The mechanism for the release of organic compounds from paint surfaces exposed to water is believed to be assisted by, and dependent upon, the rate of diffusion of water through the paint matrix.[4] This is supported by the fact that coupons aged several years (cf. the polyurethane coupons used in this study) retain significant quantities of solvents, but readily lose these solvents upon exposure to water. It is also supported by the observation that the dissolution rate appears to be independent of chemical nature of the organic compound. Finally, the water assisted dissolution is suggested by the measured activation energies. Diffusion of water through a layer of paint should have a large activation energy (E_a), typically between 50 and 100 kJ mol^{-1} (12), whereas the diffusion of a molecule away from the surface should be smaller, typically 10–20 kJ mol^{-1} (13, 14). The relationship between the adsorption of water by a polymer coating, and the release of solvents is discussed in detail elsewhere (See footnote 4). Briefly however, the apparent first order kinetic behaviour observed for the release of solvents from painted surfaces exposed to water is analogous to that observed for surface evaporation of a solvent from a solid to a final equilibrium concentration in the gas phase. The initial boundary conditions and physical processes assumed in deriving the solvent evaporation model in Ref. 15 (i.e., concentration of the diffusing species constantly decreasing in the solid and increasing outside of the solid) were consistent with our experimental conditions, and result in the first-order kinetics behaviour observed in our experiments.

The effect of radiation on the rate of dissolution of the organic compounds was negligible, although radiation rapidly decomposed the organic compounds once they had been released into the aqueous phase. This is consistent with studies described in Refs. 1 and 2. Release of MIBK from coupons in which dissolution followed a period of irradiation appeared to have the same rate constant, although the final concentrations of MIBK in solution were smaller. Solutions in contact with painted coupons that were irradiated subsequent to a dissolution period were found to yield increased gas-phase concentrations of acetaldehyde, acetone, and MEK; and reduced concentrations of MIBK. The former three compounds were found to arise as a result of decomposition of dissolved MIBK. Toluene and xylene were not observed, because the small amounts present decomposed to phenol derivatives (and to some extent to organic acids), which are non-volatile and difficult to detect in the gas phase by conventional GC techniques.

Table 5. Activation energies for the dissolution of MIBK from different painted surfaces.

Surface	Phase	pH	E_a (kJ mol^{-1})
Epoxy[a]	Aqueous	5	79 ± 5
	Aqueous	10	78 ± 3
	Gas	10	75 ± 7
	Aqueous	5	75 ± 5
Polyurethane	Aqueous	10	83 ± 0.3
	Gas	5	85 ± 5
	Gas	10	108 ± 10 (91 ± 3)[b]
	Aqueous	5	82 ± 5
Vinyl	Aqueous	10	73 ± 6
	Gas	5	72 ± 4
	Gas	10	72 ± 8

[a]Gas phase data was not obtained for pH 5.

[b]This number was obtained from 40, 60, 70, and 90°C data only.

From these observations, we concluded that irradiation at the total absorbed doses and dose rates (0.13 Gy s^{-1}) used here does *not* have a significant impact on the chemistry of the paint coating per se, although it decomposes the organic solvents that have been released to solution, affecting their concentrations observed in the aqueous and gas phases. A factor not considered in this study but which should be investigated further, is the impact of the thickness of the coating on the release rate. Presumably, as with aging time, there should be some dependence of the release rate on thickness, because it should affect the amount of MIBK originally in the coating for the surface. Also, a thicker coating may increase the length of the pathway that the organic solvent takes through the paint matrix before reaching the surface. Therefore, a study of the activation energy as function of paint thickness for one of the coatings is required to determine the effect of coating thickness on the E_a for the dissolution process (See footnote 4).

The studies on the radiolysis of organic compounds presented in Refs. 4–6 have shown that, compared to the dissolution rate, the rate of the radiolytic decomposition of organic solvents in the aqueous phase would be very fast under postulated accident containment conditions in which the radiation dose rate is expected to be in the range of 1–10 kGy h^{-1} immediately following an accident but fall off exponentially with time. These relative rates of organic dissolution and organic radiolysis have been observed in integral tests performed in the intermediate-scale Radioiodine Test Facility[5] (1, 2, 7, 16). These studies show that, (*i*) the

[4] J.M Ball, J.C. Wren, and J.R. Mitchell. Manuscript in preparation.

[5] The Radioiodine Test Facility is an intermediate scale (350 dm^{-3}) facility which provides a combination of potential reaction media (gas phase, aqueous phase and variety of surfaces) and conditions (pH, temperature, radiation, initial concentrations and speciation of iodine), simulating a reactor containment building following an accident. The RTF is equipped with various on-line sensors to follow various chemical and physical properties as a function of time. A description of the RTF and test procedures can be found in refs. (1), (2), (7), and (16).

© 2000 NRC Canada

radiolysis of organic compounds from paint coatings will occur primarily in the aqueous phase and not on the surface, and (*ii*) under reactor accident containment conditions, the rates of radiolytic decomposition of organic compounds and formation of organic iodides are much faster than the rate of organic dissolution. The slower rate for organic dissolution is the principal parameter determining the pH reduction rate. Differences in the composition of the surfaces result in small variations in the rate of pH change because of the differences in the overall radiolysis production rate of organic acids and CO_2 from the different paint constituents.

The implication of these studies on modelling the effects of organic impurities on the time dependent iodine volatility in containment following an accident is that the dissolution process appears to be the rate-determining step for the changes in pH, dissolved oxygen concentration and organic iodide concentration observed when aqueous solutions containing CsI are irradiated in the presence of painted surfaces. Consequently, detailed kinetic mechanisms for the radiolytic decomposition of organic compounds and organic iodide formation may not be necessary.

V. Conclusions

The release of organic solvents from a variety of painted coupons exhibits pseudo-first order behaviour. Values of *k*, the pseudo-first order rate constant for solvent release, are relatively insensitive to solvent type, the effect of radiation, and water pH, and are similar in magnitude for various surfaces at a given temperature. Relatively large activation energies were measured for the release of organic compounds from painted surfaces. This suggests that it is the release from the paint-matrix rather than diffusion through the solution that is the rate determining step for the dissolution mechanism. The similarities in the values of activation energies for the dissolution of different organic compounds from the paint further suggests the release rate is relatively independent of the nature of the painted surface or the type of organic compound being released from the surface. Based on these two observations, it may be possible to write a generalized rate expression for the release of organic compounds from painted surfaces in containment during an accident.

Thermodynamic values have been obtained for the partitioning of the major constituents found in paints used to coat the containment surfaces of several CANDU® nuclear generating stations. Under the conditions of these experiments, the distribution of organic compounds between the gas and aqueous phases is rapid relative to the dissolution of these organic compounds from the paint matrix. All of these constituents have large negative ΔS values (Table 3) for the distribution equilibrium, suggesting the reverse process (i.e., partitioning of the organic compound from the aqueous to the gas phase) is entropy driven.

This work, in combination with the study on the radiolysis of organic compounds (4–6) and various integral effects test results from the intermediate scale Radioiodine Test Facility (1, 2, 7, 16), has established that dissolution of organic compounds from a painted surface into water is a key rate controlling step for any changes in the iodine volatility due to organic reactions, i.e., pH change and organic iodide formation. Since the release rate appears to be largely independent of the nature of the paint for a given surface substrate, it may be possible that a generalized expression for the dissolution rate for compounds will be sufficient to describe the kinetics of pH change and organic iodide information in containment.

Metal ion–biomolecule interactions. Part 22.[1] Cr(III)-catalyzed isotopic hydrogen exchange in methylimidazoles[2]

Omoshile Clement, Ikenna Onyido, and Erwin Buncel

Abstract: The detritiation kinetics of the Cr(III) complexes **1** and **3**–**6** have been studied in aqueous buffers at 35°C, using the liquid scintillation counting technique. Results for **5** and **6** provide benchmark kinetic data for N-T/N-H exchange under the experimental conditions of the study and have aided in the delineation of N-T/N-H from C-T/C-H exchange in the parallel reactions observed experimentally. Curved first-order plots obtained for **1**, **3**, and **4** were treated to yield rate constants for two parallel exchange reactions k^{A}_{obs} and k^{B}_{obs} for the "fast" and "slow" processes, respectively. The "fast" process has been assigned to C(2)-H exchange in **1**, competing N-H and C(2)–H exchange in **3**, and N-H exchange in **4**. In all cases, the "slow" process is associated with C(4,5)-H exchange. Identification of exchange sites in **1**, **3**, and **4** was made possible by the consideration of the results of an IR spectroscopic study of hydrogen-deuterium exchange, comparison of the extent of ^{3}H incorporatation in different complexes in the tritiation experiments, and a careful analysis of the exchange kinetic data. Analysis of the rate data indicates that Cr(III) significantly enhances C(2)-H exchange in **1** and **3**, while C(4,5)-H exchange, hitherto reported in the literature only under drastic reaction conditions, was observed for **1**, **3**, and **4** under the mild conditions of the present study. Quantitation of the effect of Cr(III) coordination on ^{3}H exchange in imidazole-type nuclei was achieved fully in **1**; giving k^{M^+} values of 6×10^3 and 7×10^2 $M^{-1}s^{-1}$ for C(2)-H and C(4,5)-H exchange, respectively. Using the literature value for k^{H^+}, the second-order rate constant for C(2)-H exchange under H^+ catalysis, 2.9×10^2 $M^{-1}s^{-1}$, it follows that Cr(III) is ca. 20 times better as a catalyst for C(2)-H exchange in 1-methylimidazole than H^+, providing the first example of a metal ion being more effective than a proton in these processes. Comparison of the results obtained with **1** with literature results for **2** shows a very large (ca. 3×10^5-fold) difference in the catalytic activities of Cr(III) and Co(III), favouring the former. The dichotomy in the effectiveness of the two metal ions in catalyzing ^{3}H exchange in the imidazole nucleus has been ascribed to differences in (*i*) extent of M^{n+}—N bond polarization (and the consequent effect on ligand C-H acidity); (*ii*) electronic configuration; (*iii*) crystal field stabilization and activation energies; and (*iv*) importance of metal–ligand π back-bonding. The study highlights the diversity of factors and complexity of interactions involved in determining the role of metal ions in biological systems, especially where such processes involve complex formation between metal ions and heterocyclic fragments of biomolecules.

Key words: metal ion–biomolecule interactions, methylimidazole, isotopic hydrogen exchange, catalysis by chromium.

Résumé : Opérant à 35EC, dans des tampons aqueux et faisant appel à la technique de comptage de scintillation liquide, on a étudié la cinétique de détritiation des complexes de Cr(III) 1 et 3-6. Les résultats pour 5 et 6 sont des données cinétiques de référence pour l'échange N-T/N-H dans les conditions expérimentales de l'étude et ils ont permis de délimiter les échanges N-T/N-H et C-T/C-H dans les réactions parallèles observées expérimentalement. Les courbes du premier ordre obtenues pour les composés 1, 3 et 4 ont permis de tirer les constantes de vitesse pour les deux réactions d'échange parallèles k^{A}_{obs} et k^{B}_{obs} qui correspondent respectivement aux réactions "rapide" et "lente". On a attribué la réaction rapide à l'échange C(2)-H du composé 1 qui est en compétition avec celle du N-H, à l'échange C(2)-H du composé 3 et à l'échange N-H du composé 4. Dans chacun des cas, la réaction lente est associée à l'échange C(4,5)-H. L'identification des sites d'échange des produits 1, 3 et 4 a été rendue possible en prenant en considération les résultats d'une étude de l'échange hydrogène-deutériun par spectroscopie IR, en faisant une comparaison du taux d'incorporation du 3H dans divers complexes au cours d'expériences de tritiation et une analyse soignée des données cinétiques. L'analyse des données relatives aux vitesses indique que le Cr(III) augmente de façon significative l'échange C(2)-H des composés 1 et 3. Par ailleurs, dans les conditions douces utilisées dans cette étude, on a pu observer l'échange C(4,5)-H avec les produits 1, 3 et 4; jusqu'à maintenant, cet échange n'avait été rapporté

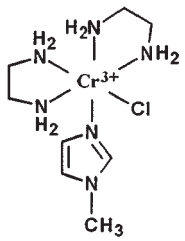
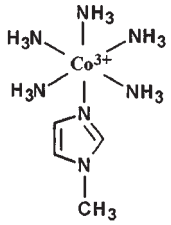
dans la littérature que pour des réactions impliquant des conditions drastiques. Dans le cas du composé 1, il a été possible de quantifier l'effet de la coordination du Cr(III) sur l'échange du 3H dans un noyau imidazole type; pour les échanges respectivement du C(2)-H et C(4,5)-H, les valeurs de k^{M^+} sont égales à 6 x 103 et 7 x 102 M^{-1} s^{-1}. Utilisant une valeur de k^{H^+} tirée de la littérature, la constante de deuxième ordre pour l'échange C(2)-H dans des conditions de catalyse par H^+ est de 2,9 x 102 M^{-1} s^{-1} et il en découle que le Cr(III) est un catalyseur approximativement 20 fois plus efficace que le H+ pour l'échange C(2)-H dans le 1-méthylimidazole; cette observation correspond au premier cas dans lequel un ion métallique est plus efficace qu'un proton dans ce type de procédé. Une comparaison entre les résultats obtenus avec le composé 1 et ceux rapportés dans la littérature pour le composé 2 met en évidence qu'il existe une très grande différence (rapport de 1 à 3 x 105 en faveur du Cr) entre les activités catalytiques de Cr(III) et Co(III). La dichotomie entre les efficacités des deux ions métalliques dans la catalyse de l'échange du 3H dans le noyau imidazole a été attribuée à des différences dans (i) le degré de polarisation de la liaison M^{n+}—N (et l'effet qui en découle sur l'acidité du C-H du ligand); (*ii*) la configuration électronique; (*iii*) la stabilisation du champ cristallin et les énergies d'activation et (*iv*) l'importance de la liaison B en retour métal-ligand. L'étude met en évidence la diversité des facteurs et la complexité des interactions impliquées dans la détermination du rôle des ions métalliques dans les systèmes biologiques, particulièrement dans les processus qui impliquent la formation d'un complexe entre des ions métalliques et des portions hétérocycliques de biomolécules.



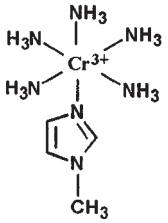
Mots clés : interactions ions métalliques/biomolécules; méthylimidazole; échange d'hydrogène isotopique; catalyse par le chrome.

[Traduit par la Rédaction]



Introduction

The imidazole nucleus and similar heterocyclic residues occur in nature as key structural components of many biologically important molecules such as proteins, enzymes, nucleic acids, some vitamins, and high-energy molecules (e.g., ATP). These biomolecules are fundamental to a variety of life processes (1, 2); their key function in biological reactions is thought to involve binding through their donor (N, O, S) heteroatoms to mediating or interacting metal ions (3).



Studies in our laboratories have focussed in part on two important aspects of metal ion-biomolecule interactions, which bear direct relevance to, and would facilitate the understanding of, the physiological roles of metal ions in living systems. Firstly, we have been involved in the study of the interactions of biomolecules with heavy metal ions like mercury and cadmium, utilizing the heterocyclic residues of the DNA framework as model systems, to elucidate the molecular basis for the toxic effects of heavy metal ions (4, 5). Secondly, we have devoted considerable effort to the investigation of isotopic hydrogen exchange reactions of some five-membered heterocyclic biomolecules like imidazole, histidine, and thiazole. The C(2)-H in these heterocycles of interest is relatively acidic; their exchange in different environments has been utilized as probes of biological function (6). Our studies in this area have revealed interesting structure-reactivity relationships (7, 8) and have also firmly established that in the presence of the proton and metal ions, the prevailing order of reactivity in isotopic hydrogen exchange is protonated >> metal ion-coordinated >> neutral forms of the substrates (7*b*, 9–11). In quantitative terms, metal ions are generally ca. 10^3–10^5 times less effective than H^+ as catalysts, but they enhance reactivity by a factor of 10^4–10^6 relative to the neutral (uncomplexed) substrates. We

[a]Obtained using pK_w (35.0°C) = 13.684 (see ref. 17).

also note that similar trends have been reported in the literature (12).

Recently, we reported in a preliminary communication (13) the first observation of a metal ion-coordinated imidazole complex, *cis*-$[Cr(en)_2(MeIm)Cl]Cl_2$ (en = ethylenediamine, MeIm = 1-methylimidazole), **1**, in which catalysis by Cr(III) was found to be more effective than by H^+, the ratio k^{M^+}/k^{H^+} being 20. In a related study (10*b*) with $[Co(NH_3)_5(MeIm)](ClO_4)_3$, **2**, we obtained $k^{M^+}/k^{H^+} \leq 10^{-4}$. Together, the studies showed clearly that (*i*) Co(III) is a much poorer catalyst than H^+, and (*ii*) the net effect of Cr(III) in promoting hydrogen exchange in 1-methylimidazole is substantially different in magnitude and direction when compared to Co(III). The present work elaborates on the preliminary study reported in our earlier communication (13). An understanding of the various factors that could influence the catalytic effectiveness of metal ions is sought; a causal relationship has been established between the effective charge at N(3) and the C(2)-H acidity of the imidazole nucleus (vide infra).

Kinetic data for the detritiation of the *substitution-inert* (14) complex cations *cis*-$[Cr(en)_2(MeIm)Cl]^{2+}$ (**1**), $[Cr(NH_3)_5MeIm]^{3+}$ (**3**), and $[Cr(NH_3)_5DMeIm]^{3+}$, and {DMeIm = 1,2-dimethylimidazole} (**4**), under experimental conditions similar to our earlier studies (7, 9, 10) are presented, thus enabling direct comparison with results obtained in previous work. The exchange kinetics of tritiated $[Cr(en)_3]^{3+}$ (**5**) and $[Cr(NH_3)_6]^{3+}$ (**6**) were also undertaken in order to obtain reliable data on the direct effect of Cr(III) on N-T/N-H exchange, thus establishing a basis for comparison with the results obtained for the same process in **1**, **3**, and **4**. There has been continuing interest in the biochemistry of the complexes of Cr(III) with nucleic and amino acids because of the importance of this metal in carbohydrate metabolism (15, 16).

The results show clearly that the ring hydrogens of 1-methylimidazole are significantly activated towards isotopic exchange through Cr(III) coordination, to the extent that the otherwise relatively inert C(4,5)-H is observed to undergo exchange under the relatively mild conditions of the study. The relationship between M^{n+}—N σ bond polarization and the electronic structure of the catalytic entity as well as the relative importance of crystal field effects and metal–ligand π back-bonding, highlight the complex nature of the physiological chemistry of (especially) transition metal ions in living systems and the diverse and complex interactions which determine reactivities and selectivities in these systems.

Results

Tritiation experiments

Details of the labelling of the complexes with ^3H, prior to detritiation experiments, are described in the Experimental Section. The tritiation data presented for **1**–**6** in Table 1 clearly demonstrate a hierachy of activities. In all cases, the experimental activities of the ^3H-labelled Cr(III) complexes containing the imidazole moiety, i.e., **1**, **3**, and **4**, are significantly higher than those without imidazole (**5** and **6**). This observation suggests that isotopic exchange in **1**, **3**, and **4** involves the ring hydrogens in addition to the ammine (*en* or NH_3), which is clearly corroborated by the curved first-order plots exhibited by these substrates in the detritiation kinetics presented below. Comparing the experimental activity of 3 to that of its Co(III) analogue, **2**, investigated earlier (10*b*), it is observed that ^3H incorporation in **3** effected for 10 h at 35°C is appreciably greater than in **2** achieved after 30h at the higher temperature of 60°C.

The C(4,5)-H in **2** were shown (10*b*) in H/D exchange experiments to be non-exchanging under the more demanding experimental conditions (p*D* 7.77–10.46, 60°C) of the study (p*D* = (measured pH) + 0.4 at room temperature). The higher tritium incorporation of **3** relative to **2** is therefore suggestive of the involvement of C(4,5)-H exchange in **3**. The results of these tritiation experiments, especially comparing the amounts of tritium incorporation in **2** and **3**, point to a difference in the action of Cr(III) relative to Co(III) in these processes.

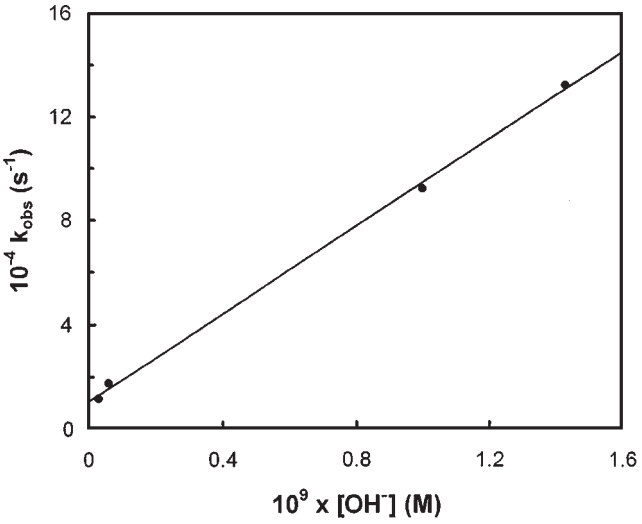
Fig. 1. Plot of k_{obs} *vs.* $[OH^-]$ for the detritiation of **6** at 35°C. A similar plot was obtained for **5**.



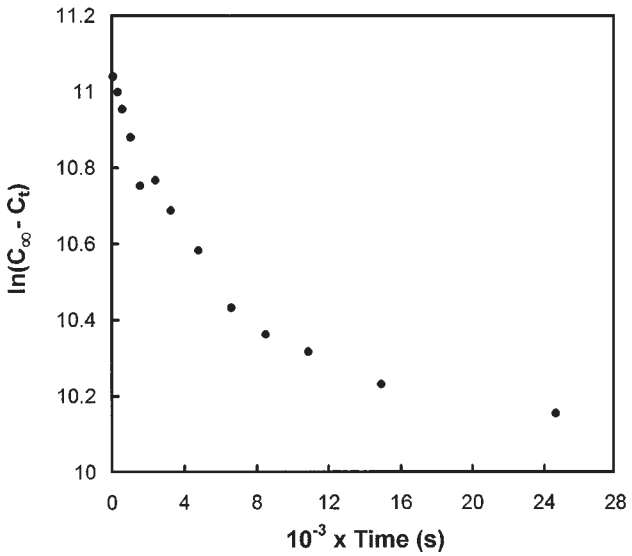


Fig. 2. Plot of ln $(C_\infty - C_t)$ vs. t for the detritiation of **1** at 35°C. Similar plots were obtained for **3** and **4**.

Kinetic Studies

Detritiation of **1** and **3**–**6** following treatment with HTO under standard conditions was performed in aqueous buffers at 35°C under first-order conditions with the substrate in significant deficit with respect to the buffer components, using the liquid scintillation counting technique (7*b*). In all cases, the reactions were monitored for at least 3 half-lives.

For exchange reactions of **1**, **3**, and **4**, the plots of ln $(C_\infty - C_t)$ vs. time were curved (where C_∞ and C_t are the counts in dpm at infinity and time t, respectively). However, for the simple N-T/N-H exchange reactions of the Cr(III)-ammine complexes complexes **5** and **6**, linear first order plots of ln $(C_\infty - C_t)$ vs. time were obtained, allowing a direct determination of the relevant k_{obs} values (Table 2). The second order rate constants (k^{M^+}) for the N-T/N-H exchange reactions in **5** and **6**, were obtained from slopes of the plots of k_{obs} vs. $[OH^-]$, see e.g., Fig.1.

Two peculiar kinetic features which facilitate the identification of exchange sites (vide infra) were noted in experiments involving **1**, **3**, and **4**. Specifically for **1**, the initial counts (dpm) in the kinetic experiments were unusually high. More generally, first-order plots for **1**, **3**, and **4** were curved (see Fig. 2 for a typical plot), indicating the occurrence of two parallel first-order processes (19). Treatment of the curved plots according to the method of Frost and Pearson (20) separated the two parallel rate processes to afford the observed first-order rate constants for the fast (k^A_{obs}) and slow (k^B_{obs}) exchange reactions. These are assembled in Table 3.

The kinetic expression for the exchange process in these substrates is given by eq. [1] (12, 15, 18) from which eq. [2] follows, k^{M^+} being the second-order rate constant for the exchange reaction of the complex.

$$[1] \qquad \text{Rate} = k^{M^+}[\text{Substrate}][OH^-]$$

$$[2] \qquad k_{obs} = k^{M^+}[OH^-]$$

The corresponding second-order rate constants k^{M^+} are gathered in Table 4 together with those for **5** and **6**. Figure 3 shows a plot of k_{obs} vs. $[OH^-]$ for the fast and slow processes in **1**. Values of k^B_{obs} for **3** and **4** are insensitive to $[OH^-]$ in the range of pH investigated; the pH range in each case was determined in separate experiments as the optimum range in

[e]First-order rate constant values for these complexes are independent of [OH^-] (see text).

Fig. 3. Plots of k_{obs} *vs.* [OH^-] for the fast (k_{obs}^A) and slow (k_{obs}^B) processes in **1**; these enable evaluation of $k_A^{M^+}$ and $k_B^{M^+}$ values given in Table 4 (see text).

which the complex of interest remained stable throughout the duration of the kinetic investigation.

The kinetic peculiarities highlighted above not only aid the identification of exchange sites in the complexes of interest but also enable the assignment of the "fast" and "slow" processes to definitive kinetic events within the context of several possibilities.

Infra-red (IR) spectroscopic studies

Hydrogen-deuterium exchange in **1** and **3**, as well as in the model substrates **5**, **6**, imidazole (Im), and MeIm was examined by IR spectroscopy. The model substrates **5** and **6** provide internal standards for N-D and C-D IR frequencies in the complexes of interest. IR spectroscopy performed on the attached ligands in **1** and **3**, following H/D exchange, provide evidence for ring C-H/C-D exchange and enable identification of N-H/N-D (*en* or NH_3) and C-H/C-D (ring) frequencies in the exchanged complexes. The results are given in Table 5. Moreover, IR spectra from a kinetic experiment with **3** reveal that while all amine N-H had exchanged at infinite reaction time, residual aromatic C-H bands remain due to incomplete deuteration of the imidazole moiety. It was ensured that the experimental conditions for H/D exchange were similar to those for detritiation kinetic studies to enable comparison. The C=C (1620 cm^{-1}) and C=N (1530 cm^{-1}) stretching bands of the imidazole ring, not shown in Table 5, persisted throughout the reaction time for **1** and **3**. Similarly, stretching frequencies for N-CH_3 of **1** and **3** (2800–2950 cm^{-1}) and for *en* of **1** (3000 cm^{-1}) were unchanged at infinite reaction time, thus providing clear evidence that the aliphatic protons, whether CH_2- in **1** or N-CH_3 in **1** and **3**, did not exchange under the conditions of the study. Diagnostic deuterium bands for N-D at 2470, 2438, and 2295 cm^{-1}, and C-D at 2360 and 2340 cm^{-1}, were observed for **3** in Table 5; these shift to 2380 and 2304 cm^{-1} for N-D and C-D, respectively, in **1**.

For IR experiments involving the free ligand 1-methylimidazole, parallel ^1H and ^2H NMR experiments were undertaken under the conditions specified in the Experimental Section to confirm exchange at C(2), C(4), and C(5) positions of the ligand. This information has enabled the confident assignment of N-H/N-D and C-H/C-D bands in the IR spectra of the complexes as accomplished in Table 5.

Discussion

Rate data and identification of C–H(T) vs. N–H(T) exchange sites

While identification of exchange sites by ^3H NMR spectroscopy has proven an invaluable tool, especially in substrates that are potentially capable of exchanging at multiple sites (11, 21) this useful technique with its unique advantage of providing explicit structural information could not be utilized in the present study because of the paramagnetic nature of Cr(III) which renders its complexes unamenable to NMR investigations.

The IR studies presented above clearly show that N-T/N-H (*en* or NH_3) and C-T/C-H (ring) exchange occurs in **1**, **3**, and **4**. For the ring protons, there is evidence in the literature, from deuteration (12*d*, 17*a*), and detritiation (12*b*, 12*e*) studies, that C(2)-H in imidazoles is much more acidic than other ring hydrogens. A practical challenge offered by the present study is the identification of exchange site(s) in **1**, **3**, and **4** in the absence of the diagnostic advantage offered by ^3H NMR spectroscopy.

As pointed out earlier, detritiation kinetics provide evidence for two parallel first-order processes in **1**, **3**, and **4**, for which subsequent dissection and analysis afforded second-order rate constants ($M^{-1}s^{-1}$) for the fast reactions ($k_A^{M^+}$) as follows: 6.0×10^3 (**1**), 4.7×10^5 (**3**), and 5.7×10^5 (**4**). For the slow reaction of **1**, a value of $k_B^{M^+} = 7.1 \times 10^2$ $M^{-1}s^{-1}$

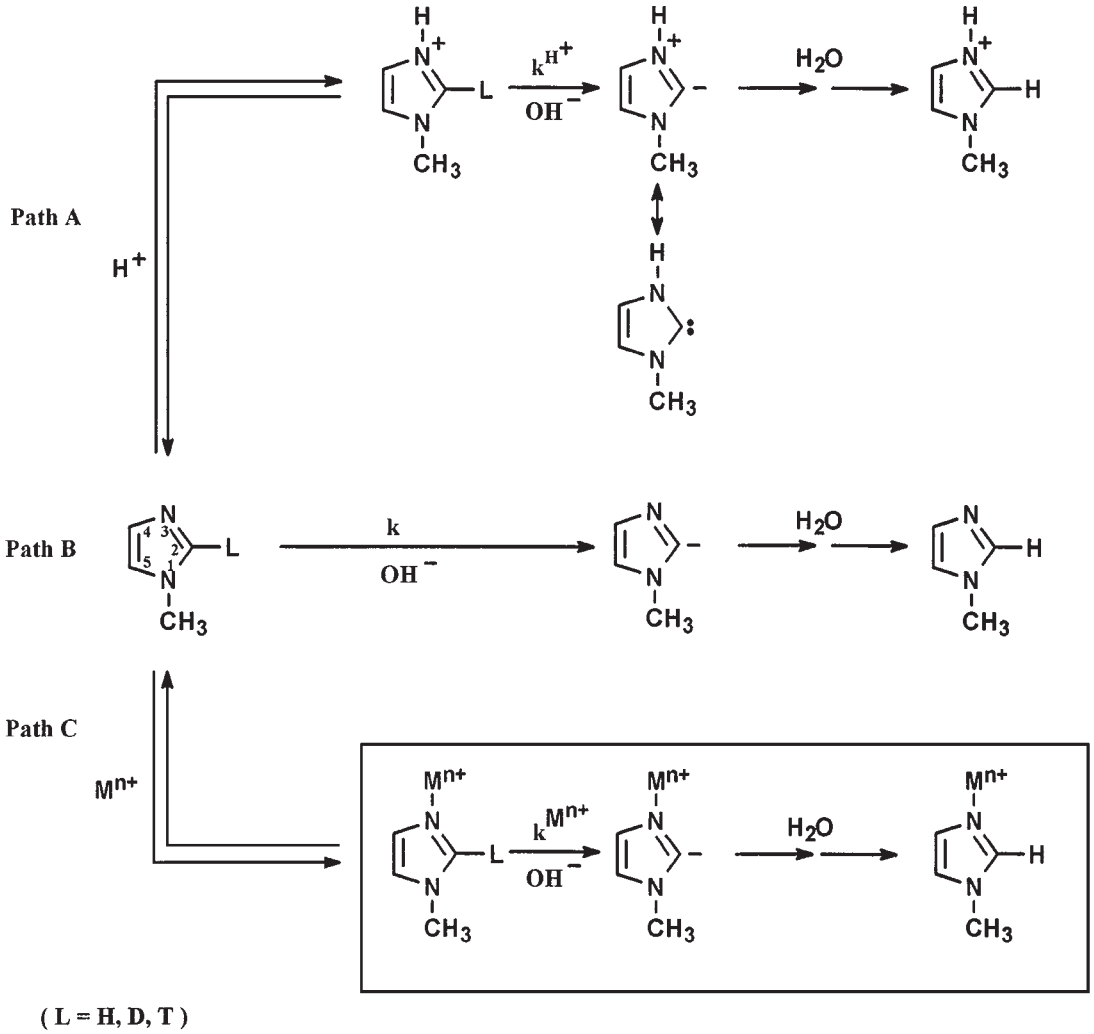
was obtained. Corresponding $k_B^{M^+}$ values for **3** and **4** could not be obtained from the observed k_{obs}^B values which remained insensitive to [OH^-] in the pH range investigated. The second-order rate constant for the single N-T/N-H exchange process (k^{M^+}, $M^{-1}s^{-1}$) was calculated as 5.0×10^5 and 8.2×10^5 for **5** and **6**, respectively. It would be expected, to a first approximation, that the rates of en N-T/N-H exchange in **1** and **5** would be similar, since substitution of 1-methylimidazole and chlorine in **5** to yield **1** would presumably have moderate but compensating effects on N-T/N-H exchange (13, 22). In the same vein, rates of amine N-T/N-H exchange in **3**, **4**, and **6** are expected to be closely similar. While these expectations were realized in the latter group (see Table 4), there is a ca. 10^2-fold difference in the k^{M^+} values of **1** and **5**, favouring **5**. This difference in rates is good evidence that the fast process in **1** cannot be due to N-T/N-H exchange. The unusually high counts (dpm) obtained in the initial assay of **1** (vide supra) show that N-T/N-H exchange had occurred by the time that first experimental point was acquired and accords with the ca. 10^2-fold difference in $k_A^{M^+}$ between **1** and **5** noted above.



The fast and slow processes in **1** are thus assigned to C(2)-T and C(4,5)-T exchange, respectively, based on the substantial difference between the acidities of C(2)-H and C(4,5)-H already documented in the literature (12, 17*c*). We are unable to specify with certainty which position is favoured, C(4) or C(5), in the slow exchange, although inductive and field effects would reasonably argue for preference for C(4) over C(5). It is important however to note that in cases where additional structural factors operate, as reported recently in the case of $[Pt(en)(Th)_2]Cl_2.2H_2O$ (Th = thiazole) (10*a*) in which the α-carbanionic intermediate formed on deprotonation at C(5) is stabilized by the adjacent sulfur atom, inductive/field effects could become less significant in determining exchange site preferences (23).

We focus next on consideration of rate data for **4**. Methyl substitution at C(2) in this substrate, absent in **1** and **3**, precludes exchange at C(2). It is therefore reasonable to assign the two first-order rate processes observed for **4** to N-T/N-H (fast) and C(4,5)-T/C(4,5)-H (slow) exchange. The value of $k_A^{M^+} = 5.7 \times 10^5\ M^{-1}s^{-1}$ obtained for N-T/N-H exchange in **4** compares reasonably well with the value of $8.2 \times 10^5\ M^{-1}s^{-1}$ measured for **6**. The slight (1.4-fold) difference in rates, favouring **6**, may be ascribed to the reduced acidity of NH_3 protons in **4** due to the replacement of one NH_3 with the more basic 1-methylimidazole. The first-order rate constant for the slow process, attributed to C(4,5)-H exchange, is independent of [OH^-] and hence the corresponding second-order rate constant ($k_B^{M^+}$) could not be obtained, contrasting with the situation in **1**. From the data in Table 2, it is noted that data acquisition was restricted to the pH range 3.8–5.0 due to concern for stability of **3** and **4**, as opposed to experiments with **1** whose stability permitted investigations in the pH range of 4.1–6.5. In particular, it is also noted that for **1**, $k_B^{M^+}$ was evaluated from first-order rate data acquired in the moderate pH region of 5.5–6.5, well beyond the pH region in which data for **3** and **4** were acquired.

It is possible that at the low pH in which data for **3** and **4** were acquired and in which [OH^-] is very low, C(4,5)-H exchange prefers an alternative pathway, not shown in Scheme 1 (vide infra), in which the abstracting base is H_2O. This appears reasonable, considering the preponderance of

Scheme 1.

H_2O molecules in the reaction system, and would explain the constant values of k_{obs}^{B} obtained for C(4,5)-H exchange in **3** and **4**. If this explanation is correct, then second order rate constants for water-catalyzed exchange of C(4,5)-H, $k_{H_2O}^{M^+}$, can be obtained as 4.5×10^{-7} M^{-1} s^{-1} and 4.8×10^{-7} $M^{-1}s^{-1}$ for **3** and **4**, respectively, noting that the concentration of water in H_2O is 55.5 M. The very large difference between $k_B^{M^+}$ for **1** (7.1×10^2 $M^{-1}s^{-1}$) and $k_{H_2O}^{M^+}$ for **3** and **4** (ca. 4.7×10^{-7} $M^{-1}s^{-1}$), the rate constants for detritiation of C(4,5)-T in these complexes, reflects the very large differences in the kinetic basicities of the two species, OH^- and H_2O. A similar observation of pH-independent first-order rate constants at low pH (pH 3–6) at 163°C has been reported by Wong and Keck (17*a*) for H/D exchange in 1-methylimidazole in D_2O; hence a precedent exists for this phenomenon in isotopic exchange studies. Although these authors made no attempt to rationalize this observation, the fact that it is reproduced in this study with **3** and **4** at the much lower temperature of 35°C consistently assigns a catalytic role to Cr(III).

The value of $k_A^{M^+} = 4.7 \times 10^5$ $M^{-1}s^{-1}$ obtained for **3** lies in the same domain as that observed for the same process in **4**; it is therefore reasonable to assign this fast process in **3** to N-T/N-H exchange. However, the possibility that this value of $k_A^{M^+}$ is a composite one for both C(2)-T/C(2)-H and N-T/N-H exchange can also not be discounted easily, given the conclusive demonstration (24) that the graphical procedure utilized in separating the two parallel rate processes is insensitive to, and therefore unsuited for use in, rate processes that differ from each other by less than a factor of 4. It is noted that the slow exchange in this substrate has been ascribed to C(4,5)-H abstraction. We point to the fact that C(2)-H abstraction should be favoured in **3**, relative to **1** for which $k_A^{M^+} = 6.0 \times 10^3$ M^{-1} s^{-1}, since the presence of the more basic *en* groups in **1** would modulate the acidifying effect of Cr(III) on the imidazole ring protons, compared to the effect of the less basic NH_3 in **3**. Thus we can justifiably estimate $k_A^{M^+} > 6 \times 10^3$ M^{-1} s^{-1} for **3**.

In summary, the foregoing analysis of the kinetic results provides quantitative data for C(2)-H and C(4,5)-H exchange in **1** as well as qualitative evidence for C(2)-H exchange in **3** and C(4,5)-H exchange in **3** and **4**. A catalytic role by Cr(III) in isotopic exchange of the ring hydrogens of **1**, **3**, and **4** is thus established. The importance and magnitude of the relevant rate constants are considered further below, to

[a]The k^{H^+}/k^{M^+} ratio is known as the proton activating factor (see ref. 12*b*).

[b]The k^{M^+}/k ratio is known as the metal activating factor (see ref. 12*b*).

include a discussion of the superior catalytic activity of H^+ relative to the general effects expressed by metal ions in these processes.

Exchange mechanism, reaction pathways, and the catalytic effects of M^{n+} and H^+

The mechanism for isotopic exchange of C(2)-H in imidazoles and related heterocycles is generalized in Scheme 1. A similar mechanism can be written for C(4)-H and C(5)-H exchange, although a significant difference that exists for exchange at these latter sites is the absence of the ylide intermediate-carbene resonance shown in path A of Scheme 1; the intermediate for proton abstraction at C(4) and C(5) would bear a localized negative charge at these positions. Paths A and B represent the reaction pathways in buffer solutions, with the protonated (path A) and neutral (path B) forms of the substrate being the reactive species. Addition of soluble salts of metal ions to buffered solutions of the ligand introduces an additional pathway (path C) in which the reactive species is the metal-complexed ligand. This pathway is often complicated because kinetically labile (11, 14, 25, 26) metal ion-ligand complexes which are derived in situ set up multiple dissociation equilibria with uncertain stoichiometries (9–11). When the ligand has a free N(3)-H, additional exchange pathways, not shown in Scheme 1, are also possible involving mainly anionic species obtained at high pH through deprotonation of the pyrrole-like N-H; such derived species, whether bound to metal ions or not, can in principle undergo isotopic exchange (10*b*, 12, 27). In all cases, the rate-determining step involves proton abstraction from the reactive species. Rate-pH profiles of various types have been reported (12, 26) and these can, in principle, provide useful information regarding the identity of the reactive species lying along the reaction coordinate. Rate-pH profiles can, in some cases, reveal the presence of unreactive species (12*b*).

The Cr(III)-imidazole complexes presented in this paper, in addition to those involving Co(III) and Pt(II) reported earlier (9*b*, 10*a*), are substitution-inert complexes (11, 27) which were synthesized, isolated and fully characterized prior to kinetic measurements. Direct rate measurements were performed on the isolated complexes under optimized experimental conditions, hence the ensuing discussion simplifies to a consideration of the boxed-in portion of Scheme 1. As required by that mechanism, the kinetic expression for the process is given by eq. [1] and [2] (12, 15, 17). The linear plots of k_{obs} vs. $[OH^-]$ obtained according to eq. [2] (Fig. 3) provide second-order rate constants for C(2)-H ($k_A^{M^+}$) and C(4,5)-H ($k_B^{M^+}$) exchange. The effect of Cr(III)-coordination on C(2)-T abstraction by OH^- in **1**, as compared to the effect of protonation of 1-methylimidazole for the same process, can now be discussed.

The value of $k^{H^+} = 1.0 \times 10^4\ M^{-1}s^{-1}$ at 85°C from our previous study (7*a*) of C(2)-T exchange in protonated 1-methylimidazole ($MeImH^+$) is reasonably close to $k_A^{M^+} = 6.0 \times 10^3\ M^{-1}s^{-1}$ measured at 35°C for the same process in **1** in our present study. This comparison of rates of C(2)-T exchange in $MeImH^+$ and **1** already shows qualitatively that Cr(III) is more effective than H^+ in activating C(2)-H exchange. Using the E_a value of 16.5 kcal mol^{-1} measured (12*e*) for the closely analogous process of detritiation of [8-^{3}H]-adenine, one obtains $k^{H^+} = 2.9 \times 10^2\ M^{-1}\ s^{-1}$ for the $MeImH^+$ system at 35°C. A comparison of the effects of H^+ and Cr(III) on C(2)-H exchange shows that Cr(III) is ca. 20 times more effective than H^+ as a catalyst for C(2)-H exchange. Furthermore, the C(4,5)-H exchange observed in this study under the mild experimental conditions employed (pH 4.1–6.5, 35°C) occurs only under very drastic conditions (pH ~ 12, 100–160°C) when catalysed by H^+ (17). These facts clearly show that Cr(III) is a superior catalyst to H^+ for isotopic exchange of the ring protons of the imidazole nucleus, thus providing the first demonstration of the order of catalytic activity $M^{n+} > H^+$ ($\equiv k^{H^+}/k^{M^+} < 1$) in this class of reaction. Previous studies involving metal ions such as Co(III), Pd(II), $CH_3Hg(II)$, Cu(II) and Ag(I) have consistently yielded the kinetic condition $k^{H^+}/k^{M^+} >> 1$ (10, 12, 26*c*, 28).

Data from this and earlier studies which compare the kinetic effect of protonation versus metal ion coordination in detritiation of several imidazole-type heterocycles are presented in Table 6. The ratios k^{H^+}/k^{M^+} and k^{M^+}/k are the so-called proton activating factor and metal activating factor, respectively (12*b*). What is quite clear from Table 6 (see also refs. 7, 9–11, 13) is that metal ions promote isotopic hydrogen exchange in these heterocycles by factors of 10^3–10^6 relative to the reaction of the neutral substrates, while they

© 2000 NRC Canada

are 10^2–10^5 times inferior to H^+ as catalyst. That is to say, the condition $k^{H^+} >> k^{M^+}$ generally holds. The only apparent exception to this trend is the behaviour of Cr(III) reported in this paper; this observation therefore critically points to the necessity for expanding the scope of transition metal ions investigated so that a wide range of metal ion characteristics (e.g., charge, size, electronic configuration, redox potential, etc.) can be factored into a discussion of metal ion effects in these systems.

The kinetic and thermodynamic rationale for the superiority of H^+ over M^{n+} as catalysts for isotopic exchange has been discussed in detail elsewhere (7, 10*b*) and need not be repeated here. However, additional evidence on the different modes of stabilization of the carbanionic intermediates which lie along the reaction coordinate is provided in the present work. The rate ratio for C(2)-H over C(4,5)-H exchange under H^+ catalysis is ~ 10^4 and this can be understood on the basis of the fact that the ylide intermediate formed on C(2)-H abstraction is resonance-stabilized (path A, Scheme 1), while the corresponding carbanions obtained through C(4,5)-H abstraction are stabilized principally through an inductive/field effect. Under Cr(III) catalysis, the rate ratio for C(2)-H over C(4,5)-H exchange diminishes to ca. 10. This levelling effect by Cr(III) accords with the metal ion exerting largely an inductive effect on the exchange process (10*a*), in which case C(2)-H abstraction is still favoured over C(4,5)-H, but not overwhelmingly so. The higher value of ~ 2×10^2 obtained for this ratio with thiazole exchanging under Pt(II) catalysis reflects, in part, the extra stabilization of the carbenoid intermediate by the sulfur atom; additionally clear differences exist between Cr(III) and Pt(II) in terms of electronic charge, electronic configuration and the magnitude of electrostatic effects which combine to make the former more effective in inducing and transmitting inductive and field effects.

Cr(III) versus Co(III) Activation

The results of Brodsky et al. (29) show that Co(III)-bound 1-methylimidazole in the complex ion $[Co(en)_2(MeIm)OH]^{2+}$ undergoes sluggish deuteration at C(2)-H (pH 12, room temperature) with $t_{1/2}$ = 16 h. These results extrapolate to reactivity ratios of ca. 2×10^{-5}:1:20 for catalysis of C(2)-H exchange by Co(III), H^+, and Cr(III) respectively. The above comparison involves ^3H out of the ligand in H_2O for $[Cr(en)_2(MeIm)Cl]^{2+}$ (**1**), and similarly for $MeImH^+$, but ^2H into the ligand for $[Co(en)_2(MeIm)OH]^{2+}$ in D_2O. If assumptions of approximate values for the solvent isotope effect and the substrate isotope effect are made, then the rate effect disfavouring Co(III) becomes even larger by a factor of ca. 10. Our recent study (10*b*) of the detritiation of $[Co(NH_3)_5MeIm]^{3+}$ (**2**), gives k^{M^+} = 0.15 $M^{-1}s^{-1}$ (pH 7.8–10.5, 60°C) which again extrapolates to reactivity ratios of ca. 6×10^{-5}:1:20 for Co(III), H^+, and Cr(III) respectively. Hence it is clear that compared to H^+, Cr(III) catalyzes C(2)-H exchange in imidazoles while Co(III) exerts an inhibitory role. Comparing the effects of the two metal ions, it is seen that Cr(III) is a ca. 3×10^5-fold better catalyst than Co(III), thus mimicking enzyme activation and inactivation consequent upon changes in the metal ion identity at the enzyme active site, at constant ionic radius and electrical charge.

A close examination of the data in Table 6 reveals a diversity of kinetic effects of different metal ions which are not readily correlated with properties of the ions, i.e., charge-type, redox potential, ionic size, etc. It becomes apparent therefore that the net effect of metal ions on reactivity in these systems is the resultant of a complex interplay of a number of factors which presumably operate on a delicate balance. A qualitative consideration of these factors is considered a profitable exercise to aid an understanding of metal ion effects in these reactions and provide a rational framework for the discussion of the intervention roles played by metal ions in biological systems.

Factors governing the catalytic effects of electrophiles ($E^+ = H^+, R^+, M^{n+}$) in C/H exchange

Magnitude of positive charge developed at N(3) by protonation and coordination

Norris et al. (30) have shown that when the imidazole nucleus is treated in simple electrostatic terms, the fractional positive charge (Z_i) on the imidazole N(3) is related to ΔpK_a as given in eq. [3], in which the standard is 1-methylimidazolium ion with unit positive charge.

$$[3] \qquad Z_i = \Delta pK_a/7.1$$

These authors demonstrated also that a plot of C(2) chemical shift as a function of Z_i for the series in which E^+ (electrophile) = (*i*) CH_3^+, (*ii*) CH_3Hg^+, (*iii*) $Co(NH_3)_5^{3+}$, and (*iv*) zero substituent shows a positive linear correlation which indicates enhanced lability of C(2)-H with increasing positive charge at N(3). It is significant that the order that emerges from this treatment is CH_3^+ (a good model for H^+) > CH_3Hg^+ ~ $Co(NH_3)_5^{3+}$. Thus the fractional positive charge at N(3) in metal complexes is lower than when the coordinating species to the ligand is CH_3^+ (and by extension H^+); evidently, almost the same amount of fractional charge is placed on N(3) by CH_3Hg^+ as by $Co(NH_3)_5^{3+}$, even though the latter species carries with it an associated (nominal) 3+ charge.

There is strong evidence in the literature which supports the hypothesis of Norris et al. (30), showing that the acidifying effect of M^{n+} is far less than that of H^+, partly because of the non-polarisable nature of H^+ and also because the positively charged centre is effectively removed from N(3) and is located on M^{n+} itself. The pK_a values of C(2)-H which measure the intrinsic acidity of different heterocycles collected from a number of sources in our previous paper (10*b*) are consistent with this idea. Rowan et al. (31) reported ^1H NMR chemical shift differences ($\Delta\delta$) of 1 and 0.5 ppm for C(2)-H of imidazole upon coordination to H^+ and Co(III) respectively while the observed (32) decrease in electron density follows the order: H^+ > Co(III) > Rh(III). Furthermore, the pK_a values of –1.7, 7.3, and 1.7 measured (11*d*, 33) for the acid–base equilibrium of eq. [4] for M = H^+, Cu(II) and Co(III) respectively clearly show that the metal ions are poorer Lewis acids than the proton.

$$[4] \qquad M(H_2O)_z^{n+} \rightleftarrows M(H_2O)_{z-1}(OH^-)^{(n-1)+} + H^+$$

From pK_a values of related protolytic equilibria involving Cr(III) and Co(III) complexes (34–36), it is apparent that,

© 2000 NRC Canada

generally, Cr(III) has a greater acidifying effect than Co(IIII) in situations where no structural features are called into play.

An explanation based solely on the simple model of E^+—N σ bond polarization cannot adequately account for the order of electrophile-induced reactivities given in Table 6 and additional factors and effects have to be considered in rationalizing the observed differences. In the following we focus on the very large difference in the effects of Cr(III) and Co(III) (Table 6) when there is a marginal difference in their acidifying effects on heterocycles, favouring Cr(III).

Electronic structure of M^{n+} and differences in crystal field stabilization energy (CFSE)

The data in Table 6, although limited in scope, already demonstrate a wide variety of electronic structures of metal ions encountered in our studies. To evaluate the contribution of electronic structure to reactivity, we focus on the Cr(III)/Co(III) pair which presents a relatively constant set of properties such as electrical charge on ion, ionic radius, and ionization energies but which differ in their electronic configuration within the first row of transition metals, i.e., d^3 for Cr(III) and d^6 for Co(III).

The differing reactivities of Cr(III) and Co(III) complexes in substitution and isotopic exchange reactions have been discussed in some detail (37–39). The general framework resulting from the application of the crystal field theory (CFT) to reactivity (38, 39) can be summarized as follows: (*i*) Cations with large crystal field stabilization energies (CFSE) are likely to have large crystal field activation energies (CFAE) with respect to substitution (39) or dissociative (38*a*) processes, with CFAE defined as in eq. [5]. (*ii*) For a dissociative process, e.g., one in which part of the ligand is

[5] CFAE = CFSE (transition state) – CFSE (initial state)

removed in the transition state as is the case with isotopic hydrogen (H/D) or water exchange, the cation with the largest CFSE has the most to lose in the transition state (39).

A formally analogous process to that described in the present study is ammine isotopic exchange in Cr(III) and Co(III) complexes shown in eq. [6]. The observed rate ratio

[6] $(NH_3)_5M^{n+}NH_3 + OD^- \rightarrow [(NH_3)_5M^{n+}NH_2^{\delta-} \cdots\cdots H \cdots\cdots OD]^{\#} \rightarrow (NH_3)_5M^{n+}NH^-_2 + H\text{-}OD$

favours Cr(III) over Co(III) by a factor of 1.5 which is qualitatively in accord with expectations on the basis of CFT and CFSE though smaller than predicted (38*a*); i.e., for d^3 Cr(III), CFSE = 1.2Δ while for d^6 (low spin) Co(III), CFSE = 2.4Δ. It is noteworthy that for the second row transition metals a rate difference of 3×10^3 was measured for $Ru(NH_3)_6^{3+}$ and $Rh(NH_3)_6^{3+}$, favouring Ru(III) (38*a*), consistent with larger crystal field strengths for second row transition metals than their first row counterparts.

The rate-determining step for isotopic exchange in the present system can be described as in eq. [7], where L represents the imidazole ligand from which tritium is

[7] $M^{n+}L\text{-}T + OH^- \rightarrow [M^{n+}L^{\delta-} \cdots\cdots T \cdots\cdots OH]^{\#} \rightarrow M^nL^- + T\text{-}OH$

removed at C-2 (or at any carbon for that matter). The analogy with ammine isotopic exchange (eq. [6]) is obvious though any electronic effect resulting from interaction of the unshared electron pair on the ligand and the *d* orbital system of the metal would be modulated in eq. [7] relative to eq. [6]. However, this would be counteracted by the fact that proton transfers from carbon centers are much more demanding energetically than transfers from electronegative atoms such as nitrogen (23*c*, 40, 41). In conclusion, C(2)-H isotopic exchange in Cr(III) complexes such as **1** (eq. [7]) is predicted to be more favorable than for Co(III) complexes (e.g., **2**) on the basis of a greater loss in crystal field stabilization energy in the rate determining transition state of the Co(III) system.

The importance of metal to ligand π back-bonding

The electronic structures of Cr(III) and Co(III) reveal differences in their capacity for π-bonding. With a d^3 configuration, Cr(III) is mainly σ-withdrawing, engaging mainly in electrostatic interactions while the d^6 structure of Co(III) predisposes the metal ion to act via a combination of σ + π (covalent) interactions (14, 27, 37*a*). As a consequence, Cr(III) complexes show very little tendency to π-back bonding (42). On the other hand, the low spin d^6 complexes of Co(III) participate in π-bonding with electron acceptor ligands (42*b*, 43). Since imidazole-type ligands are fairly good π-acceptors (44), they can accept d electrons from Co(III). Two consequences of π-back bonding can be considered. (*i*) The Co(III)-N (M^{n+}—N) bond (vide supra) is weakened resulting in poorer M^{n+}—N bond polarization with the consequent attenuation of the ring H acidities of the coordinated ligand. This ground state effect predicts lower intrinsic acidity of the ring hydrogens of Co(III)-bound imidazoles relative to their Cr(III) counterparts. (*ii*) A kinetic effect can be envisaged. Metal-to-ligand π-back donation would accentuate the electron density of the imidazole nucleus; in turn, the effect would disfavour attack by the approaching base thus raising the energy of the transition state for the reaction of the Co(III) complex. These two effects, acting individually or in concert, will favour isotopic hydrogen exchange in Cr(III) imidazole complexes relative to their Co(III) counterparts.

Concluding remarks

The present results involving Cr(III) as catalyst for isotopic hydrogen exchange in imidazoles enlarge the scope of reactivities of metal ions encountered in these systems and provide the first example of a metal ion being more effective as a catalyst than H^+. Comparison of Cr(III) and Co(III) as catalysts shows that the former is ca. 10^5 times more effective than the latter. It has been shown that at constant electronic charge and ionic size, factors such as: M^{n+}—N σ bond polarisation, electronic structure of M^{n+}, crystal field stabilization energy of M^{n+}, as well as crystal field activation energy of the reaction, and the ability of M^{n+} to participate in π back donation, all acting in the right direction can qualitatively account for the observed rate difference in the exchange reactions of Cr(III) and Co(III) imidazole complexes. The underlying significance of the present work is that it highlights the diversity of factors at play in determining

© 2000 NRC Canada

metal ion effects in the exchange reactions of heterocycles of biological importance, and emphasizes a holistic approach in the consideration of the biochemistry of metal ions.

Experimental

Materials

Anhydrous chromium trichloride (99%), 1-methylimidazole (MeIm,99%), 1,2-dimethylmidazole (DMeIm, 98%), 1,2-diaminoethane (99%), tetramethylsulfone (99%), D_2O (99.9% atom D), and trifluoromethanesulfonic acid (anhydrous, 98%) were purchased from Aldrich. DMSO-d_6 (99.9%) and CDCℓl_3 (99.8%) were Cambridge Isotopes products while HTO (1 Ci/mL) and HP-Ready Solvent liquid scintillant were obtained from NEN Du Pont and Beckman Instruments, respectively. Potassium hydrogen phthalate was oven-dried at 110°C for 48h before use. Solutions of NaOH and HCl were freshly prepared and were standardized before use. The starting complexes $[Cr(NH_3)_6](NO_3)_3$ (45), $[Cr(NH_3)_5Cl]Cl_2$ (45), $[Cr(en)_3]Cl_3{\cdot}3H_2O$ (46), *cis*-$[Cr(en)_2Cl_2]Cl{\cdot}H_2O$ (47), and $[Cr(NH_3)_5OSO_2CF_3](CF_3SO_3)_2$ (48) were synthesized and purified according to literature procedures.

Physical measurements

IR spectra for samples in KBr disks were obtained on a Bruker IFS 85 or Bomen-MB 120 FTIR spectrophotometer. UV-visible spectra were run on Cary 3 and Beckman Lamba-5 spectrophotometers, while ^1H and ^2H NMR spectra, where applicable, were recorded on Bruker AC-200 and AM-400 spectrometers. ^3H assays were performed on a Beckman LS5801 liquid scintillation counter. Melting points were determined on a Hoover Mel-Temp II apparatus and are uncorrected; elemental analyses were performed by the Canadian Microanalytical Services, Delta, B.C. All pH values are room temperature measurements obtained on a Beckman ΦpH meter calibrated with standard aqueous buffers of pH 4 and 7 (BDH). Buffer solutions in the pH range of study were prepared at room temperature according to the procedure of Perrin (49). Values of pH at 35°C were obtained by applying the temperature correction factor as described in the literature (50).

Hydrogen–deuterium exchange measurements

H/D exchange in Cr(III) ammine and methylimidazole complexes

A known quantity of the relevant complex (**1**, **3**, **5**, or **6**) was dissolved in D_2O (99.9%) in a glass-stoppered 25 mL test tube. The resulting solution, whose pH was adjusted to the desired value with either 1 M NaOD or 1 M D_2SO_4, was shaken vigourously before immersing in an oil-bath equilibrated at 35°C. 200 μL aliquots of the reaction mixture were withdrawn at known intervals, placed in a 50 mL round bottomed flask and lyophilized to remove excess D_2O. The resulting solid was ground with ca. 200 mg of IR-grade KBr; the IR spectrum of the sample was taken in KBr disks and compared with that of the undeuterated complex.

H/D Exchange in MeIm

A sample of 2.5 M solution of MeIm in D_2O (p*D* 11.77) was placed in an oil-bath operating at 35°C. Aliquots (1 mL) were withdrawn at known intervals into 10 mm diameter long-neck test tubes and extracted with 3 × 1 mL portions of $CHCl_3$. The extract was dried with anhydrous Na_2SO_4 and solvent removed under vacuum. IR (neat) and ^1H NMR (DMSO-d_6) spectra were then taken. To provide definitive information concerning exchange sites in the substrate, the ^2H NMR spectrum of a sample of MeIm in D_2O (pD 11.77) kept at 85°C was taken in $CHCl_3$ with a drop of DMSO-d_6 as internal reference. Exchange at C(2), C(4), and C(5) was observed under these conditions. The IR spectrum of the exchanged ligand provided a standard that aided assignment of bands in the complexes given in Table 5.

Tritiation of complexes

The procedure for tritiating the complexes has been published previously (7*a*, 51). Typically, 10–20 mg of the complex to be tritiated was dissolved in ca. 100 μL of freshly distilled DMSO in a heavy-walled glass ampoule stoppered with a rubber septum. HTO (10–80 μL, 1 Ci/mL) was added with a gas-tight syringe. The contents of the glass ampoule were frozen in liquid N_2 and evacuated, sealed and suspended in an oil-bath maintained at 35°C for 10–12 h. The ampoule was then removed, opened into a 25 mL pear-shaped flask and washed with 1 mL of distilled H_2O to remove labile ^3H. The solvent was removed by lyophilization. Further aliquots, usually three, of 1 mL H_2O were added and lyophilized until the activity of the lyophilized H_2O became negligible. A stock solution of the tritiated complex was then prepared by dissolving a known amount in <1 mL of freshly distilled DMSO in a test tube which was firmly stoppered and carefully stored in a refrigerator.

Kinetic measurements

Rates of detritiation of **1** and **3**–**6** were studied in aqueous buffer solutions (pH 3–6.6) following a procedure published previously (7, 10*b*). In general, the kinetics were performed under first-order conditions and reactions were monitored for at least 3 half-lives. Pseudo first-order and second-order rate constants were obtained as described in the Results section.

Synthesis of complexes

*cis-$[Cr(en)_2(MeIm)Cl]Cl_2{\cdot}2H_2O$ (**1**).* A mixture of MeIm (0.4 mL, 5.06 mmol) and *cis*-$[Cr(en)_2Cl_2]Cl{\cdot}H_2O$ (1.5 g, 5.06 mmol) in H_2O (5 mL) was stirred for 5 h at room temperature. Absolute EtOH (150 mL) was then added and the resulting solution was evaporated to dryness to yield a violet coloured solid, which was recrystallized from EtOH:H_2O (2:1 v/v). The violet hygroscopic needles obtained were washed successively with absolute EtOH and Et_2O, and dried in vacuo, yield 0.91 g (45%), mp 175–177°C (dec.); $\lambda_{max}(\varepsilon)$ in H_2O: 380, 520 nm (49, 57 M^{-1} cm^{-1}). Anal calc. for $C_8H_{27}N_6O_2Cl_3Cr$: C 24.21, H 6.56, N 21.18; found: C 23.07, H 6.66, N 21.00.

*$[Cr(NH_3)_5MeIm](ClO_4)_3{\cdot}H_2O$ (**3**).* This was prepared by a modification of the method of Curtis and Lawrence (52).

© 2000 NRC Canada

Reaction of $[Cr(NH_3)_5OSO_2CF_3](CF_3SO_3)_2$ (48) (0.5 g, 1.02 mmol) with neat MeIm (15 mL, 0.19 mol) under stirring at 40°C for 4 h produced a yellowish solution, which was decanted into a 400 mL beaker and treated with a mixture of absolute EtOH (10 mL) and Et_2O (200 mL). Upon leaving overnight, a thin film of yellow oil was formed which was recovered and treated with EtOH (5 mL) to give a yellow crystalline solid. The solid product was filtered, washed successively with EtOH (3 × 10 mL) and Et_2O (10 mL), and dried in air to yield 0.23g (46%) of the triflate complex $[Cr(NH_3)_5MeIm](CF_3SO_3)_3$. Further treatment of the triflate complex (0.163 g, 0.29 mmol) in H_2O (1 mL) with conc. $HClO_4$ (1 mL) with cooling in ice resulted in a crystalline yellow product which was filtered and washed successively with EtOH and Et_2O. The crude product was recrystallized from conc. $HClO_4$ to give the yellow light-sensitive crystals of the perchlorate complex in almost quantitative yield 0.16 g (95%), which darkens and decomposes > 200°C; λ_{max} (ε) in H_2O: 356, 469 nm (31, 35 $M^{-1}cm^{-1}$) Anal calcd. for $C_4H_{23}N_7O_{13}Cl_3Cr$: C 8.92, H 4.29, N 18.30; found: C 8.39, H 3.97, N 18.68.

*$[Cr(NH_3)_5DMeIm](ClO_4)_3$ (**4**).* This complex was obtained by a procedure (48) similar as for **3**. Reaction of $[Cr(NH_3)_5OSO_2CF_3](CF_3SO_3)_2$ (0.86 g, 1.75 mmol) and DMeIm (15 mL, 0.17 mol) gave small golden yellow crystalline plates, yield 0.20 g (26%), which darken and decompose > 200°C; λ_{max} (ε) in H_2O: 355, 471 nm (34, 42 $M^{-1}cm^{-1}$). Anal. calcd. for $C_5H_{23}N_7O_{12}Cl_3Cr$: C 11.29, H 4.33, N 18.44; found: C 11.32, H 4.20, N 18.21.

Stability of the complexes

It was essential to establish that complexes **1**, **3**, and **4** remained stable under the experimental conditions of the kinetic study. Two sets of experiments were undertaken to ascertain this fact. (*i*) Solutions of the complexes were repetitively scanned by UV–visible spectrophotometry in the pH range 5–6 at 35°C for 24 h, representing the most extreme conditions under which detritiation conditions were undertaken. Resulting spectra confirmed the stability of the complexes under the specified conditions. (*ii*) Colour changes in complexes of the type *cis*-$[Cr(III)(en)_2XY]$ are diagnostic of competitive and/or preferential side reactions. In the isotopic exchange reactions of *cis*$[Cr(en)_2(MeIm)Cl]^{2+}$, the violet colour of the complex remained unchanged throughout the duration of the experiments (pH 4–6.5, 35°C) both in the tritiation experiments (≤10 h) and in H/D exchange monitored by IR (≤12 h).

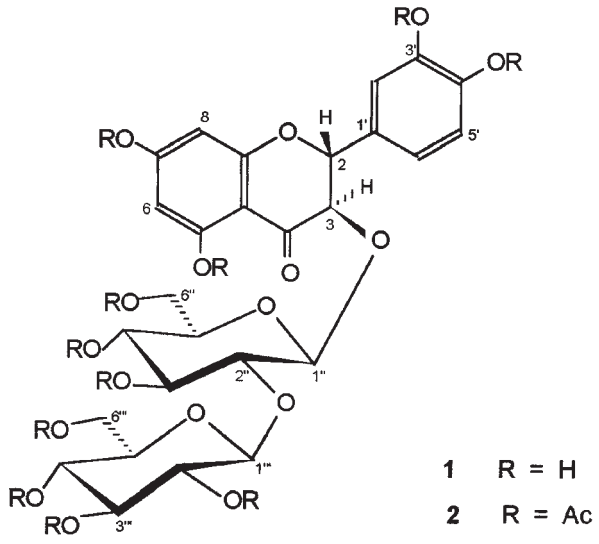
Calodendroside A: a taxifolin diglucoside from the stem bark of *Ochna calodendron*

Bernard Blaise Messanga, Beibam Luc Sondengam, and Bernard Bodo

Abstract: A new flavanone diglucoside, calodendroside A (**1**), was isolated from the methanolic extract of the stem bark of *Ochna calodendron* (Ochnaceae) and its structure elucidated as (2*R*,3*R*) taxifolin-3-*O*-glucosyl-(1→2)-glucoside by means of chemical and spectroscopic evidence including ^{1}H-^{1}H and ^{1}H-^{13}C COSY NMR. The connection of the two sugar moities was determined by the use of the heteronuclear multiple bond connectivities experiment (HMBC). To our knowledge, the present report is the first describing the isolation of a flavonoid diglucoside from a member of the Ochnaceae family.

Key words: *Ochna calodendron*, Ochnaceae, stem bark, flavanone diglucoside, calodendroside A.

Résumé : L'étude chimique de l'extrait au méthanol des écorces du tronc de *Ochna calodendron* (Ochnacées) a conduit à l'obtention d'une nouvelle flavanone diglucosée de nom systématique: (2*R*,3*R*) taxifolin-3-*O*-glucosyl-(1→2)-glucoside (**1**). La structure de ce nouveau dérivé naturel a pu être élucidée grâce à l'analyse des spectres de COSY ^{1}H-^{1}H et ^{1}H-^{13}C. L'enchaînement des deux sucres a particulièrement été défini grâce à l'analyse du spectre de corrélation à longue distance ^{1}H-^{13}C, en mode inverse (HMBC). A notre connaissance, ce rapport représente la première communication décrivant la présence d'un diglucoside de flavonoide dans la famille des Ochnacées.



Mots clés : *Ochna calodendron*, ochnacées, écorces du tronc, flavanone diglucosée, calodendroside A.

Introduction

Ochna calodendron (Gilg. and Mildbr. (Ochnaceae)) is one of the ten species of the genus *Ochna* reported in Cameroon. Major constituents previously isolated from this genus were isoflavonoids (1), flavone monoglycosides (2) and biflavonoids (3–6). We recently described the isolation from the stem bark of *O. calodendron* of three chalcone dimers, namely, calodenone, calodenin A, and lophirone K (7, 8). In continuation of our phytochemical investigation on this plant, we have isolated a new flavonoid diglucoside, calodendroside A (**1**), the structure of which is described herein.

Results and discussion

The MeOH extract of the stem bark of *O. calodendron* was chromatographed on a reverse-phase gel column (RP-2) with H_2O–MeOH gradient as eluent, yielding fourteen fractions (E_1–E_{14}). Further purification of fractions E_4–E_7 by a combination of reverse-phase Si gel (RP-8) and Sephadex LH20 column, afforded calodendroside A (**1**).

1 R = H

2 R = Ac

Compound (**1**) was isolated as an amorphous yellow powder and exhibited a green color with Fe^{+3} and a positive Molisch test. The molecular formula $C_{27}H_{32}O_{17}$ was deduced from the pseudomolecular ion at 629.1347 observed in the HRFAB mass spectrum. On acetylation (Ac_2O–pyridine) calodendroside A gave an undecaacetate (**2**) the IR spectrum of which showed no OH absorption. Acidic (2 N methanolic HCl, 1 h) and almond emulsion hydrolysis of **1** yielded D-glucose and an aglycone which was identified as the known dihydroflavonol (+)-taxifolin (2*R*,3*R*) by comparison of the

optical rotation ($[\alpha]_D^{18}$ +21.1° (*c* = 0.56, EtOH), +24.6° (*c* = 0.57, acetone)) and the ^{1}H- and ^{13}C- NMR spectra with those of an authentic sample.

The ^{1}H-NMR spectrum of calodendroside A (**1**) confirmed the presence of a taxifolin aglycone characterized by two doublet signals at δ 5.35 (*J* = 11.1 Hz) and 4.66 (*J* = 11.1 Hz) assigned to H-2 and H-3 respectively, two doublet signals at δ 5.86 (brd) and δ 5.90 (brd) assigned to H-6 and H-8 respectively and signals for three aromatic protons on the B-ring showing the ABX-type coupling [δ 6.68 (brd, H-2′), δ 6.69 (m, H-5′), δ 6.85 (m, H-6′)] (Table 1). The presence of two glycosyl units was suggested by two characteristic doublet signals correspondig to two anomeric protons at δ 4.62 (d, *J* = 7.0 Hz, H-1²) and δ 4.60 (d, *J* = 7.2 Hz, H-1‴). Each carbohydrate spin system was assigned by ^{1}H-^{1}H and ^{1}H-^{13}C COSY NMR experiments (Table 1). ^{1}H-^{13}C long-range correlations were observed in the heteronuclear long-range COSY spectra (HMBC) between H-1″ (δ 4.62) and C-3 (δ 74.0) and between H-1‴ (δ 4.60) and C-2″ (δ 81.2). This indicated a glucopyranosyl unit, linked glycosidically with the C-3 oxygen of the aglycone and linked further through its C-2 oxygen to the anomeric centre of a second glucopyranosyl unit. This sustitution pattern agreed with the deshielding effet, +8 ppm, observed for C-2″ carbon signal (Table 1) as compared to the signal of an unsubstituted 3-*O*-glucosyl. The large coupling constants (7.0 and 7.6 Hz) observed for the anomeric H-1″ and H-1‴ respectively indicated a β-configuration for both of them (Table 1). Based on these data, calodendroside A has been characterized as (2*R*,3*R*) taxifolin-3-*O*-β-D-glucopyranosyl-(1→2)-*O*-β-D-glucopyranoside (**1**). To our knowledge, this is the first paper describing the characterization of a flavanone diglycoside from a member of the Ochnaceae family.

Experimental section

General experimental procedures

IR spectra were registered on a Nicolet Impact 400D spectrometer. NMR spectra were recorded on a Bruker AC 300 spectrometer (^{1}H-, 300 MHz; ^{13}C-, 75 MHz; DMSO-d_6). Long-range ^{1}H-^{13}C COSY NMR spectra were obtained with *J* = 7 Hz. Positive FAB mass spectra were obtained on a ZAB-HF mass spectrometer. Column chromatography was carried out on silanized silica 60 gel RP-2 (70–230 mesh) Merk, on Lichroprep RP-8 (40–63) Merk, and on Sephadex LH20 (Pharmacia) using a H_2O–MeOH gradient. Elutions were checked by TLC (silica 60 F_{254}, Merk) using H_2CCl_2:MeOH (3:1) as solvent system. TLC was visualized under UV (254 nm) and spraying an ethanolic vanillin – sulfuric acid solution followed by heating.

Plant material

Stem bark of *O. calodendron* (8 kg) was extracted with MeOH exhaustively. The extract was concentrated to dryness under reduced pressure to afford a brownish material (45 g) which was re-extracted with a EtOAc. The soluble portion was concentrated to dryness and chromatographed on a RP-2 column. Elution with H_2O–MeOH gradient, starting with pure water, gave fourteen fractions (E_1–E_{14}). Purification of fractions E_4–E_7 on RP-8 column eluted with a mixture of H_2O:MeOH (4:6) yielded three fractions (E_{47}a, E_{47}b, and E_{47}c). Fraction E_{47}b (0.72g) was further purified on a Sephadex LH20 column eluted with MeOH to yield calodendroside A which was re-chromatographed on a RP-8 using H_2O:MeOH (1:1) as eluent, to give pure **1** (45 mg).

calodendroside A [taxifolin-3-O-β-*D-glucopyranosyl-(1→2)*-O-β-*D-glucopyranoside]* (**1**): $[\alpha]_D^{28}$ –92° (MeOH, *c* = 1.0) ; IR (KBr) ν: 3420, 2625, 1705, 1640, 1598, 1450, 1370, 1201, 1198, 950, 840 cm^{-1}; HR-FABMS $[M + H]^+$ 629.1347 (calcd. for $C_{27}H_{32}O_{17}$, 629.1355); ^{1}H- and ^{13}C-NMR data see Table 1.

calodendroside A undecaacetate (**2**): Acetylation of calodendroside A by Ac_2O:pyridine and usual treatment yielded **2**: ^{1}H-NMR (DMSO-d_6, 300 MHz) δ 1.90–2.35 (33H, m, OAc), 4.00–4.85 (14H, m, sugar protons), 4.90 (1H, d, *J* = 12.1 Hz, H-3), 5.72 (1H, d, *J* = 12.0 Hz, H-2), 6.22 (1H, d, *J* = 1.8 Hz, H-8), 6.13 (1H, d, *J* = 2.0 Hz, H-6), 6.98–7.05 (3H, m, B-ring protons) ppm; HR-FABMS $[M + H]^+$ 1091.2017 (calcd for $C_{49}H_{54}O_{28}$, 1091.2023); EIMS m/*z*: $M^{+\cdot}$ absent, 1048 [19, M – Ac]$^+$, 760 [36, M – Ac_4]$^+$, 636 [2,

© 2000 NRC Canada

$GlucAc_3$ – $GlucAc_4]^+$, 349 [26, $GlucAc_4]^+$, RDA fragments 236 [100, A and B-ring].

*Acid hydrolysis of **1***. Acid hydrolysis of **1** with 2 N methanolic HCl gave (+)-taxifolin (UV, TLC and $[\alpha]_D$ comparison with an authentic marker) and a sugar which was identified as glucose by PC in BAW (*n*-butanol:HOAc H_2O; 4:1:5) compared with an authentic marker (R_f: glucose 0.18, $[\alpha]_D^{20}$ = +52.4°). The sugar was detected by spraying with anisidine phtalate and *p*. anisidine phosphate. The identity of the sugar was confirmed by comparative GLC of the trimethyl ether compared with an authentic marker (R_t: glucose1.0).

Acknowledgements

We gratefully acknowledge the constructive cooperation of Professor Raphaël Ghogomu (Laboratoire de Chimie Organique, Cameroon) and Alain Blond (Laboratoire de Chimie du Muséum, France) during the course of this study. We also wish to thank Mr. Nole of the "Institut Médical des Plantes Médicinales du Cameroun" for identification and collection of the plant material. The authors are indebted to the "Centre d'Analyse du CNRS de Lyon" for the FAB measurements.

Titrage infrarouge de l'acide phosphorique

Jocelyn Baril, Jean-Joseph Max et Camille Chapados

Résumé : Le titrage par spectroscopie infrarouge (IR) de l'acide phosphorique par l'hydroxyde de sodium a été fait à des pH variant entre 0,18 et 13,4 dans le but d'obtenir les spectres des espèces ioniques pures et d'en déterminer la distribution en fonction du pH. Après la soustraction des spectres d'eau neutre, d'eau acide et d'eau basique, l'analyse par facteurs (AF) appliquée sur la série de spectres a été utilisée pour atteindre le but fixé. Les espèces ioniques les plus abondantes sont : H_3PO_4 (pH 0 à 4), $H_2PO_4^-$ (pH 0 à 9), HPO_4^{-2} (pH 4 à 14) et PO_4^{-3} (pH 9 à 14). Trois complexes, présents en faible quantité, ont pu être observés : H_3PO_4–$H_2PO_4^-$ (pH 0 à 4), $H_2PO_4^-$–HPO_4^{-2} (pH 4 à 9) et HPO_4^{-2}–PO_4^{-3} (pH 9 à 14). Les constantes d'équilibre de ces espèces avec les molécules parentes sont respectivement 0,65, 0,63 et 0,4 L/mol. Nous avons également trouvé de l'eau résiduelle qui forme, avec les espèces ioniques, des hydrates. Les pK_a obtenus à partir du titrage IR ont été utilisés pour calculer, en fonction du pH, la concentration théorique des quatre espèces ioniques principales. La courbe de distribution résultante est semblable à celle qui fut obtenue par IR.

Mots clés : spectroscopie infrarouge, FT-IR, solutions aqueuses, analyse par facteurs, titrage, acide phosphorique, pH.

Abstract: The titration of phosphoric acid by sodium hydroxide was performed by infrared (IR) spectroscopy with the objective of obtaining the infrared spectra of the pure ionic species and determining their abundance as a function of pH. In the series of spectra, taken in the pH range of 0.18–13.4, the subtraction of neutral water, acidic water, and basic water was made. Factor analysis (FA) was then applied to the series of spectra to obtain the objective. First, we found the four most abundant species : H_3PO_4 (pH 0–4), $H_2PO_4^-$ (pH 0–9), HPO_4^{-2} (pH 4–14), and PO_4^{-3} (pH 9–14). Secondly, we found three complexes in small quantities : H_3PO_4–$H_2PO_4^-$ (pH 0–4), $H_2PO_4^-$–HPO_4^{-2} (pH 4–9), and HPO_4^{-2}–PO_4^{-3} (pH 9–14). The equilibrium constants of these species with the parent molecules are 0.65, 0.63, and 0.4 L/mol, respectively. Thirdly, we found residual water that was closely bound to the ionic species which formed hydrates. The pK_a values obtained from the IR titration were used to obtain the theoretical concentration of the four principal species as a function of pH. The resulting distribution curve was found to be coincident with the distribution curve obtained by IR.

Key words : infrared spectroscopy, FT-IR, aqueous solutions, factor analysis, titration, phosphoric acid, pH.

1 Introduction

Nous avons entrepris depuis quelques temps le titrage acide–base en utilisant la spectroscopie infrarouge (titrage IR) de façon à évaluer cette technique dans de telles situations. Nous voulions voir, entre autres, comment cette technique se compare aux techniques classiques de titrage acide–base et aux autres techniques comme la spectroscopie Raman. Nous avons déjà fait le titrage de la glycine qui est un acide aminé (1) et de l'acide butoxy-propyl-amine-diacétique (BOPA) qui est un surfactant de la famille des glycinates (2). Pour ce faire, nous avons utilisé une cellule ATR avec un cristal de ZnSe en nous assurant que les phénomènes optiques ne modifiaient pas l'analyse du signal IR (3).

La difficulté d'un titrage IR réside dans la forte absorptivité de l'eau qui est le solvant utilisé pour ces titrages. Lors de ces titrages nous avons de l'eau acide, de l'eau basique, de l'eau saline et de l'eau neutre. Nous avons montré que ces différents types d'eau ont une signature spectrale IR unique (4–6) qui peut être utilisée pour faire la soustraction quantitative des bandes d'absorption de l'eau afin d'obtenir le spectre du chromophore en fonction du pH.

Lors du titrage, plusieurs espèces ioniques sont présentes simultanément et leurs spectres respectifs se superposent. Pour les séparer, nous avons utilisé la méthode d'analyse par facteurs (AF). Cette méthode, qui est décrite par Malinowski et Howery (7), conduit à des facteurs abstraits dont l'interprétation est souvent difficile. Nous avons surmonté cette difficulté en imposant des contraintes qui rendent les spectres réels (8). Pour la glycine et le BOPA, nous avons montré que cette méthode fonctionne bien (1, 2). Lors des titrages, les espèces se succèdent tout en se chevauchant, mais comme nous partons d'une solution connue, il est possible de faire la séparation des espèces en séparant directement les spectres. Un chiffrier électronique comme Excel de Microsoft permet de faire cette opération sans difficulté (2, 6).

La glycine et le BOPA sont des acides organiques faibles qui ont des bandes carbonyles caractéristiques qui évoluent en fonction du pH. Bien que nous utilisions l'ensemble du

© 2000 CNRC Canada

spectre (de 4800 à 700 cm^{-1}) pour les besoins du titrage, la variation des bandes carbonyles permet de bien faire la séparation des spectres des espèces ioniques.

Les acides inorganiques ont moins de bandes dans la région de l'IR moyen, et le titrage IR de ces acides est plus difficile. Malgré ces difficultés, nous avons montré qu'il était possible de faire le titrage de l'acide chlorhydrique par le NaOH et les résultats que nous avons obtenus sont excellents, malgré le fait que les constituants n'absorbent pas ou très peu dans l'IR. Ce sont les variations dans le spectre de l'eau qui servent de témoin lors d'un tel titrage IR.

Afin de vérifier que le titrage d'un acide inorganique complexe qui possède plusieurs constantes d'équilibre peut se faire en IR, nous avons choisi l'acide phosphorique qui a trois pK_a. Cet acide est important dans l'industrie et le groupe phosphate se trouve dans plusieurs molécules biologiques. Dans la nature, certaines eaux contiennent de l'acide phosphorique (H_3PO_4) qui est un acide faible. En fonction du pH, le H_3PO_4 s'ionise pour former successivement du $H_2PO_4^-$, du HPO_4^{-2} et du PO_4^{-3}. Une solution aqueuse d'acide phosphorique constitue un mélange complexe contenant plusieurs espèces ioniques en équilibre dans l'eau. La mesure des constantes d'équilibre de l'acide phosphorique en solution aqueuse a fait l'objet de plusieurs travaux (9–18). Dans ces travaux, les auteurs ont fait varier le degré de dissociation de l'acide phosphorique en solution aqueuse, en ajoutant une base forte ou un acide fort. L'activité des espèces dans la solution, qui est fonction de la concentration de ces espèces et de leur coefficient d'activité, a été déterminée par des mesures électrochimiques. Dans ces mesures, il faut tenir compte de la force ionique de la solution. Les mesures électrochimiques ne permettent pas une mesure directe de la concentration des espèces en solution qui doit être obtenue de façon indirecte.

Les spectres IR des quatre espèces ioniques du H_3PO_4 aqueux ont déjà été obtenus par transmission (19, 20). Les quatre espèces ioniques ont un nombre de bandes différent et des fréquences d'absorption caractéristiques. Malgré ces travaux, le titrage par IR n'a pas été effectué et c'est l'objet du présent travail.

Dans un titrage acide–base comme celui qui est l'objet de ce travail, la solution passe d'un milieu acide à un milieu basique. L'eau est influencée par la présence de ces ions et va donner de l'eau acide, de l'eau neutre et de l'eau basique (4, 5). L'eau acide est de l'eau qui contient des protons (H^+) sous la forme d'ions H_3O^+ (ou $H_5O_2^+$) auxquels sont associés un certain nombre de molécules d'eau. De la même façon, l'eau basique et l'eau salée contiennent respectivement des ions OH^- et Na^+ et Cl^- pour donner de l'eau avec des caractéristiques propres qui se manifestent par des spectres différents dans la région du continuum d'absorption entre 2900 et 2000 cm^{-1} (voir section 4.3 et la figure 3A). Même dans des mélanges, ces espèces donnent des spectres constants qui peuvent être soustraits. Dans les solutions acides qui contiendraient du sel, les spectres de l'eau acide, de l'eau neutre et de l'eau salée sont soustraits successivement par la méthode de l'AF afin d'obtenir des spectres sans ces types d'eau. Nous procédons de la même façon pour l'eau basique.

Par la suite, l'AF sera utilisée pour obtenir les spectres IR des espèces ioniques de l'acide phosphorique et leur distribution en fonction du pH. Les courbes de distribution des espèces ainsi obtenues seront comparées à celles calculées à l'aide des équations d'équilibre.

2 Considérations théoriques

2.1 Courbes de titrage volumétrique

2.1.1 Définition du problème

L'acide phosphorique est un triacide qui possède trois pK_a. dont les équilibres sont :

$$[1] \qquad H_3PO_4 \overset{K_1}{\underset{H^+}{\rightleftharpoons}} H_2PO_4^- \overset{K_2}{\underset{H^+}{\rightleftharpoons}} HPO_4^{-2} \overset{K_3}{\underset{H^+}{\rightleftharpoons}} PO_4^{-3}$$

Les équations nécessaires pour obtenir les courbes de titrage volumétrique ont été développées pour le titrage IR de la glycine en solution aqueuse qui est un acide avec deux pK_a (1) et le BOPA qui est un glycinate avec trois pK_a et qui peut exister sous forme cationique (2). Tout comme ce dernier, l'acide phosphorique possède trois pK_a mais ne possède pas de forme cationique. Comme l'acide phosphorique est une situation différente des deux cas précédents, nous ne pouvons utiliser les équations qui ont été développées pour eux. Il nous faut par conséquent développer un jeu d'équations adéquat pour cet acide.

Deux situations doivent être considérées pour le titrage en solution aqueuse : l'ajout d'une base forte et l'ajout d'un acide fort. Pour simplifier le développement mathématique, l'addition de la base forte et de l'acide fort seront considérées comme étant simultanées, même si expérimentalement ce n'est pas le cas. Après le développement, les espèces seront séparées. Nous avons :

$$[2] \qquad \begin{array}{cccccc} H_3PO_4 & + H_2O & + NaOH & + HCL & & \\ A & D & C_1 & C_{-1} & & \end{array}$$

$$\rightarrow \begin{array}{cccccc} H_3PO_4 & + H_2PO_4^- & + HPO_4^{-2} & + PO_4^{-3} & & \\ y_1 & y_2 & y_3 & y_4 & & \end{array}$$

$$+ \begin{array}{ccccc} H^+ & + OH^- & + Cl^- & + Na^+ & + H_2O \\ x & x' & c' & c & d \end{array}$$

Le membre de gauche de l'équation 2 contient les différentes espèces dans la solution avant mélange : le produit à titrer (H_3PO_4), la solution aqueuse titrante d'acide fort (HCl) et la solution aqueuse titrante de base forte (NaOH). La base forte et l'acide fort sont complètement dissociés dans l'eau et seul le produit à titrer pourra se trouver sous ses différentes formes ioniques à l'équilibre. Le membre de droite de l'équation 2 représente la situation à l'équilibre.

La deuxième ligne de l'équation 2 indique les quantités molaires des espèces impliquées dans le titrage. Les quantités à gauche (A, C_1, C_{-1} et D) sont celles des ingrédients originaux du mélange et sont donc connues. Les quantités à droite (y_1 à d) sont les valeurs que nous allons déterminer.

© 2000 CNRC Canada

2.1.2 Les équations

(a) Les relations d'équilibre : Les constantes de dissociation s'écrivent en fonction des équations d'équilibre entre les formes ioniques du H_3PO_4 et celles de l'eau. En première approximation, le coefficient d'activité de chaque espèce est considéré comme étant égal à 1.

$$[3] \quad K_1 = \frac{[H_2PO_4^-][H^+]}{H_3PO_4}$$

$$[4] \quad K_2 = \frac{[HPO_4^{2-}][H^+]}{H_2PO_4^-}$$

$$[5] \quad K_3 = \frac{[PO_4^{-3}][H^+]}{HPO_4^{-2}}$$

$$[6] \quad K_w\,[H_2O] = K_0 = [H^+][OH^-]$$

où K_1, K_2 et K_3 sont les trois constantes d'équilibre de l'acide phosphorique et K_w est la constante d'ionisation de l'eau dont la valeur est 1.00×10^{-14} à 25°C (21). Pour simplifier les équations, $[H^+]$ est utilisé à la place de $[H_3O^+]$.

Soit *V*, le volume total de la solution. La quantité molaire de chacune des espèces en solution est obtenue des équations 3 à 6 :

$$[7] \quad y_2 = [H_2PO_4^-]\,V = y_1K_1\frac{V}{x}$$

$$[8] \quad y_3 = [HPO_4^{-2}]\,V = y_1K_1K_2\left(\frac{V}{x}\right)^2$$

$$[9] \quad y_4 = [PO_4^{-3}]\,V = y_1K_1K_2K_3\left(\frac{V}{x}\right)^3$$

$$[10] \quad x' = [OH^-]\,V = K_0\frac{V^2}{x}$$

(b) La conservation des espèces : Les relations pour la conservation des espèces s'écrivent :

$$[11] \quad A = y_1 + y_2 + y_3 + y_4$$

$$[12] \quad C_{-1} = c'$$

$$[13] \quad C_1 = c$$

La quantité d'eau, *d*, ne varie pas beaucoup d'un échantillon à l'autre, et en première approximation, elle sera considérée comme constante.

(c) La relation d'électroneutralité : La solution est électriquement neutre en tout temps, c'est-à-dire :

$$[14] \quad y_2 + 2y_3 + 3y_4 + x' + c' = x + c$$

2.1.3 Résolution du problème

(a) Répartition des espèces en fonction du pH : En utilisant les équations 7 à 9 et 11, et en remplaçant x/V par $[H^+]$, on obtient :

$$[15] \quad y_1 = \frac{A}{1 + \frac{K_1}{[H^+]} + \frac{K_1K_2}{[H^+]^2} + \frac{K_1K_2K_3}{[H^+]^3}}$$

$$[16] \quad y_2 = \frac{A}{\frac{[H^+]}{K_1} + 1 + \frac{K_2}{[H^+]} + \frac{K_2K_3}{[H^+]^2}}$$

$$[17] \quad y_3 = \frac{A}{\frac{[H^+]^2}{K_1K_{2\,1}} + \frac{[H^+]}{K_2} + \frac{K_3}{[H^+]}}$$

$$[18] \quad y_4 = \frac{A}{\frac{[H^+]^3}{K_1K_2K_{3\,1}} + \frac{[H^+]^2}{K_2K_3} + \frac{[H^+]}{K_3} + 1}$$

Les concentrations relatives des quatre espèces ioniques de l'acide phosphorique en fonction du pH sont obtenues en divisant les équations 15 à 18 par *A* et en remplaçant $[H^+]$ par 10^{-pH}.

(b) Évaluation de la quantité de titrant à partir de la concentration en $[H^+]$: L'acide fort et la base forte réagissant pour former de l'eau et un sel neutre, seule la différence entre la quantité d'acide fort et de base forte influence la valeur du pH et la répartition des espèces ioniques (en négligeant la variation éventuelle des coefficients d'activité en présence d'un sel neutre). Cette différence est donnée par $C_1 - C_{-1}$. En utilisant les équations 12 et 13, nous obtenons :

$$[19] \quad C_1 - C_{-1} = c - c'$$

Et en utilisant les équations 7 à 10 et 14 et 15, nous obtenons :

$$[20] \quad C_1 - C_{-1} = A\,\frac{\frac{K_1}{[H^+]} + \frac{2K_1K_2}{[H^+]^2} + \frac{3K_1K_2K_3}{[H^+]^3}}{1 + \frac{K_1}{[H^+]} + \frac{2K_1K_2}{[H^+]^2} + \frac{3K_1K_2K_3}{[H^+]^3}} + V\,\frac{K_0}{[H^+]} - x$$

(c) Évaluation de la quantité de matière à partir de la masse de solution utilisée : Soient M_1 et M_{-1}, les masses molaires de la base BOH et de l'acide HC. Soient ε_1 et ε_{-1}, leur masse relative dans les solutions de titrant utilisées, et m_1 et m_{-1}, la masse de solution titrante introduite dans l'échantillon. Les quantités molaires de base (C_1) et d'acide (C_{-1}) s'écrivent :

$$[21] \quad C_1 = m_1\frac{\varepsilon_1}{M_1} \qquad \text{et} \qquad C_{-1} = m_{-1}\frac{\varepsilon_{-1}}{M_{-1}}$$

De même, soient M_2, ε_2 et m_2, respectivement la masse molaire de l'acide phosphorique (*A*), sa masse relative dans la solution mère et la masse de solution mère dans l'échantillon. Par définition, nous avons :

$$[22] \quad A = m_2\frac{\varepsilon_2}{M_2}$$

© 2000 CNRC Canada

En combinant les équations 20 à 22, nous obtenons :

$$[23]\quad m_1\frac{\varepsilon_1}{M_1}-m_{-1}\frac{\varepsilon_{-1}}{M_{-1}}=m_2\frac{\varepsilon_2}{M_2}\frac{\dfrac{K_1}{[H^+]}+\dfrac{2K_1K_2}{[H^+]^2}+\dfrac{3K_1K_2K_3}{[H^+]^3}}{1+\dfrac{K_1}{[H^+]}+\dfrac{2K_1K_2}{[H^+]^2}+\dfrac{3K_1K_2K_3}{[H^+]^3}}+V\frac{K_0}{[H^+]}-x$$

2.1.4 Paramètres expérimentaux

Pour simplifier l'écriture des équations, nous introduisons l'indice δ pour remplacer l'indice de ε, *m* et *M* du titrant utilisé : δ = 1 correspond à la solution alcaline et δ = –1, à la solution acide. La solution au problème est facile lorsque le titrage est effectué en conservant constant le volume (*V*) de l'échantillon. Par conséquent, la masse m_2 est fonction des masses m_δ et *m*, la masse totale de l'échantillon.

(a) La masse du titrant en fonction du pH : Le volume total (*V*) reste toujours constant. On mesure la masse de la solution titrante m_δ et la masse totale *m* résultant du mélange lorsque le volume est complété. La masse m_2 correspond donc à $m_2 = m - m_\delta$. Expérimentalement, la masse totale *m* n'est pas constante. En effet, la densité du mélange dépend de la quantité de titrant. La variation de la densité de l'échantillon est approximativement linéaire avec la quantité de titrant ajouté :

$$[24]\quad m=\rho V=\rho_0 V+\Delta\rho V=\rho_0 V+\rho_\delta m_\delta$$

Dans l'équation 24, le terme ρ_δ est un paramètre sans dimension ($\rho_\delta = \Delta\rho\ V/m_\delta$), choisi pour simplifier les expressions mathématiques. En l'utilisant et puisque $m_2 = m - m_\delta$, on a :

$$[25]\quad m_2=\rho_0 V-(1-\rho_\delta)m_\delta$$

Nous introduisons maintenant la restriction qu'un seul titrant est utilisé à la fois. À partir des équations 23 et 25, nous obtenons :

$$[26]\quad \delta m_\delta\frac{\varepsilon_\delta}{M_\delta}=[\rho_0 V-(1-\rho_\delta)m_\delta]\frac{\varepsilon_2}{M_2}\frac{\dfrac{K_1}{[H^+]}+\dfrac{2K_1K_2}{[H^+]^2}+\dfrac{3K_1K_2K_3}{[H^+]^3}}{1+\dfrac{K_1}{[H^+]}+\dfrac{2K_1K_2}{[H^+]^2}+\dfrac{3K_1K_2K_3}{[H^+]^3}}+V\frac{K_0}{[H^+]}-x$$

En isolant m_δ de l'équation 26, nous obtenons :

$$[27]\quad m_\delta=V\frac{\rho_0\dfrac{\varepsilon_2}{M_2}\left[\dfrac{K_1 10^{pH}+2K_1K_2 10^{2pH}+3K_1K_2K_3 10^{3pH}}{1+K_1 10^{pH}+2K_1K_2 10^{2pH}+3K_1K_2K_3 10^{3pH}}\right]+K_0 10^{pH}-10^{-pH}}{\delta\dfrac{\varepsilon_\delta}{M_\delta}+(1-\rho_\delta)\dfrac{\varepsilon_2}{M_2}\left[\dfrac{K_1 10^{pH}+2K_1K_2 10^{2pH}+3K_1K_2K_3 10^{3pH}}{1+K_1 10^{pH}+2K_1K_2 10^{2pH}+3K_1K_2K_3 10^{3pH}}\right]}$$

Cette équation donne la valeur de la masse de titrant en fonction du pH. Le résultat est alors la courbe de titrage volumétrique.

La valeur de la constante de dissociation de l'eau K_0 dépend de la concentration de l'eau (équation 6) et peut différer de la valeur usuelle de $1.00 \times 10^{-14}/55.5$. L'équation 27 indique que cette correction n'affectera la valeur de m_δ qu'aux valeurs élevées du pH.

2.1.5 La concentration de l'eau

En appliquant la relation de conservation des espèces OH^- à l'équation 2, nous obtenons l'expression $x' + d = C_1 + D$. La quantité d'eau, *d*, à l'équilibre est calculée à partir de :

$$[28]\quad [H_2O]=\frac{d}{V}=\frac{m_1\varepsilon_1}{V M_1}+\frac{(1-\varepsilon_2)}{M_{H_2O}}\frac{m_\delta}{V}\frac{(1-\varepsilon_2)(1-\rho_\delta)+(1-\varepsilon_\delta)}{M_{H_2O}}-\frac{K_0}{[H^+]}$$

L'équation 28 permet de vérifier que la concentration de l'eau reste approximativement constante pour la série d'échantillons.

2.2 Analyse par facteur (AF)

L'AF est effectuée en deux étapes : premièrement, en faisant la soustraction des bandes dues à l'eau, et deuxièmement, en faisant la séparation des espèces ioniques de l'acide phosphorique.

2.2.1 Soustraction des bandes d'eau

La soustraction des bandes d'absorption dues à l'eau est effectuée en utilisant un spectre propre à chacun des trois types d'eau observés : eau acide, eau neutre et eau basique (2, 4, 6). La soustraction est faite en donnant la valeur maximale des facteurs multiplicatifs (FM) affectés au spectre propre de chacun des types d'eau avec la seule contrainte de ne pas avoir d'absorption négative.

© 2000 CNRC Canada

2.2.2 Détermination du nombre d'espèces et de leur spectre propre respectif

Une fois la soustraction des bandes d'eau effectuée, l'évolution du spectre de l'échantillon en fonction du pH permet de déterminer le nombre d'espèces principales retrouvées dans l'ensemble des échantillons. L'apparition, la disparition et les changements d'intensité des bandes d'absorption peuvent être directement reliés à une espèce. Le choix des spectres propres S_i, correspondant à chacune des espèces ioniques pures, est effectué, dans un premier temps, en recherchant le spectre dont les bandes caractéristiques de l'espèce sont d'intensité maximale dans la série d'échantillons (2, 4–6). Il se peut que l'une ou l'autre des espèces ne se trouve à l'état pur dans aucun des échantillons. Dans ce cas, le spectre propre sera obtenu en retranchant une fraction du spectre propre d'une espèce voisine (2).

2.2.3 La décomposition en facteurs

Une fois la séparation des espèces effectuée, pour chaque spectre S_j de la série d'échantillons, nous retranchons une certaine proportion FM_i^j de chacun des spectres propres S_i. Le résidu est obtenu par :

$$[29] \quad R_j = S_j - \sum_i FM_i^j \; S_i$$

où j correspond à l'échantillon et i à l'espèce ionique. La somme des carrés de R_j doit être la plus faible possible. Nous obtenons ainsi des FM bruts.

2.2.4 Vérification

Les résidus indiquent s'il n'y pas d'autre espèce présente dans la série. Lorsque d'autres espèces sont détectées, le spectre propre de celles-ci est introduit dans l'AF et les FM de toutes les espèces sont réajustés.

2.2.5 Normalisation

La décomposition en facteurs, par minimisation du résidu R_j conduit, pour tout j, à :

$$[30] \quad S_j = \sum_i FM_i^j \times S_i$$

La masse m_2 de solution mère, contenue dans chacun des échantillons, varie d'un échantillon à l'autre. La masse de titrant m_δ et la masse totale de la solution m ont été mesurées. La différence entre ces deux quantités correspond à la masse m_2 de la solution mère d'acide phosphorique dans l'échantillon. Le FM correspond à la fraction du spectre propre retranché du spectre de l'échantillon. Le spectre propre S_i contient une masse m_2^i de la solution mère et le spectre de l'échantillon S_j, une masse m_2^j. Il faut donc normaliser les FM pour une même quantité d'acide phosphorique. Les spectres propres sont normalisés (S_i^0), par rapport à la masse M_2^0 qui correspond à la masse m_2 de l'échantillon qui ne contient pas de titrant :

$$[31] \quad S_i^0 = S_i \times \frac{m_2^0}{m_2^i}$$

Les FM correspondants à la série de spectres propres normalisés sont obtenus par la relation :

$$[32] \quad FM_i^{j0} = FM_i^j \times \frac{m_2^i}{m_2^0}$$

avec cette relation, pour chacun des spectres expérimentaux S_j, nous obtenons :

$$[33] \quad S_j = \sum_i FM_i^{j0} \times S_i^0$$

La normalisation des spectres S_j par rapport à m_2^0 est effectuée par la relation :

$$[34] \quad S_j^0 = S_j \times \frac{m_2^0}{m_2^j}$$

En utilisant les équations 32 à 34, nous obtenons :

$$[35] \quad S_j^0 = \sum_i FM_i^j \times \frac{m_2^i}{m_2^j} \times S_i^0$$

À partir de l'équation 35, nous déduisons que les FM normalisés sont obtenus par la relation :

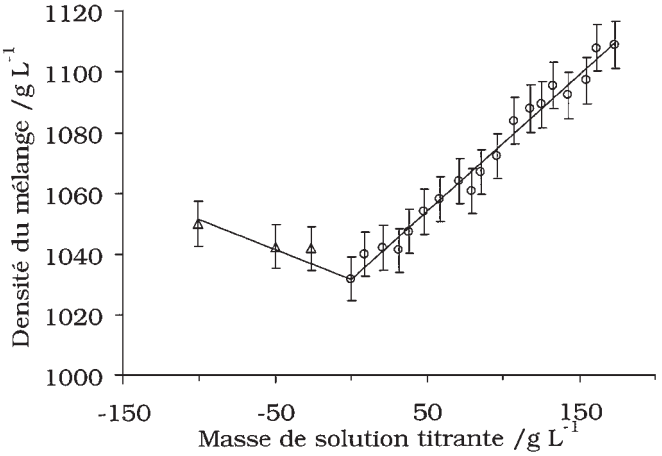
$$[36] \quad FM_i^{jN} = FM_i^j \times \frac{m_2^i}{m_2^j}$$

Ainsi, les facteurs obtenus avec l'équation 36 correspondent aux concentrations normalisées des différentes espèces présentes en solution relativement à la masse de la solution mère d'acide phosphorique m_2^j contenue dans l'échantillon.

3 Partie expérimentale

3.1 Substances utilisées et solutions

Une solution aqueuse à 85% p/p d'acide phosphorique (P.M. 98,00) 99,999%, densité 1685 g/L provenant de chez Aldrich Chemical Co. (n° de catalogue 34,524–5) ainsi que de l'eau déminéralisée (pH 6,8), ont été utilisées pour la préparation d'une solution mère à 0,715 M en H_3PO_4. La solution mère a été préparée en pesant 20,6165 g de H_3PO_4 dans un ballon jaugé de 250 mL complété au trait de jauge avec de l'eau déminéralisée pour un poids total de solution de 257,9 g. Le pH de cette solution était de 1,12. Une solution à 50% p/p de NaOH ainsi qu'une solution de HCl concentrée 37% p/p (densité 1,19 g/mL, Fisher Scientific) ont été utilisées comme titrants.



Vingt-deux échantillons, couvrant la gamme de pH entre 0,18 et 13,35, ont été préparés en pesant premièrement l'acide fort ou la base forte dans un ballon jaugé de 10,00 ± 0,04 mL, puis en complétant le volume avec la solution mère d'H_3PO_4. La masse totale de chaque échantillon a été mesurée. Les solutions étaient homogènes. Chaque échantillon était divisé en deux parties : une pour la mesure en IR et l'autre pour la mesure du pH.

3.2 Mesures de pH

Le pH a été mesuré à la température ambiante (26,5 ± 0,3°C) avec un pH mètre Omega, modèle PHH-253, équipé d'une électrode combinée (Analytical Sensors, Inc., modèle PH10107B-03-B). L'appareil a été calibré avec trois solutions tampons de pH 2.00, 7.00 et 10.00. La mesure du pH a été prise après un temps de stabilisation de 20 min.

© 2000 CNRC Canada

Fig. 1. Densité de H_3PO_4 en solution en fonction de la masse du titrant : HCl (37% p/p (Δ)) et NaOH (50,8%) p/p (○).

3.3 Mesures IR

Les mesures IR ont été effectuées avec un spectromètre FT-IR Nicolet, modèle 510P. Deux fenêtres de KBr isolaient la chambre de mesure qui était purgée avec un courant d'azote en continu pour réduire le CO_2 et la vapeur d'eau atmosphérique. Les mesures ont été prises à 26,5 ± 0,3°C dans une cellule cylindrique ATR munie d'un cristal de ZnSe (11 réflexions, SpectraTech). Chaque mesure correspond à la moyenne de 20 balayages avec une résolution de 4 cm^{-1}. La cellule était lavée et séchée pour obtenir un spectre de fond avant chaque mesure des solutions. Les spectres ont été obtenus des différents types d'eau : déminéralisée, basique et acide. Pour les deux derniers, des solutions aqueuses de NaOH 2,23 M et de HCl 1,54 M ont été utilisées.

3.4 Traitement des données

Les données obtenues du FT-IR ont été transférées sur micro-ordinateur où elles ont été traitées avec le chiffrier Microsoft Excel 97. Après la soustraction des différents types d'eau, les lignes de base n'ont pas été corrigées. Les spectres propres des espèces ioniques ont ensuite été déterminés avec la méthode mentionnée dans la section 2.2. L'AF, qui a été réalisée avec le même chiffrier, utilisait comme critère d'optimisation la minimisation de la différence quadratique, avec la contrainte de ne pas avoir de valeur d'intensité négative (hors des zones de bruit).

4 Résultats et discussion

4.1 La densité du mélange en fonction de la masse de titrant

La figure 1 montre la relation entre la densité ρ des échantillons et la masse de titrant m_δ. Les masses avec les signes négatifs représentent les échantillons avec HCl (Δ, $-m_{-1}$) et celles avec les signes positifs, ceux avec NaOH (O, $+m_1$). Cette relation est représentée par deux droites de pentes différentes : l'une, pour les échantillons avec HCl, ρ_{-1} = 0,20; l'autre, pour ceux avec NaOH, ρ_1 = 0,44. Ces valeurs seront utilisées dans le calcul des courbes théoriques de titrage volumétrique et de distribution des espèces ioniques. Les barres d'erreur proviennent des incertitudes sur le volume et la masse de l'échantillon et sur la concentration des solutions titrantes.

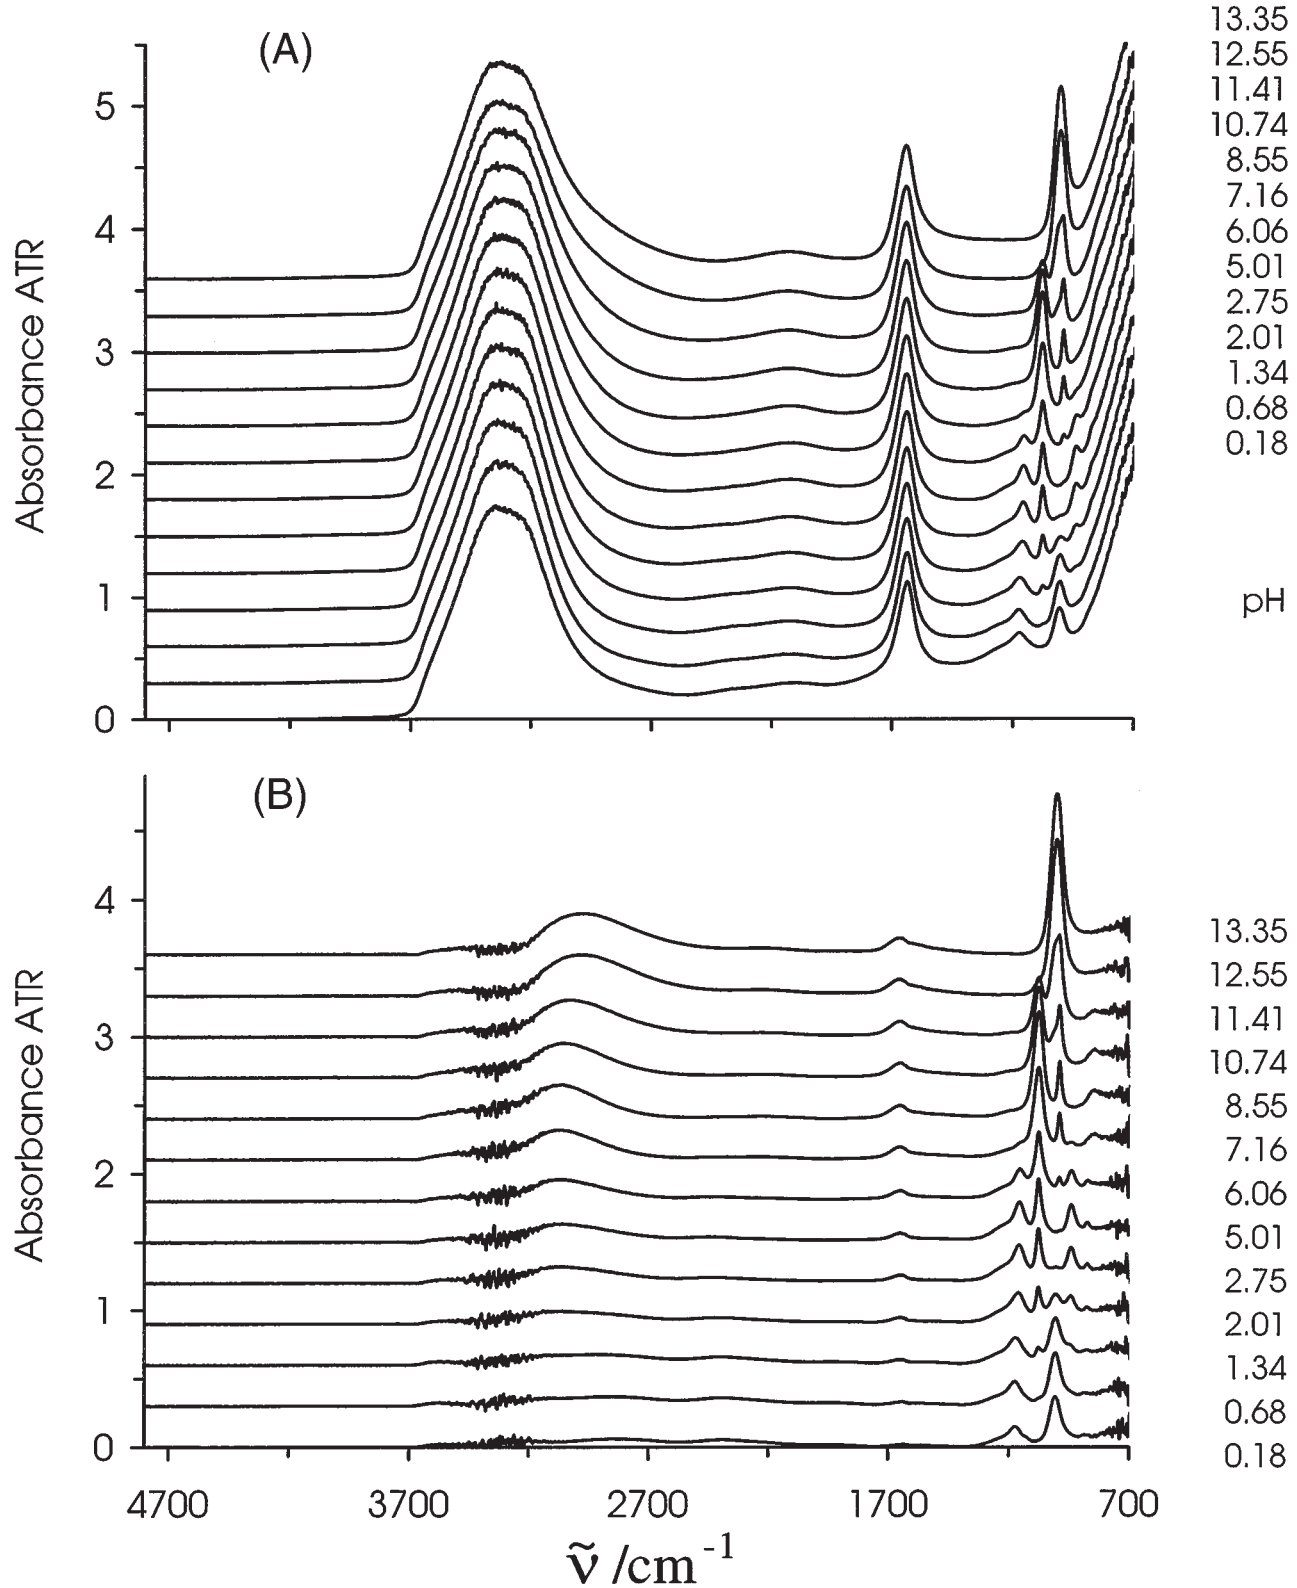
4.2 Les spectres bruts

La figure 2A présente 13 des 22 spectres de solutions aqueuses d'acide phosphorique obtenus entre les pH 0,18 et 13,35. Les bandes situées entre 1350 et 700 cm^{-1} varient en fonction de la composition ionique de la solution. Les variations spectrales dans la région entre 3700 et 3000 cm^{-1} sont dues à l'eau qui passe d'un milieu acide à un milieu alcalin.

4.3 Analyse par facteurs des différents types d'eau

La figure 3A présente les spectres des trois types d'eau utilisés pour la soustraction de l'absorption de l'eau. Les caractéristiques spectrales de l'eau changent en fonction du pH. Les trois bandes principales de l'eau changent peu de position, mais l'absorptivité change beaucoup dans les solutions de NaOH et de HCl entre 2900 et 1700 cm^{-1} et entre 1500 et 950 cm^{-1} (4, 22). La bande du groupement phosphate est affectée par l'absorptivité de l'eau qui doit donc être soustraite afin d'obtenir l'absorptivité réelle de ce groupement (2, 4–6).

La figure 2B présente les spectres obtenus après la soustraction des différents types d'eau. La ligne de base de chacun des 22 spectres se situe au niveau du zéro d'absorbance, ce qui indique que la soustraction de l'absorption de l'eau est adéquate. Les bandes résiduelles situées vers 2920 et 1590 cm^{-1} (fig. 2B) sont des bande d'eau d'un autre type que celles qui furent soustraites et sont attribuées à de l'eau complexée aux ions phosphates. Cet aspect sera discuté plus loin.



Les FM obtenus lors de la soustraction des bandes d'eau sont donnés sur la figure 3B. L'évolution de ces facteurs est approximativement linéaire par parties, dans trois régions distinctes délimitées par les masses de 55,5 et 157 g/L de NaOH à 50%.

Dans la région I, de –100 à 55,5 g/L (100 g/L de HCl à 55,5 g/L de NaOH), il y a une certaine quantité d'eau acide dans la solution. Lorsque l'acide chlorhydrique est ajouté, on s'attend effectivement à ce que de l'eau acide soit présente. Il est intéressant de noter que la quantité d'eau acide est non nulle dans la solution mère d'acide phosphorique. Cela signifie qu'une certaine portion de l'acide est dissociée en H_3O^+ et $H_2PO_4^-$. À 55,5 g/L de NaOH ajouté (fig. 3B), il n'y a plus d'eau acide, ce qui indique que la concentration d'ion hydronium est très faible ($[H^+] < 0,01$) (23). La masse de 55,5 ± 0,5 g/L de solution de soude caustique à 50% de concentration en poids correspond à 1,00 ± 0,01 équivalent molaire d'acide phosphorique en solution. On en conclut que l'acide phosphorique se dissocie dans l'eau et est en équilibre avec les ions H_3O^+ et $H_2PO_4^-$ et que l'ion $H_2PO_4^-$ ne se dissocie que très peu en H_3O^+ et HPO_4^{-2}. Une fois la première neutralisation de l'acide phosphorique atteinte, la concentration en ions hydroniums reste très faible et n'est pas observée par IR. Ce résultat est en accord avec les petites valeurs des constantes de deuxième et de troisième dissociations de l'acide phosphorique.

Dans la région II, de 55,5 à 157 g/L de NaOH à 50%, il y a une certaine quantité d'eau basique dans la solution, et cette quantité croît au fur et à mesure de l'addition du NaOH. Cette eau ne peut provenir des ions HO^- qui proviendraient de la dissociation du NaOH dans l'eau, car le pH est inférieur à 12,5. Nous attribuons cette situation aux groupements

chargés négativement -PO^- (il y a trois PO^- dans O-P-$(O^-)_3$) qui agiraient sur l'eau comme le ferait l'ion HO^-.

Dans la région III, à partir de 157 ± 1 g/L de NaOH ajouté, le changement de pente dans la variation du FM de

Fig. 3. (A) Spectres des types d'eau utilisés pour la soustraction des bandes d'eau : *a*, eau neutre (pH 6.8); *b*, NaOH 2.23 M (pH > 14); *c*, HCl 1.54 M (pH –0.17). (B) Facteurs multiplicatifs (FM) utilisés pour cette soustraction : eau neutre (+), eau acide (Δ) et eau basique (○).

l'eau basique est nettement visible sur la figure 3B (bien que seulement deux points expérimentaux soient disponibles). La masse de 157 ± 1 g/L de solution aqueuse de NaOH à 50% correspond à 3,00 ± 0,02 équivalents molaires d'acide phosphorique. Le changement de pente observé dans la quantité d'eau basique est donc en relation avec la présence d'ions HO^- libres, une fois la troisième neutralisation de l'acide phosphorique atteinte.

Les concentrations des solutions titrantes acide et alcaline utilisées sont différentes, de même que les solutions utilisées pour les spectres propres de l'eau acide et de l'eau basique. Lorsque la normalisation en regard de ces concentrations est effectuée, la variation du FM de l'eau acide en solution présente une cassure au point correspondant à la solution mère. L'absence de cassure observée sur la figure 3B au point d'abscisse 0 est fortuit.

4.4 Analyse par facteurs des ions phosphates

4.4.1 Détermination des spectres propres des espèces ioniques les plus abondantes

L'analyse des spectres en fonction du pH (fig. 2B) permet de distinguer la présence de quatre espèces phosphates principales. Les spectres des échantillons à pH 0,44, 8,55 et 13,35 sont choisis comme spectres propres des espèces ioniques H_3PO_4, HPO_4^{-2} et PO_4^{-3}. Comme aucun spectre ne représente l'espèce $H_2PO_4^-$ pure, nous avons utilisé le spectre de l'échantillon à pH 5.01 sur lequel une fraction (0,045) du spectre propre de l'espèce HPO_4^{-2} a été retranchée.

4.4.2 Résultats de l'analyse par facteurs avec quatre espèces

Les FM obtenus avec les quatre spectres propres sont présentés sur la figure 4A. La figure 5A montre les 22 résidus représentant la différence entre les spectres expérimentaux (fig. 2B) et les spectres calculés. Le niveau de bruit est élevé entre 3500 et 3100 cm^{-1} à cause de la forte absorption de l'eau dans les spectres originaux (fig. 2A). Pour cette raison, seule la différence quadratique des régions entre 4800 et 3600 cm^{-1} et 2950 et 900 cm^{-1} a été utilisée pour la détermination des FM. Sur la figure 4A, la diminution de H_3PO_4 avec l'augmentation de la quantité de HCl est due à la diminution de la quantité d'acide phosphorique, puisque le même volume est conservé pour les échantillons. Cette diminution (fig. 4A) disparaît lorsque les FM sont normalisés à une même quantité d'acide phosphorique (fig. 4B).

La figure 5A montre des résidus non négligeables dans la région de 1100 cm^{-1}. Ces bandes de faible intensité n'ont pu être soustraites avec les quatre spectres propres utilisés. Ces bandes montrent une régularité en fonction du pH et sont attribuées à la formation de complexes.

La figure 6A montre les spectres propres normalisés à 1 M des quatre espèces ioniques les plus abondantes de l'acide phosphorique. Ces spectres, qui furent utilisés pour l'AF, ne peuvent être obtenus par combinaison des autres spectres propres et sont, par conséquent, orthogonaux.

4.4.3 Spectres propres des trois complexes

Sur l'ensemble des résidus de la figure 5A, on distingue trois séries de spectres qui sont attribués à autant de complexes. La figure 6B montre les spectres propres des trois complexes normalisés à 1 M en équivalent phosphate et qui ont été tirés des spectres obtenus à pH 2,01; 6,64 et 11,41. Comme les spectres des espèces principales ont été pris en dehors de la zone d'influence des complexes, tous les spectres présentés sur la figure 6 sont normalisés et orthogonaux.

4.4.4 Résultats de l'analyse par facteurs avec sept espèces

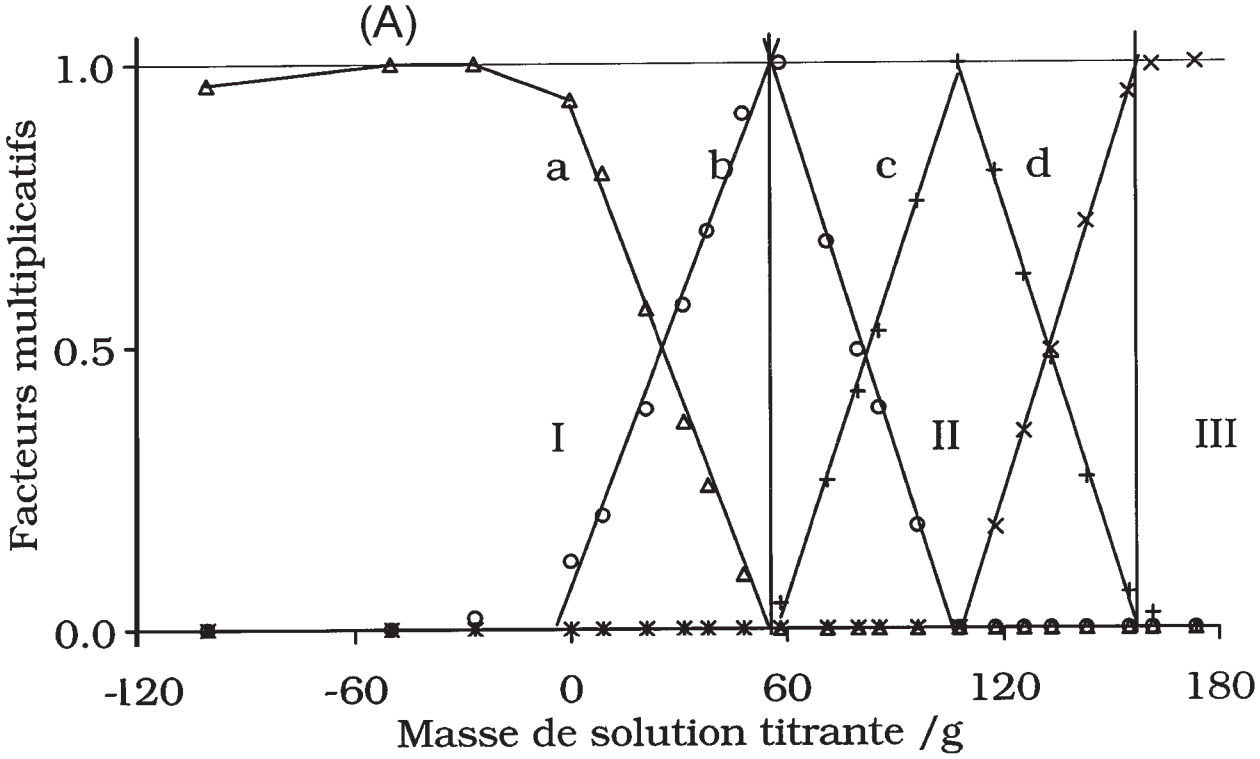
La figure 5B montre les résidus lorsque les sept spectres ont été utilisés dans l'AF. Les quatre premiers viennent de la figure 6A et les trois autres, de la figure 6B. Les FM obtenus avec ces spectres sont présentés sur la figure 4B (équation 36, section 2.2.5). Suite à l'AF, les résidus de la figure 5B, qui sont nuls pour l'ensemble des spectres, indiquent que sept spectres principaux sont donc nécessaires et suffisants pour décrire la totalité de la série de 22 solutions.

4.4.5 Distribution normalisée des espèces ioniques

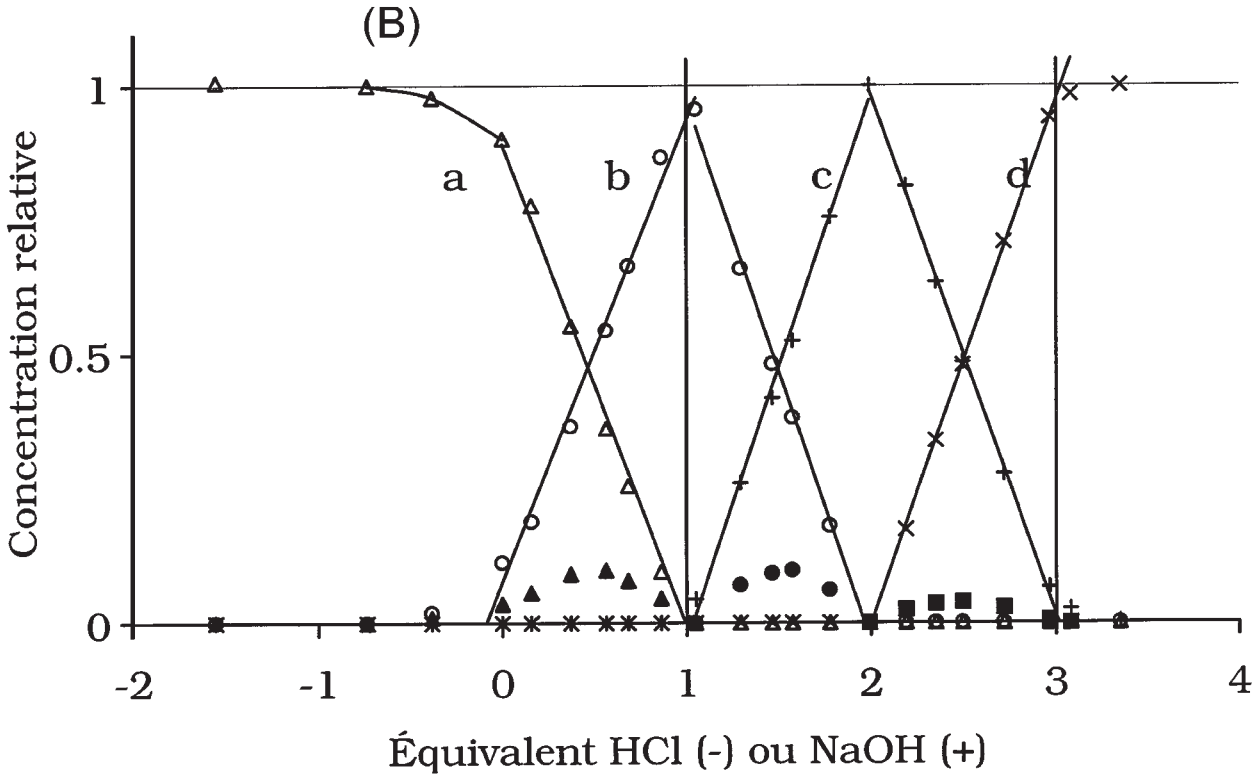
Les FM bruts, FM_i^j, ont été normalisés avec l'équation 36 pour exprimer une même quantité d'acide phosphorique. La quantité de titrant a été transformée en équivalent titrant *P* par :

$$[37] \quad P = \delta \frac{\dfrac{m_\delta \varepsilon_\delta}{M_\delta}}{\dfrac{(m - m_\delta)\,\varepsilon_2}{M_2}}$$

Le résultat de ces opérations est donné sur la figure 4B où les droites correspondent aux régressions linéaires des concentrations relatives des quatre espèces principales de l'acide phosphorique en fonction de la quantité de titrant. La pente et l'ordonnée à l'origine de ces droites sont données dans le tableau 1. Les pentes unitaires indiquent que la transformation d'une espèce principale en une autre s'effectue dans le rapport 1:1. Ceci est en accord avec le processus classique de neutralisation d'un acide faible par une basse forte. L'acide phosphorique (H_3PO_4, △), d'abord partiellement dissocié, se transforme en anion ($H_2PO_4^-$, ○) pour ensuite se transformer en (HPO_4^{-2}, +) et finalement en (PO_4^{-3}, ×). Ces transformations sont à peu près proportionnelles à la quantité de titrant (pentes unitaires), car l'abondance des complexes indiqués par des symboles pleins reste très faible.



Les trois complexes sont représentés par les symboles pleins sur la figure 4B : H_3PO_4 –$H_2PO_4^-$ (▲), $H_2PO_4^-$ –HPO_4^{-2} (●) et HPO_4^{-2} –PO_4^{-3} (■). La transformation des complexes n'est pas proportionnelle à la quantité de titrant, mais obéit aux équilibres suivants :



$$[38] \quad H_3PO_4 + H_2PO_4^- \rightleftharpoons H_5(PO_4)_2^-$$

$$K_{12} = 0{,}65 \pm 0{,}14 \text{ L/mol}$$

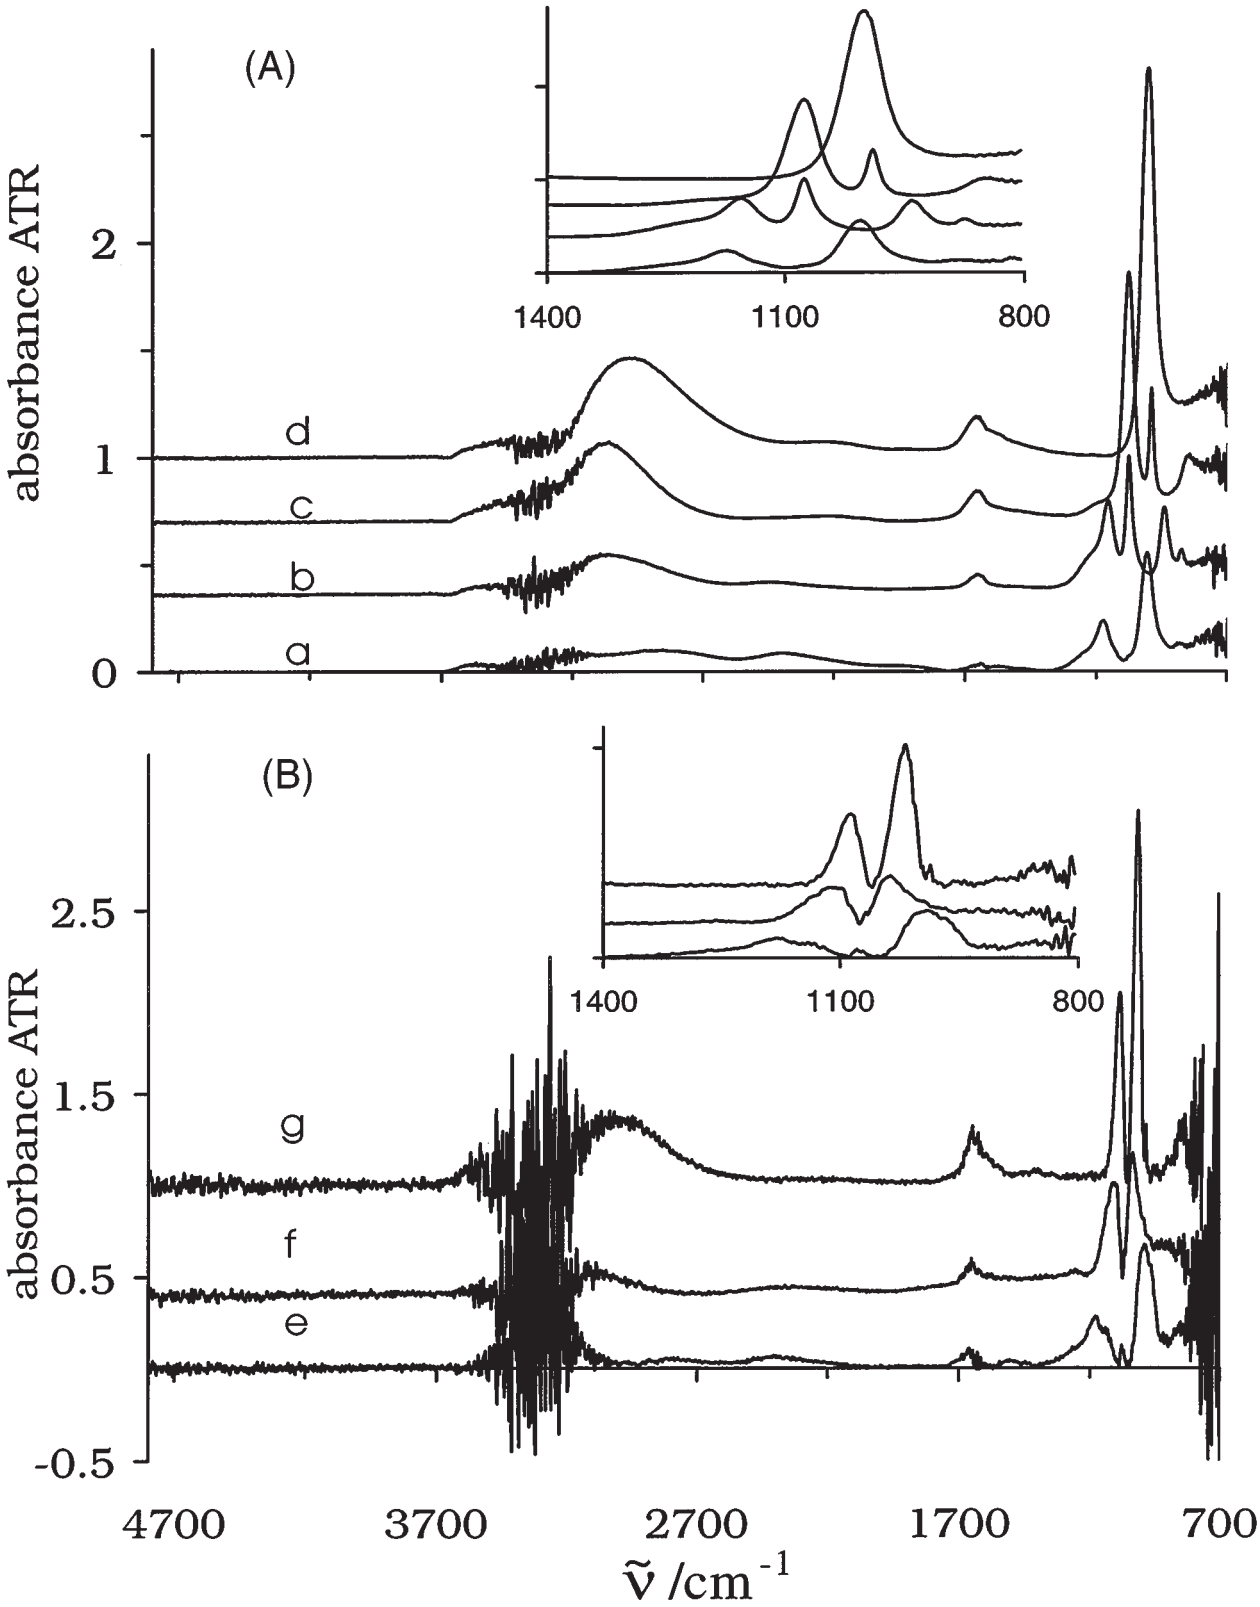
Fig. 5. Spectres des résidus : (A), avec les quatre espèces ioniques principales; (B), avec les sept espèces.

[39] $H_2PO_4^- + HPO_4^{-2} \rightleftharpoons H_3(PO_4)_2^{-3}$

$K_{23} = 0{,}63 \pm 0{,}04$ L/mol

[40] $HPO_4^{-2} + PO_4^{-3} \rightleftharpoons H(PO_4)_2^{-5}$



$K_{34} = 0{,}4 \pm 0{,}2$ L/mol

À droite des équations, se trouvent les constantes d'équilibre obtenues. L'étude de ces complexes a fait l'objet de travaux antérieurs en électrochimie et en pression de vapeurs (10, 24, 25). Le présent travail est le premier qui fournit des mesures spectroscopiques montrant l'existence de ces complexes en solution aqueuse.

Pour la constante d'équilibre [38], Childs a obtenu une valeur qui varie selon le coefficient d'activité entre 0 et 100 L/mol (10), Selvaratnam et Spiro ont obtenu une valeur de 3 L/mol (24) et Elmore et al. (25) ont obtenu une valeur de 1,263 L/mol. La valeur de 0,65 L/mol que nous avons obtenue par la présente analyse faite en IR est donc raisonnable. Pour la constante d'équilibre [39], Childs a obtenu 2,7 ± 2,5 L/mol (10). La valeur obtenue par IR se situe à l'intérieur de la marge d'erreur de Childs. Comme ce dernier et les autres auteurs ne parlent pas de la constante d'équilibre [40], nous serions les premiers à en faire état. Bien que la valeur que nous avons obtenue pour cette dernière soit légèrement inférieure aux deux précédentes, elle est du même ordre de grandeur. Comme les valeurs des constantes d'équilibre que nous avons déterminées le furent par des mesures spectroscopiques directes de quantité, ces valeurs sont entichées de moins d'erreurs que celles obtenues par les mesures électrochimiques et de tension de vapeurs et sont, par conséquent, plus précises et plus fiables que ces dernières.

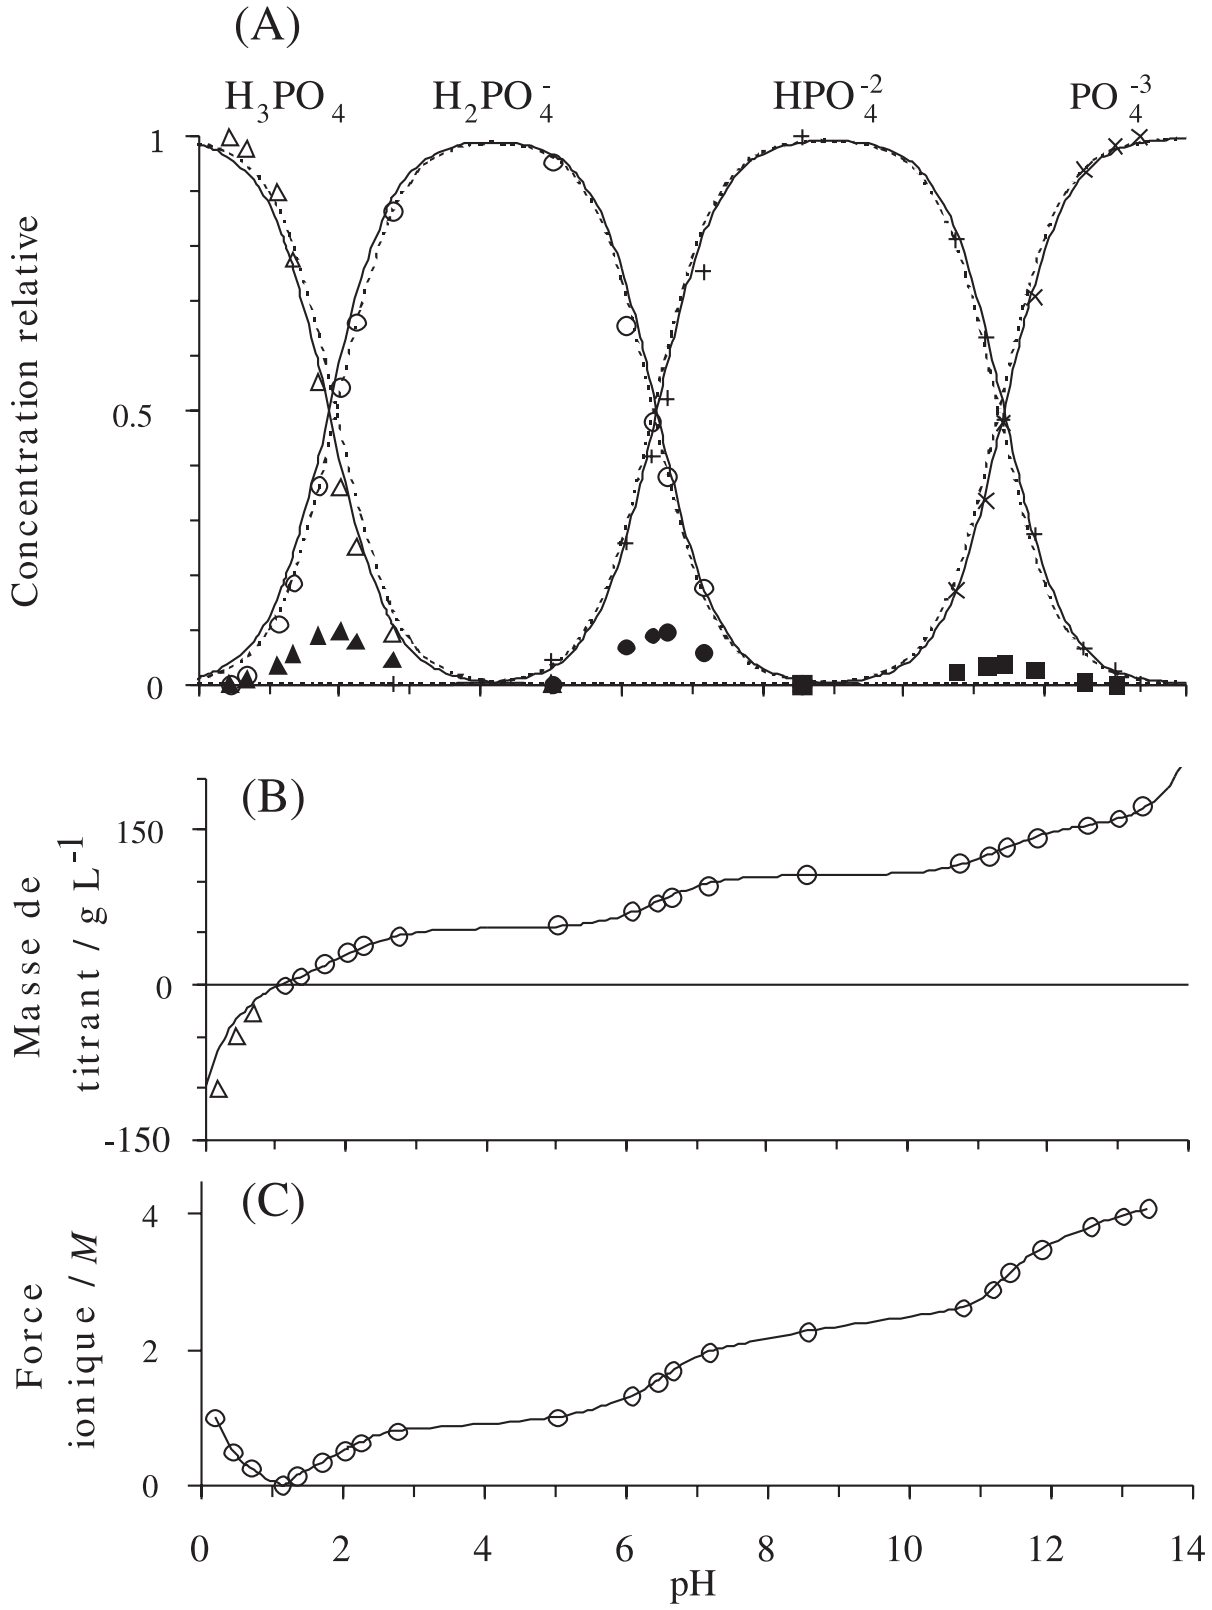
Tableau 3. Paramètres pour le calcul de la courbe de titrage volumétrique théorique.[a]

M_1 (g/mol)	M_{-1} (g/mol)	M_2 (g/mol)	ε_1 (g/g ± 0,003)	ε_{-1} (g/g ± 0,005)	ε_2 (g/g ± 0,0003)	ρ_0 (g/L ± 2)	ρ_1 (g/L ± 0,01)	ρ_{-1} (g/L ± 0,04)	V (L)	K_0
40	36,5	98	0,50	0,37	0,068	1032	0,44	0,2	0	$9{,}72 \times 10^{-15}$

[a]M_1, M_{-1} et M_2 sont les masses molaires de la basse, de l'acide et d'H_3PO_4 respectivement. ε_1, ε_{-1} et ε_2 sont les concentrations (p/p) de la base, de l'acide et d'H_3PO_4 (solution stock) respectivement. ρ_0 est la densité de la solution stock d'H_3PO_4. ρ_1 et ρ_{-1} sont des paramètres sans dimension en relation avec la variation de densité (voir section 2.1.4 et figure 7). V est le volume de chaque échantillon et K_0 correspond à la constante de dissociation de l'eau calculée en prenant la concentration moyenne de l'eau: 54,04 *M*.

4.5 Courbe de distribution en fonction du pH : titrage IR et les pK_a

La figure 7A présente la distribution normalisée des concentrations des espèces en fonction du pH : H_3PO_4 (△); $H_5(PO_4)_2^-$ (▲); $H_2PO_4^-$ (○); $H_3(PO_4)_2^{-3}$ (●); HPO_4^{-2} (+); $H(PO_4)_2^{-5}$ (■); et PO_4^{-3} (×). Puisque l'abondance des trois espèces secondaires est faible, on peut en première approximation conserver les équations d'équilibre 3 à 5. De ces équations, on montre que le pH à l'équipartition de deux espèces principales en équilibre est égal au pK_a de cet équilibre. Le tableau 2 présente les valeurs des pK_a de l'acide phosphorique, obtenues à partir de l'AF des spectres et celles obtenues par titrage volumétrique. À partir des valeurs obtenues pour les pK_a et des équations 15 à 18, 22, 25 et 27, on calcule les courbes de distribution théoriques correspondant aux équilibres 3 à 5 (seules les espèces principales sont ainsi calculées). La figure 7A montre que les résultats obtenus par ces calculs (traits pleins) et les résultats expérimentaux (indiqués par des symboles) se superposent. La présence des trois sous-espèces dont la concentration relative est inférieure à 10%, influence peu l'allure des courbes. Ceci indique que l'AF est une méthode qui permet d'obtenir les constantes de dissociation d'un composé en utilisant les bandes IR caractéristiques des différentes espèces ioniques.



Nos résultats pour les pK_a sont comparés à ceux de la littérature à dilution infinie dans le tableau 2. Les faibles différences entre les deux séries de valeurs s'expliquent par l'influence de la force ionique sur les coefficients d'activité des espèces en solution. Ces différences s'estompent lorsque nous comparons nos résultats aux valeurs de pK_a obtenues à force ionique égale (tableau 2). La force ionique de la solution aqueuse d'acide phosphorique 7% p/v a varié lors du titrage de 0 à 4,0 M entre les pH 0,18 et 13,35 (fig. 7C). Lorsque les forces ioniques sont aussi élevées, les coefficients d'activité peuvent varier de façon importante.

4.6 Le titrage volumétrique

La quantité d'eau dans les échantillons était de 54,0 ± 0,5 M comparativement à 55,5 M pour l'eau pure dans les conditions normales. Cette concentration moyenne conduit à une valeur de $9{,}72 \times 10^{-15}$ pour K_0. Le tableau 3 donne l'ensemble des paramètres permettant de calculer la courbe de titrage volumétrique théorique avec l'équation 27. Ce calcul est effectué de manière itérative afin d'ajuster les valeurs des

pK_a de façon que l'erreur quadratique entre les valeurs théoriques et expérimentales soit minimale. Les valeurs ainsi obtenues sont présentées dans le tableau 2. Les différences entre ces résultats et ceux obtenus par IR sont minimes et se trouvent à l'intérieur de la marge d'erreur. La figure 7B montre que la courbe théorique du titrage volumétrique calculée à partir de l'équation 2 (trait plein) et les points expérimentaux (Δ pour le HCl et ○ pour le NaOH) se superposent.

4.7 Les spectre IR des espèces ioniques de l'acide phosphorique

4.7.1 Attribution des bandes IR des quatre espèces principales

La figure 6 montre les spectres IR normalisés des espèces ioniques de l'acide phosphorique dans la région de pH entre 0 et 14. Le tableau 4 donne la position et l'attribution des bandes des quatre espèces ioniques principales (fig. 6A) en les comparant avec les valeurs de la littérature (19, 26–29). La position des bandes les plus intenses correspond assez bien avec les valeurs de la littérature. Cependant, comme nous avons soustrait trois types d'eau, les spectres des espèces principales se trouvent débarrassés des bandes intenses d'eau, ce qui permet d'avoir une meilleure définition des bandes pour lesquelles nous obtenons avec plus de précision la valeur des positions et des maxima. Nous observons également une certain nombre de bandes de combinaison qui n'ont pas encore été rapportées.

Sur chaque spectre des espèces principales nous avons identifié un certain nombre de bandes d'eau. Cette eau est différente de l'eau neutre, acide et basique qui ont été soustraites. Cette eau résiduelle se trouve complexée aux espèces ioniques. En comparant la surface de la bande OH d'élongation (~2900 cm^{-1}) avec celle de l'eau (fig. 3A, spectre *a*) nous arrivons aux résultats suivants : pour un ion PO_4^{-3}, nous obtenons 14 molécules d'eau; pour un ion HPO_4^{-2}, nous obtenons 9 molécules d'eau; pour un ion $H_2PO_4^-$, nous obtenons 5 molécules d'eau et pour la molécule H_3PO_4, nous obtenons 4 molécules d'eau. Pour les hydrates solides de ces ions, le nombre de molécules d'eau par ion est le suivant et est donné dans le même ordre : 12, 12, 2 et 0,5 (21). Il est intéressant de constater que les valeurs obtenues en milieu aqueux se comparent aux valeurs des hydrates solides et indiquent que nos résultats sont valables. Nous sommes les premiers à obtenir des valeurs d'hydrates en milieux aqueux pour l'acide phosphorique et ses sels. Cette méthode peut s'appliquer à d'autres substances mais dépend grandement de la précision de la soustraction des spectres d'eau. À

© 2000 CNRC Canada

mesure que la précision de cette opération cruciale va augmenter, la qualité des résultats va s'améliorer.

4.7.2 Attribution des bandes IR des trois complexes

Le spectre molaire des trois complexes situés aux pK_a des espèces principales est présenté sur la figure 6B. La position des bandes et leur attribution sont données sur le tableau 5. Cette attribution est basée sur celle des espèces principales, puisque les bandes des complexes se trouvent dans la fourchette des bandes des espèces principales. Comme il n'y a pas de bandes qui apparaissent dans des régions autres que celles où apparaissent les bandes des espèces principales, les complexes seraient formés des deux molécules parentes attachées bout à bout. Bien que nous ne puissions déterminer avec certitude la symétrie des complexes, elle serait inférieure ou égale à la symétrie de l'espèce principale qui a la plus basse symétrie. Sur le spectre des complexes nous observons des bandes d'eau dont l'intensité est voisine de celle des espèces principales (fig. 6A). Cette eau serait intimement liée aux complexes pour former un super complexe.

5 Conclusion

Nous avons présenté le titrage par spectroscopie IR de l'acide phosphorique par l'hydroxyde de sodium. Après avoir débarrassé les spectres originaux des spectres de l'eau neutre, de l'eau acide et de l'eau basique, l'AF a permis d'obtenir les spectres des espèces ioniques et de déterminer leur abondance en fonction du pH. Les spectres des quatre espèces ioniques principales qui ont été obtenus sont plus nets et plus précis que ceux qui ont été publiés jusqu'à présent. Trois complexes phosphates peu abondants ont été observés pour la première fois en IR, bien que la présence de deux d'entre eux ait été déduite de mesures potentiométriques et conductométriques. Ces complexes, dont l'abondance maximale se trouve aux pK_a de deux espèces ioniques principales, sont composés de ces espèces.

Les spectres ont été normalisés à 1 M afin de bien comparer les intensités des bandes des différentes espèces ioniques. Plusieurs bandes de faible intensité ainsi que des bandes d'eau ont été observées pour la première fois. Ces dernières ont été attribuées à de l'eau complexée aux espèces ioniques tandis que les premières sont attribuées à des bandes de combinaison. Le nombre de molécules d'eau par ion phosphate qui fut trouvé est comparable à celui des hydrates solides. C'est la première fois qu'on rapporte la présence d'hydrates observés par IR en milieux aqueux.

Nous rapportons également la distribution des espèces ioniques, en fonction du pH, de l'acide phosphorique que nous avons obtenue par IR. Cette distribution est en parfait accord avec celle qui résulte du calcul basé sur les équilibres thermodynamiques. Les pK_a de l'acide phosphorique ont été obtenus de deux façons : par mesure directe en IR des concentrations des espèces ioniques et par ajustement des courbes de titrage volumétrique expérimental et théorique. Les valeurs obtenues par les deux méthodes concordent et sont en accord avec la littérature.

On a déterminé les constantes d'équilibre de trois complexes formés par deux espèces ioniques de l'acide phosphorique dont deux avaient été déduites de mesures électrochimiques. Les valeurs obtenues pour les constantes sont en accord avec les valeurs déjà publiées. De plus les valeurs que nous rapportons ont été obtenues de mesures directes de quantités molaires et sont, par conséquent, fiables et précises.

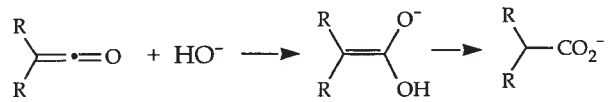
Correlation of rates of uncatalyzed and hydroxide-ion catalyzed ketene hydration. A mechanistic application and solvent isotope effects on the uncatalyzed reaction

John Andraos and A. Jerry Kresge

Abstract: Rates of hydration of a number of ketenes were measured in neutral and basic solution using flash photolytic techniques, and rate constants for their uncatalyzed, k_{uc}, and hydroxide-ion catalyzed, k_{HO}, reactions were determined. These results, plus additional data from the literature, were found to provide the remarkably good correlation log k_{uc} = –3.21 + 1.14 log k_{HO}, which spans 10 orders of magnitude in reactivity and includes 31 ketenes. This good correlation implies that uncatalyzed and hydroxide-ion catalyzed ketene hydraton occur by similar reaction mechanisms, which for the hydroxide-ion catalyzed process is known to involve nucleophilic attack on the carbonyl carbon atom of the ketene. Rate constants for phenylhydroxyketene, on the other hand, do not fit this correlation, which suggests that the mechanistic assignment upon which these rate constants are based may not be correct. Solvent isotope effects on these uncatalyzed ketene hydrations are weak; most are less than k_H/k_D = 2. It is argued that these isotope effects are largely, if not entirely, secondary in nature and that they are consistent with both a reaction mechanism in which nucleophlic attack of a single water molecule on the ketene carbonyl carbon atom produces a zwitterionic intermediate and also a mechanism that avoids this intermediate by passing through a cyclic transition state involving several water molecules.

Key words: ketene hydration, rate correlation, nucleophilic attack, solvent isotope effects, phenylhydroxyketene.



Résumé : Faisant appel à des techniques de photolyse éclair et opérant en solutions neutre et basiques, on a mesuré les vitesses d'hydratation d'un certain nombre de cétènes; on a aussi déterminé les constantes de vitesse de leurs réactions non catalysées, k_{uc}, et catalysées par l'ion hydroxyde, k_{OH}. On a trouvé que ces résultats, en combinaison avec des données additionnelles tirées de la littérature, permettent d'obtenir une corrélation relativement bonne, log k_{uc} = –3,21 + 1,14 log k_{OH}, qui couvre dix ordres de grandeur de réactivité et qui inclut trente et un cétènes. Cette bonne corrélation implique que les hydratations du cétène non catalysée ainsi que catalysée par l'ion hydroxyde se produisent par des mécanismes réactionnels similaires; dans le cas du processus catalysé par l'ion hydroxyde, il est admis que la réaction implique une attaque nucléophile sur l'atome de carbone du carbonyle du cétène. Par ailleurs, les constantes de vitesse du phénylhydroxycétène ne suivent pas la corrélation; ceci suggère que l'attribution mécanistique sur laquelle ces constantes de vitesse sont basées n'est peut-être pas correcte. Les effets isotopiques de solvant sur ces hydratations non catalysées du cétène sont faibles; dans la plupart des cas, $k_H/k_D \leq 2$. On croit que ces effets isotopiques sont en grande partie, si ce n'est pas totalement, de nature secondaire et qu'ils sont en accord à la fois avec un mécanisme réactionnel dans lequel l'attaque nucléophile d'une seule molécule d'eau sur l'atome de carbone du carbonyle du cétène produit un intermédiaire zwitterionique ainsi qu'avec un mécanisme qui évite cet intermédiaire en passant par un état de transition cyclique impliquant plusieurs molécules d'eau.

Mots clés : hydratation du cétène, corrélation de vitesse, attaque nucléophile, effets isotopiques du solvant, phénylhydroxylcétène.

[Traduit par la Rédaction]

Introduction

The generally accepted reaction mechanism for the hydroxide-ion catalyzed hydration of ketenes to carboxylate ions consists of nucleophilic addition of hydroxide to the carbonyl carbon atom of the ketene, followed by ketonization of the carboxylic acid enolate ion thus formed, eq. [1] (1).

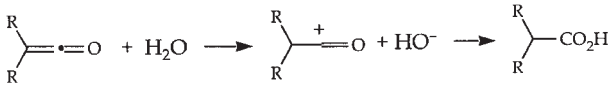
Nucleophilic attack is directed at the lowest unoccupied molecular orbital of the ketene, **1**, which lies in the ketene



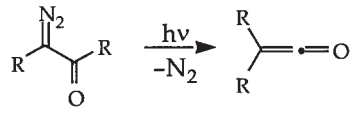
1 *2*

molecular plane, and large groups attached to the ketene β-carbon atom interfere substantially with approach of the nucleophile. The large steric rate retardations introduced in this way are in fact a hallmark of this reaction, and they provide some of the principal evidence upon which this reaction path is based.

A similar mechanism is believed to operate in uncatalyzed ketene hydration, with a water molecule acting as the nucleophile and enol and carboxylic acid replacing enolate and carboxylate ions, as shown in eq. [2]. Water, however, is

[2] 

an acid as well as a nucleophile, and another mechanism is in principle possible, in which proton transfer from a water molecule to the ketene β-carbon atom is followed by conversion of the ensuing acylium ion to a carboxylic acid, eq. [3].



[3] 

The mode of initial attack in this case is electrophilic addition to the highest occupied molecular orbital of the ketene, **2**, and, because this orbital is perpendicular to the ketene molecular plane, steric effects can be expected to be quite different from, and much less severe than, those on the nucleophilic reaction of eq. [2].

It was observed (1, 2) that substituent effects on the rate constant for uncatalyzed ketene hydration, k_{uc}, are remarkably similar to those for the hydroxide-ion catalyzed reaction, k_{HO}, and this similarity was used to support a common nucleophilic mechanism for both processes. We have now expanded the somewhat limited data upon which this earlier observation was based by determining k_{uc} and k_{HO} for a number of additional ketenes, and we have found that these values, plus data already in the literature, provide a remarkably good correlation between these two rate constants spanning ten orders of magnitude in reactivity.

We have also found a striking exception to this correlation, which suggests that the mechanistic assignment upon which this exception is based may not be correct.

The ketenes whose rate constants were measured in the present study were generated by photo-Wolff reactions of the corresponding α-diazocarbonyl compounds, eq. [4]. Because the hydration reactions were rapid, flash photolytic methods were used.

[4] 

Experimental Section

Materials

The α-diazocarbonyl compounds used as photo-Wolff reaction substrates were prepared by standard methods. Their spectra conformed to their structures and agreed with literature values. Details are available in the theses of references 3 and 4.

All other materials were best-available commercial grades.

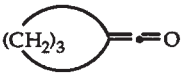
Kinetics

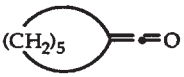
Flash photolytic rate measurements were made using conventional (microsecond) (5) and laser (nanosecond, λ = 248 nm) (6) systems that have already been described. The ketene hydration reactions were followed by monitoring the decrease in ketene absorbance at λ = 215 nm for the aliphatic ketenes and at λ = 260–300 nm for the aromatic ketenes. The temperature of all solutions upon which rate measurements were made was controlled at 25.0 ± 0.05°C. The rate data so obtained conformed to the first-order rate law well, and observed first-order rate constants were obtained by non-linear least squares fitting of an exponential function.

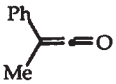
Results

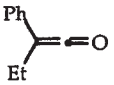
All rate measurements were made in wholly aqueous solution at an ionic strength of 0.10 M, maintained by adding $NaClO_4$ as required.

Rate profiles for ketene hydration reactions in aqueous solution typically show extensive uncatalyzed plateaus, with no base catalysis up to pH = 10–11, and correspondingly weak, or often absent, acid catalysis. Uncatalyzed hydration rate measurements were consequently made in neutral unbuffered solutions containing no added acid or base. For each substrate, 10–25 replicate determinations were made. The results are summarized in the theses of references 3 and 4, and average values are listed in Table 1.









Some rate measurements of the uncatalyzed reaction were also made in D_2O solution. These values are also summarized in the theses of references 3 and 4, and the solvent isotope effects that they produce when combined with their H_2O counterparts, $(k_{uc})_{H_2O}/(k_{uc})_{D_2O}$, are listed in Table 1.

Rate measurements of the hydroxide-ion catalyzed ketene hydration reaction were made in dilute sodium hydroxide solutions. For each substrate, 5 to 6 different sodium hydroxide concentrations were used, spanning a 5– to 25–fold variation in [NaOH], and replicate measurements were made at each concentration. The results are summarized in the theses of references 3 and 4.

In all cases, observed first-order rate constants increased linearly with hydroxide ion concentration, and the data were

therefore analyzed by least-squares fitting of eq [5]. The resulting hydroxide-ion catalytic coefficients are listed in Table 1.

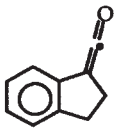
$$[5] \qquad k_{obs} = k_{uc} + k_{HO}[HO^-]$$

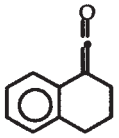
This analysis also produced uncatalyzed reaction rate constants, k_{uc}, and these were nicely consistent with the more precise values of this rate constant determined directly in neutral solution.

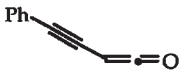
Some rate measurements were also made in dilute perchloric acid solution, using several different acid concentrations of each substrate and making replicate measurements at each acid concentration. These results are summarized in reference 3. Observed first-order rate constants increased linearly with acid concentration, and the data were analyzed by least squares fitting of the H^+ analog of eq [5]. The hydronium-ion catalytic coefficients so obtained, k_H, are also listed in Table 1. The uncatalyzed reaction rate constants produced by this analysis were once again nicely consistent with results determined in neutral solution.

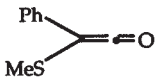
Discussion

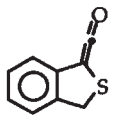
Correlation

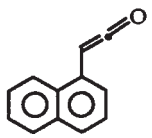












The ketenes examined here, plus others for which aqueous solution hydration rate constants are available from the literature, are assembled in Table 1. These ketenes possess a wide variety of substituents, which produces a wide range of hydration reactivity: the range covered is 2×10^{10} in k_{HO} and 5×10^{10} in k_{uc}. And yet these widely different rate constants generate the remarkably good correlation shown in Fig. 1. Linear least squares analysis[2] of the data gives $\log k_{uc} = -(3.21 \pm 0.22) + (1.14 \pm 0.04)\log k_{HO}$, with a root-mean-square deviation in $\log k_{uc}$ of 0.271, which corresponds to 0.37 kcal mol^{-1} in free energy of activation.

This good correlation implies that the various substituents present in these ketenes are affecting the uncatalyzed and

[2] The analysis was performed using simple weighting with both $\log k_{uc}$ and $\log k_{HO}$ subject to (the same) uncertainty (22).

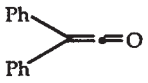
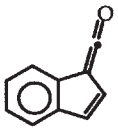
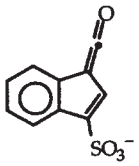
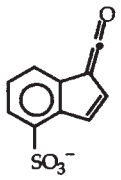
hydroxide-ion catalyzed reactions in the same way. As pointed out in the Introduction above, this could hardly be possible if one reaction involved nucleophilic attack and the other involved electrophilic attack. Since there is good evidence that the hydroxide-ion catalyzed reaction is a nucleophilic process (1) — it is, in fact, difficult to conceive of a different role for the hydroxide ion — it follows that the uncatalyzed reaction is a nucleophilic process as well.

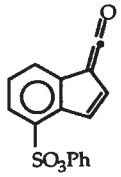
This conclusion is supported by the much poorer correlation of k_{UC} with rate constants for hydronium-ion catalyzed ketene hydration, k_H, shown in Fig. 2. Linear least squares analysis[3] of these data gives log k_{UC} = –(3.69 ± 1.97) + (1.54 ± 0.52) log k_H, with a root-mean-square deviation in log k_{UC} of 1.08, which corresponds to 1.47 kcal mol^{-1} in free energy of activation and is 4.0 times the deviation given by the k_{UC}–k_{HO} correlation. The hydronium-ion catalyzed reaction, of course, involves electrophilic attack on the ketene β-carbon atom and has very different steric requirements than nucleophilic attack of water or hydroxide ion on the ketene carbonyl carbon atom (1).

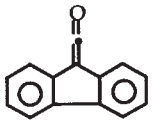


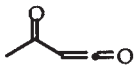












An Exception

Figure 1 shows that the point for phenylhydroxyketene provides an apparent exception to the good k_{UC}–k_{HO} correlation. This point lies 1.77 below the correlation line, which is equivalent to 2.41 kcal mol^{-1} in free energy of activation and

[3] This analysis was also performed using simple weighting with both log k_{UC} and log k_H subject to (the same) uncertainty (22).

is more than six times the root-mean-square deviation of the 31 points upon which this correlation is based. The probability that such a deviant point would occur by chance is ca. 10^{-9}.

The ketene providing this errant point was generated by Norrish type II photoelimination of benzoylformic acid esters, and hydration of this ketene provided the enol of mandelic acid, as shown in eq. [6] (23). In acidic and neutral solutions, ketonization of this enol is considerably slower than hydration of the ketene, and both transient species could be easily observed and a rate constant for uncatalyzed hydration of the ketene could be quite firmly established. In basic solution, however, the rates of ketene hydration and enol ketonization became comparable. In such a situation, assignment of rate constants to molecular processes becomes notoriously difficult (24), and it now seems likely that the hydroxide-ion catalyzed process then believed to be ketene hydration was actually enol ketonization, with ketene hydration occurring only in the more basic region not investigated. The true value of k_{HO} for this ketene would consequently be less than the number assigned, and that would move the errant point closer to the correlation line.

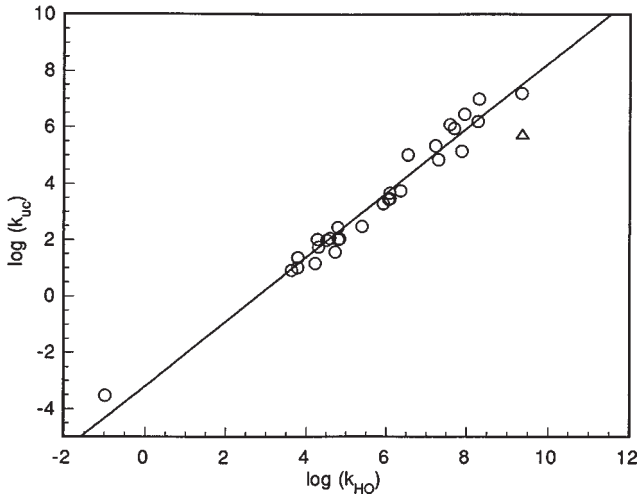

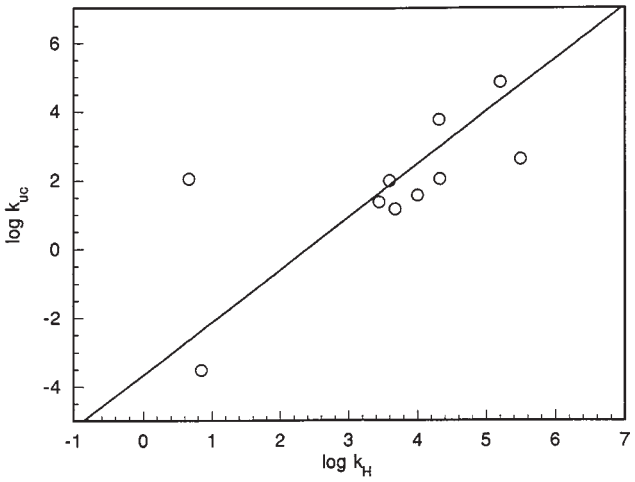

Fig. 2. Relationship between rate constants for the uncatalyzed, k_{UC}, and hydronium-ion catalyzed, k_H, hydration of ketenes in aqueous solution at 25°C.

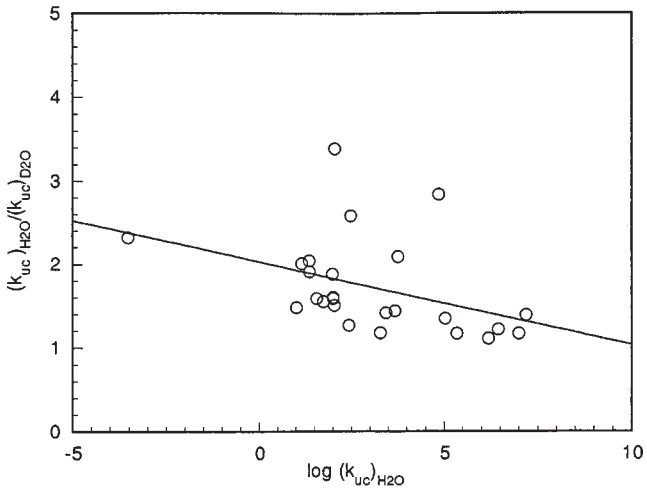
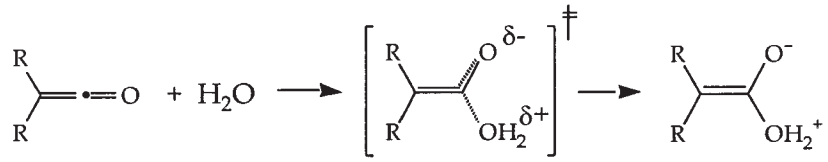


Isotope effects

The solvent isotope effects on uncatalyzed ketene hydration generated by the measurements made here in H_2O and D_2O solution, plus other values of this isotope effect determined in wholly aqueous solution available from the literature, are assembled in Table 1 and are displayed in Fig. 3. Although there is a fair amount of scatter, these isotope effects do appear to increase in strength with decreasing ketene reactivity as measured by $\log(k_{uc})_{H_2O}$; linear least squares analysis gives $(k_{uc})_{H_2O}/(k_{uc})_{D_2O} = (2.03 \pm 0.18) - (9.92 \pm 4.60) \times 10^{-2} \log(k_{uc})_{H_2O}$.[4]



It may be seen that these isotope effects are all rather weak: the strongest is only $k_H/k_D = 3.4$ and most are less than $k_H/k_D = 2.0$. Much stronger isotope effects would be expected for the electrophilic reaction mechanism of eq. [3] in which water is acting as an acid delivering a proton to the β-carbon atom of the ketene. In addition to the sizeable primary isotope effect component expected for proton transfer to carbon, this mechanism would produce a secondary effect

Fig. 3. Solvent isotope effects on uncatalyzed ketene hydration in wholly aqueous solution at 25°C.

[4] This analysis was performed using simple weighting with uncertainty in $(k_{uc})_{H_2O}/(k_{uc})_{D_2O}$ only.

[7] 

in the normal direction ($k_H/k_D > 1$) generated by solvation of the hydroxide ion being formed in this reaction (25). Strong isotope effects consistent with this expectation have in fact been observed for such reactions in other systems, e.g., $k_H/k_D = 7.5$ for hydron transfer from water to the β-carbon atom of isobutyrophenone enolate ion (26), $k_H/k_D = 6.5$ to 9.1 for the corresponding reactions of a series of ynolate ions (12), and $k_H/k_D = 7.1$ for that of the enolate dianion of fluorene-9-carboxylic acid (16). The present isotope effects therefore argue against an electrophilic mechanism for uncatalyzed ketene hydration.

These isotope effects, on the other hand, are consistent with a nucleophilic mechanism. The simplest variant of such a mechanism would involve a single water molecule and give a zwitterionic product, as shown in eq. [7]. Since no bonds to isotopically substituted hydrogen are broken or made in this process, there would be no primary component in the isotope effect on such a process. There would, however, be two secondary components: one produced by solvation of the negative charge being generated on the ketene oxygen atom and another produced by the change from neutral to positively-charged oxygen-hydrogen bonds in the attacking water molecule. The maximum value of the latter secondary component can be estimated as $1/\ell^2$, where $\ell(= 0.69)$ is the fractionation factor for a fully positively charged oxgyen-hydrogen bond (25*b*). This gives $(k_H/k_D)_{max} = 2.1$. It is more difficult to estimate the other one of these secondary isotope effect components because, although it is known that a fully negatively charged oxygen atom, such as that in the hydroxide ion, is solvated by three water molecules whose solvating oxygen-hydrogen bonds have fractionation factors $\phi \cong 0.7$ (25), the negative charge in this case is partly delocalized into the ketene double bond and the rest of the molecule. It is likely, however, that this secondary component can contribute as much as another factor of two, raising the overall maximum value to $k_H/k_D = 4$ and easily accommodating the range of isotope effects listed in Table 1.

In addition to the reaction mechanism of [eq.] 7 giving a zwitterionic product, other nucleophilic mechanisms may be written in which the zwitterion is avoided by proton transfer from the attacking water to the ketene oxygen atom through a cyclic array of several intervening water molecules. Such mechanisms are favored by *ab initio* calculations (27) and there is evidence that the hydration of ketenes in organic solvents involves more than one water molecule (28), although, of course, in purely aqueous solution the reaction order in water cannot be determined. At any rate, protons are transferred in such mechanisms, but it is unlikely that this will add much of a primary component to the overall isotope effect. In a proton transfer such as this, where the transfer is between electronegative atoms and is accompanied by heavy-atom reorganization, protonic and heavy-atom motion appear to be uncoupled, with proton transfer taking place in a rapid step either before or after the heavy-atom reorganization; protonic motion consequently does not contribute to the rate-determining reaction coordinate, and there is, therefore, no primary isotope effect (29). Even in situations where proton transfer is isolated and the only heavy-atom motion is diffusional encounter of proton donor and acceptor or separation of proton transfer products, proton transfer is not fully rate-determining and solvent isotope effects are small (30). Cyclic ketene hydration mechanisms avoiding zwitterionic products are therefore likely to show small, if any, primary isotope effects. Neutralization of the zwitterionic charge, moreover, will diminish the secondary effects produced by charge generation as described above, and the overall solvent isotope effects will be small, just like those for the zwitterionic mechanism. Small isotope effects should therefore be characteristic of uncatalyzed ketene hydration proceeding by nucleophilic attack of water on the ketene carbonyl carbon atom, no matter what the detailed reaction mechanism is.

Reductive deposition of Au^{3+}(aq) on oxidized silicon surfaces

Şefik Süzer and Ömer Dag

Abstract: X-ray photoelectron spectroscopy (XPS) is used to determine the oxidation state of gold deposited from an aqueous solution of $AuCl_4^-$ on to various oxidized surfaces of silicon. Although the observed Au4f signal decreased with the thickness of the oxide layer, the oxidation state of Au was determined as 0 for all the samples analyzed. From the angular dependence of the Si2p and Au4f signals it was determined that Au is deposited on top of the oxidized surfaces of metallic silicon. It is postulated that from an aqueous solution of $AuCl_4^-$, gold would deposit in its zerovalent form on to any surface due to its large and positive electrochemical reduction potential ($\varepsilon^\circ_{red}(Au^{3+}/Au)$ = +1.50 V) and the substrate plays a role only in providing active deposition sites. To further support the proposal, it is shown that the same process takes place even in inert and hydrophobic polypropylene substrates. Similarly, it is also shown that more gold deposits if the surface of the polypropylene is made less hydrophobic (but probably more active) via the industrially used corona discharge treatment.

Key words: XPS, gold, electroless deposition, oxidized silicon surface.

Résumé : On a utilisé la spectroscopie photoélectronique aux rayons X pour déterminer l'état d'oxydation de l'or déposé à partir d'une solution aqueuse de $AuCl_4^-$ sur diverses surfaces oxydées de silicium. Même si le signal observé pour Au4f diminue avec l'épaisseur de la couche d'oxyde, on a déterminé que l'état d'oxydation de l'or est égal à zéro pour tous les échantillons analysés. En se basant sur la dépendance angulaire des signaux Si2p et Au4f, on a déterminé que l'or se déposé au sommet des surfaces oxydées du silicium métallisé. On a fait l'hypothèse que, à partir d'une solution aqueuse de $AuCl_4^-$, l'or se déposerait dans sa forme zérovalente sur toutes les surfaces en raison de son potentiel de réduction électrochimique élevé et positif [$\varepsilon^\circ_{red}(Au^{3+}/Au)$ = +1,50 V]. Pour appuyer cette hypothèse, on montre que le même processus se produit même dans des substrats inertes et polypropyléniques hydrophobes. De la même manière, on a démontré qu'il y a plus d'or qui se dépose si la surface de polypropylène est rendue moins hydrophobe (mais probablement plus réactive) par le biais d'un traitement industriel par effluve.

Mots clés: spectroscopie photoélectronique à rayons X, dépôt sans électrode, surface de silicium oxydée.

Introduction

Interest in the chemistry of gold has renewed due especially to the ability of molecular self-assembly of aliphatic thiols on gold colloids (1) and also to form clusters in nm scales with potentially useful optical, optoelectronic, and material properties (2–4). Successful methods of preparation usually involve vapour-deposition or deposition from solution via chemical and (or) electrochemical routes. An electroless deposition of zerovalent gold nano-clusters was reported using electroactive poly(3-alkylthiophenes) from a solution of the polymer and $AuCl_4^-$ in nitromethane (5). Similar studies were reported using other electroactive polymers, such as, polyaniline and polypyrrole (6). The same group later reported on the uptake of gold and palladium from acidic solution of $AuCl_3$ and $PdCl_2$ using electroactive polymer-SiO_2 nano-composites (7). In a recent study it was claimed that porous silicon could be utilized for reductive deposition of gold nano-clusters again from an aqueous solution $AuCl_4^-$ (8). In our XPS investigation of metal ions deposited on the surface of silica tubes for atom-trapping atomic absorption spectrometric determinations, we had also reported that Au was deposited in its zerovalent state both from the vapour phase of the flame and also from the aqueous solution of $AuCl_4^-$ (9). In a later study in which we had also examined Mn and Bi, we claimed that reductive deposi-

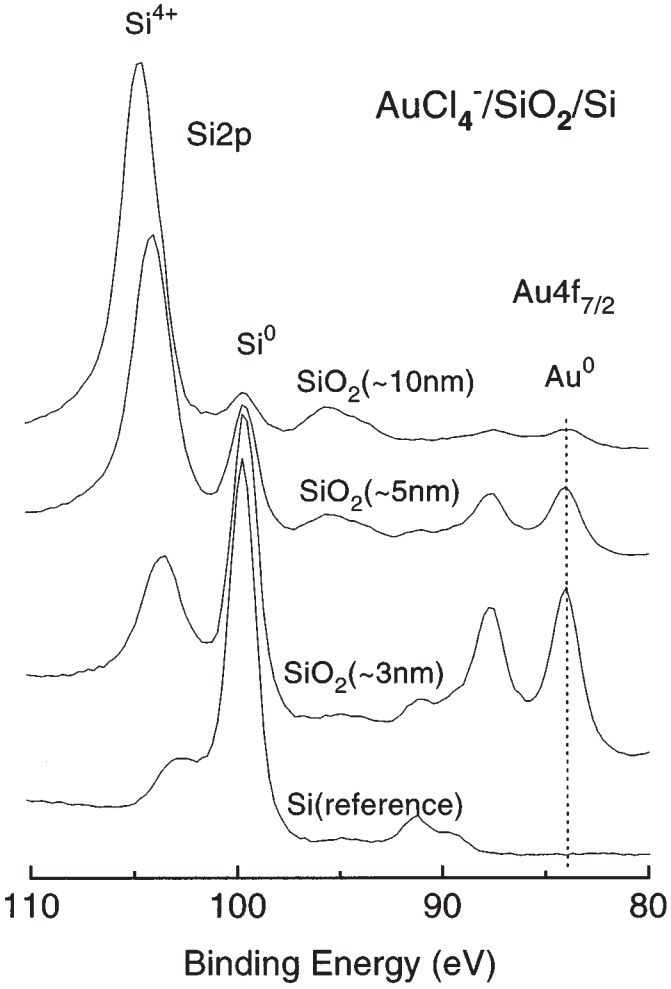
[a]The energy difference between the Si^0 and Si^{4+} levels (the chemical shift) increases as the oxide layer becomes thicker due to the differential charging of the layers (12).

tion of gold was mainly dictated by its electrochemical reduction potential rather than the properties of the substrate (10). In this contribution we demonstrate this property of gold by depositing zerovalent gold from aqueous $AuCl_4^-$ solution on to different substrates.



Experimental

Si wafers with their polished surfaces are used to deposit gold from a dilute ca. 10^{-5} M aqueous solution of $AuCl_4^-$. Si samples were cut into 5 × 15 mm slices and cleaned by 10% HF before thermal treatment and analysis. Different oxide thicknesses were obtained by heating the substrate in air at different temperatures or for different periods. The substrates were then immersed into the solution for 10 h without stirring after which they were washed with acetone, dried in air, and inserted into the spectrometer. A Kratos ES300 spectrometer with MgK X-rays was used for XPS analysis. The X-ray anode power is kept below 40 W to reduce the possibility of reduction under severe X-ray bombardment (11). SEM images were obtained using a Jeol 6400 electron microscope.

Results and discussion

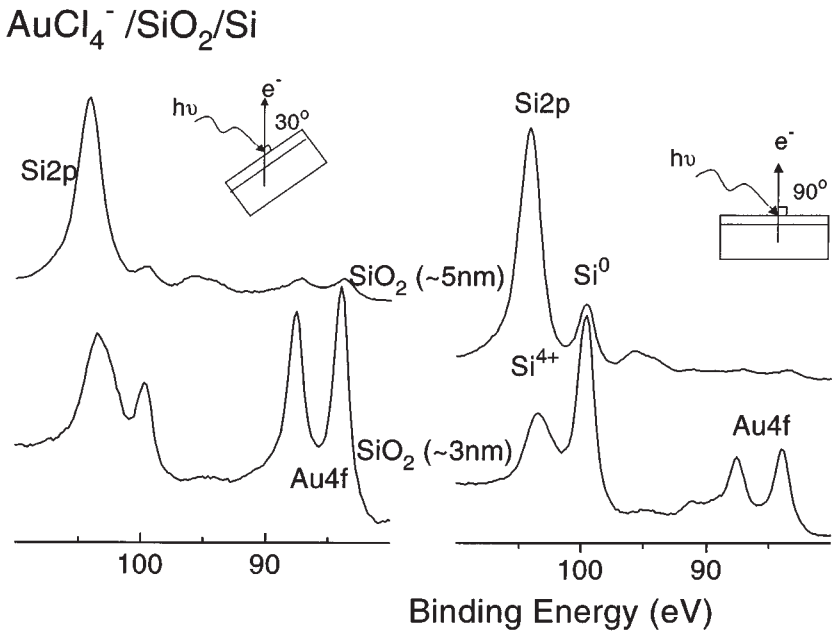


Figure 1 displays the Si2p and Au4f region of the XPS spectra of gold deposited on to silicon wafers containing approximately 3, 5, and 10 nm oxide layers and the relevant data are given in Table 1. One of the relevant observations in this investigation is that the oxidation state of gold is zero in all samples. Secondly, it is observed that the Au4f signal decreases as thickness of the oxide layer is increased. At normal electron take-off angle, the sampling depth of XPS using the MgKα X-rays is around 10 nm which can be further reduced by decreasing this electron take-off angle (11, 12). Figure 2 displays Si2p and Au4f signals recorded at normal (90°) and 30° electron take-off angles from two gold deposited samples containing ca. 3 and 5 nm oxide layers,

Fig. 1. Si2p–Au4f region of the XPS spectra of oxidized silicon surfaces containing gold deposited from a 10^{-5} M aqueous solution of $HAuCl_4$. A spectrum of a reference Si is also given for comparison.

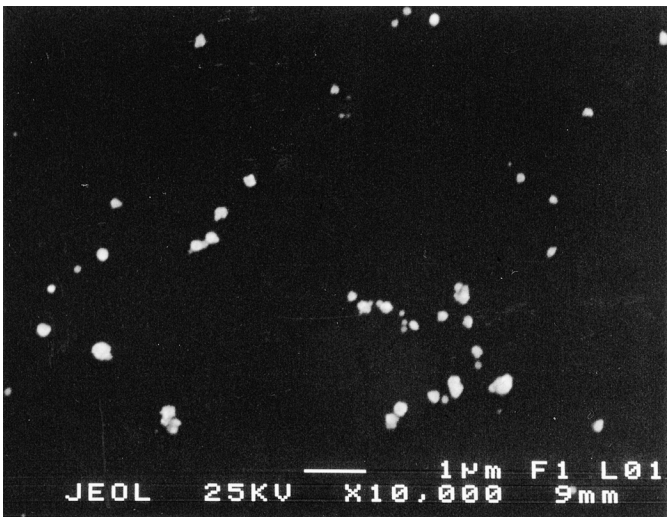

Fig. 2. Si2p–Au4f region of XPS spectra of two samples recorded at two different take-off angles.

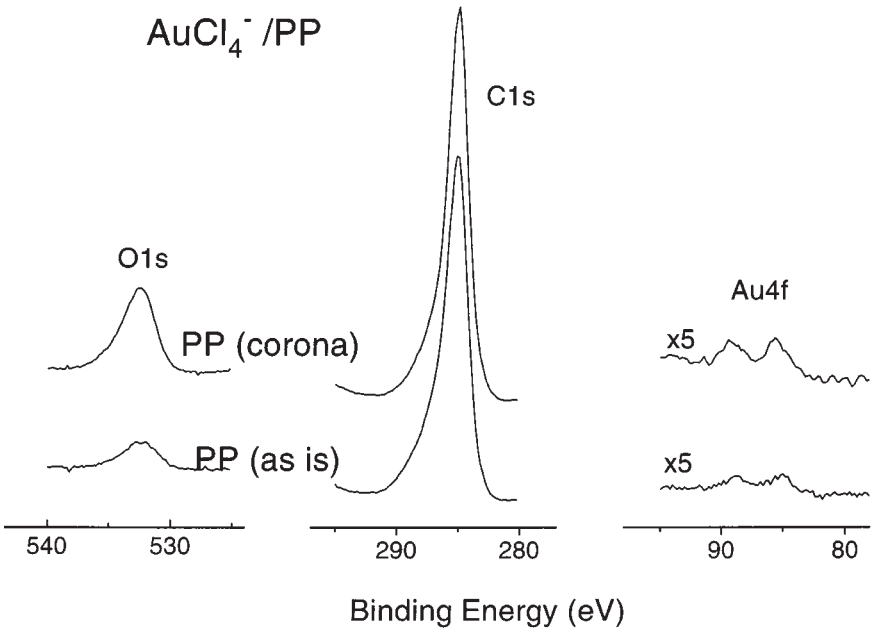
respectively. As can be seen from the figure the intensity of the $Si^0$2p signal goes down and the intensity of the Si^{4+}2p and the $Au^0$4f signals go up indicating that Au is on top of the Si^{4+} layer and is not in direct contact with the underlying Si^0 substrate. The SEM image of the samples indicate that gold is deposited on the surface of the substrate as colloidal particles of varying sizes of less than 100 nm as shown in Fig. 3.



Two important questions arise: (*i*) why does gold deposit in its zerovalent state as opposed to deposition in ionic form, and (*ii*) why do we get seemingly more deposition when we have a thinner oxide layer? The first can be related to the large and positive reduction potential of Au^{3+}, $\varepsilon^{\circ}_{red}(Au^{3+}/Au)$ = +1.50 V in aqueous solutions which is inherent to gold. The second, however, must be related to the activity of the substrate surfaces (voids, defects, pores, reduction centres, or domains etc.). Since the thicker oxide layers are obtained by the corresponding longer heating/annealing times the number of active sites must also be diminished during this process. Hence we propose that gold would deposit as zerovalent form its aqueous solution on to any substrate as long as there are active reducing sites. This of course brings the more difficult question related to the nature of the surface reducing agents at this point which we can only speculate about. The role of the substrate surface is only important, if active sites are present or created which may facilitate this deposition. As a result the claim of Coulthard et.al. (8) that porous silicon is utilized as a reducing agent for reductive deposition of gold must be interpreted as the porous silicon providing ample active sites. This point is further supported by our observation that this deposition even takes place on relatively inert and hydrophobic substrates like polyethylene and (or) polypropylene as shown in Fig. 4. It is also interesting that relatively more gold is deposited if the surface of the polypropylene is made less hydrophobic

via the corona treatment which increases the number of -COH (hydroxyl groups) as well as other active sites like defects on the surface (13) as also shown in Fig. 4. Further investigations are definitely needed to identify/clarify the mechanism of the process.

Analysis of the electrode kinetics of Ni(II) reduction at the DME in the presence of nicotine

M.S. Crespo-Pinilla, A.B. Infante, and F. Mata-Pérez

Abstract: A study of the prewave of the Ni^{2+} – nicotine system was carried out under the experimental conditions when the influence of electroreduction of nicotine is negligible. The kinetics of Ni(II) reduction in nicotine media on the dropping mercury electrode were studied by direct current Tast polarography (DC_TP) via the determination of the Koutecky's parameter, χ and the influence of different variables was analyzed. An electrochemical study of the prewave was also made by using various polarographic techniques. Values of χ depend on the nicotine concentration, pH, ionic strength (ψ-effect), and on the nature of the supporting electrolyte. The αn product (α = transfer coefficient, n = number of electrons) and the stoichometric number,ν, were determined. The prewave is interpreted as a surface reaction, the main features of the mechanism being its catalytic nature. The discharge is a two electron step and reaction between species of opposite charge is rate-determining.

Key words: catalytic, prewave, polarography, nickel(II), nicotine.

Résumé : Opérant dans des conditions expérimentales dans lesquelles l'influence de l'électroréduction de la nicotine est négligeable, on a réalisé une étude du système Ni^{2+} – nicotine dans la prévague. Faisant appel à la polarographie en système Tast à courant direct (« DC_TP »), on a étudié la cinétique de la réduction du Ni(II) dans un milieu de nicotine sur une électrode de mercure tombante par le biais de la détermination des paramètres χ de Koutecky et on a analysé l'influence des diverses variables. On a aussi effectué une étude électrochimique dans la prévague en faisant appel à diverses techniques polarographiques. Les valeurs de χ dépendent de la concentration de nicotine, du pH, de la force ionique (effet ψ) et de la nature de l'électrolyte de support. On a déterminé le produit αn (α = coefficient de transfert; n = nombre d'électrons) et le nombre de stoechiométrie,ν. On interprète la prévague en termes d'une réaction de surface dont le mécanisme est caractérisé principalement par une nature catalytique, une décharge qui se fait en une étape de deux électrons et pour lequel l'étape qui détermine la vitesse est la réaction entre des espèces de charges opposées.

Mots clés : catalyse, prévague, polarographie, nickel(II), nicotine.

Introduction

Electrocatalysis of metal ion reduction on mercury by adsorbed ligands has been the subject of a recent review (1) from which a number of important features can be noted. First, the method of direct current polarography has been the most popular as well as being the most informative method (especially from the theoretical aspect). Usually the limiting catalytic current is analyzed, since it is not complicated by the kinetics of electron transfer. Moreover, using the DME, it is possible to exclude the stage of metal crystallization, so that attention can be focused on the catalytic reaction. Besides, in polarography, the catalytic process is frequently separated, in its potential, from the noncatalytic process, resulting in the formation of so-called prewaves. In this way, Ni^{2+}–pyridine is one of the model systems. That system has been studied by us (2) and our experience with it and other systems (3, 4) supports the use of the Kouctecky's parameter, χ, as an experimental rate constant. The study of the dependence of χ on the different experimental variables is a good method for understanding the mechanism of this type of reaction.

There is a previous work of Moskatov et al. (5) about the ultrasensitive detection of nicotine, Nc, via the electroreduction of nickel(II) in its presence. A later study (6) deals with the determination of the stability constant of the nickel(II) – nicotine complex, and involves a study of the influence of both the Nc and Ni^{2+} concentration and also of the pH on the catalytic current. A qualitative scheme for the reaction has also been proposed.

However, the kinetics and mechanism of the formation of the electrochemically active complex which is responsible for the appearance of the prewave have not been explained satisfactorily. Hence, the behaviour of Ni^{2+} species at the dropping mercury electrode (DME) in media containing nicotine species is even now an open question. This work was undertaken to clarify the question by studying the kinetics of the Ni^{2+} – Nc system.

Experimental

The experimental conditions were optimized to resolve both the prewave and prepeak of Ni^{2+} induced by Nc. Chemicals used were Merck ($Ni(NO_3)_2$) and Panreac ($LiNO_3$, $NaNO_3$, KNO_3, $CsNO_3$, KOH, and HNO_3) of analytical grade. Nicotine (Merck for synthesis) was purified by vacuum distillation

© 2000 NRC Canada

(about 10 mmHg) at 150ºC. Solutions were prepared from water purified by passage through a Milli-Q system from Millipore. Experiments were performed in the presence of excess Ni^{2+} species ($5.0 \times 10^{-3} - 2.5 \times 10^{-2}$ mol dm^{-3}), with the concentration of Nc ranging from 1.0×10^{-5} to 1.0×10^{-4} mol dm^{-3}. An excess of electrolyte in the solutions was achieved by using KNO_3 (alternatively $LiNO_3$, $NaNO_3$, or $CsNO_3$), providing a constant ionic strength condition, I (0.06–0.2 mol dm^{-3}). To avoid hydrolysis of Ni^{2+}, the pH of the solutions was kept between 3.0 and 8.0. The acidity was adjusted to the desired values by using very dilute solutions of HNO_3 and KOH. Oxygen was removed from the probe solutions with a stream of purified nitrogen for 15 min (and for a further 1 min before each new experiment). The polarographic cell was thermostated from 20 to 35 (±0.1)ºC.

The electrode process was studied by using DC tast (DC_TP), normal pulse (NDP), and differential pulse polarography (DPP). All techniques were implemented with a Tacussel microprocessor unit connected to an automatic polarographic stand equipped with a DME, a Pt wire auxiliary electrode, and a SCE as the reference electrode. The drop time was maintained mechanically at 3.5 s except when studying its effect in DC_TP, when it was changed from 0.5–3.5 s. The potential scan rate was 5 mV/s and the voltage range was between –0.1 and –1.6 V. The DPP pulse amplitude was 50 mV. pH measurements were made with a Radiometer 51 instrument (pH meter, accuracy: ±0.01 pH units).

Because of the sensitivity of catalytic prewaves to the experimental conditions, the heights of both the prewave and prepeak was recorded several times under a set of given conditions. The agreement between the experimental values was, in general, satisfactory and their average was taken.

Results

Nc proved to be polarographically inactive in the supporting electrolyte, viz. KNO_3 up to 0.5 mol dm^{-3} at pH in the range 3.0–8.0. Addition of Ni^{2+} to the electrolyte caused Nc to induce one Ni^{2+} prewave in DC_TP, however. The half-wave potential ($E_{1/2}$) for the prewave was –0.70 ± 0.02 V, compared to –1.13 ± 0.02 V for the reduction wave of Ni^{2+} in the absence of nicotine.

The temperature coefficients obtained for the prewave (9–15% deg^{-1}) point to the catalytic character of the prewave. Moreover, no dependence of i_k (limiting current for the prewave) on $h^{1/2}$ (h = corrected height of the mercury column) was found, which confirms that the prewave has an unambiguous catalytic character. The main Ni^{2+} wave is diffusion-controlled under the experimental conditions of this study. This was shown by the linear dependence of i_d (limiting current for the main wave) with $h^{1/2}$.

For these experiments, the height of the prewave was less than 20% of the height of the main Ni^{2+} wave. Under these circumstances, the kinetic or catalytic limiting currents are proportional to the concentration of the Ni^{2+} species which are responsible for the appearance of the main wave. Consequently, it was verified that i_k values vary linearly with the concentration of Ni^{2+}. The dependence of i_k on the drop life time, t, is also relevant. The values of log i vs. log t are straight lines for both the prewave and the main Ni^{2+} wave. From the slopes, the direct proportionality between i_d and $t^{1/6}$ (Ilkovic's equation) was verified, while it was found that the i_k values are proportional to $t^{2/3}$.

All our results support the catalytic character of the prewave. Also, the location of its $E_{1/2}$ value as compared with the main wave indicates that the prewave is due to Ni^{2+} complexes with Nc species, where Ni^{2+} is reduced at a potential lower than that required to reduce it in the Ni^{2+} complex present in the supporting electrolyte.

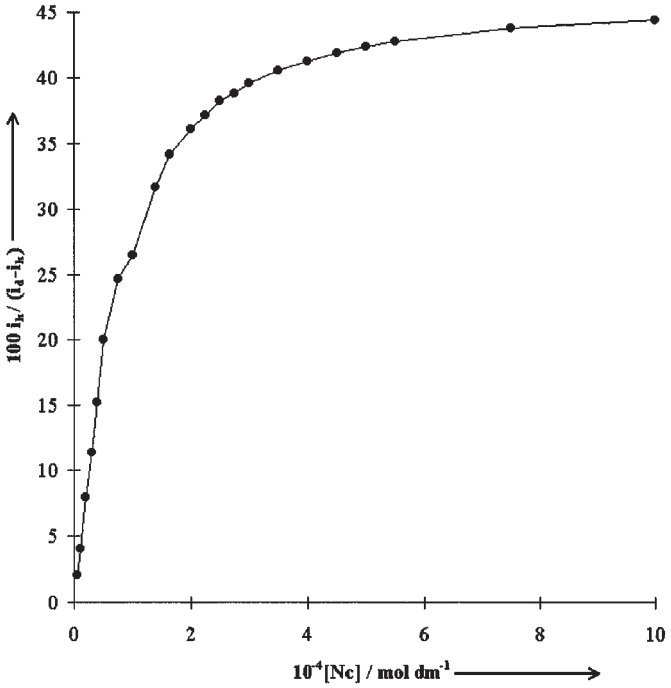
Increasing the stoichiometric concentration of Nc species in the solution raised the limiting current for the prewave to about 30% of the limiting current for the reduction wave of Ni^{2+} in the absence of Nc. This could be due to the limiting adsorption of Nc on the DME or, alternatively, to an autoinhibition effect (Nc absorbs strongly on the DME surface and therefore inhibits the electrode reaction). This behavior is contradictory with that of most reported prewaves for metal ions, where the maximum limiting current (at a high ligand catalyst concentration) virtually coincides with the limiting diffusion current for the metal ion concerned. A similar behavior has been observed for prewaves and prepeaks of Ni^{2+} in the presence of Nc by using NPP and DPP, respectively.

It seems reasonable to consider the appearance of a prewave as a special case of irreversibility of the overall wave. So, from our prior investigations (2, 3), the ratio i_k/i_d was taken as a function $F(\chi)$ of the Koutecky's parameter, χ (7, 8). In practice, the values of $F(\chi)$ were determined experimentally and the χ values were obtained by simulation using the following equation

$$[1] \qquad F(\chi) = \left(\frac{7\pi}{12}\right)^{\frac{1}{2}} \chi \exp\left(\frac{7}{12}\chi^2\right) erfc\left[\left(\frac{7}{12}\right)^{\frac{1}{2}} \chi\right]$$

The meaning of the parameter χ depends on the rate-determining step of the mechanism, explaining the appearance of the prewave. In all cases, χ actually has all the characteristics of an experimental rate constant; implying that we are employing a relaxation method. On the other hand, it is well known that the analysis of the influence of different variables (e.g., concentrations, pH, ionic strength, temperature, etc.) on the experimental rate constant is a usual method to elucidate the reaction mechanism.

Here, the Koutecky theory of polarographic kinetic currents can be applied with the assumption that the condition $[Nc]/K_2 << 1$ is realized, K_2 being the stability constant of the polarographically active compound (PAC), so that the following equation can be derived (9)



$$[2] \qquad \chi = \frac{i_k}{i_d - i_k} = \sqrt{\frac{12}{7}\frac{k_r t}{K_2}} \frac{[Nc]}{K_1 + [Nc]}$$

where K_1 and K_2 are the stability constants of the $[NiNc]^{2+}$ and $[NiNcNO_3]^{1+}$ complexes, respectively, and k_r is the rate constant of the rate-determining step (eq. [6]). The χ values are satisfactorily fitted by eq. [2], as Fig.1(*b*) shows, this being an additonal support of the mechanism that is proposed.

From the DC_TP records, the dependence of $i_k/(i_d - i_k)$ on the Nc concentration (in the range $0–10^{-3}$ mol dm^{-3}) was obtained (Fig. 1(*a*)). By using DPP, the peak currents increase with the Nc concentration (in the same range) with a curve

Fig. 1(*a*). Effect of the Nc concentration ($1.0 \times 10^{-5} - 1.5 \times 10^{-4}$ mol dm^{-3}) on the limiting current of the Ni^{2+} prewave, i_k, recorded by DC_TP. [Ni^{2+}] = 1.0×10^{-2} mol dm^{-3}. pH = 5.0. I = 0.1 mol dm^{-3} KNO_3. Temp = 25°C.

similar to Fig. 1(*a*). Accurate values of χ were obtained for the different concentrations of Nc. Analysis of these results (Fig. 1(*b*)) leads to the following equation

$$[3] \qquad \chi = \frac{a\,[\mathrm{Nc}]}{1 + b\,[\mathrm{Nc}]}$$

a = 4893.62

b = 15832.6

r_{xy} = 0.9966

For a PAC formed between the adsorbate $[Ni(H_2O)_x^{2+}]_{ES}$ and the depolarizer (Nc in this case), Čaja et al. (10) gave the following equation for Koutecky's parameter

$$[4] \qquad \chi = k\theta_{Nc}$$

where θ_{Nc} is the surface concentration on the DME of the depolarizer and k includes a number of parameters, e.g., the rate constant for the PAC formation and the ψ potential of the double layer. Equation [3] has the formal structure of the Langmuir isotherm and the χ values can be used for fitting the adsorption isotherm of Nc on the DME. Moreover, these results confirm our previous findings (vide supra) concerning the nature of the mechanism causing the prewave, explained via a surface process.

The sensitivity of the isotherm to experimental conditions, especially to the drop formation time, should be noted. This allows us to conclude that, under our experimental conditions, the Langmuir adsorption model is valid. In Fig. 1(*a*), the results actually fit to a linear function for [Nc] $\leq 1.0 \times 10^{-4}$ mol dm^{-3} (Henry's isotherm), which is consistent with a linear dependence of χ on the Nc concentration. For these circumstances, the reaction takes place partially or completely in the adsorption layer under the conditions of Henry's isotherm. On the other hand, the linear dependence of χ on $t^{1/2}$ (Fig. 2) strongly suggests that adsorption on the DME surface very quickly attains equilibrium (11). This fact supports the surface nature assumed for the PAC forming the prewave. A linear dependence of the limiting current, i_k, on the Ni^{2+} concentration was found (Fig. 3). This explains

Fig. 1(*b*). Dependence of Kouctecky's parameter χ on the Nc concentration at the same conditions.

Fig. 3. Dependence of the prewave limiting current, i_k, on the Ni^{2+} concentration. pH = 5.0. I = 0.1 mol dm^{-3} KNO_3. Temp = 25°C. [Nc]: (△) 1.0 × 10^{-5}; (□) 2.0 × 10^{-5}; and (○) 5.0 × 10^{-5} mol dm^{-3}.

the fact that no changes were observed for the χ values (DC_TP) when the Ni^{2+} concentration was changed from 5.0 × 10^{-3} to 2.5 × 10^{-2} mol dm^{-3}.

In this work, the pH is affected by both the protonation of Nc and the hydrolysis of the Ni^{2+} species, the latter being important for pH > 8.0. All experiments were conducted in the range 5.0 < pH < 8.0. If one takes into account the pK_a values for Nc (12), under these conditions, both the alkaline form and the monoprotonated form of Nc are present in solution, with the latter increasing when the pH decreases. From the dependence of Koutecky's parameter, χ, on the activity, a_{H+} (Fig. 4), one can conclude that in the PAC the alkaline form of Nc is involved. On the other hand, given the distribution of the electronic charge density on the pyridine and pyrrolidine rings, the PAC could be adsorbed on the DME via the pyridinic N-atom. This is consistent with the existence of bridge compounds, Py-Ni^{2+} (13, 14), on the DME surface.

The dependence of χ on the ionic strength (I) was also studied in the range 0.06–0.2 mol dm^{-3}, KNO_3 being the supporting electrolyte. A tentative fit of ln χ vs. $\sqrt{I}/(1+\sqrt{I})$ was made by using Guggenheim's correction (15) of the Debye–Hückel theory. In Fig. 5(*a*), the fit function is given. These results strongly suggest the existence of a kinetic salt effect for the reaction. A value of about –11.5 was found for the $z_+ \times z_-$ product. The anomalously high value of this product could be the result of the limited validity of the Debye–Hückel–Guggenheim formula for interpreting the activity coefficients of reacting molecules and of the transition state. The unambiguous negative value of this product shows that the process responsible for the prewave is controlled by a reaction between two species of opposite charge.

A decrease in the kinetic limiting current (i_k) with an increase in the ionic strength reflects the ψ-effect on the rate of chemical reactions taking place in the immediate vicinity of the electrode. Figure 5(*b*) shows the plot of ln χ vs. ψ. The ψ values were taken from Russell's table (16) for the potential value (vs. SCE) of –0.90 ± 0.02 V. This potential corresponds to the limiting current for the prewave when serious interferences are not predicted (17). A charge of +1.04 was found for the PAC. Russell's table has been used by a

Fig. 6. Analysis of the irreversibility of the polarographic curve (DC_TP) for the prewave. [Ni $^{2+}$] = 1.0×10^{-2} mol dm^{-3}. pH = 5.0. I = 0.1 mol dm^{-3} KNO_3. Temp = 25°C. [Nc] = 4.5×10^{-3} mol dm^{-3}.

of no specific adsorption of sodium or fluoride ions. The adsorption of nicotine might drastically change the properties of the double layer. For all these reasons, the ψ values are only an approximation to the actual potential on the outer Helmholtz plane for a given electrolyte (KNO_3) under our experimental conditions. Hence, the preceding conclusions about the ψ-effect have to be taken with caution.

It is well known (18) that an increase in the concentration of anions of the supporting electrolyte, which are surface-active, gives rise to an increase in the limiting currents of the prewaves. Wroblowa et al. (19) have shown that the adsorption of NO_3^- is not important for $[NO_3^-] \leq 0.5$ mol dm^{-3}. Hence, at the experimental conditions of this work, the adsorption of NO_3^- on the DME will have little effect on the magnitude of Koutecky's parameter. The only relevant role of the anionic species of the supporting electrolyte appears to be the charge of the PAC. This may be due to the association of Ni^{2+} species with anions in the surface layer (8). The effect of the cation of the supporting electrolyte on the χ values is noticeable. The χ values increase when the concentration of MNO_3 (M = Cs^+, K^+, Na^+, and Li^+) is decreased. The magnitude of this effect is proportional to the inverse of the cation size, which is consistent with specific cation adsorption.

For comparative purposes, the effect of temperature on χ was studied. Both the activation enthalpy, $\Delta H^{\neq}$ (27.8 kJ mol^{-1}), and the activation entropy, $\Delta S^{\neq}$ (–166.5 J K^{-1} mol^{-1}), were determined for [Nc] = 1.0×10^{-3} mol dm^{-3}, the rest of the experimental conditions being the same as in Fig. 1. The magnitude of $\Delta H^{\neq}$ for gravity dropping conditions is smaller by using DC_TP, while the absolute values of $\Delta S^{\neq}$ undergoes an important increase. This fact means that adsorption also plays an important role in affecting the activation parameters.

Changes of the $E_{1/2}$ values with the drop time, t, were observed, which is a sign of the irreversibility of the electrode process responsible for the appearance of the prewave.

Consequently, the irreversibility of the polarographic curve was analyzed (20) by plotting $i_k/i_d - i_k$ vs. $-E$ (i_k = the prewave current for a given potential; i_d = the prewave limiting current). A linear profile was found in all cases (Fig. 6), this being characteristic of a fully irreversible process. From the slope of those plots, the product αn can be obtained, n being the number of electrons participating in the charge transfer process and α the transfer coefficient. If it is assumed that α = 0.5, from our findings, the n values range from 1.5 to 1.8. This means that an average value of b = 0.03 can be predicted for the slope of the Tafel equation, which is consistent with a catalytic mechanism in the prewave.

The overpotential, η, at a given potential, E, is defined as the difference between this potential and the reversible potential. η is taken as the potential at the point where the base line intersects the bottom part of the extrapolated slope of the prewave. The method described by Bard and Faulkner (21) was used to calculate the exchange current, i_o. It was verified that $i_d - i_k/i_k$ vs. η is a linear function in the Tafel region under our experimental conditions (the correlation coefficients being, in all cases, $r_{xy} > 0.99$). From the respective intercepts, the i_o values were obtained. Plots of ln i_o vs. ln $[Ni^{2+}]$ are linear. The slopes are 1.0, an additional positive feature of the analysis.

When $\eta \rightarrow 0$, the kinetic order of the rate-determining step, p, and the stoichometric number, ν, were determined (22). These findings mean that the step which controls the reaction is a bimolecular process and that it does not repeat itself in the mechanism.

Formal mechanism

The dependence of the χ values on the Nc concentration shows that charge transfer is not (23) the rate-determining step for the mechanism responsible for the appearance of the prewave. On the contrary, the form of eq. [3] is consistent with a surface origin of the prewave. Moreover, the dependence of χ on the nature of the cation species of the supporting electrolytes is an additional proof of this.

Figure 4 confirms that the alkaline form of Nc is the adsorbed species on the DME. From FTIR studies (11), it has been shown that the sulfur atom is attracted to the electrode surface by strong chemical interaction forces and not through electrostatic interactions, as proposed by Parsons and Symons (24). So, the Nc species is actually adsorbed on the electrode surface, ES (denoted by $[Nc]_{ES}$).

In a former paper (3), the mechanism explaining the main wave was discussed. It consists of diffusion and dehydration (acid catalyzed) by partial loss of water molecules of the $Ni(H_2O)_6^{2+}$ species, and the discharge of the $Ni(H_2O)_x^{2+}$ ($2 < x < 4$) species on the DME. For all systems previously studied, in the mechanisms explaining the origin of the prewaves, the $Ni(H_2O)_x^{2+}$ species is involved. The mechanism for the appearance of the prewave is stated as follows

© 2000 NRC Canada

[5] $[Ni(H_2O)_x^{2+}]_H + [Nc]_{ES} \rightleftarrows [Ni(H_2O)_{x-1}Nc^{2+}]_{ES} + H_2O$

[6] $[Ni(H_2O)_{x-1}Nc^{2+}]_{ES} + [NO_3^-]_H \xrightarrow{\text{slow}} [Ni(H_2O)_{x-2}NcNO_3^+]_{ES} + H_2O$

PAC

[7] $[Ni(H_2O)_{x-2}NcNO_3^+]_{ES} \xrightarrow{2e^-} Ni(Hg) + Nc + NO_3^- + (x-2)H_2O$

H = Helmholtz plane (reaction plane)
ES = Electrode surface

It consists of a reaction between $Ni(H_2O)_x^{2+}$ species and adsorbed Nc to give a compound (eq. [5]). Reactions of this type are well known (25) and they are very fast in the bulk solution. Hence, it is reasonable to expect that the step of eq. [5] almost instantaneously reaches equilibrium conditions. The assumption of the formation of this compound is supported by the existence of bridge Ni^{2+}-Py compounds on the DME surface (13, 14).

Čaja et al. (10) assume, for similar systems, that the rate-determining step is the reaction between hexaaquonickel ion in the bulk solution and the adsorbed amine on the DME surface. We think, however, that the surface nature of the prewave is not a conclusive proof of that formulation. In fact, when the alkaline form of the amine is the kinetically active species (e.g., pyridine and pyridine derivatives), the amine concentration at the Helmholtz plane equals the value of this magnitude at the surface electrode because the alkaline form of the amine has no ionic charge. So, the dependence of Koutecky's parameter, χ, on the surface concentration of amine may arise from this. On the other hand, Čaja et al. (10) have not taken into account the adsorption of Ni^{2+} species on the DME surface.

We have assumed that the rate-determining step is the reaction between $[Ni(H_2O)_x^{2+}]_{ES}$ species and nitrate ions at the Helmholtz plane (reaction plane) to give the PAC. This assumption is consistent with both the association of Ni^{2+}-NO_3^- on the (surface) layer (8) and that the adsorption of nitrate ions is not important under the experimental conditions of this work (19).

This formulation is also supported by the small magnitude of the reaction rates of the exchange reactions (10, 26). The latter is probably not enough to consider eq. [6] to be the rate-determining step. But there are some other reasons which argue for this, such as $p = 2$ for the molecularity of the rate-determining step. Also, activation entropy values which were constantly found to be negative support the assumption that eq. [6] is the rate-determinining step. Hence, eq. [6] is formulated involving two ionic species of opposite sign, consistent with the observed salt kinetic effect and also with the ψ-effect.

The experimental value of +1.04 for the electric charge of the PAC could be a consequence of the NO_3^- effect. On the other hand, the existence of Ni^{2+} coordination complexes, in which NO_3^- participates, has been confirmed (27).

The analysis of the irreversibility of the prewave provides certain values for the αn product, which points to a two-electron transfer reaction at the DME. This fact is consistent with a value of +1 for the ionic charge of the PAC in the formulation of eq. [7]. It should also be noted that the catalytic character of the prewave is implied in the formulation of this mechanism, because the discharge of the PAC regenerates the Nc and nitrate ions.

Synthesis of 2,3-disubstituted norbornadienes

Geoffrey K. Tranmer, Carol Yip, Sean Handerson, Robert W. Jordan, and William Tam

Abstract: Various 2,3-disubstituted norbornadienes that can hardly be made by the traditional Diels–Alder method were synthesized by double lithium halide exchange of 2,3-dibromonorbornadiene in moderate to good yields.

Key words: 2,3-disubstituted norbornadienes, Diels–Alder reaction, lithium halide exchange.

Résumé: Faisant appel à un double échange de lithium/halogénure sur le 2,3-dibromonorbornadiène, on a réalisé la synthèse, avec des rendements allant de modérés à bons, de divers norbornadiènes 2,3-disubstitués qui peuvent à peine être fabriqués par la méthode traditionnelle de Diels–Alder.

Mots clés: norbornadiènes 2,3-disubstitués, réaction de Diels–Alder, échange lithium halogénure.

Introduction

During our study of the effect of a C-3 substituent on regio- and stereoselectivity in the intramolecular 1,3-dipolar cycloaddition of norbornadiene-tethered nitrile oxides (Scheme 1) (1), we came across a problem for the synthesis of the 2,3-disubstituted norbornadienes (**1**). Most of the literature syntheses of 2,3-disubstituted norbornadienes rely on Diels–Alder reactions between cyclopentadiene and highly activated acetylenes (2–6). Less activated or unactivated acetylenes are poor dienophiles in Diels–Alder reactions, thus limiting the substituents on the norbornadiene ring system to electron-withdrawing groups. In this paper, we report a more general and simple procedure for the synthesis of 2,3-disubstituted norbornadienes **8** and **9** with a variety of substituents (E_1 and E_2) (Scheme 2).

2,3-Disubstituted norbornadienes are important compounds, which have found a place as key intermediates in the synthesis of many natural products, such as prostaglandin endoperoxides PGH_2 and PGG_2 (7), *cis*-trikentrin B (8), and β-santalol (9, 10). 2,3-Disubstituted norbornadienes also serve in the reversible photoinduced isomerization of norbornadiene derivatives into the corresponding quadricyclanes (11–14). Extensive investigation of 2,3-disubstituted norbornadienes–quadricyclanes interconversion for solar energy storage has demonstrated the efficiency and switching potential of these reversible systems (15–17).

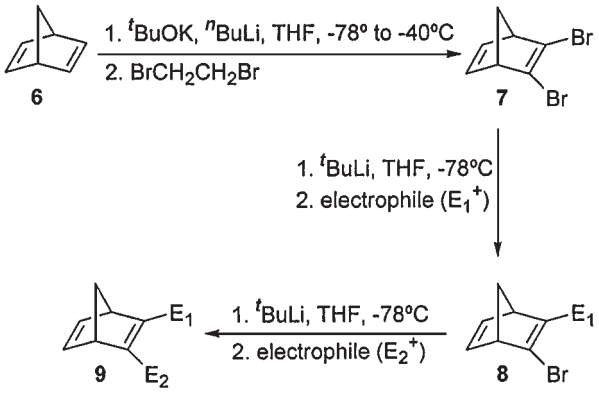
Results and discussion

Schlosser and co-workers (18) and Brandsma and co-worker (19) have shown independently that deprotonation of a vinyl hydrogen of norbornadiene **6** can be achieved by the use of Schlosser's base, a mixture of *n*-butyllithium (^{n}BuLi) and potassium or sodium *tert*-butoxide (^{t}BuOK or ^{t}BuONa). Trapping of the metalated norbornadiene **10** with electrophiles leads to the formation of 2-substituted norbornadienes (**11**) (Scheme 3). This method has been used in the synthesis of 2,3-dibromonorbornadiene (**7**) (20). We have modified the procedure to achieve a more reliable large-scale (10–20g scale) synthesis of 2,3-dibromonorbornadiene (**7**) (Scheme 4). After deprotonation of norbornadiene with Schlosser's base, 1,2-dibromoethane (0.5 equiv) was added to the norbornadienyl potassium (**10**) at –78°C, and the reaction mixture was stirred at –40°C for 1.5 h. At this point, 0.5 equiv. of 2-bromonorbornadiene (**12**) would have been formed together with the remaining 0.5 equiv. of norbornadienyl potassium (**10**). We found that the temperature control is very important at this stage. If the temperature was too low or too high, the yield of the reaction was very poor. The Br in **12** enhances the acidity of its adjacent vinyl hydrogen, and the leftover norbornadienyl potassium (**10**) is basic enough to remove that proton to generate **13**. Trapping of **13** with excess 1,2-dibromoethane leads to the formation of 2,3-dibromonorbornadiene (**7**).



Monolithium-halide exchange of the 2,3-dibromonorbornadiene (**7**) with ^{t}BuLi (2 equiv) produces 2-bromo-3-lithionorbornadiene (**14**). Trapping of this organolithium with water (Table 1, entry 1) gave **8a**, and trapping with alkyl halides (entries 2–5) and benzyl bromide (entry 6) afforded the corresponding 2,3-disubstituted norbornadienes (**8b**–**8f**) in moderate to good yields. The disubstituted analogs **8d** and **8e** have been used in the synthesis of C-2, C-3-disubstituted norbornadiene-tethered nitrile oxides **1** (Scheme 1) in our studies of intramolecular 1,3-dipolar cycloadditions (1). We prepared 2,3-disubstituted norbornadienes with heteroatoms (Si, Cl, I, and Sn) by trapping the 2-bromo-3-lithionorbornadiene (**14**) with silyl chlorides (entries 7 and 8), tosyl chloride (entry 9), iodine (entry 10), and tributyltin chloride

Scheme 2.

Scheme 3.

(entry 11). In reacting with the intermediate 2-bromo-3-lithionorbornadiene (**14**), ethyl chloroformate (entry 12) provided the corresponding ester **8l**, aldehydes (entries 13 and 14) afforded secondary alcohols **8m** and **8n**, and ketones (entries 15 and 16) gave tertiary alcohols **8o** and **8p**. In all these cases, we saw no evidence for the intermediacy of norbornenyne (**15**) (21) (Scheme 5).

A second lithium halide exchange of bromide **8b** followed by trapping with 1-bromohexane (Table 2, entry 1), 1,4-dibromobutane (entry 2), trimethylsilyl chloride (entry 3), tosyl chloride (entry 4), iodine (entry 5), ethyl chloroformate (entry 6), and acetone (entry 7) provided in moderate to good yields a broad range of 2,3-disubstituted norbornadienes (**9a**–**9g**) with various functional groups. Trapping of bromides **8c** and **8d** with 1,4-dibromobutane (entry 8) and methyl chloroformate (entry 9), respectively, led to the formation of 2,3-disubstituted norbornadienes **9h** and **9i**, which are precursors of the norbornadiene-tethered nitrile oxides in our studies of 1,3-dipolar cycloadditions (1).

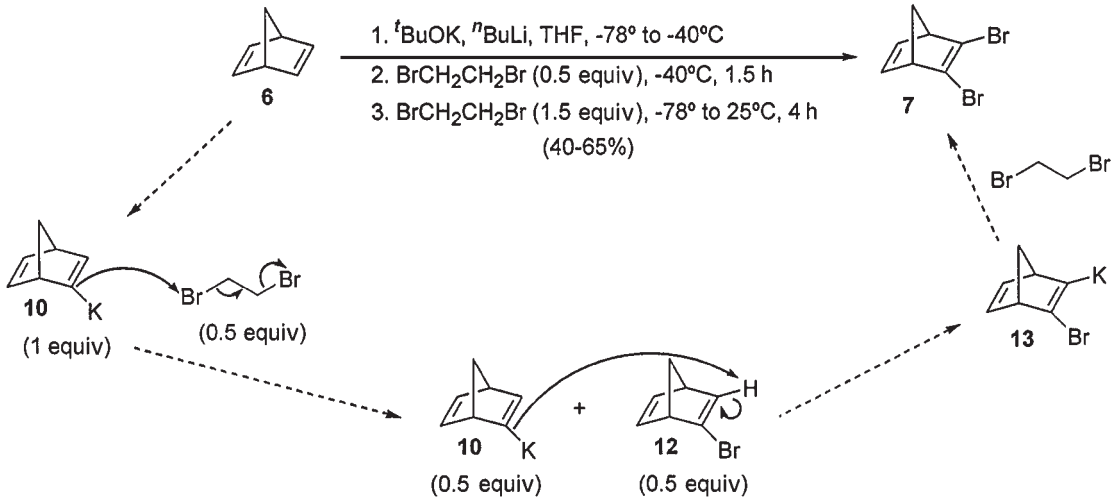
In conclusion, we have developed a simple and convenient access to a variety of 2,3-disubstituted norbornadienes that can hardly be prepared by traditional Diels–Alder methodology. Analogs **8a**–**8p** are very useful precursors for the synthesis of many other 2,3-disubstituted norbornadienes. Obviously, instead of the second lithium halide exchange as discussed above to provide 2,3-disubstituted norbornadienes such as **9a**–**9i**, one could presumably couple the bromides **8** with organotin compounds (for the Stille coupling see refs. (22) and (23)), with organoboron compounds (for the Suzuki coupling see ref. (24)), with alkenes (for the Heck reaction see ref. (25)), and with 1-alkynes (for the Castro–Stephens–Sonogashira coupling see ref. (26)) to generate broad classes of vinyl, aryl, and alkynyl norbornadienes. We are currently investigating these coupling reactions in the synthesis of novel conjugated norbornadiene-based polymers. Studies on asymmetric lithium halide exchange of 2,3-dibromonornadiene (**7**) by precomplexation of ^{t}BuLi with a chiral base are also underway in our laboratory and will be reported in due course.

Experimental

General Information

All reactions were carried out in an atmosphere of dry nitrogen at ambient temperature unless otherwise stated. Standard column chromatography was performed on 230–400 mesh silica gel (obtained from Silicycle) by use of flash column chromatography techniques (27). Analytical thin-layer chromatography (TLC) was conducted on Merck precoated silica gel 60 F_{254} plates. All glassware was flame dried under an inert atmosphere of dry nitrogen. Infrared spectra were taken on a Bomem MB-100 FTIR spectrophotometer. ^{1}H and ^{13}C NMR spectra were recorded on a Varian Gemini-200 or a Bruker-400 spectrometer. Chemical shifts for ^{1}H NMR spectra are reported in parts per million (ppm) from tetramethylsilane with the solvent resonance as the internal standard (deuterochloroform: δ 7.26). Chemical shifts for ^{13}C NMR spectra are reported in parts per million (ppm) from tetramethylsilane with the solvent as the internal standard (deuterochloroform: δ 77.0). High resolution mass spectra were done by Mass Spectrometry Laboratory Services Division at the University of Guelph. Elemental analyses were performed by Canadian Microanalytical Service Ltd., British Columbia or by Quantitative Technologies Inc., New Jersey.

Reagents



Unless stated otherwise, commercial reagents were used without purification. THF was purified by distillation from potassium/benzophenone under dry nitrogen. 1,2-Dibromoethane, 1-iodohexane, 1,4-dibromobutane, chlorotrimethylsilane, acetone, acetaldehyde, and methyl chloroformate were purified by distillation from 4 Å molecular sieves under dry nitrogen.

2,3-Dibromonorbornadiene (7)

Norbornadiene **6** (35.0 mL, 324 mmol) was added to a flame-dried 3-neck flask containing potassium *tert*-butoxide (18.7 g, 167 mmol) and THF (240 mL), which was cooled at –78°C (cryobath). *n*-Butyllithium (66.0 mL, 2.5M, 165 mmol) was added dropwise through a dropping funnel over 2 h, which the temperature was maintained below –70°C. The mixture was stirred at –65°C for 30 min. then at –40°C for 30 min. After the mixture was cooled to –78°C, 1,2-dibromoethane (7.20 mL, 83.5 mmol) was added, and

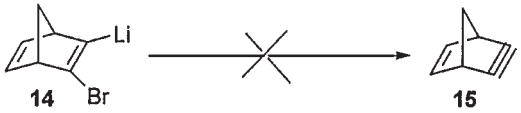
Scheme 4.



the mixture was stirred at –40°C for 1.5 h. Excess 1,2-dibromoethane (21.6 mL, 250 mmol) was then added at –70°C. The brown mixture was stirred at –40°C for 2 h then at room temperature for 4 h. After quenching the mixture with saturated ammonium chloride (150 mL) and water (300 mL), the aqueous layer was extracted with diethyl ether (4 × 300 mL), and the combined organic layers were washed sequentially with water (500 mL) and brine (500 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation, and the crude product was purified by vacuum distillation to give three fractions. The first fraction (20–30 torr (1 torr = 133.322 Pa) at 40–60°C) contained mainly the excess 1,2-dibromoethane and norbornadiene. The second fraction (10–15 torr (1 torr = 133.322 Pa) at 50–60°C) contained 2-bromonorbornadiene and 2,3-dibromonorbornadiene in a ratio of 2:1 as determined by ^{1}H NMR. The third fraction (6–9 torr (1 torr = 133.322 Pa) at 80–100°C) contained pure 2,3-dibromonorbornadiene **7** (13.6 g, 54.4 mmol, 65%) as colorless oil. R_f: 0.67 (hexanes). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 6.88 (s, 2H), 3.61 (m, 2H), 2.45 (dd, 1H, J = 6.3, 1.1 Hz), 2.18 (dt, 1H, J = 6.3, 1.4 Hz). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 141.2, 133.0, 72.0, 58.6. Spectral data were identical to those reported in the literature (20).

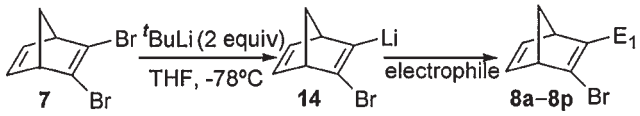
*2-Bromonorbornadiene (**8a**)*

tert-Butyllithium (1.04 mL, 1.7M, 1.77 mmol) was added to a flame-dried flask containing dibromide **7** (222 mg, 0.887 mmol) in THF (4 mL) at –78°C. After the yellow mixture was stirred for 15 min, distilled water (0.50 mL, 28.0 mmol) was added at –78°C. The mixture was stirred at –78°C for 30 min. then at room temperature for 1 h. After quenching the mixture with water (5 mL), the aqueous layer was extracted with diethyl ether (3 × 10 mL), and the combined organic layers were washed sequentially with water (10 mL) and brine (10 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (hexanes) to give **8a** (93.2 mg, 0.545 mmol, 61%) as colorless oil. Note: **8a** is not very stable and it turned to blackened oil upon standing at room temperature for a few days.

Scheme 5.

R_f: 0.69 (hexanes). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 6.89 (dd, 1H, J = 5.2, 3.2 Hz), 6.78 (dd, 1H, J = 5.2, 3.2 Hz), 6.65 (d, 1H, J = 3.2 Hz), 3.61 (br. s, 1H), 3.48 (br. s, 1H), 2.67 (dt, 1H, J = 6.0, 1.6 Hz), 2.07 (dt, 1H, J = 6.0, 1.6 Hz). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 142.9, 141.8, 139.6, 136.6, 73.9, 58.2, 51.6. Spectral data were identical to those reported in the literature (20).

*2-Bromo-3-methylnorbornadiene (**8b**)*



tert-Butyllithium (17.3 mL, 1.7M, 29.4 mmol) was added to a flame-dried flask containing dibromide **7** (3.67 g, 14.7 mmol) in THF (40 mL) at –78°C. After the yellow mixture was stirred for 1 h, methyl iodide (2.30 mL, 36.8 mmol) was added at –78°C. The mixture was stirred at –78 °C for 30 min then at room temperature for 2 h. After quenching the mixture with water (40 mL), the aqueous layer was extracted with diethyl ether (3 × 50 mL), and the combined organic layers were washed sequentially with water (100 mL) and brine (100 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by bulb-to-bulb distillation (15–20 torr (1 torr = 133.322 Pa) at 70–80°C) to give **8b** (2.39 g, 12.9 mmol, 88%) as colorless oil. R_f: 0.74 (hexanes). IR (neat, NaCl) cm^{-1}: 2973 (s), 2939 (s), 2905 (w), 2869 (w), 1639 (w), 1557 (w), 1439 (m), 1376 (w), 1262 (w). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 6.87 (dd, 1H, J = 5.0, 2.9 Hz), 6.78 (m, 1H), 3.47 (m, 1H), 3.36 (br. s, 1H), 2.21 (dt, 1H, J = 6.0, 1.5 Hz), 2.02 (dt, 1H, J = 6.0, 1.7 Hz), 1.76 (s, 3H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 147.6, 142.1, 141.5, 128.7, 71.4, 57.9, 55.2, 15.4. Anal. calcd. for C_8H_9Br: C 51.92, H 4.90; found C 51.90, H 4.84.

*2-Bromo-3-hexylnorbornadiene (**8c**)*

tert-Butyllithium (9.70 mL, 1.7M, 16.5 mmol) was added to a flame-dried flask containing dibromide **7** (1.87 g, 7.48 mmol) in THF (25 mL) at –78°C. After the yellow mixture was

*2-Bromo-3-(4-bromobutyl)norbornadiene (**8e**)*

tert-Butyllithium (8.20 mL, 1.7M, 13.9 mmol) was added to a flame-dried flask containing dibromide **7** (1.60 g, 6.40 mmol) in THF (30 mL) at –78°C. After stirring the reaction mixture for 1 h, the resulting yellow reaction mixture was added to a flame-dried flask containing 1,4-dibromobutane (5.50 mL, 46.1 mmol) in THF (30 mL) at –78°C. The mixture was stirred at –78°C for 1 h then at room temperature for 12 h. After quenching the mixture with water (100 mL), the aqueous layer was extracted with diethyl ether (4 × 50 mL), and the combined organic layers were washed sequentially with water (100 mL) and brine (100 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the excess 1,4-dibromobutane was removed by bulb-to-bulb distillation (4 torr (1 torr = 133.322 Pa) at 70°C for 4 h) and the crude product was purified by column chromatography (hexanes) to give **8e** (1.04 g, 3.40 mmol, 53%) as colorless oil. R_f: 0.50 (EtOAc:hexanes = 1:9). IR (neat, NaCl) cm^{-1}: 3066 (w), 2973 (m), 2937 (s), 2866 (w), 1632 (w), 1557 (w), 1451 (w), 1296 (s), 1249 (w). ^1H NMR ($CDCl_3$, 400 MHz) δ: 6.85 (dd, 1H, *J* = 5.1, 2.9 Hz), 6.76 (dd, 1H, *J* = 4.6, 3.0 Hz), 3.47 (m, 1H), 3.44 (m, 1H), 3.40 (t, 2H, *J* = 6.6 Hz), 2.28–2.12 (m, 3H), 2.04 (dt, 1H, *J* = 6.0, 1.7 Hz), 1.78 (m, 2H), 1.57 (m, 2H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 150.3, 141.9, 141.8, 129.9, 71.6, 57.9, 53.3, 33.7, 31.8, 28.1, 24.8. *2-Benzyl-3-bromonorbornadiene (**8f**)*

tert-Butyllithium (19.0 mL, 1.7M, 32.3 mmol) was added to a flame-dried flask containing dibromide **7** (4.0 g, 16 mmol) in THF (48 mL) at –78°C. After the yellow mixture was stirred for 1.2 h, benzyl bromide (2.85 mL, 24.0 mmol) was added at –78°C. The mixture was stirred at –78 °C for 2 h then at room temperature for 22 h. After quenching the mixture with water (25 mL), the aqueous layer was extracted with diethyl ether (4 × 25 mL), and the combined organic layers were washed sequentially with water (25 mL) and brine (25 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the excess benzyl bromide was by vacuum bulb-to-bulb distillation (5 torr (1 torr = 133.322 Pa) at 120°C for 3 h). The crude product was purified by column chromatography (hexanes) to give **8f** (2.62 g, 10.0 mmol, 63%) as yellow oil. R_f: 0.85 (EtOAc:hexanes = 1:9). IR (neat, NaCl) cm^{-1}: 3064 (m), 3027 (s), 2976 (s), 2938 (s), 2867 (s), 1630 (m), 1601 (m), 1557 (m), 1494 (s), 1453 (s), 1428 (w), 1297 (s), 1264 (m), 1224 (m), 1168 (w), 1087 (w), 1074 (m), 1029 (s), 1010 (m). ^1H NMR ($CDCl_3$, 400 MHz) δ: 7.31–7.20 (m, 3H), 7.12 (dm, 2H, *J* = 7.2 Hz), 6.81 (dd, 1H, *J* = 4.9, 3.0 Hz), 6.55 (dd, 1H, *J* = 4.9, 2.9 Hz), 3.57 (d_{AB}, 1H, *J* = 14.9 Hz), 3.55 (br. s, 1H), 3.48 (d_{AB}, 1H, *J* = 14.9 Hz), 3.30 (m, 1H), 2.21 (dt, 1H, *J* = 6.0, 1.5 Hz), 2.00 (dt, 1H, *J* = 6.0, 1.6 Hz). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 149.7, 142.0, 140.9, 137.5, 129.9, 128.8, 128.3, 126.2, 71.4, 57.9, 53.4, 35.7. HRMS *m*/*z* for $C_{14}H_{13}Br$: calcd. 260.0201; found 260.0189.

*2-Bromo-3-trimethylsilylnorbornadiene (**8g**)*

tert-Butyllithium (1.01 mL, 1.7M, 1.72 mmol) was added to a flame-dried flask containing dibromide **7** (215 mg, 0.862 mmol) in THF (4 mL) at –78°C. After the yellow mixture was stirred for 30 min, chlorotrimethylsilane (0.27 mL, 2.10 mmol) was added at –78°C. The mixture was stirred at –78°C for 1 h then at room temperature for 1 h. After quenching the mixture with water (5 mL), the aqueous layer was extracted with diethyl ether (3 × 10 mL), and the combined organic layers were washed sequentially with water (10 mL) and brine (10 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (hexanes) to give **8g** (185 mg, 0.762 mmol, 88%) as colorless oil. R_f: 0.88 (EtOAc:hexanes = 1:19). IR (neat, NaCl) cm^{-1}: 2957 (s), 2938 (s), 1571 (s), 1549 (s), 1296 (s), 1248 (s), 1022 (m), 836 (s). ^1H NMR ($CDCl_3$, 400 MHz) δ: 6.83 (dd, 1H, *J* = 5.0, 3.2 Hz), 6.70 (dd, 1H, *J* = 5.0, 3.2 Hz), 3.73 (br. s, 1H), 3.54 (br. s, 1H), 2.14 (dt, 1H, *J* = 6.1, 1.5 Hz), 1.94 (dt, 1H, *J* = 6.1, 1.5 Hz), 0.15 (s, 9H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 147.6, 147.2, 142.7, 141.0, 72.3, 61.4, 55.7, –1.7. HRMS *m*/*z* for $C_{10}H_{15}SiBr$: calcd. 242.0127; found 242.0124.

*2-Bromo-3-tert-Butyldimethylsilylnorbornadiene (**8h**)*

tert-Butyllithium (1.00 mL, 1.7M, 1.70 mmol) was added to a flame-dried flask containing dibromide **7** (212 mg, 0.847 mmol) in THF (4 mL) at –78°C. After the yellow mixture was stirred for 30 min, *tert*-butyldimethylsilyl chloride (338 mg, 2.24 mmol) was added at –78°C. The mixture was stirred at –78°C for 1 h then at room temperature for 1 h. After quenching the mixture with water (5 mL), the aqueous layer was extracted with diethyl ether (3 × 10 mL), and the combined organic layers were washed sequentially with water (10 mL) and brine (10 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (hexanes) to give **8h** (187 mg, 0.655 mmol, 77%) as colorless oil. R_f: 0.88 (EtOAc:hexanes = 1:19). IR (neat, NaCl) cm^{-1}: 2953 (s), 2928 (s), 2855 (s), 1570 (s), 1548 (s), 1470 (m), 1296 (s), 1249 (s), 1019 (s), 835 (s). ^1H NMR ($CDCl_3$, 400 MHz) δ: 6.85 (dd, 1H, *J* = 4.9, 3.1 Hz), 6.72 (dd, 1H, *J* = 4.9, 2.9 Hz), 3.77 (br. s, 1H), 3.55 (br. s, 1H), 2.18 (d, 1H, *J* = 6.1 Hz), 1.94 (dm, 1H, *J* = 6.1 Hz), 0.88 (s, 9H), 0.18 (s, 3H), 0.15 (s, 3H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 148.8, 146.1, 142.9, 140.9, 72.4, 61.7, 56.7, 26.7, 18.4, –5.4, –5.8. HRMS *m*/*z* for $C_{13}H_{21}SiBr$: calcd. 284.0596; found 284.0597.

*2-Bromo-3-chloronorbornadiene (**8i**)*

tert-Butyllithium (1.00 mL, 1.7M, 1.70 mmol) was added to a flame-dried flask containing dibromide **7** (213 mg, 0.852 mmol) in THF (4 mL) at –78°C. After the yellow mixture was stirred for 30 min, *p*-toluenesulfonyl chloride (345 mg, 1.81 mmol) was added at –78°C. The mixture was stirred at –78°C for 45 min then at room temperature for 1 h. After quenching the mixture with water (5 mL), the aqueous layer was extracted with diethyl ether (3 × 10 mL), and the combined organic layers were washed sequentially with water (10 mL) and brine (10 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (hexanes) to give **8i** (130 mg, 0.635 mmol, 75%) as colorless oil. R_f: 0.76 (hexanes). ^1H NMR ($CDCl_3$, 400 MHz) δ: 6.89 (m, 2H), 3.60 (m, 1H), 3.52 (m, 1H), 2.43 (dtd, 1H, *J* = 6.3,

1.6, 0.3 Hz), 2.19 (dt, 1H, J = 6.3, 1.9 Hz). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 144.0, 141.6, 141.1, 128.3, 71.5, 57.8, 56.8. Spectral data were identical to those reported in the literature (20).

*2-Bromo-3-iodonorbornadiene (**8j**)*

tert-Butyllithium (1.00 mL, 1.7M, 1.70 mmol) was added to a flame-dried flask containing dibromide **7** (213 mg, 0.854 mmol) in THF (3 mL) at –78°C. After the yellow mixture was stirred for 30 min, iodine (456 mg, 1.80 mmol), in a separate flame-dried flask containing 4Å molecular sieves (550 mg) and THF (1 mL), was added via a cannula at –78°C. The mixture was stirred at –78°C for 45 min then at room temperature for 1 h. After quenching the mixture with saturated sodium thiosulfate (5 mL), the aqueous layer was extracted with diethyl ether (3 × 10 mL), and the combined organic layers were washed sequentially with water (10 mL) and brine (10 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (hexanes) to give **8j** (207 mg, 0.699 mmol, 82%) as pale-yellow oil. R_f: 0.77 (hexanes). IR (neat, NaCl) cm^{-1}: 2993 (s), 2940 (s), 2867 (w), 1573 (s), 1551 (w), 1291 (s), 1220 (w), 711 (s). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 6.87 (m, 2H), 3.71 (m, 1H), 3.62 (m, 1H), 2.44 (dm, 1H, J = 6.4 Hz), 2.14 (dm, 1H, J = 6.4 Hz). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 141.9, 141.4, 140.8, 105.0, 72.5, 61.9, 59.0. HRMS m/z for C_7H_6BrI: calcd. 295.8700; found 295.8697.

*2-Bromo-3-tributylstannylnorbornadiene (**8k**)*

tert-Butyllithium (1.05 mL, 1.7M, 1.79 mmol) was added to a flame-dried flask containing dibromide **7** (233 mg, 0.894 mmol) in THF (4 mL) at –78°C. After the yellow mixture was stirred for 30 min, tributyltin chloride (0.61 mL, 2.25 mmol) was added at –78°C. The mixture was stirred at –78°C for 45 min then at room temperature for 1 h. After quenching the mixture with water (5 mL), the aqueous layer was extracted with diethyl ether (3 × 10 mL), and the combined organic layers were washed sequentially with water (10 mL) and brine (10 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (hexanes) to give **8k** (299 mg, 0.649 mmol, 73%) a$s colorless oil. R_f: 0.89 (hexanes). IR (neat, NaCl) cm^{-1}: 2956 (s), 2930 (s), 2870 (m), 2853 (m), 1566 (m), 1541 (s), 1463 (m), 1294 (s), 1009 (s), 874 (w). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 6.85 (dd, 1H, J = 5.1, 3.0 Hz), 6.65 (dd, 1H, J = 5.1, 2.9 Hz), 3.74 (br. s, 1H), 3.51 (br. s, 1H), 2.19 (dm, 1H, J = 6.0 Hz), 1.98 (dm, 1H J = 6.0 Hz), 1.49 (m, 6H), 1.29 (m, 6H), 1.00 (t, 6H, J = 8.0 Hz), 0.88 (t, 9H, J = 7.2 Hz). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 151.2, 148.9, 142.6, 141.3, 73.1, 60.3, 57.5, 29.1, 27.2, 13.7, 9.7. HRMS m/z for $C_{19}H_{33}SnBr$: calcd. 460.0788; found 460.0792.

*2-Bromo-3-ethoxycarbonylnorbornadiene (**8l**)*

tert-Butyllithium (1.20 mL, 1.7M, 2.04 mmol) was added to a flame-dried flask containing dibromide **7** (219 mg, 0.876 mmol) in THF (2.4 mL) at –78°C. After stirring the mixture for 1 h, the resulting yellow mixture was added to a flame-dried flask containing ethyl chloroformate (0.40 mL, 4.18 mmol) in THF (2 mL) at –78°C. The mixture was stirred at –78°C for 3 h. After quenching the mixture with water (15 mL), the aqueous layer was extracted with diethyl ether (4 × 15 mL), and the combined organic layers were washed sequentially with water (20 mL) and brine (20 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (EtOAc:hexanes = 1:19) to give **8l** (130 mg, 0.535 mmol, 61%) as colorless oil. R_f: 0.70 (EtOAc:hexanes = 1:4). IR (neat, NaCl) cm^{-1}: 2980 (m), 2943 (m), 2872 (w), 1718 (s), 1717 (s), 1704 (s), 1699 (s), 1695 (s), 1559 (m), 1368 (m), 1310 (s), 1290 (s), 1277 (s), 1249 (s), 1235 (s), 1203 (w), 1150 (m), 1101 (s), 1086 (s), 1024 (w). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 6.90 (dd, 1H, J = 4.9, 3.0 Hz), 6.84 (m, 1H), 4.21 (m, 2H), 3.99 (m, 1H), 3.67 (m, 1H), 2.30 (dt, 1H, J = 6.6, 1.5 Hz), 2.11 (dt, 1H, J = 6.7, 1.6 Hz), 1.30 (t, 3H, J = 7.1 Hz). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 163.7, 148.4, 143.0, 142.0, 140.4, 71.7, 61.6, 60.4, 52.0, 14.2. Anal. calcd. for $C_{10}H_{11}BrO_2$: C 49.41, H 4.56; found C 49.23, H 4.58.

*2-Bromo-3-(1-hydroxyethyl)norbornadiene (**8m**)*

tert-Butyllithium (0.50 mL, 1.7M, 0.850 mmol) was added to a flame-dried flask containing dibromide **7** (106 mg, 0.424 mmol) in THF (2 mL) at –78°C. After the yellow mixture was stirred for 45 min, acetaldehyde (0.10 mL, 2.88 mmol) was added at –78°C. The mixture was stirred at –78°C for 1 h. After quenching the mixture with water (5 mL), the aqueous layer was extracted with diethyl ether (3 × 10 mL), and the combined organic layers were washed sequentially with water (10 mL) and brine (10 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (EtOAc:hexanes = 1:4) to give **8m** (75.9 mg, 0.353 mmol, 83%, 1:1 inseparable mixture of diastereomers) as colorless oil. R_f: 0.33 (EtOAc:hexanes = 1:4); IR (neat, NaCl) cm^{-1}: 3354 (br. s), 3069 (w), 2973 (s), 2939 (s), 2869 (s), 1628 (m), 1558 (m), 1449 (m), 1368 (m), 1327 (m), 1296 (s), 1268 (m), 1224 (m), 1209 (m), 1091 (s), 1062 (s), 1030 (m), 1009 (m). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 6.86–6.76 (m, 2H), 4.70 (q, 0.5H, J = 6.2 Hz), 4.69 (q, 0.5H, J = 6.2 Hz), 3.72 (br. s, 0.5H), 3.68 (br. s, 0.5H), 3.50 (br. s, 1H), 2.16 (m, 1H), 2.04 (m, 1H), 1.87 (br. s, 1H), 1.62 (br. s, 1H), 1.33 (d, 1.5H, J = 6.4 Hz), 1.11 (d, 1.5H, J = 6.5 Hz). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 152.6, 152.4, 142.9, 142.5, 141.4, 141.2, 130.4, 130.2, 71.8, 71.3, 64.6, 64.5, 58.2, 58.1, 50.0, 49.5, 20.8, 18.9. *1-Bromo-4-(3-methyl-2-norbornadienyl)butane (**9b**)*

tert-Butyllithium (30.0 mL, 1.7M, 51.0 mmol) was added to a flame-dried flask containing bromide **8b** (4.40 g, 23.8 mmol) in THF (120 mL) at –78°C. After stirring the mixture for 1 h, the resulting yellow mixture was added to a flame-dried flask containing 1,4-dibromobutane (18.0 mL, 151 mmol) in THF (120 mL) at –78°C. The mixture was stirred at –78°C for 30 min then at room temperature for 12 h. After quenching the mixture with water (300 mL), the aqueous layer was extracted with diethyl ether (4 × 150 mL), and the combined organic layers were washed sequentially with water (150 mL) and brine (150 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by vacuum distillation to give two fractions. The first fraction (4–6 torr (1 torr = 133.322 Pa) at 70–80°C) contained mainly the excess 1,4-dibromobutane. The second fraction (0.4–1 torr (1 torr = 133.322 Pa) at 60–80°C) contained **9b** (2.35 g, 9.74 mmol, 41%) as colorless oil. R_f: 0.54 (hexanes). IR (neat, NaCl) cm^{-1}: 3066 (w), 2963 (s), 2932 (s), 2862 (m), 1557 (w), 1438 (m), 1376 (w), 1301 (m), 1249 (w), 1230 (w), 1202 (w). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 6.74 (m, 2H), 3.38 (t, 2H, *J* = 7.0 Hz), 3.29 (br. s, 1H), 3.22 (m, 1H), 2.17 (m, 1H), 2.06 (m, 1H), 1.89 (dt, 1H, *J* = 5.7, 1.5 Hz), 1.84 (m, 1H), 1.74 (m, 2H), 1.69 (br. s, 3H), 1.52 (m, 2H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 145.3, 143.5, 142.7, 142.1,

*2-Methyl-3-trimethylsilylnorbornadiene (**9c**)*

tert-Butyllithium (0.99 mL, 1.7M, 1.68 mmol) was added to a flame-dried flask containing bromide **8b** (156 mg, 0.845 mmol) in THF (4 mL) at –78°C. After the yellow mixture was stirred for 20 min, chlorotrimethylsilane (0.27 mL, 2.13 mmol) was added at –78°C. The mixture was stirred at –78°C for 45 min then at room temperature for 1 h. After quenching the mixture with water (5 mL), the aqueous layer was extracted with diethyl ether (3 × 10 mL), and the combined organic layers were washed sequentially with water (10 mL) and brine (10 mL) and dried over magnesium sulfate. The solvent was removed by rotary evaporation and the crude product was purified by column chromatography (hexanes) to give **9c** (106 mg, 596 mmol, 71%) as colorless oil. R_f: 0.79 (hexanes). Crystallographic and spectroscopic studies of adducts of indium (III) iodide with two cyclic ketones

M.A. Brown and D.G. Tuck

Abstract: Indium(III) iodide forms a 1:1 adduct with 9-xanthenone, of quasi-tetrahedral structure; triclinic, a = 10.805(4), b = 11.494(4), c = 7.493 (2) Å, α = 104.12(3), β = 106.35(3), γ = 91.165(3)°, V = 860.8(5) Å^3, Z = 2, space group $P\bar{1}$. With 9-fluorenone, the adduct has 1:2 stoichiometry, and approximately D_{3h} symmetry in the InI_3O_2 kernel; the structure is triclinic, a =11.212(2), b = 16.504(3), c = 7.537(2) Å, α = 94.57(2), β = 109.05(1), γ = 91.165(15)°, V = 1312.6(4) Å^3, Z = 2, space group $P\bar{1}$. The solid structures, and the solution chemistry, are compared with those of related neutral derivatives of indium(III) halides.

Key words: Indium(III) iodide, solution chemistry, crystal structures, adducts.

Résumé : L'iodure d'indium(III) forme un adduit 1:1 avec la 9-xanthénone de structure pratiquement tétraédrique; triclinique, groupe d'espace $P\bar{1}$, avec a = 10,805(4), b = 11,494(4) et c = 7,493(2) Å, α = 104,12(3), β = 106,35(3) et γ = 91,165(3)°, V = 860,8(5) Å^3, Z = 2. Avec la 9-fluorénone, l'adduit est de stoechiométrie 1:2 et de symétrie approximativement D_{3h} dans le noyau InI_3O_2; la structure est triclinique, groupe d'espace $P\bar{1}$, avec a = 11,212(2), b = 16,504(3) et c = 7,537(2) Å, α = 94,57(2), β = 109,05(1) et γ = 91,165(3)°, V = 1312,6(4) Å^3, Z = 2. On compare les structures solides et la chimie en solution avec celles de dérivés neutres apparentés d'halogénures d'indium(III).

Mots clés : iodure d'indium(III), chimie en solution, structures cristallines, adduits.

[Traduit par la Rédaction]

Introduction

Structural and spectroscopic studies of the neutral and anionic derivatives of the indium(III) halides have done much to help in elucidating the possible modes of coordination for such molecules in both solution and crystalline phases (1). A recent paper from this laboratory re-examined earlier work on triphenylphosphine and bis(diphenylphosphino)ethane (dppe) adducts of indium(III) iodide, and showed that the species in solution are related to, but not necessarily identical with, those in the solid phase (2). Similar conclusions were reached in analogous studies of gallium(III) iodide derivatives (3).

In addition to the intrinsic interest of such work, the solution behaviour of the neutral adducts of indium(III) halides is fundamental to an understanding of electron transfer reactions involving these compounds and substituted ortho- and paraquinones (4). It proved impossible to obtain crystals of the quinone adducts, and we have therefore studied the structure and spectroscopy of analogous compounds with the cyclic ketones xanthone (9-xanthenone) and 9-fluorenone, which form 1:1 and 1:2 adducts respectively in the solid state.

Experimental section

General techniques

Indium(III) iodide was prepared by reacting gram quantities of the elements in refluxing xylene (5). Xanthone and fluorenone were used as supplied (Aldrich, 98% pure). Solvents were distilled from suitable drying agents, and stored over molecular sieves.

Microanalysis was by Canadian Microanalytical Services Ltd. Carbon-13 and proton NMR spectra were recorded on a Bruker AC300L instrument ($\delta(Me_4Si)$ = 0), and infrared spectra on a Nicolet 3DX spectrometer.

Preparative

(i) Xanthone

Xanthone (0.20 g, 1.02 mmol) and InI_3 (0.50 g, 1.01 mmol) were dissolved in tetrahydrofuran (50 mL) and the solution was stirred under nitrogen for 12 h at room temperature. The volume of the solution was reduced by 50%; addition of *n*-hexane (10 mL) led to opalescence and on subsequent cooling a pale yellow solid precipitated. This was recrystallized from $CHCl_3$ to give pale yellow crystals of the 1:1 adduct, $InI_3(C_{13}H_8O_2)$. Anal. calcd. for $C_{13}H_8InI_3$: C 22.6, H 1.17; found: C 23.6, H 1.25. Yield 0.42 g, 61%. This compound is highly sensitive to moisture.

(ii) Fluorenone

In a similar reaction involving InI_3 (0.50 g, 1.01 mmol) and fluorenone (0.20 g, 1.1 mmol), the solution became red after about 30 min. Evaporation of the solvent after 12 h stirring gave orange-red crystals suitable for X-ray crystallography. This product is the 1:2 adduct, $InI_3(C_{13}H_8O)_2$. Anal. calcd. for $C_{26}H_{16}O_2InI_3$: C 36.5, H 1.88; found: C 36.5, H 1.87. Yield 0.38 g, 81% based on fluorenone.

Crystallographic analysis

The procedures for both $InI_3(C_{13}H_8O_2)$ **(1)** and $InI_3(C_{13}H_8O)_2$ **(2)** were essentially identical. A suitable crystal on a glass fibre was mounted in a Rigaku AFC6S diffractometer, equipped with graphite monochromated Mo-Kα radiation (λ = 0.71069 Å) and a rotating anode generator. Cell constants, and orientation matrices for data collection, were obtained from least-squares refinements, using 20 carefully centred reflections in the range $12.61 < 2\theta < 19.62°$. In each case, the space group was uniquely identified as $P\bar{1}$ (No. 2) by the lack of systematic absences, and this was confirmed by subsequent solution and refinement of the structures. Details of the intensity collection are given in Table 1. The intensities of three representative reflections were measured after every 150 reflections, and a linear correction factor was applied to correct for decay. Absorption corrections were made using PSI scan, and the values were also corrected for Lorentz and polarization effects. The structure was solved by direct methods, and expanded using Fourier techniques. In refining **1**, all non-hydrogen atoms were refined anisotropically, but for **2**, only In, I, and O were so treated due to the restricted data available. In both cases, hydrogen atoms on carbon were included in ideal positions (r = 0.95 Å), but were not refined. The final Fourier difference map calculations showed no peaks of chemical significance.

Neutral-atom scattering factors were taken from Cromer and Waber (6). Anomalous dispersion effects were included in the calculations (7); the values for $-f'$ and $-\Delta f''$ were those published by Cromer (8). All calculations were performed using the TEXSAN[2] crystallographic software package. The structures of the molecules are shown in Figs. 1 and 2, positional parameters are in Tables 2 and 4, and important bond distances and angles in Tables 3 and 5.

Tables of hydrogen-atom coordinates and thermal parameters and anisotropic thermal parameters for other atoms, other other bond distances and angles, and least-squares planes are available as supplementary data.[3]

Results and discussion

Crystallographic studies

The structure of the xanthone adduct of InI_3 (Fig. 1) demonstrates quasi-tetrahedral symmetry, which is rare for neutral adducts of indium(III) halides, and especially unusual when the ligand is an oxygen-donor, since such ligands typically form 1:2 or 1:3 complexes (1). The In—I bond distances are in the normal range for analogous four-coordinate adducts (r = 2.68 ± 0.04 Å (9)), but slightly lower by approx. 0.02 Å than those in substituted phosphino com-

Fig. 2. The molecular structure of $InI_3(C_{13}H_8O)_2$, showing the numbering system; ORTEP diagram, with 30% probability ellipsoids.

plexes (2). Other noteworthy features are the range of values, 2.654(2)–2.672(1) Å, and the fact that the sum of the angles at the indium atom is 648.8° which is significantly different from that calculated for tetrahedral coordination (657°).

The In—O bond distance, 2.1872(6) Å, is close to that in compounds with strongly polar In—O bonds; for example, r(In—O)(av) = 2.22(1) Å in In(TBSQ)Br_2pic$_2$(10) TBSQ (= 3,5-di-*tert*-butyl-1,2-semiquinonate; pic = 4-methylpyridine), 2.128(7) Å in In($O_2C_6Cl_4$)Clpic$_3$ (11), and 2.124(3) and 2.164(3) in $InCl_2$(acac)py$_2$ (12) (acac = 2,4-pentanedionate). These last three molecules are six-coordinate, and lower values of r(In—O) are to be expected in four-coordinate species in the light of related studies (cf. ref. 10). The C=O bond distance in the xanthone moiety is 1.25(5) Å, which is the same within experimental uncertainty as the value reported for 1,3,4,6,7,9-hexachloroxanthenone, 1.211(13) Å (13);

there does not appear to have been a structural determination of unsubstituted xanthone. There are no other significant differences between the coordinated xanthone and hexachloroxanthenone.

The reaction between indium(III) iodide and 9-fluorenone yields the 1:2 adduct, whose molecular structure in the solid state is based on an InI_3O_2 kernel of approximate D_{3h} symmetry (O1-In-O2 = 173.8(4°); sum of I-In-I angles = 360°). The In—I bond distances in this case are longer on average than in **1**, but significantly smaller than in the analogous phosphino derivatives $(InI_3(PPh_3)_2$, *r*(In—I) = 2.707(1) Å (2); $InI_3(PMePh_2)_2$, *r*(In—I) = 2.736(4), 2.762(2), and 2.776(2) Å (14); $[InI_3(dppe)]_3$, *r*(In—I) = 2.729(2), 2.730(2), and 2.766(3) Å (2); $(InI_3)_3(dppe)_2$ *r*(In—I) = 2.731(15) Å (15)), all of which have the same trigonal bipyramidal stereochemistry at the indium centre. The increased In—I bond distance between four and five-coordinate species is in keeping with earlier observations (9), but the significant reduction on replacing a phosphorus ligand with an oxygen donor is surprising. It seems unlikely that this is due solely to the effect of inter-ligand repulsion, since all the neutral ligands in question are quite bulky.

The In—O bonds in this molecule (*r* = 2.33(1), 2.37(1) Å) are substantially longer than in the xanthone adduct (see above), in keeping with the increased coordination number, while the C=O bonds in the coordinated ketone are identical within experimental error with that in free 9-fluorenone (1.21(2) and 1.25(2), compared with 1.220(4) Å (16)). These interdependent results indicate a relatively weak ketone → metal donation, in which case the tightening of the In—I bonds relative to those in the substituted phosphino derivatives can be ascribed to a higher positive charge at the metal in the former case.

A comparison with recent results on the 1:1 adducts of these ligands with $AlCl_3$(17) supports the argument that coordination is weak in the bis-fluorenone derivative of InI_3. The C=O bond in $AlCl_3$(fluorenone) is shorter than in the free ligand by ca 0.07 Å, and a similar result is found for the xanthenone analogue (ca. 0.05 Å). With adducts of InI_3, as noted above, there is no significant change in *r*(C=O), implying that coordination to $AlCl_3$ is stronger, in keeping with the higher charge density on the smaller metal atom. Similarly, the changes in ν(C=O) on coordination to InI_3 are ca. 5 cm^{-1} for both ligands, and these are also lower than the comparable values in the 1:1 adducts with $AlCl_3$.

We note finally an important common feature in the adducts of these cyclic ketones with both $AlCl_3$ and InI_3, namely the non-linear In—O=C bonding. The bond angles at oxygen are 159(2) and 164(2)° (av) for InI_3 and xanthone and 9-fluorenone respectively, while the values in the corresponding $AlCl_3$·L compounds are 160.0(7) and 150.2(3)° (17). This has important effects in the spectroscopic properties of

these adducts, and of the related substituted paraquinonate derivatives (4, 17).

Solution chemistry

The formation of InI_3L and InI_3L_2 with xanthone and 9-fluorenone respectively under essentially identical preparative conditions parallels a number of earlier reports in which slight changes in ligand, or solvent, were shown to affect the stoichiometry of the adduct (1, 2, 3, 18, 19). The underlying phenomenon is the existence of the solution equilibria.

$$[1] \qquad InX_3 \rightleftarrows InX_3L \rightleftarrows InX_3L_2 \rightleftarrows InX_3L_3$$

whose overall balance depends on the factors noted. In studies of the substituted phosphino derivatives of GaI_3, ^{31}P NMR spectroscopy proved to be useful in investigating the solution chemistry, and in particular processes such as eq.[1]. The ^{13}C spectra of xanthone and InI_3 (xanthone) are identical except for a small shift in *C*=O, from 177.06 to 178.95 ppm (Me_4Si = 0), and the analogous values for fluorenone and InI_3(fluorenone)$_2$ are 195.66 and 196.93 ppm. These changes are too small to allow any meaningful study of solution processes by ^{13}C NMR spectroscopy.

At first sight, it is surprising that two such apparently similar ligands as xanthone and 9-fluorenone should give adducts of different stoichiometry, and in the absence of quantitative studies (see above) it is tempting to seek an explanation based on steric or electronic effects. Before embarking on any discussion of such concepts, it should be recalled that the reaction of InI_3 and triphenylphosphine in ethyl acetate gave $InI_3(PPh_3)_2$ as the only product, but that attempts to recrystallise this compound from the same solvent gave a crystalline equimolar mixture of $InI_3(PPh_3)$ and $InI_3(PPh_3)_2$, while recrystallisation from cyclohexane yielded only $InI_3(PPh_3)$ (2,19). These results emphasize how finely balanced are the energetics of eq. [1]. In the present case, the slight structural and spectroscopic changes in xanthone and 9-fluorenone on complexation indicate the formation of weak complexes, so that the dissociation of InI_3L_2 to InI_3L and L, and the consequent formation of adducts of differing stoichiometry, is not surprising. Extended studies of solvent effects, and of the stoichiometry of adducts of InI_3 and different cyclic ketones, might well produce results similar to those with substituted phosphines (2, and refs. therein): it is not our intention to pursue such investigations.

The synthesis of hydroxysmirnovine

Veejendra K. Yadav, Philip Williams, and Michael Benn

Abstract: The synthesis of *N*-(4-acetamidobutyl)-*N*-((*Z*)-4-hydroxy-3-methyl-2-butenyl) guanidine confirmed this as the structure of the natural product hydroxysmirnovine.

Key words: hydroxysmirnovine, synthesis, naturally occurring guanidines.

Résumé : Comme suite à la synthèse de la *N*-(4-acétamidobutyl)-*N*-[(*Z*)-4-hydroxy-3-méthylbutén-2-yl]guanidine, cette structure est attribuée à l'hydroxysmirnovine, un produit naturel.

Mots clés : hydroxysmirnovine, synthèse, guanidines naturelles.

[Traduit par la Rédaction]

Introduction

In the course of an investigation of the constituents of *Galega orientalis* Lam. cv. Gale, "Fodder Galega", a plant being considered as a cold-hardy crop for Northern Canada, we isolated two compounds which we identified as hemiterpenoidal guanidines: the known smirnovine, and its previously unknown (*Z*)-4-hydroxy derivative (**1**), which we named hydroxysmirnovine (1).

We confirmed the identity of the former by synthesis, while that of the latter rested upon its spectrometric characterization. The biological role of these guanidines is unknown and, as their isolation was tedious, we decided to develop a synthesis of hydroxysmirnovine with the intention of obtaining material for biological testing as well as checking the proposed structure.

Results and discussion

As for the synthesis of smirnovine, our general strategy was to assemble the appropriate secondary amine and then elaborate it into the guanidine (see Scheme). Guided by the Leonard and Playtis synthesis of hydroxygalegine (2), we utilized the [4 + 2] cycloaddition reaction of 1-chloro-1-nitrosocyclohexane with isoprene to make the dihydro-1,2-oxazine (**2**), the ring system of which might be cleaved to generate the (*Z*)-4-amino-2-methyl-2-buten-1-ol fragment of **1**.

Alkylation of **2** with *N*-(4-bromobutyl)phthalimide provided **3,** after which the phthalimido group was replaced by hydrazinolysis, and subsequent acetylation to afford **4**. The reductive ring scission of **4** proved more troublesome than we had expected for the dihydrooxazine was recovered unchanged from a variety of treatments with zinc dust in acetic acid, with or without heating, and including the addition of hydrochloric acid (3, 4). However, treatment with aqueous sulfuric acid and zinc dust, at room temperature, smoothly converted **4** into the desired secondary amine **5**.

The guanidination procedure which we had developed for the synthesis of smirnovine, involving sequential treatment of the secondary amine with phenyl cyanate and ammonia-ammonium nitrate (1), gave a very low yield of material with the spectroscopic properties expected for **1**. Apparently 1,2-elimination from the intermediate phenyl imidate to form a cyanamide predominated over the desired nucleophilic ammonolysis. We therefore resorted to the method recently described by Lipton (5) and treated **5** with *N*,*N*′-bis(*tert*-butoxycarbonyl)-thiourea (**6**) in the presence of a stoichiometric amount of Mukaiyama's reagent (**7**). This gave the desired bis(*tert*-butoxycarbonyl)guanidine (**8**), albeit in low yield (25%, ca. 40% based on recovered **5**). Probably, as a referee has suggested, this step could be further improved by using Goodman's new procedure for the guanidinylation of amines (9). However, we completed our synthesis at this point by treating **8** with trifluoroacetic acid in dichloromethane. Passage of the reaction product through an anion exchange column (OH form) then afforded the desired compound (**1**), which had identical spectrometric (^{1}H-, and ^{13}C NMR) properties with those of the hydroxysmirnovine which we had isolated from *G. orientalis*.

Experimental

Instrumentation

NMR spectra reported here were recorded, using a Bruker DRX-400 spectrometer. For samples dissolved in $CDCl_3$, the spectra were referenced to residual $CHCl_3$ at 7.27 ppm, or the centre line of the $CDCl_3$ resonance at 77 ppm; for solutions in D_2O the signals were referenced to the methyl resonances (δ_H and δ_C = 0) of sodium trimethylsilylpropionate-[2,3-$^2H_4$]. TLC was performed using Merck silica gel 60 F-254, 0.2 mm on aluminum sheeting (Cat. 5562).

Scheme 1.

3,6-Dihydro-5-methyl-N-*(4-phthalimidobutyl)-2*H-*1,2-oxazine (3)*: To a solution of *N*-(4-bromobutyl)phthalimide (1.40 g, 4.96 mmol) (6) and 5-methyl-3,6-dihydro-1,2-oxazine hydrochloride (**2**, 2.01 g, 14.8 mmol) (7) in acetonitrile (100 mL) was added anhydrous sodium carbonate (2.5 g, 24 mmol), and the mixture was boiled under reflux for 16 h. The reaction mixture was then cooled and poured into ice-water (ca. 300 mL). After extraction with chloroform (4 × 50 mL) and removal of solvent from the combined, dried (Na_2SO_4) organic extracts, the reaction product (**3**) was purified by flash chromatography on a column of silica gel 60. The pure product (**3**) eluted with hexane – ethyl acetate (3:1 v/v) and was obtained as a white crystalline solid (1.33 g, 4.63 mmol 89%), mp 82–84°C. MS 300.1472, calcd. for $C_{17}H_{20}N_2O_3$: 300.147. NMR δ_H: 7.84 (2H, m), 7.71 (2H, m), 5.49 (1H, m), 4.15 (2H, v br s), 3.71 (2H, t, J = 7.1 Hz); 3.18 (2H, br m), 2.73 (2H, t, J = 7.1 Hz), 1.77 (2H, pt, J = 7.1 Hz), 1.66 (2H, pt, J = 7.1 Hz); δ_c 168.8 (2C, s), 134.2 (2C, d), 133.7 (2C, s), 132.6 (s), 123.6 (2C, d), 118.0 (d), 72.1 (t), 58.3 (t), 55.3 (t), 38.2 (t), 26.7 (t), 24.7 (t), and 18.4 (q).

N-*(4-acetamidobutyl)-2,3-dihydro-5-methyl-2*H-*1,2-oxazine (4)*: Hydrazine hydrate (345 mg, 6.9 mmol) was added to a solution of **3** (1.03 g, 3.4 mmol) in ethanol (30 mL) and the mixture was boiled under reflux for 3 h, at the end of which time analytical TLC (hexane – ethyl acetate 3:2 v/v) revealed no residual starting material. The mixture was filtered

© 2000 NRC Canada

and the filter cake washed with cold ethanol. The filtrate and washings were then evaporated to dryness and the solid residue was dissolved in pyridine (3 mL). Acetic anhydride (3.5 mL) was added, and the mixture left at room temperature overnight. The reddish reaction mixture was evaporated under vacuum, a process which was repeated twice more after adding water (ca. 1 mL), and the residue was then stirred with saturated aqueous sodium carbonate solution (4 mL), and extracted with chloroform (3 × 5 mL). The combined chloroform extracts were dried (Na_2SO_4) and evaporated to leave an oily residue (760 mg) which crystallized when stored overnight in a refrigerator. Recrystallization of this material from acetone-hexane afforded **4** as fine colourless needles, mp 120°C (512 mg, 2.41 mmol, 71%). NMR δ_H 5.99 (1H, br s, exchanged with D_2O), 5.50 (1H, br s), 4.16 (2H, v br s), 3.24 (q, becoming t with D_2O, J = 6.8 Hz), 3.18 (4H, br m), 2.70 (2H, t, J = 6.8 Hz), 1.94 (3H, s), 1.64 (3H, s, on 2H, m), and 1.58 (2H, pt, J = 6.8 Hz); δ_c 169.9 (s), 133.3 (s), 117.5 (d), 71.7 (t) 58.1 (t), 54.8 (t), 39.5 (t), 27.4 (t), 24.5 (t), 23.3 (q), and 18.0 (q).

N,N-*(4-acetamidobutyl)((Z)-4-hydroxyl-3-methyl-2-butenyl)amine (**5**)*: Zinc dust (700 mg, 11 mmol) was added over 1 h to a stirred solution of **4** (100 mg, 4.7 mmol) in 1 M aqueous sulfuric acid (13 mL). More zinc dust (400 mg, 6 mmol) was added over the next 30 min, and, finally, another portion (200 mg, 3 mmol) over the next 15 min. The reaction mixture was stirred for a further 1 h, then filtered and the residual zinc was washed with water (2 × 2 mL). The combined filtrate and washings were chilled in an ice-water bath and made alkaline (to pH ca. 10, indicator paper) with aqueous ammonia (d = 0.88). The solution was then diluted with ethanol (ca. 5 mL) and evaporated to dryness under reduced pressure (bath < 35°C). More ethanol (5 mL) and chloroform (5 mL) were added to the residue and the mixture taken to dryness as before. The residual solid was then extracted with chloroform (4 × 7 mL), the combined extracts were dried (Na_2SO_4) and evaporated under reduced pressure to yield **5** as a colourless oil, homogeneous by TLC and NMR analyses, (95 mg, 4.4 mmol, 94%). NMR δ_H 6.20 (1H, br s), 5.48 (1H, t, J = 6.7 Hz), 4.05 (2H, s), 3.20 (4H, m), 2.61 (2H, t, J = 6.7 Hz), 1.94 (3H, s) 1.76 3H, (s), and 1.52 (4H, br m); δ_c 170.2 (s), 142.0 (s), 123.2 (d), 62.8 (t), 48.5 (t), 46.2 (t), 39.2 (t), 27.1 (t), 26.9 (t), 23.2 (q), and 22.5 (q).

N-*(4-acetamidobutyl)* N-*((Z)-4-hydroxyl-3-methyl-2-butenyl) N′N″-bis-(*tert-*butoxycarbonyl) guanidine (**8**)*: Mukaiyama's reagent (*N*-methyl-2-chloropyridinium iodide (Aldrich Chem. Co.) **7**, 104 mg, 0.41 mmol) was added to a solution of the amine **5** (72.4 mg, 0.34 mmol) and *N*,*N*′-bis-(*tert*-butoxycarbonyl)thiourea (**6**) (112 mg, 0.41 mmol) in dichloromethane (3.5 mL), and the mixture was stirred at room temperature for 42 h. Initially a sticky solid was present but this was replaced by a free-floating crystalline solid. The suspension was filtered, and the yellow solid was washed with dichloromethane. The combined filtrate and washings were evaporated to a solid residue which was taken up in a little methanol and this solution was then passed through a column of Dowex-1 ion exchange resin (OH form, 20–50 mesh, 1.0 × 10 cm). The column was washed with methanol and the combined eluates and washings were evaporated under reduced pressure to yield a solid residue (85 mg). Flash column chromatography of this material with chloroform containing increasing amounts of methanol (0–20% v/v) eluted a substance which was homogeneous by TLC R_F 0.12 (silica gel, chloroform – methanol 95:5 v/v) and NMR analyses, (24 mg, 0.053 mmol, 15%) with more of this product (20 mg) in a fraction which contained small amounts of impurities). NMR δ_H 5.24 (1H, t, J = 7.1 Hz), 4.10 (2H, s), 4.05 (2H, d, J = 7.1 Hz), 3.35 (2H, t, J = 7.2 Hz), 3.25 (2H, q, becoming t with D_2O, J = 6.8 Hz), 1.96 (3H, s), 1.82 (3H, br s), 1.66 (2H, pt, J = 7.2 Hz), and 1.46 (18 H, s on 2 H, m); δ_c 170.4 (s), 154.9 (s), 140.0 (s) 120.7 (t), 80.9 (s), 61.2 (t), 45.9 (t), 38.7 (t), 37.6 (t), 28.1 (q, 6C), 26.4 (t), 24.7 (t), 23.1 (q), and 21.6 (q).

The dichloromethane-insoluble yellow solid was also dissolved in methanol and passed through a column of Dowex-1 resin (OH form). Evaporation of the eluates and washings gave a residue (58 mg) whose H-1 NMR spectrum revealed it to be a mixture of **5** and 2-chloropyridine.

N-*(4-acetamidobutyl)* N-*((Z)-4-hydroxy-3-methyl-2-butenyl) guanidine, Hydroxysmirnovine (**1**)*: The bis-BOC guanidine (**8**) (24 mg, 0.053 mmol) was dissolved in dichloromethane (4 mL) to which trifluoroacetic acid (6 drops) was added and the mixture was boiled under reflux for 5 h, after which TLC revealed the reaction to be complete. The solvent and excess trifluoroacetic acid were stripped off under reduced pressure, and the residue was dissolved in methanol and passed through a column of Dowex-1 resin (OH form) and the column washed with methanol. Evaporation of the eluates yielded **1** as a colourless oil (13 mg, 0.051 mmol, 95%), whose spectrometric properties (H-1 and C-13 NMR, and MS) were the same as those of the natural hydroxysmirnovine (1) δ:$_H$ (D_2O) 5.38 (1H, t, J = 6.7 Hz), 4.16 (2H,s) 4.05 (2H, d, J = 6.7 Hz), 3.35 (2H, t, J = 6.8 Hz), 3.20 (2H, t, J = 6.8Hz), 1.99 (3H,s), 1.82 (3H, br s), 1.66 (2H, pt, J = ~7 Hz), and 1.55 (2H, pt J = ~7 Hz); δ_C (D_2O) 176.9 (s), 159.3 (s), 142.2 (s), 124.0 (d), 62.8 (t), 50.9 (t), 48.9 (t), 41.7 (t), 28.4 (t), 26.8 (t), 24.7 (q), and 23.5 (q).

Diphenylboron complexes of the enol tautomers of arylpyruvic acids. Crystal and molecular structure of triethylammonium (2-nitrophenyl)pyruvato-diphenylboron(1-)[1]

Wolfgang Kliegel, Jens O. Pokriefke, Steven J. Rettig, and James Trotter

Abstract: Synthesis has been carried out of 15 examples of anionic diphenylboron complexes of arylpyruvic acids, and the structures of the compounds have been determined from spectroscopic data and from X-ray analysis of one of the compounds. Crystals of **5j** are monoclinic, $P2_1/n$, a = 9.5566(10), b = 15.961(3), c = 16.6382(6) Å, β = 99.3239(10)°, and Z = 4, at 180 K. The structure was solved by direct methods and refined by full-matrix least-squares procedures to $R(F^2)$ = 0.056 for 6662 CCD data. **5j** contains a triethylammonium cation and an anion containing a planar five-membered OBOCC ring, with cation and anion linked by an N-H···O hydrogen bond. Spectroscopic data and bond distances establish that the pyruvate ligand is the enol-tautomeric state.

Key words: arylpyruvic acids, enol tautomers, boron complexes, diphenylboron chelates, organoborate salts, crystal structure.

Résumé : On a réalisé la synthèse de quinze complexes diphénylbore anioniques d'acides arylpyruviques et on en a déterminé les structures à partir de données spectroscopiques et de diffraction des rayons X. Les cristaux du composé **5j** sont monocliniques, groupe d'espace $P2_1/n$, avec a = 9,5566(10), b = 15,961(3) et c = 16,6382(6) Å, β = 99,3239(10)° et Z = 4, à 180 K. On a résolu la structure par des méthodes directes et on l'a affinée par la méthode des moindres carrés (matrice entière) jusqu'à des valeurs de $R(F^2)$ = 0,056 pour 6662 données CCD. Le composé **5j** contient un cation triéthylammonium et un anion qui comporte un cycle planaire OBOCC à cinq chaînons; le cation et l'anion sont liés par une liaison hydrogène N-H···O. Les données spectroscopiques et les longueurs des liaisons permettent d'établir que le ligand pyruvate est dans l'état tautomère énolique.

[Traduit par la Rédaction]

Introduction

Arylpyruvic (2-oxo-3-arylpropanoic) acids, **1**, which are significant products and intermediates in the metabolism of amino acids like phenylalanine, tyrosine, or tryptophane (1) exhibit keto-enol tautomerism (2–6). Both tautomers have been identified in spectroscopic and chemical experiments, as for example about 90% of the keto form **1** in aqueous solution, or almost exclusive presence of the enol form **2** in DMSO solution (3–5). For the solid state, the enol form **2** has been found recently by an X-ray crystallographic analysis of the structure of phenylpyruvic acid (7).

Boric acid reacts with the enol tautomer of arylpyruvic acids trapping the enol form in solution (2). This reaction is used in the spectrophotometric analysis of arylpyruvates in biological and clinical chemistry, and was introduced as the "enol-borate-method" in the determination of enzymatic activities or of the concentration of substrates or products in many biochemical reactions that involve an arylpyruvic acid as an educt, intermediate, or product (8). The enol-borate 2:1-complex, **3**, first suggested by Knox and Pitt (2), had been defined on the grounds of spectrophotometric studies. From the preceding and fundamental work of Böeseken and coworkers (9) it is generally known that the conductivity of boric acid solutions can be enhanced also by 2-oxocarbonic acids, presumably mainly by virtue of the hydrated carbonyl group, enabling the borate complex formation, although the possibility of enolization was considered, too.

To corroborate the assumption of an enol-borate complex structure we report here the synthesis of the anionic diphenylboron chelate complexes of several arylpyruvic acids, carried out in the course of our investigations on organoboron

Experimental

General procedures

Arylpyruvic acids were commercial products. Oxybis(diphenylborane) was prepared according to literature methods (11). All reactions were carried out under normal conditions, without protective gas atmosphere. Melting points (uncorrected): Büchi SMP 20 apparatus. IR: Philips PU 9800 FT-IR-Spectrometer, V 3.00 and ATI Mattson Genesis Series FT-IR™ Rev. I, ATI Unicam. ^{1}H NMR: Varian EM 390. ^{11}B NMR: Bruker AC 200. Elemental analyses: Carlo Erba CHNO elemental analyzer 1106; boron titrimetrically after Schöniger-oxidation with Metrohm-Potentiograph E 536/Dosimat 655.

4-Arylmethylene-2,2-diphenyl-1,3-dioxa-2-boratacyclopentan-5-one, tertiary ammonium salts (5)

General procedure: The arylpyruvic acid **1/2** (5 mmol) and oxybis(diphenylborane) (0.87 g, 2.5 mmol) are dissolved in 5 mL of ethanol under slight heating. After cooling to room temperature the amine (5 mmol) is added. Crystallization starts spontaneously or upon cooling. The product is analytically pure in most of the cases, or is recrystallized from absolute ethanol.

The compounds **5** give a blue colored solution upon the addition of diphenylcarbazone in ethanol, indicating the presence of the chelated diphenylborenium (Ph_2B^+) ion (12).

2,2-Diphenyl-4-phenylmethylene-1,3-dioxa-2-boratacyclopentan-5-one, triethylammonium salt (5a)

From phenylpyruvic acid (0.82 g, 5 mmol) and triethylamine (0.51 g, 5 mmol). Yield: 1.83 g (85%) of colorless crystals; mp 154°C. IR (KBr, cm^{-1}): 1667 (C=O), 1654 (C=C); ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ (ppm): 0.93 (t, J = 7 Hz, 3 CH_3), 2.37–2.93 (m, 3 NCH_2), 6.00 (s, C=CH), 6.87–7.77 (m, 13 aromatic H), 7.87 (d, J = 7 Hz, 2 aromatic H), 9.67 (s, broad, exchangeable, NH); ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3) δ (ppm): 8.7 ($w_{1/2}$ = 385 Hz). Anal. calcd. for $C_{27}H_{32}BNO_3$: C 75.53, H 7.51, B 2.52, N 3.26; found: C 75.56, H 7.55, B 2.53, N 3.18.

2,2-Diphenyl-4-phenylmethylene-1,3-dioxa-2-boratacyclopentan-5-one, 1-methylpyrrolidinium salt (5b)

From phenylpyruvic acid (0.82 g, 5 mmol) and 1-methylpyrrolidine (0.43 g, 5 mmol). Yield: 1.72 g (83%) of colorless crystals; mp 155°C. IR (KBr, cm^{-1}): 1672 (C=O), 1645 (C=C); ^{1}H NMR (90 MHz, $CDCl_3$–TMS) δ: (ppm): 1.73 (m, $(CH_2)_2$), 2.37 (s, CH_3), 2.77 (m, CH_2NCH_2), 6.13 (s, C=CH), 7.00–7.80 (m, 13 aromatic H), 7.97 (d, J = 7 Hz, 2 aromatic H), 9.27 (s, broad, exchangeable, NH); ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3), δ (ppm): 11.1 ($w_{1/2}$ = 470 Hz). Anal. calcd. for $C_{26}H_{28}BNO_3$: C 75.56, H 6.83, B 2.62, N 3.39; found: C 75.63, H 6.86, B 2.66, N 3.24.

2,2-Diphenyl-4-phenylmethylene-1,3-dioxa-2-boratacyclopentan-5-one, 1-methylpiperidinium salt (5c)

From phenylpyruvic acid (0.82 g, 5 mmol) and 1-methylpiperidine (0.50 g, 5 mmol). Yield: 1.67 g (78%) of

4-(2′-Nitrophenyl)methylene-2,2-diphenyl-1,3-dioxa-2-boratacyclopentan-5-one, methylpiperidinium salt (5l)

From (2-nitrophenyl)pyruvic acid (1.05 g, 5 mmol) and 1-methylpiperidine (0.50 g, 5 mmol). Yield: 1.93 g (82%) of orange-yellow crystals; mp 141°C. IR (KBr, cm^{-1}): 1688 (C=O), 1633 (C=C), 1525 and 1323 (N=O); ^{1}H NMR (90 MHz, $CDCl_3$–TMS), δ (ppm): 1.00–2.00 (m, $(CH_2)_3$), 2.50 (s, CH_3), 2.80–4.00 (m, CH_2NCH_2), 6.60 (s, C=CH), 6.90–8.20 (m, 13 aromatic H), 8.93 (d, J = 7 Hz, 1 H of nitrophenyl), NH detected only by exchange; ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3), δ (ppm): 10.5 ($w_{1/2}$ = 342 Hz). Anal. calcd. for $C_{27}H_{29}BN_2O_5$: C 68.65, H 6.20, B 2.29, N 5.93; found: C 68.77, H 6.23, B 2.29, N 6.11.

4-(2′-Nitrophenyl)methylene-2,2-diphenyl-1,3-dioxa-2-boratacyclopentan-5-one, 1-aza-4-azoniabicyclo[2.2.2]octane salt (5m)

From (2-nitrophenyl)pyruvic acid (1.05 g, 5 mmol) and 1,4-diazabicyclo[2.2.2]octane (0.56 g, 5 mmol). Yield: 2.13 g (88%) of yellow crystals; mp 184°C. IR (KBr, cm^{-1}): 1675 (C=O), 1631 (C=C), 1517 and 1332 (N=O); ^{1}H NMR (90 MHz, DMSO-d_6–TMS), δ (ppm): 3.10 (m, $N(CH_2CH_2)_3$), 3.53 (s, C=CH), 7.00–8.00 (m, 13 aromatic H), 8.80 (d, J = 7 Hz, 1 H of nitrophenyl); ^{11}B NMR (64 MHz, DMSO-d_6–Et_2OBF_3), δ (ppm): 8.6 ($w_{1/2}$ = 470 Hz). Anal. calcd. for $C_{27}H_{28}BN_3O_5$: C 66.82, H 5.81, B 2.23, N 8.66; found: C 67.11, H 5.95, B 2.24, N 8.61.

4-(2′-Nitrophenyl)methylene-2,2-diphenyl-1,3-dioxa-2-boratacyclopentan-5-one, 4-dimethylaminopyridinium salt (5n)

From (2-nitrophenyl)pyruvic acid (1.05 g, 5 mmol) and 4-dimethylaminopyridine (0.61 g, 5 mmol). Yield: 2.26 g (91%) of a yellow powder; mp 214°C. IR (KBr, cm^{-1}): 1686 (C=O), 1646 (C=C), 1515 and 1320 (N=O); ^{1}H NMR (90 MHz, DMSO-d_6–TMS), δ (ppm): 3.20 (s, 2 CH_3), 6.20 (s, C=CH), 6.97 and 8.20 (d and d, AA′BB′, J = 7 Hz, 4 H of pyridine), 7.03–8.00 (m, 13 aromatic H), 8.80 (d, J = 7 Hz, 1 H of nitrophenyl), NH detectable only by exchange; ^{11}B NMR (64 MHz, DMSO-d_6–Et_2OBF_3), δ (ppm): 11.2 ($w_{1/2}$ = 428 Hz). Anal. calcd. for $C_{28}H_{26}BN_3O_5$: C 67.89, H 5.29, B 2.18, N 8.84; found: C 67.88, H 5.41, B 2.19, N 8.29.

2,2-Diphenyl-4-phenylmethylene-1,3-dioxa-2-boratacyclopentan-5-one, dicyclohexylammonium salt (5o)

From phenylpyruvic acid (0.87 g, 5 mmol) and dicyclohexylamine (0.91 g, 5 mmol). Yield: 0.37 g (15%) of colorless crystals; mp 173°C. IR (KBr, cm^{-1}): 1677 (C=O), 1645 (C=C); ^{1}H NMR (90 MHz, $CDCl_3$–TMS), δ (ppm): 0.67–2.20 (m, 2 $(CH_2)_5$), 2.97 (m, CH-N-CH), 5.97 (s, C=CH), 6.87–7.80 (m, 13 aromatic H), 7.90 (d, J = 7 Hz, 2 H of aromatic H), NH_2 detected only by exchange; ^{11}B NMR (64 MHz, $CDCl_3$–Et_2OBF_3), δ (ppm): 10.6 ($w_{1/2}$ = 385 Hz). Anal. calcd. for $C_{33}H_{40}BNO_3$: C 77.80, H 7.91, B 2.12, N 2.75; found: C 77.87, H 7.99, B 2.18, N 2.64.

X-ray crystallographic analysis of 5j

Crystallographic data appear in Table 1. The final unit-cell parameters were obtained by least-squares based on 13215 reflections with 2θ = 4.0–60.1°. The data were processed,[3] corrected for Lorentz and polarization effects, and absorption (based on analysis of symmetry-equivalent data).

Fig. 1. View of the structure of **5j**; 50% probability thermal ellipsoids are shown for the non-hydrogen atoms.

The structures were solved by direct methods, the coordinates of the non-hydrogen atoms being determined from *E*-maps or from subsequent difference Fourier syntheses. The non-hydrogen atoms were refined with anisotropic thermal parameters, and the hydrogen atoms were refined with isotropic thermal parameters. No corrections for secondary extinction were necessary. Neutral atom scattering factors for all atoms and anomalous dispersion corrections for the non-hydrogen atoms were taken from the *International Tables for X-Ray Crystallography* (13). Selected bond lengths and angles are listed in Table 2. Complete tables of atomic coordinates and equivalent isotropic thermal parameters, anisotropic thermal parameters, bond lengths and angles, torsion angles, intermolecular contacts, and least squares planes are included as supplementary material.[4]

Results and discussion

From the reaction of various arylpyruvic acids **1/2** (Ar = phenyl, 4-hydroxyphenyl, 2-nitrophenyl) with diphenylborinic acid anhydride (oxybis(diphenylborane)) in ethanol, the corresponding diphenylboron chelate complexes **4** could not be isolated. After addition of a tertiary amine, however, the respective salts **5** crystallized from the solution. A selection of different sufficiently basic amines was used with the intention of finding a compound with good crystallizing qualities, making possible an X-ray analysis of an example of **5**. The tertiary amines gave the salts **5a–n** in near-quantitative amounts, whereas dialkylamines did not give satisfactory yields of crystalline compounds (one example (**5o**) is included here, 15% yield). Use of primary amines was omitted because of possible azomethine formation; arylpyruvic acids and other α-ketocarbonic acids react with primary amines and diphenylborinic acid to give five-membered boron chelates with an N→B coordination.[5]

The compounds **5** have elemental analyses and ^{1}H NMR spectroscopic data consistent with the postulated diphenylborinate complex salt. The intact diphenylboron moiety is indicated by rechelatization of the Ph_2B^+ ion with diphenylcarbazone, resulting in a blue color reaction (12). A boron chelate system as in **5** is also confirmed by the ^{11}B NMR spectra, which all display typical signals for a tetracoordinated boron nucleus around $\delta(Et_2OBF_3) \sim 10$ ppm (14). In the infrared spectra of **5**, strong absorption bands between 1653 and 1688 cm^{-1} and less-intense bands between 1631 and 1654 cm^{-1} indicate the carboxyl-C=O and the enol-C=C stretching vibrations, respectively. The enol character of the arylpyruvate ligands is demonstrated by one-proton signals of the corresponding O-C=CH moiety in the ^{1}H NMR spectra of **5** between δ(TMS) 5.73 and 6.63 ppm. Crystallization tests with the different substituted arylpyruvato boron com-

pounds revealed that the triethylammonium salt of the 2-nitrophenylpyruvate complex, **5j**, gave the best crystals suitable for an X-ray analysis.

The structure of **5j** contains cation-anion pairs (triethylammonium cations and boron-containing anions), linked by an N(2)-H···O(2) hydrogen bond between the amine nitrogen atom and the carboxyl C=O of the arylpyruvato ligand (Fig. 1): N···O = 2.793(2), N-H = 0.97(1), H···O = 1.84(1) Å, N-H···O = 167(1)°; the somewhat bent N-H···O arrangement may be the result of steric interaction with neighboring groups such as the C(16)-C(21) phenyl ring, and of the orientation of the triethylammonium ion within the crystal lattice and the resulting packing forces.

The anion contains a five-membered boron chelate ring, OBOCC, which is almost exactly planar, and is similar to the boron chelate ring system in compounds of type **6** (10). Maximum atomic displacement from the mean ring plane is only 0.004(2) Å for the B atom, and the maximum torsion angle in the ring is only 0.4(1)°; the ring conformation is a very slight B-envelope. The exocyclic methylene system is also almost planar, although with slightly larger displacements from exact planarity; maximum atomic displacements are 0.015(1) Å for C(2) and 0.04 Å for the less-precisely determined H atom bonded to C(3). The torsion angle about the C=C double bond is 1.8(2)° (for O(3)-C(2)-C(3)-C(4)), so that the configuration around the C=C double bond of the enol function is (*Z*), as in the (free ligand) phenylpyruvic acid. The phenyl groups are all approximately planar, that containing the nitro group showing the largest deviations from exact planarity (maximum atomic displacement 0.014(1) Å); this ring makes an angle of 17° with the methylene plane, and the nitro group is rotated 37.3° out of the phenyl plane, presumably as a result of steric interaction with the methylene H atom.

The C(2)—O(3) and C(2)—C(3) bond distances of 1.341(1) and 1.339(2) Å, respectively, point out clearly the enol-tautomeric state of the ligand, with considerable loss of the double bond character of the carbonyl-C=O and the appearance of the neighboring enol-C=C double bond. The estimated C—O π-bond order is 0.35 from plots of bond length vs. π-bond order (15), or 0.32 from calculation (16). The C=C bond length is normal for Ar-C=C bonds (17), with a calculated π-bond order of 0.998 (16). These C—O and C=C bond lengths in **5j** are similar to those in the enol system in crystalline pyruvic acid, **2** (Ar = phenyl), where the C—O and C=C bond distances are 1.355 and 1.339 Å, respectively, (7).

A considerable difference between the enolate and carboxylate C—O bond lengths in the five-membered chelate ring (C(2)—O(3) = 1.341(4), C(1)—O(1) = 1.309(2) Å) demonstrates the more-pronounced π-bond participation in the latter, and corresponds to the weaker coordinative O—B bond from the carboxylate oxygen atom to boron (O(1)—B = 1.553(2) Å), compared to that from the enolate oxygen to boron (O(3)—B = 1.513(2) Å). Two diphenylboron complexes of type **6** (10) show similar bond length variations, B—O = 1.554(2), 1.551(3) Å for the weaker bonds, and 1.532(2), 1.518(3) Å for the stronger; the C—O distances have corresponding (although not statistically significant) differences, C—O = 1.312(2), 1.304(3) vs. 1.309(2), 1.296(3) Å. A tetrahedral arrangement about the boron atom includes a slightly compressed O-B-O angle of 101.2(1)°, a consequence of the relatively narrow bite of the bidentate ligand, and similar to the corresponding angles in the complexes of type **6** (O-B-O from 99.4 to 100.4°) (10). The C(1)—C(2) bond, 1.498(2) Å, is slightly long for a C(sp^2)—C(sp^2) bond (17), but this is not unexpected as a result of intra-ring angles of 108.8 and 109.5(1)°, and exocyclic angles of 123.1 and 126.5(1)°.

The ion pairs are linked by van der Waals interactions. These include two possibly significant intermolecular C-H···O interactions: C···O = 3.493(2) and 3.399(2) Å, H···O = 2.50 and 2.52(2) Å, C–H···O = 164 and 160(1)°. There are also five intra-anion C-H···O contacts involving methylene and phenyl hydrogen atoms and the nitro and ring oxygen atoms: C···O = 2.721(2)–2.950(2) Å, H···O = 2.23–2.52(2) Å, C–H···O = 96–123(1)°.

The X-ray analysis of **5j** thus proves the expected five-membered chelate anion, and supports the suggestions made for the chelate ring type in arylpyruvatoborate complexes like **3**, with an exocyclic positioning of the enolic C=C moiety, different from the many known borate complexes of 1,3-dicarbonyl compounds which incorporate an endocyclic enolic C=C group (19). To the best of our knowledge **5j** is the first structurally characterized example of an arylpyruvatoborate complex.

Antiviral activity of arylnaphthalene and aryldihydronaphthalene lignans

Christopher Cow, Carmen Leung, and James L. Charlton

Abstract: A practical method for large scale synthesis of 1-arylnaphthalene and 1-aryl-1,2-dihydronaphthalene lignans is described. The method makes use of the classic Stobbe condensation followed by regioselective reactions that provide access to both the common and retrolactone lignans, e.g., **2** and **3**. A total of 25 compounds, many of which are known natural products, were prepared and their antiviral activity against human cytomegalovirus measured.

Key words: lignan, Stobbe, arylnaphthalene, antiviral.

Résumé : On décrit une méthode pratique de réaliser des synthèses à grande échelle de 1-arylnaphtalène et de 1-aryl-1,2-dihydronaphtalène lignanes. La méthode fait appel à la condensation classique de Stobbe suivie de réactions régiosélectives qui conduisent aussi bien aux lignanes normales que rétrolactoniques, par exemple **2** et **3**. On a ainsi préparé vingt-cinq composés, dont plusieurs sont des produits naturels connus, et on a mesuré leur activité antivirale vis-à-vis le cytomégalovirus humain.

Mots clés : lignane, Stobbe, arylnaphtalène, antiviral.

[Traduit par la Rédaction]

Introduction

Lignans are natural products that are well known for their broad spectrum of medicinal properties (1–4). They are found in many plant species and are believed to be derived from the dimerization of two phenyl propanoid units at the central carbons of their side chains (see Scheme 1) (4).

Further cyclization of lignans can lead to cyclolignans, such as 1-arylnaphthalenes, **1**, (as well as reduced 1-arylnaphthalenes and dibenzocyclooctadienes). Natural 1-arylnaphthalene lignans often feature a γ-lactone ring at the 2,3-position most commonly oriented as in structure **2**, but also found as in **3** (retrolactone) (see Scheme 1) (4).

A recent review of the antiviral activity of lignans (5) prompted us to carry out a more extensive study of the antiviral activity of several 1-arylnapthalene and 1-aryl-1,2-dihydronaphthalene lignans, and their analogs. Although several excellent methods for the synthesis of arylnaphthalene lignans have been published (1–4, 6, 7), we sought a simple method that would yield both 1-arylnaphthalene and 1-aryl-1,2-dihydronaphthalene compounds. The general method that we have used is shown in Scheme 2.

The method is short, convergent, and the purification of intermediates is relatively straightforward. Although the classic Stobbe condensation (first step) is well known (8), it appears that the route from the Stobbe diester **5** to the 1-aryl-1,2-dihydroanthracenes **7** has not previously been investigated. DDQ oxidation of **7** led to the arylnaphthalene diesters **8** that could be regioselectively hydrolysed and reduced to form the lactones **2** or **3**. The dihydrodiesters **7** and **8,** and the lactones **2** and **3**, were tested for antiviral activity against human cytomegalovirus using a standard plaque reduction assay.

Results and discussion

The classic Stobbe condensation of diethyl succinate with piperonal (3,4-methylenedioxybenzaldehyde) (**a**), veratraldehyde (3,4-dimethoxybenzaldehyde) (**b**) and 3,4,5-trimethoxybenzaldehyde (**c**) was used to prepare the corresponding mono-acids **4a**–**c** (8, 9) The crude mono-acids were esterified to the diethyl esters **5a**–**c** (9) followed by short path distillation under vacuum. Each of the diesters was treated with strong base (LDA) and condensed with each of the three aromatic aldehydes (except for the reaction of **5c** with veratraldehyde) to provide a library of eight alcohols, **6aa**–**6ca**, and **6cc**. It was necessary to quench the condensations with acetic acid at low temperature to prevent lactonization and elimination reactions from occurring. The alcohols were not purified or characterized but were immediately dissolved in trifluoroacetic acid and stirred at room temperature for one hour to form the eight 1-aryl-1,2-dihydronaphthalenes **7aa**–**7ca** and **7cc**. Although there are many methods for the preparation of 1-aryltetralin and 1-aryldihydronaphthalene lignans in the literature, we could find no precedent for this direct and relatively straightforward preparation of 1-aryl-1,2-dihydronaphthalenes from the Stobbe diesters **5**.

Aromatization of the dihydronaphthalenes **7** was accomplished using dicyanodichloro-*p*-benzoquinone (DDQ) in refluxing toluene. This worked well for compounds **7aa**–**7bc** but did not work for the more hindered derivatives **7ca** and

Scheme 1.

7cc, presumably due to steric crowding. The naphthalenes **8aa**–**8bc** could all be recrystallized from the crude reaction mixtures using $CHCl_3$–hexanes as solvent.

The selective hydrolysis of 1-arylnaphthalene diesters similar to **8** has been described in the literature (6). We found that hydrolysis using KOH in methanol–water gave the six mono-acids **9aa**–**9bc** in good yield. Formation of the lactones **2** was accomplished by reducing **9** using borane–dimethylsulfide in THF followed by lactonization in acid. In this way, lactones **2aa** (Taiwanin C), **2ab** (Chinensin), **2ac** (dehydroanhydropodophyllotoxin), **2ba** (Justicidin B), **2bb,** and **2bc** (7-deoxydiphyllin) were prepared. Formation of the retrolactones **3** was accomplished by reducing the ester group using sodium borohydride – lithium chloride in diglyme at 120°C followed by lactonization in acid. The lactones **3aa** (Justicidin E), **3ab** (Retrochinensin), **3ac** (5′-methoxyretrocinensin), **3ba** (Retrojusticidin B), **3bb,** and **3bc** were prepared.

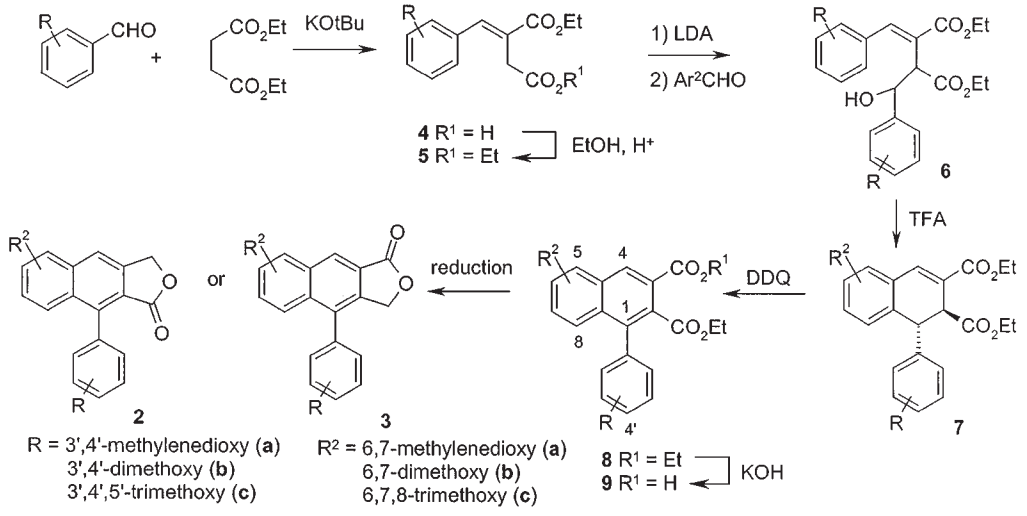
Most of the compounds represented by structures **2**, **3**, **7**, and **8** were tested for their ability to inhibit human cytomegalovirus virus using a standard plaque reduction assay. The cytotoxicities of the compounds were also measured using a tetrazolium salt MTT (10). Seven compounds had EC_{50}s in the low micromolar range (EC_{50}/TC_{50}: **7aa** 25/ >37 μM; **7ac** 1.4/ >25 μM; **7bc** 22/ >33 μM; **2aa** 1.2/ >19 μM; **2ac** 1.4/ >2.0 μM; **3ab** 63/50 μM; **3ba** 7.2/ >65 μM). Most of the remaining compounds did not show substantial antiviral activity at their solubility limit (ca. 50 μM).

Conclusions

A simple, convergent procedure has been developed for the synthesis of 1-arylnaphthalene and 1-aryl-1,2-dihydronaphthalene lignans and lignan analogs. The compounds prepared were screened for activity against human cytomegalovirus using a standard plaque reduction assay. While antiviral activity was found, the activity did not extend into the nanomolar range and was often paired with high cytotoxicity. Only **2aa** (Taiwanin C) and **3ba** (Retrojusticidin B) had a clear antiviral window.

Experimental

General methods



The general experimental procedures and instrumentation have been described in a previous publication (12).

Stobbe condensation – general procedure

tert-Butyl alcohol was charged to a 500 mL flask, and then potassium metal (1.2 equiv., ca. 0.5 M) was cut into pieces and added to the flask. The mixture was heated at reflux until the potassium metal had disappeared (ca. 1 h), and then was cooled to room temperature. Diethyl succinate (2.0 equiv.) and the substituted benzaldehyde (1.0 equiv.) were dissolved in *tert*-butyl alcohol (30 mL), and this mixture added, with stirring, via a dropping funnel over 20 min. The dropping funnel was rinsed with *tert*-butyl alcohol, and the reaction mixture stirred at room temperature for 3 h, during which time a yellow precipitate formed.

The mixture was poured into 10% HCl (100 mL) in a separatory funnel and extracted with EtOAc (3 × 100 mL). The organic layers were combined and washed with satu-

rated aqueous $NaHCO_3$ (3 × 100 mL). The basic extracts were combined, acidified with concentrated HCl, and extracted into fresh EtOAc (3 × 50 mL). This second organic extract was washed with water (10 mL), dried over anhydrous magnesium sulfate, filtered, and evaporated to give crude product, which was reacted in the next step without further purification.

*Stobbe acid – **4a***

Piperonal (3,4-methylenedioxybenzaldehyde, 15 g, 100 mmol), potassium metal (4.7 g, 120 mmol), *tert*-butyl alcohol (250 mL), and diethyl succinate (33 mL, 200 mmol), following the general procedure gave a crude product as a light yellow oil (14.0 g, 50% yield).

*Stobbe acid – **4b***

Veratraldehyde (3,4-dimethoxybenzaldehyde, 20 g, 120 mmol), potassium metal (5.6 g, 144 mmol), *tert*-butyl alcohol (250 mL), and diethyl succinate (42 mL, 240 mmol), following the general procedure gave a crude product as a light yellow oil (29.7 g, 77% yield).

*Stobbe acid – **4c***

3,4,5-Trimethoxybenzaldehyde (20 g, 102 mmol), potassium metal (4.8 g, 123 mmol), *tert*-butyl alcohol (250 mL), and diethyl succinate (34 mL, 204 mmol), following the general procedure gave crude product as a yellow oil (27.2 g, 82% yield).

Esterification reaction – general procedure

The crude acid-ester **4** was dissolved in anhydrous EtOH (100 mL, ca. 0.4 M), concentrated H_2SO_4 was added (catalytic amount) and the mixture was heated at reflux for 16 h. The majority of the ethanol was removed on a rotary evaporator, the mixture poured into saturated aqueous NaCl (150 mL) and extracted with EtOAc (3 × 50 mL). The organic extracts were combined and washed with saturated aqueous $NaHCO_3$ (3 × 50 mL) and water (50 mL). The mixture was dried over anhydrous magnesium sulfate, filtered, and evaporated to give a yellow oil. This crude oil was purified by short path, high vacuum (0.01 mm Hg) distillation to give the product.

*Stobbe diester – **5a***

Crude acid **4a** (14.0 g, 50.3 mmol), concentrated H_2SO_4 (2.5 mL), and ethanol (100 mL) gave **5a** as a clear pale yellow distillate (10.7 g, 70% yield). ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.78 (s, 1H, Ar-C*H*=C), 6.8–6.9 (m, 3H, Ar-*H*), 5.99 (s, 2H, O-CH_2-O), 4.26 (q, 2H, *J* = 7.1 Hz, CH=C-CO_2-C$H_2$$CH_3$), 4.19 (q, 2H, *J* = 7.1 Hz, CO_2-C$H_2$$CH_3$), 3.53 (s, 2H, C$H_2$-$CO_2$Et), 1.32 (t, 3H, *J* = 7.1 Hz, $CO_2CH_2CH_3$), 1.26 (t, 3H, *J* = 7.1 Hz, $CO_2CH_2CH_3$); ^{13}C NMR ($CDCl_3$, 75 MHz) δ 171.1 (*C*=O), 167.4 (*C*=O), 148.2, 147.9, 141.4, 128.9, 124.9, 123.9, 109.1, 108.5, 101.4, 61.0, 60.9, 33.8, 14.3, 14.2; EIMS *m*/*z* = 306 [M^+] (base), 261, 232, 203, 175, 159; HRMS calcd. for $C_{16}H_{18}O_6$: 306.1103, found: 306.1084.

*Stobbe diester – **5b***

Crude acid **4b** (19.0 g, 64.5 mmol), concentrated H_2SO_4 (2.5 mL), and ethanol (100 mL) gave **5b** as a clear yellow distillate (16.0 g, 77% yield). ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.78 (s, 1H, Ar-C*H*=C), 6.7–7.0 (m, 3H, Ar-*H*), 4.22 (q, 2H, *J* = 7.1 Hz, CH=C-CO_2-C$H_2$$CH_3$), 4.14 (q, 2H, *J* = 7.2 Hz, CO_2-C$H_2$$CH_3$), 3.85 (s, 3H, OC$H_3$), 3.83 (s, 3H, OC$H_3$), 3.53 (s, 2H, C$H_2$), 1.29 (t, 3H, *J* = 7.1 Hz, $CO_2CH_2CH_3$), 1.22 (t, 3H, *J* = 7.2 Hz, $CO_2CH_2CH_3$); ^{13}C NMR ($CDCl_3$, 75 MHz) δ 171.1 (*C*=O), 167.3 (*C*=O), 149.5, 148.6, 141.4, 127.5, 124.2, 122.4, 112.0, 110.9, 60.8, 60.7, 55.7, 55.6, 33.7, 14.1, 14.0; EIMS *m*/*z* = 322 [M^+] (base), 276, 249, 175; HRMS calcd. for $C_{17}H_{22}O_6$: 322.1416, found: 322.1436. The preparation of this compound has been previously reported (8).

*Stobbe diester – **5c***

Crude acid **4c** (27.2 g, 83.8 mmol), concentrated H_2SO_4 (4.0 mL), and ethanol (100 mL) gave **5c** as a clear pale yellow distillate (15.7 g, 53% yield). ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.78 (s,1H, Ar-C*H*=C), 6.59 (s, 2H, Ar-*H*), 4.24 (q, 2H, *J* = 7.13 Hz, CO_2-CH_2-CH_3), 4.14 (q, 2H, *J* = 7.13 Hz, CO_2-CH_2-CH_3), 3.83 (s, 3H, *p*-O-CH_3), 3.81 (s, 6H, *m*-O-CH_3), 3.52 (s, 2H, CH_2-CO_2), 1.30 (t, 3H, *J* = 7.12 Hz, O-CH_2CH_3), 1.22 (t, 3H, *J* = 7.13 Hz, O-CH_2CH_3); ^{13}C NMR ($CDCl_3$, 75 MHz) δ171.0 (*C*=O), 167.1 (*C*=O), 153.0, 141.6, 138.5, 130.3, 125.5, 106.2, 60.9, 60.8, 60.6, 55.9, 33.8, 14.0_3, 14.0_1; EIMS *m*/*z* = 352 [M^+] (base), 278, 263, 205; HRMS calcd. for $C_{18}H_{24}O_7$: 352.1522, found: 352.1509. The preparation of this compound has been previously reported (8).

Dihydronaphthalene diesters – general method

Lithium diisopropylamide (1.2 equiv.) was prepared by addition of *n*-BuLi (1.2 equiv., 2.5 M in hexanes) to diisopropylamine (1.3 equiv.) in freshly distilled THF at –70°C. The solution was warmed briefly to 0°C, then recooled to –70°C. A solution of the diester **5** (1 equiv.) in THF was added dropwise through a plug (ca. 1 g) of activated alumina, which was then rinsed with THF. On addition of the diester, the solution turns orange to deep red; this colour persists until the reaction is quenched. The mixture was stirred for 10 min, then a solution of the aldehyde (**a**, **b**, or **c**) in THF was added, and stirring was continued for 1 h. The reaction was quenched with glacial acetic acid at –70°C, then warmed to room temperature.

The mixture was extracted with EtOAc (3 × 20 mL), washed with water (20 mL), dried over anhydrous magnesium sulfate, filtered, and evaporated on the rotary evaporator at 30–40°C. The residue was subjected to high vacuum for 1/2 h to remove solvent, then excess trifluoroacetic acid (TFA) (3–4 mL) was added and the solution stirred at room temperature for 1 h. The reaction was poured into saturated aqueous $NaHCO_3$ and extracted into EtOAc (3 × 20 mL). The organic extracts were washed with saturated aqueous $NaHCO_3$ (3 × 10 mL) and water (10 mL), dried over anhydrous magnesium sulfate, filtered and evaporated. The products were isolated by flash column chromatography on silica gel using 20–30% (depending on the polarity of the final product) EtOAc–hexane as the eluant. The product appears as a fluorescent spot on thin layer chromatography (silica) under UV light.

*Dihydronaphthalene diester – **7aa***

Diester **5a** (1.00 g, 3.28 mmol), diisopropylamine (597 μL, 4.26 mmol), *n*-BuLi (1.79 mL of 2.2 M, 3.94 mmol), piperonal (516 mg, 3.44 mmol), and TFA

Aromatization – formation of arylnapthalene diesters – general procedure

The dihydronaphthalene diesters **7** were dissolved in toluene (ca. 0.015 M), then dicyanodichloroquinone (DDQ, 1.2 equiv.) was added, and the mixture was heated at reflux for 2–5 h. The reaction mixture was cooled to room temperature, and quenched by addition of 100 mL 0.1 M KOH. The product was extracted into 60 mL EtOAc (60 mL) and washed with aqueous KOH (0.1 M, 2 × 50 mL). The aqueous layer was extracted with additional EtOAc (2 × 50 mL), the organic layers combined and washed with water (20 mL) and saturated aqueous NaCl (20 mL). The solution was dried over anhydrous magnesium sulfate, filtered, and evaporated. The resulting red-brown residue was dissolved in the minimum amount of dichloromethane, then passed through a filter column of silica gel using 30% EtOAc–hexanes as the eluant and evaporated. Further purification, to get better than 95% purity by HPLC, required recrystallization from $CHCl_3$–hexanes.

*Arylnaphthalene diester – **8aa***

Diester **7aa** (656 mg, 1.5 mmol), DDQ (409 mg, 1.8 mmol) was heated at reflux in toluene (20 mL) for 5 h, and worked up as in the general method above to give **8aa** (571 mg, 87% yield) as off-white crystals; mp = 171–172°C; ^{1}H NMR (300 MHz, $CDCl_3$) δ 8.38 (s, 1H, C*H*=C-CO_2Et), 7.23 (s, 1H, Ar-*H*), 6.8–6.9 (m, 4H, Ar-*H*), 6.06 (s, 2H, O-CH_2-O), 6.03 (m (AB), 2H, O-CH_2-O), 4.39 (q, 2H, *J* = 7.1 Hz, CO_2-CH_2CH_3), 4.12 (q, 2H, *J* = 7.1 Hz, CO_2-CH_2CH_3), 1.40 (t, 3H, *J* = 7.1 Hz, CO_2-CH_2CH_3), 1.11 (t, 3H, *J* = 7.1 Hz, CO_2-CH_2CH_3); ^{13}C NMR (75 MHz, $CDCl_3$) δ 168.9 (*C*=O), 166.0 (*C*=O), 150.3, 148.7, 147.3, 136.9, 132.3, 130.6_4, 130.5_9, 129.9, 129.8_6, 123.9, 123.4, 111.0, 108.1, 104.9, 103.3, 101.7, 101.2, 61.5, 61.1, 14.3, 13.9 (one quaternary carbon not detected; perhaps under 147.3); EIMS *m*/*z* = 436 [M^+] (base), 391, 363; HRMS calcd. for $C_{24}H_{20}O_8$: 436.1158, found: 436.1140.

Formation of arylnapthalene mono-acids – general procedure

The arylnaphthalene diesters **8** were dissolved in MeOH (20 mL, ca. 0.05 M), aqueous KOH (0.4 M, 1.2 equiv.) was added, and the mixture was heated at reflux for 3 h. The mixture was cooled, quenched by addition of 10% HCl until precipitation occurred (pH of <2), then the mixture extracted into EtOAc (3 × 20 mL). The organic layers were combined and extracted with 3 × 20 mL (sat.) $NaHCO_3$. This basic extract was washed with EtOAc (20 mL), then acidified and extracted with ethyl acetate (3 × 10 mL), backwashing with 10 mL of water. The mixture was dried over anhydrous magnesium sulfate, filtered, and evaporated to give a powdery white solid.

*Acid – **9aa***

Arylnaphthalene diester **8aa** (356 mg, 0.82 mmol) and KOH (6 mL, 0.4 M, 2.4 mmol) were subjected to the general procedure described above, producing **9aa** (291 mg, 87% yield) as a fine white powder. ^{1}H NMR (300 MHz, acetone-d_6) δ 11.40 (br. s, 1H, CO_2*H*), 8.49 (s, 1H, C*H*=C-CO_2H), 8.00 (s, 1H, Ar-*H*), 7.48 (s, 1H, Ar-*H*), 6.97 (d, 1H, *J* = 7.7 Hz, Ar-*H*), 6.83 (s, 1H, Ar-*H*), 6.80 (d, 1H, *J* = 1.3 Hz, Ar-*H*), 6.76 (dd, 1H, *J* = 1.7, 7.7 Hz, Ar-*H*), 6.18 (2s, 2H, O-CH_2-O, hindered rotation), 6.09 (m (AB), 2H, O-CH_2-O), 4.02 (q, 2H, *J* = 7.1 Hz, CO_2-CH_2CH$_3$), 1.05 (t, 3H, *J* = 7.1 Hz, CO_2-CH$_2$CH_3); ^{13}C NMR (75 MHz, acetone-d_6) δ 168.5 (*C*=O), 166.9 (*C*=O), 151.2, 149.6, 148.2, 137.4, 132.7, 131.9, 131.4, 130.6$_2$, 130.5$_5$, 124.5, 124.3, 111.5, 108.5, 105.4, 103.1, 102.9, 102.1, 60.9, 14.0 (one quaternary carbon not observed); EIMS *m*/*z* = 408 [M^+], 362 (base), 290, 260, 232, 174; HRMS calcd. for $C_{22}H_{16}O_8$: 408.0845, found: 408.0823.

Arylnaphthalene diester **8bc** (621 mg, 1.25 mmol) and KOH (6 mL, 0.4 M, 2.4 mmol) were subjected to the general procedure described above, producing **9bc** (516 mg, 88% yield) as a fine white powder. ^{1}H NMR (300 MHz, acetone-d_6) δ 11.25 (br. s, 1H, CO_2*H*), 8.54 (s, 1H, C*H*=C-CO_2H), 7.56 (s, 1H, Ar-*H*), 7.03 (s, 1H, Ar-*H*), 6.64 (s, 2H, Ar-*H*), 4.03 (q, 2H, *J* = 7.0 Hz, CO_2-CH_2CH$_3$), 4.01 (s, 3H, OCH_3), 3.84 (s, 6H, 2 × *m*-OCH_3), 3.81 (s, 3H, OCH_3), 3.75 (s, 3H, OCH_3), 1.03 (t, 3H, *J* = 7.0 Hz, CO_2-CH$_2$CH_3); ^{13}C NMR (75 MHz, acetone-d_6) δ 168.9, 167.1, 153.9, 152.9, 151.8, 138.7, 137.3, 133.3, 130.6, 130.0, 129.3, 124.1, 108.7, 108.3, 106.0, 61.0, 60.6, 56.4, 56.0, 55.7, 14.0 (one quaternary carbon not observed); EIMS *m*/*z* = 470 [M$^+$], 424 (base), 409, 381, 363; HRMS calcd. for $C_{25}H_{26}O_9$: 470.1577, found: 470.1568.

Formation of arylnaphthalene lactones – general procedure

The arylnaphthalene mono-acids **9** were dissolved in dry THF (ca. 0.05 M) under nitrogen, a borane-dimethylsulfide solution (2.0 M in ether, 10 equiv.) added, and the mixture stirred at room temperature for 2 h. The reaction was quenched with 3% HCl–EtOH (prepared by addition of 0.5 mL acetyl chloride to 9.5 mL of anhydrous ethanol), then the solvent removed on a rotary evaporator. Anhydrous ethanol (20 mL) was added and evaporated, the solid residue dissolved in chloroform and washed with saturated aqueous $NaHCO_3$ (3 × 10 mL) to remove any remaining acid. The organic extract was washed with water (10 mL), dried over anhydrous magnesium sulfate, filtered, and evaporated to give a white powder. Further purification, to get better than 95% purity by HPLC, involved recrystallization from $CHCl_3$–hexanes.

*Taiwanin C – **2aa***

Arylnaphthalene acid **9aa** (99 mg, 0.24 mmol) and BH_3–DMS (1.2 mL, 2.4 mmol) were subjected to the above conditions to give taiwanin C (**2aa**) (70 mg, 82% yield) as a white powder. ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.68 (s, 1H, C*H*=C-CH_2O), 7.19 (s, 1H, Ar-*H*), 7.11 (s, 1H, Ar-*H*), 6.95 (d, 1H, *J* = 7.7 Hz, Ar-*H*), 6.80 (s, 1H, Ar-*H*), 6.77 (d, 1H, *J* = 1.3, 7.7 Hz, Ar-*H*), 6.08 (s, 2H, O-CH_2-O), 6.06 (2 s, 2H, O-CH_2-O, hindered rotation), 5.37 (s, 2H, CH_2-O-C=O); ^{13}C NMR (75 MHz, $CDCl_3$) δ 169.7 (*C*=O), 149.9, 148.6, 147.6, 147.5, 140.1, 139.8, 134.6, 130.5, 123.5, 128.3, 119.0, 118.9, 110.5, 108.2, 103.7 (broad, 2 carbons), 101.8, 101.2, 68.0; EIMS *m*/*z* = 348 [M$^+$] (base), 319, 289, 261; HRMS calcd. for $C_{20}H_{12}O_6$: 348.0634, found: 348.0629. ^{1}H NMR data identical to that published previously (12, 13).

*Chinensin – **2ab***

Arylnaphthalene acid **9ab** (198 mg, 0.47 mmol) and BH_3–DMS (2.3 mL, 4.7 mmol) were subjected to the above conditions to give Chinensin (**2ab**) (166 mg, 97% yield) as a white powder. ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.69 (s, 1H, C*H*=C-CH_2O), 7.20 (s, 1H, Ar-*H*), 7.12 (s, 1H, Ar-*H*), 7.02 (d, 1H, *J* = 8.0 Hz, Ar-*H*), 6.88 (dd, 1H, *J* = 1.7, 8.4 Hz, Ar-*H*), 6.86 (d, 1H, *J* = 1.7 Hz, Ar-*H*), 6.07 (s, 2H, O-CH_2-O), 5.37 (2s, 2H, CH_2-O-C=O), 3.97 (s, 3H, O-CH_3), 3.87 (s, 3H, O-CH_3); ^{13}C NMR (75 MHz, $CDCl_3$) δ 169.7 (*C*=O), 149.9, 148.9, 148.6, 148.5, 140.5, 139.8, 134.6, 130.5, 127.2, 122.5, 118.9, 118.8, 113.4, 110.8, 103.7, 103.6, 101.8, 67.9, 55.9, 55.8; EIMS *m*/*z* = 364 [M$^+$] (base); HRMS calcd. for $C_{21}H_{16}O_6$: 364.0947, found: 364.0958. ^{1}H NMR data identical to that published previously (12).

*Dehydroanhydropodophyllotoxin – **2ac***

Arylnaphthalene acid **9ac** (201 mg, 0.44 mmol) and BH_3–DMS (2.2 mL, 4.4 mmol) were subjected to the above conditions to give dehydroanhydropodophyllotoxin (**2ac**)

(122 mg, 70% yield) as a white powder. ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.70 (s, 1H, C*H*=C-CH_2O), 7.20 (s, 1H, Ar-*H*), 7.12 (s, 1H, Ar-*H*), 6.55 (s, 2H, Ar-*H*), 6.09 (s, 2H, O-CH_2-O), 5.38 (2s, 2H, CH_2-O-C=O), 3.97 (s, 3H, *p*-OCH_3), 3.84 (s, 6H, 2 × *m*-OCH_3); ^{13}C NMR (75 MHz, $CDCl_3$) δ 169.6 (*C*=O), 152.9, 150.0, 148.6, 140.4, 139.8, 137.8, 134.6, 130.3 (broad, 2 carbons), 119.1, 118.7, 107.3, 103.7, 103.6, 101.8, 68.0, 60.9, 56.1; EIMS *m*/*z* = 394 [M^+] (base), 379; HRMS calcd. for $C_{22}H_{18}O_7$: 394.1052, found: 394.1041. ^{1}H NMR data identical to that published previously (14).

Justicidin B – ***2ba***

Arylnaphthalene acid **9ba** (273 mg, 0.65 mmol) and BH_3–DMS (3.2 mL, 6.5 mmol) were subjected to the above conditions to give justicidin B (**2ba**) (223 mg, 95% yield) as a white powder. ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.69 (s, 1H, C*H*=C-CH_2O), 7.18 (s, 1H, Ar-*H*), 7.10 (s, 1H, Ar-*H*), 6.96 (d, 1H, *J* = 7.7 Hz, Ar-*H*), 6.84 (d, 1H, *J* = 2.0 Hz, Ar-*H*), 6.83 (dd, 1H, *J* = 2.0, 7.7 Hz, Ar-*H*), 6.08, 6.03 (2s, 2H, O-CH_2-O, hindered rotation), 5.37 (2s, 2H, CH_2-O-C=O), 4.04 (s, 3H, OCH_3), 3.80 (s, 3H, OCH_3); ^{13}C NMR (75 MHz, $CDCl_3$) δ 169.9 (*C*=O), 151.7, 150.0, 147.4$_9$, 147.4$_6$, 139.5$_5$, 139.4$_6$, 133.1, 128.8, 128.3, 123.4, 118.4, 118.2, 110.5, 108.1, 106.0, 105.8, 101.2, 68.0, 56.0, 55.8; EIMS *m*/*z* = 364 [M^+] (base); HRMS calcd. for $C_{21}H_{16}O_6$: 364.0947, found: 364.0958. ^{1}H NMR data identical to that published previously (15).

Lactone – ***2bb***

Arylnaphthalene acid **9bb** (304 mg, 0.69 mmol) and BH_3–DMS (3.4 mL, 6.9 mmol) were subjected to the above conditions to give lactone **2bb** (250 mg, 95% yield) as a white powder. ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.71 (s, 1H, C*H*=C-CH_2O), 7.19 (s, 1H, Ar-*H*), 7.15 (s, 1H, Ar-*H*), 7.04 (d, 1H, *J* = 8.4 Hz, Ar-*H*), 6.96 (dd, 1H, *J* = 2.0, 8.2 Hz, Ar-*H*), 6.93 (dd, 1H, *J* = 2.0 Hz, Ar-*H*), 5.38 (2s, 2H, CH_2-O-C=O), 4.05 (s, 3H, OCH_3), 3.98 (s, 3H, OCH_3), 3.88 (s, 3H, OCH_3), 3.79 (s, 3H, OCH_3); ^{13}C NMR (75 MHz, $CDCl_3$) δ 169.9 (*C*=O), 151.8, 150.0, 148.9, 148.5, 139.9, 139.6, 133.1, 128.8, 127.1, 122.6, 118.3, 118.1, 113.4, 110.8, 106.0 (broad, 2 carbons), 68.0, 56.0$_5$, 55.9$_6$, 55.8$_0$, 55.7$_7$; EIMS *m*/*z* = 380 [M^+] (base), 365; HRMS calcd. for $C_{22}H_{20}O_6$: 380.1260, found: 380.1256. ^{1}H NMR data identical to that published previously (13).

7-Deoxydiphyllin – ***2bc***

Arylnaphthalene acid **9bc** (191 mg, 0.41 mmol) and BH_3–DMS (2.0 mL, 4.1 mmol) were subjected to the above conditions to give lactone **2bc** (233 mg, 80% yield) as a white powder. ^{1}H NMR (300 MHz, $CDCl_3$) δ 7.72 (s, 1H, C*H*=C-CH_2O), 7.20 (s, 1H, Ar-*H*), 7.15 (s, 1H, Ar-*H*), 6.62 (s, 2H, 2 × Ar-*H*), 5.40 (2s, 2H, CH_2-O-C=O), 4.06 (s, 3H, OCH_3), 3.98 (s, 3H, OCH_3), 3.85 (s, 6H, 2 × *m*-OCH_3), 3.80 (s, 3H, OCH_3); ^{13}C NMR (75 MHz, $CDCl_3$) δ 169.7 (*C*=O), 152.9, 151.9, 150.1, 139.9, 139.5, 137.8, 133.2, 130.2, 128.6, 118.3, 118.2, 107.4 (broad, 2 carbons), 106.0, 68.0, 61.0, 56.2, 56.1, 55.9; EIMS *m*/*z* = 410 [M^+] (base), 395; HRMS calcd. for $C_{23}H_{22}O_7$: 410.1365, found: 410.1376. ^{1}H NMR data identical to that published previously (16).

Formation of arylnaphthalene retrolactones – general procedure

The arylnaphthalene mono-acids, **9**, sodium borohydride (10–15 equiv.), and lithium chloride (10–15 equiv.) were charged to a 25 mL flask as powders, then diglyme (10 mL) was added and the resulting mixture was heated at ~120°C for 3–16 h. The mixture was cooled and quenched with 10% HCl (10 mL), which was stirred for 1.5 h. The product was extracted into EtOAc (3 × 20 mL) and washed with saturated aqueous $NaHCO_3$ (3 × 10 mL) to remove any remaining acid. The organic extract was washed with water (10 mL), dried over anhydrous magnesium sulfate, filtered, and evaporated to give a white powder. Recrystallization from $CHCl_3$–hexanes provided a white powder, which was a mixture of the desired lactone and the corresponding diol as a side product from over-reduction. The lactone was purified by recrystallization from hot EtOH (95%), providing crystals that were >90% pure by HPLC.

Justicidin E – ***3aa***

Arylnaphthalene acid **9aa** (125 mg, 0.31 mmol), $NaBH_4$ (174 mg, 4.6 mmol), LiCl (194 mg, 4.6 mmol) were used in the general procedure above (16 h reflux time) to give justicidin E (**3aa**) (20.5 mg, 19.2% yield) as colourless crystals. ^{1}H NMR (300 MHz, $CDCl_3$) δ 8.26 (s, 1H, C*H*=C-CO_2), 7.30 (s, 1H, Ar-*H*), 7.09 (s, 1H, Ar-*H*), 6.97 (d, 1H, *J* = 8.4 Hz, Ar-*H*), 6.80 (s, 1H, Ar-*H*), 6.79 (dd, 1H, *J* = 1.6, 8.4 Hz, Ar-*H*), 6.09 (s, 2H, O-CH_2-O), 6.08 (2s, 2H, O-CH_2-O, hindered rotation), 5.20 (AB doublet, 2H, Δδ = 17.6 Hz, *J* = 15.0 Hz, C-CH_2-O); ^{13}C NMR (75 MHz, $CDCl_3$) δ 171.4 (*C*=O), 150.5, 148.4, 148.2, 147.7, 138.4, 133.4, 132.7, 131.3, 129.6, 124.7, 122.7, 121.6, 109.6, 109.0, 105.2, 102.0, 101.8, 101.4, 69.4; EIMS *m*/*z* = 348 [M^+] (base), 319, 233; HRMS calcd. for $C_{20}H_{12}O_6$: 348.0634, found: 348.0604. ^{1}H NMR spectral properties identical with those previously reported (6,12).

Retrochinensin – ***3ab***

Arylnaphthalene acid **9ab** (311 mg, 0.73 mmol), $NaBH_4$ (277 mg, 7.3 mmol), LiCl (309 mg, 7.3 mmol) were used in the general procedure above (5 h reflux time) to give retrochinensin (**3ab**) (165.7 mg, 62.3%; 86.2 mg, 32.4% yield after recrystallization from 95% EtOH) as colourless crystals. ^{1}H NMR (300 MHz, $CDCl_3$) δ 8.23 (s, 1H, C*H*=C-CO_2), 7.28 (s, 1H, Ar-*H*), 7.09 (s, 1H, Ar-*H*), 7.03 (d, 1H, *J* = 8.2 Hz, Ar-*H*), 6.89 (dd, 1H, *J* = 1.9, 8.1 Hz, Ar-*H*), 6.84 (d, 1H, *J* = 1.9 Hz, Ar-*H*), 6.08 (s, 2H, O-CH_2-O), 5.19 (AB doublet, 2H, Δδ = 17.8 Hz, *J* = 14.8 Hz, C-CH_2-O), 3.97 (s, 3H, O-CH_3), 3.88 (s, 3H, O-CH_3); ^{13}C NMR (75 MHz, $CDCl_3$) δ 171.4 (*C*=O), 150.4, 149.3, 148.9, 148.3, 138.3, 133.4, 132.9, 131.2, 128.5, 124.5, 121.6, 112.2, 111.7, 105.2, 102.0, 101.8, 69.5, 56.0$_4$, 55.9$_9$ (one quaternary carbon not observed); EIMS *m*/*z* = 364 [M^+] (base), 350, 335, 319; HRMS calcd. for $C_{21}H_{16}O_6$: 364.0947, found: 364.0927. ^{1}H NMR spectral properties identical with those previously reported (17).

5′-Methoxyretrochinensin – ***3ac***

Arylnaphthalene acid **9ab** (407 mg, 0.89 mmol), $NaBH_4$ (334 mg, 8.9 mmol), LiCl (378 mg, 8.9 mmol) were used in the general procedure above (5 h reflux time) to give 5′-

Substituent effects on stability of oxiranes, oxirenes, and dioxiranes

Kuangsen Sung

Abstract: Homodesmotic reactions were designed to study substituent effects on stability of oxiranes, oxirenes, and dioxiranes. Good or fair correlation between their homodesmotic stabilization energies and Taft's dual-substituent-parameters has been found. Oxiranes are stabilized by σ-donating and π-donating substituents but destabilized by σ-accepting and π-accepting substituents. The π-effects on oxiranes are comparable to σ-effects for π-acceptor substituents and are much stronger than σ-effects for π-donor substituents. Oxirenes are stabilized by σ-donating, π-donating, and π-accepting substituents but destabilized by σ-accepting substituents. The π-effects on oxirenes are stronger than σ-effects. Oxirenes with strong π-donor substituents such as F, OH, and NH_2, or strong σ-donor substituents such as Li and Na are neither real molecules nor transition states. Dioxiranes are stabilized by σ-donating and π-donating substituents but destabilized by σ-accepting and π-accepting substituents. The π-effects on dioxiranes are stronger than σ-effects for π-donor substituents, but weaker than σ-effects for π-acceptor substituents

Key words: oxirane, oxirene, dioxirane, homodesmotic reaction, substituent effect.

Résumé : On a mis au point des réactions homodesmotiques orientées vers l'étude des effets de substituant sur la stabilité des oxiranes, oxirènes et dioxiranes. On a observé des corrélations allant de bonnes à correctes entre les énergies de stabilisation homodesmotiques et les paramètres à doubles substituants de Taft. Les oxiranes sont stabilisés par les substituants σ-donneurs et π-donneurs, mais ils sont déstabilisés par les substituants σ- ou π-accepteurs. Les effets π sur les oxiranes sont comparables aux effets σ pour les substituants π-accepteurs et ils sont beaucoup plus forts que les effets σ pour les substituants π-donneurs. Les oxirènes sont stabilisés par les substituants σ-donneurs, π-donneurs et π-accepteurs, mais ils sont déstabilisés par les substituants σ-accepteurs. Pour les oxirènes, les effets π sont plus forts que les effets σ. Les oxirènes portant des substituants fortement π-donneurs, tel que F, OH et NH_2, ou des substituants fortement σ-donneurs, tel que Li et Na, ne sont ni des molécules ni des états de transition. Les dioxiranes sont stabilisés par des substituants σ-donneurs et π-donneurs, mais ils sont déstabilisés par des substituants σ-accepteurs et π-accepteurs. Dans le cas des dioxiranes, les effets π sont plus forts que les effets σ pour les substituants π-donneurs, mais ils sont plus faibles que les effets σ pour les substituants π-accepteurs.

Mots clés : oxirane, oxirène, dioxirane, réaction homodesmotique, effet de substituant.

Introduction

The substituent effects on structures and stability of a variety of organic compounds such as ketenes (1*a*–*c*), isocyanates (1*d*), imines (1*d*), allenes (1*c*, 2), cyclopropanes (3), diazirines (1*c*, 4*a*–*b*), diazomethanes (1*c*, 4*c*–*e*), alkanes (3*c*), alkenes (3*a*, 3*c*, 5), alkynes (3*a*, 5*b*), 1,3-dienes (6*a*), cyclopropenes (1*c*), carbonyl compounds (5*a*, 6*b*), and carbocations (7) have been extensively studied by ab initio calculations in recent years. Recently we have studied substituent effects on stablity of ketenimines, nitriles, and isocyanides by ab initio calculations (8). In the article, the same method is applied to study substituent effects on stability of oxiranes, oxirenes, and dioxiranes.

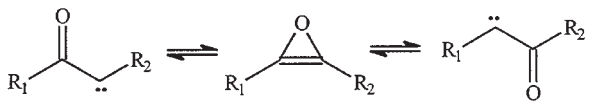
Oxiranes **1** are well-known intermediates and most of attention has been focused on their preparation, reaction, and stereochemistry (9). Since most of them can be isolated and stay stable at room temperature, their stability is not chemists' major concern and their substituent-stability relationship still remain intact.

1



5

Oxirenes **2** are a class of highly strained heterocycles whose instability and high reactivity have made isolation or direct detection difficult (10). From thermal and photochemical experiments with unsymmetrically substituted diazo ketones and from label scrambling in isotopically labeled diazo ketones, ketocarbene **3** – ketocarbene **4** interconversion has been found and explained by existence of the oxirene (11). Later, the oxirenes were observed by means of matrix-isolation techniques and laser flash photolysis experiments

(10*a*, *b*). Will substituents destabilize oxirenes and make them become unreal? Will substituents stabilize oxirenes and allow them to be isolated and to stay isolated at higher temperature for longer time?

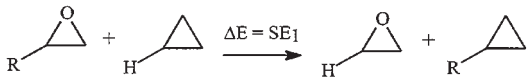
3 **2** **4**

Dioxiranes **5** with a smallest cyclic peroxide system were first isolated at low temperature in 1972 (12*a*). Since then, they have proven to be powerful oxygen transfer reagents of unusual synthetic utility (12). Most of them are generated in situ since they were reported to be explosive and unstable. In 1985, Murray and Jeyaraman were able to prepare a solution of ca. 0.1 M dimethyl dioxirane in acetone (12*b*). Methyl(trifluoromethyl)dioxirane was prepared in this way as a 0.8 M solution in $CF_3C(O)CH_3$ (12*c*). Recently difluorodioxirane was isolated and stable even at 22°C for more than 12 h (12*d*). Clearly, stability is one of major concerns for chemists to do the dioxirane chemistry.

Hammett equation and its extensions [1] described substituent effects on reaction rates (*k*) or equilibrium constants (*K*), and there exits a linear free energy relationship between the two sets of effects (13). The phenomena and concept have been applied to substituent effects on isodesmic and homodesmotic stabilization energies of cyclopropanes, ethylenes, acetylenes, benzenes, allenes, ketenimines, nitriles and isocyanides (2*a*, 3*a*, 8). Since entropy changes of isodesmic and homodesmotic reactions are so small as to be negligible, it is reasonable that isodesmic and homodesmotic stabilization energies are directly correlated with substituent constants (σ). [2] Both sign and magnitude of σ for a substituent are a measure of its capacity to perturb its environment electronically. Substituent constants σ_p and σ_m may involve both inductive and resonance contributions of substituents, but Taft's dual-substituent-parameters (DSP) provide a good way to divide the substituent constant (σ) into σ_I for inductive contribution only and σ_R for resonance contribution only (14). Therefore, in this article we study substituent effects on stability of oxiranes, oxirenes, and dioxiranes by ab initio calculations and by correlating the stabilization energies with Taft's DSP.

[1] $$m \log (K/K_0) = m\,\Delta\Delta G = \log (k/k_0) = \Delta\Delta G^{\ddagger} = \rho\sigma = \rho_I\sigma_I + \rho_R\sigma_R$$

[2] $$\Delta E \text{ (for isodesmic and homodesmotic reactions)} = \rho\sigma = \rho_I\sigma_I + \rho_R\sigma_R$$



The isodesmic reaction is one in which the total number of each type of bond is identical in the reactants and products, but there may be changes in the relationship of one bond to another (15*a*). The homodesmotic reaction is defined as a reaction in which not only is the number of bonds of each type conserved, but the number of carbon atoms with zero, one, two, or three hydrogen atoms is also conserved (15*b*). The isodesmic and homodesmotic reactions are widely used in theoretical studies because errors in the energies of reactants and products are more likely to cancel, thereby allowing simple computational approaches to give accurate estimates of heats of reactions (15*c*). Generally speaking, a substituted reactant of one type is more stable than a substituted product of the other type if the isodesmic or homodesmotic reaction is endothermic; a substituted product of one type is more stable than a substituted reactant of the other type if the reaction is exothermic.

Computation

All the calculations reported here were performed with Gaussian94 program (16). Geometry optimizations were carried out at level of HF/6–31+G* without any symmetry restriction. After geometry optimizations were performed, analytic vibration frequencies were calculated at the same level to determine the nature of the located stationary points. Thus all the stationary points found were properly characterized by evaluation of the harmonic frequencies. Single point energies of the optimized structures were carried out by density functional theory (DFT) at level of B3LYP/6–311+G(2d,p)//HF/6–31+G*, and energies of all the stationary points were calculated at the same level with scaling zero-point vibration energies included. A scaling factor of 0.8929 for zero-point vibration energies is used according to the literature (1*b*, 1*c*, 15*a*).

Results

Substituent effects on stability of oxiranes were studied with a homodesmotic reaction [3], which measures stabilizing effect of a substituent, R, on oxirane relative to the effect of the substituent on cyclopropane. The stabilization energies (SE_1) were correlated with Taft's DSP to study how

[3] 

substituents influence the stability of oxiranes via inductive and resonance routes (Table 1). Two independent parameters (σ_I and σ_R) of Taft's DSP were taken from Charton's compendium (17). Since both π-donors and π-acceptors can cause stabilization, one must treat them separately. Therefore, substituents were divided into two categories, π-donating and π-accepting substituents. In each category, values of σ_I and σ_R of the substituents were correlated with substituent stabilization energies by eq. [4]. In a category of π-donating substituents, eight substituents were chosen and their Taft's dual-substituent-parameters have a fair correlation with the stabilization energies (SE_1) of oxiranes with $r^2 = 0.85$ and sey = 1.45. [5] The sey means standard deviation of estimated stabilization energies. Coefficients of σ_I and σ_R are –0.20 and –10.14, respectively. In a category of π-accepting substituents, six substituents were chosen and a correlation between the oxirane stabilization energies (SE_1) and their Taft's dual-substituent-parameters is fair with $r^2 = 0.72$ and sey = 0.94. [5] Coefficients of σ_I and σ_R are –4.63 and –3.07, respectively.

[4] $$SE = \rho_I\sigma_I + \rho_R\sigma_R + \text{constant}$$

Substituent effects on stability of oxirenes were studied with a homodesmotic reaction [7], which measures stabilizing effect of a substituent, R, on oxirene relative to the effect of the substituent on cyclopropene. To study how inductive and resonance effects of the substituents influence the stability of oxirenes, Taft's DSP was applied and correlated with the stabilization energies (SE_2) by eq. [4] (Table 2).

[7] 

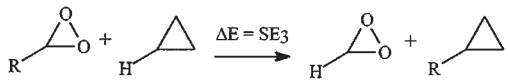
In the category of π-donating substituents, five substituents were chosen and their Taft's dual-substituent-parameters have a good correlation with oxirene stabilization energies (SE_2) with $r^2 = 0.96$ and sey = 0.58. [8] Coefficients of σ_I and σ_R are 1.90 and –30.02, respectively. In the category of π-accepting substituents, six substituents were chosen and a correlation between the oxirene stabilization energies (SE_2) and Taft's dual-substituent-parameters is fair with $r^2 = 0.71$ and sey = 2.25. [9] Coefficients of σ_I and σ_R are –10.75 and +28.73, respectively. Oxirenes with substituents like F, OH, NH_2, Li, and Na are no longer stationary points in their potential energy surfaces at level of HF/6–31+G*. In other words, they are neither local minima nor transition states.

π donors (ethynyl, vinyl, methyl, phenyl, H) :

$$SE_2 = (1.90)\,\sigma_I + (-30.02)\,\sigma_R - 0.03 \quad [8]$$
$$r^2 = 0.96, \quad \text{sey} = 0.58$$

π acceptors (CO_2H, CN, C(O)H, NO_2, CF_3, H) :

$$SE_2 = (-10.75)\,\sigma_I + (28.73)\,\sigma_R + 0.03 \quad [9]$$
$$r^2 = 0.71, \quad \text{sey} = 2.25$$



Substituent effects on stability of dioxiranes were studied with a homodesmotic reaction [10], which measures stabilizing effect of a substituent, R, on dioxirane relative to the effect of the substituent on cyclopropane. To study how inductive and resonance effects of the substituents influence the stability of dioxiranes, Taft's DSP was applied and correlated with the stabilization energies (SE_3) by eq. [4] (Table 3). In the category of π-donating substituents, eight substituents were

$$r^2 = 0.87, \quad \text{sey} = 1.43$$

Discussion

The Hammett equation and its extensions and modifications consider an induced perturbation in a reaction center A by a substituent B through a hydrocarbon framework H, that is, A-H-B (13). The present study examines an induced perturbation in a reaction center A directly by a substituent B, that is, A-B. In this article, the stabilization energies of homodesmotic reactions were correlated with Taft's DSP. Any deviation from the correlation analysis could result from through-space intramolecular interaction between reaction center A and substituent B. However, errors in the energies of reactants and products are more likely to cancel in well-designed homodesmotic reactions.

There is a fair correlation (r^2 = 0.85) between SE_1 and Taft's DSP for oxiranes with π-donating substituents. [5] The σ_I coefficient (–0.20) is too small and within standard deviation. The σ_R coefficient (–10.14) implies that π-donating substituents stabilize oxiranes. The π-donating effects outweigh σ-effects on stability of oxiranes with π-donating substituents.

There is also a fair correlation (r^2 = 0.72) between SE_1 and Taft's DSP for oxiranes with π-accepting substituents. [6] The σ_I coefficient is –4.63, indicating that σ-donating substituents stabilize oxiranes while σ-accepting substituents destabilize them. The σ_R coefficient is –3.07, indicating that π-donating substituents stabilize oxiranes while π-accepting substituents destabilize them. The π-effects on oxirane stability are comparable to σ-effects for π-acceptor substituents

Oxiranes have a strong electronegative oxygen atom on a 3-membered ring and that makes two other carbon atoms on the ring electron-deficient. Therefore, both σ-donating and π-donating substituents would enrich electron density of the ring carbons and cause stabilization. Conversely, both σ-accepting and π-accepting substituents would deplete electron density of the ring carbons and cause destabilization.

As to oxirenes with π-donating substituents, a good correlation (r^2 = 0.96) between SE_2 and Taft's DSP was obtained. [8] The σ_I coefficient (1.90) is so small and within standard deviation. The σ_R coefficient (–30.02) implies that π-donating substituents stabilize oxirenes. The π-donating effects outweigh σ-effects on stability of oxirenes with π-donating substituents. Regarding oxirenes with π-accepting substituents, there is a fair correlation (r^2 = 0.71) between SE_2 and Taft's DSP. [9] The σ_I coefficient is –10.75, indicating that σ-donating substituents stabilize oxirenes while σ-accepting substituents destabilize them. The σ_R coefficient is 28.73, indicating that π-accepting substituents stabilize oxirenes. The π-accepting effects outweigh σ-effects on stability of oxirenes with π-accepting substituents.

It was reported that parent oxirene is 11.3 kJ mol^{-1} more stable than its formylcarbene isomer at level of MP3/6–31G** (18). However, at level of HF/6–31+G*, strong π-donor substituents such as F, OH, and NH_2 make oxirenes become unreal. The same thing happens to oxirenes with strong σ-donating substituents such as Li and Na.

Correlation between dioxirane stabilization energies (SE_3) and Taft's dual-substituent-parameters is fair (r^2 = 0.86 and sey = 2.94) for dioxiranes with π-donating substituents. [11] The σ_I coefficient of –4.93 indicates that σ-donating substituents stabilize dioxiranes while σ-accepting substituents

© 2000 NRC Canada

destabilize them. The σ_R coefficient of –21.92 implies that π-donating substituents stabilize dioxiranes. The π-donating effects outweigh σ-effects on stability of dioxiranes with π-donating substituents.

There is also a fair correlation (r^2 = 0.87) between SE_3 and Taft's DSP for dioxiranes with π-accepting substituents. [12] The σ_I coefficient is –11.78, indicating that σ-donating substituents stabilize dioxiranes while σ-accepting substituents destabilize them. The σ_R coefficient is –2.77, indicating that π-donating substituents stabilize dioxiranes while π-accepting substituents destabilize them. The σ-effects outweigh π-effects on stability of dioxirane with π-accepting substituents.

Dioxiranes have two strong electronegative oxygen atoms on a 3-member ring and that causes the other carbon atom on the ring to be electron-deficient. It turns out that any effort to compensate electron density of the electron-deficient carbon on the ring would stabilize the dioxiranes. Therefore, both σ-donors and π-donors stabilize dioxiranes while both σ-acceptors and π-acceptors destabilize them.

The methyl group is a weak σ-donor (σ_I = –0.01) and a medium π-donor (σ_R = –0.16), so the methyl group has a stabilization effect (SE_3 = +7.32 kcal/mol) on dioxiranes. This is consistent with an experiment result that dimethyldioxirane was isolated and prepared as a solution storable at –20°C for several days (12*b*). The trifluoromethyl group is a medium σ-acceptor (σ_I = 0.40) and a medium π-acceptor (σ_R = 0.11), so the trifluoromethyl group has a destabilization effect (SE_3 = –5.75 kcal/mol) on dioxiranes. This is also consistent with an experiment result that methyl(trifluoromethyl)dioxirane was found to be markedly more reactive and unstable than dimethyldioxirane (12*c*). The fluorine substituent is a strong σ-acceptor (σ_I = 0.54) but it is a strong π-donor (σ_R = –0.48). The fluorine substituent should have a higher stabilization effect (SE_3 = +10.87 kcal/mol) on dioxiranes since π-donating effects outweigh σ-effects on stability of dioxiranes with π-donating substituents. Actually, difluorodioxirane has been isolated at 22°C recently and it is stable at 22°C for more than 12 h (12*d*).

Conclusions

Substituent effects on the stability of oxiranes, oxirenes, and dioxiranes can be found by correlation between their stabilization energies (SE_1, SE_2, and SE_3) and Taft's dual-substituent-parameters. As to substituent effects on the stability of oxiranes, σ-donating substituents stabilize them while σ-accepting substituents destabilize them; π-donating substituents stabilize them while π-accepting substituents destabilize them. The π-effects on oxiranes are comparable to σ-effects for π-acceptor substituents and are much stronger than σ-effects for π-donor substituents.

Regarding substituent effects on the stability of oxirenes, σ-donating substituents stabilize them while σ-accepting substituents destabilize them. Both π-donating and π-accepting substituents stabilize them. The π-effects on oxirenes are stronger than σ-effects. Oxirenes with strong π-donor substituents such as F, OH, and NH_2 and strong σ-donor substituents such as Li and Na are neither real molecules nor transition states at level of HF/6–31+G*.

As far as substituent effects on the stability of dioxiranes are concerned, σ-donating substituents stabilize them while σ-accepting substituents destabilize them; π-donating substituents stabilize them while π-accepting substituents destabilize them. The π-effects on dioxiranes are stronger than σ-effects for π-donor substituents, but π-effects on dioxiranes are weaker than σ-effects for π-acceptor substituents

Trans alkenylpyridine and alkenylamine complexes of platinum

Michael P. Shaver, Christopher M. Vogels, Andrew I. Wallbank, Tracy L. Hennigar, Kumar Biradha, Michael J. Zaworotko, and Stephen A. Westcott

Abstract: Addition of *cis*-cyclooctene (coe) to K_2PtCl_4 gives *trans*-$[PtCl_2(coe)]_2$ (**1**), which reacts with excess coe to give *trans*-$PtCl_2(coe)_2$ (**2**). Compound **2** was characterized by an X-ray diffraction study and crystals were found to be triclinic, a = 5.7838(5), b = 7.4347(6), c = 9.9972(9) Å, α = 83.924(1), β = 87.844(2), γ = 73.546(1)°, Z = 1, with space group $P\bar{1}$. Addition of 4-vinylpyridine (4vp) to **1** gave *trans*-$PtCl_2(4vp)_2$ (**5**) which was also characterized by an X-ray diffraction study. Crystals of **5** were monoclinic, a = 8.2255(6), b = 12.8254(10), c = 6.9624(5) Å, β = 98.8230(10)°, Z = 2, with space group $P2_1/c$. Although alkenylamines react with **1** to give a mixture of products, addition of one equivalent of apve ($H_2NCH_2CH_2CH_2OCH{=}CH_2$) to **1** cleanly afforded the organometallic product *trans*-$PtCl_2(coe)(thmo)$ (thmo = tetrahydro-2-methyl-1,3-oxazine) arising from a metal-catalyzed intramolecular hydroamination of the starting alkenylamine. Initial investigations into the functionalization of metal complexes containing pendant alkene groups have shown that catecholborane can be added in some cases, using a rhodium catalyst, to give the corresponding organoboronate ester platinum compounds.

Key words: alkenylamines, alkenylpyridines, hydroamination, hydroboration, platinum.

Résumé : L'addition du *cis*-cyclooctène (coe) au K_2PtCl_4 conduit à la formation de *trans*-$[PtCl_2(coe)]_2$ (**1**) qui réagit avec un excès de coe pour fournir le *trans*-$PtCl_2(coe)_2$ (**2**) que l'on a caractérisé par une étude de diffraction des rayons X. On a trouvé que les cristaux sont tricliniques, groupes d'espace $P\bar{1}$, *avec* a = 5,7838(5), b = 7,4347(6) et c = 9,9972(9) Å, α = 83,924(1), β = 87,844(2) et γ = 73,545(1)° et Z = 1. L'addition de 4-vinylpyridine (4vp) au composé **1** fournit le *trans*-$PtCl_2(4vp)_2$ (**5**) que l'on a aussi caractérisé par diffraction des rayons X. Les cristaux de **5** sont monocliniques, groupe d'espace $P2_1/c$, avec a = 8,2255(6), b = 12,8254(10) et c = 6,9624(5) Å, β = 98,8230(10)° et Z = 2. Même si les alcénylamines (L) réagissent avec **1** pour fournir un mélange de produits, l'addition d'un équivalent d'apve ($H_2NCH_2CH_2CH_2OCH{=}CH_2$) à **1** fournit proprement le produit organométallique *trans*-$PtCl_2(coe)(thmo)$ (thmo = tétrahydro-2-méthyl-1,3-oxazine) qui provient d'une hydroamination intramoléculaire catalysée par un métal de l'alcénylamine de départ. Des études initiales sur la fonctionnalisation de complexes métalliques contenant des groupes alcènes ont montré que sous l'influence d'un catalyseur de rhodium, on peut, dans certains cas, additionner du catécholborane pour obtenir les esters organoboronates du platine correspondants.

Mots clés : alcénylamines, alcénylpyridines, hydroamination, hydroboration, platine.

Introduction

Cisplatin, *cis*-$PtCl_2(NH_3)_2$, is an anti-cancer agent used extensively for the treatment of testicular and ovarian tumours, and has moderate use in the treatment of neck, bladder and lung tumours (1–6). Unfortunately, widespread application of this compound has been limited by numerous drawbacks including nausea, myelosuppression of bone marrow, renal tubular necrosis leading to kidney failure, loss of high frequency hearing, and neuropathy. These side effects, coupled with the low solubility of cisplatin in water, have resulted in a large influx of research into derivatives of cisplatin in an attempt to overcome some of these limitations. With this in mind, we have prepared a number of *trans* platinum complexes containing alkenylamine and alkenylpyridine ligands and hypothesize that further hydroboration of the pendant C=C moieties in these complexes may prove to be a facile route to making novel platinum compounds containing biologically-active boronic acid groups. Platinum complexes containing alkenylamines and

alkenylpyridines are also of interest as these ligands can coordinate to the metal centre via either the nitrogen lone pair or the alkene moiety.

Experimental

Reagents and solvents used were obtained from Aldrich Chemicals. THF, hexane, and diethyl ether were distilled from sodium benzophenone ketyl. Methylene chloride and chloroform were distilled from CaH_2. Potassium tetrachloroplatinate was obtained from Johnson Matthey Ltd. $RhCl(PPh_3)_3$ was prepared as described elsewhere (7). NMR spectra were recorded on a JEOL JNM-GSX270 FT NMR spectrometer. ^1H NMR chemical shifts are reported in ppm and referenced to residual protons in deuterated solvent at 270 MHz. $^{11}B\{^1H\}$ NMR chemical shifts are referenced to external $F_3B{\cdot}OEt_2$ at 87 MHz. $^{13}C\{^1H\}$ NMR chemical shifts are referenced to solvent carbon resonances as internal standards at 68 MHz. Multiplicities are reported as (s) singlet, (d) doublet, (t) triplet, (q) quartet, (quint) quintet, (m) multiplet, (br) broad, and (ov) overlapping. Infrared spectra were obtained using a Mattson Polaris FT-IR spectrometer and reported in cm^{-1}. Melting points were measured uncorrected with a Mel-Temp apparatus. Microanalyses for C, H, and N were carried out at Desert Analytics (Tucson, AZ).

Preparation of $[PtCl_2(coe)]_2$ (1)

$[PtCl_2(coe)]_2$ (**1**) was prepared by modification of a known procedure (8). Potassium tetrachloroplatinate (300 mg, 0.70 mmol) was dissolved in a water isopropanol mixture (10 :7 mL). A catalytic amount of tin chloride (3.8 mg, 0.02 mmol) was added to the red solution along with an excess of *cis*-cyclooctene (3.0 mL, 23.0 mmol). After 5 days, the yellow solution was decanted from a small amount of black precipitate. Compound **1** was extracted from the aqueous phase with 15 mL of methylene chloride and filtered to afford a clear yellow solution. The solvent was removed in vacuo to give a yellow solid and a small amount of yellow liquid. The liquid was dissolved in hexane (10 mL) and decanted to afford a bright yellow powder. Yield: 158 mg (58%). A yellow–orange precipitate appeared in the hexane phase after 3 days. The hexane was decanted and the solid dried. Yield: 53 mg (79% total); mp 190°C (decomposition). Spectroscopic NMR data (in $CDCl_3$): ^1H δ:1.35 (br s, 8H), 1.52 (br s, 8H), 2.18 (br d, $J_{H\text{-}H}$ = 5 Hz, 8H), 5.78 (br, 4H); $^{13}C\{^1H\}$ δ: 26.1, 27.4, 28.9, 109.2 (br). IR (nujol): 762, 817, 868, 955, 1031, 1125, 1170, 1230, 1378, 1464, 2859, 2915.

Yellow crystals of **2** could be isolated from solutions of **1** in the presence of excess coe. The mp was found to be 178°C (decomposition). Spectroscopic NMR data (in $CDCl_3$): ^1H δ: 1.45 (br s, 8H), 1.62 (br s, 8H), 2.29 (br d, $J_{H\text{-}H}$ = 5 Hz, 8H), 5.94 (br, 4H); $^{13}C\{^1H\}$ δ: 26.3, 27.6, 29.2, 113.3 (br). IR (nujol): 762, 818, 953, 1125, 1170, 1233, 1317, 1354, 1380, 1427, 1467, 1529, 2845, 2884, 2972. The formation of this monomer has been reported previously (8). Interestingly, C and H elemental analyses from this previous study varied over time, suggesting loss of the second coe ligand to give **1** is facile even in the solid state.

Preparation of *trans*-$PtCl_2$(coe)(2vp) (3)

2-Vinylpyridine (14 mg, 0.13 mmol) in 3 mL of CH_2Cl_2 was added dropwise at 0°C to a solution of *trans*-$[PtCl_2(coe)]_2$ (50 mg, 0.07 mmol) in 15 mL of CH_2Cl_2. The reaction was stirred for 4 h at which point solvent was removed under vacuum to afford a yellow solid which was washed with ether (2 × 2 mL) and hexane (3 × 5 mL). Yield: 26 mg (40%); mp 187°C (decomposition). Spectroscopic NMR data (in $CDCl_3$): ^1H δ: 1.43 (s, 4H), 1.80 (br s, 4H), 2.22–2.49 (ov m, 4H), 5.53 (m, $J_{H\text{-}Pt}$ = 70 Hz, 2H), 5.83 (d, $J_{H\text{-}H}$ = 8 Hz, 1H), 6.06 (d, $J_{H\text{-}H}$ = 15 Hz, 1H), 7.31 (t, $J_{H\text{-}H}$ = 5 Hz, 1H), 7.72 (m, 2H), 8.12 (d of d, $J_{H\text{-}H}$ = 15, 5 Hz, 1H), 8.68 (d, $J_{H\text{-}H}$ = 5 Hz, $J_{H\text{-}Pt}$ = 35 Hz, 1H); $^{13}C\{^1H\}$ δ: 26.1, 27.9, 29.0, 94.5 ($J_{C\text{-}Pt}$ = 153 Hz), 121.7, 123.2, 124.0, 135.2, 138.7, 150.3, 156.7. IR (nujol): 761, 793, 939, 957, 1108, 1127, 1163, 1229, 1377, 1465, 1562, 1602, 2857, 2897, 2941, 2966. Elemental analysis calcd. for $PtCl_2C_{15}H_{21}N$: C 37.42, H 4.41, N 2.91; found: C 37.68, H 4.50, N 3.01.

Preparation of *trans*-$PtCl_2$(coe)(4vp) (4)

4-Vinylpyridine (60 mg, 0.56 mmol) in 5 mL of CH_2Cl_2 was added dropwise to a stirred solution of **1** (200 mg, 0.27 mmol) in 15 mL of CH_2Cl_2 at 0°C. The solvent was removed under vacuum after 4 h to afford a yellow solid which was washed with hexane (3 × 5 mL). Spectroscopic NMR data (in $CDCl_3$): ^1H δ: 1.47 (s, 6H), 1.83 (br s, 2H), 2.36 (br s, 2H), 2.54 (br s, 2H), 5.55 (br d, $J_{H\text{-}H}$ = 11 Hz, $J_{H\text{-}Pt}$ = 64 Hz, 2H), 5.61 (d, $J_{H\text{-}H}$ = 11 Hz, 1H), 6.06 (d, $J_{H\text{-}H}$ = 19 Hz, 1H), 6.68 (d of d, $J_{H\text{-}H}$ = 11, 5 Hz, 1H), 7.40 (d, $J_{H\text{-}H}$ = 5 Hz, 2H), 8.78 (d, $J_{H\text{-}H}$ = 5 Hz, $J_{H\text{-}Pt}$ = 27 Hz, 2H); $^{13}C\{^1H\}$ δ: 26.4, 28.3, 29.4, 94.4 ($J_{C\text{-}Pt}$ = 158 Hz), 122.3, 122.9, 133.3, 148.3, 151.7. Attempts to isolate **4** for elemental analysis were complicated by disproportionation in solution to give **1** and **5**.

Preparation of *trans*-$PtCl_2(4vp)_2$ (5)

4-Vinylpyridine (25 mg, 0.24 mmol) in 1 mL of CH_2Cl_2 was added dropwise to a stirred solution of **1** (45 mg, 0.06 mmol) in 7 mL of CH_2Cl_2. The mixture was cooled to 0°C for 2 days and the resultant off-white precipitate was filtered and dried under vacuum. Yield: 43 mg (75%); mp 264°C (decomposition). Spectroscopic NMR data (in $CDCl_3$): ^1H δ: 5.60 (d, $J_{H\text{-}H}$ = 11 Hz, 2H), 6.02 (d, $J_{H\text{-}H}$ = 19 Hz, 2H), 6.58 (d of d, $J_{H\text{-}H}$ = 19, 11 Hz, 2H), 7.18 (d, $J_{H\text{-}H}$ = 8 Hz, 4H), 8.84 (br d, $J_{H\text{-}H}$ = 6 Hz, $J_{H\text{-}Pt}$ = 30 Hz, 4H); $^{13}C\{^1H\}$ δ: 121, 122, 133, 147, 155. IR (nujol): 666, 846, 991, 1206, 1417, 1435, 1499, 1546, 1616, 2943. Elemental analysis calcd. for $PtCl_2C_{14}H_{14}N_2$: C 35.29, H 2.97, N 5.88; found: C 34.72, H 2.99, N 5.69.

Preparation of *trans*-$PtCl_2$(coe)(4chp) (6)

4-(3-Cyclohexen-1-yl)pyridine (89 mg, 0.56 mmol) in 5 mL of CH_2Cl_2 was added dropwise to a stirred solution of **1** (200 mg, 0.27 mmol) in 15 mL of CH_2Cl_2 at 0°C. The reaction was allowed to proceed for 4 h at which point the solvent was removed under vacuum. The resultant orange oil was dissolved in 1 mL of CH_2Cl_2 after which 5 mL of hexane was added and the reaction mixture stored at 0°C for 18 h. The precipitate was collected and determined to be **7** by NMR spectroscopic data. The solvent was removed from the filtrate to afford a bright yellow solid. Spectroscopic

NMR data (in $CDCl_3$) for **6**: ^{1}H δ: 1.46 (m, 6H), 1.76 (ov m, 4H), 2.15 (s, 2H), 2.32 (m, 4H), 2.53 (m, 2H), 2.89 (s, 1H), 5.66 (d, $J_{H\text{-}H}$ = 8 Hz, $J_{H\text{-}Pt}$ = 72 Hz, 2H), 5.72 (s, 2H), 7.29 (d, $J_{H\text{-}H}$ = 5 Hz, 2H), 8.73 (br d, $J_{H\text{-}H}$ = 5 Hz, $J_{H\text{-}Pt}$ = 32 Hz, 2H); ^{13}C{^{1}H}δ: 25.0, 26.3, 28.1, 28.5, 29.3, 31.8, 39.5, 94.1 ($J_{C\text{-}Pt}$ = 156 Hz), 124.0, 125.4, 127.3, 151.2, 153.2. Attempts to isolate **6** were complicated by disproportionation in solution to give **1** and **7**.

Preparation of *trans*-$PtCl_2(4chp)_2$ (7)

4-(3-Cyclohexen-1-yl)pyridine (45 mg, 0.29 mmol) in 1 mL of CH_2Cl_2 was added dropwise to a stirred solution of **1** (50 mg, 0.07 mmol) in 15 mL of CH_2Cl_2. The solvent was removed under vacuum after the reaction was allowed to proceed for 5 h. The resultant yellow oil was dissolved in 1 mL of CH_2Cl_2 after which addition of hexane (3 mL) to the solution produced an off-white precipitate. Yield: 53 mg (68%); mp 272°C (decomposition). Spectroscopic NMR data (in $CDCl_3$): ^{1}H δ 1.60 (m, 4H), 1.93 (m, 4H), 2.25 (m, 4H), 2.87 (br s, 2H), 5.77 (s, 4H), 7.16 (d, $J_{H\text{-}H}$ = 5 Hz, 4H), 8.75 (d, $J_{H\text{-}H}$ = 5 Hz, $J_{H\text{-}Pt}$ = 32 Hz, 4H); ^{13}C{^{1}H} δ 25.1, 28.6, 32.0, 39.5, 123.9, 125.6, 127.4, 153.1, 159.2. IR (nujol): 719, 829, 1069, 1212, 1244, 1422, 1616, 2936. Elemental analysis calcd. for $PtCl_2C_{22}H_{26}N_2$: C 45.21, H 4.49, N 4.79; found: C 44.83, H 4.26, N 4.62.

Preparation of *trans*-$PtCl_2(aa)_2$ (8)

Allylamine (18 mg, 0.32 mmol) in 3 mL of CH_2Cl_2 was added to a stirred solution of **1** (50 mg, 0.07 mmol) in 10 mL of CH_2Cl_2 at 0°C. Within 30 min a yellow precipitate had formed and was collected by suction filtration. Yield: 37 mg (72%); mp 214°C (decomposition). Spectroscopic NMR data (in $CDCl_3$): ^{1}H δ: 3.49 (d, $J_{H\text{-}H}$ = 5 Hz, 4H), 5.37 (d of d, $J_{H\text{-}H}$ = 11, 5 Hz, 2H), 5.97 (m, 4H), 8.18 (br s, 4H); ^{13}C{^{1}H} δ: 44.2, 123.7, 131.9. IR (nujol): 722, 1018, 1108, 1566, 1603, 2928. Elemental analysis calcd. for $PtCl_2C_6H_{14}N_2$: C 18.95, H 3.72, N 7.37; found: C 18.95, H 3.97, N 7.23. Complex **8** eventually decomposes in solution to give a number of unidentified products.

Preparation of *trans*-$PtCl_2$(coe)(chea) (9)

2-(1-Cyclohexenyl)ethylamine (35 mg, 0.28 mmol) in 15 mL of CH_2Cl_2 was added to a solution of **1** (100 mg, 0.13 mmol) in 10 mL of CH_2Cl_2 at 0°C. The reaction was allowed to proceed for 3 h at which point solvent was removed under vacuum to afford an orange oil. The oil was dissolved in 1 mL of CH_2Cl_2 after which hexane (10 mL) was added and the reaction mixture cooled to 0°C. After 18 h, a pale yellow precipitate was collected by suction filtration and found to be a mixture of products by NMR spectroscopy. The solvent was allowed to evaporate from the filtrate over 48 h to afford bright yellow needles which were collected and dried under vacuum. Yield: 70 mg (52%); mp 122°C. Spectroscopic NMR data (in $CDCl_3$): ^{1}H δ: 1.43 (m, 6H), 1.59 (ov m, 4H), 1.78 (br s, 2H), 1.92 (br s, 2H), 2.01 (br s, 2H), 2.24 (br m, 4H), 2.39 (ov m, 2H), 3.09 (m, $J_{H\text{-}H}$ = 8 Hz, 2H), 3.72 (br s, $J_{H\text{-}Pt}$ = 59 Hz, 2H), 5.30 (d, $J_{H\text{-}H}$ = 11 Hz, $J_{H\text{-}Pt}$ = 81 Hz, 2H), 5.55 (s, 1H); ^{13}C{^{1}H} δ: 22.4, 22.8, 25.5, 26.4, 27.9, 28.1, 29.5 ($J_{C\text{-}Pt}$ = 41 Hz), 39.7, 42.7, 93.6 ($J_{C\text{-}Pt}$ = 158 Hz), 126.5, 132.8. IR (nujol): 722, 1001, 1231, 1377, 1461, 1579, 2841, 2968. Elemental analysis calcd. for $PtCl_2C_{16}H_{29}N$: C 38.31, H 5.84, N 2.79; found: C 38.72, H 5.92, N 2.86.

Preparation of *trans*-$PtCl_2$(coe)(thmo) (10)

Tetrahydro-2-methyl-1,3-oxazine (14 mg, 0.14 mmol) in 3 mL of CH_2Cl_2 was added dropwise to a solution of **1** (50 mg, 0.07 mmol) in 10 mL of CH_2Cl_2 at 0°C. Solvent was removed after 4 h to afford a yellow oil which was triturated with hexane (3 × 5 mL) and dried under vacuum to afford a yellow solid. Yield: 25 mg (40%); mp 98°C. Spectroscopic NMR data (in $CDCl_3$): ^{1}H δ: 1.37 (br s, 6H), 1.70 (ov m, 6H), 2.13 (br s, 2H), 2.29 (br s, 2H), 3.39 (m, 2H), 3.70 (t, $J_{H\text{-}H}$ = 16 Hz, 1H), 3.92 (m, 1H), 4.45 (br s, 1H), 4.60 (m, 2H), 5.27 (m, 2H); ^{13}C{^{1}H} δ: 22.3, 25.6, 25.9, 27.4, 27.6, 28.9, 48.4, 86.5, 92.9 ($J_{C\text{-}Pt}$ = 140 Hz). IR (nujol): 815, 846, 963, 1017, 1059, 1099, 1139, 1230, 1378, 1461, 2889, 3216, 3433. Elemental analysis calcd. for $PtCl_2C_{13}H_{25}NO$: C 32.71, H 5.28, N 2.93; found: C 33.10, H 5.23, N 2.90.

Catalyzed hydroboration of *trans*-$PtCl_2(4vp)_2$ (5) with catecholborane

Under an atmosphere of dinitrogen, *trans*-$PtCl_2(4vp)_2$ (25 mg, 0.05 mmol) was suspended in 1 mL of $CDCl_3$ with 7 mol% of Wilkinson's catalyst, $RhCl(PPh_3)_3$. Catecholborane (14 mg, 0.12 mmol) in 0.5 mL of $CDCl_3$ was added dropwise to the stirred suspension and the reaction mixture was allowed to stand for 48 h and then analyzed by NMR spectroscopy. Spectroscopic NMR data (in $CDCl_3$): ^{1}H δ: 1.22 (t, $J_{H\text{-}H}$ = 8 Hz), 1.50 (d, $J_{H\text{-}H}$ = 8 Hz), 1.64 (t, $J_{H\text{-}H}$ = 8 Hz), 2.12 (s), 2.69 (q, $J_{H\text{-}H}$ = 8 Hz), 3.03 (ov), 5.29 (s), 5.38 (s), 5.63 (m), 7.0 (m), 8.74 (d, $J_{H\text{-}H}$ = 5 Hz); ^{11}B{^{1}H} δ: 7.0 (s), 7.8 (s), 12.3 (s), 29.0 (s), 23.2 (br), 35.0 (br).

Catalyzed hydroboration of *trans*-$PtCl_2(4chp)_2$ (7) with catecholborane

Under an atmosphere of dinitrogen, *trans*-$PtCl_2(4chp)_2$ (52 mg, 0.09 mmol) was dissolved in 1 mL of $CDCl_3$ with 7 mol% catalyst. Catecholborane (24 mg, 0.20 mmol) in 0.5 mL of $CDCl_3$ was added dropwise to the stirred solution and the reaction was allowed to proceed for 48 h and then analyzed by NMR spectroscopy. Spectroscopic NMR data (in $CDCl_3$): ^{1}H δ: 1.45–1.59 (ov m), 2.00–2.18 (ov m), 2.66 (m), 6.92–7.39 (ov m), 8.75 (d, $J_{H\text{-}H}$ = 5 Hz), 8.88 (d, $J_{H\text{-}H}$ = 5 Hz); ^{11}B{^{1}H} δ: 12.3 (s), 23.0 (s), 36.3 (br); ^{13}C{^{1}H} δ 21.2 (br, C-B), 21.8 (br, C-B), 27.1, 27.2, 27.7, 33.3, 33.7, 34.1, 43.6, 44.4, 112.6, 112.8, 121.6, 122.9, 124.0, 148.2, 148.3, 153.5, 159.4.

The platinum aminoboronate ester was formed in situ as described in the previous procedure and removed from the dinitrogen atmosphere. Addition of 0.5 mL of D_2O to this product resulted in a convincing change in the solution's appearance from brown to orange in colour. Spectroscopic NMR data (in $CDCl_3$): ^{1}H δ: 1.48–1.58 (ov m), 1.99 (m), 2.18 (m), 2.65 (m), 6.70 (d, $J_{H\text{-}H}$ = 5 Hz), 6.88 (d, $J_{H\text{-}H}$ = 5 Hz), 7.09–7.21 (ov m), 7.39 (m), 8.73 (d, $J_{H\text{-}H}$ = 5 Hz); ^{11}B{^{1}H} δ: 19.6 (s, $B(OH)_3$), 36.9 (br); ^{13}C{^{1}H} δ 21.2 (br, C-B), 22 (br, C-B), 27.1, 27.2, 27.6, 33.0, 33.6, 33.7, 43.6, 44.3, 115.6, 120.9, 124.0, 148.2, 153.2, 159.5.

X-ray crystallographic data for 2 and 5

Crystals of **2** and **5** suitable for X-ray diffraction studies were obtained by crystallization from solutions of methylene chloride at 5°C. A summary of the crystal data and parameters for data collection is given in Table 1. Data were collected at 183 K (for **2**) and 193 K (for **5**) on a Siemens SMART/CCD diffractometer equipped with an LT-II low temperature device. Diffracted data were corrected for absorption using the SADABS[4] program. SHELXTL was used for structure solution and refinement was based on F^2.[5] All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were fixed at calculated positions and refined isotropically on the basis of the corresponding carbon atoms [*U*(H) = 1.2*U*eq(C)]. Selected bond distances and angles are given in Tables 2 and 4 and final atomic coordinates in Tables 3 and 5. Complete tables of bond distances and angles, final atomic coordinates, and anisotropic displacement parameters have been deposited as supporting material.[6]

Results and discussion

As part of our ongoing research into making novel aminoboron platinum complexes, we decided to initially prepare a number of unsaturated *trans* amine and pyridine complexes from the monoalkene dimer *trans*-$[PtCl_2(coe)]_2$ (**1**) (coe = η^2 – C_8H_{14}) (8). The starting organometallic dimer, which is soluble in common organic solvents, was readily prepared by the addition of *cis*-cyclooctene to aqueous solutions of K_2PtCl_4, and appears to be indefinitely stable in the solid state. A recent paper examining reaction mechanisms for alkene exchange with *trans*-$[PtCl_2(C_2H_4)]_2$ suggests that a two-step process incorporating *trans*-$PtCl_2(C_2H_4)_2$ might be occurring in the steady state (9). Indeed, the analogous disubstituted alkene complex *trans*-$PtCl_2(coe)_2$ (**2**) could be crystallized in minor amounts (<10%) by addition of excess coe to **1** (10).

We have carried out an X-ray diffraction study on **2** which shows the platinum metal centre in a square plane with the cyclooctene ligands lying *trans* to one another. The structure of **2** is shown in Fig. 1, summary of the crystallographic data presented in Table 1, pertinent bond distances and angles given in Table 2, and atomic coordinates provided in Table 3. Platinum–carbon bond distances of 2.258(4) and 2.278(4) Å are somewhat longer than analogous Pt(II) complexes where a chloride ligand lies *trans* to the alkene group. For instance, average bond lengths of 2.128(19), 2.13(2),

and 2.12(2) Å have been reported for $K[PtCl_3(C_2H_4)]$ (11), $PtCl(C_6H_2Me_3)(\eta^4\text{-}C_8H_{12})$ (12), and $[PtCl_2(C_7H_{12})]_2$ (13), respectively. However, the Pt—C bond distance in **2** is similar to that reported for the double bond *trans* to the mesityl group ($C_6H_2Me_3$) in the previous example (cf. 2.30(2) Å). The carbon–carbon bond distance of 1.389(5) Å shows the expected weakening of the double bond due to π-backbonding from the metal to the empty π^* orbital of the alkene (14).

Addition of neutral ligands (L) to either **1** or **2** will give complexes of the type *trans*-$PtCl_2(coe)L$ and, upon addition of a second equivalent of ligand, the disubstituted species *trans*-$PtCl_2L_2$ (15). Reactions with alkenylpyridine and alkenylamine ligands are of special interest because coordination of these ligands to a transition metal can occur via either the alkene moiety and (or) the nitrogen lone pair.

Alkenylpyridines

A number of transition metal complexes (16–23) containing alkenylpyridine ligands have been reported. For example, addition of 2-vinylpyridine (2vp = 2-$NC_5H_4CH{=}CH_2$) to $[Cu(NCCH_3)_4][ClO_4]$ gave the binuclear complex $[Cu_2(\mu\text{-}2vp)_2(2vp)_2][ClO_4]_2$ where two of the alkenylpyridine ligands use the nitrogen and the alkene to bond to two respective metal centres (16). For this study we decided to prepare *trans* complexes from three commercially available alkenylpyridines (Fig. 2).

[a]Symmetry transformations used to generate equivalent atoms: #1 (–x + 1), (–y + 1), –z.

Previous work has shown that attempts to prepare *cis*-$PtCl_2(2vp)_2$ (20) from K_2PtCl_4 resulted in the formation of several products where both the alkene and nitrogen groups are involved in bonding to platinum. Likewise, efforts to generate the *trans* derivative from *trans*-$PtCl_2(NCCH_3)_2$ have also proven unsuccessful (23). Although we were also unable to generate *trans*-$PtCl_2(2vp)_2$ from addition of 2vp to

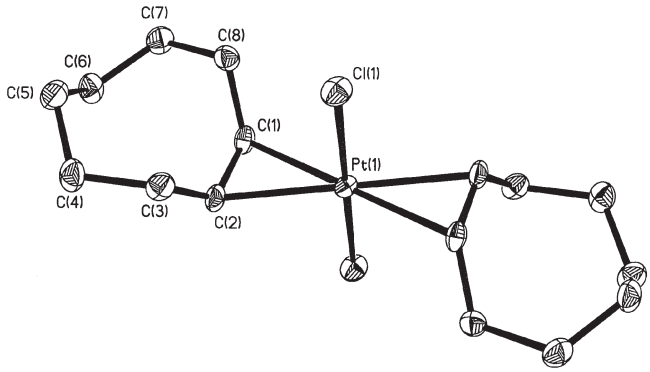
trans-$[PtCl_2(coe)]_2$ (**1**), the novel organometallic complex *trans*-$PtCl_2(coe)(2vp)$ (**3**), which is soluble in common organic solvents such as methylene chloride, could be isolated in moderate yield (40%). Steric congestion around the nitrogen atom in 2-vinylpyridine presumably inhibits addition of a second equivalent of this ligand to the metal centre. The ^{1}H NMR spectrum for **3** shows a shift for the pyridine ring's α-carbon proton from 8.54 ppm for free 2vp to 8.68 ppm in the complex. Coupling ($J_{H\text{-}Pt}$ = 35 Hz) to the ^{195}Pt nucleus (14) is also observed for this resonance. Shifts for the alkenyl peaks are also observed by ^{1}H NMR spectroscopy for this complex, suggesting that the alkenyl group may lie directly above the plane of the platinum atom (15).

The corresponding 4-vinylpyridine (4vp = 4-$NC_5H_4CH{=}CH_2$) complex, *trans*-$PtCl_2(coe)(4vp)$ (**4**), was prepared by addition of 2 equivalents of 4vp to **1**, along with minor amounts of the disubstituted product *trans*-$PtCl_2(4vp)_2$ (**5**) and unreacted **1**. For complex **4**, the diagnostic shift from 8.56 ppm for free 4vp to 8.78 ppm is observed in the ^{1}H NMR spectrum, along with coupling to platinum ($J_{H\text{-}Pt}$ = 27 Hz), for the pyridine ring's α-carbon protons. Complex **5** could be readily prepared by the addition of excess 4vp to **1**. Although NMR spectroscopic data show similar trends upon complexation to platinum, unambiguous assignment of **5** is based upon an X-ray diffraction study. The molecular structure of **5** is shown in Fig. 3, relevant bond angles and distances in Table 4, and atomic coordinates in Table 5. The platinum atom lies in a distorted square plane with two Cl atoms and two 4vp N atoms coordinated to the metal centre in a *trans* geometry. The Pt—Cl and Pt—N bond distances of 2.2996(8) and 2.020(3) Å, respectively, are similar to those reported for *cis*-$PtCl_2(4vp)_2$ (21). Bond lengths of 1.330(6) Å are typical for uncomplexed C—C double bonds. The alkenylpyridines are planar with bond distances and angles similar to those observed in other transition metal pyridine derivatives (21).

The organometallic complex *trans*-$PtCl_2(coe)(4chp)$ (**6**) (4chp = 4-(3-cyclohexen-1-yl)pyridine) and the disubstituted compound *trans*-$PtCl_2(4chp)_2$ (**7**) were readily prepared from reaction of the cyclooctene dimer **1** with 2 and 4 equivalents of 4chp, respectively, (24). Complex **6** has the diagnostic shift for the α-hydrogens of the pyridine group in the ^{1}H NMR spectrum (8.49 ppm for free 4chp to 8.73 ppm for **6**) along with coupling to the ^{195}Pt nucleus ($J_{H\text{-}Pt}$ = 72 Hz). The cyclohexenyl groups in **7** resulted in this complex having increased solubility in common organic solvents as compared to **5**.

Fig. 1. Molecular structure of *trans*-$PtCl_2(coe)_2$ (**2**).



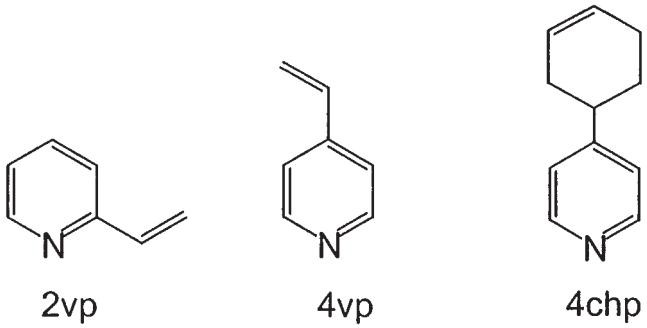


Fig. 2. Alkenylpyridines.

Alkenylamines

The synthesis of platinum complexes containing neutral and protonated alkenylamines has been reported previously (25–28). For example, addition of allylamine (aa = $NH_2CH_2CH{=}CH_2$) to acidic solutions of $[PtCl_4]^{2-}$ are known to give zwitterionic $PtCl_3(CH_2{=}CHCH_2NH_3)$ where only the C=C group of the alkenylamine is coordinated to the platinum centre (14, 25). In the absence of protonation, or by treatment with NaOH, the above complex can be transformed into a neutral alkenylamine species where the ligand is capable of coordinating in a chelating bidentate manner through both the alkene moiety and the nitrogen lone pair (26). Another allylamine complex has been reported in which the ligand bridges two metal centres by binding to one metal via the nitrogen atom and to the other platinum using the alkene group (29). We have found that addition of aa to *trans*-$[PtCl_2(coe)]_2$ (**1**) afforded the novel diamine complex *trans*-$PtCl_2(aa)_2$ (**8**) in high yield (72%). Complex **8** is only sparingly soluble in common organic solvents such as methylene chloride. The amine hydrogens appear as a broad peak in the ^{1}H NMR spectrum and shift from 1.23 for free allylamine to 8.18 ppm in **8**. Likewise, the broad methylene peak shifts from 3.36 to 3.49 ppm upon complexation. The vinyl peaks, however, remain relatively unchanged suggesting that coordination of the allylamine ligand occurs through the nitrogen atom only. IR data supports this hypothesis as the C=C π stretch found in free allylamine at 1637 cm^{-1} only shifts to 1603 cm^{-1} when the ligand coordinates to Pt(II). For metal complexes containing the

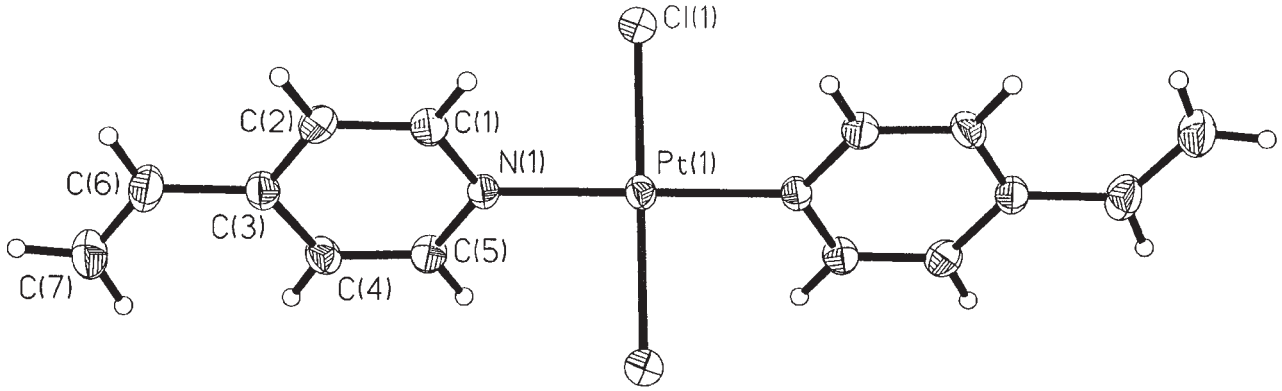
Fig. 3. Molecular structure of *trans*-$PtCl_2(4vp)_2$ (**5**).



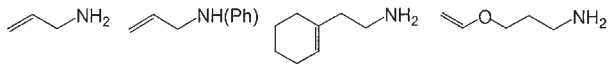


Fig. 4. Alkenylamines.

protonated alkenylamine ligands, where the alkene is directly bound to the metal centre, this band appears near 1500 cm^{-1} (26). Efforts to prepare the monoamine complex *trans*-$PtCl_2$(coe)(aa) have proven unsuccessful.

We have attempted to prepare platinum complexes with other alkenylamines (Fig. 4) in an effort to confirm the bonding modes in these unique ligands. Unfortunately, no reaction was observed between dimer **1** and secondary amine *N*-allylaniline (aA = $NH(Ph)CH_2CH{=}CH_2$). The increased steric bulk of this amine, as compared with allylamine, presumably precludes coordination to the metal centre. Conversely, *trans*-$PtCl_2$(coe)(chea) (**9**) was prepared by addition of 2-(1-cyclohexenyl)ethylamine (chea) to dimer **1**. As with the other monoamine complexes, the $^{13}C\{^1H\}$ NMR spectrum for **9** exhibits a singlet for the sp^2 carbons of the coe ligand at 93.6 ppm with diagnostic ^{195}Pt satellites ($J_{C\text{-}Pt}$ = 158 Hz). Unfortunately, treatment of **1** with four equivalents of chea led to a complex mixture of products, even at low temperatures.

Addition of aminopropylvinylether (apve = $H_2NCH_2CH_2CH_2OCH{=}CH_2$) to *trans*-$[PtCl_2(coe)]_2$ (**1**) gave the unexpected product *trans*-$PtCl_2$(coe)(thmo) (**10**) (thmo = tetrahydro-2-methyl-1,3-oxazine) in moderate yields (40%). The formation of thmo presumably arises from a platinum mediated intramolecular hydroamination of the starting apve group (30). A proposed mechanism for this reaction is shown in Fig. 5 (31). Coordination of the alkene group to the metal centre activates it towards nucleophilic attack by the amine group. Selective attack at the carbon α to the ether oxygen affords an alkylplatinum intermediate. Subsequent hydrogen abstraction from the ammonium group yields an alkylmetal hydride intermediate which undergoes reductive elimination to produce free thmo and the coordinatively unsaturated metal species '$PtCl_2$(coe)'. This complex, or unreacted **1**, rapidly traps free thmo to give *trans*-$PtCl_2$(coe)(thmo). This reaction is specific for the hydroamination product as no other apve derivatives were observed. Further work in this area will concentrate on examining the hydroamination of *N*-substituted apve derivatives, the results of which will be reported in due course.

Hydroboration of Metal Complexes

We hypothesize that hydroboration of pendant alkenyl groups in the above mentioned alkenylamine and alkenylpyridine compounds, followed by aqueous workup, should give novel platinum complexes containing boronic acids, $-B(OH)_2$ (32). Compounds containing boronic acids have extensive biological activity (33) as well as facilitate the transport of molecules across lipid bilayers (34, 35). As hydroborations of the starting alkenylamines and alkenylpyridines are known to give a number of unwanted products (36, footnote 7), this present methodology is advantageous in that coordination of the ligand to the metal centre deactivates the lone pair of nitrogen.

Initial work was conducted on the monoalkene complexes **3**, **4**, **6**, and **9**. Not surprisingly, however, hydroborations of these complexes always gave complex product distributions arising from attack of the borane at the metal centre following initial loss of the labile cyclooctene ligand. We therefore decided to concentrate our efforts on functionalizing the disubstituted analogues and proceeded by using the fully characterized pyridine complex *trans*-$PtCl_2(4vp)_2$ (**5**). Reactions of **5** with catecholborane (HBcat, cat = $O_2C_6H_4$), using 7 mol% of $RhCl(PPh_3)_3$ (37), gave mixtures of *anti*-Markovnikov (45% by ^1H NMR spectroscopy) and Markovnikov (45%) hydroboration products, products derived from a dehydrogenative borylation/hydrogenation (5% each) pathway, as well as some decomposition to platinum metal. Dehydrogenative borylation is basically a mechanism that replaces one of the alkene hydrogens with a Bcat group while generating H_2; this latter species accounts for the observation of products containing hydrogenated 4-ethylpyridine. The complex product distributions observed in these reactions is somewhat surprising in light of the fact that hydroborations of styrene derivatives ($ArCH{=}CH_2$) using HBcat can give exclusive formation of either the Markovnikov ($ArCH(Bcat)CH_3$) or *anti*-Markovnikov ($ArCH_2CH_2Bcat$) products depending upon the choice of catalyst (37, 38).

It is plausible that the numerous products observed in hydroborations of **5** may be arising from the low solubility

of the starting platinum material in organic solvents. We therefore decided to investigate the catalyzed hydroboration of organic soluble *trans*-$PtCl_2(4chp)_2$ (**7**). Addition of HBcat to **7** employing 7 mol% $RhCl(PPh_3)_3$ as a catalyst gave the desired hydroborated product (Fig. 6) as ascertained by multinuclear NMR spectroscopy. The diagnostic peak at 36 ppm in the $^{11}B\{^1H\}$ NMR spectrum suggests the formation of an organoboronate ester (38). Further evidence that the 1,2-disubstituted alkene is being reduced is indicated by the disappearance of the vinylic peak in the ^1H NMR spectrum. Preliminary results attempting to convert the hydroborated product to the corresponding boronic acid compound have also proven successful. However, because of the disubstituted nature of the alkene, it appears that this reaction is not selective as regioisomers are present as observed by ^1H and $^{13}C\{^1H\}$ NMR spectroscopy. We are currently examining the full scope of this reaction in an effort to improve selectivities and will report our results in due course.

Conclusions

We have prepared a number of *trans* platinum alkenylpyridine and alkenylamine complexes from the organometallic dimer *trans*-$[PtCl_2(coe)]_2$ (coe = *cis*-cyclooctene). Coordination in all cases appears to proceed through the nitrogen lone pair and not the alkene moiety. Several novel organometallic complexes of the type *trans*-[PtCl(coe)L] (L = alkenylpyridine or alkenylamine) have also been prepared and characterized. Initial investigations into the functionalization of the pendant alkene groups have shown that catecholborane can be added to these complexes, using a rhodium catalyst, to give the corresponding organoboronate ester platinum compounds.

Acknowledgements

Thanks are gratefully extended to the Natural Sciences and Engineering Research Council of Canada, St. Mary's University, and Mount Allison University for financial support and Johnson Matthey Ltd. for the generous supplies of platinum salts. We also wish to thank Dan Durant, Roger and Marilyn Smith, and John E. Marcone (DuPont Co.) for their expert technical assistance, Dr. Hilary Jenkins (SMU) for help with the X-ray crystallography, and Drs. Terri Bright, Sabine Weiguny and Giuliano Muccin (BASF) for the generous gift of aminopropylvinylether. Anonymous reviewers are thanked for helpful suggestions.

Glycosidase-catalyzed hydrolysis of 2-deoxyglucopyranosyl pyridinium salts: effect of the 2-OH group on binding and catalysis

Kelly S. E. Tanaka, Jiang Zhu, Xicai Huang, Francesco Lipari, and Andrew J. Bennet

Abstract: Three 2-deoxy-α-D-glucopyranosyl pyridinium tetrafluoroborates were tested for their binding affinity to a range of α-glucosidases and α-mannosidases. The α-isoquinolinium salt (**11**) binds approximately 275–fold more tightly to yeast α-glucosidase than does the isomeric quinolinium salt (**12**). In addition, compound **11** binds to the yeast enzyme approximately two-fold tighter than the corresponding glucopyranosyl isoquinolinium salt (**9**). The (k_{cat}/k_{hyd}) values for the yeast α-glucosidase-catalyzed reactions of **11** and **9** are 1.6×10^5 and 2.0×10^9, respectively, when compared to the spontaneous uncatalyzed reactions. Thus, the interaction of the 2-OH group in compound **9** with the yeast enzyme's active site generates a relative transition state stabilization of about 23.5 kJ mol^{-1}. For both compounds **11** and **12**, the observed rate accelerations for the yeast α-glucosidase-catalyzed hydrolysis, relative to the spontaneous reaction in solution, (k_{cat}/k_{hyd}) are identical within experimental error.

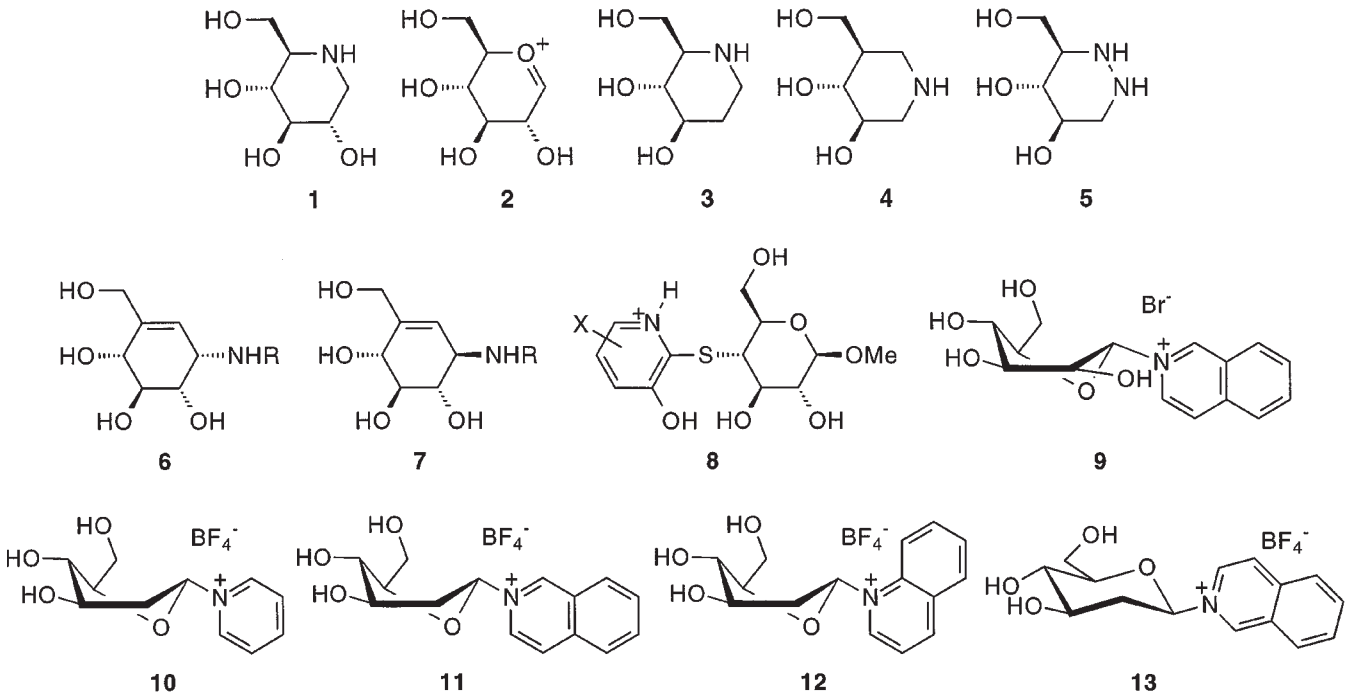
Key words: glycosidase, inhibitor, 2-deoxyglucose, pyridinium, catalysis.

Résumé : On a évalué les affinités de liaison de trois fluoroborates de 2-désoxy-α-D-glucopyranosyl pyridinium avec un ensemble d'α-glucosidases et d'α-mannosidases. Le sel d'α-isoquinoléinium (**11**) se lie approximativement 275 fois fortement à l'α-glucosidase de la levure que le sel quinoléinium isomère (**12**). De plus, le composé **11** se lie à l'enzyme de la levure approximativement deux fois mieux que le sel du glucopyranosyl isoquinoléinium correspondant (**9**). Les valeurs de (k_{cat}/k_{hyd}) pour les réactions des composés **11** et **9** catalysées par l'α-glucosidase de la levure sont égales respectivement à $1{,}6 \times 10^5$ et $2{,}0 \times 10^9$ lorsqu'on les compare aux réactions spontanées non catalysées. On en déduit que l'interaction du groupe 2-OH du composé **9** avec le site de l'enzyme de la levure génère une stabilisation relative de l'état de transition d'environ 23,5 kJ mol^{-1}. Pour chacun des composés **11** et **12**, les accélérations de vitesse observées pour les hydrolyses catalysées par l'α-glucosidase de la levure, comparées à la réaction spontanée en solution (k_{cat}/k_{hyd}) sont identiques aux erreurs expérimentales près.

Mots clés : glucosidase, inhibiteur, 2-désoxyglucose, pyridinium, catalyse.

Introduction

Recent advances in the rapidly growing field of glycobiology have provided insights into the fundamental importance of glycoproteins, glycolipids, and oligosaccharides in a myriad of biological events (1). Clearly, glycoconjugate-processing enzymes play a crucial role in the scheme of these various biological events (2). As a key subclass of glycoconjugate-processing enzymes, glycosidases are the focus of ongoing research aimed at the discovery of new glycosidase inhibitors (3). One class of naturally occurring glycosidase inhibitors are carbohydrate mimics that contain an endocyclic amino group, the so-called "imino-sugars" (4), a notable example of which is 1-deoxynojirimycin (DNJ, **1**) a compound that has the same hydroxyl configuration as 1-deoxyglucose (5). In general, imino-sugars are good inhibitors of glycosidase enzymes, probably due to protonation at physiological pH of the secondary amine of the imino-sugar, thus generating a cation mimic of the glucosyl oxacarbenium ion (**2**) which emulates the glycosylation transition state structure (3, 6).



New glycosidase inhibitors isolated from natural sources are often prototypes for the design and synthesis of analogues as potential therapeutic agents. For example,

Scheme 1.

isofagomine (**4**) an analogue of the natural product fagomine (**3**) isolated from buckwheat seeds (7) has recently been synthesized and shown to be a potent inhibitor (K_i = 0.11 μM) of the almond-emulsion β-glucosidase (8). Yet another related compound, 1-azafagomine (**5**) is a good inhibitor of both yeast α-glucosidase (K_i = 3.9 μM) and almond-emulsion β-glucosidase (K_i = 0.65 μM) (9).

A separate class of nitrogen-containing natural products is the "amino-sugars" which possess an exocyclic rather than endocyclic amino group (4). One such family of amino-sugar glycosidase inhibitors is the validamycins. which contain the critical valienamine structural motif (**6**). An example of this type of glycosidase inhibitor is the tight binding natural product acarbose (10, 11). Various epimeric analogues of valienamine, i.e., epi-valienamine (**7**) have also been synthesized and tested as potential β-glycosidase inhibitors (12).

Using an alternative strategy, Knapp et al. (13) explored the effectiveness of substituted 3-hydroxypyridines (**8**) rather than the more customary carbohydrate-based compounds as glycosylation TS mimics. The tightest binding of these aromatic compounds (**8**, X = H) was shown to be a weak competitive inhibitor (K_i = 0.8 mM) of *Agrobacterium* β-glucosidase (13).

Natural substrates generally are bound much more weakly to enzymes than the corresponding natural inhibitors (14), and as a result of this, the design of potential reversible glycosidase inhibitors rarely, if ever, exploit the modification of a natural substrate structure. Most glycosidase-catalyzed reactions are, however, monitored using nonnatural substrates that contain an aromatic aglycon leaving group. In 1985, Hosie and Sinnott (15) reported that yeast α-glucosidase efficiently catalyzes the hydrolysis of α-D-glucopyranosyl pyridinium bromides with an apparent binding constant (K_m) for the isoquinolinium substrate (**9**) of 6.6 μM. Thus, this man-made substrate binds to yeast α-glucosidase more tightly than the naturally occurring inhibitor DNJ (**1**) (K_i = 13 μM) (16).

Given that the C-2 hydroxyl-group of glycosides is critical for efficient glycosidase-catalyzed hydrolysis of carbohydrate substrates (17), we decided to test whether 2-deoxyglucopyranosyl pyridinium salts would retain the tight binding interactions exhibited by their 2-hydroxy counterparts, while simultaneously becoming more resistant to enzyme-catalyzed hydrolysis. Accordingly, the 2-deoxy-α- and β-glucopyranosyl pyridinium salts **10**, **11**, **12**, and **13** were synthesized, and their binding affinities and hydrolytic stabilities were evaluated for various glucosidase and mannosidase enzymes.

Results and discussion

The route used for the synthesis of **12** is shown in Scheme 1. This synthetic scheme involves a silver-promoted S_N2 reaction and is similar to the synthetic route employed for the production of both **10** and **11** (18).

Presented in Table 1 are the inhibition constants (K_i) measured for the interaction of **10**, **11**, **12**, and **13** with several

glycosidases. A Lineweaver–Burk plot of the kinetic data for yeast α-glucosidase-catalyzed hydrolysis of 4-nitrophenyl α-D-glucopyranoside in the presence of various concentrations of **11** is illustrated in Fig. 1. When detailed kinetic measurements were possible (K_i < 200 μM), only competitive inhibition of the glycosidases by the test compounds was observed. Consequently, these compounds are binding in a reversible manner to the enzyme active site. Table 2 presents the measured k_{cat} values for yeast α-glucosidase-catalyzed hydrolysis of **9**, **11**, and **12**. Also given in Table 2 are the corresponding spontaneous first-order reaction rates (k_{hyd}).

Hosie and Sinnott (15) proposed that yeast α-glucosidase-catalyzed hydrolysis of glucopyranosyl pyridinium salts occurs via the mechanism depicted in Scheme 2, a process in which glucosylation (k_{gluc}) is rate-limiting for k_{cat}, and a kinetically significant nonchemical step (k_2) is rate-limiting for k_{cat}/K_m.

The same scheme must hold for the reactions of the 2-deoxy salts, since: (*i*) k_{cat} for **12** is about 800–fold greater than k_{cat} for **11** (Table 2), thus k_{degluc} cannot be rate limiting (i.e., $k_{degluc} > k_{gluc}$); and (*ii*) k_{cat}/K_m for **11** and **12** are within a factor of three of each other and consequently, $_{kgluc}$ is not the major rate limiting step for k_{cat}/K_m. The apparent K_m for an enzyme-catalyzed reaction is given by eq. [1], where Σ[ES] is the sum of all enzyme bound species (14). Thus, the only two enzyme-bound species which contribute to the apparent K_m or K_i values are ES and ES′ (Scheme 2).

$$[1] \qquad K_m = \frac{[E][S]}{\sum[ES]}$$

Notably, the apparent dissociation constants measured for binding of **11** (K_i = 2.9 μM) and its 2-OH analogue [K_m = 6.6 μM (15); K_m = 7.7 μM (19)] to yeast α-glucosidase indicate that removal of the 2-hydroxyl moderately enhances the free energy for association by about 2 kJ mol^{-1} at 25°C.

The orientation of the aromatic ring is a critical variable for binding affinity of these compounds to the yeast enzyme. Specifically, fusion of a second aromatic ring onto the pyridinium compound (**10**) gives **11** and **12**, and this change causes either an increase of 8.9 kJ mol^{-1} (**11**) or a decrease of 5.0 kJ mol^{-1} (**12**) in the free energy of binding to the enzyme. An identical trend in K_i values (**11** < **10** < **12**) is also apparent for inhibition of the rice α-glucosidase, despite the attenuated potency of these compounds with this enzyme (Table 1).

It is presumed that the origin of the tight binding between the yeast enzyme and **11** results from strong hydrophobic interactions between the active-site and the isoquinoline ring. Lemieux (20) has stressed the important contribution to binding free energy that occurs as ordered water molecules

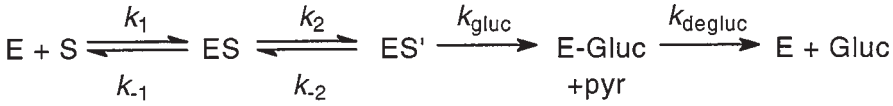
Scheme 2.



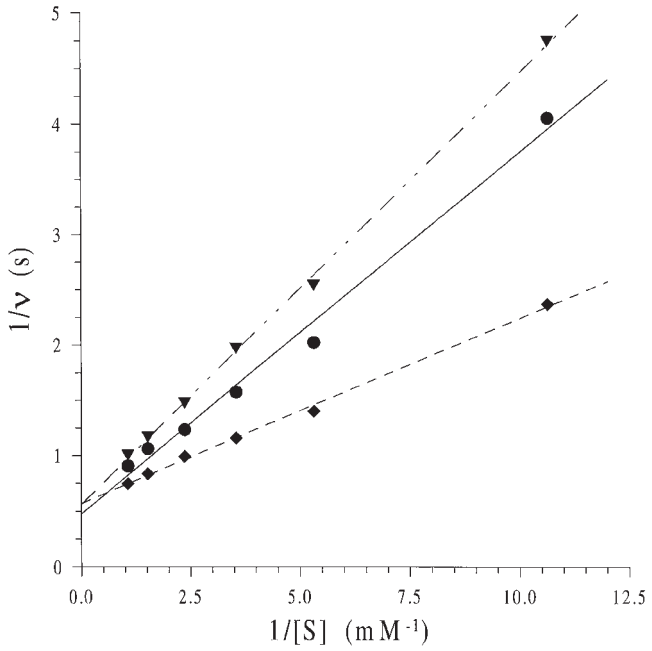


Fig. 1. Lineweaver–Burk plot for the inhibition of yeast α-glucosidase-catalyzed hydrolysis of 4-nitrophenyl α-D-glucopyranoside (**S**) by 2-deoxy-α-D-glucopyranosyl isoquinolinium tetrafluoroborate; symbols represent different concentrations of **11**: ◆ 1.57 μM, ● 3.77 μM, and ▼ 6.91 μM. Kinetic data measured at concentrations of **11** of 0.00 and 0.63 μM have been omitted for clarity.

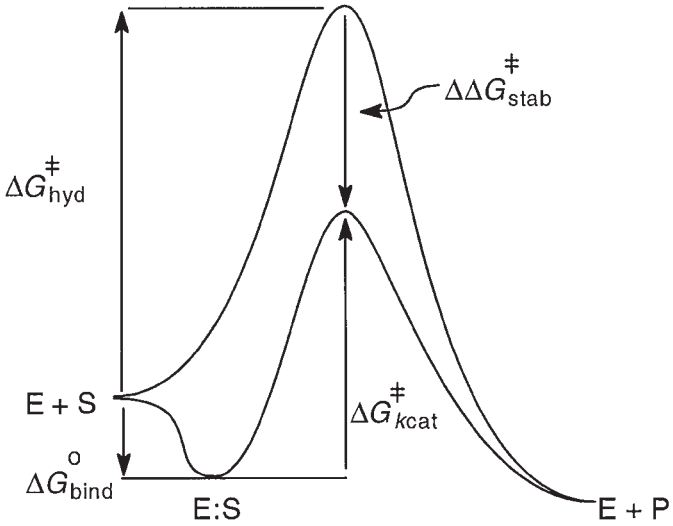

surrounding nonpolar surfaces in solution are liberated into bulk solution when a hydrophobic moiety binds to a biological receptor. Carbohydrate–protein interactions of this nature have been discussed by Wong (21) in terms of providing a favourable entropic contribution towards the free energy for binding of hydrophobic groups.

Another potential source of the tight binding of these compounds may be that their ground state conformations are $^1S_3$ skew-boats rather than the usual $^4C_1$ chair (18, 22), and thus, if these α-glucosidase enzymes bind substrates in non-chair conformations, it is to be expected that conformationally biased compounds such as **9**, **10**, and **11** will display lower binding constants (K_ms) than the natural substrates.

The β-epimer of **11**, 2-deoxy-β-D-glucopyranosyl isoquinolinium bromide (**13**), is a mediocre inhibitor of almond-emulsion β-glucosidase (K_i = 7.4 mM). Therefore, it is clear that the attachment of an extended aromatic ring onto the anomeric carbon of a carbohydrate analogue will not guarantee an increase in binding affinity of glucosidase inhibitors.

Both mannosidases investigated, namely the retaining enzyme from almond and the inverting enzyme from yeast, showed either weak or no affinity for the 2-deoxyglucopyranosyl pyridinium salts, suggesting that the 2-OH group is important for binding to α-mannosidases. However, since kinetic studies using the parent α-mannopyranosyl pyridinium

Scheme 3.

salts have not been reported, no definite conclusions concerning the mannosidase enzymes can be made at this time.

The yeast α-glucosidase hydrolysis of compound **11** is roughly 73 times less than for the glucosyl salt **9** (Table 2), a rate difference that corresponds to a $\Delta\Delta G^{\ddagger}_{kcat}$ (Scheme 3) of around 10.6 kJ mol^{-1}. A similar $\Delta\Delta G^{\ddagger}_{kcat}$ of 9.7 kJ mol^{-1} is observed for barley α-glucosidase-catalyzed hydrolysis of maltose (23). This similarity is not too surprising given that both enzymes are members of glycosidase family 31 (24). For members of other glycosidase families, the removal of a 2-OH group from the substrate can lead to larger differences in $\Delta\Delta G^{\ddagger}_{kcat}$. For example, the β-glucosidase from *Agrobacterium* gives a value for $\Delta\Delta G^{\ddagger}_{kcat}$ of 22 kJ mol^{-1} for the hydrolysis of 4-nitrophenyl β-D-glucopyranoside when compared to its 2-deoxy derivative (25).

At the present time, a more detailed analysis of the magnitude of $\Delta\Delta G^{\ddagger}_{kcat}$ is unwarranted since X-ray crystallographic 3-D structure analysis has not been reported for any member of the α-glucosidase family 31.

The spontaneous hydrolysis of **11** occurs approximately 176-fold more rapidly than that of the corresponding glucoside (Table 2) (18, 22*a*). From this, it can be concluded that removal of the 2-OH group reduces $\Delta\Delta G^{\ddagger}_{stab}$ by approximately 23.5 kJ mol^{-1} (i.e., 176 × 79–fold) for the yeast enzyme-catalyzed process. Furthermore, yeast α-glucosidase accelerates the hydrolysis of both **11** and **12** (the best and worst inhibitors, respectively) by similar amounts (Table 2). Therefore, the differential hydrophobic interactions that occur in the enzyme-substrate complexes for **11** and **12** are maintained at their respective α-glucosidase-catalyzed hydrolysis TSs, and the free energy differences associated with the measured k_{cat}/k_{hyd} rate accelerations ($\Delta G^{\ddagger}_{kcat} - \Delta G^{\ddagger}_{hyd}$, Scheme 3) are indistinguishable. In other words, the nonspe-

© 2000 NRC Canada

cific, hydrophobic interactions of the quinoline (and isoquinoline) moiety with the yeast enzyme's active site are of a similar magnitude in both the enzyme–substrate complex and the rate limiting glucosidation transition state, and as a consequence, the observed rate acceleration must be caused by an increase in binding of the 2-deoxyglucose unit to the glucosidase-catalyzed transition state relative to the E–S complex.

Materials and methods

All reagents and procedures used for the measurement of enzymatic binding constants with compounds **10**, **11**, and **13** were identical to those described previously (26, 27). Quinoline was purchased from Aldrich and purified by recrystallization of its hydrogen sulfate salt from HOAc–Et_2O, followed by neutralization and fractional distillation at atmospheric pressure.

All new compounds were fully characterized using NMR spectroscopy. All observed resonances in the NMR spectra were fully assigned using ^{1}H–homonuclear (28) and ^{1}H–^{13}C-heteronuclear (29) chemical shift correlated NMR spectroscopy techniques. All coupling constants (J) are listed in hertz (Hz). Synthesis of the substrate α-D-glucopyranosyl 4′-bromoisoquinolinium bromide (19) and the 2-deoxy compounds **10** (18), **11** (18), and **13** (30) were accomplished according to published procedures.

3,4,6-Tri-*O*-acetyl-2-deoxy-α-D-*arabino*-hexopyranosyl quinolinium tetrafluoroborate (14)

Silver tetrafluoroborate (0.63 g, 3.1 mmol) was added to a solution of the 2-thiono-1,3-dioxa-2-phosphorinane **15** (18) (1.50 g, 3.1 mmol) in quinoline (2 mL) and dichloromethane (1.5 mL). After the solution had stirred at rt for 2 h, the silver salts were precipitated by the addition of methanol (250 mL). Following filtration, the solvent was removed under reduced pressure. The resulting residue was dissolved in a minimum volume of methanol and subsequent addition of diethyl ether (500 mL) resulted in precipitation of the product. This procedure was repeated and the final colourless powder was crystallized from methanol–ether to give **14** (0.83 g, 53%), mp 111–113°C. ^{1}H NMR (400 MHz, D_2O) δ: 2.00, 2.17, 2.26 (s, 9 H, 3 × CH_3), 2.86 (ddd, 1 H, $J_{2a,1}$ = 4.2, $J_{2a,2e}$ = 15.4, $J_{2a,3}$ = 7.3, H-2a), 3.02 (ddd, 1 H, $J_{2e,1}$ = 6.2, $J_{2e,3}$ = 4.2, H-2e), 4.23 (dd, 1 H, $J_{6a,5}$ = 3.0, $J_{6a,6b}$ = 12.6, H-6a), 4.29 (ddd, 1 H, $J_{5,4}$ = 6.5, $J_{5,6b}$ = 6.7, H-5), 4.66 (dd, 1 H, H-6b), 5.21 (t, 1 H, $J_{4,3}$ + $J_{4,5}$ = 12.4, H-4), 5.53 (ddd, 1 H, $J_{3,4}$ = 5.6, H-3). 7.28 (dd, 1 H, H-1), 8.07 (ddd, 1 H, $J_{5',6'}$ = 7.9, $J_{6',7'}$ = 7.0, $J_{6',8'}$ = 0.7, ArH-6′), 8.19 (dd, 1 H, $J_{3',2'}$ = 6.2, $J_{3',4'}$ = 8.2, ArH-3′), 8.30 (ddd, 1 H, $J_{5',7'}$ = 1.4, $J_{7',8'}$ = 8.7, ArH-7′), 8.43 (dd, 1 H, $J_{2',4'}$ = 1.4, ArH-4′), 8.50 (brd, 1 H, ArH-5′), 9.26 (brd, 1 H, ArH-8′), 9.52 (dd, 1 H, ArH-2′). Anal. calcd. for $C_{21}H_{24}BF_4NO_7$: C 51.52, H 4.94, N 2.86; found: C 51.50, H 4.87, N 2.72.

2-Deoxy-α-D-*arabino*-hexopyranosyl quinolinium tetrafluoroborate (12)

A solution of sodium methoxide (4 equiv) in methanol (10 mL) was added in one portion, with stirring, to an ice-cold solution of **14** (0.12 g, 2.5 mmol) in methanol (15 mL) that was maintained under an inert atmosphere. After stirring for 15 min, the resulting solution was neutralized by the addition of I-120 Amberlite resin (H^+-form) (2.5 g). After an additional 3 min, a solution of HBF_4 in ether (35% w/v, 1 mL) was added and the resultant acidic solution was filtered directly into cold anhydrous ether (–78°C, 250 mL). The ensuing cloudy solution was kept in a freezer (–16°C) for 24 h. After decanting the solvent, addition of acetonitrile (5 mL) to the solid residue gave a clear solution. Subsequent addition of anhydrous ether (250 mL) gave a cloudy solution and this suspension was placed into a freezer (–16°C). After 48 h, the resultant colourless, hygroscopic solid was filtered and dried to give an analytically pure sample of **12** (0.65 g, 71%). ^{1}H NMR (400 MHz, D_2O) δ 2.63 (ddd, 1 H, $J_{2a,1}$ = 5.3, $J_{2a,2e}$ = 15.4, $J_{2a,3}$ = 9.9, H-2a), 2.92 (dt, 1 H, $J_{2e,1}$ + $J_{2e,3}$ = 8.3, H-2e), 3.41 (ddd, 1 H, $J_{5,6a}$ = 2.3, $J_{5,6b}$ = 5.7, $J_{5,4}$ = 8.6, H-5), 3.67 (dd, 1 H, $J_{6a,6b}$ = 12.5, H-6a), 3.71 (t, 1 H, $J_{4,3}$ + $J_{4,5}$ = 16.0, H-4), 3.82 (dd, 1 H, H-6b), 4.25 (ddd, 1 H, $J_{3,2e}$ = 4.3, $J_{3,4}$ = 7.6, H-3). 7.16 (brt, 1 H, $J_{2e,1}$ = 4.0, H-1), 7.99 (brt, 1 H, $J_{5',6'}$ + $J_{6',7'}$ = 15.4, ArH-6′), 8.07 (dd, 1 H, $J_{2',3'}$ = 6.2, $J_{3',4'}$ = 8.1, ArH-3′), 8.22 (brt, 1 H, $J_{6',7'}$ + $J_{7',8'}$ = 16.2, ArH-7′), 8.35 (brd, 1 H, $J_{5',6'}$ = 8.2, ArH-5′), 8.55 (brd, $J_{7',8'}$ = 9.2, ArH-8′), 9.16 (brd, 1 H, ArH-4′), 9.43 (brd, 1 H, ArH-2′). Anal. calcd. for $C_{15}H_{18}BF_4NO_4$: C 49.62, H 5.00, N 3.86; found: C 49.46, H 5.19, N 4.09.

Measurement of k_{cat} values

The k_{cat} value for yeast α-glucosidase-catalyzed hydrolysis of **11**, relative to that for **9**, was measured under saturation conditions ([**11**] = 303 μM and [**9**] = 110 μM) in 50 mM phosphate buffer (pH 6.8, 0.1% w/v BSA) at 25°C. The relative rate of formation of isoquinoline from the two substrates was monitored at 337 nm. Yeast α-glucosidase-catalyzed hydrolysis of **12** was monitored (using an identical enzyme concentration to that from the experiments with both **9** and **11**) at 320 nm in 50 mM phosphate buffer (pH 6.8, 0.1% w/v BSA) at 25°C. The kinetic parameters V_{max} and K_m were calculated using a nonlinear least-squares fit of the initial rate vs. concentration data. The relative k_{cat} value for α-glucosidase-catalyzed hydrolysis of **12** was calculated from the observed V_{max} values and the measured Δ(ε) values for **11** and **12** at the respective wavelengths used to monitor their hydrolysis reactions (**11**, Δ(ε) = 2010 at 337 nm; **12**, Δ(ε) = 2770 at 320 nm).

Acknowledgments

The authors are grateful to the Natural Sciences and Engineering Research Council of Canada (NSERC) and the British Columbia Health Research Foundation for financial support. In addition, the authors would like to thank NIH for a grant (GM 31265, to Dr. A. Herscovics) that supports research on the yeast α-mannosidase enzyme. Finally, we would like to thank Dr. T. E. Kitos for editorial assistance with this manuscript.

Superamidines 2. Synthesis of the bulky ligand *N,N′*-bis-(2,6-diisopropylphenyl)-trifluoroacetamidine and its molybdenum carbonyl complex[1]

René T. Boeré, Vicki Klassen, and Gotthelf Wolmershäuser

Abstract: *N,N′*-bis-(2,6-diisopropylphenyl)trifluoroacetamidine has been prepared for the first time from 2,6-diisopropylaniline and the trifluoroacylation reagent TFAP via the imidoylchloride. The crystal structure of the amidine was determined, indicating that it crystallizes in the *Z-anti* tautomer, in contrast to the nonfluorinated analogue, which is *E-anti* in the solid state. In solution, as indicated by NMR spectroscopy, it exists in two isomeric forms. The amidine reacts with $Mo(CO)_6$ to produce a coordination complex with $Mo(CO)_3$ in which the ligand is also in the *Z-anti* geometry, the metal is η^6-coordinated to the imino-2,6-diisopropylphenyl ring, and the amino N-H unit is directed towards the metal, as determined by a single-crystal X-ray structure. Unlike the analogous nonfluorinated acetamidine, there is no indication of an intermediate in which the neutral amidine is coordinated in a monodentate fashion to an $Mo(CO)_5$ unit, which we now attribute to the predominant geometry of the ligand, both in the solid state and in solution, being *Z-anti*. The high steric bulk of this superamidine ligand apparently prevents the formation of a metal–metal bonded $Mo_2(amidinate)_4$ as observed previously in a redox reaction between *N,N′*-diphenylbenzamidine and $Mo(CO)_6$ under similar thermal reaction conditions.

Key words: trifluoromethyl, superamidine, amidine, molybdenum, carbonyl, coordination.

Résumé : On a réalisé la première synthèse de la *N,N′*-bis-(2,6-diisopropylphényl)-trifluoroacétamidine à partir de la 2,6-diisopropylaniline et du réactif de trifluoroacétylation, TFAP, par le biais du chlorure d'imidoyle. On a déterminé la structure cristalline de l'amidine qui indique qu'elle cristallise sous la forme du tautomère *Z-anti*, qui diffère de la situation avec l'analogue non fluoré qui, à l'état solide, existe sous la forme *E-anti*. Sur la base des données de R.M.N., en solution, il existe dans les deux formes isomères. L'amidine réagit avec le $Mo(CO)_6$ pour donner un complexe de coordination avec le $Mo(CO)_3$ dans lequel, selon la structure déterminée par diffraction des rayons X sur un cristal unique, le ligand est aussi dans une géométrie *Z-anti*, le métal forme une η^6-coordination avec le noyau imino-2,6-diisopropylphényle et l'unité N-H de l'amino est orientée vers le métal. Contrairement à ce qui a été observé avec l'acétamidine analogue non fluorée, il ne semble pas exister d'intermédiaire dans lequel l'amidine neutre serait coordinée de façon monodentate avec une unité de $Mo(CO)_5$; on attribue maintenant cette situation à la géométrie prédominante du ligand qui est *Z-anti* tant à l'état solide qu'en solution. Le grand encombrement stérique qui l'on retrouve dans ce ligand superamidine empêche la formation d'un $Mo_2(amidinate)_4$ avec liaison métal-métal comme on l'a observé antérieurement dans une réaction redox entre la *N,N′*-diphénylbenzamidine et le $MO(CO)_6$ dans des conditions de réactions semblables.

Mots clés : trifluorométhyle, superamidine, amidine, molybdène, carbonyle, coordination.

Introduction

Amidines and amidinate anions are useful ligands in the general development of coordination chemistry (1, 2), and their complexes with the Group 13 elements catalyze the polymerization of ethylene (3–5). We have recently reported the preparation of the first *N,N′*-disubstituted amidines containing the 2,6-diisopropylphenyl (Dip) substituent on nitrogen (6). Such "super-bulky" substituents were originally developed to stabilize low-coordinate main-group elements of the third and subsequent periods. It is our contention that the use of super-bulky substituents with conventional nitrogen-based ligands will lead to unique patterns of reactivity. So far, we have demonstrated that it is possible to synthesize

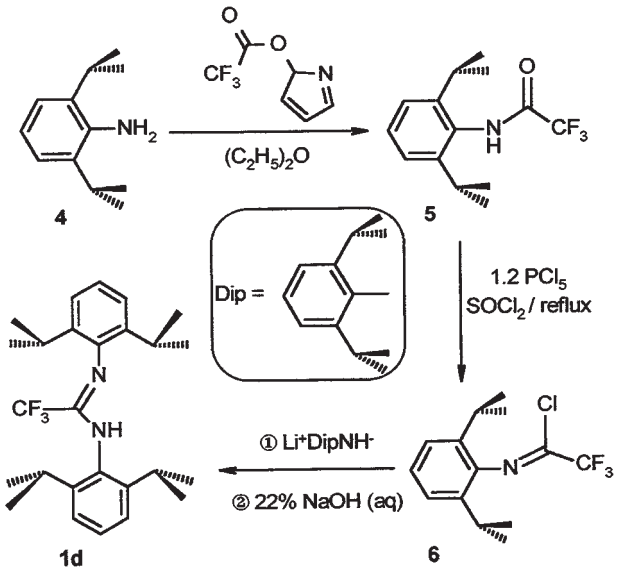
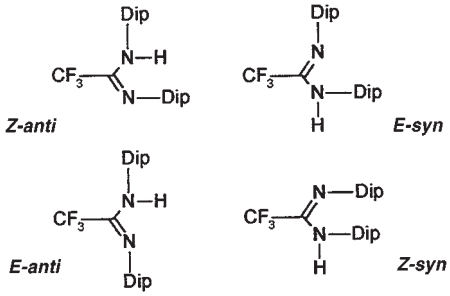
amidines **1a-c** with Dip groups on nitrogen. The ligands dissolve in typical NMR solvents ($CDCl_3$) as at least two isomeric forms, and so far, three different isomers have been detected in the solid state by X-ray crystallography (6). However, whereas analogous nonbulky amidines such as *N*,*N*′-diphenylbenzamidine produce quadruply bonded dimolybdenum(II) compounds (7) in thermal reactions with $Mo(CO)_6$ in hydrocarbon solvents, under these conditions the superamidines have only provided two different kinds of neutral coordination compounds. Thus superamidine **1a** reacts with molybdenum carbonyl in hot *n*-heptane to produce an N-coordinated $LMo(CO)_5$ complex **2a**, but on further reaction this complex loses two further CO molecules to form the half-sandwich $LMo(CO)_3$ complex **3a**. By contrast, amidines **1b**, **c** form $LMo(CO)_3$ complexes **3b**, **c** with no detectable intermediates in thermal reactions with $Mo(CO)_6$ (6).



In this work we report results on a further superamidine with Dip groups on N and a trifluoromethyl substituent on the central carbon atom, **1d**. The structure and reactivity of this compound is distinct from that of its unfluorinated analogue **1a**, and more closely resembles that of the aryl derivatives **1b**, **c**, apparently for structural rather than electronic reasons. In thermal reactions of **1d** with $Mo(CO)_6$ the only observed product is the $LMo(CO)_3$ complex **3d**.

Results and discussion

Ligand synthesis



Our synthesis follows the basic methodology outlined by Maringgele and Meller (8) for the synthesis of several *N*,*N*′-diaryl-*N*′-trimethylsilyltrifluoroacetamidines (i.e., with the remaining hydrogen on N being replaced with an $Si(CH_3)_3$ group). Each step of the procedure required extensive optimization, and in particular, differed significantly from that of the nonfluorinated analogues **1a-c**. The synthetic route is outlined in Scheme 1, and the particulars of each step are detailed in the Experimental section. Commercially available 2,6-diisopropylaniline, **4**, was converted to the corresponding amide of trifluoroacetic acid, **5**, using the trifluoroacylation reagent 2-(trifluoroacetoxy)pyridine (TFAP) (9). Dehydration and chlorination using 1.2 equiv of PCl_5 in refluxing $SOCl_2$ produced the imidoylchloride, **6**, which was isolated and purified by vacuum distillation in 63% yield. Maringgele and Meller (10) obtained a variety of *N*-aryltrifluoromethylimidoyl chlorides as byproducts in only 10–20% yield from reactions of amides with BCl_3. The ^{19}F NMR chemical shifts of these imidoyl chlorides are found at $\delta = -71.0$ to -72.0 ppm, in excellent agreement with the –71.48 ppm we find in the NMR spectrum of **6**.

Scheme 1.

The imidoylchloride does not react directly with a second equiv of **4** as the nonfluorinated analogues do (6). Instead, the lithium anilide was produced, and this reacted with the imidoyl chloride to produce the desired amidine directly. However we have found that to purify this raw product conversion first to the hydrochloride, followed by reforming the free amidine, **1d**, using 23% sodium hydroxide solution was required. All of these compounds are new, and have been fully characterized by elemental analysis, mass spectroscopy as well as ^1H and ^{13}C NMR spectroscopy. The details are given in the Experimental section.

Scheme 2.

Isomers and tautomers

In $CDCl_3$ solution, **1d** exists in two isomeric forms as shown by ^1H, ^{13}C, and ^{19}F NMR spectroscopy. Previously reported trifluoroacetamidines with a variety of nonbulky aryl groups also show isomerism in solution (8). For example, an amidine with a 2,6-dimethylphenyl group on one nitrogen and a phenyl group on the other displays two singlets at $\delta = -61.9$ and -60.4 ppm in the ^{19}F NMR spectrum (8). Similarly in **1d** there are two closely spaced singlets at $\delta = -67.24$ and -66.84 ppm. The difference in absolute shift is attributable to protonation vs. silylation at the amino nitrogen.

We have previously shown that superamidines can exist in a variety of isomeric and tautomeric forms (6). The four possible isomers of the trifluoromethyl derivative are shown in Scheme 2, using the nomenclature devised by Perrin (11)

[a]Weighting schemes used: **1d**, $w = 1/[\sigma^2(Fo^2) + (0.0500P)^2]$; **3d**, $w = 1/[\sigma^2(Fo^2) + (0.0420P)^2]$ where $P = (Fo^2 + 2Fc^2)/3$.

based on the Cahn–Ingold–Prelog sequence rules. The lowest-energy isomer of **1d**, as minimized in an AM1 calculation, is the *Z-anti* form. Relative to this, the tautomeric *E-syn* isomer lies only 1.2 kJ mol^{-1} higher in energy, while the *Z-syn* isomer lies 11.0, and the *E-anti* 26.7 kJ mol^{-1} higher in energy. Calculations on **1a**, however, indicate that the *E-anti* isomer for the methyl ligand **1a** lies only 15.5 kJ mol^{-1} higher than *Z-anti*. These calculations do not factor in the energy of hydrogen bonding, which apparently can stabilize the *E-anti* form as seen in the solid state for the methyl analogue **1a**. The typical energy of a single H-bond is ~20 kJ mol^{-1} (12). We have determined the single-crystal X-ray structure of **1d** (see Fig. 1), which indicates that it crystallizes preferentially as the *Z-anti* isomer. There are no short intermolecular contacts in the crystal. Apparently the steric bulk of a trifluoromethyl group is sufficiently large to cancel out the energetic advantage for the formation of an H-bonded dimer, which is possible only in the *E-anti* conformation. Important bond distances and angles are listed in Table 1.

Häfelinger and Kuske (13) have defined the parameter $\Delta_{CN} = d(C—N) - d(C=N)$ for the central N—C—N linkage found in all amidines, using crystallographic structural data. This parameter ranges from 0 in the structure of **1a**, to 0.178 Å in 2,6-*cis*-dimethylpiperidyl-*N*-phenyl-2,2-dimethylpropionamidine, an amidine where conjugation is minimized due to bulky substituents on nitrogen and carbon (d(C—N) = 1.441(5); d(C=N) = 1.263(5) Å), and which crystallizes in

[a] $\Delta_{CN} = d(\text{C-N}) - d(\text{C=N})$.

the rarely observed *Z-syn* form (14). In the crystal structure of **1d**, $\Delta_{CN} = 0.094$, the largest we have yet observed for a superamidine structure. The metric parameters of **1d** otherwise closely parallel those of **1c**, the only other superamidine so far which crystallizes exclusively in the *Z-anti* form, for which $\Delta_{CN} = 0.057$ (6). The C—N single bonds in **1c** and **1d** are identical within experimental error at 1.364 Å. Thus the origin of the larger Δ_{CN} value in **1d** is the *shorter* C=N double bond, which at 1.270(2) is almost 0.04 Å shorter in the fluorinated amidine. However, these values are not unprecedented. In the structure of *N′-p*-bromophenyl-*N*-(*p*-tolyl)acetamidine, which crystallizes in the *E-anti* isomer, *d*(C–N) = 1.366(8) and *d*(C=N) = 1.273(8) Å, leading to a $\Delta_{CN} = 0.093$ (15).

Reaction with $Mo(CO)_6$

Amidine **1d** was heated with $Mo(CO)_6$ in refluxing *n*-heptane under an atmosphere of N_2. The course of the reaction was easily monitored by solution infrared spectroscopy and we observed that **1d** reacted slowly, with no observable evidence by solution IR spectroscopy of any intermediate, to the final product, a bright yellow crystalline solid, which was produced in 25% yield. The structure of the compound was indicated by ^{1}H NMR and IR spectroscopy to be a half-sandwich "piano-stool" complex of $Mo(CO)_3$, in which the metal is coordinated to one of the electron-rich aromatic rings of the ligand rather than through nitrogen. In the ^{1}H NMR spectrum, the signals due to the aromatic hydrogen atoms of one of the diisopropylphenyl groups are shifted 1.45–1.49 ppm upfield, while the other signals remain at the same chemical shift. In the free ligand, the *meta* and *para* hydrogen resonances are not distinguishable, but in the complex, the upfield-shifted signals show a resolved pseudo-triplet for the *para* and a resolved pseudo-doublet for the *meta* hydrogen atoms, in the expected 1:2 intensity ratio. The magnitude of these shifts are typical of those observed for η^6-arenes coordinated to an $Mo(CO)_3$ unit. The solution IR spectrum (Table 3) showed three bands in the carbonyl-stretching region, a very strong singlet at about 1966 cm^{-1}, and a slightly less intense doublet centred at about 1885 cm^{-1}. This is the pattern expected for a *fac*-octahedral tricarbonyl metal complex with highly asymmetric coligands (16).

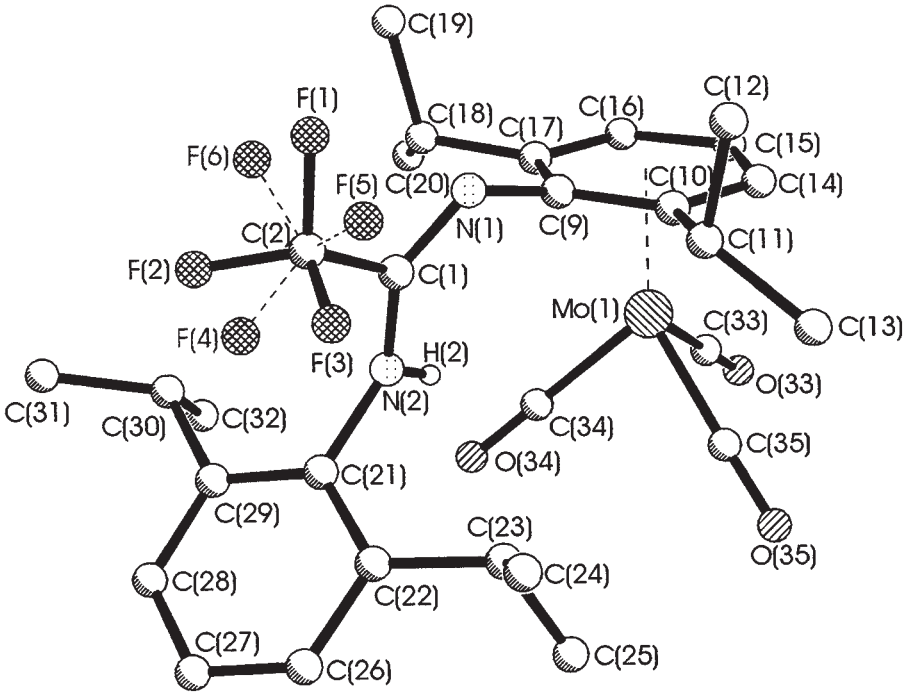
[a] *n*-Heptane solution in 0.2 mm NaCl solution cell.

The single-crystal X-ray structure of **3d** is presented in Fig. 2. The same "baseball catcher's mitt," structure is observed as previously obtained for the methyl **3a** and tolyl **3b** structures, in which the amidine ligand, itself in the *Z-anti* tautomer, has "caught" the $Mo(CO)_3$ fragment with the inside face of the imino-bearing ring. With respect to the C(1)=N(1) double bond, the metal complex also has *Z* symmetry. The N-H of the amino group corresponds to the "catcher's thumb," and there is a close contact of 3.14(3) Å between H(1) and Mo, less than a reasonable guess at the sum of their van der Waals' radii (the van der Waals radius for molybdenum is not contained in standard compilations; we have used values of neighbouring elements to provide this estimate). The similarity in structures of **3d**, **3a**, and **3b** is striking. The amidine unit in **3d** is bent further away from the molybdenum atom than in **3a**. This is evidenced by a 5° larger N(1)-C(1)-N(2) angle, and a 3° smaller N(1)-C(1)-C(2) angle. Other metric parameters between the two structures are extremely similar.



Progress of reaction with $Mo(CO)_6$

The thermal reactions with $Mo(CO)_6$ of all the superamidines that we have studied do not go on to the formation of bridged multiply bonded dimolybdenum species (6, 7). This is undoubtedly due to the high steric bulk of the Dip groups. The question that remains, however, is why **1d** reacts more like the aryl amidines **1b** and **1c**, in going directly to an η^3-$Mo(CO)_3$ complex, than the methyl amidine **1a**, which first forms an N-bonded $Mo(CO)_5$ complex, and only on further heating produces the η^3-$Mo(CO)_3$ complex?

We believe that this difference in reactivity can be traced to the structural forms of the free ligand in the solid state and in solution. Only **1a** crystallizes in the *E-anti* form as an H-bonded dimer, unlike **1b**, **1c**, and **1d**. Furthermore, **1a** is much less soluble in *n*-heptane than the others, undoubtedly due to the dimer structure. Thus visual inspection of the thermal reaction of **1a** with $Mo(CO)_6$ clearly shows that undissolved ligand is present during much of the course of the reaction. This is different from what is observed for the other three superamidines, which dissolve readily as the temperature of the solvent is increased. We hypothesize that if the three more soluble amidines dissolve in the *Z-anti* geometry they have in the solid, reaction of ligand in this configuration promotes conversion to the η^6-$Mo(CO)_3$ complex. On the other hand, if the hexacarbonyl reacts with a

Fig. 2. PLUTO diagram of **3d**, showing the atom numbering schemes. The ligand is also in the *Z-anti* conformation, with the Mo atom coordinated to the inside of the aryl ring attached to the imino nitrogen atom. The rotationally disordered CF_3 group has been modeled by two trigonal F_3 units with occupancy of 0.87, F(1)-F(3), and 0.13, F(4)-F(6).

hydrogen-bonded dimer in the *E-anti* geometry before this can isomerize to the *Z-anti* form, it forms a metal complex in which this geometry is preserved. We have previously shown that conversion of the η^1-$Mo(CO)_5$ complex to the η^6-$Mo(CO)_3$ complex is accompanied by *E* to *Z* ligand isomerism (6).

Is there any evidence that the amidines exist in solution in the *Z-anti* form? Consider the combined NMR spectroscopic parameters presented in Table 4 for all the species we have so far prepared. The proton (and ^{19}F, where applicable) NMR parameters of the *dominant* species in $CDCl_3$ solution for the free amidines in each case are strikingly similar to those of the metal tricarbonyl derivatives. If, as seems likely, the latter dissolve in the *Z-anti* geometry found in the solid state, the correspondence of the NMR spectoscopic parameters supports this isomer as the predominant form of the free ligand in $CDCl_3$ as well. Furthermore, this is also the lowest energy form in the gas phase as indicated by MO calculations.

The differences that do exist between the NMR spectroscopic parameters of free ligand and complex are readily attributed to variations in ring shielding effects. Thus the ^1H signal of the amino NH atom is further upfield in the ligand, where in the *Z-anti* form it experiences ring current shielding from the Dip group on the imino nitrogen. Similarly, one CH_3 group is significantly further upfield than the rest. Assuming that the Dip group on the amino nitrogen rocks back and forth on the C—N bond, one set of methyl groups would also experience ring current shielding from the ring attached to the imino nitrogen. In the $Mo(CO)_3$ complexes, both types of anomalously shielded protons revert to more normal chemical shifts. This is consistent with the metal carbonyl unit blocking the aromatic ring that is responsible for the shielding effect.

Experimental section

General

2,6-diisopropylaniline, 2-hydroxypyridine, trifluoroacetic anhydride, thionyl chloride, phosphorus pentachloride, *n*-butyl lithium (Aldrich), and molybdenum carbonyl (Strem) were commercial products, and used as received, except that the aniline was vacuum distilled and stored under nitrogen before use. Solvents were reagent grade, and distilled from sodium wire (toluene, THF), P_2O_5 (CH_2Cl_2), or $LiAlH_4$ (*n*-heptane). 2-(Trifluoroacetoxy)pyridine (TFAP) was prepared from 2-hydroxypyridine and trifluoroacetic anhydride by the literature method (9). Reactions involving metal carbonyl and organolithium reagents were performed under an atmosphere of purified N_2 using a dry-box, Schlenk ware, and vacuum-line techniques; all other procedures were performed in vessels open to the atmosphere but protected by $CaCl_2$ drying tubes. Infrared spectra were recorded on a BOMEM MB102 Fourier transform spectrometer, and are KBr pellets unless otherwise specified. NMR spectra were acquired at 250.13 (^1H) and 62.90 (^{13}C) MHz on a Bruker AC250-F spectrometer referenced to TMS, and on a Bruker AMX300 at 282.41 (^{19}F) MHz referenced to external C_6F_6 in C_6D_6 at –163.00 ppm on the $CFCl_3$ scale, and are in $CDCl_3$ unless otherwise specified. Mass spectra were recorded by the Mass Spectrometry Center, University of Alberta, Canada and in the Fachbereich Chemie, Universität Kaiserslautern. Elemental analyses were performed by MHW

Preparation of $CF_3C\{O\}NH(2,6\text{-}^iPrC_6H_3)$, 5

2,6-Diisopropylaniline (90.9 g, 513 mmol) in 250 mL of dry diethyl ether was added drop wise to TFAP (98.0 g, 513 mmol) in 300 mL of the same solvent, with cooling to maintain 23°C. After stirring 20 h, the solvent was removed, and the residues extracted with 1.6 L of dH_2O by vigorous stirring for 2 h, filtering and drying to give 128.6 g of pure **5** (471 mmol, 92% yield), mp 158–159°C. An analytical sample was obtained by recrystallizing from ethanol. IR: ν(N-H) 3254, ν(C=O) 1709 cm^{-1}. ^{1}H NMR: 7.54 (s, 1 H, conc. depend.), 7.40–7.20 (m, 3 H), 2.95 (hept, 6.9 Hz, 2 H), 1.19 (d, 6.9 Hz, 12 H. ^{13}C NMR: 157.11 (quart, 37 Hz), 146.17, 129.63, 128.10, 123.98, 116.34 (quart, 289 Hz), 28.83, 23.58. ^{19}F NMR: –75.47 (s, CF_3). Mass spec: 272.8 (M^+, 34%), 258 (M–CH_3^+, 12%), 204 (M–CF_3^+, 100%). Anal. calcd. for $C_{14}H_{18}F_3NO$: C 61.5, H 6.6, N 5.1%; found: C 61.5, H 6.7, N 5.2%.

Preparation of $4\text{-}CF_3C\{Cl\}N(2,6\text{-}^iPr_2C_6H_3)$, 6

5 (20.0 g, 73.2 mmol) was refluxed in 15 mL of $SOCl_2$ (excess) for 0.5 h (oil bath at 80–90°C), after which one equiv of PCl_5 (15.2 g, 73.2 mmol) was added in small increments. After a further 1.5 h reflux and NMR monitoring of the reaction, a further 2.5 g (12 mmol) PCl_5 was added, which after 3 h led to complete consumption of **5**. The bath temperature was raised to 140°C and the remaining $SOCl_2$ was distilled off. The residues were fractionally distilled under vacuum, producing **6** as a colourless liquid, bp 48°C / 4 × 10^{-2} mbar (13.5 g, 46.3 mmol, 63% yield). IR (neat): ν(X=N) 1703, ν(X–Φ) 1287, 1217, 1165. ^{1}H NMR: 7.20–7.18 (m, 3 H), 2.62 (hept, 6.9 Hz, 2 H), 1.18 (d, 6.9 Hz, 12 H). ^{13}C NMR: 140.47, 135.93, 133.94 (quart, 49 Hz), 126.35, 123.47, 116.65 (quart, 277 Hz), 28.64, 22.97. ^{19}F NMR: –71.48 (s, CF_3). Mass spec: 290.7 (M^+ on ^{35}Cl, 29%), 256 (M–Cl^+, 75%), 240 (M–CH_4Cl), 177 ($C_6H_3{}^iPr_2NH_2^+$, 48%), 162 ($C_6H_3{}^iPr_2^+$, 100%). Anal. calcd. for $C_{14}H_{17}ClF_3N$: C 57.64, H 5.87, N 4.80%; found: C 57.57, H 5.85, N 5.00%.

Preparation of $CF_3C\{N\text{-}2,6\text{-}^iPr_2C_2H_3\}NH(2,6\text{-}^iPr_2C_6H_3)$, 1d

210 mL of 1.5 M *n*BuLi (hexane solution) was added via cannula to 44 mL (233 mmol) of 2,6-diisopropylaniline in 500 mL of THF in a 1 L flask equipped with a reflux condenser. After stirring a further 30 min, 68 g (233 mmol) of **6** in 200 mL THF was added dropwise with cooling. After stirring 30 min, the mixture was heated to reflux for 10 h, filtered, and the filtrate evaporated. The resulting oil was treated with 1 L of 95% ethanol followed by 600 mL *c*HCl. After evaporation to dryness, the residues were divided into five parts, each dissolved in 200 mL ethanol, reacted with 200 mL of 23% NaOH, and extracted three times with 100 mL of toluene. The toluene phase was washed with NH_4Cl and then water, and evaporated to an oil. Extended pumping on this oil produced crystals, which could be recrystallized from *n*-heptane, to give 16 g of colourless crystals of **1d** (38 mmol, 16% yield). An analytical sample was produced by recrystallizing a second time from *n*-heptane, mp 94–98°C. IR: ν(N-H) 3451, 3358, ν(N-C-N) 1655 cm^{-1}. ^{1}H NMR: 7.37–7.06 (m, 6H), 5.50 (s, 1 H), 3.18 (hept, 6.9 Hz, 2H), 3.03 (hept, 6.7 Hz, 2 H), 1.34 (d, 6.8 Hz, 6 H), 1.27 (d, 6.8 Hz, 6 H), 1.20 (d, 6.7, 6 H), 1.00 (d, 6.7 Hz, 6 H). ^{13}C NMR: 147.51, 143.28 (quart, 33 Hz),

140.62, 138.17, 131.18, 129.03, 123.46, 118.10 (quart, 279 Hz), 28.48, 25.32, 24.16, 22.41, 22.10. ^{19}F NMR: –67.24 (s, CF_3, major species), –66.84 (s, CF_3, minor species). Mass spec: 432.27486 (M^+, 57%), 389 (M–^{i}Pr$^+$, 79%), 256 (M-$C_6H_3{}^i Pr_2NH^+$, 100%), 214 ($CF_3NC_6H_3{}^i Pr^+$, 13%), 177 ($C_6H_3{}^i Pr_2NH_2^+$, 73%). Anal. calcd. for $C_{26}H_{35}F_3N_2$: C 72.19, H 8.16, N 6.48%; found: C 71.95, H 7.99, N 6.59%.

Preparation of η^6-[CF_3C{N-2,6-$^i Pr_2C_6H_3$}NH(2,6-$^i Pr_2C_6H_3$)]Mo(CO)$_3$, 3d

Three grams (6.9 mmol) of **7** and 1.83 g (6.9 mmol) of $Mo(CO)_6$ were loaded under N_2 into a side-arm flask under N_2. One hundred fifty millilitres of dry *n*-heptane was then added, and the mixture heated to reflux. Progress of the reaction was monitored by solution IR, and heating discontinued after 42 h. Removal of the solvent followed by recrystallization from *n*-heptane provided 1.02 g (1.7 mmol, 25% yield) of **3d** as bright yellow crystals, which were analytically pure, mp 145°C dec. IR: ν(N-H) 3462, 3208, ν(C=O) 1969, 1865, ν(N-C-N) 1665 cm^{-1}. ^{1}H NMR: 8.07 (s, 1 H), 7.37–7.17 (m, 3 H), 5.89 (t, 6.5 Hz, 1 H), 5.57 (d, 6.5 Hz, 2 H), 3.14 (hept, 6.8 Hz, 2 H), 2.72 (hept, 6.9 Hz, 2 H), 1.28 (d, 6.9 Hz, 6 H), 1.27 (d, 6.8 Hz, 6 H), 1.26 (d, 6.9, 6 H), 1.22 (d, 6.8 Hz, 6 H). ^{13}C NMR spectrum not obtained due to sample instability. ^{19}F NMR: –67.54 (s, CF_3). Mass spec: 614.16607 (M^+ based on ^{98}Mo, 31%), 558 (M–2CO$^+$, 4%), 530 (MoL$^+$, 100%), 486 (MoL–^{i}Pr$^+$, 2%), 432 (L$^+$, 36%), 389 (L–^{i}Pr$^+$, 62%), 256 (M-$C_6H_3{}^i Pr_2NH^+$, 72%), 177 ($C_6H_3{}^i Pr_2NH_2^+$, 56%). Anal. calcd. for $C_{26}H_{35}F_3MoN_2O_3$: C 56.86, H 5.76, N 4.57%; found: C 57.00, H 5.60, N 4.65%.

Crystallography

Data collected on a Stoe IPDS diffractometer using monochromated Mo K_α radiation (0.71073 Å) by the ϕ-oscillation method. An analytical absorption correction was carried for **3d**, but no correction was necessary for **1d**. Both structures were solved by direct methods using SHELXS-97 (17) and refined by full-matrix least-squares on F^2 using SHELXL-97 (18) using all reflections. For **1d** all the hydrogen atoms except the one attached to N were localized geometrically and a riding model was used for refinement. The CF_3 group is rotationally disordered and was modeled by two trigonal F_3 units with occupancies of 0.85 and 0.15. For **3d**, all the hydrogen atoms were localized, and a similar disorder model was applied to the F_3 unit, with refined occupancies of 0.87 and 0.13.[3]

Electronic structure calculations

All calculations were performed using the AM1 method as implemented in HyperChem 5.1 running on a Pentium II computer under Windows 95 (19).

Acknowledgments

The Natural Sciences and Engineering Research Council of Canada, the University of Lethbridge research fund, and the Alexander von Humboldt-Foundation supported this work. R.T.B wishes to thank Prof. Dr. O.J. Scherer and Dr. G. Wolmershäuser for their hospitality during a sabbatical leave at Kaiserslautern and acknowledges the access given to the facilities of the Fachbereich Chemie of the University. We thank staff at the Chemistry Department of the University of Calgary for acquiring the ^{19}F NMR spectra, and one of the referees for many helpful suggestions.

Solution multinuclear (^{31}P,^{111}Cd,^{77}Se) magnetic resonance studies of cadmium complexes of heterocyclic aromatic thiones and the structure of [tetrakis(2(1*H*)-pyridinethione)cadmium] nitrate, $[Cd(C_5H_5NS)_4](NO_3)_2$

Umarani Rajalingam, Philip A.W. Dean, and Hilary A. Jenkins

Abstract: The complex salts $CdL_4(O_3SCF_3)_2$ (L = 2(1*H*)-pyridinethione (Py2SH), 4(1*H*)-pyridinethione (Py4SH), or 2(1*H*)-quinolinethione (Q2SH)) have been synthesized by the stoichiometric reaction of $Cd(O_3SCF_3)_2$ and the appropriate thione. Both ambient-temperature ^{13}C and reduced-temperature ^{111}Cd NMR of $CdL_4(O_3SCF_3)_2$ in solution are consistent with L being bound through sulfur. Reduced-temperature NMR (^{31}P, ^{77}Se, ^{111}Cd, as appropriate) of mixtures of $CdL_4(O_3SCF_3)_2$ and $Cd(EPCy_3)_4(O_3SCF_3)_2$ (E = Se, Cy = *c*-C_6H_{11}) and of $Cd(EPCy_3)_4(O_3SCF_3)_2$ (E = S, Se) and L in solution provides evidence for various $[CdL_n(EPCy_3)_{4-n}]^{2+}$. Similarly, reduced-temperature metal NMR of $[CdL_4]^{2+}$ and $[CdL'_4]^{2+}$ (L, L′ = Py2SH, Py4SH, Q2SH; L ≠ L′) in solution shows the formation of $[CdL_nL'_{4-n}]^{2+}$. Thus it has been demonstrated that at reduced temperature $[CdL_4]^{2+}$ is intact in solution and exchange of L is slow on the timescale of the metal chemical shift differences. From the NMR studies of $Cd(EPCy_3)_4(O_3SCF_3)_2$ (E = S, Se):L mixtures, the binding preferences are found to be L > $EPCy_3$ in solution. Similarly, from the reduced temperature metal NMR spectra of mixtures where L and L′ compete for Cd(II) in solution, the binding preferences are Py4SH > Py2SH > Q2SH. The structure of $Cd(Py2SH)_4(NO_3)_2$ (**4**) has been determined by single crystal X-ray analysis. Colorless crystals of **4** are tetragonal, I4(1)/*acd* with 8 molecules per unit cell of dimensions *a* = 18.660(3), *c* = 15.215(3) Å. The structure is comprised of recognizable NO_3^- anions and $[Cd(Py2SH)_4]^{2+}$ cations. In the cations, which have S_4 symmetry, the ligands are *S*-bound. A network of NH···O hydrogen bonds links the cations and anions.

Key words: aromatic heterocyclic thiones, cadmium complexes, phosphine chalcogenides, ^{111}Cd, ^{31}P, ^{77}Se NMR, X-ray crystallography.

Résumé : On a réalisé la synthèse des sels complexes $CdL_4(O_3SCF_3)_2$ (L = 1*H*-pyridine-2-thione (Py2HS), 1*H*-pyridine-4-thione (Py4SH) ou 1*H*-quinoléine-2-thione (Q2SH) en procédant à une réaction stoechiométrique du $Cd(O_3SCF_3)_2$ avec la thione appropriée. Les spectres RMN du ^{13}C à la température ambiante et du ^{111}Cd à température réduite des $CdL_4(O_3SCF_3)_2$ en solution sont en accord avec liaison du L par le biais de l'atome de soufre. Les spectres RMN (^{31}P, ^{77}Se ou ^{111}Cd suivant le cas) de mélanges de $CdL_4(O_3SCF_3)_2$ et de $Cd(EPCy_3)_4(O_3SCF_3)_2$ (E = Se, Cy = cyclo-C_6H_{11}) à température réduite ainsi que ceux de $Cd(EPCy_3)_4(O_3SCF_3)_2$ (E = S, Se) en présence de L en solution mettent en évidence la présence de divers ions $[CdL_n(EPCy_3)_{4-n}]^{2+}$. De la même manière, la RMN des métaux de $[CdL_4]^{2+}$ et de $[CdL'_4]^{2+}$ (L, L′ = Py2SH, Py4SH ou Q2SH; L ≠ L′), en solution et à température réduite, montre qu'il y a formation de $[CdL_nL'_{4-n}]^{2+}$. On a donc ainsi démontré que, à température réduite, le $[CdL_4]^{2+}$ est intact en solution et que l'échange de L est lent à l'échelle de temps des différences de déplacement chimique des métaux. À partir des études RMN sur des mélanges de $Cd(EPCy_3)_4(O_3SCF_3)_2$ (E = S, Se):L, on a trouvé que, en solution, les préférences de fixation sont L > $EPCy_3$. De la même manière, sur la base de spectres RMN des métaux à température réduite, de mélanges en solution dans lesquels L et L' sont en compétition pour le Cd(II), on a pu établir que les préférences de fixation sont Py4SH > Py2SH > Q2SH. On a déterminé la structure du $Cd(Py2SH)_4(NO_3)_2$ (**4**) par diffraction des rayons X par un cristal unique. Les cristaux incolores du produit **4** sont tétragonaux, groupe d'espace I4(1)/*acd*, avec huit molécules par maille élémentaire dont les dimensions sont *a* = 18,660(3) et *c* = 15,215(3) Å. Dans la structure on peut reconnaître des anions NO_3^- et des cations $[Cd(Py2SH)_4]^{2+}$. Dans les cations, de symétrie S_4, les ligands sont liés au soufre. Un réseau de liaisons hydrogènes NH···O relie les cations et les anions.

Introduction

The cysteine-rich protein metallothionein has a role in the detoxification of cadmium, a wide-spread environmental pollutant (1). In metallothionein, the cadmium ions are bound by cysteinyl sulfur atoms to give thiolate clusters (2). Although no antidote is yet available for cadmium poisoning, it seems likely that any antidote will have one or more sulfur atoms to compete with the donor atoms of the metallothionein. Thus a detailed understanding of the cadmium–sulfur bond is desirable. Previous contributions to this area from these laboratories have included synthetic, structural, and solution NMR spectroscopic studies of cadmium–thiolate (and –selenolate) complexes (3), as well as of thiobenzoato-complexes (4), and solution NMR studies of complexes of phosphine sulfides (and selenides) (5).

In the present paper we turn our attention to homoleptic complexes of cadmium with the heterocyclic thiones[4] 2(1*H*)-pyridinethione (Py2SH), 4(1*H*)-pyridinethione (Py4SH), and 2(1*H*)-quinolinethione (Q2SH).[5] Hitherto, these complexes have received little attention. To our knowledge, no information is available on the behaviour of such complexes in solution, and no structural analyses are available.[6] However, the synthesis of $Cd(Py2SH)_4(NO_3)_2$ has been reported (9). This compound is isomorphous with the Co(II) analogue, which, from its *d-d* spectrum, contains a cation with a tetrahedral CoS_4 kernel. Also, solution ^{1}H and ^{13}C NMR data have been presented for the mixed-ligand complexes $Cd(Py2SH)_2X_2$ (X = Cl, Br) and $Cd(Py4SH)_2Cl_2$ (as well as $Cd(Py2S)_2$) in DMSO-d_6 at ambient probe temperature (10).

Py2SH Py4SH Q2SH

Experimental

Methods and materials

All manipulations were carried out under an atmosphere of dry N_2(g) in a glove box or with a vacuum:N_2(g) manifold, or under an atmosphere of Ar(g) in a glove bag. Analar grade solvents (MeCN, $CHCl_3$, CH_2Cl_2, Me_2CO, Et_2O) were dried over 3 A molecular sieves and deoxygenated using Ar prior to use.

Pyridine-2-thione (Acros or Aldrich) and quinoline-2-thione (Aldrich) showed no significant impurities by ^{1}H and (or)^{13}C NMR and were used as received. Pyridine-4-thione (Acros or Aldrich) was used after repeated recrystallization from toluene–methanol. Literature methods were used to convert $Cy_3P{\cdot}CS_2$ (Strem) into Cy_3PS (5*b*) and Cy_3PSe (11),[7] and for synthesis of anhydrous $Cd(O_3SCF_3)_2$ ($Cd(trif)_2$) by dehydration of the hydrate produced from the metal oxide and aqueous CF_3SO_3H (12). The metal triflate was weighed out in the glove box.

$Cd(Py2SH)_4(O_3SCF_3)_2$ (1)

To a solution of pyridine-2-thione (0.074 g, 0.67 mmoL) in $CHCl_3$ (3.0 mL) was added a solution of $Cd(trif)_2$ (0.066 g, 0.16 mmoL) in MeCN (1 mL). Diethyl ether was layered onto the clear reaction mixture until slight turbidity was seen. The reaction vial was tightly sealed and kept in a freezer at –15°C. After a week, the first crop of white block shaped crystals was separated by filtration, washed with cold Et_2O, and vacuum dried. Yield: 0.070 g (64%), mp: 144–146°C. Further crops, up to a quantitative yield, can be obtained by further addition of Et_2O to the initial filtrate. ^{13}C NMR spectrum (CH_2Cl_2 or Me_2CO): 167.4 (C-2), 133.7 (C-3), 140.5 (C-4), 119.6 (C-5), and 142.4 (C-6). Anal. calcd for $C_{22}H_{20}Cd\ F_6N_4O_6S_6$: C 30.90, H 2.36, N 6.55; found: C 31.20, H 2.20, N 6.48.

*Synthesis of $Cd(Py4SH)_4(O_3SCF_3)_2$ (**2**)*

Pyridine-4-thione (0.074 g, 0.67 mmoL) was dissolved in $CHCl_3$ (8.0 mL). To the clear yellow solution $Cd(trif)_2$ (0.066 g, 0.16 mmoL) in acetonitrile (1 mL) was added. The bright yellow colour faded. Diethyl ether was layered onto the clear solution until slight turbidity was seen. The reaction mixture was sealed tightly and kept in a freezer at –15°C. After two weeks, a first crop of pale yellow flaky crystals was separated by filtration, washed with cold Et_2O, and vacuum dried. Yield: 0.097 g (89%); mp 178–180°C. Anal. calcd. for $C_{22}H_{20}Cd\ F_6N_4O_6S_6$: C 30.90, H 2.36, N 6.55; found: C 31.26, 31.28, H 2.21, 2.27, N 6.41, 6.63. ^{13}C NMR (Me_2CO): 180.1(C-4), 137.0 (C-2), and 131.0 (C-3). (^{13}C NMR of free Py4SH (Me_2CO): 188.5(C-4), 133.0 (C-2), 130.0(C-3)).

*Synthesis of $Cd(Q2SH)_4(O_3SCF_3)_2$ (**3**)*

Cadmium triflate (0.066 g, 0.16 mmol) in acetonitrile (1 mL) was added to the intense yellow solution of quinoline-2-thione (0.105 g, 0.65 mmol) in $CHCl_3$ (3 mL). The reaction mixture quickly turned light yellow. Diethylether (3 mL) was added and the clear solution was kept at room temperature for slow crystallization. After three days, the product, as yellow needles, was collected by filtration, washed with Et_2O, and dried under vacuum. Yield: 0.140 g (82.8%); mp 192–194°C. ^{13}C NMR (CH_2Cl_2): 139.08, 133.39, 129.89,

[4] Complexes of thiones in general have been little studied compared with thion*ates* (6).
[5] Free Py2SH and Py4SH are involved in tautomeric equilibria, e.g., ref. 7.
[6] Structural data are available for several heterocyclic aromatic thion*ates* of cadmium (8).

*$Cd(Py2SH)_4(NO_3)_2$ (**4**)*

Pyridine-2-thione (0.72 g, 6.47 mmol) was dissolved in methanol(10 mL) under an atmosphere of Ar(g). To the clear solution was added at room temperature a solution of $Cd(NO_3)_2 \cdot 4H_2O$ (0.52 g, 1.69 mmol) in MeOH (1 mL). Light yellow needle-shaped crystals formed in ca. 10 min. The crystals(1.08 g, 88.8%) were collected by filtration, washed with ice-cold MeOH (2 mL), and vacuum dried. The crystals appear to decompose above 158°C but become a yellowish liquid in the range 170–172°C. Anal. calcd. for $C_{20}H_{20}N_6O_6S_4Cd$: C 35.27, H 2.95, N 12.33; found: C 35.39, H 2.78, N 12.28. The data crystal for X-ray analysis was obtained during the synthesis.

A similar synthetic route has been given in ref. 9.

*$[Cd(SePCy_3)_4](O_3SCF_3)_2$ (**5**)*

To a solution of Cy_3PSe (0.252 g, 0.700 mmol) in 3 mL of 50% v/v Me_2CO:CH_2Cl_2 was added, with stirring, solid $Cd(trif)_2$ (0.066 g (0.161 mmol)). When the cadmium salt had dissolved, Et_2O (ca. 4 mL) was layered onto the mixture, which was then refrigerated (–15°C) overnight. The white crystals of $[Cd(SePCy_3)_4](O_3SCF_3)_2$ were separated by filtration, washed with ice-cold Et_2O, and vacuum dried. Yield: 0.262 g (88%). The product was pure by ^{31}P, ^{77}Se, and ^{111}Cd NMR. The NMR data are included in Table 2.

Compounds **1**–**5** were air-stable when dry.

NMR Spectra: ^{13}C NMR spectra were obtained at ambient probe temperature using a Varian Gemini-200 spectrometer system equipped with a 5 mm probe. The field was preshimmed, and then spectra of samples in protiated solvents were measured without a ^{2}D field/frequency lock. Field drift was negligible. 63.59-MHz ^{111}Cd{^{1}H} NMR spectra were obtained using a Varian XL-300 spectrometer system and inverse-gated decoupling to avoid the negative Overhauser effect. (In the more usual ^{113}Cd region, artifacts were present in the frequency range of interest; no primary isotope effect is expected between ^{111}Cd and ^{113}Cd NMR spectra.). The metal NMR spectra were measured with samples in protiated solvents in 10 mm o.d. NMR tubes and a preshimmed field. Again, no ^{2}*D* field/frequency lock was used, field drift being negligible. The samples were referenced to external 0.1 M $Cd(ClO_4)_2$(aq) at ambient probe temperature (294 ± 2 K). The same spectrometer system, with continuous decoupling, was used to obtain ^{31}P{^{1}H} and ^{77}Se{^{1}H} NMR spectra at 121.42 and 57.20 MHz, respectively, in an analogous manner. The external references were 85% H_3PO_4 and pure Me_2Se, respectively, at 296 ± 2 K. Concentrations of samples in 10 mm o.d. NMR tubes were prepared on the basis of mass of sample/volume of solvent, normally 1.6 × 10^{-4} mol/3 mL of solvent (= 0.053 mol/L of solvent) for starting cadmium complexes. In mixing experiments, additional cadmium complexes were added as solids to the existing volume of solution, leading to an increase in the total cadmium concentration. For reduced temperature NMR spectra, 30 min was allowed for thermal equilibration at each temperature.

X-ray structure determination

A crystal of **4** from the synthesis was cut to appropriate size, 0.25 × 0.23 × 0.18 mm, and mounted on a glass fibre. Crystal data and refinement parameters for **4** are listed in Table 1, the final positional parameters and equivalent isotropic thermal parameters are given in Table 2 and selected interatomic distances and angles are listed in Table 5. One full hemisphere of data were collected on a Nonius Kappa-CCD

© 2000 NRC Canada

system. Unit cell parameters were calculated from reflections obtained from 15 consecutive data images collected at phi intervals of one degree using DENZO v.1.9 (13) Systematic absences indicated the tetragonal space group $I4_1acd$, and this was borne out by successful refinement of the structure. Data were scaled using Scalepack (13) and no other absorption coefficient were applied. Full-matrix least-squares refinement on F^2 was performed after solving using Patterson methods and the solution package SHELXTL 5.03 (14). Anisotropic thermal parameters were applied to all non-hydrogen atoms and hydrogen atoms themselves were generated in ideal positions, although all five could be found in a difference Fourier. The Cd atoms sit on a four-fold inversion centre, while N(2) (nitrate) is on a two-fold axis. The largest residual peak was associated with the nitrate anion (0.870 eÅ^{-3}). In the final stages of refinement, $R1$ = 2.74% and $wR2$ = 7.71%.

Substitution reactions of $[M(EPCy_3)_4]^{2+}$ (M = Zn or Cd, E = S or Se) with thiones

In an Ar-filled glove bag, each equivalent of the thione was added at room temperature to a solution of the cadmium complex (0.053 mol of complex/L of 50% v/v Me_2CO–CH_2Cl_2) in a 10 mm o.d. NMR tube. The NMR tube was the transferred to the precooled NMR probe.

Elemental microanalyses:

Carbon, hydrogen, and nitrogen microanalyses were performed by Guelph Chemical Laboratories Ltd.

Results and discussion

Syntheses

Reactions of $Cd(O_3SCF_3)_2$ with a slight excess of the ligands Py2SH, Py4SH, and Q2SH in acetonitrile-chloroform under Ar(g) produced crystalline $CdL_4(O_3SCF_3)_2$ (L = Py2SH, Py4SH, and Q2SH in compounds **1**, **2**, and **3**, respectively) when the reaction mixture was layered with Et_2O and kept at –15°C. Crystallization occurred within 0.5 h for **3**, within one week for **1**, and within two weeks for **2**. The reaction of Py2SH with a slight excess of $Cd(NO_3)_2{\cdot}4H_2O$ in MeOH under Ar(g) at room temperature yielded the known compound (9) $Cd(Py2SH)_4(NO_3)_2$ (**4**) in crystalline form.

NMR Spectra

*(a) Studies of **1**, **2**, and **3***

The compounds **1**–**3** had sufficient solubility in many organic solvents (Me_2CO, MeCN, MeOH, CH_2Cl_2, DMF) to allow at least solution ^{13}C NMR studies at ambient temperature. In addition, they have in common the weakly coordinating triflate anion, which simplifies comparison of their metal NMR spectra in particular. Compound **4** has poor solubility in many solvents, e.g., CH_2Cl_2, MeOH, Me_2CO, although it is quite soluble in DMF.

In the ^{13}C NMR spectrum of **1**–**3**, the thione carbon is shielded relative to the free ligand (Experimental section) due to the aromatization of the pyridyl ring. At ambient probe temperature, the shielding is 12.8 ppm for **1**,[8] 8.4 ppm for **2**, and 6.5 ppm for **3**. The shielding is consistent with coordination of cadmium at sulfur, which should decrease the double-bond character of the thione. and increase the double-bond character of the N to (thione) C linkage, thus aromatizing the heterocyclic rings.

The ^{111}Cd NMR spectra of **1** and **2** in 50% v/v Me_2CO:CH_2Cl_2 at 189 K consist of single resonances with δ_{Cd} (approximate $\Delta\nu_{1/2}$) of 603 (45 Hz) and 622 (25 Hz). The solubility of **3** under these conditions is poor, but its resonance is probably a weak signal observed at $\delta_{Cd} \approx 566$. At ambient probe temperature, signals that are shielded and broader are observed for all three complexes, suggesting partial dissociation. The assignments of resonances that are single lines call for confirmation. Ligand mixing experiments (see below) show that the signals observed in the low temperature spectra are due to CdL_4^{2+} for **1** and **2** and strongly support a similar assignment for **3**.

The ^{111}Cd chemical shifts of **1**–**3** fall in, or close to, the range that has been established for the CdS_4 kernel (16). Thus the thiones act as S-donors in **1**–**3**, as is commonly the case (6, 8*a*, *b*), and as has been suggested for the cation in **4** on the basis of its isomorphism with the Co(II) analogue for which a CoS_4 kernel has been established from *d-d* spectroscopy (9). We note that a rough inverse correlation exists between the ^{111}Cd chemical shifts of **1**–**3** and the values of pK_a for LH^+ (pK_a = –1.07, 1.50, –1.53 for LH^+, L = Py2S, Py4S, and Q2S, respectively, (17)).

(b) Studies of cadmium complexes with mixed ligands

(i) The systems $[Cd(SePCy_3)_4]^{2+}$–$[CdL_4]^{2+}$ and $[Cd(SePCy_3)_4]^{2+}$–L (L = Py2SH, Py4SH, Q2SH): At 189 K,[9] the ^{31}P and metal NMR spectra of $[Cd(SePCy_3)_4]^{2+}$ in 50% v/v Me_2CO:CH_2Cl_2 (Table 3) are a singlet with ^{77}Se and $^{111/113}Cd$ (av) satellites, and a quintet (from ^{111}Cd–^{31}P coupling), respectively. These are consistent with earlier data (5*a*, *b*). The ^{77}Se NMR spectrum, which has not been reported previously, consists of a doublet (from $^1J(^{77}Se\text{-}^{31}P)$) with $^{111/113}Cd$ satellites (from $^1J(^{111/113}Cd\text{-}^{77}Se)$) : δ_{Se} = –403.6, $^1J(^{77}Se\text{-}^{31}P)$ = 549 Hz, $^1J(^{111/113}Cd\text{-}^{77}Se)$ = 248 Hz (Table 3). As **1** is added to the solution of **5**, a total of three new $SePCy_3$-containing species is observed by a combination of ^{31}P, ^{77}Se, and ^{111}Cd NMR. Their NMR spectra (Table 3) characterize them as $[Cd(Py2SH)_{4-n}(SePCy_3)_n]^{2+}$ (n = 1–3), with n increasing as $SePCy_3$:Py2SH increases in the mixtures. Thus the whole series $[Cd(Py2SH)_{4-n}(SePCy_3)_n]^{2+}$ (n = 0–4) has been characterized, proving that, like $[Cd(SePCy_3)_4]^{2+}$, the homoleptic complex formed between Cd(II) and Py2SH in solution is four-coordinate, $[Cd(Py2SH)_4]^{2+}$.

When Py2SH is added incrementally to **5** in 50% v/v Me_2CO:CH_2Cl_2, the ^{31}P NMR spectrum at –189°C shows first the formation of $[Cd(Py2SH)(SePCy_3)_3]^{2+}$, as confirmed by the observation of the appropriate quartet (from $^1J(^{111}Cd\text{-}^{31}P)$) in the corresponding ^{111}Cd NMR spectrum. However, with increased addition of Py2SH, separate ^{31}P NMR signals are not observed for $[Cd(Py2SH)_2(SePCy_3)_2]^{2+}$ and $[Cd(Py2SH)_3(SePCy_3)]^{2+}$, although the ^{111}Cd NMR spectrum shows the separate signals from these two species. Evidently

[8] $\delta_{C\text{-}2}$ (free Py2SH) = 180.2 (15).

[n]Not observed.

the two ^{31}P NMR spectra are coincident. In increasingly Py2SH-rich mixtures, a broad ^{31}P NMR signal from $SePCy_3$ appears. This part of spectrum becomes increasingly sharper as it comprises increasingly more of the total intensity. At Py2SH:**5** = 4.1:1, the ^{31}P NMR spectrum (now sharp) provides evidence for free $SePCy_3$ only (δ_P = 61.4, $^1J(^{77}Se\text{-}^{31}P)$ = 671 Hz). At this point, no ^{111}Cd NMR signal from $[Cd(Py2SH)_4]^{2+}$ is observed; **1** seems to have crystallized out completely over the time taken for the experiment. However, it is evident that Py2SH is a stronger ligand to Cd(II) than $SePCy_3$.

Essentially identical results to those obtained for **1**:**5** and Py2SH:**5** mixtures are observed for **2** or **3**:**5** and Py4SH or Q2SH:**5** mixtures, except that no evidence could be obtained for $[Cd(Q2SH)_3(SePCy_3)]^{2+}$. (Q2SH-rich complexes are poorly soluble at –189°C.) NMR spectral parameters for the new complexes observed are given in Table 3. Both Py4SH and Q2SH are better ligands towards Cd(II) than $SePCy_3$.

(ii) The systems $[Cd(SPCy_3)_4]^{2+}$:L (L = Py2SH, Py4SH, Q2SH):
Mixed-ligand complexes containing Cy_3PS were detected by NMR in experiments where the free thiones were added to $[Cd(SPCy_3)_4]^{2+}$ (preformed in situ in Me_2CO:CH_2Cl_2 (1:1 v/v) from Cy_3PS and $Cd(trif)_2$). At 189 K,[9] the ^{31}P NMR spectrum of $[Cd(SPCy_3)_4]^{2+}$ consists of a singlet with $^{111/113}Cd$ satellites, while the ^{111}Cd NMR spectrum consists of a quintet (from $^2J(^{111}Cd\text{-}^{31}P)$). These are in concert with data for the same complex in SO_2(l) at 203–209 K (5*a*, *b*).

When one equiv. of Py2SH is added to $[Cd(SPCy_3)_4]^{2+}$ at 189 K, the ^{31}P NMR and ^{111}Cd NMR spectra provide evidence for $[Cd(Py2SH)_1(SPCy_3)_3]^{2+}$ and $[Cd(Py2SH)_2(SPCy_3)_2]^{2+}$. Details of the NMR spectra of these two new species are given in Table 4. With the addition of second equiv. of Py2SH, the relative intensities of the spectra of the individual species that are observed shift in favour of those that are more Py2SH-rich. A new broad signal appears in the ^{31}P NMR spectrum at ~68 ppm, and the signal observed for Cy_3PS at 64 ppm is broad. Under the same conditions the ^{111}Cd NMR spectrum provides evidence for $[Cd(Py2SH)_2(SPCy_3)_2]^{2+}$. When a third equiv. of Py2SH is added, the ^{31}P NMR signal from $[Cd(SPCy_3)_4]^{2+}$ finally disappears, and the relative intensities of the broad signals at ~ 68 ppm and from free Cy_3PS increase. A signal attributable to $[Cd(Py2SH)_3(SPCy_3)_1]^{2+}$ is observed in the ^{111}Cd NMR spectrum. Evidently ligand exchange between free Cy_3PS and Cy_3PS coordinated in $[Cd(Py2SH)_2(SPCy_3)_2]^{2+}$ and $[Cd(Py2SH)_3(SPCy_3)_1]^{2+}$ occurs at a rate sufficient to broaden (or possibly collapse) the ^{31}P NMR spectra of the species involved, but not sufficient to collapse their ^{111}Cd NMR spectra. With the addition of a fourth equiv. of Py2SH, insoluble crystals, presumably $[Cd(Py2SH)_4](trif)_2$, separated and the now sharp singlet of Cy_3PS alone appears. This experiment confirms that Cd–Py2SH complex is four-coordinate in solution and also shows that Py2SH can completely displace Cy_3PS from Cd(II).

Results for addition of Py4SH and Q2SH to $[Cd(SPCy_3)_4]^{2+}$ at 189 K, were very similar to those observed for the corresponding addition of Py2SH, except that of the complexes containing Q2SH, only that with *n* = 3 gave a sharp ^{31}P NMR spectrum. Details of the NMR

spectra are included in Table 4. Again it is evident that the thiones can displace Cy_3PS from Cd(II).

(iii) The complexes $[Cd(Py2SH)_{4-n}L_n]^{2+}$ (L = Py4SH or Q2SH): The observation of slow exchange NMR spectra for many complexes $[CdL_{4-n}(EPCy_3)_n]^{2+}$ (E = S or Se) (see above) proves that in these complexes intermolecular exchange of the phosphine chalcogenide is slow, but does not provide evidence about the lability of the thione ligands. To obtain information pertinent to the latter point, and also to further confirm four-coordination of $[CdL_4]^{2+}$, reduced-temperature[9] ^{111}Cd NMR spectra of complexes with mixed thione ligands have been studied, again using a 1:1 (v/v) Me_2CO:CH_2Cl_2 as solvent.

Mixtures of **1** and **2** were prepared by adding **2** incrementally to a solution of **1** in 1:1 (v/v) Me_2CO:CH_2Cl_2. By varying the **1**:**2** ratio, a total of five singlets was observed by ^{111}Cd NMR for the mixtures at 189 K. The extreme chemical shifts are those of the parent complexes $[Cd(Py2SH)_4]^{2+}$ (603.4 ppm) and $[Cd(Py4SH)_4]^{2+}$ (624.0 ppm). The intervening resonances at δ_{Cd} = 609.6, 614.5, and 618.4 are readily assigned to $[Cd(Py2SH)_{4-n}(Py4SH)_n]^{2+}$, with *n* = 1, 2, and 3, respectively. These assignments can be confirmed by expressing the chemical shifts in terms of pairwise interactions (18).

Fig. 1. A view of the cation in $[Cd(Py2SH)_4](NO_3)_2$ (**4**), showing one of the cation···nitrate hydrogen bonds. Non-hydrogen atoms are shown as 50% probability thermal ellipsoids.

A similar experiment with mixtures of **1** and **3** also yields a total of five singlet resonances, δ_{Cd} = 603.4, 596.2, 586.9, 576.1, and 566.0. These can be assigned to $[Cd(Py2SH)_{4-n}(Q2SH)_n]^{2+}$, with *n* = 0, 1, 2, 3, and 4, respectively.

The observation of separate ^{111}Cd NMR signals for the complexes with mixed thiones shows that intermolecular exchange of the thiones is slow on the timescale of $\Delta\delta_{Cd}$ at 189 K.[10] Further the total of five signals observed when two thiones are mixed confirms that the thione complexes are of general formula $[CdL_4]^{2+}$ in solution, consistent with the results obtained using mixtures of thiones and Cy_3PE (see above).

(iv) Competition between thiones for complexation to Cd(II): At 189 K, the ^{111}Cd NMR spectrum of a mixture with Cd(trif)$_2$:Py2SH:y4SH = 1:4:1 in Me_2CO:CH_2Cl_2 (1:1, v/v) shows broad signals corresponding to $[Cd(Py2SH)_{4-n}(Py4SH)_n]^{2+}$ with *n* = 1 and *n* = 2. On the other hand, the analogous spectrum of a mixture in which Cd(trif)$_2$:Py2SH:Py4SH = 1:1:4 shows only the sharp signal of $[Cd(Py4SH)_4]^{2+}$ at 623 ppm. This experiment shows that towards Cd(II) the ligating ability is Py4SH > Py2SH.

After addition of free Q2SH to a 1:1 mixture of $[Cd(Py2SH)_4]^{2+}$:$[Cd(Q2SH)_4]^{2+}$ in Me_2CO:CH_2Cl_2 (1:1, v/v) until (total L)/M > 6, broad signals corresponding to the mixed thione species are seen in ^{111}Cd NMR at 189 K. Clearly Py2SH can compete with Q2SH for coordination to Cd(II) even when Q2SH/Cd > 4. Conversely, when free Py2SH was added to a 1:1 mixture of $[Cd(Py2SH)_4]^{2+}$ and $[Cd(Q2SH)_4]^{2+}$ until (total L)/M > 6, the metal NMR spectrum at 189 K shows only the resonance of $[Cd(Py2SH)_4]^{2+}$ at 603 ppm. Thus Q2SH cannot compete with Py2SH for coordination to Cd(II) when Py2SH/Cd > 4. Therefore for the three different thione ligands donor ability towards Cd(II) is

[9]Rapid exchange occurs at ambient probe temperature, and fine structure is lost.
[10]An alternative explanation that only exchange of Py2SH is slow, or that only exchanges of Py4SH and Q2SH are slow, seems highly improbable.

Py4SH > Py2SH > Q2SH, the order of the basicities of the ligands (see above).

Crystal structure of $[Cd(Py2SH)_4](NO_3)_2$ (4)

The crystal structure of **4** consists of recognizable $[Cd(Py2SH)_4]^{2+}$ cations and NO_3^- anions. Figure 1 shows the structure of the cation. Selected bond angles and bond distances are listed in Table 5.

In the cations the ligands behave as S-donors, as is usual for this ligand (6, 8*a*). The point group symmetry of $[Cd(Py2SH)]_4^{2+}$ is S_4, the point group symmetry of the CdS_4 core being D_{2d}. The Cd—S bond distance is 2.5163(7) Å and S-Cd-S bond angles are 105.01(2) and 118.81(3)°, there being a tetragonal compression of the core. The Cd—S distance may be compared with, for example, 2.496(6)–2.56(1) Å reported (19) for $[Cd(Me_2tu)_4](NO_3)_2$, and 2.516(2)–2.556(3) found (20) for various salts of homoleptic thiolate anions, $[Cd(SR)_4]^{2-}$.[11]

In the ligand, the C(1)-N(1)-C(5) bond angle is 123.7(2)°, implying that the proton is bonded to nitrogen and not to sulfur (22). The bond distance C(1)—S(1) is 1.716(2) Å, slightly longer than the value of 1.692(2) Å found (23) by X-ray diffraction[12] for free *2*(1*H*)-pyridinethione. Accompanying this increase are slight reductions of the C(1)—C(2) and C(3)—C(4) bond distances (1.390(3) and 1.383(4) Å compared with 1.417(4) and 1.399(4) Å in the free ligand) consistent with increasing aromatization of the pyridyl ring as the thione character of the C—S linkage is reduced. Also observed on complexation are changes in the angles subtended at C(1): the C(2)-C(1)-S(1) angle increases to 127.1(2)°, from 124.3(2)° in the free ligand, the N(1)-C(1)-S(1) angle decreases to 116.9(2)°, from 120.6(2)° in the free ligand, and there is a slight increase in the N(1)-C(1)-C(2) angle compared with the free ligand (to 116.0(2)° from 115.0°). The skeleton of the thione is planar (mean deviation 0.007 Å), and the dihedral angle between the C_5NS and C(1)-S(1)-Cd(1) planes is 20.2°.

It is interesting to note that the point group symmetry of the cations (S_4) is one of the two ideal possibilities that have been recognized (23) for $[M(SPh)_4]^{n-}$ (the other possibility is D_{2d}).[13] The anion with M = Cd and n = 2 is isoelectronic with the cation in **4**. For the anions of S_4 symmetry, a tetragonal compression is uniformly observed (23*b*), and such a compression is found here for $[Cd(Py2SH)]_4^{2+}$ also. A similar compression is evident in data for $[M(Py2SH)_4](BF_4)$ (M = Cu or Ag), although it has not been remarked upon (25). The Cu(I) and Ag(I) complexes have less regular symmetry than is observed here for $[Cd(Py2SH)]_4^{2+}$, however.

The $[Cd(Py2SH)]_4^{2+}$ cations stack in columns in the *c* direction, with a Cd···Cd distance of 7.607(1) Å. The anions, which have C_{2v} symmetry, occupy channels between the columns of cations. Extending the parallel between $[Cd(Py2SH)_4]^{2+}$, and $[M(SPh)_4]^{n-}$, a two-fold disorder of the heterocyclic rings about their C(1)-C(4) axes might be anticipated in the former. However, the NO_3^- anions are "docked" between two adjacent cations in such a way that O(2) is positioned to take part in two symmetry-related weak hydrogen bonds, to one N-*H* on each of the two cations (H(1A)···O(2) = 2.223 Å, N(1)-H(1A)-O(2) = 172(1)°, H(1A)-O(2)-H(1D) = 159(1)°). (One such hydrogen bond is shown in Fig. 1.) This hydrogen bonding network presumably prevents disorder of the pyridyl groups.[14]

Acknowledgments

We thank Dr. M. Jennings, Manager of the X-Ray Crystallographic Service at UWO, for considerable assistance with

[11]A 1995 review of all structurally characterized coordination compounds of cadmium (21) found average values of the Cd—S distance to be 2.546 and 2.527 Å for complexes of mono- and bi-dentate sulfur donors, respectively.
[12]Values obtained by neutron diffraction are given in ref. 22 also.
[13]A recent discussion of this topic is provided in ref. 24.

Redox chemistry of the selenium coronand, 1,5,9,13-tetraselenacyclohexadecane, and a mechanistic study of the electron transfer reaction of its Cu(II) complex

Raymond J. Batchelor, Frederick W.B. Einstein, Ian D. Gay, Jian-Hua Gu, B. Mario Pinto, and Xue-Min Zhou

Abstract: The crystal structure of Cu(16Se4)$(SO_3CF_3)_2$ (**1**) shows a centrosymmetric complex having tetragonally distorted octahedral coordination about Cu with *trans*-axial triflate ligands; Cu—O 2.464(5) Å. The stereochemistry of the coronand is *c*,*t*,*c*; Cu—Se 2.4592(9), 2.4553(9) Å. **1**: T = 190 K; fw = 845.83; space group $P2_1/n$; Z = 2; a = 8.220(2), b = 10.965(4), c = 14.657(5) Å; V = 1273.4 Å^3; R_f = 0.037 for 1708 data ($I_o \geq 2.5\sigma(I_o)$) and 152 variables. When recrystallized from $MeNO_2$–Et_2O **1** undergoes an electron-transfer reaction to give Cu(I) as well as the intermediate radical cation $[16Se4]^{\cdot+}$ and the stable dication $[16Se4]^{2+}$. The crystal structure of a mixed MeCN–CH_2Cl_2 solvate of $[(16Se4)][SO_3CF_3]_2$ (**2**) revealed the $[16Se4]^{2+}$ cation which displays two transannular Se—Se bonds of 2.5916(15) and 2.6689(15) Å, linking three of the Se atoms in an approximately linear relationship. The central Se atom of this grouping also has a close contact to the fourth Se atom of the molecule of 3.3941(20) Å. **2**·solv: T = 195 K; fw = 828; space group $P\bar{1}$; Z = 2; a = 9.015(2), b = 12.850(3), c = 13.835(3) Å; α = 63.98(2), β = 74.71(2), γ = 73.59(2)°; V = 1363.3 Å^3; R_f = 0.042 for 2098 data ($I_0 \geq 2.5\sigma(I_0)$) and 254 variables. A solid-state ^{77}Se NMR spectrum of **2** shows 4 lines, with isotropic shifts ranging from 173 to 737 ppm. The line widths are all different, and we obtain a tentative assignment by attributing this to differences in dipolar coupling to ^{19}F. Significant differences in chemical shift anisotropy are observed for the various selenium atoms. UV–visible absorption spectroscopy has been used to characterize **1** and its reduction products. **1** absorbs at 560, 464, and 310 nm. Reaction of **1** with the free ligand 16Se4 leads to the disappearance of these peaks, and the growth of a new peak at 320 nm. Oxidation of 16Se4 by $NOBF_4$ produced a transient peak at 320 nm, and subsequently a peak at 256 nm. From the dependence of intensity on 16Se4 concentration, we infer that the former arises from a dimeric species; we assign the lines to the radical cations $(16Se4)_2^{+\cdot}$ and $16Se4^{+\cdot}$, respectively. Electrochemical studies have been carried out on **1** and on 16Se4. Cyclic voltammetry of **1** shows a two-step reduction to Cu(II)$L^{+\cdot}$ (L = 16Se4) and subsequently to Cu(I)L^+. Electrochemical oxidation of 16Se4 leads to $16Se4^{+\cdot}$ and $16Se4^{2+}$. Spectroelectrochemical studies showed that oxidation to $16Se4^{+\cdot}$ gives rise to a band at 256 nm, as seen in chemical oxidation, and at high concentrations a band at 322 nm is also seen, supporting the assignment of this species to the dimeric radical cation. The EPR spectrum of **1** in CH_3NO_2 solution gave an isotropic g value of 2.053 with hyperfine constants A_{iso}^{Cu} = 75 G and A_{iso}^{Se} = 65 G. The low temperature EPR spectrum of **1**, measured at –148°C in CH_3NO_2:toluene (1:1 v/v), gave values of $g_{//}$ = 2.085, $A_{//}^{Cu}$ = 160 G; $g_{\perp}$ = 2.049, $A_{\perp}^{Cu}$ = 46 G. An EPR spectrum of **1** in CH_3NO_2 in the presence of added 16Se4 showed a decrease in intensity of the signals attributable to **1** and the emergence of new signals that are presumed to arise from a species with radical cation character. We have carried out kinetic studies on the reaction between **1** and 16Se4. It is found that the reaction is first order in each of these species, second order overall. The reaction stoichiometry is 2 Cu(16Se4)$^{2+}$ + 16Se4 → 2 Cu(16Se4)$^+$ + $16Se4^{2+}$. These results can be explained by the simple mechanism Cu(II)L^{2+} + L ⇌ $L^{+\cdot}$ + Cu(I)L^+, followed by Cu(II)L^{2+} + $L^{+\cdot}$ → L^{2+} + Cu(I)L^+. The activation energy is found to be 35 kJ mol^{-1}.

Key words: selenium coronands, Cu(II) complex, redox chemistry, mechanism, electron transfer.

Résumé : La structure cristalline du Cu(16Se4)$(SO_3CF_3)_2$ (**I**) indique qu'il s'agit d'un complexe centrosymétrique comportant une coordination octaédrique déformée de façon tétragonale autour du Cu avec des ligands triflates dans la position *trans*-axiale; Cu—O = 0,2464(5)Å. La stéréochimie du coronand est *c*,*t*,*c*; Cu—Se = 2,4592(9) et 2,4553Å. Pour le composé **1**, à T = 190 K, fw = 845,83; groupe d'espace $P2_1/n$; Z = 2; a = 8,220(2), b = 10,965(4) et c = 14,657(5) Å, V = 1273,4Å^3; R_f = 0,037 pour 1708 données ($I_0 \geq 2,5\sigma(I_0)$) et 152 variables. Par recristallisation d'un mélange $MeNO_2$–Et_2O, le composé **1** subit une réaction de transfert d'électron qui fournit du Cu(I) ainsi que le cation

radical intermédiaire $[16Se4]^{+\cdot}$ et le dication stable $[16Se4]^{2+}$. La structure cristalline d'un produit de solvatation mixte $MeCN–CH_2Cl_2$ et $[(16Se4)][SO_3CF_3]_2$ (**2**) révèle que le cation comporte deux liaisons Se—Se transannulaires de 2,5916(15) et 2,6689(15) Å qui relient trois des atomes de Se dans une relation approximativement linéaire. L'atome de Se central de ce groupe est aussi en contact assez intime [distance de 3,394(20) Å] avec le quatrième atome de Se de la molécule. Le produit de solvatation mixte, à T = 195K, f_w = 828; groupe d'espace $P\bar{1}$, Z = 2; a = 9,015(2), b = 12,850(3) et c = 13,835(3) Å, α = 63,98(2), β = 74,71(2) et γ = 73,59(2)°; V = 1363,3 Å^3; R_f = 0,042 pour 2098 données ($I_0 \geq 2{,}5\sigma(I_0)$) et 254 variables. Le spectre RMN du ^{77}Se du produit **2** à l'état solide présente quatre raies avec des déplacements isotropes allant de 173 à 737 ppm. Les largeurs de raies sont toutes différentes et il est possible de faire des attributions préliminaires en faisant l'hypothèse que ces résultats sont dus à des différences de couplage dipolaire avec le ^{19}F. On a observé des différences marquées dans l'anisotropie du déplacement chimique pour les divers atomes de sélénium. On a utilisé la spectroscopie d'absorption UV–visible ainsi que les produits de réduction pour caractériser le produit **1**. Le produit **1** absorbe à 560, 464 et 310 nm. La réaction de **1** avec un ligand libre 16Se4 conduit à la disparition de ces bandes et au développement d'une nouvelle bande à 320 nm. L'oxydation du 16Se4 par du $NOBF_4$ provoque l'apparition d'une bande transitoire à 320 nm qui est suivie d'une bande à 256 nm. Sur la base de la dépendance de l'intensité sur la concentration de 16Se4, on en déduit que la première bande découle d'une espèce dimère et on attribue les bandes respectivement au cation radical [16Se4] et au dication stable $[16Se4]^{2+}$. On a effectué des études électrochimiques sur le composé **1** et sur le 16Se4. La voltammétrie cyclique de **1** démontre qu'il s'agit d'une réduction en deux étapes conduisant au $Cu(II)L^{+\cdot}$ (L = 16Se4) et subséquemment au $Cu(I)L^+$. Les études spectroélectrochimiques montrent que l'oxydation en 16Se4 donne lieu l'apparition d'une bande à 256 nm, comme on l'a observé au cours de l'oxydation chimique, et que, à concentrations élevées, on observe aussi l'apparition d'une bande à 322 nm qui favorise l'attribution de cette espèce au cation radical dimère. Le spectre RPE du composé **1** en solution dans le CH_3NO_2 donne une valeur isotrope de g de 2,053 avec des constantes hyperfines A_{iso}^{Cu} = 75G et A_{iso}^{Se} = 65G. Le spectre RPE du composé **1** à basse température, mesuré à –148°C dans un mélange 1:1 v/v de CH_3NO_2:toluène permet de tirer des valeurs de $g_{//}$ = 2,085, $A_{//}^{Cu}$ = 160 G; $g_{\perp}$ = 2,049, $A_{\perp}^{Cu}$ = 46 G. Un spectre RPE du composé **1**, dans du CH_3NO_2, en présence de 16Se4 ajouté, montre qu'il y a diminution de l'intensité des signaux attribuables à **1** et l'émergence de nouveaux signaux que l'on attribue à une espèce ayant un caractère cation radical. On a aussi effectué des études cinétiques sur la réaction du composé **1** avec le 16Se4. On a trouvé que la réaction est du premier ordre pour chacune des espèces et que la réaction globale est du deuxième ordre. La stoechiométrie de la réaction est: $2Cu(16Se4)^{2+} + 16Se4 \rightarrow 2\ Cu(16Se4)^{+} + 16Se4^{2+}$. Ces résultats peuvent être expliqués par le mécanisme simple $Cu(II)L^{2+} + L \rightleftharpoons L^{+\cdot} + Cu(I)L^{+}$ suivi par $Cu(II)L^{2+} + L^{+\cdot} \rightarrow L^{2+}\ Cu(I)L^{+}$. L'énergie d'activation est de 35 kJ mol^{-1}.

Mots clés : coronands au sélénium, complexe Cu(II), chimie redox, mécanisme, transfert d'électron.

Introduction

We have been active in the study of the synthesis and conformational analysis of selenium coronands (1, 2). We have also described the synthesis and properties of polymer-bound selenium coronands (3), and the metal-ion complexation of selenium coronands (4, 6). To date, we have reported the structure of the Cu(II) complex of 1,5,9,13-tetraselenacyclohexadecane (16Se4) (4), and the stereochemical analysis of Pd(II) complexes of 16Se4 and 24Se6 (5). We have also reported the study of the adducts of 16Se4 with Cu(I) triflate and Hg(II) cyanide (6), and communicated our results on Cu(I), Cu(II), and Pd(II) complexes of 16Se4 and other selenium coronands (7). Several other reports of complexes of 16Se4, with Rh(III), Co(III) and Ir(III) (8); Pd(II) and Pt(II) (9); Ni (II), Ag (I), Cr (III), Ru (II), and Ru (III) (10) have appeared. Metal-ion complexation by mono- and di-selena (11), and tetraselena (12) macrocyclic ligands containing additional heteroatoms has also been reported.

The rich redox chemistry exhibited by metal complexes of sulfur coronands (13) promised an exciting period of discovery with complexes of the heavier congeners. In the first report of a selenium coronand complex (4), we described a Cu(II) complex of 16Se4, $[Cu(16Se4)][SO_3CF_3]_2$ (**1**), which underwent an unprecedented electron-transfer reaction in coordinating organic solvents to give Cu(I) as well as the intermediate radical cation $[16Se4]^{+\cdot}$ and the stable dication $[16Se4]^{2+}$. The salts $[16Se4]^{2+}([SO_3CF_3]^-)_2$ (**2**) and $[Cu(16Se4)][SO_3CF_3]$ (a polymeric Cu(I) adduct) (6) were isolated from these solutions by selective crystallization. We now report the detailed mechanistic investigation of this electron-transfer reaction, using electrochemistry, spectroelectrochemistry and kinetic analysis. We also include the full structural details for **1** and **2** as well as the ^{77}Se solid state NMR spectrum of **2**.

Experimental

General information

Melting points were determined on a Fisher–Johns melting-point apparatus and are uncorrected. Solvents were distilled before use and were dried, as necessary, by literature procedures. Microanalyses were performed by M. K. Yang of the Simon Fraser University Microanalytical Laboratory.

Spectroscopy

^{1}H NMR spectra were recorded on a Bruker AMX-400 NMR spectrometer operating at 400.13 MHz. Chemical shifts are given with respect to $SiMe_4$. Saturation transfer experiments were performed on **2** in $(CD_3)_2CO$ at 180 K, in the difference mode with a saturating power of 50 dB and saturating times of 0.1 to 0.5 s. The solid state ^{77}Se NMR spectrum was recorded on an instrument (built in-house)

© 2000 NRC Canada

operating at a field of 1.4 T. This produces a resonance frequency of 11.4 MHz. Spectra were excited by using single-contact Hartmann–Hahn cross polarization. The matched radio frequency field strength was 40 kHz. The same field strength was used for proton decoupling during data acquisition. The sample was spun at the magic angle at frequencies of 2–3 kHz. The magic angle was correctly set within ±0.1° by optimizing the line width on a well-crystallized sample of $(t\text{-}Bu_2Sn)_2Se_2$. Chemical shifts were measured relative to long cylindrical samples of aqueous H_2SeO_3. These were converted to shifts based on the standard Me_2Se by use of literature data.

EPR spectra were recorded on a Varian E-4 spectrometer equipped with a temperature controller. The magnetic field was calibrated with DPPH (g = 2.0036) (14). For experiments at ambient temperature, nitromethane was used as the solvent; for experiments at low temperature, nitromethane:toluene (1:1 v/v) was used. The concentration of the Cu(II) complex was 1×10^{-3} M. Measurements were obtained on samples sealed in melting point capillaries that were in turn placed in EPR tubes. In a separate experiment, a mixture of **1** (1×10^{-2} M) in CH_3NO_2 was treated with 16Se4 (1×10^{-2} M) at room temperature and the changes were monitored. Spectra were simulated with Simfonia (WINEPR, Bruker). The spectrum at ambient temperature was simulated using Lorentzian lineshapes with line width/G = 11 + m + m^2, where m is the nuclear spin z-component (–3/2, –1/2, 1/2, 3/2). The spectrum at low temperature was simulated using Gaussian lineshapes with a line width of 32 G.

IR spectra were recorded on a Bomem FT-IR spectrometer. All UV-visible spectra were measured on a Hewlett–Packard HP 89500 UV/VIS Chem Station or a Hewlett-Packard HP 8452 Diode Array Spectrophotometer. The temperature was controlled at 25°C with a thermostat, unless otherwise stated.

Electrochemistry

Cyclic voltammograms of N_2-purged solutions, under an atmosphere of N_2, were recorded on a PAR™ Model 170 or a PAR™ Model 173/175 Electrochemistry System. The reference electrode was an aqueous saturated calomel electrode (SCE) with a Luggin capillary. The working electrode was a platinum plate and the counter electrode was a platinum wire. For the kinetic analysis, cyclic voltammograms were obtained from a single scan for each concentration and each scan rate, and the surface of the electrode was cleaned with a tissue after every scan.

Controlled potential electrolysis, in continuously N_2-purged, stirred solutions, was carried out in a two-compartment electrochemical cell with a sintered-glass partition. The working and counter electrodes were Pt gauze and the reference electrode was aqueous saturated calomel with a Luggin capillary. Tetraethylammonium perchlorate (TEAP, 0.1 M) was used as the electrolyte. The species in solution were characterized by UV–visible spectroscopy; aliquots were withdrawn with a syringe and transferred into a UV cuvette. The coulometer was calibrated with MeCN solutions of ferrocene.

Cyclic voltammetry (CV) during electrolysis was carried out in a two compartment cell with two potentiostats. A PAR™ Model 170 Electrochemistry System was used for electrolysis and a PAR™ Model 173/175 Electrochemistry System was used for cyclic voltammetry. The working and counter electrodes for electrolysis were both Pt gauze. The compartment for electrolysis contained the working electrode, another Pt electrode for CV, and the SCE. 16Se4 (3.3 mM in MeCN) was electrolyzed at 1.2 V and 1.8 V. The species in solution were monitored by UV–visible spectroscopy; aliquots were withdrawn with a syringe and transferred into a UV cuvette. When the absorbance maximum of interest became the predominant peak, the CV scan was started.

Convolution analysis of cyclic voltammograms (15) was carried out after digitization of the data.

Spectroelectrochemistry

The working electrode was an optically transparent Pt-film electrode, fabricated by evaporating Pt powder (using a tungsten filament) onto quartz plates, which were then annealed in a muffle furnace at 550°C for 2 h (16–18). The UV–visible spectrum of the electrode had a broad window for UV–visible light (λ = 200–800 nm; absorbance = 0.5 – 0.6). A AgI/Ag reference electrode was prepared by dipping a thin silver plate into melted AgI in a crucible until a thin film of AgI was obtained. The counter electrode was a Pt wire kept in a glass tube with a sintered end to prevent the species generated on the counter electrode from interfering with the observation of species at the working electrode.

The electrolyses of N_2-purged solutions were carried out, under an atmosphere of N_2, in a UV cuvette. Repeated UV–visible scans were started as soon as the desired potentials (determined by CV) were applied to the electrodes.

Chemical generation of radical cations

Stock solutions of 16Se4 and $NOBF_4$, in freshly distilled MeCN, were prepared, the latter in a glove bag under N_2. The 16Se4 solution was transferred by pipette into a quartz UV cuvette which was then sealed with a septum. N_2 was bubbled through the stirred 16Se4 solution for 15 min, after which the $NOBF_4$ solution was added with a 25 μL syringe. When half of the solution had been added, the repeated scanning of the spectrum was begun.

Kinetic analysis

Flasks were flushed with N_2 before use and CH_2Cl_2 was freshly distilled from P_2O_5 under N_2. A UV cuvette containing an N_2-purged solution of the Cu(II) complex (**1**) was sealed with a septum, under N_2. An N_2-purged solution of 16Se4 was stored under N_2 in a vial, sealed with a septum. The reaction was initiated by injecting the 16Se4 solution with a 25 μL syringe into a stirred solution of **1** in the cuvette. When half of the solution had been added, the repeated scanning of the spectrum was begun, and this point was taken as t = 0 in the data treatment. The variations in intensities of the absorbance bands of the complex and intermediate with time were monitored. Three separate runs were performed for a given substrate concentration.

Synthesis

*$[Cu(16Se4)][SO_3CF_3]_2$ (**1**)*

Under N_2, 16Se4 (1) (45 mg, 0.093 mmol) in dry acetone (2 mL) was added to $Cu(SO_3CF_3)_2$ (18) (34 mg, 0.093 mmol)

© 2000 NRC Canada

in dry acetone (1 mL). The mixture was stirred for 10 min at ambient temperature. Reddish-black crystals were precipitated from the solution by the addition of dry diethyl ether (2 mL) and cooling to 0°C. The crystals were collected by filtration (34 mg, 45%). Recrystallization by diethyl ether vapor diffusion into a CH_2Cl_2 solution afforded 17 mg of reddish-black needles. UV ($MeNO_2$), λ (ϵ): 466 (2193), 556(shoulder) nm; IR (cm^{-1}, KBr) 2940, 1450, 1270, 1235, 1160–1170, 1040, 650, 550. Anal. calcd. for $C_{14}H_{24}CuF_6O_6S_2Se_4$: C 19.88, H 2.83; found: C 19.87, H 2.74.

*[16Se4][SO_3CF_3]$_2$ (**2**)*

Under N_2, 16Se4 (1) (28.7 mg, 0.059 mmol) in MeCN:CH_2Cl_2 (1 mL; 1:1 v/v) was added to $Cu(SO_3CF_3)_2$ (19) (21.4 mg, 0.059 mmol) in MeCN:CH_2Cl_2 (1 mL; 1:1 v/v). The mixture was stirred for 5 min at ambient temperature. CH_2Cl_2 (0.5 mL) was added followed by cooling to 0°C (1 h), and then to –20°C in a refrigerator (overnight). Pale yellow crystals were collected by filtration and washed with CH_2Cl_2 to give **2** (23 mg; 50%). Mp 192–3°C dec. UV (MeCN), λ_{max} (ϵ): 223 (9315) nm; IR (cm^{-1}, KBr) 2940, 1450, 1270, 1235, 1165, 1035, 645, 545. ^{1}H NMR ($(CD_3)_2CO$; RT) δ(ppm): 1.97–2.05, 2.06–2.12, 2.30–2.45, 2.62–2.73, 2.73–2.88, 3.1–3.5 (br), 3.57–3.77 (complex multiplets). ^{1}H NMR ($(CD_3)_2CO$; 180 K) δ(ppm): 1.80–1.98, 2.15–2.32, 2.32–2.48 (complex br. multiplets, β-CH_2s); 2.52–2.72 (complex br. multiplet, α- + β-CH_2s), 2.72–2.88, 2.88–3.02, 3.50–3.68, 3.78–3.95 (complex br. multiplets, α-CH_2s). CP-MAS δ^{77}Se (±1 ppm; ref Me_2Se): 173 ($W_{1/2}$ = 85 Hz), 419 ($W_{1/2}$ = 120 Hz), 502 ($W_{1/2}$ = 140 Hz), 737 ($W_{1/2}$ = 110 Hz). Anal. calcd. for $C_{14}H_{24}F_6O_6S_2Se_4$: C 21.5, H 3.09. Anal. calcd. for $C_{15.67}H_{25.67}Cl_{0.67}F_6N_{0.67}O_6S_2Se_4$ (**2** + 0.67MeCN + 0.33CH_2Cl_2): C 22.45, H 3.10, N 1.11; found: C 22.69, H 3.05, N 1.08.

X-ray crystallography

A reddish-black colored, plate-shaped crystal of **1** was mounted on a pyrex fiber with 5-minute epoxy. A yellow plate-shaped crystal grown from a MeCN:CH_2Cl_2 solution of **2** was sealed in a capillary tube. Intensity data (Mo K_α/graphite monochromator) were collected at 190 K for **1** and at 195 K for **2** using an Enraf Nonius CAD-4F diffractometer equipped with an in-house modified low temperature attachment. The data were corrected for absorption by the Gaussian integration method. Data reduction also included Lorentz and polarization corrections.

For **1**, appropriate coordinates and anisotropic displacement parameters were refined for the non-hydrogen atoms. Hydrogen atoms were placed in calculated positions (C—H, 0.95 Å) with assigned isotropic displacement parameters proportionate to the equivalent isotropic values for their respective carbon atoms — on which they were made to ride during refinement. A single parameter was refined for the hydrogen atom isotropic displacement and its shift applied to the individual values. The final full matrix least-squares refinement included 152 parameters for 1708 reflections ($I \geq 2.5\sigma(I)$). The maximum |shift/error| in the final cycle of refinement was 0.01. The largest peak in the final difference map was 1.0(2) eÅ^{-3} occurring 0.9 Å from Se(1).

In the case of **2** the crystal contained solvent of crystallization. The solvent region exhibited disorder which was modelled with partial occupancy by a molecule of MeCN (0.885(6)) or a molecule of CH_2Cl_2 (0.115). The H-atoms of the CH_2Cl_2 were omitted. A correlated orientational disorder of one of the $SO_3CF_3^-$ anions was observed and was modelled by two independent orientations. Ultimately, a single parameter was refined which accounted for the relative occupancy (constrained to total **1**) of both MeCN:CH_2Cl_2 and the two orientations of the disordered anion. Appropriate component SO_3 or CF_3 fragments were refined as rigid groups. The S—C bond lengths, C-S-O bond angles, and S-C-F bond angles were restrained by their respective mean values. The bond distances within the solvent molecules and the N-C-C bond angle were also restrained by representative values. Within the anions, anisotropic displacements for pairs of bonded atoms were restrained to have the same along-bond components. Anisotropic displacement parameters were refined for all the non-hydrogen atoms except for those of the solvent molecules and those of the minor orientation of the disordered $SO_3CF_3^-$. The latter were assigned isotropic displacement parameters derived from the equivalent isotropic displacement parameters for the major orientation. Subsequently a single parameter was refined for the isotropic displacement for this $SO_3CF_3^-$ component and its shifts were applied to the individual values. Three isotropic displacement parameters for the non-hydrogen atoms of the solvent molecules were refined — one for each pair of nearest complementarily disordered neighbours. The hydrogen atoms were treated as in **1**, above, except that two parameters were refined for their isotropic displacements — one for the H-atoms of the cation and another for those of the MeCN molecule. The latter were initially placed in calculated positions using peak positions from an electron density difference map to specify their orientation. Final full matrix least-squares refinement included 254 parameters for 2098 reflections ($I_o \geq 2.5\sigma(I_o)$) and 41 restraints. The maximum |shift/error| in the last cycle of refinement (0.1) occurred among the parameters for the disordered solvent. The maximum |shift/error| among the parameters of the cation was 0.01. The maximum peak in the final difference map was 0.7(2) eÅ^{-3} and was 1.1 Å from Se(1).

For both structures weighting schemes (20) were applied such that $< w(|F_o| - |F_c|)^2 >$ was near constant as a function of both $|F_o|$ and $(\sin\theta/\lambda)^2$. Complex scattering factors for neutral atoms (21) were used in the calculation of structure factors. The programs used for data reduction, structure solution and graphical output were from the NRCVAX Crystal Structure System (22). The program suite CRYSTALS (23) was employed in the refinement. Computations were carried out on MicroVAX-II, 80486, and Pentium computers. Crystal and refinement data for the structures are shown in Table 1. Fractional coordinates are given in Tables 2 (**1**) and 3 (**2**).

Results and discussion

Synthesis

The complex (1,5,9,13-tetraselenacyclohexadecane)copper(II) trifluoromethanesulfonate, [Cu(16Se4)][SO_3CF_3]$_2$ (**1**), was synthesized by the addition of 16Se4 to an acetone solution of $Cu(SO_3CF_3)_2$. Reddish-black needles of **1** were precipitated

[a]U_{eq} is the cube root of the product of the principal axes of the thermal ellipsoid.

from solution by the addition of Et_2O. Compound **1** is unstable in coordinating organic solvents such as MeCN, $MeNO_2$, Me_2CO, or THF. Indeed, prolonged reaction of 16Se4 and $Cu(SO_3CF_3)_2$ followed by precipitation with Et_2O yielded colorless crystals of $[Cu(16Se4)][SO_3CF_3]$ (a polymeric Cu(I) adduct) (6). Dissolution of **1** in CH_2Cl_2:MeCN (1:1) for 5 min at room temperature, followed by cooling, gave yellow crystals that were identified crystallographically as the salt $[16Se4]^{2+}([SO_3CF_3]^-)_2$. We note that the autoreduction of Cu(II) complexes of macrocyclic tetrathiaethers has been observed (24), although earlier reports (25) of such complexes did not note this phenomenon.

Crystal structures

[Cu(16Se4)][SO$_3$CF$_3$]$_2$ (1)

The molecular structure of **1**, shown in Fig. 1, displays tetragonally distorted octahedral coordination typical of Cu(II) species. Oxygen atoms of the $SO_3CF_3^-$ anions occupy the more weakly bound axial positions. The Cu atom is situated on a crystallographic center of inversion. Selected bond distances and angles are given in Table 4. Additional data are presented as supplementary material (Tables S1–S5). The configuration and conformation of the complex are analogous to those of the thia ether complex $[Cu(16S4)][ClO_4]_2$ (26). The configuration of the complex (**1**) can be described as *ctc*, denoting the relative orientations as *cis*, *trans*, *cis*, with respect to the coordination plane of the coronand, of successive pyramidal donor atom environments. The same stereochemistry of ligation has also been observed in the crystal structures of *trans*-$[RhCl_2(16Se4)][BF_4]$ (27), and $[M(16Se4)][PF_6]_2 \cdot 2MeCN$ (M = Pd, Pt) (28). In marked contrast to the latter, the crystal structures of $[Pd(16Se4)][BF_4]_2$ and

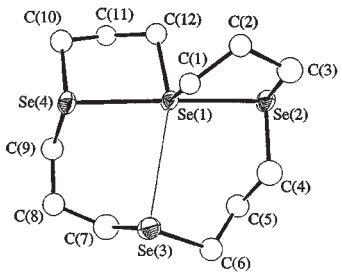

Fig. 1. Molecular structure of $[Cu(16Se4)][SO_3CF_3]_2$ (**1**) (Reproduced with permission from J. Am. Chem. Soc. **112**, 3706–3707 (1990).)

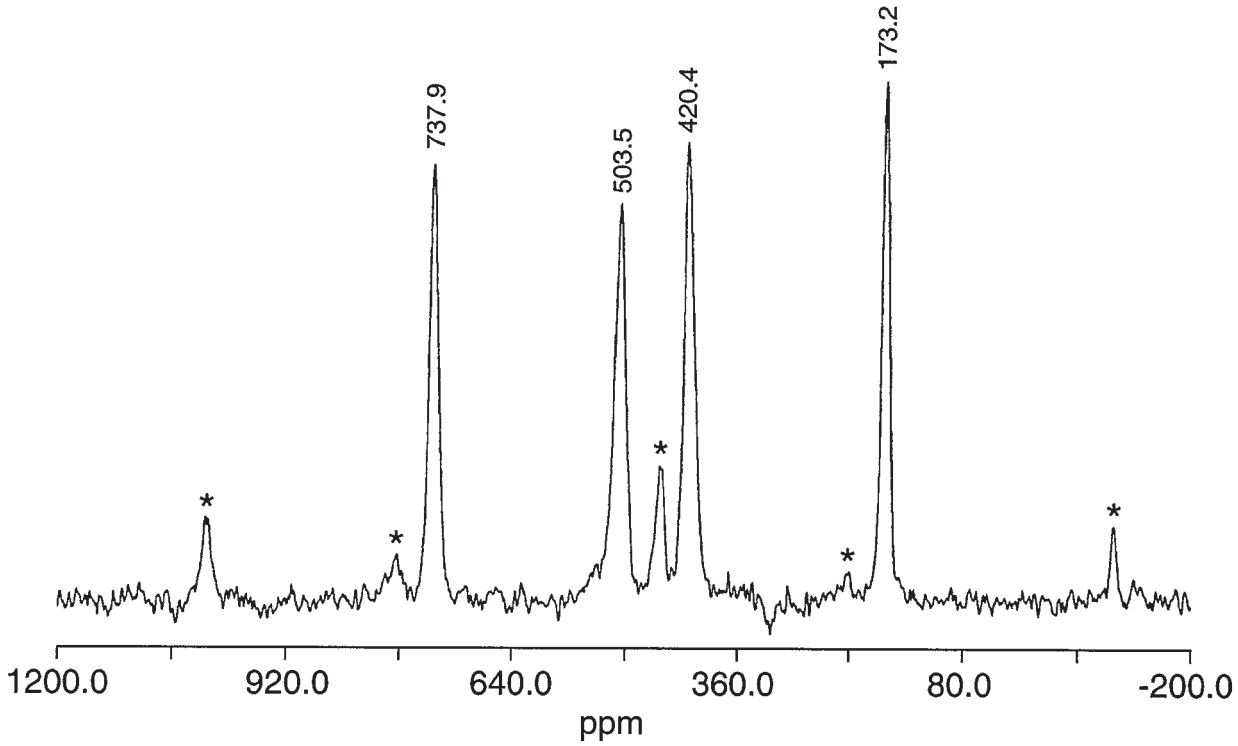
charges are delocalized over three selenium centers, is preferred over a two center transannular bond, as observed in the dication of 1,5-diselenacyclooctane (29), or the S—S transannular bond in the analogous dithiacyclooctane dication (30). The bonds to the central Se atom (Se(1)) are arranged in a pseudo-trigonal-bipyramidal geometry typical of tetracoordinate Se(IV), having the more electron withdrawing substituents ($Se^{\delta+}$) in the axial positions and the non-bonding electron pair in the equatorial plane. Similar nearly linear Se-Se-Se arrangements, displaying comparable Se—Se bond lengths, have been observed previously in the tris (selenourea) dication (31) (Se—Se 2.664(2) Å) and 6a-selenaselenophthene and its derivatives (2.548(3)–2.583(3) Å) (32).

The Se(1)—Se(3) contact distance (3.3941(20) Å), which is significantly less than twice the accepted Van der Waals radius of Se (3.8 Å), suggests a weak secondary interaction between these atoms. Although this contact could merely represent a constraint of the ring's size and its preferred conformation, the associated angles at both Se(1) and Se(3) are consistent with an attractive interaction. Se(3) is roughly trans to the Se(1)—C(12) bond (Se(3)-Se(1)-C(12) 160.2(3)°) and approximately orthogonal to the other bonds to Se(1)

Fig. 2. Molecular structure of $[16Se4][SO_3CF_3]_2 \cdot 0.89 MeCN \cdot 0.11CH_2Cl_2$ (**2**·solv) (Reproduced with permission from J. Am. Chem. Soc. **112**, 3706–3707 (1990).)

(Se(3)-Se(1)-C(1) 87.8(3)°; Se(3)-Se(1)-Se(2) 101.16(5)°; Se(3)-Se(1)-Se(4) 76.36(5)°). Thus, the environment of Se(1) might be better described as tending towards Ψ-octahedral with the lone pair trans to the Se(1)-C(1) bond. Furthermore, the Se(3)—-Se(1) vector makes angles with the bonds to Se(3) which describe a reasonable pyramidal environment for this selenium center (C(6)-Se(3)-Se(1) 94.4(3)°; C(7)-Se(3)-Se(1) 87.5(4)°). This secondary interaction may be a significant contributing factor to the overall asymmetry of the molecule, and thus indirectly to the inequality of the Se(1)—Se(2) (2.5916(15) Å) and Se(1)—Se(4) (2.6689(15) Å) bond lengths.



A few Se—O distances (3.152(7) Å Se(2)—O(2)′, where ′ = $1 - x$, $1 - y$, $1 - z$; 3.271(6) Å Se(2)—O(6); 3.299(8) Å Se(1)—O(6); 3.328(9) Å Se(3)—O(3)″, where ″ = $-x$, $1 - y$, $1 - z$) and one Se—F distance (3.294(7) Å Se(4)—F(2)‴, where ‴ = x, $1 + y$, z) are slightly shorter than the respective sums of the Van der Waals radii (3.42 Å and 3.37 Å). These are consistent with reasonable dipolar electrostatic attraction between cation and anion. The fact that Se(2) has two such Se-O interactions, whereas Se(4) has only one weaker Se-F interaction, would also appear to correlate with the asymmetry in the Se—Se bond lengths, in that the shorter of these bonds, Se(1)—Se(2), should be associated with slightly greater positive charge on Se(2) than on Se(4). The interionic interactions are clearly weaker than the S-O interactions in the triflate salt of the 1,5-dithiacyclooctane dication (30) (S—O 2.682(6) Å, cf. sum of Van der Waals radii 3.32 Å) in which the positive charge is more localized. Similarly, in the crystal structure of the tetrafluoroborate salt (acetonitrile solvate)

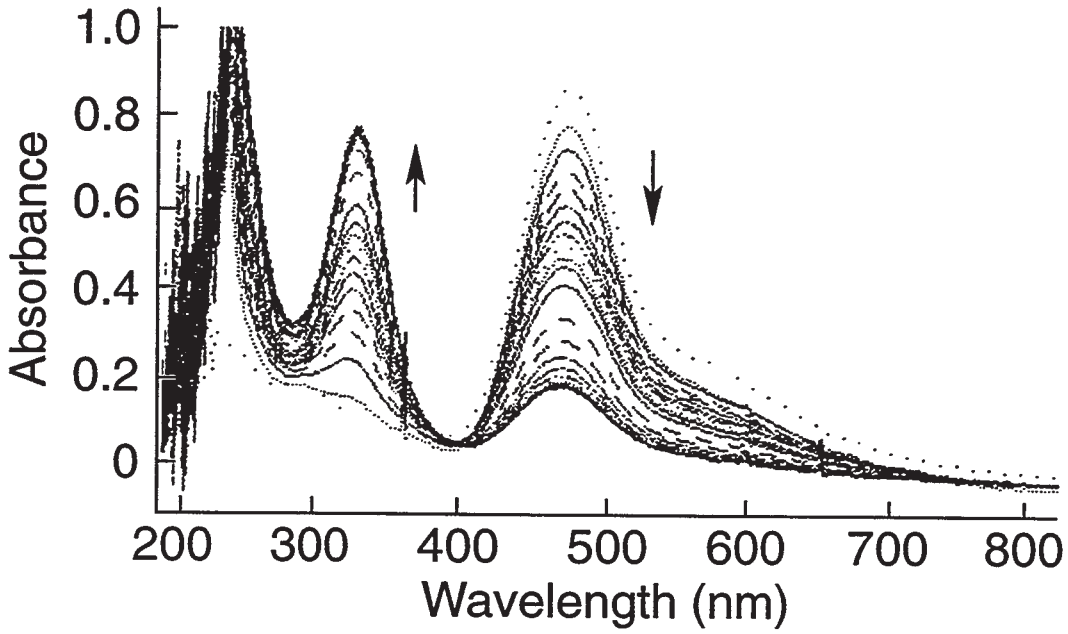
Fig. 3. Solid-state ^{77}Se CP-MAS NMR spectrum of $[16Se4][SO_3CF_3]_2 \cdot 0.89$ MeCN·$0.11CH_2Cl_2$ (**2**·solv). The peaks marked with asterisks are spinning side bands.

of the dication of 1,5-diselenacyclooctane (29), relatively strong Se-F interactions (2.81(1) and 2.89(2) Å) are observed.

While the formation of radical monocations and dications of polythiaethers is documented (33), and Musker et al. (34) have reported the oxidation of dithiacyclooctane derivatives by Cu (II) complexes, the present study reports the first selenium coronand dication resulting from an electron-transfer reaction of a metal-selenium coronand complex. The structures of other cyclic selena cations have also been reported, e.g. the radical monocation and dication of 1,2,4-triselena–3,5-diazacyclopentane (35), Se_8^{2+} and Se_{10}^{2+} (36, 37).

NMR Studies of 2

The ^1H NMR spectrum of the dication, $16Se4^{2+}$, in Me_2CO at ambient temperature consisted of several sharp, complex multiplets. Upon cooling these broadened and, at 180 K, the spectrum showed broad multiplets (reported in the Experimental section) as well as other unresolved broad peaks, suggesting a slow exchange process that had not reached the slow exchange limit. Saturation-transfer experiments at 180 K only permitted a partial assignment of the signals to α- and β-CH_2s.



The solid-state CP-MAS ^{77}Se NMR spectrum of **2**·solv is shown in Fig. 3. Unfortunately, this is a difficult sample for

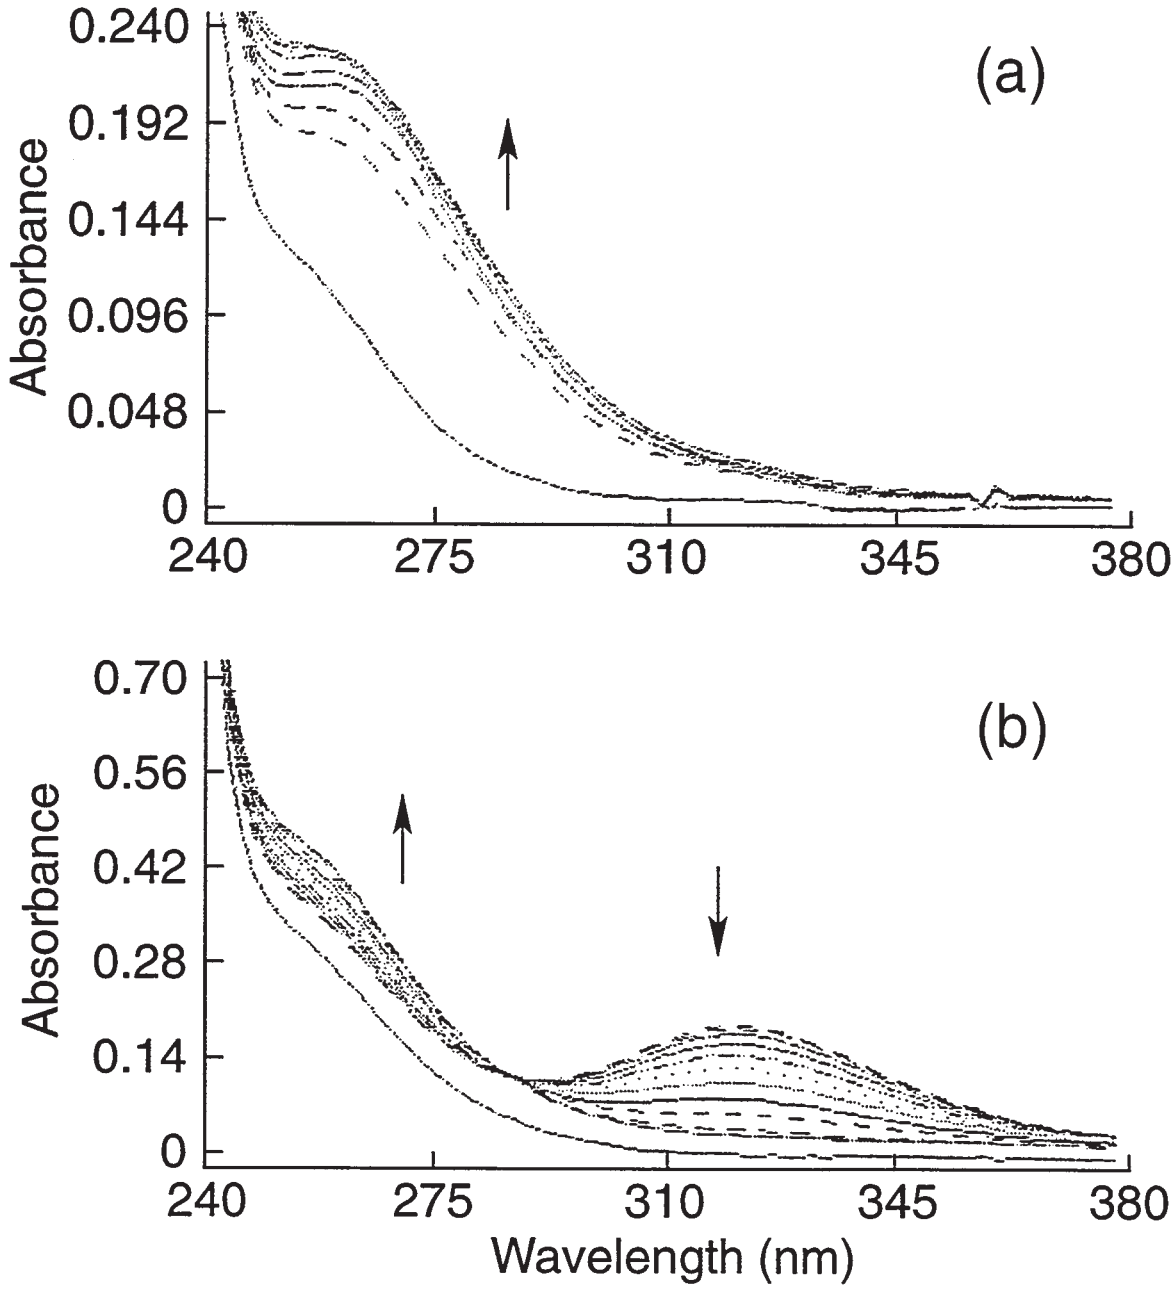
Fig. 4. UV–visible spectra of $[Cu(16Se4)][SO_3CF_3]_2$ (7.8×10^{-5} M) in CH_2Cl_2 in the presence of 16Se4 (1.78×10^{-5} M). The dotted line is the original spectrum of $[Cu(16Se4)][SO_3CF_3]_2$. The spectra were taken at intervals of 60 s.

solid-state NMR analysis, in that the proton T_1 times are long and a relaxation delay of 60 s was required. Figure 3 shows four lines, corresponding to the four unique selenium atoms in the asymmetric unit. These cover a surprisingly wide range of isotropic shift, given the chemical similarity of Se(2) and Se(4). The lines are of different widths, and have differing chemical shift anisotropies, as evidenced by spinning sidebands of varying intensities.

A tentative assignment can be made based on the varying linewidths, and on the fact that ^{19}F is not decoupled. Strong F-F dipolar coupling will render the Se-F dipolar coupling homogeneous (38) and thus a contributor to the ^{77}Se linewidth. Table 6 shows the average linewidths for each line, obtained from the spectrum shown in Fig. 3, and a second spectrum obtained at a lower spinning speed (3.0 kHz). Table 6 also shows the summation of $(r_{Se—F})^{-3}$ which should be a measure of the dipolar coupling. This sum was evaluated from the crystallographic data, including distances out to 6 Å. There is a reasonable correlation between width and the dipolar sum, leading us to make the tentative assignments shown. These assignments have the merit of giving Se(2) and Se(4) the closest pair of isotropic shifts, as would be expected on chemical grounds.

It is possible to estimate the chemical shift anisotropy from the intensities of the spinning sidebands (39). In Table 6, we give this as $\Delta\sigma = \sigma_{11} - \sigma_{33}$ for the various selenium atoms. For the line at 420 ppm no sidebands are observed, and the value given is an upper limit, based on the noise level of the spectrum. The uncertainties in the anisotropies are considerable because of the low intensities of the sidebands. The poor relaxation characteristics of this sample made measurements at lower spinning speeds, required for the determination of accurate anisotropies, impractical.



UV–visible spectroscopic studies of 1 and the radical cations of 16Se4

The UV–visible absorption spectrum of **1** in CH_2Cl_2 solution showed three absorption bands; λ_{max}(nm (ϵ)): 560 (2957), 464 (11920), 310 (1267). Addition of the ligand 16Se4 into a CH_2Cl_2 solution of **1** initiated a time dependent process, in which the intensities of the above absorption peaks decreased, together with a concomitant increase in the intensity of a new peak at 320 nm (Fig. 4). Similar behavior was also observed in a mixture of EtOH and THF.

To characterize the species that absorbs at 320 nm, 16Se4 was oxidized by $NOBF_4$ in CH_3CN solution in a UV-cell, and the mixture was monitored by UV–visible spectroscopy as soon as the $NOBF_4$ solution was added to the solution containing 16Se4. Continuous scanning was carried out at intervals of 300 s. In a typical experiment in which the concentrations of 16Se4 and $NOBF_4$ were both 5.3×10^{-4} M, a new absorption peak appeared at 320 nm whose intensity grew to a maximum value, following which it decreased, and a new peak appeared at 256 nm. There was an isosbestic

Fig. 5. UV–visible spectra of the 16Se4 radical cation recorded as a function of time. The radical cation was prepared by mixing 16Se4 with $NOBF_4$ in CH_3CN: (*a*) [$NOBF_4$] = 2.05 × 10^{-5} M; [16Se4] = 1.87 × 10^{-4} M. (*b*) [$NOBF_4$] = 2.05 × 10^{-5} M; [16Se4] = 5.62 × 10^{-4} M. The spectra were taken at intervals of 300 s. The bottom trace is the original spectrum of 16Se4.

point at about 290 nm, indicating the presence of at least two interconverting species.

Further experiments revealed that the above peak variation was dependent on the initial concentration of 16Se4. Thus, $NOBF_4$ in CH_3CN was added separately to solutions of 16Se4 of different concentrations, and UV–visible spectra were recorded as a function of time for each concentration (Table S10). At the lowest concentration of 16Se4 (1.87 × 10^{-4} M, entry 1), a peak at 256 nm was observed but the peak at 320 nm was almost absent. However, the absorption peak at 320 nm became more and more significant as the 16Se4 concentration increased (Fig. 5). At the highest concentration (entry 5), the peak at 320 nm first rose to a maximum and then fell, with a concomitant increase in intensity of the peak at 256 nm.

Oxidation of 16Se4 by $NOBF_4$ is a one-electron transfer reaction that yields the radical cation, $16Se4^{+\cdot}$. The spectroscopic results show that this radical cation is relatively stable and can be observed by UV–visible spectroscopy at room temperature. This is the first time that a selenium coronand radical cation has been detected in static conditions, to the best of our knowledge. The stability of $16Se4^{+\cdot}$ may be attributed to two-center three-electron (2c/3e) interactions (40, 41), which are well documented for the radical cations of thioethers (33*a*, 42–51) but not for the case of selenoethers (52). According to frontier molecular orbital theory (53), the

© 2000 NRC Canada

doubly and singly occupied non-bonding orbital would interact with one another to give bonding (σ) and *anti*-bonding (σ*) molecular orbitals which are occupied by three electrons. Such interactions between Se atoms, as shown in eq. [1], could be intramolecular and (or) intermolecular in nature.

[1] 

The absorption band at 320 nm is assigned to a σ–σ* transition of a dimeric radical cation, in which the 2c/3e bond is formed through interactions of an oxidized selenium in 16Se4 with a neutral selenium from another 16Se4, because the dimer is observed only at high concentrations. The absorption band at 256 nm is attributed to a σ–σ* transition of 2c/3e bonds formed through intramolecular (transannular) interactions, because it is observed at low concentrations of 16Se4.

The UV–visible absorption bands are correlated with the strength of the 2c/3e bonds and the position of the absorbance maximum of a σ–σ* transition is expected to depend on the extent of *p* orbital overlap and, therefore, the distance between the two interacting atoms (54, 55). The X-ray crystal structure of the dication $16Se4^{2+}$ shows bond distances between Se atoms that are within the sum of the covalent radii of Se, as was the case with other dications containing nearly linear Se-Se-Se arrangements (31, 32), and this species absorbs at 256 nm. This supports our assignment of the peak at 256 nm to a σ–σ* transition of a 2c/3e bond from a radical cation with transannular Se-Se interactions, and that at 320 nm to a σ–σ* transition from an intermolecular Se—Se bond formed in a dimeric radical cation.

EPR spectroscopy of 1

Analysis and simulation of the room temperature EPR spectrum of **1** in CH_3NO_2 solution gave an isotropic *g* value of 2.053 with hyperfine constants A^{Cu}_{iso} = 75G and A^{Se}_{iso} = 65 G. The low temperature EPR spectrum of **1**, measured at –148°C in CH_3NO_2:toluene (1:1 v/v), gave values of $g_{//}$ = 2.085, $A^{Cu}_{//}$ = 160 G; $g_{\perp}$ = 2.049, $A^{Cu}_{\perp}$ = 46 G. An EPR spectrum of **1** in CH_3NO_2 in the presence of added 16Se4 showed a decrease in intensity of the signals attributable to **1** and the emergence of new signals that overlapped with those of **1**, making analysis difficult. The new signals are presumably due to a species with radical cation character.

Electrochemistry of 1 and 16Se4

*Cyclic voltammetry of **1***

A cyclic voltammogram of **1** in CH_2Cl_2 on a Pt electrode was recorded. Over the scanning potential range from 1.6 to 0.3 V then back to 1.6 V, two redox waves were observed. The first redox wave with $E_{1/2}$ = 0.67 V vs. SCE at a scan rate of 20 mV/s showed an increase in the cathodic-anodic peak separation, ΔE_p, and a decrease in the ratio of anodic to cathodic current when the scan rate was increased. A plot of cathodic peak current i_c versus $\nu^{1/2}$ was linear, suggesting that the electrode reactions were diffusion controlled. The second redox wave appeared at $E_{1/2}$ = 1.06 V (ν = 20 mV/s). We tentatively assign the former to the redox pair $Cu(II)L^{+\cdot}/Cu(I)L^{+}$ (L = 16Se4) and the latter to the redox pair $Cu(II)L^{2+}/ Cu(II)L^{+\cdot}$. As the potential was swept in the cathodic direction up to –1.0 V, two more irreversible reduction peaks were seen at 0.087 V and –0.65 V. These peaks were attributed to the Cu(I)L/Cu redox couple, possibly due to the reduction of monomeric and polymeric Cu(I) complexes (6).

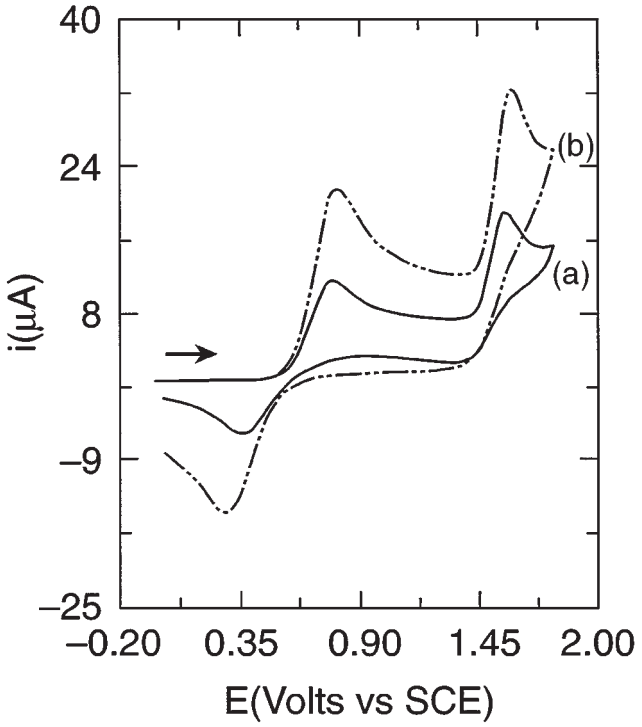
It is well known that Cu(I) undergoes a quick disproportionation reaction (56); for example, in aqueous solution the cyclic voltammogram of Cu(II) is irreversible. However, the cyclic voltammogram of **1** suggests that the redox reaction is partially chemically reversible over the timescale of the potential sweep, although the ΔE_p is large. The chemical reversibility may arise from the ability of chalcogen atoms to stabilize Cu(I) ions (57).

The large ΔE_p observed in the cyclic voltammogram of **1** suggests a kinetically quasi-reversible electrode process, which may result from the fact that electron transfer is slow. It may also suggest that electron transfer is not the sole process that takes place (58). Since changing the oxidation state from Cu(II) to Cu(I) would be accompanied by a significant configurational change (59, 60), it is possible that the spatial reorganization or conformational changes of 16Se4 may also contribute (61, 62).

Cyclic voltammetry of 16Se4

A typical cyclic voltammogram of 16Se4, measured on a platinum working electrode in CH_3CN solution, is shown in Fig. 6*a*. The potential scanning range was from 0 to 1.6 V vs. SCE. Two waves were observed with $E_{1/2}$ = 0.508 V, ΔE_p = 175 mV, and 1.41 V, ΔE_p = 150 mV at a scan rate of 50 mV/s. A plot of anodic peak current i_{a1} or i_{a2} versus $\nu^{1/2}$ was linear, suggesting that the electrode reactions were diffusion controlled. These two waves correspond to the following two redox reactions:

[2] $16Se4 - e \rightarrow 16Se4^{+\cdot}$



[3] $16Se4^{+\cdot} - e \rightarrow 16Se4^{2+}$

The separations between anodic and cathodic peak potentials were scan rate dependent, the peak separations increasing as the scan rate increased (compare Fig. 6*b* vs. 6*a*). This indicates that the electrode process is a quasi-reversible process. As the scan rates exceeded 200 mV/s (not shown), the redox reaction (3) became kinetically irreversible, as manifested by the disappearance of the second cathodic peak on the return scan. On the other hand, slow scan rates also altered the appearance of the cyclic voltammogram. At a scan rate of 5 mV/s (not shown), the second oxidation peak as well as the cathodic peak disappeared; the current plateaued after the first oxidation peak, but the first cathodic peak was still observed on the return scan. This behavior suggested complications arising from chemical reactions in solution.

To gain a better insight of the solution chemical reactions, we performed the cyclic voltammetry of 16Se4 at several initial concentrations with a scanning potential range of 0–1.2 V vs. SCE, in which only the first redox pair $16Se4/16Se4^{+\cdot}$ was of concern (data not shown). The results showed that for a given scan rate, as the initial concentrations were increased, the anodic current peak shifted to a

© 2000 NRC Canada

Fig. 6. Cyclic voltammograms of 16Se4 (1mM) in CH_3CN recorded at scan rates: (*a*) 50 mV/s; (*b*) 200 mV/s. Working electrode: Pt. Reference electrode: SCE. Electrolyte: 0.1 M tetraethylammonium perchlorate.

more positive potential while the cathodic current peak shifted to a more negative potential. In addition, the ratio of cathodic to anodic current became less than 1. Apparently, the solution chemical reactions become more significant at higher concentrations of 16Se4, affecting the concentration of the radical cation $16Se4^{+\cdot}$ and, in turn, the recovery of 16Se4 on the reverse scan. This behavior is consistent with the depletion of 16Se4 at the electrode surface by reaction with $16Se4^{+\cdot}$. The cyclic voltammetry data for the redox pair $16Se4/16Se4^{+\cdot}$ were further analyzed by convolution transformation by a numerical integration technique (15), using eq. 4.

$$[4] \qquad I(k\Delta t) = \frac{1}{\pi} \sum_{j=1}^{j=k} \frac{\Gamma(k-j+1/2}{(k-j)!} \Delta t^{1/2} i(j\Delta t)$$

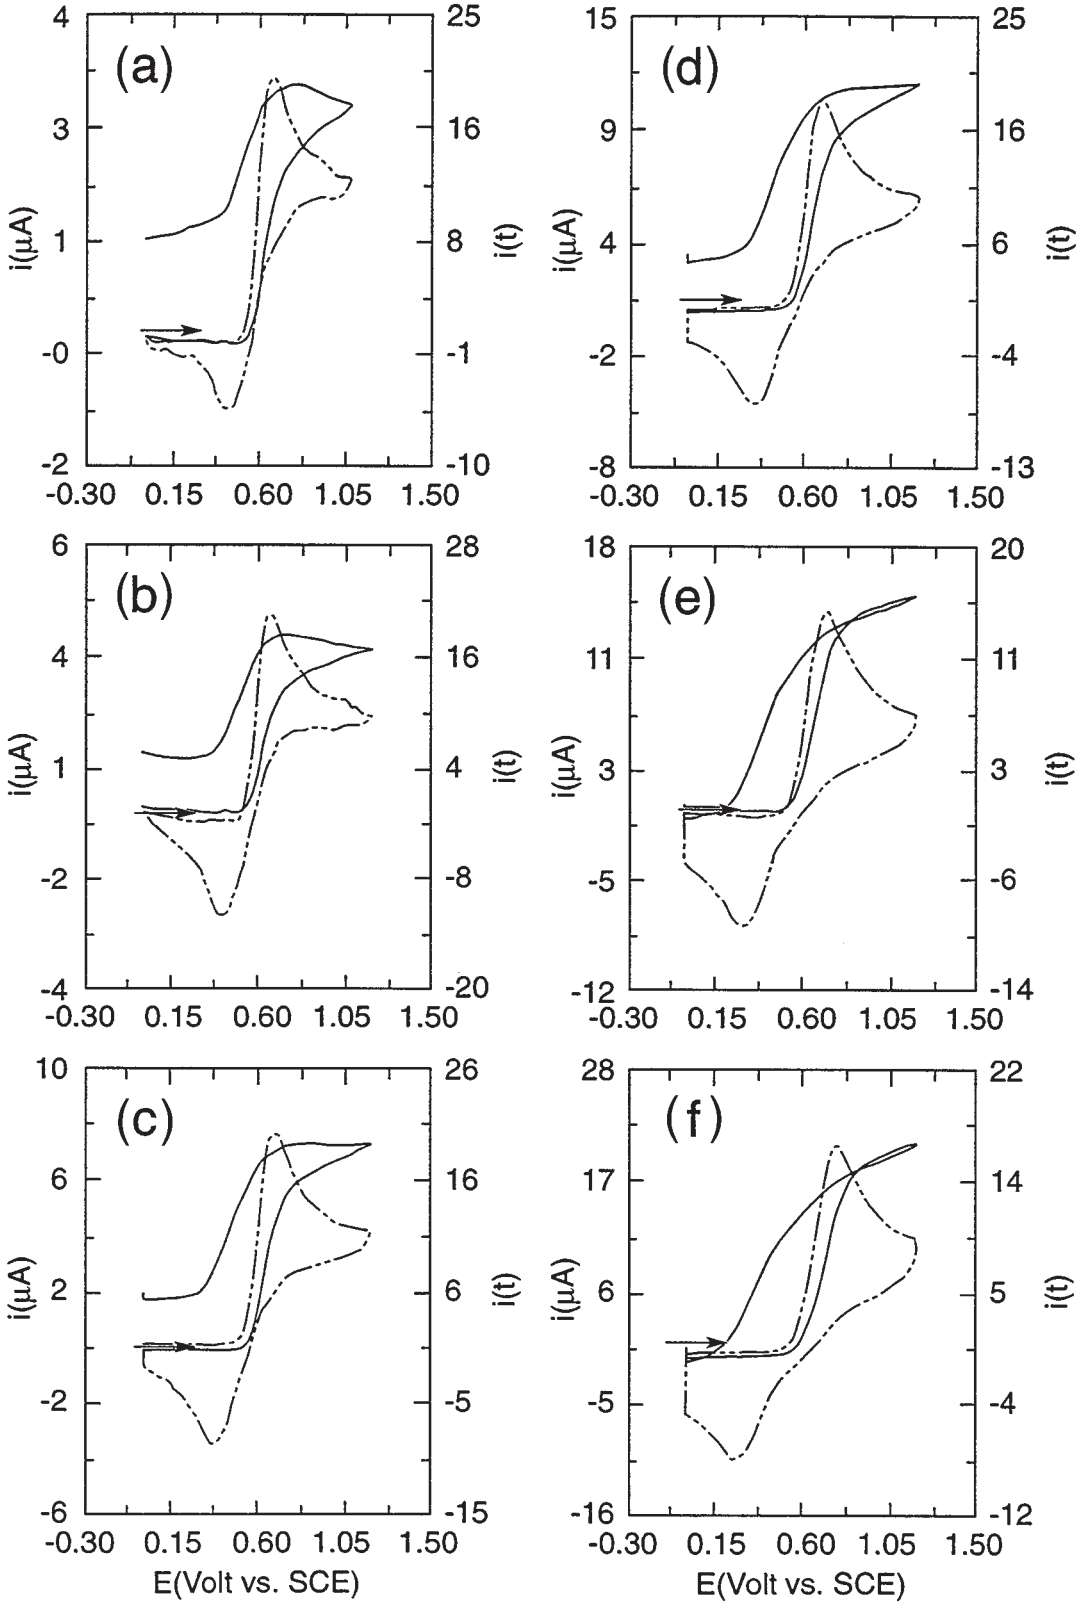
where $I(k\Delta t)$ is the convolution transformation ($I(t)$) of the experimental $i(t)$; $\Gamma(x)$ is the Gamma function of x. The results are shown in Figs. 7 and S1. These plots show that the redox system is not reversible in general because none of the forward and backward curves is superimposable. Furthermore, the maximum of the $I(t)$ function is scan rate dependent; at the lowest scan rate, the $I(t)$ function attained its largest value. Figures 7 and S1 show that the reduction of the oxidized product is a time dependent phenomenon: faster scans resulted in more recovery, as shown by the overlapped curves ($I(t)$) of forward and backward scans at the starting point of convolution voltammetry; slower scans gave rise to less recovery, as shown by separated curves for the forward and backward scans at the starting point of convolution voltammetry. Concentration effects were also shown by the convolution transformation: more recovery of 16Se4 was achieved on the reverse scan for low initial 16Se4 concentrations, consistent with the observation of the i_c/i_a ratio from cyclic voltammetry (compare Fig. 7 vs. Fig. S1).

Comparison of the X-ray structures of 16Se4 and the 16Se4 dication shows that there are significant structural differences in these two molecules. 16Se4 has most of the C—Se bonds in *gauche* conformations (1). However, in the 16Se4 dication three selenium atoms are co-linear (4). In such an arrangement, the positive charges are on the two outside selenium atoms to achieve the best separation. The fourth selenium atom interacts with the central selenium atom with van der Waals forces so that the positive charges are dispersed among the four selenium atoms. This is probably also the case in solution, so that positive charges are delocalized among the selenium atoms, as suggested by Asmus et al. (40) for the case of lower sulfur analogues. Since the oxidation of $16Se4^{+\cdot}$ to $16Se4^{2+}$ occurs at higher potential, the formation of the dication of 16Se4 through disproportionation is unlikely.

Spectroelectrochemistry.

Electrolysis of a CH_3CN solution of 16Se4 indicated a concentration-dependent phenomenon (Fig. 8). When the concentration of 16Se4 was about 10^{-4} M, only the peak at 256 nm was observed. However, at a concentration of 16Se4 of about 10^{-3} M, peaks at both 322 nm and 256 nm were observed. This indicates that the species absorbing at 322 nm is only formed when the concentration of 16Se4 is high. A plot of the logarithm of the absorbance at 256 nm versus that at 322 nm gave a straight line with a slope of about 1 (ca. 0.88, $R = 0.99$). Once again, we suggest that the species absorbing at 322 nm is a dimeric radical cation $(16Se4)_2^{+\cdot}$, because it is formed only at high concentrations of 16Se4.

Coulometric studies of 16Se4 and cyclic voltammetry of 16Se4 under electrolysis.



Electrolysis of 16Se4 at a pair of Pt gauze electrodes was undertaken. Two applied potentials (0.8 and 1.8 V vs. SCE) were chosen to effect oxidation of 16Se4 to the radical cation (one electron-transfer) and to the dication (two-electron transfer), as determined by cyclic voltammetry. These studies were performed while monitoring the electrolyte by UV–visible spectroscopy. The results of the experiments are given in the supplementary material.

Cyclic voltammetry experiments were performed on solutions of 16Se4 in CH_3CN that were being simultaneously electrolyzed with an applied potential of 1.2 V. Two sets of working electrodes were used. One set was a pair of Pt gauze electrodes for electrolysis; the other was a Pt microelectrode for cyclic voltammetry. The results of the experiments are described in the supplementary material.

The results of coulometry on 16Se4 support the contention that the dication, $16Se4^{2+}$ is formed by consecutive oxidation of $16Se4^{+\cdot}$; i. e., 16Se4 is first oxidized to $16Se4^{+\cdot}$, then to $16Se4^{2+}$. At the applied potential of 0.8 V, which is higher than the first anodic peak potential (E^1_{ap}) but lower than the second anodic peak potential (E^2_{ap}) on the cyclic voltammogram, no $16Se4^{2+}$ should be produced electrochemically because the potential is not anodic enough to oxidize $16Se4^{+\cdot}$. Therefore, at that potential the total number of

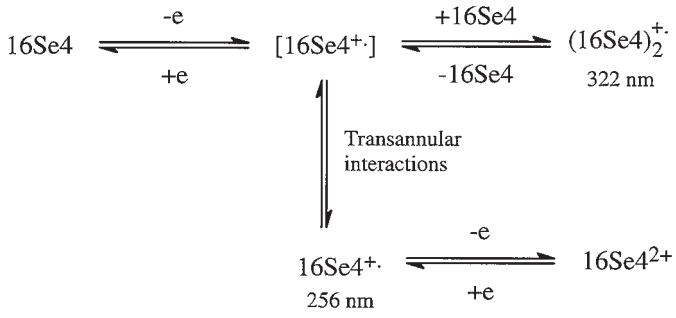
Fig. 8. UV–visible spectra of 16Se4 on a Pt transparent electrode. The applied potential was 1.2 V vs. AgI/Ag. (*a*) [16Se4] = 1.02 × 10^{-4} M; (*b*) [16Se4] = 1.02 × 10^{-3} M. Electrolyte: 0.1 M tetraethylammonium perchlorate in CH_3CN. In each case, the lowermost curve is the initial curve.

electrons involved in the reaction should be one. However, if there were a disproportionation reaction, the total number of electrons involved in the reaction would be two even if the applied potential for electrolysis was not anodic enough to oxidize $16Se4^{+\cdot}$ to $16Se4^{2+}$, because 16Se4 could be regenerated through reaction (5).

[5] $$16Se4^{+\cdot} + 16Se4^{+\cdot} \rightleftharpoons 16Se4^{2+} + 16Se4$$

The results show that only one electron is involved in the electrolysis at a potential of 0.8 V vs. SCE, and two electrons are involved at a potential of 1.8 V, which unequivocally shows that the whole process of oxidizing 16Se4 to $16Se4^{2+}$ is a two-step oxidation, and that each step is a single electron transfer process. Combining all the information from UV–visible spectroscopy, cyclic voltammetry, spectroelectrochemistry, and coulometry, the fate of the radical cation, $16Se4^{+\cdot}$, may be summarized as in Scheme 1.

Kinetic analysis



Rate law.

We have established that **1** undergoes a redox reaction with free ligand:

[6] $$2\ Cu(16Se4)^{2+} + 16Se4 \rightarrow 2\ Cu(16Se4)^{+} + 16Se4^{2+}$$

© 2000 NRC Canada

Scheme 1.

For simplicity the anion is not shown. The reaction was shown to be first order with respect to each of the reagents and to conform to the rate law as shown in eq. [7] (see supplementary material).

[7] $\text{Rate} = k_1\,[\text{Cu(II)}L^{2+}][L]$

The rate constant at 298 K is $(1.31 \pm 0.03) \times 10^3\ \text{M}^{-1}\text{s}^{-1}$ and the activation parameters are $\Delta H^{\#} = 32 \pm 2\ \text{kJmol}^{-1}$ and $\Delta S^{\#} = -103 \pm 10\ \text{Jmol}^{-1}\text{K}^{-1}$.

Reaction mechanism.

On the basis of the collective information described in the foregoing sections, we propose the following mechanism:

[8] $$\text{Cu(II)L}^{2+} + \text{L} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \text{L}^{+\cdot} + \text{Cu(I)L}^{+}$$

[9] $$\text{Cu(II)L}^{2+} + \text{L}^{+\cdot} \overset{k_2}{\rightarrow} \text{L}^{2+} + \text{Cu(I)L}^{+}$$

The driving force for the reaction is presumably the formation of the thermodynamically more stable Cu(I) complex (6).

Conclusions

We have discovered a redox reaction between the Cu (II) complex of 16Se4 (**1**) and the free ligand 16Se4, which gives rise to a Cu(I) complex and the dication of 16Se4. The reaction products have been isolated and characterized by X-ray crystallography. Further investigation of the redox reaction by UV–visible spectroscopy, cyclic voltammetry, coulometry, and spectroelectrochemistry shows that, in the initial stages, the redox reaction is first order with respect to the concentrations of **1** and 16Se4, and the stoichiometry of the reaction is 2:1. The intermediates in the reaction have been characterized by UV–visible spectroscopy and electrochemical studies, and have been shown to be monomeric and dimeric radical cations of 16Se4 that absorb at 320 nm and 256 nm, respectively. Electrochemical studies have ruled out the disproportionation reaction of $16\text{Se4}^{+\cdot}$ as a possible pathway to give the dication, 16Se4^{2+}. The dication is formed instead through two consecutive one electron transfer steps, as depicted in Scheme 1.

Nuclear magnetic shielding tensors for the carbon, nitrogen, and selenium nuclei of selenocyanates — a combined experimental and theoretical approach

Guy M. Bernard, Klaus Eichele, Gang Wu, Christopher W. Kirby, and Roderick E. Wasylishen

Abstract: The principal components of the carbon, nitrogen, and selenium chemical shift (CS) tensors for several solid selenocyanate salts have been determined by NMR measurements on stationary or slow magic-angle-spinning powder samples. Within experimental error, all three CS tensors are axially symmetric, consistent with the expected linear geometry of these anions. The spans (Ω) of the carbon and selenium CS tensors for the selenocyanate anion ($SeCN^-$) are approximately 300 and 800 ppm, respectively, much less than the corresponding values for carbon diselenide (CSe_2). This difference is a consequence of the difference in the CS tensor components perpendicular to the C_∞ symmetry axes in these systems. Ab initio calculations show that the orbital symmetries of these compounds are a significant factor in the shielding. For CSe_2, efficient mixing of the σ and π orbitals results in a large paramagnetic contribution to the total shielding of the chemical shielding tensor components perpendicular to the molecular axis. Such mixing is less efficient for the $SeCN^-$, resulting in a smaller paramagnetic contribution and hence in greater shielding in directions perpendicular to the molecular axis.

Key words: selenocyanates, solid-state NMR, carbon shielding tensors, nitrogen shielding tensors, selenium shielding tensors, ab initio calculations.

Résumé : À partir de mesures RMN sur des échantillons de poudre stationnaires ou à rotation lente à l'angle magique de plusieurs sélénocyanates solides, on en a déterminé les principaux composant des tenseurs des déplacements chimiques (DC) du carbone, de l'azote et du sélénium. Dans les limites des erreurs expérimentales, les trois tenseurs des DC sont axialement symétriques, ce qui est en accord avec la géométrie linéaire attendue pour ces anions. Les plages, Ω, des tenseurs du carbone et du sélénium pour l'anion sélénocyanate ($SeCN^-$), sont approximativement de 300 et de 800 ppm respectivement, des valeurs beaucoup plus faible que les valeurs correspondantes observées dans le disélénure de carbone (CSe_2). Cette différence est une conséquence de la différence dans les composants du tenseur DC qui sont perpendiculaire aux axes de symétrie C_2 dans ces systèmes. Des calculs ab initio montrent que les symétries des orbitales de ces composés sont un facteur important dans le blindage. Pour le CSe_2, une combinaison efficace des orbitales σ et π conduit à une contribution paramagnétique importante au blindage total des composantes du tenseur de blindage chimique perpendiculaires à l'axe moléculaire. Une telle combinaison est moins efficace pour le $SeCN^-$; il en résulte que la contribution paramagnétique est plus faible et, en conséquence, que le blindage est plus grand dans les directions perpendiculaires à l'axe moléculaire.

Mots clés : sélénocyanates, RMN à l'état solide, tenseurs de blindage du carbone, tenseurs de blindage de l'azote, tenseurs de blindage du sélénium, calculs ab initio.

Introduction

The selenocyanate ligand ($SeCN^-$) has been of considerable interest because of its ambidentate nature (1). That is, it may coordinate to a metal through the nitrogen, the selenium, or by various bridging modes. In the absence of diffraction data, NMR spectroscopy may provide the most reliable information concerning the coordination and structure of these ligands. A review by Duddeck provides an overview of the ^{77}Se NMR literature including the results of several solution NMR studies of organic selenocyanate compounds (2). Carbon-13 and nitrogen-14 or -15 NMR results for selenocyanates have been discussed in several reviews (3, 4). The coordination of metal atoms with several selenocyanate anions has been investigated by solution NMR (5, 6). An analogous study of the thiocyanate anion in copper(I) complexes was conducted using solid-state ^{13}C

NMR (7). In addition to providing insight into the coordination mode of the cation in these complexes, this study showed that conclusions about coordination to the metal drawn from solution NMR studies cannot always be extended to solids.

With four NMR-active nuclei, ^{13}C, ^{14}N, ^{15}N, and ^{77}Se, much information may be gained from solid-state NMR studies of $SeCN^-$. For example, internuclear distances may be determined from dipolar interactions, and information about the bonding modes of $SeCN^-$ is available from isotropic chemical shifts and spin–spin coupling constants. Also, examination of stationary powder samples provides the principal components of the chemical shift (CS) tensors, which potentially contain a wealth of structural information. Before embarking on a solid-state NMR study of selenocyanate–metal complexes, it is important to understand the shielding tensors for the uncoordinated ligand. Towards this end, we present the results of solid-state NMR studies of the carbon, nitrogen, and selenium CS tensors for selenocyanate salts $M^+[SeCN]^-$, M = K, NH_4, or NMe_4. Also presented are the preliminary results of a solid-state ^{13}C NMR study of a related compound, potassium cyanate. The interpretation of the observed magnetic shielding tensors is aided by high-level ab initio calculations.

Selenocyanate anions are thought to be linear; the selenocyanate ion of a copper complex which had been reported as bent (8) has recently been shown to be linear (9). Linear systems are ideal for a study of nuclear magnetic shielding since, in the absence of intermolecular effects, the orientation of the axially symmetric CS tensor is known exactly and the unique component of the CS tensor, along the C_∞ symmetry axis, is dependent only on the diamagnetic term of the shielding (*vide infra*). The relative simplicity of these systems allows one to identify the specific molecular orbitals (MOs) responsible for the paramagnetic shielding.

Although carbon and nitrogen shielding tensors are available for most functional groups, corresponding data for selenium are not as widespread (10). The first comprehensive experimental study of selenium CS tensors was that of Collins et al. (11). A surprising feature of the selenocyanate ligands is that the spans of the carbon and selenium CS tensors are much smaller than those of CSe_2 (12). With high-level ab initio calculations on $SeCN^-$ and CSe_2, the MOs responsible for the different magnetic shielding in these closely related compounds were identified.

Background theory

It is convenient to discuss the nuclear magnetic shielding (σ) of nuclei in linear molecules or ions using Ramsey's theory (13). In this model, the magnetic shielding is expressed as the sum of diamagnetic (σ^d) and paramagnetic (σ^p) components (14):

$$[1] \qquad \sigma_{ii} = \sigma_{ii}^{d} + \sigma_{ii}^{p}$$

where

$$[2] \qquad \sigma_{ii}^{d} = \frac{\mu_0}{4\pi}\frac{e^2}{2m}\left\langle 0\right| \sum_k \frac{r_k^2 - r_{ki}^2}{r_k^3} \left|0\right\rangle$$

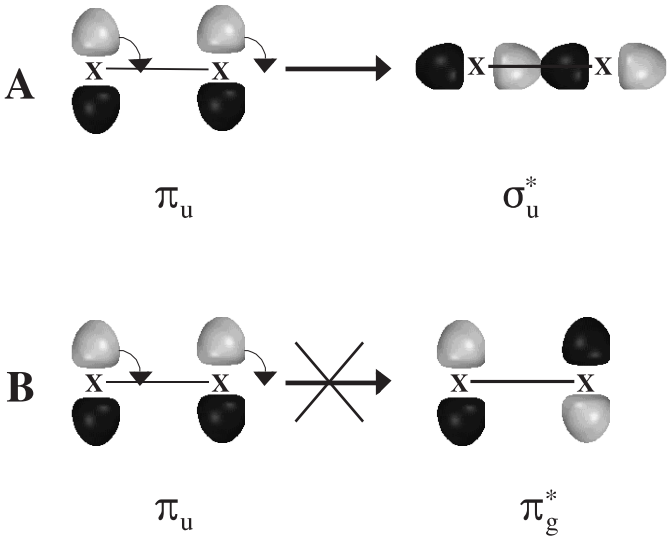
and

$$[3] \qquad \sigma_{ii}^{p} = \frac{-\mu_0}{4\pi}\frac{e^2}{2m^2}\sum_{n>0}\frac{1}{E_n - E_0}[\left\langle 0\right| \sum_k \frac{\boldsymbol{l}_{ki}}{r_k^3}\left|n\right\rangle\left\langle n\right| \boldsymbol{l}_{ki} \left|0\right\rangle + \left\langle 0\right| \sum_k \boldsymbol{l}_{ki}\left|n\right\rangle\left\langle n\right| \sum_r \frac{\boldsymbol{l}_{ki}}{r_k^3} \left|0\right\rangle]$$

In the above equations, μ_0 is the permeability of free space, e and m are the electron charge and rest mass, respectively, while $\langle 0|$ and $\langle n|$ represent ground and excited electronic states of the molecule with electronic energy E_0 and E_n, respectively. The position vector for electron k is defined by $\boldsymbol{r}_k$ and $\boldsymbol{l}_{ki}$ is the angular momentum operator. Equations 2 and 3 describe the shielding in the directions of the principal components of the chemical shielding tensor and are valid only if the nucleus of interest is chosen as the gauge origin. Expressions for the off-diagonal elements of the chemical shielding tensor and for different gauge origins have been derived (14, 15).

The contribution to shielding from σ^d (eq. [2]) is always positive, leading to increased shielding relative to the bare nucleus. Because σ^d depends only on the ground electronic state of the molecule, it can be calculated accurately at relatively low levels of theory and hence is expected to be essentially invariant to basis set size or to the effects of electron correlation. Gierke and Flygare (16) have shown that σ^d may be approximated if the molecular structure is known. For example, the shielding for nucleus A in the x-direction may be approximated by:

$$[4] \qquad \sigma_{xx}^{d} \approx \sigma_{av}^{d}(\text{free atom}) + \frac{\mu_0}{4\pi}\frac{e^2}{2m}\sum_{B\neq A}\frac{Z_B}{r_{AB}^3}(y_B^2 + z_B^2)$$



where σ_{av}^{d}(free atom) is the shielding for the "free" atom. The summation is carried out over all other atoms in the molecule, Z_B is the atomic number of the atom being summed, y_B and z_B are the Cartesian coordinates of the atoms which are a distance r_{AB} from the origin (the site of the observed nucleus). The remaining tensor components may be approximated by cyclic permutations of eq. [4]. In linear molecules, the component of the chemical shielding tensor along the C_∞ axis is labelled $\sigma_\parallel$ while the two components perpendicular to this axis are labelled $\sigma_\perp$. Since $\sigma_\parallel^p = 0$ for the nuclei of linear molecules, it follows from eq. [4] that:

$$[5] \qquad \sigma_\parallel = \sigma_\parallel^d \approx \sigma_{av}^d \quad (\text{free atom})$$

The paramagnetic term (eq. [3]) is a second-order electronic property which depends on the mixing of ground and excited electronic states of the molecule. These states correspond approximately to the occupied and unoccupied MOs (17). The paramagnetic term is usually negative and is inversely proportional to the difference in the electronic energy of the orbitals undergoing mixing. Contributions to σ^p arise from induced electron motion in the plane perpendicular to the direction of the applied magnetic field such that charge appears to rotate (17). This can be understood by considering the action of the angular momentum operator in eq. [3]. For example, consider $\boldsymbol{l}_z|p_x\rangle$; the operator $\boldsymbol{l}_z$ rotates p_x by 90° about the z-axis. Thus, there is an effective mixing between p_x and p_y. Mixing of MOs can only occur between occupied and unoccupied MOs with magnetic-dipole allowed symmetry. This is shown graphically in Fig. 1.

© 2000 NRC Canada

Fig. 1. Examples of magnetic-dipole allowed (A) and forbidden (B) mixing of orbitals for a hypothetical diatomic molecule with an applied magnetic field perpendicular to the page.

Mixing of π_u and σ_u^* MOs (Fig. 1A) is magnetic-dipole allowed, but mixing of π_u and π_g^* MOs (Fig. 1B) is forbidden by symmetry. Hence, significant deshielding is expected in directions perpendicular to the symmetry planes of occupied and virtual MOs that have the proper symmetry for mixing, and that are separated by a small energy difference. It is of interest to point out that a related discussion of nuclear shielding in terms of electronic current density conveniently leads to equivalent partitioning of the diamagnetic and paramagnetic terms (eqs. [1]–[3]) (18).

In eqs. [1]–[5], σ denotes the magnetic *shielding* relative to the bare nucleus such that $\sigma_{33} \geq \sigma_{22} \geq \sigma_{11}$. While ab initio methods calculate shielding, experimentally one measures a chemical *shift* (δ_{ii}) relative to a given reference with the convention $\delta_{11} \geq \delta_{22} \geq \delta_{33}$. The two are related by:

$$[6] \qquad \delta_{ii} = \frac{\nu_{ii} - \nu_{ref}}{\nu_{ref}}(10^6) = \frac{\sigma_{ref} - \sigma_{ii}}{1 - \sigma_{ref}}$$

where ν_{ii} and ν_{ref} are the resonance frequencies of the principal tensor components for the nucleus of interest and for the reference sample, respectively. Since $1 - \sigma_{ref} \approx 1$, $\delta_{ii} \approx \sigma_{ref} - \sigma_{ii}$. In the ensuing sections the experimental results will be discussed in terms of chemical shifts and the theoretical results will be discussed in terms of chemical shielding. The experimental data are related to those calculated by ab initio methods by using an absolute shielding scale for the nucleus of interest (19). Absolute shielding scales for carbon (20), nitrogen (21), and selenium (22) have been established by Jameson and coworkers.

It is convenient to discuss the NMR line shape of static powder samples in terms of the span, $\Omega = \sigma_{33} - \sigma_{11} \approx \delta_{11} - \delta_{33}$, and the skew, $\kappa = 3(\sigma_{iso} - \sigma_{22})/\Omega = 3(\delta_{22} - \delta_{iso})/\Omega$(23). With a few exceptions (24), $\sigma_\parallel > \sigma_\perp$ and $\kappa = +1.0$ for linear molecules with perfect axial symmetry.

Experimental

Ammonium selenocyanate (25) and tetramethylammonium selenocyanate (26) were prepared according to literature methods. Potassium cyanate and potassium selenocyanate were purchased from Aldrich and used without further purification.

Natural abundance ^{13}C, ^{15}N, and ^{77}Se NMR spectra were obtained on Bruker MSL-200 and AMX-400 NMR spectrometers (B_0 = 4.7 and 9.4 T, respectively). Samples were packed into 7 and 4 mm o.d. zirconium oxide rotors. Cross polarization (CP) and high-power proton decoupling were employed in acquiring all NMR spectra, except for KSeCN, where spectra were acquired after a single pulse. Unless otherwise noted, recycle delays were 5 s. Carbon chemical shifts were referenced to tetramethylsilane by setting the high-frequency isotropic peak of solid adamantane to 38.56 ppm (27). Nitrogen chemical shifts were referenced to $NH_3(\ell$, 293 K) by setting the NMR peak of the ammonium ion in solid $^{15}NH_4NO_3$ to +23.8 ppm. The chemical shift for $CH_3NO_2(\ell)$, another common nitrogen chemical shift reference, is 380.20 ppm with respect to $NH_3(\ell$, 293 K) (28). Selenium chemical shifts were referenced to $Se(CH_3)_2(\ell)$ by setting the ^{77}Se NMR peak of solid $(NH_4)_2SeO_4$ to +1040.2 ppm (11).

NMR spectra of MAS samples were analyzed by the method of Herzfeld and Berger (29) using the program HBA. Spectra of stationary samples were analyzed with the program WSOLIDS, which incorporates the POWDER algorithm of Alderman et al. (30). Both programs were developed in this laboratory and run on IBM compatible microprocessors.

Ab initio calculations of the carbon, nitrogen, and selenium chemical shielding tensors were performed with the Gaussian 98 suite of programs[2] mounted on an IBM RS/6000 computer. The chemical shielding tensors for all compounds were calculated at the Hartree–Fock (HF) level of theory using the gauge-independent atomic orbitals (GIAO) method (31) with the 6–311+G* basis set. The basis-set dependence of these results was determined by calculating the chemical shielding tensors for CSe_2 and $SeCN^-$ with basis sets[3] ranging from 3–21G to cc-pVQZ (32). The effects of electron correlation

Table 1. Experimental carbon, nitrogen, and selenium chemical shift tensors for some solid cyanate salts.[a]

Compound	Nucleus	δ_{iso}[b]	δ_{11}	δ_{22}	δ_{33}	Ω[c]	κ[d]
KOCN	^{13}C	130.2	—	—	—	—	—
NH_4SCN[e]	^{13}C	133.1	240	240	–81	321	1.00
NH_4SeCN	^{13}C	125.7[f]	228	226	–77	305	0.99
NMe_4SeCN	^{13}C	119.1[g]	215	212	–70	285	0.98
NH_4SCN[e]	^{15}N	211.0	349	349	–66	415	1.00
NMe_4SeCN	^{15}N	255[h]	401	401	–38	439	1.00
KSeCN	^{77}Se	–282.6[i]	25	–23	–849	874	0.89
NH_4SeCN	^{77}Se	–255.9	26	–15	–778	804	0.9
NMe_4SeCN	^{77}Se	–299.4	–40	–40	–814	854	1.00

[a]All chemical shift values are in ppm. Uncertainties are estimated to be less than 0.5 ppm for δ_{iso}; those of the individual components are estimated to be on the order of 2–3% of the total span of the tensor.

[b]δ_{iso} may not be exactly equal to the average of the individual tensor components since the values of the former were obtained from the isotropic peak of an MAS sample.

[c]Span $\Omega = \delta_{11} - \delta_{33}$.

[d]Skew $\kappa = 3(\delta_{22} - \delta_{iso})/\Omega$.

[e]Ref. 39.

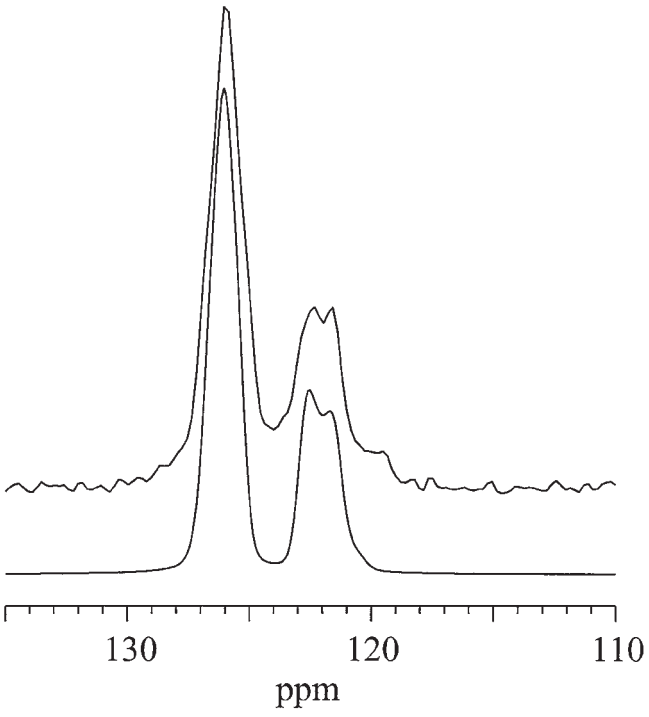
[f]From MAS spectra: $\chi(^{14}N) = -2.6 \pm 0.3$ MHz; $^1J(^{14}N, ^{13}C) = 15 \pm 3$ Hz.

[g]From MAS spectra: $\chi(^{14}N) = -2.6 \pm 0.3$ MHz; $^1J(^{77}Se, ^{13}C) = 260 \pm 30$ Hz; methyl groups: $\delta_{iso} = 56.1$ ppm.

[h]Tetramethylammonium: $\delta_{iso} = 47.3$ ppm.

[i]Surface solvated: –297.5 ppm.

on these two compounds were investigated by calculating the chemical shielding tensors at the second-order Møller–Plesset (MP2) level of theory (33). The geometries used in these calculations are from a high-level ab initio geometry optimization of $SeCN^-$ (34), a neutron diffraction study of NH_4SCN (35), a microwave study of SeCO (36), and an IR study of CSe_2 (37). To facilitate comparison, experimental chemical shifts (δ) were converted to chemical shielding (σ) according to $\sigma(exp) = \sigma(ref) - \delta(exp)$. The carbon shielding in TMS(ℓ, 300 K) was taken to be 188.1 ppm (20), that for nitrogen in NH_3(ℓ, 293 K) was taken to be 264.5 ppm (21) and that for the selenium in $Se(CH_3)_2$(ℓ) was taken to be 1769 ppm (22). The latter value is an approximate non-relativistic value. That is, in deriving the absolute shielding scale for selenium, it was assumed that σ(free ^{77}Se atom) = 2998 ppm (38).



Results and discussion

Observed chemical shift and spin–spin coupling data determined from stationary and MAS powder samples of solid selenocyanate salts investigated in this study are collected in Table 1. Included for comparison are data obtained from a previous ^{13}C and ^{15}N NMR study of ammonium thiocyanate (39).

Carbon-13 NMR spectra

The ^{13}C NMR spectrum of an MAS sample of solid ammonium selenocyanate is shown in Fig. 2. The spinning sidebands of the experimental spectrum have been added to the isotropic peak to produce the spectrum expected at the high-spinning limit. The asymmetric doublets arise because the carbon is directly bonded to the quadrupolar ^{14}N nucleus ($I = 1$, natural abundance = 99.64%). Although the isotropic ^{13}C chemical shift can be accurately determined from the spectrum of an MAS sample, it is more difficult to extract the principal components of the carbon chemical shift tensors from spinning sidebands because the presence of the dipolar interaction with ^{14}N nuclei must be considered (40).

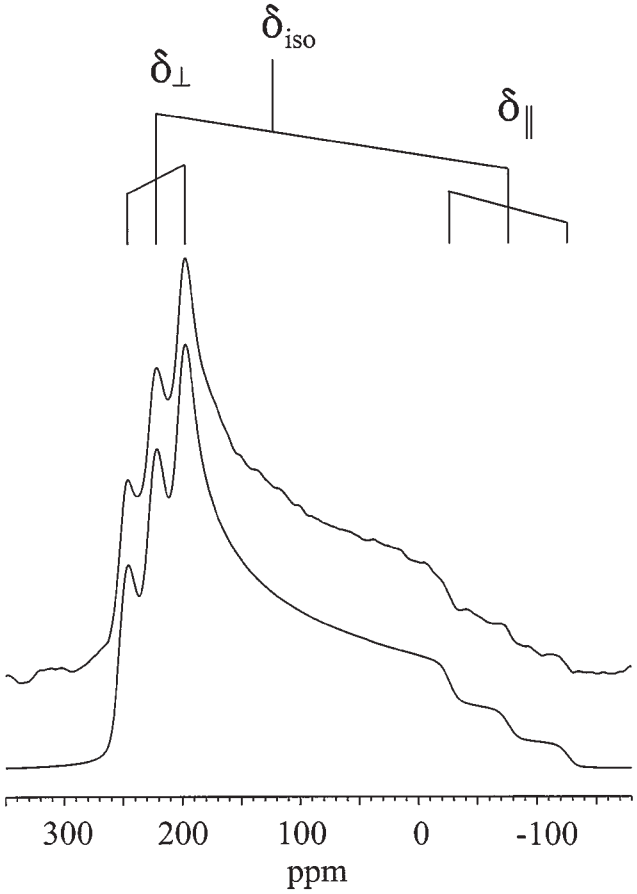


Fig. 2. Isotropic region of the experimental (top) and calculated (bottom) ^{13}C NMR spectra of NH_4SeCN acquired at 4.7 T with a spinning frequency of 3320 Hz; 7455 transients were acquired.

The ^{13}C NMR spectrum of a stationary powder sample of NH_4SeCN is shown in Fig. 3. As well as being perturbed by anisotropic shielding, the ^{13}C NMR line shape is modified by the ^{14}N, ^{13}C dipolar interaction. The splittings at $\delta_\perp$ and $\delta_\parallel$ are R_{DD} and $2R_{DD}$, respectively (41). The ^{14}N, ^{13}C direct dipolar coupling constant (R_{DD}) is defined as

© 2000 NRC Canada

Fig. 3. Experimental (top) and calculated (bottom) ^{13}C NMR spectra of a stationary powder sample of NH_4SeCN at 4.7 T; 20549 transients were acquired. The splitting of the parallel and perpendicular components arise from the dipolar interaction with ^{14}N.

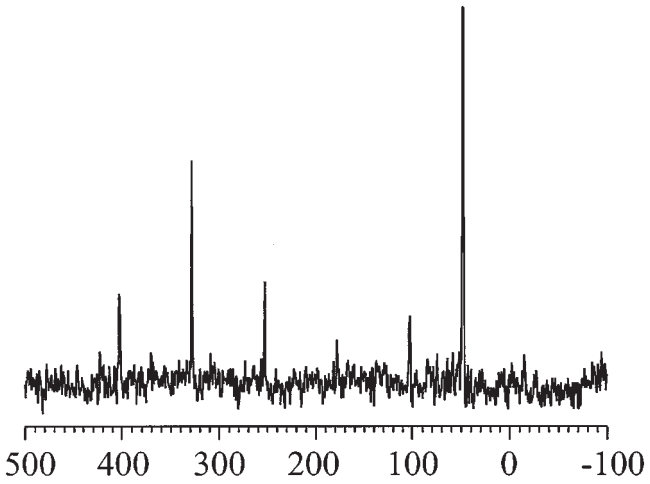
$$[7] \qquad R_{DD} = \frac{\mu_0}{4\pi}\frac{\hbar}{2\pi}\gamma(^{13}C)\,\gamma(^{14}N)\left\langle r_{CN}^{-3}\right\rangle$$

where $\langle r_{CN}\rangle$ is the motionally averaged C—N bond length. The splittings due to R_{DD} for crystallites oriented such that $\delta_\perp$ is parallel to $\mathbf{B}_0$ are clearly seen at high frequency in Fig. 3; although it is not as well resolved, the effect of R_{DD} on the spectra of crystallites oriented such that $\delta_\parallel$ is parallel to $\mathbf{B}_0$ are also observed at low frequency. From the fit of the NMR spectrum of a stationary powder sample, R_{DD} = 1250 ± 20 Hz, corresponding to r_{CN} = 1.205 ± 0.007 Å. This is significantly longer than the value of r_{CN} determined from an early X-ray diffraction study of KSeCN (42), 1.117 Å, but is in agreement with the results of an ab initio study (34). In principle, the quadrupolar interaction with ^{14}N should also be considered in the fit, but it has been shown (39–41) that this interaction has only minor effects on the positions of the critical frequencies in spectra of stationary samples acquired at the external magnetic fields used in this study. From the dipolar coupling, and assuming that the largest component of the ^{14}N EFG tensor is along the C,N bond with an asymmetry of zero, analysis of the spectrum of an MAS sample (Fig. 2) yields $C_Q(^{14}N)$ = –2.6 ± 0.3 MHz. This value is in excellent agreement with the value reported for the NCS^- anion, $|C_Q(^{14}N)|$ = 2.3 MHz (43).

The ^{13}C NMR spectrum of an MAS sample of NMe_4SeCN (not shown) contains some smaller peaks, attributed to ^{13}C nuclei bonded to the ^{77}Se nucleus (natural abundance = 7.58%, I = 1/2). The value of $^1J_{iso}(^{77}Se, ^{13}C)$ is estimated to be 260 ± 30 Hz. These satellite peaks are not resolved in the spectrum of NH_4SeCN (Fig. 2), a consequence of the broader lines. The line shape of the asymmetric doublet in the ^{13}C NMR spectrum of an MAS sample of NMe_4SeCN cannot be simulated as well as that of NH_4SeCN (Fig. 2); this may be caused by the onset of self-decoupling of the ^{14}N (44). The ^{13}C NMR spectrum of a stationary sample of NMe_4SeCN is dominated by the contribution from the four methyl groups, but the splittings due to $R_{DD}(^{14}N, ^{13}C)$ in the high-frequency region of the spectrum are well resolved. With these features and with the isotropic chemical shift obtained from the spectra of MAS samples, analysis of the spectrum is possible, yielding the principal components of the carbon CS tensors summarized in Table 1. From the ^{14}N, ^{13}C dipolar splittings observed in the high-frequency region, R_{DD} = 1180 ± 30 Hz, corresponding to r_{CN} = 1.23 ± 0.01 Å. This value is slightly longer than the value of 1.205 Å obtained for NH_4SeCN. While the difference is only slightly greater than the experimental error, the longer value obtained for NMe_4SeCN is probably a consequence of greater librational motion of the selenocyanate anion of the latter salt. Note that motion of the N—C bond will result in partial averaging of $R_{DD}(^{14}N, ^{13}C)$ and an apparent lengthening of r_{CN}.

For the ^{13}C MAS NMR spectrum of KOCN, recycle delays in excess of one hour were used, but the signal-to-noise ratio was still very low, precluding any analysis for the compound at natural abundance. Hence only the isotropic chemical shift was determined. The value of δ_{iso}, 130.2 ppm, is within experimental error of the value determined for KOCN dissolved in D_2O, 129.7 ppm (45).

Nitrogen-15 NMR spectra



The ^{15}N MAS NMR spectrum of NMe_4SeCN (Fig. 4) consists of an intense peak at 47.3 ppm, due to NMe_4^+, and a weaker, spinning rate invariant peak at 255.0 ppm due to $SeCN^-$. The spinning sidebands of the latter peak were analyzed by the Herzfeld–Berger method to obtain the span of the nitrogen CS tensor, Ω = 439 ± 10 ppm. This value is within experimental error of the value obtained for NH_4SCN, 415 ± 15 ppm (39). The average nitrogen shielding for $SeCN^-$ in solid NMe_4SeCN is 44 ppm less than the value for SCN^- of solid NH_4SCN. In aqueous solutions, the shielding of the nitrogen nuclei of $SeCN^-$ dissolved in D_2O (46) decreases by 30 ppm compared to that of the nitrogen nuclei of SCN^- dissolved in H_2O (47).

Selenium-77 NMR spectra

Selenium-77 NMR spectra of MAS samples of NMe_4SeCN are shown in Fig. 5. The isotropic ^{77}Se chemical shift is comparable to that of KSeCN measured in solution (6). The experimental spectra of the selenocyanates were simulated via a non-linear least-square implementation of the method of Herzfeld and Berger (29); the resulting data are summarized in Table 1. These simulations indicate large

anisotropies in the ^{77}Se CS tensors, making the observation of spectra of stationary powder samples difficult. Non-axially symmetric CS tensors are not precluded by the linear $SeCN^-$ anion, since the positions of the cations in the crystal lattice may affect the shielding. For example, the crystal structure of KSeCN shows that the potassium atoms are not arranged symmetrically about the selenium (42). Chemical shift tensors determined from the analysis of spinning sideband intensities in spectra of slow-spinning MAS samples are subject to significant errors if the tensor is approximately axially symmetric (48). In light of the above and considering the errors associated with the experimental data, the values quoted in Table 1 do not conclusively determine the symmetry of the selenium CS tensor. In cases where cross-polarization was used to obtain the spectra, further artifacts could be introduced in the spinning sideband intensities from anisotropy in the cross-relaxation stage of the experiment (49). For example, clear differences were observed for NMe_4SeCN in regular CP experiments (Fig. 5, top) and experiments employing variable-amplitude cross-polarization (50) (see Fig. 5, middle). In the spectrum obtained with regular CP, the intensities of the spinning sidebands in the neighbourhood of the isotropic peak (indicated with an asterisk) are much stronger relative to the higher-order spinning sidebands about the position of $\delta_\perp$ and $\delta_\parallel$ than are those obtained with VACP. The latter spectrum agrees much better with the calculated spectrum. This effect is probably due to the offset dependence of the Hartmann–Hahn matching condition (50). In spite of the possible errors and artifacts, it is clear that the selenium CS tensors do not deviate significantly from axial symmetry (the maximum deviation in κ is estimated to be 10%). In the ensuing discussion, we will assume that the carbon, nitrogen, and selenium tensors are axially symmetric, consistent with our experimental data.

Ab initio calculations

Carbon and nitrogen shielding tensors for $SeCN^-$ and related molecules

The calculated carbon and nitrogen chemical shielding tensor components are listed in Tables 2 and 3, respectively.

Fig. 5. Experimental and calculated ^{77}Se MAS NMR spectra of solid NMe_4SeCN at 9.4 T and a spinning frequency of 1500 Hz. Top: regular cross-polarization experiment with 3000 scans and 10 ms contact time. Middle: variable-amplitude cross-polarization experiment with 2532 scans and 15 ms contact time. Bottom: calculated spectrum with $\delta_{11} = \delta_{22} = -40$ ppm, $\delta_{33} = -814$ ppm. The isotropic peaks are indicated with an asterisk.

For comparison, the chemical shift values of the experimental data have been converted to chemical shielding (see experimental section). While the observed spans for the carbon CS tensors of SCN^- and $SeCN^-$ are similar (321 to 285 ppm), the span is significantly greater for SeCO (399 ppm) and CSe_2 (506 ppm). These experimental trends are reproduced by the highest level ab initio computations that we can presently apply to all three molecules, HF/6–311+G*. Likewise, ab initio calculations correctly predict a larger span for the nitrogen nucleus of the $SeCN^-$ anion than for that of the SCN^- anion.

The calculated isotropic carbon chemical shielding for $SeCN^-$ plotted against basis set size is shown in Fig. 6 (top). This figure indicates that the calculated isotropic shielding is converging to a value which is approximately 15 ppm less than the experimental value. Similar results were obtained for the calculated shielding of the nitrogen of $SeCN^-$ (Table 3) and the carbon of CSe_2 (Table 2).

The calculated carbon chemical shielding tensor components parallel to the bond are invariant to basis set size or to

[b]From reference 39. Values reported in Table 1 of this reference are slightly different from those shown here, since the values were based on an earlier absolute shielding scale for carbon.

[c]From reference 56(*a*), Vol. 25, p.48. A comparable value of σ_{iso}, 31.5 ppm, has also been reported from a solution-state study (reference 57).

[d]The individual tensor components were calculated from the experimental values of σ_{iso} (reference 57) and Ω (reference 12) according to $\sigma_\perp = \sigma_{iso} - (1/3)\Omega$ and $\sigma_\parallel = \sigma_{iso} + (2/3)\Omega$.

Fig. 6. Isotropic carbon and selenium chemical shielding, calculated at the HF level, plotted against the basis set used for the calculation. The scale for the abscissa is qualitative.

the effects of electron correlation, reflecting the fact that there is no paramagnetic contribution to this component of the chemical shielding tensor. However, the experimental values of $\sigma_\parallel$ are approximately 30 ppm less than the calculated values, perhaps a consequence of intermolecular effects. Calculations on a larger portion of the crystal lattice would be instructive but are not practical at this time given the computational requirements. In addition to intermolecular effects, vibrational effects are a factor, although these are expected to be fairly small for carbon and nitrogen (51). For example, Lounila et al. (52) calculated a vibrational correction of $\sigma_{iso} = -2.4$ ppm for the carbon of CSe_2. For molecules containing large atoms, relativistic effects (53) may become significant (*vide infra*), even for the calculated shielding of neighbouring nuclei (54).

[b]From reference 39.

The chemical shielding tensors for the carbon and nitrogen nuclei of $SeCN^-$ as well as that for the carbon of CSe_2 were calculated at the MP2 level (Tables 2 and 3). In all cases, the isotropic shielding values calculated at the MP2 level are significantly greater than the corresponding HF values, and are generally greater than the experimental values, reflecting the fact that the effects of electron correlation are not considered in HF calculations but are often overestimated by MP2 (55). A particularly large electron correlation effect is expected for the carbon of CSe_2 because of its multiple bonding (56). The large deshielding (57) and span (12) reported for the carbon of CSe_2 are in agreement with our calculations, as well as with those of an earlier computational study (52).

[b]From reference 56(*a*), Vol. 25, p. 48.

[c]The isotropic value is from a solution-state study (reference 57). The chemical shielding tensor components were calculated from this value and the experimental value of Ω (reference 56(*a*), Vol. 25, p. 48) according to $\sigma_{\perp} = \sigma_{iso} - (1/3)\Omega$ and $\sigma_{\parallel} = \sigma_{iso} + (2/3)\Omega$.

[d]Components of the chemical shielding tensor are calculated from the experimental values of σ_{iso} (reference 57) and Ω (reference 12); see footnote *c* above.

[e]A value of $\sigma_{\perp} = 1068$ ppm, determined from a solid state NMR study at –90°C, has also been reported (reference 63).

Selenium chemical shielding tensors for $SeCN^-$ and related molecules

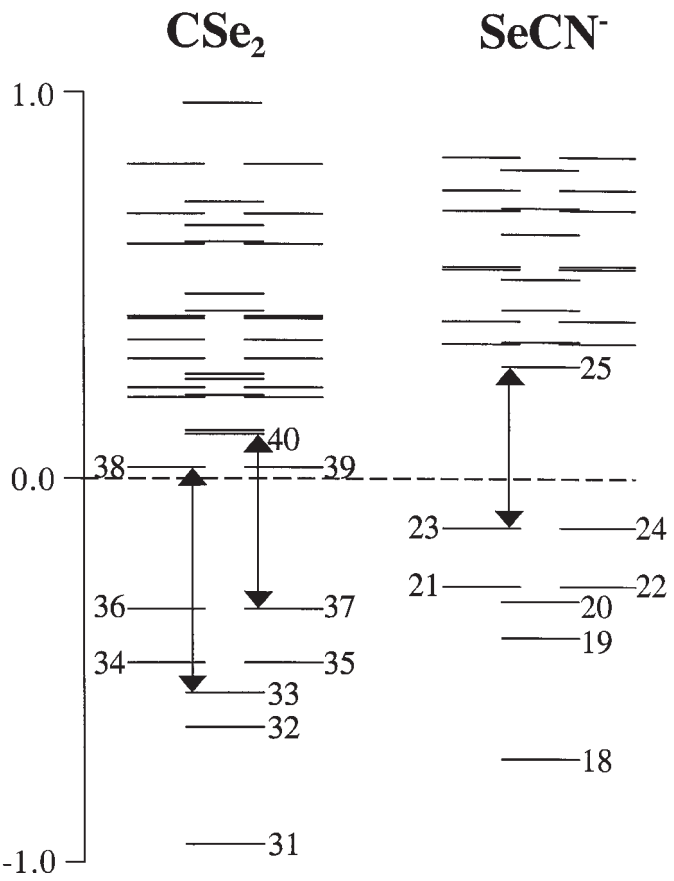
The existence of an absolute shielding scale for selenium (22) combined with experimental data on simple molecules has prompted several theoretical groups to investigate selenium chemical shielding tensors. For example, the selenium shielding for CSe_2 has been calculated at the CHF (12), HF/IGLO (55), MP2/GIAO (55, 58), CCD (58), and DFT (59) levels of theory. Recently Lounila et al. reported the results of a detailed computational study of this molecule, which included DFT and CAS calculations (52). Such calculations are challenging, a consequence of the large chemical shielding range of selenium (60) and of the fact that selenium shielding is subject to relativistic effects (53). The progress of selenium shielding calculations has been reviewed recently (56).

The calculated selenium chemical shielding tensors are listed in Table 4. The calculated results are more dependent on basis set size than are those of carbon and nitrogen (Fig. 6), reflecting the greater chemical shift range of selenium compared to those of carbon (3) or nitrogen (61). Figure 6 shows that the calculated isotropic selenium chemical shielding for both $SeCN^-$ and CSe_2 are converging to values which are significantly shielded compared to experimental values. Ab initio calculations are performed on isolated molecules, which may result in significant discrepancies between calculated and experimental results, since selenium is known to be susceptible to medium effects. For example, the isotropic shielding for gaseous H_2Se is 126.6 ppm greater than that for this compound in the liquid state, which in turn is shielded by 11.4 ppm compared to its value in the solid (62). For CSe_2, the gas-phase shielding is 74.7 ppm greater than that for the same molecule in its liquid phase (63).

An electron correlation effect of 100 ppm is predicted for $SeCN^-$, based on the results of calculations at the MP2 level. The effect is more significant for CSe_2; σ_{iso} calculated at the MP2 level is 269 ppm greater than the value calculated at the HF level (Table 4). Chesnut has noted that isotropic chemical shielding constants calculated at various orders of Møller–Plesset theory converge such that the infinite-order Møller–Plesset calculated shielding may be approximated by (64):

$$[8] \qquad \sigma_{iso} = \frac{1}{3}\sigma_{HF} + \frac{2}{3}\sigma_{MP2}$$

Substituting our calculated values for CSe_2 (Table 4), we obtain a value of $\sigma_{iso} = 1726$ ppm, close to the value calculated with the CAS method, 1755.2 ppm (52).



In the absence of intermolecular effects $\sigma_{\parallel} \approx \sigma^d_{av}$ (free atom) (eq. [5]). Our calculated values of $\sigma_{\parallel}$ (Table 4) are comparable to the non-relativistic value of σ^d_{av} (free Se), 2998 ppm (38), reflecting the fact that first-order molecular properties can usually be calculated accurately. Experimental values of $\sigma_{\parallel}$ for the selenocyanate salts are significantly smaller than the calculated values. This difference is attributed to intermolecular effects. A paramagnetic contribution to $\sigma_{\parallel}$ in the selenocyanate salts arises from the fact that, with the neighbouring nuclei such as potassium in KSeCN, the selenium atoms are not in a perfectly linear environment and hence the assumption that $\sigma^p_{\parallel} = 0$ is no longer strictly valid.

A comparison of the selenium chemical shielding tensors for $SeCN^-$ and CSe_2.

One might expect the selenium chemical shielding tensors for Se=C=N$^-$ and Se=C=Se to be similar, but this is not the case (Table 4). Particularly surprising is the large difference in the spans — that of CSe_2 is almost three times greater than the spans of the selenocyanates. This is remarkable given that selenium is directly bonded to carbon in both cases. The difference cannot be attributed to the charge on $SeCN^-$, since the span of SeCO (65) is comparable to those of the selenocyanate salts. These large differences are reproduced qualitatively by the calculations. In particular, we note that agreement between the experimental and calculated spans of SeCO is very good. Since the experimental span of SeCO was determined from spin-rotation data (65), it is that of an isolated molecule and is thus ideal for comparison with calculated values. To a first approximation, the span of the chemical shielding tensor is invariant to the effects of

Fig. 7. Molecular orbital energy levels (in hartrees) for CSe_2 and $SeCN^-$, calculated at the HF/cc-pVQZ level. Molecular orbitals below the dashed line are occupied. Some of the MOs have been labelled for reference.

relativity (52), and thus may be the best gauge of the accuracy of non-relativistic calculations.

The large difference in the spans of the selenium chemical shielding tensors for CSe_2 and $SeCN^-$ is a consequence of a large difference in their respective $\sigma_\perp$ values because $\sigma_\parallel$ does not vary greatly amongst linear molecules. The contribution to the span from σ^d can be estimated from eq. [4]. For $SeCN^-$, $\sigma^d_\parallel$ = 2998 ppm and $\sigma^d_\perp$ = 3078 ppm, giving a span in σ^d of 80 ppm. Similarly, a span of 151 ppm is predicted for σ^d of CSe_2. These numbers are much smaller and opposite in sign to those observed for σ^p. Thus, to understand the large difference between the spans of CSe_2 and $SeCN^-$, one must consider $\sigma^p_\perp$.

One of the factors contributing to $\sigma^p_\perp$ is the number of MOs undergoing mixing, since eq. [3] is a summation. Figure 7 shows the energies for the highest occupied and lowest unoccupied MOs of $SeCN^-$ and CSe_2, calculated at the HF level using the cc-pVQZ basis set. Although the energy difference between the highest occupied and lowest unoccupied MOs are comparable for the two compounds, there are more low-lying unoccupied MOs for CSe_2 than for $SeCN^-$. However, we must also consider the symmetry of these MOs, since mixing will only occur between MOs with magnetic-dipole allowed symmetry. These are indicated with arrows in Fig. 7.

Fig. 8. MOs 33 and 38 (or 39) for CSe_2, illustrating the magnetic-dipole allowed $\sigma_u \rightarrow \pi^*_u$ mixing for an applied magnetic field perpendicular to the page.

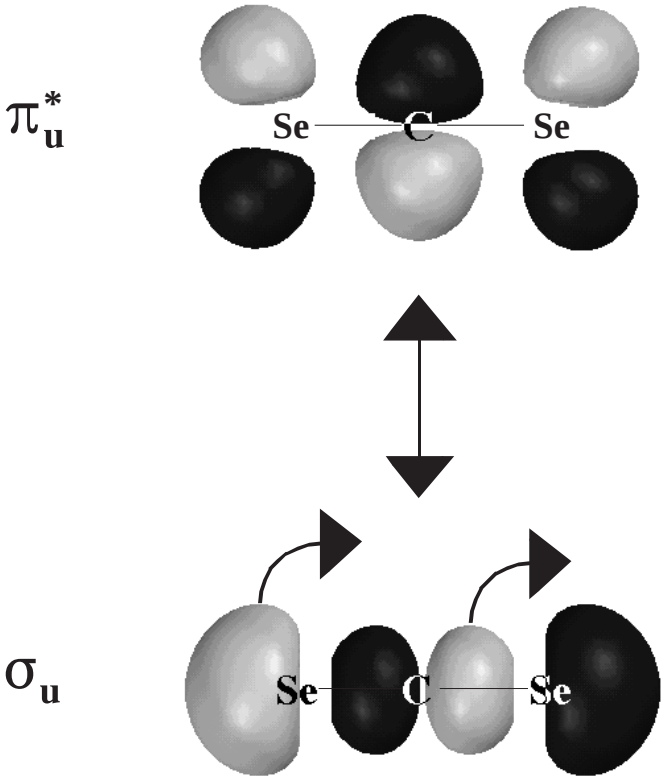

Figure 8 illustrates that MO 33 with σ_u symmetry can mix with degenerate MOs 38 or 39, with π^*_u symmetry. Because of the favourable symmetry, these MOs are expected to be a major factor in the deshielding observed in the direction perpendicular to the C_∞ axis of CSe_2. In Fig. 9, MO 36 (or degenerate MO 37) of CSe_2, with π_g symmetry, is shown along with MO 40, which has σ^*_g symmetry. Figures 8 and 9 illustrate the importance of symmetry in considering contributions to σ^p. Although MOs 36 and 37 are only separated by 0.46 hartrees from MO 40, compared to 0.57 hartrees separating MO 33 from MOs 38 and 39, the shape of the latter is much more favourable for mixing.

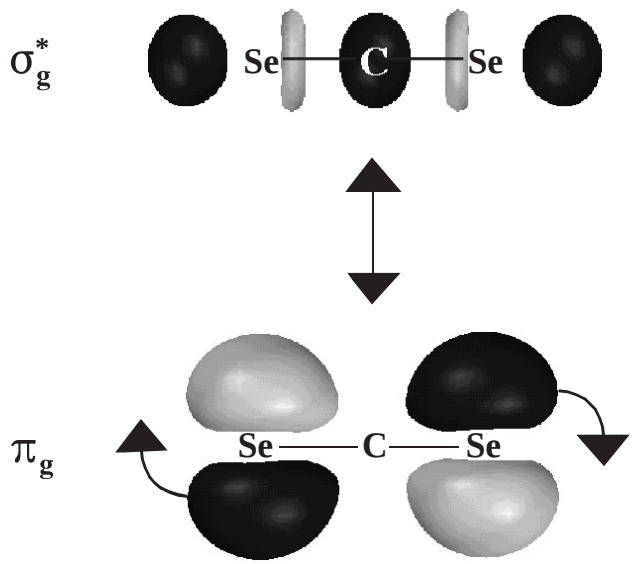
Figure 10 demonstrates why the selenium chemical shielding tensor for $SeCN^-$ has a large span which nevertheless is much smaller than that for CSe_2. The illustrated MOs, occupied π MO 23 (or degenerate MO 24) and unoccupied σ^* MO 25, have a relatively small difference in energy, 0.42 hartrees, but the symmetry of the MOs clearly is not as favourable for mixing here. Hence, these MOs are expected to be a significant factor in the deshielding perpendicular to the C_∞ axis of the anion, but the lower symmetry makes mixing much less favourable than in the case of CSe_2.

In summary, the smaller span of the chemical shielding tensor of $SeCN^-$ compared to that of CSe_2 may be attributed to two factors. The selenocyanate anion has fewer low-lying unoccupied MOs which can mix with occupied MOs and contribute to $\sigma^p_\perp$, and the mixing of most of those MOs separated by a small energy difference are not magnetic-dipole allowed. The latter may be attributed to the lower symmetry

© 2000 NRC Canada

Fig. 9. MOs 36 (or 37) and 40 of CSe_2, illustrating the magnetic-dipole allowed $\pi_g \rightarrow \sigma_g^*$ mixing for an applied magnetic field perpendicular to the page.



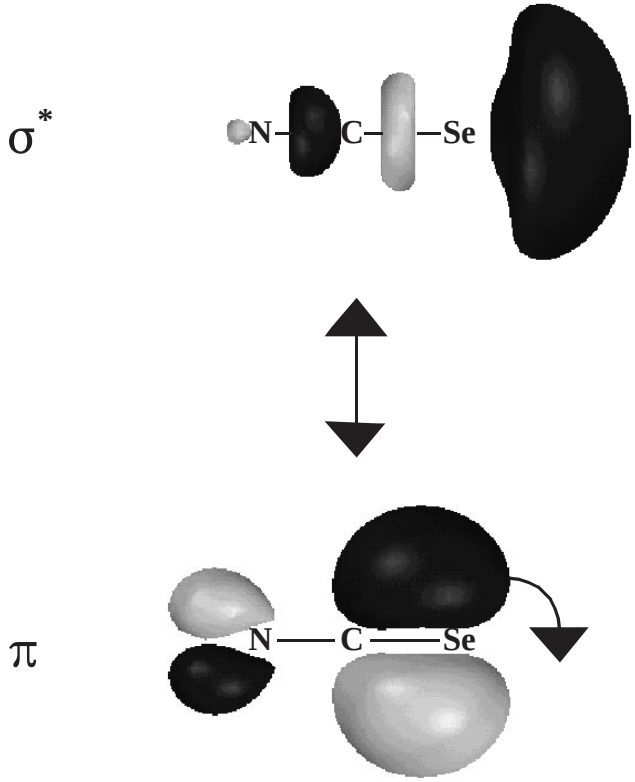


Fig. 10. MOs 23 (or 24) and 25 of CSe_2, illustrating the magnetic-dipole allowed $\pi \rightarrow \sigma^*$ mixing for an applied magnetic field perpendicular to the page.

of $SeCN^-$ ($C_{\infty v}$), compared to that of CSe_2 ($D_{\infty h}$). This conclusion is supported by the observation that the chemical shielding tensor for SeCO, which also has $C_{\infty v}$ symmetry, is comparable to that of $SeCN^-$. Finally we note that, although we have not explicitly discussed the spans of the carbon shielding tensors for $SeCN^-$ and CSe_2 (Table 2), the different spans of these shielding tensors may also be explained as above. For example, the mixing of MOs 33 with MOs 38 and 39 of CSe_2, which contributes to σ^p of the selenium chemical shielding tensor, will also be an important factor in the paramagnetic component of the carbon shielding perpendicular to the C_∞ symmetry axis.

Conclusions

The carbon, nitrogen, and selenium chemical shift tensors for several solid selenocyanate salts have been characterized by NMR. Within experimental error, the chemical shift tensors are axially symmetric. A notable result of this study is the observation that the spans of the carbon and selenium CS tensors for $SeCN^-$ are much smaller than those for CSe_2, a consequence of the smaller paramagnetic term in the shielding perpendicular to the C_∞ axis of $SeCN^-$ compared to that of CSe_2. High-level ab initio calculations show that the smaller paramagnetic term results from the lower symmetry of the MOs of $SeCN^-$ and from the fact that there are fewer low-lying unoccupied MOs for $SeCN^-$ compared to CSe_2. The shielding parallel to the C_∞ axis of $SeCN^-$ is less than expected for linear molecules, suggesting that this component is sensitive to intermolecular effects. This work has shown that multinuclear magnetic resonance studies of solids can offer much information about solid selenocyanate salts; it is hoped that this study will encourage further studies of these and related ligands.

Acknowledgments

We are grateful to Tenkir Asfaw for help in the preparation of a sample of ammonium selenocyanate. We thank Martine Ziliox for her help in initially setting up the VACP experiments on our Bruker AMX-400. We are grateful to members of the solid-state NMR group at Dalhousie University for many helpful suggestions and to Andrew D. Phillips for his help with the preparation of the molecular orbital diagrams. The financial assistance of the Natural Sciences and Engineering Research Council (NSERC) of Canada is gratefully acknowledged. GMB acknowledges NSERC, the Izaak Walton Killam Trust, and the Walter C. Sumner Foundation for postgraduate scholarships. Spectra were acquired at the Atlantic Region Magnetic Resonance Centre, which is also supported by NSERC.

An exploratory ab initio study on the conformations of ethylguanidine in its neutral [CH_3-CH_2-NH-C(=NH)NH_2] and protonated [CH_3-CH_2-NH-C(NH_2)$_2$] forms

Melody L. Mak, Salvatore J. Salpietro, R. Daniel Enriz, and Imre G. Csizmadia

Abstract: To explore the conformation intricacies of the guanidine group in the arginine side chain, ab initio computations have been carried out with ethylguanidine and the ethyl guanidinium ion. HF computations have been performed using 3–21G and 6–31G basis sets and DFT calculations were carried out at the B3LYP/6–31G(*d*) level of theory. The ethyl guanidinium ion has a single isomer due to its internal symmetry, although this structure has at least three conformations. However, several structures were found and optimized for ethylguanidine, involving the *endo*- and *exo*- orientation of the lone NH and torsional angle χ_6, as well as the torsional modes associated with χ_4 and χ_5. Torsional angle χ_5 gives rise to *s-cis* and *s-trans* structures.

Key words: ethylguanidine, ethylguanidinium ion, ab initio MO, arginine side-chain, conformational analysis.

Résumé : Dans le but d'étudier les problèmes reliés à la conformation du groupe guanidine dans la chaîne latérale de l'arginine, on a effectué des calculs ab initio sur l'éthylguanidine et l'ion éthylguanidinium. Les calculs HF ont été effectués à l'aide d'ensembles 3–21G et 6–31G alors que les calculs DFT ont été effectués au niveau B3LYP/6–31G(*d*) de la théorie. L'ion éthylguanidinium ne comporte qu'un seul isomère en raison de la symétrie interne de l'ion guanidinium même si cette structure comporte au moins trois conformations. Toutefois, on a trouvé et optimisé plusieurs structures pour l'éthylguanidine qui impliquent une orientation *endo*- et *exo*- du NH seul avec des angles de torsion χ_6 ainsi que des modes de torsion associés à χ_4 et χ_5. L'angle de torsion χ_5 conduit aux structures *s-cis* et *s-trans*.

Mots clés : éthylguanidine, ion éthylguanidinium, OM ab initio, chaîne latérale de l'arginine, analyse conformationnelle.

[Traduit par la Rédaction]

1. Introduction

Arginine is an amino acid with a positive charge at neutral pH due to its polar guanidinium group side-chain. The typical pK_a value of arginine is 12.0, the highest pK_a of all amino acids. Arginine is, therefore, important in salt bridge coupling, which is part of certain docking processes.

Arginine plays significant roles in a number of biological processes. For example, it is part of the tripeptide arginyl – glycyl – aspartic acid (RGD) which is found in adhesive proteins of extracellular matrices (1). This tripeptide serves as a cell recognition site in fibronectin. Although the cell attachment sequence is similar in different adhesive proteins, cells have the ability to distinguish them individually due to the specificity of receptors called integrins (2). Each integrin is able to recognize one RGD-containing ligand. Consequently, RGD-containing protein is extremely useful in the identification of these receptors.

Arginine is the source of nitric oxide (NO) in biological systems. NO is a free radical which serves as an intracellular second messenger and an intercellular messenger that regulates neighbouring, and possibly distant cells (3). NO takes part in many biological processes such as vasodilation, platelet aggregation, and adhesion (4–6). NO is also involved in various aspects of the central nervous system (CNS) such as the modification of pain perception, mediation of long-term potentiation and memory, controlling the cerebral blood flow, and in neurodegeneration following cerebral ischaemia (7–10). One of the two equivalent nitrogens of the terminal guanidine in L-arginine undergoes five-electron oxidation in the presence of the enzyme NO synthase (NOS), yielding NO and L-citrulline (4–6).

Current studies agree with the hypothesis that L-arginine is converted to NO by NOS in consecutive phases resulting in a multi-step mechanism (11–16). Studies by Marletta et al. (17) suggested that *N*-hydroxylation of L-arginine initiates the synthesis of NO. The discovery that the initial monooxygentation product N^G-hydroxy-L-arginine (L-NHA)

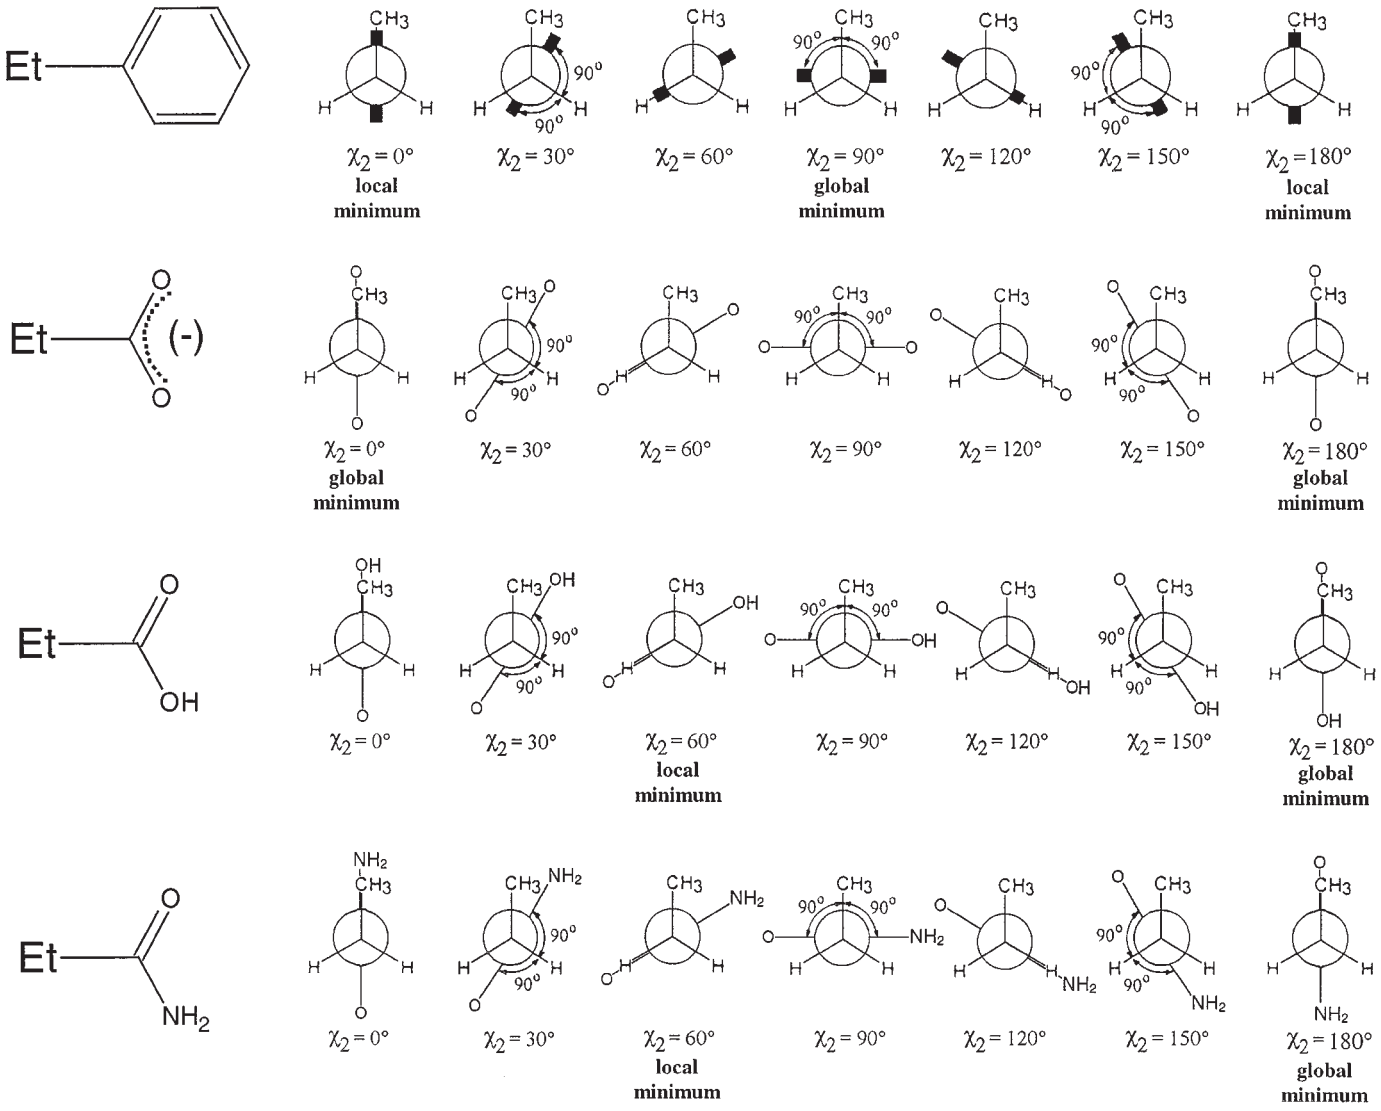
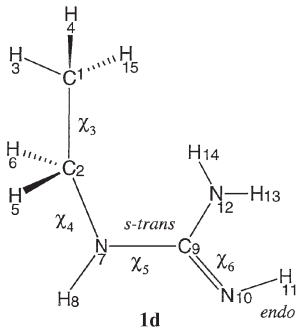
is oxidized only at the guanidine nitrogen that has the hydroxyl group (16) agrees with the mechanism proposed by Marletta et al. (17). The oxidation of *N*-hydroxyguanidine, as an L-NHA model, was first studied by Fukuto et al. (13). Recently, the nitric oxide – cyclic guanosine monophosphate (cGMP) signal transduction system is regarded as an ubiquitous pathway for intra- and intercellular communication (18, 4). It was also discovered that endogeneous vasodilators, such as acetylcholine, have no direct action on the vascular smooth muscle, but act on endothelial cells. Upon the action of vasodilators, the cells release NO, which is a "labile factor" that diffuses into the overlying smooth muscles. The smooth muscles underlying the blood vessel walls are relaxed by NO which spreads by diffusion (18, 3–6, 19*a*). For example, the release of NO by the cavernous nerves, which induces the relaxation of smooth muscles in the corpus cavernosum during sexual stimulation, has prompted the recent development of sildenafil citrate, or VIAGRA®, in treatment of erectile dysfunction.

N-methyl guanidine has been used as a model compound for arginine to study the mechanism of NO release using ab initio molecular computations (19*b*).



Previous work has already been done regarding the conformations of simple amino acids such as glycine and alanine (20). Other amino acids with more complicated side chains, such as phenylalanine (Phe) (21), serine (Ser) (22–24), cysteine (Cys) (footnote 2), selenocysteine (Sec) (25), aspartic acid (Asp) (26), and asparagine (Asn) (27) have also been studied. With the exception of proline (Pro) (28), all 19 chiral amino acids are expected to have nine different backbone conformations.



Ethylguanidine (**1**) and ethylguanidinium ion (**2**) are the terminal portions of the side chain (R-group) of the arginine

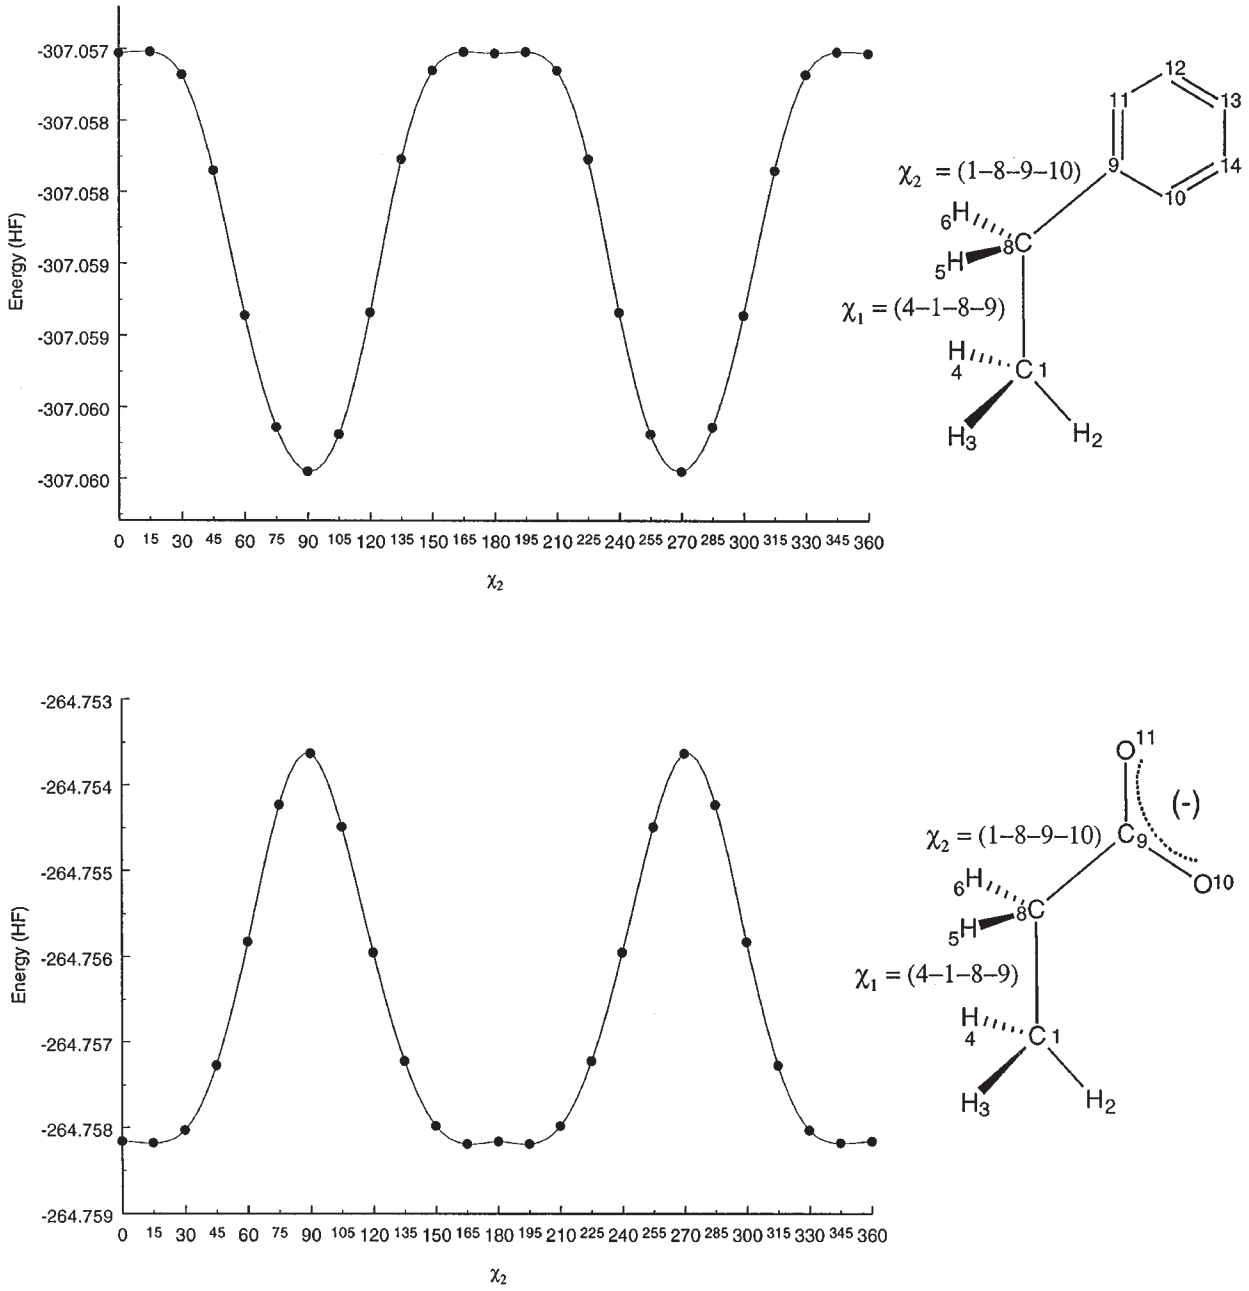
residue in *N*-formyl-argininamide (**3**) and its side chain terminal *N*-protonated form (**4**), respectively. Arginine can be divided into two portions: the backbone, which is analogous to glycine (or alanine), and the side chain, which is an alkyl guanidine.

Due to the large number of conformations of the amino acid side chain, even if it is of a modest size, it is simply not practical to optimize the entire structure before we have a preliminary knowledge about the intricacy of its conformations. As an appropriate model one may study **1** instead of **3** or, in a similar fashion, **2** in order to better understand the behavior of **4**.



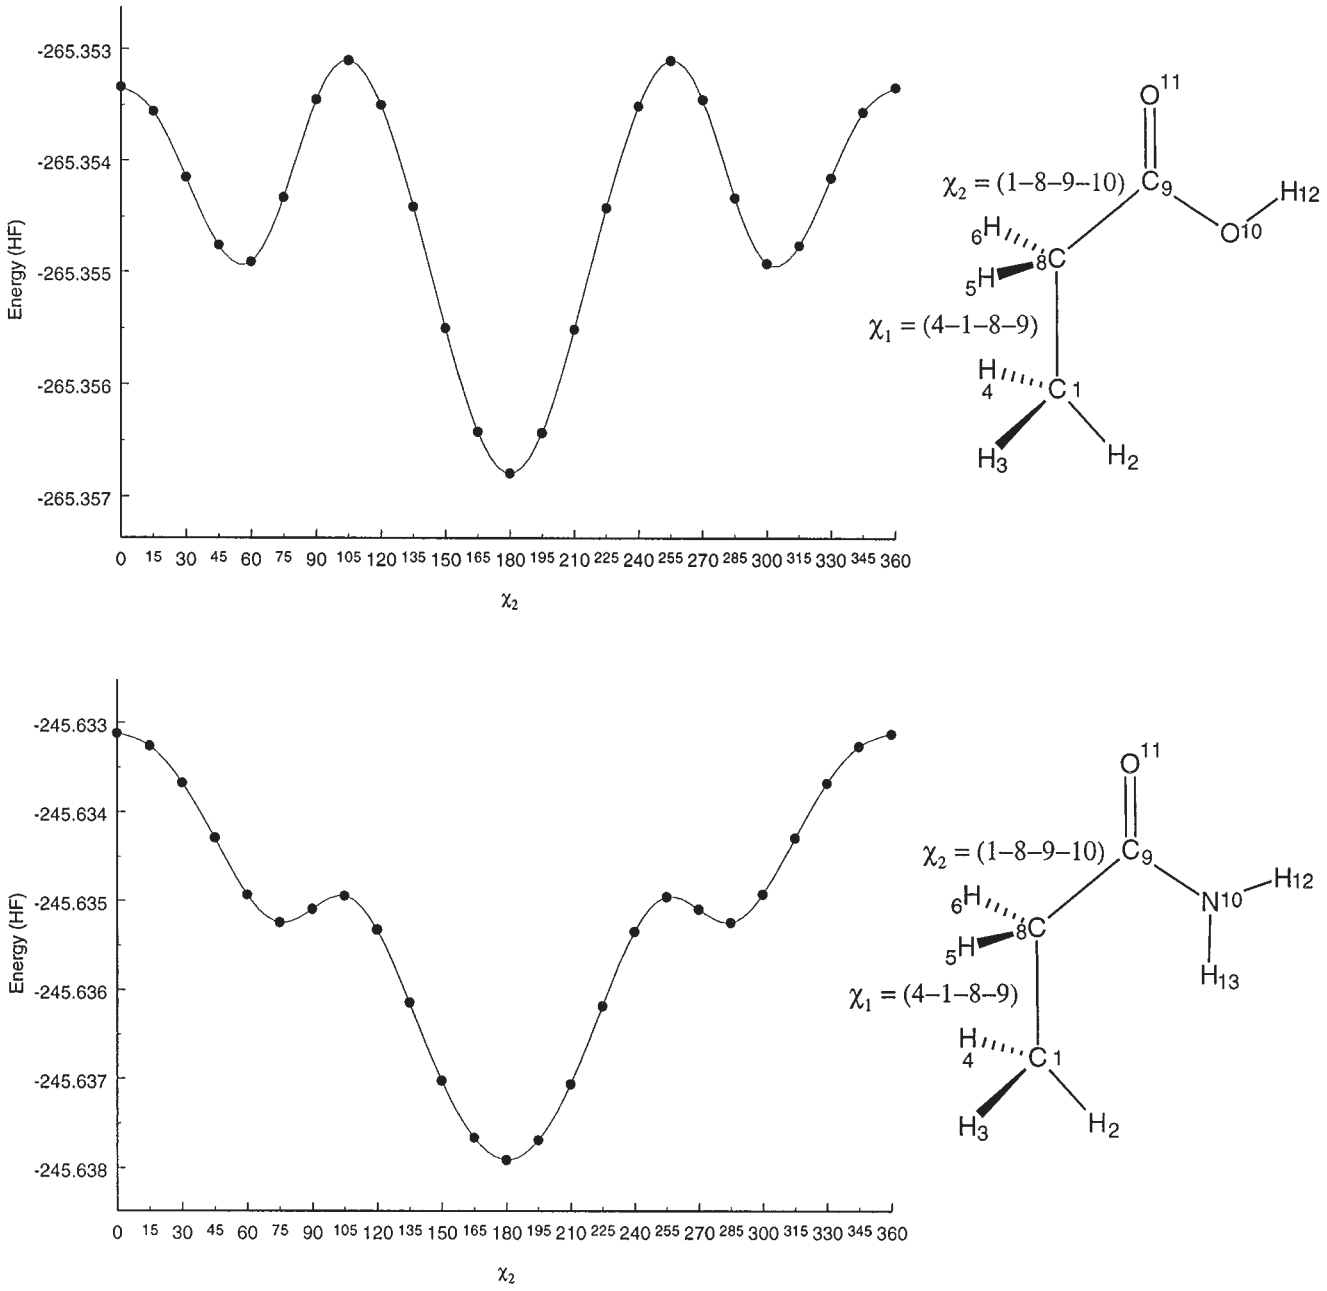
The two torsional modes of motion (rotation about the C—C and C—N bonds) are labeled as χ_3 and χ_4 respectively in all four structures (**1**–**4**) even though structures **1** and **2** have no χ_1 and χ_2 torsional modes.

2. Computational methods

Quantum chemical calculations involving geometry optimizations were carried out using the Gaussian 94 program at the Hartree Fock (HF) and DFT levels of theory using various basis sets. The following two basis sets have been employed for HF calculations: 3–21G and 6–31G. Geometries optimized at the HF level were subjected to further geometry optimization using DFT calculation at the B3LYP/6–31G(*d*) level of theory. Points calculated by the 1D-scan for the $E = E(\chi_4)$ potential energy curve (PEC) of

© 2000 NRC Canada

Fig. 1. Potential energy curve $E = E(\chi_2)$ of ethylbenzene (top) and that of propionate ion (bottom) both calculated at HF/3-21G.



1a was obtained at the HF/6–31G level of theory and the $E = E(\chi_5)$ PEC of **2** was obtained at the HF/3–21G level of theory. Surface points generated by 2D–PES scans were calculated at HF/3–21G level of theory. All curves and surface points obtained were plotted using the Axum 5.0c program.

3. Results and discussion

When a planar moiety is twisted about a single bond with respect to a tetrahedral moiety, in principle six minima may appear. Some of these conformations are shown schematically in Scheme 4. In all cases shown, the methyl group was staggered (i.e., $\chi_1 = 60°$). For the case of ethyl benzene (29) only two unique minima were shown to exist; one at $\chi_2 = 0°$ (the plane of the phenyl ring eclipsed with the C—C bond) and the other one at $\chi_2 = 90°$ (the plane of the phenyl ring being perpendicular to the C—C bond). The global minimum was found to be the one in which the planar moiety was perpendicular to the C—C bond ($\chi_2 = 90°$). Of course, both of these minima occurred twice in full 360° rotation due to the fact that the two sides of the benzene ring were identical. The potential energy curve of the other symmetrical compound, namely the propionate ion, is the exact mirror image of that associated with ethyl benzene, where the minimum of one is the maximum of the other (Fig. 1). The two asymmetrical compounds, propionic acid and

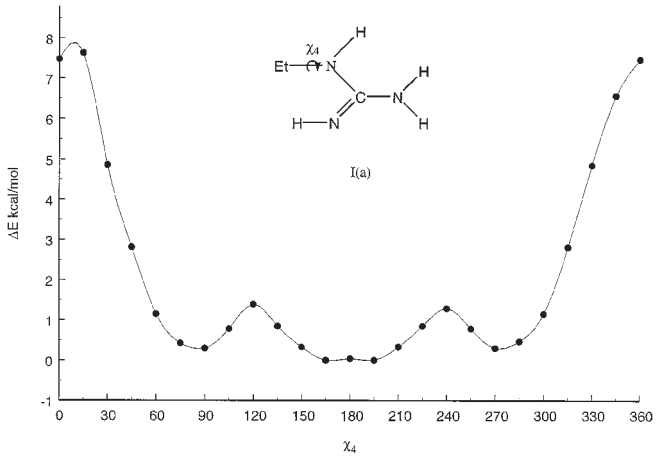
propionamide, give rise to a global minimum when they are in the *anti* conformation and local minima in the *gauche* conformations. (Fig. 2)

In the case of ethylguanidine (**1**) and the ethylguanidinium ion (**2**), there are two torsional angles χ_3 and χ_4. The dihedral numbering is in accord with the amino acid convention (corresponding to χ_1 and χ_2 in ethylbenzene). These are two kinds of bonds, C—C and C—N, with respect to which the guanidine group could be either eclipsed or perpendicular.

3.1 Energetic considerations

3.1.1 Ethylguanidine

Figure 3 shows the torsional potential, with varying χ_4, for ethylguanidine in its *s-cis*/*exo* **1a** structure calculated using the HF/6–31G level of theory. The global minimum occurs at 180° (the *anti* form). For all four structures (**1a**, **1b**, **1c**, and **1d**) g^+, a, and g^- were shown to have energy minima. We optimized these minima using three levels of theory (Hartree Fock 3–21G, 6–31 G, and DFT/B3LYP). The results are summarized in Table 1.



The ethyl rotation as characterized by the PES of the type $E = E(\chi_3, \chi_4)$ for the structures **1a**, **1b**, **1c**, and **1d** are presented in Figs. 4, 5, 6, and 7 respectively. Although the four surfaces are noticeably different, the three-fold periodicity of the CH_3 rotation (along χ_3) is fully apparent. The relative stabilities of these $4 \times 3 = 12$ structures are illustrated in Fig. 8. One can observe that the *gauche* conformation of **1b** is the global minimum, and that its *anti* conformation is of a relatively low energy comparing to the other three *anti*

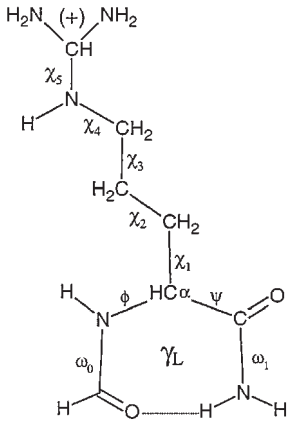
forms. The *anti* conformation of **1d** is highest in energy. It is also interesting to note that the energy difference between the *anti* and *gauche* forms of **1d** is the greatest, whereas this energetic difference is the smallest in **1b**.



3.1.2 Ethylguanidinium ion

The protonated form of the ethylguanidine (**1**) is the ethyl guanidinium ion (**2**). Due to the internal symmetry of the N-$C(NH_2)_2^+$ moiety, this species has only one arrangement, unlike **1** which has four: **1a**, **1b**, **1c**, and **1d**. Consequently, only the ethyl rotation $E = E(\chi_3, \chi_4)$ is important, of which the 1D cross-section $E = E(\chi_4)$ predominates. The energy values for the 1D-scan are computed at the HF/3–21G level of theory. This PEC is depicted in Fig. 9. The $E = E(\chi_3, \chi_4)$ PES is depicted in Fig. 10. The PEC has a pattern similar to those seen in Fig. 2. Another PEC cross-section of the PEHS $E = E(\chi_5)$ is of particular interest since it interconnects the *s-cis* and *s-trans* conformers. However, in the case of the

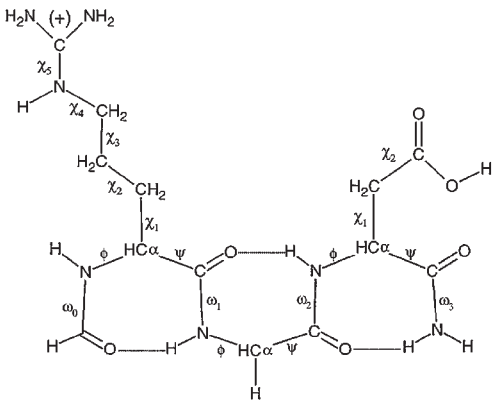
protonated form they become degenerate as shown in Fig. 11. It is interesting to note that the curve (Fig. 11) is analogous to that of Et-COO(-) of Fig. 1. The principal results of the geometry optimizations achieved at these levels of theory are summarized in Table 2.



For the proton affinity (PA) we may recognize that a number of values may be calculated. There is only one PEC for the protonated form (**2**) but there are four PECs for (**1**). Two vertical proton affinity values may be identified using these PECs. The two vertical ones involve g→g and a→a. These values are summarized in Table 3.

The first ab initio proton affinities were computed in Toronto (30) in 1968. A collection of relative proton affinities was compiled by Lias et al. (31) in 1984. In 1993, Radom (32) provided state-of-the-art calculation of various proton affinities, some of which involved saturated nitrogen compounds. Note that the present proton affinities are generated for illustrative purposes only and not for state of the art

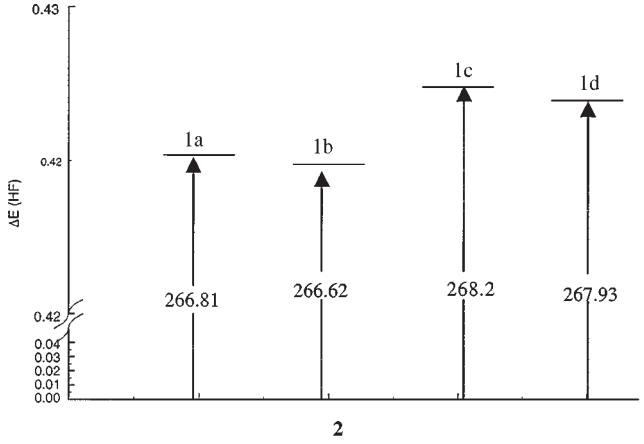
accuracy. It is worthy to mention, however, that at least the trend in proton affinities is apparent when one compares the values at the HF level with those of the DFT level of theory. These values are to show that different conformations give different proton affinities. Proton affinity is defined with a positive sign and is actually the deprotonation energy of the conjugated acid. The a→a and the g→g vertical deprotonation energies are shown in Fig. 12 and Fig. 13 respectively. In this way, one can determine the order of relative acidities of the four protons in the guanidinium ion (Fig. 14).

Proton affinities of amino acids are studied in detail (33) and the deprotonation of side chain protonated arginine (34) has also been investigated. It has also been pointed out that the proton at the first N—H bond of side chain-protonated

Fig. 12. Vertical proton affinity values for the transition a→a calculated at HF/6-31G.



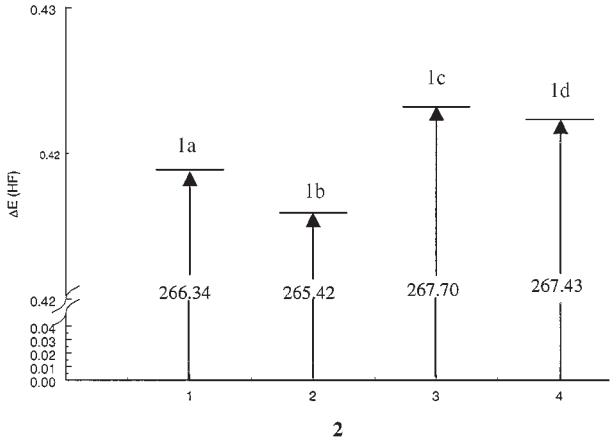


Fig. 13. Vertical proton affinity values for the transition g→g calculated at HF/6-31G.

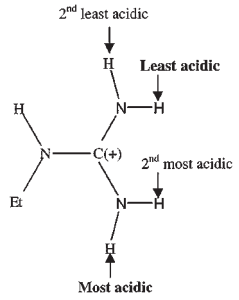
arginine (N^7—H^8 in **2**) can also deprotonate if the lone pair formed in the deprotonation is stabilized by backbone→side chain hydrogen bonding. Other reactions of the arginine side chain have also been investigated (19*b*, 35) recently.

3.2 Geometrical considerations

For the ease of identification of the various geometrical parameters, the symbolic *z*-matrix is given in Table 4. Tables 5, 6, 7, and 8 (Supplementary material)[3] summarize optimized geometrical parameters for **1a**, **1b**, **1c**, and **1d**. It may be interesting to compare how some parameters remain virtually unchanged with conformational variation while others vary noticeably.

Table 9 (Supplementary material)[3] gives the geometrical parameters for **2**. It is noteworthy to compare what happens to the C=N double bond of **1**, upon protonation, leading to ethylguanidinium ion (**2**).



3.2.1 Ethylguanidine

Ethylguanidine has four stereoisomeric forms, as shown in Fig. 8; they are *s-cis*/*endo*, *s-cis*/*exo*, *s-tran*/*endo*, and

Fig. 14. Hierarchy of acidity of the four protons of ethylguanidium ion.

s-trans/*exo*. The *cis–trans* relationship is assigned with respect to the orientation of the ethyl moiety around the torsional angle χ_5, and the *exo–endo* relationship is assigned according to the orientation of the hydrogen double bonded to the nitrogen (N^{10}=H^{11}). If the hydrogen is pointing out of plane, the isomer is assigned *exo*, with χ_6 = 180°; similarly, if the hydrogen is pointing towards the plane, the isomer is assigned *endo*, χ_6 = 0°. One can compare C^9=N^{10} (B9) and C^9—N^{12} (B11) bond lengths of **1** with the C—N bond lengths of **2**, and deduce the extent of the double bond nature. The C^9—N^{12} and C^9—N^{10} bond lengths (1.340) of **2** are between the lengths of the C^9=N^{10} bond and the C^9—N^{12} bond of **1**. The difference between these two bond lengths is the greatest in all three conformations of **1c**. So, the single bonds C^9—N^{10} and C^9—N^{12} of **2** have more "double bond" character than the single bond C^9—N^{12} of **1**.

3.2.2 Ethylguanidinium ion

While the guanidinium ion is symmetrical, ethylguanidinium is not. Presence of the ethyl moiety makes all five hydrogens of guanidinium ion inequivalent. The four hydrogens for deprotonation can lead to four isomers of the neutral ethylguanidine.

The lengths of N—H bonds of the guanidino end are identical, indicating that the positive charge is delocalized. It is also worth noting that N_{10}—H_{11} (B10) of **2** is the shortest of the four NH_2 hydrogens although H_{11} is the most acidic of the four (Fig. 14). Therefore, the N—H bond length is not governed by acidity (i.e., electronic effects), but rather by the orientation of the ethyl moiety (i.e., steric effects). N^{10}—H^{11} is *syn* with respect to the ethyl group and is therefore sterically the closest to the aliphatic group.

Cyclic five-membered phosphinate esters as transition state analogues for obtaining phosphohydrolase antibodies

Gabriel Hum, Krista Wooler, Jeremy Lee, and Scott D. Taylor

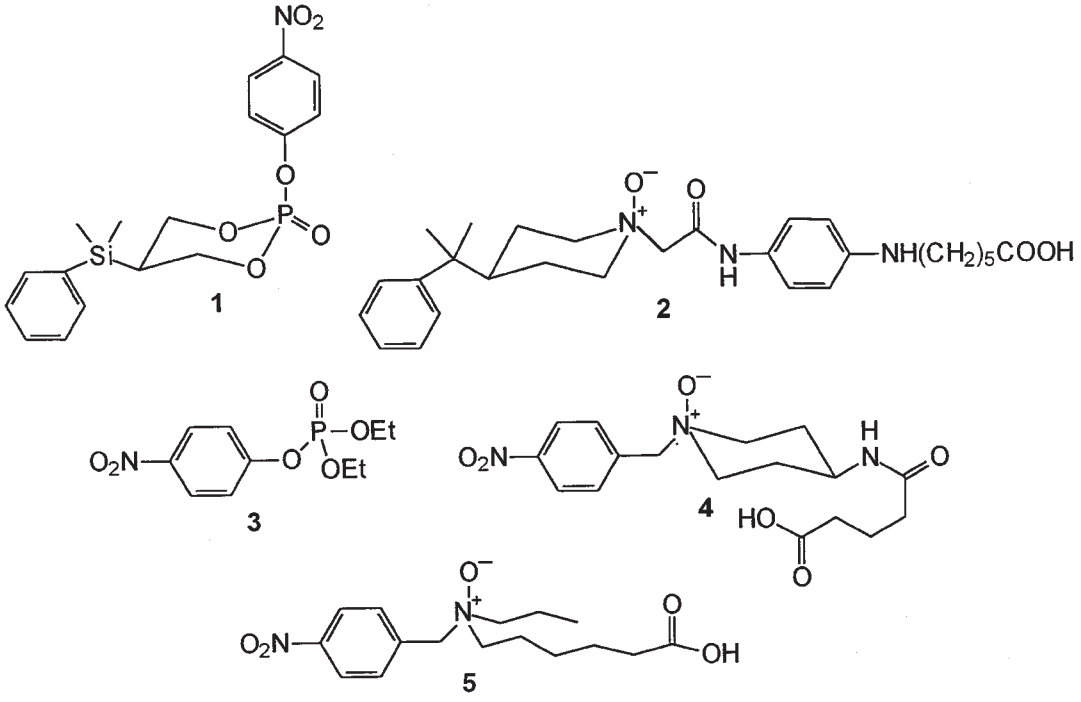
Abstract: Two novel cyclic five-membered phosphinate esters (**6** and **7**) were synthesized and used as transition state analogues (TSAs) for raising phosphohydrolase antibodies. The key step in the syntheses was a McCormack reaction between (2-chloroethyl)dichlorophosphite and 1,4-diphenyl-1,3-butadiene to form isomeric cyclic phosphinyl chlorides which upon further elaboration yielded the TSAs. X-ray crystal structures of two cyclic phosphinate TSA precursors (**14a** and **14b**) show highly compressed CPC bond angles of 94°–97° indicating that the CPC bond angles in **6** and **7** are significantly distorted towards the ideal trigonal bipyramidal equatorial–apical transition state angle of 90° formed during phosphate ester hydrolysis. Antibodies were raised to **6** and **7** using standard hybridoma technology. One antibody, Jel 541, an IgM class antibody, was obtained that was capable of catalyzing the hydrolysis of phosphonate substrate **9** and, to a much lesser extent, phosphate substrate **8**. This antibody bound TSA **6** approximately 100 times more tightly than TSA **7** as determined by solid phase radio immune assays. The activity of the antibody-catalyzed reaction was completely inhibited by the presence of TSA **6**. Although the relative instability and poor solubility of Jel 541 made it impossible to perform a detailed kinetic analysis of the antibody-catalyzed reactions, these results demonstrate that phosphohydrolase antibodies can indeed be obtained using cyclic five membered phosphinates as haptens.

Key words: transition state analogues, phosphate ester hydrolysis, catalytic antibodies.

Résumé : On a réalisé la synthèse de deux nouveaux esters phosphinates formant un cycle à cinq chaînons (**6** et **7**) et on les a utilisés comme analogues de l'état de transition (AET) pour la production d'anticorps de la phosphohydrolase. L'étape clé de la synthèse est une réaction de McCormack entre le dichlorophosphite de 2-chloroéthyle et le 1,4-diphénylbuta-1,3-diène pour former les chlorures de phosphinyle cycliques isomères qui, par réaction ultérieure, conduisent aux AET. Les structures cristallines des deux phosphinates cycliques précurseurs dAET (**14a** et **14b**), telles que déterminées par diffraction des rayons X, montrent que les angles de liaison CPC sont fortement comprimés (94–97°) et ceci indique que les angles de liaison dans les composés **6** et **7** sont fortement déformés vers l'angle idéal de 90° de l'état de transition trigonal bipyramidal équatorial-axial qui caractérise l'hydrolyse des esters phosphates. Des anticorps ont été produits à l'aide des produits **6** et **7** en faisant appel à la technologie hybridome standard. On a obtenu un anticorps, Jel 541, un anticorps de la classe IgM, capable de catalyser l'hydrolyse d'un substrat phosphonate **9** et, à un degré moindre, celle du substrat phosphonate **8**. Sur la base d'essais radioimmunologiques en phase solide, cet anticorps se lie à l'AET **6** environ 100 fois plus fortement que l'AET **7**. L'activité de la réaction catalysée par l'anticorps est complètement inhibée par la présence de l'AET **6**. Même si l'instabilité relative et la mauvaise solubilité du Jel 541 empêchent toute analyse cinétique détaillée des réactions catalysées par l'anticorps, ces résultats démontrent qu'il est possible d'obtenir des anticorps de la phosphohydrolase en utilisant des phosphinates cycliques à cinq chaînons comme haptènes.

Mots clés : analogues d'états de transition, hydrolyse d'esters phosphates, anticorps catalytiques.

Introduction



Recently, several reports have appeared describing antibodies capable of hydrolyzing phosphate triesters (1–4). Interest in generating these antibodies, as well as phosphonate-hydrolyzing abzymes, is mainly due to their potential as therapeutic agents in the treatment or prevention of organophosphorus poisoning such as paraoxon, tabun, sarin etc. The most common means of obtaining catalytic antibodies is to raise antibodies to compounds that mimic the transition state of the reaction of interest. In general, phosphate triesters and phosphonate diesters hydrolyze via pentavalent,

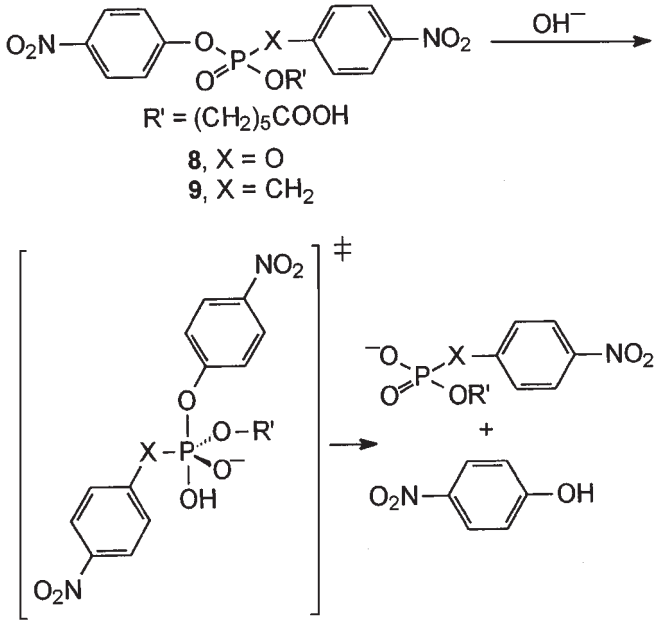
trigonal bipyramidal (TBP) transition states or intermediates (5). However, most TBP species are either too toxic or too unstable in aqueous solution to be used as haptens for immunization. Consequently, recent reports on phosphotriesterase antibodies have utilized a bait and switch approach (1–4) using tetrahedral N-oxides as transition state analogues (TSAs). For example, Rosenblum et al. (1) have reported antibodies capable of catalyzing the hydrolysis of the phosphotriester **1** with a rate enhancement of ~360-fold by raising antibodies to the N-oxide **2**. Janda and coworkers (2–4) have reported the generation of antibodies capable of catalyzing the hydrolysis of the insecticide paraoxon, **3**, utilizing employing N-oxides **4** and **5** as haptens. With the cyclic hapten **4**, the largest rate enhancement obtained was ~500-fold (2, 3). The rate enhancement was only 56-fold using the less constrained hapten **5** (4). On the basis of these results, Janda and coworkers (4) concluded that constrained haptens elicit superior catalysts for paraoxon hydrolysis.

As part of our research program on antibody-catalyzed reactions, we became interested in examining new haptens for obtaining phosphohydrolase antibodies. It has been known for many years that phosphate or phosphonate esters contained in a five-membered ring can be as much as 10^8-times more reactive than their acyclic analogues (5–8). This phenomenon has been studied in detail and has been attributed mainly to these species having strained bond angles at phosphorus approaching that of the ideal TBP equatorial–apical transition state configuration (5–9). Applying this knowledge to TSA design, we propose that cyclic five-membered phosphinic acids could be used as TSAs for raising phosphohydrolase abzymes. To test this strategy we have designed two isomeric cyclic 5-membered phosphinate esters, **6** and **7**, as TSAs for the hydrolysis of model phosphonate and phosphate esters **8** and **9** (Scheme 1). Several features of these TSAs warrant mention. First, compounds **6** and **7** should have highly compressed endocyclic C—P—C bond angles of



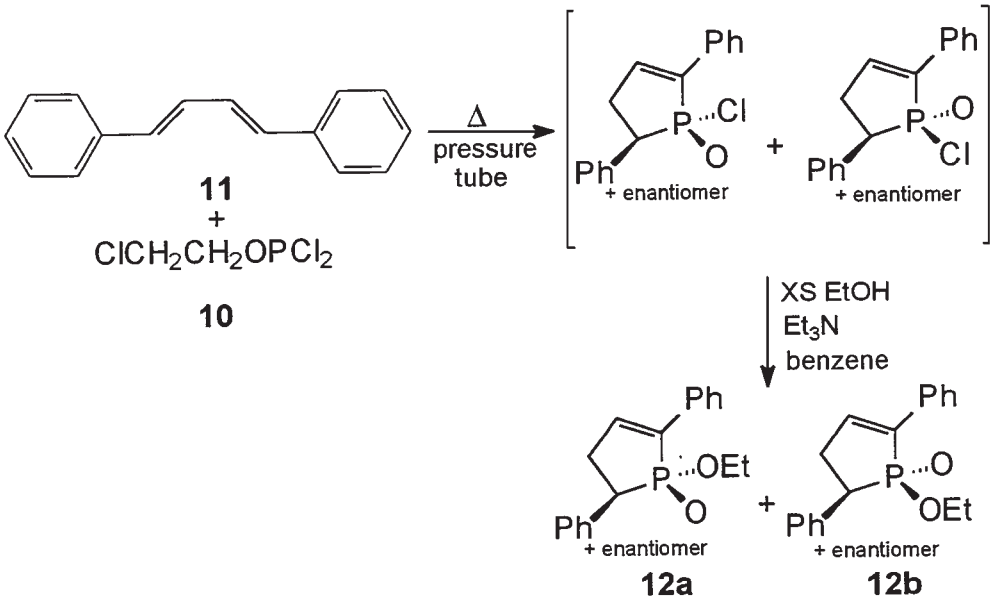
about 95°–98° (9, 10). Thus, when antibodies raised to **6** or **7** bind acyclic substrates **8** or **9**, the ArX—P—OAr bond in **8** or **9** will be compressed from the unstrained tetrahedral angle (109°) to a strained angle of 95°–98° (towards the optimal unstrained TBP transition state angle of 90°) analogous to that found in the highly reactive cyclic, five-membered phosphate and phosphonate esters. This will result in the induction of strain or stress upon the bound substrate thus preventing the substrate from falling into a thermodynamic "pit" upon binding to the abzyme. Attack of hydroxide or water at phosphorus will result in the formation of the unstrained TBP transition state. Second, although **8** and **9** are neutral, the highly polar nature of the phosphoryl bond (11) should result in the generation of complementary residues in

© 2000 NRC Canada

the antibody binding site which will aid in the stabilization of the negatively charged TBP transition state. Third, by utilizing both the *trans* (**6**, phenyl groups *trans* to one another) and *cis* (**7**, phenyl groups *cis* to one another) isomers of the TSA, crucial antigenic determinants can be ascertained. For example, if an antibody raised to the *cis* hapten binds equally well to the *trans* hapten (or vice versa) then this would imply that the antibody does not bind strongly to both phenyl rings and would probably not catalyze the reaction. Finally, both TSAs have a hexanoic acid linker arm for attaching the TSAs to carrier proteins which is necessary for immunization. The linker arm is attached to the phosphorus atom and not the aryl rings to minimize any interference by the linker arm with antibody recognition of the aryl rings.

In this report we present the synthesis of *trans* and *cis* 2,5-diarylphospholanate TSAs (**6** and **7**) and our attempts to obtain phosphohydrolase antibodies using these compounds as haptens.

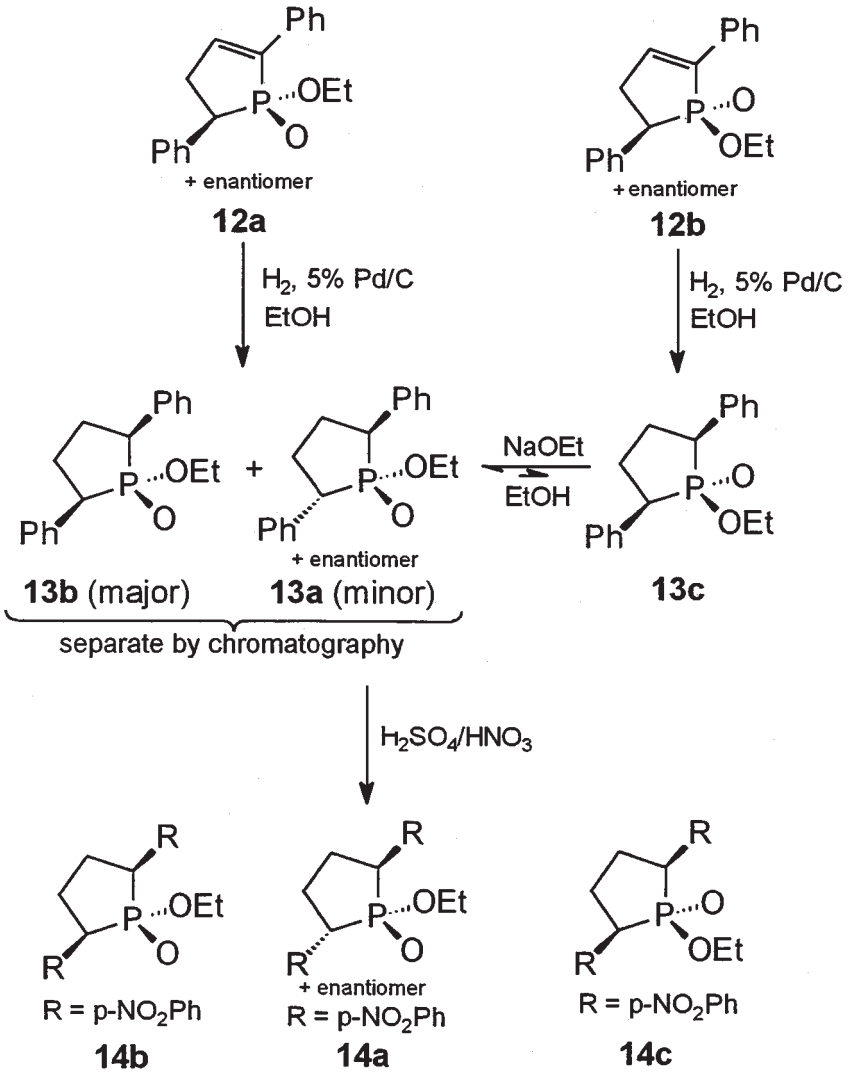
Scheme 1.



Results and discussion

Synthesis of transition state analogues 6 and 7

Although there are a variety of methods for synthesizing cyclic five-membered phosphinates (12, 13), we chose to employ a McCormack reaction since this is the most common and versatile means of constructing this class of compounds (13, 14). The McCormack reaction involves a cycloaddition reaction between a P(III) halide or in situ-generated phosphenium ion (15) and a 1,3-diene. Although this reaction usually proceeds more readily with phosphenium ions, we chose instead to employ Moedritzer's modification (16) of the McCormack reaction, which employs 2-chloroethyldichlorophosphite as the P(III) halide and directly produces cyclic phosphinyl chlorides which can be reacted in situ with alcohols to form the esters. For our purposes, 1,4-diphenyl-1,3-butadiene would be employed as the diene. However, there are very few examples in the literature of McCormack reactions between 1,4-diaryl-1,3-butadienes and P(III) halides and, in all cases reported to date, only alkylphosphonic dichlorides have been used yielding phospholes (17–19) or phospholenium salts (20). McCormack reactions between diaryl-1,3-butadienes and chlorophosphites have never been reported.



McCormack reactions are usually carried out neat or in an aprotic solvent, such as benzene, at room temperature or, more rarely, under reflux conditions (13). However, we were unable to detect any reaction between 2-chloroethyldichlorophosphite, **10**, and 1,4-diphenyl-1,3-butadiene, **11**, when performed neat (with heating) or in refluxing benzene. This is most probably due to both steric effects and the deactivating effect of the phenyl groups on the cycloaddition reaction

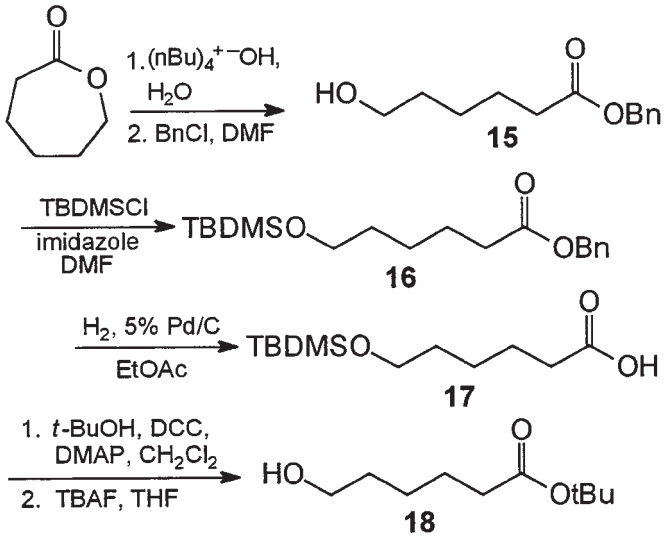
Scheme 3.

(14).[3] However, performing the reaction in a pressure tube at 170°C (neat) or 175°C (benzene as solvent) followed by reaction of the crude reaction mixture with excess ethanol in benzene and 1 equiv. of triethylamine, yielded the 2,3-dihydro cyclic phosphinate products **12a** and **12b** (Scheme 2) in an overall yield of 30–37%. Although a McCormack reaction of this type usually yields the 3,4-dihydro products, the formation of the 2,3-dihydro products **12a** and **12b** was not entirely unexpected since studies by other workers have shown that double bond migration sometimes occurs when McCormack reactions are conducted at high temperatures (13, 21). Isomers **12a** and **12b** could be separated using silica gel chromatography yielding the *trans* isomer, **12a**, (phenyl group and ethoxy group *trans* to one another) and *cis* isomer, **12b** (phenyl group and ethoxy group *cis*) in a 1:1 ratio if performed neat or 2:1 in favor of **12a** if performed in benzene.



The *cis–trans* relationship of the ethoxy and phenyl groups in **12a** and **12b** was readily determined by conventional ^{1}H NMR spectroscopy. In the *trans* isomer, **12a**, the methyl and methylene protons of the ethoxy group appear as a triplet at δ 1.15–1.25 and as a complex multiplet at δ 3.9–4.3 respectively and these chemical shifts are typical of ethoxy groups in most simple ethoxy phosphinates. However, with the *cis* isomer, **12b**, the methyl protons appear as a triplet at δ 0.85–0.95, considerably further upfield than those of the *trans* isomer. In addition, the methylene protons appear as *two separate multiplets*, one proton at δ 3.7–3.95 ppm and the other at δ 3.4–3.65, again considerably further upfield than those of the *trans* isomer. The upfield shift of these protons in the *cis* isomers is a result of the shielding effect of the phenyl moiety that is located at the 5-position on the phospholene ring. This does not occur with the *trans* isomers since the ethoxy and phenyl ring are on opposite sides of the phospholene ring. A similar phenomenon has been reported with some 2-phenyl-2-phospholene-1-oxides (22).

Hydrogenation (5% Pd/C) of the *cis* phospholenate ester, **12b**, yielded the "all *cis*" phospholanate ester **13c** (both phenyl groups and the ethoxy group *cis* to one another) exclusively in 82% yield (Scheme 3). Hydrogenation of **12a**

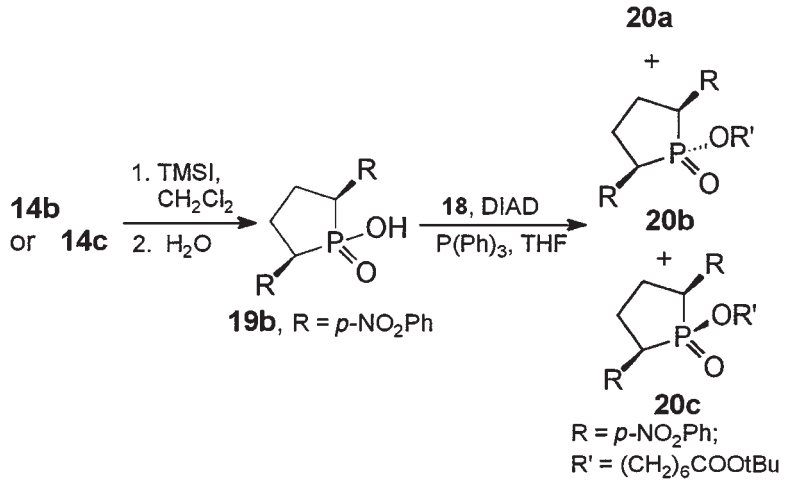
Scheme 5.

gave both the "phenyl *cis*" phospholanate ester, **13b**, (major product, the two phenyl groups *cis* to one another and the ethoxy group *trans* to the phenyl groups) and the "phenyl *trans*" phospholanate ester, **13a** as the minor product in an overall 99% yield. These two isomers could be readily separated from one another using conventional silica gel chromatography. We found that sufficient quantities of the phenyl *trans* isomer, **13a**, could be obtained by isomerization of either of the less stable *cis* esters, **13b** and **13c** in sodium ethoxide solutions. For example, a solution of pure **13b** was isomerized in a 0.5 M solution of sodium ethoxide in ethanol in just a few hours to yield mainly **13a**. This isomerization could be followed by ^{31}P NMR. After equilibrium is reached, the reaction was quenched with mild acid and two isomers were readily separated using conventional silica gel chromatography. Esters **13a**–**c** were bis-*para*-nitrated to form **14a**–**c** in moderate to good yields (55% for **14a**, 64% for **14b**, and 75% for **14c**, Scheme 3) employing classical nitration conditions (HNO_3/H_2SO_4).

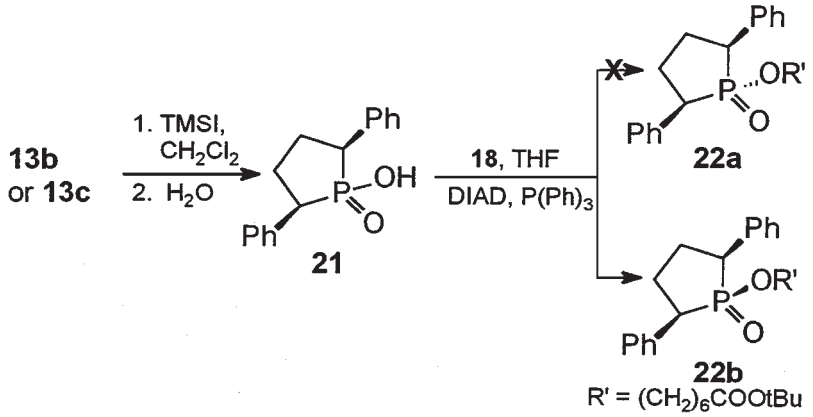
The all *cis* isomers (**13c** and **14c**) and phenyl *cis* isomers (**13b** and **14b**) could be readily distinguished from the phenyl *trans* isomers (**13a** and **14a**) since the *cis* isomers are symmetrical meso compounds and their phospholane ring carbons appear as only two sets of doublets in the ^{13}C NMR as opposed to four sets of doublets for the unsymmetrical phenyl *trans* ester. The all *cis* and phenyl *cis* isomers were readily distinguished on the basis of their ^1H NMRs. For example, in the all *cis* isomer, **13c**, the methylene protons of the ethoxy group appear considerably more upfield (δ 3.19–3.35) than is normally found with a phosphorus ethyl ester (typically δ 3.9–4.4) due to the shielding effect of the phenyl rings and are even further upfield than the benzylic phospholane ring protons (δ 3.33–3.51). In the case of the phenyl *cis* isomer, **13b**, the ethyl group is on the opposite side of the phospholane ring as the phenyl groups. Thus, the methylene protons appear much further downfield and have chemical shifts that one would expect to have for a "normal" phosphinate ethyl ester (δ 3.94–4.12) and are much further downfield than the benzylic protons (δ 3.2–3.4). The stereochemical relationship between the ethoxy and phenyl groups in all subsequent phospholanate esters reported in this study were readily determined in the same manner simply by examining the chemical shift of the -CH_2-O-P protons and by ^{13}C NMR.

A *tert*-butyl-protected linker arm was prepared as shown in Scheme 4. Thus, caprolactone was reacted with tetrabutylammonium hydroxide in water to form the carboxylate salt, followed by reaction with benzyl chloride in DMF to give the hydroxyester **15** in an overall yield of 89%. Compound **15** was converted to a *tert*-butyl ester protected linker arm by first protecting the alcohol moiety as the TBDMS ether (**16**, 92%) followed by hydrogenolysis to obtain the acid **17** (87% from **15**). The acid was converted into the *tert*-butyl ester using DCC–DMAP and *t*-butanol and the silyl protecting group removed using TBAF to give the *tert*-butyl ester protected linker arm **18** (38% from **17**).



Trans ester, **14a**, was converted into the free acid, **19a**, using TMSI followed by hydrolysis of the resulting TMS ester in an overall yield of 90% (Scheme 5). The linker arm was attached via a Mitsonobu reaction (23) between **19a** and **18** to give the protected racemic TSA **20a** in an 80% yield. Removal of the *t*-butyl group using 20% TFA in CH_2Cl_2 proceeded smoothly to give the *trans* TSA, **6** (80% yield).

Compounds **14b** or **14c** were converted into the *cis* free acid **19b** using the same procedure described for the *trans* acid **19a** (Scheme 6). However, Mitsonobu coupling of **18** to **19b** proceeded very sluggishly. Partial purification of the reaction mixture revealed that approximately equal amounts of isomers **20a**–**c** were formed (Scheme 6) in an overall low yield (45% yield). The fact that all possible isomers (**20a**–**c**) were obtained suggested that not only was isomerization taking place, but that at least some of the all *cis* isomer **19c** was formed initially. This was confirmed by performing the Mitsonobu reaction with the unnitrated acid, **21**, which yielded *exclusively the all cis ester,* **22b** in a 60% yield (Scheme 7). It also appears that the presence of the nitro groups in **19b** are responsible for the isomerization (by increasing the acidity of the benzylic protons on the phospholane ring) and that this occurs fairly readily.



Since the Mitsonobu procedure with **19b** produces a mixture of isomeric products, an alternative method for attaching the linker arm was necessary. We attempted to synthesize

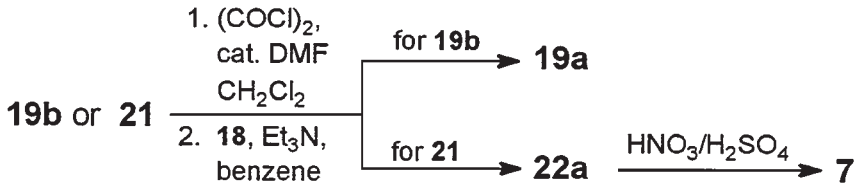
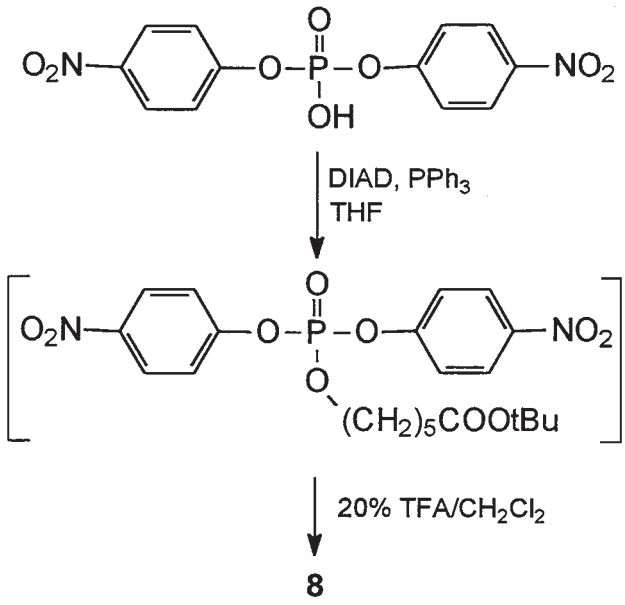


Scheme 6.

Scheme 7.

Scheme 8.



20b by converting **18b** into the acid chloride using oxalyl chloride and cat. DMF, followed by reaction with **18** in the presence of 1.0 equiv. amine base in benzene (Scheme 8). However, isomerization occurred during the reaction and the undesired "aryl *trans*" ester, **20a**, was the predominant product. However, this was not the case with the unnitrated acid **21** which yielded exclusively the desired phenyl *cis* ester **22a** in a 54% yield. To obtain the *cis* TSA **7**, we subjected **22a** to HNO_3–H_2SO_4 (Scheme 8) which we anticipated would result in both ring nitration and loss of the *tert*-butyl protecting group. This was successful, yielding TSA **7** in a 45% yield and no products resulting from isomerization were obtained.

Crucial to the success of our approach to obtaining phosphohydrolase antibodies is that the CPC bond angle in TSAs **6** and **7** is compressed towards the optimal TBP transition state angle of 90°. To our knowledge, the only report describing a crystal structure of a saturated phospholanate is that of phospholanic acid, obtained by Alver and Kjoge (9) in 1969. The CPC bond angle was reported to be 94.8°. Since it was possible that the CPC bond angles in TSAs **6** and **7** may differ significantly from that found in phospholanic acid due to the presence of the aryl groups at positions 2 and 5 in the phospholanate ring and the ester linkage, we obtained the crystal structures of the TSA precursors, **14a** and **14b**. The CPC bond angle for **14a** is 97.4° while that for **14b** is 94.0°. It is unlikely that replacing the ethyl group in **14a** or **14b** with the linker arm found in TSAs **6** and **7** would result in a significant change in the endocyclic CPC bond angles. Thus, it may be concluded that the CPC bond angles in **6** and **7** are significantly distorted or strained towards the optimal unstrained TBP transition state angle of 90°.

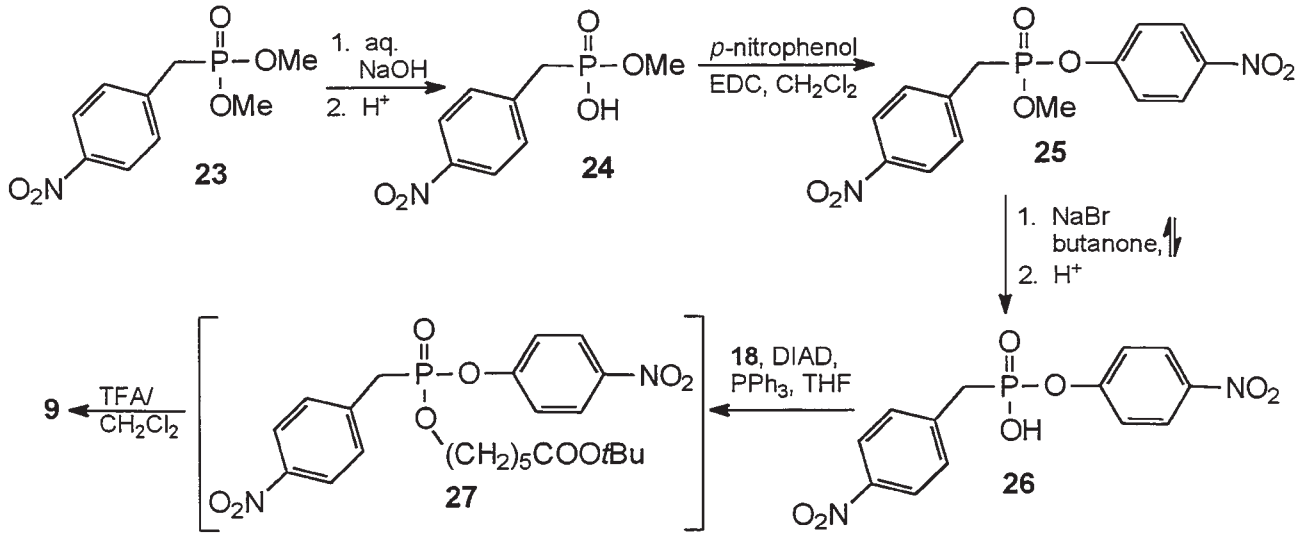
Scheme 9.

Synthesis of substrates 8 and 9

Phosphate ester substrate **8** was synthesized by coupling linker arm **18** to bis(*p*-nitrophenyl)phosphate using a Mitsonobu reaction followed by removal of the *tert*-butyl protecting group from the crude ester using TFA (73% overall yield, Scheme 9).

Phosphonate ester substrate **9** was synthesized as outlined in Scheme 10. Thus, hydrolysis of phosphonate **23** in aqueous NaOH followed by acidification gave the phosphonic acid **24** in 90% yield. EDC coupling of *p*-nitrophenol to **24** gave the ester **25** in 64% yield. Reaction of **25** with NaBr in refluxing butanone followed by acidification gave phosphonic acid **26** in 93% yield. The linker arm **18** was attached to phosphonic acid **26** using a Mitsonobu reaction. The resulting ester **27** was not isolated in pure form but instead the crude was reacted with TFA–CH_2Cl_2 to give substrate **9** (64% from **26**).



The half-lives of **8** and **9** in 10 mM CHES buffer, 50 mM NaCl at pH 9.0, were determined using spectrophotometry by measuring the increase in absorbance at 400 nm. Under these conditions, the half life of the phosphate **8** was 14 h while that of the phosphonate **9** was 29 h.

Antibody production and catalytic screening

Compounds **6** and **7** were coupled to carrier proteins BSA and KLH for monoclonal antibody production and screening by converting their carboxylic acid moieties to activated esters using *N*-hydroxy sulfosuccinimide and EDC as coupling agent followed by reaction of the resulting activated esters with BSA or KLH in 50 mM phosphate buffer. Monoclonal antibodies to each hapten (KLH conjugates) were raised using standard hybridoma technology (24). After propagation and subcloning of the hybridomas, seven hybridoma cell lines were obtained that produced antibody capable of binding the TSAs as determined by solid phase radio immune assays (SPRIA). Isotyping of the seven antibodies revealed that three were IgM's and four were IgG's. Only one of these antibodies, Jel 541, was able to distinguish, in terms of binding affinity, between the *trans* TSA and *cis* TSA, exhibiting a greater affinity for the *trans* hapten than the *cis* hapten. Surprisingly, Jel 541 was obtained from mice immunized with the *cis* hapten. To determine if this may have been due to isomerization of the *cis* hapten to the thermodynamically more stable *trans* hapten during the immunization process, *cis* hapten **7** was incubated in 50 mM phosphate buffer at pH 7.5, and then examined for the formation of the *cis* TSA **6** by HPLC over a period of one week. After 1 week, 8% of **7** had isomerized to **6**. These results suggest that some isomerization of the *cis* to the *trans* hapten occurred during the eight week immunization process.

The hybridomas clones were grown intraperitoneally in mice and the antibodies purified from ascitic fluid. Competitive SPRIA experiments with purified Jel 541 indicated that Jel 541 bound the *trans* TSA approximately 100 times more tightly than the *cis* TSA. All seven antibodies were screened for activity by incubating the antibodies (~5 μM) with substrates **8** or **9** (500 μM) in 10 mM HEPES buffer at pH 7.0

Scheme 10.

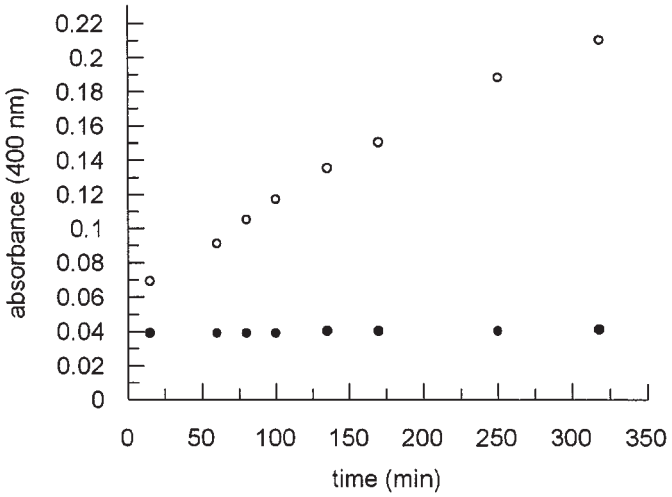
Fig. 1. Hydrolysis of phosphonate substrate **9** (0.5 mM) in 10 mM HEPES, 50 mM NaCl, pH 7.0 by buffer alone (●), 5 μM Jel 541 (○).



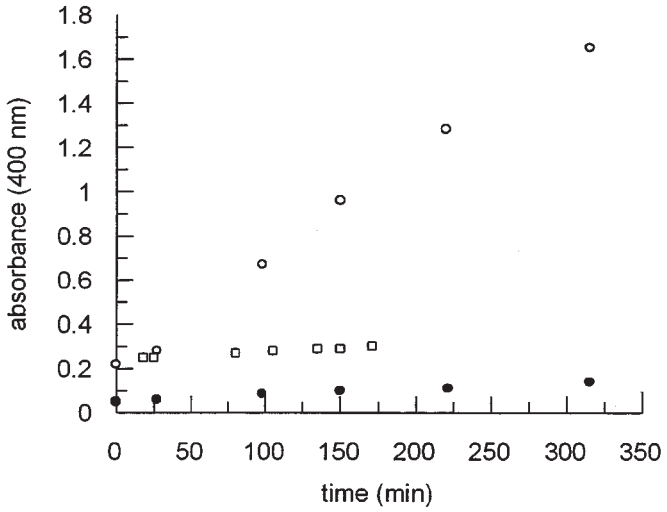


Fig. 2. Hydrolysis of phosphonate substrate **9** (0.5 mM) in 10 mM CHES, 50 mM NaCl, pH 9.0 by buffer alone (●), 5 μM Jel 541 (○), 5 μM Jel 541 + 0.5 mM TSA **6** (□).

and determining the absorbance of the reaction solution at 400 nm at various time intervals over a period of several hours. Only Jel 541, one of the IgM class antibodies, catalyzed the hydrolysis of phosphonate **9** (Fig. 1) This antibody was also capable of functioning at pH 9.0 (Fig. 2). Jel 541 also catalyzed the hydrolysis of the phosphate substrate **8** (data not shown) at pH 9.0 but to a much lesser extent than the phosphonate substrate. This result is consistent with the fact that the phosphonate substrate is structurally more similar to the hapten than the phosphate substrate. The possibility that the observed activity was due to contamination by an unknown murine phosphatase can be excluded for the following reasons. First, none of the other antibodies obtained in this study showed activity yet were prepared in an identical manner to Jel 541. Second, the catalytic activity of Jel 541 is completely inhibited by the presence of the *trans* TSA (Fig. 2). Although it is clear that Jel 541 is capable of catalyzing the hydrolysis of the substrates, the relative instability and poor solubility of Jel 541 has prevented us from performing an accurate and detailed kinetic analysis. Consequently, we have been unable to determine the basic kinetic parameters (k_{cat}/k_{uncat}, K_m etc.) of the abzyme. These are common problems when dealing with IgM class antibodies (25) which have molecular weights of approximately 10^3 kDa. To avoid some of the problems associated with IgM Mabs, we attempted to convert Jel 541 Mab into a more soluble Fab fragment by digesting the Mab with trypsin in the presence of a reducing agent such as cysteine followed by alkylation with iodoacetamide and purification (25). However, we were unable to obtain significant quantities of pure Fab using this procedure. It is clear that an IgG class abzyme will have to be obtained to fully assess the viability of our approach to phosphohydrolase abzymes.

Summary

In summary, two novel phospholanates **6** and **7** were prepared and used as TSAs for obtaining phosphohydrolase antibodies. One IgM class antibody, Jel 541, was obtained that catalyzed the hydrolysis of the phosphonate substrate **9** and to a much lesser extent the phosphate substrate **8**. Although it was not possible to characterize Jel 541 in detail, these results demonstrate that phosphohydrolase antibodies can indeed be obtained using haptens such as **6**. We are currently attempting to obtain more IgG class monoclonal antibodies to **6**, since this class of antibodies are much easier to characterize than IgM class antibodies and will allow for a more complete assessment of this approach to obtaining phosphohydrolase abzymes.

Experimental

General

All starting materials for organic synthesis were obtained from commercial suppliers (Sigma–Aldrich Canada, Oakville, Ontario, Canada or Lancaster Synthesis Inc., Windham, New Hampshire, U.S.A.) unless stated otherwise. Solvents were purchased from Caledon Laboratories (Georgetown, Ontario, Canada), Lancaster Synthesis Inc., or BDH Canada (Toronto, Canada). Reagents for hybridoma production were obtained from Gibco-BRL. Tetrahydrofuran (THF) and diethyl ether were distilled over sodium metal in the presence of benzophenone. Benzene and CH_2Cl_2 were distilled over calcium hydride. Ethanol was distilled over magnesium turnings. Dry chloroform was obtained by distillation over phosphorus pentoxide. All glassware was predried prior to use and all liquid transfers were performed using dry syringes and needles. Silica gel chromatography was performed on 40–60μ particle silica gel obtained from Toronto Research Chemicals (Toronto, Ontario, Canada). Melting points were obtained on a Electrothermal Inc. melting point apparatus and are uncorrected. ^1H and ^{31}P NMR spectra were recorded on a Varian 200-Gemini NMR machine at approximately 200 MHz, and 80 MHz respectively. ^{13}C NMR spectra were recorded on a Varian-500 NMR at 126 MHz or on a Varian 200-Gemini NMR machine at 50.3 MHz. The abbreviations s, d, t, q, qt, m, dd, and b are used for singlet, doublet, triplet, quartet, quintet, multiplet, doublet of doublets and broad respectively. Coupling constants are reported in Hertz (Hz). All NMRs were run using

© 2000 NRC Canada

$CDCl_3$ as solvent unless stated otherwise. Chemical shifts (δ) for ^1H NMR spectra run in $CDCl_3$ are reported in ppm relative to the internal standard tetramethylsilane (TMS). Chemical shifts (δ) for ^1H NMR spectra run in CD_3OD are reported in ppm relative to residual solvent protons (δ 4.87). Chemical shifts (δ) for ^1H NMR spectra run in $DMSO_{d-6}$ are reported in ppm relative to residual solvent protons (δ 2.50). For ^{13}C NMR spectra run in $CDCl_3$, chemical shifts are reported in ppm relative to the $CDCl_3$ residual carbons (δ 77.0 for the central peak). For ^{13}C NMR spectra run in $DMSO_{d-6}$, chemical shifts are reported in ppm relative to the DMSO residual carbons (δ 39.5 for the central peak). For ^{31}P NMR spectra, chemical shifts are reported in ppm relative to 85% phosphoric acid (external). Electron impact (EI) mass spectra were obtained on a Micromass 70-S-250 mass spectrometer. HPLC purifications and hapten isomerization studies were performed on a Waters LC 450 System equipped with an Waters 2487 absorbance detector using an Altech normal phase silica preparative HPLC column (250 mm × 22 mm i.d. with 10 μ Econosil silica, cat. no. 6259) or an Altech normal phase analytical HPLC column (10 μ Econosil silica, cat. no. 60090). All of the phospholanate esters reported here were analyzed by HPLC using the above system equipped with the above mentioned Altech normal phase analytical HPLC column and were found to exhibit a single peak in the HPLC chromatogram.

*(±)-*trans*-1-Ethoxy-2,5-diphenyl-2,3-dihydro-1*H*-1λ^5-phosphol-1-one (**12a**) and (±)-*cis*-1-ethoxy-2,5-diphenyl-2,3-dihydro-1*H*-1λ^5-phosphol-1-one (**12b**)*

Method A: 1,4 Diphenyl-1,3-butadiene (2.06 g, 10 mmol, 1 equiv.) was combined with 2,6-di-*tert*-butyl-4-methyl phenol (10 mg, 2 mol%) in a 15 mL ACE Glass pressure tube (cat. no. 8648–75) equipped with a stir bar and then flushed thoroughly with Ar. Phosphorous trichloride (0.545 mL, 6.33 mmol, 0.66 equiv.) and tris(2-chloroethyl) phosphite (0.635 mL, 3.33 mmol, 0.33 equiv.) was added to the tube under a stream of Ar. The glass bomb was rapidly sealed and the thick, mainly solid mixture was vigorously shaken by hand for about 30 s to mix the contents. The tube was immersed in an oil bath, stirred vigorously, and slowly heated to 170°C and maintained at this temperature for 19 h during which time the solid diene melted and the solution reaction became an orange colour. **CAUTION: This procedure must be performed in a fumehood behind a blast shield.** In addition to several broad beaks, the ^{31}P NMR of the crude reaction mixture exhibited two sharp peaks of approximately equal magnitude at 68.6 and 69.7 ppm. After removing the oil bath and allowing the tube to cool to room temperature, the tube was fitted with a septum and dry benzene (20 mL) was added to the crude reaction mixture under argon. The solution was transferred very slowly over a period of 30 min via syringe to an ice cold solution of dry ethanol (5.8 mL, 100 mmol, 10 equiv.) and triethylamine (1.7 mL, 10 mmol, 1 equiv.) in dry benzene (20 mL) and the reaction was stirred overnight at room temperature under Ar. The volume of the crude reaction mixture was reduced to one quarter by rotary evaporation and diluted with ether (75 mL) which resulted in the precipitation of triethylamine hydrochloride which was removed by suction filtration. The filter cake was washed with ether and the filtrate was washed with 0.1 N HCl (3 × 50 mL), 5% $NaHCO_3$ (3 × 50 mL), brine (3 × 50 mL), and then dried ($MgSO_4$) and concentrated in vacuo to yield a crude orange oil which was subjected to silica gel column chromatography. Flash chromatography (silica, 90% CH_2Cl_2 – 10% EtOAc, three columns required) of the crude reaction yielded **12a** as a pale yellow solid (577 mg, 19.2%). TLC (silica, 90% CH_2Cl_2 – 10% EtOAc): R_f = 0.4; mp 82–86°C. ^1H NMR δ: 1.23 (3 H, t, J = 6.9 Hz), 2.81–2.96 (1 H, m), 3.10–3.54 (2 H, m), 3.98–4.23 (2 H, m), 7.03 (1 H, t, J = 3.3 Hz), 7.42 (8 H, m), 7.65 (2 H, d, J = 6.2 Hz). ^{13}C NMR δ: 142.20 (d, J = 36.1),138.35 (br d), 136.95 (d, J = 4.6 Hz), 133.59 (d, J = 9.1 Hz), 128.70, 128.39 (d, J = 11.5 Hz), 126.96, 126.68 (d, J = 5.5 Hz), 61.58 (d, J = 6.4 Hz), 42.28 (d, J = 92.8 Hz), 35.57 (d, J = 17.8 Hz), 16.66 (d, J = 5 Hz). ^{31}P NMR δ: 60.41 (s). MS, *m*/*z* (relative intensity): 298 (64), 270 (36), 205 (100), 104 (31), 91 (41), 77 (30). HRMS calcd. for $C_{18}H_{19}O_2P$: 298.1123; found 298.1127. From the same column **12b** was obtained as a white solid (533 mg, 17.8%). TLC (silica, 90% CH_2Cl_2 – 10% EtOAc): R_f = 0.6; mp 102–104°C. ^1H NMR δ: 0.91 (3 H, t, J = 5.9 Hz), 2.84–3.93 (5.5 H, m), 7.08 (0.5 H, t, J = 3.75 Hz), 7.35 (8 H, m), 7.71 (2 H, d, J = 7 Hz). ^{13}C NMR δ: 142.23 (d, J = 35.7 Hz), 137.58, 136.12 (d, J = 6.5 Hz), 135.20, 133.14 (br d), 128.70 (d, J = 6.2 Hz), 128.34, 126.92, 126.66 (d, J = 3.7), 61.58 (d, J = 6.4), 43.44 (d, J = 90.6), 33.19 (d, J = 16.4) 16.16. ^{31}P NMR δ: 60.05 (s). MS, *m*/*z* (relative intensity) 298 (100), 270 (66), 254 (47), 205 (50), 194 (83), 91 (43), 77 (30). HRMS calcd. for $C_{18}H_{19}O_2P$: 298.1123; found 298.1134.

Method B: The above McCormack reaction can also be performed in a similar manner as described above using dry benzene as solvent (approximately 3 mL of benzene per gram of diene) and heating the reaction in the sealed tube for 72 h at 185°C. This procedure produces **12a** and **12b** in a 2:1 ratio in yields that are slightly higher that obtained by method A. **CAUTION: When performing the reaction using benzene as solvent, for safety reasons, the total volume of the reaction in the pressure tube must not be greater than half the total capacity of the pressure tube. The reaction must be performed in a fumehood behind a blast shield.**

*(±)-1-Ethoxy-*trans*-2,5-diphenyl-1λ^5-phospholan-1-one (**13a**) and (meso)-*trans*-1-ethyoxy-cis-2,5-diphenyl-1λ^5-phospholan-1-one (**13b**)*

A solution of **12a** (1.530 g, 5.03 mmol) in ethanol (20 mL) containing 10% Pd/C (100 mg) was hydrogenated overnight at 30 psi under a H_2 atmosphere using a Parr hydrogenation apparatus. The Pd catalyst was removed by filtration and the filtrate concentrated in vacuo leaving a pale yellow oil which was subjected to column chromatography (silica, 90% CH_2Cl_2 – 10% EtOAc) to give pure **13a** and **13b**. Overall yield was 99%. **13a** was obtained as a white solid (432 mg, 27%). TLC (silica, 90% CH_2Cl_2 – 10% EtOAc): R_f = 0.5; mp 103–105°C. ^1H NMR δ: 0.93 (3 H, t, J = 7.2 Hz), 2.07–2.60 (4 H, m), 3.09–3.52 (3 H, m), 3.66–3.85 (1 H, m), 7.35 (10 H, cm). ^{13}C NMR δ: 137.13 (d, J = 5.5 Hz), 128.70 (d, J = 5.5 Hz), 127.52, 126.68, 61.37 (d, J = 6.4 Hz), 43.59 (d, J = 85.1 Hz), 29.57 (d, J = 14.6 Hz), 16.69. ^{31}P NMR δ: 61.73 (s). MS, m/*z* (relative intensity): 300 (87), 206 (42), 196 (36), 104 (100), 91 (28), 78 (22).

HRMS calcd. for $C_{18}H_{21}O_2P$: 300.1279; found 300.1272. **13b** was obtained as a white solid (1.10 g, 72%). TLC (silica, 90% CH_2Cl_2 – 10% EtOAc): R_f = 0.3; mp 69–72°C. ^{1}H NMR δ: 1.24 (3 H, t, *J* = 7.1 Hz), 2.33–2.46 (4 H, m), 3.21–3.37 (2 H, m), 4.00 (2 H, m), 7.35 (10 H, m). ^{13}C NMR δ: 136.69 (bd), 136.22 (d, *J* = 2.7 Hz), 128.76, 128.56, 128.14 (d, *J* = 4.6 Hz), 126.81, 61.24 (d, *J* = 7.3 Hz), 46.68 (d, *J* = 84.1 Hz), 45.50 (d, *J* = 86.9 Hz), 30.40 (d, *J* = 12.8 Hz), 27.85 (d, *J* = 9.0 Hz), 16.26 (d, *J* = 4.6 Hz). ^{31}P NMR δ: 62.37 (s). MS, *m*/*z* (relative intensity): 300 (91), 206 (41), 196 (26), 104 (100), 91 (30), 78 (20). HRMS calcd. for $C_{18}H_{21}O_2P$: 300.1279; found 300.1294.

(meso)-cis-*1-Ethoxy*-cis-*2,5-diphenyl-1λ^5-phospholan-1-one (**13c**)*

A solution of **12b** (820 mg, 2.75 mmol) in ethanol (20 mL) containing 10% Pd/C (60 mg) was hydrogenated overnight at 30 psi under a H_2 atmosphere using a Parr hydrogenation apparatus. The Pd catalyst was removed by filtration and the filtrate concentrated in vacuo leaving a pale yellow solid. Column chromatography (silica, 100% EtOAc) yielded pure **13c** as a white solid (674 mg, 82%). TLC (silica, 100% EtOAc): R_f = 0.40; mp 133–137°C. ^{1}H NMR δ 0.64 (3 H, t, *J* = 7 Hz), 2.42 (4 H, m), 3.22–3.54 (4 H, m), 7.31 (10 H, m). ^{13}C NMR δ: 135.54 (d, *J* = 5.5 Hz), 128.41, 127.94 (d, *J* = 3.7 Hz), 126.63, 61.20 (d, *J* = 7.4 Hz), 43.96 (d, *J* = 82.4 Hz), 27.45 (d, *J* = 12.8 Hz), 15.90. ^{31}P NMR δ: 65.14 (s). MS, *m*/*z* (relative intensity): 300 (64), 206 (48), 196 (18), 104 (100), 91 (29), 78 (25)). HRMS calcd. for $C_{18}H_{21}O_2P$: 300.1279; found 300.1290.

*General procedure for the nitration of 2,5-diphenyl-1λ^5-phospholan-1-one esters **14a**,[44] **14b**,[4] and **14c***

To an ice cold solution of **13a**, **13b** or **13c** (100 mg, 0.33 mmol, 1 equiv.) in H_2SO_4 (1.5 mL) was added a solution of HNO_3:H_2SO_4 (1:1, 0.0180 mL, 0.86 mmol, 2.6 equiv. HNO_3) dropwise of a period of 1 min. The reaction was stirred at 0°C for 30 min and then poured into a beaker containing ice which upon melting left a suspension. $CHCl_3$ (20 mL) was added and the two layers were separated. The aqueous layer was further extracted with $CHCl_3$ (3 × 20 mL) and the combined organics were washed with brine (2 × 30 mL), dried ($MgSO_4$) and concentrated in vacuo leaving an oily solid residue. Pure nitrated esters (**14a**, **14b**, and **14c**) were obtained by either silica gel chromatography or recrystallization of the crude residue.

(±)-1-Ethoxy-trans-*2,5-di(4-nitrophenyl)-1λ^5-phospholan-1-one (**14a**)*: Obtained in 55% yield as a white solid from **13a** using the general procedure described above. Purification was achieved using flash chromatography (silica, 80% EtOAc – 20% hexane). TLC (80% EtOAc – 20% hexane): R_f = 0.70; mp 179–180°C. ^{1}H NMR δ: 0.98 (3 H, t, *J* = 7 Hz), 2.22 (2 H, m), 2.56 (2 H, m), 3.45 (3 H, m), 3.83 (1 H, m), 7.54 (4 H, dd, *J* = 8 Hz, *J* = 2.1 Hz), 9.24 (4 H, d, *J* = 8.4 Hz). ^{13}C NMR δ: 147.32, 144.00, 143.46 (br d, *J* = 13.8 Hz), 129.45 (d, *J* = 5.5 Hz), 128.90, 123.73, 62.10 (d, *J* = 5.4 Hz), 46.7 (d, *J* = 84.2 Hz), 45.5 (d, H = 86.1 Hz), 30.37, (d, *J* = 11 Hz), 27.73 (d, *J* = 11 Hz.), 16.30. ^{31}P NMR δ: 59.7 (s). MS, *m*/*z* (relative intensity): 390 (100), 362 (28), 296 (61), 149 (86), 119 (51), 103 (55), 77 (58). HRMS calcd. for $C_{18}H_{19}N_2O_6P$: 390.0981; found 390.0994.

(meso)-trans-*1-ethoxy-cis-2,5-di(4-nitrophenyl)-1λ^5-phospholan-1-one (**14b**)*: Obtained in 64% yield as a white solid from **13b** using the general procedure described above. Purification was achieved by recrystallization in EtOAc–hexane. mp 190–192°C. ^{1}H NMR δ: 1.24 (3 H, t, *J* = 7.2 Hz), 2.45 (6 H, m), 3.40 (2 H, m), 4.03 (2 H, m), 7.52 (4 H, dd, *J* = 2 Hz, *J* = 7 Hz), 8.22 (4 H, d, *J* = 8.7 Hz). ^{13}C NMR ($CDCl_3$) δ: 147.32, 144.16 (d, *J* = 5.4 Hz), 129.45, 123.73, 62.26 (d, *J* = 7.3 Hz), 43.66 (d, *J* = 86.1 Hz), 29.31 (d, *J* = 12.8 Hz), 16.60. ^{31}P NMR δ: 60.49 (s). MS, *m*/*z* (relative intensity): 390 (100), 362, (26), 296 (77), 148 (95), 119 (44), 103 (37), 77 (36). HRMS calcd. for $C_{18}H_{19}N_2O_6P$: 390.0981; found 390.0989.

(meso)-cis-*1-Ethoxy-cis-2,5-di(4-nitrophenyl)-1λ^5-phospholan-1-one (**14c**)*: Obtained in 75% yield as a white solid from **13c** using the general procedure described above. Purification was achieved using flash chromatography (silica, 100% EtOAc). TLC (silica): R_f = 0.3; white solid, mp 180–182°C. ^{1}H NMR δ: 0.65 (3 H, t, *J* = 7), 2.45 (4 H, m), 3.38 (2 H, m), 3.59 (2 H, m), 7.51 (4 H, dd, *J* = 2.2 Hz, *J* = 9.1 Hz), 8.21 (4 H, d, *J* = 8.8 Hz). ^{13}C NMR δ: 147.28, 143.54 (d, *J* = 8.2 Hz), 128.63 (d, *J* = 4.6 Hz), 123.62, 62.15 (d, *J* = 7.3 Hz), 44.10 (d, *J* = 81.5 Hz), 26.88 (d, *J* = 7.9 Hz), 15.94 (d, *J* = 3.7 Hz). ^{31}P NMR δ: 59.9 (s). MS, *m*/*z* (relative intensity): 390 (35), 362 (20), 296 (50), 149 (100), 119 (42), 103 (39), 77 (42). HRMS calcd. for $C_{18}H_{19}N_2O_6P$: 390.0981; found 390.0992.

*Benzyl 6-hydroxyhexanoate (**15**)*: To an aqueous solution of 20% tetrabutylammonium hydroxide (100 mL, 77.1 mmol, 1 equiv.) was added ε-caprolactone (8.79 g, 77.1 mmol, 1 equiv.) and the solution heated to 65°C for 2 h during which time the solution became homogeneous. The solution was concentrated by rotary evaporation leaving a white solid that was dried under high vacuum for several hours. The solid was dissolved in dry DMF (80 mL) and benzylchloride (10.7 g, 84.8 mmol, 1.1 equiv.) was added and the reaction stirred for 24 h. The reaction mixture was diluted with 80 mL water and the extracted with ether (4 × 150 mL). The ether layers were combined and dried (Na_2SO_4), then concentrated leaving a pale yellow oil. Flash chromatography (silica, 60% hexane – 40% EtOAc) of the oil yielded pure **15** as a colourless oil (15.2g, 89%). TLC (silica, 60% hexane – 40% EtOAc): R_f = 0.3. ^{1}H NMR δ: 1.33–1.71 (7 H, m), 1.91 (1 H, s), 2.37 (2 H, t, *J* = 7.3 Hz), 3.60 (2 H, t, *J* = 5.8 Hz), 5.10 (2 H, s), 7.34 (5 H, s). ^{13}C NMR δ: 173.43, 136.23, 128.50, 128.08, 66.05, 62.30, 34.25, 32.30, 25.34, 24.71. MS, *m*/*z* (relative intensity): 223 (3), 194 (12), 115 (59), 108

(52), 91 (100). HRMS calcd. for $C_{13}H_{18}O_3$ *m/z*: 222.1256 (M^+); found 222.1252.

*Benzyl 6-(*tert*-butyldimethylsilyloxy)hexanoate (**16**)*: To a solution of **15** (7.0 g, 31.5 mmol) in dry DMF (15 mL) was added imidazole (5.14 g, 75.6 mmol, 2.4 equiv.) and the solution stirred until all of the imidazole dissolved. *tert*-Butyldimethylsilylchloride (5.69 g, 37.8 mmol, 1.2 equiv.) was added in portions over a period of approximately 4 min and the solution stirred under argon overnight. The reaction was diluted with ether (400 mL) and washed with water (2 × 200 mL), 10% $NaHCO_3$ (2 × 200 mL), saturated brine (2 × 200 mL), dried ($MgSO_4$), and concentrated leaving a pale yellow oil. Flash chromatography (silica, 90% hexane – 10% EtOAc) of the crude oil yielded pure **16** as a colourless oil (9.71 g, 92%). TLC (silica, 90% hexane – 10% EtOAc): R_f = 0.6. ^{1}H NMR δ: 0.044 (6 H, s); 0.89 (9 H, s); 1.36–1.71 (6 H, m); 2.37 (2 H, t, *J* = 7.3 Hz); 3.59 (2 H, t, *J* = 5.9 Hz); 5.12 (2 H, s); 7.36 (5 H, s). ^{13}C NMR δ: 173.17, 136.47, 136.38, 128.46, 128.04, 65.94, 62.90, 34.34, 32.48, 25.97, 25.53, 24.82, 18.29, –5.30. MS, *m/z* (relative intensity): 279 (13), 171 (4), 91 (100). HRMS calcd. for $C_{15}H_{23}O_3Si$ *m/z*: 279.1416 ($M^+ - C_4H_9$); found 279.1411.

*6-(*tert*-Butyldimethylsilyloxy)hexanoic acid (**17**)*: To a solution of **16** (9.71 g, 28.8 mmol) in EtOAc (100 mL) was added 5% Pd/C (400 mg). The flask was fitted with a balloon filled with H_2 and the reaction stirred for 16 h. The reaction was filtered through filter paper, concentrated, and diluted with 50 mL EtOAc. The solution was filtered again, concentrated and residual solvent removed under high vacuum leaving pure **17** as a colourless oil (6.79 g, 95%). ^{1}H NMR δ: 0.044 (6 H, s), 0.89 (9 H, s), 1.39–1.69 (6 H, m), 2.36 (2 H, t, *J* = 7.3 Hz), 3.61 (2 H, t, *J* = 5.9 Hz), 11.05 (1 H, bs). ^{13}C NMR δ: 179.18, 62.85, 33.97, 32.39, 25.89, 25.40, 24.51, 18.23, –5.39. MS, *m/z* (relative intensity): 231 (2), 229 (4), 213 (7), 189 (37), 171 (89), 75 (100). HRMS calcd. for $C_{11}H_{23}O_3Si$ *m/z*: 231.1416 ($M^+ - CH_3$); found 231.1416.

tert-*Butyl 6-hydroxyhexanoate (**18**)*: To a solution of **17** (4g, 16.2 mmol) in dry CH_2Cl_2 (15 mL) was added DMAP (396 mg, 20 mol%), *t*-BuOH (6.19 mL, 64.8 mmol, 4 equiv.) and the solution was cooled in an ice bath. DCC was added (3.52g, 17.0 mmol, 1.05 equiv.) in portions over a three min period. The solution was stirred for 1 h at 0°C and then allowed to warm to room temperature then stirred for a further 24 h. The reaction was filtered and the filtrate concentrated leaving a pale yellow oil. The oil was dissolved in ether (300 mL) and washed with water (2 × 150 mL), 10% $NaHCO_3$ (1 × 150 mL), saturated brine (1 × 150 mL), dried ($MgSO_4$) and concentrated to approximately 20 mL. The solution was filtered and the filtrate concentrated leaving a yellow oil. The oil was distilled (bp 65–68°C, 100 μm) to give 3.0 g of a colourless oil. In addition to the desired *tert*-butyl ester of **17**, the ^{1}H NMR of the distilled material indicated that small amounts (approximately 5%) of both DCC and DCU were present. 2.5 g (approximately 8.25 mmol) of the impure distilled oil was dissolved in dry THF (6 mL). To this was added TBAF (24 mL of a 1.0 M solution in THF, 24 mmol) and the solution stirred for 48 h. The solution was diluted with ether (300 mL) and then washed with water (7 × 200 mL), 10% $NaHCO_3$ (2 × 200 mL), saturated brine (1 × 200 mL), dried ($MgSO_4$) and concentrated leaving a yellow oil. Flash chromatography (silica, 70% hexane – 30% EtOAc) of the oil yielded pure **18** as a pale yellow oil (1.15 g, 38%). TLC (silica, 70% hexane – 30% EtOAc): R_f = 0.25. ^{1}H NMR δ: 1.36–1.63 (6 H, m), 1.41 (9 H, s), 1.86 (1 H, s), 2.20 (2 H, t, *J* = 7.3 Hz), 3.60 (2 H, bt). ^{13}C NMR δ: 173.14, 79.90, 61.99, 35.37, 32.17, 27.95, 25.17, 24.71. MS, *m/z* (relative intensity): 132 (8), 115 (48), 97 (34), 69 (35), 57 (100). HRMS calcd. for $C_{11}H_{23}O_3Si$ *m/z*: 132.0777 ($M^+ - C_4H_9$); found 132.0786.

*General procedure for the deprotection of esters **13b**, **13c**, **14a**, **14b**, and **14c***

Trimethyl silyl iodide (1.2 equiv.) was added dropwise to a solution of the ester (**13b**, **13c**, **14a**, **14b**, or **14c**) in dry CH_2Cl_2 (approx. 1 mmol ester/mL of solvent) and the reaction stirred for 2 h under an Ar atmosphere. Additional CH_2Cl_2 was added and the product was extracted into a 0.1 N sodium hydroxide solution. The two layers were immediately separated and the aqueous layer rapidly acidified to pH 2 (pH paper) with 6 N hydrochloric acid which resulted in the formation of the desired acid product as a precipitate. The product (**19a**, **19b**, or **21**) was recovered by suction filtration. In some instances, further purification by HPLC was necessary.

(±)-1-Hydroxy-trans-*2,5-di(4-nitrophenyl)-1λ^5-phospholan-1-one (**19a**)*: Obtained in a 90% yield as amorphous yellow solid from **14a** using the general procedure for ester deprotection described above; mp 271–273°C. ^{1}H NMR (DMSO-d_6) δ: 2.04–2.45 (4 H, m), 3.40–3.64 (2 H, m), 7.62 (4 H, d, *J* = 5.8 Hz), 8.27 (4 H, d, *J* = 5.8 Hz). ^{13}C (DMSO-d_6) δ: 146.26, 129.68 (d, *J* = 5.4 Hz), 123.17, 45.68 (d, *J* = 82.2 Hz), 28.54 (d, *J* = 10 Hz). ^{31}P NMR (DMSO-d_6) δ: 58.60 (s). *(±)-6-{[*trans-*2,5-Di(4-nitrophenyl)-1-oxo-1λ⁵-phospholan-1-yl]oxy}hexanoic acid (**6**)*: **20a** (35 mg, 0.066 mmol) was dissolved in 20% TFA – CH_2Cl_2 (1.5 mL) and stirred overnight at room temperature. The CH_2Cl_2 and TFA was removed by rotary evaporation. Flash chromatography (silica, 80% EtOAc – 20% hexane) on the crude residue yielded pure **6** as a clear colourless oil (25 mg, 80%). TLC (silica, 80% EtOAc – 20% hexane): R_f = 0.5. ^{1}H NMR δ: 1.09–1.65 (6 H, m), 2.05–2.75 (6 H, m), 3.17–3.98 (4 H, m), 7.52 (4 H, m), 8.22 (4 H, m). ^{13}C NMR δ: 175.92, 147.44, 143.65 (d, *J* = 3.7 Hz), 143.11 (d, *J* = 6.4 Hz), 129.53 (d, *J* = 5.5 Hz), 128.87 (d, *J* = 3.7 Hz), 123.82, 65.83 (d, *J* = 7.3 Hz), 46.64 (d, *J* = 84.2 Hz), 45.50 (d, *J* = 85.1 Hz), 33.23, 30.33, 30.02, 24.80, 24.02. ^{31}P NMR δ: 60.17 (s). MS *m/z* (relative intensity): 477, 444 (8), 363 (83), 280 (84), 216 (53), 149 (54), 119 (56), 69 (82). HRMS calcd. for $C_{22}H_{25}N_2O_8P$ (-OH): 459.1321; found 459.1327.

*(meso)-*trans-tert-*Butyl 6-{[1-oxo-*cis-*2,5-diphenyl-1λ⁵-phospholan-1-yl]oxy}hexanoate (**22a**)*: To a solution of **21** (120 mg, 0.55 mmol, 1 equiv.) in dry CH_2Cl_2 (2 mL) was added oxalyl chloride (0.144 mL, 1.65 mmol, 3 equiv.) dropwise over a period of 1 min and the solution was stirred for 3 h. The solvent was removed by rotary evaporation and the crude acid chloride subjected to high vacuum for 12 h. The crude acid chloride was dissolved in dry benzene (1 mL) and a solution of **18** (125 mg, 0.66 mmol, 1.1 equiv.) and triethylamine (0.100 mL, 0.72 mmol, 1.2 equiv.) in dry benzene (1 mL) was added dropwise over a period of 2 min and the reaction was stirred for 24 h. Ether was added which resulted in the precipitation of triethylamine hydrochloride which was removed by vacuum filtration and the filtrate was concentrated by rotary evaporation. Flash chromatography (silica, 90% CH_2Cl2 – 10% EtOAc) on the crude residue yielded pure **22a** as a clear colourless oil (140 mg, 57%). TLC (silica, 90% CH_2Cl_2 – 10% EtOAc): R_f = 0.6. ^{1}H NMR δ: 1.23–1.65 (15 H, m), 2.18 (2 H, t, *J* = 7.3 Hz), 2.40 (4 H, m), 3.29 (2 H, m), 3.91 (2 H, q, *J* = 6.6 Hz), 7.35 (10 H, m). ^{13}C NMR δ: 172.66, 137.07 (d, *J* = 4.6 Hz), 128.75, 128.63, 128.50, 126.68, 79.92, 65.18 (d, *J* = 6.5), 43.51 (d, *J* = 86.0 Hz), 35.39, 30.49 (d, *J* = 5.5 Hz), 29.51 (d, *J* = 14.7 Hz), 28.15, 25.13, 24.62. ^{31}P NMR δ: 62.56 (s). MS, *m/z* (relative intensity): 442, 386 (99), 369 (33), 272 (60), 104 (100). HRMS calcd. for $C_{26}H_{35}O_4P$: 442.2297; found 442.2293.

*(meso)-*trans-*6-{[*cis-*2,5-Di(4-nitrophenyl)-1-oxo-1λ⁵-phospholan-1-yl]oxy}hexanoic acid (7)*: **22a** (120 mg, 0.27 mmol, 1 equiv.) was dissolved in 0.5 mL of H_2SO_4 at 0°C. A solution of HNO_3–H_2SO_4 (1:1, 0.062 mL, 2.6 equiv. HNO_3) was added and the reaction was stirred at 0°C for 30 min. The reaction was poured into a beaker containing ice which upon melting left a suspension. $CHCl_3$ (5 mL) was added and the two layers were separated. The aqueous layer was further extracted with $CHCl_3$ (4 × 10 mL) and the combined organics were washed with brine (2 × 15 mL), dried ($MgSO_4$), and concentrated in vacuo leaving an oily of solid residue. Attempts to obtain pure product by subjecting the crude residue to silica gel flash chromatography were unsuccessful. Final purification of the desired product was accomplished using HPLC (isocratic, 70% EtOAc – 30% hexane, retention time = 18 min) to give **7** as a clear colourless oil (51 mg, 44%). ^{1}H NMR δ: 1.23–1.68 (6H, m), 2.24 (2 H, t, *J* = 7 Hz), 2.35–2.60 (4 H, m), 3.35–3.57 (2 H, m), 3.87–4.03 (2 H, dd, *J* = 6.6 Hz, *J* = 7.7 Hz), 7.52 (4 H, dd, *J* = 1.8 Hz, *J* = 6.9 Hz), 8.19 (4 H, dd, *J* = 8.4 Hz). ^{13}C NMR δ: 176.79, 147.28, 143.97 (d, *J* = 7.3 Hz), 129.46 (d, *J* = 5.5 Hz), 123.84, 66.23 (d, *J* = 7.3 Hz), 43.56 (d, *J* = 84.2 Hz), 33.48, 30.30 (d, *J* = 5.5 Hz), 29.26 (d, *J* = 14.7 Hz), 24.96, 24.1. ^{31}P NMR ($CDCl_3$) δ: 61.11 (s). MS, *m/z* (relative intensity): 363(53), 280(57), 149(52). HRMS calcd. for $C_{22}H_{25}N_2O_8P$: 477.1427; found 477.1432.

*(meso)-*cis-tert-*Butyl 6-{[1-oxo-cis-2,5-diphenyl-1λ⁵-phospholan-1-yl]oxy}hexanoate (**22b**)*: **18** (60 mg, 0.33 mmol, 1.5 equiv.), triphenyl phosphine (87 mg, 0.33 mmol, 1.5 equiv.), **21** (60 mg, 0.22 mmol, 1 equiv.), and DIAD (65 uL, 67 mg, 0.33 mmol, 1.5 equiv.) were dissolved in dry THF (1.5 mL) and stirred at room temperature for 30 min. The solvent was removed under reduced pressure. Flash chromatography of the crude residue (silica, 60% EtOAc – 40% hexane) yielded **22b** as a clear colourless oil (58.5 mg, 60%). TLC (silica, 60% EtOAc – 40% hexane): R_f = 0.4. ^{1}H NMR δ: 0.65–0.85 (2 H, br m), 0.89–1.04 (2 H, br m), 1.20–1.26 (3 H, br m), 1.439, (7 H, s), 1.75 (1 H, s), 1.97 (3 H, t, *J* = 8.1 Hz), 2.35–2.48 (4 H, br m), 3.11–3.20 (2 H, br m), 3.38–3.54 (2 H, br m), 7.20–7.35 (10 H, br m). ^{13}C NMR δ: 172.94, 136.29 (d, *J* = 8.1 Hz), 128.43 (d, *J* = 2.2 Hz), 127.80 (d, *J* = 5.1 Hz), 126.65 (d, *J* = 3.0 Hz), 79.83, 64.69 (d, *J* = 7.4 Hz), 43.74 (d, *J* = 82.0 Hz), 35.24, 29.87 (d, *J* = 5.1 Hz), 28.05, 27.48 (d, *J* = 7.2 Hz), 24.44, 24.34. ^{31}P NMR δ: 61.75 (s). MS, *m/z* (relative intensity): 443 (18), 387 (58), 272 (49), 104 (100). HRMS calcd. for $C_{26}H_{35}O_4P$: 442.2273; found 442.2264.

Formation of bovine serum albumin (BSA)–TSA and keyhole lympet hemocyanin (KLH)–TSA conjugates

To a solution of TSAs **6** or **7** (~6 mg, ~0.013 mmol) in DMF:water (3:2, 3 mL) was added *N*-hydroxysulfosuccinimide

© 2000 NRC Canada

(3.5 mg, 0.016 mmol) and EDC (3.1 mg, 0.016 mmol). The reaction was stirred at rt for 3 h. The reaction mixture was divided into two equal aliquots (1.5 mL each). One aliquot was added to a solution of BSA (6.3 mg) in 50 mM phosphate buffer (pH 7.5, 3 mL) and the other aliquot was added to a solution of KLH (6.1 mg) in the same buffer. The reaction were shaken at 4°C for 16 h. Unconjugated hapten was removed by dialysis (6 × 1 L, 3 h each) in 50 mM phosphate buffer, pH 7.5 at 4°C. The number of haptens per BSA was determined using the method of Habeeb (27). The number of *trans* haptens **6** per BSA was 11 and the number of *cis* haptens **7** per BSA was 19. We were unable to determine the number of haptens per KLH due to the nonhomogeneous nature of the KLH solutions. The conjugates were stored at –20°C.

*6-{[*Di*(4-nitrophenoxy)phosphoryl]oxy}hexanoic acid (**8**)*: To a solution of **18** (125 mg, 0.66 mmol) in dry THF (4 mL) was added bis(4-nitrophenyl)phosphate (150 mg, 0.44. mmol), triphenyl phosphine (173 mg, 0.66 mmol), and DIAD (130 uL, 130 mg, 0.66 mmol). The solution was stirred under argon for 30 min, the solvent was then removed by rotary evaporation and the crude residue chromatographed (silica, 95% CH_2Cl_2 – 5% EtOAc). TLC (silica, 95% CH_2Cl_2 – 5% EtOAc): R_f = 0.7. Due to slow product breakdown, it was not possible to separate the *tert*-butyl-6-{[di(4-nitrophenoxy)phosphoryl]oxy}hexanoate product from trace amounts of 4-nitrophenol. Thus, the impure product was dissolved in a solution of TFA:CH_2Cl_2 (1:5) and stirred for 16 h. The solvent was removed by rotary evaporation and the product obtained by flash chromatography (silica, 50% hexane – 50% EtOAc) yielded **8** as a white solid (146 mg, 73% overall yield). TLC (silica, 50% hexane – 50% EtOAc): R_f = 0.2; mp 77–78°C. ^{1}H NMR δ: 1.20–1.90 (7 H, c m), 2.35 (2 H, t, *J* = 7 Hz), 4.34 (2 H, q, *J* = 6.6 Hz), 7.40 (4 H, d, *J* = 9.2 Hz), 8.26 (4 H, d, *J* = 7.3 Hz). ^{13}C NMR δ: 178.16, 154.74 (d, *J* = 6.4 Hz), 145.40, 125.81, 120.71 (d, *J* = 4.7 Hz), 70.49, 33.57, 29.81, 24.84, 24.02. ^{31}P NMR δ: –15.83 Hz (s). MS, *m*/*z* (relative intensity): 341 (80), 316 (51), 139 (100), 109 (82), 65 (70). HRMS calcd. for $C_{18}H_{19}0_{10},N_2P$: 455.08556; found 455.0830.

*Methyl hydrogen (4-nitrobenzyl)phosphonate (**24**)*: A mixture composed of dimethyl (4-nitrobenzyl)phosphonate (26) (2.5 g, 10.2 mmol) and sodium hydroxide (816 mg, 20.4 mmol) in water (60 mL) was heated at 75°C until homogeneous. The solution was acidified to pH 1 with concentrated hydrochloric acid (6 M), filtered, the precipitate washed with water giving **24** as a white solid (2.12 g, 90% yield); mp 132–134°C. ^{1}H NMR ($DMSO_{d6}$) δ: 3.19 (2 H, d, *J* = 22.8 Hz), 3.59 (3 H, d, *J* = 11.3 Hz), 7.44 (2 H, dd, *J* = 2.5 Hz, *J* = 8.8 Hz), 8.17 (2 H, d, *J* = 8 Hz). ^{13}C NMR δ: 146.28, 142.02 (d, *J* = 9.2 Hz), 130.90 (d, *J* = 5.5 Hz), 123.13, 51.72 (d, *J* = 6.4 Hz), 33.30 (d, *J* = 131.8). ^{31}P NMR δ: 25.48 (s). MS, *m*/*z* (relative intensity): 231 (50), 214 (100), 184 (31), 136 (31), 107 (62), 89 (52). HRMS calcd. for $C_8H_{10}O_5NP$: 231.0297; found 231.0314.

*Methyl (4-nitrophenyl) (4-nitrobenzyl) phosphonate (**25**)*: Compound **24** (1 g, 4.33 mmol) was suspended in dry methylene chloride (40 mL). To the suspension was added 4-nitrophenol (722 mg, 5.19 mmol) and EDC (995 mg, 5.19 mmol). The reaction was stirred under argon for 72 h. The solution was diluted with methylene chloride (20 mL), washed with 5% sodium bicarbonate (2 × 50 mL), 0.1 N HCl (2 × 50 mL), and saturated brine (1 × 50 mL), dried ($MgSO_4$) and concentrated leaving a solid residue. Recrystallization of the crude in hexane–ethyl acetate yielded pure **25** as a white solid (64% yield); mp 112–114°C. ^{1}H NMR δ: 3.48 (2 H, d, *J* = 22.7 Hz), 3.80 (3 H, d, *J* = 11 Hz), 7.29 (2 H, d, *J* = 8.8 Hz), 7.51 (2 H, dd, *J* = 2.9 Hz, *J* = 5.9 Hz), 8.22 (4 H, d, *J* = 8.8 Hz). ^{13}C NMR δ: 155.31 (d, *J* = 8.2 Hz), 147.48, 144.90, 138.09 (d, *J* = 9.1 Hz), 130.78 (d, *J* = 6.4 Hz), 125.61, 123.86, 120.85 (d, *J* = 4.6 Hz), 53.91 (d, *J* = 6.4 Hz), 33.55 (d, *J* = 139.1 Hz). ^{31}P NMR δ: 20.94. MS, *m*/*z* (relative intensity): 352 (100), 335 (41), 305 (27), 257 (34), 136 (49). HRMS calcd. for $C_{14}H_{13}O_7N_2P$: 352.0460; found 352.0450.

*4-nitrophenyl hydrogen (4-nitrobenzyl)-phosphonate (**26**)*: To a solution of **25** (1.83 g, 5.4 mmol) in dry butanone (40 mL) was added NaBr (833 mg, 8.10 mmol) and the resulting solution refluxed for 16 h. Upon cooling the solution to rt, a precipitate formed. The mixture was filtered and the precipitate washed with cold butanone. The solid was dissolved in water and the solution was acidified with 6 N HCl to pH 2 which resulted in the formation of a white precipitate. The mixture was filtered and the precipitate washed with cold water then dried under vacuum to give **26** as a white solid (535 mg, 93% yield). ^{1}H NMR ($DMSO_{d6}$) δ: 3.54 (2 H, dd, *J* = 8.1 Hz, *J* = 23 Hz), 7.38 (2 H, d, *J* = 8 Hz), 7.59 (2 H. d. *J* = 5.9 Hz), 8.19 (4 H, d, *J* = 9.5 Hz). ^{13}C NMR δ: 156.20, 146.44, 143.68, 141.11 (d, *J* = 9.1 Hz), 131.07 (d, *J* = 6.4 Hz), 125.48, 123.19, 121.07 (d, *J* = 4.6 Hz), 34.35 (d, *J* = 133.6 Hz). ^{31}P NMR δ: 21.66. MS, *m*/*z* (relative intensity): 338 (33), 228 (18), 210 (24), 139 (100), 109 (83). HRMS calcd. for $C_{13}H_{11}O_7N_2P$: 338.0304; found 338.0310.

*6-{[4-Nitrobenzyl)(4-nitrophenoxy)phosphoryl]oxy}hexanoic acid (**9**)*: To a solution of hydroxy ester **18** (156 mg, 0.83 mmol) in dry THF (1.5 mL) was added phosphonic acid **26** (180 mg, 0.55 mmol), triphenyl phosphine (218 mg, 0.83 mmol), and DIAD (180 ul, 180 mg, 0.83 mmol). The reaction was stirred for 1 h. The solvent was removed by rotary evaporation and the crude purified by chromatography (silica. 40% hexane – 60% EtOAc). We were unable to separate the phosphonate product **27** from small amounts of contaminating of *p*-nitrophenol. Consequently, the slightly impure phosphonate **27** was dissolved in a solution of 20% TFA–CH_2Cl_2 (1 mL) and stirred for 16 h. The solvent was removed by rotary evaporation and the crude residue chromatographed (silica, 20% hexane – 80% EtOAc) to yield pure **9** as a thick colourless oil (159 mg, 64% overall yield). TLC (silica, 20% hexane – 80% EtOAc): R_f = 0.6. ^{1}H NMR ($DMSO_{d6}$) δ: 0.75–1.75 (7 H, m), 2.30 (2 H, t, *J* = 7.2 Hz), 3.52 (2 H, *J* = 22.7 Hz), 4.15 (2 H, m), 7.29 (2 H, d, *J* = 9.6 Hz), 7.51 (2 H, dd, *J* = 2.6 Hz, 8.20 (4 H, d, *J* = 8.8 Hz). ^{13}C NMR δ: 177.47, 155.16 (d, *J* = 7.1 Hz), 147.50, 144.93, 138.07 (d, *J* = 9.1 Hz), 130.85 (d, *J* = 5.5 Hz), 125.63, 123.84, 121.00, 67.83 (d, *J* = 7.3 Hz), 33.80 (d, *J* = 138.1), 33.61, 29.92 (d, *J* = 4.6 Hz), 24.84, 24.07. ^{31}P NMR δ: 19.7. MS, *m*/*z* (relative intensity): 339 (64), 314 (58), 139

(77), 109 (51), 97 (66), 69 (100). HRMS calcd. for $C_{19}H_{21}0_9,N_2P$: 453.1063; found 453.1086.

Kinetic studies with substrates 8 and 9 in the absence of antibody

A 20 μL aliquot of a 1 mM stock solution of **8** or **9** in DMF was added to a cuvette containing 980 μL of 10 mM CHES, 50 mM NaCl, pH 9.0 preincubated at 25°C. The cuvette was incubated at 25°C and the hydrolysis reaction was followed by measuring the absorbance at 400 nm every 30 min using a Cary 1B UV–Vis spectrophotometer until the reaction had proceeded to approximately 3–4 half-lives. The data was fitted to the first-order rate equation using the GraFit program (28). Each reaction was performed in duplicate.

Isomerization studies with 7

A 500 μM solution of **7** (3.0 mL) in 20 mM phosphate buffer at pH 7.5 was incubated at 25°C. Aliquots (0.5 mL) were removed at various time intervals and quenched with 1 M HCl (40 μL) and then extracted with EtOAc (0.5 mL). The extent of isomerization to **6** was determined by normal phase HPLC analysis of the EtOAc solutions using EtOAc as eluant (1.0 mL/min for 5 min then switching to 2.0 mL for 6 min) and the detector set at 280 nm. Under these conditions, the retention time of the *cis* TSA **7** was 4.2 min and the *trans* TSA **6** was 6.2 min.

Antibody production

Balb/c mice were immunized IP five times at ten day intervals with 50 μg of the KLH conjugates. The first four injections were given intraperitoneally after emulsification of the conjugate with Freund's adjuvant while the final injection was given intravenously with just conjugate in PBS. Three days after the final injection, hybridoma production was initiated as described previously (29, 30). The fusion was screened by solid phase radio immune assays (SPRIA) (29, 30) using PVC plates coated with the BSA conjugates. Seven cell lines, two obtained from mice immunized with the *trans* TSA **6** and five obtained from mice immunized with the *trans* TSA **7**, were cloned. Isotyping of the antibodies obtained from mice immunized with the trans hapten **6** revealed that one was an IgM class and one an IgG class antibody, while those obtained from mice immunized with the *cis* hapten **7** revealed that three were IgG class antibodies and two were IgM class antibodies. Ascites fluid was prepared (29, 30) from these seven cell lines and the antibodies were purified by gel exclusion chromatography on a Sephracryl S-200 column as previous described (29, 30). SDS-PAGE (12%) analysis of Jel 541 revealed only a single band at the top of the gel (Coomassie Blue staining). Competitive SPRIAs (29, 30) were performed with plates coated with the BSA conjugate of the *cis* TSA **7**.

Antibody kinetics

Purified antibody was dialyzed overnight into 10 mM CHES, 50 mM NaCl, pH 9.0 or 10 mM HEPES, 50 mM NaCl, pH 7.0. A stock solution of the substrates in DMSO was added directly to the antibody solutions. The final volume was 0.300 mL and the total amount of DMSO in the assay mix was 1% (v/v). The change in absorbance at 400 nm was monitored at 25°C in a Gilford 260 spectrophotometer.

Efficient method for the preparation of pinacols derived from aromatic and aliphatic ketones by using low-valent titanium reagents in dichloromethane–pivalonitrile

Akifumi Kagayama, Koji Igarashi, and Teruaki Mukaiyama

Abstract: The reductive coupling reaction of aldehydes and ketones, including unsymmetrical aliphatic ketones, proceeded smoothly to give the corresponding pinacols in good to high yields under mild conditions by using combination of titanium(II) chloride and zinc or titanium(IV) chloride and zinc in dichloromethane–pivalonitrile. *Meso*-selective formation of the coupling products was observed in the cases of some aliphatic ketones. The diastereoselectivities of coupling products depend on both difference of bulkiness of 2-, and 2′-substituents of carbonyl group of the reactant, and overall steric effect around the carbonyl groups.

Key words: diastereoselective pinacol reaction, dichloromethane-pivalonitrile, titanium(II) chloride, titanium(IV) chloride, zinc.

Résumé : La réaction de couplage réducteur d'aldéhydes ou des cétones, y compris des cétones aliphatiques non symétriques, se produit facilement et elle conduit aux pinacols correspondants avec des rendements allant de bons à élevés, dans des conditions douces, en opérant dans un mélange de dichlorométhane et de pivalonitrile en présence de zinc et de chlorure de titane(II) ou de chlorure de titane(IV). On a observé une formation sélective de l'isomère *méso* dans les cas de quelques cétones aliphatiques. Les diastéréosélectivités des produits de couplage dépendent de la différence de taille des substituants en positions 2 et 2′ par rapport au groupe carbonyle qui réagit ainsi que de l'effet stérique global autour des groupes carbonyles.

Mots clés : réaction pinacolique diastéréosélective, dichlorométhane-pivalonitrile, chlorure de titane(II), chlorure de titane(IV), zinc.

[Traduit par la Rédaction]

Introduction

The reductive coupling of carbonyl compounds using low-valent metal species has been known as pinacol coupling reaction since last century. In 1973, two research groups, Mukaiyama (1*a*) and Tyrlik (1*b*), independently reported this coupling reaction and its subsequent deoxygenation reaction that afforded olefin with low-valent titanium species. In the above two methods, the former used either combination of $TiCl_4$ and Zn, or $TiCl_4$ and $LiAlH_4$, and the latter employed the combination of $TiCl_3$ and Mg for the generation of active low-valent species. McMurry and co-workers studied this coupling reaction in detail by using either $TiCl_3$ and $LiAlH_4$, or $TiCl_3$ and Zn-Cu from 1974 (1*c*). The coupling reactions using other transition metals as a reducing reagent have been extensively studied in this decade (2).

Concerning intermolecular type pinacol reactions, recent topics are directed to investigate the formation of C_2 or S_2 symmetric homocoupling products with high diastereoselectivities (*dl* or *meso*) under mild conditions. In the cases of aromatic aldehydes, for example, the corresponding homocoupling products were afforded with high *dl*-selectivities when several kinds of low-valent metals such as Ti (3), Sm (4), and Nb (5) were used.[2] Further, it was recently reported that *dl*-homocoupling product was preferentially formed from acetophenone by the combined use of a $TiCl_3$–Mg–catechol system (7).

This *dl*-selection was explained by assuming the generation of intermediate radical species as sketched in Scheme 1, in which oxygen atoms of two ketyl radicals are placed side by side and phenyl groups are arranged *anti* to each other to minimize the steric interaction when these ketyl radicals approach each other. The location of two oxygen atoms was controlled by the interaction between metal on the ketyl radical and oxygen atom of the other ketyl radical, and (or)

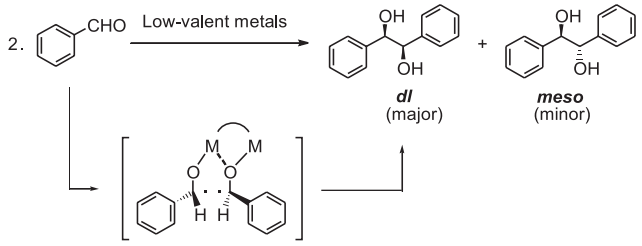
bridged two metal atoms. However, there has been no systematic study on relationship between the diastereoselectivities of coupling products and the steric effects of substituents at 2- and 2′-positions of carbonyl group of the reactants.

To investigate this subject, it is appropriate to examine the coupling reaction of unsymmetrical aliphatic ketones; however, in this reductive coupling, the reactivities of aliphatic ketones are generally low and the required severe reaction conditions cause pinacol rearrangement or deoxygenation of the initially produced pinacol to form the corresponding olefins.



Recently, we found that pinacol coupling reaction of aliphatic ketones proceeded smoothly in dichloromethane–pivalonitrile by using the combination of titanium(II) chloride and zinc at room temperature (8). Further, usefulness of $TiCl_2$ was demonstrated in the following experiment, i.e., in our total synthesis of antitumor agent Taxol (9), construction of the A ring onto the BC ring system was performed by intramolecular pinacol coupling reaction using low-valent titanium species prepared in situ from $TiCl_2$–$LiAlH_4$. Though a similar reaction was observed by the combined use of $TiCl_3$–$LiAlH_4$, the generation of low-valent titanium species took place in less acidic media when the former combination was employed. The titanium(II) reagent, $TiCl_2$, is facilely prepared from $TiCl_4$ and hexamethyldisilane according to the reported procedure (10), and it can be stored under argon atmosphere for a long time.[3] In this article, we would like to describe the relationship between the diastereoselectivities of coupling products and the steric effects of substituents at 2-, and 2′-positions of carbonyl group of the reactants in the pinacol coupling reaction by using $TiCl_2$ and Zn. The results obtained by further examination of this type of coupling reaction using a combination of $TiCl_4$ and Zn are also discussed herein.

Results and discussion

Acetophenone was reductively coupled by using $TiCl_2$ and Zn in THF at 0°C to give 2,3-diphenyl-2,3-butanediol in 93% yield (*dl*:*meso* = 76:24) while 4-phenyl-2-butanone did not react under the same reaction conditions. Porta et al. reported that $TiCl_3$ could reduce benzaldehyde in dichloromethane to afford the corresponding pinacol though the same reaction did not proceed in THF which is commonly employed solvent in these reactions (3b). Actually, 4-phenyl-2-butanone was reductively coupled by using the combination of $TiCl_2$–Zn in dichloromethane and the desirable pinacol was obtained in 23% yield and 65% of the 4-phenyl-2-butanone was recovered.

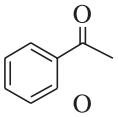
Although several additives such as pyridine (12) and HMPA (13) used to be known effective in this coupling reaction, these two additives and 2-methyloxazoline were not effective for the present reaction when the combination of $TiCl_2$ and Zn system was used (0, 0, and 13% yields, respectively). On the other hand, it was found that nitriles, especially pivalonitrile, accelerated this reaction to give the pinacol in 63% yield by using 2 molar equivalents of $TiCl_2$ and Zn. Finally, it was found that the yield was improved up to 87% when 2 molar equivalents of $TiCl_2$ were gradually added to the reaction mixture for the duration of the 6 h period in the presence of Zn and pivalonitrile at room temperature. When acetonitrile or *o*-methoxybenzonitrile was used as a co-solvent in the above reaction, the corresponding pinacol was obtained in 78 or 52% yield, respectively. Fürstner and Hupperts demonstrated the beneficial effect of a cyano function tethered to a chlorosilane on the reductive coupling reaction using a catalytic amount of $TiCl_3$–Zn–chlorosilane system in their indole synthesis reaction (15).

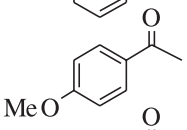
Scheme 1.

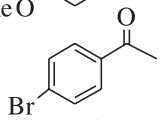
These results indicate that nitriles moderately coordinate to the low-valent titanium species to form the active complexes, which helps both the solvation of the titanium particles and electron donation of the titanium complex to the carbonyl compounds.[4,5] On the other hand, other additives (pyridine, HMPA, and 2-methyloxazoline) coordinate too strongly to the low-valent titanium species, which result in the decreased reactivities.

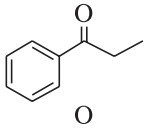
Yields and diastereoselectivities of the pinacol coupling reactions using several ketones and aldehydes are summarized in Table 1. Aromatic ketones were transformed to the corresponding pinacols in high yields with *dl*-selectivies (Entries 1–5) though the selectivity in case of acetophenone was rather low in comparison with the reported one (7). This *dl*-selectivity increased either when electron-donating group substituted benzaldehyde derivatives or carbonyl compound with bulky group at the 2-position were used, that is, the diastereoselectivity came up kinetically. This consideration may be supported by the results that no diastereoselectivity was observed in the case of highly reactive benzaldehyde while moderate selectivity was observed in the reaction of less reactive 3-phenylpropanal (Entries 11 and 12).

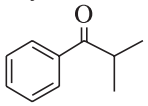
In the reactions of aliphatic ketones (Entries 6–10), the corresponding pinacols were obtained in good to high yields except for 3,3-dimethyl-2-butanone. The diastereoselectivity was not observed when 4-phenyl-2-butanone was used as a substrate that has a set of methyl and methylene groups attached to 2- and 2′-positions of carbonyl group of the reactant (Entry 6). On the other hand, the *meso*-selective reaction took place when substrates that have two dimensionally different substituents, i.e., the respective combination of

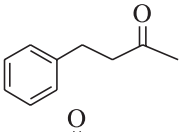


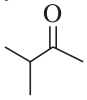


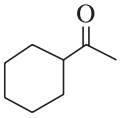


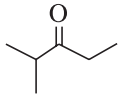


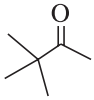


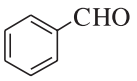


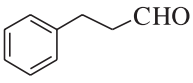












[3] A few types of titanium(II) chloride complexes were used for pinacol coupling reactions, which were carried out only in ethers such as $TiCl_2$·LiCl (11a) or $TiCl_2(thf)_2$·xLiCl (11b).

[4] Actually, on ^{13}C NMR spectra, signals of pivalonitrile (δ: 27.5, 27.8 and 125.3 ppm) shifted and broadened (δ: 24.8, 31.0 and 131.3 ppm) by addition of 1/3 molar equivalent of $TiCl_2$ in chloroform-*d* at room temperature. This result indicates the formation of coordinated complex.

[5] Structural data on the coordination of nitriles onto low-valent titanium are shown in ref 14. Fowles and Lester reported the structure of isolated polymeric titanium(II) complexes as TiX_2·$2CH_3CN$ (14*b*).

methyl and methyne (Entries 7 and 8), or methylene and methyne (Entry 9) groups, were used.

McMurry and Siemers studied intramolecular pinacol coupling reaction of several dialdehydes, in which the relationship between the diastereoselectivities and the ring number of products was examined in detail (16). In the present experiment, two types of diketones were examined (Table 2), and the selectivity decreased a little in the case of aliphatic diketone while aromatic diketone reacted in perfect *cis*-selective manner. It suggested that the interaction

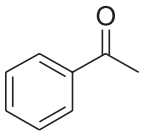
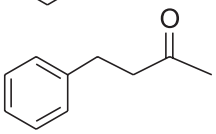
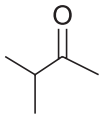
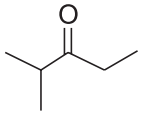
between Ti and oxygen would be rather weak in the case of aliphatic ketone than that of aromatic ketone.

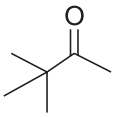
Benzaldehyde and acetophenone were reductively coupled by using $TiCl_2$ in the absence of Zn (Table 3). Though the yields were rather low, *dl*-selectivities became very much higher than those of the reaction when a $TiCl_2$–Zn system was applied. These results may be explained by considering the kinetic effect and the Lewis acidity of titanium species which may also influence the above diastereoselectivities (see Scheme 1). The higher-valent metal behaved as a stronger Lewis acid compared with the lower-valent one, so that, in the absence of Zn, the Ti(III) atom on the ketyl radical (formed from $TiCl_2$ and the carbonyl compound) is coordinated more strongly to build a Ti-bridging intermediate (3b) (17) compared with Ti(I) (or Ti(II)) atom on the ketyl radical existed in the reaction using the $TiCl_2$–Zn system.











From these results, the mechanism of diastereoselection in the present reaction may be explained as shown in Scheme 2. When isobutyrophenone is used, the generated ketyl radical species form an intermediate Ti-bridging complex **A**, which is in turn connected to *dl*-products. When other aromatic ketones are used, more highly reactive ketyl radicals would be generated because these compounds are less hindered compared to isobutyrophenone. Therefore,

other pathways to be connected to *meso*-products can be assumed to exist in addition to that mentioned above and relatively lower stereoselectivities were observed. On the other hand, in the cases of aliphatic ketones, the highly symmetrical intermediate **B**, a pair of two ketyl radicals, is formed to preferentially produce *meso*-pinacol because these radical species would be relatively unstable and the interaction between titanium and oxygen atoms in the intermediate would be rather weak.

It is noted that the selectivity depends on the difference of bulkiness of the 2- and 2′-substituents of the carbonyl group of the reactants and the overall steric interaction around the carbonyl group.

Application of $TiCl_4$ instead of $TiCl_2$ was studied in this type of reaction in dichloromethane–pivalonitrile. So far many kinds of low-valent titanium reagents have been generated from $TiCl_3$ rather than from $TiCl_4$ because the latter is coordinated so strongly by THF which has been generally considered as the most effective solvent for reductive coupling reaction. Concerning the reaction using low-valernt titanium reagent generated from $TiCl_4$ and Zn in THF, Mukaiyama et al. reported that aliphatic aldehydes or ketones were reduced to give the corresponding pinacols at rather high temperatures (1*a*). Therefore, it was considered that the highly active low-valent titanium species giving the corresponding olefin could only be generated from $TiCl_3$.

Since the present reaction proceeded at room temperature in dichloromethane–pivalonitrile by using the $TiCl_2$–Zn system, the similar reactions using $TiCl_3$ or $TiCl_4$ were also tried under the same reaction conditions. While a system ($TiCl_3$ and 1.5 equivalents Zn) in dichloromethane–pivalonitrile did not reduce the 4-phenyl-2-butanone, a system ($TiCl_4$ and 2 equivalents Zn) produced the desired coupling product in 86% yield.

Titanium(IV) chloride did not react with Zn in dichloromethane solvent; however, the addition of pivalonitrile to this mixture induced the generation of low-valent titanium species in which the gray suspension turned to dark blue, and then to dark brown. On the other hand, when acetonitrile was used as a co-solvent, the mixture of generated low-valent titanium species was not homogeneous and the yield of pinacol originated from 4-phenyl-2-butanone decreased to 24%. These results indicate that pivalonitorile would increase the solubility of generated low-valent titanium species by forming a soluble complex and the polarity of the reaction media to help both electron-transfer reaction.[6]

The yields and diastereoselectivities of the pinacols formed from several ketones by using $TiCl_4$–Zn are summarized in

[6] It is generally known that the nitriles are one of the most popular solvents for the electrochemical studies

© 2000 NRC Canada

Table 4, together with the results using $TiCl_2$–Zn. These reactions employing equimolar amount of $TiCl_4$ proceeded smoothly to give several coupling products of aliphatic ketones in high yields except 3,3-dimethyl-2-butanone. Since the generated low-valent titanium species from $TiCl_4$ was more soluble in the above solvent, results obtained here were better than those using $TiCl_2$.

Summary

The reductive coupling reactions of various ketones and aldehydes including aliphatic unsymmetrical ketones proceeded under mild conditions by using $TiCl_2$–Zn or $TiCl_4$–Zn in dichloromethane–pivalonitrile. It was also shown that the diastereoselectivities of coupling products depend not only on the difference of bulkiness of 2-, and 2′-substituents of carbonyl group of the reactants, but also on overall steric effect around the carbonyl groups.

Experimental Section

General

Melting points were recorded on a Yanaco MP-S3 micro melting point apparatus. Elemental analyses were performed by MC Research Center Inc. FT-IR spectra were recorded on a Horiba FT-300 infrared spectrometer. ^1H- and ^{13}C NMR spectra were recorded on a JEOL JNM-EX270L, a JEOL JNM-LA400, and a JEOL JNM-LA500 spectrometer using tetramethylsilane (TMS) or chloroform-*d* ($CDCl_3$) as internal standard. The following abbreviations are used: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, and br = broad. High-resolution mass spectra were recorded on a JEOL JMS-SX102A instrument with 4-nitrobenzyl alcohol as a matrix. Thin layer chromatography used routinely for purification and separation of product mixtures was performed on Wakogel B5F. Analytical thin layer chromatography was performed using E. Merck 0.25 mm silica gel 60 F254 plates, and visualization was accomplished with ethanolic phosphomolybdic acid. All reactions were carried out under argon atmosphere in dried glassware. Dichloromethane and pivalonitrile were distilled from diphosphorus pentoxide, then calcium hydride, and dried over MS 4A. All substrates were purchased from Tokyo Kasei Kogyo, Kanto Chemical, Aldrich Chemical, or Merck. Ketones and aldehydes were used after purification by distillation. 1,4-Dibenzoylbutane and 2,6-octanedione were used as received.

Titanium(II) chloride was prepared by Nalura's procedure (9). Anal. calcd. for $TiCl_2$: Ti 40.31, Cl 59.69; found: Ti 39.89, Cl 59.28. Zinc powder (Kanto Chemical) was activated by 1 N HCl, washed with distilled water and ether successively, and dried in vacuo.

Typical procedure for the reductive titanium(II) chloride and zinc in dichloromethane with pivalonitrile:

Method A

To a suspension of $TiCl_2$ (59 mg, 0.5 mmol) and activated Zn powder (32 mg, 0.5 mmol) in CH_2Cl_2 (2.5 mL) was added ^{t}BuCN (0.22 mL, 2 mmol). After the resulting dark brown suspension was cooled to 0°C, a solution of acetophenone (60 mg, 0.5 mmol) in CH_2Cl_2 (1.3 mL) was added dropwise. Once TLC analysis indicated that all of the ketone had been consumed (<16 h), saturated aqueous NH_4Cl was added to the reaction mixture. The reaction mixture was filtered, and the filtrate was separated. The aqueous portion was extracted with CH_2Cl_2 (4 mL × 3), and combined organic layers were washed successively with a saturated aqueous $NaHCO_3$ and brine, and dried over Na_2SO_4, filtered, and concentrated. The crude product was subjected to thin-layer chromatography (hexane – ethyl acetate) to afford the desired pinacol (56 mg, 93%).

Method B

To a gray suspension of activated Zn powder (65 mg, 1 mmol) and ^{t}BuCN (0.44 mL, 4 mmol) in CH_2Cl_2 (2.5 mL) was added a solution of 4-phenyl-2-butanone (74 mg, 0.5 mmol) in CH_2Cl_2 (1.3 mL). After stirring for 30 min, $TiCl_2$ (119 mg, 1 mmol) was added gradually (divided in 6 times at interval of 1 h) under argon by powder inlet equipped to the reaction apparatus. The resulting mixture was stirred for an additional 1 h, and then saturated aqueous NH_4Cl was added. The same work up as method A gave the desired pinacol (65 mg, 87%).

Typical procedure for the reductive coupling reaction of ketones using titanium(IV) chloride and zinc in dichloromethane with pivalonitrile

To a gray suspension of $TiCl_4$ (95 mg, 0.5 mmol) and activated Zn powder (65 mg, 1 mmol) in CH_2Cl_2 (2.5 mL) was added ^{t}BuCN (0.22 mL, 2 mmol) dropwise. After the resulting dark brown suspension was stirred for 30 min, a solution of 4-phenyl-2-butanone (74 mg, 0.5 mmol) in CH_2Cl_2 (1.3 mL) was added. The reaction mixture was stirred for 16 h at room temperature and then saturated aqueous NH_4Cl was added. The same work up as above procedure gave the desired pinacol (64 mg, 86%).

Diastereoselectivities of pinacols

400 MHz ^1H NMR spectra assignments were used for the determination of the *dl*:*meso* ratio of the crude pinacols obtained.

meso- *and* dl-*2,3-Diphenyl-2,3-butanediol* (***18***): Colorless solid; ^1H NMR ($CDCl_3$) δ: 1.48 (6H, s, CH_3, *dl*), 1.57(6H, s, CH_3, *meso*), 2.36 (2H, br, OH, *meso*), 2.63 (2H, br, OH, *dl*), 7.24–7.15 (20H, m, Ph-H). Assignments were made by comparing the relative heights of methyl signals at δ 1.48 and δ 1.57, respectively.

meso- *and* dl-*2,3-Bis(4-methoxyphenyl)-2,3-butanediol* (***17***): Colorless solid; ^1H NMR ($CDCl_3$) δ: 1.45 (6H, s, CH_3, *dl*), 1.54 (6H, s, CH_3, *meso*), 2.35 (2H, br, OH, *meso*), 2.64 (2H, br, OH, *dl*), 3.78 (6H, s, OCH_3, *meso*), 3.79 (6H, s, OCH_3, *dl*), 6.75–7.11 (16H, m, Ph-H). Assignments were made by comparing the relative heights of methyl signals at δ 1.45 and δ 1.54, respectively.

meso- *and* dl-*2,3-Bis(4-bromophenyl)-2,3-butanediol* (***17***): Colorless solid; ^1H NMR ($CDCl_3$) δ: 1.45 (6H, s, CH_3, *dl*), 1.53 (6H, s, CH_3, *meso*), 2.28 (2H, br, OH, *meso*), 2.60 (2H, br, OH, *dl*), 7.02–7.36 (16H, m, Ph-H). Assignments were made by comparing the relative heights of methyl signals at δ 1.45 and δ 1.53, respectively.

meso- *and* dl-*3,4-Diphenyl-3,4-hexanediol (**19**)*: Colorless solid; ^{1}H NMR ($CDCl_3$) δ: 0.59 (6H, dd, *J* = 7.3, 7.3 Hz, CH_3, *meso*), 0.60 (6H, dd, *J* = 7.3, 7.3 Hz, CH_3), 1.59 (2H, dq, *J* = 7.3, 14.3 Hz, CH_2, *meso*), 1.71 (2H, dq, *J* = 7.3, 14.3Hz, CH_2), 2.07 (2H, dq, *J* = 7.3, 14.3Hz, CH_2), 2.13 (2H, br, OH, *meso*), 2.60 (2H, br, OH), 2.27 (2H, dq, *J* = 7.3, 14.3 Hz, CH_2, *meso*), 7.28–7.15 (20H, m, Ph-H). Assignments were made by comparing the relative areas of methylene signals at δ 1.71 and δ 1.59, respectively.

meso- *and* dl-*2,5-Dimethyl-3,4-diphenyl-3,4-hexanediol (**19**)*: Colorless solid; ^{1}H NMR ($CDCl_3$) δ: 0.39 (6H, d, *J* = 6.9 Hz, CH_3, *dl*), 0.67 (6H, d, *J* = 6.9 Hz, CH_3, *meso*), 0.75 (6H, d, *J* = 6.6 Hz, CH_3, *meso*), 1.22 (6H, d, *J* = 6.3 Hz, CH_3, *dl*), 1.78 (2H, sep, *J* = 6.6 Hz, CH, *dl*), 2.30 (2H, sep, *J* = 6.9 Hz, CH, *meso*), 2.84 (2H, s, OH, *dl*), 2.95 (2H, s, OH, *meso*), 7.45–7.23 (20H, m, Ph-H). Assignments were made by comparing the relative areas of methyl signals at δ 0.39 and δ 0.67, respectively.

meso- *and* dl-*3,4-Dimethyl-1,6-diphenyl-3,4-hexanediol (**6a**)*: Colorless oil; IR (neat) ν: 3432, 3024, 2954, 2924, 1604, 1496, 1450, 1373, 1111, 1056, 949, 748, 702 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.25 (6H, s, CH_3), 1.28 (6H, s, CH_3), 1.64–1.74 (4H, m, CH_2), 1.87–1.98 (4H, m, CH_2), 2.05 (4H, br, OH), 2.64–2.72 (4H, m, CH_2), 2.76–2.85 (4h, m, CH_2), 7.15–7.30 (20H, m, Ph-H); ^{13}C NMR ($CDCl_3$) δ: 20.8, 21.1, 30.2, 30.3, 38.2, 38.5, 76.98, 125.7, 128.1, 128.37, 128.40, 142.6, 142.7; HRMS ([M + Na]$^+$): calcd for $C_{20}H_{26}O_2Na$: 321.1831; found: 321.1847. Diastereomeric ratio (50:50) was determined from the two equivalent methyl signals at 1.25 and δ 1.28 in the ^{1}H NMR spectrum of the crude product. It was supported that almost equivalent amounts of two isomers of 2,2-dimethyl-1,3-dioxolane derivatives were obtained from acetonide protection described below.

cis- *and* trans-*2,2-Dimethyl-4,5-bis(3-phenylethyl)-1,3-dioxolane*: To a solution of *meso*- and *dl*-3,4-Dimethyl-1,6-diphenyl-3,4-hexanediol (50 mg, 0.17 mmol) in CH_2Cl_2 (2 mL) and 2,2-dimethoxypropane (4 mL) at 0°C was added CSA (28 mg, 0.12 mmol). After the reaction mixture had been stirred for 16 h at room temperature, triethylamine (0.3 mL) was added. After evaporation of the solvent, the thin-layer chromatography to afford *cis*- and *trans*-2,2-dimethyl-4,5-*bis*(3-phenylethyl)-1,3-dioxolane. *cis*-Isomer (26 mg, 45%): colorless oil; IR (neat) ν: 3062, 2993, 2939, 2870, 1604, 1496, 1458, 1373, 1211, 1111, 1065, 1011, 895, 841, 748, 701, 517 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.29 (6H, s, CH_3), 1.54 (6H, s, CH_3), 1.64 (2H, ddd, *J* = 4.9, 5.0, 13.1 Hz, CH_2), 2.11 (2H, ddd, *J* = 4.2, 4.2, 13.1 Hz, CH_2), 2.73 (2H, ddd, *J* = 4.2, 5.0, 13.2 Hz, CH_2), 2.87 (2H, ddd, *J* = 4.2, 4.9, 13.2 Hz, CH_2), 7.20–7.37 (10H, m, Ph-H); ^{13}C NMR ($CDCl_3$) δ: 19.5, 29.6, 30.2, 38.9, 84.7, 106.6, 125.8, 128.3, 128.4, 142.7; HRMS ([M + Na]$^+$): calcd for $C_{23}H_{30}O_2Na$: 361.2144; found: 361.2158. *trans*-Isomer (24 mg, 42%): colorless oil; IR (neat) ν: 3062, 2985, 2939, 2870, 1743, 1604, 1496, 1458, 1373, 1219, 1180, 1065, 1011, 895, 841, 748, 701, 525 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 1.33 (6H, s, CH_3), 1.49 (3H, s, CH_3), 1.51 (3H, s, CH_3), 1.57 (ddd, *J* = 4.9, 5.1, 13.1 Hz, 2H, CH_2), 1.99 (ddd, *J* = 4.1, 4.4, 13.1 Hz, 2H, CH_2), 2.70 (ddd, *J* = 4.4, 5.1, 13.1 Hz, 2H, CH_2), 2.81 (ddd, *J* = 4.1, 4.9 Hz, 2H, CH_2), 7.07–7.35 (10H, m, Ph-H); ^{13}C NMR ($CDCl_3$) δ: 19.5, 29.6, 29.8, 30.4, 38.1, 38.9, 84.7, 106.7, 125.8, 128.3, 128.4, 142.5; HRMS ([M + Na]$^+$): calcd for $C_{23}H_{30}O_2Na$: 361.2144; found: 361.2113.

meso- *and* dl-*2,3,4,5-Tetramethyl-3,4-hexanediol (**20**)*: Colorless oil. Anal. calcd. for $C_{10}H_{22}O_2$: C 68.92, H 12.72; found: C 69.30, H 12.30. Assignments were made by comparing the relative heights of methyl signals at δ 1.14 and δ 1.15, respectively. Separation of the pure isomers from crude reaction mixture was achieved by benzylidene protection,[7] thin-layer chromatography (hexane – ethyl acetate), and cleavage of the protecting group as described below.

*(4*R,*5*RS*)- and (2*R,*4*RS,*5*SR*)-4,5-Diisopropyl-4,5-dimethy-2-phenyl-1,3-dioxolane*: To a solution of *meso*- and *dl*-2,3,4,5-tetramethyl-3,4-hexanediol (50 mg, 0.29 mmol) in CH_2Cl_2 (2 mL) and α,α-dimethoxytoluene (175 mg, 1.2 mmol) at 0°C was added CSA (35 mg, 0.15 mmol). After the reaction mixture had been stirred for 16 h at room temperature, triethylamine (0.5 mL) was added. After evaporation of the solvent, the crude product was purified by the thin-layer chromatography to afford (4*RS*,5*RS*)- and (2*R*,4*RS*,5*SR*)[8]-4,5-diisopropyl-4,5-dimethy-2-phenyl-1,3-dioxolane.

*(4*RS,*5*RS*)-Isomer (27 mg, 36%)*: Colorless oil; IR (neat) ν: 3062, 2970, 2877, 1466, 1381, 1219, 1095, 1026, 895, 702 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 0.91 (3H, d, *J* = 7.0 Hz, CH_3) 0.93 (3H, d, *J* = 7.0 Hz, CH_3), 0.95 (3H, d, *J* = 6.6 Hz, CH_3), 1.07 (3H, d, *J* = 6.6 Hz, CH_3), 1.22 (3H, s, CH_3), 1.25 (3H, s, CH_3), 2.15 (1H, qq, *J* = 7.0, 6.6 Hz, CH), 2.26 (1H, qq, *J* = 7.0, 6.6 Hz, CH), 5.85 (1H, s, CHPh), 7.30–7.37 (3H, m, Ph-H), 7.46–7.49 (2H, m, Ph-H); ^{13}C NMR ($CDCl_3$) δ: 13.3, 15.9, 19.1, 19.2, 19.5, 19.8, 31.5, 32.9, 88.1, 88.2, 98.6, 126.5, 128.1, 128.5, 139.9; HRMS ([M + Na]$^+$): calcd for $C_{17}H_{26}O_2Na$: 285.1831; found: 285.1872.

*(2*R,*4*RS,*5*SR*)-Isomer (16 mg, 21%)*: Colorless oil; IR (neat) ν: 3060, 2978, 2877, 1458, 1381, 1219, 925, 864, 725 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 0.90 (6H, d, *J* = 6.1 Hz, CH_3), 0.92 (6H, d, *J* = 6.2 Hz, CH_3), 1.22 (6H, s, CH_3), 2.17 (2H, qq, *J* = 6.1, 6.2 Hz, CH), 5.93 (1H, s, CHPh), 7.29–7.36 (3H, m, Ph-H), 7.48 (2H, m, Ph-H); ^{13}C NMR ($CDCl_3$) δ: 14.9, 19.1, 19.6, 31.3, 87.8, 98.6, 126.1, 128.0, 128.1, 140.0; HRMS ([M + Na]$^+$): calcd for $C_{17}H_{26}O_2Na$: 285.1831; found: 285.1799.

dl-*2,3,4,5-Tetramethyl-3,4-hexanediol*: To a solution of (4*RS*,5*RS*)-4,5-diisopropyl-4,5-dimethyl-2-phenyl-1,3-dioxolane (27 mg, 0.10 mmol) in EtOH (2 mL) was added $Pd(OH)_2$ (14 mg, 0.10 mmol) under an argon atmosphere. Hydrogen gas was purged through the mixture and stirred for 1 h. The reaction mixture was filtered and evaporated. Thin-layer chromatography afforded *dl*-2,3,4,5-tetramethyl-3,4-hexanediol (17 mg, 0.097 mmol, 97%). Colorless solid; mp 45–47°C; IR (neat) ν: 3471, 2993, 2962, 2915, 1466, 1381, 1173, 1118, 1072, 1018, 918, 887, 594 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 0.99 (6H, d, *J* = 6.7 Hz, CH_3), 1.00 (6H, d, *J* = 6.4 Hz,

[7] The acetonide protection for 2,3,4,5-tetramethyl-3,4-hexanediol was tried, but the corresponding 2,2-dimethyl-1,3-dioxolane derivatives were not obtained at all.

dq, J = 7.6, 14.7 Hz, CH_2), 1.71 (2H, dq, J = 7.6, 14.7 Hz, CH_2), 2.08 (2H, qq, J = 7.0, 7.0 Hz, CH), 2.18 (2H, br, OH); ^{13}C NMR ($CDCl_3$) δ: 9.6, 18.9, 19.4, 27.1, 33.6, 80.7. Anal. calcd. for $C_{12}H_{26}O_2$: C 71.23, H 12.95; found: C 70.99, H 12.94.

meso-*3,4-diethyl-2,5-Dimethyl-3,4-hexanediol*: This isomer was obtained from (2*R*,4*RS*,5*SR*)-4,5-diisopropyl-4,5-diethyl-2-phenyl-1,3-dioxolane in 94% yield. Colorless solid; mp 50–51°C; IR (KBr) ν: 3471, 2970, 2939, 1466, 1389, 1103, 957, 532 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 0.99 (6H, dd, J = 7.5, 7.3 Hz, CH_3), 0.99 (6H, d, J = 7.0 Hz, CH_3), 1.03 (6H, d, J = 7.0 Hz, CH_3), 1.59 (2H, dq, J = 7.3, 18.5 Hz, CH_2), 1.71 (2H, dq, J = 7.5, 18.5 Hz, CH_2), 2.07 (2H, qq, J = 7.0, 7.0 Hz, CH), 2.34 (2H, br, OH); ^{13}C NMR ($CDCl_3$) δ: 9.7, 18.9, 19.4, 26.4, 34.2, 80.9. Anal. calcd. for $C_{12}H_{26}O_2$: C 71.23, H 12.95; found: C 71.04, H 12.78.

meso-, *and* dl-*1,2-Diphenyl-1,2-ethanediol (**18**)*: Colorless solid; ^{1}H NMR ($CDCl_3$) δ: 2.38 (2H, br, OH, *meso*), 3.04 (2H, br, OH, *dl*), 4.65 (2H, s, CH, *dl*), 4.79 (2H, s, CH, *meso*), 7.07–7.30 (20H, m, Ph-H). Assignments were made by comparing the relative heights of carbinol proton signals at δ 4.67 and δ 4.79, respectively.

meso-, *and* dl-*1,6-Diphenyl-3,4-hexanediol (**6a,b,d**)*: Colorless solid; ^{1}H NMR ($CDCl_3$) δ: 1.76–1.87 (8H, m, CH_2), 2.65–2.90 (12H, m, CH_2 + OH), 3.50 (2H, m, CH, *dl*), 3.65 (2H, m, CH, *meso*), 7.22–7.36 (20H, m, Ph-H). Assignments were made by comparing the relative areas of carbinol proton signals at δ 3.50 and δ 3.65, respectively.

cis-*1,2-Diphenyl-1,2-cyclohexanediol (**15**)*: Colorless solid; ^{1}H NMR ($CDCl_3$) δ: 2.02–1.91 (6H, m, CH_2), 2.74–2.22 (2H, m, CH_2), 2.94 (2H, br, OH), 7.12–7.03 (10H, m,Ph-H). ^{13}C NMR ($CDCl_3$) δ: 21.9, 35.9, 77.2, 126.7, 126.9, 127.1, 144.1.

cis-, *and* trans-*1,2-Dimethyl-1,2-cyclohexanediol*: Assignments were made by comparing the relative hights of methyl signals at δ 1.27 and δ 1.21, respectively. Identification of each isomer was achieved as described below.

cis-*1,2-Dimethyl-1,2-cyclohexanediol (**21**)*: Repeated thin layer chromatography of the crude pinacol product gave pure *cis*-isomer: Colorless solid; mp 48–50°C (lit. 51°C); ^{1}H NMR ($CDCl_3$) δ: 1.21 (6H, s, CH_3), 1.36–1.51 (4H, m, CH_2), 1.57–1.64 (2H, m, CH_2), 1.71–1.77 (2H, m, CH_2), 2.20 (2H, br, OH); ^{13}C NMR ($CDCl_3$) δ: 22.4, 23.6, 36.7, 74.0.

trans-*1,2-Dimethyl-1,2-cyclohexanediol (**21**)*: Separation of the pure *trans*-isomer from crude reaction mixture was not achieved. It was prepared according to the litarature. Colorless solid, mp 90–92°C (lit. 93°C); ^{1}H NMR ($CDCl_3$) δ: 1.26 (6H, s, CH_3), 1.43–1.50 (2H, m, CH_2), 1.46 (2H, br, OH), 1.55–1.60 (4H, m, CH_2), 1.71–1.75 (2H, m, CH_2); ^{13}C NMR ($CDCl_3$) δ: 22.0, 23.3, 36.4, 74.3.

Silver-catalyzed asymmetric amination of silyl enol ethers

Yasuhiro Yamashita, Haruro Ishitani, and Shū Kobayashi

Abstract: Catalytic amination of silyl enol ethers with azo diester compounds was investigated. It was shown that $Cu(OTf)_2$ or AgOTf had high catalytic activity and that AgOTf was the most efficient among the catalysts tested in the reactions. In asymmetric reactions, the $AgClO_4$–BINAP system showed high enantioselectivity. In a mixture of toluene or mesitylene and THF, silyl enol ethers reacted with dibenzyl azodicarboxylate (DBnAD) smoothly to afford the corresponding amination adducts in excellent yields with up to 86% ee.

Key words: amination, amino acid, asymmetric synthesis, chiral catalyst, silver.

Résumé : On a étudié l'amination catalytique d'éthers énoliques silylés par des composés azodiesters. Il a été démontré que le $Cu(OTf)_2$ et le AgOTf possèdent une activité catalytique élevée et que le AgOTf est l'un des catalyseurs les plus efficaces pour ces réactions. Dans les réactions asymétriques, le système $AgClO_4$·BINAP donne lieu à une énantiosélectivité élevée. Dans un mélange de toluène ou de mésitylène avec du THF, les éthers énoliques silylés réagissent facilement avec l'azodicarboxylate de dibenzyle (ADDBn) pour conduire à la formation des adduits d'amination correspondants, avec d'excellents rendements et un ee pouvant aller jusqu'à 86%.

Mots clés : amination, acide aminé, synthèse asymétrique, catalyseur chiral, argent.

[Traduit par la Rédaction]

Introduction

Amination at the α-position of carbonyls provides one of the most efficient methods for synthesis of α-amino acids and their derivatives (for a review see ref. (1)). Several electrophilic aminations have been reported (1) and among them, the reactions of silyl enol ethers with azo diesters are promising because the starting materials are stable and readily available, and the hydrazine groups produced are easily converted to amino groups by reductive N—N bond cleavage (Scheme 1) (2, 3). In the previous reports, however, thermal conditions (4) or stoichiometric amounts of Lewis acids (2*a*, *d*–*f*) were required for the reaction of silyl enol ethers with azo diesters. Quite recently, we have reported our preliminary results on silver and copper-catalyzed amination of silyl enol ethers (5). This was the first example of catalytic amination of silyl enol ethers, and we have since continued to investigate asymmetric versions of these reactions. As for asymmetric amination, although many diastereoselective approaches using lithium enolates or silyl enol ethers and azo compounds were reported, (2*a*–*d*, 6) examples of catalytic enantioselective reactions have been limited. In 1997, Evans and Nelson (7) reported enantioselective amination of *N*-acyloxazolines with an azodicarboxylate using a chiral magnesium bis(sulfonamide). In this paper, we report full details of our results on catalytic asymmetric amination, including the first finding of efficient achiral catalysts. (Quite recently, Evans and Johnson reported chiral copper-catalyzed enantioselective amination of enolsilanes with azodicarboxylate derivatives. See ref. (8)).

Results and discussion

Recently, we have found that metal trifluoromethanesulfonates (triflates) are excellent catalysts in several carbon–carbon bond-forming reactions. Based on these results, we first examined the reaction of the silyl enol ether derived from *S*-ethyl propanethioate with dibenzyl azodicarboxylate (DBnAD) using catalytic amounts of several metal triflates (Table 1) (for recent reports on reactions using metal triflates as catalysts see ref. (9)). When $Zn(OTf)_2$, $Fe(OTf)_3$, $Yb(OTf)_3$, $Zr(OTf)_4$, or $Hf(OTf)_4$ was used, little rate enhancement was observed. On the other hand, while the reaction proceeded moderately in the presence of $Sn(OTf)_2$ or $Sc(OTf)_3$, the desired products were obtained in high yields when AgOTf or $Cu(OTf)_2$ was employed as the catalyst.

We then investigated the effect of solvents using AgOTf as a catalyst (Table 2). While the amination reaction proceeded cleanly in dichloromethane, lower yields were obtained in toluene, THF, and propionitrile. For azo diester compounds, not only DBnAD but also diethyl azodicarboxylate and *tert*-butyl azodicarboxylate gave the corresponding amination

13		AgOTf (10)	0, 0.5	91

worked well as a silyl moiety instead of the trimethylsilyl group. When less reactive silyl enol ethers derived from ketones were examined, it was found that the reactions also proceeded smoothly in the presence of a catalytic amount of AgOTf or $Cu(OTf)_2$. Also in these cases, AgOTf showed higher activity than $Cu(OTf)_2$.

We then examined asymmetric versions of these aminations. In the presence of a catalytic amount of a AgOTf–BINAP system, (10) the silyl enol ether of propiophenone was treated with DBnAD in THF. The reaction proceeded smoothly at –45°C to afford the corresponding amination adduct in 83% yield with 29% ee. Several reaction conditions were then examined to improve the selectivity. The effect of silver salts is shown in Table 5. When $AgClO_4$ was used as a catalyst, the ee was improved to 68%. The effects of temperature, azo compounds, and solvents are summarised in Tables 6, 7, and 8, respectively. The ee obtained at –45°C was not improved even when the reaction was carried out at lower temperatures such as –60°C and –78°C. As for azo compounds, DBnAD gave the best result. We observed interesting effects of the solvents. When a single solvent of THF or toluene was used, 68% ee (THF) or 67% ee (toluene) was obtained. On the other hand, greater than 74% ee were observed when a mixture of THF and toluene, *m*-xylene, or mesitylene was used. The best ee (86%) was obtained when a 5:1 mixture of mesitylene and THF was employed as the solvent. It is interesting to note that no chiral induction was observed when dichloromethane was used as a solvent, albeit the reaction proceeded cleanly to give the desired adduct in 90% yield.

Several examples of catalytic asymmetric amination are shown in Table 9. The silyl enol ethers derived from α-tetralone and phenyl propyl ketone reacted with DBnAD in the presence of a catalytic amount of $AgClO_4$–BINAP to afford the corresponding amination adducts in high yields with good ee. In the reaction of the silyl enolate of phenyl propionate, 51% ee of the amination adduct was obtained using the same system. As for the absolute configuration of the amination product, the product was converted to the literature known compound (**1**) (8)[3] according to standard procedures (Scheme 2).

[3] $[\alpha]_D^{31}$ = +8.9 (c 1.69, $CHCl_3$) (63% ee) (lit. (8) $[\alpha]_D^{24}$ = –17.9 (c 1.15, $CHCl_3$); $[\alpha]_D^{20}$ = –15.9 (c 0.38, $CHCl_3$) (4*R*,5*R*)) (11).

Table 7. Effect of Azo Compounds

Entry	R	Conditions	Yield (%)	ee (%)
1	Bn	–45°C, 1 h	99	68
2	Et	–45°C, 1 h	91	46
3	^{t}Bu	–45°C, 18 h	88	31

In summary, amination reactions of silyl enol ethers with azo diester compounds proceeded smoothly in the presence of a catalytic amount of AgOTf or $Cu(OTf)_2$. AgOTf gave better results than $Cu(OTf)_2$ in most cases. Various kinds of silyl enol ethers including those derived from esters, thioesters, and ketones worked well. It is noted that all the examined reactions proceeded cleanly using a small amount of the catalyst, and that the procedures are very simple. As for the catalytic asymmetric version of these aminations, $AgClO_4$–BINAP worked well to afford the corresponding adducts in excellent yields with moderate to high ee. Interesting solvent effects were observed, and these silver-catalyzed asymmetric aminations would provide one of the most efficient methods for the preparation of chiral and achiral α-amino carbonyl compounds.

Experimental

General

Melting points were uncorrected. ^{1}H and ^{13}C NMR spectra were recorded on a JEOL JNM-LA300, JNM-LA400, or JNM-LA500 spectrometer in $(CD_3)_2SO$. $(CD_3)_2SO$ was used as internal standard (δ = 2.49 for ^{1}H NMR and δ = 39.5 for ^{13}C NMR). IR spectra were measured with JASCO FT/IR-610 spectrometers. High-resolution mass spectra (HRMS) were measured with JEOL JMX-SX-102 mass spectrometer. High-performance liquid chromatography was carried out using the following apparatuses: SHIMADZU LC-10AT (liquid chromatograph), SHIMADZU SPD-10A (UV detector), and SHIMADZU C-R6A Chromatopac. Column chromatography was conducted on Silica gel 60 (Merck) and preparative thin-layer chromatography was carried out using Wakogel B-5F. All chemical compounds were purified based on standard procedures.

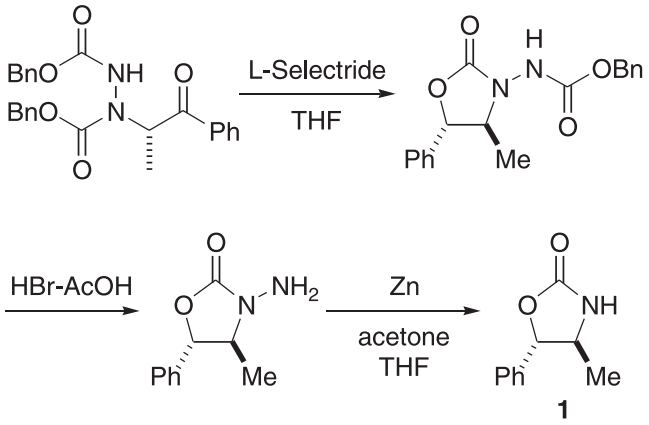
A general procedure of asymmetric reactions



Achiral reactions

A typical experimental procedure is as follows: To a stirred suspension of AgOTf (0.040 mmol) in CH_2Cl_2 (1.0 mL) was added DBnAD (0.44 mmol) in CH_2Cl_2 (0.5 mL) at the temperature shown in Table 2. After stirring for 10 min, a silyl enol ether (0.40 mmol) in CH_2Cl_2 (0.5 mL) was added dropwise, and the mixture was stirred at the same temperature. A 20% HF(aq)–THF (1:1) solution was then added and the mixture was stirred for 1 h at room temperature. After being basified with saturated aq $NaHCO_3$, the aqueous layer was extracted with CH_2Cl_2. The organic layers were combined and dried over anhyd Na_2SO_4. After filtration and concentration, the residue was purified by preparative thin layer chromatography on silica gel to afford the desired amination adduct.

Asymmetric reactions

$AgClO_4$ (0.040 mmol, 10 mol%) and (*R*)-BINAP (0.048 mmol, 12 mol%) were dissolved in THF (1 mL). After stirring for 30 min at room temperature, the mixture was cooled to the desired temperatures. In cases of the reactions in toluene or toluene–THF, THF of the catalyst solution was removed under reduced pressure (1.0 mmHg, 30 min) first, and the desired solvent was added. To the cooled catalyst solution was added DBnAD (0.44 mmol) in the solvent (0.5 mL). After stirring for 10 min, a silyl enol ether (0.4 mmol) in the solvent (0.5 mL) was added dropwise, and the mixture was stirred at the same temperature. An aqueous 20% HF–THF (1:1) solution was then added and the mixture was stirred for 1h at room temperature. After basified with saturated $NaHCO_3$, the aqueous layer was extracted with dichloromethane. The organic layers were combined and dried over anhyd Na_2SO_4. After filtration and concentration, the residue was purified by preparative thin layer chromatography on silica gel to afford the desired adduct. The enantiomeric excess was determined by HPLC analysis (DAICEL CHIRALCEL OD or AS).

Scheme 2.

S-Ethyl 2-(N,N′-dibenzyloxycarbonylhydrazino)propanethioate: IR (neat) (cm^{-1}): 3304, 1759, 1724, 1687. ^1H NMR ($(CD_3)_2SO$, 70°C) δ: 1.16 (t, 3H, *J* = 7.0 Hz), 1.31 (d, 3H, *J* = 7.1 Hz), 2.81 (q, 2H, *J* = 7.0 Hz), 4.75 (m, 1H), 5.10 (s, 2H), 5.12 (s, 2H), 7.2–7.4 (m, 10H), 9.48 (br, 1H). ^{13}C NMR ($(CD_3)_2SO$, 70°C) δ: 13.6, 13.9, 22.2, 63.2, 66.0, 67.1, 127.0, 127.2, 127.6, 127.9, 128.0, 135.7, 136.0, 154.8, 156.1, 198.2. Diastereoselective alkylations of chiral, phosphorus-stabilized carbanions: *N*-alkyl substituent effects in *P*-alkyl-1,3,2-diazaphosphorinane 2-oxides

Scott E. Denmark and Jung-Ho Kim

Abstract: A systematic study of the diastereoselective alkylation of anions derived from racemic *N*-substituted *P*-alkyl 1,3,2-diazaphosphorinane 2-oxides was carried out with variation of the *N*-substituent. High diastereoselectivity for the methylation of a *P*-benzyl anion has been achieved with *N*-neopentyl derivative **5d**. Similarly, a *P*-ethyl anion derived from *N*-neopentyl derivative **6d** showed high diastereoselectivity upon benzylation. The observed difference in alkylation diastereoselectivity between *P*-ethyl and *P*-benzyl anions for various *N*-alkyl substituents is discussed.

Key words: phosphonamide-stabilized carbanions, alkylation, asymmetric, stereoselective, organolitihium.

Résumé : On a réalisé une étude systématique de l'alkylation diastéréosélective d'anions dérivés de 2-oxydes de *P*-alkyl-1,3,2-diazaphosphorinanes *N*-substitués racémiques portant divers substituants sur l'azote. Avec l'anion **5d** qui porte des groupes *P*-benzyle et *N*-néopentyle, la méthylation se fait avec une diastéréosélectivité élevée. Il en est de même lors de la réaction de benzylation de l'anion **6d** qui porte des groupes *P*-éthyle et *N*-néopentyle. On discute des différences observées dans la diastéréosélectivité des anions *P*-éthyle et *P*-benzyle portant divers substituants *N*-alkyles.

Mots clés : carbanions phosphonamides stabilisés, alkylation, asymétrique, stéréosélective, organolithium.

Introduction and background

In recent years there has been considerable interest in carbon–carbon single-bond forming reactions involving heteroatom-stabilized carbanions (for reviews see ref. (1)). Among them, phosphorus-based reagents have great potential for auxiliary-based chiral modification (2). As part of an ongoing program on the chemistry of chiral, phosphorus-stabilized carbanions (3) we have been interested in developing general auxiliaries which give rise to highly selective transformations at the anionic carbon. The design criteria we formulated require that the auxiliary be capable of biasing the rotameric population about the C—P bond and also shield one of the anion faces to achieve a highly selective approach of the electrophilic reagents. In addition, other practical considerations were: (*i*) ease of synthesis in enantiomerically pure form, (*ii*) chemical stability under the attachment and recovery conditions, and (*iii*) structural simplicity while providing high stereochemical bias. Auxiliaries (4, 5) and controller groups (6) of C_2-symmetry have been utilized a great deal in asymmetric synthesis. In the chemistry of phosphorus-stabilized anions as well, Hanessian has pioneered the use of the 1,2-cyclohexanediamine based auxiliary for controlling the environment in a phosphonamide (7). Cyclic phosphonamides derived from C_2-symmetric diamines exist as a single pair of enantiomers because phosphorus is not a stereogenic center. Therefore, these auxiliaries can eliminate problems associated with amino alcohol auxiliaries in which the P-atom is stereogenic and contains a strong P—O bond (3*f*). As part of our examination of the relationship of anion structure and reaction stereoselectivity, we were interested in evaluating the various aspects of ring size, polycyclic structure, and nitrogen substituent in the design of phosphorus-based auxiliaries and the investigation of the anions derived therefrom. With this in mind we have chosen a collection of candidates in the C_2-diamine family to survey (Chart 1).

Our previously reported X-ray crystal structural analysis (8) of the lithio 2-benzyl-1,3-dimethyl-1,3,2-diazaphosphorinane 2-oxide showed that the anion is intrinsically chiral as the nitrogens are pyramidal and the *N*-methyl groups are oriented in equatorial and axial positions (Fig. 1). Furthermore, the key features of this structure are: (*i*) there is no C-Li contact, (*ii*) the carbanion is almost planar, and (*iii*) the phenyl group is oriented *anti* to the P=O bond (O–P–C–C dihedral angle = 168.9°). Further studies on the dynamic, solution behavior (8*a*, 9) of this and related anions and computational studies (10) have shown that the rotational

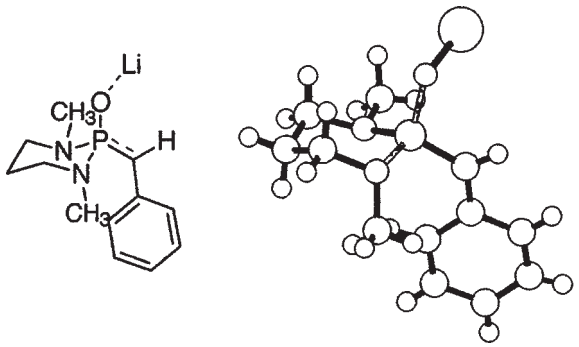

Chart 1.

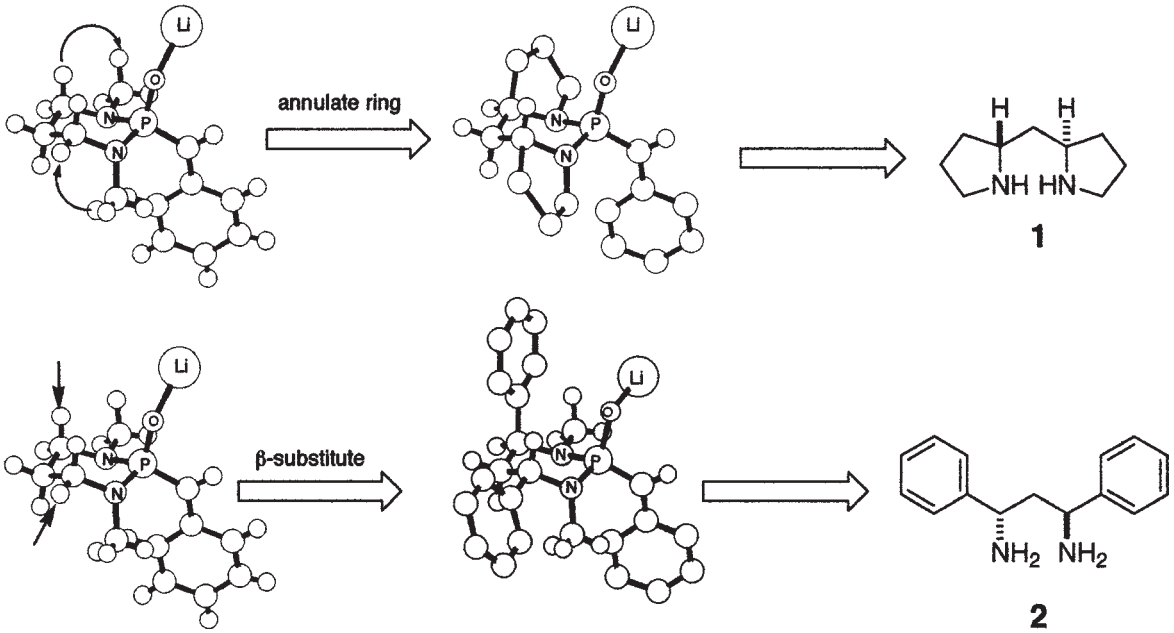
barrier around the C—P bond in the benzyl anion is extremely low (ca. 6–8 kcal/mol). On the basis of the observations in the simple six-membered ring system, the chirally modified diazaphosphorinane **ii** was selected to investigate alkylation behavior of the derived *P*-alkyl anions. By comparison to five- and seven-membered analogs **i** and **iii**, system **ii** has the advantage of having the *N*-alkyl group closest to the anionic center due to ring angles[2].

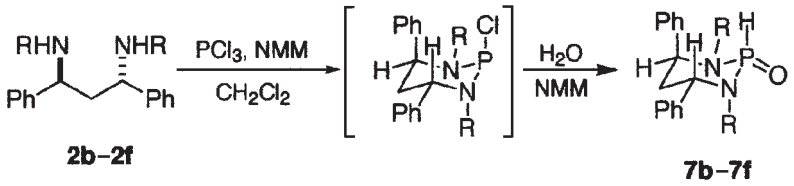


The key controlling attribute to obtaining high selectivity in alkylation was expected to be the ability to preordain the disposition of the N-substituents which in turn provide the chiral environment necessary for asymmetric reaction. On the basis of the assumption that chirally modified system **ii** would maintain the basic features of the parent system as elucidated in the X-ray crystal structure (8), diamines **1** and **2** were chosen as specific models to be investigated (Fig. 2). As shown in Fig. 2, the two proposed mechanisms for controlling the disposition of the N-substituents are: (*i*) annulating two five-membered rings to the central 1,3,2-diazaphospholidine ring thus leading to the dipyrrolidinomethane **1**, and (*ii*) placing substituents at the C(4) and C(6) positions to influence the hybridization of the nitrogen through torsional interactions. The *P*-alkyl anions derived from **1** and **2** provide six-membered ring phosphorus heterocycles which are expected to maintain a chair conformation, though the distortions due to the axially oriented phenyl group were not a priori obvious. Additionally, the *P*-benzyl-1,3,2-diazaphosphorinane 2-oxide anions generated from diamines **1** and **2** should adopt a conformation similar to the model in which the nitrogens are pyramidal. Thus, the disposition of the *N*-alkyl groups or the two *N*-methylenes of the fused rings distinguish the faces in the anions.

Fig. 1. Chem-3D presentation of lithio 2-benzyl-1,3-dimethyl-1,3,2-diazaphosphorinane 2-oxide (8).

In a preliminary study we prepared the tricyclic *P*-benzyl diazaphosphorinane **3** derived from **1** by simple condensation with benzylphosphonic dichloride[3] (11). The methylation diastereoselectivity of the lithio anion derived from **3**

Fig. 2. Chiral 1,3-diamine design to control nitrogen substituent pyramidality.



[2] In the five-membered-ring analog **i**, the N-substituents are pulled away from the anion due to the external bond angles. In the seven-membered analog **iii**, the ring is considerably more flexible allowing the N-substituents to avoid the anionic center.

[3] The diamine **3** was prepared in enantiomerically enriched form (96% ee) from L-proline in nine steps and convertd to **3** using benzylphosphonic dichloride.

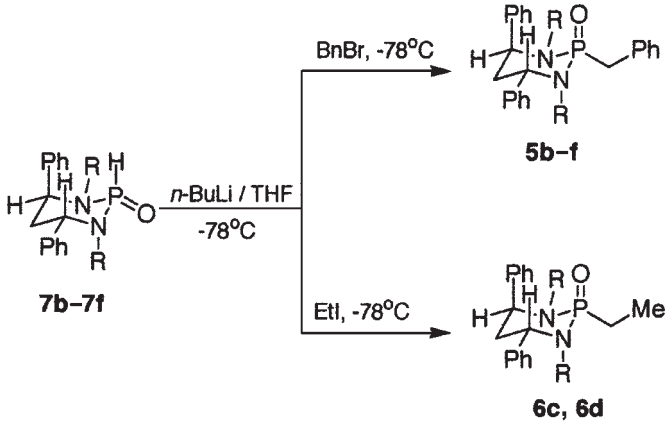
was 5.7/1 (Scheme 1). Since perhydropyrimidines normally exist in chair conformations (12), we expected the tricyclic system **3** to adopt a *cis*/*anti*/*cis* chair conformation thereby forcing the two different methylene units to orient in equatorial and axial positions. Thus, electrophiles approach away from the axial *N*-methylene unit. Unfortunately, the steric bulk of the methylene unit does not provide a sufficiently strong π-facial discrimination. Further variation was considered to be impractical since placing additional substituents in the five-membered rings would be synthetically challenging. Consequently, we chose to pursue the opportunities provided by the acyclic 1,3-diamine **2** which is much more amenable to variation in the size of the N-substituent. We describe herein a systematic examination of the effect of steric bulk of the N-substituent in the alkylation selectivity of anions derived from diamine **2**.

Results

Preparation of *P*-alkyl-1,3,2-diazaphosphorinanes

For the systematic study of the steric effect of *N*-alkyl substituents, six different *P*-benzyl-1,3,2-diazaphosphorinanes (*N*-methyl (**5a**), *N*-ethyl (**5b**), *N*-isopropyl (**5c**), *N*-neopentyl (**5d**), *N*-benzyl (**5e**), and *N*-mesitylmethyl (**5f**)) and three different *P*-ethyl-1,3,2-diazaphosphorinanes (*N*-methyl (**6a**), *N*-isopropyl (**6c**), and *N*-neopentyl (**6d**)) were chosen. All six requisite diamines (**2a**–**f)** were prepared by our previously reported procedures (13). Generally, the preparation of *P*-alkyl-1,3,2-diazaphosphorinanes was accomplished in a straightforward manner by combining the appropriate alkylphosphonic dichlorides (14) with the requisite diamines in the presence of triethylamine (2, 15). Sterically less demanding *N*,*N*′-dimethyl-1,3-diphenyl-1,3-propanediamine (**2a**) was amenable to these reaction conditions, providing *P*-benzyl- and *P*-ethyl diazaphosphorinane **5a** and **6a** in 86% and 96% yield, respectively (Scheme 2). Unfortunately, other higher alkyl diamines (**2b**–**f**) did not provide products in reasonable yield presumably due to the steric bulk of the diamines.

Scheme 2.



Fortunately, diamines **2b**–**f** did react with phosphorus trichloride (PCl_3) in the presence of *N*-methylmorpholine (NMM) or triethylamine (Et_3N) to afford *P*-chlorodiazaphosphorinanes which upon hydrolysis produced cyclic hydrogen phosphites **7b**–**f** in good yield (63–96%) (Table 1). Phosphites **7b**–**f** were unexpectedly stable and could be purified by silica gel column chromatography. It is important to note the buttressing effect of the 4 and 6-phenyl groups toward *N*-alkyl groups which will make the phosphorus center more sterically hindered and thus less sensitive to oxidation. The characteristic structural feature of phosphites **7b**–**f** is strong tautomeric preference for cyclic hydrogen phosphondiamide structure as evidenced by a strong infrared stretching band for the P=O group (1217–1246 cm^{-1}) and a diagnostic stretching band for the P—H unit (2211–2384 cm^{-1}) (16). The magnitude of the P—H coupling constant (J_{PH} = 595–629 Hz) is strongly suggestive of an axial P—H bond (17) The characteristic NMR spectral data are summarized in Table 2. Unlike trivalent trialkyl phosphites in which the phosphorus resonance appears in the neighborhood of 140 ppm (17), all resonances of the hydrogen phosphonamides **7b**–**f** appeared at –0.86–12.69 ppm.

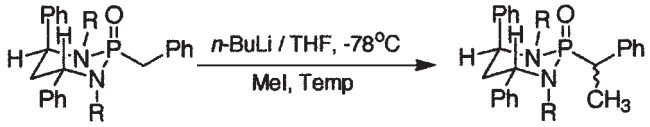
[a]Yields are for isolated products after chromatography.



Though less acidic than the corresponding dioxa analogs,[4] the hydrogen phosphonamides **7b–f** are sufficiently acidic to be deprotonated by *n*-BuLi at low temperature (–78°C). Importantly, no nucleophilic addition products to the phosphorus center were observed in the diaza analogs, presumably due to a combination of steric hindrance coupled with electronic deactivation of phosphonamides versus phosphonates. The use of triethylamine led to a sluggish reaction even at elevated temperatures and hydride bases such as NaH and KH were not suitable, affording unidentified side products. However, treatment of hydrogen phosphites **7b–f** with *n*-BuLi followed by alkylation with ethyl iodide and benzyl bromide afforded *P*-alkyl-1,3,2-diazaphosphorinane 2-oxides **5b–f, 6c,** and **6d**, in reasonable yields (61–97%) (Table 3).

The structures of the *P*-alkyl-1,3,2-diazaphosphorinanes **5a–f** and **6a**, **6c**, **6d**, and were secured by spectroscopic methods. First, in the ^{13}C NMR spectra, the α-methylene carbons displayed resonances at 38.55–43.40 ppm ($^1J_{CP}$ = 102.7–121.6 Hz) for *P*-benzyl-1,3,2-diazaphosphorinane 2-oxides **5a–f** and 25.43–29.35 ppm ($^1J_{CP}$ = 121.8–129.7 Hz) for *P*-ethyl-1,3,2-diazaphosphorinanes **6a**, **6c**, and **6d**. Second, diagnostic α-methylene protons showed phosphorus-coupled eight-line patterns at 3.35–3.69 ppm for *P*-benzyl-1,3,2-diazaphosphorinanes **5a–f** and 1.88–2.38 ppm for *P*-ethyl-1,3,2-diazaphosphorinanes **6a**, **6c**, and **6d**. Finally, the observation of a strong, characteristic P=O stretch (1208–1271 cm^{-1}) obviously eliminated the possibility of the formation of regioisomeric *O*-alkylated products. It is noteworthy that the reaction of the lithiated phosphite with silylating agents provided *O*-silylated phosphite exclusively (18). Additional characteristic features were noted in the ^{31}P NMR as all *P*-alkyl 1,3,2-diazaphosphorinane 2-oxides displayed resonances in the region shifted downfield (21.64–31.73 ppm)

[4]Diethyl hydrogenphosphonate is easily deprotonated at 0°C using NaH or Et_3N.

compared to those of hydrogen phosphoramides **7b**–**f** (Table 2). The ring conformation is believed to adopt an axial P=O unit on the basis of X-ray crystallographic evidence (19) and the large difference in ^{1}H NMR resonances for HC(4) and HC(6) in **5** and **6** compared to **7**.

Diastereoselective methylation of *P*-benzyl-1,3,2-diazaphosphorinane 2-oxides 5a–f

The methylation of benzylic carbanions derived from **5a**–**f** was examined first. The sterically least demanding *N*-methyl analog **5a** and *N*-benzylic derivatives **5e**, and **5f** reacted rapidly and were completely methylated at –78°C within 2 to 2.5 h. However, in the case of sterically demanding substrates **5b**, **5c**, and **5d**, the reaction was sluggish at –78°C but proceeded at –60°C within 3 h. Clearly, the steric bulk of the *N*-alkyl group controlled the facility of the approach of the electrophile to the anionic center. *N*-Benzylic derivatives **5e** and **5f**, which are somewhat bulkier than methyl groups, may also benefit from contributions of the aromatic ring. As shown in Table 4, the methylation of the *P*-stabilized benzylic carbanions Li^+**5a**–**f**$^-$ proceeded with moderate to high diastereoselectivity. Interestingly, diastereoselectivity was not merely a function of the steric bulk of the alkyl group on the nitrogen as the *N*-methyl analog **5a** afforded remarkably high diastereoselectivity compared to the corresponding *N*-ethyl (**5b**) and *N*-isopropyl (**5c**) analogs. The most sterically demanding *N*-neopentyl analog **5d** showed the highest selectivity (entry 4). Moderate selectivities were found in the case of benzyl and mesityl analogs **5e** and **5f**.

Diastereoselective benzylations of *P*-ethyl-1,3,2-diazaphosphorinanes 6a, 6c, and 6d

P-Ethyl anions were much more reactive than the corresponding *P*-benzyl anions as evidenced by the consumption of educt which was complete at –78°C within 30 min. Moreover, in contrast to the alkylation behavior of the *P*-benzyl anions, the benzylation of the *P*-ethyl anions from **6a**, **6c**, and **6d** showed a qualitative linear dependency of diastereoselectivity as a function of steric bulk of the *N*-alkyl groups (Table 5). The most sterically demanding *N*-neopentyl

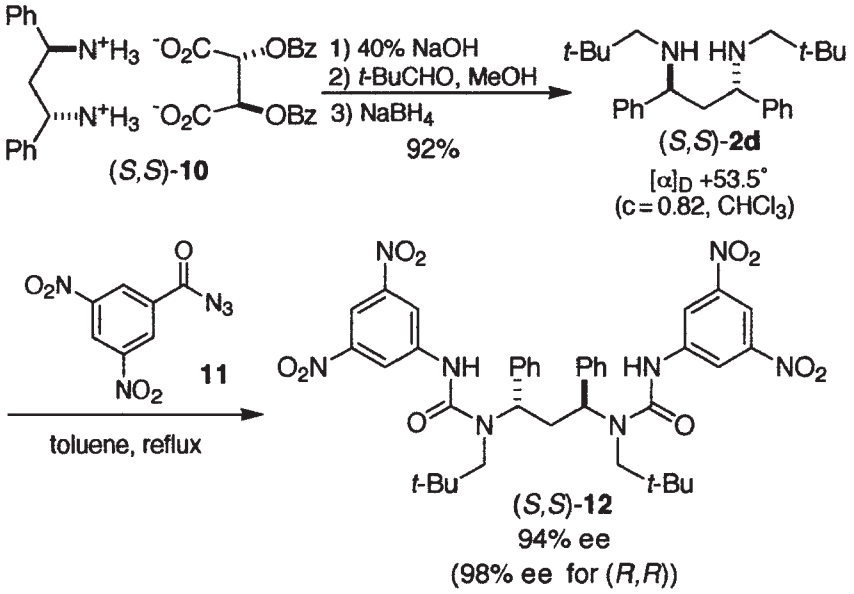
analog **6d** gave the highest selectivity (entry 3) whereas the sterically least demanding *N*-methyl analog **6a** afforded the lowest selectivity (entry 1). The disparate behavior of the *P*-benzyl and *P*-ethyl series may ultimately relate to the differences in conformational composition and rotational barriers (vide infra). The discrepancy between *N*-isopropyl analogs **5c** and **6c** might also be explained by the size difference of the electrophiles (benzyl vs. methyl). An electrophile dependence in the alkylation of related *P*-benzyl 1,3,2-oxazaphosphorinane 2-oxides has been previously noted, however in this case, methylation proceeds with higher selectivity than benzylation (3*c*)[5].

Stereochemical course of the reaction

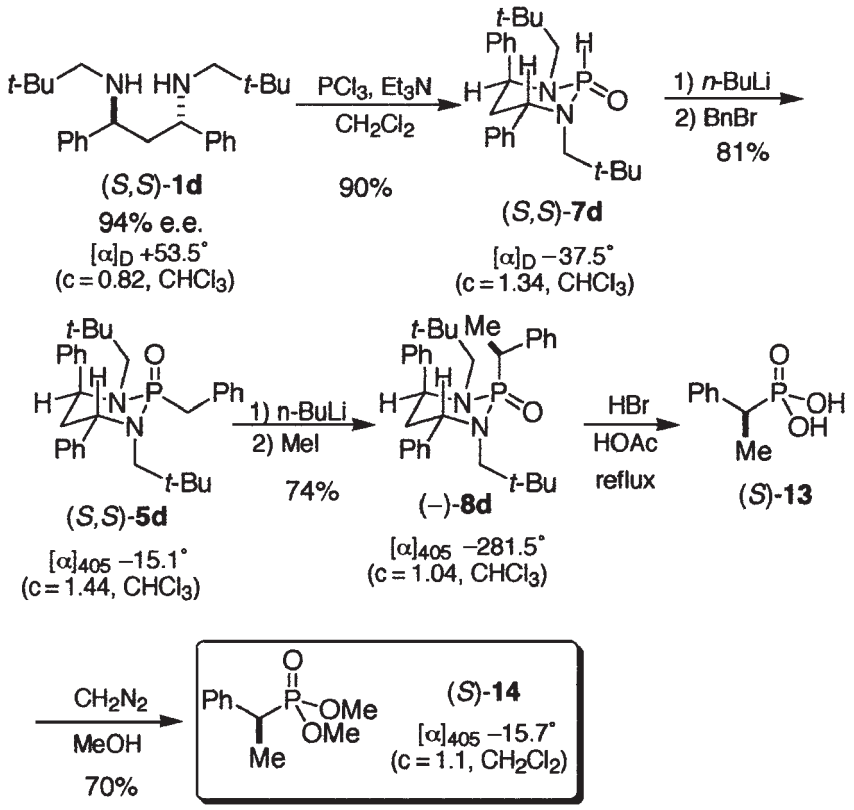
In the course of the routine characterization of the alkylation products we noticed an interesting trend which suggested that the sense of asymmetric induction may not be the same for all of the substrates **5a–5f.** The two diagnostic features are the ^{31}P NMR chemical shifts and the HPLC elution orders for the two diastereomeric methylation products (Table 6). For the *N*-methyl (**8a**), *N*-ethyl (**8b**), and *N*-isopropyl (**8c**) alklyation products, the major diastereomer displays a lower field ^{31}P NMR chemical shift and is more strongly retained on the HPLC (aminopropyl silica). The *N*-benzyl alkylation products (**8e**) display a single ^{31}P resonance, but have a similar behavior on HPLC. Curiously, the *N*-neopentyl (**8d**) and *N*-mesityl (**8f**) analogs exhibit the reverse trend, i.e., the major diastereomer appears at *higher field* and is *less retained* on the HPLC. We thus suspected that the sense of relative asymmetric induction for **5a–5c** and **5e** might be different from that for **5d** and **5f**. This is an intriguing hypothesis which would require a complex conformational/mechanistic analysis to explain the reversal. It would however, help clarify the "non-linear" dependence of alkylation selectivity on N-substituent. Thus, to verify this hypothesis we elected to independently establish the configurations of the major alkylation products from the most selective representatives in the series, **8a** and **8d**.

The sense of asymmetric induction in the major alkylation product **8a** was established by a single crystal X-ray analysis of the racemic compound. The ORTEP image is shown in Fig. 3. Simple inspection of the structure provides the answer that the (*S*,*S*)-diazaphosphorinane induced the *S* configuration at the newly created stereogenic center in the alkylation. Other implications of the structure and an interpretation of the origin of stereoselection are provided in the discussion section.



To establish the stereochemical course for the alkylation reaction of **5d**, diamine **2** was resolved with dibenzoyl-D-tartaric acid according to the literature procedure (20). The enantiomeric purity of the diamine was determined for the *N*,*N*-dineopentyldiamine derivative **2d** by analyzing the Pirkle derivative by chiral HPLC on an *N*-naphthyl-L-alanine column (21). The enantiomeric excesses were 94% for the (*S*,*S*)-enantiomer and 98% for (*R*,*R*)-enantiomer (Scheme 3).

Preparation of enantiomerically enriched (*S*,*S*)-**5d** was carried out following the procedure for the racemic material described previously (Scheme 4). Thus, treatment of diamine (*S*,*S*)-**2d** with PCl_3 and Et_3N followed by hydrolytic workup gave phosphite (*S*,*S*)-**7d** in 90% yield. Subsequent transformation of (*S*,*S*)-**7d** to (*S*,*S*)-**5d** was performed in 81% yield. The asymmetric methylation of (*S*,*S*)-**5d** was accomplished by treatment with *n*-BuLi followed by addition of an excess of methyl iodide to give a 15.7:1 ratio of mixture of diastereomers of (–)-**8d** and 21% of unreacted (*S*,*S*)-**5d**. The



[5] Attempted benzylation of Li^+**5d**$^-$ at –60°C was unsuccessful. Warming to –20°C resulted in a diastereomeric mixture (2:1) of benzylated products.

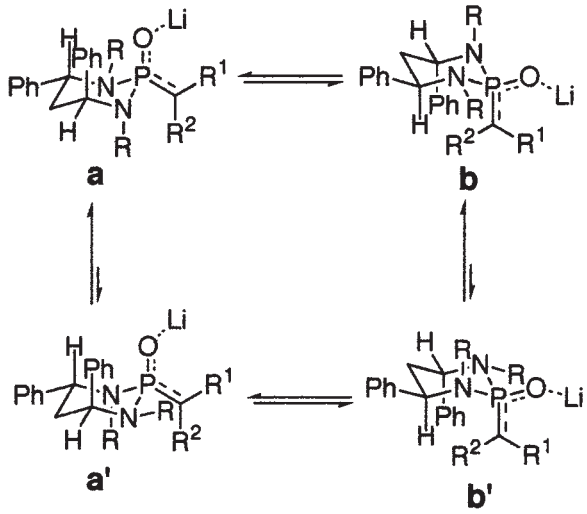
Scheme 3.



Scheme 4.

mixture of diastereomers was subjected to conventional hydrolysis conditions to give the phosphonic acid: 1 N HCl in THF, 6 N or 12 N HCl in dioxane. However, the very sterically hindered alkylation product (–)-**8d** was unaffected by these conditions. Eventually, (–)-**8d** was cleanly hydrolyzed with aqueous 48% HBr in refluxing acetic acid to give phosphonic acid (–)-**13**. The phosphonic acid (–)-**13** was purified by ion-exchange column chromatography and then was converted to the dimethyl phosphonate ester (–)-**14** by treatment with diazomethane (70% yield) followed by further purification by silica gel column chromatography. The absolute configuration of the dimethyl phosphonate (–)-**14** was confirmed to be *S* by comparison of its specific rotation with the literature value (3*c*, 3*f*). Therefore, net result of the

Fig. 4. Limiting chair-like conformations of the anions.

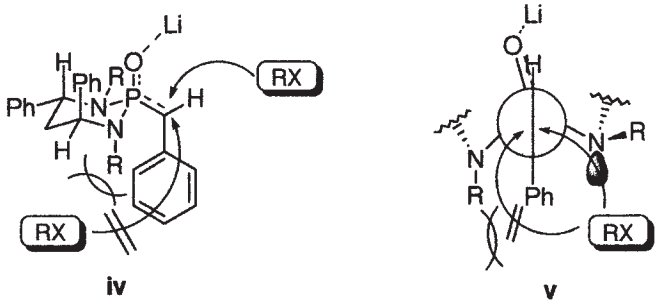
reaction is stereochemical conversion of 2-benzyl-1,3,2-diazaphosphorinane 2-oxide ((*S*,*S*)-**5d**) to dimethyl phosphonate (*S*)-**14**. *This fact then establishes unambiguously that the stereochemical course of alkylation of* ***5a*** *and* ***5d*** *proceeded in the same relative sense.*

Discussion

The central issue in all of our studies of phosphorus-stabilized anions is to create a structural model of reactivity which provides an understanding and ultimately a prediction of the stereochemical course of the reactions at the anionic centers. For the molecules examined in this study, the key question is the way in which the chirality of the 1,3,2-diazaphosphorinane skeleton (due to the phenyl substituents) is manifest in the dissymetry of the two faces of the benzylic anion.

To begin the analysis, we make recourse to the X-ray crystal structures of the achiral, unsubstituted lithio 1,3,2-oxazaphosphorinane 2- oxides, e.g., Fig. 1. The first point of consideration is the aggregation state of the anions. Even though the model anion crystallized as a dimer (8), the more sterically demanding 3,5-diphenyl substituted chiral anions might exist as *monomeric species*. Moreover, the aggregation state of these anions has been shown to be dependent on the nature of the substituents on nitrogen. For example, the anion derived from highly sterically demanding 1,3-bis(*tert*-butyl)-2-isopropyl-1,3,2-diazaphosphorinane has shown characteristic dynamic solution behavior of a monomer (10)[6]. That notwithstanding, Denmark et al. (8) have previously shown that aggregation effects for the oxaza-analog did not influence diastereoselectivity (21). Indeed, the anion derived from enantiomerically enriched (94% ee) diazaphosphorinane (*S*,*S*)-**5d** produced a diastereomeric mixture in a similar ratio compared to the anion derived from (±)-**5d**. Addition of the highly coordinating triamine, pentamethyldiethylentriamine, to the reaction in THF did not change the reaction selectivity. This implied that either the aggregate structure (homochiral vs. heterochiral dimers) is not responsible for the different alkylation selectivities or the reactive species are monomeric.

Fig. 5. Rationale for the diastereoselective methylation of *P*-benzyl-1,3,2-diazaphosphorinanes (**5**).



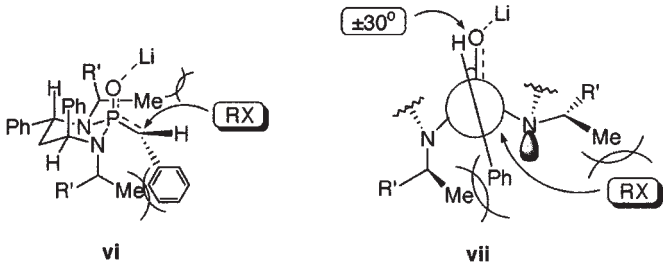


Fig. 6. Proposed skewed conformation of the anions.

The second critical issue is the conformation of the anion. Without direct spectroscopic information, we can only speculate about the ring conformation on the basis of the X-ray structures of unsubstituted anions and the neutral alkylation product (*S**,*S**,*S**)-**8a**. Close inspection of this structure reveals a surprising, albeit understandable deviation from the ideal chair conformation usually seen for these structures. The ring in (*S**,*S**,*S**)-**8a** is a flattened boat. The reason for this conformation most likely originates in a second unusual feature namely the axial positioning of the 1-phenylethyl group which itself results from an avoidance of non-bonding interactions of this phosphorus substituent with the neighboring *N*-methyl groups. Thus, to avert severe 1,3-diaxial interactions with one of the phenyl groups, the ring distorts to a boat. The flattening of the ring is due to the near planarity of the nitrogen atoms. It is however noteworthy that N(1) is slightly pyramidalized (Σangles = 356.3°) compared to N(2) (Σangles = 359.9°). Finally, the locations of the peripheral *N*-alkyl groups are determined by a combination of the ring conformation, gauche interactions with the phenyl groups at C(3) and C(5) and the hybridization of the nitrogen atoms.

Clearly, the proximal *N*-alkyl groups of the anions served as the chiral controlling elements during the course of the alkylation reaction. If we assume that the anion takes up a chair-like conformation, the limiting structures to consider at depicted in Fig. 4. We propose that the preferred anion is represented by structures **a**/**a′** in which the phosphonyl oxygen (and attendant lithium counterion with solvent) is in an axial position and the phenyl group is antiperiplanar to the P—O bond (R^1 = H, R^2 = Ph). The **a**/**a′** equilibrium relates

[6] P.C. Miller. Unpublished results from these laboratories.

© 2000 NRC Canada

to the alternative invertomers at the nitrogen atoms assuming, as is the case in all 1,3,2-diazaphosphorinane 2-oxide anions, that one substituent is axial and one is equatorial. Examination of the non-bonding interactions of the substituents around the ring shows that vicinally located pair of *N*-alkyl *C*-phenyl groups prefer invertomer **a** due to the elimination of one gauche interaction.

The high diastereoselectivity obtained from *N*-neopentyl analog **5d** results from a strong stereochemical bias between two π-faces of the derived planar anion Li^+**5d**$^-$ in which the phenyl ring might similarly orient anti to the P=O bond as shown in the model. The simplified structure of the antiperiplanar anion is depicted as **iv** and Newman projection **v** in Fig. 5. The electrophile would approach from the side away from the axially disposed *N*-alkyl group to avoid van der Waals interactions. For the neopentyl derivatives, the differentially disposed *N*-*tert*-butyl groups tethered by a methylene chain locate differently with respect to the anionic center.

The low diastereoselectivity observed from the *P*-benzyl anions derived from *N*-ethyl and *N*-isopropyl derivatives is believed to arise from a change in location of the phenyl ring. The phenyl group of the anion is believed to exist in a skew form and thus reside anticlinal (±150°) to the P=O bond to avoid non-bonding interaction with the substituent on the axially disposed *N*-alkyl group. The reactive conformation of this anion (**vi**) along with its Newman (**vii**) are shown in Fig. 6. Approach of the electrophile to either face of this anion experiences similar interactions with either of the N-substituents thus affording little bias in the alkylation event.

The direct relationship of the diastereoselectivity to steric bulkiness of the *N*-alkyl groups in the case of benzylation of the *P*-ethyl anion is explained by invoking the antiperiplanar anionic conformer **vii**. Since the α-methyl group of the anion is comparably small, the interaction with axially disposed *N*-alkyl group is insufficient to force the anion to be skewed. Thus, the diastereoselectivity directly reflects the steric bulkiness of *N*-alkyl groups. The erosion of selectivity for *P*-ethyl anions is mostly due to the low rotation barrier of the P—C bond and the lesser bias toward the antiperplanar vs. the synplanar conformation.[7]

It should also be recognized that the anions may exist in flattened boat-like conformations with an axially standing *P*-benzyl group. Here, the shielding of the anion faces is much less predictable. Moreover, the anion ring conformation may in fact be dependent on the ring substituents, making a consistent analysis impossible.

In summary, the methylation of Li^+**5a**$^-$–Li^+**5h**$^-$ proceeds with moderate to high diastereoselectivity and was highly conformation dependent due to the *N*-alkyl substituents. The benzylation selectivity of Li^+**6a**$^-$, Li^+**6c**$^-$, and Li^+**6d**$^-$ showed linear dependency on the *N*-alkyl steric bulk. *N*-Neopentyl analogs **5d** and **6d** afforded the highest selectivities (92:8) in both cases. From a systematic study of *N*-alkyl substituents and a comprehensive understanding of the structure of the anions, new C_2-symmetric diamine-based auxiliaries and their utilities in the reaction of the phosphorus-based alkyl anions can be developed in the future.

Experimental section

General Methods

See supporting information.[8]

Starting materials

The diamines **2a**–**f** were prepared in these laboratories and the procedures have been reported elsewhere (14). Ethylphosphonic dichloride is commercially available. Benzylphosphonic dichloride was prepared by a literature procedure and used after recrystallization from pentane (15).

*(*RS*)-(4*l*,6*l*)-2-Benzyl-1,3-dimethyl-4,6-diphenyl-1,3,2-diazaphosphorinane 2-oxide (**5a**)*: In a 25-mL, three-necked round bottom flask equipped with a reflux condenser, a N_2 inlet tube, a rubber septum, and a magnetic stirring bar was placed with 0.57 mL (4.13 mmol) of Et_3N in 5 mL of CH_2Cl_2. This solution was heated to reflux and then 420 mg (1.65 mmol) of diamine **2a** in 6 mL of CH_2Cl_2 and 362 mg (1.73 mmol) of benzylphosphonic dichloride in CH_2Cl_2 (6 mL) were simultaneously added over 1 h by syringe pump. After heating to reflux for 10 h, the oil bath was removed. The cooled reaction mixture was poured into water (20 mL) and extracted with CH_2Cl_2 (3 × 30 mL). The extracts were dried (Na_2SO_4), filtered, and concentrated to give 700 mg of yellow orange oil, which was purified by SiO_2 column chromatography (EtOAc/*i*-PrOH, 19:1) to give 552 mg (86%) of diazaphosphorinane **5a** as a colorless solid. An analytical sample was obtained by recrystallization from pentane/Et_2O: mp 147–148°C. IR (CCl_4): 3065 w, 1271 s. TLC: R_f 0.35 (EtOAc/*i*-PrOH, 19:1). ^{1}H NMR (300 MHz): 7.45–7.29 (m, 11 H), 7.18 (t, J = 3.0, 2 H), 6.79 (dd, J = 6.0, 3.0, 2 H), 4.23 (dt, J = 13.7, 3.8, 1 H), 3.75 (dd, J = 11.5, 3.5, 2 H), 3.51 (dd, J = 19.4, 4.8, 1 H), 3.36 (dd, J = 18.5, 4.8, 1 H), 2.66 (d, J = 8.2, 3 H), 2.48 (d, J = 9.0, 3 H), 1.80 (m, 2 H, 2 H). ^{13}C NMR (75.5 MHz): 142.38 (J_{CP} = 6.5), 140.15, 134.76 (J_{CP} = 8.9), 129.82, 129.74, 128.67, 128.34, 128.29, 128.24, 127.36, 127.15, 126.84, 126.48, 126.41, 62.65, 58.58, 41.43 (J_{CP} = 3.5), 38.55 (J_{CP} = 121.6), 34.07 (J_{CP} = 4.6), 32.28 (J_{CP} = 3.0). ^{31}P NMR (121.6 MHz): 27.67. MS (70 eV): 390 (M^+ < 0.1), 299 (100). Anal. calcd. for $C_{24}H_{27}N_2OP$ (390.46): C 73.83, H 6.97, N 7.17, P 7.93; found: C 73.79, H 6.98, N 7.11, P 7.84.

*(*RS*)-(4*l*,6*l*)-1,3-Dimethyl-4,6-diphenyl-2-ethyl-1,3,2-diazaphosphorinane 2-oxide (**6a**)*: In a 50-mL, three-necked round bottom flask equipped with a N_2 inlet tube, a septum and a magnetic stirring bar was placed 370 mg (1.45 mmol) of diamine **2a** and 0.51 mL (3.63 mmol) of Et_3N in 15 mL of CH_2Cl_2. Ethylphosphonic dichloride (170 μL, 1.60 mmol) was then added by a syringe over a time period of 5 min.

[7] S.E. Denmark, K.A. Swiss, R.L. Dorow, P.C. Miller, and S.R. Wilson. In a detailed NMR study, no decoalescence of the achiral parent of **6a** was detected down to –117°C (500 MHz, ^{1}H NMR observation). Manuscript in preparation.

[8] General experimental methods along with full spectroscopic data and assignments for **5a-f**, **6a**, **6c**, **6d**, **7b-f**, **8a-f**, **9a**, **9c**, **9d**, and **14** (15 pages). After stirring for 22 h at rt, the reaction mixture was concentrated under reduced pressure. The residue was treated with EtOAc (15 mL), filtered, and the filter cake was washed with EtOAc (2 × 10 mL). The combined filtrates were washed with brine (15 mL) and the aqueous layer was extracted with EtOAc (2 × 10 mL). The combined organic extracts were dried (Na_2SO_4), filtered, and concentrated to give a colorless oil, which was purified by SiO_2 column chromatography (hexane/EtOAc/*i*-PrOH, 35:62:3, then EtOAc/*i*-PrOH (9:1) to afford 457 mg (96%) of diazaphosphorinane **6a** as a foam. An analytical sample was obtained by recrystallization from pentane/TBME: mp 66–68°C. TLC: R_f 0.30 (EtOAc/*i*-PrOH, 9:1). IR (CCl_4): 3030 w, 1267 s. ^{1}H NMR (300 MHz): 7.50–7.11 (m, 10 H), 4.33 (dt, J = 13.4, 3.8, 1 H), 3.78 (dd, J = 10.1, 1.7, 1 H), 2.70 (d, J = 8.1, 3 H), 2.54 (d, J = 8.8, 3 H), 2.40 (ddd, J = 14.2, 12.4, 4.6, 1 H), 2.20–1.88 (m, 3 H), 1.31 (dt, J = 19.3, 7.5, 3 H). ^{13}C NMR (75.5 MHz): 142.01 (J_{CP} = 5.0), 140.06, 128.44, 128.33, 127.13, 126.93, 126.29, 126.11, 62.33, 59.42, 41.90 (J_{CP} = 5.2), 33.52 (J_{CP} = 4.7), 32.66 (J_{CP} = 3.1), 25.43 (J_{CP} = 129.7), 7.68 (J_{CP} = 6.3). ^{31}P NMR (121.6 MHz) 31.73. MS (70 eV): 329 (M^+ + 1, 22), 328 (M^+, 98), 299 (100). Anal. calcd. for $C_{19}H_{25}N_2OP$ (328.39): C 69.49, H 7.67, N 8.53, P 9.43; found: C 69.49, H 7.69, N 8.51, P 9.40.

*Representative procedure for the preparation of cyclic hydrogen phosphites **7b-f***

The detailed procedure for the preparation of **7b** is given. For all of the other phosphites only the amounts of reagents and methods of purification are provided along with the analytical data.

*(*RS*)-(4*l*,6*l*)-1,3-Diethyl-4,6-diphenyl-1,3,2-diazaphosphorinane 2-oxide (**7b**)*: In a 25-mL, three-necked, round bottom flask, equipped with a reflux condenser, a rubber septum, a N_2 inlet tube and a magnetic stirring bar was placed 109 μL (1.25 mmol) of PCl_3, and a solution of 0.35 mL (2.51 mmol) of Et_3N in 5 mL of CH_2Cl_2. The mixture was heated to reflux and a solution of 335 mg (1.19 mmol) of diamine **2b** in CH_2Cl_2 (5 mL) was added via syringe over a time period of 5 min. After heating to reflux for an additional 1.5 h, 0.18 mL (1.25 mmol) of Et_3N was added. The oil bath was removed and the reaction mixture was poured into 20 mL of water and extracted with CH_2Cl_2 (3 × 20 mL). The combined extracts were dried (Na_2SO_4) and concentrated to give a yellow oil which was purified by SiO_2 column chromatography eluting with EtOAc/*i*-PrOH (19:1) to give 247 mg (63%) of cyclic phosphite **7b** as a colorless oil which solidified at –20°C. An analytical sample was obtained by recrystallization from Et_2O: mp 111–112°C. IR (CCl_4): 3031 w, 1240 s. TLC: R_f 0.34 (EtOAc/*i*-PrOH, 19:1). ^{1}H NMR (300 MHz): 7.74 (d, J = 599.4, 1 H), 7.45–7.23 (m, 10 H), 4.27–4.14 (m, 2 H), 3.37–3.16 (m, 2 H), 2.91–2.81 (m, 2 H), 2.36 (m, 2 H), 1.03 (t, J = 7.1, 3 H), 0.97 (t, J = 7.1, 3 H). ^{13}C NMR (75.5 MHz): 141.39, 140.72, 128.49, 128.41, 127.30, 127.35, 126.72, 126.28, 57.67, 57.47, 42.42 (J_{CP} = 9.6), 40.45 (J_{CP} = 5.6), 40.25 (J_{CP} = 8.1), 14.08, 13.44. ^{31}P NMR (121.6 MHz): 3.61. Representative procedure for the preparation of 2-alkyl-1,3,2-diaza-phosphorinane 2-oxides

The detailed procedure for the preparation of **5b** is given. For all of the other diazaphosphorinanes only the amounts of reagents and methods of purification are provided along with the analytical data.

*(*RS*)-(4*l*,6*l*)-2-Benzyl-1,3-diethyl-4,6-diphenyl-1,3,2-diazaphosphorinane 2-oxide (**5b**)*: To a flame-dried, 25-mL, three-necked, round bottom flask equipped with a thermometer, a rubber septum, a N_2 inlet, and a magnetic stirring bar was added a solution of 180 mg (0.55 mmol) of phosphite **7b** in THF (10 mL). The mixture was cooled to –78°C and 0.34 mL (0.58 mmol) of *n*-BuLi (1.71 M) was slowly added to give a yellow-orange solution which was stirred at –78°C for 15 min. Benzyl bromide (71 μL, 0.60 mmol) was then added via syringe and the color dissipated immediately. After being stirred for 1 h at –78°C, the reaction mixture was warmed to rt, poured into water (20 mL), extracted with EtOAc (3 × 15 mL), washed with brine (10 mL), and dried (Na_2SO_4). Filtration followed by concentration gave a yellow oil which was purified by SiO_2 column chromatography (hexane/EtOAc/*i*-PrOH, 35:62:3) to afford 140 mg (61%) of diazaphosphorinane **5b** as a foam. An analytical sample was obtained by recrystallization from pentane/Et_2O: mp 98–99°C. IR (CCl_4): 3031 w, 1239 s. TLC: R_f 0.22 (hexane/EtOAc/*i*-PrOH, 34:63:3). ^{1}H NMR (300 MHz): 7.52–7.16 (m, 13 H), 6.77 (m, 2 H), 4.49 (dt, J = 15.4, 3.7, 1 H), 3.93 (dd, J = 12.0, 3.0, 1 H), 3.45 (d, J = 18.9, 2 H), 3.51–3.35 (m, 1 H), 3.24 (heptet, J = 7.3, 1 H), 2.90 (heptet, J = 7.3, 1 H), 2.53–2.36 (m, 1 H), 2.07 (ddd, J = 14.0, 12.3, 4.3, 1 H), 1.91 (dt, J = 14.0, 3.2, 1 H), 1.01 (t, J = 7.1, 3 H), 0.96 (t, J = 6.9, 3 H). ^{13}C NMR (75.5 MHz): 141.35 (J_{CP} = 5.0), 140.55, 134.90 (J_{CP} = 8.4), 129.97, 129.89, 128.45, 128.34, 128.31, 128.21, 127.30, 127.12, 126.94, 126.78, 126.35, 126.31, 58.14, 54.58, 41.66 (J_{CP} = 4.7), 40.54 (J_{CP} = 121.3), 39.87 (J_{CP} = 4.6), 38.87 (J_{CP} = 3.6), 13.52 (J_{CP} = 2.4), 13.36. ^{31}P NMR (121.6 MHz): 24.96. MS (70 eV): 328 (M^+ + 1 – $PhCH_2$, 22), 327 (M^+ – $PhCH_2$, 100). Anal. calcd. for $C_{26}H_{31}N_2OP$ (418.52): C 74.62, H 7.47, N 6.69, P 7.40; found: C 74.49, H 7.57, N 6.63, P 7.25.

*(*RS*)-(4*l*,6*l*)-2-Benzyl-1,3-bis-(1-methylethyl)-4,6-diphenyl-1,3,2-diaza-phosphorinane 2-oxide (**5c**)*: From 195 mg (0.55 mmol) of diamine **7c**, 0.33 mL (0.61 mmol) of *n*-BuLi (1.84 M), and 78 μL (0.66 mmol) of benzyl bromide followed by purification by SiO_2 column chromatography (hexane/EtOAc/*i*-PrOH, 45:52:3) was obtained 198 mg (81%) of **5c** as a colorless solid. An analytical sample was obtained by recrystallization from Et_2O: mp 144–145°C. IR (CCl_4): 3065 w, 1240 s. Representative procedure for the alkylation of 1,3,2-diazaphosphorinane 2-oxides

The detailed procedure for the methylation of **5a** to afford **8a** is given. For all of the other alkylations, only the amounts of reagents, methods of analysis of diastereomeric mixtures and purification of the products are provided, along with the analytical data.

*(*RS*)-(4*l*,6*l*,1′*x*)-1,3-Dimethyl-4,6-diphenyl-2-(1-phenylethyl)-1,3,2-diaza-phosphorinane 2-oxide (**8a**)*: A flame-dried, 25-mL, three-necked, round-bottomed flask was charged with 105 mg (0.27 mmol) of diazaphosphorinane **5a** and 4 mL of THF. The flask was cooled to –78°C using a dry ice-acetone bath. *n*-BuLi (0.16 mL, 0.27 mmol, 1.71 M) was added to give a pale-yellow solution which was stirred for 30 min. Methyl iodide (65 μL, 1.04 mmol) was added by a syringe and the color dissipated slowly. After stirring for 1.1 h at –78°C, the reaction mixture was quenched with water (0.2 mL), then poured into water (10 mL), extracted with EtOAc (3 × 10 mL), and dried (Na_2SO_4). Filtration followed by concentration gave a pale yellow oil, which was assayed by HPLC (Supelco LC-NH_2) and found to be a mixture of diastereomers (87:13). Purification by column chromatography (hexane/EtOAc/*i*-PrOH, 35:62:3) gave 19 mg (17.5%) of minor **8a′** and 79.8 mg (73.3%) of major **8a** as a colorless solids. Data for **8a**: mp 141–142°C (pentane/Et_2O). IR (CCl_4): 3065 w, 1267 s. TLC: R_f = 0.3 (hexane/EtOAc/*i*-PrOH, 35:62:3). ^{1}H NMR (300 MHz): 7.48–7.17 (m, 13 H),

*(*S*)-Dimethyl-1-phenylethylphosphonate (**14**)*: In a 25-mL, round-bottomed flask equipped with a reflux condenser was placed a solution of (–)-**8d** in 4 mL of HOAc acid and 48% HBr solution. The reaction mixture was heated to reflux for 15 h, then was concentrated under reduced pressure to give a yellow orange oil. The oil was passed through ion-exchange resin column (AG® 50W-X8) using water as eluent. The major fraction was collected and concentrated to give a white solid. The solid was dissolved in water and basified with 1 N NaOH solution (pH ~ 13), reacidified, concentrated, and the acidic residue dissolved in methanol. The methanolic solution of **13** was treated with excess etheneal diazomethane diluted with water (10mL) and extracted with diethyl ether (3 × 10 mL). The combined organic layers were dried (Na_2SO_4), filtered, and concentrated to give a yellow oil. The oil was purified by SiO_2 column chromatography (EtOAc/*i*-PrOH, 99:1) to give 53 mg (70%) of (*S*)-**14** as a colorless oil. An analytical sample was obtained by Kugelrohr distillation: bp 115°C (0.3 Torr (1 Torr = 133.322 Pa)). $[\alpha]_{405}$ –15.7 c = 1.1, CH_2Cl_2) ((*S*)-configuration, 87% ee). TLC: R_f 0.23 (EtOAc/*i*-PrOH, 99:1). ^{1}H NMR (300 MHz): 7.37–7.24 (m, 5 H), 3.69 (d, *J* = 10.0, 3 H), 3.53 (d, *J* = 10.0, 3 H), 3.21 (dq, *J* = 22.7, 7.7, 1 H), 1.58 (dd, *J* = 18.5, 7.5, 3 H). ^{31}P NMR (121.6 MHz): 32.75.

Acknowledgment

We wish to thank the National Institute of Health (PHS R01 GM45532) for financial support. We are grateful to Dr. Michael Kranz for obtaining the X-ray crystal structure of (*S**,*S**,*S**)-**8a**.

Delineating the possibilities for intramolecular interception of the squarate ester cascade through the use of metalated enecarbamates

Jinsung Tae and Leo A. Paquette

Abstract: Highly functionalized and annulated 2,4-cyclooctadienones are formed in a stereoselective manner by sequential treatment of squarate esters with a lithiated enecarbamate (six-membered ring or larger) and a cycloalkenyl- or 1-alkenyllithium reagent. The mechanistic details of this multistep process are presented. Particular attention is drawn to the step that involves intramolecular nucleophilic attack by a proximal oxido anion at the carbamate carbonyl and results in redirection of the cascade. This step is thwarted when five-membered cyclic enecarbamates are employed because of the excessive buildup of ring strain in the associated transition state.

Key words: squarate esters, enecarbamates, conrotatory ring opening, intramolecular acylation, alkenyllithium reagents.

Résumé : Des cyclooctadiène-2,4-ones à anneaux et hautement fonctionnalisées se forme de façon stéréosélective par un traitement séquentiel d'esters de l'acide squarique avec un ènecarbamate lithié (cycle à six chaînons ou plus) et un réactif cycloalcényl- ou 1-alcényllithium. On présente les détails mécanistiques de ce processus en plusieurs étapes. On porte une attention particulière à l'étape qui implique l'attaque nucléophile intramoléculaire d'un anion oxydo se trouvant à proximité sur le carbonyle du carbamate et qui conduit à une redirection de la cascade. En raison de l'augmentation excessive de la tension de cycle dans l'état de transition qui lui est associé, cette étape ne se produit pas lorsqu'on utilise des ènecarbamates cycliques à cinq chaînons.

Mots clés : esters de l'acide squarique, ènecarbamates, ouverture de cycle conrotatoire, acylation intramoléculaire, réactifs alcényllithium.

Introduction

The appreciable electrophilic character, highly functionalized nature, and inordinately strained features of squarate esters have the combined effect of rendering these reagents particularly susceptible to ring expansion following nucleophilic addition. The growing family of rearrangements that has been discovered is most impressive (1–4). Eguchi, Liebeskind, Moore, and their associates continue their efforts toward defining the regio- and (or) stereocontrol attainable in several of these multistep processes (5–7). Our laboratory has been engaged in elucidating the mechanistic features of the so-called "squarate ester cascade" that arises following the *twofold* addition of alkenyllithium reagents (8). Customarily, trans 1,2-addition of such organometallics (either the same or different) dominates, thereby setting the stage for the subsequent chemical events depicted in Scheme 1 (9). In those instances where the first nucleophile is chiral, diastereomeric 1:1 adducts arise at nearly equivalent levels. This initial lack of diastereoselection has no impact on the overall stereochemical outcome because the ensuing conrotatory ring opening and subsequent mechanistic developments result in a loss of the initial sense of chirality (10). In fact, only during ultimate conrotatory 8π closure to form the mesocyclic dienolates **3** and **4** is product configuration regulated. This uncommon series of chemical events is made possible because of helical equilibration that allows ready interconversion between **1** and **2**. The sterically least crowded transition state associated with formation of the eight-membered ring is kinetically favored (11). In the example shown, **5** is formed exclusively.

Under normal circumstances and in the absence of β-eliminatable substituents (8*b*, 11*c*, 12) dienolates such as **4** are the resting points of the cascade. Ensuing chemistry operates only following the addition of an electrophile. If those cases where water is involved, transannular aldol cyclization ensues after monoprotonation to deliver polycyclic products. An alternative synthetic ploy for utilizing the ease of assembly of reactive intermediates of type **4** is to intercept these species by some intramolecular means. Herein we disclose that recourse to metalated enecarbamates as one of the nucleophilic reagents can indeed result in redirection of the cascade under the proper circumstances (13).

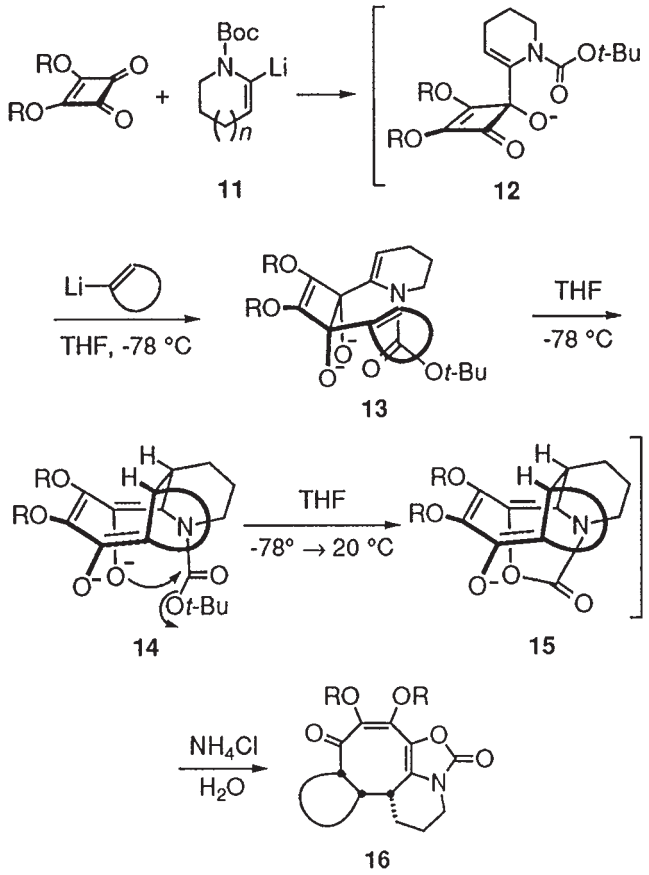
Results and discussion



Intramolecular enolate interception

Although a wide range of α-heteroatom-substituted 1-alkenyllithium reagents is available (14), the direct application of metalated enecarbamates to synthetic endeavors has been undertaken only recently. Beak and Lee have demonstrated that **6** is amenable to α-lithiation with *sec*-butyllithium in the presence of TMEDA (15). This species is an effective reaction partner with electrophiles, giving

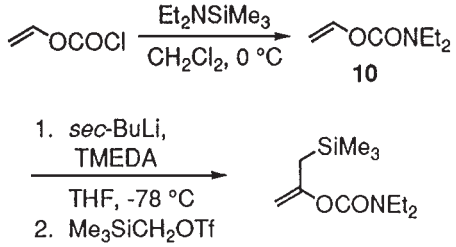
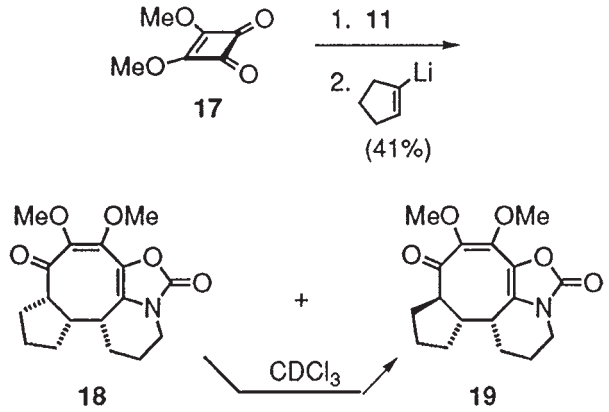


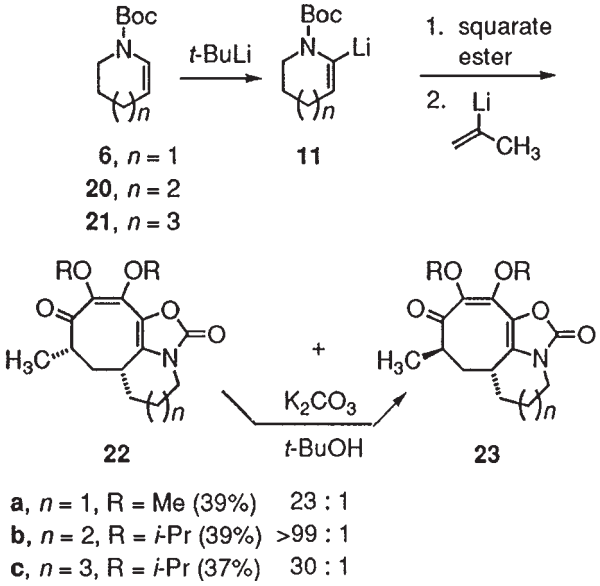
Scheme 2.



rise to **7** or **8** depending upon the chemical constitution of the co-reactant. Lander and Hegedus made recourse to vinylstannane precursors such as **9** in their quest of similar intermediates (16). Sengupta and Snieckus recognized that

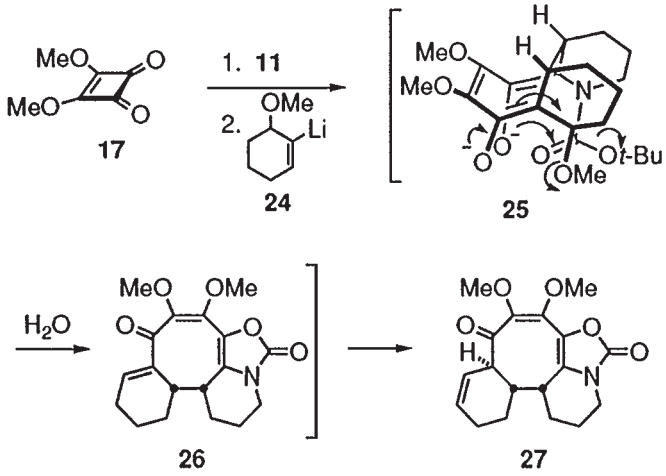
the structurally simple building block **10** constitutes a versatile acyl anion equivalent (17). Other variants on this theme have been reported (18).

Scheme 3.



Our plan was to use the heterocyclic building block **11** as the lead nucleophile and to vary the structural specifications of the alkenyllithium as shown in Scheme 2. The expectation was that strong chelative interactions of the second anion to the carbamate functionality in monoadduct **12** would draw this reagent into kinetically favored *cis* addition and provide **13**. Should this reaction channel operate, charge-accelerated [3,3] sigmatropy was certain to ensue rapidly with formation of dienolate **14** via a boatlike transition state. With stereodirected arrival at **14**, two *cis* hydrogens will have been set, thereby making it possible for one of the oxido anions to attack the flanking ester group. The likelihood of this intramolecular acylation to generate **15** was suggested by prior discovery of the **6** → **8** conversion. The conformationally inflexible tub conformation held by **15** can be expected to be conducive to protonation from the exterior thereby delivering the all-*syn* stereoisomer **16**. The simplicity of this stereochemically distinctive route to polycondensed heterocyclic systems in one laboratory operation is emphasized.

Indeed, when dimethyl squarate (**17**) (19) was sequentially treated with **11** and cyclopentenyllithium, mixtures of **18** and **19** were produced in highly variable proportions (Scheme 3). The discovery was soon made that this product distribution was intimately linked to two time elements: the duration of the quenching process and the speed with which the stereoisomers were removed from the basic aqueous solution. The epimerization of **18** was subsequently discovered to be especially facile in acidic or alkaline environments. As an example, dissolution of pure **18** in $CDCl_3$ resulted in conversion to a 1:3 mixture of **18** and **19** within only 5 min. The *trans*, *cis* arrangement of the three contiguous stereogenic centers in **19** was readily deduced on the basis of NOE measurements. This finding requires that **18** have *cis*, *cis* stereochemistry, completely in agreement with expectations based on Scheme 2. The thermodynamic preference for *cis*, *trans* fusion of two five-membered rings to a cyclooctane core has been noted previously in a different context (20).



Pairing **11** with 2-lithiopropene had the effect of delivering a chromatographically inseparable 23:1 mixture of **22a** and **23a** (Scheme 4). As in the preceding example, the predominance of the *syn* isomer was clearly demonstrated to be the consequence of kinetic control. Thus, treating the **22a**–**23a** mixture with potassium carbonate in *tert*-butyl alcohol resulted in a pronounced increase in the proportion of **23a** to

Scheme 4.

Scheme 5.

ca. 90%. Advantage was taken of the high crystallinity of **23a** to confirm the stereochemical assignments by means of X-ray diffraction.

In order to expand on these observations, literature precedent was followed to prepare the homologous enecarbamates **20** and **21** (21). The cascade reactions involving their lithiated counterparts **11** (n = 2 and 3) were found to be equally diastereoselective, giving rise very predominantly to **22b** and **22c**, respectively. Comparative NOE studies of these cyclooctadienones established that they share in common a *syn*, *cis* α-methyl substituent.

The involvement of methoxy-substituted cyclohexenyllithium **24** as the second nucleophile was expected to result in the ultimate introduction of another degree of unsaturation in the product as a consequence of the β-elimination depicted in **25** (Scheme 5). If operative, this step would lead in combination with the ejection to *t*-butoxide ion to **26**. In actuality, the admixing of this triad of reagents led to the formation of **27** in modest yield. The migration of the cyclohexenyl double bond to the β,γ-position presumably operates in order to reduce the strain in **26**. It is reasonable to conclude that this ring strain is likewise contributory to the diminished efficiency with which **27** is formed.

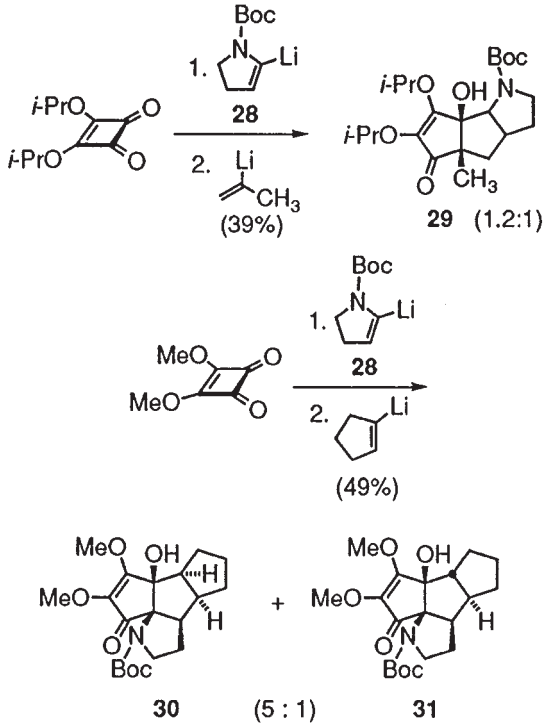
The consequences of ring size

The issue of structural constraint surfaces in a more dramatic fashion when the ring size of the enecarbamate is reduced to the pyrrolidine level. In our hands, all experiments involving **28** resulted in an inability to intercept the bisenolate as in **14** or **25**. Apparently, a five-membered heterocycle is insufficiently flexible to allow further progression in the direction followed by the homologous enecarbamates. Azapolycyclics such as **29–31** are consequently formed instead (Scheme 6). These products bear a close resemblance to those formed in the non-intercepted squarate ester cascade.

Since the two isomers of **29** were chromatograhically inseparable, it proved inadvisable to distinguish the specific stereochemical features of the heterocyclic ring fusion. The near equitable proportion of these epimers significantly diminishes the importance of this distinction. In the 1-lithiocyclopentene example, **30** is formed with a fivefold greater preference than **31**. The major isomer was readily separated by crystallization and identified as the all-*syn* stereoisomer by NOE measurements (see Experimental section).

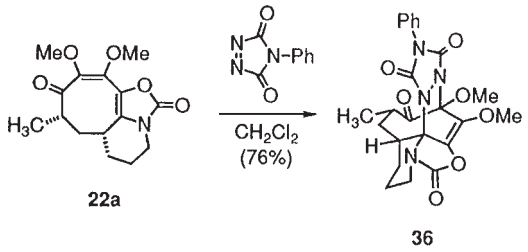
Although all of the yields reported are moderate, control experiments have shown that the lowered levels of product formation are due predominantly to the efficiency of the enecarbamate metalation step and are not intrinsic to the cascade. No attempt was made to enhance yields by making stoichiometric adjustments different from the above.

Selected chemical transformations of 22a



The structural features of the mesocyclic products resulting from the interrupted squarate cascade were considered to be sufficiently unusual to warrant modest exploration of their chemical reactivity. The readily available prototype **22a** was selected for further study. Enolate anion generation proved feasible provided that recourse was made to a hindered non-nucleophilic base. The use of potassium *tert*-butoxide in dimethyl sulfoxide is exemplary. As anticipated from precedent (22), this reagent combination was particularly conducive to *O*-methylation when coupled with the use of dimethyl sulfate. Triene **32** was isolated in 76% yield (Scheme 7).

When **22a** was dissolved instead in a 1:1 mixture of methanol and THF containing sodium methoxide, nucleophilic attack at the carbamate carbonyl and epimerization of the α-proton occurred to generate the alternative enolate anion **33**. As a consequence of proximity effects, transannular aldolization operates readily with formation of the *cis*-fused diquinane **34**. The generation of this alkoxide opens the way for ultimate ejection of methoxide ion with formation of the isomeric carbamate **35** in which five heteroatoms are bonded to the same cyclopentene ring.



As a diene, **22a** proved unreactive to most dienophiles, a likely consequence of the nonplanarity of its two double bonds. Notwithstanding, [4+2] cycloaddition was realized in the presence of *N*-phenyltriazolinedione with formation of **36**. The direction of the overwhelming π-facial diastereoselectivity

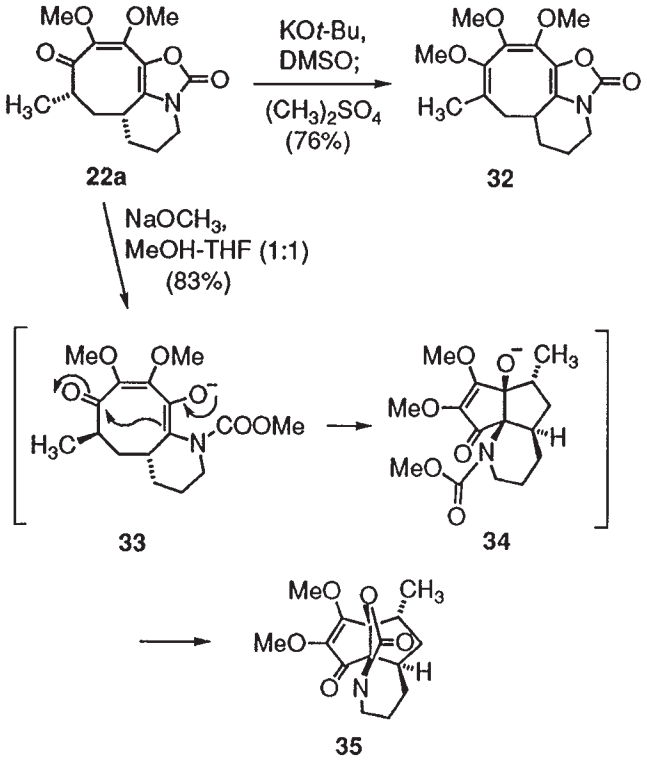
Scheme 6.



observed for this process was ascertained by X-ray crystallographic analysis of the only product.

Conclusions

A new method for accessing highly functionalized eight-membered ring ketones in a single laboratory step is described. The mechanistic requirements for this multistep transformation of squarate esters involve initial 1,2-addition of a metalated enecarbamate, chelation-controlled *cis* addition of an alkenyllithium co-reactant, dianionic oxy-Cope rearrangement of the resulting doubly charged intermediate via a boatlike transition state, and intramolecular nucleophilic capture of the carbamate functionality. The cyclic enecarbamates must be six-membered or larger in order to perform satisfactorily in the product-defining step. The excessive strain present when lower homologs are involved does not allow for rerouting of the cascade, and polycyclic nitrogen-containing products indicative of this fact make their appearance. Finally, adoption of the sigmatropic pathway necessarily provides all-*syn* stereoisomeric products as the end result of kinetic control. Since these isomers are often not the thermodynamically favored epimers, their exposure to mildly acidic or basic conditions suffices to make available a companion set of configurationally distinctive compounds for further investigation.

Scheme 7.

Experimental

General information

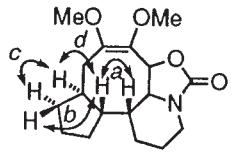
Tetrahydrofuran and ether were distilled from sodium benzophenone ketyl under nitrogen just prior to use. For dichloromethane and dimethyl sulfoxide, the drying agent was calcium hydride. All reactions were performed under a nitrogen atmosphere. Analytical thin-layer chromatography was carried out on E. Merck silica gel 60 F_{254} aluminum-backed plates. The 230–400 mesh size of the same absorbent was utilized for all chromatographic purifications. The organic extracts were dried over anhydrous $MgSO_4$. ^1H and ^{13}C NMR spectra were recorded on Bruker instruments at 300 and 75 MHz, respectively. Infrared spectra were recorded with a Perkin–Elmer 1320 spectrometer. The high-resolution mass spectra were recorded at The Ohio State University Campus Chemical Instrumentation Center.

Prototypical procedure for cascade rearrangements involving the enecarbamates

A. A cold (–78°C) solution of **6** (515 mg, 2.81 mmol) in dry THF (10 mL) was treated dropwise with *tert*-butyllithium (1.84 mL of 1.7 M). After 1 h of stirring at this temperature, a solution of dimethyl squarate (266 mg, 1.87 mmol) in THF (5 mL) was next introduced in dropwise fashion. One hour later, 1-lithiocyclopentene (prepared from the iodide (726 mg, 3.74 mmol) and *tert*-butyllithium (7.48 mmol) at –78°C during 30 min) was added rapidly. After an additional 2 h at –78°C, the reaction mixture was allowed to warm to room temperature overnight, recooled to

© 2000 NRC Canada

0°C, treated with deoxygenated saturated NH_4Cl solution (10 mL), stirred for 30 min, and warmed to room temperature. After 30 min, saturated $NaHCO_3$ solution was added and the separated aqueous layer was extracted with ether. The combined organic layers were dried and concentrated to leave a residue that was chromatographed on silica gel. Elution with 50% ethyl acetate in hexanes afforded 244 mg (41%) of a 1:5 mixture of **18** and **19**.



Upon crystallization from 5% CH_2Cl_2 in hexanes, it was possible to obtain samples of **18** having >99% isomeric purity. Dissolution of a pure sample of **18** in $CDCl_3$ resulted in conversion to a 1:3 mixture of **18** and **19** within 5 min.

For **18**: white crystals, mp 140–142°C; IR (film) ν: 1759, 1693, 1644, 1452, 1256 cm^{-1}; ^1H NMR (C_6D_6) δ: 3.51 (3H, s), 3.43 (3H, s), 3.30 (1H, m), 2.70 (1H, m), 2.50 (1H, m), 2.14–1.98 (2H, m), 1.77–1.64 (1H, m), 1.57–1.37 (3H, m), 1.37–1.17 (1H, m), 1.17–1.05 (1H, m), 0.95–0.70 (4H, m) ppm; ^{13}C NMR (C_6D_6) δ: 202.8, 154.8, 144.3, 129.1, 128.2, 127.9, 59.1, 58.9, 58.5, 53.0, 40.6, 34.9, 30.0, 27.1, 23.8, 23.0, 17.1 ppm; HRMS (EI) calcd. for $C_{17}H_{21}NO_5$, *M*: 319.1419; found: 319.1432. Anal. calcd. for $C_{17}H_{21}NO_5$: C 63.94, H 6.63; found: C 63.66, H 6.60.

For **19**: colorless oil; IR (film) ν: 1760, 1651, 1446, 1238 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 3.87 (3H, s), 3.75 (1H, m), 3.65 (3H, s), 3.42 (1H, m), 2.99 (1H, m), 2.82 (1H, m), 2.63 (1H, m), 2.11 (1H, m), 2.05–1.55 (8H, series of m), 1.33 (1H, m); ^{13}C NMR ($CDCl_3$) δ 197.8, 154.2, 148.7, 142.0, 131.5, 129.2, 62.2, 61.1, 60.5, 52.3, 40.7, 30.8, 29.8, 25.3, 22.6, 21.9, 19.4; HRMS (EI) calcd. for $C_{17}H_{21}NO_5$, *M*: 319.1419; found: 319.1419.

The following NOE interactions were observed:

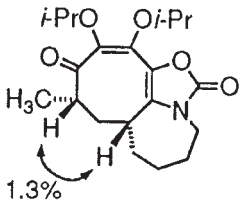
Structure 1.

a: 12.5% **c**: 5.8%
b: 3.0% **d**: 0%

B. Reaction of 573 mg (3.12 mmol) of **6** with dimethyl squarate (296 mg, 2.08 mmol), and 2-lithiopropene (4.17 mmol) in the predescribed manner furnished 235 mg (39%) of a 23:1 mixture of **22a** and **23a**. Treating a 50 mg sample of this mixture with potassium carbonate (50 mg) in *tert*-butyl alcohol (5 mL) at room temperature overnight gave a mixture rich in **23b** (now 1:10). Crystallization of this material from ether:CH_2Cl_2 (10:1) gave pure **23b**.

For **22a**: colorless oil; IR (film) ν: 1760, 1694, 1651, 1455, 1412, 1328, 1257 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 3.80–3.60 (1H, m), 3.70 (3H, s), 3.69 (3H, s), 3.25 (1H, m), 3.02 (1H, m), 2.90 (1H, m), 1.95–1.65 (6H, m), 1.09 (3H, d, *J* = 6.7 Hz) ppm; ^{13}C NMR ($CDCl_3$) δ: 207.6, 154.8, 141.9, 129.4, 128.4, 128.3, 59.6, 58.8, 45.1 (2 C), 40.8, 29.8, 27.5, 17.3, 16.3 ppm; HRMS (EI) calcd. for $C_{15}H_{19}NO_5$, *M*: 293.1263; found: 293.1268.

For **23a**: yellowish crystals, mp 149–151°C; IR (film) ν: 1759, 1613, 1535, 1452, 1250 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 3.90–3.80 (1H, m), 3.86 (3H, s), 3.61 (3H, s), 3.25 (1H, m), 3.05–2.80 (2H, m), 2.20–1.95 (2H, m), 1.95–1.80 (2H, m), 1.80–1.60 (2H, m), 1.03 (3H, d, *J* = 6.5 Hz) ppm; ^{13}C NMR ($CDCl_3$) δ: 202.2, 153.9, 148.1, 139.7, 132.1, 128.2, 60.8, 60.1, 48.1, 40.7, 40.1, 28.8, 23.6, 16.8, 16.0 ppm; HRMS (EI) calcd. for $C_{15}H_{19}NO_5$, *M*: 293.1263; found: 293.1264. Anal. calcd. for $C_{15}H_{19}NO_5$: C 61.42, H 6.53; found: C 61.34, H 6.50.



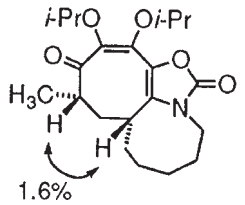
The structure of **23a** was corroborated by X-ray diffraction analysis.

C. From 373 mg (1.89 mmol) of **20**, 250 mg (1.26 mmol) of diisopropyl squarate, and 2-lithiopropene (2.52 mmol), there was isolated 180 mg (39% of a >99:1 mixture of **22b** and **23b**.

For **22b**: yellow crystals, mp 94–96°C; IR (film) ν: 1760, 1650, 1555, 1455, 1375, 1245 cm^{-1}; ^1H NMR ($CDCl_3$) δ 4.47 (1H, septet, *J* = 6.1 Hz), 4.26 (1H, m), 4.10 (1H, septet, *J* = 6.2 Hz), 3.29 (1H, m), 3.00 (1H, m), 2.81 (1H, septet, *J* = 6.5 Hz), 2.25–1.50 (6H, series of m), 1.33 (3H, d, *J* = 6.2 Hz), 1.23 (3H, d, *J* = 6.2 Hz) 1.17 (3H, d, *J* = 6.2 Hz), 1.14 (3H, d, *J* = 6.2 Hz), 1.05 (3H, d, *J* = 6.5 Hz), 1.90–1.70 (2H, m) ppm; ^{13}C NMR ($CDCl_3$) δ: 202.3, 154.4, 145.1, 141.5, 135.9, 128.8, 74.7, 74.3, 46.8, 45.2, 40.5, 33.9, 30.3, 27.6, 23.8, 22.7, 22.6, 22.5, 22.3, 16.0 ppm; HRMS (EI) calcd. for $C_{20}H_{29}NO_5$, *M*: 363.2045; found: 363.2055.

The following NOE interaction was observed:

Structure 2.



D. Parallel reaction of **21** (358 mg, 1.81 mmol) with diisopropyl squarate (239 mg, 1.20 mmol) and 2-lithiopropene (2.41 mmol) afforded 168 mg (37%) of a 30:1 mixture of **22c** and **23c**.

For **22c**: yellow solid, mp 131–133°C; IR (film), ν: 1765, 1658, 1452, 1371, 1211 cm^{-1}; ^1H NMR (C_6D_6) δ: 4.41–4.31 (2H, m), 3.97 (1H, m), 2.95 (1H, m), 2.71 (1H, septet, *J* = 6.1 Hz), 2.48 (1H, m), 1.80–1.50 (3H, m), 1.50–0.60 (7H, series of m), 1.34 (3H, d, *J* = 6.1 Hz), 1.25 (3H, d, *J* = 6.1 Hz), 1.24 (3H, d, *J* = 6.1 Hz), 1.09 (3H, d, *J* = 6.1 Hz), 1.02 (3H, d, *J* = 6.4 Hz) ppm; ^{13}C NMR (C_6D_6) δ: 200.5, 154.3, 141.7, 134.5, 128.6, 127.1, 74.1, 73.7, 50.4, 41.4, 39.8, 34.6, 29.2, 26.3, 26.0, 22.8, 22.5, 22.4, 22.2, 21.7, 16.0 ppm; HRMS (EI) calcd. for $C_{21}H_{32}NO_5$, *M*: 377.2202; found: 377.2211. Anal. calcd. for $C_{21}H_{32}NO_5$: C 66.82, H 8.28; found: C 66.87, H 8.29.

E. From 265 mg (1.87 mmol) of dimethyl squarate, 5.13 mg (2.80 mmol) of **6**, and 713 mg (3.73 mmol) of 1-bromo-6-methoxycyclohexene, there was isolated 99 mg (16%) of **27** as a colorless oil; ^{1}H NMR ($CDCl_3$) δ: 5.96 (1H, m), 5.44 (1H, m), 3.92 (3H, s), 3.84 (1H, m), 3.64 (3H, s), 3.56 (1H, m), 3.40 (1H, m), 2.50 (1H, m), 2.38–2.24 (2H, m), 2.17–1.95 (2H, m), 1.95–1.81 (3H, m), 1.78–1.58 (2H, m) ppm; ^{13}C NMR ($CDCl_3$) δ: 198.3, 154.1, 148.2, 140.5, 132.4, 130.4, 128.4, 123.9, 61.0 (2 C), 49.6, 46.3, 41.0, 33.9, 25.6, 22.6, 20.6, 16.7 ppm; HRMS (EI) calcd. for $C_{18}H_{21}NO_5$, *M*: 331.1420; found: 331.1403.

F. Reaction of *N*-(*tert*-butoxycarbonyl)-2-pyrroline (320 mg, 1.89 mmol), diisopropyl squarate (250 mg, 1.89 mmol), and 2-bromopropene (0.224 mL, 2.52 mmol) according to the general procedure gave 335 mg (39%) of **29** as a 1.2:1 mixture of isomers); colorless oil; IR (film) ν: 3462, 1698, 1620, 1393, 1298 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 5.39 (0.45H, quintet, *J* = 6.2 Hz), 5.27 (0.55H, quintet, *J* = 6.2 Hz), 4.94 (1H, m), 4.32 (0.55H, d, *J* = 8.6 Hz), 4.27 (0.45H, d, *J* = 8.5 Hz), 3.35–3.15 (2H, m), 2.62 (1H, m), 2.19 (0.45H, d, *J* = 5.1 Hz), 2.14 (0.55H, d, *J* = 5.1 Hz), 1.90–1.70 (2H, m), 1.52 (4.05H, s), 1.47 (4.95H, s), 1.65–1.40 (1H, m), 1.40–1.15 (12H, series of d), 1.11 (1.65H, s), 1.10 (1.35H, s) ppm; ^{13}C NMR (C_6D_6) δ: (major isomer) 302.0, 167.6, 155.2, 131.0, 84.2, 78.9, 74.0, 73.2, 71.2, 56.7, 47.6, 40.9, 36.4, 29.8, 28.2 (3C), 22.9 (2C), 22.2 (2C), 20.1 ppm; δ: (minor isomer) 202.7, 166.9, 153.8, 131.0, 84.2, 79.1, 74.0, 73.6, 71.4, 56.5, 47.5, 41.9, 36.2, 29.8, 28.2 (3C), 22.7 (2C), 22.4 (2C), 20.3 ppm; HRMS (EI) calcd. for $C_{22}H_{35}NO_6$, *M*: 409.2464; found: 409.2469. Anal. calcd. for $C_{22}H_{35}NO_6$: C 64.52, H 8.61; found: C 64.61; H 8.66.

G. Reaction of *N*-(*tert*-butoxycarbonyl)-2-pyrroline (474 mg, 2.80 mmol) dimethyl squarate (265 mg, 1.87 mmol), and 1-iodocyclopentene (747 mg, 3.73 mmol) as described above gave 345 mg (49%) of a 5:1 mixture of **30** and **31**. Major product **30** was obtained as white crystals, mp 99–101°C; IR (film) ν: 3412, 1714, 1664, 1631, 1459, 1395; ^{1}H NMR ($CDCl_3$) δ: 4.45 (1H, s), 4.16 (3H, s), 3.79 (3H, s), 3.48–3.16 (2H, m), 2.73 (1H, m), 2.62 (1H, q, *J* = 9.0 Hz), 2.42 (1H, m), 2.00–1.30 (8H, series of m), 1.39 (9H, s); ^{13}C NMR ($CDCl_3$) δ: 199.0, 168.5, 157.1, 134.2, 83.0, 81.1, 80.1, 59.6 (2C), 51.9, 50.9, 50.0, 43.8, 28.2 (3C), 28.1, 27.4, 27.0, 26.5; HRMS (EI) calcd. for $C_{20}H_{29}NO_6$, *M*: 379.1995; found: 379.1991. Anal. calcd. for $C_{20}H_{29}NO_6$: C 63.31, H 7.70; found: C 63.34, H, 7.69.

The following NOE interactions were observed:

Structure 4.

*4,5,5a,6-Tetrahydro-8,9,10-trimethoxy-7-methyl-2*H,3H-*1-oxa-2a-azacyclooct[*cd*]inden-2-one (**32**)*: A solution of potassium *tert*-butoxide (230 mg, 2.05 mmol) in DMSO (7 mL) was cooled to 0°C and treated with a solution of **22a** (100 mg, 0.341 mmol) in DMSO (3 mL). After 30 min of stirring in the cold, dimethyl sulfate (0.20 mL, 2.1 mmol) was introduced and the reaction mixture was allowed to warm to room temperature over 15 h. After dilution with ether and brine the separated aqueous phase was extracted with ether and the combined organic layers were dried and concentrated. Flash chromatography of the residue on silica gel (elution with 20% ethyl acetate in hexanes) gave 80 mg (76%) of **32** as white crystals, mp 124–126°C (from hexanes:ether 1:5); IR (film) ν: 3495, 1755, 1633, 1454, 1410, 1292 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 3.80 (1H, dd, *J* = 12.5, 5.7 Hz), 3.68 (3H, s), 3.57 (3H, s), 3.43 (3H, s), 3.24 (1H, dt, *J* = 12.5, 5.7 Hz), 2.90–2.78 (2H, m), 2.12–2.03 (2H, m), 1.90–1.63 (2H, m), 1.81 (3H, s), 1.53 (1H, m) ppm; ^{13}C NMR ($CDCl_3$) δ: 154.6, 145.4, 137.5, 132.8, 127.7, 126.9, 121.5, 59.2, 57.2, 56.5, 40.6, 36.0, 35.3, 27.6, 22.8, 17.9 ppm; HRMS (EI) calcd. for $C_{16}H_{21}NO_5$, *M*: 307.1419; found: 307.1448. Anal. calcd. for $C_{16}H_{21}NO_5$: C 62.53, H 6.89; found: C 62.60, H 6.88.

*(4a*R**,6*R**,6a*S**,12a*R**)-2,3,4,4a,5,6-Hexahydro-7,8-dimethoxy-6-methyl-9*H*-6a,1-(epoxymethano)-1H-pentaleno[6a,1-*b*]pyridine-9,11-dione (**35**)*: To an excess of sodium methoxide (from 50 mg of sodium metal) in methanol (5 mL) and THF (3 mL) was added 100 mg (0.34 mmol) of **22a** dissolved in THF (2 mL). After 1 h, the reaction mixture was quenched with saturated NH_4Cl solution (10 mL) and ether (10 mL). The separated aqueous phase was extracted with ether, and the combined organic layers were dried and concentrated. Flash chromatography of the residue on silica gel (elution with 20% ethyl acetate in hexanes) gave **35** (83 mg, 83%) as white crystals, mp 98–100°C (from ether:CH_2Cl_2 20:1); IR (film) ν: 1761, 1712, 1625, 1461, 1389, 1339 cm; ^{1}H NMR ($CDCl_3$) δ: 4.10 (3H, s), 3.86 (3H, s), 3.77 (1H, m), 3.15 (1H, m), 2.51 (1H, quintet, *J* = 6.4 Hz), 2.35–2.05 (3H, m), 1.72 (1H, m), 1.65–1.49 (3H, m), 0.96 (3H, d, *J* = 7.6 Hz) ppm; ^{13}C NMR ($CDCl_3$) δ: 193.9, 163.2, 156.4, 135.9, 90.7, 69.4, 59.3, 59.2, 40.5, 39.9, 36.2, 33.6, 22.3, 19.2, 15.6 ppm; HRMS (EI) calcd. for $C_{15}H_{19}NO_5$, *M*: 293.1263; found: 293.1268. Anal. calcd. for $C_{15}H_{19}NO_5$: C 61.42, H, 6.53; found: C 61.31, H 6.49.

The structural assignment to **35** was corroborated by X-ray diffraction analysis.

*(3*R**,5*S**,6a*R**,13a*S**)-3,4,5,6,6a,7,8,9-Octahydro-3,14-dimethoxy-5-methyl-4,11-dioxo-*N*-phenyl-3,13-metheno-11*H*,13*H*-oxazolo[3′,4′:1,2]pyrido[2,3-*c*]-1,2-diazoline-1,2-dicarboxylate (**36**)*: To a cold (–78°C) solution of 4-phenyl-1,2,4-triazoline-3,5-dione (30 mg, 0.17 mmol) in CH_2Cl_2 (5 mL) was added a solution of **22a** (33 mg, 0.11 mmol) in CH_2Cl_2 (2 mL). After 30 min of stirring, the reaction mixture was allowed to warm to room temperature over 2 h and concentrated under vacuum. Flash chromatography on silica gel (elution with 20% ethyl acetate in hexanes) afforded **36** as white crystals (40 mg, 76%) of mp 193–195°C dec (from ether:CH_2Cl_2 20:1); IR (film) ν: 1805, 1782, 1731, 1600, 1503, 1415, 1247 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ: 7.56–7.38 (5H, m), 4.13–3.93 (2H, m), 3.99 (3H, s), 3.37 (3H, s), 2.70 (1H, m), 2.10–1.62 (6H, series of m), 1.20 (3H, d, *J* = 6.7 Hz), 1.07 (1H, m) ppm; ^{13}C NMR ($CDCl_3$) δ: 197.4, 154.5, 152.4, 147.0, 130.3, 129.3 (2C), 129.1, 128.8, 126.1, 125.1 (2C), 88.9, 82.5, 61.1, 52.3, 49.7, 45.1, 41.9, 40.3, 27.1, 20.9, 18.1 ppm; HRMS (EI) calcd. for $C_{23}H_{24}N_4O_9$, *M*: 468.1644,

Efficient synthesis of optically active 2-amino-2′-diphenylphosphino-1,1′-binaphthyl and its derivatives

Kenzo Sumi, Takao Ikariya, and Ryoji Noyori

Abstract: Optically active 2-amino-2′-diphenylphosphino-1,1′-binaphthyls having various functional groups, such as amino, alkoxycarbonylamino, acylamino, mono- and dialkylamino, and sulfonylamino at C2 position were prepared. The key intermediate of the above aminophosphines was 2-carbamoyl-2′-diphenylphosphinyl-1,1′-binaphthyl synthesized from optically active 2-cyano-2′-diphenylphosphinyl-1,1′-binaphthyl. The transformation of the carbamoyl group to an amino group was effected by the Hofmann reaction.

Key words: aminophosphine ligand, Hofmann reaction, optically active phosphine ligand.

Résumé : On a préparé des 2-amino-2′-diphénylphosphino-1,1′-binaphtyles optiquement actifs portant divers groupes fonctionnels, tels que amino, alkoxycarbonylamino, acylamino, mono- et dialkylamino et sulfonylamino en position C-2. L'intermédiaire clé de ces aminophosphines est le 2-carbamoyl-2′-diphénylphosphinyl-1,1′-binaphtyle synthétisé à partir du 2-cyano-2′-diphénylphosphinyl-1,1′-binaphtyle optiquement actif. La transformation du groupe carbamoyle en groupe amino a été réalisée par le biais d'une réaction d'Hofmann.

Mots clés : ligand aminophosphine, réaction d'Hofmann, ligand phosphine optiquement actif.

[Traduit par la Rédaction]

1. Introduction

Asymmetric reactions catalyzed by transition metal complexes containing optically active phosphine ligands have attracted significant interest for their synthetic utility.[2] Recent catalytic asymmetric synthesis has utilized atropisomeric diphosphine ligands, among which BINAP (**2**) is preeminent (2). The 1,1′-binaphthyl ring system is a key component of a number of chiral ligands that have been used very successfully for asymmetric synthesis (3). Most notable are 2,2′-disubstituted systems such as dihydroxy derivative **1** (4) and diphosphine **2** (2), other heteroatom substituted systems such as **3** (and derivatives of thereof) (5), **4** (6), and **5** (7) have also been recently described. In this way, a great deal of attention has been focused on atropisomeric C_2 symmetry binaphthyl derivatives.

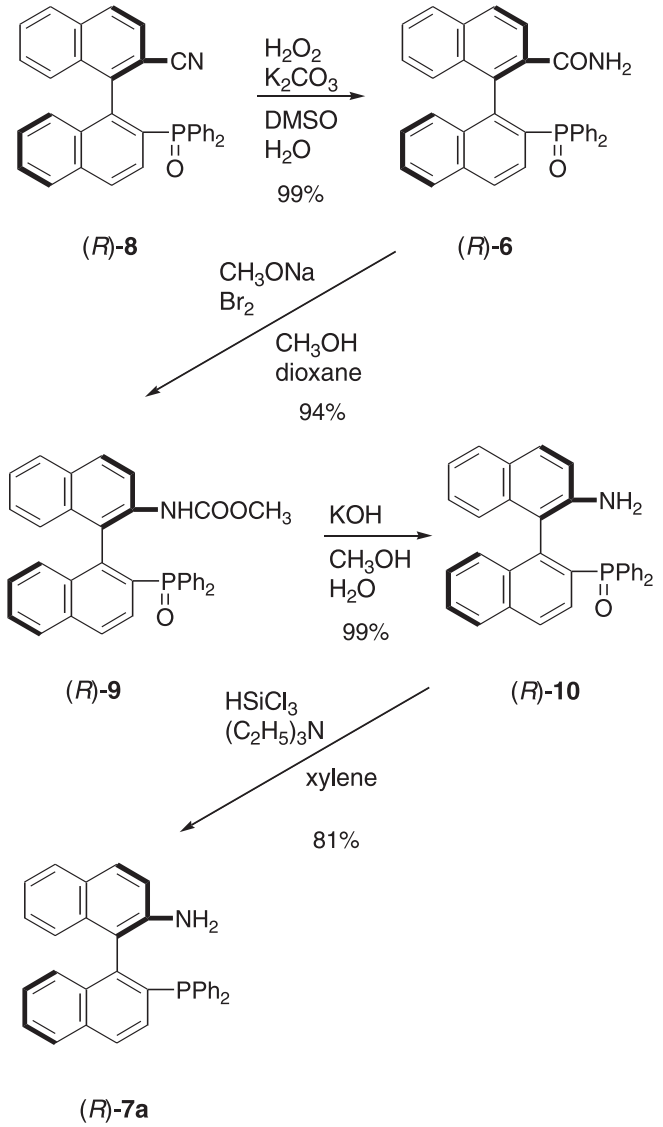
[2]For recent reviews on catalytic asymmetric reactions see ref. 1.

Chelating aminophosphines are often effective ligands for asymmetric homogeneous catalysis. Mixed *P,N*-ferrocenyl ligands have been shown by Cullen et al. (8) to give enantioselectivities as high as 84% in the rhodium-catalyzed hydrogenation of acetamidocinnamic acid (8*a*, *b*). The use of nitrogen-containing ligands in the coupling of secondary Grignard reagents with alkenyl halides has been pioneered by Hayashi and Kumada (9). The most successful ligands used for this reaction are chelating *P,N*-systems, derived from amino acids (10) or from chiral ferrocenyl systems (11). Some chiral pyridylphosphines bearing the chiral group bound to the phosphorus atom by an N—P linkage (12) and optically active pyridylphosphines without N—P bonds (13) have been described. Chiral aminophosphine derivatives bearing *N*-sulfonyl groups were efficient ligands for asymmetric Heck-type hydroarylation of norbornene with phenyl triflate (14). Furthermore, the activity of $RuCl_2[P(C_6H_5)_3]_3$ for hydrogenation of acetophenone was dramatically enhanced with an addition of ethylenediamine (15). Therefore, bidentate phosphine–nitrogen ligands containing soft phosphorus and hard nitrogen donors are expected to exhibit unique catalytic activities.



For these reasons, an alternative *P,N* chelate ligand was sought which might provide more tractable intermediates, and an atropisomerically chiral monoaminophosphine compound of type **7** (MAPs) is an attractive target. In order to increase the applicability of the axially chiral phosphine, we introduced several functional groups on the binaphthyl skeleton. We report here the preparation of 2-functionalized-2′-diphenylphosphino-1,1′-binaphthyls that contain amino,

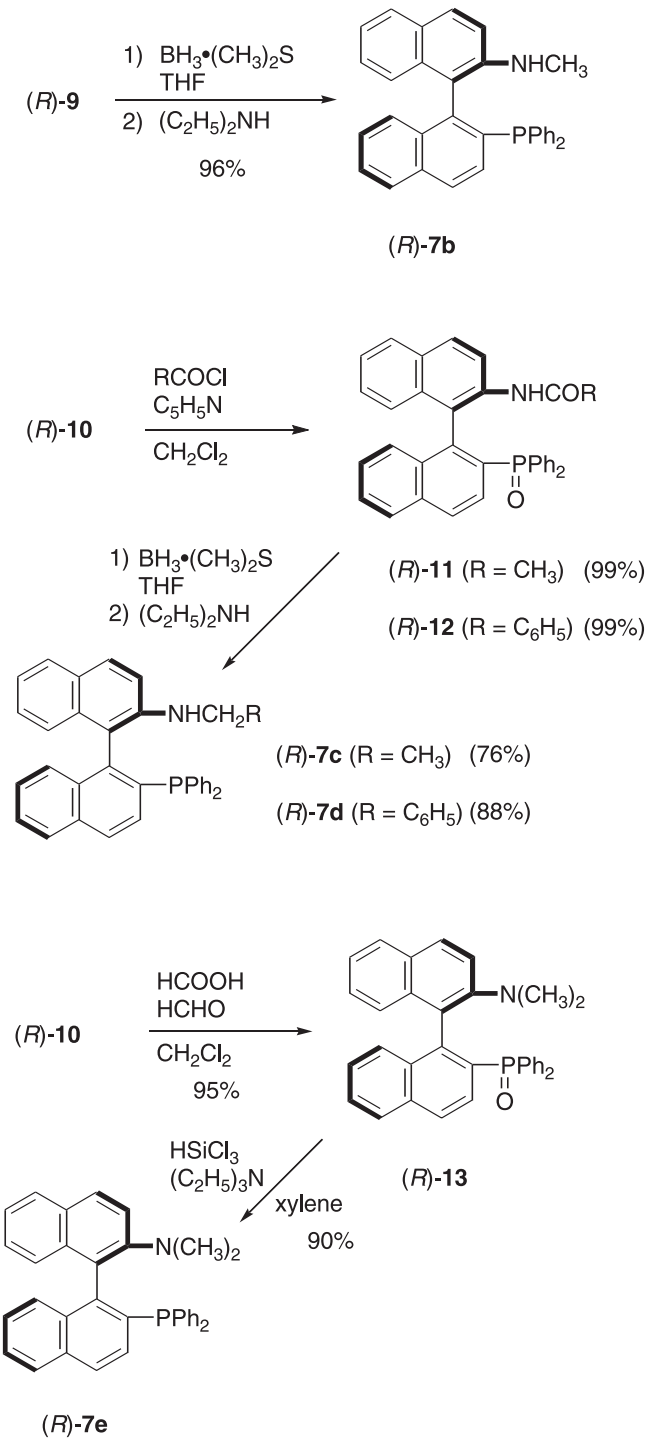
Scheme 1.

alkoxycarbonylamino, acylamino, mono- and di-alkylamino, and sulfonylamino groups at the C2 position. These functional groups are expected to interact with transition metals or reacting substrates. Though ligands of this type have been made recently by Vyskocil et al. (16) and Ding et al. (17), during our study, carcinogenic 2-naphthylamine is indispensable to the method for the preparation of optically active *P,N*-type binaphthyl ligands from a binapthyl-type amino alcohol, NOBIN, available by Cu(II)-mediated oxidative coupling of 2-naphthol with 2-naphthylamine. Aranyos et al. (18) reported the preparation of racemic 2-dimethylamino-2′-di-*tert*-butylphosphino-1,1′-binaphthyl from racemic 2,2′-dibromo-1,1′-binaphthyl.



2. Results and discussion

As a part of our work aimed at the synthesis of chiral amino phosphine ligands, we undertook a study on methods to obtain chiral monodentate phosphine ligand, MOPs (**5**) (7), from optically active 1,1′-binaphthalene-2,2′-diol (**1**). This approach would access a series of binaphthyl-type phosphines, analogous to Hayashi's MOP, but having a nitrogen atom in place of oxygen. Wallis and Moyer (19) carried out the Hofmann reaction (20) on a chiral amide in a most convincing demonstration of the intramolecularity of the migration step. During rearrangement, the amide would lose chirality if the migrating bond simply stretched enough to allow rotation about the benzene—naphthalene bond. However, loss of chirality is not observed and the amide rearranges with retention of configuration. The result attracted our attention as a versatile starting compound for the preparation of chiral monoaminophosphine ligands **7**.

After optimization, a multistep synthesis resulting on good yield of the title compounds was succeeded based on the Hofmann reaction of a (*R*)-2-carbamoyl-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**6**) with bromine in a basic methanol solution (21) to afford a (*R*)-2-methoxycarbonylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**9**). The amide (*R*)-**6** was obtained from (*R*)-2-cyano-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**8**) whose preparation has been reported by Hayashi and coworkers (7*c*). Though the cyano group resisted acid or alkaline hydrolysis

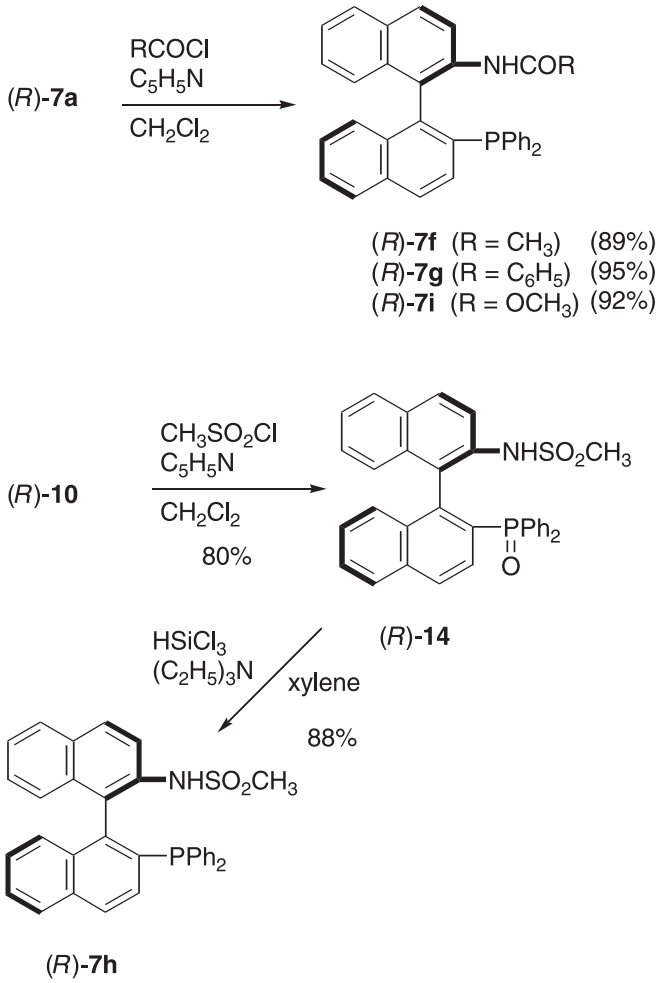

Scheme 2.

to a carbamoyl group, the amide (*R*)-**6** was prepared with alkaline hydrogen peroxide according to the procedures reported by Katritzky et al. (22).

The (*R*)-2-amino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**10**) was prepared by alkaline hydrolysis of the carbamate (*R*)-**9** with aqueous KOH in methanol upon heating. Subsequent reduction of (*R*)-**10** with trichlorosilane gave rise to the required (*R*)-2-amino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7a**). For this simple class of *P,N*-type

Scheme 3.

ligand **7a**, we propose the acronym SMAP, standing for a simple monoaminophosphine, in analogy with MOP.

The carbamate (*R*)-**9** was reduced with borane to afford (*R*)-2-methylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7b**). The reduction of the amido phosphine oxide, (*R*)-2-acetylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**11**) and (*R*)-2-benzoylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**12**), obtained from acylation of the aminophosphine oxide (*R*)-**10**, with borane gave (*R*)-2-ethylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7c**) and (*R*)-2-benzylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7d**), directly. Dimethylation of the primary amine in (*R*)-**10** with formaldehyde and formic acid (23) afforded (*R*)-2-dimethylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**13**), whose reduction with trichlorosilane produced (*R*)-2-dimethylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7e**). (*R*)-2-acetylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7f**) and (*R*)-2-benzoylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7g**), or (*R*)-2-methoxycarbonylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7i**) were derived from (*R*)-**7a** with the corresponding acyl chloride or methoxycarbonyl chloride. *N*-Sulfonylation of (*R*)-**10** with methanesulfonyl chloride gave (*R*)-2-methylsulfonylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**14**). Phosphine oxide (*R*)-**14** was reduced by trichlorosilane/triethylamine to

© 2000 NRC Canada

give (*R*)-2-methylsulfonylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7h**).

In summary, a new practical method for the synthesis of optically active aminophosphine ligands, MAPs, was developed. SMAP (**7a**) was obtained from the nitrile **8** via the Hofmann rearrangement of the amide **6** under controlled conditions. The flexibility of the synthetic route realizes the fine tuning of the properties of the phosphine ligand. Work directed toward the extension of the series of different ligands of the aminophosphine ligand, and further applications in homogeneous asymmetric catalysis, including mechanistic studies, is in progress and will be reported in due course.

3. Experimental

General

All reactions were run under an atmosphere of dry nitrogen unless otherwise indicated. Anhydrous solvents were transferred by oven-dried syringe or canula. Acetonitrile, dichloromethane, methanol, dimethyl sulfoxide (DMSO), and pyridine were distilled from calcium hydride. Tetrahydrofuran (THF) was distilled from sodium benzophenone ketyl. Xylene was distilled from sodium.

Melting points were determined on a hot stage microscope (YANACO MP-500D) and were uncorrected. ^{1}H NMR spectra were measured on a Bruker DRX500 (500 MHz) or a Varian Gemini 200 (200 MHz) in $CDCl_3$. Chemical shifts of protons were reported in δ ppm referred to tetramethysilane as an internal standard. $^{31}P\{^1H\}$ NMR spectra were measured on a Bruker DRX500 (202 MHz) in $CDCl_3$ using H_3PO_4 as an external standard. Optical rotations were measured on a JASCO DIP-360 polarimeter. IR spectra were recorded on a Nocolet Avatar 360 spectrometer. EI mass spectra and high-resolution mass spectra were measured on a Hitachi M-2000A spectrometer at an ionization voltage of 70 eV. Silica gel column chromatography was carried out using Merck silica gel 60 (230–400 mesh ASTM). (*R*)-(+)-2-cyano-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**8**) was prepared according to a literature procedure (7*c*).

*(*R*)-(+)-2-Carbamoyl-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**6**)*

To a stirred solution of (*R*)-(+)-2-cyano-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**8**) (7*c*) (9.99 g, 20.8 mmol) in DMSO (100 mL), cooled in an ice bath, were added 30% H_2O_2 (50 mL) and anhydrous K_2CO_3 (57.6 g). The mixture was allowed to warm up to room temperature (rt) (exothermic effect was observed). After 30 min, distilled water (43 mL) and DMSO (43 mL) were added, cooling applied, and the mixture was stirred at rt for 15 h. The reaction mixture was diluted with EtOAc and quenched with saturated NH_4Cl (100 mL). The organic phase was washed twice with H_2O and with brine, dried over Na_2SO_4, and concentrated under reduced pressure. The residue was purified by silica gel column chromatography (elution with EtOAc) giving 10.23 g of (*R*)-**6** (99%), mp 120–122°C, $[\alpha]_D^{24}$ 157 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1662, 1119. ^{1}H NMR δ: 9.44 (bs, 1H), 7.91 (d, *J* = 8.3 Hz, 1H), 7.86 (d, *J* = 8.8 Hz, 2H), 7.8–7.7 (m, 3H), 7.62 (d, *J* = 7.8 Hz, 1H), 7.6–7.4 (m, 5H), 7.3–7.2 (m, 1H), 7.2–7.0 (m, 5H), 7.0–6.9 (m, 2H), 6.64 (t, *J* = 7.0 Hz, 1H), 6.33 (d, *J* = 8.3 Hz, 1H), 5.52 (bs, 1H). $^{31}P\{^1H\}$ NMR δ: 30.9 (s). EIMS *m*/*z*: 497 (M^+, base peak). HRMS calcd for $C_{33}H_{24}NO_2P$: 497.1543; found: 497.1511.

*(*R*)-(–)-2-Methoxycarbonylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**9**)*

To a solution of 19.9 mL of 28% sodium methoxide in methanol (97.3 mmol) was added methanol (161 mL). The solution was cooled to –78°C and bromine (1.84 mL, 35.7 mmol) was added dropwise with vigorous stirring. After stirring at –78°C for 15 min, a solution of (*R*)-**6** (8.07 g, 16.2 mmol) in methanol (145 mL) and dioxane (145 mL) was added dropwise for 1 h. The reaction mixture was stirred at ambient temperature for 1 h and then stirred at 55°C for 1 h. After being cooled to rt, the mixture was diluted with EtOAc and quenched with saturated NH_4Cl. The organic layer was washed with brine and dried over Na_2SO_4. After removal of the solvent, the residue was chromatographed on silica gel (elution with *n*-hexane:EtOAc, 1:2) to give (*R*)-**9** (8.05 g, 94%), mp 127–128°C,$[\alpha]_D^{24}$ –155 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1723, 1507, 1238, 1171, 1115. ^{1}H NMR δ: 8.72 (bs, 1H), 7.9–7.6 (m, 5H), 7.65 (d, *J* = 8.8 Hz, 1H), 7.6–7.4 (m, 6H), 7.3–7.1 (m, 4H), 7.08 (d, *J* = 8.8 Hz, 1H), 6.94 (t, *J* = 7.1 Hz, 1H), 6.80 (t, *J* = 7.0 Hz, 1H), 6.7–6.6 (m, 2H), 6.50 (d, *J* = 6.8 Hz, 1H), 3.04 (bs, 3H). $^{31}P\{^1H\}$ NMR δ: 28.2 (s). EIMS *m*/*z*: 527 (M^+, base peak). HRMS calcd for $C_{34}H_{26}NO_3P$: 527.1648; found: 527.1592.

*(*R*)-(–)-2-Amino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**10**)*

To a solution of (*R*)-**9** (8.01 g, 15.2 mmol) in methanol (304 mL) was added 152 mL of 40% KOH solution and the mixture was refluxed for 2 h. After being cooled to rt, the mixture was diluted with EtOAc. The organic phase was washed with brine, dried over Na_2SO_4, and concentrated under reduced pressure. The crude material was purified by silica gel column chromatography (elution with EtOAc) giving 7.16 g (99%) of (*R*)-**10**, mp 133–134°C, $[\alpha]_D^{24}$ –199 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1622, 1172, 1115. ^{1}H NMR δ: 8.0–7.8 (m, 2H), 7.8–7.6 (m, 5H), 7.6–7.4 (m, 1H), 7.4–7.3 (m, 5H), 7.3–7.1 (m, 4H), 7.1–6.9 (m, 1H), 6.9–6.8 (m, 3H), 6.8–6.7 (m, 2H), 6.51 (d, *J* = 8.3 Hz, 1H), 3.94 (bs, 2H). $^{31}P\{^1H\}$ NMR δ: 27.1 (s). EIMS *m*/*z*: 469 (M^+, base peak). HRMS calcd for $C_{32}H_{24}NOP$: 469.1594; found: 469.1556.

*(*R*)-(–)-2-Amino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7a**)*

Aminophosphine oxide (*R*)-**10** (7.16 g, 15.2 mmol) was placed in a pressure tube, then xylene (381 mL) added and stirred. Triethylamine (42.5 mL, 305.0 mmol) then trichlorosilane (7.70 mL, 76.3 mmol) were added at 0°C. After sealing the tube, the mixture was stirred at 150°C for 18 h. The reaction mixture was allowed to cool to rt, diluted with Et_2O, and quenched with saturated NH_4Cl. The organic layer was dried over Na_2SO_4 and concentrated under reduced pressure. The crude phosphine was purified by silica gel column chromatography (elution with *n*-hexane:EtOAc, 4:1) giving 5.60 g (81%) of (*R*)-**7a**, mp 104–106°C, $[\alpha]_D^{24}$ –27 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1622, 1514, 1433. ^{1}H NMR δ: 7.87 (d, *J* = 8.3 Hz, 2H), 7.77 (d, *J* = 8.7 Hz, 1H), 7.71 (d, *J* = 7.8 Hz, 1H), 7.5–7.4 (m, 2H), 7.4–7.2 (m, 7H), 7.2–7.0 (m, 6H), 7.0–6.9 (m, 2H), 6.67 (d, *J* = 8.8 Hz, 1H),

3.25 (bs, 2H). $^{31}P\{^{1}H\}$ NMR δ: –13.1 (s). EIMS *m/z*: 453 (M^+, base peak). HRMS calcd for $C_{32}H_{24}NP$: 453.1646; found: 453.1648.

*(*R*)-(–)-Methylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7b**)*

To a solution of (*R*)-**9** (3.59 g, 6.81 mmol) in THF (170 mL) was added 2M borane – dimethyl sulfide complex in THF (27.2 mL, 54.4 mmol) at 0°C, the mixture was refluxed for 18 h. After being cooled to rt, the mixture was diluted with EtOAc and quenched with saturated NH_4Cl. The organic layer was washed with brine and dried over Na_2SO_4 and concentrated under reduced pressure. To the residue was added 272 mL of diethylamine and the reaction mixture was stirred at rt for 30 min. After removal of diethylamine, the residue was chromatographed on silica gel (elution with *n*-hexane:EtOAc, 16:1) to give (*R*)-**7b** (3.05 g, 96%), mp 100–101°C, $[\alpha]_D^{24}$ –27 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1599, 1555, 1345. ^1H NMR δ: 7.9–7.8 (m, 3H), 7.73 (d, *J* = 8.3 Hz, 1H), 7.5–7.4 (m, 2H), 7.3–6.9 (m, 15H), 6.70 (d, *J* = 8.3 Hz, 1H), 3.04 (bs, 1H), 2,37 (s, 3H). $^{31}P\{^{1}H\}$ NMR δ: –13.9 (s). EIMS *m/z*: 467 (M^+, base peak). HRMS calcd for $C_{33}H_{26}NP$: 467.1802; found: 467.1838.

*(*R*)-(–)-2-Acetylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**11**)*

To a solution of (*R*)-**10** (141 mg, 0.30 mmol) in 6 mL of CH_2Cl_2 were added pyridine (29 μL, 0.36 mmol) and acetyl chloride (24 μL, 0.33 mmol) at 0°C and the mixture was stirred at rt for 1 h. The mixture was diluted with CH_2Cl_2 and washed with saturated NH_4Cl and brine. The organic phase was dried over Na_2SO_4 and concentrated under reduced pressure. The residue was chromatographed on silica gel (elution with *n*-hexane:EtOAc, 4:1) giving 155 mg (99%) of (*R*)-**11**, mp 95–96°C, $[\alpha]_D^{24}$ –153 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1670, 1597, 1504, 1439, 1167. ^1H NMR δ: 9.73 (s, 1H), 8.0–7.9 (m, 4H), 7.8–7.6 (m, 2H), 7.6–7.4 (m, 6H), 7.3–7.1 (m, 5H), 7.0–6.9 (m, 1H), 6.8–6.7 (m, 1H), 6.7–6.6 (m, 1H), 6.53 (d, *J* = 8.3 Hz, 1H), 1.93 (s, 3H). $^{31}P\{^{1}H\}$ NMR δ: 29.6 (s). EIMS *m/z*: 511 (M^+, base peak). HRMS calcd for $C_{34}H_{26}NO_2P$: 511.1700; found: 511.1717.

*(*R*)-(–)-Ethylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7c**)*

To a solution of (R)-**11** (127 mg, 0.25 mmol) in THF (6 mL) was added 2M borane – dimethyl sulfide complex in THF (620 μL, 1.24 mmol) at 0°C, the mixture was refluxed for 18 h. After being cooled to rt, the mixture was diluted with EtOAc and quenched with saturated NH_4Cl. The organic layer was washed with brine and dried over Na_2SO_4 and concentrated under reduced pressure. To the residue was added 8.2 mL of diethylamine and the reaction mixture was stirred at rt for 3 h. After removal of diethylamine, the residue was chromatographed on silica gel (elution with *n*-hexane:EtOAc, 50:1) to give (*R*)-**7c** (91 mg, 76%), mp 83–84°C, $[\alpha]_D^{24}$ –47 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1619, 1599, 1514, 1434, 1302, 1153. ^1H NMR δ: 8.0–7.8 (m, 3H), 7.74 (d, *J* = 8.5 Hz, 1H), 7.5–7.4 (m, 2H), 7.3–6.9 (m, 16H), 6.59 (d, *J* = 8.5 Hz, 1H), 3.07 (m, 2H), 2.9–2.7 (m, 1H), 0.78 (t, *J* = 7.0 Hz, 3H). $^{31}P\{^{1}H\}$ NMR δ: –13.3 (s). EIMS *m/z*: 481 (M^+, base peak). HRMS calcd for $C_{34}H_{28}NP$: 481.1958; found: 481.1996.

*(*R*)-(–)-2-Benzoylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**12**)*

To a solution of (*R*)-**10** (188 mg, 0.40 mmol) in 8 mL of CH_2Cl_2 were added pyridine (39 μL, 0.48 mmol) and benzoyl chloride (51 μL, 0.44 mmol) at 0°C and the mixture was stirred at rt for 1.5 h. The mixture was diluted with CH_2Cl_2 and washed with saturated NH_4Cl and brine. The organic phase was dried over Na_2SO_4 and concentrated under reduced pressure. The residue was chromatographed on silica gel (elution with *n*-hexane:EtOAc, 1:1) giving 228 mg (99%) of (*R*)-**12**, mp 247–249°C, $[\alpha]_D^{24}$ –98 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) ν: 1653, 1507, 1489, 1292, 1167. ^1H NMR δ: 10.62 (s, 1H), 8.0–7.8 (m, 7H), 7.72 (d, *J* = 8.0 Hz, 1H), 7.8–7.1 (m, 15H), 7.0–6.9 (m, 1H), 6.9–6.7 (m, 1H), 6.7–6.6 (m, 1H), 6.51 (d, *J* = 7.9 Hz, 1H). $^{31}P\{^{1}H\}$ NMR δ: 29.9 (s). EIMS *m/z*: 573 (M^+, base peak). HRMS calcd for $C_{39}H_{28}NO_2P$: 573.1857; found: 573.1895.

*(*R*)-(–)-Benzylamino-2′-diphenylphosphino-1,1′-binaphthyl ((*R*)-**7d**).*

To a solution of (R)-**12** (29 mg, 0.05 mmol) in THF (1.3 mL) was added 2M borane – dimethyl sulfide complex in THF (88 μL, 0.18 mmol) at 0°C, the mixture was refluxed for 18 h. After being cooled to rt, the mixture was diluted with EtOAc and quenched with saturated NH_4Cl. The organic layer was washed with brine and dried over Na_2SO_4 and concentrated under reduced pressure. To the residue was added 1.5 mL of diethylamine and the reaction mixture was stirred at rt for 5 h. After removal of diethylamine, the residue was chromatographed on silica gel (elution with *n*-hexane:EtOAc, 20:1) to give (*R*)-**7d** (24 mg, 88%), mp 70–71°C, $[\alpha]_D^{24}$ –34 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1599, 1496, 1342. ^1H NMR δ: 7.9–7.8 (m, 2H), 7.80 (d, *J* = 8.9 Hz, 1H), 7.69 (d, *J* = 8.8 Hz, 1H), 7.6–7.4 (m, 2H), 7.4–7.0 (m, 19H), 7.0–6.9 (m, 1H), 6.61 (d, *J* = 8.4Hz, 1H), 4.17 (d, *J* = 15.3 Hz, 1H), 3.99 (d, *J* = 15.3 Hz, 1H), 3,68 (bs, 1H). $^{31}P\{^{1}H\}$ NMR δ: –13.1 (s). EIMS *m/z*: 543 (M^+, base peak). HRMS calcd for $C_{39}H_{30}NP$: 543.2115; found: 543.2158.

*(*R*)-(–)-2-Dimethylamino-2′-diphenylphosphinyl-1,1′-binaphthyl ((*R*)-**13**)*

A mixture of (*R*)-**10** (3.18 g, 6.76 mmol), formic acid (67.6 mL, 1.79 mol), and 37% aqueous formaldehyde (67.6 mL, 0.89 mol) was refluxed for 20 h. The reaction mixture was made alkaline by the addition of saturated $NaHCO_3$ and extracted with Et_2O. The organic phase was dried over Na_2SO_4 and concentrated under reduced pressure. The residue was chromatographed on silica gel (elution with *n*-hexane:EtOAc, 1:1) giving 3.21 g (95%) of (*R*)-**13**, mp 82–83°C, $[\alpha]_D^{24}$ –17 (*c* 1.0, $CHCl_3$). IR ($CHCl_3$) cm^{-1} ν: 1597, 1506, 1438. ^1H NMR δ: 8.0–7.8 (m, 2H), 7.8–7.7 (m, 1H), 7.6–7.4 (m, 5H), 7.4–7.0 (m, 10H), 7.0–6.9 (m, 3H), 6.71 (d, *J* = 8.5 Hz, 1H), 2,37 (s, 6H). $^{31}P\{^{1}H\}$ NMR δ: 29.5 (s). EIMS *m/z*: 497 (M^+, base peak). HRMS calcd for $C_{34}H_{28}NOP$: 497.1907; found: 497.1927.

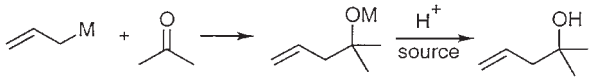
Preparation of homoallylic alcohols by reaction of aldehydes with η^3-allyl- and η^3-crotylmolybdenum complexes

Kevin P. Gable, M. Sundaram Shanmugham, and James D. White

Abstract: η^3-Allyl and η^3-methallyl complexes of molybdenum react with aldehydes to give homoallylic alcohols in preparative yields when water is used as a proton source, but the scope of the reaction is narrowed in the case of the η^3-crotylmolybdenum complex by the formation of both transposed and nontransposed products.



Key words: molybdenum, allylation, chelate model, transposition.

Résumé : Lorsqu'on utilise l'eau comme source de proton, les complexes η^3-allyle et η^3-méthallyle du molybdène réagissent avec les aldéhydes pour conduire aux alcools homoallyliques, avec des rendements préparatifs. Toutefois, dans le cas du complexe η^3-crotylmolybdène, la réaction est limitée par la formation de produits non transposés ainsi que de produits de transposition.

Mots clés : molybdène, allylation, modèle d'un chélate, transposition.

Introduction

The reaction of allylmetal reagents with carbonyl compounds provides a valuable method for the preparation of homoallylic alcohols (eq. [1]). A wide range of metals has been successfully employed in this process even though many allylmetal reagents are unstable and must generally be prepared and used in situ (1). In addition, allylboranes (2) and boronates (3) have found broad utility in applications where a homoallylic alcohol is needed in high enantiomeric excess.

[1] 

In 1989, Faller and co-workers (4) reported that η^3-allyl, η^3-methallyl, and η^3-crotyl complexes of bromo-(cyclopentadienyl)(nitroso)molybdenum react with aldehydes to give homoallylic alcohols. Faller et al. (5) further demonstrated that a chiral η^3-methallylmolybdenum complex could be resolved, and in a NMR experiment showed that its reaction with an aldehyde resulted in high asymmetric induction (6). Although the synthetic potential of these molybdenum compounds as reagents for the preparation of homoallylic alcohols is clear, the scope and limitations of their reactivity remain poorly defined. As part of a program designed to fabricate polyol substructures found in natural products, we were drawn to these π-allylmolybdenum reagents (7) by the fact that they are air and moisture stable substances which react with aldehydes under mild conditions (8).

Results and discussion

Molybdenum complexes **1**–**3** were prepared from tris(acetonitrile)molybdenum tricarbonyl (**4**) (9) via the dicarbonyl complex **5** using a variant of Faller's protocol (8) in which the bromine ligand was introduced with tetramethylammonium bromide. All three complexes are stable, yellow-orange solids that can be stored for many weeks with no special precautions. The η^3-crotyl complex **3** is a mixture of *syn* and *anti* stereoisomers, and there is evidence that these equilibrate during the reaction with aldehydes.

Since Faller had carried out all reactions of **2** in a mixture of dichloromethane and methanol, we first investigated the effect of varying the solvent on the reaction of **2** with benzaldehyde in the belief that the source of protons could play a pivotal role in this process. The results in Table 1 confirm that this is indeed the case, and that water is the most effective proton source. Optimized conditions for obtaining homoallylic alcohol **6** were realized with 3 equiv of water in dichloromethane; the absence of a proton source or the presence of a more acidic alcohol (CF_3CH_2OH) resulted in a significant proportion of the oxidized byproduct **7**.

The origin of the improved efficacy that the use of water imparts to these allylations bears comment. Faller et al. (5) have noted this effect and have attributed it in part to suppression of hemiacetal formation. However, this cannot be a significant factor. Intermolecular hemiacetal formation from aliphatic aldehydes and methanol is characterized by a small equilibrium constant, and at room temperature this process is

rapid compared to the allylation reaction (10). This literature also suggests that the equilibrium for hydration is actually more favored than that for hemiacetal formation. The possibility that pK_a of the proton source is the critical factor is ruled out by the fact that methanol and water have very similar acidities (11). Further, we see that trifluoroethanol leads to marginal improvement over running the reaction without a proton source prior to workup. The isolation of ketone **7**, presumably arising from a β-hydride elimination, suggests that timing of the proton transfer may be linked to binding of the conjugate base to the metal. A weakly Lewis basic species such as trifluoroethanol would not favour the

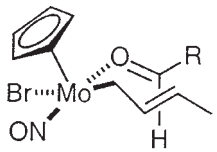

Scheme 2.

alkoxide exchange necessary to free the homoallylic alcohol, despite the enhanced proton availability. Methanol or other alcohols offer an improvement due to inductive donation by the alkyl group. Water, however, can engage in additional π-donation to the moderately oxophilic molybdenum centre, which encourages displacement of the product. Steric interference with other ligands is also minimized by this mechanism.

Application of the optimized conditions described above to the reaction of various aldehydes with 0.2–1 mmol of molybdenum complexes **1** and **2** afforded good to excellent yields of isolated and purified homoallylic alcohols (Table 2). The metal complexes react equally well with hindered (entry 3) and unhindered aldehydes (entry 1); however, they fail to react with ketones. Surprisingly, when the same aldehydes were exposed to molybdenum complex **3**, both transposed (**8**) and nontransposed (**9**) crotylation products were observed, the higher proportion of **9** being obtained with more sterically hindered aldehydes (entries 2 and 3). The configuration of the transposed homoallylic alcohol (**8**) in each case was found to be exclusively *anti* within the limits of detection, consistent with a six-centered, chelate transition state involving η^3-crotylmolybdenum complex **10**. However, the formation of **9** suggests that with **3** either a four-centre transition state or a non-chelate pathway must operate as well.

The question of facial (i.e., Felkin) selectivity in the reaction of molybdenum π-complexes with substrates bearing a

10

stereogenic center α to the aldehyde was addressed with (*R*)-3-benzyloxy-2-methylpropionaldehyde (**11**) and glyceraldehyde acetonide (**12**). In both cases, *syn* (**13**, **15**) and *anti* (**14**, **16**) products were formed in equal quantity, indicating complete absence of substrate stereocontrol in these reactions. This is consistent with an observation previously made by Faller et al. (6), and confirms that the overwhelming size of the metal complex dominates the stereochemical outcome with chiral aldehydes.

Conclusions

The reaction of η^3-allyl, η^3-methallyl, and η^3-crotyl complexes of bromo(cyclopentadienyl)(nitroso)molybdenum with aldehydes is shown to be a preparatively useful route to

© 2000 NRC Canada

homoallylic alcohols, supporting observations previously made by Faller and co-workers (4) on the basis of NMR experiments. The reactions are clean, and separation of the alcohol product from molybdenum byproducts presents no problems. The presence of water as a cosolvent is essential for optimum yields, but the role of water in these reactions is unclear. In reactions of η^3-crotyl molybdenum complexes with aldehydes, a complicating factor can be the formation of both transposed and nontransposed products. The latter are prevalent when a sterically hindered aldehyde is employed, indicating that these substrates interact with the bulky molybdenum reagent via a mechanism different from the conventional six-centered chelate model.

Experimental

In a typical procedure, *n*-heptanal (0.096 g, 0.84 mmol) and water (0.045 mL, 2.50 mmol) were added to a stirred solution of **1** (0.315 g, 1.00 mmol) in CH_2Cl_2 (4 mL). The biphasic mixture was stirred at room temperature for 12 h, after which the solvent was evaporated in vacuo. The crude residue was purified by column chromatography on silica gel, using ether–hexane (1:4) as eluent, to give 4-hydroxy-1-decene (0.111 g, 85%) as a colorless oil. The product was identified by comparison of its spectral properties with those described (12).

Enantiomerically pure decalinic structures from carbohydrates using intramolecular Diels–Alder and Ferrier carbocyclization

Claude Taillefumier and Yves Chapleur

Abstract: The synthesis of enantiomerically pure decalinic structures, advanced intermediates for the synthesis of the hexahydronaphtalen part of mevinic acids, is described. The key steps are the intramolecular Diels–Alder cycloaddition of a suitably substituted sugar enone obtained via the Ferrier rearrangement of tri-*O*-acetyl-D-glucal with the appropriate alcohol representing the diene part of the system. Chemical manipulation of the resulting, diastereomerically pure, cycloadduct led to a 5,6-unsaturated carbohydrate which was submitted to the Ferrier carbocylization. This reaction proved difficult likely because of the embedding of the aglycon in a cycle, the hydration product of the double bond being the main product. This compound was in turn transformed into the decalinic structures by treatment in basic medium. The inverse strategy, Ferrier carbocyclization followed by IMDA of an enone and a diene linked via an ester bond was unsuccessful.

Key words: Intramolecular Diels–Alder reaction, enantiomerically pure decalin, Ferrier carbocyclization, carbohydrates.

Résumé : La synthèse de structures décaliniques énantiomériquement pures, intermédiaires avancés dans la synthèse de la partie hexahydronaphtalene des acides méviniques est décrite. Les étapes clés sont une cycloaddition de Diels–Alder sur une énone dérivée d'un sucre obtenu par réarrangement de Ferrier du tri-*O*-acetyl-D-glucal avec un alcool représentant la partie dièniique du système. Le cycloadduit obtenu, diastéréoisomériquement pur, est ensuite transformé en sucre 5,6 insaturé pouvant subir une carbocyclisation de Ferrier. Cette réaction donne, outre les décalones attendues, les produits d'hydratation de la double liaison, très probablement à cause de l'inclusion de l'aglycone dans un cycle. Un des produits d'hydratation a été carbocyclisé en milieu basique, sans l'aide de sels mercuriques, pour conduire aux structures décaliniques recherchées. La stratégie inverse, carbocyclisation de Ferrier suivie d'une cycloaddition intramoléculaire de l'énone résultante avec un diène lié par un pont ester s'est révèlée improductive.

Mots clés : Réaction de Diels–Alder intramoléculaire, décaline énantiomériquement pure, carbocyclisation de Ferrier, hydrates de carbone.

Introduction

Many naturally occuring compounds consist of a basic decalinic structure decorated with substituents and (or) functional groups. Among them, compounds such as mevinic acids mevinolin, pravastatin, and congeners (1) or diterpenoids like forskolin and representatives of the labdane series (2) are of interest as pharmaceuticals. Accordingly much synthetic work, devoted to the preparation of suitable functionalized decalinic structures, has been published in connection with the search for new drugs. The Diels–Alder cycloaddition played a prominent role in the synthesis of cyclohexane ring systems and the intramolecular version of this useful reaction (IMDA) (3–6) also led to major achievements in the field of mevinic acids synthesis (7). This reaction is also well precedented in carbohydrate chemistry (8).

In connection with a synthetic program originally dealing with the synthesis of the hexahydronaphthalene ring of mevinic acids using the Chiron approach (9), we have investigated the synthetic possibilities of two six-membered ring forming reactions namely IMDA and the Ferrier carbocyclization (10) This mercury-catalyzed intramolecular aldol reaction is a major breakthrough in carbohydrate chemistry which transforms a 5,6-unsaturated pyranoside into a chiral cyclohexanone. The high diastereoselection of the process led to numerous studies for the synthesis of highly functionalized cyclohexanes such as inositol (11), conduritols (12), and other natural products (13, 14). An elegant variant, using a 6-substituted 5,6-unsaturated pyranoside, allowed the synthesis of α-substituted cyclohexanone (15). In addition other conditions, which do not rely on a mercury catalysis, have led to interesting developments of this sugar to carbocycle transformation (16). However, if numerous examples of this basic transformation to form isolated cyclohexane rings are available, application of this reaction on annelated pyranose is very limited.

We have investigated such an approach with some success by combining an intramolecular Diels–Alder on a suitably

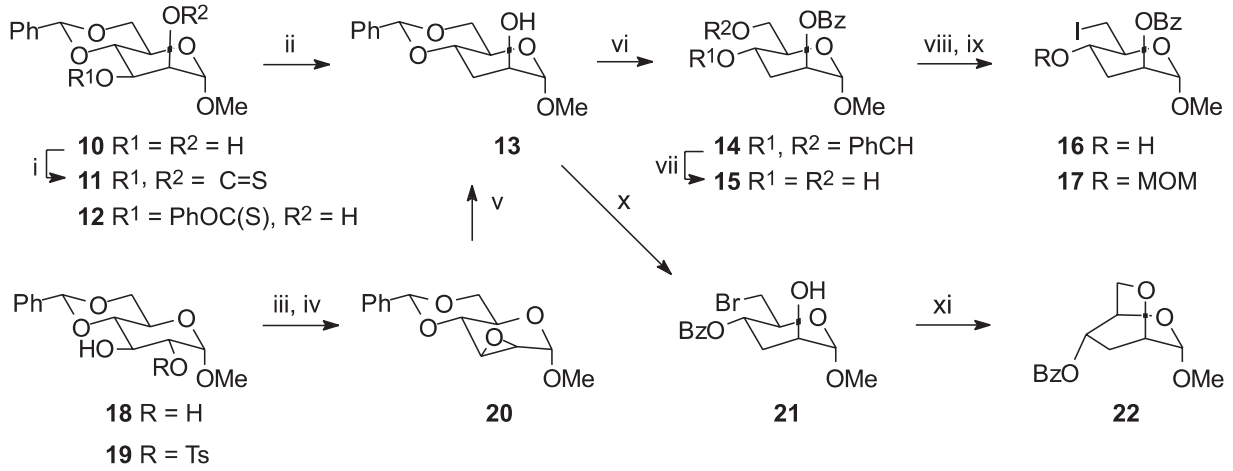
Scheme 1. Two strategies for the synthesis of *cis* decalinic structures.

functionalized sugar followed by the Ferrier carbocyclization of the resulting annulated pyranoside. We have reported our preliminary results along this line (17). This paper describes the full details of our investigations together with another approach combining the Ferrier carbocyclization followed by IMDA on the resulting cyclohexenone which proved unsuccessful.

The dihydroxylated decalinic structure **1** seemed a particularly interesting target and the two retrosynthetic strategies toward this compound are depicted in Scheme 1. In the first approach (Route (a)) the IMDA was planned at the end of the synthesis. A chiral cyclohexenone would be the dienophile and the electron-rich diene was tethered to this first cyclohexane ring by an ester linkage on an hydroxyl group of the cyclohexenone **2**. The absolute configuration of the carbon bearing the tether was chosen to secure the required absolute stereochemistry of the ring junction by forcing the diene to interact preferentially with one face of the dienophile. The synthesis of cyclohexenone **2** was based on the Ferrier carbocyclization of an appropriate deoxy sugar **4** giving the aldol product **3** (10*b*). The starting sugar **5**, a precursor of the key intermediate **4** of the Ferrier carbocyclization, should be prepared from D-mannose by deoxygenation at C-3 (carbohydrate numbering) or from D-glucose by the same procedure and further inversion of configuration at C-2.

In the second approach (Route (b)) the Ferrier carbocyclization was now planned at the end of the synthesis on the annulated pyranoside **6**. The IMDA reaction could be also performed on a suitably activated double bond, i.e., the enone function of **7**. The advantage of this strategy relies on the fact that the tether between the diene and the dienophile does not have to be a detachable link because the Ferrier carbocyclization would cleave the glycosidic link. The trienic system **8** could came from the Ferrier rearrangement of tri-*O*-acetyl-D-glucal (**9**)with the corresponding dienic alcohol (18).

Results



First approach

Two routes to the key intermediate **4** were explored, the first one involving selective protection at C-2 of the known mono-benzylidene derivative of D-mannose (**10**) (19). Assuming that subsequent deoxygenation should reasonably be carried out using a radical reaction, we attempted to introduce a phenylthionocarbonate group at C-3 by selective alkylation with phenylthionocarbonyl chloride (PTCCl) (20) using the stannylene approach as described by Nashed (21) for the synthesis of the 3-*O*-*para*-methoxybenzyl derivative of **10**. Thus treatment of **10** with dibutyltin oxide in refluxing methanol led to the intermediate stannylene which was treated with PTCCl in dimethylformamide at 100°C for 30 min. However, only the known cyclic thionocarbonate **11** was isolated (22). Gratifyingly the treatment of **10** with PTCCl, (1 molar equiv.) under standard conditions led to the expected monophenylthionocarbonate **12** in 54% yield and to the thionocarbonate **11** in 36% yield after chromatography on silica gel. Treatment of **12** with 1.3 equiv. of tris(trimethylsilyl)-silane (23, 24) and a catalytic amount of AIBN in refluxing toluene gave the deoxy-derivative **13** in 68% yield. The low overall yield of this sequence, prompted us to use a more efficient route from the known epoxide **20** (25) which was transformed into the alcohol **13** upon treatment with $LiAlH_4$.(26)

The next problem to address was the introduction of a leaving group at C-6 and to differentiate the two secondary hydroxyl groups at C-2 and C-4. We tried to take advantage of the presence of the benzylidene protecting group. Hanessian–Hullar opening of this acetal using our modified conditions (27), gave the corresponding 6-bromo derivative **21** but all attempts to eliminate hydrobromic acid using silver fluoride in hot pyridine led only to the unexpected 2,6-anhydro structure **22**. All other conditions, (AgF, pyridine, rt; DBU, rt) left the starting material unchanged.

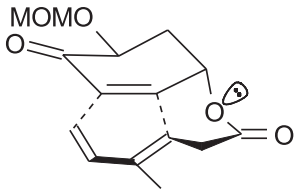
Scheme 2. Reagents: (*i*) Phenyl thionocarbonyl chloride 1.1 equiv.; CH_2Cl_2–acetone–pyr 2 h, 54%; (*ii*) tris(trimethylsilyl) silane, 1.2 equiv.; AIBN, degassed toluene reflux, 68%; (*iii*) TsCl 1.4 equiv.; NaOH 5%; Bu_4NHSO_4, CH_2Cl_2, 93%; (*iv*) MeONa, MeOH reflux, quant.; (*v*) $LiAlH_4$, THF, 50°C, 100%; (*vii*) HCl 12 N; EtOH–H_2O (10:1), reflux, 67%; (*viii*) PPh_3, imidazole, I_2, toluene, 55°C, 82%; (*ix*) NaH, MOMCl; (*x*) NBS, 1.1 equiv.; $CaCO_3$, CCl_4, reflux, 98%; (*xi*) AgF, pyridine, 80°C.

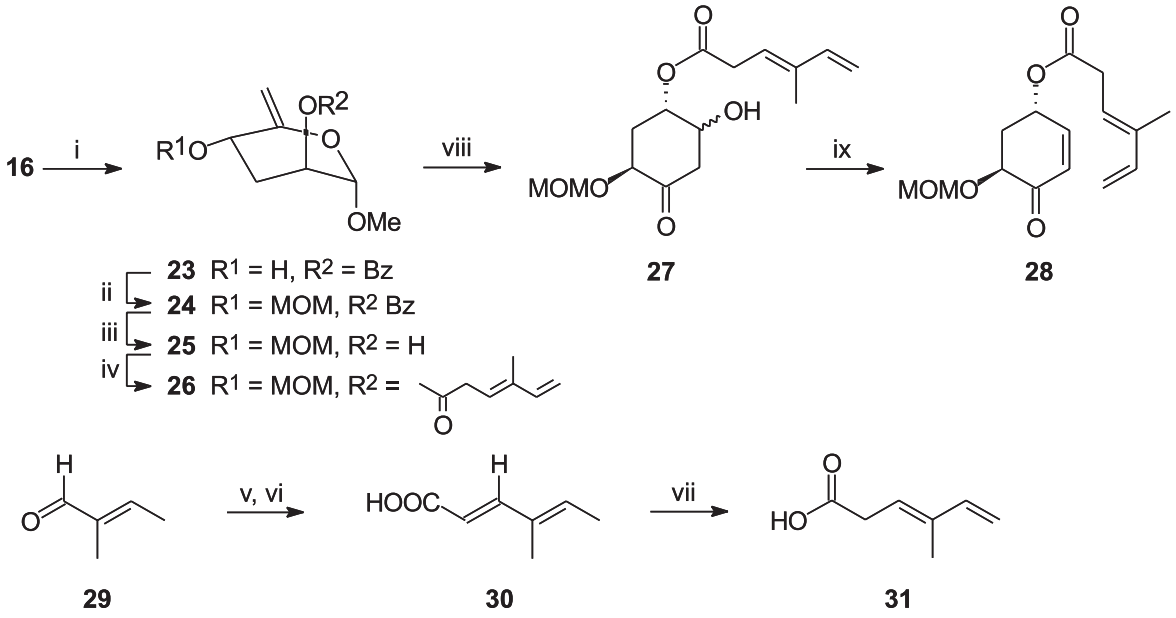


Hydrogenolysis of the benzylidene according to the Liptak procedure was also explored (28), but probably because of the absence of a chelating oxygen at C-3, a mixture of 4-*O*-benzyl and 6-*O*-benzyl derivatives in a 1:1 ratio was obtained. A multi-step sequence was then carried out which consisted first in the protection of the hydroxyl group at C-2 as a benzoate followed by acid hydrolysis of the benzylidene ring to give the diol **15** in 67% overall yield. This diol was treated with triphenylphosphine, imidazole, and I_2 to provide the iodo-derivative **16** in 82% yield. Treatment of **16** with silver fluoride in pyridine at room temperature gave the 5,6-unsaturated compound **23** (52%), which was treated with MOMCl to provide the fully protected derivative **24** in 85% yield. Alternately the alcohol **16** could be protected as the MOM ether **17** (71%) and subsequent elimination of iodohydric acid led to **24** in the same overall yield. Treatment of **24** with ammonia in methanol gave quantitatively the alcohol **25** which was esterified with the dienic acid **31**. The latter was prepared through a three-step sequence involving Wittig olefination of 2-methyl butenal (**29**) with carbethoxymethyl triphenylphosphorane followed by saponification of the resulting ester to provide **30**. Treatment with a base and trapping the kinetic enolate (29) gave the expected carboxylic acid **31**. Esterification of alcohol **25** using DCC activation gave the key intermediate **26** in 89% yield. In spite of the number of olefinic bonds and the presence of the MOM acetal, Ferrier carbocyclization catalyzed by mercuric sulfate proceeded uneventfully to give **27** and treatment of this compound with triflic anhydride at –10°C gave the expected enone **28** in modest yield.

Treatment of enone **28** in degassed toluene in the presence of hydroquinone failed to give any cyclized product. The only observable reaction was the splitting of the MOM protecting group. No reaction was observed using Lewis acid catalyst such as diethyl aluminium chloride which has been reported to have beneficial effects (30).

The presence of the ester function in the tether of the diene and the dienophile was likely responsible for the failure of this IMDA cyclization. One explanation should be that the preferred *transoid* form of the ester impedes the correct geometrical arrangement in the transition state. Another more likely reason is that the lone pair of the ester oxygen is almost perpendicular to the π orbital of the carbonyl in the transition state as shown on the approximate geometry of the transition state depicted on Fig. 1. Thus the absence of orbital overlap should destabilize the transition state of the cyclization. Such an explanation has already been invoked to explain the more drastic conditions needed to achieve intramolecular Diels–Alder reaction involving an ester junction (31).

Fig. 1. Approximate geometry of an *exo* transition state for the IMDA of **28**.



Second approach

The first crucial step of this second approach was the glycoside formation using Ferrier rearrangement of tri-*O*-acetyl-D-glucal with the dienic alcohol **33**. This homoallylic alcohol **33** was prepared in two steps from commercially available ocimen (**32**) by ozonolysis – sodium borohydride reduction according to patent literature (32). This alcohol was reacted with tri-*O*-acetyl-D-glucal (**9**) in the presence of boron trifluoride–etherate as the catalyst under carefully controlled conditions because compound **33** was prone to degradation in the presence of this catalyst. The unsaturated glycoside **34** was prepared in 84% as a α and β (80:20) mixture.

Saponification of the acetates under standard conditions led to the corresponding diols from which compound **35** was obtained as a pure product by column chromatography. Selective protection by selective pivaloylation was troublesome due to the high reactivity of the secondary allylic alcohol and gave **36** and the diester **37** as a 7:3 mixture. However the diester **37** could be recycled to the diol **35** by $LiAlH_4$ re-

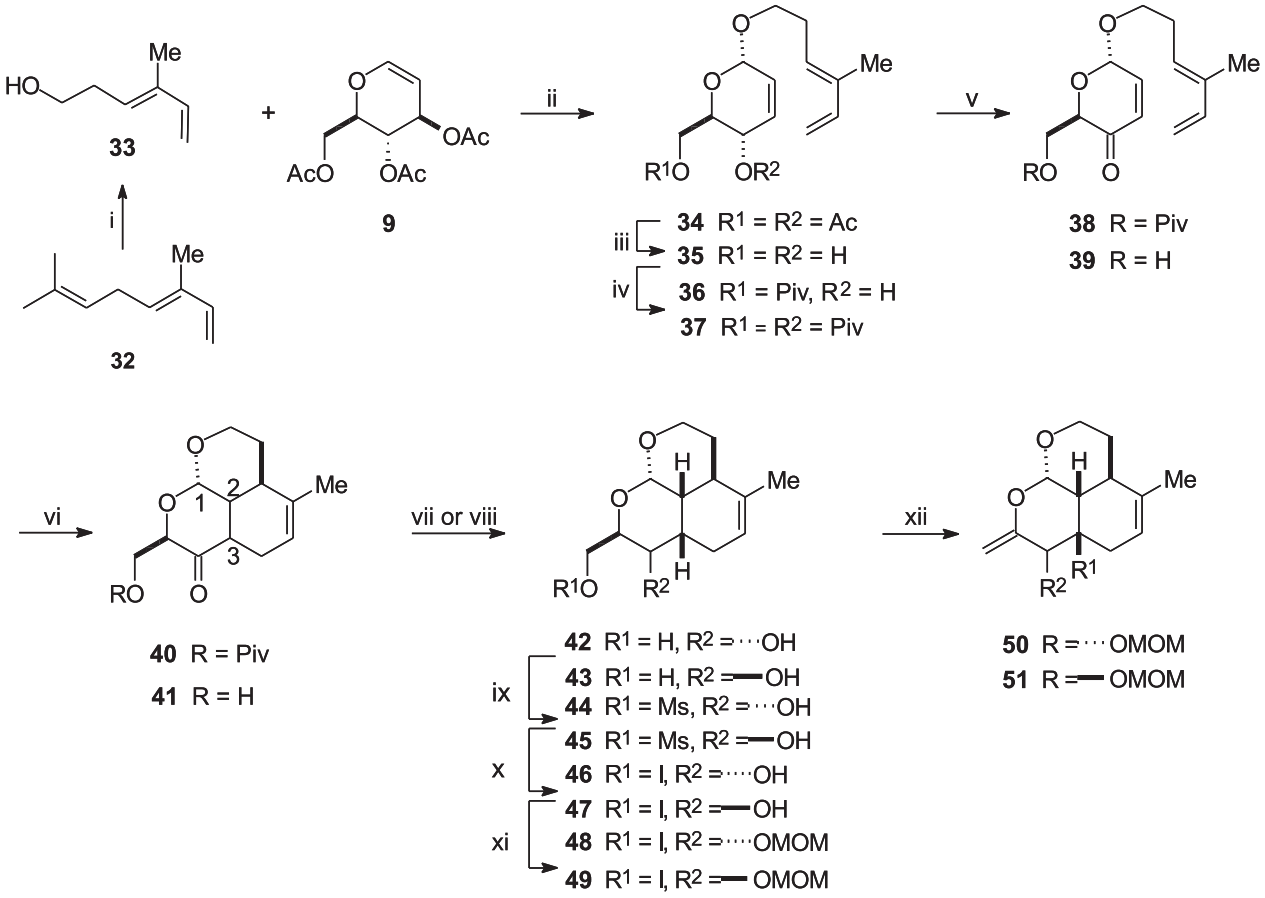
duction. Oxidation of the alcohol **36** with pyridinium dichromate yielded the ketone **38** in 50–55% yield, and freshly prepared manganese dioxide cleanly oxidized the allylic alcohol in up to 90% yield. Ketone **38** proved very unstable and underwent decomposition, maybe by β-elimination of the ester group upon concentration, and was kept in solution.

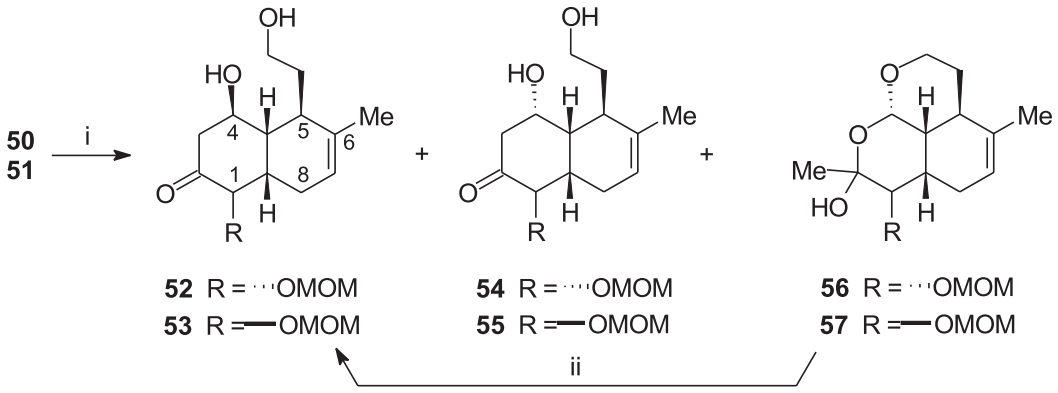
The intramolecular Diels–Alder reaction proceeded uneventfully by simple treatment of **38** in degassed toluene at 155°C in a sealed tube in the presence of hydroquinone. The cycloadduct **40** was obtained in 75% overall yield. As seen from careful examination of the NMR spectrum, a single isomer was formed and the observed coupling constants $J_{1,2}$ 2.0 Hz and $J_{2,3}$ 3.5 Hz were in favour of an all *cis* arrangement of these three protons. This was in agreement with an attack of the enone double bond from the α face as expected. Determination of the configuration at C-3 (see Scheme 4), which reflects the attack from one face of the diene (i.e., *endo–exo* transition state) could not be determined on the basis of coupling constants due to signal overlaps. It was anticipated that an *exo* transition state would be favoured over the *endo* one to minimize steric interactions between the diene and the sugar ring.

Reduction of the keto group of **40** was achieved by lithium aluminium hydride, conditions which also removed the pivaloyl group. Low diastereoselection was observed for the ketone reduction and a 1.7:1 mixture of diols **42** and **43** was obtained.



In the meantime, a shorter route to these compounds was sought which would avoid the formation of the bis-protected derivative **37**. Thus, selective oxidation of the allylic alcohol of the diol **35** by manganese dioxide was carried out to afford the ketone **39** in 83% yield. This unstable ketone was immediately engaged in the IMDA under our standard conditions to provide the adduct **41** in 66% yield as a single isomer. Formation of the diols **42** and **43** in almost equal amounts was achieved by sodium borohydride reduction of **41** in 88% yield.

The next problem to address was the chemical manipulation of the annulated pyranoside **40** to secure the formation of the 5,6-unsaturation required for the Ferrier carbocyclization. Selective mesylation of the primary alcohol of the **42** and **43** mixture gave the mesylates **44** and **45** respectively, easily separated by column chromatography. Substitution of the mesylate group by iodide was carried out separately on each compound giving **46** and **47** in 60 and 82% yield, respectively. If elimination of iodohydric acid can be performed cleanly on alcohol **46**, the same sequence cannot be applied to **47** without formation of an oxetane by intramolecular substitution of iodine by the hydroxyl group at C-4. Protection of the hydroxyl group of **46** and **47** was achieved and formation of the methoxy methyl ether proceeded in 60% yield to provide **48** and **49** respectively. Once again, treatment of each iodo-derivative with silver fluoride in pyridine cleanly gave **50** and **51** in 72% and 87% yield, respectively.



Only a few examples of the Ferrier carbocyclization on annulated pyranose have been reported in the literature (33). In addition, our substrates **50** and **51** bear two electron-rich double bonds which are susceptible to reaction with the mercury catalyst. Ferrier carbocyclization was investigated on these two key intermediates. A large panel of different catalysts and reaction conditions have been proposed in the literature for this reaction (10*b*). Mercuric trifluoroacetate, a catalyst we have introduced in 1984 for the carbocyclization of amino sugars (34), and which is efficient in a number of cases (35, 13), proved disappointing in our reaction. The catalytic method based on the use of mercury sulfate, introduced by Machado et al. (36), was more efficient. Thus, treatment of the unsaturated pyranoside **50** gave a mixture of three compounds **52**, **54,** and **56** in a 1:1:6 ratio in 95% overall yield. If compounds **52** and **54** where the expected

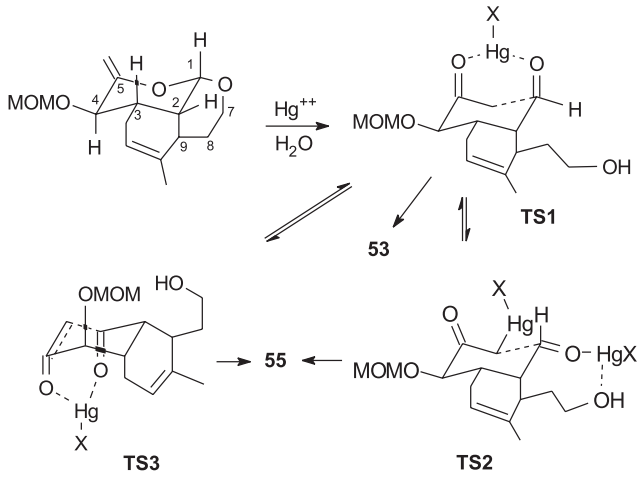
cyclohexanones, compound **56** was clearly the result of the hydroxy-mercuration of the 5,6-double bond. Suspecting an interruption of the catalytic cycle of mercury, we used a stoichiometric amount of mercury sulfate but **56** was still the major product of this reaction. The same results were obtained from olefin **51**. Three compounds **53**, **55**, and **57** were formed in a 1:1:2 ratio in 84% yield. The hydration product **57** again predominated. It should be emphasized that carbocyclization occurred without notable diastereoselection in contrast with other reported cases where one isomer is formed preferentially and even exclusively.

The formation of hydration products **56** and **57**, which are rarely observed in the Ferrier carbocyclization, may be due to the involvement of the aglycon into a tricyclic ring system. This arrangement should preclude the formation of the free aldehyde group needed for carbocyclization. The reaction is then considerably slowed down so that the intermediate mercury species did cyclize but was hydrolysed to the

© 2000 NRC Canada

Fig. 2. Transition states of the IMDA cyclization of **38** and **39**.



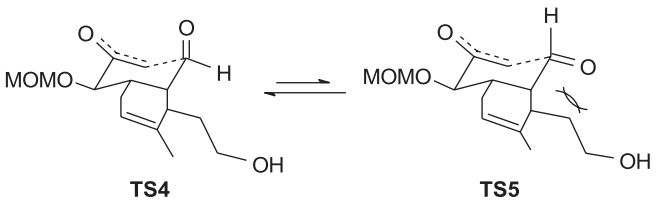
hydration products. Such hydration products have been observed by Blattner et al. (37) in the carbocyclization of 5,6-unsaturated pyranose having a benzoate group at the anomeric position. Hydration was believed to proceed by hydrolysis of the postulated intermediate 6-mercuriated species. This difficulty was overcome by using a stoichiometric amount of mercuric acetate to catalyse the carbocyclization. These conditions were tested on compounds **51** and a mixture of **53**, **55**, and **57** in a 2.5:1:1.7 ratio was obtained. It is worthy of note that the main product **53** has a "3,5-*trans*" (cyclohexanone numbering) relative stereochemistry which prevails in most of the reported Ferrier carbocyclizations (38).

Examination of the structure of compounds **56** and **57** shows that all requirements needed to perform an intramolecular aldol reaction, i.e., the keto group at C-5 and aldehyde at C-1, were present. We thus examined the possibility of going from compound **57** to carbocycles **53** or **55** without the use of mercury catalysis. After some experiments, we found that basic conditions in a protic medium, Na_2CO_3, DBU in THF/MeOH were well suited to transform compound **57** into aldol **53** *as a single isomer* in 50% yield and 50% recovered starting material. No attempt was made at this time for the cyclization of **56**. The structure of compound **53** was firmly established by single crystal X-ray diffraction (17). The absolute configurations at C-1, C-4, C-5, C-5a, and C-8a (See Scheme 5) which were tentatively assigned by NMR were thus confirmed. The complete stereocontrol of the IMDA reaction which occurred in the *exo* mode with attack of the diene from the bottom face of the dienophile was confirmed by the configuration of C-5. Moreover, this configuration was that of the mevinic acids (see Fig. 2).

It is worthy of note that the conformation of the decalone ring of **53** in the solid state as shown by X-ray crystal structure (17) is opposite to that determined on the basis of the ^{1}H NMR spectrum. The OH group was found to be in an equatorial orientation in solution as shown by the large $J_{2,3}$ = 10.3 Hz and $J_{3,4}$ = 9.5 Hz in benzene solution, which are typical of *trans* diaxial arrangement of these protons. The smaller values of these coupling constants in DMSO suggested that, in this solvent, a conformational equilibrium should take place. Molecular mechanics calculations performed on the two conformers have shown that the energy difference between these two conformers was less than 1.5 kcal/mol.

Formation of a single isomer in the carbocyclization of **57** to **53** deserves comments. Usually Ferrier carbocyclization gives high diastereoselection, the product having a 3,5 *trans* arrangement (cyclohexanone numbering) being formed preferentially (38). On the other hand, it has been shown that the stereochemistry at C-5 of the formed cyclohexanone can be correlated with the conformation of the starting sugar (36). Several mechanistic explanations for this phenomenon have been proposed. One explanation is based on a chelation by a mercury atom of the oxygen atoms of both the aldehyde and the ketone groups involved in this aldol-type reaction (39, 40). A chair transition state in which these carbonyl groups occupy two axial positions (see **TS1**, Fig. 3) should be favoured over a twisted transition state in which the two carbonyl groups are pseudo-equatorial. Another explanation involves a chelation between the mercury atom linked to C-6 and the substituent at C-3 (carbohydrate numbering) leading to a boat transition state in which the two carbonyl groups are located on the opposite side of the C-3 substituent. This explanation is supported by the absence of stereoselectivity in the Ferrier carbocyclization of 3-deoxy sugars (38).

Fig. 3. Possible transition states for the Ferrier carbocyclization of **51**.



The C-2—C-3 and C-8—C-9 bonds in compounds **51** or **50** are in a *trans* relationship which forces these groups to be only in equatorial orientations. Thus, the conformation of the unsaturated pyranose ring is more or less fixed and should adopt only the $^1C_4$ conformation or the $^{2,5}B$ conformation. In compound **51**, the chair conformation places the C-4 OMOM substituent in an equatorial orientation and should be favoured over the boat conformation. This is confirmed by the coupling constant value in the ^{1}H NMR spectrum of **51** ($J_{3,4}$ = 10.5 Hz). On this basis, according to Machado et al. (36), it could be predicted that the major isomer would be compound **53**. The boat transition state involving chelation of the substituent at C-3 cannot be invoked in our case because of the absence of such a chelating group and because of the conformational bias. The transition state **TS1** leading to **53** should be a chair having the two oxygen chelated by mercury in an axial orientation.

To explain the substantial amount of the other isomer **55**, two possibilities can be envisioned. In the first one, the conformation of the intermediate resulting from the opening of the acetal function changes so that the orientation of the carbonyl groups are reversed and thus the aldehyde is then attacked from the other face via transition state **TS3** (Fig. 3). Another, maybe better, explanation takes into account the

© 2000 NRC Canada

Fig. 4. Possible transitions states for the ring closure of **57**.

presence of the hydroxyl group at C-7 which can be involved in a chelation with the aldehyde group and mercury so that again the *Si* face of the aldehyde is presented to the attacking carbon atom in **TS2** leading to **55**. In both hypotheses the presence of the bicyclic system or the hydroxyl group are responsible for the absence of selectivity. Support of this assumption is given by the fact that the aldol reaction conducted in basic medium in the absence of mercury is highly selective and probably involves a transition state in which the steric interactions rather than chelation govern the stereochemical course. As shown on Fig. 4, two transition states should be devised leading to both isomers but **TS4**, in which the carbonyl group points upwards is likely favoured over **TS5** in which strong 1,3-diaxial interactions between the carbonyl and the methylene groups may exist.

Experimental

All reactions were performed under nitrogen atmosphere. Melting points are uncorrected and recorded with a Büchi capillary tube melting-point apparatus. Optical rotations were measured on a Perkin Elmer 141 polarimeter in a 1 dm cell at 20°C. FTIR spectra were recorded on a Perkin–Elmer Spectrum 1000 on NaCl windows or KBr pellets. Unless otherwise stated ^{1}H NMR and ^{13}C spectra were recorded on a Bruker AC 250 spectrometer at 250 MHz and 62.5 MHz respectively. 400 MHz ^{1}H NMR were recorded on a Bruker AC 400 spectrometer. Chemical shifts are reported in ppm using the residual of chloroform as internal standard (7.27 ppm and 77.0 ppm respectively). Attribution of ^{13}C signals are based on the *J*-modulated spin-echo sequence. Analytical thin-layer chromatography were performed on Merck $60F_{254}$ precoated silica gel glass plates. Compounds were visualized on developed plates by UV light followed by charring with 10% H_2SO_4 in methanol. Preparative chromatography was performed on silica gel 60 (230–40 mesh ASTM) using ethyl acetate and hexane mixtures or by high pressure liquid chromatography using Merck silica gel 60H (45μM).

Methyl-4,6-*O*-phenylmethylene-2,3-thionocarbonyl-α-D-mannopyranoside (11)

To a solution of methyl-4,6-*O*-phenylmethylene-α-D-mannopyranoside (1,69 g, 6 mmol) in anhydrous methanol (200 mL) was added dibutyltin oxide (4.2 g, 16.8 mmol, 2.8 equiv.). The solution was heated at reflux for 4 h. Methanol was removed under vacuum, the residue was diluted with DMF (40 mL) and PTCCl (2.5 mL, 18 mmol, 3 equiv.) was added. The mixture was stirred at 100°C for 0.5 h then quenched with methanol and concentrated in vacuo. The residue was diluted with CH_2Cl_2, washed successively with 3 N aqueous NaOH, brine, dried over Na_2SO_4 and concentrated in vacuo. Chromatography on silica gel with *n*-hexane–EtOAc (9:1) yielded compound **11** (1,59 g, 0.51 mmol, 85%) as a white solid; mp 140–142°C (lit. (22) = 144–145°C). R_f 0.50 (hexane/EtOAc, 7:3). $[\alpha]_D^{22}$ –89.7° (c 1.0, $CHCl_3$) (lit. (22) = value $[\alpha]_D^{22}$ –85.7° (c 0.6, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 3.43 (s, 3 H, OCH_3), 3.72–3.90 (m, 3 H, H-4, H-6 and H-6′), 4.36 (m, 1 H, H-5), 4.78 (d, 1 H, $J_{2,3}$ 7.0 Hz, H-2), 5.07 (m, 1H, H-3), 5.10 (s, 1 H, H-1), 5.60 (s, 1 H, PhC*H*), 7.33–7.53 (m, 5 H, Ph). ^{13}C NMR ($CDCl_3$) δ: 55.75 (OCH_3), 59.52, 69.04, 77.97, 79.54, and 80.42 (C-2, C-3, C-4, C-5, and C-6), 96.62 (C-1), 102.11 (O*C*HPhO), 126.39 (Ph), 128.62 (Ph), 129.66 (Ph), 136.67 (Ph), 189.69 (C=S). Anal. calcd. for $C_{15}H_{16}O_6S$: C 55.54, H 4.97, S 9.88; found: C 55.71, H 5.05, S 9.77.

Methyl-4,6-*O*-phenylmethylene-3-*O*-phenylthionocarbonyl-α-D-mannopyranoside (12)

Methyl-4,6-*O*-phenylmethylene-α-D-mannopyranoside (980 g, 3.5 mmol) was dissolved in an anhydrous CH_2Cl_2–acetone–pyridine (4:2:1) mixture (35 mL) under nitrogen. To this solution cooled to 0°C was added dropwise phenyl chlorothionoformate (0.50 mL, 3.85 mmol, 1.1 equiv.). After being stirred for 2 h the reaction mixture was quenched with ethanol and solvents were evaporated under reduced pressure. The residue was diluted with CH_2Cl_2, washed with water until neutral, dried over Na_2SO_4, and concentrated in vacuo. At this stage, TLC revealed the presence of a single product (*Rf* 0.22 (hexane–EtOAc, 7:3)). The crude product was chromatographed on silica gel to afford the expected compound **12** (800 mg, 1.91 mmol, 54%) accompanied with the cyclic thionocarbonate **11** (400 mg, 1.28 mmol, 36%), the latter being formed during purification. R_f 0.22 (hexane–EtOAc, 7:3). ^{1}H NMR ($CDCl_3$) δ: 2.60 (br s, 1 H, OH), 3.43 (s, 3 H, OCH_3), 3.41–3.80 (m, 2 H, H-5 and H-6), 4.27–4.39 (m, 2 H, $J_{4,5}$ 9.5 Hz, H-4 and H-6′), 4.47 (br s, 1 H, H-2), 4.81 (d, 1 H, $J_{1,2}$ 1.5 Hz, H-1), 5.61 (s, 1 H, PhC*H*), 5.79 (dd, 1 H, $J_{2e,3a}$ 3.0; $J_{3a,4a}$ 10.0 Hz, H-3), 7.05–7.54 (m, 10 H, Ph).

Methyl 3-deoxy-4,6-*O*-phenylmethylene-α-D-arabino-hexopyranoside (13)

(*i*) By radical deoxygenation of **12**: To a solution of phenylthionocarbonate (**12**) (400 mg, 0.95 mmol) in degassed toluene (20 mL) under nitrogen was added in one portion AIBN (200 mg, 1.21 mmol, 1.2 equiv.). To the resulting mixture was added dropwise tris(trimethylsilyl)silane (0.38 mL, 1.23 mmol, 1.26 equiv.). The solution was then heated to reflux and after 40 min, TLC (hexane–EtOAc, 7:3) indicated complete reduction of the starting material. The solution was cooled and concentrated under reduced pressure. The residue was chromatographed on silica gel to give pure deoxy-compound **13** (170 mg, 0.64 mmol, 68%) as a white solid.

(*ii*) By epoxide opening: To 180 mg (4.7 mmol, 3.5 equiv.) of $LiAlH_4$ suspended in dry THF (20 mL) was added dropwise a solution of epoxide **20** (350 mg, 1.32 mmol) in dry THF. The resulting mixture was stirred for 18 h at 50°C and then treated successively with water (0.18 mL), aqueous 30% NaOH (0.54 mL), and water (0.54 mL). The salts were filtered off through a pad of Celite, washed with hot THF. The solvent was removed and the residue was chromatographed on silica gel with hexane/EtOAc (1:1) as eluent to give **13** in

nearly quantitative yield, mp 109°C (lit. (26) mp 111–112°C. R_f 0.31 (hexane–EtOAc, 3:2). $[\alpha]_D^{22}$ +95.5 (c 0.81, $CHCl_3$) (lit. (26) $[\alpha]_D^{22}$ +107.3° (c 0.94, $CHCl_3$)). IR (cm^{-1}): 3452 (OH). ^1H NMR ($CDCl_3$) δ: 1.99–2.18 (m, 2 H, 2 × H-3), 3.41 (s, 3 H, OCH_3), 3.73–4.04 (m, 4 H, H-2, H-5, and 2 × H-6), 4.25 (m, 1 H, H-4), 4.55 (s, 1 H, H-1), 5.58 (s, 1 H, PhC*H*), 7.31–7.52 (m, 5 H, Ph).

Methyl 2-*O*-benzoyl-3-deoxy-α-D-arabino-hexopyranoside (15)

To a solution of alcohol **13** (413 mg,1.55 mmol) in dry pyridine (15 mL) under argon was added dropwise benzoyl chloride (1.86 mmol, 1.2 equiv.). After being stirred overnight, pyridine was evaporated and the residue was codistillated three times with toluene to provide the expected crude benzoate as a crystalline solid. It was dissolved in a mixture of ethanol–water (10:1, 55 mL) and three drops of 12 N HCl were added. After 3 h at reflux the reaction was over. The pH was adjusted to 7 with aqueous 3 N NaOH, the solvent was evaporated under reduced pressure and the residue was taken up in CH_2Cl_2. The organic layer was washed with saturated aqueous $NaHCO_3$ and water, dried over Na_2SO_4, and concentrated in vacuo. Chromatography on silica gel with hexane–EtOAc as eluent yielded diol **15** (294 mg, 1.04 mmol 67%)as a white solid, mp 105°C (lit. (41) mp 109°C). R_f 0.39 (hexane–EtOAc, 1:4). $[\alpha]_D^{22}$ +49.4 (c 0.37, $CHCl_3$) (lit. (41)value $[\alpha]_D^{22}$ +52.2° (c 1.1, $CHCl_3$)). ^1H NMR ($CDCl_3$) δ: 2.05 (ddd, 1 H, J_{gem} 14.0, $J_{2,3a}$ 3.0, $J_{3a,4}$ 11.5 Hz, H-3a), 2.26 (ddd, 1 H, $J_{2,3e}$ 3.5, $J_{3e,4}$ 5.0 Hz, H-3e), 2.40–2.90 (m, 2 H, 2 × OH), 3.43 (s, 3 H, OCH3), 3.67 (ddd, 1 H, $J_{4,5}$ 10.0, $J_{5,6}$ 4.5, $J_{5,6'}$5.0 Hz, H-5), 3.83–3.97 (m, 2 H, H-6 and H-6′), 4.10 (ddd, 1 H, H-4), 4.71 (br s, 1 H, H-1), 5.16 (m, 1 H, $J_{1,2}$ 1.5 Hz, H-2), 7.40–8.12 (m, 5 H, Ph).

Methyl 2-*O*-benzoyl-3,6-dideoxy-6-iodo-α-D-arabino-hexopyranoside (16)

A mixture of diol **15** (483 mg, 1.71 mmol), triphenylphosphine (0.61 g, 2.32 mmol, 1.5 equiv.), imidazole (0.31 g, 4.65 mmol, 3 equiv.), and iodine (0.47 g, 1.86 mmol, 12 equiv.) in dry toluene (30 mL) was vigorously stirred at 55°C for 4 h. Toluene was evaporated and the residue was taken up in CH_2Cl_2, washed successively with aqueous 0.5 N HCl, aqueous 1 N $NaHCO_3$, and water. The organic layer was dried over $MgSO_4$ and concentrated in vacuo. Chromatography on silica gel eluting with hexane–EtOAc (4:1) gave the iodo-derivative **16** (503 mg, 1.28 mmol, 82%). R_f 0.27 (hexane–EtOAc, 4:1). $[\alpha]_D^{22}$ +77.5 (c 0.85, $CHCl_3$). IR (cm^{-1}): 3466, 1720. ^1H NMR ($CDCl_3$) δ: 2.06 (ddd, 1 H, J_{gem} 13.5, $J_{2,3a}$ 3.0, $J_{3a,4}$ 11.5 Hz H-3a), 2.25 (ddd, 1 H, $J_{2,3e}$ 4.0, $J_{3e,4}$ 5.0 Hz, H-3e), 3.37–3.55 (m, 5 H, OCH_3, H-5, H-6 and H-6′), 3.88 (m, 1 H, H-4), 4.73 (br s, 1 H, H-1), 5.15 (m, 1 H, H-2), 7.22–7.65 and 8.01–8.12 (m, 5 H, Ph). ^{13}C NMR ($CDCl_3$) δ: 8.06 (C-6), 32.51 (C-3), 55.30 (OCH_3), 66.75, 70.75, 72.36 (C-2, C-4 and C-5), 97.65 (C-1), 128.54 (Ph), 129.84 (Ph), 133.47 (Ph), 165.79 (C=O). Anal. calcd. for $C_{14}H_{17}O_5I$: C 42.87, H 4.36, I 32.35; found: C 42.36, H 4.43, I 32.52.

Methyl 2-*O*-benzoyl-3,6-dideoxy-6-iodo-4-*O*-methoxymethyl-α-D-arabino-hexopyranoside (17)

The alcohol **16** (4.0 g, 10.20 mmol) was protected as the methoxymethylether according to the procedure described for the preparation of **24** (3.16 g, 7.25 mmol, 71%). R_f 0.59 (hexane–EtOAc, 4:1). $[\alpha]_D^{22}$ +70.8 (c 0.70, $CHCl_3$). IR (cm^{-1}): 1722. ^1H NMR (250 MHz, $CDCl_3$) δ: 2.07 (ddd, 1 H, J_{gem} 13.5, $J_{2,3a}$ 3.0, $J_{3a,4}$ 11.0 Hz; H-3a), 2.35 (ddd, 1 H, $J_{2,3e}$ 3.5, $J_{3e,4}$ 4.5 Hz, H-3e), 3.28 (s, 3 H, CH_2OCH_3), 3.41 (dd, 1 H, J_{gem} 10.0, $J_{5,6}$ 6.5 Hz, H-6), 3.48 (s, 3 H, OCH_3), 3.52 (m, 1 H, H-5), 3.61 (dd, 1 H, $J_{5,6'}$ 2.5 Hz, H-6′), 3.80 (ddd, 1 H, $J_{4,5}$ 9.5 Hz, H-4), 4.69 (m, 2 H, J_{gem} 7.0 Hz, CH_2OCH_3), 4.72 (br s, 1 H, H-1), 5.15 (ddd, 1 H, $J_{1,2}$ 2.0 Hz, H-2), 7.40–8.12 (m, 5 H, Ph). ^{13}C NMR ($CDCl_3$) δ: 7.88 (C-6), 30.05 (C-3), 55.18, and 55.76 (2 × OCH_3) 70.05, 70.45, 72.43 (C-2, C-4, and C-5), 95.65, 97.59 (C-1 and OCH_2OCH_3), 128.37 (Ph), 129.79 (Ph), 133.20 (Ph), 165.46 (C=O). EIMS: 405 (M-OCH_3), 309 (M-I) 233 (100%), 221. Anal. calcd. for $C_{16}H_{21}IO_6$: C 44.05, H 4.85, I 29.06; found: C 44.36, H 4.95, I 28.54.

Methyl 4-*O*-benzoyl-6-bromo-3,6-dideoxy-α-D-arabino-hexopyranoside (21)

Compound **13** (350 mg, 1.31 mmol) was dissolved in dry CCl_4 (20 mL) under argon and N-bromosuccinimide (250 mg, 1.44 mmol, 1.1 equiv.) and calcium carbonate (140 mg, 1.44 mmol, 1.1 equiv.) were added successively. The mixture was refluxed for a few minutes. The resulting orange mixture was diluted with CH_2Cl_2, washed successively with aqueous 10% $NaHSO_3$ and water, dried over $MgSO_4$, and concentrated in vacuo. Chromatography on silica gel eluting with hexane–EtOAc (7:3) gave compound **21** (447 mg, 1.29 mmol, 98%) as a gum. R_f 0.47 (hexane–EtOAc, 3:2). $[\alpha]_D^{22}$ +87.6 (c 0.59, $CHCl_3$). IR (cm^{-1}): 3462 (OH), 1720 (C=O), 1601. ^1H NMR ($CDCl_3$) δ: 2.04 (ddd, 1 H, J_{gem} 13.0, $J_{2,3a}$ 3.0, $J_{3a,4}$ 12.0 Hz, H-3a), 2.33 (ddd, 1 H, $J_{2,3e}$ 4.0, $J_{3e,4}$ 4.5 Hz, H-3e), 3.40–3.54 (m, 4 H, $J_{5,6}$ 7.5 Hz, H-6 and OCH_3), 3.58 (dd, 1 H, J_{gem} 11.0, $J_{5,6'}$ 2.5 Hz, H-6′), 3.94 (m, 1 H, $J_{1,2}$ 2.0 Hz, H-2), 4.10 (m, 1 H, H-5), 4.67 (br s, 1 H, H-1), 5.26 (ddd, 1 H, $J_{4,5}$ 10.5 Hz, H-4), 7.40–8.10 (m, 5 H, Ph). Anal. calcd. for $C_{14}H_{17}BrO_5$: C 48.71, H 4.96, Br 23.14; found: C 48.92, H 5.03, Br 22.84.

Methyl 2,6-anhydro-4-*O*-benzoyl-3-deoxy-α-D-arabino-hexopyranoside (22)

Compound **21** (370 mg, 1.07 mmol) was suspended in dry pyridine (20 mL) with AgF (227 mg, 1.78 mmol, 1.7 equiv.) and the mixture was stirred overnight in the dark without any evolution. An additional amount of AgF (200 mg, 1.57 mmol) was added and the suspension was stirred at 80°C for 4 h. The mixture was then diluted with EtOAc, filtered off through Celite, and the solvent was evaporated. Chromatography of the brown residue with hexane–EtOAc (4:1) as eluent yielded **22** (80 mg, 0.30 mmol, 28%), mp 57–58°C, and starting material (129 mg, 0.37 mmol, 36%). R_f 0.54 (hexane–EtOAc, 3:2). $[\alpha]_D^{22}$ +20.0° (c 0.24, $CHCl_3$). IR (cm^{-1}): 1715 (C=O), 1602. ^1H NMR ($CDCl_3$) δ: 2.26 (m, 1 H, H-3e), 2.45 (ddd, 1 H, J_{gem} 14.5, $J_{2,3a}$ 3.5, $J_{3a,4}$ 10.0 Hz, H-3a), 3.51 (s, 3 H, OCH_3), 3.79–3.89 (m, 2 H, 2 × H-6), 4.07 (m, 1 H, $J_{5,6}$ 10.0, $J_{4,5}$ 3.0 Hz, H-5), 4.20 (m, 1 H, H-2), 5.06 (br d, 1 H, $J_{1,2}$ 3.0 Hz, H-1), 5.10 (ddd, 1 H, $J_{3e,4}$ 2.5 Hz, H-4), 7.40–7.43 and 8.06–8.15 (m, 5H, Ph). ^{13}C NMR ($CDCl_3$) δ: 28.57 (C-3), 54.93 (OCH_3), 65.33, 65.99, 67.31, 69.00 (C-2, C-4, C-5, and C-6), 99.76 (C-1), 128.41 (Ph), 129.79 (Ph), 130.25 (Ph), 133.12 (Ph), 166.27 (C=O). Methyl 2-*O*-benzoyl-3,6-dideoxy-α-D-*threo*-hex-5-enopyranoside (23)

Silver fluoride (0.45 g, 3.59 mmol, 1.5 equiv.) was suspended in dry pyridine (25 mL) containing the iodo-derivative **16** (940 mg, 2.39 mmol). Stirring was maintained overnight, in the dark and the mixture was poured in EtOAc (200 mL). After filtration of the salts, the solvent was evaporated and the brown residue was chromatographed with hexane–EtOAc (7:3) to yield derivative **23** (332 mg, 1.25 mmol, 52%). R_f 0.27 (hexane–EtOAc, 7:3). ^{1}H NMR ($CDCl_3$) δ: 2.13 (ddd, 1 H, J_{gem} 13.5, $J_{2,3a}$ 3.0, $J_{3a,4}$ 11.0 Hz, H-3a), 2.30 (ddd, 1 H, $J_{2,3e}$ 3.5, $J_{3e,4}$ 6.0 Hz, H-3e), 3.50 (s, 3 H, OCH_3), 4.55 (m, 1 H, H-4), 4.72 (br s, 1 H, H-1), 4.80 (br s, 1 H, H-6), 4.82 (br s, 1 H, H-6′), 5.24 (m, 1 H, $J_{1,2}$ 2.5 Hz, H-2), 7.40–8.12 (m, 5 H, Ph).

Methyl 2-*O*-benzoyl-3,6-dideoxy-4-*O*-methoxymethyl-α-D-*threo*-hex-5-enopyranoside (24)

To a solution of **23** (330 mg, 1.25 mmol) in anhydrous CH_2Cl_2 (15 mL) was added successively diisopropylethylamine (0.87 mL, 5 mmol, 4 equiv.) and MOMCl (0.19 mL, 2.5 mmol, 2 equiv.). The stirring was maintained for 12 h under argon and the mixture was diluted with CH_2Cl_2. The organic layer was washed with aqueous 3 N HCl, dried over $MgSO_4$, and concentrated in vacuo. Chromatography on silica gel gave **24** (328 mg, 1.06 mmol, 85%) as a gum. R_f 0.66 (hexane–EtOAc, 7:3). $[\alpha]_D^{22}$ –24.5 (c 0.36, $CHCl_3$). IR (cm^{-1}): 1722, 1662. ^{1}H NMR ($CDCl_3$) δ: 2.20–2.29 (m, 2 H, 2 × H-3), 3.40 (s, 3 H, CH_2OCH_3), 3.50 (s, 3 H, OCH_3), 4.45 (br dd, 1 H, H-4), 4.68–4.82 (m, 5 H, H-1, 2 × H-6 and CH_2OCH_3), 5.26 (br dd, 1 H, H-2), 7.40–8.12 (m, 5 H, Ph). ^{13}C NMR ($CDCl_3$) δ: 31.59 (C-3), 55.27, and 55.60 (2 × OCH_3), 68.44, 69.99 (C-2 and C-4), 95.40, 95.45, 99.67 (C-1, OCH_2O, and C-6), 128.39 (Ph), 129.75 (Ph), 133.27 (Ph), 155.63 (C-5), 165.47 (C=O). Methyl-3,6-dideoxy-4-*O*-methoxymethyl-α-D-*threo*-hex-5-enopyranoside (25)

Ammonia was bubbled through a solution of **24** (328 mg, 1.06 mmol) in MeOH (20 mL) for 5 h. The solvent was evaporated and the residue was chromatographed on silica gel with hexane–EtOAc (7:3) to give the alcohol **25** in quantitative yield. R_f 0.18 (hexane–EtOAc, 7:3). $[\alpha]_D^{22}$ +44.6 (c 1.82, $CHCl_3$). IR (cm^{-1}): 3436, 1660. ^{1}H NMR ($CDCl_3$) δ: 1.90 (ddd, 1 H, J_{gem} 13.5, $J_{2,3}$ 8.0, $J_{3,4}$ 4.5 Hz, H-3), 2.16 (ddd, 1 H, $J_{2,3'}$ 4.0, $J_{3',4}$ 6.5 Hz, H-3′), 2.35 (br d, 1 H, OH), 3.37 (s, 3 H, CH_2OCH_3), 3.53 (s, 3 H, OCH_3), 3.94 (ddd, 1 H, H-2), 4.28 (dd, 1 H, H-4), 4.39 (d, 1 H, $J_{1,2}$ 5.5 Hz, H-1), 4.56–4.62 (m, 2 H, J_{gem} 7.0, H-6 and $CHOCH_3$), 4.70–4.76 (m, 2 H, H-6′ and $CHOCH_3$). ^{13}C NMR ($CDCl_3$) δ: 34.36 (C-3), 55.49 and 56.23 (OCH_3 and OCH_2OCH3), 66.63 (C-2), 68.92 (C-4), 94.00 (OCH_2OCH_3), 97.65 (C-6), 105.08 (C-1), 155.02 (C-5).

4-Methyl-2,4-hexadienoic acid (30)

A mixture of carbethoxymethyl triphenylphosphorane (16.36 g, 46.95 mmol, 1.2 equiv.) and (*trans*) 2-methyl-2-butenal (3.78 mL, 39.13 mmol) in dry THF (225 mL) under argon was refluxed for 24 h. The solvent was evaporated and the residue was chromatographed with hexane–EtOAc (10:0.3) to afford the expected diene (4.77 g, 30.93 mmol, 80%) as an oil. Saponification of the ester function of the latter was carried out using one equiv. of aqueous 1 N NaOH in reflux methanol. The mixture was concentrated and the residue was acidified with 3 N aqueous HCl. The expected carboxylic acid was extracted with ether and then transformed into its carboxylate sodium salt with 1 N NaOH. The aqueous layer was acidified with 3 N HCl and extracted with ether. The organic layer was dried over $MgSO_4$ and concentrated in vacuo to provide the carboxylic acid **30** (3.11 g, 24.74 mmol, 80%) which was used in the next step without further purification.

4-Methyl-3,5-hexadienoic acid (31)

A solution of lithium diisopropylamide (2.2 equiv.) in THF was prepared by the slow addition of *n*-BuLi (46.80 mmol in hexane) to a solution of diisopropylamine (6.60 mL, 46.80 mmol) in dry THF (30 mL) under N_2. The solution was cooled to –80°C and dry hexamethyl phosphoramide (8.15 mL, 46.80 mmol) was added dropwise and the mixture allowed to stir for 0.5 h. Diene **30** (3.28 g, 21.28 mmol) was added to the cooled solution over 1h. Stirring was maintained an additional hour at –80°C and the mixture was transferred into a rapidly stirred solution of acetic acid (6.5 g) in water (130 mL). The resulting solution was adjusted to pH 1 with 3 N HCl and extracted with Et_2O. The organic layer was dried over $MgSO_4$ and concentrated under reduced pressure. Chromatography on silica gel with hexane–EtOAc (9:1) as eluent yielded compound **31** (2.13 g, 13.83 mmol, 65%) as an oil. ^{1}H NMR ($CDCl_3$) δ: 1.77 (s, 3 H, CH_3), 3.24 (d, 2 H, $J_{2,3}$ 7.5 Hz, 2 × H-2), 5.03 (d, 1 H, J_{cis} 10.5 Hz, H-6), 5.18 (d, 1 H, J_{trans} 17.5 Hz, H-6′), 5.64 (t, 1 H, H-3), 6.41 (dd, 1 H, H-5), 10–11 (br s, 1 H, COOH).

Methyl-3,6-dideoxy-2-*O*-[4′-methyl-3′,5′-hexadienoyl]-4-*O*-methoxymethyl-α-D-*threo*-hex-5-enopyranoside (26)

To a solution of alcohol **25** (200 mg, 0.98 mmol) in dry CH_2Cl_2 were added successively under argon, the carboxylic acid **31** (285 mg, 2.26 mmol, 2.3 equiv.), a catalytic amount of DMAP, and DCC (300 mg, 1.5 mmol, 1.5 equiv.) in solution in CCl_4. The mixture was stirred for 1 h and the salts were filtered off. After evaporation of the solvent, the brown residue was chromatographed on silica gel eluting with hexane–EtOAc (20:1) to give compound **26** (273 mg, 0.87 mmol, 89%). R_f 0.66 (hexane–EtOAc, 7:3). $[\alpha]_D^{22}$ –9.5 (c 1.09, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 1.77 (s, 3 H, CH_3 vinyl), 2.06–2.14 (m, 2 H, $J_{3,4} = J_{3',4}$ 8.0, H-3 and H-3′), 3.24 (m, 2 H, H-8 and H-8′), 3.39 (s, 3 H, CH_2OCH_3), 3.45 (s, 3 H, OCH_3), 4.33 (br dd, 1 H, 4-H), 4.64 (d, 1 H, $J_{1,2}$ 2.5 Hz, H-1), 4.65–4.76 (m, 4 H, H-6, H-6′ and CH_2OCH_3), 4.97–5.05 (m, 2 H, H-2 and H-12), 5.17 (d, 1 H, $J_{11,12'}$ 17.5 Hz, H-12′), 5.65 (dd, 1 H, $J_{8,9}$ 7.0, $J_{8',9}$ 7.5 Hz, H-9), 6.40 (dd, 1 H, $J_{11,12}$ 10.5 Hz, H-11).

(4*S*, 6*S*)-4-(4′-Methyl-3′,5′-hexadienoyl)oxy-6-methoxymethoxy-cycohex-2-enone (28)

To a solution of **26** (273 mg, 0.87 mmol) in dioxane (10 mL) was added $HgSO_4$ (5 mg, 0.017 mmol, 0.02 equiv.)

© 2000 NRC Canada

and 5 mM H_2SO_4 (2.6 mL). The mixture was stirred at 50°C for 4 h. The mixture was then cooled to room temperature, diluted with CH_2Cl_2, and washed with water until neutral. The organic layer was dried over $MgSO_4$, concentrated in vacuo to afford crude **27**. To a solution of the latter in CH_2Cl_2–pyridine (10:1, 11 mL) mixture under argon at –10°C was added triflic anhydride (0.15 mL, 0.97 mmol, 1.5 equiv.). The cooled mixture was stirred for 20 min and more triflic anhydride (0.15 mL) was added. The stirring was continued for 15 min and the mixture was diluted with CH_2Cl_2, washed with aqueous saturated $NaHCO_3$ and brine. The organic layer was dried over $MgSO_4$, concentrated in vacuo, and the residue was chromatographed on silica gel eluting with hexane–EtOAc (4:1) to afford **28** (69 mg, 0.25 mmol, 30%) as a gum. R_f 0.76 (hexane–EtOAc, 3:2). $[\alpha]_D^{22}$ –239.1 (c 0.32, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 1.79 (s, 3 H, CH_3 vinyl), 2.31 (ddd, 1 H, J_{gem} 13.5, $J_{4,5}$ 5.5, $J_{5,6}$ 5.0 Hz, H-5), 2.45 (ddd, 1 H, $J_{4,5'}$ 4.5, $J_{5',6}$ 8.5 Hz, H-5′), 3.24 (m, 2 H, H-2′a and H-2′b), 3.39 (s, 3 H, CH_2OCH_3), 4.36 (dd, 1 H, H-6), 4.71 (d, 1 H, J_{gem} 7.0 Hz, $CHHOCH_3$), 4.80 (d, 1 H, $CHHOCH_3$), 5.03 (d, 1 H, J_{cis} 10.5 Hz, H-6a′), 5.18 (d, 1 H, J_{trans} 17.5 Hz, H-6′b), 5.58–5.73 (m, 2 H, H-4 and H-3′), 6.07 (br d, 1 H, $J_{2,3}$ 10.5 Hz, H-2), 6.40 (dd, 1 H, H-5′), 6.84 (dd, 1 H, $J_{3,4}$ 4.0 Hz, H-3). Anal. calcd. for $C_{15}H_{20}O_5$: C 64.27, H 7.19; found: C 64.15, H 7.04.

Thermal cycloaddition of **28**: A solution of enone **28** (69 mg, 0.25 mmol) and hydroquinone (10 mg, 0.09 mmol, 0.37 equiv.) in degassed toluene (10 mL) was placed in a sealed tube and heated at 135°C for 6 h, 165°C for 12 h, and 220°C for 12 h. At the end of each period of heating, the crude mixture was analyzed by ^{1}H NMR spectroscopy, but no cycloadduct compound was detected. After concentration in vacuo, the residue was chromatographed on silica gel eluting with hexane–EtOAc (85:15) to afford the starting material (20 mg, 0.075 mmol, 30%) and a more polar product resulting from the splitting of the MOM protecting group (25 mg, 0.10 mmol, 44%).

(*E*)-(4′-Methyl-3′,5′-hexadien)yl 2,3-dideoxy-4,6-di-*O*-acetyl-α-D-*erythro*-hex-2-enopyranoside (34)

To a stirred solution of tri-*O*-acetyl-D-glucal (5.71 g, 21 mmol) and homoallylic alcohol **33** (2.7 g, 24 mmol, 1.15 equiv.) in anhydrous CH_2Cl_2 (200 mL) was added under argon boron trifluoride ethyl etherate (21 drops) over a period of 3.30 h. At the end of the addition the resulting brown mixture was quenched with pyridine (1 mL) and washed successively with aqueous saturated $NaHCO_3$ and brine. The organic layer was dried over $MgSO_4$, concentrated in vacuo, and chromatographed with hexane–EtOAc (4:1) to give an unseparable mixture of α and β-glycosides (**34**) in a 4:1 ratio (5.77 g, 17.8 mmol, 84%). R_f 0.35 (hexane–EtOAc, 4:1). $[\alpha]_D^{22}$ +69.6 (c 3.0, $CHCl_3$). (*E*)-(4′-Methyl-3′,5′-hexadien)yl 2,3-dideoxy-6-(2,2-dimethylpropionyl)-α-D-*erythro*-hex-2-enopyranoside (36)

To a stirred solution of diol **35** (3.5 g, 14.5 mmol) in a CH_2Cl_2–pyridine (1:1.5, 25 mL) mixture was added dropwise, under argon at –5°C pivaloyl chloride (1.79 mL, 17.4 mmol, 1.2 equiv.). The solution was stirred for 1.30 h and a further amount of pivaloyl chloride (0.35 mL, 2.9 mmol, 0.2 equiv.) was added. Stirring for 2 additional h was followed by quenching with water and extractive work-up (CH_2Cl_2). The organic layer was dried over Na_2SO_4, concentrated in vacuo, and chromatographed with hexane–EtOAc (4:1) to give the ester **36** (2.96 g, 2.13 mmol, 63%) as a gum. R_f 0.25 (hexane–EtOAc, 4:1). $[\alpha]_D^{22}$ +3.5 (c 1.09, $CHCl_3$). IR (cm^{-1}): 3455, 1733, 1713, 1600. ^{1}H NMR ($CDCl_3$) δ: 1.25 (s, 9 H, $CO(CH_3)_3$), 1.75 (s, 3 H, CH_3 vinyl), 2.45 (m, 2 H, 2 × H-2′), 3.53 (ddd, 1 H, J_{gem} 14.0, $J = J'$ 7.0 Hz, H-1′a), 3.75–3.87 (m, 2 H, H-5 and H-1′b), 3.98 (m, 1 H, $J_{4,5}$ 9.5 Hz, H-4), 4.25 (dd, 1 H, $J_{5,6}$ 2.0, J_{gem} 12.5 Hz, H-6), 4.45 (dd, 1 H, $J_{5,6'}$ 5.0, H-6′), 4.92 –5.01 (m, 2 H, H-1 and H-6′a), 5.11 (d, 1 H, J_{trans} 17.5, H-6′b), 5.48 (t, 1 H, *J* 7.0 Hz, H-3′), 5.74 (m, 1 H, $J_{2,3}$ 10.0, $J_{3,4}$ 2.5 Hz, H-3), 5.95 (m, 1 H, H-2), 6.36 (dd, 1 H, J_{cis} 11.0 Hz, H-5′).

[2*R*-[2α,6β(*E*)]] 2,2-Dimethyl-[3,6-dihydro-6-[(4′-methyl-3′,5′-hexadienyl)oxy]-3-oxo-2*H*-pyran-2-yl]methyl ester propanoic acid (38)

(*i*) PDC oxidation: Freshly prepared pyridinium dichromate (1.57 g, 4.2 mmol, 1.38 equiv.) was suspended in dry CH_2Cl_2 (1.5 mL) containing the alcohol **36** (1.0 g, 3.08 mmol). The mixture was stirred for 20 h, a further amount of PDC (300 mg, 0.80 mmol, 0.26 equiv.) was added, and stirring was still maintained for 12 h. The mixture was diluted with hexane and the salts were filtered off through Celite, washed with a mixture of CH_2Cl_2 and hexane. After concentration of

© 2000 NRC Canada

the filtrate, the residue was chromatographed on silica gel eluting with hexane–EtOAc (9:1) to give the expected ketone **38** (545 mg, 1.69 mmol, 55%) as a gum.

(*ii*) Activated MnO_2 oxidation: Freshly prepared manganese dioxide (25 g) was suspended in dry carbon tetrachloride (350 mL) containing the alcohol **36** (3.0 g, 9.25 mmol). The resulting mixture was vigorously stirred for 3 h. Filtration over a pad of Celite and evaporation of the filtrate gave a residue which was chromatographed on silica gel eluting with hexane–EtOAc (9:1) to afford **38** (2.68 g, 8.32 mmol, 90%) as a gum. *Rf* 0.51 (hexane–EtOAc, 4:1). $[\alpha]_D^{22}$ –131.6 (c 0.58, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 1.17 (s, 9 H, $CO(CH_3)_3$), 1.75 (s, 3 H, CH_3 vinyl), 2.48 (m, 2 H, 2 × H-2′), 3.63 (ddd, 1 H, J_{gem} 9.5, *J* 6.5, *J′* 7.0, H-1′a), 3.86 (ddd, 1 H, *J* = *J′* 7.0 Hz, H-1′b), 4.42 (dd, 1 H, J_{gem} 12.0, *J* 5.5 Hz, C*H*HOCO$(CH_3)_3$), 4.52 (dd, 1 H, *J* 2.5 Hz, CH*H*OCO$(CH_3)_3$), 4.65 (dd, 1 H, H-2), 4.96 (d, 1 H, J_{cis} 11.0 Hz, H-6′a), 5.11 (d, 1 H, J_{trans} 17.5 Hz, H-6′b), 5.25 (d, 1 H, $J_{5,6}$ 3.5 Hz, H-6), 5.46 (m, 1 H, H-3′), 6.11 (d, 1 H, $J_{4,5}$ 10.5 Hz, H-4), 6.35 (dd, 1 H, H-5′), 6.87 (dd, 1 H, H-5).

[2*R*-[2α,6β(*E*)]] [3,6-Dihydro-6-[(4′-methyl-3′,5′-hexadienyl)oxy]-3-oxo-2*H*-pyran-2-yl]methanol (39)

Compound **39** was obtained in 83% yield from diol **35** according to the above mentioned procedure. *Rf* 0.29 (hexane–EtOAc, 1:1). ^{1}H NMR ($CDCl_3$) δ: 1.75 (s, 3 H, CH_3 vinyl), 2.30 (m, 1 H, $J_{2'a,3'}$ 7.0, J_{gem} 14.0 Hz, H-2′a), 2.50 (m, 1 H, $J_{2'b,3'}$ 7.5 Hz, H-2′b), 3.63 (ddd, 1 H, J_{gem} 13.0, *J* 6.5, *J′* 7.0, H-1′a), 3.80 (ddd, 1 H, *J* = *J′* 7.0 Hz, H-1′b), 3.90 (dd, 1 H, J_{gem} 12.0, *J* 4.5 Hz, C*H*HOH), 4.52 (dd, 1 H, *J* 2.5 Hz, CH*H*OH), 4.55 (dd, 1 H, H-2), 4.96 (d, 1 H, J_{cis} 11.0 Hz, H-6′a), 5.11 (d, 1 H, J_{trans} 17.5 Hz, H-6′b), 5.25 (d, 1 H, $J_{5,6}$ 3.5 Hz, H-6), 5.36 (m, 1 H, H-3′), 6.11 (d, 1 H, $J_{4,5}$ 10.5 Hz, H-4), 6.35 (dd, 1 H, H-5′), 6.87 (dd, 1 H, H-5).

[2*R*-(2α, 3aα, 6aβ, 9aα, 9bα)] 2,2-Dimethyl-(3, 3a, 4, 6a, 7, 8, 9a, 9b-octahydro-6-methyl-3-oxo-2*H*-pyrano[4, 3, 2-*ij*][2]benzopyran-2-yl)methyl ester propanoic acid (40)

A solution of enone **38** (2.5 g, 7.76 mmol) and hydroquinone (0.14 g, 1.39 mmol, 0.18 equiv.) in degassed toluene (150 mL) was placed in a sealed tube and heated at 155°C for 14 h. The resulting mixture was then cooled to room temperature, concentrated in vacuo, and purified by column chromatography with hexane–EtOAc (9:1) to provide the single cycloadduct **40** (1.87 g, 5.82 mmol, 75%) as a gum. *Ferrier carbocyclization of **51** using a stoichiometric amount of mercuric acetate*

To a solution of **51** (78 mg, 0.29 mmol) in a mixture of acetone (12 mL) and water (5 mL) was added $Hg(OAc)_2$ (160 mg, 0.52 mmol, 1.8 equiv.) and acetic acid (0.17 mL). The mixture was stirred at reflux for 12 h, solvents were evaporated under reduced pressure, and the residue was taken up with CH_2Cl_2. The organic layer was washed with saturated aqueous $NaHCO_3$, water, dried over $MgSO_4$, and concentrated in vacuo. Column chromatography on silica gel eluting with hexane–EtOAc afforded the cyclohexanones **53** (23 mg, 0.08 mmol, 28%) and **55** (9 mg, 0.03 mmol, 11%) and the hydration product **57** (14.5 mg, 0.05 mmol, 18%) [**53**:**55**:**57** (2.5:1:1.7)].

Conclusions

This work allowed the preparation of the bicyclic structures **55** and **54** which can be regarded as key compounds for the synthesis of the hexahydro-naphthalene ring of mevinic acids such as pravastatin and mevinolin, the keto group at C-1 being amenable to reduction or Wittig methylenation. This strategy is applicable for the synthesis of other complex decalinic structures present in a number of natural products. The IMDA reaction of cyclohexenone as the dienophile failed likely because of the ester link used in the tether. Other links like mixed acetals should be devised. This type of link was efficient in the IMDA of a sugar enone to provide bis-annulated pyranosides. However it is worth noting that the Ferrier carbocyclization on these bis-annulated pyranosides is less efficient than in the pyranoside series in terms of stereoselectivity and of yield. But one interesting consequence of this limitation was also the direct carbocyclization of **57** without mercury catalysis. It is likely that direct hydration of the double bond of **51** or **50** followed by base-catalyzed carbocyclization would be a good alternative and a good improvement of our synthetic sequence.

Hydrogen bonded supramolecular structures: a further insight into the diamine–diol recognition and self-assembly

Stefano Roelens, Paolo Dapporto, and Paola Paoli

Abstract: A new H-bonded supramolecular assembly of the diamine–diol family has been obtained from (1*R*,2*R*)-1,2-diaminocyclohexane (DAC) and (*S*)-1-phenyl-1,2-ethanediol (PED). The structure was characterized by single-crystal X-ray analysis and showed the typical architecture of DAC based assemblies, consisting of a three-stranded helicate coiling around a H-bonded core, with a predictable helicity sense determined by the configuration of DAC. The new assembly, while reconfirming the unique role of DAC as a powerful assembler of supramolecular structures, demonstrated that the C_2 symmetry of diol partners employed so far is not essential for assembling helicates, although chirality is. In the case of the adduct between (1*R*,2*R*)-1,2-diaminocyclohexane and (2*R*,3*R*)-2,3-butanediol, molecular recognition and self-assembly have been shown to take place even in the absence of solvent, in the gas phase, where long crystals were formed by spontaneous organized aggregation of diamine–diol units. A thorough analysis of the results from the present and previous investigations has lead to a deeper understanding of the key features of the diamine–diol molecular code and of the requirements for recognition and assembly.

Key words: supramolecular, hydrogen bonding, molecular recognition, self-assembly, diamines, diols.

Résumé : On a obtenu un nouvel assemblage supramoléculaire à liaisons hydrogènes de la famille diamine–diol à partir du (1*R*,2*R*)-1,2-diaminocyclohexane (DAC) et du (*S*)-1-phényléthane-1,2-diol (PED). On a caractérisé la structure par diffraction des rayons X et elle présente l'architecture typique des assemblages à base de DAC; elle est constituée d'une hélice à trois brins enroulée autour d'un noyau à liaisons hydrogènes avec un sens d'hélicité qui peut être prédit à partir de la configuration du DAC. Le nouvel assemblage reconfirme le rôle unique du DAC comme promoteur puissant de la formation de structures supramoléculaires et démontre que la symétrie C_2 des partenaires diols utilisés jusqu'à maintenant n'est pas essentielle pour la formation d'assemblages en hélice, même si la chiralité l'est. Dans le cas de l'adduit entre le (1*R*,2*R*)-1,2-diaminocyclohexane et le (2*R*,3*R*)-butane-2,3-diol, il a été démontré que la reconnaissance moléculaire et l'autoassemblage se produisent même en l'absence de solvant, en phase gazeuse, alors qu'il se forme de longs cristaux par l'agrégation organisée spontanée d'unités diamine–diol. Une analyse détaillée des résultats obtenus dans le présent travail et dans d'autres rapportés antérieurement permet de mieux comprendre les caractéristiques principales du code moléculaire diamine–diol et les impératifs pour la reconnaissance et l'assemblage.

Mots clés : supramoléculaire, liaison hydrogène, reconnaissance moléculaire, autoassemblage, diamines, diols.

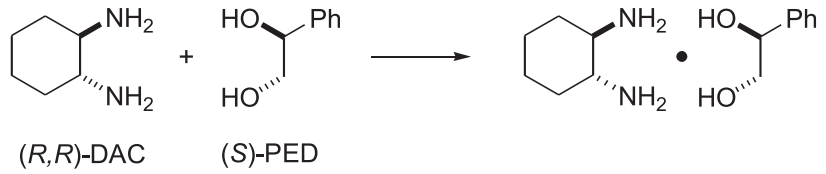
[2]A Chemical Abstract search for general reviews on hydrogen-bonded structures gave 957 references dating back from 1967, of which 47 references specifically dealing with supramolecular structures appeared from 1992–1999.

Introduction



There is an overwhelming literature on hydrogen bonded supramolecular structures.[2] The vast majority of these are based on amidic type H-bonding, which is strong enough to ensure stability to the resulting entity. However, it has recently been shown that even much weaker H-bonding, such as that established between simple aromatic (1) and aliphatic (2) amino and hydroxy functionalities, is capable of generating supramolecular structures. Alcohols and primary amines are complementary H-bonding partners in that a single donor – double acceptor (oxygen) perfectly matches the coordination properties of a double donor – single acceptor (nitrogen). We (2*a*) and others (1*a*) have found that this complementarity constitutes a primary driving force for molecular recognition and self-assembly because saturation of the fourfold tetrahedral coordination capabilities of both heteroatoms provides the energetic advantage of the process through the establishment of additional H-bonds, overriding

(*R,R*)-DAC (*S*)-PED

(*R,R*)-DAC (*R*)-PED

the natural donor–acceptor roles of oxygen and nitrogen (3). With chiral diamine and diol partners, such process determines not only molecular recognition and self-assembly into unique supramolecular architectures, but also the helical folding of the assembly, as the way to achieve full coordination of heteroatoms and the formation of the maximum number of H-bonds (2*a*); depending on the steric requirements of partners, in favorable cases this gives rise to a helical architecture of both the tertiary structure and the H-bonding network (2*b*, *c*). A number of examples of helicates based on *trans*-1,2-diaminocyclohexane (DAC) have been described (2), showing that the process relies on the remarkable assembling ability of DAC as well as on the information encoded in the two interacting partners. The helical motif is indeed a dominant feature of the architectural design of DAC; furthermore, the stereochemical information encoded in DAC drives the assembling process to select a specific chirality sense of the helicate, depending on the DAC enantiomer used. Such fascinating supramolecular architectures are thus the ultimate expression of a code imprinted in the partners' complementary structures and functionalities, which is read by the recognition process.

While several features of such H-bonded architectures have been unraveled, there is still a number of open issues concerning the rules that govern their molecular recognition and self-assembly. For example, is the diamine–diol the only perfect pair of partners or do other well-matched pairs exist? Is the C_2 symmetry of partners utilized so far essential for building helical superstructures? Is the assembling process a spontaneous build-up of diamine–diol units or rather a fit of the diol into the diamine crystal lattice? In an effort to gain a deeper insight into the many peculiar aspects of this phenomenon, we have explored in more detail the factors that are involved in the molecular recognition and self-assembly of the diamine–diol motif, in the belief that the understanding of the constitutional prerequisites and the elucidation of the molecular code may disclose unexpected chemical features and may open the way to a rational design of H-bonded supramolecular architectures. In a previous work (2*b*) it was noted that supramolecular structures could be obtained from DAC with several diols, but not vice versa. This led to the belief that DAC may possess specific recognition and assembling instructions that are not shared by other diamines or diols. Although another diamine, *trans*-2,3-diaminobutane, has been shown to be effective in some cases (2*c*), DAC was selected as the best suited *assembler* for the investigation.

Results and discussion

Diamine–diol supramolecular architectures were obtained by crystallization of the 1:1 mixture of the two partners from a nonpolar solvent that would not interfere with the forming H-bonds (2). In a typical procedure, equimolar amounts of DAC and of the selected diol, both enantiopure, were suspended in benzene and heated to complete solution (Scheme 1). Crystal needles normally separated upon standing at room temperature in a length of time ranging from few minutes to few hours. The crystalline form of needles is indicative of self-assembly into helicates, which typically grow monodirectionally around the core. Only one of the two diastereomeric pairs is well assorted: the well-matched pair diastereomer normally crystallizes faster, whereas the mismatched pair takes longer, if it crystallizes at all.

As mentioned, all the diols used so far were C_2 symmetry partners for the C_2 symmetrical DAC. A basic question is therefore what role symmetry and chirality are playing in the recognition and assembling process and how critical is the C_2 symmetry. To investigate this aspect, we treated (1*R*,2*R*)-DAC (Fluka, mp 43–45°C, $[\alpha]_D^{20}$ –25.5°, c = 5 in 1 N HCl) with both enantiomers of 1-phenyl-1,2-ethanediol ((*R*)-PED, Fluka, mp 66–68 °C, $[\alpha]_D^{20}$ –40°, c = 3 in acetone; (*S*)-PED, Fluka, mp 66–68 °C, $[\alpha]_D^{20}$ +40°, c = 3 in acetone), diols possessing C_1 symmetry, according to the general crystallization procedure (Scheme 2). Long needles (69%, mp 57–58°C)

Fig. 1. ORTEP drawing of the molecular structure of the 1:1 adduct between (1*R*,2*R*)-diaminocyclohexane (DAC) and (*S*)-1-phenyl-1,2-ethanediol (PED) with atom numbering scheme. H-bonds are represented as black lines.

crystallized soon from the diol of *S* configuration, whereas no crystalline material could be obtained from the *R* enantiomer even after long standing and concentration of the solution, which afforded glassy material. This evidence clearly indicated which was the well-matched pair of partners. The X-ray structure of the crystals (Tables 1–3)[3] showed a 1:1 adduct consisting of one molecule of (*R*,*R*)-DAC and one of (*S*)-PED, held together by two H-bonds linking a NH donor to an OH acceptor in the first and the reverse in the second (Fig. 1): the interchangeable H-bonding role of the two groups is clearly apparent. The supramolecular architecture of the adduct is displayed by crystal packing projections. From the top view (Fig. 2), the typical array of assemblies based on DAC is observed, consisting of a H-bonded

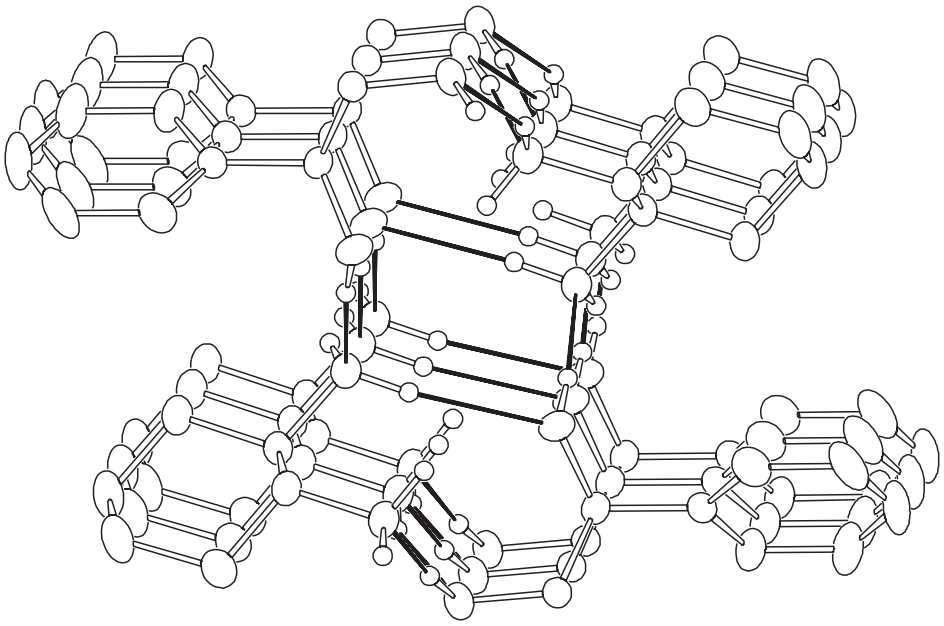
central core surrounded by four stacks of aliphatic and phenyl ring residues. Two side rows of additional H-bonds flank the assembly, engaging the second amino and hydroxy groups of each molecule not involved in the central core. The side view of the assembly (Fig. 3) shows instead the helicity of the central H-bonding network, reinforced by the two H-bonds side rows that run in the opposite direction of donation with respect to that of the core. Although NH···O bonds are longer than OH···N bonds, they are all well within the typical H-bonding distance (Table 4). All the heteroatoms in the structure are tricoordinated, with one NH and one oxygen lone pair apparently unemployed. However, in the central core these are engaged in a looser H-bonding interaction, showing an NH···O distance of 3.00 Å, slightly larger than the sum of their Van der Waals radii, and an angle of 152°. As a consequence, although the H-bonding network is not fully formed, the helicate shape of the assembly, typical of the family, is retained. The helical supramolecular structure of residues is better perceived from the spacefilling representation of the assembly, in which diamine and diol molecules linked by the row of H-bonds including the looser interaction are shown in different shades of gray (Fig. 4). Right-handed coiling of residues around the core, predictable from the configuration of DAC, is easily appreciated from Fig. 4, which also shows that three such rows of molecules run parallel giving rise to a trihelicate architecture.



The supramolecular structure of the (*R*,*R*)-DAC–(*S*)-PED adduct presented here shed some light on the role of chirality and symmetry in the diamine–diol recognition. Indeed, the close analogy of the present assembly with those previously reported (2) demonstrate that the C_2 symmetry of the diol partner is not essential, although chirality certainly is. We were not able in fact to obtain crystals from unsubstituted ethylene glycol under the same conditions, while from a *cis* substituted diol (*meso*-1,2-cyclohexanediol) crystallization of a layered structure was reported (2*c*), evidence suggesting that a "chiral twist" (4) is somehow necessary for recognition and assembly with a chiral diamine. Analogously, ethylene diamine failed to give recognition with (2*R*,3*R*)-2,3-butanediol and with either enantiomer of *trans*-1,2-cyclohexanediol, which separated on standing from the diamine by evaporation of the solvent, whereas DAC was shown to give the strongest assemblies with these diols (2*b*). Adducts from planar, achiral aromatic diamines and diols have been reported to self-assemble, giving rise to achiral diamond-type structures (1*a*, *c*). However, we did not observe molecular recognition and self-assembly with nonplanar, achiral aliphatic diamine–diol pairs, such as ethylene diamine–ethylene glycol and *meso*-1,2-diaminocyclohexane–*meso*-1,2-cyclohexanediol. Further demonstration that chirality plays a crucial role in these architectures comes from a closer inspection of the assembly (Fig. 2). The hydroxy group engaged in the H-bonded core, responsible for the formation of the helicate, belongs to the phenyl-bearing stereogenic carbon, whereas the methylene hydroxyl group takes part in the flanking H-bonding side rows, although steric considerations would suggest the opposite arrangement. Correspondingly, the OH···N bonds in the side rows are shorter than those in the core; evidently, the need for a "chiral twist" overrides the steric congestion penalty imposed by the substituent. Such a compromise between chirality and steric requirements

confirmed previous observations on the related C_2 symmetrical 1,2-diphenyl-1,2-ethanediol (DPED) (2*b*), from which two different supramolecular structures were obtained by the interaction of (*R*,*R*)-DAC with its two enantiomers: the *S*,*S* diol, the well-matched partner, gave the right-handed helicate showing the recurrent H-bonded core motif, whereas the *R*,*R* diol afforded lower melting crystals characterized by a layered structure, consisting of contiguous units of diamine and diol dimers. The result was ascribed to the sterically demanding phenyl groups in the mismatched diamine–diol pair, which caused disruption of the helicate architecture. Although the H-bonding network of the (*R*,*R*)-DAC–(*S*)-PED adduct is analogous to that of (*R*,*R*)-DAC–(*S*,*S*)-DPED, both featuring a spiral-shaped motif of the core, the relative position of diamine and diol molecules around the core resembles that exhibited by the adduct of DAC with cyclohexanediol, a more tightly bound assembly, probably a consequence of the steric relief for the missing phenyl substituent. The assembly of the monophenyl substituted diol represents the evidence that the compromise between chiral and steric requirements is still conducive to self-assembly with partners bearing a single stereocenter.

From the above discussion, *complementarity* emerges unambiguously as the fundamental requirement for recognition and assembly, in full agreement with the well known general principle (5). Besides the chirality requirement, functional, coordinative, symmetry, and steric complementarity have been demonstrated to be leading prerequisites in the diamine–diol structures described so far. An even subtle decrease in the complementarity of partners can induce degradation or loss of recognition and assembly. For example, it might be expected that a H-bonding group more acidic than the hydroxyl, such as the thiol group, would be an equally good or even better partner for DAC. Instead, while *trans*-1,2-cyclohexanediol was efficiently resolved by crystallization with enantiopure DAC because of the significantly different solubility of the two diastereomeric assemblies (6), resolution of *trans*-1,2-cyclohexanedithiol could not be obtained under the same conditions, which only gave the unaltered mixture of reagents as an oil. Analogous results were observed with 2,3-butanedithiol. This suggested that replacement of hydroxyl with thiol groups may disrupt the functional complementarity of partners to such an extent that recognition was prevented, despite the greater thiol acidity: matching of donating–accepting properties appears to take priority over acidity. Recognition was also suppressed by a variation as subtle as the replacement of the cyclohexane with the cyclopentane ring in the diol partner. Again, all attempts of resolution of *trans*-1,2-cyclopentanediol made by us and others (2*c*) met with disappointment. Thus geometric and conformational issues, likely related to the achievement of a perfectly staggered conformation as in the cyclohexane ring, appear to play a significant role in the process as well. All the described failures give an idea of how crucial the complementarity requirements can be in systems featuring weak H-bonding.

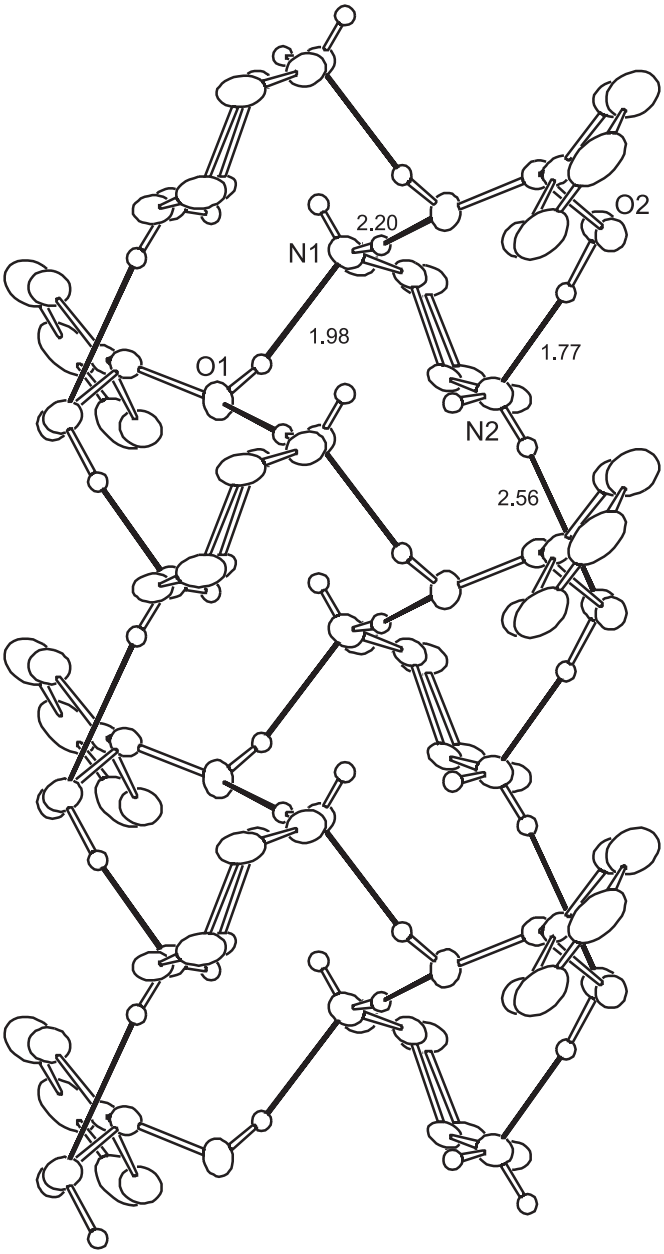
Fig. 3. ORTEP drawing of the H-bonded assembly of the (*R*,*R*)-DAC–(*S*)-PED adduct (side view along the *a* axis) with relevant H-bonding distances (Å). H-bonds are represented as black lines. H-atoms on carbon are omitted for clarity.



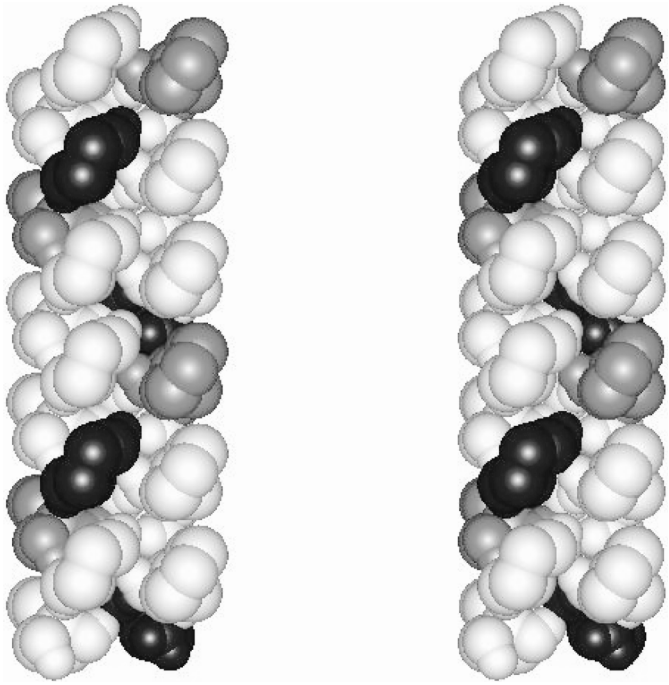


Fig. 4. Spacefilling (CPK) representation (stereoview) of the right-handed, triple-stranded helicate structure of the (*R*,*R*)-DAC–(*S*)-PED adduct (side view along the *a* axis). One of the three strands of diamines and diols linked by the same H-bonding row is represented in darker (DAC) and medium (PED) shades of gray, while the remaining two strands are in lighter shades of gray. H-atoms on carbon are omitted for clarity.

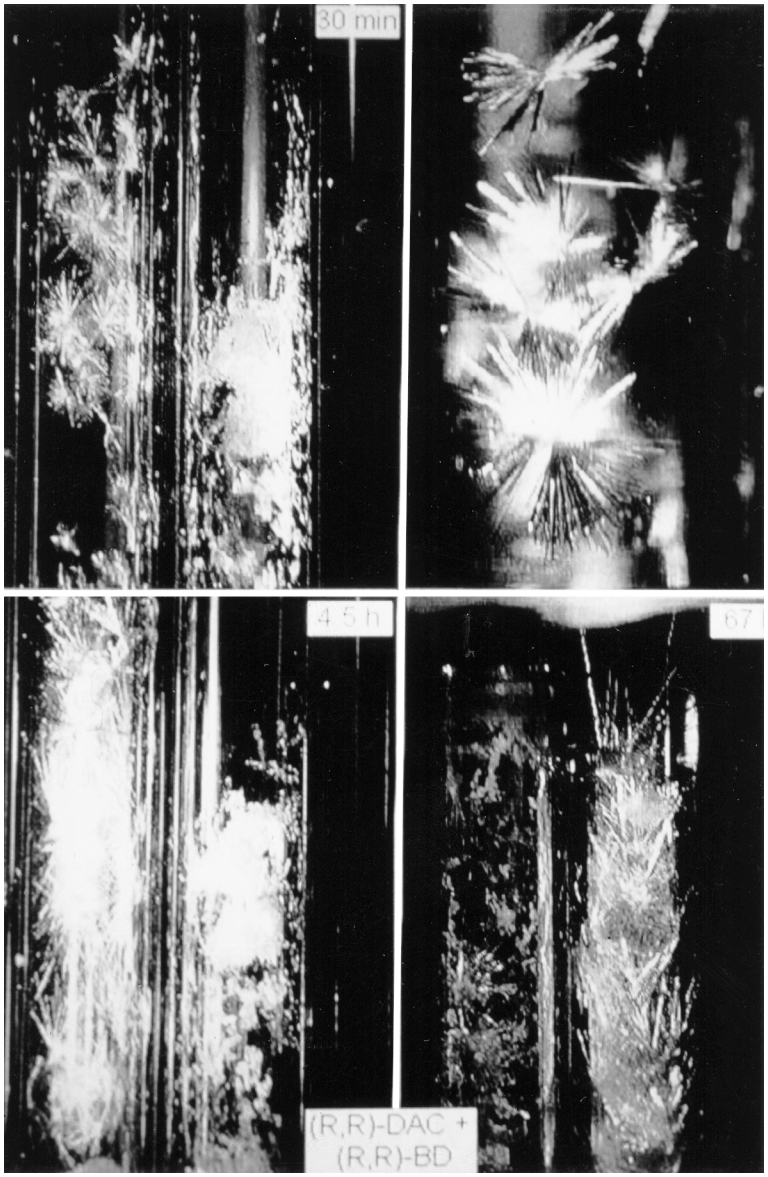

A clear-cut answer came from an experiment designed to ascertain whether self-assembly occurs by insertion of the diol partner in the crystal lattice of the diamine (inclusion) or by organized aggregation of diamine–diol units (build-up). (*R*,*R*)-DAC and (2*R*,3*R*)-2,3-butanediol (BD) have been shown to give the most largely H-bonded assembly observed, featuring full tetracoordination of *all* the heteroatoms and a helical arrangement of both the assembly *and* the H-bonding network. The two reagents (DAC, low melting solid; BD, liquid) were placed neat in two separate capillary tubes, which were introduced in a tube under moderate vacuum. Crystals in the shape of needles growing from nucleation points began to form shortly on the glass walls of the capillary containing the least volatile diol. After a few hours, crystals had filled the capillary and complete consumption of the solid diamine in a few days produced a bulky agglomerate of crystals several centimeters long (Fig. 5). The obtained crystals had the same physical and spectroscopic properties as those used for the structure solution. Molecular recognition and self-assembly of the two partners had taken place in the gas phase, in the absence of solvent, simply driven by H-bonding, unambiguously demonstrating a build-up process. The inclusion process, feasible in solution, can not occur in the gas phase; however, under both conditions, the organization of the assembly is dominated by the strong directing ability of the diamine.

Diamine–diol recognition and self-assembly: features and requirements

From the analysis of results presented here and of previously reported structures (2), which now constitute a significantly broad family of 13 members, several aspects of the interaction between diamines and diols have been understood. Even though from the available data it is not possible yet to predict if a diamine–diol pair will self-assemble into a supramolecular structure, it is nevertheless possible to infer the basic requirements and the key features characterizing the molecular recognition and self-assembling code of this family of H-bonding partners. We believe it useful to highlight them briefly.

Fig. 5. Top left: crystals of the 1:1 adduct between (1*R*,2*R*)-diaminocyclohexane (DAC) and (2*R*,3*R*)-2,3-butanediol (BD) growing under vacuum on the wall of the 5 mm capillary tube on the left containing neat BD, from neat DAC contained in the 5 mm capillary tube on the right, after 30 min. Top right: same as above, in a magnified representation. Bottom left: same as above, after 4.5 h. Bottom right: same as above, after 67 h. The capillary tube containing residual DAC is on the left side while that originally containing BD is on the right side.

Complementarity

Electronic as well as coordinative complementarity make the primary amino and the hydroxy groups the perfect matching functional groups for H-bonding. Aliphatic vicinal diamines and diols are constitutionally capable of exploiting such a H-bonding complementarity for giving rise to molecular recognition and for self-assembling into supramolecular architectures. Tendency to achieve full tetracoordination of both nitrogen and oxygen is the driving force, whereas acidity–basicity or donor–acceptor properties of partners do not appear to be determinant prerequisites.

Chirality

Chirality of both partners is essential for self-assembly into helicate architectures. C_2 has proved to be the optimum symmetry for best geometric complementarity, although C_1 symmetry is effective as well, but the "chiral twist" is a necessary feature. A well-matched combination of partners' enantiomers consistently gives rise to assemblies of higher symmetry and larger H-bonds number than does its diastereomeric counterpart. Achiral aliphatic species as the diamine and (or) the diol partners either give layered structures in special cases (only a single example at present) or, more commonly, do not assemble at all.

Steric and conformational prerequisites

Due to weak H-bonding, diamine–diol assemblies appear to be critically sensitive to the steric and conformational requirements. While methyl and cyclohexano substituents are accepted, the size of phenyl groups appear to be at the limit

© 2000 NRC Canada

for self-assembly. Even minimal changes in the size and geometry of partners induce drastic modifications of the architecture. Conformational flexibility is advantageous for partners to adapt to each other and for the assembly to fold in order to achieve the largest number of H-bonds, but the rigid and perfectly staggered conformation of cyclohexane, although preventing the assembly from folding, with well-matched complementary partners gives rise to thermodynamically more stable structures, most likely for entropic reasons related to the lack of conformational freedom loss. Again, minor conformational changes such as those resulting from replacing cyclohexane with cyclohexene or cyclopentane, produce dramatic consequences on the H-bonded network motif.

The assembler

trans-1,2-Diaminocyclohexane (DAC) is a superior assembler of supramolecular structures. It possesses optimal geometric, functional, symmetry, steric, and conformational properties to assemble a whole family of diols into organized architectures. The more flexible *trans*-2,3-diaminobutane is also effective with constrained cyclohexanediol partners, but it lacks the "preorganization" of DAC. Other chiral diamines failed to give self-assembly. Furthermore, the assembling properties of DAC are not shared by any of the diols investigated so far, unable to assemble diamines.

Supramolecular architecture

The helicate is the preferred structural motif. The backbones of diamine and diol molecules linked by H-bonding rows coil around the H-bonded core in a helical fashion. Typically, three strands of such rows run parallel in the assembly, generating a triple-stranded helicate. Whenever permitted by steric, geometric and complementarity requirements, the ribbon-shaped H-bonded core also folds over in a helical fashion, thus allowing full tetracoordination of all the heteroatoms involved. Degradation of the helical motif is caused by steric or symmetry reasons, first leading to unfolded ribbon (pleated sheet) and to incompletely bonded core still exhibiting a persistent helicate structure of the backbone, then to layered structures and eventually to suppression of self-assembly. The helicity sense of the assembly is determined by the diamine: a right-handed helicity is predicted for the diamine of (*R*,*R*) configuration; when *both* the backbone and the core are helical, they show opposite helicity and the sense of the core's helix takes priority over that of the backbone, folding in a right-handed way.

Solution and gas phase features

Diamine–diol assemblies are supramolecular solid-state architectures. In solution, NMR evidence unequivocally demonstrated that these are fast-exchanging aggregates, showing molecular recognition and chiral discrimination. While molecular recognition is exhibited by a much larger set of diamine–diol pairs than the described set of X-ray structures, not all give rise to self-assembly, demonstrating that the requirements for the latter process are more restrictive than those for the former. Formation of crystals from a diamine–diol solution is strongly indicative that, beyond molecular recognition, the self-assembling process has the energy gain required to take place. Sublimation of crystals into unaltered supramolecular structures guarantees the stability of the assembly. Needles growing in the gas-phase from neat reagents show that self-assembly is carried out by an organized build-up of diamine–diol units, and suggest the formation of a helicate occurring through the establishment of a monodirectional H-bonding network.

In conclusion, the body of data collected on the diamine–diol family has grown large enough to provide a basic understanding of the fundamental features and requirements that characterize their molecular recognition and self-assembling code. Hopefully, this knowledge will inspire the design of new and exciting architectures.

Experimental section

Crystal data and refinement

Crystal data and refinement details of the structure are reported in Table 1. Unit cell parameters and intensity data were obtained from crystals sealed in a capillary tube under Ar atmosphere on a Nonius CAD4 diffractometer. Cell dimensions were determined by least-squares fitting of 25 centered reflections. Intensity data were corrected for Lorentz and polarization effects, an absorption correction was applied once the structure was solved by using the Walker and Stuart method (7). The structure was solved by direct methods, using the SIR-92 program (8) and subsequently refined by the full-matrix least-squares program SHELXL-93.[4] The hydrogen atoms linked to nitrogen and oxygen atoms were localized in ΔF Fourier syntheses and individually refined. The hydrogen atoms of the carbon atoms, on the contrary, were introduced in calculated positions, and their coordinates refined in agreement with those of the linked atoms. The hydrogen atoms linked to carbon atoms were refined with an overall isotropic temperature factor [U = 0.082(3) Å^2], whereas the hydrogen atoms linked to N1, N2 O1 and O2 were refined with an individual isotropic temperature factor. All the non-hydrogen atoms were refined anisotropically. Atomic scattering factors and anomalous dispersion corrections for all the atoms were taken from International Tables for X-ray Crystallography (9). Geometrical calculations were performed by PARST93 (10). The molecular plots were produced by the ORTEP program (11). Table 2 reports the atomic coordinates of the non-hydrogen atoms and Table 3 bond lengths and angles.

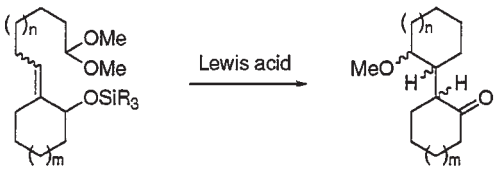
A new strategy for synthesis of attached rings

Larry E. Overman and Lewis D. Pennington

Abstract: The first investigation of the use of pinacol-terminated Prins cyclizations to form attached rings is reported. Treatment of triisopropylsilyl ethers of (*Z*)- or (*E*)-[2-(6,6-dimethoxyhexylidene)cyclohexanol with $SnCl_4$ provides bicyclic products having attached rings. The approach is synthetically useful in the *Z* alkylidenecyclohexane series, proceeding selectively by a pathway involving carbon migration in the pinacol rearrangement step, to provide methoxy epimers of 1-(2-methoxycyclohexyl)cyclopentylcarboxaldehyde. Reaction of the corresponding *E* stereoisomer is more complex and yields a mixture of products resulting from both hydride and carbon migration in the pinacol rearrangement step.

Key words: Prins cyclization, pinacol rearrangement, attached rings.



Résumé : On a réalisé la première étude de l'utilisation de cyclisations de Prins terminées par du pinacol dans le but de former produits auxquels des cycles sont attachés. Le traitement des éthers triisopropyliques des (*Z*)- et (*E*)-[2-(6,6-diméthoxyhexylidène)]-cyclohexanol avec du $SnCl_4$ conduit à la formation de produits bicycliques auxquels des cycles sont attachés. L'approche est utile en synthèse dans la série du *Z*-alkylidènecyclohexane puisque, par le biais d'une voie impliquant la migration d'un carbone dans l'étape du réarrangement pinacolique, elle conduit d'une façon sélective aux 1-(2-méthoxycyclohexyl)-cyclopentylcarboxaldéhydes épimères au niveau du méthoxy. La réaction du stéréoisomère *E* correspondant est plus complexe et elle conduit à un mélange de produits qui, dans l'étape du réarrangement pinacolique, résultent de migrations tant d'hydrure que de carbone.

Mots clés : cyclisation de Prins, réarrangement pinacolique, cycles attachés.

[Traduit par la Rédaction]

Introduction

Myriad opportunities in ring construction are realized by utilizing a pinacol rearrangement to terminate a Prins cyclization. One of the earliest examples is credited to Mousset and co-workers (1), who discovered serendipitously the synthesis of substituted tetrahydrofurans by acid-promoted reaction of allylic diols with aldehydes. Recent investigations in our laboratory (for brief reviews of our early work in this area, see ref. 2) (3), and elsewhere (for contributions from other laboratories, see ref. 4) have documented the utility of "Prins-pinacol" reactions for forming various oxacyclic and carbocyclic ring systems. We have highlighted the power of this ring construction method by employing it as the key strategic element in the synthesis of natural products having diverse architectures (5). Prins-pinacol reactions have been most widely employed to form fused polycyclic ring systems (2–5), while their use to form spirocyclic rings is less developed (3*i*). Herein we report the first use of a Prins-pinacol reaction to access attached rings, rings linked by a C—C σ-bond (eq. [1]). When the attachment centers are stereogenic,

[1] 

attached rings pose a notable challenge for stereocontrolled synthesis (the insect antifeedant azadirachtin is exemplary, see ref. 6).

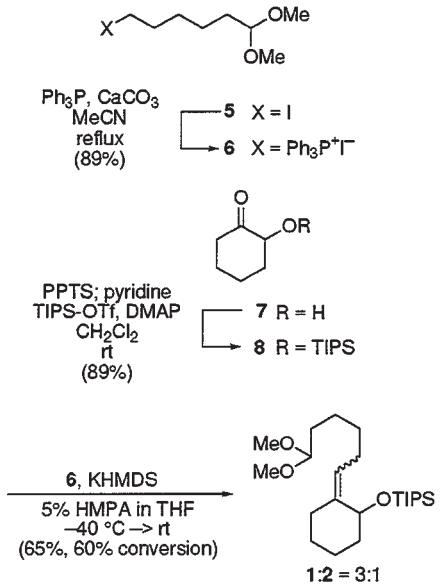
Results



The *Z* and *E* alkylidenecyclohexanes **1** and **2** were chosen for this exploratory investigation (Scheme 1). The stereochemical outcome of the Prins-pinacol reactions studied in our laboratory is accommodated by a sequence in which stereochemistry is dictated in the Prins cyclization step, that is pinacol rearrangement occurs more rapidly than conformational changes of the putative carbocation generated upon Prins cyclization (3*i*). Thus, our initial expectation was that **1** and **2** would cyclize to give aldehyde **3** and ketone **4**, respectively. This prediction follows from the presumption that allylic interactions between the siloxy group and the alkylidene side chain ($A^{1,3}$ strain) would favor cyclization topography **A** for the *Z* substrate (7), while an electronic preference for having an electronegative oxygen substituent in the plane of the nucleophilic alkene π-system would favor topography **C** for the *E* substrate (8).

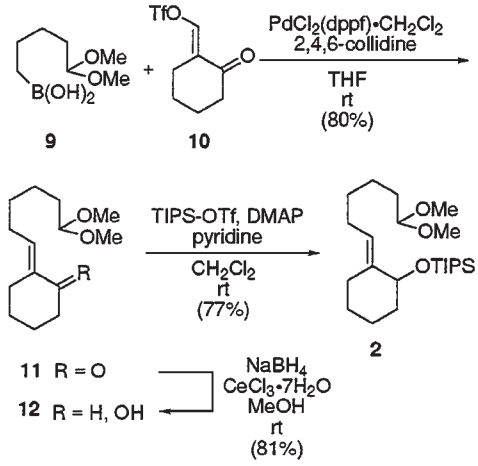
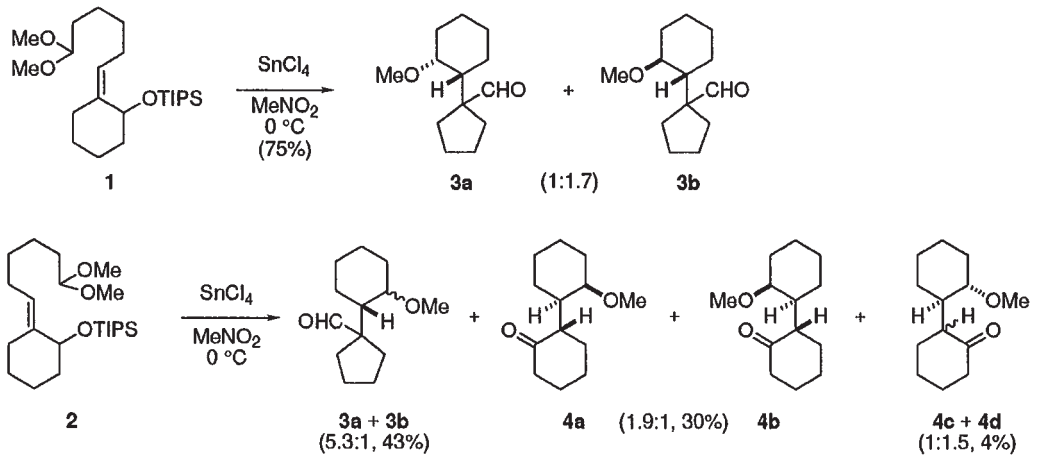


Scheme 1.

Scheme 2.

Scheme 3.

Pinacol rearrangement of carbocation **B** would occur by migration of a ring carbon to yield **3**, since the C_1—H σ-bond is orthogonal to the vacant *p*-orbital, preventing hydride migration. Pinacol rearrangement of carbenium ion **D** would produce **4** if hydride migration occurred in preference to migration of ring bond a (for reviews of the pinacol rearrangement, see ref. (9*a*)). The relative stereochemistry at the stereogenic attached carbons of **4** would be governed by which face of the alkene participated in the transformation of **C** → **D**. Additionally, the stereochemistry of the methoxy substituent in the products would be determined by the orientation of the alkene and the oxocarbenium ion during Prins cyclization. Although our exploratory investigations would be carried out with racemic substrates, one appeal of the route to **4** proposed in Scheme 1 was the expectation that **2** would also be readily available in enantioenriched form.



Alkylidenecyclohexyl ethers **1** and **2** were initially prepared by coupling phosphonium salt **6** (the known iodide **5** (10) was prepared in three steps and 72% yield from 6-bromohexan-1-ol: (*i*) PCC, CH_2Cl_2, rt; (*ii*) *p*-TsOH·H_2O, MeOH, rt; and (*iii*) NaI, acetone, rt) and α-siloxycyclohexanone **8**, utilizing "salt-free" Wittig conditions (11) (Scheme 2). The 3:1 mixture of **1** and **2** thus obtained could be separated by flash chromatography using $AgNO_3$-impregnated silica gel.

A route that would lend itself to obtaining enantioenriched **2** by enantioselective reduction of an enone precursor (12) was also developed (Scheme 3). The key step in this sequence was Suzuki coupling of boronic acid **9** generated in situ from the corresponding alkene (14) by a standard hydroboration–oxidation sequence (13), and enol triflate **10** (15) (although not mentioned in (15), triflate 10 decomposed rapidly at room temperature if 2,4,6-collidine was not present) to give enone **11**. Luche reduction (16) of **11** produced alcohol **12**, which was then silylated to furnish **2**.

^{1}H NMR nOe difference experiments readily confirmed stereochemical assignments for the alkylidene stereoisomers: **2** displayed reciprocal nOe enhancements between the vinylic and C1 hydrogens, while **1** did not. ^{1}H NMR spectra of **1** and **2** suggested somewhat different conformations for the two substrates. Diagnostic were signals for the C1

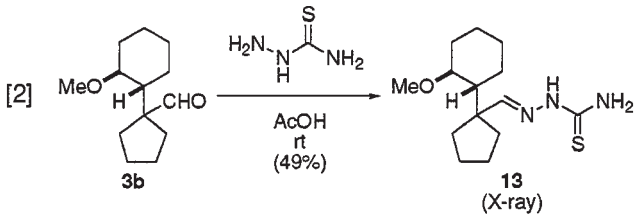
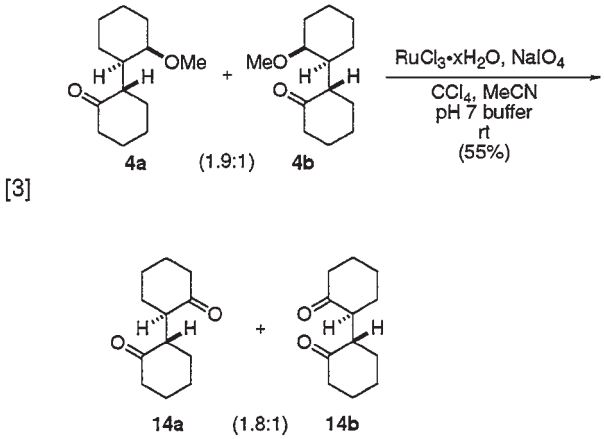


Scheme 4.



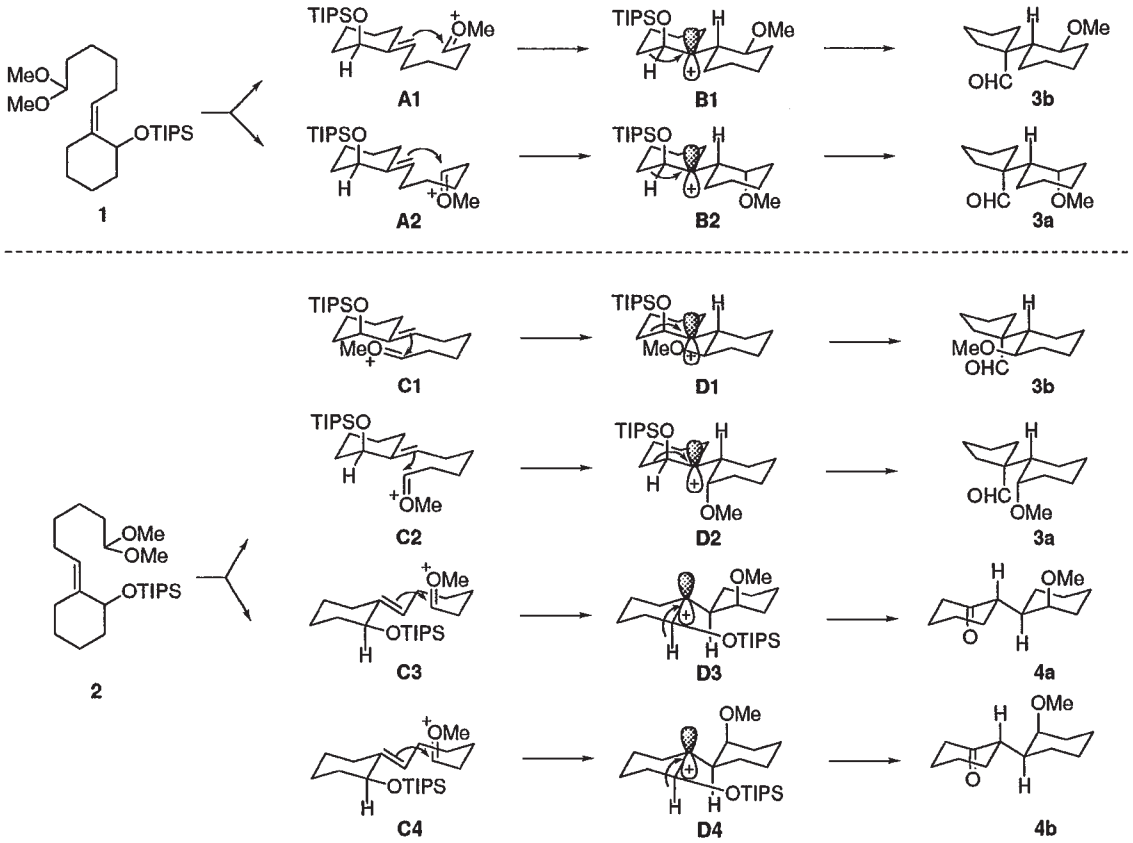
hydrogen, which for **1** appeared as a broad singlet ($w_{h/2}$ = 7.7 Hz) at δ 4.71, whereas the corresponding hydrogen of **2** appeared as a multiplet ($w_{h/2}$ = 15.4 Hz) at δ 4.10. These differences reflect the greater proportion of conformers having the siloxy substituent axial in **1**.

Exposure of **1** or **2** in $MeNO_2$ to 0.5 equiv. of $SnCl_4$ at 0°C for 2 h resulted in efficient Prins-pinacol reaction to give bicyclic products (Scheme 4). No reaction was observed under identical conditions at –23°C. The *Z* alkylidene substrate **1** provided exclusively aldehyde products **3a** and **3b** in a 1:1.7 ratio. In contrast, the *E* alkylidene substrate **2** delivered a complex mixture of six products, in which the ratio of cyclopentylcarboxyaldehyde to cyclohexanone products was 1.3:1. In this latter case, aldehyde stereoisomer **3a** was favored to the extent of 5.3:1, while two major ketone stereoisomers **4a** and **4b** were produced in a 1.9:1 ratio. With the exception of **4a** and **4b**, all products could be separated by medium pressure liquid chromatography (MPLC). The mixture of **4a** and **4b** was contaminated with triisopropylsiloxy residues, thus the yield and ratio of these products are estimates based on ^{1}H NMR analysis.

The stereochemistry of **3a** and **3b** were defined by single-crystal X-ray analysis of thiosemicarbazone derivative **13** prepared from **3b**[2] (eq. [2]). The relative stereochemistry of

the attached stereogenic carbons of **4a** and **4b** was determined by oxidizing (17) a 1.9:1 mixture of these stereoisomers with RuO_4 to yield a 1.8:1 mixture of the known diketones **14a** and **14b** (18) (eq. [3]). These diketones were readily separated by MPLC and characterized by their distinctive ^{1}H and ^{13}C NMR spectra (18). The

axial disposition of the methoxy substituent in **4a** and **4b** was readily apparent from ^{1}H NMR spectra: the ether methine hydrogens in the **4a**–**4b** mixture appear as partially overlapping broad singlets at δ 3.39 and δ 3.36, while the corresponding signals of **4c** and **4d** appear as diagnostic triplet of doublets at δ 3.30 (*J* = 10.3, 4.0 Hz) and δ 2.84 (*J* = 9.7, 4.0 Hz), respectively.



Discussion

The results summarized in Scheme 4 establish that Prins-pinacol reactions can be profitably employed to prepare attached ring systems. However, our initial expectations were realized to only a limited extent. As we had anticipated, the pinacol rearrangement step in the reaction of *Z* alkylidene stereoisomer **1** occurs exclusively by ring contraction (carbon migration) to form 1-(cyclohexyl)cyclopentylcarboxaldehyde products **3** (Scheme 5). Since hydride migration to form ketone products was not observed, conformational conversion of **B1** or **B2** to their pseudoequatorial siloxy counterparts apparently was not competitve with pinacol rearrangement. Attack of the alkene is depicted in Scheme 5

[2] The authors have deposited atomic coordinates for 13 with the Cambridge Crystallographic Data Centre. The coordinates can be obtained, on request, from the Director, Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge, CB2, 1EZ, U.K.

Scheme 5.

to occur opposite the siloxy group in **A1** and **A2**, although there is no experimental support for this supposition. The stereochemical information necessary to define face selectivity is lost since C1 in **3** is not stereogenic.

The generation of both cyclopentylcarboxaldehyde and cyclohexanone products from Prins-pinacol reaction of *E* stereoisomer **2** is consistent with cyclization–rearrangement occurring through pathways of similar energy having the siloxy substituent either pseudoequatorial or pseudoaxial in the starting cyclohexane ring (Scheme 5). If this group is axial, cyclopentylcarboxaldehydes **3a** and **3b** would be formed (**C1** → **D1** → **3b** and **C2** → **D2** → **3a**). Alternatively, Prins cyclization of oxocarbenium ion conformers **C3** and **C4** having the siloxy substituent equatorial, would initially generate cyclohexyl cations **D3** and **D4**. Migration of either the ring bond to generate **3a**, or methine hydrogen to generate **4a** from **D3** (and **4b** from **D4**), is stereoelectronically feasible (the dihedral angle between both of these groups and the vacant *p*-orbital would be ca. 60°C; this analysis assumes that pinacol rearrangement occurs faster than conformational interconversion of the cyclohexylcarbenium ion (3*i*)). The typical preference for hydride migration in stereoelectronically unbiased systems suggest that **4a** and **4b** would be the major products of these latter pathways (for pinacol rearrangements of cyclohexylcarbenium ions, see ref. (9*b*)).

The stereochemistry of the methoxy substituent in aldehydes **3** and ketones **4** reflects the orientation of the alkene and the oxocarbenium ion in the Prins cyclization (Fig. 1). If

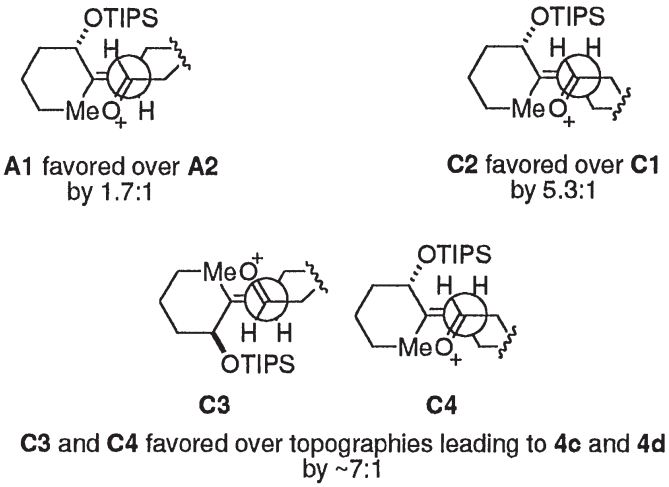

Fig. 1. Favored synclinal orientations in the Prins cyclization step of the exocyclic alkene and the α-alkoxycarbenium ion.

one assumes that the stereoisomeric products are generated by the sequences proposed in Scheme 5, a synclinal orientation (19) having the methoxy portion of the oxocarbenium ion oriented away from the siloxy group is favored in both reaction manifolds (Fig. 1).

Experimental section[3]

2-(Triisopropylsiloxy)cyclohexanone (8)

A mixture of pyridinium *p*-toluenesulfonate (PPTS, 0.22 g, 0.88 mmol), 2-hydroxycyclohexanone (1.0 g, 8.7 mmol), and CH_2Cl_2 (33 mL) was stirred at rt for 3 h. Pyridine (1.1 mL, 14 mmol), triisopropylsilyl triflate (TIPS-OTf, 3.3 mL, 12 mmol), and 4-(dimethylamino)pyridine (DMAP, 0.11 g, 0.92 mmol) were added sequentially and the resulting mixture was stirred at rt for 10 min. The mixture was partitioned between saturated aqueous $NaHCO_3$ (200 mL) and pentane (200 mL), the layers were separated and the organic layer was washed sequentially with H_2O (200 mL), and brine (200 mL), dried ($MgSO_4$), and concentrated. Purification of the residue by column chromatography on silica gel (18:1 hexane–ethyl acetate) gave 2.1 g (89%) of **8** as a clear pale yellow oil. FT-IR (neat): 1727 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$) δ: 4.21–4.16 (m, 1H), 2.68–2.59 (m, 1H), 2.26–2.17 (m, 1H), 2.08–1.58 (m, 6H), 1.15–0.96 (m, 21H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 210.4, 39.7, 37.3, 27.7, 22.2, 17.9, 17.7, 12.2. HRMS (FAB): *m*/*z* 271.2098 (MH, 271.2093 calcd. for $C_{15}H_{31}O_2Si$). Anal. calcd. for $C_{15}H_{30}O_2Si$: C 66.61, H 11.18; found: C 66.70, H 11.12.

***Z*-[2-(6,6-Dimethoxyhexylidene)cyclohexyloxy]triisopropylsilane (1)**

Calcium carbonate (0.81 g, 8.1 mmol), Ph_3P (5.1 g, 19 mmol), and CH_3CN (5.0 mL) were added sequentially to iodide **5** (10, 11, 24) (4.4 g, 16 mmol). After bubbling N_2 through the mixture for 5 min, the mixture was heated to reflux. After stirring for 2.5 h, the mixture was cooled to rt and concentrated. The crude product was purified by column chromatography on neutral alumina (sequential elution, 1:1 hexane–ethyl acetate, to isolate excess Ph_3P; 18:1 CH_2Cl2–MeOH, to isolate **6**) to give 7.7 g (89%) of slightly impure **6** as a hygroscopic and colorless waxy solid. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.75–7.61 (m, 15H), 4.21 (t, *J* = 5.5 Hz, 1H), 3.57–3.48 (m, 2H), 3.19 (s, 6H), 1.59–1.23 (m, 8H). HRMS (CI): *m*/*z* 407.2131 (M–I, 407.2140 calcd. for $C_{26}H_{32}O_2P$).

Using a modified version of the general procedure of Koreeda et al. (12), potassium bis(trimethylsilyl)amide (KHMDS, 30 mL, 15 mmol, 0.5 M solution in toluene) was added to a solution of phosphonium salt **6** (7.4 g, 14 mmol) in THF (83 mL) and hexamethylphosphoramide (HMPA, 9.2 mL) at –40°C. After stirring the resulting mixture for 10 min, a cooled (–40°C) solution of **8** (1.9 g, 9.9 mmol) and THF (7.7 mL) was added, and the cooling bath was removed. After 1 h, saturated aqueous $NaHCO_3$ (100 mL) and hexanes (200 mL) were added and the layers were separated. The organic layer was washed sequentially with saturated aqueous $NaHCO_3$ (200 mL), 10% aqueous $Na_2S_2O_3$ (200 mL), H_2O (100 mL), brine (100 mL), dried ($MgSO_4$), and concentrated. The crude product was purified by column chromatography on $AgNO_3$-impregnated silica gel (9:1 CH_2Cl_2–benzene), yielding 0.92 g of a mixture of **1** and **8** and 0.13 g of a mixture of **1** and **2**.

Pure **1** was obtained from the mixture of **1** and **8** as follows. Sodium borohydride ($NaBH_4$, 41 mg, 1.1 mmol) was added to a solution of the **1**–**8** mixture (0.92 g) and MeOH (5.0 mL). After stirring for 20 min, saturated aqueous $NaHCO_3$ (5 mL) and hexanes (100 mL) were added, the organic layer was washed with saturated aqueous $NaHCO_3$ (3 × 50 mL) and brine (100 mL), dried ($MgSO_4$), and concentrated. The silyl ether protecting group of the diols derived from **8** was then selectively removed (to facilitate isolation of pure **1**) by maintaining a solution of this residue, tetra-*n*-butylammonium fluoride (TBAF, 0.86 mL, 0.86 mmol, 1.0 M solution in THF), and THF (5.0 mL) at rt for 12 h. Saturated aqueous $NaHCO_3$ (10 mL) and hexanes (70 mL) were added, the organic layer was washed with saturated aqueous $NaHCO_3$ (5 × 50 mL), brine (50 mL), dried ($MgSO_4$), and concentrated. The crude product was purified by column chromatography on silica gel (18:1 hexane–ethyl acetate) to give 0.70 g (42%, 3 steps, 60% conversion during Wittig coupling) of **1** as a clear yellow oil. ^1H NMR (300 MHz, $CDCl_3$) δ: 5.01 (t, *J* = 6.9 Hz, 1H), 4.71 (br s, 1H), 4.35 (t, *J* = 5.6 Hz, 1H), 3.31 (s, 6H), 2.50–2.45 (m, 1H), 2.03–1.22 (m, 15H), 1.04–0.93 (m, 21H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 141.8, 121.5, 104.4, 66.0, 52.6, 52.5, 36.1, 32.4, 30.0, 28.9, 27.0, 24.4, 20.5, 18.1, 18.0, 12.3. FT-IR (neat): 2938, 2864 cm^{-1}. HRMS (FAB): *m*/*z* 397.3148 (M–H, 397.3138 calcd. for $C_{23}H_{45}O_3Si$). Anal. calcd. for $C_{23}H_{46}O_3Si$: C 69.29, H 11.63; found: C 69.38, H 11.53.

***E*-[2-(6,6-Dimethoxyhexylidene)]cyclohexanone (11)**

A mixture of 9-borabicyclo[3.3.1]nonane (9-BBN, 2.5 g, 10 mmol) in THF (65 mL) was added to a solution of 1,1-dimethoxypent-4-ene (15) (2.4 mL, 16 mmol) and THF (21 mL) at 0°C, and the cooling bath was removed. After stirring for 6 h, 3 M aqueous NaOH (7.6 mL, 23 mmol) was added, and after stirring vigorously for an additional 15 min, the crude organoborane was added by cannula to a solution of triflate **10** (2.1 g, 8.3 mmol), 2,4,6-collidine (3.0 g, 25 mmol), $PdCl_2(dppf)\bullet CH_2Cl_2$ (0.93 g, 1.1 mmol), and THF (40 mL). After stirring for 30 min, the reaction mixture was partitioned between pentane (200 mL) and H_2O (200 mL) and the layers were separated. The organic layer was washed sequentially with saturated aqueous $CuSO_4$ (3 × 200 mL), saturated aqueous $NaHCO_3$ (200 mL), and brine (200 mL), dried ($MgSO_4$), and concentrated. The residue was triturated with pentane and the filtrate was concentrated. The crude product was purified by column chromatography on silica gel (5:1 hexane–ethyl acetate) to give 2.2 g (80%) of **11** as a clear pale yellow oil. ^1H NMR (300 MHz, $CDCl_3$) δ: 6.58 (t, *J* = 7.5 Hz, 1H), 4.32 (t, *J* = 5.7 Hz, 1H), 3.28 (s, 6H), 2.46–2.37 (m, 4H), 2.08 (q, *J* = 7.3 Hz, 2H), 1.86–1.30 (m, 10H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 201.1, 139.2, 136.2, 104.3, 52.6, 40.1, 32.2, 28.2, 27.6, 26.6, 24.3, 23.5, 23.3. 1594, 1534 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$) δ: 8.99 (br s, 1H), 7.33 (s, 1H), 7.03 (br s, 1H), 6.26 (br s, 1H), 3.47 (br s, 1H), 3.19 (s, 3H), 2.13–1.92 (m, 3H), 1.76–1.13 (m, 14H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 177.8, 154.8, 77.2, 55.5, 53.3, 52.9, 34.8, 34.7, 28.1, 26.5, 23.7, 23.4, 19.8. HRMS (CI): *m*/*z* 283.1712 (M, 283.1718 calcd. for $C_{14}H_{25}N_3OS$). Anal. calcd. for $C_{14}H_{25}N_3OS$: C 59.33, H 8.89, N 14.83; found: C 59.45, H 8.86, N 14.71.

(±)-*rel*-*S*,*S*-[1-(2-Methoxycyclohexyl)cyclopentylmethylene]thiosemicarbazone (13)

The procedure followed was identical to that described for **3a**; **3b** gave 0.088 g (49%) of **13** as a colorless solid, mp 168–170°C. FT-IR (KBr): 3430, 3269, 3142, 1589, 1522 cm^{-1}. ^1H NMR (300 MHz, $CDCl_3$) δ: 10.03 (br s, 1H), 7.29 (s, 1H), 7.05 (d, *J* = 3.0 Hz, 1H), 6.68 (br s, 1H), 3.21 (s, 3H), 2.76 (td, *J* =10.0, 3.9 Hz, 1H), 2.13–1.93 (m, 3H), 1.84–0.91 (m, 14H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 177.4, 154.8, 82.1, 55.4, 52.7, 52.1, 36.4, 32.6, 31.2, 27.3, 25.8, 24.5, 24.2, 23.2. HRMS (CI): *m*/*z* 283.1719 (M, 283.1718 calcd. for $C_{14}H_{25}N_3OS$). Anal. calcd. for $C_{14}H_{25}N_3OS$: C 59.33, H 8.89, N 14.83; found: C 59.36, H 8.84, N 14.72.

Conclusions

This study constitutes the first investigation of the use of pinacol-terminated Prins cyclizations to form attached rings. In the *Z* alkylidenecyclohexane series, the approach is synthetically useful, proceeding selectively by a pathway involving carbon migration, to provide methoxy epimers of 1-(2-methoxycyclohexyl)cyclopentylcarboxaldehyde. Reaction of the corresponding *E* stereoisomer is more complex and yields a mixture of products resulting from both hydride and carbon migration. Future efforts to exploit this novel approach to the synthesis of attached rings should focus on *Z* alkylidene substrates.

Stereoselective synthesis of renin inhibitor BILA 2157 BS

Bruno Simoneau, Pierre Lavallée, Murray Bailey, Jean-Simon Duceppe, Chantal Grand-Maître, Louis Grenier, William W. Ogilvie, Marc-André Poupart, and Bounkham Thavonekham

Abstract: We have developed a convergent and stereoselective synthesis of orally active renin inhibitor **BILA 2157 BS**. Three building blocks were used to generate the basic skeleton of the inhibitor. The key feature consisted of the late elaboration of the 2-amino-4-thiazolyl heterocycle from a vinylbromide precursor. The synthetic sequence, which required a total of 22 chemical steps, provided 0.6 kg of **BILA 2157 BS** in 7.3% overall yield.

Key words: renin, inhibitor, peptidomimetic, stereoselective synthesis.

Résumé: On a développé une synthèse convergente et stéréosélective de **BILA 2157 BS**, un inhibiteur de la rénine actif oralement. Trois synthons ont été utilisés pour assembler le squelette de base de l'inhibiteur. L'élaboration tardive de l'hétérocycle, le 2-amino-4-thiazolyl, à partir d'un précurseur bromovinyl a constitué l'étape clé de l'approche utilisée. La synthèse, qui a requis un total de 22 transformations chimiques, a fourni 0.6 kg de **BILA 2157 BS** avec 7.3% de rendement.

Mots clés : rénine, inhibiteur, peptido-mimétique, synthèse stereosélective.

Introduction

Renin, an aspartyl protease, catalyzes in the first and rate-limiting step of the renin–angiotensin cascade (1). Renin cleaves its substrate angiotensinogen to generate angiotensin I, a decapeptide, that is in turn processed to angiotensin II by the angiotensin converting enzyme (ACE). Angiotensin II is one of the most potent vasoconstrictors known. The success of ACE inhibitors in the treatment of hypertension has been an incentive for the search for other modes of intervention in the same cascade. Considerable efforts were invested in the search for orally active renin inhibitors (1) and angiotensin II antagonists (2). Our own efforts led to the identification of **BILA 2157 BS**, a potent and specific inhibitor of human renin (3). This inhibitor exhibited IC_{50} values of 1.4 and 2.7 nM in human plasma renin assays at pH 6.0 and 7.4 respectively. **BILA 2157 BS** was selected as a candidate for pre-development based on its high in vivo efficacy in a primate model of hypertension. This compound was orally active at a dose of 3 mg/kg in conscious sodium depleted cynomolgus monkeys and possessed an outstanding oral bioavailability of 40% in cynomolgus monkey. A large amount of **BILA 2157 BS** was required for toxicity studies. We report here an improved synthetic sequence for the preparation of **BILA 2157 BS** on a 0.6 kg scale.

Discussion

BILA 2157 BS is a non-peptidic renin inhibitor that contains four stereogenic centers. Three of them are located in the transition state analog moiety (P_1-P_1') and one is located on the P_2-P_3 butanediamide segment. A convergent approach based on three key fragments was originally used in medicinal chemistry to provide the inhibitor in 23 steps and in about 6% yield overall (Scheme 1). This synthetic approach, developed for structure-activity relationship studies, was utilized for the preparation of inhibitors on a relatively small scale (from 100 mg to a few grams).

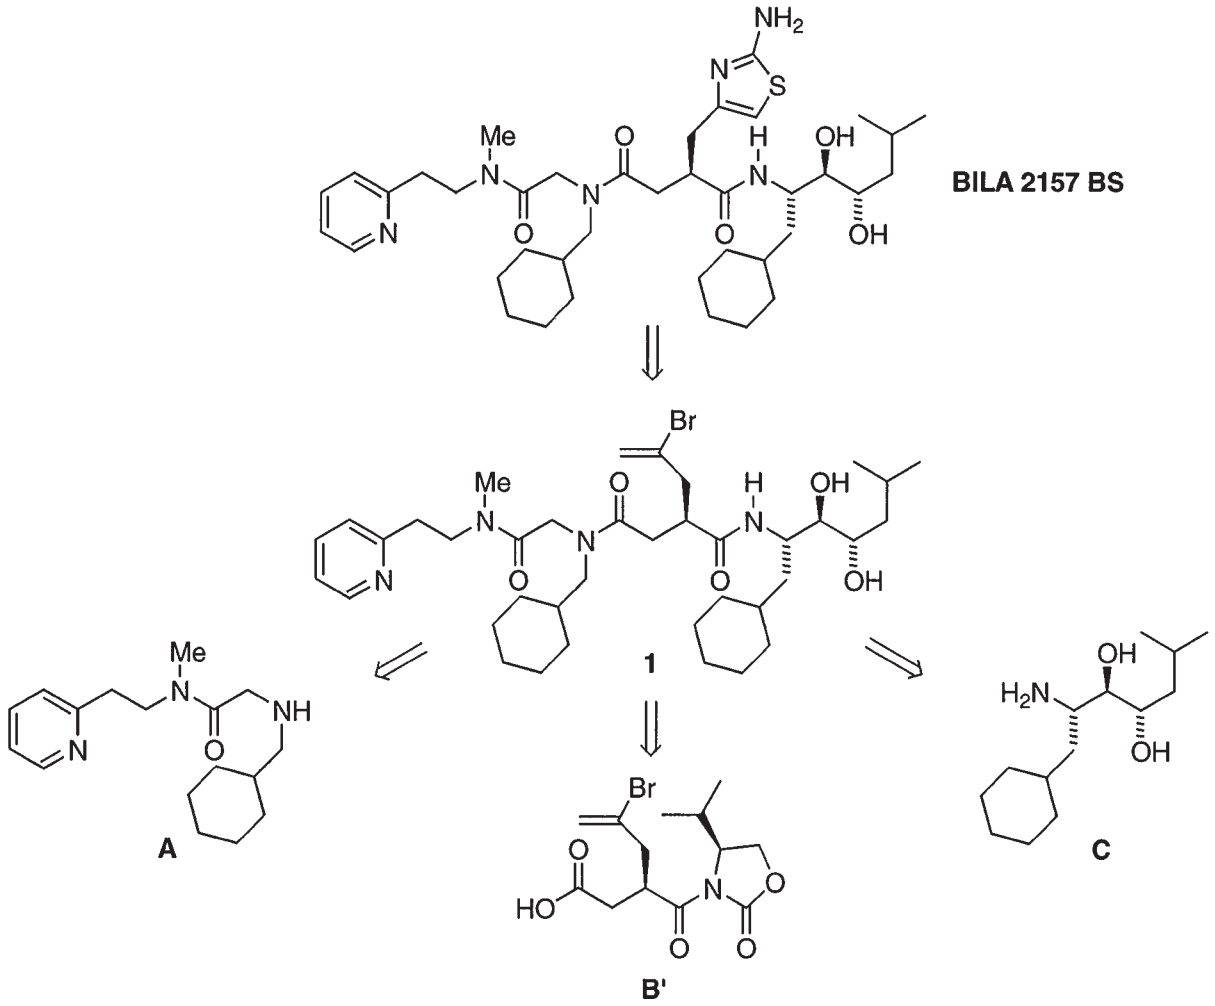
In the analysis of the original synthesis (3), we realized that some critical problems had to be considered and solved for the preparation of hundreds of grams of **BILA 2157 BS**. We considered that the fragments **A** and **C** (4, 5) could be amenable to kilogram scale preparation using the existing synthetic sequences. In contrast, the use of diazomethane in the preparation of fragment **B** should preferably be avoided on large scale. In addition, the use of the rather expensive chiral oxazolidinone was also a pertinent question although it provided high diastereoselectivity and could be recycled. The major drawback of this synthesis was the concomitant formation of the 2(*S*)-butanediamide epimer (5 to 10%) in the coupling of the **A**-**B** acid unit to **C**, which made purification of the trichloroethyl carbamate derivative, or **BILA**

 © 2000 NRC Canada

Scheme 1. Original synthesis of **BILA 2157 BS**.

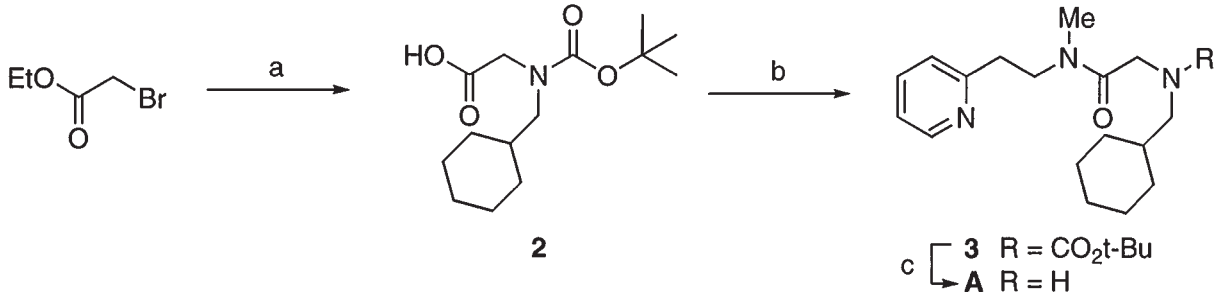
2157 BS itself, extremely difficult. Since these two compounds were amorphous solids, chromatography was the only solution for removal of this undesired side product. The separation and purification could be achieved on a gram scale but was considered to be impractical on large amounts. The formation of salts of **BILA 2157 BS** did not produce any crystalline salt and was complicated by the presence of products resulting from *N*,*O*-acyl shift of the aminodiol portion (6).[3] A potential solution to the problem generated by the presence of the 2(*S*)-butanediamide epimer came from the observations made during the optimization of the P_2 side-chain of the inhibitors. During these studies, we realized that neutral side-chains such as cyclopropylmethyl or thienylmethyl produced very low levels of the undesired epimer at C-2 of the 4-oxo-4-substituted aminobutanoic acids. It was therefore decided to delay the introduction of the 2-amino-4-thiazolyl heterocycle until the end of the synthesis while maintaining a convergent approach.

As a result of this exercise, we selected synthon **B′** (Scheme 2), which had a 2-bromo-2-propenyl substituent in contrast to the synthon **B** utilized in the first approach. The bromovinyl moiety could be easily converted into the corresponding bromoketone with aqueous NBS (7) and finally into the 2-amino-4-thiazolyl heterocycle with thiourea (Hantzsch's synthesis). For reason of expediency, the Evans' alkylation method was retained for the control of the formation of the lone stereogenic center of **B′**. While this approach was sufficient for the short term and the scale of the sequence, alternative strategies were examined in parallel to address the long-term practicality and cost efficiency of installing this stereogenic center. The new global strategy used for the preparation of **BILA 2157 BS** is outlined in Scheme 2.



Results

Fragment **A** was prepared using basically the same five-step synthetic sequence that was used on small scale (Scheme 3). The first three chemical steps were combined into a one-pot procedure. Cyclohexanemethylamine was first alkylated with ethyl 2-bromoacetate in the presence of Et_3N in THF. On a kilogram scale, the reagents were mixed at



[3] For a detailed analysis of *N*,*O*-acyl transfer on a related compound, see reference 6.

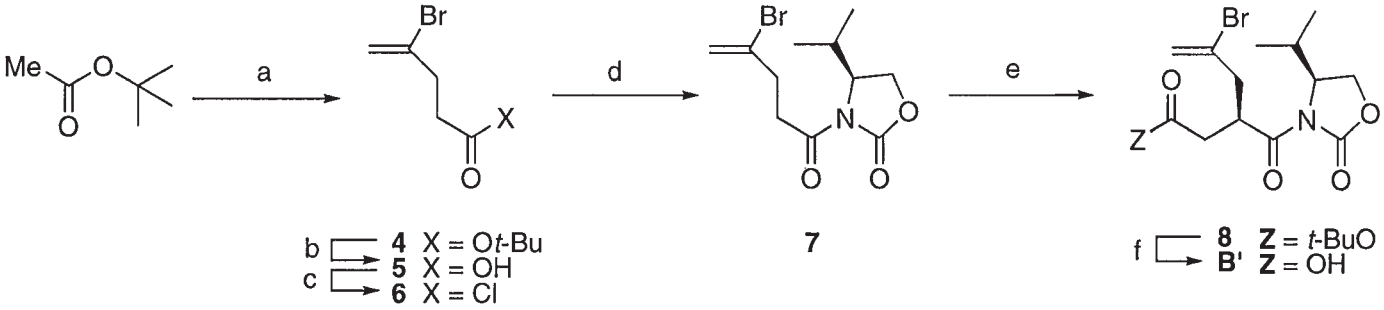
Scheme 2. Retrosynthetic analysis of **BILA 2157 BS**.



Scheme 3. Synthesis of amine **A**. Reagents and conditions: (*a*) (*c*-C_6H_{11})CH_2NH_2, Et_3N, THF, 25°C then $(BOC)_2O$, 25°C then aq. 2 N NaOH, 25°C, 70%; (*b*) $(CH_3)_3CCOCl$, Et_3N, THF then 2-pyr$(CH_2)_2$NHMe, 0 to 15°C; (*c*) 4 N HCl, dioxane, 25°C, 87% from **2**.

–50°C but the reaction occurred smoothly at 25°C. The resulting secondary amine was then transformed into the BOC derivative by simple addition of $(BOC)_2O$ to the reaction mixture. Finally, aqueous NaOH was introduced to saponify the ethyl ester. Acid **2** was isolated in 70% yield by a simple acid-base extraction procedure. The by-products generated in the course of the three-step sequence consisted of *N*-(cyclohexylmethyl)-*N*-(carboxymethyl)glycine (ca. 5%) and *tert*-butyl *N*-(cyclohexylmethyl)carbamate (ca. 5%). The former resulted from the double alkylation of cyclohexanemethylamine by ethyl 2-bromoacetate and subsequent ester hydrolysis while the second came from reaction of the remaining cyclohexanemethylamine with $(BOC)_2O$. Both of these by-products were easily eliminated in the extractive work-up. The coupling of commercially available 2-[2-(methylamino)ethyl]pyridine with the mixed anhydride derived from acid **2** and pivaloyl chloride gave amide **3**. After cleavage of the BOC protective group of **3** with 4 N HCl in dioxane and neutralization of the resulting hydrochloride salt, amine **A** was isolated in 87% yield from acid **2**. This

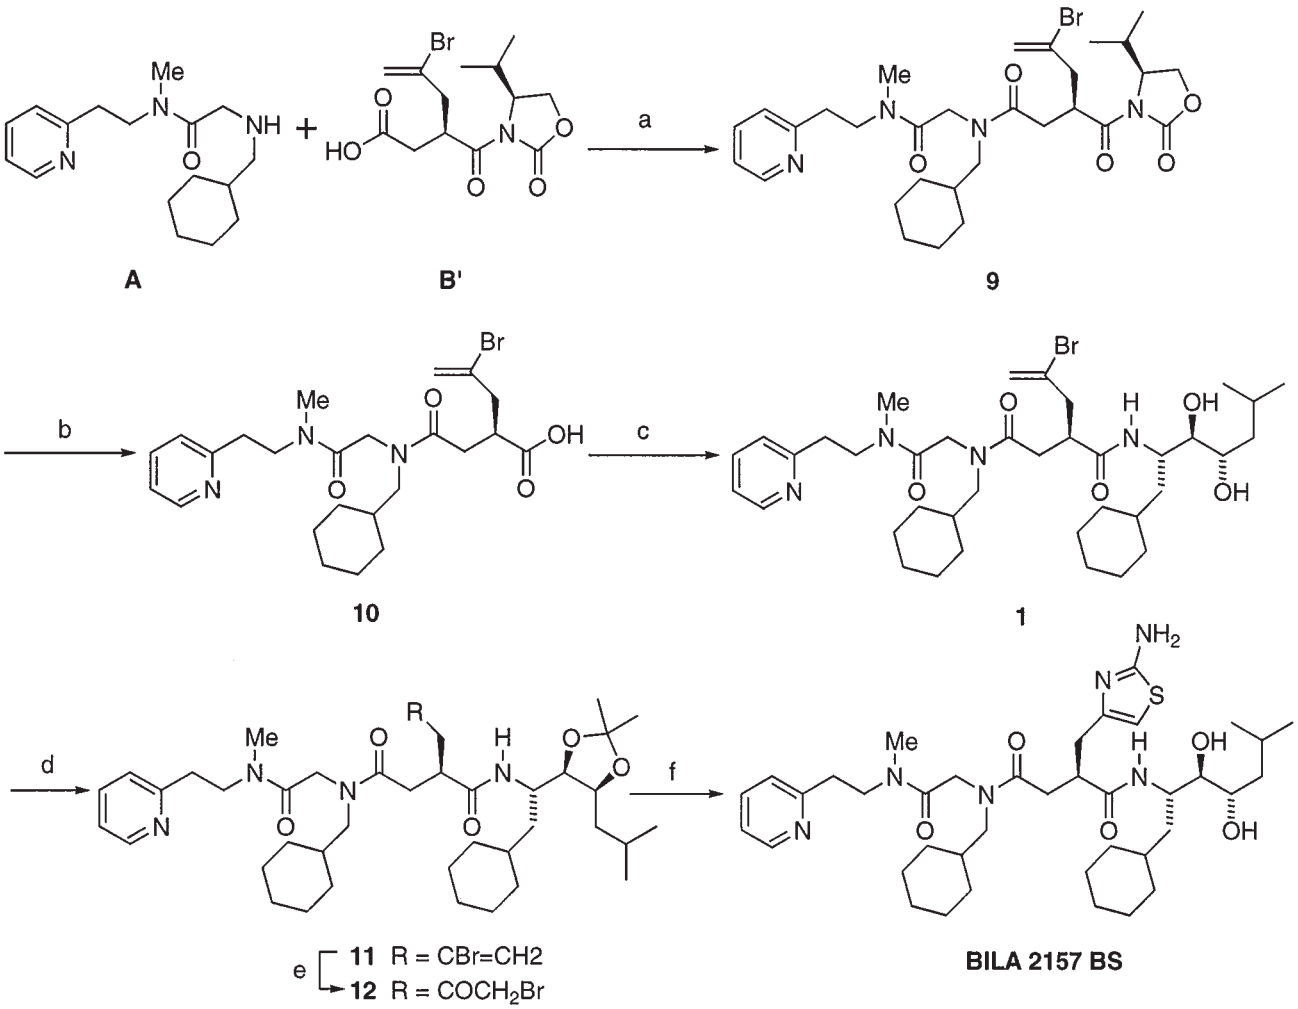
Scheme 4. Preparation of fragment **B′**. Reagents and conditions: (*a*) LDA, THF, –78°C then CH_2=$CBrCH_2Br$, 64%; (*b*) 4 N HCl, dioxane, 25°C, 82%; (*c*) $(COCl)_2$, DMF cat., CH_2Cl_2, 0 to 25°C, 99%; (*d*) Lithium 4(*S*)-$((CH_3)_2CH)$-2-oxazolidinone, THF, –78°C; (*e*) NaHMDS, THF, –78°C then $BrCH_2CO_2t$-Bu, 53% from **6**; (*f*) 4 N HCl, dioxane, 25°C, 100%.

sequence produced 1.16 kg of **A**, a viscous oil, in 60% yield overall. The crude product was of sufficient purity (>97% by HPLC) for direct use in the assembly sequence.

Fragment **B′** was prepared from *tert*-butyl acetate in six steps as described in Scheme 4. The lithium enolate of *tert*-butyl acetate was first alkylated with 2,3-dibromo-1-propene at –78°C to provide *tert*-butyl 4-bromo-4-pentenoate (**4**) in 64% yield after purification by distillation. Treatment of ester **4** with 4 N HCl in dioxane gave acid **5** in 82% yield. Although it was not used for this particular synthesis, we found that **5** could also be obtained in three steps (54% yield overall) from the alkylation of dimethyl malonate with 2,3-dibromo-1-propene in the presence of sodium methoxide in methanol, followed by the usual saponification and decarboxylation reactions. Acid **5** was then converted into acyl chloride **6** using oxalyl chloride.

Reaction of crude acyl chloride **6** with the lithium salt of 4(*S*)-(1-methylethyl)-2-oxazolidinone provided acyl oxazolidinone **7** which was used without any purification in the Evans' alkylation reaction (8). The sodium enolate of acyl oxazolidinone **7** was treated with *tert*-butyl 2-bromoacetate to give, after purification by crystallization, **8** in 53% yield (from acid **5**). The diastereomeric excess was greater than 99% as determined by HPLC. The high crystallinity of **8** (the compound crystallized from the reaction mixture as soon as it was formed) and its ease of preparation facilitated its use on a scale of hundreds of grams. Finally, the *tert*-butyl ester was cleaved using 4 N HCl in dioxane to give acid **B′** in quantitative yield. A total of 1.27 kg of acid **B′** was obtained in 28% yield overall from *tert*-butyl acetate.

Fragment **C** was prepared from *N*-BOC-cyclohexylalaninol using the five-step procedure described by Abbott scientists (4, 5). The required 0.7 kg of **C** was obtained in two batches in 25% overall yield. The cyanohydrin route was preferred to the one using an osmylation reaction.



The assembly of the three fragments and the transformation of the bromovinyl moiety into the 2-amino-4-thiazolyl heterocycle required six steps (Scheme 5). The mixed anhydride generated by the treatment of acid **B′** with *iso*-butyl chloroformate at –40°C was treated with amine **A** to give **9**. Cleavage of the chiral auxiliary using LiOOH (9) at 0°C provided the corresponding acid **10** in 77% yield for the two steps. Acid **10** was contaminated with a small amount of the chiral auxiliary (2% w/w), which was not detrimental to the next step. The coupling of acid **10** and aminodiol **C** was the key step of our synthetic strategy. We had envisaged that having a 2-bromo-1-propenyl side-chain, the coupling of **10** and **C** should not produce large amounts of the 2(*R*)-butanediamide epimer as had been observed when a protected 2-amino-4-thiazolylmethyl group was used. In the original synthetic sequence (Scheme 1), the presence of this epimer made the purification difficult even on a small scale. We have therefore investigated many reagents for the coupling of **10** and **C** and found, as expected, only a small amount of the unwanted 2(*R*)-butanediamide epimer (<1%) in each case. For convenience, TBTU was selected as the coupling agent. Starting with 1.4 kg of **10** and 0.70 kg of **C**, the coupling occurred smoothly with TBTU to give **1**. In contrast to **BILA 2157 BS**, **1** was crystalline and was purified by recrystallization to give a 69% yield of highly pure material (>98%, HPLC). In the process, the small amount of the 2(*R*)-epimer (ca. 0.5%) was completely removed and the sole detectable impurity consisted of the corresponding pyridine *N*-oxide (0.3%, HPLC). This impurity was probably formed by oxidation with the peracid intermediate generated in situ during the cleavage of the chiral auxiliary. In addition to controlling the amount of the 2(*R*)-epimer, compound **1**, which had the basic skeleton of **BILA 2157 BS**, turned out to be a very valuable crystalline intermediate.

The last requirement for the completion of the synthesis was the transformation of the vinylbromide moiety present in **1** into the 2-amino-4-thiazolyl heterocycle. Attempts to generate the required bromoketone from **1** with aqueous NBS in the presence of the diol resulted in a complex mixture. The diol was therefore protected using 2-methoxypropene in the presence of PPTS to give acetonide **11** in quantitative yield.

Using acetonide **11**, transformation of the vinylbromide into bromoketone **12** occurred smoothly with NBS (7, 10) in aqueous acetonitrile. The rather unstable bromoketone **12** was not isolated. Instead, the small excess of remaining NBS in the reaction mixture was quenched by the addition of 2-methoxypropene followed by treatment with thiourea to generate the 2-amino-4-thiazolyl ring, which was produced as the hydrobromide salt. Upon heating to complete the heterocycle formation, the HBr catalyzed the concomitant hydrolysis of the acetonide to provide **BILA 2157 BS**. This final sequence, the formation of the bromoketone, the elaboration of the heterocycle, and finally the hydrolysis of the acetonide could be achieved efficiently in a one-pot operation. Using acid-base extraction procedures and precipitation, **BILA 2157 BS** was obtained in 93% homogeneity as determined

Scheme 5. Synthesis of **BILA 2157 BS**. Reagents and conditions: (*a*) $ClCO_2i$-Bu, Et_3N, THF, –40 to 25°C, 100%; (*b*) LiOOH, THF-H_2O, 0°C, 77%; (*c*) TBTU, *i*-Pr_2NEt, **C**, MeCN, 0 to 25°C, 70%; (*d*) CH_2=CMe(OMe), PPTS, CH_2Cl_2, 25°C; (*e*) NBS, aq. MeCN, 25°C; (*f*) thiourea, 25°C to Δ, 50% from **11**.

by HPLC. Since the compound could not be purified further by conventional extractive or crystallization procedures, **BILA 2157 BS** was filtered through a column of silica gel. A total of 0.59 kg of **BILA 2157 BS** of high purity (homogeneity >99% by HPLC) was obtained for a 50% yield from **1**.

Conclusions

The original synthetic sequence leading to **BILA 2157 BS** was improved in order to generate 0.6 kg of this renin inhibitor for preliminary toxicity studies. Three building blocks, readily accessible from commercially available starting materials, were used to generate the basic skeleton of the inhibitor. The key modification consisted in the late stage elaboration of the 2-amino-4-thiazolyl heterocycle from a vinylbromide precursor. This modification allowed us to eliminate the purification problems due to the formation of the undesired 2-substituted butanediamide epimer in the original sequence. A valuable advanced crystalline intermediate, compound **1**, was also generated as a result of this strategic decision. While the synthetic sequence required 22 distinct chemical steps, a few multi-step one-pot operations were implemented to generate **BILA 2157 BS** in 7.3% yield. Nevertheless, this convergent and stereoselective synthesis has to be further improved in a cost related fashion for multikilogram scale. The most important issue concerns the fragment **B′**. Alternatives for the use of an expensive chiral auxiliary and three low temperature operations for its preparation are needed. Optimization of the reactions transforming key crystalline intermediate **1** into **BILA 2157 BS** should also help to facilitate final purification and eliminate the sole chromatographic purification. Work is well underway to improve the 22-step sequence described here and the results will be described elsewhere.

Experimental section

All reactions were performed under a nitrogen atmosphere. Reagents and anhydrous solvents were obtained from commercial sources and were used without further purification or treatment. Melting points were determined on an electrothermal Büchi 510 apparatus and are uncorrected. NMR spectra were recorded on a Bruker AMX400 spectrometer.

© 2000 NRC Canada

Optical rotations were measured on a Perkin–Elmer 241 polarimeter. IR spectra were recorded on a Perkin–Elmer 781. Fast atom bombardment (FAB) mass spectra were determined on a VG AutoSpec-Q or Kratos M550 apparatus at the Université de Montréal mass spectrometry center. Microanalyses were performed on a Carlo Erba 1100 or Fisons EA 1108 instruments. Residual amounts of H_2O were quantified using the Karl Fisher method with a Metrohn 652 KF-coulometer. RP-HPLC analyses were performed on a Waters 600-MS system (A: Supelcosil™ LC-ABZ; MeCN + 0.1% TFA–H_2O + 0.1% TFA) and (or) a Waters 625 system (B: Nova-Pak™ C_8 column; MeCN–NaH_2PO_4 50 mM, pH 4.4) using a photodiode array detector.

1,1-Dimethylethyl N-*(carboxymethyl)*-N-*(cyclohexylmethyl)carbamate (**2**)*: To a cold (–50°C) solution of Et_3N (1398 g, 13.88 mol) and cyclohexanemethylamine (783 g, 6.91 mol) in THF (4 L) was added ethyl 2-bromoacetate (1.156 kg, 6.91 mol) over 5 min. The cold bath was removed and after 25 min the mixture was diluted with THF (4 L). Stirring was maintained for an additional 2.5 h at room temperature. After cooling to 10°C, $(BOC)_2O$ (1.52 kg, 6.98 mol) was added at such a rate so as to maintain the internal temperature below 25°C. After 2 h, a solution of NaOH (1.10 kg) in H_2O (4.5 L) was added slowly, followed by MeOH (800 mL), and the mixture was left stirring overnight. The volatiles were removed under reduced pressure, the oily residue was diluted with water (8 L), and the mixture washed with hexane (2 × 4 L). The aqueous solution was acidified with citric acid (1.27 kg) and extracted with EtOAc (3 × 2 L). The combined organic extracts were washed successively with 10% citric acid solution (1 L), water (3 L), and brine (2 L). The solution was then dried ($MgSO_4$) and concentrated under reduced pressure to give acid **2** (1.32 kg, 70%) as a yellow solid: mp 78.5–80.5°C; IR (KBr) ν_{max}: 3120–2540, 1730, 1690 cm^{-1}; ^1H NMR ($CDCl_3$) δ: (*1.3*:1.0 mixture of rotamers) *3.97*, 3.90 (2s, 2H), 3.11 (broad d, J = 6.4 Hz, 2H), 1.73–1.67 (m, 5H), 1.56–1.47 (m, 1H), *1.47*, 1.43 (2s, 9H), 1.27–1.14 (m, 3H), 0.94–0.89 (m, 2H); ^{13}C NMR ($CDCl_3$) δ: 175.6, 175.1, 156.5, 155.5, 80.5, 80.3, 54.7, 54.5, 49.8, 49.2, 37.1, 36.9, 30.8, 30.7, 28.3, 28.2, 26.4, 25.8; MS (CI) *m*/*z*: 272 (MH^+). Anal. calcd. for $C_{14}H_{25}NO_4$: C 61.99, H 9.20, N 5.16; found: C 61.99, H 9.45, N 5.26.

1,1-Dimethylethyl N-*[2-[methyl[2-(2-pyridinyl)ethyl]amino]-2-oxoethyl]*-N-*(cyclohexylmethyl)carbamate (**3**)*: To an ice-cold solution of acid **3** (1.31 kg, 4.84 mol) in THF (8 L) was added Et_3N (745 mL, 5.34 mol) over a period of 5 min. The mixture was stirred until the temperature reached 5°C and then, trimethylacetyl chloride (565 g, 4.69 mol) was added dropwise over 45 min. After stirring the pale yellow suspension at 5–10°C for 1 h, 2-[(2-methylamino)ethyl]pyridine (625 g, 4.58 mol) was added slowly over 45 min. The mixture was stirred at 15°C for 2.5 h, then diluted with H_2O (4 L) and extracted with EtOAc (7 × 1 L). The combined organic extracts were washed with saturated $NaHCO_3$ solution (2 × 1 L), H_2O (1 L), brine (2 × 1 L), dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The residue was further dried under reduced pressure overnight to afford **3** as a viscous liquid (2.16 kg, 121% mass recovery) containing H_2O (1.74% w/w) and EtOAc (2% w/w, determined by ^1H NMR): ^1H NMR ($CDCl_3$) δ: (3:3:1:1 mixture of rotamers) 8.60–8.58, 8.54 (m and d, J = 4.5 Hz, 1H), 7.64–7.60 (m, 1H), 7.26–7.13 (m, 2H), 3.98, 3.90, 3.89, 3.80 (4s, 2H), 3.74–3.68 (m, 2H), 3.12–2.97, 2.93, 2.92 (m and 2s, 7H), 1.73–1.60 (m, 5H), 1.58–1.44 (m, 1H), 1.47, 1.45, 1.41, 1.40 (4s, 9H), 1.28–1.14 (m, 3H), 0.98–0.84 (m, 2H); MS (FAB) *m*/*z*: 390 (MH^+). The crude product was used directly in the next step.

2-[(Cyclohexylmethyl)amino]-N-*methyl*-N-*[2-(2-pyridinyl)ethyl]-acetamide (**A**)*: To an ice-cold solution of crude **3** (2.16 kg, 4.59 mol) in 1,4-dioxane (1.5 L) was slowly added over 75 min a 4 N solution of HCl in 1,4-dioxane (4 L). The light yellow suspension was stirred at ambient temperature for 3 h leaving a gummy precipitate at the bottom of the flask. The solvent was then removed and the precipitate solubilized in H_2O (7 L). The resulting solution was cooled to 0°C, rendered basic with NaOH (550 g), and extracted with ether (2 × 1.5 L) and EtOAc (3 × 1.5 L). The combined organic extracts were washed with H_2O (1 L), brine (1 L), dried (Na_2SO_4), filtered, and concentrated under reduced pressure. The residue was further dried under reduced pressure (0.5 mm Hg, 6 h) to afford the amine **A** as a brownish oil (1.16 kg, 84% from **2**) contaminated with 1,4-dioxane (0.3% w/w determined by ^1H NMR): IR (film) ν_{max}: 3520–3300, 1650, 1590 cm^{-1}; ^1H NMR ($CDCl_3$) δ: (*1.2*:1.0 mixture of rotamers) 8.46, *8.42* (2 broad d, J = 4.8 Hz, 1H), 7.54–7.49 (m, 1H), 7.12–7.02 (m, 2H), 3.67, 3.58 (2t, J = 7.0 Hz, 2H), *3.24*, 3.14 (2s, 2H), 2.93 (t, J = 7.0 Hz, 2H), 2.86, *2.77* (2s, 3H), 2.41 (broad s, 1H), *2.32*, 2.18 (2d, J = 6.7 Hz, 2H), 1.70–1.54 (m, 5H), 1.39–1.28 (m, 1H), 1.19–1.03 (m, 3H), 0.88–0.76 (m, 2H); MS (FAB) *m*/*z*: 290 (MH^+). Anal. calcd. for $C_{17}H_{27}N_3O$ + 4.0% (w/w) H_2O (and accounting for 1,4-dioxane content): C 67.79, H 9.47, N 13.92; found: C 67.69, H 9.50, N 13.77. RP-HPLC (A) indicated 98.4% homogeneity. The material was kept at 4°C, in darkness, and under an inert atmosphere.

*1,1-Dimethylethyl 4-bromo-4-pentenoate (**4**)*: A solution of *tert*-butyl acetate (581 g, 5.00 mol) in THF (350 mL) was added dropwise over 45 min to a cold (–78°C) solution of LDA — prepared at –30°C from *n*-BuLi (2.5 M in hexanes, 2.20 L, 5.50 mol) and *i*-Pr_2NH (771 mL, 5.50 mol) — in THF (2.2 L). After stirring at –78°C for 45 min, a solution of 2,3-dibromopropene (620 mL, 6.00 mol) (filtered on neutral alumina and dried over 4 Å molecular sieves) in THF (600 mL) was slowly added over 2 h while the temperature was maintained below –60°C. After 3.5 h, a saturated solution of NH_4Cl (1 L) was added and the mixture was allowed to warm to room temperature and stirred for an additional 12 h. The reaction mixture was partitioned between ether (500 mL) and H_2O (1.5 L) and the aqueous phase was extracted with Et_2O (2 × 250 mL). The combined organic extracts were washed with H_2O (3 × 100 mL), 2 N HCl solution (5 × 150 mL), brine (2 × 300 mL), dried ($MgSO_4$ and charcoal), filtered over a pad of Celite®, and concentrated under reduced pressure to give a red-brown oil. Distillation of the oily residue using a short Vigreux column afforded the expected ester **4** as a colorless oil (749 g, 64%), contaminated with 2% of 2,3-dibromopropene: bp 55–65°C at 0.5 mm Hg; IR (film) ν_{max}: 1735, 1635 cm^{-1}; ^1H NMR

© 2000 NRC Canada

(200 MHz, $CDCl_3$) δ: 5.63 (dt, *J* = 1.7, 1.1 Hz, 1H), 5.43 (d, *J* = 1.7 Hz, 1H), 2.72 (t, *J* = 7.4 Hz, 2H), 2.48 (td, *J* = 7.4, 1.1 Hz, 2H), 1.45 (s, 9H); MS (CI) *m*/*z*: 235/237 (MH^+). Similarly, starting with twice the amount of *tert*-butyl acetate (1.16 kg, 10.0 mol), 1.63 kg (69%) of **4** was obtained.

*4-Bromo-4-pentenoic acid (**5**)*: A 4 N HCl solution in 1,4-dioxane (4.8 L, 19.2 mol) was added to ester **4** (1.48 kg, 6.30 mol) while stirring under inert atmosphere. After 18 h an additional portion of 4 N HCl in 1,4-dioxane (800 mL, 3.20 mol) was introduced. After stirring for an additional 24 h, the solvent was removed under reduced pressure, the residue was dissolved in Et_2O (3 L), and the solution washed with 2 N NaOH (4 × 1 L). The combined aqueous washings were acidified with 6 N HCl (1.4 L, 8.4 mol) to pH 2 and extracted with a 5:1 mixture of Et_2O:EtOAc (3 × 1.2 L). The combined organic extracts were washed with brine (1 L), dried ($MgSO_4$), filtered, and the solvent evaporated under reduced pressure. The residue was co-evaporated with hexane and dried under reduced pressure to give acid **5** as a tan solid (919 g, 82%): IR (KBr) ν_{max}: 3130–2900 (broad), 1715, 1635 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 10.57 (broad s, 1H), 5.67 (q, *J* = 1.0 Hz, 1H), 5.46 (d, *J* = 1.0 Hz, 1H), 2.78 (t, *J* = 7.3 Hz, 2H), 2.66 (td, *J* = 7.3, 1.0 Hz, 2H); MS (CI) *m*/*z*: 179/181 $(MH)^+$. The product was used directly in the next step. Alternatively, TFA (490 mL, 6.40 mol) was added over 60 min to an ice-cold solution of **4** (748 g, 3.18 mol) in CH_2Cl_2 (1 L). The mixture was stirred at 25°C for 48 h then was concentrated under reduced pressure. The residue was diluted with Et_2O (2 L) and the solution was extracted with aqueous 2 N NaOH (5 × 400 mL). The combined aqueous extracts were rendered acidic with 6 N HCl (500 mL) and extracted with Et_2O (4 × 500 mL). The combined ethereal extracts were washed with H_2O (3 × 300 mL) and brine (300 mL), dried (Na_2SO_4), filtered, and concentrated under reduced pressure. The residue was dissolved in toluene and concentrated under reduced pressure to give **5** (488 g, 86%) as a yellowish solid: analytical data identical to those described above.

*4-Bromo-4-pentenoyl chloride (**6**)*: To a cold (0°C) solution of the crude acid **5** (918 g, 5.13 mol) in CH_2Cl_2 (2.0 L) containing DMF (0.5 mL) was added oxalyl chloride (490 mL, 5.60 mol) over a period of 3 h. After stirring for 18 h at room temperature, the solvent was removed under reduced pressure and the residue dried under reduced pressure (0.5 mm Hg, 1.5 h) to afford crude acyl chloride **6** as a liquid (1003 g, 99%): ^1H NMR ($CDCl_3$) δ: 5.71 (broad d, *J* = 1.9 Hz, 1H), 5.51 (d, *J* = 1.9 Hz, 1H), 3.19 (t, *J* = 7.2 Hz, 2H), 2.82 (broad t, *J* = 7.2 Hz, 2H). The material was used directly in the next step. Similarly, a second run starting with about half the quantity of **5** (487 g, 2.72 mol) gave 533 g of **6** (99%), identical to the material obtained above.

*3-(4-Bromo-1-oxo-4-pentenyl)-4(*S*)-(1-methylethyl)-2-oxazolidinone (**7**)*: To a cold (–78°C) solution of 4(*S*)-(1-methylethyl)-2-oxazolidinone (642 g, 4.97 mol) and Ph_3CH (300 mg, as indicator) in dry THF (9 L) was added dropwise *n*-BuLi (2.5 M in hexanes, 2.05 L, 5.12 mol) until a pink color appeared. After stirring the suspension for 1 h, crude acyl chloride **6** (1001 g, 5.07 mol) was added via cannula over a 1.5 h period. Stirring was maintained for an additional 15 min at –78°C and for 2.5 h at room temperature. The mixture was diluted with H_2O (4 L) and saturated $NaHCO_3$ solution (2 L) and extracted with Et_2O (4 × 1.5 L). The combined organic extracts were washed with water (2 × 800 mL), brine (1.5 L), dried ($MgSO_4$), filtered, and the solvent evaporated under reduced pressure. The residue was further dried under reduced pressure (0.5 mm Hg, 15 h) to afford **7** as a yellow solid (1.42 kg, 98%). ^1H NMR ($CDCl_3$) δ: 5.66 (broad d, *J* = 1.7 Hz, 1H), 5.44 (d, *J* = 1.7 Hz, 1H), 4.42 (ddd, *J* = 8.3, 3.8, 3.2 Hz, 1H), 4.28 (dd, *J* = 9.1, 8.3 Hz, 1H), 4.21 (dd, *J* = 9.1, 3.2 Hz, 1H), 3.29–3.12 (m, 2H), 2.80 (broad t, *J* = 7.5 Hz, 2H), 2.36 (sept d, *J* = 7.0, 3.8 Hz, 1H), 0.91 (d, *J* = 7.0 Hz, 3H), 0.87 (d, *J* = 7.0 Hz, 3H). The material was used in the subsequent reaction without further purification. Similarly, a second run starting with 532 g of **6** (2.69 mol) produced 710 g of **7** (92%), identical to the material described above.

*3-[4-Bromo-2(*S*)-[2-(1,1-dimethylethoxy)-2-oxoethyl]-1-oxo-4-pentenyl]-4(*S*)-(1-methylethyl)-2-oxazolidinone (**8**)*: To a cold (–78°C) solution of crude acyl oxazolidinone **7** (1.42 kg, 4.90 mol) in dry THF (3 L) was added dropwise a 1 M solution of NaHMDS in THF (5.5 L, 5.50 mol) over a 2 h period. After stirring mechanically for 1.5 h at –78°C, a solution of *tert*-butyl 2-bromoacetate (900 mL, 5.57 mol) in THF (1 L) was added dropwise over 1.5 h. The mixture was stirred for an additional 1.5 h and a saturated $NaHCO_3$ solution (4 L) was introduced. After warming to room temperature, the THF extract was removed and the aqueous extract was extracted with EtOAc (2 × 2 L). The combined organic solutions (THF and EtOAc) were concentrated under reduced pressure to give a solid residue which was suspended in hexane (3 L) and filtered. The material was washed with H_2O (2 × 1 L), hexane (2 × 1.5 L), filtered, and dried under reduced pressure over P_2O_5. The solid was dissolved in CH_2Cl_2 (3.5 L), the solution was filtered through a microglass filter, and concentrated under reduced pressure to a semi-solid mass. After dilution with hexane (3.5 L), the resulting crystals were filtered and dried under reduced pressure to afford **8** as small white needles (1.02 kg, 53%): mp 121–122.5°C; $[\alpha]_D^{25}$ + 49.8° (*c* 1.28, $CHCl_3$); IR (KBr) ν_{max}: 1770, 1735, 1705, 1640 cm^{-1}; ^1H NMR ($CDCl_3$) δ: 5.67 (broad s, 1H), 5.50 (d, *J* = 1.6 Hz, 1H), 4.51–4.44 (m, 1H), 4.42 (ddd, *J* = 8.1, 3.8, 3.2 Hz, 1H), 4.27 (dd, *J* = 9.2, 8.1 Hz, 1H), 4.22 (dd, *J* = 9.2, 3.2 Hz, 1H), 2.87 (broad dd, *J* = 14.5, 6.4 Hz, 1H), 2.73 (dd, *J* = 16.5, 9.1 Hz, 1H), 2.56 (broad dd, *J* = 14.5, 7.6 Hz, 1H), 2.52 (dd, *J* = 16.5, 5.1 Hz, 1H), 2.38 (sept d, *J* = 7.0, 3.8 Hz, 1H), 1.42 (s, 9H), 0.93 (d, *J* = 7.0 Hz, 3H), 0.91 (d, *J* = 7.0 Hz, 3H); ^{13}C NMR ($CDCl_3$) δ: 173.9, 170.4, 153.5, 129.9, 119.8, 80.8, 63.3, 58.8, 42.4, 38.5, 36.5, 28.2, 28.0, 18.4, 14.6; MS (FAB) *m*/*z*: 404/406 (MH^+). Anal. calcd. for $C_{17}H_{26}NO_5Br$: C 50.50, H 6.48, N 3.46; found: C 50.20, H 6.50, N 3.49. The diastereomeric purity was found to be >99% when assessed by HPLC using a chiral column (CHIRALPAK® AS, Daicel Chem. Co.; 0.5% EtOH in hexane). A second run starting with 707 g (2.44 mol) of **7** yielded 514 g (52%) of **8**.

*3-[4-Bromo-2(*S*)-(carboxymethyl)-1-oxo-4-pentenyl]-4(*S*)-(1-methylethyl)-2-oxazolidinone (**B′**)*: Ester **8** (1.48 kg, 3.67 mol) was dissolved in 4 N HCl 1,4-dioxane (8.8 L, 35.2 mol) and the solution was stirred at room temperature for

© 2000 NRC Canada

20 h. The yellow solution was concentrated to half volume by partial evaporation of the solvent under reduced pressure and then poured into water (40 L). The white solid formed was filtered and re-dissolved in Et_2O (10 L). The solution was washed with brine (3 × 1 L), treated with anhydrous $MgSO_4$ and charcoal, and filtered through a pad of Celite®. The pale yellow filtrate was concentrated under reduced pressure to give a white solid which, after drying under reduced pressure for 3 h, afforded **B′** as an amorphous product (1.27 kg, 100% mass recovery, containing 2.47% w/w of 1,4-dioxane): mp 124–125°C; ^{1}H NMR ($CDCl_3$) δ: 5.70 (broad s, 1H), 5.54 (d, *J* = 1.6 Hz, 1H), 4.54–4.48 (m, 1H), 4.43 (ddd, *J* = 7.9, 3.5, 3.2 Hz, 1H), 4.30–4.22 (m, 2H), 2.89 (dd, *J* = 17.4, 10.2 Hz, 1H), 2.86 (dd, *J* = 14.1, 5.1 Hz, 1H), 2.64 (dd, *J* = 17.4, 4.3 Hz, 1H), 2.53 (dd, *J* = 14.1, 8.6 Hz, 1H), 2.37 (sept d, *J* = 7.0, 3.5 Hz, 1H), 0.91 (d, *J* = 7.0 Hz, 3H), 0.89 (d, *J* = 7.0 Hz, 3H); MS (FAB) *m*/*z*: 348/350 (M^+). Anal. calcd. for $C_{13}H_{18}NO_5Br$ (+ 2.47% w/w 1,4-dioxane): C 45.08, H 5.32, N 3.92; found: C 45.15, H 5.69, N 3.62.

*3-[4-Bromo-2(*S*)-[2-[(cyclohexylmethyl)[2-[methyl[2-(2-pyridinyl)ethyl]amino]-2-oxoethyl]amino]-2-oxoethyl]-1-oxo-4-pentenyl]-4(*S*)-(1-methylethyl)-2-oxazolidinone (**9**)*: Et_3N (1.02 L, 7.30 mol) was added in one portion to a solution of **B′** (1.27 kg, 3.65 mol) in dry THF (5 L). The mixture was cooled to –45°C and iso-butyl chloroformate (497 mL, 3.83 mol) was added dropwise over a 30 min period while maintaining the temperature below –40°C. After stirring for 30 min, a solution of amine **A** (1.16 kg, 3.99 mol, 1.1 equiv.) in dry THF (2 L) was added dropwise over 45 min and the resulting mixture was stirred at room temperature for 2.5 h. H_2O (7 L) was added and the mixture was extracted with EtOAc (6 × 1 L). The combined organic extracts were washed successively with a 10% citric acid solution (6 × 500 mL), H_2O (2 × 1 L), saturated $NaHCO_3$ solution (3 × 1 L), and brine (2 × 1 L). The solution was treated with anhydrous $MgSO_4$ and charcoal, filtered through a pad of Celite®, and concentrated under reduced pressure to give amide **9** as a yellow gum (2.27 kg, 100%): ^{1}H NMR ($CDCl_3$) δ: (3:3:1:1 mixture of rotamers) 8.61, 8.55, 8.51 (3d, *J* = 4.1, 4.8, 3.8 Hz, 1H), 7.68–7.58 (m, 1H), 7.24–7.11 (m, 2H), 5.72, 5.67, 5.64 (3s, 1H), 5.52, 5.51, 5.48, 5.46 (4d, *J* = 1.6, 1.3, 1.3, 1.6 Hz, 1H), 4.57–4.47 (m, 1H), 4.45–4.40 (m, 1H), 4.28–4.17 (m, 2H), 4.17–3.68 (m, 4H), 3.50–3.30 and 3.19–2.83 (m, 5H), 2.97, 2.95, 2.90, 2.87 (4s, 3H), 2.75–2.54 (m, 2H), 2.43–2.36 (m, 1H), 2.15–2.07 (m, 1H), 1.76–1.45 (m, 6H), 1.29–1.15 (m, 3H), 0.95–0.85 (m, 8H); MS (FAB) *m*/*z*: 619/621 (MH^+). The material was used directly in the subsequent reaction.

*2(*S*)-(2-Bromo-2-propenyl)-4-[(cyclohexylmethyl)[2-[methyl[2-(2-pyridinyl)ethyl]amino]-2-oxo-ethyl]amino]-4-oxobutanoic acid (**10**)*: To a mechanically stirred solution of the crude tertiary amide **9** (2269 g, 3.65 mol) in a 6:1 THF:H_2O mixture (16 L) cooled to 0°C, was added a 30% H_2O_2 solution (2042 mL, 18.31 mol). After 10 min, $LiOH•H_2O$ (384 g, 9.16 mol) was added and the mixture was stirred vigorously for 40 min. A Na_2SO_3 solution (2552 g in 5.7 L of H_2O) was slowly added over 40 min while keeping the temperature below 25°C. After stirring for an additional 15 min to ensure complete neutralization of the peroxide, the solution was concentrated under reduced pressure to remove the THF. The aqueous extract was extracted with EtOAc (6 × 1 L) and the combined organic extracts were extracted with saturated $NaHCO_3$ (8 × 500 mL). The combined aqueous extracts containing the carboxylic acid sodium salt were extracted manually with ether (7 × 750 mL) and then submitted to continuous extraction with Et_2O (4 L) for 17 h. All the organic extracts were combined and evaporated to dryness allowing recovery of the chiral auxiliary. The aqueous extracts were acidified with solid citric acid to pH 3 and extracted with EtOAc (4 × 1 L). The combined organic extracts were washed with brine (2 × 600 mL), treated with anhydrous $MgSO_4$ and charcoal, filtered through Celite®, and concentrated under reduced pressure. The resulting gummy residue was further dried at 45°C under reduced pressure for 8 h to afford acid **10** as a yellow glassy solid (1.51 kg, 77%) contaminated with EtOAc (2.5% w/w) and residual chiral auxiliary (2.5% w/w): ^{1}H NMR ($CDCl_3$) δ: 10.00 (broad s, 1H), 8.62, 8.58, 8.55, 8.53 (4d, *J* = 4.4, 4.8, 5.1, 5 Hz, 1H), 7.73–7.66 (m, 1H), 7.33–7.17 (m, 2H), 5.74, 5.69, 5.63 (3s, 1H), 5.50, 5.47, 5.45 (3 broad s, 1H), 4.09–3.85 (m, 2H), 3.77–3.60 (m, 2H), 3.25–3.04 (m, 5H), 2.98, 2.97, 2.94, 2.90 (4s, 3H), 2.99–2.88, 2.74–2.67 and 2.51–2.30 (m, 4H), 1.76–1.44 (m, 6H), 1.27–1.13 (m, 3H), 0.95–0.85 (m, 2H); MS (FAB) *m*/*z*: 508/510 (MH^+). Homogeneity was determined to be 97.8% (chiral auxiliary not detected by UV) by RP-HPLC (A). This acid (**10**) was used directly in the subsequent reaction.

N^4*-(Cyclohexylmethyl)*-N^4*-[2-[methyl[2-(2-pyridinyl)ethyl]amino]-2-oxoethyl]*-N^1*-[1(*S*)-(cyclohexylmethyl)-2(*R*),3(*S*)-dihydroxy-5-methylhexyl]-2(*S*)-(2-bromo-2-propenyl)butanediamide (**1**)*: A mixture of acid **10** (1394 g, 2.74 mol), aminodiol **C** (704.5 g, 2.89 mol), and TBTU (880.4 g, 2.74 mol, 1 equiv.) was dissolved in MeCN (7 L) and cooled to 0–5°C under an inert atmosphere before i-Pr_2NEt (1433 mL, 8.23 mol) was added portionwise over a 15 min period raising the temperature to 15°C. The bath was removed and the mixture was stirred at room temperature for 2 h. Water (8 L) was added and the mixture was extracted with EtOAc (6 × 650 mL). The combined organic extracts were washed successively with 10% citric acid solution (6 × 1 L), water (6 × 1 L), saturated $NaHCO_3$ solution (4 × 1 L), and brine (2 × 1 L). The organic solution was treated with anhydrous $MgSO_4$ and charcoal, and filtered through a pad of Celite®. The solution was filtered twice through a pad of silica gel and washed with EtOAc (2 × 5 L). The combined organic filtrates were concentrated under reduced pressure to give a 6 L solution which was left at room temperature overnight to allow crystallization. The solid was filtered, washed with hexane (3 × 1 L), and dried overnight under reduced pressure to afford a first crop of **1** as white micro-needles (1.20 kg, 59.9%): mp 139–141°C; ^{1}H NMR (DMSO-d_6) δ: (1.7:1.0:1.0 mixture of rotamers) 8.54–8.51, 8.48 (m and d, *J* = 4.8 Hz, 1H), 7.75–7.67 (m, 2H), 7.33–7.19 (m, 2H), 5.77, 5.71, 5.68 (3s, 1H), 5.42, 5.40, 5.38 (s and 2d, *J* = 1.5, 1.5 Hz, 1H), 4.61 (broad s, 1H), 4.51 (broad s, 1H), 4.21–3.88 (m, 3H), 3.70–3.54 (m, 2H), 3.10–2.85, 2.84, 2.80 (m and 2 s, 10H), 2.70–2.65 (1H), 2.52–2.05 (m, 3H), 1.76–1.10 (m, 23H), 0.92–0.70 (m, 4H), 0.86 (d, *J* = 6.6 Hz, 3H), 0.79 (d, *J* = 6.6 Hz, 3H); MS (FAB) *m*/*z*: 733/735 (MH^+). $C_{38}H_{61}N_4O_5Br$: C 62.20, H 8.38, N 7.63; found: C 61.54, H 8.48, N 7.66. Homogeneity was determined to be 98.6% by RP-HPLC (A), with 0.3% of the corresponding pyridine *N*-oxide derivative. This first crop of **1** was used directly in the subsequent reaction sequence leading to **BILA 2157 BS**.

Concentration of the mother liquors under reduced pressure gave a solid residue that was filtered and washed successively with a 1:1 EtOAc–hexane mixture (2 L) and then hexane (3 L). The solid was dissolved in hot EtOAc (1 L), the solution was filtered through Celite®, and stored at 0–5°C overnight. The crystalline white solid was filtered, washed with hexane, and dried under reduced pressure to afford an impure crop of intermediate **1** (281 g): mp 132–133°C. RP-HPLC (A) indicated 92% homogeneity. The solid was dissolved in EtOAc (3 L) and the resulting solution was filtered twice through a pad of silica gel and washed with EtOAc (2 × 600 mL). The combined organic filtrates were concentrated under reduced pressure to give a 1 L solution which was left at room temperature overnight to allow crystallization. The solid was filtered, washed with hexane, and dried over P_2O_5 under reduced pressure to afford a second crop of **1** as a white powder (189 g, 9.5%): mp 140–142°C; $[\alpha]_D^{25}$ –27.1° (*c* 1.03, MeOH); IR (KBr) ν_{max}: 3450, 3280, 1655, 1630 cm^{-1}; ^1H NMR and MS identical to those of first crop of **1**. Anal. calcd. for $C_{38}H_{61}N_4O_5Br$: C 61.82, H 8.38, N 7.63; found: C 61.82, H 8.44, N 7.63. RP-HPLC (A) indicated 99.2% homogeneity.

N^4*-(Cyclohexylmethyl)*-N^4*-[2-[methyl[2-(2-pyridinyl)ethyl]-amino]-2-oxoethyl]*-N^1*-[1(*S*)-(cyclohexylmethyl)-2(*R*),3(*S*)-dihydroxy-5-methylhexyl]-2(*R*)-[(2-amino-4-thiazolyl)methyl]butanediamide (**BILA 2157 BS**)*: To a solution of butanediamide intermediate **1** (1.20 kg, 1.63 mol) in CH_2Cl_2 (6.5 L), was added 2-methoxypropene (783 mL, 8.18 mol) followed by a catalytic amount of PPTS (41.0 g, 163 mmol). The mixture was stirred at room temperature for 15 h. The solvent was evaporated under reduced pressure and the residue was co-evaporated with Et_2O (3 × 1 L). The oily residue was dissolved in EtOAc (2.5 L) and washed successively with H_2O (2 × 500 mL) and saturated $NaHCO_3$ solution (2 × 500 mL). The solution was treated with anhydrous $MgSO_4$ and charcoal, and filtered through a pad of Celite®. The filtrate was concentrated under reduced pressure to afford the corresponding crude acetonide derivative **11** as a yellow gum (1.35 kg, 107% mass recovery). RP-HPLC (B) analysis indicated homogeneity of 94%. The crude product was used immediately in the subsequent reaction.

To a solution of crude acetonide **11** (1.35 kg, 1.63 mol) in a mixture of MeCN (12 L) and H_2O (3 L) protected from light, was added NBS (349 g, 1.96 mol) in two portions at 10 min intervals. The mixture was stirred for 50 min and treated with 2-methoxypropene (31.0 mL, 0.33 mol) to neutralize the excess NBS. After 5 min, thiourea (156 g, 2.04 mol) was added in one portion. After 15 min, the mixture was heated to 60–65°C under reduced pressure to distill off 5 L of MeCN while completing the hydrolysis of the acetonide (4.5 h). Water (4 L) was then added and the mixture was left stirring at room temperature overnight. The remaining MeCN was removed under reduced pressure and the solution was washed successively with TBME (8 × 2 L), EtOAc (8 × 2 L), and CH_2Cl_2 (8 × 2 L). The aqueous solution containing **BILA 2157 BS** as its HBr salt was treated with charcoal, filtered through a pad of Celite®, and brought to pH 9 by addition of solid NaOH (290 g). The mixture was extracted with $CHCl_3$ (3 × 2 L) and the combined organic extracts were washed with H_2O (3 × 1.5 L) and brine (2 × 1 L). The solution was filtered through a pad of silica gel (G-60, 500 g) and the pad was washed with $CHCl_3$ (500 mL). The combined filtrate and washing solutions were evaporated under reduced pressure to give 930 g of crude **BILA 2157 BS** (93% homogeneity by RP-HPLC, A). This crude product was purified in 6 portions by flash chromatography (silica gel G-60, 6 kg) using a gradient of MeOH in EtOAc (5 to 20%) as eluent. Following RP-HPLC analysis, fractions containing pure product were combined and the solvent was evaporated to dryness. The residue (603.6 g) was dissolved in EtOAc (2 L) and the solution was filtered through a microfiber filter. After evaporation of the solvent, the residue was co-evaporated with MeOH (2 × 1.5 L) and then dissolved in MeOH (700 mL). The brown solution was added dropwise over a 1 h period to a mixture of water (30 L) and ice (5 L) under vigorous mechanical stirring. The resulting precipitate was filtered, air dried overnight, and then dried under reduced pressure for 48 h to afford **BILA 2157 BS** as an off-white amorphous solid (518 g, 44%): mp 92–97°C; $[\alpha]_D^{25}$ –26.0° (*c* 1.02, MeOH); IR (KBr) ν_{max}: 3600–3040, 1645 (broad) cm^{-1}; ^1H NMR (DMSO-d_6) δ: (1:1:1:1 mixture of rotamers) 8.54–8.51, 8.48 (m and d, *J* = 4.8 Hz, 1H), 7.75–7.67 (m, 1H), 7.59, 7.56, 7.53 (3d, *J* = 9.0, 9.9, 9.6 Hz, 1H), 7.33–7.19 (m, 2H), 6.77, 6.73 (2s, 2H), 6.18, 6.17, 6.10, 6.06 (4s, 1H), 4.64–4.61, 4.59, 4.56 (m and 2d, *J* = 6.6, 6.6 Hz, 2H), 4.18, 4.17, 4.11, 4.09–4.01, 3.88, 3.85 (3d, m and 2d, *J* = 17.8, 16.2, 16.5, 17.8, 16.2 Hz, 3H), 3.69–3.51 (m, 2H), 3.10–2.80 (m, 7H), 2.90, 2.89, 2.83, 2.80 (4s, 3H), 2.74–2.62 (m, 1H), 2.51–2.32, 2.24, 2.14, 2.02 (m and 3dd, *J* = 15.8, 7.8 Hz, *J* = 16.1, 5.7 Hz, *J* = 15.8, 5.7 Hz, 3H), 1.78–1.05 (m, 23H), 0.90–0.69 (m, 4H), 0.86 (d, *J* = 6.9, 3H), 0.77 (d, *J* = 6.6 Hz, 3H); MS (FAB) *m*/*z*: 727 (MH^+). Anal. calcd. for $C_{39}H_{62}N_6O_5S$ + 1.53% (w/w) H_2O: C 63.45, H 8.63, N 11.39; found: C 63.03, H 8.64, N 11.31. RP-HPLC analysis indicated homogeneities of 99.9% (A) and 99.6% (B). An additional amount of **BILA 2157 BS** (73.0 g, 6%) was obtained after purification by flash chromatography of the mixed fractions: mp 88–94°C; $[\alpha]_D^{25}$ –25.5° (*c* 1.03, MeOH); IR, ^1H NMR and MS identical to those described above. Anal. calcd. for $C_{39}H_{62}N_6O_5S$ + 0.78% (w/w) H_2O: C 63.93, H 8.62, N 11.47; found: C 63.96, H 9.02, N 11.29. RP-HPLC analysis indicated homogeneities of 99.9% (A) and 99.6% (B).

Construction of bicyclic tetrahydroisoquinolinones by combination of an IMDAF-ring cleavage reaction of *N*-allyl-2-furan-2-yl-acetamides

Albert Padwa and Thomas S. Reger

Abstract: The intramolecular Diels–Alder reaction of furanyl amides derived from 2-furylacetic acid has been examined. Substrates containing either an imide or tertiary amide linkage between the furan and the dienophile underwent smooth cycloaddition upon thermolysis. By varying the reaction conditions, either the primary cycloadduct or the ring-opened and acetylated product could be isolated in excellent yield. The stereochemical outcome of the IMDAF cycloaddition has the side arm of the tethered alkenyl group oriented *syn* with respect to the oxygen bridge. Semi-empirical AM1 calculations show that the *exo*-cycloadduct is 11 kcal lower in energy than the corresponding *endo* adduct and, presumably, some of this energy difference is reflected in the transition state for the cycloaddition. The IMDAF reaction of *N*-allyl-[2-(3,4-dimethoxyphenethyl)]-2-furanyl-2-yl-acetamide proceeded in 90% yield upon heating in xylene. The 4+2-cycloadduct undergoes ring-opening on treatment with base and the resulting alcohol was converted into the corresponding benzyl ether. Raney nickel reduction followed by Bischler–Napieralski cyclization furnished the tetracyclic skeleton of the berberine alkaloids.

Key words: intramolecular, cycloaddition, Diels–Alder, furanylamide, heterocycle.

Résumé : On a étudié la réaction de Diels–Alder intramoléculaire de furanylamides (« IMDAF ») dérivés de l'acide furyl-2-acétique. Par thermolyse, les substrats comportant soit une liaison imide ou amide tertiaire entre le furane et le diénophile subissent une cycloaddition facile. En faisant varier les conditions réactionnelles, on peut isoler avec un excellent rendement soit le cycloadduit primaire ou le produit dérivant d'une ouverture de cycle et d'une acétylation. D'un point de vue stéréochimique, la cycloaddition « IMDAF » conduit à un produit dans lequel la chaîne latérale du groupe alcényle prend une orientation *syn* par rapport au pont oxygéné. Des calculs semi-empiriques AM1 montrent que l'énergie du cycloadduit *exo* est inférieure de 11 kcal par rapport à celle de l'adduit *endo* correspondant; il est vraisemblable qu'une partie de cette différence d'énergie se reflète dans l'état de transition de la cycloaddition. La réaction « IMDAF » du *N*-allyl-[2-(3,4-diméthoxyphénéthyl)]-2-furanyl-2-yl-acétamide se produit avec un rendement de 90% par chauffage dans le xylène. Le cycloadduit 4+2 subit une ouverture de cycle par traitement avec une base et l'alcool qui en résulte a été transformé en éther benzylique correspondant. Une réduction à l'aide de nickel de Raney, suivie d'une cyclisation de Bischler–Napieralski, conduit au squelette tétracyclique des alcaloïdes de la berbérine.

Mots clés : intramoléculaire, cycloaddition, Diels–Alder, furanylamide, hétérocycle.

Introduction

Furans are common substructures found in numerous natural products and are also present in many commercial products, including pharmaceuticals, fragrances, and dyes (1–4). Furans also play an important role as intermediates in many synthetic pathways, primarily because they react as a special class of vinyl ethers (5, 6) or as dienes in the Diels–Alder reaction (7). The resultant 7-oxabicyclo-[2.2.1]heptanes are valuable synthetic intermediates which have been further elaborated to substituted arenes, carbohydrate derivatives, and various natural products (8–17). A crucial synthetic transformation employing these oxabicyclic compounds involves cleavage of the oxygen bridge to produce functionalized cyclohexene derivatives (18–23). The intramolecular Diels–Alder reactions of furans, often designated as IMDAF, has proven to be an extremely valuable method for the construction of more complex oxygenated, bicyclic structures (7). The IMDAF generally proceeds at lower temperature than its bimolecular counterpart and, more importantly, often allows for the use of unactivated alkenes as dienophiles (24). Recent work in our laboratory has shown that the intramolecular Diels–Alder of 2-amido substituted furans such as **1** represents an effective route to indolines and tetrahydroquinolines (25). This methodology has also been utilized for the synthesis of the hexahydroindolinone skeleton found in numerous alkaloids (26). Intramolecular cycloaddition of the 2-amidofuran followed by ring opening gives a zwitterionic intermediate **3** that can be channeled to different products depending on the

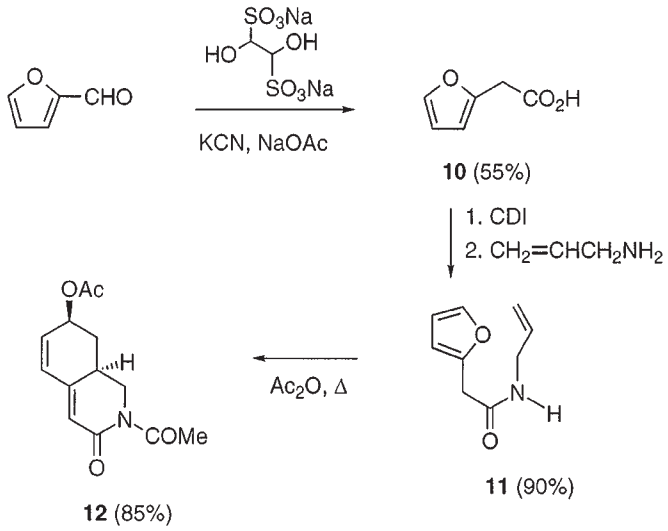


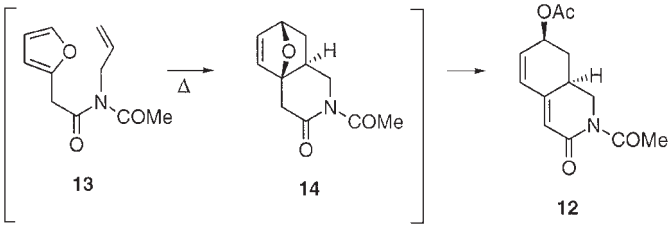
Scheme 2.

nature of the substituent group attached to the π-bond (i.e., R_1) (Scheme 1).

One of the most attractive features of this reaction sequence is the propensity for nitrogen assisted ring-opening and subsequent iminium ion formation of the oxabicyclic cycloadducts (i.e., **2** → **3**). The majority of work carried out by other investigators on the IMDAF reaction utilizing nitrogen containing tethers was done with furfurylamine derived substrates whose cycloadducts are not predisposed to spontaneous ring-opening (27–29). As an extension of our earlier work in this area, we believed that related furanyl amides such as **6** should also be excellent substrates for intramolecular Diels–Alder cycloaddition and oxabicyclic

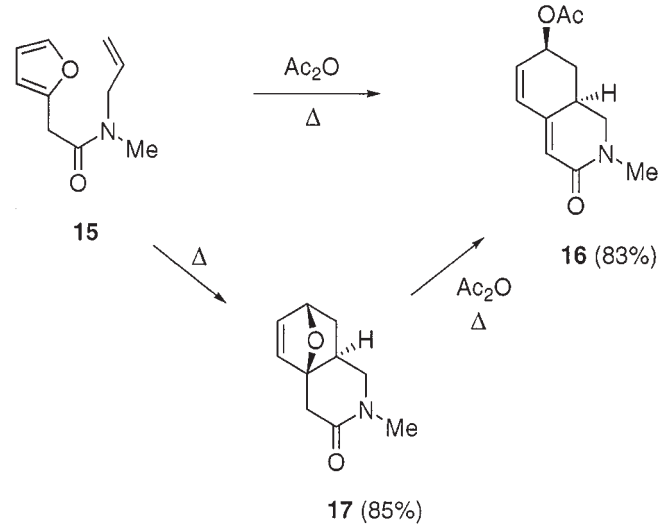
Scheme 3.

ring-opening as a consequence of the acidic nature of the protons adjacent to the oxygen bridge (Scheme 2). To the best of our knowledge, amides derived from 2-furylacetic acid have not been utilized in Diels–Alder chemistry. A study to examine the synthesis of furans such as **6** and their subsequent cycloaddition and ring-opening chemistry was initiated with the intention of using this method as an entry into the berberine alkaloid family (30). The biological activity that these molecules display varies widely and includes anti-inflammatory, antimicrobial and antileukemic, as well as antitumor, properties (30). In the light of these properties and due to the general challenge that the construction of complex alkaloids offers, the development of new methods for the stereoselective synthesis of these nitrogen heterocycles is of considerable interest. In this paper we report the results of our IMDAF studies dealing with *N*-allyl 2-furan-2-yl-acetamides.



Results and discussion

As an entry into furanyl amides such as **6**, 2-furylacetic acid (**10**) was required as the key starting material. In our hands, the most reliable synthesis corresponds to the one-pot reaction between 2-furaldehyde and potassium cyanide (31). Reaction of these two reagents in the presence of sodium carbonate and glyoxal (sodium bisulfite addition compound hydrate) in a 20:1 water:dioxane solution reproducibly gave **10** in 55% yield. Carboxylic acid **10** was converted to the *N*-allyl amide **11** in 90% yield by reaction with 1,1-carbonyldiimidazole (CDI) followed by quenching with allylamine (Scheme 3). The attempted Diels–Alder cycloaddition of **11** in refluxing toluene or xylene led only to recovered starting material. This result is perfectly consistent with the earlier reports of Jung (27) and Parker (28) who found that related furans containing secondary amide tethers failed to undergo the Diels–Alder reaction. Cycloaddition could be effected, however, by heating **11** in refluxing acetic anhydride.[2] Under these conditions, the initial formation of imide **13** presumably



[2] The role of acetic anhydride in this reaction is to promote the [4+2]-cycloaddition by acylation at nitrogen as well as to assist in the subsequent oxa-bridge cleavage.

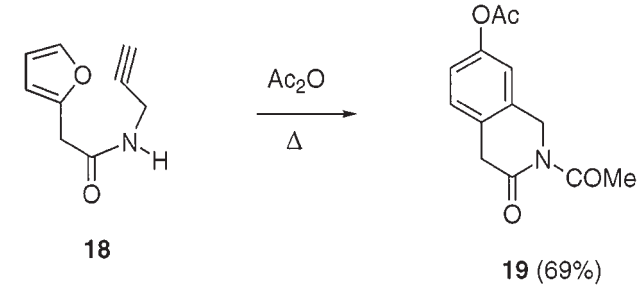
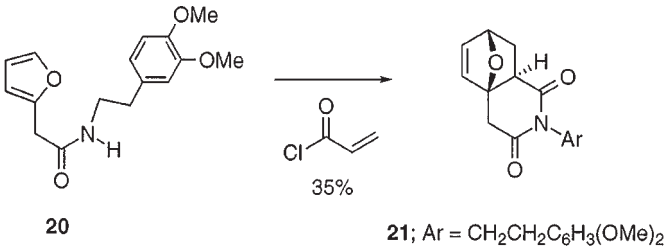
Scheme 5.

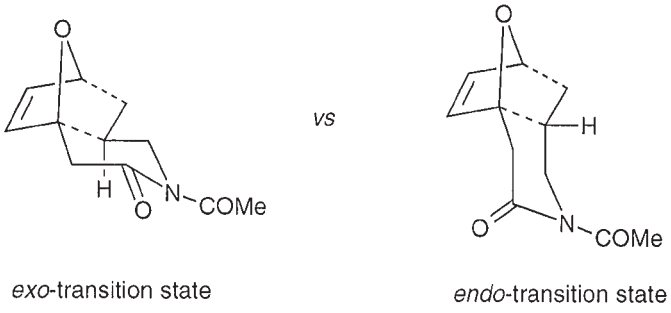


facilitates the Diels–Alder reaction to give the oxabicyclic intermediate **14**. The cycloadduct was not isolated as it undergoes spontaneous ring-opening and O-acetylation to furnish **12** as a single diastereomer in 85% yield (Scheme 4).



The *trans* relationship between the acetate and the bridgehead hydrogen is derived from the presumed cycloadduct **14** which results from *exo* orientation of the tether during the cycloaddition. This mode of cyclization for the IMDAF reaction of substrates containing nitrogen in the tether is analogous to that reported by others for related furanyl systems possessing short tethers (32, 33). The ring-opened acetate **12** is thus derived from an IMDAF cycloaddition where the side arm of the tethered alkenyl group is oriented *syn* (*exo*) with respect to the oxygen bridge. Products resulting from an *endo* side arm transition state were neither detected nor isolated. This result is not so surprising since, in these mobile cycloaddition equilibria, the *exo* adducts are expected to be thermodynamically more favored. Indeed, semi-empirical AM1 calculations show that the *exo*-cycloadduct is 11 kcal lower in energy than the corresponding *endo* (with respect to the tether) adduct and, presumably, some of this energy difference is reflected in the transition state for cycloaddition.

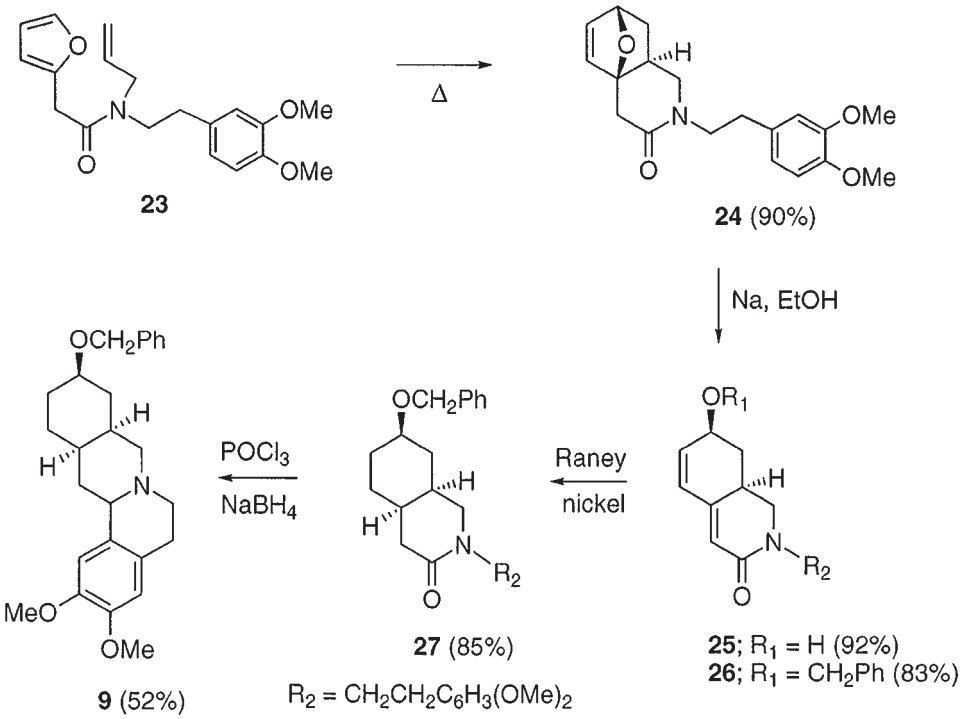
We next turned our attention to determining whether a tertiary amide linkage between the furan and alkene would allow the cycloaddition to proceed. Amide **15** was prepared in 94% yield by reaction of carboxylic acid **10** with CDI followed by quenching with *N*-methylallylamine. Upon thermolysis of **15** in acetic anhydride, the expected ring-opened and acetylated lactam **16** was isolated in 83% yield as a single diastereomer. The formation of **16** proceeds by a



Scheme 6.

Scheme 7.

Structure 1.



similar pathway to that described for **13**. Interestingly, when amide **15** was heated in refluxing toluene, the primary cycloadduct **17** was obtained in 85% yield, also as a single diastereomer, and could be quantitatively converted to **16** by heating in acetic anhydride (Scheme 5).

To further examine the scope of this cycloaddition with respect to the dienophile, furan **18** containing an alkyne tether was prepared in 86% yield. Heating a sample of **18** in acetic anhydride gave the isoquinoline derivative **19** in 69% yield (Scheme 6).

We next turned our attention to substrates bearing both a dienophile and an electron-rich aromatic group connected to the amide nitrogen (i.e., **23**). It was envisioned that a Bischler–Napieralski type cyclization (vide infra) could be effected on the Diels–Alder cycloaddition product. To this end, amide **20** was prepared in 87% yield by the usual reaction of 2-furylacetic acid with CDI and quenching with 3,4-dimethoxyphenethylamine. Unfortunately, all of our attempts to alkylate **20** with allyl bromide using a variety of bases (Cs_2CO_3 (DMF); NaH (THF); NaOH, K_2CO_3, Bu_4NHSO_4) failed to give any product. Imide formation with acryloyl chloride at room temperature in the presence of 4 Å molecular sieves did produce cycloadduct **21**, but only in 35% yield (Scheme 7).

© 2000 NRC Canada

Scheme 8.

As an alternative route to **23**, the known secondary amine allyl-[2-(3,4-dimethoxyphenethylamine)] (**22**) (34) was prepared and used to generate the desired tertiary amide directly. Thus, the reaction of carboxylic acid **10** with CDI followed by addition of amine **22** gave the desired cyclization precursor **23** in 77% yield. Upon heating **23** in refluxing xylene, cycloadduct **24** was isolated in 90% yield as a single diastereomer. A variety of bases were examined to induce ring-opening of **24** to the allylic alcohol **25**. Triethylamine, sodium hydride, and potassium *tert*-butoxide were all successful, but the use of the sodium in ethanol gave the highest yield (92%) and cleanest reaction. We then attempted a Bischler–Napieralski cyclization of the aromatic ring onto the amide carbonyl of **25** but this gave only a complex mixture of unidentifiable products. Instead, the alcohol was protected as its benzyl ether with sodium hydride and benzyl bromide in 83% yield. Compound **26** was then reduced to the decahydroisoquinoline **27** with Raney nickel in 85% yield. This compound was formed as a single diastereomer and there is literature precedence for a similar transformation in which Raney nickel reduction occurs from the *exo* face of a bicyclic structure to yield a *cis* ring junction (35). The Bischler–Napieralski cyclization of **27** was effected with $POCl_3$ followed by $NaBH_4$ and furnished **9** in 52% yield (Scheme 8). The appearance of two singlets in the aromatic region of the ^{1}H-NMR spectrum of **9** was indicative that the desired cyclization had taken place. This reaction proved to be very sensitive to the experimental conditions and, unfortunately, even the use of freshly distilled $POCl_3$ offered no advantage in terms of reaction yield. Nevertheless, the tetracyclic compound **9** containing the core skeleton of the berberine alkaloids was readily accessible in just five steps from relatively simple cyclization precursors.

In conclusion, the intramolecular Diels–Alder reaction of furanyl amides derived from 2-furylacetic acid proceeds smoothly and in high yield. The cyclization precursors are easily synthesized from readily available starting materials. The cycloaddition can be carried out under a variety of conditions to yield either the primary cycloadduct or the ring-opened and acetylated product. Consistent with previous studies, only compounds bearing imide or tertiary amide linkages between the furan and tethered dienophile were suitable substrates for cycloaddition. Overall, this methodology represents an efficient route to functionalized members of the tetrahydroisoquinolinone ring system in various oxidation states which could serve as intermediates to members of the berberine alkaloid family. Applications toward specific natural products and the further development of the IMDAF are currently underway and will be reported in due course.

Experimental section

Melting points are uncorrected. Mass spectra were determined at an ionizing voltage of 70 eV. Unless otherwise noted, all reactions were performed in flame-dried glassware under an atmosphere of dry argon. Solutions were evaporated under reduced pressure with a rotary evaporator, and the residue was chromatographed on a silica gel column using an ethyl acetate – hexane mixture as the eluent unless specified otherwise.

N-*Allyl-2-furan-2-yl-acetamide (**11**)*: To a solution containing 1.4 g (11 mmol) of furan-2-yl-acetic acid (**10**) (31) in 25 mL of CH_2Cl_2 was added 2.0 g (12.6 mmol) of 1,1′-carbonyldiimidazole. After stirring at room temperature for 1.5 h, 1.3 g (22 mmol) of allylamine was added and the mixture was stirred for an additional 1 h. The mixture was concentrated under reduced pressure and the crude product was purified by silica gel chromatography to give 1.6 g (90%) of

After stirring at room temperature for 1 h, 0.5 g (2.4 mmol) of allyl-[2-(3,4-dimethoxyphenethyl)]amine (**22**) (34) was added and the mixture was stirred for an additional 2 h. The solution was concentrated under reduced pressure and the crude product was purified by silica gel chromatography to give 0.4 g (77%) of **23** as a clear oil which contained a mixture of amide rotamers in solution; IR (neat) ν: 1651, 1515, 1457, and 1260 cm^{-1}; ^{1}H-NMR (400 MHz, $CDCl_3$) δ: 2.74 (2H, t, *J* = 7.2 Hz) and 2.82 (2H, t, *J* = 7.2 Hz), 3.51–3.56 (2H, m), 3.70 (1H, s), 3.82–3.83 (2H, m), 3.84 (3H, s) and 3.85 (3H, s), 3.86 (3H, s) and 3.87 (3H, s), 4.02 (1H, d, *J* = 6.0 Hz), 5.13–5.21 (2H, m), 5.71 (1H, m) and 5.81 (1H, m), 6.14–6.18 (1H, m), 6.31–6.34 (1H, m), 6.65–6.83 (3H, m), and 7.33–7.36 (1H, m) ppm; ^{13}C-NMR (100 MHz, $CDCl_3$) δ: 33.4, 33.5, 33.7, 34.5, 48.0, 48.6, 49.2, 51.1, 55.7, 55.8, 55.9, 107.4, 107.5, 110.4, 110.5, 111.1, 111.4, 111.8, 111.9, 116.6, 117.1, 120.6, 120.7, 130.5, 131.6, 132.7, 133.1, 141.6, 141.7, 147.4, 147.8, 148.7, 148.8, 168.3, and 168.7 ppm; Anal. calcd. for $C_{19}H_{23}NO_4$: C 69.28, H 7.04, N 4.17; found: C 68.98, H 7.04, N 4.22.

*4-[2-(3,4-Dimethoxyphenethyl)]-11-oxa-4-aza-tricyclo[6.2.1.0^{1,6}] undec-9-en-3-one (**24**)*: A solution containing 0.17 g (5.2 mmol) of furan **23** in 10 mL of xylene was heated at reflux for 20 h. The solution was concentrated under reduced pressure and the crude solid was purified by silica gel chromatography to give 0.15 g (90%) of **24** as a white solid, mp 119–120°C; IR (neat) ν: 1644, 1513, 1449, and 1154 cm^{-1}; ^{1}H-NMR (400 MHz, $CDCl_3$) δ: 1.39–1.44 (2H, m), 1.71–1.75 (1H, m), 2.79–2.83 (2H, m), 2.92 (1H, d, *J* = 18.8 Hz), 3.15 (1H, d, *J* = 18.8 Hz), 3.18–3.22 (2H, m), 3.51–3.58 (1H, m), 3.66–3.73 (1H, m), 3.86 (3H, s), 3.88 (3H, s), 4.89 (1H, dd, *J* = 4.0 and 1.6 Hz), 6.14 (1H, d, *J* = 5.6 Hz), 6.37 (1H, dd, *J* = 5.6 and 1.6 Hz), and 6.75–6.81 (3H, m) ppm; ^{13}C-NMR (100 MHz, $CDCl_3$) δ: 30.3, 33.5, 35.9, 36.0, 50.0, 51.6, 55.7, 55.8, 78.1, 85.6, 111.1, 111.8, 120.6, 131.4, 137.3, 137.4, 147.4, 148.7, and 168.6 ppm; Anal. calcd. for $C_{19}H_{23}NO_4$: C 69.28, H 7.04, N 4.25; found: C 69.11, H 7.09, N 4.21.

*2-[2-(3,4-Dimethoxyphenethyl)]-7-hydroxy-1,7a,8,8a-tetrahydro-2*H*-isoquinoline-3-one (**25**)*: To a solution containing 0.24 g (10 mmol) of sodium metal in 25 mL of EtOH was added 1.0 g (3.0 mmol) of cycloadduct **24** at 0 °C. After stirring for 1 h at room temperature, 20 mL of water was added and the solution was extracted with CH_2Cl_2. The organic layer was dried over $MgSO_4$, concentrated under reduced pressure, and the crude product was purified by silica gel chromatography to give 0.9 g (92%) of **25** as a white solid, mp 137–139°C; IR (neat) ν: 3348, 1641, 1511, 1478, and 1244 cm^{-1}; ^{1}H-NMR (400 MHz, $CDCl_3$) δ: 1.21–1.30 (1H, m), 1.91 (1H, d, *J* = 6.6 Hz, exchangeable with D_2O), 2.08–2.13 (1H, m), 2.57–2.60 (1H, m), 2.80–2.85 (2H, m), 3.17 (1H, s), 3.20 (1H, d, *J* = 3.6 Hz), 3.51–3.73 (2H, m), 3.86 (3H, s), 3.87 (3H, s), 4.41 (1H, dd, *J* = 10.0 and 4.8 Hz), 5.71 (1H, d, *J* = 1.6 Hz), 6.17 (2H, dd, *J* = 18.8 and 10.0 Hz), and 6.76–6.83 (3H, m) ppm; ^{13}C-NMR (100 MHz, $CDCl_3$) δ: 31.8, 33.5, 35.4, 49.0, 51.9, 55.6, 55.7, 65.9, 111.2, 111.9, 118.3, 120.6, 126.0, 131.3, 141.1, 147.4, 148.7, and 165.8 ppm; Anal. calcd. for $C_{19}H_{23}NO_4$: C 69.28, H 7.04, N 4.25; found: C 69.14, H 7.05, N 4.20.

*7-Benzyloxy-2-[2-(3,4-dimethoxyphenethyl)]-1,7a,8,8a-tetrahydro-2*H*-isoquinolin-3-one (**26**)*: To a 5 mL solution of THF was added 0.04 g (1.0 mmol) of NaH (60% dispersion) which had been rinsed with hexane. After cooling to 0°C, 0.13 g (0.4 mmol) of alcohol **25** in 10 mL of THF was added and the mixture was warmed to room temperature. After stirring for 2 h, 0.24 g of benzyl bromide was added and the solution was heated at 60°C for 15 h. The reaction was cooled to 0°C and 10 mL of water was added slowly. The mixture was extracted with ethyl acetate and the organic layer was dried over $MgSO_4$ and concentrated under reduced pressure. Purification of the crude mixture by silica gel chromatography gave 0.12 g (83%) of **26** as a white solid, mp 118–119°C; IR (neat) ν: 1647, 1510, 1453, and 1260 cm^{-1}; ^{1}H-NMR (400 MHz, $CDCl_3$) δ: 1.25–1.38 (1H, m), 2.14–2.19 (1H, m), 2.50–2.58 (1H, m), 2.81–2.85 (2H, m), 3.11–3.21 (2H, m), 3.52–3.73 (2H, m), 3.85 (3H, s), 3.87 (3H, s), 4.21 (1H, dd, *J* = 10.4 and 5.2 Hz), 4.62 (2H, s), 5.74 (1H, d, *J* = 2.4 Hz), 6.22 (2H, s), 6.75–6.81 (3H, m), and 7.30–7.36 (5H, m) ppm; ^{13}C-NMR (100 MHz, $CDCl_3$) δ: 31.8, 32.7, 33.7, 49.0, 52.1, 55.7, 55.8, 70.5, 73.2, 111.1, 111.9, 119.4, 120.6, 126.9, 127.6, 127.8, 128.4, 131.6, 137.9, 146.6, 147.4, 148.8, and 165.2 ppm; Anal. calcd. for $C_{26}H_{29}NO_4$: C 74.44, H 6.97, N 3.34; found: C 74.28, H 6.90, N 3.31.

*7-Benzyloxy-2-[2-(3,4-dimethoxyphenethyl)]-octahydroisoquinolin-3-one (**27**)*: To a solution of 0.05 g (0.13 mmol) of **26** in 8 mL of EtOH was added a slight excess of Raney nickel. After stirring at room temperature for 15 h, the mixture was filtered through Celite with ethyl acetate. The

solution was concentrated under reduced pressure and the crude product was purified by silica gel chromatography to give 0.047 g (85%) of **27** as a clear oil; IR (neat) ν: 1636, 1511, 1452, and 1264 cm^{-1}; ^{1}H-NMR (400 MHz, $CDCl_3$) δ: 1.49–1.69 (5H, m), 1.83–1.91 (2H, m), 2.07–2.11 (2H, m), 2.27–2.47 (2H, m), 2.76–2.85 (2H, m), 3.07 (1H, dd, *J* = 12.0 and 2.8 Hz), 3.33–3.43 (3H, m), 3.68–3.75 (1H, m), 3.84 (3H, s), 3.87 (3H, s), 4.54 (2H, d, *J* = 2.4 Hz), 6.73–6.77 (3H, m), and 7.25–7.35 (5H, m) ppm; ^{13}C-NMR (100 MHz, $CDCl_3$) δ: 26.3, 26.7, 30.8, 31.4, 32.3, 32.6, 33.1, 49.1, 52.9, 55.7, 55.8, 69.8, 76.1, 111.1, 112.0, 120.7, 127.3, 127.4, 128.3, 131.6, 138.7, 147.4, 148.8, and 168.9 ppm; HRMS calcd. for $C_{26}H_{33}NO_4$: 423.2410; found: 423.2397.

*10-Benzyloxy-2,3-dimethoxy-5,8,8a,9,10,11,12,12a,13,13a-decahydro-6*H*-isoquino[3,2-a]isoquinoline (**9**)*: To a solution of 0.3 g (0.6 mmol) of **27** in 10 mL of benzene was added 0.2 g (1.3 mmol) of phosphorous oxychloride. After heating at reflux for 2 h, the solvent was removed under reduced pressure and the crude product was taken up in 10 mL of methanol. To this solution was added 0.05 g (1.3 mmol) of sodium borohydride and the mixture was stirred for an additional 2 h. The solvent was removed under reduced pressure and the crude material was purified by silica gel chromatography to give 0.15 g (52%) of **9** as a yellow foam; IR (neat) ν: 1601, 1510, and 1270 cm^{-1}; ^{1}H-NMR (400 MHz, $CDCl_3$) δ: 1.32–1.45 (1H, m), 1.56–2.04 (9H, m), 2.39 (1H, dt, *J* = 11.6 Hz and 3.6 Hz), 2.50–2.57 (2H, m), 2.72 (1H, dd, *J* = 11.6 and 1.6 Hz), 2.81–2.85 (1H, m), 3.02–3.11 (2H, m), 3.34–3.42 (1H, m), 3.84 (3H, s), 3.85 (3H, s), 4.55 (2H, dd, *J* = 23.6 and 12.4 Hz), 6.57 (1H, s), 6.68 (1H, s), and 7.24–7.33 (5H, m) ppm; ^{13}C-NMR (100 MHz, $CDCl_3$) δ: 27.0, 29.4, 29.5, 32.0, 32.3, 34.3, 35.1, 52.6, 55.7, 55.9, 62.0, 63.3, 69.3, 78.0, 108.0, 111.3, 127.0, 127.1, 127.3, 128.2, 130.5, 139.3, 147.0, and 147.1 ppm; HRMS calcd. for $C_{26}H_{33}NO_3$: 408.2539; found: 408.2526.

Studies on the synthesis of the decahydro-*as*-indacene ring system of (–)-spinosyn A via transannular Diels–Alder reactions of substituted (*E,E,E*)-cyclododeca-1,6,8-trienes

Scott A. Frank, Andrea B. Works, and William R. Roush

Abstract: Stereoselective syntheses of decahydro-*as*-indacenes **31** and **54** are reported. The key features of our syntheses of **31** and **54** are the tandem Ireland–Claisen ring contraction of lactones **29** and **38** followed by the transannular Diels–Alder cyclization of cyclododecatrienes **30** and **35**. Transition state modeling of both the transannular Diels–Alder reaction and the Ireland–Claisen ring contraction using PCModel is also described.

Key words: transannular Diels–Alder reactions, tandem reactions, Claisen ring contraction, Spinosyn A, synthetic study.

Résumé : On a réalisé la synthèse stéréosélective des décahydro-*as*-indacènes **31** et **54**. Les principales caractéristiques de nos synthèses de ces produits sont les contractions de cycle d'Ireland–Claisen en tandem des lactones **29** et **38**, suivies d'une cyclisation transannulaire de Diels–Alder des cyclodécatriènes **30** et **35**. On décrit aussi la modélisation moléculaire à l'aide d'un ordinateur des états de transition de la réaction de Diels–Alder transannulaire ainsi que de la réaction de contraction de cycle d'Ireland–Claisen.

Mots clés : réactions de Diels–Alder transannulaires, réactions en tandem, contraction de cycle de Claisen, Spinosyn A., étude synthétique.

[Traduit par la Rédaction]

Introduction

Spinosyn A (**1**) and D (**2**), ikarugamycin (**3**), and capsimycin (**4**) are natural products that possess perhydro-*as*-indacene subunits (Scheme 1). While ikarugamycin and capsimycin are relatively potent anti-bacterial agents (1, 2), the spinosyns display very potent insecticidal activity (3, 4) and are marketed for use against a wide variety of insects (5). Several total syntheses of these natural products have been developed (6–13). Many of the syntheses of **1** and **3** have utilized intramolecular Diels–Alder reactions of appropriately substituted (*E,E,E*)-dodeca-2,7,9-trienes to construct a trans-fused hexahydroindene subunit, with the third ring of the indacene nucleus being formed by a subsequent annulation sequence. We were intrigued with the notion that the tricyclic nucleus **6** of the spinosyns could be assembled in a single step by the transannular Diels–Alder reaction of an appropriately substituted (*E,E,E*)-cyclododeca-1,6,8-triene, such as **5**, as shown in Scheme 2. Hirata has suggested that a transannular Diels–Alder reaction may be involved in the biosynthesis of **3** (14), and Kirst has suggested that a similar transformation may occur in the biosynthetic pathway to **1** (15).

Transannular Diels–Alder reactions display significant advantages over conventional intramolecular Diels–Alder variants (16, 17) due to a lowered $\Delta G^{\ddagger}$ resulting from a decreased $\Delta S^{\ddagger}$. As a result, reactions which generally do not proceed intramolecularly work smoothly in the transannular version (18, 19). This process has also been used for the synthesis of strained, medium-sized rings via the transannular cyclization of macrocyclic trienes, a procedure representing an overall ring contraction, as we have demonstrated in our work on nargenicin A_1 (20). While the transannular Diels–Alder reaction is emerging as a powerful tool for the construction of fused, polycyclic ring systems (21), the factors that control the stereochemical outcome of these reactions are still being elucidated (22). Indeed, prior to the initiation of our studies, we were aware of only one other report detailing the preparation of an unsubstituted perhydro-*as*-indacene by a transannular Diels–Alder reaction (23).

From the outset, we realized that forming the requisite 12-membered triene **5** could be difficult. In general, the formation of 11, 12, and 13-membered macrocyclic dienes and trienes by direct cyclization of acyclic precursors can be troublesome as we and other groups have observed (24–27). Fortunately, access to strained, medium-sized rings can be achieved by other means. A particularly useful strategy involves the ring contraction of a larger and more accessible ring system. Although a number of ring contraction protocols exist, we were interested in using the Ireland–Claisen

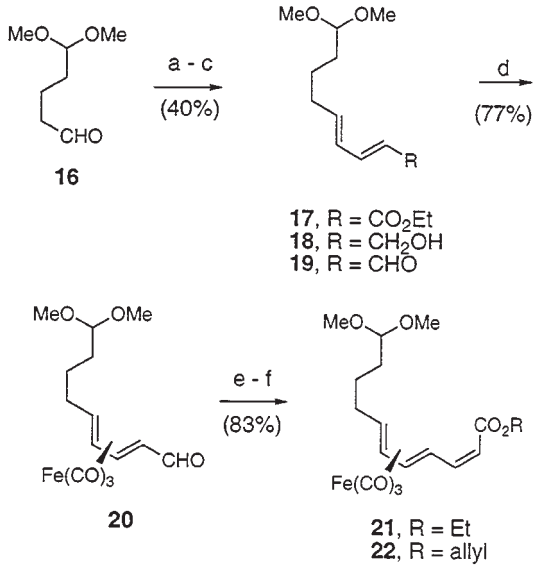
reaction (28–31) for these purposes since a product properly functionalized for further elaboration towards **1** would be produced. Extensive studies of the ring contractive Claisen rearrangement indicate that *cis*-disubstituted carbocycles (referring to the stereochemistry of the new vinyl and carboxylate stereocenters) generally are obtained with good diastereoselectivity (32–34). Accordingly, we targeted the synthesis of a macrocyclic lactone substrate such as **7**. Owing to the significant rate accelerations associated with Diels–Alder reactions performed in the transannular mode, we anticipated that the ring contraction and transannular Diels–Alder reaction could be performed as a single step (35, 36), thereby providing **9** directly from **7** via intermediate triene **8** (Scheme 3).

For this strategy to be applied successfully to the synthesis of **1**, two critical stereochemical issues needed to be resolved. First, a method for controlling the stereochemistry of the ring contraction of **7** would need to be devised such that the remote C(3)–C(9) stereochemical relationship of **8** could be controlled. Second, the stereochemical course of the transannular Diels–Alder reaction would also need to be regulated as four different tricycles can be generated from **8**.

Scheme 4.

Scheme 5.

With respect to the first issue, at the outset we anticipated that it might be possible to relay the stereochemical information at the C(9)-alkoxy group via a chiral diene(irontricarbonyl) complex which would serve as the stereochemical control element for the Claisen ring contraction step. Our previous studies on the Ireland–Claisen rearrangements of η^4-(1-acyloxy-2,4,6-octatrienyl)tricarbonyliron complexes **10** and **11** established that very high diasterofacial selectivity could be achieved with respect to the iron(tricarbonyl) group, as shown in Scheme 4 (37).



Although mixtures of **12** and **13** were obtained in these experiments, we established that the mixture of C(2)-epimers resulted from poor control of enolate geometry (38, 39). We hoped that constraints imposed by the macrocycle would facilitate greater stereochemical control in the Claisen ring contraction of **14** (Scheme 5). However, rather than embark immediately on the synthesis of **14**, we decided it was prudent to access the simplified substrate **15** in order to study both the stereochemistry of the Claisen ring contraction as well as the transannular Diels–Alder reaction.

Synthesis and attempted Ireland–Claisen ring contraction of 15

We began by treating 5,5-dimethoxypentanal **16** (40) with the lithium anion of triethylphosphonocrotonate (41) which provided the dienylic ester **17** in 61% yield (Scheme 6). DIBAL reduction of the ester (71%) followed by barium manganate (42) oxidation of allylic alcohol **18** gave diene aldehyde **19** (93%). Iron(tricarbonyl) complex **20** was obtained in 77% yield by portionwise addition of diiron nonacarbonyl to a heated solution of the diene in benzene over 5 h (43). A Still modified Horner–Wadsworth–Emmons olefination of **20** afforded the triene ester **21** in high yield (>95%) and as a single (*Z*)-olefin isomer (44). Transesterification of **21** was accomplished in 85% yield by treatment with the sodium salt of allyl alcohol in the presence of 3 Å sieves. Incorporation

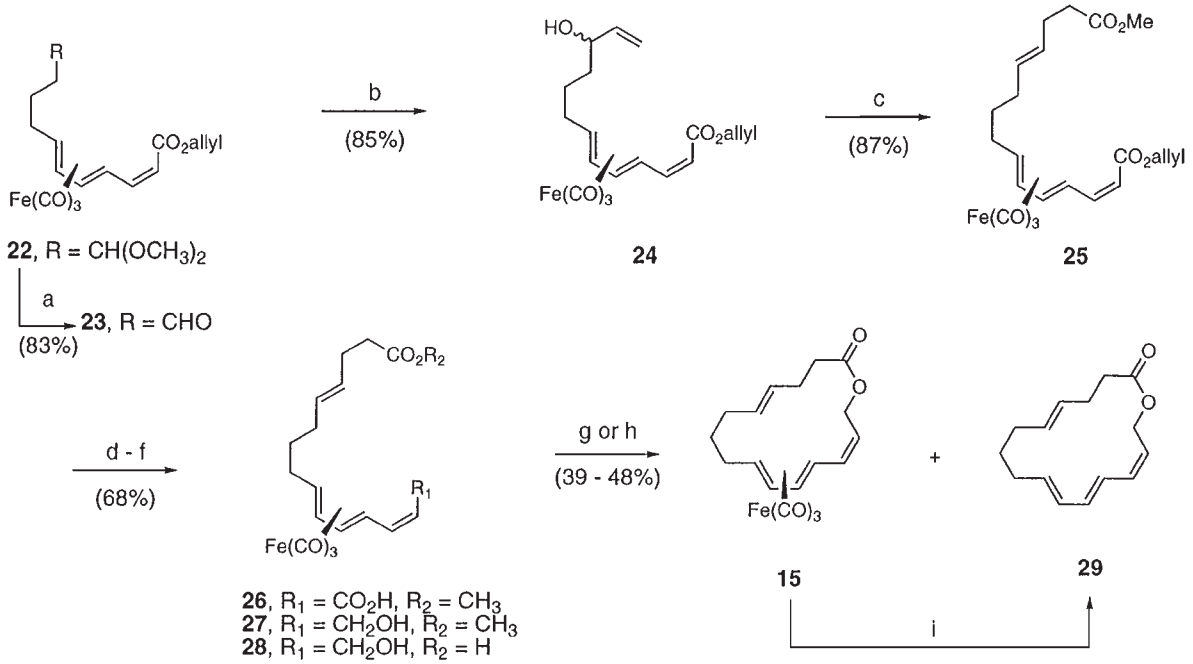
of the allyl ester permits deprotection of the trienoate in the presence of a methyl ester at a later point in the synthesis.

Deprotection of the dimethyl acetal of **22** with 4:1 acetic acid:water gave aldehyde **23** which was treated with vinyl magnesium bromide to afford a mixture of allylic alcohols, **24** (Scheme 7). This mixture was then treated with trimethyl orthoacetate and catalytic propionic acid at 78°C for 48 h to afford **25** in 87% yield as a single olefin isomer (45). The allyl ester of **25** was deprotected in the presence of the methyl ester by using catalytic tetrakis(triphenylphosphine)palladium(0) and diethylamine, (46) yielding mono-acid **26** in 90% yield. Acid **26** was converted to a mixed anhydride and then reduced to alcohol **27** with sodium borohydride in ethanolic tetrahydrofuran (79%) (47). Hydrolysis of the methyl ester of **27** was accomplished using lithium hydroxide in 4:1 dimethoxyethane:water to give the very unstable seco-acid **28** (>95%). This intermediate was used immediately in the macrolactonization (48, 49), which could be carried out in one of two ways. One procedure (50) involved addition of a –78°C solution of **28** dropwise over 12 h to a suspension of 4-dimethylaminopyridine and bromotrispyrrollidino-phosphonium hexafluorophosphate (PyBroP) (51) in 12:1 toluene:dichloromethane. This method provided **15** in 48% yield. Alternatively, **28** could be converted to a mixed anhydride by using 2,4,6-trichlorobenzoyl chloride in the presence of triethylamine (52). Filtration of the amine hydrochloride salts, followed by slow addition of the mixed anhydride solution into a mixture of 4-dimethylaminopyridine and toluene at 63°C gave **15** (39%) and **29** (12%) (53, 54). Finally, complexed lactone **15** could be converted to **29** by treatment with ferric chloride in propionitrile at –50°C (67%).

With **15** now in hand we were ready to investigate the planned Ireland–Claisen ring contraction (Scheme 8). Unfortunately, all attempts at performing the Ireland–Claisen ring contraction on **15** were unsuccessful. For example, treatment of **15** with potassium hexamethyldisilazide in the presence of *tert*-butyldimethylsilyl triflate, conditions successfully employed in our studies of **10** and **11**, led to decomposition products. We were very pleased however to discover that the uncomplexed tetraene **29** underwent the desired ring contraction and transannular Diels–Alder reaction to give **31** after hydrolytic workup. A second isomer (**32**) was also obtained and separated from **31** (4:1 ratio of **31**:**32**) by recrystallization. Triene **30** was not detected during the course of the experiment. The stereochemistry of **31** was confirmed by X-ray crystallographic analysis,[2] but the stereostructure of **32** was not determined.

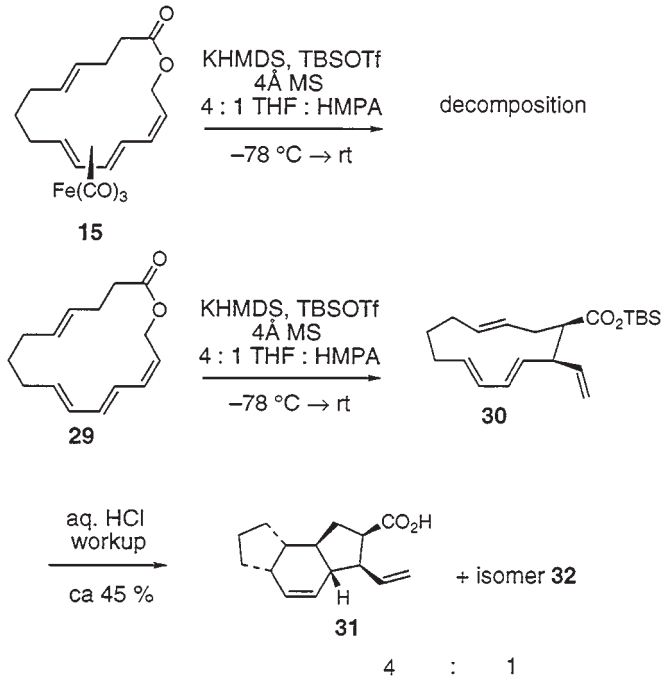
The stereochemistry of **31** requires that macrocyclic triene **30** is *cis*-disubstituted, and that **31** derives from transition state **A** (Scheme 9). Examination of transition states **A**–**C** indicates that **A** contains no serious nonbonded interactions, with C(14)-H and C(12)-H in a *cis*-relationship, and with C(5) of the diene unit *cis* to C(3)-H, thereby minimizing allylic interactions at this position (55). In contrast the carboxyl unit of **30** interacts with C(12)-H in transition state **B**, and an allylic interaction occurs between C(5) and the C(3)-vinyl substituent in **C**, thereby raising the energy of transition states **B** and **C** compared to **A**.

While we were encouraged by the ability to access macrocyclic triene **30** via the Claisen ring contraction of **29**, it was readily apparent that some means of altering the relative energetics of transition states **A** and **B** would be required if we hoped to apply this strategy towards a synthesis of spinosyn A: we required that vinyl and carboxyl substituents emerge on the *cis*-fused cyclopentane ring (as in **33**), and not in the *trans*-fused ring, as is the case with **31**. Coupled with the requirement that C(9) would need to be functionalized prior to the transannular reaction, we considered using macrocyclic triene **35** containing geminal carboalkoxy groups at C(9). Examination of transition states **D** and **E**, analogous to **A** and **B**, respectively, (Scheme 10), suggested that transition state **E** might be destabilized relative to **D** by virtue of the interaction between the axial carboalkoxy substituent and C(11)-H. Dreiding model analysis of **D** and **E** also indicated the presence of interactions involving the *gem*-carboalkoxy group in **E**, in principle further destabilizing this transition state. Use of the *gem*-carboalkoxy substituents would also allow for a very simple synthesis involving the dialkylation of a malonate ester with two allylic electrophiles, **39** and **40**, as suggested in Scheme 11 (56). Finally, we thought it likely that the *gem*-carboalkoxy substituents of **37** could serve as a predecessor of the oxygen functionality needed at this position (57, 58). Hence, substrate **38** was elected as the immediate precursor to the tandem Ireland–Claisen contraction and Diels–Alder cycloaddition.



Synthesis and tandem Ireland–Claisen contraction and Diels–Alder reaction of 38

Di-*tert*-butyl malonate **41** was treated with butadiene monoepoxide **42** in the presence of 1 mole % tetrakis(triphenylphosphine)palladium(0) (59), giving allylic



[2] We thank Dr. John Huffman for the X-ray structure determination of **31** (Indiana University Molecular Structure Center Report No. 95180).

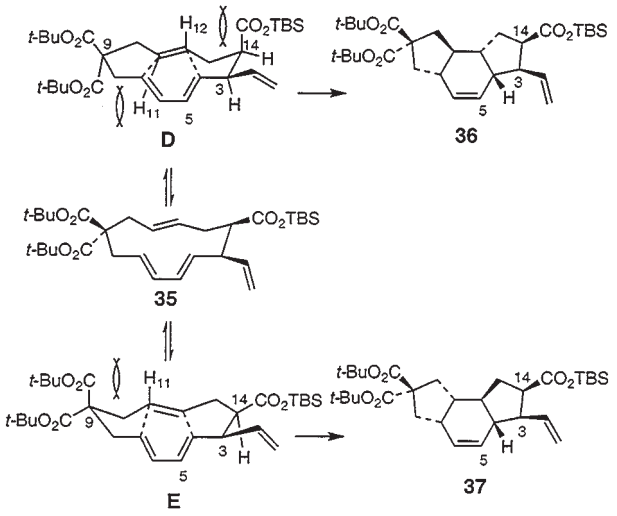
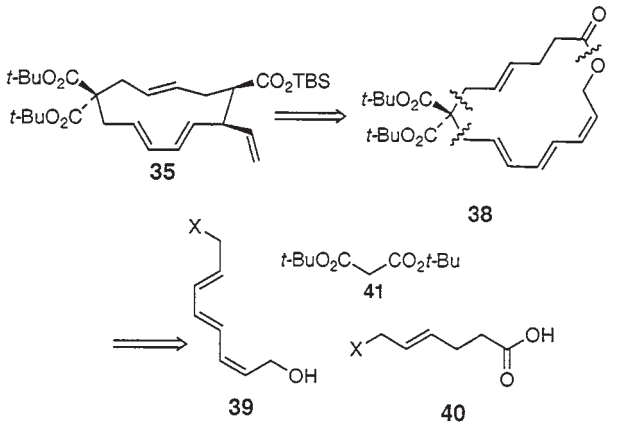
Scheme 9.



alcohol **43** in 79% yield as a 2:1 mixture of *E*:*Z* olefin isomers (Scheme 12). Preparation of the dienophilic portion of the macrocycle **38** was accomplished starting from bromohydrin **44**, which is readily available from butadiene and aqueous *N*-bromosuccinimide (60). Allylic alcohol **44** was subjected to the Johnson orthoester Claisen rearrangement (45), and methyl ester **45** was isolated in moderate yield (56%). The coupling of **43** and **45** was effected with sodium hydride in refluxing THF, and product **46** was isolated in good yield (78%). Allylic alcohol **46** was oxidized with PCC (61), and the resulting enal **47** was obtained in 93% yield as a single olefin isomer.



Exposure of **47** to chromous chloride and iodoform in tetrahydrofuran (62) followed by stirring the reaction mixture for 30 min with a 1 M aqueous sodium serinate solution (63) afforded dienyl iodide **48**, as summarized in Scheme 13. The isomeric purity of the newly formed olefin was 7:1 (*E*:*Z*). Use of Kishi's serinate workup procedure for the Takai olefination gave the best results, as omitting this step from the reaction workup provided **48** in lower yield. Crude **48** was dissolved in triethylamine and treated with

catalytic bis(triphenylphosphine)palladium(II) dichloride, cuprous iodide, and propargyl alcohol to give trienyne **49** in 59% overall yield from enal **47** (64). We now turned our attention to the *cis*-reduction of alkyne **49**. Studies on related systems had indicated that Lindlar hydrogenations yielded a mixture of products, including products of overreduction (65). However, use of an activated zinc species to reduce **49** afforded tetraene **50** in 93% yield (66). Hydrolysis of the methyl ester was effected with lithium hydroxide in a mixture of tetrahydrofuran, methanol, and water to give the very unstable seco acid **51** in 80% yield, which was best used immediately in the next step as the C(2)–C(3) (*Z*)–olefin would undergo isomerization if **51** was stored at ambient temperature.

Macrolactonization of **51** (see Scheme 14) was accomplished using the Mukaiyama procedure (43% yield) (67). Other macrolactonization methods (Yamaguchi (52) and Mitsunobu (68) protocols) gave reduced yields of **38**. The low yield of **38** may be due in part to its thermal instability, as purified samples of this lactone decomposed when heated overnight. When the Mukaiyama macrolactonization was performed at a lower temperature, diminished amounts of **38** were obtained. Interestingly, the macrolactonization of **52** proceeded in only ca. 5% yield, indicating that the *gem*-

carboalkoxy substituent exerts a beneficial Thorpe–Ingold effect on this reaction (69).

In an effort to improve the efficiency of the macrocyclization step, we examined the intramolecular alkylation of **53**, shown below in Scheme 15. Unfortunately, we were unable to isolate any of the desired macrolactone from the attempted cyclization of **53**. Treatment of **53** with either cesium carbonate and 18-crown-6 in refluxing acetonitrile

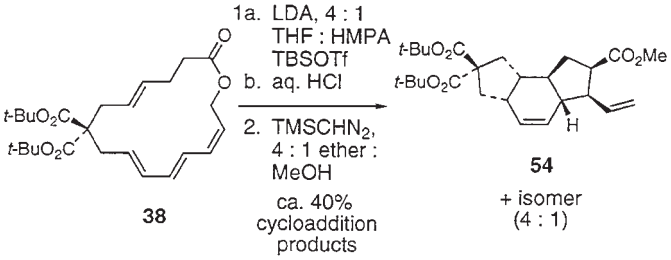

Scheme 15.

(0.005 M) (27), 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) at 0.003 M in dichloromethane, or finally potassium *tert*-butoxide in tetrahydrofuran (at 0.003 and at 0.0001 M), provided only decomposition, recovered starting material, or dimeric products.

Treatment of a solution of lactone **38** in 4:1 THF:HMPA at –78°C with *t*-butyldimethylsilyl triflate followed by addition of LDA and then warming this mixture to room temperature yielded two cycloadducts in a 4:1 product ratio (Scheme 16). Esterification of this mixture with trimethylsilyldiazomethane afforded the two cycloadducts in 40% yield. Although we were unable to separate this mixture by recrystallization or chromatography, we were successful in assigning the stereochemistry depicted in structure **54** to the major product using a combination of COSY and NOESY ^{1}H HMR techniques. While the ^{1}H NMR spectrum of **54** was complex in C_6D_6, in $CDCl_3$ a much more highly resolved spectrum was obtained. The *cis*-relationship of C(7)-H and C(11)-H, as well as the *cis*-relationship between C(3)-H and C(14)-H, was assigned based upon the NOE data. In addition, the 1,3- and 1,4-*syn* relationships of C(12)-H with C(14)-H and C(3)-H were assigned based upon the presence of observed NOEs. Unfortunately, **54** does not possess the correct stereochemistry for use in a synthesis of **1**.

Scheme 16.

As before, we were unable to determine the stereochemistry of the minor product.

Transition state modeling of the transannular Diels–Alder reaction

While we were successful in developing a tandem Claisen ring contraction and transannular Diels–Alder sequence, our goal of constructing the perhydro-*as*-indacene subunit of **1** remained unrealized. In an effort to define what interactions were controlling the outcome of the Diels–Alder reaction, and also to aid in the design of improved substrates for preparing **1**, we turned to molecular modeling to estimate the energies of the various transition states for the cyclizations of trienes **55**–**60** (Scheme 17). For this purpose, we used the transition state subroutine within PCModel.[3] The transition states are depicted as structures **F**–**I** with the values obtained from the modeling provided in Table 1 (kcal/mol).

We initially examined the transition states **H** and **I** for the Diels–Alder reaction of trienes **55** and **58** (entries 1 and 4). The defining interaction for these two transition states apparently is the interaction of the C(14)-carboxyl group with C(12)-H, thus **I** is favored by 0.8 to 1.4 kcal/mol (entries 1 and 4). For the cyclization of **58** (entry 4), the 1,3 interaction that R_1 experiences with C(11)-H in **H** also occurs with R_2 in **I**. Thus, these two interactions nullify each other and transition state **I** predominates both computationally and experimentally. Based upon these calculations, we believe that the minor isomer isolated from the transannular Diels–Alder reaction is most likely **61**. Clearly, the conformational bias which we had anticipated based upon the Dreiding model analysis of transition states **H** and **I** is not substantial enough to alter the product distribution.

We next analyzed transition states **F** and **G** for the cyclization of **55** and **58** (leading to products **63** and **64**), which are destabilized by *A*-1,3 strain between the diene and the vinyl group. These two transition states are predicted to be ca. 1.4 kcal/mol higher in energy than analogous transition states **H** and **I**. This prediction is consistent with our experimental results, as cycloadducts **63** and **64** were not observed.

To determine if we could favor transition state **H**, we examined the placement of a steric directing group upon the diene at C(6), trienes **56**, **57**, **59**, and **60** (entries 2–3 and 5–6) (70). This strategy has been successfully used in other intramolecular Diels–Alder reactions to alter the energetics of competing transition states. In all cases studied thus far,

[3] PCModel uses the MMX force field and is available from Serena Software, Bloomington, IN 47405. Bond orders of 0.3 were used for both the bond breaking and bond forming atoms in the MMXE subroutine within PCModel.

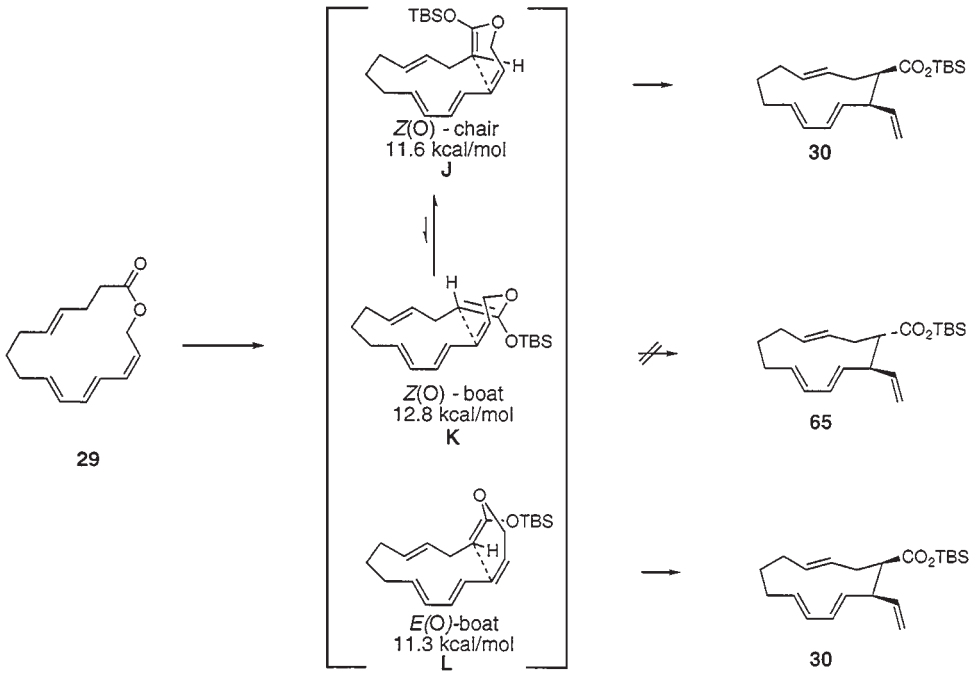
the steric directing group enhances formation of a *trans*-ring fusion at the adjacent position (71). Trimethylsilyl and bromo substituents (X = TMS or Br) have been used for these purposes. Unfortunately, PCModel will not allow the attachment of halogen or silyl substituents to the atoms of the transition state that are undergoing rehybridization. Consequently, we chose to approximate the trimethylsilyl group as either a *tert*-butyl or an iso-propyl group. Based upon an *A*-value analysis, the iso-propyl group is a more accurate approximation of a trimethylsilyl group than is a *tert*-butyl group (72). Nonetheless, we incorporated both of these groups into our modeling efforts. While it appears that introduction of a *tert*-butyl group at C(6) significantly favors transition state **H** for the cyclization of triene **57**, the isopropyl substituted triene **58** seems only moderately biased to cyclize via transition state **H**. For trienes **59** and **60**, the transition states appear to be much closer in energy. However, the desired trans ring junction is predicted to appear on the side adjacent to the directing group. Efforts to test these predictions experimentally are in progress.

Transition state modeling of the Ireland–Claisen ring contraction

We also used molecular modeling to examine the transition states of the Ireland–Claisen rearrangement of the 16-membered lactone **29** (Scheme 18) (73, 74). We were interested to determine what influence the enolate geometry would have on the outcome of the rearrangement, and thus, if we could access the trans-disubstituted cyclododecatriene by altering the enolate geometry (38, 75). For this purpose, we again used the transition state subroutine present in PCModel.[3] The results of these studies are summarized below.



Our modeling predicts that regardless of what enolate geometry is generated from **29**, the cis-substituted product will be preferentially formed. The *E*(*O*)-silyl ketene acetal boat transition state **L** and *Z*(*O*)-silyl ketene acetal chair transition state **J**, which both lead to **30**, are of comparable energy. The *Z*(*O*)-silyl ketene acetal boat transition state **K**, which leads to **65**, is notably higher in energy than **J**. The *E*(*O*)-silyl ketene acetal chair transition state (which is not shown) is substantially higher energetically (>5 kcal) than **J**–**L**. From these modeling results, we fully expect that regardless of enolate geometry, *cis*-disubstituted product **29** will predominate in lieu of **65**.

Conclusions

We have demonstrated that the combination of an Ireland–Claisen ring contraction of a 16-membered lactone in tandem with a transannular Diels–Alder reaction of the newly formed cyclododecatriene is an effective protocol to prepare decahydro-*as*-indacenes with good diastereoselectivity. Although we were unsuccessful in developing a

© 2000 NRC Canada

Scheme 18.

system that would be applicable to **1**, we were encouraged that our after the fact transition state modeling was in good agreement with the experimental results. We are hopeful that the knowledge gained from the modeling exercise will aid in the development of substrates useful for the stereoselective synthesis of the *as*-indacene nucleus of **1**. Results of these efforts will be reported in due course.

Experimental section[4]

*Ethyl (2*E*,4*E*)-9,9-dimethoxy-nona-2,4-dienoate (**17**)*: To distilled hexamethyldisilazane (24.2 mL, 115 mmol) in THF (200 mL) at –78°C was added *n*-butyllithium (2.5 M in hexanes, 46 mL, 115 mmol). After 20 min at –78°C, the solution was warmed to –30°C and triethyl phosphonocrotonate (25 mL, 126 mmol) was added. The reaction was then cooled to –50°C and a solution of aldehyde **16** (40) (23.5 g, 161 mmol) in THF (50 mL) was added via cannula. The reaction mixture was warmed to 10°C over 2 h and was then diluted with ether (200 mL) and quenched with saturated aqueous $NaHCO_3$ (250 mL). The layers were separated and the organic phase was washed with saturated aqueous $NaHCO_3$ (250 mL). The combined aqueous phases were washed with ether (3 × 50 mL), and the combined organic phases were washed with saturated aqueous NaCl (5 mL), dried ($MgSO_4$), concentrated, and purified by flash chromatography. Ester **17** (17.2 g, 61%) was isolated as a clear oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.28–7.21 (m, 1H), 6.21–6.06 (m, 2H), 5.78 (d, *J* = 15.4 Hz, 1H), 4.36 (t, *J* = 5.6 Hz, 1H), 4.19 (q, *J* = 7.1 Hz, 2H), 3.31 (s, 6H), 2.19 (q, *J* = 7.1 Hz, 2H), 1.64–1.57 (m, 2H), 1.53–1.45 (m, 2H), 1.29 (t, *J* = 7.1 Hz, 3H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 167.3, 144.8, 143.7, 128.7, 119.5, 104.2, 60.2, 52.7, 32.7, 31.9, 23.7, 14.3; IR (CCl_4) 3000, 2980, 1720, 1650, 1620, 1370, 1250, 1130, 1000, 950 cm^{-1}; HRMS calcd. for $C_{12}H_{19}O_3$ $[M–OCH_3]^+$: 211.1334, found: 211.1328 *m*/*z*.

*(2*E*,4*E*)-9,9-Dimethoxy-nona-2,4-dien-1-ol (**18**)*: To a solution of ester **17** (14.4 g, 59.5 mmol) in toluene (200 mL) at –78°C was added diisobutylaluminum hydride (1.5 M in toluene, 90 mL, 135 mmol). After 5 min, excess MeOH was slowly added to the vigorously stirred solution at –78°C. When hydrogen evolution had ceased, the solution was warmed to room temperature and stirred overnight with saturated aqueous sodium potassium tartrate (200 mL). The biphasic mixture was separated, and the organic phase was washed with aqueous sodium potassium tartrate (3 × 40 mL). The combined aqueous phases were washed with ether (3 × 25 mL), and the combined organic phases were washed with saturated aqueous NaCl (5 mL), dried ($MgSO_4$), concentrated, and purified by flash chromatography. Alcohol **18** (8.48 g, 71%) was isolated as a clear oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.22–6.16 (m, 1H), 6.07–6.00 (m, 1H), 5.74–5.63 (m, 2H), 4.35 (t, *J* = 5.66 Hz, 1H), 4.14 (d, *J* = 5.50 Hz, 1H), 3.30 (s, 3H), 3.29 (s, 3H), 2.09 (q, *J* = 7.23 Hz, 2H), 1.62–1.56 (m, 2H), 1.47–1.40 (m, 4H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 134.8, 131.8, 129.8, 129.7, 104.3, 63.4, 52.6, 32.3, 31.9, 24.1; IR (CCl_4) 3620 (s), 3450 (br), 3000, 2960, 990 cm^{-1}; HRMS calcd. for $C_{10}H_{15}O$ $[M–OCH_3–H_2O]^+$: 151.1123, found: 151.1118 *m*/*z*. Anal. calcd. for $C_{11}H_{20}O_3$: C 65.97, H 10.07; found: C 65.96, H 10.32.

*(2*E*,4*E*)-9,9-Dimethoxy-nona-2,4-dienal (**19**) (43)*: To a solution of alcohol **18** (8.25 g, 41 mmol) in CH_2Cl_2 (150 mL) at 25°C was added $BaMnO_4$ (12 g, 46.9 mmol). After 1 h, more $BaMnO_4$ (12 g, 46.9 mmol) was added, and the

mixture was stirred overnight. An additional portion of $BaMnO_4$ (3 g, 11.7 mmol) was then added, and the mixture was stirred for 3 h and then filtered through a short plug of Celite® and silica gel using copious amounts of ethyl acetate as eluant. Concentration of the filtrate afforded aldehyde **19** (7.62 g, 93%) as a clear oil which used without further purification: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 9.53 (d, *J* = 8.0 Hz, 1H), 7.07 (dd, *J* = 15.3, 10.1 Hz, 1H), 6.36–6.21 (m, 2H), 6.07 (dd, *J* = 15.3, 8.0 Hz, 1H), 4.37 (t, *J* = 5.5 Hz, 1H), 3.32 (s, 6H), 2.25 (apparent q, *J* = 7.1 Hz, 2H), 1.66–1.59 (m, 2H), 1.57–1.49 (m, 2H); ^{13}C NMR (100 MHz, $CDCl_3$) δ:193.9, 152.6, 146.4, 130.3, 129.0, 104.2, 52.8, 32.9, 32.0, 23.5; IR (CCl_4) 2960, 2840, 1690, 1640, 1130, 1010, 990 cm^{-1}; HRMS calcd. for $C_{10}H_{15}O_2$ $[M–OCH_3]^+$: 167.1072, found: 167.1073 *m/z*.

*Tricarbonyl [(2*E*,4*E*)-(2–5-*η*^{4})-9,9-dimethoxy-nona-2,4-dienal]iron (**20**)*: To a degassed solution of aldehyde **19** (560 mg, 2.83 mmol) in benzene (100 mL) was added diiron nonacarbonyl (800 mg, 2.20 mmol) and the solution was brought to a gentle reflux. Additional diiron nonacarbonyl (4 × 800 mg) was added at intervals of 45 min–1 h, after which time ^{1}H NMR analysis indicated complete consumption of starting material. The solution was cooled to ambient temperature, filtered through Celite® using ether as eluant and concentrated to a final volume of 15 mL. The residue was purified by careful chromatography using a slow gradient of hexanes → 1:1 hexanes:ether. Complexed aldehyde **20** (783 mg, 77%) was isolated as an orange oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 9.26 (d, *J* = 4Hz, 1H), 5.78 (ddd, *J* = 8.2, 5.0 Hz, 1.1 Hz, 1H), 5.29 (ddd, *J* = 8.9, 5.0 Hz, 0.4 Hz, 1H), 4.36 (t, *J* = 5.6 Hz, 1H), 1.81–1.46 (m, 7H), 1.13 (ddd, *J* = 8.4, 4.4 Hz, 1.2 Hz, 1H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 209.2 (broad), 196.1, 104.2, 88.5, 81.5, 66.2, 54.7, 52.9, 52.8, 33.9, 32.0, 27.0; IR (CCl_4) 2940, 2060 (vs), 1990, 1680, 1650, 1445, 1120 cm^{-1}; HRMS calcd. for $C_{13}H_{15}O_5Fe$ $[M–OCH_3]^+$: 307.0269, found 307.0254 *m/z*; HRMS calcd. for $C_{11}H_{15}O_3Fe$ $[M–OCH_3–2(CO)]^+$: 251.0371, found: 251.0372 *m/z*. *Tricarbonyl [methyl (2*Z*,4*E*,6*E*)-(4–7-*η*^{4})-9,9-dimethoxy-undeca-(2,4,6)-trienoate]iron (**21**) (**44**)*: To a solution of 18-crown-6 (23 g, 86 mmol) and ethyl bis(2,2-trifluoroethyl)phosphonoacetate (4.1 mL, 19 mmol) in THF (380 mL) at –78°C was added potassium hexamethyldisilazide (0.5 M in toluene, 38 mL, 19 mmol). After 5 min, the solution was warmed to 0°C for 10 min, then was re-cooled to –78°C and aldehyde **20** (5.9 g, 17 mmol) in THF (50 mL) was added dropwise via cannula. The mixture was stirred for 1 h at –78°C, then saturated aqueous $NaHCO_3$ (150 mL) was added, and the layers were separated. The organic layer was washed with saturated aqueous $NaHCO_3$ (2 × 50 mL), and the combined aqueous layers were washed with ether (4 × 100 mL). The organic layers were washed with saturated aqueous NaCl (15 mL), dried ($MgSO_4$), concentrated, and purified by flash chromatography (5:1 → 3:1 hexanes:ether). Unsaturated ester **21** (6.2 g, 91%) was isolated as a yellow oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.07 (t, *J* = 11.0 Hz, 1H), 5.57 (d, *J* = 11.2 Hz, 1H), 5.29 (dd, *J* = 8.9, 4.8 Hz, 1H), 5.10 (dd, *J* = 8.0, 4.8 Hz, 1H), 4.35 (t, *J* = 5.6 Hz, 1H), 3.71 (s, 3H), 3.32 (s, 3H), 3.31 (s, 3H), 3.06 (dd, *J* = 10.5, 9.5 Hz, 1H), 1.71–1.50 (m, 7H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 211.1 (broad), 166.9, 150.0, 115.0, 104.3, 86.1, 84.8, 64.7, 54.0, 52.9, 52.6, 51.1, 34.1, 32.1, 27.1; IR (CCl_4) 2940, 2810, 2025 (vs), 1990, 1970, 1710, 1610, 1200, 1180 cm^{-1}; HRMS calcd. for $C_{15}H_{22}O_5Fe$ $[M–2(CO)]^+$: 338.0725, found 338.0815 *m/z*; HRMS calcd. for $C_{14}H_{23}O_4Fe$ $[M–2(CO) + H]^+$: 311.0809, found: 311.0804 *m/z*. Anal. calcd. for $C_{17}H_{22}O_7Fe$: C 51.79, H 5.63; found: C 52.05, H 5.47.

*Tricarbonyl [(2*Z*,4*E*,6*E*)-(4–7-*η*^{4})-9,9-dimethoxy-undeca-(2,4,6)-trienoic acid allyl ester]iron (**22**) (**76**)*: Allyl alcohol (freshly distilled from CaH_2, 100 mL) was treated with Na^0 (sodium metal) (1.4 g, 60.9 mmol) at 0°C. To this solution was added 3 Å sieves (flame-dried in vacuo, 5.2 g). Methyl ester **21** (6.1 g, 15.5 mmol) in allyl alcohol (20 mL) was then added dropwise via cannula. The reaction mixture was stirred for 3 h, then was filtered and partitioned between ether and saturated. aqueous NaCl (100 mL each). The organic layer was washed with saturated. aqueous NaCl (3 × 100 mL), and the combined aqueous layers were washed with ether (4 × 50 mL). The organic layers were washed with saturated. aqueous NaCl (5 mL), dried ($MgSO_4$), concentrated, and purified by flash chromatography (slow gradient from hexanes → 5:1 hexanes:ether). Allyl ester **22** (5.56 g, 85%) was isolated as an orange oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.08 (t, *J* = 11.1 Hz, 1H), 5.95 (ddt, *J* = 17.1, 10.4, 5.7 Hz, 1H), 5.60 (dd, *J* = 11.1, 0.8 Hz, 1H), 5.35 (q, *J* = 1.6 Hz, 1H), 5.31–5.22 (m, 3H), 5.10 (dd, *J* = 7.9, 5.2 Hz, 1H), 4.66–4.57 (m, 2H), 4.36 (t, *J* = 5.6 Hz, 1H), 3.32 (s, 3H), 3.31 (s, 3H), 3.10–3.05 (m, 1H), 1.74–1.46 (m, 7H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 211.1 (broad), 166.1, 150.3, 132.4, 118.2, 115.1, 104.3, 86.0, 84.8, 64.8, 54.1, 52.8, 52.7, 34.1, 32.1, 27.1; IR (CCl_4) 3070, 2970, 2850, 2040 (vs), 1980, 1710, 1610, 1170, 980, 930 cm^{-1}; HRMS calcd. for $C_{16}H_{24}O_4Fe$ $[M–3(CO)]^+$: 336.1024, found: 336.1037 *m/z*. Anal. calcd. for $C_{19}H_{24}O_7Fe$: C 54.30, H 5.76; found: C 54.50, H 5.87.

*Tricarbonyl [(2*Z*,4*E*,6*E*)-(4–7-*η*^{4})-11-oxo-undeca-2,4,6-trienoic acid allyl ester]iron (**23**)*: Allyl ester **22** (522 mg, 1.24 mmol) was suspended in a 4:1 mixture of acetic acid and water and stirred until acetal hydrolysis was complete by TLC analysis. The solvents were removed by lyophilization, and the residue was purified by flash chromatography (slow gradient from hexanes → 1:1 hexanes:ether). Aldehyde **23** (387 mg, 83%) was isolated as a viscous orange oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 9.77 (s, 1H), 6.09 (apparent t, *J* = 11.1 Hz, 1H), 5.95 (dddd, *J* = 17.3, 10.4, 5.8, 5.7 Hz, 1H), 5.61 (dd, *J* = 11.2, 0.8 Hz, 1H), 5.35–5.23 (m, 3H), 5.10 (ddd, *J* = 4.9, 3.8, 1.1 Hz, 1H), 4.67–4.57 (m, 2H), 3.12–3.07 (m, 1H), 2.56–2.42 (m, 2H), 1.74–1.46 (m, 7H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 210.8 (broad), 201.8, 166.1, 150.1, 132.3, 118.2, 115.3, 85.9, 84.9, 64.7, 63.5, 54.2, 43.2, 33.6, 24.3; IR (CCl_4) 2055 (vs), 1990, 1970, 1730, 1710, 1610, 1170, 980, 930 cm^{-1}; HRMS calcd. for $C_{15}H_{18}O_4Fe$ $[M–2(CO)]^+$: 318.0555; found: 318.0537 *m/z*; HRMS calcd. for $C_{14}H_{18}O_3Fe$ $[M–3(CO)]^+$: 290.0606; found: 3290.0600 *m/z*. sieves (~75 mg) for 20 min. The solution was then cooled to –97°C and vinyl magnesium bromide (1 M in THF, 1.05 mL, 1.05 mmol) was added. The reaction temperature was maintained between –95 and –100°C for 20 min, then was warmed to –90°C for 10 min and –78°C for 2 h. The reaction was then quenched at this temperature with 1 M HCl in saturated aqueous NaCl (10 mL). After the mixture reached ambient temperature, ether (10 mL) was added and the layers were separated. The organic layer was washed with 1 M HCl in saturated aqueous NaCl (2 × 10 mL) and saturated aqueous NaCl (2 × 5 mL), and the combined aqueous layers were washed with ether (3 × 15 mL). The organic layers were washed with saturated aqueous NaCl (5 mL), dried ($MgSO_4$), concentrated, and purified by flash chromatography (slow gradient from 3:1 → 1:1 hexanes:ether). Allylic alcohol **24** (355 mg, 85%) was isolated as an orange oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.08 (apparent t, *J* = 11.1 Hz, 1H), 5.91 (dddd, *J* = 17.3, 10.4, 5.8, 5.7 Hz, 1H), 5.86 (dddd, *J* = 17.1, 10.4, 6.5, 0.8 Hz, 1H), 5.60 (dd, *J* = 11.2, 0.8 Hz, 1H), 5.35 (q, *J* = 1.6 Hz, 1H), 5.31–5.21 (m, 3H), 5.15–5.08 (m, 2H), 4.68–4.58 (m, 2H), 4.14–4.06 (m, 1H), 3.07 (dt, *J* = 9.9, 1.0 Hz, 1H), 1.76–1.46 (m, 7H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 211.2 (broad), 166.2, 150.3, 140.9, 132.3, 118.2, 115.1, 86.1, 84.7, 73.1, 73.0, 64.9, 64.7, 54.0, 36.4, 34.2, 27.8, 27.8; IR (CCl_4) 3620, 3400 (br), 3080, 2940, 2025 (vs), 1990, 1970, 1710, 1610, 1170, 985, 920 cm^{-1}; HRMS calcd. for $C_{16}H_{22}O_3Fe$ [M–3(CO)]$^+$: 318.0919, found: 318.0915 *m*/*z*. Anal. calcd. for $C_{19}H_{22}O_6Fe$: C 56.74, H 5.51; found: C 57.02, H 5.58.

*Tricarbonyl [allyl (2*Z*,4*E*,6*E*,11*E*)-(4–7-*η^4*)-15-carbomethoxy-pentadeca-(2,4,6,11)-tetraenoate]iron (**25**) (45)*: Allylic alcohol **24** (355 mg, 0.88 mmol), trimethyl orthoacetate (5 mL, 39.3 mmol), and propionic acid (6.5 μL, 0.09 mmol) were heated at 80°C (oil bath temperature) under a steady stream of nitrogen until TLC analysis indicated complete consumption of starting alcohol. This process usually required 2–4 h, and trimethyl orthoacetate was replenished as it was depleted. The flask was sealed (for larger scale reactions, a reflux condenser is advised) and the reaction was heated at 78°C for 2 d. Concentration of the mixture in vacuo and purification of the crude product by flash chromatography (5:1 hexanes:ether) afforded methyl ester **25** (352 mg, 87%) as an orange oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.08 (t, *J* = 11.0 Hz, 1H), 5.95 (ddt, *J* = 17.1, 10.4, 5.8 Hz, 1H), 5.59 (dd, *J* = 11.0, 0.8 Hz, 1H), 5.48–5.36 (m, 2H), 5.34 (dd, *J* = 3.1, 1.5 Hz, 1H), 5.31–3.21 (m, 2H), 5.08 (dd, *J* = 7.5, 4.8 Hz, 1H), 4.66–4.56 (m, 2H), 3.67 (s, 3H), 3.09–3.04 (m, 1H), 2.39–2.27 (m, 4H), 2.10–1.93 (m, 2H), 1.74–1.46 (m, 5H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 211.0 (very broad), 173.6, 166.1, 150.3, 132.2, 130.9, 128.7, 118.2, 115.0, 86.1, 84.6, 65.2, 64.7, 54.0, 51.5, 34.1, 33.7, 32.0, 31.7, 27.8; IR (CCl_4) 2940, 2045 (vs), 1980, 1965, 1740, 1710, 1610, 1170, 990, 970, 930 cm^{-1}; HRMS calcd. for $C_{19}H_{26}O_4Fe$ [M–3CO]$^+$: 374.1181, found: 374.1174 *m*/*z*; HRMS calcd. for $C_{16}H_{21}O_4Fe$ [M–3CO–C_3H_5]$^+$: 333.0789, found: 333.0758 *m*/*z*. Anal. calcd. for $C_{22}H_{26}O_7Fe$: C 57.66, H 5.72; found: C 57.90; H 5.83.

*Tricarbonyl [(2*Z*,4*E*,6*E*,11*E*)-(4–7-*η^4*)-15-carbomethoxy-pentadeca-(2,4,6,11)-tetraenoic acid]iron (**26**) (46)*: Allyl ester **25** (311 mg, 0.68 mmol) and $(Ph_3P)_4Pd$ (39 mg, 0.03 mmol) were degassed in vacuo and then dissolved in THF (freshly distilled, 14 mL). Diethylamine (350 μL, 3.4 mmol) was added and the mixture was stirred at ambient temperature for 6 h. The reaction mixture was concentrated and applied directly to a hexanes-packed silica gel column with benzene. Ordinary flash chromatography (slow gradient from hexanes → 1:1 hexanes:ether, all containing 2% acetic acid) afforded the unstable acid **26**, which contained 4% decomplexed acid: mp 54.5–56.5°C; ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.17 (t, *J* = 11.2 Hz, 1H), 5.57 (t, *J* = 11.2 Hz, 1H), 5.48–5.36 (m, 2H), 5.29 (dd, *J* = 8.7, 5.0 Hz, 1H), 5.10 (dd, *J* = 7.5, 5.0 Hz, 1H), 3.66 (s, 3H), 2.96 (apparent t, *J* = 9.8 Hz, 1H), 2.39–2.29 (m, 4H), 2.08–1.94 (m, 2H), 1.70–1.46 (m, 5H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 210.9 (very broad), 173.7, 171.8, 152.7, 130.9, 128.7, 114.4, 86.4, 84.9, 65.2, 53.7, 51.5, 34.0, 33.7, 32.0, 31.6, 27.8; IR (CCl_4) 3600–2400 (br), 2940, 2025 (vs), 1990, 1970, 1740, 1690, 1610, 1430, 1230, 970 cm^{-1}; HRMS calcd. for $C_{16}H_{22}O_4Fe$ [M–3CO]$^+$: 334.0868; found: 334.0856 *m*/*z*.

*Tricarbonyl [(4*E*,9*E*,11*E*,13*Z*)-(9–12-*η^4*)-15-hydroxy-pentadeca-(4,9,11,13)-tetraenoic acid methyl ester]iron (**27**) (47)*: To a solution of carboxylic acid **26** (236 mg, 0.56 mmol) and triethylamine (310 μL, 2.25 mmol) in THF (5 mL) at 0°C was added methyl chloroformate (90 μL, 1.13 mmol). This reaction was stirred at 0°C for 30 min. The solution was then diluted with hexanes (10 mL) and filtered through a plug of Celite®. The filtrate was concentrated and the residue was immediately dissolved in 5 mL of THF and 5 mL of absolute ethanol and cooled to –35°C. Sodium borohydride (31 mg) was added in one portion and the reaction was warmed to ambient temperature over a period of 30 min. Ether (10 mL) and 1 M HCl in saturated aqueous NaCl (15 mL) were then added, and the layers were separated. The organic layer was washed with 1 M HCl in saturated aqueous NaCl (3 × 5 mL), and the aqueous layers were back-extracted with ether (2 × 5 mL). The combined organic layers were washed with saturated aqueous NaCl (5 mL), dried ($MgSO_4$), filtered, and concentrated. Purification of the crude product by flash chromatography (1:1 hexanes:ether) afforded alcohol **27** (180 mg, 79%) as a yellow oil which was contaminated with 8% of decomplexed alcohol: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.56–5.36 (m, 4H), 5.17 (ddd, *J* = 8.5, 4.9, 1.10 Hz, 1H), 5.04 (ddd, *J* = 9.0, 4.9, 0.8 Hz, 1H), 4.26 (t, *J* = 5.5 Hz, 2H), 3.66 (s, 3H), 2.39–2.27 (m, 4H), 2.10–1.93 (m, 2H), 1.84 (t, *J* = 8.8 Hz, 1H), 1.74–1.63 (m, 2H), 1.58–1.42 (m, 2H), 1.33–1.27 (m, 2H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 212.0 (very broad), 173.7, 133.3, 131.0, 128.7, 128.3, 84.8, 82.6, 64.0, 59.0, 55.0, 51.5, 34.1, 33.6, 32.0, 31.7, 27.8; IR (CCl_4) 3600–3100 (br), 2930, 2030 (vs), 1930 (br), 1740, 970, 790, 765 cm^{-1}; HRMS calcd. for $C_{16}H_{24}O_3Fe$ [M–3CO]$^+$: 320.1075, found: 320.0189 *m*/*z*. Anal. calcd. for $C_{19}H_{24}O_6Fe$: C 56.45, H 5.98; found: C 56.74, H 6.18.

*Tricarbonyl [(5*E*,10*E*,12*E*,14*Z*)-(10–13-*η^4*)-oxacyclohexadeca-(5,10,12,14)-tetraene-2-one]iron (**15**)*:

A. Via Yamaguchi lactonization (52). To a solution of ester **27** (101 mg, 0.25 mmol) in 4:1 dimethoxyethane:water (5 mL) was added LiOH (36 mg, 1.5 mmol). The resulting heterogeneous mixture was stirred for 5 h. The reaction was acidified to pH = 3 with 1 M HCl in saturated aqueous

NaCl, then ether (10 mL) was added and the layers were separated. The organic layer was washed with aqueous HCl (pH = 3, 3 × 5 mL), and the combined aqueous layers were washed with ether (2 × 5 mL). The combined organic layers were washed with saturated aqueous NaCl (5 mL), dried ($MgSO_4$), filtered through a plug of silica gel (ether as eluant), and concentrated. Seco-acid **28** (97 mg, >95%) was isolated as a highly unstable yellow oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.53 (broad s), 5.45 (broad s), 5.18 (broad s), 5.05 (broad s), 4.27 (broad s), 2.42 (broad s), 2.33 (broad s), 2.02 (broad s), 1.86 (broad s), 1.68 (broad s), 1.51 (broad s), 1.33 (broad s), 1.25 (broad s); IR (thin film) 3670–2415 (v br), 2934, 2864, 2047 (vs), 1978, 1710, 1555, 1204 cm^{-1}; HRMS calcd. for $C_{15}H_{22}O_3Fe$ [M–3CO]$^+$: 306.0919, found: 306.0930 *m/z*.

The seco-acid **28** produced above was immediately used in the next reaction. A suspension of crude **28** (97 mg, 0.25 mmol) and 4 Å sieves (33 mg) in THF (10 mL) was cooled to 0°C. To this solution was added triethylamine (104 μL, 0.75 mmol) and trichlorobenzoyl chloride (47 μL, 0.30 mmol). The reaction was stirred at 0°C for 4.5 h, then was filtered, diluted with toluene (50 mL), and added over 6 h via cannula to a 63°C solution (oil bath temperature) of DMAP (915 mg, 29 mM) in toluene (200 mL). After being stirred for 9 h, the solution was cooled, concentrated, and partitioned between ether and saturated aqueous $NaHCO_3$ (30 mL each). The layers were separated, the organic layer was washed with saturated aqueous $NaHCO_3$ (3 × 15 mL), and the combined aqueous layers were washed with ether (3 × 10 mL). The combined organic layers were washed with saturated aqueous NaCl (5 mL), dried ($MgSO_4$), and concentrated. The residue was purified by flash chromatography using 5:1 hexanes:ether as eluant. Lactone **15** (37 mg, 39%) was isolated as a yellow oil, along with a small amount of decomplexed lactone **29** (3 mg, 12%). Analytical data is reported for lactone **15**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.67 (t, *J* = 10.9 Hz, 1H), 5.61–5.42 (m, 3H), 5.15–5.11 (m, 1H), 5.00–4.97 (m, 1H), 4.63 (dd, *J* = 5.8, 0.7 Hz, 2H), 2.59–2.52 (m, 1H), 2.44–2.32 (m, 3H), 2.30–2.21 (m, 1H), 2.16–2.07 (m, 1H), 1.78–1.66 (m, 4H), 1.64–1.56 (m, 2H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 212.1 (broad), 173.3, 137.8, 133.4, 128.5, 120.9, 84.6, 81.3, 64.6, 60.5, 56.4, 34.4, 33.8, 32.7, 28.3, 27.1; IR (CCl_4) 3030, 2930, 2030 (vs), 1990–1965, 1740, 1440, 1140, 975, 790 cm^{-1}; HRMS calcd. for $C_{16}H_{20}O_3Fe$ [M–2CO]$^+$: 316.0762, found: 316.0767 *m/z*. Anal. calcd. for $C_{18}H_{20}O_5Fe$: C 58.09, H 5.42; found: C 58.09, H 5.42.

B. Via PyBroP lactonization (46). Seco-acid **28** prepared as described above (38.5 mg, 0.10 mmol) was dissolved in toluene (15 mL) and dichloromethane (5 mL), and cooled to –78°C. This solution was added via cannula over 12 h to a solution of PyBroP (51) (550 mg, 1.18 mmol) and DMAP (488 mg, 25 mM) in toluene (125 mL) and dichloromethane (10 mL) at ambient temperature. After stirring for 4 h, the solution was worked up as described above for the Yamaguchi lactonization, and the residue was purified by flash chromatography (20:1 → 5:1 hexanes:ether). Lactone **15** (17.5 mg, 48%) was isolated as a yellow oil.

*(5*E*,10*E*,12*E*,14*Z*)-Oxacyclohexadeca-(5, 10, 12, 14)-tetraene-2-one (29)*: To a solution of iron(tricarbonyl)-complexed lactone **15** (39 mg, 0.10 mmol) in propionitrile (5 mL) maintained at –50°C was added $FeCl_3$ (170 mg, 1.05 mmol) portion wise over 45 min. The reaction was partitioned between ether and saturated aqueous $NaHCO_3$ (20 mL each). The layers were separated, the organic layer was washed with saturated aqueous $NaHCO_3$ (3 × 10 mL), and the combined aqueous layers were washed with ether (5 × 5 mL). The combined organic layers were washed with saturated aqueous NaCl (2 × 5 mL), dried ($MgSO_4$), and concentrated. The residue was purified by flash chromatography (slow gradient from hexanes → 7:1 hexanes:ether as eluant), giving lactone **29** (16.3 mg, 67%) as a clear oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.48 (dd, *J* = 15.1, 10.9 Hz, 1H), 6.22 (dd, *J* = 10.9, 0.8 Hz, 1H), 6.12 (dd, *J* = 15.1, 9.3 Hz, 1H), 5.95 (ddd, *J* = 15.4, 9.3, 0.8 Hz, 1H), 5.74 (dt, *J* = 15.4, 6.9 Hz, 1H), 5.53 (dt, *J* = 10.9, 5.5 Hz, 1H), 5.44–5.28 (m, 2H), 4.79 (dd, *J* = 5.5, 1.3 Hz, 2H), 2.46–2.43 (m, 2H), 2.38–2.33 (m, 2H), 2.13 (q, *J* = 6.3 Hz, 2H), 2.07 (qd, *J* = 6.3, 1.1 Hz, 2H), 1.61–1.55 (m, 2H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 172.3, 132.9, 132.7, 132.6, 131.8, 131.4, 129.1, 126.3, 122.8, 61.0, 34.0, 32.5, 31.6, 27.1, 25.8; IR (CCl_4) 3020, 2960, 1740, 1440, 1150, 995, 970, 910, 725, 650 cm^{-1}; HRMS calcd. for $C_{15}H_{20}O_2$ [M]$^+$: 232.1463, found: 232.1469 *m/z*.; HRMS calcd. for $C_{15}H_{21}O_2$ [M + H]$^+$: 233.1541, found: 233.1538 *m/z*.

*3-Vinyl-1,2,3,3a,5a,6,7,8,8a,8b-decahydro-*as*-indacene-2-carboxylic acid (31)*: Lactone **29** (31.5 mg, 0.14 mmol) and activated, crushed 4 Å molecular sieves (16 mg) were stirred at room temperature in a mixture of dry THF (2.1 mL) and hexamethylphosphoramide (625 μL) for 30 min. The mixture was cooled to –78°C, then *tert*-butyldimethylsilyl triflate (35 μL) was added to the vigorously stirred solution, followed approximately 2 min later by potassium hexamethyldisilazide (315 μL, 0.47 M in toluene). The cooling bath was removed 1 min later, and the reaction mixture was allowed to warm to ambient temperature. The mixture was stirred overnight at 65°C, then 5 mL of a 1 M HCl in saturated aqueous NaCl and 3 mL of ether were added, and this heterogeneous mixture was stirred vigorously for 2 min. The layers were separated, and the organic layer was further washed with 1 M HCl in saturated aqueous NaCl (3 × 5 mL). The aqueous layers were washed with ether (3 × 5 mL), and the combined organic layers were washed with saturated aqueous NaCl, dried ($MgSO_4$), concentrated, and purified by flash chromatography (slow gradient from 5:1 hexanes:ether → 98% 1:1 hexanes:ether + 2% acetic acid). Lactone **29** (8.4 mg, 27%) was recovered, and acid **31** (13.8 mg, 44%) containing ca. 20% of diastereomer **32** was isolated as a white solid. A portion of this solid was recrystallized from an ether–hexanes mixture: mp 127–128°C; ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.80–5.66 (m, 3H), 5.15–5.10 (m, 2H), 3.10 (apparent q, *J* = 8.8 Hz, 1H), 2.52–2.44 (m, 1H), 2.44–2.36 (m, 1H), 2.13–1.96 (m, 3H), 1.91–1.83 (m, 2H), 1.72–1.63 (m, 2H), 1.56–1.37 (m, 2H), 1.28–1.17 (m, 3H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 180.1, 136.8, 132.3, 126.9, 117.3, 50.9, 46.8, 46.8, 42.4, 42.2, 33.0, 32.9, 31.0, 25.2; IR (CCl_4) 3600–2500 (br), 3030, 2900, 1700, 1640, 905 cm^{-1}; HRMS calcd. for $C_{15}H_{21}O_2$ [M + H]$^+$: 233.1541, found: 233.1534 *m/z*; HRMS calcd. for $C_{15}H_{20}O_2$ [M]$^+$: 232.1463, found 232.1469 *m/z*.

*(*E*)-6-Bromo-hex-4-enoic acid methyl ester (45) (45)*: To a solution of **44** (60) (6.2 g, 41.1 mmol) in toluene (65 mL)

© 2000 NRC Canada

was added trimethyl orthoacetate (26.0 mL, 205.4 mmol) and propionic acid (0.3 mL, 4.1 mmol). The reaction was refluxed for 72 h and then all of the solvents were removed in vacuo. The crude product was purified by column chromatography (3:1 hexanes:diethyl ether) to give 4.80 g of **45** (56%) as a light yellow oil: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.79–5.67 (m, 2H), 3.94 (d, *J* = 6.6 Hz, 2H), 3.69 (s, 3H), 2.42–2.40 (m, 4H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 173.1, 133.9, 127.6, 51.6, 33.2, 32.8, 27.3; IR (thin film) 3020, 2980, 2960, 2870, 1750, 1660, 1500, 1200, 970; HRMS calcd. for $C_7H_{15}O_2BrN$ [M + NH_4]$^+$: 224.0286, found: 224.0289 *m*/*z*.

*(*E*)-2-(4′-Hydroxy-but-2′-enyl)-malonic acid di*-tert-*butyl ester (**43**) (59)*: To a 0°C solution of butadiene monoepoxide **42** (0.95 g, 13.6 mmol) in THF (15 mL) was added $(Ph_3P)_4Pd$ (0.16 g, 0.01 mmol). Di-*tert*-butyl malonate **41** (3.6 mL, 16.3 mmol) was dropwise by syringe over 5 min. The mixture was stirred at 0°C for 30 min and at ambient temperature for an additional 3 h. The mixture was concentrated, and the crude residue was directly chromatographed using 1.5:1 ether:hexanes as eluant, giving allylic alcohol **43** as a light yellow oil (3.54 g, 79%). The olefin ratio was determined to be 2:1 *E*:*Z* by ^{1}H NMR analysis. An analytical sample was prepared by HPLC (1:1 ethyl acetate:hexanes): ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.76–5.62 (m, 2H), 4.08 (d, *J* = 5.0 Hz, 2H), 3.20 (t, *J* = 7.5 Hz, 1H), 2.55 (t, *J* = 6.8 Hz, 1H), 1.45 (s, 18H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 168.3, 131.8, 128.3, 81.6, 63.4, 53.7, 31.7, 28.0; IR (thin film) 3444 (br s), 2979, 2934, 2872, 1728 (s), 1478, 1457, 1394, 1369, 1251, 1144 (s), 1007, 971, 848 cm^{-1}; HRMS calcd. for $C_{15}H_{27}O_5$ [M + H]$^+$: 287.1858, found: 287.1868 *m*/*z*. Anal. calcd. for $C_{15}H_{26}O_5$: C 62.91, H 9.15; found: C 62.63, H 9.25.

*(2′*E*,2″*E*)-2-(4′-Hydroxy-but-2′-enyl)-2-(5″-carbomethoxy-hex-2″-enyl)malonic acid di*-tert-*butyl ester (**46**)*: Sodium hydride (0.09 g, 3.62 mmol, rinsed with dry THF) was slurried in THF (5 mL) and cooled to 0°C. Alcohol **43** (1.00 g, 3.62 mmol) in THF (5 mL) was carefully added to the slurry via cannula to control hydrogen evolution. The solution was allowed to warm to ambient temperature and to stir for 30 min. Allylic bromide **45** (0.75 g, 3.62 mmol) in THF (5 mL) was added to the malonate anion solution via cannula. The resulting mixture was then heated in a 65°C oil bath overnight. The resulting suspension was cooled to room temperature and partitioned with ether (50 mL) and water (20 mL). The aqueous layer was separated and the organic layer was washed sequentially with saturated aqueous NH_4Cl and an aqueous saturated NaCl solution. The organic layer was dried over $MgSO_4$ and filtered. Concentration of the solution followed by column chromatography (2:1 ether:hexanes) of the crude product afforded 1.16 g (78%) of **46** as a 2:1 *E*:*Z* mixture of olefin isomers, as determined by ^{1}H NMR analysis. An analytical sample was prepared by HPLC (1:1 ethyl acetate:hexanes). Selected data is reported for the (*E*)–olefin isomer only: ^{1}H NMR (500 MHz, $CDCl_3$) δ: 5.70 (dt, *J* = 15.4, 5.9 Hz, 1H), 5.53–5.47 (m, 2H), 5.28 (dt, *J* = 15.1, 7.6 Hz, 1H), 4.06 (d, *J* = 5.6 Hz, 2H), 3.65 (s, 3H), 2.50 (d, *J* = 7.3 Hz, 2H), 2.46 (d, *J* = 7.6 Hz, 2H), 2.36–2.29 (m, 4H), 1.42 (s, 18H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 173.5, 170.0, 133.4, 132.6, 126.3, 125.1, 81.3, 63.4, 57.9, 51.6, 35.1, 34.8, 33.8, 28.0, 27.9; IR (thin film) 3457 (br s), 2978, 2932, 2857, 1727 (s), 1438, 1369, 1288, 1250, 1163 (s), 1147 (s), 972, 847 cm^{-1}; HRMS calcd. for $C_{22}H_{40}O_7N$ [M + NH_4]$^+$: calcd. 430.2805, found: 430.2792 *m*/*z*.

(2′E,2″E)-2-(4′-Oxo-but-2′-enyl)-2-(5″-carbomethoxy-hex-2″-enyl)malonic acid di-tert-*butyl ester (**47**) (61)*: To a solution of alcohol **46** (1.0 g, 2.42 mmol) in CH_2Cl_2 (8 mL) was added Celite® (2 g) and pyridinium chlorochromate (0.65 g, 3.03 mmol). The solids were rinsed into the flask with an additional amount of CH_2Cl_2 (2 mL). The mixture was stirred at room temperature for 4 h. The dark brown mixture was then diluted with a 1:1 mixture of ether:hexanes (100 mL). The solution was filtered and concentrated and the crude dark brown residue was redissolved in ether (10 mL). The suspension was then filtered through a plug of 1:1 Celite®:Florisil® and rinsed with ether (100 mL). The solution was concentrated to afford 0.92 g (93%) of enal **47** as a light yellow oil. An analytical sample was prepared by HPLC (2:1 hexanes:ethyl acetate): ^{1}H NMR (400 MHz, $CDCl_3$) δ: 9.48 (d, *J* = 7.7 Hz, 1H), 6.72 (dt, *J* = 15.4, 7.3 Hz, 1H), 6.10 (ddt, *J* = 15.4, 8.1, 1.1 Hz, 1H), 5.52 (dt, *J* = 15.4, 6.2 Hz, 1H), 5.27 (dt, *J* = 15.0, 7.3 Hz, 1H), 3.65 (s, 3H), 2.73 (dd, *J* = 7.3, 1.1 Hz, 2H), 2.50 (d, *J* = 7.7 Hz, 2H), 2.35–2.30 (m, 4H), 1.42 (s, 18H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 193.5, 173.3, 169.3, 152.9, 135.6, 133.5, 124.5, 82.0, 57.7, 51.6, 36.2, 35.7, 33.7, 27.9, 27.8; IR (thin film) 2979, 2743, 1732 (s), 1694 (s), 1641, 1438, 1369, 1290 (s), 1256 (s), 1148 (s), 976, 846 cm^{-1}; HRMS calcd. for $C_{22}H_{38}O_7N$ [M + NH_4]$^+$: 428.2648, found 428.2633 *m*/*z*. Anal. calcd. for $C_{22}H_{37}O_7$: C 64.37, H 8.35; found: C 64.35, H 8.49.

*(2′*E*,4′*E*,2″*E*)-2-(5′-Iodo-penta-2′,4′-dienyl)-2-(5″-carbomethoxy-hex-2″-enyl)-malonic acid di*-tert-*butyl ester (**48**) (62)*: A 250 mL round bottom single necked flask containing $CrCl_2$ (11.5 g, 93.6 mmol) was cooled to 0°C and the solid was suspended in THF (100 mL). To the purple mixture was added a solution of CHI_3 (16.3 g, 41.4 mmol) and enal **47** (6.8 g, 16.6 mmol) in THF (20 mL) via cannula. The reaction was allowed to warm to room temperature and to stir for 1 h. The dark brown mixture was diluted a 1 M sodium serinate solution and the resulting biphasic mixture was stirred for 15 min. The organic layer was separated and the aqueous layer was washed twice with a 1:1 hexanes:ethyl acetate mixture and the combined organics dried over $MgSO_4$. The mixture was filtered and the solution was concentrated affording vinyl iodide **48** (>10 g) as a crude yellow oil contaminated with residual iodoform. The vinyl iodide was used immediately in the subsequent step. ^{1}H NMR analysis indicated the iodoolefin to consist of a 6.5:1 *E*:*Z* isomer mixture. Analytical data is reported for the mixture and for the ^{1}H NMR, only selected data for **48** is reported: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.97 (ddd, *J* = 14.3, 10.6, 0.7 Hz, 1H), 6.23 (d, *J* = 14.3 Hz, 1H), 6.00 (dd, *J* = 15.0, 10.6 Hz, 1H), 5.58–5.46 (m, 2H), 5.32–5.24 (m, 1H), 3.67 (s, 3H), 2.49 (d, *J* = 7.7 Hz, 2H), 2.46 (d, *J* = 7.7 Hz, 2H), 2.37–2.31 (m, 4H), 1.43 (s, 18H); IR (thin film) 2977, 2927, 1726 (s), 1368, 1290, 1250, 1145, 1161, 980, 847 cm^{-1}; HRMS calcd. for $C_{23}H_{39}O_6IN$ [M + NH_4]$^+$: 552.1824, found: 552.1817 *m*/*z*.

*(2′*E*,4′*E*,2″* E*)-2-(8′-Hydroxy-octa-2′,4′-dien-6′-ynyl)-2-(5″-carbomethoxy-hex-2″-enyl)-malonic acid di*-tert-*butyl ester (**49**) (64)*: The crude vinyl iodide **48** (>10 g, 16.6 mmol) was dissolved in triethylamine (160 mL) and nitrogen was vigorously bubbled through the solution for 15 min. Propargyl alcohol (1.20 mL, 19.9 mmol) and $(Ph_3P)_2PdCl_2$ (0.58 g, 0.83 mmol) were then added. The flask was covered with aluminum foil and CuI (0.32 g, 1.66 mmol) was added. The reaction mixture was vigorously stirred for 3 h and then diluted with 200 mL of ether. Saturated aqueous ammonium chloride was added and this mixture was stirred for 30 min. The organic layer was separated, washed twice with 1 M HCl, and dried over $MgSO_4$. Filtration followed by concentration of the filtrate afforded a crude oil which was purified by column chromatography (1:1 ether:hexanes → 3:1 ether:hexanes), giving dienyne **49** (4.50 g, 59% from enal **47**). An analytical sample was prepared by HPLC (1.2:1 ethyl acetate:hexanes): ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.52 (dd, *J* = 15.7, 11.0 Hz, 1H), 6.09 (dd, *J* = 15.0, 11.0 Hz, 1H), 5.62 (dt, *J* = 15.0, 8.1 Hz, 1H), 5.54–5.46 (m, 2H), 5.28 (dt, *J* = 15.4, 7.3 Hz, 1H), 4.39 (br s, 2H), 3.66 (s, 3H), 2.54 (d, *J* = 7.7 Hz, 2H), 2.26 (d, *J* = 7.3 Hz, 2H), 2.37–2.30 (m, 4H), 1.42 (s, 18H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 173.3, 169.9, 142.0, 133.0, 132.7, 131.7, 125.1, 109.3, 89.4, 84.9, 81.4, 58.1, 51.7, 51.6, 35.7, 35.6, 33.8, 28.0, 27.9; IR (thin film) 3515 (br s), 2978, 2932, 1727 (s), 1438, 1394, 1369, 1289, 1251, 1165, 1023, 987, 846 cm^{-1}; HRMS calcd. for $C_{26}H_{42}O_7N$ $[M + NH_4]^+$: 480.2961, found: 480.2957 *m*/*z*.

*(2′*E*,4′*E*,6′*Z*,2″* E*)-2-(8′-Hydroxy-octa-2′,4′,6′-trienyl)-2-(5″- carbomethoxy-hex-2″-enyl)-malonic acid di*-tert-*butyl ester (**50**) (66)*: Zinc (32.0 g, 496 mmol) which had been prewashed with 1 M HCl was suspended in water (150 mL). Nitrogen was bubbled through the vigorously stirred mixture for 30 min, then $Cu(OAc)_2 \times 2H_2O$ (3.30 g, 16.5 mmol) was added. This mixture was stirred for 30 min, and then $AgNO_3$ (3.21 g, 19.5 mmol) was added. The mixture was stirred for 1 h (exotherm), at which time it was filtered. The filter cake was washed twice successively with water, methanol, acetone, and ether (75 mL each). The filter cake was then resuspended in 1:1 methanol:water (100 mL) and then **49** (4.50 g, 9.73 mmol) was added to the mixture in methanol (20 mL). The reaction mixture was stirred overnight at ambient temperature, then was filtered through Celite®. The solids were washed twice with ether (200 mL each) and the organic layer was separated. The aqueous layer was washed with ether (50 mL) and then combined organics were dried over $MgSO_4$, filtered, and concentrated. The crude residue was redissolved in ether (100 mL) and washed with a saturated aqueous NaCl solution. The organic layer was dried over $MgSO_4$, filtered, and concentrated to afford 4.20 g of tetraene **50** (93%) as a light yellow oil. An analytical sample was prepared by HPLC (1.2:1 ethyl acetate:hexanes): ^{1}H NMR (400 MHz, C_6D_6) δ: 6.37 (dd, *J* = 14.4, 11.5 Hz, 1H), 6.18 (dd, *J* = 14.6, 10.7 Hz, 1H), 6.08 (dd, *J* = 14.6, 11.0 Hz, 1H), 5.95 (apparent t, *J* = 11.2 Hz, 1H), 5.75 (dt, *J* = 14.9, 7.6 Hz, 1H), 5.52–5.43 (m, 3H), 4.04 (d, *J* = 6.6 Hz, 2H), 3.37 (s, 3H), 2.87 (d, *J* = 7.6 Hz, 2H), 2.78 (d, *J* = 5.6 Hz, 2H), 2.22–2.19 (m, 2H), 2.12 (dd, *J* = 7.8, 7.1 Hz, 2H), 1.36 (s, 18H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 173.4, 170.0, 134.4, 133.9, 132.6, 130.7, 129.6, 129.5, 126.0, 125.1, 81.3, 58.8, 58.1, 51.6, 35.6, 35.4, 33.9, 27.9, 27.9; IR (thin film) 3449 (s br), 2978, 2932, 2953, 1726 (s), 1438, 1369, 1289, 1252, 1163 (s), 1146 (s), 997, 846 cm^{-1}; HRMS calcd. for $C_{25}H_{38}O_7$ $[M + H]^+$: 465.2852, found: 465.2848 *m*/*z*.

*(2′*E*,4′*E*,6′*Z*,2″* E*)-2-(8′-Hydroxy-octa-2′,4′,6′-trienyl)-(5″-carboxy-hex-2″-enyl)-malonic acid di*-tert-*butyl ester (**51**)*: Tetraene **50** (0.22 g, 0.47 mmol) was dissolved in 1:1 methanol:THF (2 mL), then a solution of LiOH (0.04 g, 0.98 mmol) in water (1 mL) was added. The mixture was stirred at room temperature for 3 h, diluted with ether (25 mL), and then acidified with 1 M HCl. The organic layer was separated and dried over $MgSO_4$. The crude product was purified by rapid column chromatography (12:1 dichloromethane:methanol), giving 0.17 g (80%) of seco acid **51**. Partial analytical data reported is for a mixture of **51** and the all *E* tetraene, which was generated upon concentration of the sample. For the ^{1}H NMR, selected data for **51** is reported: ^{1}H NMR (400 MHz, C_6D_6) δ: 6.48 (dd, *J* = 14.6, 11.7 Hz, 1H), 6.19 (dd, *J* = 14.9, 10.7 Hz, 1H), 6.08 (dd, *J* = 10.7, 7.1 Hz, 1H), 5.98 (apparent t, *J* = 10.7 Hz, 1H), 5.70 (dt, *J* = 14.9, 7.6 Hz, 1H), 5.50–5.41 (m, 3H), 4.09 (d, *J* = 6.8 Hz, 2H), 2.86 (d, *J* = 7.6 Hz, 2H), 2.75 (d, *J* = 6.3 Hz, 2H), 2.18–2.12 (m, 4H), 1.34 (s, 18H); IR (thin film) 3449 (br s), 2978, 2932, 1724 (s), 1394, 1369, 1291, 1251, 1160 (s), 1146 (s), 998, 846 cm^{-1}; HRMS calcd. for $C_{25}H_{42}O_7N$ $[M + NH_4]^+$: 468.2961, found: 468.2961 *m*/*z*.

*(5*E*, 10*E*, 12*E*, 14*Z*)-Oxacyclohexadeca-(5, 10, 12, 14)-tetraene-8-bis(carbo-*tert-*butoxy)-2-one (**38**) (67)*: To a 70°C solution of 2-chloro-1-methylpyridinium iodide (0.23 g, 0.89 mmol) in acetonitrile (65 mL) was added a solution of seco-acid **51** (0.10 g, 0.22 mmol) and Et_3N (0.25 mL, 1.76 mmol) in acetonitrile (10 mL). The addition was performed using a Hamilton syringe pump over 5 h. Upon completion of the addition of the triethylamine–seco-acid mixture, the reaction was allowed to stir at 70°C for an additional 2 h. The solution was allowed to cool to room temperature and concentrated. The residue was dissolved with ether (50 mL) and washed with a 1 M aqueous $NaHSO_4$ solution and than a saturated aqueous NaCl solution. The organic layer was dried over $MgSO_4$, filtered, and concentrated. Purification of the crude residue by column chromatography (CH_2Cl_2 → 9:1 CH_2Cl_2:MeOH) yielded 0.04 g (40%) of lactone **38** as an off white solid. A portion was recrystallized from a ca. 15:1 hexanes:ether mixture: mp 130–132°C; ^{1}H NMR (400 MHz, C_6D_6) δ: 6.75 (dd, *J* = 14.9, 11.2 Hz, 1H), 6.04–5.88 (m, 3H), 5.66 (dt, *J* = 15.1, 7.6 Hz, 1H), 5.53–5.47 (m, 1H), 5.44–5.38 (m, 1H), 5.04 (dt, *J* = 11.5, 4.2 Hz, 1H), 4.57 (d, *J* = 2.7 Hz, 2H), 2.92 (d, *J* = 7.6 Hz, 2H), 2.77 (d, *J* = 6.8 Hz, 2H), 2.19–2.08 (m, 4H), 1.35 (s, 18H); ^{13}C NMR (100 MHz, $CDCl_3$) δ: 172.3, 170.6, 136.7, 133.4, 131.7, 129.9, 128.6, 126.0, 124.3, 123.9, 81.3, 77.3, 62.5, 56.8, 36.9, 36.0, 33.9, 27.9, 27.1; IR (thin film) 2978, 2931, 1724 (s), 1432, 1393, 1369, 1282, 1253, 1163 (s), 1000, 847 cm^{-1}; HRMS calcd. for $C_{25}H_{40}O_6N$ $[M + NH_4]^+$: 450.2856, found: 450.2846 *m*/*z*. Anal. calcd. for $C_{25}H_{36}O_6$: C 69.42, H 8.39; found: C 69.43, H 8.65.

*2-Carbomethoxy-3-vinyl-7-bis(carbo-*tert-*butoxy)-1,2,3,3a,5a,6,7,8,8a,8b-decahydro-as-indacene (**54**)*: Powdered 4 Å molecular sieves (15 mgs) were flame dried under high

© 2000 NRC Canada

vacuum. The dried sieves were allowed to cool to room temperature, then a solution of lactone **38** (0.10 g, 0.24 mmol) in THF (3.0 mL) was added via cannula. Hexamethylphosphoramide (0.8 mL) was added then the suspension was cooled to –78°C and *t*-butyldimethylsilyl triflate (68 µL, 0.30 mmol) was added by syringe. A slurry immediately formed. To the slurry was added lithium diisopropylamide (0.50 mL of a 0.5 M solution, 0.25 mmol) and the reaction was allowed to stir at –78°C for 15 min. An initial yellow color which developed upon addition of the lithium diisopropylamide dissipated upon prolonged stirring. After 15 min, the reaction was allowed to warm to room temperature and to stir overnight. The mixture was diluted with ether (10 mL) and stirred with 1 M HCl (3 mL) for 30 min. The organic layer was separated, washed twice with 1:1 aqueous saturated NaCl:1 M HCl, and dried over $MgSO_4$. The crude product was purified by column chromatography (20:1 CH_2Cl_2:methanol). A small amount of lactone **38** was recovered (0.02 g, 20%) along with 0.06 g of tricyclic carboxylic acids. The acid was dissolved in 4:1 ether:methanol (5 mL) and treated with trimethylsilyldiazomethane (0.50 mL of 2 M solution, 1.00 mmol). The resulting yellow solution was stirred for 1 h, and then concentrated. HPLC purification of a portion (ca. 0.04 g) of the crude methyl ester (6:1 hexanes:ethyl acetate) afforded 0.02 g (ca. 40%) of the tricyclic adduct **54** and an inseparable diastereomer. Analytical data reported is for the mixture of **54** and the inseparable isomer. For the ^1H and ^{13}C NMR, selected data for **54** is reported: ^1H NMR (400 MHz, $CDCl_3$) δ: 5.69–5.58 (m, 3H), 5.10–5.05 (m, 2H), 3.63 (s, 3H), 3.10 (dt, *J* = 10.6, 8.1 Hz, 1H), 2.67–2.62 (m, 1H), 2.50 (ddd, *J* = 13.9, 8.8, 0.7 Hz, 1H), 2.42–2.33 (m, 2H), 2.23–2.15 (m, 1H), 2.09 (ddd, *J* = 12.5, 8.4, 6.6 Hz, 1H), 1.98 (apparent t, *J* = 11.5 Hz, 1H), 1.90 (dd, *J* = 14.3, 4.4 Hz, 1H), 1.77 (t, *J* = 12.8 Hz, 1H), 1.67 (dt, *J* = 12.1, 7.7 Hz, 1H), 1.45 (s, 9H), 1.43 (s, 9H), 1.27–1.21 (m, 1H); ^{13}C NMR (125 MHz, $CDCl_3$) δ: 175.5, 171.6, 137.0, 130.4, 127.9, 117.1, 81.1, 81.0, 61.5, 51.4, 50.8, 46.9, 46.9, 46.6, 42.0, 41.0, 40.0, 38.2, 32.5, 27.9; IR (thin film) 2977, 1725 (s), 1458, 1393, 1368, 1281, 1170, 1144, 849 cm^{-1}; HRMS calcd. for $C_{26}H_{39}O_6$ $[M + H]^+$: 447.2746, found: 447.2743 *m*/*z*. Anal. calcd. for $C_{26}H_{38}O_6$: C 69.93, H 8.58; found: C 69.83, H 8.57.

Synthesis of novel pentacyclic β-lactam antibacterial agents

Daniele Andreotti, Stefano Biondi, Daniele Donati, Sergio Lociuro, and Gilles Pain

Abstract: The search for new antibacterial agents still represents an active area of research. In this paper the synthesis of a new class of β-lactam agents characterized by an interesting antibacterial profile is reported; together with a description of the most significant synthetic aspects encountered during this work.

Key words: β-lactams, pentacyclic, O-alkylation, trinem.

Résumé : La recherche de nouveaux agents antibactériens constitue toujours un champ de recherche actif. Cet article rapporte la synthèse d'une nouvelle classe de β-lactames caractérisés par un intéressant profil antibactérien, ainsi que la description des aspects synthétiques les plus importants rencontrés au cours de ces travaux.

Mots clés : β-lactames, pentacyclique, O-alkylation, trinème.

Introduction

The search for new β-lactam motifs able to address problems both in clinical practice and in community acquired infection has seen the involvement of both pharmaceutical companies and research groups (1). One of the most significant problems in clinical practice is the constant occurrence in the isolation of methicillin resistant *Staphylococcus aureus* (MRSA) against which most of the β-lactams, acting through irreversible inhibition of Penicillin Binding Proteins (PBPs), are ineffective. In these strains the expression of an additional high molecular weight PBP, known as PBP2a (PBP2′), with extremely low affinity for all β-lactam antibiotics, has been recognized as the cause of resistance (2). Consequently the search for new antibacterial agents able to effectively treat infections caused by MRSA represents an active area of investigation.

Recently in our laboratories we identified a class of trinem derivatives (**1)** endowed with high affinity for both PBP2a and other essential PBPs. These compounds are characterized by the presence of an unsaturated side chain bearing a (hetero)aromatic substitution at position 4 of the trinem nucleus (3), and showed a broad spectrum of activity including MRSA.

Received October 12, 1999. Published on the NRC Research Press website on June 9, 2000.

Dedicated to Professor Stephen Hanessian in recognition of his significant contributions to the art of organic synthesis.

As an extension of this class we decided to investigate whether conformationally more constrained pentacyclic β-lactams of general formula **2** would further improve the antimicrobial potency (Fig. 1). This paper describes the synthesis of these compounds.

Results and discussion

According to the retrosynthetic analysis, the azetidinone derivatives **9**–**12** (see Scheme 1) were identified as key intermediates in the synthesis of β-lactams **2**. Such intermediates have then been obtained by direct condensation of the corresponding aromatic ketones **4**–**8** (Fig. 2), with the commercially available azetidinone **3**.

Ketones **4**–**8** whose synthesis has been already reported in the literature (4) were selected to investigate the effect of chemical modification of rings D or E on the microbiological profile of this new class of β-lactams.

The nitrogen atom in the aromatic ring D of **2** was chosen to offer potential advantage in terms of both chemical feasibility and water-solubility of the final molecule.

With respect to the stereochemistry at position 16 of β-lactams **2**, we expected, on the basis of our previous experience (1*i*, 5) in the field, that compounds with the *R* configuration [16β] would posses a better microbiological profile than the corresponding epimer.

The validity of such a hypothesis has then been taken into consideration by preparing and testing a number of different isomers.

Treatment of the 4-acetoxyazetidinone **3** with 2.5 equivalents of the enolate derived from **4** furnished in 33% yield a diastereomeric mixture **9** (2′α:2′β = 1:1) which was then submitted to a cyclization protocol (6) leading to the formation of pentacyclic β-lactams **13a** and **13b**. At this stage the diastereoisomers were separated by flash chromatography to afford the β isomer **13b** in 23% yield and the α isomer **13a** in 12% yield. A subsequent deprotection of the secondary

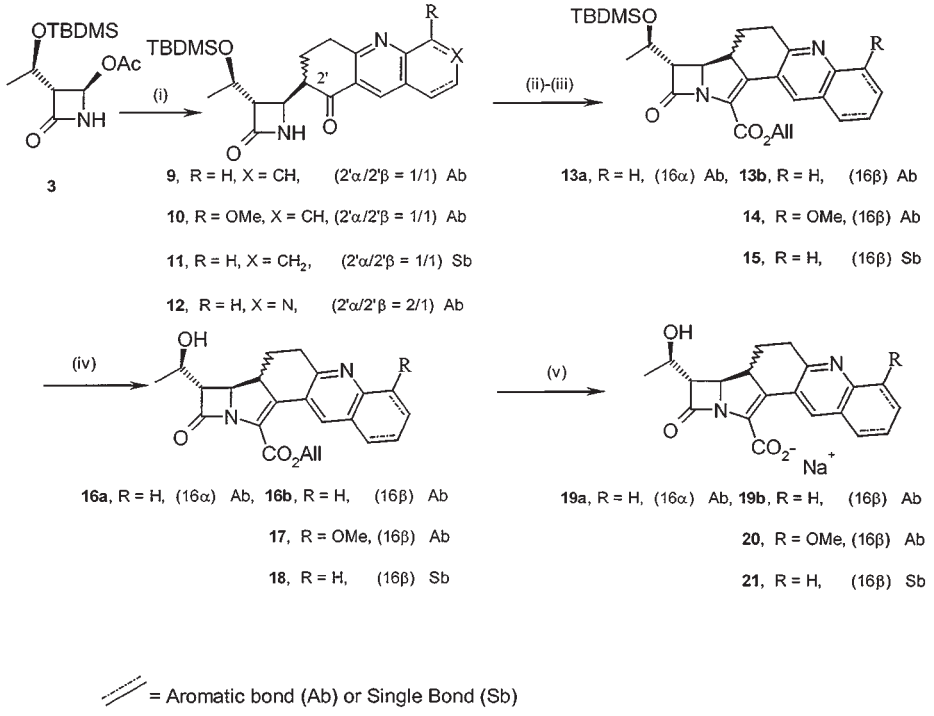

Figure 1.

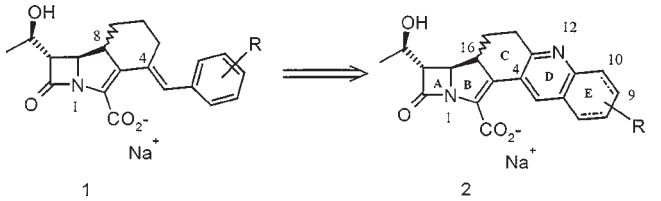

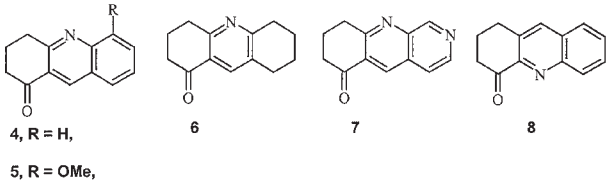

Figure 2.

hydroxyl group of **13a** by means of TBAF in acetic acid led in 40% yield to **16a** which was then transformed, using $Pd(Ph_3P)_4$ and sodium 2-ethylhexanoate (7), to the corresponding sodium salt **19a**[2] (70% yield). Repeating the same procedure on diastereoisomer **13b**, the pentacyclic β-lactam **19b**[3] was obtained in 31% overall yield from **13b**.

Similarly, condensation between **5** and **3** gave a mixture of compounds containing the desired mixture of azetidinones **10** in a diastereoisomeric ratio 2′α:2′β = 1:1 (32%) and the O-alkylated adduct **22** (22% yield) as side product (Fig. 3). The formation of this kind of O-alkylated side product occurs mainly when the oxygen of the enolate is poorly associated with the cation, as the case of Na- and K-enolates. In the case of Li-enolate where there is a strong interaction between oxygen and Li^+, the C-alkylation is normally preferred. Although in this case we are using the Li enolate, it is possible that the cation is chelated intermolecularly by both the nitrogen and oxygen present in the electron rich enolate of 8-methoxy-quinoline system, giving rise to a poorly associated Li-enolate.

A similar result was obtained during the condensation of ketone **7** with **3**. The desired 2′β isomers of **12** (2′α = 14%, 2′β = 6%) were obtained in a very low yield, discouraging any further effort to prepare the corresponding pentacyclic β-lactam derivative, while the product of O-alkylation (**23**, Fig 3) was obtained in 30% yield.

Intriguingly, after cyclization of the diastereoisomeric mixture **10** using the standard procedure, only the β isomer **14** was isolated (22% yield), while no significant traces of the corresponding α isomer were detected. Preliminary indications suggested that the α isomer gave rise to a reduction product such as **24** (Fig. 3); however, further studies would be required to fully characterize this product. Deprotection of compound **14** at the hydroxyethyl moiety following standard procedure gave the intermediate **17**, which was in turn

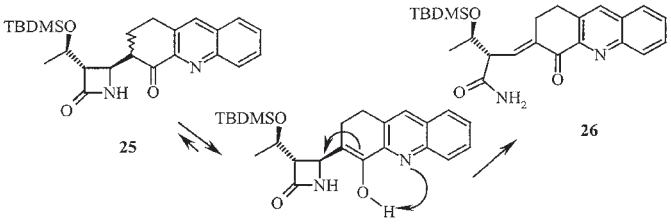
converted to the deallylated desired compound **20**[4] in 21% yield from **14**.

Starting from **3** and using the ketone **6**, the compound **21**[5] was eventually obtained in approximately 6% overall yield using the procedures already described in Scheme 1.

Although **11** was obtained as an equimolar mixture of diastereomers (2′α:2′β = 1:1), after the cyclization procedure, only the isomer **15** [16β] was isolated and progressed.



By reacting the lithium enolate of the ketone **8** with the 4-acetoxyazetidinone **3**, only **26** was isolated (25% yield). Such an unexpected result could be explained assuming that a desired product **25** is converted to **26**, by a nitrogen-assisted retro-Michael reaction as depicted in Fig. 4.

In conclusion, a new class of β-lactam antibacterial agent has been disclosed. Clearly, the procedures used to obtain the final β-lactams were extrapolated from our previous experience on the chemistry of β-lactam trinems and have not yet been optimized. In a few cases it has been possible to recover the starting ketone, however, all the reported yields are based on the amount of reagent **3** used during the reaction of condensation with the corresponding ketone.

All the final target molecules were shown to possess good water solubility.

The microbiological activities of **19a**, **19b**, **20**, and **21** (Table 1) were assayed against a panel of Gram-positive and Gram-negative strains including methicillin resistant staphylococci, in comparison with trinem **1** (R = H, 8β) and the glycopeptide vancomycin. The latter is a pure anti-Gram-positive agent and it is considered the last resort for the treatment of infection caused by drug resistant Gram-positive bacteria. Similarly to what was observed in other trinem classes, the α stereochemistry at the corresponding position 16 (e.g. **19a** compared to **19b**) has a detrimental effect on the antibacterial activity of these compounds. Compounds **19b**, **20**, and **21** showed comparable anti-MRSA activity to vancomycin with the advantage of possessing a broader antibacterial spectrum including relevant Gram-negative strains. The presence of ring D gives rise to a more conformationally constrained pentacyclic β-lactam ring which retains a comparable, and in same cases better, in vitro antimicrobial profile to the corresponding 4-*exo* methylene trinem derivative (e.g. **19b** compared to **1**). Aromaticity of ring E does not seem to be an essential requirement for retaining good antibacterial activity (e.g. **21** compared to **1**) within this new class of pentacyclic β-lactams.

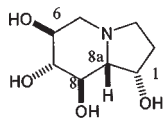
Synthesis of 8-*epi*-castanospermine and 6,7,8-tri-*epi*-castanospermine

Yves St-Denis and Tak Hang Chan

Abstract: 8-*epi*-Castanospermine (**11**) and 6,7,8-tri-*epi*-castanospermine (**12**) were synthesized from the hydroxyproline precursor **13** which was obtained enantioselectively via an enzymatic process.

Key words: castanospermine, synthesis of, enzymatic reduction, enzymatic resolution, asymmetric synthesis.

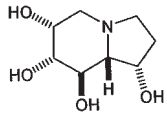
Résumé : On a synthétisé les 8-*épi*-castanospermine (**11**) et 6,7,8-tri-*épi*-castanospermine (**12**) à partir du précurseur hydroxyproline (**13**) obtenu de façon énantiosélective par le biais d'un processus enzymatique.



Mots clés : castanospermine, synthèse, réduction enzymatique, résolution enzymatique, synthèse asymétrique.

Introduction

Castanospermine (**1**) is a polyhydroxylated indolizidine alkaloid which has elicited much biological and chemical interest (1). It was isolated from the Australian legume *Castanospermum australe* (Moreton Bay chestnut) and has been shown to be a potent inhibitor of various glycosidases (2). It also inhibits the processing of *N*-linked glycoproteins (3). Castanospermine and its analogs have been examined as potential therapeutic agents (4) in the treatment of cancer (5) and HIV-I (6). Epimers of castanospermine, including 6-*epi*-castanospermine (**2**) (7) and 6,7-di-*epi*-castanospermine (**3**) (8), have been isolated as well. Comparison of their inhibitory activities toward different glycosidases showed that the change of stereochemistry at a single hydroxy group could alter the inhibitory properties.



Many syntheses of **1** and its modifications have been reported (9). A commonly used synthetic approach is to start with the appropriate carbohydrate precursor. Depending on the carbohydrate precursor used, epimers of castanospermine have also been synthesized. Thus, the syntheses of 6-*epi*- (**2**), 1,6-di-*epi*- (**4**), 1-*epi*- (**5**), 1,6,8-tri-*epi*- (**6**), 1,7,8-tri-*epi*- (**7**), and 1,6,7,8-tetra-*epi*-castanospermine (**8**) have all been reported (10). We recently reported on the use of the amino acid derivative (*S*)-prolinol (**9**) as the precursor for the synthesis of various isomers of 1-deoxycastanospermine (**10**) (11, 12, footnote 2). We have now extended the approach by starting with an amino acid precursor with the incorporation of the 1-hydroxy function. The results gave rise to a synthesis of 8-*epi*- (**11**) and 6,7,8-tri-*epi*-castanospermine (**12**) (13).

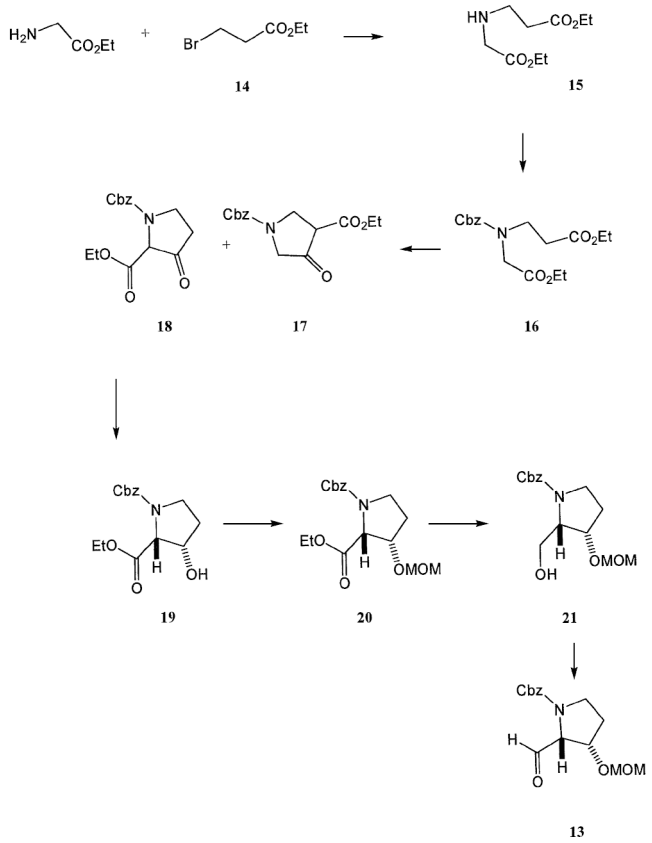
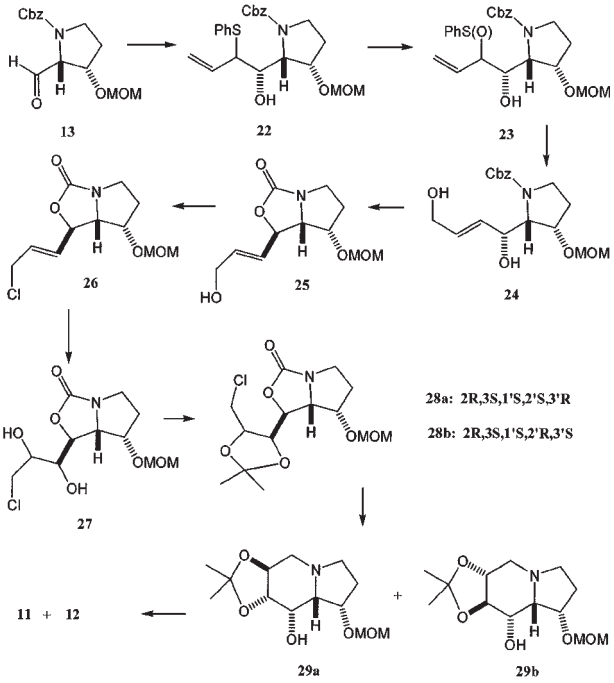
Results and discussion

Preparation of (2*R*,3*S*)-*N*-benzyloxycarbonyl-3-methoxymethyloxypyrrolidine-2-carboxaldehyde (13)



Since the stereochemistry of the 8a position of castanospermine itself corresponds to the unnatural *R*-configuration of proline, the requisite 3-hydroxylated proline precursor **13** cannot be prepared from the natural amino acids. In the literature, Sih and coworkers have used microbial enzymatic reduction or hydrolysis to prepare (2*R*,3*S*)-3-hydroxyproline derivatives (3*b*). Alternatively, Sibi and Christensen improved an already known baker's yeast reduction method to give the (2*R*,3*S*)-Boc-protected proline ester in good chemical and optical yields (14). Since the baker's yeast reduction is easy to perform, we adopted this method with modification (15) to prepare the Cbz protected compound **13** according to Scheme 1. Thus, condensation of ethyl 3-bromopropionate (**14**) with freshly prepared ethyl glycinate was accomplished in refluxing benzene to give a good yield of the *N*,*N*-disubstituted aminodiester **15**. Protection of the free amine with the Cbz group was performed to provide the carbamate **16** in good yield (16). Dieckmann cyclization of **16** using potassium *t*-butoxide in toluene afforded a 1.3:1 mixture of regioisomers **17** and **18** which could be separated by distillation and chromatography. Even though the required **18** was the minor isomer, the sequence for its preparation was nevertheless quite short and utilized cheap and readily available starting materials. Baker's yeast reduction of **18** gave the (2*R*,3*S*)-β-hydroxyester **19** in good enantioselectivity (>99% ee). For comparison purpose, sodium borohydride reduction of **18** in ethanol gave the racemic **19** as the sole diastereomer, spectroscopically identical to the enantiomerically pure compound. Many of the subsequent reactions could therefore be explored with the racemic compound first. Protection of the secondary alcohol of (+)-**19** with the MOM protecting group gave compound **20**. Reduction of **20** with lithium borohydride in ether gave a good yield of the primary alcohol **21**, which was oxidized by the Swern oxidation to the aldehyde **13** in quantitative yield.

Synthesis of 8-*epi*- (11) and 6,7,8-tri-*epi*-castanospermine (12) (Scheme 2)



Coupling of **13** with the titanium reagent derived from the anion of allyl phenyl sulfide gave only one stereoisomer, **22** (17). It is interesting to compare the stereoselectivity in the present coupling with our previously reported coupling of *N*-Cbz-pyrrolidine-2-carboxaldehyde where the 3-MOM substituent was missing (11). The stereoselectivity is much higher in the present case, presumably due to the influence of the MOM group. Since it was established by Yamamoto and co-workers that the coupling reaction gave excellent erythro selectivity (17), the two newly created stereogenic centers could have either the 1′*S*, 2′*S* or the 1′*R*, 2′*R* configurations. Definitive assignment could not be made at this point. Furthermore, the stereochemistry at the carbon 2 position is of no real interest to us since it will be destroyed in the subsequent reactions. In any case, oxidation of the

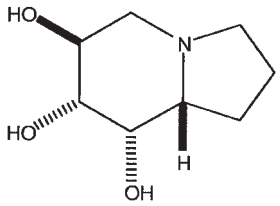
© 2000 NRC Canada

Scheme 1.

Scheme 2.

sulfide **22** to the corresponding sulfoxide **23** followed by trimethyl phosphite treatment (18) gave the rearranged diol **24**. In conformity with similar rearrangements observed previously (11), the double bond in **24** was expected to have the *trans* stereochemistry. This was confirmed through the coupling constants of the olefinic protons in the bicyclic compound **25** prepared by intramolecular cyclization of **24** under basic conditions. The primary allylic alcohol function in **25** was transformed to the chloride **26** with triphenylphosphine in carbon tetrachloride (19). Hydroxylation of the double bond of **26** with osmium tetroxide and *N*-methylmorpholine *N*-oxide (20) led to an inseparable mixture of diols **27a** and **27b**. Conversion of the diols to the corresponding acetonides allowed separation into individual compounds **28a** and **28b** in a ratio of about 5:3. Base hydrolysis of compound **28a,** the major isomer, followed by spontaneous intramolecular cyclization gave the protected indolizidine **29a**. Removal of the MOM and the isopropylidene protecting groups of **29a** under aqueous acidic conditions gave in quantitative yield the product **11** which we subsequently assigned the structure as (+)-8-*epi*-castanospermine (vide infra). Base hydrolysis of **28b**, the minor isomer, led not only to cyclization but deprotection as well to give product **12** to which the structure 6,7,8-tri-*epi*-castanospermine was assigned.

Assignment of stereochemistry



Castanospermine (**1**) itself has the 1*S*, 6*S*, 7*R*, 8*R*, and 8a*R* configurations. From the ^{1}H and ^{13}C NMR spectra of compounds **11** and **12**, it is clear that they are not identical to that of castanospermine (9*f*). In starting from the known pyrrolidinecarboxaldehyde **13**, the stereochemistries of carbons 1 and 8a (corresponding to carbons 2 and 3 of **13**) are secured as 1*S* and 8a*R* in the final products **11** and **12**. Since the dihydroxylation of double bond with osmium tetroxide has been well established to give the *cis* diol (20), the relative stereochemistry of carbons 6 and 7 in compounds **11** and **12** must be *trans*. There were two reactions in Scheme 2 which could give rise to uncertain stereochemical outcomes. The first was the conversion of **13** to **22**, which created the stereogenic carbon 8 in the final products. The stereochemistry could be either 8*S* or 8*R*. The second was that, in the hydroxylation step, the relative stereochemistry of the *cis* diol with respect to the existing stereogenic carbon 8 could be *syn* or *anti* (21). Consequently, there could be four stereochemical outcomes from Scheme 2. If, in the conversion of **13** to **22** the stereochemistry was 8*R*, then the final two products must have either 1*S*, 6*S*, 7*R*, 8*R*, 8a*R* (castanospermine **1**) or 1*S*, 6*R*, 7*S*, 8*R*, 8a*R* (6,7-di-*epi*-castanospermine **3**) stereochemistry. These two possibilities can be ruled out because the NMR spectra of neither **11** nor **12** correspond to the known **1** (9*f*) and **3** (8). If, on the other hand, in the conversion of **13** to **22** the stereochemistry was 8*S*, then the final two products must have either 1*S*, 6*S*, 7*R*, 8*S*, 8a*R* (8-*epi*-castanospermine) or 1*S*, 6*R*, 7*S*, 8*S*, 8a*R* (6,7,8-tri-*epi*-castanospermine) stereochemistry. We were able to assign compound **11** to the 8-*epi*-castanospermine structure based on comparison of the coupling constants in the ^{1}H NMR spectrum of **11** with those reported for the various stereoisomers of castanospermine (Table 1). In particular, the H6 proton has a *trans*-diaxial coupling with H7 (J = 9.5 Hz), which has a gauche coupling with H8 (J = 3.0 Hz), fully compatible with the 6*S*, 7*R*, 8*S* relative configurations of *trans*-diaxial/gauche relationship between the three protons. Martin et al. recently reported on the synthesis of 1-deoxy-8-*epi*-castanospermine (**30**) (22). The three protons

H6, H7, and H8 in compound **30** have the same relative configurations of 6*S*, 7*R*, and 8*S* and similar coupling constants of $J_{H6–H7}$ = 9.6 Hz and $J_{H7–H8}$ = 3.5 Hz.

Experimental[3]

The assignment of the peaks for some ^{1}H and ^{13}C NMR spectra were complicated because of the geometric isomers produced by the Cbz group in compounds **16**, **18**, **19**, **20**, **21**, **13**, **22**, and **24**.

Ethyl *N*-(2-ethoxycarbonylethyl)-glycinate (15)

To a solution of freshly prepared ethyl glycinate (10.2 g, 98.4 mmol: from ethyl glycinate hydrochloride neutralized with 10 M NaOH: pH 9.5 and extracted with chloroform) in dry benzene (10 mL) was added ethyl 3-bromopropionate (**14**. 6.3 mL, 0.5 equiv.) in benzene (5 mL). A white solid formed immediately upon addition. The suspension was heated at 60°C for 5 h and poured into saturated aqueous sodium carbonate solution. The aqueous phase was extracted with chloroform (3×) and the combined organic extracts were dried ($MgSO_4$) and evaporated. The residue was distilled (95°C, 0.25 mm Hg) to yield **15** as a colorless oil (6.3 g, 63%). IR (neat): 3348, 2985, 1721, and 1121 cm^{-1}. ^{1}H NMR ($CDCl_3$): 4.05 (q, 2H, *J* = 7.2), 4.01 (q, 2H, *J* = 7.2), 3.27 (s, 2H), 2.76 (t, 2H, *J* = 6.6), 2.36 (t, 2H, *J* = 6.6), 1.72 (s, 1H), 1.14 (t, 3H, *J* = 7.2), 1.12 (t, 3H, *J* = 7.2). ^{13}C NMR ($CDCl_3$): 172.8, 172.6, 61.1, 60.8, 51.2, 45.1, 35.2, 14.6. MS: 204 (5), 203 (7), 174 (2), 158 (4), 130 (100), 116 (49), 84 (76), 56 (14), 42 (38).

Ethyl *N*-benzoxycarbonyl-*N*-(2-ethoxycarbonylethyl)-glycinate (16)

To a solution of **15** (3.88 g, 20.2 mmol) in dry acetonitrile (40 mL) at 0°C, under argon, was added slowly benzyl chloroformate (3.17 mL, 1.1 equiv.). The solution was stirred at 0°C for 1 h after which it was poured into water (50 mL). The phases were separated and the aqueous layer was extracted with methylene chloride (3×). The combined organic extracts were washed with 5% HCl, water, brine, and dried ($MgSO_4$). Evaporation of the solvents was followed by distillation (198°C, 0.25 mm Hg) to afford **16** as a colorless oil (5.4 g, 80%). IR (neat): 2978, 1722, and 1693 cm^{-1}. ^{1}H NMR ($CDCl_3$): 7.40–7.18 (m, 5H), 5.13 + 5.07 (2s, 2H), 4.14 + 4.11 (2q, 2H, *J* = 7.1), 4.06 (2q, 2H, *J* = 7.1), 3.59 + 3.58 (2t, 2H, *J* = 6.4), 2.64 + 2.58 (2t, 2H, *J* = 6.4), 1.22 + 1.15 (2t, 3H, *J* = 7.1), 1.21 + 1.20 (2t, 3H, *J* = 7.1). ^{13}C NMR ($CDCl_3$): 172.7 + 172.4, 170.4 + 170.3, 156.7 + 156.2, 136.8, 129.0 + 128.9, 128.5 + 128.4, 128.3 + 128.2, 68.0 + 67.8, 61.6, 61.1 + 61.0, 50.9, 45.8 + 45.0, 34.6 + 34.0, 14.6. MS: 337 (4), 229 (2), 264 (2), 220 (12), 202 (28), 91 (100).

Ethyl *N*-benzoxycarbonyl-3-oxopyrrolidine-2-carboxylate (18)

To a suspension of potassium *t*-butoxide (2.52 g, 1.4 eq) in dry toluene (54 mL) at 0°C, under argon, was added **16** (5.41 g, 16.0 mmol) in toluene (10 mL) over a period of 10 min. The suspension was stirred at 0°C for 30 min after which 2 mL of glacial acetic acid were added, immediately followed by a solution of sodium dihydrogen phosphate hydrate (9.1 g) in water (91 mL). The heterogeneous mixture was extracted with chloroform (3×), and the combined organic extracts were dried ($MgSO_4$) and concentrated. The residue was dissolved in cold toluene (100 mL) and washed with cold, pH 9.5 carbonate buffer (3×). The toluene solution was washed with water, dried ($MgSO_4$), and concentrated. The residue was distilled (Kugelrohr: oven temperature 160°C, 0.03 mm Hg) and the distillate was purified by flash chromatography over silica gel with hexanes:ethyl acetate (2:1) as eluent. Compound **18** was obtained as a colorless oil (slightly contaminated with compound **17**). IR (neat): 2978, 1741, 1712, and 1695 cm^{-1}. ^{1}H NMR ($CDCl_3$): 7.41–7.23 (m, 5H), 5.22 + 5.15 and 5.20 + 5.07 (2 AB, 2H, *J* = 8.2), 4.58 + 4.54 (2s, 1H), 4.24 (q, 2H, *J* = 4.7), 4.08 (m, 1H), 3.96 (m, 1H), 3.85 (m, 1H), 2.67 (t, 2H, *J* = 4.9), 1.28 + 1.14 (2t, 3H, *J* = 4.7). ^{13}C NMR ($CDCl_3$): 204.6, 166.4, 154.9, 136.6 + 136.4, 128.9, 128.7,

128.5 + 128.4, 68.03, 65.9 + 65.8, 62.8, 42.6, 37.3 + 36.7, 14.5 + 14.4. MS: 292 (100), 248 (80), 176 (32), 158 (23).

Ethyl (2*R*,3*S*)-*N*-benzoxycarbonyl-3-hydroxypyrrolidine-2-carboxylate (19)

To a solution of sucrose (300 mg) in distilled water (4.1 mL) was added baker's yeast (200 mg). The flask was equipped with a bubble counter and the suspension was heated at 32°C for 1 h. The content of the flask was then poured into a 15 mL flask containing the keto ester **18** (0.12 g, 0.42 mmol). Stirring was continued for 24 h after which additional sucrose (300 mg) in warm (40°C) distilled water (1 mL) was added. After 48 h, celite (500 mg) was added to the mixture and the suspension was filtered through a sintered glass funnel (medium porosity). After the filtrate was washed with water, the aqueous layer was extracted with ether (3×) and the combined organic extracts were dried ($MgSO_4$). After filtration, the solvent was evaporated and the residue was purified by flash chromatography (silica gel, 3:7 hexanes:ethyl acetate) to give the optically active compound **19** (55 mg, 45%). $[\alpha]_D^{20}$ = +22.8° (*c*: 2.7 in CH_2Cl_2); lit. $[\alpha]_D^{20}$ = +21.9° (*c*: 2.0 in CH_2Cl_2)(15). IR (neat): 3378, 2978, 1741, 1701 cm^{-1}. ^1H NMR ($CDCl_3$): 7.40–7.22 (m, 5H), (5.13 + 5.00) + 5.11 (1 AB and 1s, 2H, J_{AB} = 12.5), 4.56 (q, 1H, *J* = 6.4), 4.39 (t, 1H, *J* = 6.4), 4.19–4.06 (m, 2H), 3.66 (m, 1H), 3.49 (m, 1H), 2.02 (m, 1H), 1.23 + 1.11 (2t, 3H, *J* = 7.1). ^{13}C NMR ($CDCl_3$): 170.7 + 170.5, 155.4 + 154.9, 136.9 + 136.8, 128.9 + 128.8, 128.5, 128.4 + 128.2, 72.7 + 71.8, 67.6, 64.4 + 64.1, 61.8 + 61.7, 44.9 + 44.7, 33.2 + 32.4, 14.6 + 14.5. Exact mass calcd. for $C_{15}H_{19}NO_5$ ($M^{\cdot+}$ + H): 294.1342, found: 284.1341.

Racemic **19** was prepared by the reduction of **18** with sodium borohydride. To a solution of **18** (0.29 g, 0.72 mmol) in absolute ethanol (3.6 mL) at 0°C, under argon, was added sodium borohydride (29.8 mg, 1.1 equiv.). The solution was stirred at 0°C for 60 min after which a few drops of acetic acid were added. The solution was poured in saturated aqueous sodium bicarbonate and the aqueous layer was extracted with ether (3×). The combined organic extracts were washed with brine and dried ($MgSO_4$). After fitration, the solvents were evaporated and the residue was purified by flash chromatography to give racemic **19** (0.14 g, 66%), identical in all spectroscopic aspects with those of (+)-**19**.

Ethyl (2*R*,3*S*)-*N*-benzoxycarbonyl-3-methoxymethyloxypyrrolidine-2-carboxylate (20)

To a solution of the alcohol (+)-19 (0.14 g, 0.48 mmol) in methylene chloride (4.8 mL) at 0°C, under argon, was successively added diisopropylethylamine (0.25 mL, 3 equiv.) and chloromethyl methyl ether (0.11 mL, 3 equiv.). The solution was stirred at rt for 24 h after which it was poured into 5% HCl. The aqueous phase was extracted with methylene chloride (3×) and the combined organic extracts were washed with saturated aqueous sodium bicarbonate and dried ($MgSO_4$). After evaporation of the solvent, the residue was purified by flash chromatography on silica gel with 1:1 hexanes:ethyl acetate as eluent to give compound **20** as a colorless oil (0.15 g, 92%). $[\alpha]_D^{20}$ = –18.4° (*c*: 1.1 in $CHCl_3$). IR (neat) : 2957, 1746, 1701 cm^{-1}. ^1H NMR ($CDCl_3$): 7.42–7.20 (m, 5H), (5.14 + 5.02) + 5.11 (AB + s, 2H, J_{AB} = 12.2), (4.68 + 4.60) + (4.66 + 4.58) (2 AB, 2H, *J* = 6.9), 4.21–4.07 (2q, 2H, *J* = 7.1), 3.70 (m, 1H), 3.49 (m. 1H), 3.34 + 3.33 (2s, 3H), 2.10 (m, 2H), 1.25 + 1.14 (2t, 3H, *J* = 7.1). ^{13}C NMR ($CDCl_3$): 170.0 + 169.9, 155.2 + 154.8, 136.9, 128.9 + 128.8, 128.5 + 128.4, 128.2, 96.1, 76.7 + 76.0, 67.6, 62.6 + 62.3, 61.5 + 61.4, 56.2, 44.8 + 44.6, 31.0 + 30.2, 14.7 + 14.6. Exact mass calcd. for $C_{17}H_{23}NO_6$ ($M^{\cdot+}$ + H): 338.1605, found: 338.1604.

(2*S*,3*S*)-*N*-Benzoxycarbonyl-2-hydroxymethyl-3-methoxymethyloxypyrrolidine (21)

To a solution of the ester **20** (0.84 g, 2.48 mmol) in ether (25 mL) at 0°C, under argon, was added lithium borohydride (0.12 g, 2.2 eq) and the suspension was stirred at 0° for 4 h. Acetic acid (1 mL) was then added to destroy the excess hydride and the solution was poured in saturated aqueous sodium bicarbonate solution. The phases were separated and the aqueous phase was extracted with ether (2×). The combined organic phase was washed with brine and dried ($MgSO_4$). Filtration and evaporation of the solvent was followed by flash chromatography (silica gel, 4:6 hexanes:ethyl acetate) of the residue to give alcohol **21** as a colorless oil (0.53 g, 72%). $[\alpha]_D^{20}$ = +44.7° (*c*: 1.1 in $CHCl_3$). IR (neat): 3450, 2948, 2888, 1704 cm^{-1}. ^1H NMR ($CDCl_3$): 7.40–7.22 (m, 5H), 5.12 (s, 2H), 4.71–4.58 (m, 2H), 4.32 (q, 1H, *J* = 5.3), 3.96 (m. 1H), 3.89–3.75 (m, 2H), 3.51 (t, 2H, *J* = 6.8), 3.36 (s, 3H), 3.27 (bs, 1H), 1.98 (t, 2H, *J* = 6.8). ^{13}C NMR ($CDCl_3$): 156.9, 136.9, 129.0, 128.6, 128.4, 96.2, 77.8, 67.7, 63.4, 63.2, 56.3, 45.1, 30.6. Exact mass calcd. for $C_{15}H_{21}NO_5$ ($M^{\cdot+}$ + H): 296.1499, found: 296.1498.

(2*R*,3*S*)-*N*-Benzoxycarbonyl-3-methoxymethyloxypyrrolidine-2-carboxaldehyde (13)

Dimethyl sulfoxide (49.3 µl, 2.84 equiv.) was slowly added to a solution of oxalyl chloride (30.1 µl, 1.41 equiv.) in methylene chloride (2 mL) under argon at –78°C. The colorless solution was stirred for 15 min after which a solution of the alcohol **21** (72.2 mg, 0.24 mmol) in methylene chloride (1 mL) was added dropwise over a period of 5 min. A white precipitate was formed and the suspension was stirred for 1 h. Triethylamine (0.17 mL, 5 equiv.) in methylene chloride was added and the solution was allowed to slowly warm to room temperature. The mixture was diluted with methylene chloride (10 mL) and washed successively with 5% HCl, water, brine, and dried ($MgSO_4$). Evaporation of the solvent under vacuum gave a pale brown oil which was purified by flash chromatography (silica gel, 1:1 hexanes:ethyl acetate) to give the aldehyde **13** as a pale yellow oil (70.0 mg, 98%). $[\alpha]_D^{20}$ = +70.4° (*c*: 1.1 in $CHCl_3$). IR (neat): 2958, 2888, 1736, 1701 cm^{-1}. ^1H NMR ($CDCl_3$): 9.53 + 9.44 (2d, 1H, *J* = 2.5), 7.42–7.21 (m, 5H), 5.14 + 5.09 (2s, 2H), 4.72–4.51 (m, 3H), 4.27 + 4.21 (2dd, 1H, *J* = 2.5, 5.7), 2.75–3.60 (m, 2H), 3.29 (s, 3H), 2.16–1.80 (m, 2H). ^{13}C NMR ($CDCl_3$): 200.2 + 200.1, 155.7 + 154.8, 136.8 + 136.6, 129.0, 128.6, 128.5 + 128.4, 95.8, 79.4 + 78.3, 68.4 + 68.0, 67.8, 56.3, 45.7 + 45.1, 31.5 + 30.9. Exact mass calcd. for $C_{15}H_{19}NO_5$ ($M^{\cdot+}$ + H): 294.1342, found: 294.1341.

(2*R*,3*S*,1′*S*,2′*S*)-*N*-Benzoxycarbonyl-2-(1′-hydroxy-2′thiophenyl-3′-butenyl)-3-methoxymethyloxypyrrolidine (22)

To a solution of allyl phenyl sulfide (0.35 g, 15 equiv.) in dry THF (10.5 mL) at –78°C, under argon, was added

© 2000 NRC Canada

n-butyllithium (2.0 M in pentane, 1.16 mL, 1.5 equiv.) and the solution was stirred at 0°C for 30 min. It was then brought back to –78°C and titanium (IV) isopropoxide (0.69 mL, 1.5 equiv.) was added slowly. After 10 min, aldehyde **13** (0.45 g, 1.55 mmol) in THF (5 mL) was added over a period of 10 min. The solution was stirred for 10 min and warmed up at 0°C for 30 min. It was then poured into 5% HCl and extracted with ether (3×). The combined organic extracts were washed with brine, dried ($MgSO_4$), and filtered. Evaporation of the solvent followed by flash chromatography (silica gel, 1:1 hexanes:ethyl acetate) gave the product **22** as a colorless oil (0.49 g, 72%). $[\alpha]_D^{20}$ = +50.2° (*c*: 1.1 in $CHCl_3$). IR (neat): 3424, 2948, 2893, 1693 cm^{-1}. ^1H NMR ($CDCl_3$): 7.54–7.09 (m, 10H), 6.06 (m, 1H), 5.12 (s, 2H), 5.06 (d, 1H, *J* = 10.7), 4.90 (d, 1H, *J* = 17.2), 4.63 (s, 2H), 4.60 (m, 1H), 4.26 (q, 1H, *J* = 6.0), 4.14 (bs, 1H), 3.95 (d, 1H, *J* = 9.6), 3.66–3.42 (m, 2H), 3.33 (s, 3H), 2.15–1.84 (m, 2H). ^{13}C NMR ($CDCl_3$): 158.2, 136.7, 134.9, 133.4, 129.1, 128.7, 128.6, 127.6, 126.0, 118.5, 96.4, 77.1, 72.8, 68.0, 63.1, 56.8, 56.5, 45.3, 30.8. Exact mass calcd. for $C_{24}H_{29}NO_5S$ ($M^{\cdot+}$ + H): 444.1846, found: 444.1845.

(2*R*,3*S*,1′*R*)-*N*-Benzoxycarbonyl-2-(1′,4′-dihydroxy-2′-butenyl)-3-methoxymethyloxypyrrolidine (24)

To a solution of the hydroxysulfide **22** (0.49 g, 1.11 mmol) in methylene chloride (11.1 mL) at 0°C under argon was added *m*-chloroperoxybenzoic acid (0.27 g, 1.4 equiv.) and the solution was stirred for 60 min. It was then dissolved in ether, washed with saturated aqueous sodium bicarbonate solution (2×), dried ($MgSO_4$), filtered, and the solvent was evaporated. The residue was dissolved in dry methanol (11.1 mL) and trimethyl phosphite (0.65 mL, 5 equiv.) was added slowly. After 2 h of stirring at 60°C, the methanol was evaporated and the thick residual oil was purified by flash chromatography (silica gel, 2:8 hexanes:ethyl acetate, then ethyl acetate as eluents) to give the allylic alcohol **24** (0.28 g, 71%). $[\alpha]_D^{20}$ = +31.2° (*c*: 1.5 in $CHCl_3$). IR (neat): 3450, 2948, 2888, 1704, 1671 cm^{-1}. ^1H NMR ($CDCl_3$): 7.42–7.21 (m, 5H), 5.96–5.70 (m, 2H), 5.12 (s, 2H), 4.67 (s, 2H), 4.51 (m, 1H), 4.29 (m, 1H), 4.21–3.88 (m. 3H), 3.62–3.43 (m, 2H), 3.37 (s, 3H), 3.29 (m, 1H), 3.16 (bs, 1H), 2.20–1.91 (m, 2H). ^{13}C NMR ($CDCl_3$): 157.3, 136.9, 131.8, 131.0, 129.0, 128.6, 128.4, 97.0, 78.2, 72.1, 67.8, 63.2, 56.4, 45.5, 30.9. Exact mass calcd. for $C_{18}H_{25}NO_6$ ($M^{\cdot+}$ + H): 352.1761, found: 352.1760.

(2*R*,3*S*,1′*R*)-1,1′-*N*,*O*-Carbonyl-2-(1′,4′-dihydroxy-2′-butenyl)-3-methoxymethyloxypyrridine (25)

To a solution of the allylic diol **24** (0.21 g, 0.61 mmol) in 2-propanol:water (2:1, 6.1 mL) was added finely powdered potassium carbonate (0.17 g, 2 equiv.) and the solution was heated at 65°C for 15 h. The solvent was evaporated and the residue purified by flash chromatography (silica gel, ethyl acetate) to give the product **25** as a colorless oil (0.11 g, 77%). $[\alpha]_D^{20}$ = +99.6° (*c*: 1.1 in $CHCl_3$). IR (neat): 3436, 2946, 2895, 1751, 1674 cm^{-1}. ^1H NMR ($CDCl_3$): 5.96 (dt, 1H, *J* = 4.0, 15.5), 5.83 (dd, 1H, *J* = 6.5, 15.5), 5.04 (dd, 1H, *J* = 3.6, 6.5), 4.63 (AB, 2H, *J* = 7.0), 4.13 (d, 2H, *J* = 4.0), 4.08 (td, 1H, *J* = 0.9, 3.6), 3.62 (t, 1H, *J* = 3.6), 3.54 (ddd, 1H, *J* = 7.8, 9.5, 10.8), 3.32 (s, 3H), 3.19 (ddd, 1H, *J* = 2.1, 9.6, 10.8), 2.83 (bs, 1H), 2.25 (dddd, 1H, *J* = 0.9, 2.1, 7.8, 14.1), 1.92 (dddd, 1H, *J* = 3.6, 9.5, 9.6, 14.1). ^{13}C NMR ($CDCl_3$): 162.2, 134.5, 127.6, 95.5, 75.5, 75.4, 69.4, 62.3, 56.3, 44.2, 32.6. Exact mass calcd. for $C_{11}H_{17}NO_5$ ($M^{\cdot+}$ + H): 244.1186, found: 244.1185.

(2*R*,3*S*,1′*R*)-1,1′-*N*,*O*-Carbonyl-2-(1′hydroxy-4′-chloro-2′-butenyl)-3-methoxymethyloxypyrrolidine (26)

To a solution of the allylic alcohol **25** (0.11 g, 0.47 mmol) in a mixture of carbon tetrachloride:methylene chloride (4:1, 6.0 mL) were added successively finely powdered potassium carbonate (0.13 g, 2 equiv.) and triphenylphosphine (0.31 g, 2.5 equiv.) and the solution was stirred at 60°C for 8 h. The solvent was evaporated and the residue was purified by flash chromatography (silica gel, 2:8 hexanes:ethyl acetate) affording the chloride **26** (83.9 mg, 70%) as a pale yellow oil. $[\alpha]_D^{20}$ = +87.7° (*c*: 1.5 in $CHCl_3$). IR (neat): 2965, 2895, 1751 cm^{-1}. ^1H NMR ($CDCl_3$): 6.06–5.84 (m, 2H), 5.06 (dd, 1H, *J* = 3.6, 5.1), 4.65 (AB, 2H, *J* = 7.0), 4.11 (td, 1H, *J* = 1.1, 3.6), 4.05 (d, 2H, *J* = 6.2), 3.62 (t, 1H, *J* = 3.6), 3.58 (ddd, 1H, *J* = 7.9, 9.5, 11.0), 3.33 (s, 3H), 3.22 (ddd, 1H, *J* = 2.2, 9.7, 11.0), 2.28 (dddd, 1H, *J* = 1.1, 2.2, 7.9, 14.1), 1.93 (dddd, 1H, *J* = 3.6, 9.5, 9.7, 14.1). ^{13}C NMR ($CDCl_3$): 161.8, 131.7, 129.9, 95.5, 75.6, 74.4, 69.1, 56.4, 44.3, 43.9, 32.5. Exact mass calcd. for $C_{11}H_{16}NO_4Cl$ ($M^{\cdot+}$ + H): 262.0847, found: 262.0846.

(2*R*,3*S*,1′*S*,2′*S*,3′*R*)- and (2*R*,3*S*,1′*S*,2′*R*,3′*R*)-1,1′-*N*,*O*-Carbonyl-2-(1′,2′,3′-trihydroxy-4′-chlorobutanyl)-3methoxymethyloxypyrrolidine (27a and 27b)

To a solution of the chloride **26** (83.9 mg, 0.32 mmol) in a mixture of acetone:water:*t*-butanol (6:3:1, 2.0 mL) were added successively *N*-methylmorpholine-*N*-oxide (45.1 mg, 1.2 equiv.) and osmium tetroxide (15.0 mg, 0.05 equiv.). The orange solution was stirred at room temperature for 3 h, after which 2 mL of a solution-suspension of magnesium silicate and sodium hydrosulfite (1.2 g and 0.1 g respectively in 8 mL of water) was added. The slurry was filtered through celite and the cake was rinsed with acetone. The solvents were evaporated and the dark residual oil was purified by flash chromatography (silica gel, ethyl acetate) to provide a mixture of the products **27a** and **27b** (2:1 by NMR, 94.8 mg, 99%). IR (neat): 3335, 2952, 1751 cm^{-1}. ^1H NMR ($CDCl_3$): 4.83–4.59 (m, 3H), 4.09 (m, 2H), 3.95 (m, 1H), 3.86 (m, 1H), 3.77–3.46 (m, 5H), 3.32 (s, 3H), 3.27 (m, 1H), 2.29 (m, 1H), 2.01 (m, 1H). ^{13}C NMR ($CDCl_3$): **27a**: 162.1, 95.7, 76.1, 75.5, 71.1, 70.8, 66.1, 56.3, 45.8, 44.0, 33.0; **27b**: 162.0, 95.5, 76.4, 75.3, 72.1, 71.6, 66.0, 56.3, 45.8, 44.0, 32.8. Exact mass calcd. for $C_{11}H_{18}NO_6Cl$ ($M^{\cdot+}$ + H): 296.0902, found: 296.0901.

(2*R*,3*S*,1′*S*,2′*S*,3′*R*)- and (2*R*,3*S*,1′*S*,2′*R*,3′*S*)-1,1′-*N*,*O*-Carbonyl-2-(1′hydroxy-2′,3′-*O*-isopropylidene-4′-chlorobutanyl)-3-methoxymethyloxypyrrolidine (28a and 28b)

To a solution of the diol mixture **27a** and **27b** (94.8 mg, 0.32 mmol) in dry acetone (3.2 mL) at room temperature under argon were added 2,2-dimethoxypropane (0.20 mL, 5 equiv.) and camphorsulfonic acid (5.2 mg, 0.05 equiv.). The solution was stirred for 15 h at room temperature and heated at 40°C for 1 h after which a few drops of conc. ammonium hydroxide were added. The solvent was evaporated and the residue was taken up in ethyl acetate. The organic solution

© 2000 NRC Canada

was washed with brine and dried ($MgSO_4$). Evaporation of the solvent followed by flash chromatography (silica gel, 6:4 hexanes:ethyl acetate) purification gave **28a** (51.0 mg, 48%) and **28b** (31.7 mg, 29%) separately, for a combined yield of 77%. Compound **28a** (white solids): mp 74–76°C. $[\alpha]_D^{20}$ = +50.8° (*c*: 1.0 in $CHCl_3$). IR ($CHCl_3$): 2980, 1751 cm^{-1}. ^1H NMR ($CDCl_3$): 4.70 + 4.62 (AB, 2H, *J* = 7.0), 4.60 (dd, 1H, *J* = 3.2, 8.3), 4.21 (ddd, 1H, *J* = 3.8, 5.2, 7.0), 4.13 (td, 1H, *J* = 0.9, 3.2), 4.05 (dd, 1H, *J* = 7.0, 8.3), 3.88 (t, 1H, *J* = 3.2), 3.80 (dd, 1H, *J* = 3.8, 11.8), 3.65 (dd, 1H, *J* = 5.2, 11.8), 3.59 (ddd, 1H, *J* = 7.8, 9.5, 10.8), 3.34 (s, 3H), 3.26 (ddd, 1H, *J* = 2.1, 9.8, 10.8), 2.32 (dddd, 1H, *J* = 0.9, 2.1, 7.8, 14.1), 1.98 (dddd, 1H, *J* = 3.2, 9.5, 9.8, 14.1), 1.44 (s, 3H), 1.40 (s, 3H). ^{13}C NMR ($CDCl_3$): 162.0, 112.1, 96.3, 80.8, 79.4, 76.5, 76.4, 67.7, 57.2, 45.7, 45.1, 33.5, 28.6, 28.4. Exact mass calcd. for $C_{14}H_{22}NO_6Cl$ ($M^{\cdot+}$ + H): 336.1215, found: 336.1214.

Compound **28b** (white solids): mp 153–155°C. $[\alpha]_D^{20}$ = +66.1° (*c*: 1.6 in $CHCl_3$). IR ($CHCl_3$): 2997, 1751 cm^{-1}. ^1H NMR ($CDCl_3$): 4.77 (dd, 1H, *J* = 1.8, 3.4), 4.71 + 4.63 (AB, 2H, *J* = 7.0), 4.40 (ddd, 1H, *J* = 4.4, 6.6, 7.5), 4.11 (td, 1H, *J* = 0.9, 3.4), 4.08 (dd, 1H, *J* = 1.8, 7.5), 3.91 (t, 1H, *J* = 3.4), 3.73 (dd, 1H, *J* = 4.4, 11.4), 3.62 (dd, 1H, *J* = 6.6, 11.4), 3.40 (ddd, 1H, *J* = 8.0, 9.5, 10.9), 3.34 (s, 3H), 3.31 (ddd, 1H, *J* = 2.1, 9.8, 10.9), 2.32 (dddd, 1H, *J* = 0.9, 2.1, 8.0, 14.3), 1.97 (dddd, 1H, *J* = 3.4, 9.5, 9.8, 14.3), 1.43 (s, 6H). ^{13}C NMR ($CDCl_3$): 171.1, 112.1, 96.4, 81.8, 76.7, 76.5, 74.1, 67.1, 57.3, 45.4, 45.3, 33.5, 28.6, 27.9. Exact mass calcd. for $C_{14}H_{22}NO_6Cl$ ($M^{\cdot+}$ + H): 336.1215, found: 336.1214.

(1*S*,6*S*,7*R*,8*S*,8a*R*)-1-Methoxymethyloxy-6,7-*O*-isopropylidene-8-hydroxyindolizidine (29a)

To a solution of the chloride **28a** (51.0 mg, 0.15 mmol) in a mixture of methanol:water (1:1, 2 mL) was added sodium hydroxide (18.3 mg, 3 equiv.) and the solution was stirred at 85°C for 18 h. The solvents were evaporated and the solid residue was extracted with chloroform. The chloroform solution was evaporated to give the aminoalcohol **29a** as a waxy solid (41.0 mg, 98%). $[\alpha]_D^{20}$ = +50.6° (*c*: 0.83 in $CHCl_3$). IR ($CHCl_3$): 3450, 2986 cm^{-1}. ^1H NMR ($CDCl_3$): 4.67 + 4.59 (AB, 2H, *J* = 7.1), 4.54 (bs, 1H), 4.46 (m, 1H), 4.35 (td, 1H, *J* = 4.2, 10.2), 3.49 (dd, 1H, *J* = 4.2, 9.3), 3.36 (s, 3H), 3.33 (m, 1H), 3.19 (t, 1H, *J* = 8.4), 2.25–2.12 (m, 4H), 1.95 (m, 1H), 1.46 (s, 3H), 1.42 (s, 3H). ^{13}C NMR ($CDCl_3$): 111.5, 95.1, 83.2, 77.9, 77.7, 71.3, 68.4, 66.4, 54.0, 51.7, 32.5, 27.4, 27.1. Exact mass calcd. for $C_{13}H_{23}NO_5$ ($M^{\cdot+}$ + H): 274.1655, found: 274.1654.

(1*S*,6*S*,7*R*,8*S*,8a*R*)-1,6,7,8,-Tetrahydroxyindolidine (8-*epi*-castanospermine, 11)

A solution of compound **29a** (41.0 mg, 0.15 mmol) in a 4:4:2 mixture of 6 M HCl:water:tetrahydrofuran was stirred for 15 h after which the solvents were evaporated. The residue was dissolved in methanol and stirred for 1 h with Amberlyst A-26 ion exchange resin (OH^- form). Filtration followed by evaporation of the methanol gave a brownish solid which was purified by flash chromatography (silica gel, 70:20:5:5 chloroform:methanol:water:NH_4OH; spray reagent: $KMnO_4$–NaOH in water) affording the tetraol **11** as an off white solid in quantitative yield (28.4 mg). It had a melting point of 190–192°C. $[\alpha]_D^{20}$ = +44.4° (*c*: 1.3 in H_2O). IR (KBr): 3450 cm^{-1}. ^1H NMR (D_2O): 4.07 (ddd, 1H, *J* = 2.1, 4.5, 6.5), 3.89 (dd, 1H, *J* = 1.2, 3.0), 3.43 (ddd, 1H, *J* = 5.5, 9.5, 11.2), 3.09 (ddd, 1H, *J* = 4.4, 9.0, 10.0), 3.07 (dd, 1H, *J* = 5.5, 11.2), 2.96 (dd, 1H, *J* = 3.0, 9.5), 2.70 (d, 1H, *J* = 4.5), 2.45 (ddd, 1H, *J* = 7.9, 10.0, 10.1), 2.23 (t, 1H, *J* = 11.2), 1.87 (dddd, 1H, *J* = 4.4, 6.5, 10.1, 14.3), 1.31 (dddd, 1H, *J* = 2.1, 7.9, 9.0, 14.3). ^{13}C NMR (D_2O): 76.2, 73.1, 71.8, 69.8, 67.9, 56.0, 53.8, 35.4. Exact mass calcd. for $C_8H_{15}NO_4$ ($M^{\cdot+}$ + H): 190.1080, found: 190.1079.

(1*S*,6*R*,7*S*,8*R*,8a*R*)-1,5,7,8-Tetrahydroxyindolizidine (6,7,8-tri-*epi*-castanospermine, 12)

The same experimental procedures for the conversion of compound **28a** to **29a** were followed by starting with compound **28b**. The deprotection of the MOM ether group as well as the isopropylidene occurred during the cyclization. The reaction time was 36 h. The purification procedures for **11** were followed but with 70:24:3:3 chloroform:methanol:water:NH_4OH as eluent for the flash chromatography (silica gel) to give compound **12** in 65% yield. $[\alpha]_D^{20}$ = –7.3° (*c*: 1.0 in H_2O). IR (KBr): 3500 cm^{-1}. ^1H NMR (D_2O): 4.00 (ddd, 1H, *J* = 2.4, 4.8, 7.1), 3.55 (t, 1H, *J* = 4.3), 3.27 (t, 1H, *J* = 4.8), 3.14 (q, 1H, *J* = 4.2), 2.79–2.59 (m, 2H), 2.46–2.31 (m, 2H), 2.17 (m, 1H), 1.71 (dddd, 1H, *J* = 3.8, 7.1, 9.5, 14.0), 1.21 (dddd, 1H, *J* = 2.4, 8.8, 8.8, 14.0). ^{13}C NMR (D_2O): 74.5, 72.7, 72.6, 71.2, 68.07, 56.9, 55.0, 34.7. Exact mass calcd. for $C_8H_{15}NO_4$ ($M^{\cdot+}$ + H): 190.1080, found: 190.1079.

Dimerization of conjugated 1-indanones

Yves Leblanc, Claude Dufresne, Rajiv Dhawan, Jason Ollerenshaw, Adam Littke, Laird A. Trimble, and Nancy N. Tsou

Abstract: Conjugated 1-indanones dimerize under basic conditions to provide spirodimers. For example when 2-(*E*)-carbomethoxymethylene-1-indanone (**5**) was treated with Cs_2CO_3 in CH_3CN, two spirodimers, **6** and **7**, were produced via two modes of reaction (mode A and mode B). With 2-(*E*)-cyanomethylene-1-indanone (**9**) only mode A dimerized spiro products (**10** and **11**) were observed whereas with 2-chloromethylidene-1-indanone (**12**) a 1,2-dimer (**13**) was obtained instead of the expected spirodimer.

Key words: dimerization, conjugated 1-indanones, spirodimers.

Résumé : Les 1-indanones dimérisent en présence d'une base pour donner des spirodimères. Par exemple, lorsqu'on traite le 2-(*E*)-carbomethoxymethylène-1-indanone (**5**) avec Cs_2CO_3 dans CH_3CN on obtient les spirodimères **6** et **7**. Ces deux dimères sont produits par deux modes de dimérisation (mode A et mode B). Dans le cas du 2-(*E*)-cyanomethylène-1-indanone (**9**) uniquement la dimérization de type A a lieu pour produire les produits spiros **10** et **11** tandis qu'avec le 2-chloromethylidène-1-indanone (**12**) comme produit de départ on obtient un dimère de type 1,2 (**13**).

Mots clés : dimérisation, 1-indanones conjugués, spirodimères.

Introduction

In a previous report we presented our study on the dimerization of 2-benzylidene-1-indanone (**1a**, Scheme 1) (1). The structure and the stereochemistry of the major spirodimer (**3a**) obtained from this reaction had initially been established by COSY, HMQC, HMBC, and NOESY NMR correlation techniques. The structure was then confirmed by X-ray crystallography (1). The stereochemistry assigned for dimer **3a** (Scheme 1) differs from previous reports (2, 3) where X-ray crystallographic analysis was not used to prove the stereochemistry. To the best of our knowledge no examples of this dimerization other than the benzylidene case (**1a**) have been published. Herein we describe new results on the dimerization of substituted benzylidene-1-indanones and other conjugated 1-indanones to assess the generality of the reaction.

Results and discussion

For the benzylidene cases, the monomers **1b** (X = SMe) and **1c** (X = SO_2Me) were chosen as substrates to verify the effect of the electronic nature of the aromatic substituents on the outcome of the reaction. The monomer **1b** was readily prepared by condensation of 1-indanone with 4-thiomethylbenzaldehyde in EtOH under acidic conditions. The monomer **1c** derives from oxidation of **1b** with Oxone® in CH_2Cl_2–MeOH. With monomers **1b** and **1c** (Table 1), the reactions proceeded smoothly to provide the corresponding dimers (Scheme 1). Moderate yields (60%) of the spirodimers were obtained with Cs_2CO_3 as the base (entry 3 and 5, Table 1). In addition, it has been observed that in the case where KHMDS was used as the base for substrate **1b,** the reaction took place very rapidly (5 min) at –78°C to provide the corresponding spirodimers **3b** and **4b** in high yields (85%) (Table 1). The relative stereochemistry of the predominant dimers (**3b** and **3c**) is the same as that observed for the unsubstituted case (**3a**). In all cases the dimerization gave, as the major product, the spirodimers with the phenyl substituents on the convex face of the molecule.

The preceding results suggest that the electronic nature of the substituents on the aromatic ring have little influence on the outcome of the reaction. Following these results, we turned our attention to other conjugated 1-indanones without a phenyl ring. With 2-(*E*)-carbomethoxy-methylene-1-indanone (**5**) as the substrate (Scheme 2), rapid dimerization (0.5 h) was observed with Cs_2CO_3 in CH_3CN (entry 1, Table 2) providing two spirodimers, **6** and **7**, in a 1:1 ratio. The KHMDS reaction conditions (entry 2, Table 2) were also applied to indanone **5** to afford dimers **6** and **7**, also in a 1:1

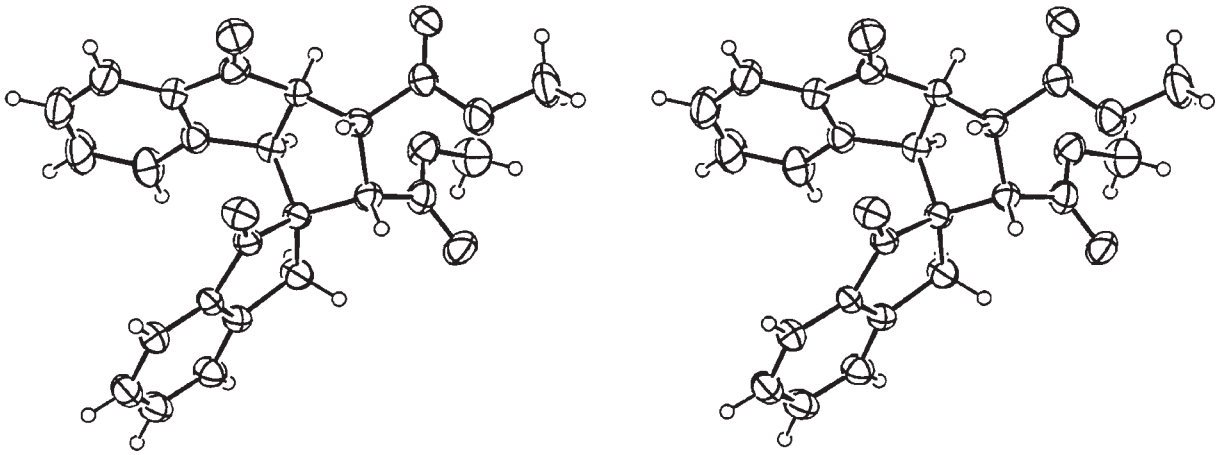
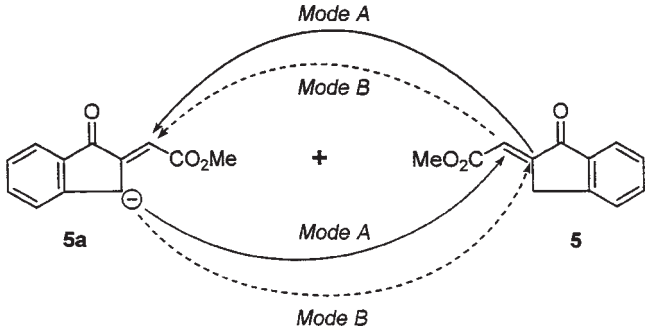
Scheme 2.



ratio. In the case where the dimerization was achieved with DBU as a base (entry 4, Table 2), a third dimer (**8**) was produced late in the reaction. This dimer is also formed from dimer **7** using DBU which suggests that compound **8** is derived by epimerization of **7**. The dimerization of **5** can also be achieved with (–)-spartine in THF to provide dimers **6** and **7** in a 1:2 ratio (entry 3, Table 2). Under these conditions no enantioselectivity was observed for this dimerization using chiral HPLC column for analysis. The spirodimers **6** and **7** are easily separable by TLC. The more mobile dimer **6** is produced by the same mode of dimerization (mode A, see Scheme 3) as observed in the benzylidene cases **1**. The second dimer originates from a different mode of dimerization (mode B) providing the vicinal diester **7**. As described in Scheme 3, the latter dimer results from the addition of the enolate **5a** onto the β carbon of the ester of a second monomer (**5**), followed by an intramolecular addition to the β carbon of the ketone. Initially, the structure and the stereochemistry of dimer **6** and of dimer **7** were established by the same NMR techniques used for the spirodimer **3a**. To prove the structure of dimer **7,** it was submitted for X-ray crystallographic analysis. As depicted in Fig. 1, the X-ray structure is identical to the structure derived from NMR.



When the dimerization of the cyano compound **9** was studied, a similar reaction pattern to that obtained with the corresponding ester **5** was expected. Using Cs_2CO_3 as a base, the dimerization of **9** was completed within a few minutes and, in contrast to ester **5**, two dimers **10** and **11** were isolated that arose from a mode A type addition. No

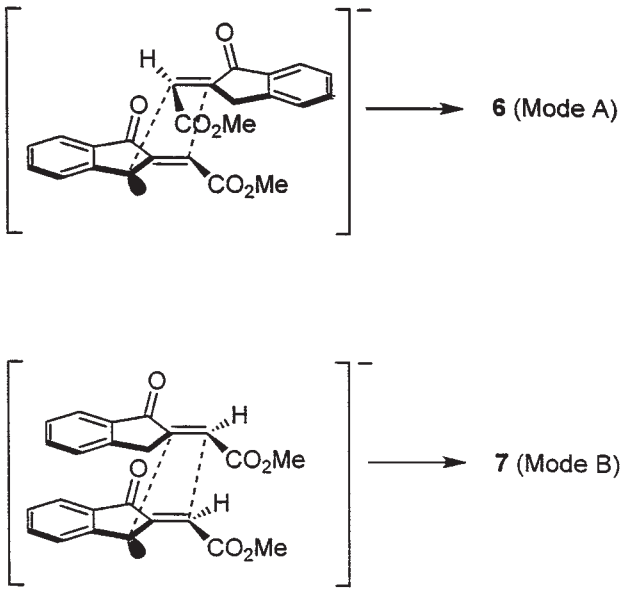
Scheme 5.

formation of a mode B type dimer was observed (Scheme 4). Presumably, the cyano compound undergoes only mode A dimerization because the addition onto the β carbon of the nitrile would lead to an intermediate with a negative charge α to the nitrile, and would thus make it less stable than in the ester case. As was the case for ester **7**, treatment of dimer **10** under basic conditions (Cs_2CO_3–CH_3CN) resulted in the production of its epimer **11**.

The last case studied was the chloromethylene analog **12** which was prepared according to a literature procedure (4). Interestingly, when this monomer was subjected to basic conditions (LiHMDS, THF, –78°C), none of the expected spirodimer was produced; however, the 1,2-dimer **13**[2] was formed exclusively (Scheme 5). It appears that the electronic nature of the substituent on the double bond has an effect on the site of reactivity of both the cross conjugated enolate and the monomer.

In conclusion, conjugated 1-indanones provide spirodimers when exposed to basic conditions. This allows the preparation of molecules containing five stereogenic centers from achiral monomers in a single step. The only exception to this statement so far is the chloromethylene analog **12**. The formation of the spirodimers is probably the result of either a double Michael reaction as already proposed (1) or of an ionic cycloaddition (Scheme 6) which could explain the high degree of diastereoselectivity observed in these reactions.

Experimental



2-(*E*)-*p*-thiomethylbenzylidene-1-indanone (1b)

To a mixture of 1-indanone (4.97 g, 37.6 mmol) and 4-thiomethylbenzaldehyde (4.60 mL, 34.6 mmol) in EtOH (50 mL) was added 25 drops of concentrated HCl. The resulting mixture was refluxed at 80°C for 19 h and then allowed to cool to room temperature to give a yellow solid. The solid was filtered and washed with EtOH to provide 8.16 g (89%) of the title compound **1b**: mp 130–133°C (EtOH); ^{1}H NMR

[2] The stereochemistry of the double bond has not been established.

2-(*E*)-*p*-methylsulfonebenzylidene-1-indanone (1c)

To a solution of **1b** (1.00 g, 3.75 mmol) in a mixture of MeOH (53 mL) and CH_2Cl_2 (5 mL) was added dropwise a suspension of OXONE® (10 g, 16.3 mmol) in water (37 mL). The resulting mixture was stirred for 28 h and then partitioned between H_2O and CH_2Cl_2. The organic phase was separated, dried over Na_2SO_4, filtered, and evaporated under reduced pressure to yield a white solid. The crude solid was stirred vigourously with Et_2O for about 5 min, filtered, and dried under vacuum for several hours to provide 0.97 g (87%) of the title compound **1c**: mp 211–214°C (EtOH); ^{1}H NMR (300 MHz, acetone-d_6, 27°C) δ: 8.06–8.04 (m, 4H), 7.83 (d, *J* = 7.8 Hz, 1H),7.75–7.68 (m, 2H), 7.62 (t, *J* = 2.3 Hz, 1H), 7.50 (t, *J* = 8.0 Hz, 1H), 4.21 (d, *J* = 2.1 Hz, 2H), 3.17 (s, 3H). ^{13}C NMR (125 MHz, acetone-d_6, 27°C) δ: 193.9, 151.0, 142.5, 141.3, 139.4, 138.4, 135.9, 132.0, 131.4, 128.7, 128.6, 127.5, 124.7, 44.2, 32.8. Dimerization of 2-(*E*)-*p*-thiomethylbenzylidene-1-indanone (1b) using CS_2CO_3 as a base to yield 3b and 4b

To a stirring solution of **1b** (0.65 g, 2.00 mmol) in CH_3CN (9.5 mL) was added Cs_2CO_3 (0.65 g, 2.00 mmol). The resulting mixture was stirred for 50 h at room temperature and was then quenched by the addition of aqueous NH_4OAc (10 mL), followed by addition of ethyl acetate (50 mL). The organic phase was separated and the aqueous phase was extracted twice more with ethyl acetate (2 × 50 mL). The organic portions were combined, dried over Na_2SO_4, filtered, and evaporated under reduced pressure. The crude mixture was then purified by column chromatography with 5% EtOAc in toluene followed by a preparative plate purification (5% EtOAc in toluene) to yield 0.25 g (52%) of pure dimer **3b** and 0.040 g (8%) of isomer **4b**.

*Isomer **3b***: mp 181–183°C (EtOH); ^{1}H NMR (500 MHz, benzene-d_6, 27°C) δ: 7.78 (d, *J* = 7.1 Hz, 1H), 7.60 (d, *J* = 7.4 Hz, 1H), 7.23 (d, *J* = 8.3 Hz, 2H), 7.09 (d, *J* = 8.6 Hz, 2H), 7.01–6.91 (m, 3H), 6.89 (d, *J* = 1.6 Hz, 2H), 6.88 (d, *J* = 1.6 Hz, 2H), 6.68 (t, *J* = 7.3 Hz, 1H), 6.60 (app. q, 2H), 4.31 (d, *J* = 11.0 Hz, 1H), 4.06 (dd, *J* = 9.0 Hz, 1H), 3.90 (d, *J* = 11.0 Hz, 1H), 3.60 (dd, *J* = 9.0, 11.0 Hz, 1H), 2.79 (s, 2H), 1.80 (s, 3H), 1.79 (s, 3H). Dimerization of 2-(*E*)-*p*-methylsulfonebenzylidene-1-indanone (1c) using Cs_2CO_3–CH_3CN to afford 3c and 4c

To a stirring solution of **1c** (0.10g, 0.35 mmol) in CH_3CN (1.8 mL) was added Cs_2CO_3 (0.13 g, 0.39 mmol). The resulting mixture was stirred for 16 h at room temperature and was then quenched by the addition of aqueous NH_4OAc (2 mL), followed by addition of ethyl acetate (10 mL). The organic phase was separated and the aqueous phase was extracted twice more with ethyl acetate (2 × 10 mL). The organic portions were combined, dried over Na_2SO_4, filtered, and evaporated under reduced pressure. Addition of a 70% EtOAc in hexane solution to the crude mixture resulted in the precipitation of the major isomer **3c** as a white solid, which was filtered and dried under vacuum for several hours; to afford 0.05 g (51%). Purification of the filtrate by preparative plate (7% EtOAc–hexane) yielded a further 0.006 g of isomer **3c** (total mass obtained: 0.060 g, 57%), and 0.002 g (3%) of isomer **4c**.

*Isomer **3c***: mp 249–251°C (EtOH); ^{1}H NMR (500 MHz, benzene-d_6, 27°C) δ: 7.75 (d, *J* = 7.3 Hz, 1H), 7.56 (d, *J* = 8.4 Hz, 2H), 7.54 (d, *J* = 8.4 Hz, 2H), 7.46 (d, *J* = 7.6 Hz, 1H), 7.24 (d, *J* = 8.4 Hz, 2H), 7.08 (d, *J* = 7.9 Hz, 2H), 7.00 (t, *J* = 7.6 Hz, 1H), 6.96 (t, *J* = 7.6 Hz, 1H), 6.72 (d, *J* = 7.2 Hz, 1H), 6.59 (t, *J* = 7.6 Hz, 1H), 6.53 (t, *J* = 6.9 Hz, 1H), 6.38 (d, *J* = 7.6 Hz, 1H), 4.18 (d, *J* = 10.8 Hz, 1H), 3.95 (t, *J* = 9.4 Hz, 1H), 3.76 (d, *J* = 10.5 Hz, 1H), 3.47 (dd, *J* = 8.9, 10.7 Hz, 1H), 2.52 (d, *J* = 17.5 Hz, 1H), 2.47 (d,

Dimerization of 2-(*E*)-*p*-thiomethylbenzylidene-1-indanone (1b) using $KN(SiMe_3)_2$ to yield 3b and 4b

To a solution of **1b** (0.15 g, 0.56 mmol) in THF (1.6 mL) at –78°C was added dropwise via syringe a 0.5 M toluene solution of $KN(SiMe_3)_2$ (1.2 mL, 0.60 mmol). The solution was allowed to stir for one hour at –78°C and was then quenched by addition of 3 mL of aqueous NH_4OAc via syringe followed by immediate warming to room temperature. The workup and purification procedure followed was the same as that described for the dimerization of **1b** using Cs_2CO_3–CH_3CN and yielded 0.12 g (80%) of isomer **3b** and 0.005 g (5%) of isomer **4b**.

Dimerization of 2-(*E*)-benzylidene-1-indanone (1a) using $KN(SiMe_3)_2$ to yield 3a and 4a

The experimental procedure and workup followed was that as described above for the dimerization of **1b** using $KN(SiMe_3)_2$. Quantities of reagents and solvents used: 2-(*E*)-benzylidene-1-indanone (0.10 g, 0.45 mmol); THF 1.1 mL; $KN(SiMe_3)_2$ (0.5 M, 0.92 mL, 0.460 mmol). Purification was achieved by flash column chromatography (6% EtOAc in toluene), which separated most of isomer **3a** from **4a**, followed by a preparative plate purification (6% EtOAc in toluene) to separate the remaining fractions from the previous column. This procedure yielded 0.08 g (81%) of isomer **3a** and 0.006 g (6%) of isomer **4a**. The isomers were identified on the basis of their ^{1}H NMR spectra, which were identical to those reported previously (1).

Dimerization of 2-carbomethoxymethylene-1-indanone (5) using Cs_2CO_3–CH_3CN to afford 6 and 7

To a solution of 2-carbomethoxymethylene-1-indanone (**5**) (5) (0.50 g, 2.30 mmol) in CH_3CN (22 mL) was added Cs_2CO_3 (0.75 g, 2.30 mmol). The resulting mixture was stirred at room temperature for 0.5 h. The reaction mixture was partitioned between 25% aqueous NH_4OAc and ethyl acetate. The organic phase was separated, dried over Na_2SO_4, and evaporated. The crude mixture was purified by flash chromatography to afford dimer **6** (0.19 g, 43%) and dimer **7** (0.19 g, 42%).

Dimer ***6***: mp 163–164°C. ^{1}H NMR (500 MHz, benzene-d_6, 22°C) δ: 7.79 (d, J = 7.7 Hz, 1H), 7.69 (d, J = 7.7 Hz, 1H), 7.51 (d, J = 7.7 Hz, 1H), 7.10 (t, J = 7.5 Hz, 1H), 7.04 (t, J = 7.3 Hz, 1H), 6.95 (d, J = 8.0 Hz, 2H), 6.92 (t, J = 7.3 Hz, 1H), 6.84 (t, J = 7.3 Hz, 1H), 4.16 (t, J = 9.9 Hz, 1H), 3.78 (t, J = 9.4 Hz, 1H), 3.67 (d, J = 9.5 Hz, 1H), 3.30 (d, J = 10.1 Hz, 1H), 3.07 (d, J = 17.6 Hz, 1H), 2.83 (s, 3H), 2.79 (s, 3H), 2.77 (d, J = 16.6 Hz, 1H). ^{13}C NMR (125.6 MHz, acetone-d_6, 22°C) δ: 203.8, 202.0, 171.0, 170.4, 154.5, 151.0, 137.0, 136.0, 135.0, 127.7, 127.6, 126.3, 126.0, 124.6, 124.4, 124.1, 63.4, 58.0, 53.5, 52.1, 51.1, 51.0, 45.0, 32.4. Dimerization of 2-carbomethoxymethylene-1-indanones (5) using $KN(SiMe_3)_2$ to yield 6 and 7

The indanone **5** (0.05 g, 0.25 mmol) was dissolved in THF (1.5 mL) and cooled to –78°C for 5 min. This was followed by the addition of a 0.05 M solution of $KN(SiMe_3)_2$ in toluene (0.10 eq, 50 μL). The crude deep purple mixture was partitioned between ethyl acetate and 25% aqueous NH_4OAc. The organic layer was separated, dried over $MgSO_4$, and filtered through silica gel to provide the title products **6** and **7** (0.04 g, 80% yield) in a 1:1 ratio.

Dimerization of 2-carbomethoxymethylene-1-indanones (5) using DBU to yield 6,7 and 8

To a solution of the indanone **5** (0.25 g, 1.24 mmol) in THF (5 mL) was added DBU (0.18 mL, 6.20 mmol). The resulting dark purple solution was allowed to react overnight and this resulted in an additional dimeric product that was more polar than those seen previously (**6** and **7**). The mixture of dimers was purified to afford: 0.07 g (28.4%) of **6**, 0.06 g (22.4%) of **7** and 0.008 g (8.0%) of **8**: Dimer **8** mp 198–200°C. ^{1}H NMR (500 MHz, acetone-d_6, 22°C) δ: 7.66 (t, J = 7.3 Hz, 1H), 7.62 (d, J = 7.7 Hz, 1H), 7.56 (d, J = 7.3 Hz, 1H), 7.30 (t, J = 7.5 Hz, 1H), 7.27 (t, J = 7.5 Hz, 1H), 7.23 (t, J = 7.5 Hz, 1H), 7.13 (d, J = 7.1 Hz, 1H), 6.91 (d, J = 7.5 Hz, 1H), 4.43 (d, J = 8.7 Hz, 1H), 4.02 (dd, J = 6.0, 11.5 Hz, 1H), 3.98 (d, J = 11.5 Hz, 1H), 3.89 (d, J = 17.5 Hz, 1H), 3.82 (d, J = 17.5 Hz, 1H), 3.77 (s, 3H), 3.50 (dd, J = 6.2, 9.0 Hz, 1H), 3.35 (s, 3H). ^{13}C NMR (125.6 MHz, acetone-d_6, 22°C) δ: 206.4, 206.1, 175.2, 171.4, 153.5, 150.8, 138.4, 138.1, 135.9, 134.9, 129.3, 128.3, 127.2, 126.5, 124.0, 123.8, 60.1, 59.4, 55.8, 54.3, 52.6, 52.1, 46.5, 40.1. HRMS calcd. for $C_{24}H_{21}O_6$ $[M + H]^+$: 405.1339, found: 405.1338.

Preparation of spirodimer 8 from dimer 7

To a solution of dimer **7** (0.02 g, 0.04 mmol) in THF (0.40 mL) was added DBU (0.06 mL, 0.39 mmol). After a

© 2000 NRC Canada

period of 72 h at room temperature, the reaction mixture was partitioned between ethyl acetate and 25% aqueous NH_4OAc. The organic layer was separated, dried over Na_2SO_4, filtered, and evaporated. After purification by flash chromatography, dimer **8** was obtained (0.012 g, 75%).

Preparation of 2-(1-oxo-1,3-dihydro-2*H*-inden-2-ylidene)acetonitrile (9)

To a mixture of 2-carboxymethylene-1-indanone (6) (0.50 g, 2.66 mmol) in dichloromethane (5.0 mL) was added an excess of oxalyl chloride (1.0 mL, 11.5 mmol) and a catalytic amount of dry DMF. This resulting mixture was allowed to react for 1.5 h at room temperature. At this point, the solvent was evaporated in vacuo and the excess of oxalyl chloride co-evaporated with dichloromethane (3 × 5 mL). The acid chloride was then dissolved in THF (10 mL) and added to a cold solution of saturated NH_4OAc (50 mL). The ice cooled reaction mixture was then stirred for 30 min. The aqueous phase was extracted with ethyl acetate and the organic layer was dried over $MgSO_4$, filtered, and the solvent evaporated under reduced pressure to provide 0.38 g (77%) of a white solid. The acetamide was used to synthesize the nitrile without further purification. To a 0°C solution of the acetamide (0.16 g, 0.85 mmol) and pyridine (0.13 g, 1.70 mmol) in 1,4-dioxane was then added trifluoroacetic anhydride (0.19 g, 0.94 mmol) over a period of 1 hour. The slurry was kept at 0°C during the addition of the trifluoroacetic anhydride. The reaction was stirred for an additional 5 min and was then poured onto a cold NH_4OAc buffer solution. The aqueous layer was extracted with ethyl acetate, dried over $MgSO_4$, and the solvent evaporated in vacuo to provide a crude brown solid. The compound was purified by flash chromatography (20% ethyl acetate – hexanes) to provide **9** as a white crystalline material (0.10 g, 69%), mp 138–140°C. ^{1}H NMR (500 MHz, acetone-d_6, 22°C) δ: 7.83 (d, J = 7.8 Hz, 1H), 7.80 (t, J = 7.5 Hz, 1H), 7.71 (d, J = 7.7 Hz, 1H), 7.54 (t, J = 7.4 Hz, 1H), 6.50 (t, J = 2.5 Hz, 1H), 4.10 (d, J = 2.3 Hz, 2H).^{13}C NMR (500 MHz, acetone-d_6, 295 K) δ: 190.5, 156.6, 149.6, 137.5, 136.8, 129.0, 127.2, 124.8, 116.5, 101.0, 32.0. calcd. for $C_{11}H_7NO$: C 78.09, H 4.17, N 8.28; found: C 78.18, H 4.02, N 8.19. Mass spectrum m/z = 168 (M – 1).

Dimerization of 2-(1-oxo-1,3-dihydro-2*H*-inden-2-ylidene)acetonitrile (9) with Cs_2CO_3–CH_3CN to yield 10 and 11

To a solution of the nitrile **9** (0.14 g, 0.89 mmol) in acetonitrile (8 mL) was added Cs_2CO_3 (0.75 g, 2.30 mmol). After a period of 10 min, followed by standard work up procedure, the crude mixture was purified on silica gel using flash chromatography (40% ethyl acetate – hexanes followed by 60% ethyl acetate – hexanes for the more polar compound). This afforded one major dimer **10** (0.06 g, 43%) mp >230°C and a minor dimer **11** (0.006 g, 4%) mp >230°C.

*Dimer **10***: ^{1}H NMR (500 MHz, chloroform-d_3, 22°C) δ: 7.86 (d, J = 7.8 Hz, 2H), 7.79 (t, J = 7.4 Hz, 1H), 7.78 (t, J = 6.8 Hz, 1H), 7.68 (d, J = 7.9 Hz, 1H), 7.66 (d, J = 8.0 Hz, 1H), 7.60 (t, J = 7.7 Hz, 1H), 7.52 (t, J = 7.7 Hz, 1H), 4.35 (t, J = 9.7 Hz, 1H), 3.69 (d, J = 17.5 Hz, 1H), 3.67 (t, J = 8.8 Hz, 1H), 3.65 (d, J = 17.5 Hz, 1H), 3.35 (d, J = 9.2 Hz, 1H), 3.07 (d, J = 10.1 Hz, 1H). ^{13}C NMR (125.6 MHz, acetone-d_6, 22°C) δ: 201.9, 200.9, 153.0, 152.5, 137.9, 137.1, 136.4, 135.6, 130.5, 129.6, 128.0, 126.6, 125.3, 125.3, 117.9, 117.8, 64.5, 54.2, 48.1, 42.4, 37.8, 34.7. Calcd. for $C_{22}H_{14}N_2O_2$: C 78.09, H 4.17, N 8.28; found: C 77.87, H 4.21, N 8.02. Mass spectrum m/z = 339 $(M - H)^-$.

*Dimer **11***: ^{1}H NMR (500 MHz, chloroform-d_3, 22°C) δ: 7.90 (d, J = 7.7 Hz, 1H), 7.86 (d, J = 7.7 Hz, 1H), 7.79 (t, J = 7.6 Hz, 1H), 7.75 (t, J = 7.9 Hz, 1H), 7.71 (d, J = 7.6 Hz, 1H), 7.59 (t, J = 7.5 Hz, 1H), 7.56 (d, J = 7.7 Hz, 1H), 7.51 (t, J = 7.4 Hz, 1H), 4.37 (t, J = 8.7 Hz, 1H), 3.77 (t, J = 9.8 Hz, 1H), 3.74 (d, J = 17.1 Hz, 1H), 3.62 (d, J = 8.7 Hz, 1H), 3.40 (d, J = 9.2 Hz, 1H), 3.25 (d, J = 17.3 Hz, 1H). ^{13}C NMR (125.6 MHz, CD_3CN, 22°C) δ: 202.6, 201.3, 153.7, 152.4, 137.9, 137.6, 135.7, 130.7, 129.8, 128.0, 127.2, 125.4, 125.1, 119.1, 117.8, 118.6, 63.6, 53.8, 48.4, 41.6, 39.6, 37.9. HRMS calcd. for $C_{22}H_{14}N_2O_2$ $[M + H]^+$: 339.1332, found: 339.1333.

Preparation of spirodimer 11 from dimer 10

To a solution of the dimer **10** (0.02 g, 0.06 mmol) in THF (0.40 mL) was added DBU (0.03 mL, 0.19 mmol). After a period of 72 h at room temperature, the reaction mixture was partitioned between EtOAc and saturated NH_4OAc. The organic layer was separated, dried over Na_2SO_4, filtered, and evaporated. After purification by flash chromatography, dimer **11** was obtained (0.006 g, 30%), with no trace of **10** in the reaction.

Dimerization of 2-chloromethylidene-1-indanone (12) using LiHMDS to yield 13

To a solution of 2-chloromethylidene-1-indanone (**12**) (4) (0.15 g, 0.84 mmol) in THF (4 mL) at –78°C was added LiHMDS 500 μL of 1.0 M solution in THF, 0.50 mmol). After a period of 5 min, followed by standard workup procedure, the crude mixture was purified by flash chromatography (20% ethyl acetate – hexanes). White crystalline, air sensitive material was isolated in 57% yield (0.08 g). Compound **13** mp 90–110°C (decomposes). ^{1}H NMR (500 MHz, acetone-d_6, 22°C) δ: 8.66 (s, 1H), 7.88 (d, J = 7.5 Hz, 1H), 7.80 (td, J = 7.5, 0.9 Hz, 1H), 7.66 (d, J = 7.7 Hz, 1H), 7.56 (td, J = 7.2, 0.7 Hz, 1H), 7.41 (d, J = 7.4 Hz, 1H), 7.39 (dd, J = 6.9, 0.5 Hz, 1H), 7.36 (td, J = 7.1, 1.0 Hz, 1H), 7.29 (t, J = 7.8 Hz, 1H), 6.71 (t, J = 2.7 Hz, 1H), 4.03 (d, J = 21.1 Hz, 1H), 3.98 (d, J = 21.1 Hz, 1H), 3.89 (dd, J = 21.1, 2.2 Hz, 1H), 3.79 (dd, J = 21.1, 2.2 Hz, 1H). ^{13}C NMR (125.6 MHz, acetone-d_6, 22°C) δ: 194.1, 155.8, 150.8, 150.5, 149.5, 147.1, 140.3, 139.7, 137.3, 135.8, 130.3, 129.1, 128.5, 127.2, 125.8, 125.2, 118.5, 89.6, 37.5, 36.6. HRMS calcd. for $C_{20}H_{15}Cl_2O_2$ $[M + H]^+$: 357.0448, found: 357.0449.

On the reduction of tertiary radicals by samarium diiodide (SmI_2)

Tadamichi Nagashima, Alexey Rivkin, and Dennis P. Curran

Abstract: Reduction of *o*-iodophenyl 3-methylbut-2-enyl ether with samarium diiodide generates mixtures of 3-isopropyl-2,3-dihydrobenzofuran and 3-(2-propenyl)-2,3-dihydrobenzofuran along with a small amount of dimer. If a source of deuterium is present during the reduction, then the 3-isopropyl product predominates and this product is labeled with one deuterium. However, attempts to quench the putative tertiary organosamarium reagent by adding a deuterium source after the reduction were not very successful at room temperature. But at 0°C, the organosamarium reagent was generated (at least to the extent of about 50%, as measured by deuterium quenching), and its decomposition was followed over time by a series of quenching experiments. The results suggest that tertiary radicals are reduced to a significant extent by SmI_2 to form an anionic (presumably alkylsamarium) species. This species is thermally unstable and decomposes to the corresponding reduced and eliminated products. The reduced product is consistently formed in slight excess over the eliminated one, and the mechanism of formation of these products is not yet clear.

Key words: samarium diiodide, SmI_2, reduction, alkyl samarium.

Résumé : La réduction de l'oxyde d'*o*-iodophényle et de 3-méthylbut-2-ényle par le diiodure de samarium conduit à un mélange de 3-isopropyl-2,3-dihydrobenzofurane et de 3-(prop-2-ényl)-2,3-dihydrobenzofurane en plus de faibles quantités de dimères. Si la réduction se fait en présence d'une source de deutérium. Le produit 3-isopropyle est alors prédominant et il est marqué par un deutérium. Toutefois, tous les essais effectués à la température ambiante en vue de piéger le réactif organosamarium tertiaire putatif par addition d'une source de deutérium après la réduction ont été infructueux. Toutefois, à 0°C, on a généré le réactif organosamarium (au moins jusqu'à un niveau de 50% si l'on se base sur le produit piégé au deutérium) et on a étudié sa décomposition en fonction du temps en faisant appel à des expériences de piégeage. Les résultats suggèrent que le SmI_2 provoque une importante réduction des radicaux tertiaires avec formation d'espèces anioniques (probablement de l'alkylsamarium). Cette espèce est thermiquement instable et elle se décompose pour donner les produits correspondants de réduction et d'élimination. Il y a toujours formation d'une quantité légèrement supérieure de produit réduit par rapport au produit d'élimination et le mécanisme de formation de ces produits n'est toujours pas clair.

Mots clés : diiodure de samarium, SmI_2, réduction, alkylsamarium.

Introduction

Samarium diiodide (SmI_2) is a powerful and soluble reducing agent whose popularity in organic synthesis is continually increasing (1). The use of samarium diiodide to control sophisticated sequences of radical and ionic reactions (2) rests on the understanding of how SmI_2 reacts with functional groups, radicals, and radical ions. It is well demonstrated that the reductions of halides by SmI_2 initially produce radicals (1), and it is now generally accepted that these radicals often can be reduced by another equivalent of SmI_2 to give putative organosamarium intermediates (eq. [1]) (3, 4). Little is known about the structure of these intermediates, and they sometimes have limited stability (4*a*, 5). But they often behave like "carbanions" and combine with reactive electrophiles to give trapped products (1–4).

Reduction by SmI_2 occurs readily for radicals bearing electron withdrawing groups as well as primary alkyl radicals. In contrast, most vinyl and aryl radicals appear to undergo radical–solvent reactions (H-abstraction, addition) faster than they are reduced by SmI_2 (however, when electron withdrawing groups are present, vinyl radicals may be reduced to vinylsamarium reagents. See ref. (6)). The situation with secondary and especially tertiary radicals is less clear. Labeling studies (4*a*, *b*) with electrophiles show that secondary radicals can be reduced to organosamarium reagents, but the trapped products are frequently accompanied by small amounts of products of (apparent) radical disproportionation. Tertiary radicals frequently do not give trapped products at all (4–6). (Qualitatively similar behavior is seen in solid phase reactions. See ref. (7)).

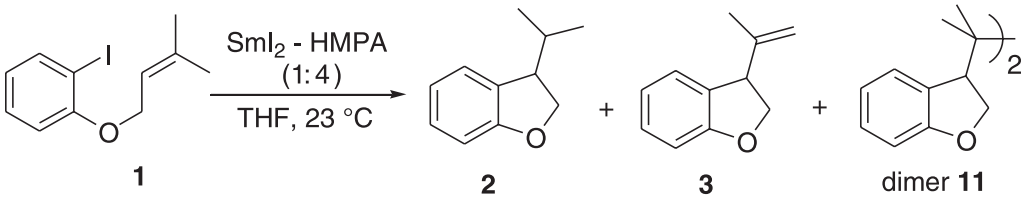

Fig. 1. Generation and reaction of 3°-radicals by SmI_2. (*a*) See Curran and Totleben (4*b*); (*b*) See Inanaga et al. (8); (*c*) See Molander and McKie (4*c*).

Three key reactions of precursors of tertiary radicals in the presence of SmI_2 are shown in Fig. 1. We reported (4*b*) that the reduction of aryl iodide **1** by SmI_2 in THF/HMPA without a proton source provided products **2** and **3** in a 60:40 ratio and concluded that these products probably resulted from radical disproportionation. This result is typical of other related systems (7). However, Inanaga (8) reported that a very similar reduction of **4** with SmI_2/HMPA in the presence of *tert*-butanol provided **5** in 99% yield. In an intramolecular example, Molander and McKie (4*c*) reported that the reduction of **6** with SmI_2/HMPA in the presence of 1% $Fe(DBM)_3$ gave the cyclized product **7** in 57% yield along with 30% yield of a 1:1 mixture of **8** and **9** (and a trace of **10**). These divergent results are difficult to compare directly due to the different reaction conditions and because the presence of the ketone in **6** may alter the reduction pathway (9), so we decided to undertake a series of experiments designed to probe how tertiary radicals

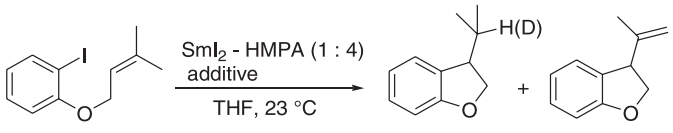
react with SmI_2. We show that both in the presence and absence of proton sources, tertiary radicals can be reduced by SmI_2. These resulting anionic species are unstable and decompose to reduced and eliminated products.

Results and discussion

We initially chose to repeat the reduction of **1**. If the products from this reaction are formed exclusively by radical–radical reactions, then **2** and **3** should be formed in a 50:50 (not 60:40) ratio, and there should also be some dimer **11** from radical recombination and perhaps the other possible regioisomeric alkene (not shown) from disproportionation. Formation of products by radical–radical reactions also only requires 1 equiv. of SmI_2, whereas electrophile-trapped products generally consume 2 equiv. of SmI_2. It is known that 4 equiv. of HMPA are required to generate SmI_2 with maximum reducing power (3, 10), and for consistency all reactions in this work employed those conditions. In addition, aqueous quenches were not used in any reactions, since it is also known that SmI_2 does not react rapidly with water and that water increases the reduction potential of SmI_2 (in other words, addition of water tends to promote reductions rather than stopping them (11)). Reactions were quenched by bubbling dry air through the mixture until the color of SmI_2 had dissipated (a few seconds). Data for the initial reductions of **1** are shown in Table 1.

Reduction of **1** with 2.2 equiv. of SmI_2 (Table 1, entry 1) gave results very similar to those reported (4*b*), except that we were now able to carefully separate and characterize a small amount of dimer **11** (as a *meso–d,l*-mixture). The starting iodide **1** was completely consumed in this reaction, even though the characteristic purple color of the SmI_2 never dissipated. Products **2**, **3**, and **11** were formed in 85% combined (isolated) yield in a ratio of 53:44:3. Thus, dimer **11** is formed, but the regioisomeric alkene of **3** (not shown) is not, and there is somewhat more **2** than **3**. The reaction was repeated with 1.1 equiv. of SmI_2 (entry 2), and this time the SmI_2 rapidly decolorized. The same three products were isolated in the same ratio in 79% yield. The starting iodide **1** was recovered in 7% yield, thus accounting for the marginally lower yield.



These results seem reasonably consistent with formation of products by radical reactions, if one hypothesizes that the excess of **2** over **3** can be accounted for by a small amount of two electron reduction followed by protonation (proton source unknown). If about 10% of **2** is formed by two electron reduction, then this could even account for the observation that 1.1 equiv. of SmI_2 was not quite sufficient to consume all of **1**. However, the authentic product ratios of radical–radical reactions are not known, and the results in Table 1 might also be explained by reduction of the tertiary radical to an organosamarium reagent, followed by decomposition to the observed products with regeneration of Sm(II). This decomposition must be quite rapid, otherwise more starting material should have been recovered from experiment 2. This possibility is not unreasonable, since many organometallic species decompose by disproportionation and coupling reactions that do not involve free radicals.

To investigate the effect of proton sources, we next conducted the reduction of **1** in the presence of alcohols, and the results of these experiments are reported in Table 2. Consistent with the results of Inanaga (8), reduction of **1** with 2.2 equiv. SmI_2 in the presence of *tert*-butanol now provided only protonated product **2** in 79% yield (Table 2, entry 1). Neither the alkene **3** nor the dimer **11** was detected. The use of methanol-d_4 provided mostly the reduced product **2** along with a trace of the alkene **3** (ratio 97:3). The yield was somewhat diminished (54%), but **2** contained 89% deuterium at the methine position based on GC–MS analysis (Table 2, entry 2). In two related experiments, **1** was reduced in the absence of methanol, and then methanol-d_4 was added (prior to oxygen quenching) after 30 s and 5 min, respectively, (Table 2, entries 3 and 4). As expected, this gave results similar to entries 1 and 2 of Table 1, although the yields were not quite as high (we did not analyze for the dimer in these experiments). Interestingly, the reduced product **2** contained 7–8% deuterium.

We next ran a series of experiments at 0°C in an effort to see if a more long-lived organosamarium species could be generated. Blank experiments using a slight deficiency of SmI_2 (1.8 equiv.) showed that at 0°C the color dissipated about 30–40 s after the end of the addition of the iodide. Thus, we choose 1 min as the shortest quench to ensure that the deuterium source was not introduced prior to the consumption of the starting material. In a series of experiments, the time between completion of addition of **1** and addition of the quench was extended from 1 min to 180 min, as shown

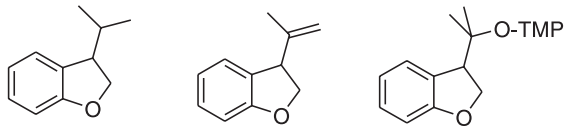
in Table 3, entries 2–12. The Table shows the %D incorporation of **2**D as well as the ratio of **2**D:**2**H:**3**. Accepting that product **2**D is a marker for the formation of an anionic (organosamarium) species, these data show that at least about 60% of **1** is reduced to an anionic species in the absence of an added proton source. Over 3 h, the evolution of this species is revealed by tracing the decrease in the yield of **2**D (to 0%) and the increases in the yield of both **2**H and **3**. Over this time, the combined isolated yield of the three products remains constant (about 90%). Accordingly, the initial 59% of anionic species (reflected by the amount of **2**D in entry 2) decomposed over 3 h to 31% **2**H and 28% **3**.



We have recently shown that organosamarium reagents react with TEMPO (12), so we tried duplicate quenching experiments with TEMPO in place of methanol, as shown in Table 4. In addition to **2** and **3**, these experiments also provided the TEMPO quenched product **12**, although the efficiency of the TEMPO quenching (21–23%) at 10 min is considerably less than that of the MeOD quenching (35°C, see Table 3, entry 6). The experiments also prove that reactions were complete when the alcohol or TEMPO quench was added. A separate experiment showed that addition of **1** and SmI_2 to TEMPO provided recovered starting material **1**; presumably, the TEMPO was reduced by SmI_2.

To complement the quenching studies with deuterated methanol, we next prepared hexa-deutero substrates **13a**, **b** shown in Table 5 (see the Experimental section for their synthesis). These substrates were reduced as usual with 1.1

equiv. of SmI_2, and then the product ratios were assessed by recording and integrating the crude ^{1}H NMR spectra of the reaction mixtures. The results of these two experiments are shown in Table 5, entries 1,2. While the reduction of the iodide **13b** was instantaneous, the bromide **13a** required 2 h for decolorization of the SmI_2, and 20% unreacted bromide was still recovered after workup. The formation of substantial amounts of d_7 product **15** in both cases clearly shows that protonation cannot account for formation of all the reduced products and that some form of disproportionation is occurring. Interestingly, the reduction of the (less reactive) bromide **13b** gave considerably more of the d_6 (protonated) product **14**. If the increased amount of **14** in the case of bromide was a result of more efficient reduction to the 3°-alkylsamarium reagent, then this could explain why 20% of bromide remained after the samarium was consumed. However, the bromide and iodide must yield the same radical after reduction, so it is unclear how the nature of the original radical precursor can affect the fate of the cyclized radical. Due caution should be exercised in interpreting these experiments due to possible experimental error; in each experiment, the recorded yield of the d_7 product **15** somewhat exceeded that of the d_5 alkene product **16**. This is not possible according to any mechanism, since the average total of deuteria per molecule must be six.

Finally, to gauge the effect of an added ketone, we conducted reduction of **13a** in the presence of ketone **18** (Fig. 2). This experiment is complicated because the ketone

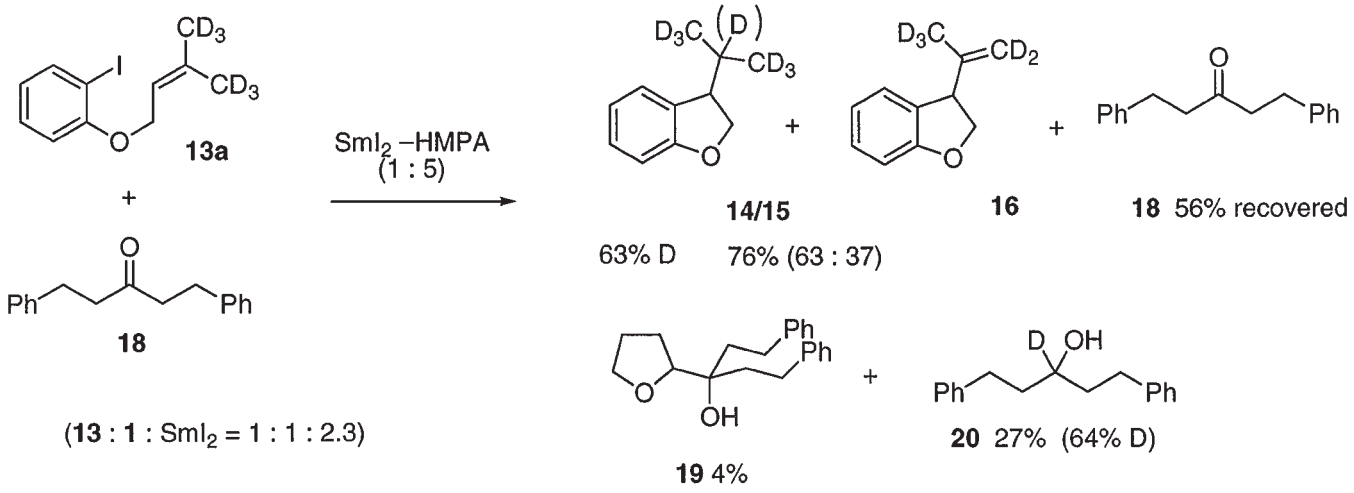
Fig. 2. Coreduction of **13a** and a ketone.



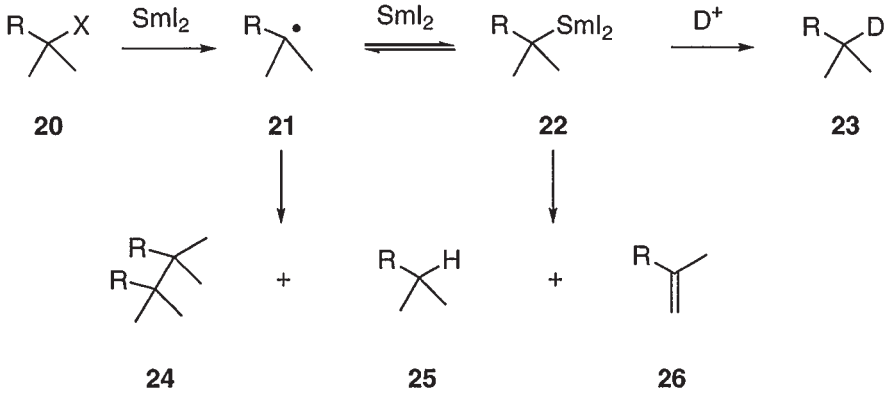


Fig. 3. Pathways for product formation reduction of 3°-halides by SmI_2.

can be reduced in competition with the iodide. As before, disproportionation products **14**/**15**/**16** were produced and the reduction product **14**/**15** contains a significant amount (63%) of deuterium in the methine position. The ratio of reduced product **14**/**15** to alkene **16** is also higher than in the experiments without the ketone. As for the fate of the ketone **16** itself, 56% is recovered unchanged while 4% is trapped as the THF adduct **19** (this product is thought to result from H-abstraction from the THF followed by reduction to an organosamarium reagent and addition to the ketone) (4). About 27% of ketone **18** is reduced to alcohol **20**. In turn, this alcohol also contains 64% D, showing that there is a significant pathway for transfer of allyl hydrogen from **13a**.

Conclusions

The results in this paper provide new insights into the behavior of tertiary radicals in the presence of SmI_2. Some of the possible reaction pathways are illustrated in Fig. 3. Tertiary radical **21** could directly recombine and disproportionate to give the observed products **24**–**26**. Alternatively, it could be reduced to a tertiary alkylsamarium species **22**, which in turn provides the final products either by protonation (to give **23**) in competition with bimolecular disproportionation (to give **24**–**26**) and (or) homolysis back to the radical **21** (that is, the reduction step is reversible). In either case, an equivalent of Sm(II) must be regenerated in tandem with disproportionation.

When the reduction is carried out in the presence of a proton source at either 25°C or 0°C, a good yield of the labeled, reduced product **23** is formed. This strongly suggests that the tertiary organosamarium species **22** is formed. Whether or not the organosamarium species **22** is formed when the reduction is conducted in the absence of proton source is less clear. While proton sources are known to boost the reduction potential of SmI_2 in the absence of HMPA (11), the strong ligating capabilities of HMPA for Sm (10) suggest that it would dampen or eliminate any effect of added proton sources. If this is correct, then the reductions in the absence of the proton source should also provide the tertiary alkyl samarium reagent **22**, and we interpret our inability to efficiently trap this intermediate by subsequent addition of a proton source as due to its instability with respect to disproportionation. Supporting this analysis are the results of the study at 0°C (Table 3), in which a significant amount of the organosamarium reagent was generated and its decomposition to the disproportionation products was followed over time.

While the results support the postulate that a substantial amount of the products derive from alkylsamarium reagents,

© 2000 NRC Canada

they certainly do not exclude the formation of some products through radical reactions. For example, the dimer **24** may form through a radical recombination (although we cannot exclude the possibility of coupling of organosamarium reagents), and the inability to ever observe quantitative deuterium incorporation in the reduced product **23** may point to the occurrence of radical hydrogen transfer reactions from the solvent. In addition, the mechanism of the decomposition of the intermediate organosamarium reagent **22** is also not clear. This reagent could return to the radical **21** by the reverse of the reduction or it could decompose by a number of ionic pathways. At this point, the radical pathway seems less likely since the ratio of disproportionation products to recombination products is higher than that for typical tertiary radicals.

In summary, tertiary halides are not very cooperative partners in a number of C—C bond forming processes mediated by SmI_2. In the past, this has been interpreted by us and others as due to the inability of SmI_2 to reduce 3°-radicals to samarium reagents. Our new results suggest that SmI_2 is more efficient at reducing 3°-radicals than previously thought, and that the problems with subsequent bond forming reactions arise due to the instability of the samarium reagents, which disproportionate over a period of minutes or less at room temperature.

Experimental

Typical procedure for the reduction of *O*-prenyl-2-iodophenol (1) by SmI_2–HMPA in the absence of electrophile

HMPA (0.60 mL, 3.45 mmol) was added to SmI_2 (0.10 M in THF, 8.8 mL, 0.88 mmol) at 23°C. After 1 h, *O*-prenyl-2-iodophenol **1** (0.116 g, 0.402 mmol) in THF (0.7 mL) was added. After 21 h, dry air was bubbled through the mixture until the color changed to light brown and then 0.1 N HCl (20 mL) was added. The mixture was extracted with Et_2O (3 × 20 mL). The combined ether layers were washed with 5% $Na_2S_2O_3$ (1 × 20 mL), sat. NH_4Cl (1 × 20 mL), and brine (1 × 20 mL), and were dried over $MgSO_4$. The ratio of the products (**2**, **3**, and **11**) was determined by recording the ^1H NMR spectrum of the crude mixture. The products were purified by flash chromatography (SiO_2, hexanes/EtOAc = 15:1) to give the dimer **11** (1.6 mg, 2% yield) and a mixture (34.4 mg) of 3-(2-propyl)-2,3-dihydrobenzofuran (**1**) and 3-(propen-2-yl)-2,3-dihydrobenzofuran (**2**). The ratio of these products was determined by ^1H NMR spectrum of the mixture.

(*dl*,*meso*)-2,3-Bis(2,3-dihydrobenzofuran-3-yl)-2,3-dimethylbutane (11)

^1H NMR (300 MHz, $CDCl_3$) (mixture of *dl* and *meso*) δ: 7.23 (2 H, d, *J* = 7.5 Hz), 7.19–7.09 (2 H, m), 6.91–6.77 (8 H, m), 4.78–4.66 (2 H, m), 4.42 (2 H, q, *J* = 9.4 Hz), 3.55 (1 H, dd, *J* = 8.6, 1.6 Hz), 3.48 (1 H, dd, *J* = 9.0, 3.1 Hz), 1.05 (3 H, s), 1.00 (3 H, s), 0.95 (3 H, s), 0.84 (3 H, s). MS (EI) *m*/*z*: 322, 238, 161, 119. HRMS (EI) *m*/*z*: Anal. calcd. for $C_{22}H_{26}O_2$ 322.1933; found: 322.1923.

Typical procedure for the reduction of *O*-prenyl-2-iodophenol (1) in the presence of a proton source

HMPA (0.25 mL, 1.44 mmol) was added to SmI_2 (0.10 M in THF, 3.3 mL, 0.33 mmol) at 23°C. After 30 min, ^{t}BuOH (16 μL, 0.17 mmol) was added, and 5 min later, *O*-prenyl-2-iodophenol (**1**) (42.7 mg, 0.148 mmol) in THF (0.5 mL) was added in one portion at 23°C. After 30 min, dry air was bubbled for 1 min, and then 0.1 N HCl (10 mL) was added. The mixture was extracted with Et_2O (3 × 10 mL). The combined ether layers were washed with 5% $Na_2S_2O_3$ (1 × 10 mL), sat. NH_4Cl (1 × 15 mL), and brine (1 × 15 mL), and were dried over $MgSO_4$. The mixture was passed through a SiO_2 column (eluent: hexanes/Et_2O = 2:1) to give 3-(2-propyl)-2,3-dihydrobenzofuran (**2**) (19.0 mg, 0.117 mmol, 79% yield).

General procedure for the reduction of *O*-prenyl-2-iodophenol (1) by SmI_2–HMPA with CD_3OD quenching

To SmI_2 (0.10 M in THF, 40.0 mL, 4.00 mmol) was added HMPA (3.5 mL, 20 mmol) at 23°C. After 1 h, 3.82 mL of the mixture was transferred to another flask, and cooled to 0°C. A solution of *O*-prenyl-2-iodophenol (**1**) (50 mg, 0.17 mmol) in THF (0.3 mL) was added dropwise over the period of 20 s, and 5 min later, CD_3OD (0.2 mL, 4.9 mmol) was added. After 2 min, air was bubbled through the mixture until the color turned to yellow. After the addition of 0.1 N HCl (5 mL), the mixture was extracted with Et_2O (3 × 5 mL). The combined ether layers were concentrated and the mixture was passed through a short SiO_2 column (eluent: dichloromethane) to give a mixture of products (25.3 mg). The product ratio was determined by ^1H NMR spectrum of the mixture.

Ethyl 3-trideuteriomethyl-4,4,4-trideuterio-2-butenoate

Triethyl phosphonoacetate (20.5 mL, 10.3 mmol) was added dropwise into a suspension of NaH (2.15 g, 89.6 mmol) in THF 100 mL at 0°C. After 5 min, the cooling bath was removed. After 1.5 h, acetone-d_6 (8.0 mL, 0.11 mol) was added. After 2 h, the mixture was poured into 10% NH_4Cl (500 mL), and was extracted with Et_2O (1 × 100 mL and 2 × 50 mL). The combined ether layers were washed with sat. NH_4Cl (1 × 50 mL) and brine (1 × 50 mL), and were dried over $MgSO_4$. The product was purified by distillation (bp = 76.0–76.5°C at 54 mmHg) to give the product (7.57 g, 56.4 mmol, 62% based on NaH). IR (film)(cm^{-1}): 1694, 1144. ^1H NMR (300 MHz, $CDCl_3$) δ: 5.66 (1 H, s), 4.13 (2 H, q, *J* = 7.1 Hz), 1.26 (3 H, t, *J* = 7.1 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 166.21 (s), 155.72 (s), 115.95 (d), 58.97 (t), 26.0 (m), 18.8 (m), 13.97 (q). MS (EI) *m*/*z*: 134, 106, 89, 83. HRMS (EI) m/*z*: Anal. calcd. for $C_7H_6D_6O_2$ 134.1214; found: 134.1254.

3-Trideuteriomethyl-4,4,4-trideuterio-2-buten-1-ol

DIBALH (1.0 M in hexane, 100 mL, 0.10 mol) was added dropwise to a solution of the above ester (6.76 g, 50.4 mmol) in CH_2Cl_2 (50 mL) at 0°C. After 1.5 h, MeOD (6 mL) was added dropwise. After the mixture became cloudy, sat. potassium sodium tartrate (25 mL) was added. The mixture was poured into Et_2O (150 mL), and 2 N HCl (150 mL) was added. After the separation, the aqueous layer was extracted with Et_2O (1 × 100 mL). The combined organic

© 2000 NRC Canada

layers were washed with 1 N HCl (1 × 50 mL) and brine (2 × 25 mL), and were dried over $MgSO_4$. The product was purified by distillation at normal pressure (bp = 129–139°C) to give alcohol (3.12 g, 33.9 mmol, 67%). IR (film) (cm^{-1}): 3322, 1101, 1070. ^1H NMR (300 MHz, $CDCl_3$) δ: 5.41 (1 H, t, *J* = 7.1 Hz), 4.20–4.08 (2 H, m), 1.20 (1 H, m). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 135.37 (s), 123.76 (d), 58.88 (t), 24.5 (m), 17.0 (m). MS (EI) *m/z*: 92, 74. HRMS (EI) *m/z*: Anal. calcd. for $C_5H_4D_6O$ 92.1108; found: 92.1114.

O-(3-Trideuteriomethyl-4,4,4-trideuterio-2-buten-1-yl)-2-iodophenol (13b)

Diethyl azodicarboxylate (2.96 g, 17.0 mmol) in THF (2 mL) was added into a mixture of 2-iodophenol (3.52 g, 16.0 mmol), PPh_3 (4.20 g, 16.0 mmol), and the above prenyl alcohol-d_6 (1.39 g, 15.1 mmol) in THF (35 mL) at 0°C. The temperature was gradually raised to 23°C. After 16 h, most of the solvent was removed under reduced pressure, and pentane (100 mL) was added to give a precipitate. After the removal of the precipitate by filtration, the product was purified by flash chromatography (SiO_2, hexanes/Et_2O = 30:1) to give **13b** (3.05 g, 10.4 mmol, 69% yield). IR (film) (cm^{-1}): 1469, 1275, 1239, 1016, 748. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.77 (1 H, dd, *J* = 7.7, 1.6 Hz), 7.28 (1 H, dt, *J* = 8.5, 1.6 Hz), 6.82 (1 H, dd, *J* = 8.2, 0.9 Hz), 6.70 (1 H, dt, *J* = 1.1, 7.6 Hz), 5.51 (1 H, t, *J* = 6.5 Hz), 4.58 (2 H, d, *J* = 6.5 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 157.38, 139.68, 137.68, 129.30, 122.38, 119.52, 112.57, 86.89, 66.16, (two CD_3 carbons were not detected). MS (EI) *m/z*: 294, 221, 75. HRMS (EI) *m/z*: Anal. calcd. for $C_{11}H_7D_6IO$ 294.0388; found: 294.0382.

1-[2-(2,3-Dihydrobenzofuran-3-yl)propyl-2-oxy]-2,2,6,6-tetra-methylpiperidine (12)

HMPA (4.0 mL, 23 mmol) was added to SmI_2 (0.1 M in THF, 44.0 mL, 4.40 mmol) at 23°C. After 14 min, the mixture was cooled to 0°C, and *O*-prenyl-2-iodophenol (**1**) (0.576 g, 2.00 mmol) in THF (2 mL) was added dropwise over the period of 2 min. After 10 min, TEMPO (0.943 g, 6.04 mmol) in THF (1 mL) was added in one portion. After 1 min, a mixture of sat. potassium sodium tartrate (10 mL), sat. $NaHCO_3$ (5 mL), and 5% $Na_2S_2O_3$ (5 mL) was added, and the mixture was extracted with Et_2O (3 × 15 mL). The combined ether layers were washed with 5% $Na_2S_2O_3$ (1 × 15 mL), a mixture of sat. potassium sodium tartrate and sat. $NaHCO_3$ (5 mL each, 1 ×), H_2O (2 × 15 mL), and brine (1 × 15 mL), and were dried over $MgSO_4$. The product was purified by flash chromatography (SiO_2, hexanes/Et_2O = 10:1) to give **12** (0.122 g, 0.385 mmol, 19% yield). IR (film) (cm^{-1}): 1483, 1460, 1375, 1364, 1234, 1132, 748.; ^1H NMR (300 MHz, $CDCl_3$) δ: 7.33 (1 H, d, *J* = 7.3 Hz), 7.13 (1 H, t, *J* = 7.4 Hz), 6.83 (1 H, t, *J* = 7.0 Hz), 6.78 (1 H, d, *J* = 8.0 Hz), 4.73 (1 H, dd, *J* = 9.5, 5.5 Hz), 4.54 (1 H, t, *J* = 9.6 Hz), 3.94 (1 H, dd, *J* = 9.5, 5.4 Hz), 1.68–1.45 (4 H, m), 1.38 (3 H, s), 1.37–1.26 (2 H, m), 1.16 (3 H, s), 1.154 (3 H, s), 1.146 (3 H, s), 1.12 (3 H, s), 1.11 (3 H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 161.10 (s), 128.75 (s), 128.36 (d), 125.72 (d), 119.99 (d), 109.54 (d), 80.90 (s), 73.34 (t), 59.56 (s), 59.43 (s), 53.25 (d), 40.96 (t), 35.23 (q), 35.13 (q), 23.71 (q), 23.32 (q), 23.71 (q), 23.32 (q), 21.03 (q), 20.90 (q), 17.18 (t). MS (CI) *m/z*: 318 [M + H], 157, 142.

O-(3-Trideuteriomethyl-4,4,4-trideuterio-2-buten-1-yl)-2-bromo-phenol (13a)

Diethyl azodicarboxylate (2.96 g, 17.0 mmol) in THF (2 mL) was added into a mixture of 2-bromophenol (2.78 g, 16.1 mmol), PPh_3 (4.20 g, 16.0 mmol), and the above alcohol (1.38 g, 15.0 mmol) in THF (40 mL) at 0°C. The temperature was gradually raised to 23°C. After 17.5 h, most of the solvent was removed under reduced pressure, and pentane (100 mL) was added to give a precipitate. After the removal of the precipitate by filtration, the product was purified by flash chromatography (SiO_2, hexanes/Et_2O = 10:1) followed by distillation (bp = 90–98°C at 0.2 mmHg) to give **13a** (2.64 g, 10.7 mmol, 71% yield). IR (film) (cm^{-1}): 1476, 1276, 1030, 744 ^1H NMR (300 MHz, $CDCl_3$) δ: 7.54 (1 H, dd, *J* = 7.7, 1.6 Hz), 7.24 (1 H, dt, *J* = 1.6, 7.4 Hz), 6.90 (1 H, dd, *J* = 8.3, 1.1 Hz), 6.82 (1 H, dt, *J* = 1.5, 7.7 Hz), 5.51 (1 H, t, *J* = 6.6 Hz), 4.60 (2 H, d, *J* = 6.6 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 155.11, 137.21, 128.26, 121.60, 119.40, 113.52, 112.19, 65.93, (two CD_3 carbons were not detected). MS (EI) *m/z*: 248, 246, 228, 188, 186, 175, 173. HRMS (EI) *m/z*: Anal. calcd. for $C_{11}H_7D_6BrO$ 246.0526; found: 246.0490.

General procedure for the reduction of *O*-prenyl(d_6)-2-halophenol 13a, b by SmI_2–HMPA

To SmI_2 (0.10 M in THF, 11.0 mL, 1.10 mmol) was added HMPA (0.85 mL, 4.89 mmol) at 23°C. After 20 min, *O*-prenyl(d_6)-2-iodophenol (**13a**) (0.299 g, 1.02 mmol) in THF (1 mL) was added. After 8 h, dry air was bubbled until the mixture turned to yellow, and then 0.1 N HCl (15 mL) was added. After the extraction with Et_2O (3 × 10 mL), the combined ether layers were washed with 5% $Na_2S_2O_3$ (1 × 10 mL), 0.1 N HCl (1 × 10 mL), and brine (1 × 10 mL), and were dried over $MgSO_4$. The crude mixture was passed through a SiO_2 column (eluent: hexanes/Et_2O = 10:1) to give a mixture of products (0.130 g). The products ratio was determined by ^1H NMR spectrum of the mixture.

SmI_2 reduction of *O*-prenyl(d_6)-2-iodophenol (13a) in the presence of the ketone 18

HMPA (0.95 mL, 5.5 mmol) was added to SmI_2 (0.1 M in THF, 11.0 mL, 1.10 mmol) at 23°C. After 50 min, a mixture of *O*-prenyl(d_6)-2-iodophenol (**13a**) (0.142 g, 0.483 mmol) and 1,5-diphenylpentan-3-one (**18**) (0.120 g, 0.504 mmol) in THF (1 mL) was added in one portion. After 1 h, dry air was bubbled through the mixture, and then 0.1 N HCl (15 mL) and brine (5 mL) were added. After the extraction with Et_2O (3 × 10 mL), the combined ether layers were washed with 5% $Na_2S_2O_3$ (1 × 10 mL), 0.1 N HCl (1 × 10 mL), and brine (1 × 10 mL), and were dried over $MgSO_4$. The products were separated by flash chromatography (SiO_2, hexanes/EtOAc = 10:1 – 5:1) to give a mixture of 3-(2-propyl)-2,3-dihydrobenzofuran (d_6 and d_7) (**14** and **15**) and 3-(propen-2-yl)-2,3-dihydrobenzofuran (d_5) (**16**) (61.1 mg), a mixture of 1,5-diphenyl-3-pentanol (**20**) and 1,5-diphenyl-3-(2-tetrahydrofuranyl)-3-pentanol (**19**) (39.1 mg), and 1,5-diphenyl-3-pentanone (**18**) (67.0 mg, 56% recovery).

1,5-Diphenyl-3-(tetrahydrofuran-2-yl)pentan-3-ol (19)

The authentic sample of **19** was prepared as follows: HMPA (0.95 mL, 5.46 mmol) was added to SmI_2 (0.1 M in

© 2000 NRC Canada

THF, 11 mL, 1.1 mmol) at 23°C. After 40 min, a mixture of iodobenzene (0.334 g, 1.64 mmol) and 1,5-diphenylpentan-3-one (**18**) (113.9 mg, 0.478 mmol) in THF (1 mL) was added. After 21 h, 0.1 N HCl (15 mL) was added. The mixture was extracted with Et_2O (3 × 10 mL). The combined ether layers were washed with 5% $Na_2S_2O_3$ (1 × 10 mL), 0.1 N HCl (1 × 10 mL), and brine (1 × 10 mL), and dried over $MgSO_4$. The product was purified by flash chromatography (SiO_2, hexanes/EtOAc = 5:1 – 3:1) to give **19** (0.124 g, 0.398 mmol, 83% yield). IR (film) (cm^{-1}): 3461, 1495, 1453, 1066, 749, 699.; ^1H NMR (300 MHz, $CDCl_3$) δ: 7.37–7.13 (10 H, m), 3.94–3.77 (3 H, m), 2.83–2.57 (4 H, m), 2.08 (1 H, s), 2.07–1.82 (7 H, m), 1.73 (1 H, dt, J = 5.3, 12.6 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 142.56 (s), 142.44 (s), 128.49 (d), 128.42 (d), 125.94 (d), 125.81 (d), 83.32 (d), 74.47 (s), 68.58 (t), 38.89 (t), 36.59 (t), 30.27 (t), 29.79 (t), 26.27 (t), 25.59 (t). Trifluoroacetic acid-mediated intramolecular formal N-H insertion reactions with amino-α-diazoketones: a facile and efficient synthesis of optically pure pyrrolidinones and piperidinones

Hua Yang, Valdas Jurkauskas, Nicole Mackintosh, Tobias Mogren, Corey R. J. Stephenson, Katherine Foster, William Brown, and Edward Roberts

Abstract: Trifluoroacetic acid (TFA) was found to promote intramolecular formal N-H insertion reactions. Upon treatment with TFA, optically pure *N*-Boc-β′-amino-α-diazoketones (**5a**–**c**) and *N*-Boc-γ′-amino-α-diazoketones (**10a**–**d**) can be converted, with retention of chirality, into pyrrolidinones (**11a**–**c**) and piperidinones (**12a**–**d**), respectively, with concomitant removal of the Boc group, in good to excellent yields.

Key words: α-diazoketone, amino acid, pyrrolidinone, piperidinone, N-H insertion.

Résumé : Le TFA induit des réactions d'insertion formelle de N-H intramoléculaires. Par traitement avec du TFA, les *N*-Boc-β′-amino-α-diazocétones (**5a**–**c**) et les *N*-Boc-γ′-amino-α-diazocétones (**10a**–**d**) optiquement pures peuvent être converties avec rétention de chiralité en pyrrolidinones (**11a**–**c**) et pipéridinones (**12a**–**d**) avec déprotection simultanée de l'amine dans de bons à excellents rendements.

Mots clés : α-diazocétone, acide aminé, pyrrolidinone, pipéridinone, insertion de N-H.

Introduction

C—N bond forming reactions are one of the most interesting research areas in synthetic organic and medicinal chemistry (for recent reviews on the synthesis of C—N bond containing heterocycles see ref. (1)). N-H insertion reactions with α-diazoketones are one of the frequently utilized techniques to form C—N bonds (for recent reviews on the applications of N-H insertion reactions with α-diazoketones in organic synthesis, see ref. (2)). These N-H insertion reactions can be performed either in an intermolecular or intramolecular fashion (2). The intramolecular N-H insertion reactions give access to a variety of heterocyclic molecules, including azetidinones (for selected examples of N-H insertion reactions to generate azetidinone derivatives, see ref. (3)), pyrrolidinones (for selected examples of N-H insertion reactions to form pyrrolidinone derivatives, see ref. (4) and also refs. (3*e*) and (5*b*)), and piperidinones (for selected examples of N-H insertion reactions to form piperidinone derivatives see ref. (5) and also ref. (4*a*), (4*c*)), which have been widely used in drug discovery processes (for selected examples, see ref. (6)). These reactions with α-diazoketones commonly employ metal catalysts, such as rhodium(II) and copper(I). However, Rh(II) and Cu(I) catalyzed N-H insertion reactions are sometimes accompanied with a significant level of C-H insertion or other side reactions (2, 3*d*, 4*a*), depending upon the structures of the α-diazoketones.

As part of the ongoing research program exploiting the chemistry of α-diazoketones and its applications in medicinal chemistry at our laboratory, we have found that upon treatment with trifluoroacetic acid (TFA), *N*-Boc-α-amino α′-diazoketones can be converted into 1,3-oxazine-2,5-diones via an intramolecular oxygen insertion pathway with good to excellent yields (Scheme 1).[2] It is of interest to investigate if the oxygen insertion reaction could also be conducted with homolagated *N*-Boc-amino-α-diazoketones. Surprisingly,

[2]H. Yang, T. Mogren, C.R.J. Stephenson, V. Jurkauskas, W. Brown, and E. Roberts. Unpublished results. Upon treatment of the *N*-Boc-α-amino-α′-diazoketones with TFA, *1,3*-oxazine-*2,5*-diones were produced with good to excellent yields. Presumably the reactions proceed through a six-membered ring oxonium intermediate, which was generated from an intramolecular oxygen addition. In situ FTIR studies of the reactions suggested the presence of the oxonium intermediate before it cleaved the *tert*-butyl to the final product.

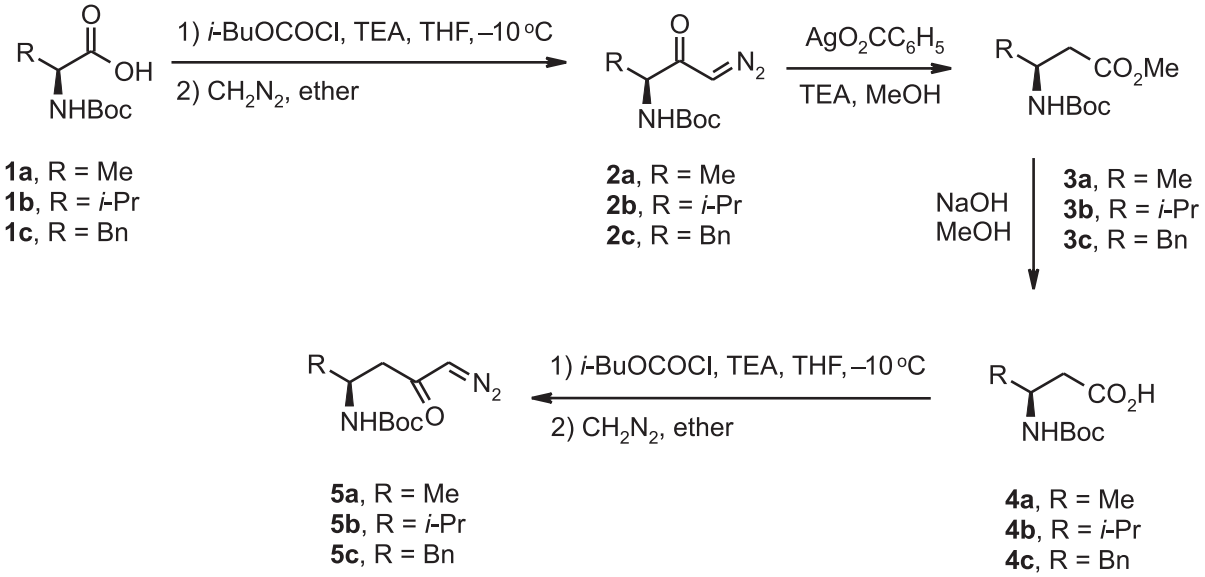
treatment of the *N*-Boc-β-amino-α′-diazoketones and *N*-Boc-γ-amino-α′-diazoketones with TFA, respectively, results in the isolation of the corresponding pyrrolidinones and piperidinones, presumably via an intramolecular formal N-H insertion pathway. It has been documented in the literature that protic acid and Lewis acid can also promote other intramolecular reactions, such as C—C bond formation from α-diazoketones (*2a*). Thus, the results we found would further extend the utility of acid-mediated intramolecular cyclization with α-diazoketones. In this paper, we would like to report our research efforts on the synthesis of pyrrolidinones and piperidinones using TFA-mediated formal N-H insertion reactions with amino-α-diazoketones.

Results and discussion

Synthesis of the β′-amino-α-diazoketones

Synthesis of the precursors of the *N*-Boc-β′-amino-α-diazoketones can be accomplished starting from commercially available α-amino acids, as depicted in Scheme 2. The commercially available *N*-Boc-α-amino acids (**1a**–**c**) were treated with *i*-BuOCOCl followed by diazomethane (*3b*) to afford α-diazoketones (**2a**–**c**). Silver benzoate-catalyzed Wolff rearrangement reactions (7) with compounds **2a**–**c** followed by hydrolysis resulted in the formation of homologated β′-amino-acids (**4a**–**c**). Repetition of steps 1 and 2 with **4a**–**c** furnished the desired precursors *N*-Boc-β′-amino-α-diazoketones (**5a**–**c**).

Synthesis of the γ′-amino-α-diazoketones



The synthesis of the *N*-Boc-γ′-amino-α-diazoketones can also be efficiently achieved starting from commercially available *N*-Boc-α-amino-acids, as shown in Scheme 3. DIBAL-H reduction of methyl esters **6a**–**d** followed by in situ Wittig reaction (8) gave the α, β-unsaturated methyl esters **7a**–**d**. Treatment of the esters **7a**–**d** with a sequence of reactions, involving hydrolysis, hydrogenation, mixed anhydride generation, and diazomethane coupling, resulted in the isolation of the desired precursors *N*-Boc-γ′-amino-α-diazoketones (**10a**–**d**). With both types of the precursors in hand, we set the stage to examine the TFA mediated intramolecular formal N-H insertion reactions with **5a**–**c** and **10a**–**d**.

Results and discussion

First, we examined the TFA-mediated reactions with the corresponding *N*-Boc-β′-amino-α-diazoketones. Thus, these *N*-Boc-β′-amino-α-diazoketones (**5a**–**c**) were treated with TFA in dichloromethane at –78°C. Interestingly, an intramolecular formal N-H insertion reaction was observed with concomitant removal of the Boc group, instead of the oxygen insertion, resulting in the generation of five-membered-ring pyrrolidinones **11a**–**c** in good to excellent yields (84–93%), as shown in Table 1.

All these reactions had gone to completion in less than 5 min. These reactions were very clean, and usually required no further purification after evaporation and washing with ether prior to subsequent chemical manipulations, such as reductive amination. However, a low concentration is essential to ensure a clean and high-yielding formal intramolecular N-H insertion. It is noted that concentrations of 0.005 M were sufficient for most of the reactions tested thus far. We reasoned that a low concentration might prevent side reactions related to intermolecular couplings with the diazo moiety. In contrast, *N*-Boc-α′-amino-α-diazoketones can undergo TFA-mediated intramolecular oxygen insertion reactions at concentrations as high as 0.5 M, without compromising the quality of the reaction.[2] This difference implies that the six-

membered ring oxygen insertion may be a much more efficient process than the five-membered ring nitrogen insertion in the cases we have studied thus far. Presumably, the nucleophilicity of the nitrogen atom was markedly reduced by the Boc group.

Next, the *N*-Boc-γ′-amino-α-diazoketones **10a**–**c** were treated with TFA in dichloromethane at –78°C. Not surprisingly, six-membered ring piperidinones **12a**–**c** were isolated with good to excellent yields (62–88%), after removal of the solvent and the excess TFA (entries 1–3, Table 2). Presumably, a formal N-H insertion with concomitant cleavage of the Boc group is involved, an observation similar to the five-membered ring pyrrolidinone generation reactions. Interestingly, the construction of the six-membered ring piperidinones is as efficient as that of the five-membered ring pyrrolidinones. They are all very clean, and no further purification is required after removal of the solvent and the excess TFA, provided that low concentrations are applied while running the reactions. The fact that high concentrations may increase the level of potential side reactions also

Scheme 4.

suggests that a six-membered ring formal N-H insertion reaction is not as efficient as the six-membered ring oxygen insertion in the cases we have studied thus far.[2]

We also examined the chemistry of *N*-Boc-γ′-amino-α-diazoketone **10d**, derived from *N*-Boc-proline (Scheme 3) under the reaction condition described above. Interestingly, α-diazoketone **10d** (entry 4, Table 2) underwent a formal intramolecular N-H insertion reaction with concomitant Boc removal to afford the expected azobicyclic molecule **12d**. This reaction continues to have enjoyed the characteristics of the TFA-mediated intramolecular formal N-H insertion reaction, being fast (<5 min) and clean at low concentrations.

We believe that all the intramolecular formal N-H insertion reactions in Tables 1 and 2 may proceed through the same type of intermediate: nitronium species, as depicted in Scheme 4. The neutralization of the cation intermediate may constitute the driving force in the subsequent step of cleaving the Boc group. In situ FTIR studies of the intramolecular formal N-H insertion reactions with these amino-α′-diazoketones support this hypothesis. The poor nucleophilicity of the TFA counteranion together with low concentration may have suppressed the possible undesired intermolecular reactions. The detailed results of the mechanistic studies of the TFA-mediated intramolecular formal N-H insertion will be reported in due course.

Conclusions

We have demonstrated that TFA is an efficient reagent to promote intramolecular formal N-H insertion reactions with *N*-Boc-β′- and γ′-amino-α-diazoketones. A nitronium species might be involved in this transformation. Pyrrolidinones, piperidinones, and azabicyclic molecules have been readily prepared using this method. This method will find a variety of applications in synthetic organic and medicinal chemistry (9), complementary to the existing synthetic methodology (2).

Experimental part

General

Specific optical rotations ($[\alpha]_D$) were measured on a Perkin–Elmer 243B Polarimeter using a 1 dm path length micro cell and are reported in deg dm^{-1}. The concentration (*c*) is given in 10 mg mL^{-1} in the specified solvent. NMR spectra were recorded on a Varian 400GX Fourier Transform Spectrometer. The chemical shifts (δ) are expressed in parts per million (ppm) and coupling constants (*J*) are reported in Hertz (Hz). Infrared spectra were recorded on a Perkin–Elmer FTIR Spectrometer Paragon 1000 (ν in cm^{-1}). Mass spectroscopy data were obtained using either a Micromass Quattro LC (LC–MS–MS) or a Micromass LCT (time of flight) spectrometer; HRMS data were obtained by the University of Montreal mass spec. facility. Thin layer chromatography was performed on Silica Gel 60 F_{254} precoated plates and visualized with ultraviolet light and developed by staining with either basic potassium permanganate solution or acidic ammonium molybdate (IV). Column chromatography was carried out using Silica Gel 60 (70–230 mesh).

Organic solvents were used as purchased in sure sealed bottles and stored on molecular sieves. All reagents were used as received from commercial suppliers unless otherwise stated.

Diazomethane was prepared by dissolving Diazald® in diethyl ether and the resulting solution was added dropwise to a stirring solution of KOH in ethanol and water at 65°C. Diazomethane solution in diethyl ether obtained by distillation from the reaction's mixture is used without further purification (10).

N-Boc-α-amino-α′-diazoketones

General procedure A

The α-amino acid was dissolved in THF and cooled to –10°C. Triethylamine was added followed by the dropwise addition of isobutylchloroformate. The reaction was stirred at –10°C, under a nitrogen atmosphere, for 20 min then the white precipitate was filtered through celite. The filtrate was cooled to –10°C and freshly prepared diazomethane was added dropwise. The reaction was allowed to warm to room temperature and stirred for 18 h. The reaction was quenched with saturated aqueous NH_4Cl and the resulting layers were separated. The aqueous layer was extracted with EtOAc (3×) and the combined organic layers were washed with H_2O (1×) and saturated aqueous NaCl (1×), dried over Na_2SO_4, filtered, and concentrated.

(3S)-tert-*Butyl 3-diazo-1-methyl-2-oxopropylcarbamate (**2a**)*: Following the general procedure A. (2*S*)-*N*-Boc-alanine **1a** (3.0 g, 15.8 mmol) in THF (100 mL) with triethylamine (6.6 mL, 47.0 mmol) and isobutylchloroformate (2.5 mL, 19.0 mmol). Approximately 2 equiv. of diazomethane in ether solution. MPLC (Silica gel 60, EtOAc–Heptane (50:50)) gave **2a** as a yellow solid (2.84 g, 84%). IR (NaCl disc) υ: 3334, 2978, 2106, 1701, 1636, 1517, 1453, 1366, 1166 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.33 (3H, d, *J* = 6.6 Hz), 1.44 (9H, s), 4.22 (1H, brs), 5.11 (1H, brs), 5.43 (1H, brs).

(3S)-tert-*Butyl 3-diazo-1-isopropyl-2-oxopropylcarbamate (**2b**)*: Following the general procedure A. (2*S*)-*N*-Boc-valine **1b** (3.0 g, 13.8 mmol) in THF (100 mL) with triethylamine (5.8 mL, 41.4 mmol) and isobutylchloroformate (2.2 mL, 16.5 mmol). Approximately 2 equiv. of diazomethane in ether solution. MPLC (Silica gel 60, EtOAc–Heptane (50:50)) gave **2b** as a yellow oil (3.08 g, 92%). IR (NaCl disc) υ: 3334, 2967, 2105, 1716, 1698, 1650, 1634, 1519, 1504, 1367, 1172 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.89 (3H, d, *J* = 7.3 Hz), 0.98 (3H, d, *J* = 6.6 Hz), 1.44 (9H, s), 2.08 (1H, q, *J* = 6.3 Hz), 4.06 (1H, brs), 5.13 (1H, brs), 5.42 (1H, brs).

(3S)-tert-*Butyl 1-benzyl-3-diazo-2-oxopropylcarbamate (**2c**)*: Following the general procedure A. (2*S*)-*N*-Boc-phenylalanine **1c** (3.0 g, 11.3 mmol) in THF (100 mL) with triethylamine (4.7 mL, 34.0 mmol) and isobutylchloroformate (1.8 mL, 13.5 mmol). Approximately 2 equiv. of diazomethane in ether solution. MPLC (Silica gel 60, EtOAc–Heptane (50:50)) gave **2c** as a brown solid (3.30 g, 100%). IR (NaCl disc) υ: 3334, 2976, 2359, 2106, 1706, 1698, 1635, 1496, 1366, 1166 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ: 1.41 (9H, s), 3.03 (2H, d, *J* = 6.6 Hz), 4.42 (1H, brs), 5.09 (1H, brs), 5.22 (1H, brs), 7.17–7.34 (5H, m).

N-Boc-β-amino acid methyl esters

General procedure B

A solution of silver benzoate in triethylamine was added dropwise to a solution of α-diazoketone in MeOH at room temperature under a nitrogen atmosphere. Upon addition of the silver benzoate, bubbles were observed, the reaction darkened in color. It was noted that the reaction was exothermic. The resulting mixture was allowed to stir for 18 h and filtered through Celite® and concentrated to give a crude sample which was purified by MPLC.

*Methyl (3S)-3-[(*tert-*butoxycarbonyl)amino]butanoate (**3a**)*: Following the general procedure B. α-Diazoketone **2a** (2.84 g, 13.3 mmol) in MeOH (100 mL) and silver benzoate (0.31 g, 1.33 mmol) in triethylamine (10 mL). MPLC (Silica gel 60, EtOAc–Heptane (50:50)) gave **3a** as a yellow solid (2.77 g, 96%). ^1H NMR (400 MHz, $CDCl_3$) δ: 1.21 (3H, d, *J* = 6.6 Hz), 1.44 (9H, s), 2.45–2.57 (2H, m), 3.69 (3H, s), 4.04 (1H, brs), 4.94 (1H, brs). MS (*m*/*z*): 218.16 (M + H).

*Methyl (3R)-3-[(*tert-*butoxycarbonyl)amino]-4-methylpentanoate (**3b**)*: Following the general procedure B. α-Diazoketone **2b** (3.07 g, 12.7 mmol) in MeOH (100 mL) and silver benzoate (0.29 g, 1.27 mmol) in triethylamine (10 mL). MPLC (Silica gel 60, EtOAc–Heptane (50:50)) gave **3b** as a yellow oil (2.92 g, 93%). ^1H NMR (400 MHz, $CDCl_3$) δ: 0.92 (6H, d, *J* = 6.6 Hz), 1.45 (9H, s), 1.72–1.86 (1H, m), 2.41–2.57 (2H, m), 3.68 (3H, s), 3.69–3.80 (1H, m), 4.86 (1H, brs). MS (*m*/*z*): 246.15 (M + H).

*Methyl (3S)-3-[(*tert-*butoxycarbonyl)amino]-4-phenylbutanoate (**3c**)*: Following the general procedure B. α-Diazoketone **2c** (3.20 g, 11.0 mmol) in MeOH (100 mL) and silver benzoate (0.259 g, 1.10 mmol) in triethylamine (10 mL). MPLC (Silica gel 60, EtOAc–Heptane (50:50)) gave **3c** as a yellow oil (3.25 g, 100%). ^1H NMR (400 MHz, $CDCl_3$) δ: 1.41 (9H, s), 2.40–2.55 (2H, m), 2.75–2.98 (2H, m), 3.69 (3H, s),

4.06–4.21 (1H, m), 5.04 (1H, brs), 7.10–7.32 (5H, m). MS (*m*/*z*): 294.14 (M + H).

N-Boc-γ-amino-α,β-unsaturated methyl esters

General procedure C

0.5 M solution of DIBAL-H (2 equiv.) in toluene at –78°C was added dropwise over 2 h to a solution of *N*-Boc-α-amino acid methyl ester in toluene (0.1 M) at –78°C. The reaction was monitored by TLC. Methanol was added at this temperature and the resulting mixture stirred for additional 30 min. Then methyl (triphenylphosphoranylidene) acetate (1.15 equiv.) was added at –78°C and the resulting mixture stirred for 12 h allowing it to warm to room temperature. The mixture was filtered over Celite®, washed with warm ethyl acetate, concentrated in vacuo, and purified by chromatography.

*Methyl (E,4R)-4-[(*tert-*butoxycarbonyl)amino]-2-pentenoate (**7a**)*: Following the general procedure C. (2*R*)-*N*-Boc-alanine methyl ester **6a** (1.00 g, 4.92 mmol) in toluene (100 mL) at –78°C and DIBAL-H (9.64 mL, 9.64 mmol, 1 M in toluene). Reaction was quenched with MeOH (1 mL). Added methyl (triphenylphosphoranylidene) acetate (1.90 g, 5.69 mmol). Chromatography (Silica gel 60, EtOAc–Heptane (30:70)) gave unsaturated ester **7a** as a colorless oil (0.812 g, 72%). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.25 (3H, d, *J* = 6.6 Hz), 1.44 (9H, s), 3.77 (3H, s), 4.40 (1H, brs), 4.58 (1H, brs), 5.91 (1H, dd, *J* = 15.4, 1.5 Hz), 6.88 (1H, dd, *J* = 15.4, 4.4 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 20.97, 29.02, 47.71, 52.31, 120.38, 150.39, 155.56, 167.51.

*Methyl (*E,4R*)-4-[(*tert-*butoxycarbonyl)amino]-5-methyl-2-hexenoate (**7b**)*: Following the general procedure C. (2*R*)-*N*-Boc-valine methyl ester **6b** (2.11 g, 91.1 mmol) in toluene (100 mL) at –78°C and DIBAL-H (18.22 mL, 18.22 mmol, 1 M in toluene). The reaction was quenched with MeOH (2 mL). Added methyl (triphenylphosphoranylidene) acetate (3.66 g, 11.0 mmol). Chromatography (Silica gel 60, EtOAc–Heptane (30:70)) gave unsaturated ester **7b** as a white solid (2.17 g, 93%). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.83 (6H, t, *J* = 6.6 Hz), 1.35 (9H, s), 1.72–1.81 (1H, m), 3.64 (3H, s), 4.07 (1H, brs), 4.71 (1H, d, *J* = 8.8 Hz), 5.84 (1H, d, *J* = 16.1 Hz), 6.78 (1H, dd, *J* = 15.4, 5.1 Hz).

*Methyl (*E,4S*)-4-[(*tert-*butoxycarbonyl)amino]-5-phenyl-2-pentenoate (**7c**)*: Following the general procedure C. (2*S*)-*N*-Boc-phenylalanine methyl ester **6c** (4.59 g, 16.4 mmol) in toluene (250 mL) at –78°C and DIBAL-H (33.0 mL, 33.0 mmol, 1 M in toluene). The reaction was quenched with MeOH (2 mL). Added methyl (triphenylphosphoranylidene) acetate (6.30 g, 18.86 mmol). Usual work-up gave unsaturated ester **7c** as a crude sample that was used directly in the next step.

tert-*Butyl (2S)-2-[(*E*)-3-methoxy-3-oxo-1-propenyl]-1-pyrrolidinecarboxylate (**7d**)*: Following the general procedure C. (2*S*)-*N*-Boc-proline methyl ester **6d** (3.36 g, 14.65 mmol) in toluene (120 mL) at –78°C and DIBAL-H (15.0 mL, 15.0 mmol, 1 M in toluene). Reaction was quenched with MeOH (2 mL). Added methyl (triphenylphosphoranylidene) acetate (5.63 g, 16.85 mmol). Chromatography (Silica gel 60, EtOAc–Heptane (30:70)) gave unsaturated ester **7d** which was used immediately in the next step. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.41 (9H, s), 1.60–2.00 (4H, m), 3.34–3.59 (2H, m), 3.73 (3H, s), 4.37 (1H, brs), 5.83 (1H, d, *J* = 14.6 Hz), 6.78–6.90 (1H, m).

N-Boc-amino acids

General procedure D

The *N*-Boc-amino acid methyl ester was dissolved in MeOH and treated with 10% aqueous NaOH. The reaction was stirred for 18 h at room temperature. The MeOH was removed in vacuo and the remaining mixture was diluted with H_2O. The aqueous layer was washed with EtOAc (2×) and acidified to pH 2 with 10% aqueous HCl. The aqueous layer was extracted with EtOAc (3×) and the combined organic layers washed with saturated aqueous NaCl (1×), dried over Na_2SO_4, filtered, and concentrated.

*(3S)-3-[(*tert*-Butoxycarbonyl)amino]butanoic acid (**4a**)*: Following the general procedure D. The β-amino acid methyl ester **3a** (2.73 g, 12.6 mmol) in MeOH (50 mL) and 10% aqueous NaOH (50 mL). Flash chromatography (silica gel 60, 100% EtOAc) gave β-amino acid **4a** as a pale yellow viscous oil (2.60 g, 100%). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.24 (3H, d, *J* = 6.6 Hz), 1.45 (9H, s), 2.46–2.62 (2H, m), 4.05 (1H, brs), 4.95 (1H, brs). MS (*m*/*z*): 204.10 (M + H).

*(3*R*)-3-[(*tert-*Butoxycarbonyl)amino]-4-methylpentanoic acid (**4b**)*: Following the general procedure D. The β-amino acid methyl ester **3b** (2.90 g, 11.8 mmol) in MeOH (50 mL) and 10% aqueous NaOH (50 mL). Flash chromatography (Silica gel 60, 100% EtOAc) gave β-amino acid **4b** as a pale yellow viscous oil (2.80 g, 100%). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.93 (3H, d, *J* = 6.6 Hz), 1.44 (9H, s), 1.76–1.91 (1H, m), 2.40–2.65 (2H, m), 3.70–3.82 (1H, m), 4.92 (1H, d, *J* = 9.5 Hz). MS (*m*/*z*): 232.09 (M + H).

*(3*S*)-3-[(*tert-*Butoxycarbonyl)amino]-4-phenylbutanoic acid (**4c**)*: Following the general procedure D. The β-amino acid methyl ester **3c** (3.26 g, 11.1 mmol) in MeOH (50 mL) and 10% aqueous NaOH (50 mL). Flash chromatography (Silica gel 60, 100% EtOAc) gave β-amino acid **4c** as a pale yellow solid (0.56 g, 19%). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.40 (9H, s), 2.45–2.61 (2H, m), 2.80–3.00 (2H, m), 4.18 (1H, brs), 5.06 (1H, brs), 7.17–7.33 (5H, m). MS (*m*/*z*) 280.21 (M + H).

*(*E,4R*)-4-[(*tert-*Butoxycarbonyl)amino]-2-pentenoic acid (**8a**)*: Following the general procedure D. The unsaturated γ-amino acid methyl ester **7a** (0.65 g, 2.83 mmol) in MeOH (5 mL) and 10% aqueous solution NaOH (5 mL). MPLC (Silica gel 60, EtOAc–Heptane (40:60 – 60:40)) gave unsaturated acid **8a** (367 mg, 61%). IR (NaCl disc) υ: 3330 (br), 2976, 1703, 1646 cm^{-1}. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.28 (3H, d, *J* = 6.6 Hz), 1.45 (9H, s), 4.44 (1H, brs), 4.56 (1H, brs), 5.91 (1H, d, *J* = 15.4 Hz), 6.98 (1H, dd, *J* = 15.4, 4.4 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 14.1, 20.1, 28.1, 28.2, 119.3, 151.8.

*(*E,4R*)-4-[(*tert-*Butoxycarbonyl)amino]-5-methyl-2-hexenoic acid (**8b**)*: Following the general procedure D. The unsaturated γ-amino acid methyl ester **7b** (1.98 g, 7.73 mmol) in MeOH (2 mL) and 10% aqueous NaOH (2 mL). MPLC

© 2000 NRC Canada

(Silica gel 60, EtOAc–Heptane (40:60 – 60:40)) gave unsaturated acid **8b** (1.56 g, 83%) as a white foam. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.94 (6H, m), 1.45 (9H, s), 1.84–1.92 (1H, m), 4.23 (1H, brs), 4.60 (1H, brs), 5.94 (1H, d, *J* = 16.1 Hz), 6.96 (1H, dd, *J* = 15.4, 5.1 Hz).

*(*E*,4*S*)-4-[(*tert*-Butoxycarbonyl)amino]-5-phenyl-2-pentenoic acid (**8c**)*: Following the general procedure D. The unsaturated γ-amino acid methyl ester **7c** in MeOH (30 mL) and 10% aqueous NaOH (30 mL). MPLC (Silica gel 60, EtOAc–Heptane (40:60 – 60:40)) gave unsaturated acid **8c** (1.40 g, 29% over 2 steps) as a white solid. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.40 (9H, s), 2.90 (2H, brs), 4.12 (1H, q, *J* = 7.3 Hz), 4.60 (1H, m), 5.85 (1H, d, *J* = 15.4 Hz), 6.99 (1H, dd, *J* = 16.1, 5.1 Hz), 7.15–7.39 (5H, m).

*(*E*)-3-[(2*S*)-1-(*tert*-Butoxycarbonyl)pyrrolidinyl]-2-propenoic acid (**8d**)*: Following the general procedure D. The unsaturated γ-amino acid methyl ester **7d** in MeOH (30 mL) and 10% aqueous NaOH (30 mL). MPLC (Silica gel 60, EtOAc–Heptane (40:60 – 60:40)) gave unsaturated acid **8d** (3.24 g, 92% over 2 steps) as a colourless oil. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.39 (9H, s), 1.70–1.93 (4H, m), 3.22–3.48 (2H, m), 4.34 (3H, brs), 5.80 (1H, d, *J* = 16.1 Hz), 6.80–6.96 (1H, m), 9.80 (1H, brs).

N-Boc-γ-amino acids (9)

General procedure E

The *N*-Boc-γ-amino-α,β-unsaturated acid was dissolved in ethyl acetate followed by addition of 10% Pd/C (10% in weight). The resulting mixture was shaken under the hydrogen atmosphere (45 psi) for 3 h. The catalyst was filtered over Celite®, and the filtrate washed with ethyl acetate and concentrated in vacuo to give the γ-amino acid which was used in the next step without further purification.

*(4*R*)-4-[(*tert*-Butoxycarbonyl)amino]pentanoic acid (**9a**)*: Following the general procedure E. The unsaturated γ-amino acid **8a** (0.36 g, 1.7 mmol) in EtOAc (20 mL) and cat. 10% Pd/C with H_2. Washed with EtOAc (120 mL) to give γ-amino acid **9a** (0.37 g, 100%) as a white solid. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.14 (3H, d, *J* = 3.6 Hz), 1.41 (9H, s), 1.60–1.71 (1H, m), 1.72–1.82 (1H, m), 2.39 (2H, t, *J* = 2.8 Hz), 3.69 (1H, brs), 4.40 (1H, brs).

*(4*S*)-4-[(*tert*-Butoxycarbonyl)amino]-5-methylhexanoic acid (**9b**)*: Following the general procedure E. The unsaturated γ-amino acid **8b** (1.28 g, 5.26 mmol) in EtOAc (10 mL) and cat. 10% Pd/C with H_2. Washed with EtOAc (120 mL) to give γ-amino acid **9b** (1.22 g, 95%) as a white solid. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.86 (6H, t, *J* = 6.6 Hz), 1.39 (9H, s), 1.50–1.58 (1H, m), 1.60–1.72 (1H, m), 1.74–1.87 (1H, m), 2.31–2.40 (2H, m), 3.30–4.46 (1H, m), 4.37 (1H, d, *J* = 10.2 Hz). MS (*m*/*z*): 246.23 (M + H).

*(4*R*)-4-[(*tert*-Butoxycarbonyl)amino]-5-phenylpentanoic acid (**9c**)*: Following the general procedure E. The unsaturated γ-amino acid **8c** (1.39 g, 4.77 mmol) in EtOAc (10 mL) and cat. 10% Pd/C with H_2. Washed with EtOAc (120 mL) to give γ-amino acid **9c** (1.24 g, 87%) as a white solid. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.38 (9H, s), 1.82–1.91 (2H, m), 2.33–2.46 (2H, m), 2.70–2.82 (2H, m), 3.80–3.90 (1H, m), 4.39 (1H, d, *J* = 10.2 Hz), 7.13–7.33 (5H, m).

*3-[(2*S*)-1-(*tert*-Butoxycarbonyl)pyrrolidinyl]propanoic acid (**9d**)*: Following the general procedure E. The unsaturated γ-amino acid **8d** (3.24 g, 13.4 mmol) in EtOAc (40 mL) and cat. 10% Pd/C with H_2. Washed with EtOAc (120 mL) to give γ-amino acid **9d** as a white solid (2.45 g, 74%). $[\alpha]_D$ + 85.6° (MeOH, c 0.74).

N-Boc-β-amino-α′-diazoketones

*tert-Butyl (1*S*)-1-methyl-4-diazo-3-oxobutylcarbamate (**5a**)*: Following the general procedure A. β-Amino acid **4a** (2.70 g, 13.3 mmol) in THF (100 mL) with triethylamine (5.5 mL, 39.8 mmol) and isobutylchloroformate (2.07 mL, 15.9 mmol). Approximately 2 equiv. of diazomethane in ether solution. MPLC (Silica gel 60, EtOAc–Heptane (20 – 50:80 – 50)) gave diazoketone **5a** as a yellow solid (0.33 g, 10%). $[\alpha]_D$ + 19.03° (MeOH, c 0.77). IR (NaCl disc) υ: 3370, 2976, 2100, 1710, 1694, 1681, 1633, 1519, 1371, 1163 cm^{-1}. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.23 (3H, d, *J* = 6.6 Hz), 1.44 (9H, s), 2.52 (2H, brs), 3.98 (1H, brs), 4.99 (1H, brs), 5.32 (1H, brs). MS (*m*/*z*): 228.2 (M + H). HRMS calcd. for $C_{10}H_{17}N_3O_3$ + H: 228.1348; found: 228.1346.

*tert-Butyl (1*R*)-1-isopropyl-4-diazo-3-oxobutylcarbamate (**5b**)*: Following the general procedure A. β-Amino acid **4b** (2.80 g, 12.1 mmol) in THF (100 mL) with triethylamine (5.1 mL, 36.3 mmol) and isobutylchloroformate (1.88 mL, 14.5 mmol). Approximately 2 equiv. of diazomethane in ether solution. MPLC (Silica gel 60, EtOAc–Heptane (20 – 50:80 – 50)) gave diazoketone **5b** as a yellow solid (0.26 g, 9%). $[\alpha]_D$ + 28.23° (MeOH, c 0.58). IR (NaCl disc) υ: 3376, 3074, 2964, 2102, 1688, 1631, 1519, 1386, 1366, 1248, 1173 cm^{-1}. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.91 (6H, d, *J* = 6.6 Hz), 1.43 (9H, s), 1.86 (1H, brs), 2.51 (2H, brs), 3.68 (1H, brs), 4.92 (1H, brs). MS (*m*/*z*): 256.2 (M + H). HRMS calcd. for $C_{12}H_{21}N_3O_3$ + H: 256.1661; found: 256.1649.

*tert-Butyl (1*S*)-1-benzyl-4-diazo-3-oxobutylcarbamate (**5c**)*: Following the general procedure A. β-Amino acid **4c** (0.58 g, 2.07 mmol) in THF (25 mL) with triethylamine (0.87 mL, 6.22 mmol) and isobutylchloroformate (0.32 mL, 2.49 mmol). Approximately 2 equiv. of diazomethane in ether solution. MPLC (Silica gel 60, EtOAc–Heptane (20 – 50:80 – 50)) gave α-diazoketone **5c** as a yellow solid (80.1 mg, 13%). IR (NaCl disc) υ: 3364, 3076, 2979, 2102, 1691, 1633, 1523, 1386, 1366, 1249, 1171 cm^{-1}. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.41 (9H, s), 2.48 (2H, brs), 2.78–3.04 (2H, m), 4.04–4.15 (1H, m), 5.14–5.30 (2H, m), 7.17–7.32 (5H, m). MS (*m*/*z*): 304.2 (M + H). HRMS calcd. for $C_{16}H_{21}N_3O_3$ + H: 304.1661; found: 304.1673.

N-Boc-γ-amino-α′-diazoketones

*tert-Butyl (1R)-5-diazo-1-methyl-4-oxopentylcarbamate (**10a**):* Following the general procedure A. To a solution of γ-amino acid **9a** (0.373 g, 1.728 mmol) in 15 mL of THF was added *i*BuOCOCl (0.27 mL, 2.07 mmol), triethylamine (0.73 mL, 5.18 mmol), followed by about 10-fold excess of diazomethane solution in ether. Compound **10a** was obtained

© 2000 NRC Canada

(0.135 g, 32%) as a yellow solid. $[\alpha]_D$ –13.7° (MeOH, c 0.68). R_f = 0.30 in 30% of EtOAc in heptane. IR (NaCl disc) ν: 3358, 3082, 2975, 2101, 1682, 1633, 1531, 1455, 1389 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.05 (3H, d, J = 6.5 Hz), 1.45 (9H, s), 1.6–1.8 (2H, m), 2.40 (2H, brs), 3.70 (1H, brs), 4.20 (1H, brs), 5.25 (1H, brs). HRMS (FAB) calcd. for $C_{11}H_{20}O_3N_3$ + H: 242.1505; found: 242.1498.

tert-*Butyl (1*S*)- 5-diazo-1-isopropyl-4-oxopentylcarbamate (**10b**)*: Following the general procedure A. To a solution of γ-amino acid **9b** (1.22 g, 4.97 mmol) in 40 mL of THF, was added *i*BuOCOCl (0.78 mL, 5.96 mmol) and triethylamine (2.10 mL, 14.9 mmol), followed by 10-fold excess of diazomethane in ether. Compound **10b** (0.74 g, 55%) was obtained as a yellow crystal. $[\alpha]_D$ –20.1° (CH_2Cl_2, c 0.74). R_f = 0.30 in 30% of EtOAc in heptane. IR (NaCl disc) ν: 3347, 2963, 2104, 1703, 1633, 1519, 1366, 1248, 1172, 1067 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.90 (6H, d, J = 6.5 Hz), 1.25 (9H, s), 1.6–1.8 (2H, m), 1.85 (1H, m), 2.40 (2H, brs), 3.40 (1H, m), 4.17 (1H, d, J = 6.5 Hz), 5.15 (1H, brs). HRMS (FAB) calcd. for $C_{13}H_{24}O_3N_3$ + H: 270.1817; found: 270.1824.

tert-*Butyl (1*R*)-5-diazo-1-benzyl-4-oxopentylcarbamate (**10c**)*: Following the general procedure A. To a solution of γ-amino acid **9c** (1.20 g, 4.09 mmol) in 40 mL of THF, was added *i*BuOCOCl (0.64 mL, 4.90 mmol) and triethylamine (1.73 mL, 12.26 mmol) followed by 10-fold excess of diazomethane in ether. Compound **10c** (0.35 g, 27%) was obtained as a yellow solid. $[\alpha]_D$ + 14.44° (MeOH, c 0.45). R_f = 0.30 in 35% of EtOAc in heptane. IR (NaCl disc) ν: 3352, 3083, 2979, 2357, 2101, 1682, 1633, 1524, 1447, 1385, 1348 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.45 (9H, s), 1.70–1.60 (1H, brs), 1.90–1.80 (1H, brs), 2.40 (2H, brs), 2.90–2.80 (2H, ddd), 3.80 (1H, brs), 4.40 (1H, brs), 5.15 (1H, brs), 7.40–7.20 (5H, m). HRMS (FAB) calcd. for $C_{17}H_{24}O_3N_3$ + H: 318.1818; found: 318.1832.

tert-*Butyl (2*S*)-2-(4-diazo-3-oxobutyl)-1-pyrrolidinecarboxylate (**10d**)*: Following the general procedure A. To a solution of γ-amino acid **9d** (2.45 g, 10.2 mmol) in 80 mL of THF, was added *i*BuOCOCl (1.72 mL, 13.2 mmol) and triethylamine (4.65 mL, 32.9 mmol) followed by 10-fold excess of diazomethane in ether. Compound **10d** (1.54 g, 56%) was obtained as a yellow oil. $[\alpha]_D$ + 91.80° (MeOH, c 0.74). R_f = 0.30 in 30% of EtOAc in heptane. IR (NaCl disc) ν: 2974, 2103, 1692, 1392, 1165 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.40 (9H, d), 2.0–1.60 (6H, m), 2.30 (1H, brs), 3.30 (2H, brs), 3.40 (2H, brs), 3.70 (1H, brs), 4.20 (1H, m), 5.20 (1H, m). HRMS (FAB) calcd. for $C_{13}H_{22}O_3N_3$ + H: 268.1661; found: 268.1666.

Intramolecular formal N-H insertion reactions

General procedure F

The α′-diazoketone was dissolved in CH_2Cl_2 and cooled to –78°C. Trifluoroacetic acid was added dropwise and the reaction stirred under a nitrogen atmosphere for 5 min and then concentrated in vacuo to give the desired product as a TFA salt. The excess TFA could also be removed by washing with ether (2×).

3-Pyrrolidinones

*(5*S*)-5-Methyl-3-pyrrolidinone trifluoroacetate (**11a**)*: Following the general procedure F. α-Diazoketone **5a** (5.1 mg, 0.022 mmol) in CH_2Cl_2 (10 mL) with trifluoroacetic acid (1 mL) gave cyclized product **11a** as a yellow solid (4.1 mg, 86%). $[\alpha]_D$ + 162.5° (MeOH, c 0.20). IR (NaCl disc) υ: 3391, 1694, 1446, 1318, 1179 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.38 (3H, d, J = 6.6 Hz), 2.86–3.03 (2H, m), 3.88–3.98 (1H, m), 4.54 (1H, d, J = 16.9 Hz), 4.80 (1H, d, J = 16.9 Hz), 6.99 (1H, s). HRMS calcd. for C_5H_9NO: 99.0685; found: 99.0709.

*(5*R*)-5-Isopropyl-3-pyrrolidinone trifluoroacetate (**11b**)*: Following the general procedure F. α-Diazoketone **5b** (4.9 mg, 0.019 mmol) in CH_2Cl_2 (10 mL) with trifluoroacetic acid (1 mL) gave cyclized product **11b** as a yellow viscous oil (4.3 mg, 93%). $[\alpha]_D$ + 84.40° (MeOH, c 0.25). IR (NaCl disc) υ: 3417, 1766, 1682, 1201 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.00 (3H, d, J = 6.0 Hz), 1.01 (3H, d, J = 6.0 Hz), 1.83–1.94 (1H, m), 2.73–3.08 (2H, m), 3.63–3.88 (1H, m), 4.50 (1H, d, J = 16.8 Hz), 4.70 (1H, d, J = 16.8 Hz), 6.74 (1H, s). HRMS calcd. for $C_7H_{13}NO$ + H: 128.1076; found: 128.0322.

*(5*S*)-5-Benzyl-3-pyrrolidinone trifluoroacetate (**11c**)*: Following the general procedure F. α-Diazoketone **5c** (5.9 mg, 0.019 mmol) in CH_2Cl_2 (10 mL) with trifluoroacetic acid (1 mL) gave cyclized product **11c** as an off-white solid (4.7 mg, 84%). $[\alpha]_D$ + 41.60° (MeOH, c 0.25). IR (NaCl disc) υ: 3390, 2931, 1770, 1682, 1455, 1319, 1172 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 2.84–3.05 (4H, m), 3.90–3.99 (1H, m), 4.53 (1H, d, J = 16.8 Hz), 4.72 (1H, d, J = 16.8 Hz), 6.53 (s, 1H), 7.14–7.40 (m, 5H). MS (*m*/*z*): 176.2 (M + H). HRMS calcd. for $C_{11}H_{13}NO$ + H: 176.1075; found: 176.1079.

3-Piperidinoes

*(6*R*)-6-Methyl-3-piperidinone trifluoroacetate (**12a**)*: Following the general procedure F. To a solution of γ-amino-α′-diazoketone **10a** (9 mg, 0.037 mmol) in CH_2Cl_2 (6 mL) was added TFA (2 mL). Compound **12a** (69%) was obtained. $[\alpha]_D$ –57.1° (CH_2Cl_2, c 0.21). IR (NaCl disc) ν: 3365, 2976, 1736, 1676, 1424, 1202, 1179, 1134 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.5 (3H, d, J = 6.6 Hz), 2.0–1.9 (1H, m), 2.70–2.60 (1H, m), 3.20–3.10 (2H, m), 4.55 (1H, m), 4.80 (2H, brs). MS (*m*/*z*): 114.1 (M + 1). HRMS calcd. for $C_6H_{11}NO$ + H: 114.0919; found: 114.0916.

*(6*S*)-6-Isopropyl-3-piperidinone trifluoroacetate (**12b**)*: Following the general procedure F. To a solution of γ-amino-α′-diazoketone **10b** (8.0 mg, 0.030 mmol) in CH_2Cl_2 (10 mL) was added TFA (1 mL). Compound **12b** (6.0 mg, 79%) was obtained. $[\alpha]_D$ –30.68° (CH_2Cl_2, c 0.37). IR (NaCl disc) ν: 2967, 1770, 1673, 1504, 1192, 1080, 1014 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.9 (3H, d, J = 6.6 Hz), 1.1 (3H, d), 2.2–2.0 (2H, m), 2.4 (1H, m), 3.1 (2H, m), 4.3 (1H, m), 4.8 (2H, m). HRMS (FAB) calcd. for $C_8H_{16}ON$ + H: 142.1232; found: 142.1229.

*(6*R*)-6-Benzyl-3-piperidinone trifluoroacetate (**12c**)*: Following the general procedure F. To a solution of γ-amino-

© 2000 NRC Canada

α′-diazoketone **10a** (9.8 mg, 0.031 mmol) in CH_2Cl_2 (10 mL) was added TFA (1 mL). Compound **12c** (5.8 mg, 62%) was obtained. $[\alpha]_D$ + 19.58° (MeOH, c 0.24). IR (NaCl disc) ν: 2969, 2358, 1770, 1681, 1504, 1417, 1139, 1163, 1081 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 2.2 (1H, m), 2.5–2.4 (1H, m), 2.8–2.6 (1H, m), 2.9 (1H, m), 3.0 (1H, m), 3.2 (1H, m), 4.70–4.80 (3H, m), 7.4–7.2 (5H, m). HRMS (FAB) calcd. for $C_{12}H_{16}ON$ + H: 190.1232; found: 190.1226.

*(8a*S*)-Hexahydro-6(5*H*)-indolizinone trifluoroacetate (**12d**)*: Following the general procedure F. To a solution of γ-amino-α′-diazoketone **10d** (11.8 mg, 0.044 mmol) in CH_2Cl_2 (10 mL) was added TFA (1 mL). Compound **12d** (9.4 mg, 88%) was obtained. $[\alpha]_D$ + 172.9° (CH_2Cl_2, c 0.36). IR (NaCl disc) ν: 3417, 2988, 2555, 1782, 1673, 1446, 1326, 1177 cm^{-1}. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.3 (1H, m), 2.1–1.8 (4H, m), 2.4 (1H, m), 2.6 (1H, m), 3.4 (1H, m), 3.7 (2H, m), 4.1 (1H, m), 4.8–4.5 (2H, m). HRMS (FAB) calcd. for $C_8H_{14}ON$ + H: 140.1075; found: 140.1072.

Acknowledgments

We thank Dr. M. Evans for HRMS analysis, Dr. Chris Walpole for helpful discussion.

Straightforward synthesis of new tetrahydroquinoline derivatives

Romano Di Fabio, Giuseppe Alvaro, Barbara Bertani, and Simone Giacobbe

Abstract: To identify novel classes of glycine antagonists, compounds potentially useful as neuroprotective after stroke, novel substituted tetrahydroquinoline derivatives, satisfying the key pharmacophoric requirements for glycine antagonists, were designed. To explore the SAR of these compounds an efficient synthetic route was set up exploiting the outstanding reactivity of suitable *N*-aryl imine derivatives. In particular an allylmetalation reaction or the addition of bis(trimethyldisilyl)ketene acetals allowed the preparation of versatile intermediates which were smoothly transformed into the desired bicycle tetrahydroquinoline derivatives by a Heck-type cyclization reaction.

Key words: glycine antagonists, neuroprotection, tetrahydroquinolines, synthesis, allylmetalation.

Résumé : Pour identifier de nouvelles classes d'antagonistes du récepteur de la glycine, composées potentiellement utiles en tant qu'agents neuroprotectifs après l'ischémie cérébrale, une nouvelle classe de dérivés de la tétrahydroquinoline substituée, satisfaisant les prérequis pharmacophorique pour les antagonistes du récepteur de la glycine, fut proposée. Afin d'explorer la relation structure-activité (SAR) de ces composés, une route synthétique efficace fut développée exploitant la haute réactivité des dérivés des *N*-aryl imines. En particulier, la réaction d'allylmétalation ou l'addition des bis(triméthyldisilyl)cétènes acétals permirent la préparation d'intermédiaires facilement transformables en dérivés bicycliques de la tétrahydroquinoline utilisant une réaction de cyclisation du type Heck.

Mots clés : antagonistes de la glycine, neuroprotection, tétrahydroquinoléines, synthèse, allylmétallation.

The modulation of the NMDA receptor (1) is considered as one of the most promising biological strategies to identify effective neuroprotective agents able to block the dynamic progression of the brain damage after stroke (for a review on different neuroprotective approaches potentially useful to control the progression of the brain damage after stroke see ref. (2)). In this event, noncompetitive NMDA antagonists acting at the glycine binding site (3), have been proven to counteract efficaciously the excitotoxic cascade triggered by glutamate in animal model of cerebral ischemia, after permanent occlusion of the middle cerebral artery (MCA) (4).

The extensive exploration performed by GlaxoWellcome of the indole-2-carboxylate template allowed identification of several compounds exhibiting outstanding neuroprotective activity in rats and a clean safety profile (5). Among those, the indole-2-carboxylate derivative GV150526 shown in Fig. 1, is undergoing Phase III clinical trails to prove the glycinergic hypothesis in man. To discover a novel series of glycine antagonists the tetrahydroquinoline (THQ) derivatives of general structure A as depicted in Fig. 1, were proposed as potential ligands of the glycine binding site satisfying the key pharmacophoric requirements (5*g*). To explore in detail the SAR of these new compounds, and in particular of the *N*-aryl moiety belonging to the α,β-unsaturated chain, an efficient synthetic route was needed (for an alternative synthesis of THQ derivatives see ref. (6)). In this event, Scheme 1 is shows the first retrosynthetic analysis proposed. Considering the possibility of performing a sequential Wittig-type olefination reaction to introduce the α,β-unsaturated side chain followed by a Heck-type cyclization reaction (7), the dissection of the *exendo* bond and the allylic double bond, respectively, seemed to be the most appropriate. To test this working hypothesis, identification of an efficient synthesis to prepare in large scale the *N*-aryl allyl glycine derivative, was perceived as the most urgent problem to solve. Among the different potential synthetic approaches (i.e., disconnection of C—N or N—C bond or, alternatively, of the C—C allylic bond), it was speculated that, as shown in Scheme 2, the addition of an allyl metal derivative **2** to the *N*-aryl aldimine **1**, generated in situ from a substituted aniline and a suitable glyoxylic ester in the presence of a Lewis acid, could afford the desired key intermediate **3**. To our surprise this allylmetalation reaction, although widely explored with different imines (for a review on the addition of different organometallic reagents to imines see ref. (8)), was unknown for the aldimine derivative of type **1**.

Following this preliminary analysis, the synthetic route shown in Scheme 3 was performed. In particular, as far as the key allylmetalation reaction is concerned, when the aryl

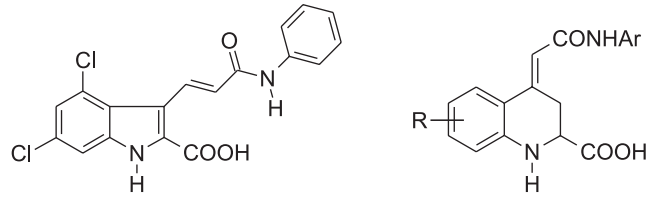
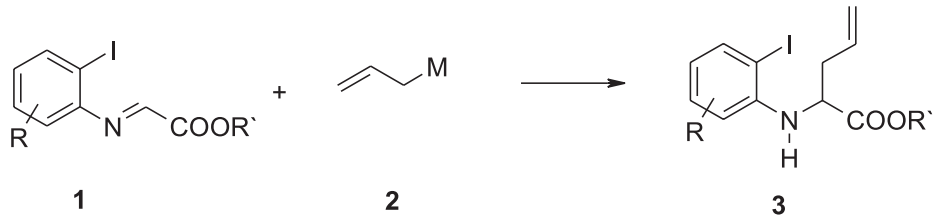


Scheme 1.

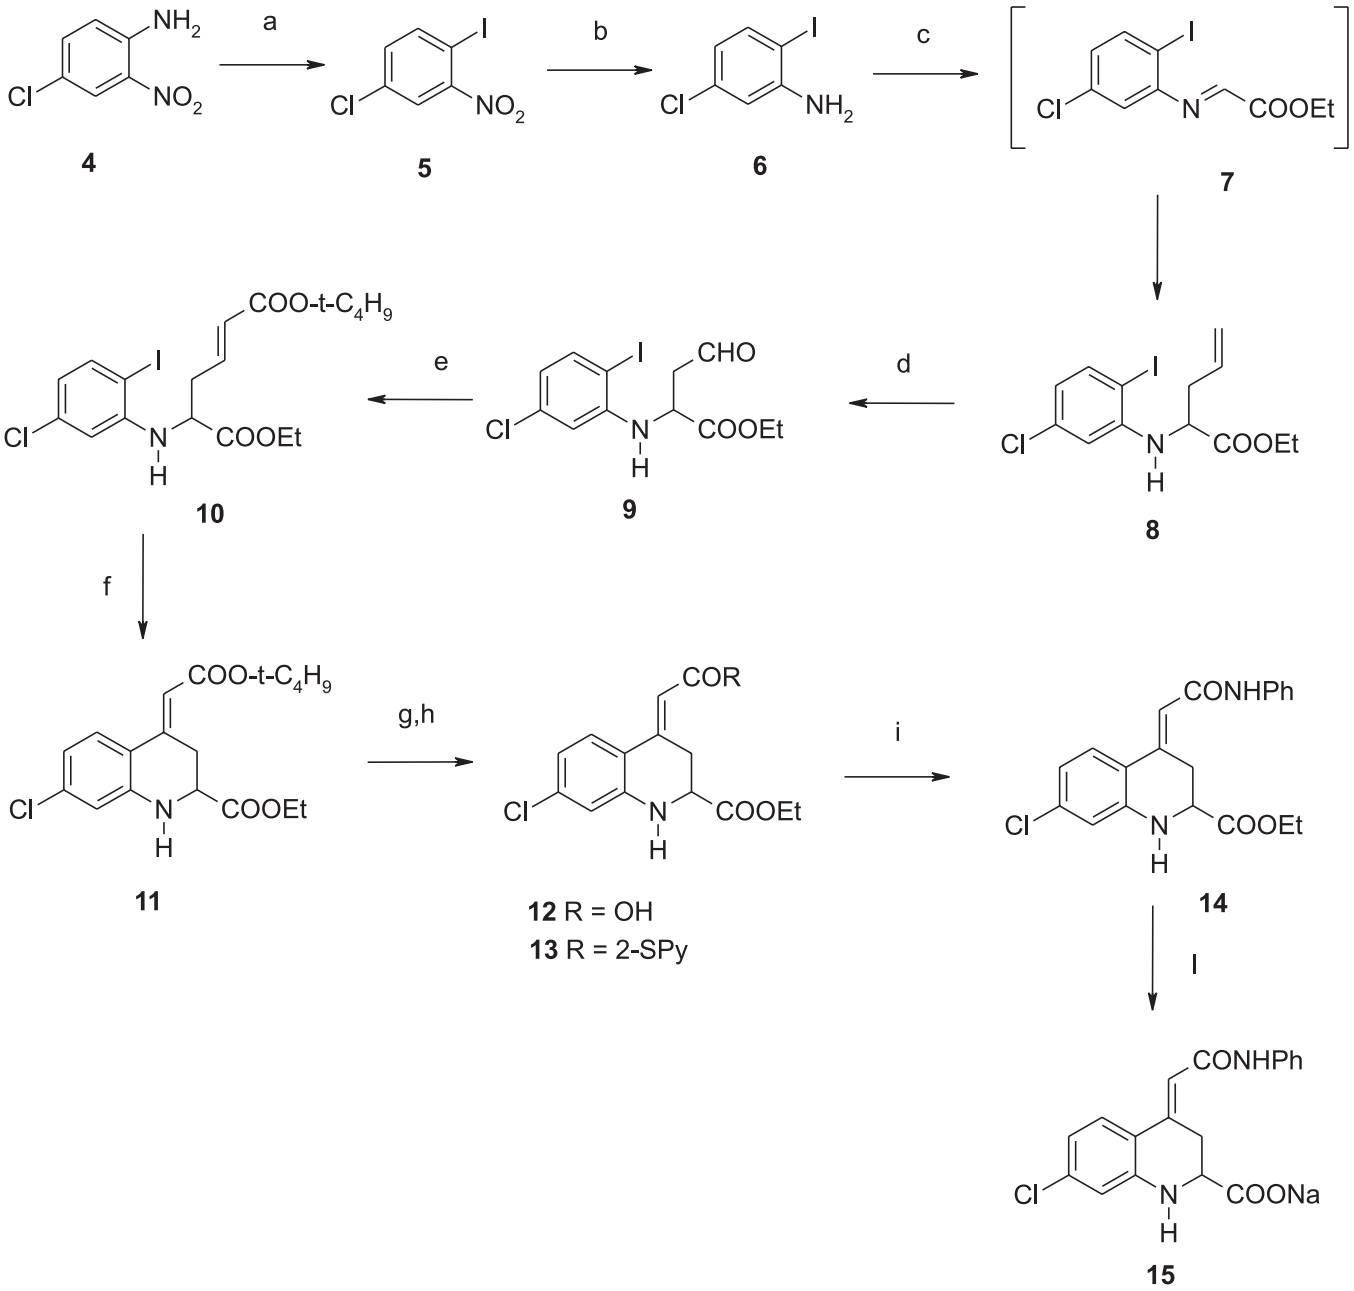
amine **6**, smoothly prepared in two steps and high total yield from the commercially available 3-chloro-2-nitroaniline **4**, was treated with ethyl glyoxylate overnight in refluxing toluene continuously removing H_2O from the reaction mixture by a Dean–Stark apparatus, the desired aldimine **7** was obtained. After evaporation of the solvent, without any purification, the crude intermediate **7** was dissolved in dry CH_2Cl_2 and treated at –78°C with $TiCl_4$ (1.1 equiv.). Then allyltributyltin (1.2 equiv.) was dropped into the reaction mixture resulting in a smooth addition reaction to give the desired *N*-aryl α amino ester derivative **8** in 88% yield from **6**, after purification by flash chromatography. As highlighted above, the addition of allyl metal derivatives to aldimines of this type has not been reported. Because of the synthetic versatility of the allyl double bond, this reaction represents a straightforward method to prepare substituted *N*-aryl amino acids.

After the identification of an efficient route to introduce a formal allyl glycine residue on the aromatic moiety, the allyl derivative **8** was transformed into the α,β-unsaturated compound **10** in two steps in high overall yield. The aldehyde derivative **9**, easily generated by ozonolysis, was submitted to a Wittig-type reaction with (*tert*-butylcarbonylmethylene)triphenylphosphorane in dry toluene at reflux to afford the olefinic compound **10** with high stereocontrol in the formation of the expected *E* isomer (ratio *E*/*Z* = 98:2), which was isolated, as pure compound, by flash chromatography in 90% yield. The following Heck-type cyclization reaction was performed in DMF at 120°C for 2 h with Et_3N in the presence of catalytic amount of $Pd(PPh_3)_4$, to give the desired *exo* compound **11** in 85% yield. As expected, the *E*

Fig. 1.



stereochemistry of the double bond was completely controlled. Chemoselective removal of the *tert*-butyl protecting group with HCOOH yielded quantitatively the free carboxyl derivative **12**, the key intermediate for the exploration of the SAR of the northeastern region of the THQ template. As an example, **12** was transformed into the corresponding *N*-phenyl amide derivative **14**. Among the different amidation methods available, excellent results were obtained when the carboxyl group was activated via the corresponding 2-pyridyl thiolester (9). When compound **12** was treated with 2,2′-dipyridyldisulfide and PPh_3 in THF at room temperature for 3 h, the intermediate **13** was isolated in 67% yield after purification by flash chromatography. Subsequent reaction with aniline in toluene at reflux for 2 h gave the amido derivative **14** in high yield. Finally, the ester group of this compound was hydrolized with NaOH in EtOH–MeOH (95:5) to furnish the desired sodium carboxylate **15**.



In summary, this synthetic approach allowed efficient preparation of the desired compound **15**, as the first member

Scheme 4. (*a*) $CHOCO_2Et$, toluene, 1,1-bis(trimethylsilyloxy)buta-1,3-diene, $TiCl_4$, CH_2Cl_2, –78°C; (*b*) $Pd(PPh_3)_4$, Et_3N, DMF, 120°C, 3 h, 70% from **7**.

of a novel and promising class of glycine antagonists. However, this synthesis was affected by two main drawbacks: the presence of Bu_3SnCl formed during the allylmetalation reaction, resulting in a more difficult purification of intermediate **8** in case of scale up, and the following hazardous ozonolysis of the allylic double bond. Therefore, to further increase the efficiency of this synthesis, in view of the observed outstanding reactivity of the *N*-aryl imine **7**, the synthetic sequence shown in Scheme 4 was carried out. This novel route, avoiding both the allylmetalation of the aldimine **7** and the following ozonolysis reaction, could result in a straightforward preparation of intermediate **12**. Thus, the 1,1-bis(trimethylsilyloxy)buta-1,3-diene **16**, prepared from crotonic acid as previously described (10), was treated with aldimine **7** in the presence of $TiCl_4$ in CH_2Cl_2 at –78°C, to give a smooth addition reaction to afford the free carboxyl derivative **17**. Remarkably, complete regio- and stereocontrol was observed in the formation of the linear derivative (for some examples of the addition of ketene bis(timethylsilyl) acetals to aldimines see ref. (11)) **17**. The following Heck-type cyclization reaction, performed this time without protecting the carboxyl group, afforded the target intermediate **12** in 70% yield from **7**, which was then transformed into the final *N*-aryl amide derivatives as previously described.

In conclusion an efficient preparation of THQ derivatives, in six-steps from the commercially available aniline derivative **4**, was developed. Following this versatile synthetic approach an in depth and rapid exploration of the SAR of this class of glycine antagonists was performed.[2]

Experimental section

All the reactions were performed in oven-dried glassware under a positive pressure of nitrogen. Unless otherwise noted, materials were obtained from commercial suppliers and used without further purification. THF was distilled from Na–benzophenone ketyl; CH_2Cl_2 was distilled from P_2O_5; anhydrous DMF and CH_3CN were purchased from Aldrich. ^{1}H NMR spectra were recorded on Bruker AC 200F (200 MHz), Varian VXR5000S (300 MHz), and Varian Unity (400 MHz) spectrometers. The data are reported as follows: chemical shift in ppm from the internal standard Me_4Si on δ scale, multiplicity (b = broad, s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet), and coupling constants (Hertz). IR spectra were recorded on a Bruker IFS48 instrument. Mass spectra were recorded on a Fisons VG-4 instrument in FAB mode. Melting points (mp) are uncorrected and were determined on a Buchi 510 apparatus. Analytical thin layer chromatography (TLC) was performed on Merck silica gel 60 F254 plates (0.25mm); all R_f values are determined visualizing all spots with UV light (254 nm) and (or) phosphomolybdic acid solution. Flash chromatography was performed on Merck silica gel 60 (230–400 mesh).

4-Chloro-1-iodo-2-nitrobenzene (5)

To a suspension of 5-chloro-2-nitroaniline (10 g, 58 mmol) in H_2SO_4 (100 mL, 37% soln) at 0°C, a solution of $NaNO_2$ (5.2 g, 75 mmol) in H_2SO_4 (40 mL, 37% soln) was carefully added. To the resulting mixture, PPA (80 mL) was added and the reaction mixture was allowed to warm at room

temperature and stirred for 3 h. The solution was poured into crushed ice and urea was added until gas evolution ceased. The resulting solution was treated with an aqueous solution of KI (13.5 g, 81.2 mmol) and heated at 70°C for 2 h. To the red solution, brine (100 mL) was added followed by AcOEt (300 mL). The organic layer was separated, washed with brine, dried over anhydrous Na_2SO_4 and concentrated in vacuo. The crude mixture was purified by flash chromatography (eluant cyclohexane–AcOEt, 98:2) to afford the title compound as a yellow solid (13.5g, 82%), mp 55–57°C. IR (Nujol): 1535, 1354 cm^{-1}. ^1H NMR ($CDCl_3$, 300MHz) δ: 7.98 (d, 1H), 7.80 (d, 1H), 7.28 (dd, 1H). MS *m*/*e*: 283 (M + 1), 237, 110. Anal. calcd. for $C_6H_3ClINO_2$: C 25.42, H 1.07, Cl 12.51, I 44.77, N 4.94; found: C 25.38, H 1.05, Cl 12.49, I 44.69, N 4.91.

5-Chloro-2-iodoaniline (6)

To a solution of intermediate **5** (13 g, 45.8 mmol) in 95% EtOH (80 mL) and glacial AcOH (80 mL), Fe powdered (11 g, 196 mmol) was added. The reaction mixture was heated at 100°C for 1 h then diluted with a saturated solution of $NaHCO_3$ and extracted with AcOEt. The organic layer was washed with brine, dried over anhydrous Na_2SO_4 and evaporated in vacuo to give a crude residue which was purified by flash chromatography (cyclohexane–AcOEt, 90:10) to afford the title compound as a pale yellow solid (9.5g, 82%), mp 75–77°C. IR (Nujol): 3468, 3371, 1592 cm^{-1}. ^1H NMR ($CDCl_3$, 300MHz) δ: 7.5 (d, 1H), 6.70 (d, 1H), 6.5 (dd, 1H), 4.20 (bs, 2H). MS *m*/*e*: 253, 126. HRMS calcd. for C_6H_5ClIN: 252.915529; found: 252.915582.

Ethyl-(5-chloro-2-iodophenylimino)acetate (7)

A solution of ethyl glyoxylate (4.78 mL, 23.67 mmol) in dry toluene (20 mL) was refluxed for 30 min in the presence of a Dean–Stark apparatus. Then, a solution of 5-chloro-2-iodoaniline (5 g, 19.7 mmol) in dry toluene (40 mL) and anhydrous $MgSO_4$ (15 g) was added. The resulting mixture was heated at 120°C for 2 h. After filtration, the solvent was evaporated in vacuo to afford the title compound as an yellow oil (6.4 g, 100%). IR (Nujol): 1744 cm^{-1}. ^1H NMR (DMSO, 300 MHz) δ: 7.92 (d, 1H), 7.89 (s,1H), 7.33 (d, 1H), 7.15 (dd, 1H), 4.33 (m, 2H), 1.31 (t, 3H). MS *m*/*e*: 338 (M + 1).

(±)-Ethyl-2-(5-chloro-2-iodo-phenylamino)-pent-4-enoate (8)

To intermediate **7** (3 g, 8.9 mmol) dissolved in dry CH_2Cl_2 (50 mL)) was added $TiCl_4$ (1.07 mL, 9.79 mmol) at –78°C. Then, tributylallyltin (3.3 mL, 10.7 mmol) was dropped into the reaction mixture and the resulting suspension was stirred for 1 h. A saturated solution of NH_4Cl was added and the mixture was extracted with AcOEt. The organic layer was washed with brine, dried over anhydrous Na_2SO_4, and evaporated in vacuo. The crude residue was purified by flash chromatography (cyclohexane–AcOEt, 95:5) to afford the title compound as a colourless oil (2.97g, 88%). IR (neat): 3373, 1739, 1572 cm^{-1}. ^1H NMR (DMSO, 300 MHz) δ: 7.57 (1H, d), 6.49 (1H, dd), 6.45 (1H, dd), 5.79 (1H, m), 5.24 (1H, dd), 5.25 (1H, dd), 4.83 (1H, d), 4.25 (2H, q), 4.13 (1H, m), 2.66 (2H, m), 1.3 (3H, t). MS *m*/*e*: 380 (M + 1), 379, 338. Anal. calcd. for $C_{14}H_{17}ClINO_2$: C 42.72, H 4.35, Cl 9.01, I 32.24, N 3.56; found C 42.61, H 4.28, Cl 8.95, I 32.15, N 3.48.

(±)-Ethyl-2-(5-chloro-2-iodo-phenylamino)-4-oxo-butyrrate (9)

Ozone was bubbled through a solution of intermediate **8** (2 g, 5.3 mmol) in dry CH_2Cl_2 (50 mL) at –78°C until a brick-red color appeared (20 min). PPh_3 (1.5 g, 5.7 mmol) was added and the mixture stirred at room temperature for 2 h. The solvent was evaporated in vacuo and the crude residue was purified by flash chromatography (cyclohexane–AcOEt, 80:20) to afford the title compound as a white foam (1.4 g, 69%). IR (Nujol): 3372, 1738, 1732cm^{-1}. ^1H NMR ($CDCl_3$, 300 MHz) δ: 9.80 (t, 1H), 7.57 (d, 1H), 6.55 (d, 2H), 6.51 (dd, 1H), 4.99 (d, 1H), 4.46 (m, 1H), 4.24 (q, 2H), 3.08 (m, 2H), 1.28 (t, 3H). MS *m*/*e*: 382 (M + 1). Anal. calcd. for $C_{13}H_{15}ClINO_3$: C 39.47, H 3.82, Cl 8.96, I 32.08, N 3.54; found: C 39.41, H 3.79, Cl 8.91, I 32.01, N 3.49.

(±)-Ethyl-6-(*E*)-5-(5-chloro-2-iodo-phenylamino)-hex-2-enoate-1-*tert*-butylester (10)

(*tert*-Butoxycarbonylmethylene)triphenyl phosphorane (1.38 g, 3.67 mmol) was added to a solution of intermediate **9** (1.4 g, 3.67 mmol) in dry toluene (30 mL). The mixture was refluxed for 1 h, then the solvent was evaporated in vacuo and the crude residue was purified by flash cromatography (cyclohexane–AcOEt, 90:10) to afford the title compound as a yellow oil (1.58 g, 90%). IR (Nujol): 3371, 1732, 1628 cm^{-1}. ^1H NMR (DMSO, 300 MHz) δ: 7.65 (d, 1H), 6.73 (m, 1H), 6.70 (d, 1H), 6.53 (dd, 1H), 5.8 (d, 1H), 5.21 (d, 1H), 4.59 (m, 1H), 4.19 (m, 2H), 2.78 (m, 2H), 1.43 (s, 9H), 1.19 (t, 3H). HRMS calcd. for $C_{18}H_{23}ClINO_4$: 479.036038; found: 479.036030.

(±)-Ethyl-(*E*)-7-chloro-4-*tert*-butoxycarbonylmethylene-1,2,3,4-tetrahydro-quinoline-2-carboxylate (11)

$Pd(PPh_3)_4$ (0.12 g, 0.10 mmol) and TEA (0.35 mL, 2.50 mmol) were added to a solution of compound **10** (1 g, 2.08 mmol) in dry DMF (50 mL). The mixture was heated to 120°C for 2 h. A saturated solution of NH_4Cl was added and the resulting mixture was extracted with AcOEt. The organic layer was washed with brine, dried over anhydrous Na_2SO_4 and the solvent was evaporated in vacuo. The crude residue was purified by flash chromatography (cyclohexane–AcOEt, 90:10) to afford the title compound as a yellow oil (0.62 g, 85%). IR (Nujol): 3371, 1724, 1707 cm^{-1}. ^1H NMR (DMSO, 300 MHz) δ: 7.65 (d, 1H), 7.26 (d, 1H), 6.69 (m, 2H), 6.29 (d, 1H), 4.29 (m, 1H), 4.12–3.94 (m, 2H), 4.01 (m, 1H), 2.68 (m, 1H), 1.44 (s, 9H), 1.14 (t, 3H). Anal. calcd. for $C_{18}H_{22}ClNO_4$: C 61.45, H 6.30, Cl 10.08, N 3.98, O 18.19; found: C 61.42, H 6.28, Cl 10.01, N 3.95.

(±)-Ethyl-(*E*)-7-chloro-4-carboxymethylene-1,2,3,4-tetrahydro-quinoline-2-carboxylate (12)

Intermediate **11** (0.6 g, 1.7 mmol) was dissolved in HCOOH (10 mL, 96%) and stirred at room temperature for 24 h. The reaction mixture was then evaporated in vacuo to give the title compound (0.5 g, 100%) as a yellow solid, mp 172–174°C. IR (Nujol): 3379, 1715, 1685cm^{-1}. ^1H NMR (DMSO, 300 MHz) δ: 12.1 (s, 1H), 7.45 (d, 1H), 6.94 (d, 1H), 6.77 (d, 1H), 6.53 (dd, 1H), 6.16 (s, 1H), 4.18 (m, 1H), 4.12–3.8 (m, 2H), 3.86 (dd, 1H), 2.96 (m, 1H), 1.17 (t, 3H).

(±)-Ethyl-(*E*)-7-chloro-4-(pyridin-2-ylsulfanylcarbonyl-methylene)-1,2,3,4-tetrahydro quinoline-2-carboxylate (13)

PPh_3 (1 g, 3.81 mmol) and 2,2′-dipyridyldisulphide (0.84 mg, 3.81 mmol) were added to a solution of intermediate **12** (0.45 g, 1.52 mmol) in dry THF (25 mL). The resulting solution was stirred at room temperature for 3 h, then diluted with a 0.5 M NaOH. The mixture was extracted with AcOEt. The organic layer was washed with brine, dried over anhydrous Na_2SO_4 and the solvent was evaporated in vacuo. The crude residue was purified by flash chromatography (cyclohexane–AcOEt, 70:30) to afford the title compound as a yellow solid (0.4 g, 67%), mp 163–165°C. IR (Nujol): 3380, 1716, 1677cm^{-1}. ^{1}H NMR (DMSO, 300 MHz) δ: 8.60 (m, 1H), 7.90 (m, 1H), 7.67 (d, 1H), 7.64 (m, 1H), 7.44 (d, 1H), 7.15 (d, 1H), 6.83 (d, 1H), 6.71 (s, 1H), 6.58 (dd, 1H), 4.21–4.00 (m, 3H), 3.70 (dd, 1H), 3.03 (m, 1H), 1.10 (t, 3H). (±)-Ethyl-(*E*)-7-chloro-4-(phenylcarbamoylmethylene)-1,2,3,4-tetrahydroquinoline-2-carboxylate (14)

Aniline (0.134 mL, 1.465 mmol) was added to a solution of intermediate **13** (0.38 g, 0.977 mmol) in dry toluene (10 mL) and the mixture was refluxed for 2 h. The yellow solution was allowed to warm to room temperature and the solid formed was filtered and washed with Et_2O to afford the title compound as a pale yellow solid (0.28 g, 78%), mp 198–200°C. IR (Nujol): 3386, 3316, 1723, 1651cm^{-1}. ^{1}H NMR (DMSO, 300 MHz) δ: 10.02 (bs, 1H), 7.63 (d, 1H), 7.38–7.30 (m, 4H), 7.03 (d, 1H), 6.89 (d, 1H), 6.79 (s, 1H), 6.62 (dd, 1H), 6.48 (s, 1H), 4.18 (m, 1H), 4.14–3.89 (m, 2H), 3.95 (dd, 1H), 3.08 (m, 1H), 1.08 (t, 3H). MS *m*/*e*: 371 (M + 1), 341, 297, 278, 204. Anal. calcd. for $C_{20}H_{19}ClN_2O_3$: C 64.78, H 5.16, Cl 9.56, N 7.55; found: C 64.75, H 5.18, Cl 9.55, N 7.55.

(±)-(*E*)-7-chloro-4-(phenylcarbamoylmethylene)-1,2,3,4-tetrahydroquinoline-2-carboxylic acid, sodium salt (15)

NaOH (1 M, 0.57 mL, 0.57 mmol) was added to a solution of intermediate **14** (0.2 g, 0.5476 mmol) dissolved in EtOH–MeOH (95:5) (5 mL). After 4 h at room temperature, the solvent was evaporated and the solid treated with Et_2O (5 mL) to give a pale yellow solid (0.175 g, 90%), mp 198–200°C. IR (Nujol): 3180–3500, 1651, 1599 cm^{-1}. ^{1}H NMR (DMSO, 300MHz) δ: 10.89 (bs, 1H), 7.70 (d, 2H), 7.30 (d, 1H), 7.27 (t, 2H), 6.99 (t, 1H), 6.77 (d, 1H), 6.42 (dd, 1H), 6.37 (s, 1H), 6.25 (s, 1H), 3.42–3.25 (m, 2H), 2.69 (dd, 1H). MS *m*/*e*: 365 (M + 1), 343. HRMS calcd. for $C_{18}H_{14}ClN_2O_3Na$: 365.066890; found: 365.066950.

6-Ethyl-(±)-(*E*)-5-(5-chloro-2-iodo-phenylamino)-hex-2-endioic acid (17)

$TiCl_4$ (0.22 mL, 2 mmol) was added dropwise at –78°C to a solution of intermediate **7** (3.4 g, 10 mmol) in dry CH_2Cl_2 (50 mL). Then, a solution of 1,1-bis(trimethylsilyloxy)-buta-1,3-diene (2.5 g, 12 mmol) in dry CH_2Cl_2 (10 mL) was slowly added and the resulting solution was stirred for 1 h. A saturated solution of NH_4Cl was added and the mixture was extracted with AcOEt. The organic layer was washed with brine, dried over Na_2SO_4, and evaporated in vacuo to give crude intermediate **17** (4 g) used without any purification in the next step. IR (Nujol): 3371, 3400–2500, 1732–1698 cm^{-1}. ^{1}H NMR (DMSO, 300 MHz) δ: 12.27 (bs, 1H), 7.65 (d, 1H), 6.76 (d, 1H), 6.68 (d, 2H), 6.53 (dd, 1H), 6.16 (s, 1H), 5.88 (dd,1H), 4.98 (d, 1H), 4.57 (m, 1H), 4.15 (m, 2H), 2.75 (m, 2H), 1.19 (t, 3H). MS *m*/*e*: 424 (M + 1), 338.

Ethyl-(±)-(*E*)-7-chloro-4-carboxymethylene-1,2,3,4-tetrahydro-quinoline-2-carboxylate (12)

$Pd(PPh_3)_4$ (2.3 g, 2 mmol) and TEA (4.18 mL, 30 mmol) were added to a solution of intermediate **17** in DMF (100 mL). The mixture was heated to 120°C for 2 h. Then, a saturated solution of NH_4Cl was added and the resulting mixture was extracted with AcOEt. The organic layer was washed with brine, dried over anhydrous Na_2SO_4, and the solvent was evaporated in vacuo. The crude residue was purified by flash chromatography (cyclohexane–AcOEt, 50:50) to afford the title compound **12** as a yellow oil (2.06 g, 70% from intermediate **7**).

On diastereomeric perturbations

Christian Girard and Henri B. Kagan

Abstract: For more than a century, organic chemists have been playing in Nature's laboratory. Their first goal was to understand the organization of atoms in the living matter and then to reproduce it by synthesis. This quest gave rise to several efficient techniques to synthesise molecules; many of them still in use nowadays, as such or with little modifications. Even at the beginning of this journey, the chemists discovered that their methods were far from being as efficient as the ones used by Nature to produce substances. The natural molecules were chiral and there was even an enantiomer that was produced over the other;a lesson of perfection. This was another challenge for the chemists and they succeeded by first developing techniques to separate enantiomers and more recently reagents and reactions to produce only the desired stereoisomer. Asymmetric synthesis uses chiral auxiliaries, reagents or catalysts to create chirality into the desired compound. The common perception, as a minimum condition, was that the chiral substance used to perform such a transformation has to be of the highest enantiomeric purity to obtain a very high selectivity. The relation between the enantiomeric excesses of the chiral substance and the product was suggested to be linear. But there were a lot of surprises left in the laboratory. Who would have thought that an impure substance could give an enantiomeric excess in the product higher than its own purity? The molecules are acting in different ways in solution. Self-organization and aggregation can arise depending on the structure of the substance or its environment. Such phenomenon can generate deviations to the awaited behaviour of the molecules that can be observed in many cases. This article tries to present some examples of the historical reports of such peculiar behaviours, their influence on physico-chemical properties and the final discovery of the now well-known nonlinear effects in asymmetric synthesis.

Key words: asymmetric synthesis, diastereomeric interactions, nonlinear effects.

Résumé : Depuis plus d'un siècle, les chimistes organiciens ont investi le laboratoire de Mère Nature. Leur objectif initial était de déterminer la structure des molécules isolées d'organismes vivants et de la reproduire par voie de synthèse. Ils ont donc dû développer nombre de techniques pour réaliser la synthèse de molécules, plusieurs d'entre elles très efficaces et étant encore utilisées de nos jours sous leur forme originelle ou d'une variante. Cependant les chimistes ont rapidement découvert que la Nature leur donnait une leçon de perfection. Les molécules isolées étaient chirales et, qui plus est, un énantiomère était produit préférentiellement. Les chimistes ont donc dû relever un autre défi qui fut dans un premier temps la mise au point des techniques permettant de séparer les deux énantiomères produits par leurs méthodes. Ils surent par la suite développer des réactions et des réactifs sélectifs permettant de n'obtenir que le stéréoisomère désiré. La synthèse asymétrique était née utilisant auxiliaires, réactifs ou catalyseurs chiraux pour induire la chiralité dans la substance à synthétiser. On croyait alors que la pureté énantiomérique de la substance utilisée pour effectuer une transformation de ce type était un gage minimum d'obtention d'une haute énantio sélectivité. La relation entre les excès énantiomériques de la substance chirale et du produit de la réaction était considérée linéaire et personne ne remettait en question ces hypothèses. Mais c'était sans compter sur les surprises que réserve le laboratoire. Qui eut cru qu'une substance chirale énantiomériquement impure puisse donner naissance à un produit dont la pureté énantiomérique est supérieure à la sienne? Les molécules peuvent se comporter de différentes façons en solution. Des phénomènes d'autoassociation et d'agrégation, qui sont fonction de la structure de la molécule et de son environnement, sont monnaie courante. Ils produisent en général des perturbations du système qui font en sorte que les molécules sont loin de se comporter de façon idéale. Cet article essaie de retracer quelques-uns des rapports historiques ayant mis à jour de tels phénomènes, leur influence sur des propriétés physico-chimiques et la découverte plus récente de ce nous connaissons maintenant sous le nom d'effets non-linéaires en synthèse asymétrique.

Mots clés : synthèse asymétrique, interactions diastéréoisomériques, effets non-linéaires.

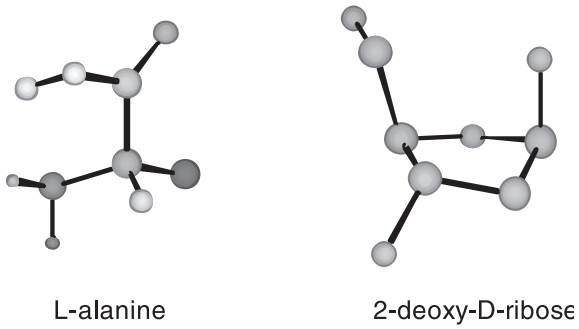
Fig. 1. Enantiomers; mirror images of the same spatial arrangement in a molecule.

1. Introduction

Organic chemistry; the Art of Synthesis of molecules issued from and for the living. The organic chemist is an artist playing with atoms, reagents, molecules… a never-ending quest to find the perfect transformation that will ultimately lead to "gold" from carbon, hydrogen, oxygen, nitrogen and other simple elements… he is an alchemist.

Historically, organic chemistry started by the synthesis of simple molecules, natural or artificial, to try to reproduce Nature's perfection. Urea, dyes, salicylic acid and its derivatives, sugars, antibiotics, perfumes, and poisons; the molecular complexity was increasing and with it the tools to synthesise molecules. And this journey was creating fields that were to become independent sciences: pharmacology, biochemistry, molecular biology to name a few.



Nowadays, these sciences reach the conclusion that all the knowledge on molecules, their structure, synthesis, behaviour and activity are all intimately linked; expressions of the subtle ways the organic substances exist and interact.

This paper does not intend to be an history of organic chemistry or of asymmetric synthesis. It will try to present only a few historical hints of unexpected molecular behaviours chemists encountered while developing organic synthesis and moreover the field dealing with enantiomers and generation of chirality. The observation of these perturbations ultimately led to the discovery of non-linear effects in asymmetric synthesis.

2. The mirror image

Since the work of Biot (1), the organic chemist found out that some molecules can rotate the plane of polarized light. Furthermore, molecules having the same composition but different spatial arrangements of the constituents have different properties. Some are only geometrical isomers. But what if the substituents are arranged in a way that two molecules have the same spatial distribution differing only by the fact that they are the exact mirror image one to another? They become what we call *enantiomers*; mirror replicas of the same compound that are not superimposable (Fig. 1).

Fig. 2. Nature and her selection of L-amino acids and D-sugars.

They are therefore defined as *chiral* molecules. Each enantiomer has the exact same influence on polarized light but in the exact opposite direction. They are optically active substances (2). One of the enantiomers rotates the plane of polarized light to the right and is called the *dextro isomer* (+) (or *d*) the other one rotating the light to the left being called the *lævo isomer* (–) (or *l*).[2] That is the only difference in their physico-chemical properties. Mix them together in equal amounts and the rotation becomes equal to zero, the effect of each enantiomer being cancelled by the other. This mixture was called *racemic* and could not be separated by classical methods based on the differences of physico-chemical properties.

With the help of polarimetry, chemists found out that living systems were quite selective in their production of chiral substances. The products were enantiomerically pure and some classes of compounds has the same sense of chirality. Proteins are all constituted of L-amino acids and nucleic acids of D-sugars. Life is based on a twist in chirality that selected only one (3) (Fig. 2).

While Nature was producing only one enantiomer, the first syntheses were giving racemic mixtures. Following Pasteur's discoveries, organic chemists found the possibility to separate the two produced enantiomers by using a now well-known technique; the resolution of racemic mixtures (4). This method is based on the use of a chiral molecule, enantiopure, which can form complexes or salts with the product to resolve (2, 5). The chirality of the resolving agent gave the opportunity to form preferentially an association with only one enantiomer of the racemic mixture, one of the *diastereomeric* complexes being then separated by crystallization (Fig. 3).

The diastereomeric complexes, $d\cdot X^*$ vs. $l\cdot X^*$ for example, are not mirror images. They thus possess different physico-chemical properties which allowed the chemists to effect the separation of enantiomers. This method of separation is therefore based on the difference in properties between the complex and the remaining enantiomer and the preference of a diastereomeric complex with the resolving agent over the other.

[2] Remember that the old notation *d* and *l* refers to the sense of deviation of polarized light by the molecule (to the right or the left) in specific rotation while D and L refer only to the configuration of the last carbon in the Fischer projection by comparison with glyceraldehyde (D on the right side, L on the left side). There is no direct relationship between the two descriptors since, for example, a L product can be dextrorotatory (*d*).

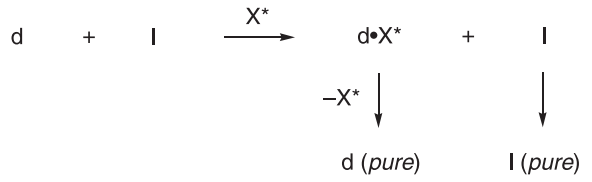
Fig. 3. Resolution of a racemic (*d* + *l*) mixture using a chiral resolving agent (X*).



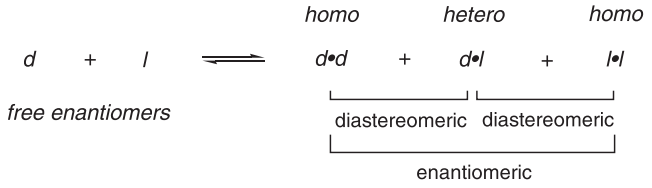


Fig. 4. Association of enantiomers to form two homodimers and a heterodimer.

But what happens if the enantiomers can interact together, without any external influence, if they can form pairs or higher associated species. Lets consider the case of enantiomers able to form dimers by association through weak interactions; like hydrogen bonding for example. If we consider all the possible permutations in a racemic mixture, we should expect the formation of three different couples (Fig. 4).

The two homodimers (*d*·*d* and *l*·*l*) are in fact enantiomers and will not differ in properties. However, the heterodimer (*d*·*l* or *l*·*d* which is the same) is in a diastereomeric relationship with the homo ones. The properties of this hetero combination will therefore be quite different to the properties of the homo associations.

In regard to these associations of enantiomers, the chemists became interested in studying the behaviour of such diastereomeric species. As we will see in the following sections, the evaluation of the properties of enantiomeric relations gave rise to numerous interesting observations.

3. Pasteur and tartaric acid

One of the most widely studied natural products, thanks to the French wine industry, was tartaric acid and its derivatives (Fig. 5). Pasteur first discovered, by studying the optical rotation of solutions of tartaric acid, that the natural acid was dextrorotatory while the synthetic one was not deviating the light having thus a zero value of rotation (6). The natural substance was optically active, the artificial one was racemic.

But this was only the beginning of Pasteur's work that laid the foundations of stereochemistry (2, 7, 8) and later the elucidation of the geometry of the carbon atom (9). The most important discovery was done by a combination of observation and serendipity. From a solution of the sodium ammonium salt of racemic tartaric acid, Pasteur was able to manually separate enantiomorphous crystals according to their hemihedral morphology (Fig. 6).

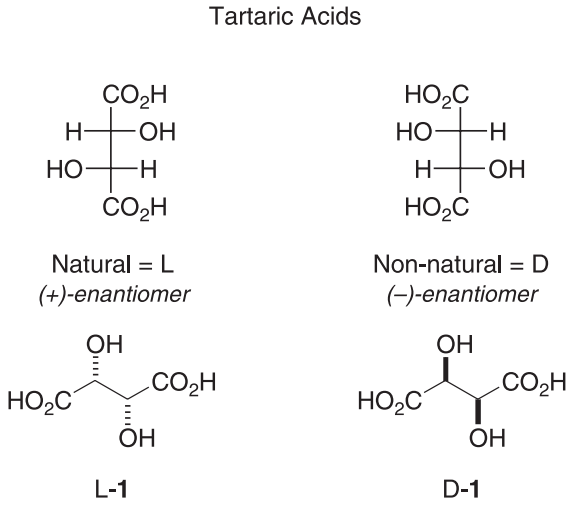
The separated acid salt crystals were then hydrolyzed back to the acid and gave two samples of tartaric acid; one which had the same rotation as the natural acid (+) and the other one with the exact opposite rotation (–). The sodium ammonium tartrate is a rare example of those crystals in which the enantiomers prefer to crystallize separately by forming conglomerate, allowing a spontaneous resolution (for a recent highlight on this still up to date subject, see ref. (10)).

This discovery triggered the examination of enantiopure substances and racemic mixtures to evaluate the possibilities of stereoselective associations of enantiomers in solid, liquid state and solution.

Pasteur observed in 1850 that the mixing of two concentrated solutions of both enantiomers of tartaric acid was somewhat exothermic (11). This was later confirmed by measurement by Berthelot and Jungfleisch (12). The heat evolved was calculated to be of 4.4 kcal mol^{-1} and was suggested to be the consequence of the formation of a "solid racemate" (13).[3]

Several other properties of the solutions of tartaric acid were then measured. Small differences were found for the densities of pure and racemic acids (5×10^{-4} for 25%

Fig. 5. The tartaric acid under its natural configuration (L-**1**) and the nonnatural enantiomericform (D-**1**).



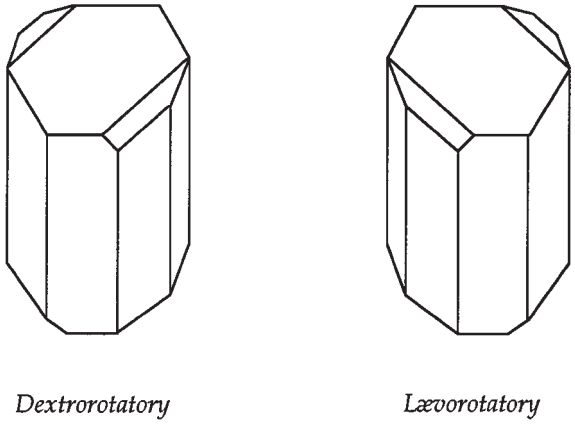


Fig. 6. The two enantiomorphous crystals of sodium ammonium tartrate.

[3] A much smaller value was later found by Amaya and co-workers (13). Measurements made at the end of the 19th century were very dependent on the sensitivity and the efficiency of the instrument and sometimes even on the purity of the substances.

Table 1. Melting point and solubility in water of the pure tartaric acid enantiomers (L and D) and the racemate (DL).

Tartaric acid	Melting point (°C)	Water solubility (g/100 mL at 20°C)
L	168–170	139
DL	206	20.6
D	168–170	139

aqueous solutions) by Perkin and Marchlewski (14*a*, *b*) that were said to be the consequence of a stronger association between the D·L pair, thus more stable, than for the homochiral associations (D·D, L·L). The same conclusion was reached by Raoult (15) while evaluating the molecular masses by cryoscopy and by Stewart (16) by ultraviolet spectroscopy.

The most spectacular experiment in this series is the one by Cotton (17) who mixed two light-blue solutions of D- and L-copper potassium tartrate to give a deep-blue one. The explanation was that there was formation of racemates in solution. Wilkinson (18) for whom the colour change could be attributed to the polymerization degree of the diasteromeric complexes, confirmed the idea that there was diastereomeric associations.

There are also huge differences in the melting points and solubilities (19) of the pure and racemic tartaric acids (Table 1). These values can suggest that the DL pair is much more stable than the LL or DD ones, by its higher fusion temperature and sparing solubility in water.

Many other substances were studied to evaluate their behaviour as pure enantiomers and racemates. Molecules from natural sources like terpenes, hydroxy acids, amines, and alcohols were examined similarly, but unfortunately the differences were very small or the measurements difficult to reproduce (20; only a few studies of enthalpic properties of diastereomeric salts were conducted but the subject is still of interest, see ref. (21*a*, *b*)).

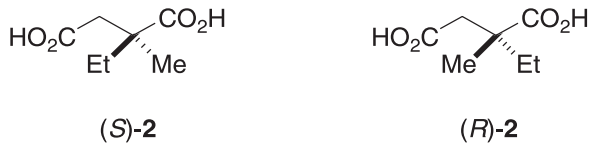
During the last century, the study of racemic and enantiopure substances continued. This gave rise to a better understanding of their properties but also ultimately led to modern stereochemistry, the relationships between isomers, the ways to separate or produce them, and to wonderful total syntheses of natural products. But much later, more than one century after the first studies of Pasteur and others, a new field of organic chemistry emerged as mature, the enantioselective synthesis.

Since enantioselective reactions were not and are not always totally selective, the organic chemists developed methods to assess the enantiomeric purity of the synthesised substances. But the question rose once again: what if the substance is not racemic nor enantiomerically pure; what if there was interactions in solution? Would these associations have any influence on the analysis technique that was used?

4. The enantiomerically impure

One of the first exhaustive studies of the influence of the enantiomeric purity on the characterization of a substance is the one of 1-ethyl-1-methylsuccinic acid **2** (20, 22). Horeau et al. studied in great details the behaviour of this compound starting by the investigation of the observed variation of specific rotation of the enantiopure diacid **2** as a function of its concentration (Fig. 7).

Fig. 7. The two enantiomers of 1-ethyl-1-methylsuccinic acid (**2**).



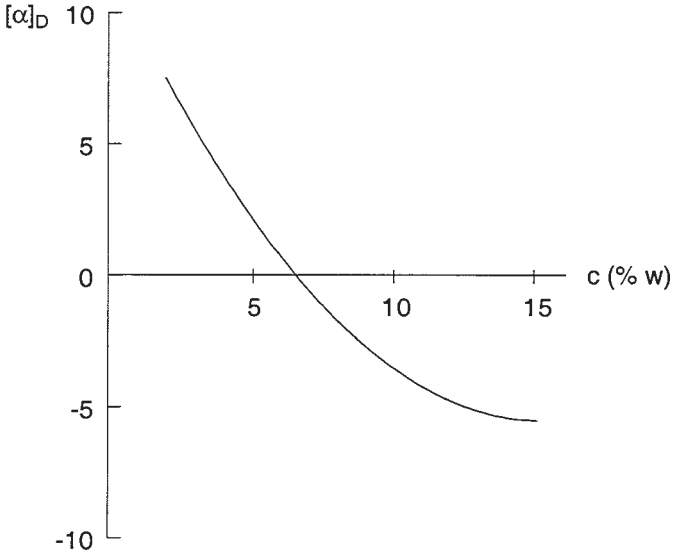


Fig. 8. Variations of specific rotation ($[\alpha]_D$) of (*S*)-1-ethyl-1-methylsuccinic acid (*S*)-**2** as a function of its concentration (*c*, % $^{w}/_{w}$) in chloroform.

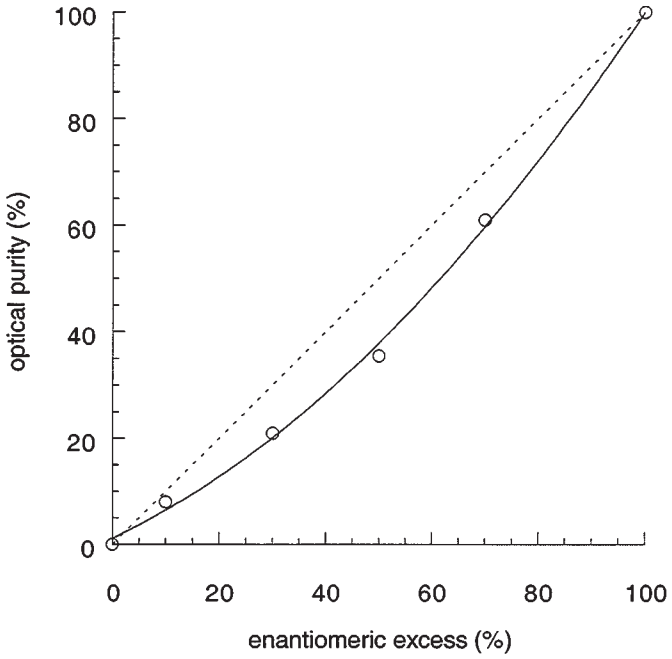
This was true in chloroform as it can be seen in Fig. 8. At low concentration, the acid (*S*)-**2** is dextrorotatory while at high concentration it is lævorotatory. The specific rotation of the enantiomerically pure substance even becomes equal to zero at 6.3% w, as if it was racemic!



The same behaviour was observed in dichloromethane and for the corresponding α-isopropyl-α-methyl diacid. However, when the rotation was measured in polar solvents like ethyl and methyl alcohol, pyridine, diglyme, or acetonitrile, the phenomenon just disappeared. This first observation was suggestive of association of the molecules of the diacid **2** in solution, probably by hydrogen bonding, which had a striking influence on the specific rotation. The use of polar solvents was breaking down the oligomeric structures and giving a perfectly normal reading.

If there were interactions between the molecules of an enantiopure substance in solution, Horeau et al. (20, 22) were then interested in studying the cases where the enantiomeric excess (ee)[4] of that substance was different from 0% (racemic) and 100% (enantiomerically pure). The first thing they discovered was that the relation between the

[4] The enantiomeric excess being defined as the difference between the quantities of each enantiomer on their sum, for a *R*-rich substance ee = $(R - S)/(R + S)$.

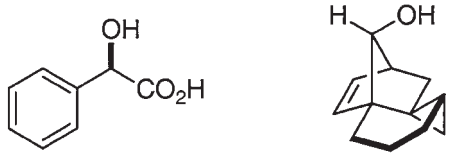
Fig. 9. Optical purity of 1-ethyl-1-methylsuccinic acid (**2**) as a function of its enantiomeric excess (ee). Dotted line: the awaited linear relationship. Plain line and open circles: experimental curve.

enantiomeric excess and the optical purity[5] of 1-ethyl-1-methylsuccinic acid (**2**) was not a linear one (Fig. 9).

If no interactions between the molecules in chloroform were taking place, there would not have been any difference between the optical purities and enantiomeric excesses and their relation should have been linear. In the present case, the measured optical purity is always lower than the ee. The molecules in solution are interacting and lowering the specific rotation of the sample.

Horeau and Guetté (20) interpreted the phenomenon in the following way: "Les écarts à la linéarité dans les variations du pouvoir rotatoire en fonction de la composition énantiomérique seraient dus aux différences de stabilité des associations diastéréoisomères des antipodes en solution."[6]

Furthermore, they were able to determine the heat generated while mixing two solutions of both enantiomers of **2** to be of 140 J mol^{-1} at 25°C for a concentration of 0.8% in chloroform. The explanation becomes more precise with the hypothesis that since the mixing of the two enantiomers was exothermic, the stability of the D–L interactions was greater than those of D–D and L–L. Vapour pressure osmometry indicated that the molecules exist as dimers, even in very dilute solutions and readily forms oligomeric species as the concentration increases.



Their study was completed by recording the proton nuclear magnetic resonance spectra (NMR) of 1-ethyl-1-methylsuccinic acid (**2**) at three different enantiomeric purities in deuteriochloroform (Table 2).

They analyzed the α-methylene AB signal and discovered that there were only small differences between the enantiomerically pure and the racemic ($\Delta\delta$). The spectrum of the sample of 50% ee gave however two different sets of signals. Once again the differences were explained by the stability of the diastereomeric species in solution.

Table 2. ^{1}H-NMR of 1-ethyl-1-methylsuccinic acid (**2**) in $CDCl_3$ at 100 MHz at various enantiomeric excess (ee) showing the chemical shift of the 2-methylene hydrogens (δ_1, δ_2), difference between the values ($\Delta\delta$), and the coupling constant (J_{AB}).

Diacid **2**	δ_1 (ppm)	$\Delta\delta_1$ (ppm)	δ_2 (ppm)	$\Delta\delta_2$ (ppm)	J_{AB} (Hz)
100% ee	2.514	0	2.349	0	16.5
50% ee	2.504	0.010	2.335	0.014	16.9

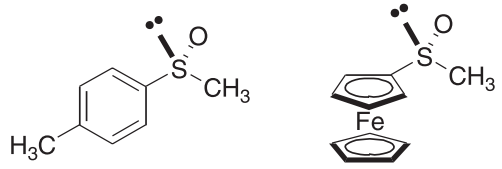
Fig. 10. Mandelic acid (**3**) and the borneol (**4**) exhibit spontaneous resolution during sublimation when partially resolved.

(*R*)-(–)-isomer **3** (–)-isomer **4**

Similar differences in NMR spectra was already observed by Uskokovic and co-workers (23) while analyzing samples of racemic and natural (enantiomerically pure) dihydroquinine. In this case, the phenomenon was called self-induced nonequivalence (24) and was also encountered sometimes while working molecules capable of autoassociation like amino acids, ureas and stannoxanes, to name a few (25).

The surprises uncovered by these different groups were not the last. While the racemic mixtures were inseparable, reports of enhancement of enantiomeric excesses of partially resolved chiral compounds began to appear. Nowadays, it is well known that the ee of a compound could sometimes be increased by fractional crystallization.

Enantiomeric enrichment can also occur using other purification methods. One of the first examples was the use of sublimation which was then exemplified in several other cases (26). Compounds like mandelic acid (**3**) and the borneol **4** (27) exhibit such a partial resolution when subjected to sublimation (Fig. 10).



The associations herein existing gave rise to the preferential sublimation of an enantiomerically enriched solid while the one left is sometimes racemic.

This type of associations can also lead to a enantiomeric fractionation during chromatographic separation on an achiral stationary phase (like silica or alumina of an enantiomerically impure compound). Several examples have been published for compounds like amino acid derivatives, peptides, natural and biologically active substances (28), and more recently (Fig. 11) for many sulphoxides like (*R*)-methyl

[5] The optical purity is evaluated by the ratio of the measured $[\alpha]_D$ of the sample on the $[\alpha]_D$ of the enantiomerically pure substance.
[6] Differences to the linearity as a function of the ee are due to diastereomeric associations of the enantiomers in solution.

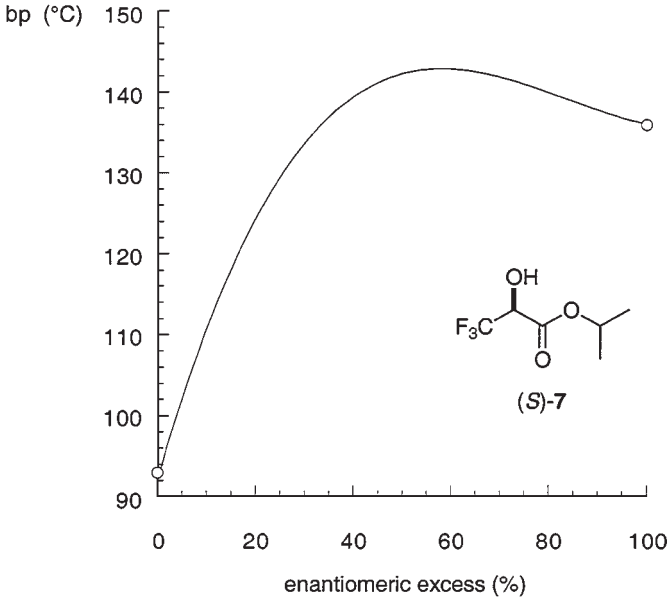
Fig. 11. (*R*)-methyl *p*-tolyl sulphoxide (**5**) and (*R*)-ferrocenyl methyl suphoxide (**6**) can be enantiomerically enriched on achiral stationary phases.

5 **6**

p-tolyl sulphoxide (**5**) and (*R*)-ferrocenyl methyl sulphoxide (**6**) (29).

In the case of the sulphoxides **5** and **6**, the first fractions being eluted are always enriched (10–20% ee higher) and the last ones of lower ee than the initial ee of the injected sulphoxide. In those cases, the explanation can be that either there is stronger association of the racemate on the stationary phase or that the sulfoxides are associated in the mobile phase, thus giving rise to the formation of diastereomeric species of different mobilities.

The last, but not the least example of resolution occurred during the distillation of a trifluorolactate (30*a*). There are striking differences in the boiling point of isopropyl trifluorolactate (**7**) depending on its enantiomeric excess. Under atmospheric pressure, the racemate boiled at 93°C while the enantiomerically pure compound (*S*)-**7** had a boiling point of 136°C, a difference of 43°C! (Fig. 12).



The resolution in this particular case is surprising and hardly understood. The possibility of fractionation by distillation of a mixture of enantiomers has already been discussed, but all attempts had thus so far failed (20).

The authors suggested that the origins of the phenomenon was based on the presence of hydrogen bonding and a possible participation of fluorine atoms in the discrimination process, since the nonfluorinated ethyl lactate has a constant boiling point (154°C). But the exact origin by which the effect is taking place is not quite clear and could also be attributed to resolution through a sublimation and (or) crystallization process (30*b*).

Selective associations between enantiomers were thus once again the cause of this phenomenon and all those discussed before. The interest of Pasteur for enantiomers and their interactions was the focal point where started all the investigations on their behaviour. The study of racemate and enantiomers is still going on today, but during more than a century a lot was discovered. Nowadays, we know more about the ways they interact between them or with chiral molecules. We know how to resolve them. We also developed techniques for the analysis and separation of enantiomers using chiral stationary phases. We know how to evaluate enantiomeric purity by chiral chromatography or numerous other methods.

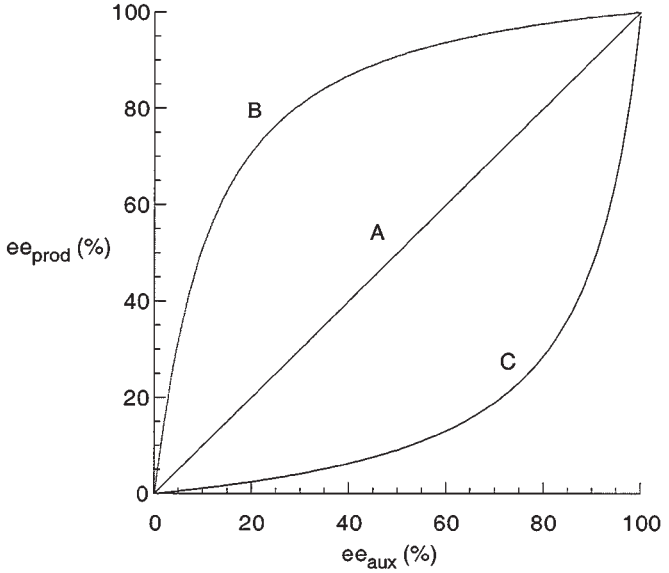
But all the knowledge we were able to obtain from the study of the molecules themselves was the result of a simple goal. The organic chemist was looking to synthesise chiral molecules. He wanted to be able to effect a transformation and to obtain only the desired stereoisomer with the highest

Fig. 12. Boiling point (bp) of isopropyl trifluorolactate (**7**) as a function of its enantiomeric excess (ee).

selectivity. This never ending quest gave rise to the Art of asymmetric synthesis.

Asymmetric synthesis is giving access to chiral molecules using the principle of stereoselection. This is possible by the use of another chiral molecule which is readily available from natural sources or simple transformations on natural or chiral synthetic products. Resolution is still in use for the preparation of such synthetic precursors but we can also take advantage of the chirality found in Nature to prepare precursors for our tools and even for natural products synthesis itself (31).

These chiral compounds and their chirality were and are used in enantioselective transformations as, for example, auxiliaries grafted on the molecule to transform, chiral additives to protonate selectively, or catalysts to form transient species, and ligands to chelate organometallic reagents or metals to catalyze a reaction. They are the source of the stereoselectivity, the molecules having the stereochemistry dictated by the chiral compound used in such a transformation.



But what are those chiral auxiliaries used in asymmetric synthesis? There are mainly natural products like amino acids and their derivatives, amino alcohols, tartaric acid or esters, alkaloids, as well as artificial compounds like atropoisomeric biphenyls and binaphthyls and other related structures. Almost all the chiral molecules used are capable of interactions between themselves as such or when chelating ions or metals.

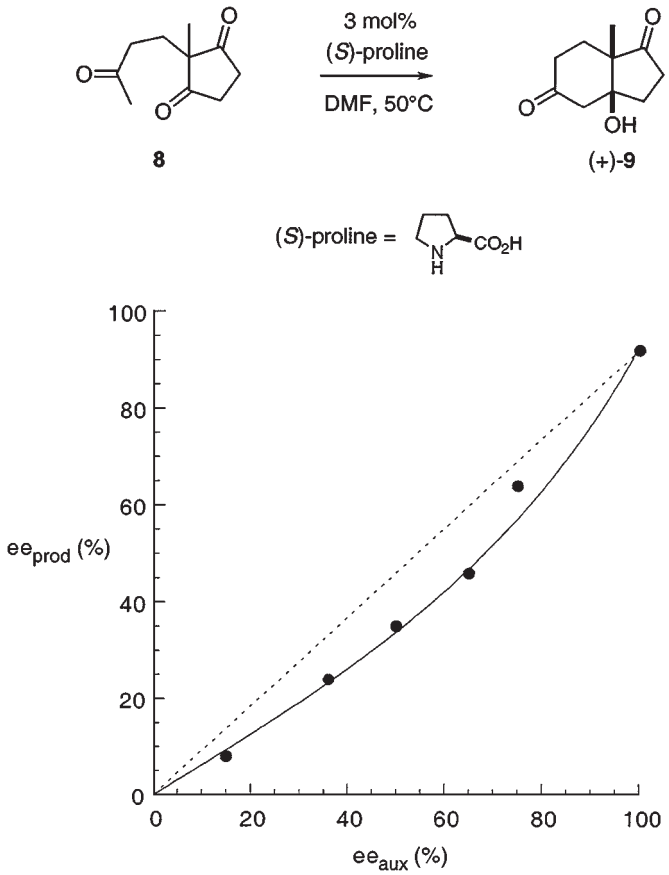
5. Nonlinear effects

In 1986, Kagan and co-workers (32) started to study asymmetric synthesis using a nonenantiomerically pure chiral catalyst or auxiliary. They questioned the well accepted hypothesis that the ee of an asymmetric synthesis product (ee_{prod}) was proportional to the ee of the chiral auxiliary (ee_{aux}) used, according to a linear relationship. The

© 2000 NRC Canada

Fig. 13. Enantiomeric excess of the product of an asymmetric reaction (ee_{prod}) as a function of the enantiomeric excess of the chiral auxiliary (ee_{aux}) showing the linear relationship (**A**) and positive (**B**) and negative (**C**) nonlinear effects.

usual way to obtain an approximation of the experimental ee (ee_{prod}) when using a nonenantiopure auxiliary was to used the simple formulæ: $ee_{prod} = ee_o \times ee_{aux}$ with the term ee_o being the ee_{prod} reached using the enantiopure chiral auxiliary under the same reaction conditions.



But this simple equation was to be used with caution. A caveat was that this approximation was based on the fact that each enantiomer of the chiral auxiliary was acting independently. But what if there was the type of interactions we previously encountered? There will be an influence on the outcome of the asymmetric synthesis and the results obtained to be different from the linear prediction; the relationship between the enantiomeric excesses will then behave nonlinearly.

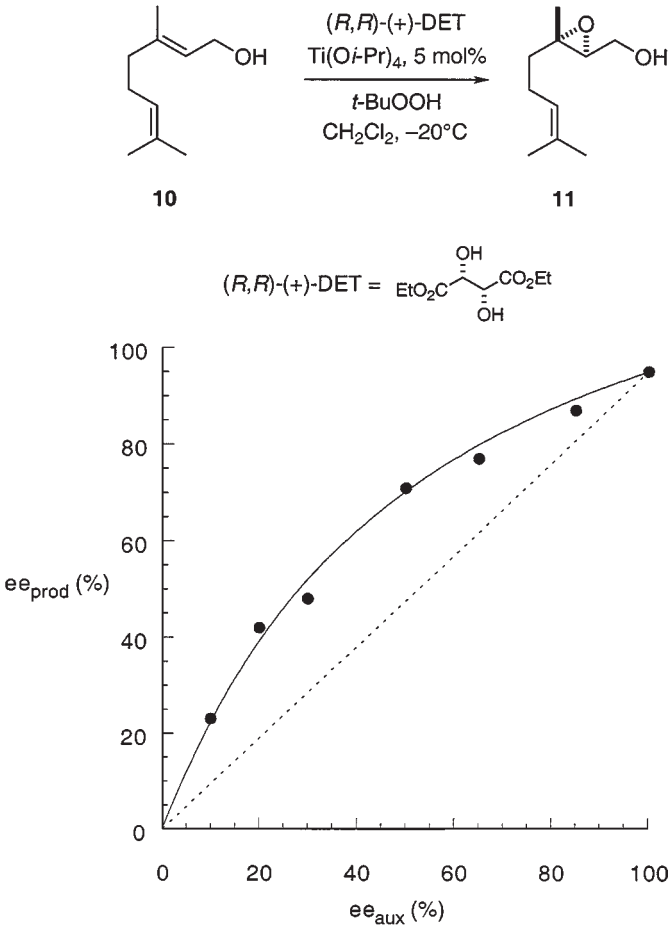
The nonlinearities should be the result of interaction between the enantiomers of the chiral catalyst, generating diastereomeric perturbations of the system. This may occur by autoassociation, or association around a matrix, of the chiral species. The perturbations will then add a multiplication factor to the previous equation, a quantification of the deviation from linearity of the relation between ee_{prod} and ee_{aux}.

The graphical representation in Fig. 13 gives a better way to see the effects and influence of such associations during asymmetric reactions. The theoretical linear relationship, for an ee_o = 100%, is given by curve A. Since the linearity should not be followed in systems when interactions between the catalytic species occurs, there are two possibilities. The multiplication factor can increase the awaited ee_{prod} and a plain curve above the line (curve B) called positive nonlinear effect or (+)-NLE should be obtained. If the effect is giving a product with an ee_{prod} lower than expected, a curve below the line (curve C), a negative nonlinear effect or (–)-NLE, will then be drawn.

To test their hypothesis, Kagan et al. (32) studied three different systems. The first reaction was the asymmetric

Fig. 14. Hajos–Parrish–Wiechert reaction of the triketone **8** catalyzed by (*S*)-proline. A slight (–)-NLE between the ee of proline (ee_{aux}) and the ee of bicyclic product **9** (ee_{prod}) is observed.

Robinson annulation, or Hajos–Parrish–Wiechert reaction (33), of the triketone **8** using catalytic amounts of (*S*)-proline (Fig. 14). The ee of (*S*)-proline (ee_{aux}) was plotted as a function of the ee of the produced *cis*-ketol **9** (ee_{prod}), and a slight (–)-NLE was observed in this case.



Investigations of the mechanism of this reaction by Agami (34*a*, *b*) demonstrated that two steps took place before cyclization can occur: chiral enamine formation followed by complexation of the intermediate with a molecule of catalyst. This was confirmed by a kinetic model based on a second-order reaction dependence on proline. The (–)-NLE was explained by the fact that heterochiral complexes reacted twice as fast as the homochiral complexes.

For the second reaction, another behaviour was recorded during Katsuki-Sharpless' (35) epoxidation of geraniol (**10**). A positive nonlinear effect is taking place when varying the ee of (*R*,*R*)-(+)-diethyl tartrate {(*R*,*R*)-(+)-DET} used as the catalyst (Fig. 15). The enantiomeric excess of the resulting epoxide **11** (ee_{prod}) was indeed greater than expected when plotted as a function of the ee of (+)-DET (ee_{aux}). A less reactive dimeric heterochiral species, thus more stable, than its homochiral counterparts was suggested to be the cause of the (+)-NLE, since some racemic DET will be retained in the inactive meso complex.

This hypothesis was compatible with the Sharpless mechanism of asymmetric epoxidation, which indicates the

© 2000 NRC Canada

Fig. 15. Sharpless' epoxidation of geraniol **10** catalyzed by (*R*,*R*)-(+)-DET. The reaction shows a (+)-NLE between the ee of DET (ee_{aux}) and the ee of epoxide **11** (ee_{prod}).

intervention of a dimeric complex, introducing two tartrate units in the active species.

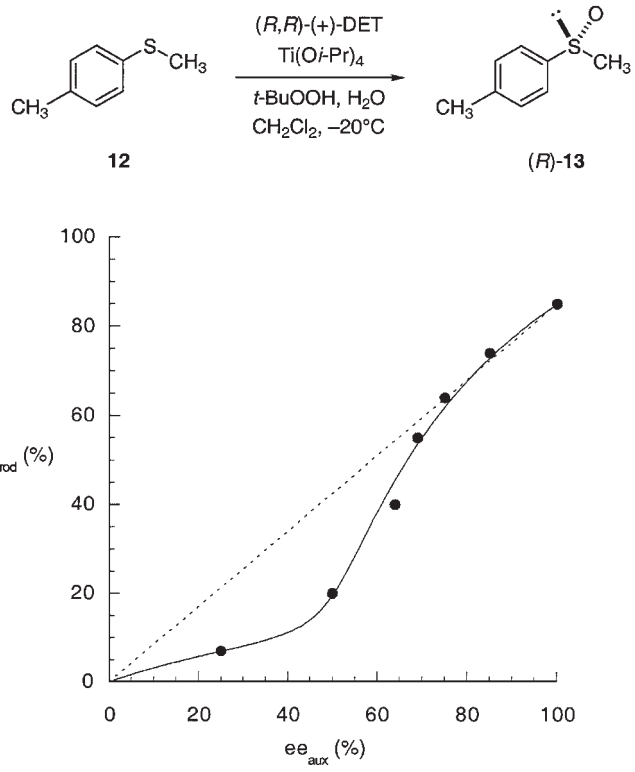
For the last reaction, the authors tested their water-modified Sharpless reagent for asymmetric oxidation of sulphides by hydroperoxides (36). Oxidation of methyl *p*-tolyl sulphide **12** into sulphoxide **13** gave a NLE which was quite different from the previous results (Fig. 16).

The relation between the ee's is clearly a (–)-NLE but this effect is taking place up to a value of 70% ee of diethyl tartrate. The linear relationship is then prevailing until 100% ee. This perturbed behaviour is indicative of a complicated structure for the water-modified reagent.

These first experiments were a revelation in the behaviour of mixtures of enantiomeric reagents or catalysts. They were an indication of subtle interactions taking place in their solutions with participation of diastereomeric species. Furthermore, the analysis of the perturbations generated by mixing various amounts of enantiomers on the enantioselectivity of the reaction was also giving information about the reaction itself.

Mathematical models were developed by Kagan and coworkers (37) that helped to understand and to quantify the nonlinear effect phenomenon. Most of the NLEs to be reported could be explained based on the "ML_2 model" (Fig. 17). The chiral substance (L) used for an asymmetric

Fig. 16. Kagan's asymmetric oxidation of sulphide **12** into sulphoxide **13**. A (–)-NLE between the ee of DET (ee_{aux}) and the one of sulphoxide **13** (ee_{prod}) is observed up to 70% ee DET.



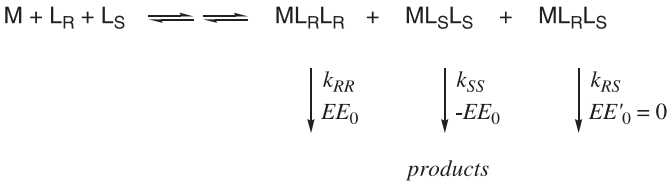


Fig. 17. Kagan's ML_2 model for nonlinear effects.

transformation is usually interacting with a metallic centre (M) to form the reagent or catalyst. If both enantiomers are present (L_R and L_S), the species formed will be constituted of homo (ML_RL_R and ML_SL_S) and hetero (ML_RL_S) complexes.

These complexes will then react to give the desired product, the homo complexes giving the products with opposite configuration while the hetero one will give the racemate. If there is one of the complex type which is more stable than the other, a NLE will be observed. If the meso ML_RL_S species is more reactive, there will more racemate produced and the ee lower than expected, generating a (–)-NLE. If however this meso complex is more stable, the homo species will enter the reaction cycle giving rise to a (+)-NLE since the minor enantiomer of the chiral ligand will be trapped inside the less reactive ML_RL_S species. The discussion is exactly the same if one assumes the formation of dimeric species of $(ML)_2$ type, this case being similar to diastereomeric interactions that were reported for the chiral substances alone (vide supra).

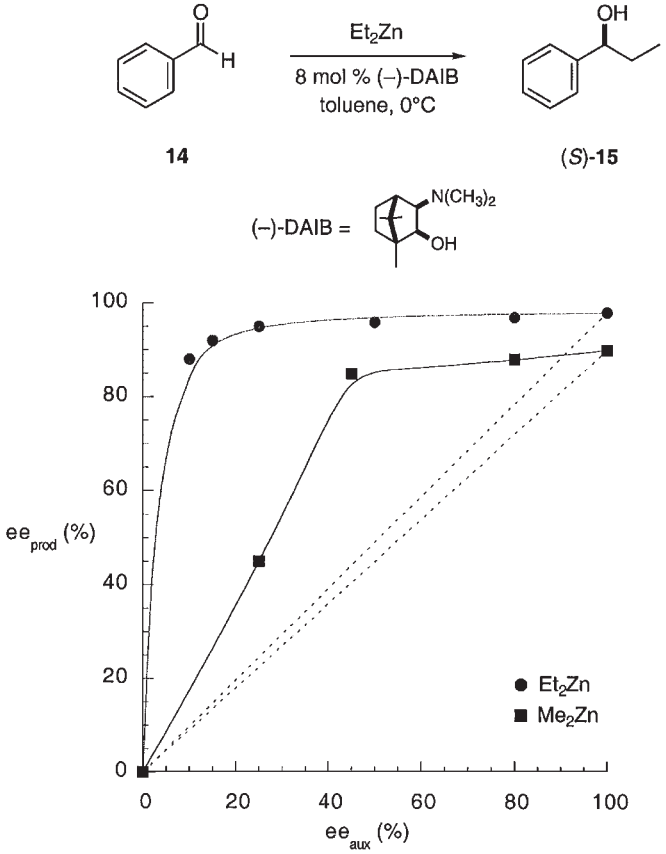
Fig. 18. Asymmetric diethylzinc (curve ●) reaction on benzaldehyde (**14**) catalyzed by DAIB leading to the alcohol **15** showing a strong (+)-NLE. A smaller effect was also observed when using Me_2Zn (curve ■).



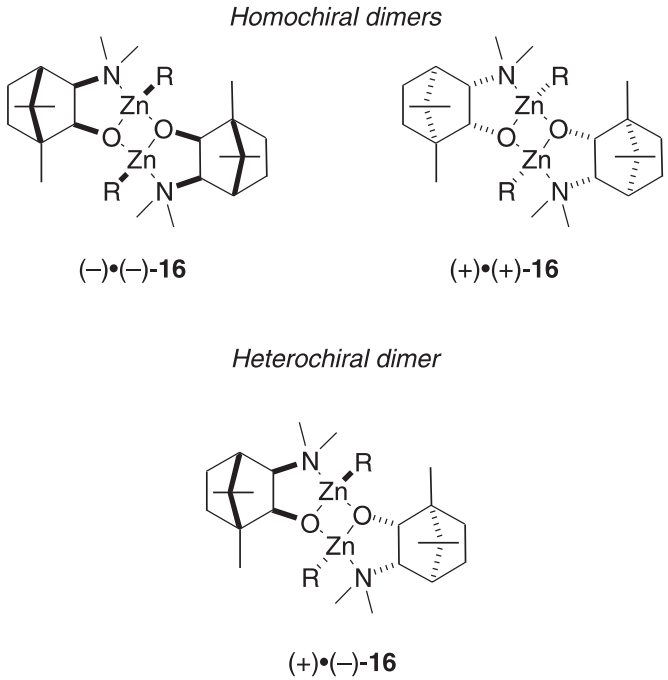


Fig. 19. Mixtures of (–)- and (+)-DAIB and dialkylzinc form enantiomeric DAIB-ZnR organometallics. The active reagent then forms homodimers (–)·(–)-**16** and (+)·(+)-**16** and the heterochiral one (–)·(+)-**16**.

It became clear that looking for non-linear effects in a given system is a probe for analysing the nature of the catalytic species involved in an asymmetric synthesis. Results emerging from the data collected were clear indications that such nonlinear effects were to be encountered in many cases. The following section will present only a few examples of nonlinear effects that were published after their initial discovery in 1986. Exhaustive recollection of NLE in asymmetric synthesis can be found in highlights and reviews on the subject (38, 39).

6. NLE, an ubiquitous phenomenon

One useful method of alkylating carbonyl compounds is the use of organozincs coupled with a catalyst which is needed to observe any reaction. During their work on alkylation of benzaldehyde (**14**) by diethylzinc, Oguni et al. (40) discovered in 1988 that a positive nonlinear effect (called *asymmetric amplification* by the authors) was present when chiral β-amino alcohols were used as catalysts.

The following year, Noyori and co-workers (41) published a detailed mechanistic study on catalysed addition of organozincs on aldehydes. They observed as well a strong (+)-NLE when using (–)-3-*exo*-(dimethylamino)isoborneol, or (–)-DAIB, in various ee's as a catalyst (Fig. 18). This effect was very impressive, the maximum enantioselectivity of the reaction being reached at very low *ee* of DAIB (curve ●). The 1-phenylpropanol (*S*)-**9** can thus be prepared with very high enantioselectivity (95% *ee*) with a very impure catalyst (15% ee). A similar but less pronounced effect was also observed when using dimethylzinc (curve ■) for the alkylation.

Noyori et al. (41) suggested that this strong (+)-NLE was due to autoassociation of the chiral reagent. The organometallic DAIB-zinc formed is undergoing dimerisation as depicted in Fig. 19. When the mixture of (–) and (+)-DAIB is used, there is formation of two types of dimeric species: the usual homochiral complexes (–)·(–)-**16** and (+)·(+)-**16** and the heterochiral one (–)·(+)-**16**.[7] The enantiomeric monomers of DAIB-ZnR (*R* = Me or Et) are herein the active reagents and each one will produce one enantiomer of the alcohol **15**.

The existence of dimeric species was confirmed by several experiments. Cryoscopic molecular weight measurements demonstrated that DAIB-ZnR was dimeric in solution. Nuclear magnetic resonance (NMR) of homochiral and heterochiral reagents gave insights on the relative stability of the dimeric organozincs. Upon addition of benzaldehyde, noticeable changes were observed in the NMR spectrum of the homochiral dimer, whereas the spectrum of the heterochiral complex remained unchanged, revealing a lower reactivity.

The differences were understood by X-ray diffraction analysis of each of the dimers obtained by reaction of dimethylzinc with the chiral ligand. The homochiral species (–)·(–)-**16** (*R* = CH_3) possess a C_2 symmetry with a Zn_2O_2 four-membered ring showing a *syn* relationship between the

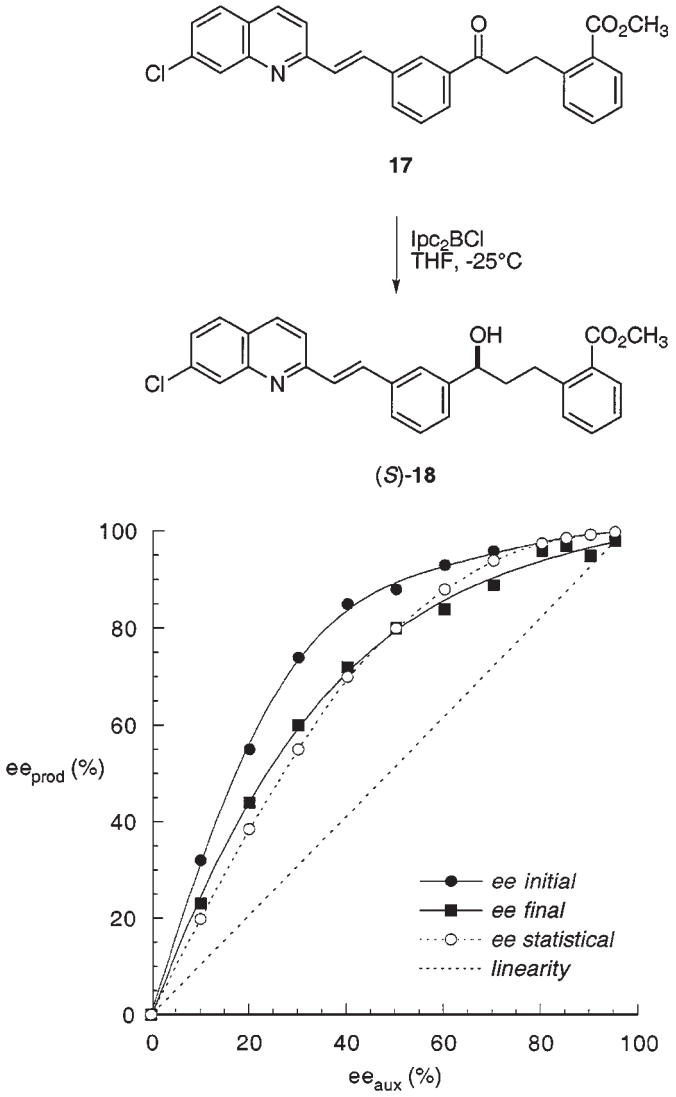
Fig. 20. Nonlinear effects during Ipc_2BCl reduction of the ketone **17**. The ee of the alcohol **18** (ee_{prod}) is higher than the ee of pinene (ee_{aux}) used to prepare the reagent at the beginning (curve ●) and the end of the reaction (curve ■). Calculated ees of **18**, based on a statistical distribution of the pinene in the reagent, are also included (curve ○).



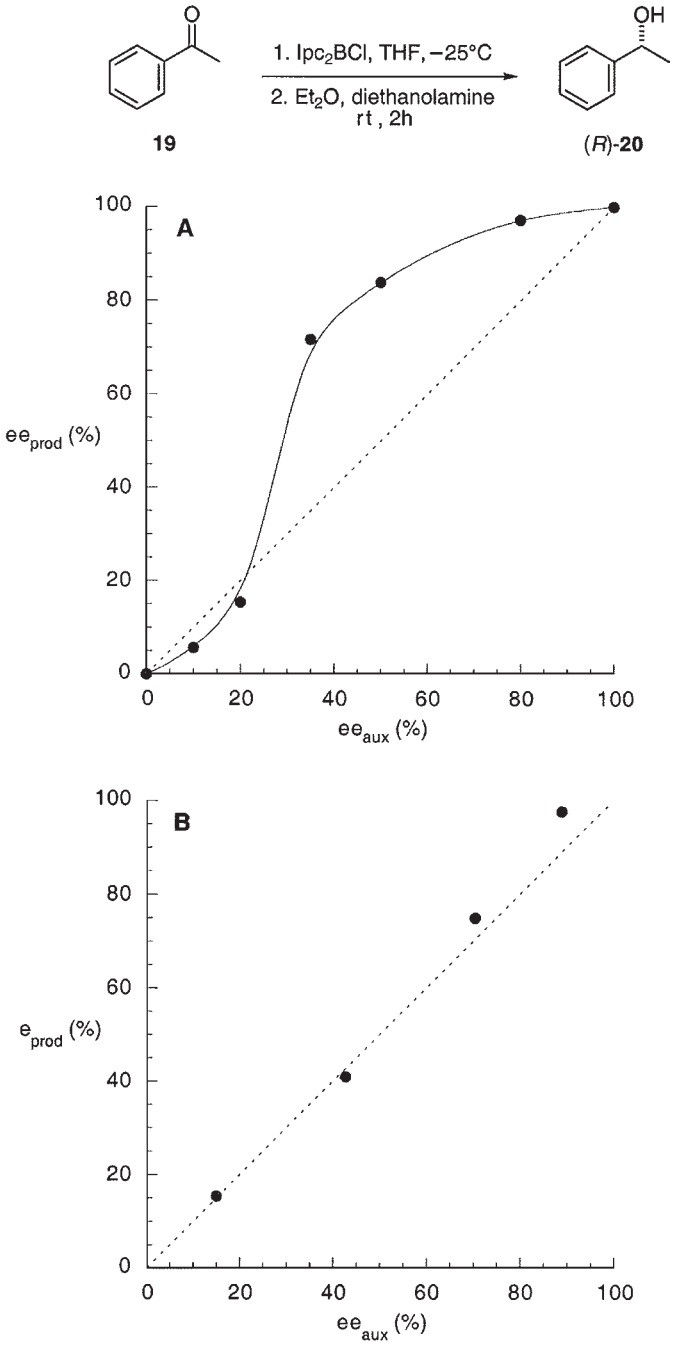


Fig. 21. Reduction of acetophenone (**19**) into chiral alcohol **20** with Ipc_2BCl. Curve **A** was obtained with the reagent prepared from pinene of various enantiomeric purity. Curve **B** was drawn from reactions using Ipc_2BCl in variable enantiomeric excesses prepared by mixing enantiomers of the reagent itself.

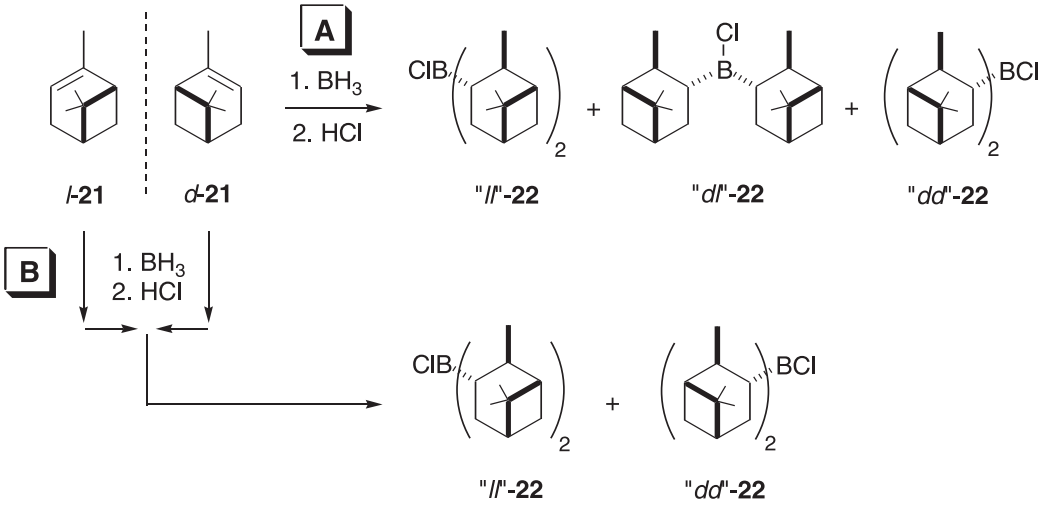

methyls borne by the zinc atoms. This ring is "*endo*-fused" relative to the DAIB-Zn system. The heterochiral dimer (+)·(–)-**16** ($R = CH_3$) also have a Zn_2O_2 cycle *endo*-fused but the methyls on metallic centres, as well as the DAIB fragments, are oriented in an *anti* fashion one to another; this feature being responsible for the greater thermodynamical stability of this dimer. This was later complemented by energetic calculations on simpler models.

Nonlinear effects were not only found in catalytic asymmetric reactions. The use of chiral reagents incorporating nonenantiopure material can also give rise to a very similar phenomenon.

One of the first examples was published in 1994 by Merck researchers (42) and regarding the asymmetric production of an alcohol, which is a useful intermediate in synthesis of a LTD_4 antagonist. The use of Brown's diisopinocampheyl chloroborane (Ipc_2BCl), prepared from (–)-α-pinene and BH_2Cl, to reduce ketone **17** into alcohol **18**, showed a nonlinear behaviour. Starting from pinene of 98% or 70% ee gave the alcohol **18** with an enantiomeric purity of 97% ee and 95% ee respectively (Fig. 20). It was hypothesized that three reagents (two homochiral and one *meso*) were present and statistically distributed, the *meso* borane being very

© 2000 NRC Canada

Fig. 22. Different methods for the preparation of Ipc_2BCl. Method **A**: from pinene (**21**) of various ee; and Method **B**: by mixing boranes of different ee. The two methods produce homoboranes *ll*–**22** and *dd*–**22**, while the heteroborane *dl*–**22** is present only in Method **A**.

sluggish to react, thus being the cause of the observed (+)-NLE.

The same system was studied in 1995 by Kagan et al. in the asymmetric reduction of acetophenone (**19**) by Ipc_2BCl (4 equiv.) using the reagent derived from (–)-α-pinene (43) and prepared accordingly to H. C. Brown procedure (44). It was shown that the way the reagent was synthesized had a great influence on the outcome of the reduction (Fig. 21). As a matter of fact, when Ipc_2BCl was prepared with pinene of various ee, a strong (+)-NLE between the ee of the alcohol **20** and the pinene one took place (curve **A**). If however the reducing agent was obtained by mixing Ipc_2BCl of different enantiomeric purities, the relation became perfectly linear (curve **B**).

The linear relationship suggested that each of the enantiomeric reagents was acting independently in the reduction process. The separate preparation of Ipc_2BCl (**22**), from enantiopure α-pinenes (**21**) gave both enantiomers *"ll"*–**22** and *"dd"*–**22**, which were then mixed in various amounts to reach the desired ee_{aux} (Method **B**, Fig. 22). Such a mixture should behave linearly since each enantiomer of the reagent is acting independently and producing an enantiomer of the alcohol **20**. In the other procedure, the reagent was obtained starting from mixtures of (–)- and (+)-α-pinene in various ees (*l*- and *d*-**21**). This method (**A**) was suggested to generate three boranes: *"ll"*–**22**, *"dd"*–**22**, and *"dl"*–**22** (Fig. 22). The (+)-NLE is in agreement with a very low reactivity of the *meso* reagent *"dl"*–**22** formed in this case which was trapping the minor enantiomer of pinene, thus increasing the effective ee of the reagent.

As an added proof, studies by the Merck group demonstrated that the ee of their reduction product was time-dependent (**18**, Fig. 20). The NLE was indeed more important at lower conversion than after completion of the reaction (45). The curves however keep the same shape during the course of the reduction; which is close to the calculated curve based on a statistical distribution of the pinene on the boron atom. Girard and Kagan (46) also published another study where the stoichiometry of Ipc_2BCl was varied. The curves had the same shape but the NLE was increasing with the amount of reductant used. These complementary results suggest that the more reactive homochiral species is giving better ee at the beginning of the reaction or by the use of a larger quantity of reagent. But as soon as the amount of this species drops the less reactive heterochiral borane becomes involved in the reduction, thus lowering slightly the ee of the product.

Apart from mechanistic interests (47), the possibility of creating a strong (+)-NLE in Ipc_2BCl reductions, allows one to avoid the use of expensive enantiopure α-pinene and to replace it with the one of ees lower than 90%.

The few reports discussed in the last sections highlighted the fact that diastereomeric interactions could lead to perturbations in the behaviour of chiral substances. The discovery of nonlinear effects while using chiral reagents, auxiliaries and catalysts was of a great importance for the understanding of enantioselective systems. They often gave the opportunity to clarify mechanisms or the nature of species involved in some enantioselective reactions.

7. Conclusion and perspectives

The examples presented in this article show how important the influence of diastereomeric perturbations may be on the properties of a chiral material or the outcome of an asymmetric synthesis. They highlight the fact that chiral molecules sometimes present a behaviour which is not the predicted one. The impact of diastereomeric associations may be beneficial, allowing resolution of enantiomers or highly selective asymmetric synthesis using a nonenantiopure chiral substance if a (+)-nonlinear effect is present. On the other hand, the same interactions can lead to the opposite phenomenon where the reaction will not be as selective as it should be, even if the chiral auxiliary is quite pure, if a (–)-NLE rules the system. The effect can be much more complex if higher aggregated species are present and a caveat should be made about empirical predictions of the selectivity of a reaction.

© 2000 NRC Canada

But the study of nonlinear effects also provides a simple and additional probe to detect and explain aggregation or self-assemblies that may arise. Furthermore, the presence of a strong asymmetric amplification could be a very useful property which allows the use of enantiomerically impure chiral auxiliaries, thus giving the opportunity to produce chiral compounds in a faster and cheaper way. It also paves the way to the possibility to build some autocatalytic systems with autoinduction (48*a–c*; for a mathematical model of autoinduction, see ref. (48*d*)). These systems could be synthetically useful or can suggest additional models for prebiotic generation of optical activity on earth (49).

The basic concepts which are the roots of the nonlinear effects in enantioselective reactions should apply as well to kinetic resolution (50), diastereoselective reactions, the use of pseudo-enantiomeric (51) and diastereomeric (52) catalysts in enantioselective synthesis.

The diastereomeric perturbations are thus a long time companion of the organic chemist. Sometimes hidden, a few being uncovered during the short history of organic chemistry, these effects are nowadays coming out in many cases using chiral substances (during the preparation of this manuscript, a short historical review on "NLE" has been published, see ref. (53)). Reports on the interactions between hetero and homo species formed by the mirror images will for sure continue to exert a delightful fascination in the future.

Solid phase assisted synthesis of HIV-1 protease inhibitors. Expedient entry to unsymmetrical substitution of a C_2 symmetric template

Karin Oscarsson, Björn Classon, Ingemar Kvarnström, Anders Hallberg, and Bertil Samuelsson

Abstract: A solid phase synthesis has been developed leading up to unsymmetrical HIV-1 protease inhibitors that are not readily available by conventional solution phase chemistry (**18a–g)**. To prepare these compounds the hydroxyl group of (1*S*,2*R*)-(–)-*cis*-1-phthalimido-2-indanol (**3**) was coupled to a Merrifield resin via a dihydropyrane linker. Cleavage of the phthalimido protecting group and reaction of the liberated amine with the bis-activated symmetrical diacid **15** resulted in the resin bound amide **16**. Coupling of **16** with amino acids and amines followed by hydrolysis produced the desired unsymmetrical products **18a–g** from which potent HIV-1 protease inhibitors were identified, e.g., **18e** (k_i = 0.1 nM), **18a** (k_i = 0.2 nM) and **18c** (k_i = 2 nM).

Key words: HIV, inhibitor, protease, solid phase.

Résumé : On a mis au point une synthèse en phase solide qui permet d'obtenir des inhibiteurs non symétriques de protéase HIV-1 (**18a–g**) qu'il est difficile d'obtenir par la chimie conventionnelle en solution. Dans cette synthèse, on couple le groupement hydroxyle du (1*S*,2*R*)-(–)-*cis*-1-phtalimido-indan-2-ol (**3**) à une résine de Merrifield à l'aide d'une liaison avec un dihydropyrane. Après clivage du groupe phtalimido protecteur et réaction de l'amine libérée avec le diacide symétrique **15** doublement activé, on obtient l'amide **16** lié à la résine. Le couplage de **16** avec des acides aminés ou avec des amines suivi d'une hydrolyse permet d'obtenir les produits non symétriques désirés **18a–g** à partir desquels il a été possible d'identifier de puissants inhibiteurs de protéase de l'HIV-1, par exemple **18e** (k_i = 0,1 nM), **18a** (k_i = 0,2 nM) et **18c** (k_i = 2 nM).

Mots clés : HIV, inhibiteur, protéase, phase solide.

[Traduit par la Rédaction]

Introduction

The human immunodeficiency virus (HIV) has been identified as the etiologic agent of AIDS (1, 2). The HIV-1 protease is a member of the aspartic protease family of enzymes (3–5), producing essential structural and functional viral proteins by proteolytic processing of the *gag*- and *gag-pol* viral gene products (6, 7). Inhibition of the HIV-1 PR have been shown to lead to the inactivation of HIV-1 (4, 8–10). Notably, protease inhibitors have shown clinical efficacy and there are presently five protease inhibitors approved by the FDA for the treatment of HIV-1 infection: saquinavir, ritonavir, indinavir, nelfinavir, and amprenavir (11, 12). Whereas these inhibitors effectively reduce the plasma viral load in infected individuals (11), the rapid turnover of HIV-1 and the high frequency of mutations in the HIV genome eventually results in the selection of mutant strains and in development of clinical resistance (5, 13–15). Moreover, the high cost of therapy precludes the widespread use of the currently approved HIV-1 protease inhibitors. Not withstanding the progress achieved to date there is thus a pressing need for the development of new and cost-effective HIV-1 protease inhibitors.

We recently reported on the design, synthesis, and antiviral activity of new carbohydrate based C_2-symmetrical protease inhibitors e.g., compounds **1** and **2** (Table 1) (16) which are readily prepared in three steps from commercially available starting materials. However, to prepare unsymmetrical inhibitors based on the C_2-symmetric core template (Fig. 1), a new synthetic procedure had to be developed, as treatment

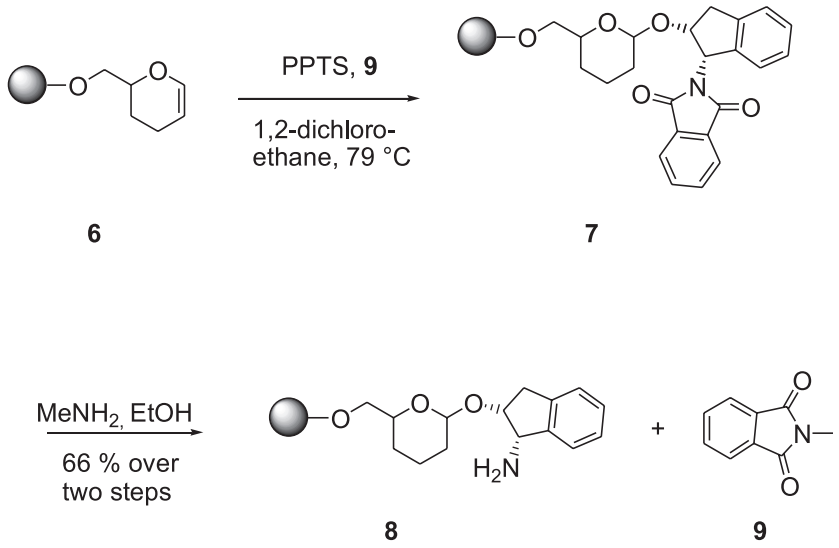
of either the bislactone (**10**) or the activated L-mannaric acid (**15**) with amines at various conditions preferentially gives the symmetrical products with only minor amounts of the monosubstituted product being present in the reaction mixture at any given time. We now report on the use of solid phase synthesis to prepare unsymmetrical protease inhibitors based on the previously disclosed C_2-symmetric core template (16). The amino indanol **3** has been shown by others (17–19) and us (16) to be an excellent *P*2/*P*2′ ligand for the *S*2/*S*2′ pockets of the HIV-1 protease. Thus in the present work the amino indanol *P*2 residue (**3**) has been kept constant while the *P*2′ residue has been varied using parallel synthesis (Fig. 1). The protected amino indanol **5** was coupled to a THP linker (20) on a Merrifield resin (21), followed by deprotection of the phthalimido group liberating

Figure 1. Unsymmetrical inhibitors, A = Amines.

the free amino function which was reacted with the bis-activated L-mannaric acid (**15**) resulting in the resin bound monoactivated amide **16**. Coupling of **16** with a selection of amines, followed by hydrolysis gave the desired products **18a**–**g** and **1**. Not withstanding this selectivity, a minor amount of the symmetrical inhibitor **1** was formed from "in-land" cross- coupling as evidenced by analysis of the products formed in the reaction. Notably the present solid phase chemistry methodology opens up for further developments of this class of compounds using combinatorial chemistry (22, 23). The compounds produced were screened for HIV-1 protease inhibition and for anti HIV-1 activity in a cell culture assay.

Results and discussion



Chemistry

The phthalimido derivative **5** was prepared in two steps by reacting compound **3** with phthalic anhydride in the presence of triethylamine in methanol followed by pyridine – acetic anhydride to give **4** in 83% yield. Deacetylation with sodium methoxide in methanol–dichloromethane gave **5** in 65% yield (Scheme 1). The protected amino indanol **5** was coupled to the solid support 3,4-dihydro-2*H*-2-ylmethoxymethyl polystyrene (**6**) in 1,2-dichloroethane using pyridinium *p*-toluenesulfonate (PPTS) (24) as a catalyst to give **7** (Scheme 2) (22). The phthalimido protecting-group was thereafter cleaved off using methylamine in ethanol for 16 h to give the free amine **8** and the liberated *N*-methyl phthalimide (**9**) in solution. The loading onto the solid support was calculated to be 66% based on the recovery of **9**.

Initial attempts to react the bislactone (**10**) (16) (lactone ring opening) with the free amino group on the solid support **8** failed to give satisfactory results due to unexpected low reactivity under standard reaction conditions (dichloromethane, reflux). Instead an alternative route was investigated

Scheme 2. Coupling of protected (1*S*,2*R*)-(–)-*cis*-1-amino-2-indanol to Merrifield resin.

employing the bissuccinimidyl ester (**15**) (16) for which a new and improved synthetic route was developed. Benzylated bislactone (**10**) (16) was thus reacted with methylamine catalyzed by 2-hydroxypyridine to give bisamide (**11**) in 87% yield (Scheme 3). Use of 2-hydroxypyridine (25) as a catalyst for this reaction gave the highest yields due to suppression of a β-elimination side reaction. The diol in compound **11** was protected using 2,2-dimethoxypropane in acetone containing camphorsulfonic acid to give **12** in 85% yield (16). The corresponding dicarboxylic acid (**14**) was prepared in essentially quantitative yield by reacting compound **12** with dinitrogen tetraoxide (26) and anhydrous sodium acetate in dichloromethane (27, 28) to provide the bis-[*N*-nitrosoamide] (**13**), which was hydrolyzed with lithium hydroxide and hydrogen peroxide (29, 30) to furnish the dicarboxylic acid (**14**). Activation of **14** with *N*,*N*-disuccinimidyl carbonate delivered the corresponding activated bissuccinimidyl ester (**15**) in 95% yield (16).

The amino indanol on the solid support (**8**), was reacted with compound **15** to give the monoamide **16** (Scheme 4) and subsequent coupling of **16** with a series of amines (A = amine, Table 2) gave the unsymmetrical products **17a**–**g** as well as the symmetrical product **17h** linked to solid support. Hydrolysis with 2.3 M HCl in methanol produced compounds **18a**–**g** together with the symmetrical inhibitor **1**. The yields of pure products (**18a**–**g**) over the three steps, based on the loading of the solid support, ranged from 17–47%. Approximately 4% yield of symmetrical inhibitor **1** isolated by chromatography, was formed in each reaction (Table 2).

HIV-1 protease inhibition

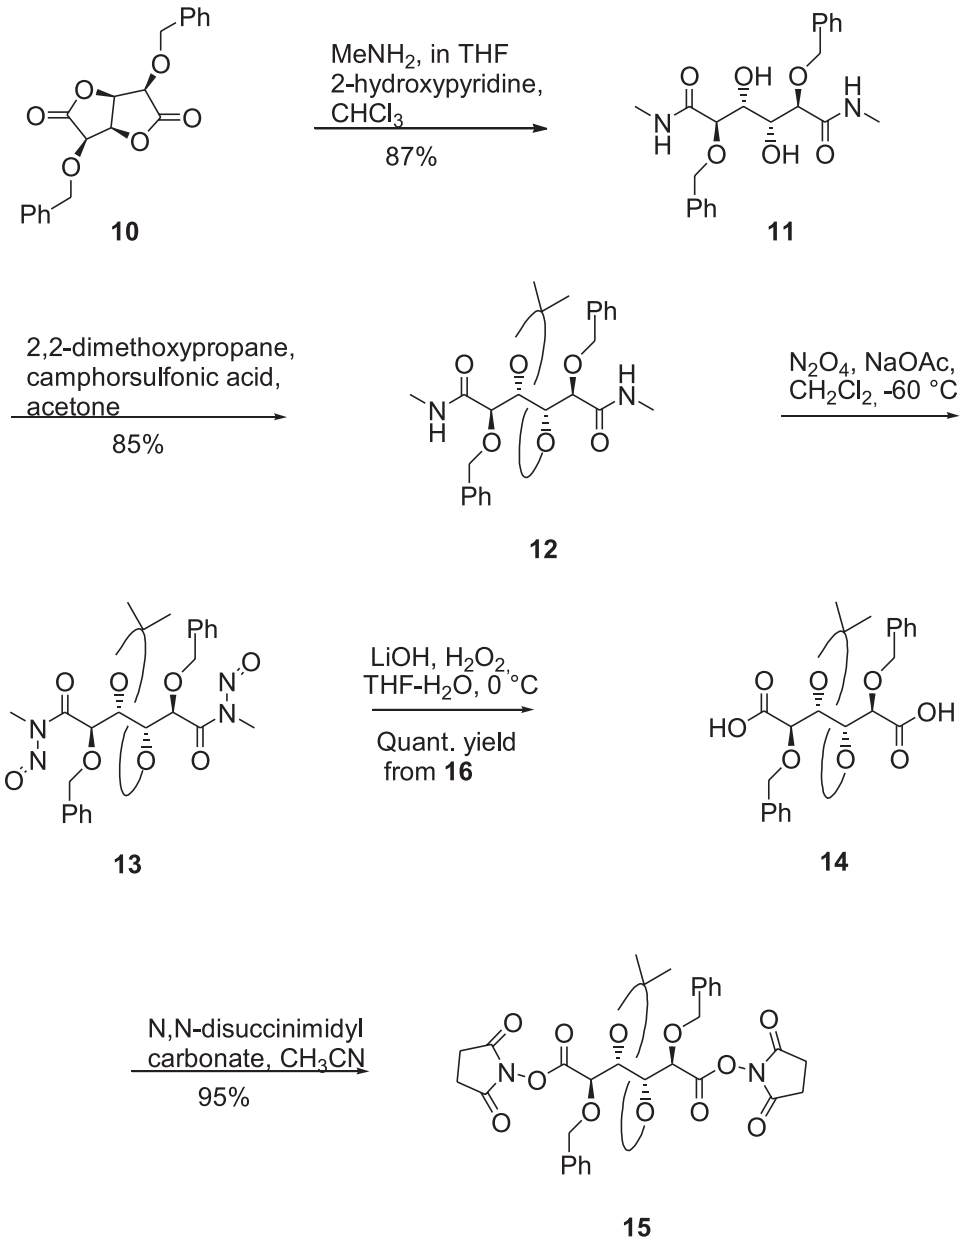
(Table 1 and 2) HIV-1 protease was cloned and heterologously expressed in *Escherichia coli* (31). K_i-values were determined in a fluorometric assay (32).

In vitro anti-HIV activity

(Table 1 and 2) The anti-HIV activity was assayed by a HIV cytopathic assay in MT-4 cells where the effects were quantified using vital dye XTT (33). The 50% inhibitory concentrations (ED_{50}) were calculated from the percent cytoprotection for individual compounds.

Structure activity relationship

From Table 2 it is evident that unsymmetrical L-mannaric amides of simple structures can be potent HIV-1 protease inhibitors. The potency of inhibitor **18e** (K_i = 0.1 nM) is somewhat surprising. The *P*2′ benzyl group of inhibitor **18e** can be viewed as a truncated *P*2′ amino indanol of **1** lacking the conformational rigidity of the amino indanol and lacking the hydrogen bond of the corresponding amino indanol hydroxyl group to the Asp 29 of the HIV-1 protease (16). Indeed, the X-ray crystal structure of **18e** complexed with HIV-1 protease shows that the phenyl group is superimposed onto the aryl part of the corresponding amino indanol in inhibitor **1**.[2] However, substitution of the benzyl *P*2′ residue with hydrogen bond accepting or electron donating groups as in the inhibitors **18f** and **18g** leads to less active compounds. These results correlate well with earlier observations, that aromatic substitutions lead to less active inhibitors (15).



Inhibitor **18a** has similar potency (k_i = 0.2 nM) as the potent corresponding symmetrical inhibitors **1** (k_i = 0.4 nM) and **2** (k_i = 0.6 nM) (16). Inhibitors **18b**, **18c**, and **18d** are *P*2′ truncated simplified analogues of **18a**. Both **18b** and **18d** are considerably less potent, while the methyl amide **18c** (k_i = 2 nM) is notably potent. This inhibitor effectively lacks a *P*2′ residue and the high potency presumably results from an energetically more favorable hydrogen bond interaction between the methyl amide carboxyl oxygen and the structural water that is tetra- coordinated to the inhibitor carbonyls and the Ile 50/150 residues of the HIV-1 protease.

In spite of the promising HIV-1 protease inhibition activities obtained for some of these inhibitors, the antiviral activities in cell culture (ED_{50}) were not improved over inhibitor **1** although inhibitor **18a** was equipotent (Table 2). Further studies are necessary to rationalize the SAR for antiviral activity in cell culture for this class of compounds (34, 35).

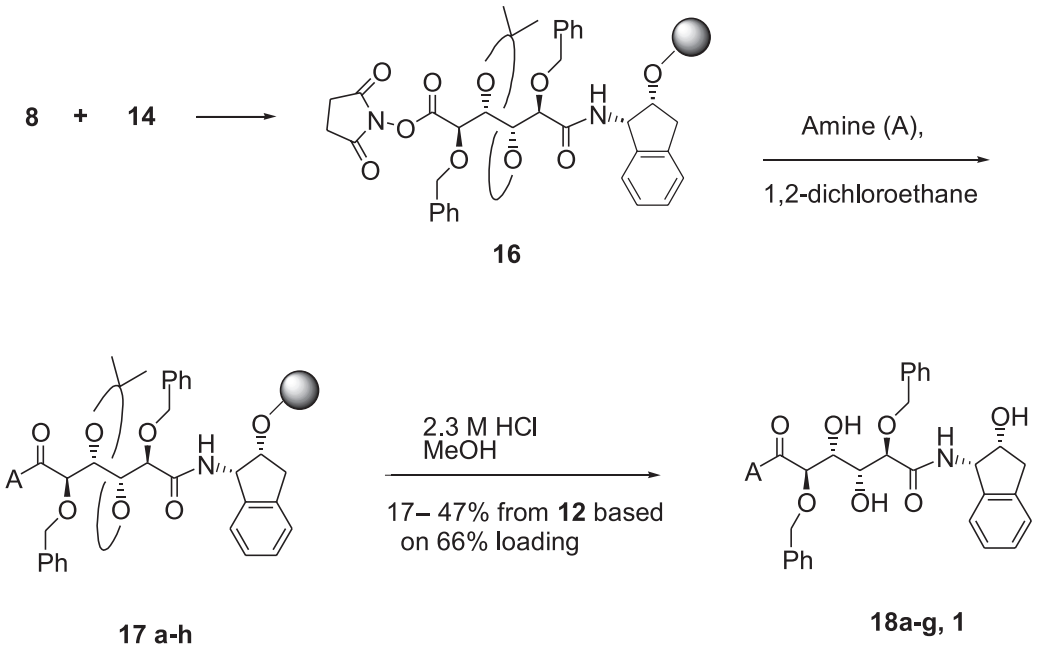
Scheme 3. Synthesis of bissuccinimidyl ester.

Experimental section



Thin layer chromatography was performed using silica gel 60 F-254 (Merck) plates with detection by UV and (or) charring with 8% sulphuric acid or by charring with ammonium molybdate (100 g):Cer(IV)sulfate (2 g):sulfuric acid (10%, 2 L). Column chromatography was performed on silica gel (Matrix Silica Si 60A, 35–70m, Amicon). Organic phases were dried over anhydrous sodium sulfate or magnesium sulphate. Concentrations were performed under reduced pressure. NMR spectra were recorded on a JEOL GSX-270 instrument (^{13}C NMR 67 MHz and ^{1}H NMR 270 MHz). Chemical shifts are reported in ppm (δ) downfield from tetramethylsilane in $CDCl_3$, unless otherwise stated. Accurate mass measurements were recorded on a Finnigan MAT 900S Electrospray. Mass spectra were recorded on a Hewlett–Packard 1100MSD.

(1*S*,2*R*)-(–)-*cis*-1-Phthalimido-2-*O*-acetoxy (4)

A mixture of **3** (3.0 g, 20 mmol), phthalic anhydride (3.6 g, 24.3 mmol), and triethylamine (2.8 mL, 20.0 mmol) in MeOH (50 mL) was stirred at room temperature for 70 min under an argon atmosphere. After concentration the oily residue was dissolved in pyridine (40 mL) and acetic anhydride (20 mL) and stirred at room temperature for 16 h. The mixture was worked-up by adding CH_2Cl_2 (100 mL) extracted with cold 10% HCl (2 × 40 mL). The combined aqueous phases were washed with CH_2Cl_2 (2 × 50 mL) and the organic layer was washed with saturated $NaHCO_3$ (2 × 100 mL) and saturated NaCl (2 × 100 mL). The combined aqueous phases were washed with CH_2Cl_2 (2 × 75 mL), dried and concentrated. The crude product was purified using column chromatography (toluene – ethyl acetate, 15:1) to give **4** (5.3 g 83%) as a yellow solid. ^{1}H NMR ($CDCl_3$) δ: 1.86 (s, 3H, 1 CH_3), 3.46–3.49 (t, 2H, 1 CH_2), 5.64–5.72 (q,

1H, 1 CH), 5.96–5.99 (d, 1H, 1 CH), 7.20–7.32 (m, 4H, Ar), 7.71–7.86 (m, 4H, Ar). ^{13}C NMR (67MHz, $CDCl_3$) δ: 20.3 (CH_3), 37.7 (CH_2), 54.4 (*C*H-N), 72.6 (*C*H-O), 123.0, 124.3, 124.5, 126.9, 128.7, 131.4, 133.8, 136.4, and 140.6 (aromatic C), 167.4 and 168.9 (C=O). MS (API-ES) calcd. for 321.10; found: 321.1.

(1*S*,2*R*)-(–)-*cis*-1-Phthalimido-2-indanol (5)

To a stirred solution of **4** (5.3 g, 16 mmol) in MeOH (250 mL) and CH_2Cl_2 (100 mL), sodium methoxide in MeOH (0.1 M) was added dropwise until pH reached 7.5. After 5 h Dowex® HCR-W2 (H^+) ion exchange resin was added to neutralize the solution. The product was purified using column chromatography (toluene – ethyl acetate, 5:1). Concentration gave pure **5** (2.98 g, 65%) as a white solid. ^{1}H NMR ($CDCl_3$) δ: 2.84 (s, 1H, 1 OH), 3.20–3.38 (m, 2H, 1 CH_2), 4.75–4.77 (q, 1H, CHOH), 5.77–5.80 (d, 1H, CHN), 7.09–7.33 (m, 4H, Ar), 7.67–7.83 (m, 4H, Ar). ^{13}C NMR (67MHz, $CDCl_3$) δ: 41.2 (CH_2), 57.7 (*C*H-N), 74.0 (*C*H-OH), 123.4, 124.2, 125.5, 126.9, 128.5, 131.8, 134.1, 137.1, and 140.2 (aromatic C), 169.0 (C=O). Anal. calcd. ($C_{17}H_{13}NO_3$): C 73.11, H 4.69, N 5.02; found: C 72.98, H 4.55, N 4.98.

(1*S*,2*R*)-(–)-*cis*-1-Phthalimido-2-indanol on solid support (7)

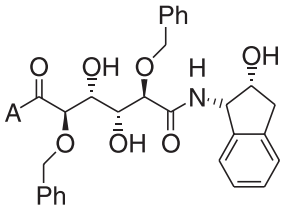
Dry Merrifield resin with a dihydropyran linker (**6**) (400 mg, 0.51 mmol/g, 0.20 mmol linker) was swollen in dry 1,2-dichloroethane (5.5 mL) under an argon atmosphere. Anhydrous PPTS (100 mg, 0.40 mmol) and **5** (200 mg, 0.72 mmol) were added and the mixture was heated to 79°C. After 16 h the mixture was cooled to room temperature and the solid support was rinsed with CH_2Cl_2 (20 mL) and MeOH (20 mL) to give **7**. The filtrate was concentrated and the solid residue was purified using column chromatography (toluene – ethyl acetate, 5:1) to recover unreacted **3** (104 mg, 0.47 mmol). All the solid phase was used in the subsequent step.

(1*S*,2*R*)-(–)-*cis*-1-Amino-2-indanol on solid support (8)

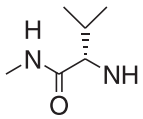
Methylamine in ethanol (4.5 mL, 33%) was added to the solid phase from the previous step (**7**) and stirred for 16 h. The solid phase was rinsed with CH_2Cl_2 (10 mL), MeOH (10 mL), and then $CHCl_3$ (10 mL) to give **8**. All the solid phase will be used in the subsequent step.

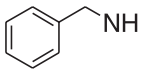
The combined organic phases were concentrated and the formed *N*-methylphthalimide (**9**) was purified using column chromatography (chloroform–methanol, 20:1) which gave pure **9** as a white solid (21 mg, loading 66%). ^{1}H NMR (270 MHz, $CDCl_3$) δ: 2.94 (s, 3H, 1 CH_3), 7.01–7.67 (m, 4H, Ar). ^{13}C NMR (67MHz, $CDCl_3$) δ: 26.8 (CH_3), 125.7, 128.3, 129.0, 130.1, 134.6, and 140.7 (aromatic C), 170.0 (C=O).

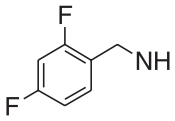
***N*1,*N*6-Dimethyl-(2*R*,3*R*,4*R*,5*R*)-2,5-dibenzyloxy-3,4-dihydroxy hexanediamide (11)**

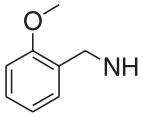


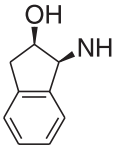
A mixture of benzylated bislactone (**10**) (7.64 g, 21.6 mmol), 2-hydroxypyridine (2.06 g, 21.7 mmol), and methylamine in THF (2 M, 23 mL, 46 mmol) in $CHCl_3$ (60 mL) was stirred at ambient temperature for 15 min. The organic phase was washed with saturated $NaHCO_3$ (3x), dried, concentrated, and the residue purified by column chromatography ($CHCl_3$–MeOH, 20:1) to give pure **11** (7.83 g, 18.8 mmol, 87%) as a white solid. ^{13}C NMR ($CDCl_3$) δ: 25.8 (2 *C*H_3-NH), 71.1, 73.8, 79.6 (2 O*C*H_2Ph, C2, C3, C4, and C5), 128.1, 128.2, 128.6, 136.7 (aromatic C), 172.7 (2 C=O). MS (API-ES) calcd. for 416.1; found: 416.1.











***N*1,*N*6-Dimethyl-(2*R*,3*R*,4*R*,5*R*)-2,5-dibenzyloxy-3,4-dihydroxy-3,4-*O*-isopropylidenehexanediamide (12)**

Dimethoxypropane (15 mL, 123 mmol) and camphorsulfonic acid (2.66 g, 11.5 mmol) were added to a stirred mixture of **11** (6.0 g, 14.4 mmol) in dry acetone (70 mL). The precipitated product was filtered off after 15 min to give pure **12**. The solution was concentrated, CH_2Cl_2 was added

bath was replaced with an ice salt bath after 30 min and the mixture was stirred at –10°C until the substrate was consumed (1 h). The solution was poured into ice and water and the phases were separated. The organic phase was washed with ice cold 5% sodium bicarbonate. The organic phase was washed with ice cold 5% sodium bicarbonate, dried briefly at 0°C, and concentrated to give **13** as a yellow oil. The nitrosoamide solution was never allowed to warm above 0°C. All the product was used immediately in the next step.

2,5-Di-*O*-benzyl-3,4-*O*-isopropylidene-L-mannaric acid (14)

Hydrogen peroxide (12.5 g 30%) and LiOH (1.26 g, 52.7 mmol) were added to a stirred solution of **13** from the previous step in THF–H_2O (3:1) (100 mL) at 0°C. The mixture was stirred for 20 min at 0°C. The reaction was quenched with Na_2SO_3 (15 mL, 1.5 M). The THF was evaporated and the water phase was acidified with Dowex® HCR-W2 (H^+) ion exchange resin, and extracted with EtOAc. The phases were separated and the organic phase was dried and concentrated to give **14** (3.05 g, 7.08 mmol, 100%) as a white solid. ^{13}C NMR (CD_3OD) δ: 27.5 (2 CH_3), 73.6, 80.0, 80.3 (2 OCH_2Ph, C2, C3, C4, and C5), 112 (O-*C*-O), 129.0, 129.3, 129.4, 138.5 (aromatic C), 173.1 (C=O).

***N*1-[(2*R*)-Hydroxy-1(*S*)indanyl]-*N*6-succinimidyl-(2*R*,3*R*,4*R*,5*R*)-2,5-dibenzyloxy-3,4-dihydroxy-3,4-*O*-isopropylidenehexanediamide on solid support (16)**

The solid phase from the previous step (**8**) was swollen in dry 1,2-dichloroethane (4.5 mL) for 40 min under an argon atmosphere. The bissuccinimidyl diester (**15**) (900 mg, 1.44 mmol) was added and the mixture was stirred for 16 h under an argon atmosphere at 60°C. The solid phase was rinsed with $CHCl_3$ (20 mL), THF (10 mL), and then 1,2-dichloroethane (10 mL) to give **16**. All the solid phase was used in the subsequent step.

General procedure for preparation of compounds 17a–h

The solid phase from the previous step (**16**) was swollen in dry 1,2-dichloroethane (4 mL) for 40 min under an argon atmosphere. The amine (2.0 mmol) was added and the mixture was stirred for 16 h under argon at 60°C. The solid phase was rinsed with $CHCl_3$ (20 mL), THF (10 mL), and then 1,2-dichloroethane (10 mL) to give **17a–h**. All the solid phase was used in the subsequent step.

Conclusions

A solid phase parallel synthesis of unsymmetrical inhibitors has been developed which will aid further development and combinatorial amplification. A number of new potent inhibitors were discovered.

A facile new procedure for the deprotection of allyl ethers under mild conditions

Yun-Jin Hu, Romyr Dominique, Sanjoy Kumar Das, and René Roy

Abstract: A novel isomerization of *O*-allyl glycosides into prop-1-enyl glycosides was observed instead of cross-metathesis during an olefin metathesis reaction using Grubbs' ruthenium benzylidene catalyst $(Cy_3P)_2RuCl_2$=CHPh (**1**), *N*-allyltritylamine, and *N*,*N*-diisopropylethylamine as necessary auxiliary reagents. In the search for a better catalytic system, it has been found that dichlorotris(triphenylphosphine)ruthenium(II), $[(C_6H_5)_3P]_3RuCl_2$, (**2**) was much more efficient for the isomerization of allylic ethers. The labile prop-1-enyl group was easily hydrolyzed using $HgCl_2$–HgO and the hemiacetals (**25**–**32**) were isolated in excellent yields (ca. 90%).

Key words: allyl ether, carbohydrate, Grubbs' catalyst, isomerization, metathesis, deprotection.

Résumé : Au cours d'une réaction de métathèse d'oléfine impliquant du catalyseur de Grubbs, le benzylidène de ruthénium, $(Cy_3P)_2RuCl_2$=CHPh (**1**), de la *N*-allyltritylamine et du *N*,*N*-diisopropyléthylamine comme réactifs auxiliaires nécessaires, on a observé une nouvelle isomérisation des glycosides de *O*-allyle en glycosides de prop-2-ényle. Au cours de nos travaux en vue développer un meilleur système catalytique, on a trouvé que le dichlorotris(triphénylphosphine)ruthénium(II), $[(C_6H_5)_3P]_3RuCl_2$ (**2**), est beaucoup plus efficace pour l'isomérisation des éthers allyliques. Le groupe prop-1-ényle labile est hydrolysé facilement à l'aide de $HgCl_2$–H_2O et on a isolé les hémiacétals (**25**–**32**) avec d'excellents rendements (environ 90%).

Mots clés : éther allylique, catalyseur de Grubbs, isomérisation, métathèse, déprotection.

[Traduit par la Rédaction]

Introduction

The use of allyl ether protecting groups is of great importance in carbohydrate chemistry and other natural product syntheses (1) because of their ready availability and stability under reasonably strong acidic and basic conditions. Several methods for the deprotection of allyl ethers have already been described in the literature (2–11). Most methods involve initial isomerization of allyl to prop-1-enyl ethers with either a base such as $[(CH_3)_3COK]$ (2) or transition metals: Ti(0) (3), Rh(I) (4), Ir(I) (5), Pd-C (6), $Pd(PPh_3)_4$ (7), $Pd(OAc)_2$ (7), $H_2Ru(PPh_3)_4$ (8), $Fe(CO)_5$ (9). The labile prop-1-enyl ethers can then be cleaved to the corresponding alcohols by mineral acids or $HgCl_2$–HgO (10) (Scheme 1). Direct cleavage of allyl ethers is generally carried out using stoichiometric amounts of palladium salts or complexes such as $PdCl_2(PhCN)_2$, $PdCl_2$ (11). However, some of these methods are still less than satisfactory for practical use and sometimes are found to be capricious (12). Herein, we wish to report a new method for the deprotection of the allyl group from carbohydrate derivatives using Grubbs' ruthenium benzylidene catalyst $(Cy_3P)_2RuCl_2$=CHPh **1** or dichlorotris(triphenylphosphine)ruthenium(II) (**2**) in excellent yields (ca. 90%).

Results and discussion

Recently we have been interested in the metathesis reaction of *O*-allyl glycosides using Grubbs' catalyst **(**$Cy_3P)_2Cl_2Ru$=CHPh (**1**) (13, 14). However, when the cross-metathesis reaction between *N*-allyltritylamine **3** (15) and allyl 2,3,4,6-tetra-*O*-acetyl-α-D-galactopyranoside **9** (16) was carried out with **1**, an unexpected isomerization product **17** was isolated in 30% yield instead of the anticipated cross metathesis compound. Furthermore, neither sugar nor *N*-allyltritylamine dimer could be detected. Treatment of **9** with 1,4-diazabicyclo[2,2,2]octane (DABCO) in the presence of Grubbs' catalyst **1** afforded only 4% of the isomerized product **17** together with 40% of allyl α-D-galactopyranoside homodimer (14). Similar results were obtained when triethylamine was used as base. Neither isomerization nor metathesis products were detected when diethylamine or pyridine were used (Table 1, entries 6 and 7). The isomerized product **17** was obtained with the highest yield when **9** was treated with diisopropylethylamine (DIPEA) in the presence of Grubbs' catalyst **1**. However, all the isomerization yields of those reactions were still very low in the absence of *N*-allyltritylamine **3** (Scheme 2). When both **3** and 1 equiv. of DIPEA were simultaneously used in the reaction, the isomerization yield was improved dramatically to 80% (Table 1, entry 8). Furthermore, there was no self-metathesis product that could be detected.

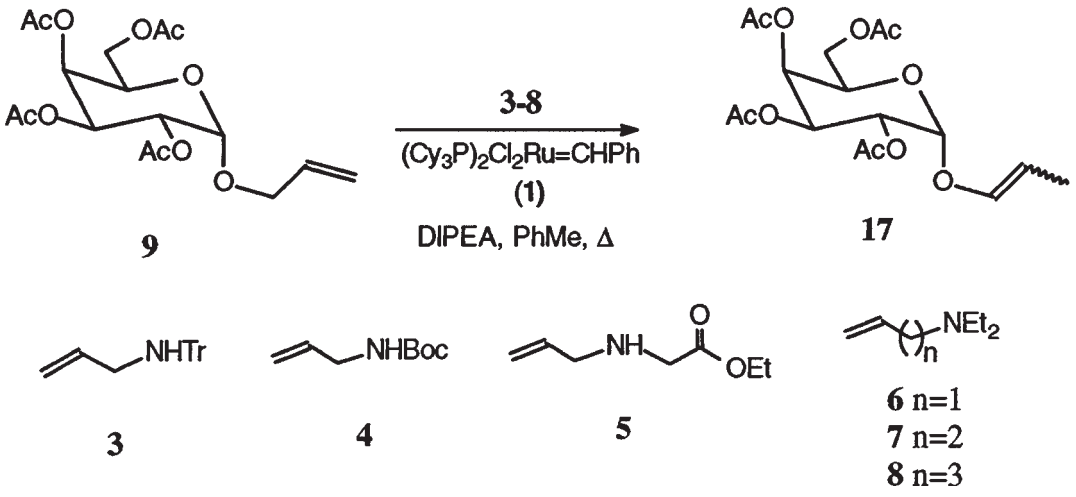
[a]NMM: *N*-methylmorpholine.

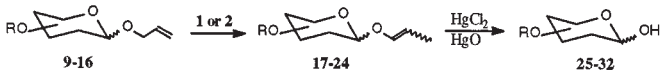
Scheme 1.



Bearing in mind the above observations, alternative bases which could provide both basicity and olefinic functionality were explored. To this end, several *N*-allylated amine derivatives (**4**–**8**) that could mimic the structure of amine **3** were synthesized to test the reaction. It was found that Boc-allyl carbamate **4** and amine **5** did not catalyze this reaction at all. Several tertiary amines **6**–**8** with increasing chain length also failed to afford the desired isomerization products with **3** and catalyst **1** when they were subjected to the optimum conditions. This demonstrates that the strong steric hindrance of *N*-allyltritylamine also had an important influence on the isomerization of **9** as well as its basicity. At this stage, we believed the presence of the secondary amine **3** as an auxiliary reagent was crucial for the isomerization to occur.

More detailed studies showed that the isomerization of allyl ethers to propenyl ethers with Grubbs' catalyst proceeded smoothly in the presence of amine **3** and a stoichiometric amount of base such as diisopropylethylamine (DIPEA). To improve the yield of the isomerization and suppress the formation of metathesis products, 1.0 equiv. of DIPEA and 2.0 equiv. of **3** were treated with different glycosides in the presence of 0.1 equiv. of **1** (toluene, reflux, 4 h). Good yields were obtained without any metathesis product being detected in any of these experiments (Table 2).

The ratios of the unseparated *E* and *Z* stereoisomers in the pro-1-enyl glycosides were determined from the analysis of the ^1H NMR spectra of the crude mixtures by observation of the $^3J_{H,H}$ coupling constants of the alkenyl protons (17). Interestingly, the *cis* stereoisomers predominated. Isomerization of partially protected glycosides **12** and **15** proceeded in lower yields, presumably because some of the remaining free hydroxyl groups of the substrates coordinated to some extent with the catalyst and reduced or prevented its activity. When control experiments were performed in the absence of **3** and DIPEA, only the expected self-metathesis products were obtained in high yields (14).



We noticed that olefin isomerization of allylic ether and allyl alcohol can be catalyzed by $Ru(II)(H_2O)_6(tos)_2$ (tos = *p*-toluenesulfonate) (18) in aqueous solution and

$(PPh_3)_2X_2Ru$=CH-CH=CPh_2 (X = Cl or CF_3COO) (19) in dichloromethane. When compared to existing methodologies, however, Ru(II)$(H_2O)_6(tos)_2$, $(PPh_3)_2X_2Ru$=CH-CH=CPh_2, or Grubbs' catalyst are relatively expensive and the isomerization yields are not competitive. We therefore initiated a search for a better catalyst by screening a family of ruthenium complexes for activity in this reaction. From this investigation, it was found that the commercially available, dichlorotris(triphenylphosphine)ruthenium(II) [$(PPh_3)_3RuCl_2$ (**2**)] can be used as an efficient catalyst for the deprotection of allyl group from the glycosides **9–16** following a two-step procedure.

We began with the isomerization reaction of peracetylated allyl α-D-galactopyranoside (**9**) in different aprotic solvents

such as tetrahydrofuran, acetonitrile, dichloromethane, and toluene in the presence of **2** and DIPEA (Table 3). No isomerization was detected when THF and acetonitrile were used as solvents. When the reaction was carried out in refluxing dichloromethane, the isomerized product (**17)** was obtained in 80% yield. The best result was obtained when the reaction was performed in toluene under refluxing conditions. Lower yields were obtained when the reactions were performed in anhydrous methanol or aqueous ethanol due to competing de-*O*-acetylation. It is noteworthy that no isomerized product was detected in the absence of catalyst or base, even under forcing conditions such as prolonged reaction time, higher reaction temperature, and the use of up to 20 mol% of catalyst. Several common organic bases were examined for activity in the isomerization of **11**. No isomerization product was formed in pyridine. Upon treatment with triethylamine or 1,4-diazabicyclo[2,2,2]octane, the isomerization reactions proceeded smoothly. It was found that diisopropylethylamine (DIPEA) was the most suitable base for the system in terms of the high yields obtained for both **9** and **11** (Table 3). This novel isomerization reaction most likely follows the metal hydride addition-elimination mechanism (18).

Various allyl glycosides were subjected to the following standard conditions: a catalytic amount of **2** (10 mol%) was utilized as catalyst and a stoichiometric amount of DIPEA as base and the reactions were performed in refluxing toluene. Isomerized products were obtained in excellent yields (Table 2). It is also noteworthy that even those *O*-allyl glycosides (**12, 15**) with free hydroxyl groups, which were not suitable for the metathesis reaction because of the coordination to the metal in the Grubbs' catalyst, were still good substrates for these isomerization conditions.

As expected, hydrolysis of the enol ethers proceeded rapidly under acidic conditions (pH = 2) to provide hemiacetals (4). Alternatively, treatment of prop-1-enyl ethers with $HgCl_2$–HgO in aqueous acetone at room temperature for 1 h gave deprotected products in high yields. The whole procedure could be simplified as a two-step one-pot reaction: after isomerization of allyl ether, toluene and DIPEA were removed under reduced pressure and the resulting residue was then subjected to 0.5 equiv. of HgO and 1.0 equiv. of $HgCl_2$ in aqueous acetone (water:acetone – v/v 1:1) at room temperature for 1 h.

The excellent results described above provide a new route towards the deprotection of *O*-allyl glycosides in the field of carbohydrate chemistry. Up to now, there were several methods reported for the deprotection of *O*-allyl ethers (2–10, 20–22), however, these methods have been limited by severe reaction conditions such as: using strong base (2) or strong acid (20) as catalyst, performing reactions in aqueous alcohol (4) or alkaline solution (9), using oxidizing (21) or reducing (22) conditions, and operating under severe oxygen-free and anhydrous conditions (5). Compared to Wilkinson's catalyst (4), which is commonly used for deprotection of *O*-allyl ether in carbohydrate chemistry, ruthenium (II) complexes have two advantages with similarly effective performance with respect to promoting the

© 2000 NRC Canada

isomerization of *O*-allyl glycosides. First, the ruthenium (II) complex is more than two times cheaper than Wilkinson's catalyst; second, the ruthenium (II) complex does not reduce the alkene as is sometimes observed when using $(Ph_3P)_3RhCl$ (23). As for Felkin's Ir (I) catalyst, which is not commercially available, the procedure must be performed under strictly oxygen-free and anhydrous conditions (5). Our method for the isomerization of allyl groups by dichlorotris(triphenylphosphine)ruthenium(II) (**2**) is widely applicable and easy to perform under mild reaction conditions (Table 2). The isomerization of *O*-allyl ethers proceeds readily at refluxing temperature without affecting free hydroxyl, *O*-isopropylidene, trityl, acetyl, benzyl, or *p*-methoxylbenzyl groups.

Saloman and coworkers (24) reported the selective rearrangement of diallyl ethers catalyzed by dichlorotris(triphenylphosphine)ruthenium(II) (**2**) involving a preliminary rearrangement to allyl vinyl ethers followed by a Claisen rearrangement. However, high temperature (200°C) instead of an organic base was used in their experiments. A recent report showed that isomerization of *O*-allyl ethers using **2** at 130°C led to the formation of many byproducts (9), so it would appear that its use has not been exploited until now. To the best of our knowledge, there are no other reports of the application of this catalyst for the deprotection of *O*-allyl groups.

The simplicity and mildness of this methodology led us to explore this procedure for the deprotection of allyl ether from 6-*O*-allyl-1,2:3,4-di-*O*-isopropylidene-α-D-galactopyranose (**33**). Treatment of **33** with catalyst **2** and DIPEA under the same reaction conditions gave the isomerized product **34** in 95% yield (Scheme 3).

Conclusions

In conclusion, an efficient isomerization of *O*-allyl glycosides has been achieved in the presence of a catalytic amount of dichlorotris(triphenylphosphine)ruthenium(II) (**2**), from which we have developed a facile method for the deprotection of *O*-allyl acetals and ethers. This is preparatively a very useful method, which is performed under mild conditions and is compatible with the presence of various protecting groups. It is also worth noting that the commercially available polystyrene-anchored $(PPh_3)_2RuCl_2$ should show similar activity towards the isomerization of *O*-allyl glycosides, which would make the actual procedure even more attractive (25).

Experimental section

Materials

^1H and ^{13}C NMR spectra were recorded at 500 or 200 MHz and 125 or 50 MHz respectively, with tetramethylsilane (0.00 ppm) as an internal reference. Thin-layer chromatography (TLC) was performed using silica gel 60 F_{254} aluminum sheets purchased from E. Merck. Reagents used for developing plates include ceric sulfate (1% w/v) and ammonium sulfate (2.5% w/v) in 10% (v/v) aqueous sulfuric acid, iodine, dilute aqueous potassium permanganate, and UV light. TLC plates were heated to approximately 150°C when necessary. Purifications were performed by gravity or flash chromatography on silica gel 60 (230–400 mesh; E. Merck No. 9385). Solvents were evaporated under reduced pressure using a rotary evaporator connected to a water aspirator. All chemicals used in experiments were of reagent grade. Solvents were purified by published procedures. Compounds **10** and **11** were synthesized by the reported procedure (26). Compound **12** was prepared by the method reported by Fraser–Reid et al. (27). Allyl α-L-rhamnopyranosides (**13**–**15**) were prepared according to the method reported by Luckas et al. (28). Allyl glycoside **16** was synthesized by the published procedure (16).

Typical procedure for isomerization of glycosides by Grubbs' catalyst (1); procedure A

To a solution of glycoside (0.1 mmol) in toluene (2 mL), *N*-allyltritylamine (**3**) (0.2 mmol), Grubbs' catalyst **1** (8.2 mg, 0.01 mmol) and DIPEA (0.1 mmol) were added under a nitrogen atmosphere. The reaction mixture was stirred under reflux conditions for 4 h. The resulting red solution was concentrated using a rotary evaporator and the residue was partitioned between water and dichloromethane. The organic layer was dried (Na_2SO_4), concentrated, and purified by column chromatography.

Typical procedure for isomerization using $(Ph_3P)_3Cl_2Ru$ (2); procedure B

To a solution of glycosides (0.1 mmol) in toluene (2 mL), dichlorotris(triphenylphosphine)ruthenium(II) (9.6 mg, 0.01 mmol) and DIPEA (0.2 mmol) were added under a nitrogen atmosphere. The resulting solution was stirred under reflux conditions for 2 h and then toluene and DIPEA were removed under reduced pressure. The residue was purified by silica gel column chromatography to obtain the appropriate isomerized product.

Procedure for the deprotection of prop-1-enyl group

The purified isomerization product (0.1 mmol) was dissolved in 2 mL of acetone:water (1:1). To the solution, HgO (10.8 mg, 0.05 mmol) and $HgCl_2$ (27.2 mg, 0.1 mmol) were added. After stirring for 1 h at room temperature, with monitoring by TLC, the deprotected product was extracted with ethyl acetate and washed with potassium iodide solution to remove mercuric compounds. Following a usual work-up, colorless oil was obtained and purified by silica gel column chromatography to obtain the appropriate product as an α and β mixture.

Prop-1-enyl 2,3,4,6-tetra-O-*acetyl*-α-D-*galactopyranoside* (***17***): After silica gel column chromatography with ethyl acetate and hexane as eluent (1:2), compound **17** (as a mixture of *E* and *Z* isomers in 1:2 ratio) was isolated as a syrup, R_f (hexane:EtOAc = 2:1): 0.38. For *E* isomer: ^1H NMR (200 MHz, $CDCl_3$), δ: 6.13 (dq, 1H, J = 12.3, 1.6 Hz), 5.50–5.35 (m, 2H), 5.36–5.29 (m, 1H), 5.25–5.09 (m, 2H), 4.27–4.15 (m, 1H), 4.12–3.98 (m, 2H), 2.14 (s, 3H), 2.07 (s, 3H), 2.02 (s, 3H), 2.00 (s, 3H), 1.55 (dd, 3H, J = 7.0, 1.6 Hz). For *Z* isomer: ^1H NMR (200 MHz, $CDCl_3$), δ: 6.05 (dq, 1H, J = 6.1, 1.6 Hz), 5.50–5.35 (m, 2H), 5.36–5.29 (m, 1H), 5.25–5.09 (m, 1H), 4.70–4.59 (m, 1H), 4.27–4.15 (m, 1H), 4.12–3.98 (m, 2H), 2.14 (s, 3H), 2.07 (s, 3H), 2.02 (s, 3H), 2.00 (s,

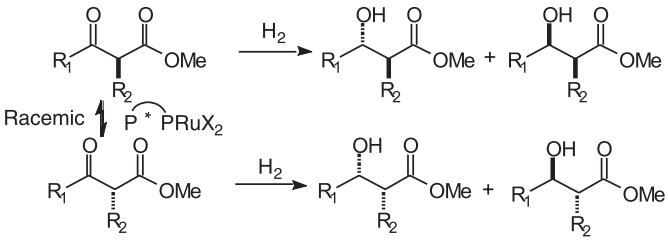
Synthetic applications of the ruthenium-catalyzed hydrogenation via dynamic kinetic resolution

Virginie Ratovelomanana-Vidal and Jean-Pierre Genêt

Abstract: This review summarizes some recent work in the field of homogeneous ruthenium-catalyzed hydrogenation via dynamic kinetic resolution. The hydrogenation reaction of various α-substituted β-oxo esters using chiral ruthenium(II) catalysts is presented as well as the synthesis of some key intermediates of pharmaceutical interest.

Key words: dynamic kinetic resolution, ruthenium, hydrogenation, α-substituted β-keto ester.

Résumé : Cette revue résume quelques resultats récents dans le domaine de l'hydrogénation asymétrique, catalysée par des complexes du ruthénium en utilisant le principe du dédoublement cinétique dynamique appliquée aux β-céto esters α-substitués. L'hydrogénation stéréosélective de β-céto esters α-substitués variés ainsi que la préparation de quelques intermédiaires clefs d'intérêt thérapeutique sont présentés.



Mots clés : dédoublement cinétique dynamique, ruthénium, hydrogénation, β-céto esters α-substitués.

Introduction

In contrast with kinetic resolution processes where the maximum theoretical yield of one enantiomer is limited to 50%, the dynamic kinetic resolution involving in situ racemization of the substrates can afford the desired isomer in a yield approaching 100%. This process is thus much more efficient. A racemic starting material such as α-substituted β-keto esters bearing a configurationally labile stereogenic center and a prochiral unsaturated moiety, can be converted to one major *syn* or *anti* stereoisomer, among the four stereoisomers, through enantioselective hydrogenation via dynamic kinetic resolution (for general reviews on dynamic kinetic resolution, see ref. (1*a*–*f*); for a mathematical treatment of the kinetics in the DKR, see ref. (1*g*, *h*)). In this process, the slower reacting isomer is converted into the other one in situ (Scheme 1). In this paper, we detail how both *syn* and *anti* α-substituted β-hydroxy esters were synthesized using some selective ruthenium-catalyzed hydrogenation reactions based on this principle.

Because asymmetric catalysis is widely used in organic synthesis (2–14), it is important to expand this area of research to find new catalytic routes to obtain optically pure compounds. One of the easiest way to introduce an hydrogen atom in an appropriate prochiral center is to use asymmetric hydrogenation. The first homogeneous asymmetric hydrogenation has been reported independently by Horner and Knowles and co-workers (15, 16). The breakthrough in this topic was the discovery of the DIOP, a C_2 symmetric

Scheme 1.

chiral diphosphine obtained from tartaric acid, by Kagan coworkers (17). Today, a large number of amino acids are readily synthesized in ee up to 99% with chiral phosphine rhodium catalysts. However, the scope of Rh-catalyzed hydrogenations is not wide in comparison with Ru-catalyzed hydrogenation reactions. The first chiral Ru(II)-catalyst was reported by James et al. (18) in 1975 to catalyze the hydrogenation of unsaturated carboxylic acids in 60% ee. Since the discovery of the $[RuCl_2(Binap)]_2NEt_3$ complex by Ikariya et al. (19) and the subsequent discovery of $Ru(OAc)_2$[(*R*) or (*S*)-Binap] by Noyori et al. (20), the use of these catalysts in many enantioselective hydrogenations has drawn considerable

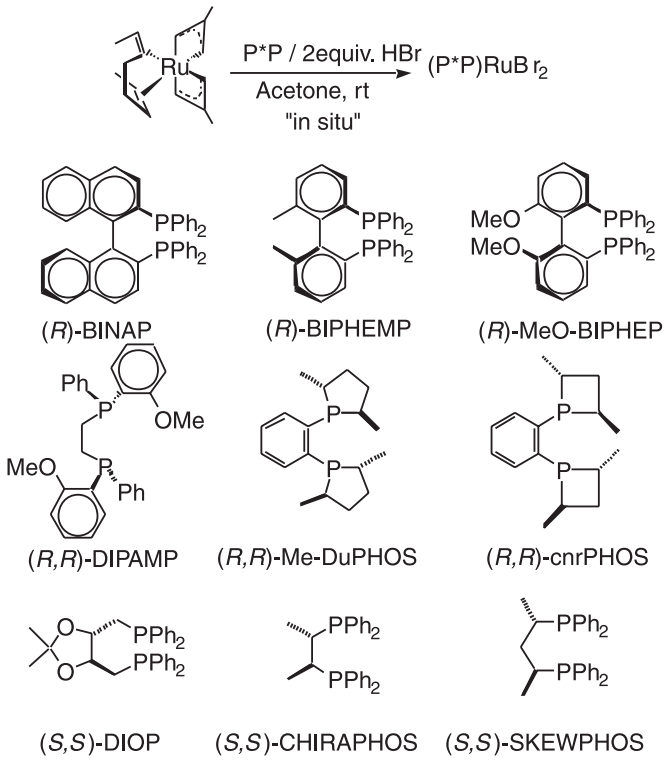
attention to homogeneous hydrogenations catalyzed by Ru(II)-complexes (for some reviews see ref. (21)). The simultaneous work of Noyori and co-workers (22) and Genêt and co-workers(23)[2] led to the first examples of enantioselective ruthenium-promoted hydrogenations of racemic α-acetamido β-keto esters via dynamic kinetic resolution. Noyori et al. reported the hydrogenation of 2-acetamido derivative (Scheme 2) in dichloromethane leading to the protected *syn L*-threonine (98% ee) and *anti* allothreonine with 99:1 selectivity. This remarkable *syn* stereoselectivity was also observed for some threonine type products which were synthesized with excellent ees and in high yields using the BINAP-Ru catalyzed hydrogenation (22). We achieved simultaneously the synthesis of *L* and *D*-threonine via asymmetric hydrogenation of racemic 2-acylamino-3-oxobutyrates, prepared in a two-step sequence from the corresponding β-keto ester (23)[2] (Scheme 2).

Scheme 2.

An ideal dynamic kinetic resolution was obtained by using the BINAP-Ru(II) complex. The ruthenium dihalide catalysts containing CHIRAPHOS, prepared as shown in Scheme 3, catalyzed the hydrogenation of methyl 2-acetamido-3-oxobutanoate affording the corresponding *syn* α-amino β-hydroxy ester in dichloromethane with high enantio (85% ee) and diastereomeric excesses. The use of methanol as solvent instead of dichloromethane resulted in a decreased diastereoselectivity. In the last few years, we have been interested in the ruthenium-promoted hydrogenation reactions and we have developed a general strategy for the synthesis of chiral Ru(II)-catalysts (24) (Scheme 3). This method can be applied to a whole set of chiral diphosphines such as the atropoisomeric ligands BINAP, BIPHEMP, and

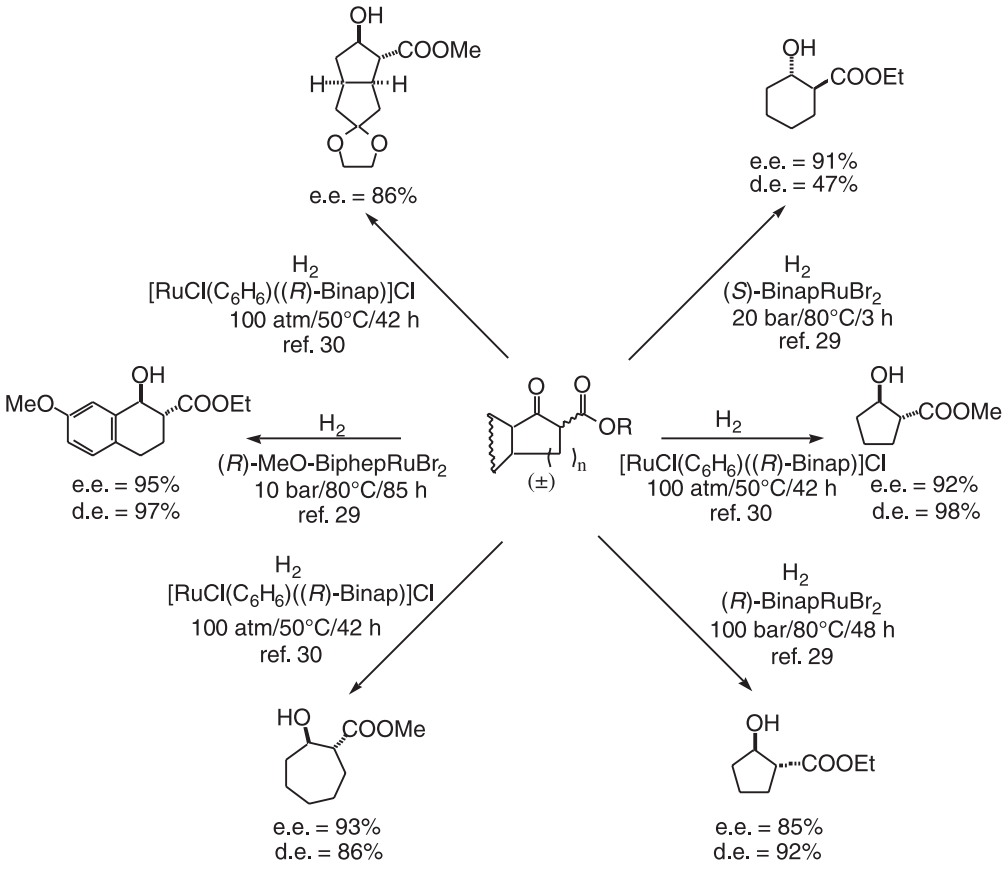


Scheme 3.

MeO-BIPHEP, but also DIPAMP, DIOP, CHIRAPHOS, Me-DuPHOS (24), SKEWPHOS (25), Cnr-PHOS (26) etc. The corresponding halogen-containing ruthenium complexes with the empirical formula $(P^*P)RuBr_2$ are efficient for the asymmetric hydrogenations of olefins and carbonyl groups, which lead to functionalized alcohols with high levels of enantioselectivity (27).

The catalyst synthesis was improved (24); the halogen-containing catalysts were more conveniently prepared in situ under milder conditions, in a one-step sequence from a commercially available starting material, $(COD)Ru(\eta^3\text{-}(CH_2)_2CCH_3)_2$ (24) (Scheme 4). This technique is advantageous for several reasons: (*i*) wide scope; (*ii*) predictable absolute configurations of the chiral functionalized alcohols;

Scheme 4.



(*iii*) and ready availability of the chiral Ru(II)-catalysts in either enantiomeric forms. Furthermore, this process gives high yields and is easy to perform on large scale.

The ruthenium-promoted hydrogenation reaction of cyclic 2-substituted 3-oxo carboxylic esters has been examined (Scheme 5) by Noyori et al. and our group using the in situ generated ruthenium(II) catalysts. The stereochemical course of the reaction was highly influenced by substrate structures and reactions conditions (28, 29). When comparing the asymmetric hydrogenation of the five-membered ring to those obtained with cyclic six-membered rings, the following comment can be made: in the case of 2-(ethoxycarbonyl)cyclopentanone or (methoxycarbonyl)cyclopentanone, the hydrogenation reaction proceeded with high diastereo- and enantioselectivity (respectively, de = 92%, ee = 85% and de = 98%, ee = 92%) by using (*R*)-BINAP as chiral auxiliary, leading to the corresponding (2*R*,3*R*) *trans* product. However, in increasing the ring size to a six-membered ring with (*S*)-BinapRu(II) catalyst, the diastereoselectivity decreased to some extent (de = 47%). Nevertheless, significant enantiomeric excess was reached for the ruthenium-promoted hydrogenation reaction of 2-(ethoxycarbonyl)cyclohexanone (28) in dichloromethane affording the (2*S*,3*S*) *trans* product

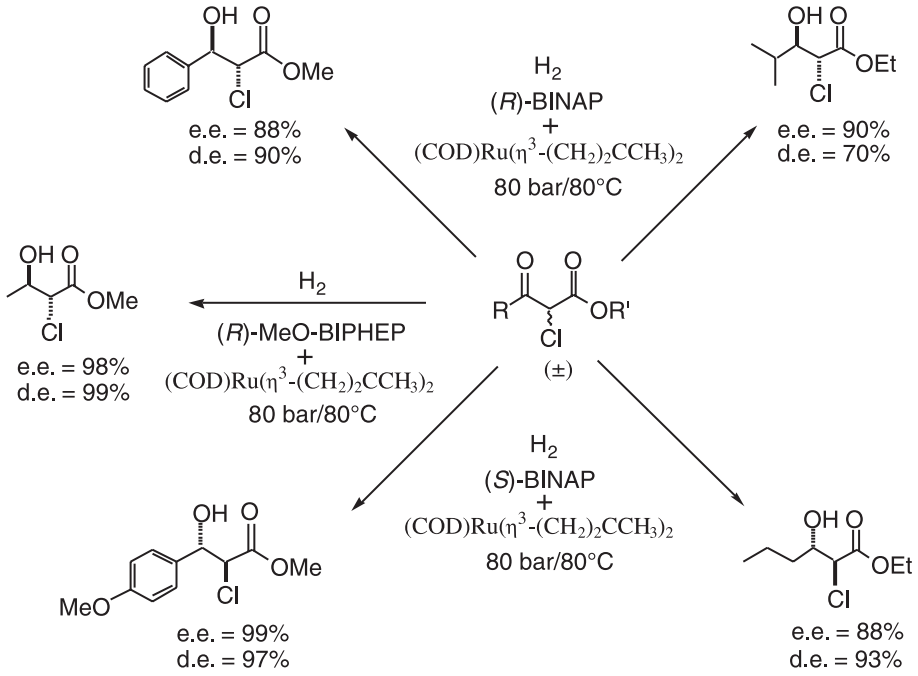
Scheme 5.

Scheme 6.

(ee = 91%). A relevant dynamic kinetic resolution was achieved for cyclic β-keto esters containing a tetralone moiety i.e., 7-methoxy-2(ethoxycarbonyl)tetralone. The *trans* cyclic β-hydroxy ester was synthesized in methanol using (*R*)-MeO-BIPHEP as chiral auxiliary with excellent enantio- and diastereofacial discrimination (de = 97%, ee = 95%) under 10 bar of hydrogen pressure and 80°C. The absolute configuration of the hydroxyl-substituted carbon was determined by the configuration of the chiral auxiliary (BINAP or MeO-BIPHEP) although the configuration of the α stereogenic center was dependent on the nature of the substrate and reaction conditions. The ruthenium-promoted hydrogenation reaction of a bicyclic substrate that contained one chirally labile and two stable stereogenic centers (29) has been reported using 0.36 mol% of [RuCl(C_6H_6)(*R*)-Binap]Cl and the alcohol was obtained in 86% ee and in 32% yield.

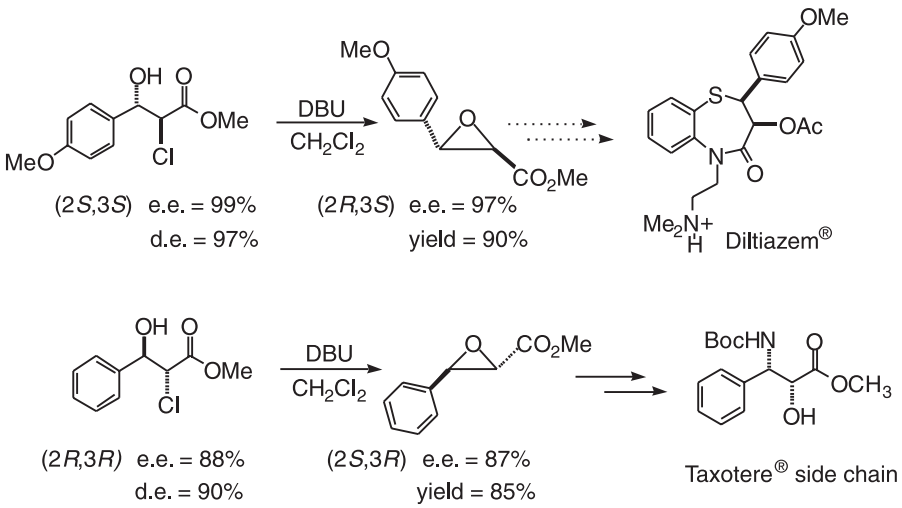
Hydrogenation of racemic 2-acetyl-4-butanolide (Scheme 6) proceeded with 96% *syn* diastereoselectivity and good enantiomeric excesses (29).

The hydrogenation reaction of α-chloro β-keto esters has been studied (30) (Scheme 7). Behavior of the open chain α-chloro β-keto esters was different from the cyclic substrates. We succeeded in the hydrogenation by using a simple catalytic system prepared by mixing (COD)Ru(η^3-$(CH_2)_2CCH_3)_2$ and the chiral diphosphine (BINAP or MeO-BIPHEP). Under optimized conditions (80 bar and 80°C) in dichloromethane, the corresponding *anti* α-chloro β-hydroxy esters bearing an alkyl or an aromatic substituent were synthesized with high levels of enantio- and diastereoselection varying from 70 to 99%. Indeed, the use of methanol as solvent resulted in the formation of the *syn* chlorhydrins with moderate de (30). A *syn* diastereoselectivity was also reported using a (*R*)-BinapRu(II) catalyst (31).



These enantiomerically enriched α-chloro β-hydroxy esters were used to synthesize optically active glycidates (30) (Scheme 8) such as (2*R*,3*S*)-3-(4-methoxyphenyl) glycidate which was a practical key intermediate for the synthesis of diltiazem®, a potent channel blocker. The *trans* (2*S*,3*R*)-methyl-3-phenylglycidate was obtained under similar conditions and provided an efficient route to taxotere® side chain.

The dynamic kinetic resolution of α-acetamido β-keto ester was successfully applied to produce an important intermediate (Scheme 9) for the synthesis of carbapenems (32).



The synthesis of (2*S*,3*R*) methyl *p*-chloro-3-hydroxytyrosinate, a component of Vancomycin, was achieved using the dynamic kinetic resolution of an α-acetamido β-keto ester prepared from *m*-chloro-*p*-hydroxybenzoic acid

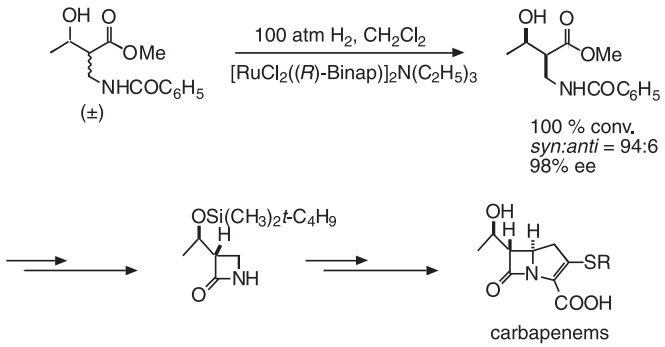
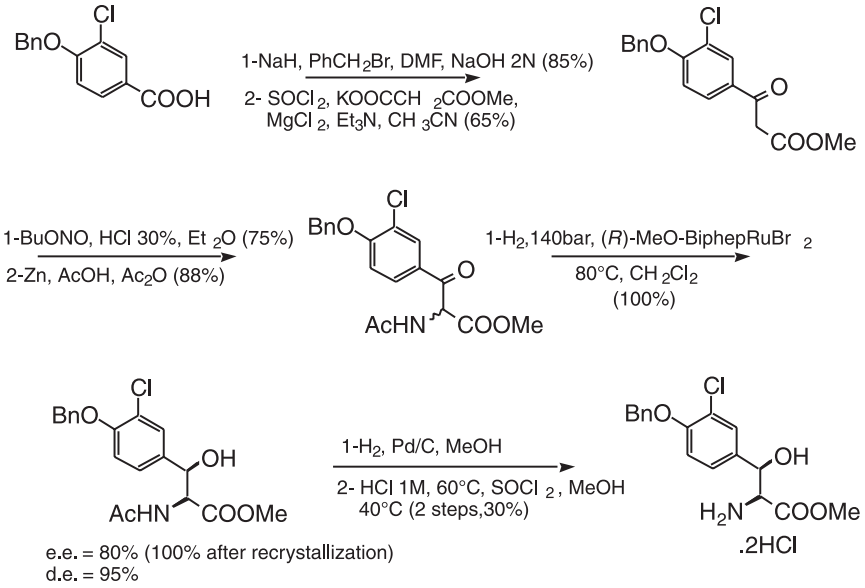


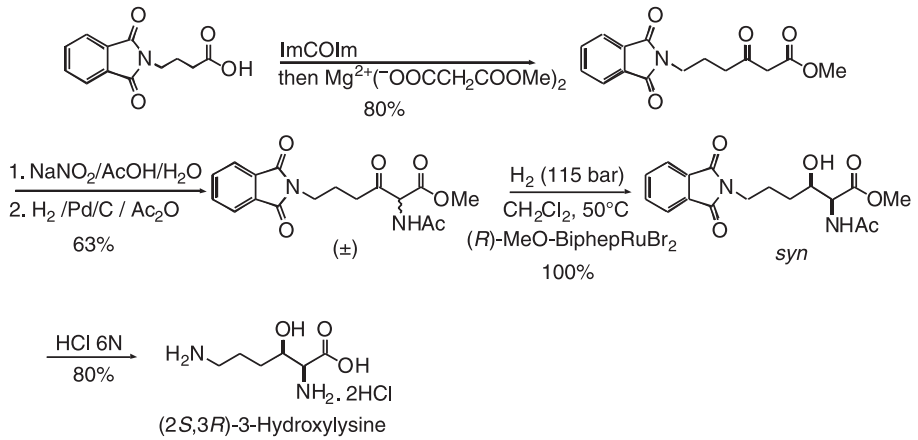
Scheme 7.

Scheme 8.

Scheme 9.



(Scheme 10) (33). The *syn* β-hydroxy α-amino ester was quantitatively synthesized and isolated as optically pure after two recrystallizations in ethanol.



The reactions using dynamic kinetic resolution of α-substituted β-keto esters have been used for the total synthesis of statine and analogues (34), HMG-CoA synthase inhibitor 1233 A (35), a chiral diphosphine (36), Biphenomycin A (37), and roxaticin (38). Genêt and co-workers (39) recently achieved an efficient synthesis of (2*S*,3*R*)-3-hydroxylysine from the commercially available 4-phtalimidobutyric acid (Scheme 11); an ideal dynamic kinetic resolution of racemic methyl-2-acetamido-3-keto-6-phtalimidohexanoate was obtained under 115 bar of hydrogen pressure at 50°C in dichloromethane affording the desired optically pure *syn* α-acetamido β-hydroxy ester in quantitative yield. This key step allowed the formation of both stereogenic centers

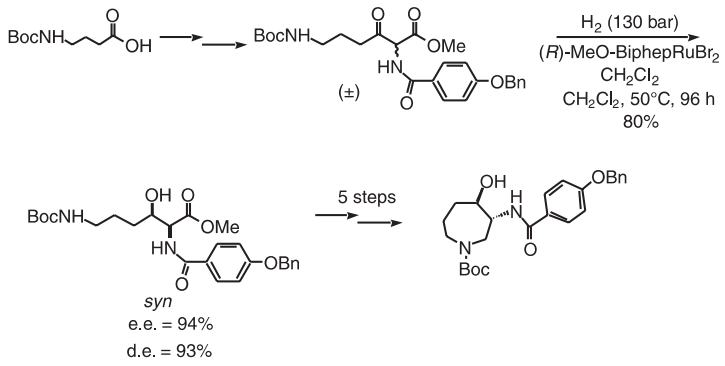
Scheme 10.

Scheme 11.



of (2*S*,3*R*)-3-hydroxylysine in a single stereocontrolled catalytic step using (*R*)-MeO-BIPHEP as the chiral auxiliary.

The same strategy has been used for an expeditive synthesis of the hexahydroazepine unit (40) of (–)-balanol (proteine kinase C inhibitor) (Scheme 12).

The dynamic kinetic resolution through ruthenium-promoted hydrogenation of chirally labile racemic α-substituted β-keto ester is a method of choice to synthesize chiral compounds of high enantiomeric purity. In ideal situations, it is possible in one single step to obtain the desired

Scheme 12.

Free radicals and Lewis acid. Chelation-controlled radical allylations of substituted α-halo- or α-phenylseleno-β-alkoxy esters. The endocyclic effect.

B. Guérin, C. Chabot, N. Mackintosh, W.W. Ogilvie, and Y. Guindon

Abstract: The radical allylation of a series of α-halo or α-phenylseleno-β-alkoxy esters in the presence of $MgBr_2 \cdot OEt_2$ is reported and compared with analogous reactions under non-chelating conditions. The addition of $MgBr_2 \cdot OEt_2$ gives excellent selectivity favoring *anti* products; in some cases ratios >100:1 are obtained. Varying the substrate substituents reveals that these reactions are quite tolerant of alkyl functionalities at the β-position. Changes to the alkoxy function indicate that a chelate is involved in the reaction. The reactions are successful with secondary iodides, bromides, and phenylselenides, as well as tertiary iodides, which all give very high ratios under chelation control. Performing less well under the same conditions are substrates with a radical exocyclic to a tetrahydrofuran ring. EDTA titration is used to determine the amount of Mg^{2+} dissolved in the allylation reaction mixture, and ^{13}C NMR is employed to better define the nature of the complex formed (chelate or monodentate) prior to the reaction. Competition experiments suggest that the chelate and monodentate pathways are in competition for the radical allylation with allyltributyltin.

Key words: allylation, radicals, Lewis acid, stereoselectivity, 1,2-induction.

Résumé : Les allylations radicalaires, pour une série d'esters α-halo or phenylseleno-β-alkoxylés, en présence de $MgBr_2 \cdot OEt_2$, sont rapportées et comparées aux réactions analogues sans acide de Lewis. L'addition de $MgBr_2 \cdot OEt_2$ conduit à une excellente sélectivité en faveur des produits *anti*, pour certains cas, des ratios >100:1 ont été obtenus. Les variations des substituants sur les substrats montrent que ces réactions tolèrent une variété de fonctions alkyles en position β. Les changements de la fonction alkoxy suggèrent qu'un chelate est impliqué lors de la réaction. Les allylations fonctionnent bien avec les iodures, les bromures ainsi qu'avec les phénylsélenures secondaires. Les iodures tertiaires donnent des ratios très élevés en présence d'acide de Lewis. Les substrats générant un radical exocyclique à un cycle tetrahydrofurane donnent de moins bons résultats sous ces conditions. Le titrage à l'EDTA a été utilisé pour déterminer la quantité de Mg^{2+} dissous dans le mélange réactionnel lors de l'allylation, et les données RMN ^{13}C ont été utilisées pour mieux définir la nature des complexes formés (chelate ou monodentate) avant la réaction. Les expériences de compétition suggèrent que les deux chemins réactionnels, chelate et monodentate, sont en compétition pour l'allylation radicalaire avec l'allyle d'étain.

Mots clés : allylation, radicaux, acide de Lewis, stéréoselectivité, induction-1,2.

1. Introduction

This decade (1) has shown that free radical based reactions could be useful synthetic approaches for making acyclic molecules with high levels of diastereoselectivity and enantioselectivity. Significant levels of stereocontrol have been achieved in strategies involving pre-existing chiral centers (2, 3) or chiral auxiliaries (4). The scope of these reactions has been expanded by using mono (5) or bidentate Lewis acids (6, 7), solvent complexation (8), and intramolecular hydrogen bonding (9). Additionally, reagent control approaches employing chiral Lewis acid or chiral tin hydride have been recently devised (10).

We have been particularly interested in studying the reactivity of radicals flanked by an ester and a stereogenic center bearing a heteroatom in reactions involving hydrogen-atom

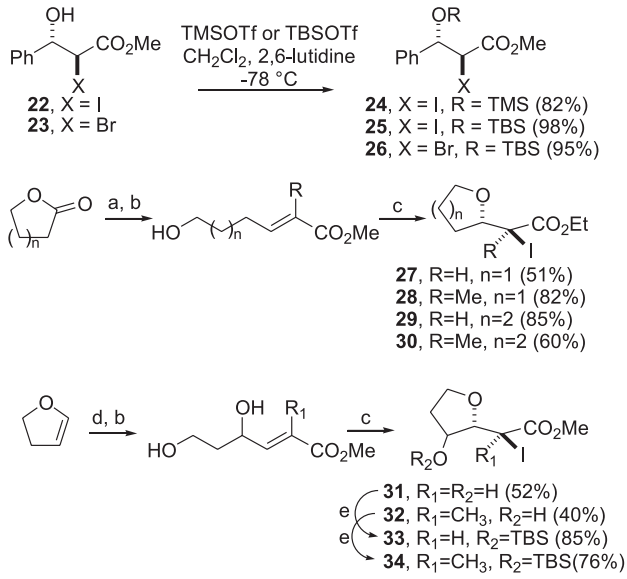
transfer (3), additions to olefins (7*e*), cyclizations (3*f*), and allylation reactions (3*b*, 3*g*, 7*b*). Our first studies dealing with the induction of new chiral centers on acyclic molecules, using free radical chemistry, spawned from unexpected experimental results. The realization that the planarity of radicals adjacent to an ester or amide group might resemble *Z*-enolates led to the hypothesis that allylic 1,3-strain (1*a*, 2*c*) could be one of the factors controlling stereoselectivity. The stereochemical outcome of the allylation reaction has been best rationalized by transition state **A** (Scheme 1*a*) (1, 2, 3, 4), which takes into account allylic 1,3-strain and electronic factors such as dipole–dipole repulsion (3) and hyperconjugative stabilization (3*e*). Thus, the *syn* isomer is the major compound obtained when such a radical intermediate, originating from the homolytic extrusion of a phenylseleno ether or a halogen, is reacted with allyltributyltin.



In response to this finding, our group hypothesized that a bidentate Lewis acid could, through complexation with the oxygen of the stereogenic center and the carbonyl of the ester, reposition the R_1 group onto the opposite face of the radical, thus allowing for a preferred attack on the top side leading to the *anti* product (Scheme 1*b*, transition state **B**). Our previous work in hydrogen-atom transfer reactions (7*a*, *e*) had shown that this approach could be feasible. Those findings inspired studies to show that the facial selectivity of a radical based allylation could be inverted (from *syn* to *anti*) through the simple expedient of adding $MgBr_2 \cdot OEt_2$ to the reaction mixture (7*b*). This strategy was further shown by both our group (7*c*) and Porter's group (11) to be successful in atom transfer reactions. Reported now are the full experimental details of chelation-controlled allylations of β-alkoxy esters, including studies on the importance of the stereochemistry of the starting material in such radical processes and on the possible formation of bidentate intermediates. Preliminary experiments that explain the need for an excess of $MgBr_2 \cdot OEt_2$ in the reaction and that elucidate further mechanistic details will also be presented.

2. Preparation of materials and standards

Secondary and tertiary iodides **9**–**13**, **16**, **19**–**21**, and bromides **14** and **17**, were prepared, by halo-etherification reaction, from the corresponding olefins **1**–**8** as shown in Table 1 (12, 13). Phenylselenides **15** and **18** were synthesized using a modification of the same method wherein AgOTf, a soluble silver salt, was used in place of $AgNO_3$. *Syn* substrates **16**–**18** were prepared from the appropriate *Z* olefin using

Scheme 2. (*a*) DIBAL-H, CH_2Cl_2, –78°C; (*b*) $Ph_3{=}C(R)CO_2Me$ (ethyl ester was used when R=Me), $PhCO_2H$, THF, reflux; (*c*) I_2, $NaHCO_3$, THF, 25°C; (*d*) *m*-CPBA, Et_2O, H_2O, 0 to 25°C; (*e*) TBSOTf, CH_2Cl_2, 2,6-lutidine, 0°C.

procedures analogous to those of the corresponding *anti* substrate (12). Silyl ethers **24**–**26** were readily derivated from the secondary alcohols (14) as described previously (Scheme 2) (15). Tetrahydrofurans **27**–**28** and tetrahydropyrans **29**–**30** were prepared in three steps as outlined in Scheme 2 (3*d*, 7*c*). DIBAL reduction of γ-butyrolatone or δ-valerolactone followed by Wittig olefination of the resultant lactols afforded the corresponding α,β-unsaturated esters. Cyclization of the olefins under kinetic conditions (I_2, $NaHCO_3$, THF, 25°C) (16) produced the expected iodoesters. Tetrahydrofurans **31** and **32** (17) were prepared by treating dihydrofuran with *m*-CPBA (H_2O–Et_2O, 82%) to give the hemiacetal that was then subjected to $Ph_3P{=}C(R)CO_2Et$ (THF, reflux). An iodocyclization reaction was done on the resulting compound. Protection of alcohols **31** and **32** (*t*-$BuMe_2SiOTf$, CH_2Cl_2, 2,6-lutidine, 0°C) gave either **33** or **34** (Scheme 2).

The relative configurations of the allylated products were established by independent synthesis and correlation of the NMR spectra (7*c*). In every case, the difference in chemical shift between the NMR resonances of the methylene protons in the allyl side chain (Δυ) for the *anti* diastereoisomers was greater than the Δυ values for the *syn* diastereoisomers. The chemical shifts of the resonances of the same hydrogens in the *anti* series were also consistently upfield to the resonances of the corresponding *syn* counterparts (18).

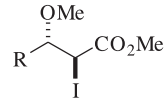
3. The radical-mediated allylations of α-halo- or α-phenylseleno-β-alkoxy esters

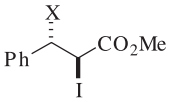
Treating a solution of 3-methyl-3-methoxy-2-iodopropionate **9** with allyltributyltin and 3 equivalents of $MgBr_2{\cdot}OEt_2$ gave a mixture of adducts in a 51:1 ratio favoring the *anti* product (Table 2, entry 1). Achieving interesting diastereoselectivity has been shown (vide infra) to require the presence of an excess of $MgBr_2{\cdot}OEt_2$. In the absence of $MgBr_2{\cdot}OEt_2$, substrate **9** showed a preference for the *syn* product, but poor selectivity was observed (entry 2). Other acyclic secondary iodides performed well under chelation-controlled conditions, affording *anti* isomers with excellent diastereofacial selectivity (entries 3, 5, 7). These substrates displayed a preference for the *syn* adduct in the absence of $MgBr_2{\cdot}OEt_2$ (entries 4, 6, 8). A greater selectivity was observed for substrate **12** when the reaction was conducted in toluene at –78°C (entry 8 versus 9).

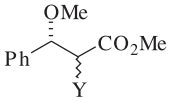
Modifications to the β-alkoxy group (X) and their effects on the allylation reactions are shown in entries 7–15. Replacement of the methoxy group by a benzyloxy ether led to an erosion of *anti* diastereoselectivity under chelation-controlled conditions (entries 7 and 10). When the methoxy group was replaced by a silyl ether, the Lewis acid lost its influence in controlling the stereochemical outcome (entries 7, 8, 12–15). Generally, the steric congestion offered by the larger silyl groups (relative to Me) should preclude chelation of the oxygen with Lewis acid (19). As was hypothesized at the onset of this study, these results strongly suggest that the formation of cyclic intermediates, through $MgBr_2{\cdot}OEt_2$ complexation with the oxygens of the alkoxy and the carbonyl functions, is required in order to obtain *anti* adducts in this series of molecules.

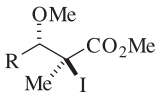
In addition to *anti* iodide **12**, *anti* bromide **14** and *anti* phenylselenide **15** were also transformed into their corresponding allyl derivatives with excellent selectivity and yield when $MgBr_2{\cdot}OEt_2$ was present (entries 7, 16, and 18). For each substrate, the *anti* isomer was formed preferentially to the extent of 38:1, 19:1, and 65:1, respectively. Under the same conditions, *syn* iodide **16** led to reduced levels of diastereoselectivity and gave a 5:1 ratio in favor of the *anti* product (entry 20). By contrast, ratios greater than 20:1 were observed for *syn* bromide **17** and *syn* phenylselenide **18** (entries 22 and 24). Without Lewis acid, the allylation reactions favored the *syn* isomer (entries 8, 17, 19, 21, 23, and 25) in a consistent ratio of approximately 5:1. One should note that the presence of Lewis acid usually reverses the facial bias and is accompanied by a significant increase in diastereoselectivity (entries 7, 16, and 18 versus 8, 17, and 19, respectively).

Tertiary iodides displayed excellent diastereoselectivity in chelation-controlled allylations (entries 26, 28, and 30). Since asymmetric quaternary centers are difficult to form, these reactions clearly have interesting synthetic utility (20). Compared to the secondary iodides, the tertiary iodides in the absence of $MgBr_2{\cdot}OEt_2$ showed lower reactivity[3] but slightly higher diastereoselectivity favoring the *syn* product (entries 2, 4, 6, and 8 versus 27, 29, and 31).









Assuming that the cyclic intermediate bearing a carbon-based radical was at the origin of the *anti* diastereoselectivity noted for the chelation-controlled allylation (the endocyclic effect) (Scheme 1*b*), we were anxious to evaluate the effect of a ring adjacent to the radical. Indeed, a bicyclic intermediate had to then be considered in this scenario.

Table 3 lists some preliminary results from this study. Note that entries 1 and 3 indicate a lower preference for the

[3] The lower reactivity is reflected by longer reaction times, even when conducted in hexanes at reflux.

[a]A:2.0 equiv of allylSnBu$_3$, 3.0 equiv of MgBr$_2$·OEt$_2$, 0.2 equiv of Et$_3$B, CH$_2$Cl$_2$, –78°C. B:2.0 equiv of allylSnBu$_3$, 0.2 equiv of AIBN, hexanes, reflux.

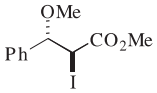
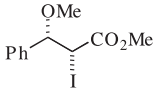
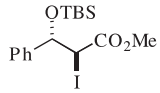
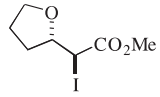
anti product when the carbon bearing the radical was adjacent to a tetrahydrofuran (THF) ring and when MgBr$_2$·OEt$_2$ was present. This trend is magnified in the tertiary iodide series (entries 1 and 3 versus 5 and 7), where a 7:1 ratio favoring the *anti* isomer was the best selectivity obtained. In contrast, substrates bearing a tetrahydropyran (THP) ring α to the radical gave excellent diastereoselectivity under chelation-controlled conditions (entries 9 and 11). From the THF and THP substrates, *syn* isomers were obtained in good ratios in the absence of Lewis acid, considering that the reactions were performed in hexanes at reflux (entries 2, 4, 6, 8, 10, and 12). The bicyclic intermediate chelate with two 6-membered rings was clearly more efficient in inducing *anti* diastereoselectivity than the bicyclic intermediate with one 5- and one 6-membered ring.

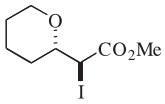
4. The role of MgBr$_2$·OEt$_2$. Determination of the amount of Mg^{2+} present in the allylation reaction by EDTA titration











With conditions for the chelation-controlled allylation optimized, we turned our attention to the problem of why an excess of MgBr$_2$·OEt$_2$ (3 equivalents) was needed to maximize diastereoselectivity. Table 4 (entries 1–3) shows that 0.25, 1, and 3 equivalents of MgBr$_2$·OEt$_2$, complexed with iodide **12,** gave ratios of 1.6:1, 7:1, and 38:1, respectively; however, no increase in ratio was noted with 5 equivalents of MgBr$_2$·OEt$_2$ (see entry 4). The results were surprising because the subequimolar amount of MgBr$_2$·OEt$_2$ was accompanied by insoluble material in the reaction medium. We had, of course, expected that one equimolar amount of Lewis acid would be sufficient for the chelation (vide infra), but our assumption had not taken into account the possibility of other competing intermediates.

To shed some light on the above results, we decided to determine the amount of Mg^{2+} actually present in the reaction mixture. The first step in doing so was to allow the Lewis acid to equilibrate at –78°C in the presence of iodide **12** (5 mL of 0.1 M solution) and allyltributyltin. After 10 min, 3 mL of the solution was filtered and analyzed for magnesium content by EDTA titration (21). Et$_3$B was added to the remaining solution to measure allylation efficacy and diastereoselectivity.

The amount of Mg^{2+} dissolved in solution increased concomitantly with the amount of MgBr$_2$·OEt$_2$ introduced at the beginning of the reaction (entries 1, 2, and 3). A maximum of 1.6 equivalents of dissolved Mg^{2+} was reached in the reaction containing 3 equivalents of MgBr$_2$·OEt$_2$ (entry 3). Concurrently, the *anti*:*syn* ratio of the allylated products steadily increased, giving a maximum selectivity of 38:1

[b]Equivalents of Mg^{2+} measured relative to the amount of substrate.

[c]Experiment run under identical conditions relative to reactions with substrate present.

when the 3 equivalents of $MgBr_2 \cdot OEt_2$ were used. More than 3 equivalents of $MgBr_2 \cdot OEt_2$ did not increase further either the amount of Mg^{2+} in solution or the allylation ratio (entry 4).

In the absence of the substrate, the solubility of Mg^{2+} in CH_2Cl_2 at –78°C, relative to the amount of substrate normally used, was found to be 0.25 equivalent (entry 5). Note that the number of equivalents reported is always relative to the number of mmoles of substrate normally used. From the above results can be concluded that the intrinsic solubility of $MgBr_2 \cdot OEt_2$ in CH_2Cl_2 is low and that the substrate brings into solution an additional equivalent of Mg^{2+}, suggesting a strong interaction between the substrate and the Lewis acid. Note that there is a ca 30% excess of the added $MgBr_2 \cdot OEt_2$ that does not go into solution (entries 1 and 2), and that this amount in suspension can vary depending on the source of Lewis acid.[4] However, the ratio being the same with or without filtration strongly indicates that the insoluble materials have no effect on the outcome of the reactions.

This experimental protocol was repeated for *syn* isomer **16**, which gave the same amount of Mg^{2+} dissolved in solution but much less impressive diastereoselectivity, as already noted (entry 6).

One equivalent of Mg^{2+} was found for silyl compound derivative **25** in the presence of $MgBr_2 \cdot OEt_2$ compared to 0.25 equivalent without the substrate (entry 7 versus 1). Therefore, around 0.7 equivalent was brought in solution by the substrate. Qualitatively, this result is not so surprising. The Lewis acid can easily form a monodentate complex with substrate **25** since the latter presents a Lewis base functionality, the ester.

Similarly, THF derivative **27** (entry 8) and silyl compound **25** (entry 7), which formed a monodentate complex, extracted almost the same amount of Mg^{2+}. This contrasts the result for THP **29**, which brought into solution 1.85 equivalents of Mg^{2+} (entry 9). This is as much as methyl ether **12**, the bidentate chelate, brought. One has to remember that THF derivative **27** gave a much poorer ratio in favor of the *anti* product than THP derivative **29** afforded (entries 8 versus 9).

These measurements of Mg^{2+} dissolved in solution indicate that an equimolar complex with $MgBr_2 \cdot OEt_2$ is formed

[4]The material in suspension could be less soluble magnesium salts.

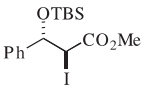
5	$MgBr_2 \cdot OEt_2$	23	3.80	66.7	1.29	14.8
6	OEt_2	23	3.44	66.1	1.15	15.5

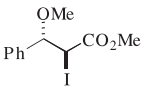
with iodides **12** and **29,** which suggests a chelation. Such a condition seems to be essential for achieving good *anti* diastereoselection in this series of substrates. However, it may not be a sufficient condition, considering the modest diastereoselectivity noted for *syn* iodide **16**. This realization led us to another set of experiments, but this time using ^1H and ^{13}C NMR studies.

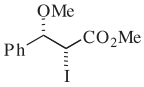
5. NMR studies of $MgBr_2 \cdot OEt_2$ complexes

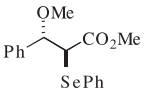
The first consideration for this study was whether or not diethyl ether was present as a ligand on magnesium. Table 5 shows the ^1H and ^{13}C chemical shifts of diethyl ether measured alone (entries 3 and 6), in solution as part of the $MgBr_2 \cdot OEt_2$ (entries 2 and 5), or in chelate form using iodide **12** (entries 1 and 4). The latter two results being the same indicates that most if not all of the diethyl ether is still attached to the magnesium following the formation of complexes with **12**, regardless of temperature (entries 1–2, 4–5).

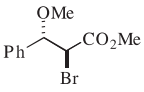
Previous studies done by Eliel (22), on chelates as intermediates in nucleophilic additions to α- and β-alkoxy ketones, have suggested that a strong chelation is consistent with a greater extent of change in the ^{13}C chemical shift of the carbonyl. Table 6 presents comparable NMR studies that consider various substrates in the presence of 3 equivalents of $MgBr_2 \cdot OEt_2$.

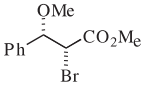












As seen in entry 1, the carbonyl signal of the ester for silyl ether **25** shifted only slightly downfield (2.7 ppm) when Lewis acid was present in the reaction, suggesting a preference for the formation of a monodentate complex with the ester. The difference in carbonyl chemical shift was significantly higher for methyl ether **12** (7.5 ppm), which is consistent with chelation (entry 2). The magnitude of these shifts concurs with Eliel's results (22).

Syn iodide **16** gave a shift of 4.8 ppm. As already shown by the solubility experiments, s*yn* iodide **16** formed a complex with $MgBr_2 \cdot OEt_2$ strong enough to bring into solution an amount of Lewis acid equivalent to that obtained from *anti* iodide **12** (Table 4, entry 6 versus 3). Yet, the ^{13}C data suggests that the *syn* iodide chelate should be qualitatively less strong than the one formed by the *anti* iodide (4.8 versus 7.5, Table 6, entries 2–3).[5] This would be consistent with the lower stereocontrol observed for **16** in chelation-controlled radical allylations.

Anti phenylselenide **15**, as well as bromides **14** and **17**, showed large displacements of the carbonyl signal upon the addition of $MgBr_2 \cdot OEt_2$ (entries 4–6) that correlate with strong chelation and high selectivity in the allylation. It would seem that the greater the carbonyl signal shift, the greater the *anti* preference; but this statement would need to be validated by additional experiments.

So far, the solubility experiments have shown that both monodentate and bidentate species bring Mg^{2+} in solution. The NMR studies have facilitated the ability to differentiate

between these species prior to the reaction. Remaining to be determined is whether or not the species participate competitively in the establishment of the final product distribution resulting from the allylation reaction. Preliminary experiments involving competition reactions have been designed to shed some light in this regard. (Vide infra.)

6. Competition reactions

All of the competition experiments were performed with two substrates of equimolar amounts, which were dissolved in CH_2Cl_2 together with allyltributyltin in either the absence or presence of $MgBr_2 \cdot OEt_2$ (3 equivalents). Only half an equivalent of allyltributyltin was used to obtain 50% conversion to the allylated products. NMR spectra of the crude reaction isolates were recorded to determine the relative conversion of each reactant. The results of these experiments are summarized in Table 7.

As seen in entry 1, a 1:1.8 ratio of unreacted methyl ether **12** to unreacted silyl ether **25** was noted, indicating that the methyl ether reacted faster than the silyl ether in the absence of Lewis acid. Similar results were obtained when $MgBr_2 \cdot OEt_2$ was present in the reaction mixture (entry 2). For the analogous bromide series, the consumption of methyl ether **14** (bidentate) was found to be slightly higher than that of silyl ether **26** (monodentate) in the presence of

© 2000 NRC Canada

$MgBr_2 \cdot OEt_2$ (entry 4). In the control experiment (entry 3), performed in the absence of Lewis acid, species **14** and **26** reacted at the same rate.

Next, the relative stereochemistry of bromides, selenides, and iodides was examined. In the presence of Lewis acid, *anti* and *syn* bromides **14** and **17** reacted at the same rate, as did the corresponding selenides **15** and **18** (entries 6 and 8). *Syn* iodide **16** reacted faster than *anti* iodide **12** both in the presence and absence of Lewis acid (entries 9 and 10). Notably, both *syn* selenide **18** and *syn* iodide **16**[6] reacted faster than their *anti* counterparts in the control experiments (entries 7 and 9). This result is without explanation at this time.

Two reactions were then done in parallel with *anti* silyloxy iodide **25** under standard conditions. The sole variable was $MgBr_2 \cdot OEt_2$, which was present in only one of the reactions. Comparable yields of allylated products (80%) were repeatedly obtained; however, the time to complete the reaction was shorter when Lewis acid was present.

Apparent from these studies is that the chelate intermediate, proposed in the case of the methyl ethers, does not have a significant advantage from a reactivity standpoint over the silyl ethers, which reacted only as monodentate complexes or free substrates. As demonstrated by entries 4 and 12, under chelation-controlled conditions, the allylation reaction differs from the hydrogen-atom transfer reactions (7*e*) with the bromide substrates. In the latter case, silyl ether **68** was consumed eight times faster than methyl ether **67**, indicating that the bidentate pathway was at a strong disadvantage.

7. Discussion

The chelation of the Lewis acid to the β-alkoxy ester is envisioned as the initial step of the allylation process (Scheme 3).[7] Subsequent homolytic cleavage of the α-halide or α-phenylselenide by attack of the tin radical ($Bu_3Sn\cdot$) gives a cyclic free-radical intermediate, which may benefit from the endocyclic (chelated) effect. Note that variations in the alkoxy function, and their ultimate effect on the ratio, support strongly the involvement of an endocyclic radical (Table 2, entries 7–15). The presence of the chelate prior to the generation of the radical is also supported by our ^{13}C NMR studies. The chelate is strong enough to bring into solution an equimolar amount of magnesium.

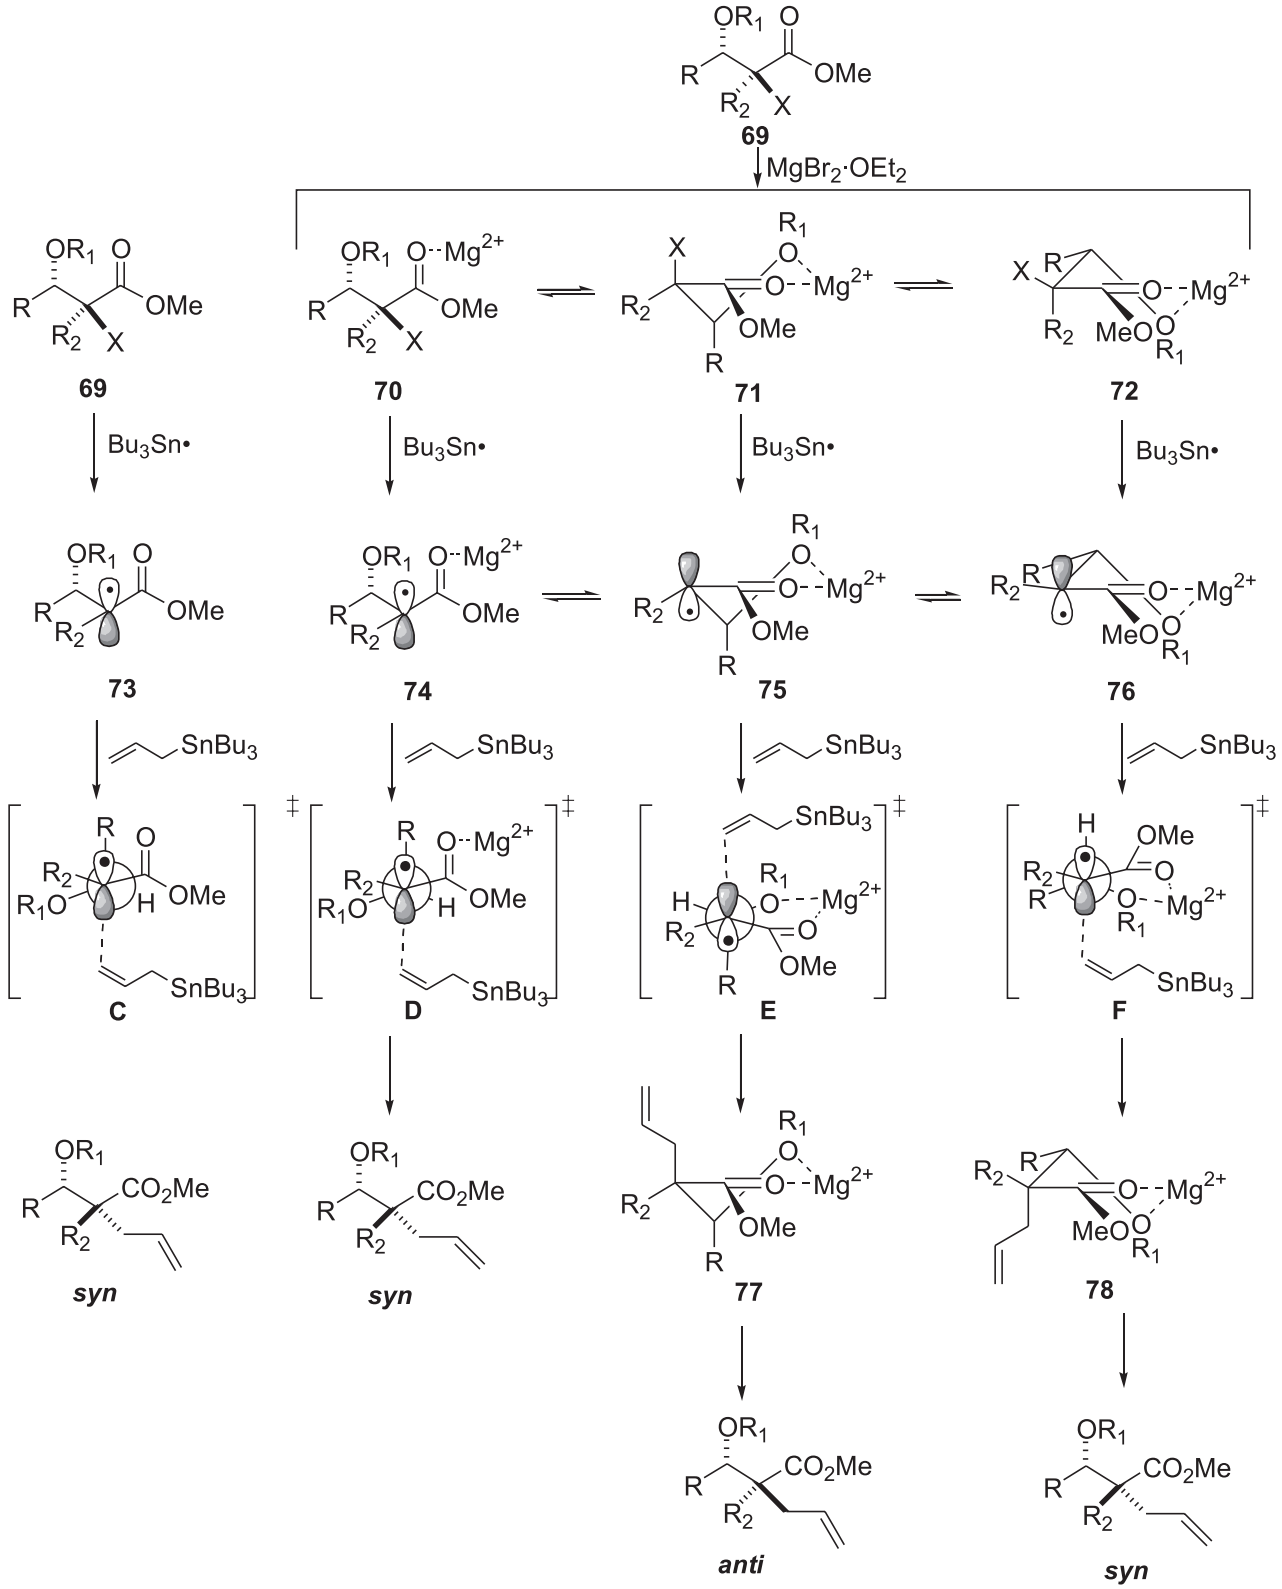
Once formed, the chelated radical may exist in two conformers, **75** and **76**, that lead to transition states **E** and **F**, respectively. The *anti* predictive transition state **E** should be favored over the *syn* predictive **F** on both electronic and steric grounds. Electronically, the electron-poor radical should be better stabilized, through hyperconjugation, by the overlap of the C—R (R = alkyl) bond in **E** than by that of the C—H bond in **F** (3*e*). From a steric standpoint, when R_2 is a methyl group, an additional allylic 1,2-strain between R and R_2 should increase the energy of transition state **F** relative to that of **E**.

Two other transition states should also be examined. Transition state **C** considers the radical in the absence of Lewis acid, while transition state **D** reflects the radical in a monodentate complex form. Both **C** and **D** are *syn* predictive transition states.

The rate of halogen abstraction by an electropositive tin radical should be enhanced by the presence of an adjacent electron-withdrawing group, such as an ester. A more electrophilic ester, obtained via coordination with a Lewis acid, should further facilitate the abstraction rate. The rate of addition should also be improved by the reaction of a more electrophilic radical with an electron rich double bond, such as the one on the allyltributyltin. Therefore, transition state **E** should be of lower energy than **C**. Indeed, allylation was apparently faster with $MgBr_2 \cdot OEt_2$ in the parallel reactions performed for the competition experiments.

One should note that transition states **D** and **E** both benefit from activation by the Lewis acid. The fact that the methoxy and silyloxy derivatives reacted at comparable rates in competitive experiments suggests the possibility that the monodentate acyclic pathway could actually be as rapid as, and therefore an alternative to, the cyclic pathway. As depicted in Scheme 3, a potential equilibrium could exist between **74** and **75** (or **70** and **71**). After all, these species differ by only a simple folding of the substrate molecule. If such equilibrium were to exist, the difference in energy between transition states **D** and **E** would likely dictate the outcome of the reaction.

The comparable reaction rates of the silyloxy and methoxy derivatives suggest that transition states **D** and **E** are of similar energy in the allylation. This result contrasts that of competition experiments involving hydrogen-atom transfer reactions, which showed the monodentate pathway to be favored over the bidentate (7*e*), indicating that a transition state similar to **D** would be lower in energy than a transition state analogous to **E** when tributyltin hydride is involved. It should be noted that the major product obtained originated, in both cases, from the attack on the top face of the radical (transition state **E**) in the presence of $MgBr_2 \cdot OEt_2$.



It should be remembered that significant levels of selectivity and differences in ratios, depending upon the stereochemistry of the halides and selenides (precursors to the same radical), were noted for the allylation reactions (vide supra). These results, along with those obtained from competition experiments, are more consistent with the equilibrium between **74** and **75** being rather slow, which suggests that the reactions are dependent upon the pre-existing mixture of complexes **70**, **71**, and **72**.

This dependency can explain the low selectivity obtained for the THF derivatives. A potential rationale illustrated by Scheme 4 shows that, for these substrates, the formation of a bicyclic intermediate may be impaired by the development of eclipsing interactions between the C–O bond and an Mg–Br bond in the *cis* bicyclo complex. An additional eclipsing interaction could be observed between the C–I bond and the Mg–Br (or $Mg–OEt_2$) bond if the geometry of the magnesium is either square planar pyramidal or bipyramidal trigonal. Such interaction implies that the preexisting complex mixture could have contained monodentate complexes or uncomplexed substrates. The smaller amount of Mg^{2+} found in solution supports this argument. By contrast, less

[6] The ratios were also verified by ^1H NMR prior to the allylation.
[7] The ligands on Mg^{2+} have been excluded for simplicity.

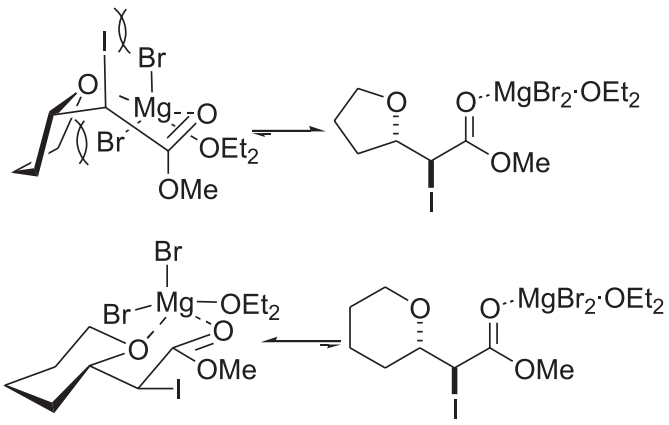
Scheme 3.



steric interaction is present for the bicyclo complex with THP. The pre-equilibrium for the THP substrates seems to favor the chelate formation. This conclusion is further supported by the high level of selectivity obtained for this series and by the amount of Mg^{2+} found in solution.

This discussion may not have sufficiently appreciated an important contributor: the $MgBr_2 \cdot OEt_2$. What is the nature of the complexes formed with the alkoxy esters and the $MgBr_2 \cdot OEt_2$? For instance, could there be two alkoxy esters serving as ligands on a magnesium (23) for the monodentate

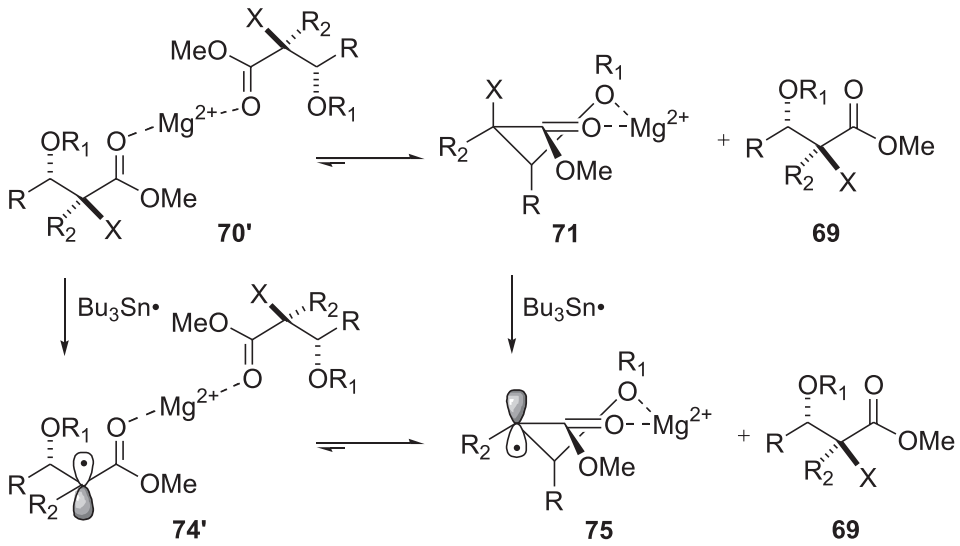
© 2000 NRC Canada

Scheme 4.

complex (**70′**, Scheme 5)?[7] If so, an excess of $MgBr_2 \cdot OEt_2$ could then be important in the pre-equilibrium phase for assuring the formation of another species involving one alkoxy ester as a ligand, depicted as bidentate complex **71** (Scheme 3). This would explain why the equilibrium between **74** and **75** is slow. Indeed, a ligand (another substrate) might have to be displaced in order for **74′** to reach **75**; a process that may not be fast enough to allow for kinetic selection between the two pathways (Scheme 4).

Only recently has the structure of $MgBr_2 \cdot OEt_2$ been resolved (24). The structure of complexes generated by alkoxy esters and $MgBr_2 \cdot OEt_2$ remain to be better defined. This is the topic of ongoing research.

8. Conclusion



The described chemistry represents a significant advance in the field of stereocontrol in radical reactions. Our studies of substituent effects clearly establish the scope and limitations of the chelation-controlled radical allylation of α-halo or α-phenylseleno-β-alkoxy esters. This reaction tolerates a wide variety of substitutions and, except for THF and *syn* iodide substrates, gives a high level of diastereoselectivity favoring *anti* products. This is true even for secondary iodides, bromides, and phenylselenides, as well as tertiary iodides. The requirement of radical initiation and the fact that the reaction can be inhibited are indicative of a free radical process. Other types of acyclic radical-based reactions are presently being evaluated. The influence of Lewis acid on the outcome of these reactions will also be studied.

9. Experimental section

General methods

All reactions requiring anhydrous conditions were conducted under a positive nitrogen atmosphere in oven-dried glassware using standard syringe techniques. The anhydrous solvents were purchased from Aldrich and were used as received. i-Pr_2NH and Et_3N were freshly distilled from CaH_2 under N_2 atmosphere. Allyltributyltin and triethylborane (1 M solution in hexane) were also purchased from Aldrich and used as received. Flash chromatography was performed on Merck silica gel 60 (0.040–0.063 mm) using nitrogen pressure. Analytical thin-layer chromatography (TLC) was carried out on precoated (0.25 mm) Merck silica gel F-254 plates. The uncorrected melting points were determined on an electrothermal melting point apparatus. NMR spectra were recorded via Bruker AC200, AMX300, ARX400, or Varian VXR-400S spectrometers, with chemical shifts reported relative to residual chloroform at 7.26 ppm. IR spectra were recorded on a Perkin-Elmer 781 spectrophotometer. CI and EI mass spectra were recorded on an MF 50 TATC instrument operating at 70 eV. FAB mass spectra were performed on a VG AutospecQ. Capillary GC analyses were performed on a Shimadzu GC-9AM instrument or a HP 6890 instrument using 0.25 mm × 30 m Supelcowax™10 and SE-30 columns.

Preparation of starting materials

The preparation and characterization data of **9**–**12** (7*d*), **14**–**21** (7*d*), **25** (7*d*), **27**–**30** (3*d*, 7*d*), and **34** (7*a*) have been reported previously.

*Methyl (±)-(2*S**,3*S**)-2-iodo-3-benzyloxy-3-phenylpropanoate (**13**)*: To a solution of methyl cinnamate (381 mg, 2.35 mmol) in benzylalcohol (3.5 mL) were added successively $AgNO_3$ (305 mg, 2.82 mmol) and iodine (710 mg, 2.82 mmol). The reaction mixture was stirred at room temperature in the dark for 24h, then filtered through celite and concentrated. The residue was taken up in EtOAc and washed with 10% $Na_2S_2O_3$, water, and brine. The organic layer was dried ($MgSO_4$), filtered, and concentrated to afford a residue, which was then purified by flash chromatography (CH_2Cl_2) to afford pure iodide **13** as a white solid (568 mg, 61%); mp 50–51°C; ^{1}H NMR (400 MHz, $CDCl_3$) δ 3.77 (s, 3H), 4.31 (d, *J* = 10.6 Hz, 1H), 4.40 (d, *J* = 10.6 Hz, 1H), 4.45 (d, *J* = 11.3 Hz, 1H), 4.80 (d, *J* = 11.3 Hz, 1H), 7.18–7.41 (m, 10H); ^{13}C NMR (100 MHz, $CDCl_3$) δ 24.80, 52.99, 71.89, 82.89, 127.85, 127.97, 128.33, 128.49, 129.08, 137.46, 137.58, 170.80; IR ($CHCl_3$) 3030, 2950, 1740, 1455 cm^{-1}; MS (FAB) 397 (MH, 8), 289 (35), 154 (49), 91 (100); HRMS calcd. for $C_{17}H_{18}O_3I$ (MH): 397.0301, found: 397.0290 (2.7 ppm). Anal. calcd. for $C_{17}H_{17}IO_3$: C 51.53, H 4.32; found: C 51.36, H 4.26.

*Methyl (±)-(2*S**,3*S**)-2-iodo-3-[(trimethylsilyl)oxy]-3-phenylpropanoate (**24**)*: To a solution of iodohydrin **22** (7*d*) (713 mg, 2.32 mmol) and 2,6-lutidine (540 μL, 4.64 mmol) in CH_2Cl_2 (25 mL) at –78°C was added slowly trimethylsilyl trifluoromethanesulfonate (670 μL, 3.48 mmol). After the reaction was judged complete by TLC, the mixture was diluted with ether and washed with water, saturated NH_4Cl, and brine. Drying over $MgSO_4$ followed by flash chromatography (4% EtOAc in hexanes) afforded silyl ether **24** as a colorless oil (720 mg, 82%). ^{1}H NMR (300 MHz, $CDCl_3$) δ –0.05 (s, 9H), 3.81 (s, 3H), 4.37 (d, *J* = 10.2 Hz, 1H), 5.05 (d, *J* = 10.1 Hz, 1H) 7.34–7.38 (m, 5H); ^{13}C NMR (100 MHz, $CDCl_3$) δ –0.26, 27.44, 52.66, 77.21, 127.50, 128.03, 128.44, 140.32, 170.73; IR (neat) 2955, 1742, 1495, 1435, 1252, 1166, 1070, 873 cm^{-1}; MS (FAB) 379 (MH, 11), 363 (24), 289 (77), 179 (100), 121 (42); HRMS calcd. for $C_{13}H_{20}IO_3Si$ (MH) 379.0226, found: 379.0209 (4.6 ppm). Anal. calcd. for $C_{13}H_{19}IO_3Si$: C 41.28, H 5.06; found: C 41.11, H 4.80.

*Methyl (±)-(2*S**,3*S**)-2-bromo-3-[((1,1-dimethylethyl)dimethylsilyl)oxy]-3-phenylpropanoate (**26**)*: Compound **26** was prepared with bromohydrin **23** (14) (1.20 g, 4.62 mmol) and *t*-butyldimethylsilyl trifluoromethanesulfonate (1.60 mL, 6.92 mmol) following the procedure described above for **24**. Purification by flash chromatography (CH_2Cl_2) afforded silyl ether **26** as a white solid (1.64 g, 95%). Mp 38°C; ^{1}H NMR (400 MHz, $CDCl_3$) δ –0.30 (s, 3H), 0.01 (s, 3H), 0.78 (s, 9H), 3.82 (s, 3H), 4.21 (d, *J* = 10.0 Hz, 1H), 4.98 (d, *J* = 10.0 Hz, 1H) 7.33–7.37 (m, 5H); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ –5.42, –4.75, 17.95, 25.49, 49.29, 52.85, 76.61, 127.62, 128.21, 128.63, 140.02, 169.53; IR ($CDCl_3$) 2850, 1745, 1590, 1450, 1355, 1315, 1080, cm^{-1}; MS (FAB) 373 (MH, 12), 317 (17), 221 (15), 131 (13), 73 (100); HRMS calcd. for $C_{16}H_{25}{}^{79}BrO_3Si$ (MH) 372.0756, found: 372.0746 (2.7 ppm). Anal. calcd. for $C_{16}H_{25}BrO_3Si$: C 51.47, H 6.75; found: C 51.55, H 6.92.

*Ethyl (±)-(2*S**)-2-[(2*S**,3*R**)-3-((1,1-dimethylethyl)dimethylsilyl)oxytetrahydrofuran-2-yl]-2-iodopropanoate (**33**)*: Compound **33** was prepared with iodoester **31** (17) (775 mg, 2.58 mmol) and *t*-butyldimethylsilyl trifluoromethanesulfonate (0.90 mL, 3.87 mmol) following the procedure described above for **24**. Purification by flash chromatography (5% EtOAc in hexanes) afforded silyl ether **33** (908 mg, 85%) as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ 0.15 (s, 3H), 0.22 (s, 3H), 0.95 (s, 9H), 1.30 (t, *J* = 7.1 Hz, 3H), 1.91–2.09 (m, 1H), 4.04–4.12 (m, 2H), 4.23 (q, *J* = 7.1 Hz, 2H), 4.35–4.36 (m, 2H), 4.53–4.55 (m, 1H); ^{13}C NMR (100 MHz, $CDCl_3$) δ –4.46, –4.09, 13.69, 18.01, 18.22, 25.92, 35.96, 61.79, 68.69, 72.64, 84.41, 170.54; IR (neat) 2960, 1740, 1470, 1260 cm^{-1}; MS (CI, CH_4) *m*/*z* 415 (MH^+, 95), 399 (37), 369 (100), 357 (27), 283 (39), 155 (9). Anal. calcd. for $C_{14}H_{27}IO_4Si$: C 40.58, H 6.57; found: C 40.93, H 6.43.

Allylation products

The preparation and characterization data of **35**–**42**, **47**–**56**, **63**, and **64** have been reported previously (7*d*).

General procedure for the allylation of α-iodoesters under chelation-controlled conditions (Conditions A)

To a stirred solution of α-iodoester (1 equiv) in dry CH_2Cl_2 (0.1 M) at –78°C was added $MgBr_2{\cdot}OEt_2$ (3 equiv). The mixture was stirred for 15 min at the same temperature before allyltributyltin (2 equiv) and Et_3B (0.2 equiv of a 1.0 M solution in hexanes) were added. The resulting suspension was stirred at –78°C, and 0.2 equivalent of Et_3B was added each 30 min until the reaction was judged complete by TLC. 1,3-Dinitrobenzene (0.2 equiv) was then added to the solution and the mixture was stirred an additional 15 min at –78°C. The reaction mixture was poured into a saturated $NaHCO_3$ solution and extracted with CH_2Cl_2. The combined organic extracts were washed with brine, dried over $MgSO_4$, filtered, and concentrated under reduced pressure.

*Methyl (±)-(2*S**,3*S**)-2-[propen-3-yl]-3-benzyloxy-3-phenylpropanoate (**43**)*: Compound **43** was prepared with iodoester **13** (97 mg, 0.24 mmol) following the general procedure described above. A 5:1 ratio of *anti*:*syn* products was determined by GC and ^{1}H NMR analyses of the crude isolate. Purification by flash chromatography (5% EtOAc in hexanes) afforded allylated products **43** and **44** (40 mg, 52%). **43**: Colorless oil; ^{1}H NMR (400 MHz, $CDCl_3$) δ 1.77–1.83 (m, 1H), 2.05–2.18 (m, 1H), 2.81–2.94 (m, 1H), 3.73 (s, 3H), 4.21 (d, *J* = 11.8 Hz, 1H), 4.39 (d, *J* = 11.8 Hz, 1H), 4.47 (d, *J* = 9.9 Hz, 1H), 4.87–4.98 (m, 2H), 5.47–5.59 (m, 1H), 7.17–7.45 (m, 10H); ^{13}C NMR (100 MHz, $CDCl_3$) δ 33.22, 51.45, 53.07, 70.45, 82.58, 116.80, 127.43, 127.62, 127.75, 128.12, 128.40, 128.56, 134.43, 138.89, 137.97, 174.17; IR (neat) 2980, 1738, 1642, 1434, 1195 cm^{-1}; MS (FAB) 311 (MH, 100), 203 (22), 171 (25), 143 (87), 133 (83); HRMS calcd. for $C_{20}H_{23}O_3$ (MH) 311.1647, found: 311.1659 (–3.7 ppm).

General procedure for the allylation of α-iodoesters in the absence of Lewis acid (Conditions B)

To a solution of α-iodoester (1 equiv.) in hexanes (0.1 M) at 23°C were added allyltributyltin (2 equiv) and AIBN (0.2 equiv). After being allowed to reflux, the mixture was stirred until the reaction was judged complete by TLC.

Methyl (±)-(2R,3S*)-2-[propen-3-yl]-3-benzyloxy-3-phenylpropanoate (**44**)*: To a solution of iodoester **13** (175 mg, 0.44 mmol) in CH_2Cl_2 (4.5 mL) at –78°C were added allyltributyltin (275 μL, 0.88 mmol) and Et_3B (90 μL of a 1.0 M solution in hexanes, 0.09 mmol). The reaction mixture was stirred at –78°C with 0.2 equivalent of Et_3B added each 30 min until the reaction was judged complete by TLC. A 1:10 ratio of *anti*:*syn* products was determined by GC and ^{1}H NMR analyses of the crude isolate. Purification by flash chromatography (5% EtOAc in hexanes) afforded allylated products **43** and **44** (82 mg, 60%). **44**: Colorless oil; ^{1}H NMR (400 MHz, $CDCl_3$) δ 2.41–2.57 (m, 1H), 2.66–2.78 (m, 1H), 2.86–2.92 (m, 1H), 3.41 (s, 3H), 4.22 (d, *J* = 11.6 Hz, 1H), 4.44 (d, *J* = 11.6 Hz, 1H), 4.47 (d, *J* = 8.8 Hz, 2H), 4.95–5.09 (m, 2H), 5.78–5.81 (m, 1H), 7.25–7.43 (m,

*Ethyl (±)-(2*R*)-2-[(2*S*,3*R*)-3-((1,1-dimethylethyl)dimethylsilyl)oxytetrahydrofuran-2-yl]-2-[propen-3-yl]-propanoate (**58**)*: Compound **58** was prepared with iodoester **33** (52.5 mg, 0.13 mmol) following the general procedure described above. A 1:51 ratio of *anti*:*syn* products was determined by GC and ^{1}H NMR analyses of the crude isolate. Purification by flash chromatography (5% EtOAc in hexanes) afforded allylated product **58** as a colorless oil (30.5 mg, 74%). ^{1}H NMR (400 MHz, $CDCl_3$) δ 0.00 (s, 3H), 0.06 (s, 3H), 0.88 (s, 9H), 1.25 (t, *J* = 7.1 Hz, 3H), 1.78–1.91 (m, 1H), 2.00–2.18 (m, 1H), 2.44–2.52 (m, 1H), 2.60–2.67 (m, 1H), 2.81–2.92 (m, 1H), 3.73–4.25 (m, 5H), 4.38–4.43 (m, 1H), 4.97–5.11 (m, 2H), 5.69–5.90 (m, 1H); ^{13}C NMR (100 MHz, $CDCl_3$) δ –5.40, –4.49, 14.19, 17.87, 25.62, 34.26, 36.14, 44.33, 59.82, 65.82, 72.27, 81.66, 116.74, 134.83, 173.38; IR (neat) 2910, 1730, 1645, 1460, 1370, 1240, 1175, 1070, 820 cm^{-1}; MS (FAB) *m/z* 329 (MH^+, 12), 283 (16), 271 (82), 149 (100); HRMS calcd. for $C_{17}H_{33}O_4Si$ *m/z* (MH^+) 329.2148, found: 329.2130 (5.5 ppm).

*Ethyl (±)-(2*R*)-2-[(2*S*)-tetrahydrofuran-2-yl]-2-[propen-3-yl]-2-methylpropanoate (**60**)*: Compound **60** was prepared with iodoester **28** (163 mg, 0.55 mmol) following the general procedure described above. A 1:10 ratio of *anti*:*syn* products was determined by GC and ^{1}H NMR analyses of the crude isolate. Purification by flash chromatography (10% EtOAc in hexanes) afforded allylated products **59** and **60** (94 mg, 81%). **60**: Colorless oil; ^{1}H NMR (400 MHz, $CDCl_3$) δ 1.11 (s, 3H), 1.25 (t, *J* = 7.1 Hz, 3H), 1.68–1.91 (m, 4H), 2.32 (dd, *J* = 7.9, 13.6 Hz, 1H), 2.54 (dd, *J* = 6.8, 13.6 Hz, 1H), 3.73–3.85 (m, 2H), 4.02–4.07 (m, 1H), 4.14 (q, *J* = 7.1 Hz, 2H), 5.03–5.10 (m, 2H), 5.67–5.79 (m, 1H); ^{13}C NMR (100 MHz, $CDCl_3$) δ 14.12, 15.86, 26.01, 26.87, 41.59, 49.83, 60.17, 68.49, 82.85, 117.62, 134.05, 174.94; IR (neat) 2990, 1730, 1645, 1465, 1380, 1140, 1065 cm^{-1}; MS (EI) *m/z* 213 (MH^+, 14), 171 (10), 142 (21), 69.5 (100); HRMS cacld for $C_{12}H_{21}O_3$ *m/z* (MH^+) 213.1491, found: 213.1499 (–3.9 ppm). Anal. calcd. for $C_{12}H_{20}O_3$: C 67.89, H 9.50; found: C 67.96, H 9.35.

*Ethyl (±)-(2*R*)-2-[(2*S*,3*R*)-3-((1,1-dimethylethyl)dimethylsilyl)oxytetrahydrofuran-2-yl]-2-[propen-3-yl]-2-methylpropanoate (**62**)*: Compound **62** was prepared with iodoester **34** (33.5 mg, 0.08 mmol) following the general procedure described above. A 1:16 ratio of *anti*:*syn* products was determined by GC and ^{1}H NMR analyses of the crude isolate. Purification by flash chromatography (5% EtOAc in hexanes) afforded allylated products **61** and **62** (17.5 mg, 65%). **62**: Colorless oil; ^{1}H NMR (200 MHz, $CDCl_3$) δ 0.05 (s, 6H), 0.86 (s, 9H), 1.25 (t, *J* = 7.1 Hz, 3H), 1.67–1.97 (m, 2H), 2.19 (dd, *J* = 7.7, 13.6 Hz, 1H), 2.57 (dd, *J* = 6.9, 13.6 Hz, 1H), 3.77–3.98 (m, 3H), 4.02–4.22 (m, 2H), 4.30–4.36 (m, 1H), 5.01–5.09 (m, 2H), 5.60–5.78 (m, 1H); ^{13}C NMR (50.3 MHz, $CDCl_3$) δ –4.86, –4.33, 14.19, 17.43, 17.75, 25.68, 36.59, 40.93, 48.90, 60.47, 67.03, 73.37, 91.81, 117.98, 133.93, 174.66; IR (neat) 2950, 1725, 1645, 1460, 1375, 1250, 1070, 910, 830, 770 cm^{-1}; MS (CI, CH_4) *m/z* 343 (MH^+, 25), 327 (19), 285 (9), 269 (8), 257 (12), 210 (100), 169 (10).

*Ethyl (±)-(2*R*)-2-[(2*S*)-tetrahydropyran-2-yl]-2-[propen-3-yl]-2-methylpropanoate (**66**)*: Compound **66** was prepared with iodoester **30** (187 mg, 0.60 mmol) following the general procedure described above. A 1:18 ratio of *anti*:*syn* products was determined by GC and ^{1}H NMR analyses of the crude isolate. Purification by flash chromatography (10% EtOAc in hexanes) afforded allylated product **66** as a colorless oil (105 mg, 77%). ^{1}H NMR (400 MHz, $CDCl_3$) δ 1.01 (s, 3H), 1.24 (t, *J* = 7.1 Hz, 3H), 1.36–1.53 (m, 5H), 1.82–1.86 (m, 1H), 2.30 (dd, *J* = 7.9, 13.6 Hz, 1H), 2.50 (dd, *J* = 6.9, 13.6 Hz, 1H), 3.36–3.46 (m, 2H), 3.97–4.02 (m, 1H), 4.13 (q, *J* = 7.1 Hz, 2H), 5.01–5.08 (m, 2H), 5.65–5.79 (m, 1H); ^{13}C NMR (100 MHz, $CDCl_3$) δ 14.12, 15.98, 23.60, 26.01, 26.32, 40.88, 50.26, 60.12, 68.99, 81.77, 117.50, 134.33, 174.98; IR (neat) 2920, 1725, 1450, 1300, 1210, 1085, 910 cm^{-1}; MS (FAB) *m/z* 227 (MH^+, 100), 199 (13), 185 (27), 151 (31), 143 (15), 135 (25); HRMS cacld for $C_{13}H_{23}O_3$ *m/z* (MH^+) 227.1647, found: 227.1656 (–3.9 ppm). Anal. calcd. for $C_{13}H_{22}O_3$: C 68.99, H 9.80; found: C 68.58, H 10.17.

Determination of magnesium concentrations in allylation reaction mixtures by filtration and EDTA titration

Preparation of the sample: To a stirred solution of α-iodoester (0.5 mmol) in dry CH_2Cl_2 (5 mL) at –78°C was added $MgBr_2{\cdot}OEt_2$. The mixture was stirred for 15 min at this temperature before allyltributyltin (1.0 mmol) was added. A 3 mL aliquot of the solution was removed from the flask using a syringe equipped with a filter (Millex HV 0.45 mm). This 3 mL aliquot was then concentrated under reduced pressure.

Titration of magnesium by EDTA: Deionized water (5 mL) and CH_2Cl_2 (5 mL) were added to the sample. The mixture was then shaken and poured into a 125 mL erlenmeyer flask. Deionized water (10 mL), NH_3–NH_4Cl buffer solution at pH = 10 (4 mL), and six drops of Calmagite indicator were added successively to the stirred solution, which was then titrated with a standardized EDTA solution (0.099 M, Aldrich) until the color changed completely from red to blue. The amount of Mg (mmol) in the total sample = 0.099 mmol/mL × V_{EDTA} added (mL) × (5/3).

The buffer pH = 10 was prepared from concentrated NH_4OH solution (57 mL) and 7 g of NH_4Cl in sufficient deionized water to give 100 mL of solution.

The calmagite indicator solution was prepared by adding 0.05 g of calmagite to 50 mL of deionized water.

^{13}C observations of β-alkoxyesters in the presence of a saturating amount of $MgBr_2{\cdot}OEt_2$ in CD_2Cl_2 at –23°C.

To a stirred solution of α-iodoester (1 equiv) in CD_2Cl_2 (0.1 M) at –23°C was added $MgBr_2{\cdot}OEt_2$ (3 equiv). The solution was then stirred for 15 min at the same temperature. A 1.5 mL aliquot of solution was removed from the flask using a syringe equipped with a filter (Millex HV 0.45 mm). The aliquot was placed in an NMR tube and kept at –23°C

until the ^{13}C NMR spectrum was recorded on a Bruker ARX400 spectrometer at that temperature.

Competition experiments

Substrates **A** (0.5 equiv) and **B** (0.5 equiv) were dissolved in $CDCl_3$ and the mixture was analyzed by NMR ^1H integration to determine the exact **A**:**B** ratio before the allylation reaction. The solution was concentrated and redissolved in dry CH_2Cl_2 (0.1 M) at –78°C before $MgBr_2 \cdot OEt_2$ (3 equiv) was added. The mixture was then stirred for 15 min at the same temperature, and allyltributyltin (0.5 equiv) as well as Et_3B (0.2 equiv of a 1.0 M solution in hexanes) were subsequently added. The resulting suspension was stirred at –78°C, and 0.2 equivalent of Et_3B was added each 30 min until the reaction was judged complete by TLC. The reaction mixture was then poured into a saturated $NaHCO_3$ solution and extracted with CH_2Cl_2. The combined organic extracts were washed with brine, dried over $MgSO_4$, filtered, and concentrated under reduced pressure. Another ^1H NMR analysis was done on the crude mixture to determine the exact **A**:**B** ratio after the allylation reaction.

Diastereoselective double ring closing metathesis reactions as an approach to symmetrical bicyclodienes

Mark Lautens, Gregory Hughes, and Valentin Zunic

Abstract: A new class of bicyclic dienes which contain a σ plane of symmetry are efficiently prepared in a diastereoselective fashion using ring closing metathesis reactions. These molecules have potential as starting materials for a wide range of organic targets.

Key words: metathesis, catalysis, stereoselective, decalin, desymmetrization.

Résumé : Faisant appel à des réactions de métathèse de fermeture de cycle, on a développé une méthode efficace de préparer de façon diastéréosélective une nouvelle classe de dienes bicycliques qui contiennent un plan de symétrie σ. Ces molécules pourraient éventuellement servir de produit de départ pour une grande variété de cibles organiques.

Mots clés : métathèse, catalyse, stéréosélective, décaline, désymétrisation.

Introduction

In recent years there has been tremendous interest in ring closing olefin metathesis (RCM) chemistry due largely to the development of well defined transition metal alkylidenes such as $[Cl_2(Cy_3P)_2Ru{=}CHPh]$ (**1**) and $[PhMe_2CCH{=}Mo{=}N\{2,6\text{-}(i\text{Pr})_2C_6H_3\}\{OCMe(CF_3)_2\}_2]$ (**2**) which display tolerance to a significant range of functional groups (for recent reviews of olefin metathesis see ref. (1)). We became interested in using RCM methodology as a key step in the projected total synthesis of the HMG CoA reductase inhibitor (+)-mevinolin (Scheme 1). We reasoned that a diastereoselective double ring closing metathesis strategy involving **A**, followed by an alkene selective sigmatropic rearrangement of a substrate such as **B**, would provide convenient access to the carbon skeleton of the hexahydronaphthalene portion of the target (for other examples of diastereoselective RCM reactions see ref. (2)); (for other examples of double RCM reactions see ref. (3)). A preliminary report on these investigations has appeared (4).

Received March 7, 2000. Published on the NRC Research Press website on June 15, 2000.

Dedicated to Professor Stephen Hanessian on the occasion of his 65th birthday.

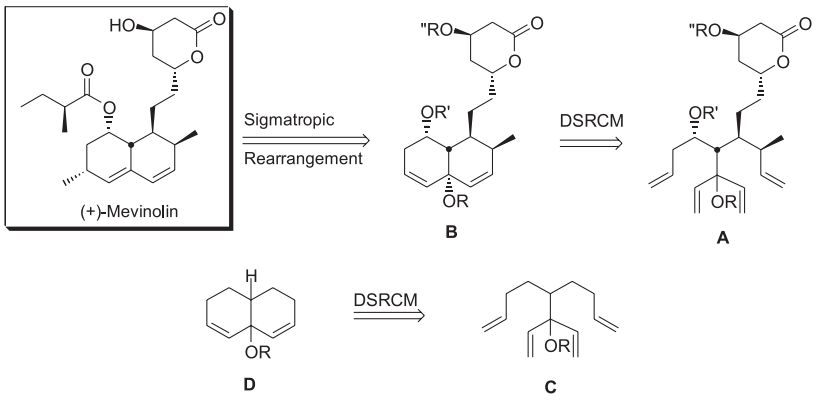
[2]4-Bromo-1-butene: $1088.91/mol; 3-buten-1-ol: $432.44/mol; 1,4-dichlorobut-2-ene (mixture of *cis* and *trans*): $20.70/mol. Prices in Canadian dollars listed in Aldrich's 1999 catalogue for the largest available denomination.

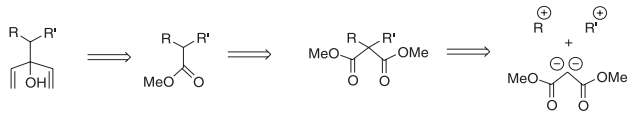
We opted to use unsubstituted tetraenes **C** for our initial studies. This simplified system is particularly attractive since the product of double ring closing metathesis, **D**, is a useful starting material for subsequent investigations in the area of enantioselective alkene differentiation reactions.

Results



We envisioned a general approach to a variety of tertiary diallylic alcohols involving dialkylation of malonate, Krapcho decarboxylation and addition of two equivalents of a vinyl organometallic reagent (Scheme 2).

For our first investigations we wanted to prepare a tetraene derived from double alkylation of malonate with a butenyl electrophile. The most obvious butenyl source would be commercially available 4-bromo-1-butene, or a derivative of 3-buten-1-ol (e.g., $CH_2{=}CH(CH_2)_2OTs$, $CH_2{=}CH(CH_2)_2OTf$, $CH_2{=}CH(CH_2)_2I$). However, the expense of both 4-bromo-1-butene and 3-buten-1-ol,[2] as well as the need to use these electrophiles in moderate excess due to their tendency to undergo elimination under basic conditions made this approach less attractive for the large scale preparation of materials needed for our investigations. We examined an alternative approach involving sequential additions of malonate to acrolein, followed by Wittig olefination. While the route furnished the desired dibutenylated malonate, the procedure was laborious, and the yields were low to moderate. In addition, the large quantities of triphenyl phosphine oxide produced on scaling up the reaction made this approach unattractive.



Inspired by the work of Tsuji and co-workers (5) and Shimizu and co-workers (5), we developed an alternative strategy for the butenylation of malonates, as well as a variety of other nucleophiles (6). In this approach, the appropriate nucleophile is alkylated with 1,4-dichlorobutene, which is a fraction of the cost of either 4-bromo-1-butene or 3-buten-1-ol,[2] to afford an allyl chloride. Formate reduction

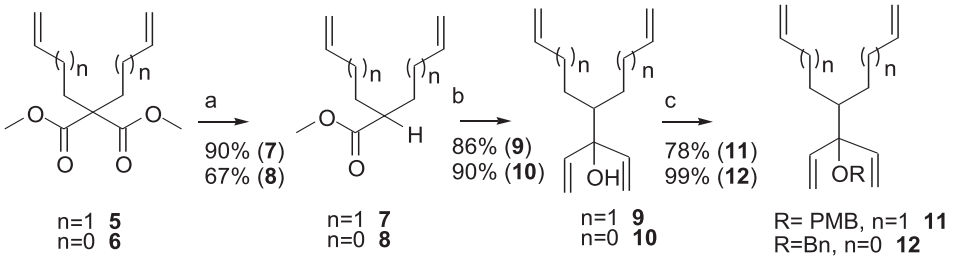
Scheme 2. Synthetic approach to model systems.

Scheme 3. Preparation of a dibutenylated malonate: (*a*) MeO^-Na^+ (1.5 equiv.), $ClCH_2CH{=}CHCH_2Cl$ (4.0 equiv., mixture of *cis* and *trans*), MeOH, 23°C→reflux, 57%; (*b*) HCO_2NH_4 (2.2 equiv.), Pd_2dba_3 (0.25 mol%), nBu_3P (2 mol%), toluene, 100°C, 16 h, 90%.

under Pd catalysis affords the desired butenylated compound as a single regioisomer within the detection limits of ^1H NMR. Dimethyl monobutenylated malonate **3** was prepared from dimethyl malonate and *trans*-1,4-dichloro-2-butene according to a two step procedure described by Shimizu and Aida (6*a*). This product was then converted to allyl chloride **4** using standard alkylation chemistry and finally to **5** by a Pd catalyzed formate reduction (Scheme 3). In this manner, **5** could be easily prepared in good overall yield in batches of 50 g.

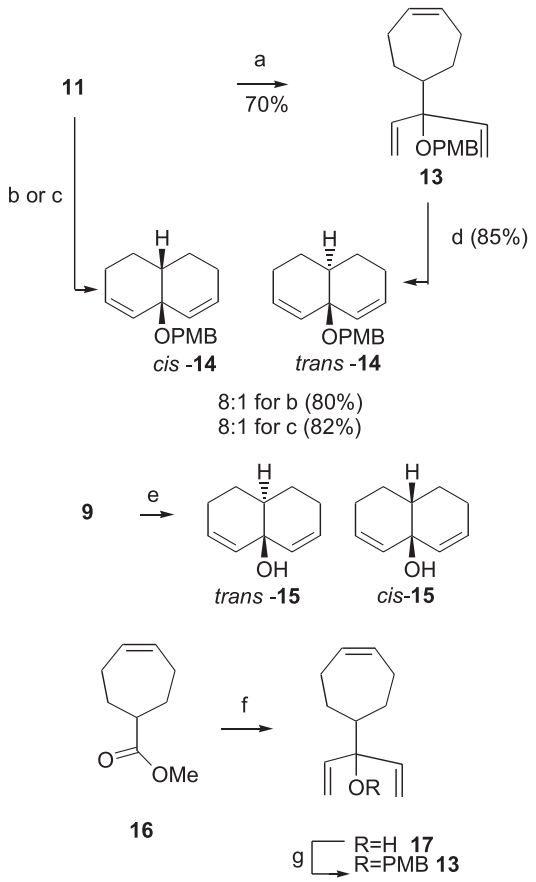
Decarboxylation of **5** and its diallyl analogue **6** proceeded in good yield to give the desired methyl esters **7** and **8**. The addition of 2 equiv. of vinyl lithium or magnesium reagents to **7** and **8** proved troublesome as the second equivalent strongly preferred to undergo conjugate addition, to afford less than 10% of the desired tertiary alcohols **9** and **10** (7). It had been reported that the addition of two equivalents of a vinyl cerium reagent to an ester could generate a tertiary alcohol in 35% yield (8). The literature conditions called for the use of 3 equiv. each of vinylmagnesium bromide and predried $CeCl_3$ at 0°C. We found that more extensive drying of the $CeCl_3{\cdot}7H_2O$ (6–12 h at 140°C, <0.1 mmHg), lower reaction temperatures (–78°C), and the use of 3.5 equiv. of vinylmagnesium bromide and 4.0 equiv. of $CeCl_3$ gave **9** and **10** in 86 and 90% respectively. The alcohols were then converted to ethers **11** and **12** under standard conditions (Scheme 4).

With the desired tetraenes in hand we initiated the diastereoselective RCM (DSRCM) studies. Treating **11** with 3 mol% of **1** for 3 h gave the cycloheptene **13** in 70% yield. Ring closing metathesis via sequential reaction of the two less hindered alkenes occurs, in spite of the fact that this leads to seven-membered ring formation rather than the cyclohexene. However, by increasing the catalyst loading to 10–12mol%, increasing the reaction time to 22 h, and conducting the reaction in the presence of ethylene, it was possible to isolate *cis*- and *trans*-**14** in 80% as an 8:1 mixture of diastereomers with the *syn* product predominating (Scheme 5). Similar results were realized using **2** as a catalyst. The successful conversion of **13** to **14** suggested a more efficient route to **14** using **16**. Fortunately, this methyl ester can be prepared on large scale in good yield from inexpensive materials as outlined in Scheme 6 (9).



In contrast to the reactions of ethers **10** or **12** which give *cis*-fused bicyclic compounds, treating free alcohol **9** with **1** for 30 min gave a 2.7:1 mixture of diastereomers where the *trans*-fused isomer of **15** is favored (Scheme 5).

We could also form *cis*-fused diquinane **19** from tetraene **12** by treating it with 4 mol% of **1** for 18 h (Scheme 7). A 6.5:1 ratio was observed between **19** and cyclopentene **20** which fails to undergo further RCM reactions as this would result in the formation of a highly strained *trans* bicyclo[3.3.0]octadiene system. Again, cyclization with the less hindered olefin appears to occur initially to give symmetrical cyclopentene **18**, but upon prolonged reaction times this intermediate then ring opens and recyclizes to give the desired bicyclic product.



To examine the diastereoselectivity in the first step of the cyclization and its reversibility, trienes **22**, **23**, **26**, and **27** were prepared as outlined in Scheme 8. Six-membered ring precursors were prepared by alkylation of **3** with $TBDPSO(CH_2)_3Br$, followed by Krapcho decarboxylation and vinylcerium addition to give **22**. Protection of the free

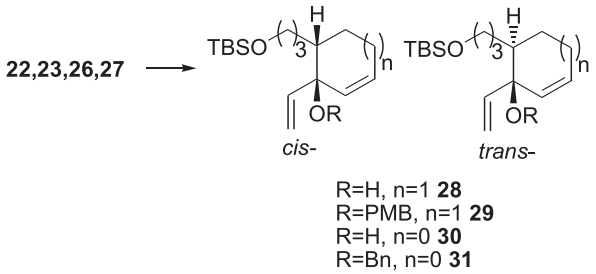
Scheme 7. DSRCM as an approach to diquinane systems: **1** (4 mol%), CH_2Cl_2, 18 h.

alcohol gave **23**. Five-membered ring precursors were prepared by alkylation of dimethylmalonate with $TBSO(CH_2)_3Br$, followed by allylation. Krapcho decarboxylation and vinyl cerium addition then gave **26** and protection of the free alcohol gave **27**.



Results from treating these trienes with **1** and **2** are summarized in Table 1. Treating **22** with **1** gave a 1:2.8 mixture of diastereomers favoring *trans*-**28** (CH_2=CH ↔ $(CH_2)_3OSiR_3$) (entry 1),[3] whereas treating **23** with **1** gave a 6.1:1 mixture of diastereomers favoring the *cis* (CH_2=CH↔$(CH_2)_3OSiR_3$) isomer (entry 2), and switching to **2** gave slightly higher levels of stereoselectivity (7.8:1, entry 3). Cyclopentenol **30** was formed as a 1:1 mixture of diastereomers upon treatment with **1** (entry 4), whereas the benzyl ether gave rise to cyclopentene **31** in an 8.0:1 mixture of diastereomers, favoring *cis*-**31** (entry 5). The use of **2** gave the same sense of selectivity in forming **31**, but with significantly lower levels of stereoselectivity (1.7:1, entry 6).

These results parallel the observations made in bicycle formation suggesting that although RCM transformations are potentially reversible we did not observe that process in this series. In fact submitting the minor isomers isolated from the reaction mixtures to the original reaction conditions failed to show any equilibration.

[3] While somewhat unorthodox, the nomenclature used here to designate relative stereochemistry was chosen for the sake of clarity. In using (*R**,*S**) vs. (*R**,*R**) nomenclature, the designation reverses when ring size is changed from five to six without changing the relative orientations of the vinyl and alkyl substiuents. The *cis* and *trans* designations were chosen on the basis of whether a *cis*- or *trans*-fused bicyclic system would be formed were a second RCM reaction possible. For proof of stereochemistry, see supporting information of ref. (2).

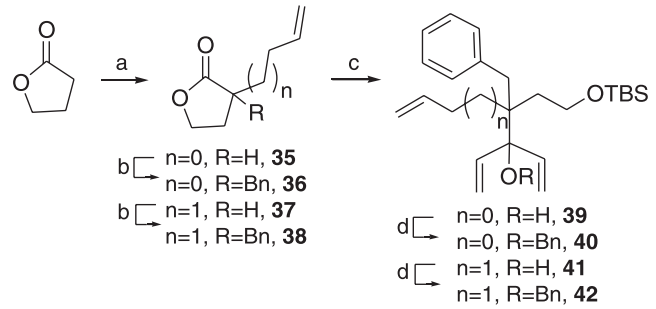
6	**27**	**29**	2	6/0.5	94	1.7:1

Scheme 8. Synthesis of triene tertiary diallylic alcohols and ethers: (*a*) NaH (5.0 equiv.), $Br(CH_2)_3OTBDPS$ (1.5 equiv.), THF, 60°C, 48%; (*b*) NaCl (2.4 equiv.), H_2O, DMSO, 180°C, 4 h, 58%; (*c*) CH_2=CHMgBr (3.5 equiv.), $CeCl_3$ (4.0 equiv., anhydrous), THF, –78°C, 57% (**22**), 32% (**26**); (*d*) NaH (2.0 equiv.), PMBBr (2.0 equiv.), DMF, 23°C, 67%; (*e*) (*i*) NaH (1.0 equiv.), $Br(CH_2)_3OTBS$ (0.3 equiv.), THF, 60°C, 31%; (*ii*) NaH (2.0 equiv.), allyl bromide (1.5 equiv.) THF, 60°C, 83%; (*f*) KH (1.5 equiv.), BnBr (1.5 equiv.), THF, 60°C, 89%.

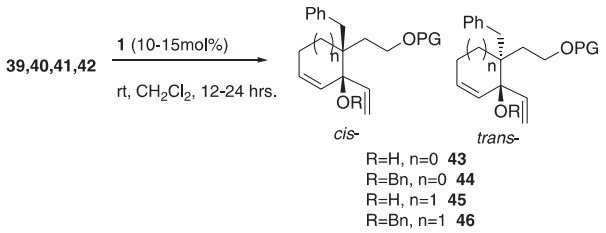


Scheme 9. Failure of esters having an α tertiary center to undergo reaction with vinyl cerium.

To probe the effect of bridgehead substituents on the efficiency and diastereoselectivity of the DRCM, substrates **32** and **33** were treated with the vinylcerium reagent but both failed to give the desired products. Steric effects at the α position may be responsible. (Scheme 9).

This problem was overcome by the use of lactones, where the third substituent is incorporated into the ring. For example, double alkylation to give lactones **36** and **38** followed by reaction with vinylcerium gave tertiary alcohols **39** and **41** in good overall yields as outlined in Scheme 10. Selective protection of the primary alcohols followed by benzylation of the tertiary alcohols furnished ethers **40** and **42**.

Scheme 10. Preparation of 3° alcohols from α,α-disubstituted lactones: (*a*) *n* = 0: LDA, allyl bromide, THF, –78°C, 80%; *n* = 1: (*i*) LDA, 1,4-dichlorobut-2-ene, THF– HMPA (7:1), –78°C; (*ii*) HCO_2NH_4, Pd_2dba_3, nBu_3P, toluene, 100°C, 3 h, 45% (2 steps); (*b*) LDA, BnBr, THF, 77% (**36**), 74% (**38**); (*c*) (*i*) CH_2=CHMgBr (3.5 equiv.), $CeCl_3$ (4.0 equiv., anhydrous), THF, –78°C; (*ii*) TBSCl (1.05 equiv.), imidazole (1.5 equiv.), DMF, 23°C, 57% (**39**), 48% (**41**); (*d*) KH (3.0 equiv.), BnBr (1.5 equiv.), THF, 23°C, 12 h, 85% (**40**), 90% (**42**).



The butenylation of butyrolactone with conventional methodologies gave only low yields of **37** (<10%), but the two step approach mentioned above for the butenylation of a variety of nucleophiles proved to be more successful (6). Thus, alkylation with 1,4-dichlorobut-2-ene, followed by Pd catalyzed formate reduction furnished **37** in 45% yield over two steps.

The results from treating these trienes with Grubbs' catalyst are summarized in Table 2. Reaction of **39** with **1** (24-hour portion-wise addition) gave cyclopentene **43** as essentially a single diastereomer in 60% isolated yield. This diastereomer was shown to be *trans*-**43** (CH_2=CH↔$(CH_2)_2OSiR_3$) by ROSEY experiments (10). Treatment of **40** with the same catalyst gave a 2:1 mixture with *cis*-**44** (CH_2=CH↔$(CH_2)_3OSiR_3$) now being favored.

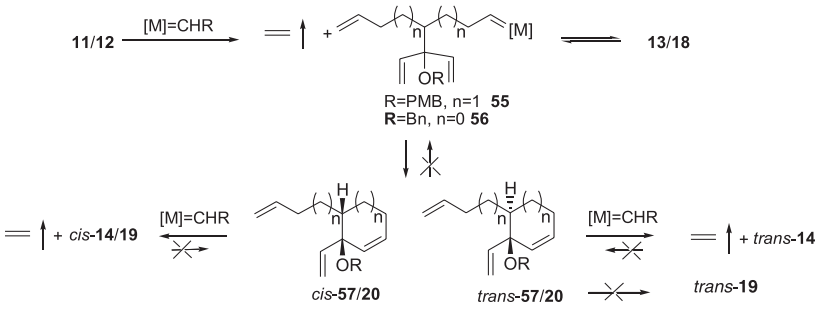
Scheme 11. [2,3] Wittig rearrangements as an approach to the hexahydronaphthalene portion (+)–melvinolin: (*a*) KH (3.0 equiv.), 18-crown-6 (cat.), ICH_2SnBu_3 (1.5 equiv.), THF, reflux, 93%; (*b*) **1** (12 mol%), CH_2=CH_2, CH_2Cl_2, reflux, 86%; (*c*) MeLi (1.05 equiv.), HMPA (4.0 equiv.), THF, –78°C, 67%; (*d*) KH (2.0 equiv.), TMSCl (1.05 equiv.), THF, 90%; (*e*) **2** (10 mol%), C_6H_6, 99%, dr = 5:1; (*f*) TBAF (3.0 equiv.), THF, 23°C, 86%; (*g*) NaH (5.0 equiv.), $BrCH_2C{\equiv}CH$ (5.0 equiv.), THF, 46%; (*h*) *n*-BuLi (1.1 equiv.), MeI (1.5 equiv.), THF, –78°C, 90%; (*i*) *t*-BuLi (4.0 equiv.), THF,–78°C, 63% (dr = 2:1).

Cyclohexenes having a bridgehead substituent were also formed in good yields. Treatment of the free alcohol **41** with **1** provided **45** as a 1:1 mixture of diastereomers. The analogous benzyl protected ethers were formed in a 4.5:1 mixture of diastereomers, favoring *cis*-**46**.

We have investigated potentially useful derivatizations of the bicyclic compounds. Deprotonation of **8** with KH, followed by alkylation with an iodomethyl stannane proceeds in good yield. DSRCM occurred in high yield to give the desired bicycle **48**. Treating this stannyl methyl ether with MeLi at –78°C afforded a 67% yield of the [2,3]-Wittig rearrangement product **49** (Scheme 11) (11).

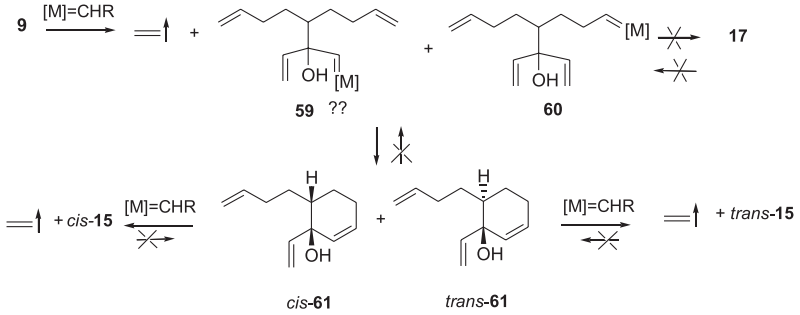
A variation of the Wittig rearrangement was also investigated involving methyl propargyl ether **53**, prepared as outlined in Scheme 11 (12). DSRCM of **50** with **2** (12 mol%, 0.5 h) gave a 5:1 mixture of diastereomers. Desilylation afforded a separable mixture of free alcohols. The *cis*-fused free alcohol *cis*-**15** was converted to propargyl ether **53** in two steps. Treatment with *t*-BuLi at –78°C gave the [2,3]-Wittig rearrangement product in 63% yield as a 2:1 mixture of diastereomeric alcohols.

Discussion



Based on our studies and previous work outlining the reactivity patterns of various olefins (13), we propose the following reaction pathway for decalin formation from **11** and **12**.

Transalkylidenation in **11** or **12** occurs at one of the two olefins lacking an α substituent to give **55**/**56** (Scheme 12). These intermediates then cyclizes initially to give cycloalkenes **13** or **18**. The formation of both **13** and **18** is reversible, as demonstrated by the observation that **13** and **18** are alternative entries into the catalytic cycle. A second less favorable but irreversible pathway involves cyclization onto one of the two more sterically hindered diastereotopic olefins to give either *cis*-**57**/**20** or *trans*-**57**/**20**. The formation of these cycloalkenes has been proven to be irreversible under all conditions examined to date. RCM between the two remaining acyclic olefins then affords bicyclic products, a process which should also be initiated by reaction at the less hindered alkene. While both *cis*- and *trans*-**57** will go on to give the corresponding *cis*- and *trans*-fused hexahydronaphthalenes, only *cis*-**20** goes onto to *cis*-fused diquinane as further cyclization of *trans*-**20** would give rise to a highly unstable *trans*-fused bicyclo[3.3.0] compound.



Double cyclization of free alcohols display interesting differences in diastereoselectivity compared to their protected analogues. As others have previously noted (14), free alcohols appear to cyclize at accelerated rates relative to the analogous ethers. For example whereas the *p*-methoxybenzyl ether **11** reacts to give the cycloheptene **13** faster than to form a cyclohexene **57**, we have been unable to observe the formation of cycloheptene **17** when free alcohol **9** is used as starting material. In fact, when **17** is used as starting material, no conversion to decalin is observed, suggesting that alkylidene formation may be taking place at the more hindered olefin (Scheme 13). The implications of these observations with regard to stereoselectivity issues are intriguing and are currently under investigation.

© 2000 NRC Canada

Scheme 12. Reaction pathway of decalin and diquinane formation.

Scheme 13. DSRCM reactions involving free alcohols.

The effect of added ethylene depends on the structure of the tetraene (for examples of other systems where added ethylene was found to enhance RCM see ref. (15)), enhancing the conversion with some substrates and hindering the cyclization of others. For example, when cyclizing free alcohol **9**, the use of an ethylene atmosphere resulted in incomplete conversion (~50%) before the catalyst decomposed. If the reaction was repeated but using a stream of Ar, the reaction also failed to go to completion. However when the reaction was conducted in a sealed system so that the ethylene produced upon cyclization was retained, complete consumption of starting material was observed. The cause of these effects are somewhat puzzling and warrant further study.

The relative sensitivities of the *cis*- and *trans*-fused decalins also warrants further mention. As one might expect, the tertiary diallylic alcohols and ethers are susceptible to solvolysis under acidic conditions. While most of the RCM precursors and the monocyclic intermediates could be isolated without difficulty, bicyclic materials were found to decompose upon chromatography unless the silica gel was neutralized with triethyl amine. The *trans*-fused decalins were found to be particularly acid sensitive, decomposing during TLC development, while the *cis*-fused analogues did not. Geometry optimization calculations (3–21G*) of *cis*-**15** and *trans*-**15** revealed that the dihedral angles between the olefin planes and the allylic C—O bond are 130° and 97° for *cis*-**15**, whereas both dihedral angles in *trans*-**15** are 90°, leaving the C—O bond in an antiperiplanar orientation with both double bonds, which would be expected to lower the energy barrier to carbenium ion formation.

Experimental

Toluene and THF were distilled from sodium–benzophenone. DMF was dried by prolonged standing over molecular sieves. HMPA was distilled under reduced pressure from CaH_2. CH_2Cl_2 was distilled from CaH_2. Grubbs' catalyst was prepared according to a literature procedure (16) and triturated for 12–18 h in a 1:1 mixture of acetone and methanol. The absence of free tricyclohexyl phosphine and tricyclohexyl phosphine oxide was confirmed by ^{31}P NMR, and was crucial in order for the double metathesis reactions to proceed. Schrock's catalyst was used as received from Strem. Computational work was done using MacSpartan Plus©, version 1.1.7 (Wavefunction Int. Irvine, Calif. 1996–1997).

General procedure for the decarboxylation of dimethyl malonates

To a 23°C solution of malonate in DMSO (1.0 M) was added NaCl (1.5 equiv.) and water (1 drop/1 mL DMSO). The resulting mixture was heated to 180°C for 5–10 h. The mixture was cooled to 23°C, diluted with ether and washed with water. The aqueous layer was extracted three times with ether. The organic layers were combined, washed with brine, dried over magnesium sulfate, and filtered. The filtrate was concentrated in vacuo and purified by flash chromatography on silica gel.

General procedure for the conversion of methyl esters to diallylic tertiary alcohols

$CeCl_3 \cdot 7H_20$ (4.0 equiv.) was ground with a mortar and pestle, placed under vacuum (<0.1 mmHg) and warmed to 140°C for 2 h. A stir bar was added and heating under vacuum continued for a further 4–10 h. The resulting powder was cooled to 0°C and THF (3 mL/mmol of $CeCl_3$) was added via cannula under vacuum. The remaining vacuum was displaced with N_2 and the resulting suspension stirred for 24 h, then cooled to –78°C. Vinylmagnesium bromide (~1 M in THF, 3.5 equiv.) was added via syringe at a rate such that the internal temperature was kept below –65°C.

© 2000 NRC Canada

After 1 h a solution of ester (1.0 equiv.) in THF (~1 M) was added via cannula at a rate such that the internal temperature did not exceed –65°C. After 30 min, the mixture was diluted with ethyl acetate and water was added. The organic layer was decanted off and the aqueous slurry extracted three times with ethyl acetate. The organic layers were combined, washed with brine, dried over sodium sulfate, and filtered. The filtrate was concentrated in vacuo and purified by flash chromatography on triethyl amine washed silica gel.

General procedure for the p-methoxy benzylation of tertiary diallylic alcohols

NaH (60% suspension in oil, 5.0 equiv.) was washed three times with pentane, dried under a stream of N_2 and suspended in DMF (0.3 M). A solution of alcohol in DMF (1.0 M) was added via cannula at a rate such the H_2 evolution is controlled. After 5 min, PMBBr was added via syringe and the resulting mixture was stirred at 23°C for 16 h. The mixture was diluted with ether and the reaction carefully quenched by drop-wise addition of saturated ammonium chloride. The aqueous layer was extracted three times with ether; the organic layers were combined, washed with brine, dried over sodium sulfate, and filtered. The filtrate was concentrated in vacuo and purified by flash chromatography on triethyl amine washed silica gel.

General procedure for the benzylation of tertiary diallylic alcohols

Potassium hydride (35% suspension in oil, 1.5 equiv.) was washed three times with pentane, dried under a stream of argon, and suspended in THF (half of total reaction volume). A solution of alcohol in THF (half of reaction volume, reaction concentration of 0.2 M) was added via cannula. The resulting suspension was warmed to 60°C and after 10 min benzyl bromide (1.5 equiv.) was added via syringe and the resulting mixture was stirred for an hour, cooled to 23°C, diluted with ether, and quenched carefully by drop-wise addition of water. The aqueous layer was extracted two times with ether, the organic layers were combined, washed with brine, dried over sodium sulfate, filtered and concentrated in vacuo. The residue was purified by flash chromatography on triethyl amine washed silica gel.

*Methyl 2-(but-3-enyl) hex-5-enoate (**7**)*

2,2 Di-(2-but-3-enyl) malonic acid dimethyl ester **5** (6.70 g, 27.9 mmol) was reacted according to the general procedure for decarboxylation. The crude product was purified by flash chromatography (3% ether–hexanes) to yield the title compound as a colorless oil (3.62 g, 71%). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.48–1.57 (m, 2H), 1.64–1.76 (m, 2H), 1.94–2.08 (m, 4H), 2.35–2.43 (m, 1H), 4.94 (dq, J = 9, 1 Hz, 2H), 4.98 (dm, J = 17, 2 Hz, 2H), 5.69–5.79 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 31.52, 44.35, 51.36, 114.89, 137.70, 176.00.

*2-But-3-enyl-1-vinyl-octa-1,7-dien-3-ol (**9**)*

Methyl ester **7** (1.00 g, 5.49 mmol) was reacted according to the general procedure for the conversion of methyl esters to tertiary diallylic alcohols. The crude mixture was purified by flash chromatography (3% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a colorless oil (606 mg, 53%). IR (neat): 3478, 3078, 2934, 2978, 1640, 1456, 1414, 1300, 996, 912, 735. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.18–1.28 (m, 2H), 1.41–1.49 (m, 2H), 1.59–1.69 (m 2H), 1.97–2.08 (m, 2H), 2.09–2.20 (m, 2H), 4.92 (dm, J = 10 Hz, 2H), 4.98 (dq, J = 17, 2 Hz, 2H), 5.14(dd, J = 11, 1 Hz, 2H), 5.25 (dd, J = 17, 1 Hz, 2H), 5.71–5.82 (m, 2H), 5.94 (dd, J = 17, 11 Hz, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 29.39, 32.99, 45.78, 79.05, 113.42, 114.41, 138.97, 142.07.

*4-Allyl-3-vinyl-hepta-1,5-dien-3-ol (**10**)*

Methyl 2-propenylpent-4-enoate **8** (600 mg, 3.89 mmol) was reacted according to the general procedure for the formation of a tertiary diallylic alcohol. Purification by flash chromatography (5% ether–hexanes) on triethyl amine washed silica gel yielded the title compound as a colorless oil (460 mg, 66%). R_f = 0.19 (5% ether). IR (neat): 3072, 2933, 2859, 1738, 1642, 1473, 1428, 1390, 1195, 1164, 1112, 998, 917, 824, 741, 703, 614. ^{1}NMR (400 MHz, $CDCl_3$) δ: 1.70 (sept., J = 4 Hz, 1H), 1.87 (s, 1H), 2.07 (quint, J = 8 Hz, 2H), 2.28–2.36 (m, 2H), 5.00 (d, J = 9 Hz, 2H), 5.03 (d, J = 17 Hz, 2H), 5.79–5.91 (m, 2H), 5.95 (dd, J = 17 Hz, 11 Hz, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.20, 23.65, 26.85, 31.60, 32.38, 36.42, 45.32, 51.33, 63.60, 116.62, 127.57, 129.49, 134.05, 135.50, 135.54, 176.04. HRMS calcd. for $(M\text{-}H)^+$: 177.1279; found: 177.1287.

*[2-But-3-enyl-1,1-divinyl-hex-5-enyloxymethyl]-4-methoxybenzene (**11**)*

Alcohol **9** (200 mg, 0.969 mmol), was reacted according to the general procedure for the *p*-methoxy benzylation of tertiary diallylic alcohols. The crude mixture was purified by flash chromatography (5% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a pale green oil (240 mg, 76%). IR (neat): 3478, 3078, 2934, 2978, 1640, 1456, 1414, 1300, 996, 912, 735. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.11–1.22 (m, 2H), 1.60 (hept, J = 4 Hz, 1H), 1.67–1.77 (m, 2H), 2.02–2.21 (m, 4H), 3.81 (s, 3H), 4.31 (s, 2H), 4.94 (dm, J = 10 Hz, 2H), 5.01 (dq, J = 17, 2 Hz, 2H), 5.31 (dd, J = 18, 1.5 Hz, 2H), 5.37 (dd, J = 11, 2 Hz, 2H), 5.76–5.86 (m, 2H), 5.88 (dd, J = 18, 11 Hz, 2H), 6.88 (AB, J = 9 Hz, 2H), 7.26 (AB, J = 9 Hz, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 30.05, 33.37, 47.30, 55.24, 64.82, 83.96, 113.57, 114.18, 117.39.

*[2-Allyl-1,1-divinyl-pent-4-enyloxymethyl] benzene (**12**)*

Tertiary alcohol **10** (500 mg, 2.80 mmol) was reacted according to the general procedure for the benzylation of tertiary diallylic alcohols. The crude product was purified by flash chromatography (100% hexanes –> 2% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a colorless oil (590 mg, 78%). R_f = 0.29 (2% ether–hexanes). IR (neat): 3074, 2920, 1639, 1497, 1453, 1414, 1377, 1096, 1064, 1000, 910, 729. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.84 (sept., J = 4 Hz, 1H), 1.96 (dt, J = 14, 8 Hz, 2H), 2.44 (dm, J = 14.5 Hz, 2H), 4.38 (s, 2H), 4.94 (d, J = 11 Hz, 2H), 4.98 (d, J = 18 Hz, 2H), 5.79–5.90 (m, 2H), 5.90 (dd, J = 18, 11 Hz, 2H), 7.21–7.26 (m, 1H), 7.29–7.36 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 34.41, 48.07, 65.15, 83.53, 115.12, 117.63, 126.79, 126.85, 128.15,

137.87, 138.73, 139.88. HRMS calcd. for $(M-H)^+$: 267.1749; found: 267.1734.

*4a-(4-Methoxy-benzyloxy)-1,2,4a,7,8,8a-hexahydronaphthalene (**14**) (Ru Cat.)*

To a solution of **11** (200 mg, 0.613 mmol) in dichloromethane (12 mL) at 23°C was added **1** (61 mg, 0.073 mmol) and the mixture was placed under an atmosphere of ethylene. After 18 h, the mixture was concentrated in vacuo. The residue was purified by flash chromatography (3% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a colorless oil (115 mg, 70%). R_f = 0.15 (4% ether–hexanes). IR (neat): 3019, 2826, 1653, 1613, 1586, 1559, 1513, 1456, 1374, 1301, 1248, 1172, 1034, 947, 821. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.50–1.61 (m, 2H), 1.85 (quintd, *J* = 6.5, 3.5 Hz, 2H), 1.98–2.14 (m, 4H), 2.19 (hept, *J* = 4 Hz, 1H), 3.79 (s, 3H), 4.38 (s, 2H), 5.61 (dt, *J* = 10, 2 Hz, 2H), 5.87 (dt, *J* = 10, 4 Hz, 2H), 6.85 (AB, *J* = 9 Hz, 2H), 7.25 (AB, *J* = 9 Hz, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 23.32, 24.29, 34.43, 55.25, 64.10, 74.14, 113.70, 129.05, 129.64, 130.27, 132.18, 158.87. HRMS calcd. form M^+: 270.1620; found: 270.1611.

Cycloheptene intermediate: 5-(penta-1,4-dien-3-ol, *p*-methoxy benzyl ether)-cyclohept-1-ene (**13**): R_f = 0.37 (4% ether–hexanes). IR (neat): 2919, 1612, 1585, 1512, 1450, 1300, 1247, 1108, 1037, 927, 820, 737, 697. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.05 (q, *J* = 11 Hz, 2H)1.77 (tt, *J* = 11, 3 Hz, 1H), 1.92–2.06 (m, 4H), 2.21–2.33 (m, 2H), 3.79 (s, 3H), 4.29 (s, 2H), 5.28 (dd, *J* = 18, 6 Hz, 2H), 5.35 (dd, *J* = 11, 2 Hz, 2H), 5.72–5.80 (m, 2H), 5.86 (dd, *J* = 18, 11 Hz, 2H), 6.87 (AB, *J* = 9 Hz, 2H), 7.26 (AB, *J* = 9 Hz, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 27.98, 28.02, 52.62, 55.24, 64.72, 83.36, 117.25, 128.21, 131.87, 132.06, 138.16, 158.65.

*4a-(4-Methoxy-benzyloxy)-1,2,4a,7,8,8a-hexahydronaphthalene (**14**) (Mo Cat.)*

To a solution of **11** (47 mg, 0.142 mmol) in C_6H_6 (0.5 mL) at 23°C was added a solution of **2** (12 mg, 0.016 mmol) in C_6H_6 (1.5 mL). After 20 h the mixture was concentrated in vacuo and the residue purified by flash chromatography (3% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a colorless oil (28 mg, 73%).

cis- *and* trans-*2,7,8,8a-Tetrahydro-1*H-*naphthalen-4-ol (**15**)*

To a solution of **9** (100 mg, 0.242 mmol) in dichloromethane (4.5 mL) at 23°C was added **1** (40 mg, 0.049 mmol). After 1 hour PPh_3 (17 mg, 0.065 mmol) was added and the mixture was concentrated in vacuo and the residue was purified by flash chromatography (30% ether–hexanes) on triethyl amine washed silica gel to yield the title compounds as a white solid and a colorless oil (45 mg, 62% (*trans*)), (16 mg, 22% (*cis*)). Due to the sensitivity of the *trans* compound, it was immediately hydrogenated and characterized. The structure of the resulting decahydronaphthalenol was confirmed by comparison to spectral data reported in the literature (17).

cis-: IR (neat): 3351, 3023, 2908, 1429, 1383, 1326, 1204, 1021, 960. ^{1}H NMR (400 Mhz, $CDCl_3$) δ: 1.49–1.60 (m, 2H), 1.76–1.84 (m, 2H), 1.87–1.94 (m, 1H), 2.01–2.07 (m, 4H), 5.58 (dt, *J* = 10, 2 Hz, 2H), 5.77 (dt, *J* = 10, 3.7 Hz, 2H). ^{13}C NMR δ: 23.11, 24.27, 39.70, 38.34, 128.19, 131.34. HRMS calcd. for $C_{10}H_{14}O^+$ (M^+): 150.1045; found: 150.1044.

cis-*3a-Benzyloxy-1,3a,6,6a-tetrahydro-pentalene (**19**) (Ru Cat.)*

To a solution of benzyl ether **12** (100 mg, 0.372 mmol) in dichloromethane (4 mL) at 23°C was added **1** (12 mg, 0.04 equiv.). The resulting solution was stirred under an ethylene atmosphere for 20 h before PPh_3 (14 mg, 0.053 mmol) was added and the mixture concentrated in vacuo. The residue was purified by flash chromatography (2% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a colorless oil along with cyclopentene **20** (63 mg, 80%) and (12 mg, 13%), respectively. R_f = 0.11 and 0.34 (2% ether–hexanes) respectively. IR (neat) 3053, 2919, 2848, 1497, 1448, 1378, 1349, 1216, 1139, 1099, 1028, 991, 733, 697. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.06–2.15 (m, 2H), 2.81–2.91 (m, 3H), 4.42 (s, 2H), 5.83 (dt, *J* = 6, 2 Hz, 2H), 5.92 (dt, *J* = 6, 2 Hz, 2H), 7.21–7.26 (m, 1H), 7.28–7.35 (m, 4H). ^{13}C NMR δ: 40.72, 43.03, 65.58, 105.70, 127.16, 127.55, 128.25, 132.54, 134.27, 139.56. HRMS calcd. for $C_{15}H_{16}O$ (M^+): 212.1201; found: 212.1196.

*Cyclopentene intermediate **11***: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.38 (d, *J* = 6 Hz, 4H), 2.74 (quint, *J* = 8Hz, 1H), 4.43 (s, 2H), 5.32 (AB, *J* = 1.5 Hz, 2H), 5.35 (q, *J* = 1.5 Hz, 2H), 5.62 (s, 2H), 5.90 (dd, *J* = 18, 10.5 Hz, 2H), 7.22–7.26 (m, 1H), 7.30–7.37 (m, 4H). ^{13}C NMR δ: 34.27, 45.33, 65.089, 82.77, 117.11, 126.82, 126.87, 128.15, 129.74, 138.04.

2-But-3-enyl-2-(3-tert-*butyldiphenylsiloxy-propyl) malonic acid dimethyl ester (**20**)*

Sodium hydride (1.10 g, 32.2 mmol) was washed three times with pentane, dried under a stream of nitrogen, and suspended in DMF (40 mL). A solution of dimethyl but-3-enyl malonate **3** (4.00 g, 21.5 mmol) in DMF (10 mL) was added via cannula at a rate such that hydrogen evolution was controlled. After 30 min, a solution $TBDPSO(CH_2)_3Br$ in DMF (10 mL) was added via cannula. After 20 h, the mixture diluted with ether and quenched by careful addition of water. The aqueous layer was extracted with ether, the organic layers were combined, washed with brine, dried over magnesium sulfate, filtered and concentrated in vacuo. The residue was purified by flash chromatography (5% ether–hexanes) to yield the title compound as a colorless oil (5.00 g, 48%). IR (neat): 2954, 2858, 1732, 1434, 1257, 1104, 837, 776. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.05 (s, 9H), 1.36–1.46 (m, 3H), 1.89–2.05 (m, 7H) 3.65 (t, *J* = 6 Hz, 2H), 3.70 (s, 6H), 4.97 (dd, *J* = 10, 1.5 Hz, 1H), 5.03 (dd, *J* = 17, 1.5 Hz, 1H), 5.72–5.83 (m, 1H), 7.36–7.45 (m, 6H), 7.64–7.67 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.17, 26.81, 27.28, 28.30, 28.91, 31.60, 52.29, 57.04, 63.57, 115.00, 127.60, 129.56, 133.79, 135.52, 137.46, 172.02. HRMS calcd. for $C_{24}H_{29}O_5Si$ ($M-C_4H_9$): 425.1784; found: 425.1793.

2-(3-tert-*Butyldiphenylsiloxy-propyl)-hex-5-enoic acid methyl ester (**21**)*

Malonate **20** (5.00 g, 10.4 mmol) was reacted according to the general procedure for decarboxylation. The crude mixture was purified by flash chromatography (5% ether–hexanes) to yield title compound as a colorless oil (2.58 g,

58%). IR (neat): 2930, 1734, 1428, 1111. ^{1}H NMR ($CDCl_3$) δ: 1.05 (s, 9H), 1.49–1.79 (m, 6H), 2.00–2.08 (m, 2H), 2.35–2.44 (m, 1H), 3.63–3.68 (m, 5H), 4.97 (dm, *J* = 10 Hz, 1H), 5.02 (dq, *J* = 17, 2 Hz, 1H), 5.72–5.83 (m, 1H), 7.36–7.46 (m, 6H), 7.65–7.69 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.20, 26.84, 28.59, 30.22, 31.47, 31.54, 44.62, 51.33, 63.51, 115.02, 127.59, 129.53, 133.94, 135.54, 137.85, 176.51. HRMS calcd. for $C_{22}H_{25}O_3Si$ (M-$C_4H_9^+$): 367.1729; found: 367.1725.

4-(3-tert-*Butyldiphenylsiloxy-propyl)-3-vinyl-hepta-1,6-dien-3-ol (**22**)*

Methyl ester **26** (1.25 g, 2.94 mmol) was reacted according to the general procedure for the conversion of a methyl ester to a tertiary diallylic alcohol. The crude product was purified by flash chromatography (8% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a pale green oil (754 mg, 57%). R_f = 0.25 (10% ether–hexanes). IR (neat): 3475, 2930, 1636, 1472, 1427, 1111. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.05 (s, 9H), 1.14–1.26 (m, 2H), 1.38–1.44 (m, 1H), 1.46–1.69 (m, 5H), 1.94–2.06 (m, 1H), 2.09–2.20 (m, 1H), 3.63 (t, *J* = 6 Hz, 2H), 4.93 (dm, *J* = 10 Hz, 1H), 4.98 (dq, *J* = 17, 2 Hz, 1H), 5.14 (ddd, *J* = 11, 3.5, 1 Hz, 2H), 5.25 (ddd, *J* = 17, 4, 1 Hz, 2H), 5.71–5.82 (m, 1H), 5.94 (ddd, *J* = 17, 11, 2 Hz, 2H), 7.35–7.45 (m, 6H), 7.65–7.69 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.19, 26.09, 26.87, 29.38, 31.86, 32.86, 46.18, 64.14, 79.10, 113.37, 114.39, 127.56, 129.50, 134.05, 135.57, 139.02, 142.06, 142.15. HRMS calcd. for $C_{25}H_{31}O_2Si$ (M-$C_4H_9^+$): 391.2093; found: 391.2098.

[2-(3-tert-*Butyldiphenylsiloxy-propyl)-1,1-divinyl-hex-5-enyloxymethyl]-4-methoxy-benzene (**23**)*

Alcohol **22** (400 mg, 0.891 mmol) was reacted according to the general procedure for the *p*-methoxy benzylation of tertiary diallylic alcohols. The crude material was purified by flash chromatography (2% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a colorless oil (325 mg, 65%). R_f = 0.22 (5% ether–hexanes). IR (neat): 2930, 1615, 1513, 1428, 1247, 1111. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.08 (s, 9H), 1.12–1.24 (m, 2H), 1.55–1.80 (m, 5H), 2.02–2.23 (m, 2H), 3.66 (t, *J* = 6 Hz, 2H), 3.81 (s, 3H), 4.32 (s, 2H), 4.95 (dm, *J* = 10 Hz, 1H), 5.01 (dq, *J* = 17, 2 Hz, 1H), 5.31 (dt, *J* = 18, 1.5 Hz, 2H), 5.37 (ddd, *J* = 11, 4, 1.5 Hz, 2H), 5.78–5.87 (m 1H), 5.88 (ddd, *J* = 18, 11, 1 Hz, 2H), 6.87 (AB, *J* = 9 Hz, 2H), 7.27 (AB, *J* = 9 Hz, 2H), 7.37–7.47 (m, 6H), 7.68–7.72 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 19.20, 26.81, 26.88, 30.01, 32.29, 33.28, 47.70, 55.22, 64.37, 64.82, 84.01, 113.58, 114.13, 117.28, 127.54, 128.13, 129.45, 132.14, 134.16, 135.57, 138.15, 138.23, 139.35, 158.54. HRMS calcd. for $C_{33}H_{39}O_3Si$ (M-$C_4H_9^+$): 511.2668; found: 511.2689.

2-Allyl-(3-tert-*Butyldimethylsiloxy-propyl)-malonic acid dimethyl ester (**24**)*

Sodium hydride (4.16 g, 104.1 mmol) and potassium hydride (cat.) were washed three times with pentane, suspended in DMF (75 mL) and cooled to 0°C. A solution of dimethyl malonate (11.9 mL, 104.1 mmol) in DMF (50 mL) was added via addition funnel at a rate such that the evolution of H_2 was controlled. The mixture was warmed to room temperature. After 30 min, a solution of TBDPSO$(CH_2)_3$Br (8.80 g, 34.7 mmol) in DMF (10 mL) was added via cannula. After 14 h, the mixture was diluted with ether and quenched carefully with water. The aqueous layer was washed three times with ether; the organic layers were combined, washed with brine, dried over magnesium sulfate, and filtered. The filtrate was concentrated in vacuo and the residue purified by fractional distillation. Collection of the fraction boiling between 100–110°C (0.1 mmHg) yielded the monoalkylated malonate as a colorless liquid (3.26 g, 31%). R_f = 0.23 (15% ether–hexanes). IR (neat): 2955, 2858, 1768, 1436, 1389, 1255, 1155, 1099, 1009, 837, 777. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.03 (s, 6H), 0.88 (s, 9H), 1.49–1.57 (m, 2H), 1.91–2.00 (m, 2H), 3.41 (t, *J* = 8 Hz, 1H), 3.62 (t, *J* = 6 Hz, 2H), 3.73 (s, 6H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.41, 18.26, 25.47, 25.87, 30.27, 51.35, 52.39, 62.40, 169.86. HRMS calcd. for (M-CH_3)$^+$: 289.1471; found: 289.1474.

Sodium hydride (0.509 g, 21.2 mmol) was washed three times with pentane and suspended in THF (20 mL). A solution of the monoalkylated malonate prepared as described above (3.00 g, 9.85 mmol) in THF (20 mL) was added via cannula at a rate such that H_2 evolution is controlled. After 15 min, allyl bromide (1.86 mL, 21.2 mmol) was added via syringe. After 1 h the mixture was diluted with ether, quenched carefully with water, and the aqueous layer was extracted two times with ether. The organic layers were combined, washed with brine, dried over magnesium sulfate and filtered. The filtrate was concentrated in vacuo and purified by flash chromatography (10% ether–hexanes) on silica gel to yield the title compound as a colorless oil (2.80 g, 83%). R_f = 0.32 (15% ether–hexanes). IR (neat): 2954, 2858, 1737, 1435, 1388, 1361, 1256, 1210, 1099, 1034, 921, 837, 776. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.03 (s, 6H), 0.87 (s, 9H), 1.35–1.44 (m, 2H), 1.87–1.95 (m, 2H), 2.64 (d, *J* = 7 Hz, 2H), 3.58 (t, *J* = 6 Hz, 2H), 3.70 (s, 6H), 5.05–5.13 (m, 2H), 5.57–5.69 (m, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.36, 18.26, 25.89, 27.45, 28.84, 37.09, 52.29, 57.38, 62.86, 118.91, 132.38, 171.68. HRMS calcd. for (M-CH_3)$^+$: 329.1784; found: 329.1801.

2-(3-tert-*Butyldimethylsiloxy-propyl)-pentenoic acid methyl ester (**25**)*

Malonate **24** (2.61 g, 7.58 mmol) was reacted according to the general decarboxylation procedure. The crude mixture was purified by flash chromatography (7% ether–hexanes) to yield the title compound as a colorless oil (960 mg, 44%). R_f = 0.20 (5% ether–hexanes). IR (neat): 2952, 2858, 1740, 1361, 1256, 1167, 1102, 1006, 915, 837, 776. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.02 (s, 6H), 0.87 (s, 9H), 1.44–1.66 (m, 4H), 2.18–2.26 (m, 1H), 2.30–2.40 (m, 1H), 2.41–2.49 (m, 1H), 3.58 (td, *J* = 6, *J* = 2 Hz, 2H), 3.65 (s, 3H), 4.97–5.08 (m, 2H), 5.66–5.78 (m, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.36, 18.27, 25.89, 28.07, 30.40, 36.45, 44.97, 51.34, 62.72, 116.68, 135.41, 175.97. HRMS calcd. for (M-CH_3)$^+$: 271.1729; found: 271.1742.

4-(3-tert-*Butyldimethylsiloxy-propyl)-3-vinyl-hepta-1,6-dien-3-ol (**26**)*

Methyl ester **25** (0.900 g, 3.13 mmol) was reacted under standard condition for the conversion of methyl esters to

© 2000 NRC Canada

diallylic tertiary alcohols. The crude product was purified by flash chromatography (7% ether–hexanes) on triethyl amine washed silica gel to yield the title compound as a pale green oil (314 mg, 32%). R_f = 0.25 (10% ether–hexanes). IR (neat): 3475, 3079, 2929, 2858, 1639, 1472, 4109, 1361, 1256, 1100, 999, 921, 836, 775, 735. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.04 (s, 6H), 0.88 (s, 9H), 1.16–1.26 (m, 1H), 1.42–1.52 (m, 1H), 1.53–1.70 (m, 3H), 1.83 (s, 1H), 2.02 (quint, *J* = 7 Hz, 1H), 2.30–2.38 (m, 1H), 3.56 (t, *J* = 6 Hz, 2H), 4.98 (dquint, *J* = 10, 0.5 Hz, 1H), 5.02 (dq, *J* = 17, 0.5 Hz, 1H), 5.16 (dd, *J* = 11, 1 Hz, 2H), 5.28 (dt, *J* = 17, 1 Hz, 2H), 5.81–6.00 (m, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.29, 18.31, 25.32, 25.94, 31.75, 34.34, 46.51, 63.31, 79.23, 113.48, 115.80, 138.37, 141.79, 142.20. HRMS calcd. for $C_{17}H_{31}O_2Si$ $(M\text{-}CH_3)^+$: 295.2091; found: 295.2091.

2-(3-tert-*Butyldimethylsiloxy-propyl)-1,1-divinyl-pent-4-enyloxymethyl)-benzene (**27**)*

Alcohol **26** (288 mg, 0.927 mmol) was reacted according to the general benzylation procedure to yield the title compound as a colorless oil (329 mg, 89%). R_f = 0.21 (2% ether–hexanes). IR (neat): 3086, 2929, 2858, 1639, 1497, 1472, 1408, 1380, 1255, 1099, 1027, 1004, 929, 836, 775, 728, 695, 661. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.03 (s, 6H), 0.88 (s, 9H), 1.10–1.20 (m, 1H), 1.46–1.57 (m, 1H), 1.58–1.74 (m, 3H), 1.82–1.94 (m, 1H), 2.46–2.54 (m, 1H), 3.55 (t, *J* = 6 Hz, 2H), 4.37 (s, 2H), 4.93 (d, *J* = 10 Hz, 1H), 4.99 (dq *J* = 17, 1 Hz, 1H), 5.30 (dd, *J* = 17, 1.5 Hz, 2H), 5.36 (dd, *J* = 11, 1.5 Hz, 2H), 5.80–5.90 (m, 1H), 5.89 (dd, *J* = 18, 11 Hz, 2H), 7.21–7.26 (m, 1H), 7.29–7.36 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.26, 18.33, 25.97, 26.36, 32.30, 35.13, 48.00, 63.56, 65.12, 83.79, 114.92, 117.48, 117.55, 126.75, 126.81, 128.14, 137.81, 138.16, 139.06, 139.98. HRMS calcd. for $C_{19}H_{27}O_2Si$ ($M\text{-}C_4H_9$): 315.1780; found: 315.1781.

cis- *and* trans-*5-(3*-tert-*Butyldimethylsiloxy-propyl)-1-vinyl-cyclopent-2-enyloxy benzyl ether (**31**) (Ru Cat.)*

To a solution of triene **27** (39 mg, 0.097 mmol) in dichloromethane (1.0 mL) at 23°C was added **1** (2.4 mg, 0.003 mmol). The resulting solution was stirred for 1 h before PPh_3 (3 mg, 0.014 mmol) was added and the mixture concentrated in vacuo. A crude ^{1}H NMR showed an 8:1 mixture favoring the (*cis*-). The ratio was determined by comparing the integration of the doublets of triplets appearing at δ 5.81 (*cis*-) and δ 6.17 (*trans*-) in the crude ^{1}H NMR. The mixture was purified by flash chromatography (1% ether–hexanes) on triethyl amine washed silica gel to yield the title compounds as colorless oils (36 mg, 99%).

*3-Allyl-3-benzyl-dihydro-furan-2-one (**36**)*

Diisopropylamine (10.98 mmol, 1.32 mL) is added to THF (13 mL) and the resulting solution is cooled to –78°C. *n*-BuLi (10.98 mmol, 2.5 M in hexanes, 4.39 mL) is then added dropwise. The solution is stirred for an additional 30 min at –78°C at which time 3-allyl-dihydro-furan-2-one (18) in THF (13mL) is added dropwise by cannula addition. The solution is stirred for an additional 30 min at –78°C followed by dropwise addition of benzyl bromide (11.98 mmol, 1.42 mL) in HMPA(2.2 mL). The solution is stirred for an additional 3 h at –78°C. The reaction is quenched with aq. sat'd. ammonium chloride solution and the mixture is diluted with ether. The layers are separated and the aqueous layer is extracted with ether (three times). The combined organic layers are dried over $MgSO_4$, filtered, and concentrated. The crude product is purified by flash chromatography (20% Et_2O–hexanes) to yield the title compound as a colorless oil (1.39 g, 77%). IR (neat): 2915 (m), 1757 (s), 1212 (w), 1166 (s), 1029 (s), 920 (m), 702 (m). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.15 (t, *J* = 8 Hz, 2H), 2.33 (dd, *J* = 13.8 Hz, 8 Hz, 1H), 2.51 (dd, *J* = 14 Hz, 6.4 Hz, 1H), 2.74 (d, *J* = 13.2 Hz, 1H), 3.07 (d, *J* = 13.2 Hz, 1H), 3.46 (q, *J* = 8.8 Hz, 1H), 4.02 (q, *J* = 6.4 Hz, 1H), 5.17 (dd, *J* = 9.2 Hz, 1.2 Hz, 1H), 5.21 (s, 1H), 5.79 (qt, *J* = 8.4 Hz, 2 Hz, 1H), 7.19–7.32 (m, 5H). ^{13}C NMR (100MHz, $CDCl_3$) δ: 29.87, 42.15, 42.88, 48.07, 65.43, 119.98, 127.23, 128.68, 130.08, 132.80, 136.63, 180.96. HRMS calcd. (M^+): 216.1150; found: 216.1152.

*4-Benzyl-4-(2-*tert*-butyldimethylsiloxy-ethyl)-3-vinyl-hepta-1,6-diene-3-ol (**39**)*

3-Allyl-3-benzyl-dihydro-furan-2-one (1.0 g, 4.6 mmol) was reacted under standard conditions for the conversion of methyl esters to diallylic tertiary alcohols. The crude product was dissolved in DMF (40 mL) and imidazole (0.469 g, 6.9 mmol) and *tert*-butyldimethylsilyl chloride (0.69 g, 4.6 mmol) were added. The solution is stirred at room temperature for 12 h. The reaction volume is doubled with water and extract with ether (three times). Wash the organic layers with water, dry over Na_2SO_4, filter, and concentrate. Flash chromatography (5% Et_2O–hexanes) provided the title compound as a colourless oil (1.0 g, 57% over two steps). IR (neat): 3359 (s), 2936 (s), 2838 (w), 2309 (w), 1254 (m), 1081 (s), 997 (m), 916 (m), 839 (m), 772 (w). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.08 (s, 6H), 0.91 (s, 9H), 1.72 (t, *J* = 6 Hz, 2H), 2.20 (dd, *J* = 15 Hz, 6.4 Hz, 1H), 2.41 (dd, *J* = 15 Hz, 6.4 Hz, 1H), 2.80 (d, *J* = 14 Hz, 1H), 2.88 (d, *J* = 14 Hz, 1H), 3.77 (t, *J* = 6 Hz, 2H), 4.10 (brs, 1H), 4.93–5.01 (m, 2H), 5.19 (ddd, *J* = 10.8 Hz, 4.8 Hz, 1.6 Hz, 2H), 5.35 (ddd, *J* = 18.5 Hz, 3 Hz, 1.6 Hz, 2H), 5.59–5.70 (m, 1H), 6.15 (dd, *J* = 14.8 Hz, 10.8 Hz, 1H), 6.20 (dd, 14.8 Hz, 10.8 Hz, 1H), 7.16–2.27 (m, 5H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.23, –5.18, 18.57, 26.17, 36.33, 38.99, 40.49, 47.62, 60.35, 80.24, 114.73, 114.76, 116.98, 126.23, 128.11, 131.21, 1136.70, 139.36, 140.55, 140.58. HRMS calcd. $(M\text{-}CH_3)^+$: 371.2406; found: 371.2414.

trans-*5-Benzyl-5-(2-*tert*-butyldimethylsiloxy-ethyl)-1-vinyl-cyclopent-2-enol (**43**)*

To a solution of triene (240 mg, 0.6217 mmol) in dichloromethane (25 mL) at 23°C was added **1** (25.5 mg, 0.03 mmol). The solution is stirred for 6 h at room temperature at which time **1** (25.5 mg, 0.03 mmol) is again added. The solution is stirred for an additional 12 h at room temperature, when **1** (25.5 mg, 0.03 mmol) is added for the final time. After stirring at room temperature for an additional 6 h, the reaction is opened to air and the solvent is removed in vacuo. Flash chromatography(5% Et_2O– hexanes) provides the title compound (134 mg, 60%) as a single diastereomer, as a colourless oil. The stereochemistry was determined by ROESY experiment. R_f = 0.10 (5% Et_2O–hexanes). IR (neat): 3397 (s), 2928 (s), 1495 (m), 1257(s), 1079 (s), 1023 (m), 836 (m), 720 (m). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.55 (s, 6H), 0.90 (s, 9H), 1.26 (m, 2H), 1.86 (ddd, *J* = 15.2 Hz, 10.4 Hz, 2.4 Hz, 1H), 1.20 (dd, *J* = 16.2 Hz, 1.6 Hz, 1H), 2.55 (d, *J* = 16.4 Hz, 1H), 2.64 (d, *J* = 13.6 Hz, 1H), 2.80 (d, *J* = 13.6 Hz, 1H), 3.54 (td, *J* = 10.4 Hz, 1.2 Hz, 1H), 3.65 (ddd, *J* = 10.5 Hz, 5.8 Hz, 2.8 Hz, 1H), 5.16 (dd, *J* = 10.6 Hz, 2 Hz, 1H), 5.21 (s, 1H), 5.25 (dd, *J* = 17.4 Hz, 2 Hz, 1H), 5.64–5.66 (m, 1H), 5.84–5.87 (m, 1H), 5.97 (dd, *J* = 17.4 Hz, 10.8 Hz, 1H), 7.11–7.26 (m, 5H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.57, –5.38, 18.38, 26.05, 37.81, 41.81, 43.20, 52.59, 59.92, 87.75, 112.91, 126.03, 128.06, 129.32, 130.46, 138.24, 140.22, 140.72. *4-Benzyloxy-4-(2-*tert*-butyldimethylsiloxy-ethyl)-3-vinyl-octa-1,7-dien-3-ol (**41**)*

3-Benzyl-3-but-3-enyl-dihydro-furan-2-one **38** (1.0 g, 4.37 mmol) was reacted under standard conditions for the conversion of methyl esters to tertiary diallylic alcohols. The crude product was dissolved in DMF (50 mL) and imidazole (0.469 g, 6.9 mmol) and *tert*-butyldimethylsilyl chloride (0.69 g, 4.6 mmol) were added. After stirring at room temperature for 12 h, water (50 mL) is added. Extract with ether (three times) and wash with water. Dry over Na_2SO_4, filter, and concentrate. Flash chromatography (5% Et_2O–hexanes) provides 0.825 g (48% over two steps) of the title compound as a colourless oil. R_f = 0.3 (5% Et_2O–hexanes). IR (neat): 3371 (s), 2929 (s), 1639 (w), 1471 (m), 1255 (m), 1079 (s), 910 (s), 836 (m), 733 (m). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.12 (s, 6H), 0.94 (s, 9H), 1.50–1.96 (m, 6H), 2.81 (d, *J* = 14 Hz, 1H), 2.86 (d, *J* = 14 Hz, 1H), 3.76–3.84 (m, 2H), 3.98 (br s, 1H), 4.88 (s, 1H), 4.91 (d, *J* = 6.8 Hz, 1H), 5.20 (dd, *J* = 12 Hz, 1.6 Hz, 1H), 5.23 (dd, *J* = 12 Hz, 1.6 Hz, 1H), 5.38 (dd, *J* = 17.2 Hz, 2 Hz, 1H), 5.39 (dd, *J* = 17.2 Hz, 2 Hz, 1H), 5.66–5.76 (m, 1H), 6.20 (dd, *J* = 17.2 Hz, 10.8 Hz, 1H), 6.20 (dd, *J* = 17.2 Hz, 10.8 Hz, 1H), 7.17–7.29 (m, 5H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.21, –5.17, 18.55, 26.16, 29.30, 33.00, 36.30, 40.78, 47.17, 60.39, 80.19, 114.02, 114.02, 114.73, 114.84, 126.20, 128.11, 130.97, 139.40, 139.54, 140.59, 140.76. HRMS calcd. $(M\text{-}C_4H_9)^+$: 343.0183; found: 343.0187.

*[2-(1-Benzyloxy-1-vinyl-allyl)-2-(2-*tert*-butyldimethylsiloxy-ethyl)-hex-5-enyl]-benzene (**42**)*

Alcohol **41** (150 mg, 0.375 mmol) was reacted according to the general benzylation procedure to yield the title compound as a colourless oil (165 mg, 90%) after flash chromatography (100% hexanes). R_f = 0.7 (5% Et_2O–hexanes). IR (neat): 2950 (m), 2859 (m), 1641 (m), 1451 (m), 1254 (m), 1081 (s), 930 (m), 835 (s). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.01 (s, 6H), 0.87 (s, 9H), 1.42–2.11 (m, 6H), 2.86 (d, *J* = 14 Hz, 1H), 2.92 (d, *J* = 13.6 Hz, 1H), 3.60–3.67 (m, 1H), 3.82–3.88 (m, 1H), 4.33 (s, 2H), 4.87 (s, 1H), 4.90 (d, *J* = 7.8 Hz, 1H), 5.34 (dd, *J* = 19.4 Hz, 2 Hz, 1H), 5.34 (dd, *J* = 17.6 Hz, 1.6 Hz, 1H), 5.46 (dd, *J* = 11 Hz, 2 Hz, 1H), 5.46 (dd, *J* = 11.2 Hz, 1.2 Hz, 1H), 5.65–5.75 (m, 1H), 6.02 (dd, *J* = 17.8 Hz, 11 Hz, 1H), 6.07 (dd, *J* = 17.8 Hz, 11 Hz, 1H), 7.19–7.36 (m, 10H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: –5.00, 18.49, 26.19, 29.45, 33.58, 37.54, 40.03, 47.45, 60.83, 65.77, 86.63, 113.85, 118.47, 118.70, 126.06, 127.07, 127.10, 128.00, 128.37, 131.11, 136.16, 136.52, 139.65, 139.76, 139.81. HRMS calcd. $(M\text{-}C_4H_9)^+$: 433.2562; found: 433.2576.

*6-Benzyl-6-(2-*tert*-butyldimethylsiloxy-ethyl)-1-vinyl-cyclohex-2-en-1-ol (**45**)*

To a solution of triene **41** (100 mg, 0.25 mmol) id dichloromethane(20 mL) is added **1** (24 mg, 0.03 mmol). The solution is stirred for 12 h at room temperature at which time the reaction is opened to air and the solvent is removed in vacuo. A crude ^{1}H NMR showed a 1:1 mixture of diastereomers at 100% conversion. The residue is purified by flash chromatography (5% Et_2O–hexanes) to provide the R*,S* diastereomer (37.6 mg, 40%) and the R*,R* diastereomer (30 mg, 32%) as colourless oils. The stereochemistry of the R*,S* diastereomer was proven by ROESY experiment.

*5-(1-Tributylstannylmethoxy-1-vinyl-allyl)-nona-1,8-diene (**47**)*

Potassium hydride (729 mg, 7.27 mmol) was washed three times with pentane, dried under a stream of argon and suspended in THF (5 mL). A solution of alcohol **8** (500 mg, 2.42 mmol) in THF (3 mL) was added via cannula. After 5 min, a solution of ICH_2SnBu_3 in THF (2 mL) was added via cannula followed by a small crystal of dry 18-crown-6. The resulting mixture was heated to reflux for 1 h, cooled to 23°C, diluted with ether, and quenched carefully by dropwise addition of water. The aqueous layer was extracted two times with ether, the organic layers were combined, washed with brine, dried over sodium sulfate, filtered and concentrated in vacuo. The residue was purified by flash chromatography (100% hexanes) on triethyl amine washed silica gel to yield the title compound as a colorless oil (1.15 g, 93%). R_f = 0.55 (100% hexanes). IR (neat): 3079, 2926, 1640, 1456, 1416, 1017, 909. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.89 (t, *J* = 7 Hz, 9H), 0.89 (tt, $J^{(H\text{-}Sn)}$ = 25 Hz, $J^{(H\text{-}H)}$ = 8 Hz, 6H), 1.04–1.14 (m, 2H), 1.30 (hex., *J* = 7 Hz, 6H), 1.40–1.82 (m, 11H), 1.86–2.18 (m, 5H), 3.40 (t, $J^{(H\text{-}Sn)}$ = 10 Hz, 2H), 4.92 (dm, *J* = 10 Hz, 2H), 4.97 (dq, *J* = 17, 2 Hz, 2H), 5.17 (dd, *J* = 18, 2 Hz, 2H), 5.34 (dd, 11, 2 Hz, 2H), 5.74 (dd, *J* = 18, 11 Hz, 2H), 5.72–5.86 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 8.84 (t, $J^{(C\text{-}Sn)}$ = 61 Hz), 13.73, 27.36 (t, $J^{(C\text{-}Sn)}$ = 26 Hz), 29.21 (t, $J^{(C\text{-}Sn)}$ = 10 Hz), 30.12, 33.46, 47.02, 52.46, 85.45, 114.03, 117.42, 137.92, 139.40. Conclusions

In conclusion, we have demonstrated a novel diastereoselective double ring closing metathesis reaction as an approach to the synthesis of bicyclo[4.4.0]decadienes and bicyclo[3.3.0]octadienes. The new bicyclic compounds allow for further synthetic transformations enabling the construction of valuable intermediates such as that found in the HMG CoA Reductase inhibitor (+)-Mevinolin. Present efforts are directed towards enantioselective alkene differentiation reactions that would allow the synthesis of enantioenriched bicyclic compounds. The methodology and concepts outlined in this paper should prove useful in the synthesis of complex natural products.

Acknowledgements

M.L. thanks the Merck Frosst Center for Therapeutic Research and Natural Sciences and Engineering Research Council of Canada (NSERC) for support of this work. G.H. and V.Z. both thank NSERC for predoctoral fellowships. G.H. thanks the Walter C. Sumner Foundation for a predoctoral fellowship. We thank Professor Ian Flemming, Cambridge, for bringing the synthesis outlined in Scheme 6 to our attention.

Synthesis of aspartic acid derivatives useful for the preparation of misacylated transfer RNAs

Michiel Lodder, Curtis F. Crasto, Andrei L. Laikhter, Haoyun An, Tuncer Arslan, Vladimir A. Karginov, Glenn F. Short, III, and Sidney M. Hecht

Abstract: Several derivatives of aspartic acid were protected on N^{α} as their NVOC derivatives, and on the side chain carboxylates as nitroveratryl esters. Following activation as the cyanomethyl esters, these fully protected aspartate derivatives were converted to the respective pdCpA esters. The protected aspartyl-pdCpA esters were then utilized as substrates for T4 RNA ligase in the presence of in vitro transcripts of tRNA lacking the pCpA dinucleotide normally found at the 3′-end. In this fashion, several misacylated tRNAs were prepared; following photolytic deprotection, these were employed successfully for incorporation into proteins at predetermined positions.

Key words: aminoacylated nucleotides, amino acid protection, protein synthesis, tRNA activation.

Résumé : On a préparé plusieurs dérivés de l'acide aspartique dans lesquels le N^{α} est protégé par un groupe "NVOC" et les groupes carboxyles de la chaîne latérale sont protégés par des esters nitrovératryles. Ces dérivés de l'acide aspartique totalement protégés, activés sous la forme d'esters cyanométhyles, ont été transformés en esters "pdCpA." Les esters aspartyl-pdCpA protégés ont alors été utilisés comme substrats pour la ligase d'ARN T4, en présence de produits de transcriptions in vitro de *t*-ARN ne portant pas le dinucléotide pCpA que l'on retrouve normalement à l'extrémité 3′. De cette façon, on a pu préparer plusieurs tARN anormalement aminoacétylés; après déprotection photolytique, ces produits ont été incorporés avec succès dans des protéines à des positions prédéterminées.

Mots clés : nucléotides aminoacétylés, protection d'acides aminés, synthèse de protéines, activation de la tARN.

[Traduit par la Rédaction]

Introduction

In 1962, Chapeville et al. (1) demonstrated that a cysteine-specific transfer RNA (tRNA) misactivated with alanine could be used to direct the incorporation of alanine into protein at sites intended for cysteine. While the lack of a general method for elaborating misacylated tRNAs initially limited the strategy to misacylated tRNAs accessible by chemical modification of enzymatically activated tRNAs (2), the Hecht laboratory discovered that virtually any misacylated tRNA could be prepared via the T4 RNA ligase-mediated condensation of a chemically synthesized aminoacylated pCpA derivative with a tRNA from which the last two nucleotides had been removed (3). Technical modifications, including the use of aminoacylated pdCpA derivatives (4) and in vitro RNA transcripts lacking the terminal CpA moiety (5) have facilitated the preparation of misacylated tRNAs by the use of this strategy, as have the development of methods for reversible *N*-protection of the aminoacyl moiety, resulting in aminoacylated dinucleotides and tRNAs of enhanced stability (3, 6).

The availability of misacylated tRNAs of diverse structure has permitted the elaboration of modified peptides (3, 7, 8) and proteins (9). That the elaborated species can include peptide and protein analogues of altered connectivity (8, 10) underscores the potential of this strategy for creating novel biomaterials, and for defining the chemistry that the ribosome is actually capable of mediating in the presence of suitable aminoacyl-tRNA analogues.

While the synthesis of aminoacylated dinucleotides for the preparation of misacylated tRNAs has been described (3, 6–9), modifications of the chemistry are required when the amino acid of interest has side-chain functionality. Presently, we describe the chemistry employed for the synthesis of pdCpA derivatives esterified with aspartate analogues, and the use of the derived dinucleotides for the elaboration of misacylated aspartyl-tRNAs. We have previously described the use of such species for the preparation of structurally modified analogues of dihydrofolate reductase (11) and HIV-1 protease (12).

Results and discussion

The aspartic acid derivatives shown in Fig. 1 were commercially available with the exception of the carboxyproline

Fig. 1. Aspartic acid derivatives used for the preparation of misacylated tRNAs.

derivatives and β,β-dimethylaspartic acid. *Threo*- and *erythro*-carboxyproline were prepared as described (13).

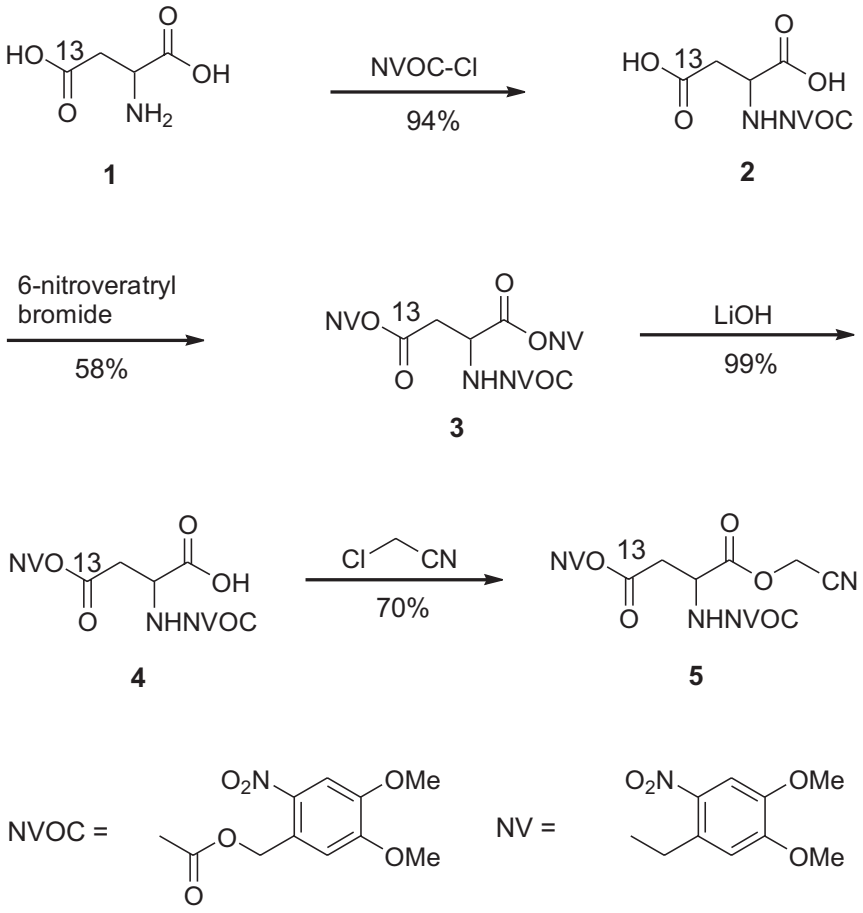
With the exception of β,β-dimethylaspartic acid, all of the aspartic acid derivatives shown in Fig. 1 were converted to suitably protected cyanomethyl esters as exemplified in Scheme 1 for [α-^{13}C]aspartic acid. In all cases, N^{α} was protected with the NVOC group, while the side-chain carboxylate was protected as the nitroveratryl ester. As shown in Scheme 1, treatment of [α-^{13}C]aspartic acid (**1**) with 6-nitroveratryl chloroformate (14), followed by treatment with 6-nitroveratryl bromide (15) provided fully protected **3** in good yield. Selective hydrolysis of the substituted benzyl ester with 1 equiv. of LiOH (16) gave β-monoester **4** in nearly quantitative yield. This intermediate was converted to cyanomethyl ester **5** (17) in 70% yield by treatment with chloroacetonitrile and triethylamine. It may be noted that this method has been utilized previously for the synthesis of **5** lacking ^{13}C enrichment (4). The other aspartic derivatives shown in Fig. 1 were converted to their fully protected cyanomethyl esters analogously, and in reasonable yields.

The strategy used for the synthesis and protection of β,β-dimethylaspartic acid is shown in Scheme 2. Known compound **6** (18) was treated with potassium bis(trimethylsilyl)amide and methyl iodide to provide the respective dimethylated derivative **7**. Removal of the 9-phenylfluorenyl group by hydrogenation, followed by treatment with 6-nitroveratryl chloroformate gave NVOC protected **8** in 98% yield. Hydrolysis of the methyl esters and treatment with 6-nitroveratryl bromide then provided bis-nitroveratryl ester **9**. Finally, in analogy with the transformations described for compound **3**, compound **9** was converted to cyanomethyl ester **11** by selective hydrolysis and treatment with chloroacetonitrile.

Table 1. Yields of incorporation of aspartic acid analogues into position 25 of HIV-1 protease.

Aspartic acid derivative	Yield (%)
Aspartic acid	22
erythro-β-Methylaspartic acid	33
threo-β-Methylaspartic acid	17
β,β-Dimethylaspartic acid	17

Scheme 3 shows an example of the attachment of an aspartic acid analogue to the dinucleotide pdCpA (4) and the subsequent ligation of the aminoacylated pdCpA derivative to a tRNA transcript lacking the 3′-terminal pCpA moiety. The cyanomethyl ester of (*2S, 3R*)-carboxyproline (**12**) was treated with the tetrabutylammonium salt of pdCpA as described (4). The protected aminoacylated dinucleotide **13** was then ligated to a truncated tRNA (tRNA-C_{OH}) via the agency of T4 ligase (3, 8–11). Removal of the protecting groups was accomplished by irradiation with a 500 W mercury–xenon lamp for 5 min. The deblocked misacylated tRNAs (e.g., **II**) were used promptly in an in vitro protein biosynthesizing system, yielding proteins containing the unnatural aspartic acid derivatives at predetermined sites (11, 12). The incorporation yields for several aspartic derivatives are illustrated in Table 1 using an optimized bacterial protein synthesizing system (19) programmed to elaborate analogues of HIV-1 protease.



Experimental

General information

Melting points were taken on a capillary melting point apparatus and are uncorrected. Moisture sensitive reactions were conducted under argon in oven-dried glassware.

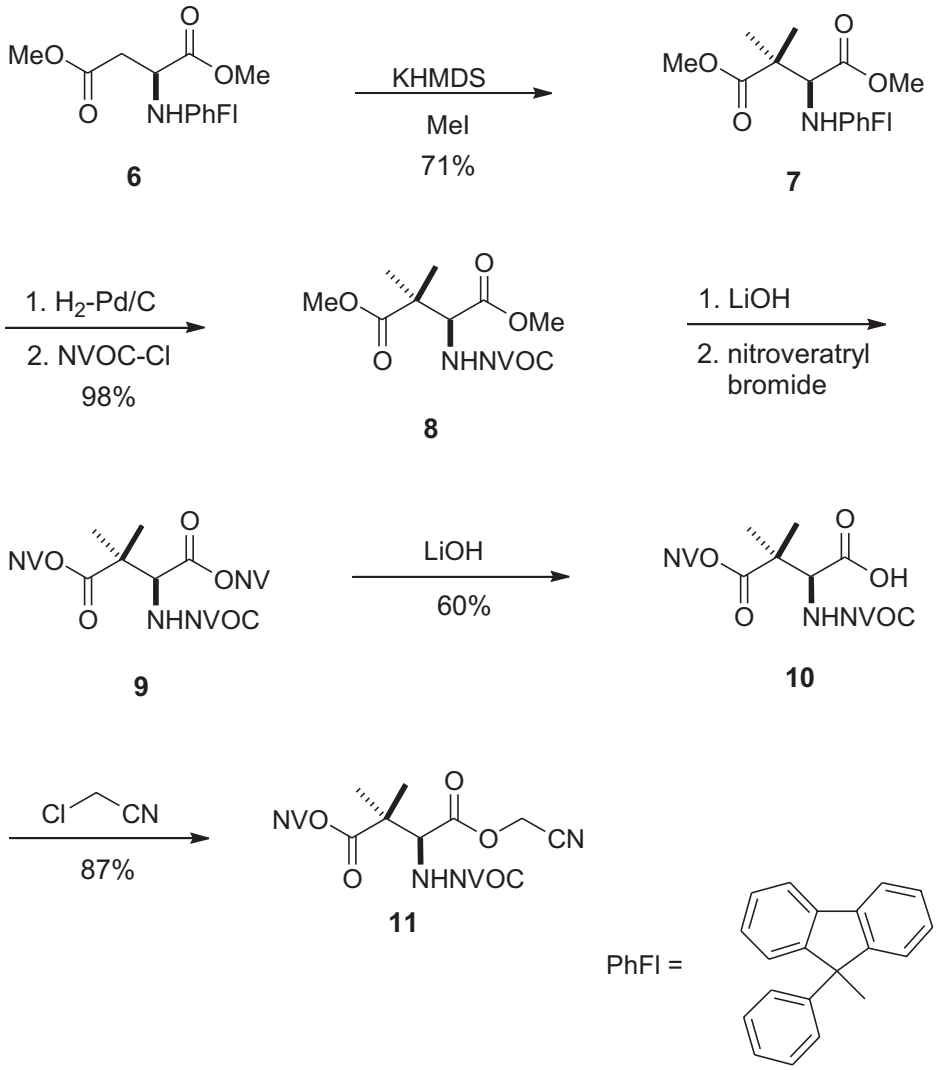
Scheme 1.

Acetonitrile and dichloromethane were distilled from CaH_2, and DMF was distilled from CaH_2 under diminished pressure. THF was distilled from $LiAlH_4$. Triethylamine was distilled from P_2O_5. All other chemicals were purchased from Aldrich Chemicals or Sigma Chemicals and were used without further purification. Analytical thin layer chromatography was performed on 60 F_{254} (E. Merck) plates. Flash chromatography was performed using 230–400 mesh silica gel. High resolution mass spectra were recorded at the Michigan State University-NIH Mass Spectrometry Facility in East Lansing, MI. T4 RNA ligase was purchased from Amersham Pharmacia Biotech.

N-*(6-Nitroveratryloxycarbonyl)-4-*^{13}*C-(*RS*)-aspartate (**2**)*



To a solution containing 50 mg (0.37 mmol) of 4-^{13}C-(*RS*)-aspartic acid (**1**) and 157 mg (1.87 mmol) of $NaHCO_3$ in 5 mL of dioxane and 2 mL of H_2O was added a solution of 184 mg (0.67 mmol) of 6-nitroveratryl chloroformate. After stirring at room temperature for 5 h the reaction mixture was diluted with 10 mL of 1 N $NaHSO_4$ and extracted with four 6-mL portions of ethyl acetate. The combined extract was dried (Na_2SO_4) and concentrated under diminished pressure. The crude product was applied to a silica gel column (25 × 2 cm); elution with 5:1:4 ethyl acetate – acetic acid – hexanes provided *N*-(6-nitroveratryloxycarbonyl)-4-^{13}C-(*RS*)-aspartate (**2**) as an orange solid: yield 131 mg (94%), mp 168–172°C. Silica gel TLC R_f: 0.31 (5:1:4 ethyl acetate – acetic acid – hexanes). ^{1}H NMR ($CDCl_3$) δ: 2.73–2.83 (m, 1H), 2.90–2.98 (m, 1H), 3.87 (s, 3H), 3.92 (s, 3H), 4.47–4.53 (m, 1H), 5.43–5.53 (m, 3H), 6.99 (s, 1H), 7.64 (s, 1H). ^{13}C NMR ($CDCl_3$) δ: 30.0, 56.6, 64.1, 108.5, 109.8, 139.6, 148.3, 154.4, 156.5, 173.6. Mass spectrum (chemical ionization) *m/z*: 374.090 $(M+H)^+$ ($C_{13}{}^{13}CH_{17}N_2O_{10}$ requires 374.0917).

Dinitroveratryl N-*(6-nitroveratryloxycarbonyl)-4-*^{13}*C-(*RS*)-aspartate (**3**)*

To a solution containing 131 mg (0.35 mmol) of *N*-(6-nitroveratryloxycarbonyl)-4-^{13}C-(*RS*)-aspartate (**2**) and 292 mg (1.06 mmol) of 6-nitroveratryl bromide in 5 mL of DMF was added 161 mg (1.06 mmol) of CsF. After stirring at room temperature for 24 h the reaction mixture was diluted with 10 mL of ethyl acetate and washed with 10 mL of saturated aqueous $NaHCO_3$ and with 10 mL of brine. The organic layer was dried (Na_2SO_4) and concentrated under diminished pressure. The crude product was applied to a silica gel column (27 × 2 cm); elution with 10–50% ethyl acetate in hexanes provided dinitroveratryl *N*-(6-nitroveratryloxycarbonyl)-4-^{13}C-(*RS*)-aspartate (**3**) as a yellow solid: yield 160 mg (58%), mp 126–134°C. Silica gel TLC R_f: 0.17 (1:1 ethyl acetate–hexanes). ^{1}H NMR ($CDCl_3$) δ: 2.90–3.15 (m, 2H), 3.88 (m, 18H), 4.71 (m, 1H), 5.37–5.45 (m, 6H), 5.50 (br, 1H), 6.89 (s, 1H), 6.98 (s, 2H), 7.62 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 30.1, 36.3, 37.9, 50.9, 56.7, 64.4, 64.5, 108.6,

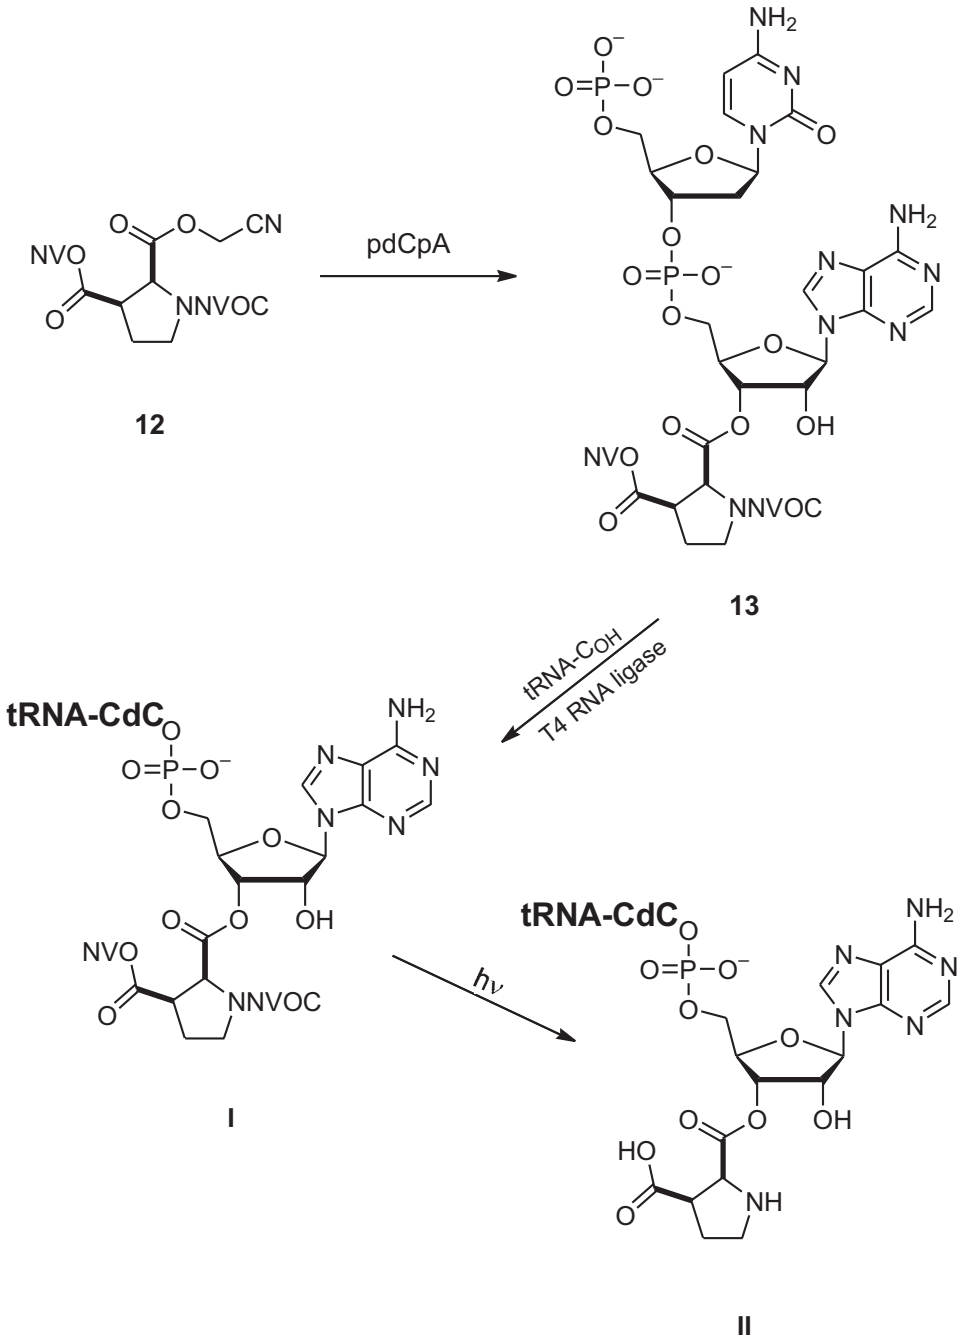
β-*Nitroveratryl* N-*(6-nitroveratryloxycarbonyl)-4-*^{13}*C-(*RS*)-aspartate (4)*



To a cooled (0–5°C) solution containing 89 mg (0.12 mmol) of dinitroveratryl *N*-(6-nitroveratryloxycarbonyl)-4-^{13}C-(*RS*)-aspartate (**3**) in 13 mL of acetone and 2 mL of H_2O was added 12 mL of a 0.1 N solution of LiOH in H_2O. After stirring at room temperature for 16 h, the reaction mixture was diluted with 20 mL of 1 N $NaHSO_4$ and extracted with five 10-mL portions of CH_2Cl_2. The combined organic extract was washed with 10 mL of brine, dried ($MgSO_4$), and concentrated under diminished pressure. The crude product was applied to a silica gel column (26 × 2 cm); elution with 10:1:1:8 ethyl acetate – acetic acid – MeOH – hexanes provided β-nitroveratryl *N*-(6-nitroveratryloxycarbonyl)-4-^{13}C-(*RS*)-aspartate (**4**) as a yellow solid: yield 65 mg (99%). Silica gel TLC R_f: 0.18 (10:1:1:8 ethyl acetate – acetic acid – MeOH – hexanes). ^{1}H NMR ($CDCl_3$) δ: 2.95–3.04 (m, 1H), 3.16–3.24 (m, 1H), 3.93–3.97 (m, 12H), 4.78 (m, 1H), 5.48–5.56 (m, 4H), 5.97 (br, 1H), 6.94 (m, 2H), 7.02 (s, 1H), 7.68–7.70 (m, 2H). Mass spectrum (electron impact) *m*/*z*: 569.142 $(M+H)^+$ ($C_{22}{}^{13}CH_{26}N_3O_{14}$ requires 569.1448).

Cyanomethyl β-*nitroveratryl* N-*(6-nitroveratryloxycarbonyl)-4-*^{13}*C-(*RS*)-aspartate (5)*

To a solution containing 66 mg (0.12 mmol) of β-nitroveratryl *N*-(6-nitroveratryloxycarbonyl)-4-^{13}C-(*RS*)-aspartate (**4**) in 2 mL of acetonitrile was added 100 μL (0.72 mmol) of Et_3N, followed by 0.5 mL (7.90 mmol) of chloroacetonitrile. After stirring at room temperature for 24 h, the reaction mixture was diluted with 10 mL of 1 N HCl and extracted with five 4-mL portions of CH_2Cl_2. The combined organic extract was washed with 5 mL of brine, dried (Na_2SO_4), and concentrated under diminished pressure. The crude product was applied to a silica gel column (12 × 2 cm); elution with 10–50% ethyl acetate in hexanes provided cyanomethyl β-nitroveratryl *N*-(6-nitroveratryloxycarbonyl)-4-^{13}C-(*RS*)-aspartate (**5**) as a yellow solid: yield 50 mg (70%), mp 129–134°C. Silica gel TLC R_f: 0.51 (1:4 ethyl acetate–CH_2Cl_2). ^{1}H

Scheme 3.

NMR ($CDCl_3$) δ: 3.00 (m, 1H), 3.21 (m, 1H), 3.96–4.02 (m, 12H), 4.78 (m, 3H), 5.43–5.59 (m, 4H), 5.80 (br, 1H), 6.95 (s, 1H), 7.05 (s, 1H), 7.73 (s, 2H). ^{13}C NMR (acetone-d_6) δ: 35.0, 35.8, 48.5, 50.2, 55.2, 55.4, 63.24, 63.39, 107.6, 109.3, 110.2, 124.7, 125.8, 127.4, 127.6, 128.4, 139.0, 147.8, 148.1, 153.5, 155.1, 169.0, 169.2. Mass spectrum (chemical ionization) *m/z*: 608.152 $(M+H)^+$ ($C_{24}{}^{13}CH_{27}N_4O_{14}$ requires 608.1557).

Dimethyl N-*(9-phenylfluorenyl)*-β,β-*dimethyl-(*S*)-aspartate (7)*

To a cooled (–78°C) solution containing 5.17 mL of a 0.5 M solution of potassium bis(trimethylsilyl)amide in toluene (2.58 mmol) in 30 mL of THF was added dropwise a solution of 683 mg (1.70 mmol) of dimethyl *N*-(9-phenylfluorenyl)-(*S*)-aspartate (**6**) in 20 mL of THF. After stirring for 1 h, a solution containing 0.45 mL (7.18 mmol) of methyl iodide in 1 mL of THF was added. After stirring for an additional 1 h, another 5.20 mL portion of the 0.5 M potassium bis(trimethylsilyl)amide solution was added. After 2 h the reaction mixture was quenched with 2 mL of MeOH, diluted with 30 mL of 1 N H_3PO_4, and extracted with three 15-mL portions of ethyl acetate. The organic extract was washed with 10 mL of brine, dried ($MgSO_4$), and concentrated under diminished pressure. The crude product was applied to a silica gel column (20 × 2 cm); elution with 4:1 hexanes–ethyl acetate provided dimethyl *N*-(9-phenylfluorenyl)-β,β-dimethyl-(*S*)-aspartate (**7**) as a pale yellow oil: yield 522 mg

(71%). Silica gel TLC R_f: 0.24 (1:1 ethyl acetate–hexanes). ^{1}H NMR ($CDCl_3$) δ: 1.12 (s, 3H), 1.28 (s, 3H), 2.93 (d, 1H, J = 11 Hz), 3.19 (s, 3H), 3.55 (s, 3H), 5.20 (s, 1H), 7.20–7.75 (m, 13H). ^{13}C NMR ($CDCl_3$) δ: 21.4, 22.7, 46.9, 51.7, 52.4, 54.0, 61.5, 73.1, 120.4, 127.3, 127.7, 127.8, 128.1, 148.4, 148.7, 174.6, 176.4. Mass spectrum (electron impact) *m*/*z*: 429.194 ($C_{27}H_{27}NO_4$ requires 429.1940).

Dimethyl N-*(6-nitroveratryloxycarbonyl)*-β,β-*dimethyl-(*S*)-aspartate (**8**)*

To a solution containing 250 mg (0.58 mmol) of dimethyl *N*-(9-phenylfluorenyl)-β,β-dimethyl-(*S*)-aspartate (**7**) in MeOH was added 125 mg of 10% Pd/C. The reaction mixture was shaken under H_2 at 50 psi for 24 h. The reaction mixture was filtered through Celite and the filtrate was concentrated under diminished pressure. The residue was dissolved in 5 mL of H_2O and washed with three 5-mL portions of CH_2Cl_2. The aqueous layer was diluted with 6 mL of dioxane and 122 mg (1.45 mmol) of $NaHCO_3$ was added, followed by a solution containing 289 mg (1.05 mmol) of 6-nitroveratryl chloroformate in 4 mL of dioxane. After stirring at room temperature for 16 h, the reaction mixture was diluted with 20 mL of 1 N $NaHSO_4$ and extracted with four 25-mL portions of ethyl acetate. The combined extract was washed with 15 mL of brine, dried ($MgSO_4$), and concentrated under diminished pressure. The crude product was applied to a silica gel column (20 × 2 cm); elution with 10–50% ethyl acetate in hexanes gave dimethyl *N*-(6-nitroveratryloxycarbonyl)-β,β-dimethyl-(*S*)-aspartate (**8**) as a yellow solid: yield 244 mg (98%). Silica gel TLC R_f: 0.24 (2:3 ethyl acetate–hexanes). ^{1}H NMR ($CDCl_3$) δ: 1.14 (s, 3H), 1.24 (s, 3H), 3.64 (s, 3H), 3.65 (s, 3H) 3.87 (s, 3H), 3.91 (s, 3H), 4.55 (d, 1H, J = 10 Hz), 4.88 (s, 2H), 5.44 (br, 1H), 6.92 (s, 1H), 7.61 (s, 1H). ^{13}C NMR ($CDCl_3$) δ: 22.3, 23.3, 52.9, 56.7, 56.8, 60.5, 62.8, 64.4, 108.4, 108.5, 110.1, 110.9, 133.1, 139.8, 148.1, 154.3, 156.4, 171.2, 176.2. Mass spectrum (electron impact) *m*/*z*: 428.142 ($C_{18}H_{24}N_2O_{10}$ requires 428.1431).

Dinitroveratryl N-*(6-nitroveratryloxycarbonyl)*-β,β-*dimethyl-(*S*)-aspartate (**9**)*

To a solution containing 249 mg (0.58 mmol) of dimethyl *N*-(6-nitroveratryloxycarbonyl)-β,β-dimethyl-(*S*)-aspartate (**8**) in 12 mL of acetone and 6 mL of H_2O was added 14.6 mL of a 0.1 N solution of LiOH in H_2O. After stirring at 40°C for 2 days the reaction mixture was diluted with 10 mL of ethyl acetate and the layers were separated. The aqueous layer was acidified with 1 N $NaHSO_4$ and extracted with four 10-mL portions of ethyl acetate. The combined extract was washed with 10 mL of brine, dried ($MgSO_4$), and concentrated under diminished pressure. The crude diacid was dissolved in 2 mL of DMF and 155 mg (0.56 mmol) of 6-nitroveratryl bromide was added, followed by 85 mg (0.56 mmol) of CsF. After stirring at room temperature for 2 days, the reaction mixture was diluted with 10 mL of ethyl acetate and washed with 10 mL of saturated aqueous $NaHCO_3$ and 10 mL of brine. The organic layer was dried (Na_2SO_4) and concentrated under diminished pressure. The crude product was applied to a silica gel column (18 × 2 cm); elution with 10–50% ethyl acetate in hexanes gave dinitroveratryl *N*-(6-nitroveratryloxycarbonyl)-β,β-dimethyl-(*S*)-aspartate (**9**) as a yellow syrup: yield 124 mg (27%). Silica gel TLC R_f: 0.50 (3:2 ethyl acetate–hexanes). ^{1}H NMR ($CDCl_3$) δ: 1.29 (s, 3H), 1.41 (s, 3H), 3.90–3.93 (m, 18H), 4.71 (d, 1H, J = 10 Hz), 5.39–5.50 (m, 6H), 6.02 (br, 1H), 6.91 (s, 1H), 6.97 (s, 2H), 7.62–7.66 (m, 3H). ^{13}C NMR ($CDCl_3$) δ: 22.8, 23.8, 45.8, 60.7, 64.5, 64.9, 108.5, 110.0, 110.9, 111.3, 126.2, 126.6, 128.2, 140.0, 140.3, 148.6, 148.8, 154.0, 154.2, 156.4, 170.3, 175.3. Mass spectrum (FAB) *m*/*z*: 791.226 $(M+H)^+$ ($C_{34}H_{39}N_4O_{18}$ requires 791.2259).

β-*Nitroveratryl* N-*(6-nitroveratryloxycarbonyl)*-β,β-*dimethyl-(*S*)-aspartate (**10**)*

To a cooled (0–5°C) solution containing 119 mg (0.15 mmol) of dinitroveratryl *N*-(6-nitroveratryloxycarbonyl)-β,β-dimethyl-(*S*)-aspartate (**9**) in 5 mL of acetone and 2 mL of H_2O was added 1.6 mL (0.16 mmol) of a 0.1 N solution of LiOH in H_2O. After stirring at room temperature for 24 h, the reaction mixture was concentrated under diminished pressure. The residue was dissolved in 4 mL of saturated aqueous $NaHCO_3$ and washed with three 5-mL portions of ethyl acetate. The aqueous layer was acidified with 1 N $NaHSO_4$ and extracted with three 6-mL portions of ethyl acetate. The combined extract was washed with 6 mL of brine, dried ($MgSO_4$), and concentrated under diminished pressure. The crude product was applied to a silica gel column (13 × 2 cm); elution with 10:1:1:8 ethyl acetate – MeOH – acetic acid – hexanes gave β-nitroveratryl *N*-(6-nitroveratryloxycarbonyl)-β,β-dimethyl-(*S*)-aspartate (**10**) as a pale yellow syrup: yield 54 mg (60%). Silica gel TLC R_f: 0.48 (10:1:9 ethyl acetate – MeOH – hexanes). ^{1}H NMR ($CDCl_3$) δ: 1.23 (s, 3H), 1.41 (s, 3H), 3.94–3.97 (m, 12H), 4.65 (d, 1H, J = 10 Hz), 5.51 (m, 4H), 6.02 (br, 1H), 7.02 (s, 2H), 7.67 (s, 2H), 11.0 (br, 1H). Mass spectrum (FAB) *m*/*z*: 596.170 $(M + H)^+$ ($C_{25}H_{30}N_3O_{14}$ requires 596.1728).

Cyanomethyl β-*nitroveratryl* N-*(6-nitroveratryloxycarbonyl)*-β,β-*dimethyl-(*S*)-aspartate (**11**)*

To a solution containing 52 mg (0.087 mmol) of β-nitroveratryl *N*-(6-nitroveratryloxycarbonyl)-β,β-dimethyl-(*S*)-aspartate (**10**) in 2 mL of acetonitrile was added 61 μL (0.44 mmol) of Et_3N, followed by 100 μL (1.58 mmol) of chloroacetonitrile. After stirring at room temperature for 24 h the reaction mixture was diluted with 5 mL of CH_2Cl_2 and washed successively with 4 mL of 1 N HCl, two 4-mL portions of saturated aqueous $NaHCO_3$, and 5 mL of brine. The organic layer was dried (Na_2SO_4) and concentrated under diminished pressure. The crude product was applied to a silica gel column (15 × 2 cm); elution with 10–50% ethyl acetate in hexanes provided cyanomethyl β-nitroveratryl *N*-(6-nitroveratryloxycarbonyl)-β,β-dimethyl-(*S*)-aspartate (**11**) as a pale yellow solid: yield 48 mg (87%), mp 69–72°C. Silica gel TLC R_f: 0.24 (1:1 ethyl acetate–hexanes). ^{1}H NMR ($CDCl_3$) δ: 1.33 (s, 3H), 1.44 (s, 3H), 3.96 (s, 6H), 4.00 (s, 6H), 4.65 (m, 1H), 4.71 (m, 2H), 5.51 (m, 2H), 5.56 (m, 2H), 5.92, (br, 1H), 7.03 (s, 2H), 7.72 (s, 2H). Mass spectrum (FAB) *m*/*z*: 634.172 ($C_{27}H_{30}N_4O_{14}$ requires 634.1759).

β-*Nitroveratryl* N-*(6-nitroveratryloxycarbonyl)-(2*S*,3*R*)-carboxyproline pdCpA ester (**13**)*

A solution of 4 mg (2.94 μmol) of the tris(tetrabutylammonium) salt of pdCpA and 9.8 mg (13.7 μmol) of β-nitroveratryl *N*-(6-nitroveratryloxycarbonyl)-(*2S,3R*)-carboxy-

© 2000 NRC Canada

proline cyanomethyl ester (**12**) in 50 μL of DMF was stirred at room temperature for 4 h. A 10-μL aliquot of the mixture was diluted with 90 μL of 1:1 CH_3CN – 50 mM NH_4OAc, pH 4.5. Ten μL of the diluted aliquot was analyzed by HPLC on a C_{18} reversed phase column (250 × 10 mm). The column was washed with 1→63% CH_3CN in 50 mM NH_4OAc, pH 4.5, over a period of 45 min at a flow rate of 3.5 mL/min (monitoring at 260 nm). The reaction mixture was diluted to a total volume of 400 μL of 1:1 CH_3CN – 50 mM NH_4OAc, pH 4.5, and purified using the same semipreparative C_{18} reversed phase column, affording β-nitroveratryl *N*-(6-nitroveratryloxycarbonyl)-(*2S*,*3R*)-carboxyproline pdCpA ester (**13**) as a pale yellow foam: yield 0.5 mg (14%). Mass spectrum (FAB) *m/z*: 1212.257 $(M+H)^+$ ($C_{44}H_{52}N_{11}O_{26}P_2$ requires 1212.2560).

Synthesis of misacylated tRNAs

Ligation reactions were carried out in 50 μL of 50 mM Na Hepes buffer, pH 7.5, containing 5 μL (~0.2 nmol) of $tRNA_{(CUA)}C_{OH}$, 0.5 A_{260} unit (~20 nmol) of an aminoacyl-pdCpA, 0.5 mM ATP, 15 mM $MgCl_2$, 10% dimethylsulfoxide, and 100 units of T4 RNA ligase. Reaction mixtures were incubated at 37°C for 25 min and then quenched by the addition of 5 μL of 3 M Na acetate, pH 4.5. The aminoacylated tRNA (**I**) was precipitated with 2.5 volumes of ethanol, collected by centrifugation, washed with 70% ethanol, and dried. The product was redissolved in 1 mM KOAc to a final concentration of 1 μg/μL and then irradiated with a 500 W mercury–xenon lamp using Pyrex and water filters. The protected aminoacyl tRNA (**I**) was cooled in an ice bath during irradiation, which was typically carried out for 5 min for amino acid derivatives containing an NVOC group and a nitroveratryl ester. The deprotected aminoacyl-tRNAs (**II**) were used in in vitro suppression experiments soon after deprotection.

Substrate specificity of fucosyl transferase III: An efficient synthesis of sialyl Lewis^x-, sialyl Lewis^a-derivatives and mimetics thereof

Beat Ernst, Bea Wagner, Gabi Baisch, Andreas Katopodis, Tammo Winkler, and Reinhold Öhrlein

Abstract: Fucosyl transferase III (FucT III) has previously been characterized as the most general enzyme of the FucT family, as judged from its ability to catalyze the transfer of fucose to both Galβ(1–3)Glc*N*Ac and Galβ(1–4)Glc*N*Ac. In order to explore the synthetic potential of FucT III for the enzymatic synthesis of sialyl Lewis^x and sialyl Lewis^a derivatives, its substrate specificity has been probed using a number of natural substrate mimetics. A remarkable range of acceptor substrates was found when *N*-acetyl glucosamine was replaced by D-glucal, (*R*,*R*)-1,2-cyclohexanediol and (*R*,*R*)-butan-2,3-diol. Although the reaction rates were low compared to the reaction with the natural substrates, they proved to be sufficient for the synthesis of preparative amounts.

Key words: fucosyl transferase III, sialyl Lewis^a, sialyl Lewis^x, carbohydrate mimetics.

Résumé : La fucosyle transférase III (FucT III) a déjà été caractérisée comme étant l'enzyme le plus général de la famille des FucT, tel que le prouve sa capacité à catalyser le transfert du fucose aux deux Gal 1–3 Glc*N*Ac et Gal 1–4 GlcVAc. Dans le but d'explorer le potentiel synthétique du FucT III pour la synthèse enzymatique des dérivés du sialyl Lewis^x et du sialyl Lewis^a, on a mis en évidence la spécificité de son substrat en utilisant divers analogues de substrats naturels. On trouvé un remarquable échantillonnage de substrats accepteurs lorsqu'on remplace la *N*-Acétyl glucosamine par le D-glucal, le (*R*,*R*)-1,2-cyclohexanediol et le (*R*,*R*)-butan-2,3-diol. Bien que les vitesses de réaction soient plus lentes que celles des produits naturels, elles se révèlent acceptables pour la synthèse à grande échelle.

Mots clés : fucosyle transférase III, sialyl Lewis^x et du sialyl Lewis^a, analogues d'hydrates de carbone.

[Traduit par la Rédaction]

Introduction

Numerous diseases and pathological situations are associated with excessive influx of leukocytes into tissues. Although this influx normally represents an essential defense mechanism against infection, excessive, or inappropriate leukocyte accumulation results in injury to host tissues as observed in ischemia-reperfusion injury, respiratory disease, dermatitis, or gastro-intestinal inflammation (1).

Early in the inflammatory response leukocytes adhere to and roll along endothelial cells on the inner surface of blood vessels. It has been clearly shown that an inducible set of calcium dependent adhesion molecules, the selectins, mediates this initial event (2). Since leukocyte rolling is a prerequisite for later inflammatory events, inhibition of selectins is a valuable strategy for preventing the deleterious consequences of excessive leukocyte influx.

Studies of the carbohydrate specificity of E- and P-selectin uncovered a recognition motif common to both receptors, the sialylated and fucosylated tetrasaccharide antigens sialyl Lewis^x (**1**) (3) and sialyl Lewis^a (**2**) (4). Later, L-selectin was also shown to bind sLe^x and sLe^a containing oligosaccharides (5). These two tetrasaccharides have therefore served as lead structures in our search for selectin antagonists with increased biological activity, simplified structure and improved bioavailability (6). For the discovery of their structure-activity relationship, numerous derivatives of **1** and **2** have been synthesized. It is worth mentioning that these derivatives have not only been obtained by chemical (7) but also by enzymatic synthesis (Scheme 1); e.g., sialyl Lewis^x and sialyl Lewis^a derivatives with a modified *N*-acyl group of the D-glucosamine nitrogen (e.g., **3**, **4**) (8) or compounds where fucose is replaced by other L-sugars (e.g., **5**, **6**) (9).

Although a number of studies showed that non-natural substrates are accepted by glycosyl transferases (10), only a limited number of structurally more distant compouds have been probed to date (11). To further explore the synthetic potential of the enzymatic approach for the synthesis of sialyl Lewis^x and sialyl Lewis^a derivatives and to widen the synthetic value of these biocatalysts, we decided to

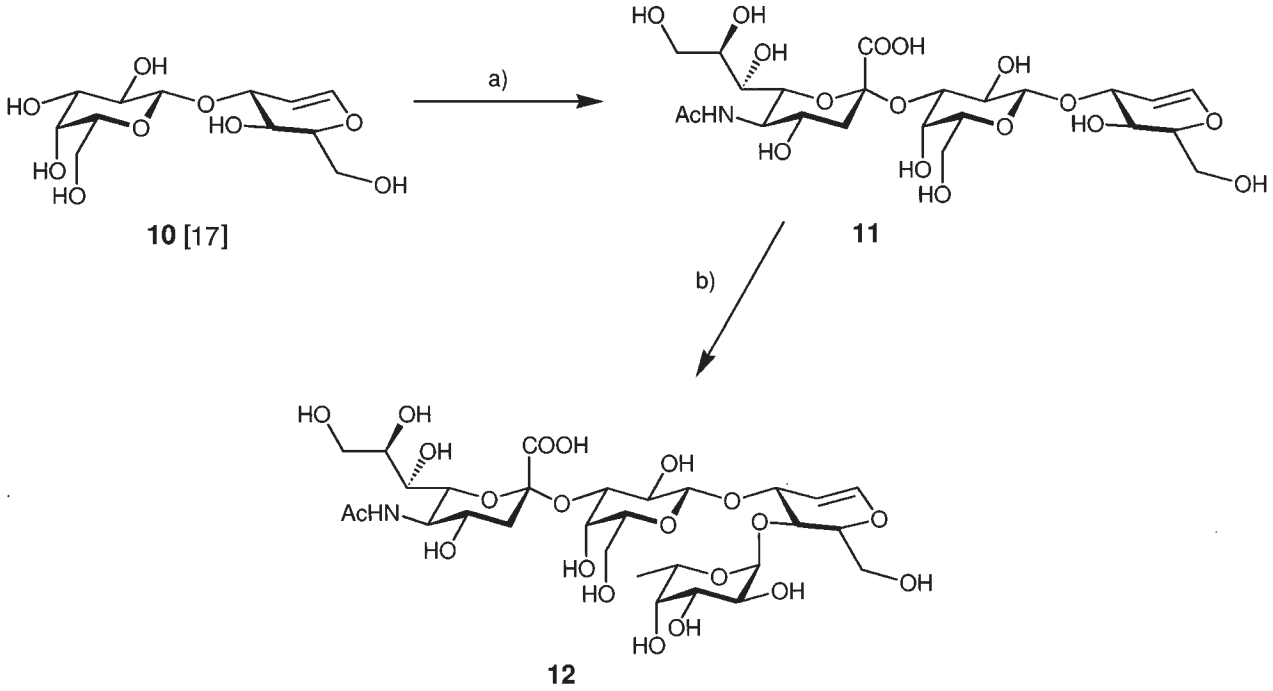
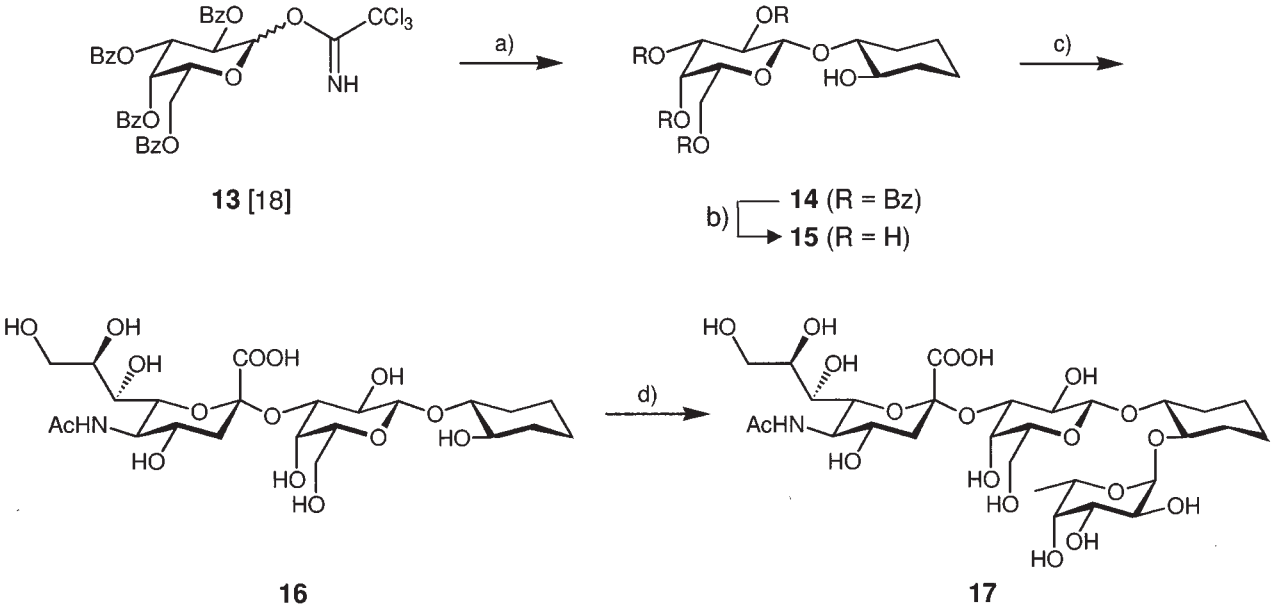
investigate the substrate specificity of the enzymatic fucosylation reaction. As judged from its ability to catalyze the transfer of fucose to both α1,3 and α1,4 linkages FucT III has previously been characterized as the most general enzyme of the FucT III family (12). We therefore concentrated our investigation on the substrate specificity of FucT III.



Results and discussion

Since the chemical approach to sialyl Lewis^x and sialyl Lewis^a analogs requires multi-step syntheses, the chemoenzymatic approach was considered as an alternative. The advantages of using glycosyl transferases for the construction of glycosidic bonds include mild reaction conditions, the lack of requirement for protection and deprotection steps and the regio- and stereospecificity of the glycosylation.



In a first attempt, lactal **7**, which can easily be obtained from D-lactose (13) served as a mimic of *N*-acetyllactosamine (Scheme 2). It was first incubated with recombinant α(2–3)sialyl transferase (14) and subsequently with recombinant fucosyl transferase FucT III (15). As expected, α-sialylation occurred at the 3-OH of galactose. Surprisingly, the allylic OH-group of the glucal moiety was fucosylated exclusively, generating the desired sLe^x derivative **9**. A

similar reaction sequence starting from **7** had previously been carried out successfully by Wong et al. (16) using FucT V instead of FucT III.

Galactosyl-β(1–3)glucal **10** (17), a type I congener of lactal **7**, could equally well be sialylated (→ **11**) (Scheme 3). Also in this case, FucT III accepted a glucal derivative as substrate. Therefore, the *N*-acetyl group of the natural glucosamine substrate is not a prerequisite for a successful fucosylation.

In a further step (see Scheme 4), the glucal ring system was replaced by (*R*,*R*)-cyclohexan-1,2-diol. The precursor pseudodisaccharide **15** was obtained in a two step procedure by galactosylation of commercially available (*R*,*R*)-1,2-cyclohexanediol using the trichloroacetimidate **13** (18) as the galactosyl donor and TESOTf as the promotor (→ **14**) followed by removal of the benzoate protecting groups by transesterification. In the first enzymatic step, **15** was incubated with CMP-Neu-5-NAc and recombinant α(2–3)sialyl transferase (14) to yield **16**. As observed for **7** and **10,** the activity of the α(2–3)sialyl transferase was not affected by the character of the aglycon at the reducing end of the galactose moiety. In the subsequent fucosylation step, incubation

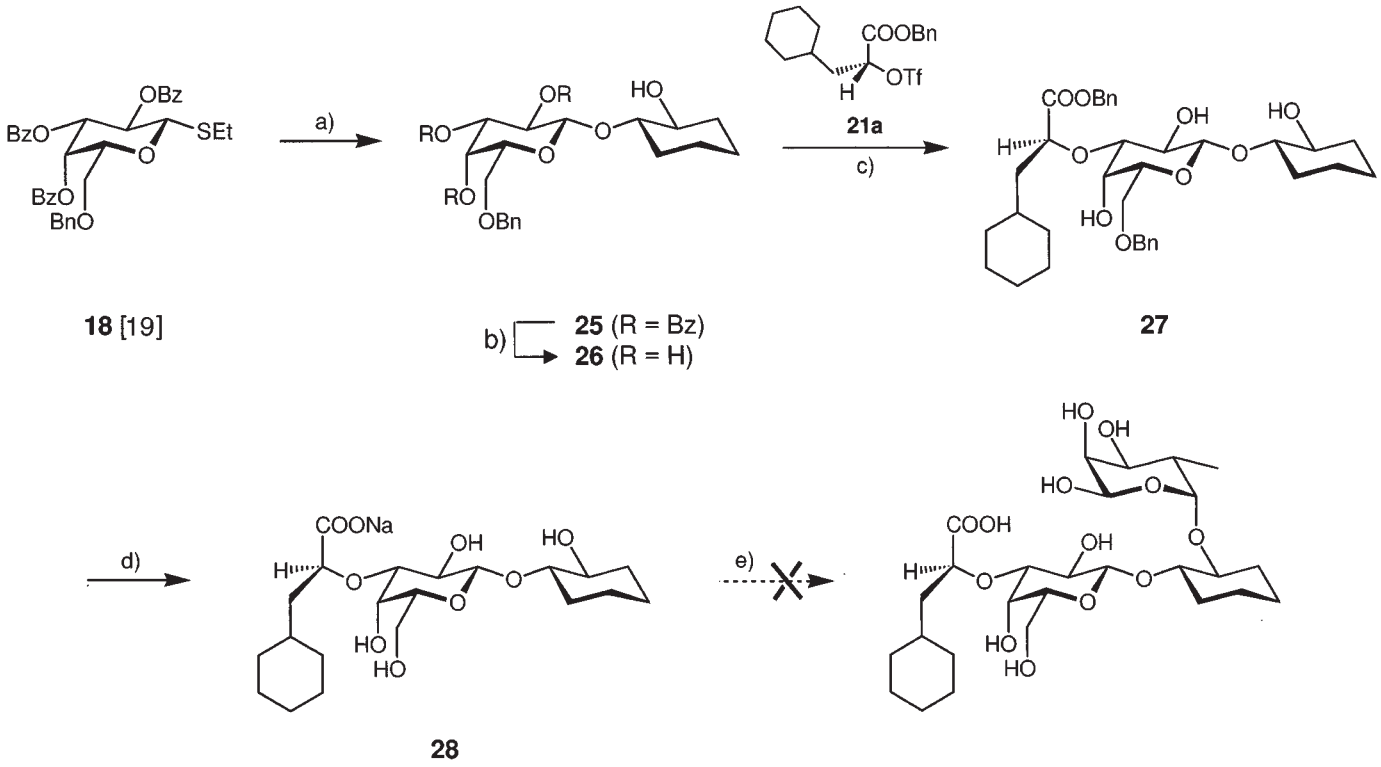
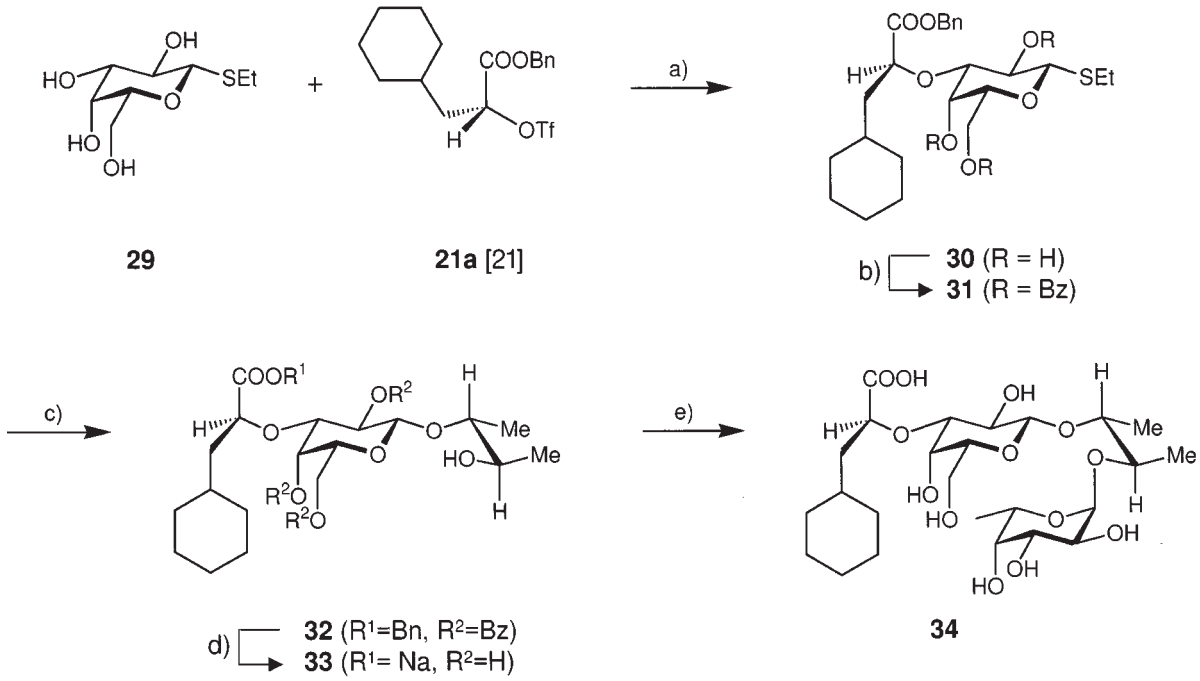
of the trisaccharide **16** with GDP-fucose and recombinant FucT III (15) gave **17**, which can be regarded as mimic of either sLe^x or a sLe^a. The connectivity pattern in **17** was confirmed by ROESY.

Next, the enzymatic fucosylations of the pseudotrisaccharides **23a**–**c** were examined. In these compounds the D-glucosamine and the *N*-acetylneuraminic acid moiety of the natural substrate are replaced by (*R*,*R*)-cyclohexan-1,2-diol and *R*- and *S*-lactic acid derivatives, respectively. The glycosyl acceptors **23a**–**c** were obtained by galactosylation of (*R*,*R*)-cyclohexan-1,2-diol with ethyl 6-*O*-benzyl-2,3,4-tri-*O*-benzoyl-1-thio-β-D-galactopyranoside **18** (19) using dimethylmethylthiosulfonium triflate (DMTST) (20) as promoter (→ **19**) followed by the removal of the benzoate protecting groups by transesterification (→ **20**). Finally, alkylation of **20** with the lactic acid derivatives **21a,b** (21) and **21c** (22), respectively, (→ **22a**–**c**) and final deprotection by hydrogenolysis gave the substrates **23a**–**c**. As observed for **16**, the hydroxy group of the cyclohexane moiety was fucosylated with good to excellent yield using FucT III. The replacement of neuraminic acid by lactic acid derivatives does not influence proper fucosylation. Furthermore, the stereochemical orientation of the lactic acid substituents – with *S*-configuration in **23a** and *R*-configuration in **23b** – did not affect the outcome of the fucosylation.



D-Galactose carrying a substituent with the acceptor OH group in the proper stereochemical arrangement at the reducing end is therefore the only structural motif critical for recognition by FucT III. (*R*,*R*)-cyclohexan-1,2-diol can be considered as a perfect mimic for the 3- and 4-hydroxy groups of a D-glucose/D-glucosamine in the $^4C_1$ conformation.

We further investigated (*S*,*S*)-cyclohexan-1,2-diol, which represents a mimic of *N*-acetyl-L-glucosamine. The pseudotrisaccharide **28** was obtained in analogy to **23a** (see Scheme 6): β-Galactosylation of (*S*,*S*)-cyclohexan-1,2-diol gave the pseudodisaccharide **25** in moderate yield. After removal of the benzoates, **26** was regioselectively alkylated with benzyl (*R*)-3-cyclohexyl-2-trifluoromethansulfonyloxy-propionate. Finally, the benzyl protective groups were removed by hydrogenation to yield **28**, which however did not act as a substrate for FucT III as well as for FucT VI (23).



Finally, we examined (*R*,*R*)-butan-2,3-diol as a mimic of the 3- and 4-hydroxy groups of a D-glucose/D-glucosamine. For the synthesis of the corresponding substrate **33,** the 3-hydroxy group of ethyl 1-thio-β-D-galactopyranoside **29**, was regioselectively alkylated. For this purpose, the stannylene acetal (24) of the two trans hydroxy groups (2- and 3-position) of ethyl 1-thio-β-D-galactopyranoside **29** was formed in situ and treated with benzyl (*R*)-3-cyclohexyl-2-trifluoromethansulfonyloxy-propionate **21a** in DME at room temperature in the presence of caesium fluoride. The resulting thiogalactoside **30** was then perbenzoylated (BzCl, pyridine, DMAP) to yield the glycosyl donor **31**, which was used for the galactosylation of (*R*,*R*)-2,3-butandiol with DMTST (19) as promotor. After deprotecton by saponification, the substrate for the enzymatic step was obtained in excellent yield. The trisaccharide mimic **33** was then incubated with FucT III and GDP-fucose. To our surprise, this highly flexible compound proved to be an excellent substrate

of FucT III yielding the α-fucosylated product **34**. This structure was confirmed based on the ^{1}H and ^{13}C chemical shift of H-1 and C-1 of the fucose moiety (4.99 ppm (J = 3.3 Hz) and 96.4 ppm, respectively). In addition, the ^{13}C signals of both CHO carbons of the butandiol moiety which are shifted upfield by approximately 2 ppm proving the site of the fucosylation.

In the examples shown, the FucT III was found to have a remarkable flexibility in the recognition of acceptor substrates. Further modifications are under current investigation. However, in many cases the reaction rates were very low compared to the reaction with the natural substrate sialylα(2–3)lacNAc. Such rates, however, proved to be sufficient for the synthesis of preparative amounts of oligosaccharide derivatives and mimics.

A severe drawback for the feasibility of the enzymatic synthesis of oligosaccharides and derivatives thereof stems from the availability of glycosyl transferases. Although an increasing number of transferases are commercially available, they are still prohibitively expensive, particularly for synthesis on a preparative scale. For this reason, we have initiated programs to clone and overexpress our own transferases for mechanistic and synthetic studies.

The sugar nucleotides CMP-NeuNAc and GDP-Fuc are commericially available (footnotes 2, 3) and numerous chemical and chemo-enzymatic approaches for their syntheses have been developed in recent years (25). This has decisively improved the availability of activated sugars in preparative amounts and therefore the feasibility of the enzymatic synthesis of oligosaccharides and derivatives thereof.

Experimental

General methods

Chemicals used were reagent grade and were used as supplied except where noted. Solvents were either dried by standard procedures or used as purchased. Unless otherwise stated, all reactions were performed under an argon atmosphere. All chemical glycosylation reactions were performed using molecular sieves, which were flame-dried under high vacuum immediately before the reaction. Analytical thin-layer-chromatography (TLC) was performed using silica gel 60 F_{254} glass plates (MERCK); compound spots were visualized by UV light (254 nm) and by staining with a solution containing *p*-anisaldehyde (25 mL), conc. sulfuric acid (15 mL), glacial acidic acid (5 mL) in EtOH (900 mL). Flash column chromatography was performed on silica gel 60 (0.040–0.063 mm, MERCK).

Bovine serum albumine (BSA) was obtained from BOEHRINGER (no. 28031). Calf intestine alkaline phosphatase (CIAP) (E.C.3.1.3.1) was purchased from BOEHRINGER (no. 108146, 7500 U / 498 µl). Recombinant α (2,3)sialyl transferase (~100 U/l, from transfected insect cells) (14) (EMBL accession no. M97754), recombinant fucosyl transferase III (~10 U/l, baculovirus transfected insect cells) (15) (EMBL accession no. X53578), and recombinant fucosyl transferase VI (~16 U/l, from transfected CHO-cells) (23) (EMBL accession no. LO1698) were used. GDP-fucose was donated by YAMASA–corp.[2] CPM-Neu-5-*N*Ac was purchased from Forschungszentrum Jülich GmbH.[3]

^{1}H NMR and ^{13}C NMR spectra were recorded on a BRUKER AC 400 and (or) a VARIAN Unity 500 spectrometer. COSY, TOCSY, HMBC, and HSQC experiments were performed using the manufacturer's software. ^{1}H NMR-shifts and ^{13}C NMR-shifts are referenced to the solvent line (given in ppm) unless otherwise stated. Chemical shifts marked with an asterisk (*) may be interchanged. ESI-MS were recorded on VG Platform II (MicroMass, Manchester U.K.) equipped with a HP 1050 and a CTC PAL autosampler. Flow injection mass spectrometry was done with 100 µL/min in H_2O:CH_3CN, 1:4 over a mass range of (+) 100–1500 Da / 1.5 s, (–) 120–1500 Da / 1.5 s.

*5-Acetamido-3,5-dideoxy-*D*-glycero-*α*-*D*-galacto-2-nonulopyranosylonic acid-(2–3)*-O-β-*D*-*galactopyranosyl-(1–4)-glucal (**8**)*: In a buffered solution containing sodium cacodylate buffer (75 µL, 0.5 M), $MnCl_2$-solution (100 µL, 0.5 m) and bidistilled water (2.1 mL), *O*-β-D-galactopyranosyl(1–4)-1,5-anhydro-D-arabino-hex-1-enitol (D-lactal) **7** (20.0 mg, 64.9 µmol) (13), CMP-sialic acid (23.2 mg, 79.8 µmol), and bovine serum albumine (1.5 mg) were dissolved. The clear solution was incubated for 24 h with α(2–3)sialyl transferase (20 µL, 160 µU) and calf intestine alkaline phosphatase (2 µL, 30 U) at 37°C. A second portion of CMP-sialic acid (24.9 mg, 85,6 µmol) α(2–3)sialyl transferase (20 µL, 160 mU) was added and the incubation continued for 2 days. The reaction mixture was then lyophilized and passed over sephadex G-10. The sugar containing fractions were combined and chromatographed on silica (CH_2Cl_2:MeOH:H_2O, 10:4:0.1 to 6:4:1) to yield **8** (24.5 mg, 65%): ^{1}H NMR (D_2O, 250.13 MHz) δ: 1.78 (1H, t, J = 12.8 Hz, H-3_{sia}), 2.00 (3H, s, Ac), 2.73 (1H, dd, J = 4.2 Hz, 12.8 Hz, H-3_{sia}), 3.51–4.06 (17H, m), 4.10 (1H, dd, J = 2.8 Hz, 9.8 Hz, H-3_{gal}), 4.59 (1H, d, J = 8.3 Hz, H-1_{gal}), 6.41 (1H, dd, J = 1.4 Hz, 6.2 Hz, H_{vinyl}); ^{13}C (D_2O, 62.89 MHz) δ: 24.00, 41.57, 53.63, 61.54, 62.92, 64.51, 69.17, 69.37, 70.03, 70.34, 71.34, 73.73, 74.82, 77.05, 77.47, 78.74, 79.21, 101.79, 103.76, 104.57, 145.92, 175.88, 176.96; m/z = 598 [M^+ – H]; Anal. calcd. for $C_{23}H_{37}NO_{17}$: C 46.1, H 6.2; found: C 45.6, H 6.0.

*5-Acetamido-3,5-dideoxy-*D*-glycero-*α*-*D*-galacto-2-nonulopyranosylonic acid-(2–3)*-O-β-*D*-*galactopyranosyl-(1–3)*-O-[α-*L*-fucopysanosyl]-(1–4)-glucal (**9**)*: GDP-fucose (25.1 mg, 39.5 µmol) and bovine serum albumine (1.6 mg) were added to a mixture of sodium cacodylate buffer (450 µL, 250 mM, pH 6.5), of $MnCl_2$-solution (150 µL, 250 mM) and bidistilled water (600 µl) **8** (20.0 mg, 33.4 µmol). The clear solution was incubated at 37°C with a solution of recombinant FucT III (83 µL, 498 µU) and calf intestine alkaline phosphatase (2 µL, 30 U) for one day. After 2 h a second portion of GDP-fucose (10.0 mg, 15.7 µmol) and transferase (16.6 µL, 99.6 mU) were added and the incubation continued, until TLC control (EtOAc:iso-propanol:water, 2:2:1) indicated the complete consumption of the substrate **8**. For the work-up, the reaction mixture was centrifugated, lyophilized and chromatographed on silica (ethyl acetate:iso-propanol: water, 2:2:1). The product containing fractions were

combined, passed over a sephadex G-10 column and lyophilized to yield **9** (20.6 mg, 83%): ^{1}H NMR (D_2O, 500.13 MHz) δ: 1.12 (3H, d, *J* = 6.5 Hz, H-6_{fuc}), 1.82 (1H, t, *J* = 13.0 Hz, H-3_{sia}), 2.03 (3H, s, Ac), 2.74 (1H, dd, *J* = 4.8 Hz, 13.0 Hz, H-3_{sia}), 3.53 (1H, dd, *J* = 7.0 Hz, 9.5 Hz, H-2_{gal}), 3.55–3.70 (7H, m, H-6_{gal}, H-4,6,7,8, 9_{sia}, H-6_{cycl}), 3.78 (1H, dd, *J* = 3.6 Hz, 8.3 Hz, H-2_{fuc}), 3.79 (1H, d, *J* = 3.0 Hz, H-4_{fuc}), 3.82–3.92 (5H, m, H-6′$_{gal}$, H-5,9′$_{sia}$, H-3_{fuc}, H-6′$_{cycl}$), 3.93 – 4.00 (2H, m, H-5_{gal}, H-5_{cycl}), 4.09 (1H, dd, *J* = 2.4 Hz, 10.0 Hz, H-3_{gal}), 4.14–4.19 (2H, m, H-4_{gal}, H-4_{cycl}), 4.32 (1H, broad s, H-3_{cycl}), 4.47 (1H, q, *J* = 6.5 Hz, H-5_{fuc}), 4.62 (1H, d, *J* = 8.0 Hz, H-1_{gal}), 4.98 (1H, dd, *J* = 2.8 Hz, 6.0 Hz, H-2_{cycl}), 5.04 (1H, d, *J* = 3.6 Hz, H-1_{fuc}), 6.26 (1H, d, *J* = 6.0 Hz, H-1_{cycl}); ^{13}C (D_2O, 62.9 MHz) δ: 18.74, 25.52, 43.14, 55.17, 62.58, 64.68, 66.08, 70.26, 70.80, 71.25, 71.58, 71.85, 72.94 (2 × C), 73.41, 75.37, 75.87, 76.37, 78.44, 79.15, 80.91, 99.52, 102.34, 103.26, 105.33, 147.85, 177.41, 178.50. The connections of the carbohydrate residues were confirmed by a ROESY experiment. In detail, sialylation of the 3-OH of the galactosyl moiety is shown by a strong crosspeak between the axial H-3_{sia} and H-3_{gal}. Fucosylation at H-3_{cycl} is similarily shown by a strong crosspeak between H-1_{fuc} and H-3_{cycl}. A further strong crosspeak between H-4_{cycl} and H-1_{gal} corroborates the attachment of the galactose at O-C(4) of the glucal moiety. The fucosyl residue occupies the usual preferred position below the galactosyl residue as evidenced by a weak crosspeak between H-5_{fuc} and H-2_{gal}; *m*/*z* = 768 [M^+ + Na]; Anal. calcd. for $C_{29}H_{47}NO_{21}$: C 46.7, H 6.3; found: C 46.9, H 6.3.

*5-Acetamido-3,5-dideoxy-*D*-glycero-*α*-*D*-galacto-2-nonulopyranosylonic acid-(2–3)*-O-β-*D*-*galactopyranosyl-(1–3)-glucal **(11)***: D-galβ(1–3)glucal **10** (28.8 mg, 93.4 μmol) (16), CMP-sialic acid (30.0 mg, 113.8 μmol) and bovine serum albumine (2.1 mg) were dissolved in a buffered solution containing sodium cacodylate buffer (75 μL, 0.5 M), $MnCl_2$-solution (100 μL, 0.5 m) and bidistilled water (2.1 mL). The clear solution was then incubated at 37°C with α(2–3)sialyl 30 U transferase (200 μL, 700 μU) and calf intestine alkaline phosphatase (2 μL, 30 U) for 3 days. A second portion of CMP-sialic acid (45.0 mg, 167 μmol) and sialyl transferase (100 μL, 350 μU) were added and the incubation continued. After 3 days the reaction mixture was lyophilized and chromatographed on silica (CH_2Cl_2:MeOH:H_2O, 10:4:0.1 to 6:4:1). The product containing fractions were passed over sephadex G-10 to yield **11** (51.2 mg, 92%): ^{1}H NMR (D_2O, 250.13 MHz) δ: 1.81 (1H, t, *J* = 12.8 Hz, H-3_{sia}), 2.04 (3H, s, Ac), 2.78 (1H, dd, *J* = 4.2 Hz, 12.8 Hz, H-3_{sia}), 3.51–4.06 (17H, m), 4.14 (1H, dd, *J* = 2.8 Hz, 9.8 Hz, H-3_{gal}), 4.41 (1H, m), 4.41 (1H, m), 4.99 (1H, d, *J* = 8.3 Hz, H-1_{gal}), 6.49 (1H, dd, *J* = 1.4 Hz, 6.2 Hz, H_{vinyl}); ^{13}C (D_2O, 62.89 MHz) δ: 24.18, 41.73, 53.81, 62.15, 63.14, 64.71, 69.07 (2 × C), 69.61, 70.22, 70.49, 71.26, 73.89, 74.96, 77.20, 77.93, 78.83, 80.08, 101.85, 102.00, 103.29, 146.92, 175.99, 177.15; *m*/*z* = 598 [M^+ – H].

*5-Acetamido-3,5-dideoxy-*D*-glycero-*α*-*D*-galacto-2-nonulopyranosylonic acid-(2–3)*-O-β-*D*-*galactopyranosyl-(1–4)*-O-[α-*L*-fucopysanosyl]-(1–3)-glucal **(12)***: Trisaccharide **11** (18.0 mg, 30.0 μmol), GDP-fucose (26.3 mg, 41.4 μmol) and bovine serum albumine (1.6 mg) were added to a mixture of sodium cacodylate buffer (450 μL, 250 mM, pH 6.5), $MnCl_2$-solution (150 μL, 250 mM) and bidistilled water (600 μL). The clear mixture was incubated at 37°C with recombinant FucT III (100 μL, 600 μU/mL) and calf intestine alkaline phosphatase (2 μL, 30 U). After three days TLC control (EtOAc:iso-propanol:water, 2:2:1) indicated that all the starting material had been consumed. For the work-up, the reaction mixture was centrifugated, lyophilized, and chromatographed on silica. The product was finally passed over a sephadex G-10 column and lyophilized to yield **12** (18.1 mg, 82%). ^{1}H NMR (D_2O, 500.13 MHz) δ: 1.21 (3H, d, *J* = 6.5 Hz, H-6_{fuc}), 1.81 (1H, t, *J* = 13.0 Hz, H-3_{sia}), 2.04 (3H, s, Ac), 2.79 (1H, dd, *J* = 4.8 Hz, 13.0 Hz, H-3_{sia}), 3.58 (1H, dd, *J* = 7.0 Hz, 9.5 Hz, H-2_{gal}), 3.60–3.76 (7H, m, H-5,6_{gal}, H-4,6,7,8, 9_{sia}), 3.78 (1H, dd, *J* = 3.6 Hz, 8.3 Hz, H-2_{fuc}), 3.79 (1H, d, *J* = 3.0 Hz, H-4_{fuc}), 3.83–3.93 (5H, m, H-6′$_{gal}$, H-5,9′$_{sia}$, H-3_{fuc}, H-6′$_{cycl}$), 3.93–4.00 (2H, m, H-5_{gal}, H-5_{cycl}), 4.05 (1H, broad t, *J* = 6.0 Hz, H-4_{cycl}), 4.10 (1H, dd, *J* = 2.4 Hz, 10.0 Hz, H-3_{gal}), 4.15 (1H, m, H-5_{cycl}), 4.46 (1H, q, *J* = 6.5 Hz, H-5_{fuc}), 4.53 (1H, broad t, *J* = 4 Hz, H-3_{cycl}), 4.61 (1H, d, *J* = 8.0 Hz, H-1_{gal}), 5.07 (1H, dd, *J* = 2.8 Hz, 6.0 Hz, H-2_{cycl}), 5.10 (1H, d, *J* = 3.6 Hz, H-1_{fuc}), 6.51 (1H, d, *J* = 6.0 Hz, H-1_{cycl}); ^{13}C (D_2O, 125 MHz) δ: 17.00, 23.57, 41.18, 53.23, 60.78, 62.77, 64.11, 68.57, 69.00, 69.53, 69.65, 69.96, 70.58, 70.82, 73.21, 73.33, 73.43, 73.70, 74.37, 76.35, 77.38, 78.96, 100.03, 100.59, 101.38, 101.72, 146.28, 175.55, 176.59; Structure confirmed by a ROESY experiment as detailed for **9**; *m*/*z* = 768 [M^+ + Na]; Anal. calcd. for $C_{29}H_{47}NO_{21}$: C 46.7, H 6.3; found: C 46.9, H 6.4.

(1R,2R) 2-Hydroxy-cyclohexyl β-*D*-*galactopyranoside **(15)***: At room temperature the imidate **13** (640 mg, 1.0 mmol) and (*R*,*R*)-cyclohexan-1,2-diol (174 mg, 1.50 mmol) were dissolved in CH_3CN (5 mL) and treated with trimetylsilyl triflate (20 μL). After 1 h the solvent was rotovaped off and the residue chromatographed on silica (petrolether 40/60:EtOAc, 2:3) to yield (1*R*,2*R*) 2-hydroxy-cyclohexyl 2,3,4,6-tetra-*O*-benzoyl-β-D-galactopyranoside (**14**) (506 mg, 73%). **14** was dissolved in MeOH (5 mL) containing catalytic amounts of NaOMe and stirred for 6 h. Then the reaction mixture was neutalized with AcOH, evaporated and chromatographed on silica (toluene:EtOH, 1:1) to give **15** (152 mg, 75%): ^{1}H NMR (CD_3OD, 400.13 MHz) δ: 1.19 (4H, m), 1.62 (2H, m), 1.98 (2H, m), 3.35 (2H, m, 2 × C*H*O$_{cycl}$), 3.44 (3H, m, H-2,3,5$_{gal}$), 3.63 (1H, dd, *J* = 6.6 Hz, 9.8 Hz, H-6), 3.71 (1H, dd, *J* = 7.4 Hz, 11.5 Hz, H-6′), 3.76 (1H, broad d, *J* = 4.1 Hz, H-4), 4.28 (1H, d, *J* = 7.4 Hz, H-1).

*(1*R,*2*R*) 2-Hydroxy-cyclohexyl 3*-O-*[2*-O-*(5-acetamido-3,5-dideoxy-*D*-glycero-α-*D*-galacto-2-nonulopyranosonate)]*-β-*D*-*galactopyranoside **(16)***: The cyclohexane derivative **15** (23.5 mg, 84.4 μmol), CMP-sialic acid (68.5 mg, 104.0 μmol) and bovine serum albumine (1.8 mg) were dissolved in a buffered solution containing sodium cacodylate buffer (2 mL, 0.05 M), $MnCl_2$-solution (2 mL, 0.06 m) and bidistilled water (1.3 mL). The clear solution was incubated at 37°C with α(2–3)sialyl transferase (100 μL, 700 μU) and calf intestine alkaline phosphatase (2 μL, 30 U) for 24 h. After the addition of a second portion of CMP-sialic acid (10 mg, 15.2 μmol) the incubation was continued for 5 h. The reaction mixture was then lyophilized and

chromatographed on silica (CH_2Cl_2:MeOH:H_2O, 10:4:0.5) to yield **16** (31.2 mg, 64%): ^{1}H NMR (D_2O, 250.13 MHz) δ: 1.30 (4H, m), 1.73 (2H, m), 1.85 (1H, t, *J* = 12.8 Hz, H-3_{sia}), 2.08 (3H, s, Ac), 2.11 (2H, m), 2.80 (1H, dd, *J* = 4.2 Hz, 12.8 Hz, H-3_{sia}), 3.51–3.96 (13H, m), 4.00 (1H, d, *J* = 2.8 Hz, H-4_{gal}), 4.14 (1H, dd, *J* = 2.8 Hz, 8.3 Hz, H-3_{gal}), 4.61 (1H, d, *J* = 8.3 Hz, H-1_{gal}); ^{13}C (D_2O, 100.03 MHz) δ: 20.43, 21.76, 21.93, 28.15, 30.44, 37.94, 50.07, 59.48, 60.95, 65.97, 66.48, 66.80, 67.55, 70.14, 71.22, 71.30, 73.26, 74.19, 81.25, 98.27, 98.78, 172.34, 173.40.

2-O-*{1*-O-*[(1*R,*2*R*) 2*-O-*(*α-L-*fucopyranosyl)cyclohexyl]*β-D-*galactopyranos-3-yl} 5-acetamido-3,5-dideoxy-D*-glycero-α-D-galacto-*2-nonulopyranosylonic acid (17)*: The sialic acid derivative **16 (**17.5 mg, 29.3 μmol), GDP-fucose (33.9 mg, 53.4 μmol) and bovine serum albumine (1.9 mg) were added to a mixture of sodium cacodylate buffer (450 μL, 250 mM, pH 6.5), $MnCl_2$-solution (150 μL, 250 mM) and bidistilled water (600 μL). The clear mixture was incubated at 37°C with recombinant FucT III solution (83 μL, 498 μU/mL) and calf intestine alkaline phosphatase (2 μL, 30 U) for one day, until TLC control (CH_2Cl_2:MeOH, 6:4) of the turbid incubation mixture indicated that **16** was consumed. After lyophilization the residue was chromatographed on silica (CH_2Cl_2:MeOH, 6:4). The product containing fractions were combined and finally passed over a sephadex G-10 column and lyophilized to yield **17** (15.6 mg, 71%): $[\alpha]_{589}$ –17.8° (*c* = 1.25, H_2O); ^{1}H NMR (D_2O, 500.13 MHz) δ: 1.24 (3H, d, *J* = 6.5 Hz, H-6_{fuc}), 1.30 (4H, m), 1.76 (2H, m), 1.87 (1H, t, *J* = 13.0 Hz, H-3_{sia}), 2.09 (3H, s, Ac), 2.14 (1H, m), 2.19 (1H, m), 2.81 (1H, dd, *J* = 4.8 Hz, 13.0 Hz, H-3_{sia}), 3.56 (1H, dd, *J* = 7.7 Hz, 9.5 Hz, H-2_{gal}), 3.58 (1H, m, CHO_{cycl}), 3.63–3.69 (4H, m, H-5_{gal}, H-6,7,9_{sia}), 3.70–3.79 (3H, m, H-6_{gal}, H-4,8_{sia}), 3.80–3.86 (3H, m, H-2,4_{fuc}, CHO_{cycl}), 3.90 (1H, t, *J* = 10.0 Hz, H-5_{sia}), 3.92–3.96 (2H, m, H-6_{gal}, H-8_{sia}), 3.97 (1H, dd, *J* = 3.5 Hz, 10.0 Hz, H-3_{fuc}), 3.98 (1H, d, *J* = 3.2 Hz, H-4_{gal}), 4.13 (1H, dd, *J* = 3.2 Hz, 9.5 Hz, H-3_{gal}), 4.63 (1H, d, *J* = 7.7 Hz, H-1_{gal}), 4.68 (q, 1 H, *J* = 6.5 Hz, H-5_{fuc}), 5.04 (1H, d, *J* = 5.5 Hz, H-1_{fuc}); ^{13}C (D_2O, 100.03 MHz) δ: 15.55, 17.73, 22.36, 23.49, 29.54, 29.91, 39.90, 52.01, 61.75, 62.89, 66.78, 67.86, 68.25, 68.42, 68.74, 69.69, 69.87, 72.07, 72.34, 73.13, 74.92, 76.26, 77.45, 78.37, 95.77, 99.75, 100.17, 174.35, 175.34; Structure confirmed by a ROESY experiment as detailed for **9**; Anal. calcd. for $C_{29}H_{49}NO_{19}$: C 48.7, H 6.9; found: C 48.2, H 6.6.

*(1*R,*2*R*)-2-Hydroxy-cyclohexyl 6*-O-*benzyl-2,3,4-tri*-O-*benzoyl*-β-D-*galactopyranoside (19)*: Under argon 23.0 g of finely ground 4 Å molecular sieves were added to a mixture of ethyl 6-*O*-benzyl-2,3,4-tri-*O*-benzoyl-thio-β-D-galactopyranoside **18** (11.41 g, 18.0 mmol) (19) and (*R,R*)-*trans*-1,2-cyclohexandiol (1.76 g, 15.2 mmol) in 100 mL dry CH_2Cl_2. After stirring for 2 h at room temperature, dimethylmethylthiosulfonium triflate (DMTST) (7.83 g, 30.0 mmol) (20) dissolved in dry CH_2Cl_2 (70 mL) was added portionwise over 1 h. The slurry was stirred for 3 h and then diluted with CH_2Cl_2. After filtration over celite, the organic phase was washed with 10% $NaHCO_3$ and brine, dried over $NaSO_4$ and concentrated. The residue was chromatographed on silica (toluene:EtOAc, 95:1 to 85:15) to yield **19** (6.85 g, 67%): $[\alpha]_{589}$ +105.2° (*c* = 0.79, $CHCl_3$); ^{1}H NMR ($CDCl_3$, 400.13 MHz) δ: 1.22 (4H, m), 1.69 (3H, m), 2.08 (1H, m), 3.39 (1H, m), 3.50 (1H, m), 3.68 (2H, m, H-6,6′), 3.93 (1H, s, OH), 4.23 (1H, broad t, *J* = 4.4 Hz, H-5), 4.46 (1H, d, *J* = 12.1 Hz, C*H*$_2$Bn), 4.57 (1H, d, *J* = 12.1 Hz, C*H*$_2$Bn), 4.87 (1H, d, *J* = 8.8 Hz, H-1), 5.59 (1H, dd, *J* = 7.7 Hz, 4.4 Hz, H-3), 5.76 (1H, dd, *J* = 8.8 Hz, 7.7 Hz, H-2), 5.97 (1H, dd, *J* = 4.4 Hz, 4.4 Hz, H-4), 7.24 (7H, m), 7.48 (6H, m), 7.64 (1H, m), 7.80 (2H, m), 7.98 (2H, m), 8.06 (2H, m); ^{13}C ($CDCl_3$, 100.03 MHz) δ: 23.65, 24.18, 30.75, 31.99, 67.62, 68.24, 70.00, 71.76, 72.87, 72.96, 73.64, 87.87, 101.90, 127.76–137.26 aromatics, 165.21, 165.51, 165.55; Anal. calcd. for $C_{40}H_{40}O_{10}$: C 70.6, H 5.9; found: C 70.4, H 6.0.

*(1*R,*2*R*) 2-Hydroxy-cyclohexyl 6*-O-*benzyl*-β-D-*galactopyranoside (20)*: The pseudodisaccharide **19** (2.0 g, 2.9 mmol) was suspended in dry methanol (40 mL), a catalytic amount of sodium methanolate was added and the reaction mixture stirred at room temperature for 3 h until TLC control (CH_2Cl_2:MeOH, 9:1) indicated complete consumption of the starting material. Then the mixture was neutralized with amberlyste 15 and filtered over celite. Evaporation leaves an oil which is chromatographed on silica (CH_2Cl_2:MeOH, 19:1 to 9:1) to yield **20** (1.01 g, 94%): $[\alpha]_{589}$ –33.2° (*c* = 0.94, CH_2Cl_2); ^{1}H NMR ($CDCl_3$, 400.13 MHz) δ: 1.28 (4H, m), 1.73 (2H, m), 2.06 (2H, m), 3.40 (4H, m), 3.61 (1H, dd, *J* = 4.4 Hz, 8.8 Hz), 3.74 (4H, m), 4.01 (1H, t, *J* = 3.3 Hz), 4.34 (1H, d, *J* = 8.8 Hz, H-1), 4.60 (2H, q, 2 H, *J* = 12.1 Hz, C*H*$_2$Bn), 7.43 (5H, m); ^{13}C ($CDCl_3$, 100.03 MHz) δ: 23.84, 24.31, 30.98, 32.46, 69.00, 69.07, 71.34, 73.10, 73.48, 73.61, 73.66, 85.63, 102.43, 127.82, 128.46, 137.67; Anal. calcd. for $C_{19}H_{28}O_7$: C 61.9, H 7.7; found: C 61.7, H 7.7.

*Benzyl (2*R*) 3-cyclohexyl-2*-O-*{1*-O-*[(1*R,*2*R*) cyclohexyl]-6*-O-*benzyl*-β-D-*galactopyranos-3-yl}propanoate (22a):*
Glycoside **20** (0.98 g, 2.66 mmol) and dibutyltin oxide (995 mg, 3.99 mmol) in MeOH (40 mL) were refluxed for 2.5 h to give a clear, colourless solution. After removal of the solvent, the residue (white foam) was dissolved in dry CH_2Cl_2 (29 mL), CsF (2.02 g,13.3 mmol) and the triflate **21a** (5.25 g, 13.3 mmol) were added and the resulting solution stirred vigorously for 3 h. The reaction mixture was then diluted with CH_2Cl_2 and washed with 10% KF–KH_2PO_4 and brine. After drying the combined organic layers with Na_2SO_4, the solvent was evaporated and the resulting oil chromatographed on silica (hexane:EtOAc, 6:4) to yield **22a** (1.25 g, 76%): $[\alpha]_{589}$ –40.7° (*c* = 0.59, $CHCl_3$); ^{1}H NMR ($CDCl_3$–D_2O, 400.13 MHz) δ: 0.91 (2H, m), 1.28 (8H, m), 1.70 (9H, m), 2.04 (2H, m), 3.29 (1H, dd, *J* = 3.3 Hz, 8.8 Hz, H-2), 3.37 (1H, m, C*H*O-cyclohexanol), 3.44 (1H, m, C*H*O-cyclohexanol), 3.70 (3H, m, H-5, 6, 6′), 3.79 (1H, t, *J* = 3.3 Hz, H-4), 3.83 (dd, *J* = 3.3 Hz, 9.9 Hz, H-2), 4.28 (1H, dd, *J* = 2.3 Hz, 10.0 Hz), 4.31 (1H, d, *J* = 9.9 Hz, H-1), 4.60 (2H, q, *J* = 12.1 Hz, C*H*$_2$Bn), 5.19 (2H, q, *J* = 12.1 Hz, C*H*$_2$Bn), 7.43 (10H, m); ^{13}C ($CDCl_3$, 100.03 MHz) δ: 23.80, 24.34, 26.01, 26.21, 26.40, 31.21, 32.12, 32.20, 33.53, 33.92, 40.92, 66.83, 67.15, 68.95, 70.72, 73.05, 73.61, 73.66, 82.87, 86.78, 103.03, 127.72, 127.92, 128.40, 128.51, 128.62, 128.66, 135.12, 137.92, 174.72; Anal. calcd. for $C_{35}H_{48}O_9$: C 68.6, H 7.9; found: C 68.4, H 7.8.
