, 0.78 mmol), acrylonitrile (5.0 mL), ambient temperature, 24 h. Flash chromatography (silica gel; hexane–EtOAc, 3:1) of the crude product obtained on work-up afforded **17** (508 mg, 81% from ketolactone) as a colorless crystalline solid, mp 71°C; IR ($CHCl_3$): 3550 (sharp), 3500–3100, 3000–2850, 2250, 1780, 1465, 1400, 1370 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ:1.13 (3H, s), 1.19 (3H, s), 3.55 (1H, s), 4.09 (2H, ABq, J_{AB} = 8.9 Hz, $\Delta\nu$ = 22.9 Hz), 6.15 (1H, s), 6.26 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 136.0756 (7) ($M^+ - H - CO_2$) (calcd. for $C_8H_{10}NO$: 136.0763), 122 (100) (C_7H_8NO).

Dihydro-4,4-dimethyl-3-hydroxy-3-(1′-formylvinyl)-furanone 18

To a solution of dihydro-4,4-dimethyl-2,3-furandione **7** (533 mg, 4.2 mmol) in dry THF containing 3-QDL (105 mg, 0.83 mmol) was added acrolein (0.3 mL, 4.5 mmol). The mixture was stirred at ambient temperature in a closed vessel for 3

For personal use only.

days. (Addition of more acrolein during the course of the reaction did not enhance the yield.) Flash chromatography (silica gel; hexane–EtOAc, 2:1) of the crude product obtained on work-up afforded **18** (240 mg, 31% from ketolactone) as a pale yellow crystalline solid, mp 77°C; IR ($CHCl_3$): 3600–3200, 3150–2800, 1775, 1730, 1685, 1465, 1380 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 0.91 (3H, s), 1.18 (3H, s), 3.95 (1H, br), 3.99 (2H, ABq, J_{AB} = 8.8 Hz, $\Delta\nu$ = 35.4 Hz), 6.39 (1H, s), 6.56 (1H, s), 9.57 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 139.0757 (4) ($M^+ - H - CO_2$) (calcd. for $C_8H_{11}O_2$: 139.0759), 125 (100) ($C_7H_9O_2$), 107 (12) (C_7H_7O).

2-Oxo-3-(*endo*)-hydroxy-3-(*exo*)-(1′-cyanovinyl)-bicyclo[2.2.1]heptane 10[5]

A solution of 2-norbornanone (2.88 g, 26.1 mmol) in xylenes (ca. 10 mL) was heated at 135°C with selenium dioxide (3.861 g, 35.0 mmol) for 4 h. The (crude) yellow-orange solid obtained after filtration and removal of solvent in vacuo was dissolved in acrylonitrile (ca. 5 mL) and 3-QDL (436 mg, 3.4 mmol) was added. The red reaction mixture was stirred at ambient temperature in a closed vessel for 24 h. The crude material obtained on work-up was purified on silica gel and **10** (366 mg, 8% from 2-norbornanone) was eluted with hexane–EtOAc (2:1). The product **10** was a colorless solid, mp 83°C; IR ($CHCl_3$): 3550, 3000–2850, 2220, 1750 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.60–1.69 (3H, m), 1.75–1.79 (1H, m), 1.88–1.96 (1H, m), 2.05–2.12 (1H, m), 2.70–2.72 (1H, m), 2.83–2.84 (1H, m), 3.26 (1H, s), 5.79 (1H, s), 6.03 (1H, s); ^{13}C NMR ($CDCl_3$) δ: 19.7 (t), 27.1 (t), 32.4 (t), 44.4 (d), 48.8 (d), 80.1 (s), 116.3 (s), 123.5 (s), 133.1 (t), 215.4 (s); HREIMS, *m/z* (relative intensity) (ion): 177.0796 (7) (M^+) (calcd. for $C_{10}H_{11}NO_2$: 177.0790), 149 (13) ($M^+ - CO$), 108 (100) (C_6H_6NO).

Acrylonitrile-homoadamantane-2,3-dione reaction

Standard procedure: homoadamantane-2,3-dione **4** (prepared according to ref. 10 with some modifications) (98 mg, 0.55 mmol), 3-QDL (15 mg, 0.01 mmol), acrylonitrile (ca 5 mL), ambient temperature, 24 h. Flash chromatography (silica gel; hexane–EtOAc, 2:1) of the crude product obtained on work-up afforded **13** (88 mg,70%) as a colorless crystalline solid, mp 78°C; IR ($CHCl_3$): 3500, 2950, 2240, 1700, 1450 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 1.63–2.14 (11H, m), 2.32–2.34 (1H, m), 2.88–2.97 (2H, m), 3.75 (1H, br), 5.49 (1H, s), 5.99 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 231.1260 (52) (M^+) (calcd. for $C_{14}H_{17}NO_2$: 231.1260), 203 (26) ($M^+ - CO$), 202 (16) ($M^+ - H - CO$), 121 (23) (C_9H_{13}), 108 (42) (C_8H_{12}), 107 (24) (C_8H_{11}), 95 (75) (C_7H_{11}), 79 (100) (C_6H_7).

Acrylonitrile–bicyclo[3.3.2]decane-9,10-dione reaction

Standard procedure: bicyclo[3.3.2]decane-9,10-dione **5** (48.5 mg, 0.29 mmol) (prepared from bicyclo[3.3.1]nonan-9-one by reduction of the corresponding cyanohydrin silyl ether, Tiffeneau–Demyanov ring expansion (13), and selenium dioxide oxidation of the ring-expanded ketone (cf. ref. 10)), 3-QDL (10 mg, 0.079 mmol), acrylonitrile (5.0 mL), ambient temperature, 24 h. Preparative TLC (silica gel; hexane–EtOAc, 5:1) of the crude product obtained on work-up afforded **14** (43 mg, 68%) as a colorless crystalline solid, mp 90°C; IR ($CHCl_3$): 3600–3400, 3000–2800, 2240, 1690, 1450 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 1.46–2.00 (11H, m), 2.14–2.19 (1H, m), 2.55–2.57 (1H, m), 3.08–3.13 (1H, m), 3.5 (1H, br), 5.50 (1H, s), 5.99 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 219.1256 (5) (M^+) (calcd. for $C_{13}H_{17}NO_2$: 219.1260), 191 (49) ($M^+ - CO$), 176 (12) ($M^+ - CO - CH_3$), 162 (20) ($C_{10}H_{12}NO$), 148 (15) ($C_9H_{10}NO$), 134 (12) (C_8H_8NO), 121 (28) (C_7H_7NO), 120 (10) (C_7H_6NO), 96 (100) (C_7H_{12}).

Reaction of camphorquinone with Grignard reagent from 2-bromopropene

Camphorquinone (racemic) **3** (1.87 g,11.3 mmol) in anhydrous THF was added under argon during 15 min to the Grignard reagent prepared from 2-bromopropene (1.02 mL, 11.5 mmol) and magnesium turnings (280 mg, 11.5 mg atom) in THF at −78°C. The mixture was stirred at the same temperature under an argon atmosphere for 2 h and the reaction was then quenched by addition of saturated NH_4Cl solution. Flash chromatography (silica gel; hexane–EtOAc, 5:1) of the crude product obtained on conventional work-up gave a clean mixture of regioisomeric products resulting from (*endo* sterically favored) attack of the reagent at the 2- or the 3-carbonyl group of camphorquinone. NMR analysis of the mixture indicated that the ratio of products arising from attack at C-2 and C-3, respectively, was about 6:5. Repeated flash chromatography of the mixture using the same solvent system allowed the isomers to be separated and isolated as crystalline solids. Their structures could be distinguished on the basis of nOe experiments, in particular the nOe enhancement between the hydroxyl and the bridgehead protons in the 3-hydroxy-3-isopropenyl isomer **20**, and its absence in the "C-2" regioisomer, **21**. The latter was the less polar product, mp 45°C; IR ($CHCl_3$): 3600–3500 (sharp), 3300–3200 (br), 3000–2800, 1730 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 0.95 (3H, s), 1.07 (3H, s), 1.08 (3H, s), 1.45–1.55 (2H, m), 1.61–1.68 (1H, m), 1.82–1.86 (4 H), 2.18–2.20 (1H, d), 2.32 (1H, s), 4.69 (1H, s), 4.83 (1H, d, J = 0.8 Hz); HREIMS, *m/z* (relative intensity) (ion): 208.1455 (33) (M^+) (calcd. for $C_{13}H_{20}O_2$: 208.1464), 111 (100) ($C_7H_{11}O$) ($M^+ - C_6H_9O$), 193 (13) ($M^+ - CH_3$), 153 ($C_9H_{13}O_2$) ($M^+ - C_4H_7$), 152($C_9H_{12}O_2$) ($M^+ - C_4H_8$), 140 (21) ($C_8H_{12}O_2$), 137 (15) ($C_9H_{13}O$), 126 ($C_7H_{10}O_2$), 121 (10) (C_9H_{13}).

The 3-hydroxy-3-isopropenyl isomer **20** had mp 57°C; IR ($CHCl_3$): 3600–3500 (sharp), 3500–3200 (br), 3000–2800, 1730 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz) δ: 0.95 (3H, s), 0.98 (3H, s), 1.05 (3H, s), 1.32–1.42 (2H, m), 1.59 (1H, m), 1.79–1.84 (4H), 2.07 (1H, d, J = 4.4 Hz), 2.28 (1H, s), 4.72 (1H, s), 4.82 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 208.1462 (26) (M^+) (calcd. for $C_{13}H_{20}O_2$: 208.1464), 180 (32) ($M^+ - CO$), 137 (12) ($C_9H_{13}O$) ($M^+ - C_4H_7O$), 97 (100) (C_6H_9O), 84 (71) (C_6H_{12}), 69 (13) (C_5H_9), 69 (13) (C_4H_5O).

Keto-hydroxyenal 11*a*

To the 3-hydroxy-3-isopropenyl Grignard product **20** (472 mg, 2.27 mmol) in dry methylene chloride (ca. 10 mL) was added selenium dioxide (504 mg, 4.5 mmol) and *tert*-butyl hydroperoxide (0.9 mL of 90% solution, 9.1 mmol). The mixture was heated under gentle reflux for 6 days. When cool, the mixture was filtered, and the filtrates were washed with water and brine and dried over $MgSO_4$. The crude product, obtained after removal of solvent in vacuo, was subjected to flash chro-

[5] Stereochemistry tentatively assigned, based on presumably preferred *exo* attack of nucleophile on carbonyl.

matography on silica gel (hexane–EtOAc, 5:1), affording 328 mg (65%) of chromatographically pure **11***a* as an orange-colored oil; IR ($CHCl_3$): 3600–3500 (sharp), 3100–2800, 1745, 1690 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 0.95 (3H, s), 0.99 (3H, s), 1.10 (3H, s), 1.20–1.34 (2H, m), 1.54–1.68 (1H, m), 1.76–1.91 (1H, m), 2.51 (1H, d, J = 4.4 Hz), 2.86 (1H, br), 6.07 (1H, s), 6.21 (1H, s), 9.57 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 222.1259 (21) (M^+) (calcd. for $C_{13}H_{18}O_3$: 222.1256), 194 (15), ($M^+ - CO$), 179 (35) ($M^+ - CO - CH_3$), 138 (100) ($C_8H_{10}O_2$) ($M^+ - C_5H_8O$), 125 (13) ($C_7H_9O_2$) ($M^+ - C_6H_9O$), 123 (11) ($C_7H_7O_2$) ($M^+ - C_6H_{11}O$), (121) (11) (C_8H_9O), 95 (18) (C_7H_{11}).

Keto-hydroxyenal 19

Procedure as for isomer **11***a* using 2-hydroxy-2-isopropenyl precursor **21** (240 mg, 1.15 mmol) in methylene chloride (5.0 mL), selenium dioxide (256 mg, 2.3 mmol), and *tert*-butyl hydroperoxide (0.46 mL of 90% solution, 4.6 mmol). The product, **19**, was obtained after chromatography as a yellow oil in a yield of 179 mg (70%); IR ($CHCl_3$): 3600–3500 (sharp), 3100–2900, 1750, 1680 cm^{-1}; ^1H NMR ($CDCl_3$, 200 MHz) δ: 0.97 (3H, s), 1.03 (3H, s), 1.12 (3H, s), 1.16–1.27 (1H, m), 1.43–1.71 (2 H, m), 1.80–1.91 (1H, m), 2.29 (1H, d, J = 4.8 Hz), 3.60 (1H, br), 6.18 (1H, s), 6.23 (1H, s), 9.54 (1H, s); HREIMS, *m/z* (relative intensity) (ion): 222.1250 (11) (M^+) (calcd. for $C_{13}H_{18}O_3$: 222.1256), 221 (34) ($M^+ - H$), 207 (28) ($M^+ - CH_3$), 205 (30) ($M^+ - OH$), 179 (17) ($M^+ - CO - CH_3$), 161 (14) ($M^+ - CO - CH_3$-H_2O), 151 (12) ($C_6H_{11}O_2$) ($M^+ - C_4H_7O$), 125 (100) ($C_7H_9O_2$) ($M^+ - C_6H_9O$), 121 (C_9H_{13}), 112 (17) ($C_6H_8O_2$) ($M^+ - C_7H_{10}O$), 111 (31) ($C_6H_7O_2$) ($M^+ - C_7H_{11}O$), 109 (26) (C_8H_{13}), 109 (21) (C_7H_9O), 97 (28) (C_6H_9O), 95 (55) (C_7H_{11}).

Bioassays

Bioassay wells consisted of 10 mL test tubes containing 7 mL of autoclaved 8% water–agar that had been allowed to harden. A 10 000 ppm stock solution in ethyl acetate and a dilution series of each test compound in the same solvent was prepared. A 500 μL volume of the appropriate test solution was deposited as a layer on the surface of the agar in each well. The solvent was allowed to evaporate in a laminar air flow, leaving a residue of the compound on the agar surface. (In cases where capillary attraction and rapid crystallization deposited the compounds on the sides of the test tubes rather than on the agar, the crystals were redissolved in 500 μL of ethyl acetate and the solvent evaporated again.) Controls were untreated and solvent treated.

Four or five sterilized leaf lettuce seeds were then placed in contact with the treated agar surface in each vial, and the vials were wrapped in foil to maintain sterile conditions and exclude light (four replicates per treatment). After 8 days, inhibition of germination was rated visually. In Table 2, the score "+++" indicates maximum inhibition (usually seed coat split with no radicle development). The designation "−" indicates normal (or near normal) germination and seedling growth (seedling length) relative to controls.

Acknowledgements

Financial support from the Canadian Forest Service Green Plan BICOVER Network and from the Ontario Ministry of Natural Resources (ARIO) is gratefully acknowledged. We are indebted to Dr. Peter Penner, University of New Brunswick, for recording some of the NMR spectra, and to Mr. Dan Drummond, UNB, for the mass spectra.

Studies on the transannular Diels–Alder reaction of 15-membered macrocyclic trienes containing a *trans-trans* diene. Part I: Synthesis and isomerization of various model cyclopentadecatrienes[1]

Dennis G. Hall, Renate Müller, and Pierre Deslongchamps

Abstract: The transannular Diels–Alder reaction of 15-membered macrocyclic trienes with a *trans-trans-cis* (TTC) olefin geometry can lead to A.B.C.[6.6.7] tricyclic products of *trans-syn-trans* (TST) and *cis-syn-cis* (CSC) stereochemistry whereas the TTT isomers can produce the *trans-anti-cis* (TAC) and *cis-anti-trans* (CAT) tricycles. In order to study the influence of the position (pro-6.6 or pro-6.7) and the nature (alkyl, alkoxymethyl, or formyl) of the dienophile substituent, a set of 10 model cyclopentadecatrienes was prepared. The synthesis of appropriately functionalized trisubstituted dienophile and diene synthons, as well as their coupling reactions affording acyclic precursors, is described in this paper (first in a series of two). A mild and efficient macrocyclization protocol yielded the required methyl- or alkoxymethyl-substituted cyclic substrates. Further transformations led to the formyl-substituted ones. In particular, the TTT macrocycles containing an enal as a dienophile could be completely isomerized to the corresponding TTC thermodynamic isomers in acidic aqueous media.

Key words: transannular, Diels–Alder, 15-membered ring, A.B.C.[6.6.7] tricycles, diterpene.

Résumé : La réaction de Diels–Alder transannulaire des triènes macrocycliques à 15 membres ayant une géométrie *trans-trans-cis* (TTC) peut mener aux produits tricycliques A.B.C.[6.6.7] de stéréochimie *trans-syn-trans* (TST) et *cis-syn-cis* (CSC) tandis que les isomères TTT peuvent produire les tricycles *trans-anti-cis* (TAC) et *cis-anti-trans* (CAT). Dans le but d'étudier l'influence de la position (pro-6.6 ou pro-6.7) et la nature (alkyle, alkoxyméthyle ou formyle) du substituant sur le diénophile, un ensemble de 10 cyclopentadécatriènes modèles fut préparé. La synthèse de synthons diénophiles trisubstitués et dienes adéquatement fonctionnalisés ainsi que leur réaction de couplage fournissant les précurseurs acycliques sera décrite dans cet article (le premier dans une série de deux). Un protocole de macrocyclisation doux et efficace a fourni les substrats cycliques désirés substitués d'un méthyle ou d'un groupement alkoxyméthyle. Des transformations subséquentes ont mené aux dérivés substitués avec un groupement formyle. En particulier, les macrocycles TTT contenant un énal comme diénophile ont pu être complètement isomérisés, en milieu aqueux acide, aux isomères thermodynamiques TTC correspondants.

Mots clés : transannulaire, Diels–Alder, cycle à 15 membres, tricycles A.B.C.[6.6.7], diterpène.

Introduction

One major goal of contemporary organic synthesis is to raise chemical efficiency by allowing a methodology, or a reaction, to accomplish the construction of complex structures in a minimal number of steps (1). Such efforts from our laboratory (2) and others (3) have led to the development of a promising synthetic stategy: the transannular Diels–Alder (TADA) reaction. In this case, the [4+2] cycloaddition of macrocyclic trienes is associated with a smaller energy of activation than that of acyclic trienes. This is a great benefit of the TADA strategy, leading to the one-step formation of tricyclic compounds possessing four new stereogenic centers. We have indeed exploited this higher state of reactivity in the past by successfully employing cycloaddition partners normally associated with poor reactivity. Such examples include enol ethers (4) and unactivated tetrasubstituted alkenes (5) as dienophiles as well as open-chain dienes with a strongly disfavored *trans-cis* geometry (6).[3]

[3] The superiority of the TADA approach versus its intramolecular variant, the IMDA reaction (7), was further demonstrated by us (2) and by Schreiber and co-workers (3*d*). In each of these examples, a given triene failed to undergo the desired cycloaddition even at high temperatures whereas prior cyclization gave highly reactive cyclic trienes, which indeed gave satisfaction to their conceptors by reacting smoothly at low temperatures.

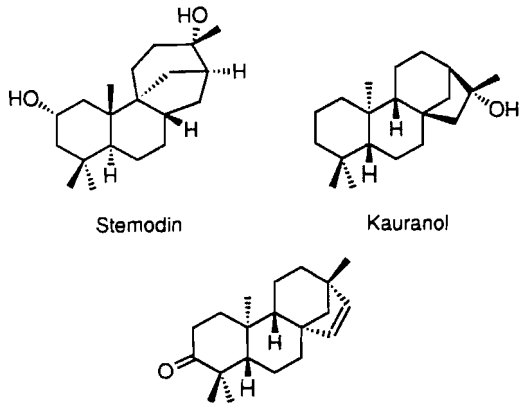
Scheme 1.



Previous fundamental studies from our group concentrated on 13- and 14-membered macrocyclic trienes, leading, respectively, to A.B.C.[6.6.5] and [6.6.6] tricycles (2). A logical step in extending the scope of the TADA strategy is to explore other systems such as 15-membered macrocyclic trienes. The resulting A.B.C[6.6.7] tricyclic compounds are part of a substructure found in a substantial number of naturally occurring compounds such as the stemodanes, kauranes, and stachanes (8). Some significant examples are illustrated in Scheme 1.

We wish to report in this article the full details of our investigation on the TADA reaction of 15-membered macrocyclic trienes bearing a *trans-trans* (TT) diene and various dienophiles with either *trans* (T) or *cis* (C) geometry.[4]

In comparison with their lower homologs, these larger substrates are likely to require higher temperatures to collapse into tricycles owing to larger activation parameters ($\Delta H^{\neq}$ and $\Delta S^{\neq}$). In other words, proximity effects are expected to show a reduced influence along the reaction pathway. Whereas the 14-membered TTC and TTT macrocyclic trienes[5] were concomitantly undergoing the TADA reaction under macrocyclization conditions (80°C) (*6b*), the 15-membered trienes should be isolable on the basis of the aforementioned arguments. Accordingly, an investigation of the reaction conditions will be a possible issue. A study of dienophile substituent effects (nature, geometry, and position) is indeed highly desirable in order to identify and understand the factors controlling stereoselection. To this end, a set of model cyclopentadecatrienes containing an *E,E*-diene moiety was devised (Scheme 2). These substrates were planned to bear a methyl, a methoxymethyl (MOM)-protected hydroxymethyl, or a formyl substituent on the dienophile, either placed at a position leading to a substitution at the angular [6.6] or [6.7] ring junction. In principle, by virtue of *endo* or *exo* approaches, TTT macrocycles (**1–5**) can lead to two tricyclic diasteromers, namely of *trans-anti-cis* (TAC) (**1a–5a**) and CAT (**1b–5b**) stereochemistry at ring junctions. In turn, the TTC geometrical isomers (**6–10**) can give tricycles of *trans-syn-trans* (TST) (**5a–10a**) and CSC (**5b–10b**) stereochemistry. The construction of conveniently functionalized dienophile and diene synthons, as well as their elaboration into macrocyclic trienes **1–10**, is described in this article (Part I).

Methods and discussion

Our general retrosynthetic approach for the synthesis of model macrocyclic substrates **1–10** is outlined in Scheme 3. This simple convergent strategy, using preformed diene and dienophile synthons with malonate connectors, is based on our earlier work on smaller ring systems (2). Thus, macrocyclic trienes are obtained through anionic cyclization of the corresponding chlorotrienes. The latter derive from a coupling reaction of a diene-substituted malonate anion with a homoallylic chloride. The appropriately functionalized dienophile synthons (methyl or MOMO-methyl) are prepared by a methodology allowing the obtention of both geometric isomers in pure form. Position isomerism, i.e., a pro-6.6 or pro-6.7 dienophile substituent,[6] depends on the selected site of substitution in the coupling reaction. Finally, formyl-substituted macrocyclic trienes are accessed via a hydrolysis–oxidation sequence on the corresponding MOMO-methyl analogs.

Preparation of *E,E* dienes 21 and 23

The basic strategy for the preparation of *trans-trans* diene synthons **21** and **23**, as illustrated in Scheme 4, employs Horner–Emmons methodolgy for stereoselective olefination (10). Mono-protection of propanediol as a tetrahydropyranyl ether, followed by Swern oxidation (11), gave aldehyde **12**. Condensation of the latter with the sodium anion of ethyl diisopropyl phosphonoacetate yielded the *E* α,β-unsaturated ester **13**. Diisobutylaluminum hydride reduction then furnished allylic alcohol **14** in high yield. A second oxidation–olefination–reduction sequence led to alcohol **17**, which was protected as its *tert*-butyldiphenylsilyl ether **18**. The homoallylic alcohol function was liberated through acidic alcoholysis of the tetrahydropyranyl ether[7] to give **19**. Mesylation of the latter followed by nucleophilic substitution with the sodium anion of dimethyl malonate resulted in the isolation of diene synthon **21**. Protecting group interchange could be realized by silyl ether cleavage with fluoride ion, yielding alcohol **22**, which was acylated with pivaloyl chloride to give **23**.

Preparation of *E* dienophile 28 and *Z*-30

An *E/Z* mixture of trisubstituted alkene **26**, prepared according to our previously reported method (*6a*), was treated with tetra-*n*-butylammonium fluoride to give alcohols **27** and **29**, which were separated by chromatography although with some difficulties (Scheme 5). Each of these could be activated prior to the subsequent coupling reaction by formation of the corresponding methanesulfonate esters **28** and **30**.

Preparation of *Z* dienophile 40 and *E* 47

The syntheses of isomeric (methoxymethoxy)methyl-substituted dienophiles **40** and **47** (Scheme 6) also relies on a Horner-Emmons reaction, using α-diethylphosphono-γ-butyrolactone (12) to generate a 47:53 **33*E*/33*Z*** mixture upon con-

[4] For preliminary communications of this work see ref. 9.

[5] The letters (C and T) refer to the olefin geometry of the macrocycles only; the first two letters refer to the diene geometry and the last one to that of the dienophile.

[6] The pro-6.7 and pro-6.6 nomenclature refers to the respective C1 (R^1) and C2 (R^2) angular positions on the resulting tricycles (see Scheme 2).

densation with aldehyde **32**. Such a lack of selectivity was desirable to fulfill our needs in both isomers as the resulting *E* and *Z* alkylidene lactones can be easily separated on silica gel chromatography. Confirmation of double bond geometries came from ^{1}H nmr nOe experiments where only one lactone, evidently **33***E*, showed some enhancement between the allylic methylenes. The *Z* synthon **40** was constructed by making use of the same straightforward sequence applied for the recently reported synthesis of the *E* isomer **47** (13). To this end, lactone **33***Z* was subjected to a four-step sequence dealing with some unstable intermediates that had to be reacted without delay. Diisobutylaluminum hydride reduction furnished a crude mixture of **34** and **35** that was then treated with manganese dioxide, yielding homogeneous aldehyde **35**. Acetylation of the remaining alcohol function gave **36** and sodium borohydride reduction furnished pure allylic alcohol **37** in 56% overall yield from **33***Z*. Protection of alcohol **37** as a MOM ether gave **38**. Then, methanolysis of the acetate group led to the isolation of alcohol **39**, the ready precursor of mesylate **40**.

Preparation of *Z* dienophile 49

Compared to **40**, the preparation of **49** was envisaged for coupling with the diene synthon at the opposite extremity of the unsymmetrical dienophile, thus eventually leading to macrocycles with alkoxymethyl substitution at the pro-6.6 position. Desilylation of **38** with fluoride ion followed by mesylation of the resulting alcohol **48** furnished the desired dienophilic coupling partner **49** (Scheme 7).

Synthesis of TTT macrocyclic substrate 1 and TTC 6

As shown in Scheme 3, the elaboration of acyclic trienes into the desired macrocycles starts with the coupling reaction of an appropriately functionalized diene synthon with the required dienophile counterpart. The syntheses of isomeric macrocyclic trienes TTT **1** and TTC **6** with a methyl substituent on the dienophile use the same reaction sequence, performed in parallel from both *E* and *Z* alkenes **28** and **30** (Scheme 8). Thus, the sodium anion derived from diene-substituted malonate **21** was alkylated with the aforementioned homoallylic

pentadecatrienes **53** and **59**. Silyl ether cleavage of the latter compounds gave the respective alcohols **54** and **60**. These intermediates were then chlorinated using the method of Collington and Meyers (14), and the corresponding sensitive chlorides **55** and **61** were immediately cyclized at 75°C under our usual pseudo-high-dilution conditions (syringe pump addition over >10 h into a stirred cesium carbonate suspension), affording high yields of TTT macrocycle **1** and TTC isomer **6**.

Following our expectation as discussed in the introduction, no Diels–Alder products were observed under these mild conditions. Also, no detectable amount of dimerization products was formed. The conservation of the double bond geometries in macrocyclic products **1** and **6** and all others in this article has been confirmed by comparing ^1H nmr data with those of their corresponding triene precursors. Finally, the structures of the macrocyclic trienes described herein were rigorously established by spectroscopic methods including ^1H and ^{13}C nmr, ir, and low- and high-resolution ms.

Synthesis of TTT macrocyclic substrate 4 and TTC 9

The synthetic pathway for isomeric macrocyclic trienes **4** and **9** is similar to that previously described for **1** and **6**. Thus, *E,E* diene **23** was coupled to the *Z* dienophile synthon **40**, affording triene **62** (Scheme 9). The alcohol function was deprotected to give **63**, which was mesylated and substituted with the sodium anion of dimethyl malonate, yielding tetraester **65**.

The pivaloyl ester was cleaved to give alcohol **66** and chlorination of this intermediate gave chloride **67**. This chlorotriene was cyclized under the usual conditions, giving TTT macrocyclic triene **4** in high yield. This compound gave nice crystals and X-ray diffraction analysis confirmed its structure[8] and thereby that of previous intermediates, including the *Z/E* geometrical assignment on alkylidene lactones **33**. The TTC isomer **9** was synthesized through an identical sequence starting from the *E* dienophile synthon **47**.

Synthesis of TTT macrocyclic substrate 2

TTT macrocyclic triene **2** bearing an alkoxymethyl substituent at the pro-6.6 position was constructed from building blocks **21** and **49** (Scheme 10). Upon anionic coupling according to the usual conditions, triene **74** was isolated in moderate yield. The acetate protecting group was cleaved to yield **75** and the installment of a second malonate connecting unit led to the obtention of tetraester **77**. Desilylation of the latter intermediate gave alcohol **78**, which was transformed into the corresponding chloride **79**. Cyclization of this chlorotriene afforded the TTT macrocyclic triene **2** in high yield. Except for signals ascribed to the pro-6.6 substituent, ^1H nmr spectra of **2** and **1** were virtually identical.

Transformation of alkoxymethyl-substituted macrocycles into formyl-substituted macrocyclic substrates 5, 10, and 3

Upon hydrolysis of the methoxymethyl protecting group of **4**, alcohol **80** was isolated in high yield (Scheme 11). Manganese dioxide oxidation of this allylic alcohol afforded TTT formyl-substituted macrocyclic triene **5**. Macrocyclic triene **9** was also subjected to the same conditions, this time using the Dess–Martin periodinane (15) as the oxidant, yielding aldehyde **10**. In turn, aldehyde **3** was obtained via **82** in high yield from MOM ether **2**.

The *trans* to *cis* enal isomerization of 3 and 5 to 8 and 10; synthesis of 7

Upon treatment with a small amount of 1 N aqueous hydrochloric acid in tetrahydrofuran for a few hours, TTT formyl-substituted macrocyclic trienes **3** and **5** could be entirely transformed in almost quantitative yields to their parent TTC macrocycles **8** and **10** (Scheme 11). This alkene chemical inversion process[9] was unambiguously confirmed by comparing nmr data with an authentic sample of **10** originating from **9** by the direct route described above. This olefin inversion indicates that having three *E*-double bonds is a highly unfavorable situation for our 15-membered macrocycles. This trend is probably further reinforced by the preferred *transoid* conformation of the diene moiety, which can be deduced from the X-ray structure of **4** and ^1H nmr coupling constants[10] on some macrocyclic trienes described herein.

[9] Presumably occurring through an addition–elimination mechanism: protonation of the aldehyde carbonyl triggers nucleophilic attack (by chlorine ion or water) at the distal alkene carbon. Rotation of the sp^3 rehybridized bond and elimination restores the double bond with net inversion. For a review on alkene inversion, see ref. 16.

[10] The usual vicinal constants between central hydrogens of a 1,3 diene are the following (17): $J_{transoid}$: ~10 Hz; J_{cisoid}: ~5 Hz.

Although the *transoid* conformation of 1,4-disubstituted *E,E* 1,3-dienes minimizes allylic strain compared to the compact *cisoid* conformation (18), it has the effect of orienting the two ring chains in opposite directions. As a result, there is less conformational freedom for the remaining methylenes, and a *Z* geometry at the dienophile double bond is thus preferable in alleviating this situation since it returns the two ring chains in the same direction. This thermodynamic preference was corroborated by performing molecular modeling experiments (Fig. 1). Energy minimization of ester-truncated TTT **5** and

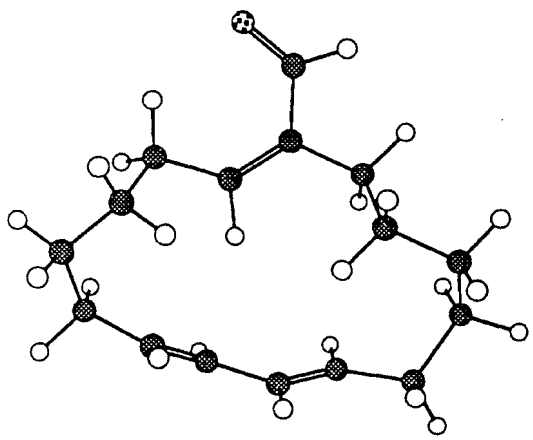
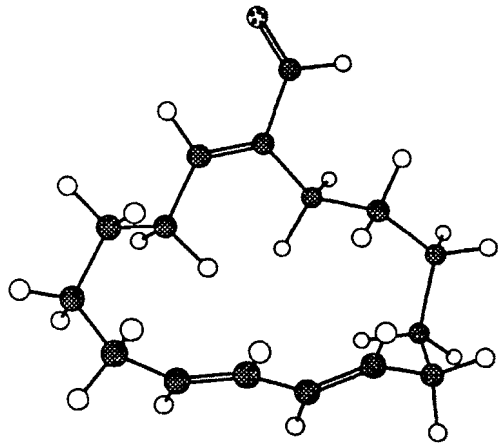
Fig. 1. AM1 optimized structures in s-*cis* enal conformation with truncated ester functions.



TTT **5** (E = H)
$\Delta H°_f$ = - 38.2 kcal/mol



TTC **10** (E = H)
$\Delta H°_f$ = - 41.3 kcal/mol

TTC **10** using the semi-empirical Hamiltonian AM1 (19) gave a much lower $\Delta H°_f$ (3.1 kcal/mol) for the TTC isomer.[11]

Due to their propensity for enal inversion, manipulation of TTT macrocyclic substrates **3** and **5** needed special attention.[12] However, this behaviour could be exploited most advantageously to save time and effort on synthesis and gain access to more macrocyclic substrates from a single one. For instance, it was shown above that $MOMOCH_2$-substituted macrocyclic triene **2** could be transformed to TTC formyl-substituted derivative **8**. Then, sodium borohydride reduction of the aldehyde function yielded allylic alcohol **83** and protection of the latter with methoxymethyl chloride afforded model macrocyclic substrate **7** (Scheme 11). Thus, the enal inversion process carried out on **3** provided a short access to **7**, skirting a much longer route starting from a performed *cis* dienophilic building block.

Conclusion

In summary, the present paper describes the efficient and highly convergent preparation of a set of model 15-membered macrocyclic trienes **1**–**10** containing a *trans-trans* diene. Various trisubstituted dienophile building blocks with *E* or *Z* geometry, and bearing a methyl, MOMO-methyl, or formyl substituent, were prepared and coupled with a diene synthon to eventually give acyclic triene precursors. A smooth macrocyclization protocol afforded high yields (>85%) of the aforementioned cyclopentadecatrienes, which, unlike their lower homologs, were found insensible to a TADA transformation at the temperature of macrocyclization (75°C). Also, it was found that TTT macrocyclic trienes with an enal moiety as a dienophile could be isomerized quantitatively to their corresponding TTC congeners in aqueous acidic media. This observation gave many insights into the relative stability and conformational behaviour of our model macrocyclic trienes. A

[11] Computational procedure: all the calculations were done at the RHF level. Input files for MOPAC 6.00 were generated by importing X-ray structure **4** and an analogue of **9** ($R^1 = nBu_3Sn$, Scheme 2, M. Drouin and G. Falardeau. Unpublished results) into SYBYL 6.01 (Tripos Associates, Inc.: 16995 Hanley Rd., Suite 303, St. Louis, Missouri 63144-2913) for IBM RISC 6000 computers. Ester-truncated **5** and **10** were then minimized with either a s-*cis* or s-*trans* dienophile conformation using Maximin force field within SYBYL and were submitted to AM1 for full optimization. The s-*trans* conformers (not shown) were higher in energy although with a comparable $\Delta\Delta H°_f$ (2.4 kcal/mol).

[12] MnO_2 oxidation of **80** and **82** tends to give minor amounts of the TTC aldehydes **10** and **8** with prolonged reaction times.

study of their reactivity toward the transannular Diels–Alder reaction leading to A.B.C.[6.6.7] tricyclic compounds is described in the following paper of this issue (Part II).

Experimental

General

For the benefit of homogeneity in the nomenclature of analogous series of compounds, substituent numbering was kept constant in spite of the existing rules. Reactions were performed under nitrogen atmosphere with oven- (150°C) or flame-dried glassware. All solvents were dried and distilled shortly before use: diethyl ether and tetrahydrofuran (sodium – benzophenone ketyl); benzene, dichloromethane, dimethylformamide, and dimethyl sulfoxide (calcium hydride); methanol (magnesium–iodine). Most amines were dried over calcium hydride and distilled, dimethyl malonate was distilled as such, and methanesulfonyl chloride was dried over phosphorus pentoxide and distilled. Cesium carbonate, lithium chloride, and potassium iodide were flame-dried under reduced pressure before use. All other starting materials and reactants were obtained commercially and used as such or purified by standard means. All solvents and reactants purified and dried were stored under nitrogen. Analytical (0.25 mm) and preparative thin-layer chromatography (desorption solvent: ethyl acetate) were carried out on prcoated glass plates with silica gel 60F-250 (Merck). Materials were detected by visualization under an ultraviolet lamp and by dipping into a solution of phosphomolybdic acid (10% in ethanol) followed by heating on a hot plate. For flash chromatography, Merck Kieselgel silica gel 60 (230–400 Mesh A.S.T.M.) was used. All solvents used in chromatography were distilled. Concentration of organic solutions implies evaporation on a rotary evaporator followed by reduced pressure (>0.5 Torr; 1 Torr = 133.3 Pa).

The infrared (ir) spectra were taken on a Perkin–Elmer 681 spectrophotometer or on a Perkin–Elmer 1600 FT-ir spectrometer. Proton nuclear magnetic resonance (nmr) spectra were recorded on a Bruker WM-250 or Bruker AC-300 instrument. The following abbreviations were used: br, broad; s, singlet; d, doublet; dd, doublet of doublet; t, triplet; q, quartet; qn, quintet; and m, multiplet. Chemical shifts are reported in δ values relative to chloroform (7.26 ppm) or benzene (7.15 ppm) as internal standard. Proton-decoupled carbon nmr spectra used chloroform (77.00 ppm) or benzene (126.00 ppm) as internal standard. Where necessary, decoupling experiments and two-dimensional techniques were performed. Mass spectral (ms) assays were obtained on a VG Micromass ZAB-2F instrument. Melting points of crystalline materials were determined on a Büchi M-50 or on a Reichert apparatus and are uncorrected. Crystallographic analyses were performed on a Enraf–Nonius CAD-4 diffractometer (Mo Kα radiation; λ = 0.70930 Å).

3-Tetrahydropyranyloxy propanol (11)

3,4-Dihydro-2*H*-pyran (81 mL, 0.89 mol) was added to a solution of 1,3-propanediol (161 mL, 2.23 mol) and *p*-toluenesulfonic acid (5.93 g, 31 mmol) in dichloromethane (250 mL) at 0°C. The mixture was stirred 3 h and a saturated sodium bicarbonate solution (200 mL) was added. The organic phase was segregated and the aqueous layer was extracted with ethyl acetate (3 × 100 mL). The combined organic layers were dried with anhydrous magnesium sulfate, filtered, and concentrated. The crude product was purified by flash chromatography (10–50% ethyl acetate in hexanes) to afford 73.7 g (52%) of alcohol **11** as an oil; ir (CH_2Cl_2): 3620, 3540, 2950, 2880 cm^{-1}; ^1H nmr (250 MHz) ($CDCl_3$) δ (ppm): 4.59 (1H, dd, J = 4.5 Hz, 2.5 Hz, -O-CH-O-), 3.99–3.72 (4H, m) and 3.65–3.45 (2H, m) (3 × $-CH_2O-$), 2.45 (1H, m, -OH), 1.95–1.40 (8H, m, 4 × $-CH_2-$); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 98.92, 65.51, 62.33, 60.54, 32.01, 30.46, 25.15, 19.48;

ms *m/e*: 159 (M^+ − H). Exact Mass calcd. for $C_8H_{15}O_3$: 159.1021; found: 159.1026 ± 0.0005.

3-Tetrahydropyranyloxypropanal (12)

Dimethyl sulfoxide (23.5 mL, 0.36 mol) in dichloromethane (70 mL) was added over a 10 min period to a solution of oxalyl chloride (14.5 mL, 0.17 mol) in dichloromethane (315 mL) at −78°C. The flask was stirred 20 min and the alcohol **11** (24.1 g, 0.15 mol) in dichloromethane (140 mL) was added over a 25 min period. The solution was stirred 45 min and triethylamine (96 mL, 0.69 mol) was added. The thick white mixture was allowed to warm to room temperature for 1 h and water (200 mL) was added, followed by extractions with dichloromethane (3 × 100 mL). The combined organic phases were washed with water (2 × 70 mL), saturated aqueous sodium chloride (150 mL), dried over anhydrous magnesium sulfate, filtered, and concentrated. The crude material was then purified by flash chromatography (25% ethyl acetate in hexanes) giving aldehyde **12** (19.22 g, 81%); ir (CH_2Cl_2): 2950, 2880, 2740, 1725 cm^{-1}; ^1H nmr (250 MHz) ($CDCl_3$) δ: 9.81 (1H, t, J = 2.0 Hz, -CHO), 4.62 (1H, dd, J = 4.0 Hz, 2.5 Hz, -OCHO-), 4.09 (1H, dt, J = 10.5 Hz, 6.0 Hz, -O*H*CHCH$_2$CHO), 3.90–3.78 (1H, m, -(CH$_2$)$_3$-*H*CHO-), 3.75 (1H, dt, J = 10.5 Hz, 6.0 Hz, -OHC*H*CH$_2$CHO), 3.58-3.45 (1H, m, -(CH$_2$)$_3$-HC*H*O-), 2.69 (2H, dt, J = 6.0 Hz, 2.0 Hz, -C*H*CHO), 1.90–1.40 (6H, m, -CH(C*H*$_2$)$_3$CH$_2$O-); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 201.30, 99.00, 62.25, 61.21, 43.82, 30.48, 25.73, 19.32; ms *m/e*: 159 (MH^+), 157 (M^+ − H). Exact Mass calcd. for $C_8H_{13}O_3$: 157.0864; found: 157.0868 ± 0.0005.

(*E*)-Ethyl 5-tetrahydropyranyloxy-2-pentenoate (13)

A solution of ethyl diisopropylphosphonoacetate (45.98, 0.183 mol) in tetrahydrofuran (100 mL) was added dropwise over a period of 0.5 h to a stirred suspension of sodium hydride (5.84 g, 0.147 mol, 60% in mineral oil) in tetrahydrofuran (600 mL) cooled to 0°C. After stirring for 10 min, the solution was cooled to −78°C and a solution of aldehyde **12** (19.2 g, 0.121 mol) in tetrahydrofuran (240 mL) was added within 0.5 h. Stirring was continued for 15 min and the reaction mixture was allowed to warm to room temperature (~1 h). A solution of saturated aqueous ammonium chloride was added and the mixture was extracted thrice with diethyl ether. The combined organic layers were washed with brine, dried over anhydrous magnesium sulfate, filtered, concentrated, and the residue was purified by flash chromatography (17% ethyl acetate in hexanes), yielding ester **13** (22.12 g, 80% colorless oil); ir (CH_2Cl_2): 2950, 1715, 1655 cm^{-1}; ^1H nmr (250 MHz) ($CDCl_3$) δ (ppm): 6.99 (1H, dt, J = 15.5 Hz, 7.0 Hz, -C*H*=CHCO$_2$Et), 5.90 (1H, dt, J = 15.5 Hz, 1.5 Hz, -CH=C*H*CO$_2$Et), 4.60 (1H, m, -OCHO-), 4.19 (2H, q, J = 7.0 Hz, -CO$_2$C*H*$_2$CH$_3$), 3.86 (1H, dt, J = 9.5 Hz, 6.5 Hz, -O*H*CH-CH$_2$CH=), 3.90–3.80 (1H, m, -(CH$_2$)$_3$*H*CHO-), 3.51 (1H, dt, J = 9.5 Hz, 6.5 Hz, -OHCHCH$_2$CH=), 3.55–3.47 (1H, m, -(CH$_2$)$_3$HC*H*O-), 2.51 (2H, ddt, J = 6.5 Hz, 6.5 Hz, 1.5 Hz, -CH=CH-C*H*$_2$-), 1.87–1.45 (6H, m, -CH(C*H*$_2$)$_3$CH$_2$O-), 1.29 (3H, t, J = 7.0 Hz, -CO$_2$CH$_2$C*H*$_3$); ms *m/e*: 227 (M^+ − H), 183 (M^+ − EtO).

(*E*)-5-Tetrahydropyranyloxy-2-pentenol (14)

Diisobutylaluminum hydride (381 mL, 0.381 mol, 1.0 M in dichloromethane) was added to a cooled solution (−78°C) of ester **13** (39.5 g, 0.173 mol) in diethyl ether (1.5 L). After stirring for 1 h at −78°C methanol (200 mL) was added and the mixture was allowed to warm to room temperature and washed with a 30% aqueous solution of disodium tartrate (4 × 400 mL). The combined aqueous phases were extracted with diethyl ether (3 × 200 mL) and the resulting organic layers were dried over anhydrous magnesium sulfate, filtered, and concentrated, yielding pure alcohol **14** (31.13 g, 97%, colorless oil); ir (CH_2Cl_2): 3600, 3460, 2950 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 5.78 (2H, m, -CH=CH-), 4.09 (3H, m, -OCHO-, -C*H*$_2$OH), 3.90–3.80 (1H, m, -(CH$_2$)$_3$*H*CHO-), 3.77 (1H, dt, J = 9.5 Hz, 7.0 Hz, -O*H*CHCH$_2$CH=), 3.52–3.45 (1H, m, -CH$_2$)$_3$HC*H*O-), 3.44 (1H, dt, J = 9.5 Hz, 7.0 Hz, -OHC*H*CH$_2$CH=), 2.40–2.30 (2H, m, -CH=CHC*H*$_2$-), 1.90–1.41 (7H, m, -CH(C*H*$_2$)$_3$CH$_2$O-, OH); ms *m/e*: 185 (M^+ − H).

(*E,E*)-Ethyl 7-tetrahydropyranyloxy-2,4-heptadienoate (16)

Pyridinium chorochromate (24.0 g, 0.111 mol) was added to a stirred suspension of alcohol **14** (13.8 g, 0.074 mol) and powdered 3 Å molecular sieves (32 g) in dichloromethane (400 mL) at 0°C. The mixture was allowed to warm to room temperature and stirred for 1.5 h. Then, diethyl ether (1 L) was added and the reaction mixture was filtered over a short pad of silica gel. The solvent was evaporated and the residue was purified by flash chromatography (35% ethyl acetate in hexanes), giving aldehyde **15** (8.3 g, 63%, colorless oil). This material was immediately reacted with diisopropylphosphonoacetate, following the procedure described for the preparation of **13**, yielding ester **16** (7.62 g, 68%, colorless oil) after purification by flash chromatography (20% ethyl acetate in hexanes); ir (neat): 2940, 2870, 1715, 1645 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 7.25 (1H, dd, J = 15.5 Hz, 10.0 Hz, -C*H*=CH-CO$_2$Et), 6.25 (1H, dd, J = 15.5 Hz, 10.0 Hz, -CH$_2$CH=C*H*-), 6.14 (1H, dt, J = 15.5 Hz, 6.5 Hz, -CH$_2$C*H*=C*H*-), 5.80 (1H, d, J = 15.5 Hz, -CH=C*H*CO$_2$Et), 4.59 (1H, m, -OCHO-), 4.19 (2H, q, J = 7.0 Hz, CO$_2$C*H*$_2$CH$_3$), 3.90–3.80 (1H, m, -(CH$_2$)$_3$*H*CHO-), 3.82 (1H, dt, J = 9.5 Hz, 6.5 Hz, THPO-*H*CH-), 3.55–3.45 (1H, m, -(CH$_2$)$_3$HC*H*O-), 3.45 (1H, dt, J = 9.5 Hz, 6.5 Hz, THPO-HC*H*CH$_2$-), 2.47 (2H, dt, J = 6.5 Hz, THPOCH$_2$C*H*$_2$CH=), 1.90–1.45 (6H, m, -CH(C*H*$_2$)$_3$CH$_2$O-), 1.29 (3H, t, J = 7.0 Hz, CO$_2$CH$_2$C*H*$_3$); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 167.69, 144.64, 140.50, 129.89, 119.77, 98.78, 66.10, 62.20, 60.16, 33.32, 30.58, 25.36, 19.42, 14.22; ms *m/e*: 254 (M^+), 209 (M^+ − OEt).

(*E-E*)-1-*tert*-Butyldiphenylsiloxy-2,4-heptadien-7-ol (19)

Using the procedure employed for the preparation of **14**, ester **16** (6.95 g, 27.4 mmol) was treated with diisobutylaluminum hydride (40.1 mL, 60.2 mmol, 1.5 M in toluene) in diethyl ether (220 mL), giving the crude alcohol **17** (5.0 g, 86%). This material was dissolved in tetrahydrofuran (150 mL) and imidazole (4.02 g, 59.0 mmol), followed by addition of *tert*-butyldiphenylchlorosilane (7.4 mL, 28 mmol), The solution was stirred 1 h at room temperature and saturated aqueous ammonium chloride (100 mL) was added. The resulting mixture was extracted with hexanes – diethyl ether (1:1, 3 × 100 mL) and the combined organic phases were washed with brine, dried over anhydrous magnesium sulfate, filtered, and concentrated to give the crude silyl ether **18**. Pyridinium *p*-toluenesulfonate (0.73 g, 2.9 mmol) was added to a solution of crude **18** in isopropanol (250 mL). The solution was stirred under reflux for

For personal use only.

1 h and allowed to cool to room temperature. Solid potassium carbonate (0.6 g) was added under stirring and the mixture was filtered and concentrated. The crude product was purified by flash chromatography (25% ethyl acetate in hexanes), affording dienic alcohol **19** (6.70 g, 78% from **16**, colorless oil); ir (CH_2Cl_2): 3600, 2940, 1690 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 7.71–7.66 (4H, m) and 7.43–7.34 (6H, m) (2 × Ph); 6.35–6.12 (2H, m, -CH=C*H*-C*H*=CH-), 5.77–5.59 (2H, m, -C*H*=CH-CH=C*H*-), 4.23 (2H, d, J = 5.0 Hz, TBDPSOCH_2CH=), 3.69 (2H, m, -CH_2OH), 2.36 (2H, dt, J = 6.5 Hz, 6.5 Hz, =CHCH_2CH_2OH), 1.40 (1H, m, OH), 1.06 (9H, s, -Si$(CH_3)_3$); ms *m/e*: 309 (M^+ − *t*Bu).

(*E,E*)-8-*tert*-Butyldiphenylsiloxy-1,1-bis(methoxycarbonyl)-4,6-octadiene (21)

Methanesulfonyl chloride (1.49 mL, 19.2 mmol) was added to a cooled solution (0°C) of alcohol **19** (6.70 g, 18.3 mmol) and triethylamine (3.83 mL, 27.4 mmol) in dichloromethane (220 mL). After stirring at 0°C for 1 h, the reaction mixture was poured into water and extracted with dichloromethane (3 × 150 mL). The combined organic layers were washed with brine (50 mL), dried over anhydrous magnesium sulfate, filtered, and concentrated to give the crude mesylate **20** (8.15 g, 100%), which was immediately used for the next reaction.

Dimethylmalonate (10.5 mL, 91.5 mmol) was added dropwise to a suspension of sodium hydride (3.29 g, 82.3 mmol, 60% dispersion in mineral oil) in dimethylformamide (180 mL) and stirred until the bubbling had stopped. A solution of the crude mesylate **20** in tetrahydrofuran (180 mL) and potassium iodide (0.61 g, 3.60 mmol) were added to the clear solution. The reaction mixture was stirred 15 h at 70–75°C and allowed to cool to room temperature. Aqueous saturated ammonium chloride (200 mL) was added and the mixture was extracted with ether–hexanes (1:2, 1 × 400 mL, 3 × 100 mL). The combined organic layers were dried over anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by flash chromatography (20% ethyl acetate in hexanes) to give the alkylation product **21** (7.31 g, 83% from **19**, colorless oil); ir (neat): 3080–3000, 2960, 2860, 1755, 1740 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 7.69–7.66 (4H, m) and 7.43–7.34 (6H, m) (2 × Ph), 6.24 (1H, dd, J = 15.0 Hz, 10.5 Hz, TBDPSOCH$_2$CH=C*H*-CH=CH-), 6.06 (1H, dd, J = 15.0 Hz, 10.5 Hz, TBDPSOCH$_2$CH=CH-C*H*=CH-), 5.68 (1H, dt, J = 15.0 Hz, 5.0 Hz, TBDPSOCH$_2$C*H*=CH-), 5.58 (1H, dt, J = 15.0 Hz, TBDPSOCH$_2$CH=CH-CH=C*H*-), 4.22 (2H, br d, J = 5.0 Hz, TBDPSOCH_2CH=), 3.74 (6H, s, -CH$(CO_2CH_3)_2$), 3.40 (1H, t, J = 7.5 Hz, -C$H(CO_2CH_3)_2$), 2.18–2.09 (2H, m, =HCCH_2CH_2-), 2.06–1.97 (2H, m, =HCCH$_2$CH_2-), 1.06 (9H, s, -SiC$(CH_3)_3$; ^{13}C nmr (62.5 MHz, $CDCl_3$) δ (ppm): 169.7, 135.5, 133.6, 131.6, 131.3, 130.7, 129.6, 127.6, 64.1, 52.4, 50.8, 30.1, 28.3, 26.8, 19.2; ms *m/e*: 480 (M^+), 423 (M^+ − *t*Bu). Exact Mass calcd. for $C_{28}H_{36}O_5Si$: 480.2332; found: 480.2324 ± 0.0014.

(*E,E*)-1,1-bis(Methoxycarbonyl)-4,6-octadien-1-ol (22)

To a solution of silyl ether **21** (1.40 g, 2.9 mmol) in tetrahydrofuran (24 mL) was added tetra-*n*-butyl ammonium fluoride (3.2 mL, 3.2 mmol, 1.0 M in tetrahydrofuran) and the flask was stirred 3 h at room temperature. Aqueous saturated ammonium chloride (10 mL) was added and the mixture was extracted with diethyl ether (4 × 50 mL). The combined organic layers were washed with brine (5 mL), dried over anhydrous magnesium sulfate, filtered, and concentrated. The crude product was purified by flash chromatography (50% ethyl acetate in hexanes), yielding alcohol **22** (0.62 g, 88%, colorless oil); ir (neat): 3460 (br), 3020, 2980–2840, 1745 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.21 (1H, dd, J = 15.5 Hz, 10.5 Hz, HOCH$_2$CH=C*H*-CH=), 6.06 (1H, dd, J = 15.5 Hz, 10.5 Hz, HOCH$_2$CH=CH-C*H*=CH), 5.76 (1H, dt, J = 14.5 Hz, 6.5 Hz, HOCH$_2$C*H*=CH-), 5.64 (1H, dt, J = 14.5 Hz, 7.0 Hz, HOCH$_2$CH=CH-CH=C*H*-), 4.17 (2H, dd, J = 5.5 Hz, 5.5 Hz, HOCH_2CH=), 3.74 (6H, s, 2 × CH_3O-), 3.38 (1H, t, J = 7.0 Hz,- CH_2C$H(CO_2CH_3)_2$), 2.15 (2H, dt, J = 7.0 Hz, 7.0 Hz, =CHCH_2CH_2-), 2.02 (2H, dt, J = 7.0 Hz, 7.0 Hz, =CHCH$_2$CH_2-), 1.32 (1H, t, J = 5.5 Hz, *H*OCH$_2$-); ms *m/e*: 224 (M^+−H_2O). Exact Mass calcd. for $C_{12}H_{16}O_4$: 224.1049; found: 224.1037 ± 0.0006.

(*E,E*)-8-Pivaloyloxy-1,1-bis(methoxycarbonyl)-4,6-octadiene (23)

To a cooled solution (0°C) of alcohol **22** (0.494 g, 2.04 mmol) in dichloromethane (20 mL) were successively added triethylamine (0.85 mL, 6.1 mmol), a few crystals of 4-dimethylaminopyridine (cat.), and trimethylacetyl chloride (0.75 mL, 6.1 mmol). The solution was stirred 2 h at 0°C, then 1 h at room temperature, and a saturated aqueous solution of ammonium chloride (15 mL) was added. The mixture was extracted with dichloromethane (3 × 50 mL) and the combined organic layers were washed with water (5 mL) and brine (5 mL), dried with anhydrous magnesium sulfate, filtered, and concentrated. The crude product was purified by flash chromatography (5% ethyl acetate in hexanes), giving pivaloyl ester **23** (0.575 g, 86%, yellowish oil); ir (neat): 2990–2840, 1735 (br) cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.23 (1H, dd, J = 15.0 Hz, 10.5 Hz, PivOCH$_2$CH=C*H*-CH=), 6.05 (1H, dd, J = 15.0 Hz, 10.5 Hz, PivOCH$_2$CH=CH-C*H*=CH-), 5.66 (2H, dt, J = 15.0 Hz, 6.0 Hz, PivOCH$_2$C*H*=CH-CH=C*H*-), 4.56 (2H, d, J = 6.0 Hz, PivOCH_2CH=), 3.74 (6H, s, 2 × CH_3O-), 2.23–1.92 (4H, m, -CH_2CH_2CH$(CO_2CH_3)_2$), 1.21 (9H, s, $(CH_3)_3CCO_2$-); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 177.95, 169.44, 133.41, 130.56, 125.28, 64.37, 52.27, 50.62, 38.55, 29.97, 27.95, 26.98; ms *m/e*: 241 (M^+ − $(CH_3)_3CO$). Exact Mass calcd. for $C_{12}H_7O_5$: 241.1076; found: 241.1074 ± 0.0007.

(*E*)-3-Methyl-1-tetrahydropyranyloxy-3-hexen-6-ol (27) and (*Z*)-3-methyl-1-tetrahydropyranyloxy-3-hexen-6-ol (29)

A crude mixture of inseparable *cis* and *trans* isomers **26** (7.79 g, 17.2 mmol) was dissolved in tetrahydrofuran (160 mL) and cooled to 0°C. Tetra-*n*-butylammonium fluoride (18.9 mL, 18.9 mmol, 1.0 M in tetrahydrofuran) was added and the solution was stirred 1 h at 0°C. The volatiles were then evaporated to near-dryness and the residue was purified by flash chromatography (5% acetone, 45% dichloromethane in hexanes) giving **29** (0.940 g, 26%), **27** (0.872 g, 24%), and a nonseparated fraction (1.65 g, 45%):

cis Isomer **29**: ir ($CHCl_3$): 3420, 2950 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 5.27 (1H, t, J = 7.5 Hz, -C*H*=C(CH_3)-), 4.58 (1H, m, -OCHO-), 3.86 (1H, dt, J = 9.5 Hz, 7.0 Hz, -*H*CHOTHP), 3.90–3.80 (1H, m, -$(CH_2)_3$*H*CHO-), 3.64–3.58 (2H, m, HOCH_2-), 3.55–3.45 (1H, m, -$(CH_2)_3$HC*H*O-), 3.46 (1H, dt, J = 9.5 Hz, 6.5 Hz,

-HC*H*OTHP), 2.43–2.27 (4H, m, -C*H*$_2$CH=C(CH$_3$)C*H*$_2$-), 1.18 (1H, m, -OH), 1.90–1.50 (6H, m, -(C*H*$_2$)$_3$CH$_2$O-), 1.77 (3H, s, -CH$_3$); ^{13}C nmr (62.5 MHz, CDCl$_3$) δ (ppm): 135.1, 123.1, 98.7, 65.2, 62.0, 31.9, 31.2, 30.3, 25.2, 23.3, 19.3; ms *m/e*: 214 (M$^+$), 199 (M$^+$ − CH$_3$).

trans Isomer **27**: ir (CHCl$_3$): 3420, 2960 cm^{-1}; ^{1}H nmr (250 MHz, CDCl$_3$) δ (ppm): 5.20 (1H, tq, *J* = 7.7 hz, *J* ≈ 1Hz, -C*H*=C(CH$_3$)-), 4.57 (1H, m, -OCHO-), 3.90–3.80 (1H, m, -(CH$_2$)$_3$*H*CHO-), 3.81 (1H, dt, *J* = 9.5 Hz, 7.0 Hz, -*H*CHOTHP), 3.60 (2H, m, -C*H*$_2$OH), 3.48 (1H, dt, *J* = 9.5 Hz, 6.5 Hz, -HC*H*OTHP), 3.55–3.45 (1H, m, -(CH$_2$)$_3$HC*H*O-), 2.34–2.28 (4H, m, -C*H*$_2$CH=C(CH$_3$)C*H*$_2$-), 1.90–1.50 (7H, m, -(C*H*$_2$)$_3$CH$_2$O-, OH), 1.68 (3H, d, *J* = 1.0 Hz, -CH$_3$); ^{13}C nmr (62.5 MHz, CDCl$_3$) δ (ppm): 135.6, 121.8, 98.8, 66.0, 62.4, 62.1, 39.7, 31.4, 30.6, 25.4, 19.6, 16.4; ms *m/e*: 214 (M$^+$), 199 (M$^+$ − CH$_3$).

(*Z*)-3-Hydroxymethyl-1-acetoxy-6-*tert*-butyldimethylsiloxy-3-hexene (37)

Diisobutylaluminum hydride (17.2 mL, 26.0 mmol, 1.5 M in toluene) was added over a few minutes to a solution of lactone **33***Z* (3.00 g, 11.7 mmol) in diethyl ether (90 mL) at −78°C. The solution was stirred for 2.5 h after which methanol (15 mL) was added and the mixture allowed to warm to room temperature. It was then extracted with a 30% aqueous solution of disodium tartrate (4 × 25 mL) and the combined aqueous phases were extracted with diethyl ether (4 × 50 mL). The combined organic layers were washed with brine (25 mL), dried with anhydrous magnesium sulfate, and filtered over a short pad of silica gel. Concentration of the solvents left a mixture (2.59 g, ~85%) of diol **34** along with aldehyde **35**, originating from incomplete reduction. This sensitive material was immediately used for the next step by dilution into chloroform (70 mL). Manganese dioxide (10.0 g, 117 mmol) was added and the mixture was stirred 12 h (more manganese dioxide might be needed depending on its activity), after which it was filtered over a pad of Celite (rinsed with chloroform). The filtrate was concentrated to give 2.37 g (theoretically: 9.2 mmol, ~84%) of crude aldehyde **35** (homogeneous by TLC). Without delay, the latter intermediate was dissolved in dichloromethane (200 mL) and the solution was cooled to 0°C. Acetic anhydride (4.05 mL, 43 mmol), triethylamine (6.05 mL, 43 mmol), and 4-dimethylaminopyridine (a few crystals, cat.) were successively added. The solution was stirred 3 h at 0°C and aqueous saturated ammonium chloride (100 mL) was then added. The mixture was extracted with dichloromethane (3 × 100 mL) and the combined organic layers were washed with water (30 mL) and brine (30 mL), dried with anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by flash chromatography (40% ethyl acetate in hexanes), yielding pure unstable acetate **36** (2.40 g, 87%, colorless oil), which was immediately reacted in the following step. A 0.91 g portion of **36** (3.03 mmol) was dissolved in methanol (50 mL) and the solution was cooled to 0°C. Sodium borohydride (87 mg, 2.8 mmol) was added and the mixture was stirred 45 min at 0°C. A solution of aqueous saturated ammonium chloride (25 mL) was added and the bulk of methanol was evaporated. The resulting mixture was diluted with water (15 mL) and extracted with diethyl ether (4 × 50 mL). The combined organic layers were dried over anhydrous magnesium sulfate, filtered, and evaporated. The crude product was purified by flash chromatography (20–70% ethyl acetate in hexanes), affording allylic alcohol **37** (0.75 g, 83% (56% overall from **33***Z*), colorless oil); ir (neat): 3460 (br), 2990, 1740 cm^{-1}; ^{1}H nmr (250 MHz, CDCl$_3$) δ (ppm): 5.38 (1H, t, *J* = 8.0 Hz, =C*H*CH$_2$-), 4.18 (2H, t, *J* = 7.0 Hz, -C*H*$_2$OAc), 4.08 (2H, s, -C*H*$_2$OH), 3.62 (2H, t, *J* = 6.0 Hz, -CH$_2$OTBS), 2.44 (2H, t, *J* = 7.0 Hz, -C*H*$_2$CH$_2$OAc), 2.40 (1H, br, -OH), 2.32 *H* (2H, dt, *J* = 8.0 Hz, 6.0 Hz, -C*H*$_2$CH$_2$OTBS), 2.03 (3H, s, CH$_3$CO$_2$-), 0.88 (9H, s, -SiC(CH$_3$)$_3$), 0.06 (6H, s, -Si(CH$_3$)$_2$); ms *m/e*: 245 (M$^+$ − (CH$_3$)$_3$C). Exact Mass calcd. for C$_{11}$H$_{21}$O$_4$Si: 245.1209; found: 245.1208 ± 0.0007.

(*Z*)-3-(Methoxymethoxy)methyl-1-acetoxy-6-*tert*-butyldimethylsiloxy-3-hexene (38)

To a solution of *Z* allylic alcohol **37** (0.74 g, 2.5 mmol) in dichloromethane (50 mL) were successfully added diisopropylethylamine (1.3 mL, 7.5 mmol) and methoxymethyl chloride (0.37 mL, 4.9 mmol). The reaction mixture was stirred for 20 h at room temperature, after which a saturated solution of ammonium chloride (15 mL) was added. The mixture was extracted with dichloromethane (3 × 50 mL) and the combined organic layers were washed with water (5 mL) and brine (5 mL), dried with anhydrous magnesium sulfate, filtered, and concentrated. Purification of the residue by flash chromatography (30% ethyl acetate in hexanes) furnished compound **38** (0.82 g, 96%, colorless oil); ir (neat): 2990–2820, 1740, 1470 cm^{-1}; ^{1}H nmr (250 MHz, CDCl$_3$) δ (ppm): 5.48 (1H, t, *J* = 7.5 Hz, =C*H*CH$_2$-), 4.60 (2H, s, -OCH$_2$O-), 4.17 (2H, t, *J* = 7.0 Hz, -C*H*$_2$OAc), 4.09 (2H, s, -CH$_2$OMOM), 3.59 (2H, t, *J* = 7.0 Hz, -CH$_2$OTBS), 3.37 (3H, s, -OCH$_3$), 2.43 (2H, t, *J* = 7.0 Hz, -C*H*$_2$CH$_2$OAc), 2.32 (2H, dt, *J* = 7.0 Hz, 7.0 Hz, -C*H*$_2$CH$_2$OTBS), 2.03 (3H, s, CH$_3$CO$_2$-), 0.88 (9H, s, -SiC(CH$_3$)$_3$), 0.04 (6H, s, -Si(CH$_3$)$_2$); ms *m/e*: 289 (M$^+$ − (CH$_3$)$_3$C). Exact Mass calcd. for C$_{13}$H$_{25}$O$_5$Si: 289.1471; found: 289.1477 ± 0.0008.

(*Z*)-3-(Methoxymethoxy)methyl-6-*tert*-butyldimethylsiloxy-3-hexenol (39)

Potassium carbonate (30 mg, 0.22 mmol) was added to a solution of compound **38** (0.38 g, 1.10 mmol) in methanol (12 mL). The solution was stirred 3 h at room temperature and then diluted with diethyl ether (25 mL). The resulting mixture was filtered over a short column of silica gel (rinsed with diethyl ether) and the filtrate was concentrated to give pure alcohol **39** (0.34 g, 100%, colorless oil); ir (neat): 3425 (br), 2990–2840 cm^{-1}; ^{1}H nmr (250 MHz, CDCl$_3$) δ (ppm): 5.53 (1H, t, *J* = 8.0 Hz, =C*H*CH$_2$-), 4.63 (2H, s, -OCH$_2$O-), 4.09 (2H, s, -CH$_2$OMOM), 3.70 (2H, t, *J* = 6.0 Hz, -CH$_2$OH), 3.62 (2H, t, *J* = 6.5 Hz, -CH$_2$OTBS), 3.38 (3H, s, -OCH$_3$), 2.44–2.30 (4H, m, -C*H*$_2$C=CHC*H*$_2$-), 1.80 (1H, br, -OH), 0.88 (9H, s, -SiC(CH$_3$)$_3$), 0.04 (6H, s, -Si(CH$_3$)$_2$); ms *m/e*: 243 (M$^+$ − MOMO). Extract Mass calcd. for C$_{13}$H$_{27}$O$_2$Si: 243.1780; found: 243.1777 ± 0.0007.

(*Z*)-(Methoxymethoxy)methyl-1-acetoxy-3-hexen-6-ol (48)

To a solution of **38** (0.445 g, 1.28 mmol) in tetrahydrofuran (10 mL) was added tetra-*n*-butylammonium fluoride (1.35 mL, 1.35 mmol, 1 M in tetrahydrofuran) and one drop of triethylamine as an acid scavenger. The reaction mixture was stirred for 1 h at room temperature after which a saturated solution of aqueous ammonium chloride (10 mL) was

(*E,E,E*)-3-Methyl-14-*tert*-butyldiphenylsiloxy-7,7-bis(methoxycarbonyl)-1-tetrahydropyranyloxy-tetradeca-3,10,12-triene (50)

To a solution of *E* hexenol **27** (0.556 g, 2.60 mmol) in dichloromethane (32 mL) were successively added triethylamine (0.55 mL, 3.9 mmol) and methanesulfonyl chloride (0.21 mL, 2.70 mmol). After stirring at room temperature for 2 h, the reaction mixture was poured into water (50 mL) and extracted with dichloromethane (4 × 25 mL). The combined organic layers were washed with brine, dried with anhydrous magnesium sulfate, filtered, and concentrated to give crude mesylate **28** (0.761 g, ~100%). This sensitive material was immediately used for the next step.

A solution of malonate **21** (0.921 g, 1.92 mmol) in dimethylformamide (11 mL) was added to a suspension of sodium hydride (82.0 mg, 2.05 mmol, 60% dispersion in mineral oil) in dimethylformamide (11 mL). After stirring at 35–40°C for 1 h, the reaction mixture became clear and a solution of crude mesylate **28** in tetrahydrofuran (22 mL), followed by anhydrous potassium iodide (68 mg, 0.40 mmol), was added and the reaction flask was stirred at ~70°C for 12 h. Saturated aqueous ammonium chloride (75 mL) was added and the resulting mixture was extracted with diethyl ether – hexanes (1:1, 5 × 75 mL). The combined organic phases were washed with water and brine, dried with anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by flash chromatography (10% ethyl acetate in hexanes), affording the coupling product **50** (0.902 g, 70%, colorless oil) along with recovered malonate **21** (210 mg, 23%); ir (CH_2Cl_2): 2960–2880, 1730 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 7.69–7.66 (4H, m) and 7.43–735 (6H, m) (2 × Ph); 6.23 (1H, dd, J = 15.0 Hz, 10.0 Hz, TBDPSOCH_2CH=C*H*-), 6.07 (1H, dd, J = 15.0 Hz, 5.0 Hz, TBDPSOCH_2CH=CH-C*H*=), 5.71–5.55 (2H, m, -C*H*=CH-CH=C*H*-), 5.16 (1H, m, -*H*C=C(CH_3)-), 4.59 (1H, m, -OCHO-), 4.22 (2H, d, J = 4.5 Hz, -CH_2OTBDPS), 3.90–3.67 (2H, m, -*H*CHOTHP + -$(CH_2)_3$*H*CHO-), 3.71 (6H, s, 2 × CH_3O-), 3.52–3.41 (2H, m, -HC*H*OTHP + -$(CH_2)_3$HC*H*O-), 2.27 (2H, t, J = 7.0 Hz, -CH_2CH_2OTHP), 2.05–1.80 (8H, m, -CH_2CH_2-C(CO_2CH_3)$_2$CH_2CH_2-), 1.80–1.50 (6H, m -CH(CH_2)$_3$-CH_2O-), 1.62 (3H, s, CH_3-), 1.05 (9H, s, -SiC(CH_3)$_3$); ms *m/e*: 676 (M^+), 619 (M^+ − *t*Bu), 591 (M^+ − THP).

(*E,E,E*)-3-Methyl-14-*tert*-butyldiphenylsiloxy-7,7-bis(methoxycarbonyl)-tetradeca-3,10,12-trien-1-ol (51)

A solution of tetrahydropyranyl ether **50** (0.894 g, 1.32 mmol) and pyridinium *p*-toluenesulfonate (33.5 mg, 0.13 mmol) in isopropanol (17 mL) was stirred under reflux for 1 h. The solution was allowed to cool to room temperature and potassium carbonate (60 mg) was added. The mixture was stirred 15 min and filtered on a fritted glass funnel and concentrated. Purification of the residue by flash chromatography (30% ethyl acetate in hexanes) gave alcohol **51** (0.712 g, 90%, colorless oil); ir (neat): 3450, 2980–2880, 1735 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 7.69–7.65 (4H, m) and 7.43–7.34 (6H, m) (2 × Ph); 6.23 (1H, dd, J = 15.0 Hz, 10.5 Hz, -C*H*=CHCH_2OTBDPS), 6.06 (1H, dd, J = 15.0 Hz, 10.5 Hz, =C*H*-CH=CH-CH_2OTBDPS), 5.67 (1H, dt, J = 15.0 Hz, 4.5 Hz, =C*H*CH_2OTBDPS), 5.65–5.55 (1H, m, =C*H*(CH_2)$_2$-), 5.20 (1H, m, -C*H*=C(CH_3)-), 4.22 (2H, dd, J = 4.5 Hz, 1 Hz, -CH_2OTBDPS), 3.72 (6H, s, 2 × CH_3O-), 3.66 (2H, m, -CH_2OH), 2.23 (2H, t, J = 6.0 Hz, -CH_2CH_2OH), 2.03–1.97 (4H, m) and 1.97–1.91 (4H, m) (-(CH_2)$_2$C(CO_2CH_3)$_2$-(CH_2)$_2$-); 1.62 (3H, d, J = 1.0 Hz, -CH=C(C*H*$_3$)-), 1.39 (1H, m, OH), 1.05 (9H, s, -Si(CH_3)$_3$); ms *m/e*: 592 (M^+), 535 (M^+ − *t*Bu).

(*E,E,E*)-4-Methyl-1,1,8,8-tetrakis(methoxycarbonyl)-pentadeca-4,11,13-trien-15-ol (54)

To a cooled solution (0°C) of alcohol **51** (0.705 g,1.19 mmol) and triethylamine (0.25 mL, 1.8 mmol) in dichloromethane (15 mL) was added methanesulfonyl chloride (0.097 mL, 1.25 mmol). After stirring at room temperature for 1.5 h the reaction mixture was poured into water (50 mL) and extracted with dichloromethane (5 × 30 mL). The combined organic layers were washed with brine, dried with anhydrous magnesium sulfate, filtered, and concentrated to give the crude mesylate **52** (0.799 g, ~100%). This sensitive material was immediately consumed in the next step.

Dimethyl malonate (0.68 mL, 6.0 mmol) was added dropwise to a stirred suspension of sodium hydride (0.21 g, 5.4 mmol, 60% dispersion in mineral oil) in dimethylformamide (14 mL). After ~30 min at room temperature the reaction mixture became clear and a solution of crude mesylate **52** in tetrahydrofuran (14 mL), followed by anhydrous potassium iodide (40 mg, 0.24 mmol), was added. The flask was stirred at 70–75°C for 18 h after which aqueous saturated ammonium chloride (50 mL) was added. The resulting mixture was extracted with petroleum ether – diethyl ether (2:1, 5 × 25 mL) and the combined organic layers were dried over anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by flash chromatography (20% ethyl acetate in hexanes), giving alkylation product **53** (0.860 g) contaminated with dimethyl malonate. This material was dissolved in tetrahydrofuran (12 mL) and tetra-*n*-butylammonium fluoride (1.20 mL, 1.20 mmol, 1 M in tetrahydrofuran) was added. The reaction mixture was stirred at room temperature for 3 h, after which the bulk of the solvent was evaporated. The residue was purified by flash chromatography (50% ethyl acetate in hexanes), yielding alcohol **54** (0.357 g, 64% overall from **51**, colorless oil); ir (neat): 3520, 2970–2880, 1735 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.20 (1H, dd, J = 15.0 Hz, 10.5 Hz, $HOCH_2$CH=C*H*-), 6.06 (1H, dd, J = 15.0 Hz, 10.5 Hz, $HOCH_2$CH=CH-C*H*=), 5.74 (1H, dt, J = 15.0 Hz, 6.0 Hz,

For personal use only.

$HOCH_2CH$=), 5.64 (1H, dt, J = 15.0 Hz, 3.0 Hz, $HOCH_2CH$=CH-CH=), 5.14–5.06 (1H, m, -CH=C(CH_3)-), 4.16 (2H, d, J = 6.0 Hz, -CH_2OH), 3.73 (6H, s, 2 × CH_3O-), 3.71 (6H, s, 2 × CH_3O-), 3.32 (1H, t, J = 7.0 Hz, -CH(CO_2CH_3)$_2$), 2.04–1.84 (13H, m, 6 × -CH_2-, OH), 1.57 (3H, d, J = 1.0 Hz, -CH=C(CH_3)-); ms *m/e*: 468 (M^+), 450 ($M^+ - H_2O$).

(*E,E,E*)-4-Methyl-1,1,8,8-tetrakis(methoxycarbonyl)-cyclopentadeca-4,11,13-triene (1)

Methanesulfonyl chloride (0.023.0 mL, 0.30 mmol) was added to a cooled solution (0°C) of alcohol **54** (46.3 mg, 0.099 mmol), anhydrous lithium chloride (25.2 mg, 0.594 mmol), and s-collidine (0.039 mL, 0.297 mmol) in dimethylformamide (1.0 mL). The reaction mixture was stirred at 0°C for 30 min (a thick white preciptate appeared after ~10 min), then warmed at room temperature for 2.5 h, after which it was poured into ice–water (~20 mL) and extracted with diethyl ether – petroleum ether (1:1, 4 × 25 mL). The combined organic layers were successively washed with saturated aqueous cupric sulfate (2 × 15 mL), water and brine, dried with anhydrous magnesium sulfate, filtered, and concentrated. The residue was quickly purified by flash chromatography on a short column (25% ethyl acetate in hexanes), affording unstable allylic chloride **55** (37.5 mg, 78%, colorless oil), which was used without delay for the following macrocyclization reaction.

To a vigorously stirred suspension of dry cesium carbonate (195 mg, 0.59 mmol) in dimethylformamide–tetrahydrofuran (5 mL:5 mL) at ~75°C was slowly added allylic chloride **55** (37.5 mg, 0.077 mmol) in dimethylformamide–tetrahydrofuran (3.5 mL:3.5 mL) via syringe pump within 11 h (final concentration: 4.5 × 10^{-3} M). After additional stirring for 13 h, the reaction mixture was allowed to cool to room temperature, filtered through a fritted glass funnel, and concentrated (the rotary evaporator was connected to an oil pump to remove dimethylformamide). The residue was purified by flash chromatography (15% ethyl acetate in hexanes) and crystallized from ethyl acetate – hexanes (mp 188–131°C), giving TTT macrocyclic triene **1** (29.6 mg, 85%, white solid); ir -CH_2Cl_2): 2980–2860, 1730 cm^{-1}; ^{1}H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.04 (2H, m, -HC=CH-CH=CH-), 5.51–5.25 (2H, m, -HC=CH-CH=CH-), 5.02 (1H, m, -C(CH_3)=CH-), 3.74 (6H, s, 2 × CH_3O-), 3.72 (6H, s, 2 × CH_3O-), 2.75 (2H, d, J = 7.5 Hz, =CHCH_2C(CO_2CH_3)$_2$-), 2.16–1.95 (8H, m) and 1.85–1.65 (4H, m) (6 × -CH_2-); 1.54 (3H, s, -CH=C(CH_3)-); ^{1}H nmr (250 MHz, C_6D_6) δ (ppm): 5.89–5.73 (2H, m, -CH=CH-CH=CH-), 5.48 (1H, dt, J = 14.5 Hz, 7.5 Hz, -(CH_3O_2C)$_2$CCH_2CH=), 5.25 (1H, dt, J = 14.5 Hz, 7.5 Hz, -CH=CH(CH_2)$_2$-), 5.06 (1H, tq, J = 7.0 Hz, 1.5 Hz, -CH=C)CH_3)-), 3.32 (6H, s, 2 × CH_3O-), 3.31 (6H, s, 2 × CH_3O-), 2.97 (2H, d, J = 7.0 Hz, -(CH_3O_2C)$_2$CCH_2CH=), 2.36–2.21 (6H, m, 3 × -CH_2CH=), 2.06–1.83 (6H, m, 3 × -CH_2-), 1.41 (3H, d, J = 1.5 Hz, -CH=C)CH_3)-); ^{13}C nmr (62.5 MHz, $CDCl_3$) δ (ppm): 172.0, 136.0, 135.5, 134.5, 130.8, 124.9, 124.5, 58.3, 57.2, 52.5, 52.4, 35.6, 31.1, 30.2, 29.8, 29.1, 27.1, 20.3, 16.7; ms *m/e*: 450 (M^+), 435 ($M^+ - CH_3$). Exact Mass calcd. for $C_{24}H_{34}O_8$: 450.2253; found: 450.2246 ± 0.0013.

(3*Z*,10*E*,12*E*)-3-Methyl-14-*tert*-butyldiphenylsiloxy-7,7-bis(methoxycarbonyl)-1-tetrahydropyranyloxy-tetradeca-3,10,12-triene (56)

Using the procedure employed for the preparation of **28**, *Z* hexenol **29** (0.606 g, 2.83 mmol) was transformed into the corresponding crude mesylate **30** (0.825 g, ~100%). It was immediately reacted with malonate **21** (1.20 g, 2.50 mmol) as described for **50**, yielding the coupling product **56** (1.17 g, 66% from **29**, colorless oil) along with recovered malonate **21** (0.140 g, 12%); ir (CH_2Cl_2): 2980–2860, 1730 cm^{-1}; ^{1}H nmr (250 MHz, $CDCl_3$) δ (ppm): 7.69–7.65 (4H, m) and 7.46–7.33 (6H, m) (2 × Ph); 6.22 (1H, dd, J = 15.0 Hz, 10.0 Hz, TBDPSOCH_2CH=CH-), 6.05 (1H, dd, J = 15.0 Hz, 10.0 Hz, TBDPSOCH_2CH=CH-CH=), 5.68 (1H, dt, J = 15.0 Hz, 5.0 Hz, TBDPSOCH_2CH=), 5.67–5.54 (1H, m, TBDPSOCH_2CH=CH-CH=CH-), 5.22–5.15 (1H, m, -CH=C(CH_3)-), 4.61–4.57 (1H, m, -OCHO-), 4.23 (2H, d, J = 5.0 Hz, TBDPSOCH_2-), 3.90–3.80 (1H, m, -(CH_2)$_3$$H$CHO-), 3.76 (1H, dt, J = 9.0 Hz, 7.5 Hz, -HCHOTHP) 3.71 (6H, s, 2 × CH_3)-), 3.55–3.45 (1H, m, -(CH_2)$_3$HCHO-), 3.41 (1H, dt, J = 9.0 Hz, 7.5 Hz, -HCHOTHP), 2.30 (2H, t, J = 7.5 Hz, =CH_2CH_2OTHP), 2.02–1.96 (4H, m) and 1.96–1.90 (4H, m) (-(CH_2)$_2$-C(CO_2CH_3)-(CH_2)$_2$-); 1.71 (3H, s, -CH=C(CH_3)-), 1.90–1.45 (6H, m, -CH(CH_2)$_3$$CH_2$O-), 1.05 (9H, s, -SiC($CH_3$)$_3$); ms *m/e*: 676 ($M^+$), 619 ($M^+$ – *t*Bu), 591 (M^+ – THP).

(3*Z*,10*E*,12*E*)-3-Methyl-14-*tert*-butyldiphenylsiloxy-7,7-bis(methoxycarbonyl)-tetradeca-3,10,12-trienol (57)

Using the procedure described for the preparation of **51**, triene **56** (1.17 g, 1.73 mmol) was transformed into alcohol derivative **57** (0.80 g, 78%, colorless oil); ir $CHCl_3$): 3610, 3980–3840, 1730 cm^{-1}; ^{1}H nmr (250 MHz, $CDCl_3$) δ (ppm): 7.70–7.65 (4H, m) and 7.46–7.34 (6H, m) (2 × Ph); 6.24 (1H, dd, J = 15.0 Hz, 10.0 Hz, TBDPSOCH_2CH=CH-), 6.06 (1H, dd, J = 15.0 Hz, 10.0 Hz, TBDPSOCH_2CH=CH-CH=), 5.68 (1 H, dt, J = 15.0 Hz, 5.0 Hz, TBDPSOCH_2CH=), 5.68–5.55 (1H, m, TBDPSOCH_2CH=CH-CH=CH-), 5.33–5.23 (1H, m, -CH=C(CH_3)-), 4.22 (2H, d, J = 5.0 Hz, TBDPSOCH_2-), 3.72 (6H, s, 2 × CH_3O-), 3.72–3.62 (2H, m, -CH_2OH), 2.29 (2H, t, J = 6.5 Hz, -CH_2CH_2OH), 2.05–1.97 (4H, m) and 1.97–1.90 (4H, m) (-(CH_2)$_2$C(CO_2CH_3)$_2$-(CH_2)$_2$-); 1.72 (3H, d, J = 1.0 Hz, -CH=C(CH_3)-), 1.45 (1H, m, -OH), 1.06 (9H, s, -SiC(CH_3)$_3$); ms *m/e*: 592 (M^+), 535 (M^+ – *t*Bu).

(4*Z*,11*E*,13*E*)-4-Methyl-1,1,8,8-tetrakis(methoxycarbonyl)-pentadeca-4,11,13-trien-15-ol (60)

Using the procedure described for the preparation of **54**, alcohol **57** (0.737 g, 1.24 mmol) was successively mesylated (**58**, 0.835 g, ~100%) and alkylated with dimethyl malonate (reaction time, 15 h). Silyl ether cleavage of **59** yielded pure alcohol **60** (0.451 g, 65% overall from **57**, colorless oil); ir ($CHCl_3$): 3500, 2980–2880, 1735 cm^{-1}; ^{1}H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.20 (1H, dd, J = 15.0 Hz, 10.0 Hz, $HOCH_2$- CH=CH-), 6.05 (1H, dd, J = 15.0 Hz, 10.0 Hz, $HOCH_2$-CH=CH-CH=), 5.75 (1H, dt, J = 15.0 Hz, 6.0 Hz, $HOCH_2$CH=), 5.71–5.61 (1H, m, $HOCH_2$CH=CH-CH=CH-), 5.18–5.10 (1H, m, -CH=C-(CH_3)-), 4.16 (2H, d, J = 6.0 Hz, $HOCH_2$-), 3.73 (6H, s, 2 × CH_3O-), 3.72 (6H, s, 2 × CH_3O-), 3.31 (1H, t, J = 7.0 Hz, -CH(CO_2CH_3)$_2$), 2.15–1.75 (13H, m, 6 × -CH_2-, OH), 1.67 (3H, s, -CH=C(CH_3)-); ms *m/e*: 450 (M^+ – H_2O).

(4*Z*,11*E*,13*E*)-4-Methyl-1,1,8,8-tetrakis(methoxycarbonyl)-cyclopentadeca-4,11,13-triene (6)

Using the procedure described for the preparation of **1**, alcohol **60** (0.351 g, 0.75 mmol) was transformed (reaction time, 1 h) into the corresponding allylic chloride **61** (297 mg, 81%, colorless oil). Macrocyclization of the latter (0.227 g, 0.467 mmol) proceeded within 20 h of slow addition with 5 h of further stirring (**61** dissolved in dimethylformamide–tetrahydrofuran (25 mL:25 mL) and added to cesium carbonate in the same solvent at 70°C (33 mL:33 mL; final concentration: 4.1×10^{-3} M), yielding TTC macrocyclic triene **6** (0.183 g, 87%, white solid, crystallized: mp 119–138°C); ir ($CHCl_3$): 2960–2860, 1730 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.25–6.10 (2H, m, -CH=C*H*-C*H*=CH-), 5.83–5.70 (1H, m) and 5.66–5.53 (1H, m) (-C*H*=CH-CH=C*H*-); 5.00–4.92 (1H, br t, $J = 7.0$ Hz, -C*H*=C(CH_3)-, 3.74 (6H, s, 2× CH_3O-), 3.71 (6H, s, 2 × CH_3O-), 2.67 (2H, d, J = 7.5 Hz, -(CH_3O_2C)$_2$CC*H*$_2$CH=), 2.12–1.92 (4H, m), and 1.97–1.85 (2H, m) (3 × -CH_2CH=); 1.85–1.80 (4H, m) and 1.70–1.55 (2H, m) (3 × -CH_2-); 1.63 (3H, s, -CH=C(C*H*$_3$)-); ^1H nmr (250 MHz, C_6D_6) δ (ppm): 6.00–5.72 (3H, m, -(CH_3O_2C)$_2$CCH$_2$C*H*=C*H*-C*H*=CH-), 5.62 (1H, dt, $J = 14.0$ Hz, 7.0 hz, -CH=CH-CH=C*H*-), 5.12 (1H, tq, $J = 8.0$ Hz, 1.5 Hz, -C*H*=C(CH_3)-), 3.33 (12H, s, 4 × CH_3O-), 2.83 (2H, d, $J = 6.5$ Hz, -(CH_3O_2C)CC*H*$_2$CH=), 2.30–2.05 (6H, m, 3 × -C*H*$_2$CH=), 2.05–1.88 (4H, m), and 1.88–1.74 (2H, m) (3 × -CH_2-); 1.69 (3H, d, J = 1.5 Hz, -CH=C(C*H*$_3$)-); ^{13}C nmr (62.5 MHz, $CDCl_3$) δ (ppm): 172.1, 171.9, 135.1, 134.1, 133.6, 131.2, 125.5 (2), 59.1, 56.7, 52.5, 52.4, 37.0, 31.4, 31.3, 30.4, 26.6, 25.5, 23.3, 22.0; ms *m/e*: 450 (M^+), 435 ($M^+ - CH_3$). Exact Mass calcd. for $C_{24}H_{34}O_8$: 450.2253; found: 450.2263 ± 0.0013.

(3*Z*,10*E*,12*E*)-4-(Methoxymethoxy)methyl-1-*tert*-butyldimethysiloxy-7,7-bis(methoxycarbonyl)-14-pivaloyloxy-tetradeca-3,10,12-triene (62)

To a cooled (0°C) solution of *Z* hexenol **39** (0.322 g, 1.09 mmol) in dichloromethane (8 mL) were successively added triethylamine (0.21 mL, 1.52 mmol) and methanesulfonyl chloride (0.093 mL, 1.20 mmol). After stirring at 0°C for 1 h, water (10 mL) was added and the mixture was extracted with dichloromethane (4 × 15 mL). The combined organic layers were washed with brine (5 mL), dried over anhydrous magnesium sulfate, filtered, and concentrated. The crude compound was quickly purified by flash chromatography (30% ethyl acetate in hexanes) on a short column, yielding pure mesylate **40** (0.415 g, 100%, colorless oil). This sensitive material was immediately used for the following coupling reaction.

A solution of malonate **23** (0.356 g, 1.09 mmol, coevaporated several times with benzene) in dimethylformamide (1.0 mL) was added to a stirred suspension of sodium hydride (45.0 mg, 1.12 mmol, 60% dispersion in mineral oil) in dimethylformamide (2.0 mL). After stirring at 40°C for 1 h, hydrogen evolution ceased and the yellowish mixture became clear. Then, a solution of the above mesylate **40** in tetrahydrofuran (3.0 mL), followed by potassium iodide (93 mg, 0.53 mmol), was added and the reaction flask was stirred 6 h at 75°C and 12 h at ~65°C. A solution of aqueous saturated ammonium chloride (20 mL) was added and the resulting mixture was extracted with diethyl ether – petroleum ether (1:2, 4 × 30 mL). The combined organic phases were washed with brine, dried over anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by flash chromatography (1° dichloromethane for removing starting malonate **23**, 2° 30% ethyl acetate in hexanes), yielding coupling product **62** (0.445 g, 67%, colorless oil) and recovered malonate **23** (0.12 g, 10%); ir (neat): 2990–2840, 1740 (br) cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.22 (1H, dd, J = 15.0 Hz, 10.5 Hz, PivOCH$_2$CH=C*H*-CH=), 6.05 (1H, dd, J = 15.0 Hz, 10.5 Hz, PivOCH$_2$CH=CH-C*H*=), 5.77–5.57 (2H, m, -C*H*=CH-CH=C*H*-), 5.42 (1H, br t, $J = 7.5$ Hz, =CH-*HC*=), 4.59 (2H, s, -OCH$_2$O-), 4.56 (2H, br d, $J = 6.5$ Hz, PivOC*H*$_2$CH=), 4.05 (2H, s, -C*H*$_2$OMOM), 3.71 (6H, s, 2 × -CO_2CH_3), 3.59 (2H, t, J = 7.0 Hz, -C*H*$_2$OTBS), 2.30 (2H, dt, J = 7.0 Hz, 7.0 Hz, -C*H*$_2$CH$_2$OTBS), 2.13–1.84 (8H, m, -(C*H*$_2$)$_2$C(CO_2CH_3)$_2$ -(C*H*$_2$)$_2$-), 1.20 (9H, s, (CH_3)$_3$ CCO_2-), 0.88 (9H, s, -SiC(CH_3)$_3$), 0.04 (6H, s, -Si(CH_3)$_2$); ^{13}C nmr (62.5 MHz, $CDCl_3$) δ (ppm): 178.00, 171.69, 136.34, 134.24, 133.68, 129.80, 126.32, 125.12, 95.45, 64.42, 64.23, 62.69, 57.02, 55.07, 52.13, 38.59, 34.47, 31.76, 31.46, 31.26, 29.65, 27.06, 25.79, 18.16, −5.37; ms *m/e*: 597 ($M^+ - CH_3$), 555 (M^+ − C(CH_3)$_3$). Exact Mass calcd. for $C_{31}H_{53}O_9Si$: 597.3459; found: 597.3453 ± 0.0018.

3*Z*,10*E*,12*E*)-4-(Methoxymethoxy)methyl-7,7-bis(methoxycarbonyl)-14-pivaloyloxy-tetradeca-3,10,12-trienol (63)

To a solution of silyl ether **62** (0.440 g, 0.72 mmol) in tetrahydrofuran (6 mL) was successively added tetra-*n*-butylammonium fluoride (0.76 mL, 0.75 mmol, 1 M in tetrahydrofuran) and triethylamine (one drop, used as an acid scavenger). The solution was stirred at room temperature for 4.5 h, after which aqueous saturated ammonium chloride (10 mL) was added. The resulting mixture was extracted with diethyl ether (4 × 30 mL) and the combined organic phases were washed with brine, dried over anhydrous magnesium sulfate, filtered, and concentrated. The crude product was purified by flash chromatography (70% ethyl actetate in hexanes), giving alcohol **63** (0.345 g, 96%, colorless oil); ir (neat): 3480 (br), 2990–2820, 1730 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.22 (1H, dd, J = 15.0 Hz, 10.0 Hz, PivOCH$_2$CH=C*H*-), 6.05 (1H, dd, J = 15.0 Hz, 10.0 Hz, PivOCH$_2$CH=CH-C*H*=), 5.78–5.57 (2H, m, -C*H*=CH-CH=C*H*-), 5.46 (1H, br t, J = 8.0 Hz, -CH=C-), 4.60 (2H, s, -OCH$_2$O-), 4.56 (2H, br d, $J = 7.0$ Hz, PivOC*H*$_2$CH=), 4.06 (2H, s, -C*H*$_2$OMOM), 3.71 (6H, s, 2 × -CO_2CH_3), 3.64 (2H, t, J = 6.0 Hz, -C*H*$_2$OH), 3.37 (3H, s, CH_3O-), 2.35 (2H, dt, J = 6.0 Hz, 6.0 Hz, -C*H*$_2$CH$_2$OH), 2.16–1.82 (8H, m, -(C*H*$_2$)$_2$-C(CO_2CH_3)$_2$-(C*H*$_2$)$_2$-), 1.86–1.50 (1H, br, -OH), 1.20 (9H, s, (CH_3)$_3$$CCO_2$-); ms *m/e*: 466 ($M^+ - CH_3OH$), 436 ($M^+$ − MOM). Exact Mass calcd. for $C_{25}H_{38}O_8$: 466.2566; found: 466.2557 ± 0.0014.

(4*Z*,11*E*,13*E*)-5-(Methoxymethoxy)methyl-1,1,8,8-tetrakis(methoxycarbonyl)-15-pivaloyloxy-pentadeca-4,11,13-triene (65)

To a cooled solution (0°C) of trienol **63** (0.340 g, 0.68 mmol) and triethylamine (133 μL, 0.96 mmol) in dichloromethane (8 mL) was added methanesulfonyl chloride (59 μL, 0.75 mmol). After stirring at 0°C for 1.5 h, water (10 mL) was added and the mixture was extracted with dichloromethane (4 × 25 mL). The combined organic layers were washed with brine (10 mL), dried over anhydrous magne-

For personal use only.

sium sulfate, filtered, and concentrated. The crude compound was quickly purified by flash chromatography (40% ethyl acetate in hexanes) on a short column, yielding pure mesylate **64** (0.392 g, 99% colorless oil). This sensitive material was immediately used for the following alkylation reaction.

Dimethyl malonate (0.39 mL, 3.38 mmol) was added dropwise to a stirred suspension of sodium hydride (0.120 g, 3.05 mmol, 60% dispersion in mineral oil) in dimethylformamide (3.0 mL). After ~30 min at 40°C, hydrogen evolution ceased and the solution became clear. Then, a solution of the above mesylate in tetrahydrofuran (3.0 mL), followed by potassium iodide (56 mg, 0.34 mmol), was added and the reaction flask was stirred 5 h at 75°C and 12 h at 40°C. A solution of aqueous saturated ammonium chloride (50 mL) was added and the resulting mixture was extracted with diethyl ether – petroleum ether (1:2, 4 × 25 mL). The combined organic phases were washed with brine (5 mL), dried with anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by flash chromatography (25% ethyl acetate in hexanes), giving product **65** (0.365 g, 88%, colorless oil); ir (neat): 3000–2840, 1735 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.22 (1H, dd, J = 15.0 Hz, 10.0 Hz, $PivOCH_2CH{=}CH$-), 6.05 (1H, dd, J = 15.0 Hz, 10.0 Hz, $PivOCH_2CH{=}CH\text{-}CH{=}$), 5.77–5.57 (2H, m, -$CH$=CH-CH=$CH$-), 5.36 (1H, br d, J = 7.0 Hz, -CH=C-), 4.57 (2H, s, -OCH_2O-), 4.55 (2H, d, J = 6.0 Hz, $PivOCH_2CH{=}$), 4.01 (2H, s, -CH_2OMOM), 3.74 (6H, s, 2 × -CO_2CH_3), 3.71 (6H, s, 2 × CO_2CH_3), 3.36 (1H, t, J = 7.5 Hz, -$CH(CO_2CH_3)_2$), 3.35 (3H, s, CH_3O-), 2.20–1.82 (12H, m, 6 × -CH_2-), 1.20 (9H, s, $(CH_3)_3CCO_2$-); ms *m/e*: 581 (M^+ − CH_3O), 549 (M^+ − $MOMOH_2$). Exact Mass calcd. for $C_{30}H_{44}O_{11}$: 581.2960; found: 581.2956 ± 0.0023.

(4*Z*,11*E*,13*E*)-5-(Methoxymethoxy)methyl-1,1,8,8-tetrakis(methoxycarbonyl)-pentadeca-4,11,13-trien-15-ol (66)

A solution of sodium methoxide (1.2 mL, 1.18 mmol, 1.0 M in methanol; freshly prepared from sodium and anhydrous methanol) was added to triene **65** (0.362 g, 0.59 mmol) in methanol (3.0 mL). The solution was stirred at room temperature for 5 h (3.6 mL of sodium methoxide solution were added after 2 h), after which aqueous saturated ammonium chloride (10 mL) was added. The resulting mixture was extracted with diethyl ether (6 × 30 mL) and ethyl acetate (25 mL). The combined organic layers were dried over anhydrous magnesium sulfate, filtered, and concentrated. The crude product was purified by flash chromatography (65% ethyl acetate in hexanes), affording alcohol **66** (0.268 g, 86%, colorless oil); ir (neat): 3450 (br), 2980–2820, 1730 cm^{-1}; ^1H nmr (250 MHz, $CDCl_3$) δ (ppm): 6.20 (1H, dd, J = 15.0 Hz, 10.0 Hz, $HOCH_2CH{=}CH$-), 6.06 (1H, dd, J = 15.0 Hz, 10.0 Hz, $HOCH_2CH{=}CH\text{-}CH{=}$), 5.82–5.57 (2H, m, -$CH$=CH-CH=$CH$-), 5.36 (1H, br t, J = 7.0 Hz, -CH=C-), 4.57 (2H, s, -OCH_2O-), 4.16 (2H, br d, J = 6.0 Hz, $HOCH_2$-), 4.01 (2H, s, -CH_2OMOM), 3.74 (6H, s, 2 × -CO_2CH_3), 3.71 (6H, s, 2 × -CO_2CH_3), 3.36 (1H, t, J = 6.5 Hz, -$CH(CO_2CH_3)_2$), 3.36 (3H, s, CH_3O-), 2.25–1.78 (12H, m, 6 × -CH_2-), 1.46–1.27 (1H, br, -OH); ms *m/e*: 510 (M^+ − H_2O). Exact Mass calcd. for $C_{26}H_{38}O_{10}$: 510.2465; found: 510.2471 ± 0.0015.

(4*Z*,11*E*,13*E*)-5-(Methoxymethoxy)methyl-1,1,8,8-tetrakis(methoxycarbonyl)-cyclopentadeca-4,11,13-triene (4)

Methanesulfonylchloride (0.047 mL, 0.60 mmol) was added to a cooled solution (0°C) of alcohol **66** (0.264 g, 0.50 mmol), s-collidine (0.083 mL, 0.63 mmol), and lithium chloride (25 mg, 0.58 mL) in dimethylformamide (1.0 mL). The reaction mixture was stirred at 0°C for 1.5 h (a thick white precipitate appeared after ~10 min), after which s-collidine (17 μL), lithium chloride (5 mg), and methanesulfonyl chloride (10 μL) were added in order to complete the reaction (2 h of additional stirring at 0°C). The reaction mixture was then poured into ice-water (10 mL) and extracted with diethyl ether – petroleum ether (1:1, 4 × 25 mL). The combined organic layers were successively washed with aqueous saturated cupric sulfate (5 mL) and brine (2 × 5 mL), dried with anhydrous magnesium sulfate, filtered, and concentrated. The residue was quickly purified by flash chromatography (40% ethyl acetate in hexanes) over a short column, affording unstable allylic chloride **67** (0.220 g, 81%, colorless oil). This material was used without delay for the following macrocyclization reaction.

To a vigorously stirred suspension of cesium carbonate (0.790 g, 2.42 mmol) in dimethylformamide–tetrahydrofuran (30 mL:30 mL) at 75°C was slowly added the above allylic chloride **67** (coevaporated several times with benzene) in dimethylformamide–tetrahydrofuran (20 mL:20 mL) via syringe pump within 12 h (final concentration: 4 × 10^{-3} M). After additional stirring for 5 h, the reaction mixture was allowed to cool to room temperature, filtered through a fritted glass, and concentrated (the rotary evaporator was connected to an oil pump for removing dimethylformamide). The residue was purified by flash chromatography (25% ethyl acetate in hexanes), giving pure TTT macrocyclic triene **4** (0.181 g, 88%, foamy solid). A sample of this compound could be recrystallized in dichloromethane–hexanes, giving small needles (mp 53–58°C) from which a suitable one was submitted to X-ray crystallographic analysis for structure confirmation; ir (neat): 3000–2780, 1730 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ (ppm): 6.00 (1H, dd, J = 14.0 Hz, 10.0 Hz, -HC=CH-CH=CH-), 5.95 (1H, dd, J = 14.0 Hz, 10.0 Hz, -HC=CH-CH=CH-), 5.55 (1H, dt, J = 14.0 Hz, 6.5 Hz, -HC=CH-CH=CH-), 5.40–5.27 (2H, m, -HC=CH-CH=CH,-CH=C-), 4.55 (2H, s, -OCH_2O-), 3.94 (2H, s, -CH_2OMOM), 3.71 (6H, s, 2 × -CO_2CH_3), 3.69 (6H, s, 2 × -CO_2CH_3), 3.34 (3H, s, CH_3O-), 2.74 (2H, d, J = 8.0 Hz, -$(CH_3O_2C)_2CCH_2CH{=}$), 2.20–2.00 (6H, m, 3 × -$CH_2CH{=}$), 2.00–1.85 (4H, m) and 1.85–1.70 (2H, m) (3 × -CH_2-); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 171.95, 171.90, 136.76, 135.20, 134.03, 131.82, 130.32, 124.86, 95.72, 64.51, 58.40, 58.21, 55.17, 52.56, 52.35, 35.79, 31.98, 29.67, 29.11, 27.96, 27.87, 19.99; ms *m/e*: 510 (M^+), 478 (M^+ − CH_3OH), 448 (M^+ − MOMOH). (*E*,*E*,*E*)-4-Hydroxymethyl-1,1,8,8-tetrakis(methoxycarbonyl)-cyclopentadeca-4,11,13-triene (83)

To a cooled solution (0°C) of TTC-macrocyclic trienal **8** (42 mg, 0.091 mmol) in methanol–tetrahydrofuran (1:1, 2 mL), was added sodium borohydride (3.5 mg, 0.091 mmol). The solution was stirred 1 h, after which a solution of aqueous ammonium chloride (5 mL) was added. The aqueous phase was extracted with diethyl ether (3 × 10 mL) and ethyl acetate (2 × 10 mL) and the combined organic layers were washed with brine, dried over anhydrous magnesium sulfate, and filtered over a fritted glass funnel filled with a 1.5 cm thick silica gel pad (rinsed with ethyl acetate). The filtrate was concentrated, leaving pure alcohol **83** (41 mg, 97%, colorless oil); ir (neat): 3540 (br), 2955, 2860, 1730 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ (ppm): 6.23–6.10 (2H, m, -CH=C*H*-C*H*=CH-), 5.78 (1H, dt, *J* = 14.5 Hz, 7.0 Hz, -C*H*=CH-CH=CH-), 5.57 (1H, dt, *J* = 14.0 Hz, 7.0 Hz, -CH=CH-CH=C*H*-), 5.24 (1H, t, *J* = 8.0 Hz, -C=CH-), 3.98 (2H, br s, -CH_2OH), 3.72 (6H, s, 2 × -CO_2CH_3), 3.70 (6H, s, 2 × -CO_2CH_3), 2.67 (2H, d, *J* = 7.0 Hz, -(CH_3O_2C)$_2$CCH_2CH=), 2.12–1.60 (13H, m, 3 × -CH_2CH_2, -OH); ^{13}C nmr (75 MHz, $CDCl_3$): 171.99, 171.75, 138.03, 135.32, 133.56, 131.34, 126.65, 125.34, 66.85, 59.02, 56.53, 52.63, 52.49, 36.44, 31.84, 30.97 (2), 26.61, 21.69, 21.32; ms *m/e*: 466 (M^+), 448 (M^+ − H_2O). Exact Mass calcd. for $C_{24}H_{34}O_9$: 466.2203; found: 466.2198 ± 0.0013.

(*E*,*E*,*E*)-4-(Methoxymethoxy)methyl-1,1,8,8-tetrakis(methoxycarbonyl)-cyclopentadeca-4,11,13-triene (7)

To a solution of TTC-macrocyclic trienol **83** (41 mg, 0.088 mmol) in dichloromethane (1.5 mL), were successively added diisopropylethylamine (0.046 mL, 0.26 mmol) and methoxymethyl chloride (0.014 mL, 0.18 mmol). The mixture was stirred 5 h at room temperature, after which a solution of aqueous saturated ammonium chloride (5 mL) was added. The resulting mixture was extracted with dichloromethane (3 × 10 mL) and the combined organic layers were washed with brine, dried over anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by flash chromatography (30% ethyl acetate in hexanes), yielding TTC macrocycle **7**

(34 mg, 77%, foamy oil); ir (neat): 2950, 1735 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ (ppm): 6.22–6.10 (2H, m, -CH=C*H*-C*H*=CH-), 5.78 (1H, dt, J = 15.0 Hz, 7.0 Hz, -C*H*=CH-CH=CH-), 5.55 (1H, dt, J = 15.0 Hz, 7.0 Hz, -CH=CH-CH=C*H*-), 5.27 (1H, t, J = 8.0 Hz, -C=CH-), 4.56 (2H, s, -OCH_2O-), 3.87 (2H, s, -CH_2OMOM), 3.72 (6H, s, 2 × CO_2CH_3), 3.70 (6H, s, 2 × CO_2CH_3), 3.34 (3H, s, -OCH_3), 2.68 (2H, d, J = 7.0 Hz, -$(CH_3O_2C)_2CCH_2CH$=); 2.12–1.97 (4H, m) and 1.97–1.78 (6H, m) and 1.78–1.63 (2H, m) (3 × -CH_2CH_2-); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 172.00, 171.75, 135.23, 133.55, 131.44, 129.26, 127.70, 125.40, 95.49, 71.28, 59.08, 56.66, 55.23, 52.54, 36.69, 32.00, 31.09, 30.90, 26.55, 21.93, 21.69; ms *m/e*: 510 (M^+) 478 ($M^+ - CH_3OH$), 448 (M^+ − MOMOH). Exact Mass calcd. for $C_{26}H_{38}O_{10}$: 510.2465; found: 510.2471 ± 0.0015.

Acknowledgements

This research was financially supported by the Natural Sciences and Engineering Research Council of Canada (NSERC, Ottawa) and by the "Ministère de l'Enseignement Supérieur et de la Science (Fonds FCAR, Québec)." D.G.H. thanks NSERC for a 1967 Postgraduate Award. We wish to acknowledge the help of Dr. Solo Goldstein and Prof. Yves L. Dory for the molecular modeling calculations, and Mr. Gilles Provencher for his technical assistance in the preparation of some intermediates.

Studies on the transannular Diels–Alder reaction of 15-membered macrocyclic trienes containing a *trans-trans* diene. Part II: Evidence for unsymmetrical transition states in the formation of A.B.C.[6.6.7] tricyclic products[1]

Dennis G. Hall, Renate Müller, and Pierre Deslongchamps

Abstract: In the preceding paper (Part I) we described the preparation of 10 model TTT and TTC cyclopentadecatrienes. Their conversion to A.B.C.[6.6.7] tricyclic products via a transannular Diels–Alder (TADA) reaction and the analysis of the resulting diastereoselection along with proofs of structures are described in the present article (Part II). The required temperature of reaction was significantly higher (~100°C) in comparison to that required for the 14-membered lower homologs, indicating that proximity effects are playing a key role in the TADA reaction. The presence of ester groups in the chain was found to favor either of the two possible transition states (*endo* or *exo*) on the basis of steric effects, thus controlling the TST/CSC ratio of tricycles from TTC macrocycles, and the TAC/CAT ratio from TTT macrocycles. A formyl substituent on the dienophile can further influence the diastereoselection through the hypothesis of unsymmetrical transition states and allowed, for the first time, the use of Lewis acids as catalysts in the TADA reaction. This investigation demonstrates a general methodology for the stereocontrolled synthesis of A.B.C.[6.6.7] tricycle structures related to several polycyclic natural products.

Key words: transannular, Diels–Alder, 15-membered ring, A.B.C.[6.6.7] tricycles, diterpene.

Résumé : Dans l'article précédent (Partie I), nous avons décrit la préparation de 10 cyclopentadécatrienes modèles de géométrie TTT et TTC. Leur conversion en produits tricycliques A.B.C.[6.6.7] via une réaction de Diels–Alder transannulaire (DATA) et l'analyse de la diastéréosélection résultante accompagnée des preuves de structure sont décrites dans l'article qui suit (Partie II). La température de réaction requise fut significativement plus élevée (~100°C) à comparer aux homologues inférieurs à 14 membres, indiquant que les effets de proximité jouent un rôle clé dans la réaction DATA. La présence de groupements ester sur la chaîne a permis de favoriser un ou l'autre des deux états de transition possibles (*endo* ou *exo*) par des effets stériques, contrôlant ainsi le ratio des tricycles TST/CSC à partir des macrocycles TTC, et le ratio TAC/CAT à partir des macrocycles TTT. Un substituant formyle sur le diénophile peut influencer davantage la diastéréosélection à travers l'hypothèse d'états de transition non-symétriques et a aussi permis, pour la première fois, l'utilisation d'acides de Lewis comme catalyseurs dans la réaction DATA. Cette étude démontre une méthodologie générale permettant de synthétiser de manière stéréocontrôlée des structures tricycliques A.B.C.[6.6.7] que l'on retrouve chez plusieurs produits naturels polycycliques.

Mots clés : transannulaire, Diels–Alder, cycle à 15 membres, tricycles A.B.C.[6.6.7], diterpène.

Introduction

In the preceding article (1), we reported the synthesis of 10 model 15-membered macrocyclic trienes **1–10** (cf. Tables 1 and 2), each containing a *trans-trans* diene and a *cis* or *trans* trisubstituted dienophile. In this paper (Part II), we wish to report our results on the investigation of the reaction conditions and the analysis of the stereochemical outcome of their thermal conversions to A.B.C.[6.6.7] tricyclic products through a transannular Diels–Alder (TADA) reaction. Such a general study, in which the geometry (*trans* or *cis*), the nature, and the position (pro-6.6 or pro-6.7) of a substituent on the dienophile are systematically varied, should enable a better understanding of the factors governing diastereoselection. In particular, the obtention of formyl-substituted macrocyclic substrates (**3, 5, 8, 10**) opens doors for effecting Lewis acid catalysis for the first time on transannular systems with the benefit of milder reaction conditions.

Results and discussion

Each model macrocyclic triene **1–10** can, in principle, yield two diastereomeric products via two possible boat-type transi-

tion states, arising from either an *endo* or an *exo* approach. In the preceding paper of this series (Part I) it was shown that the ground state conformation of the diene moiety in our substrates is the *transoid* form. To collapse into tricycles, the *cisoid* form is required (2). This conformational factor, along with others such as steric and electronic effects stemming from the dienophile substituent, will be discussed herein. A special emphasis will be placed on a comparison with the IMDA reaction for which an excellent review article recently appeared (3). It should be stated, however, that the superior level of sophistication of the transannular variant (the intramolecular variant is limited to the formation of bicyclic systems) is associated with more parameters. For instance, two ring junctions (A.B.[6.6] and B.C.[6.7] are formed in a single operation instead of only one for the IMDA reaction. Also, whereas the IMDA literature is overflowing with examples in the decalin series (see example in Scheme 1), we are aware of only three cases (4) reporting the preparation of bicyclo-[6.7] systems (Scheme 2).

The discussion also includes the proof of structures for the various tricyclic compounds reported herein as well as a comparison with results previously obtained with 14-membered macrocyclic trienes.

TADA reaction of pro-6.7-substitued TTC macrocyclic substrates 9 and 10

Macrocyclic trienes **9** and **10** can give a *trans-syn-trans* (TST) tricycle via an *endo* approach and a *cis-syn-cis* (CSC) tricycle, this time formed from an *exo* approach[3] (Scheme 3). Upon heating at 200°C for 3.0 h in a sealed tube, MOMO-methyl-

[3] The *endo/exo* denomination employed herein is relative to the dienophile substituent.

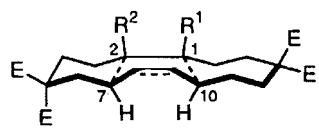
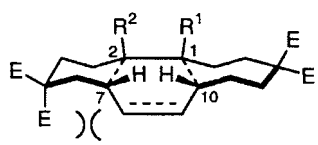
substituted macrocyclic triene **9** gave a high yield of an inseparable 85:15 mixture favoring TST tricycle **9a** over CSC **9b** (Table 1, entry 1). A comparison of the two transition states mentioned above reveals, in the CSC case, the presence of a

Scheme 3.



TST (*endo*) transition state



CSC (*exo*) transition state

severe 1,3-diaxial steric interaction between the pseudo-axial ester function of ring A in a chair conformation[4] and one of the sp^2 carbons (C7) of the diene. Such an interaction being absent in the TST transition state, the preferential formation of TST tricycle **9a** over CSC **9b** is readily explained. Due to the twist-

[4] In this case, with $R^2 = H$, a high-energy boat conformation in ring A could compete with this sterically hindered chair (see ref. 5).

Scheme 4.

chair conformation[5] of the seven-membered ring C being formed, it seems likely that the second malonate unit, on the basis of its steric interactions, will not help in discriminating between processes. This hypothesis is in agreement with a former observation from our laboratory concerning TTC 14-membered macrocycles (Scheme 4). In this example (7), two cooperative axial ester groups were necessary to prevent the formation of the CSC tricyclic product, indicating that only a single one is strongly involved in the present case. It is interesting to note the relatively lower reaction temperature (~80°C) needed in the latter example compared to that of **9**. Thus, an additional methylene group makes a significant difference, indicating that proximity and entropy effects play a very important role in the TADA reaction.

Following hydrolysis of the MOM ether of the mixture **9a/9b** (Scheme 5), the corresponding allylic alcohols TST **11a** and CSC **11b** could be separated with some difficulty by preparative thin-layer chromatography and individually characterized by standard means (ir, ^1H nmr, ^{13}C nmr, ms). Confirmation of the ring junction stereochemistry by nmr techniques was found impracticable for these compounds and for most others in this study. Key coupling constants could not be extracted from the complicated superposed multiplets observed in the ^1H nmr spectra. However, a more convenient way of effecting separation on a larger scale also offered a concomitant chemical proof of structure. Indeed, treatment of the **11a/11b** mixture under Bartlett's kinetic iodoetherification

CSC **11b** iodoetherification transition state

conditions (8, 9) (Scheme 5) afforded TST iodoether **12** and unreacted CSC alcohol **11b**, very easily separable on silica gel. In fact, the alcohol and alkene functions of **11b** cannot be brought in close proximity for an iodine-mediated reaction, as strongly disfavored steric interactions would be created by the required conformational change (Scheme 6). On the other hand, iodoether **12**, which structure was confirmed by spectroscopic methods including ^1H nmr analysis (Scheme 6), could

[5] Cycloheptanes are more flexible than cyclohexanes. Conformational analysis of the former reveals the existence of more accessible conformations such as the twist-chair and chair, which readily interconvert (6).

be reconverted to the TST alcohol **11a** by treatment with zinc in acetic acid (Scheme 5).

The formyl macrocyclic analog **10** gave TST tricycle **10a** exclusively, under both thermal and Lewis acid-catalyzed conditions[6] (Table 1, entries 2–4).[7] It is noteworthy to mention the milder reaction conditions allowed in this reaction by the use of Lewis acids, with a temperature lowering of >100°C. The absence of any of the CSC diastereomer **10b** was confirmed by carrying out oxidation if CSC alcohol **11b** (Scheme 5). The corresponding ^{1}H nmr formyl peak of the putative aldehyde **10b** was clearly absent from crude spectra of thermolyzed **10** even after baseline amplification. Such a stereospecificity finds some precedent in the IMDA reaction of terminally activated decatrienes (Scheme 1), although in this example (14) reported by Roush et al., the thermal uncatalyzed reaction affords a rather modest selectivity (i.e., 75:25). The increase in selectivity observed on going from macrocycle **9** to activated analogue **10** can in principle be explained by the *endo* effect, which leads to a lower energy transition state presumably due to stabilizing secondary orbital interactions (2*a*). However, it was demonstrated decades ago that such an effect is weakly operative at temperatures higher than 75°C (15) although it is rather efficient at lower temperatures. In agreement with this, the *endo* effect is also known to have a reduced influence on the thermal IMDA reaction (3). Since TST tricycle **10a** is the exclusive product even at 150°C, a more viable explanation relies on the "concerted asynchronous transition state" hypothesis for unsymmetrically activated Diels–Alder substrates (3). Indeed, with R^1 = CHO as in **10**, the largest LUMO coefficient for acrolein-type dienophiles (16) lies at the β-site (C2), resulting at the transition state level in a short C2—C7 and a longer C1—C10 distance and indicating that the incipient bonding is more advanced in the former case (Scheme 3). Therefore, it follows that the importance of steric interactions in the vicinity of C2 and C7 must be emphasized,[8] including the key pseudo-1,3-diaxial interaction that is taking place in the CSC transition state as mentioned above. Consequently, as this steric interaction is magnified, the preclusion of the CSC tricycle **10b** is well understood when compared with the slight proportion of **9b** from macrocycle **9**. An alternative explanation, also relying on the crucial role of the short C2—C7 incipient bond, suggests that a *trans*-[6.6] ring junction will be strongly favored in such situations of decalin formation. This generalization has been drawn from the IMDA study of terminally activated decatrienes (3) (Scheme 1).

Tricyclic compound **10a** was chemically correlated to tricycle **9a** for structure confirmation by reduction with sodium borohydride, yielding alcohol **11a**, which was found spectroscopically identical to the alcohol obtained via hydrolysis of **9a**. Moreover, interesting arguments for the determination of the relative stereochemistry were deduced from the proton nmr analysis of tricycles **10a** and **10b** (the latter obtained from **9b** as in Scheme 5). Aside from its chemical correlation with **9a**, the *endo* (TSC) stereochemistry of **10a** was implied on the basis of a J_w coupling (1.0 Hz) between the aldehyde proton and the methine proton on the *trans* B.C.[6.7] ring junction.[9] A similar W spatial arrangement is indeed unattainable in **10b** and no coupling is actually observed.

TADA reaction of pro-6.6-substituted TTC macrocyclic substrates 6, 7, and 8

Like their regioisomers described in the previous section, TTC pro-6.6-substituted macrocyclic trienes **6, 7**, and **8** can give TST and CSC tricycles via transition states with dienophile substituents permuted from C1 to C2 (Scheme 3). Model macrocycle **6** having a methyl substituent on the dienophile was heated at 200°C for 4.0 h, giving an 86:14 mixture favoring TST tricycle **6a** over the CSC diastereomer **6b** in moderate yield (Table 1, entry 5). These TADA products were separated by preparative tlc and fully characterized by standard means. The major isomer was subjected to an alkene epoxidation procedure with trifluoroperacetic acid, leading to the formation of putative epoxide **13** (eq. [1], Scheme 7). The indicated oxirane stereochemistry is based on a presumed attack of the reagent from the less congested exocyclic face. This hypothesis, along with the TST relationship at ring junctions, is in line with the observed ^{1}H nmr coupling constants for HC7–HC8 and HC9–HC10 (9.0 Hz), which are characteristic of pseudo-diaxial arrangements.

The analogous macrocyclic triene **7**, bearing a $CH_3OCH_2OCH_2$- substituent, gave a similar ratio (90:10) of TST tricycle **7a** and CSC **7b** (Table 1, entry 6). The less polar TST product **7a** was isolated in pure form by preparative tlc, resulting in a modest yield of 55%. A substantial amount of a more polar fraction was found to contain one or more unknown macrocyclic by-products[10] as major components with a small proportion (ca. 15%) of CSC tricycle **7b**. The latter could not be formally identified from this mixture. However, its presence and proportion were assessed through a hydrolysis–oxidation sequence followed by comparison of ^{1}H nmr data of the resulting aldehyde mixture with those of pure **8b** originating from the TADA reaction of macrocycle **8** (vide infra). The proportion of **7b** in the original impure tlc fraction was then deduced and an approximate ratio with **7a** could be estimated. The predominance of TST tricyclic products **6a** and **7a** over their respective CSC diastereomers is readily explained using the same analysis as described for regioisomeric macrocycle **9** (see above). Indeed, a pseudo-diaxial steric interaction between an ester group of incipient ring A and sp^2 carbon 8 is still responsible for the superior energy of activation associated with the CSC transition state (Scheme 3). Compared to the case of model macrocycle **9**, inspection of molecular models shows that a permutation of the dienophile

[6] Excess acid was used since the malonate units of our model substrates can form strong chelates (10).

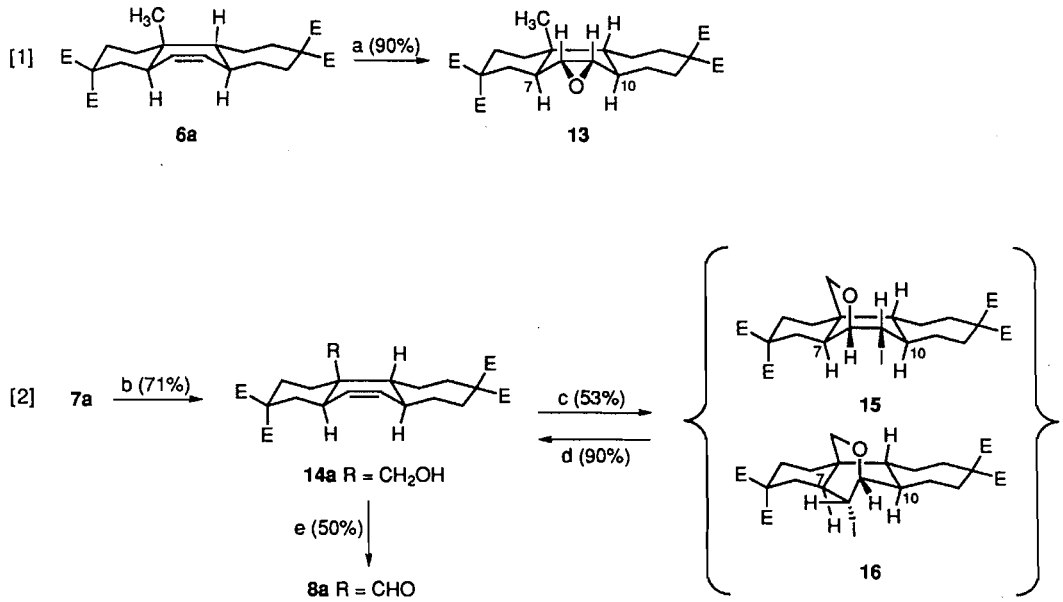
[7] Some exploratory experiments using "unclassical" reaction media were also tried. The use of 5 M $LiClO_4$ – Et_2O (11) for 48 h afforded only ~20% **10a**. Water–methanol 1:1 as a solvent was also shown to accelerate the transformation of **10** (80°C, 3 h, 60% conversion; 100°C, sealed tube, 3 h, 95% conversion). Unactivated macrocycle **6** (vide infra) was insensitive to the effect of hydroxyl-based solvents. These results are in opposition to Breslow's theory of hydrophobic acceleration (12) and point rather toward hydrogen-bonding effects (13) on the formyl group.

[8] We should be reminded here that the energy of nonbonding interactions developed between two sites is related to distance (r) by a factor of $1/r^6$ (17)!

[9] For other examples, see ref. 18. This observation is similar to the broadening effect of methyl signals in *trans* ring junctions of steroid derivatives (19).

[10] Upon heating at high temperatures, hypothetical side processes include transannular ene reactions and allylic MOM ether pyrolysis as a retro-ene reaction (20).

Scheme 7. Chemical derivatization for pro-6.6 substituted TST and CSC tricycles.



(a) NaH_2PO_4, CF_3CO_3H, $(ClCH_2)_2$, 0°C, 20 min. (b) conc. $HCl_{(aq.)}$ / H_2O / MeOH, 60-65°C, 12h.
(c) $NaHCO_3$, I_2, THF, rt, 2h. (d) Zn, conc. $AcOH_{(aq.)}$, rt, 2h. (e) NMO, TPAP, 4A m.s., CH_3CN, rt, 2h

substituent from C1 (pro-6.7) to C2 (pro-6.6) as in **6** and **7** should not affect the balance of steric interactions encountered in both transition states. Whether placed at C1 or C2, the substituent is not involved in any significant nonbonded interactions with the malonate moieties or any other group of rings A and C, hence explaining the comparable diastereoselection arising from macrocycles **9**, **6**, and **7**.

As for **9**, the *endo* (TST) stereochemistry of the major tricyclic product obtained from macrocycle **7** was confirmed by hydrolysis of **7a** and subjection of the resulting alcohol **14a** to conditions of iodoetherification (Scheme 7, eq. [2]). This could serve as well as a structure confirmation for **6a** since its ^1H nmr spectra is identical to those of **7a** and **14a** except for signals attributed to the C2 substituent. In contrast with **9a**, isomer **7a** led to the obtention of two inseparable cyclic iodoethers in a 4:3 ratio favoring the "normal" one (**15**) formed via a 5-membered ring closure at the proximal sp^2 carbon of **7a**. In this case, we believe that the minor iodoether **16** is observed because of the greater flexibility of the B.C.[6.7] ring junction in bringing the distal carbon (C9) close to the hydroxyl group, so that closure of the six-membered ring can take place. Compound **16** can adopt the stable conformation of a bicyclo[2.2.2] ring system and was readily differentiated from **15** on the basis of coupling constants from the C8 and C9 hydrogens (Scheme 7). The observed values are in agreement with the expected dihedral angles (ϕ) estimated by molecular model analysis.[11] Upon treatment in zinc – acetic acid suspension, the **15/16** mixture returned to the mother TST alcohol **7a** by reductive elimination.

[11] For **15**: ϕ H7CCH8 ~90°, J = 0 Hz; ϕ H8CCH9 ~90°, J = 0 Hz; ϕ H9CCH10 ~180°, J = 9.5 Hz. For **16**: ϕ H7CCH8 ~100°, J = 0 Hz; ϕ H8CCH9 ~30°, J = 2.5 Hz; ϕ H9CCH10 ~45°, J = 7.0 Hz.

Compared to macrocycle **10** and in contrast to the known behaviour of carbonyl-activated dienophiles, macrocycle **8** with an aldehyde function at the pro-6.6 position led to a decrease in *endo*-selectivity, giving a **8a/8b** ratio of 76:24 under thermal activation (Table 1, entries 7 and 8). This result is quite surprising on the basis of the aforementioned arguments according to which substrates **8** and **10** can be considered as sterically unbiased. However, the "asynchronous transition state" hypothesis still offers a satisfactory explanation. The shortest, and determining, incipient bond of unsymmetrical transition states arising from macrocycle **8** (Scheme 3; R^2 = CHO, R^1 = H) is now C1–C10, resulting in a situation the reverse of that encountered with macrocycle **10**. Therefore, it follows that the importance of steric interactions in the vicinity of C2 and C7 must be diminished, including the key pseudo-1,3-diaxial interaction that is taking place in the CSC transition state. As this steric interaction is weakened, the formation of a slightly greater proportion of CSC (*exo*) tricycle **8b** than of **6b** and **7b** is now clarified. This result is also a clear demonstration of the inhibition of *endo* stabilization at high temperatures.

It is known from the IMDA reaction (3) that the effect of Lewis acid catalysis is twofold: (*a*) secondary orbital interactions become substantially more important as a large increase in *endo* selectivity is generally observed; (*b*) the asynchronicity of bond formation is greatly enhanced. Both of these effects find their origin in the accentuation of the size difference already present between the LUMO coefficients on both the carbonyl and the olefin (16). The use of tin tetrachloride for activating the TADA reaction of macrocycle **8** led to a rise in *endo* selectivity with an **8a/8b** ratio of 87:13 obtained (entry 10). The intrinsically stronger Lewis acid (21), boron trifluoride etherate, allowed the reaction to proceed slowly at room temperature, with the associated advantage of a better dia-

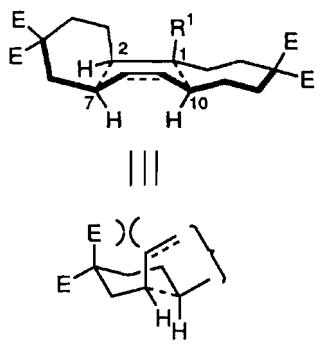
stereomer bias standing at 95:5 (entry 11). Also, this result is still in line with a corresponding enforcement of *endo* stabilization through temperature lowering. Thus, the first of the two effects described above tends to overcome the latter since increased asynchronicity leading to a longer C2—C7 forming bond translates into a reduced ester–C8 interaction in the CSC transition state.

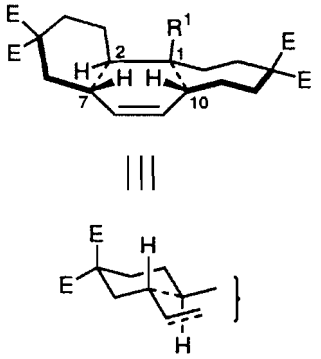
Also, the TADA reaction of macrocyclic triene **8** is significantly slower than that of **10**, as exemplified by entries 2 and 8 (thermal) and entries 3 and 4 and 9–11 (Lewis acid catalyzed). In particular, tin tetrachloride failed to cause any reaction of **8** at room temperature whereas **10** reacted completely in less than 2 h under the same conditions. Assuming that a six-membered ring closure is faster than that of a seven-membered ring at transition state level, this observation is also in line with the above theoretical arguments. Indeed, the TADA reaction of **10** gives rise to the six-membered ring A by closure at the most advanced bonding site (C2—C7) whereas the fastest developing bond of **8** (C1—C10) involves rather the disfavored seven-membered ring C closure. Clearly, only an asynchronous mechanism can account for such observations.[12]

As expected, the major TST (*endo*) product **8a** showed the doublet signal (J = 1.0 Hz) diagnostic of *trans* stereochemistry for the aldehyde ^{1}H nmr resonance whereas CSC aldehyde appeared as a singlet. Futhermore, tricycle **8a** was chemically correlated to **7a** by oxidation (22) of **14a** (Scheme 7). Finally and most importantly, the less favored CSC tricycle **8b** was heated at 210°C for 5 h and remained unchanged. This control experiment served in ascertaining the kinetic nature of the diastereomeric ratios resulting from the TADA reactions described in this article.

Scheme 8.



CAT (*endo*) transition state



TAC (*exo*) transition state

TADA reaction of pro-6.7-substituted TTT macrocyclic substrates 4 and 5

In principle, macrocyclic trienes **4** and **5** can lead to a *cis-anti-trans* (CAT) tricycle via an *endo* approach and a *trans-anti-cis* (TAC) diastereomer from an *exo* approach (Scheme 8). Actually, the TAC tricycle **4a** was found to dominate over CAT **4b** by a 78:22 ratio in the thermal reaction of macrocycle **4** (Table 2, entry 1). In this case, the pseudo-1,3-diaxial interaction due to one of the ester functions of ring A is now present in the *endo* transition state (Scheme 8). The absence of a similar steric interaction in the *exo* transition state explains the preponderance of the corresponding TAC tricycle **4a**. The resulting tricycles **4a** and **4b** could not be separated on silica gel plates even with many attempts under various solvent systems. Hydrolysis of the MOM ether of the **4a/4b** mixture gave pure TAC tricyclic alcohol **17a** and pure CAT diastereomer **17b** (Scheme 9) after separation by preparative thin-layer chromatography. The major TAC tricyclic alcohol **17A** was oxidized with pyridinium chlorochromate (23) to give aldehyde **5a**. The proton nmr signal of the aldehyde hydrogen showed the expected singlet since no W arrangement is possible with the C10 methine hydrogen in this TAC stereochemistry.

The TTT formyl-substituted macrocyclic triene **5** gave a similar diastereomeric ratio of 77:23, again favoring TAC tricycle **5a** over CAT tricycle **5b** when heated at 320°C for 1.5 min (Table 1, entry 2). Unfortunately, the crude mixture was accompanied by ca. 40% of TST tricycle **10a**. The latter tricycle formed after in situ thermal isomerization of TTT macrocycle **5** to the TTC geometrical isomer **10**, as discussed thoroughly in the preceding paper (Part I). This process, which might also be promoted by the glass wall acidic sites, was even more important at lower temperatures for longer times (entry 3). However, the extent of this undesirable isomerization reaction could be limited by making use of Lewis acid catalysis at room temperature (entry 5). A **5a/5b** ratio of 84:16, close to the ratio observed in the uncatalyzed thermal reaction examined above, was obtained under aluminium trichloride catalysis. The decreased proportion of CAT tricycle **5b** can be attributed to the strengthening of the aforementioned 1,3-diaxial interaction present in the CAT transition state (Scheme 8), caused by the enhancement of asynchronicity induced by Lewis acid complexation. Again, contrary to **5a**, the possibility of having a W arrangement with C10—H made the minor tricyclic product **5b** show a typical doublet (J = 1.0 Hz) for the ^{1}H nmr signal of the aldehyde hydrogen.

TADA reaction of pro-6.6-substituted TTT macrocyclic substrates 1, 2, and 3

Macrocyclic trienes **1–3** can theoretically afford the TAC tricycle (*endo* approach) and the CAT diastereomeric tricycle (*exo* approach). Methyl-substituted marcocycle **1** and MOMO-methyl-substituted analog **2** both have moderate yields and similar diastereomeric ratios (~90:10) favoring TAC tricyclic products **1a** and **2a** over CAT tricycles **1b** and **2b** (Table 2, entries 6 and 7). Inspection of the CAT transition state (Scheme 10) reveals a severe 1,3-diaxial steric interaction

[12] The mechanistic consequences related to this phenomenon will be soon communicated as a detailed kinetic study.

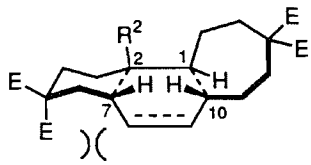
TAC (*endo*) transition state



CAT (*exo*) transition state

between the pseudo-axial ester function of ring A in a chair conformation and a sp^2 carbon (C8) of ring B. This interaction being absent in the TAC transition state leading to **1a** and **2a**, the ratio in favor of these tricycles is readily understood. The second pair (**2a** and **2b**) was not separable on silica gel but recrystallization of the diastereomeric mixture afforded nice pure monocrystals of TAC tricycle **2a**, for which the stereochemistry was confirmed by X-ray diffraction analysis (24). Since ^1H nmr spectra of **1a** and **2a**, and **1b** and **2b**, were identical in all respects except for the C2 substituent, this proof of structure served as well for the methyl-substituted series. Moreover, the half-widths of the C2-methyl singlets of **6a** and **6b**, which measured, respectively, 2.0 and 1.0 Hz, are in line with an expected signal broadening due to long-range W coupling with H-C7 in such *trans*-decalin systems as TST **6a** (19). The **2a/2b** mixture was also characterized through hydrolysis of the MOM protecting group and facile separation of the corresponding alcohols **18a** and **18b** (Scheme 11).

As for its regioisomer **5**, enal inversion remained an unsolved problem for the TADA reaction of TTT formyl-substituted macrocyclic triene **3** (Table 2, entries 8–11). Although TAC tricycle **3a** was the exclusive TADA product from macrocycle **3**, it was also accompagnied by tricycles **8a** and **8b** originating from TTC macrocyclic triene **8** formed in situ. As for the TTC series, the Lewis acid catalyzed reaction (entries 10 and 11) was slower in the case of pro-6.6-activation than for **5** (entries 4 and 5), and the higher temperature required for the TADA reaction of **3** resulted in complete isomerization to **8** and isolation of its corresponding tricycles **8a** and **8b**. This unwanted competing process confers little synthetic potential upon the present example of TTT macrocycle **3**. However, its stereospecific conversion to TAC tricycle **3a** is doubtlessly valuable from a theoretical point of view. In analogy with the thermal TADA reaction of TTC macrocycle **8**, this result can also be rationalized with the asynchronous transition state hypothesis. Indeed, the presence of a formyl substituent (R^2) at the pro-6.6 position (Scheme 10) results in transition states having a short C1—C10 and a longer C2—C7 distance, a logical consequence of faster bonding development at the site bearing the larger β-LUMO coefficient. The magnitude of steric interactions around the short C1—C10 incipient bond is then raised, conferring upon the B.C.[6.7] ring junction a decisive role in transition state discrimination. When such a situation exists, as for **8**, an increased trend toward obtaining a *cis* B.C.[6.7] ring junction is observed.[13] Compared to unactivated macrocycles **1** and **2**, this elusive factor further favors the TAC transition state leading to **3a**. The absence of CAT tricycle **3b** in the crude nmr spectra was confirmed by its indirect synthesis, which was carried out through oxidation of **18b** with tetra-*n*-propylammonium perruthenate (TPAP) (22). Pure TAC tricycle **3a** was obtained in a similar fashion from alcohol **18a**. With the secured X-ray structure of **2a** in hand, these chemical derivatization efforts proved the reliability of our ^1H nmr argument concerning the multiplicity of aldehyde protons that was exploited throughout this study. A clear doublet (J = 1.5 Hz) was indeed observed for the aldehyde signal of **3a** whereas **3b** exhibited a sharp singlet.

Conclusion

In contrast to the 14-membered macrocyclic trienes, the 15-membered homologs described herein were isolable and showed that an additional methylene group makes a significant difference in reactivity, indicating that proximity effects play a key role in the TADA reaction. A systematic study of dienophile substituent effects enables us to answer questions about the factors governing the stereochemical outcome of the cycloaddition reaction. Thus, only one substituent, such as an ester, along the tethering chains is necessary to exert a strong stereodirecting effect and favor either of the two possible approaches (*endo* or *exo*). Moreover, it was found that a formyl substituent on the dienophile can alter the geometry of the transition state, thereby influencing the extent of steric interactions and thus leading to different diastereomeric excess compared to unactivated cases. These observations can be considered as additional evidence for the asynchronous transition state theory. In particular, Lewis acid catalyzed

[13] Owing to their superior conformational flexibility, bicyclo[6.7] systems do not seem to have a clear preference for a *trans* ring junction as in the more rigid decalin series.

Diels–Alder reactions were performed for the first time at the transannular level and were shown again to have a tremendous accelerating effect.

The work reported herein further extends the scope of the transannular Diels–Alder reaction for the stereoselective preparation of A.B.C.[6.6.7] tricyclic compounds. The power of this strategy, coupled with the ease with which rings can now be made, makes it very appealing for natural products syntheses. Such applications are presently underway in our laboratory.

Experimental section

General

The reader is referred to this section in the preceding paper (Part I). Lewis acids such as $SnCl_4$ and BF_3OEt_2 were purchased from Aldrich Chemical Co. and used without further purification. The diastereomer ratios were evaluated by measuring peak height and surface of representative signals on the ^1H nmr spectra of crude reaction mixtures.

Model procedures for the TADA reactions

A. Noncatalyzed thermal reactions in sealed tubes (ref. 25)

A clean Pyrex tube (20 cm long, exterior diameter 9 mm, interior diameter 5 mm; quartz was used for reactions with low boiling point solvents at T >250°C) was washed with ammonium hydroxyde, rinsed with distilled water, and oven and flame dried. The macrocyclic triene was added[14] and the tube was sealed under vacuum. For reactions using solvent, 0.5–1.0 mL were inserted and sometimes small quantities of a tertiary amine were added as an acid scavenger.[15] The tube was heated in a temperature-controlled oven for a given time and allowed to cool to room temperature, after which it was opened. The contents were transferred in a flask with diethyl ether and concentrated. The crude product was purified as indicated.

B. Lewis acid-catalyzed reactions

To a stirred solution of the formyl-substituted macrocyclic triene in a given anhydrous solvent at room temperature was added the Lewis acid (generally 3.0 equiv.). The mixture was stirred at the desired temperature for a given time and a solution of aqueous saturated sodium bicarbonate was added at room temperature (for small-scale reactions, a few drops may be added and the mixture directly purified by flash chromatography over a silica gel column). The mixture was extracted four times with diethyl ether or ethyl acetate and the combined organic layers were dried with anhydrous magnesium sulfate, filtered, and concentrated. The crude product was analyzed and purified as indicated.

TADA reaction of macrocycle ***9****: mixture of (7,2-*trans*-2,1-*syn*-1,10-*trans*)-1-(methoxymethoxy)methyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene* ***9a*** *and (7,2-*cis*-2,1-*syn*-1,10-*cis*)-1-(methoxymethoxy)methyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene* ***9b***

Following general procedure A, TTC macrocycle triene **9** (0.210 g, 0.41 mmol) was heated in toluene (1.0 mL) at 200°C for 3.0 h, yielding a crude mixture of tricyclic products **9a** and **9b** (0.22 g, quant., ratio: **9a**:**9b** = 85:15). Preparative thin-layer chromatography purification (20 cm × 20 cm, 4 plates, 0.05 cm thickness, 30% ethyl acetate in hexanes, three elutions) gave a pure mixture of **9a** and **9b** (0.184 g, 88%, viscous oil). These tricyclic products were found inseparable even under various solvent systems. They were individually characterized as their alcohol derivatives **11a** and **11b** (see below).

TST **9a**/CSC **9b**: ir (neat): 2980–2820, 1730 (br) cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ (ppm) (unless indicated, similar peaks arising from both diastereomers are superimposed and indistinguishable): 5.56 (1H, br d, *J* = 9.0 Hz, -*H*C=CH- **9a**), 5.51 (1H, br d, *J* = 9.0 Hz, -HC=C*H*- **9a**), 5.42 (1H, ddd, *J* 10.0 Hz, 2.5 Hz, 2.5 Hz, -*H*C=CH- **9b**), 5.28 (1H, br d, *J* = 10.0 Hz, -HC=C*H*- **9b**), 4.54 (2H, AB m, -OCH_2O-), 3.77 (3H, s, -CO_2CH_3 **9b**), 3.76 (3H, s, -CO_2CH_3 **9a**), 3.72 (1H, d, *J* = 10.0 Hz, -*H*CHOMOM **9b**), 3.72 (3H, s, -CO_2CH_3 **9a**), 3.70 (6H, s, -CO_2CH_3 **9a**), 3.69 (3H, s, -CO_2CH_3 **9b**), 3.68 (3H, s, -CO_2CH_3 **9b**), 3.67 (3H, s, -CO_2CH_3 **9b**), 3.58 (1H, d, *J* = 9.0 Hz, -HCHOMOM **9a**), 3.32 (3H, s, -OCH_3), 3.26 (1H, d, *J* = 10.0 Hz, -HC*H*OMOM **9b**), 3.12 (1H, d, *J* = 9.0 Hz, -HC*H*OMOM **9a**), 2.65–1.15 (17H, m, other -CH_2- and -CH- from both diastereomers); ms *m/e*: 495 (M^+-CH_3), 478 (M^+-CH_3OH), 435 ($M^+-CH_3OCH_2OH$). Exact Mass calcd. for $C_{25}H_{35}O_{10}$: 495.2230; found: 495.2211 ± 0.0014.

(0.182 g, 0.36 mmol) was stirred 5.0 h at 60–65°C in the following solvent system: concentrated aqueous hydrochloric acid – water–methanol (0.5:1.0:8.5, 5.0 mL). The mixture was allowed to cool to room temperature and quenched with a solution of acqueous saturated sodium bicarbonate (20 mL). The resulting mixture was extracted with diethyl ether (3 × 15 mL) and ethyl acetate (2 × 10 mL). The combined organic phases were dried over anhydrous magnesium sulfate, filtered, and concentrated, giving a crude mixture of alcohol derivatives TST **11a** and CSC **11b** (0.158 g, 95%, ratio **11a**:**11b** = 85:15, white foamy solid). These diastereomers could hardly be separated on a small scale (10 mg/plate) using the following preparative tlc conditions: 20 cm × 20 cm plate, 0.05 cm thickness, 25% diethyl ether in benzene, four elutions. For larger quantities, the chemical procedure described below was found more convenient.

TST **11a** (less polar): ir (neat): 3550 (br), 2950, 1730 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ (ppm): 5.56 (2H, narrow AB m, -HC═CH-), 3.75 (3H, s, $-CO_2CH_3$), 3.71 (3H, s, $-CO_2CH_3$), 3.69 (6H, s, 2 × $-CO_2CH_3$), 3.59 (1H, d, *J* = 10.5 Hz, -*H*CHOH), 3.40 (1H, d, *J* = 10.5 Hz, -HC*H*OH), 2.61 (1H, dd, *J* = 10.0 Hz, 2.0 Hz) and 2.45 (1H, m) and 2.30–2.25 (2H, m) and 2.12–1.95 (2H, m) and 1.90–1.60 (8H, m) and 1.48–1.17 (4H, m) (other $-CH_2-$ and -CH-, -OH); ^{13}C NMR (75 MHz, $CDCl_3$) δ (ppm): 173.31, 172.64 (2), 171.44, 134.79, 133.38, 67.05, 57.22, 55.04, 52.61, 52.51, 46.76, 44.65, 44.34, 37.25, 35.73, 33.39, 32.33, 28.47, 27.80, 26.41, 25.93; ms *m/e*: 448 (M^+-H_2O), 435 (M^+-OCH_3). Exact Mass calcd. for $C_{25}H_{35}O_9$: 448.2097; found: 448.2093 ± 0.0013.

CSC **11b** (more polar): ir (neat): 3545 (br), 2955, 1730 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ (ppm): 5.43 (1H, ddd, *J* = 10.0 Hz, 2.5 Hz, 2.5 Hz, -*H*C═CH-), 5.29 (1H, br d, *J* = 10.0 Hz, -HC═C*H*), 3.78 (3H, s, $-CO_2CH_3$), 3.693 (3H, s, $-CO_2CH_3$), 3.684 (3H, s, $-CO_2CH_3$), 3.678 (3H, s, $-CO_2CH_3$), 3.47 (1H, d, *J* = 11.0 Hz, -*H*CHOH), 3.37 (1H, d, *J* = 11.0 Hz, -HC*H*OH), 2.62 (1H, br s) and 2.58–2.45 (2H, m) and 2.40 (1H, dm, *J* = 11.0 Hz) and 2.28 (1H, ddd, *J* = 14.0 Hz, 9.0 Hz, 2.0 Hz) and 2.13 (1H, dd, *J* = 14.0 Hz, 5.5 Hz), and 2.02–1.85 (2H, m) and 1.75–1.20 (10H, m) (other $-CH_2-$ and -CH-, -OH); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 173.14 (2), 171.99, 171.44, 132.27, 127.08, 64.64, 58.33, 52.86, 52.59, 52.43, 52.07, 42.15, 37.63, 37.06, 35.13, 32.17, 31.46, 27.52, 26.92, 24.74, 19.33; ms *m/e*: 448 (M^+-H_2O), 435 (M^+-OCH_3). Exact Mass calcd. for $C_{24}H_{32}O_8$: 448.2097; found: 448.2093 ± 0.0013.

*Iodoether **12** and CSC alcohol **11b***

To a stirred solution of the above mixture of tricyclic alcohols **11a/11b** (0.155 g, 0.33 mmol, ratio: **11a:11b** = 85:15) in tetrahydrofuran (3.0 mL) were successively added powdered sodium bicarbonate (0.17 g, 2.0 mmol) and iodine (0.51 g, 2.0 mmol). The mixture was stirred 3.0 h at room temperature, after which diethyl ether (50 mL) and a saturated aqueous solution of sodium thiosulfate (50 mL) were added. The phases were separated after the organic layer had faded out and the aqueous layer was extracted with diethyl ether (3 × 25 mL). The combined organic layers were washed with brine, dried over anhydrous magnesium sulfate, filtered, and concentrated. The residue was purified by flash chromatography (30% ethyl acetate in hexanes), yielding unreacted CSC tricyclic alcohol **11b** (19.1 mg, 12%, clear oil and TST tetracyclic iodoether **12** (0.138 g, 70%, white powder). No traces of iodoether originating from alcohol **11b** were found whereas alcohol **11a** was totally consumed (combined yield: 82%, isolated ratio **12**:**11b** = 85:15).

*TADA reaction of macrocycle 7: (7,2-*trans*-2,1-*syn*-1,10-*trans*)-2-(methoxymethoxy)methyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene **7a** and (7,2-*cis*-2,1-*syn*-1,10-*cis*)-2-(methoxymethoxy)methyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene **7b***

Following general procedure A, TTC macrocyclic triene **7** (11.0 mg, 0.021 mmol) in toluene (1.0 mL) was heated at 200°C for 3.0 h, yielding a crude mixture (12.0 mg) of tricyclic products **7a** and **7b**, along with one or more unknown macrocycles. Preparative thin-layer chromatography purification (20 cm × 20 cm, 0.05 cm thickness, 30% ethyl acetate in hexanes, two elutions) gave pure TST tricycle **7a** (6.6 mg, 55%, clear oil) and a more polar fraction (4.5 mg) containing one or more unknown macrocycles and presumably a weak proportion of CSC tricycle **7b**, for which no signals could be formally assigned from the ^1H nmr analysis of the mixture. All attempts in separating the compounds of this second fraction on silica gel were unsuccessful. However, its presence and approximate proportion were confirmed through the following sequence of reactions. MOM ether hydrolysis was carried out on the impure fraction using the conditions previously described in this article. The resulting crude mixture of alcohols was oxidized under standard conditions using *n*-tetrapropylammonium perruthenate, giving a crude mixture of aldehydes (homogeneous spot by tlc). The ^1H nmr analysis of this material showed, upon integration, a ca 15% proportion of CSC tricycle **8b** (see below for its formation from **8** and spectral characteristics). If this proportion was kept constant during the aforementioned transformations, the polar fraction originating from thermolysis of **7** contained ~0.7 mg (4.5 mg × 15%) of CSC tricycle **7b**, resulting in a **7a/7b** ratio of about 90:10.

TST **7a** (less polar): ir (neat): 2950, 1730 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ (ppm): 5.60 (1H, ddd, J = 9.0 Hz, 2.5 Hz, 2.5 Hz, -*H*C=CH-), 5.40 (1H, ddd, J = 9.0 Hz, 3.0 Hz, 3.0 Hz, -HC=C*H*), 4.56 (1H, d, J = 6.5 Hz, -O*H*CHO-), 4.52 (1H, d, J = 6.5 Hz, -OHC*H*O-), 3.75 (3H, s, $-CO_2CH_3$), 3.71 (9H, s, 3 × $-CO_2CH_3$), 3.58 (1H, d, J = 9.5 Hz, *H*CHO-MOM), 3.33 (3H, s, $-OCH_3$), 3.07 (1H, d, J = 9.5 Hz, -HC*H*OMOM), 2.42–2.19 (4H, m) and 2.06–1.50 (10H, m) and 1.47–1.20 (3H, m) (other $-CH_2-$ and -CH-); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 173.29, 172.77, 172.66, 171.62, 135.20, 130.53, 96.99, 69.47, 56.63, 55.33, 54.87, 52.67, 52.60, 52.54, 52.33, 46.42, 41.19, 40.73, 36.14, 33.35, 32.43, 31.95, 31.62, 26.76, 26.02, 25.81; ms *m/e*: 478 (M^+-CH_3OH), 448 (M^+-MOMOH). *Mixture of iodoethers **15** and **16***

To a stirred solution of TST tricyclic alcohol **14a** (3.0 mg, 0.0064 mmol) in tetrahydrofuran (0.5 mL) at room temperature were successfully added sodium bicarbonate (3.2 mg, 0.038 mmol) and crystalline iodine (10.0 mg, 0.038 mmol). The mixture was stirred at room temperature for 2.0 h, after which it was diluted with diethyl ether (20 mL) and extracted with a saturated aqueous sodium thiosulfate solution (5 mL). The organic layer was washed twice with brine (3 mL), dried over anhydrous magnesium sulfate, filtered, and concentrated. Purification of the residue by preparative thin-layer chromatography (10 × 20 cm, 0.05 cm thickness, 40% ethyl acetate in hexanes) afforded a pure inseparable mixture of tetracyclic iodoethers **15** and **16** (2.0 mg, 53%, ratio by ^1H nmr: **15/16** = 4:3).

15/16: tlc: uv visible; ir (neat): 2950, 1735 cm^{-1}; ^1H nmr (300 MHz, $CDCl_3$) δ (ppm): 4.38 (1H, s, -OCH- **15**), 4.07 (1H, d, J = 9.0 Hz, -*H*CHO- **16**), 3.94 (1H, d, J = 8.0 Hz, -*H*CHO- **15**), 3.84 (1H, dd, J = 7.0 Hz, 2.5 Hz, -OCH- **16**), 3.80 (3H, s, $-CO_2CH_3$ **16**), 3.78 (3H, s, $-CO_2CH_3$ **15**), 3.77 (3H, s, $-CO_2CH_3$ **15**), 3.73 (3H, s, $-CO_2CH_3$ **15**), 3.724 (3H, s, $-CO_2CH_3$ **16**), 3.716 (3H, s, $-CO_2CH_3$ **16**), 3.71 (3H, s, $-CO_2CH_3$ **16**), 3.70 (3H, s, $-CO_2CH_3$ **15**), 3.68 (1H, d, J = 9.5 Hz, -HC-I **15**), 3.47 (1H, d, J = 2.5 Hz, -HC-I **16**), 3.33 (1H, d, J = 8.0 Hz, -HC*H*O- **15**), 3.22 (1H, d, J = 9.0 Hz, -HC*H*O- **16**), 2.71 (1H, ddd, J = 13.5 Hz, 5.0 Hz, 2.0 Hz, C7-H **16**) 2.48−0.92 (33H, m, other $-CH_2-$ and -CH- from **15** and **16**); ms *m/e*: 561 (M^+-CH_3O), 465 (M^+-I). Exact Mass calcd. for $C_{23}H_{30}O_8I$: 561.0985; found: 561.0977 ± 0.0017.

*TST alcohol **14a** via reductive elimination of **15/16***

To a solution of tetracyclic iodoether mixture **15/16** (~1.5 mg, 0.0025 mmol) in glacial acetic acid (0.5 mL) was added powdered zinc (~2 mg, 0.025 mmol). The suspension was vigorously stirred for 2.0 h at room temperature, after which it was filtered over a cotton plug (rinsed with dichloromethane). The filtrate was neutralized with a solution of saturated aqueous sodium bicarbonate (5 mL) and the aqueous phase was extracted with dichloromethane (4 × 5 mL). The combined organic layers were washed with brine (3 mL), dried over anhy-

*TST aldehyde **8a** via oxidation of **14a***

To a stirred solution of TST tricyclic alcohol **14a** (3.0 mg, 0.0064 mmol) in acetonitrile (0.3 mL) at room temperature were successively added molecular sieves (4Å, 5 mg), *N*-methylmorpholine oxide (1 mg, 0.0096 mmol), and tetra-*n*-propylammonium perruthenate (a few crystals, cat.) The resulting mixture was stirred for 2.0 h and then concentrated to dryness. The residue was filtered over a small column of silica gel (application with dichloromethane) under the conditions of flash chromatography purification (30% ethyl acetate in hexanes), yielding pure TST 2-formyl-substituted tricycle **8a** (1.5 mg, 50%, foamy oil). This aldehyde was found identical by ^{1}H nmr analysis to the one obtained from the TADA reaction of macrocycle **8** (see above).

*TADA reaction of macrocycle **4**: mixture of (7,2-*trans*-2,1-*anti*-1,10-*cis*)-1-(methoxymethoxy)methyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene **4a** and (7,2-*cis*-2,1-*anti*-1,10-*trans*)-1-(methoxymethoxy)methyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene **4b***

Following general procedure A, neat TTT macrocyclic triene **4** (33.0 mg, 0.065 mmol) was heated at 200°C for 6.5 h, yielding a crude mixture of tricyclic products **4a** and **4b** (32.0 mg, 98%, ratio by ^{1}H nmr: **4a**:**4b** = 78:22). Preparative thin-layer chromatography purification (20 cm × 20 cm, 0.05 cm thickness, 30% ethyl acetate in hexanes, two elutions) gave a pure mixture of **4a** and **4b** (20.5 mg, 62%, oil) along with another fraction containing starting macrocyclic triene **4** (1.9 mg, 6%). These tricyclic products were found inseparable even under various solvent systems. They were individually characterized as their alcohol derivatives **17a** and **17b** (see below).

TAC **4a**/CAT **4b**: ir (neat): 2950–2820, 1750, 1740 cm^{-1}; ^{1}H nmr (300 MHz, $CDCl_3$) δ (ppm): 5.47 (1H, ddd, *J* = 9.5 Hz, 2.5 Hz, 2.5 Hz, -*H*C=CH **4a**), 5.32 (1H, br d, *J* = 9.5 Hz, -HC=C*H* **4a**), 5.50–5.25 (2H, m, -*H*C=C*H* **4b**), 4.60–4.47 (4H, m, -OCH_2O- **4b/4a**), 3.74 (3H, s, -CO_2CH_3 **4a**), 3.73 (3H, s, -CO_2CH_3 **4a**), 3.70 (6H, s, 2 × -CO_2CH_3 **4b**), 3.69 (6H, s, 2 × -CO_2CH_3 **4b**), 3.68 (6H, s, 2 × -CO_2CH_3 **4b**), 3.52 (1H, d, *J* = 10.5 Hz, -*H*CHOMOM **4b**), 3.43 (1H, d, *J* = 10.5 Hz, -HC*H*OMOM **4b**), 3.41 (1H, d, *J* = 9.5 Hz, -*H*CHOMOM **4a**), 3.33 (3H, s, -OCH_3 **4b**), 3.30 (3H, s, -OCH_3 **4a**), 3.25 (1H, d, *J* = 9.5 Hz, -HC*H*OMOM **4a**), 2.55–1.10 (34H, m, other -CH_2- and -CH- **4b/4a**); ^{1}H nmr (300 MHz, C_6D_6) δ (ppm): 5.44 (1H, br ddd, *J* = 9.0 Hz, 2.5 Hz, 2.5 Hz, -*H*C=CH- **4b**), 5.31 (2H, s, -*H*C=C*H*- **4a**), 5.18 (1H, br ddd, *J* = 9.0 Hz, 2.5 Hz, 2.5 Hz, -HC=C*H*- **4b**), 4.47 (1H, d, *J* = 6.5 Hz, -O*H*CHO- **4b**), 4.45 (1H, d, *J* = 6.5 Hz, -OHC*H*O- **4b**), 4.38 (1H, d, *J* = 6.5 Hz, -O*H*CHO- **4a**), 4.33 (1H, d, *J* = 6.5 Hz, -OHC*H*O- **4a**), 3.64 (1H, d, *J* = 10.0 Hz, -*H*CHOMOM **4b**), 3.56 (1H, d, *J* = 10.0 Hz, -*H*CHOMOM **4a**), 3.52 (1H, d, *J* = 10.0 Hz, -HC*H*OMOM **4b**), 3.37 (3H, s, -CO_2CH_3 **4a**), 3.36 (6H, s, 2 × -CO_2CH_3 **4b**), 3.32 (3H, s, -CO_2CH_3 **4b**), 3.30 (6H, s, 2 × -CO_2CH_3 **4a**), 3.26 (6H, s, -CO_2CH_3 **4a** and -CO_2CH_3 **4b**), 3.24 (3H, s, -OCH_3 **4b**), 3.22 (1H, d, *J* = 10.0 Hz, -HC*H*OMOM **4a**), 3.15 (3H, s, -OCH_3 **4a**), 2.8–0.8 (34H, m, other -CH_2- and -CH- **4b/4a**); ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm) (peaks without an annotation belong to **4a**, remaining peaks from **4b** are indistinguishable from the baseline): 172.67, 171.48, 131.63 (**4b**), 131.46, 130.86 (**4b**), 128.82, 97.13 (**4b**), 96.71, 71.55, 57.71, 55.17, 52.68, 52.52, 49.08, 43.56, 40.16, 37.88, 34.35, 32.37, 31.71, 29.68, 27.52, 25.80, 22.43, and many other minor peaks tentatively ascribed to **4b**: ms *m/e*: 495 (M^+−CH_3), 478 (M^+−CH_3OH), 465 (M^+−MOM). TADA reaction of macrocycle **2**: *(7,2-*trans*-2,1-*anti*-1,10-*cis*)-2-(methoxymethoxy)methyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene* **2a** *and (7,2-*cis*-2,1-*anti*-1,10-*trans*)-2-(methoxymethoxy)methyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene* **2b**

Following general procedure A, neat TTT macrocyclic triene **2** (31.0 mg, 0.061 mmol) in toluene (1.0 mL) was heated at 200°C for 3.0 h, yielding a crude mixture of TAC tricyclic products **2a** and CAT **2b** (32.0 mg, quant., ratio: **2a**:**2b** = 90:10). Preparative thin-layer chromatography purification (20 cm × 20 cm, 2 plates, 0.05 cm thickness, 30% ethyl acetate in hexanes, two elutions) gave pure mixture **2a** and **2b** (19.0 mg, 61%, clear oil). These tricycles were found inseparable on silica gel even with many attempts under various solvent systems. However, a portion of pure mixture **2a/2b** could be recrystallized (dichloromethane–hexanes), affording nice pure crystals (mp 168–170°C) of TAC tricycle **2a** as thick prisms. A suitable crystal was analyzed by X-ray diffraction and confirmed the stereochemistry expected for **2a**. The mother liquor as concentrated and gave substantially enriched (>90%) CAT tricycle **2b**. These two diastereomeric tricycles were also more conveniently characterized in pure form as their alcohol derivatives **18a** and **18b** (see below).

TAC **2a**/CAT **2b** (pure mixture): ir (neat): 2950, 1730, 1440 cm^{-1}.

TAC **2a**: ^1H nmr (300 MHz, $CDCl_3$) δ (ppm): 5.56 (1H, ddd, J = 10.0 Hz, 3.0 Hz, 3.0 Hz, -*H*C=CH-), 5.19 (1H, ddd, J = 10.0 Hz, 2.0 Hz, 2.0 Hz, -HC=C*H*-), 4.52 (2H, narrow m, $-OCH_2O$-), 3.75 (3H, s, $-CO_2CH_3$), 3.71 (3H, s, $-CO_2CH_3$), 3.70 (3H, s, $-CO_2CH_3$), 3.68 (3H, s, $-CO_2CH_3$), 3.53 (1H, d, J = 10.5 Hz, -*H*CHOMOM), 3.47 (1H, d, J = 10.5 Hz, -HC*H*OMOM), 3.35 (3H, s, $-OCH_3$), 2.58 (1H, m) and 2.47–2.33 (2H, m) and 2.32–2.16 (4H, m) and 2.06–1.20 (9H, m) and 1.00 (1H, dt, J = 13.5 Hz, 3.5 Hz) (other $-CH_2$- and -CH-), ^{13}C nmr (75 MHz, $CDCl_3$) δ (ppm): 173.37, 172.62, 171.93, 171.58, 134.23, 127.02, 97.09, 65.24, 58.47, 55.50, 55.10, 52.51 (br), 52.18, 48.94, 40.91, 40.59, 37.68, 32.31, 30.21, 28.72, 27.60, 26.72, 22.19; ms *m/e*: 479 (M^+-OCH_3), 448 ($M^+-MOMOH$). *(7,2-*trans*-2,1-*anti*-1,10-*cis*)-2-Hydroxymethyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene* **18a** *and (7,2-*cis*-2,1-*anti*-1,10-*trans*)-2-hydroxymethyl-5,5,13,13-tetrakis(methoxycarbonyl)-tricyclo[8.5.0.0^{2,7}]pentadec-8-ene* **18b**

The above mixture of tricyclic methoxymethyl ethers **2a/2b** (17.0 mg, 0.033 mmol) was stirred at 60–65°C for 12.0 h in the following solvent system: concentrated aqueous hydrochloric acid – water – methanol (0.5:1.0:8.5, 2.0 mL). The mixture was then allowed to warm to room temperature and quenched with a solution of aqueous saturated sodium bicarbonate (5 mL). The resulting mixture was extracted with diethyl ether (2 × 10 mL) and ethyl acetate (2 × 5 mL). The combined organic phases were dried over anhydrous magnesium sulfate and filtered on a medium fritted glass funnel covered with a 1 cm thick silica gel pad. Concentration of the filtrate left a crude mixture (1.50 mg, 94%) of alcohol derivatives TAC **18a** and CAT **18b**. A facile separation by preparative thin-layer chromatography (20 cm × 20 cm plate, 0.05 cm thickness, 50% ethyl acetate in hexanes, one elution) yielded pure TAC tricyclic alcohol **18a** (12.0 mg, 75%, clear oil) and CAT diastereomer **18b** (1.4 mg, 9%, clear oil).

Raman and resonance-Raman spectra of polypyrrole with application to sensor – gas probe interactions

Stephen J. Vigmond, Vida Ghaemmaghami, and Michael Thompson

Abstract: Raman spectra of the oxidized and neutral forms of polypyrrole show a relative intensity shift from the high wave number region to the low wave number region as the source wavelength is increased from 514.5 to 1064 nm. Variations in band positions are also observed with changes in excitation source; particularly, two C=C stretches at 1500 and 1605 cm^{-1} can be observed with the neutral polymer but only a single band is observed at 1575 cm^{-1} when sources of higher energy are used. These changes arise from differences in the electronic states of the two forms that can greatly alter the intensities of the numerous bands. The oxidized and neutral forms of the polymer both act as electron acceptors towards the gas phase species tested here (toluene, water, methanol, and ammonia). The increased electron density induces an upward shift of the peaks at 915 and 1035 cm^{-1} of the neutral polymer and increases the relative intensity of the 1575 cm^{-1} peak of the oxidized polymer using 1064 and 514.5 nm sources, respectively.

Key words: polypyrrole, Raman spectroscopy, gas probe interactions.

Résumé : Lorsqu'on augmente la longueur d'onde de la source de 514,5 à 1064 nm, les spectres Raman des formes oxydées et neutres du polypyrrole présentent un déplacement de l'intensité relative de la région des nombres d'onde élevés à celle des nombres d'onde plus faibles. On a aussi observé des variations dans les positions des bandes avec des changements dans la source d'excitation; en particulier, on peut observer deux élongations C=C à 1500 et 1605 cm^{-1} avec le polymère neutre, mais on observe une seule bande à 1575 cm^{-1} lorsqu'on utilise des sources d'énergie plus élevée. Ces changements proviennent de différences dans les états électroniques des deux formes qui peuvent modifier considérablement les intensités des diverses bandes. Les formes oxydées et neutres du polymère agissent toutes les deux comme accepteurs d'électron par rapport aux espèces gazeuses étudiées ici (toluène, eau, méthanol et ammoniac). Lorsqu'on utilise respectivement des sources respectivement de 1064 et de 514,5 nm, l'augmentation de la densité électronique induit un déplacement vers des valeurs plus grandes des pics à 915 et 1035 cm^{-1} du polymère neutre et une augmentation de l'intensité relative du pic à 1575 cm^{-1} du polymère oxydé.

Mots clés : polypyrrole, spectroscopie Raman, étude des interactions gazeuses.

[Traduit par la rédaction]

Introduction

Although conducting polymers have been extensively studied over the past 15 years, there is still much to learn about these unique materials (1). The insolubility of many of these polymers limits the methods available for their analysis. Some of the more common techniques used to probe these materials include cyclic voltammetry (2), UV–visible (3), and IR (4) absorption spectroscopies, X-ray photoelectron spectroscopy (5), and ellipsometry (6). We have been investigating polypyrrole, one of the most stable conducting polymers, with respect to its potential role as a chemical sensor (7, 8). In its employment as a gas phase sensor, the resistance of the oxidized, conducting form is monitored (9–12). In the presence of various analytes, cationic sites along the polymer backbone become neutralized, either by electron donation to the polymer or by proton abstraction from the polymer (9), which decreases the measured conductivity. It is the nature of these interactions that we wish to examine.

Infrared and UV–visible spectroscopies have previously been used to study the interactions of selected vapors with polypyrrole. Several problems limit the utility of IR in this area; Ratcliffe (10) found polypyrrole to be too thin for analysis and Gustafsson et al. (9) reported that ammonia obscures the interesting features of the polypyrrole spectrum if the spectrum is collected during experimental exposure. From UV–visible spectroscopy and work function analysis, Topart and Josowicz (13) concluded that polypyrrole can be either an electron donor or acceptor, with its behavior being dependent upon the counteranion present.

The analysis of polypyrrole by Raman spectroscopy provides greater spectral information than UV–visible spectroscopy and may circumvent some of the difficulties associated with IR spectroscopy. The fact that Raman spectroscopy is based on scattering phenomena leads to the possibility of analysis of insoluble samples that require no sample preparation.

Several Raman studies of polypyrrole have been published previously where the source used generally has a wavelength of 514.5 nm (14, 15). A list of generally accepted assignments is provided in Table 1. Recently, FT-Raman spectra of neutral and oxidized polypyrrole (with relatively large counterions) have been published (20). In addition, an FT-Raman study of a polypyrrole-polyester composite has been discussed (21). As the electronic states of polypyrrole are altered with an increase in the oxidation level of the polymer, through the formation of polaron and bipolaron structures, absorption maxima in the UV–visible region will shift (see Table 1). Typically, the electronic absorptions of conducting polymers shift toward the near-infrared region as the oxidation level is increased. Therefore, as noted for other conducting polymers (22, 23), Raman spectra of polypyrrole will be a function of the excitation wavelength resulting from resonance or near-resonance conditions that originate from the localized structures formed in the polymer. These effects, which may be related to the increasing double-bond character of the $C_{\alpha-\alpha'}$ and $C_{\beta-\beta}$ bonds but the decreasing electron density along $C_{\alpha-\beta}$ (24), will be manifested in shifts of the relative intensities of the absorption bands and their positions.

In the present work, Raman spectra of polypyrrole are collected using sources of 514.5, 568, 752, and 1064 nm, the latter being part of an FT-Raman system. While other studies have employed more than one source, this study utilizes, to our knowledge, the widest range of source wavelengths to date. The initial stage of this study is an analysis of the changes observed in the Raman spectra of both the oxidized and neutral forms of polypyrrole as the excitation wavelength and the type of instrument are varied. Perchlorate, a relatively small dopant, is used as the counterion. The shift in relative intensities in the spectra arising from changes in the source wavelengths allows some control over which segments of the polymer are being probed. The second part deals with the application of this methodology to the in situ analysis of gas phase interactions of polypyrrole. It is hoped that this methodology can specifically resolve the question of electron donation or acceptance in the presence of various analytes and, more generally, provide greater understanding of the types of molecular interactions that may occur. Most previous work in this field has concentrated on interactions with the oxidized polymer only. However, the oxidized form is mainly composed of neutral segments so their contribution to the ultimate behavior of a polypyrrole sensor needs to be considered also and this is possible using this spectroscopic technique. These results are put in context with complementary mass-based results from acoustic wave sensor work that we report in a companion paper (25). Here frequency decreases indicate the relative degrees of interaction between the analytes and polypyrrole. Furthermore, the shapes of the response curves provide information regarding changes in the viscoelastic properties of the polymer and also the net retention or loss of its solvation sheath.

Experimental section

Materials

Pyrrole was purchased from Aldrich (Milwaukee, Wis.) and distilled prior to use. Tetrabutylammonium perchlorate (TBAP), electrochemical grade, was supplied by Fluka (Switzerland) and used as received. All solvents, used both in the electrochemical procedures and to generate the vapors, were of reagent grade and procured from BDH (Toronto, Canada). Water was passed through a Corning column to remove organic compounds and was doubly distilled. Pure helium and ammonia-in-helium were purchased from Matheson.

Instrumentation

Gold-plated 9 MHz piezoelectric quartz crystals were obtained from International Crystal Manufacturing Company, Oklahoma. These crystals were utilized as working electrodes (0.25 cm^2 gold on each side) in the polymerization of pyrrole with a combined platinum wire and Ag/AgCl (3 M KCl) electrode from Metrohm as the counter and reference electrodes, respectively. Electrochemical oxidations and reductions were performed with a polarographic analyzer (model 473) from ECO Instruments (Cambridge, Mass.).

FT-Raman spectra were acquired with a Bomem Ramspec 150 spectophotometer employing a Quantronix Nd:YAG laser emitting at 1064 nm and an InGaAs detector. The incident laser power was adjusted such that the power reaching the detector was in the range of 0.20–0.25 W. Spectra were accumulated in a backscattering geometry with the resolution set at 4 cm^{-1}. One hundred scans were accumulated over approximately 10 min. Data collection and manipulation were performed with Bomem Easy (version 1.45) software. Spectral intensities were normalized against an instrument response curve.

Micro Raman spectra were measured with a triplemate spectrometer (model 1877D, Spex Industries Inc.), which incorporated a microscope (1482D Micromate; 40× for polymer analysis, 10× for gas probe experiments) that focused the incident radiation down to an approximately 10 μm spot. An argon ion visible laser and a near-infrared krypton laser were available as excitation sources. Laser power settings of 400 mW were found to provide power of 6–7 mW at the sample with the Micro system. The detectors used were an intensified linear diode array (model IRY/G from Princeton Instruments, Inc.) and a liquid-nitrogen-cooled charge-coupled device

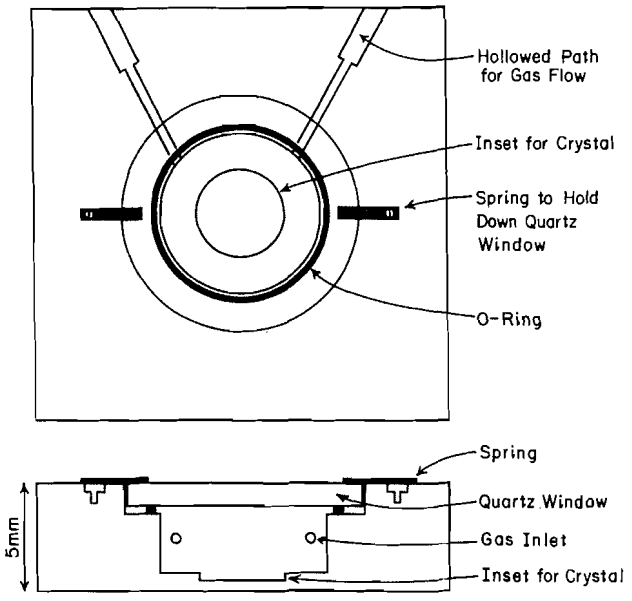
Fig. 1. Schematic of cell employed in Raman gas-probe experiments.



(CCD) detector (model LN/CCD from Princeton, Instruments, Inc.). Accumulation times of 3 min were typically employed for polymer analysis and 5 min for gas phase studies. The programs NSMA and CSMA (part of the ST-120 package from Princeton Instruments, Inc.) were used to control data acquisition with the diode array and CCD detectors, respectively. Conversion of diode numbers to wavenumbers was accomplished by running calibration spectra of neon at the settings used to collect the Raman scattering.

With both Raman systems, the samples for polymer analysis were mounted onto glass slides so that the source beam impinged directly onto the polymer. For the spectra relating to the gas phase analyses, the samples were enclosed in the cell shown schematically in Fig. 1. In this configuration, the excitation beam and the scattered light both have to pass through a 1-mm-thick window.

Procedures

Electrochemical polymerizations and oxidation state modifications were performed as described previously (7). Briefly, electrochemical procedures were performed in a cell that protected the electrical contacts of the piezoelectric crystal from the electrolyte solution. Electropolymerization was carried out in a solution of pyrrole and TBAP (both 0.1 M) in acetonitrile, after deoxygenation by bubbling nitrogen through the solution, at +1.0 V (vs. Ag/AgCl) for 1 min. Scanning electron micrographs indicate the films are approximately 0.3 μm thick (7). Oxidations (at +1.0 V) and reductions (at −1.5 V) of the as-prepared films were performed in 0.1 M TBAP, also after deoxygenation, for 10 min. Simultaneous measurements of the current indicated that this amount of time was sufficient to reach an equilibrium state.

For the gas phase experiments, helium flow rates were maintained at approximately 35 mL/min. Methanol, water, and toluene were introduced into the flow-through train by diverting the helium flow over a 50 mL reservoir of the appropriate solvent contained in a solvent trap (previously described in greater detail) (7). The concentrations of methanol, water, and toluene were determined by trapping the vapors from trial runs of approximately 1 h in a liquid nitrogen bath and found to be 95 ± 10, 15 ± 5, 10 ± 5 ppm, respectively. Ammonia was supplied as a mixture in helium and used without further dilution (2.09 ± 0.05%). After spectra were collected in the presence of the gaseous analytes, pure helium was reintroduced in order to observe the recovery of the system.

Results and discussion

The reason for employing gold-coated piezoelectric crystals as the polymer substrate was to maintain our previous experimental conditions (25). Although we are not reporting any new microgravimetric results, this ensures the most relevant comparisons to previous results and also allows us to work with well-characterized samples. Raman spectra of as-prepared and neutral polypyrrole were recorded using 514.5, 752, and 1064 nm sources. A spectrum of the as-prepared polymer using a 568 nm source was also obtained. The spectra are presented in Figs. 2–5 and a summary of the band positions is provided in Table 2.

Wavelength dependence of intensities

The spectra clearly demonstrate the variation in relative intensities produced by altering the excitation wavelength. The spectra recorded with the 514.5 nm source (Fig. 2) agree with most other published spectra using sources of similar wavelength. Generally, spectra recorded with excitations of 514.5 nm or shorter are dominated by the C=C stretch near 1575 cm^{-1} for both the oxidized and neutral states. Choi and Tachikawa (18) attribute the strong signal to the fact that it arises from resonance Raman scattering. One advantage of the 488 nm source over the 514.5 nm source used in this study is that the shorter wavelength is closer to the valence-to-conduction and (or) upper-bipolaron bands of the polymer and, accordingly, this generates spectra with greater intensities (26). As the excitation wavelength becomes longer, there appears to be a gradual enhancement of the relative intensities of the bands at lower wave numbers. Even an increase to 530.9 nm is shown to produce a weaker C=C stretch compared to bands at 1414 and 1320 cm^{-1} for the as-prepared polymer (15).

The spectrum of the oxidized polymer using the 568 nm line (Fig. 3) shows a more even distribution of intensities across the entire range. This wavelength was selected in an effort to induce the SERS phenomenon. Thinner polymer samples were employed (20 s polymerizations corresponding to approximately 10^3 Å) and the underlying gold was roughened by slowly vapor-depositing 40 Å of gold on top (which had a UV-visible absorption maximum near 630 nm), but no enhancements could be detected. The lack of enhancement is likely associated with the thickness of the sample since the phenomenon decays as r^{-3} from the surface. Shorter polymerization times produce less uniform coatings so thinner coatings were not attempted. Virdee and Hester (15) failed to observe SERRS effects with gold electrodes that had been subjected to numerous oxidation–reduction cycles, but the films in this study were also relatively thick.

The spectra recorded with the 752 nm source (Fig. 4) begin to be dominated by bands in the lower wave number region and good resolution of the peaks is observed. The FT-Raman spectra (Fig. 5) are even more skewed in this direction. At this longer excitation wavelength, the intensity of the Raman signals from the neutral polypyrrole are quite weak above 1100 cm^{-1} so they appear noisy but the peaks below this are strong and sharp. The previously reported FT-spectra (20) are significantly broader in this region due to recording the spectra at a

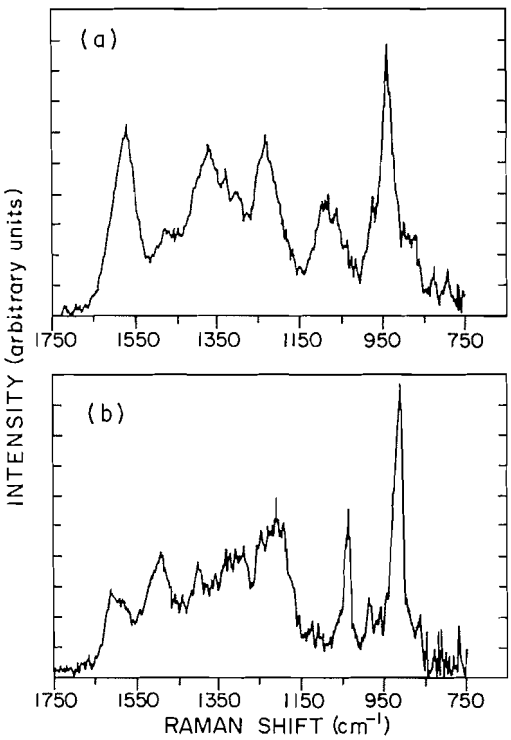
Fig. 5. FT-Raman spectra of (*a*) as-prepared and (*b*) neutral polypyrrole with 1064 nm source.



lower resolution and using larger counteranions that may have produced a greater degree of disorder in the polymer. The weaker spectrum from the neutral polymer is a result of the UV–visible absorbances discussed previously. Oxidized polypyrrole has a very broad absorbance above 1000 nm so that resonance conditions are possible with the 1064 nm source, but no such enhancement is possible with the neutral form.

Wavelength dependence of band positions

The broadness of the Raman bands makes it difficult to detect small shifts in the frequency with changes in the source excitation but some trends are evident (see Table 2). The C=C stretches appear at slightly higher wave numbers as the excitation wavelength is increased to 752 nm but the band of the oxidized polymer is lower in the FT-Raman spectrum. The C=C stretch of the neutral polymer produces a broad peak at 1575 cm^{-1} but generates two peaks with longer wavelength sources; while an intense, single peak is observed with the 514.5 nm source (and up to at least a 632 nm source (14, 24)), the other spectra show peaks at approximately 1500 cm^{-1} (although it is very weak in the 752 nm spectrum) and 1605 cm^{-1}. Jenden *et al.* (20) attribute the peak near 1500 cm^{-1} to some pyrrole rings adapting a *cis* geometry but peaks near 1500 and 1600 cm^{-1} are typical of C=C stretching bands in the spectra of 2,5-dialkylpyrrole derivatives so we consider the longer sources to be probing a nonconjugated component of the neutral polymer.

Therefore, the peak near 1575 cm^{-1} appears to be quite sensitive to the oxidation state of the polymer and the experimental conditions used to collect the spectrum. While we could not discern a frequency shift between the two states with the 514.5 nm source (see Table 2), in situ monitoring of the electrochemical cycling of the polymer with this source typically shows a 10 cm^{-1} decrease upon going from the oxidized form to the neutral form (15, 26). Burkowska and Jackowska (26) attribute the shift to the amount of charge on the polymer modulating the force constants of the pyrrole ring. Our spectra of these free-standing films do show that subsequent oxidations of as-prepared polypyrrole at +1.0 V or +1.4 V shift this band 10–15 cm^{-1} upwards with all sources used in this study, which may arise from the polymer being in a higher oxidation state or be an effect from the partial chlorination incurred upon oxidation.

The central region, from about 1200 to 1400 cm^{-1}, cannot be monitored as easily because the peaks are broad and tend to overlap. No wavelength dependence on excitation is detected in this region. The C–H deformations near 1050 cm^{-1} also remain consistent as the source is varied; the neutral spectra display a relatively sharp peak at 1040 cm^{-1} while the oxidized state has two almost equal and broader components at 1080 and 1055 cm^{-1}. The C–H out-of-plane deformations (900–1000 cm^{-1}) are very sensitive to the experimental conditions. While both polypyrrole states exhibit a pair of near-equal intensity peaks at approximately 930 and 980 cm^{-1} with the shorter wavelength sources, the two bands are nearly coincident with the 752 and 1064 nm sources (Figs. 4 and 5, respectively); in both cases the remaining peaks appear skewed to the high wave number side. From the spectra presented here and others published previously (14, 15), the higher peak is observed at progressively lower wave numbers as the excitation wavelength is increased while the lower wave number peak remains fixed at 930 cm^{-1} for the oxidized form and 915 cm^{-1} for the neutral state.

Furukawa et al. (14) have assigned the peaks at 930 and 1080 cm^{-1} to the bipolaron structure and those at 970 and 1050 cm^{-1} to the polaron structure, while the strong band at 1580 cm^{-1} is considered to be an overlap of the two oxidized structures. Although the 980 cm^{-1} peak coalesces into the lower one making relative intensities difficult to ascertain, the two peaks at 1080 and 1050 cm^{-1} remain clearly resolved and of constant relative intensity, indicating no wavelength preference between the two structures. This is not surprising as the absorption bands are similar for the cationic and dicationic species.

The spectra discussed to this point illustrate the sensitivity of the Raman technique to the structure of polypyrrole. The characteristic band positions observed in Figs. 2–5 clearly differentiate the oxidized and neutral forms as well as providing some discrimination between the polaron and bipolaron components, which arises from the changing charge densities along the polymer. They also show the advantage of using several sources to maximize the resolution of certain regions; with the 514.5 nm source, C–H out-of-plane deformations produce two peaks that are not resolved by the higher wavelength sources but the higher wavelength sources are able to separate two C=C stretches in the neutral polymer. Although Raman frequencies are not a function of the excitation source, the complex structure of polypyrrole allows resonance conditions of particular structures to become more dominant as the source is changed and cause certain bands to appear at slightly different frequencies. This phenomenon has previously been described in the analysis of several conducting polymers; it was attributed to the existence of several radical cation structures in polypyrrole (14), nonuniformly doped domains of

Can. J. Chem. Downloaded from www.nrcresearchpress.com by 80.90.12.36 on 09/08/12
For personal use only.

polyacetylene (23), and to the probing of different degrees of delocalization in polyfuran (22). A full analysis of the effects of the source wavelength permits us to more fully exploit the capabilities of Raman spectroscopy for studying the behavior of polypyrrole.

Practical considerations also affect the usefulness of the two Raman systems. The major advantages of the FT-Raman spectrometer are the inherent accuracy in determining the frequencies of the bands and the accumulation of the entire spectrum in a single run. Therefore, much smaller shifts may be measured more reliably with this spectrometer. The Spex Micro system can only monitor spectral regions of fixed ranges so several spectra may be required to obtain a complete spectrum at a desired resolution. Although each grating and filter setting requires a separate calibration, the microscope attachment provides more efficient collection of the Raman scattering, which reduces accumulation time. However, it is through this combination of instruments that the wide range of excitation sources is possible and able to provide a more thorough analysis of polypyrrole. The gas phase analyses therefore examined the extreme experimental conditions available (i.e., 514.5 and 1064 nm sources) in order to determine the type of information that may be acquired.

Gas phase studies with the 1064 nm source

The four probe gases (water, ammonia, methanol, and toluene) were found to have no effect on the relative intensities of any of the peaks with the 1064 nm source. However, while most of the peaks in the central region of the spectra are broad and their positions are difficult to assign accurately, the bands at 915 and 1035 cm^{-1} in the spectrum of neutral polypyrrole and 930 cm^{-1} in the oxidized spectrum are all quite sharp and show small shifts towards higher wave numbers in the presence of all the analytes tested. The most obvious increase occurs with the 915 cm^{-1} peak of the neutral polymer that typically shifts between two and three wave numbers for all of the analytes while the 1035 cm^{-1} peak increases between one and two wave numbers. The results from the as-prepared and further-oxidized samples are less consistent; the shifts are smaller and in some cases even decrease. The as-prepared polymer shows increases in the C–H bending band of approximately 1.5 and 1.0 cm^{-1} in the presence of water and toluene, respectively, but the other cases are less clear.

The 915–930 cm^{-1} peaks have been attributed to the pyrrole ring deformation and the 1035 cm^{-1} band to a C–H bend (14). The shift to higher wave numbers is consistent with the formation of hydrogen bonds to the pyrrole units. From semi-empirical calculations, Campos-Vallette et al. (27) have proposed that pyrrole forms N–H···π hydrogen-bonded complexes. This type of interaction would hinder the deformation vibrations and cause their upward shift. The fact that the neutral polymer exhibits larger shifts implies that this phenomenon occurs through the neutral rings in the polymer backbone. The weaker shifts observed with the oxidized polymers result from the fact that although this state is partially composed of neutral segments, it also contains a large number of cationic pyrrole units. The shift of the C–H band at the 1035 cm^{-1} band, with respect to the 915 cm^{-1} peak, is 90, 70, 70, and 30% (each approximately $\pm$10%) for toluene, ammonia, water, and methanol, respectively. Since electron donation to the pyrrole rings may occur through several modes, depending upon the analyte, such as an overlap of aromatic rings or hydrogen bonding with an -OH group, the various Raman bands of the pyrrole ring will be affected differently. At this point, the significantly lower relative shift of the 1035 cm^{-1} band induced by methanol cannot be explained.

Gas phase studies with the 514.5 nm source

The spectra from the 514.5 nm source are slightly broader, making the determination of frequency shifts even more difficult. From the superpositioning of spectra with and without the gas probe being present, small upwards shifts of the 915 cm^{-1} band may be observed in the presence of water and methanol. No shifts were observed in any of the experiments with toluene. With this source also, the shift is more predominant in the spectra of the neutral polymer. The software employed with the dispersive Raman spectrometer makes it more difficult to determine the size of the shifts but it is approximately the same as that observed with the FT-Raman system.

From the careful analysis of approximately 100 gas phase spectra, a relative intensity change is detected with the 514.5 nm source upon introduction of some of the gaseous probes. By overlaying the 1575 cm^{-1} peaks of the spectra from the polymer with and without the gas probe, a relative decrease in the rest of the spectrum is often found in the presence of the probe; this most plausibly indicates a relative increase of the 1575 cm^{-1} peak itself (Fig. 6). This is more pronounced in the spectra of the oxidized polymer. The relative increase of this band is likely the reverse scenario of the response phenomenon observed by Battisti and Aroca (28) upon adsorption of NO_x on Langmuir–Blodgett monolayers of phthalocyanine complexes. The electron-withdrawing capability of NO_x decreases the electron density of the pyrrole moieties in these complexes. An explanation lies in the loss of electronic density about the nuclei involved in the vibration with resulting change in the polarizability of the bonds and loss of scattering intensity. This is reflected in the relative intensity of a band at 1530 cm^{-1}, which is assigned to a stretching vibration with a strong contribution from the pyrrole structures present. An increase in the relative intensity of the 1575 cm^{-1} band, therefore, implies that water and methanol increase the electron density of the analogous stretch. Results with toluene are often ambiguous and may have required longer exposures to create more significant effects.

The combination of excitation wavelengths and equipment provides complementary information. The 1064 nm source generates the greatest relative intensity and sharpest peaks in the low wave number region. Hence, the neutral polymer shows the greatest sensitivity to the gas phase probes with this source. Because it is part of the FT-Raman system, it further provides the most accurate determination of the band positions. Conversely, the 514.5 nm source appears to enhance the high wave number region and allows the most sensitive detection of changes to the 1575 cm^{-1} peak. Therefore, by varying the source wavelength, changes in band position and relative intensities are independently monitored. Changes in vibrational frequency are typically a result of intermolecular interactions and the shift of the 915 cm^{-1} peak to higher wave numbers is consistent with the formation of hydrogen bonds to the neutral polymer, inhibiting the deformation vibrations. Variations of relative intensities usually indicate an electronic

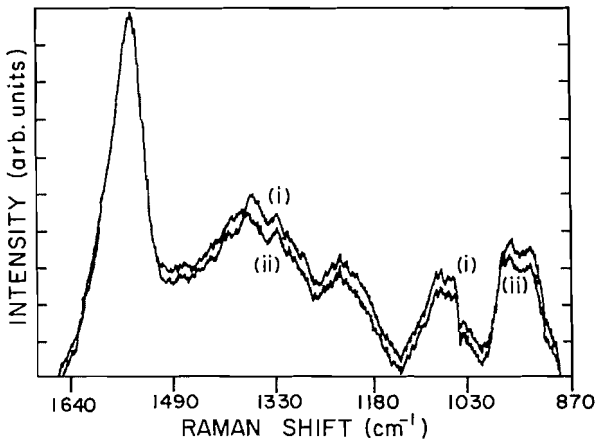
Fig. 6. Superposition of as-prepared polypyrrole in (*i*) helium and with (*ii*) toluene in helium using gas-cell and 514.5 nm source.



interaction and this is what is observed with the oxidized polymer. This suggests a different type of interaction, an electron donation through the cationic structures of the conducting polymer.

The magnitudes of the band shifts and enhancement are not very large but are reasonable for the low analyte levels being measured. The veracity of the effect is supported by the reproducibility of the phenomenon and the fact that the reversible nature of the interactions was detected in the cycle of pure He, gas-probe-in-He, and then the return to pure He. It is hoped that more polar probes will produce greater effects.

Comparison with microgravimetric analysis

Monitoring the gas phase interactions of polypyrrole with polymer-coated thickness–shear mode (TSM) piezoelectric crystals indicates two types of interactions, one through the neutral polymer and the other through the cationic (or dicationic) sites of the oxidized polymer. While the mass-based response to toluene is approximately two times greater with the neutral material than the oxidized polymer, hydrogen-bonding species such as water and methanol exhibit maximum degrees of interaction when the polymer is in an extreme oxidation state (i.e., after applying the most oxidizing or reducing potential). These observations are supported by the Raman results presented here. Again, two types of interaction are independently observed, one with the neutral polymer when the 1064 nm source is used and the other with the oxidized polymer using the 514.5 nm source.

Although both the neutral and oxidized states of polypyrrole act as electron acceptors, the two modes of interaction generate different spectral phenomena that appear to be determined by the oxidation state of the polymer. While water and methanol would be expected to interact through the -OH group with the neutral polymer, toluene must interact by another mode, perhaps by the overlap of the aromatic rings, yet the introduction of all species produces upward shifts of the 915 and 1035 cm^{-1} peaks. The response of the oxidized polymer also appears restricted; in this case only changes in relative intensities are observed, but a wider range of gas probes needs to be examined.

At least for the concentrations of the gas phase probes used in this study, there does not appear to be any spectral interference from the analytes. While this has been reported to be a limitation of analogous studies using IR spectroscopy, the Raman spectra presented here do not exhibit bands from the analytes themselves. On the other hand, the spectra yield no information about the importance of the role of polymer solvation as detected with the TSM piezoelectric crystals. The microgravimetric work suggests that in most cases a certain amount of analyte is retained upon return to pure helium and, in certain cases, an exchange between analyte and the original solvent (acetonitrile from the preparation of the polymer) occurs. The magnitude of these phenomena is a function of the oxidation state of the polymer and the relative strengths of the solvent and analyte interactions. The net retention of analyte is probably the reason for the incomplete recovery observed by Raman spectroscopy with both modes of interaction. However, as the upward shifts of the neutral polymer are quite small themselves and it is difficult to accurately quantify the relative intensity increases, no attempt was made to estimate the degree of retention.

Therefore, both the Raman spectra and the TSM piezoelectric sensors are useful techniques for the study of polypyrrole. Initially, TSM sensors appear to be far superior in their ability to provide quantitative data, but this must be tempered by the fact that the frequency shifts that are observed are also extremely sensitive to changes in the viscoelastic properties of the polymer that will occur from interactions with solvents. Caution must be exercised in their analysis. Therefore, several different techniques should be applied to the analysis of polypyrrole, and the sensitivity of Raman spectra to changes in the electronic states of conducting polymers makes it a powerful complementary method.

Conclusions

The electronic states of polypyrrole that are generated by the oxidation of the polymer are seen to couple with the experimental conditions used to obtain Raman spectra. Both relative intensities and band positions are functions of the excitation wavelength employed. This sensitivity towards the experimental conditions has been exploited to discriminate between interactions occurring with the neutral and oxidized segments of polypyrrole, which should help to better define their respective roles in the behavior of the conducting polymer. Information regarding the neutral polymer dominates the FT-Raman spectra while the behavior of the oxidized form dominates the spectra from the dispersive instrument with a source wavelength of 514.5 nm. Dispersive instruments are able to provide spectra with good resolution in a short time if restricted to small spectral windows, so improved sensitivity in detecting shifts of the 900–1100 cm^{-1} bands with the 514.5 nm source should be possible. Although only qualitative results have thus far been obtained with the gas phase probes, it was determined that both the neutral and oxidized components act as electron acceptors with the gas phase probes tested here, although probably by different mechanisms. A more complete correlation between the shifts and gas phase concentrations will follow and it will also be interesting to apply this methodology to cases where the polymer acts as an electron donor.

Anticipating molecular polarity 1: a back-of-the-envelope approach to topologically induced polarity in non-alternant monocycles

James Clayton Baum, Eric Donald Martin, Jack Leon Ginsburg, and Richard Francis Langler

Abstract: Perturbation theory is applied to fully π-bonded non-alternant monocycles at the Hückel level. An effective "back-of-the-envelope" approach is developed that permits one to anticipate Hückel charge patterns for these monocycles. Very little modification is required to alter the basic approach so that it will permit rapid anticipation of AM1-calculated charge patterns for such compounds.

Key words: hydrocarbon polarity, perturbation theory.

Résumé : On a appliqué la théorie perturbationnelle (au niveau de Hückel) à des monocycles complètement liés par des liaisons π non alternantes. On a développé une approche efficace «pouvant être effectuée sur le dos d'une enveloppe» qui permet d'anticiper les patrons de charge de Hückel de ces monocycles. Il suffit d'apporter des modifications mineures pour modifier l'approche de base et pour ainsi pouvoir arriver à une anticipation rapide des patrons de charge de tels composés, tels que calculés par AM1.

Mots clés : polarité de hydrocarbure, théorie perturbationnelle.

[Traduit par la rédaction]

Introduction

In an earlier study (1), we reached the conclusion that topologically induced polarity in some hydrocarbon ground states cannot be anticipated with aromaticity arguments. We have, therefore, sought to develop an approach that would be independent of aromaticity arguments. The present account describes a perturbational approach to anticipating topologically induced polarity in fully π-bonded non-alternant hydrocarbon monocycles (e.g., **1**).

Previous studies (1–3) have described non-alternant molecules with nonbonding electrons in their Lewis structures. This structural feature leads to extremes for hydrocarbon singlet-state polarity. We now examine fully π-bonded non-alternant monocycles.

Both π-ylides (e.g., **2**) and non-π-ylides (e.g., **3**) have nonbonding molecular orbitals (2) (NBMOs). The occupation or non-occupation of these NBMOs plays a pivotal role in determining their polarity. In graph-theoretical terms (4, 5), any fully π-bonded structure containing n carbon atoms must have at least one acyclic Sachs' graph s_n. Because non-alternant monocycles have no even-membered rings, there can be no cyclic Sachs' graphs s_n. Therefore, the constant term (a_n) in the characteristic polynomial cannot be zero. No fully π-bonded non-alternant hydrocarbon monocycle has an NBMO.

Methods

We now develop a method for deducing the nodal properties of the HOMOs and LUMOs of neutral even acyclic polyenes. If such an acyclic polyene has n carbon atoms, its HOMO will have (n/2)-1 nodes. *The HOMO nodal pattern may be rapidly generated by bringing together a set of ethylene HOMOs so that each contact point introduces a phase dislocation.*

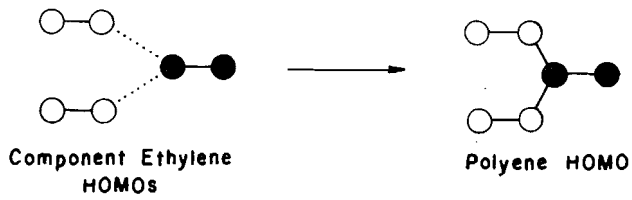
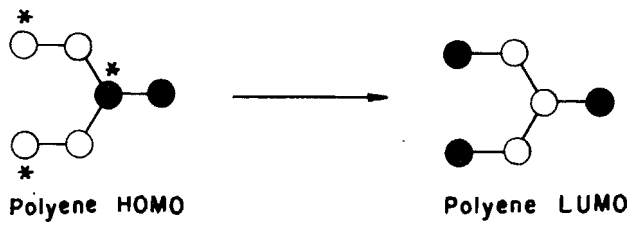
Scheme 1.



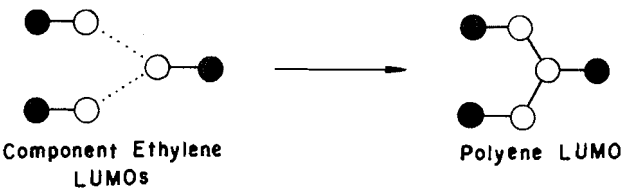
Every other atom in the polyene may be starred. From the Pairing Theorem (6), the LUMO's nodal properties may be deduced from those of the HOMO since the sign of each starred LUMO coefficient is reversed from that in the HOMO.

Scheme 2.



The nodal properties of the polyene LUMO may be deduced directly by bringing together a set of ethylene LUMOs so that each contact point introduces a bonding interaction.

Scheme 3.



AM1 computations were done using the MOPAC 5 program (7).

Simple Hückel calculations were carried out in the usual way (assuming the orthogonality of adjacent p orbitals). Hückel calculations were also carried out in partially recombined fragments (bond integrals < β) in the same manner described previously (8) for pentadienyl and methine.

The orientations of dipole moments are indicated by arrows whose heads represents the *negative* end of the dipole.

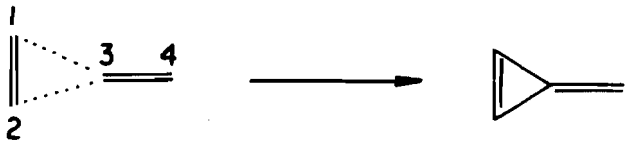
Results and discussion

A. Anticipating polarization at the Hückel level

(i) Odd substituents

We applied a first-order perturbational analysis (9) to methylene cyclopropene **1**. First, envision two ethylene units "docking" to form methylene cyclopropene as shown in Scheme 4. The ethylene unit (C_1C_2) with two contact points will be called the "cap" and the ethylene unit (C_3C_4) with one contact point will be called the "stem."

Scheme 4.



As the ethylene units dock, the stem and cap molecular orbitals mix. Table 1 presents the π-molecular orbitals (*i*) at the outset of this process, (*ii*) after docking (first-order molecular orbitals), and (*iii*) after docking (Hückel molecular orbitals for methylene cyclopropene **1**).

Table 1. Zeroth-order, first-order, and Hückel molecular orbitals for two ethylene units docking to form methylene cyclopropene (**1**) as depicted in Scheme 4.

Stage	Molecular orbitals
Zeroth order	ϕ_1: $0.500p_1 + 0.500p_2 + 0.500p_3 + 0.500p_4$
	ϕ_2: $0.500p_1 + 0.500p_2 - 0.500p_3 - 0.500p_4$
	ϕ_3: $0.707p_1 - 0.707p_2$
	ϕ_4: $0.707p_3 - 0.707p_4$
First order	ϕ_1: $0.471p_1 + 0.471p_2 + 0.707p_3 + 0.236p_4$
	ϕ_2: $0.471p_1 + 0.471p_2 - 0.236p_3 - 0.707p_4$
	ϕ_3: $0.707p_1 - 0.707p_2$
	ϕ_4: $0.371p_1 + 0.371p_2 - 0.632p_2 + 0.632p_4$
Methylene cyclopropene	ϕ_1: $0.522p_1 + 0.522p_2 + 0.611p_3 + 0.281p_4$
	ϕ_2: $0.368p_1 + 0.368p_2 - 0.253p_3 - 0.815p_4$
	ϕ_3: $0.707p_1 - 0.707p_2$
	ϕ_4: $0.302p_1 + 0.302p_2 - 0.749p_3 + 0.505p_4$

The polarization of the methylene cyclopropene **1** framework (Hückel level) can be deduced from ϕ_2 and ϕ_3 (see Table 1 and Scheme 4). ϕ_2 and ϕ_3 are "reverse polarizing," i.e., in ϕ_2 (occupied) the stem-derived portion has the largest coefficient(s) and in ϕ_3 (vacant) the cap-derived portion has the largest coefficient(s). Electron density is compartmentalized and the framework polarized so that the stem is electron-rich and the cap electron-deficient as shown in **1**.

Close examination of Hückel results for even non-alternant monocycles has led us to the following generalization. *The Polarity Postulate: polarity of the lowest-lying singlet state of any fully π-bonded even non-alternant hydrocarbon monocycle can be anticipated by inspection of a single pair of π-orbitals.*

The nodal properties of the polarizing orbitals (ϕ_2, ϕ_3 for methylene cyclopropene in Table 1) arise from a linear combination of the acyclic polyene frontier molecular orbitals (see the Methods section), i.e., $HOMO_{stem} - HOMO_{cap}$ leads to the nodal properties for the occupied polarizing orbital of the monocycle and $LUMO_{stem} + LUMO_{cap}$ leads to the nodal properties for the vacant polarizing orbital of the monocycle.

One of the polarizing orbitals for **1** (ϕ_3) is derived from a very weakly perturbed cap orbital. The weakness of the perturbation can be anticipated on the grounds that docking introduced two equal interactions, one bonding, one antibonding. Scheme 5 presents a generalized representation for the cap-weighted product orbital to cover those cases that lack symmetry and will then have small but non-zero stem coefficients in the final orbital.

The other polarizing orbital for **1** (ϕ_2) is derived from a strongly perturbed cap orbital. A strong perturbation is expected whenever *both* stem–cap interactions are bonding or *both* are antibonding. Not only does a strong perturbation pro-

Scheme 5.

duce a stem-weighted orbital but, for methylene cyclopropene (Table 1), a first-order perturbation introduces moderate mixing of ϕ_4 (zeroth order) with ϕ_2 (zeroth order). Thus, the stem-weighted orbital mixes $HOMO_{cap} - HOMO_{stem} + LUMO_{stem}$ with the greatest weight given to $HOMO_{stem}$, i.e., X > Y in Scheme 6.

Scheme 6.
